About This Manual.....	87
Notational Conventions.....	87
Glossary.....	87
Related Documentation From Texas Instruments.....	87
Support Resources.....	87
Trademarks.....	88
1 C2000™ Microcontrollers Software Support	89
1.1 Introduction.....	90
1.2 C2000Ware Structure.....	90
1.3 Documentation.....	90
1.4 Devices.....	90
1.5 Libraries.....	90
1.6 Code Composer Studio™ Integrated Development Environment (IDE).....	90
1.7 SysConfig and PinMUX Tool.....	91
2 C28x Processor	93
2.1 Introduction.....	94
2.2 C28X Related Collateral.....	94
2.3 Features.....	94
2.4 Floating-Point Unit.....	95
2.5 Trigonometric Math Unit (TMU).....	95
2.6 VCRC Unit.....	96
3 System Control and Interrupts	97
3.1 Introduction.....	98
3.1.1 SYSCTL Related Collateral.....	98
3.1.2 LOCK Protection on System Configuration Registers.....	98
3.1.3 EALLOW Protection.....	98
3.2 Power Management.....	99
3.3 Device Identification and Configuration Registers.....	99
3.4 Resets.....	99
3.4.1 Reset Sources.....	99
3.4.2 External Reset (XRS).....	100
3.4.3 Simulate External Reset (SIMRESET.XRS).....	100
3.4.4 Power-On Reset (POR).....	100
3.4.5 Brown-Out-Reset (BOR).....	100
3.4.6 Debugger Reset (SYSRS).....	101
3.4.7 Simulate CPU Reset (SIMRESET.CPU1RS).....	101
3.4.8 Watchdog Reset (WDRS).....	101
3.4.9 Hardware BIST Reset (HWBISTRS).....	101
3.4.10 NMI Watchdog Reset (NMIWDRS).....	101
3.4.11 DCSM Safe Code Copy Reset (SCCRESET).....	101
3.5 Peripheral Interrupts.....	102
3.5.1 Interrupt Concepts.....	102
3.5.2 Interrupt Architecture.....	102
3.5.3 Interrupt Entry Sequence.....	104
3.5.4 Configuring and Using Interrupts.....	105
3.5.5 PIE Channel Mapping.....	107
3.5.6 Vector Tables.....	109
3.6 Exceptions and Non-Maskable Interrupts.....	115

3.6.1 Configuring and Using NMIs.....	115
3.6.2 Emulation Considerations.....	115
3.6.3 NMI Sources.....	115
3.6.4 CRC Fail.....	116
3.6.5 ERAD NMI.....	116
3.6.6 Illegal Instruction Trap (ITRAP).....	116
3.6.7 Error Pin.....	116
3.7 Clocking.....	117
3.7.1 Clock Sources.....	118
3.7.2 Derived Clocks.....	121
3.7.3 Device Clock Domains.....	121
3.7.4 XCLKOUT.....	122
3.7.5 Clock Connectivity.....	122
3.7.6 Clock Source and PLL Setup.....	124
3.7.7 Using an External Crystal or Resonator.....	124
3.7.8 Using an External Oscillator.....	125
3.7.9 Choosing PLL Settings.....	125
3.7.10 System Clock Setup.....	126
3.7.11 SYS PLL Bypass.....	126
3.7.12 Clock (OSCCLK) Failure Detection.....	126
3.8 32-Bit CPU Timers 0/1/2.....	129
3.9 Watchdog Timer.....	130
3.9.1 Servicing the Watchdog Timer.....	131
3.9.2 Minimum Window Check.....	131
3.9.3 Watchdog Reset or Watchdog Interrupt Mode.....	132
3.9.4 Watchdog Operation in Low-Power Modes.....	132
3.9.5 Emulation Considerations.....	132
3.10 Low-Power Modes.....	133
3.10.1 Clock-Gating Low-Power Modes.....	133
3.10.2 IDLE.....	133
3.10.3 STANDBY.....	134
3.10.4 HALT.....	134
3.10.5 Flash Power-down Considerations.....	135
3.11 Memory Controller Module.....	136
3.11.1 Dedicated RAM (Mx RAM).....	136
3.11.2 Local Shared RAM (LSx RAM).....	136
3.11.3 Global Shared RAM (GSx RAM).....	137
3.11.4 CLA-CPU Message RAM.....	137
3.11.5 CLA-DMA Message RAM.....	137
3.11.6 Access Arbitration.....	138
3.11.7 Access Protection.....	139
3.11.8 Memory Error Detection and Correction, and Error Handling.....	140
3.11.9 Application Test Hooks for Error Detection and Correction.....	142
3.11.10 RAM Initialization.....	142
3.12 JTAG.....	143
3.12.1 JTAG Noise and TAP_STATUS.....	143
3.13 Live Firmware Update.....	143
3.13.1 LFU Background.....	143
3.13.2 LFU Switchover Steps.....	144
3.13.3 Device Features Supporting LFU.....	144
3.13.4 LFU Switchover.....	148
3.13.5 LFU Resources.....	148
3.14 System Control Register Configuration Restrictions.....	148
3.15 Software.....	149
3.15.1 INTERRUPT Examples.....	149
3.15.2 SYSTCTL Examples.....	151
3.15.3 TIMER Examples.....	152
3.15.4 LPM Examples.....	152
3.15.5 MEMCFG Examples.....	154
3.15.6 WATCHDOG Examples.....	155
3.16 System Control Registers.....	156

3.16.1	SYSCTRL Base Address Table.....	156
3.16.2	ACCESS_PROTECTION_REGS Registers.....	157
3.16.3	CLK_CFG_REGS Registers.....	185
3.16.4	CPU_SYS_REGS Registers.....	208
3.16.5	CPUTIMER_REGS Registers.....	254
3.16.6	DEV_CFG_REGS Registers.....	261
3.16.7	DMA_CLA_SRC_SEL_REGS Registers.....	291
3.16.8	MEM_CFG_REGS Registers.....	298
3.16.9	MEMORY_ERROR_REGS Registers.....	351
3.16.10	NMI_INTRUPT_REGS Registers.....	373
3.16.11	PERIPH_AC_REGS Registers.....	390
3.16.12	PIE_CTRL_REGS Registers.....	437
3.16.13	SYNC_SOC_REGS Registers.....	489
3.16.14	SYS_STATUS_REGS Registers.....	495
3.16.15	TEST_ERROR_REGS Registers.....	502
3.16.16	UID_REGS Registers.....	506
3.16.17	WD_REGS Registers.....	515
3.16.18	XINT_REGS Registers.....	522
3.16.19	LFU_REGS Registers.....	531
3.16.20	Register to Driverlib Function Mapping.....	543
4	ROM Code and Peripheral Booting.....	563
4.1	Introduction.....	564
4.2	ROM Related Collateral.....	564
4.3	Device Boot Sequence.....	565
4.4	Device Boot Modes.....	565
4.4.1	Default Boot Modes.....	565
4.4.2	Custom Boot Modes.....	566
4.5	Device Boot Configurations.....	566
4.5.1	Configuring Boot Mode Pins.....	567
4.5.2	Configuring Boot Mode Table Options.....	569
4.5.3	Boot Mode Example Use Cases.....	570
4.6	Device Boot Flow Diagrams.....	571
4.6.1	Boot Flow.....	571
4.6.2	Emulation Boot Flow.....	573
4.6.3	Standalone Boot Flow.....	574
4.7	Device Reset and Exception Handling.....	575
4.7.1	Reset Causes and Handling.....	575
4.7.2	Exceptions and Interrupts Handling.....	575
4.8	Boot ROM Description.....	576
4.8.1	Boot ROM Configuration Registers.....	576
4.8.2	Entry Points.....	577
4.8.3	Wait Points.....	578
4.8.4	Secure Flash Boot.....	578
4.8.5	Firmware Update (FWU) Flash Boot.....	581
4.8.6	Memory Maps.....	582
4.8.7	ROM Tables.....	583
4.8.8	Boot Modes and Loaders.....	583
4.8.9	GPIO Assignments.....	599
4.8.10	Secure ROM Function APIs.....	601
4.8.11	Clock Initializations.....	602
4.8.12	Boot Status Information.....	602
4.8.13	ROM Version.....	604
4.9	Application Notes for Using the Bootloaders.....	604
4.9.1	Bootloader Data Stream Structure.....	604
4.9.2	The C2000 Hex Utility.....	606
4.10	Software.....	608
4.10.1	BOOT Examples.....	608
5	Dual Code Security Module (DCSM).....	609
5.1	Introduction.....	610
5.1.1	DCSM Related Collateral.....	610
5.2	Functional Description.....	610

5.2.1 CSM Passwords.....	611
5.2.2 Emulation Code Security Logic (ECSL).....	613
5.2.3 CPU Secure Logic.....	613
5.2.4 Password Lock.....	613
5.2.5 JTAGLOCK.....	614
5.2.6 Link Pointer and Zone Select.....	614
5.2.7 C Code Example to Get Zone Select Block Addr for Zone1.....	617
5.3 Flash and OTP Erase/Program.....	617
5.4 Secure Copy Code.....	617
5.5 SecureCRC.....	618
5.6 CSM Impact on Other On-Chip Resources.....	619
5.7 Incorporating Code Security in User Applications.....	620
5.7.1 Environments That Require Security Unlocking.....	620
5.7.2 CSM Password Match Flow.....	620
5.7.3 C Code Example to Unsecure C28x Zone1.....	622
5.7.4 C Code Example to Resecure C28x Zone1.....	622
5.7.5 Environments That Require ECSL Unlocking.....	622
5.7.6 ECSL Password Match Flow.....	622
5.7.7 ECSL Disable Considerations for any Zone.....	624
5.7.8 Device Unique ID.....	624
5.8 Software.....	625
5.8.1 DCSM Examples.....	625
5.9 DCSM Registers.....	625
5.9.1 DCSM Base Address Table.....	625
5.9.2 DCSM_Z1_REGS Registers.....	626
5.9.3 DCSM_Z2_REGS Registers.....	674
5.9.4 DCSM_COMMON_REGS Registers.....	712
5.9.5 DCSM_Z1_OTP Registers.....	728
5.9.6 DCSM_Z2_OTP Registers.....	745
6 Flash Module.....	755
6.1 Introduction to Flash and OTP Memory.....	756
6.1.1 FLASH Related Collateral.....	756
6.1.2 Features.....	756
6.1.3 Flash Tools.....	757
6.1.4 Default Flash Configuration.....	757
6.2 Flash Bank, OTP, and Pump.....	757
6.3 Flash Module Controller (FMC).....	758
6.4 Flash and OTP Memory Power-Down Modes and Wakeup.....	758
6.5 Active Grace Period.....	759
6.6 Flash and OTP Memory Performance.....	759
6.7 Flash Read Interface.....	760
6.7.1 C28x-FMC Flash Read Interface.....	760
6.8 Flash Erase and Program.....	762
6.8.1 Erase.....	762
6.8.2 Program.....	763
6.8.3 Verify.....	763
6.9 Error Correction Code (ECC) Protection.....	764
6.9.1 Single-Bit Data Error.....	765
6.9.2 Uncorrectable Error.....	766
6.9.3 SECDED Logic Correctness Check.....	767
6.10 Reserved Locations Within Flash and OTP Memory.....	768
6.11 Migrating an Application from RAM to Flash.....	768
6.12 Procedure to Change the Flash Control Registers.....	769
6.13 Software.....	770
6.13.1 FLASH Examples.....	770
6.14 Flash Registers.....	772
6.14.1 FLASH Base Address Table.....	772
6.14.2 FLASH_CTRL_REGS Registers.....	773
6.14.3 FLASH_ECC_REGS Registers.....	784
6.14.4 FLASH Registers to Driverlib Functions.....	806
7 Control Law Accelerator (CLA).....	809

7.1 Introduction.....	810
7.1.1 Features.....	810
7.1.2 CLA Related Collateral.....	810
7.1.3 Block Diagram.....	811
7.2 CLA Interface.....	812
7.2.1 CLA Memory.....	812
7.2.2 CLA Memory Bus.....	813
7.2.3 Shared Peripherals and EALLOW Protection.....	813
7.2.4 CLA Tasks and Interrupt Vectors.....	814
7.3 CLA and CPU Arbitration.....	818
7.3.1 CLA Message RAM.....	818
7.3.2 Peripheral Registers (ePWM, HRPWM, Comparator).....	818
7.4 CLA Configuration and Debug.....	819
7.4.1 Building a CLA Application.....	819
7.4.2 Typical CLA Initialization Sequence.....	819
7.4.3 Debugging CLA Code.....	820
7.4.4 CLA Illegal Opcode Behavior.....	822
7.4.5 Resetting the CLA.....	823
7.5 Pipeline.....	823
7.5.1 Pipeline Overview.....	823
7.5.2 CLA Pipeline Alignment.....	824
7.5.3 Parallel Instructions.....	828
7.5.4 CLA Task Execution Latency.....	828
7.6 Software.....	829
7.6.1 CLA Examples.....	829
7.7 Instruction Set.....	833
7.7.1 Instruction Descriptions.....	833
7.7.2 Addressing Modes and Encoding.....	834
7.7.3 Instructions.....	837
7.8 CLA Registers.....	963
7.8.1 CLA Base Address Table.....	964
7.8.2 CLA_ONLY_REGS Registers.....	965
7.8.3 CLA_SOFTINT_REGS Registers.....	974
7.8.4 CLA_REGS Registers.....	978
7.8.5 CLA Registers to Driverlib Functions.....	1026
8 Dual-Clock Comparator (DCC).....	1029
8.1 Introduction.....	1030
8.1.1 Features.....	1030
8.1.2 Block Diagram.....	1030
8.2 Module Operation.....	1031
8.2.1 Configuring DCC Counters.....	1032
8.2.2 Single-Shot Measurement Mode.....	1033
8.2.3 Continuous Monitoring Mode.....	1034
8.2.4 Error Conditions.....	1035
8.3 Interrupts.....	1037
8.4 Software.....	1038
8.4.1 DCC Examples.....	1038
8.5 DCC Registers.....	1040
8.5.1 DCC Base Address Table.....	1040
8.5.2 DCC_REGS Registers.....	1041
8.5.3 DCC Registers to Driverlib Functions.....	1051
9 Background CRC-32 (BGCR).....	1053
9.1 Introduction.....	1054
9.1.1 BGCR Related Collateral.....	1054
9.1.2 Features.....	1054
9.1.3 Block Diagram.....	1054
9.1.4 Memory Wait States and Memory Map.....	1055
9.2 Functional Description.....	1056
9.2.1 Data Read Unit.....	1056
9.2.2 CRC-32 Compute Unit.....	1056
9.2.3 CRC Notification Unit.....	1057

9.2.4 Operating Modes.....	1058
9.2.5 BGCRC Watchdog.....	1058
9.2.6 Hardware and Software Faults Protection.....	1058
9.3 Application of the BGCRC.....	1058
9.3.1 Software Configuration.....	1059
9.3.2 Decision on Error Response Severity.....	1060
9.3.3 Decision of Controller for CLA_CRC.....	1060
9.3.4 Execution of Time Critical Code from Wait-States Memories.....	1060
9.3.5 BGCRC Execution.....	1060
9.3.6 Debug/Error Response for BGCRC Errors.....	1061
9.3.7 BGCRC Golden CRC-32 Value Computation.....	1062
9.4 Software.....	1063
9.4.1 BGCRC Examples.....	1063
9.5 BGCRC Registers.....	1064
9.5.1 BGCRC Base Address Table.....	1064
9.5.2 BGCRC_REGS Registers.....	1065
9.5.3 BGCRC Registers to Driverlib Functions.....	1091
10 General-Purpose Input/Output (GPIO).....	1093
10.1 Introduction.....	1094
10.1.1 GPIO Related Collateral.....	1096
10.2 Configuration Overview.....	1096
10.3 Digital Inputs on ADC Pins (AIOs).....	1097
10.4 Digital Inputs and Outputs on ADC Pins (AGPIOs).....	1097
10.5 Digital General-Purpose I/O Control.....	1098
10.6 Input Qualification.....	1099
10.6.1 No Synchronization (Asynchronous Input).....	1099
10.6.2 Synchronization to SYSCLKOUT Only.....	1099
10.6.3 Qualification Using a Sampling Window.....	1100
10.7 GPIO and Peripheral Muxing.....	1103
10.7.1 GPIO Muxing.....	1103
10.7.2 Peripheral Muxing.....	1106
10.8 Internal Pullup Configuration Requirements.....	1107
10.9 Software.....	1108
10.9.1 GPIO Examples.....	1108
10.9.2 LED Examples.....	1109
10.10 GPIO Registers.....	1109
10.10.1 GPIO Base Address Table.....	1109
10.10.2 GPIO_CTRL_REGS Registers.....	1110
10.10.3 GPIO_DATA_REGS Registers.....	1207
10.10.4 GPIO_DATA_READ_REGS Registers.....	1230
10.10.5 GPIO Registers to Driverlib Functions.....	1233
11 Crossbar (X-BAR).....	1237
11.1 Input X-BAR and CLB Input X-BAR.....	1238
11.1.1 CLB Input X-BAR.....	1241
11.2 ePWM, CLB, and GPIO Output X-BAR.....	1242
11.2.1 ePWM X-BAR.....	1242
11.2.2 CLB X-BAR.....	1244
11.2.3 GPIO Output X-BAR.....	1247
11.2.4 CLB Output X-BAR.....	1249
11.2.5 X-BAR Flags.....	1250
11.3 XBAR Registers.....	1252
11.3.1 XBAR Base Address Table.....	1252
11.3.2 INPUT_XBAR_REGS Registers.....	1253
11.3.3 XBAR_REGS Registers.....	1272
11.3.4 EPWM_XBAR_REGS Registers.....	1300
11.3.5 CLB_XBAR_REGS Registers.....	1393
11.3.6 OUTPUT_XBAR_REGS Registers.....	1486
11.3.7 Register to Driverlib Function Mapping.....	1587
12 Direct Memory Access (DMA).....	1593
12.1 Introduction.....	1594
12.1.1 Features.....	1594

12.1.2 Block Diagram.....	1595
12.2 Architecture.....	1596
12.2.1 Peripheral Interrupt Event Trigger Sources.....	1596
12.2.2 DMA Bus.....	1600
12.3 Address Pointer and Transfer Control.....	1600
12.4 Pipeline Timing and Throughput.....	1606
12.5 CPU and CLA Arbitration.....	1607
12.6 Channel Priority.....	1608
12.6.1 Round-Robin Mode.....	1608
12.6.2 Channel 1 High-Priority Mode.....	1609
12.7 Overrun Detection Feature.....	1609
12.8 Software.....	1610
12.8.1 DMA Examples.....	1610
12.9 DMA Registers.....	1610
12.9.1 DMA Base Address Table.....	1610
12.9.2 DMA_REGS Registers.....	1611
12.9.3 DMA_CH_REGS Registers.....	1616
12.9.4 DMA Registers to Driverlib Functions.....	1642
13 Embedded Real-time Analysis and Diagnostic (ERAD).....	1645
13.1 Introduction.....	1646
13.1.1 ERAD Related Collateral.....	1646
13.2 Enhanced Bus Comparator Unit.....	1647
13.2.1 Enhanced Bus Comparator Unit Operations.....	1647
13.2.2 Event Masking and Exporting.....	1648
13.3 System Event Counter Unit.....	1649
13.3.1 System Event Counter Modes.....	1649
13.3.2 Reset on Event.....	1654
13.3.3 Operation Conditions.....	1654
13.4 ERAD Ownership, Initialization and Reset.....	1654
13.5 ERAD Programming Sequence.....	1655
13.5.1 Hardware Breakpoint and Hardware Watch Point Programming Sequence.....	1655
13.5.2 Timer and Counter Programming Sequence.....	1656
13.6 Cyclic Redundancy Check Unit.....	1656
13.6.1 CRC Unit Qualifier.....	1657
13.6.2 CRC Unit Programming Sequence.....	1658
13.7 Program Counter Trace.....	1659
13.7.1 Functional Block Diagram.....	1660
13.7.2 Trace Qualification Modes.....	1661
13.7.3 Trace Memory.....	1664
13.7.4 Trace Input Signal Conditioning.....	1665
13.7.5 PC Trace Software Operation.....	1666
13.7.6 Trace Operation in Debug Mode.....	1666
13.8 Software.....	1667
13.8.1 ERAD Examples.....	1667
13.9 ERAD Registers.....	1675
13.9.1 ERAD Base Address Table.....	1675
13.9.2 ERAD_GLOBAL_REGS Registers.....	1676
13.9.3 ERAD_HWBP_REGS Registers.....	1699
13.9.4 ERAD_COUNTER_REGS Registers.....	1706
13.9.5 ERAD_CRC_GLOBAL_REGS Registers.....	1717
13.9.6 ERAD_CRC_REGS Registers.....	1720
13.9.7 ERAD Registers to Driverlib Functions.....	1723
14 Host Interface Controller (HIC).....	1727
14.1 Introduction.....	1728
14.1.1 Features.....	1728
14.1.2 Block Diagram.....	1728
14.1.3 HIC Related Collateral.....	1729
14.2 Functional Description.....	1729
14.2.1 Memory Map.....	1729
14.2.2 Connections.....	1730
14.2.3 Interrupts and Triggers.....	1731

14.3 Operation.....	1733
14.3.1 Mailbox Access Mode Overview.....	1733
14.3.2 Direct Access Mode Overview.....	1735
14.3.3 Controlling Reads and Writes.....	1737
14.3.4 Data Lines, Data Width, Data Packing and Unpacking.....	1739
14.3.5 Address Translation.....	1742
14.3.6 Access Errors.....	1743
14.3.7 Security.....	1743
14.3.8 HIC Usage.....	1744
14.4 Usage Scenarios for Reduced Number of Pins.....	1744
14.5 Software.....	1745
14.5.1 HIC Examples.....	1745
14.6 HIC Registers.....	1746
14.6.1 HIC Base Address Table.....	1746
14.6.2 HIC_CFG_REGS Registers.....	1747
14.6.3 HIC Registers to Driverlib Functions.....	1815
15 Analog Subsystem.....	1819
15.1 Introduction.....	1820
15.1.1 Features.....	1820
15.1.2 Block Diagram.....	1820
15.2 Optimizing Power-Up Time.....	1825
15.3 Digital Inputs on ADC Pins (AIOs).....	1826
15.4 Digital Inputs and Outputs on ADC Pins (AGPIOs).....	1826
15.5 Analog Pins and Internal Connections.....	1827
15.6 Analog Subsystem Registers.....	1830
15.6.1 ASBSYS Base Address Table.....	1830
15.6.2 ANALOG_SUBSYS_REGS Registers.....	1831
15.6.3 ASYSCTL Registers to Driverlib Functions.....	1846
16 Analog-to-Digital Converter (ADC).....	1849
16.1 Introduction.....	1850
16.1.1 ADC Related Collateral.....	1850
16.1.2 Features.....	1851
16.1.3 Block Diagram.....	1852
16.2 ADC Configurability.....	1853
16.2.1 Clock Configuration.....	1853
16.2.2 Resolution.....	1853
16.2.3 Voltage Reference.....	1854
16.2.4 Signal Mode.....	1854
16.2.5 Expected Conversion Results.....	1854
16.2.6 Interpreting Conversion Results.....	1855
16.3 SOC Principle of Operation.....	1856
16.3.1 SOC Configuration.....	1857
16.3.2 Trigger Operation.....	1857
16.3.3 ADC Acquisition (Sample and Hold) Window.....	1857
16.3.4 ADC Input Models.....	1857
16.3.5 Channel Selection.....	1858
16.4 SOC Configuration Examples.....	1859
16.4.1 Single Conversion from ePWM Trigger.....	1859
16.4.2 Oversampled Conversion from ePWM Trigger.....	1859
16.4.3 Multiple Conversions from CPU Timer Trigger.....	1860
16.4.4 Software Triggering of SOCs.....	1861
16.5 ADC Conversion Priority.....	1861
16.6 Burst Mode.....	1864
16.6.1 Burst Mode Example.....	1864
16.6.2 Burst Mode Priority Example.....	1865
16.7 EOC and Interrupt Operation.....	1866
16.7.1 Interrupt Overflow.....	1867
16.7.2 Continue to Interrupt Mode.....	1867
16.7.3 Early Interrupt Configuration Mode.....	1867
16.8 Post-Processing Blocks.....	1868
16.8.1 PPB Offset Correction.....	1869

16.8.2 PPB Error Calculation.....	1869
16.8.3 PPB Limit Detection and Zero-Crossing Detection.....	1869
16.8.4 PPB Sample Delay Capture.....	1871
16.9 Opens/Shorts Detection Circuit (OSDETECT).....	1872
16.9.1 Implementation.....	1873
16.9.2 Detecting an Open Input Pin.....	1873
16.9.3 Detecting a Shorted Input Pin.....	1873
16.10 Power-Up Sequence.....	1874
16.11 ADC Calibration.....	1874
16.11.1 ADC Zero Offset Calibration.....	1874
16.12 ADC Timings.....	1875
16.12.1 ADC Timing Diagrams.....	1875
16.13 Additional Information.....	1878
16.13.1 Ensuring Synchronous Operation.....	1878
16.13.2 Choosing an Acquisition Window Duration.....	1881
16.13.3 Achieving Simultaneous Sampling.....	1883
16.13.4 Result Register Mapping.....	1883
16.13.5 Internal Temperature Sensor.....	1883
16.13.6 Designing an External Reference Circuit.....	1883
16.13.7 ADC-DAC Loopback Testing.....	1884
16.13.8 Internal Test Mode.....	1885
16.13.9 ADC Gain and Offset Calibration.....	1885
16.14 Software.....	1886
16.14.1 ADC Examples.....	1886
16.15 ADC Registers.....	1891
16.15.1 ADC Base Address Table.....	1891
16.15.2 ADC_RESULT_REGS Registers.....	1892
16.15.3 ADC_REGS Registers.....	1913
16.15.4 ADC Registers to Driverlib Functions.....	2026
17 Buffered Digital-to-Analog Converter (DAC)	2031
17.1 Introduction.....	2032
17.1.1 DAC Related Collateral.....	2032
17.1.2 Features.....	2032
17.1.3 Block Diagram.....	2032
17.2 Using the DAC.....	2033
17.2.1 Initialization Sequence.....	2033
17.2.2 DAC Offset Adjustment.....	2034
17.2.3 EPWMSYNCPER Signal.....	2034
17.3 Lock Registers.....	2034
17.4 Software.....	2035
17.4.1 DAC Examples.....	2035
17.5 DAC Registers.....	2035
17.5.1 DAC Base Address Table.....	2035
17.5.2 DAC_REGS Registers.....	2036
17.5.3 DAC Registers to Driverlib Functions.....	2043
18 Comparator Subsystem (CMPSS)	2045
18.1 Introduction.....	2046
18.1.1 CMPSS Related Collateral.....	2046
18.1.2 Features.....	2046
18.1.3 Block Diagram.....	2047
18.2 Comparator.....	2047
18.3 Reference DAC.....	2048
18.4 Ramp Generator.....	2049
18.4.1 Ramp Generator Overview.....	2049
18.4.2 Ramp Generator Behavior.....	2050
18.4.3 Ramp Generator Behavior at Corner Cases.....	2051
18.5 Digital Filter.....	2052
18.5.1 Filter Initialization Sequence.....	2053
18.6 Using the CMPSS.....	2053
18.6.1 LATCHCLR, EPWMSYNCPER, and EPWMBLANK Signals.....	2053
18.6.2 Synchronizer, Digital Filter, and Latch Delays.....	2053

18.6.3	Calibrating the CMPSS	2054
18.6.4	Enabling and Disabling the CMPSS Clock.....	2054
18.7	Software.....	2055
18.7.1	CMPSS Examples.....	2055
18.8	CMPSS Registers.....	2056
18.8.1	CMPSS Base Address Table.....	2056
18.8.2	CMPSS_REGS Registers.....	2057
18.8.3	CMPSS Registers to Driverlib Functions.....	2081
19	Sigma Delta Filter Module (SDFM)	2085
19.1	Introduction.....	2086
19.1.1	SDFM Related Collateral.....	2086
19.1.2	Features	2087
19.1.3	Block Diagram.....	2088
19.2	Configuring Device Pins.....	2090
19.3	Input Qualification.....	2091
19.4	Input Control Unit.....	2092
19.5	SDFM Clock Control.....	2092
19.6	Sinc Filter.....	2093
19.6.1	Data Rate and Latency of the Sinc Filter.....	2095
19.7	Data (Primary) Filter Unit.....	2096
19.7.1	32-bit or 16-bit Data Filter Output Representation.....	2097
19.7.2	Data FIFO.....	2097
19.7.3	SDSYNC Event.....	2099
19.8	Comparator (Secondary) Filter Unit.....	2101
19.8.1	Higher Threshold (HLT) Comparators	2103
19.8.2	Lower Threshold (LLT) Comparators	2103
19.8.3	Digital Filter.....	2104
19.9	Theoretical SDFM Filter Output.....	2105
19.10	Interrupt Unit.....	2107
19.10.1	SDFM (SDyERR) Interrupt Sources	2107
19.10.2	Data Ready (DRINT) Interrupt Sources.....	2108
19.11	Software.....	2110
19.11.1	SDFM Examples.....	2110
19.12	SDFM Registers.....	2114
19.12.1	SDFM Base Address Table.....	2114
19.12.2	SDFM_REGS Registers.....	2115
19.12.3	SDFM Registers to Driverlib Functions.....	2209
20	Enhanced Pulse Width Modulator (ePWM)	2215
20.1	Introduction.....	2216
20.1.1	EPWM Related Collateral.....	2217
20.1.2	Submodule Overview.....	2218
20.2	Configuring Device Pins.....	2223
20.3	ePWM Modules Overview.....	2223
20.4	Time-Base (TB) Submodule.....	2225
20.4.1	Purpose of the Time-Base Submodule.....	2225
20.4.2	Controlling and Monitoring the Time-Base Submodule.....	2226
20.4.3	Calculating PWM Period and Frequency.....	2228
20.4.4	Phase Locking the Time-Base Clocks of Multiple ePWM Modules.....	2233
20.4.5	Simultaneous Writes to TBPRD and CMPx Registers Between ePWM Modules.....	2233
20.4.6	Time-Base Counter Modes and Timing Waveforms.....	2233
20.4.7	Global Load.....	2238
20.5	Counter-Compare (CC) Submodule.....	2240
20.5.1	Purpose of the Counter-Compare Submodule.....	2240
20.5.2	Controlling and Monitoring the Counter-Compare Submodule.....	2241
20.5.3	Operational Highlights for the Counter-Compare Submodule.....	2242
20.5.4	Count Mode Timing Waveforms.....	2243
20.6	Action-Qualifier (AQ) Submodule.....	2246
20.6.1	Purpose of the Action-Qualifier Submodule.....	2246
20.6.2	Action-Qualifier Submodule Control and Status Register Definitions.....	2247
20.6.3	Action-Qualifier Event Priority.....	2249
20.6.4	AQCTLA and AQCTLB Shadow Mode Operations.....	2250

20.6.5 Configuration Requirements for Common Waveforms.....	2252
20.7 Dead-Band Generator (DB) Submodule.....	2259
20.7.1 Purpose of the Dead-Band Submodule.....	2259
20.7.2 Dead-band Submodule Additional Operating Modes.....	2260
20.7.3 Operational Highlights for the Dead-Band Submodule.....	2262
20.8 PWM Chopper (PC) Submodule.....	2266
20.8.1 Purpose of the PWM Chopper Submodule.....	2266
20.8.2 Operational Highlights for the PWM Chopper Submodule.....	2266
20.8.3 Waveforms.....	2267
20.9 Trip-Zone (TZ) Submodule.....	2270
20.9.1 Purpose of the Trip-Zone Submodule.....	2270
20.9.2 Operational Highlights for the Trip-Zone Submodule.....	2271
20.9.3 Generating Trip Event Interrupts.....	2273
20.10 Event-Trigger (ET) Submodule.....	2276
20.10.1 Operational Overview of the ePWM Event-Trigger Submodule.....	2277
20.11 Digital Compare (DC) Submodule.....	2281
20.11.1 Purpose of the Digital Compare Submodule.....	2283
20.11.2 Enhanced Trip Action Using CMPSS.....	2283
20.11.3 Using CMPSS to Trip the ePWM on a Cycle-by-Cycle Basis.....	2283
20.11.4 Operation Highlights of the Digital Compare Submodule.....	2284
20.12 ePWM Crossbar (X-BAR).....	2291
20.13 Applications to Power Topologies.....	2292
20.13.1 Overview of Multiple Modules.....	2292
20.13.2 Key Configuration Capabilities.....	2293
20.13.3 Controlling Multiple Buck Converters With Independent Frequencies.....	2294
20.13.4 Controlling Multiple Buck Converters With Same Frequencies.....	2296
20.13.5 Controlling Multiple Half H-Bridge (HHB) Converters.....	2298
20.13.6 Controlling Dual 3-Phase Inverters for Motors (ACI and PMSM).....	2300
20.13.7 Practical Applications Using Phase Control Between PWM Modules.....	2302
20.13.8 Controlling a 3-Phase Interleaved DC/DC Converter.....	2303
20.13.9 Controlling Zero Voltage Switched Full Bridge (ZVSFB) Converter.....	2306
20.13.10 Controlling a Peak Current Mode Controlled Buck Module.....	2308
20.13.11 Controlling H-Bridge LLC Resonant Converter.....	2309
20.14 Register Lock Protection.....	2310
20.15 High-Resolution Pulse Width Modulator (HRPWM).....	2311
20.15.1 Operational Description of HRPWM.....	2313
20.15.2 SFO Library Software - SFO_TI_Build_V8.lib.....	2334
20.16 Software.....	2337
20.16.1 EPWM Examples.....	2337
20.16.2 HRPWM Examples.....	2341
20.17 ePWM Registers.....	2344
20.17.1 EPWM Base Address Table.....	2344
20.17.2 EPWM_REGS Registers.....	2345
20.17.3 Register to Driverlib Function Mapping.....	2475
21 Enhanced Capture (eCAP).....	2487
21.1 Introduction.....	2488
21.1.1 Features.....	2488
21.1.2 ECAP Related Collateral.....	2488
21.2 Description.....	2489
21.3 Configuring Device Pins for the eCAP.....	2489
21.4 Capture and APWM Operating Mode.....	2493
21.5 Capture Mode Description.....	2495
21.5.1 Event Prescaler.....	2496
21.5.2 Edge Polarity Select and Qualifier.....	2496
21.5.3 Continuous/One-Shot Control.....	2497
21.5.4 32-Bit Counter and Phase Control.....	2498
21.5.5 CAP1-CAP4 Registers.....	2498
21.5.6 eCAP Synchronization.....	2498
21.5.7 Interrupt Control.....	2499
21.5.8 DMA Interrupt.....	2501
21.5.9 Shadow Load and Lockout Control.....	2501

21.5.10 APWM Mode Operation.....	2501
21.6 Application of the eCAP Module.....	2503
21.6.1 Example 1 - Absolute Time-Stamp Operation Rising-Edge Trigger.....	2503
21.6.2 Example 2 - Absolute Time-Stamp Operation Rising- and Falling-Edge Trigger.....	2504
21.6.3 Example 3 - Time Difference (Delta) Operation Rising-Edge Trigger.....	2505
21.6.4 Example 4 - Time Difference (Delta) Operation Rising- and Falling-Edge Trigger.....	2506
21.7 Application of the APWM Mode.....	2507
21.7.1 Example 1 - Simple PWM Generation (Independent Channels).....	2507
21.8 Software.....	2508
21.8.1 ECAP Examples.....	2508
21.9 eCAP Registers.....	2509
21.9.1 ECAP Base Address Table.....	2509
21.9.2 ECAP_REGS Registers.....	2510
21.9.3 ECAP Registers to Driverlib Functions.....	2528
22 High Resolution Capture (HRCAP)	2531
22.1 Introduction.....	2532
22.1.1 HRCAP Related Collateral.....	2532
22.1.2 Features.....	2532
22.1.3 Description.....	2532
22.2 Operational Details.....	2533
22.2.1 HRCAP Clocking.....	2535
22.2.2 HRCAP Initialization Sequence.....	2535
22.2.3 HRCAP Interrupts.....	2535
22.2.4 HRCAP Calibration.....	2536
22.3 Known Exceptions.....	2537
22.4 Software.....	2538
22.4.1 HRCAP Examples.....	2538
22.5 HRCAP Registers.....	2538
22.5.1 HRCAP Base Address Table.....	2538
22.5.2 HRCAP_REGS Registers.....	2539
22.5.3 HRCAP Registers to Driverlib Functions.....	2550
23 Enhanced Quadrature Encoder Pulse (eQEP)	2553
23.1 Introduction.....	2554
23.1.1 EQEP Related Collateral.....	2556
23.2 Configuring Device Pins.....	2556
23.3 Description.....	2557
23.3.1 EQEP Inputs.....	2557
23.3.2 Functional Description.....	2560
23.3.3 eQEP Memory Map.....	2561
23.4 Quadrature Decoder Unit (QDU).....	2562
23.4.1 Position Counter Input Modes.....	2562
23.4.2 eQEP Input Polarity Selection.....	2565
23.4.3 Position-Compare Sync Output.....	2565
23.5 Position Counter and Control Unit (PCCU).....	2565
23.5.1 Position Counter Operating Modes.....	2565
23.5.2 Position Counter Latch.....	2568
23.5.3 Position Counter Initialization.....	2570
23.5.4 eQEP Position-compare Unit.....	2571
23.6 eQEP Edge Capture Unit.....	2573
23.7 eQEP Watchdog.....	2577
23.8 eQEP Unit Timer Base.....	2577
23.9 QMA Module.....	2578
23.9.1 Modes of Operation.....	2579
23.9.2 Interrupt and Error Generation.....	2580
23.10 eQEP Interrupt Structure.....	2581
23.11 Software.....	2582
23.11.1 EQEP Examples.....	2582
23.12 eQEP Registers.....	2585
23.12.1 EQEP Base Address Table.....	2585
23.12.2 EQEP_REGS Registers.....	2586
23.12.3 EQEP Registers to Driverlib Functions.....	2623

24 Serial Peripheral Interface (SPI)	2627
24.1 Introduction.....	2628
24.1.1 Features.....	2628
24.1.2 SPI Related Collateral.....	2628
24.1.3 Block Diagram.....	2629
24.2 System-Level Integration.....	2630
24.2.1 SPI Module Signals.....	2630
24.2.2 Configuring Device Pins.....	2631
24.2.3 SPI Interrupts.....	2631
24.2.4 DMA Support.....	2633
24.3 SPI Operation.....	2634
24.3.1 Introduction to Operation.....	2634
24.3.2 Master Mode.....	2635
24.3.3 Slave Mode.....	2636
24.3.4 Data Format.....	2638
24.3.5 Baud Rate Selection.....	2639
24.3.6 SPI Clocking Schemes.....	2640
24.3.7 SPI FIFO Description.....	2641
24.3.8 SPI DMA Transfers.....	2642
24.4 Programming Procedure.....	2643
24.4.1 Initialization Upon Reset.....	2643
24.4.2 Configuring the SPI.....	2643
24.4.3 Data Transfer Example.....	2644
24.5 Software.....	2645
24.5.1 SPI Examples.....	2645
24.6 SPI Registers.....	2647
24.6.1 SPI Base Address Table.....	2647
24.6.2 SPI_REGS Registers.....	2648
24.6.3 SPI Registers to Driverlib Functions.....	2666
25 Serial Communications Interface (SCI)	2669
25.1 Introduction.....	2670
25.1.1 Features.....	2670
25.1.2 SCI Related Collateral.....	2671
25.1.3 Block Diagram.....	2671
25.2 Architecture.....	2671
25.3 SCI Module Signal Summary.....	2671
25.4 Configuring Device Pins.....	2673
25.5 Multiprocessor and Asynchronous Communication Modes.....	2673
25.6 SCI Programmable Data Format.....	2674
25.7 SCI Multiprocessor Communication.....	2675
25.7.1 Recognizing the Address Byte.....	2675
25.7.2 Controlling the SCI TX and RX Features.....	2675
25.7.3 Receipt Sequence.....	2675
25.8 Idle-Line Multiprocessor Mode.....	2676
25.8.1 Idle-Line Mode Steps.....	2676
25.8.2 Block Start Signal.....	2677
25.8.3 Wake-Up Temporary (WUT) Flag.....	2677
25.8.4 Receiver Operation.....	2677
25.9 Address-Bit Multiprocessor Mode.....	2678
25.9.1 Sending an Address.....	2678
25.10 SCI Communication Format.....	2679
25.10.1 Receiver Signals in Communication Modes.....	2680
25.10.2 Transmitter Signals in Communication Modes.....	2681
25.11 SCI Port Interrupts.....	2682
25.11.1 Break Detect.....	2684
25.12 SCI Baud Rate Calculations.....	2684
25.13 SCI Enhanced Features.....	2685
25.13.1 SCI FIFO Description.....	2685
25.13.2 SCI Auto-Baud.....	2687
25.13.3 Autobaud-Detect Sequence.....	2687
25.14 Software.....	2688

25.14.1 SCI Examples.....	2688
25.15 SCI Registers.....	2690
25.15.1 SCI Base Address Table.....	2690
25.15.2 SCI_REGS Registers.....	2691
25.15.3 SCI Registers to Driverlib Functions.....	2713
26 Inter-Integrated Circuit Module (I2C).....	2717
26.1 Introduction.....	2718
26.1.1 I2C Related Collateral.....	2718
26.1.2 Features.....	2719
26.1.3 Features Not Supported.....	2719
26.1.4 Functional Overview.....	2720
26.1.5 Clock Generation.....	2721
26.1.6 I2C Clock Divider Registers (I2CCLKL and I2CCLKH).....	2722
26.2 Configuring Device Pins.....	2723
26.3 I2C Module Operational Details.....	2723
26.3.1 Input and Output Voltage Levels.....	2723
26.3.2 Selecting Pullup Resistors.....	2723
26.3.3 Data Validity.....	2723
26.3.4 Operating Modes.....	2723
26.3.5 I2C Module START and STOP Conditions.....	2727
26.3.6 Non-repeat Mode versus Repeat Mode.....	2728
26.3.7 Serial Data Formats.....	2728
26.3.8 Clock Synchronization.....	2731
26.3.9 Arbitration.....	2732
26.3.10 Digital Loopback Mode.....	2733
26.3.11 NACK Bit Generation.....	2734
26.4 Interrupt Requests Generated by the I2C Module.....	2734
26.4.1 Basic I2C Interrupt Requests.....	2735
26.4.2 I2C FIFO Interrupts.....	2738
26.5 Resetting or Disabling the I2C Module.....	2738
26.6 Software.....	2739
26.6.1 I2C Examples.....	2739
26.7 I2C Registers.....	2741
26.7.1 I2C Base Address Table.....	2741
26.7.2 I2C_REGS Registers.....	2742
26.7.3 I2C Registers to Driverlib Functions.....	2765
27 Power Management Bus Module (PMBus).....	2767
27.1 Introduction.....	2768
27.1.1 PMBUS Related Collateral.....	2768
27.1.2 Features.....	2768
27.1.3 Block Diagram.....	2769
27.2 Configuring Device Pins.....	2769
27.3 Slave Mode Operation.....	2770
27.3.1 Configuration.....	2770
27.3.2 Message Handling.....	2770
27.4 Master Mode Operation.....	2780
27.4.1 Configuration.....	2780
27.4.2 Message Handling.....	2780
27.5 PMBus Registers.....	2790
27.5.1 PMBUS Base Address Table.....	2790
27.5.2 PMBUS_REGS Registers.....	2791
27.5.3 PMBUS Registers to Driverlib Functions.....	2811
28 Controller Area Network (CAN).....	2813
28.1 Introduction.....	2814
28.1.1 DCAN Related Collateral.....	2814
28.1.2 Features.....	2814
28.1.3 Block Diagram.....	2815
28.2 Functional Description.....	2817
28.2.1 Configuring Device Pins.....	2817
28.2.2 Address/Data Bus Bridge.....	2817
28.3 Operating Modes.....	2819

28.3.1 Initialization.....	2819
28.3.2 CAN Message Transfer (Normal Operation).....	2820
28.3.3 Test Modes.....	2821
28.4 Multiple Clock Source.....	2825
28.5 Interrupt Functionality.....	2826
28.5.1 Message Object Interrupts.....	2826
28.5.2 Status Change Interrupts.....	2826
28.5.3 Error Interrupts.....	2826
28.5.4 Peripheral Interrupt Expansion (PIE) Module Nomenclature for DCAN Interrupts.....	2826
28.5.5 Interrupt Topologies.....	2827
28.6 DMA Functionality.....	2828
28.7 Parity Check Mechanism.....	2828
28.7.1 Behavior on Parity Error.....	2828
28.8 Debug Mode.....	2829
28.9 Module Initialization.....	2829
28.10 Configuration of Message Objects.....	2830
28.10.1 Configuration of a Transmit Object for Data Frames.....	2830
28.10.2 Configuration of a Transmit Object for Remote Frames.....	2830
28.10.3 Configuration of a Single Receive Object for Data Frames.....	2830
28.10.4 Configuration of a Single Receive Object for Remote Frames.....	2831
28.10.5 Configuration of a FIFO Buffer.....	2831
28.11 Message Handling.....	2831
28.11.1 Message Handler Overview.....	2832
28.11.2 Receive/Transmit Priority.....	2832
28.11.3 Transmission of Messages in Event Driven CAN Communication.....	2832
28.11.4 Updating a Transmit Object.....	2833
28.11.5 Changing a Transmit Object.....	2833
28.11.6 Acceptance Filtering of Received Messages.....	2834
28.11.7 Reception of Data Frames.....	2834
28.11.8 Reception of Remote Frames.....	2834
28.11.9 Reading Received Messages.....	2834
28.11.10 Requesting New Data for a Receive Object.....	2835
28.11.11 Storing Received Messages in FIFO Buffers.....	2835
28.11.12 Reading from a FIFO Buffer.....	2835
28.12 CAN Bit Timing.....	2837
28.12.1 Bit Time and Bit Rate.....	2837
28.12.2 Configuration of the CAN Bit Timing.....	2842
28.13 Message Interface Register Sets.....	2846
28.13.1 Message Interface Register Sets 1 and 2 (IF1 and IF2).....	2846
28.13.2 Message Interface Register Set 3 (IF3).....	2847
28.14 Message RAM.....	2848
28.14.1 Structure of Message Objects.....	2848
28.14.2 Addressing Message Objects in RAM.....	2851
28.14.3 Message RAM Representation in Debug Mode.....	2852
28.15 Software.....	2853
28.15.1 CAN Examples.....	2853
28.16 CAN Registers.....	2855
28.16.1 CAN Base Address Table.....	2855
28.16.2 CAN_REGS Registers.....	2856
28.16.3 CAN Registers to Driverlib Functions.....	2912
29 Modular Controller Area Network (MCAN).....	2917
29.1 MCAN Introduction.....	2918
29.1.1 MCAN Related Collateral.....	2918
29.1.2 MCAN Features.....	2919
29.2 MCAN Environment.....	2919
29.3 CAN Network Basics.....	2920
29.4 MCAN Integration.....	2921
29.5 MCAN Functional Description.....	2923
29.5.1 Module Clocking Requirements.....	2924
29.5.2 Interrupt Requests.....	2924
29.5.3 Operating Modes.....	2925

29.5.4 Transmitter Delay Compensation.....	2928
29.5.5 Restricted Operation Mode.....	2930
29.5.6 Bus Monitoring Mode.....	2930
29.5.7 Disabled Automatic Retransmission (DAR) Mode.....	2931
29.5.8 Clock Stop Mode.....	2931
29.5.9 Test Modes.....	2934
29.5.10 Timestamp Generation.....	2935
29.5.11 Timeout Counter.....	2937
29.5.12 Safety.....	2937
29.5.13 Rx Handling.....	2939
29.5.14 Tx Handling.....	2945
29.5.15 FIFO Acknowledge Handling.....	2949
29.5.16 Message RAM.....	2949
29.6 Software.....	2960
29.6.1 MCAN Examples.....	2960
29.7 MCAN Registers.....	2963
29.7.1 MCAN Base Address Table.....	2963
29.7.2 MCANSS_REGS Registers.....	2964
29.7.3 MCAN_REGS Registers.....	2976
29.7.4 MCAN_ERROR_REGS Registers.....	3054
29.7.5 MCAN Registers to Driverlib Functions.....	3079
30 Local Interconnect Network (LIN)	3085
30.1 Introduction.....	3086
30.1.1 SCI Features.....	3086
30.1.2 LIN Features.....	3087
30.1.3 LIN Related Collateral.....	3087
30.1.4 Block Diagram.....	3088
30.2 Serial Communications Interface Module.....	3091
30.2.1 SCI Communication Formats.....	3091
30.2.2 SCI Interrupts.....	3101
30.2.3 SCI DMA Interface.....	3105
30.2.4 SCI Configurations.....	3106
30.2.5 SCI Low-Power Mode.....	3108
30.3 Local Interconnect Network Module.....	3109
30.3.1 LIN Communication Formats.....	3109
30.3.2 LIN Interrupts.....	3128
30.3.3 Servicing LIN Interrupts.....	3128
30.3.4 LIN DMA Interface.....	3129
30.3.5 LIN Configurations.....	3129
30.4 Low-Power Mode.....	3131
30.4.1 Entering Sleep Mode.....	3132
30.4.2 Wakeup.....	3132
30.4.3 Wakeup Timeouts.....	3133
30.5 Emulation Mode.....	3133
30.6 Software.....	3134
30.6.1 LIN Examples.....	3134
30.7 SCI/LIN Registers.....	3136
30.7.1 LIN Base Address Table.....	3136
30.7.2 LIN_REGS Registers.....	3137
30.7.3 LIN Registers to Driverlib Functions.....	3191
31 Fast Serial Interface (FSI)	3197
31.1 Introduction.....	3198
31.1.1 FSI Related Collateral.....	3198
31.1.2 FSI Features.....	3198
31.2 System-level Integration.....	3199
31.2.1 CPU Interface.....	3199
31.2.2 Signal Description.....	3201
31.2.3 FSI Interrupts.....	3202
31.2.4 CLA Task Triggering.....	3204
31.2.5 DMA Interface.....	3204
31.2.6 External Frame Trigger Mux.....	3205

31.3 FSI Functional Description.....	3206
31.3.1 Introduction to Operation	3206
31.3.2 FSI Transmitter Module.....	3207
31.3.3 FSI Receiver Module.....	3213
31.3.4 Frame Format.....	3219
31.3.5 Flush Sequence.....	3223
31.3.6 Internal Loopback.....	3223
31.3.7 CRC Generation.....	3224
31.3.8 ECC Module.....	3224
31.3.9 Tag Matching.....	3225
31.3.10 User Data Filtering (UDATA Matching).....	3225
31.3.11 TDM Configurations.....	3225
31.3.12 FSI Trigger Generation.....	3228
31.3.13 FSI-SPI Compatibility Mode.....	3230
31.4 FSI Programing Guide.....	3234
31.4.1 Establishing the Communication Link.....	3234
31.4.2 Register Protection.....	3236
31.4.3 Emulation Mode.....	3236
31.5 Software.....	3237
31.5.1 FSI Examples.....	3237
31.6 FSI Registers.....	3245
31.6.1 FSI Base Address Table.....	3245
31.6.2 FSI_TX_REGS Registers.....	3246
31.6.3 FSI_RX_REGS Registers.....	3273
31.6.4 FSI Registers to Driverlib Functions.....	3321
32 Configurable Logic Block (CLB).....	3327
32.1 Introduction.....	3328
32.1.1 CLB Related Collateral.....	3328
32.2 Description.....	3328
32.2.1 CLB Clock.....	3330
32.3 CLB Input/Output Connection.....	3331
32.3.1 Overview.....	3331
32.3.2 CLB Input Selection.....	3331
32.3.3 CLB Output Selection.....	3340
32.3.4 CLB Output Signal Multiplexer.....	3342
32.4 CLB Tile.....	3344
32.4.1 Static Switch Block.....	3345
32.4.2 Counter Block.....	3347
32.4.3 FSM Block.....	3351
32.4.4 LUT4 Block.....	3353
32.4.5 Output LUT Block.....	3353
32.4.6 Asynchronous Output Conditioning (AOC) Block.....	3354
32.4.7 High Level Controller (HLC).....	3357
32.5 CPU Interface.....	3361
32.5.1 Register Description.....	3361
32.5.2 Non-Memory Mapped Registers.....	3362
32.6 DMA Access.....	3362
32.7 CLB Data Export Through SPI RX Buffer.....	3363
32.8 Software.....	3364
32.8.1 CLB Examples.....	3364
32.9 CLB Registers.....	3370
32.9.1 CLB Base Address Table.....	3370
32.9.2 CLB_LOGIC_CONFIG_REGS Registers.....	3371
32.9.3 CLB_LOGIC_CONTROL_REGS Registers.....	3423
32.9.4 CLB_DATA_EXCHANGE_REGS Registers.....	3456
32.9.5 CLB Registers to Driverlib Functions.....	3458
33 Advanced Encryption Standard (AES) Accelerator.....	3463
33.1 Introduction.....	3464
33.1.1 AES Block Diagram.....	3464
33.1.2 AES Algorithm.....	3467
33.2 AES Operating Modes.....	3468

33.2.1 GCM Operation.....	3468
33.2.2 CCM Operation.....	3469
33.2.3 XTS Operation.....	3470
33.2.4 ECB Feedback Mode.....	3471
33.2.5 CBC Feedback Mode.....	3472
33.2.6 CTR and ICM Feedback Modes.....	3473
33.2.7 CFB Mode.....	3474
33.2.8 F8 Mode.....	3475
33.2.9 F9 Operation.....	3476
33.2.10 CBC-MAC Operation.....	3477
33.3 Extended and Combined Modes of Operations.....	3478
33.3.1 GCM Protocol Operation.....	3478
33.3.2 CCM Protocol Operation.....	3478
33.3.3 Hardware Requests.....	3478
33.4 AES Module Programming Guide.....	3479
33.4.1 AES Low-Level Programming Models.....	3479
33.5 Software.....	3484
33.5.1 AES Examples.....	3484
33.6 AES Registers.....	3485
33.6.1 AES Base Address Table.....	3485
33.6.2 AES_REGS Registers.....	3486
33.6.3 AES_SS_REGS Registers.....	3530
33.6.4 Register to Driverlib Function Mapping.....	3533
34 Embedded Pattern Generator (EPG).....	3537
34.1 Introduction.....	3538
34.1.1 Features.....	3538
34.1.2 EPG Block Diagram.....	3538
34.1.3 EPG Related Collateral.....	3539
34.2 Clock Generator Modules.....	3540
34.2.1 DCLK (50% duty cycle clock).....	3540
34.2.2 Clock Stop.....	3541
34.3 Signal Generator Module.....	3542
34.4 EPG Peripheral Signal Mux Selection.....	3545
34.5 EPG Example Use Cases.....	3547
34.5.1 EPG Example: Synchronous Clocks with Offset.....	3547
34.5.2 EPG Example: Serial Data Bit Stream (LSB first).....	3548
34.5.3 EPG Example: Serial Data Bit Stream (MSB first).....	3549
34.6 EPG Interrupt.....	3550
34.7 Software.....	3551
34.7.1 EPG Examples.....	3551
34.8 EPG Registers.....	3552
34.8.1 EPG Base Address Table.....	3552
34.8.2 EPG_REGS Registers.....	3553
34.8.3 EPG_MUX_REGS Registers.....	3581
34.8.4 EPG Registers to Driverlib Functions.....	3586
35 Revision History.....	3589

About This Manual

This Technical Reference Manual (TRM) details the integration, the environment, the functional description, and the programming models for each peripheral and subsystem in the device.

The TRM should not be considered a substitute for the data sheet, rather a companion guide that can be used alongside the device-specific data sheet to understand the details to program the device. The primary purpose of the TRM is to abstract the programming details of the device from the data sheet. This allows the data sheet to outline the high-level features of the device without unnecessary information about register descriptions or programming models.

Note

Texas Instruments is transitioning to use more inclusive terminology. Some language may be different than what you would expect to see for certain technology areas.

Notational Conventions

This document uses the following conventions.

- Hexadecimal numbers can be shown with the suffix h or the prefix 0x. For example, the following number is 40 hexadecimal (decimal 64): 40h or 0x40.
- Registers in this document are shown in figures and described in tables.
 - Each register figure shows a rectangle divided into fields that represent the fields of the register. Each field is labeled with its bit name, its beginning and ending bit numbers above, and its read/write properties with default reset value below. A legend explains the notation used for the properties.
 - Reserved bits in a register figure can have one of multiple meanings:
 - Not implemented on the device
 - Reserved for future device expansion
 - Reserved for TI testing
 - Reserved configurations of the device that are not supported
 - Writing nondefault values to the Reserved bits could cause unexpected behavior and should be avoided.

Glossary

[TI Glossary](#) This glossary lists and explains terms, acronyms, and definitions.

Related Documentation From Texas Instruments

Chapter 1

C2000™ Microcontrollers Software Support

This chapter discusses the C2000Ware for the C2000™ microcontrollers. The C2000Ware can be downloaded from: www.ti.com/tool/C2000WARE

1.1 Introduction.....	90
1.2 C2000Ware Structure.....	90
1.3 Documentation.....	90
1.4 Devices.....	90
1.5 Libraries.....	90
1.6 Code Composer Studio™ Integrated Development Environment (IDE).....	90
1.7 SysConfig and PinMUX Tool.....	91

1.1 Introduction

C2000Ware for the C2000™ microcontrollers is a cohesive set of development software and documentation designed to minimize software development time. From device-specific drivers and libraries to device peripheral examples, C2000Ware provides a solid foundation to begin development and evaluation of your product.

C2000Ware can be downloaded from: www.ti.com/tool/C2000WARE

1.2 C2000Ware Structure

The C2000Ware software package is organized into the following directory structure as shown in [Table 1-1](#).

Table 1-1. C2000Ware Root Directories

Directory Name	Description
boards	Contains the hardware design schematics, BOM, Gerber files, and documentation for C2000 controlCARDS.
device_support	Contains all device-specific support files, bit field headers and device development user's guides.
docs	Contains the C2000Ware package user's guides and the HTML index page of all package documentation.
driverlib	Contains the device-specific driver library and driver-based peripheral examples.
libraries	Contains the device-specific and core libraries.

1.3 Documentation

Within C2000Ware, there is an extensive amount of development documentation ranging from board design documentation, to library user's guides, to driver API documentation. The "boards" directory contains all the hardware design, BOM, Gerber files, and more for controlCARDS. To assist with locating the necessary documentation, an HTML page is provided that contains a full list of all the documents in the C2000Ware package. Locate this page in the "docs" directory.

1.4 Devices

C2000Ware contains the necessary software and documentation to jumpstart development for C2000™ microcontrollers. Each device includes device-specific common source files, peripheral example projects, bit field headers, and if available, a device peripheral driver library. Additionally, documentation is provided for each device on how to set up a CCS project, as well as give an overview of all the included example projects and assist with troubleshooting. For devices with a driver library, documentation is also included that details all the peripheral APIs available.

To learn more about C2000™ microcontrollers, visit: www.ti.com/c2000.

1.5 Libraries

The libraries included in C2000Ware range from fixed-point and floating-point math libraries, to specialized DSP libraries, as well as calibration libraries. Each library includes documentation and examples, where applicable. Additionally, the Flash API files and boot ROM source code are located in the "libraries" directory.

1.6 Code Composer Studio™ Integrated Development Environment (IDE)

Code Composer Studio™ is an integrated development environment (IDE) that supports TI's microcontroller and embedded processors portfolio. The Code Composer Studio™ IDE comprises a suite of tools used to develop and debug embedded applications. The latest version of Code Composer Studio™ IDE can be obtained at: www.ti.com/ccstudio

All projects and examples in C2000Ware are built for and tested with the Code Composer Studio™ IDE. Although the Code Composer Studio™ IDE is not included with the C2000Ware installer, Code Composer Studio™ IDE is easily obtainable in a variety of versions.

1.7 SysConfig and PinMUX Tool

To help simplify configuration challenges and accelerate software development, Texas Instruments™ created SysConfig, an intuitive and comprehensive collection of graphical utilities for configuring pins, peripherals, subsystems, and other components. SysConfig helps you manage, expose, and resolve conflicts visually so that you have more time to create differentiated applications.

The tool's output includes C header and code files that can be used with C2000Ware examples or used to configure custom software.

The SysConfig tool automatically selects the pinmux settings that satisfy the entered requirements. The SysConfig tool is delivered integrated in the Code Composer Studio™ IDE, in the C2000Ware GPIO example, as a standalone installer, or can be used by way of the cloud tools portal at: dev.ti.com

2.3 Features

The CPU features include a modified Harvard architecture and circular addressing. The RISC features are single-cycle instruction execution, register-to-register operations, and modified Harvard architecture. The microcontroller features include ease of use through an intuitive instruction set, byte packing and unpacking, and bit manipulation. The modified Harvard architecture of the CPU enables instruction and data fetches to be performed in parallel. The CPU can read instructions and data while it writes data simultaneously to maintain the single-cycle instruction operation across the pipeline.

2.4 Floating-Point Unit

The C28x plus floating-point (C28x+FPU) processor extends the capabilities of the C28x fixed-point CPU by adding registers and instructions to support IEEE single-precision floating point operations.

Devices with the C28x+FPU include the standard C28x register set plus an additional set of floating-point unit registers. The additional floating-point unit registers are the following:

- Eight floating-point result registers, RnH (where n = 0–7)
- Floating-point Status Register (STF)
- Repeat Block Register (RB)

All of the floating-point registers, except the repeat block register, are shadowed. This shadowing can be used in high-priority interrupts for fast context save and restore of the floating-point registers.

Fast Integer Division (FINTDIV) supports Truncated, Modulo, and Euclidean division formats without cycle penalty and provides results in integer and remainder representation.

For more information, see the [TMS320C28x Extended Instruction Sets Technical Reference Manual](#).

2.5 Trigonometric Math Unit (TMU)

The trigonometric math unit (TMU) extends the capabilities of a C28x+FPU by adding instructions and leveraging existing FPU instructions to speed up the execution of common trigonometric and arithmetic operations listed in [Table 2-1](#).

Table 2-1. TMU Supported Instructions

Instructions	C Equivalent Operation	Pipeline Cycles
MPY2PIF32 RaH,RbH	$a = b * 2\pi$	2/3
DIV2PIF32 RaH,RbH	$a = b / 2\pi$	2/3
DIVF32 RaH,RbH,RcH	$a = b/c$	5
SQRTF32 RaH,RbH	$a = \text{sqrt}(b)$	5
SINPUF32 RaH,RbH	$a = \sin(b*2\pi)$	4
COSPUF32 RaH,RbH	$a = \cos(b*2\pi)$	4
ATANPUF32 RaH,RbH	$a = \text{atan}(b)/2\pi$	4
QUADF32 RaH,RbH,RcH,RdH	Operation to assist in calculating ATANPU2	5

Exponent instruction IEXP2F32 and logarithmic instruction LOG2F32 have been added to support computation of floating-point power function for the nonlinear proportional integral derivative control (NLPID) component of the C2000 Digital Control Library. These two added instructions reduce the power function calculations from a typical of 300 cycles using library emulation to less than 10 cycles.

No changes have been made to existing instructions, pipeline, or memory bus architecture. All TMU instructions use the existing FPU register set (R0H to R7H) to carry out the operations.

For more information, see the [TMS320C28x Extended Instruction Sets Technical Reference Manual](#).

2.6 VCRC Unit

Cyclic redundancy check (CRC) algorithms provide a straightforward method for verifying data integrity over large data blocks, communication packets, or code sections. The C28x+VCRC can perform 8-bit, 16-bit, 24-bit, and 32-bit CRCs. A CRC result register contains the current CRC, which is updated whenever a CRC instruction is executed.

The following are the CRC polynomials used by the CRC calculation logic of VCRC:

- CRC8 polynomial = 0x07
- CRC16 polynomial1 = 0x8005
- CRC16 polynomial2 = 0x1021
- CRC24 polynomial = 0x5D 6DCB
- CRC32 polynomial1 = 0x04C1 1DB7
- CRC32 polynomial2 = 0x1EDC 6F41

This module can calculate CRCs for a byte of data in a single cycle. The CRC calculation for CRC8, CRC16, CRC24 and CRC32 is done byte-wise (instead of computing on a complete 16-bit or 32-bit data read by the C28x core) to match the byte-wise computation requirement mandated by various standards.

The VCRC Unit also allows the user to provide the size (1b-32b) and value of any polynomial to fit custom CRC requirements. The CRC execution time increases to 3 cycles when using a custom polynomial.

For more information, see the [TMS320C28x Extended Instruction Sets Technical Reference Manual](#).

Chapter 3 System Control and Interrupts

The system-level functionality of this microcontroller configures the clocking, resets, and interrupts of the CPU and peripherals, as well as the operation of the on-chip memories, timers, and security features.

3.1 Introduction	98
3.2 Power Management	99
3.3 Device Identification and Configuration Registers	99
3.4 Resets	99
3.5 Peripheral Interrupts	102
3.6 Exceptions and Non-Maskable Interrupts	115
3.7 Clocking	117
3.8 32-Bit CPU Timers 0/1/2	129
3.9 Watchdog Timer	130
3.10 Low-Power Modes	133
3.11 Memory Controller Module	136
3.12 JTAG	143
3.13 Live Firmware Update	143
3.14 System Control Register Configuration Restrictions	148
3.15 Software	149
3.16 System Control Registers	156

3.1 Introduction

System-level configuration is controlled by a group of submodules that are collectively referred to as the system control module. The system control module provides the following capabilities:

- System-level resets, including power-on and brownout resets
- Clock source selection and PLL configuration
- Missing clock detection
- Clock-gating low-power modes
- Peripheral interrupt handling
- Non-maskable interrupts for certain fault conditions
- Three 32-bit timers
- Windowed watchdog timer, which can generate an interrupt or a reset
- RAM initialization, write protection, and mastership control
- Flash memory ECC, wait state, and cache configuration
- Dual-zone code security module

3.1.2 LOCK Protection on System Configuration Registers

Several system configuration registers are protected from spurious CPU writes by LOCK registers. Once these associated LOCK register bits are set, the respective locked registers can no longer be modified by software. See the register descriptions for details.

3.1.3 EALLOW Protection

Some registers in the system are protected from spurious CPU writes by the EALLOW protection mechanism. This uses the special CPU instructions EALLOW and EDIS to enable and disable access to protected registers. The current protection state is given by the EALLOW bit in the CPU ST1 register, as shown in [Table 3-1](#).

Register protection is enabled by default at startup. While protected, all writes to protected registers by the CPU are ignored. Only CPU reads, JTAG reads, and JTAG writes are allowed. If protection is disabled by executing the EALLOW instruction, the CPU is allowed to write freely to protected registers. After modifying registers, the registers can once again be protected by executing the EDIS instruction to clear the EALLOW bit.

Writes to the clock configuration and peripheral clock enable registers can be disabled until the next reset by writing to special lock registers.

Table 3-1. Access to EALLOW-Protected Registers

EALLOW Bit	CPU Writes	CPU Reads	JTAG Writes	JTAG Reads
0	Ignored	Allowed ⁽¹⁾	Allowed	Allowed
1	Allowed	Allowed	Allowed	Allowed

(1) The EALLOW bit is overridden by way of the JTAG port, allowing full access of protected registers during debug from the Code Composer Studio™ IDE interface.

3.2 Power Management

The TMS320F28003x MCU supports both internal and external VREG selectable using the VREGENZ pin to supply the 1.2V rail. However, not all packages support the external VREG option. For packages that do not support external VREG, the VREGENZ pin is replaced by GPIO39. For more details, see the data sheet.

3.3 Device Identification and Configuration Registers

The device identification registers and configuration registers provide information on the part number, product family, revision, pin count, qualification status, and feature availability of the device.

All of the device information is part of the DEV_CFG_REGS space. The identification registers are PARTIDL, PARTIDH, and REVID.

A 256-bit Unique ID (UID) is available in UID_REGS. The 256 bits are separated into these registers:

- UID_PSRAND0-5: 192 bits of pseudo-random data
- UID_UNIQUE: 32-bit unique data; the value in this register is unique across all devices in the same PARTIDH
- UID_CHECKSUM: 32-bit Fletcher checksum of UID_PSRAND0-5 and UID_UNIQUE and calculated as either little- or big-endian during factory testing

3.4 Resets

This section explains the types and effects of the different resets on this device.

3.4.1 Reset Sources

Table 3-2 summarizes the various reset signals and the effect on the device.

Table 3-2. Reset Signals

Reset Source	CPU Core Reset (C28x, FPU, VCU, TMU)	Peripherals Reset	JTAG / Debug Logic Reset	IOs	XRS Output
POR	Yes	Yes	Yes	Hi-Z	Yes
BOR	Yes	Yes	Yes	Hi-Z	Yes
XRS Pin	Yes	Yes	No	Hi-Z	-
WDRS	Yes	Yes	No	Hi-Z	Yes
NMIWDRS	Yes	Yes	No	Hi-Z	Yes
SYSRS (Debugger Reset)	Yes	Yes	No	Hi-Z	No
SCCRESET	Yes	Yes	No	Hi-Z	No
SIMRESET.XRS	Yes	Yes	No	Hi-Z	Yes
SIMRESET.CPU1RS	Yes	Yes	No	Hi-Z	No
HWBISTRS	Yes	No	No	No	No

The resets can be divided into two groups:

- Chip-level resets (\overline{XRS} , POR, BOR, \overline{WDRS} , $\overline{SIMRESET.XRS}$ and $\overline{NMIWDRS}$), which reset all or almost all of the device.
- System resets (\overline{SYSRS} , $\overline{SIMRESET.CPU1RS}$ and $\overline{SCCRESET}$), which reset a large subset of the device but maintain some system-level configuration.
- Special resets ($\overline{HWBISTRS}$ and \overline{TRST}), which enable specific device functions.

After a reset, the reset cause register (RESC) is updated with the reset cause. The bits in this register maintain the state across multiple resets. The bits can only be cleared by a power-on reset (POR) or by writing ones to the RESCCLR register. Some are cleared by the boot ROM as part of the start-up routines.

Many peripheral modules have individual resets accessible through the SOFTPRESx registers. For information about a module's reset state, refer to the chapter for that module.

After any reset, the CPU begins execution from address 0x3FFFC0 (the reset vector), which is in the boot ROM. After running the boot ROM code, the CPU typically branches to the start of the Flash memory at address 0x80000. For more information on controlling the boot process, see [Chapter 4](#).

Note

After a POR, the boot ROMs clear the M0/M1, LSx, GSx, and message RAMs to make sure that the memory contains valid ECC.

3.4.2 External Reset (\overline{XRS})

The external reset (\overline{XRS}) is the main chip-level reset for the device and resets the CPU, all peripherals and I/O pin configurations, and most of the system control registers. There is a dedicated open-drain pin for \overline{XRS} . This pin can be used to drive reset pins for other ICs in the application, and can be driven by an external source. The \overline{XRS} is driven internally during watchdog, NMI, and power-on resets.

The XRSn bit in the RESC register is set whenever \overline{XRS} is driven low for any reason. This bit is then cleared by the boot ROM.

3.4.3 Simulate External Reset (SIMRESET. \overline{XRS})

The user can simulate an external reset (\overline{XRS}) in software. This can be done by setting the XRSn bit to 1 in the SIMRESET register through software. This toggles the \overline{XRS} pin; hence, resetting the full device (just like an external reset).

After this reset, the SIMRESET_XRSn and the XRSn bits in the RESC register are set. Software can read these bits to know the cause of the reset and clear the status by writing a 1 into the corresponding bits in the RESCCLR register.

3.4.4 Power-On Reset (POR)

The power-on reset (POR) circuit creates a clean reset throughout the device during power-up, suppressing glitches on the GPIOs. The \overline{XRS} pin is held low for the duration of the POR. In most applications, \overline{XRS} is held low long enough to reset other system ICs, but some applications may require a longer pulse. In these cases, the \overline{XRS} pin can be driven low externally to provide the correct reset duration. A POR resets everything that \overline{XRS} does, along with a few other registers – the reset cause register (RESC), the NMI shadow flag register (NMISHDFLG), and the X1 clock counter register (X1CNT). A POR also resets the debug logic used by the JTAG port.

After a POR, the POR and XRSn bits in RESC are set. These bits are then cleared by the boot ROM.

3.4.5 Brown-Out-Reset (BOR)

The brown-out-reset (BOR) is an internal supply voltage supervisor (SVS) circuit which monitors the VDDIO supply for glitches or supply interruptions. If the VDDIO supply voltage drops below operational voltage range, this circuit forces the XRSn pin low until the fault is removed and the supply voltage returns to the minimum operational voltage. A BOR resets everything in the same manner as a POR reset.

The BOR circuit is enabled by default and therefore is always active during power up or after any type of reset. To disable the BOR circuit, set the BORLVMONDIS bit in the VMONCTL register.

3.4.6 Debugger Reset ($\overline{\text{SYSRS}}$)

During development, it is sometimes necessary to reset the CPU and its peripherals without disconnecting the debugger or disrupting the system-level configuration. To facilitate this, the CPU has a subsystem reset, which can be triggered by a debugger using Code Composer Studio™ IDE. This reset ($\overline{\text{SYSRS}}$) resets the CPU, the peripherals, many system control registers (including the clock gating and LPM configuration), and all I/O pin configurations.

The $\overline{\text{SYSRS}}$ does not reset the ICEPick debug module, the device capability registers, the clock source and PLL configurations, the missing clock detection state, the PIE vector fetch error handler address, the NMI flags, the analog trims, or anything reset only by a POR (see [Section 3.4.4](#)).

3.4.7 Simulate CPU Reset ($\overline{\text{SIMRESET.CPU1RS}}$)

The user can simulate a CPU reset ($\overline{\text{SYSRS}}$) in software. This can be done by setting the CPU1RSn bit to a 1 in the SIMRESET register through software. This toggles the CPU1.SYSRS signals; hence, resetting the CPU (just like the debugger reset).

After this reset, the SIMRESET_CPU1RSn bit in the RESC register is set. Software can read this bit to know the cause of the reset and clear the status by writing a 1 into the corresponding bit in the RESCCLR register.

3.4.8 Watchdog Reset ($\overline{\text{WDRS}}$)

The device has a watchdog timer that can optionally trigger a reset if it is not serviced by the CPU within a user-specified amount of time. This watchdog reset ($\overline{\text{WDRS}}$) produces an $\overline{\text{XRS}}$ that lasts for 512 INTOSC1 cycles.

After a watchdog reset, the WDRSn and XRSn bits in RESC are set.

3.4.9 Hardware BIST Reset ($\overline{\text{HWBISTR}}$)

The Hardware Built-In Self-Test (HWBIST) module tests the functionality of the CPU. At the end of the test, it resets the CPU to return it to a working state. This reset ($\overline{\text{HWBISTR}}$) only affects the CPU itself. The peripherals and system control remain as previously configured. The CPU state is restored in software as part of a special boot ROM flow. For more information on the HWBIST flow, contact your local TI representative.

After a HWBIST reset, the HWBISTn bit in RESC is set. Software can read this bit to know the cause of reset and clear the status by writing '1' into corresponding bit in RESCCLR register.

3.4.10 NMI Watchdog Reset ($\overline{\text{NMIWDRS}}$)

The device has a non-maskable interrupt (NMI) module that detects hardware errors in the system. The NMI module has a watchdog timer that triggers a reset if the CPU does not respond to an error within a user-specified amount of time. This NMI watchdog reset ($\overline{\text{NMIWDRS}}$) produces an $\overline{\text{XRS}}$ that lasts for 512 INTOSC1 cycles.

After an NMI watchdog reset, the NMIWDRSn and XRSn bits in RESC are set.

3.4.11 DCSM Safe Code Copy Reset ($\overline{\text{SCCRESET}}$)

The device has a dual-zone code security module (DCSM) that blocks read access to certain areas of the Flash memory. To facilitate CRC checks and copying of CLA code, TI provides ROM functions to securely access those memory areas. To prevent security breaches, interrupts must be disabled before calling these functions. If a vector fetch occurs in a safe copy or CRC function, the DCSM triggers a reset. This security reset ($\overline{\text{SCCRESET}}$) is similar to a $\overline{\text{SYSRS}}$. However, the security reset also resets the debug logic to deny access to a potential attacker.

After a security reset, the SCCRESETn bit in RESC is set.

3.5 Peripheral Interrupts

This section explains the peripheral interrupt handling on the device. Non-maskable interrupts are covered in [Section 3.6](#). Software interrupts and emulation interrupts are not covered in this document. For information on those, see the [TMS320C28x CPU and Instruction Set Reference Guide](#).

3.5.1 Interrupt Concepts

An interrupt is a signal that causes the CPU to pause the current execution and branch to a different piece of code known as an interrupt service routine (ISR). This is a useful mechanism for handling peripheral events, and involves less CPU overhead or program complexity than register polling. However, because interrupts are asynchronous to the program flow, care must be taken to avoid conflicts over resources that are accessed both in interrupts and in the main program code.

Interrupts propagate to the CPU through a series of flag and enable registers. The flag registers store the interrupt until the interrupt is processed. The enable registers block the propagation of the interrupt. When an interrupt signal reaches the CPU, the CPU fetches the appropriate ISR address from a list called the vector table.

3.5.2 Interrupt Architecture

The C28x CPU has fourteen peripheral interrupt lines. Two of them (INT13 and INT14) are connected directly to CPU timers 1 and 2, respectively. The remaining twelve are connected to peripheral interrupt signals through the enhanced Peripheral Interrupt Expansion module (ePIE, or PIE as a shortened version). The PIE multiplexes up to 16 peripheral interrupts into each CPU interrupt line and also expands the vector table to allow each interrupt to have an ISR. This allows the CPU to support a large number of peripherals.

An interrupt path is divided into three stages – the peripheral, the PIE, and the CPU. Each stage has enable and flag registers. This system allows the CPU to handle one interrupt while others are pending, implement and prioritize nested interrupts in software, and disable interrupts during certain critical tasks.

[Figure 3-1](#) shows the interrupt architecture for this device.

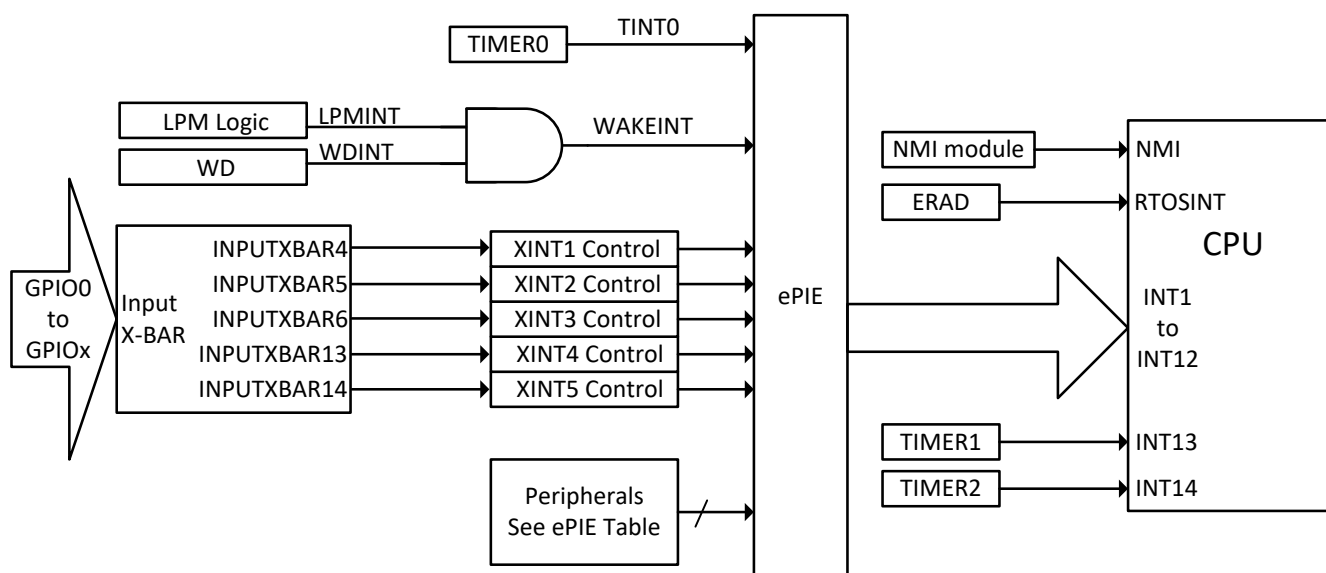

Figure 3-1. Device Interrupt Architecture

3.5.2.1 Peripheral Stage

Each peripheral has a unique interrupt configuration, which is described in that peripheral's chapter. Some peripherals allow multiple events to trigger the same interrupt signal. For example, a communications peripheral can use the same interrupt to indicate that data has been received or that there has been a transmission error. The cause of the interrupt can be determined by reading the peripheral's status register. Often, the bits in the status register must be cleared manually before another interrupt is generated.

3.5.2.2 PIE Stage

The PIE provides individual flag and enable register bits for each of the peripheral interrupt signals, which are sometimes called PIE channels. These channels are grouped according to the associated CPU interrupt. Each PIE group has one 16-bit enable register (PIEIERx), one 16-bit flag register (PIEIFRx), and one bit in the PIE acknowledge register (PIEACK). The PIEACK register bit acts as a common interrupt mask for the entire PIE group.

When the CPU receives an interrupt, the CPU fetches the address of the ISR from the PIE. The PIE returns the vector for the lowest-numbered channel in the group that is both flagged and enabled. This gives lower-numbered interrupts a higher priority when multiple interrupts are pending.

If no interrupt is both flagged and enabled, the PIE returns the vector for channel 1. This condition does not happen unless software changes the state of the PIE while an interrupt is propagating. [Section 3.5.4](#) contains procedures for safely modifying the PIE configuration once interrupts have been enabled.

3.5.2.3 CPU Stage

Like the PIE, the CPU provides flag and enable register bits for each of the interrupts. There is one enable register (IER) and one flag register (IFR), both of which are internal CPU registers. There is also a global interrupt mask, which is controlled by the INTM bit in the ST1 register. This mask can be set and cleared using the CPU's SETC and CLRC instructions. In C code, C2000Ware's DINT and EINT macros can be used for this purpose.

Writes to IER and INTM are atomic operations. In particular, if INTM is set, the next instruction in the pipeline runs with interrupts disabled. No software delays are needed.

3.5.3 Interrupt Entry Sequence

Figure 3-2 shows how peripheral interrupts propagate to the CPU.

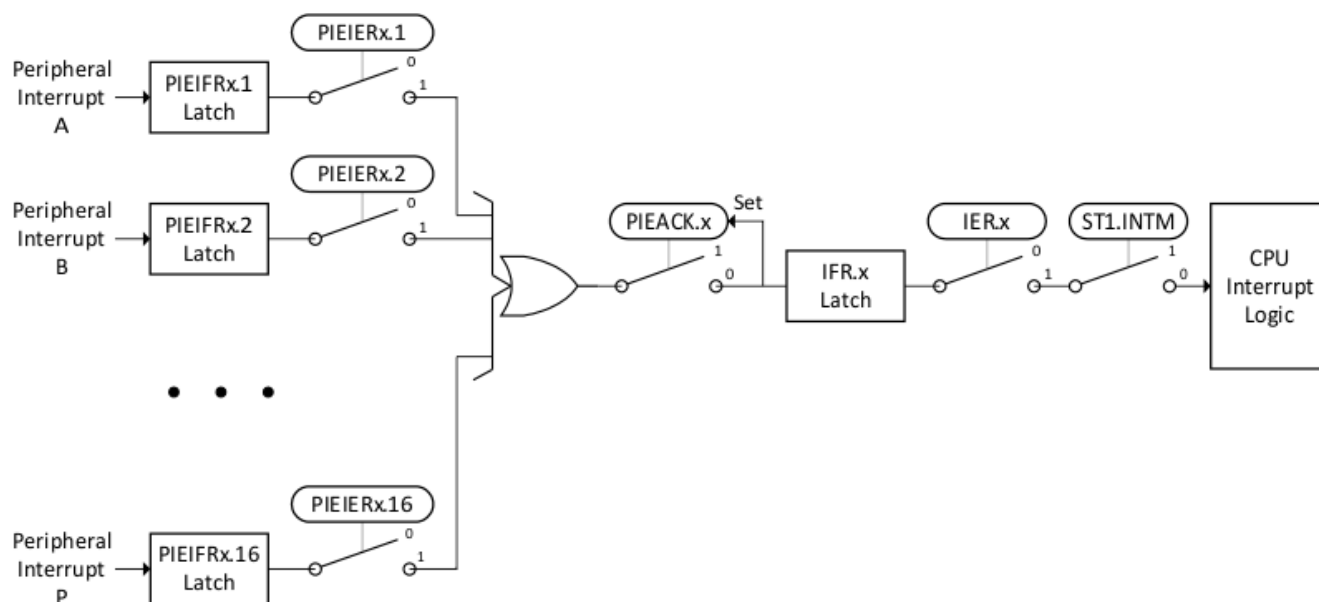

Figure 3-2. Interrupt Propagation Path

When a peripheral generates an interrupt (on PIE group x, channel y), the interrupt triggers the following sequence of events:

1. The interrupt is latched in PIEIFRx.y.
2. If PIEIERx.y is set, the interrupt propagates.
3. If PIEACK.x is clear, the interrupt propagates and PIEACK.x is set.
4. The interrupt is latched in IFR.x.
5. If IER.x is set, the interrupt propagates.
6. If INTM is clear, the CPU receives the interrupt.
7. Any instructions in the D2 or later stage of the pipeline are run to completion. Instructions in earlier stages are flushed.
8. The CPU saves the context on the stack.
9. IFR.x and IER.x are cleared. INTM is set. EALLOW is cleared.
10. The CPU fetches the ISR vector from the PIE. PIEIFRx.y is cleared.
11. The CPU branches to the ISR.

The interrupt latency is the time between PIEIFRx.y latching the interrupt and the first ISR instruction entering the execution stage of the CPU pipeline. The minimum interrupt latency is 14 SYSCLK cycles. Wait states on the ISR or stack memories add to the latency. External interrupts add a minimum of 2 SYSCLK cycles for GPIO synchronization plus extra time for input qualification (if used). Loops created using the C28x RPT instruction cannot be interrupted.

3.5.4 Configuring and Using Interrupts

At power-up, no interrupts are enabled by default. The PIEIER and IER registers are cleared and INTM is set. The application code is responsible for configuring and enabling all peripheral interrupts.

3.5.4.1 Enabling Interrupts

To enable a peripheral interrupt, perform the following steps:

1. Disable interrupts globally (DINT or SETC INTM).
2. Enable the PIE by setting the ENPIE bit of the PIECTRL register.
3. Write the ISR vector for each interrupt to the appropriate location in the PIE vector table, which can be found in [Section 3.5.6](#). Note that the vector table is EALLOW-protected.
4. Set the appropriate PIEIERx bit for each interrupt. The PIE group and channel assignments can be found in [Section 3.5.6](#).
5. Set the CPU IER bit for any PIE group containing enabled interrupts.
6. Enable the interrupt in the peripheral.
7. Enable interrupts globally (EINT or CLRC INTM).

Step 4 does not apply to the Timer1 and Timer2 interrupts, which connect directly to the CPU.

3.5.4.2 Handling Interrupts

ISRs are similar to normal functions, but must do the following:

1. Save and restore the state of certain CPU registers (if used).
2. Clear the PIEACK bit for the interrupt group.
3. Return using the IRET instruction.

Requirements 1 and 3 are handled automatically by the TMS320C28x C compiler if the function is defined using the `__interrupt` keyword. For information on this keyword, see the Keywords section of the [TMS320C28x Optimizing C/C++ Compiler v6.2.4 User's Guide](#). For information on writing assembly code to handle interrupts, see the Standard Operation for Maskable Interrupts section of the [TMS320C28x CPU and Instruction Set Reference Guide](#).

The PIEACK bit for the interrupt group must be cleared manually in user code. This is normally done at the end of the ISR. If the PIEACK bit is not cleared, the CPU does not receive any further interrupts from that group. This does not apply to the Timer1 and Timer2 interrupts, which do not go through the PIE.

3.5.4.3 Disabling Interrupts

To disable all interrupts, set the CPU's global interrupt mask using DINT or SETC INTM. It is not necessary to add NOPs after setting INTM or modifying IER – the next instruction executes with interrupts disabled.

Individual interrupts can be disabled using the PIEIERx registers, but care must be taken to avoid race conditions. If an interrupt signal is already propagating when the PIEIER write completes, the signal can reach the CPU and trigger a spurious interrupt condition. To avoid this, use the following procedure:

1. Disable interrupts globally (DINT or SETC INTM).
2. Clear the PIEIER bit for the interrupt.
3. Wait 5 cycles to make sure that any propagating interrupt has reached the CPU IFR register.
4. Clear the CPU IFR bit for the interrupt's PIE group.
5. Clear the PIEACK bit for the interrupt's PIE group.
6. Enable interrupts globally (EINT or CLRC INTM).

Interrupt groups can be disabled using the CPU IER register. This cannot cause a race condition, so no special procedure is needed.

The PIEIFR bits must never be cleared in software, since the read/modify/write operation can cause incoming interrupts to be lost. The only safe way to clear a PIEIFR bit is to have the CPU take the interrupt. The following procedure can be used to bypass the normal ISR:

1. Disable interrupts globally (DINT or SETC INTM).
2. Modify the PIE vector table to map the PIEIFR bit's interrupt vector to an empty ISR. This ISR only contains a return from interrupt instruction (IRET).
3. Disable the interrupt in the peripheral registers.
4. Enable interrupts globally (EINT or CLRC INTM).
5. Wait for the pending interrupt to be serviced by the empty ISR.
6. Disable interrupts globally.
7. Modify the PIE vector table to map the interrupt vector back to the original ISR.
8. Clear the PIEACK bit for the interrupt's PIE group.
9. Enable interrupts globally.

3.5.4.4 Nesting Interrupts

By default, interrupts do not nest. It is possible to nest and prioritize interrupts using software control of the IER and PIEIERx registers. Example code can be found in C2000Ware and documentation is available at software-dl.ti.com/C2000/docs/c28x_interrupt_nesting/html/index.html.

3.5.4.5 Vector Address Validity Check

There are two copies of the ePIE vector table. The primary vector table is located at addresses 0xD00 - 0xEFF. The redundant vector table is located at addresses 0x01000D00 - 0x01000EFF. A write to a primary vector address writes to both tables, while a write to a redundant vector address only writes to the redundant table. Both tables are read independently.

During a vector fetch, the ePIE performs a hardware comparison of both vector table outputs. If there is a mismatch between the two vector tables, the CPU branches to the address in the PIEVERRADDR register and the ePIE sends trip signals to the PWMs. If the PIEVERRADDR register value has not been set, the default boot ROM handler at address 0x003FFFBE is used.

3.5.5 PIE Channel Mapping

Table 3-3 shows the PIE group and channel assignments for each peripheral interrupt. Each row is a group, and each column is a channel within that group. When multiple interrupts are pending, the lowest-numbered channel is the lowest-numbered group is serviced first. Thus, the interrupts at the top of the table have the highest priority, and the interrupts at the bottom have the lowest priority.

Table 3-3. PIE Channel Mapping

	INTx.1	INTx.2	INTx.3	INTx.4	INTx.5	INTx.6	INTx.7	INTx.8	INTx.9	INTx.10	INTx.11	INTx.12	INTx.13	INTx.14	INTx.15	INTx.16

3.5.5.1 PIE Interrupt Priority

3.5.5.1.1 Channel Priority

For every PIE group, the low number channels in the group have the highest priority. For instance in PIE group 1, channel 1.1 has priority over channel 1.3. If those two enabled interrupts occurred simultaneously, channel 1.1 is serviced first with channel 1.3 left pending. Once the ISR for channel 1.1 completes and provided there are no other enabled and pending interrupts for PIE group 1, channel 1.3 is serviced. However, for the CPU to service any more interrupts from a PIE group, PIEACK for the group must be cleared. For this specific example, for channel 1.3 to be serviced, channel 1.1 ISR has to clear PIEACK for group 1.

The following example describes an alternative scenario: channel 1.1 is currently being serviced by the CPU, channel 1.3 is pending and before channel 1.1 ISR completes, channel 1.2 that is enabled also comes in. Since channel 1.2 has a higher priority than channel 1.3, the CPU services channel 1.2 and channel 1.3 is still left pending. Using the steps from the Interrupt Entry Sequence ([Section 3.5.3](#)), channel 1.2 interrupt can happen as late as step 10 (the CPU fetches the ISR vector from the PIE. PIEIFRx.y is cleared) and the channel 1.2 interrupt is still serviced ahead of channel 1.3.

3.5.5.1.2 Group Priority

Generally, the lowest channel in the lowest PIE group has the highest priority. An example of this is channels 1.1 and 2.1. Those two channels have the highest priority in the respective groups. If the interrupts for those two enabled channels happened simultaneously and provided there are no other enabled and pending interrupts, channel 1.1 is serviced first by the CPU with channel 2.1 left pending.

However, there are cases where channel priority supersedes group priority. This special case happens depending on which step the CPU is currently at in the Interrupt Entry Sequence ([Section 3.5.3](#)).

The following illustrates an example of this special case.

The CPU is about to service channel 2.3 and is currently going through the steps in the Interrupt Entry Sequence ([Section 3.5.3](#)).

1. As the CPU reaches step 10 (The CPU fetches the ISR vector from the PIE. PIEIFRx.y is cleared), two enabled interrupts: channel 1.1 and channel 2.1 come in.
2. Due to channel priority, channel 2.1 is serviced ahead of channel 2.3. However, group priority dictates that channel 1.1 be serviced ahead of channels 2.1 and 2.3.
3. Channel priority supersedes here and channel 2.1 is serviced ahead of 1.1 and 2.3.
4. After channel 2.1 completes, channel 1.1 is serviced followed by channel 2.3.

Group priority is only maintained if no interrupts are currently being serviced, that is, the Interrupt Entry Sequence ([Section 3.5.3](#)) is not executing.

3.5.6 Vector Tables

Table 3-4 shows the CPU interrupt vector table. The vectors for INT1 – INT12 are not used in this device. The reset vector is fetched from the boot ROM instead of from this table. All vectors are EALLOW-protected.

Table 3-5 shows the pie vector table.

Table 3-4. CPU Interrupt Vectors

Name	Vector ID	Address	Size (x16)	Description	Core Priority	ePIE Group Priority
Reset	0	0x0000 0D00	2	Reset is always fetched from location 0x003F_FFC0 in Boot ROM	1 (Highest)	-
INT1	1	0x0000 0D02	2	Not used. See PIE Group 1	5	-

3.6 Exceptions and Non-Maskable Interrupts

This section describes system-level error conditions that can trigger a non-maskable interrupt (NMI). The interrupt allows the application to respond to the error.

3.6.1 Configuring and Using NMIs

An incoming NMI sets a status bit in the NMIFLG register and starts the NMI watchdog counter. This counter is clocked by the SYSCLK, and if it reaches the value in the NMIWDPDR register, it triggers an NMI watchdog reset (NMIWDRS). To prevent this, the NMI handler must clear the flag bit using the NMIFLGCLR register. Once all flag bits are clear, the NMIINT bit in the NMIFLG register may also be cleared to allow future NMIs to be taken.

The NMI module is enabled by the boot ROM during the startup process. To respond to NMIs, an NMI handler vector must be written to the PIE vector table.

3.6.2 Emulation Considerations

The NMI watchdog counter behaves as follows under debug conditions:

CPU Suspended	When the CPU is suspended, the NMI watchdog counter is suspended.
Run-Free Mode	When the CPU is placed in run-free mode, the NMI watchdog counter resumes operation as normal.
Real-Time Single-Step Mode	When the CPU is in real-time single-step mode, the NMI watchdog counter is suspended. The counter remains suspended even within real-time interrupts.
Real-Time Run-Free Mode	When the CPU is in real-time run-free mode, the NMI watchdog counter operates as normal.

3.6.3 NMI Sources

There are several types of hardware errors that can trigger an NMI. Additional information about the error is usually available from the module that detects it.

3.6.3.1 Missing Clock Detection

The missing clock detection logic monitors OSCCLK for failure. If the OSCCLK source stops, the PLL is bypassed, OSCCLK is connected to INTOSC1, and an NMI is fired to the CPU. For more information on missing clock detection, see [Section 3.7.12.1](#).

3.6.3.2 RAM Uncorrectable Error

A double-bit ECC data error, or single-bit ECC address error in a RAM read triggers an NMI. This applies to CPU and DMA reads. Single-bit ECC data errors do not trigger an NMI, but can optionally trigger a normal peripheral interrupt. For more information on RAM error detection, see [Section 3.11.8](#).

3.6.3.3 Flash Uncorrectable ECC Error

A double-bit ECC data error or single-bit ECC address error in a Flash read triggers an NMI. Single-bit ECC data errors do not trigger an NMI, but can optionally trigger a normal peripheral interrupt. For more information on Flash error detection, see [Section 3.11.8](#).

3.6.3.4 CPU HWBIST Error

If the Hardware Built-in self (HWBIST) module detects a fault in the CPU, an NMI is generated.

3.6.3.5 Software-Forced Error

There is a special NMI source that can only be triggered by writing to the SWERR bit in the NMIFLGFRC register. Since the SWERR flag is never set by a real hardware fail, it can be used to implement a self-test mode for the NMI subsystem.

3.6.4 CRC Fail

A CRC fail result from the Background CRC (BGCRC) module can generate NMI. By default, this NMI is enabled. To disable this feature, the NMIDIS configuration field in the BGCRC_CTRL1 register has to be written with 1010.

3.6.5 ERAD NMI

The ERAD module can generate NMI based on different events. This is configurable in the GLBL_NMI_CTL register.

3.6.6 Illegal Instruction Trap (ITRAP)

If the CPU tries to execute an illegal instruction, the CPU generates a special interrupt called an illegal instruction trap (ITRAP). This interrupt is non-maskable and has a vector in the PIE vector table. For more information about ITRAPs, see the Illegal-Instruction Trap section of the [TMS320C28x DSP CPU and Instruction Set Reference Guide](#).

Note

A RAM fetch access violation triggers an ITRAP in addition to the normal peripheral interrupt for RAM access violations. The CPU handles the ITRAP first.

3.6.7 Error Pin

A signal called ERRORSTS can be output to GPIO24, GPIO28, GPIO29, or GPIO55. This signal goes low when any bit is set in the NMI shadow flag register (NMISHDFLG). This signal can be used to alert an external system to a problem in the microcontroller. Since the state of ERRORSTS is based on the shadow flags, ERRORSTS remains low until the flags are cleared by the CPU or a power-on reset occurs.

All GPIO pins are inputs on power-up. If the state of the chosen ERRORSTS pin during power-up is important, an external pull-down must be connected to the pin.

3.7 Clocking

This section explains the clock sources and clock domains on this device, and how to configure them for application use. Figure 3-3 and Figure 3-4 provide an overview of the device's clocking system.

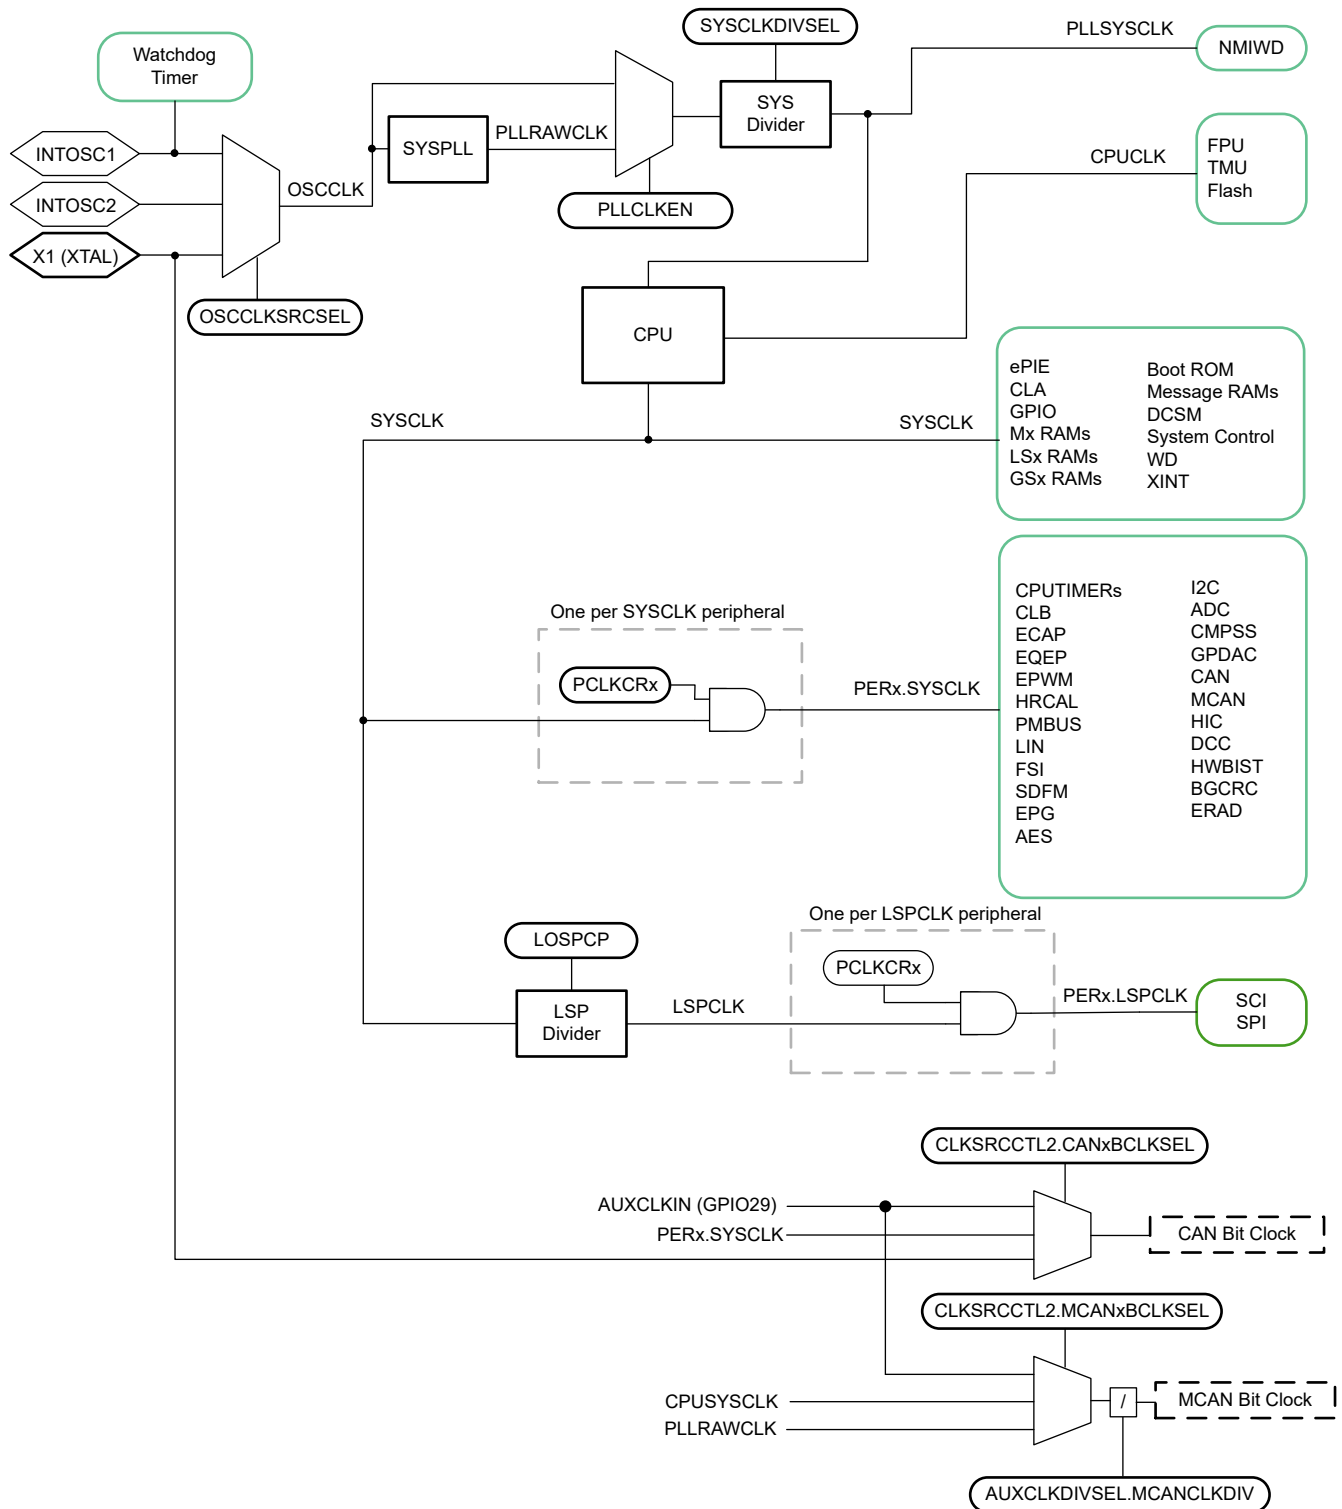

Figure 3-3. Clocking System

SYSPLL

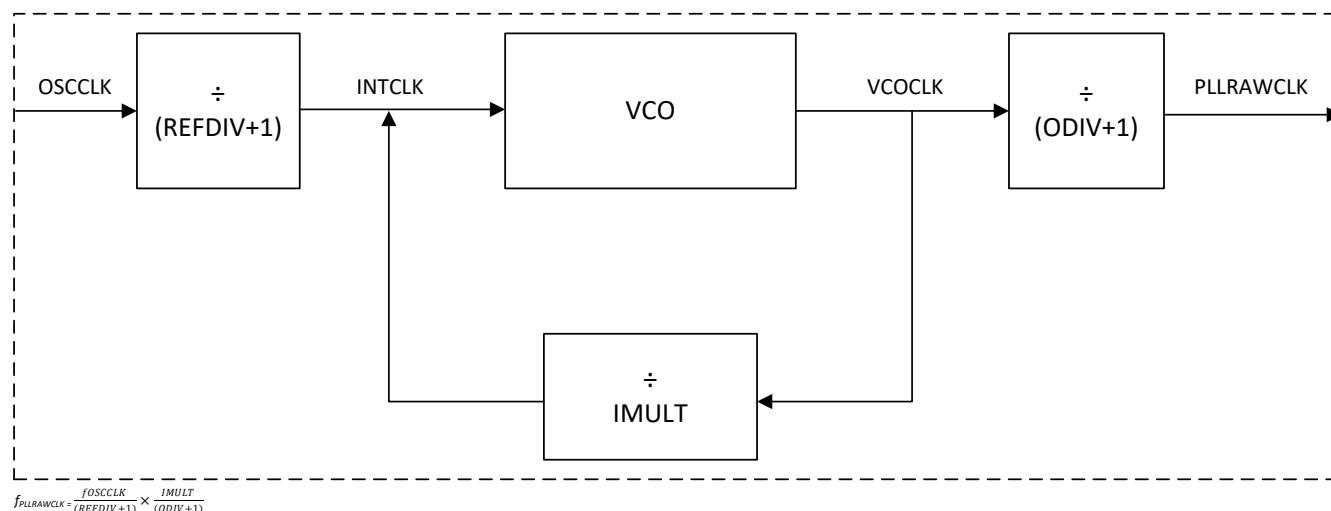

Figure 3-4. System PLL

3.7.1 Clock Sources

All of the clocks in the device are derived from one of four clock sources.

3.7.1.1 Primary Internal Oscillator (INTOSC2)

At power-up, the device is clocked from an on-chip 10-MHz oscillator (INTOSC2). INTOSC2 is the primary internal clock source and is the default system clock at reset. It is used to run the boot ROM and can be used as the system clock source for the application. Note that the INTOSC2 frequency tolerance is too loose to meet the timing requirements for CAN. Use of the CAN modules requires an external oscillator. When INTOSC2 is used as the system clock source, GPIO19 (X1) and GPIO18 (X2) are available as GPIO pins.

3.7.1.2 Backup Internal Oscillator (INTOSC1)

The device also includes a redundant on-chip 10 MHz oscillator (INTOSC1). INTOSC1 is a backup clock source that normally only clocks the watchdog timers and missing clock detection circuit (MCD). If MCD is enabled and a missing system clock is detected, the system PLL is bypassed and all system clocks are connected to INTOSC1 automatically. INTOSC1 may also be manually selected as the system clock source for debug purposes.

3.7.1.3 Auxiliary Clock Input (AUXCLKIN)

An additional external clock source is supported on GPIO29 (AUXCLKIN). This must be a single-ended 3.3V external clock as shown in [Figure 3-5](#) and can be used as the clock source for DCAN and MCAN. Frequency limits and timing requirements are found in the [TMS320F28003x Real-Time Microcontrollers Data Sheet](#). The external clock can be connected directly to the GPIO29 pin.

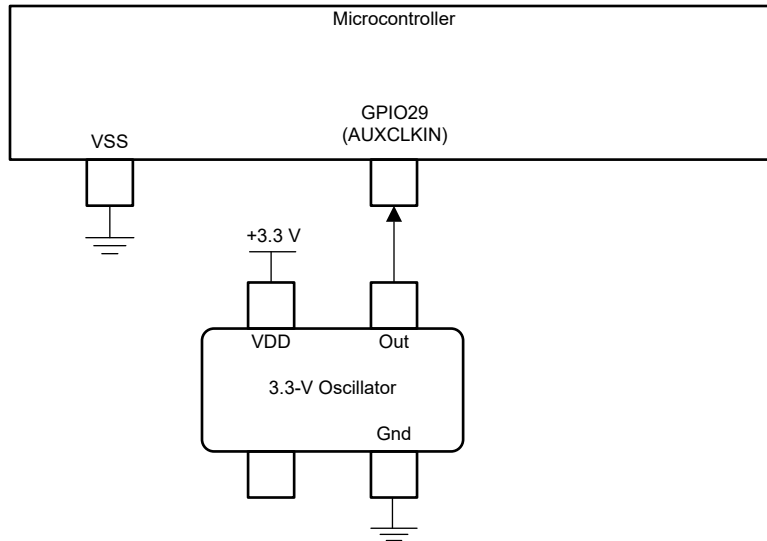

Figure 3-5. AUXCLKIN

3.7.1.4 External Oscillator (XTAL)

The device supports an external clock source (XTAL), which can be used as the main system and CAN bit clock source. Frequency limits and timing requirements are found in the [TMS320F28003x Real-Time Microcontrollers Data Sheet](#). External clock sources use the X1/GPIO19 and X2/GPIO18 pins. After power-up, the X1 and X2 pin functionality can be enabled by following the procedure in [Section 3.7.6](#).

Three types of external clock sources are supported:

- A single-ended 3.3V external clock. The clock signal must be connected to X1, as shown in [Figure 3-6](#).

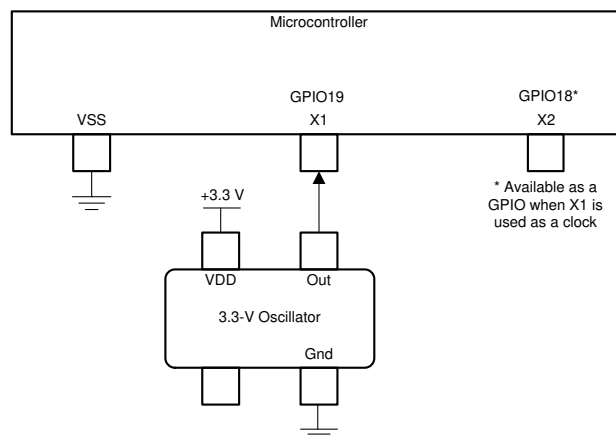

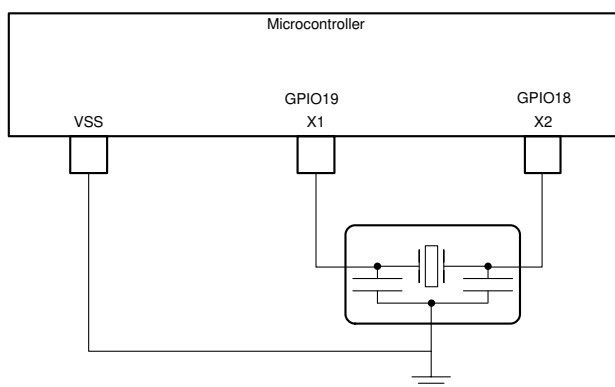

Figure 3-6. Single-ended 3.3V External Clock

- An external crystal. The crystal must be connected across X1 and X2 with the load capacitors connected to VSS as shown in [Figure 3-7](#).

Figure 3-7. External Crystal

- An external resonator. The resonator must be connected across X1 and X2 with the ground connected to VSS as shown in [Figure 3-8](#).

Figure 3-8. External Resonator
Table 3-6. ALT Modes

XTALCR Bit ⁽¹⁾		Operating Mode	GPIO19 Available on X1?	GPIO18 Available on X2?
OSCOFF	SE			
0	0	Crystal Mode: Quartz crystal connected to X1/X2	No	No
0	1	Single-Ended Mode: External clock on X1	No	Yes
1	0	Oscillator off	Yes	Yes
1	1	Single-Ended Mode: External clock on X1	No	Yes

(1) OSCOFF and SE determine the ALT mode of GPIO18 and GPIO19.

3.7.2 Derived Clocks

The clock sources discussed in the previous section can be multiplied (using PLL) and divided down to produce the desired clock frequencies for the application. This process produces a set of derived clocks, which are described in this section.

3.7.2.1 Oscillator Clock (OSCCLK)

One of INTOSC2, XTAL, or INTOSC1 must be chosen to be the master reference clock (OSCCLK) for the CPU and most of the peripherals. OSCCLK may be used directly or fed through the system PLL to reach a higher frequency. At reset, OSCCLK is the default system clock, and is connected to INTOSC2.

3.7.2.2 System PLL Output Clock (PLLRAWCLK)

The system PLL allows the device to run at the maximum rated operating frequency, and in most applications generates the main system clock. This PLL uses OSCCLK as a reference. PLLRAWCLK is the output of the PLL's voltage-controlled oscillator (VCO). For configuration instructions, see [Section 3.7.6](#).

3.7.3 Device Clock Domains

The device clock domains feed the clock inputs of the various modules in the device. They are connected to the derived clocks, either directly or through an additional divider.

3.7.3.1 System Clock (PLLSYSCLK)

The NMI watchdog timer has a clock domain (PLLSYSCLK). Despite the name, PLLSYSCLK can be connected to the system PLL (PLLRAWCLK) or to OSCCLK. The chosen clock source is run through a frequency divider, which is configured using the SYSCLKDIVSEL register. PLLSYSCLK is gated in HALT mode.

3.7.3.2 CPU Clock (CPUCLK)

The CPU has a clock (CPUCLK) that is used to clock the CPU and Flash wrapper. This clock is identical to PLLSYSCLK, but is gated when the CPU enters IDLE or HALT mode.

3.7.3.3 CPU Subsystem Clock (SYSCLK and PERx.SYSCLK)

Each peripheral clock has an independent clock gating that is controlled by the PCLKCRx registers.

Note

The application needs to wait for 5 SYSCLK cycles after enabling the clock to the peripherals when using PCLKCRx.

3.7.3.4 Low-Speed Peripheral Clock (LSPCLK and PERx.LSPCLK)

The SCI and SPI modules can communicate at bit rates that are much slower than the CPU frequency. These modules are connected to a shared clock divider, which generates a low-speed peripheral clock (LSPCLK) derived from SYSCLK. LSPCLK uses a /4 divider by default, but the ratio can be changed using the LOSPCP register. Each SCI and SPI module's clock (PERx.LSPCLK) can be gated independently using the PCLKCRx registers.

3.7.3.5 CAN Bit Clock

The required frequency tolerance for the DCAN and MCAN bit clock depends on the bit timing setup and network configuration, and can be as tight as 0.1%. Since the main system clock (in the form of SYSCLK) can not be precise enough, the bit clock can also be connected to XTAL, AUXCLKIN and PLLRAWCLK using the CLKSRCCTL2 register. There is an independent selection for each CAN module. See the CLKSRCCTL2 register for the valid options for the MCAN and DCAN.

To maintain correct operation, the frequency of the CAN bit clock must be less than or equal to the SYSCLK frequency.

3.7.3.6 CPU Timer2 Clock (TIMER2CLK)

CPU timers 0 and 1 are connected to PERx.SYSCLK. Timer 2 is connected to PERx.SYSCLK by default, but can also be connected to INTOSC1, INTOSC2, or XTAL using the TMR2CLKCTL register. This register also provides a separate prescale divider for timer 2. If a non-SYSCLK source is used, the source must be divided down to no more than half the SYSCLK frequency.

The main reason to use a non-SYSCLK source is for internal frequency measurement. In most applications, timer 2 runs off of SYSCLK.

3.7.4 XCLKOUT

It is sometimes necessary to observe a clock directly for debug and testing purposes. The external clock output (XCLKOUT) feature supports this by connecting a clock to an external pin, which can be GPIO16 or GPIO18. The available clock sources are PLLSYSCLK, PLLRAWCLK, SYSCLK, INTOSC1, INTOSC2, and XTAL.

To use XCLKOUT, first select the clock source using the CLKSRCCTL3 register. Next, select the desired output divider using the XCLKOUTDIVSEL register. Finally, connect GPIO16 or GPIO18 to mux channel 11 using the GPIO configuration registers.

3.7.5 Clock Connectivity

[Table 3-7](#) shows the clock connections sorted by the clock domain.

Table 3-7. Clock Connections Sorted by Clock Domain

Clock Domain	Module Name
CPUCLK	FPU TMU Flash
SYSCLK	CLA ePIE Mx RAMs LSx RAMs GSx RAMs Message RAMs Boot ROM GPIO Input Sync and Qual WD XINT DCSM
PLLSYSCLK	CPU NMIWD
PERx.SYSCLK	AES CLB Timer0 - 2 DCC0 - 1 FSI ePWM1 - 8 eCAP1 - 3 eQEP1 - 2 ADCA, B, C GPDACA, B CMPSS1 - 4 DCAN MCAN I2CA - B PMBUSA LINA - B HICA HWBIST BGCRC HRCAL EPG SDFM ERAD
PERx.LSPCLK	SCIA - B SPIA - B
CAN Bit Clock	DCAN, MCAN
WDCLK (INTOSC1)	Watchdog Timer

3.7.6 Clock Source and PLL Setup

The needs of the application are what ultimately determine the clock configuration. Specific concerns such as application performance, power consumption, total system cost, and EMC are beyond the scope of this document, but can provide answers to the following questions:

1. What is the desired CPU frequency?
2. Is CAN required?
3. What types of external oscillators or clock sources are available?

If CAN is used in the application, use an external clock source with a precise frequency as the reference clock. Otherwise, use only INTOSC2 and avoid the need for more external components.

3.7.7 Using an External Crystal or Resonator

The X1 and X2 pins double as GPIO19 and GPIO18. At power-up, these pins are in GPIO mode and the on-chip crystal oscillator is powered off. The following procedure can be used to switch the pins to X1 and X2 mode and enable the oscillator:

1. Clear the XTALCR.OSCOFF bit.
2. Wait for the crystal to power up. 1ms is the typical wait time but this depends on the crystal that is being used.
3. Clear the X1 counter by writing a 1 to X1CNT.CLR and keep clearing until the X1 counter value in the X1CNT register is no longer saturated 2047 (0x7FF).
4. Wait for the X1 counter value in the X1CNT register to reach 2047 (0x7FF).
5. Repeat steps 3-4 three additional times.
6. Select XTAL as the OSCCLK source by writing a 1 to CLKSRCCTL1.OSCCLKSRCSEL.
7. Check the MCLKSTS bit in the MCDCCR register. If the bit is set, the oscillator has not finished powering up, and more time is required:
 - a. Clear the missing clock status by writing a 1 to MCDCCR.MCLKCLR.
 - b. Repeat steps 2-7. Do not reset the device, as doing so powers down the oscillator, which requires the procedure to be restarted from step 1.
 - c. If the oscillator has not finished powering up in 10ms, there is a real clock failure.
8. If MCDCCR.MCLKSTS is clear, the oscillator startup is a success. The system clock is now derived from XTAL.

3.7.7.1 X1/X2 Precondition Circuit

The GPIO19/18 alternate functionality on X1/X2 can be used to speed up the start-up time of the crystal by as much as 30% if needed. This functionality is achieved by preconditioning the load capacitors CL1 and CL2 to a known state before the XTAL is turned on.

The steps below outline the procedure to precondition X1/X2 before turning on the XTAL:

1. ClkCfgRegs.XTALCR2.bit.XIF = 1; // Precondition X1 to High
2. ClkCfgRegs.XTALCR2.bit.XOF = 1; // Precondition X2 to High
3. ClkCfgRegs.XTALCR2.bit.FEN = 1; // Enable X1/X2 Precondition
4. DEVICE_DELAY_US(1);
5. ClkCfgRegs.XTALCR.bit.OSCOFF = 0; // Removes Precondition and Turns on the XTAL
6. ClkCfgRegs.XTALCR2.bit.FEN = 0; // Disables X1/X2 Precondition

3.7.8 Using an External Oscillator

The procedure for using an external oscillator connected to the X1 pin is similar to the procedure for using a crystal or resonator:

1. Clear the XTALCR.OSCOFF bit.
2. Set the XTALCR.SE bit to enable single-ended mode.
3. Clear the X1 counter by writing a 1 to X1CNT.CLR and keep clearing until the X1 counter value in the X1CNT register is no longer saturated 2047 (0x7FF).
4. Wait for the X1 counter value in the X1CNT register to reach 2047 (0x7FF).
5. Repeat steps 3-4 three additional times.
6. Select XTAL as the OSCCLK source by writing a 1 to CLKSRCCTL1.OSCCLKSRCSEL.
7. Check the MCLKSTS bit in the MCDCCR register. If the bit is set, either the external oscillator or the device has failed.
8. If MCLKSTS is clear, the switch to the external clock is a success. The system clock is now derived from XTAL.

3.7.9 Choosing PLL Settings

The equation shown in [Figure 3-4](#) must be used to configure the PLL.

IMULT is the integer value of the multiplier.

REFDIV is the reference divider for the OSCCLK.

ODIV is the output divider of the PLLRAWCLK.

PLLSYSCLKDIV is the system clock divider.

For the permissible values of the multipliers and dividers, see the documentation for the respective registers.

Many combinations of multiplier and divider can produce the same output frequency. However, the product of the reference clock frequency and the multiplier (known as the VCO frequency) must be in the range specified in the [TMS320F28003x Real-Time Microcontrollers Data Sheet](#).

Note

The system clock frequency (PLLSYSCLK) must not exceed the limit specified in the [TMS320F28003x Real-Time Microcontrollers Data Sheet](#). This limit does not allow for oscillator tolerance.

3.7.10 System Clock Setup

Once the application requirements are understood, a specific clock configuration can be determined. The default configuration is for INTOSC2 to be used as the system clock (PLLSYSCLK) with a divider of 1. The following procedure must be used to set up the desired application configuration:

Refer to your device SysCtl_setClock() function inside C2000Ware installation for an example.

Recommended sequence to set up the system PLL:

1. Bypass the PLL by clearing SYSPLLCTL1[PLLCLKEN]. Allow at least 60 NOP instructions for this to take effect.
2. Power down the PLL by writing to SYSPLLCTL1.PPLEN = 0 and allow at least 60 NOP instructions for this to take effect.
3. Select the reference clock source (OSCCLK) by writing to CLKSRCCTL1.OSCCLKSRCSEL. Allow at least 300 NOP instructions for this to take effect.
4. Set the system clock divider to /1 to make sure the fastest PLL configuration by clearing SYSCLKDIVSEL[PLLSYSCLKDIV].
5. Set the IMULT, REFDIV, and ODIV simultaneously by writing a 32-bit value in SYSPLLMULT at once to automatically enable the PLL. Be sure the settings for the multiplier and dividers do not violate the frequency specifications defined in the [TMS320F28003x Real-Time Microcontrollers Data Sheet](#).
6. Wait for PLL to lock by polling for the lock status bit to go high, that is, SYSPLLSTS.LOCKS = 1.
7. Configure DCC with reference clock as OSCCLK and clock under measurement as PLLRAWCLK, and verify the frequency of the PLL. If the frequency is out of range, do not enable PLLRAWCLK as SYSCLK, stop here and troubleshoot. Refer to [Chapter 8](#) for more information on the configuration and usage.
8. Switch to the PLL as the system clock by setting SYSPLLCTL1[PLLCLKEN].

Note

1. SYSPLL must be bypassed and powered down manually before changing the OSCCLK source.
2. At least a 60 CPU clock cycles delay is needed after bypassing PLL, that is, SYSPLLCTL1.PLLCLKEN = 0.
3. At least a 60 CPU clock cycles delay is needed after PLL is powered down, that is, SYSPLLCTL1.PPLEN = 0.
4. At least a 300 CPU clock cycles delay is needed after OSSCLK source is changed.
5. PLL SLIP bit is not supported. The DCC must be used to check the validity of the PLL clock. This feature is included as part of SysCtl_setClock() function inside C2000Ware.

3.7.11 SYS PLL Bypass

If the application requires the PLL clock to be bypassed from the system, then the application needs to configure SYSPLLCTL1.PLLCLKEN = 0. The bypass can take up to 60 CPU clock cycles before the bypass is effective. In the meantime, if PLLSYSCLKDIV is reduced to a lower value (for example from /2 to /1 or /4 to /2) the device can be clocked above the maximum rated frequency and can lead to unpredictable device behavior. Hence, a delay of 60 CPU clock cycles is required after bypassing the PLL from enable state, that is, going from PLLCLKEN = 1 to PLLCLKEN = 0.

3.7.12 Clock (OSCCLK) Failure Detection

To achieve safety diagnostic, Missing Clock Detection (MCD) can be used. [Table 3-8](#) lists the details.

Table 3-8. Clock Source (OSCCLK) Failure Detection

Clock Failure Detection Circuitry	Clocks Detected	Time for Detection (in Cycles)	Limitations
Missing Clock Detection (MCD)	INTOSC2, XTAL/X1	8192 INTOSC1 cycles	Cannot detect INTOSC1 clock failure.

3.7.12.1 Missing Clock Detection

The missing clock detect (MCD) logic detects OSCCLK failure, using INTOSC1 as the reference clock source. This circuit only detects complete loss of OSCCLK and doesn't do any detection of frequency drift on the OSCCLK.

This circuit monitors the OSCLK (primary clock) using the 10MHz clock provided by the INTOSC1 (secondary clock) as a backup clock. This circuit functions as:

1. The primary clock (OSCCLK) clock keeps ticking a 7-bit counter (named as MCDPCNT). This counter is asynchronously reset with XRSn.
2. The secondary clock (INTOSC1) clock keeps ticking a 13-bit counter (named as MCDSCNT). This counter is asynchronously reset with XRSn.
3. Each time MCDPCNT overflows, the MCDSCNT counter is reset. Thus, if OSCCLK is present or not slower than INTOSC1 by a factor of 64, MCDSCNT never overflows.
4. If OSCCLK stops for some reason or is slower than INTOSC1 by at least a factor of 64, the MCDSCNT overflows and a missing clock condition is detected on OSCCLK.
5. The above check is continuously active, unless the MCD is disabled using MCDPCR register (by making the MCLKOFF bit 1)
6. If the circuit ever detects a missing OSCCLK, the following occurs:
 - The MCDSTS flag is set.
 - The MCDSCNT counter is frozen to prevent further missing clock detection.
 - The CLOCKFAIL signal goes high, which generates TRIP events to PWM modules and fires NMIs to CPU1.NMIWD.
 - PLL is forcefully bypassed and OSCCLK source is switched to INTOSC1 (New, System Clock Frequency = INTOSC1 Freq 10MHz)/SYSDIV). In the meantime when the clock switches to INTOSC1, the System runs on PLL limp Clock.
 - SYSPLLMULT.IMULT is zeroed out automatically in this case.
 - While the MCDSTS bit is set, the OSCCLKSRCSEL bits have no effect and OSCCLK is forcefully connected to INTOSC1.
 - PLLRAWCLK going to the system is automatically switched to INTOSC1.
7. If the MCLKCLR bit is written (this is a W = 1 bit), MCDSTS bit is cleared and OSCCLK source is decided by the OSCCLKSRCSEL bits. Writing to MCLKCLR also clears the MCDPCNT and MCDSCNT counters to allow the circuit re-evaluate missing clock detection. If user wants to lock the PLL after missing clock detection, switch the clock source to INTOSC1 (using OSCCLKSRCSEL register), do a MCLKCLR and re-lock the PLL.
8. The MCD is enabled at power up.

Figure 3-9 shows the missing clock logic functional flow.

Note

On a complete clock failure when OSCCLK is dead, it can take a maximum time of 8192 INTOSC1 cycles (that is, 0.8192 ms) before the CLOCKFAIL signal goes high, after which:

- NMI is generated
 - OSCCLK is switched to INTOSC1
 - PWM Trip happens
-

Figure 3-9. Missing Clock Detection Logic

3.8 32-Bit CPU Timers 0/1/2

This section describes the three 32-bit CPU timers (TIMER0/1/2) shown in Figure 3-10.

Timer0 and Timer1 can be used in user applications. Timer2 is reserved for real-time operating system uses (for example, TI-RTOS). If the application is not using an operating system that utilizes this timer, then Timer2 can be used in the application. timer interrupt signals (TINT0, TINT1, TINT2) are connected as shown in Figure 3-11.

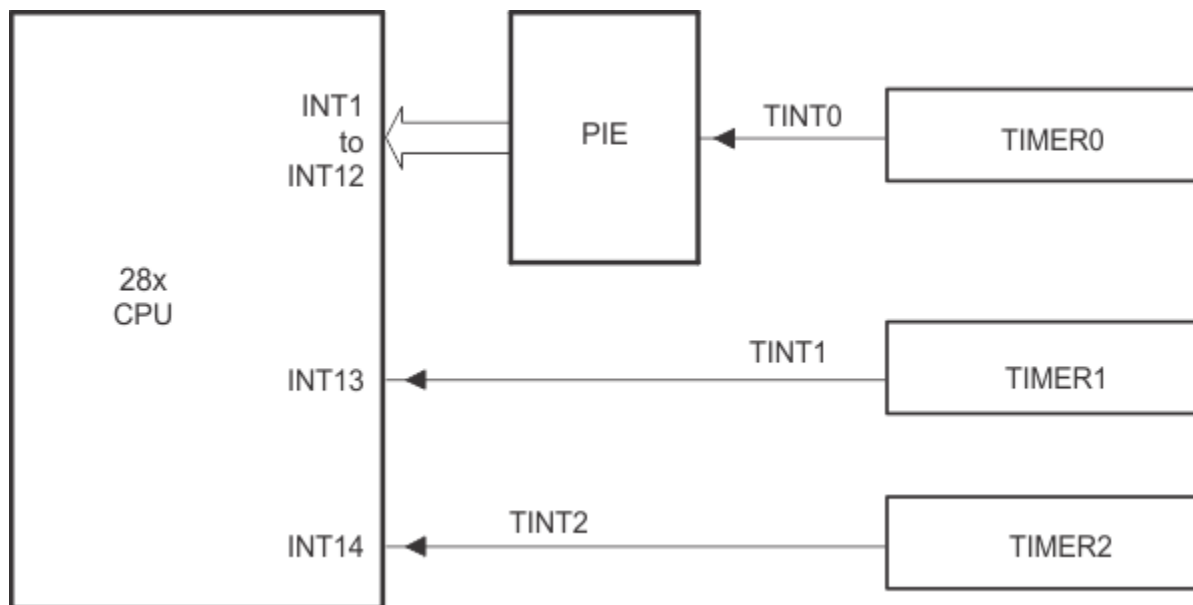

Figure 3-10. CPU Timers

- A. The timer registers are connected to the memory bus of the C28x processor.
- B. The CPU Timers are synchronized to SYSCLKOUT.

Figure 3-11. CPU Timer Interrupt Signals and Output Signal

The general operation of a CPU timer is as follows:

- The 32-bit counter register, TIMH:TIM, is loaded with the value in the period register PRDH:PRD
- The counter decrements once every $(TPR[TDDR:H:TDDR]+1)$ SYSCLK cycles, where TDDR:H:TDDR is the timer divider.
- When the counter reaches 0, a timer interrupt output signal generates an interrupt pulse.

The registers listed in Section 3.16 are used to configure the timers.

3.9 Watchdog Timer

The watchdog module consists of an 8-bit counter fed by a prescaled clock (WDCLK, which is connected to INTOSC1). When the counter reaches the maximum value, the module generates an output pulse 512 WDCLKs wide. This pulse can generate an interrupt or a reset. The CPU must periodically write a 0x55 + 0xAA sequence into the watchdog key register to reset the watchdog counter. The counter can also be disabled.

The counter's clock is divided down from WDCLK by two dividers. The prescaler is adjustable from /1 to /64 in powers of two. The pre-divider defaults to /512 for backwards compatibility, but is adjustable from /2 to /4096 in powers of two. This allows a wide range of timeout values for safety-critical applications.

Figure 3-12 shows the various functional blocks within the watchdog module.

Figure 3-12. Watchdog Timer Module

3.9.1 Servicing the Watchdog Timer

The watchdog counter (WDCNTR) is reset when the proper sequence is written to the WDKEY register before the 8-bit watchdog counter overflows. The WDCNTR is reset-enabled when a value of 0x55 is written to the WDKEY. When the next value written to the WDKEY register is 0xAA, then the WDCNTR is reset. Any value written to the WDKEY other than 0x55 or 0xAA causes no action. Any sequence of 0x55 and 0xAA values can be written to the WDKEY without causing a system reset; only a write of 0x55 followed by a write of 0xAA to the WDKEY resets the WDCNTR.

The first action that enables the WDCNTR to be reset is shown in Step 3 in [Table 3-9](#). The WDCNTR is not actually reset until step 6. Step 8 again re-enables the WDCNTR to be reset and step 9 resets the WDCNTR. Step 10 again re-enables the WDCNTR to be reset. Writing the wrong key value to the WDKEY in step 11 causes no action, however the WDCNTR is no longer enabled to be reset and the 0xAA in step 12 now has no effect.

If the watchdog is configured to reset the device, then a WDCR overflow or writing the incorrect value to the WDCR[WDCHK] bits resets the device and sets the watchdog flag (WDRSn) in the reset cause register (RESC). After a reset, the program can read the state of this flag to determine whether the reset is caused by the watchdog. After doing this, the program can clear WDRSn to allow subsequent watchdog resets to be detected. Watchdog resets are not prevented when the flag is set.

Table 3-9. Example Watchdog Key Sequences

Step	Value Written to WDKEY	Result
1	0xAA	No action
2	0xAA	No action
3	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
4	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
5	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
6	0xAA	WDCNTR is reset.
7	0xAA	No action
8	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
9	0xAA	WDCNTR is reset.
10	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
11	0x32	Improper value written to WDKEY. No action, WDCNTR no longer enabled to be reset by next 0xAA.
12	0xAA	No action due to previous invalid value.
13	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
14	0xAA	WDCNTR is reset.

3.9.2 Minimum Window Check

To complement the timeout mechanism, the watchdog also contains an optional "windowing" feature that requires a minimum delay between counter resets. This can help protect against error conditions that bypass large parts of the normal program flow but still include watchdog handling.

To set the window minimum, write the desired minimum watchdog count to the WDWCR register. This value takes effect after the next WDKEY sequence. From then on, any attempt to service the watchdog when WDCNTR is less than WDWCR triggers a watchdog interrupt or reset. When WDCNTR is greater than or equal to WDWCR, the watchdog can be serviced normally.

At reset, the window minimum is zero, which disables the windowing feature.

3.9.3 Watchdog Reset or Watchdog Interrupt Mode

The watchdog can be configured in the SCSR register to either reset the device (\overline{WDRST}) or assert an interrupt (\overline{WDINT}), if the watchdog counter reaches the maximum value. The behavior of each condition is:

- **Reset mode:** If the watchdog is configured to reset the device, then the \overline{WDRST} signal pulls the device reset (\overline{XRS}) pin low for 512 INTOSC1 cycles when the watchdog counter reaches the maximum value.
- **Interrupt mode:** When the watchdog counter expires, the counter asserts an interrupt by driving the \overline{WDINT} signal low for 512 INTOSC1 cycles. The falling edge of \overline{WDINT} triggers a WAKEINT interrupt in the PIE, if enabled. Because the PIE is edge-triggered, re-enabling the WAKEINT while \overline{WDINT} is active does not produce a duplicate interrupt.

To avoid unexpected behavior, software must not change the configuration of the watchdog while \overline{WDINT} is active. For example, changing from interrupt mode to reset mode while \overline{WDINT} is active immediately resets the device. Disabling the watchdog while \overline{WDINT} is active causes a duplicate interrupt if the watchdog is later re-enabled. If a debug reset is issued while \overline{WDINT} is active, the reset cause register (RESC) shows a watchdog reset. The WDINTS bit in the SCSR register can be read to determine the current state of \overline{WDINT} .

3.9.4 Watchdog Operation in Low-Power Modes

In IDLE mode, the watchdog interrupt (\overline{WDINT}) signal can generate an interrupt to the CPU to take the CPU out of IDLE mode. As with any other peripheral, the watchdog interrupt triggers a WAKE interrupt in the PIE during IDLE mode. User software must determine which peripheral caused the interrupt.

Note: If the watchdog interrupt is used to wake-up from an IDLE low-power mode condition, software must make sure that the \overline{WDINT} signal goes back high before attempting to reenter the IDLE mode. The \overline{WDINT} signal is held low for 512 INTOSC1 cycles when the watchdog interrupt is generated. The current state of \overline{WDINT} can be determined by reading the watchdog interrupt status bit (WDINTS) bit in the SCSR register. WDINTS follows the state of \overline{WDINT} by 2 SYSCLKOUT cycles.

In HALT mode, the internal oscillators and watchdog timer are kept active if the user sets CLKSRCCTL1.WDHALTI = 1. A watchdog reset can wake the system from HALT mode, but a watchdog interrupt cannot.

3.9.5 Emulation Considerations

The watchdog module behaves as follows under various debug conditions:

CPU Suspended	When the CPU is suspended, the watchdog clock (WDCLK) is suspended.
Run-Free Mode	When the CPU is placed in run-free mode, then the watchdog module resumes operation as normal.
Real-Time Single-Step Mode	When the CPU is in real-time single-step mode, the watchdog clock (WDCLK) is suspended. The watchdog remains suspended even within real-time interrupts.
Real-Time Run-Free Mode	When the CPU is in real-time run-free mode, the watchdog operates as normal.

3.10 Low-Power Modes

This device has HALT, IDLE, and STANDBY as clock-gating low-power modes.

All low-power modes are entered by setting the LPMCR register and executing the IDLE instruction. More information about this instruction can be found in the [TMS320C28x CPU and Instruction Set Reference Guide](#).

Low-power modes must not be entered while a Flash program or erase operation is ongoing. Entering HALT stops all CPU and peripheral activities. This includes active transmissions and control algorithms. When preparing to enter HALT mode, the application must make sure that the system is prepared to enter a period of inactivity.

Before entering HALT mode, check the value of the GPIODAT register of the pin selected for HALT wake-up (GPIOLPMSEL0/1) before entering the low-power mode to make sure that the wake event has not already been asserted.

3.10.1 Clock-Gating Low-Power Modes

IDLE and HALT modes on this device are similar to those on other C28x devices. [Table 3-10](#) describes the effect on the system when any of the clock-gating low-power modes are entered.

Table 3-10. Effect of Clock-Gating Low-Power Modes on the Device

Modules/ Clock Domain	IDLE	STANDBY	HALT
SYSCLK	Active	Gated	Gated
CPUCLK	Gated	Gated	Gated
Clock to modules connected to PERx.SYSCLK	Active	Gated	Gated
WDCLK	Active	Active	Gated if CLKSRCCTL1.WDHALTI = 0
PLL	Powered	Powered	Software must power down PLL before entering HALT.
INTOSC1	Powered	Powered	Powered down if CLKSRCCTL1.WDHALTI = 0
INTOSC2	Powered	Powered	Powered down if CLKSRCCTL1.WDHALTI = 0
Flash ⁽¹⁾	Powered	Powered	Powered
XTAL ⁽²⁾	Powered	Powered	Powered

(1) The Flash module is not powered down by hardware in any LPM. It may be powered down using software if required by the application. For more information, see the *Flash Module* chapter.

(2) The XTAL is not powered down by hardware in any LPM. It may be powered down by software setting the XTALCR.OSCOFF bit to 1. This can be done at any time during the application if the XTAL is not required.

3.10.2 IDLE

IDLE is a standard feature of the C28x CPU. In this mode, the CPU clock is gated while all peripheral clocks are left running. IDLE can thus be used to conserve power while a CPU is waiting for peripheral events.

Any enabled interrupt wakes up the CPU]from IDLE mode.

To enter IDLE mode, set LPMCR.LPM to 0x0 and execute the IDLE instruction.

The CPU resumes normal operations upon any enabled interrupt event.

3.10.3 STANDBY

STANDBY is a more aggressive low-power mode that gates both the CPU clock and any peripheral clocks derived from the CPU SYSCLK. The watchdog however, is left active. STANDBY is best suited for an application where the wake-up signal comes from an external system (or CPU subsystem) rather than a peripheral input.

An NMI (or optionally) a watchdog interrupt or a configured GPIO can wake the CPU from STANDBY mode. Each GPIO from GPIO0-60 can be configured to wake the CPU when the GPIO are driven active low. Upon wakeup, the CPU receives the WAKEINT interrupt if configured.

To enter STANDBY mode:

1. Set LPMCR.LPM to 0x1.
2. Enable the WAKEINT interrupt in the PIE.
3. For watchdog interrupt wakeup, set LPMCR.WDINTE to 1 and configure the watchdog to generate interrupts.
4. For GPIO wakeup, set GPIOLPMSEL0 and GPIOLPMSEL1 to connect the chosen GPIOs to the LPM module, and set LPMCR.QUALSTDBY to select the number of OSCCLK cycles for input qualification.
5. Execute the IDLE instruction to enter STANDBY.

To wake up from STANDBY mode:

1. Configure the desired GPIO to trigger the wakeup.
2. Drive the selected GPIO signal low; the signal must remain low for the number of OSCCLK cycles specified in the QUALSTDBY bits in the LPMCR register. If the signal is sampled high during this period, the count restarts.

At the end of the qualification period, the PLL enables the CLKIN to the CPU and the WAKEINT interrupt is latched in the PIE block.

The CPU is now out of STANDBY mode and can resume normal execution.

3.10.4 HALT

HALT is a global low-power mode that gates almost all system clocks and allows for power-down of oscillators and analog blocks.

Unlike on other C2000™ devices, HALT mode does not automatically power down the XTAL upon HALT entry. Additionally, if the XTAL is not powered on, waking up from HALT mode does not automatically power on the XTAL. The XTALCR.OSCOFF bit has been added to power on and off the XTAL circuitry when not needed through application software.

For applications that require minimal power consumption during HALT mode, application software must power off the XTAL prior to entering HALT. If the OSCCLK source is configured to be XTAL, the application must first switch the OSSCLK source to INTOSC1 or INTOSC2 prior to setting XTALCR.OSCOFF.

GPIO0-60 can be configured to wake up the system from HALT. No other wakeup option is available. However, the watchdog timer may still be clocked, and can be configured to produce a watchdog reset if a timeout mechanism is needed. On wakeup, the CPU receives a WAKEINT interrupt.

To enter HALT mode:

1. Enable the WAKEINT interrupt in the PIE .
2. Set LPMCR.LPM to 0x2. Set GPIOLPMSEL0 and GPIOLPMSEL1 to connect the chosen GPIOs to the LPM module.
3. Set CLKSRCCTL1.WDHALTI to 1 to keep the watchdog timer active and INTOSC1 and INTOSC2 powered up in HALT.
4. Set CLKSRCCTL1.WDHALTI to 0 to disable the watchdog timer and power down INTOSC1 and INTOSC2 in HALT.
5. Execute the IDLE instruction to enter HALT.

If an interrupt or NMI is received while the IDLE instruction is in the pipeline, the system begins executing the WAKEINT ISR. After HALT wakeup, ISR execution resumes where execution left off.

Note

Before entering HALT mode, if the system PLL is locked (SYSPLL.LOCKS = 1), the device must also be connected to the system clock (PLLCTL1.PLLCLKEN = 1). Otherwise, the device never wakes up.

To wake up from HALT mode:

1. Drive the selected GPIO low for a minimum 5 μ s. This activates the WAKEINT PIE interrupt.
2. Drive the wake-up GPIO high again to initiate the powering up of the SYSPLL
3. Wait 16 μ s plus 1024 OSCLK cycles to allow the PLLs to lock and the WAKEINT ISR to be latched.
4. Execute the WAKEINT ISR.

The device is now out of HALT mode and can resume normal execution.

3.10.5 Flash Power-down Considerations

The Flash module on this device can be powered down at any time during an application. There are some considerations that must be made when powering down the Flash.

When the application software powers down the Flash, the application must make sure that the function that puts the Flash to sleep is executed from RAM. Note that there must not be any access to Flash after the Flash is put to sleep to realize the power savings. If there is an access to Flash, Flash wakeup process (wakeup time depends on PSLEEP and RWAIT) gets initialized and the application does not realize Flash power savings. For example, if the application has to execute any code after putting the Flash to sleep and before putting the device in low-power mode, the application must execute that code from RAM and not from Flash.

PSLEEP and RWAIT can be optimized to reduce the Flash wakeup time for a given SYSCLK frequency. BootROM configures the best possible PSLEEP value for the 120MHz operation. However, the application software can decrease the PSLEEP value to reduce the Flash wakeup time if the application SYSCLK is less than 120MHz. This is applicable in the context of an application entering the Halt mode since PLL must be disabled before entering the Halt mode. In this case, the PSLEEP value can be decreased to get a faster Flash wakeup upon exit from LPM.

If the Wake ISR is in Flash, optimize the PSLEEP and RWAIT values before entering the LPM and after the Flash is in sleep, since the application does not get a chance to modify the values before Flash is awake after exiting from LPM. However, after the LPM exit and once the Flash is awake, the application must branch to RAM to restore RWAIT and PSLEEP (as per the application SYSCLK to which PLL is locked for) and then proceed with Flash execution to lock the PLL.

If the Wake ISR is in RAM, application can optimize the PSLEEP and RWAIT values in the Wake ISR and then do a dummy Flash access to initiate the Flash wakeup process. While the Flash is waking up, the application can initialize the PLL lock process. Once the Flash is awake, the application can put the PLL in clock path. If the user does not want to lock the PLL from RAM, PLL can be locked from Flash (this means Flash wakeup and PLL lock are not done in parallel), but in any case make sure to restore the RWAIT and PSLEEP (as per the application SYSCLK to which PLL is locked for) in Wake ISR before proceeding to Flash execution.

The Flash fallback mode is not automatically configured as active mode upon a Flash wakeup in the device and instead the device stays as configured before entering the Flash low-power mode. Hence, the BootROM code and the Flash initialization routine in C2000Ware configure the Flash fallback mode to active mode to avoid Flash falling back to low-power mode after the grace period expiration. Similarly, in the context of the device LPM, the application software must change the Flash Fallback mode to the Active state in the Wake ISR if required. If not, Flash enters the configured fallback power mode when the grace period expires. This applies to all low-power modes on this device.

3.11 Memory Controller Module

On this device, the RAMs have different characteristics. These are:

- Dedicated to the CPU: M0, M1 RAMs
- Shared between the CPU and CLA: LSx RAMs
- Shared between the CPU, DMA, and HIC: GSx RAMs
- Used to send and receive messages between processors: MSG RAMs

All these RAMs are highly configurable to achieve control for write access and fetch access from different masters. All the RAMs are enabled with the ECC feature (both data and address). Some of the memories are secure memory as well. Refer to [Chapter 5](#) for more details. Each RAM has a controller that takes care of the access protection/security related checks and ECC features for that RAM. [Figure 3-13](#) shows the configuration of these RAMs.

Figure 3-13. Memory Architecture

3.11.1 Dedicated RAM (Mx RAM)

This device has two dedicated RAM blocks: M0 and M1. M0 and M1 memories are small blocks of memory which are tightly coupled with the CPU. Only the CPU has access to these memories. No other masters (CLA, DMA or HIC) have access to these memories.

All dedicated RAMs have ECC and access protection (CPU write protection/CPU fetch protection) feature. Each type of access protection for each RAM block can be enabled/disabled by configuring the specific bit in the access protection register, allocated to each subsystem (DxACCPROT).

3.11.2 Local Shared RAM (LSx RAM)

Local shared RAMs (LSx RAMs) are secure memories and have ECC. These memories are shared between the CPU and CLA but are by default dedicated to the CPU only. CLA access can be enabled by configuring MSEL_LSx bit field in the LSxMSEL register.

Further, when these memories are shared between the CPU and CLA, the user could choose to use these memories as CLA program memory by configuring the CLAPGM_LSx bit field in the LSxCLAPGM registers. CPU access to all memory blocks, which are programmed as CLA program memory, are blocked.

All these RAMs have the access protection (CPU write and CPU fetch) feature. Each type of access protection for each RAM block can be enabled or disabled by configuring the specific bit in the local shared RAM access protection registers, mapped to each CPU subsystem. [Table 3-11](#) shows the LSx RAM features.

Table 3-11. Local Shared RAM

MSEL_LSx	CLAPGM_LSx	CPUx Allowed Access	CPUx.CLA1 Allowed Access	Comment
00	X	All	-	LSx memory is configured as CPU dedicated RAM
01	0	All	Data Read Data Write	LSx memory is shared between CPU and CLA1
01	1	Emulation Read Emulation Write	Fetch Only Emulation Read Emulation Write	LSx memory is CLA1 program memory

3.11.3 Global Shared RAM (GSx RAM)

RAM blocks which are accessible from the CPU, DMA and HIC are called global shared RAMs (GSx RAMs).

[Table 3-12](#) shows the features of the GSx RAM.

Table 3-12. Global Shared RAM

CPU (Fetch)	CPU (Read)	CPU (Write)	CPU.DMA (Read)	CPU.DMA (Write)	HIC (Read)	HIC (Write)
Yes	Yes	Yes	Yes	Yes	Yes	Yes

The shared RAM has different levels of access protection that can be enabled or disabled by configuring specific bits in the GSxACCPROT registers.

Access protection configuration for the GSx RAM block can be locked by the user to prevent further updates to this bit field. The user can also choose to permanently lock the configuration to individual bit fields by setting the specific bit fields in the GSxCOMMIT register (refer to the register description for more details). Once a configuration is committed for a particular GSx RAM block, it can not be changed further until CPU.SYSRS is issued.

3.11.4 CLA-CPU Message RAM

These RAM blocks can be used to share data between the CPU and CLA. The CLA has read and write access to the "CLA to CPU MSGRAM." The CPU has read and write access to the "CPU to CLA MSGRAM." The CPU and CLA both have read access to both MSGRAMs.

3.11.5 CLA-DMA Message RAM

These RAMs blocks can be used to share data between CLA and DMA. The CLA has read and write access to the "CLA to DMA MSGRAM." The DMA has read and write access to the "DMA to CLA MSGRAM." The CLA and DMA both have read access to both MSGRAMs.

3.11.6 Access Arbitration

For a shared RAM, multiple accesses can happen at any given time. The maximum number of accesses to any shared RAM at any given time depends on the type of shared RAM. On this device, a combination of a fixed and round-robin scheme is followed to arbitrate multiple access at any given time.

The following is the order of fixed priority for CPU accesses:

1. Data Write/Program Write
2. Data Read
3. Program Read/Program Fetch

The following is the order of fixed priority for CLA accesses:

1. Data Write
2. Data Read/Program Fetch

Figure 3-14 represents the arbitration scheme on global shared memories.

Figure 3-15 represents the arbitration scheme on local shared memories.

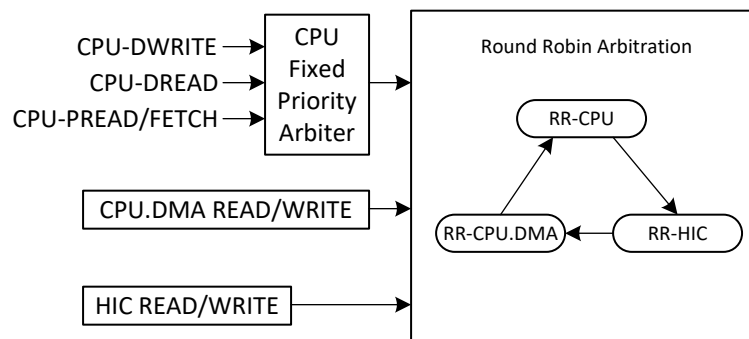

Figure 3-14. Arbitration Scheme on Global Shared Memories

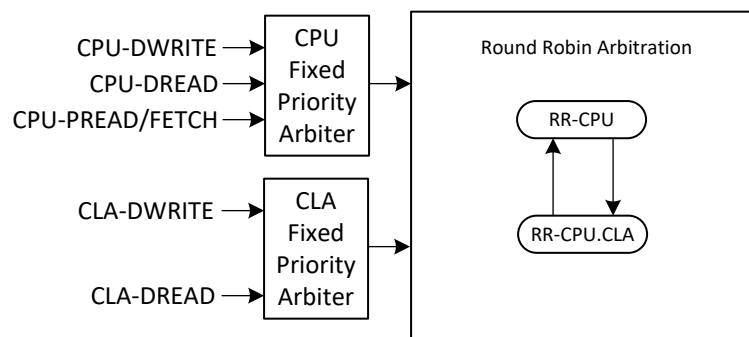

Figure 3-15. Arbitration Scheme on Local Shared Memories

3.11.7 Access Protection

The RAM blocks have different levels of protection. This feature allows the user to enable or disable specific access to individual RAM blocks from individual masters. There is no protection for read accesses; hence, reads are always allowed from all the masters that have access to that RAM block.

The following sections describe the different kinds of protection available for RAM blocks on this device.

Note

For debug accesses, all the protections are disabled.

All access protections are ignored during debug accesses. Write access to a protected memory goes through when the write is done using the debugger, irrespective of the write protection configuration for that memory.

3.11.7.1 CPU Fetch Protection

Fetch accesses from the CPU can be protected by setting the FETCHPROTx bit of the specific register to '1.' If fetch access is done by the CPU to a memory where CPU fetch protection is enabled, a fetch protection violation occurs.

If a fetch protection violation occurs, it results in an ITRAP for CPU. A flag gets set in the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched into the appropriate CPU fetch access violation address register.

3.11.7.2 CPU Write Protection

Write accesses from the CPU can be protected by setting the CPUWRPROTx bit of the specific register to '1.' If write access is done by a CPU to memory where it is protected, a write protection violation occurs.

If a write protection violation occurs, the write gets ignored, a flag gets set in the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched into the appropriate CPU write access violation address register. Also, an access violation interrupt is generated if enabled in the interrupt enable register.

3.11.7.3 CPU Read Protection

For local shared RAM, if memory is shared between the CPU and the CLA, the CPU only has access if the memory is configured as data RAM for the CLA. If the memory is programmed as program RAM, all the access from the CPU, including a read, is blocked and the violation is considered as a non-master access violation.

If a read protection violation occurs, a flag gets set in the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched in the appropriate CPU read access violation address register. Also, an access violation interrupt is generated, if enabled in the interrupt enable register.

3.11.7.4 CLA Fetch Protection

If local shared RAM is configured as dedicated RAM for the CPU, or if it is configured as data RAM for the CLA, any fetch access from the CLA to that particular LSx RAM results in a CLA fetch protection violation, which is a non-master access violation.

If a CLA fetch protection violation occurs, it results in a MSTOP, a flag gets set into the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched into the appropriate CLA fetch access violation address register. Also, an access violation interrupt is generated to the master CPU if enabled in the interrupt enable register.

3.11.7.5 CLA Read Protection

If local shared RAM is configured as dedicated RAM for the CPU, or if it is configured as program RAM for the CLA, any data read access from the CLA to that particular LSx RAM results in a CLA read protection violation, which is a non-master access violation.

If a CLA read protection violation occurs, a flag gets set into the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched into the appropriate CLA read access violation address register. Also, an access violation interrupt is generated to the master CPU if enabled in the interrupt enable register.

3.11.7.6 CLA Write Protection

If local shared RAM is configured as dedicated RAM for the CPU, or if it is configured as program RAM for the CLA, any data write access from the CLA to that particular LSx RAM results in a CLA write protection violation, which is a non-master access violation. Similarly any data write access from CLA to CPUTOCLA or DMATOCLA MSGRAM will result in a CLA write protection violation, which is a non-master access violation.

If a CLA write protection violation occurs, write gets ignored, a flag gets set into the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched into the appropriate CLA write access violation address register. Also, an access violation interrupt is generated to the master CPU if enabled in the interrupt enable register.

3.11.7.7 HIC Write Protection

Write accesses from the HIC can be protected by setting the HICWRPROTx bit of a specific register to '1.' If a write access is done by the HIC to protected memory, a write protection violation occurs.

If a write access is made to GSx memory by a non-master HIC, it is called a non-master write protection violation. If a write access is made to a dedicated or shared memory by a master HIC, and HICWRPROTx is set to '1' for that memory, it is called a master HIC write protection violation.

A flag gets set in the HIC access violation flag register, and the memory address where the violation happened gets latched in the HIC fetch access violation address register. These are dedicated registers for each subsystem.

3.11.7.8 DMA Write Protection

Write accesses from the DMA can be protected by setting the DMAWRPROTx bit of a specific register to '1.' If a write access is done by the DMA to protected memory, a write protection violation occurs.

If a write access is made to GSx memory by a non-master DMA, it is called a non-master write protection violation. If a write access is made to a dedicated or shared memory by a master DMA, and DMAWRPROTx is set to '1' for that memory, it is called a master DMA write protection violation.

A flag gets set in the DMA access violation flag register, and the memory address where the violation happened gets latched in the DMA fetch access violation address register. These are dedicated registers for each subsystem.

3.11.8 Memory Error Detection and Correction, and Error Handling

These devices have memory error detection and correction features to satisfy safety standards requirements. These requirements warrant the addition of detection mechanisms for finite dangerous failures.

In this device, all RAMs support error correction code (ECC) protection. The ECC scheme used is Single Error Correction Double Error Detection (SECCDED). ECC will cover the data bits stored in memory as well as address.

ECC calculation is done inside the memory controller module and written into the memory along with the data. ECC is computed for 16-bit data; hence, for each 32-bit of data, there will be three 7-bit ECC codes, two of which are for data and a third one for the address.

3.11.8.1 Error Detection and Correction

Error detection is done while reading the data from memory. The error detection is performed for data as well as address. For ECC memory, along with a single-bit error, a double-bit error also gets detected. These errors are called correctable and uncorrectable errors. The following are characteristics of these errors:

- Single-bit ECC errors are correctable errors
- Double-bit ECC errors are uncorrectable errors
- Address ECC errors are also uncorrectable errors

Correctable errors get corrected by the memory controller module and then correct data is given back as read data to the master. It is also written back into the memory to prevent a double-bit error due to another single-bit error at the same memory address.

3.11.8.2 Error Handling

For each correctable error, the count in the correctable error count register will increment by one. When the value in this count register becomes equal to the value configured in the correctable error threshold register, an interrupt is generated to the CPU, if the interrupt is enabled in the correctable interrupt enable register. The user needs to configure the correctable error threshold register based on the system requirements. Also, the address for which the error occurred, gets latched into a register and a flag also gets set in a status register.

If there are uncorrectable errors, an NMI gets generated for the CPU. In this case also, the address for which the error occurred gets latched into a register, and a flag gets set in a status register.

[Table 3-13](#) summarizes different error situations that can arise. These need to be handled appropriately in the software, using the status and interrupt indications provided.

Table 3-13. Error Handling in Different Scenarios

Access Type	Error Found In	Error Type	Status Indication	Error Notification
Reads	Data read from memory	Uncorrectable Error (Double bit Error for ECC RAMs)	Yes -CPU/CPU.DMA/ CPU.CLA1/DMA/CLA Read Error Address Register Data returned to CPU/ CPU.DMA/CPU.CLA1 is incorrect	NMI for CPU access NMI for CPU.DMA access NMI to CPU for CPU.CLA1 access
Reads	Data read from memory	Single-bit error for ECC RAMs	Yes - CPU/CPU.DMA CPU/DMA Read Error Address Register Increment single error counter	Interrupt when error counter reaches the user programmable threshold for single errors
Reads	Address	Address error	Yes - CPU/CPU.DMA/ CPU.CLA1/DMA/CLA Read Address Error Register Data returned to CPU/ CPU.DMA/CPU.CLA1 is incorrect	NMI to CPU for CPU access NMI to CPU for CPU.DMA access NMI to CPU for CPU.CLA1 access

Note

In the case of an uncorrectable error during fetch on the CPU, there is the possibility of getting an ITRAP before an NMI exception, since garbage instructions enter into the CPU pipeline before the NMI gets generated.

During debug accesses, correctable as well as uncorrectable errors are masked.

3.11.9 Application Test Hooks for Error Detection and Correction

Since error detection and correction logic is part of safety critical logic, safety applications can need to make sure that the logic is always working fine (during run time also). To enable this, a test mode is provided, in which a user can modify the data bits (without modifying the ECC bits) or ECC bits directly. Using this feature, an ECC error can be injected into data.

Note

The memory map for ECC bits and data bits are the same. The user must choose a different test mode to access ECC bits. In test mode, all access to memories (data as well as ECC) can be done as 32-bit access only.

Table 3-14 shows the bit mapping for the ECC bits when the bits are read in RAMTEST mode using the respective addresses.

Table 3-14. Mapping of ECC Bits in Read Data from ECC Address Map

Data Bits Location in Read Data	Content (ECC Memory)
6:0	ECC Code for lower 16 bits of data
7	Not Used
14:8	ECC Code for upper 16 bits of data
15	Not Used
22:16	ECC Code for address
31:23	Not Used

3.11.10 RAM Initialization

To make sure that read/fetch from uninitialized RAM locations do not cause ECC errors, the RAM_INIT feature is provided for each memory block. Using this feature, any RAM block can be initialized with 0x0 data and respective ECC bits accordingly. This can be initiated by setting the INIT bit to 1 for the specific RAM block in INIT registers. To check the status of RAM initialization, software must poll for the INITDONE bit for that RAM block in the INITDONE register to be set. Unless this bit gets set, no access must be made to that RAM memory block.

Note

None of the masters must access the memory while initialization is taking place. If memory is accessed before RAMINITDONE is set, the memory read/write as well as initialization does not happen correctly.

3.12 JTAG

Gel files perform certain initialization tasks. This helps the users in a debug environment. However, when executed standalone (without the emulator connected) the application can not work as expected, since there is no gel file to perform those initializations. For example, gel file disables watchdog. If user code does not service the watchdog in the application (or fails to disable the watchdog), there is a difference in how the application behaves with the debugger and without the debugger.

Common tasks performed by the gel files (but not boot-ROM):

- On Reset:
 - Disable Flash ECC on some devices.
 - Disabling ECC only when using Flash API functions, see the Flash API User Guide for details. Otherwise, TI suggests to always program ECC and enable ECC-check.
 - Disable Watchdog
 - Enable CLA clock
 - Select real-time mode or C28x mode
- On Restart:
 - Select real-time mode or C28x mode
 - Clear IER and IFR
- On Target Connect:
 - Select real-time mode or C28x mode

For more information, see [C2000 MCU JTAG Connectivity Debug Application Note](#).

3.12.1 JTAG Noise and TAP_STATUS

The TAP_STATUS register reflects the status of the JTAG TAP at any given time. Normally when no JTAG is connected to the device, the status can be IDLE. In some cases with excessive PCB noise, there can be unwanted TMS and TCK toggles that take JTAG out of the IDLE state. When persistent, this can ultimately lead to unwanted activation of the JTAG Boundary Scan or some other JTAG mode that can interfere with the intended application. To avoid this scenario, place strong enough pull resistors on the board to prevent noise from activating JTAG. As a debug tool, the TAP_STATUS register can be polled by the application code to detect if this is a cause of device disturbance. The SOFTPRES40[JTAG_nTRST] register can also be used to reset the JTAG TAP through software. Use this reset register with caution, as this prevents connecting a debugger unless the code qualifies writes to this register with some other GPIO state or other means to distinguish between noise and debugger accesses.

3.13 Live Firmware Update

This device includes hardware hooks to streamline firmware updates. These hardware hooks enable seamless switching from the old firmware to the new firmware without resetting the application.

This section discusses the Live Firmware Update (LFU) and the hardware features present on the device to support LFU.

3.13.1 LFU Background

End equipment like Server Power Supply (PSU) are high availability systems that need to have minimum downtime, even during firmware upgrades. Firmware upgrades are essential to add additional functionality, enhance performance and fix software bugs/vulnerabilities. LFU helps update firmware while the application is running, thus eliminating downtime (with respect to critical real-time interrupts) and also providing a more cost-effective alternative compared to manually updating firmware.

LFU has traditionally been implemented in the C2000 family of MCUs using software-only techniques. This impacts LFU switchover time, which is the time to switchover to new firmware once the transition has begun. User application code initiates this transition, typically by jumping to an entry point in the new firmware. There, a compiler provided initialization routine specific to LFU is called. This initializes user-specified data variables.

When execution arrives in main() of the new application, user application code performs minimal initialization to get the new application running.

3.13.2 LFU Switchover Steps

A simplified representation of the LFU switchover is shown in [Figure 3-16](#), and is described in the following steps:

1. In typical systems, a host – typically a PC or another MCU, will initiate LFU (depicted as LFU Request) on the application MCU (in this case, the C2000 MCU) that is executing the real-time control application. This initiates the Flash Program sequence in the application MCU. This runs as a background process even as the application MCU continues executing firmware (depicted as Firmware - 1).
2. Since the compiler may move existing PIE vectors and function pointers to new locations between firmware versions, or PIE vectors or function pointers could get added or removed between firmware versions, user application code needs to manage these properly and efficiently during LFU. In the absence of Flash remapping (where different Flash memory banks can be mapped to the same address), PIE vector table remapping, that is “swapping” and RAM memory block swapping are features supported on the device. Without swapping, user application code would need to individually update each PIE vector and each function pointer, adding valuable cycles to the LFU switchover time. With swapping, prior to LFU switchover, user application code can populate a different PIE vector table (depicted as PIE Swap Memory Update) and a different LS RAM region (depicted as LSx Swap Memory Update).
3. When complete, at a suitable time (depicted as LFU Switchover – waiting for appropriate time), user application code initiates the transition to new firmware. Once the compiler LFU initialization routine completes and transfers execution to the new application (depicted as Firmware – 2), user application code needs to perform necessary initialization before the new application can begin running. Since PIE vectors and function pointers have already been populated in the “swap” locations, all that is required is a PIE vector table swap and LSx RAM Memory Swap (depicted as PIE Vector Swap, LSx Memory Swap).

Figure 3-16. Simplified LFU Representation

3.13.3 Device Features Supporting LFU

The new hardware capabilities implemented in the device to support LFU are:

1. Multi-Bank Flash
2. PIE Vector Table Swap
3. LS0/LS1 RAM Memory Swap

3.13.3.1 Multi-Bank Flash

The device has up to three Flash banks, each of size 128KB. With multiple banks, it is possible to Program/Erase a bank while other banks are in read mode.

3.13.3.2 PIE Vector Table Swap

The device contains an additional PIE vector table, in addition to the typical PIE vector table that is present. This allows PIE vector addresses for the new firmware to be populated prior to the LFU switchover. During LFU switchover, a simple swap operation which activates the PIE vector swap table and deactivates the previously active PIE vector table is initiated by user application code, and this operation takes just 1 CPU clock cycle. To initiate the swap, user application code sets `LFUConfig.PieVectorSwap = 1`. The PIE vector table swap features

are also implemented on a redundant PIE vector table implemented for safety. Therefore, to implement PIE vector table swap, the sizes of PIE vector memory and redundant PIE vector memory are both doubled.

The changes are summarized in Figure 3-17. In previous devices, PIE vector RAM and redundant PIE vector RAM are present. In this device, these are duplicated. There are now four physical PIE vector RAM memories – Block A, Block B, Block C, and Block D. By default, Block A and Block B are *active*, and are mapped to addresses 0x0000_0D00-0x0000_0EFF and 0x0100_0D00-0x0100_0EFF respectively. Block C and Block D are *inactive*, and are mapped to addresses 0x0100_0900-0x0100_0AFF and 0x0100_0B00-0x0100_0CFF respectively.

When user application code initiates a PIE vector table swap by setting LFUConfig.PieVectorSwap = 1, Block C and Block D *become active*, and are mapped to addresses 0x0000_0D00-0x0000_0EFF and 0x0100_0D00-0x0100_0EFF respectively. Block A and Block B *become inactive*, and are mapped to addresses 0x0100_0900-0x0100_0AFF and 0x0100_0B00-0x0100_0CFF respectively.

Thus, note that the active addresses are always 0x0000_0D00-0x0000_0EFF, and 0x0100_0D00-0x0100_0EFF (for redundancy). The inactive addresses are always 0x0100_0900-0x0100_0AFF, and 0x0100_0B00-0x0100_0CFF (for redundancy). As mentioned above, prior to the LFU switchover, user application code needs to write to the inactive addresses with the PIE vector locations corresponding to the new firmware.

The register bit LFUStatus.PieVectorSwap provides the status of Pie Vector Swap.

Writes to addresses 0x0000_0D00-0x0000_0EFF update both the currently active block and the redundant counterpart. Writes to addresses 0x0100_0900-0x0100_0AFF update both the currently inactive block and the redundant counterpart.

Reads from addresses 0x0000_0D00-0x0000_0EFF issue reads from both addresses 0x0000_0D00-0x0000_0EFF and the redundant counterpart 0x0100_0D00-0x0100_0EFF. The read values are compared, and any data mismatches generate the same error response as that of the existing PIE vector fetch mismatch (refer to PIEVERRADDR). A read from or write to the redundant PIE vector RAM (0x0100_0D00-0x0100_0EFF or 0x0100_0B00-0x0100_0CFF) impacts only the redundant PIE vector RAM.

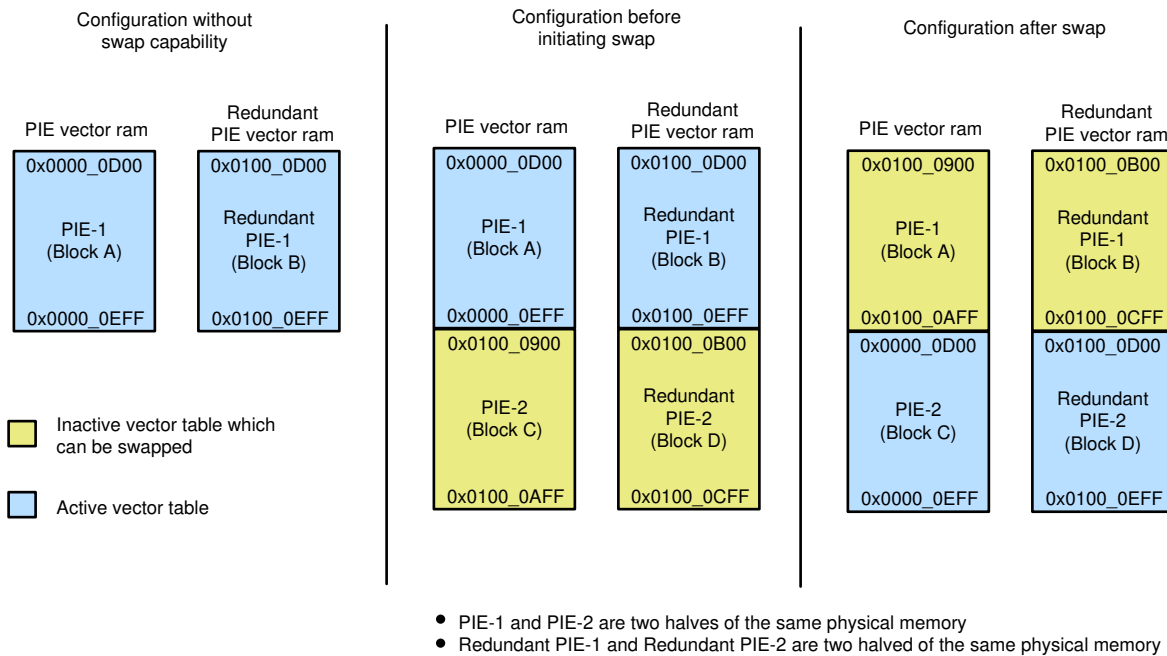

Figure 3-17. PIE Vector Table Swap

3.13.3.3 LS0/LS1 RAM Memory Swap

Similar to PIE Vector Table Swap, LS0 and LS1 physical RAM memory blocks can also be swapped. The memory architecture is similar to PIE vector table swap, and is shown in [Figure 3-18](#). By default, physical Block 1 is assigned to addresses 0x8000-0x87FF (that is, the address range for LS0), and physical Block 2 is assigned to addresses 0x8800-0x8FFF (that is, the address range for LS1). By configuring LFUConfig.LS01Swap = 1, user application code can execute a swap, where physical *Block 2* is now assigned to addresses 0x8000-0x87FF (that is, the address range for LS0), and physical *Block 1* is now assigned to addresses 0x8800-0x8FFF (that is, the address range for LS1).

If physical memory Block 1 contains function pointers for the current firmware, the same relative locations in physical memory Block 2 can be populated with function pointers for the new firmware prior to LFU switchover. During LFU switchover, a simple swap operation is initiated by user application code, and this operation takes just 1 CPU clock cycle. This allows user application code to always have function pointers in LS0, yet have two different physical blocks that can map to the LS0 address range.

For example, if current firmware contains 10 function pointers present at the start of Block 1 (LS0 address space). If the new firmware contains the same 10 function pointers that now need to be updated, the user application code can place these at the start of Block 2 (LS1 address space) prior to LFU switchover. During LFU switchover, the user application code can execute a LS0/LS1 RAM memory swap, where the physical RAM block previously mapped to the LS1 address space can now be mapped to the LS0 address space, and can be used seamlessly for function pointer addressing for the new firmware.

The register bit LFUStatus.LS01Swap provides the status of LS0/LS1 RAM memory swap.

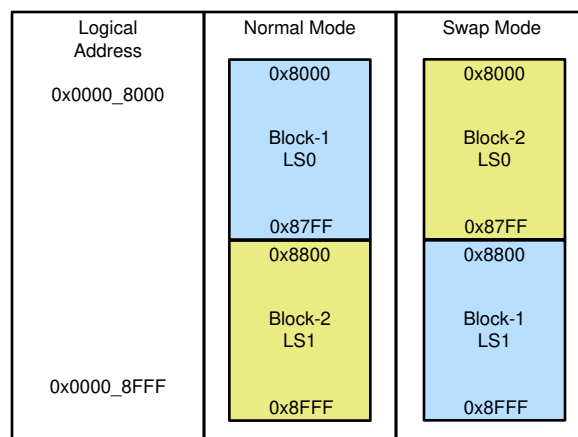

Figure 3-18. LS0/LS1 RAM Memory Swap

Additional points pertaining to LS0/LS1 RAM memory swap are described below:

1. LFU registers can be accessed from both CPU and CLA.
2. Only LS0 and LS1 blocks can be swapped. LS2 to LS7 blocks cannot be swapped.
3. LS0 and LS1 blocks have ECC protection. Address ECC is computed based on the physical address and does not change based on the memory swap.
4. A number of LSx RAM registers are available to the user application code to configure options such as master select (LSxMSEL.MSEL_LS0, LSxMSEL.MSEL_LS1), fetch protect (LSxACCPROT0.FETCHPROT_LS0, LSxACCPROT0.FETCHPROT_LS1), write protect (LSxACCPROT0.CPUWRPROT_LS0, LSxACCPROT0.CPUWRPROT_LS1), CLA program memory (LSxCLAPGM.CLAPGM_LS0, LSxCLAPGM.CLAPGM_LS1). These register bits indicate the status of the memory block that is deemed as LS0 (CPU address 0x8000 to 0x87FF) and LS1 (CPU address 0x8800 to 0x8FFF) at any point of time. When a LS0/LS1 RAM memory swap occurs, the corresponding control/status bits also automatically swap.
5. It is recommended to service all pending errors (access violation, ECC, parity) associated with memory before initiating a LS0/LS1 RAM memory swap.

6. LS0/LS1 RAM memory swap shall be initiated only after completion of RAM initialization for both LS0 and LS1 memories (LSxINITDONE.INITDONE_LS0 = 1 and LSxINITDONE.INITDONE_LS1 = 1).
7. LS0/LS1 RAM memory swap shall not be initiated when RAM-test (LSxTEST.TEST_LS0 = 1 or LSxTEST.TEST_LS1 = 1) is in progress for LS0 or LS1 blocks.
8. With DCSM security on the device, in general, LS0 and LS1 RAM blocks can be assigned to different security zones. However, with LS0/LS1 RAM memory swaps, different physical RAM blocks can get mapped to the same address space. Application software shall therefore make sure that both LS0 and LS1 have the same security settings (for example, zone, EXE protection), if there is a plan to implement LS0/LS1 RAM memory swap. Hardware logic is implemented on the device to prevent swap of LS0 and LS1 if the blocks have different security configurations.
9. To prevent security vulnerabilities, LS0/LS1 RAM memory swap is not allowed if initiated by code from a different zone. For example, (i) If LS0 and LS1 are part of Zone1, swap is not allowed if code that initiates the swap resides in Zone2 or unsecure zone; (ii) If LS0 and LS1 are part of Zone2, swap is not allowed if code that initiates the swap resides in Zone1 or unsecure zone; (iii) If LS0 and LS1 are part of the same zone that is unsecure, swap is allowed in all cases irrespective of where the code that initiates the swap resides; (iv) if LS0 and LS1 are part of the same zone and is unlocked, the swap can be initiated from code residing anywhere (including from the debugger).
10. Once swap is initiated, the swap happens in the next cycle, subject to the swap meeting the security requirements mentioned above. After initiation of a swap, application software shall check if the swap was correctly configured by checking the LFUStatus.LS01Swap status register. Consistency between LFUStatus.LS01Swap and LFUConfig.LS01Swap helps determine if the swap was correctly configured. If LFUStatus.LS01Swap does not match LFUConfig.LS01Swap, LFUConfig.LS01Swap needs to be cleared by user application code.
11. Since the logical address accessed by BGCRC changes with LS0/LS1 RAM memory swap, the computed CRC values for these memories need to be updated after the LS0/LS1 RAM memory swap.

3.13.3.3.1 Applicability to CLA LFU

The device does not support a swap table for the CLA task vectors (MVECTs). CLA LFU is implemented typically on the CPU side, where the MVECTs are updated sequentially at an appropriate time. The techniques for when to update the MVECTs are described in the LFU system reference design guide, but noted here that the approach is different from the CPU PIE vector table case, where a simple single cycle swap achieves the switch to the new PIE vector table.

For the LS0/LS1 RAM memory swap feature to be useful for CLA LFU switchover, two conditions need to be satisfied:

- CLA code has to fit into a single LSx block. The MVECT table contains CLA task vectors, whose addresses correspond to locations in the LSx block. For example, if the current firmware CLA code is present in LS0, MVECTs point to various locations in LS0. If the new firmware CLA code is present in LS1, MVECTs point to various locations in LS1.
- When switching over from current to new firmware, the MVECTs need to be updated, unless the MVECTs reside at the same relative location in both LS0 and LS1. If that is the case, then simply swapping LS0/LS1 RAM memory blocks effectively updates the MVECT table, without the need to sequentially update the MVECTs.

3.13.4 LFU Switchover

After the new firmware has been programmed to Flash, the user application code needs to determine when appropriate to switchover to the new firmware. The techniques to determine this difference between real-time critical firmware running on the CPU and CLA, and these techniques are beyond the scope of this document. The techniques are described in the LFU system reference design guide.

The device supports two register bits that can be set or reset to indicate that the LFU switchover is in progress on the CPU (LFUConfig.LFU_CPU) and CLA (LFUConfig.LFU_CLA1). These bits do not impact any hardware logic on the device. For example, LFUConfig.LFU_CPU can be set by the user application code at the start of switchover, and then tested in the initialization code in main(). This can enable only the LFU switchover specific initialization to be performed (for example, PIE vector table swap, LS0/LS1 RAM memory swap), while bypassing all other initialization that typically happens after a device reset.

3.13.5 LFU Resources

The following are additional LFU resources available.

- [Live Firmware Update With Device Reset on C2000™ MCUs User's Guide](#)
- [Live Firmware Update Reference Design with C2000™ Real-Time MCUs](#)

3.14 System Control Register Configuration Restrictions

Memory-mapped registers in the System Control operate on INTOSC1 clock domain; hence, any CPU writes to these registers requires a delay between subsequent writes otherwise a second write can be lost. The application needs to take this into consideration and add a delay in terms of the number of NOP instructions after every write to these registers that are mentioned in [Table 3-15](#). The formula to compute delay between subsequent writes:

$$\text{Delay (in SYSCLK cycles)} = 3 \times (F_{\text{SYSCLK}} \div F_{\text{INTOSC1}}) + 9$$

For Example - For SYSCLK = 100MHz

$$\text{Delay (in SYSCLK cycles)} = 3 \times (100\text{MHz} \div 10\text{MHz}) + 9 = 39 \text{ SYSCLK cycles}$$

3.15.1 INTERRUPT Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/interrupt

Cloud access to these examples is available at the following link: dev.ti.com [C2000Ware Examples](#).

3.15.1.1 External Interrupts (*ExternalInterrupt*)

FILE: interrupt_ex1_external.c

This program sets up GPIO0 as XINT1 and GPIO1 as XINT2. Two other GPIO signals are used to trigger the interrupt (GPIO10 triggers XINT1 and GPIO11 triggers XINT2). The user is required to externally connect these signals for the program to work properly.

XINT1 input is synced to SYSCLKOUT.

XINT2 has a long qualification - 6 samples at 510*SYSCLKOUT each.

GPIO16 will go high outside of the interrupts and low within the interrupts. This signal can be monitored on a scope.

Each interrupt is fired in sequence - XINT1 first and then XINT2

External Connections

- Connect GPIO10 to GPIO0. GPIO0 will be assigned to XINT1
- Connect GPIO11 to GPIO1. GPIO1 will be assigned to XINT2

Monitor GPIO16 with an oscilloscope. GPIO16 will be high outside of the ISRs and low within each ISR.

Watch Variables

- xint1Count for the number of times through XINT1 interrupt
- xint2Count for the number of times through XINT2 interrupt
- loopCount for the number of times through the idle loop

3.15.1.2 Multiple interrupt handling of I2C, SCI & SPI Digital Loopback

FILE: interrupt_ex2_with_i2c_sci_spi_loopback.c

This program is used to demonstrate how to handle multiple interrupts when using multiple communication peripherals like I2C, SCI & SPI Digital Loopback all in a single example. The data transfers would be done with FIFO Interrupts.

It uses the internal loopback test mode of these modules. Both the TX and RX FIFOs and their interrupts are used. Other than boot mode pin configuration, no other hardware configuration is required.

A stream of data is sent and then compared to the received stream. The sent data looks like this for I2C and SCI:

```
0000 0001
0001 0002
0002 0003
....
00FE 00FF
00FF 0000
etc..
```

The sent data looks like this for SPI:

```
0000 0001
0001 0002
0002 0003
....
```

FFFE FFFF

FFFF 0000

etc..

This pattern is repeated forever.

External Connections

- None

Watch Variables

- *sDataI2cA* - Data to send through I2C
- *rDataI2cA* - Received I2C data
- *rDataPoint* - Used to keep track of the last position in the receive I2C stream for error checking
- *sDataSpiA* - Data to send through SPI
- *rDataSpiA* - Received SPI data
- *rDataPointSpiA* - Used to keep track of the last position in the receive SPI stream for error checking
- *sDataSciA* - SCI Data being sent
- *rDataSciA* - SCI Data received
- *rDataPointA* - Keep track of where we are in the SCI data stream. This is used to check the incoming data

3.15.1.3 CPU Timer Interrupt Software Prioritization

FILE: interrupt_ex3_sw_prioritization.c

This examples demonstrates the software prioritization of interrupts through CPU Timer Interrupts. Software prioritization of interrupts is achieved by enabling interrupt nesting.

In this device, hardware priorities for CPU Timer 0, 1 and 2 are set as timer 0 being highest priority and timer 2 being lowest priority. This example configures CPU Timer0, 1, and 2 priority in software with timer 2 priority being highest and timer 0 being lowest in software and prints a trace for the order of execution.

For most applications, the hardware prioritizing of the interrupts is sufficient. For applications that need custom prioritizing, this example illustrates how this can be done through software. User specific priorities can be configured in `sw_prioritized_isr_level.h` header file.

To enable interrupt nesting, following sequence needs to followed in ISRs. *Step 1:* Set the global priority: Modify the IER register to allow CPU interrupts with a higher user priority to be serviced. Note: at this time IER has already been saved on the stack. *Step 2:* Set the group priority: (optional) Modify the appropriate PIEIERx register to allow group interrupts with a higher user set priority to be serviced. Do NOT clear PIEIER register bits from another group other than that being serviced by this ISR. Doing so can cause erroneous interrupts to occur. *Step 3:* Enable interrupts: There are three steps to do this: a. Clear the PIEACK bits b. Wait at least one cycle c. Clear the INTM bit. *Step 4:* Run the main part of the ISR *Step 5:* Set INTM to disable interrupts. *Step 6:* Restore PIEIERx (optional depending on step 2) *Step 7:* Return from ISR

Refer to below link on more details on Interrupt nesting in C28x devices:

<C2000Ware>\docs\c28x_interrupt_nesting\html\index.html

External Connections

- None

Watch Variables

- `traceISR` - shows the order in which ISRs are executed.

3.15.1.4 EPWM Real-Time Interrupt

FILE: interrupt_ex4_epwm_realtime_interrupt.c

This example configures the ePWM1 Timer and increments a counter each time the ISR is executed. ePWM interrupt can be configured as time critical to demonstrate real-time mode functionality and real-time interrupt capability.

The example uses 2 LEDs - LED1 is toggled in the main loop and LED2 is toggled in the EPWM Timer Interrupt. FREE_SOFT bits and DBGIER.INT3 bit must be set to enable ePWM1 interrupt to be time critical and operational in real time mode after halt command

How to run the example?

- Add the watch variables as mentioned below and enable Continuous Refresh.
- Enable real-time mode (Run->Advanced->Enable Silicon Real-time Mode)
- Initially, the DBGIER register is set to 0 and the EPWM emulation mode is set to EPWM_EMULATION_STOP_AFTER_NEXT_TB (FREE_SOFT = 0)
- When the application is running, you will find both LEDs toggling and the watch variables EPwm1TimerIntCount, EPwm1Regs.TBCTR getting updated.
- When the application is halted, both LEDs stop toggling and the watch variables remain constant. EPWM counter is stopped on debugger halt.
- To enable EPWM counter run during debugger halt, set emulation mode as EPWM_EMULATION_FREE_RUN (FREE_SOFT = 2). You will find EPwm1Regs.TBCTR is running, but EPwm1TimerIntCount remains constant. This means, the EPWM counter is running, but the ISRs are not getting serviced.
- To enable real-time interrupts, set DBGIER.INT3 = 1 (EPWM1 interrupt is part of PIE Group 3). You will find that the EPwm1TimerIntCount is incrementing and the LED starts toggling. The EPWM ISR is getting serviced even during a debugger halt.

For more details, watch this video : [C2000 Real-Time Features](#)

External Connections

- None

Watch Variables

- EPwm1TimerIntCount - EPWM1 ISR counter
- EPwm1Regs.TBCTR.TBCTR - EPWM1 Time Base counter
- EPwm1Regs.TBCTL.FREE_SOFT - Set this to 2 to enable free run
- DBGIER.INT3 - Set to 1 to enable real time interrupt

3.15.2 SYSCCTL Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location: C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/sysctl

Cloud access to these examples is available at the following link: [dev.ti.com C2000Ware Examples](#).

3.15.2.1 Missing clock detection (MCD)

FILE: sysctl_ex1_missing_clock_detection.c

This example demonstrates the missing clock detection functionality and the way to handle it. Once the MCD is simulated by disconnecting the OSCCLK to the MCD module an NMI would be generated. This NMI determines that an MCD was generated due to a clock failure which is handled in the ISR.

Before an MCD the clock frequency would be as per device initialization (120Mhz). Post MCD the frequency would move to 10Mhz or INTOSC1.

The example also shows how we can lock the PLL after missing clock, detection, by first explicitly switching the clock source to INTOSC1, resetting the missing clock detect circuit and then re-locking the PLL. Post a re-lock the clock frequency would be 120Mhz but using the INTOSC1 as clock source.

External Connections

- None.

Watch Variables

- *fail* - Indicates that a missing clock was either not detected or was not handled correctly.

- *mcd_clkfail_isr* - Indicates that the missing clock failure caused an NMI to be triggered and called an the ISR to handle it.
- *mcd_detect* - Indicates that a missing clock was detected.
- *result* - Status of a successful handling of missing clock detection

3.15.2.2 XCLKOUT (External Clock Output) Configuration

FILE: sysctl_ex2_xclkout_config.c

This example demonstrates how to configure the XCLKOUT pin for observing internal clocks through an external pin, for debugging and testing purposes.

In this example, we are using INTOSC1 as the XCLKOUT clock source and configuring the divider as 8.
 Expected frequency of XCLKOUT = (INTOSC1 freq)/8 = 10/8 = 1.25MHz

View the XCLKOUT on GPIO16 using an oscilloscope.

3.15.3 TIMER Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:
 C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/timer

Cloud access to these examples is available at the following link: dev.ti.com [C2000Ware Examples](#).

3.15.3.1 CPU Timers

FILE: timer_ex1_cputimers.c

This example configures CPU Timer0, 1, and 2 and increments a counter each time the timer asserts an interrupt. In order to migrate the project within syscfg to any device, click the switch button under the device view and select your corresponding device to migrate, saving the project will auto-migrate your project settings.

3.15.4 LPM Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:
 C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/lpm

Cloud access to these examples is available at the following link: dev.ti.com [C2000Ware Examples](#).

3.15.4.1 Low Power Modes: Device Idle Mode and Wakeup using GPIO

FILE: lpm_ex1_idlewake_gpio.c

This example puts the device into IDLE mode and then wakes up the device from IDLE using XINT1 which triggers on a falling edge of GPIO0.

The GPIO0 pin must be pulled from high to low by an external agent for wakeup. GPIO0 is configured as an XINT1 pin to trigger an XINT1 interrupt upon detection of a falling edge.

Initially, pull GPIO0 high externally. To wake device from IDLE mode by triggering an XINT1 interrupt, pull GPIO0 low (falling edge). The wakeup process begins as soon as GPIO0 is held low for the time indicated in the device datasheet.

GPIO1 is pulled high before entering the IDLE mode and is pulled low when in the external interrupt ISR.

External Connections

- GPIO0 needs to be pulled low to wake up the device.
- On device wakeup, the GPIO1 will be low and LED1 will start blinking

3.15.4.2 Low Power Modes: Device Idle Mode and Wakeup using Watchdog

FILE: lpm_ex2_idlewake_watchdog.c

This example puts the device into IDLE mode and then wakes up the device from IDLE using watchdog timer.

The device wakes up from the IDLE mode when the watchdog timer overflows, triggering an interrupt. A pre scalar is set for the watchdog timer to change the counter overflow time.

GPIO1 is pulled high before entering the IDLE mode and is pulled low when in the wakeup ISR.

External Connections

- On device wakeup, the GPIO1 will be low and LED1 will start blinking

3.15.4.3 Low Power Modes: Device Standby Mode and Wakeup using GPIO

FILE: lpm_ex3_standbywake_gpio.c

This example puts the device into STANDBY mode. If the lowest possible current consumption in STANDBY mode is desired, the JTAG connector must be removed from the device board while the device is in STANDBY mode.

This example puts the device into STANDBY mode and then wakes up the device from STANDBY using an LPM wakeup pin.

The pin GPIO0 is configured as the LPM wakeup pin to trigger a WAKEINT interrupt upon detection of a low pulse. Initially, pull GPIO0 high externally. To wake device from STANDBY mode, pull GPIO0 low for at least (2+QUALSTDBY), OSCLKS, then pull it high again.

The example then wakes up the device from STANDBY using GPIO0. GPIO0 wakes the device from STANDBY mode when a low pulse (signal goes high->low->high) is detected on the pin. This pin must be pulsed by an external agent for wakeup.

GPIO1 is pulled high before entering the STANDBY mode and is pulled low when in the wakeup ISR.

External Connections

- GPIO0 needs to be pulled low to wake up the device.
- On device wakeup, the GPIO1 will be low and LED1 will start blinking

3.15.4.4 Low Power Modes: Device Standby Mode and Wakeup using Watchdog

FILE: lpm_ex4_standbywake_watchdog.c

This example puts the device into STANDBY mode. If the lowest possible current consumption in STANDBY mode is desired, the JTAG connector must be removed from the device board while the device is in STANDBY mode.

This example puts the device into STANDBY mode then wakes up the device from STANDBY using watchdog timer.

The device wakes up from the STANDBY mode when the watchdog timer overflows triggering an interrupt. In the ISR, the GPIO1 is pulled low. the GPIO1 is toggled to indicate the device is out of STANDBY mode. A pre scalar is set for the watchdog timer to change the counter overflow time.

GPIO1 is pulled high before entering the STANDBY mode and is pulled low when in the wakeup ISR.

External Connections

- On device wakeup, the GPIO1 will be low and LED1 will start blinking

3.15.4.5 Low Power Modes: Halt Mode and Wakeup using GPIO

FILE: lpm_ex5_haltwake_gpio.c

This example puts the device into HALT mode. If the lowest possible current consumption in HALT mode is desired, the JTAG connector must be removed from the device board while the device is in HALT mode.

For applications that require minimal power consumption during HALT mode, application software should power off the XTAL prior to entering HALT by setting the XTALCR.OSCOFF bit or by using the driverlib function SysCtl_turnOffOsc(SYSCTL_OSCSRC_XTAL);. If the OSCCLK source is configured to be XTAL, the application should first switch the OSSCLK source to INTOSC1 or INTOSC2 prior to setting XTALCR.OSCOFF.

This example puts the device into HALT mode and then wakes up the device from HALT using an LPM wakeup pin.

The pin GPIO0 is configured as the LPM wakeup pin to trigger a WAKEINT interrupt upon detection of a low pulse. The GPIO0 pin must be pulled from high to low by an external agent for wakeup.

GPIO1 is pulled high before entering the STANDBY mode and is pulled low when in the wakeup ISR.

External Connections

- On device wakeup, the GPIO1 will be low and LED1 will start blinking

3.15.4.6 Low Power Modes: Halt Mode and Wakeup

FILE: lpm_ex6_haltwake_gpio_watchdog.c

This example puts the device into HALT mode. If the lowest possible current consumption in HALT mode is desired, the JTAG connector must be removed from the device board while the device is in HALT mode.

For applications that require minimal power consumption during HALT mode, application software should power off the XTAL prior to entering HALT by setting the XTALCR.OSCOFF bit or by using the driverlib function SysCtl_turnOffOsc(SYSCTL_OSCSRC_XTAL);. If the OSCCLK source is configured to be XTAL, the application should first switch the OSSCLK source to INTOSC1 or INTOSC2 prior to setting XTALCR.OSCOFF.

This example puts the device into HALT mode and then wakes up the device from HALT using an LPM wakeup pin.

The pin GPIO0 is configured as the LPM wakeup pin to trigger a WAKEINT interrupt upon detection of a low pulse. The GPIO0 pin must be pulled from high to low by an external agent for wakeup.

In this example, the watchdog timer is clocked, and is configured to produce watchdog reset as a timeout mechanism.

GPIO1 is pulled high before entering the STANDBY mode and is pulled low when in the wakeup ISR.

External Connections

- On device wakeup, the GPIO1 will be low and LED1 will start blinking

3.15.5 MEMCFG Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:

C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/memcfg

Cloud access to these examples is available at the following link: dev.ti.com [C2000Ware Examples](#).

3.15.5.1 Correctable & Uncorrectable Memory Error Handling

FILE: memcfg_ex1_error_handling.c

This example demonstrates error handling in case of various erroneous memory read/write operations. Error handling in case of CPU read/write violations, correctable & uncorrectable memory errors has been demonstrated.

Test functions used in this example

- generateMasterCPUWrViolation -
 - This test configures Memconfig to block CPU writes to GS0 RAM. A write attempt to this memory location by CPU causes RAM_ACC_VIOL Interrupt
- generateECCMemCorrError
 - This test induces single bit ECC error in LS6 RAM. A read from the corrupted memory location causes INT_RAM_CORR_ERR Interrupt
- generateECCMemUncorrError
 - This test induces double bit ECC error in LS7 RAM. A read from the corrupted memory location causes NMI
- forceNonMasterDMAReadViolation
 - This forces a DMA access violation using MemCfg_forceViolationInterrupt API. This casuses RAM_ACC_VIOL Interrupt

External Connections

- None

Watch Variables

- *testStatusGlobal* - Equivalent to *TEST_PASS* if test finished correctly, else the value is set to *TEST_FAIL*
- *errCountGlobal* - Error counter

3.15.6 WATCHDOG Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:

C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/watchdog

Cloud access to these examples is available at the following link: dev.ti.com [C2000Ware Examples](#).

3.15.6.1 Watchdog

FILE: watchdog_ex1_service.c

This example shows how to service the watchdog or generate a wakeup interrupt using the watchdog. By default the example will generate a Wake interrupt. To service the watchdog and not generate the interrupt, uncomment the SysCtl_serviceWatchdog() line in the main for loop.

External Connections

- None.

Watch Variables

- *wakeCount* - The number of times entered into the watchdog ISR
- *loopCount* - The number of loops performed while not in ISR

3Ch	NMHICRDAVADDR	Non-Master HIC Read Access Violation Address		Go
3Eh	NMHICWRAVADDR	Non-Master HIC Write Access Violation Address		Go

Complex bit access types are encoded to fit into small table cells. Table 3-18 shows the codes that are used for access types in this section.

Table 3-18. ACCESS_PROTECTION_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1S	W1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		

Table 3-18. ACCESS_PROTECTION_REGS Access Type Codes (continued)

Access Type	Code	Description
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.2.1 NMAVFLG Register (Offset = 0h) [Reset = 0000000h]

NMAVFLG is shown in [Figure 3-19](#) and described in [Table 3-19](#).

Return to the [Summary Table](#).

3.16.3 CLK_CFG_REGS Registers

Table 3-41 lists the memory-mapped registers for the CLK_CFG_REGS registers. All register offset addresses not listed in Table 3-41 should be considered as reserved locations and the register contents should not be modified.

Table 3-41. CLK_CFG_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
2h	CLKCFGLOCK1	Lock bit for CLKCFG registers	EALLOW	Go
8h	CLKSRCCTL1	Clock Source Control register-1	EALLOW	Go
Ah	CLKSRCCTL2	Clock Source Control register-2	EALLOW	Go
Ch	CLKSRCCTL3	Clock Source Control register-3	EALLOW	Go
Eh	SYSPLLCTL1	SYSPLL Control register-1	EALLOW	Go
14h	SYSPLLMULT	SYSPLL Multiplier register	EALLOW	Go
16h	SYSPLLSTS	SYSPLL Status register		Go
22h	SYSCLKDIVSEL	System Clock Divider Select register	EALLOW	Go
24h	AUXCLKDIVSEL	Auxillary Clock Divider Select register	EALLOW	Go
28h	XCLKOUTDIVSEL	XCLKOUT Divider Select register	EALLOW	Go
2Ah	CLBCLKCTL	CLB Clocking Control Register	EALLOW	Go
2Ch	LOSPCP	Low Speed Clock Source Prescaler	EALLOW	Go
2Eh	MDCDR	Missing Clock Detect Control Register	EALLOW	Go
30h	X1CNT	10-bit Counter on X1 Clock		Go
32h	XTALCR	XTAL Control Register	EALLOW	Go
3Ah	XTALCR2	XTAL Control Register for pad init	EALLOW	Go
3Ch	CLKFAILCFG	Clock Fail cause Configuration	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 3-42 shows the codes that are used for access types in this section.

Table 3-42. CLK_CFG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
WSONCE	W SONCE	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.

Table 3-42. CLK_CFG_REGS Access Type Codes (continued)

Access Type	Code	Description
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.3.1 CLKCFGLOCK1 Register (Offset = 2h) [Reset = 0000000h]

CLKCFGLOCK1 is shown in [Figure 3-41](#) and described in [Table 3-43](#).

Return to the [Summary Table](#).

Lock bit for CLKCFG registers

Notes:

[1] Any bit in this register, once set can only be cleared through a CPU1.SYSRSn. Write of 0 to any bit of this register has no effect

[2] The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed

Table 3-44. CLKSRCCTL1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-6	RESERVED	R-0	0h	Reserved
5	WDHALTI	R/W	0h	Watchdog HALT Mode Ignore Bit: This bit determines if WD is functional in the HALT mode or not. 0 = WD is not functional in the HALT mode. Clock to WD is gated when system enters HALT mode. Additionally, INTOSC1 and INTOSC2 are powered-down when system enters HALT mode 1 = WD is functional in the HALT mode. Clock to WD is not gated and INTOSC1/2 are not powered-down when system enters HALT mode Reset type: XRSn
4	RESERVED	R/W	0h	Reserved
3	INTOSC2OFF	R/W	0h	Internal Oscillator 2 Off Bit: This bit turns oscillator 2 off: 0 = Internal Oscillator 2 On (default on reset) 1 = Internal Oscillator 2 Off This bit could be used by the user to turn off the internal oscillator 2 if it is not used. NOTE: Ensure no resources are using a clock source prior to disabling it. For example OSCCLKSRCSEL (SYSPLL), TMR2CLKSRCSEL (CPUTIMER2) and XCLOCKOUT (XCLKOUT). Reset type: XRSn
2	RESERVED	R-0	0h	Reserved

Table 3-44. CLKSRCCTL1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1-0	OSCCLKSRCSEL	R/W	0h	<p>Oscillator Clock Source Select Bit: This bit selects the source for OSCCLK.</p> <p>00 = INTOSC2 (default on reset) 01 = External Oscillator (XTAL) 10 = INTOSC1 11 = reserved (default to INTOSC1)</p> <p>At power-up or after an XRSn, INTOSC2 is selected by default. Whenever the user changes the clock source using these bits, the SYSPLLMULT[13:0] register will be forced to zero and the PLL will be bypassed and powered down. This prevents potential PLL overshoot. The user will then have to write to the SYSPLLMULT register to configure the appropriate multiplier.</p> <p>The user must wait 10 OSCCLK cycles before writing to SYSPLLMULT or disabling the previous clock source to allow the change to complete..</p> <p>Notes: [1] INTOSC1 is recommended to be used only after missing clock detection. If user wants to re-lock the PLL with INTOSC1 (the back-up clock source) after missing clock is detected, he can do a MCLKCLR and lock the PLL.</p> <p>Reset type: XRSn</p>

3.16.3.3 CLKSRCCTL2 Register (Offset = Ah) [Reset = 0000000h]

CLKSRCCTL2 is shown in [Figure 3-43](#) and described in [Table 3-45](#).

Return to the [Summary Table](#).

Clock Source Control register-2

This memory mapped register requires a delay of 45 SYCLK cycles between subsequent writes to the register, otherwise a second write can be lost. This delay can be realized by adding 45 NOP instructions.

Complex bit access types are encoded to fit into small table cells. Table 3-61 shows the codes that are used for access types in this section.

Table 3-61. CPU_SYS_REGS Access Type Codes

Access Type	Code	Description
Read Type		

Table 3-61. CPU_SYS_REGS Access Type Codes (continued)

Access Type	Code	Description
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
WOnce	W Once	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.4.1 CPUSYSLOCK1 Register (Offset = 0h) [Reset = 0000000h]

CPUSYSLOCK1 is shown in [Figure 3-58](#) and described in [Table 3-62](#).

Return to the [Summary Table](#).

Lock bit for CPUSYS registers

Notes:

[1] Any bit in this register, once set can only be cleared through a CPU1.SYSRSn. Write of 0 to any bit of this register has no effect

[2] The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed

3.16.4.2 CPUSYSLOCK2 Register (Offset = 2h) [Reset = 0000000h]

CPUSYSLOCK2 is shown in [Figure 3-59](#) and described in [Table 3-63](#).

Return to the [Summary Table](#).

Lock bit for CPUSYS registers

Notes:

[1] Any bit in this register, once set can only be cleared through a CPU1.SYSRSn. Write of 0 to any bit of this register has no effect

[2] The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed

3.16.4.28 TMR2CLKCTL Register (Offset = 7Ch) [Reset = 0000000h]

TMR2CLKCTL is shown in [Figure 3-85](#) and described in [Table 3-89](#).

Return to the [Summary Table](#).

Timer2 Clock Measurement functionality control register

This memory mapped register requires a delay of 45 SYSCLK cycles between subsequent writes to the register, otherwise a second write can be lost. This delay can be realized by adding 45 NOP instructions.

3.16.5 CPUTIMER_REGS Registers

Table 3-96 lists the memory-mapped registers for the CPUTIMER_REGS registers. All register offset addresses not listed in Table 3-96 should be considered as reserved locations and the register contents should not be modified.

Table 3-96. CPUTIMER_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	TIM	CPU-Timer, Counter Register		Go
2h	PRD	CPU-Timer, Period Register		Go
4h	TCR	CPU-Timer, Control Register		Go
6h	TPR	CPU-Timer, Prescale Register		Go
7h	TPRH	CPU-Timer, Prescale Register High		Go

Complex bit access types are encoded to fit into small table cells. Table 3-97 shows the codes that are used for access types in this section.

Table 3-97. CPUTIMER_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
Reset or Default Value		
-n		Value after reset or the default value

3.16.5.1 TIM Register (Offset = 0h) [Reset = 0000FFFFh]

TIM is shown in [Figure 3-92](#) and described in [Table 3-98](#).

Return to the [Summary Table](#).

CPU-Timer, Counter Register

Figure 3-92. TIM Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 3-98. TIM Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	MSW	R/W	0h	CPU-Timer Counter Registers The TIMH register holds the high 16 bits of the current 32-bit count of the timer. The TIMH:TIM decrements by one every (TDDRH:TDDR+1) clock cycles, where TDDRH:TDDR is the timer prescale dividedown value. When the TIMH:TIM decrements to zero, the TIMH:TIM register is reloaded with the period value contained in the PRDH:PRD registers. The timer interrupt (TINT) signal is generated. Reset type: SYSRSn
15-0	LSW	R/W	FFFFh	CPU-Timer Counter Registers The TIM register holds the low 16 bits of the current 32-bit count of the timer. The TIMH:TIM decrements by one every (TDDRH:TDDR+1) clock cycles, where TDDRH:TDDR is the timer prescale dividedown value. When the TIMH:TIM decrements to zero, the TIMH:TIM register is reloaded with the period value contained in the PRDH:PRD registers. The timer interrupt (TINT) signal is generated. Reset type: SYSRSn

3.16.5.2 PRD Register (Offset = 2h) [Reset = 0000FFFFh]

PRD is shown in [Figure 3-93](#) and described in [Table 3-99](#).

Return to the [Summary Table](#).

CPU-Timer, Period Register

7		6		5		4		3		2		1		0	
RESERVED				TRB		TSS		RESERVED							
R-0h				R/W-0h		R/W-0h		R-1h							

Table 3-100. TCR Register Field Descriptions

Bit	Field	Type	Reset	Description
15	TIF	R/W1C	0h	CPU-Timer Overflow Flag. TIF indicates whether a timer overflow has happened since TIF was last cleared. TIF is not cleared automatically and does not need to be cleared to enable the next timer interrupt. Reset type: SYSRSn 0h (R/W) = The CPU-Timer has not decremented to zero. Writes of 0 are ignored. 1h (R/W) = This flag gets set when the CPU-timer decrements to zero. Writing a 1 to this bit clears the flag.
14	TIE	R/W	0h	CPU-Timer Interrupt Enable. Reset type: SYSRSn 0h (R/W) = The CPU-Timer interrupt is disabled. 1h (R/W) = The CPU-Timer interrupt is enabled. If the timer decrements to zero, and TIE is set, the timer asserts its interrupt request.
13-12	RESERVED	R	0h	Reserved
11	FREE	R/W	0h	If the FREE bit is set to 1, then, upon a software breakpoint, the timer continues to run. If FREE is 0, then the SOFT bit controls the emulation behavior. Reset type: SYSRSn 0h (R/W) = Stop after the next decrement of the TIMH:TIM (hard stop) (SOFT bit controls the emulation behavior) 1h (R/W) = Free Run (SOFT bit is don't care, counter is free running)
10	SOFT	R/W	0h	If the FREE bit is set to 1, then, upon a software breakpoint, the timer continues to run (that is, free runs). In this case, SOFT is a don't care. But if FREE is 0, then SOFT takes effect. Reset type: SYSRSn 0h (R/W) = Stop after the next decrement of the TIMH:TIM (hard stop). (ONLY if FREE=0, if FREE=1 this bit is don't care) 1h (R/W) = Stop after the TIMH:TIM decrements to 0 (soft stop) In the SOFT STOP mode, the timer generates an interrupt before shutting down (since reaching 0 is the interrupt causing condition). (ONLY if FREE=0, if FREE=1 this bit is don't care)
9-6	RESERVED	R	0h	Reserved

Table 3-100. TCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	TRB	R/W	0h	Timer reload Reset type: SYSRSn 0h (R/W) = The TRB bit is always read as zero. Writes of 0 are ignored. 1h (R/W) = When you write a 1 to TRB, the TIMH:TIM is loaded with the value in the PRDH:PRD, and the prescaler counter (PSCH:PSC) is loaded with the value in the timer dividedown register (TDDR:H:TDDR).
4	TSS	R/W	0h	CPU-Timer stop status bit. TSS is a 1-bit flag that stops or starts the CPU-timer. Reset type: SYSRSn 0h (R/W) = Reads of 0 indicate the CPU-timer is running. To start or restart the CPU-timer, set TSS to 0. At reset, TSS is cleared to 0 and the CPU-timer immediately starts. 1h (R/W) = Reads of 1 indicate that the CPU-timer is stopped. To stop the CPU-timer, set TSS to 1.
3-0	RESERVED	R	1h	Reserved

3.16.5.4 TPR Register (Offset = 6h) [Reset = 0000h]

TPR is shown in [Figure 3-95](#) and described in [Table 3-101](#).

Return to the [Summary Table](#).

TDDR							
R/W-0h							

Table 3-101. TPR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	PSC	R	0h	<p>CPU-Timer Prescale Counter.</p> <p>These bits hold the current prescale count for the timer. For every timer clock source cycle that the PSCH:PSC value is greater than 0, the PSCH:PSC decrements by one. One timer clock (output of the timer prescaler) cycle after the PSCH:PSC reaches 0, the PSCH:PSC is loaded with the contents of the TDDRH:TDDR, and the timer counter register (TIMH:TIM) decrements by one. The PSCH:PSC is also reloaded whenever the timer reload bit (TRB) is set by software. The PSCH:PSC can be checked by reading the register, but it cannot be set directly. It must get its value from the timer divide-down register (TDDRH:TDDR). At reset, the PSCH:PSC is set to 0.</p> <p>Reset type: SYSRSn</p>
7-0	TDDR	R/W	0h	<p>CPU-Timer Divide-Down.</p> <p>Every (TDDRH:TDDR + 1) timer clock source cycles, the timer counter register (TIMH:TIM) decrements by one. At reset, the TDDRH:TDDR bits are cleared to 0. To increase the overall timer count by an integer factor, write this factor minus one to the TDDRH:TDDR bits. When the prescaler counter (PSCH:PSC) value is 0, one timer clock source cycle later, the contents of the TDDRH:TDDR reload the PSCH:PSC, and the TIMH:TIM decrements by one. TDDRH:TDDR also reloads the PSCH:PSC whenever the timer reload bit (TRB) is set by software.</p> <p>Reset type: SYSRSn</p>

3.16.5.5 TPRH Register (Offset = 7h) [Reset = 0000h]

TPRH is shown in [Figure 3-96](#) and described in [Table 3-102](#).

Complex bit access types are encoded to fit into small table cells. Table 3-104 shows the codes that are used for access types in this section.

Table 3-104. DEV_CFG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write

Table 3-104. DEV_CFG_REGS Access Type Codes (continued)

Access Type	Code	Description
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
WOnce	W Once	Write Write once
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.6.1 PARTIDL Register (Offset = 8h) [Reset = 00XXXXX0h]

3.16.7 DMA_CLA_SRC_SEL_REGS Registers

Table 3-132 lists the memory-mapped registers for the DMA_CLA_SRC_SEL_REGS registers. All register offset addresses not listed in Table 3-132 should be considered as reserved locations and the register contents should not be modified.

Table 3-132. DMA_CLA_SRC_SEL_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	CLA1TASKSRCSELLOCK	CLA1 Task Trigger Source Select Lock Register	EALLOW	Go
4h	DMACHSRCSELLOCK	DMA Channel Trigger Source Select Lock Register	EALLOW	Go
6h	CLA1TASKSRCSEL1	CLA1 Task Trigger Source Select Register-1	EALLOW	Go
8h	CLA1TASKSRCSEL2	CLA1 Task Trigger Source Select Register-2	EALLOW	Go
16h	DMACHSRCSEL1	DMA Channel Trigger Source Select Register-1	EALLOW	Go
18h	DMACHSRCSEL2	DMA Channel Trigger Source Select Register-2	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 3-133 shows the codes that are used for access types in this section.

Table 3-133. DMA_CLA_SRC_SEL_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WOnce	W Once	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.7.1 CLA1TASKSRCSELLOCK Register (Offset = 0h) [Reset = 0000000h]

A0h	ROM_LOCK	ROM Config Lock Register		Go
A2h	ROM_TEST	ROM TEST Register		Go
A4h	ROM_FORCE_ERROR	ROM Force Error register		Go

Complex bit access types are encoded to fit into small table cells. Table 3-141 shows the codes that are used for access types in this section.

Table 3-141. MEM_CFG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read

Table 3-141. MEM_CFG_REGS Access Type Codes (continued)

Access Type	Code	Description
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
WOnce	W Once	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.8.1 DxLOCK Register (Offset = 0h) [Reset = 0000000h]

DxLOCK is shown in [Figure 3-130](#) and described in [Table 3-142](#).

Return to the [Summary Table](#).

3.16.9 MEMORY_ERROR_REGS Registers

Table 3-175 lists the memory-mapped registers for the MEMORY_ERROR_REGS registers. All register offset addresses not listed in Table 3-175 should be considered as reserved locations and the register contents should not be modified.

Table 3-175. MEMORY_ERROR_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	UCERRFLG	Uncorrectable Error Flag Register		Go
2h	UCERRSET	Uncorrectable Error Flag Set Register	EALLOW	Go
4h	UCERRCLR	Uncorrectable Error Flag Clear Register	EALLOW	Go
6h	UCCPUREADDR	Uncorrectable CPU Read Error Address		Go
8h	UCDMAREADDR	Uncorrectable DMA Read Error Address		Go
Ah	UCCLA1READDR	Uncorrectable CLA1 Read Error Address		Go
10h	UCHICAREADDR	Uncorrectable HICA Read Error Address		Go
20h	CERRFLG	Correctable Error Flag Register		Go
22h	CERRSET	Correctable Error Flag Set Register	EALLOW	Go
24h	CERRCLR	Correctable Error Flag Clear Register	EALLOW	Go
26h	CCPUREADDR	Correctable CPU Read Error Address		Go
28h	CDMAREADDR	Correctable DMA Read Error Address		Go
2Ah	CCLA1READDR	Correctable CLA1 Read Error Address		Go
2Eh	CERRCNT	Correctable Error Count Register		Go
30h	CERRTHRES	Correctable Error Threshold Value Register	EALLOW	Go
32h	CEINTFLG	Correctable Error Interrupt Flag Status Register		Go
34h	CEINTCLR	Correctable Error Interrupt Flag Clear Register	EALLOW	Go
36h	CEINTSET	Correctable Error Interrupt Flag Set Register	EALLOW	Go
38h	CEINTEN	Correctable Error Interrupt Enable Register	EALLOW	Go
3Ah	CHICREADDR	Correctable HIC Read Error Address		Go

Complex bit access types are encoded to fit into small table cells. Table 3-176 shows the codes that are used for access types in this section.

Table 3-176. MEMORY_ERROR_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1S	W1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.

Table 3-176. MEMORY_ERROR_REGS Access Type Codes (continued)

Access Type	Code	Description
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.9.1 UCERRFLG Register (Offset = 0h) [Reset = 0000000h]

UCERRFLG is shown in [Figure 3-163](#) and described in [Table 3-177](#).

Return to the [Summary Table](#).

Bh	ERRORLOCK	Lock register to Error pin registers.	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 3-198 shows the codes that are used for access types in this section.

Table 3-198. NMI_INTRUPT_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1S	W1S	Write 1 to set
WOnce	WOnce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.10.1 NMICFG Register (Offset = 0h) [Reset = 0000h]

NMICFG is shown in [Figure 3-183](#) and described in [Table 3-199](#).

Return to the [Summary Table](#).

Table 3-203. NMIWDCNT Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	NMIWDCNT	R	0h	<p>NMI Watchdog Counter: This 16-bit incremental counter will start incrementing whenever any one of the enabled FAIL flags are set. If the counter reaches the period value, an NMIRSn signal is fired which will then resets the system. The counter will reset to zero when it reaches the period value and will then restart counting if any of the enabled FAIL flags are set.</p> <p>If no enabled FAIL flag is set, then the counter will reset to zero and remain at zero until an enabled FAIL flag is set.</p> <p>Normally, the software would respond to the NMI interrupt generated and clear the offending FLAG(s) before the NMI watchdog triggers a reset. In some situations, the software may decide to allow the watchdog to reset the device anyway.</p> <p>The counter is clocked at the SYSCLKOUT rate.</p> <p>Reset type: SYSRStn</p>

3.16.10.6 NMIWDPRD Register (Offset = 5h) [Reset = FFFFh]

NMIWDPRD is shown in [Figure 3-188](#) and described in [Table 3-204](#).

Table 3-210. ERRORLOCK Register Field Descriptions

Bit	Field	Type	Reset	Description
15-1	RESERVED	R-0	0h	Reserved
0	ERRORCTL	R/WOnce	0h	0, Writes to ERRORCTL register allowed. 1, Writes to ERRORCTL register is blocked. Writes of 0 to this bit has no effect. Write of 1 will set this bit, cleared only on a SYSRSn. Reset type: SYSRSn

3.16.11 PERIPH_AC_REGS Registers

Table 3-211 lists the memory-mapped registers for the PERIPH_AC_REGS registers. All register offset addresses not listed in Table 3-211 should be considered as reserved locations and the register contents should not be modified.

Table 3-211. PERIPH_AC_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	ADCA_AC	ADCA Master Access Control Register	EALLOW	Go
2h	ADCB_AC	ADCB Master Access Control Register	EALLOW	Go

1AEh	AESA_AC	AES Master Access Control Register	EALLOW	Go
1FEh	PERIPH_AC_LOCK	Lock Register to stop Write access to peripheral Access register.	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. [Table 3-212](#) shows the codes that are used for access types in this section.

Table 3-212. PERIPH_AC_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WOnce	W Once	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.11.1 ADCA_AC Register (Offset = 0h) [Reset = 00000FFh]

ADCA_AC is shown in [Figure 3-195](#) and described in [Table 3-213](#).

Return to the [Summary Table](#).

Based on control settings allows Full, Protected Read, No Access to peripheral from corresponding connected master.

7	6	5	4	3	2	1	0
PIEVECT							ENPIE
R-0h							R/W-0h

Table 3-260. PIECTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-1	PIEVECT	R	0h	These bits indicate the vector address of the vector fetched from the ePIE vector table. The least significant bit of the address is ignored and only bits 1 to 15 of the address are shown. The vector value can be read by the user to determine which interrupt generated the vector fetch. Note: When a NMI is serviced, the PIEVECT bit-field does not reflect the vector as it does for other interrupts. Reset type: SYSRSn
0	ENPIE	R/W	0h	Enable vector fetching from ePIE block. This bit must be set to 1 for peripheral interrupts to work. All ePIE registers (PIEACK, PIEIFR, PIEIER) can be accessed even when the ePIE block is disabled. Reset type: SYSRSn

3.16.12.2 PIEACK Register (Offset = 1h) [Reset = 0000h]

PIEACK is shown in [Figure 3-241](#) and described in [Table 3-261](#).

Return to the [Summary Table](#).

Acknowledge Register

When an interrupt propagates from the ePIE to a CPU interrupt line, the interrupt group's PIEACK bit is set. This prevents other interrupts in that group from propagating to the CPU while the first interrupt is handled. Writing a 1 to a PIEACK bit clears it and allows another interrupt from the corresponding group to propagate. ISRs for PIE interrupts should clear the group's PIEACK bit before returning from the interrupt.

Writes of 0 are ignored.

3.16.12.3 PIEIER1 Register (Offset = 2h) [Reset = 0000h]

PIEIER1 is shown in [Figure 3-242](#) and described in [Table 3-262](#).

Return to the [Summary Table](#).

Interrupt Group 1 Enable Register

These register bits individually enable an interrupt within a group. They behave very much like the bits in the CPU interrupt enable register (IER).

Setting a bit to 1 allows the corresponding interrupt to propagate to the CPU.

Setting a bit to 0 prevents the corresponding interrupt from propagating. Note that a peripheral interrupt signal can still set the PIEIFR bit for the disabled interrupt.

3.16.12.4 PIEIFR1 Register (Offset = 3h) [Reset = 0000h]

PIEIFR1 is shown in [Figure 3-243](#) and described in [Table 3-263](#).

Return to the [Summary Table](#).

Interrupt Group 1 Flag Register

These register bits indicate whether each interrupt in the group is currently pending. They behave very much like the bits in the CPU interrupt flag register (IFR).

When a peripheral sends an interrupt, the corresponding bit is set. This bit is cleared when the interrupt propagates to the CPU, at which point PIEACK is set.

NOTE: PIE IFR flags can be written to create software interrupts.

The IFR flag will be cleared on a write of zero. Hence, when the intent is to fire an interrupt it may cause inadvertent cancellation of other interrupts. It is recommended to use this only for testing or with extreme caution in the application code. Reading the PIE IFR registers is safe.

3.16.12.12 PIEIFR5 Register (Offset = Bh) [Reset = 0000h]

PIEIFR5 is shown in [Figure 3-251](#) and described in [Table 3-271](#).

Return to the [Summary Table](#).

Interrupt Group 5 Flag Register

These register bits indicate whether each interrupt in the group is currently pending. They behave very much like the bits in the CPU interrupt flag register (IFR).

When a peripheral sends an interrupt, the corresponding bit is set. This bit is cleared when the interrupt propagates to the CPU, at which point PIEACK is set.

NOTE: PIE IFR flags can be written to create software interrupts.

The IFR flag will be cleared on a write of zero. Hence, when the intent is to fire an interrupt it may cause inadvertent cancellation of other interrupts. It is recommended to use this only for testing or with extreme caution in the application code. Reading the PIE IFR registers is safe.

3.16.12.20 PIEIFR9 Register (Offset = 13h) [Reset = 0000h]

PIEIFR9 is shown in [Figure 3-259](#) and described in [Table 3-279](#).

Return to the [Summary Table](#).

Interrupt Group 9 Flag Register

These register bits indicate whether each interrupt in the group is currently pending. They behave very much like the bits in the CPU interrupt flag register (IFR).

When a peripheral sends an interrupt, the corresponding bit is set. This bit is cleared when the interrupt propagates to the CPU, at which point PIEACK is set.

NOTE: PIE IFR flags can be written to create software interrupts.

The IFR flag will be cleared on a write of zero. Hence, when the intent is to fire an interrupt it may cause inadvertent cancellation of other interrupts. It is recommended to use this only for testing or with extreme caution in the application code. Reading the PIE IFR registers is safe.

3.16.13 SYNC_SOC_REGS Registers

Table 3-286 lists the memory-mapped registers for the SYNC_SOC_REGS registers. All register offset addresses not listed in Table 3-286 should be considered as reserved locations and the register contents should not be modified.

Table 3-286. SYNC_SOC_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	SYNCSELECT	Sync Input and Output Select Register	EALLOW	Go
2h	ADCSOCOUTSELECT	External ADCSOC Select Register	EALLOW	Go
4h	SYNCSOCLOCK	SYNCSEL and EXTADCSOC Select Lock register	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 3-287 shows the codes that are used for access types in this section.

Table 3-287. SYNC_SOC_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WOnce	W Once	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.13.1 SYNCSELECT Register (Offset = 0h) [Reset = E003FFFFh]

SYNCSELECT is shown in [Figure 3-266](#) and described in [Table 3-288](#).

Return to the [Summary Table](#).

3.16.17 WD_REGS Registers

Table 3-312 lists the memory-mapped registers for the WD_REGS registers. All register offset addresses not listed in Table 3-312 should be considered as reserved locations and the register contents should not be modified.

Table 3-312. WD_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
22h	SCSR	System Control & Status Register	EALLOW	Go
23h	WDCNTR	Watchdog Counter Register	EALLOW	Go
25h	WDKEY	Watchdog Reset Key Register	EALLOW	Go
29h	WDCR	Watchdog Control Register	EALLOW	Go
2Ah	WDWCR	Watchdog Windowed Control Register	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 3-313 shows the codes that are used for access types in this section.

Table 3-313. WD_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1C	W1C	Write 1 to clear
W1S	W1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.17.1 SCSR Register (Offset = 22h) [Reset = 0005h]

SCSR is shown in [Figure 3-284](#) and described in [Table 3-314](#).

Return to the [Summary Table](#).

System Control & Status Register

It is recommended to only use 16 bit accesses to write to this register. Use a read-modify-write instruction may inadvertently clear other bits.

Table 3-314. SCSR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-3	RESERVED	R-0	0h	Reserved
2	WDINTS	R	1h	<p>Watchdog Interrupt Status</p> <p>This bit indicates the state of the active-low watchdog interrupt signal (synchronized to SYSCLK). If the watchdog interrupt is used to wake the system from a low-power mode, then that mode should only be entered while this bit is high. Likewise, this bit must go high before the watchdog can be safely disabled and re-enabled.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = The watchdog interrupt signal is active.</p> <p>1h (R/W) = The watchdog interrupt signal is inactive.</p>
1	WDENINT	R/W	0h	<p>Watchdog Interrupt Enable/Reset Disable</p> <p>This bit determines whether the watchdog triggers an interrupt (WAKE/WDOG) or a reset (WDRS) when the counter expires.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Counter expiration triggers a reset. This is the default state on power-up and after any system reset.</p> <p>1h (R/W) = Counter expiration triggers an interrupt.</p>
0	WDOVERRIDE	R/W1C	1h	<p>If this bit is set to 1, the user is allowed to change the state of the Watchdog disable (WDDIS) bit in the Watchdog Control (WDCR) register. If the WDOVERRIDE bit is cleared, by writing a 1 the WDDIS bit cannot be modified by the user. Writing a 0 will have no effect. If this bit is cleared, then it will remain in this state until a reset occurs. The current state of this bit is readable by the user.</p> <p>Reset type: SYSRSn</p>

3.16.17.2 WDCNTR Register (Offset = 23h) [Reset = 0000h]

WDCNTR is shown in [Figure 3-285](#) and described in [Table 3-315](#).

Return to the [Summary Table](#).

Watchdog Counter Register

Bit	Field	Type	Reset	Description
15-8	RESERVED	R-0	0h	Reserved
7-0	WDKEY	R/W	0h	Watchdog Counter Reset Writing 0x55 followed by 0xAA will cause the watchdog counter to reset to zero, preventing an overflow. Writing other values has no effect. Reads of this register return the value of the WDCR register. Reset type: IORSn

3.16.17.4 WDCR Register (Offset = 29h) [Reset = 0000h]

WDCR is shown in [Figure 3-287](#) and described in [Table 3-317](#).

Return to the [Summary Table](#).

Watchdog Control Register

This memory mapped register requires a delay between subsequent writes to the register, otherwise a second write can be lost. The required delay is 69 SYSCLK cycles for a 200 MHz device, 45 SYSCLK cycles for a 120 MHz device, and 39 SYSCLK cycles for a 100 MHz device. This delay can be realized by adding NOP instructions corresponding to the required delay cycles.

R/W1S-0h	R/W-0h	R-0/W-0h		R/W-0h			

Table 3-317. WDCR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-12	RESERVED	R-0	0h	Reserved
11-8	WDPRECLKDIV	R/W	0h	Watchdog Clock Pre-divider These bits determine the watchdog clock pre-divider, which is the first of the two dividers between INTOSC1 and the watchdog counter clock (WDCLK). The frequency of WDCLK is given by the formulas: $PREDIVCLK = INTOSC1 / \text{Pre-divider}$ $WDCLK = PREDIVCLK / \text{Prescaler}$ Reset type: IORSn 0h (R/W) = $PREDIVCLK = INTOSC1 / 512$ 1h (R/W) = $PREDIVCLK = INTOSC1 / 1024$ 2h (R/W) = $PREDIVCLK = INTOSC1 / 2048$ 3h (R/W) = $PREDIVCLK = INTOSC1 / 4096$ 4h (R/W) = Reserved 5h (R/W) = Reserved 6h (R/W) = Reserved 7h (R/W) = Reserved 8h (R/W) = $PREDIVCLK = INTOSC1 / 2$ 9h (R/W) = $PREDIVCLK = INTOSC1 / 4$ Ah (R/W) = $PREDIVCLK = INTOSC1 / 8$ Bh (R/W) = $PREDIVCLK = INTOSC1 / 16$ Ch (R/W) = $PREDIVCLK = INTOSC1 / 32$ Dh (R/W) = $PREDIVCLK = INTOSC1 / 64$ Eh (R/W) = $PREDIVCLK = INTOSC1 / 128$ Fh (R/W) = $PREDIVCLK = INTOSC1 / 256$
7	WDFLG	R/W1S	0h	Watchdog reset status flag bit. This bit, if set, indicates a watchdog reset (WDRSTn) generated the reset condition. If 0, then it was an external device or power-up reset condition. This bit remains latched until the user writes a 1 to clear the condition. Writes of 0 will be ignored. Reset type: IORSn
6	WDDIS	R/W	0h	Watchdog Disable Setting this bit disables the watchdog module. Clearing this bit enables the watchdog module. This bit can be locked by the WDOVERRIDE bit in the SCSR register. The watchdog is enabled on reset. Reset type: IORSn

Table 3-317. WDCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5-3	WDCHK	R-0/W	0h	Watchdog Check Bits During any write to this register, these bits must be written with the value 101 (binary). Writing any other value will immediately trigger the watchdog reset or interrupt. Reset type: IORSn
2-0	WDPS	R/W	0h	Watchdog Clock Prescaler These bits determine the watchdog clock prescaler, which is the second of the two dividers between INTOSC1 and the watchdog counter clock (WDCLK). The frequency of WDCLK is given by the formulas: $PREDIVCLK = INTOSC1 / \text{Pre-divider}$ $WDCLK = PREDIVCLK / \text{Prescaler}$ The watchdog reset or interrupt pulse is 512 INTOSC1 cycles long, so the counter period must be longer. To guarantee this, the product of the prescaler and pre-divider must be greater than or equal to four. The default prescaler value is 1. Reset type: IORSn 0h (R/W) = $WDCLK = PREDIVCLK / 1$ 1h (R/W) = $WDCLK = PREDIVCLK / 1$ 2h (R/W) = $WDCLK = PREDIVCLK / 2$ 3h (R/W) = $WDCLK = PREDIVCLK / 4$ 4h (R/W) = $WDCLK = PREDIVCLK / 8$ 5h (R/W) = $WDCLK = PREDIVCLK / 16$ 6h (R/W) = $WDCLK = PREDIVCLK / 32$ 7h (R/W) = $WDCLK = PREDIVCLK / 64$

3.16.17.5 WDWCR Register (Offset = 2Ah) [Reset = 0000h]

WDWCR is shown in [Figure 3-288](#) and described in [Table 3-318](#).

Return to the [Summary Table](#).

Watchdog Windowed Control Register

Table 3-326. XINT1CTR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	INTCTR	R	0h	This is a free running 16-bit up-counter that is clocked at the SYSCLKOUT rate. The counter value is reset to 0x0000 when a valid interrupt edge is detected and then continues counting until the next valid interrupt edge is detected. The counter must only be reset by the selected POLARITY edge as selected in the respective interrupt control register. When the interrupt is disabled, the counter will stop. The counter is a free-running counter and will wrap around to zero when the max value is reached. The counter is a read only register and can only be reset to zero by a valid interrupt edge or by reset. Reset type: SYSRSn

3.16.18.7 XINT2CTR Register (Offset = 9h) [Reset = 0000h]

XINT2CTR is shown in [Figure 3-295](#) and described in [Table 3-327](#).

Return to the [Summary Table](#).

Bit	Field	Type	Reset	Description
15-0	INTCTR	R	0h	This is a free running 16-bit up-counter that is clocked at the SYSCLKOUT rate. The counter value is reset to 0x0000 when a valid interrupt edge is detected and then continues counting until the next valid interrupt edge is detected. The counter must only be reset by the selected POLARITY edge as selected in the respective interrupt control register. When the interrupt is disabled, the counter will stop. The counter is a free-running counter and will wrap around to zero when the max value is reached. The counter is a read only register and can only be reset to zero by a valid interrupt edge or by reset. Reset type: SYSRSn

3.16.19 LFU_REGS Registers

Table 3-329 lists the memory-mapped registers for the LFU_REGS registers. All register offset addresses not listed in Table 3-329 should be considered as reserved locations and the register contents should not be modified.

Table 3-329. LFU_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	LFUConfig	LFU configuration Register	EALLOW	Go
2h	LFUStatus	LFU Configuration Status Register		Go
10h	SWConfig1_SYSRSn	Spare registers reset by SYSRSn	EALLOW	Go
12h	SWConfig2_SYSRSn	Spare registers reset by SYSRSn	EALLOW	Go
14h	SWConfig1_XRSn	Spare registers reset by XRSn	EALLOW	Go
16h	SWConfig2_XRSn	Spare registers reset by XRSn	EALLOW	Go
18h	SWConfig1_PORESETn	Spare registers reset by PORESETn	EALLOW	Go
1Ah	SWConfig2_PORESETn	Spare registers reset by PORESETn	EALLOW	Go
1Ch	LFU_LOCK	LFU Lock Configuration		Go
1Eh	LFU_COMMIT	LFU Commit Configuration		Go

Complex bit access types are encoded to fit into small table cells. Table 3-330 shows the codes that are used for access types in this section.

Table 3-330. LFU_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WOnce	W Once	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.16.19.1 LFUConfig Register (Offset = 0h) [Reset = 0000000h]

LFUConfig is shown in [Figure 3-297](#) and described in [Table 3-331](#).

Return to the [Summary Table](#).

Chapter 4
ROM Code and Peripheral Booting

This chapter explains the boot procedure, the available boot modes, and the various details of the ROM code including memory maps, initializations, reset handling, and status information.

4.1 Introduction	564
4.2 ROM Related Collateral	564
4.3 Device Boot Sequence	565
4.4 Device Boot Modes	565
4.5 Device Boot Configurations	566
4.6 Device Boot Flow Diagrams	571
4.7 Device Reset and Exception Handling	575
4.8 Boot ROM Description	576
4.9 Application Notes for Using the Bootloaders	604
4.10 Software	608

4.1 Introduction

The purpose of this chapter is to explain the boot read-only memory (ROM) code functionality for the CPU core, including the boot procedure. This chapter also discusses the functions and features of the boot ROM code, and provides details about the ROM memory-map contents. On every reset, the device executes a boot sequence in the ROM depending on the reset type and boot configuration. This sequence initializes the device to run the application code. For the CPU, the boot ROM also contains peripheral bootloaders that can be used to load an application into RAM. These bootloaders can be disabled for safety or security purposes.

See [Table 4-1](#) for details on available boot features for the C28x CPU. Additionally, [Table 4-2](#) shows the sizes of the various ROMs on the device.

For details on the security APIs provided, refer to [Section 4.8.10](#).

Various tables are provided in ROM for use in software library, refer to [Section 4.8.7](#) for more details.

Table 4-1. Boot System Overview

Boot Feature	CPU
Initial boot process	Device reset
Boot mode selection	GPIOs
Boot modes supported	Flash boot Secure Flash boot RAM boot Firmware update (FWU) boot
Peripheral boot loaders supported	Parallel IO SCI / Wait CAN CAN-FD I2C SPI

Table 4-2. ROM Memory

ROM	CPU Size
Unsecure boot ROM	64KB
Secure ROM	48KB
CLA data ROM	8KB

4.2 ROM Related Collateral

4.3 Device Boot Sequence

Table 4-3 describes the general boot ROM procedure each time the CPU core is reset.

During boot, boot ROM code updates a boot status location in RAM that details the actions taken during this process. Refer to Section 4.8.12 for more details.

Table 4-3. Device Boot ROM Sequence

Step	CPU Action
1	After reset, check for HWBIST reset. If it is a HWBIST reset, immediately branch and return to the user application. If it is not a HWBIST reset, then continue boot and check the FUSE error register for any errors and handle accordingly.
2	Clock configuration and Flash power-up
3	Peripheral trimming and device configuration registers are loaded from OTP.
4	On power-on reset (POR), all RAMs are initialized.
5	Non-maskable interrupt (NMI) handling is enabled and DCSM initialization is performed.
6	Device calibration is performed; trimming the specified peripherals with set OTP values.
7	Determine if polling the GPIO pins are needed for determining the boot mode and, if so, read the boot mode GPIO pins to determine the boot mode to run.
8	Based on the boot mode and options, the appropriate boot sequence is executed. Refer to Section 4.6.1 for a flow chart of the boot sequences.

4.4 Device Boot Modes

This section explains the default boot modes, as well as all the available boot modes supported on this device. The boot ROM uses the boot mode select, general purpose input/output (GPIO) pins to determine the boot mode configuration.

4.4.1 Default Boot Modes

Table 4-4 shows the boot mode options available for selection by the default boot mode select pins. Users have the option to program the device to customize the boot modes selectable in the boot-up table as well as the boot mode select pin GPIOs used.

Table 4-4. Device Default Boot Modes

Boot Mode	GPIO24 (Default boot mode select pin 1)	GPIO32 (Default boot mode select pin 0)
Parallel IO	0	0
SCI / Wait Boot ⁽¹⁾	0	1
CAN	1	0
Flash	1	1

(1) SCI boot mode is used as a wait boot mode as long as SCI continues to wait for an 'A' or 'a' during the SCI autobaud lock process.

Refer to Section 4.8.8.1 for functional details of the boot modes.

Refer to Section 4.8.9 for GPIOs used for selecting the boot modes.

Refer to Section 4.5 for details of boot configurations.

Note

All the peripheral boot modes that are supported use the first instance of the peripheral module (SCIA, SPIA, I2CA, CANA, and so forth). Whenever these boot modes are referred to in this chapter, such as SCI boot, the reference is the first module instance, which means the SCI boot on the SCIA port. The same applies to the other peripheral boot modes.

4.4.2 Custom Boot Modes

Once the user programs a custom boot table in user OTP, an entry in the custom table is used for booting. Users can customize the boot mode select pins in the end system design by programming the BOOTPIN_CONFIG location in user OTP. This allows customers to use 0, 1, 2, or 3 boot mode select pins as needed. You can also customize the boot definition table and indicate which location to boot from by programming the boot mode definition table in the BOOTDEF location of user OTP. [Table 4-5](#) shows the options for various boot modes.

Table 4-5. Custom Boot Modes

Boot Mode Number	Boot Modes
0	Parallel
1	SCI / Wait
2	CAN
3	Flash
4	Wait
5	RAM
6	SPI
7	I2C
8	CAN-FD
10	Secure Flash
11	FWU Flash

4.5 Device Boot Configurations

This section details what boot configurations are available and how to configure them. This device supports from **one** boot mode select pins up to **three** boot mode select pins as well as from **one** configured boot mode up to **eight** configured boot modes.

To change and configure the device from the default settings to custom settings for your application, use the following process:

1. Determine all the various ways you want application to be able to boot. (For example: Primary boot option of Flash boot for your main application, secondary boot option of CAN boot for firmware updates, tertiary boot option of SCI boot for debugging, etc)
2. Based on the number of boot modes needed, determine how many boot mode select pins (BMSPs) are required to select between your selected boot modes. (For example: **Two** BMSPs are required to select between **three** boot mode options)
3. Assign the required BMSPs to a physical GPIO pin. (For example, BMSP0 to GPIO10, BMSP1 to GPIO51, and BMSP2 left as default which is disabled). Refer to [Section 4.5.1](#) for all the details on performing these configurations.
4. Assign the determined boot mode definitions to indexes in your custom boot table that correlate to the decoded value of the BMSPs. For example, BOOTDEF0=Boot to Flash, BOOTDEF1=CAN Boot, BOOTDEF2=SCI Boot; all other BOOTDEFx are left as default/nothing). Refer to [Section 4.5.2](#) for all the details on setting up and configuring the custom boot mode table.

Additionally, [Section 4.5.3](#) provides some example use cases on how to configure the BMSPs and custom boot tables.

4.5.1 Configuring Boot Mode Pins

This section explains how the boot mode select pins ARE customized by the user, by programming the BOOTPIN-CONFIG location (refer to [Table 4-6](#)) in the user-configurable dual-zone security module (DCSM) OTP. The location in the DCSM OTP is Z1-OTP-BOOTPIN-CONFIG or Z2-OTP-BOOTPIN-CONFIG. When debugging, EMU-BOOTPIN-CONFIG is the emulation equivalent of Z1-OTP-BOOTPIN-CONFIG/Z2-OTP-BOOTPIN-CONFIG, and can be programmed to experiment with different boot modes without writing to OTP. The device can be programmed to use **zero, one, two** or **three** boot mode select pins as needed.

Note

When using Z2-OTP-BOOTPIN-CONFIG, the configurations programmed in this location take priority over the configurations in Z1-OTP-BOOTPIN-CONFIG. It is **recommended** to use Z1-OTP-BOOTPIN-CONFIG first and then if OTP configurations need to be altered, switch to using Z2-OTP-BOOTPIN-CONFIG.

Table 4-6. BOOTPIN-CONFIG Bit Fields

Bit	Name	Description
31:24	Key	Write 0x5A to these 8-bits to tell the boot ROM code that the bits in this register are valid.
23:16	Boot Mode Select Pin 2 (BMSP2)	Refer to BMSP0 description.
15:8	Boot Mode Select Pin 1 (BMSP1)	Refer to BMSP0 description.
7:0	Boot Mode Select Pin 0 (BMSP0)	Set to the GPIO pin to be used during boot (up to 255). 0x0 = GPIO0, 0x01 = GPIO1, and so on. Writing 0xFF disables this BMSP and this pin is no longer used to select the boot mode.

Note

GPIO 20, 21, 224 to 253 are analog pins, but digital inputs are possible on these pins provided the software writes to the GPIOHAMSEL register bits.

The following GPIOs **cannot** be used as a BMSP. If selected for a particular BMSP, the boot ROM will automatically select the factory default GPIOs for BMSP0 and BMSP1. Factory default for BMSP2 is 0xFF, which disables the BMSP.

- GPIO 36 and GPIO 38 (Not available on any package)
 - GPIO 62 to GPIO 223 (Not available on any package)
 - GPIO 20 and GPIO 21 are analog pins on 80-pin package only
-

Table 4-7. Standalone Boot Mode Select Pin Decoding

BOOTPIN_CONFIG Key	BMSP0	BMSP1	BMSP2	Realized Boot Mode
!= 0x5A	Don't Care	Don't Care	Don't Care	Boot as defined by the factory default BMSPs
= 0x5A	0xFF	0xFF	0xFF	Boot as defined in the boot table for boot mode 0 (All BMSPs disabled)
	Valid GPIO	0xFF	0xFF	Boot as defined by the value of BMSP0 (BMSP1 and BMSP2 disabled)
	0xFF	Valid GPIO	0xFF	Boot as defined by the value of BMSP1 (BMSP0 and BMSP2 disabled)
	0xFF	0xFF	Valid GPIO	Boot as defined by the value of BMSP2 (BMSP0 and BMSP1 disabled)
	Valid GPIO	Valid GPIO	0xFF	Boot as defined by the values of BMSP0 and BMSP1 (BMSP2 disabled)
	Valid GPIO	0xFF	Valid GPIO	Boot as defined by the values of BMSP0 and BMSP2 (BMSP1 disabled)
	0xFF	Valid GPIO	Valid GPIO	Boot as defined by the values of BMSP1 and BMSP2 (BMSP0 disabled)
	Valid GPIO	Valid GPIO	Valid GPIO	Boot as defined by the values of BMSP0, BMSP1, and BMSP2
	Invalid GPIO	Valid GPIO	Valid GPIO	BMSP0 is reset to the factory default BMSP0 GPIO Boot as defined by the values of BMSP0, BMSP1, and BMSP2
	Valid GPIO	Invalid GPIO	Valid GPIO	BMSP1 is reset to the factory default BMSP1 GPIO Boot as defined by the values of BMSP0, BMSP1, and BMSP2
Valid GPIO	Valid GPIO	Invalid GPIO	BMSP2 is reset to the factory default state, which is disabled Boot as defined by the values of BMSP0 and BMSP1	

Note

When decoding the boot mode, BMSP0 is the least-significant-bit and BMSP2 is the most-significant-bit of the boot table index value. It is **recommended** when disabling BMSPs to start with disabling BMSP2. For example, in an instance when only using BMSP2 (BMSP1 and BMSP0 are disabled), then only the boot table indexes of 0 and 4 will be selectable. In the instance when using only BMSP0, then the selectable boot table indexes are 0 and 1.

4.5.2 Configuring Boot Mode Table Options

This section explains how to configure the boot definition table, BOOTDEF, for the device and the associated boot options. The 64-bit location is located in user-configurable DCSM OTP in the Z1-OTP-BOOTDEF-LOW and Z1-OTP-BOOTDEF-HIGH locations. When debugging, EMU-BOOTDEF-LOW and EMU-BOOTDEF-HIGH are the emulation equivalents of Z1-OTP-BOOTDEF-LOW and Z1-OTP-BOOTDEF-HIGH, and can be programmed to experiment with different boot mode options without writing to OTP. The range of customization to the boot definition table depends on how many boot mode select pins (BMSP) are being used. For example, 0 BMSPs equals to 1 table entry, 1 BMSP equals to 2 table entries, 2 BMSPs equals to 4 table entries, and 3 BMSPs equals to 8 table entries. Refer to [Section 4.5.3](#) for examples on how to setup the BOOTPIN_CONFIG and BOOTDEF values.

Note

The locations Z2-OTP-BOOTDEF-LOW and Z2-OTP-BOOTDEF-HIGH will be used instead of Z1-OTP-BOOTDEF-LOW and Z1-OTP-BOOTDEF-HIGH locations when Z2-OTP-BOOTPIN-CONFIG is configured. Refer to [Section 4.5.1](#) for more details on BOOTPIN_CONFIG usage.

Table 4-8. BOOTDEF Bit Fields

BOOTDEF Name	Byte Position	Name	Description
BOOT_DEF0	7:0	[3:0] BOOT_DEF0 Mode	Set the boot mode number from Section 4.4.2 . Any unsupported boot mode will cause the device to either go to wait boot (debugger connected) or boot to Flash (standalone).
		[7:4] BOOT_DEF0 Options	Set alternate / additional boot options. This can include changing the GPIOs for a particular boot peripheral or specifying a different Flash entry point. Refer to Section 4.8.9 for valid BOOTDEF values to set in the table.
BOOT_DEF1	15:8	BOOT_DEF1 Mode/Options	Refer to BOOT_DEF0 description.
BOOT_DEF2	23:16	BOOT_DEF2 Mode/Options	
BOOT_DEF3	31:24	BOOT_DEF3 Mode/Options	
BOOT_DEF4	39:32	BOOT_DEF4 Mode/Options	
BOOT_DEF5	47:40	BOOT_DEF5 Mode/Options	
BOOT_DEF6	55:48	BOOT_DEF6 Mode/Options	
BOOT_DEF7	63:56	BOOT_DEF7 Mode/Options	

4.5.3 Boot Mode Example Use Cases

This section demonstrates some use cases for configuring the boot mode select pins and boot modes.

4.5.3.1 Zero Boot Mode Select Pins

This use case demonstrates a scenario for an application that does not use any boot mode select pins and always has the device boot to Flash.

1. Program the BOOTPIN_CONFIG location in OTP as follows:
 - Set BOOTPIN_CONFIG.BMSP0 to 0xFF
 - Set BOOTPIN_CONFIG.BMSP1 to 0xFF
 - Set BOOTPIN_CONFIG.BMSP2 to 0xFF
 - Set BOOTPIN_CONFIG.KEY to 0x5A for boot ROM to treat these register bits as valid and use the custom boot table.
2. Program the BOOTDEF location options for the device. This essentially sets up a device-specific boot mode table. Refer to [Section 4.8.9](#) for valid BOOTDEF values to set in the table.
 - Set BOOTDEF.BOOTDEF0 to 0x03 for booting to Flash (entry address option 0). This sets Flash boot to boot table index 0.
 - Refer to [Section 4.8.2](#) for the available Flash entry points.

Table 4-9. Zero Boot Pin Boot Table Result

Boot Mode Table Number	Boot Mode
0	Flash Boot (0x03)

4.5.3.2 One Boot Mode Select Pin

This use case demonstrates a scenario for an application using one boot mode select pin to select between booting to Flash or using CAN boot.

1. Program the BOOTPIN_CONFIG location in OTP as follows:
 - Set BOOTPIN_CONFIG.BMSP0 to a user specified GPIO, such as 0x0 for GPIO0
 - Set BOOTPIN_CONFIG.BMSP1 to 0xFF
 - Set BOOTPIN_CONFIG.BMSP2 to 0xFF
 - Set BOOTPIN_CONFIG.KEY to 0x5A for boot ROM to treat these register bits as valid and use the custom boot table.
2. Program the BOOTDEF location options for the device. This essentially sets up a device-specific boot mode table. Refer to [Section 4.8.9](#) for valid BOOTDEF values to set in the table.
 - Set BOOTDEF.BOOTDEF0 to 0x02 for CAN booting. This sets CAN boot to boot table index 0.
 - Set BOOTDEF.BOOTDEF1 to 0x03 for booting to Flash (entry address option 0). This sets Flash boot to boot table index 1.

Table 4-10. One Boot Pin Boot Table Result

Boot Mode Table Number	Boot Mode
0	CAN Boot (0x02)
1	Flash Boot (0x03)

4.5.3.3 Three Boot Mode Select Pins

This use case demonstrates a scenario for an application using three boot mode select pins to select between various boot modes in the custom boot table.

1. Program the BOOTPIN_CONFIG location in OTP as follows:
 - Set BOOTPIN_CONFIG.BMSP0 to a user specified GPIO, such as 0x0 for GPIO0
 - Set BOOTPIN_CONFIG.BMSP1 to a user specified GPIO, such as 0x1 for GPIO1
 - Set BOOTPIN_CONFIG.BMSP2 to a user specified GPIO, such as 0x2 for GPIO2
 - Set BOOTPIN_CONFIG.KEY to 0x5A for boot ROM to treat these register bits as valid and use the custom boot table.
2. Program the BOOTDEF location options for the device. This essentially sets up a device-specific boot mode table. Refer to [Section 4.8.9](#) for valid BOOTDEF values to set in the table.
 - Set BOOTDEF.BOOTDEF0 to 0x02 for CAN booting. This sets CAN boot to boot table index 0.
 - Set BOOTDEF.BOOTDEF1 to 0x03 for booting to Flash (entry address option 0). This sets Flash boot to boot table index 1.
 - Set BOOTDEF.BOOTDEF2 to 0x24 for booting to wait boot (alternate option). This sets wait boot to boot table index 2.
 - Set BOOTDEF.BOOTDEF3 to 0x66 for SPI booting (alternate GPIO option 3). This sets SPI boot to boot table index 3.
 - Set BOOTDEF.BOOTDEF4 to 0x43 for booting to Flash (entry address option 2). This sets Flash boot to boot table index 4.

Table 4-11. Three Boot Pins Boot Table Result

Boot Mode Table Number	Boot Mode
0	CAN Boot (0x02)
1	Flash Boot (0x03)
2	Wait Boot - Alt (0x24)
3	SPI - Alt3 (0x66)
4	Flash Boot - Alt2 (0x43)
5, 6, 7	Not used in this example

4.6 Device Boot Flow Diagrams

This section details the boot flow diagrams for standalone and emulation boot flows.

4.6.1 Boot Flow

Upon reset, the CPU follows the boot flow shown in [Figure 4-1](#). Depending on whether a JTAG debugger is connected to the device, the CPU either continues booting following the emulation boot flow or the standalone boot flow.

Note

BOR follows same flow as POR.

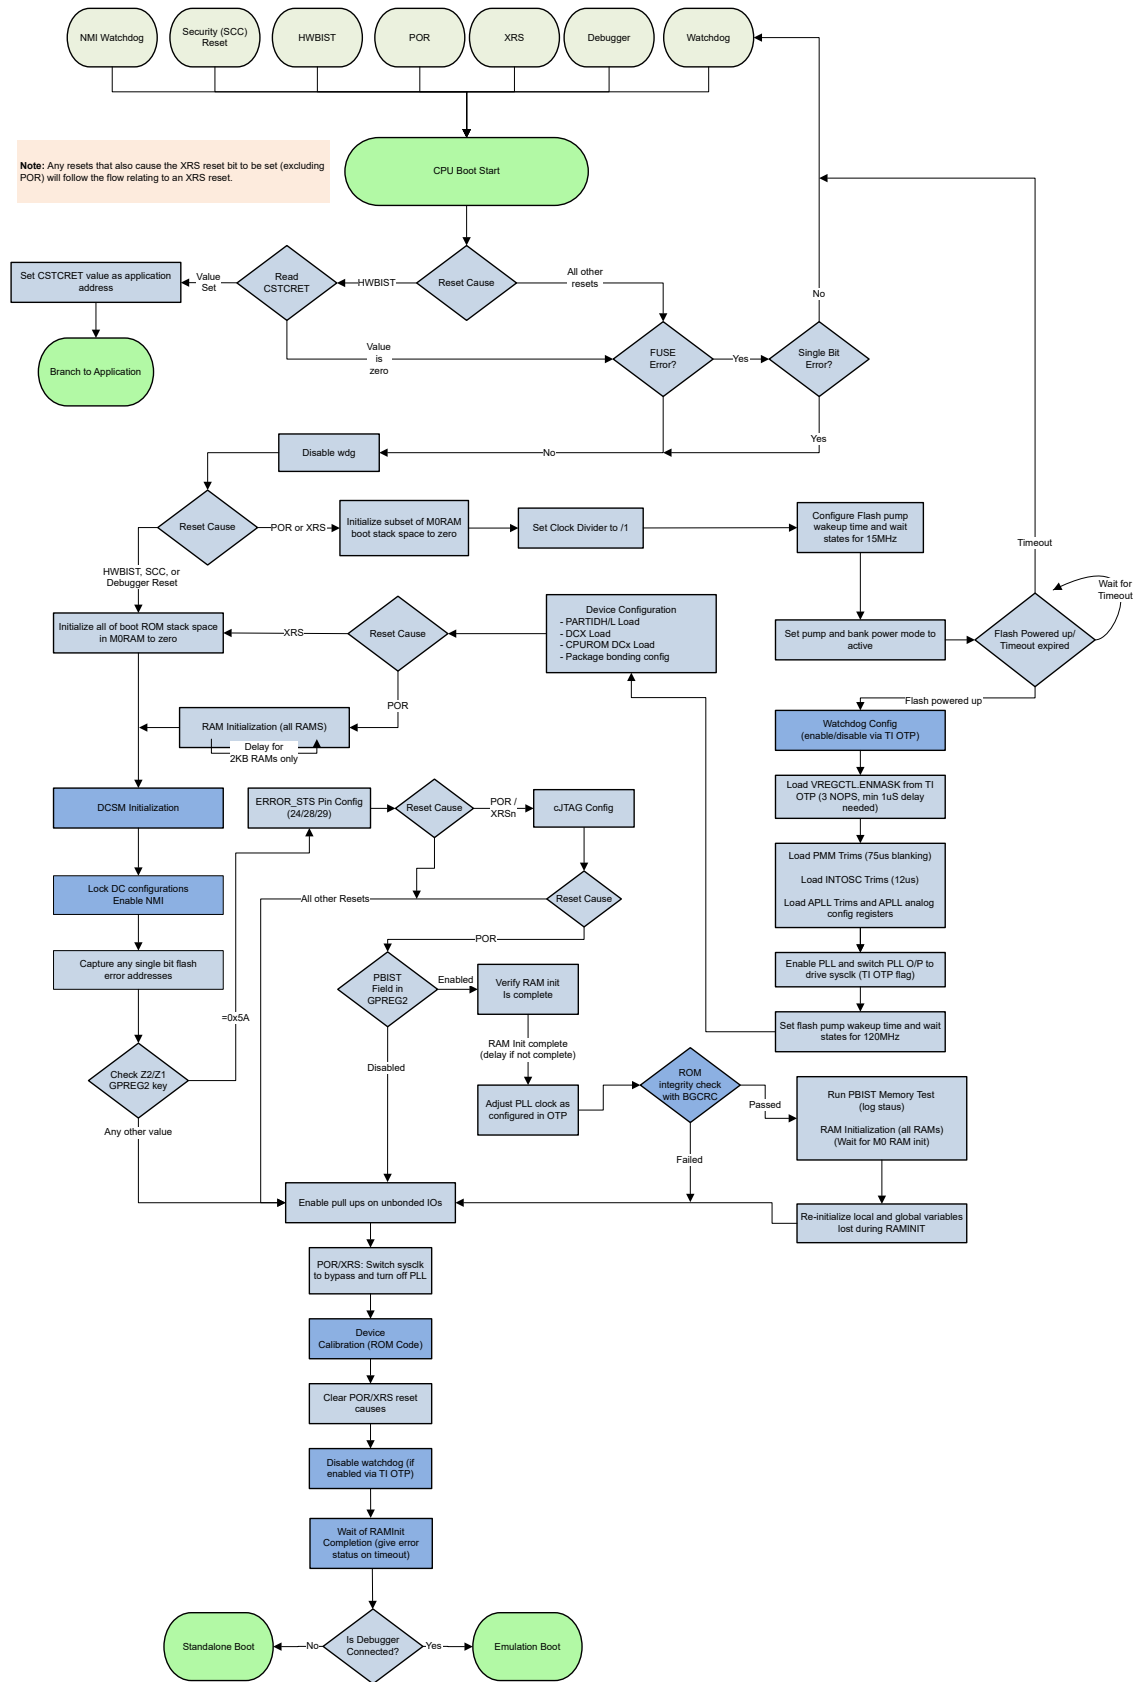

Figure 4-1. Device Boot Flow

4.6.2 Emulation Boot Flow

Figure 4-2 shows the emulation boot flow when JTAG debugger is connected.

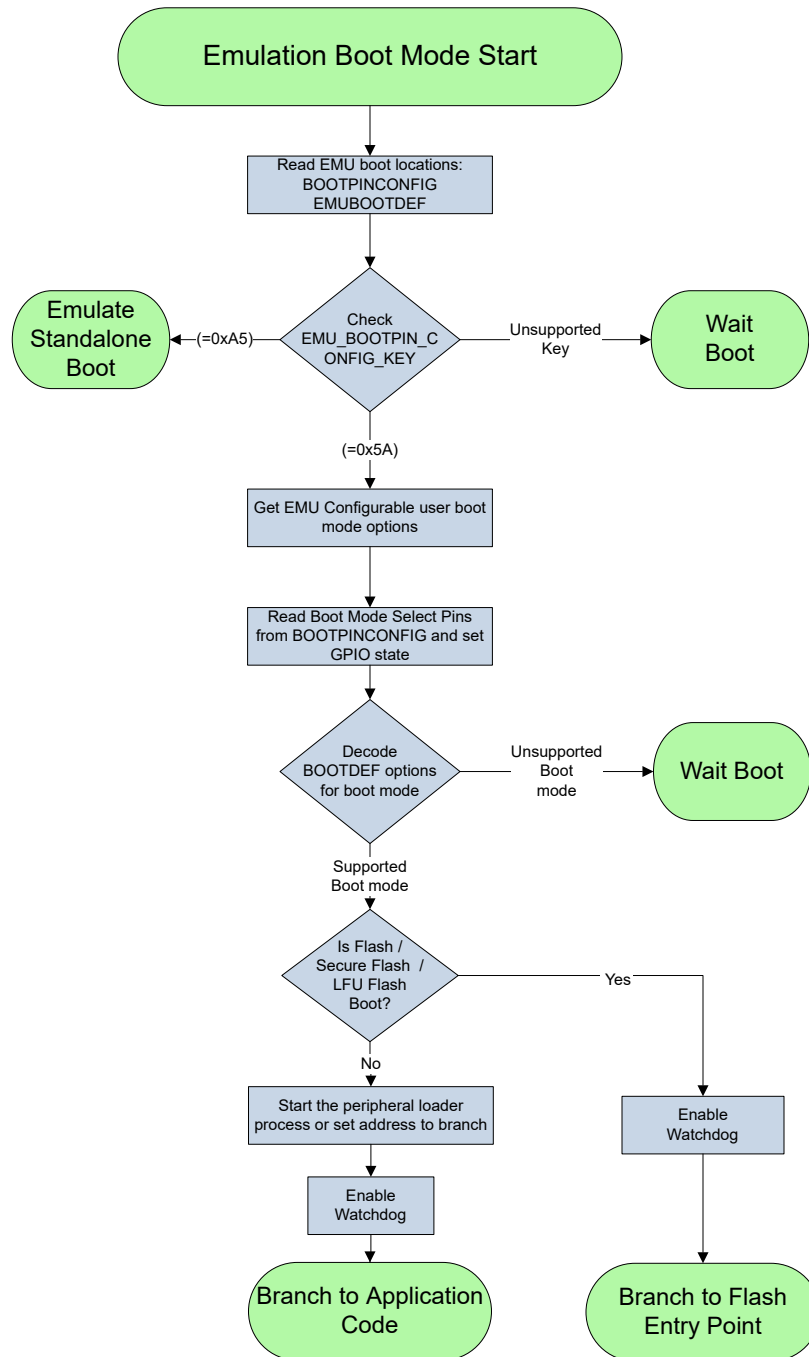

Figure 4-2. Emulation Boot Flow

4.6.3 Standalone Boot Flow

Figure 4-3 shows the standalone boot flow when no JTAG debugger is connected to the device.

Figure 4-3. CPU Standalone Boot Flow

4.7 Device Reset and Exception Handling

4.7.1 Reset Causes and Handling

Table 4-12 explains the actions each boot ROM performs upon reset for a specific reset cause.

Table 4-12. Boot ROM Reset Causes and Actions

Reset Source	Boot ROM Action
Power on Reset (POR)	<ol style="list-style-type: none"> 1. Configure Clock Divider 2. Flash Power Up 3. Device configuration and trimming 4. RAM Initialization 5. Continue default boot flow
External Reset (XRS) Includes: <ul style="list-style-type: none"> • Watchdog Reset • NMI Watchdog Reset • SIMRESET XRS 	<ol style="list-style-type: none"> 1. Configure Clock Divider 2. Flash Power Up 3. Device configuration and trimming 4. Clear RAM for boot stack 5. Continue default boot flow
Hardware Built-In Self Test (HWBIST)	<ol style="list-style-type: none"> 1. Read HWBIST return address 2. If set, branch to address 3. If not set, continue boot following "Debugger" boot flow
Secure Copy Code (SCC) Reset	<ol style="list-style-type: none"> 1. Clear RAM for boot stack 2. Continue default boot flow
SIMRESET	<ol style="list-style-type: none"> 1. Clear RAM for boot stack 2. Continue default boot flow
Debugger Reset	<ol style="list-style-type: none"> 1. Clear RAM for boot stack 2. Continue default boot flow

4.7.2 Exceptions and Interrupts Handling

Table 4-13 explains the actions boot ROM performs if any exceptions occur during boot. The exception handling philosophy in most cases, is to log the error and continue booting to reach the application.

Table 4-13. Boot ROM Exceptions and Actions

Exception Event Source	Boot ROM Action	Event Logged
Single-bit error in FUSEERR	Ignore and continue to boot	No
Multi-bit error in FUSEERR	Reset the device	No
Clock Fail	Clear the NMI flag and continue to boot	Yes
RAM Uncorrectable Error ROM Parity Error	Perform RAM initialization and reset the device	Yes ⁽¹⁾
Flash Uncorrectable Error	Reset the device	Yes
HWBIST Error	Clear the NMI flag and continue to boot	Yes
Embedded Real-time Analysis and Diagnostic (ERAD) NMI	Clear the NMI flag and continue to boot	Yes
RL NMI (CLB)	Clear the NMI flag and continue to boot	Yes
Software NMI error (Software self test error)	Reset the device	No
ITRAP Exception	Record memory address of where the illegal instruction was executed and let device reset	Yes
Unsupported PIE Interrupts	Ignore and continue to boot	No

(1) A RAM uncorrectable error or ROM parity error will clear the boot status information stored in RAM because a RAM initialization is performed to attempt to correct the error. Since the boot status information is erased, this exception can be identified in that a NMIWD reset occurred and all the RAMs are erased.

4.8 Boot ROM Description

This section explains the details regarding the device boot ROMs.

4.8.1 Boot ROM Configuration Registers

The boot ROM code involves several memory addresses and registers used during execution. There are two sets of configurations; one for emulation and one for standalone boot flow. The emulation locations located in RAM emulate the OTP configurations and can be written to as many times as needed. The user configurable DCSM OTP locations used in the standalone boot flow program the device OTP and hence can only be written once. [Table 4-14](#) details these locations. For bit field configuration details for BOOTPIN-CONFIG and BOOTDEF, see [Section 4.5.1](#) and [Section 4.5.2](#).

Additionally, the boot ROM supports boot configurations from DCSM zone 1 and zone 2 registers. Zone 2 configurations supercede zone 1 configurations, so use zone 1 configurations and use zone 2 as a secondary option.

Table 4-14. Boot ROM Registers

Boot Flow	Register Name	Boot ROM Name	Register Address	User OTP Address
Emulation	-	EMU-BOOTPIN-CONFIG	0x0000 0D00	-
	-	EMU-GPREG2	0x0000 0D02	-
	-	EMU-BOOTDEF-LOW	0x0000 0D04	-
	-	EMU-BOOTDEF-HIGH	0x0000 0D06	-
Standalone (Using Z1)	Z1-GPREG1	Z1-OTP-BOOTPIN-CONFIG	0x0005 F008	0x0007 8008
	Z1-GPREG2	Z1-OTP-BOOT-GPREG2	0x0005 F00A	0x0007 800A
	Z1-GPREG3	Z1-OTP-BOOTDEF-LOW	0x0005 F00C	0x0007 800C
	Z1-GPREG4	Z1-OTP-BOOTDEF-HIGH	0x0005 F00E	0x0007 800E
Standalone (Using Z2)	Z2-GPREG1	Z2-OTP-BOOTPIN-CONFIG	0x0005 F088	0x0007 8208
	Z2-GPREG2	Z2-OTP-BOOT-GPREG2	0x0005 F08A	0x0007 820A
	Z2-GPREG3	Z2-OTP-BOOTDEF-LOW	0x0005 F08C	0x0007 820C
	Z2-GPREG4	Z2-OTP-BOOTDEF-HIGH	0x0005 F08E	0x0007 820E

4.8.1.1 GPREG2 Usage and MPOST Configuration

Table 4-15 explains how the bit field values from the user configurable DCSM OTP location, Z1-OTP-BOOT-GPREG2 or Z2-OTP-BOOT-GPREG2, are decoded by boot ROM.

Note

Z1-GPREG2 shares ECC with Z1-GPREG1, so users can program both these locations at the same time in User OTP.

Table 4-15. DCSM Z1/Z2 GPREG2 Bit Fields

Bit	Name	Description	Boot ROM Action
31:24	Key	Write 0x5A to indicate to the boot ROM code that the bits in this register are valid.	If user sets to 0x5A, boot ROM uses the values in this register. If set to any other value, boot ROM ignores values in this register.
23:8	Reserved	Reserved	No Action
7:6	MPOST ⁽¹⁾	0x0 = Run MPOST with PLL disabled (10-MHz internal oscillator) 0x1 = Run MPOST with PLL enabled for 95 MHz 0x2 = Run MPOST with PLL enabled for 47.5 MHz 0x3 = Disable MPOST	When configured to a valid value, MPOST POR memory self-test is run on all device memories
5:4	ERROR_STS_PIN configuration	0x0 – GPIO24, MUX Option 13 0x1 – GPIO28, MUX Option 13 0x2 – GPIO29, MUX Option 13 0x3 – ERROR_STS function disabled (default)	This indicates which GPIO pin is supposed to be used as ERROR_PIN and boot ROM configures the mux for the pin. The ERROR_STS pin mux configuration is locked by the boot ROM, but not committed.
3:0	CJTAGNODEID	CJTAGNODEID[3:0]	Boot ROM takes this values and programs the lower 4 bits of the CJTAGNODEID register.

- (1) If MPOST is configured to run with PLL enabled and the PLL fails to lock, then the MPOST run is skipped. This does not apply, if MPOST is configured to use INTOSC2 with PLL disabled.

4.8.2 Entry Points

This sections gives details about the entry point addresses for various boot modes. These entry points direct the boot ROM what address to branch to at the end of booting as per the selected boot mode.

Table 4-16 gives details about the entry point addresses for Flash boot mode.

Table 4-17 gives details about the entry point addresses for RAM boot mode.

Table 4-16. Flash Entry Point Addresses

Option	BOOTDEFx Value	Flash Sector	Address	Packages Supported
0	0x03	CPU Bank 0 Sector 0	0x0008 0000	All
1	0x23	CPU Bank 0 Sector 8	0x0008 8000	All
2	0x43	CPU Bank 0 End of Sector 15	0x0008 FFF0	All
3	0x63	CPU Bank 1 Sector 0	0x0009 0000	All
4	0x83	CPU Bank 1 End of Sector 7	0x0009 7FF0	All
5	0xA3	CPU Bank 1 End of Sector 15	0x0009 FFF0	All
6	0xC3	CPU Bank 2 Sector 0	0x000A 0000	All
7	0xE3	CPU Bank 2 End of Sector 15	0x000A FFF0	All

Table 4-17. RAM Entry Point Address

Option	BOOTDEFx Value	RAM Entry Point	Package Supported
0	0x05	0x0000 0000	All

4.8.3 Wait Points

The wait mode puts the CPU in a loop in the boot ROM code and does not branch to the user application code. The device can enter wait boot mode either through manually being set or because of some issue during boot up. Using wait boot mode is recommended when using a debugger to avoid any JTAG issues. There is an ESTOP provided for debugging during Wait boot.

Table 4-18. Wait Boot Options

Option	BOOTDEFx Value	Watchdog Status	Package Supported
0 (default)	0x04	Enabled	All
1	0x24	Disabled	All

During boot ROM execution, there are situations where the CPU can enter a wait loop in the code. This state can occur for a variety of reasons. [Table 4-19](#) details the address ranges that the CPU PC register value falls between if the CPU has entered one of these instances.

Following are the actions for entering wait boot mode:

- Wait boot is set by the user as the boot mode.
- Boot mode is unrecognizable and a debugger is connected to the device.
- The emulation BOOTPIN_CONFIG key isn't equal to 0xA5 or 0x5A.
- An error occurs during emulation boot and the boot mode pins are decoded with a value not recognized as a valid boot mode.

Table 4-19. Wait Point Addresses

Address Range	Description
0x3FB8B9 – 0x3FB8C0	In Wait Boot Mode
0x3FC7D0 – 0x3FC7D8	In SCI Boot waiting on autobaud lock
0x3FEDFE – 0x3FEDEC	In NMI Handler
0x3FEDEC9 – 0x3FEEDF9	In ITRAP ISR
0x3FCB96 - 0x3FCB9A	In Parallel boot waiting for control signal

4.8.4 Secure Flash Boot

Secure Flash boot mode is similar to Flash boot mode in that the boot flow branches to the configured memory address in Flash except only after the Flash memory contents have been authenticated. The Flash authentication uses a Cipher-based Message Authentication Protocol (CMAC) to authenticate 16 KB of Flash starting from the configured Flash entry point address. The CMAC calculation requires a user-defined 128-bit key programmed in the CPU User OTP Zone 1 Header OTP CMACKEY bit field. Additionally, the user must calculate the golden CMAC tag based on the 16 KB Flash memory range and store the CMAC tag along with the user code at a hardcoded address in Flash. During secure Flash boot, the calculated CMAC tag is compared to the user golden CMAC tag in Flash to determine the pass/fail status of the CMAC authentication. When authentication passes, boot flow continues and branches to Flash to begin executing the application. When authentication fails, the device is reset.

For the available secure Flash boot entry address options, refer to [Section 4.8.2](#).

For generating the secure Flash golden CMAC tag for CPU, refer to the [TMS320C28x Assembly Language Tools User's Guide](#) within section "Using Secure Flash Boot on TMS320F2838x Devices" for instructions.

Note

Both the CMAC golden signature and CMAC key are stored in the most-significant double format, but each 32-bit section is in little-endian format.

Key: 2B7E 1516 28AE D2A6 ABF7 1588 09CF 4F3C

(MSB is 2B and LSB is 3C)

CMACKEY0 = 0x2B7E 1516

CMACKEY1 = 0x28AE D2A6

CMACKEY2 = 0xABF7 1588

CMACKEY3 = 0x09CF 4F3C

Make sure that the Flash sector that encompasses the configured Flash entry point and the first 16KB of Flash is assigned to Zone 1 for the core setup for secure Flash boot.

Recommended to use the device JTAGLOCK when using secure Flash boot.

APIs for CMAC calculation and authentication is provided as part of ROM. Details are available in [Section 4.8.10](#)

Table 4-20. Secure Flash Boot Details

Details	Location Address
CMAC Signature Address	Flash Entry Point Address + 0x2
CMAC Key Address (128-bit key)	DCSM Z1 OTP CMACKEY0/1/2/3
Flash Entry Point (Bank 0, Sector 0)	0x0008 0000
Flash Entry Point (Bank 0, Sector 8)	0x0008 8000
Flash Entry Point (Bank 0, End of Sector 15)	0x0008 FFF0
Flash Entry Point (Bank 1, Sector 0)	0x0009 0000
Flash Entry Point (Bank 1, End of Sector 7)	0x0009 7FF0
Flash Entry Point (Bank 1, End of Sector 15)	0x0009 FFF0
Flash Entry Point (Bank 2, Sector 0)	0x000A 0000
Address Range for CMAC Calculation	Start: Flash Entry Point Address End: Flash Entry Point Address + 16KB

Table 4-21. Secure Flash Tag and Key Details

Name	Address	Details
CMAC Golden Tag (128-bit)	CPU: <i>Flash Entry Point Address + 0x2</i>	<p>Located in Flash, offset from the entry point address, by 2 words (CPU). When CMAC calculations are performed, the golden tag location in memory is considered all 0xFs. Refer to Example 4-1 for an example regarding linker configuration on CPU.</p> <p>Lower memory contains the tag's MSW and higher memory contains the LSW.</p> <p>Example (on CPU): Tag = 0x0011 2233 4455 6677 8899 AABB CCDD EEFF Address 0x0 = 0x0011 2233 Address 0x2 = 0x4455 6677 Address 0x4 = 0x8899 AABB Address 0x6 = 0xCCDD EEFF</p>

Table 4-21. Secure Flash Tag and Key Details (continued)

Name	Address	Details
CMAC 128-Bit Key	0x0007 8018	Located in CPU Zone 1 User Header OTP (CMACKEY0, CMACKEY1, CMACKEY2, CMACKEY3) CMACKEY0 contains the key's MSW and CMACKEY3 contains the LSW. Example: Key = 0x0011 2233 4455 6677 8899 AABB CCDD EEFF CMACKEY0 = 0x0011 2233 CMACKEY1 = 0x4455 6677 CMACKEY2 = 0x8899 AABB CMACKEY3 = 0xCCDD EEFF

Table 4-22. Secure Flash Authentication Failure Actions

CPU	Action on Failed Authentication
C28x CPU	1. Emulation only - Halt debugger (ESTOP) 2. Wait in endless loop (for device reset due to WD reset)

Table 4-23. Secure Flash on all CPUs Recommended Flow

Step	Action
1	Secure Flash boot CPU
2	Any Flash beyond the first 16KB from the entry point that is planned for use can be authenticated by the user using a different CMAC golden tag embedded at an address somewhere within the already authenticated 16KB of Flash.

Example 4-1. Secure Flash CPU1 Linker File Example

```

MEMORY
{

  .
}
    
```

4.8.5 Firmware Update (FWU) Flash Boot

Firmware Update (FWU) boot mode is required to handle the Firmware Update feature. In this boot mode, the boot loader reads the version number from images present in multiple banks and identifies the latest image. The boot ROM then hands off the execution to the application with the latest version. To support FWU boot mode, each Flash bank containing an application image needs a few fields as shown in [Table 4-24](#).

Table 4-24. FWU Application Image Format

Image Address Offset	Content
0x0	Application entry point (32-bit)
0xA	Key (32-bit) Valid Key = 0x5A5A 5A5A
0xC	Firmware version number (32-bit)

Application entry point: This is the code execution start address of the image stored in Flash.

Key: This 32-bit field determines if this image is valid. The image in a bank is considered valid only if the location contains the value 0x5A5A 5A5A. In case all banks have invalid keys, an error is flagged in `boot_status` variable and program jumps to a while loop in standalone boot mode (ESTOP in emulation boot mode).

Firmware version number: This 32-bit field is the version number of the firmware or application. 0xFFFF FFFF is considered as the initial value and this needs to be decremented after every update. The image with lower version number is the latest application. If all valid images have same version number, then bank-0 (or the lowest numbered bank) is chosen.

For example, if bank-0 has invalid **Key** and bank-1 and bank-2 have valid keys, then the one having lowest **Firmware version number** is selected for boot. If both are the same, then bank-1 is selected.

[Table 4-25](#) shows the entry points for FWU boot mode.

Table 4-25. FWU Entry Point Addresses

Option	BOOTDEFx Value	Bank 0	Bank 1	Bank 2
0	0x0B	0x0008 0000	0x0009 0000	0x000A 0000
1	0x2B	0x0008 8000	0x0009 8000	0x000A 8000
2	0x4B	0x0008 FFF0	0x0009 FFF0	0x000A FFF0
3	0x6B	0x0008 8000	0x0009 0000	0x000A 0000
4	0x8B	0x0008 EFF0	0x0009 7FF0	0x0008 7FF0

For example, if Option 0 with Bank 0 has the application image:

[0008 0000-0008 0001] = Application entry point

[0008 000A-0008 000B] = Key

[0008 000C-0008 000D] = Firmware version number

4.8.6 Memory Maps

4.8.6.1 Boot ROM Memory Maps

Table 4-26 details the ROM memory maps.

Table 4-26. Boot ROM Memory Map

Memory	Origin Address	Length (Words)
ROM Signature	0x003F 0000	0x0002

Data (Run)	0x0000 F870	0x078A
Version (Run)	0x0000 FFFA	0x0006

4.8.6.3 Reserved RAM Memory Maps

[Table 4-29](#) details memory usage in RAM that is reserved for boot ROM to use. These memory sections must be reserved in the user application.

Table 4-29. Reserved RAM Memory Map

Memory	Description	Origin Address	Length (Words)
RAM	Boot Status, Boot Mode, MPOST Status, Boot Stack	0x0000 0002	0x0126

4.8.7 ROM Tables

[Table 4-30](#) details the boot ROM symbol libraries that can be integrated into an application to use the available ROM functions and tables.

Table 4-30. ROM Symbol Tables

ROM Symbols	Library Name	Location
ROM Bootloaders and Functions	F28003xCPU_BootROM_Symbols	Under <i>/libraries/boot_rom</i> in C2000Ware
FPU32 Tables	F28003xCPU_BootROM_Symbols	
IQmath	F28003xCPU_IQMathROM_Symbols	

4.8.8 Boot Modes and Loaders

The available boot modes and bootloaders supported on this device are detailed in this section.

4.8.8.1 Boot Modes

This section details the available boot modes that do not involve a peripheral boot loader. [Table 4-31](#) details the available boot modes that do not involve a peripheral boot loader.

Table 4-31. Boot Mode Availability

Boot Mode	CPU Support
Flash Boot	C28x CPU
RAM Boot	C28x CPU
Wait Boot	C28x CPU
Secure Flash Boot	C28x CPU
FWU Flash Boot	C28x CPU

4.8.8.1.1 Flash Boot

Flash boot mode branches to the configured memory address in Flash. Refer to [Section 4.8.2](#) for all the available Flash address options.

4.8.8.1.2 RAM Boot

RAM boot mode branches to the configured memory address in RAM. Refer to [Section 4.8.2](#) for all the available RAM address options.

4.8.8.1.3 Wait Boot

Wait boot mode branches to the memory address as mentioned in [Section 4.8.3](#).

Table 4-32. Wait Boot Options

Option	BOOTDEFx Value	Watchdog Status	Package Supported
0 (default)	0x04	Enabled	All
1	0x24	Disabled	All

4.8.8.2 Bootloaders

This section details the available boot modes that use a peripheral boot loader. For more specific details on the supported data stream structure used by the following bootloaders, refer to [Section 4.9.1](#).

4.8.8.2.1 SCI Boot Mode

The SCI boot mode asynchronously transfers code from SCI-A to internal memory. This boot mode only supports an incoming 8-bit data stream and follows the data flow as shown in [Figure 4-4](#).

Figure 4-4. Overview of SCI Bootloader Operation

The device communicates with the external host by communication through the SCI-A peripheral. The autobaud feature of the SCI port is used to lock baud rates with the host. For this reason the SCI loader is very flexible and you can use a number of different baud rates to communicate with the device.

After each data transfer, the bootloader echoes back the 8-bit character received to the host. This allows the host to check that each character was received by the bootloader.

At higher baud rates, the slew rate of the incoming data bits can be affected by transceiver and connector performance. While normal serial communications work well, this slew rate can limit reliable auto-baud detection at higher baud rates (typically beyond 100 kbaud) and cause the auto-baud lock feature to fail. To avoid this, the following is recommended:

1. Achieve a baud-lock between the host and SCI bootloader using a lower baud rate.
2. Load the incoming application or custom loader at this lower baud rate.
3. The host can then handshake with the loaded application to set the SCI baud rate register to the desired high baud rate.

Figure 4-5. Overview of SCI Boot Function

4.8.8.2.2 SPI Boot Mode

The SPI loader expects an SPI-compatible 16-bit or 24-bit addressable serial EEPROM or serial Flash device to be present on the SPI-A pins as shown in Figure 4-6. The SPI bootloader supports an 8-bit data stream and does not support a 16-bit data stream.

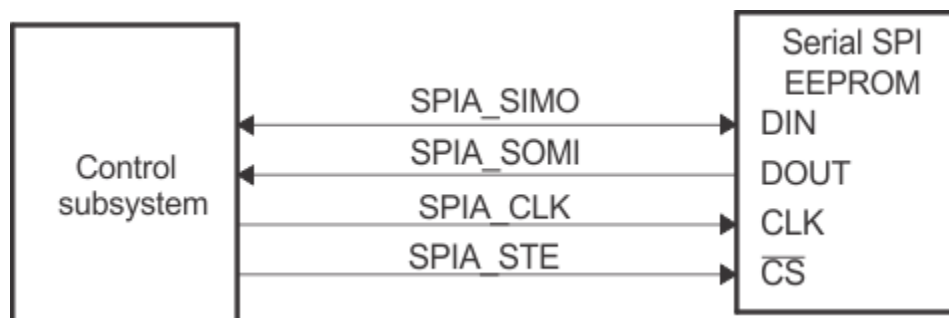

Figure 4-6. Overview of SPI Bootloader Operation

The SPI boot ROM loader initializes the SPI module to interface to a serial SPI EEPROM or Flash. Devices of this type include, but are not limited to, the Xicor X25320 (4Kx8) and Xicor X25256 (32Kx8) SPI serial SPI EEPROMs and the Atmel AT25F1024A serial Flash.

The SPI boot ROM loader initializes the SPI with the following settings: FIFO enabled, 8-bit character, internal SPICLK master mode and talk mode, clock phase = 1, polarity = 0, using the slowest baud rate.

If the download is to be performed from an SPI port on another device, then that device must be set up to operate in the slave mode and mimic a serial SPI EEPROM. Immediately after entering the SPI_Boot function, the pin functions for the SPI pins are set to primary and the SPI is initialized. The initialization is done at the slowest speed possible. Once the SPI is initialized and the key value read, you can specify a change in baud rate or low-speed peripheral clock. Table 4-33 shows the 8-bit data stream used by the SPI.

Table 4-33. SPI 8-Bit Data Stream

Byte	Contents

...	Blocks of data in the format size/destination address/data as shown in the generic data stream description
...
...	Data for this section.
n	LSB: 00h
n+1	MSB: 00h - indicates the end of the source

The data transfer is done in "burst" mode from the serial SPI EEPROM. The transfer is carried out entirely in byte mode (SPI at 8 bits/character). A step-by-step description of the sequence is:

1. The SPI-A port is initialized.
2. The GPIO pin, as defined by SPI option configured from [Table 4-43](#), is used as a chip-select for the serial SPI EEPROM or Flash.
3. The SPI-A outputs a read command for the serial SPI EEPROM or Flash.
4. The SPI-A sends the serial SPI EEPROM an address 0x0000; that is, the host requires that the EEPROM or Flash must have the downloadable packet starting at address 0x0000 in the EEPROM or Flash. The loader is compatible with both 16-bit addresses and 24-bit addresses.
5. The next word fetched must match the key value for an 8-bit data stream (0x08AA). The least-significant byte (LSB) of this word is the byte read first and the most-significant byte (MSB) is the next byte fetched. This is true of all word transfers on the SPI. If the key value does not match, then the load is aborted and the bootloader jumps to Flash.
6. The next two bytes fetched can be used to change the value of the low speed peripheral clock register (LOSPCP) and the SPI baud rate register (SPIBRR). The first byte read is the LOSPCP value and the second byte read is the SPIBRR value. The next seven words are reserved for future enhancements. The SPI bootloader reads these seven words and discards them.
7. The next two words makeup the 32-bit entry point address where execution continues after the boot load process is complete. This is typically the entry point for the program being downloaded through the SPI port.
8. Multiple blocks of code and data are then copied into memory from the external serial SPI EEPROM through the SPI port. The blocks of code are organized in the standard data stream structure presented earlier. This is done until a block size of 0x0000 is encountered. At that point in time the entry point address is returned to the calling routine that then exits the bootloader and resumes execution at the address specified.

Figure 4-7. Data Transfer from EEPROM Flow

4.8.8.2.3 I2C Boot Mode

The I2C bootloader expects an 8-bit wide I2C-compatible EEPROM device to be present at address 0x50 on the I2C-A bus as shown in Figure 4-8. The EEPROM must adhere to conventional I2C EEPROM protocol, as described in this section, with a 16-bit base address architecture.

Figure 4-8. EEPROM Device at Address 0x50

If the download is to be performed from a device other than an EEPROM, then that device must be set up to operate in the slave mode and mimic the I2C EEPROM. Immediately after entering the I2C boot function, the GPIO pins are configured for I2C-A operation and the I2C is initialized. The following requirements must be met when booting from the I2C module:

- The input frequency to the device must be in the appropriate range.
- The EEPROM must be at slave address 0x50.

The bit-period prescalers (I2CCLKH and I2CCLKL) are configured by the bootloader to run the I2C at a 50 percent duty cycle at 100kHz bit rate (standard I2C mode) when the system clock is 10MHz. These registers can be modified after receiving the first few bytes from the EEPROM. This allows the communication to be increased up to a 400kHz bit rate (fast I2C mode) during the remaining data reads.

Arbitration, bus busy, and slave signals are not checked. Therefore, no other master is allowed to control the bus during this initialization phase. If the application requires another master during I2C boot mode, that master must be configured to hold off sending any I2C messages until the application software signals that it is past the bootloader portion of initialization.

The non-acknowledgment bit is checked only during the first message sent to initialize the EEPROM base address. This is to make sure that an EEPROM is present at address 0x50 before continuing. If an EEPROM is not present, the non-acknowledgment bit is not checked during the address phase of the data read messages (I2C_Get Word). If a non-acknowledgment is received during the data read messages, the I2C bus hangs. Table 4-34 shows the 8-bit data stream used by the I2C.

The I2C EEPROM protocol required by the I2C bootloader is shown in Figure 4-10 and Figure 4-11. The first communication, which sets the EEPROM address pointer to 0x0000 and reads the KeyValue (0x08AA), is shown in Figure 4-10. All subsequent reads are shown in Figure 4-11 and are read two bytes at a time.

Figure 4-9. Overview of I2C Boot Function

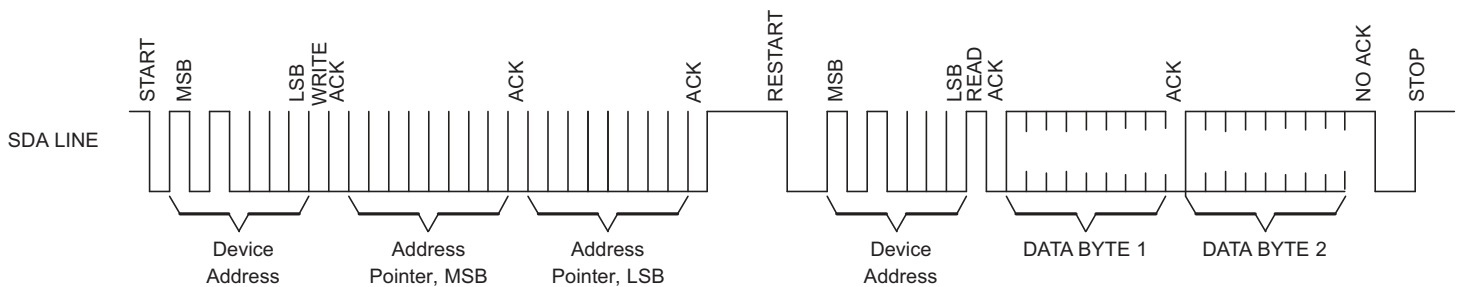

Figure 4-10. Random Read

Figure 4-11. Sequential Read

4.8.8.2.4 Parallel Boot Mode

The parallel general purpose I/O (GPIO) boot mode asynchronously transfers code from the host to the C28x internal memory. Each value is 8-bits long and follows the same data flow as outlined in [Figure 4-12](#).

Figure 4-12. Overview of Parallel GPIO Bootloader Operation

The control subsystem communicates with the external host device by polling/driving the Host Control and C28x control lines. The handshake protocol shown in [Figure 4-13](#) must be used to successfully transfer each word using GPIO [D0:D7]. This protocol is very robust and allows for a slower or faster host to communicate with the master subsystem.

Two consecutive 8-bit words are read to form a single 16-bit word. The least-significant byte (LSB) is read first followed by the most-significant byte (MSB). In this case, data is read from GPIO[D0:D7].

The 8-bit data stream is shown in [Table 4-35](#).

Table 4-35. Parallel GPIO Boot 8-Bit Data Stream

Bytes	GPIO[D0:D7] (Byte 1 of 2)	GPIO[D0:D7] (Byte 2 of 2)	Description
1 2	AA	08	0x08AA (KeyValue for memory width = 16 bits)

27 28	DD	CC	Destination address of first block Addr[15:0] (Addr = 0xAABB CCDD)
29 30	BB	AA	First word of the first block in the source being loaded = 0xAABB
...			...
...			Data for this section.
...			...
.	BB	AA	Last word of the first block of the source being loaded = 0xAABB
.	NN	MM	Block size of the 2nd block to load = 0xMMNN words
.	BB	AA	Destination address of second block Addr[31:16]
.	DD	CC	Destination address of second block Addr[15:0]
.	BB	AA	First word of the second block in the source being loaded
.			...
n n+1	BB	AA	Last word of the last block of the source being loaded (More sections if required)
n+2 n+3	00	00	Block size of 0000h - indicates end of the source program

The device first signals the host that the device is ready to begin data transfer by pulling the C28x control pin low. The host load then initiates the data transfer by pulling the DSP control pin low. The complete protocol is shown in Figure 4-13.

Figure 4-13. Parallel GPIO Bootloader Handshake Protocol

1. The device indicates the device is ready to start receiving data by pulling the C28x control pin low.
2. The bootloader waits until the host puts data on GPIO [D0:D7]. The host signals to the device that data is ready by pulling the host control pin low.
3. The device reads the data and signals the host that the read is complete by pulling C28x control high.
4. The bootloader waits until the host acknowledges the device by pulling host control high.
5. The device again indicates the device is ready for more data by pulling the C28x control pin low.

This process is repeated for each data value to be sent.

Figure 4-14 shows an overview of the Parallel GPIO bootloader flow.

Figure 4-14. Overview of Parallel GPIO Boot Function

Figure 4-15 shows the transfer flow from the host side. The operating speed of the CPU and host are not critical in this mode as the host waits for the device and the device waits for the host. In this manner, the protocol works with both a host running faster and a host running slower than the device.

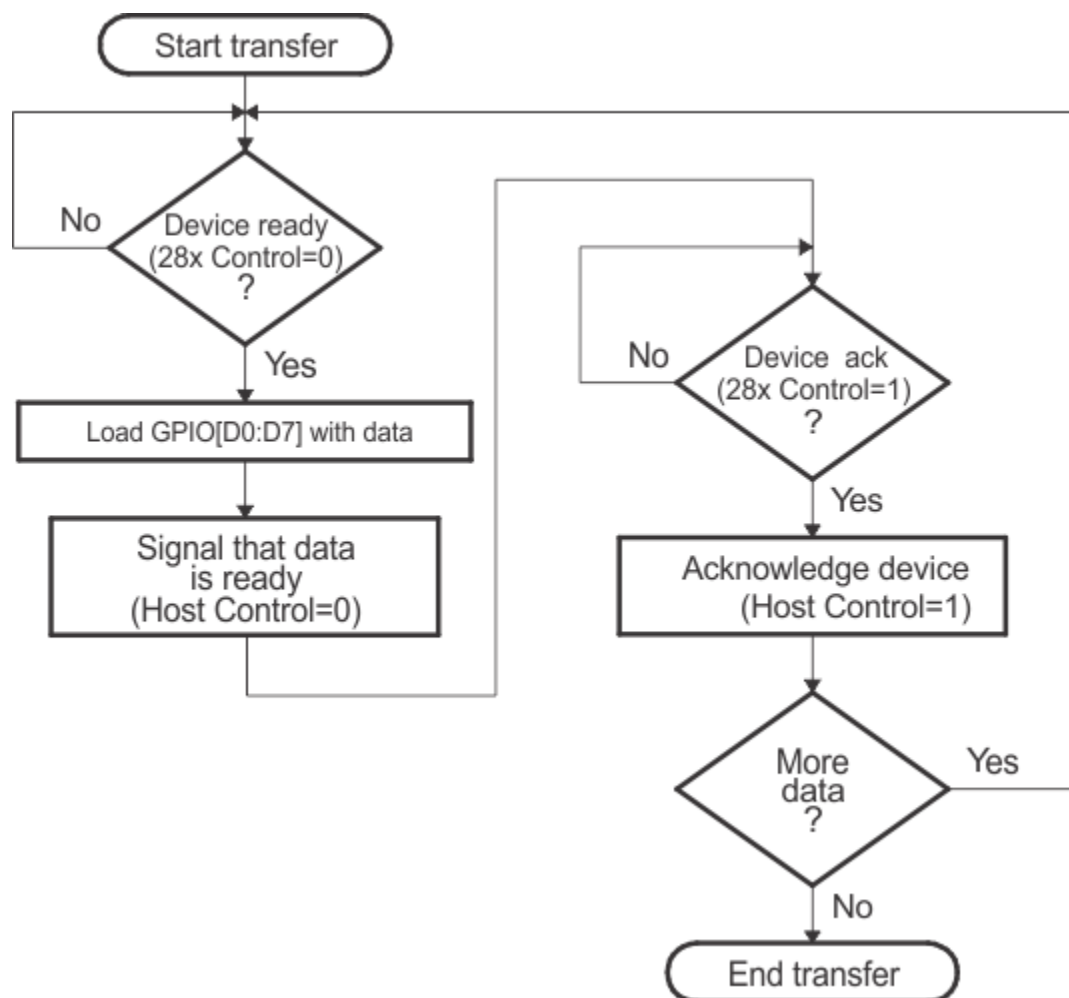

Figure 4-15. Parallel GPIO Mode - Host Transfer Flow

Figure 4-16 shows the flow used to read a single word of data from the parallel port.

- **8-bit data stream**

The 8-bit routine, shown in Figure 4-16, discards the upper eight bits of the first read from the port and treats the lower eight bits masked with D7 in bit position 7 and D6 in bit position six as the least-significant byte (LSB) of the word to be fetched. The routine then performs a second read to fetch the most-significant byte (MSB). The routine then performs a second read to fetch the MSB and then combines the MSB and LSB into a single 16-bit value to be passed back to the calling routine.

Figure 4-16. 8-Bit Parallel GetWord Function

4.8.8.2.5 CAN Boot Mode

The CAN bootloader asynchronously transfers code from CAN-A to internal memory as shown in [Figure 4-17](#). The host can be any CAN node. The communication is first done with 11-bit standard identifiers (with a MSGID of 0x1) using two bytes per data frame. The host can download a kernel to reconfigure the CAN if higher data throughput is desired.

Figure 4-17. Overview of CAN-A Bootloader Operation

The bit timing registers are programmed in such a way that a 100kbps bit rate is achieved with a 20MHz external oscillator, as shown in [Table 4-36](#).

Table 4-36. Bit-Rate Value for Internal Oscillators

OSCCLK	SYSCLK	Bit Rate
20MHz	10MHz	100kbps

The SYSCLKOUT values shown are the reset values with the default PLL setting. The BRP and bit-time values are hard-coded to 10 and 20, respectively.

Note

The CAN boot loader uses XTAL as the bit clock source and INTOSC2 as the system clock source.

Mailbox 1 is programmed with a standard MSGID of 0x1 for boot-loader communication. The CAN host can transmit only two bytes at a time, LSB first and MSB next. For example, to transmit the word 0x08AA to the device, transmit AA first, followed by 08. The program flow of the CAN bootloader is identical to the SCI bootloader. The data sequence for the CAN bootloader is shown in [Table 4-37](#).

Table 4-37. CAN 8-Bit Data Stream

4.8.8.2.6 CAN-FD Boot Mode

The CAN-FD bootloader asynchronously transfers code from CAN-FD to internal memory and follows the same bootloader execution flow as [Section 4.8.8.2.5](#). The host can be any CAN-FD node. The communication is first done with 11-bit standard identifiers (with a MSGID of 0x1) using two bytes per data frame. The CAN-FD uses a fixed 64-byte payload size and default bit rate of 1Mbps for nominal phase and 2Mbps for data phase. Bit data timing can be optionally reconfigured after receiving first data segment. The CAN-FD supports the same debug boot mode and GPIO option 0 as the CAN bootloader.

Mailbox 1 is programmed with a standard MSGID of 0x1 for boot-loader communication. The CAN-FD host can transmit only two bytes at a time, LSB first and MSB next. For example, to transmit the word 0x08AA to the device, transmit AA first, followed by 08. The program flow of the CAN-FD bootloader is identical to the CAN bootloader. The data sequence for the CAN-FD bootloader is shown in [Table 4-38](#).

Table 4-38. CAN-FD 8-Bit Data Stream

Bytes	Byte 1 of 2	Byte 2 of 2	Description	
1	2	AA	08	0x08AA (KeyValue for memory width = 16 bits)
3	4	XX (for example, BB)	XX (for example, AA)	0: Ignored Nonzero: Custom nominal bit register timing [31:16]

4.8.9 GPIO Assignments

This section details the GPIOs and boot option values used for boot mode set in the BOOT_DEF memory location located at Z1-OTP-BOOTDEF-LOW/ Z2-OTP-BOOTDEF-LOW and Z1-OTP-BOOTDEF-HIGH/ Z2-OTP-BOOTDEF-HIGH. Refer to [Section 4.5.2](#) on how to configure BOOT_DEF. When selecting a boot mode option, make sure to verify that the necessary pins are available in the pin mux options for the specific device package being used.

Table 4-39. SCI Boot Options

Option	BOOTDEF Value	SCITXDA GPIO	SCIRXDA GPIO
0 (default)	0x01	GPIO29	GPIO28
1	0x21	GPIO16	GPIO17
2	0x41	GPIO8	GPIO9
3	0x61	GPIO2	GPIO3
4	0x81	GPIO16	GPIO3

Table 4-40. CAN Boot Options

Option	BOOTDEF Value	CANTXA GPIO	CANRXA GPIO
0 (default)	0x02	GPIO4	GPIO5
1	0x22	GPIO32	GPIO33
2	0x42	GPIO2	GPIO3
3	0x62	GPIO13	GPIO12
4 ⁽¹⁾	0x82	GPIO4	GPIO5
5 ⁽¹⁾	0xA2	GPIO32	GPIO33
6 ⁽¹⁾	0xC2	GPIO2	GPIO3
7 ⁽¹⁾	0xE2	GPIO13	GPIO12

- (1) These options use the same GPIO pins for communication as the preceding rows. However, the GPIO pins transmit a frame before beginning the boot-loading process to help ascertain proper functionality of the module.

Table 4-41. CAN-FD Boot Options

Option	BOOTDEFx Value	CANTXA GPIO	CANRXA GPIO
0	0x08	GPIO4	GPIO5
1	0x28	GPIO1	GPIO0
2	0x48	GPIO13	GPIO12
3 ⁽¹⁾	0x68	GPIO4	GPIO5
4 ⁽¹⁾	0x88	GPIO1	GPIO0
5 ⁽¹⁾	0xA8	GPIO13	GPIO12

- (1) These options use the same GPIO pins for communication as the preceding rows. However, the GPIO pins transmit a frame before beginning the boot-loading process to help ascertain proper functionality of the module.

4.8.10 Secure ROM Function APIs

There are a few functions that are available within Secure ROM to be called by the application to perform EXEONLY Flash/RAM tasks in a secure manner.

Note

The application must disable interrupts before calling one of the EXEONLY function APIs.

If a vector fetch request is given by the CPU (C28) while the program counter (PC) is within the EXEONLY function API code of the Secure ROM, a reset initiates (RSN, if from C28). The consequence of this is if an NMI or ITRAP or Bus Fault occurs while the PC is executing one of the EXEONLY API functions, the NMI/ITRAP/Fault cannot be serviced because a reset is initiated to the subsystem.

The **secure copy code zone 1 and zone 2 functions** allow EXEONLY Flash to be copied to EXEONLY RAM in a secure manner. The source must be from EXEONLY Flash and the destination to EXEONLY RAM. There is no support to copy EXEONLY ROM or EXEONLY RAM to RAM. Both Flash and RAM must be set to EXEONLY and configured for the same zone. Additionally, the copy size must not cross over the Flash sector boundary. Any violations of these requirements results in a failure status returned. Upon successful copy of the data, the number of 16-bit words copied is returned.

Table 4-45. Secure Copy Code Function

CPU	Function Prototype	Function Parameters	Function Return Value
CPU (C28x)	<pre>uint16_t SecureCopyCodeZ1(uint32_t size, uint16_t *dst, uint16_t *src) uint16_t SecureCopyCodeZ2(uint32_t size, uint16_t *dst, uint16_t *src)</pre>	<p><i>size</i> : The number of 16-bit words to copy</p> <p><i>dst</i> : The destination memory address in EXEONLY RAM</p> <p><i>src</i> : The source memory address in EXEONLY Flash</p>	<p>0xFFFF : Returns the number of 16-bit words copied</p> <p>0x0000 : Indicates one of the following: Copy length is zero; Copy size crosses over Flash sector boundary; Flash and RAM do not belong to the same zone; Flash and/or RAM are not set to EXEONLY; Error occurred during data copy</p>

The **secure CRC calculation zone 1 and zone 2 functions** allow a safety CRC check of EXEONLY memory in a secure manner. The CRC length provided must be a value from 1 to 8 where 1 represents a CRC size of 32 16-bit words and 8 represents a CRC size of 4096 16-bit words. The source address specifies the starting address for the CRC and the destination address is the location that the resulting CRC value is stored. The source and destination memories must be configured for the same zone. Additionally, the CRC length must not cross over the Flash sector or RAM block boundary. Any violations of these requirements results in a failure status returned. Upon successful CRC, the number of 16-bit words CRC'd is returned.

Table 4-46. Secure CRC Calculation Function

CPU	Function Prototype	Function Parameters	Function Return Value
CPU (C28x)	<pre>uint16_t SecureCRCCalcZ1(uint16_t len_id, uint16_t *dst, uint16_t *src) uint16_t SecureCRCCalcZ2(uint16_t size, uint16_t *dst, uint16_t *src)</pre>	<p><i>len_id</i> : A number from 1 to 8 that corresponds to length options of 32, 64, 128, 256, 512, 1024, 2048, or 4096 16-bit words</p> <p><i>dst</i> : The destination memory address for resulting CRC</p> <p><i>src</i> : The source memory address to begin CRC calculation</p>	<p>0xFFFF : Returns the number of 16-bit words CRC'd</p> <p>0x0000 : Indicates one of the following: Invalid length option; Source address is not modulo of length value; Destination address is not within secure RAM; CRC size crosses over Flash sector or RAM block boundary; The source and destination memory do not belong to the same zone; On CM, CRCLOCK is enabled</p>

The **CMAC calculate and compare function** allows to calculate CMAC signature of a Flash memory block and compare against a golden signature. This is used in the secure boot mode to authenticate the boot image.

Table 4-47. Secure CRC Calculation Function

CPU	Function Prototype	Function Parameters	Function Return Value
CPU (C28x)	<pre>uint32_t CPU1BROM_calculateCMAC(uint32_t startAddress, uint32_t endAddress, uint32_t signatureAddress)</pre>	<p>startAddress: Starting address of memory for which CMAC has to be calculated</p> <p>endAddress: Ending address of memory for which CMAC has to be calculated</p> <p>signatureAddress: Address of location where golden CMAC signature is stored</p>	<p>0xFFFF FFFFU: Calculated CMAC signature did not match golden signature (fail)</p> <p>0xA5A5 A5A5U: Memory range provided is not aligned to 128-bit boundary or length is zero</p> <p>0xE1E1 E1E1U: AES Engine timed out</p> <p>0x0000 0000U: No Error</p>

4.8.11 Clock Initializations

During boot-up, the boot ROM initializes the device clocking, depending upon the reset source, to assist in faster boot time response. Clock configurations are performed by the boot ROM code only for POR and XRS reset types. For all other resets, the boot ROM starts executing with the clocks that were already set up before reset.

Note

CPU performs clock configurations during boot up. If the PLL is used during the boot process, the PLL is bypassed by the boot ROM code before branching to the user application.

Table 4-48. CPU Boot Clock Sources

Source	Frequency	Description
INTOSC2	10MHz	Default clock source
INTOSC1	10MHz	Set as clock source if missing clock is detected at power up or right after device reset.
SYSPLL	115MHz, 57.5MHz	Enabled optionally as part of main boot flow or as part of MPOST POR memory test boot flow. PLL is bypassed and disabled after memory test has completed. See more details regarding enabling MPOST POR memory test in Section 4.8.1.1 .

Table 4-49. CPU Clock State After Boot

Reset Source	Clock State
POR/XRS	<ol style="list-style-type: none"> Using INTOSC2 System clock divider set to /1
All other Resets	Maintain clocks setup before device reset.

4.8.12 Boot Status Information

Boot ROM keeps a record of the various actions and events that occur during boot ROM execution. The reason for this is because NMI and other exceptions are enabled by default in the device and must be handled accordingly. Boot ROM stores the boot status information in a RAM location so that the user application can read this boot status and take the necessary actions per application's needs to handle these events.

4.8.12.1 Booting Status

Boot ROM health and booting status is written to a 32-bit address in M0RAM. This status is cleared on a POR or XRS reset. The previous status is retained on any other reset. For example, clear the status before performing a debugger device reset to view the latest boot ROM actions reflected in the status.

Table 4-50. Boot Status Address

Description	Address
Boot ROM Status	0x0000 0002

Table 4-51. Boot Status Bit Fields

Value	Description
0x8000 0000	HWBIST reset is handled successfully
0x2000 0000	EFuse Single Bit Error
0x1000 0000	FWU Flash Boot Error
0x0800 0000	Flash Verification Error
0x0400 0000	DCSM initialization LP Error
0x0200 0000	DCSM Initialization Invalid LP
0x0100 0000	SYSPLL enabled successfully
0x0080 0000	HWBIST NMI occurred
0x0040 0000	Missing clock NMI occurred
0x0020 0000	RAM Uncorrectable Error NMI occurred
0x0010 0000	Flash Uncorrectable Error NMI occurred
0x0008 0000	RL NMI occurred
0x0004 0000	ERAD NMI occurred
0x0002 0000	Boot ROM detected a PIE mismatch
0x0001 0000	Boot ROM detected an ITRAP
0x0000 8000	Boot ROM has completed running
0x0000 2000	Boot ROM handled POR
0x0000 1000	Boot ROM handled XRS
0x0000 0800	Boot ROM handled all the resets
0x0000 0400	POR memory test has completed
0x0000 0200	DCSM initialization has completed
0x0000 0100	RAM Initialization Complete
0x0000 000C	FWU boot has started
0x0000 000B	Wait boot has started
0x0000 000A	CAN-FD boot has started
0x0000 0009	CAN boot has started
0x0000 0008	I2C boot has started
0x0000 0007	SPI boot has started
0x0000 0006	SCI boot has started
0x0000 0005	RAM boot has started
0x0000 0004	Parallel boot has started
0x0000 0003	Secure Flash boot has started
0x0000 0002	Flash boot has started
0x0000 0001	Boot ROM has started running

4.8.12.2 Boot Mode and MPOST (Memory Power On Self-Test) Status

Once the boot mode is decoded during the boot flow, the boot mode value is written to RAM. Additionally when running the MPOST POR memory test, the test result is written to RAM.

For more information, see the [C2000™ Memory Power-On Self-Test \(M-POST\) Application Report](#).

Table 4-52. Boot Mode and MPOST Status Addresses

Description	Address
Boot Mode	0x0000 0004
MPOST POR Memory Test Result	0x0000 0006

4.8.13 ROM Version

The ROM revision and release date information is stored at the ROM locations specified in [Table 4-53](#). Reading a revision number value of “0x100” represents version “1.0”, “0x101” represents version “1.1”, and so on. Reading a revision date value of “0x0119” represents “01/19” or “January 2019”.

Table 4-53. Boot ROM Version Information

Contents	Address
Revision Number	0x003F 8044
Revision Date	0x003F 8045
Build Number	0x003F 8046

4.9 Application Notes for Using the Bootloaders

4.9.1 Bootloader Data Stream Structure

This section details the data transfer protocols or stream structures that allow boot data transfer between boot ROM and host device. This data transfer protocol is compatible to the respective bootloaders on C2000 devices.

[Table 4-54](#) and [Example 4-2](#) show the structure of the data stream incoming to the bootloader. The basic structure is the same for all the bootloaders and is based on the C54x source data stream generated by the C54x hex utility. The C28x hex utility (hex2000.exe) has been updated to support this structure. The hex2000.exe utility is included with the C2000 code generation tools. All values in the data stream structure are in hex. Refer to [Section 4.9.2](#) for more details on using the C28x hex utility to convert a project to this format.

The first 16-bit word in the data stream is known as the key value. The key value is used to notify the bootloader the width of the incoming stream: 8 or 16 bits. Note that not all bootloaders accept both 8- and 16-bit streams. Refer to the detailed information on each loader for the valid data stream width. For an 8-bit data stream, the key value is 0x08AA; for a 16-bit data stream, the key value is 0x10AA. If a bootloader receives an invalid key value, then the load is aborted.

The next eight words are used to initialize register values or otherwise enhance the bootloader by passing values to the bootloader. If a bootloader does not use these values then the values are reserved for future use and the bootloader simply reads the value and then discards the value. Currently only the SPI and I2C and parallel bootloaders use these words to initialize registers.

The tenth and eleventh words comprise the 22-bit entry point address. This address is used to initialize the PC after the boot load is complete. This address is most likely the entry point of the program downloaded by the bootloader.

The twelfth word in the data stream is the size of the first data block to be transferred. The size of the block is defined as 8-bit data stream format. For example, to transfer a block of 20 8-bit data values from an 8-bit data stream, the block size is 0x000A to indicate 10 16-bit words.

The next two words tell the loader the destination address of the block of data. Following the size and address is the 16-bit words that makeup that block of data.

This pattern of block size/destination address repeats for each block of data to be transferred. Once all the blocks have been transferred, a block size of 0x0000 signals to the loader that the transfer is complete. At this point, the loader returns the entry point address to the calling routine, which cleans up and exits. Execution then continues at the entry point address as determined by the input data stream contents.

Table 4-54. LSB/MSB Loading Sequence in 8-Bit Data Stream

		Contents	
Byte		LSB (First Byte of 2)	MSB (Second Byte of 2)
1	2	LSB: AA (KeyValue for memory width = 8 bits)	MSB: 08h (KeyValue for memory width = 8 bits)
3	4	LSB: Register initialization value or reserved	MSB: Register initialization value or reserved
5	6	LSB: Register initialization value or reserved	MSB: Register initialization value or reserved
7	8	LSB: Register initialization value or reserved	MSB: Register initialization value or reserved
...
...
17	18	LSB: Register initialization value or reserved	MSB: Register initialization value or reserved
19	20	LSB: Upper half of Entry point PC[23:16]	MSB: Upper half of entry point PC[31:24] (Always 0x00)
21	22	LSB: Lower half of Entry point PC[7:0]	MSB: Lower half of Entry point PC[15:8]
23	24	LSB: Block size in words of the first block to load. If the block size is 0, this indicates the end of the source program; otherwise, another block follows. For example, a block size of 0x000A indicates 10 words or 20 bytes in the block.	MSB: block size
25	26	LSB: MSW destination address, first block Addr[23:16]	MSB: MSW destination address, first block Addr[31:24]
27	28	LSB: LSW destination address, first block Addr[7:0]	MSB: LSW destination address, first block Addr[15:8]
29	30	LSB: First word of the first block being loaded	MSB: First word of the first block being loaded
...
...
.	.	LSB: Last word of the first block to load	MSB: Last word of the first block to load
.	.	LSB: Block size of the second block	MSB: Block size of the second block
.	.	LSB: MSW destination address, second block Addr[23:16]	MSB: MSW destination address, second block Addr[31:24]
.	.	LSB: LSW destination address, second block Addr[7:0]	MSB: LSW destination address, second block Addr[15:8]
.	.	LSB: First word of the second block being loaded	MSB: First word of the second block being loaded
...
...
.	.	LSB: Last word of the second block	MSB: Last word of the second block
.	.	LSB: Block size of the last block	MSB: Block size of the last block
.	.	LSB: MSW of destination address of last block Addr[23:16]	MSB: MSW destination address, last block Addr[31:24]
.	.	LSB: LSW destination address, last block Addr[7:0]	MSB: LSW destination address, last block Addr[15:8]
.	.	LSB: First word of the last block being loaded	MSB: First word of the last block being loaded
...
...
.	.	LSB: Last word of the last block	MSB: Last word of the last block
n	n+1	LSB: 00h	MSB: 00h - indicates the end of the source

Example 4-2. Data Stream Structure 8-bit

```

AA 08      ; 0x08AA 8bit key value
00 00 00 00 ; 8 reserved words
00 00 00 00
00 00 00 00
00 00 00 00
3F 00 00 80 ; 0x003F8000 EntryAddr, starting point after boot load completes
05 00      ; 0x0005 First block consists of 5 16-bit words
3F 00 10 90 ; 0x003F9010 First block is loaded starting at 0x3F9010
01 00      ; Data loaded = 0x0001 0x0002 0x0003 0x0004 0x0005
02 00
03 00
04 00
05 00
02 00      ; 0x0002 - 2nd block consists of 2 16bit words
3F 00 00 80 ; 0x003F8000 2nd block is loaded starting at 0x3F8000
00 77      ; Data loaded = 0x7700 0x7625
25 76
00 00      ; 0x0000 Size of 0 indicates end of data stream
After load has completed, the following memory values are initialized as follows:
Location Value
0x3F9010 0x0001
0x3F9011 0x0002
0x3F9012 0x0003
0x3F9013 0x0004
0x3F9014 0x0005
0x3F8000 0x7700
0x3F8001 0x7625
PC Begins execution at 0x3F8000

```

4.9.2 The C2000 Hex Utility

To use the features of the bootloader, you must generate a data stream and boot table as described in [Section 4.9.1](#). The hex conversion utility tool, included with the 28x code generation tools, can generate the required data stream including the required boot table. This section describes the hex2000 utility. An example of a file conversion performed by hex2000 is described in [Example 4-3](#).

The hex utility supports creation of the boot table required for the SCI, SPI, I2C, CAN, and parallel I/O loaders. That is, the hex utility adds the required information to the file such as the key value, reserved bits, entry point, address, block start address, block length and terminating value. The contents of the boot table vary slightly depending on the boot mode and the options selected when running the hex conversion utility. The actual file format required by the host (ASCII, binary, hex, and so on) differs from one specific application to another and some additional conversion can be required.

To build the boot table, follow these steps:

1. **Assemble or compile the code.** This creates the object files that then are used by the linker to create a single output file.
2. **Link the file.** The linker combines all of the object files into a single output file in common object file format (ELF). The specified linker command file is used by the linker to allocate the code sections to different memory blocks. Each block of the boot table data corresponds to an initialized section in the ELF file. Uninitialized sections are not converted by the hex conversion utility. The following options are useful:
 - The linker `-m` option can be used to generate a map file. This map file shows all of the sections that were created, the location in memory, and the length. The linker can be useful to check this file to make sure that the initialized sections are where you expect them.
 - The linker `-w` option configures the linker to show, if the linker assigned a section to a memory region automatically. For example, if you have a section in your code called `.TI.ramfunc`.
3. **Run the hex conversion utility.** Choose the appropriate options for the desired boot mode and run the hex conversion utility to convert the ELF file produced by the linker to a boot table.

See the [TMS320C28x Assembly Language Tools User's Guide](#) and the [TMS320C28x Optimizing C/C++ Compiler User's Guide](#) for more information on the compiling and linking process.

Table 4-55 summarizes the hex conversion utility options available for the bootloader. See the [TMS320C28x Assembly Language Tools User's Guide](#) for a detailed description of the hex2000 operations used to generate a boot table. Updates are made to support the I2C boot. See the Codegen release notes for the latest information.

Table 4-55. Boot Loader Options

Option	Description
-boot	Convert all sections into bootable form (use instead of a SECTIONS directive)
-sci8	Specify the source of the bootloader table as the SCI-A port, 8-bit mode
-spi8	Specify the source of the bootloader table as the SPI-A port, 8-bit mode
-gpio8	Specify the source of the bootloader table as the GPIO port, 8-bit mode
-bootorg value	Specify the source address of the bootloader table
-lospcp value	Specify the initial value for the LOSPCP register. This value is used only for the spi8 boot table format and ignored for all other formats. If the value is greater than 0x7F, the value is truncated to 0x7F.
-spibrr value	Specify the initial value for the SPIBRR register. This value is used only for the spi8 boot table format and ignored for all other formats. If the value is greater than 0x7F, the value is truncated to 0x7F.
-e value	Specify the entry point at which to begin execution after boot loading. The value can be an address or a global symbol. This value is optional. The entry point can be defined at compile time using the linker -e option to assign the entry point to a global symbol. The entry point for a C program is normally <code>_c_int00</code> unless defined otherwise by the -e linker option.
-i2c8	Specify the source of the bootloader table as the I2C-A port, 8-bit
-i2cpsc value	Specify the value for the I2CPSC register. This value is loaded and takes effect after all I2C options are loaded, prior to reading data from the EEPROM. This value is truncated to the 8 least-significant bits and can be set to maintain an I2C module clock of 7 to 12MHz.
-i2cclk value	Specify the value for the I2CCLKH register. This value is loaded and takes effect after all I2C options are loaded, prior to reading data from the EEPROM.
-i2cclk value	Specify the value for the I2CCLKL register. This value is loaded and takes effect after all I2C options are loaded, prior to reading data from the EEPROM.

Example 4-3. HEX2000.exe Command Syntax

```
C: HEX2000 GPIO34TOG.OUT -boot -gpio8 -a
where:
- boot Convert all sections into bootable form.
- gpio8 Use the GPIO in 8-bit mode data format. The eCAN
        uses the same data format as the GPIO in 8bit mode.
- a     Select ASCII-Hex as the output format.
```

Chapter 5
Dual Code Security Module (DCSM)

This chapter explains the Dual Code Security Module.

5.1 Introduction	610
5.2 Functional Description	610
5.3 Flash and OTP Erase/Program	617
5.4 Secure Copy Code	617
5.5 SecureCRC	618
5.6 CSM Impact on Other On-Chip Resources	619
5.7 Incorporating Code Security in User Applications	620
5.8 Software	625
5.9 DCSM Registers	625

5.1 Introduction

The dual code security module (DCSM) is a security feature incorporated in this device. It prevents access and visibility to on-chip secure memories (and other secure resources) by unauthorized persons. It also prevents duplication and reverse-engineering of proprietary code. The term “secure” means that access to on-chip secure memories and resources is blocked. The term “unsecure” means that access is allowed; that is, the contents of the memory could be read by any means (for example, through a debugging tool such as Code Composer Studio™ IDE).

The CSM has dual-zone security, Zone1 (Z1) and Zone2 (Z2).

5.1.1 DCSM Related Collateral

Getting Started Materials

- [C2000 DCSM Security Tool Application Report](#)
- [C2000 Unique Device Number Application Report](#)
- [Enhancing Device Security by Using JTAGLOCK Feature Application Report](#)

5.2 Functional Description

The security module restricts the CPU access to on-chip secure memory and resources without interrupting or stalling CPU execution. When a read occurs to a secure memory location, the read returns a zero value and CPU execution continues with the next instruction. This, in effect, blocks read and write access to secure memories through the JTAG port or external peripherals.

The code security mechanism offers protection for two zones, Zone1 (Z1) and Zone2 (Z2). The security mechanism for both the zones is identical. Each zone has a dedicated secure resource and allocated secure resource. The following are different secure resources available on this device:

- **OTP:** Each zone has a dedicated secure OTP (USER OTP). This contains the security configurations for the individual zone. If a zone is secure, the USER OTP content (including CSM passwords) can be read (execution not allowed) only if the zone is unlocked using the password match flow (PMF).
- **RAM:** All LSx RAMs can be secure RAM on this device. These RAMs can be allocated to either zone by configuring the respective GRABRAM locations in the USER OTP.
- **Flash Sectors:** Flash sectors of each CPU subsystems can be made secure on this device. Each Flash sector can be allocated to either zone by configuring the respective GRABSECT locations in the bank's USER OTP.
- **Secure ROM:** This device also has secure ROM on each CPU subsystem which is EXEONLY-protected. These ROM contains specific function for the user, provided by TI.

[Table 5-1](#) shows the status of a RAM block/Flash sector based on the configuration in the GRABRAM/GRABSECT register.

The security of each zone is protected by a 128-bit (four 32-bit words) password (CSM password). The password for each zone is stored in USER OTP. A zone can be unsecured by executing the password match flow (PMF), described in [Section 5.7.4](#).

There are three types of accesses: data/program reads, JTAG access, and instruction fetches (calls, jumps, code executions, ISRs). Instruction fetches are never blocked. JTAG accesses are always blocked when a memory is secure. Data reads to a secure memory are always blocked unless the program is executing from a memory which belongs to the same zone. Data reads to unsecure memory are always allowed. [Table 5-2](#) shows the levels of security.

Table 5-1. RAM/Flash Status

Zone 1 GRABRAMx/GRABSECTx Bits	Zone 2 GRABRAMx/GRABSECTx Bits	Ownership and Accessibility
01	10	RAM block/Flash Sector belongs to Zone1
01	11 ⁽²⁾	RAM block/Flash Sector belongs to Zone1
10	01	RAM block/Flash Sector belongs to Zone2
11 ⁽¹⁾	01	RAM block/Flash Sector belongs to Zone2
10	10	RAM block/Flash Sector is unsecure
11	11	RAM block/Flash Sector inaccessible if either of the zone is secure (CSM passwords are programmed). Never leave these values as default (11), if CSM passwords are programmed for even one zone.

- (1) Zone1 must be unsecure. Assumption in this case is that the user is not using Zone1 so none of the fields, including passwords, in Zone1 USER OTP are programmed by user; hence, Zone1 is always unsecure.
- (2) Zone2 must be unsecure. Assumption in this case is that the user is not using Zone2 so none of the fields, including passwords, in Zone2 USER OTP are programmed by user; hence, Zone2 is always unsecure.

CAUTION

Never program any other values in these fields. Failing any of these conditions for a RAM block/Flash sector makes that RAM block/Flash sector inaccessible.

Table 5-2. Security Levels

PMF Executed With Correct Password?	Operating Mode of the Zone	Program Fetch Location	Security Description
No	Secure	Outside secure memory	Only instruction fetches by the CPU are allowed to secure memory. In other words, code can still be executed, but not read.
No	Secure	Inside secure memory	CPU has full access (except for EXEONLY memories where read is not allowed). JTAG port cannot read the secured memory contents.
Yes	Unsecure	Anywhere	Full access for CPU and JTAG port to secure memory of that zone.

5.2.1 CSM Passwords

Unlike earlier C2000™ devices, on this device ALL_1 value (0xFFFF FFFF, 0xFFFF FFFF, 0xFFFF FFFF, 0xFFFF FFFF) for CSM password for a zone does not unsecure the zone. Instead, if for any zone the CSM password values get loaded as ALL_1 from USER OTP, the device is in the BLOCKED state. Due to this reason, TI programs a few bits in the second 32-bit password value (ZxOTP_CSMPSWD1) in every zone select block of each zone with value 0. The default value for this password location is chosen in a manner that the respective ECC value remains ALL_1. Due to this, the CSMPSWD1 value programmed by TI for every zone select block is different. See [Table 5-3](#) for ZxOTP_CSMPSWD1 value, programmed by TI on every device. Since ECC is not programmed, the user can change this value by flipping the bits that are 1 to 0 but leaving the ones that are already programmed by TI as 0. The BOOTROM code writes the default password value into the KEYx register to unlock the device as part of device initialization sequence.

If the password locations of a zone have all 128 bits as zeros (ALL_0), that zone becomes permanently secure (LOCKED state) regardless of the contents of the CSMKEYx registers which means the zone cannot be unlocked using PMF, the password match flow described in [Section 5.7.4](#). Therefore, the user must never use ALL_0 as password. A password of ALL_0 prevents debug of secure code or reprogramming the Flash sectors. CSMKEYx registers are user-accessible registers that are used to unsecure the zones.

Table 5-3. Default Value of ZxOTP (Programmed by TI)

Zone Select Block	Zone1 USER OTP		Zone2 USER OTP	
	Address	Value	Address	Value
JLM_ENABLE (JTAGLOCK)	0x0007 8006	0xFFFF 000F	NA	NA
PSWDLOCK	0x0007 8010	0xFB7F FFFF	0x0007 8210	0x1F7F FFFF
CRCLOCK	0x0007 8012	0x7FFF FFFF	0x0007 8212	0x3FFF FFFF
JTAGPSWDH0	0x00078014	0x4BFF FFFF	NA	NA
JTAGPSWDH1	0x0007 8016	0x3FFF FFFF	NA	NA
Zone_Select_Block0	0x0007 8022 (CSMPSWD1)	0x4D7F FFFF	0x0007 8222 (CSMPSWD1)	0x1F7F FFFF
Zone_Select_Block0	0x0007 803E (JTAGPSWDL1)	0x2BFF FFFF	NA	NA
Zone_Select_Block1	0x0007 8042 (CSMPSWD1)	0x5F7F FFFF	0x0007 8242 (CSMPSWD1)	0xE57F FFFF
Zone_Select_Block1	0x0007 805E (JTAGPSWDL1)	0x27FF FFFF	NA	NA
Zone_Select_Block2	0x0007 8062 (CSMPSWD1)	0x1DFF FFFF	0x0007 8262 (CSMPSWD1)	0x4FFF FFFF
Zone_Select_Block2	0x0007 807E (JTAGPSWDL1)	0x7B7F FFFF	NA	NA
Zone_Select_Block3	0x0007 8082 (CSMPSWD1)	0xAF7F FFFF	0x0007 8282 (CSMPSWD1)	0xE37F FFFF
Zone_Select_Block3	0x0007 809E (JTAGPSWDL1)	0xC9FF FFFF	NA	NA
Zone_Select_Block4	0x0007 80A2 (CSMPSWD1)	0x1BFF FFFF	0x0007 82A2 (CSMPSWD1)	0x57FF FFFF
Zone_Select_Block4	0x0007 80BE (JTAGPSWDL1)	0x7D7F FFFF	NA	NA
Zone_Select_Block5	0x0007 80C2 (CSMPSWD1)	0x17FF FFFF	0x0007 82C2 (CSMPSWD1)	0x5BFF FFFF
Zone_Select_Block5	0x0007 80DE (JTAGPSWDL1)	0x6F7F FFFF	NA	NA
Zone_Select_Block6	0x0007 80E2 (CSMPSWD1)	0xBD7F FFFF	0x0007 82E2 (CSMPSWD1)	0xF17F FFFF
Zone_Select_Block6	0x0007 80FE (JTAGPSWDL1)	0x33FF FFFF	NA	NA
Zone_Select_Block7	0x0007 8102 (CSMPSWD1)	0x9F7F FFFF	0x0007 8302 (CSMPSWD1)	0x3B7F FFFF
Zone_Select_Block7	0x0007 811E (JTAGPSWDL1)	0x0FFF FFFF	NA	NA
Zone_Select_Block8	0x0007 8122 (CSMPSWD1)	0x2BFF FFFF	0x0007 8322 (CSMPSWD1)	0x8FFF FFFF
Zone_Select_Block8	0x0007 813E (JTAGPSWDL1)	0xBB7F FFFF	NA	NA
Zone_Select_Block9	0x0007 8142 (CSMPSWD1)	0x27FF FFFF	0x0007 8342 (CSMPSWD1)	0x6BFF FFFF
Zone_Select_Block9	0x0007 815E (JTAGPSWDL1)	0x5F7F FFFF	NA	NA
Zone_Select_Block10	0x0007 8162 (CSMPSWD1)	0x7B7F FFFF	0x0007 8362 (CSMPSWD1)	0x377F FFFF
Zone_Select_Block10	0x0007 817E (JTAGPSWDL1)	0x1DFF FFFF	NA	NA
Zone_Select_Block11	0x0007 8182 (CSMPSWD1)	0xC9FF FFFF	0x0007 8382 (CSMPSWD1)	0x9BFF FFFF
Zone_Select_Block11	0x0007 819E (JTAGPSWDL1)	0xAF7F FFFF	NA	NA
Zone_Select_Block12	0x0007 81A2 (CSMPSWD1)	0x7D7F FFFF	0x0007 83A2 (CSMPSWD1)	0x2F7F FFFF
Zone_Select_Block12	0x0007 81BE (JTAGPSWDL1)	0x1BFF FFFF	NA	NA
Zone_Select_Block13	0x0007 81C2 (CSMPSWD1)	0x6F7F FFFF	0x0007 83C2 (CSMPSWD1)	0xCB7F FFFF
Zone_Select_Block13	0x0007 81DE (JTAGPSWDL1)	0x17FF FFFF	NA	NA
Zone_Select_Block14	0x0007 81E2 (CSMPSWD1)	0x33FF FFFF	0x0007 83E2 (CSMPSWD1)	0x97FF FFFF
Zone_Select_Block14	0x0007 81FE (JTAGPSWDL1)	0xBD7F FFFF		

5.2.2 Emulation Code Security Logic (ECSL)

In addition to the CSM, the emulation code security logic (ECSL) has been implemented using a 64-bit password (part of existing CSM password) for each zone to prevent unauthorized users from stepping through secure code. A halt in secure code while the emulator is connected trips the ECSL and breaks the emulation connection. To allow emulation of secure code, while maintaining the CSM protection against secure memory reads, write the correct 64-bit password into the CSMKEY (0/1) registers, which matches the password value stored in the USER OTP of that zone. This disables the ECSL for the specific zone.

When initially debugging a device with the password locations in OTP programmed (secured), the emulator takes some time to take control of the CPU. During this time, the CPU starts running and can execute an instruction that performs an access to a protected ECSL area. If the CPU is halted when the program counter (PC) is pointing to a secure location, the ECSL trips and causes the emulator connection to be broken.

To solve this problem, use the Wait Boot Mode boot option. In this mode, the CPU is in a loop and does not jump to the user application code. Using this BOOTMODE, you can connect to CCS IDE and debug the code.

5.2.3 CPU Secure Logic

The CPU Secure Logic (CPUSL) on this device prevents a hacker from reading the CPU registers in a watch window while code is running in a secure zone. All accesses to CPU registers when the PC points to a secure location are blocked by this logic. The only exception to this is read access to the PC. It is highly recommended not to write into the CPU register in this case, because proper code execution may get affected. If the CSM is unlocked using the CSM password match flow, the CPUSL logic also gets disabled.

5.2.4 Password Lock

The password locations in USER OTP for each zone can be locked by programming the zone PSWDLOCK field with any value other than 1111 (0xF) at the PSWDLOCK location in OTP. Until the passwords of a zone are locked, password locations are not secure and can be read from the debugger as well as code running from non-secure memory. This feature can be used to avoid accidental locking of the zone while programming the Flash sectors during the software development phase. On a new device, the value for password lock fields for all zones at the PSWDLOCK location in OTP is 1111, which means the password for all zones is unlocked.

Note

Password unlock only makes password locations non-secure. All other secure memories remains secure as per security settings. Since password locations are non-secure, anyone can read the password and make the zone unsecure by running through PMF, user must program PSWDLOCK locations to lock the password before sending the device in field.

5.2.5 JTAGLOCK

Sometimes you want to disable the JTAG access on a device to avoid any debug access to it. This can be done by using the JTAGLOCK feature on this device. You need to follow a two step process to enable the JTAGLOCK feature (both steps can be performed at the same time).

1. Program the JTAG passwords. This device has a 128-bit JTAG password that needs to be programmed in Z1 USER OTP. JTAG passwords are split into two parts, JTAGPSWDH and JTAGPSWDL. JTAGPSWDH is part of Z1 USER OTP header and JTAGPSWDL is part of Z1 Zone Select Block (ZSB). What this means is program JTAGPSWDH once and change the JTAGPSWDL multiple times, if needed. Code Composer Studio has an integrated tool that you need to use to unlock the JTAGLOCK on device.
2. After programming the JTAG passwords, you need to enable the JTAGLOCK module (JLM) by programming bit [3:0] of Z1OTP_JLM_ENABLE with any value other than 0xF. It is recommended to program all four bits with a value 0x0.

5.2.6 Link Pointer and Zone Select

For each of the two security zones, a dedicated OTP block exists that holds the configuration related to zone's security. The following are user programmable configurations:

- | | |
|----------------------|----------------------|
| • ZxOTP_LINKPOINTER1 | • ZxOTP_CSMPSWD1 |
| • ZxOTP_LINKPOINTER2 | • ZxOTP_CSMPSWD2 |
| • ZxOTP_LINKPOINTER3 | • ZxOTP_CSMPSWD3 |
| • Z1OTP_JLM_ENABLE | • ZxOTP_GRABSECT1 |
| • ZxOTP_GPREG1 | • ZxOTP_GRABSECT2 |
| • ZxOTP_GPREG2 | • ZxOTP_GRABSECT3 |
| • ZxOTP_GPREG3 | • ZxOTP_GRABRAM1 |
| • ZxOTP_GPREG4 | • ZxOTP_GRABRAM2 |
| • ZxOTP_PSWDLOCK | • ZxOTP_GRABRAM3 |
| • ZxOTP_CRCLOCK | • ZxOTP_EXEONLYSECT1 |
| • Z1OTP_JTAGPSWDH | • ZxOTP_EXEONLYSECT2 |
| • Z1OTP_CMACKKEY | • ZxOTP_EXEONLYRAM1 |
| • ZxOTP_CSMPSWD0 | • Z1OTP_JTAGPSWDL |

Since OTP cannot be erased, the following configurations are placed in zone select blocks of each zone's OTP Flash of both the banks:

- | | |
|-------------------|----------------------|
| • ZxOTP_CSMPSWD0 | • ZxOTP_GRABRAM1 |
| • ZxOTP_CSMPSWD1 | • ZxOTP_GRABRAM2 |
| • ZxOTP_CSMPSWD2 | • ZxOTP_GRABRAM3 |
| • ZxOTP_CSMPSWD3 | • ZxOTP_EXEONLYSECT1 |
| • ZxOTP_GRABSECT1 | • ZxOTP_EXEONLYSECT2 |
| • ZxOTP_GRABSECT2 | • ZxOTP_EXEONLYRAM1 |
| • ZxOTP_GRABSECT3 | • Z1OTP_JTAGPSWDL |

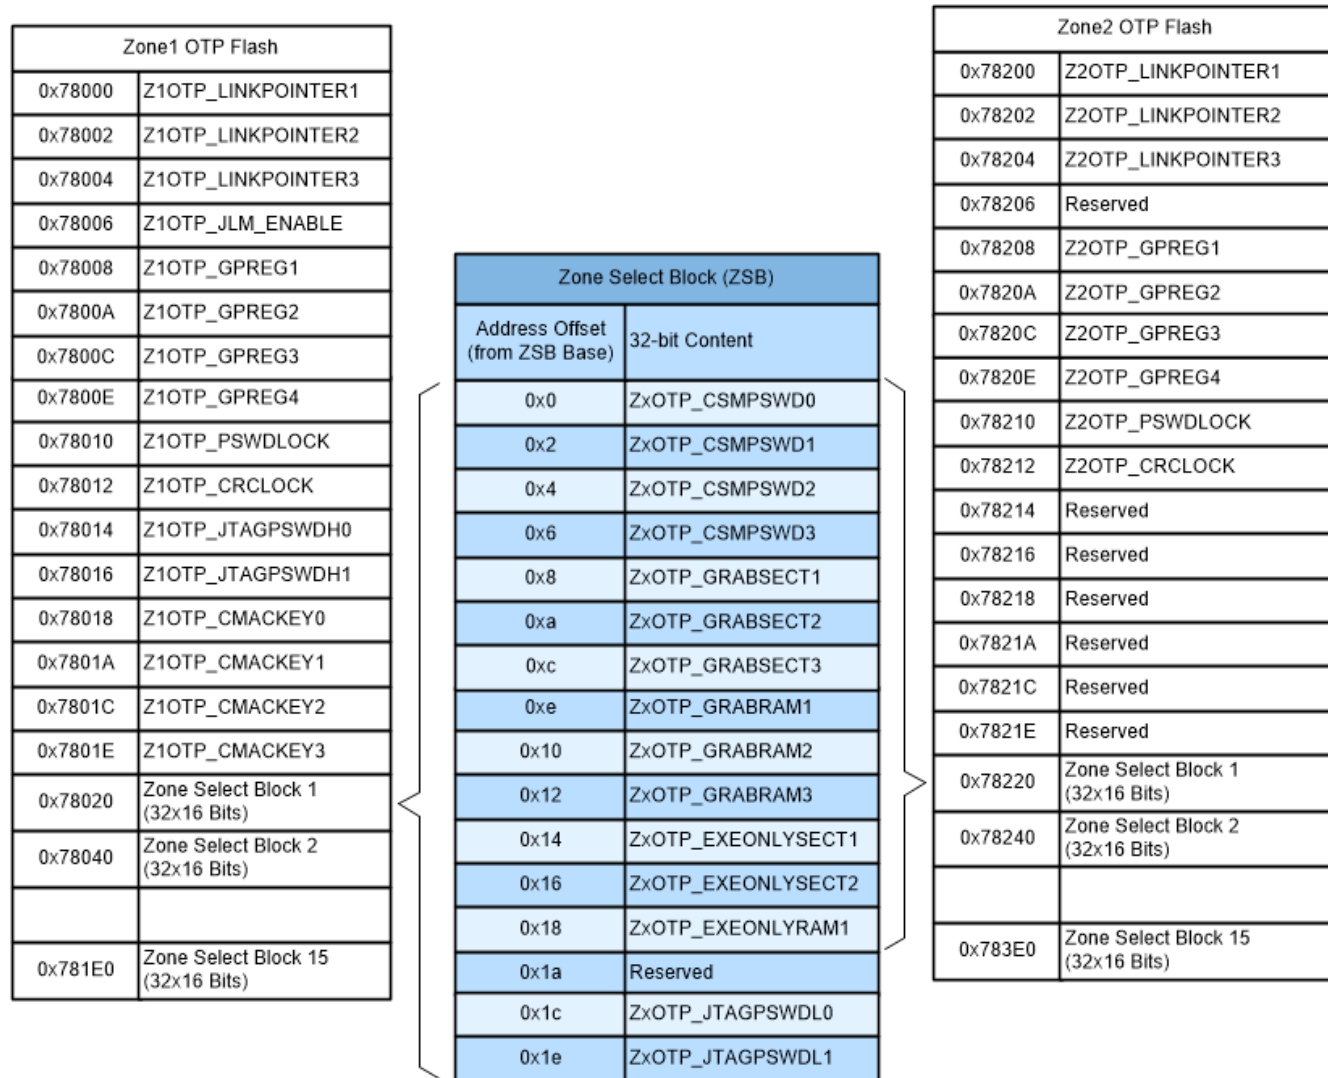

The location of the valid zone select block in OTP is decided based on the value of three 14-bit link pointers (Zx-LINKPOINTERx) programmed in the OTP of each zone. All OTP locations except link pointers and Z1OTP_JLM_ENABLE locations are protected with ECC. Since the link pointer locations are not protected with ECC, three link pointers are provided that need to be programmed with the same value. The final value of the link pointer is resolved in hardware, when a dummy read is done to all the link pointers, by comparing all the three values (bit-wise voting logic). Since in OTP, a 1 can be flipped by the user to 0, but 0 can not be flipped to 1 (no erase operation for OTP), the most-significant bit position in the resolved link pointer that is 0, defines the valid base address for the zone select block. While generating the final link pointer value, if the bit pattern is not one of those listed in [Figure 5-1](#), the final link pointer value becomes All_1 (0xFFFF_FFFF), which selects the Zone-Select-Block1 (also known as the default zone select block).

Zx-LINKPOINTER	Selected ZSB	Zone1 ZSB Address	Zone2 ZSB Address
32xxxxxxxxxxxxxxxxxxxx11111111111111	ZSB1	0x78020	0x78220
32xxxxxxxxxxxxxxxxxxxx11111111111110	ZSB2	0x78040	0x78240
32xxxxxxxxxxxxxxxxxxxx11111111111100	ZSB3	0x78060	0x78260
32xxxxxxxxxxxxxxxxxxxx111111111111000	ZSB4	0x78080	0x78280
32xxxxxxxxxxxxxxxxxxxx1111111111110000	ZSB5	0x780a0	0x782a0
32xxxxxxxxxxxxxxxxxxxx11111111111100000	ZSB6	0x780c0	0x782c0
32xxxxxxxxxxxxxxxxxxxx111111111111000000	ZSB7	0x780e0	0x782e0
32xxxxxxxxxxxxxxxxxxxx1111111100000000	ZSB8	0x78100	0x78300
32xxxxxxxxxxxxxxxxxxxx1111111000000000	ZSB9	0x78120	0x78320
32xxxxxxxxxxxxxxxxxxxx1111100000000000	ZSB10	0x78140	0x78340
32xxxxxxxxxxxxxxxxxxxx1111000000000000	ZSB11	0x78160	0x78360
32xxxxxxxxxxxxxxxxxxxx1110000000000000	ZSB12	0x78180	0x78380
32xxxxxxxxxxxxxxxxxxxx1100000000000000	ZSB13	0x781a0	0x783a0
32xxxxxxxxxxxxxxxxxxxx1000000000000000	ZSB14	0x781c0	0x783c0
32xxxxxxxxxxxxxxxxxxxx0000000000000000	ZSB15	0x781e0	0x783e0

Figure 5-1. Storage of Zone-Select Bits in OTP

Note

Address locations for other security settings that are not part of Zone Select blocks can be programmed only once; therefore, program the address locations toward end of the development cycle.

Figure 5-2. Location of Zone-Select Block Based on Link-Pointer
CAUTION

The USER OTP is ECC protected. Program the ECC value while programming the security setting in the USER OTP. Failing to program the correct ECC value causes the device to be blocked permanently and you have to replace the device.

5.2.7 C Code Example to Get Zone Select Block Addr for Zone1

```

unsigned long LinkPointer;
unsigned long *ZoneSelBlockPtr;
int Bitpos = 13;
int ZeroFound = 0;
// Read Z1-Linkpointer register of DCSM module.
LinkPointer = *(unsigned long *)0x5F000;
// Bits 31 to 15 as most-significant 0 are reserved LinkPointer options
LinkPointer = LinkPointer << 18;
while ((ZeroFound == 0) && (bitpos > -1))
{
    if ((LinkPointer & 0x80000000) == 0)
    {
        ZeroFound = 1;
        ZoneSelBlockPtr = (unsigned long *) (0x78000 + ((bitpos + 2)*32));
    }
    else
    {
        bitpos--;
        LinkPointer = LinkPointer << 1;
    }
}
if (ZeroFound == 0)
{
    //Default in case there is no zero found.
    ZoneSelBlockPtr = (unsigned long *)0x78020;
}

```

5.3 Flash and OTP Erase/Program

On this device, OTP as well as normal Flash, are secure resources. Each zone has a dedicated OTP, whereas normal Flash sectors can be allocated to any zone based on the value programmed in the GRABSECTx location in OTP. Each zone has a 128-bit CSM passwords. Read and write accesses are not allowed to resources assigned to Z1 by code running from memory allocated to Z2 and conversely. Before programming any secure Flash sector, the user must either unlock the zone to which that particular sector belongs using PMF or execute the Flash programming code from secure memory which belongs to the same zone. The same is the case for erasing any secure Flash sector. To program the security settings in OTP Flash, the user must unlock the CSM of the respective zone. Unless the zone is unlocked, security settings in OTP Flash can not be updated. The OTP content cannot be erased.

A semaphore mechanism is provided to avoid the program/erase conflict between Z1 and Z2. A zone needs to grab this semaphore to successfully complete the erase/program operation on the secure Flash sectors allocated to that zone. A semaphore can be grabbed by a zone by writing the appropriate value in the SEM field of the FLSEM register. For further details of this field, see the register description.

5.4 Secure Copy Code

In some applications, the user can want to copy the code from secure Flash to secure RAM for better performance. The user cannot do this for EXEONLY Flash sectors because EXEONLY secure memories cannot be read from anywhere. TI provides specific “Secure Copy Code” library functions for each zone to enable the user to copy content from EXEONLY secure Flash sectors to EXEONLY RAM blocks. These functions do the copy-code operation in a highly secure environment and allow a copy to be performed only when the following conditions are met:

- The secure RAM block and the secure Flash sector belong to the same zone.
- Both the secure RAM block and the secure Flash sector have EXEONLY protection enabled.

For further usage of these library functions, see [Chapter 4](#).

5.5 SecureCRC

Since reads from EXEONLY memories are not allowed, the user cannot calculate the CRC on content in EXEONLY memories using the CRC engine available on this device (for example, VCUCRC, GCRC) or software. In some safety-critical applications, the user may have to calculate the CRC even on these memories. To enable this without compromising on security, TI provides specific “SecureCRC” library functions for each zone. These functions do the CRC calculation in highly secure environment and allow a CRC calculation to be performed only when the following conditions are met:

- The source address must be modulo the number of words (based on length_id) for which the CRC needs to be calculated.
- The destination address must belong to the same zone as the source address.

For further usage of these library functions, see the device-specific Boot ROM documentation.

Note

The user must disable all the interrupts before calling the secure functions in ROM. If there is a vector fetch during secure function execution, the CPU gets reset immediately.

Disclaimer: The Code Security Module (CSM) included on this device was designed to password protect the data stored in the associated memory and is warranted by Texas Instruments (TI), in accordance with its standard terms and conditions, to conform to TI's published specifications for the warranty period applicable for this device. TI DOES NOT, HOWEVER, WARRANT OR REPRESENT THAT THE CSM CANNOT BE COMPROMISED OR BREACHED OR THAT THE DATA STORED IN THE ASSOCIATED MEMORY CANNOT BE ACCESSED THROUGH OTHER MEANS. MOREOVER, EXCEPT AS SET FORTH ABOVE, TI MAKES NO WARRANTIES OR REPRESENTATIONS CONCERNING THE CSM OR OPERATION OF THIS DEVICE, INCLUDING ANY IMPLIED WARRANTIES OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. IN NO EVENT SHALL TI BE LIABLE FOR ANY CONSEQUENTIAL, SPECIAL, INDIRECT, INCIDENTAL, OR PUNITIVE DAMAGES, HOWEVER CAUSED, ARISING IN ANY WAY OUT OF YOUR USE OF THE CSM OR THIS DEVICE, WHETHER OR NOT TI HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES. EXCLUDED DAMAGES INCLUDE, BUT ARE NOT LIMITED TO LOSS OF DATA, LOSS OF GOODWILL, LOSS OF USE OR INTERRUPTION OF BUSINESS OR OTHER ECONOMIC LOSS.

5.6 CSM Impact on Other On-Chip Resources

On this device, some of the memories are not secure. To avoid any potential hacking when the device is in the default state (post reset), accesses (all types) to all memories (secure as well as non-secure, except BOOT-ROM and OTP) are disabled until proper security initialization is done. This means that after reset none of the memory resources except BOOT_ROM and OTP is accessible to the user.

The following steps are required by CPU after reset (any type of reset) to initialize the security on device.

Security Initialization

- Dummy Read to address location of SECDC (0x703F0, TI-reserved register) in TI OTP
- Dummy Read to address location of Z1OTP_LINKPOINTER1 in Z1 OTP
- Dummy Read to address location of Z1OTP_LINKPOINTER2 in Z1 OTP
- Dummy Read to address location of Z1OTP_LINKPOINTER3 in Z1 OTP
- Dummy Read to address location of Z2OTP_LINKPOINTER1 in Z2 OTP
- Dummy Read to address location of Z2OTP_LINKPOINTER2 in Z2 OTP
- Dummy Read to address location of Z2OTP_LINKPOINTER3 in Z2 OTP
- Dummy Read to address location Z1OTP_JLM_ENABLE in Z1 OTP
- Dummy Read to address location of Z1OTP_GPREG1, Z1OTP_GPREG2, Z1OTP_GPREG3, Z1OTP_GPREG4 in Z1 OTP
- Dummy Read to address location of Z1OTP_PSWDLOCK in Z1 OTP
- Dummy Read to address location of Z1OTP_CRCLOCK in Z1 OTP
- Dummy Read to address location of Z1OTP_JTAGPSWDH0, Z1OTP_JTAGPSWDH1 in Z1 OTP
- Dummy Read to address location of Z2OTP_GPREG1, Z2OTP_GPREG2, Z2OTP_GPREG3, Z2OTP_GPREG4 in Z2 OTP
- Dummy Read to address location of Z2OTP_PSWDLOCK in Z2 OTP
- Dummy Read to address location of Z2OTP_CRCLOCK in Z2 OTP
- Read to memory map register of Z1_LINKPOINTER in DCSM module to calculate the address of zone select block for Z1
- Dummy read to address location of Z1OTP_GRABSECT1, Z1OTP_GRABSECT2, Z1OTP_GRABSECT3 in Z1 OTP
- Dummy read to address location of Z1OTP_GRABRAM1, Z1OTP_GRABRAM2, Z1OTP_GRABRAM3 in Z1 OTP
- Dummy read to address location of Z1OTP_EXEONLYSECT1, Z1OTP_EXEONLYSECT2 in Z1 OTP
- Dummy read to address location of Z1OTP_EXEONLYRAM1 in Z1 OTP
- Dummy Read to address location of Z1OTP_JTAGPSWDL0, Z1OTP_JTAGPSWDL1 in Z1 OTP
- Read to memory map register of Z2_LINKPOINTER in DCSM module to calculate the address of zone select block for Z2
- Dummy read to address location of Z2OTP_GRABSECT1, Z2OTP_GRABSECT2, Z2OTP_GRABSECT3 in Z2 OTP
- Dummy read to address location of Z2OTP_GRABRAM1, Z2OTP_GRABRAM2, Z2OTP_GRABRAM3 in Z2 OTP
- Dummy read to address location of Z2OTP_EXEONLYSECT1, Z2OTP_EXEONLYSECT2 in Z2 OTP
- Dummy read to address location of Z2OTP_EXEONLYRAM1 in Z2 OTP

Note

Security Initialization is done by BOOTROM code on all the resets (as part of device initialization) that assert SYSRSn. This is not part of the user application code.

The order of initialization matters; hence, if a memory watch window with the USER OTP address is opened in the debugger (CCS IDE), the security initialization can occur in an incorrect order locking the device down. To avoid this, do not keep a memory window with the USER OTP address opened in the debugger (CCS IDE) when performing a reset.

5.7 Incorporating Code Security in User Applications

Code security is typically not required in the development phase of a project. However, security is needed once a robust code is developed for a zone. Before such a code is programmed in the Flash memory, a CSM password must be chosen to secure the zone. Once a CSM password is in place for a zone, the zone is secured (programming a password at the appropriate locations and either performing a device reset or setting the FORCESEC bit (Zx_CR.31) is the action that secures the device). From that time on, access to debug the contents of secure memory by any means (using JTAG, code running off external/on-chip memory, and so forth) requires a valid password. A password is not needed to run the code out of secure memory (such as in a typical end-user usage); however, access to secure memory contents for debug purposes, requires a password.

5.7.1 Environments That Require Security Unlocking

The following are the typical situations under which unsecuring the zone can be required:

- Code development using debuggers (such as Code Composer Studio™ IDE). This is the most common environment during the design phase of a product.
- Flash programming using TI's Flash utilities such as Code Composer Studio On-Chip Flash Programmer plug-in or the Uniflash tool. Flash programming is common during code development and testing. Once the user supplies the necessary password, the Flash utilities disable the security logic before attempting to program the Flash. In custom programming solutions that use the Flash API supplied by TI, unlocking the CSM can be avoided by executing the Flash programming algorithms from secure memory.
- Custom environment defined by the application
 - In addition to the above, access to secure memory contents can be required in situations such as:
 - Using the on-chip bootloader to load code or data into secure SARAM or to erase and program the Flash.
 - Executing code from on-chip unsecure memory and requiring access to secure memory for the lookup table. This is not a suggested operating condition as supplying the password from external code could compromise code security.

The unsecuring sequence is identical in all the above situations. This sequence is referred to as the password match flow (PMF) for simplicity. [Figure 5-3](#) explains the sequence of operation that is required every time the user attempts to unsecure a particular zone. A code example is listed for clarity.

5.7.2 CSM Password Match Flow

Password match flow (PMF) is essentially a sequence of four dummy reads from password locations (PWL) followed by four writes (32-bit writes) to CSMKEY(0/1/2/3) registers. [Figure 5-3](#) shows how PMF helps to initialize the security logic registers and disable security logic.

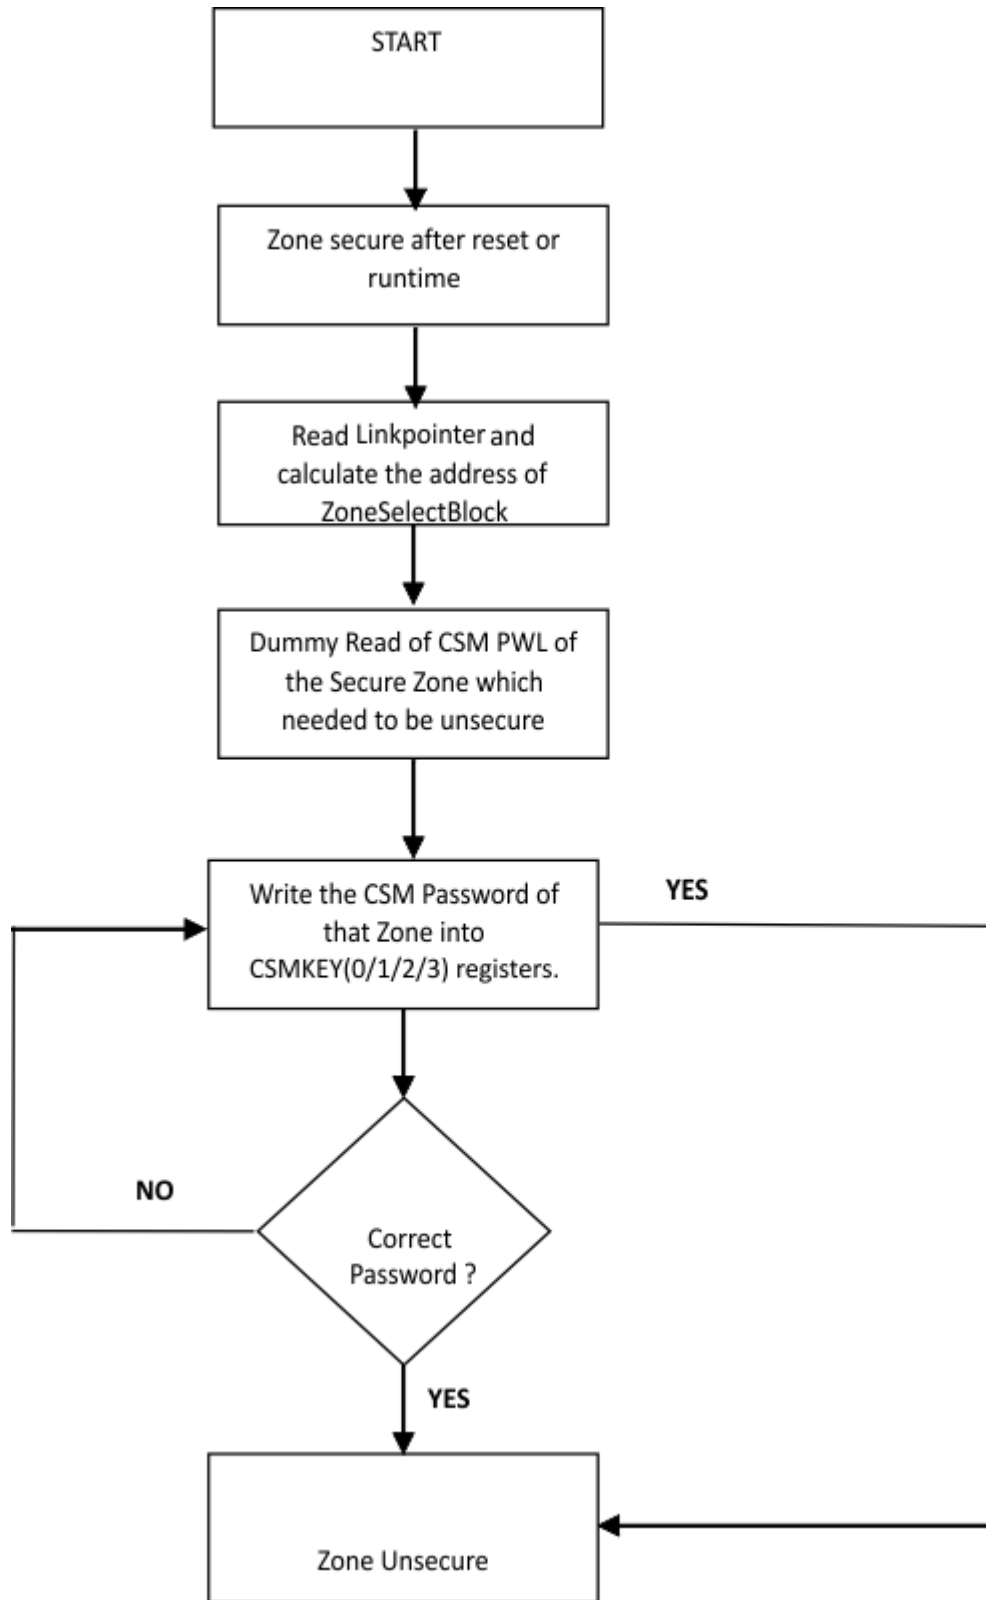

Figure 5-3. CSM Password Match Flow (PMF)

5.7.3 C Code Example to Unsecure C28x Zone1

```
volatile long int *CSM = (volatile long int *)5F090; //CSM register file volatile
long int *CSMPWL = (volatile long int *)0x78020; //CSM Password location (assuming default zone
select block)
volatile int tmp;
int I;
// Read the 128-bits of the CSM password locations (PWL)
//
for (I=0;I<4; I++) tmp = *CSMPWL++;
// write the 128-bit password to the CSMKEY registers
// If this password matches that stored in the
// CSLPWL, then the CSM becomes unsecure. If the password does not
// match, then the zone remains secure.
// An example password of: // 0x11112222333344445555666677778888 is used.
*CSM++ = 0x22221111; // Register Z1_CSMKEY0 at 0x5F090
*CSM++ = 0x44443333; // Register Z1_CSMKEY1 at 0x5F092
*CSM++ = 0x66665555; // Register Z1_CSMKEY2 at 0x5F094
*CSM++ = 0x88887777; // Register Z1_CSMKEY3 at 0x5F096
```

5.7.4 C Code Example to Resecure C28x Zone1

```
volatile int *Z1_CR = 0x5F019; //CSMSCR register
//Set FORCESEC bit
*Z1_CR = 0x8000;
```

5.7.5 Environments That Require ECSL Unlocking

The following are the typical situations under which unsecuring can be required:

- The user develops some main IP, and then outsources peripheral functions to a subcontractor who must be able to run the user code during debug and can halt while main IP code is running. If ECSL is not unlocked, then Code Composer Studio IDE connections get disconnected, which can be inconvenient for the user. Note that unlocking ECSL does not enable access to secure code but only avoids disconnection of the CCS IDE (JTAG).

5.7.6 ECSL Password Match Flow

A password match flow (PMF) is essentially a sequence of eight dummy reads from password locations (PWL) followed by two writes to KEY registers. [Figure 5-4](#) shows how the PMF helps to initialize the security logic registers and disable security logic.

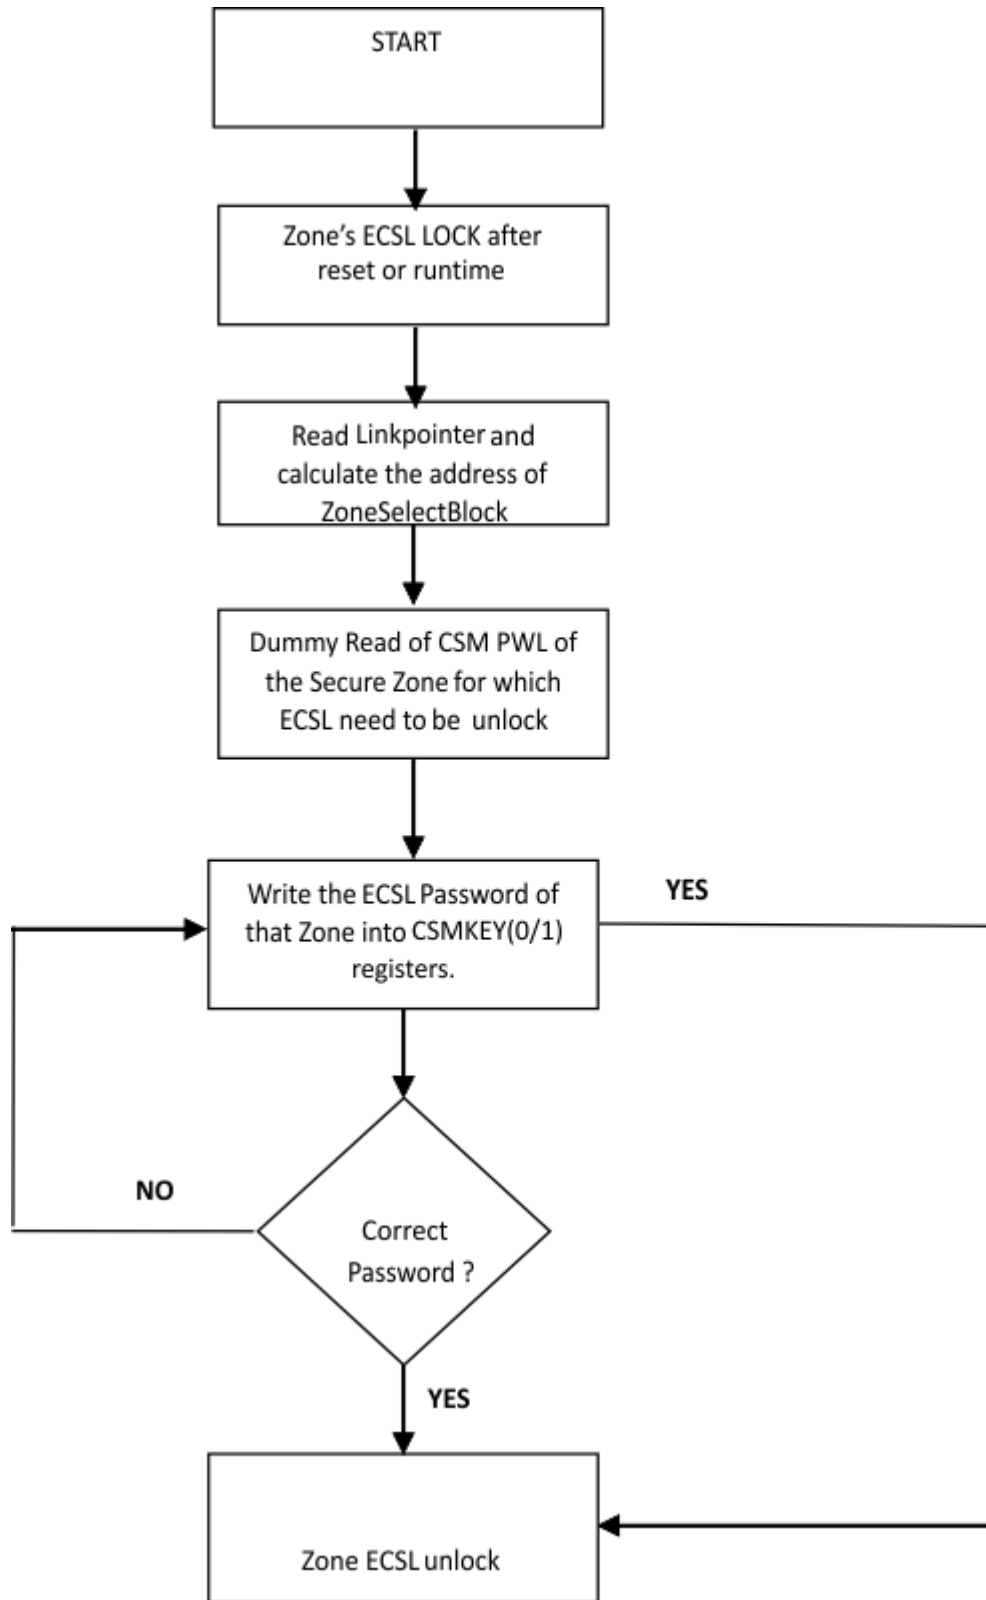

Figure 5-4. ECSSL Password Match Flow (PMF)

5.7.7 ECSL Disable Considerations for any Zone

A zone with ECSL enabled must have a predetermined ECSL password stored in the ECSL password locations in Flash (same as lower 64 bits of CSM passwords). The following are steps to disable the ECSL for any particular zone:

- Perform a dummy read of CSM password locations of that Zone.
- Write the password into the CSMKEY0/1 registers, corresponding to that Zone.
- If the password is correct, the ECSL gets disabled; otherwise, the ECSL stays enabled.

5.7.7.1 C Code Example to Disable ECSL for C28x Zone1

```
volatile long int *ECSL = (volatile int *)0x5F090; //ECSL register file
volatile long int *ECSLPWL = (volatile int *)0x78028; //ECSL Password location (assuming default
Zone sel block)
volatile int tmp;
int I;
// Read the 64-bits of the password locations (PWL).
for (I=0;I<2; I++) tmp = *ECSLPWL++;
// Write the 64-bit password to the CSMKEYx registers
// If this password matches that stored in the
// CSMPWL, then ECSL gets disabled. If the password does not
// match, then the zone remains secure.
// An example password of: // 0x1111222233334444 is used.
*ECSL++ = 0x22221111; // Register Z1_CSMKEY0 at 0x5F090
*ECSL++ = 0x44443333; // Register Z1_CSMKEY1 at 0x5F092
```

5.7.8 Device Unique ID

TI OTP contains a 256-bit value that is made up of both random and sequential parts. This value can be used as a seed for code encryption. The starting address of the value is 0x70200. The first 192 bits are random, the next 32 bits are sequential, and the last 32 bits are a checksum value.

5.8 Software

5.8.1 DCSM Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/dcsm

Cloud access to these examples is available at the following link: [dev.ti.com C2000Ware Examples](#).

5.8.1.1 Empty DCSM Tool Example

FILE: dcsm_security_tool.c

This example is an empty project setup for DCSM Tool and Driverlib development. For guidance refer to: [C2000 DCSM Security Tool](#)

5.9 DCSM Registers

This section describes the various DCSM registers.

5.9.1 DCSM Base Address Table

Table 5-4. DCSM Base Address Table

Bit Field Name		DriverLib Name	Base Address	CPU1	DMA	HIC	CLA	Pipeline Protected
Instance	Structure							
DcsmZ1Regs	DCSM_Z1_REGS	DCSM_Z1_BASE	0x0005_F000	YES	-	-	-	YES
DcsmZ2Regs	DCSM_Z2_REGS	DCSM_Z2_BASE	0x0005_F080	YES	-	-	-	YES
DcsmCommonRegs	DCSM_COMMON_REGS	DCSMCOMMON_BASE	0x0005_F0C0	YES	-	-	-	YES
DcsmZ1OtpRegs	DCSM_Z1_OTP	DCSM_Z1OTP_BASE	0x0007_8000	YES	-	-	-	-
DcsmZ2OtpRegs	DCSM_Z2_OTP	DCSM_Z2OTP_BASE	0x0007_8200	YES	-	-	-	-

5.9.2 DCSM_Z1_REGS Registers

Table 5-5 lists the memory-mapped registers for the DCSM_Z1_REGS registers. All register offset addresses not listed in Table 5-5 should be considered as reserved locations and the register contents should not be modified.

Table 5-5. DCSM_Z1_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	Z1_LINKPOINTER	Zone 1 Link Pointer		Go
2h	Z1_OTPSECLOCK	Zone 1 OTP Secure Lock		Go
4h	Z1_JLM_ENABLE	Zone 1 JTAGLOCK Enable Register		Go
6h	Z1_LINKPOINTERERR	Link Pointer Error		Go
8h	Z1_GPREG1	Zone 1 General Purpose Register-1		Go
Ah	Z1_GPREG2	Zone 1 General Purpose Register-2		Go
Ch	Z1_GPREG3	Zone 1 General Purpose Register-3		Go
Eh	Z1_GPREG4	Zone 1 General Purpose Register-4		Go
10h	Z1_CSMKEY0	Zone 1 CSM Key 0		Go
12h	Z1_CSMKEY1	Zone 1 CSM Key 1		Go
14h	Z1_CSMKEY2	Zone 1 CSM Key 2		Go
16h	Z1_CSMKEY3	Zone 1 CSM Key 3		Go
18h	Z1_CR	Zone 1 CSM Control Register		Go
1Ah	Z1_GRABSECT1R	Zone 1 Grab Flash Status Register 1		Go
1Ch	Z1_GRABSECT2R	Zone 1 Grab Flash Status Register 2		Go
1Eh	Z1_GRABSECT3R	Zone 1 Grab Flash Status Register 3		Go
20h	Z1_GRABRAM1R	Zone 1 Grab RAM Status Register 1		Go
26h	Z1_EXEONLYSECT1R	Zone 1 Execute Only Flash Status Register 1		Go
28h	Z1_EXEONLYSECT2R	Zone 1 Execute Only Flash Status Register 2		Go
2Ah	Z1_EXEONLYRAM1R	Zone 1 Execute Only RAM Status Register 1		Go
2Eh	Z1_JTAGKEY0	JTAG Unlock Key Register 0		Go
30h	Z1_JTAGKEY1	JTAG Unlock Key Register 1		Go
32h	Z1_JTAGKEY2	JTAG Unlock Key Register 2		Go
34h	Z1_JTAGKEY3	JTAG Unlock Key Register 3		Go
36h	Z1_CMACKKEY0	Secure Boot CMAC Key Status Register 0		Go
38h	Z1_CMACKKEY1	Secure Boot CMAC Key Status Register 1		Go
3Ah	Z1_CMACKKEY2	Secure Boot CMAC Key Status Register 2		Go
3Ch	Z1_CMACKKEY3	Secure Boot CMAC Key Status Register 3		Go

Complex bit access types are encoded to fit into small table cells. Table 5-6 shows the codes that are used for access types in this section.

Table 5-6. DCSM_Z1_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
Reset or Default Value		

**Table 5-6. DCSM_Z1_REGS Access Type Codes
(continued)**

Access Type	Code	Description

Table 5-22. Z1_GRABSECT3R Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
13-12	GRAB_SECT6	R	0h	Value in this field gets loaded from Z1_GRABSECT3[13:12] when a read is issued to address location of Z1_GRABSECT3 in OTP. 00 : Invalid. Bank 2 Flash Sector 6 is inaccessible. 01 : Request to allocate Bank 2 Flash Sector 6 to Zone1. 10 : No request for Bank 2 Flash Sector 6 11 : No request for Bank 2 Flash Sector 6 when this zone is UNLOCKED. Else Bank 2 Flash Sector 6 is inaccessible if this zone is LOCKED. Reset type: SYSRSn
11-10	GRAB_SECT5	R	0h	Value in this field gets loaded from Z1_GRABSECT3[11:10] when a read is issued to address location of Z1_GRABSECT3 in OTP. 00 : Invalid. Bank 2 Flash Sector 5 is inaccessible. 01 : Request to allocate Bank 2 Flash Sector 5 to Zone1. 10 : No request for Bank 2 Flash Sector 5 11 : No request for Bank 2 Flash Sector 5 when this zone is UNLOCKED. Else Bank 2 Flash Sector 5 is inaccessible if this zone is LOCKED. Reset type: SYSRSn
9-8	GRAB_SECT4	R	0h	Value in this field gets loaded from Z1_GRABSECT3[9:8] when a read is issued to address location of Z1_GRABSECT3 in OTP. 00 : Invalid. Bank 2 Flash Sector 4 is inaccessible. 01 : Request to allocate Bank 2 Flash Sector 4 to Zone1. 10 : No request for Bank 2 Flash Sector 4 11 : No request for Bank 2 Flash Sector 4 when this zone is UNLOCKED. Else Bank 2 Flash Sector 4 is inaccessible if this zone is LOCKED. Reset type: SYSRSn
7-6	GRAB_SECT3	R	0h	Value in this field gets loaded from Z1_GRABSECT3[7:6] when a read is issued to address location of Z1_GRABSECT3 in OTP. 00 : Invalid. Bank 2 Flash Sector 3 is inaccessible. 01 : Request to allocate Bank 2 Flash Sector 3 to Zone1. 10 : No request for Bank 2 Flash Sector 3 11 : No request for Bank 2 Flash Sector 3 when this zone is UNLOCKED. Else Bank 2 Flash Sector 3 is inaccessible if this zone is LOCKED. Reset type: SYSRSn
5-4	GRAB_SECT2	R	0h	Value in this field gets loaded from Z1_GRABSECT3[5:4] when a read is issued to address location of Z1_GRABSECT3 in OTP. 00 : Invalid. Bank 2 Flash Sector 2 is inaccessible. 01 : Request to allocate Bank 2 Flash Sector 2 to Zone1. 10 : No request for Bank 2 Flash Sector 2 11 : No request for Bank 2 Flash Sector 2 when this zone is UNLOCKED. Else Bank 2 Flash Sector 2 is inaccessible if this zone is LOCKED. Reset type: SYSRSn
3-2	GRAB_SECT1	R	0h	Value in this field gets loaded from Z1_GRABSECT3[3:2] when a read is issued to address location of Z1_GRABSECT3 in OTP. 00 : Invalid. Bank 2 Flash Sector 1 is inaccessible. 01 : Request to allocate Bank 2 Flash Sector 1 to Zone1. 10 : No request for Bank 2 Flash Sector 1 11 : No request for Bank 2 Flash Sector 1 when this zone is UNLOCKED. Else Bank 2 Flash Sector 1 is inaccessible if this zone is LOCKED. Reset type: SYSRSn

Table 5-22. Z1_GRABSECT3R Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1-0	GRAB_SECT0	R	0h	Value in this field gets loaded from Z1_GRABSECT3[1:0] when a read is issued to address location of Z1_GRABSECT3 in OTP. 00 : Invalid. Bank 2 Flash Sector 0 is inaccessible. 01 : Request to allocate Bank 2 Flash Sector 0 to Zone1. 10 : No request for Bank 2 Flash Sector 0 11 : No request for Bank 2 Flash Sector 0 when this zone is UNLOCKED. Else Bank 2 Flash Sector 0 is inaccessible if this zone is LOCKED. Reset type: SYSRSn

5.9.2.17 Z1_GRABRAM1R Register (Offset = 20h) [Reset = 0000000h]

Z1_GRABRAM1R is shown in [Figure 5-21](#) and described in [Table 5-23](#).

5.9.4 DCSM_COMMON_REGS Registers

Table 5-56 lists the memory-mapped registers for the DCSM_COMMON_REGS registers. All register offset addresses not listed in Table 5-56 should be considered as reserved locations and the register contents should not be modified.

Table 5-56. DCSM_COMMON_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	FLSEM	Flash Wrapper Semaphore Register	EALLOW	Go
8h	SECTSTAT1	Flash Sectors Status Register 1		Go
Ah	SECTSTAT2	Flash Sectors Status Register 2		Go
Ch	SECTSTAT3	Flash Sectors Status Register 3		Go
10h	RAMSTAT1	RAM Status Register 1		Go
18h	SECERRSTAT	Security Error Status Register		Go
1Ah	SECERRCLR	Security Error Clear Register		Go
1Ch	SECERRFRC	Security Error Force Register		Go

Complex bit access types are encoded to fit into small table cells. Table 5-57 shows the codes that are used for access types in this section.

Table 5-57. DCSM_COMMON_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

5.9.4.1 FLSEM Register (Offset = 0h) [Reset = 0000000h]

FLSEM is shown in [Figure 5-52](#) and described in [Table 5-58](#).

6.1 Introduction to Flash and OTP Memory

Flash is an electrically erasable/programmable nonvolatile memory that can be programmed and erased many times to ease code development. Flash memory can be used primarily as a program memory for the core, and secondarily as static data memory.

This section describes the proper sequence to configure the wait states and operating mode of Flash. It also includes information on Flash and OTP power modes, how to improve Flash performance by enabling the Flash prefetch/cache mode, and the SECDED safety feature.

6.1.1 FLASH Related Collateral

Foundational Materials

- [C2000 Academy - FLASH](#)
- [Embedded Flash Memory](#) (Video)

Getting Started Materials

- [\[FAQ\] FAQ for Flash ECC usage in C2000 devices - Includes ECC test mode, Linker ECC options:](#)
- [\[FAQ\] FAQ on Flash API usage for C2000 devices](#)
- [\[FAQ\] Flash - How to modify an application from RAM configuration to Flash configuration?](#)
- [\[FAQ\] How can we improve the Flash tool performance?](#)

6.1.2 Features

Features of Flash memory include:

- Three Flash banks (Bank0, 1, 2) (refer to the device data sheet for the size of the Flash bank)
- 128 bits (bank width) can be programmed at a time along with ECC
- Multiple sectors providing the option of leaving some sectors programmed and only erasing specific sectors
- User-programmable OTP locations (in user-configurable DCSM OTP, also called USER OTP) for configuring security, OTP boot-mode and boot-mode select pins (if the user is unable to use the factory-default boot-mode select pins)
- Flash pump shared by the two banks
- Enhanced performance using the code prefetch mechanism and data cache in FMC
- Configurable wait states to give the best performance for a given execution speed
- Safety Features:
 - SECDED - single-error correction and double-error detection is supported in the FMC
 - Address bits are included in ECC
 - Test mode to check the health of ECC logic
- Supports low-power modes for Flash bank and pump for power savings
- Built-in power mode control logic
- Integrated Flash program/erase state machine (FSM) in the FMC
 - Simple Flash API algorithms
 - Fast erase and program times (refer to the device data sheet for details)
- Dual Code Security Module (DCSM) to prevent unauthorized access to the Flash (refer to the *Dual Code Security Module (DCSM)* chapter for details)

6.1.3 Flash Tools

Texas Instruments provides the following tools for Flash:

- Code Composer Studio™ (CCS) IDE - the development environment with integrated Flash plugin. TI recommends performing a debug reset and restart after programming the code into Flash using CCS.
- Flash API Library - a set of software peripheral functions to erase/program Flash
- UniFlash - standalone tool to erase/program/verify the Flash content through JTAG. No CCS is required.
- Users must check and install available updates for CCS On-Chip Flash Plugin and UniFlash tools.

6.1.4 Default Flash Configuration

The following are Flash module configuration settings at power-up:

- Dedicated Flash banks are in sleep mode (BNKPWR bit field in the FBFALLBAC register)
- Shared pump is in sleep mode (PMPPWR bit field in the FPAC1 register)
- ECC is enabled
- Wait-states are set to the maximum (0xF)
- Code-prefetch mechanism and data cache are disabled in all three FMCs
- Bank and pump active grace periods are set to 0x0 (refer to the BAGP field in the FBAC register and PAGP bit field in the FPAC2 register)

Note that boot ROM changes the BNKPWR and PMPPWR bit fields to active mode.

User application software must initialize wait-states using the FRDCNTL register, and configure cache/prefetch features using the FRD_INTF_CTRL register, to achieve optimum system performance. Software that configures Flash settings like wait-states, cache/prefetch features, and so on, must be executed only from RAM memory, **not** from Flash memory.

Note

Before initializing wait-states, turn off the prefetch and data caching in the FRD_INTF_CTRL register.

6.2 Flash Bank, OTP, and Pump

There is a dedicated Flash bank for CPU subsystem. Also, there is a one-time programmable (OTP) memory called USER OTP, which the user can program only once and cannot erase. Flash and OTP are uniformly mapped in both program and data memory space.

The CPU subsystem has a TI-OTP that contains manufacturing information like settings used by the Flash state machine for erase and program operations, and so on. Users can read TI-OTP but TI-OTP cannot be programmed or erased. For memory maps and size information for the Flash Banks, TI-OTP, USER OTP, and corresponding ECC locations, refer to the device data sheet.

The *Location of Zone-Select Block Based on Link-Pointer* figure in the *Dual Code Security Module (DCSM)* chapter shows the user-programmable OTP locations in USER-OTP. For more information on the functionality of these fields, refer to the *Dual Code Security Module (DCSM)* and the *ROM Code and Peripheral Booting* chapters.

6.3 Flash Module Controller (FMC)

The CPU interfaces with the FMC, which in turn interfaces with the Flash bank and the pump, to perform erase or program operations, to read data, and execute code from the Flash bank.

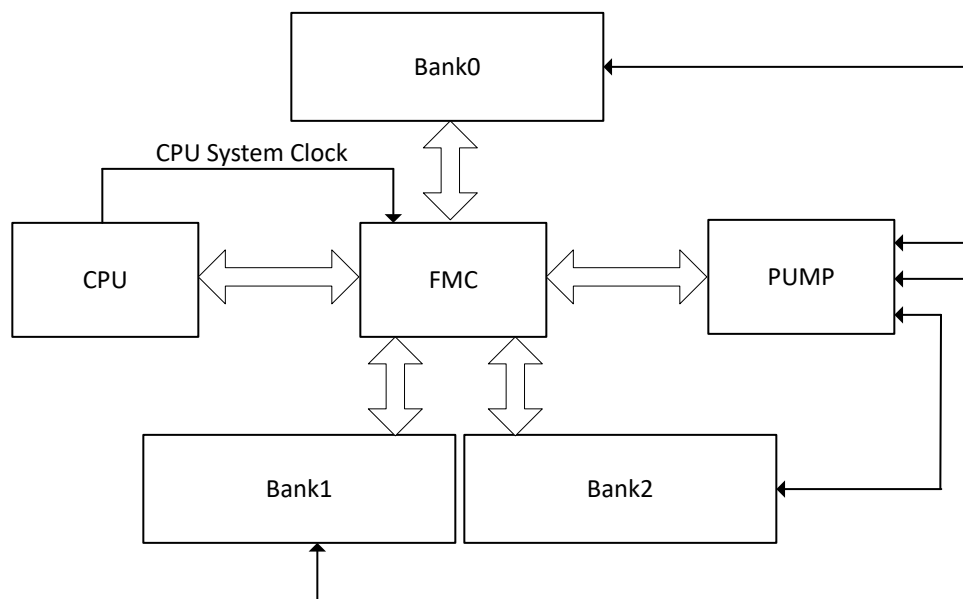

Figure 6-1. FMC Interface with Core, Bank, and Pump

6.4 Flash and OTP Memory Power-Down Modes and Wakeup

The Flash bank and pump consume a significant amount of power when active. The Flash module provides a mechanism to power-down Flash banks and pump. Special timers automatically sequence the power-up of the CPU Flash bank. The charge pump module includes an independent power-up timer as well.

The Flash bank and OTP memory operate in three power modes: Sleep (lowest power), Standby, and Active (highest power)

- **Sleep State**
This is the state after a device reset. In this state, a CPU data read or opcode fetch automatically initiates a change in power mode to the standby state and then to the active state. During this transition time to the active state, the CPU execution is automatically stalled.
- **Standby State**
This state uses more power than the sleep state, but takes a shorter time to transition to the active or read state. In this state, a CPU data read or opcode fetch automatically initiates a change in power mode to the active state. During this transition time to the active state, the CPU execution is automatically stalled. Once the Flash/OTP has reached the active state, the CPU access completes as normal.
- **Active or Read State**
In this state, the bank and pump are in active power mode state (highest power)

The charge pump operates in two power modes:

- Sleep (lowest power)
- Active (highest power)

Any access to any Flash bank/OTP causes the charge pump to go into active mode, if in sleep mode. An erase or program command causes the charge pump and bank to become active. If any bank is in active or in standby mode, the charge pump is in active mode, independent of the pump power mode control configuration (PMPPWR bit field in the FPAC1 register). While the pump is in sleep state, a charge pump sleep down counter holds a user-configurable value (PSLEEP bit field in the FPAC1 register) and when the charge pump exits sleep

power mode, the down counter delays from 0 to PSLEEP prescaled SYSCLK clock cycles (prescaled clock is SYSCLK/2) before putting the charge pump into active power mode.

Following are the numbers of cycles for the bank and pump to wake up from low-power modes.

1. Pump sleep to active = PSLEEP * (SYSCLK/2) cycles
2. Bank sleep to standby = 254 Flash clock cycles
3. Bank standby to active = 55 Flash clock cycles

Where: Flash clock = SYSCLK/(RWAIT+1)

6.5 Active Grace Period

The active grace period (AGP) can be used to optimize the Flash module power consumption versus access time. Faster access times are associated with higher-power modes of operation. At one extreme, the power control logic can attempt to reduce power consumption by putting the bank and charge pump into a low-power mode immediately at the end of every Flash access. However, if accesses are only a few cycles apart, this can actually increase power consumption versus leaving the Flash powered, because the bank and charge pump consume more power during Flash startup and access.

The active grace periods allows the bank and charge pump to be maintained in active mode for a specified period following an access. This is done in anticipation of another read within the AGP time, to allow the subsequent read to have a faster access and spend less time dissipating power, than if the bank went into one of the low-power modes immediately. If the next access does not occur within the AGP time, the power control logic can automatically put the bank and charge pump into a low-power mode to reduce power consumption during long periods of inactivity.

The AGP value is programmed by a set of programmable counters (FBAC and FPAC2) that keep the Flash bank or charge pump in active mode until the counter expires, at which time the bank or charge pump reverts to the fallback power mode as defined in the FBFALLBACK and FPAC1 (refer to PMPPWR bit-field) registers. The application software can configure the fallback power mode to reduce power consumption, or configure the power mode to be active mode to keep the bank active regardless of counter settings (default is SLEEP). The charge pump AGP counter remains in the initialized state when the bank is active, including the AGP counter of the bank. The charge pump AGP counter begins counting when the bank has become inactive.

The application software can check the current power mode of Flash bank and charge pump by reading the FBPRDY register.

6.6 Flash and OTP Memory Performance

Flash read or instruction fetch accesses can be classified either as a Flash access (access to an address location in Flash), or an OTP access (access to an address location in OTP).

When the CPU performs an access to a Flash memory address, data is returned after (RWAIT+1) SYSCLK cycles.

For a USER-OTP access, data is returned after 11 SYSCLK cycles.

RWAIT defines the number of random access wait states, and is configured using the RWAIT field in the FRDCNTL register. At reset, RWAIT defaults to a worst-case wait state count (15), and therefore must be initialized to the appropriate number of wait states to improve performance, based on the CPU clock frequency and the access time of the Flash. The Flash supports zero-wait accesses when RWAIT is set to zero, when the CPU clock frequency is low enough to accommodate the Flash access time.

For a given system clock frequency, configure RWAIT using the following formula:

For C28x Flash Bank: $RWAIT = \text{ceiling}[(SYSCLK/FCLK)-1]$

where SYSCLK is the system operating frequency for CPU1, and FCLK is the clock frequency for Flash.

FCLK must be $\leq FCLK_{max}$, the allowed maximum Flash clock frequency at RWAIT=0.

If RWAIT results in a fractional value when calculated using the above formula, round up RWAIT to the nearest integer.

6.7 Flash Read Interface

This section provides details about the data read modes to access Flash bank/OTP and the configuration registers that control the read interface. In addition to a standard read mode, the FMC has a built-in prefetch and cache mechanism to allow increased clock speeds and CPU throughput wherever applicable.

6.7.1 C28x-FMC Flash Read Interface

6.7.1.1 Standard Read Mode

Standard read mode is the default Flash read mode after reset. In this mode, the code prefetch mechanism and data cache are disabled. When standard read mode is active, every read access to Flash is decoded by the Flash wrapper to fetch the data from the addressed location, and the data is returned after RWAIT+1 cycles (except User OTP).

Flash data buffers associated with the prefetch mechanism and data cache are bypassed in standard read mode; therefore, every access to the Flash/OTP is used by the CPU immediately, and every access creates a unique Flash bank access.

Standard read mode is the recommended mode for lower system frequency operation, where RWAIT can be set to zero to provide single-cycle access operation. The FMC can operate at higher frequencies using standard read mode, at the expense of adding wait states. At higher system frequencies, it is recommended to enable the data cache and prefetch mechanisms to improve performance. Refer to the device data sheet to determine the maximum Flash frequency allowed in standard read mode (that is, maximum Flash clock frequency with RWAIT=0, FCLK_{MAX}).

6.7.1.2 Prefetch Mode

Flash memory is typically used to store application code. During code execution, instructions are fetched from contiguous memory addresses, except when a discontinuity occurs. Usually, the portion of the code that resides in contiguous address locations makes up the majority of the application code, and is referred to as linear code. To improve the performance of linear code execution, a Flash prefetch mechanism has been implemented.

[Figure 6-2](#) illustrates how this mode functions.

The prefetch mechanism does a look-ahead prefetch on linear address increments, starting from the address of the last instruction fetch. The Flash prefetch mechanism is disabled by default. To enable prefetch mode, set the PREFETCH_EN bit in the FRD_INTF_CTRL register, or call the `Flash_enablePrefetch()` driverlib function.

Each instruction fetch from the Flash or OTP reads out 128 bits. The starting address of the access from Flash is automatically aligned to a 128-bit boundary, such that the instruction location is within the 128 bits to be fetched. When Flash prefetch mode is enabled, the 128 bits read from the instruction fetch are stored in a 128-bit wide by 2-level deep instruction prefetch buffer. The contents of this prefetch buffer are then sent to the CPU for processing as required.

Up to four 32-bit or eight 16-bit instructions can reside within a single 128-bit access. The majority of C28x instructions are 16 bits, so for every 128-bit instruction fetch from the Flash bank there are up to eight instructions in the prefetch buffer ready to process through the CPU. During the time to process these instructions, the Flash prefetch mechanism automatically initiates another access to the Flash bank to prefetch the next 128 bits. The Flash prefetch mechanism works in the background to keep the instruction prefetch buffers as full as possible. Using this technique, the overall efficiency of sequential code execution from Flash or OTP is improved significantly.

Note

If the prefetch mechanism is enabled, then the last two rows (16 16-bit words, 256 bits) of a Flash bank can not be used if there are no valid Flash memory addresses beyond the bank boundary. This is necessary to prevent the Flash prefetch mechanism from attempting to preload the instruction buffer with data from invalid address locations, causing an ECC error.

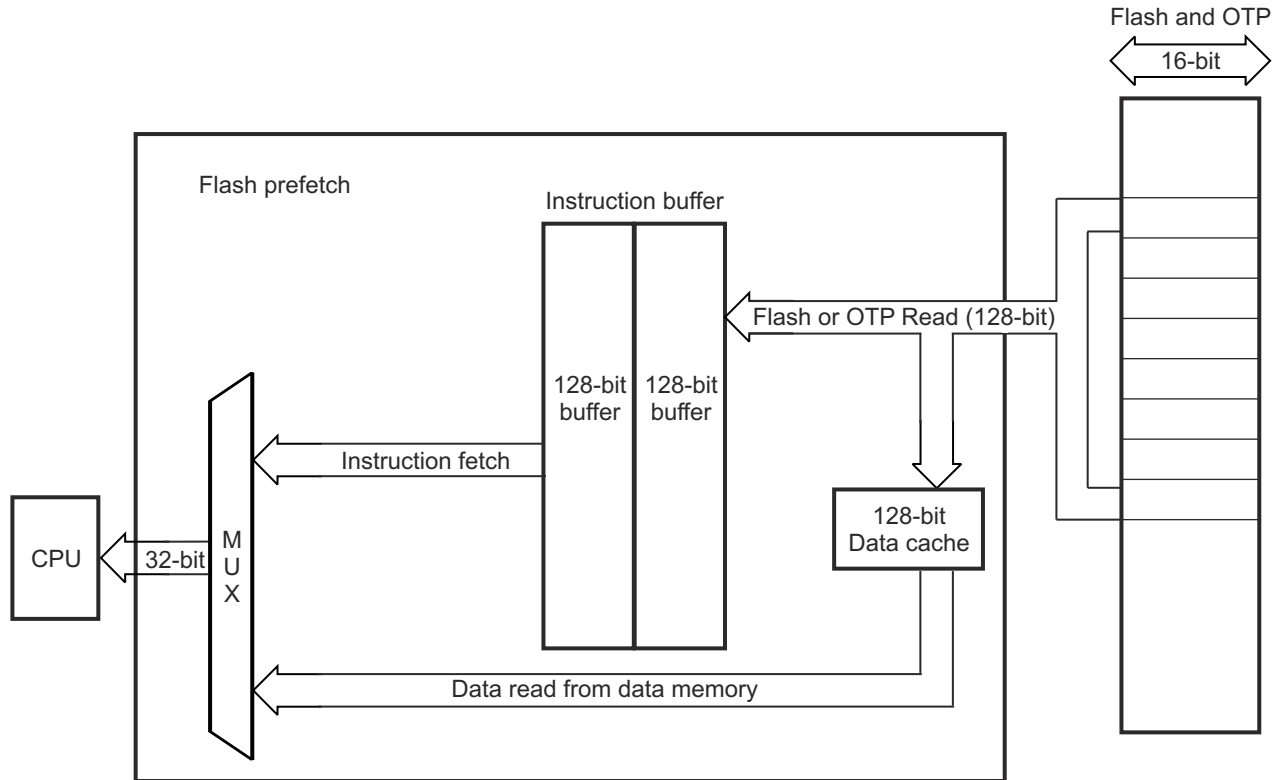

Figure 6-2. Flash Prefetch Mode

The Flash prefetch is aborted only when there is a code discontinuity caused by executing an instruction such as a branch, function call, or loop. When this occurs, the prefetch mechanism is aborted, and the contents of the prefetch buffer are flushed. There are two possible scenarios when this occurs:

1. If the destination address is within the Flash or OTP, the prefetch aborts and then resumes at the destination address.
2. If the destination address is outside of the Flash and OTP, the prefetch is aborted, and begins again only when the code branches back into the Flash or OTP. The Flash prefetch mechanism only applies to instruction fetches from program space. Data reads from data memory and from program memory do not utilize the prefetch mechanism and thus bypass the prefetch buffer. For example, instructions such as MAC, DMAC, and PREAD read a data value from program memory. When such a read happens, the prefetch buffer is bypassed, but the buffer is not flushed. If an instruction prefetch is already in progress when a data read operation is initiated, then the data read is stalled until the prefetch completes.

Note that the prefetch mechanism gets bypassed when RWAIT is configured as zero.

6.7.1.2.1 Data Cache

In addition to the prefetch mechanism, a data cache of 128-bits wide has been implemented to improve data space read performance. This data cache is separate from the instruction prefetch buffer, and is used for data reads only. Whenever a data read access is performed by the CPU to a Flash bank address, if the data located at that address is not presently loaded into the data cache, then the Flash wrapper reads 128 bits of data from the Flash bank and stores the data in the data cache. This data is eventually sent to the CPU for processing. The starting address of the Flash bank access is automatically aligned to a 128-bit boundary, such that the requested address location is within the 128 bits to be read from the bank.

The data cache is disabled by default at reset. To enable the data cache, set the DATA_CACHE_EN bit in the FRD_INTF_CTRL register, or call the Flash_enableCache() driverlib function. Note that the data cache gets bypassed when RWAIT is set to zero.

Note

The data cache does not get updated on a debugger access, or when a read to the ECC memory-mapped region is performed.

6.8 Flash Erase and Program

Flash memory can be programmed either by using the CCS Flash plug-in or by using the UniFlash application. If these methods are not feasible in an application, the Flash API can be used. The Flash memory can be programmed, erased, and verified only by using the Flash API library. These functions are written, compiled and validated by Texas Instruments. The Flash module contains a Flash state machine (FSM) to perform program and erase operations.

The recommended flow for programming Flash is:

Erase → Program → Verify

6.8.1 Erase

When the target Flash is erased, the Flash reads as all 1s. This state is called 'blank.' The erase function must be executed before programming. The user cannot skip erase on sectors that read as 'blank' because these sectors can require additional erasing due to marginally erased bits columns. The FSM provides an Erase Sector command to erase the target sector. The erase function erases the data and the ECC together. Bank erase is also supported in this device.

Note

To provide the correct sector mask for the bank erase command is important. If the mask is mistakenly chosen to erase an inaccessible sector (belongs to another security zone), the bank erase command continues attempting to erase the sector endlessly and the FSM never exits (since erase does not succeed). To avoid such a situation, the user must take care to provide the correct mask. However, given that there is a chance of choosing an incorrect mask, TI suggests to initialize the maximum allowed erase pulses to zero after the maximum number of pulses are issued by the FSM for the bank erase operation. This makes sure that the FSM ends the bank erase command after trying to erase the inaccessible sector up to the maximum allowed erase pulses.

The Example_EraseBanks() function in the C2000Ware's Flash API usage example depicts the implementation of this sequence (content of the while loop waiting for the FSM to complete the bank erase command). Users must use this code as-is irrespective of whether or not security is used by the application to also make sure that the FSM exits from bank erase operations in case of an erase-failure.

6.8.2 Program

The Flash controller provides a command to program the Flash and User OTP. This command is also used to program ECC check bits.

Note

The main array Flash programming must be aligned to 64-bit address boundaries, and each 64-bit word can only be programmed once per write/erase cycle.

The DCSM OTP programming must be aligned to 128-bit address boundaries and each 128-bit word can only be programmed once. The exceptions are:

- The DCSM Zx-LINKPOINTER1 and Zx-LINKPOINTER2 values in the DCSM OTP can be programmed together and can be programmed one bit at a time as required by the DCSM operation.
 - The DCSM Zx-LINKPOINTER3 values in the DCSM OTP can be programmed one bit at a time as required by the DCSM operation.
-

6.8.3 Verify

After programming, the user must perform verify using API function `Fapi_doVerify()`. This function verifies the Flash contents against supplied data.

Application software typically perform a CRC check of the Flash memory contents during power-up and at regular intervals during runtime (as needed). Apart from this, ECC logic, when enabled (enabled by default), catches single-bit errors, double-bit errors, and address errors whenever the CPU reads/fetches from a Flash address.

6.9 Error Correction Code (ECC) Protection

CPU1-FMC and CPU2-FMC contain an embedded single error correction and double error detection (SECDED) module. SECDED, when enabled, provides the capability to screen out memory faults. SECDED can detect and correct single-bit data errors and detect address errors/double-bit data errors. For every 64 bits of Flash/OTP data (aligned on a 64-bit memory boundary) that is programmed, eight ECC check bits have to be calculated and programmed in ECC memory space. Refer to the device data sheet for the Flash/OTP ECC memory-map. SECDED works with a total of eight user-calculated error correction code (ECC) check bits associated with each 64-bit wide data word and the corresponding 128-bit memory-aligned address. Users must program ECC check bits along with Flash data. TI recommends using the AutoEccGeneration option available in the Plugin/API to program ECC. Users can use the Flash API to calculate and program ECC data along with Flash data. Flash API uses hardware ECC logic in the device to generate the ECC data for the given Flash data. The Flash Plugin, the Flash programming tool integrated with the Code Composer Studio™ IDE, uses the Flash API to generate and program ECC data.

Figure 6-3 illustrates the ECC logic inputs and outputs.

During an instruction fetch or a data read operation, the 19 most significant address bits (three least significant bits of address are not considered), together with the 64-bit data/8-bit ECC read-out of Flash banks/ECC memory map area, pass through the SECDED logic and the eight checkbits are produced in FMC. These eight calculated ECC check bits are then XORed with the stored check bits (user programmed check bits) associated with the address and the read data. The 8-bit output is decoded inside the SECDED module to determine one of three conditions:

- No error occurred
- A correctable error (single bit data error) occurred
- A non-correctable error (double bit data error or address error) occurred

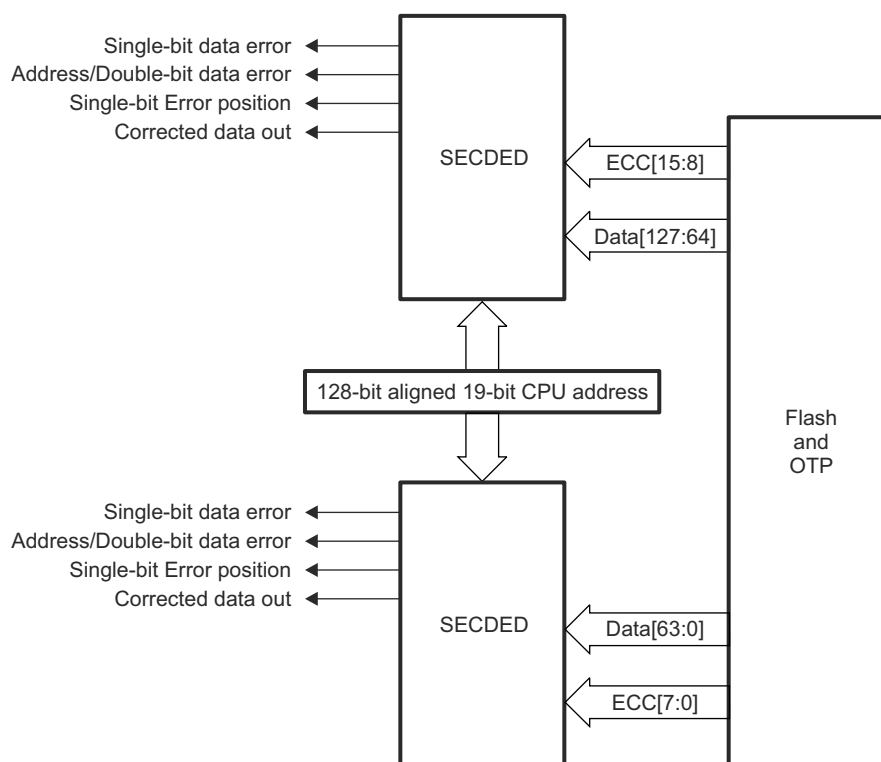

Figure 6-3. ECC Logic Inputs and Outputs

If the SECEDED logic finds a single-bit error in the address field, then the error is considered to be a non-correctable error.

Note

Since ECC is calculated for an entire 64-bit data, a non 64-bit read such as a byte read or a half-word read still forces the entire 64-bit data to be read and calculated, but only the byte or half-word are actually used by the CPU.

This ECC (SECEDED) feature is enabled at reset. The ECC_ENABLE register can be used to configure (enable/disable) the ECC feature. The ECC for the application code must be programmed. There are two SECEDED modules in each FMC. Out of the 128-bit data (aligned on a 128-bit memory boundary) read from the bank/OTP address, the lower 64 bits of data and corresponding 8 ECC bits (read from user programmable ECC memory area) are fed as inputs to one SECEDED module along with 128-bit aligned 19-bit address from where data has been read. The upper 64 bits of data and corresponding 8 ECC bits are fed as inputs to another SECEDED module in parallel, along with 128-bit aligned 19-bit address. Each of the SECEDED modules evaluate the inputs and determine if there is any single-bit data error or double-bit data error/address error.

ECC logic is bypassed when the 64 data bits and the associated ECC bits fetched from the bank are either all ones or zeros.

6.9.1 Single-Bit Data Error

This section provides information for both single-bit data errors and single-bit ECC check bit errors. If there is a single bit flip (0 to 1 or 1 to 0) in Flash data or in ECC data, then the error is considered as a single-bit data error. The SECEDED module detects and corrects single-bit errors, if any, in the 64-bit Flash data or eight ECC check bits read from the Flash/ECC memory map before the read data is provided to the CPU.

When SECEDED finds and corrects single bit data errors, the following information is logged in the ECC registers if the ECC feature is enabled:

- Address where the error occurred: if the single-bit error occurs in the lower 64 bits of a 128-bit memory-aligned Flash data word, the address of the lower 64-bit word is captured in the SINGLE_ERR_ADDR_LOW register. If the single-bit error occurs in the upper 64 bits of the 128-bit data word, then the address of the upper 64-bit word is captured in the SINGLE_ERR_ADDR_HIGH register.
- Whether the error occurred in data bits or ECC bits: the ERR_TYPE_L and ERR_TYPE_H bit fields in the ERR_POS register indicate whether the error occurred in data bits or ECC bits of the lower 64 bits, or the upper 64 bits respectively, of a 128-bit memory-aligned Flash data word.
- Bit position at which the error occurred: the ERR_POS_L and ERR_POS_H bit fields in the ERR_POS register indicate the bit position of the error in the lower 64 bits/lower 8-bit ECC, or the upper 64 bits/upper 8-bit ECC respectively, of a 128-bit memory-aligned Flash data word.
- Whether the corrected value is 0 (FAIL_0_L, FAIL_0_H flags in ERR_STATUS register).
- Whether the corrected value is 1 (FAIL_1_L, FAIL_1_H flags in ERR_STATUS register).
- A single bit error counter that increments on every single bit error occurrence (ERR_CNT register) until a user-configurable threshold (see ERR_THRESHOLD) is met.
- A flag that gets set when one or more single-bit errors occurs after ERR_CNT equals ERR_THRESHOLD (SINGLE_ERR_INT_FLG flag in the ERR_INTFLG register).

When the ERR_CNT value equals ERR_THRESHOLD+1, and a single bit error occurs, the Flash module sets the SINGLE_ERR_INT flag and generates an interrupt signal. To enable propagation of the generated interrupt pulse to the CPU, the user application must enable the FLASH_CORRECTABLE_ERROR channel in the C28 Peripheral Interrupt Expansion module (PIE). The interrupt signal remains high until the application clears the SINGLE_ERR_INTFLG flag by writing to the SINGLE_ERR_INTCLR bit in the ERR_INTCLR register. The Flash module cannot generate any further FLASH_CORRECTABLE_ERROR interrupt signals to the PIE/CPU until SINGLE_ERR_INTFLG is cleared, as this is an edge-based interrupt.

When multiple single-bit errors have been detected by ECC logic, the contents of the Flash ECC registers reflect the most recent ECC error. When multiple single-bit errors have been detected, both FAIL_0_L and FAIL_1_L (or FAIL_0_H and FAIL_1_H) can be set, indicating that single-bit fail0/fail1 occurred in different 64-bit aligned addresses.

Although ECC is calculated on 64-bit basis, a read of any address location within a 128-bit aligned Flash data word causes the single-bit error flag to get set, if there is a single-bit error in both or in either the lower 64 or upper 64 bits (or corresponding ECC check bits) of that 128-bit data word.

6.9.2 Uncorrectable Error

Uncorrectable errors include address errors and double-bit errors in data or ECC. When the ECC logic finds uncorrectable errors, the following information is logged in ECC registers if the ECC feature is enabled:

- Address where the error occurred: if the uncorrectable error occurs in the lower 64 bits of a 128-bit memory-aligned Flash data word, the lower 64-bit memory-aligned address is captured in the UNC_ERR_ADDR_LOW register. If the uncorrectable error occurs in the upper 64 bits of a 128-bit memory-aligned Flash data word, the upper 64-bit memory-aligned address is captured in the UNC_ERR_ADDR_HIGH register.
- A flag is set indicating that an uncorrectable error occurred – the UNC_ERR_L and UNC_ERR_H flags in the ERR_STATUS register indicate the uncorrectable error occurrence in the lower 64 bits/lower 8-bit ECC, or the upper 64 bits/upper 8-bit ECC, respectively, of a 128-bit memory-aligned Flash data word.
- A flag is set indicating that an uncorrectable error interrupt is generated (UNC_ERR_INTFLG in ERR_INTFLG register).

When an uncorrectable error occurs, the Flash module sets the UNC_ERR_INTFLG bit and generates an uncorrectable error interrupt. This uncorrectable error interrupt generates a non-maskable interrupt (NMI), if enabled, in the CPU. If an uncorrectable error interrupt flag is not cleared by writing to the UNC_ERR_INTCLR bit in the ERR_INTCLR register, the Flash module cannot generate new uncorrectable interrupt signals, as this is an edge-based interrupt.

Although ECC is calculated on 64-bit basis, a read of any address location within a 128-bit aligned Flash word causes the uncorrectable error flag to get set, and an uncorrectable error interrupt/NMI to occur, when there is a uncorrectable error in both or in either the lower 64 bits or upper 64 bits (or corresponding ECC check bits) of that 128-bit data word.

6.9.3 SECEDED Logic Correctness Check

Since error detection and correction logic are part of safety-critical logic, safety applications often need to make sure that the SECEDED logic is always working properly. For these safety concerns, to confirm the correctness of the SECEDED logic, an ECC test mode is provided to test the correctness of ECC logic periodically. In this ECC test mode, data/ECC and address inputs to the ECC logic are controlled by the ECC test mode registers FDATAH_TEST, FDATAL_TEST, FECC_TEST, and FADDR_TEST, respectively. Using this test mode, users can introduce single-bit errors, double-bit errors, or address errors and check whether or not SECEDED logic is catching those errors. Users can also check if SECEDED logic is reporting any false errors when no errors are introduced.

This ECC test mode can be enabled by setting the ECC_TEST_EN bit in the FECC_CTRL register. When ECC test mode is enabled, the CPU cannot read the data from Flash. Instead, the CPU gets data from the ECC test mode registers (FDATAH_TEST/FDATAL_TEST). This is because the ECC test mode registers (FDATAH_TEST, FDATAL_TEST, FECC_TEST) are multiplexed with data from the Flash. For this reason, ECC test mode code must be executed from RAM and not from Flash.

Only one of the SECEDED modules (out of the two SECEDED modules that work on lower 64 bits and upper 64 bits of a read 128-bit data) at a time can be tested. The ECC_SELECT bit in the FECC_CTRL register can be configured by users to select one of the SECEDED modules for test.

To test the ECC logic using ECC test mode, follow these steps:

1. Obtain the ECC for a given Flash address (128-bit aligned) and 64-bit data by using the Auto ECC generation option provided in Flash API.
2. Develop an application to test ECC logic using the above data. In this application:
 - Write the 128-bit aligned 19-bit Flash address in FADDR_TEST.
 - Write 64-bit data in FDATAx_TEST (FDATAL_TEST and FDATAH_TEST) registers.
 - Write the corresponding 8-bit ECC in the FECC_TEST register.
 - In any of the above three steps, the application can insert errors (single-bit data error or double-bit data error or address error or single-bit ECC error or double-bit ECC error) to check whether or not ECC logic is able to detect the errors.
 - Select the ECC logic block (lower 64-bits or upper 64-bits) which needs to be tested using the ECC_SELECT bit in the FECC_CTRL register.
 - Enable ECC test mode using the ECC_TEST_EN bit in FECC_CTRL register.
 - Write a value of 1 in the DO_ECC_CALC bit in FECC_CTRL register to enable ECC test logic for a single cycle to evaluate the address, data, ECC in FADDR_TEST, FDATAx_TEST and FECC_TEST registers for ECC errors.

Once the above ECC test mode registers are written by the user:

- The FECC_OUTH register holds the data output bits 63:32 from the SECEDED block under test.
- The FECC_OUTL register holds the data output bits 31:0 from the SECEDED block under test.
- The FECC_STATUS register holds the status of single-bit error occurrence, uncorrectable error occurrence, and error position of single-bit error in data/check bits.

6.10 Reserved Locations Within Flash and OTP Memory

When allocating code and data to Flash and OTP memory, keep the following reserved locations in mind:

- The entire OTP has reserved user-configurable locations for security and boot process. For more details on the functionality of these fields, refer to the *Dual Code Security Module (DCSM)* and the *ROM Code and Peripheral Booting* chapters.
- Refer to the *ROM Code and Peripheral Booting* chapter for reserved locations in Flash for real-time operating system usage and a boot-to-Flash entry point. A boot-to-Flash entry point is reserved for an entry-into-Flash branch instruction. When the boot-to-Flash boot option is used, the boot ROM jumps to this address in Flash. If the user programs a branch instruction here, that then redirects code execution to the entry point of the application.

6.11 Migrating an Application from RAM to Flash

To migrate an existing application that is configured to run from RAM to a Flash-based linker configuration, follow these steps:

1. Replace the RAM linker command file with a Flash linker command file. For examples of Flash-based linker command files, see the `device_support\<device>\common\cmd` directory.
2. When modifying the Flash-based linker command file, be sure to map any initialized sections to Flash memory regions.
3. Make sure the boot mode pins are configured for Flash boot. This tells the boot ROM to redirect execution to the application programmed into Flash memory after boot code execution is complete. For more information on boot mode configuration, see *Detailed Description* □ *Device Boot Modes* in the device data sheet.
4. When the device is configured for Flash boot, the boot ROM redirects execution to the Flash entry point location (defined as BEGIN in TI-provided Flash linker command files) at the end of boot code execution. Make sure there is a branch instruction at the Flash entry point to your code initialization (for example, `_c_int00`) function. In the C2000Ware examples, the entry point code is specified in the `codestartbranch.asm` file.
5. To achieve best performance for Flash execution, configure the Flash wait states as per the device operating clock frequency, as specified in the device data sheet. In addition, enable prefetch mode and data cache mode. Calling the `Flash_initModule()` driverlib function achieves these steps. Note that code that initializes the Flash module must execute from a RAM location. This is accomplished by assigning the Flash initialization function to the `.TI.ramfunc` section. In the linker command file, map this section to Flash for load, and RAM for execution. The example cmd files provided in C2000Ware show how to do this correctly.
6. For any functions that require 0- or 1-wait state performance, be sure to map to RAM for execution in the linker command file, similar to the Flash initialization function. The `.TI.ramfunc` section in the TI-provided Flash linker command files accomplishes this purpose.
7. Align all code and data sections to 128-bit address boundaries when mapping to Flash memory, using the ALIGN directive in the linker command file.
8. For EABI executable formats, define all uninitialized sections mapped to RAM as NOINIT sections (using the directive "`type=NOINIT`") in the linker command file.
9. Be sure to program ECC bits correctly for the Flash application image. Keep the AutoEccGeneration option enabled in the Code Composer Studio Flash Plugin or UniFlash GUI.

6.12 Procedure to Change the Flash Control Registers

During Flash configuration, no accesses to the Flash or OTP can be in progress. This includes instructions still in the CPU pipeline, data reads, and instruction prefetch operations. To be sure that no access takes place during the configuration change, follow the procedure shown below for any code that modifies the Flash control registers.

1. Start executing application code from RAM/Flash/OTP.
2. Branch to or call the Flash configuration code (that writes to Flash control registers) in RAM. This is required to properly flush the CPU pipeline before the configuration change. The function that changes the Flash configuration cannot execute from the Flash or OTP and must reside in RAM.
3. Execute the Flash configuration code (located in RAM) that writes to Flash control registers like FRDCNTL, FRD_INTF_CTRL, and so on.
4. At the end of the Flash configuration code execution, wait eight cycles to let the write instructions propagate through the CPU pipeline. This must be done before the return-from-function call is made.
5. Return to the calling function that resides in RAM or Flash/OTP and continue execution.

6.13 Software

6.13.1 FLASH Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/flash

Cloud access to these examples is available at the following link: dev.ti.com [C2000Ware Examples](#).

6.13.1.1 Flash Programming with AutoECC, DataAndECC, DataOnly and EccOnly

FILE: flashapi_ex1_programming.c

This example demonstrates how to program Flash using API's following options

1. AutoEcc generation
2. DataOnly and EccOnly
3. DataAndECC

External Connections

- None.

Watch Variables

- None.

6.13.1.2 Flash ECC Test Mode

FILE: flash_ex2_ecc_test_mode.c

This example demonstrates ECC Test mode.

6.13.1.3 Boot Source Code

FILE: flash_kernel_ex3_boot.c

Functions: void copyData(void) uint32_t getLongData(void) void readReservedFn(void)

6.13.1.4 Erase Source Code

FILE: flash_kernel_ex3_erase.c Functions:

6.13.1.5 Live DFU Command Functionality

FILE: flash_kernel_ex3_ldfu.c This file contains the functionality of the Live Device Firmware Update (Live DFU or LDFU) Command and bank selection logic. The command functionality has 1 build configuration for each bank: BANK0_LDFU, BANK1_LDFU, and BANK2_LDFU

For the BANK0 build configurations, the following steps are taken when the kernel receives the Live DFU command:

1. Read an SCI Boot hex formatted file until information related to each block of data remains
2. Read and store the revision values of banks 2, 1 and 0 from flash (B1_REV_ADD: 0x92006, B2_REV_ADD: 0xA2006)
1. Erase sectors 2-15 of bank 1 or 2 depending on the revision number
2. Write 64 bits of 'START' value to B1_START_ADD/B2_START_ADD to indicate that erasing is done and programming/verifying is about to start
3. Program and verify bank 1/2 by receiving the SCI boot hex formatted file one block of data at a time, writing each byte to flash, and verifying each byte (the data must not be linked to an address that is less than 0x92008/0xA2008 (B1_RESERVED/B2_RESERVED))
4. Decrement the revision value of bank 1 or 2
5. Write the 'KEY' value to 0x92004/0xA2004 (B1_KEY_ADD/B2_KEY_ADD) and the revision value of bank 1 to 0x92006 (B1_REV_ADD) or of bank 2 to 0xA2006 (B2_REV_ADD)
6. Configure the watchdog for a reset and enable the watchdog in order for a reset to occur

For the BANK1 build configurations, the following steps are taken when the kernel receives the Live DFU command:

1. Read an SCI Boot hex formatted file until information related to each block of data remains
2. Read and store the revision value of bank 0, 1 and 2 from flash (B0_REV_ADD: 0x82006, B2_REV_ADD: 0xA2006)
1. Erase sectors 2-15 of bank 0 or 2 depending on the revision number
2. Write 64 bits of 'START' value to B0_START_ADD/B2_START_ADD to indicate that erasing is done and programming/verifying is about to start
3. Program and verify bank 0/2 by receiving the SCI boot hex formatted file one block of data at a time, writing each byte to flash, and verifying each byte (the data must not be linked to an address that is less than 0x82008/0xA2008 (B0_RESERVED/B2_RESERVED))
4. Decrement the revision value of bank 0 or 2
5. Write the 'KEY' value to 0x82004/0xA2004 (B0_KEY_ADD/B2_KEY_ADD) and the revision value of bank 0 to 0x82006 (B0_REV_ADD) or of bank 2 to 0xA2006 (B2_REV_ADD)
6. Configure the watchdog for a reset and enable the watchdog in order for a reset to occur

For the BANK2 build configurations, the following steps are taken when the kernel receives the Live DFU command:

1. Read an SCI Boot hex formatted file until information related to each block of data remains
2. Read and store the revision value of bank 0, 1 and 2 from flash (B1_REV_ADD: 0x92006)
1. Erase sectors 2-15 of bank 0 or 1 depending on the revision number
2. Write 64 bits of 'START' value to B0_START_ADD/B1_START_ADD to indicate that erasing is done and programming/verifying is about to start
3. Program and verify bank 0/1 by receiving the SCI boot hex formatted file one block of data at a time, writing each byte to flash, and verifying each byte (the data must not be linked to an address that is less than 0x92008/0xA2008 (B1_RESERVED/B2_RESERVED))
4. Decrement the revision value of bank 1 or 2
5. Write the 'KEY' value to 0x82004/0xA2004 (B0_KEY_ADD/B2_KEY_ADD) and the revision value of bank 0 to 0x82006 (B0_REV_ADD) or of bank 2 to 0xA2006 (B2_REV_ADD)
6. Configure the watchdog for a reset and enable the watchdog in order for a reset to occur

Bank selection logic (bankSelect) is the entry point for the BANK0 build configurations; it is also the first thing to run after a reset occurs. Bank selection logic branches to the most recently programmed bank or to the kernel setup when no banks have been programmed using the Live DFU command. When no banks have been programmed using the Live DFU command, a program must be loaded to bank 1 by using the Live DFU command.

Bank selection logic is located at 0x80000; therefore the device must be configured to boot to flash at 0x80000 for correct functionality.

When running BANK0 configurations, a breakpoint may need to be placed at the beginning of bankSelect if CCS debug tools are needed. The breakpoint may be removed afterwards to prevent the program from stopping after each update.

6.13.1.6 Verify Source Code

FILE: flash_kernel_ex3_verify.c

6.13.1.7 SCI Boot Mode Routines

FILE: flash_kernel_ex3_sci_boot.c Functions: uint32_t sciBoot(void) void scialnit(void) uint32_t sciaGetWordData(void)

6.13.1.8 Flash Programming Solution using SCI

FILE: flash_kernel_ex3_sci_flash_kernel.c

In this example, we set up a UART connection with a host using SCI, receive commands for CPU1 to perform which then sends ACK, NAK, and status packets back to the host after receiving and completing the tasks. This kernel has the ability to program, verify, unlock, reset, and run an application. Each command either expects no data from the command packet or specific data relative to the command.

In this example, we set up a UART connection with a host using SCI, receive an application for CPU01 in -sci8 ascii format to run on the device and program it into Flash.

6.14 Flash Registers

This section describes the Flash Module Registers.

6.14.1 FLASH Base Address Table

Table 6-1. FLASH Base Address Table

Bit Field Name		DriverLib Name	Base Address	CPU1	DMA	HIC	CLA	Pipeline Protected
Instance	Structure							
Flash0CtrlRegs	FLASH_CTRL_REGS	FLASH0CTRL_BASE	0x0005_F800	YES	-	-	-	YES
Flash0EccRegs	FLASH_ECC_REGS	FLASH0ECC_BASE	0x0005_FB00	YES	-	-	-	YES

6.14.2 FLASH_CTRL_REGS Registers

Table 6-2 lists the memory-mapped registers for the FLASH_CTRL_REGS registers. All register offset addresses not listed in Table 6-2 should be considered as reserved locations and the register contents should not be modified.

Table 6-2. FLASH_CTRL_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	FRDCNTL	Flash Read Control Register	EALLOW	Go
1Eh	FBAC	Flash Bank Access Control Register	EALLOW	Go
20h	FBFALLBACK	Flash Bank Fallback Power Register	EALLOW	Go
22h	FBPRDY	Flash Bank Pump Ready Register	EALLOW	Go
24h	FPAC1	Flash Pump Access Control Register 1	EALLOW	Go
26h	FPAC2	Flash Pump Access Control Register 2	EALLOW	Go
2Ah	FMSTAT	Flash Module Status Register	EALLOW	Go
180h	FRD_INTF_CTRL	Flash Read Interface Control Register	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 6-3 shows the codes that are used for access types in this section.

Table 6-3. FLASH_CTRL_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

6.14.2.1 FRDCNTL Register (Offset = 0h) [Reset = 0000F00h]

FRDCNTL is shown in [Figure 6-4](#) and described in [Table 6-4](#).

Return to the [Summary Table](#).

Flash Read Control Register

22h	FOUTH_TEST	Test Data Out High	EALLOW	Go
24h	FOUTL_TEST	Test Data Out Low	EALLOW	Go
26h	FECC_STATUS	ECC Status	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 6-13 shows the codes that are used for access types in this section.

Table 6-13. FLASH_ECC_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1S	W1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.

Table 6-13. FLASH_ECC_REGS Access Type Codes (continued)

Access Type	Code	Description
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

6.14.3.1 ECC_ENABLE Register (Offset = 0h) [Reset = 000000Ah]

ECC_ENABLE is shown in [Figure 6-12](#) and described in [Table 6-14](#).

Return to the [Summary Table](#).

Table 6-19. ERR_STATUS Register Field Descriptions

Bit	Field	Type	Reset	Description
31-19	RESERVED	R	0h	Reserved
18	UNC_ERR_H	R	0h	Uncorrectable error. A value of 1 indicates that an un-correctable error occurred in upper 64bits of a 128-bit aligned address. Cleared by writing a 1 to UNC_ERR_H_CLR bit of ERR_STATUS_CLR register. Reset type: SYSRSn
17	FAIL_1_H	R	0h	Fail on 1. 0 Fail on 1 single bit error did not occur in upper 64bits of a 128-bit aligned address. 1 A value of 1 would indicate that a single bit error occurred in upper 64bits of a 128-bit aligned address and the corrected value was 1. Cleared by writing a 1 to FAIL_1_H_CLR bit of ERR_STATUS_CLR register. Note: This bit is updated on every flash access which results in a single bit error, So, in case of multiple single bit error, the status would correspond to the last error which occurred. Reset type: SYSRSn
16	FAIL_0_H	R	0h	Fail on 0. 0 Fail on 0 single bit error did not occur in upper 64bits of a 128-bit aligned address. 1 A value of 1 would indicate that a single bit error occurred in upper 64bits of a 128-bit aligned address and the corrected value was 0. Cleared by writing a 1 to FAIL_0_H_CLR bit of ERR_STATUS_CLR register. Note: This bit is updated on every flash access which results in a single bit error, So, in case of multiple single bit error, the status would correspond to the last error which occurred. Reset type: SYSRSn
15-3	RESERVED	R	0h	Reserved

Table 6-19. ERR_STATUS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
2	UNC_ERR_L	R	0h	Uncorrectable error. A value of 1 indicates that an un-correctable error occurred in lower 64bits of a 128-bit aligned address. Cleared by writing a 1 to UNC_ERR_L_CLR bit of ERR_STATUS_CLR register. Reset type: SYSRSn
1	FAIL_1_L	R	0h	Fail on 1. 0 Fail on 1 single bit error did not occur in lower 64bits of a 128-bit aligned address. 1 A value of 1 would indicate that a single bit error occurred in lower 64bits of a 128-bit aligned address and the corrected value was 1. Cleared by writing a 1 to FAIL_1_L_CLR bit of ERR_STATUS_CLR register. Note: This bit is updated on every flash access which results in a single bit error. So, in case of multiple single bit error, the status would correspond to the last error which occurred. Reset type: SYSRSn
0	FAIL_0_L	R	0h	Fail on 0. 0 Fail on 0 single bit error did not occur in lower 64bits of a 128-bit aligned address. 1 Would indicate that a single bit error occurred in lower 64bits of a 128-bit aligned address and the corrected value was 0. Cleared by writing a 1 to FAIL_0_L_CLR bit of ERR_STATUS_CLR register. Note: This bit is updated on every flash access which results in a single bit error. So, in case of multiple single bit error, the status would correspond to the last error which occurred. Reset type: SYSRSn

6.14.3.7 ERR_POS Register (Offset = Ch) [Reset = 0000000h]

ERR_POS is shown in [Figure 6-18](#) and described in [Table 6-20](#).

Return to the [Summary Table](#).

Chapter 7 Control Law Accelerator (CLA)

The Control Law Accelerator (CLA) Type-2 is an independent, fully-programmable, 32-bit floating-point math processor that brings concurrent control-loop execution to the C28x family. The low interrupt latency of the CLA allows the CLA to read ADC samples "just-in-time." This significantly reduces the ADC sample to output delay to enable faster system response and higher MHz control loops. By using the CLA to service time-critical control loops, the main CPU is free to perform other system tasks such as communications and diagnostics. This chapter provides an overview of the architectural structure and components of the control law accelerator.

7.1 Introduction	810
7.2 CLA Interface	812
7.3 CLA and CPU Arbitration	818
7.4 CLA Configuration and Debug	819
7.5 Pipeline	823
7.6 Software	829
7.7 Instruction Set	833
7.8 CLA Registers	963

7.1 Introduction

The Control Law Accelerator extends the capabilities of the C28x CPU by adding parallel processing. Time-critical control loops serviced by the CLA can achieve low ADC sample to output delay. Thus, the CLA enables faster system response and higher frequency control loops. Utilizing the CLA for time-critical tasks frees up the main CPU to perform other system and communication functions concurrently.

7.1.1 Features

The following is a list of major features of the CLA:

- C compilers are available for CLA software development.
- Clocked at the same rate as the main CPU (SYSCLKOUT).
- An independent architecture allowing CLA algorithm execution independent of the main C28x CPU.
 - Complete bus architecture:
 - Program Address Bus (PAB) and Program Data Bus (PDB)
 - Data Read Address Bus (DRAB), Data Read Data Bus (DRDB), Data Write Address Bus (DWAB), and Data Write Data Bus (DWDB)
 - Independent eight stage pipeline.
 - 16-bit program counter (MPC)
 - Four 32-bit result registers (MR0-MR3)
 - Two 16-bit auxiliary registers (MAR0, MAR1)
 - Status register (MSTF)
- Instruction set includes:
 - IEEE single-precision (32-bit) floating-point math operations
 - Floating-point math with parallel load or store
 - Floating-point multiply with parallel add or subtract
 - 1/X and 1/sqrt(X) estimations
 - Data type conversions.
 - Conditional branch and call
 - Data load/store operations
- The CLA program code can consist of up to eight tasks or interrupt service routines
 - The start address of each task is specified by the MVECT registers.
 - No limit on task size as long as the tasks fit within the configurable CLA program memory space.
 - One task is serviced at a time until completion. There is no nesting of tasks.
 - Upon task completion a task-specific interrupt is flagged within the PIE.
 - When a task finishes the next highest-priority pending task is automatically started.
- Task trigger mechanisms:
 - C28x CPU using the IACK instruction
 - Task1 to Task8: trigger sources from peripherals connected to the shared bus on which the CLA assumes secondary ownership.
- Memory and Shared Peripherals:
 - Two dedicated message RAMs for communication between the CLA and the main CPU.
 - The C28x CPU can map CLA program and data memory to the main CPU space or CLA space.

7.1.3 Block Diagram

Figure 7-1 is a block diagram of the CLA.

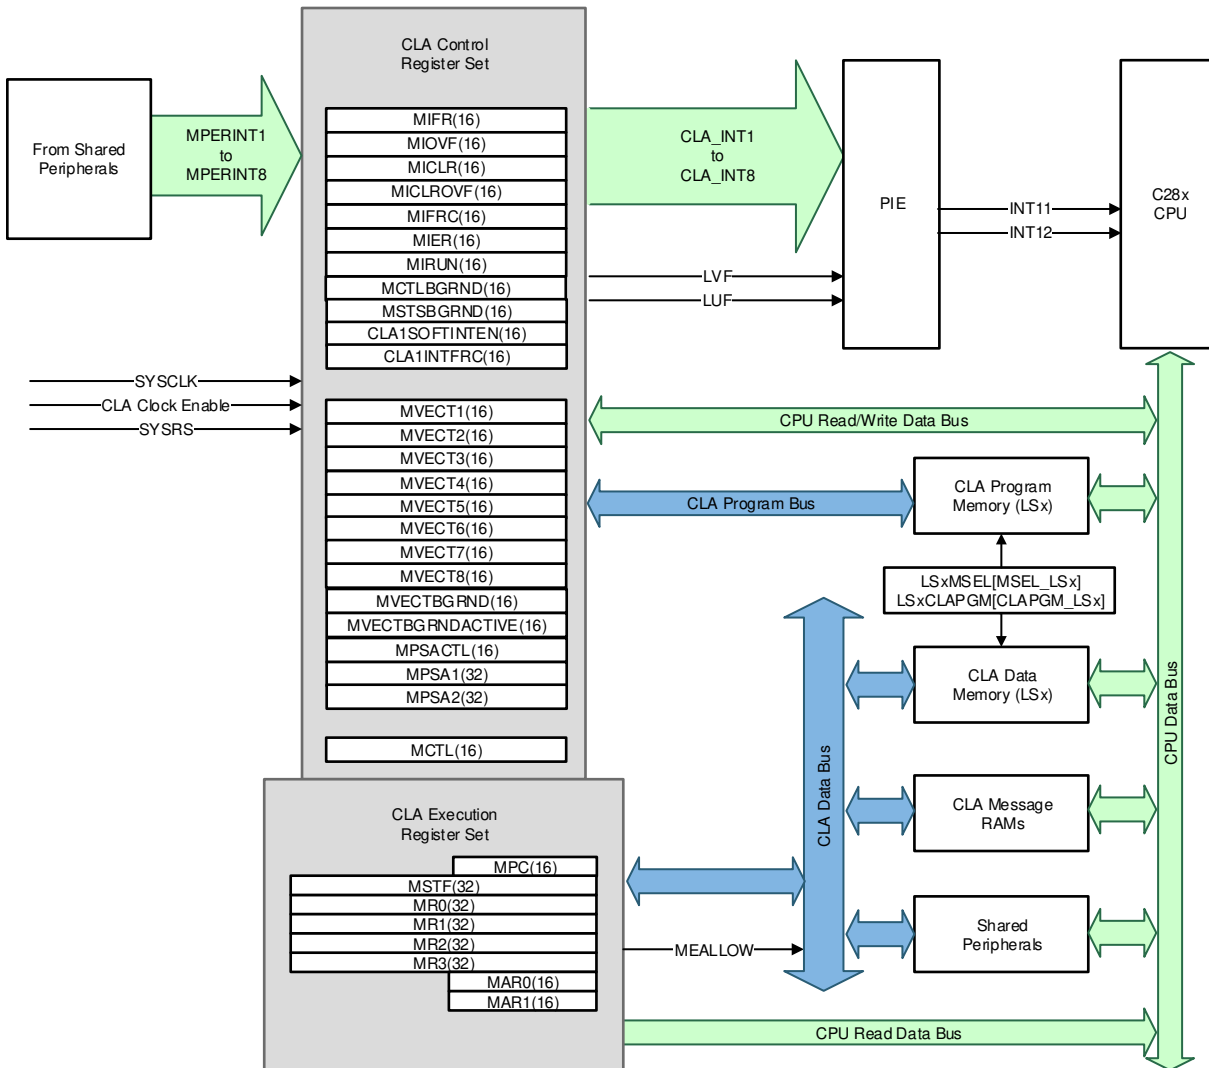

Figure 7-1. CLA (Type 2) Block Diagram

7.2 CLA Interface

This section describes how the C28x main CPU can interface to the CLA and conversely.

7.2.1 CLA Memory

The CLA can access three types of memory: program, data and message RAMs. The behavior and arbitration for each type of memory is described in this chapter. The CLA RAMs are protected by the DCSM module. Refer to the *Dual Code Security Module (DCSM)* chapter for more details on the security scheme.

- **CLA Program Memory**

The CLA program can be loaded with any of the local shared memories (LSxRAM). At reset, all memory blocks are mapped to the CPU. While mapped to the CPU space, the CPU can copy the CLA program code into the memory. During debug, the memory can also be loaded directly by the Code Composer Studio™ IDE.

Once the memory is initialized with CLA code, the CPU maps the memory to the CLA program space by:

1. Assigning ownership of the memory block to the CLA by writing a 1 to the memory block's MemCfgRegs.LSxMSEL[MSEL_LSx] bit.
2. Specifying the memory block as a code block for the CLA by writing a 1 to the MemCfgRegs.LSxCLAPGM[CLAPGM_LSx] bit.

When a memory block is configured as CLA program memory, debug accesses are allowed only on cycles where the CLA is not fetching a new instruction. A detailed explanation of the memory configurations and access arbitration (CPU, CLA, and DEBUG) process can be found in the *Memory Controller Module* section of the *System Control and Interrupts* chapter.

All CLA program fetches are performed as 32-bit read operations and all opcodes must be aligned to an even address. Since all CLA opcodes are 32-bits, this alignment occurs naturally.

- **CLA Data Memory**

Any of the device's LSxRAMs can serve as data memory blocks to the CLA. At reset, all blocks are mapped to the CPU memory space, whereby the CPU can initialize the memory with data tables, coefficients, and so on, for the CLA to use.

Once the memory is initialized with CLA data, the CPU maps the memory to the CLA data space by:

1. Assigning ownership of the memory block to the CLA by writing a 1 to the memory block's MemCfgRegs.LSxMSEL[MSEL_LSx] bit.
2. Specifying the memory block as a data block for the CLA by writing a 0 to the MemCfgRegs.LSxCLAPGM[CLAPGM_LSx] bit. The value of this bit at reset is 0.

When a memory block is configured as CLA data memory, CLA read and write accesses are arbitrated along with CPU accesses. The user has the option of turning on CPU fetch or write protection to the memory by writing to the appropriate bits of the MemCfgRegs.LSxACCPROTx registers. A detailed explanation of the memory configurations and access arbitration (CPU, CLA, and DEBUG) process can be found in the *Memory Controller Module* section of the *System Control and Interrupts* chapter.

- **CLA Shared Message RAMs**

There are two memory blocks for data sharing and communication between the CLA and the CPU. The message RAMs are always mapped to both CPU and CLA memory spaces, and only data access is allowed; no program fetches can be performed.

- **CLA to CPU Message RAM:** The CLA can use this block to pass data to the CPU. This block is both readable and writable by the CLA. This block is also readable by the CPU but writes by the CPU are ignored.
- **CPU to CLA Message RAM:** The CPU can use this block to pass data and messages to the CLA. This message RAM is both readable and writable by the CPU. The CLA can perform reads but writes by the CLA are ignored.

7.2.2 CLA Memory Bus

The CLA has dedicated bus architecture similar to that of the C28x CPU where there are separate program read, data read, and data write buses. Thus, there can be simultaneous instruction fetch, data read, and data write in a single cycle. Like the C28x CPU, the CLA expects memory logic to align any 32-bit read or write to an even address. If the address-generation logic generates an odd address, the CLA can begin reading or writing at the previous even address. This alignment does not affect the address values generated by the address-generation logic.

- **CLA Program Bus**

The CLA program bus has an access range of 32-bit instructions. Since all CLA instructions are 32 bits, this bus always fetches 32 bits at a time and the opcodes must be even-word aligned. The amount of program space available for the CLA is limited to the number of blocks. This number is device-dependent and can be described in the data sheet.

- **CLA Data Read Bus**

The CLA data read bus has a 64K x 16 address range. The bus can perform 16 or 32-bit reads and can automatically stall if there are memory access conflicts. The data read bus has access to both the message RAMs, CLA data memory, and the shared peripherals.

- **CLA Data Write Bus**

The CLA data write bus has a 64K x 16 address range. This bus can perform 16 or 32-bit writes. The bus can automatically stall if there are memory access conflicts. The data write bus has access to the CLA to CPU message RAM, CLA data memory, and the shared peripherals.

7.2.3 Shared Peripherals and EALLOW Protection

Refer to the device data sheet for the list of peripherals connected to the bus.

Several peripheral control registers are protected from spurious 28x CPU writes by the EALLOW protection mechanism. These same registers are also protected from spurious CLA writes. The EALLOW bit in the CPU status register 1 (ST1) indicates the state of protection for the CPU. Likewise, the MEALLOW bit in the CLA status register (MSTF) indicates the state of write protection for the CLA. The MEALLOW CLA instruction enables write access by the CLA to EALLOW protected registers. Likewise, the MEDIS CLA instruction disables write access. This way the CLA can enable and disable write access independent of the CPU.

The ADC offers the option to generate an early interrupt pulse at the start of a sample conversion. If this option is used to start an ADC-triggered CLA task, use the intervening cycles until the completion of the conversion to perform preliminary calculations or loads and stores before finally reading the ADC value. The CLA pipeline activity for this scenario is shown in [Section 7.5](#).

7.2.4 CLA Tasks and Interrupt Vectors

The CLA program code is divided up into tasks or interrupt service routines. Tasks do not have a fixed starting location or length. The CLA program memory can be divided up as desired. The CLA uses the contents of the interrupt vectors (MVECT1 to MVECT8) to determine where a task begins; tasks are terminated by the MSTOP instruction.

The CLA supports eight tasks. Task 1 has the highest priority and task 8 has the lowest priority. The Type-2 CLA offers the option of setting the lowest priority task, for example, task 8, as a background task that, once triggered, runs continuously until the user either terminates the task or resets the CLA or the device. The remaining tasks, 1 through 7, maintain the priority levels and interrupt the background task when triggered.

The background task is enabled by setting the BGEN bit in the MCTLBGRND register; this causes the hardware to disable task 8 in the MIER register. The background task derives the interrupt vector from the MVECTBGRND register instead of MVECT8.

A task can be requested by a peripheral interrupt or by software:

- **Peripheral interrupt trigger**

Each task can be triggered by software-selectable interrupt sources. The trigger for each task is defined by writing an appropriate value to the DmaClaSrcSelRegs.CLA1TASKSRCSELx[TASKx] bit field. Each option specifies an interrupt source from a specific peripheral on the shared bus. The peripheral interrupt triggers are listed in [Table 7-1](#).

For example, task 1 (MVECT1) can be set to trigger on EPWMINT1 by writing 36 to DmaClaSrcSelRegs.CLA1TASKSRCSEL1.TASK1. To disable the triggering of a task by a peripheral, set the DmaClaSrcSelRegs.CLA1TASKSRCSELx[TASKx] bit field to 0. Note that a CLA task only triggers on a level transition (an edge) of the configured interrupt source.

- **Software Trigger**

CPU software can trigger tasks by writing to the MIFRC register or by the IACK instruction. Using the IACK instruction is more efficient because the instruction does not require the need to issue an EALLOW to set MIFR bits. Set the MCTL[JACKE] bit to enable the IACK feature. Each bit in the operand of the IACK instruction corresponds to a task. For example, IACK #0x0001 sets bit 0 in the MIFR register to start task 1. Likewise, IACK #0x0003 set bits 0 and 1 in the MIFR register to start task 1 and task 2.

- **Background Task**

The Type-2 CLA allows the use of Task 8 as a background task that runs continuously until Task 8 disables the task or resets the device (or the CLA using a soft reset). The background task vector is given by the MVECTBGRND register and the operation is controlled by the MCTLBGRND register; the task is enabled by setting the BGEN bit to 1. Then start the task through software by writing a 1 to the BGSTART bit (TRIGEN must be 0), or through a peripheral by setting the TRIGEN bit to 1 and then setting the trigger source in the bit-field, DmaClaSrcSelRegs.CLA1TASKSRCSEL2.bit.TASK8. By default, the background task is interruptible; the highest priority pending task is executed first. When a task completes and there are not any pending tasks, the execution returns to the background task. The CLA keeps track of the branching point by saving the return address to the MVECTBGRNDACTIVE register, and then popping this address to the MPC when execution returns. Choose to make sections of the background task uninterruptible by possibly doing this with the MSETC BGINTM assembly instruction.

Subsequently, enabling interrupts with the MCLRC BGINTM instruction.

The background interrupt mask bit, BGINTM, can be queried in the MSTSBGRND register. This register also provides the current status of the background task. If the task is currently executing, the RUN bit is set to 1, if another trigger for the background task is received while the task has already started, the overflow (BGOVF) bit is set.

The CLA has a fetch mechanism and can run and execute a task independently of the CPU. Only one task is serviced at a time; there is no nesting of tasks unless the background task is enabled, then one level of nesting is possible. The task currently running is indicated in the MIRUN register; if the background task is enabled and running, the task is reflected in the MSTSBGRND register (the RUN bit).

Interrupts that have been received but not yet serviced are indicated in the flag register (MIFR). If an interrupt request from a peripheral is received and that same task is already flagged, then the overflow flag bit is set. Overflow flags remain set until the flags are cleared by the CPU. If the CLA is idle (no task is currently running) or is executing the background task, then the highest priority interrupt request that is both flagged (MIFR) and enabled (MIER) starts.

The flow is as follows:

1. The associated RUN register bit is set (MIRUN) and the flag bit (MIFR) is cleared.
2. The CLA begins execution at the location indicated by the associated interrupt vector (MVECTx). MVECT contains the absolute 16-bit address of the task in the lower 64K memory space. If a task is interrupting the background task then the current program address is stored in the MVECTBGRNDACTIVE register before execution jumps to the task; this saved address is restored to the MPC when the task completes and execution returns to the background task.
3. The CLA executes instructions until the MSTOP instruction is found. This indicates the end of the task.
4. The MIRUN bit is cleared.
5. The task-specific interrupt to the PIE is issued. This informs the main CPU that the task has completed.
6. The CLA returns to idle (or to the background task, if enabled). Once a task completes the next highest-priority pending task is automatically serviced and this sequence repeats.

7.3 CLA and CPU Arbitration

Typically, CLA activity is independent of the CPU activity. Under the circumstance where the CLA or CPU attempt to concurrently access memory or a peripheral register within the same interface, an arbitration procedure occurs. This section describes this arbitration.

The arbitration follows a fixed arbitration scheme with highest priority first:

Refer to the Memory Controller Module section of the *System Control and Interrupts* chapter.

7.3.1 CLA Message RAM

Message RAMs consist of blocks:

- CLA to CPU Message RAM
- CPU to CLA Message RAM

These blocks are useful for passing data between the CLA and CPU. No opcode fetches, from either the CLA or CPU, are allowed from the message RAMs. A write protection violation is not generated if the CLA attempts to write to the CPU to CLA message RAM, but the write is ignored. The arbitration scheme for the message RAMs are the same as those for the shared memories, described in the Memory Controller Module section of the *System Control and Interrupts* chapter.

The message RAMs have the following characteristics:

- CLA to CPU Message RAM:
The following accesses are allowed:
 - CPU reads
 - CLA data reads and writes
 - CPU debug reads and writes
 The following accesses are ignored:
 - CPU writes
- CPU to CLA Message RAM:
The following accesses are allowed:
 - CPU reads and writes
 - CLA reads
 - CPU debug reads and writes
 The following accesses are ignored:
 - CLA writes

7.3.2 Peripheral Registers (ePWM, HRPWM, Comparator)

Accesses to the registers follow these rules:

- If both the CPU and CLA request access at the same time, then the CLA has priority and the main CPU is stalled.
- If a CPU access is in-progress and another CPU access is pending, then the CLA has priority over the pending CPU access. In this case, the CLA access begins when the current CPU access completes.
- While a CPU access is in-progress, any incoming CLA access is stalled.
- While a CLA access is in-progress, any incoming CPU access is stalled.
- A CPU write operation has priority over a CPU read operation.
- A CLA write operation has priority over a CLA read operation.
- If the CPU is performing a read-modify-write operation and the CLA performs a write to the same location, the CLA write can be lost if the operation occurs in-between the CPU read and write. For this reason, do not mix CPU and CLA accesses to same location.

7.4 CLA Configuration and Debug

This section discusses the steps necessary to configure and debug the CLA.

7.4.1 Building a CLA Application

The control law accelerator can be programmed in either CLA assembly code, using the instructions described in [Section 7.7](#), or a reduced subset of the C language. CLA assembly code resides in the same project with C28x code. The only restriction is the CLA code must be in the assembly section. This can be easily done using the `.sect` assembly directive. This does not prevent CLA and C28x code from being linked into the same memory region in the linker command file.

System and CLA initialization are performed by the main CPU. This can typically be done in C or C++ but can also include C28x assembly code. The main CPU also copies the CLA code to the program memory and, if needed, initialize the CLA data RAMs. Once system initialization is complete and the application begins, the CLA services the interrupts using the CLA assembly code (or tasks). The main CPU can perform other tasks concurrently with CLA program execution.

7.4.2 Typical CLA Initialization Sequence

A typical CLA initialization sequence is performed by the main CPU as described in this section.

1. **Copy CLA code into the CLA program RAM:** The source for the CLA code can initially reside in the Flash or a data stream from a communications peripheral or anywhere the main CPU can access. The debugger can also be used to load code directly to the CLA program RAM during development.
2. **Initialize CLA data RAM, if necessary:** Populate the CLA data RAM with any required data coefficients or constants.
3. **Configure the CLA registers:** Configure the CLA registers, but keep interrupts disabled until later (leave MIER = 0):
 - **Enable the CLA peripheral clock using the assigned PCLKCRn register:** The peripheral clock control (PCLKCRn) registers are defined in the *System Control and Interrupts* chapter.
 - **Populate the CLA task interrupt vectors:**
 - MVECT1 to MVECT8
 - **Select the task interrupt sources:** For each task select the interrupt source in the CLA1TASKSRCSELx register. If a task is software triggered, select no interrupt.
 - **Enable IACK to start a task from software, if desired:** To enable the IACK instruction to start a task set the MCTL[IACKE] bit. Using the IACK instruction avoids having to set and clear the EALLOW bit.
 - **Map CLA data RAM to CLA space, if necessary**
 - **Map CLA program RAM to CLA space**
4. **Initialize the PIE vector table and registers:** When a CLA task completes, the associated interrupt in the PIE is flagged. The CLA overflow and underflow flags also have associated interrupts within the PIE.
5. **Enable CLA tasks/interrupts:** Set appropriate bits in the interrupt enable register (MIER) to allow the CLA to service interrupts. Note that a CLA task only triggers on a level transition (a falling edge) of the configured interrupt source. If a peripheral is enabled and an interrupt fires before the CLA is configured, then the CLA does not recognize the interrupt edge and does not respond. To avoid this, configure the CLA before the peripherals or clear any pending peripheral interrupts before setting bits in the MIER register.
6. **Initialize other peripherals:** Initialize any peripherals (such as ePWM, ADC, and others) that generate interrupt triggers for enabled CLA tasks.

The CLA is now ready to service interrupts and the message RAMs can be used to pass data between the CPU and the CLA. Mapping of the CLA program and data RAMs typically occurs only during the initialization process. If the RAM mapping needs to be changed after initialization, the CLA interrupts must be disabled and all tasks must be completed (by checking the MIRUN register) prior to modifying the RAM ownership.

7.4.3 Debugging CLA Code

Debugging the CLA code is a simple process that occurs independently of the main CPU.

7.4.3.1 Software Breakpoint Support (MDEBUGSTOP1)

The MDEBUGSTOP1 instruction is meant to be used as a software breakpoint; the instruction on which the execution must halt is replaced with this instruction.

The MDEBUGSTOP1 and MDEBUGSTOP instructions differ in how the CLA pipeline is treated. When halted, the MDEBUGSTOP1 instruction flushes all the instructions that have already been fetched; on a single-step or run-free command, the CLA refetches the same instruction that it replaced. [Table 7-2](#) illustrates the pipeline behavior.

Table 7-2. Pipeline Behavior of the MDEBUGSTOP1 Instruction

Cycles	F1	F2	D1	D2	R1	R2	E	W	Comments
1	i1								
2	i2	i1							
3	i3	i2	i1						
4	i4	i3	i2	i1					
5	MDEBUG STOP1	i4	i3	i2	i1				
6	i6	MDEBUG STOP1	i4	i3	i2	i1			
7	i7	i6	MDEBUG STOP1	i4	i3	i2	i1		
9	i8	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	i4	i3	i2	i1	CLA halted
10	i5(MDEBUGSTOP1)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	i4	i3	i2	CLA step/run
11	i6	i5(MDEBUGSTOP1)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	i4	i3	CLA step/run
12	i7	i6	i5(MDEBUGSTOP1)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	i4	CLA step/run
13	i8	i7	i6	i5(MDEBUGSTOP1)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	CLA step/run

A software breakpoint is placed at instruction i5. The instruction, i5, is then replaced with MDEBUGSTOP1. It takes 3 cycles for the MDEBUGSTOP1 to reach the D2 phase at which point the instructions i6, i7, and i8 that were previously fetched are now flushed from the pipeline. The instruction, i5, is then re-fetched and execution continues as before.

7.4.3.2 Breakpoint Support (MDEBUGSTOP)

1. Insert a breakpoint in CLA code

Insert a CLA breakpoint (MDEBUGSTOP instruction) into the code where the CLA is to halt, then rebuild and reload the code. Because the CLA does not flush the pipeline when in single-step, the MDEBUGSTOP instruction must be inserted as part of the code. The debugger cannot insert the MDEBUGSTOP instruction as needed.

If CLA breakpoints are not enabled, then the MDEBUGSTOP instruction is ignored and is treated as a MNOP. The MDEBUGSTOP instruction can be placed anywhere in the CLA code as long as the MDEBUGSTOP instruction is not within three instructions of a MBCNDD, MCCNDD, or MRCNDD instruction. When programming in C, the user can use the `__mdebugstop()` intrinsic instead; the compiler makes sure that the placement of the MDEBUSTOP instruction in the generated assembly does not violate any of the pipeline restrictions.

2. Enable CLA breakpoints

Enable the CLA breakpoints in the debugger. In the Code Composer Studio™ IDE, this is done by connecting to the CLA core (or tap) from the debug perspective. Breakpoints are disabled when the core is disconnected.

3. Start the task

There are three ways to start the task:

- a. The peripheral can assert an interrupt,
- b. The main CPU can execute an IACK instruction, or
- c. The user can manually write to the MIFRC register in the debugger window

When the task starts, the CLA executes instructions until the MDEBUGSTOP is in the D2 phase of the pipeline. At this point, the CLA halts and the pipeline is frozen. The MPC register reflects the address of the MDEBUGSTOP instruction.

4. Single-step the CLA code

Once halted, the user can single-step the CLA code. The behavior of a CLA single-step is different than the main C28x. When issuing a CLA single-step, the pipeline is clocked only one cycle and then again frozen. On the C28x CPU, the pipeline is flushed for each single-step.

Run to the next MDEBUGSTOP or to the end of the task. If another task is pending, the task automatically starts when run to the end of the task.

Note

A CLA fetch has higher priority than CPU debug reads. For this reason, it is possible for the CLA to permanently block CPU debug accesses if the CLA is executing in a loop. This can occur when initially developing CLA code due to a bug that causes an infinite loop. To avoid locking up the main CPU, the program memory returns all 0x0000 for CPU debug reads when the CLA is running. When the CLA is halted or idle, then normal CPU debug read and write access to CLA program memory can be performed.

If the CLA gets caught in an infinite loop, use a soft or hard reset to exit the condition. A debugger reset also exits the condition.

There are special cases that can occur when single-stepping a task such that the program counter, MPC, reaches the MSTOP instruction at the end of the task.

- **MPC halts at or after the MSTOP with a task already pending**

If single-stepping or halted in "task A" and "task B" comes in before the MPC reaches the MSTOP, then "task B" starts if continuing to step through the MSTOP instruction. Basically, if "task B" is pending before the MPC reaches MSTOP in "task A" then there is no issue in "task B" starting and no special action is required.

- **MPC halts at or after the MSTOP with no task pending**

In this case, if single-stepped or halted in "task A" and the MPC has reached the MSTOP with no tasks pending. If "task B" comes in at this point, "task B" is flagged in the MIFR register but "task B" can or cannot start if continuing to single-step through the MSTOP instruction of "task A."

Depending on exactly when the new task comes in, to reliably start "task B", perform a soft reset and reconfigure the MIER bits. Once this is done, start single-stepping "task B."

This case can be handled slightly differently if there is control over when "task B" comes in (for example, using the IACK instruction to start the task). In this case, the task is single-stepped or halted in "task A" and the MPC has reached the MSTOP with no tasks pending. Before forcing "task B," run free to force the CLA out of the debug state. Once this is done, force "task B" and continue debugging.

5. Disable CLA breakpoints, if desired

In the Code Composer Studio™ IDE, disable the CLA breakpoints by disconnecting the CLA core in the debug perspective. Make sure to first issue a run or reset; otherwise, the CLA is halted and no other tasks start.

7.4.4 CLA Illegal Opcode Behavior

If the CLA fetches an opcode that does not correspond to a legal instruction, the CLA behaves as follows:

- The CLA halts with the illegal opcode in the D2 phase of the pipeline as if a breakpoint. This occurs whether CLA breakpoints are enabled or not.
- The CLA issues the task-specific interrupt to the PIE.
- The MIRUN bit for the task remains set.

Further single-stepping is ignored once execution halts due to an illegal op-code. To exit this situation, issue either a soft or hard reset of the CLA as described in [Section 7.4.5](#).

7.4.5 Resetting the CLA

There are times when resetting the CLA is needed. For example, during code debug the CLA can enter an infinite loop due to a code bug. The CLA has two types of resets: hard and soft. Both of these resets can be performed by the debugger or by the main CPU.

- **Hard Reset** Writing a 1 to the MCTL[HARDRESET] bit performs a hard reset of the CLA. The behavior of a hard reset is the same as a system reset (using $\overline{\text{XRS}}$ or the debugger). In this case, all CLA configuration and execution registers can be set to the default state and CLA execution halts.
- **Soft Reset** Writing a 1 to the MCTL[SOFTRESET] bit performs a soft reset of the CLA. If a task is executing, the task halts and the associated MIRUN bit is cleared. All bits within the interrupt enable (MIER) register are also cleared, so that no new tasks start.

7.5 Pipeline

This section describes the CLA pipeline stages and presents cases where pipeline alignment must be considered.

7.5.1 Pipeline Overview

The CLA pipeline is very similar to the C28x pipeline with eight stages:

1. **Fetch 1 (F1):** During the F1 stage the program read address is placed on the CLA program address bus.
2. **Fetch 2 (F2):** During the F2 stage the instruction is read using the CLA program data bus.
3. **Decode 1 (D1):** During D1 the instruction is decoded.
4. **Decode 2 (D2):** Generate the data read address. Changes to MAR0 and MAR1 due to post-increment using indirect addressing takes place in the D2 phase. Conditional branch decisions are also made at this stage based on the MSTF register flags.
5. **Read 1 (R1):** Place the data read address on the CLA data-read address bus. If a memory conflict exists, the R1 stage is stalled.
6. **Read 2 (R2):** Read the data value using the CLA data read data bus.
7. **Execute (EXE):** Execute the operation. Changes to MAR0 and MAR1 due to loading an immediate value or value from memory take place in this stage.
8. **Write (W):** Place the write address and write data on the CLA write data bus. If a memory conflict exists, the W stage is stalled.

7.5.2 CLA Pipeline Alignment

The majority of the CLA instructions do not require any special pipeline considerations. This section lists the few operations that do require special consideration.

- **Write Followed by Read**

In both the C28x pipeline and the CLA pipeline, the read operation occurs before the write. This means that if a read operation immediately follows a write, then the read completes first as shown in [Table 7-3](#). In most cases this does not cause a problem since the contents of one memory location does not depend on the state of another. For accesses to peripherals where a write to one location can affect the value in another location, the code must wait for the write to complete before issuing the read as shown in [Table 7-4](#).

This behavior is different for the C28x CPU. For the C28x CPU, any write followed by read to the same location is protected by what is called write-followed-by-read protection. This protection automatically stalls the pipeline so that the write completes before the read. In addition, some peripheral frames are protected such that a C28x CPU write to one location within the frame always completes before a read to the frame. The CLA does not have this protection mechanism. Instead, the code must wait to perform the read.

Table 7-3. Write Followed by Read - Read Occurs First

Instruction	F1	F2	D1	D2	R1	R2	E	W
I1 MMOV16 @Reg1, MR3	I1							
I2 MMOV16 MR2, @Reg2	I2	I1						
		I2	I1					
			I2	I1				
				I2	I1			
					I2	I1		
						I2	I1	
							I2	I1

Table 7-4. Write Followed by Read - Write Occurs First

Instruction	F1	F2	D1	D2	R1	R2	E	W
I1 MMOV16 @Reg1, MR3	I1							
I2	I2	I1						
I3	I3	I2	I1					
I4	I4	I3	I2	I1				
I5 MMOV16 MR2, @Reg2	I5	I4	I3	I2	I1			
		I5	I4	I3	I2	I1		
			I5	I4	I3	I2	I1	
				I5	I4	I3	I2	I1
					I5	I4	I3	I1
						I5	I4	I1
							I5	I1

- **Delayed Conditional instructions: MBCNDD, MCCNDD, and MRCNDD**

Referring to [Example 7-1](#), the following applies to delayed conditional instructions:

- **I1:** I1 is the last instruction that can effect the CNDF flags for the branch, call, or return instruction. The CNDF flags are tested in the D2 phase of the pipeline. That is, a decision is made whether to branch or not when MBCNDD, MCCNDD, or MRCNDD is in the D2 phase.
- **I2, I3, and I4:** The three instructions preceding MBCNDD can change the MSTF flags but have no effect on whether the MBCNDD instruction branches or not. This is because the flag modification occurs after the D2 phase of the branch, call, or return instruction. These three instructions must not be a MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.
- **I5, I6, and I7:** The three instructions following a branch, call, or return are always executed irrespective of whether the condition is true or not. These instructions must not be MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.

For a more detailed description, refer to the description for [MBCNDD](#), [MCCNDD](#), and [MRCNDD](#).

Example 7-1. Code Fragment For MBCNDD, MCCNDD, or MRCNDD

```

<Instruction 1>      ; I1 Last instruction that can affect flags for
                    ;   the branch, call or return operation
<Instruction 2>      ; I2 Cannot be stop, branch, call or return
<Instruction 3>      ; I3 Cannot be stop, branch, call or return
<Instruction 4>      ; I4 Cannot be stop, branch, call or return
<branch/call/ret>   ; MBCNDD, MCCNDD or MRCNDD
                    ; I5-I7: Three instructions after are always
                    ;   executed whether the branch/call or return is
                    ;   taken or not
<Instruction 5>      ; I5 Cannot be stop, branch, call or return
<Instruction 6>      ; I6 Cannot be stop, branch, call or return
<Instruction 7>      ; I7 Cannot be stop, branch, call or return
<Instruction 8>      ; I8
<Instruction 9>      ; I9
....

```

- **Stop or Halting a Task: MSTOP and MDEBUGSTOP**

The MSTOP and MDEBUGSTOP instructions cannot be placed three instructions before or after a conditional branch, call or return instruction (MBCNDD, MCCNDD, or MRCNDD). Refer to [Example 7-1](#). To single-step through a branch/call or return, insert the MDEBUGSTOP at least four instructions back and step from there.

- **Loading MAR0 or MAR1**

A load of auxiliary register MAR0 or MAR1 occurs in the EXE phase of the pipeline. Any post increment of MAR0 or MAR1 using indirect addressing occurs in the D2 phase of the pipeline. Referring to [Example 7-2](#), the following applies when loading the auxiliary registers:

- **I1 and I2:** The two instructions following the load instruction use the value in MAR0 or MAR1 before the update occurs.
- **I3:** Loading of an auxiliary register occurs in the EXE phase while updates due to post-increment addressing occur in the D2 phase. Thus I3 cannot use the auxiliary register or there is a conflict. In the case of a conflict, the update due to address-mode post increment wins and the auxiliary register is not updated with #_X.
- **I4:** Starting with the 4th instruction MAR0 or MAR1 has the new value.

Example 7-2. Code Fragment for Loading MAR0 or MAR1

```

; Assume MAR0 is 50 and #_X is 20
MMOVI16 MAR0, #_X ; Load MAR0 with address of X (20)
<Instruction 1> ; I1 uses the old value of MAR0 (50)
<Instruction 2> ; I2 uses the old value of MAR0 (50)
<Instruction 3> ; I3 Cannot use MAR0
<Instruction 4> ; I4 uses the new value of MAR0 (20)
<Instruction 5> ; I5 uses the new value of MAR0 (20)
....
    
```

7.5.2.1 ADC Early Interrupt to CLA Response

The ADC can be configured to generate an early interrupt pulse before the ADC conversion completes. If this option is used to start a CLA task, the CLA is able to read the result as soon as the conversion result is available in the ADC result register. This combination of just-in-time sampling along with the low interrupt response of the CLA enable faster system response and higher frequency control loops. The CLA task trigger to first instruction fetch interrupt latency is 4 cycles.

Timings for ADC conversions are shown in the timing diagrams of the ADC chapter. If the ADCCLK is a divided down version of the SYSCLK, the user has to account for the conversion time in SYSCLK cycles.

From a CLA perspective, the pipeline activity is shown in [Table 7-5](#) for an N-cycle (SYSCLK) ADC conversion. The N-2 instruction arrives in the R2 phase just in time to read the result register. While the prior instructions enter the R2 phase of the pipeline too soon to read the conversion, the instructions can be efficiently used for pre-processing calculations needed by the task.

Table 7-5. ADC to CLA Early Interrupt Response

ADC Activity	CLA Activity	F1	F2	D1	D2	R1	R2	E	W
Sample									
Sample									
...									
Sample									
Conversion _(Cycle 1)	Interrupt Received								
Conversion _(Cycle 2)	Task Startup								
Conversion _(Cycle 3)	Task Startup								
Conversion _(Cycle 4)	I _(Cycle 4)	I _(Cycle 4)							
Conversion _(Cycle 5)	I _(Cycle 5)	I _(Cycle 5)	I _(Cycle 4)						
Conversion _(...)		
Conversion _(Cycle N-6)	I _(Cycle N-6)	I _(Cycle N-6)	I _(Cycle N-7)	I _(Cycle N-8)	I _(Cycle N-9)	I _(Cycle N-10)	I _(Cycle N-11)		
Conversion _(Cycle N-5)	I _(Cycle N-5)	I _(Cycle N-5)	I _(Cycle N-6)	I _(Cycle N-7)	I _(Cycle N-8)	I _(Cycle N-9)	I _(Cycle N-10)		
Conversion _(Cycle N-4)	I _(Cycle N-4)	I _(Cycle N-4)	I _(Cycle N-5)	I _(Cycle N-6)	I _(Cycle N-7)	I _(Cycle N-8)	I _(Cycle N-9)		
Conversion _(Cycle N-3)	I _(Cycle N-3)	I _(Cycle N-3)	I _(Cycle N-4)	I _(Cycle N-5)	I _(Cycle N-6)	I _(Cycle N-7)	I _(Cycle N-8)		
Conversion _(Cycle N-2)	Read RESULT	Read RESULT	I _(Cycle N-3)	I _(Cycle N-4)	I _(Cycle N-5)	I _(Cycle N-6)	I _(Cycle N-7)		
Conversion _(Cycle N-1)			Read RESULT	I _(Cycle N-3)	I _(Cycle N-4)	I _(Cycle N-5)	I _(Cycle N-6)		
Conversion _(Cycle N-0)				Read RESULT	I _(Cycle N-3)	I _(Cycle N-4)	I _(Cycle N-5)		
Conversion Complete					Read RESULT	I _(Cycle N-3)	I _(Cycle N-4)		
RESULT Latched						Read RESULT	I _(Cycle N-3)		
RESULT Available							Read RESULT		

The ADCINTCYCLE register of the ADC can be programmed by the application to adjust the generation of the interrupt pulse to align with the ADC read operation. For example, if the first instruction in the task reads the ADC and the conversion time is N SYSCLK cycles, then the delay programmed is (N-2) - 4 = N-6.

7.5.3 Parallel Instructions

Parallel instructions are single opcodes that perform two operations in parallel. The following types of parallel instructions are available: math operation in parallel with a move operation, or two math operations in parallel. Both operations complete in a single cycle and there are no special pipeline alignment requirements.

Example 7-3. Math Operation with Parallel Load

```

; MADDF32 || MMOV32 instruction: 32-bit floating-point add with parallel move
; MADDF32 is a 1 cycle operation
; MMOV32 is a 1 cycle operation
    MADDF32    MR0, MR1, #2    ; MR0 = MR1 + 2,
    || MMOV32  MR1, @val       ; MR1 gets the contents of val
                                ; <-- MMOV32 completes here (MR1 is valid)
                                ; <-- DDF32 completes here (MR0 is valid)
    MPPYF32 MR0, MR0, MR1     ; Any instruction, can use MR1 and/or MR0

```

Example 7-4. Multiply with Parallel Add

```

; MPPYF32 || MADDF32 instruction: 32-bit floating-point multiply with parallel add
; MPPYF32 is a 1 cycle operation
; MADDF32 is a 1 cycle operation
    MPPYF32 MR0, MR1, MR3    ; MR0 = MR1 * MR3
    || MADDF32 MR1, MR2, MR0 ; MR1 = MR2 + MR0 (Uses value of MR0 before MPPYF32)
                                ; <-- MPPYF32 and MADDF32 complete here (MR0 and MR1 are valid)
    MPPYF32 MR1, MR1, MR0    ; Any instruction, can use MR1 and/or MR0

```

7.5.4 CLA Task Execution Latency

The CLA task execution latency depends on the state of the system:

- CLA task trigger of new task (normal or background) without background task active:

Task takes 8 cycles from CLA task trigger to first instruction of task to reach the D2 phase of pipeline.

Note

If background task has been configured in the system, then the compiler during code compilation adds context save instructions at the start of each regular task and restore instructions at end of each task so that register content can be saved and restored in case a background task is executing while the regular task is triggered. When a regular task is entered, this compiler-generated context save instruction is the first instruction of the task.

- CLA task trigger of normal task when background task is active:

Task takes 9 cycles from CLA task trigger to first instruction of normal task to reach the D2 phase of pipeline. There is a difference of one clock cycle to force the MSTOP in the D2 phase of the background task before the task exits as compared to a new task trigger without the background task active.

Note

If the MBCNDD/MCCNDD/MRCNDD instructions in the background task are in the D2 phase of the pipeline when a new task gets triggered, the task takes a minimum of 3 more cycles to complete these uninterruptible instructions adding to the delay.

- Returning to background task from normal task:

The task takes 5 cycles to return from a normal task to resume the background task instruction at the D2 phase of the pipeline.

7.6 Software

7.6.1 CLA Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/cla

Cloud access to these examples is available at the following link: dev.ti.com [C2000Ware Examples](#).

7.6.1.1 CLA arcsine(x) using a lookup table (cla_asin_cpu01)

FILE: cla_ex1_asin.c

In this example, Task 1 of the CLA will calculate the arcsine of an input argument in the range (-1.0 to 1.0) using a lookup table.

Note that since this example does not use background CLA task, the compile flag `cla_background_task` is turned off for this project. Set this flag as on to enable background CLA task. The option is available in Project Properties -> C2000 Build -> C2000 Compiler -> Advanced Options -> Runtime Model Options.

Memory Allocation

- CLA1 Math Tables (RAMLS1)
 - CLAasinTable - Lookup table
- CLA1 to CPU Message RAM
 - fResult - Result of the lookup algorithm
- CPU to CLA1 Message RAM
 - fVal - Sample input to the lookup algorithm

Watch Variables

- fVal - Argument to task 1
- fResult - Result of arcsin(fVal)

7.6.1.2 CLA arctangent(x) using a lookup table (cla_atan_cpu01)

FILE: cla_ex2_atan.c

In this example, Task 1 of the CLA will calculate the arctangent of an input argument using a lookup table.

Note that since this example does not use background CLA task, the compile flag `cla_background_task` is turned off for this project. Set this flag as on to enable background CLA task. The option is available in Project Properties -> C2000 Build -> C2000 Compiler -> Advanced Options -> Runtime Model Options.

Memory Allocation

- CLA1 Math Tables (RAMLS1)
 - CLAatan2Table - Lookup table
- CLA1 to CPU Message RAM
 - fResult - Result of the lookup algorithm
- CPU to CLA1 Message RAM
 - fNum - Numerator of sample input
 - fDen - Denominator of sample input

Watch Variables

- fVal - Argument to task 1
- fResult - Result of arctan(fVal)

7.6.1.3 CLA background nesting task

FILE: cla_ex3_background_nesting_task.c

This example configures CLA task 1 to be triggered by EPWM1 running at 2 Hz (period = 0.5s). A background task is configured to be triggered by CPU timer running at .5 Hz (period = 2s). CLA task 1 toggles LED1 at the

start and end of the task and the background task toggles LED2 at the start and end of the task. Background task will be preempted by Task1 and hence LED1 will be toggling even while LED2 is ON.

Note that the compile flag `cla_background_task` is turned on in this project. Enabling background task adds additional context save/restore cycles during task switching thus increasing the overall trigger-to-task latency. If the application does not use the background CLA task, it is recommended to turn this flag off for better performance. The option is available in Project Properties -> C2000 Build -> C2000 Compiler -> Advanced Options -> Runtime Model Options.

7.6.1.4 Controlling PWM output using CLA

FILE: `cla_ex4_pwm_control.c`

This example showcases how to update PWM signal output using CLA. EPWM1 is configured to generate complementary signals on both of its channels of fixed frequency 100 KHz. EPWM4 is configured to trigger a periodic CLA control task of frequency 10 KHz. The CLA task implements a very simple logic to vary the duty of the EPWM1 outputs by increasing it by 0.1 in every iteration and maintaining it in the range of 0.1-0.9. For actual use-cases, the control logic could be modified to much more complex depending upon the application. The other CLA task (CLA task 8) is triggered by software at beginning to initialize the CLA global variables

External Connections

- Observe GPIO0 (EPWM1A) on oscilloscope
- Observe GPIO1 (EPWM1B) on oscilloscope

Watch Variables

7.6.1.5 Just-in-time ADC sampling with CLA

FILE: `cla_ex5_adc_just_in_time.c`

This example showcases how to utilize early-interrupt feature of ADC in combination with the low interrupt response of CLA to enable faster system response and achieve high frequency control loops. EPWM1 is configured to generate a PWM output signal of frequency 1 MHz and this is also used to trigger the ADC sampling at each cycle. ADCA is configured to sample the input on Channel 0 and to generate the early interrupt at the end of S/H + offset cycles. This interrupt is used to trigger the CLA control task. The CLA task implements the control logic to update the duty of the PWM output based on reading the ADC sample data just-in-time i.e. as soon as the ADC results gets latched. The early interrupt feature and low interrupt latency of CLA allows to do some pre-processing as well before reading the ADC data and still completes updating the PWM output before the next interrupts comes in i.e. data read and PWM update is done within a 1 MHz cycle. For illustration purposes, 3-point moving average filter is used to simulate some processing and few steps of the filtering code are done before reading the ADC result which we consider as pre-processing code. The ADC interrupt offset is programmed based on the cycles consumed by the pre-processing code.

The calculation for interrupt offset value is as follows :-
 -ADC acquisition cycles programmed = 10 SYSCCLKS
 -Conversion time for 12-bit data = 10.5 ADCCLKS = N = 42 SYSCCLKS
 -CLA task trigger to first instruction in Fetch delay = 4
 -Let the interrupt offset value be 'x'
 -The code inside CLA control task before ADC read takes below cycles :
 Setting up profiling gpio : 3 cycles
 Pre-processing : 13 cycles
 Total = 3 + 13 = 16 cycles

As described in device TRM, in order to read just-in-time the total delay before reading ADC should be (N-2) cycles = 40 i.e. : $x + 4 + 16 = 40$: $x = 20$

NOTE :- The optimization is off for this project and the cycles quoted above corresponds to that case.

GPIO2 is used for profiling purposes. GPIO2 is set at the beginning of CLA task 1 and is reset at the end of the task. Thus ON time of GPIO2 indicates the CLA activity. In order to validate the example functionality, observe the GPIO0 (PWM output) and GPIO2 (profiling GPIO) on CRO. The cycles difference between the rising edge of the GPIO0 and GPIO2 indicate the total delay from the time of ADC trigger to setting up of profiling GPIO inside CLA task which should be around 44 cycles (367 ns) based on the above calculation.

External Connections

- Provide constant DC input on ADCA0 for quick validation. GND -> Should observe PWM output duty = 0.1
3.3V -> Should observe PWM output duty = 0.9 Can also provide analog input in range 0 - 3.3V upto $f_s / 10 = 100$ KHz for observing continuous duty variations
- Observe GPIO0 on oscilloscope
- Observe GPIO2 on oscilloscope

Watch Variables

- None

7.6.1.6 Optimal offloading of control algorithms to CLA

FILE: `cla_ex6_cpu_offloading.c`

This example showcases how to optimally offload the control algorithms from CPU to CLA in order to meet the system requirements. In this example, two control loops are simulated, the faster one (loop1) running at 200 KHz and the slower one (loop2) running at 20 KHz. Loop1 senses the first parameter at ADCA Channel 0, runs the PI controller to achieve the target and contributes to the duty of EPWM1A output with 80% weightage. Loop2 senses the second parameter at ADCB Channel 2, runs the PI controller and contributes to the duty of EPWM1A output with 20% weightage. It is important to note that since these are just software simulated control loops but there is no actual physical process involved and hence updating the duty is not going to have any affect on sampled inputs. ADCA is configured to oversample the first parameter using SOCs 0-3 to suppress the noise and similarly ADCB is used to oversample the second parameter. EPWM4 and EPWM5 are configured to trigger the ADCA and ADCB sampling at loop1 and loop2 frequencies respectively. Once the conversion of all 4 SOCs complete, a CPU ISR or a CLA task is triggered based on the user-configuration. There is also a background task running in the main loop which disables the entire system including PWM output and the control loops when "system_OFF" is set to 1. The system gets enabled again once "system_OFF" is restored back to 0. By default system_OFF is set to 0 but it's value can be updated dynamically by adding it to expression window and writing to it. DCL library is included in the project to make use of optimal PI controllers used in both the loops. User-configurable pre-defined symbol "run_loop1_cla" has been added to the project options in order to specify whether to run the loop1 on C28x or CLA. GPIO2 and GPIO3 are used to profile the execution of loop1 and loop2.

For `run_loop1_cla == 0` i.e. both loops running on CPU -> Loop1 Utilization = ~77.5% (measured using profiling GPIO2) -> Loop2 Utilization = ~6% (measured using profiling GPIO3) -> Background task in a while loop -> Total CPU utilization is greater than Utilization bound (UB) Hence the system is non-schedulable, lower priority task (Loop2) execution never completes (no toggling observed on GPIO3) and also background task never gets chance to execute

For `run_loop1_cla == 1` i.e. high frequency control loop (loop1) is offloaded to CLA while loop2 runs on CPU -> Loop1 Utilization (CLA) = ~73% -> Loop2 Utilization (CPU)= ~6% -> Total CPU utilization has come down to just ~6% Hence the system is perfectly schedulable, no miss happens for any of the loops and offloading of loop1 to CLA saves CPU bandwidth to execute background tasks as well

For quick inspection of the example functionality, constant DC HIGH/LOW inputs can be provided to the analog channels instead of varying analog voltages. The target value for both the loops are set as some intermediate value i.e. 3500 corresponds to ~2.8V. Now since the sensed inputs are constant and not same as target so the controller outputs will get saturated soon to either 1 or 0. Thus the "duty" variable can take only fixed values based on the equations used in the loops. Infact the duty output would be very intuitive, for instance if both inputs are LOW(GND), the controller will try to produce the maximum duty as the target is higher than sensed value hence the duty should be $1.0(0.2 + 0.8)$ but will get saturated to 0.9(the maximum value defined). Similarly

if both inputs are made HIGH, the duty will be 0.1 (the minimum saturation value defined). The final duty table is shown below :

External Connections

- Observe GPIO2 (Loop1 Profiling) on oscilloscope
- Observe GPIO3 (Loop2 Profiling) on oscilloscope
- Observe GPIO0 (EPWM1A Output) on oscilloscope
- Provide constant HIGH(3.3V)/LOW(0V) on both ADCA Ch0 and ADCB Ch2 for quick validation, the following duty value should be observable at EPWM1A for various combinations if the system is perfectly schedulable i.e. both loops gets chance to execute properly :- A0 B2 duty GND GND 0.9 3.3V GND 0.2 GND 3.3V 0.8 3.3V 3.3V 0.1 Note :- The optimization is OFF for this project and all the profiling data quoted above corresponds to this case.

7.6.1.7 Handling shared resources across C28x and CLA

FILE: cla_ex7_shared_resource_handling.c

This example showcases how to handle shared resource challenges across C28x and CLA. As the peripherals are shared between CLA and the CPU, overlapping read-modify-write to the registers by them can lead to data race conditions ultimately leading to data violation or incorrect functionality. In this example, CPU ISR and CLA tasks runs independently. CPU ISR gets triggered by EPWM4 @10KHz and toggles the EPWM1B output via software by controlling CSFB bits of AQCSFRC. CLA task gets triggered by EPWM5 @100KHz and toggles the EPWM1A output via software by controlling CSFA bits of AQCSFRC. Thus in this process both CPU and CLA do read-modify-write to AQCSFRC register independently at different frequencies so there is chance of race condition and updates due to one of them can get lost/. overwritten. This can be clearly observed by updating "phase_shift_ON" to 0U and probing the EPWM1A and 1B outputs on a scope.

This is a standard critical section problem and can be handled by software handshaking mechanism like mutex etc. But most of the real-time control applications are time-sensitive and cannot afford addition software overhead hence this example suggests an alternative hardware based technique to avoid shared resource conflicts between CPU and CLA. The phase shifting mechanism of the EPWM modules is utilized to schedule the CLA task and CPU ISR as desired. EPWM4 generates a synchronous pulse every ZERO event and provides a phase shift of 20 cycles to EPWM5. This way both CLA task and C28x ISR runs at original frequencies i.e. 100KHz and 10KHz but CLA task leads with a phase offset of 20 cycles wrt CPU ISR. Hence concurrent read-modify-writes to AQCSFRC never happens and the EPWM1A and EPWM1B outputs behave as desired i.e. consistent 50 KHz PWM output on EPWM1A and 5 KHz PWM output on EPWM1B with a duty ~50% on both should be generated. In order to utilize this phase shifting mechanism in this example, please make sure "phase_shift_ON" is set to 1.

External Connections

- Observe GPIO0 (EPWM1A Output) on oscilloscope
- Observe GPIO1 (EPWM1B Output) on oscilloscope
- Observe GPIO2 (CLA Task Profiling) on oscilloscope
- Observe GPIO3 (CPU ISR Profiling) on oscilloscope

Note :- The phase offset value can easily be configured by updating TBPHS register to schedule the CLA task and C28x ISR as desired depending upon the application need so as to avoid overlapping register writes by CPU and CLA

Note :- The optimization is on and set to O2 for the project and all the results quoted correspond to this case.

7.7 Instruction Set

This section describes the assembly language instructions of the control law accelerator. Also described are parallel operations, conditional operations, resource constraints, and addressing modes. The instructions listed here are independent from C28x and C28x+FPU instruction sets.

7.7.1 Instruction Descriptions

This section gives detailed information on the instruction set. Each instruction presents the following information:

- Operands
- Opcode
- Description
- Exceptions
- Pipeline
- Examples
- See also

The example INSTRUCTION is shown to familiarize you with the way each instruction is described. The example describes the kind of information you find in each part of the individual instruction description and where to obtain more information. CLA instructions follow the same format as the C28x instructions; the source operands are always on the right and the destination operands are on the left.

The explanations for the syntax of the operands used in the instruction descriptions for the CLA are given in [Table 7-6](#).

Table 7-6. Operand Nomenclature

Symbol	Description
#16FHi	16-bit immediate (hex or float) value that represents the upper 16-bits of an IEEE 32-bit floating-point value. Lower 16-bits of the mantissa are assumed to be zero.
#16FHiHex	16-bit immediate hex value that represents the upper 16-bits of an IEEE 32-bit floating-point value. Lower 16-bits of the mantissa are assumed to be zero.
#16FLoHex	A 16-bit immediate hex value that represents the lower 16-bits of an IEEE 32-bit floating-point value
#32Fhex	32-bit immediate value that represents an IEEE 32-bit floating-point value
#32F	Immediate float value represented in floating-point representation
#0.0	Immediate zero
#SHIFT	Immediate value of 1 to 32 used for arithmetic and logical shifts.
addr	Opcode field indicating the addressing mode
CNDF	Condition to test the flags in the MSTF register
FLAG	Selected flags from MSTF register (OR) 8 bit mask indicating which floating-point status flags to change
MAR0	Auxiliary register 0
MAR1	Auxiliary register 1
MARx	Either MAR0 or MAR1
mem16	16-bit memory location accessed using direct, indirect, or offset addressing modes
mem32	32-bit memory location accessed using direct, indirect, or offset addressing modes
MRa	MR0 to MR3 registers
MRb	MR0 to MR3 registers
MRc	MR0 to MR3 registers
MRd	MR0 to MR3 registers
MRe	MR0 to MR3 registers
MRf	MR0 to MR3 registers
MSTF	CLA Floating-point Status Register
shift	Opcode field indicating the number of bits to shift.
VALUE	Flag value of 0 or 1 for selected flag (OR) 8 bit mask indicating the flag value; 0 or 1

Each instruction has a table that gives a list of the operands and a short description. Instructions always have the destination operands first followed by the source operands.

Table 7-7. INSTRUCTION dest, source1, source2 Short Description

	Description
dest1	Description for the 1st operand for the instruction
source1	Description for the 2nd operand for the instruction
source2	Description for the 3rd operand for the instruction
Opcode	This section shows the opcode for the instruction
Description	Detailed description of the instruction execution is described. Any constraints on the operands imposed by the processor or the assembler are discussed.
Restrictions	Any constraints on the operands or use of the instruction imposed by the processor are discussed.
Pipeline	This section describes the instruction in terms of pipeline cycles as described in Section 7.5
Example	Examples of instruction execution. If applicable, register and memory values are given before and after instruction execution. Some examples are code fragments while other examples are full tasks that assume the CLA is correctly configured and the main CPU has passed the CLA data.
Operands	Each instruction has a table that gives a list of the operands and a short description. Instructions always have the destination operands first followed by the source operands.

7.7.2 Addressing Modes and Encoding

The CLA uses the same address to access data and registers as the main CPU. For example, if the main CPU accesses an ePWM register at address 0x00 6800, then the CLA accesses the register using address 0x6800. Since all CLA accessible memory and registers are within the low 64k x 16 of memory, only the low 16-bits of the address are used by the CLA.

To address the CLA data memory, message RAMs and shared peripherals, the CLA supports two addressing modes:

- Direct addressing mode: Uses the address of the variable or register directly.
- Indirect addressing with 16-bit post increment. This mode uses either XAR0 or XAR1.

The CLA does not use a data page pointer or a stack pointer. The two addressing modes are encoded as shown [Table 7-8](#).

Table 7-8. Addressing Modes

Addressing Mode	'addr' Opcode Field Encode ⁽¹⁾	Description
@dir	0000	<p>Direct Addressing Mode</p> <p>Example 1: MMOV32 MR1, @_VarA</p> <p>Example 2: MMOV32 MR1, @_EPwm1Regs.CMPA.all</p> <p>In this case, the 'm m m m m m m m m m m m m m m m' opcode field is populated with the 16-bit address of the variable. This is the low 16-bits of the address to access the variable using the main CPU.</p> <p>For example, @_VarA populates the address of the variable VarA. and @_EPwm1Regs.CMPA.all populates the address of the CMPA register.</p>
*MAR0[#imm16]++	0001	<p>MAR0 Indirect Addressing with 16-bit Immediate Post Increment</p> <p>MAR1 Indirect Addressing with 16-bit Immediate Post Increment</p> <p>addr = MAR0 (or MAR1) Access memory using the address stored in MAR0 (or MAR1). MAR0 (or MAR1) += #imm16 Then post increment MAR0 (or MAR1) by #imm16.</p> <p>Example 1: MMOV32 MR0, *MAR0[2]++</p> <p>Example 2: MMOV32 MR1, *MAR1[-2]++</p> <p>For a post increment of 0, the assembler accepts both *MAR0 and *MAR0[0]++.</p> <p>The 'm m m m m m m m m m m m m m m m' opcode field is populated with the signed 16-bit pointer offset. For example, if #imm16 is 2, then the opcode field is 0x0002. Likewise, if #imm16 is -2, then the opcode field is 0xFFFFE.</p> <p>If addition of the 16-bit immediate causes overflow, then the value wraps around on a 16-bit boundary.</p>
*MAR1[#imm16]++	0010	

(1) Values not shown are reserved.

Encoding for the shift fields in the MASR32, MLSR32 and MLSL32 instructions is shown in [Table 7-9](#).

Table 7-9. Shift Field Encoding

Shift Value	'shift' Opcode Field Encode
1	0000
2	0001
3	0010
....
32	1111

For instructions that use MR_x (where x can be 'a' through 'f') as operands, the trailing alphabet appears in the opcode as a two-bit field. For example:

```
MMPYF32 MRa, MRb, MRC ||
MADD32 MRd, MRe, MRf
```

whose opcode is,

```
LSW: 0000 ffee ddc bbaa
MSW: 0111 1010 0000 0000
```

The two-bit field specifies one of four working registers according to [Table 7-10](#).

Table 7-10. Operand Encoding

Two-Bit Field	Working Register
00	MR0
01	MR1
10	MR2
11	MR3

[Table 7-11](#) shows the condition field encoding for conditional instructions such as MNEGF, MSWAPF, MBCNDD, MCCNDD, and MRCNDD.

Table 7-11. Condition Field Encoding

Encode ⁽¹⁾	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF ⁽²⁾	Unconditional with flag modification	None

(1) Values not shown are reserved.

(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

7.7.3 Instructions

The instructions are listed alphabetically.

Instruction Set Summary

MABSF32 MRa, MRb — 32-Bit Floating-Point Absolute Value.....	839
MADD32 MRa, MRb, MRc — 32-Bit Integer Add.....	840
MADDF32 MRa, #16FHi, MRb — 32-Bit Floating-Point Addition.....	841
MADDF32 MRa, MRb, #16FHi — 32-Bit Floating-Point Addition.....	843
MADDF32 MRa, MRb, MRc — 32-Bit Floating-Point Addition.....	845
MADDF32 MRd, MRe, MRf MMOV32 mem32, MRa — 32-Bit Floating-Point Addition with Parallel Move.....	846
MADDF32 MRd, MRe, MRf MMOV32 MRa, mem32 — 32-Bit Floating-Point Addition with Parallel Move.....	847
MAND32 MRa, MRb, MRc — Bitwise AND.....	849
MASR32 MRa, #SHIFT — Arithmetic Shift Right.....	850
MBCNDD 16BitDest {, CNDF} — Branch Conditional Delayed.....	852
MCCNDD 16BitDest {, CNDF} — Call Conditional Delayed.....	857
MCMP32 MRa, MRb — 32-Bit Integer Compare for Equal, Less Than or Greater Than.....	861
MCMPF32 MRa, MRb — 32-Bit Floating-Point Compare for Equal, Less Than or Greater Than.....	863
MCMPF32 MRa, #16FHi — 32-Bit Floating-Point Compare for Equal, Less Than or Greater Than.....	864
MDEBUGSTOP — Debug Stop Task.....	866
MEALLOW — Enable CLA Write Access to EALLOW Protected Registers.....	867
MEDIS — Disable CLA Write Access to EALLOW Protected Registers.....	868
MEINVF32 MRa, MRb — 32-Bit Floating-Point Reciprocal Approximation.....	869
MEISQRTF32 MRa, MRb — 32-Bit Floating-Point Square-Root Reciprocal Approximation.....	871
MF32TOI16 MRa, MRb — Convert 32-Bit Floating-Point Value to 16-Bit Integer.....	873
MF32TOI16R MRa, MRb — Convert 32-Bit Floating-Point Value to 16-Bit Integer and Round.....	874
MF32TOI32 MRa, MRb — Convert 32-Bit Floating-Point Value to 32-Bit Integer.....	875
MF32TOUI16 MRa, MRb — Convert 32-Bit Floating-Point Value to 16-bit Unsigned Integer	877
MF32TOUI16R MRa, MRb — Convert 32-Bit Floating-Point Value to 16-bit Unsigned Integer and Round.....	878
MF32TOUI32 MRa, MRb — Convert 32-Bit Floating-Point Value to 32-Bit Unsigned Integer	879
MFRACF32 MRa, MRb — Fractional Portion of a 32-Bit Floating-Point Value.....	880
MI16TOF32 MRa, MRb — Convert 16-Bit Integer to 32-Bit Floating-Point Value	881
MI16TOF32 MRa, mem16 — Convert 16-Bit Integer to 32-Bit Floating-Point Value	882
MI32TOF32 MRa, mem32 — Convert 32-Bit Integer to 32-Bit Floating-Point Value	883
MI32TOF32 MRa, MRb — Convert 32-Bit Integer to 32-Bit Floating-Point Value	884
MLSL32 MRa, #SHIFT — Logical Shift Left.....	885
MLSR32 MRa, #SHIFT — Logical Shift Right.....	887
MMACF32 MR3, MR2, MRd, MRe, MRf MMOV32 MRa, mem32 — 32-Bit Floating-Point Multiply and Accumulate with Parallel Move.....	888
MMAXF32 MRa, MRb — 32-Bit Floating-Point Maximum.....	891
MMAXF32 MRa, #16FHi — 32-Bit Floating-Point Maximum.....	893
MMINF32 MRa, MRb — 32-Bit Floating-Point Minimum.....	895
MMINF32 MRa, #16FHi — 32-Bit Floating-Point Minimum.....	897
MMOV16 MARx, MRa, #16I — Load the Auxiliary Register with MRa + 16-bit Immediate Value.....	899
MMOV16 MARx, mem16 — Load MAR1 with 16-bit Value.....	902
MMOV16 mem16, MARx — Move 16-Bit Auxiliary Register Contents to Memory.....	905
MMOV16 mem16, MRa — Move 16-Bit Floating-Point Register Contents to Memory.....	906
MMOV32 mem32, MRa — Move 32-Bit Floating-Point Register Contents to Memory	908
MMOV32 mem32, MSTF — Move 32-Bit MSTF Register to Memory.....	910
MMOV32 MRa, mem32 {, CNDF} — Conditional 32-Bit Move.....	911
MMOV32 MRa, MRb {, CNDF} — Conditional 32-Bit Move.....	913
MMOV32 MSTF, mem32 — Move 32-Bit Value from Memory to the MSTF Register.....	915
MMOVD32 MRa, mem32 — Move 32-Bit Value from Memory with Data Copy.....	916
MMOVF32 MRa, #32F — Load the 32-Bits of a 32-Bit Floating-Point Register.....	918

MMOVI16 MARx, #16I — Load the Auxiliary Register with the 16-Bit Immediate Value.....	920
MMOVI32 MRa, #32FHex — Load the 32-Bits of a 32-Bit Floating-Point Register with the Immediate.....	922
MMOVIZ MRa, #16FHi — Load the Upper 16-Bits of a 32-Bit Floating-Point Register	924
MMOVZ16 MRa, mem16 — Load MRx with 16-Bit Value.....	925
MMOVXI MRa, #16FLoHex — Move Immediate Value to the Lower 16-Bits of a Floating-Point Register.....	926
MMPYF32 MRa, MRb, MRc — 32-Bit Floating-Point Multiply.....	927
MMPYF32 MRa, #16FHi, MRb — 32-Bit Floating-Point Multiply	928
MMPYF32 MRa, MRb, #16FHi — 32-Bit Floating-Point Multiply	930
MMPYF32 MRa, MRb, MRc MADDF32 MRd, MRe, MRf — 32-Bit Floating-Point Multiply with Parallel Add..	932
MMPYF32 MRd, MRe, MRf MMOV32 MRa, mem32 — 32-Bit Floating-Point Multiply with Parallel Move.....	934
MMPYF32 MRd, MRe, MRf MMOV32 mem32, MRa — 32-Bit Floating-Point Multiply with Parallel Move.....	936
MMPYF32 MRa, MRb, MRc MSUBF32 MRd, MRe, MRf — 32-Bit Floating-Point Multiply with Parallel Subtract	937
MNEGF32 MRa, MRb{, CNDF} — Conditional Negation.....	939
MNOP — No Operation.....	941
MOR32 MRa, MRb, MRc — Bitwise OR.....	942
MRCNDD {CNDF} — Return Conditional Delayed.....	943
MSETFLG FLAG, VALUE — Set or Clear Selected Floating-Point Status Flags.....	946
MSTOP — Stop Task.....	947
MSUB32 MRa, MRb, MRc — 32-Bit Integer Subtraction.....	949
MSUBF32 MRa, MRb, MRc — 32-Bit Floating-Point Subtraction.....	950
MSUBF32 MRa, #16FHi, MRb — 32-Bit Floating-Point Subtraction.....	951
MSUBF32 MRd, MRe, MRf MMOV32 MRa, mem32 — 32-Bit Floating-Point Subtraction with Parallel Move....	953
MSUBF32 MRd, MRe, MRf MMOV32 mem32, MRa — 32-Bit Floating-Point Subtraction with Parallel Move....	954
MSWAPF MRa, MRb {, CNDF} — Conditional Swap.....	955
MTESTTF CNDF — Test MSTF Register Flag Condition.....	957
MUI16TOF32 MRa, mem16 — Convert Unsigned 16-Bit Integer to 32-Bit Floating-Point Value.....	959
MUI16TOF32 MRa, MRb — Convert Unsigned 16-Bit Integer to 32-Bit Floating-Point Value.....	960
MUI32TOF32 MRa, mem32 — Convert Unsigned 32-Bit Integer to 32-Bit Floating-Point Value.....	961
MUI32TOF32 MRa, MRb — Convert Unsigned 32-Bit Integer to 32-Bit Floating-Point Value.....	962
MXOR32 MRa, MRb, MRc — Bitwise Exclusive Or.....	963

MBSF32 MRa, MRb

32-Bit Floating-Point Absolute Value

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1110 0010 0000
```

Description

The absolute value of MRb is loaded into MRa. Only the sign bit of the operand is modified by the MBSF32 instruction.

```
if (MRb < 0) {MRa = -MRb};
else {MRa = MRb};
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified as follows:

```
NF = 0;
ZF = 0;
if ( MRa(30:23) == 0) ZF = 1;
```

Pipeline

This is a single-cycle instruction.

Example

```
MMOVIZ MR0, #-2.0 ; MR0 = -2.0 (0xc0000000)
MBSF32 MR0, MR0 ; MR0 = 2.0 (0x40000000), ZF = NF = 0
MMOVIZ MR0, #5.0 ; MR0 = 5.0 (0x40A00000)
MBSF32 MR0, MR0 ; MR0 = 5.0 (0x40A00000), ZF = NF = 0
MMOVIZ MR0, #0.0 ; MR0 = 0.0
MBSF32 MR0, MR0 ; MR0 = 0.0 ZF = 1, NF = 0
```

See also

[MNEGF32 MRa, MRb {, CNDF}](#)

MADD32 MRa, MRb, MRc**32-Bit Integer Add****Operands**

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point destination register (MR0 to MR3)
MRc	CLA floating-point destination register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 000cc bbaa
MSW: 0111 1110 1100 0000
```

Description

32-bit integer addition of MRb and MRc.

```
MRa(31:0) = MRb(31:0) + MRc(31:0);
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; };
```

Pipeline

This is a single-cycle instruction.

Example

```
; Given A = (int32)1
; B = (int32)2
; C = (int32)-7
;
; Calculate Y2 = A + B + C
;
_Cla1Task1:
    MMOV32 MR0, @_A      ; MR0 = 1 (0x00000001)
    MMOV32 MR1, @_B      ; MR1 = 2 (0x00000002)
    MMOV32 MR2, @_C      ; MR2 = -7 (0xFFFFFFFF9)
    MADD32 MR3, MR0, MR1 ; A + B
    MADD32 MR3, MR2, MR3 ; A + B + C = -4 (0xFFFFFFFFFC)
    MMOV32 @_y2, MR3     ; Store y2
    MSTOP                ; end of task
```

MADDF32 MRa, #16FHi, MRb

32-Bit Floating-Point Addition

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0.
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: IIII IIII IIII IIII
MSW: 0111 0111 1100 bbaa
```

Description

Add MRb to the floating-point value represented by the immediate operand. Store the result of the addition in MRa.

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. #16FHi is most useful for representing constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler accepts either a hex or float as the immediate value. That is, the value -1.5 can be represented as #-1.5 or #0xBFC0.

```
MRa = MRb + #16FHi:0;
```

This instruction can also be written as MADDF32 MRa, MRb, #16FHi.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

Example

```
; Add to MR1 the value 2.0 in 32-bit floating-point format
; Store the result in MR0
MADDF32 MR0, #2.0, MR1 ; MR0 = 2.0 + MR1
; Add to MR3 the value -2.5 in 32-bit floating-point format
; Store the result in MR2
MADDF32 MR2, #-2.5, MR3 ; MR2 = -2.5 + MR3
; Add to MR3 the value 0x3FC00000 (1.5)
; Store the result in MR3
MADDF32 MR3, #0x3FC0, MR3 ; MR3 = 1.5 + MR3
```

32-Bit Floating-Point Addition

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0.

Opcode

```
LSW: IIII IIII IIII IIII
MSW: 0111 0111 1100 bbaa
```

Description

Add MRb to the floating-point value represented by the immediate operand. Store the result of the addition in MRa.

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. #16FHi is most useful for representing constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler accepts either a hex or float as the immediate value. That is, the value -1.5 can be represented as #-1.5 or #0xBFC0.

```
MRa = MRb + #16FHi:0;
```

This instruction can also be written as MADDF32 MRa, #16FHi, MRb.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

MADDF32 MRa, MRb, #16FHi (continued)

32-Bit Floating-Point Addition
Example 1

```

; X is an array of 32-bit floating-point values
; Find the maximum value in an array X
; and store the value in Result
;
;
_Cla1Task1:
    MMOV16    MAR1, #_X          ; Start address
    MUI16TOF32 MR0, @_len      ; Length of the array
    MNOP      ; delay for MAR1 load
    MNOP      ; delay for MAR1 load
    MMOV32    MR1, *MAR1[2]++   ; MR1 = X0
LOOP
    MMOV32    MR2, *MAR1[2]++   ; MR2 = next element
    MMAXF32   MR1, MR2          ; MR1 = MAX(MR1, MR2)
    MADDF32   MR0, MR0, #-1.0   ; Decrement the counter
    MCMPF32   MR0, #0.0         ; Set/clear flags for MBCNDD
    MNOP
    MNOP
    MNOP
    MBCNDD    LOOP, NEQ         ; Branch if not equal to zero
    MMOV32    @_Result, MR1     ; Always executed
    MNOP      ; Always executed
    MNOP      ; Always executed
    MSTOP
    ; End of task

```

Example 2

```

; Show the basic operation of MADDF32
;
; Add to MR1 the value 2.0 in 32-bit floating-point format
; Store the result in MR0
; MADDF32 MR0, MR1, #2.0 ; MR0 = MR1 + 2.0
; Add to MR3 the value -2.5 in 32-bit floating-point format
; Store the result in MR2
; MADDF32 MR2, MR3, #-2.5 ; MR2 = MR3 + (-2.5)
; Add to MR0 the value 0x3FC00000 (1.5)
; Store the result in MR0
; MADDF32 MR0, MR0, #0x3FC0 ; MR0 = MR0 + 1.5

```

MADDF32 MRa, MRb, MRc

32-Bit Floating-Point Addition

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
MRc	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 000 0000 00cc bbaa
MSW: 0111 1100 0010 0000
```

Description

Add the contents of MRc to the contents of MRb and load the result into MRa.

```
MRa = MRb + MRc;
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

Example

```
; Given M1, X1, and B1 are 32-bit floating-point numbers
; Calculate Y1 = M1*X1+B1
;
;
_Cla1Task1:
  MMOV32 MR0,@M1      ; Load MR0 with M1
  MMOV32 MR1,@X1      ; Load MR1 with X1
  MPPYF32 MR1,MR1,MR0 ; Multiply M1*X1
  || MMOV32 MR0,@B1    ; and in parallel load MR0 with B1
  MADDF32 MR1,MR1,MR0 ; Add M*X1 to B1 and store in MR1
  MMOV32 @Y1,MR1      ; Store the result
  MSTOP               ; end of task
```

MADDF32 MRd, MRe, MRf|MMOV32 mem32, MRa
32-Bit Floating-Point Addition with Parallel Move
Operands

MRd	CLA floating-point destination register for the MADDF32 (MR0 to MR3)
MRe	CLA floating-point source register for the MADDF32 (MR0 to MR3)
MRf	CLA floating-point source register for the MADDF32 (MR0 to MR3)
mem32	32-bit memory location accessed using one of the available addressing modes. This is the destination of the MMOV32.
MRa	CLA floating-point source register for the MMOV32 (MR0 to MR3)

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0101 ffee ddaa addr
```

Description

Perform an MADDF32 and a MMOV32 in parallel. Add MRf to the contents of MRe and store the result in MRd. In parallel move the contents of MRa to the 32-bit location mem32.

```
MRd = MRe + MRf;
[mem32] = MRa;
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

Pipeline

Both MADDF32 and MMOV32 complete in a single cycle.

Example

```
; Given A, B, and C are 32-bit floating-point numbers
; Calculate Y2 = (A * B)
;           Y3 = (A * B) + C
;
;
_cla1Task2:
  MMOV32  MR0, @_A      ; Load MR0 with A
  MMOV32  MR1, @_B      ; Load MR1 with B
  MMPYF32 MR1, MR1, MR0 ; Multiply A*B
  || MMOV32 MR0, @_C      ; and in parallel load MR0 with C
  MADDF32 MR1, MR1, MR0 ; Add (A*B) to C
  || MMOV32 @_Y2, MR1     ; and in parallel store A*B
  MMOV32  @_Y3, MR1     ; Store the A*B + C
  MSTOP                ; end of task
```

MADDF32 MRd, MRe, MRf ||MMOV32 MRa, mem32
32-Bit Floating-Point Addition with Parallel Move
Operands

MRd	CLA floating-point destination register for the MADDF32 (MR0 to MR3). MRd cannot be the same register as MRa.
MRe	CLA floating-point source register for the MADDF32 (MR0 to MR3)
MRf	CLA floating-point source register for the MADDF32 (MR0 to MR3)
MRa	CLA floating-point destination register for the MMOV32 (MR0 to MR3). MRa cannot be the same register as MRd.
mem32	32-bit memory location accessed using one of the available addressing modes. This is the source for the MMOV32.

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0001 ffee ddaa addr
```

Description

Perform an MADDF32 and a MMOV32 operation in parallel. Add MRf to the contents of MRe and store the result in MRd. In parallel move the contents of the 32-bit location mem32 to MRa.

```
MRd = MRe + MRf;
MRa = [mem32];
```

Restrictions

The destination register for the MADDF32 and the MMOV32 must be unique. That is, MRa and MRd cannot be the same register.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

The MMOV32 Instruction sets the NF and ZF flags as follows:

```
NF = MRa(31);
ZF = 0;
if(MRa(30:23) == 0) { ZF = 1; NF = 0; };
```

Pipeline

The MADDF32 and the MMOV32 both complete in a single cycle.

MADDF32 MRd, MRe, MRf || MMOV32 MRa, mem32 (continued)
32-Bit Floating-Point Addition with Parallel Move
Example 1

```

; Given A, B, and C are 32-bit floating-point numbers
; Calculate Y1 = A + 4B
;           Y2 = A + C
;
;
;_Cla1Task1:
  MMOV32 MR0, @A      ; Load MR0 with A

Bitwise AND

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
MRc	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 00cc bbaa
MSW: 0111 1100 0110 0000
```

Description

Bitwise AND of MRb with MRc.

```
MRa(31:0) = MRb(31:0) AND MRc(31:0);
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; }
```

Pipeline

This is a single-cycle instruction.

Example

```
MMOVIZ MR0, #0x5555 ; MR0 = 0x5555AAAA
MMOVXI MR0, #0xAAAA
MMOVIZ MR1, #0x5432 ; MR1 = 0x5432FEDC
MMOVXI MR1, #0xFEDC
; 0101 AND 0101 = 0101 (5)
; 0101 AND 0100 = 0100 (4)
; 0101 AND 0011 = 0001 (1)
; 0101 AND 0010 = 0000 (0)
; 1010 AND 1111 = 1010 (A)
; 1010 AND 1110 = 1010 (A)
; 1010 AND 1101 = 1000 (8)
; 1010 AND 1100 = 1000 (8)
MAND32 MR2, MR1, MR0 ; MR3 = 0x5410AA88
```

MASR32 MRa, #SHIFT**Arithmetic Shift Right****Operands**

MRa	CLA floating-point source/destination register (MR0 to MR3)
#SHIFT	Number of bits to shift (1 to 32)

Opcode

```
LSW: 0000 0000 0shi ftaa
MSW: 0111 1011 0100 0000
```

Description

Arithmetic shift right of MRa by the number of bits indicated. The number of bits can be 1 to 32.

```
MARa(31:0) = Arithmetic Shift(MARa(31:0) by #SHIFT bits);
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; }
```

Pipeline

This is a single-cycle instruction.

Example

```
; Given m2 = (int32)32
; x2 = (int32)64
; b2 = (int32)-128
;
; calculate
; m2 = m2/2
; x2 = x2/4
; b2 = b2/8
;
_Cla1Task2:

MBCNDD 16BitDest {, CNDF}**Branch Conditional Delayed****Operands**

16BitDest	16-bit destination if condition is true
CNDF	Optional condition tested

Opcode

```
LSW: dest dest dest dest
MSW: 0111 1001 1000 cndf
```

Description

If the specified condition is true, then branch by adding the signed 16BitDest value to the MPC value. Otherwise, continue without branching. If the address overflows, the address wraps around. Therefore, a value of "0xFFFFE" puts the MPC back to the MBCNDD instruction.

Refer to the Pipeline section for important information regarding this instruction.

```
if (CNDF == TRUE) MPC += 16BitDest;
```

CNDF is one of the following conditions:

Encode ⁽¹⁾	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF ⁽²⁾	Unconditional with flag modification	None

(1) Values not shown are reserved.

(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

Restrictions

The MBCNDD instruction is not allowed three instructions before or after a MBCNDD, MCCNDD, or MRCNDD instruction. Refer to the Pipeline section for more information.

Flags

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

MBCNDD 16BitDest {, CNDF} (continued)

Branch Conditional Delayed
Pipeline

The MBCNDD instruction alone is a single-cycle instruction. As shown in [Table 7-12](#), 6 instruction slots are executed for each branch; 3 slots before the branch instruction (I2-I4) and 3 slots after the branch instruction (I5-I7). The total number of cycles for a branch taken or not taken depends on the usage of these slots. That is, the number of cycles depends on how many slots are filled with a MNOP as well as which slots are filled. The effective number of cycles for a branch can, therefore, range from 1 to 7 cycles. The number of cycles for a branch taken cannot be the same as for a branch not taken.

Referring to [Table 7-12](#) and [Table 7-13](#), the instructions before and after MBCNDD have the following properties:

- **I1**
 - I1 is the last instruction that can effect the CNDF flags for the MBCNDD instruction. The CNDF flags are tested in the D2 phase of the pipeline. That is, a decision is made whether to branch or not when MBCNDD is in the D2 phase.
 - There are no restrictions on the type of instruction for I1.
- **I2, I3, and I4**
 - The three instructions proceeding MBCNDD can change MSTF flags but have no effect on whether the MBCNDD instruction branches or not. This is because the flag modification occurs after the D2 phase of the MBCNDD instruction.
 - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.
- **I5, I6, and I7**
 - The three instructions following MBCNDD are always executed irrespective of whether the branch is taken or not.
 - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.

```

<Instruction 1> ; I1 Last instruction that can affect flags for
                ; the MBCNDD operation
<Instruction 2> ; I2 Cannot be stop, branch, call or return
<Instruction 3> ; I3 Cannot be stop, branch, call or return
<Instruction 4> ; I4 Cannot be stop, branch, call or return
MBCNDD _Skip, NEQ ; Branch to Skip if not equal to zero
                ; Three instructions after MBCNDD are always
                ; executed whether the branch is taken or not
<Instruction 5> ; I5 Cannot be stop, branch, call or return
<Instruction 6> ; I6 Cannot be stop, branch, call or return
<Instruction 7> ; I7 Cannot be stop, branch, call or return

[MCCNDD 16BitDest, CNDF](#)
[MRCNDD CNDF](#)

MCCNDD 16BitDest {, CNDF}

Call Conditional Delayed

Operands

16BitDest	16-bit destination if condition is true
CNDF	Optional condition to be tested

Opcode

```
LSW: dest dest dest dest
MSW: 0111 1001 1001 cndf
```

Description

If the specified condition is true, then store the return address in the RPC field of MSTF and make the call by adding the signed 16BitDest value to the MPC value. Otherwise, continue code execution without making the call. If the address overflows, the address wraps around. Therefore a value of "0xFFFFE" puts the MPC back to the MCCNDD instruction.

Refer to the Pipeline section for important information regarding this instruction.

```
if (CNDF == TRUE)
{
    RPC = return address;
    MPC += 16BitDest;
};
```

CNDF is one of the following conditions:

Encode ⁽¹⁾	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF ⁽²⁾	Unconditional with flag modification	None

(1) Values not shown are reserved.

(2) This is the default operation if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

Restrictions

The MCCNDD instruction is not allowed three instructions before or after a MBCNDD, MCCNDD, or MRCNDD instruction. Refer to the Pipeline section for more details.

Flags

This instruction does not modify flags in the MSTF register.

MCCNDD 16BitDest {, CNDF} (continued)

Call Conditional Delayed

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

The MCCNDD instruction alone is a single-cycle instruction. As shown in [Table 7-14](#), 6 instruction slots are executed for each call; 3 before the call instruction (I2-I4) and 3 after the call instruction (I5-I7). The total number of cycles for a call taken or not taken depends on the usage of these slots. That is, the number of cycles depends on how many slots are filled with a MNOP as well as which slots are filled. The effective number of cycles for a call can, therefore, range from 1 to 7 cycles. The number of cycles for a call taken cannot be the same as for a call not taken.

Referring to the following code fragment and the pipeline diagrams in [Table 7-14](#) and [Table 7-15](#), the instructions before and after MCCNDD have the following properties:

- **I1**
 - I1 is the last instruction that can effect the CNDF flags for the MCCNDD instruction. The CNDF flags are tested in the D2 phase of the pipeline. That is, a decision is made whether to branch or not when MCCNDD is in the D2 phase.
 - There are no restrictions on the type of instruction for I1.
- **I2, I3, and I4**
 - The three instructions proceeding MCCNDD can change MSTF flags but have no effect on whether the MCCNDD instruction makes the call or not. This is because the flag modification occurs after the D2 phase of the MCCNDD instruction.
 - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.
- **I5, I6, and I7**
 - The three instructions following MCCNDD are always executed irrespective of whether the branch is taken or not.
 - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.

MCMP32 MRa, MRb

32-Bit Integer Compare for Equal, Less Than or Greater Than

Operands

MRa	CLA floating-point source register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1111 0010 0000
```

Description

Set ZF and NF flags on the result of MRa - MRb where MRa and MRb are 32-bit integers. For a floating-point compare, refer to [MCMPF32](#).

Note

A known hardware issue exists in the MCMP32 instruction. Signed-integer comparisons using MCMP32 alone set the status bits in a way that is not useful for comparison when the difference between the two operands is too large, such as when the inputs have opposite sign and are near the extreme 32-bit signed values. This affects both signed and unsigned integer comparisons.

The compiler (version 18.1.5.LTS or higher) has implemented a workaround for this issue. The compiler checks the upper bits of the operands by performing a floating point comparison before proceeding to do the integer comparison or subtraction.

The compiler flag `--cla_signed_compare_workaround` enables this workaround.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
If(MRa == MRb) {ZF=1; NF=0;}
If(MRa > MRb) {ZF=0; NF=0;}
If(MRa < MRb) {ZF=0; NF=1;}
```

Pipeline

This is a single-cycle instruction.

Example

```
; Behavior of ZF and NF flags for different comparisons
;
; Given A = (int32)1
; B = (int32)2
; C = (int32)-7
;
MMOV32 MR0, @_A ; MR0 = 1 (0x00000001)
MMOV32 MR1, @_B ; MR1 = 2 (0x00000002)
MMOV32 MR2, @_C ; MR2 = -7 (0xFFFFFFFF9)
MCMP32 MR2, MR2 ; NF = 0, ZF = 1
MCMP32 MR0, MR1 ; NF = 1, ZF = 0
MCMP32 MR1, MR0 ; NF = 0, ZF = 0
```

MCMP32 MRa, MRb (continued)

32-Bit Integer Compare for Equal, Less Than or Greater Than

See also

[MADD32 MRa, MRb, MRc](#)
[MSUB32 MRa, MRb, MRc](#)

MCMPF32 MRa, MRb

32-Bit Floating-Point Compare for Equal, Less Than or Greater Than

Operands

MRa	CLA floating-point source register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1101 0000 0000
```

Description

Set ZF and NF flags on the result of MRa - MRb. The MCMPF32 instruction is performed as a logical compare operation. This is possible because of the IEEE format offsetting the exponent. Basically the bigger the binary number, the bigger the floating-point value.

Special cases for inputs:

- Negative zero is treated as positive zero.
- A denormalized value is treated as positive zero.
- Not-a-Number (NaN) is treated as infinity.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified as follows:

```
If(MRa == MRb) {ZF=1; NF=0;}
If(MRa > MRb) {ZF=0; NF=0;}
If(MRa < MRb) {ZF=0; NF=1;}
```

Pipeline

This is a single-cycle instruction.

Example

```
; Behavior of ZF and NF flags for different comparisons
MMOVIZ MR1, #-2.0 ; MR1 = -2.0 (0xc0000000)
MMOVIZ MR0, #5.0 ; MR0 = 5.0 (0x40A00000)
MCMPF32 MR1, MR0 ; ZF = 0, NF = 1
MCMPF32 MR0, MR1 ; ZF = 0, NF = 0
MCMPF32 MR0, MR0 ; ZF = 1, NF = 0
```

[MMAXF32 MRa, MRb](#)
[MMINF32 MRa, #16FHi](#)
[MMINF32 MRa, MRb](#)

MCMPF32 MRa, #16FHi**32-Bit Floating-Point Compare for Equal, Less Than or Greater Than****Operands**

MRa	CLA floating-point source register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0.

Opcode

```
LSW: IIII IIII IIII IIII
MSW: 0111 1000 1100 00aa
```

Description

Compare the value in MRa with the floating-point value represented by the immediate operand. Set the ZF and NF flags on (MRa - #16FHi:0).

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. This addressing mode is most useful for constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler accepts either a hex or float as the immediate value. That is, -1.5 can be represented as #-1.5 or #0xBFC0.

The MCMPF32 instruction is performed as a logical compare operation. This is possible because of the IEEE floating-point format offsets the exponent. Basically the bigger the binary number, the bigger the floating-point value.

Special cases for inputs:

- Negative zero is treated as positive zero.
- Denormalized value is treated as positive zero.
- Not-a-Number (NaN) is treated as infinity.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified as follows:

```
If(MRa == #16FHi:0) {ZF=1, NF=0;}
If(MRa > #16FHi:0) {ZF=0, NF=0;}
If(MRa < #16FHi:0) {ZF=0, NF=1;}
```

Pipeline

This is a single-cycle instruction

Example 1

```
; Behavior of ZF and NF flags for different comparisons
MMOVIZ MR1, #-2.0 ; MR1 = -2.0 (0xC0000000)
MMOVIZ MR0, #5.0 ; MR0 = 5.0 (0x40A00000)
MCMPF32 MR1, #-2.2 ; ZF = 0, NF = 0
MCMPF32 MR0, #6.5 ; ZF = 0, NF = 1
MCMPF32 MR0, #5.0 ; ZF = 1, NF = 0
```

MDEBUGSTOP

Debug Stop Task

Operands

none	This instruction does not have any operands
------	---

Opcode

LSW: 0000 0000 0000 0000
MSW: 0111 1111 0110 0000

Description

When CLA breakpoints are enabled, the MDEBUGSTOP instruction is used to halt a task so that the task can be debugged. That is, MDEBUGSTOP is the CLA breakpoint. If CLA breakpoints are not enabled, the MDEBUGSTOP instruction behaves like a MNOP. Unlike the MSTOP, the MIRUN flag is not cleared and an interrupt is not issued. A single-step or run operation continues execution of the task.

Restrictions

The MDEBUGSTOP instruction cannot be placed 3 instructions before or after a [MBCNDD](#), [MCCNDD](#), or [MRCNDD](#) instruction.

Flags

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

See also

[MSTOP](#)

MEALLOW

Enable CLA Write Access to EALLOW Protected Registers

Operands

none	This instruction does not have any operands
------	---

Opcode

LSW: 0000 0000 0000 0000
MSW: 0111 1111 1001 0000

Description

This instruction sets the MEALLOW bit in the CLA status register MSTF. When this bit is set, the CLA is allowed write access to EALLOW protected registers. To again protect against CLA writes to protected registers, use the MEDIS instruction.

MEALLOW and MEDIS only control CLA write access; reads are allowed even if MEALLOW has not been executed. MEALLOW and MEDIS are also independent from the main CPU's EALLOW/EDIS. This instruction does not modify the EALLOW bit in the main CPU's status register. The MEALLOW bit in MSTF only controls access for the CLA while the EALLOW bit in the ST1 register only controls access for the main CPU.

As with EALLOW, the MEALLOW bit is overridden using the JTAG port, allowing full control of register accesses during debug from Code Composer Studio.

Flags

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

```

; C header file including definition of
; the EPwm1Regs structure
;
; The ePWM TZSEL register is EALLOW protected
;
.cdecls C,LIST,"CLAShared.h"
...
_Cla1Task1:
...
MEALLOW                ; Allow CLA write access
MMOV16 @_EPwm1Regs.TZSEL.all, MR3 ; write to TZSEL
MEDIS                  ; Disallow CLA write access
...
...
MSTOP

```

See also

[MEDIS](#)

MEDIS**Disable CLA Write Access to EALLOW Protected Registers****Operands**

none	This instruction does not have any operands
------	---

Opcode

LSW: 0000 0000 0000 0000
MSW: 0111 1111 1011 0000

Description

This instruction clears the MEALLOW bit in the CLA status register MSTF. When this bit is clear, the CLA is not allowed write access to EALLOW-protected registers. To enable CLA writes to protected registers, use the MEALLOW instruction.

MEALLOW and MEDIS only control CLA write access; reads are allowed even if MEALLOW has not been executed. MEALLOW and MEDIS are also independent from the main CPU's EALLOW/EDIS. This instruction does not modify the EALLOW bit in the main CPU's status register. The MEALLOW bit in MSTF only controls access for the CLA while the EALLOW bit in the ST1 register only controls access for the main CPU.

As with EALLOW, the MEALLOW bit is overridden using the JTAG port, allowing full control of register accesses during debug from the Code Composer Studio™ IDE.

Flags

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

MEINVF32 MRa, MRb**32-Bit Floating-Point Reciprocal Approximation****Operands**

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1111 0000 0000
```

Description

This operation generates an estimate of $1/X$ in 32-bit floating-point format accurate to approximately 8 bits. This value can be used in a Newton-Raphson algorithm to get a more accurate answer. That is:

```
Ye = Estimate(1/X);
Ye = Ye*(2.0 - Ye*X);
Ye = Ye*(2.0 - Ye*X);
```

After two iterations of the Newton-Raphson algorithm, you get an exact answer accurate to the 32-bit floating-point format. On each iteration, the mantissa bit accuracy approximately doubles. The MEINVF32 operation does not generate a negative zero, DeNorm, or NaN value.

```
MRa = Estimate of 1/MRb;
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MEINVF32 generates an underflow condition.
- LVF = 1 if MEINVF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

MEINVF32 MRa, MRb (continued)**32-Bit Floating-Point Reciprocal Approximation****Example**

```

; Calculate Num/Den using a Newton-Raphson algorithm for 1/Den

MEISQRTF32 MRa, MRb

32-Bit Floating-Point Square-Root Reciprocal Approximation

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1110 0100 0000
```

Description

This operation generates an estimate of $1/\sqrt{X}$ in 32-bit floating-point format accurate to approximately 8 bits. This value can be used in a Newton-Raphson algorithm to get a more accurate answer. That is:

```
Ye = Estimate(1/sqrt(X));
Ye = Ye*(1.5 - Ye*Ye*X/2.0);
Ye = Ye*(1.5 - Ye*Ye*X/2.0);
```

After 2 iterations of the Newton-Raphson algorithm, you get an exact answer accurate to the 32-bit floating-point format. On each iteration, the mantissa bit accuracy approximately doubles. The MEISQRTF32 operation does not generate a negative zero, DeNorm, or NaN value.

```
MRa = Estimate of 1/sqrt (MRb);
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MEISQRTF32 generates an underflow condition.
- LVF = 1 if MEISQRTF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

MF32TOUI16 MRa, MRb

Convert 32-Bit Floating-Point Value to 16-bit Unsigned Integer

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1110 1010 0000
```

Description

Convert the 32-bit floating point value in MRb to an unsigned 16-bit integer value and truncate to zero. The result is stored in MRa. To instead round the integer to the nearest even value, use the MF32TOUI16R instruction.

```
MRa(15:0) = F32TOUI16(MRb);
MRa(31:16) = 0x0000;
```

Flags

This instruction does not affect any flags:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

```
MMOVIZ    MR0, #9.0      ; MR0 = 9.0 (0x41100000)
MF32TOUI16 MR1, MR0      ; MR1(15:0) = MF32TOUI16(MR0) = 9 (0x0009)
              ; MR1(31:16) = 0x0000
MMOVIZ    MR2, #-9.0     ; MR2 = -9.0 (0xc1100000)
MF32TOUI16 MR3, MR2     ; MR3(15:0) = MF32TOUI16(MR2) = 0 (0x0000)

This is a single-cycle instruction.

Example

```
; Given X, M and B are IQ24 numbers:
; X = IQ24(+2.5) = 0x02800000
; M = IQ24(+1.5) = 0x01800000
; B = IQ24(-0.5) = 0xFF800000
;
; Calculate Y = X * M + B
;
; Convert M, X, and B from IQ24 to float
;
_Cla1Task3:
MI32TOF32 MR0, @_M      ; MR0 = 0x4BC00000
MI32TOF32 MR1, @_X      ; MR1 = 0x4C200000
MI32TOF32 MR2, @_B      ; MR2 = 0xCB000000
MMPYF32 MR0, MR0, #0x3380 ; M = 1/(1*2^24) * iqm = 1.5 (0x3FC00000)
MMPYF32 MR1, MR1, #0x3380 ; X = 1/(1*2^24) * iqx = 2.5 (0x40200000)
MMPYF32 MR2, MR2, #0x3380 ; B = 1/(1*2^24) * iqb = -.5 (0xBF000000)
MMPYF32 MR3, MR0, MR1    ; M*X
MADDF32 MR2, MR2, MR3    ; Y=MX+B = 3.25 (0x40500000)
; Convert Y from float32 to IQ24
MMPYF32 MR2, MR2, #0x4B80 ; Y * 1*2^24
MF32TOI32 MR2, MR2      ; IQ24(Y) = 0x03400000
MMOV32 @_Y, MR2        ; store result
MSTOP                  ; end of task
```

MI32TOF32 MRa, MRb**Convert 32-Bit Integer to 32-Bit Floating-Point Value****Operands**

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1101 1000 0000
```

Description

Convert the signed 32-bit integer in MRb to a 32-bit floating-point value and store the result in MRa.

```
MRa = MI32TOF32(MRb);
```

Flags

This instruction does not affect any flags:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

```
MMOVIZ MR2, #0x1111 ; MR2(31:16) = 4369 (0x1111)
MMOVXI MR2, #0x1111 ; MR2(15:0) = 4369 (0x1111)
; MR2 = +286331153 (0x11111111)
MI32TOF32 MR3, MR2 ; MR3 = MI32TOF32 (MR2) = 286331153.0 (0x4D888888)
```

MLSL32 MRa, #SHIFT

Logical Shift Left

Operands

MRa	CLA floating-point source/destination register (MR0 to MR3)
#SHIFT	Number of bits to shift (1 to 32)

Opcode

```
LSW: 0000 0000 0shi ftaa
MSW: 0111 1011 1100 0000
```

Description

Logical shift-left of MRa by the number of bits indicated. The number of bits can be 1 to 32.

```
MARa(31:0) = Logical Shift Left(MARa(31:0) by #SHIFT bits);
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; }
```

Pipeline

This is a single-cycle instruction.

Example

```
; Given m2 = (int32)32
; x2 = (int32)64
; b2 = (int32)-128
;
; calculate:
; m2 = m2*2
; x2 = x2*4
; b2 = b2*8
;
_Cla1Task3:
  MMOV32 MR0, @_m2 ; MR0 = 32 (0x00000020)
  MMOV32 MR1, @_x2 ; MR1 = 64 (0x00000040)
  MMOV32 MR2, @_b2 ; MR2 = -128 (0xFFFFF80)
  MLSL32 MR0, #1 ; MR0 = 64 (0x00000040)
  MLSL32 MR1, #2 ; MR1 = 256 (0x00000100)
  MLSL32 MR2, #3 ; MR2 = -1024 (0xFFFFFC00)
  MMOV32 @_m2, MR0 ; Store results
  MMOV32 @_x2, MR1
  MMOV32 @_b2, MR2
  MSTOP ; end of task
```

MLSL32 MRa, #SHIFT (continued)**Logical Shift Left**

MLSR32 MRa, #SHIFT

Logical Shift Right

Operands

MRa	CLA floating-point source/destination register (MR0 to MR3)
#SHIFT	Number of bits to shift (1 to 32)

Opcode

```
LSW: 0000 0000 0shi ftaa
MSW: 0111 1011 1000 0000
```

Description

Logical shift-right of MRa by the number of bits indicated. The number of bits can be 1 to 32. Unlike the arithmetic shift (MASR32), the logical shift does not preserve the number's sign bit. Every bit in the operand is moved the specified number of bit positions, and the vacant bit positions are filled in with zeros.

```
MARa(31:0) = Logical Shift Right(MARa(31:0) by #SHIFT bits);
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1;}
```

Pipeline

This is a single-cycle instruction.

Example

```
; illustrate the difference between MASR32 and MLSR32
MMOVIZ MR0, #0xAAAA ; MR0 = 0xAAAA5555
MMOVXI MR0, #0x5555
MMOV32 MR1, MR0 ; MR1 = 0xAAAA5555
MMOV32 MR2, MR0 ; MR2 = 0xAAAA5555
MASR32 MR1, #1 ; MR1 = 0xD5552AAA
MLSR32 MR2, #1 ; MR2 = 0x55552AAA
MASR32 MR1, #1 ; MR1 = 0xEAAA9555
MLSR32 MR2, #1 ; MR2 = 0x2AAA9555
MASR32 MR1, #6 ; MR1 = 0xFFAAA555
MLSR32 MR2, #6 ; MR2 = 0x00AAA555
```

MMACF32 MR3, MR2, MRd, MRe, MRf ||MMOV32 MRa, mem32
32-Bit Floating-Point Multiply and Accumulate with Parallel Move
Operands

MR3	floating-point destination/source register MR3 for the add operation
MR2	CLA floating-point source register MR2 for the add operation
MRd	CLA floating-point destination register (MR0 to MR3) for the multiply operation MRd cannot be the same register as MRa
MRe	CLA floating-point source register (MR0 to MR3) for the multiply operation
MRf	CLA floating-point source register (MR0 to MR3) for the multiply operation
MRa	CLA floating-point destination register for the MMOV32 operation (MR0 to MR3). MRa cannot be MR3 or the same register as MRd.
mem32	32-bit source for the MMOV32 operation

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0011 ffee ddaa addr
```

Description

Multiply and accumulate the contents of floating-point registers and move from register to memory. The destination register for the MMOV32 cannot be the same as the destination registers for the MMACF32.

```
MR3 = MR3 + MR2;
MRd = MRe * MRf;
MRa = [mem32];
```

Restrictions

The destination registers for the MMACF32 and the MMOV32 must be unique. That is, MRa cannot be MR3 and MRa cannot be the same register as MRd.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MMACF32 (add or multiply) generates an underflow condition.
- LVF = 1 if MMACF32 (add or multiply) generates an overflow condition.

MMOV32 sets the NF and ZF flags as follows:

```
NF = MRa(31);
ZF = 0;
if(MRa(30:23) == 0) { ZF = 1; NF = 0; }
```

Pipeline

MMACF32 and MMOV32 complete in a single cycle.

MMACF32 MR3, MR2, MRd, MRe, MRf ||MMOV32 MRa, mem32 (continued)
32-Bit Floating-Point Multiply and Accumulate with Parallel Move
Example 1

```

; Perform 5 multiply and accumulate operations:
;
; X and Y are 32-bit floating-point arrays
;
; 1st multiply: A = X0 * Y0
; 2nd multiply: B = X1 * Y1

MMAXF32 MRa, MRb

32-Bit Floating-Point Maximum

Operands

MRa	CLA floating-point source/destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1101 0010 0000
```

Description

```
if(MRa < MRb) MRa = MRb;
```

Special cases for the output from the MMAXF32 operation:

- NaN output is converted to infinity
- A denormalized output is converted to positive zero.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The ZF and NF flags are configured on the result of the operation, not the result stored in the destination register.

```
if(MRa == MRb) {ZF=1; NF=0;}
if(MRa > MRb) {ZF=0; NF=0;}
if(MRa < MRb) {ZF=0; NF=1;}
```

Pipeline

This is a single-cycle instruction.

Example 1

```
MMOVIZ MR0, #5.0 ; MR0 = 5.0 (0x40A00000)
MMOVIZ MR1, #-2.0 ; MR1 = -2.0 (0xC0000000)
MMOVIZ MR2, #-1.5 ; MR2 = -1.5 (0xBFC00000)
MMAXF32 MR2, MR1 ; MR2 = -1.5, ZF = NF = 0
MMAXF32 MR1, MR2 ; MR1 = -1.5, ZF = 0, NF = 1
MMAXF32 MR2, MR0 ; MR2 = 5.0, ZF = 0, NF = 1
MAXF32 MR0, MR2 ; MR2 = 5.0, ZF = 1, NF = 0
```

MMAXF32 MRa, #16FHi

32-Bit Floating-Point Maximum

Operands

MRa	CLA floating-point source/destination register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0.

Opcode

```
LSW: IIII IIII IIII IIII
MSW: 0111 1001 0000 00aa
```

Description

Compare MRa with the floating-point value represented by the immediate operand. If the immediate value is larger, then load the value into MRa.

```
if(MRa < #16FHi:0) MRa = #16FHi:0;
```

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. This addressing mode is most useful for constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler accepts either a hex or float as the immediate value. That is, -1.5 can be represented as #-1.5 or #0xBFC0.

Special cases for the output from the MMAXF32 operation:

- NaN output is converted to infinity
- A denormalized output is converted to positive zero.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The ZF and NF flags are configured on the result of the operation, not the result stored in the destination register.

```
if(MRa == #16FHi:0) {ZF=1; NF=0;}
if(MRa > #16FHi:0) {ZF=0; NF=0;}
if(MRa < #16FHi:0) {ZF=0; NF=1;}
```

Pipeline

This is a single-cycle instruction.

Example

```
MMOVIZ MR0, #5.0 ; MR0 = 5.0 (0x40A00000)
MMOVIZ MR1, #4.0 ; MR1 = 4.0 (0x40800000)
MMOVIZ MR2, #-1.5 ; MR2 = -1.5 (0xBFC00000)
MMAXF32 MR0, #5.5 ; MR0 = 5.5, ZF = 0, NF = 1
MMAXF32 MR1, #2.5 ; MR1 = 4.0, ZF = 0, NF = 0
MMAXF32 MR2, #-1.0 ; MR2 = -1.0, ZF = 0, NF = 1
MMAXF32 MR2, #-1.0 ; MR2 = -1.5, ZF = 1, NF = 0
```

Description

Compare MRa with the floating-point value represented by the immediate operand. If the immediate value is smaller, then load the value into MRa.

```
if(MRa > #16FHi:0) MRa = #16FHi:0;
```

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. This addressing mode is most useful for constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler accepts either a hex or float as the immediate value. That is, -1.5 can be represented as #-1.5 or #0xBFC0.

Special cases for the output from the MMINF32 operation:

- NaN output is converted to infinity
- A denormalized output is converted to positive zero.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The ZF and NF flags are configured on the result of the operation, not the result stored in the destination register.

```
if(MRa == #16FHi:0) {ZF=1; NF=0;}
if(MRa > #16FHi:0) {ZF=0; NF=0;}
if(MRa < #16FHi:0) {ZF=0; NF=1;}
```

Pipeline

This is a single-cycle instruction.

Example

```
MMOVIZ MR0, #5.0 ; MR0 = 5.0 (0x40A00000)
MMOVIZ MR1, #4.0 ; MR1 = 4.0 (0x40800000)
MMOVIZ MR2, #-1.5 ; MR2 = -1.5 (0xBFC00000)
MMINF32 MR0, #5.5 ; MR0 = 5.0, ZF = 0, NF = 1
MMINF32 MR1, #2.5 ; MR1 = 2.5, ZF = 0, NF = 0
MMINF32 MR2, #-1.0 ; MR2 = -1.5, ZF = 0, NF = 1
MMINF32 MR2, #-1.5 ; MR2 = -1.5, ZF = 1, NF = 0
```

MMOV16 MARx, MRa, #16I

Load the Auxiliary Register with MRa + 16-bit Immediate Value

Operands

MARx	Auxiliary register MAR0 or MAR1
MRa	CLA Floating-point register (MR0 to MR3)
#16I	16-bit immediate value

Opcode

```
LSW: IIII IIII IIII IIII (opcode of MMOV16 MAR0, MRa, #16I)
MSW: 0111 1111 1101 00AA
LSW: IIII IIII IIII IIII (opcode of MMOV16 MAR1, MRa, #16I)
MSW: 0111 1111 1111 00AA
```

Description

Load the auxiliary register, MAR0 or MAR1, with MRa(15:0) + 16-bit immediate value. Refer to the Pipeline section for important information regarding this instruction.

```
MARX = MRa(15:0) + #16I;
```

Flags

This instruction does not modify flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction. The load of MAR0 or MAR1 occurs in the EXE phase of the pipeline. Any post increment of MAR0 or MAR1 using indirect addressing occurs in the D2 phase of the pipeline. Therefore, the following applies when loading the auxiliary registers:

- **I1 and I2**

The two instructions following MMOV16 use MAR0 or MAR1 before the update occurs. Thus, these two instructions use the old value of MAR0 or MAR1.

- **I3**

Loading of an auxiliary register occurs in the EXE phase while updates due to post-increment addressing occur in the D2 phase. Thus, I3 cannot use the auxiliary register or there is a conflict. In the case of a conflict, the update due to address-mode post increment wins and the auxiliary register is not updated with #_X.

- **I4**

Starting with the 4th instruction, MAR0 or MAR1 is the new value loaded with MMOV16.

```
; Assume MAR0 is 50, MR0 is 10, and #_X is 20
MMOV16 MAR0, MR0, #_X ; Load MAR0 with address of x (20) + MR0 (10)
<Instruction 1> ; I1 Uses the old value of MAR0 (50)
<Instruction 2> ; I2 Uses the old value of MAR0 (50)
<Instruction 3> ; I3 Cannot use MAR0
<Instruction 4> ; I4 Uses the new value of MAR0 (30)
<Instruction 5> ; I5
```

LSW: mmmm mmmm mmmm mmmm (Opcode for MMOV16 MAR1, mem16)
MSW: 0111 0110 0100 addr
```

Description

Load MAR0 or MAR1 with the 16-bit value pointed to by mem16. Refer to the Pipeline section for important information regarding this instruction.

```
MAR1 = [mem16];
```

Flags

No flags MSTF flags are affected.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction. The load of MAR0 or MAR1 occurs in the EXE phase of the pipeline. Any post increment of MAR0 or MAR1 using indirect addressing occurs in the D2 phase of the pipeline. Therefore, the following applies when loading the auxiliary registers:

- **I1 and I2**

The two instructions following MMOV16 use MAR0 or MAR1 before the update occurs. Thus, these two instructions use the old value of MAR0 or MAR1.

- **I3**

Loading of an auxiliary register occurs in the EXE phase while updates due to post-increment addressing occur in the D2 phase. Thus, I3 cannot use the auxiliary register or there is a conflict. In the case of a conflict, the update due to address-mode post increment, the auxiliary register is not updated with #_X.

- **I4**

Starting with the 4th instruction, MAR0 or MAR1 is the new value loaded with MMOV16.

```
; Assume MAR0 is 50 and @_X is 20
MMOV16 MAR0, @_X ; Load MAR0 with the contents of x (20)
<Instruction 1> ; I1 Uses the old value of MAR0 (50)
<Instruction 2> ; I2 Uses the old value of MAR0 (50)
<Instruction 3> ; I3 Cannot use MAR0
<Instruction 4> ; I4 Uses the new value of MAR0 (20)
<Instruction 5> ; I5
....
```

Pipeline

This is a single-cycle instruction.

One of the uses of this instruction is to save off the return PC (RPC) prior to calling a function. The decision to jump to a function is made when the MCCNDD is in the decode2 (D2) phase of the pipeline; the RPC is also updated in this phase. The actual jump occurs 3 cycles later when MCCNDD enters the execution (E) phase. You must save the old RPC before MCCNDD updates in the D2 phase; that is, save MSTF 3 instructions prior to the function call.

Example

The following example illustrates the pipeline flow for the context save (of the flags and RPC) prior to a function call. The first column in the comments shows the pipeline stages for the MMOV32 instruction while the second column pertains to the MCCNDD instruction.

```
MMOV32 @_temp, MSTF ; D2 | |
MNOP                ; R1 | F1 | MCCNDD is fetched
MNOP                ; R2 | F2 |
MNOP                ; E  | D1 |
MCCNDD _bar, UNC    ; W  | D2 | old RPC written to memory,
                   ;   |   | RPC updated with MPC+1
MNOP                ;   | R1 |
MNOP                ;   | R2 |
MNOP                ;   | E  | execution branches to _bar
```

[MMOV32 mem32, MRa](#)

MMOV32 MRa, mem32 {, CNDF}
Conditional 32-Bit Move
Operands

MRa	CLA floating-point destination register (MR0 to MR3)
mem32	32-bit memory location accessed using one of the available addressing modes
CNDF	Optional condition

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0111 00cn dfaa addr
```

Description

If the condition is true, then move the 32-bit value referenced by mem32 to the floating-point register indicated by MRa.

```
if (CNDF == TRUE) MRa = [mem32];
```

CNDF is one of the following conditions:

Encode ⁽¹⁾	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF ⁽²⁾	Unconditional with flag modification	None

(1) Values not shown are reserved.

(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

```
if(CNDF == UNCF)
{
  NF = MRa(31);
  ZF = 0;
  if(MRa(30:23) == 0) { ZF = 1; NF = 0; }
}
else No flags modified;
```

MMOV32 MRa, mem32 {, CNDF} (continued)

Conditional 32-Bit Move

Pipeline

This is a single-cycle instruction.

Example

```

; Given A, B, X, M1 and M2 are 32-bit floating-point numbers
;
; if(A == B) calculate Y = X*M1
; if(A! = B) calculate Y = X*M2
;
_Cla1Task5:
    MMOV32    MR0, @_A
    MMOV32    MR1, @_B
    MCMPF32   MR0, MR1
    MMOV32    MR2, @_M1, EQ ; if A == B, MR2 = M1
                    ; Y = M1*X
    MMOV32    MR2, @_M2, NEQ ; if A! = B, MR2 = M2
                    ; Y = M2*X

    MMOV32    MR3, @_X
    MMPYF32   MR3, MR2, MR3 ; Calculate Y
    MMOV32    @_Y, MR3      ; Store Y
    MSTOP
; end of task
    
```

Conditional 32-Bit Move
Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
CNDF	Optional condition

Opcode

```
LSW: 0000 0000 cndf bbaa
MSW: 0111 1010 1100 0000
```

Description

If the condition is true, then move the 32-bit value in MRb to the floating-point register indicated by MRa.

```
if (CNDF == TRUE) MRa = MRb;
```

CNDF is one of the following conditions:

Encode ⁽¹⁾	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF ⁽²⁾	Unconditional with flag modification	None

(1) Values not shown are reserved.

(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF, and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

```
if(CNDF == UNCF)
{
  NF = MRa(31); ZF = 0;
  if(MRa(30:23) == 0) {ZF = 1; NF = 0;}
}
else No flags modified;
```

MMOV32 MRa, MRb {, CNDF} (continued)

Conditional 32-Bit Move

Pipeline

This is a single-cycle instruction.

Example

```

; Given: X = 8.0
;         Y = 7.0
;         A = 2.0
;         B = 5.0
; _ClTask1
MMOV32 MR3, @_X      ; MR3 = X = 8.0
MMOV32 MR0, @_Y      ; MR0 = Y = 7.0
MMAXF32 MR3, MR0     ; ZF = 0, NF = 0, MR3 = 8.0
MMOV32 MR1, @_A, GT  ; true, MR1 = A = 2.0
MMOV32 MR1, @_B, LT  ; false, does not load MR1
MMOV32 MR2, MR1, GT  ; true, MR2 = MR1 = 2.0
MMOV32 MR2, MR0, LT  ; false, does not load MR2
MSTOP
    
```

MMOV32 MSTF, mem32**Move 32-Bit Value from Memory to the MSTF Register****Operands**

MSTF	CLA status register
mem32	32-bit source memory location

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0111 0111 0000 addr
```

Description

Move from memory to the CLA's status register MSTF. This instruction is most useful when nesting function calls (using MCCNDD).

```
MSTF = [mem32];
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	Yes	Yes	Yes	Yes	Yes

Loading the status register can overwrite all flags and the RPC field. The MEALLOW field is not affected.

Pipeline

This is a single-cycle instruction.

[MMOV32 MRa, mem32 {,CNDF}](#)

MMOVF32 MRa, #32F

Load the 32-Bits of a 32-Bit Floating-Point Register

Operands

This instruction is an alias for the MMOVIZ and MMOVXI instructions. The second operand is translated by the assembler such that the instruction becomes:

```
MMOVIZ MRa, #16FHiHex MMOVXI MRa, #16FLoHex
```

MRa	CLA floating-point destination register (MR0 to MR3)
#32F	Immediate float value represented in floating-point representation

Opcode

```
LSW: IIII IIII IIII IIII (opcode of MMOVIZ MRa, #16FHiHex)
MSW: 0111 1000 0100 00aa
LSW: IIII IIII IIII IIII (opcode of MMOVXI MRa, #16FLoHex)
MSW: 0111 1000 1000 00aa
```

Description

This instruction accepts the immediate operand only in floating-point representation. To specify the immediate value as a hex value (IEEE 32-bit floating-point format), use the MOVI32 MRa, #32FHex instruction.

Load the 32-bits of MRa with the immediate float value represented by #32F.

#32F is a float value represented in floating-point representation. The assembler only accepts a float value represented in floating-point representation. That is, 3.0 can only be represented as #3.0 (#0x40400000 results in an error).

```
MRa = #32F;
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

Depending on #32F, this instruction takes one or two cycles. If all of the lower 16-bits of the IEEE 32-bit floating-point format of #32F are zeros, then the assembler converts MMOVF32 into only an MMOVIZ instruction. If the lower 16-bits of the IEEE 32-bit floating-point format of #32F are not zeros, then the assembler converts MMOVF32 into MMOVIZ and MMOVXI instructions.

Example

```
MMOVF32 MR1, #3.0 ; MR1 = 3.0 (0x40400000)
                  ; Assembler converts this instruction as
                  ; MMOVIZ MR1, #0x4040
MMOVF32 MR2, #0.0 ; MR2 = 0.0 (0x00000000)
                  ; Assembler converts this instruction as
                  ; MMOVIZ MR2, #0x0
MMOVF32 MR3, #12.265 ; MR3 = 12.625 (0x41443D71)
                    ; Assembler converts this instruction as
                    ; MMOVIZ MR3, #0x4144
                    ; MMOVXI MR3, #0x3D71
```

MMOVI16 MARx, #16I**Load the Auxiliary Register with the 16-Bit Immediate Value****Operands**

MARx	Auxiliary register MAR0 or MAR1
#16I	16-bit immediate value

Opcode

```

LSW: IIII IIII IIII IIII (opcode of MMOVI16 MAR0, #16I)
MSW: 0111 1111 1100 0000
LSW: IIII IIII IIII IIII (opcode of MMOVI16 MAR1, #16I)
MSW: 0111 1111 1110 0000

```

Description

Load the auxiliary register, MAR0 or MAR1, with a 16-bit immediate value. Refer to the Pipeline section for important information regarding this instruction.

```
MARX = #16I;
```

Flags

This instruction does not modify flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction. The immediate load of MAR0 or MAR1 occurs in the EXE phase of the pipeline. Any post increment of MAR0 or MAR1 using indirect addressing occurs in the D2 phase of the pipeline. Therefore, the following applies when loading the auxiliary registers:

- **I1 and I2**

The two instructions following MMOVI16 use MAR0 or MAR1 before the update occurs. Thus, these two instructions use the old value of MAR0 or MAR1.

- **I3**

Loading of an auxiliary register occurs in the EXE phase while updates due to post-increment addressing occur in the D2 phase. Thus, I3 cannot use the auxiliary register or there is a conflict. In the case of a conflict, the update due to address-mode post increment, the auxiliary register is not updated with #_X.

- **I4**

Starting with the 4th instruction, MAR0 or MAR1 is the new value loaded with MMOVI16.

```

; Assume MAR0 is 50 and #_X is 20
MMOVI16 MAR0, #_X          ; Load MAR0 with address of X (20)
<Instruction 1>             ; I1 Uses the old value of MAR0 (50)
<Instruction 2>             ; I2 Uses the old value of MAR0 (50)
<Instruction 3>             ; I3 Cannot use MAR0
<Instruction 4>             ; I4 Uses the new value of MAR0 (20)
<Instruction 5>             ; I5
....

```

MMOVI16 MARx, #16I (continued)

Load the Auxiliary Register with the 16-Bit Immediate Value
Table 7-18. Pipeline Activity for MMOVI16 MAR0/MAR1, #16I

Instruction	F1	F2	D1	D2	R1	R2	E	W
MMOVI16 MAR0, #_X	MMOVI16							
I1	I1	MMOVI16						
I2	I2	I1	MMOVI16					
I3	I3	I2	I1	MMOVI16				
I4	I4	I3	I2	I1	MMOVI16			
I5	I5	I4	I3	I2	I1	MMOVI16		
I6	I6	I5	I4	I3	I2	I1	MMOVI16	

MMOVI32 MRa, #32FHex

Load the 32-Bits of a 32-Bit Floating-Point Register with the Immediate

Operands

MRa	Floating-point register (MR0 to MR3)
#32FHex	A 32-bit immediate value that represents an IEEE 32-bit floating-point value.

This instruction is an alias for the MMOVIZ and MMOVXI instructions. The second operand is translated by the assembler such that the instruction becomes:

```
MMOVIZ MRa, #16FHiHex
MMOVXI MRa, #16FLoHex
```

Opcode

```
LSW: IIII IIII IIII IIII (opcode of MMOVIZ MRa, #16FHiHex)
MSW: 0111 1000 0100 00aa
LSW: IIII IIII IIII IIII (opcode of MMOVXI MRa, #16FLoHex)
MSW: 0111 1000 1000 00aa
```

Description

This instruction only accepts a hex value as the immediate operand. To specify the immediate value with a floating-point representation, use the MMOVF32 MRa, #32F instruction.

Load the 32-bits of MRa with the immediate 32-bit hex value represented by #32FHex.

#32FHex is a 32-bit immediate hex value that represents the IEEE 32-bit floating-point value of a floating-point number. The assembler only accepts a hex immediate value. That is, 3.0 can only be represented as #0x40400000 (#3.0 results in an error).

```
MRa = #32FHex;
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

Depending on #32FHex, this instruction takes one or two cycles. If all of the lower 16-bits of #32FHex are zeros, then the assembler converts MOV32 to an MMOVIZ instruction. If the lower 16-bits of #32FHex are not zeros, then the assembler converts MOV32 to MMOVIZ and MMOVXI instructions.

MMOVI32 MRa, #32FHex (continued)

Load the 32-Bits of a 32-Bit Floating-Point Register with the Immediate
Example

```

MOVI32  MR1, #0x40400000 ; MR1 = 0x40400000
                          ; Assembler converts this instruction as
                          ; MMOVIZ MR1, #0x4040
MOVI32  MR2, #0x00000000 ; MR2 = 0x00000000
                          ; Assembler converts this instruction as
                          ; MMOVIZ MR2, #0x0
MOVI32  MR3, #0x40004001 ; MR3 = 0x40004001
                          ; Assembler converts this instruction as
                          ; MMOVIZ MR3, #0x4000
                          ; MMOVXI MR3, #0x4001
MOVI32  MR0, #0x00004040 ; MR0 = 0x00004040
                          ; Assembler converts this instruction as
                          ; MMOVIZ MR0, #0x0000
                          ; MMOVXI MR0, #0x4040
  
```

[MMOVF32 MRa, #32F](#)

MMOVIZ MRa, #16FHi**Load the Upper 16-Bits of a 32-Bit Floating-Point Register****Operands**

MRa	Floating-point register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0.

Opcode

```
LSW: IIII IIII IIII IIII
MSW: 0111 1000 0100 00aa
```

Description

Load the upper 16-bits of MRa with the immediate value #16FHi and clear the low 16-bits of MRa.

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. The assembler only accepts a decimal or hex immediate value. That is, -1.5 can be represented as #-1.5 or #0xBFC0.

MMOVIZ is useful for loading a floating-point register with a constant in which the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). If a constant requires all 32-bits of a floating-point register to be initialized, then use MMOVIZ along with the MMOVXI instruction.

```
MRa(31:16) = #16FHi;
MRa(15:0) = 0;
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

```
; Load MR0 and MR1 with -1.5 (0xBFC00000)
MMOVIZ MR0, #0xBFC0 ; MR0 = 0xBFC00000 (1.5)
MMOVIZ MR1, #-1.5 ; MR1 = -1.5 (0xBFC00000)
; Load MR2 with pi = 3.141593 (0x40490FDB)
MMOVIZ MR2, #0x4049 ; MR2 = 0x40490000
MMOVXI MR2, #0x0FDB ; MR2 = 0x40490FDB
```

MMOVZ16 MRa, mem16**Load MRx with 16-Bit Value****Operands**

MRa	CLA floating-point destination register (MR0 to MR3)
mem16	16-bit source memory location

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0111 0101 10aa addr
```

Description

Move the 16-bit value referenced by mem16 to the floating-point register indicated by MRa.

```
MRa(31:16) = 0;
MRa(15:0) = [mem16];
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = 0;
if (MRa(31:0) == 0) { ZF = 1; }
```

Pipeline

This is a single-cycle instruction.

MMOVXI MRa, #16FLoHex**Move Immediate Value to the Lower 16-Bits of a Floating-Point Register****Operands**

MRa	CLA floating-point register (MR0 to MR3)
#16FLoHex	A 16-bit immediate hex value that represents the lower 16-bits of an IEEE 32-bit floating-point value. The upper 16-bits are not modified.

Opcode

```
LSW: IIII IIII IIII IIII
MSW: 0111 1000 1000 00aa
```

Description

Load the lower 16-bits of MRa with the immediate value #16FLoHex. #16FLoHex represents the lower 16-bits of an IEEE 32-bit floating-point value. The upper 16-bits of MRa are not modified. MMOVXI can be combined with the MMOVIZ instruction to initialize all 32-bits of a MRa register.

```
MRa(15:0) = #16FLoHex;
MRa(31:16) = Unchanged;
```

Flags

Flag	TF	ZF	NF	LUF	LVF

32-Bit Floating-Point Multiply

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
MRc	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 00cc bbaa
MSW: 0111 1100 0000 0000
```

Description

Multiply the contents of two floating-point registers.

```
MRa = MRb * MRc;
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MMPYF32 generates an underflow condition.
- LVF = 1 if MMPYF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

Example

```
; Calculate Num/Den using a Newton-Raphson algorithm for 1/Den
; Ye = Estimate(1/X)
; Ye = Ye*(2.0 - Ye*X)
; Ye = Ye*(2.0 - Ye*X)
;

MMPYF32 MRa, #16FHi, MRb**32-Bit Floating-Point Multiply****Operands**

MRa	CLA floating-point destination register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The lower 16-bits of the mantissa are assumed to be all 0.
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: IIII IIII IIII IIII
MSW: 0111 0111 1000 bbaa
```

Description

Multiply MRb with the floating-point value represented by the immediate operand. Store the result of the addition in MRa.

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The lower 16-bits of the mantissa are assumed to be all 0. #16FHi is most useful for representing constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler accepts either a hex or float as the immediate value. That is, the value -1.5 can be represented as #-1.5 or #0xBFC0.

```
MRa = MRb * #16FHi:0;
```

This instruction can also be written as MMPYF32 MRa, MRb, #16FHi.

Flags

This instruction modifies the following flags in the MSTF register:.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MMPYF32 generates an underflow condition.
- LVF = 1 if MMPYF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

Example 1

```
; Same as example 2 but #16FHi is represented in float
MMOVIZ MR3, #2.0 ; MR3 = 2.0 (0x40000000)
MMPYF32 MR0, #3.0, MR3 ; MR0 = 3.0 * MR3 = 6.0 (0x40c00000)
MMOV32 @_X, MR0 ; Save the result in variable X
```

Example 2

```
; Same as example 1 but #16FHi is represented in Hex
MMOVIZ MR3, #2.0 ; MR3 = 2.0 (0x40000000)
MMPYF32 MR0, #0x4040, MR3 ; MR0 = 0x4040 * MR3 = 6.0 (0x40c00000)

Opcode

```
LSW: 0000 0000 cndf bbaa
MSW: 0111 1010 1000 0000
```

Description

```
if (CNDF == true) {MRa = - MRb; }
else {MRa = MRb; }
```

CNDF is one of the following conditions:

Encode ⁽¹⁾	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF ⁽²⁾	Unconditional with flag modification	None

(1) Values not shown are reserved.

(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF, and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

Pipeline

This is a single-cycle instruction.

MNEGF32 MRa, MRb{, CNDF} (continued)

Conditional Negation
Example 1

```

; Show the basic operation of MNEGF32
;
;
MMOVIZ MR0, #5.0 ; MR0 = 5.0 (0x40A00000)
MMOVIZ MR1, #4.0 ; MR1 = 4.0 (0x40800000)
MMOVIZ MR2, #-1.5 ; MR2 = -1.5 (0xBFC00000)
MMPYF32 MR3, MR1, MR2 ; MR3 = -6.0
MMPYF32 MR0, MR0, MR1 ; MR0 = 20.0
MMOVIZ MR1, #0.0
MCMPIF32 MR3, MR1 ; NF = 1
MNEGF32 MR3, MR3, LT ; if NF = 1, MR3 = 6.0
MCMPIF32 MR0, MR1 ; NF = 0
MNEGF32 MR0, MR0, GEQ ; if NF = 0, MR0 = -20.0

```

Example 2

```

; Calculate Num/Den using a Newton-Raphson algorithm for 1/Den
; Ye = Estimate(1/X)
; Ye = Ye*(2.0 - Ye*X)
; Ye = Ye*(2.0 - Ye*X)
;
;
_Cla1Task1:

MNOP

No Operation

Operands

none	This instruction does not have any operands
------	---

Opcode

LSW: 0000 0000 0000 0000
MSW: 0111 1111 1010 0000

Description

Do nothing. This instruction is used to fill required pipeline delay slots when other instructions are not available to fill the slots.

Flags

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

```

; X is an array of 32-bit floating-point values
; Find the maximum value in an array X
; and store the value in Result
;
;_Cla1Task1:
    MMOV16    MAR1, #_X          ; Start address
    MUI16TOF32 MR0, @_len      ; Length of the array
    MNOP                      ; delay for MAR1 load
    MNOP                      ; delay for MAR1 load
    MMOV32    MR1, *MAR1[2]++   ; MR1 = X0
LOOP
    MMOV32    MR2, *MAR1[2]++   ; MR2 = next element
    MMAXF32   MR1, MR2          ; MR1 = MAX(MR1, MR2)
    MADD32    MR0, MR0, #-1.0   ; Decrement the counter
    MCMPF32   MR0, #0.0         ; Set/clear flags for MBCNDD
    MNOP                      ; Too late to affect MBCNDD
    MNOP                      ; Too late to affect MBCNDD
    MNOP                      ; Too late to affect MBCNDD
    MBCNDD    LOOP, NEQ         ; Branch if not equal to zero
    MMOV32    @_Result, MR1     ; Always executed
    MNOP                      ; Pad to separate MBCNDD and MSTOP
    MNOP                      ; Pad to separate MBCNDD and MSTOP
    MSTOP

```

MOR32 MRa, MRb, MRc**Bitwise OR****Operands**

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
MRc	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 00cc bbaa
MSW: 0111 1100 1000 0000
```

Description

Bitwise OR of MRb with MRc.

```
MARa(31:0) = MARb(31:0) OR MRC(31:0);
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; }
```

Pipeline

This is a single-cycle instruction.

Example

```
MMOVIZ MR0, #0x5555 ; MR0 = 0x5555AAAA
MMOVXI MR0, #0xAAAA
MMOVIZ MR1, #0x5432 ; MR1 = 0x5432FEDC
MMOVXI MR1, #0xFEDC
; 0101 OR 0101 = 0101 (5)
; 0101 OR 0100 = 0101 (5)
; 0101 OR 0011 = 0111 (7)
; 0101 OR 0010 = 0111 (7)
; 1010 OR 1111 = 1111 (F)
; 1010 OR 1110 = 1110 (E)
; 1010 OR 1101 = 1111 (F)
; 1010 OR 1100 = 1110 (E)
MOR32 MR2, MR1, MR0 ; MR3 = 0x5555FEFE
```

MRCNDD {CNDF}

Return Conditional Delayed

Operands

CNDF	Optional condition
------	--------------------

Opcode

LSW: 0000 0000 0000 0000
MSW: 0111 1001 1010 cndf

Description

If the specified condition is true, then the RPC field of MSTF is loaded into MPC and fetching continues from that location. Otherwise, program fetches continue without the return.

Refer to the Pipeline section for important information regarding this instruction.

```
if (CNDF == TRUE) MPC = RPC;
```

CNDF is one of the following conditions:

Encode ⁽¹⁾	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF ⁽²⁾	Unconditional with flag modification	None

(1) Values not shown are reserved.

(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

Flags

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

The MRCNDD instruction is a single-cycle instruction. As shown in [Table 7-19](#), 6 instruction slots are executed for each return; 3 slots before the return instruction (d5-d7) and 3 slots after the return instruction (d8-d10). The total number of cycles for a return taken or not taken depends on the usage of these slots. That is, the number of cycles depends on how many slots are filled with a MNOP as well as which slots are filled.

MRCNDD {CNDF} (continued)**Return Conditional Delayed**

The effective number of cycles for a return can, therefore, range from 1 to 7 cycles. The number of cycles for a return taken cannot be the same as for a return not taken.

Referring to the following code fragment and the pipeline diagrams in [Table 7-19](#) and [Table 7-20](#), the instructions before and after MRCNDD have the following properties:

```

;
;
<Instruction 1> ; I1 Last instruction that can affect flags for
; the MCCNDD operation
<Instruction 2> ; I2 Cannot be stop, branch, call or return
<Instruction 3> ; I3 Cannot be stop, branch, call or return
<Instruction 4> ; I4 Cannot be stop, branch, call or return
MCCNDD _func, NEQ ; Call to func if not equal to zero
; Three instructions after MCCNDD are always
; executed whether the call is taken or not
<Instruction 5> ; I5 Cannot be stop, branch, call or return
<Instruction 6> ; I6 Cannot be stop, branch, call or return
<Instruction 7> ; I7 Cannot be stop, branch, call or return
<Instruction 8> ; I8 The address of this instruction is saved
; in the RPC field of the MSTF register.
; Upon return this value is loaded into MPC
; and fetching continues from this point.
<Instruction 9> ; I9
<Instruction 10> ; I10
....
....
_func:
<Destination 1> ; d1 Can be any instruction
<Destination 2> ; d2
<Destination 3> ; d3
<Destination 4> ; d4 Last instruction that can affect flags for
; the MRCNDD operation
<Destination 5> ; d5 Cannot be stop, branch, call or return
<Destination 6> ; d6 Cannot be stop, branch, call or return
<Destination 7> ; d7 Cannot be stop, branch, call or return
MRCNDD NEQ ; Return to <Instruction 8> if not equal to zero
; Three instructions after MRCNDD are always
; executed whether the return is taken or not
<Destination 8> ; d8 Cannot be stop, branch, call or return
<Destination 9> ; d9 Cannot be stop, branch, call or return
<Destination 10> ; d10 Cannot be stop, branch, call or return
<Destination 11> ; d11
<Destination 12> ; d12
....
....
MSTOP
....

```

- **d4**
 - d4 is the last instruction that can effect the CNDF flags for the MRCNDD instruction. The CNDF flags are tested in the D2 phase of the pipeline. That is, a decision is made whether to return or not when MRCNDD is in the D2 phase.
 - There are no restrictions on the type of instruction for d4.
- **d5, d6, and d7**
 - The three instructions proceeding MRCNDD can change MSTF flags but have no effect on whether the MRCNDD instruction makes the return or not. This is because the flag modification occurs after the D2 phase of the MRCNDD instruction.
 - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.
- **d8, d9, and d10**
 - The three instructions following MRCNDD are always executed irrespective of whether the return is taken or not.

MRCNDD {CNDF} (continued)**Return Conditional Delayed**

- These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.

MSETFLG FLAG, VALUE

Set or Clear Selected Floating-Point Status Flags

Operands

FLAG	8-bit mask indicating which floating-point status flags to change.
VALUE	8-bit mask indicating the flag value: 0 or 1.

Opcode

```
LSW: FFFF FFFF VVVV VVVV
MSW: 0111 1001 1100 0000
```

Description

The MSETFLG instruction is used to set or clear selected floating-point status flags in the MSTF register. The FLAG field is an 11-bit value that indicates which flags are changed. That is, if a FLAG bit is set to 1, that flag is changed; all other flags are not modified. The bit mapping of the FLAG field is:

9	8	7	6	5	4	3	2	1	0
RNDF 32	Reserved		TF	Reserved		ZF	NF	LUF	LVF

The VALUE field indicates the value the flag can be set to: 0 or 1.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	Yes	Yes	Yes	Yes	Yes

Any flag can be modified by this instruction. The MEALLOW and RPC fields cannot be modified with this instruction.

Pipeline

This is a single-cycle instruction.

Example

To make it easier and legible, the assembler accepts a FLAG=VALUE syntax for the MSETFLG operation as:

```
MSETFLG RNDF32=0, TF=0, NF=1; FLAG = 11000100; VALUE = 00XXX1XX;
```

MSTOP

Stop Task

Operands

none	This instruction does not have any operands
------	---

Opcode

LSW: 0000 0000 0000 0000
MSW: 0111 1111 1000 0000

Description

The MSTOP instruction must be placed to indicate the end of each task. In addition, placing MSTOP in unused memory locations within the CLA program RAM can be useful for debugging and preventing run away CLA code. When MSTOP enters the D2 phase of the pipeline, the MIRUN flag for the task is cleared and the associated interrupt is flagged in the PIE vector table.

There are three special cases that can occur when single-stepping a task such that the MPC reaches the MSTOP instruction.

1. If you are single-stepping or halted in "task A" and "task B" comes in before the MPC reaches the MSTOP, then "task B" starts if you continue to step through the MSTOP instruction. Basically, if "task B" is pending before the MPC reaches MSTOP in "task A" then there is no issue in "task B" starting and no special action is required.
2. In this case, you have single-stepped or halted in "task A" and the MPC has reached the MSTOP with no tasks pending. If "task B" comes in at this point, "task B" is flagged in the MIFR register but "task B" can or cannot start if you continue to single-step through the MSTOP instruction of "task A". It depends on exactly when the new task comes in. To reliably start "task B", perform a soft reset and reconfigure the MIER bits. Once this is done, you can start single-stepping "task B".
3. Case 2 can be handled slightly differently if there is control over when "task B" comes in (for example using the IACK instruction to start the task). In this case you have single-stepped or halted in "task A" and the MPC has reached the MSTOP with no tasks pending. Before forcing "task B", run free to force the CLA out of the debug state. Once this is done you can force "task B" and continue debugging.

Restrictions

The MSTOP instruction cannot be placed 3 instructions before or after a [MBCNDD](#), [MCCNDD](#), or [MRCNDD](#) instruction.

Flags

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

MSTOP (continued)**Stop Task****Pipeline**

This is a single-cycle instruction. [Table 7-21](#) shows the pipeline behavior of the MSTOP instruction. The MSTOP instruction cannot be placed with 3 instructions of a [MBCNDD](#), [MCCNDD](#), or [MRCNDD](#) instruction.

Table 7-21. Pipeline Activity for MSTOP

....								

Example

```

; Given A = (int32)1
; B = (int32)2
; C = (int32)-7
;
; Calculate y2 = A - B - C
_Cla1Task3:
  MMOV32 MR0, @_A      ; MR0 = 1 (0x00000001)
  MMOV32 MR1, @_B      ; MR1 = 2 (0x00000002)
  MMOV32 MR2, @_C      ; MR2 = -7 (0xFFFFFFFF9)
  MSUB32 MR3, MR0, MR1 ; A + B
  MSUB32 MR3, MR3, MR2 ; A + B + C = 6 (0x00000006)
  MMOV32 @_y2, MR3     ; Store y2
  MSTOP                ; End of task

```

See also[MDEBUGSTOP](#)

MSUB32 MRa, MRb, MRc

32-Bit Integer Subtraction

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point destination register (MR0 to MR3)
MRc	CLA floating-point destination register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 00cc bbaa
MSW: 0111 1100 1110 0000
```

Description

32-bit integer addition of MRb and MRc.

```
MARa(31:0) = MARb(31:0) - MRC(31:0);
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified as follows:

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; }
```

Pipeline

This is a single-cycle instruction.

Example

```
; Given A = (int32)1
;         B = (int32)2
;         C = (int32)-7
;
;
; Calculate Y2 = A - B - C
;
_Cla1Task3:
  MMOV32 MR0, @_A      ; MR0 = 1 (0x00000001)
  MMOV32 MR1, @_B      ; MR1 = 2 (0x00000002)
  MMOV32 MR2, @_C      ; MR2 = -7 (0xFFFFFFFF9)
  MSUB32 MR3, MR0, MR1 ; A + B
  MSUB32 MR3, MR3, MR2 ; A + B + C = 6 (0x00000006)
  MMOV32 @_y2, MR3     ; Store y2
  MSTOP                ; End of task
```

MSUBF32 MRa, MRb, MRc**32-Bit Floating-Point Subtraction****Operands**

MRa	CLA floating-point destination register (MR0 to R1)
MRb	CLA floating-point source register (MR0 to R1)
MRc	CLA floating-point source register (MR0 to R1)

Opcode

```
LSW: 0000 0000 00cc bbaa
MSW: 0111 1100 0100 0000
```

Description

Subtract the contents of two floating-point registers

```
MRa = MRb - MRc;
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MSUBF32 generates an underflow condition.
- LVF = 1 if MSUBF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

Example

```
; Given A, B, and C are 32-bit floating-point numbers
; Calculate Y2 = A + B - C
;
;
_Cla1Task5:
  MMOV32  MR0, @_A      ; Load MR0 with A
  MMOV32  MR1, @_B      ; Load MR1 with B
  MADD32  MR0, MR1, MR0 ; Add A + B
  || MMOV32 MR1, @_C      ; and in parallel load C
  MSUBF32 MR0, MR0, MR1 ; Subtract C from (A + B)
  MMOV32  @Y, MR0       ; (A+B) - C
  MSTOP
```

32-Bit Floating-Point Subtraction
Operands

MRa	CLA floating-point destination register (MR0 to R1)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The lower 16-bits of the mantissa are assumed to be all 0.
MRb	CLA floating-point source register (MR0 to R1)

Opcode

```
LSW: IIII IIII IIII IIII
MSW: 0111 1000 0000 baaa
```

Description

Subtract MRb from the floating-point value represented by the immediate operand. Store the result of the addition in MRa.

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The lower 16-bits of the mantissa are assumed to be all 0. #16FHi is most useful for representing constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler accepts either a hex or float as the immediate value. That is, the value -1.5 can be represented as #-1.5 or #0xBFC0.

```
MRa = #16FHi:0 - MRb;
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MSUBF32 generates an underflow condition.
- LVF = 1 if MSUBF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

MSUBF32 MRa, #16FHi, MRb (continued)

32-Bit Floating-Point Subtraction
Example

```

; Y = sqrt(X)
; Ye = Estimate(1/sqrt(X));
; Ye = Ye*(1.5 - Ye*Ye*X*0.5)
; Ye = Ye*(1.5 - Ye*Ye*X*0.5)
; Y = X*Ye
;
_Cla1Task3:
  MMOV32      MR0, @_x          ; MR0 = X
  MEISQRTF32 MR1, MR0          ; MR1 = Ye = Estimate(1/sqrt(X))
  MMOV32      MR1, @_x, EQ      ; if(X == 0.0) Ye = 0.0
  MMPYF32     MR3, MR0, #0.5    ; MR3 = X*0.5
  MMPYF32     MR2, MR1, MR3     ; MR2 = Ye*X*0.5
  MMPYF32     MR2, MR1, MR2     ; MR2 = Ye*Ye*X*0.5
  MSUBF32     MR2, #1.5, MR2    ; MR2 = 1.5 - Ye*Ye*X*0.5
  MMPYF32     MR1, MR1, MR2     ; MR1 = Ye = Ye*(1.5 - Ye*Ye*X*0.5)
  MMPYF32     MR2, MR1, MR3     ; MR2 = Ye*X*0.5
  MMPYF32     MR2, MR1, MR2     ; MR2 = Ye*Ye*X*0.5
  MSUBF32     MR2, #1.5, MR2    ; MR2 = 1.5 - Ye*Ye*X*0.5
  MMPYF32     MR1, MR1, MR2     ; MR1 = Ye = Ye*(1.5 - Ye*Ye*X*0.5)
  MMPYF32     MR0, MR1, MR0     ; MR0 = Y = Ye*X
  MMOV32      @_y, MR0         ; Store Y = sqrt(X)
  MSTOP
; end of task

```

MSUBF32 MRd, MRe, MRf ||MMOV32 MRa, mem32
32-Bit Floating-Point Subtraction with Parallel Move
Operands

MRd	CLA floating-point destination register (MR0 to MR3) for the MSUBF32 operation MRd cannot be the same register as MRa
MRe	CLA floating-point source register (MR0 to MR3) for the MSUBF32 operation
MRf	CLA floating-point source register (MR0 to MR3) for the MSUBF32 operation
MRa	CLA floating-point destination register (MR0 to MR3) for the MMOV32 operation MRa cannot be the same register as MRd
mem32	32-bit memory location accessed using one of the available addressing modes. Source for the MMOV32 operation.

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0010 ffee ddaa addr
```

Description

Subtract the contents of two floating-point registers and move from memory to a floating-point register.

```
MRd = MRe - MRf;
MRa = [mem32];
```

Restrictions

The destination register for the MSUBF32 and the MMOV32 must be unique. That is, MRa cannot be the same register as MRd.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MSUBF32 generates an underflow condition.
- LVF = 1 if MSUBF32 generates an overflow condition.

The MMOV32 instruction sets the NF and ZF flags.

Pipeline

Both MSUBF32 and MMOV32 complete in a single cycle.

Example

```
NF = MRa(31);
ZF = 0;
if(MRa(30:23) == 0) { ZF = 1; NF = 0; }
```

MRe	CLA floating-point source register (MR0 to MR3) for the MSUBF32 operation
MRf	CLA floating-point source register (MR0 to MR3) for the MSUBF32 operation
mem32	32-bit destination memory location for the MMOV32 operation
MRa	CLA floating-point source register (MR0 to MR3) for the MMOV32 operation

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0110 ffee ddaa addr
```

Description

Subtract the contents of two floating-point registers and move from a floating-point register to memory.

```
MRd = MRe - MRf;
[mem32] = MRa;
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MSUBF32 generates an underflow condition.
- LVF = 1 if MSUBF32 generates an overflow condition.

Pipeline

Both MSUBF32 and MMOV32 complete in a single cycle.

MSWAPF MRa, MRb {, CNDF}
Conditional Swap
Operands

MRa	CLA floating-point register (MR0 to MR3)
MRb	CLA floating-point register (MR0 to MR3)
CNDF	Optional condition tested based on the MSTF flags

Opcode

```
LSW: 0000 0000 CNDF bbaa
MSW: 0111 1011 0000 0000
```

Description

Conditional swap of MRa and MRb.

```
if (CNDF == true) swap MRa and MRb;
```

CNDF is one of the following conditions:

Encode ⁽¹⁾	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF ⁽²⁾	Unconditional with flag modification	None

(1) Values not shown are reserved.

(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

No flags affected

Pipeline

This is a single-cycle instruction.

MSWAPF MRa, MRb {, CNDF} (continued)

Conditional Swap
Example

```

; X is an array of 32-bit floating-point values
; and has length elements. Find the maximum value in
; the array and store the value in Result
;
;
; Note: MCMPPF32 and MSWAPF can be replaced by MMAXF32
;
;
;_Cla1Task1:
;  MMOV16    MAR1, #_X          ; Start address

;  MNOP
;  MBCNDD    LOOP, NEQ        ; Branch if not equal to zero
;  MMOV32    @_Result, MR1    ; Always executed
;  MNOP      ; Always executed
;  MNOP      ; Always executed
;  MSTOP     ; End of task

```

MTESTTF CNDF

Test MSTF Register Flag Condition

Operands

CNDF	Condition to test based on MSTF flags
------	---------------------------------------

Opcode

```
LSW: 0000 0000 0000 cndf
MSW: 0111 1111 0100 0000
```

Description

Test the CLA floating-point condition and if true, set the MSTF[TF] flag. If the condition is false, clear the MSTF[TF] flag. This is useful for temporarily storing a condition for later use.

```
if (CNDF == true) TF = 1;
else TF = 0;
```

CNDF is one of the following conditions:

Encode ⁽¹⁾	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF ⁽²⁾	Unconditional with flag modification	None

(1) Values not shown are reserved.

(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	Yes	No	No	No	No

```
TF = 0;
if (CNDF == true) TF = 1;
```

Note: If (CNDF == UNC or UNCF), the TF flag is set to 1.

Pipeline

This is a single-cycle instruction.

MTESTTF CNDF (continued)**Test MSTF Register Flag Condition****Example**

```

; if (State == 0.1)
;   RampState = RampState || RAMPMASK
; else if (State == 0.01)
;   CoastState = CoastState || COASTMASK
; else
;   SteadyState = SteadyState || STEADYMASK
;
_Cla1Task2:

```

MUI16TOF32 MRa, mem16
Convert Unsigned 16-Bit Integer to 32-Bit Floating-Point Value
Operands

MRa	CLA floating-point destination register (MR0 to MR3)
mem16	16-bit source memory location

Opcode

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0111 0101 01aa addr
```

Description

When converting F32 to I16/UI16 data format, the MF32TOI16/UI16 operation truncates to zero while the MF32TOI16R/UI16R operation rounds to the nearest (even) value.

```
MRa = UI16TOF32[mem16];
```

Flags

This instruction does not affect any flags:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

7.8 CLA Registers

This section describes the Control Law Accelerator registers.

7.8.1 CLA Base Address Table

Table 7-22. CLA Base Address Table

Bit Field Name		DriverLib Name	Base Address	CPU1	DMA	HIC	CLA	Pipeline Protected
Instance	Structure							
Cla1OnlyRegs	CLA_ONLY_REGS	CLA1_ONLY_BASE	0x0000_0C00	-	-	-	YES	-
Cla1SoftIntRegs	CLA_SOFTINT_REGS	CLA1_SOFTINT_BASE	0x0000_0CE0	-	-	-	YES	-
Cla1Regs	CLA_REGS	CLA1_BASE	0x0000_1400	YES	-	-	-	-

7.8.2 CLA_ONLY_REGS Registers

Table 7-23 lists the memory-mapped registers for the CLA_ONLY_REGS registers. All register offset addresses not listed in Table 7-23 should be considered as reserved locations and the register contents should not be modified.

Table 7-23. CLA_ONLY_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
80h	_MVECTBGRNDACTIVE	Active register for MVECTBGRND.	EALLOW	Go
C0h	_MPSACTL	CLA PSA Control Register	EALLOW	Go
C2h	_MPSA1	CLA PSA1 Register	EALLOW	Go
C4h	_MPSA2	CLA PSA2 Register	EALLOW	Go
E0h	SOFTINTEN	CLA Software Interrupt Enable Register		Go
E2h	SOFTINTFRC	CLA Software Interrupt Force Register		Go

Complex bit access types are encoded to fit into small table cells. Table 7-24 shows the codes that are used for access types in this section.

Table 7-24. CLA_ONLY_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1S	W1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

7.8.2.1 _MVECTBGRNDACTIVE Register (Offset = 80h) [Reset = 0000h]

_MVECTBGRNDACTIVE is shown in [Figure 7-2](#) and described in [Table 7-25](#).

Return to the [Summary Table](#).

Gives the current interrupted MPC value of the background task, if the background task was running and interrupted, or reflects the MVECTBGRND value, if MCTLBGRND.BGSTART bit is 0.

7.8.3 CLA_SOFTINT_REGS Registers

Table 7-31 lists the memory-mapped registers for the CLA_SOFTINT_REGS registers. All register offset addresses not listed in Table 7-31 should be considered as reserved locations and the register contents should not be modified.

Table 7-31. CLA_SOFTINT_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	SOFTINTEN	CLA Software Interrupt Enable Register		Go
2h	SOFTINTFRC	CLA Software Interrupt Force Register		Go

Complex bit access types are encoded to fit into small table cells. Table 7-32 shows the codes that are used for access types in this section.

Table 7-32. CLA_SOFTINT_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

7.8.3.1 SOFTINTEN Register (Offset = 0h) [Reset = 0000h]

SOFTINTEN is shown in [Figure 7-8](#) and described in [Table 7-33](#).

Return to the [Summary Table](#).

Enables the ability to generate CLA task interrupt from within the task, by writing to SOFTINTFRC register. SOFTINTFRC register can only be written from CLA.

MVECT6 is shown in [Figure 7-15](#) and described in [Table 7-42](#).

Return to the [Summary Table](#).

Each CLA interrupt has its own interrupt vector (MVECT1 to MVECT8). This interrupt vector points to the first instruction of the associated task. When a task begins, the CLA will start fetching instructions at the location indicated by the appropriate MVECT register .

Table 7-45. MCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-3	RESERVED	R	0h	Reserved
2	IACKE	R/W	0h	<p>IACK Operation Enable Bit: Writing a '1' to this bit will enable the IACK operation for setting the MIFR bits in the same manner as the MIFRC register (write of '1' will set respective MIFR bit). At reset, this feature is disabled.</p> <p>This feature enables the C28 CPU to efficiently trigger a task.</p> <p>Note: IACK operation should ignore EALLOW status of C28 core when accessing the MIFRC register.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = The CLA ignores the IACK instruction. (default)</p> <p>1h (R/W) = Enable the main CPU to use the IACK #16bit instruction to set MIFR bits in the same manner as writing to the MIFRC register. Each bit in the operand, #16bit, corresponds to a bit in the MIFRC register. Using IACK has the advantage of not having to first set the EALLOW bit. This allows the main CPU to efficiently trigger a CLA task through software.</p> <p>Examples IACK #0x0001 Write a 1 to MIFRC bit 0 to force task 1</p> <p>IACK #0x0003 Write a 1 to MIFRC bit 0 and 1 to force task 1 and task 2</p>
1	SOFTRESET	R-0/W1S	0h	<p>Soft Reset Bit: Writing a '1' to this bit will stop a current task, clear the RUN flag and also clear all bits in the MIER register. Writes of '0' are ignored and reads always return a '0'.</p> <p>Note: After issuing SOFTRESET command, user should wait at least 1 clock cycle before attempting to write to MIER register.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = This bit always reads back 0 and writes of 0 are ignored.</p> <p>1h (R/W) = Writing a 1 will cause a soft reset of the CLA. This will stop the current task, clear the MIRUN flag and clear all bits in the MIER register. After a soft reset you must wait at least 1 SYSCLKOUT cycle before reconfiguring the MIER bits. If these two operations are done back-to-back then the MIER bits will not get set.</p>
0	HARDRESET	R-0/W1S	0h	<p>Hard Reset Bit: Writing a '1' to this bit will cause a HARD reset on the CLA. The behavior of a HARD reset is the same as a system reset SYSRSn on the CLA. Writes of '0' are ignored and reads always return a '0'.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = This bit always reads back 0 and writes of 0 are ignored.</p> <p>1h (R/W) = Writing a 1 will cause a hard reset of the CLA. This will set all CLA registers to their default state.</p>

7.8.4.10 _MVECTBGRNDACTIVE Register (Offset = 1Bh) [Reset = 0000h]

_MVECTBGRNDACTIVE is shown in [Figure 7-19](#) and described in [Table 7-46](#).

Return to the [Summary Table](#).

Gives the current interrupted MPC value of the background task, if the background task was running and interrupted, or reflects the MVECTBGRND value, if MCTLBGRND.BGSTART bit is 0.

7.8.4.15 MIFR Register (Offset = 20h) [Reset = 0000h]

MIFR is shown in [Figure 7-24](#) and described in [Table 7-51](#).

Return to the [Summary Table](#).

Each bit in the interrupt flag register corresponds to a CLA task. The corresponding bit is automatically set when the task request is received from the peripheral interrupt. The bit can also be set by the main CPU writing to the MIFRC register or using the IACK instruction to start the task. To use the IACK instruction to begin a task first enable this feature in the MCTL register. If the bit is already set when a new peripheral interrupt is received, then the corresponding overflow bit will be set in the MIOVF register.

The corresponding MIFR bit is automatically cleared when the task begins execution. This will occur if the interrupt is enabled in the MIER register and no other higher priority task is pending. The bits can also be cleared manually by writing to the MICLR register. Writes to the MIFR register are ignored.

7.8.4.16 MIOVF Register (Offset = 21h) [Reset = 0000h]

MIOVF is shown in [Figure 7-25](#) and described in [Table 7-52](#).

Return to the [Summary Table](#).

Each bit in the overflow flag register corresponds to a CLA task. The bit is set when an interrupt overflow event has occurred for the specific task. An overflow event occurs when the MIFR register bit is already set when a new interrupt is received from a peripheral source. The MIOVF bits are only affected by peripheral interrupt events. They do not respond to a task request by the main CPU IACK instruction or by directly setting MIFR bits. The overflow flag will remain latched and can only be cleared by writing to the overflow flag clear (MICLROVF) register. Writes to the MIOVF register are ignored.

7.8.4.17 MIFRC Register (Offset = 22h) [Reset = 0000h]

MIFRC is shown in [Figure 7-26](#) and described in [Table 7-53](#).

Return to the [Summary Table](#).

The interrupt force register can be used by the main CPU to start tasks through software. Writing a 1 to a MIFRC bit will set the corresponding bit in the MIFR register. Writes of 0 are ignored and reads always return 0. The IACK #16bit operation can also be used to start tasks and has the same effect as the MIFRC register. To enable IACK to set MIFR bits you must first set the MCTL[IACKE] bit. Using IACK has the advantage of not having to first set the EALLOW bit. This allows the main CPU to efficiently trigger CLA tasks through software.

7.8.4.18 MICLR Register (Offset = 23h) [Reset = 0000h]

MICLR is shown in [Figure 7-27](#) and described in [Table 7-54](#).

Return to the [Summary Table](#).

Normally bits in the MIFR register are automatically cleared when a task begins. The interrupt flag clear register can be used to instead manually clear bits in the interrupt flag (MIFR) register. Writing a 1 to a MICLR bit will clear the corresponding bit in the MIFR register. Writes of 0 are ignored and reads always return 0.

7.8.4.20 MIER Register (Offset = 25h) [Reset = 0000h]

MIER is shown in [Figure 7-29](#) and described in [Table 7-56](#).

Return to the [Summary Table](#).

Setting the bits in the interrupt enable register (MIER) allow an incoming interrupt or main CPU software to start the corresponding CLA task. Writing a 0 will block the task, but the interrupt request will still be latched in the flag register (MIFLG). Setting the MIER register bit to 0 while the corresponding task is executing will have no effect on the task. The task will continue to run until it hits the MSTOP instruction. When a soft reset is issued, the MIER bits are cleared. There should always be at least a 1 SYSCLKOUT delay between issuing the soft reset and reconfiguring the MIER bits.

Writing a '0' blocks the interrupt, but the interrupt can still be latched by the MIFR register. When an interrupt is enabled and the corresponding MIFR bit is set to '1', the CLA will start executing the corresponding task and automatically clear the corresponding MIFR bit.</p> <p>Interrupts are be serviced in normal priority order.</p> <p>Notes: [1] If a task is currently executing and the corresponding MIER bit is cleared to '0', it will have no effect on the task. The task will run until it hits the STOP instruction.</p> <p>Reset type: SYSRSn 0h (R/W) = TASK_INT_DISABLE Task 1 interrupt is disabled (default) 1h (R/W) = TASK_INT_ENABLE Task 1 interrupt is enabled</p>

7.8.4.21 MIRUN Register (Offset = 26h) [Reset = 0000h]

MIRUN is shown in [Figure 7-30](#) and described in [Table 7-57](#).

Return to the [Summary Table](#).

The interrupt run status register (MIRUN) indicates which task is currently executing. Only one MIRUN bit will ever be set to a 1 at any given time. The bit is automatically cleared when the task completes and the respective interrupt is fed to the peripheral interrupt expansion (PIE) block of the device. This lets the main CPU know when a task has completed. The main CPU can stop a currently running task by writing to the MCTL[SOFTRESET] bit. This will clear the MIRUN flag and stop the task. In this case no interrupt will be generated to the PIE.

7.8.4.25 _MSTF Register (Offset = 2Eh) [Reset = 0000000h]

_MSTF is shown in [Figure 7-34](#) and described in [Table 7-61](#).

Return to the [Summary Table](#).

The CLA status register (MSTF) reflects the results of different operations. These are the basic rules for the flags:

- Zero and negative flags are cleared or set based on:
- floating-point moves to registers
- the result of compare, minimum, maximum, negative and absolute value operations
- the integer result of operations such as MMOV16, MAND32, MOR32, MXOR32, MCMP32, MASR32, MLSR32
- Overflow and underflow flags are set by floating-point math instructions such as multiply, add, subtract and 1/x. These flags may also be connected to the peripheral interrupt expansion (PIE) block on your device. This can be useful for debugging underflow and overflow conditions within an application.

Chapter 8
Dual-Clock Comparator (DCC)

This chapter describes the Dual-Clock Comparator (DCC) module.

8.1 Introduction	1030
8.2 Module Operation	1031
8.3 Interrupts	1037
8.4 Software	1038
8.5 DCC Registers	1040

8.1 Introduction

The dual-clock comparator module is used for evaluating and monitoring the clock input based on a second clock, which can be a more accurate and reliable version. This instrumentation is used to detect faults in clock source or clock structures, thereby enhancing the system's safety metrics.

8.1.1 Features

The main features of each of the DCC modules are:

- Allows the application to make sure that a fixed ratio is maintained between frequencies of two clock signals.
- Supports the definition of a programmable tolerance window in terms of the number of reference clock cycles.
- Supports continuous monitoring without requiring application intervention.
- Supports a single-sequence mode for spot measurements.
- Allows the selection of a clock source for each of the counters, resulting in several specific use cases.

8.1.2 Block Diagram

Figure 8-1 shows how the DCC connects to the rest of the system. Figure 8-2 shows the main concept of the DCC module.

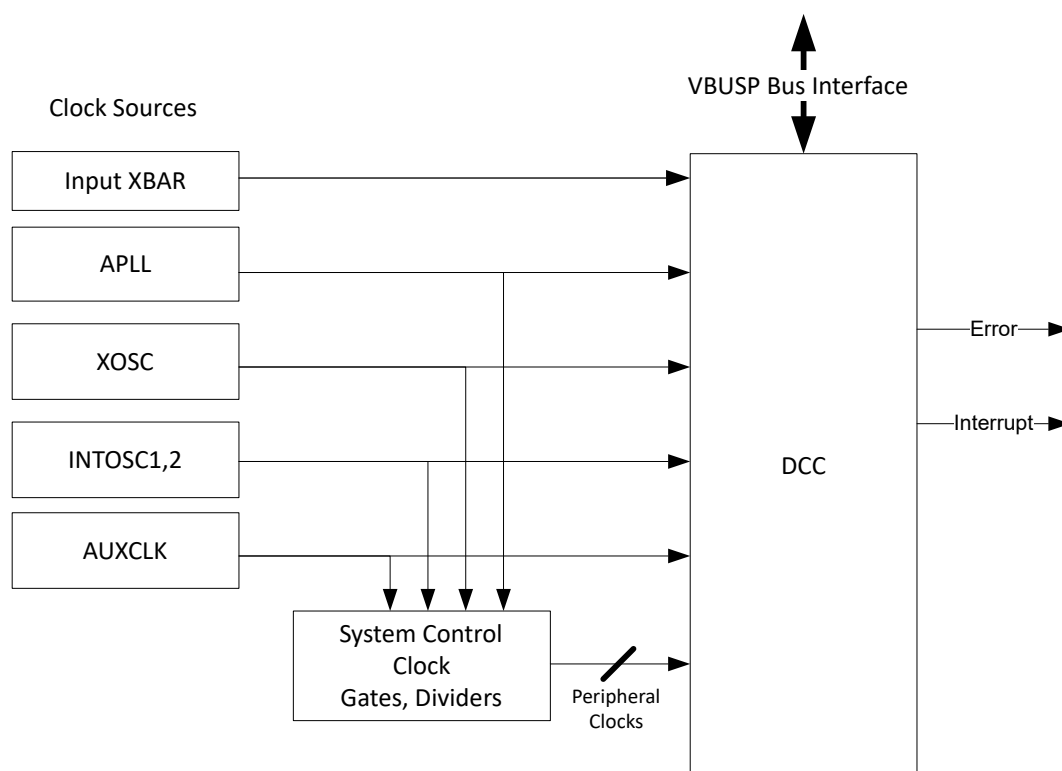

Figure 8-1. DCC Module Overview

Figure 8-2. DCC Operation

8.2 Module Operation

As shown in Figure 8-2, DCC contains three counters – Counter0, Valid0 and Counter1. Initially, all counters are loaded with the user-defined, pre-load value. Counter0 and Counter1 start decrementing once the DCC is enabled at rates determined by the frequencies of Clock0 and Clock1, respectively. When Counter0 equals 0 (expires), the Valid0 counter decrements at a rate determined by Clock0. If Counter1 decrements to 0 in the valid window, then no error is generated and Clock1 is considered to be good within allowable tolerance as configured by the user.

8.2.1 Configuring DCC Counters

Counter0 and Counter1 are configured based on the ratio between the frequencies of Clock0 and Clock1 ($F_{clk1} \times \text{Counter0} = F_{clk0} \times \text{Counter1}$). The Valid0 counter provides tolerance and is configured based on the error in DCC. Since Clock0 and Clock1 are asynchronous, the start and stop of the counters do not occur synchronously. Hence, while configuring the counters, two different sources of errors must be accounted for:

- DCC Errors due to the asynchronous timing of Clock0 and Clock1: this depends on the frequency of Clock0 and Clock1:
 - If $F_{clk1} > F_{clk0}$, then Async. Error (in Clock0 cycles) = $2 + 2 \times (F_{sysclk} / F_{clk0})$
 - If $F_{clk1} < F_{clk0}$, then Async. Error (in Clock0 cycles) = $2 \times (F_{clk0} / F_{clk1}) + 2 \times (F_{sysclk} / F_{clk0})$
 - If F_{clk1} is unknown, then Async. Error (in Clock0 cycles) = $2 + 2 \times (F_{sysclk} / F_{clk0})$
- Digitization Error = 8 Clock0 cycles

DCC Error (in Clock0 Cycles) = Async. Error + Digitization Error

DCC error shows up as a frequency error for clock under measurement. This error is DCC induced and does not represent error in frequency of clock under measurement. The application needs to take this into consideration while configuring the counters, and determine a desirable tolerance for DCC error that defines the window of measurement. To illustrate:

Window (in Clock0 Cycles) = (DCC Error) / (0.01 × Tolerance)

For example, if DCC Error is 10 and the tolerance desired is +/-0.1%, then:

$$\text{Window (in Clock0 Cycles)} = 10 / (0.01 \times 0.1) = 10000$$

Based on above formula for Window, if the desired tolerance is low, then the counter values are large and increase the window of measurement. This means that counter values for a tolerance of 0.1% are larger than that of 0.2%. So, based on the application defined tolerance, define the window of measurement in terms of Clock0 cycles.

The clock under measurement can have an allowed frequency error. If this error is expected, then the error can also be accounted while configuring counters. For example, if measuring INTOSC1/2 frequency using an external crystal as a reference clock, the allowable tolerance of INTOSC1/2 (for example, +/-1%) can be accounted for and factored into the counter configuration. The formula is:

$$\text{Frequency Error Allowed (in Clock0 Cycles)} = \text{Window} \times (\text{Allowable Frequency Tolerance (in \%)} / 100)$$

$$\text{Total Error (in Clock0 Cycles)} = \text{DCC Error} + \text{Frequency Error Allowed}$$

The following equations are used to configure counter values:

$$\text{Counter0 (DCCNTSEED0)} = \text{Window} - \text{Total Error}$$

$$\text{Valid0 (DCCVALIDSEED0)} = 2 \times \text{Total Error}$$

$$\text{Counter1 (DCCNTSEED1)} = \text{Window} \times (F_{clk1} / F_{clk0})$$

Note

Counter1 is a 20-bit counter, so the maximum possible value cannot exceed 1048575. If the value does exceed, then increase the desired Tolerance for DCC error, so that Window of measurement is lowered. The following formula can be used to compute minimum tolerance possible:

$$\text{Tolerance (\%)} = (100 \times \text{DCC Error} \times (F_{clk1} / F_{clk0})) / 1048575$$

8.2.2 Single-Shot Measurement Mode

The DCC module can be programmed to count down one time by enabling the single-shot mode. In this mode, the DCC stops operating when the down counter0 and the valid counter0 reach 0.

At the end of one sequence of counting down in this single-shot mode, the DCC gets disabled automatically, which prevents further counting. This mode is typically used for spot-checking the frequency of a signal.

Example-1: Validating PLLRAWCLK frequency

A practical example of the usage is to validate the PLL output clock frequency using the XTAL as the reference clock. Assume XTAL is 10MHz, PLL output frequency is 100MHz, SYSCLK is 100MHz, allowable Frequency Tolerance is 0.1%, and DCC Tolerance required is 0.1%. The measurement sequence proceeds as follows:

- Set Clock0 source for Counter0 and Valid0 as XTAL, and Clock1 source for Counter1 as PLL output clock.
- Based on the equations defined in [Section 8.2.1](#), calculated seed values for Counters can be Counter0 = 29940; Valid0 = 120; Counter1 = 300000
- Once the DCC is enabled, the counters Counter0 and Counter1 both start counting down from the seed values.
- When Counter0 reaches zero, Counter0 automatically triggers the Valid0 counter.
- When Valid0 reaches zero and Counter1 is not zero, an ERROR status flag is set and a "DCC error" is sent to the PIE. Counter1 is frozen so that the counter stops counting down any further. The application can enable an interrupt to be generated from the PIE whenever this DCC error is indicated. Refer to the PIE Channel Mapping table in the *System Control and Interrupts* chapter to determine the channel mapping of the DCC Interrupt.
- The application then needs to clear the ERROR status flag and restart the DCC module so that the module is ready for the next spot measurement.

If there is no error generated at the end of the sequence, then the DONE status flag is set and a DONE interrupt is generated. The application must clear the DONE flag before restarting the DCC.

Error Conditions:

An error condition is generated by any one of the following:

1. Counter1 counts down to 0 before Counter0 reaches 0. This means that Clock1 is faster than expected, or Clock0 is slower than expected. This error includes the case when Clock0 is stuck at 1 or 0.
2. Counter1 does not reach 0 even when Counter0 and Valid0 have both reached 0. This means that Clock1 is slower than expected. This error includes the case when Clock1 is stuck at 1 or 0.

Any error freezes the counters from counting. An application can then read out the counter values to help determine what caused the error.

Example-2: Measuring AUXCLKIN frequency

Another example of single-shot mode is to measure the frequency of AUXCLKIN (unknown frequency) using INTOSC1 (10MHz) as the reference clock and SYSC1K is 10MHz. The measurement sequence proceeds as follows:

- Set Clock0 source for Counter0 and Valid0 as INTOSC1 (10MHz), and Clock1 source for Counter1 as AUXCLKIN.
- Now configure counter values using equations in [Section 8.2.1](#). For tolerance = ±0.1%, Total Error = 10 clock0 cycles; Window = 10000 clock0 cycles; Counter0 = 9990; Valid0 = 20. Since Clock1 frequency (Fclk1) is unknown, the Counter1 value can be set to the maximum value, 1048575 (0xFFFFF).
- Once the DCC is enabled, the counters Counter0 and Counter1 both start counting down from the seed values.
- Since Counter1 is set to the maximum value, 1048575, the counter does not expire when Counter0 and Valid0 have expired. This generates an error that is expected and the application ignores this error and uses Counter1 values to compute the frequency of Clock1 (Fclk1).
- Knowing the frequency of Clock0 (INTOSC1), Fclk0 = 10MHz, and using [Equation 1](#), the frequency of AUXCLKIN, Fclk1, can be measured:

$$F_{clk1} = \frac{F_{clk0} \times (1048575 - Meas. Counter1)}{(Counter0 + Valid0)} = \frac{10 \times (1048575 - Meas. Counter1)}{(9990 + 20)} \quad (1)$$

8.2.3 Continuous Monitoring Mode

In this mode, the DCC is used by the application to make sure that two clock signals maintain the correct frequency ratio. Suppose the application wants to make sure that the PLL output signal always maintains a fixed frequency relationship with the XTAL:

- In this case, the application can use the XTAL as the Clock0 signal (for Counter0 and Valid0) and the PLL output as the Clock1 (for Counter1).
- The seed values of Counter0, Valid0 and Counter1 are selected based on the equations defined in [Section 8.2.1](#) such that if the actual frequencies of Clock0 and Clock1 are equal to the expected frequencies, then the Counter1 reaches zero during the count down of the Valid0 counter.
- If the Counter1 reaches zero during the count down of the Valid0 counter, then all the counters (Counter0, Valid0, Counter1) are reloaded with the initial seed values.
- This sequence of counting down and checking then continues as long as there is no error, or until the DCC module is disabled.
- The counters must get reloaded if the application resets and restarts the DCC module.

Error Conditions:

An error condition is generated by one of the following:

1. Counter1 counts down to 0 before Counter0 reaches 0. This means that Clock1 is faster than expected or Clock0 is slower than expected. This condition includes the case when Clock0 is stuck at 1 or 0.
2. Counter1 does not reach 0 even when Counter0 and Valid0 have both reached 0. This means that Clock1 is slower than expected. This condition includes the case when Clock1 is stuck at 1 or 0.

Any error freezes the counters from counting. An application can then read out the counter values to help determine what caused the error.

8.2.4 Error Conditions

While operating in continuous mode, the counters get reloaded with the seed values and continue counting down under the following conditions:

- The module is reset or restarted by the application, OR
- Counter0, Valid 0, and Counter1 all reach 0 without any error.

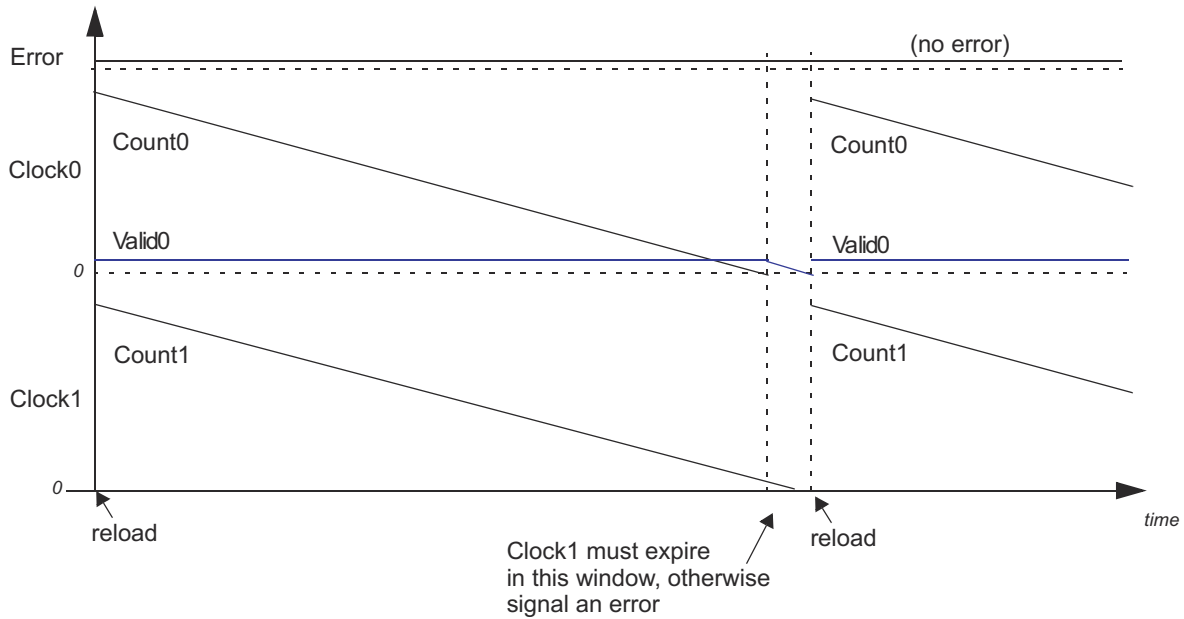

Figure 8-3. Counter Relationship

Figure 8-4. Clock1 Slower Than Clock0 - Results in an Error and Stops Counting

Figure 8-5. Clock1 Faster Than Clock0 - Results in an Error and Stops Counting

Figure 8-6. Clock1 Not Present - Results in an Error and Stops Counting

Figure 8-7. Clock0 Not Present - Results in an Error and Stops Counting

8.3 Interrupts

DCC generates an interrupt on either of two events:

- DCC finishes counting and all the counters expire within a defined window indicating DONE operation, provided `DCCGCTRL.DONENA=1`.
- DCC finishes counting with error where counters do not expire in a defined window. This indicates an ERROR event, and sets an interrupt provided `DCCGCTRL.ERRENA=1`.

Interrupts generated by DONE or ERROR events are ORed and flagged as DCCx interrupts. Refer to the PIE Channel Mapping table in the *System Control and Interrupts* chapter to determine the interrupt channel mapping. The application interrupt service routine needs to check the status flag inside the DCCSTATUS register to determine whether the interrupt is due to ERROR or DONE.

DCC Error interrupts can also be configured as a Non-Maskable Interrupt (NMI) by enabling the `CLKFAILCFG.DCCx_ERROR_EN` flag.

8.4 Software

8.4.1 DCC Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/dcc

Cloud access to these examples is available at the following link: dev.ti.com [C2000Ware Examples](#).

8.4.1.1 DCC Single shot Clock verification

FILE: dcc_ex1_single_shot_verification.c

This program uses the XTAL clock as a reference clock to verify the frequency of the PLLRAW clock.

The Dual-Clock Comparator Module 0 is used for the clock verification. The clocksource0 is the reference clock (Fclk0 = 20Mhz) and the clocksource1 is the clock that needs to be verified (Fclk1 = 120Mhz). Seed is the value that gets loaded into the Counter.

Please refer to the TRM for details on counter seed values to be set.

External Connections

- None

Watch Variables

- *status/result* - Status of the PLLRAW clock verification

8.4.1.2 DCC Single shot Clock measurement

FILE: dcc_ex2_single_shot_measurement.c

This program demonstrates Single Shot measurement of the INTOSC2 clock post trim using XTAL as the reference clock.

The Dual-Clock Comparator Module 0 is used for the clock measurement. The clocksource0 is the reference clock (Fclk0 = 20Mhz) and the clocksource1 is the clock that needs to be measured (Fclk1 = 10Mhz). Since the frequency of the clock1 needs to be measured an initial seed is set to the max value of the counter.

Please refer to the TRM for details on counter seed values to be set.

External Connections

- None

Watch Variables

- *result* - Status if the INTOSC2 clock measurement completed successfully.
- *meas_freq1* - measured clock frequency, in this case for INTOSC2.

8.4.1.3 DCC Continuous clock monitoring

FILE: dcc_ex3_continuous_monitoring_of_clock.c

This program demonstrates continuous monitoring of PLL Clock in the system using INTOSC2 as the reference clock. This would trigger an interrupt on any error, causing the decrement/ reload of counters to stop.

The Dual-Clock Comparator Module 0 is used for the clock monitoring. The clocksource0 is the reference clock (Fclk0 = 10Mhz) and the clocksource1 is the clock that needs to be monitored (Fclk1 = 120Mhz). The clock0 and clock1 seed are set to achieve a window of 340us. Seed is the value that gets loaded into the Counter. For the sake of demo a slight variance is given to clock1 seed value to generate an error on continuous monitoring.

Please refer to the TRM for details on counter seed values to be set. Note : When running in flash configuration it is good to do a reset & restart after loading the example to remove any stale flags/states.

External Connections

- None

Watch Variables

- *status/result* - Status of the PLLRAW clock monitoring
- *cnt0* - Counter0 Value measure when error is generated
- *cnt1* - Counter1 Value measure when error is generated
- *valid* - Valid0 Value measure when error is generated

8.4.1.4 DCC Continuous clock monitoring

FILE: dcc_ex3_continuous_monitoring_of_clock_syscfg.c

This program demonstrates continuous monitoring of PLL Clock in the system using INTOSC2 as the reference clock. This would trigger an interrupt on any error, causing the decrement/ reload of counters to stop. The Dual-Clock Comparator Module 0 is used for the clock monitoring. The clocksource0 is the reference clock (Fclk0 = 10Mhz) and the clocksource1 is the clock that needs to be monitored (Fclk1 = 120Mhz). The clock0 and clock1 seed are set automatically by the error tolerances defined in the sysconfig file included this project. For the sake of demo an un-realistic tolerance is assumed to generate an error on continuous monitoring.

Please refer to the TRM for details on counter seed values to be set. Note : When running in flash configuration it is good to do a reset & restart after loading the example to remove any stale flags/states.

External Connections

- None

Watch Variables

- *status/result* - Status of the PLLRAW clock monitoring
- *cnt0* - Counter0 Value measure when error is generated
- *cnt1* - Counter1 Value measure when error is generated
- *valid* - Valid0 Value measure when error is generated

8.4.1.5 DCC Detection of clock failure

FILE: dcc_ex4_clock_fail_detect.c

This program demonstrates clock failure detection on continuous monitoring of the PLL Clock in the system using XTAL as the osc clock source. Once the oscillator clock fails, it would trigger a DCC error interrupt, causing the decrement/ reload of counters to stop. In this examples, the clock failure is simulated by turning off the XTAL oscillator. Once the ISR is serviced, the osc source is changed to INTOSC1 and the PLL is turned off.

The Dual-Clock Comparator Module 0 is used for the clock monitoring. The clocksource0 is the reference clock (Fclk0 = 20Mhz) and the clocksource1 is the clock that needs to be monitored (Fclk1 = 120Mhz). Seed is the value that gets loaded into the Counter.

In the current example, the XTAL is expected to be a Resonator running in Crystal mode which is later switched off to simulate the clock failure. If an SE Crystal is used, you will need to physically disconnect the clock on the board. Please refer to the TRM for details on counter seed values to be set. Note : When running in flash configuration it is good to do a reset & restart after loading the example to remove any stale flags/states.

External Connections

- None

Watch Variables

- *status/result* - Status of the clock failure detection

8.5 DCC Registers

This section describes the Dual Clock Comparator Registers.

Note

DCC is used by Boot ROM, hence the register values can be different than the hardware reset value. The user needs to make sure to configure the values of these registers to the desired value before enabling DCC.

8.5.1 DCC Base Address Table

Table 8-1. DCC Base Address Table

Bit Field Name		DriverLib Name	Base Address	CPU1	DMA	HIC	CLA	Pipeline Protected
Instance	Structure							
Dcc0Regs	DCC_REGS	DCC0_BASE	0x0005_E700	YES	-	-	-	YES
Dcc1Regs	DCC_REGS	DCC1_BASE	0x0005_E740	YES	-	-	-	YES

8.5.2 DCC_REGS Registers

Table 8-2 lists the memory-mapped registers for the DCC_REGS registers. All register offset addresses not listed in Table 8-2 should be considered as reserved locations and the register contents should not be modified.

Table 8-2. DCC_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	DCCGCTRL	Starts / stops the counters. Clears the error signal.		Go
8h	DCCCNTSEED0	Seed value for the counter attached to Clock Source 0.		Go
Ch	DCCVALIDSEED0	Seed value for the timeout counter attached to Clock Source 0.		Go
10h	DCCCNTSEED1	Seed value for the counter attached to Clock Source 1.		Go
14h	DCCSTATUS	Specifies the status of the DCC Module.		Go
18h	DCCCNT0	Value of the counter attached to Clock Source 0.		Go
1Ch	DCCVALID0	Value of the valid counter attached to Clock Source 0.		Go
20h	DCCCNT1	Value of the counter attached to Clock Source 1.		Go
24h	DCCCLKSRC1	Selects the clock source for Counter 1.		Go
28h	DCCCLKSRC0	Selects the clock source for Counter 0.		Go

Complex bit access types are encoded to fit into small table cells. Table 8-3 shows the codes that are used for access types in this section.

Table 8-3. DCC_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
R-1	R -1	Read Returns 1s
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

8.5.2.1 DCCGCTRL Register (Offset = 0h) [Reset = 00005555h]

DCCGCTRL is shown in [Figure 8-8](#) and described in [Table 8-4](#).

Return to the [Summary Table](#).

Starts / stops the counters. Clears the error signal.

Chapter 9
Background CRC-32 (BGCR)

The Background CRC (BGCR) module that helps to identify memory faults and corruption, is discussed in this chapter.

9.1 Introduction	1054
9.2 Functional Description	1056
9.3 Application of the BGCR	1058
9.4 Software	1063
9.5 BGCR Registers	1064

9.1 Introduction

The Background CRC (BGCRC) module computes a CRC-32 on a configurable block of memory. It accomplishes this by fetching the specified block of memory during idle cycles (when the CPU, CLA, or DMA is not accessing the memory block). The calculated CRC-32 value is compared against a golden CRC-32 value to indicate a pass or fail. In essence, the BGCRC helps identify memory faults and corruption. There are two BGCRC modules, CPU_CRC and CLA_CRC. The two BGCRC modules differ only in the memories they test.

9.1.1 BGCRC Related Collateral

Getting Started Materials

- [CRC Engines in C2000 Devices Application Report](#)

9.1.2 Features

The BGCRC module has the following features:

- One cycle CRC-32 computation on 32 bits of data
- No CPU bandwidth impact for zero wait state memory
- Minimal CPU bandwidth impact for non-zero wait state memory
- Dual operation modes (CRC-32 mode and scrub mode)
- Watchdog timer to time CRC-32 completion
- Ability to pause and resume CRC-32 computation

9.1.3 Block Diagram

Figure 9-1 shows the BGCRC block diagram.

Figure 9-1. BGCRC Block Diagram

9.1.4 Memory Wait States and Memory Map

Figure 9-2 shows the memory map of the BGCR module. M0, M1, MSGRAM, LS[x]RAM, and GS[x]RAM are all zero wait-state memories. BGCR accesses these memories with minimal impact on normal program operation. For instance, if a BGCR access is being made to a zero wait-state memory in the current cycle, the earliest the operating program can make access to the same memory location is in the next cycle. Similarly for the non-zero wait state memories SECROM, DATAROM and BOOTROM, the worst case delay for functional access after a BGCR access is the wait-state amount.

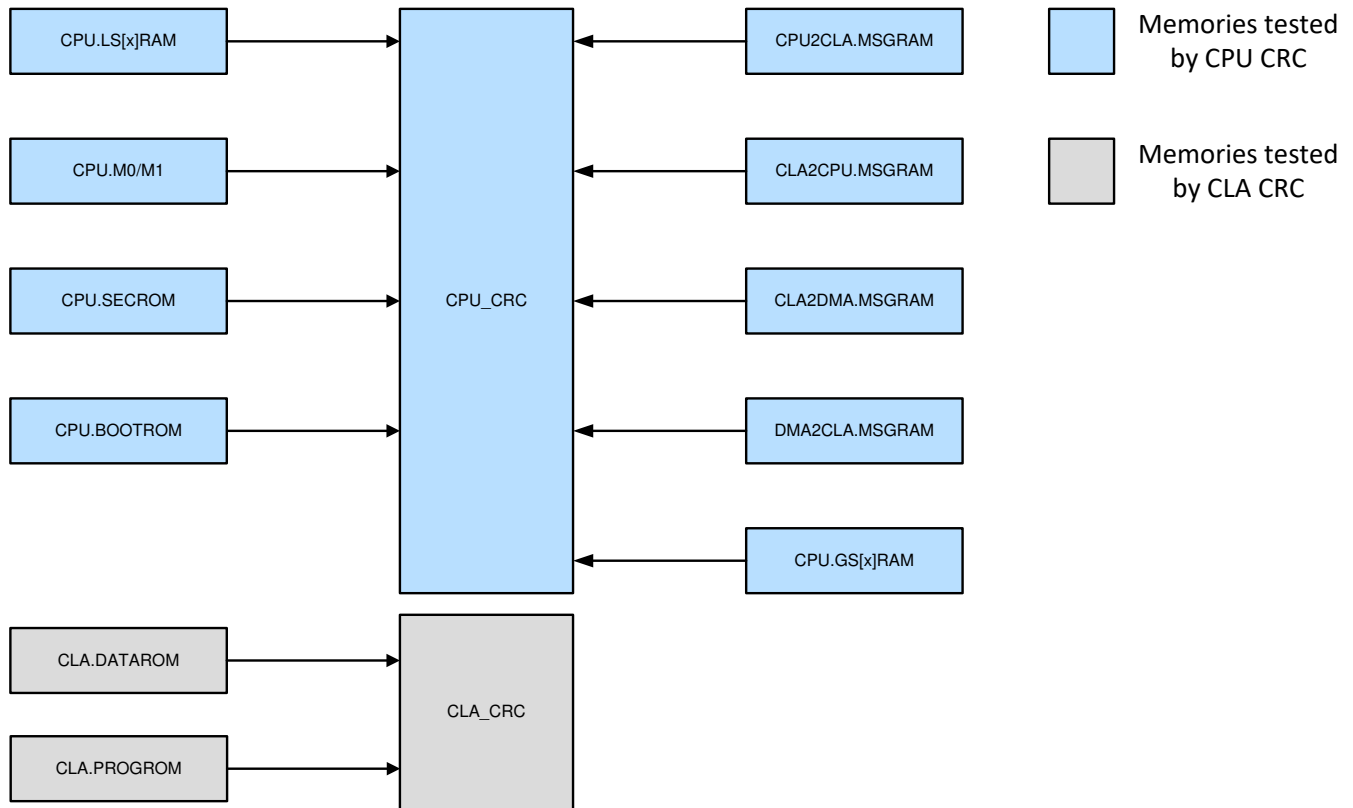

Figure 9-2. BGCR Memory Map

9.2 Functional Description

The CRC-32 calculation of the BGCR module can be kicked off by configuring the register BGCR_EN.START to 1010. Once started, the module performs the background memory checks without CPU or CLA intervention. However, on completion of the CRC-32 calculation or in the event of a failure, the CPU or CLA is notified through an interrupt and task, respectively.

As highlighted in the overview, there are two BGCR modules. CPU_CRC that is configurable by the CPU can only generate an interrupt. CLA_CRC however, can be configured by both the CPU and CLA and can generate an interrupt to the CPU or task for the CLA.

9.2.1 Data Read Unit

Once the CRC-32 calculation is started, the BGCR module continuously reads data from memory as a background process. These reads happen during the idle times (when the CPU, CLA or DMA is not accessing the memory block) and so does not impact functional access. The data read unit only reads data if there is no pending functional access. The data read unit begins operation by reading a block of data BGCR_CTRL2.BLOCK_SIZE from address BGCR_START_ADDR. Note that BGCR_START_ADDR must be 0x80 word aligned. For a non-0x80 word aligned BGCR_START_ADDR, the LSB bits are zeroed out to get a 0x80 word aligned BGCR_START_ADDR. For instance, if the programmed BGCR_START_ADDR = 0x1AF3, the internal 0x80 word aligned start address is 0x1A80.

When the data read unit reads a block of data, ECC and parity are checked. Any ECC or parity errors that occur during the read is indicated by setting the respective NMI and generating an interrupt if configured as so. The BGCR module, however, does not write back the corrected memory contents on the occurrence of a correctable ECC error. Writing back the corrected values is handled by software.

9.2.2 CRC-32 Compute Unit

After the data read unit reads a block of data, the data read unit feeds this data to the CRC-32 compute unit. This unit computes the CRC-32 using the standard polynomial $0x04C11DB7$ ($x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$). The CRC-32 unit retrieves 32-bit of data at a time from the block of data to compute the polynomial. This computation takes 1 cycle. For instance, the CRC-32 calculation for 1KB block of data is 256 cycles, 1 cycle for each of the 256 32-bit chunks. The initial value for the CRC-32 computation can be configured using BGCR_SEED.

After the CRC-32 calculation is complete for a data block, the final result is loaded into BGCR_RESULT. Note that BGCR_RESULT only contains the final calculation for the whole data block; intermediate 32-bit calculations do not update BGCR_RESULT. The value in BGCR_RESULT is compared against the value in BGCR_GOLDEN by hardware and the NMI/Interrupt flags are set accordingly by the CRC notification unit.

Once CRC-32 calculation is commenced, the calculation can be halted by setting BGCR_CTRL2.TEST_HALT to 1010. Clearing this bit resumes CRC-32 calculation from the halt point.

9.2.3 CRC Notification Unit

After the CRC-32 compute unit completes the CRC-32 calculation for a block of data or fails to complete the calculation within BGCR_C_WD_MIN and BGCR_C_WD_MAX, if configured, the CRC-32 compute unit sends out a NMI/Interrupt on the occurrence of a pass or fail. In addition, during a data read by the data read unit, if an ECC or parity error occurs, the CRC notification unit can send out a NMI/Interrupt. In the case of an ECC or parity error, the BGCR stops operation and BGCR_C_CURR_ADDR contains the memory address that caused the ECC or parity error. The contents of BGCR_C_CURR_ADDR in addition to the NMI/Interrupt flags can be used to debug a BGCR failure.

9.2.3.1 CPU Interrupt, CLA Task and NMI

The BGCR module has configurable interrupt and NMI lines. NMIs are enabled by default but can be disabled by writing 0xA to BGCR_C_CTRL1.NMIDIS register. Conversely, all interrupts are disabled by default but can be enabled by writing 0x7E to BGCR_C_INTEN register. When an error occurs in the BGCR, the BGCR can be configured to generate an NMI or interrupt. Since NMIs are enabled by default, all BGCR errors cause an NMI. Figure 9-3 and Figure 9-4 show the NMI and Interrupt lines, respectively.

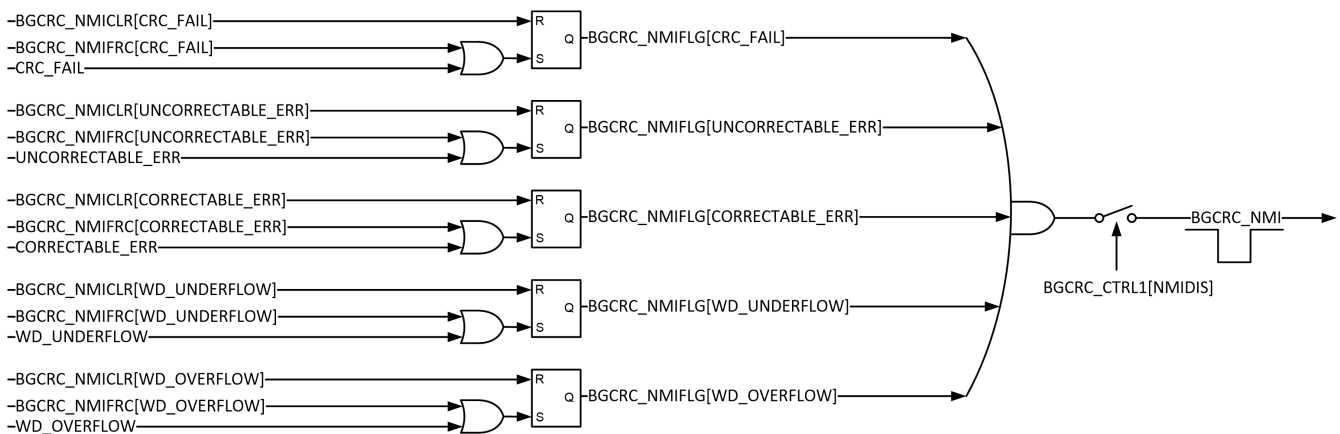

Figure 9-3. BGCR NMI

Figure 9-4. BGCR Interrupt

9.2.4 Operating Modes

BGCR module supports two modes of operation: CRC mode and scrub mode. The mode of operation can be configured by clearing or setting the register BGCR_CTRL2.SCRUB_MODE.

9.2.4.1 CRC Mode

In CRC mode, the BGCR module operates as explained in [Section 9.2.2](#). CRC-32 calculation is performed on a block of data and the result compared against a golden value. ECC and parity errors are checked in this mode. Result mismatch, ECC or parity error can trigger an NMI/Interrupt.

9.2.4.2 Scrub Mode

In scrub mode, the CRC-32 result is not compared against the golden value and BGCR_RESULT register is not updated. ECC and parity errors are also checked in this mode. However unlike CRC mode, NMI/Interrupt are only from ECC or parity error. In scrub mode, Parity and ECC bits of the memory block need to be initialized by the CPU and/or CLA.

9.2.5 BGCR Watchdog

The BGCR module has an embedded windowed watchdog that is used as a diagnostic to check memory test completion within the expected time window. This can protect against hardware defects that can cause the memory check not to complete in the allotted time, which cannot be caught by the system watchdog as the error can be due to the CLA or DMA having continuous access. Windowing also helps detect additional failure modes in the watchdog operation, for example, stuck watchdog.

The BGCR watchdog is enabled by default and starts when the BGCR module begins reading from memory. The watchdog can be disabled using the register BGCR_WD_CFG.WDDIS. The BGCR watchdog counter is a 32-bit counter with the value reflected in BGCR_WD_CNT register. The lower and upper window settings are configured using BGCR_WD_MIN and BGCR_WD_MAX, respectively. BGCR_WD_MIN and BGCR_WD_MAX need to be configured before the test is started and must not be changed while the BGCR is operating. If configured, an NMI or interrupt is triggered if the memory test fails to complete within the configured time window. The counter stops on completion of the CRC-32 check done, CRC-32 check failure and ECC/Parity errors. The counter is reset when the next memory check begins.

The BGCR watchdog can be halted by configuring the BGCR_WD_CFG.WDDIS register. After the watchdog resumes from being halted, the counter starts counting from the previous count unless a new memory check operation is initiated. The counter is not halted when CRC-32 computation halts but by default halts during a debug halt. The behavior of the watchdog during emulation can be changed by configuring the appropriate BGCR registers. In addition, due to the changing nature of memory contents during emulation, it is not recommended to run BGCR during emulation. CRC-32 computation continues during a watchdog failure and software needs to address this condition.

9.2.6 Hardware and Software Faults Protection

The configuration registers are protected using a lock and commit configuration. Each of the configuration registers can be individually locked and committed. The register once locked, can no longer be updated until the lock is removed. However if the register lock is committed, no further writes is permitted until the device is reset. It is recommended to lock the registers after configuration to protect against corruption due to software faults. In addition, registers critical to the module functionality and fault detection are implemented using multi-bit fields to protect against hardware faults.

9.3 Application of the BGCR

This section contains use case scenarios of how the BGCR module can be configured to test a block of memory. However, the use case scenarios presented are for reference only and do not cover all the possible application scenarios. These use case scenarios can be used as a starting point to configure the BGCR module for specific applications.

9.3.1 Software Configuration

The configuration registers for the BGCR can be split into three groups (see [Table 9-1](#)):

- **CFG1:** Registers that determine the operating mode and configured at the beginning.
- **CFG2:** Registers that need to be updated during kickoff of a new test.
- **CFG3:** Registers used for test and error management.

CFG1 registers are expected to be locked and committed after initial configuration. It is recommended to lock the CFG2 and CFG3 registers after configuration. [Figure 9-5](#) shows the BGCR execution sequence.

Table 9-1. BGCR Register Groups

CFG1 - One Time Configuration Registers	CFG2 - Periodic Configuration Registers	CFG3 - Registers Used for Test and Error Management
BGCR_CTRL1	BGCR_EN	BGCR_NMICLR
BGCR_WD_CFG	BGCR_CTRL2	BGCR_INTCLR
BGCR_INTEN	BGCR_START_ADDR	BGCR_NMIFRC
BGCR_SEED	BGCR_GOLDEN	BGCR_INTFRC
	BGCR_WD_MIN	
	BGCR_WD_MAX	

Figure 9-5. BGCR Execution Sequence Flow

9.3.2 Decision on Error Response Severity

The error sources for BGCRC are:

- Test completion before BGCRC_WD_MIN.
- Test completed after BGCRC_WD_MAX.
- Mismatch between the calculated CRC and golden CRC.
- Uncorrectable error during data read (single bit error for parity memory or double bit error for ECC memory).
- Correctable error during memory read (single bit error for ECC memory).

Error severity can be chosen as either NMI or interrupt. By default, error severity is set to NMI. It is not possible to configure error response for each individual error source. The response can be chosen as either interrupt or NMI for all error sources. When error severity is chosen as NMI, ERROR_STS pin is asserted during an error. CPU and CLA must be assigned the same error severity.

9.3.3 Decision of Controller for CLA_CRC

CPU_CRC can only be kicked off by the CPU. However, CLA_CRC can be kicked off by the CPU or CLA. If BGCRC error severity is chosen as NMI, it is possible to handle the background test using the CLA and error response with the CPU. Once the controller for BGCRC is chosen, it is possible to prevent accesses from other controllers by using the system-level access protection configuration.

9.3.4 Execution of Time Critical Code from Wait-Stated Memories

BGCRC access to functionally wait-stated memories is also wait-stated by the same number. Since it is impossible to predict the next functional access, any ongoing BGCRC access has to complete before functional access is granted. To mitigate delay in functional access, the BGCRC can be halted when time-critical code that accesses the wait-stated memories is in progress. When BGCRC execution is halted, the BGCRC watchdog is not halted. This is consistent with the safety requirement to complete the background test in a predictable window irrespective of the user code. In such scenarios, it is recommended to adjust the upper BGCRC watchdog window limit to account for the halt duration during functional access. However, if required, the BGCRC watchdog can be disabled.

9.3.5 BGCRC Execution

Two notes about BGCRC execution are:

- BGCRC task can run as a background task once kicked off.
- BGCRC task does not impact functional execution for zero-wait stated memories. For memories with higher wait-states, the BGCRC engine can be halted to make functional execution predictable.

[Figure 9-6](#) shows a few examples of BGCRC execution sequences.

CPU_CRC executed in parallel with functional execution. CRC-32 check can be stalled during time critical ISRs if ISRs require access to non-zero wait-stated memories.

CLA_CRC executed in parallel with other CLA tasks. This can cause delay in functional execution.

Functional tasks prioritized over CLA_CRC tasks. CLA_CRC will be stalled by functional tasks to avoid delays in functional execution.

Figure 9-6. BGCR Execution Sequence Example

9.3.6 Debug/Error Response for BGCR Errors

The BGCR error severity can be decoded by reading the BGCR_INTFLG or BGCR_NMIFLG. The errors can be:

- **WD_OVERFLOW/WD_UNDERFLOW:** The test did not complete in the programmed window. System timing needs to be checked to understand reason for non-completion of the test. BGCR_CURR_ADDR and BGCR_WD_CNT indicate how far the test progressed.
- **UNCORRECTABLE_ERR:** BGCR_CURR_ADDR contains the address of the memory location causing the error. This error is due to single bit failure for Parity SRAM or double bit failure for ECC SRAM. The memory location can be reloaded (if possible, for cases where code is copied from Flash) to see if the problem resolves. If the problem persists, the problem can be a permanent defect.
- **CORRECTABLE_ERR:** This error is due to single bit failure for ECC SRAM. If the problem location is accessed again (execution from the location for execute only memory or reading the location in other cases), the expectation is that the single bit error is corrected. If the single bit error is not corrected, this can be an indication of a permanent defect.
- **CRC_FAIL:** This indicates a failure in the computation of the CRC-32 value. This error does not occur in scrub mode. For SRAMs with protection, in the absence of code bugs, this error is less likely since the error is most often manifest as a correctable/uncorrectable error. Code bugs can cause failure if the code inadvertently writes to a wrong address thus causing a CRC-32 error.

9.3.7 BGCRC Golden CRC-32 Value Computation

The C28x is a little-endian, 16-bit word addressable CPU. Therefore, the 32-bit value of 0x12345678 stored at address 0x100 is stored in the C28x memory as shown in [Table 9-2](#).

Table 9-2. Data Address Location Example 1

Address	0x100	0x101
Data	0x5678	0x1234

The BGCRC order of byte calculations of the above example is 0x78, 0x56, 0x34, 0x12 and yields 0x6A330D2D. The 32-bit polynomial 0x04C11DB7 is used with an initialization vector of 0x00000000. The following code snippet shows the effective bit processing. Processing for all 32-bits within a word occurs in a single cycle within the BGCRC hardware.

```

seed = 0x0UL; //Initialize with Seed
poly = 0x04C11DB7UL; //32-Bit Polynomial
crc32 = seed;

for(i=0; i<dataSize; i++)
{
    byteSwappedData = ((data[i] & 0x000000FF) << 24) |
                     = ((data[i] & 0x0000FF00) << 8) |
                     = ((data[i] & 0x00FF0000) >> 8) |
                     = ((data[i] & 0xFF000000) >> 24);

    crc32 = byteSwappedData^crc32;
    for(j=0; j<32; j++)
    {
        if(crc32 & 0x80000000) crc32 = (crc32 << 1)^poly;
        else crc32 = crc32 << 1;

        crc32 = crc32 & 0xFFFFFFFF;
    }
}
    
```

A second example ([Table 9-3](#)) with two 32-bit words, 0x12345678 and 0x9ABCDEF0 at address 0x100 and 0x102 successively, calculates the bytes in the order 0x78, 0x56, 0x34, 0x12, 0xDE, 0xBC, and 0x9A and yield 0x7E0B4164.

Table 9-3. Data Address Location Example 2

Address	0x100	0x101	0x102	0x103
Data	0x5678	0x1234	0xDEF0	0x9ABC

All data input to the BGCRC must align to a 32-bit boundary, both in the starting address and the size. It is possible to include 16-bit data within the span of data; however, when the data is read by the BGCRC, it always assume 32-bits and conform to the above calculation order. For example, if two 16-bit words (0xA0B1 and 0xC2D3) were placed in between the previous two 32-bit words ([Table 9-4](#)), the calculations are performed in byte order 0x78, 0x56, 0x34, 0x12, 0xB1, 0xA0, 0xD3, 0xC2, 0xF0, 0xDE, 0xBC, and 0x9A and yield 0x2AEFD987.

Table 9-4. Data Address Location Example 3

Address	0x100	0x101	0x102	0x103	0x104	0x105
Data	0x5678	0x1234	0xA0B1	0xC2D3	0xDEF0	0x9ABC

9.4 Software

9.4.1 BGCRC Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location: C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/bgcr

Cloud access to these examples is available at the following link: dev.ti.com [C2000Ware Examples](#).

9.4.1.1 BGCRC CPU Interrupt Example

FILE: bgcrc_ex1_cpuinterrupt.c

This example demonstrates how to configure and trigger BGCRC from the CPU. BGCRC module is configured for 1 KB of GS0 RAM which is programmed with a known data. The pre-computed CRC value is used as the golden CRC value. Interrupt is generated once the computation is done and checks if no error flags are raised. Calculation uses the 32-bit polynomial 0x04C11DB7 and seed value 0x00000000.

External Connections

- None.

Watch Variables

- pass - This should be 1.
- runStatus - BGCRC running status. This will be BGCRC_ACTIVE if the module is running, BGCRC_IDLE if the module is idle

9.4.1.2 BGCRC Example with Watchdog and Lock

FILE: bgcrc_ex2_cpubgcr_basic.c

This example demonstrates how to configure and trigger BGCRC from the CPU. It also showcases how to configure the CRC watchdog and lock the registers after configuring the module. The watchdog is used as a diagnostic to check memory test completion within the expected time window. An error signal is generated if the test does not complete in the specified time window.

The module is configured for 1kB of GS0 RAM which is programmed with random data. The golden CRC value for comparison is computed using software method. Interrupt is generated once the computation is done and checks if no error flags are raised. The NMI is enabled and is triggered if an error is detected.

External Connections

- None.

Watch Variables

- pass
- bgcrcDone

9.4.1.3 CLA-BGCRC Example in CRC mode

FILE: bgcrc_ex3_clabgcr_crcmode.c

This example demonstrates how to configure and trigger CLABGCRC from the CPU. It also showcases how to configure the CRC watchdog and lock the registers after configuring the module. The watchdog is used as a diagnostic to check memory test completion within the expected time window. An error signal is generated if the test does not complete in the specified time window.

The module is configured for 1kB of CLA ROM memory. The golden CRC value for comparison is computed using software method. Interrupt is generated once the computation is done and checks if no error flags are raised. The NMI is enabled and is triggered if an error is detected.

External Connections

- None.

Watch Variables

- pass
- bgcrcDone

9.4.1.4 CLA-BGCR Example in Scrub Mode

FILE: bgcrc_ex4_clabgcr_scrubmode.c

This example demonstrates how to configure and trigger CLA-BGCR in Scrub mode. In Scrub mode, CRC of data is not compared with the golden CRC. Error check is done using the ECC/Parity logic. It also showcases how to configure the CRC watchdog and lock the registers after configuring the module. The watchdog is used as a diagnostic to check memory test completion within the expected time window. An error signal is generated if the test does not complete in the specified time window.

The module is configured for 256 bytes of CLA ROM memory. Interrupt is generated once the computation is done and checks if no error flags are raised. The NMI is enabled and is triggered if an error is detected.

External Connections

- None.

Watch Variables

- pass
- bgcrcDone

9.5 BGCR Registers

This section describes the Background CRC registers.

9.5.1 BGCR Base Address Table

Table 9-5. BGCR Base Address Table

Bit Field Name		DriverLib Name	Base Address	CPU1	DMA	HIC	CLA	Pipeline Protected
Instance	Structure							
BgcrCpuRegs	BGCR_REGS	BGCR_CPU_BAS E	0x0000_6340	YES	-	-	-	YES
BgcrCla1Regs	BGCR_REGS	BGCR_CLA1_BAS E	0x0000_6380	YES	-	-	YES	YES

9.5.2 BGCR_REGS Registers

Table 9-6 lists the memory-mapped registers for the BGCR_REGS registers. All register offset addresses not listed in Table 9-6 should be considered as reserved locations and the register contents should not be modified.

Table 9-6. BGCR_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	BGCR_EN	BGCR Enable	EALLOW	Go
2h	BGCR_CTRL1	BGCR Control register 1	EALLOW	Go
4h	BGCR_CTRL2	BGCR Control register 2	EALLOW	Go
6h	BGCR_START_ADDR	Start address for the BGCR check	EALLOW	Go
8h	BGCR_SEED	Seed for CRC calculation	EALLOW	Go
Eh	BGCR_GOLDEN	Golden CRC to be compared against	EALLOW	Go
10h	BGCR_RESULT	CRC calculated		Go
12h	BGCR_CURR_ADDR	Current address register		Go
1Ch	BGCR_WD_CFG	BGCR windowed watchdog configuration	EALLOW	Go
1Eh	BGCR_WD_MIN	BGCR windowed watchdog min value	EALLOW	Go

Chapter 10

General-Purpose Input/Output (GPIO)

The GPIO module controls the device's digital and analog I/O multiplexing, which uses shared pins to maximize application flexibility. The pins are named by the general-purpose I/O name (for example, GPIO0, GPIO25, GPIO58). These pins can be individually selected to operate as digital I/O (also called GPIO mode), or connected to one of several peripheral I/O signals. The input signals can be qualified to remove unwanted noise.

10.1 Introduction	1094
10.2 Configuration Overview	1096
10.3 Digital Inputs on ADC Pins (AIOs)	1097

10.5 Digital General-Purpose I/O Control	1098
10.6 Input Qualification	1099
10.7 GPIO and Peripheral Muxing	1103
10.8 Internal Pullup Configuration Requirements	1107
10.9 Software	1108
10.10 GPIO Registers	1109

10.1 Introduction

Up to twelve independent peripheral signals are multiplexed on a single GPIO-enabled pin in addition to the CPU-controlled I/O capability. Each pin output can be controlled by either a peripheral or one of the two CPU masters.

- CPU1
- CPU1.CLA

There are up to 8 possible I/O ports:

- Port A consists of GPIO0-GPIO31
- Port B consists of GPIO32-GPIO63
- Port C consists of GPIO64-GPIO95
- Port D consists of GPIO96-GPIO127
- Port E consists of GPIO128-GPIO159
- Port F consists of GPIO160-GPIO191
- Port G consists of GPIO192-GPIO223
- Port H consists of GPIO224-GPIO255

Note

Some GPIO and I/O ports can be unavailable on particular devices. See the *GPIO Registers* section for available GPIO and I/O ports.

The analog signals on this device are multiplexed with digital inputs and outputs. Some of these analog IO (AIO) pins do not have digital output capability. Others of these pins are analog pins capable of full digital input and output capability (AGPIO). Analog pins with AIO (digital input only) capability contain "AIO" signals in the Pin Attributes table of the device data sheet. Analog pins with full input and output capability (AGPIO pins) contain "GPIO" signals in the Pin Attributes table of the device data sheet. AGPIO pins also have pin names with both analog signals and GPIO in the name.

Note

By default, all analog pins with digital input support shall come up in analog mode. To turn ON the digital input functionality, GPHAMSEL register needs to be configured.

Figure 10-1 shows the GPIO logic for a single pin.

There are two key features to note in Figure 10-1. The first is that the input and output paths are entirely separate, connecting only at the pin. The second is that peripheral muxing takes place far from the pin. As a result, for both CPUs and CLAs to read the physical state of the pin independent of CPU mastering and peripheral muxing is possible. Likewise, external interrupts can be generated from peripheral activity. All pin options such as input qualification and open-drain output are valid for all masters and peripherals. However, the peripheral muxing, CPU muxing, and pin options can only be configured by CPU1. Table 10-1 provides details of GPIO registers accessible by different masters.

Note

JTAG uses a different signal path that does not support inversion or qualification.

GPIO18/X2 and GPIO19/X1 have different timings due to the load placed on them by the oscillator circuit. For information on using GPIO18/X2 and GPIO19/X1 as GPIOs, see the data sheet and the *Clocking* section of this document.

If digital signals with sharp edges (high dv/dt) are connected to the AIOs or AGPIOs, cross-talk can occur with adjacent analog signals. Therefore, limit the edge rate of signals connected to AIOs or AGPIOs if adjacent channels are being used for analog functions.

10.2 Configuration Overview

I/O pin configuration consists of several steps:

1. **Plan the device pin-out:** Make a list of all required peripherals for the application. Using the peripheral mux information in the device data sheet, choose which GPIOs to use for the peripheral signals. Decide which of the remaining GPIOs to use as inputs and outputs for each CPU and CLA.

Once the peripheral muxing has been chosen, implement the mux by writing the appropriate values to the GPyMUX1/2 and GPyGMUX1/2 registers. When changing the GPyGMUX value for a pin, always set the corresponding GPyMUX bits to zero first to avoid glitching in the muxes. By default, all pins are general-purpose I/Os, not peripheral signals, with the exception of GPIO35 and GPIO37.

2. **(Optional) Enable internal pullup resistors:** To enable or disable the pullup resistors, write to the appropriate bits in the GPIO pullup disable registers (GPyPUD). All pullups are disabled by default. Pullups can be used to keep input pins in a known state when there is no external signal driving them.
3. **Select input qualification:** If the pin is used as an input, specify the required input qualification, if any. The input qualification sampling period is selected in the GPyCTRL registers, while the type of qualification is selected in the GPyQSEL1 and GPyQSEL2 registers. By default, all qualification is synchronous with a sampling period equal to PLLSYSCLK, with the exception of GPIO35 and GPIO37. For an explanation of input qualification, see [Section 10.6](#).
4. **Select the direction of any general-purpose I/O pins:** For each pin configured as a GPIO, specify the direction of the pin as either input or output using the GPyDIR registers. By default, all GPIO pins are inputs. Before changing a pin to an output, load the output latch with the value to be driven by writing that value to the GPySET, GPyCLEAR, or GPyDAT registers. Once the latch is loaded, write to GPyDIR to change the pin direction. By default, all output latches are zero.

The GPyDAT_R register can be used to read what value was written to the GPyDAT register.

5. **Select low-power mode wake-up sources:** GPIOs 0-63 can be used to wake the system up from low power modes. To select one or more GPIOs for wake-up, write to the appropriate bits in the GPIOLPMSEL0 and GPIOLPMSEL1 registers. These registers are part of the CPU system register space. For more information on low-power modes and GPIO wake-up, see the Low-Power Modes section in the *System Control and Interrupts* chapter.
6. **Select external interrupt sources:** Configuring external interrupts is a two-step process. First, the interrupts themselves must be enabled and the polarity must be configured using the XINTnCR registers. Second, the XINT1-5 GPIO pins must be set by selecting the sources for Input X-BAR signals 4, 5, 6, 13, and 14, respectively. For more information on the Input X-BAR architecture, see the *Crossbar (X-BAR)* chapter.

10.3 Digital Inputs on ADC Pins (AIOs)

Some GPIOs are multiplexed with analog pins and only have digital input functionality. These are also referred to as AIOs. Pins with only an AIO option on this port can only function in input mode. See the device data sheet for list of AIO signals. By default, these pins function as analog pins and the GPIOs are in a high-impedance state. The GPyAMSEL register is used to configure these pins for digital or analog operation.

Note

If digital signals with sharp edges (high dv/dt) are connected to the AIOs, cross-talk can occur with adjacent analog signals. Therefore, limit the edge rate of signals connected to AIOs if adjacent channels are being used for analog functions.

10.4 Digital Inputs and Outputs on ADC Pins (AGPIOs)

Some GPIOs on this device are multiplexed with analog pins. These are also referred to as AGPIOs. Unlike AIOs, AGPIOs have full input and output capability. This device has two GPIOs (GPIO20 and GPIO21) that offer this feature on the 100-pin PZ and 80-pin PN packages.

100-Pin PZ: On this package, there are dedicated pins for B5 (pin 32) and B11 (pin 30) that also have AIO252 and AIO251 functionality, respectively. In addition, GPIO20 (pin 48) and GPIO21 (pin 49) are also available as B5 and B11, respectively. Since B5 and B11 are dedicated pins on this package, use these pins instead of the pins on GPIO20/21.

80-Pin PN: On this package, GPIO20 (pin 33) and GPIO21 (pin 34) are also available as B5 and B11, respectively. There are no dedicated pin for B5 and B11.

By default, the AGPIOs are not connected and are configured. [Table 10-2](#) shows how to configure the AGPIOs using B5 (pin 32) and GPIO20 (pin 48) on the 100-pin PZ as an example.

Table 10-2. AGPIO Configuration

AGPIOTRLA.bit. GPIO20	GPAAMSEL.bit. GPIO20	GPHAMSEL.bit. GPIO252	B5 Connected To			GPIO20 Connected To		
			ADC	GPIO20	AIO252	ADC	GPIO20	AIO252
0	0	1	Yes	-	-	-	Yes	-
0	1	1	Yes	-	-	-	-	-
1	0	1	Yes	-	-	-	Yes	-
1	1	1	-	-	-	Yes	-	-
0	0	0	Yes	-	Yes	-	Yes	-
0	1	0	Yes	-	Yes	-	-	-
1	0	0	Yes	-	Yes	-	Yes	-
1	1	0	-	-	Yes	Yes	-	-

Note

If digital signals with sharp edges (high dv/dt) are connected to the AGPIOs, cross-talk can occur with adjacent analog signals. The user must therefore limit the edge rate of signals connected to AGPIOs, if adjacent channels are being used for analog functions.

10.5 Digital General-Purpose I/O Control

The values on the pins that are configured as GPIO can be changed by using the following registers.

- **GPyDAT Registers**

Each I/O port has one data register. Each bit in the data register corresponds to one GPIO pin. No matter how the pin is configured (GPIO or peripheral function), the corresponding bit in the data register reflects the current state of the pin after qualification. Writing to the GPyDAT register clears or sets the corresponding output latch and if the pin is enabled as a general-purpose output (GPIO output), the pin is also driven either low or high. If the pin is not configured as a GPIO output, then the value is latched but the pin is not driven. Only if the pin is later configured as a GPIO output is the latched value driven onto the pin.

When using the GPyDAT register to change the level of an output pin, be cautious to not accidentally change the level of another pin. For example, to change the output latch level of GPIOA1 by writing to the GPADAT register bit 0 using a read-modify-write instruction, a problem can occur if another I/O port A signal changes level between the read and the write stage of the instruction. Following is an analysis of why this happens:

The GPyDAT registers reflect the state of the pin, not the latch. This means the register reflects the actual pin value. However, there is a lag between when the register is written to when the new pin value is reflected back in the register. This can pose a problem when this register is used in subsequent program statements to alter the state of GPIO pins. An example is shown below where two program statements attempt to drive two different GPIO pins that are currently low to a high state.

If Read-Modify-Write operations are used on the GPyDAT registers, because of the delay between the output and the input of the first instruction (I1), the second instruction (I2) reads the old value and writes the value back.

```
GpioDataRegs.GPADAT.bit.GPIO1 = 1; //I1 performs read-modify-write of GPADAT
GpioDataRegs.GPADAT.bit.GPIO2 = 1; //I2 also a read-modify-write of GPADAT
//GPADAT gets the old value of GPIO1 due to the delay
```

The second instruction waits for the first to finish the write due to the write-followed-by-read protection on this peripheral frame. There is some lag, however, between the write of (I1) and the GPyDAT bit reflecting the new value (1) on the pin. During this lag, the second instruction reads the old value of GPIO1 (0) and writes the value back along with the new value of GPIO2 (1). Therefore, GPIO1 pin stays low.

One answer is to put some NOPs between instructions. A better answer is to use the GPySET/GPyCLEAR/GPyTOGGLE registers instead of the GPyDAT registers. These registers always read back a 0 and writes of 0 have no effect. Only bits that need to be changed can be specified without disturbing any other bits that are currently in the process of changing.

- **GPyDAT_R Registers**

The GPyDAT_R registers are read only registers that return the value written to the GPyDAT registers instead of pin status. Writes to these registers have no effect.

- **GPySET Registers**

The set registers are used to drive specified GPIO pins high without disturbing other pins. Each I/O port has one set register and each bit corresponds to one GPIO pin. The set registers always read back 0. If the corresponding pin is configured as an output, then writing a 1 to that bit in the set register sets the output latch high and the corresponding pin is driven high. If the pin is not configured as a GPIO output, then the value is latched but the pin is not driven. Only if the pin is later configured as a GPIO output is the latched value driven onto the pin. Writing a 0 to any bit in the set registers has no effect.

- **GPyCLEAR Registers**

The clear registers are used to drive specified GPIO pins low without disturbing other pins. Each I/O port has one clear register. The clear registers always read back 0. If the corresponding pin is configured as a general-purpose output, then writing a 1 to the corresponding bit in the clear register clears the output latch and the pin is driven low. If the pin is not configured as a GPIO output, then the value is latched but the pin is not driven. Only if the pin is later configured as a GPIO output is the latched value driven onto the pin. Writing a 0 to any bit in the clear registers has no effect.

- **GPyTOGGLE Registers**

The toggle registers are used to drive specified GPIO pins to the opposite level without disturbing other pins. Each I/O port has one toggle register. The toggle registers always read back 0. If the corresponding pin is configured as an output, then writing a 1 to that bit in the toggle register flips the output latch and pulls the corresponding pin in the opposite direction. That is, if the output pin is driven low, then writing a 1 to the corresponding bit in the toggle register pulls the pin high. Likewise, if the output pin is high, then writing a 1 to the corresponding bit in the toggle register pulls the pin low. If the pin is not configured as a GPIO output, then the value is latched but the pin is not driven. Only if the pin is later configured as a GPIO output is the latched value driven onto the pin. Writing a 0 to any bit in the toggle registers has no effect.

10.6 Input Qualification

The input qualification scheme has been designed to be very flexible. Select the type of input qualification for each GPIO pin by configuring the GPyQSEL1 and GPyQSEL2 registers. In the case of a GPIO input pin, the qualification can be specified as only synchronized to SYSCLKOUT or qualification by a sampling window. For pins that are configured as peripheral inputs, the input can also be asynchronous in addition to synchronized to SYSCLKOUT or qualified by a sampling window. The remainder of this section describes the options available.

10.6.1 No Synchronization (Asynchronous Input)

This mode is used for peripherals where input synchronization is not required or the peripheral performs the synchronization. Examples include communication ports McBSP, SCI, SPI, and I²C. In addition, the ePWM trip zone (\overline{TZn}) signals can function independent of the presence of SYSCLKOUT.

Note

Using input synchronization when the peripheral performs the synchronization can cause unexpected results. The user must make sure that the GPIO pin is configured for asynchronous in this case.

10.6.2 Synchronization to SYSCLKOUT Only

This is the default qualification mode of all the pins at reset. In this mode, the input signal is only synchronized to the system clock (SYSCLKOUT). Because the incoming signal is asynchronous, a SYSCLKOUT period of delay is needed for the input to the device to be changed. No further qualification is performed on the signal.

10.6.3 Qualification Using a Sampling Window

In this mode, the signal is first synchronized to the system clock (SYSCLKOUT) and then qualified by a specified number of cycles before the input is allowed to change. Figure 10-2 and Figure 10-3 show how the input qualification is performed to eliminate unwanted noise. Two parameters are specified by the user for this type of qualification: 1) the sampling period, or how often the signal is sampled, and 2) the number of samples to be taken.

Figure 10-2. Input Qualification Using a Sampling Window

Time between samples (sampling period):

To qualify the signal, the input signal is sampled at a regular period. The sampling period is specified by the user and determines the time duration between samples, or how often the signal is sampled, relative to the CPU clock (SYSCLKOUT).

The sampling period is specified by the qualification period (QUALPRDn) bits in the GPxCTRL register. The sampling period is configurable in groups of 8 input signals. For example, GPIO0 to GPIO7 use GPxCTRL[QUALPRD0] setting and GPIO8 to GPIO15 use GPxCTRL[QUALPRD1]. Table 10-3 and Table 10-4 show the relationship between the sampling period or sampling frequency and the GPxCTRL[QUALPRDn] setting.

Table 10-3. Sampling Period

Sampling Period	
If GPxCTRL[QUALPRDn] = 0	$1 \times T_{\text{SYSCLKOUT}}$
If GPxCTRL[QUALPRDn] ≠ 0	$2 \times \text{GPxCTRL[QUALPRDn]} \times T_{\text{SYSCLKOUT}}$
Where $T_{\text{SYSCLKOUT}}$ is the period in time of SYSCLKOUT	

Table 10-4. Sampling Frequency

Sampling Frequency	
If GPxCTRL[QUALPRDn] = 0	$f_{\text{SYSCLKOUT}}$
If GPxCTRL[QUALPRDn] ≠ 0	$f_{\text{SYSCLKOUT}} \times 1 \div (2 \times \text{GPxCTRL[QUALPRDn]})$
Where $f_{\text{SYSCLKOUT}}$ is the frequency of SYSCLKOUT	

From these equations, the minimum and maximum time between samples can be calculated for a given SYSCLKOUT frequency:

Example: Maximum Sampling Frequency:

If GPxCTRL[QUALPRDn] = 0

then the sampling frequency is $f_{\text{SYSCLKOUT}}$

If, for example, $f_{\text{SYSCLKOUT}} = 60\text{MHz}$

then the signal is sampled at 60MHz or one sample every 16.67ns.

Example: Minimum Sampling Frequency:

If GPxCTRL[QUALPRDn] = 0xFF (255)

then the sampling frequency is $f_{\text{SYSCLKOUT}} \times 1 \div (2 \times \text{GPxCTRL[QUALPRDn]})$

If, for example, $f_{\text{SYSCLKOUT}} = 60\text{MHz}$

then the signal is sampled at $60\text{MHz} \times 1 \div (2 \times 255)$ (117.647kHz) or one sample every 8.5 μs .

Number of samples:

The number of times the signal is sampled is either three samples or six samples as specified in the qualification selection (GPAQSEL1, GPAQSEL2, GPBQSEL1, and GPBQSEL2) registers. When three or six consecutive cycles are the same, then the input change is passed through to the device.

Total Sampling-Window Width:

The sampling window is the time during which the input signal is sampled as shown in [Figure 10-3](#). By using the equation for the sampling period, along with the number of samples to be taken, the total width of the window can be determined.

For the input qualifier to detect a change in the input, the level of the signal must be stable for the duration of the sampling-window width or longer.

The number of sampling periods within the window is always one less than the number of samples taken. For a three-sample window, the sampling-window width is two sampling-periods wide where the sampling period is defined in [Table 10-3](#). Likewise, for a six-sample window, the sampling-window width is five sampling-periods wide. [Table 10-5](#) and [Table 10-6](#) show the calculations used to determine the total sampling-window width based on GPxCTRL[QUALPRDn] and the number of samples taken.

Table 10-5. Case 1: Three-Sample Sampling-Window Width

	Total Sampling-Window Width
If GPxCTRL[QUALPRDn] = 0	$2 \times T_{\text{SYSCLKOUT}}$
If GPxCTRL[QUALPRDn] \neq 0	$2 \times 2 \times \text{GPxCTRL[QUALPRDn]} \times T_{\text{SYSCLKOUT}}$
	Where $T_{\text{SYSCLKOUT}}$ is the period in time of SYSCLKOUT

Table 10-6. Case 2: Six-Sample Sampling-Window Width

	Total Sampling-Window Width
If GPxCTRL[QUALPRDn] = 0	$5 \times T_{\text{SYSCLKOUT}}$
If GPxCTRL[QUALPRDn] \neq 0	$5 \times 2 \times \text{GPxCTRL[QUALPRDn]} \times T_{\text{SYSCLKOUT}}$
	Where $T_{\text{SYSCLKOUT}}$ is the period in time of SYSCLKOUT

Note

The external signal change is asynchronous with respect to both the sampling period and SYSCLKOUT. Due to the asynchronous nature of the external signal, the input must be held stable for a time greater than the sampling-window width to make sure the logic detects a change in the signal. The extra time required can be up to an additional sampling period + T_{SYSCLKOUT}.

The required duration for an input signal to be stable for the qualification logic to detect a change is described in the data sheet.

Example Qualification Window:

For the example shown in Figure 10-3, the input qualification has been configured as follows:

- GPxQSEL1/2 = 1,0. This indicates a six-sample qualification.
- GPxCTRL[QUALPRDn] = 1. The sampling period is $t_w(SP) = 2 \times GPxCTRL[QUALPRDn] \times T_{SYSCLKOUT} = 2 \times T_{SYSCLKOUT}$.

This configuration results in the following:

- The width of the sampling window is:

$$t_w(IQSW) = 5 \times t_w(SP) = 5 \times 2 \times GPxCTRL[QUALPRDn] \times T_{SYSCLKOUT} = 5 \times 2 \times T_{SYSCLKOUT}$$

- If, for example, T_{SYSCLKOUT} = 16.67ns, then the duration of the sampling window is:

$$\text{Sampling period, } t_w(SP) = 2 \times T_{SYSCLKOUT} = 2 \times 16.67\text{ns} = 33.3\text{ns}$$

$$\text{Sampling window, } t_w(IQSW) = 5 \times t_w(SP) = 5 \times 33.3\text{ns} = 166.7\text{ns}$$

- To account for the asynchronous nature of the input relative to the sampling period and SYSCLKOUT, up to a single additional sampling period and SYSCLK period is required to detect a change in the input signal. For this example:

$$t_w(IQSW) + t_w(SP) + T_{SYSCLKOUT} = 166.7\text{ns} + 33.3\text{ns} + 16.67\text{ns} = 216.7\text{ns}$$

- In Figure 10-3, the glitch (A) is shorter than the qualification window and is ignored by the input qualifier.

A. This glitch will be ignored by the input qualifier. The QUALPRD bit field specifies the qualification sampling period. It can vary from 00 to 0xFF. If QUALPRD = 00, then the sampling period is 1 SYSCLKOUT cycle. For any other value "n", the qualification sampling period in 2n SYSCLKOUT cycles (i.e., at every 2n SYSCLKOUT cycles, the GPIO pin will be sampled).
 B. The qualification period selected via the GPxCTRL register applies to groups of 8 GPIO pins.
 C. The qualification block can take either three or six samples. The QUAL_SEL Register selects which sample mode is used.
 D. In the example shown, for the qualifier to detect the change, the input should be stable for 10 SYSCLKOUT cycles or greater. In other words, the inputs should be stable for (5 x QUALPRD x 2) SYSCLKOUT cycles. That would ensure 5 sampling periods for detection to occur. Since external signals are driven asynchronously, an 13-SYSCLKOUT-wide pulse ensures reliable recognition.

Figure 10-3. Input Qualifier Clock Cycles

10.7 GPIO and Peripheral Muxing

10.7.1 GPIO Muxing

Up to twelve different peripheral functions are multiplexed to each pin along with a general-purpose input/output (GPIO) function. This allows you to choose the peripheral mix and pinout that works best for your particular application. Refer to [Table 10-7](#) for muxing combinations and definitions.

10.7.2 Peripheral Muxing

For example, multiplexing for the GPIO6 pin is controlled by writing to GPAGMUX[13:12] and GPAMUX[13:12]. By writing to these bits, GPIO6 is configured as either a general-purpose digital I/O or one of several different peripheral functions. An example of GPyGMUX and GPyMUX selection and options for a single GPIO are shown in [Table 10-8](#).

Note

The following table is for example only. Refer to the device data sheet to check the availability of GPIO6 on this device. If GPIO6 is available, the functions mentioned in the table may not match the actual functions available. See [Section 10.7.1](#) for correct list of GPIOs and corresponding mux options for this device.

Table 10-8. GPIO and Peripheral Muxing

GPAGMUX1[13:12]	GPAMUX1[13:12]	Pin Functionality
00	00	GPIO6
00	01	Peripheral 1
00	10	Peripheral 2
00	11	Peripheral 3
01	00	GPIO6
01	01	Peripheral 4
01	10	Peripheral 5
01	11	
10	00	GPIO6
10	01	
10	10	Peripheral 6
10	11	Peripheral 7
11	00	GPIO6
11	01	Peripheral 8
11	10	Peripheral 9
11	11	Peripheral 10

The devices have different multiplexing schemes. If a peripheral is not available on a particular device, that mux selection is reserved on that device and must not be used.

CAUTION

If a reserved GPIO mux configuration that is not mapped to either a peripheral or GPIO mode is selected, the state of the pin is undefined and the pin is driven. Unimplemented configurations are for future expansion and must not be selected. In the device mux table (see the data sheet), these options are indicated as Reserved or left blank.

Some peripherals can be assigned to more than one pin by way of the mux registers. For example, OUTPUTXBAR1 can be assigned to GPIOs p, q, or r (where p, q, and r are example GPIO numbers), depending on individual system requirements. An example of this is shown in [Table 10-9](#).

Note

The following table is for example only. Bit ranges cannot correspond to OUTPUTXBAR1 on this device. See [Section 10.7.1](#) for correct list of GPIOs and corresponding mux options for this device.

If none or more than one of the GPIO pins is configured as peripheral input pins, then that GPIO is set to a hard-wired default value.

Table 10-9. Peripheral Muxing (Multiple Pins Assigned)

GMUX Configuration	MUX Configuration	
Choice 1: GPIOp	GPyGMUX1[5:4]=01	GPyMUX1[5:4]=01
or Choice 2: GPIOq	GPyGMUX2[17:16]=00	GPyMUX2[17:16]=01
or Choice 3: GPIOr	GPyGMUX1[7:6]=01	GPyMUX1[7:6]=01

10.8 Internal Pullup Configuration Requirements

On reset, GPIOs are in input mode and have the internal pullups disabled. An un-driven input can float to a mid-rail voltage and cause wasted shoot-through current on the input buffer. The user must always put each GPIO in one of these configurations:

- Input mode and driven on the board by another component to a level above V_{ih} or below V_{il}
- Input mode with GPIO internal pullup enabled
- Output mode

On devices with lesser pin count packages, pull-ups on unbonded GPIOs are by default enabled to prevent floating inputs. The user must take care to avoid disabling these pullups in the application code.

On devices with larger pin count packages, the pullups for any internally unbonded GPIO must be enabled to prevent floating inputs. TI has provided functions in controlSUITE/C2000Ware that users can call to enable the pullup on any unbonded GPIO for the package in use. This function, `GPIO_EnabledUnbondedIOPullups()`, resides in the `(Device)_Sysctrl.c` file and is called by default from `InitSysCtrl()`. The user must take care to avoid disabling these pullups in the application code.

10.9 Software

10.9.1 GPIO Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/gpio

Cloud access to these examples is available at the following link: dev.ti.com [C2000Ware Examples](#).

10.9.1.1 Device GPIO Setup

FILE: gpio_ex1_setup.c

Configures the device GPIO into two different configurations. This code is verbose to illustrate how the GPIO could be setup. In a real application, lines of code can be combined for improved code size and efficiency.

This example only sets-up the GPIO. Nothing is actually done with the pins after setup.

In general:

- All pullup resistors are enabled. For ePWMs this may not be desired.
- Input qual for communication ports (CAN, SPI, SCI, I2C) is asynchronous
- Input qual for Trip pins (TZ) is asynchronous
- Input qual for eCAP and eQEP signals is synch to SYSCLKOUT
- Input qual for some I/O's and __interrupts may have a sampling window

10.9.1.2 Device GPIO Toggle

FILE: gpio_ex2_toggle.c

Configures the device GPIO through the sysconfig file. The GPIO pin is toggled in the infinite loop. In order to migrate the project within syscfg to any device, click the switch button under the device view and select your corresponding device to migrate, saving the project will auto-migrate your project settings.

10.9.1.3 Device GPIO Interrupt

FILE: gpio_ex3_interrupt.c

Configures the device GPIOs through the sysconfig file. One GPIO output pin, and one GPIO input pin is configured. The example then configures the GPIO input pin to be the source of an external interrupt which toggles the GPIO output pin.

10.9.1.4 External Interrupt (XINT)

FILE: gpio_ex4_aio_external_interrupt.c

In this example AIO pins are configured as digital inputs. Two other GPIO signals (connected externally to AIO pins) are toggled in software to trigger external interrupt through AIO224 and AIO225 (AIO224 assigned to XINT1 and AIO225 assigned to XINT2). The user is required to externally connect these signals for the program to work properly. Each interrupt is fired in sequence: XINT1 first and then XINT2.

GPIO34 will go high outside of the interrupts and low within the interrupts. This signal can be monitored on a scope.

ExternalConnections

- Connect GPIO30 to AIO224. AIO224 will be assigned to XINT1
- Connect GPIO31 to AIO225. AIO225 will be assigned to XINT2
- GPIO34 can be monitored on an oscilloscope

Watch Variables

- xint1Count for the number of times through XINT1 interrupt
- xint2Count for the number of times through XINT2 interrupt
- loopCount for the number of times through the idle loop

10.9.2 LED Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/led

Cloud access to these examples is available at the following link: dev.ti.com [C2000Ware Examples](#).

10.10 GPIO Registers

This section describes the General-Purpose Input/Output Registers.

10.10.1 GPIO Base Address Table

Table 10-10. GPIO Base Address Table

Bit Field Name		DriverLib Name	Base Address	CPU1	DMA	HIC	CLA	Pipeline Protected
Instance	Structure							
GpioCtrlRegs	GPIO_CTRL_REGS	GPIOCTRL_BASE	0x0000_7C00	YES	-	-	-	YES
GpioDataRegs	GPIO_DATA_REGS	GPIODATA_BASE	0x0000_7F00	YES	-	-	YES	YES
GpioDataReadRegs	GPIO_DATA_READ_REGS	GPIODATAREAD_BASE	0x0000_7F80	YES	-	YES	YES	YES

10.10.2 GPIO_CTRL_REGS Registers

Table 10-11 lists the memory-mapped registers for the GPIO_CTRL_REGS registers. All register offset addresses not listed in Table 10-11 should be considered as reserved locations and the register contents should not be modified.

Table 10-11. GPIO_CTRL_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	GPACTRL	GPIO A Qualification Sampling Period Control (GPIO0 to 31)	EALLOW	Go
2h	GPAQSEL1	GPIO A Qualifier Select 1 Register (GPIO0 to 15)	EALLOW	Go
4h	GPAQSEL2	GPIO A Qualifier Select 2 Register (GPIO16 to 31)	EALLOW	Go
6h	GPAMUX1	GPIO A Mux 1 Register (GPIO0 to 15)	EALLOW	Go
8h	GPAMUX2	GPIO A Mux 2 Register (GPIO16 to 31)	EALLOW	Go
Ah	GPADIR	GPIO A Direction Register (GPIO0 to 31)	EALLOW	Go
Ch	GPAPUD	GPIO A Pull Up Disable Register (GPIO0 to 31)	EALLOW	Go
10h	GPAINV	GPIO A Input Polarity Invert Registers (GPIO0 to 31)	EALLOW	Go
12h	GPAODR	GPIO A Open Drain Output Register (GPIO0 to GPIO31)	EALLOW	Go
14h	GPAAMSEL	GPIO A Analog Mode Select register (GPIO0 to GPIO31)	EALLOW	Go
20h	GPAGMUX1	GPIO A Peripheral Group Mux (GPIO0 to 15)	EALLOW	Go
22h	GPAGMUX2	GPIO A Peripheral Group Mux (GPIO16 to 31)	EALLOW	Go
28h	GPACSEL1	GPIO A Core Select Register (GPIO0 to 7)	EALLOW	Go
2Ah	GPACSEL2	GPIO A Core Select Register (GPIO8 to 15)	EALLOW	Go

1EEh	GPHCSEL4	GPIO H Core Select Register (GPIO248 to 255)	EALLOW	Go
1FCh	GPHLOCK	GPIO H Lock Configuration Register (GPIO224 to 255)	EALLOW	Go
1FEh	GPHCR	GPIO H Lock Commit Register (GPIO224 to 255)	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. [Table 10-12](#) shows the codes that are used for access types in this section.

Table 10-12. GPIO_CTRL_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
WOnce	W Once	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

10.10.2.1 GPACTRL Register (Offset = 0h) [Reset = 0000000h]

GPACTRL is shown in [Figure 10-4](#) and described in [Table 10-13](#).

Return to the [Summary Table](#).

GPIO A Qualification Sampling Period Control (GPIO0 to 31)

10.10.2.4 GPAMUX1 Register (Offset = 6h) [Reset = 0000000h]

GPAMUX1 is shown in [Figure 10-7](#) and described in [Table 10-16](#).

Return to the [Summary Table](#).

GPIO A Mux 1 Register (GPIO0 to 15)
Defines pin-muxing selection for GPIO.

Notes:

The respective GPyGMUXn.GPIOz must be configured prior to this register to avoid intermediate peripheral selects being mapped to the GPIO. Refer to GPIO chapter for more details.

Figure 10-7. GPAMUX1 Register

10.10.2.5 GPAMUX2 Register (Offset = 8h) [Reset = 0000000h]

GPAMUX2 is shown in [Figure 10-8](#) and described in [Table 10-17](#).

Return to the [Summary Table](#).

GPIO A Mux 2 Register (GPIO16 to 31)

Defines pin-muxing selection for GPIO.

Notes:

The respective GPyGMUXn.GPIOz must be configured prior to this register to avoid intermediate peripheral selects being mapped to the GPIO. Refer to GPIO chapter for more details.

10.10.2.6 GPADIR Register (Offset = Ah) [Reset = 0000000h]

GPADIR is shown in [Figure 10-9](#) and described in [Table 10-18](#).

Return to the [Summary Table](#).

GPIO A Direction Register (GPIO0 to 31)

Controls direction of GPIO pins when the specified pin is configured in GPIO mode.

0: Configures pin as input.

1: Configures pin as output.

Reading the register returns the current value of the register setting.

10.10.2.7 GPAPUD Register (Offset = Ch) [Reset = FFFFFFFFh]

GPAPUD is shown in [Figure 10-10](#) and described in [Table 10-19](#).

Return to the [Summary Table](#).

GPIO A Pull Up Disable Register (GPIO0 to 31)

Disables the Pull-Up on GPIO.

0: Enables the Pull-Up.

1: Disables the Pull-Up.

Reading the register returns the current value of the register setting.

Note:

[1] The Pull-Ups on the GPIO pins are disabled asynchronously when IORSn signal is low.

10.10.2.8 GPAINV Register (Offset = 10h) [Reset = 0000000h]

GPAINV is shown in [Figure 10-11](#) and described in [Table 10-20](#).

Return to the [Summary Table](#).

GPIO A Input Polarity Invert Registers (GPIO0 to 31)

Selects between non-inverted and inverted GPIO input to the device.

0: selects non-inverted GPIO input

1: selects inverted GPIO input

Reading the register returns the current value of the register setting.

10.10.2.9 GPAODR Register (Offset = 12h) [Reset = 0000000h]

GPAODR is shown in [Figure 10-12](#) and described in [Table 10-21](#).

Return to the [Summary Table](#).

GPIO A Open Drain Output Register (GPIO0 to GPIO31)

Selects between normal and open-drain output for the GPIO pin.

0: Normal Output

1: Open Drain Output

Reading the register returns the current value of the register setting.

Note:

[1] In the Open Drain output mode, if the buffer is configured for output mode, a 0 value to be driven out comes out on the on the PAD while a 1 value to be driven out tri-states the buffer.

10.10.2.10 GPAAMSEL Register (Offset = 14h) [Reset = 00300000h]

GPAAMSEL is shown in [Figure 10-13](#) and described in [Table 10-22](#).

Return to the [Summary Table](#).

GPIO A Analog Mode Select register (GPIO0 to GPIO31)

Selects between digital and analog functionality for GPIO pins.

0: The analog function of the pin is disabled and the pin is capable of digital functions as specified by the other GPIO configuration registers

1: The analog function of the pin is enabled and the pin is capable of analog functions

Reading the register returns the current value of the register setting.

Note:

[1] This register and bits are only valid for GPIO signals that share analog function through a unified I/O pad. For all the IOs, the corresponding bits in these registers don't have any affect.

10.10.2.24 GPBDIR Register (Offset = 4Ah) [Reset = 0000000h]

GPBDIR is shown in [Figure 10-27](#) and described in [Table 10-36](#).

Return to the [Summary Table](#).

GPIO B Direction Register (GPIO32 to 63)

Controls direction of GPIO pins when the specified pin is configured in GPIO mode.

0: Configures pin as input.

1: Configures pin as output.

Reading the register returns the current value of the register setting.

10.10.2.25 GPBPUD Register (Offset = 4Ch) [Reset = FFFFFFFh]

GPBPUD is shown in [Figure 10-28](#) and described in [Table 10-37](#).

Return to the [Summary Table](#).

GPIO B Pull Up Disable Register (GPIO32 to 63)

Disables the Pull-Up on GPIO.

0: Enables the Pull-Up.

1: Disables the Pull-Up.

Reading the register returns the current value of the register setting.

Note:

[1] The Pull-Ups on the GPIO pins are disabled asynchronously when IORSn signal is low.

10.10.2.27 GPBODR Register (Offset = 52h) [Reset = 0000000h]

GPBODR is shown in [Figure 10-30](#) and described in [Table 10-39](#).

Return to the [Summary Table](#).

GPIO B Open Drain Output Register (GPIO32 to GPIO63)

Selects between normal and open-drain output for the GPIO pin.

0: Normal Output

1: Open Drain Output

Reading the register returns the current value of the register setting.

Note:

[1] In the Open Drain output mode, if the buffer is configured for output mode, a 0 value to be driven out comes out on the on the PAD while a 1 value to be driven out tri-states the buffer.

10.10.2.39 GPHMUX1 Register (Offset = 1C6h) [Reset = 0000000h]

GPHMUX1 is shown in [Figure 10-42](#) and described in [Table 10-51](#).

Return to the [Summary Table](#).

GPIO H Mux 1 Register (GPIO224 to 239)

Defines pin-muxing selection for GPIO.

Notes:

The respective GPyGMUXn.GPIOz must be configured prior to this register to avoid intermediate peripheral selects being mapped to the GPIO. Refer to GPIO chapter for more details.

10.10.2.41 GPHPUD Register (Offset = 1CCh) [Reset = FFFFFFFFh]

GPHPUD is shown in [Figure 10-44](#) and described in [Table 10-53](#).

Return to the [Summary Table](#).

GPIO H Pull Up Disable Register (GPIO224 to 255)

Disables the Pull-Up on GPIO.

0: Enables the Pull-Up.

1: Disables the Pull-Up.

Reading the register returns the current value of the register setting.

Note:

[1] The Pull-Ups on the GPIO pins are disabled asynchronously when IORSn signal is low.

2	GPIO226	R/W	0h	0: selects non-inverted GPIO input 1: selects inverted GPIO input Notes: [1] Reading the register returns the current value of the register setting. Reset type: SYSRSn
1	GPIO225	R/W	0h	0: selects non-inverted GPIO input 1: selects inverted GPIO input Notes: [1] Reading the register returns the current value of the register setting. Reset type: SYSRSn
0	GPIO224	R/W	0h	0: selects non-inverted GPIO input 1: selects inverted GPIO input Notes: [1] Reading the register returns the current value of the register setting. Reset type: SYSRSn

10.10.2.43 GPHAMSEL Register (Offset = 1D4h) [Reset = FFFFFFFFh]

GPHAMSEL is shown in [Figure 10-46](#) and described in [Table 10-55](#).

Return to the [Summary Table](#).

GPIO H Analog Mode Select register (GPIO224 to GPIO255)

Selects between digital and analog functionality for GPIO pins.

0: The analog function of the pin is disabled and the pin is capable of digital functions as specified by the other GPIO configuration registers

1: The analog function of the pin is enabled and the pin is capable of analog functions

Reading the register returns the current value of the register setting.

Note:

[1] This register and bits are only valid for GPIO signals that share analog function through a unified I/O pad. For all the IOs, t

10.10.3 GPIO_DATA_REGS Registers

Table 10-64 lists the memory-mapped registers for the GPIO_DATA_REGS registers. All register offset addresses not listed in Table 10-64 should be considered as reserved locations and the register contents should not be modified.

Table 10-64. GPIO_DATA_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	GPADAT	GPIO A Data Register (GPIO0 to 31)		Go
2h	GPASET	GPIO A Data Set Register (GPIO0 to 31)		Go
4h	GPACLEAR	GPIO A Data Clear Register (GPIO0 to 31)		Go
6h	GPATOGGLE	GPIO A Data Toggle Register (GPIO0 to 31)		Go
8h	GPBDAT	GPIO B Data Register (GPIO32 to 63)		Go
Ah	GPBSET	GPIO B Data Set Register (GPIO32 to 63)		Go
Ch	GPBCLEAR	GPIO B Data Clear Register (GPIO32 to 63)		Go
Eh	GPBTOGGLE	GPIO B Data Toggle Register (GPIO32 to 63)		Go
38h	GPHDAT	GPIO H Data Register (GPIO224 to 255)		Go

Complex bit access types are encoded to fit into small table cells. Table 10-65 shows the codes that are used for access types in this section.

Table 10-65. GPIO_DATA_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

10.10.3.1 GPADAT Register (Offset = 0h) [Reset = 0000000h]

GPADAT is shown in [Figure 10-55](#) and described in [Table 10-66](#).

Return to the [Summary Table](#).

GPIO A Data Register (GPIO0 to 31)

Reading this register indicates the current status of the GPIO pin, irrespective of which mode the pin is in. Writing to this register will set the GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero.

DESIGNER NOTE:

[1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the GPIODAT register.

10.10.3.5 GPBDAT Register (Offset = 8h) [Reset = 0000000h]

GPBDAT is shown in [Figure 10-59](#) and described in [Table 10-70](#).

Return to the [Summary Table](#).

GPIO B Data Register (GPIO32 to 63)

Reading this register indicates the current status of the GPIO pin, irrespective of which mode the pin is in. Writing to this register will set the GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero.

DESIGNER NOTE:

[1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the GPIODAT register.

10.10.3.9 GPHDAT Register (Offset = 38h) [Reset = 0000000h]

GPHDAT is shown in [Figure 10-63](#) and described in [Table 10-74](#).

Return to the [Summary Table](#).

GPIO H Data Register (GPIO224 to 255)

Reading this register indicates the current status of the GPIO pin, irrespective of which mode the pin is in. Writing to this register will set the GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero.

DESIGNER NOTE:

[1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the

Writing to this register will set this GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero. DESIGNER NOTE: [1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the GPIODAT register. Reset type: SYSRSn

10.10.4 GPIO_DATA_READ_REGS Registers

Table 10-75 lists the memory-mapped registers for the GPIO_DATA_READ_REGS registers. All register offset addresses not listed in Table 10-75 should be considered as reserved locations and the register contents should not be modified.

Table 10-75. GPIO_DATA_READ_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	GPADAT_R	GPIO A Data Read Register		Go
2h	GPBDAT_R	GPIO B Data Read Register		Go
Eh	GPHDAT_R	GPIO H Data Read Register		Go

Complex bit access types are encoded to fit into small table cells. Table 10-76 shows the codes that are used for access types in this section.

Table 10-76. GPIO_DATA_READ_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

10.10.4.1 GPADAT_R Register (Offset = 0h) [Reset = 00000000h]

The crossbars (referred to as X-BAR throughout this chapter) provide flexibility to connect device inputs, outputs, and internal resources in a variety of configurations.

The device contains a total of six X-BARs:

- Input X-BAR
- CLB Input X-BAR
- Output X-BAR
- CLB Output X-BAR
- CLB X-BAR
- ePWM X-BAR

Each of the X-BARs is named according to where the X-BAR takes signals. For example, the Input X-BAR and CLB Input X-BAR bring external signals “in” to the device. The Output X-BAR and CLB Output X-BAR take internal signals “out” of the device to a GPIO. The CLB X-BAR and ePWM X-BAR take signals to the CLB and ePWM modules, respectively.

11.1 Input X-BAR and CLB Input X-BAR	1238
11.2 ePWM, CLB, and GPIO Output X-BAR	1242
11.3 XBAR Registers	1252

11.1 Input X-BAR and CLB Input X-BAR

On this device, the Input X-BAR is used to route signals from a GPIO to many different IP blocks such as the ADC, eCAP, ePWM, and external interrupts. The input of each Input X-BAR instance (INPUTx) can be any GPIO, while the output of each instance connects to various IP blocks in the device. The digital input of AIOs are also available as inputs to the Input X-BAR. This flexibility relieves some of the constraints on peripheral muxing by allowing the user to connect any GPIO to the specified outputs of each Input X-BAR instance. Note that the GPIO selected by the Input X-BAR can be configured as either an input or an output. The Input X-BAR simply connects the signal on the input buffer to the output of the selected Input X-BAR instance. Therefore, you can do things such as route the output of an ePWM to the eCAP module for a frequency test).

The Input X-BAR is configured by way of the INPUTxSELECT registers. The destinations for each INPUTx are shown in [Figure 11-1](#) and [Table 11-1](#). For additional details on how each Input X-BAR connects to other IP blocks throughout the device, look for references to Input X-BAR in the chapter associated with that IP. Note that the destinations of each INPUTx are fixed and are not user-configurable. For more information on configuring the Input X-BAR, see the INPUT_XBAR_REGS register definitions in the *XBAR Registers* section.

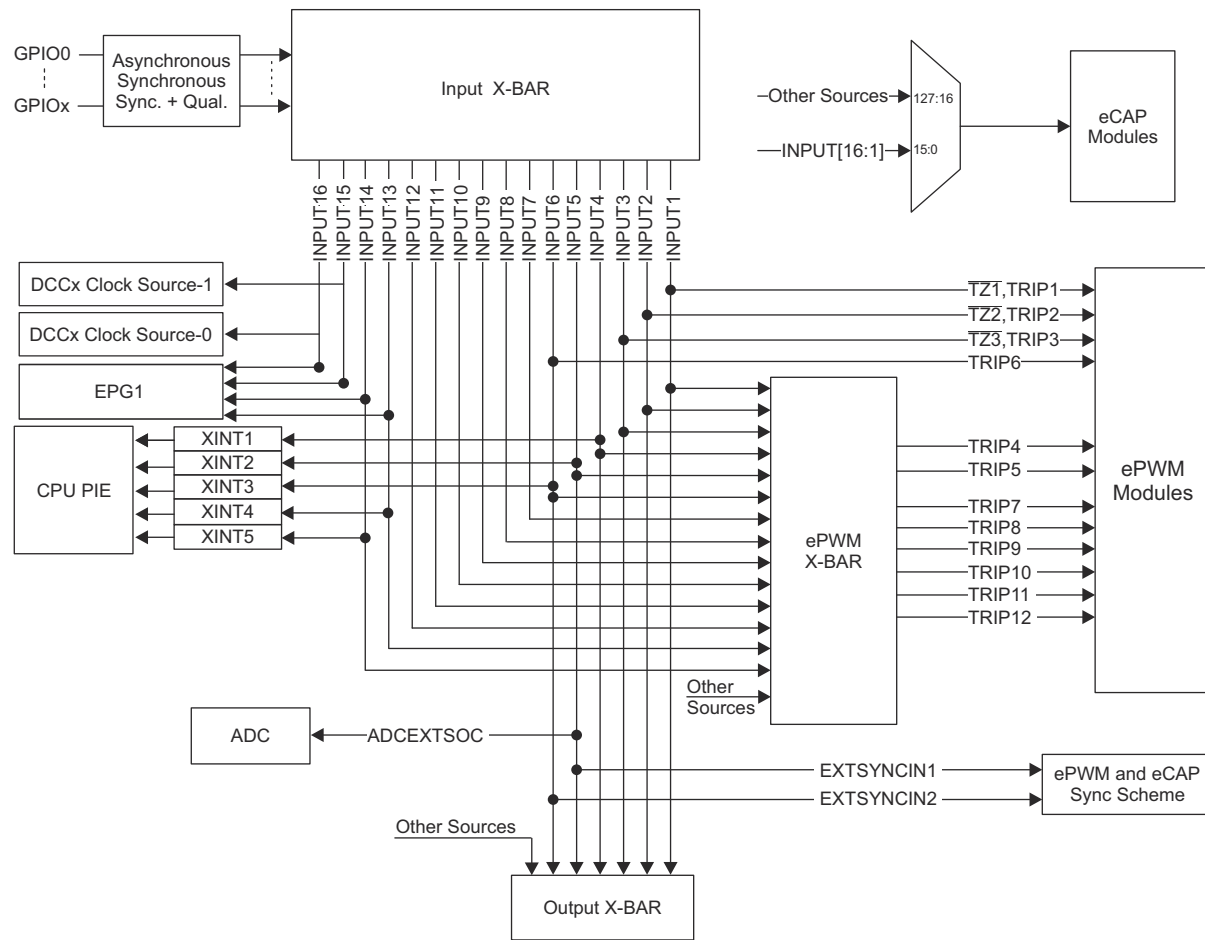

Figure 11-1. Input X-BAR

Note

INPUTXBARx, INPUTXBAR_INPUTx, and INPUTx (when referenced in the context of Input X-BAR) are equivalent in all C2000 software and documentation.

Table 11-1. Input X-BAR Destinations

16	Yes	-	-	-	-	-	-	-	CLK0	EPG1IN4	Yes

11.1.1 CLB Input X-BAR

The CLB Input X-BAR is architecturally identical to the Input X-BAR. The only difference is the destination for each INPUTx. The destination for each INPUTx is only the CLB Tiles as shown in [Table 11-2](#). This allows for GPIOs to be accessed by the CLB tiles without using the combination of Input X-BAR and CLB X-BAR.

Note

Signals routed into the CLB using the XBAR must be synchronized within the CLB.

11.2 ePWM, CLB, and GPIO Output X-BAR

This section describes the ePWM, CLB, and GPIO Output X-BAR. .

11.2.1 ePWM X-BAR

The ePWM X-BAR brings signals to the ePWM modules. Specifically, the ePWM X-BAR is connected to the Digital Compare (DC) submodule of each ePWM module for actions such as tripzones and syncing. Refer to the *Enhanced Pulse Width Modulator (ePWM)* chapter for more information on additional ways the DC submodule can be used. Figure 11-2 shows the architecture of the ePWM X-BAR. Note that the architecture of the ePWM X-BAR is identical to the architecture of the GPIO Output X-BAR (with the exception of the output latch).

11.2.1.1 ePWM X-BAR Architecture

The ePWM X-BAR has eight outputs that are routed to each ePWM module. Figure 11-2 represents the architecture of a single output, but this output is identical to the architecture of all of the other outputs.

First, determine the signals that can be passed to the ePWM by referencing Table 11-3. Select up to one signal per mux for each TRIPx output. Select the inputs to ePWM X-BAR using the TRIPxMUX0TO15CFG and TRIPxMUX16TO31CFG registers. To pass any signal through to the ePWM, enable the signal using the TRIPxMUXENABLE register. All signals that are enabled are logically ORed before being passed on to the respective TRIPx signal on the ePWM. To optionally invert the signal, use the TRIPOUTINV register.

Figure 11-2. ePWM X-BAR Architecture - Single Output

Note

Do not use "Reserved" signals in your application.

11.2.2 CLB X-BAR

The CLB X-BAR brings signals to the CLB modules. [Figure 11-3](#) shows the architecture of the CLB X-BAR. Note that the architecture of the CLB X-BAR is identical to the architecture of the GPIO Output X-BAR (with the exception of the output latch).

11.2.2.1 CLB X-BAR Architecture

The CLB X-BAR has eight outputs that are routed to each CLB module. [Figure 11-3](#) represents the architecture of a single output, but the output is identical to the architecture of all of the other outputs.

First, determine the signals that can be passed to the CLB by referencing [Table 11-4](#). Select up to one signal per mux (31 total muxes) for each AUXSIGx output. Select the inputs to each mux using the AUXSIGxMUX0TO15CFG and AUXSIGxMUX16TO31CFG registers. To pass any signal through to the CLB, enable the mux in the AUXSIGxMUXENABLE register. All muxes that are enabled are logically ORed before being passed on to the respective AUXSIGx signal on the CLB. To optionally invert the signal, use the AUXSIGOUTINV register.

11.2.3 GPIO Output X-BAR

The GPIO Output X-BAR takes signals from inside the device and brings them out to a GPIO. Figure 11-5 shows the architecture of the GPIO Output X-BAR. The X-BAR contains eight outputs and each contains at least one position on the GPIO mux, denoted as OUTPUTXBARx. The X-BAR allows the selection of a single signal or a logical-OR of up to 32 signals.

11.2.3.1 GPIO Output X-BAR Architecture

The GPIO Output X-BAR has eight outputs that are routed to the GPIO module. Figure 11-5 represents the architecture of a single output, but this output is identical to the architecture of all of the other outputs. Note that the architecture of the Output X-BAR (with the exception of the output latch) is similar to the architecture of the ePWM X-BAR.

First, determine the signals that can be passed to the GPIO by referencing Table 11-5. Select up to one signal per mux (32 total muxes) for each OUTPUTXBARx output. Select the inputs to each mux using the OUTPUTxMUX0TO15CFG and OUTPUTxMUX16TO31CFG registers. To pass any signal through to the GPIO, enable the mux in the OUTPUTxMUXENABLE register. All muxes that are enabled are logically ORed before being passed on to the respective OUTPUTx signal on the GPIO module. To optionally invert the signal, use the OUTPUTINV register. The signal is only recognized on the GPIO, if the proper OUTPUTx muxing options are selected using the GpioCtrlRegs.GPxMUX and GpioCtrlRegs.GPxGMUX registers.

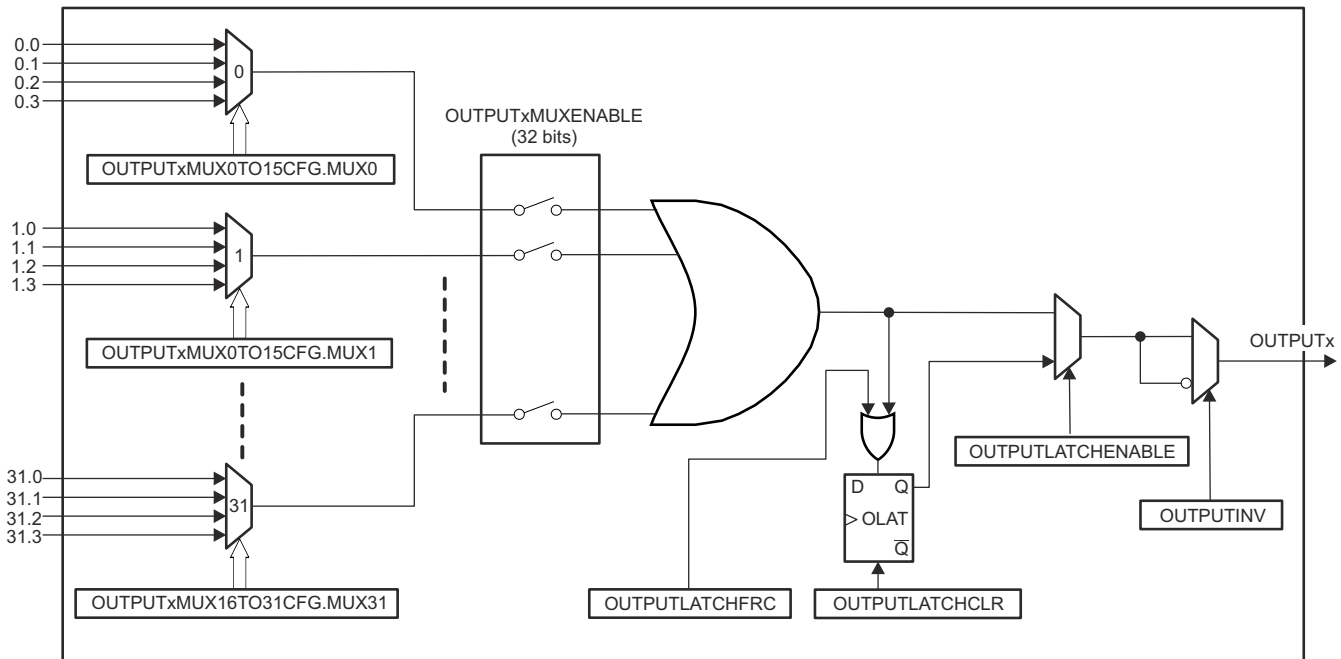

Figure 11-5. GPIO Output X-BAR Architecture

Note

Do not use "Reserved" signals in your application.

11.2.5 X-BAR Flags

With the exception of the CMPSS signals, the ePWM X-BAR and the Output X-BAR have all of the same input signals. Due to the inputs being similar between the ePWM X-BAR, CLB X-BAR, and Output X-BAR, all X-BAR modules leverage a single set of input flags to indicate which input signals have been triggered. This allows software to check the input flags when an event occurs. See [Figure 11-6](#) for more information. There is a bit allocated for each input signal in one of the XBARFLGx registers. The flag remains set until cleared through the appropriate XBARCLR_x register.

Note

Not all input sources are routed to all X-BAR modules. Refer to the X-BAR specific configuration tables for exact connections.

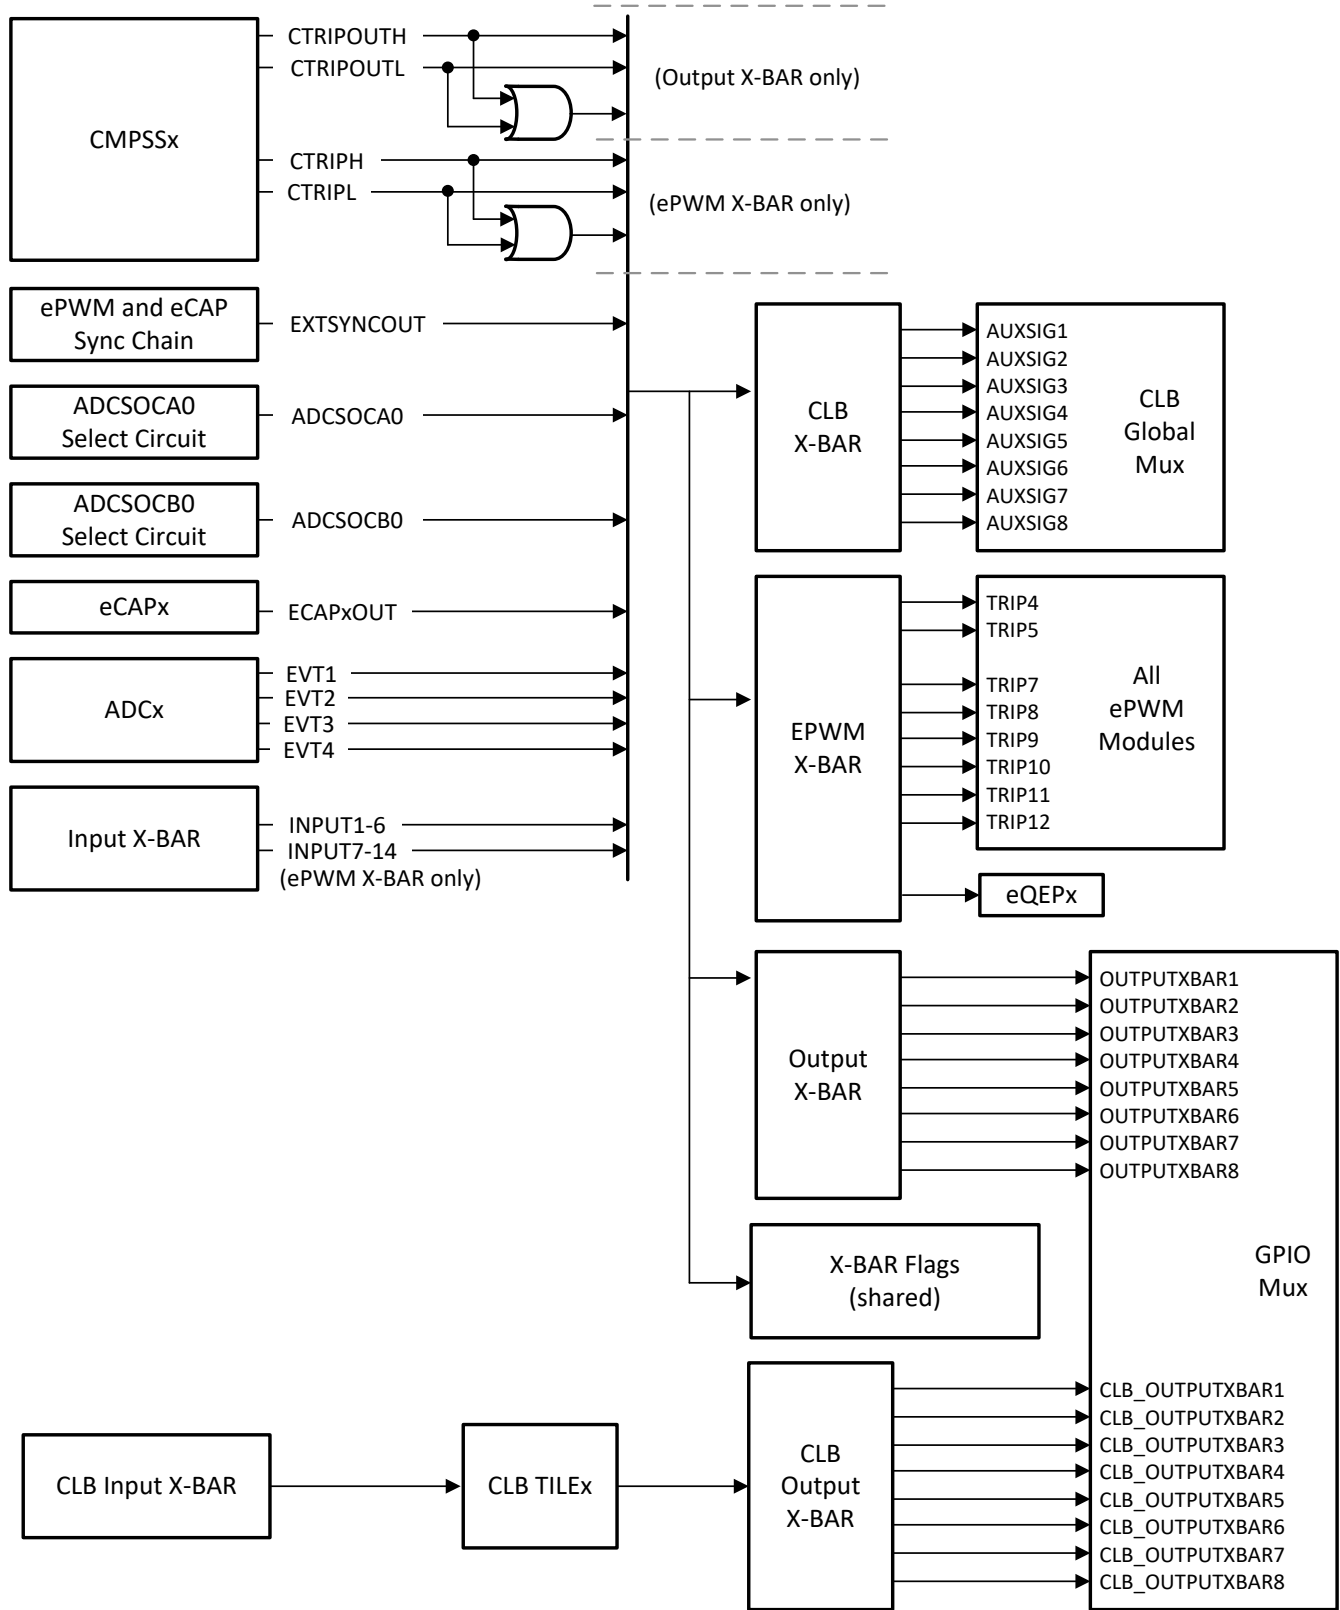

Figure 11-6. X-BAR Input Sources

11.3 XBAR Registers

This section describes the Crossbar registers.

11.3.1 XBAR Base Address Table

Table 11-7. XBAR Base Address Table

Bit Field Name		DriverLib Name	Base Address	CPU1	DMA	HIC	CLA	Pipeline Protected
Instance	Structure

Complex bit access types are encoded to fit into small table cells. Table 11-9 shows the codes that are used for access types in this section.

Table 11-9. INPUT_XBAR_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
WOnce	W Once	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

11.3.2.1 INPUT1SELECT Register (Offset = 0h) [Reset = FFFEh]

11.3.2.17 INPUTSELECTLOCK Register (Offset = 1Eh) [Reset = 0000000h]

INPUTSELECTLOCK is shown in [Figure 11-23](#) and described in [Table 11-26](#).

Return to the [Summary Table](#).

Input Select Lock Register.

Any bit in this register, once set can only be cleared through SYSRSn. Write of 0 to any bit of this register has no effect. Reads to the registers which have LOCK protection are always allowed.

11.3.3 XBAR_REGS Registers

Table 11-27 lists the memory-mapped registers for the XBAR_REGS registers. All register offset addresses not listed in Table 11-27 should be considered as reserved locations and the register contents should not be modified.

Table 11-27. XBAR_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	XBARFLG1	X-Bar Input Flag Register 1		Go
2h	XBARFLG2	X-Bar Input Flag Register 2		Go
4h	XBARFLG3	X-Bar Input Flag Register 3		Go
6h	XBARFLG4	X-Bar Input Flag Register 4		Go
8h	XBARCLR1	X-Bar Input Flag Clear Register 1		Go
Ah	XBARCLR2	X-Bar Input Flag Clear Register 2		Go
Ch	XBARCLR3	X-Bar Input Flag Clear Register 3		Go
Eh	XBARCLR4	X-Bar Input Flag Clear Register 4		Go

Complex bit access types are encoded to fit into small table cells. Table 11-28 shows the codes that are used for access types in this section.

Table 11-28. XBAR_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

11.3.3.1 XBARFLG1 Register (Offset = 0h) [Reset = 0000000h]

XBARFLG1 is shown in [Figure 11-24](#) and described in [Table 11-29](#).

Return to the [Summary Table](#).
