Complex bit access types are encoded to fit into small table cells. Table 16-63 shows the codes that are used for access types in this section.

**Table 16-63. INPUT\_XBAR\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WOnce	W Once	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 16.3.3.17 INPUTSELECTLOCK Register (Offset = 1Eh) [Reset = 0000000h]

INPUTSELECTLOCK is shown in [Figure 16-74](#) and described in [Table 16-80](#).

Return to the [Summary Table](#).

Input Select Lock Register.

Any bit in this register, once set can only be cleared through SYSRSn. Write of 0 to any bit of this register has no effect. Reads to the registers which have LOCK protection are always allowed.

Complex bit access types are encoded to fit into small table cells. Table 16-82 shows the codes that are used for access types in this section.

**Table 16-82. XBAR\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s

**Table 16-82. XBAR\_REGS Access Type Codes (continued)**

Access Type	Code	Description
Write Type		
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 16.3.4.1 XBARFLG1 Register (Offset = 0h) [Reset = 0000000h]

XBARFLG1 is shown in [Figure 16-75](#) and described in [Table 16-83](#).

Return to the [Summary Table](#).

This register is used to flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered.

### 16.3.4.32 XBARCLR16 Register (Offset = 3Eh) [Reset = 0000000h]

XBARCLR16 is shown in [Figure 16-106](#) and described in [Table 16-114](#).

Return to the [Summary Table](#).

This register is used to clear the flag(s) in the XBARFLG register.

1: Clears the corresponding bit in the XBARFLG register.

0: Writing 0 has no effect

Complex bit access types are encoded to fit into small table cells. Table 16-116 shows the codes that are used for access types in this section.

**Table 16-116. MINDB\_XBAR\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WOnce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

Complex bit access types are encoded to fit into small table cells. Table 16-135 shows the codes that are used for access types in this section.

**Table 16-135. ICL\_XBAR\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WOnce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
WOnce	W Once	Write Set once
Reset or Default Value		
-n		Value after reset or the default value

Access Type	Code	Description
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

Complex bit access types are encoded to fit into small table cells. [Table 16-182](#) shows the codes that are used for access types in this section.

**Table 16-182. OUTPUT\_XBAR\_EXT64\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1S	W1S	Write 1 to set
WOnce	WOnce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

19	MUX19	R/W	0h	Selects the output of Mux19 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux19 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux19 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
18	MUX18	R/W	0h	Selects the output of Mux18 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux18 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux18 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
17	MUX17	R/W	0h	Selects the output of Mux17 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux17 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux17 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
16	MUX16	R/W	0h	Selects the output of Mux16 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux16 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux16 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
15	MUX15	R/W	0h	Selects the output of Mux15 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux15 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux15 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
14	MUX14	R/W	0h	Selects the output of Mux14 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux14 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux14 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
13	MUX13	R/W	0h	Selects the output of Mux13 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux13 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux13 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
12	MUX12	R/W	0h	Selects the output of Mux12 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux12 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux12 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

11	MUX11	R/W	0h	Selects the output of Mux11 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux11 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux11 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
10	MUX10	R/W	0h	Selects the output of Mux10 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux10 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux10 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
9	MUX9	R/W	0h	Selects the output of Mux9 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux9 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux9 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
8	MUX8	R/W	0h	Selects the output of Mux8 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux8 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux8 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
7	MUX7	R/W	0h	Selects the output of Mux7 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux7 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux7 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
6	MUX6	R/W	0h	Selects the output of Mux6 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux6 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux6 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5	MUX5	R/W	0h	Selects the output of Mux5 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux5 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux5 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
4	MUX4	R/W	0h	Selects the output of Mux4 to drive OUTPUT1 of OUTPUT-XBAR 0: Respective output of Mux4 is disabled to drive the OUTPUT1 of OUTPUT-XBAR 1: Respective output of Mux4 is enabled to drive the OUTPUT1 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

19	MUX19	R/W	0h	Selects the output of Mux19 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux19 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux19 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
18	MUX18	R/W	0h	Selects the output of Mux18 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux18 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux18 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
17	MUX17	R/W	0h	Selects the output of Mux17 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux17 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux17 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
16	MUX16	R/W	0h	Selects the output of Mux16 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux16 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux16 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
15	MUX15	R/W	0h	Selects the output of Mux15 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux15 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux15 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
14	MUX14	R/W	0h	Selects the output of Mux14 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux14 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux14 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
13	MUX13	R/W	0h	Selects the output of Mux13 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux13 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux13 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
12	MUX12	R/W	0h	Selects the output of Mux12 to drive OUTPUT6 of OUTPUT-XBAR 0: Respective output of Mux12 is disabled to drive the OUTPUT6 of OUTPUT-XBAR 1: Respective output of Mux12 is enabled to drive the OUTPUT6 of OUTPUT-XBAR Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Chapter 17  
**Analog Subsystem**

---

The analog subsystem module is described in this chapter.

<b>17.1 Introduction</b> .....	<b>3150</b>
<b>17.2 Optimizing Power-Up Time</b> .....	<b>3156</b>
<b>17.3 Digital Inputs on ADC Pins (AIOs)</b> .....	<b>3157</b>
<b>17.4 Digital Inputs and Outputs on ADC Pins (AGPIOs)</b> .....	<b>3157</b>
<b>17.5 Analog Subsystem Registers</b> .....	<b>3158</b>

## 17.1 Introduction

The analog modules on this device include the Analog-to-Digital Converter (ADC), Temperature Sensor, Buffered Digital-to-Analog Converter (DAC), and Comparator Subsystem (CMPSS).

### 17.1.1 Features

The analog subsystem has the following features:

- Flexible voltage references:
  - The ADCs are referenced to VREFHix and VREFLOx pins.
    - VREFHIA pin voltage can be driven in externally or can be generated by an internal bandgap voltage reference. VREFHIB and VREFHIC can be connected to the internal reference using an external on-board connection.
    - The internal voltage reference range can be selected to be 0V to 3.3V or 0V to 2.5V.
  - The buffered DACs are referenced to VREFHix and VSSA
    - Alternately, these DACs can be referenced to the VDAC pin and VSSA
  - The comparator DACs are referenced to VDDA and VSSA
    - Alternately, these DACs can be referenced to the VDAC pin and VSSA
- Flexible pin usage
  - Buffered DAC outputs, comparator subsystem inputs, and digital inputs (AIOs)/outputs (AGPIOs) are multiplexed with ADC inputs
  - Internal connection to  $V_{REFLO}$  on ADCA and ADCC for offset self-calibration

### 17.1.2 Block Diagram

The following analog subsystem block diagrams show the connections between the different integrated analog modules to the device pins. These pins fall into two categories: analog module inputs/outputs and reference pins.

The reference pins, VREFHIA to VREFHIC and VREFLOA to VREFLOC, can be used to supply an external voltage reference to the associated ADCs. VREFHIA can also be used to supply the voltage reference to DAC A, and VREFHIB can be used to supply the voltage reference to DAC C. An internal voltage reference is available and connects to VREFHIA. To use the internal voltage reference on ADC B, ADC C or DAC C, connect VREFHIA to VREFHIB and/or VREFHIC externally.

The VDAC reference pin can be used to set an alternate range for DAC A and DAC C, and for the DACs inside the CMPSS modules (the CMPSS DACs are referenced to VDDA and VSSA by default). Using this pin as a reference prevents the channel from being used as an ADC input (but the ADC can be used to sample the VDAC voltage, if desired). The choice of reference is configurable per module for each CMPSS or buffered DAC; the selection is made using the module's configuration registers.

Some analog pins support digital functionality through muxed AIOs and AGPIOs. AIOs only support digital input functionality, while AGPIOs support full digital input and output functionality.

The following notes apply to all packages:

- Not all analog pins are available on all devices. See the device data sheet to determine which pins are available.
- See the device data sheet to determine the allowable voltage range for VREFHI and VREFLO.
- An external capacitor is required on the VREFHI pins. See the device data sheet for the specific value required.
- For buffered DAC modules, VSSA is the low reference whether VREFHix or VDAC is selected as the high reference.
- For CMPSS modules, VSSA is the low reference whether VDAC or VDDA is selected as the high reference.

---

#### Note

If all ADCs are operating in internal VREF mode, then VREFHIA, VREFHIB, and VREFHIC must be manually connected externally.

---

Figure 17-1. Analog System Block Diagram (ADC A, ADC B, and ADC C)

Input connections to the CMPSS modules are selectable through a programmable input mux. Figure 17-2 shows the CMPSS input connections. Table 17-1 shows the mapping of ADC input signals to CMPSS mux inputs.

- To configure the CPH\_POSIN input mux for CMPSSx, write to the CMPxHPMXSEL field in the CMPHPMXSEL or CMPHPMXSEL1 analog subsystem register.
- To configure the CPH\_NEGIN input mux for CMPSSx, write to the CMPxHNMXSEL field in the CMPHNMXSEL analog subsystem register.
- To configure the CPL\_POSIN input mux for CMPSSx, write to the CMPxLPMXSEL field in the CMPLPMXSEL or CMPLPMXSEL1 analog subsystem register.
- To configure the CPL\_NEGIN input mux for CMPSSx, write to the CMPxLNMXSEL field in the CMPLNMXSEL analog subsystem register.

## 17.2 Optimizing Power-Up Time

The analog-to-digital converters (ADC) and buffered digital-to-analog converters (DAC) share a common reference circuit. If needed, an application using one or more of these modules can optimize power-up time by taking advantage of the shared reference. Once one of the modules using the shared reference has been initialized in internal reference mode, the power-up time for subsequent modules can be optimized by subtracting the reference power-up time from the minimum power-up time requirement.

For instance, if ADCA requires  $t_{ADCPUINT}$  to power up in internal reference mode, and  $t_{ADCPUEXT}$  to power up in external reference mode, the application does not need to wait  $t_{ADCPUINT}$  to power up a second ADC instance such as ADCC in internal reference mode. In this case, the application can simply wait for  $t_{ADCPUEXT}$  after powering up ADCC, even though both ADCs are used in internal reference mode. In the same scenario, if the application wished to use DACA in internal reference mode, the required wait time after power-up is  $t_{DACPUEXT}$ , not the longer  $t_{DACPUINT}$ .

There is also a wait time associated with power-up in internal reference mode when switching between 2.5V and 3.3V range. See the device data sheet for wait time values.

### 17.3 Digital Inputs on ADC Pins (AIOs)

Some GPIOs are multiplexed with analog pins and only have digital input functionality. These are also referred to as AIOs. Pins with only an AIO option on this port can only function in input mode. See the device data sheet for list of AIO signals. By default, these pins function as analog pins and the GPIOs are in a high-impedance state. The GPyAMSEL register is used to configure these pins for digital or analog operation.

#### Note

If digital signals with sharp edges (high  $dv/dt$ ) are connected to the AIOs, cross-talk can occur with adjacent analog signals. Therefore, limit the edge rate of signals connected to AIOs if adjacent channels are being used for analog functions.

### 17.4 Digital Inputs and Outputs on ADC Pins (AGPIOs)

Some GPIOs are multiplexed with analog pins and have digital input and output functionality. These are also referred to as AGPIOs. Unlike AIOs, AGPIOs have full input and output capability. By default, the AGPIOs are not connected and must be configured. [Table 17-5](#) shows how to configure the AGPIOs. To enable the analog functionality, set the register AGPIOTRlX from analog subsystem. To enable the digital functionality, set the register GPxAMSEL from the *General-Purpose Input/Output (GPIO)* chapter.

**Table 17-5. AGPIO Configuration**

AGPIOTRlX.GPIOy (Default = 0)	GPxAMSEL.GPIOy (Default = 1)	Pin Connected To:	
		ADC	GPIOy
0	0	-	Yes
<b>0</b>	<b>1</b>	- <sup>(1)</sup>	- <sup>(1)</sup>
1	0	-	Yes
1	1	Yes	-

(1) By default there are no signals connected to AGPIO pins. One of the other rows in the table must be chosen for pin functionality.

#### Note

If digital signals with sharp edges (high  $dv/dt$ ) are connected to the AGPIOs, cross-talk can occur with adjacent analog signals. The user must therefore limit the edge rate of signals connected to AGPIOs, if adjacent channels are being used for analog functions.

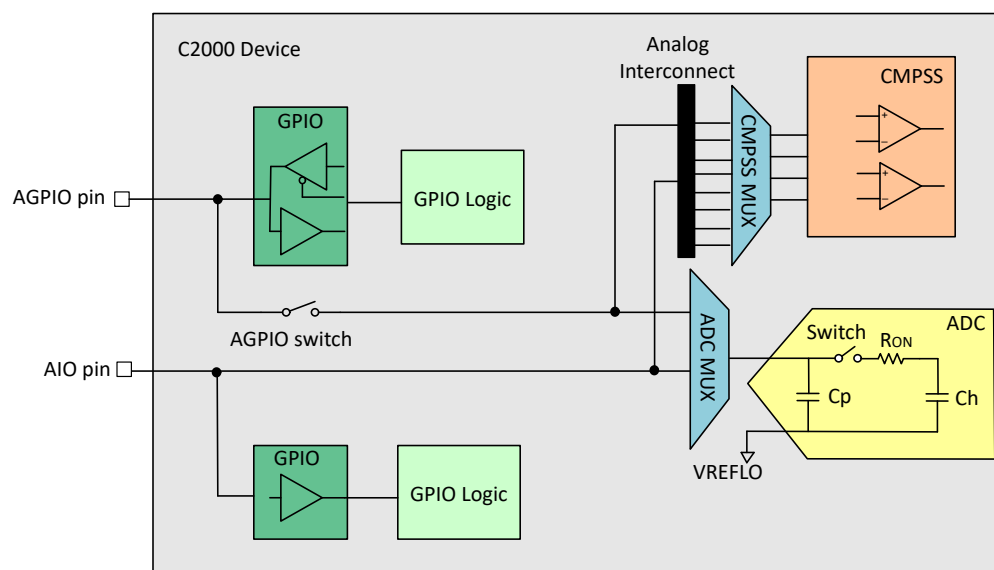

The general schematic of analog subsystem with AGPIO implementation is illustrated in [Figure 17-3](#). The combinations of use cases for a specific analog input pin need special consideration are shown in [Table 17-6](#). The AGPIO analog pin path contains an extra series switch of 53Ω. This creates a low capacitance isolated node shared by the ADC and CMPSS Comparator as shown in [Figure 17-3](#). This node can be disturbed when the ADC samples the channel (depending on the prior voltage stored on the ADC sample and hold capacitor), and this disturbance can cause a false CMPSS event of up to 50ns. As shown in [Table 17-6](#), special considerations or workarounds need to be used for the combination of CMPSS Input, ADC Sampling, and AGPIO. To accommodate this potential disturbance the following workarounds can be implemented:

1. Use a different pin (that is AIO pin type) for analog channels which need both ADC and CMPSS together.
2. Use the CMPSS Digital Filter with a setting of 50ns or greater, which filters the temporary disturbance.
3. Precondition the sample and hold capacitor of the ADC so the disturbance does not cause a false trip. For example, perform a dummy read of a 3.3V connection from a different channel on the ADC immediately before the impacted channel is read so the disturbance is in the positive direction, away from the false trip. The opposite dummy read of a 0V signal can be used if the false trip is inverted in polarity.

	Yes	-	Yes	-	Yes

**Analog-to-Digital Converter (ADC)**

---

The analog-to-digital converter (ADC) module described in this chapter is a Type 4 ADC. See the [C2000 Real-Time Control Peripheral Reference Guide](#) for a list of all devices with modules of the same type, to determine the differences between the types, and for a list of device-specific differences within a type.

## 18.1 Introduction

The ADC module is a successive approximation (SAR) style ADC with selectable resolution of either 16 bits or 12 bits. The ADC is composed of a core and a wrapper. The core is composed of the analog circuits which include the channel select MUX, the sample-and-hold (S/H) circuit, the successive approximation circuits, voltage reference circuits, and other analog support circuits. The wrapper is composed of the digital circuits that configure and control the ADC. These circuits include the logic for programmable conversions, result registers, interfaces to analog circuits, interfaces to the peripheral buses, post-processing circuits, and interfaces to other on-chip modules.

Each ADC module consists of a single sample-and-hold (S/H) circuit. The ADC module is designed to be duplicated multiple times on the same chip, allowing simultaneous sampling or independent operation of multiple ADCs. The ADC wrapper is start-of-conversion (SOC) based (see [Section 18.3](#)).

### 18.1.2 Features

Each ADC has the following features:

- Selectable resolution of 12 bits or 16 bits
- Ratiometric external reference set by VREFHI and VREFLO pins
- Selectable internal reference of 2.5V or 3.3V
- Differential signal conversions
- Single-ended signal conversions
- Input multiplexer with up to 26 channels (single-ended) or 10 channels (differential)
- External channel mux option to expand available ADC channels
- 16 configurable SOCs
- 16 individually addressable result registers
- Two trigger repeater modules, enabling customizable hardware oversampling and undersampling modes with little or no CPU overhead
- Multiple trigger sources
  - S/W (with available global synchronization for multiple ADCs) - software immediate start
  - All ePWMs - ADCSOC A or B
  - GPIO XINT2
  - CPU Timers 0/1/2 (from each C28x core present)
  - ADCINT1/2
  - ECAP events in capture mode (CEVT1, CEVT2, CEVT3, and CEVT4) and APWM mode (period match, compare match, or both)
- Four flexible PIE interrupts
- Configurable interrupt placement
- Burst mode
- Four post-processing blocks, each with:
  - Saturating offset calibration
  - Error from set-point calculation
  - High, low, and zero-crossing compare, with interrupt and ePWM trip capability
  - Trigger-to-sample delay capture
  - Aggregation functions: max, min, sum, and average (binary shift)
  - Absolute value function
- Result safety checkers to compare SOC results on same ADC or multiple ADC instances

---

#### Note

Not every channel is pinned out from all ADCs. Check the device data sheet to determine which channels are available.

### 18.1.3 Block Diagram

Figure 18-1 shows the block diagram for the ADC core and ADC wrapper.

Figure 18-1. ADC Module Block Diagram

#### Note

- The ADC block diagram reflects the number of ADC channels internally configurable on the device. The actual number of available external ADC inputs varies depending on part and package.

## 18.2 ADC Configurability

Some ADC configurations are individually controlled by the SOCs, while others are globally controlled per ADC module. [Table 18-1](#) summarizes the basic ADC options and the level of configurability. The subsequent sections discuss these configurations.

**Table 18-1. ADC Options and Configuration Levels**

Options	Configurability
Clock	Per module <sup>(1)</sup>
Resolution	Per module <sup>(1)</sup>
Signal mode	Per module
Reference voltage source	Per module (external or internal) <sup>(2)</sup>
Trigger source	Per SOC <sup>(1)</sup>
Converted channel	Per SOC
Acquisition window duration	Per SOC <sup>(1)</sup>
EOC location	Per module
Burst Mode	Per module <sup>(1)</sup>

- (1) Writing these values differently to different ADC modules can cause the ADCs to operate asynchronously. See [Section 18.14.1](#) for guidance on when the ADCs are operating synchronously or asynchronously.
- (2) Lower pin count packages can share one VREFHI pin among multiple ADCs. In this case, the ADCs that share a reference pin must have the reference modes configured identically

### 18.2.1 Clock Configuration

The base ADC clock is provided directly by the system clock (SYSCLK). SYSCLK is used to generate the ADC acquisition window. The register ADCCTL2 has a PRESCALE field that determines the ADCCLK. ADCCLK is used to clock the converter, and is only active during the conversion phase. At all other times, including during the sample-and-hold window, the ADCCLK signal is gated off.

In 16-bit mode, the core requires approximately 29.5 ADCCLK cycles to process a voltage into a conversion result, while in 12-bit mode, this process requires approximately 10.5 ADCCLK cycles. The choice of resolution also determines the necessary duration of the acquisition window, see [Section 18.14.2](#).

#### Note

To determine an appropriate value for ADCCTL2.PRESCALE, see the device data sheet to determine the maximum SYSCLK and ADCCLK frequency.

### 18.2.2 Resolution

The resolution of the ADC determines how finely the analog range is quantized into digital values. Each ADC module supports a configurable resolution of 16 bits or 12 bits.

The resolution can be configured by using either the `AdcSetMode()` or `ADC_setMode()` functions, depending on the header files used, provided in C2000ware. These functions make sure that the correct trim is loaded into the ADC trim registers, and must be called at least once after a device reset. Do not configure the resolution by directly writing to the ADCCTL2 register.

The resolution can be changed at any time when the ADC is idle (no active or pending SOCs). No wait time is necessary after changing the resolution before conversions can be initiated. If SOCs are active or pending when the resolution is changed, those SOCs can produce incorrect conversion results.

### 18.2.3 Voltage Reference

#### 18.2.3.1 External Reference Mode

Each ADC has a VREFHI input and a VREFLO input. In external reference mode, these pins are used as a ratiometric reference to determine the ADC conversion input range.

See [Section 18.14.6](#) for information on how to supply the reference voltage.

---

#### Note

- On devices with no external VREFLO pin, VREFLO is internally connected to the device analog ground, VSSA.
  - See the device data sheet to determine the allowable voltage range for VREFHI and VREFLO.
  - The external reference mode requires an external capacitor on the VREFHI pin. See the device data sheet for the specific value required.
- 

#### 18.2.3.2 Internal Reference Mode

In internal reference mode, the device drives a voltage out onto the VREFHI pin. The VREFHI and VREFLO pins then set the ADC conversion range.

The internal reference voltage can be configured to be either 2.5V or 1.65V. When the 1.65V internal reference voltage is selected, the ADC input signal is internally divided by 2 before conversion, which effectively makes the ADC conversion range from VREFLO to 3.3V.

The 1.65V internal reference mode is not supported when the ADC is configured for 16-bit resolution.

---

#### Note

The internal reference mode also requires an external capacitor on the VREFHI pin. See the device data sheet for the specific value required.

---

#### 18.2.3.3 Ganged References

On some packages, the voltage reference pins for multiple ADCs can be combined. In this case, configure the ganged references identically when selecting external versus internal reference mode and for selecting an internal reference voltage range of 3.3V or 2.5V.

For example, if ADC A and ADC B reference pins are combined and the desired reference mode is 2.5V internal reference mode, the following reference configuration code can be run:

```
//ADCA VREFHI and ADCB VREFHI share a pin
//ADCA VREFLO and ADCB VREFLO share a pin
//Both references must be explicitly configured
//Both references must be configured identically
SetVREF(ADC_ADCA, ADC_INTERNAL, ADC_VREF2P5);
SetVREF(ADC_ADCB, ADC_INTERNAL, ADC_VREF2P5);
```

Internal device hardware makes sure multiple references do not drive conflicting voltages onto the same pin. Because of this, references can be configured in any order or over any amount of time.

#### 18.2.3.4 Selecting Reference Mode

The voltage reference mode must be configured by using either the ADC\_setVREF() or the SetVREF() functions, depending on the header files used, provided in C2000Ware. Using either of these functions makes sure that the correct trim is loaded in the ADC trim registers. This function must be called at least once after a device reset. Do not configure the voltage reference mode by directly writing to the ANAREFCTL register.

### 18.2.4 Signal Mode

The ADC supports two signal modes: single-ended and differential.

In single-ended mode, the input voltage to the converter is sampled through a single pin (ADCINx), referenced to VREFLO.

In differential signaling mode, the input voltage to the converter is sampled through a pair of input pins, one of which is the positive input (ADCINxP) and the other is the negative input (ADCINxN). The actual input voltage is the difference between the two (ADCINxP – ADCINxN).

---

#### Note

- In differential signal mode, VREFLO must be connected to VSSA.
- In differential signal mode, the common mode voltage is  $V_{CM} = (ADCINxP + ADCINxN)/2$

The data sheet for a particular device places some requirements on how close this voltage needs to be to:  $(VREFHI + VREFLO)/2$

**Note:** The above condition is not met by connecting the negative input to VSSA or VREFLO.

- Differential signaling mode is advantageous because noise encountered on both inputs is largely canceled. The effect can be maximized by routing the positive and negative traces for the same differential input as close together as possible and keeping them symmetrical with respect to the signal reference.
- 

The signal mode must be configured by using either the ADC\_setMode() or AdcSetMode() functions, depending on the header files used, provided in C2000warein f28p65x\_adc.c. These functions make sure that the correct trim is loaded into the ADC trim registers. These functions must be called at least once after a device reset. The signal mode must not be configured by writing to the ADCCTL2 register directly.

### 18.2.5 Expected Conversion Results

Based on a given analog input voltage, the expected digital conversion is given in [Table 18-2](#) and [Table 18-3](#). Fractional values are truncated.

**Table 18-2. Analog to 12-bit Digital Formulas**

	Analog Input	Digital Result
<b>Single-Ended</b>	when $ADCINy \leq VREFLO$	$ADCRESULTx = 0$
	when $VREFLO < ADCINy < VREFHI$	$ADCRESULTx = 4096 \left( \frac{ADCINy - VREFLO}{VREFHI - VREFLO} \right)$
	when $ADCINy \geq VREFHI$	$ADCRESULTx = 4095$
<b>Differential</b>	when $ADCINyP - ADCINyN \leq -(VREFHI - VREFLO)$	$ADCRESULTx = 0$
	when $-(VREFHI - VREFLO) < ADCINyP - ADCINyN \leq (VREFHI - VREFLO)$	$ADCRESULTx = 4096 \left( \frac{ADCINyP - ADCINyN + VREFHI - VREFLO}{2(VREFHI - VREFLO)} \right)$
	when $ADCINyP - ADCINyN \geq (VREFHI - VREFLO)$	$ADCRESULTx = 4095$

**Table 18-3. Analog to 16-bit Digital Formulas**

	when $ADCINy \geq VREFHI$	$ADCRESULTx = 65535$
<b>Differential</b>	when $ADCINyP - ADCINyN \leq -(VREFHI - VREFLO)$	$ADCRESULTx = 0$
	when $-(VREFHI - VREFLO) < ADCINyP - ADCINyN \leq (VREFHI - VREFLO)$	$ADCRESULTx = 65536 \left( \frac{ADCINyP - ADCINyN + VREFHI - VREFLO}{2(VREFHI - VREFLO)} \right)$
	when $ADCINyP - ADCINyN \geq (VREFHI - VREFLO)$	$ADCRESULTx = 65535$

### 18.2.6 Interpreting Conversion Results

Based on a given ADC conversion result, the corresponding analog input is given in [Table 18-4](#) and [Table 18-5](#). This corresponds to the center of the possible range of analog voltages that can produce this conversion result.

**Table 18-4. 12-Bit Digital-to-Analog Formulas**

	Digital Value	Analog Equivalent
<b>Single-Ended</b>	when ADCRESULT <sub>y</sub> = 0	$ADCIN_x \leq VREFLO$ (2)
	when $0 < ADCRESULT_y < 4095$	$ADCIN_x = (VREFHI - VREFLO) \left( \frac{ADCRESULT_y}{4096} \right) + VREFLO$ (3)
	when ADCRESULT <sub>y</sub> = 4095	$ADCIN_x \geq VREFHI$ (4)
<b>Differential</b>	when ADCRESULT <sub>y</sub> = 0	$ADCIN_{xP} - ADCIN_{xN} \leq (VREFHI - VREFLO)$ (5)
	when $0 < ADCRESULT_y < 4095$	$ADCIN_{xP} - ADCIN_{xN} = (VREFHI - VREFLO) \left( \frac{ADCRESULT_y}{2048} - 1 \right)$ (6)
	when ADCRESULT <sub>y</sub> = 4095	$ADCIN_{xP} - ADCIN_{xN} \geq (VREFHI - VREFLO)$ (7)

**Table 18-5. 16-Bit Digital-to-Analog Formulas**

	Digital Value	Analog Equivalent
<b>Single-Ended</b>	when ADCRESULT <sub>y</sub> = 0	$ADCIN_x \leq VREFLO$ (8)
	when $0 < ADCRESULT_y < 65535$	$ADCIN_x = (VREFHI - VREFLO) \left( \frac{ADCRESULT_y}{65536} \right) + VREFLO$ (9)
	when ADCRESULT <sub>y</sub> = 65535	$ADCIN_x \geq VREFHI$ (10)
<b>Differential</b>	when ADCRESULT <sub>y</sub> = 0	$ADCIN_{xP} - ADCIN_{xN} \leq (VREFHI - VREFLO)$ (11)
	when $0 < ADCRESULT_y < 65535$	$ADCIN_{xP} - ADCIN_{xN} = (VREFHI - VREFLO) \left( \frac{ADCRESULT_y}{32768} - 1 \right)$ (12)
	when ADCRESULT <sub>y</sub> = 65535	$ADCIN_{xP} - ADCIN_{xN} \geq (VREFHI - VREFLO)$ (13)

### 18.3 SOC Principle of Operation

The ADC triggering and conversion sequencing is accomplished through configurable start-of-conversions (SOCs). Each SOC is a configuration set defining the single conversion of a single channel. In that set, there are three configurations: the trigger source that starts the conversion, the channel to convert, and the acquisition (sample) window duration. Upon receiving the trigger configured for a SOC, the wrapper makes sure that the specified channel is captured using the specified acquisition window duration.

Multiple SOCs can be configured for the same trigger, channel, and acquisition window as desired. Configuring multiple SOCs to use the same trigger allows the trigger to generate a sequence of conversions. Configuring multiple SOCs to use the same trigger and channel allows for oversampling. Oversampling can also be achieved using a single trigger source by configuring the trigger repeater module. See [Section 18.3.2.2](#) for more information.

Figure 18-2. SOC Block Diagram

### 18.3.1 SOC Configuration

Each SOC has a configuration register, ADCSOCxCTL. Within this register, SOCx can be configured for trigger source, channel to convert, optional external channel mux selection, and acquisition (sample) window duration.

### 18.3.2 Trigger Operation

Each SOC can be configured to start on one of many input triggers. The primary trigger select for SOCx is in the ADCSOCxCTL.TRIGSEL register, which can select between:

- Disabled (software only)
- CPU Timers 0/1/2 (from each C28x core present)
- GPIO: Input X-Bar INPUT5
- ADCSOCA or ADCSOCB from each ePWM module
- eCAP events
- Either of the two trigger repeater blocks. This can be used to achieve oversampling, undersampling, or to apply a trigger delay.
- A global synchronous software trigger. This is achieved by configuring the ADCSOCFRCGBSEL and ADCSOCFRCGB analog subsystem registers.

In addition, each SOC can also be triggered when the ADCINT1 flag or ADCINT2 flag is set. This is achieved by configuring the ADCINTSOCSEL1 register (for SOC0 to SOC7) or the ADCINTSOCSEL2 register (for SOC8 to SOC15). This is useful for creating continuous conversions.

### 18.3.2.1 Global Software Trigger

This ADC supports synchronous global software triggers. Synchronous global triggers allow the application to trigger SOC0s on multiple ADC instances that are exactly simultaneous in time. To generate a global software trigger, configure the analog subsystem register ADCSOCFRCGBSEL to select the ADC instances to be triggered, then write to ADCSOCFRCGB to trigger the desired SOC0s simultaneously on each ADC.

For example, to trigger SOC0, SOC1, and SOC2 on ADCA and ADCC:

1. Set ADCSOCFRCGBSEL.ADCA = 1 and ADCSOCFRCGBSEL.ADCC = 1 by writing 0x5 to the ADCSOCFRCGBSEL register.
2. Trigger SOC0s, 1, and 2 by writing 0x7 to the ADCSOCFRCGB register.

### 18.3.2.2 Trigger Repeaters

Each ADC instance contains two trigger repeater modules. These modules can select any of the regular ADC triggers that are selectable by the ADCSOCxCTL.TRIGGER register, and generate a number of repeat pulses as configured in the REPxN.NSEL register. [Figure 18-3](#) shows a functional block diagram of the ADC trigger repeater module.

Each repeater module can apply four types of trigger modifications:

- Oversampling mode
- Undersampling mode
- Phase delay
- Re-trigger spread

Each of these trigger modification features is explained in detail in the following sections.

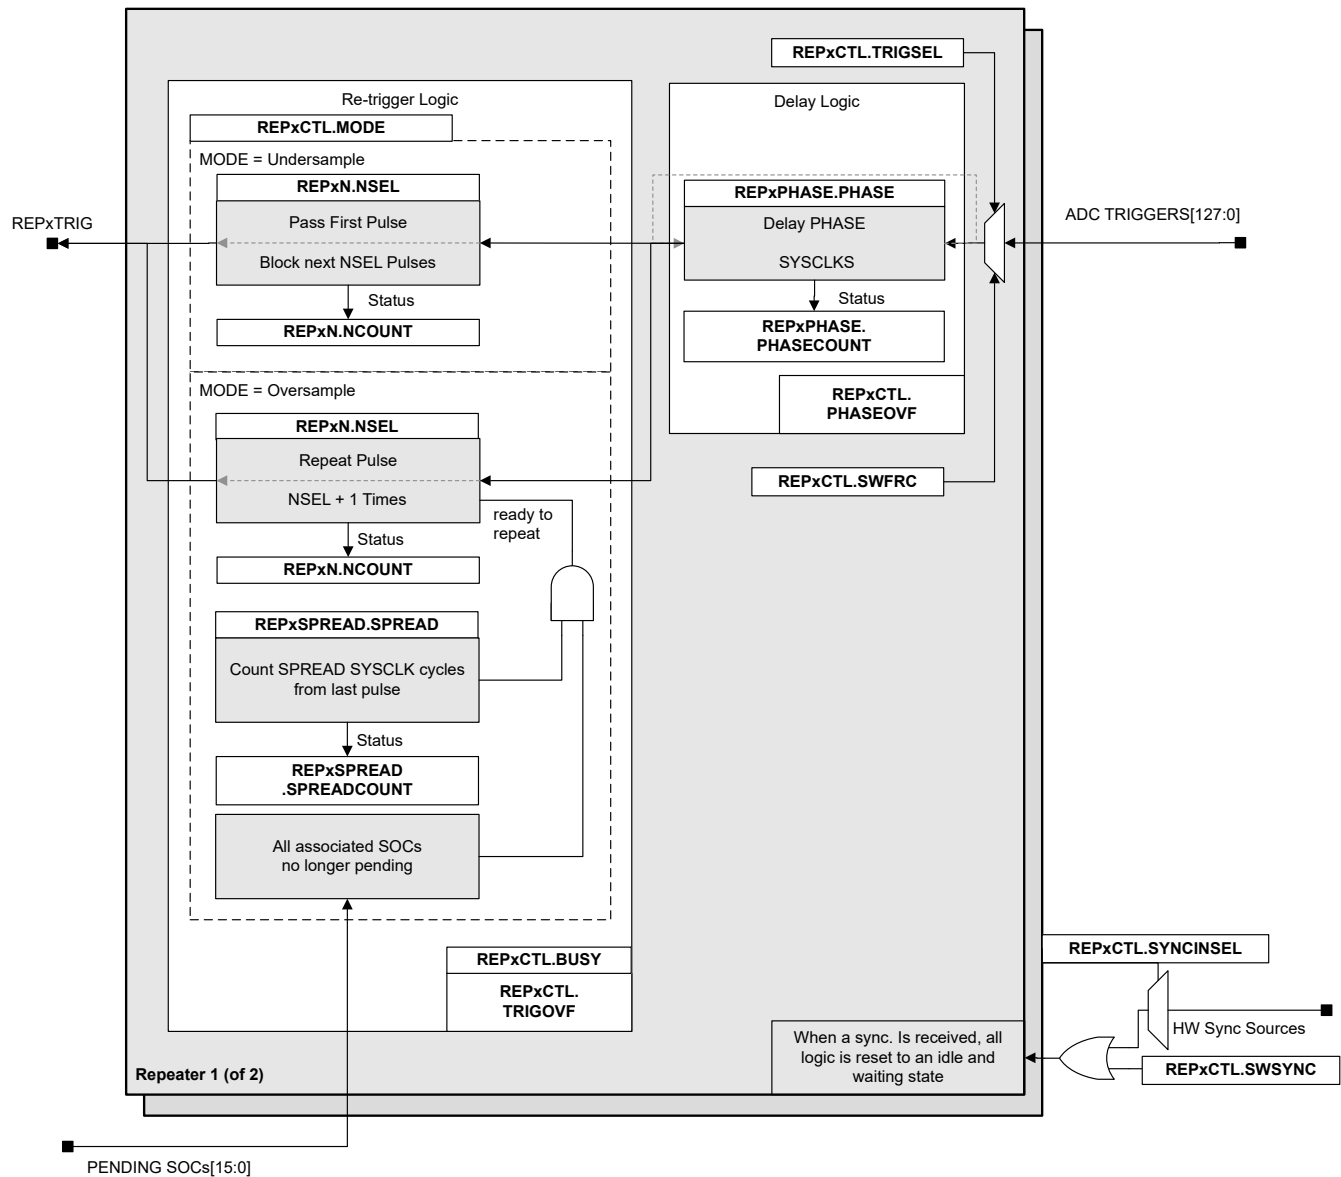

Figure 18-3. ADC Trigger Repeater Block Diagram

18.3.2.2.1 Oversampling Mode

In this mode, the repeater module passes the initial trigger through to the output. As soon as all SOCs configured to receive the trigger are in progress or completed, the repeater issues the trigger again. The process repeats until the configured number of trigger pulses (NSEL + 1) have been issued.

This mode allows the application to easily perform multiple back-to-back samples from a single trigger pulse. When used in conjunction with the aggregation options in the post-processing block, this mode enables oversampling, averaging, or peak detection. Figure 18-4 shows an example of oversampling SOCs generated from a single ePWM trigger.

TRIGGER = ePWM SOCA, NSEL = 3, PHASE = 0, MODE = Oversampling, SPREAD = 0

Figure 18-4. Oversampled ADC Trigger Example

### 18.3.2.2.2 Undersampling Mode

In this mode, the repeater module passes the initial trigger through to the output, and then blocks subsequent triggers until the configured number of trigger pulses (NSEL + 1) arrive. The result is that only 1 in every (NSEL + 1) pulses passes through to the output. [Figure 18-5](#) shows an example of undersampled SOCs from multiple ePWM triggers.

This mode enables the application to scale down the trigger frequency for one or more SOCs. This is useful for charge-sharing input drivers which have increased error with higher sampling frequencies.

TRIGGER = ePWM SOCA, NSEL = 7, PHASE = 0, MODE = Undersampling, SPREAD = (don't care)

**Figure 18-5. Undersampled ADC Trigger Example**

#### Note

Oversampling and undersampling modes are mutually exclusive for each repeater module. However, multiple repeater modules can (and are intended to) be used in different modes concurrently.

### 18.3.2.2.3 Trigger Phase Delay

The repeater module can delay the initial trigger by a specified number of SYSCLK cycles. This feature can be used in combination with oversampling or undersampling modes, or as a standalone delay by setting NSEL = 0. The phase delay does not affect the timing between subsequent repeated oversampled triggers—the phase delay only delays the initial trigger. When PHASE = 0, the initial trigger arrives at the same time as an unmodified trigger. [Figure 18-6](#) shows an example of phase delay combined with oversampling. [Figure 18-7](#) shows an example of a standalone phase delay with a single SOC trigger.

Phase delay enables the application to tie the trigger start point to an ePWM event while allowing for a necessary sampling delay (for example, settling time). In addition, when phase delay is combined with oversampling functionality, a single trigger can generate an interleaved burst of conversions across multiple ADCs. To achieve this, set PHASE in increments of  $(t_{\text{sample}}/n_{\text{interleaved\_ADCs}})$ . [Figure 18-8](#) shows an example of interleaving 12 samples across 3 ADCs.

TRIGGER = ePWM SOCA, NSEL = 3, PHASE = 100, MODE = Oversampling, SPREAD = 0

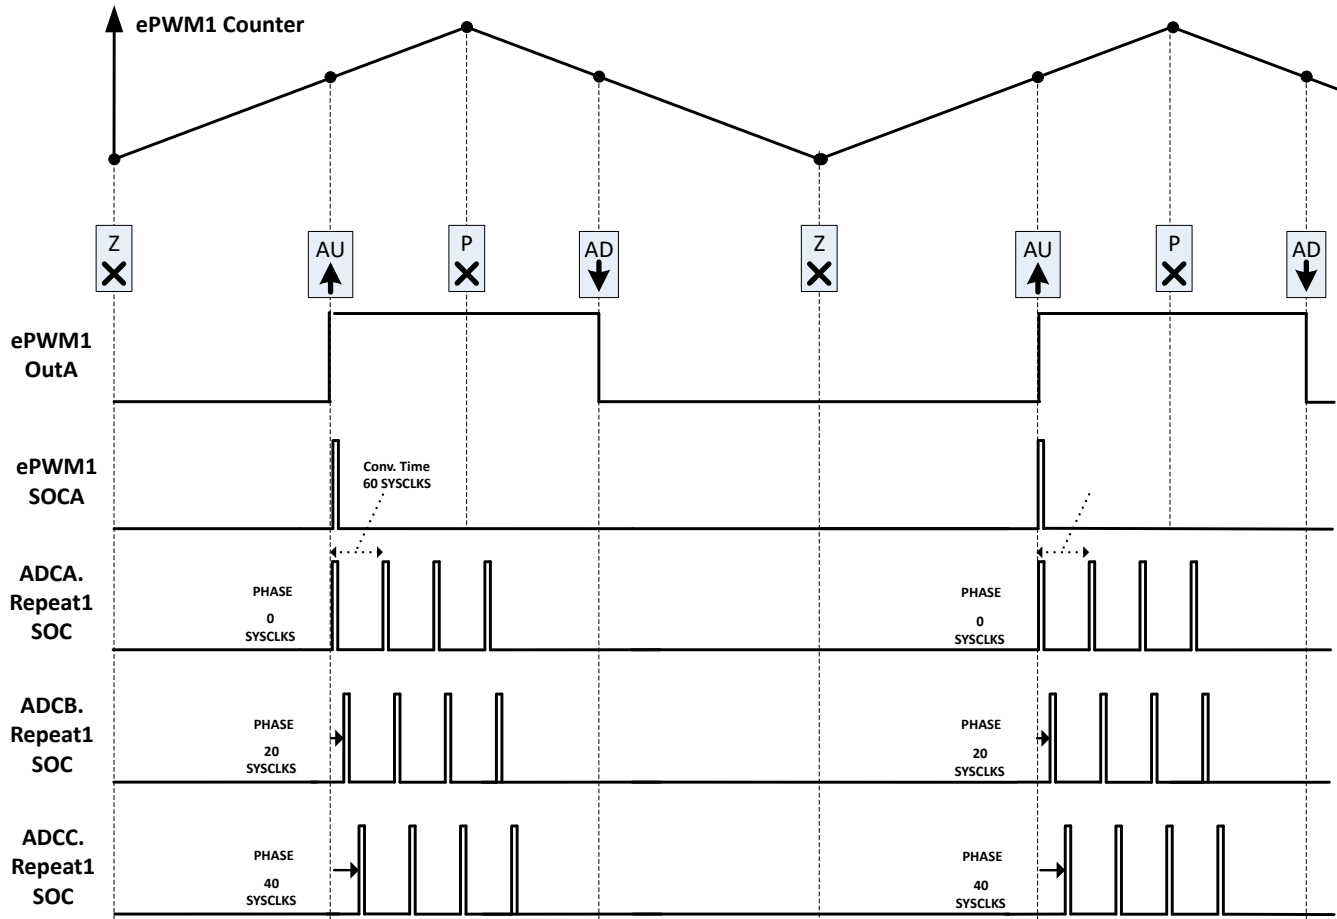

Figure 18-6. Oversampled ADC Trigger Example with Phase Delay

TRIGGER = ePWM SOCA, NSEL = 0, PHASE = 100, MODE = (either), SPREAD = (don't care)

Figure 18-7. ADC Trigger Example with Phase Delay

TRIGGER = ePWM SOCA, NSEL = 3, MODE = Oversampling, PHASE = (varies per ADC), SPREAD = 0

**Figure 18-8. ADC Interleaved Trigger Example (12 Samples Across 3 ADCs)**

18.3.2.2.4 Re-trigger Spread

If additional time between samples is desired, the application can configure SPREAD equal to the number of SYSCLK cycles desired between samples. Figure 18-9 shows an example of oversampling from an ePWM trigger with a 500-cycle spread between samples.

- By default, SPREAD = 0, and samples are re-triggered as soon as all associated SOCs are no longer pending.
- If SPREAD is set to a value smaller than the time needed for the associated SOCs to complete, then the ADC performs the triggered conversions back-to-back, and SPREAD is effectively 0.
- SPREAD has no effect in undersampling mode, or when NSEL = 0.

TRIGGER = ePWM SOCA, NSEL = 3, MODE = Oversampling, PHASE = 0, SPREAD = 500

Figure 18-9. ADC Repeated Trigger Example with Sample Spread

### 18.3.2.2.5 Trigger Repeater Configuration

To configure ADC oversampling or undersampling using the trigger repeater module, follow this procedure:

1. Set up the SOC by writing to ADCSOCxCTL. Specify one of the two repeater modules (REP1TRIG or REP2TRIG) as the trigger source.
2. Configure the repeater module by writing to the REPxCTL register:
  - a. Configure oversampling or undersampling mode using the MODE bit.
  - b. Specify the desired SOC trigger source in the TRIGGER field.
  - c. If desired, configure a sync source for the repeater module in the SYNCINSEL field. A sync event resets all repeater registers to a ready and waiting state, while preserving NSEL, PHASE and MODE. A software-initiated sync is also possible by writing 1 to the SWSYNC bit. [Table 18-7](#) contains a list of possible sync sources for the trigger repeater.
  - d. If desired, clear any previously set phase and trigger overflow flags by writing to the PHASEOVF and TRIGGEROVF bits.
3. Configure the trigger repeat count by writing to the REPxN.NSEL register. The repeater module supports up to 128 repeats for each trigger.
4. Configure the repeater phase delay by writing to the REPxPHASE.PHASE register.
5. To configure a re-trigger spread delay in oversampling mode, write the desired delay value in SYSCLK cycles to the REPxSPREAD.SPREAD register.
6. Configure the PPBLIMIT register. This register defines how many samples the post-processing block accumulates before loading the partial sum value in ADCPPBxPSUM into ADCPPBXSUM.
7. The post-processing block (PPB) and trigger repeater module have independent sync source configurations. To configure the PPB sync source, write to the ADCPPBxCONFIG2 register. For more information on how to configure the ADC post-processing block, see [Section 18.8](#).

#### Note

When NSEL = 0, the repeater module essentially acts as a pass-through for SOC triggers, but is still useful for applying phase delay. SOC triggers are passed through in both oversampling mode and undersampling mode, even if there are still pending SOC. In this scenario, the ADC sets a trigger overflow flag for the individual SOC (ADCSOCOVF1.SOCx), not the repeater module. When oversampling with NSEL > 0, the ADC sets the oversampled trigger overflow flag (REPxCTL.TRIGGEROVF) if a trigger arrives while there are pending SOC.

When NSEL = 0, the repeater module does not set the REPxCTL.MODULEBUSY indicator. In this scenario, the application must make sure that all associated SOC flags have completed before enabling oversampling or undersampling mode by setting NSEL > 0.

#### 18.3.2.2.5.1 Register Shadow Updates

To avoid latency or processing delays between triggers, the application can write updated values to the NSEL, PHASE and SPREAD registers while the repeater module is still actively working. When a new SOC trigger is received, these values are loaded into the NCOUNT, PHASECOUNT and SPREADCOUNT registers, which then count down to zero as each SOC is triggered by the repeater module.

In addition, the application can change the repeater module's oversampling or undersampling mode by writing to the REPxCTL.MODE register while the repeater is actively working, without affecting the current operation. The repeater module loads the value of REPxCTL.MODE into REPxCTL.ACTIVEMODE when a new SOC trigger is received.

### 18.3.2.2.6 Re-Trigger Logic

The repeater module determines when to re-trigger based on the values of ADCSOCxCTL.TRIGSEL and the SOC flags in ADCSOCFLG1. A repeat trigger is issued when all SOCs configured to be triggered by the repeater module instance are no longer pending. Figure 18-10 describes the trigger repeat logic. Because the SOC pending flag goes low at the end of the sample and hold phase, the module has plenty of time to re-trigger conversions without introducing any latency between repeat conversions.

**Figure 18-10. Trigger Repeater Repeat Logic**

### Re-triggering in Burst Mode

If the ADC is in burst mode, and the repeater is selected as the BURSTTRIG source, then the repeater fires a re-trigger pulse whenever there are no high-priority associated SOCs pending, and there are no round-robin SOCs pending.

### 18.3.2.2.7 Multi-Path Triggering Behavior

With the trigger repeater modules, it is possible to have one trigger source take multiple paths to set SOCs in various ways. For example, ePWM1 can directly trigger SOC3 and SOC4, while one repeater block uses ePWM1 to generate oversampling triggers on SOCs 0-2, and the second repeater block generates undersampled triggers to SOC5. Assuming all SOCs are configured for round-robin priority and the various triggers all arrive in the same cycle, the conversion order is SOC0 to SOC5 in increasing order; this is then followed by the oversampled conversions on SOC0-SOC2.

### 18.3.3 ADC Acquisition (Sample and Hold) Window

External signal sources vary in the ability to drive an analog signal quickly and effectively. To achieve rated resolution, the signal source needs to charge the sampling capacitor in the ADC core to within 0.5 LSBs of the signal voltage. The acquisition window is the amount of time the sampling capacitor is allowed to charge and is configurable for SOCx by the ADCSOCxCTL.ACQPS register.

ACQPS is a 9-bit register that can be set to a value between 0 and 511, resulting in an acquisition window duration of:

$$\text{Acquisition window} = (\text{ACQPS} + 1) \times (\text{System Clock (SYSCLK) cycle time})$$

- The acquisition window duration is based on the System Clock (SYSCLK), not the ADC clock (ADCCLK).
- The selected acquisition window duration must be at least as long as one ADCCLK cycle.
- The data sheet specifies a minimum acquisition window duration (in nanoseconds). The user is responsible for selecting an acquisition window duration that meets this requirement.

### 18.3.4 ADC Input Models

For single-ended operation, the ADC input characteristics for values in the single-ended input model (see [Figure 18-11](#)) can be found in the device data sheet.

**Figure 18-11. Single-Ended Input Model**

For differential operation, the ADC input characteristics for values in the differential input model (see [Figure 18-12](#)) can be found in the device data sheet.

These input models must be used along with actual signal source impedance to determine the acquisition window duration. See [Section 18.14.2](#) for more information.

**Figure 18-12. Differential Input Model**

### 18.3.5 Channel Selection

Each SOC can be configured to convert any of the ADC channels. This behavior is selected for SOCx by the ADCSOCxCTL.CHSEL register. Depending on the signal mode, the selection is different. For single-ended signal mode, the value in CHSEL selects a single pin as the input. For differential signal mode, the value in CHSEL selects an even-odd pin pair to be the positive and negative inputs. This is summarized in [Table 18-8](#).

**Table 18-8. Channel Selection of Input Pins**

### 18.3.5.1 External Channel Selection

The ADCSOCxCTRL.EXTCHSEL field for each SOC can be used to automatically control an external mux with digital output pins ADCxEXTMUX[3:0]. This functionality enables the application to add additional ADC channels using an external mux, with minimal software overhead. The ADCxEXTMUX[3:0] outputs can be mapped to GPIO pins by configuring the GPIO output crossbar accordingly. The EXTCHSEL field supports up to 4-bit muxes, but fewer mux selection output pins can be configured if desired.

To select a specific channel on the external mux, configure ADCSOCxCTRL.CHSEL to select the ADC pin that is connected to the mux output, and configure ADCSOCxCTRL.EXTCHSEL to select the desired mux input channel. There are a variety of potential mux topologies possible. A basic example can be a single external mux connected to a single ADC input channel. This setup is illustrated in [Figure 18-13](#).

- To select ADCxIN0.4, the user configures the SOC with CHSEL = 0 and EXTCHSEL = 4.
- To select ADCxIN3, the user configures the SOC with CHSEL = 3. The value of EXTCHSEL does not affect the conversion.

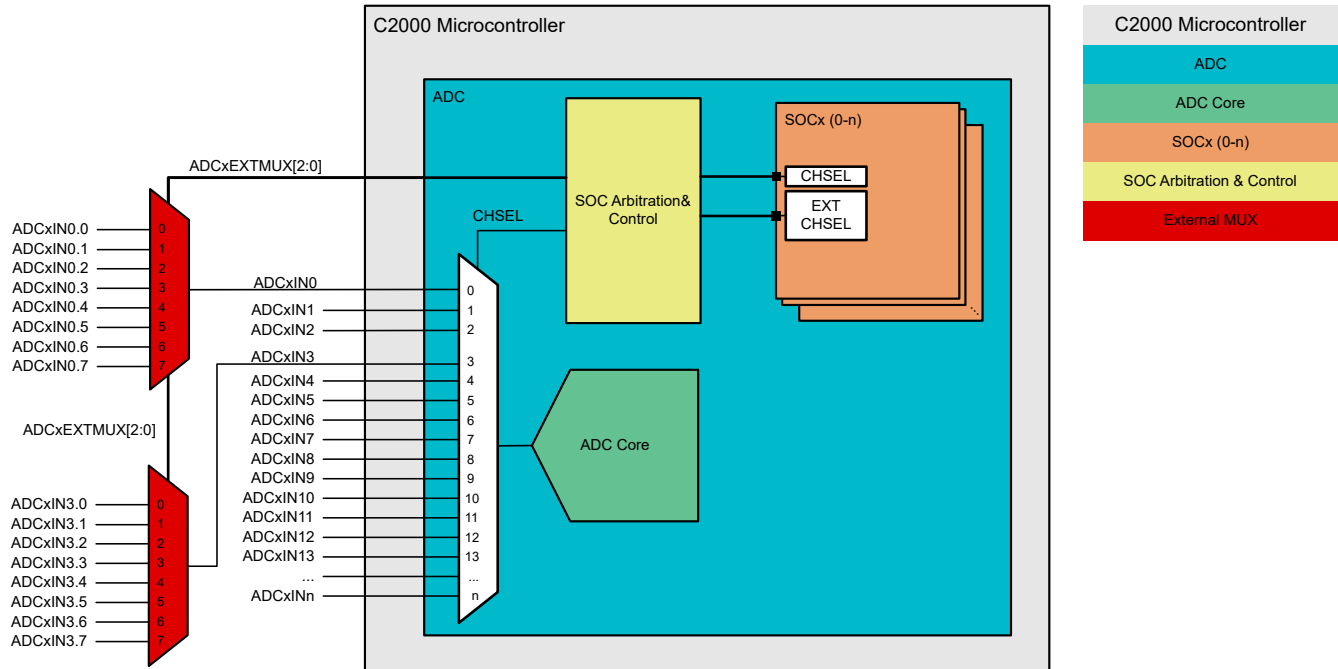

**Figure 18-13. ADC with External Input Mux**

Another example can be to use multiple external muxes connected to different ADC inputs. This setup is illustrated in [Figure 18-14](#).

- To select ADCxIN0.4, the user configures the SOC with CHSEL = 0 and EXTCHSEL = 4.
- To select ADCxIN3.2, the user configures the SOC with CHSEL = 3 and EXTCHSEL = 2.
- To select ADCxIN5, the user configures the SOC with CHSEL = 5. The value of EXTCHSEL does not affect the conversion.

This scheme saves one digital mux pin, at the expense of using two small muxes instead of a single large mux, and a second ADC input pin.

**Figure 18-14. ADC with Multiple External Input Muxes and Shared Selection**

When using an external channel mux, make sure to comprehend the mux selection and switching delay in the sample/hold time requirement for the SOC. This requirement includes the propagation delay for the output X-BAR (if this is used to configure the mux selection pin), any mux switching delays, and the total resistance and capacitance added to the ADC input network by the external mux device. For more information on calculating the acquisition window size, see [Section 18.14.2](#).

**Note**

While the external channel selection can technically be used to select up to 16 times the number of total ADC pins (by placing a 16-input mux on each external ADC channel), the system incurs significant added overhead if the total number of channels (internal and external) exceeds 16 – the total number of available SOCx available on the ADC instance. A sensible option is to map the ADCxEXTMUX outputs to ADC pins (AGPIOs). For instance, using one ADC input to sample an external mux output, and 4 inputs for external channel selection, the application effectively gains an additional 11 ADC inputs (from 5 to 16 pins), without using up any additional device pins.

Externally multiplexed ADC channels lose the ability to practically use the analog comparators in the comparator subsystem. However, the digital limit compares in the post-processing block can still be used to generate interrupts and/or PWM trips. For more information, see [Section 18.8](#).

### 18.3.5.1.1 External Channel Selection Timing

The ADCxEXTMUX output follows two possible timing schemes, depending on the setting of the EXTMUXPRESELECTEN bit in the ADCCTL1 register:

- When EXTMUXPRESELECTEN is set to 0, the ADCxEXTMUX output changes at the beginning of the associated SOC's sample and hold period. The applied external mux setting is maintained until the start of the next SOC sample-and-hold period. This is the default configuration at reset. Examples of SOC timings in this mode are shown in [Figure 18-15](#) and [Figure 18-17](#). When external mux preselect is disabled, make sure to configure the SOC acquisition window duration to account for both external mux settling time and internal channel settling time.
- When EXTMUXPRESELECTEN is set to 1, the ADCxEXTMUX output changes at least one SYSCLK cycle after the end of the sample and hold period. At this point, the ADC sets the external mux selection based on the next highest priority SOC that is pending. If no SOC is pending, then the mux selection is based on the next highest priority SOC, based on the current SOC priority scheme (see [Section 18.5](#) for more information on SOC priority schemes). Examples of SOC timings in this mode are shown in [Figure 18-16](#) and [Figure 18-18](#). Enabling preselect mode enables the application to avoid increasing the acquisition window duration due to external mux switching and settling delays.

#### Note

When EXTMUXPRESELECTEN is enabled, setting SOC0 as high priority without actually triggering SOC0 conversions is a good way to define an idle value for ADCxEXTMUX. SOC0 always has the highest priority when no SOC's are pending, so the value of ADCSOC0CTL.EXTCHSEL is always pushed onto the mux select pins by default.

**Figure 18-15. ADC External Channel Select Timing Example**

In [Figure 18-15](#), the ADC is configured as follows:

- SOC1 and SOC2 are triggered from ePWM1A;
- No high priority SOC's are defined.

The ADC performs the SOC operation sequence in the following order:

1. The initial ePWM1A trigger arrives, setting the SOC1 and SOC2 to pending. SOC1 gains priority, and the sample-and-hold period for SOC1 begins. The ADC pushes the value of ADCSOC1CTL.EXTCHSEL onto the ADCxEXTMUX pins at the same time when the SOC1 sample-and-hold begins.
2. At the end of the sample-and-hold for SOC1, the conversion begins. ADCxEXTMUX remains unchanged until the start of the next SOC sample-and-hold period.

3. In this example case, there are no asynchronous high priority triggers defined, so SOC2 sample-and-hold starts as soon as SOC1 conversion ends. The ADC pushes ADCSOC2CTL.EXTCHSEL onto the ADCxEXTMUX pins.
4. At the end of the sample-and-hold for SOC2, there are no more pending SOC's. SOC2 begins conversion, and ADCxEXTMUX is unchanged.
5. The SOC2 conversion ends. There are no pending SOC's or triggers, so ADCxEXTMUX remains unchanged.

**Figure 18-16. ADC External Channel Timing Example in Preselect Mode**

In [Figure 18-16](#), the ADC is configured as follows:

- SOC1 and SOC2 are triggered from ePWM1A;
- No high priority SOC's are defined.

The ADC performs the SOC operation sequence in the following order:

1. The initial ePWM1A trigger arrives, setting the SOC1 and SOC2 to pending. SOC1 gains priority, and the sample-and-hold period for SOC1 begins. The ADC pushes the value of ADCSOC1CTL.EXTCHSEL onto the ADCxEXTMUX pins at the same time when the SOC1 sample-and-hold begins.
2. At the end of the sample-and-hold for SOC1, the highest priority SOC that is pending is SOC2, so the ADC pushes the value of ADCSOC2CTL.EXTCHSEL onto the ADCxEXTMUX pins.
3. In this example case, there are no asynchronous high priority triggers defined, so SOC2 sample-and-hold starts as soon as SOC1 conversion ends. The ADC pushes ADCSOC2CTL.EXTCHSEL onto the ADCxEXTMUX pins again, but this is already the current value so there is no change.
4. At the end of the sample-and-hold for SOC2, there are no more pending SOC's. SOC3 has the next highest priority by way of the round-robin pointer, so the ADC pushes the value of ADCSOC3CTL.EXTCHSEL onto ADCxEXTMUX. In this case, the application can set ADCSOC3CTL.EXTCHSEL = ADCSOC1CTL.EXTCHSEL. Although SOC3 is not actually used, this makes sure that the external mux channel is already preselected when the next ePWM1 SOC arrives.
5. The SOC2 conversion ends. There are no pending SOC's or triggers, so ADCxEXTMUX remains unchanged.

**Figure 18-17. ADC External Channel Select Timing Example with Asynchronous Trigger**

In [Figure 18-17](#), the ADC is configured as follows:

- SOC1 and SOC2 are triggered from ePWM1A;
- SOC0 is triggered from CPUTIMER1, and has a high priority.

With this configuration, the ADC performs the SOC operation sequence in the following order:

1. The initial ePWM1A trigger arrives, setting the SOC1 and SOC2 flags to pending. SOC1 gains priority, and the SOC1 sample-and-hold period begins. The ADC pushes the value of ADCSOC1CTL.EXTCHSEL onto the ADCxEXTMUX pins at the same time when the SOC1 sample-and-hold begins.
2. At the end of the sample-and-hold for SOC1, the SOC1 conversion begins. ADCxEXTMUX remains unchanged until the start of the next SOC sample-and-hold period.
3. CPUTIMER1 issues a trigger asynchronously, setting the SOC0 flag to pending.
4. Since SOC0 has high priority, SOC0 converts next instead of SOC2. The ADC pushes ADCSOC0CTL.EXTCHSEL onto ADCxEXTMUX when the sample-and-hold period for SOC0 starts.
5. At the end of the sample-and-hold period for SOC0, the conversion for SOC0 begins. ADCxEXTMUX remains unchanged until the start of the next SOC sample-and-hold period.
6. At the end of the conversion for SOC0, SOC2 is the next pending SOC. SOC2's sample-and-hold period begins, and ADCSOC2CTL.EXTCHSEL is pushed onto the ADCxEXTMUX pins.
7. The SOC2 conversion begins, and there are no pending SOC's left. ADCxEXTMUX remains unchanged until a new SOC trigger arrives.

**Figure 18-18. ADC External Channel Timing Example in Preselect Mode with Asynchronous Trigger**

In [Figure 18-18](#), the ADC is configured as follows:

- SOC1 and SOC2 are triggered from ePWM1A;
- SOC0 is triggered from CPUTIMER1, and has a high priority.

With this configuration, the ADC performs the SOC operation sequence in the following order:

1. The initial ePWM1A trigger arrives, setting the SOC1 and SOC2 flags to pending. SOC1 gains priority, and the SOC1 sample-and-hold period begins. The ADC pushes the value of ADCSOC1CTL.EXTCHSEL onto the ADCxEXTMUX pins at the same time when the SOC1 sample-and-hold begins.
2. At the end of the sample-and-hold for SOC1, the highest priority SOC that is pending is SOC2, so the ADC pushes the value of ADCSOC2CTL.EXTCHSEL onto the ADCxEXTMUX pins.
3. CPUTIMER1 issues a trigger asynchronously, setting the SOC0 flag to pending.
4. Since SOC0 has high priority, SOC0 converts next instead of SOC2. The ADC overwrites the previous speculative external mux selection (ADCSOC2CTL.EXTCHSEL) with ADCSOC0.EXTCHSEL when the sample-and-hold period for SOC0 starts. In situations like this where asynchronous triggers are possible, make sure to set the acquisition window size of the priority SOC large enough to allow for both external mux settling and internal channel settling.
5. At the end of the sample-and-hold period for SOC0, the highest priority SOC that is pending is SOC2, so the ADC pushes EXTCHSEL value for SOC2 onto the ADCxEXTMUX pins. SOC0 begins converting.
6. At the end of the SOC0 conversion, SOC2 is the next highest-priority pending SOC, and so SOC2's sample-and-hold period begins. The ADC again pushes ADCSOC2CTL.EXTCHSEL onto the ADCxEXTMUX pins, but since this is already the current value, the mux pins are unchanged.
7. At the end of the sample-and-hold period for SOC2, there are no SOC's pending. SOC0 has the next highest priority, since the ADC has been configured to give SOC0 high priority. The ADC pushes ADCSOC0CTL.EXTCHSEL onto the ADCxEXTMUX pins.

## 18.4 SOC Configuration Examples

The following sections provide some specific examples of how to configure the SOCs to produce some conversions.

### 18.4.1 Single Conversion from ePWM Trigger

To configure ADCA to perform a single conversion on channel ADCINA1 when the ePWM timer reaches the period match, a few things are necessary. First, ePWM3 must be configured to generate an SOCA or SOCB signal (in this statement, SOC refers to a signal in the ePWM module). See the *Enhanced Pulse Width Modulator Module (ePWM)* chapter on how to do this. Assume that SOCB was chosen.

SOC5 is chosen arbitrarily. Any of the 16 SOCs can be used.

Assuming a 100ns sample window is desired with a SYSCLK frequency of 200MHz, then the acquisition window duration must be  $100\text{ns}/5\text{ns} = 20$  SYSCLK cycles. The ACQPS field must be set to  $20 - 1 = 19$ .

```
AdcaRegs.ADCSOC5CTL.bit.CHSEL = 1;      //SOC5 converts ADCINA1
AdcaRegs.ADCSOC5CTL.bit.ACQPS = 19;    //SOC5 uses a sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC5CTL.bit.TRIGSEL = 10;  //SOC5 begins conversion on ePWM3 SOCB
```

As configured, when ePWM3 matches the period and generates the SOCB signal, the ADC begins sampling channel ADCINA1 (SOC5) immediately if the ADC is idle. If the ADC is busy, ADCINA1 begins sampling when SOC5 gains priority (see [Section 18.5](#)). The ADC control logic samples ADCINA1 with the specified acquisition window width of 100ns. Immediately after the acquisition is complete, the ADC begins converting the sampled voltage to a digital value. When the ADC conversion is complete, the results are available in the ADCRESULT5 register (see [Section 18.13](#) for exact sample, conversion, and result latch timings).

### 18.4.2 Oversampled Conversion from ePWM Trigger

To configure the ADC to oversample ADCINA1 4 times, we use the same configurations as the previous example, but apply them to SOC5, SOC6, SOC7, and SOC8.

```
AdcaRegs.ADCSOC5CTL.bit.CHSEL = 1;      //SOC5 converts ADCINA1
AdcaRegs.ADCSOC5CTL.bit.ACQPS = 19;    //SOC5 uses a sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC5CTL.bit.TRIGSEL = 10;  //SOC5 begins conversion on ePWM3 SOCB
AdcaRegs.ADCSOC6CTL.bit.CHSEL = 1;      //SOC6 converts ADCINA1
AdcaRegs.ADCSOC6CTL.bit.ACQPS = 19;    //SOC6 uses a sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC6CTL.bit.TRIGSEL = 10;  //SOC6 begins conversion on ePWM3 SOCB
AdcaRegs.ADCSOC7CTL.bit.CHSEL = 1;      //SOC7 converts ADCINA1
AdcaRegs.ADCSOC7CTL.bit.ACQPS = 19;    //SOC7 uses a sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC7CTL.bit.TRIGSEL = 10;  //SOC7 begins conversion on ePWM3 SOCB
AdcaRegs.ADCSOC8CTL.bit.CHSEL = 1;      //SOC8 converts ADCINA1
AdcaRegs.ADCSOC8CTL.bit.ACQPS = 19;    //SOC8 uses a sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC8CTL.bit.TRIGSEL = 10;  //SOC8 begins conversion on ePWM3 SOCB
```

As configured, when ePWM3 matches the period and generates the SOCB signal, the ADC begins sampling channel ADCINA1 (SOC5) immediately if the ADC is idle. If the ADC is busy, ADCINA1 begins sampling when SOC5 gains priority (see [Section 18.5](#)). Once the conversion is complete for SOC5, SOC6 begins converting ADCINA1 and the results for SOC5 are placed in the ADCRESULT5 register. All four conversions eventually are completed sequentially, with the results in ADCRESULT5, ADCRESULT6, ADCRESULT7, and ADCRESULT8 for SOC5, SOC6, SOC7, and SOC8, respectively.

#### Note

It is possible, but unlikely, that the ADC can begin converting SOC6, SOC7, or SOC8 before SOC5 depending on the position of the round-robin pointer when the ePWM trigger is received. See [Section 18.5](#) to understand how the next SOC to be converted is chosen.

### 18.4.3 Multiple Conversions from CPU Timer Trigger

This example shows how to sample multiple signals with different acquisition window requirements. CPU1 Timer 2 is used to generate the trigger. To see how to configure the CPU timer, see the *System Control and Interrupts* chapter.

A good first step when designing a sampling scheme with many signals is to list out the signals and the required acquisition window. From this, calculate the necessary number of SYSCLK cycles for each signal, then the ACQPS register setting. This is shown in [Table 18-9](#), where a SYCLK of 200MHz is assumed (5ns cycle time).

**Table 18-9. Example Requirements for Multiple Signal Sampling**

Signal Name	Acquisition Window Requirement	Acquisition Window (SYSCLK Cycles)	ACQPS Register Value
Signal 1	>120ns	120ns/5ns = 24	24 – 1 = 23
Signal 2	>444ns	444ns/5ns = 89 (round up)	89 – 1 = 88
Signal 3	>110ns	110ns/5ns = 22	22 – 1 = 21
Signal 4	>291ns	291ns/5ns = 59 (round up)	59 – 1 = 58

Next decide which ADC pins to connect to each signal. This is highly dependent on the application board layout. Once the pins are selected, determining the value of CHSEL is straightforward (see [Table 18-10](#)).

**Table 18-10. Example Connections for Multiple Signal Sampling**

Signal Name	ADC Pin	CHSEL Register Value
Signal 1	ADCINA5	5
Signal 2	ADCINA0	0
Signal 3	ADCINA3	3
Signal 4	ADCINA2	2

With the information tabulated, generate the SOC configurations:

```

AdcaRegs.ADCSOC0CTL.bit.CHSEL = 5;           //SOC0 converts ADCINA5
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 23;         //SOC0 uses a sample duration of 24 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 3;        //SOC0 begins conversion on CPU1 Timer 2
AdcaRegs.ADCSOC1CTL.bit.CHSEL = 0;          //SOC1 converts ADCINA0
AdcaRegs.ADCSOC1CTL.bit.ACQPS = 88;         //SOC1 uses a sample duration of 89 SYSCLK cycles
AdcaRegs.ADCSOC1CTL.bit.TRIGSEL = 3;        //SOC1 begins conversion on CPU1 Timer 2
AdcaRegs.ADCSOC2CTL.bit.CHSEL = 3;          //SOC2 converts ADCINA3
AdcaRegs.ADCSOC2CTL.bit.ACQPS = 21;         //SOC2 uses a sample duration of 22 SYSCLK cycles
AdcaRegs.ADCSOC2CTL.bit.TRIGSEL = 3;        //SOC2 begins conversion on CPU1 Timer 2
AdcaRegs.ADCSOC3CTL.bit.CHSEL = 2;          //SOC3 converts ADCINA2
AdcaRegs.ADCSOC3CTL.bit.ACQPS = 58;         //SOC3 uses a sample duration of 59 SYSCLK cycles
AdcaRegs.ADCSOC3CTL.bit.TRIGSEL = 3;        //SOC3 begins conversion on CPU1 Timer 2

```

As configured, when CPU1 Timer 2 generates an event, SOC0, SOC1, SOC2, and SOC3 eventually is sampled and converted, in that order. The conversion results for ACINA5 (Signal 1) are in ADCRESULT0. Similarly, The results for ADCINA0 (Signal 2), ADCINA3 (Signal 3), and ADCINA2 (Signal 4) are in ADCRESULT1, ADCRESULT2, and ADCRESULT3, respectively.

#### Note

There is a possibility, but unlikely, that the ADC can begin converting SOC1, SOC2, or SOC3 before SOC0 depending on the position of the round-robin pointer when the CPU Timer trigger is received. See [Section 18.5](#) to understand how the next SOC to be converted is chosen.

#### 18.4.4 Software Triggering of SOC's

At any point, whether or not the SOC's have been configured to accept a specific trigger, a software trigger can set the SOC's to be converted. This is accomplished by writing bits in the ADCSOCFRC1 register.

Software triggering of the previous example without waiting for the CPU1 Timer 2 to generate the trigger can be accomplished by the statement:

```
AdcaRegs.ADCSOCFRC1.a11 = 0x000F;           //set SOC flags for SOC0 to SOC3
```

#### 18.5 ADC Conversion Priority

When multiple SOC flags are set at the same time, one of two forms of priority determines the converted order. The default priority method is round-robin. In this scheme, no SOC has an inherent higher priority than another. Priority depends on the round-robin pointer (RRPOINTER). The RRPOINTER reflected in the ADCSOCPRIORITYCTL register points to the last SOC converted. The highest priority SOC is given to the next value greater than the RRPOINTER value, wrapping around back to SOC0 after SOC15. At reset the value is 16 since 0 indicates a conversion has already occurred. When RRPOINTER equals 16 the highest priority is given to SOC0. The RRPOINTER is reset when the ADC module is reset or when the reset value is written to the SOCPRIORITY register. The ADC module is reset by writing and clearing the SOFTPRES bit corresponding to the ADC instance.

An example of the round-robin priority method is given in [Figure 18-19](#).

The SOCPRIORITY field in the ADCSOCPRIORITYCTL register can be used to assign high priority from a single to all of the SOC's. When configured as high priority, an SOC interrupts the round-robin wheel after any current conversion completes and inserts in as the next conversion. After the conversion completes, the round-robin wheel continues where the conversion was interrupted. If two high priority SOC's are triggered at the same time, the SOC with the lower number takes precedence.

High priority mode is assigned first to SOC0, then in increasing numerical order. The value written in the SOCPRIORITY field defines the first SOC that is not high priority. In other words, if a value of 4 is written into SOCPRIORITY, then SOC0, SOC1, SOC2, and SOC3 are defined as high priority, with SOC0 the highest.

An example using high priority SOC's is given in [Figure 18-20](#).

- A** After reset, SOC0 is highest priority SOC ; SOC7 receives trigger ; SOC7 configured channel is converted immediately .
- B** RRPOINTER changes to point to SOC 7 ; SOC8 is now highest priority SOC .
- C** SOC2 & SOC12 triggers rcvd . simultaneously ; SOC12 is first on round robin wheel ; SOC12 configured channel is converted while SOC2 stays pending .
- D** RRPOINTER changes to point to SOC 12 ; SOC2 configured channel is now converted .
- E** RRPOINTER changes to point to SOC 2 ; SOC3 is now highest priority SOC .

## 18.6 Burst Mode

Burst mode allows a single trigger to walk through the round-robin SOC's one or more at a time. Setting the bit BURSTEN in the ADCBURSTCTL register configures the ADC wrapper for burst mode. This causes the TRIGSEL field to be ignored, but only for SOC's that are configured for round-robin operation (not high priority). Instead of the TRIGSEL field, all round-robin SOC's are triggered based on the BURSTTRIG field in the ADCBURSTCTL register. Upon reception of the burst trigger, the ADC wrapper does not set all round-robin SOC's to be converted, but only (ADCBURSTCTL.BURSTSIZE + 1) SOC's. The first SOC to be set is the SOC with the highest priority based on the round-robin pointer, and subsequent SOC's are set until BURSTSIZE SOC's have been set.

### Note

When configuring the ADC for burst mode, the user is responsible for ensuring that each burst of conversions is allowed to complete before the next burst trigger is received. The value of (ADCBURSTCTL.BURSTSIZE + 1) must be less than or equal to the number of SOC's configured for round-robin priority. If the previous burst is not complete at the time when a new burst trigger arrives, for each SOC that was already pending and receives a new trigger, the corresponding overflow flag in ADCSOCOVF1 is set.

For example, if SOCPRIORITY = 12, that is, SOC12, SOC13, SOC14, and SOC15 are in round-robin, ADCBURSTCTL.BURSTSIZE setting must be  $\leq 3$  for burst mode to operate correctly.

### 18.6.1 Burst Mode Example

Burst mode can be used to sample a different set of signals on every other trigger. In the following example, ADCIN7 and ADCIN5 are converted on the first trigger from CPU1 Timer 2 and every other trigger thereafter. ADCIN2 and ACIN3 are converted on the second trigger from CPU1 Timer 2 and every other trigger thereafter. All signals are converted with 20 SYSCLK cycle wide acquisition windows, but different durations can be configured for each SOC as desired.

```

AdcaRegs.BURSTCTL.BURSTEN = 1;           //Enable ADC burst mode
AdcaRegs.BURSTCTL.BURSTTRIG = 3;         //CPU1 Timer 2 triggers burst of conversions
AdcaRegs.BURSTCTL.BURSTSIZE = 1;         //conversion bursts are 1 + 1 = 2 conversions long
AdcaRegs.SOCPRICTL.bit.SOCPRIORITY = 12; //SOC0 to SOC11 are high priority
AdcaRegs.ADCSOC12CTL.bit.CHSEL = 7;      //SOC12 converts ADCINA7
AdcaRegs.ADCSOC12CTL.bit.ACQPS = 19;     //SOC12 uses sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC13CTL.bit.CHSEL = 5;      //SOC13 converts ADCINA5
AdcaRegs.ADCSOC13CTL.bit.ACQPS = 19;     //SOC13 uses sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC14CTL.bit.CHSEL = 2;      //SOC14 converts ADCINA2
AdcaRegs.ADCSOC14CTL.bit.ACQPS = 19;     //SOC14 uses sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC15CTL.bit.CHSEL = 3;      //SOC15 converts ADCINA3
AdcaRegs.ADCSOC15CTL.bit.ACQPS = 19;     //SOC15 uses sample duration of 20 SYSCLK cycles

```

When the first CPU1 Timer 2 trigger is received, SOC12 and SOC13 are converted immediately if the ADC is idle. If the ADC is busy, SOC12 and SOC13 are converted once the SOC's gain priority. The results for SOC12 and SOC13 are in ADCRESULT12 and ADCRESULT13, respectively. After SOC13 completes, the round-robin pointer gives the highest priority to SOC14. Because of this, when the next CPU1 Timer 2 trigger is received, SOC14 and SOC15 is set as pending and eventually converted. The results for SOC14 and SOC15 are in ADCRESULT14 and ADCRESULT15, respectively. Subsequent triggers continue to toggle between converting SOC12 and SOC13, and converting SOC14 and SOC15.

While the above example toggles between two sets of conversions, three or more different sets of conversions can be achieved using a similar approach.

### 18.6.2 Burst Mode Priority Example

An example of priority resolution using burst mode and high-priority SOC's is presented in Figure 18-21.

Example when SOC PRIORITY = 4, BURSTEN = 1, and BURSTSIZE = 1

- A After reset, SOC4 is 1<sup>st</sup> on round robin wheel; BURSTTRIG trigger is received; SOC4 & SOC5 are set and configured channels converted immediately.
- B RRPOINTER changes to point to SOC5; SOC6 is now 1<sup>st</sup> on round robin wheel.
- C BURSTTRIG & SOC1 triggers rcvd. simultaneously; SOC1, SOC6, and SOC7 are set; SOC1 interrupts round robin wheel and SOC1 configured channel is converted while SOC6 and SOC7 stay pending.
- D RRPOINTER stays pointing to 5; SOC6/SOC7 configured channels are now converted.
- E RRPOINTER changes to point to SOC7; SOC8 is now 1<sup>st</sup> on round robin wheel, waiting for BURSTTRIG.

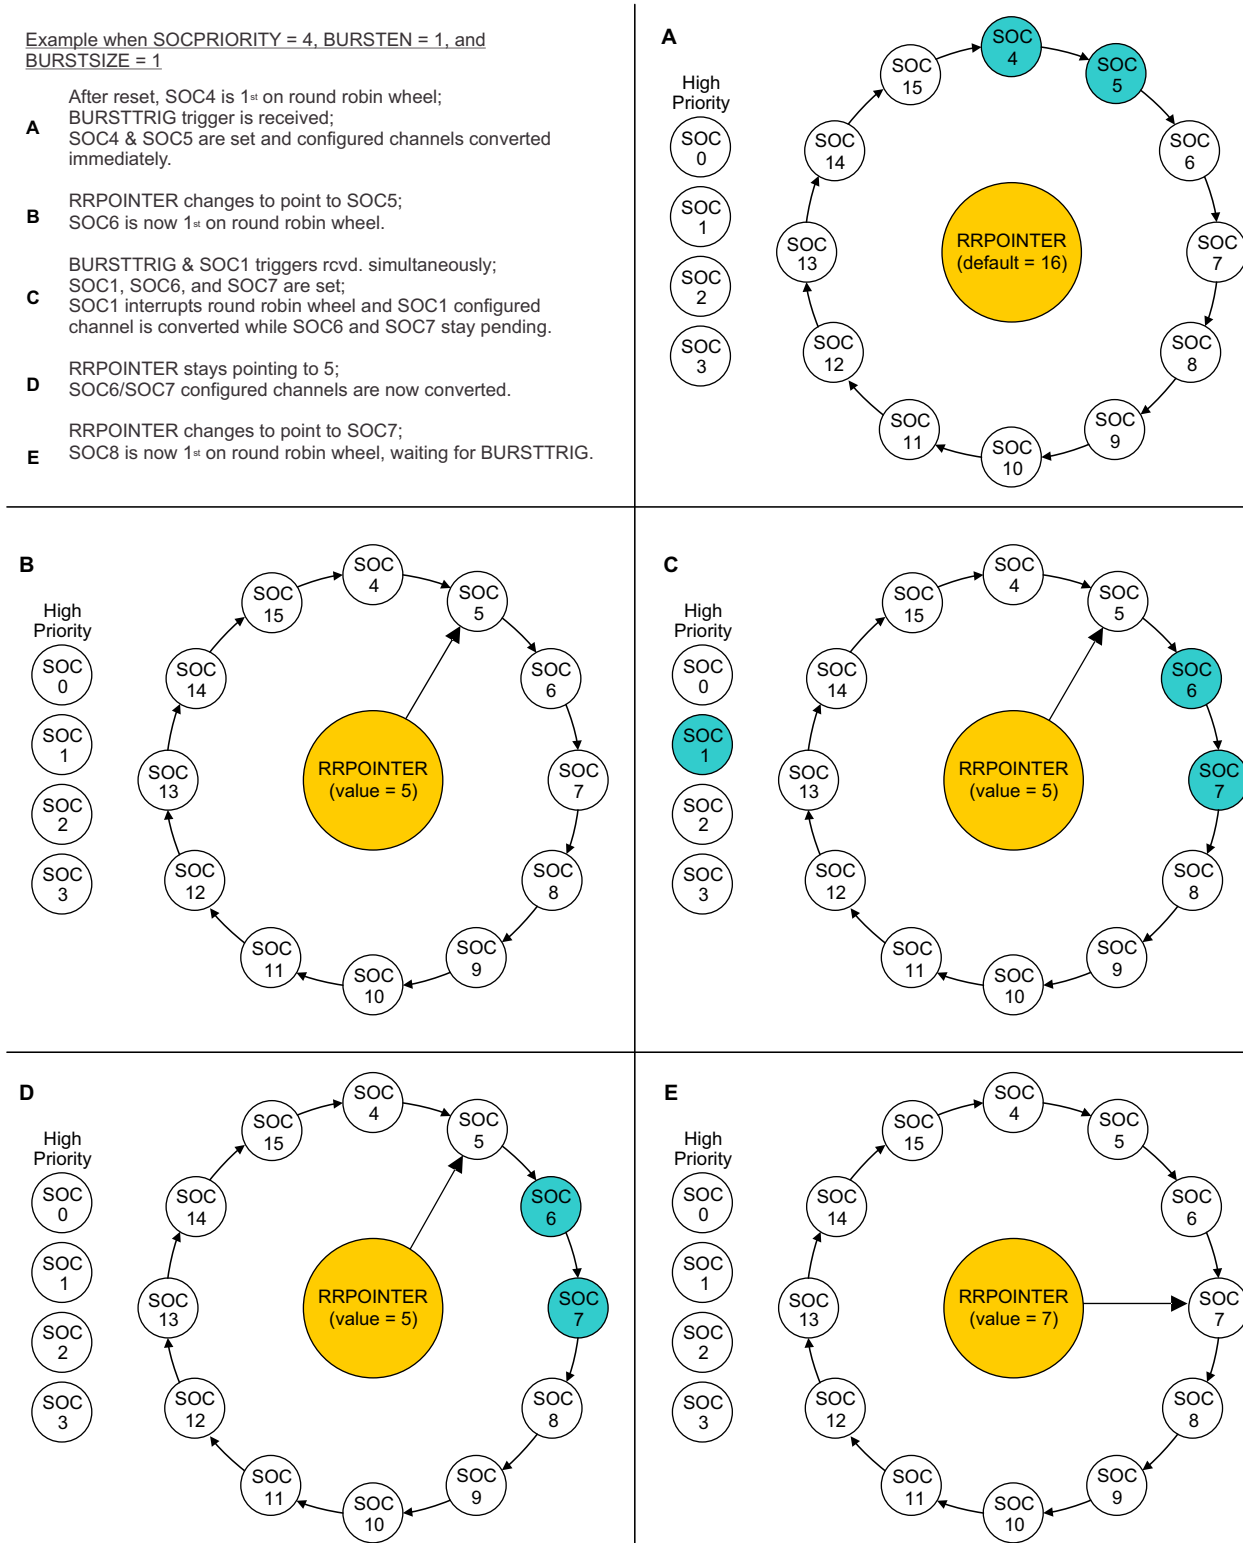

Figure 18-21. Burst Priority Example

### 18.7 EOC and Interrupt Operation

Each SOC has a corresponding end-of-conversion (EOC) signal. This EOC signal can be used to trigger an ADC interrupt. The ADC can be configured to generate the EOC pulse at either the end of the acquisition window or at the end of the voltage conversion. This is configured using the bit INTPULSEPOS in the ADCCTL1 register. See Section 18.13 for exact EOC pulse location.

Each ADC module has 4 configurable ADC interrupts. These interrupts can be triggered by any of the 16 EOC signals. The flag bit for each ADCINT can be read directly to determine if the associated SOC is complete or the interrupt can be passed on to the PIE. Each ADCINT flag also has a corresponding ADCINTxRESULT flag. The ADCINTxRESULT flag is only set when results corresponding to the EOC are latched. This is useful for interrupt service routines or CLA tasks with early interrupt timing configured, allowing the application code to perform some pre-processing or setup work, and then acting on the ADC conversion result as soon as the result is latched.

It is also possible to generate an ADC interrupt based on a PPB oversampling logic event, such as when the sample count matches the configured limit. There are four oversampling interrupt (OSINT) flags available in each module for this purpose. Any of the ADCINT flags can be configured for an OSINT by configuring the INTxSEL field the corresponding ADCINTSELxNy register.

**Note**

The ADCCTL1.ADCBSY bit being clear does not indicate that all conversions in a set of SOCs have completed, only that the ADC is ready to process the next conversion. To determine if a sequence of SOCs is complete, link an ADCINT flag to the last SOC in the sequence and monitor that ADCINT flag.

Figure 18-22 shows a block diagram of the ADC interrupt structure.

Figure 18-22. ADC EOC Interrupts

### 18.7.1 Interrupt Overflow

If the EOC signal sets a flag in the ADCINTFLG register, but that flag is already set, an interrupt overflow occurs. By default, overflow interrupts are not passed on to the PIE module. When an overflow occurs on a given flag in the ADCINTFLG register, the corresponding flag in the ADCINOVF register is set. This overflow flag is only used to detect that an overflow has occurred; the flag does not block further interrupts from propagating to the PIE module.

When an ADC interrupt overflow occurs, the application must check the appropriate ADCINTOVF flag inside the ISR or in the background loop and take appropriate action when an overflow is detected. The following code snippets demonstrate how to check the ADCINTOVF flag inside the ISR after attempting to clear the ADCINT flag.

```
// Clear the interrupt flag
AdcaRegs.ADCINTFLGCLR.bit.ADCINT1 = 1;    //clear INT1 flag for ADC-A

// check if an overflow has occurred
if(1 == AdcaRegs.ADCINTOVF.bit.ADCINT1)    //ADCINT overflow occurred
{
    AdcaRegs.ADCINTOVFCLR.bit.ADCINT1 = 1  //Clear overflow flag
    AdcaRegs.ADCINTFLGCLR.bit.ADCINT1 = 1  //Re-clear ADCINT flag
}
```

```
//
// Clear the interrupt flag
//
ADC_clearInterruptStatus(ADCA_BASE, ADC_INT_NUMBER1);

//
// check if an overflow has occurred
//
if(true == ADC_getInterruptOverflowStatus(ADCA_BASE, ADC_INT_NUMBER1))
{
    ADC_clearInterruptOverflowStatus(ADCA_BASE, ADC_INT_NUMBER1);
    ADC_clearInterruptStatus(ADCA_BASE, ADC_INT_NUMBER1);
}
```

### 18.7.2 Continue to Interrupt Mode

The INTxCONT bits in the ADCINTSEL1N2 and ADCINTSEL3N4 registers configure how interrupts are handled when an ADCINTFLG has not yet been cleared from a prior interrupt. This mode is disabled by default and additional overlapping interrupts are not issued to the PIE. By activating this mode, ADC interrupts always reach the PIE. If interrupts occur while ADCINTFLG is set, the ADCINTOVF register remains set regardless of the configuration of the INTxCONT bits.

### 18.7.3 Early Interrupt Configuration Mode

Enabling early interrupt mode can allow the application to enter the ADC interrupt service routine before the ADC results are ready. This allows the application to do any necessary pre-work so that the application can act on the ADC results immediately when the ADC results become available. If the timing of the early interrupt is too early, then the application needs to waste time until the updated ADC results become available. To prevent this situation, the time the ADC interrupt is entered in early interrupt mode is configurable by way of the DELAY field in the ADCINTCYCLE register.

- To use the configurable interrupt time, the ADC must be in early interrupt mode. To achieve this, clear the bit INTPULSEPOS to 0 in ADCCTL1.
- The DELAY value in the ADCINTCYCLE register sets the number of additional SYSCLK cycles after the falling edge of the SOC pulse before the ADCINT flag is set.
- If the value of DELAY goes beyond EOC, the ADC interrupt is generated along with EOC.
- Writing values to DELAY when INTPULSEPOS is set to 1 does not have any effect on the interrupt generation.

To determine exactly when the ADC result has been latched into the ADCRESULT register, poll the ADCINTxRESULT flag bit in the ADCINTFLG register.

### 18.8 Post-Processing Blocks

Each ADC module contains four post-processing blocks (PPB). These blocks can be associated with any of the 16 RESULT registers using the ADCPPBxCONFIG.CONFIG bit field. The post-processing blocks have the ability to:

- Remove an offset associated with the ADCIN channel
- Subtract out a reference value
- Aggregate successive samples using sum, max, and min calculations
- Automatically calculate average of oversampled conversions without CPU overhead, when sample count is a power of 2
- Transform the conversion result into an absolute value
- Flag a zero-crossing point, with the option to trip a PWM and generate an interrupt
- Flag a high or low compare limit, with the option to trip a PWM and generate an interrupt
- Record the delay between the associated SOC trigger and when sampling actually begins

Figure 18-23 presents the structure of each PPB. Subsequent sections explain the use of each submodule.

Figure 18-23. ADC PPB Block Diagram

### 18.8.1 PPB Offset Correction

In many applications, external sensors and signal sources produce an offset. A global trimming of the ADC offset is not enough to compensate for these offsets, which vary from channel to channel. The post-processing block can remove these offsets with zero overhead, saving numerous cycles in tight control loops.

Offset correction is accomplished by first pointing the ADCPPBxCONFIG.CONFIG to the desired SOC, then writing an offset correction value to the ADCPPBxOFFCAL.OFFCAL register. The post-processing block automatically adds or subtracts the value in the OFFCAL register from the raw conversion result and stores the value in the ADCRESULT register. This addition/subtraction saturates at 0 on the low end and either 4095 or 65535 on the high end for 12-bit or 16-bit mode, respectively.

---

#### Note

- Writing a 0 to the OFFCAL register effectively disables the offset correction feature, passing the raw result unchanged to the ADCRESULT register.
  - To point multiple PPBs to the same SOC is possible. In this case, the OFFCAL value that is actually applied comes from the PPB with the lowest number.
- 

### 18.8.2 PPB Error Calculation

In many applications, an error from a set point or expected value must be computed from the digital output of an ADC conversion. In other cases, a bipolar signal is necessary or convenient for control calculations. The PPB can perform these functions automatically, reducing the sample to output latency and reducing software overhead.

Error calculation is accomplished by first pointing the ADCPPBxCONFIG.CONFIG to the desired SOC, then writing a value to the ADCPPBxOFFCAL.OFFREF register. The post-processing block automatically subtracts the value in the OFFREF register from the ADCRESULT value and stores the value in the ADCPPBxRESULT register. This subtraction produces a sign-extended 32-bit result. It is also possible to selectively invert the calculated value before storing in the ADCPPBxRESULT register by setting the TWOSCOMPEN bit in the ADCPPBxCONFIG register.

If desired, the absolute value of the ADC result after the offset reference calculation can be obtained by setting the ADCPPBxCONFIG.ABSEN bit. The absolute value is computed before evaluating the TWOSCOMPEN logic, so setting both TWOSCOMPEN and ABSEN always results in a negative value stored in ADCPPBxRESULT.

---

#### Note

- In 12-bit mode, do not write a value larger than 12 bits to the ADCPPBxOFFREF register.
  - Since the ADCPPBxRESULT register is unique for each PPB, to point multiple PPBs to the same SOC and get different results for each PPB is possible.
  - Writing a 0 to the ADCPPBxOFFREF register effectively disables the error calculation feature, passing the ADCRESULT value unchanged to the ADCPPBxRESULT register.
- 

### 18.8.3 PPB Limit Detection and Zero-Crossing Detection

Many applications perform a limit check against the ADC conversion results. The PPB can automatically perform a check against high and low limits, or whenever ADCPPBxRESULT changes sign. Based on these comparisons, the PPB can generate a trip to the PWM and an interrupt automatically, lowering the sample to ePWM latency and reducing software overhead. This functionality also enables safety-conscious applications to trip the ePWM based on an out-of-range ADC conversion without any CPU intervention.

To enable this functionality, first point the ADCPPBxCONFIG.CONFIG to the desired SOC, then write a value to one or both of the registers ADCPPBxTRIPHI.LIMITHI and ADCPPBxTRIPLO.LIMITLO (zero-crossing detection does not require further configuration). Whenever these limits are exceeded, the PPBxTRIPHI bit or PPBxTRIPLO bit is set in the ADCEVTSTAT register. Note that the PPBxZERO bit in the ADCEVTSTAT

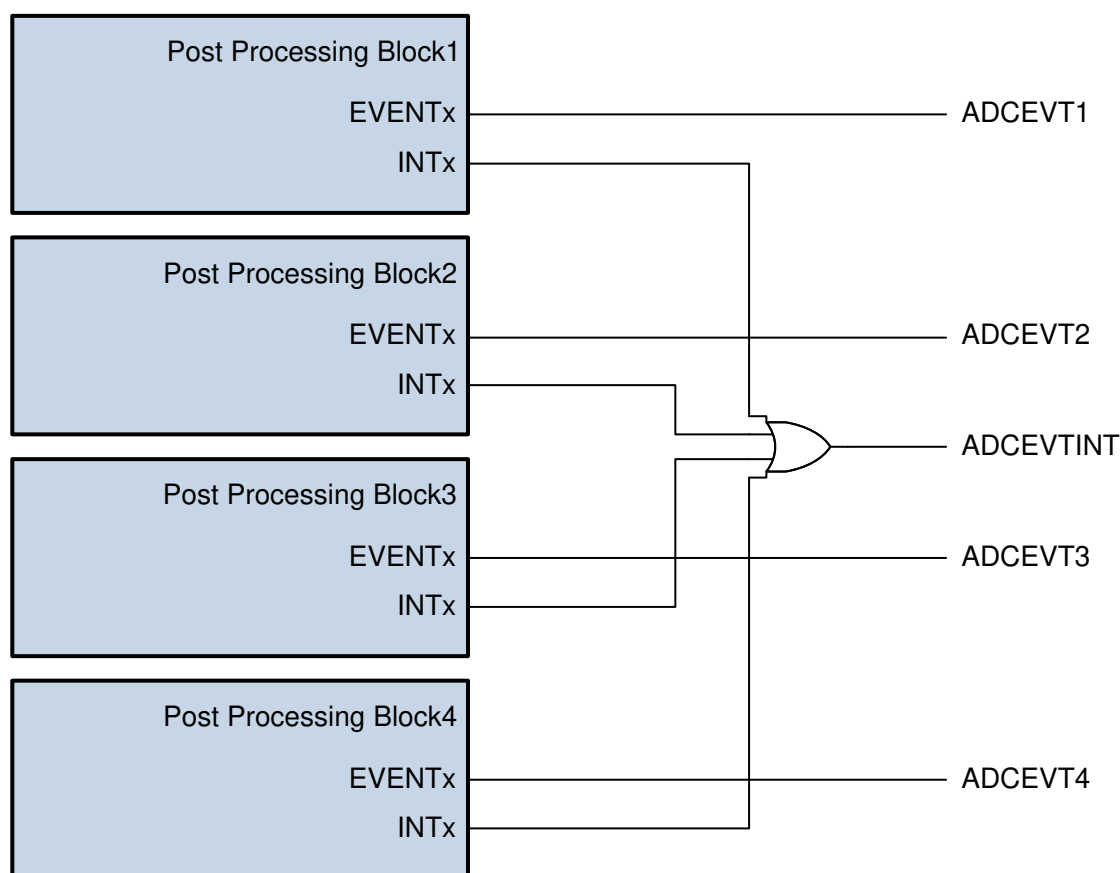

register is gated by end-of-conversion (EOC), not by the sign change in the ADCPPBxRESULT register. The ADCEVTCLR register has corresponding bits to clear these event flags. The ADCEVTSEL register has corresponding bits which allow the events to propagate through to the PWM. The ADCEVTINTSEL register has corresponding bits that allow the events to propagate through to the PIE.

One PIE interrupt is shared between all the PPBs for a given ADC module as shown in [Figure 18-24](#).

[Figure 18-25](#) illustrates the ADC limit compare and zero-crossing logic.

#### Note

- If different actions need to be taken for different PPB events from the same ADC module, then the ADCEVTINT ISR has to read the PPB event flags in the ADCEVTSTAT register to determine which event caused the interrupt.
- If different ePWM trips need to be generated separately for high compare, low compare, and zero-crossing, this can be achieved by pointing multiple PPBs to the same SOC.
- The zero-crossing detect circuit considers a result of zero to be positive.

#### 18.8.4 PPB Sample Delay Capture

When multiple control loops are running asynchronously on the same ADC, there is a chance that an ADC request from two or more loops collide, causing one of the samples to be delayed. This shows up as a measurement error in the system. By knowing when this delay occurs and the amount of delay that has occurred, software can employ extrapolation techniques to reduce the error.

To this effect, each PPB has the field DLYSTAMP in the ADCPPBxSTAMP register. This field contains the number of SYSCLK cycles between when the associate SOC was triggered and when the SOC began converting.

This is achieved by having a global 12-bit free running counter based off of SYSCLK, which is in the field FREECOUNT in the ADCCOUNTER register. When the trigger for the associated SOC arrives, the value of this counter is loaded into the bit field ADCPPBxTRIPLO.REQSTAMP. When the actual sample window for that SOC begins, the value in REQSTAMP is subtracted from the current FREECOUNT value and stored in DLYSTAMP.

#### Note

If more than 4096 SYSCLK cycles elapse between the SOC trigger and the actual start of the SOC acquisition, the FREECOUNT register can overflow more than once, leading to incorrect DLYSTAMP value. Be cautious when using very slow conversions to prevent this from happening.

The sample delay capture does not function, if the associated SOC is triggered using software. The sample delay capture, however, correctly records the delay, if the software triggering of a different SOC causes the SOC associated with the PPB to be delayed

### 18.8.5 PPB Oversampling

This ADC has built-in support for oversampling in the post-processing block, including an accumulator, min/max for peak detection, and outlier removal. The oversampling support module exists at the output of the sample correction module, as shown in [Figure 18-23](#). The oversampling module works by accumulating results in partial registers until either the sample count limit defined in the ADCPPBxLIMIT register is reached, an external hardware sync event occurs, or the software forces a sync event by writing to the SWSYNC bit in the ADCPPBxCONFIG2 register. The application can configure the PPB to sync from any of the hardware sources defined in [Table 18-11](#) by writing to the SYNCINSEL field of the ADCPPBxCONFIG2 register.

### 18.8.5.1 Accumulation, Minimum, Maximum, and Average Functions

At the end of each ADC sample conversion, the PPB updates the partial result registers ADCPPBxPSUM, ADCPPBxPMIN, and ADCPPBxPMAx with the newly processed conversion result from the ADCPPBxRESULT register, and the partial conversion count register (ADCPPBxPCOUNT) increments by 1. When the partial conversion count equals the limit defined in ADCPPBxLIMIT, or the PPB receives a hardware or software sync signal, the PPB takes the following actions:

1. The PPB loads the values of the respective partial result registers into the final result registers ADCPPBxPSUM, ADCPPBxPMIN, and ADCPPBxPMAx.
2. The PPB loads the partial count in ADCPPBxPCOUNT into the final conversion count register ADCPPBxCOUNT.
3. The partial count register and partial result registers reset to zero.
4. The ADC generates an oversampling interrupt (OSINTx) event pulse, which triggers a CPU interrupt if so configured in the ADCINTSEL1N2 or ADCINTSEL3N4 registers.

The PPB can also be configured to generate an oversampling interrupt when there is a hardware or software sync event. To trigger an OSINTx pulse when a sync event occurs, write 1 to the OSINTSEL bit in the ADCPPBxCONFIG2 register.

The PPB can automatically compute the average of the accumulated samples if ADCPPBxLIMIT is set to a power of 2 (up to a maximum of 1024 samples). To perform automatic averaging over  $2^n$  samples, set the SHIFT field in the ADCPPBxCONFIG2 register to  $n$ . When this field is set, the PPB divides the value of ADCPPBxPSUM by  $2^n$  before loading into ADCPPBxSUM.

To compute an average from the accumulated sum when the number of samples is not a power of 2, divide the value of ADCPPBxSUM by the value of ADCPPBxCOUNT using the CPU.

---

#### Note

When using a sync signal to the repeater module and post-processing block to reset the ADC, note that the repeater sync signal does not stop or abort any pending SOCs. If both sync signals are issued simultaneously, any additional pending SOCs can propagate through the post-processing block after the sync signal has been issued. To fully clear or reset the ADC when using the repeater and PPB accumulation logic together:

1. Disable the repeater module trigger source.
  2. Reset the trigger repeater by issuing a sync signal to the repeater module.
  3. Wait for any pending SOCs to complete.
  4. Finally, issue a sync signal to the post-processing block to complete the ADC reset.
- 

### 18.8.5.2 Outlier Rejection

The post-processing block enables the application to easily perform outlier rejection, by eliminating the largest and smallest samples during each SOC burst. To eliminate outliers, the following formula can be used in a software routine or ISR:

$$\text{Average} = \frac{(\text{ADCPPBxSUM} - \text{ADCPPBxMAX} - \text{ADCPPBxMIN})}{(\text{ADCPPBxCOUNT} - 2)} \quad (14)$$

### 18.9 Result Safety Checker

For safety-critical applications, this device provides the ability to automatically compare ADC conversion results from multiple ADC modules against each other for consistency. The number of available safety checker tiles is specified in the device data sheet. Each ADC checker tile captures conversion results from the associated ADCs as soon as the conversions are complete, and compares the absolute value of the difference to the configured tolerance. If the computed delta is out of range, the checker can generate a trip event signal that is sent to an ePWM or output crossbar, and can also trigger an CPU interrupt. Figure 18-26 illustrates the structure and operation of an ADC result safety checker tile.

Figure 18-26. ADC Safety Checker Tile Diagram

### 18.9.1 Result Safety Checker Operation

Each ADC result safety checker tile can be configured to automatically compare two ADC conversion results against a set tolerance value, and generate an interrupt if an out-of-tolerance (OOT) event occurs. The selected results can be from the same ADC instance, or from different ADCs. The safety checker tiles exist outside of the ADC module, enabling the user application to compare results from two separate ADCs. To enable result safety checking, the application must first configure one or more ADCs to enable output of the desired results to the safety checker bus, and then configure the safety checker tile to compare those results.

To configure an ADC result safety checker tile:

1. Enable output of the desired ADC results for each ADC by writing to the ADC\_REGSn.ADCSAFECHECKRESEN register. For each SOC, any one of the conversion result, PPB result, or PPB sum can be enabled for output to the safety checker bus by writing to ADCSAFECHECKRESEN.SOCxCHKEN.
2. Select the first result to compare by writing to the ADC\_SAFECHECK\_REGSn.ADCRESSEL1 register. Write to the ADCRESSEL1.ADCSEL field to select the ADC instance to test, and write to the ADCRESSEL1.ADCRESULTSEL field to select the corresponding SOC conversion result from that ADC to compare.
3. Select the second result to compare by writing to the ADC\_SAFECHECK\_REGSn.ADCRESSEL2 register. Write to ADCRESSEL2.ADCSEL to select the ADC instance to test, and write to ADCRESSEL2.ADCRESULTSEL to select the SOC conversion result from that ADC to compare. Any one of the SOC results, PPB module results or PPB sums can be selected in the ADCRESULTSEL field.
4. Configure the checker tolerance by writing to the ADC\_SAFECHECK\_REGSn.TOLERANCE register. The safety check result is out of tolerance if the difference between the two conversion results exceeds the value configured in TOLERANCE.
5. Enable the checker tile by writing 1 to ADC\_SAFECHECK\_REGSn.CHECKCONFIG.CHKEN.
6. Optionally, write 1 to ADC\_SAFECHECK\_REGSn.CHECKCONFIG.SWSYNC to force a reset of any currently set result safety checker event flags.

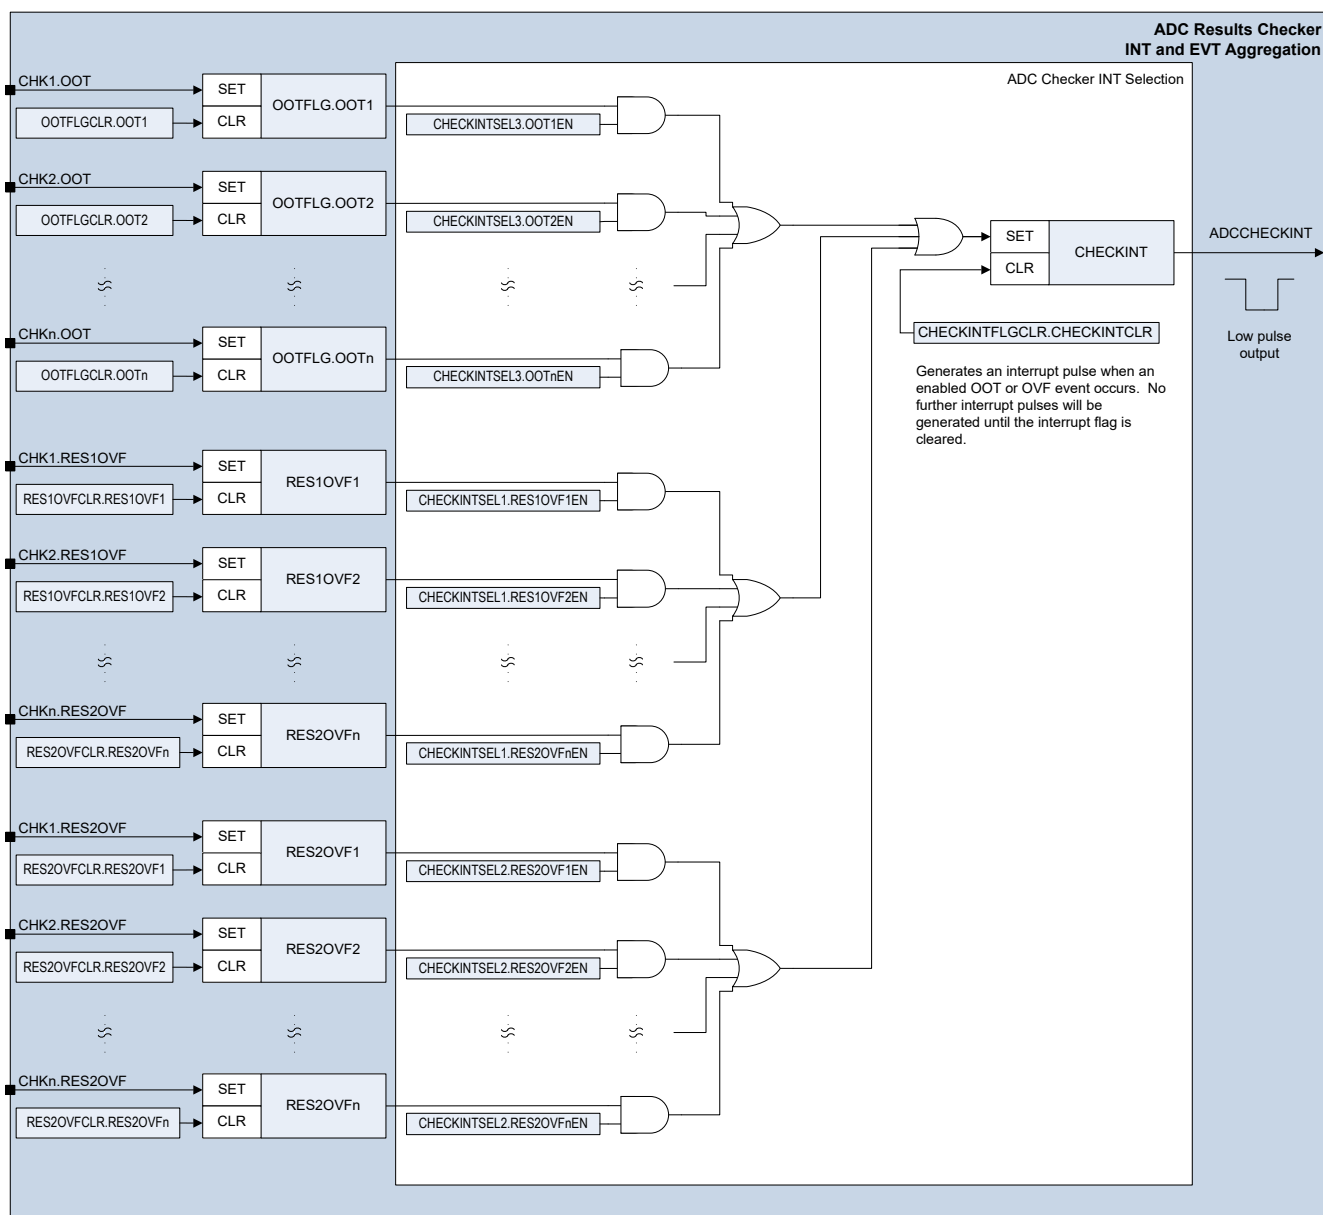

Each of the two result selectors waits for the configured ADC result to become available on the bus. When an ADC result becomes available, the checker reads the result into the CHECKRESULTx register, and sets the CHECKSTATUS.RESxRDY flag. Once both results are available, the checker clears the RESxRDY flags, compares the two results against each other, and sets the CHECKSTATUS.OOT flag if the configured tolerance is exceeded. This flag is also reflected in the corresponding bit for the selected checker tile in the OOTFLG register, and can be cleared by writing 1 to the corresponding bit in the OOTFLGCLR register. The checker does not perform any new comparisons while the OOT flag is set; to enable new comparisons, the flag must be cleared.

If two conversion results arrive in one selector before the other selector result becomes available, the checker sets the RESxOVF flag. This overflow flag does not prevent the comparison from occurring—the flag is for information only. To clear the overflow flag, write 1 to the corresponding bit for the selected checker tile in the RESxOVFCLR register.

### 18.9.2 Result Safety Checker Interrupts and Events

Each ADC result safety checker tile can generate an interrupt signal from out-of-tolerance (OOT) flags and result overflow flags (RESxOVF). These events are aggregated into a single interrupt signal, CHECKINT. [Figure 18-27](#) shows a block diagram of the result checker interrupt aggregation. To enable a checker flag as a source for CHECKINT, write 1 to the corresponding bit in the CHECKINTSEL1, CHECKINTSEL2 or CHECKINTSEL3 register. To clear a previously set checker interrupt flag, write 1 to the CHECKINTFLGCLR.CHECKINTCLR register.

**Figure 18-27. ADC Result Checker Interrupt Aggregation**

In addition, safety checker tiles can also generate events that can be sent to the X-BAR, so that automatic hardware actions such as an ePWM trip can be generated. This device has 4 checker event signals (CHECKEVTx) that can be generated. For each event signal, any number of checker tile OOT or OVF flags can be aggregated into the single event signal. [Figure 18-28](#) shows a block diagram of the ADC result checker event aggregation. To enable a checker flag as a source for a CHECKEVT signal, write 1 to the corresponding bit in the CHECKEVTxSEL1, CHECKEVTxSEL2 or CHECKEVTxSEL3 registers.

## 18.10 Opens/Shorts Detection Circuit (OSDETECT)

The opens/shorts detection circuit (OSDETECT) can be used to detect pin faults in the system. The circuit connects to the ADC input after the channel select multiplexer but before the S+H circuit as shown in Figure 18-29.

### Note

- The divider resistance tolerances can vary widely; hence, this feature must not be used to check for conversion accuracy.
- See the data sheet for implementation and availability of analog input channels.
- Due to high drive impedance, a S+H duration much longer than the ADC minimum is needed.

**Figure 18-29. Opens/Shorts Detection Circuit**

The circuit can be operated by writing a value to the DETECTCFG field in the ADCOSDETECT register. This causes the circuit to source a voltage onto the input during the S+H phase of any conversion. The voltage and drive strength of the OSDETECT circuit for different DETECTCFG settings is given in Table 18-12.

**Table 18-12. DETECTCFG Settings**

### 18.10.1 Implementation

A representative circuit with the OSDETECT implementation consists of the signal source with series resistance  $R_S$ , shunt capacitor  $C_P$ , the equivalent OSDETECT resistance  $R_{OSDETECT}$  and voltage  $V_{OSDETECT}$  is shown in Figure 18-30 and can be used as a basis to calculate the signal level going in to the sampling capacitor.  $R_{OSDETECT}$  and  $V_{OSDETECT}$  are the equivalent input resistance and voltage source contributed by the OSDETECT circuit with values shown in Table 18-12 for the different configuration settings. Refer to Figure 18-30 when deriving the input signal to S/H if signal source  $V_S$  is driving while the OSDETECT feature is enabled.

Figure 18-30. Input Circuit Equivalent with OSDETECT Enabled

The input impedance  $R_S$  and  $C_P$  are integral parts of the signal source or can have been implemented in the design to precondition the signal or to control signal settling time to meet S/H requirements. The input path has to be considered when using the OSDETECT feature, as this affects the conversion results. For instance, driving an input signal when this feature is enabled connects signal  $V_S$  to the OSDETECT circuit through  $R_S$  and affects the ADC results. Larger  $C_P$  values (in the order greater than hundreds of pF) require using higher ACQPS to make sure the signal at the input has settled prior to conversion.

To enable the circuit:

1. Configure the ADC for conversion (for example, channel, SOC, ACQPS, prescaler, trigger, and so on).
2. Set up the ADCOSDETECT register for the desired voltage divider connection as shown in Table 18-12.
3. Initiate a conversion and inspect the conversion result.

Interpret the results based on what is driving on the input side and what are the values of  $R_S$  and  $C_P$ . If the  $V_S$  signal can be disconnected from the input pin, the circuit can be used to detect open and shorted input pins as described in the following sections.

#### 18.10.2 Detecting an Open Input Pin

By cycling through the various OSDETECT settings, the input signal is pulled towards the sourced voltages. An input with good drive strength (pin not open) is minimally affected. However, if the pin is open, the sampled voltages is close to the source voltages specified in Table 18-12.

#### 18.10.3 Detecting a Shorted Input Pin

By cycling through the various OSDETECT settings, the input signal is pulled towards the sourced voltages. An input with finite drive strength (pin not shorted) is pulled toward each sourced voltage. However, if the pin is shorted, the signal remains at the same voltage.

## 18.11 Power-Up Sequence

Upon device power-up or system level reset, the ADC is powered down and disabled. When powering up the ADC, use the following sequence:

1. Set the bit to enable the desired ADC clock in the PCLKCR13 register.
2. Set the desired ADC clock divider in the PRESCALE field of ADCCTL2.
3. Power up the ADC by setting the ADCPWDNZ bit in ADCCTL1.
4. Allow a delay before sampling. See the data sheet for the necessary time.

If multiple ADCs are powered up simultaneously, steps 1 and step 3 can each be done for all ADCs in one write instruction. Also, only one delay is necessary as long as the delay occurs after all the ADCs have begun powering up.

## 18.12 ADC Calibration

During the fabrication and test process, Texas Instruments calibrates the gain, offset, and linearity of the ADCs and the offset of the buffered DACs. These trim settings are stored in TI reserved OTP memory, and can be loaded using C-callable functions.

- The Device\_cal() function copies the trim values for ADC and DAC offset from OTP memory to the respective trim registers.
- The trim functions in Device\_cal() can be called individually in C2000Ware as ADC\_setOffsetTrim(), ADC\_setINLTrim() and DAC\_setOffsetTrim(). These functions fetch production test trim values from TI reserved OTP memory locations, and write the values to the corresponding analog module register destinations.

Until the appropriate factory trim is loaded, the ADC and other analog modules are not specified to operate within the data sheet specifications. Similarly, if trim values other than the factory settings are placed into the trim registers, the ADC (and other modules) is not specified to operate within the data sheet specifications.

The boot ROM calls the calibration functions, so trim values are initially populated without user intervention. However, if the trims are cleared due to a module reset or modified for some other reason, then the user must call the calibration functions (defined in the C2000Ware header files).

### 18.12.1 ADC Zero Offset Calibration

ADC offset error is determined and calibrated during factory testing. However, the user still has the option to perform offset calibration if the end application specifically requires this. This section describes how to perform offset calibration using internal VREFLO connection for single-ended operation, and external channels for differential operation. Refer to the register descriptions for ADCCTL2.OFFTRIMMODE, ADCOFFTRIM, ADCOFFTRIM2 and ADCOFFTRIM3 for proper offset correction parameters. The C2000Ware function ADC\_setMode() sets the value of OFFTRIMMODE to 1. In this mode, the ADC selects the appropriate offset calibration values from one of the three ADCOFFTRIMx registers, depending on the signal mode and channel type (odd or even) used.

Zero offset error is defined as the difference from 0 that occurs when converting a voltage at VREFLO (for single-ended operation), or the difference from MAX\_CODE/2 when converting ADCINxP = ADCINxN (for differential mode). The zero offset error can be positive or negative. To correct this error, an adjustment of equal magnitude and opposite polarity is written into the ADCOFFTRIMx register. The value contained in this register is applied before the results are available in the ADC result registers. This operation is fully contained within the ADC core, so the timing of the results is not affected, and the full dynamic range of the ADC is maintained for any trim value.

---

#### Note

Regardless of the converter resolution, the size of each ADCOFFTRIMx step is  $(VREFHI - VREFLO) / 65536$ .

---

Use the following procedure to re-calibrate the ADC offset in 12-bit single-ended mode:

1. Set ADCOFFTRIMx to +112 steps (0x70). This adds an artificial offset to account for negative offset that can reside in the ADC core.
2. Perform some multiple of 16 conversions on VREFLO (internal connection), accumulating the results (for example, 32\*16 conversions = 512 conversions). Use the maximum value of ACQPS to make sure longer settling time to account for parasitic impedance of internal VREFLO connections. To sample internal VREFLO channels, use the driverlib function ADC\_setupSOCRefloChannel(). After VREFLO conversion has taken place, call ADC\_disableIntRefloConnection() to disconnect the ADC input multiplexer from the internal VREFLO connection.
3. Divide the accumulated result by the multiple of 16 (for example, for 512 conversions, divide by 32).
4. Set ADCOFFTRIMx to 112 – result from step 3.

Use the following procedure to recalibrate the ADC offset in 16-bit or 12-bit differential mode:

1. Set ADCOFFTRIMx to no adjustment (0x00).
2. Short ADCINxP and ADCINyN together (external connection) to a voltage near Vrefcm and accumulate some multiple of 16 conversions (for example, 32\*16 conversions = 512 conversions).
3. Divide the accumulated result by the number of conversions (for example, for 512 conversions, divide by 512 for 16-bit mode, or divide by 32 for 12-bit mode).
4. Set ADCOFFTRIMx to 0 – result from step 3).

### 18.13 ADC Timings

The process of converting an analog voltage to a digital value is broken down into an S+H phase and a conversion phase. The ADC sample and hold circuits (S+H) are clocked by SYSCLK while the ADC conversion process is clocked by ADCCLK. ADCCLK is generated by dividing down SYSCLK based on the PRESCALE field in the ADCCTL2 register.

The S+H duration is the value of the ACQPS field of the SOC being converted, plus one, times the SYSCLK period. The user must make sure that this duration exceeds both 1 ADCCLK period and the minimum S+H duration specified in the data sheet. The conversion time is approximately 10.5 ADCCLK cycles in 12-bit mode and 29.5 ADCCLK cycles in 16-bit mode. The exact conversion time is always a whole number of SYSCLK cycles. See the timing diagrams and tables in [Section 18.13.1](#) for exact timings.

#### 18.13.1 ADC Timing Diagrams

The following diagrams show the ADC conversion timings for two SOC's given the following assumptions:

- SOC0 and SOC1 are configured to use the same trigger.
- No other SOC's are converting or pending when the trigger occurs.
- The round robin pointer is in a state that causes SOC0 to convert first.
- ADCINTSEL is configured to set an ADCINT flag upon end of conversion for SOC0 (whether this flag propagates through to the CPU to cause an interrupt is determined by the configurations in the PIE module).

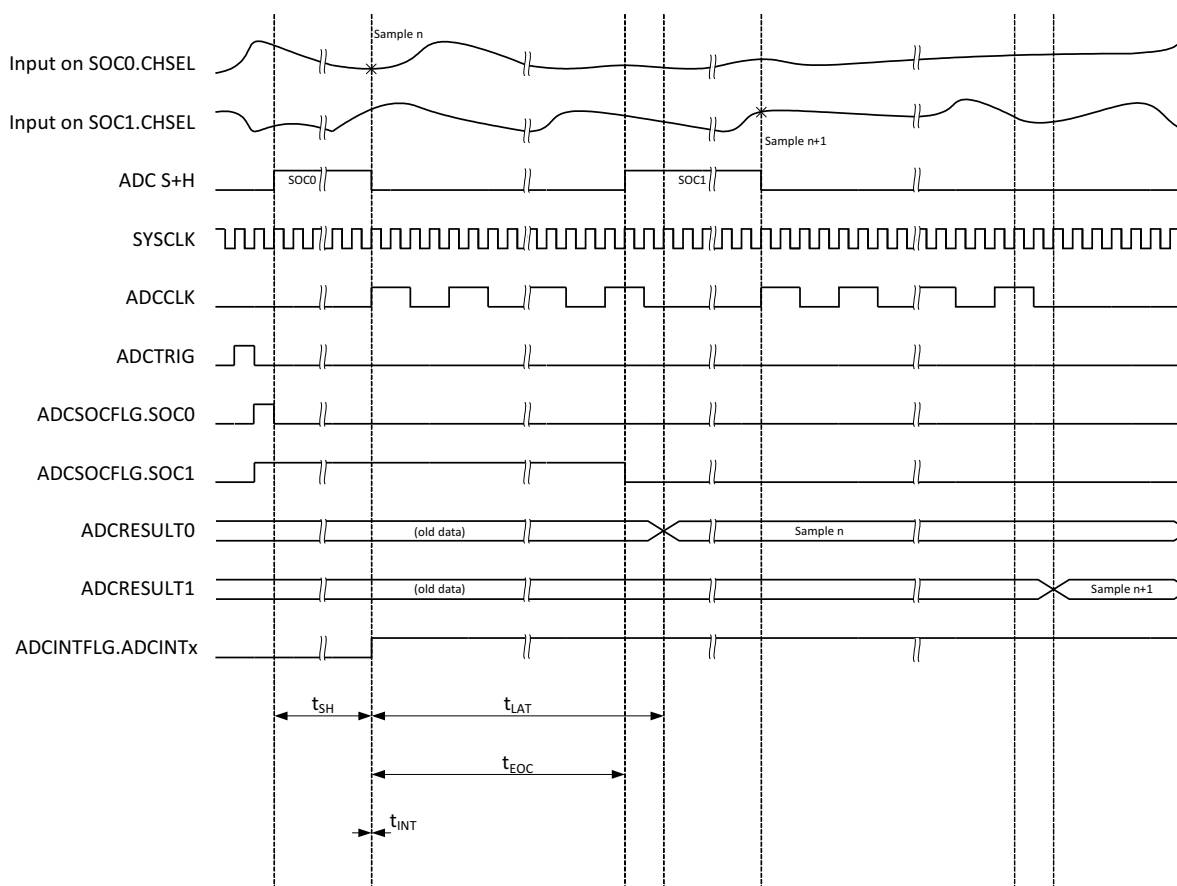

[Table 18-13](#) describes the parameters in the following timing diagrams. [Table 18-14](#) and [Table 18-15](#) list the ADC timings..

**Table 18-13. ADC Timing Parameter Descriptions**

Parameter	Description
$t_{SH}$	<p>The duration of the S+H window.</p> <p>At the end of this window, the value on the S+H capacitor becomes the voltage to be converted into a digital value. The duration is given by (ACQPS + 1) SYSCLK cycles. ACQPS can be configured individually for each SOC, so <math>t_{SH}</math> is not necessarily the same for different SOC's.</p> <p><b>Note:</b> The value on the S+H capacitor is captured approximately 5ns before the end of the S+H window regardless of device clock settings.</p>
$t_{LAT}$	<p>The time from the end of the S+H window until the ADC results latch in the ADCRESULTx register.</p> <p>If the ADCRESULTx register is read before this time, the previous conversion results are returned.</p>

**Table 18-13. ADC Timing Parameter Descriptions (continued)**

Parameter	Description
$t_{EOC}$	The time from the end of the S+H window until the S+H window for the next ADC conversion can begin. In 16-bit mode, this coincides with the latching of the conversion results, while in 12-bit mode, the subsequent sample can start before the conversion results are latched.
$t_{INT}$	The time from the end of the S+H window until an ADCINT flag is set (if configured). If the INTPULSEPOS bit in the ADCCTL1 register is set, $t_{INT}$ coincides with the end of conversion (EOC) signal. If the INTPULSEPOS bit is 0, and the OFFSET field in the ADCINTCYCLE register is not 0, then there is a delay of OFFSET SYSCLK cycles before the ADCINT flag is set. This delay can be used to enter the ISR or trigger the DMA exactly when the sample is ready. If the INTPULSEPOS bit is 0, $t_{INT}$ coincides with the end of the S+H window. If $t_{INT}$ triggers a read of the ADC result register (directly through DMA or indirectly by triggering an ISR that reads the result), care must be taken to make sure the read occurs after the results latch (otherwise, the previous results are read).
$t_{DMA}$	The time from the end of the S+H window until a DMA read of the ADC conversion result is triggered, when ADCCTL1.TDMAEN = 1. If TDMAEN is set to 0, then the DMA trigger occurs at $T_{INT}$ . In certain conditions, the ADCINT flag can be set before the ADCRESULT value is latched. To make sure that the DMA read occurs after the ADCRESULT value has been latched, write 1 to ADCCTL1.TDMAEN to enable DMA timings.

### 18.13.2 Post-Processing Block Timings

The value of ADCRESULT is always available at time  $t_{LAT}$ , as specified in [Section 18.13.1](#). The value of ADCPPBxRESULT, and the limit and zero-crossing comparisons are available 1 SYSCLK cycle later, as long as multiple PPB instances do not point to the same SOC. [Table 18-16](#) shows PPB result availability timings when there are no SOCs shared between multiple PPBs. In cases where multiple PPBs point to the same SOC, PPB results become available sequentially, starting with the lowest numbered PPB. The first ADCPPBxRESULT becomes available 1 SYSCLK cycle after  $t_{LAT}$ , and each subsequent ADCPPBxRESULT becomes available 1 SYSCLK cycle after the previous PPB has completed the limit and zero-crossing comparison. The serialized PPB results are therefore spaced 2 or 3 SYSCLK cycles apart, depending on whether the comparison uses ADCPPBxRESULT or PSUM/SUM respectively. This timing is as shown in [Table 18-17](#). PPB aggregation values (PSUM, SUM, PCOUNT, COUNT, PMAX, MAX, PMIN, MIN, PMINI, MINI, PMAXI, MAXI) are available 1 cycle after the associated ADCPPBxRESULT becomes available.

Furthermore, the LIMIT and zero-crossing compares occur 1 cycle after the compared results become available. In the case that the comparison is done against ADCPPBxRESULT, the comparison occurs 1 SYSCLK cycle after ADCPPBxRESULT becomes available. In the case that the comparison is done against PSUM or SUM, the comparison occurs 2 SYSCLK cycles after ADCPPBxRESULT is available.

## 18.14 Additional Information

The following sections contain additional practical information.

### 18.14.1 Ensuring Synchronous Operation

For best performance, all ADCs on the device must be operated synchronously. The device data sheet specifies the performance in both synchronous and asynchronous mode for those parameters which differ between the modes of operation.

To make sure synchronous operation, all ADCs on the device must operate in lockstep. This is accomplished by writing configurations to all ADCs that cause the sampling and conversion phases of all ADCs to be exactly aligned. The easiest way to accomplish this is to write identical values to the SOC configurations for each ADC for trigger select and ACQPS (S+H duration). In addition, synchronous ADCs must also configure identical values for the SOC priority control, burst mode, burst trigger, and burst size.

#### 18.14.1.1 Basic Synchronous Operation

The following example configures two SOC's each on ADCA and ADCC with identical trigger select and ACQPS values. This results in synchronous operation between ADCA and ADCC. For devices with more than two ADCs, the same principles can be used to synchronize all the ADCs.

##### Example: Basic Synchronous Operation

```

AdcaRegs.ADCSOC0CTL.bit.CHSEL = 4; //SOC0 converts ADCINA4
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 19; //SOC0 uses sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10; //SOC0 begins conversion on ePWM3 SOCB
AdccRegs.ADCSOC0CTL.bit.CHSEL = 0; //SOC0 converts ADCINC0
AdccRegs.ADCSOC0CTL.bit.ACQPS = 19; //SOC0 uses sample duration of 20 SYSCLK cycles
AdccRegs.ADCSOC0CTL.bit.TRIGSEL = 10; //SOC0 begins conversion on ePWM3 SOCB

AdcaRegs.ADCSOC1CTL.bit.CHSEL = 4; //SOC1 converts ADCINA4
AdcaRegs.ADCSOC1CTL.bit.ACQPS = 30; //SOC1 uses sample duration of 31 SYSCLK cycles
AdcaRegs.ADCSOC1CTL.bit.TRIGSEL = 10; //SOC1 begins conversion on ePWM3 SOCB
AdccRegs.ADCSOC1CTL.bit.CHSEL = 1; //SOC1 converts ADCINC1
AdccRegs.ADCSOC1CTL.bit.ACQPS = 30; //SOC1 uses sample duration of 31 SYSCLK cycles
AdccRegs.ADCSOC1CTL.bit.TRIGSEL = 10; //SOC1 begins conversion on ePWM3 SOCB
    
```

Figure 18-35. Example: Basic Synchronous Operation

Several things can be noted from Figure 18-35. First, while the ACQPS values must be the same for SOC's with the same number, different ACQPS values can be used for SOC's with different numbers. Because of this, synchronous operation does not require a single global S+H time, but instead only channels sampled simultaneously require identical S+H durations. Another important point from this example is that any channel select value can be used for any SOC. Finally, this example assumes round-robin operation. If high-priority SOC's are to be used, the priority must be configured the same on all ADCs.

### 18.14.1.2 Synchronous Operation with Multiple Trigger Sources

As long as each set of SOCs has identical trigger select and ACQPS settings, multiple trigger sources can be used while still achieving synchronous operation.

The following example demonstrates synchronous operation between ADCA and ADCC while using three SOCs and two trigger sources. [Figure 18-36](#) demonstrates that any combination of relative trigger timings still results in synchronous operation.

#### Example: Synchronous Operation with Multiple Trigger Sources

```

AdcaRegs.ADCSOC0CTL.bit.CHSEL = 4; //SOC0 converts ADCINA4
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 19; //SOC0 uses sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10; //SOC0 begins conversion on ePWM3 SOCB
AdccRegs.ADCSOC0CTL.bit.CHSEL = 0; //SOC0 converts ADCINC0
AdccRegs.ADCSOC0CTL.bit.ACQPS = 19; //SOC0 uses sample duration of 20 SYSCLK cycles
AdccRegs.ADCSOC0CTL.bit.TRIGSEL = 10; //SOC0 begins conversion on ePWM3 SOCB

AdcaRegs.ADCSOC1CTL.bit.CHSEL = 4; //SOC1 converts ADCINA4
AdcaRegs.ADCSOC1CTL.bit.ACQPS = 30; //SOC1 uses sample duration of 31 SYSCLK cycles
AdcaRegs.ADCSOC1CTL.bit.TRIGSEL = 10; //SOC1 begins conversion on ePWM3 SOCB
AdccRegs.ADCSOC1CTL.bit.CHSEL = 1; //SOC1 converts ADCINC1
AdccRegs.ADCSOC1CTL.bit.ACQPS = 30; //SOC1 uses sample duration of 31 SYSCLK cycles
AdccRegs.ADCSOC1CTL.bit.TRIGSEL = 10; //SOC1 begins conversion on ePWM3 SOCB

AdcaRegs.ADCSOC2CTL.bit.CHSEL = 0; //SOC2 converts ADCINA0
AdcaRegs.ADCSOC2CTL.bit.ACQPS = 19; //SOC2 uses sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC2CTL.bit.TRIGSEL = 2; //SOC2 begins conversion on CPU Timer1
AdccRegs.ADCSOC2CTL.bit.CHSEL = 2; //SOC2 converts ADCINC2
AdccRegs.ADCSOC2CTL.bit.ACQPS = 19; //SOC2 uses sample duration of 20 SYSCLK cycles
AdccRegs.ADCSOC2CTL.bit.TRIGSEL = 2; //SOC2 begins conversion on CPU Timer1
    
```

**Figure 18-36. Example: Synchronous Operation with Multiple Trigger Sources**

Note that any trigger source that can be selected in the TRIGSEL field can be used except for software triggering. There is no way to issue the software triggers for all ADCs simultaneously, so likely results in asynchronous operation. ADCINT1 or ADCINT2 can also be used as a trigger as long as the ADCINTSOCSEL1 and ADCINTSOCSEL2 registers are configured identically for all ADCs and software triggering is not used to start the chain of conversions.

### 18.14.1.3 Synchronous Operation with Uneven SOC Numbers

If only one trigger source is used, one ADC can use more SOC's than the other ADCs while still operating synchronously.

**Example: Synchronous Operation with Uneven SOC Numbers**

```

AdcaRegs.ADCSOC0CTL.bit.CHSEL = 4; //SOC0 converts ADCINA4
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 19; //SOC0 uses sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10; //SOC0 begins conversion on ePWM3 SOCB
AdccRegs.ADCSOC0CTL.bit.CHSEL = 0; //SOC0 converts ADCINC0
AdccRegs.ADCSOC0CTL.bit.ACQPS = 19; //SOC0 uses sample duration of 20 SYSCLK cycles
AdccRegs.ADCSOC0CTL.bit.TRIGSEL = 10; //SOC0 begins conversion on ePWM3 SOCB

AdcaRegs.ADCSOC1CTL.bit.CHSEL = 4; //SOC1 converts ADCINA4
AdcaRegs.ADCSOC1CTL.bit.ACQPS = 30; //SOC1 uses sample duration of 31 SYSCLK cycles
AdcaRegs.ADCSOC1CTL.bit.TRIGSEL = 10; //SOC1 begins conversion on ePWM3 SOCB
AdccRegs.ADCSOC1CTL.bit.CHSEL = 1; //SOC1 converts ADCINC1
AdccRegs.ADCSOC1CTL.bit.ACQPS = 30; //SOC1 uses sample duration of 31 SYSCLK cycles
AdccRegs.ADCSOC1CTL.bit.TRIGSEL = 10; //SOC1 begins conversion on ePWM3 SOCB

AdcaRegs.ADCSOC2CTL.bit.CHSEL = 0; //SOC2 converts ADCINA0
AdcaRegs.ADCSOC2CTL.bit.ACQPS = 30; //SOC2 uses sample duration of 31 SYSCLK cycles
AdcaRegs.ADCSOC2CTL.bit.TRIGSEL = 10; //SOC2 begins conversion on ePWM3 SOCB
    
```

Figure 18-37. Example: Synchronous Operation with Uneven SOC Numbers

Note that if the trigger comes again before all SOC's have completed the conversions, ADCC begins converting immediately on SOC0 while ADCA does not start converting SOC0 again until SOC2 is complete. This results in asynchronous operation, so care must be taken to not overflow the trigger.

Figure 18-38. Example: Asynchronous Operation with Uneven SOC Numbers – Trigger Overflow

#### 18.14.1.4 Synchronous Operation with Different Resolutions

Configuring different ADCs to use different resolutions results in asynchronous operation. This occurs because the conversion time for 12-bit mode and 16-bit mode are different. Synchronous operation requires both the start and end of the conversion phase to be aligned, so even using the same S+H window duration does not result in synchronous operation.

**Example: Asynchronous Operation with Different Resolutions**

```
//ADCA = 12-bit mode
AdcaRegs.ADCSOC0CTL.bit.CHSEL = 4; //SOC0 converts ADCINA4
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 50; //SOC0 uses sample duration of 51 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10; //SOC0 begins conversion on ePWM3 SOCB

//ADCB = 16-bit mode
AdcbRegs.ADCSOC0CTL.bit.CHSEL = 0; //SOC0 converts ADCINB0/B1
AdcbRegs.ADCSOC0CTL.bit.ACQPS = 50; //SOC0 uses sample duration of 51 SYSCLK cycles
AdcbRegs.ADCSOC0CTL.bit.TRIGSEL = 10; //SOC0 begins conversion on ePWM3 SOCB
```

**Figure 18-39. Example: Asynchronous Operation with Different Resolutions**

To achieve synchronous operation while using both 12-bit and 16-bit resolution, conversions must be done in parallel at one resolution. Once conversions are complete at one resolution, the CPU must switch the resolution on all ADCs and then cause another trigger (this trigger must not be a software SOC force, as all ADCs cannot be started simultaneously using this method).

**Figure 18-40. Example: Synchronous Operation with Different Resolutions**

### 18.14.1.5 Non-overlapping Conversions

If conversion timings can be made sure to not overlap by the user, then it is not necessary to configure all SOCs identically on all ADCs to achieve performance equivalent to synchronous operation. For example, if the two ADC triggers in a system come from two ePWM sources that are always 180-degrees out-of-phase, then SOC0 can be used for both ADCA and ADCC with different trigger sources and different ACQPS values.

**Example: Operation with Non-overlapping Conversions**

```
//ePWM3 SOCA and SOCB are 180 degrees out of phase
AdcaRegs.ADCSOC0CTL.bit.CHSEL = 4; //SOC0 converts ADCINA4
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 19; //SOC0 uses sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10; //SOC0 begins conversion on ePWM3 SOCB
AdccRegs.ADCSOC0CTL.bit.CHSEL = 0; //SOC0 converts ADCINC0
AdccRegs.ADCSOC0CTL.bit.ACQPS = 19; //SOC0 uses sample duration of 20 SYSCLK cycles
AdccRegs.ADCSOC0CTL.bit.TRIGSEL = 9; //SOC0 begins conversion on ePWM3 SOCA
```

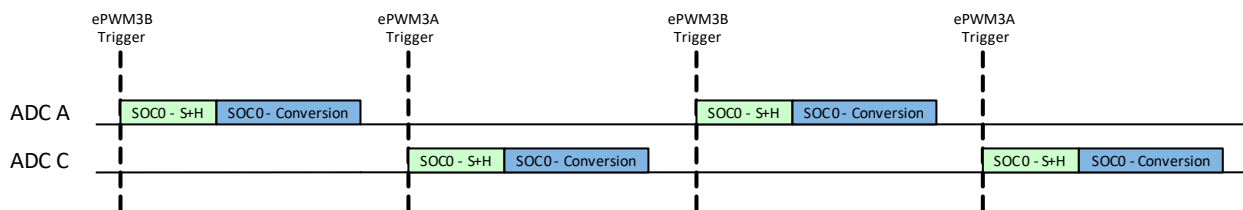

Figure 18-41. Example: Synchronous Equivalent Operation with Non-Overlapping Conversions

### 18.14.2 Choosing an Acquisition Window Duration

For correct operation, the input signal to the ADC must be allowed adequate time to charge the sample and hold capacitor, Ch. Typically, the S+H duration is chosen such that the sampling capacitor is charged to within ½ LSB or ¼ LSB of the final value, depending on the tolerable settling error.

The best methodology to determine the required settling time is to simulate the ADC and ADC driving circuits to make sure adequate settling performance. See [ADC Input Circuit Evaluation for C2000 MCUs](#) and [Charge-Sharing Driving Circuits for C2000 ADCs](#) for additional guidance on ADC signal conditioning circuit design and evaluation.

An approximation of the required settling time can also be determined using an RC settling model. The time constant for the model is given by the equation:

$$\tau = (R_S + R_{on}) \times C_h + R_S \times (C_S + C_p) \tag{15}$$

And the number of time constants needed is given by the equation:

$$k = \ln\left(\frac{2^n}{\text{settling error}}\right) - \ln\left(\frac{C_S + C_P}{CH}\right) \tag{16}$$

So the total S+H time must be set to at least:

$$t = k \cdot \tau \tag{17}$$

Where the following parameters are provided by the ADC input model in the device data sheet:

- $n$  = ADC resolution (in bits)
- $R_{ON}$  = ADC sampling switch resistance (provided in  $\Omega$ )
- $C_H$  = ADC sampling capacitor (provided in pF)
- $C_p$  = ADC channel parasitic input capacitance (provided in pF)

And the following parameters are dependent on the application design:

- settling error = tolerable settling error (in LSBs)
- $R_s$  = ADC driving circuit source impedance (typically in  $\Omega$  or  $k\Omega$ )
- $C_s$  = capacitance on ADC input pin (typically in pF or nF)

For example, assuming the following parameters:

- $n$  = 12-bits
- $R_{ON}$  =  $500\Omega$
- $C_H$  =  $12.5\text{pF}$
- $C_p$  =  $12.7\text{pF}$
- settling error =  $\frac{1}{4}$  LSB
- $R_s$  =  $180\Omega$
- $C_s$  =  $150\text{pF}$

The time constant is calculated as:

$$\tau = (180\Omega + 500\Omega) \times 12.5\text{pF} + 180\Omega \times (150\text{pF} + 12.7\text{pF}) = 37.8\text{ns} \quad (18)$$

And the number of required time constants is:

$$k = \ln\left(\frac{2^{12}}{0.25}\right) - \ln\left(\frac{150\text{pF} + 12.7\text{pF}}{12.5\text{pF}}\right) = 9.70 - 2.57 = 7.13 \quad (19)$$

So the S+H time must be set to at least:  $37.8\text{ns} \times 7.13 = 270\text{ns}$

If  $\text{SYSCLK} = 200\text{MHz}$ , then each  $\text{SYSCLK}$  cycle is  $5\text{ns}$ . S+H duration is  $270\text{ns}/5\text{ns} = 54$   $\text{SYSCLK}$  cycles, so  $\text{ACQPS}$  for this input is set to at least  $\text{CEILING}(54.0) - 1 = 53$ .

While this gives a rough estimate of the required acquisition window, a better method is to setup a circuit with the ADC input model, a model of the source impedance/capacitance, and any board parasitics in SPICE (or similar software) and simulate to verify that the sampling capacitor settles to the desired accuracy.

---

#### Note

The device data sheet specifies a minimum ADC S+H window duration. Do not use an  $\text{ACQPS}$  value that gives a duration less than this specification.

---

### 18.14.3 Achieving Simultaneous Sampling

While each ADC does not have dual S+H circuits, achieving simultaneous sampling is accomplished by setting the SOC triggers on two or more ADC modules to use the same trigger source. The following example demonstrates simultaneous sampling on 3 ADCs based on an ePWM3 event. ADCINA3, ADCINB2, and ADCINC5 are sampled. An acquisition window of 20 SYSCLK cycles is used, but different durations are possible.

```
AdcaRegs.ADCSOC0CTL.bit.CHSEL = 3;           //SOC0 converts ADCINA3
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 19;          //SOC0 uses sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10;        //SOC0 begins conversion on ePWM3 SOCB
AdcbRegs.ADCSOC0CTL.bit.CHSEL = 2;           //SOC0 converts ADCINB2
AdcbRegs.ADCSOC0CTL.bit.ACQPS = 19;          //SOC0 uses sample duration of 20 SYSCLK cycles
AdcbRegs.ADCSOC0CTL.bit.TRIGSEL = 10;        //SOC0 begins conversion on ePWM3 SOCB
AdccRegs.ADCSOC0CTL.bit.CHSEL = 5;           //SOC0 converts ADCINC5
AdccRegs.ADCSOC0CTL.bit.ACQPS = 19;          //SOC0 uses sample duration of 20 SYSCLK cycles
AdccRegs.ADCSOC0CTL.bit.TRIGSEL = 10;        //SOC0 begins conversion on ePWM3 SOCB
```

When the ePWM3 trigger is received, all 3 ADCs begin converting in parallel immediately. All results are stored in the ADCRESULT0 register for each ADC. Note that this assumes that all ADCs are idle when the trigger is received. If one or more ADCs is busy, the samples do not happen at exactly the same time.

### 18.14.4 Result Register Mapping

The ADC results and the ADC PPB results are duplicated for each memory bus controller in the system. Bus controllers include all CPUs, DMAs, and CLAs present on the specific part family and part number. For each bus controller, no access configuration is needed to allow read access to the result registers, and no contention occurs in cases where multiple bus controllers try to read the ADC results simultaneously.

### 18.14.5 Internal Temperature Sensor

The internal temperature sensor measures the junction temperature of the device. The output of the sensor can be sampled with the ADC through an internal connection. This can be enabled on channel ADCIN13 on ADCA, ADCIN18 on ADCB, and on the CMPSS3\_HP4 and CMPSS5\_HP4 inputs by setting the ENABLE bit in the TSNSCTL register.

To convert the temperature sensor reading into a temperature, pass the temperature sensor reading to the ADC\_getTemperatureC() function in the ADC driverlib.

---

#### Note

To sample the temperature sensor, the ADC must be in single-ended 12-bit mode.

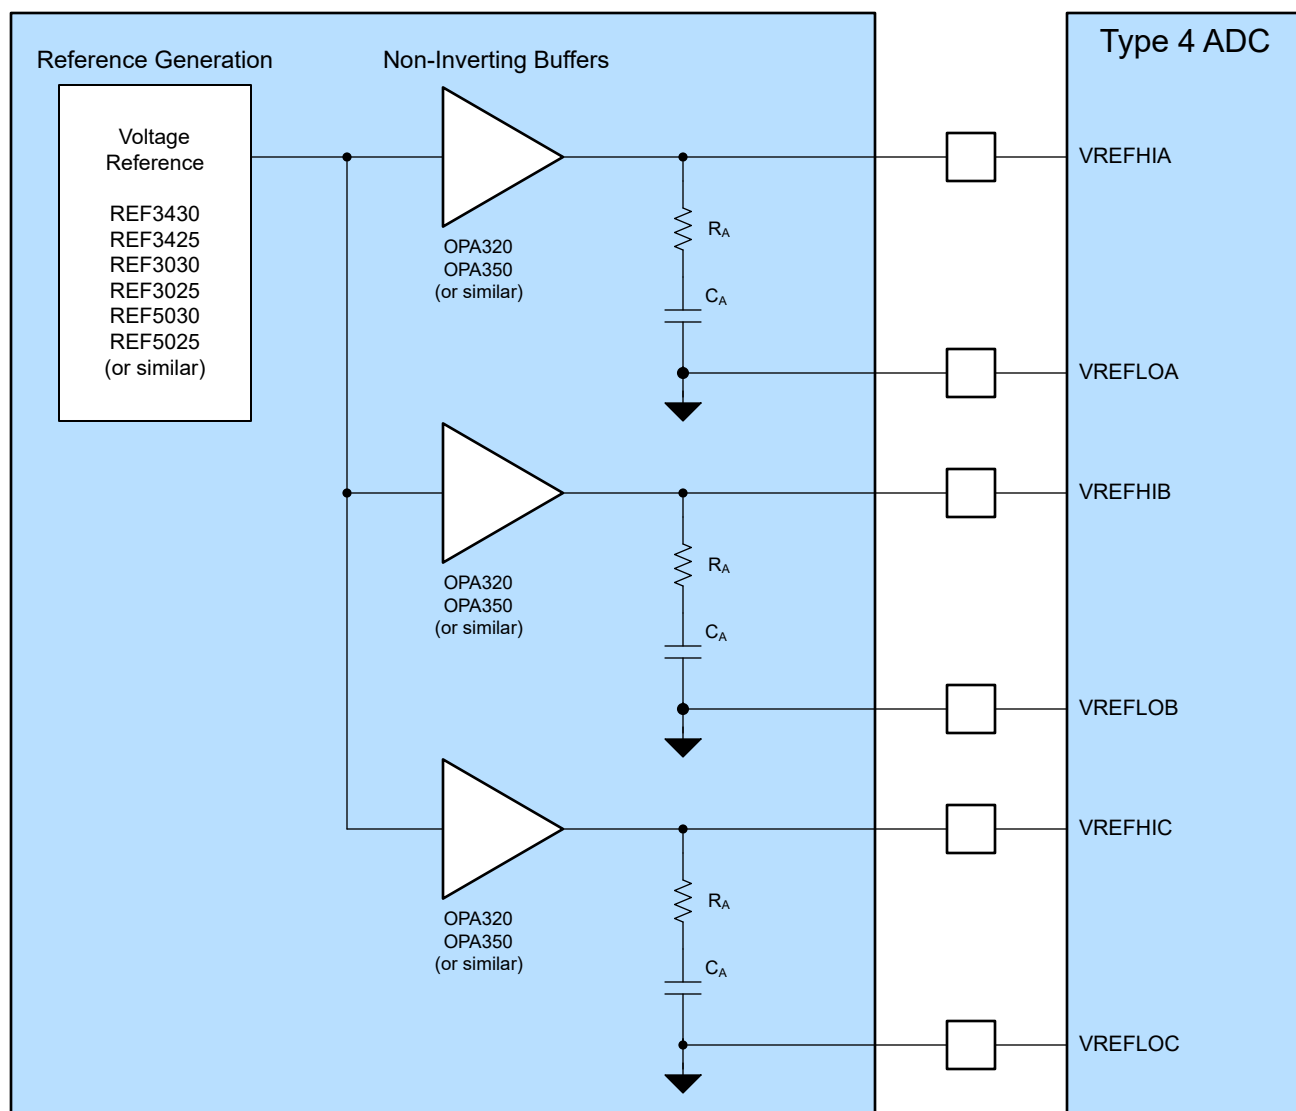

If the temperature sensor is sampled in 16-bit mode, this can cause incorrect ADC results.

---

### 18.14.6 Designing an External Reference Circuit

Figure 18-42 shows the basic organization of the external voltage reference generation circuitry. TI recommends that a single reference voltage generation source is shared by all ADC modules. This minimizes reference voltage mismatch between ADC modules. For best performance, the externally generated reference voltage must be buffered by a precision op-amp with good bandwidth and low output impedance before being driven into the ADC reference pin. A capacitor between the high and low reference pins must be placed on the PCB as close to the pins as practical to help absorb high-frequency currents. A series resistor (typically  $<1\Omega$ ) in series with this capacitor is sometimes necessary to maintain op-amp stability.

To share two reference pins between one op-amp driver is possible. This organization is shown in Figure 18-43. This can give slightly reduced performance compared to the case where each reference pin has a dedicated op-amp buffer, but can still be possible to achieve all ADC specifications in the data sheet.

**Figure 18-42. ADC Reference System**

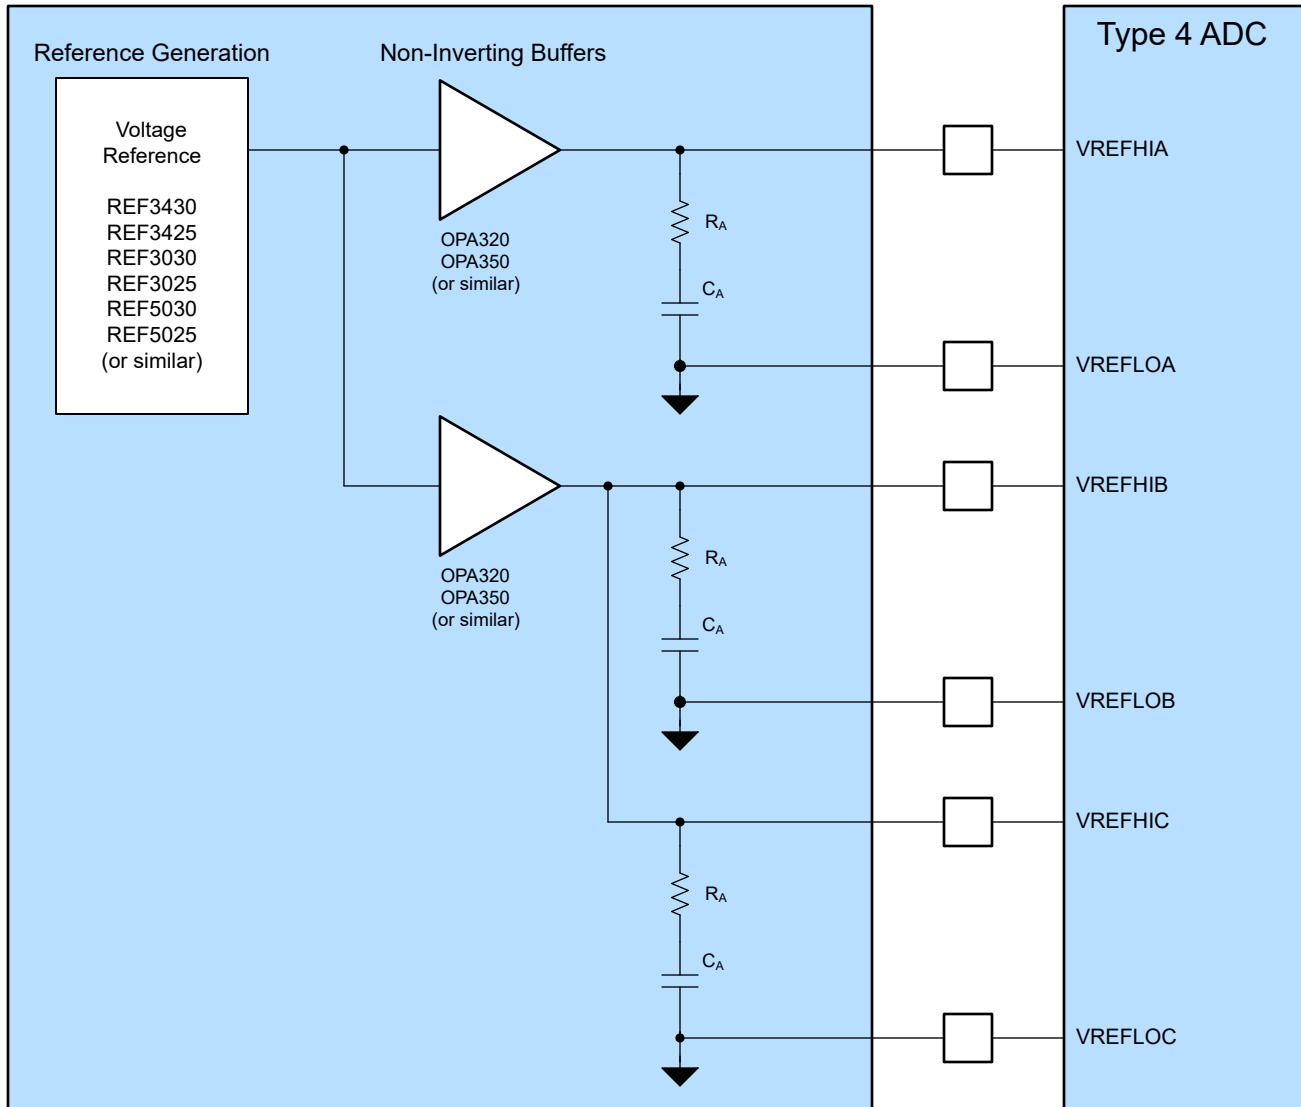

Figure 18-43. ADC Shared Reference System

### 18.14.7 ADC-DAC Loopback Testing

For system diagnostic or functional safety purposes, the user application can perform a loopback test of the ADC module to verify that the ADC is converting correctly. Using the output of the DAC in the first CMPSS module, the device can be configured to supply a series of known voltages to the input of the converter, and the conversion result verified against expected results. Loopback test mode is enabled by setting the bit corresponding to the ADC module under test in the ADCLOOPBACK register in the analog subsystem module to 1. Figure 18-44 shows the connection between the CMPSS DAC output and the ADC.

**Figure 18-44. CMPSS to ADC Loopback Connection**

In ADC loopback test mode, the following special considerations apply:

- The ADC module always samples the CMPSS1 DACL output, regardless of what channel is selected in the ADCSOCxCTL.CHSEL field.
- The minimum sampling window size (ACQPS) when converting the DAC output is 2.56 $\mu$ s (512 SYSCLK cycles at 200MHz SYSCLK) .
- The output resolution of the CMPSS DAC is 6 bits. The lower 6 bits of the input DACVAL are discarded.
- ADC loopback test mode affects CMPSS trip voltages. Avoid enabling ADC loopback mode during regular CMPSS operation.

For more information on the CMPSS module and how to configure the CMPSS DAC, see the *Comparator Subsystem (CMPSS)* chapter.

### 18.14.8 Internal Test Mode

For diagnostic purposes, the ADC can sample various internal node voltages using a special input selection mux called INTERNALTEST. When internal test mode is enabled, the INTERNALTEST mux selection overrides the ADC-A input channel mux: ADC-A samples the INTERNALTEST selection instead of the channel selected by ADCSOCxCTL.CHSEL. Internal test mode can be used to sample the VDDCORE voltage, VREFLO, VDDA, VSSA, and the CMPSS DAC outputs.

To enable internal test mode, write the desired node selection to the TESTSEL field of the INTERNALTESTCTL analog subsystem register. For safety, INTERNALTESTCTL includes a write key field that must be simultaneously written with the value 0xA5A5 for writes to take effect; otherwise, writes to this register are ignored. For details of internal test mux connections to various internal device voltage nodes, refer to the INTERNALTESTCTL register description.

To disable internal test mode, write 0 to the TESTSEL field of the INTERNALTESTCTL register.

When using internal test mode, the following special considerations apply:

- INTERNALTESTCTL.TESTSEL overrides the value of ADCSOCxCTL.CHSEL on ADCA when a non-zero value is configured.
- The minimum sampling window size (ACQPS) when converting INTERNALTEST is 2.56 $\mu$ s (512 SYSCLK cycles at 200MHz SYSCLK).
- The effective resolution of the CMPSS DAC outputs to INTERNALTEST is 6 bits.

For more information on the CMPSS module and how to configure the CMPSS DAC, see the *Comparator Subsystem (CMPSS)* chapter.

### 18.14.9 ADC Gain and Offset Calibration

Using the INTERNALTEST mux, gain balancing between multiple ADCs can be performed. By calculating the relative gain error between the ADCs, conversion results can be post-processed in software such that each ADC has the same output for each equivalent input.

To activate gain calibration mode, configure the TESTSEL field of the INTERNALTESTCTL analog subsystem register to select ENZ\_CALIB\_GAIN\_3P3V. In this mode, the voltage sampled by all ADCs when triggered is (VREFHI \* 0.9), overriding the channel selection in ADCSOCxCTL.CHSEL. To turn off gain calibration mode and return to normal operation, configure the TESTSEL field of INTERNALTESTCTL to 0.

### 18.15.1 ADC Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/adc

Cloud access to these examples is available at the following link: [dev.ti.com C2000Ware Examples](https://dev.ti.com/C2000Ware/Examples).

#### 18.15.1.1 ADC Software Triggering - SINGLE\_CORE

FILE: adc\_ex1\_soc\_software.c

This example converts some voltages on ADCA and ADCC based on a software trigger.

The ADCC will not convert until ADCA is complete, so the ADCs will not run asynchronously. However, this is much less efficient than allowing the ADCs to convert synchronously in parallel (for example, by using an ePWM trigger).

##### External Connections

- A0, A1, C2, and C3 should be connected to signals to convert

##### Watch Variables

- *myADC0Result0* - Digital representation of the voltage on pin A0
- *myADC0Result1* - Digital representation of the voltage on pin A1
- *myADC1Result0* - Digital representation of the voltage on pin C2
- *myADC1Result1* - Digital representation of the voltage on pin C3

#### 18.15.1.2 ADC ePWM Triggering - SINGLE\_CORE

FILE: adc\_ex2\_soc\_epwm.c

This example sets up ePWM1 to periodically trigger a conversion on ADCA.

##### External Connections

- A0 should be connected to a signal to convert

##### Watch Variables

- *myADC0Results* - A sequence of analog-to-digital conversion samples from pin A0. The time between samples is determined based on the period of the ePWM timer.

#### 18.15.1.3 ADC Temperature Sensor Conversion - SINGLE\_CORE

FILE: adc\_ex3\_temp\_sensor.c

This example sets up the ePWM to periodically trigger the ADC. The ADC converts the internal connection to the temperature sensor, which is then interpreted as a temperature by calling the `ADC_getTemperatureC()` function.

##### Watch Variables

- *sensorSample* - The raw reading from the temperature sensor
- *sensorTemp* - The interpretation of the sensor sample as a temperature in degrees Celsius.

#### 18.15.1.4 ADC Synchronous SOC Software Force (adc\_soc\_software\_sync) - SINGLE\_CORE

FILE: adc\_ex4\_software\_sync.c

This example converts some voltages on ADCA and ADCC using input 5 of the input X-BAR as a software force. Input 5 is triggered by toggling GPIO0, but any spare GPIO could be used. This method will ensure that both ADCs start converting at exactly the same time.

##### External Connections

- A0, A1, C0, C1 pins should be connected to signals to convert

##### Watch Variables

- *myADC0Result0* : a digital representation of the voltage on pin A0
- *myADC0Result1* : a digital representation of the voltage on pin A1
- *myADC1Result0* : a digital representation of the voltage on pin C0
- *myADC1Result1* : a digital representation of the voltage on pin C1

#### 18.15.1.5 ADC Continuous Triggering (*adc\_soc\_continuous*) - SINGLE\_CORE

FILE: *adc\_ex5\_soc\_continuous.c*

This example sets up the ADC to convert continuously, achieving maximum sampling rate.

##### *External Connections*

- A0 pin should be connected to signal to convert

##### *Watch Variables*

- *adcAResults* - A sequence of analog-to-digital conversion samples from pin A0. The time between samples is the minimum possible based on the ADC speed.

#### 18.15.1.6 ADC Continuous Conversions Read by DMA (*adc\_soc\_continuous\_dma*) - SINGLE\_CORE

FILE: *adc\_ex6\_continuous\_dma.c*

This example sets up two ADC channels to convert simultaneously. The results will be transferred by the DMA into a buffer in RAM.

##### *External Connections*

- A3 & C3 pins should be connected to signals to convert

##### *Watch Variables*

- *myADC0DataBuffer* : a digital representation of the voltage on pin A3
- *myADC1DataBuffer* : a digital representation of the voltage on pin C3

#### 18.15.1.7 ADC PPB Offset (*adc\_ppb\_offset*) - SINGLE\_CORE

FILE: *adc\_ex7\_ppb\_offset.c*

This example software triggers the ADC. Some SOCs have automatic offset adjustment applied by the post-processing block. After the program runs, the memory will contain ADC & post-processing block(PPB) results.

##### *External Connections*

- A0, C0 pins should be connected to signals to convert

##### *Watch Variables*

- *myADC0Result* : a digital representation of the voltage on pin A0
- *myADC0PPBResult* : a digital representation of the voltage on pin A0, minus 100 LSBs of automatically added offset
- *myADC1Result* : a digital representation of the voltage on pin C0
- *myADC1PPBResult* : a digital representation of the voltage on pin C0 plus 100 LSBs of automatically added offset

#### 18.15.1.8 ADC PPB Limits (*adc\_ppb\_limits*) - SINGLE\_CORE

FILE: *adc\_ex8\_ppb\_limits.c*

This example sets up the ePWM to periodically trigger the ADC. If the results are outside of the defined range, the post-processing block will generate an interrupt.

The default limits are 1000LSBs and 3000LSBs. With VREFHI set to 3.3V, the PPB will generate an interrupt if the input voltage goes above about 2.4V or below about 0.8V.

##### *External Connections*

- A0 should be connected to a signal to convert

##### *Watch Variables*

- None

#### 18.15.1.9 ADC PPB Delay Capture (adc\_ppb\_delay) - SINGLE\_CORE

FILE: adc\_ex9\_ppb\_delay.c

This example demonstrates delay capture using the post-processing block.

Two asynchronous ADC triggers are setup:

- ePWM1, with period 2048, triggering SOC0 to convert on pin A0
  - ePWM2, with period 9999, triggering SOC1 to convert on pin A1
- Each conversion generates an ISR at the end of the conversion. In the ISR for SOC0, a conversion counter is incremented and the PPB is checked to determine if the sample was delayed.
- After the program runs, the memory will contain:

*conversion* : the sequence of conversions using SOC0 that were delayed

- *delay* : the corresponding delay of each of the delayed conversions

#### 18.15.1.10 ADC ePWM Triggering Multiple SOC - SINGLE\_CORE

FILE: adc\_ex10\_multiple\_soc\_epwm.c

This example sets up ePWM1 to periodically trigger a set of conversions on ADCA and ADCC. This example demonstrates multiple ADCs working together to process a batch of conversions using the available parallelism across multiple ADCs.

ADCA Interrupt ISRs are used to read results of both ADCA and ADCC.

##### External Connections

- A0, A1, A2 and C2, C3, C4 pins should be connected to signals to be converted.

##### Watch Variables

- *adcAResult0* - Digital representation of the voltage on pin A0
- *adcAResult1* - Digital representation of the voltage on pin A1
- *adcAResult2* - Digital representation of the voltage on pin A2
- *adcCResult0* - Digital representation of the voltage on pin C2
- *adcCResult1* - Digital representation of the voltage on pin C3
- *adcCResult2* - Digital representation of the voltage on pin C4

#### 18.15.1.11 ADC Burst Mode - SINGLE\_CORE

FILE: adc\_ex11\_burst\_mode\_epwm.c

This example sets up ePWM1 to periodically trigger ADCA using burst mode. This allows for different channels to be sampled with each burst.

Each burst triggers 3 conversions. A0 and A1 are part of every burst while the third conversion rotates between A2, A3, and A4. This allows high importance signals to be sampled at high speed while lower priority signals can be sampled at a lower rate.

ADCA Interrupt ISRs are used to read results for ADCA.

##### External Connections

- A0, A1, A2, A3, A4

##### Watch Variables

- *adcAResult0* - Digital representation of the voltage on pin A0
- *adcAResult1* - Digital representation of the voltage on pin A1
- *adcAResult2* - Digital representation of the voltage on pin A2
- *adcAResult3* - Digital representation of the voltage on pin A3
- *adcAResult4* - Digital representation of the voltage on pin A4

#### 18.15.1.12 ADC Burst Mode Oversampling - SINGLE\_CORE

FILE: adc\_ex12\_burst\_mode\_oversampling.c

This example is an ADC oversampling example implemented with software. The ADC SOCs are configured in burst mode, triggered by the ePWM SOC A event trigger.

##### External Connection

- A2

##### Watch Variables

- *Iv\_results* - Array of digital values measured on pin A2 (oversampling is configured by Oversampling\_Amount)

#### 18.15.1.13 ADC SOC Oversampling - SINGLE\_CORE

FILE: adc\_ex13\_soc\_oversampling.c

This example sets up ePWM1 to periodically trigger a set of conversions on ADCA including multiple SOCs that all convert A2 to achieve oversampling on A2.

ADCA Interrupt ISRs are used to read results of ADCA.

##### External Connections

- A0, A1, A2 should be connected to signals to be converted.

##### Watch Variables

- *adcAResult0* - Digital representation of the voltage on pin A0
- *adcAResult1* - Digital representation of the voltage on pin A1
- *adcAResult2* - Digital representation of the voltage on pin A2

#### 18.15.1.14 ADC PPB PWM trip (adc\_ppb\_pwm\_trip) - SINGLE\_CORE

FILE: adc\_ex14\_ppb\_pwm\_trip.c

This example demonstrates EPWM tripping through ADC limit detection PPB block. ADCAINT1 is configured to periodically trigger the ADCA channel 2 post initial software forced trigger. The limit detection post-processing block(PPB) is configured and if the ADC results are outside of the defined range, the post-processing block will generate an ADCxEVTy event. This event is configured as EPWM trip source through configuring EPWM XBAR and corresponding EPWM's trip zone and digital compare sub-modules. The example showcases

- one-shot
- cycle-by-cycle
- and direct tripping of PWMs through ADCAEVT1 source via Digital compare submodule.

The default limits are 0LSBs and 3600LSBs. With VREFHI set to 3.3V, the PPB will generate a trip event if the input voltage goes above about 2.9V.

##### External Connections

- A2 should be connected to a signal to convert
- Observe the following signals on an oscilloscope
  - ePWM1(GPIO0 - GPIO1)
  - ePWM2(GPIO2 - GPIO3)
  - ePWM3(GPIO4 - GPIO5)
- 

##### Watch Variables

- *adcA2Results* - digital representation of the voltage on pin A2

#### 18.15.1.15 ADC Trigger Repeater Oversampling - SINGLE\_CORE

FILE: adc\_ex15\_trigger\_repeater\_oversampling.c

This example configures ADC for oversampling using trigger repeater block. The ePWM1 is configured to periodically trigger the ADC SOC and the trigger repeater module is configured to generate 4 repeated pulses. Post-processing block will take the repeated pulses, accumulates them and stores the results in ppb sum register.

#### *External Connections*

- A0 should be connected to signals to convert.

#### *Watch Variables*

- *myADC0Result* - Digital representation of the voltage on pin A0
- *myPPB0Result* - Digital representation of the voltage of the 4 repeated pulses on pin A0

#### **18.15.1.16 ADC Trigger Repeater Undersampling - SINGLE\_CORE**

FILE: adc\_ex16\_trigger\_repeater\_undersampling.c

This example configures ADC for undersampling using trigger repeater block. The ePWM1 is configured to periodically trigger the ADC SOC and the trigger repeater module is configured to generate 1 pulse out of three pulses. Post-processing block will take the undersampled pulse, accumulates them and stores the results in ppb sum register.

#### *External Connections*

- A0 should be connected to signals to convert.

#### *Watch Variables*

- *myADC0Result* - Digital representation of the voltage on pin A0
- *myPPB0Result* - Digital representation of the voltage of the undersample pulse on pin A0

#### **18.15.1.17 ADC Safety Checker - SINGLE\_CORE**

FILE: adc\_ex17\_safety\_checker.c

This example compares the absolute value of the two ADC conversion results with the set tolerance value.

The ADCA is used with A0 and A1 to compare the two ADC conversions. If the difference between two conversion results exceeds the value configured as tolerance then the ADC result safety checker tile generates an interrupt signal from out-of-tolerance.

#### *External Connections*

- A0 and A1 should be connected to signals to convert.

#### *Watch Variables*

- *myADC0Result0* - Digital representation of the voltage on pin A0
- *myADC0Result1* - Digital representation of the voltage on pin A1
- *tolerance* - Set digital tolerance limit for ADC safety checker
- *count* - number of times the OOT flag is generated

**Table 18-20. ADC\_RESULT\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

9-0	MAXI	R	0h	Post Processing Block 4 Oversampling Final Index of the Max. When either a count-match event occurs (PCOUNT = LIMIT) or PPB4 receives a sync. event, the value of PMAXI is loaded into this register. In the case of a count-match event, the max index loaded into this register includes the value from the most recent conversion. This result is available 1 SYSCLK cycle after the associated ADCPPB4RESULT is available (only in case of a count-match event). This will be 2 SYSCLK cycles after the associated ADCRESULT is available, unless multiple PPBs point to the same SOC (refer to the ADCPPB4RESULT timing information). Reset type: SYSRSn

Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

14	EXTMUXPRESELECTEN	R/W	0h	If th the ADC SOC sequence is deterministic, the ADCEXTMUX pins can be set earlier: at the end of the S+H window of the previous conversion instead of the beginning of the S+H window of the current conversion. This allows some of the external mux settling time to be pipelined with the previous conversion's conversion time. Range is +127 steps to -128 steps (2's complement format). Regardless of the converter resolution, the size of each trim step is (VREFHI-VREFLO)/65536. Reset type: XRSn
7-0	OFFTRIM	R/W	0h	ADC Offset Trim. Adjusts the conversion results of the converter up or down to account for offset error in the ADC. A different offset trim is required for each combination of resolution and signal mode. If ADCCLT2.OFFTRIMMODE = 0, then using the AdcSetMode function to set the resolution and signal mode will ensure that the correct offset trim is loaded into this register. If ADCCLT2.OFFTRIMMODE = 1, then this register will supply offset trim only when the ADC is in 12-bit single-ended mode and only for even channels. Range is +127 steps to -128 steps (2's complement format). Regardless of the converter resolution, the size of each trim step is (VREFHI-VREFLO)/65536. Reset type: XRSn

This 16-bit unsigned value is subtracted from the ADCRESULT register before being passed through an optional two's complement function and stored in the ADCPPB4RESULT register. This subtraction is not saturated. 0000h No change. The ADCRESULT value is passed on. 0001h ADCRESULT - 1 is passed on. 0002h ADCRESULT - 2 is passed on. ... 8000h ADCRESULT - 32,768 is passed on. ... FFFFh ADCRESULT - 65,535 is passed on. NOTE: In 12-bit mode the size of this register does not change from 16-bits. It is the user's responsibility to ensure that only a 12-bit value is written to this register when in 12-bit mode. Reset type: SYSRSn

7	TRIGGEROVF	R/W1C	0h	ADC Trigger Repeater 1 Oversampled Trigger Overflow. Indicates that a trigger was dropped because a trigger arrived while the repeater was still generating repeated oversampled triggers (NCOUNT was not 0 or SOCs associated with Repeater 1 were still pending). Writing a 1 will clear this flag. Note: This flag won't be set in undersampling mode or when NSEL = 0 if a trigger arrives before the previous SOCs have completed, the trigger will be passed and the overflow flags of the SOCs that were still pending will be set. Note: If software sets the clear bit on the same cycle that hardware is trying to set the flag bit, then hardware has priority and the overflow bit will not be set Reset type: SYSRSn
6	PHASEOVF	R/W1C	0h	ADC Trigger Repeater 1 Phase Delay Overflow. Indicates that a trigger was dropped because a trigger arrived when the phase delay logic was still waiting to send the delayed trigger (PHASECOUNT was not 0). Writing a 1 will clear this flag. **Table 18-150. REP2SPREAD Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	SPREADCOUNT	R	0h	ADC trigger repeater 2 spread status. When a trigger is sent to the ADC in oversampling mode, this register will start counting down from SPREAD until SPREADCOUNT equals 0. The next repeated trigger to the ADC in oversampling mode will not occur until SPREADCOUNT is 0 (minimum time is complete) and REP2CTL.BUSY = 0 (SOCs associated with trigger repeater 2 are no longer pending). Reset type: SYSRSn
15-0	SPREAD	R/W	0h	ADC trigger repeater 2 spread delay configuration. In oversampling mode, defines the minimum number of SYSCLKs to wait before creating the next repeated trigger to the ADC. If SPREAD is less than the time needed for all SOCs associated with repeater 2 to sample and convert, then the repeater will generate triggers as fast as the ADC can convert the associated conversions. If SPREAD is greater than the time needed for all SOCs associated with repeater 2 to sample and convert, then repeated triggers to the ADC will be SPREAD SYSCLK cycles apart. 0 = oversampled repeated triggers occur as fast as the ADC can sample and convert associated SOCs 1 = time between repeated triggers is at least 1 SYSCLKs 2 = time between repeated triggers is at least 2 SYSCLKs ... 65535 = time between repeated triggers is at least 65535 SYSCLKs Reset type: SYSRSn

23-0	PSUM	R	0h	Post Processing Block 4 Oversampling Partial Sum. Each time a new result propagates through the PPB signal chain and latches into ADCPPB4RESULT the result is subsequently accumulated into this register. This register is reset when either a count-match event occurs (PCOUNT = LIMIT) or PPB4 receives a sync. event. This result is available 1 SYSCLK cycle after the associated ADCPPB4RESULT is available. This will be 2 SYSCLK cycles after the associated ADCRESULT is available, unless multiple PPBs point to the same SOC. In the case of multiple PPBs associated with the same SOC, the lowest numbered PPB's result will be available 2 SYSCLK cycle after the associated ADCRESULT and subsequent results (in order from lowest numbered PPB to highest) will each become available every 2-3 SYSCLK cycles (refer to the TRM for detailed timing information). Access Type	Code	Description
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 18.16.5 ADC\_SAFECHECK\_REGS Registers

Table 18-213 lists the memory-mapped registers for the ADC\_SAFECHECK\_REGS registers. All register offset addresses not listed in Table 18-213 should be considered as reserved locations and the register contents should not be modified.

**Table 18-213. ADC\_SAFECHECK\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	CHECKCONFIG	ADC Check Configuration Register		<a href="#">Go</a>
2h	CHECKSTATUS	ADC Check Status Register		<a href="#">Go</a>
4h	ADCRESSEL1	ADC Check 1 Select Register		<a href="#">Go</a>

Ch	CHECKRESULT1	ADC Check Captured Result 1		<a href="#">Go</a>
Eh	CHECKRESULT2	ADC Check Captured Result 2		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 18-214 shows the codes that are used for access types in this section.

**Table 18-214. ADC\_SAFECHECK\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1S	W1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

Chapter 19

## **Buffered Digital-to-Analog Converter (DAC)**

---

The buffered digital-to-analog converter (DAC) is an analog module that can output a programmable, arbitrary reference voltage.

<b>19.1 Introduction</b> .....	<b>3586</b>
<b>19.2 Using the DAC</b> .....	<b>3587</b>
<b>19.3 Lock Registers</b> .....	<b>3588</b>
<b>19.4 Software</b> .....	<b>3589</b>
<b>19.5 DAC Registers</b> .....	<b>3589</b>

## 19.1 Introduction

The buffered DAC module consists of an internal 12-bit DAC and an analog output buffer that is capable of driving an external load. For driving even higher loads than typical, a trade-off can be made between load size and output voltage swing. For the load conditions of the buffered DAC, see the device-specific data sheet. The buffered DAC is a general-purpose DAC that can be used to generate a DC voltage in addition to AC waveforms such as sine waves, square waves, triangle waves and so forth. Software writes to the DAC value register can take effect immediately or can be synchronized with EPWMSYNCPER events.

### 19.1.2 Features

Each buffered DAC has the following features:

- 12-bit programmable internal DAC
- Selectable reference voltage source
- x1 and x2 gain modes when using internal VREFHI
- Ability to synchronize with EPWMSYNCPER

### 19.1.3 Block Diagram

The block diagram for the buffered DAC is shown in [Figure 19-1](#).

**Figure 19-1. DAC Module Block Diagram**

## 19.2 Using the DAC

The internal DAC's reference voltage source, DACREF, is selectable between VDACC and VREFHI. The x2 gain mode is only available when VREFHI is set as DACREF and internal reference mode is used, which can be configured by DACCTL[MODE] register. The internal reference circuit generates 1.65V and 2.5V. To select either 2.5V or 1.65V, configure ANAREF2P5 register and set ANAREFSEL register to 0 (see the *Analog Subsystem* chapter on how to switch to internal reference mode). Even though the buffered DAC has an x2 gain mode, the maximum output voltage from the buffered DAC is not greater than VDDA. Table 19-1 lists the gain mode combinations supported by the buffered DAC. In this table, x = A or B, X = Don't Care, VDACC/ VREFHI = 2.5v, VDDA = 3.3v, and DACVAL = 4095.

**Table 19-1. DAC Supported Gain Mode Combinations**

DACREFSEL	ANAREFSEL	ANAREF2P5	Reference Source	Reference Voltage (V)	Mode	Maximum DAC Output (V)	Support Status
0	X	X	External	VDACC	0	2.5	Supported
0	X	X	External	VDACC	1	2.5	Not Supported
1	0	0	Internal	1.65	0	1.65	Not Supported
1	0	0	Internal	1.65	1	3.3	Supported
1	0	1	Internal	2.5	0	2.5	Supported
1	0	1	Internal	2.5	1	2.5	Not Supported
1	1	X	External	VREFHI	0	2.5	Supported
1	1	X	External	VREFHI	1	2.5	Not Supported

Two sets of DACVAL registers, DACVALA and DACVALS, are present in the buffered DAC module. DACVALA is a read-only register that actively controls the buffered DAC value. DACVALS is a writable shadow register that loads into DACVALA either immediately or synchronized with the next EPWMSYNCPER event. If the clock to the buffered DAC is disabled while the buffered DAC is outputting a voltage, the output voltage remains unaffected, but DACVALA and DACVALS is no longer updated with register writes. Enabling the clock to the buffered DAC restores the DAC to the state before the clock was disabled.

The output of the internal DAC is calculated with the following equation:

$$DACOUT = \frac{DACVALA * DACREF}{4096} \quad (20)$$

The output buffer of the buffered DAC can exhibit non-linear behavior near the supply rails (VDDA/VSSA). To determine the linear range of the buffered DAC, see the device-specific data sheet.

### 19.2.1 Initialization Sequence

1. Enable the buffered DAC clock.
2. Set DACREF with DACREFSEL.
3. Power up the buffered DAC with DACOUTEN.
4. Wait for the power-up time to elapse before outputting a voltage. To determine the power-up time of the buffered DAC, see the device data sheet.
5. For predictable behavior of the buffered DAC, consecutive writes to DACVALS must be spaced apart according to the settling time of the buffered DAC. To determine the settling time of the buffered DAC, see the device data sheet.

### 19.2.2 DAC Offset Adjustment

Zero offset error is defined as the difference between the voltage at midcode (2048) and 1.25V (for 2.5V reference voltage). DAC offset error is calibrated at 2.5V reference voltage and loaded into the DAC offset trim register as part of the `Device_cal()` function. If the DAC is used at any reference voltage other than 2.5V, the offset trim must be adjusted to make sure the offset error performance stays within the device-specific data sheet limits. The DAC offset register is a 16-bit register that contains the 8-bit signed offset trim in the lower half of the register. Use the function call `DAC_tuneOffsetTrim()` found in `C2000Ware` to adjust the offset.

### 19.2.3 EPWMSYNCPER Signal

EPWMSYNCPER comes from the Time-Base submodule of the EPWM. For a detailed description of how this signal is generated, refer to the *Time-Base Submodule* section of the *Enhanced Pulse Width Modulator (ePWM)* chapter.

The EPWMSYNCPER signal that loads DACVALA when DACCTL [LOADMODE] = 1 is a level trigger load. If TBCTR and TBPRD of the EPWM are both 0, EPWMSYNCPER is held at a high level and DACVALA is immediately loaded from DACVALS irrespective of the value of DACCTL [LOADMODE]. Due to this, configure the EPWM first before setting DACCTL [LOADMODE] to 1.

---

#### Note

The name of the sync signal that the GPDAC receives from the EPWM has been updated from PWMSYNC to EPWMSYNCPER (SYNCPER/PWMSYNCPER/EPWMxSYNCPER) to avoid confusion with the other EPWM sync signals EPWMSYNCI and EPWMSYNCO. For a description of these signals, see the *Enhanced Pulse Width Modulator (ePWM)* chapter.

---

## 19.3 Lock Registers

A DACLOCK register is provided to prevent spurious writes from modifying the DACCTL, DACVALS, and DACOUTEN registers. Once a register is protected through DACLOCK, write access are locked out until the device is reset.

#### 19.4.1.1 Buffered DAC Enable - SINGLE\_CORE

FILE: buffdac\_ex1\_enable.c

This example generates a voltage on the buffered DAC output, DACOUTA/ADCINA0 and uses the default DAC reference setting of VDAC.

##### External Connections

- When the DAC reference is set to VDAC, an external reference voltage must be applied to the VDAC pin. This can be accomplished by connecting a jumper wire from 3.3V to ADCINB0.

##### Watch Variables

- None.

## Chapter 20 Comparator Subsystem (CMPSS)

---

The Comparator Subsystem (CMPSS) consists of analog comparators and supporting circuits that are useful for power applications such as peak current mode control, switched-mode power, power factor correction, voltage trip monitoring, and so forth.

See the [C2000 Real-Time Control Peripheral Reference Guide](#) for a list of all devices with modules of the same type, to determine the differences between the types, and for a list of device-specific differences within a type.

## 20.1 Introduction

The comparator subsystem is built around a number of modules. Each subsystem contains two comparators, two reference 12-bit DACs, and two digital filters. The subsystem also includes two ramp generators. The ramp generators ramp up and down. Comparators are denoted "H" or "L" within each module where "H" and "L" represent high and low, respectively. Each comparator generates a digital output which indicates whether the voltage on the positive input is greater than the voltage on the negative input. The positive input of the comparator is driven from an external pin (see the *Analog Subsystem* chapter for mux options available to the CMPSS). The negative input can be driven by an external pin or by the programmable reference 12-bit DAC. Each comparator output passes through a programmable digital filter that can remove spurious trip signals. An unfiltered output is also available if filtering is not required.

Two ramp generator circuits are optionally available to control the reference 12-bit DAC values for the high and low comparators in the subsystem. The DAC along with a wrapper can be used to generate a ramp which is used for slope compensation in Peak Current Mode Control (PCMC) and other applications. The subsystem also works with the EPWM to support Diode Emulation Mode.

### 20.1.2 Features

Each CMPSS includes:

- Two analog comparators
- Two independently programmable reference 12-bit DACs
- Dual decrementing/incrementing ramp generators
- Two digital filters, max filter clock prescale =  $2^{24}$
- Ability to synchronize submodules with EPWMSYNCPER
- Ability to extend clear signal with EPWMBLANK
- Ability to synchronize output with SYSCLK
- Ability to latch output
- Ability to invert output
- Option to use hysteresis on the input
- Option for negative input of comparator to be driven by an external signal or by the reference DAC
- The DAC reference voltage can be set to VDDA or VDACC
- External connection to CMPSS filters
- Diode emulation support
- Ramp generator prescaler
- CMPSS Type-6 supports connection with ePWM Type-5
- CMPSS based Low Power Mode (LPM) wakeup

### 20.1.3 Block Diagram

The block diagram for the CMPSS is shown in Figure 20-1.

- CTRIPx(x= "H" or "L") signals are connected to the ePWM X-BAR for ePWM trip response. See the *Enhanced Pulse Width Modulator (ePWM)* chapter for more details on the ePWM X-BAR mux configuration.
- CTRIPxOUTx(x= "H" or "L") signals are connected to the Output X-BAR for external signaling. See the *General-Purpose Input/Output (GPIO)* chapter for more details on the Output X-BAR mux configuration.

Figure 20-1. CMPSS Module Block Diagram

### 20.2 Comparator

The comparator generates a high digital output when the voltage on the positive input is greater than the voltage on the negative input, and a low digital output when the voltage on the positive input is less than the voltage on the negative input. The comparator is illustrated in Figure 20-2.

Figure 20-2. Comparator Block Diagram

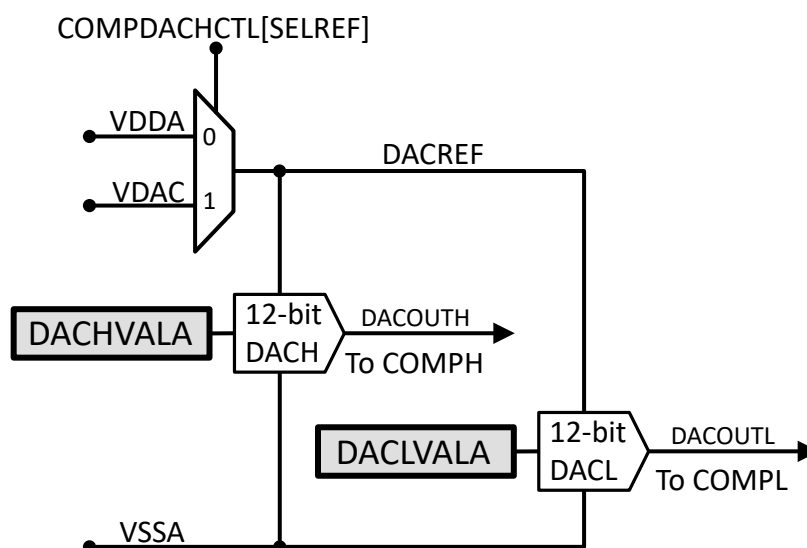

Voltages	Output
Voltage A > Voltage B	1
Voltage A < Voltage B	0

## 20.3 Reference DAC

Each reference 12-bit DAC can be configured to drive a reference voltage into the negative input of the respective comparator. The reference 12-bit DAC output is internal only and cannot be observed externally.

Two sets of DACxVAL registers, DACxVALA and DACxVALS, are present for each reference 12-bit DAC. DACxVALA is a read-only register that actively controls the reference 12-bit DAC value. DACxVALS is a writable shadow register that loads into DACxVALA either immediately or synchronized with the next EPWMSYNCPER event. The high and low reference 12-bit DAC (DACx) can optionally source the register DACxVALA value from the ramp generator instead of the register DACxVALS.

The operating range of the reference 12-bit DAC is bounded by DACREF and VSSA. The high-voltage reference is VDDA by default, but the high voltage reference can be configured to be VDAC using the COMPDACHCTL register. The reference 12-bit DAC is illustrated in Figure 20-3.

**Figure 20-3. Reference DAC Block Diagram**

The output of the reference 12-bit DAC can be calculated as:

$$DACOUT = \frac{(1 + DACVALA) * DACREF}{4096} \quad (21)$$

### Note

- In the situations where both the DACH and DACL are driving the high and low comparators, a trip on one comparator can temporarily disturb the DAC output of the other comparator. The amount and length of time of this disturbance is specified in the device data sheet as “CMPSS DAC output disturbance” and “CMPSS DAC disturbance time”, respectively.

Users must design the system carefully so that if the input signal crosses either DACH or DACL and trips the associated comparator, the input signal stays more than a “CMPSS DAC output disturbance” away from the other comparator trip point for “CMPSS DAC disturbance time”.

- The DACH setting must always be higher than the DACL setting. If the user is not using the DACL, the DACLVALS register must be set to 0 to avoid the comparator COMPL from tripping and affecting the DACH. In this case, there is no limitation on the DACHVALS setting. Accordingly, when not using the DACH, the user must set the DACHVALS register to the maximum.
- The CMPSS instance can be enabled before programming the reference DAC values.

## 20.4 Ramp Generator

This section discusses the characteristics and behavior of the ramp generator.

### 20.4.1 Ramp Generator Overview

The ramp generator produces a falling or rising ramp input for the high-reference 12-bit DAC and the low-reference 12-bit DAC when selected. In this mode, the reference 12-bit DAC uses the most-significant 12 bits of the RAMPSTS countdown register as the input. The low 4 bits of the RAMPSTS countdown register effectively act as a prescaler for the falling or rising ramp rate configurable with RAMPxSTEPVALA. There is an additional dedicated prescaler for the ramp generator configurable with the RAMPCLKDIV register.

The ramp generator is enabled by setting DACSOURCE = 1. When DACSOURCE = 1 is selected, the value of RAMPSTS is loaded from RAMPxREFS and the register remains static until the selected TRIGSYNC signal is received. After receiving the selected TRIGSYNC signal, the value of RAMPxSTEPVALA is subtracted from RAMPSTS on every subsequent SYSCLK cycle.

To prevent the subtraction from commencing a SYSCLK cycle after a TRIGSYNC event, the RAMPDLYA register that serves as a delay counter can be used to hold off the RAMPSTS subtraction or addition. On receiving a TRIGSYNC event, the value of RAMPDLYA is decremented by one on every SYSCLK cycle until the register reaches zero. So, the RAMPSTS subtraction only begins when RAMPDLYA is zero. Similarly, in increment mode (RAMPDIR = 1), the RAMPSTS addition only begins when RAMPDLYA is zero.

---

#### Note

- For the ramp decrement mode of operation, set the registers COMPXINV and RAMPDIR to 0, and for the ramp increment mode of operation, set the registers COMPXINV and RAMPDIR to 1.
-

**20.4.2 Ramp Generator Behavior**

The ramp generator makes state changes on every rising edge of DACSOURCE, TRIGSYNC, and COMPSTS.

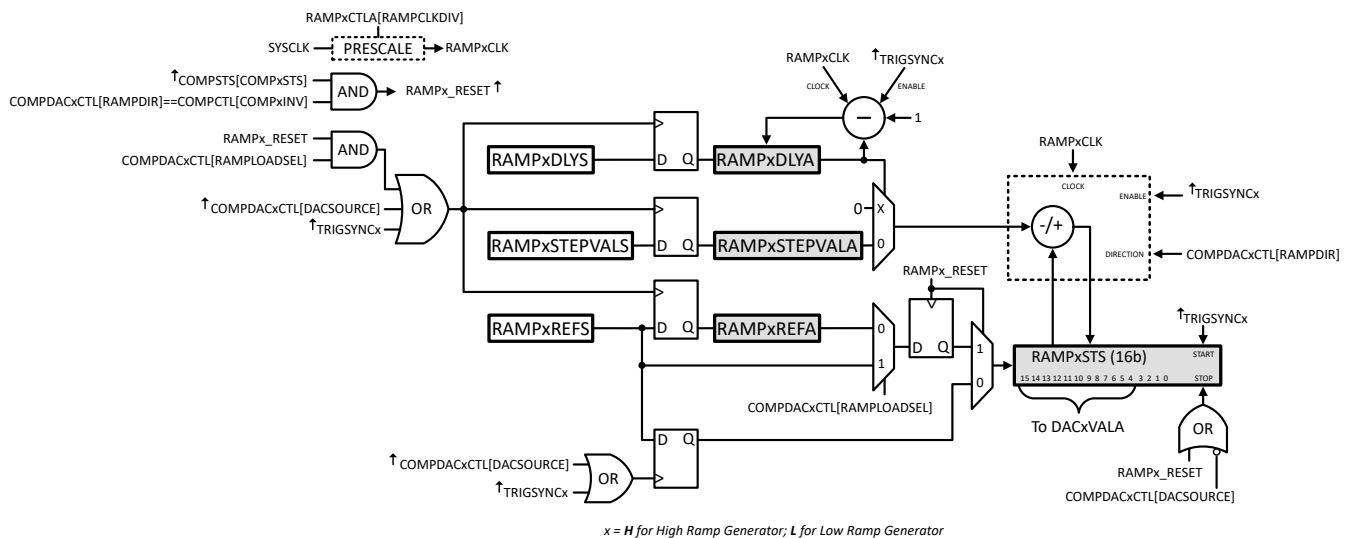

On the rising edge of DACSOURCE: the registers RAMPxREFA, RAMPxSTEPVALA, and RAMPDLYA are loaded with the shadow registers. Also, the register RAMPSTS is loaded with RAMPxREFS.

On the rising edge of the selected TRIGSYNC: the registers RAMPxREFA, RAMPxSTEPVALA, and RAMPDLYA are loaded with the shadow registers. Also, the register RAMPSTS is loaded with RAMPxREFS and starts decrementing in the decrement mode (RAMPDIR = 0) or incrementing in the increment mode (RAMPDIR = 1) when RAMPDLYA counter reaches zero.

On the rising edge of COMPSTS with RAMPLOADSEL = 1: the registers RAMPxREFA, RAMPxSTEPVALA, and RAMPDLYA are loaded with the shadow registers. Also, the register RAMPSTS is loaded with RAMPxREFS and stops decrementing in the decrement mode (RAMPDIR = 0) or incrementing in the increment mode (RAMPDIR = 1).

On the rising edge of COMPSTS with RAMPLOADSEL = 0: the register RAMPSTS is loaded with RAMPxREFA. So, the register RAMPSTS stops decrementing and incrementing in the decrement mode and the increment mode, respectively.

Additionally, if the value of RAMPSTS reaches zero and the ramp generator is in the decrement mode (RAMPDIR = 0), the RAMPSTS register remains static at zero until the next TRIGSYNC is received. If the ramp generator is in the increment mode (RAMPDIR = 1) and the value of RAMPSTS reaches 0xFFFF, the RAMPSTS register value remains at that value until the next TRIGSYNC is received. These state changes are illustrated in the ramp generator block diagram in Figure 20-4.

**Figure 20-4. Ramp Generator Block Diagram**

### 20.4.3 Ramp Generator Behavior at Corner Cases

Since the ramp generator makes state changes on every rising edge of TRIGSYNCx and COMPHSTS, the following behavior can be expected on instances when these two events occur simultaneously or very close together.

Case 1: COMPHSTS rising edge occurs one or more cycles before TRIGSYNC rising edge. RAMPSTS stops decrementing on COMPHSTS rising edge event. RAMPSTS starts decrementing on TRIGSYNCx rising edge event when RAMPDLYA reaches 0.

Case 2: COMPHSTS rising edge occurs simultaneously as TRIGSYNCx rising edge. EPWMSYNCPER rising edge event takes precedence and RAMPSTS starts decrementing when RAMPDLYA reaches 0. COMPHSTS rising edge event is ignored and does not halt RAMPSTS.

Case 3: COMPHSTS rising edge occurs one or more cycles after TRIGSYNCx rising edge but before RAMPDLYA reaches 0. RAMPSTS does not decrement when RAMPDLYA reaches 0.

Case 4: COMPHSTS rising edge occurs simultaneously as RAMPDLYA reaches 0 from TRIGSYNCx rising edge. RAMPSTS does not decrement.

This behavior is also illustrated in [Figure 20-5](#).

---

#### Note

For the ramp decrement mode of operation, set the registers COMPXINV and RAMPDIR to 0, and for the ramp increment mode of operation, set the registers COMPXINV and RAMPDIR to 1.

**Figure 20-5. Ramp Generator Behavior**

## 20.5 Digital Filter

The digital filter works on a window of FIFO samples (SAMPWIN) taken from the input. The filter output resolves to the majority value of the sample window, where majority is defined by the threshold (THRESH) value. If the majority threshold is not satisfied, the filter output remains unchanged.

For proper operation, the value of THRESH must be greater than  $SAMPWIN / 2$  and less than or equal to SAMPWIN.

A prescale function (CLKPRESCALE) determines the filter sampling rate, where the filter FIFO captures one sample every prescale system clocks. Old data from the FIFO is discarded.

Note that for SAMPWIN, THRESH and CLKPRESCALE, the internal number used by the digital filter is + 1 in all cases. In essence, samples = SAMPWIN + 1, threshold = THRESH + 1 and prescale = CLKPRESCALE + 1.

A conceptual model of the digital filter is shown in Figure 20-6.

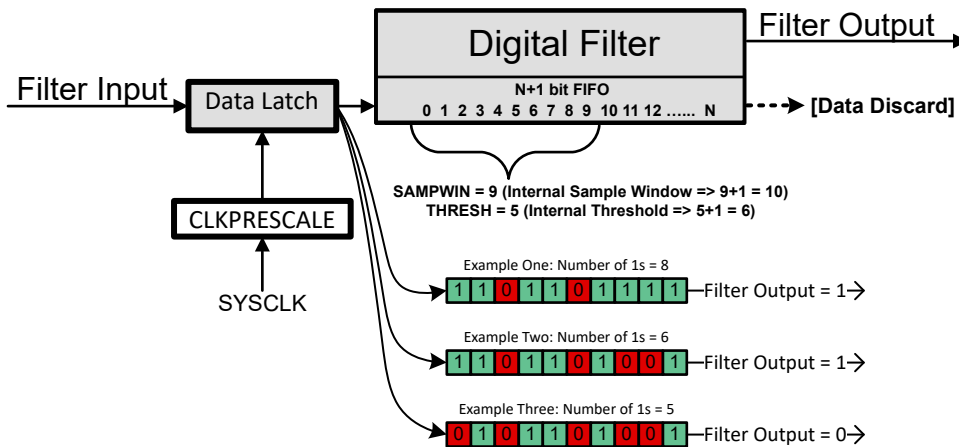

Figure 20-6. Digital Filter Behavior

Equivalent C code of the filter implementation is:

```

if (FILTER_OUTPUT == 0) {
    if (Num_1s_in_SAMPWIN >= THRESH) {
        FILTER_OUTPUT = 1;
    }
} else {
    if (Num_0s_in_SAMPWIN >= THRESH) {
        FILTER_OUTPUT = 0;
    }
}

```

### 20.5.1 Filter Initialization Sequence

For proper operation of the digital filter, the following initialization sequence is recommended:

1. Configure and enable the comparator for operation.
2. Configure the digital filter parameters for operation:
  - Set SAMPWIN for the number of samples to monitor in the FIFO window.
  - Set THRESH for the threshold required for majority qualification.
  - Set CLKPRESCALE for the digital filter clock prescale value.
3. Initialize the sample values in the digital FIFO window by setting FILINIT.
4. Clear COMPSTS latch using COMPSTSCLR, if the latched path is desired.
5. Configure the CTRIP and CTRIPOUT signal paths.
6. If desired, configure the destination module, for example, ePWM, GPIO, and so on to accept the filtered signals.

## 20.6 Using the CMPSS

### 20.6.1 LATCHCLR, EPWMSYNCPER, and EPWMBLANK Signals

The LATCHCLR signal holds the digital filter, synchronization block, and the latch output in reset (0) after the required delays. The LATCHCLR signal is activated in software using xLATCHCLR (x = H or L). The LATCHCLR signal can also be activated by EPWMSYNCPER when xSYNCCLREN (x = H or L) is set. If a longer LATCHCLR signal is required, the EPWMBLANK signal can be used to extend the LATCHCLR signal by setting BLANKEN.

EPWMSYNCPER and EPWMBLANK (BLANKWDW) come from the Time-Base and Digital Compare submodules of the EPWM, respectively. For a detailed description of how these two signals are generated, refer to the respective submodule section in the *Enhanced Pulse Width Modulator (ePWM)* chapter.

The EPWMSYNCPER signal that loads DACxVALA when COMPDACHCTL[SWLOADSEL] = 1 is a level trigger load. If TBCTR and TBPRD of the EPWM are both 0, EPWMSYNCPER is held at level high and DACxVALA is loaded immediately from DACxVALS irrespective of the value of COMPDACHCTL[SWLOADSEL]. Due to this, configure the EPWM first before setting COMPDACHCTL[SWLOADSEL] to 1.

---

#### Note

The name of the sync signal that the CMPSS receives from the EPWM has been updated from PWMSYNC to EPWMSYNCPER (SYNCPER/PWMSYNCPER/EPWMxSYNCPER) to avoid confusion with the other EPWM sync signals EPWMSYNCL and EPWMSYNCO. For a description of what are these signals, see the *Enhanced Pulse Width Modulator (ePWM)* chapter.

---

### 20.6.2 Synchronizer, Digital Filter, and Latch Delays

The synchronization block adds a delay of 1-2 sysclks. If the digital filter is bypassed (all filter settings are 0), the digital filter adds a delay of 2 sysclks. The latch adds 1 sysclk delay.

### 20.6.3 Calibrating the CMPSS

The CMPSS has two sources of offset errors: comparator offset error and compdac offset error. In the data sheet, the comparator offset error is referred to as **Input referred offset error** and compdac offset error is referred to as **Static offset error**. See the device data sheet for the values.

If both inputs of the comparator are driven from a pin, only the comparator offset error applies. However if the inverting input of the comparator is driven from the compdac, then only the compdac offset error applies. This is because the compdac offset error includes comparator offset error.

Due to the offset errors, the CMPSS must be calibrated to make sure trips happen at the expected levels. The following flow outlines how the calibration can be performed if the inverting input of the comparator is driven from the compdac.

Notes before calibration:

1. A static DC signal is required on the non-inverting input of the comparator.
2. Hysteresis can be disabled for calibration and can be re-enabled after calibration is complete.
3. A noisy input can make calibration difficult, so use the latch with non-zero filter settings depending on how noisy is the signal on the non-inverting input.

This approach sweeps down the compdac:

1. Set the starting compdac value to max, 0xFFFF.
  - Optional: Instead of setting the starting compdac value to maximum, set to **Vtarget + Static offset error + Margin**. Where **Vtarget** is the approximate DC voltage on the non-inverting input, **Static offset error** is the compdac offset error specification and **Margin** is some amount of guard band. This can lead to a faster calibration but only works if **Vtarget** is known. Alternatively, if **Vtarget** is unknown, the ADC can be used to convert **Vtarget**.
2. Decrement compdac value by 1.
3. Wait for compdac to settle.
4. Clear latch.
5. Wait for possible latch set.
6. If latch is set, trip code is found exit.
  - Optional: The trip code can be double checked by:
    - a. Increasing compdac value by 1.
    - b. Clear latch.
    - c. Wait for possible latch set.
    - d. Latch can be unset.
7. If latch is unset, go back to step 2 and repeat.

It is also possible to calibrate the CMPSS, if both inputs of the comparator are driven from a pin. For this case, the flow stays the same but the voltage on the inverting pin of the comparator is swept externally.

### 20.6.4 Enabling and Disabling the CMPSS Clock

If the clock to the CMPSS module is disabled while the comparator is active, the following behavior can be expected:

- The comparator remains unaffected and continues to trip from voltages on the inputs.
- If the reference 12-bit DAC is driving the negative input of the comparator, the voltage on the negative input remains static and unaffected but DACVALA can no longer be updated from the ramp generator or DACVALS.
- The ramp generator, synchronize block and digital filter freeze on the current states.

Enabling the clock to the CMPSS restores the clock to the state before the clock was disabled.

### 20.7.1 CMPSS Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/cmpss

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 20.7.1.1 CMPSS Asynchronous Trip - SINGLE\_CORE

FILE: cmpss\_ex1\_asynch.c

This example enables the CMPSS1 COMPH comparator and feeds the asynchronous CTRIPOUTH signal to the GPIO4/OUTPUTXBAR3 pin and CTRIPH to GPIO1/EPWM1B.

CMPSS is configured to generate trip signals to trip the EPWM signals. CMPIN1P is used to give positive input and internal DAC is configured to provide the negative input. Internal DAC is configured to provide a signal at VDD/2. An EPWM signal is generated at GPIO1 and is configured to be tripped by CTRIPOUTH.

When a low input(VSS) is provided to CMPIN1P,

- Trip signal(GPIO4) output is low
- PWM1B(GPIO1) gives a PWM signal

When a high input(higher than VDD/2) is provided to CMPIN1P,

- Trip signal(GPIO4) output turns high
- PWM1B(GPIO1) gets tripped and outputs as high

#### External Connections

- Give input on CMPIN1P
- Outputs can be observed on GPIO4 and GPIO1 using an oscilloscope

#### Watch Variables

- None

#### 20.7.1.2 CMPSS Digital Filter Configuration - SINGLE\_CORE

FILE: cmpss\_ex2\_digital\_filter.c

This example enables the CMPSS1 COMPH comparator and feeds the output through the digital filter to the GPIO4/OUTPUTXBAR3 pin.

CMPIN1P is used to give positive input and internal DAC is configured to provide the negative input. Internal DAC is configured to provide a signal at VDD/2.

When a low input(VSS) is provided to CMPIN1P,

- GPIO4 output is low

When a high input(higher than VDD/2) is provided to CMPIN1P,

- GPIO4 output turns high

## Enhanced Capture (eCAP) and High Resolution Capture (HRCAP)

---

This chapter describes the enhanced capture (eCAP) module and the high resolution capture (HRCAP) module, which are used in systems where accurate timing of external events is important.

The enhanced capture (eCAP) module is a Type 3 eCAP.

The high resolution capture (HRCAP) module is part of the eCAP module. HRCAP measures the width of external pulses to a higher degree of accuracy than the eCAP module.

See the [C2000 Real-Time Control Peripheral Reference Guide](#) for a list of all devices with an eCAP and HRCAP module of the same type, to determine the differences between the types, and for a list of device-specific differences within a type. A detailed description of all referenced functions can be found in the C2000Ware documentation.

## 21.1 Introduction

### 21.1.1 Features

The features of the eCAP module include:

- Speed measurements of rotating machinery (for example, toothed sprockets sensed by way of Hall sensors)
- Elapsed time measurements between position sensor pulses
- Period and duty cycle measurements of pulse train signals
- Decoding current or voltage amplitude derived from duty cycle encoded current/voltage sensors

The eCAP module features described in this chapter include:

- 4-event time-stamp registers (each 32 bits)
- Edge polarity selection for up to four sequenced time-stamp capture events
- Interrupt on either of the four events
- Single-shot capture of up to four event time-stamps
- Continuous mode capture of time stamps in a four-deep circular buffer
- Absolute time-stamp capture
- Difference (Delta) mode time-stamp capture
- When not used in capture mode, the eCAP module can be configured as a single-channel PWM output

The capture functionality of the Type 1 eCAP is enhanced from the Type 0 eCAP with the following added features:

- Event filter reset bit
  - Writing a 1 to ECCTL2[CTRFILTRESET] clears the event filter, the modulo counter, and any pending interrupts flags. Resetting the bit is useful for initialization and debug. Note that this is not applicable for signal monitoring interrupts, which do not get affected by the event filter reset bit.
- Modulo counter status bits
  - The modulo counter (ECCTL2 [MODCNRSTS]) indicates which capture register is loaded next. In the Type 0 eCAP, to know the current state of the modulo counter was not possible
- DMA trigger source
  - eCAPxDMA was added as a DMA trigger. CEVT[1-4] can be configured as the source for eCAPxDMA.
- Input multiplexer
  - ECCTL0 [INPUTSEL] selects one of 128 input signals, which are detailed in [Section 21.3](#).
- EALLOW protection
  - EALLOW protection was added to critical registers. To maintain software compatibility with Type-0, configure DEV\_CFG\_REGS.ECAPTYPE to make these registers unprotected.

The capture functionality of the Type 2 eCAP is enhanced from the Type 1 eCAP with the following added features:

- Added ECAPxSYNCINSEL register
  - ECAPxSYNCINSEL register is added for each eCAP to select an external SYNCIN. Every eCAP can have a separate SYNCIN signal.

The capture functionality of the Type 3 eCAP is enhanced from the Type 2 eCAP with the following added features:

- Two signal monitoring units to monitor edge, pulse width, and period
  - Signal monitoring can optionally be tightly coupled with ePWM global load strobes and trip events
- Increased the number of multiplexed capture inputs from 128 to 256
- DMA event generation capability in PWM mode of operation
- ADC SOC generation capability, to trigger ADC conversion

## 21.2 Description

The eCAP module represents one complete capture channel that can be instantiated multiple times, depending on the target device. In the context of this guide, one eCAP channel has the following independent key resources:

- Capture inputs can be connected using the Input X-BAR
- 256:1 input multiplexer
- Output X-BAR is used to configure output in APWM mode
- 32-bit time base (counter)
- 4 x 32-bit time-stamp capture registers (CAP1-CAP4)
- Four-stage sequencer (modulo4 counter) that is synchronized to external events, eCAP pin rising/falling edges.
- Modulo counter status register (MODCNRSTS) to indicate sequencer state
- Independent edge polarity (rising/falling edge) selection for all four events
- Input capture signal prescaling (from 2-62 or bypass)
- One-shot compare register (two bits) to freeze captures after 1-4 time-stamp events
- Control for continuous time-stamp captures using a four-deep circular buffer (CAP1-CAP4) scheme
- Interrupt capabilities on any of the four capture events
- Separate DMA trigger
- EALLOW protection to control registers
- Signal monitoring capability for edge, pulse width, and period
- DMA event generation capability in APWM mode
- ADC SOC event generation capability, to trigger ADC conversion

## 21.3 Configuring Device Pins for the eCAP

The Input X-BAR connects the device pins to the module as input. Any GPIO on the device can be configured as an input. The GPIO input qualification can be set to synchronous or asynchronous mode by setting the GPXQSELn register bits. Using synchronized inputs can help with noise immunity but affects the eCAP accuracy by  $\pm 2$  cycles. The internal pull-ups can be configured in the GPYPUD register. Since the GPIO mode is used, the GPYINV register can invert the signals.

New to the Type 1 eCAP module, a 128:1 input multiplexer must also be configured (see [Figure 21-3](#)). This multiplexer can select a variety of inputs detailed in [Table 21-1](#) by configuring ECCTL0.INPUTSEL.

The Output X-BAR must be used to connect output signals to the OUTPUTXBARx output locations. The GPIO mux must then be configured to connect the OUTPUTXBARx lines to any of several IO pins with the GPIO mux. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux, GPIO settings, and XBAR configuration.

---

**Note**

ECAPxIN has to be at least  $2 \times \text{SYSCLK}$ -cycles wide to be properly captured by the eCAP module; otherwise, the input pulse can get missed from sampling by the SYSCLK.

### 21.4 Capture and APWM Operating Mode

Use the eCAP module resources to implement a single-channel PWM generator (with 32-bit capabilities) when the eCAP module is not being used for input captures. The counter operates in count-up mode, providing a time-base for asymmetrical pulse width modulation (PWM) waveforms. The CAP1 and CAP2 registers become the active period and compare registers, respectively, while CAP3 and CAP4 registers become the period and compare shadow registers, respectively. Figure 21-1 is a high-level view of both the capture and auxiliary pulse-width modulator (APWM) modes of operation.

Figure 21-2 further describes the output of the eCAP in APWM mode based on the CMP and PRD values.

- A. A single pin is shared between CAP and APWM functions. In capture mode, the pin is an input; in APWM mode, the pin is an output.
- B. In APWM mode, writing any value to CAP1/CAP2 active registers also writes the same value to the corresponding shadow registers CAP3/CAP4. This emulates immediate mode. Writing to the shadow registers CAP3/CAP4 invokes the shadow mode.

**Figure 21-1. Capture and APWM Modes of Operation**

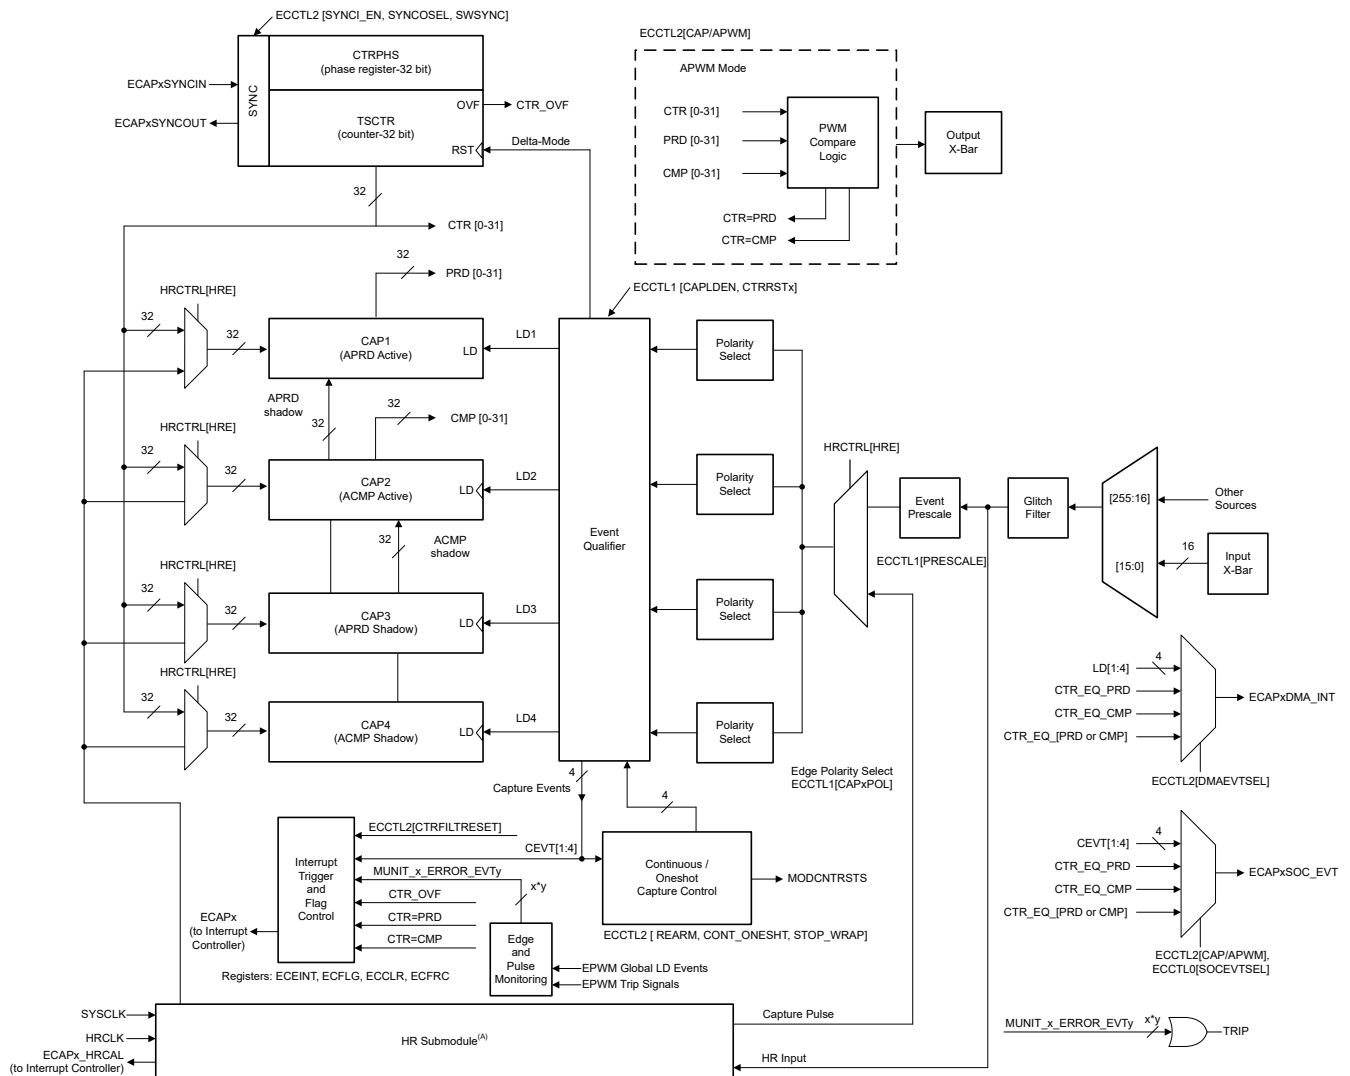

Figure 21-2. Counter Compare and PRD Effects on the eCAP Output in APWM Mode

### 21.5 Capture Mode Description

Figure 21-3 shows the various components that implement the capture function.

A. The HRCAP submodule is not available on all eCAP modules; in this case, the high-resolution muxes and hardware are not implemented.

Figure 21-3. eCAP Block Diagram

### 21.5.1 Event Prescaler

An input capture signal (pulse train) can be prescaled by  $N = 2-62$  (in multiples of 2) or can bypass the prescaler. This is useful when very high frequency signals are used as inputs. Figure 21-4 shows a functional diagram and Figure 21-5 shows the operation of the prescale function. The event prescaler can be reset by setting the ECCTL2.CTRFILTRESET register bit.

- A. When a prescale value of 1 is chosen (ECCTL1[13:9] = 0,0,0,0,0), the input capture signal bypasses the prescale logic completely.
- B. The first Rise edge after Prescale configuration change is not passed to Capture logic, prescaler value takes into effect on the second rising edge after the configuration.

Figure 21-4. Event Prescale Control

Figure 21-5. Prescale Function Waveforms

### 21.5.2 Glitch Filter

A glitch filter is included to reduce internal and external noise glitches on the source signal being measured by the eCAP.

The glitch filter can be used to filter out glitches of a specified time period in terms of SYSCLK cycles. The supported range is from 1 to 15 cycles. By default, the glitch filter is disabled (ECCCTL0[QUALPRD] = 0) to maintain compatibility.

---

#### Note

The glitch filter can be disabled when using HRCAP as the filter changes the pulse width of the signal. Also note that when enabled, the glitch filter delays the signal by QUALPRD+1, which must be accounted for in applications utilizing the feature.

---

### 21.5.3 Edge Polarity Select and Qualifier

Functionality and features include:

- Four independent edge polarity (rising edge/falling edge) selection muxes are used, one for each capture event.
- Each edge (up to 4) is event qualified by the Modulo4 sequencer.
- The edge event is gated to the respective CAPx register by the Mod4 counter. The CAPx register is loaded on the falling edge.

### 21.5.4 Continuous/One-Shot Control

Operation of eCAP in Continuous/One-Shot mode:

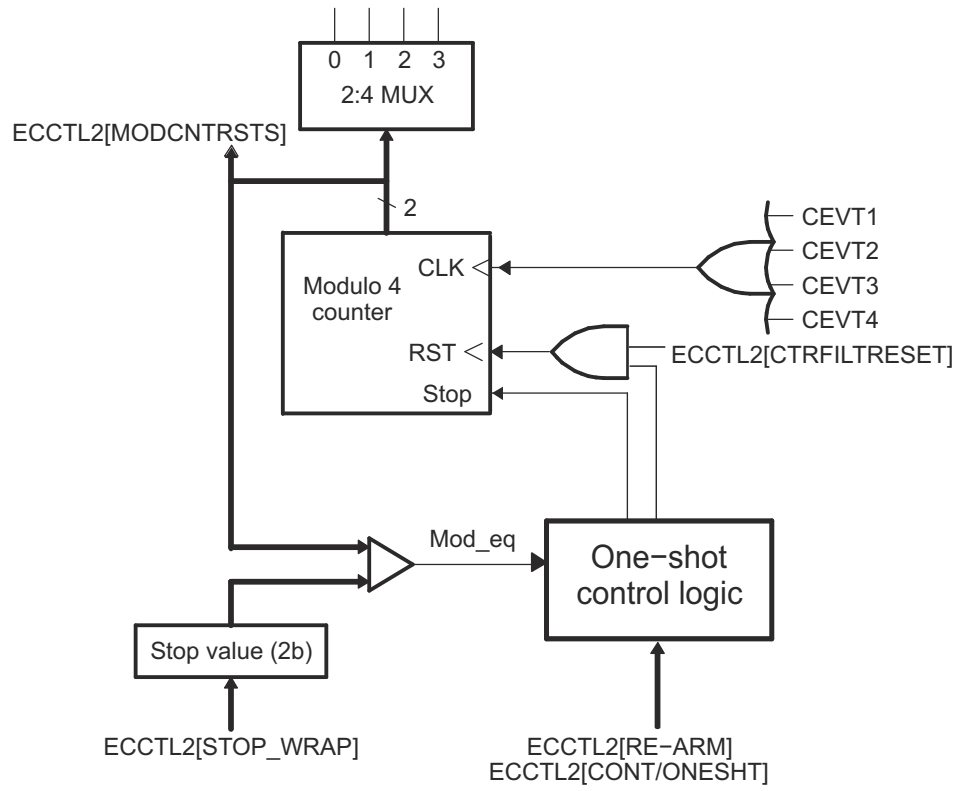

- The Mod4 (2-bit) counter is incremented using edge qualified events (CEVT1-CEVT4).
- The Mod4 counter continues counting (0->1->2->3->0) and wraps around unless stopped.
- During one-shot operation, a 2-bit stop register (STOP\_WRAP) is used to compare the Mod4 counter output, and when equal, stops the Mod4 counter and inhibits further loads of the CAP1-CAP4 registers. In this mode, if TSCCTR counter is configured to reset on capture event (CEVTx) by configuring ECCTL1.CTRRSTx bit, the operation still keeps resetting the TSCCTR counter on capture event (CEVTx) after the STOP\_WRAP value is reached and re-arm (REARM) has not occurred.

The continuous/one-shot block controls the start, stop and reset (zero) functions of the Mod4 counter, using a mono-shot type of action that can be triggered by the stop-value comparator and re-armed using software control.

Once armed, the eCAP module waits for 1-4 (defined by stop-value) capture events before freezing both the Mod4 counter and contents of CAP1-4 registers (time stamps).

Re-arming prepares the eCAP module for another capture sequence. Also, re-arming clears (to zero) the Mod4 counter and permits loading of CAP1-4 registers again, providing the CAPLDEN bit is set.

In continuous mode, the Mod4 counter continues to run (0->1->2->3->0, the one-shot action is ignored, and capture values continue to be written to CAP1-4 in a circular buffer sequence.

**Figure 21-6. Details of the Continuous/One-shot Block**

### 21.5.5 32-Bit Counter and Phase Control

This counter provides the time-base for event captures, and is clocked using the system clock.

A phase register is provided to achieve synchronization with other counters using a hardware and software forced sync. This is useful in APWM mode when a phase offset between modules is needed.

On any of the four event loads, an option to reset the 32-bit counter is given. This is useful for time difference capture. The 32-bit counter value is captured first, then the counter value is reset to 0 by any of the LD1-LD4 signals.

### 21.5.6 CAP1-CAP4 Registers

These 32-bit registers are supplied by the 32-bit counter timer bus, CTR[0-31], and are loaded (capture a time-stamp) when the respective LD inputs are strobed.

Control bit CAPLDEN can inhibit loading of the capture registers. During one-shot operation, this bit is cleared (loading is inhibited) automatically when a stop condition occurs, StopValue = Mod4.

CAP1 and CAP2 registers become the active period and compare registers, respectively, in APWM mode.

CAP3 and CAP4 registers become the respective shadow registers (APRD and ACMP) for CAP1 and CAP2 during APWM operation.

### 21.5.7 eCAP Synchronization

eCAP modules can be synchronized with each other by selecting a common SYNCIN source. SYNCIN source for eCAP can be either software sync-in or external sync-in. The external sync-in signal can come from eCAP, X-Bar or EPWM. The SWSYNC of the eCAP module is logical ORed with the SYNC signal as shown in Figure 21-7. The SYNC signal is defined by the selection of ECAPxSYNCINSEL[SEL] as shown in Figure 21-8.

**Note**

ECAPxSYNCOUT going to the ECAPSYNCIN multiplexer is disabled. For example, ECAP1SYNCOUT cannot be a sync in to ECAP1, but ECAP1SYNCOUT can be a sync in to ECAP2, ECAP3, and so on.

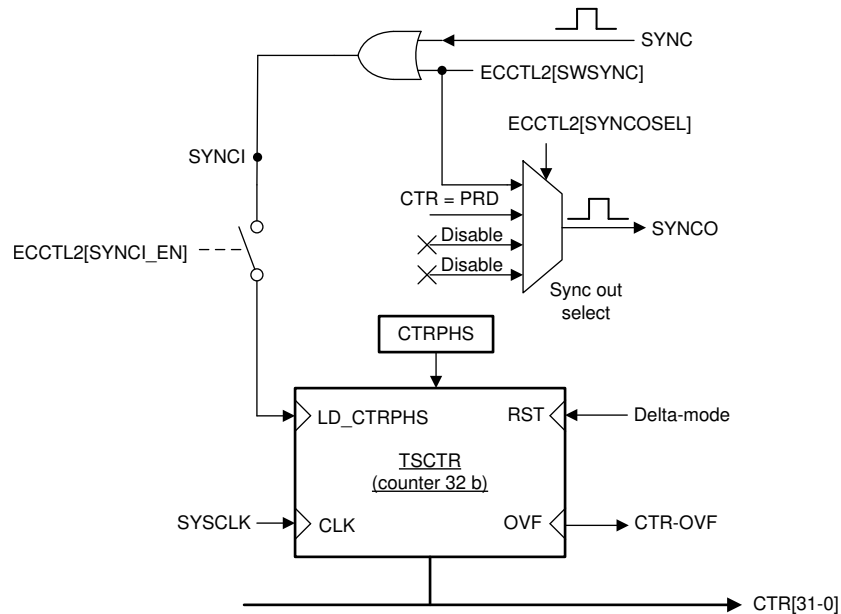

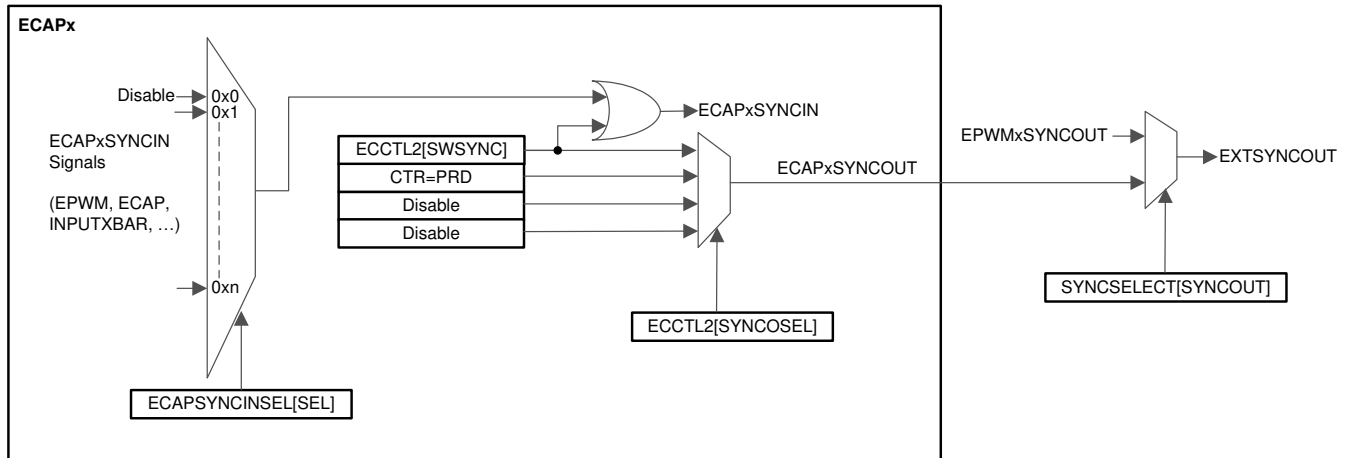

Figure 21-7. Details of the Counter and Synchronization Block

**Figure 21-8. eCAP Synchronization Scheme**

### 21.5.7.1 Example 1 - Using SWSYNC with ECAP Module

Implement the following steps to use SWSYNC with ECAP1 and ECAP2.

- Configure ECAP[1..2].ECAPSYNCINSEL.SEL = 0x0 to disable external SYNCIN coming to eCAP1.
- Configure ECAP[1..2].ECCTL2.SWSYNC = 0x1, to force Software Synchronization of the TSCTR counter.

To use SWSYNC with other eCAP modules, make sure that the previous eCAP chain is not generating a SYNCOUT signal that interferes with the software synchronization.

### 21.5.8 Interrupt Control

Operation and features of the eCAP interrupt control include (see [Figure 21-9](#)):

- An interrupt can be generated on capture events (CEVT1-CEVT4, CTROVF) or APWM events (CTR = PRD, CTR = CMP).
- An interrupt can be generated on signal monitoring errors (MUNIT\_1\_ERROR\_EVT1, MUNIT\_1\_ERROR\_EVT1, MUNIT\_2\_ERROR\_EVT1, MUNIT\_2\_ERROR\_EVT2)
- A counter overflow event (FFFFFFFF->00000000) is also provided as an interrupt source (CTROVF).
- The capture events are edge and sequencer-qualified (ordered in time) by the polarity select and Mod4 gating, respectively.
- One of these events can be selected as the interrupt source (from the eCAPx module) going to the PIE and CLA.
- Seven interrupt events (CEVT1, CEVT2, CEVT3, CEVT4, CNTOVF, CTR=PRD, CTR=CMP) can be generated.
- An additional four interrupt events (MUNIT\_1\_ERROR\_EVT1, MUNIT\_1\_ERROR\_EVT1, MUNIT\_2\_ERROR\_EVT1, MUNIT\_2\_ERROR\_EVT2) can be generated from the signal monitoring unit.
- The interrupt enable register (ECEINT) is used to enable/disable individual interrupt event sources. The interrupt flag register (ECFLG) indicates if any interrupt event has been latched and contains the global interrupt flag bit (INT). An interrupt pulse is generated to the PIE only if any of the interrupt events are enabled, the flag bit is 1, and the INT flag bit is 0. The interrupt service routine must clear the global interrupt flag bit and the serviced event using the interrupt clear register (ECCLR) before any other interrupt pulses are generated. All interrupt flags are cleared upon an event filter reset by writing a 1 to ECCTL2[CLRFILTRESET]. To force an interrupt event, use the interrupt force register (ECFRC). This is useful for test purposes.

---

#### Note

The CEVT1, CEVT2, CEVT3, CEVT4 flags are only active in capture mode (ECCTL2[CAP/APWM == 0]). The CTR=PRD, CTR=CMP flags are only valid in APWM mode (ECCTL2[CAP/APWM == 1]). CNTOVF flag is valid in both modes.

---

Figure 21-9. Interrupts in eCAP Module

### **21.5.9 DMA Interrupt**

On Type 0 eCAP modules, the CPU was required to begin data transfers using DMA. New to the Type 1 eCAP, a separate DMA Trigger (ECAP\_DMA\_INT) enables continuous transfer of capture data from eCAP registers to on-chip memory using DMA. Any one of the four available interrupt events (LD1, LD2, LD3, and LD4) can be selected as the trigger source for ECAP\_DMA\_INT using ECCTL2 [DMAEVTSEL].

New to the Type 3 eCAP is the ability to trigger DMA events in APWM mode. Any one of three available events (period match, compare match, or both) can be selected as the trigger source for ECAP\_DMA\_INT using ECCTL2 [DMAEVTSEL].

### **21.5.10 ADC SOC Event**

Type 3 introduces the capability to generate ADC SOC events in capture mode and in APWM mode of operation. The ability to start ADC conversions allows for increased APWM functionality, as well as the ability to synchronize capture events with ADC samples.

In capture mode, one of the four available interrupt events (CEVT1, CEVT2, CEVT3, and CEVT4) can be selected as ECAP\_SOC\_EVT using ECCCTL0[SOCEVTSEL].

In APWM mode, any one of three available events (period match, compare match, or both) can be selected as ECAP\_SOC\_EVT using ECCCTL0[SOCEVTSEL].

### **21.5.11 Shadow Load and Lockout Control**

In capture mode, this logic inhibits (locks out) any shadow loading of CAP1 or CAP2 from APRD and ACMP registers, respectively.

In APWM mode, shadow loading is active and two choices are permitted:

- Immediate - APRD or ACMP are transferred to CAP1 or CAP2 immediately upon writing a new value.
- On period equal, CTR[31:0] = PRD[31:0].

### **21.5.12 APWM Mode Operation**

Main operating highlights of the APWM section:

- The time-stamp counter bus is made available for comparison by way of 2 digital (32-bit) comparators.
- When CAP1/2 registers are not used in capture mode, the contents can be used as Period and Compare values in APWM mode.
- Double buffering is achieved using shadow registers APRD and ACMP (CAP3/4). The shadow register contents are transferred over to CAP1/2 registers, either immediately upon a write, or on a CTR = PRD trigger.
- In APWM mode, writing to CAP1/CAP2 active registers also writes the same value to the corresponding shadow registers CAP3/CAP4. This emulates immediate mode. Writing to the shadow registers CAP3/CAP4 invokes the shadow mode.
- During initialization, write to the active registers for both period and compare. This automatically copies the initial values into the shadow values. For subsequent compare updates during run-time, use the shadow registers.

Figure 21-10. PWM Waveform Details Of APWM Mode Operation

The behavior of APWM active high mode (APWMPOL == 0) is as follows:

CMP = 0x00000000, output low for duration of period (0% duty)

CMP = 0x00000001, output high 1 cycle

CMP = 0x00000002, output high 2 cycles

CMP = PERIOD, output high except for 1 cycle (<100% duty)

CMP = PERIOD+1, output high for complete period (100% duty)

CMP > PERIOD+1, output high for complete period

The behavior of APWM active low mode (APWMPOL == 1) is as follows:

CMP = 0x00000000, output high for duration of period (0% duty)

CMP = 0x00000001, output low 1 cycle

CMP = 0x00000002, output low 2 cycles

CMP = PERIOD, output low except for 1 cycle (<100% duty)

CMP = PERIOD+1, output low for complete period (100% duty)

CMP > PERIOD+1, output low for complete period

**Figure 21-11. Time-Base Frequency and Period Calculation**

### 21.5.13 Signal Monitoring Unit

The signal monitoring unit can be used for edge, pulse width, and period monitoring of ECAP input signals. This allows for detection that is useful for many applications. For example, EPWM pulse width boundary monitoring can be accomplished for safety applications.

The high-level features of the signal monitoring unit include:

- Measure pulse width (high or low) and check if the pulse width is in expected range
- Measure period (rise-to-rise or fall-to-fall) and check if the period is in expected range
- Monitor signal edge (rise or fall) and check if the signal edge occurs in a user-programmed time window

### 21.5.13.1 Pulse Width and Period Monitoring

The signal monitoring unit has the ability to measure pulse width (either low or high) or period (rise-to-rise edge or fall-to-fall edge) and automatically generate an error when the pulse width is outside of a programmable expected range.

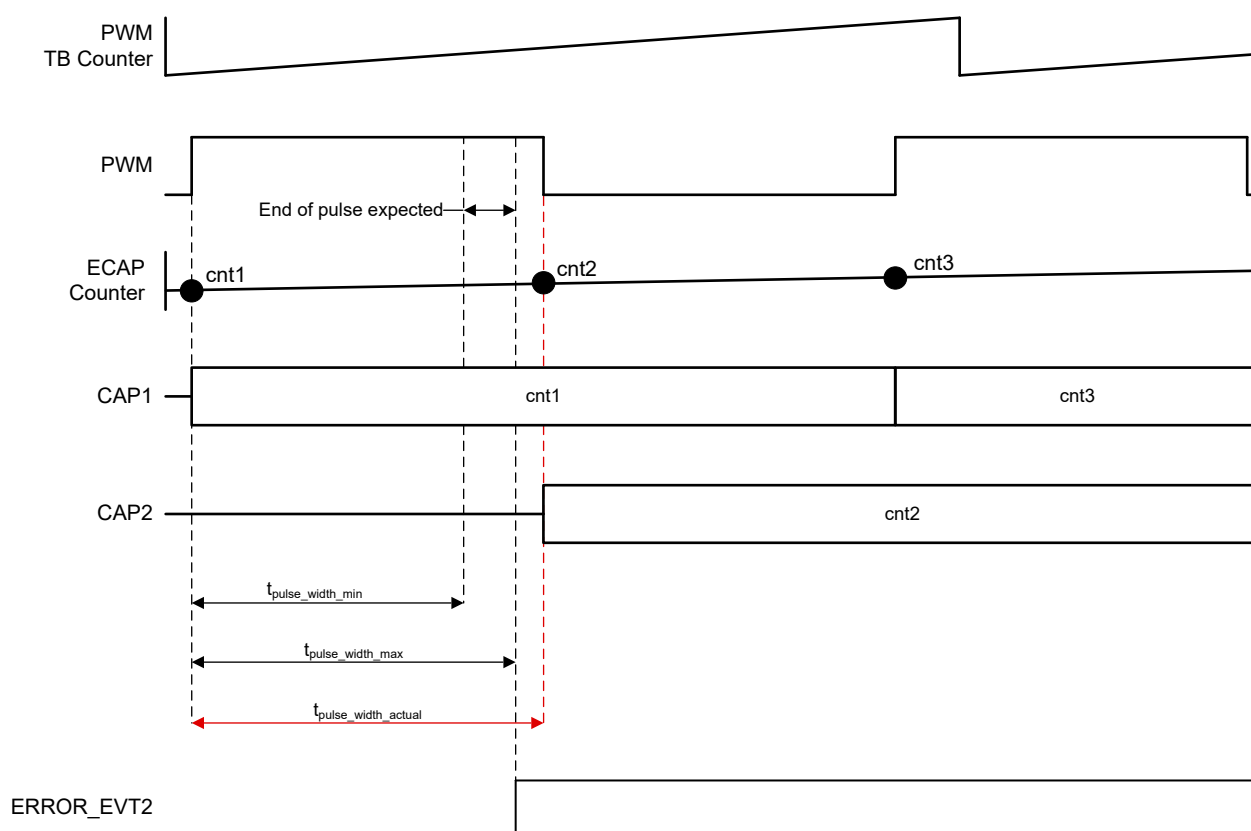

The expected pulse width range is programmable using the following configuration registers (or their respective shadow registers):

- `MUNIT_#_MIN` programs the minimum pulse width capture value
- `MUNIT_#_MAX` programs the maximum pulse width capture value

Any pulse width outside of these programmed bounds triggers one of two error events:

- `MUNIT_#_ERROR_EVT1` generated when measured pulse width is less than `MUNIT_#_MIN`
- `MUNIT_#_ERROR_EVT2` generated when measured pulse width is greater than `MUNIT_#_MAX`

The following diagram provides an example in which the measured pulse width exceeds the MAX value, generating an `ERROR_EVT2` event.

**Figure 21-12. ECAP Signal Monitoring Unit Pulse Width Error Example**

### Configuration Requirements

To enable this mode, the following settings must be configured:

- Absolute mode must be set for the ECAP counter, so that the counter is free running and does not get reset on any capture events
- Continuous mode must be enabled (one-shot mode can be used, but is not recommended given the short duration)
- Sync feature for the counter must be disabled (`ECCTL2.SYNCl_EN = 0`)
- A minimum of two captures must be enabled (`ECCTL2.STOP_WRAP >= 1`, and at least CAP1 and CAP2 enabled)

- Capture Edge (ECCTL1.CAPxPOL) of used capture modules (any of CAP1 to CAP4) must be configured to capture two edges of interest
  - High pulse: one rising edge and one falling edge
  - Low pulse: one rising edge and one falling edge
  - Period rise-to-rise: two rising edges
  - Period fall-to-fall: two falling edges

---

**Note**

If a pulse width is greater than the MAX value, a second edge can arrive late or never even occur. Because of this, the DISABLE\_EARLY\_MAX\_ERR field in the MUNIT\_#\_CTL register can be used to choose when a MAX error occurs. By setting the bit to 0, an error is generated as soon as the pulse width is greater than the specified maximum value. By setting the bit to 1, an error is generated when the second event has occurred.

---

### 21.5.13.2 Edge Monitoring

The signal monitoring unit has the ability to monitor and check if a rise or fall edge occurs within a specified time window and automatically generate an error when an edge occurs outside of this window.

The time window of an expected edge event can be programmed using the following configuration registers (or their respective shadow registers):

- MUNIT\_#\_MIN programs the minimum pulse width capture value
- MUNIT\_#\_MAX programs the maximum pulse with capture value

Any edge that occurs outside of these programmed bounds triggers the following error event:

- MUNIT\_#\_ERROR\_EVT1 generated when edge occurs outside the bounds of MUNIT\_#\_MIN and MUNIT\_#\_MAX.

Additionally, ERROR\_EVT2 is generated if either MIN or MAX did not occur between two sync events.

The following diagram provides an example in which a rising edge does not occur during the expected window, generating an ERROR\_EVT1 event.

**Figure 21-13. ECAP Signal Monitoring Unit Edge Error Example**

### Configuration Requirements

To enable this mode, the following settings must be configured:

- The ECAP counter must be synced with an EPWM module
- Absolute mode must be set for the ECAP counter, so that the counter is free running and does not get reset on any capture events
- Continuous mode can be enabled (one-shot mode can be used, but is not recommended given the modes short duration)
- A minimum of one capture can be enabled (ECCTL2.STOP\_WRAP >= 0, and at least CAP1 enabled)
- Capture Edge (ECCTL1.CAPxPOL) of used capture modules (any of CAP1 to CAP4) must be configured to capture an edge of interest
- The time window defined using MIN and MAX can not cross the sync boundary

#### Note

The following are important considerations when configuring the edge monitoring feature:

- If the EPWM counter or ECAP counter are loaded with a non-zero phase value, the MIN and MAX values must be adjusted accordingly in SW. This also applies when the glitch filter is enabled, as the glitch filter delays the signal by QUALPRD+1
- The edge monitoring logic restarts on a sync event. This is to avoid any deadlock in case MIN, MAX, or both events do not occur between two sync events. ERROR\_EVT2 is generated, if MIN or MAX match did not occur between two sync events
- The time window defined using MIN and MAX can not cross the sync boundary

## 21.6 Application of the eCAP Module

The following sections provide applications examples to show how to operate the eCAP module.

### 21.6.1 Example 1 - Absolute Time-Stamp Operation Rising-Edge Trigger

Figure 21-14 shows an example of continuous capture operation (Mod4 counter wraps around). In this figure, TSCTR counts-up without resetting and capture events are qualified on the rising edge only, this gives period (and frequency) information.

On an event, the TSCTR contents (time-stamp) is first captured, then Mod4 counter is incremented to the next state. When the TSCTR reaches FFFFFFFF (maximum value), the Mod4 counter wraps around to 00000000 (not shown in Figure 21-14), if this occurs, the CTROVF (counter overflow) flag is set, and an interrupt (if enabled) occurs. Captured Time-stamps are valid at the point indicated by the diagram (after the fourth event); hence, event CEVT4 can conveniently be used to trigger an interrupt and the CPU can read data from the CAPx registers.

Figure 21-14. Capture Sequence for Absolute Time-stamp and Rising-Edge Detect

### 21.6.2 Example 2 - Absolute Time-Stamp Operation Rising- and Falling-Edge Trigger

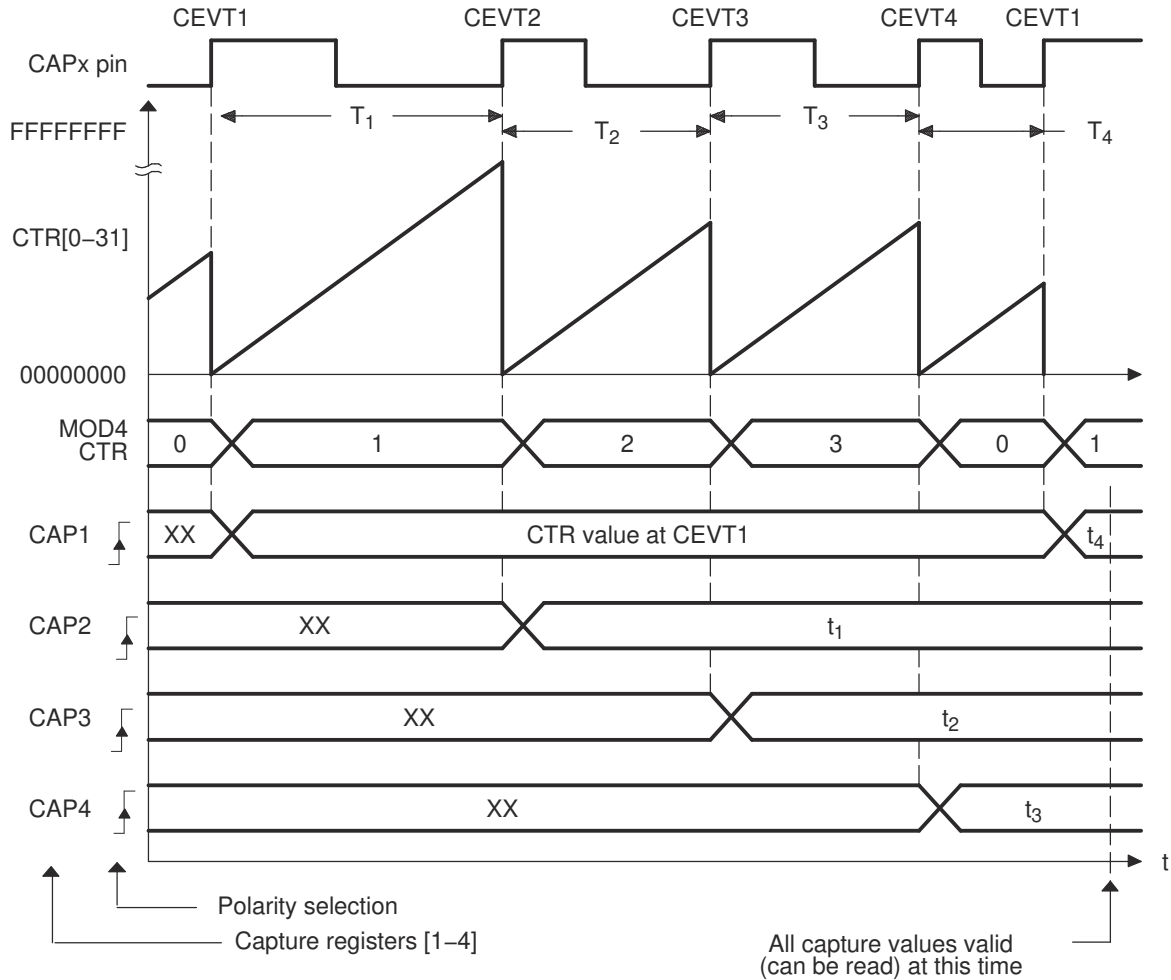

In Figure 21-15, the eCAP operating mode is almost the same as in the previous section except capture events are qualified as either rising or falling edge, this now gives both period and duty cycle information, that is: Period1 =  $t_3 - t_1$ , Period2 =  $t_5 - t_3$ , ...and so on. Duty Cycle1 (on-time %) =  $(t_2 - t_1) / \text{Period1} \times 100\%$ , and so on. Duty Cycle1 (off-time %) =  $(t_3 - t_2) / \text{Period1} \times 100\%$ , and so on.

**Figure 21-15. Capture Sequence for Absolute Time-stamp with Rising- and Falling-Edge Detect**

**21.6.3 Example 3 - Time Difference (Delta) Operation Rising-Edge Trigger**

Figure 21-16 shows how the eCAP module can be used to collect delta timing data from pulse train waveforms. Here Continuous Capture mode (TSCTR counts-up without resetting, and Mod4 counter wraps around) is used. In Delta-time mode, TSCTR is reset back to zero on every valid event. Here capture events are qualified as rising edge only. On an event, TSCTR contents (Time-Stamp) is captured first, and then TSCTR is reset to zero. The Mod4 counter then increments to the next state. If TSCTR reaches FFFFFFFF (maximum value), before the next event, the Mod4 counter wraps around to 00000000 and continues, a CNTOVF (counter overflow) flag is set, and an interrupt (if enabled) occurs. The advantage of Delta-time mode is that the CAPx contents directly give timing data without the need for CPU calculations, that is, Period1 =  $T_1$ , Period2 =  $T_2$ , and so on. As shown in Figure 21-16, the CEVT1 event is a good trigger point to read the timing data,  $T_1$ ,  $T_2$ ,  $T_3$ ,  $T_4$  are all valid here.

**Figure 21-16. Capture Sequence for Delta Mode Time-stamp and Rising Edge Detect**

### 21.6.4 Example 4 - Time Difference (Delta) Operation Rising- and Falling-Edge Trigger

In Figure 21-17, the eCAP operating mode is almost the same as in previous section except capture events are qualified as either rising or falling edge, this now gives both period and duty cycle information, that is: Period1 =  $T_1+T_2$ , Period2 =  $T_3+T_4$ , and so on. Duty Cycle1 (on-time %) =  $T_1 / \text{Period1} \times 100\%$ , Duty Cycle1 (off-time %) =  $T_2 / \text{Period1} \times 100\%$ , and so on.

During initialization, write to the active registers for both period and compare. This action automatically copies the init values into the shadow values. For subsequent compare updates during run-time, the shadow registers must be used.

## 21.7 Application of the APWM Mode

In this example, the eCAP module is configured to operate as a PWM generator. Here, a very simple single-channel PWM waveform is generated from the APWMx output pin. The PWM polarity is active high, which means that the compare value (CAP2 reg is now a compare register) represents the on-time (high level) of the period. Alternatively, if the APWMPOL bit is configured for active low, then the compare value represents the off-time.

## 21.8 High Resolution Capture (HRCAP) Module

This section describes the High Resolution Capture module.

### 21.8.1 Introduction

Uses for the HRCAP module include:

- Capacitive touch applications
- High-resolution period and duty cycle measurements of pulse train cycles
- Instantaneous speed measurements
- Instantaneous frequency measurements
- Voltage measurements across an isolation boundary
- Distance/sonar measurement and scanning
- Measuring flow

#### 21.8.1.2 Features

The HRCAP module includes the following features:

- Pulse-width capture in either non-high-resolution or high-resolution modes
- Absolute mode pulse-width capture
- Continuous or one-shot capture
- Interrupt on either falling or rising edge
- Continuous mode capture of pulse widths in 4-deep buffer
- Hardware calibration logic for precision high-resolution capture

All of the previous resources are available on any pin using the Input X-BAR.

#### 21.8.1.3 Description

Improvements from the Type 0 HRCAP are:

- Simplified calibration scheme:
  - HRCAP is always functional; never offline to perform calibration
  - Calibration is always running in the background; drastically reduced software overhead to calibrate
- Reduced software overhead to compute fractional bits
- Fractional and integer portions are packed into 32 bits
- All eCAP hardware is accessible when using the HRCAP enhancements. See [Section 21.8.3](#) for practical considerations.
- Usage of the HRCAP is now unified with the eCAP

The HRCAP enhancement has been added to eCAP 6 and eCAP 7 to allow signals to be captured asynchronously to SYSCLK. Each HRCAP submodule includes one capture channel in addition to a hardware calibration block. All eCAP hardware is accessible when using the HRCAP enhancements; however, using the Event Filter or the Input Qualifier is not valid, as these are synchronous to SYSCLK.

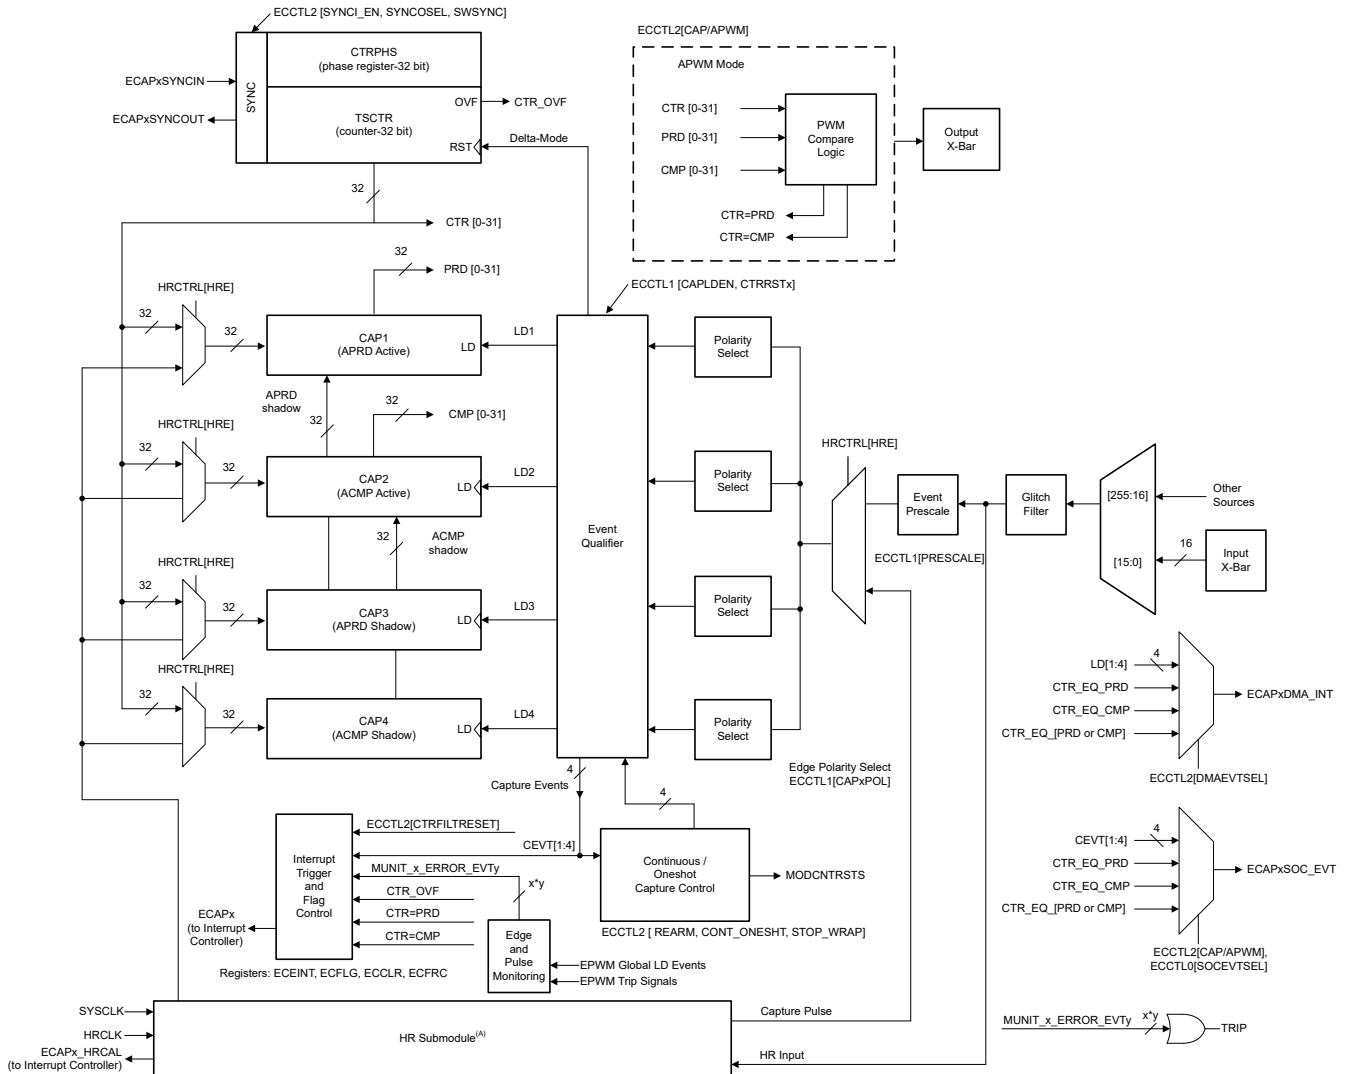

Each HRCAP-capable channel has the following independent key resources:

- All hardware of the respective eCAP
- High-resolution calibration logic
- Dedicated calibration interrupt

### 21.8.2 Operational Details

Figure 21-19 shows the various components that implement the high-resolution capture functionality of the eCAP module. Note that existing eCAP resources are reused, which requires that the eCAP module is set up before using the HRCAP enhancements. For simplicity, absolute timestamp measurements are recommended. See Section 21.8.3 for more details.

All HRCAP measurements are relative-time measures, in terms of minimum step size. Calibration hardware as well as software functions, have been provided to convert relative-time measurements to time-converted measurements in terms of seconds. The calibration hardware and software is only required if time-converted measurements are required.

A. The HRCAP submodule is not available on all eCAP modules; in this case, the high-resolution muxes and hardware are not implemented.

### 21.8.2.1 HRCAP Clocking

Unlike previous Type-0 HRCAP modules, the Type-1 eCAP, with HRCAP functionality, does not require a second PLL. However, the module still requires both SYSCLK and a second asynchronous clock source called HRCLK. The HRCLK is sensitive to changes in both temperature and voltage. For this reason, when using time-converted measurements, it is required to make periodic continuous calibrations.

### 21.8.2.2 HRCAP Initialization Sequence

Following are the HRCAP initialization sequence steps. When using the HRCAP to take relative-time measurements, only steps 1-5 are required. When using the HRCAP to take time-converted measurements, all steps are required.

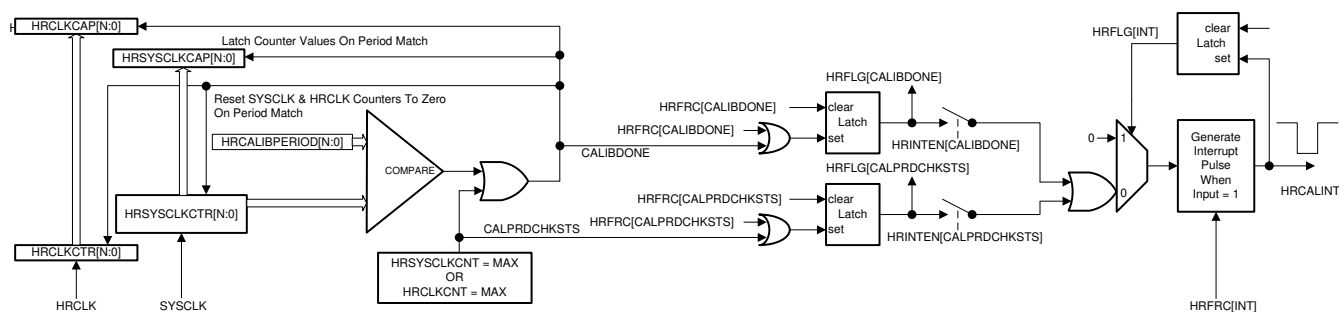

1. Enable HRCLK using HRCAP\_enableHighResolutionClock()
2. Delay 1 $\mu$ s
3. Enable HR mode using HRCAP\_enableHighResolution()
4. Delay 1 $\mu$ s
5. Configure the eCAP module as desired, including interrupts
6. Set calibration period using HRCAP\_setCalibrationPeriod()
7. Enable continuous calibration using HRCAP\_setCalibrationMode()
8. Enable interrupts using HRCAP\_enableCalibrationInterrupt()
9. Start calibration using HRCAP\_startCalibration()

### 21.8.2.3 HRCAP Interrupts

The HRCAP enhancements leverage the existing eCAP interrupts (see *Interrupt Control* in the ECAP chapter) in addition to HRCALINT, which is used exclusively by the hardware calibration block. HRCALINT can be triggered by the following conditions:

1. SYSCLKCTR = HRCALIBPERIOD
2. SYSCLKCTR or HRCLKCTR experience an overflow condition

Figure 21-20 shows this logic.

**Figure 21-20. HRCAP Calibration**

### 21.8.2.4 HRCAP Calibration

---

#### Note

For HRCAP calibration to work, the system needs to operate at SYSCLK frequency > 100MHz.

---

The following section applies only to time-converted measurements; calibration for relative-time measurements is not required. All values captured by the HRCAP submodule are in number of HRCLK cycles. The HRCLK speed varies widely with temperature and voltage, thus a scale factor is required to convert the capture value to the SYSCLK domain. For the same reason, periodically recalculate the scale factor. The HRCAP submodule has a calibration block to reduce software overhead when calculating a scale factor between HRCLK and SYSCLK.

The calibration block contains the following key resources:

- **HRSYSCLKCNT:** A 32-bit counter connected to SYSCLK. The counter starts counting when CALIBSTART is set.
- **HRCLKCNT:** A 32-bit counter connected to HRCLK. The counter starts counting when CALIBSTART is set.
