About This Manual.....	125
Notational Conventions.....	125
Glossary.....	125
Related Documentation From Texas Instruments.....	125
Support Resources.....	126
Trademarks.....	126
<b>1 C2000™ Microcontrollers Software Support</b> .....	127
1.1 Introduction.....	128
1.2 C2000Ware Structure.....	128
1.3 Documentation.....	128
1.4 Devices.....	128
1.5 Libraries.....	128
1.6 Code Composer Studio™ Integrated Development Environment (IDE).....	128
1.7 SysConfig and PinMUX Tool.....	129
<b>2 C28x Processor</b> .....	130
2.1 Introduction.....	131
2.2 C28X Related Collateral.....	131
2.3 Features.....	131
2.4 Floating-Point Unit (FPU).....	132
2.5 Trigonometric Math Unit (TMU).....	132
2.6 VCRC Unit.....	133
<b>3 C28x System Control and Interrupts</b> .....	134
3.1 C28x System Control Introduction.....	135
3.1.1 SYSCTL Related Collateral.....	135
3.2 System Control Functional Description.....	135
3.2.1 Device Identification.....	136
3.3 Resets.....	136
3.3.1 Reset Sources.....	136
3.3.2 External Reset ( $\overline{XRS}$ ).....	137
3.3.3 Simulate External Reset (SIMRESET. $\overline{XRS}$ ).....	137
3.3.4 Power-On Reset (POR).....	137
3.3.5 Debugger Reset (SYSRS).....	138
3.3.6 Simulate CPU1 Reset (SIMRESET).....	138
3.3.7 Watchdog Reset ( $\overline{WDRS}$ ).....	138
3.3.8 NMI Watchdog Reset (NMIWDRS).....	138
3.3.9 Secure Code Copy Reset (SCCRESET).....	138
3.3.10 EtherCAT SubDevice Controller (ESC) Module Reset Output.....	139
3.4 Peripheral Interrupts.....	139
3.4.1 Interrupt Concepts.....	139
3.4.2 Interrupt Architecture.....	139
3.4.3 Interrupt Entry Sequence.....	141
3.4.4 Configuring and Using Interrupts.....	142
3.4.5 PIE Channel Mapping.....	144
3.4.6 System Error Interrupts.....	146
3.4.7 Vector Tables.....	147
3.5 Exceptions and Non-Maskable Interrupts.....	153
3.5.1 Configuring and Using NMIs.....	153
3.5.2 Emulation Considerations.....	153

3.5.3 NMI Sources.....	153
3.5.4 Illegal Instruction Trap (ITRAP).....	154
3.6 Safety Features.....	154
3.6.1 Write Protection on Registers.....	154
3.6.2 CPU1 and CPU2 ePIE Vector Address Validity Check.....	155
3.6.3 NMIWDs.....	155
3.6.4 ECC and Parity Enabled RAMs, Shared RAMs Protection.....	155
3.6.5 ECC Enabled Flash Memory.....	155
3.6.6 ERRORSTS Pin.....	156
3.7 Clocking.....	156
3.7.1 Clock Sources.....	158
3.7.2 Derived Clocks.....	160
3.7.3 Device Clock Domains.....	161
3.7.4 External Clock Output (XCLKOUT).....	162
3.7.5 Clock Connectivity.....	162
3.7.6 Using an External Crystal or Resonator.....	164
3.7.7 PLL/AUXPLL.....	164
3.7.8 Clock (OSCCLK) Failure Detection.....	168
3.8 Clock Configuration Semaphore.....	170
3.9 32-Bit CPU Timers 0/1/2.....	170
3.10 Watchdog Timers.....	172
3.10.1 Servicing the Watchdog Timer.....	173
3.10.2 Minimum Window Check.....	173
3.10.3 Watchdog Reset or Watchdog Interrupt Mode.....	174
3.10.4 Watchdog Operation in Low-Power Modes.....	174
3.10.5 Emulation Considerations.....	174
3.11 Low-Power Modes.....	175
3.11.1 IDLE.....	175
3.11.2 STANDBY.....	175
3.11.3 HALT.....	176
3.12 Memory Controller Module.....	177
3.12.1 Dedicated RAM (Dx RAM).....	178
3.12.2 Local Shared RAM (LSx RAM).....	178
3.12.3 Global Shared RAM (GSx RAM).....	179
3.12.4 CPU Message RAM (CPU MSG RAM).....	179
3.12.5 CLA Message RAM (CLA MSGRAM).....	179
3.12.6 CLA-DMA MSG RAM.....	179
3.12.7 Access Arbitration.....	180
3.12.8 Access Protection.....	181
3.12.9 Memory Error Detection, Correction, and Error Handling.....	184
3.12.10 Application Test Hooks for Error Detection and Correction.....	186
3.12.11 ROM Test.....	187
3.12.12 RAM Initialization.....	187
3.13 JTAG.....	188
3.13.1 JTAG Noise and TAP_STATUS.....	188
3.14 Live Firmware Update (LFU).....	188
3.14.1 LFU Background.....	188
3.14.2 LFU Switchover Steps.....	189
3.14.3 Device Features Supporting LFU.....	190
3.14.4 LFU Switchover.....	195
3.14.5 LFU Resources.....	195
3.15 System Control Register Configuration Restrictions.....	195
3.16 MCU Configuration (MCUCNFx).....	196
3.17 Software.....	196
3.17.1 SYSCTL Examples.....	196
3.17.2 MEMCFG Examples.....	197
3.17.3 NMI Examples.....	198
3.17.4 TIMER Examples.....	199
3.17.5 WATCHDOG Examples.....	199
3.18 System Control Registers.....	200
3.18.1 SYSCTRL Base Address Table.....	200

3.18.2 LFU Base Address Table.....	201
3.18.3 CPUTIMER_REGS Registers.....	202
3.18.4 PIE_CTRL_REGS Registers.....	209
3.18.5 WD_REGS Registers.....	261
3.18.6 NMI_INTRUPT_REGS Registers.....	268
3.18.7 XINT_REGS Registers.....	288
3.18.8 SYNC_SOC_REGS Registers.....	297
3.18.9 CPU1_DMA_CLA_SRC_SEL_REGS Registers.....	305
3.18.10 CPU2_DMA_CLA_SRC_SEL_REGS Registers.....	312
3.18.11 DEV_CFG_REGS Registers.....	316
3.18.12 CLK_CFG_REGS Registers.....	406
3.18.13 CPU1_SYS_REGS Registers.....	438
3.18.14 CPU2_SYS_REGS Registers.....	504
3.18.15 CPU1_SYS_STATUS_REGS Registers.....	570
3.18.16 CPU2_SYS_STATUS_REGS Registers.....	579
3.18.17 CPU1_PERIPH_AC_REGS Registers.....	596
3.18.18 CPU2_PERIPH_AC_REGS Registers.....	685
3.18.19 MEM_CFG_REGS Registers.....	774
3.18.20 ACCESS_PROTECTION_REGS Registers.....	851
3.18.21 MEMORY_ERROR_REGS Registers.....	876
3.18.22 ROM_WAIT_STATE_REGS Registers.....	901
3.18.23 TEST_ERROR_REGS Registers.....	903
3.18.24 UID_REGS Registers.....	907
3.18.25 CPU1_LFU_REGS Registers.....	916
3.18.26 CPU2_LFU_REGS Registers.....	928
3.18.27 CPU1TOCPU2_IPC_REGS_CPU1VIEW Registers.....	940
3.18.28 CPU1TOCPU2_IPC_REGS_CPU2VIEW Registers.....	973
3.18.29 CPU2_DMA_CLA_SRC_SEL_REGS Registers.....	1006
3.18.30 Register to Driverlib Function Mapping.....	1010
<b>4 ROM Code and Peripheral Booting.....</b>	<b>1034</b>
4.1 Introduction.....	1035
4.1.1 ROM Related Collateral.....	1035
4.2 Device Boot Sequence.....	1036
4.3 Device Boot Modes.....	1037
4.3.1 Default Boot Modes.....	1037
4.3.2 Custom Boot Modes.....	1038
4.4 Device Boot Configurations.....	1039
4.4.1 Configuring Boot Mode Pins.....	1040
4.4.2 Configuring Boot Mode Table Options.....	1042
4.4.3 Boot Mode Example Use Cases.....	1043
4.5 Device Boot Flow Diagrams.....	1044
4.5.1 Boot Flow.....	1044
4.5.2 Emulation Boot Flow.....	1046
4.5.3 Standalone Boot Flow.....	1047
4.6 Device Reset and Exception Handling.....	1049
4.6.1 Reset Causes and Handling.....	1049
4.6.2 Exceptions and Interrupts Handling.....	1050
4.7 Boot ROM Description.....	1051
4.7.1 Boot ROM Configuration Registers.....	1051
4.7.2 Booting CPU2.....	1053
4.7.3 Entry Points.....	1055
4.7.4 Wait Points.....	1056
4.7.5 Secure Flash Boot Mode.....	1057
4.7.6 Memory Maps.....	1059
4.7.7 ROM Tables.....	1060
4.7.8 Boot Modes and Loaders.....	1060
4.7.9 GPIO Assignments.....	1081
4.7.10 Secure ROM Function APIs.....	1084
4.7.11 Clock Initializations.....	1085
4.7.12 Boot Status Information.....	1086
4.7.13 ROM Version.....	1088

4.8 Application Notes for Using the Bootloaders.....	1088
4.8.1 Bootloader Data Stream Structure.....	1088
4.8.2 The C2000 Hex Utility.....	1090
4.9 Software.....	1091
4.9.1 BOOT Examples.....	1091
<b>5 Dual Code Security Module (DCSM).....</b>	<b>1092</b>
5.1 Introduction.....	1093
5.1.1 DCSM Related Collateral.....	1093
5.2 Functional Description.....	1093
5.2.1 CSM Passwords.....	1094
5.2.2 Emulation Code Security Logic (ECSL).....	1096
5.2.3 CPU Secure Logic.....	1096
5.2.4 Execute-Only Protection.....	1096
5.2.5 Password Lock.....	1096
5.2.6 JTAGLOCK.....	1097
5.2.7 Link Pointer and Zone Select.....	1097
5.2.8 C Code Example to Get Zone Select Block Addr for Zone1.....	1100
5.3 Flash and OTP Erase/Program.....	1100
5.4 Secure Copy Code.....	1100
5.5 SecureCRC.....	1101
5.6 CSM Impact on Other On-Chip Resources.....	1102
5.6.1 RAMOPEN.....	1103
5.7 Incorporating Code Security in User Applications.....	1104
5.7.1 Environments That Require Security Unlocking.....	1104
5.7.2 CSM Password Match Flow.....	1104
5.7.3 C Code Example to Unsecure C28x Zone1.....	1106
5.7.4 C Code Example to Resecure C28x Zone1.....	1106
5.7.5 Environments That Require ECSL Unlocking.....	1106
5.7.6 ECSL Password Match Flow.....	1106
5.7.7 ECSL Disable Considerations for any Zone.....	1108
5.7.8 Device Unique ID.....	1108
5.8 Software.....	1109
5.8.1 DCSM Examples.....	1109
5.9 DCSM Registers.....	1110
5.9.1 DCSM Base Address Table.....	1110
5.9.2 DCSM_Z1_REGS Registers.....	1111
5.9.3 DCSM_Z2_REGS Registers.....	1161
5.9.4 DCSM_COMMON_REGS Registers.....	1200
5.9.5 DCSM_Z1_OTP Registers.....	1224
5.9.6 DCSM_Z2_OTP Registers.....	1241
5.9.7 DCSM Registers to Driverlib Functions.....	1250
<b>6 Background CRC-32 (BGCRC).....</b>	<b>1255</b>
6.1 Introduction.....	1256
6.1.1 BGCRC Related Collateral.....	1256
6.1.2 Features.....	1256
6.1.3 Block Diagram.....	1256
6.1.4 Memory Wait States and Memory Map.....	1257
6.2 Functional Description.....	1258
6.2.1 Data Read Unit.....	1258
6.2.2 CRC-32 Compute Unit.....	1258
6.2.3 CRC Notification Unit.....	1259
6.2.4 Operating Modes.....	1260
6.2.5 BGCRC Watchdog.....	1260
6.2.6 Hardware and Software Faults Protection.....	1260
6.3 Application of the BGCRC.....	1260
6.3.1 Software Configuration.....	1261
6.3.2 Decision on Error Response Severity.....	1262
6.3.3 Decision of Controller for CLA_CRC.....	1262
6.3.4 Execution of Time Critical Code from Wait-States Memories.....	1262
6.3.5 BGCRC Execution.....	1262
6.3.6 Debug/Error Response for BGCRC Errors.....	1263

6.3.7 BGCRC Golden CRC-32 Value Computation.....	1264
6.4 Software.....	1265
6.4.1 BGCRC Examples.....	1265
6.5 BGCRC Registers.....	1266
6.5.1 BGCRC Base Address Table.....	1266
6.5.2 BGCRC_REGS Registers.....	1267
6.5.3 BGCRC Registers to Driverlib Functions.....	1293
<b>7 Control Law Accelerator (CLA)</b> .....	<b>1295</b>
7.1 Introduction.....	1296
7.1.1 Features.....	1296
7.1.2 CLA Related Collateral.....	1296
7.1.3 Block Diagram.....	1297
7.2 CLA Interface.....	1298
7.2.1 CLA Memory.....	1298
7.2.2 CLA Memory Bus.....	1299
7.2.3 Shared Peripherals and EALLOW Protection.....	1300
7.2.4 CLA Tasks and Interrupt Vectors.....	1300
7.2.5 CLA Software Interrupt to CPU.....	1305
7.3 CLA, DMA, and CPU Arbitration.....	1306
7.3.1 CLA Message RAM.....	1306
7.3.2 CLA Program Memory.....	1307
7.3.3 CLA Data Memory.....	1308
7.3.4 Peripheral Registers (ePWM, HRPWM, Comparator).....	1308
7.4 CLA Configuration and Debug.....	1309
7.4.1 Building a CLA Application.....	1309
7.4.2 Typical CLA Initialization Sequence.....	1309
7.4.3 Debugging CLA Code.....	1310
7.4.4 CLA Illegal Opcode Behavior.....	1312
7.4.5 Resetting the CLA.....	1313
7.5 Pipeline.....	1313
7.5.1 Pipeline Overview.....	1313
7.5.2 CLA Pipeline Alignment.....	1314
7.5.3 Parallel Instructions.....	1319
7.5.4 CLA Task Execution Latency.....	1319
7.6 Software.....	1320
7.6.1 CLA Examples.....	1320
7.7 Instruction Set.....	1325
7.7.1 Instruction Descriptions.....	1325
7.7.2 Addressing Modes and Encoding.....	1326
7.7.3 Instructions.....	1329
7.8 CLA Registers.....	1459
7.8.1 CLA Base Address Table.....	1459
7.8.2 CLA_ONLY_REGS Registers.....	1460
7.8.3 CLA_SOFTINT_REGS Registers.....	1469
7.8.4 CLA_REGS Registers.....	1473
7.8.5 CLA Registers to Driverlib Functions.....	1521
<b>8 Configurable Logic Block (CLB)</b> .....	<b>1524</b>
8.1 Introduction.....	1525
8.1.1 CLB Related Collateral.....	1525
8.2 Description.....	1525
8.2.1 CLB Clock.....	1527
8.3 CLB Input/Output Connection.....	1529
8.3.1 Overview.....	1529
8.3.2 CLB Input Selection.....	1529
8.3.3 CLB Output Selection.....	1543
8.3.4 CLB Output Signal Multiplexer.....	1545
8.4 CLB Tile.....	1548
8.4.1 Static Switch Block.....	1549
8.4.2 Counter Block.....	1551
8.4.3 FSM Block.....	1555
8.4.4 LUT4 Block.....	1557

8.4.5 Output LUT Block.....	1557
8.4.6 Asynchronous Output Conditioning (AOC) Block.....	1558
8.4.7 High Level Controller (HLC).....	1561
8.5 CPU Interface.....	1566
8.5.1 Register Description.....	1566
8.5.2 Non-Memory Mapped Registers.....	1567
8.6 DMA Access.....	1567
8.7 CLB Data Export Through SPI RX Buffer.....	1568
8.8 CLB Pipeline Mode.....	1569
8.9 Software.....	1570
8.9.1 CLB Examples.....	1570
8.10 CLB Registers.....	1576
8.10.1 CLB Base Address Table.....	1576
8.10.2 CLB_LOGIC_CONFIG_REGS Registers.....	1577
8.10.3 CLB_LOGIC_CONTROL_REGS Registers.....	1629
8.10.4 CLB_DATA_EXCHANGE_REGS Registers.....	1662
8.10.5 CLB Registers to Driverlib Functions.....	1664
<b>9 Dual-Clock Comparator (DCC).....</b>	<b>1668</b>
9.1 Introduction.....	1669
9.1.1 Features.....	1669
9.1.2 Block Diagram.....	1669
9.2 Module Operation.....	1670
9.2.1 Configuring DCC Counters.....	1671
9.2.2 Single-Shot Measurement Mode.....	1672
9.2.3 Continuous Monitoring Mode.....	1673
9.2.4 Error Conditions.....	1674
9.3 Interrupts.....	1676
9.4 Software.....	1677
9.4.1 DCC Examples.....	1677
9.5 DCC Registers.....	1678
9.5.1 DCC Base Address Table.....	1678
9.5.2 DCC_REGS Registers.....	1679
9.5.3 DCC Registers to Driverlib Functions.....	1690
<b>10 Direct Memory Access (DMA).....</b>	<b>1692</b>
10.1 Introduction.....	1693
10.1.1 Features.....	1693
10.1.2 Block Diagram.....	1694
10.2 Architecture.....	1695
10.2.1 Peripheral Interrupt Event Trigger Sources.....	1695
10.2.2 DMA Bus.....	1701
10.3 Address Pointer and Transfer Control.....	1701
10.4 Pipeline Timing and Throughput.....	1707
10.5 CPU and CLA Arbitration.....	1708
10.6 Channel Priority.....	1709
10.6.1 Round-Robin Mode.....	1709
10.6.2 Channel 1 High-Priority Mode.....	1710
10.7 Overrun Detection Feature.....	1710
10.8 Software.....	1711
10.8.1 DMA Examples.....	1711
10.9 DMA Registers.....	1712
10.9.1 DMA Base Address Table.....	1712
10.9.2 DMA_REGS Registers.....	1713
10.9.3 DMA_CH_REGS Registers.....	1718
10.9.4 DMA_CLA_SRC_SEL_REGS Registers.....	1745
10.9.5 DMA Registers to Driverlib Functions.....	1751
<b>11 External Memory Interface (EMIF).....</b>	<b>1754</b>
11.1 Introduction.....	1755
11.1.1 Purpose of the Peripheral.....	1755
11.1.2 EMIF Related Collateral.....	1755
11.1.3 Features.....	1756
11.1.4 Functional Block Diagram.....	1757

11.1.5 Configuring Device Pins.....	1757
11.2 EMIF Module Architecture.....	1758
11.2.1 EMIF Clock Control.....	1758
11.2.2 EMIF Requests.....	1758
11.2.3 EMIF Signal Descriptions.....	1759
11.2.4 EMIF Signal Multiplexing Control.....	1760
11.2.5 SDRAM Controller and Interface.....	1760
11.2.6 Asynchronous Controller and Interface.....	1773
11.2.7 Data Bus Parking.....	1785
11.2.8 Reset and Initialization Considerations.....	1785
11.2.9 Interrupt Support.....	1785
11.2.10 DMA Event Support.....	1786
11.2.11 EMIF Signal Multiplexing.....	1786
11.2.12 Memory Map.....	1786
11.2.13 Priority and Arbitration.....	1787
11.2.14 System Considerations.....	1787
11.2.15 Power Management.....	1788
11.2.16 Emulation Considerations.....	1788
11.3 Example Configuration.....	1788
11.3.1 Hardware Interface.....	1788
11.3.2 Software Configuration.....	1789
11.4 Software.....	1797
11.4.1 EMIF Examples.....	1797
11.5 EMIF Registers.....	1799
11.5.1 EMIF Base Address Table.....	1799
11.5.2 EMIF_REGS Registers.....	1800
11.5.3 EMIF1_CONFIG_REGS Registers.....	1820
11.5.4 EMIF Registers to Driverlib Functions.....	1824
<b>12 Flash Module.....</b>	<b>1826</b>
12.1 Introduction to Flash and OTP Memory.....	1827
12.1.1 FLASH Related Collateral.....	1827
12.1.2 Features.....	1827
12.1.3 Flash Tools.....	1828
12.1.4 Default Flash Configuration.....	1828
12.2 Flash Bank, OTP, and Pump.....	1828
12.3 Flash Wrapper.....	1829
12.4 Flash and OTP Memory Performance.....	1830
12.5 Flash Read Interface.....	1830
12.5.1 C28x-Flash Read Interface.....	1830
12.6 Flash Erase and Program.....	1833
12.6.1 Flash Controller Access Semaphore.....	1833
12.6.2 Erase.....	1833
12.6.3 Program.....	1833
12.6.4 Verify.....	1834
12.7 Error Correction Code (ECC) Protection.....	1834
12.7.1 Single-Bit Data Error.....	1835
12.7.2 Uncorrectable Error.....	1836
12.7.3 Mechanism to Check the Correctness of ECC Logic.....	1837
12.8 Reserved Locations Within Flash and OTP.....	1839
12.9 Migrating an Application from RAM to Flash.....	1839
12.10 Procedure to Change the Flash Control Registers.....	1840
12.11 Software.....	1840
12.11.1 FLASH Examples.....	1840
12.12 Flash Registers.....	1841
12.12.1 FLASH Base Address Table.....	1841
12.12.2 FLASH_CTRL_REGS Registers.....	1842
12.12.3 FLASH_ECC_REGS Registers.....	1846
12.12.4 FLASH Registers to Driverlib Functions.....	1848
<b>13 Embedded Real-time Analysis and Diagnostic (ERAD).....</b>	<b>1850</b>
13.1 Introduction.....	1851
13.1.1 ERAD Related Collateral.....	1851

13.2 Enhanced Bus Comparator Unit.....	1852
13.2.1 Enhanced Bus Comparator Unit Operations.....	1852
13.2.2 Event Masking and Exporting.....	1853
13.3 System Event Counter Unit.....	1854
13.3.1 System Event Counter Modes.....	1854
13.3.2 Reset on Event.....	1860
13.3.3 Operation Conditions.....	1860
13.4 ERAD Ownership, Initialization and Reset.....	1861
13.5 ERAD Programming Sequence.....	1862
13.5.1 Hardware Breakpoint and Hardware Watch Point Programming Sequence.....	1862
13.5.2 Timer and Counter Programming Sequence.....	1863
13.6 Cyclic Redundancy Check Unit.....	1863
13.6.1 CRC Unit Qualifier.....	1864
13.6.2 CRC Unit Programming Sequence.....	1865
13.7 Program Counter Trace.....	1866
13.7.1 Functional Block Diagram.....	1867
13.7.2 Trace Qualification Modes.....	1868
13.7.3 Trace Memory.....	1868
13.7.4 Trace Input Signal Conditioning.....	1869
13.7.5 PC Trace Software Operation.....	1870
13.7.6 Trace Operation in Debug Mode.....	1870
13.8 Software.....	1871
13.8.1 ERAD Examples.....	1871
13.9 ERAD Registers.....	1879
13.9.1 ERAD Base Address Table.....	1879
13.9.2 ERAD_GLOBAL_REGS Registers.....	1880
13.9.3 ERAD_HWBP_REGS Registers.....	1903
13.9.4 ERAD_COUNTER_REGS Registers.....	1910

## About This Manual

This Technical Reference Manual (TRM) details the integration, the environment, the functional description, and the programming models for each peripheral and subsystem in the device.

The TRM should not be considered a substitute for the data sheet, rather a companion guide that can be used alongside the device-specific data sheet to understand the details to program the device. The primary purpose of the TRM is to abstract the programming details of the device from the data sheet. This allows the data sheet to outline the high-level features of the device without unnecessary information about register descriptions or programming models.

---

### Note

Texas Instruments is transitioning to use more inclusive terminology. Some language may be different than what you would expect to see for certain technology areas.

---

## Notational Conventions

This document uses the following conventions.

- Hexadecimal numbers can be shown with the suffix h or the prefix 0x. For example, the following number is 40 hexadecimal (decimal 64): 40h or 0x40.
- Registers in this document are shown in figures and described in tables.
  - Each register figure shows a rectangle divided into fields that represent the fields of the register. Each field is labeled with its bit name, its beginning and ending bit numbers above, and its read/write properties with default reset value below. A legend explains the notation used for the properties.
  - Reserved bits in a register figure can have one of multiple meanings:
    - Not implemented on the device
    - Reserved for future device expansion
    - Reserved for TI testing
    - Reserved configurations of the device that are not supported
  - Writing nondefault values to the Reserved bits could cause unexpected behavior and should be avoided.

## Glossary

[TI Glossary](#) This glossary lists and explains terms, acronyms, and definitions.

## Related Documentation From Texas Instruments

For a complete listing of related documentation and development-support tools for these devices, visit the Texas Instruments website at [www.ti.com](http://www.ti.com).

Additionally, the [TMS320C28x DSP CPU and Instruction Set Reference Guide](#) and the [TMS320C28x Floating Point Unit and Instruction Set Reference Guide](#) must be used in conjunction with this TRM.

# C2000™ Microcontrollers Software Support

---

This chapter discusses the C2000Ware for the C2000™ microcontrollers. The C2000Ware can be downloaded from: [www.ti.com/tool/C2000WARE](http://www.ti.com/tool/C2000WARE)

<b>1.1 Introduction</b> .....	<b>128</b>
<b>1.2 C2000Ware Structure</b> .....	<b>128</b>
<b>1.3 Documentation</b> .....	<b>128</b>
<b>1.4 Devices</b> .....	<b>128</b>
<b>1.5 Libraries</b> .....	<b>128</b>
<b>1.6 Code Composer Studio™ Integrated Development Environment (IDE)</b> .....	<b>128</b>
<b>1.7 SysConfig and PinMUX Tool</b> .....	<b>129</b>

## 1.1 Introduction

C2000Ware for the C2000™ microcontrollers is a cohesive set of development software and documentation designed to minimize software development time. From device-specific drivers and libraries to device peripheral examples, C2000Ware provides a solid foundation to begin development and evaluation of your product.

C2000Ware can be downloaded from: [www.ti.com/tool/C2000WARE](http://www.ti.com/tool/C2000WARE)

## 1.2 C2000Ware Structure

The C2000Ware software package is organized into the following directory structure as shown in [Table 1-1](#).

**Table 1-1. C2000Ware Root Directories**

Directory Name	Description
boards	Contains the hardware design schematics, BOM, Gerber files, and documentation for C2000 controlCARDS.
device_support	Contains all device-specific support files, bit field headers and device development user's guides.
docs	Contains the C2000Ware package user's guides and the HTML index page of all package documentation.
driverlib	Contains the device-specific driver library and driver-based peripheral examples.
libraries	Contains the device-specific and core libraries.

## 1.3 Documentation

Within C2000Ware, there is an extensive amount of development documentation ranging from board design documentation, to library user's guides, to driver API documentation. The "boards" directory contains all the hardware design, BOM, Gerber files, and more for controlCARDS. To assist with locating the necessary documentation, an HTML page is provided that contains a full list of all the documents in the C2000Ware package. Locate this page in the "docs" directory.

## 1.4 Devices

C2000Ware contains the necessary software and documentation to jumpstart development for C2000™ microcontrollers. Each device includes device-specific common source files, peripheral example projects, bit field headers, and if available, a device peripheral driver library. Additionally, documentation is provided for each device on how to set up a CCS project, as well as give an overview of all the included example projects and assist with troubleshooting. For devices with a driver library, documentation is also included that details all the peripheral APIs available.

To learn more about C2000™ microcontrollers, visit: [www.ti.com/c2000](http://www.ti.com/c2000).

## 1.5 Libraries

The libraries included in C2000Ware range from fixed-point and floating-point math libraries, to specialized DSP libraries, as well as calibration libraries. Each library includes documentation and examples, where applicable. Additionally, the Flash API files and boot ROM source code are located in the "libraries" directory.

## 1.6 Code Composer Studio™ Integrated Development Environment (IDE)

Code Composer Studio™ is an integrated development environment (IDE) that supports TI's microcontroller and embedded processors portfolio. The Code Composer Studio™ IDE comprises a suite of tools used to develop and debug embedded applications. The latest version of Code Composer Studio™ IDE can be obtained at: [www.ti.com/ccstudio](http://www.ti.com/ccstudio)

All projects and examples in C2000Ware are built for and tested with the Code Composer Studio™ IDE. Although the Code Composer Studio™ IDE is not included with the C2000Ware installer, Code Composer Studio™ IDE is easily obtainable in a variety of versions.

## 1.7 SysConfig and PinMUX Tool

To help simplify configuration challenges and accelerate software development, Texas Instruments™ created SysConfig, an intuitive and comprehensive collection of graphical utilities for configuring pins, peripherals, subsystems, and other components. SysConfig helps you manage, expose, and resolve conflicts visually so that you have more time to create differentiated applications.

The tool's output includes C header and code files that can be used with C2000Ware examples or used to configure custom software.

The SysConfig tool automatically selects the pinmux settings that satisfy the entered requirements. The SysConfig tool is delivered integrated in the Code Composer Studio™ IDE, in the C2000Ware GPIO example, as a standalone installer, or can be used by way of the cloud tools portal at: [dev.ti.com](https://dev.ti.com)

This chapter contains a short description of the C28x processor and extended instruction sets.

## 2.3 Features

The CPU features include a modified Harvard architecture and circular addressing. The RISC features are single-cycle instruction execution, register-to-register operations, and modified Harvard architecture. The microcontroller features include ease of use through an intuitive instruction set, byte packing and unpacking, and bit manipulation. The modified Harvard architecture of the CPU enables instruction and data fetches to be performed in parallel. The CPU can read instructions and data while the CPU writes data simultaneously to maintain the single-cycle instruction operation across the pipeline.

## 2.4 Floating-Point Unit (FPU)

The C28x plus floating-point (C28x+FPU) processor extends the capabilities of the C28x fixed-point CPU by adding registers and instructions to support IEEE single-precision floating point operations.

Devices with the C28x+FPU include the standard C28x register set plus an additional set of floating-point unit registers. The additional floating-point unit registers are the following:

- Eight floating-point result registers, RnH (where n = 0–7)
- Floating-point Status Register (STF)
- Repeat Block Register (RB)

All of the floating-point registers, except the repeat block register, are shadowed. This shadowing can be used in high-priority interrupts for fast context save and restore of the floating-point registers.

For more information, see the [TMS320C28x Extended Instruction Sets Technical Reference Manual](#).

## 2.5 Trigonometric Math Unit (TMU)

The trigonometric math unit (TMU) extends the capabilities of a C28x+FPU by adding instructions and leveraging existing FPU instructions to speed up the execution of common trigonometric and arithmetic operations listed in [Table 2-1](#).

**Table 2-1. TMU Supported Instructions**

Instructions	C Equivalent Operation	Pipeline Cycles
MPY2PIF32 RaH,RbH	$a = b * 2\pi$	2/3
DIV2PIF32 RaH,RbH	$a = b / 2\pi$	2/3
DIVF32 RaH,RbH,RcH	$a = b/c$	5
SQRTF32 RaH,RbH	$a = \text{sqrt}(b)$	5
SINPUF32 RaH,RbH	$a = \sin(b*2\pi)$	4
COSPUF32 RaH,RbH	$a = \cos(b*2\pi)$	4
ATANPUF32 RaH,RbH	$a = \text{atan}(b)/2\pi$	4
QUADF32 RaH,RbH,RcH,RdH	Operation to assist in calculating ATANPU2	5

Exponent instruction IEXP2F32 and logarithmic instruction LOG2F32 have been added to support computation of floating-point power function for the nonlinear proportional integral derivative control (NLPID) component of the C2000 Digital Control Library. These two added instructions reduce the power function calculations from a typical of 300 cycles using library emulation to less than 10 cycles.

No changes have been made to existing instructions, pipeline, or memory bus architecture. All TMU instructions use the existing FPU register set (R0H to R7H) to carry out the operations.

For more information, see the [TMS320C28x Extended Instruction Sets Technical Reference Manual](#).

## 2.6 VCRC Unit

Cyclic redundancy check (CRC) algorithms provide a straightforward method for verifying data integrity over large data blocks, communication packets, or code sections. The C28x+VCRC can perform 8-bit, 16-bit, 24-bit, and 32-bit CRCs. A CRC result register contains the current CRC, which is updated whenever a CRC instruction is executed.

The following are the CRC polynomials used by the CRC calculation logic of VCRC:

- CRC8 polynomial = 0x07
- CRC16 polynomial1 = 0x8005
- CRC16 polynomial2 = 0x1021
- CRC24 polynomial = 0x5D 6DCB
- CRC32 polynomial1 = 0x04C1 1DB7
- CRC32 polynomial2 = 0x1EDC 6F41

This module can calculate CRCs for a byte of data in a single cycle. The CRC calculation for CRC8, CRC16, CRC24 and CRC32 is done byte-wise (instead of computing on a complete 16-bit or 32-bit data read by the C28x core) to match the byte-wise computation requirement mandated by various standards.

The VCRC Unit also allows the user to provide the size (1b-32b) and value of any polynomial to fit custom CRC requirements. The CRC execution time increases to 3 cycles when using a custom polynomial.

For more information, see the [TMS320C28x Extended Instruction Sets Technical Reference Manual](#).

## Chapter 3 C28x System Control and Interrupts

This chapter explains system control and interrupts for the C28x cores found on this MCU. The system control module configures and manages the overall operation of the device, and provides information about the device status. Configurable features in system control include reset control, NMI operation, peripheral interrupts, power control, clock control, and low-power modes.

### 3.1 C28x System Control Introduction

On this device, the CPU1 subsystem acts as a controller, and by default (upon reset), the CPU1 subsystem owns all the configuration and control. Through software running on CPU1, peripherals and I/Os can be configured to be accessible by the CPU2 subsystem and the chosen configurations can be locked.

The PLL clock configuration is also owned by the CPU1 subsystem by default, but a clock control semaphore is provided by which CPU2 can grab access to the clock configuration registers.

Each CPU can be independently configured to accept interrupts from different peripherals. The interrupt path is divided into three stages – the peripheral, the PIE, and the CPU. All stages must be configured and enabled for an interrupt to propagate to the CPU.

Each CPU has their own NMI module to handle different exceptions during run time. If the NMI was on CPU1, any NMI exception that is not handled before the NMI Watchdog (NMIWD) timer expiration resets the entire device. If the NMI was on the CPU2 subsystem, then the CPU2 subsystem alone is reset, in which case the CPU1 subsystem is informed by another NMI that the CPU2 subsystem was reset because of NMIWD timer expiration.

Each CPU subsystem has their own watchdog timer module for software to use. Watchdog timer expiration on CPU2 resets the CPU2 subsystem alone when configured to generate a reset, but watchdog timer expiration on CPU1 resets the entire device.

Except for a CPU2 standalone internal reset, such as CPU2.NMIWD or CPU2.WD, each time the device is reset, the CPU2 subsystem is held under reset until the CPU1 subsystem brings the CPU2 subsystem out of reset. This is done by the boot ROM software running on the CPU1 core.

The register space of the device system control module can be found in [Section 3.18](#).

This chapter explains the system control module on both the CPU subsystems.

### 3.2 System Control Functional Description

The system control module provides the following capabilities:

- Device identification and configuration registers
- Reset control
- Exceptions and Interrupt control
- Safety and error handling features of the device
- Power control
- Clock control

- Low Power modes
- Security module
- Inter-Processor Communication (IPC)

### 3.2.1 Device Identification

Device identification registers provide information on device class, device family, revision, part number, pin count, and device qualification status.

All of the device information is part of the DEV\_CFG\_REGS space and is accessible only by the software running on the CPU1 subsystem.

The C28x device identification registers are: PARTIDL, PARTIDH, and REVID.

A 256-bit Unique ID (UID) is available in UID\_REGS. The 256 bits are separated into these registers:

- UID\_PSRAND0-4: 160 bits of pseudo-random data
- UID\_UNIQUE: 64-bit unique data; the value in this register is unique across all devices with the same PARTIDH
- UID\_CHECKSUM: 32-bit Fletcher checksum of UID\_PSRAND0-4 and UID\_UNIQUE and calculated as either little- or big-endian during factory testing

## 3.3 Resets

This section explains the types and effects of the different resets on this device.

### 3.3.1 Reset Sources

[Table 3-1](#) summarizes the various reset signals and the effect on the device.

**Table 3-1. Reset Signals**

Reset Source	CPU1 Core Reset (C28x, TMU, FPU, VCRC)	CPU1 Peripheral Reset	CPU2 Core Reset (C28x, TMU, FPU, VCRC)	CPU2 and Peripheral Reset	JTAG / Debug Logic Reset	IOs	XRSn Output
POR	Yes	Yes	Yes	Yes	Yes	Hi-Z	Yes
XRS Pin	Yes	Yes	Yes	Yes	-	Hi-Z	-
CPU1.SIMRESET.XRSn	Yes	Yes	Yes	Yes	-	Hi-Z	Yes
CPU1.WDRS	Yes	Yes	Yes	Yes	-	Hi-Z	Yes
CPU1.NMIWDRS	Yes	Yes	Yes	Yes	-	Hi-Z	Yes
CPU1.SYSRS (Debugger Reset)	Yes	Yes	Yes	Yes	-	Hi-Z	-
CPU1.SIMRESET.CPU1RSn	Yes	Yes	Yes	Yes	-	Hi-Z	-
CPU1.SCCRESET	Yes	Yes	Yes	Yes	-	Hi-Z	-
CPU1.HWBISTR	Yes	-	-	-	-	-	-
CPU2.SYSRS (Debugger Reset)	-	-	Yes	Yes	-	-	-
CPU2.WDRS	-	-	Yes	Yes	-	-	-
CPU2.NMIWDRS	-	-	Yes	Yes	-	-	-
CPU2.SCCRESET	-	-	Yes	Yes	-	-	-
CPU2.HWBISTR	-	-	Yes	-	-	-	-
ECAT_RESET_OUT	Yes	Yes	Yes	Yes	-	Hi-Z	Yes

---

**Note**

After a reset, the reset cause register (RESC) is updated with the reset cause. The bits in this register maintain the state across multiple resets. These can only be cleared by a power-on reset (POR) or by writing 1 to the corresponding bit in RESCCLR register (status can be cleared by also writing a 1 to the RESC register bits). Each CPU has a RESC register, referred to as CPU1.RESC and CPU2.RESC.

---

The resets can be divided into these groups:

- Chip-level resets ( $\overline{XRS}$ , POR, CPU1. $\overline{WDRS}$ , and CPU1. $\overline{NMIWDRS}$ , SIMRESET.XRSn, ECAT\_RESET\_OUT (if enabled)), which reset all or almost all of the device.
- System resets (CPU1.SYSRS and CPU1.SCCRESET, SIMRESET.CPU1RSn), which reset a large subset of the device but maintain some system-level configuration.
- CPU2 subsystem resets (CPU2.SYSRS, CPU2. $\overline{WDRS}$ , CPU2. $\overline{NMIWDRS}$ , and CPU2.SCCRESET), which reset only CPU2 and the peripherals.
- Special resets (CPU1.HWBISTRs, CPU2.HWBISTRs, and TRSTn), which enable specific device functions.

Whenever the CPU1 subsystem is reset, CPU2 also gets reset and held in reset until CPU1 brings CPU2 out of reset by writing to the CPU2RESCTL register. This is done by user application code on CPU1.

Many peripheral modules have individual resets accessible through the system control registers. For information about a module reset state, refer to the appropriate chapter for that module.

---

**Note**

After a POR, the boot ROMs clear all of the system and message RAMs on both CPUs.

---

### 3.3.2 External Reset ( $\overline{XRS}$ )

The external reset ( $\overline{XRS}$ ) is the main chip-level reset for the device and resets both C28x CPUs, all peripherals and I/O pin configurations, and most of the system control registers.  $\overline{XRS}$  also holds CPU2 in reset. There is a dedicated open-drain pin for  $\overline{XRS}$ . This pin can be used to drive reset pins for other ICs in the application, and can be driven by an external source. The  $\overline{XRS}$  is driven internally during watchdog, NMI, and power-on resets.

The XRSn bit in the RESC register is set whenever  $\overline{XRS}$  is driven low for any reason. This bit is then cleared by the boot ROM.

### 3.3.3 Simulate External Reset (SIMRESET. $\overline{XRS}$ )

The user can simulate an external reset ( $\overline{XRS}$ ) in software. This can be done by setting the XRSn bit to 1 in the SIMRESET register by CPU1 software. This toggles the  $\overline{XRS}$  pin; hence, resetting the full device (just like an external reset).

After this reset, the SIMRESET\_XRSn bit in the RESC register is set. Software can read this bit to know the cause of the reset and clear the status by writing a 1 into the corresponding bit in the RESCCLR register.

### 3.3.4 Power-On Reset (POR)

The power-on reset (POR) circuit creates a clean reset throughout the device during power-up, suppressing glitches on the GPIOs. The  $\overline{XRS}$  pin is held low for the duration of the POR. In most applications,  $\overline{XRS}$  is held low long enough to reset other system ICs, but some applications can require a longer pulse. In these cases,  $\overline{XRS}$  can be driven low externally to provide the correct reset duration. A POR resets everything that  $\overline{XRS}$  does, along with a few other registers – the reset cause register (RESC), the NMI shadow flag register (NMISHDFLG).

After a POR, the POR and XRSn bits in RESC are set. These bits are then cleared by the boot ROM.

### 3.3.5 Debugger Reset ( $\overline{\text{SYSRS}}$ )

During development, it is sometimes necessary to reset the CPU and the peripherals without disconnecting the debugger or disrupting the system-level configuration. To facilitate this, each CPU has a subsystem reset, which can be triggered by a debugger using Code Composer Studio IDE. CPU2 subsystem reset (CPU2. $\overline{\text{SYSRS}}$ ) resets only CPU2, the peripherals, and the clock gating and LPM configuration. The CPU2 subsystem does not hold the CPU2 in reset. CPU1 subsystem reset (CPU1. $\overline{\text{SYSRS}}$ ) resets CPU1, the peripherals, many system control registers (including the clock gating and LPM configuration and the peripheral CPU ownership), and all I/O pin configurations. The CPU1 subsystem also produces a CPU2. $\overline{\text{SYSRS}}$  (CCS Gel file can have code to release CPU2 out of reset on CPU1 debug reset).

Neither  $\overline{\text{SYSRS}}$  resets the ICEPick debug module, the device capability registers, the clock source and PLL configurations, the missing clock detection state, the PIE vector fetch error handler address, the NMI flags, the analog trims, or anything reset only by a POR (see [Section 3.3.4](#)).

### 3.3.6 Simulate CPU1 Reset ( $\text{SIMRESET}$ )

The user can simulate a CPU1 reset (CPU1. $\overline{\text{SYSRS}}$ ) in software. This can be done by setting the CPU1RSn bit to 1 in the SIMRESET register by CPU1 software. This toggles the CPU1. $\overline{\text{SYSRS}}$  signals; hence, resetting CPU1 as well as CPU2 (just like the debugger reset).

After this reset, the SIMRESET\_CPU1RSn bit in the RESC register is set. Software can read this bit to know the cause of the reset and clear the status by writing a 1 into the corresponding bit in the RESCCLR register.

### 3.3.7 Watchdog Reset ( $\overline{\text{WDRS}}$ )

Each CPU has a watchdog timer that can optionally trigger a reset that lasts for 512 INTOSC1 cycles. CPU1 watchdog reset (CPU1. $\overline{\text{WDRS}}$ ) produces an  $\overline{\text{XRS}}$ . CPU2 watchdog reset (CPU2. $\overline{\text{WDRS}}$ ) produces a CPU2. $\overline{\text{SYSRS}}$  and triggers an NMI on CPU1.

After a watchdog reset, the WDRSn bit in the RESC register is set. Software can read this bit to know the cause of reset and clear the status by writing a 1 into the corresponding bit in the RESCCLR register.

### 3.3.8 NMI Watchdog Reset ( $\overline{\text{NMIWDRS}}$ )

Each CPU has a nonmaskable interrupt (NMI) module that detects hardware errors in the system. Each NMI module has a watchdog timer that triggers a reset if the CPU does not respond to an error within a user-specified amount of time. CPU1 NMI watchdog reset (CPU1. $\overline{\text{NMIWDRS}}$ ) produces an  $\overline{\text{XRS}}$ . The CPU2 NMI watchdog reset (CPU2. $\overline{\text{NMIWDRS}}$ ) produces a CPU2. $\overline{\text{SYSRS}}$  and triggers an NMI on CPU1.

After an NMI watchdog reset, the NMIWDRSn bit in the RESC register is set.

### 3.3.9 Secure Code Copy Reset ( $\overline{\text{SCCRESET}}$ )

The Dual-zone Code Security Module (DCSM) on this device locks read access to secure memories of each CPU subsystem. To facilitate CRC checks and copying of CLA code, TI provides ROM functions to securely access those memory areas. To prevent security breaches, interrupts must be disabled before calling these functions. If a vector fetch occurs in a secure copy or CRC function, the DCSM triggers a reset. CPU1 security reset (CPU1. $\overline{\text{SCCRESET}}$ ) is similar to a CPU1. $\overline{\text{SYSRS}}$ , and CPU2 security reset (CPU2. $\overline{\text{SCCRESET}}$ ) is similar to a CPU2. $\overline{\text{SYSRS}}$ . However, the security reset also resets the debug logic to deny access to a potential attacker.

After a security reset, the SCCRESETn bit in the RESC register is set. Software can read this bit to know the cause of reset and clear the status by writing a 1 into the corresponding bit in the RESCCLR register.

### 3.3.10 EtherCAT SubDevice Controller (ESC) Module Reset Output

The EtherCAT Subordinate Device Controller (ESC) module can be configured to drive the  $\overline{XRS}$  pin low whenever the ESC module receives a reset by setting the `DEVICE_RESET_EN` bit to 1 in the `ECAT_RESET_DEST_CONFIG` register of the ESC module (EtherCAT subsystem). By default, this is not enabled. Since this toggles the  $\overline{XRS}$  pin, all effects of an external  $\overline{XRS}$  reset take effect.

After an `ECAT_RESET_OUT` reset, the `ECAT_RESET_OUT` bit in the `RESC` register is set. Software can read this bit to know the cause of reset and clear the status by writing a 1 into the corresponding bit in the `RESCCLR` register.

## 3.4 Peripheral Interrupts

This section explains the peripheral interrupt handling on the device. Non-maskable interrupts are covered in [Section 3.5](#). Software interrupts and emulation interrupts are not covered in this document. For information on those, see the [TMS320C28x CPU and Instruction Set Reference Guide](#).

### 3.4.1 Interrupt Concepts

An interrupt is a signal that causes the CPU to pause current execution and branch to a different piece of code known as an interrupt service routine (ISR). This is a useful mechanism for handling peripheral events, and involves less CPU overhead or program complexity than register polling. However, because interrupts are asynchronous to the program flow, care must be taken to avoid conflicts over resources that are accessed both in interrupts and in the main program code.

Interrupts propagate to the CPU through a series of flag and enable registers. The flag registers store the interrupt until the interrupt is processed. The enable registers block the propagation of the interrupt. When an interrupt signal reaches the CPU, the CPU fetches the appropriate ISR address from a list called the vector table.

### 3.4.2 Interrupt Architecture

The C28x CPU has fourteen peripheral interrupt lines. Two of the interrupt lines (`INT13` and `INT14`) are connected directly to CPU timers 1 and 2, respectively. The remaining twelve interrupt lines are connected to peripheral interrupt signals through the enhanced Peripheral Interrupt Expansion module (ePIE, or PIE as a shortened version). The PIE multiplexes up to sixteen peripheral interrupts into each CPU interrupt line and also expands the vector table to allow each interrupt to have an ISR. This allows the CPU to support a large number of peripherals.

An interrupt path is divided into three stages: the peripheral, the PIE, and the CPU. Each stage has enable and flag registers. This system allows the CPU to handle one interrupt while others are pending, implement and prioritize nested interrupts in software, and disable interrupts during certain critical tasks.

[Figure 3-1](#) shows the interrupt architecture for this device.

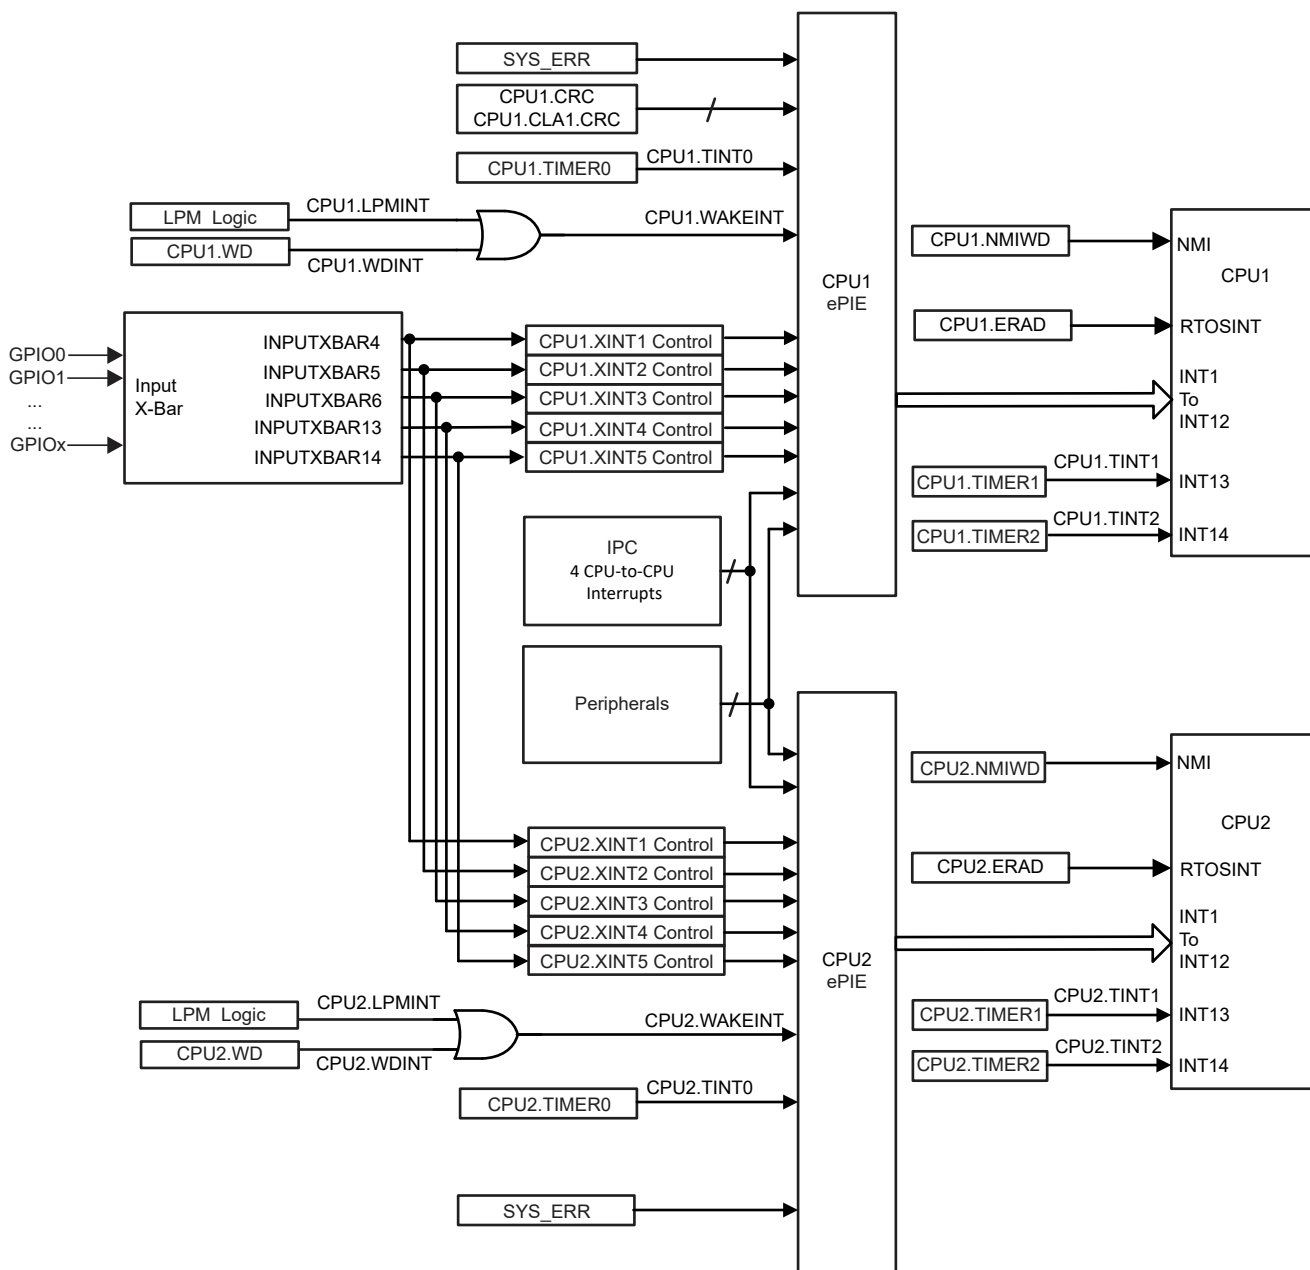

Figure 3-1. Device Interrupt Architecture

### 3.4.2.1 Peripheral Stage

Each peripheral has a unique interrupt configuration, which is described in that peripheral's chapter. Some peripherals allow multiple events to trigger the same interrupt signal. For example, a communications peripheral can use the same interrupt to indicate that data has been received or that there has been a transmission error. The cause of the interrupt can be determined by reading the peripheral's status register. Often, the bits in the status register must be cleared manually before another interrupt is generated.

### 3.4.2.2 PIE Stage

The PIE provides individual flag and enable register bits for each of the peripheral interrupt signals, which are sometimes called PIE channels. These channels are grouped according to their associated CPU interrupt. Each PIE group has one 16-bit enable register (PIEIERx), one 16-bit flag register (PIEIFRx), and one bit in the PIE acknowledge register (PIEACK). The PIEACK register bit acts as a common interrupt mask for the entire PIE group.

When the CPU receives an interrupt, the CPU fetches the address of the ISR from the PIE. The PIE returns the vector for the lowest-numbered channel in the group that is both flagged and enabled. This gives lower-numbered interrupts a higher priority when multiple interrupts are pending.

If no interrupt is both flagged and enabled, the PIE returns the vector for channel 1. This condition does not happen unless software changes the state of the PIE while an interrupt is propagating. Section 3.4.4 contains procedures for safely modifying the PIE configuration once interrupts have been enabled.

### 3.4.2.3 CPU Stage

Like the PIE, the CPU provides flag and enable register bits for each of the interrupts. There is one enable register (IER) and one flag register (IFR), both of which are internal CPU registers. There is also a global interrupt mask, which is controlled by the INTM bit in the ST1 register. This mask can be set and cleared using the CPU's SETC instruction. In C code, C2000Ware's DINT and EINT macros can be used for this purpose.

Writes to IER and INTM are atomic operations. In particular, if INTM is cleared, the next instruction in the pipeline runs with interrupts disabled. No software delays are needed.

### 3.4.2.4 Dual-CPU Interrupt Handling

Each CPU has its own PIE. Both PIEs must be configured independently.

Some interrupts come from shared peripherals that can be owned by either CPU, such as the ADCs and SPIs. These interrupts are sent to both PIEs regardless of the ownership of the peripheral. Thus, a peripheral owned by one CPU can cause an interrupt on the other CPU, if that interrupt is enabled in the other CPU's PIE.

### 3.4.3 Interrupt Entry Sequence

Figure 3-2 shows how peripheral interrupts propagate to the CPU.

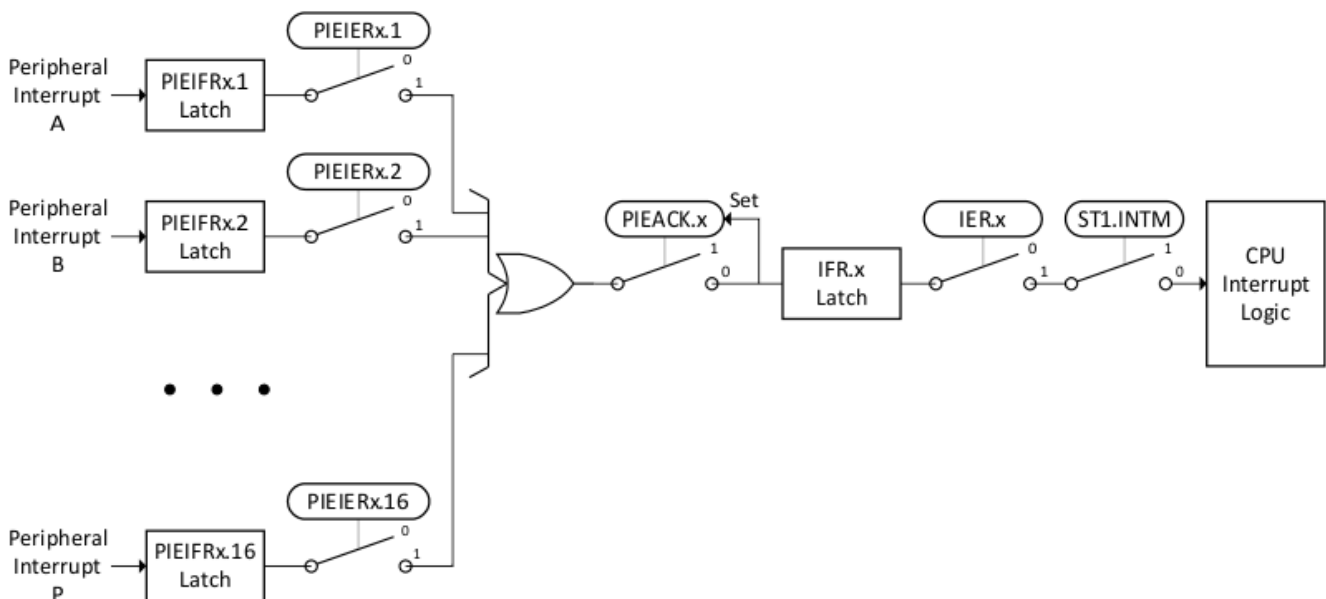

Figure 3-2. Interrupt Propagation Path

When a peripheral generates an interrupt (on PIE group x, channel y), the interrupt triggers the following sequence of events:

1. The interrupt is latched in PIEIFRx.y.
2. If PIEIERx.y is set, the interrupt propagates.
3. If PIEACK.x is clear, the interrupt propagates and PIEACK.x is set.
4. The interrupt is latched in IFR.x.
5. If IER.x is set, the interrupt propagates.
6. If INTM is clear, the CPU receives the interrupt.
7. Any instructions in the D2 or later stage of the pipeline are run to completion. Instructions in earlier stages are flushed.
8. The CPU saves the context on the stack.
9. IFR.x and IER.x are cleared. INTM is set. EALLOW is cleared.
10. The CPU fetches the ISR vector from the PIE. PIEIFRx.y is cleared.
11. The CPU branches to the ISR.

The interrupt latency is the time between PIEIFRx.y latching the interrupt and the first ISR instruction entering the execution stage of the CPU pipeline. The minimum interrupt latency is 14 SYSCLK cycles. Wait states on the ISR or stack memories add to the latency. External interrupts add a minimum of 2 SYSCLK cycles for GPIO synchronization plus extra time for input qualification (if used). Loops created using the C28x RPT instruction cannot be interrupted.

### 3.4.4 Configuring and Using Interrupts

At power-up, no interrupts are enabled by default. The PIEIER and IER registers are cleared and INTM is set. The application code is responsible for configuring and enabling all peripheral interrupts.

#### 3.4.4.1 Enabling Interrupts

To enable a peripheral interrupt, perform the following steps:

1. Disable interrupts globally (DINT or SETC INTM).
2. Enable the PIE by setting the ENPIE bit of the PIECTRL register.
3. Write the ISR vector for each interrupt to the appropriate location in the PIE vector table, found in [Section 3.4.7](#).
4. Set the appropriate PIEIERx bit for each interrupt. The PIE group and channel assignments are found in [Section 3.4.7](#).
5. Set the CPU IER bit for any PIE group containing enabled interrupts.
6. Enable the interrupt in the peripheral.
7. Enable interrupts globally (EINT or CLRC INTM).

Step 4 does not apply to the Timer1 and Timer2 interrupts, which connect directly to the CPU.

#### 3.4.4.2 Handling Interrupts

ISRs are similar to normal functions, but must do the following:

1. Save and restore the state of certain CPU registers (if used).
2. Clear the PIEACK bit for the interrupt group.
3. Return using the IRET instruction.

Requirements 1 and 3 are handled automatically by the TMS320C28x C compiler if the function is defined using the `__interrupt` keyword. For information on this keyword, see the Keywords section of the [TMS320C28x Optimizing C/C++ Compiler v6.2.4 User's Guide](#). For information on writing assembly code to handle interrupts, see the Standard Operation for Maskable Interrupts section of the [TMS320C28x CPU and Instruction Set Reference Guide](#).

The PIEACK bit for the interrupt group must be cleared manually in user code. This is normally done at the end of the ISR. If the PIEACK bit is not cleared, the CPU does not receive any further interrupts from that group. This does not apply to the Timer1 and Timer2 interrupts, which do not go through the PIE.

#### 3.4.4.3 Disabling Interrupts

To disable all interrupts, set the CPUs global interrupt mask using DINT or SETC INTM. It is not necessary to add NOPs after setting INTM or modifying IER – the next instruction executes with interrupts disabled.

Individual interrupts can be disabled using the PIEIERx registers, but care must be taken to avoid race conditions. If an interrupt signal is already propagating when the PIEIER write completes, the interrupt can reach the CPU and trigger a spurious interrupt condition. To avoid this, use the following procedure:

1. Disable interrupts globally (DINT or SETC INTM).
2. Clear the PIEIER bit for the interrupt.
3. Wait 5 cycles to make sure that any propagating interrupt has reached the CPU IFR register.
4. Clear the CPU IFR bit for the interrupt's PIE group.
5. Clear the PIEACK bit for the interrupt's PIE group.
6. Enable interrupts globally (EINT or CLRC INTM).

Interrupt groups can be disabled using the CPU IER register. This cannot cause a race condition, so no special procedure is needed.

PIEIFR bits must never be cleared in software since the read/modify/write operation can cause incoming interrupts to be lost. The only safe way to clear a PIEIFR bit is to have the CPU take the interrupt. The following procedure can be used to bypass the normal ISR:

1. Disable interrupts globally (DINT or SETC INTM).
2. Modify the PIE vector table to map the PIEIFR bit's interrupt vector to an empty ISR. This ISR only contains a return from interrupt instruction (IRET).
3. Disable the interrupt in the peripheral registers.
4. Enable interrupts globally (EINT or CLRC INTM).
5. Wait for the pending interrupt to be serviced by the empty ISR.
6. Disable interrupts globally.
7. Modify the PIE vector table to map the interrupt vector back to the original ISR.
8. Clear the PIEACK bit for the interrupt's PIE group.
9. Enable interrupts globally.

#### 3.4.4.4 Nesting Interrupts

By default, interrupts do not nest. It is possible to nest and prioritize interrupts using software control of the IER and PIEIERx registers. Example code can be found in the C2000Ware and the documentation is available at [software-dl.ti.com/C2000/docs/c28x\\_interrupt\\_nesting/html/index.html](https://software-dl.ti.com/C2000/docs/c28x_interrupt_nesting/html/index.html).

### 3.4.5 PIE Channel Mapping

Table 3-2 shows the PIE group and channel assignments for each peripheral interrupt. Each row is a group, and each column is a channel within that group. When multiple interrupts are pending, the lowest-numbered channel in the lowest-numbered group is serviced first. Thus, the interrupts at the top of the table have the highest priority, and the interrupts at the bottom have the lowest priority.

**Note**

Cells marked "-" are Reserved. CPUx is CPU1 for CPU1 PIE and CPU2 for CPU2 PIE.

**Table 3-2. PIE Channel Mapping**

### 3.4.5.1 PIE Interrupt Priority

#### 3.4.5.1.1 Channel Priority

For every PIE group, the low-number channels in the group have the highest priority. For instance in PIE group 1, channel 1.1 has priority over channel 1.3. If those two enabled interrupts occurred simultaneously, channel 1.1 is serviced first with channel 1.3 left pending. Once the ISR for channel 1.1 completes and provided there are no other enabled and pending interrupts for PIE group 1, channel 1.3 is serviced. However, for the CPU to service any more interrupts from a PIE group, PIEACK for the group must be cleared. For this specific example, for channel 1.3 to be serviced, channel 1.1's ISR has to clear PIEACK for group 1.

The following example describes an alternative scenario: channel 1.1 is currently being serviced by the CPU, channel 1.3 is pending and before channel 1.1's ISR completes, channel 1.2 that is enabled also comes in. Since channel 1.2 has a higher priority than channel 1.3, the CPU services channel 1.2 and channel 1.3 remains pending. Using the steps from the Interrupt Entry Sequence ([Section 3.4.3](#)), channel 1.2 interrupt can happen as late as step 10 (The CPU fetches the ISR vector from the PIE. PIEIFRx.y is cleared) and the channel 1.2 interrupt is serviced ahead of channel 1.3.

#### 3.4.5.1.2 Group Priority

Generally, the lowest channel in the lowest PIE group has the highest priority. An example of this is channels 1.1 and 2.1. Those two channels have the highest priority in their respective groups. If the interrupts for those two enabled channels happened simultaneously and provided there are no other enabled and pending interrupts, channel 1.1 is serviced first by the CPU with channel 2.1 left pending.

However, there are cases where channel priority supersedes group priority. This special case happens depending on which step the CPU is currently at in the Interrupt Entry Sequence ([Section 3.4.3](#)).

The following illustrates an example of this special case.

The CPU is about to service channel 2.3 and is currently going through the steps in the Interrupt Entry Sequence ([Section 3.4.3](#)).

1. As the CPU reaches step 10 (The CPU fetches the ISR vector from the PIE. PIEIFRx.y is cleared), two enabled interrupts: channel 1.1 and channel 2.1 come in.
2. Due to channel priority, channel 2.1 is serviced ahead of channel 2.3. However, group priority dictates that channel 1.1 be serviced ahead of channels 2.1 and 2.3.
3. Channel priority supersedes here and channel 2.1 is serviced ahead of channels 1.1 and 2.3.
4. After channel 2.1 completes, channel 1.1 is serviced followed by channel 2.3.

Group priority is only maintained if no interrupts are currently being serviced, that is, the Interrupt Entry Sequence ([Section 3.4.3](#)) is not executing.

### 3.4.6 System Error Interrupts

SYS\_ERR consolidates several sources of interrupts. These sources set the respective bit in the SYS\_ERR\_INT\_FLG. Any set bit in the SYS\_ERR\_INT\_FLG registers also sets the GINT (Global Interrupt) bit. The GINT bit has to be cleared before anymore SYS\_ERR interrupt is generated. If the GINT bit is cleared with the source flags still set, another SYS\_ERR interrupt is fired; therefore, clear the source flags before clearing the GINT bit.

Figure 3-3 shows the sources for SYS\_ERR interrupts.

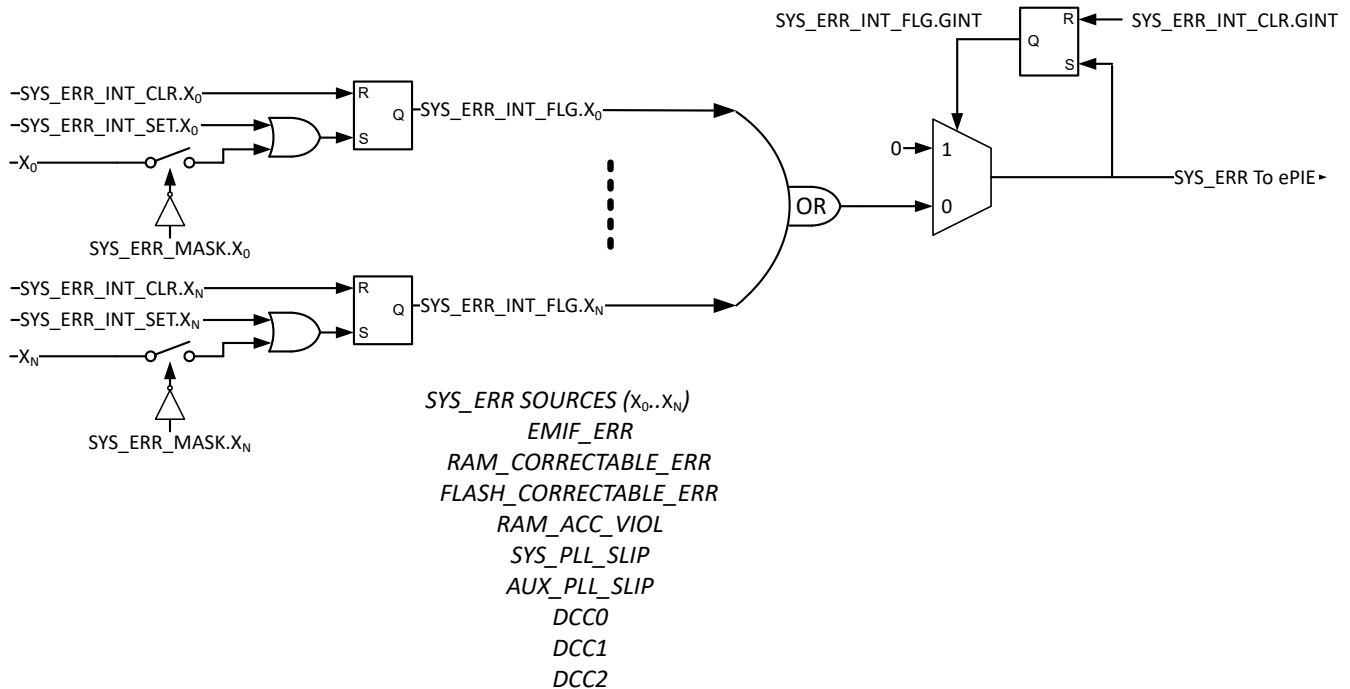

Figure 3-3. System Error Interrupt Sources

### 3.4.7 Vector Tables

Table 3-3 shows the CPU interrupt vector table. The vectors for INT1–INT12 are not used in this device. The reset vector is fetched from the boot ROM instead of from this table.

**Table 3-3. CPU Interrupt Vectors**

Name	Vector ID	Address	Size (x16)	Description	Core Priority	ePIE Group Priority
Reset	0	0x0000 0D00	2	Reset is always fetched from location 0x003F_FFC0 in Boot ROM	1 (Highest)	-
INT1	1	0x0000 0D02	2	Not used. See PIE Group 1	5	-

USER 12	31	0x0000 0D3E	2	User-Defined Trap	-	-

Table 3-4 shows the PIE interrupt vector table.

**Table 3-4. PIE Interrupt Vectors**

Name	Vector ID	Address	Size (x16)	Description	Core Priority	ePIE Group Priority
INT1.1	32	0x0000 0D40	2	ADCA1 interrupt	5	1 (Highest)
INT1.2	33	0x0000 0D42	2	ADCB1 interrupt	5	2
INT1.3	34	0x0000 0D44	2	ADCC1 interrupt	5	3
INT1.4	35	0x0000 0D46	2	XINT1 interrupt	5	4
INT1.5	36	0x0000 0D48	2	XINT2 interrupt	5	5
INT1.6	37	0x0000 0D4A	2	Reserved	5	6
INT1.7	38	0x0000 0D4C	2	TIMER0 interrupt	5	7
INT1.8	39	0x0000 0D4E	2	WAKE/WDINT interrupt	5	8
INT1.9	128	0x0000 0E00	2	I2CA interrupt	5	9
INT1.10	129	0x0000 0E02	2	SYS_ERR interrupt	5	10
INT1.11	130	0x0000 0E04	2	ECAT SYNC0 interrupt	5	11
INT1.12	131	0x0000 0E06	2	ECAT INTn interrupt	5	12
INT1.13	132	0x0000 0E08	2	CIPC0 interrupt	5	13
INT1.14	133	0x0000 0E0A	2	CIPC1 interrupt	5	14
INT1.15	134	0x0000 0E0C	2	CIPC2 interrupt	5	15
INT1.16	135	0x0000 0E0E	2	CIPC3 interrupt	5	16 (Lowest)
INT2.1	40	0x0000 0D50	2	EPWM1_TZ interrupt	6	1 (Highest)
INT2.2	41	0x0000 0D52	2	EPWM2_TZ interrupt	6	2
INT2.3	42	0x0000 0D54	2	EPWM3_TZ interrupt	6	3
INT2.4	43	0x0000 0D56	2	EPWM4_TZ interrupt	6	4
INT2.5	44	0x0000 0D58	2	EPWM5_TZ interrupt	6	5
INT2.6	45	0x0000 0D5A	2	EPWM6_TZ interrupt	6	6
INT2.7	46	0x0000 0D5C	2	EPWM7_TZ interrupt	6	7
INT2.8	47	0x0000 0D5E	2	EPWM8_TZ interrupt	6	8
INT2.9	136	0x0000 0E10	2	EPWM9_TZ interrupt	6	9
INT2.10	137	0x0000 0E12	2	EPWM10_TZ interrupt	6	10
INT2.11	138	0x0000 0E14	2	EPWM11_TZ interrupt	6	11
INT2.12	139	0x0000 0E16	2	EPWM12_TZ interrupt	6	12
INT2.13	140	0x0000 0E18	2	EPWM13_TZ interrupt	6	13
INT2.14	141	0x0000 0E1A	2	EPWM14_TZ interrupt	6	14
INT2.15	142	0x0000 0E1C	2	EPWM15_TZ interrupt	6	15
INT2.16	143	0x0000 0E1E	2	EPWM16_TZ interrupt	6	16 (Lowest)
INT3.1	48	0x0000 0D60	2	EPWM1 interrupt	7	1 (Highest)
INT3.2	49	0x0000 0D62	2	EPWM2 interrupt	7	2
INT3.3	50	0x0000 0D64	2	EPWM3 interrupt	7	3
INT3.4	51	0x0000 0D66	2	EPWM4 interrupt	7	4
INT3.5	52	0x0000 0D68	2	EPWM5 interrupt	7	5
INT3.6	53	0x0000 0D6A	2	EPWM6 interrupt	7	6
INT3.7	54	0x0000 0D6C	2	EPWM7 interrupt	7	7
INT3.8	55	0x0000 0D6E	2	EPWM8 interrupt	7	8
INT3.9	144	0x0000 0E20	2	EPWM9 interrupt	7	9
INT3.10	145	0x0000 0E22	2	EPWM10 interrupt	7	10
INT3.11	146	0x0000 0E24	2	EPWM11 interrupt	7	11
INT3.12	147	0x0000 0E26	2	EPWM12 interrupt	7	12
INT3.13	148	0x0000 0E28	2	EPWM13 interrupt	7	13
INT3.14	149	0x0000 0E2A	2	EPWM14 interrupt	7	14

**Table 3-4. PIE Interrupt Vectors (continued)**

Name	Vector ID	Address	Size (x16)	Description	Core Priority	ePIE Group Priority
INT3.15	150	0x0000 0E2C	2	EPWM15 interrupt	7	15
INT3.16	151	0x0000 0E2E	2	EPWM16 interrupt	7	16 (Lowest)
INT4.1	56	0x0000 0D70	2	ECAP1 interrupt	8	1 (Highest)
INT4.2	57	0x0000 0D72	2	ECAP2 interrupt	8	2
INT4.3	58	0x0000 0D74	2	ECAP3 interrupt	8	3
INT4.4	59	0x0000 0D76	2	ECAP4 interrupt	8	4
INT4.5	60	0x0000 0D78	2	ECAP5 interrupt	8	5
INT4.6	61	0x0000 0D7A	2	ECAP6 interrupt	8	6
INT4.7	62	0x0000 0D7C	2	ECAP7 interrupt	8	7
INT4.8	63	0x0000 0D7E	2	Reserved	8	8
INT4.9	152	0x0000 0E30	2	FSITXA_INT1 interrupt	8	9
INT4.10	153	0x0000 0E32	2	FSITXA_INT2 interrupt	8	10
INT4.11	154	0x0000 0E34	2	FSITXB_INT1 interrupt	8	11
INT4.12	155	0x0000 0E36	2	FSITXB_INT2 interrupt	8	12
INT4.13	156	0x0000 0E38	2	FSIRXA_INT1 interrupt	8	13
INT4.14	157	0x0000 0E3A	2	FSIRXA_INT2 interrupt	8	14
INT4.15	158	0x0000 0E3C	2	FSIRXB_INT1 interrupt	8	15
INT4.16	159	0x0000 0E3E	2	FSIRXB_INT2 interrupt	8	16 (Lowest)
INT5.1	64	0x0000 0D80	2	EQEP1 interrupt	9	1 (Highest)
INT5.2	65	0x0000 0D82	2	EQEP2 interrupt	9	2
INT5.3	66	0x0000 0D84	2	EQEP3 interrupt	9	3
INT5.4	67	0x0000 0D86	2	EQEP4 interrupt	9	4
INT5.5	68	0x0000 0D88	2	CLB1 interrupt	9	5
INT5.6	69	0x0000 0D8A	2	CLB2 interrupt	9	6
INT5.7	70	0x0000 0D8C	2	CLB3 interrupt	9	7
INT5.8	71	0x0000 0D8E	2	CLB4 interrupt	9	8
INT5.9	160	0x0000 0E40	2	SDFM1 interrupt	9	9
INT5.10	161	0x0000 0E42	2	SDFM2 interrupt	9	10
INT5.11	162	0x0000 0E44	2	ECATRSTINTn interrupt	9	11
INT5.12	163	0x0000 0E46	2	ECAT SYNC1 interrupt	9	12
INT5.13	164	0x0000 0E48	2	SDFM1 DR1 interrupt	9	13
INT5.14	165	0x0000 0E4A	2	SDFM1 DR2 interrupt	9	14
INT5.15	166	0x0000 0E4C	2	SDFM1 DR3 interrupt	9	15
INT5.16	167	0x0000 0E4E	2	SDFM1 DR4 interrupt	9	16 (Lowest)
INT6.1	72	0x0000 0D90	2	SPIA_RX interrupt	10	1 (Highest)
INT6.2	73	0x0000 0D92	2	SPIA_TX interrupt	10	2
INT6.3	74	0x0000 0D94	2	SPIB_RX interrupt	10	3
INT6.4	75	0x0000 0D96	2	SPIB_TX interrupt	10	4
INT6.5	76	0x0000 0D98	2	LINA_0 interrupt	10	5

## 3.5 Exceptions and Non-Maskable Interrupts

This section describes system-level error conditions that can trigger a non-maskable interrupt (NMI). The interrupt allows the application to respond to the error.

### 3.5.1 Configuring and Using NMIs

Each CPU subsystem has an NMI module. This section provides detail of NMI on C28x subsystems. An incoming NMI sets a status bit in the NMIFLG register and starts the NMI watchdog counter. This counter is clocked by the SYSCLK, and if the counter reaches the value programmed in the NMIWDPDR register, the counter triggers an NMI watchdog reset (NMIWDRS). To prevent this, the NMI handler must clear the flag bit using the NMIFLGCLR register. Once all flag bits are clear, the NMIINT bit in the NMIFLG register must be cleared to allow future NMIs to be taken.

The NMI module is enabled by the boot ROM during the startup process. To respond to NMIs, an NMI handler vector must be written to the PIE vector table.

### 3.5.2 Emulation Considerations

The NMI watchdog counter behaves as follows under debug conditions:

CPU Suspended:	When the CPU is suspended, the NMI watchdog counter is suspended.
Run-Free Mode:	When the CPU is placed in run-free mode, the NMI watchdog counter resumes operation as normal.
Real-Time Single-Step Mode:	When the CPU is in real-time single-step mode, the NMI watchdog counter is suspended. The counter remains suspended even within real-time interrupts.
Real-Time Run-Free Mode:	When the CPU is in real-time run-free mode, the NMI watchdog counter operates as normal.

### 3.5.3 NMI Sources

There are several types of hardware errors that can trigger an NMI. Additional information about the error is usually available from the module that detects the error.

#### 3.5.3.1 Missing Clock Detection

The missing clock detection logic monitors OSCCLK for failure. If the OSCCLK source stops, the PLL is bypassed, OSCCLK is connected to INTOSC1, and NMIs are fired to both CPUs. For more information on missing clock detection, see [Section 3.7.8.1](#).

#### 3.5.3.2 RAM Uncorrectable Error

A single-bit parity error, double-bit ECC data error, or single-bit ECC address error in a RAM read triggers an NMI. This applies to CPU, CLA, and DMA reads. Single-bit ECC data errors do not trigger an NMI, but can optionally trigger a normal peripheral interrupt. For more information on RAM error detection, see [Section 3.12.9](#).

#### 3.5.3.3 Flash Uncorrectable ECC Error

A double-bit ECC data error or single-bit ECC address error in a Flash read triggers an NMI. Single-bit ECC data errors do not trigger an NMI, but can optionally trigger a normal peripheral interrupt.

#### 3.5.3.4 ROM Uncorrectable Error

On this device, ROM has a parity feature and a parity mismatch during read or execution triggers an NMI.

#### 3.5.3.5 NMI Vector Fetch Mismatch

Each CPU's Peripheral Interrupt Expansion module (PIE) has redundant vector tables. If a mismatch in these tables is detected during a vector fetch, a user-specified error handler is run instead of the ISR. If the vector fetch was caused by an NMI, a second NMI is fired to the other CPU. Mismatches for other interrupts do not trigger an NMI. For more information about the vector address check, see [Section 3.6.2](#).

### 3.5.3.6 CPU2 Watchdog or NMI Watchdog Reset

A watchdog reset or NMI watchdog reset on CPU2 triggers an NMI on CPU1. Since a CPU1 reset also resets CPU2, this NMI source is not available on CPU2. Watchdog interrupts do not trigger an NMI.

### 3.5.3.7 EtherCAT Reset Out

A reset out from EtherCAT module can generate NMI on CPU1. To enable this feature, you need to set the CPU\_NMI\_EN configuration bit in the ESCSS\_RESET\_DEST\_CONFIG register.

### 3.5.3.8 CRC Fail

A CRC fail result from the BGCRC module can generate an NMI to the respective CPU. By default, this NMI is enabled. To disable this feature, configure the NMIDIS configuration field in the BGCRC\_CTRL1 register with a value of 1010.

### 3.5.3.9 ERAD NMI

ERAD module can generate NMI based on different events which user can configure in ERAD.

## 3.5.4 Illegal Instruction Trap (ITRAP)

If the CPU tries to execute an illegal instruction, the CPU generates a special interrupt called an illegal instruction trap (ITRAP). This interrupt is non-maskable and has a vector in the PIE vector table. For more information about ITRAPs, see the Illegal-Instruction Trap section of the [TMS320C28x DSP CPU and Instruction Set Reference Guide](#).

---

#### Note

A RAM fetch access violation triggers an ITRAP in addition to the normal peripheral interrupt for RAM access violations. The CPU handles the ITRAP first.

---

## 3.6 Safety Features

This section gives details on features that monitor device operation during run-time to detect any error in operation.

### 3.6.1 Write Protection on Registers

#### 3.6.1.1 LOCK Protection on System Configuration Registers

Several system configuration registers are protected from spurious CPU writes by LOCK registers. Once these associated LOCK register bits are set, the respective locked registers can no longer be modified by software. See the register descriptions for details.

#### 3.6.1.2 EALLOW Protection

Several control registers are protected from spurious CPU writes by the EALLOW protection mechanism. The EALLOW bit in status register 1 (ST1) indicates the state of protection as shown in [Table 3-5](#).

**Table 3-5. Access to EALLOW-Protected Registers**

EALLOW Bit	CPU Writes	CPU Reads	JTAG Writes	JTAG Reads
0	Ignored	Allowed	Allowed <sup>(1)</sup>	Allowed
1	Allowed	Allowed	Allowed	Allowed

(1) The EALLOW bit is overridden using the JTAG port, allowing full access of protected registers during debug from the Code Composer Studio IDE.

At reset, the EALLOW bit is cleared, enabling EALLOW protection. While protected, all writes to protected registers by the CPU are ignored and only CPU reads, JTAG reads, and JTAG writes are allowed. If this bit is set, by executing the EALLOW instruction, the CPU is allowed to write freely to protected registers. After modifying registers, the registers can once again be protected by executing the EDIS instruction to clear the EALLOW bit.

### 3.6.2 CPU1 and CPU2 ePIE Vector Address Validity Check

The ePIE vector table on each CPU is duplicated into these two parts:

- Main ePIE Vector Table mapped from 0xD00 to 0xEFF in the C28x memory space
- Redundant ePIE Vector Table mapped from 0x1000D00 to 0x1000EFF in the C28x memory space

Following is the behavior of accesses to the ePIE memories:

- Data Writes to Main Vector Table: Writes to both memories
- Data Writes to Redundant Vector Table: Writes only to the Redundant Vector Table
- Vector Fetch: Data from both the vector tables are compared
- Data Read: Can read the Main and Redundant vector table separately

On every vector fetch from the ePIE, a hardware comparison (no cycle penalty is incurred to do the comparison) of both the vector table outputs is performed and if there is a mismatch between the two vector table outputs, the following occurs:

1. If the PIEVERRADDR register (default value = 0x3F FFFF) is not initialized, the default error handler at address 0x3F FFBE gets executed.

But, when the PIEVERRADDR register is initialized to the address of the user-defined routine, the user-defined routine is executed instead of the default error handler.

**Note:** Each CPU has a copy of the PIE Vector Fetch Error Handler register (CPU1.PIEVERRADDR and CPU2.PIEVERRADDR).

2. Hardware also generates EPWM Trip signals that trip the PWM outputs using TRIPIN15.
3. An NMI to the other CPU is sent if the current mismatch is during a vector fetch. For example, on an NMI vector fetch error for CPU2, an NMI is also fired to CPU1.NMIWD.

If there is no mismatch, the correct vector is jammed onto the C28x program control.

### 3.6.3 NMIWDs

Each CPU has user-programmable NMIWD period registers that set a limit on how much time to allocate for the device to acknowledge the NMI. If the NMI is not acknowledged, the NMI causes a device reset.

### 3.6.4 ECC and Parity Enabled RAMs, Shared RAMs Protection

Each CPU subsystem has different RAM blocks. Some RAM blocks are ECC-enabled and others are parity-enabled. All single-bit errors in ECC RAM are auto-corrected and an error counter is incremented every time a single bit error is detected. If the error counter reaches a predefined user configured limit, an interrupt is generated to the corresponding CPU. Refer to [Section 3.12](#) for more details on RAM errors.

All uncorrectable double-bit errors end up triggering an NMI to corresponding CPUs.

### 3.6.5 ECC Enabled Flash Memory

When ECC is programmed and enabled, Flash single-bit errors are corrected automatically by ECC logic before giving data to the CPU, but the Flash single-bit errors are not corrected in Flash memory. Flash memory still contains wrong data until another erase/program operation happens to correct the Flash contents. Irrespective of whether the error interrupt is enabled or disabled, single-bit errors are always corrected before giving data to the CPU. When the interrupt is disabled, users can check the single-bit error counter register for any single-bit error occurrences. The error counter stops incrementing once the value is equal to the threshold + 1. Set the threshold register to a non-zero value so that the error counter can increment. The user decides the threshold value to reprogram the Flash with the correct data.

When ECC is programmed and enabled, Flash uncorrectable errors end up triggering an NMI to the respective CPU. Refer to [Section 3.12](#) for more details on Flash error correction and error catching mechanisms.

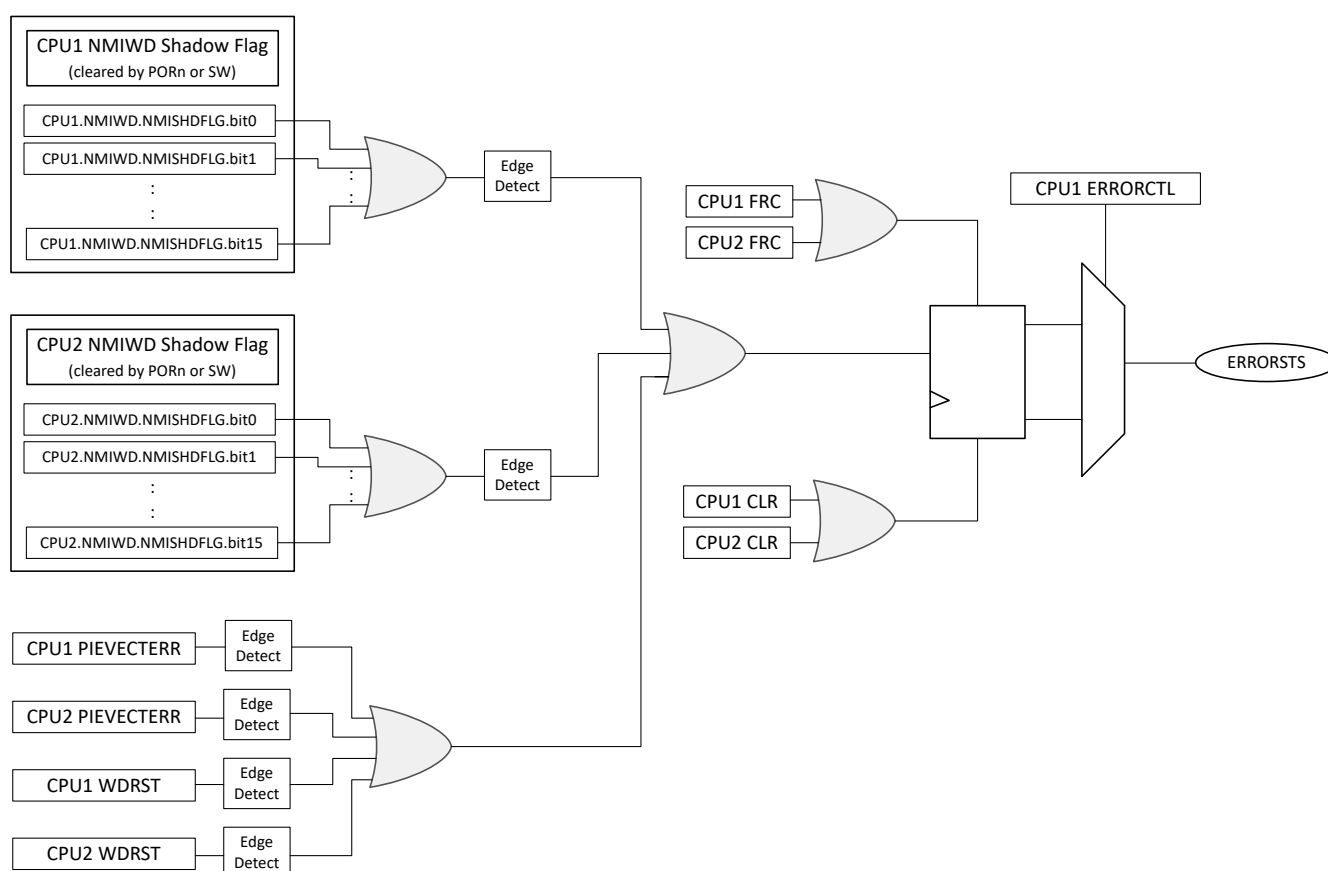

### 3.6.6 ERRORSTS Pin

The ERRORSTS pin is an ‘always output’ pin and remains high until an error is detected inside the chip. On an error, the ERRORSTS pin goes low (default polarity) until the corresponding internal error status flag for that error source is cleared. [Figure 3-4](#) shows the functionality of the ERRORSTS pin.

The ERRORSTS pin is tri-stated until the chip power rails ramp up to the lower operational limit. As the ERRORSTS pin is an active-low pin (default polarity), users who care about the state of this pin during power-up can connect an external pull-down on this pin.

Following enhancement has been made on this device for ERRORSTS pin logic:

- Polarity of Error pin has been made configurable (default setting is active-low polarity).
- To enable testing of the Error pin, capability to force and clear the Error pin from software has been provided.
- Additional sources of Error have been added to ERRORSTS:
  - CPU1 Watchdog reset
  - Error on a PIE vector fetch

**Figure 3-4. ERRORSTS Pin Diagram**

## 3.7 Clocking

This section explains the clock sources and clock domains on this device, and how to configure them for application use. [Figure 3-5](#) provides an overview of the device clocking system.

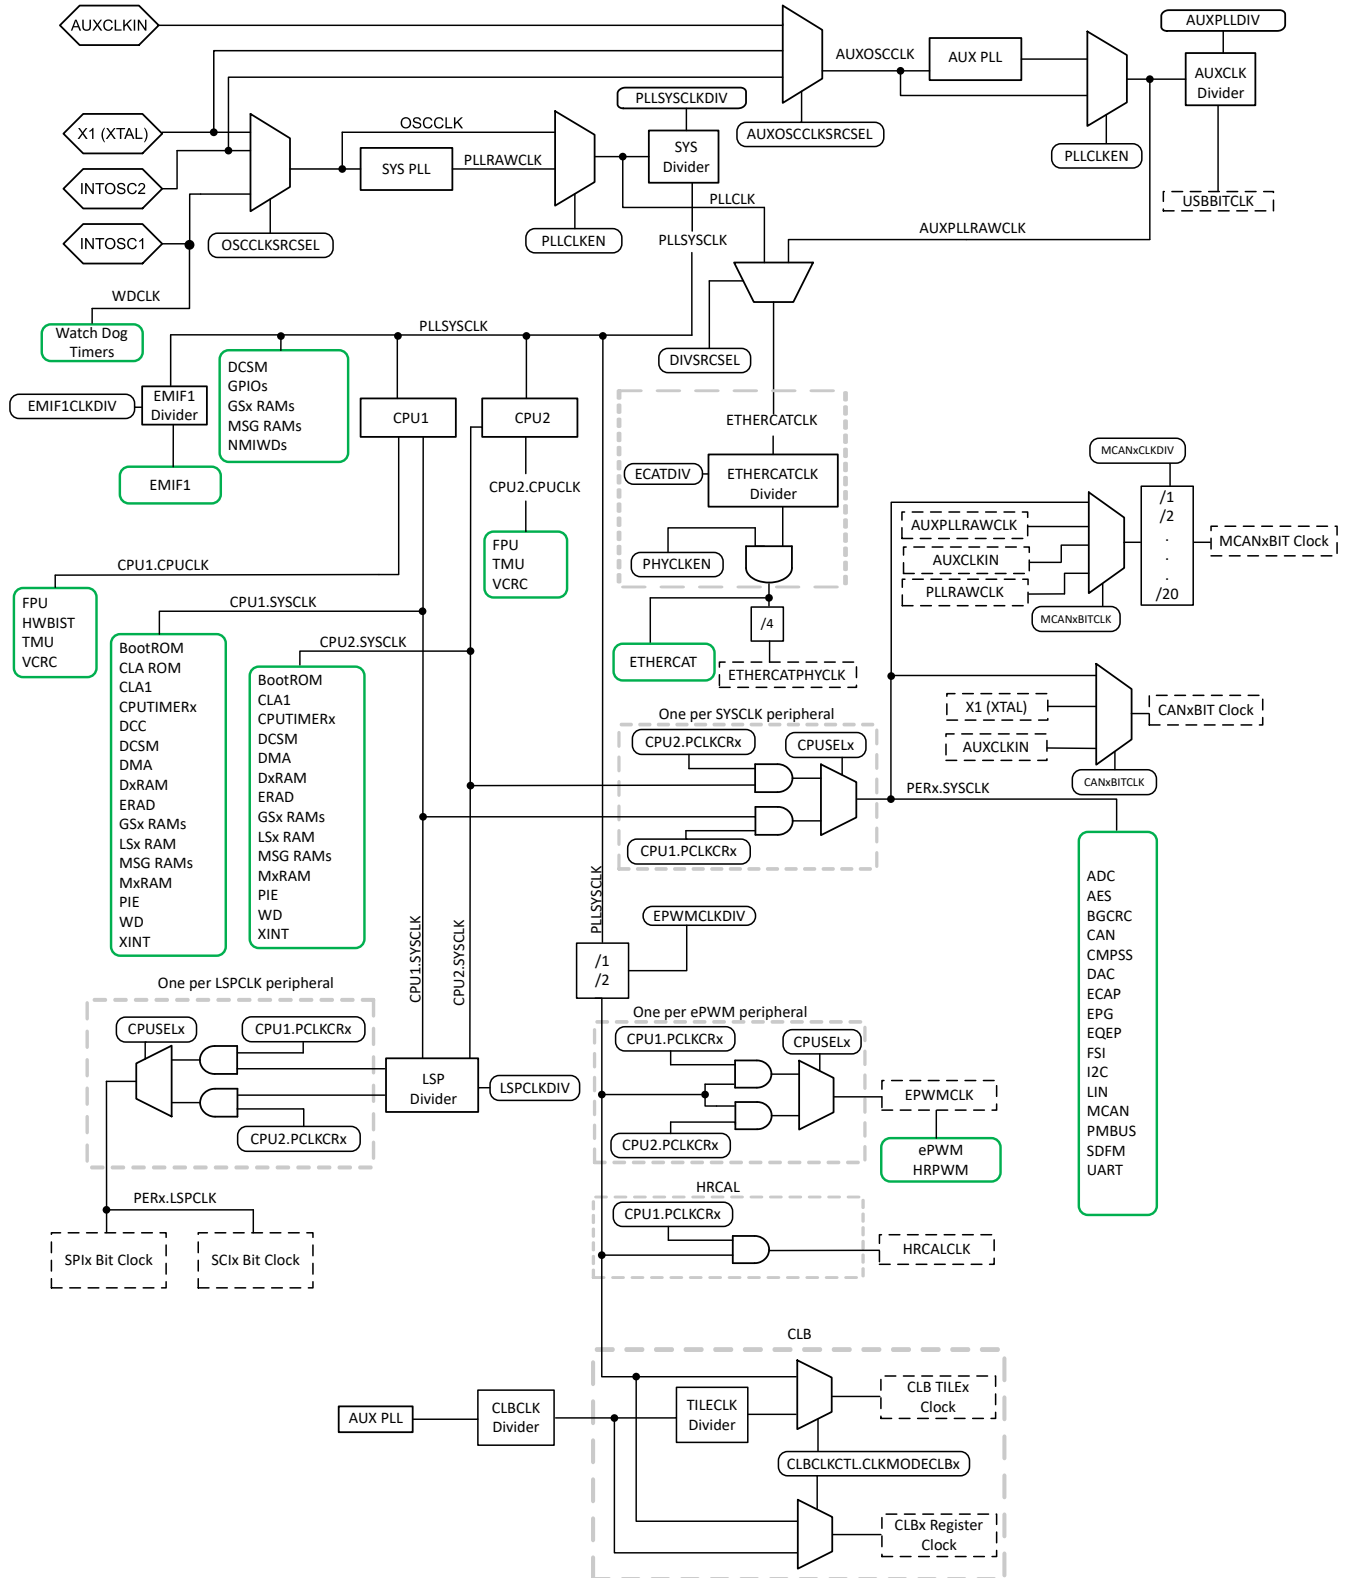

Figure 3-5. Clocking System

### 3.7.1 Clock Sources

The needs of the application are what ultimately determine the clock configuration. Specific concerns such as application performance, power consumption, total system cost, and EMC are beyond the scope of this document, but the concerns must provide answers to the following questions:

1. What is the desired CPU frequency?
2. Are there any additional communication protocols or peripherals, such as CAN or USB, required?
3. What types of external oscillators or clock sources are available?

If CAN or USB is required, an external clock source with a precise frequency must be used as a reference clock. Otherwise, use only INTOSC2 and avoid the need for more external components.

All of the clocks in the device are derived from one of four clock sources.

#### 3.7.1.1 Primary Internal Oscillator (INTOSC2)

At power-up, the device is clocked from an on-chip 10MHz oscillator (INTOSC2). INTOSC2 is the primary internal clock source and is the default system clock at reset. INTOSC2 is used to run the boot ROM and can be used as the system clock source for the application.

#### Note

INTOSC2 frequency tolerance is too loose to meet the timing requirements for some peripherals such as CAN and USB, so an external clock must be used to support those features.

#### 3.7.1.2 Backup Internal Oscillator (INTOSC1)

The device also includes a redundant on-chip 10MHz oscillator (INTOSC1). INTOSC1 is a backup clock source that normally only clocks the watchdog timers and missing clock detection circuit (MCD). If MCD is enabled and a missing system clock is detected, the system PLL is bypassed and all system clocks are connected to INTOSC1 automatically. INTOSC1 can also be manually selected as the system and auxiliary clock source for debug purposes.

#### 3.7.1.3 External Oscillator (XTAL)

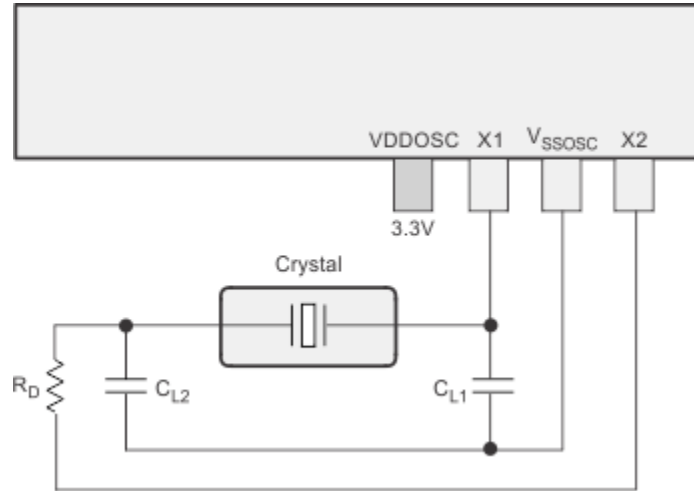

The dedicated X1 and X2 pins support an external clock source (XTAL), which can be used as the main system and auxiliary clock source. Frequency limits and timing requirements can be found in the [TMS320F28P65x Real-Time Microcontrollers Data Sheet](#). Three types of external clock sources are supported:

- A single-ended 3.3V external clock. The clock signal must be connected to X1 while X2 is left unconnected, as shown in [Figure 3-6](#).

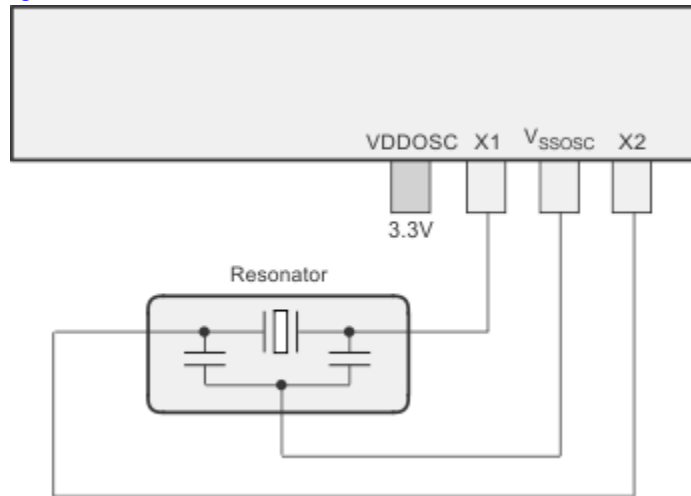

**Figure 3-6. Single-ended 3.3V External Clock**

- An external crystal. The crystal must be connected across X1 and X2 with the load capacitors connected to VSSOSC as shown in [Figure 3-7](#).

**Figure 3-7. External Crystal**

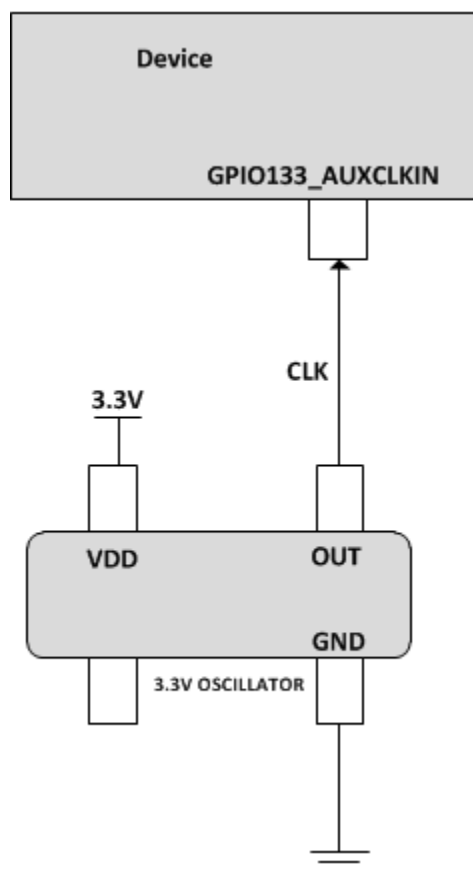

- An external resonator. The resonator must be connected across X1 and X2 with the ground connected to VSSOSC as shown in [Figure 3-8](#).

**Figure 3-8. External Resonator**

### 3.7.1.4 Auxiliary Clock Input (AUXCLKIN)

An additional external clock source is supported on GPIO133 (AUXCLKIN). This must be a single-ended 3.3V external clock. AUXCLKIN can be used as the clock source for the USB, CAN, and Communication Manager Subsystem. Frequency limits and timing requirements can be found in the [TMS320F28P65x Real-Time Microcontrollers Data Sheet](#). The external clock must be connected directly to the GPIO133 pin, as shown in Figure 3-9.

**Figure 3-9. Auxiliary Clock Input (AUXCLKIN)**

## 3.7.2 Derived Clocks

The clock sources discussed in the previous section can be multiplied (using PLL) and divided down to produce the desired clock frequencies for the application. This process produces a set of derived clocks, which are described in this section.

### 3.7.2.1 Oscillator Clock (OSCCLK)

One of INTOSC2, XTAL, or INTOSC1 must be chosen to be the controller reference clock (OSCCLK) for the CPU and most of the peripherals. OSCCLK can be used directly or applied through the system PLL to reach a higher frequency. At reset, OSCCLK is the default system clock and is connected to INTOSC2.

### 3.7.2.2 System PLL Output Clock (PLLRAWCLK)

The system PLL allows the device to run at the maximum rated operating frequency and in most applications generates the main system clock. This PLL uses OSCCLK as a reference, and features a fractional multiplier and slip detection. For configuration instructions, see [Section 3.7.7](#).

### 3.7.2.3 Auxiliary Oscillator Clock (AUXOSCCLK)

One of INTOSC2, XTAL, or AUXCLKIN can be chosen to be the auxiliary reference clock (AUXOSCCLK) for the USB module. (This selection does not affect the CAN bit clock, which uses AUXCLKIN directly). AUXOSCCLK can be used directly or applied through the auxiliary PLL to reach a higher frequency. At reset, AUXOSCCLK is connected to INTOSC2, but only an external oscillator can meet the USB timing requirements.

### 3.7.2.4 Auxiliary PLL Output Clock (AUXPLLRAWCLK)

The auxiliary PLL is used to generate a clock for USB, CAN, and EtherCAT. This PLL uses AUXOSCCLK as a reference and features slip detection. For configuration instructions, see [Section 3.7.7](#).

## 3.7.3 Device Clock Domains

The device clock domains feed the clock inputs of the various modules in the device. They are connected to the derived clocks, either directly or through an additional divider.

### 3.7.3.1 System Clock (PLLSYSCLK)

The system control registers, GS RAMs, IPC module, GPIO qualification, and NMI watchdog timers each have a clock domain (PLLSYSCLK). Despite the name, PLLSYSCLK can be connected to the system PLL (PLLRAWCLK) or to OSCCLK. The chosen clock source is run through a frequency divider, which is configured using the SYSCLKDIVSEL register.

### 3.7.3.2 CPU Clock (CPUCLK)

Each CPU has a clock (CPU1.CPUCLK and CPU2.CPUCLK) that is used to clock the CPU, the coprocessors, the private RAMs (M0, M1, D0-D1 for CPU1, and D2-D5 for CPU2), and the boot ROM and Flash wrapper. This clock is identical to PLLSYSCLK, but is gated when the CPU enters IDLE or STANDBY mode.

### 3.7.3.3 CPU Subsystem Clock (SYSCLK and PERx.SYSCLK)

Each CPU provides a clock (CPU1.SYSCLK and CPU2.SYSCLK) to the CLA, DMA, and most owned peripherals. This clock is identical to PLLSYSCLK, but is gated when the CPU enters STANDBY mode.

Each peripheral clock can be connected to either CPU1.SYSCLK or CPU2.SYSCLK. This selection is made by CPU1 using the CPUSELx registers. Each peripheral clock also has an independent clock gating that is controlled by the CPU PCLKCRx registers. By default, the ePWM and EMIF1 clocks each have an additional /2 divider, which is required to support CPU frequencies over 100MHz. At slower CPU frequencies, these dividers can be disabled using the PERCLKDIVSEL register.

---

#### Note

The application needs to wait for 5 SYSCLK cycles after enabling the clock to the peripherals, when using PCLKCRx.

---

### 3.7.3.4 Low-Speed Peripheral Clock (LSPCLK and PERx.LSPCLK)

The SCI, SPI, and UART modules can communicate at bit rates that are much slower than the CPU frequency. These modules are connected to a shared clock divider, which generates a low-speed peripheral clock (LSPCLK) derived from SYSCLK. LSPCLK uses a /4 divider by default, but the ratio can be changed using the LOSPCP register. Each SCI, SPI, and McBSP module clock (PERx.LSPCLK) can be gated independently using the PCLKCRx registers.

### 3.7.3.5 USB Auxiliary Clock (AUXPLLCLK)

The USB module requires a fixed 60MHz clock for bit sampling. Since the main system clock is usually not a multiple of 60MHz, the correct frequency cannot be achieved with a simple divider. Instead, the USB clock is provided through an auxiliary clock path (AUXPLLCLK), which can use an independent clock source and PLL to generate the correct frequency.

USB clock tolerances are very tight. As stated in section 7.1.11 of the USB 2.0 specification, low-speed devices (1.50Mbps) have a tolerance of  $\pm 1.5\%$ , while high-speed devices (12.000Mbps) have a tolerance of  $\pm 0.25\%$ . Typically, these tolerances are achieved by using an external crystal or resonator as the source for AUXOSCCLK.

### 3.7.3.6 CAN Bit Clock

The required frequency tolerance for the CAN bit clock depends on the bit timing setup and network configuration, and can be as tight as 0.1%. Since the main system clock (in the form of PERx.SYSCLK) cannot be precise enough, the bit clock can also be connected to XTAL or AUXCLKIN using the CLKSRCCTL2 register. There is an independent selection for each CAN module.

### 3.7.3.7 CPU Timer2 Clock (TIMER2CLK)

CPU timers 0 and 1 are connected to PERx.SYSCLK. Timer 2 is connected to PERx.SYSCLK by default, but can also be connected to INTOSC1, INTOSC2, XTAL, or AUXPLLCLK using the TMR2CLKCTL register. This register also provides a separate prescale divider for timer 2. If a source other than SYSCLK is used, the SYSCLK frequency must be at least twice the source frequency to make sure of correct sampling. Each CPU has independent CPU timers and TMR2CLKCTL register.

The main reason to use a non-SYSCLK source is for internal frequency measurement. In most applications, timer 2 runs off of the SYSCLK.

### 3.7.4 External Clock Output (XCLKOUT)

It is sometimes necessary to observe a clock directly for debug and testing purposes. The external clock output (XCLKOUT) feature supports this by connecting a clock to external pins, GPIO73 and GPIO224. The available clock sources are PLLSYSCLK, PLLRAWCLK, CPU1.SYSCLK, AUXPLLRAWCLK, CPU2.SYSCLK, INTOSC1, and INTOSC2.

To use XCLKOUT, first select the clock source using the CLKSRCCTL3 register. Next, select the desired output divider using the XCLKOUTDIVSEL register. Finally, connect either GPIO73 or GPIO224 to mux channel 3 using the GPIO configuration registers.

### 3.7.5 Clock Connectivity

Table 3-6 provides details on the clock connections of every module present in the device.

**Table 3-6. Clock Connections Sorted by Clock Domain**

Clock Domain	CPU1 Subsystem	CPU2 Subsystem	Shared Modules
CPUx.CPUCLK	CPU1	CPU2	
	CPU1.VCRC	CPU2.VCRC	
	CPU1.FPU	CPU2.FPU	
	CPU1.TMU	CPU2.TMU	
	CPU1.Flash	CPU2.Flash	
	CPU1.DCSM	CPU2.DCSM	
	CPU1.HWBIST	CPU2.HWBIST	

**Table 3-6. Clock Connections Sorted by Clock Domain (continued)**

Clock Domain	CPU1 Subsystem	CPU2 Subsystem	Shared Modules
CPUx.SYSCLK	CPU1.ePIE CPU1.LS0-LS9 RAMs CPU1.M0-M1 RAMs CPU1.D0-D1 RAMs  CPU1.BootROM CPU1.CLA1 Message RAMs CPU1.Timer0-2 CPU1.DMA CPU1.XINT CPU1.CLA1 CPU1.BGCRC CPU1.ERAD	CPU2.ePIE  CPU2.M0-M1 RAMs  CPU2.BootROM  CPU2.Timer0-2 CPU2.DMA CPU2.XINT  CPU2.BGCRC CPU2.ERAD	D2-D5 RAMs mappable to CPU1 or CPU2

PERx.LSPCLK			SCI SPI
CAN Bit Clock			CAN
AUXPLLCLK	USB		
WDCLK (INTOSC1)	CPU1.Watchdog	CPU2.Watchdog	

### 3.7.6 Using an External Crystal or Resonator

The X1 and X2 pins double as GPIO221 and GPIO220. At power-up, these pins are in GPIO mode and the on-chip crystal oscillator is powered off. The following procedure can be used to switch the pins to X1 and X2 mode and enable the oscillator:

1. Clear the XTALCR.OSCOFF bit.
2. Wait for the crystal to power up. 1ms is the typical wait time but this depends on the crystal that is being used.
3. Clear the X1 counter by writing a 1 to X1CNT.CLR and keep clearing until the X1 counter value in the X1CNT register is no longer saturated 2047 (0x7FF).
4. Wait for the X1 counter value in the X1CNT register to reach 2047 (0x7FF).
5. Repeat steps 3-4 three additional times.
6. Select XTAL as the OSCCLK source by writing a 1 to CLKSRCCTL1.OSCCLKSRCSEL.
7. Check the MCLKSTS bit in the MCDCCR register. If the bit set, the oscillator has not finished powering up, and more time is required:
  - a. Clear the missing clock status by writing a 1 to MCDCCR.MCLKCLR.
  - b. Repeat steps 2-7. Do not reset the device. Doing so powers down the oscillator, which requires the procedure to be restarted from step 1.
  - c. If the oscillator has not finished powering up in 10ms, there is a real clock failure.
8. If MCDCCR.MCLKSTS is clear, the oscillator startup is a success. The system clock is now derived from XTAL.

#### 3.7.6.1 X1/X2 Precondition Circuit

The GPIO220/221 alternate functionality on X1/X2 can be used to speed up the start-up time of the crystal by as much as 30% if needed. This functionality is achieved by preconditioning the load capacitors CL1 and CL2 to a known state before the XTAL is turned on.

The steps below outline the procedure to precondition X1/X2 before turning on the XTAL:

1. DevCfgRegs.XTALCR2.bit.XIF = 1; // Precondition X1 to High
2. DevCfgRegs.XTALCR2.bit.XOF = 1; // Precondition X2 to High
3. DevCfgRegs.XTALCR2.bit.FEN = 1; // Enable X1/X2 Precondition
4. DEVICE\_DELAY\_US(1);
5. DevCfgRegs.XTALCR.bit.OSCOFF = 0; // Removes Precondition and Turns on the XTAL
6. DevCfgRegs.XTALCR2.bit.FEN = 0; // Disables X1/X2 Precondition

### 3.7.7 PLL/AUXPLL

The PLL/AUXPLL is responsible for synthesizing an output frequency from the input clock (from the oscillator). [Figure 3-10](#) shows a simple block diagram of the PLL/AUXPLL. The PLL/AUXPLL divides the reference input for a lower frequency input into the PLL/AUXPLL by (REFDIV + 1). Then multiplies this internal frequency by IMULT to get the VCO output clock. The PLL/AUXPLL output is divided by (ODIV + 1) to generate PLLRAWCLK/AUXPLLRAWCLK that is further divided by SYSCLKDIVSEL.PLLSYSCLKDIV/AUXCLKDIVSEL.AUXPLLDIV to generate PLLSYSCLK/AUXCLK.

There are two PLLs (SYSPLL and AUXPLL) and the equations shown in [Figure 3-10](#) can be used to configure the respective PLL.

- IMULT is the integer value of the multiplier
- REFDIV is the reference divider for the OSCCLK/AUXOSCCLK
- ODIV is the output divider of the PLLRAWCLK/AUXPLLRAWCLK
- PLLSYSCLKDIV is the system clock divider
- AUXPLLDIV is the auxiliary clock divider

For the permissible values of the multipliers and dividers, see the documentation for the respective registers.

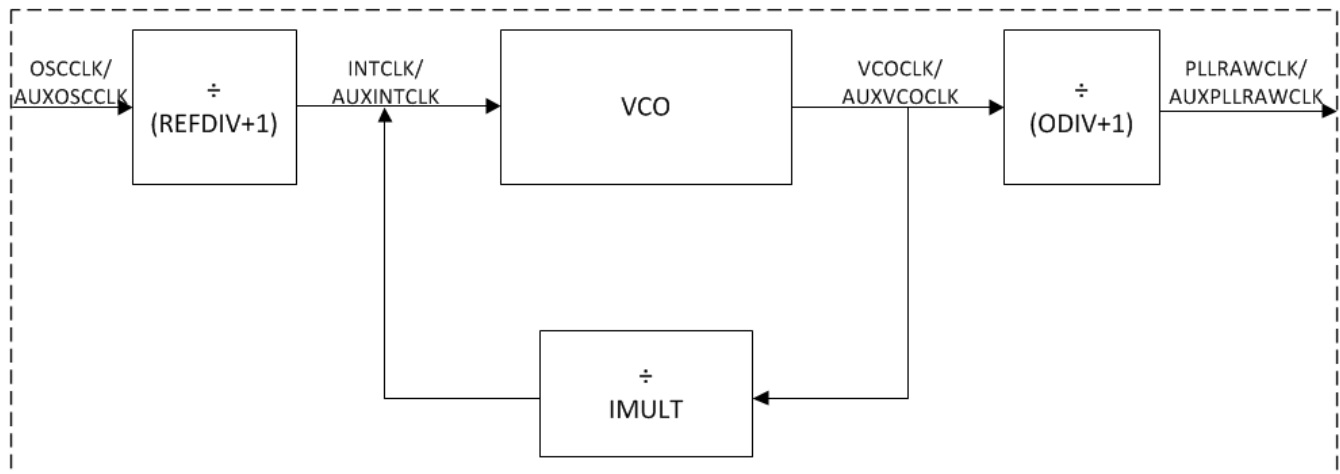

Many combinations of multiplier and divider can produce the same output frequency. However, the product of the reference clock frequency and the multiplier (known as the VCO frequency) must be in the range specified in the data manual.

**Note**

The system clock frequency (PLLSYSCLK) cannot exceed the limit specified in the [TMS320F28P65x Real-Time Microcontrollers Data Sheet](#). This limit does not allow for oscillator tolerance.

The clock source and PLL configuration registers are shared between the two CPUs (CPU1 and CPU2). Register access is controlled by way of a semaphore, which is described in [Chapter 15](#).

**SYSPLL / AUXPLL**

$$f_{PLLRAWCLK} = \frac{f_{OSCCLK}}{(REFDIV+1)} \times \frac{IMULT}{(ODIV+1)}$$

$$f_{AUXPLLRAWCLK} = \frac{f_{AUXOSCCLK}}{(REFDIV+1)} \times \frac{IMULT}{(ODIV+1)}$$

**Figure 3-10. PLL/AUXPLL**

### 3.7.7.1 System Clock Setup

Once the application requirements are understood, a specific clock configuration can be determined. The default configuration is for INTOSC2 to be used as the system clock (PLLSYSCLK) with a divider of 1. The following procedure can be used to set up the desired application configuration:

Refer to your device SysCtl\_setClock() function inside C2000Ware installation for an example.

Recommended sequence to set up the system PLL:

1. Bypass the PLL by clearing SYSPLLCTL1[PLLCLKEN] and wait for at least 120 CPU clock cycles by adding 120 NOP instructions.
2. Power down the PLL by writing to SYSPLLCTL1.PPLEN = 0 and wait for at least 60 CPU clock cycles by adding 60 NOP instructions.
3. Select the reference clock source (OSCCLK) by writing to CLKSRCCTL1.OSCCLKSRCSEL and wait for at least 300 CPU clock cycles by adding 300 NOP instructions.
4. Set the system clock divider to /1 to make sure of the fastest PLL configuration by clearing SYSCLKDIVSEL[ PLLSYSCLKDIV].
5. Set the IMULT, REFDIV, and ODIV simultaneously by writing 32-bit value in SYSPLLMULT at once. This automatically enables the PLL. Be sure the settings for multiplier and dividers do not violate the frequency specifications as defined in the [TMS320F28P65x Real-Time Microcontrollers Data Sheet](#).
6. Wait for PLL to lock by polling for lock status bit to go high, that is, SYSPLLSTS.LOCKS = 1
7. Configure DCC with reference clock as OSCCLK and clock under measurement as PLLRAWCLK, and verify the frequency of the PLL. If the frequency is out of range, do not enable PLLRAWCLK as SYSCLK, stop here and troubleshoot. Refer to [Chapter 9](#) for more information on the configuration and usage.
8. If the PLLRAWCLK is within the valid range, then set the system clock divider one setting higher than the final desired value. For example ClkCfgRegs.SYSCLKDIVSEL.bit.PLLSYSCLKDIV = divsel + 1. This limits the current increase when switching to the PLL.
9. Switch to the PLL as the system clock by setting SYSPLLCTL1[PLLCLKEN] and wait for 200 PLLSYSCLK cycles for current to stabilize by adding 200 NOP instructions.
10. Change the system clock divider (PLLSYSCLKDIV) to the appropriate value.

---

#### Note

1. SYSPLL must be bypassed and powered down manually before changing the OSCCLK source.
  2. At least 120 CPU clock cycles delay is needed after bypassing PLL, that is, SYSPLLCTL1.PLLCLKEN = 0.
  3. At least 60 CPU clock cycles delay is needed after PLL is powered down, that is, SYSPLLCTL1.PPLEN = 0.
  4. At least 300 CPU clock cycles delay is needed after OSSCLK source is changed.
  5. PLL SLIP bit is not supported. DCC can be used to check the validity of the PLL clock. This feature is included as part of SysCtl\_setClock() function inside C2000Ware.
-

### 3.7.7.2 USB Auxiliary Clock Setup

Refer to your device SysCtl\_setAuxClock() function inside C2000Ware installation for an example.

If USB functionality is needed, the auxiliary clock (AUXPLLCLK) must be configured to produce 60MHz. The procedure is similar to the system clock setup:

1. Bypass the PLL by clearing AUXPLLCTL1[PLLCLKEN] and wait for at least 120 CPU clock cycles by adding 120 NOP instructions..
2. Power down the PLL by writing to AUXPLLCTL1.PLLEN = 0 and wait for at least 60 CPU clock cycles by adding 60 NOP instructions.
3. Select the reference clock source (AUXOSCCLK) by writing to CLKSRCCTL2.AUXOSCCLKSRCSEL and wait for at least 60 CPU clock cycles by adding 60 NOP instructions.
4. Set the IMULT, REFDIV, and ODIV simultaneously by writing 32-bit value in AUXPLLMULT at once. This automatically enables the PLL. Be sure the settings for multiplier and dividers do not violate the frequency specifications as defined in the [TMS320F28P65x Real-Time Microcontrollers Data Sheet](#) .
5. Wait for PLL to lock by polling for lock status bit to go high (AUXPLLSTS.LOCKS = 1)
6. Configure DCC with reference clock as AUXOSCCLK and clock under measurement as AUXPLLRAWCLK, and verify the frequency of the PLL. If the frequency is out of range, stop here and troubleshoot. Refer to [Chapter 9](#) for more information on the configuration and usage.
7. Connect the auxiliary PLL output clock (AUXPLLRAWCLK) to AUXPLLCLK by writing a 1 to AUXPLLCTL1.PLLCLKEN.

The auxiliary clock configuration can be changed at run time. Changing the AUXOSCCLK source automatically bypasses the PLL and sets the multiplier to zero. Changing the multiplier from one non-zero value to another temporarily bypasses the PLL until the PLL re-locks.

---

#### Note

1. AUXPLL must be bypassed and powered down manually before changing the AUXOSCCLK source.
  2. At least 120 CPU clock cycles delay is needed after bypassing PLL, that is, AUXPLLCTL1.PLLCLKEN = 0.
  3. At least 60 CPU clock cycles delay is needed after PLL is powered down, that is, AUXPLLCTL1.PLLEN = 0.
  4. At least 60 CPU clock cycles delay is needed after AUXOSCCLK source is changed.
  5. AUXPLL SLIP bit is not supported. DCC can be used to check the validity of the AUXPLL clock. This feature is included as part of SysCtl\_setAuxClock() function inside C2000Ware.
- 

### 3.7.7.3 SYS PLL/AUX PLL Bypass

If the application requires the PLL clock to be bypassed from the system, then the application needs to configure SYSPLLCTL1.PLLCLKEN = 0 or AUXPLLCTL1.PLLCLKEN = 0. It takes up to 120 CPU clock cycles before the bypass is effective. In the meantime, if PLLSYSCLKDIV/AUXPLLDIV is reduced to a lower value (for example, from /2 to /1 or /4 to /2), the device can be clocked above the maximum rated frequency and can lead to unpredictable device behavior. Hence, a delay of 120 CPU clock cycles is required after bypassing the PLL from the enable state, that is, going from PLLCLKEN = 1 to PLLCLKEN = 0.

### 3.7.8 Clock (OSCCLK) Failure Detection

To achieve safety diagnostic, Missing Clock Detection (MCD) can be used.

Table 3-7 lists the details.

**Table 3-7. Clock Source (OSCCLK) Failure Detection**

Clock Failure Detection Circuitry	Clocks Detected	Time for Detection (in Cycles)	Limitations
Missing Clock Detection (MCD)	INTOSC2, XTAL/X1	8192 INTOSC1 cycles	Cannot detect INTOSC1 clock failure.

#### 3.7.8.1 Missing Clock Detection Logic

The missing clock detect (MCD) logic detects OSCCLK failure, using INTOSC1 as the reference clock source. This circuit only detects complete loss of OSCCLK and does not do any detection of frequency drift on the OSCCLK.

This circuit monitors the OSCCLK (primary clock) using the 10MHz clock provided by the INTOSC1 (secondary clock) as a backup clock. This circuit functions as:

- The primary clock (OSCCLK) clock keeps ticking a 7-bit counter (named as MCDPCNT). This counter is asynchronously reset with XRSn.
- The secondary clock (INTOSC1) clock keeps ticking a 13-bit counter (named as MCDSCNT). This counter is asynchronously reset with XRSn.
- Each time MCDPCNT overflows, the MCDSCNT counter is reset. Thus, if OSCCLK is present or not slower than INTOSC1 by a factor of 64, MCDSCNT never overflows.
- If OSCCLK stops for some reason or is slower than INTOSC1 by at least a factor of 64, the MCDSCNT overflows and a missing clock condition is detected on OSCCLK.
- The above check is continuously active, unless the MCD is disabled using MCDCCR register (by making the MCLKOFF bit 1).
- If the circuit ever detects a missing OSCCLK, the following occurs:
  - The MCDSTS flag is set.
  - The MCDSCNT counter is frozen to prevent further missing clock detection.
  - The CLOCKFAIL signal goes high, which generates TRIP events to PWM modules and fires NMIs to CPU1.NMIWD and CPU2.NMIWD.
  - PLL is forcefully bypassed and OSCCLK source is switched to INTOSC1 (System Clock Frequency = INTOSC1 Frequency (10MHz)/SYSDIV). PLLMULT is zeroed out automatically in this case.
  - While the MCDSTS bit is set, the OSCCLKSRCSEL bits have no effect and OSCCLK is forcefully connected to INTOSC1.
  - PLLRAWCLK going to the system is switched to INTOSC1 automatically.
- If the MCLKCLR bit is written (this is a W = 1 bit), MCDSTS bit is cleared and OSCCLK source is decided by the OSCCLKSRCSEL bits. Writing to MCLKCLR also clears the MCDPCNT and MCDSCNT counters to allow the circuit re-evaluate missing clock detection. If the user wants to lock the PLL after missing clock detection, switch the clock source to INTOSC1 (using OSCCLKSRCSEL register), do a MCLKCLR, and relock the PLL.
- The MCD is enabled at power up.

Figure 3-11 shows the missing clock logic functional flow.

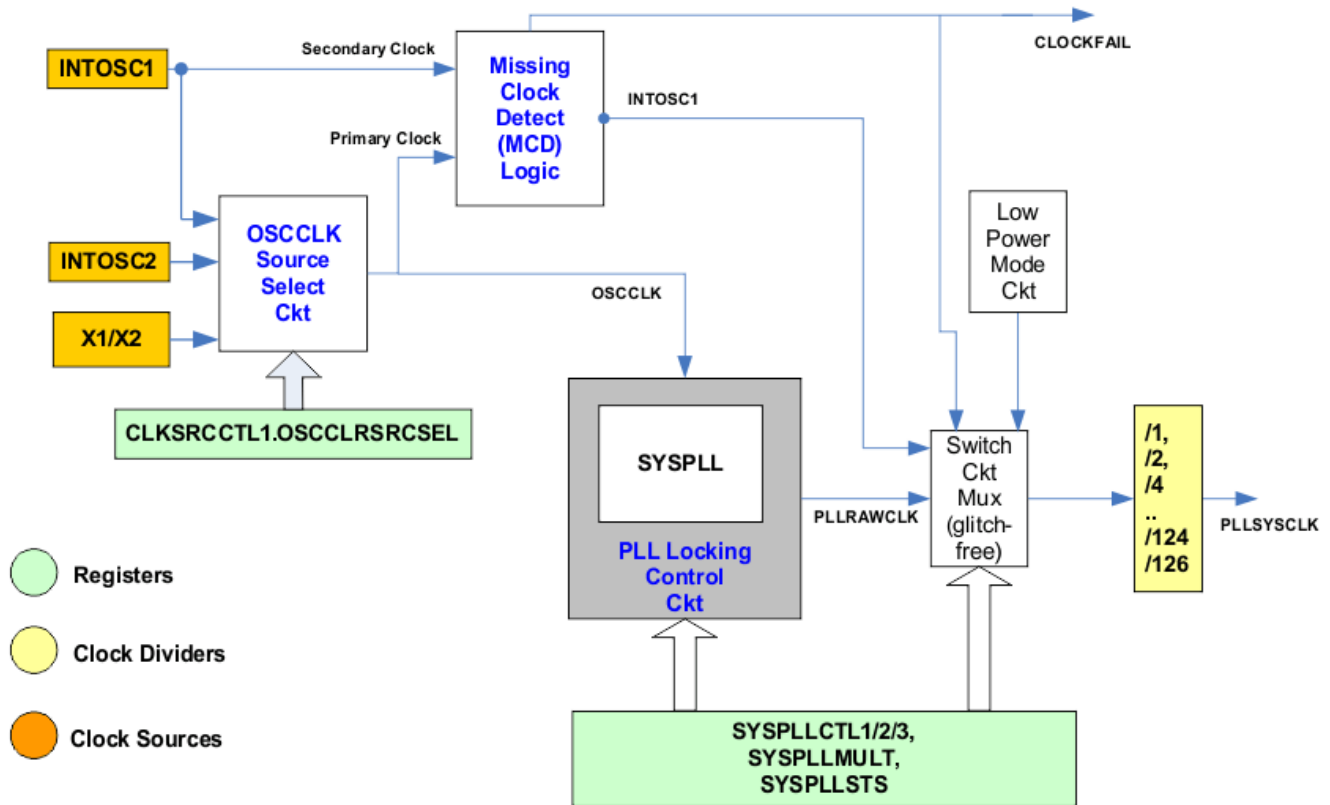

Figure 3-11. Missing Clock Detection Logic

**Note**

On a complete clock failure when OSCCLK is not operating, the operation can take a maximum time of 8192 INTOSC1 cycles (that is, 0.8192ms) before the CLOCKFAIL signal goes high, after which:

- NMI is generated
- OSCCLK is switched to INTOSC1
- PWM trip happens

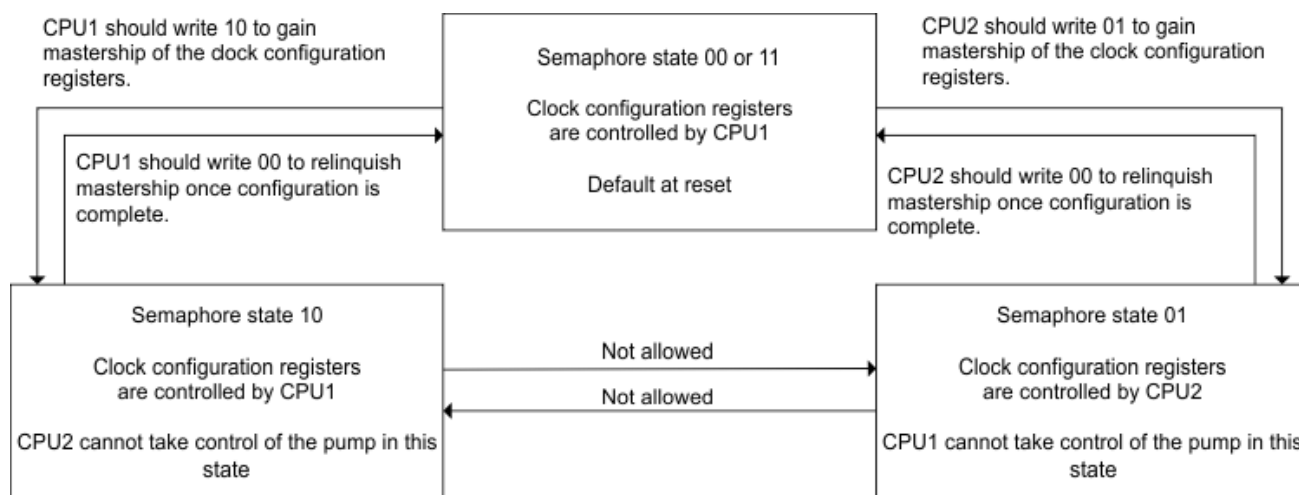

### 3.8 Clock Configuration Semaphore

Both CPUs can access the PLL and peripheral clock configuration registers. The clock configuration semaphore allows one CPU to access the registers without being interrupted by the other CPU.

The clock configuration semaphore is implemented as a two-bit field in a register with special write protections. This register requires a key field to be written at the same time as the semaphore bits. The possible semaphore states are:

- 00 or 11      Either CPU can write to the semaphore. CPU1 has control of the clock configuration registers by default. 00 is the reset state.
- 01              CPU2 has exclusive control of the clock configuration registers and exclusive write access to the semaphore.
- 10              CPU1 has exclusive control of the clock configuration registers and exclusive write access to the semaphore.

Each CPU is only allowed to take control of the clock configuration registers for itself. However, CPU1 can force both semaphores into the default state (00) at any time by putting CPU2 into reset. [Figure 3-12](#) shows the allowed states and state transitions.

**Figure 3-12. Clock Configuration Semaphore (CLKSEM) State Transitions**

### 3.9 32-Bit CPU Timers 0/1/2

This section describes the three 32-bit CPU-Timers (TIMER0/1/2) shown in [Figure 3-13](#).

CPU-Timer2 is reserved for real-time operating system uses (for example, TI-RTOS), but if CPU-Timer2 is not used by real-time operating systems then, CPU-Timer2 can also be used for other applications. The CPU-Timer0 and CPU-Timer1 run off of SYSCLK. The CPU-Timer2 normally runs off of SYSCLK, but can also use INTOSC1, INTOSC2, XTAL, and AUXPLLCLK. The CPU-Timer interrupt signals (TINT0, TINT1, TINT2) are connected as shown in [Figure 3-14](#).

The general operation of the CPU-Timer is as follows:

- The 32-bit counter register, TIMH:TIM, is loaded with the value in the period register PRDH:PRD.
- The counter decrements once every  $(TPR[TDDRH:TDDR]+1)$  SYSCLKOUT cycles, where TDDRH:TDDR is the timer divider.
- When the counter reaches 0, a timer interrupt output signal generates an interrupt pulse.

The registers listed in Section 3.18 are used to configure the timers.

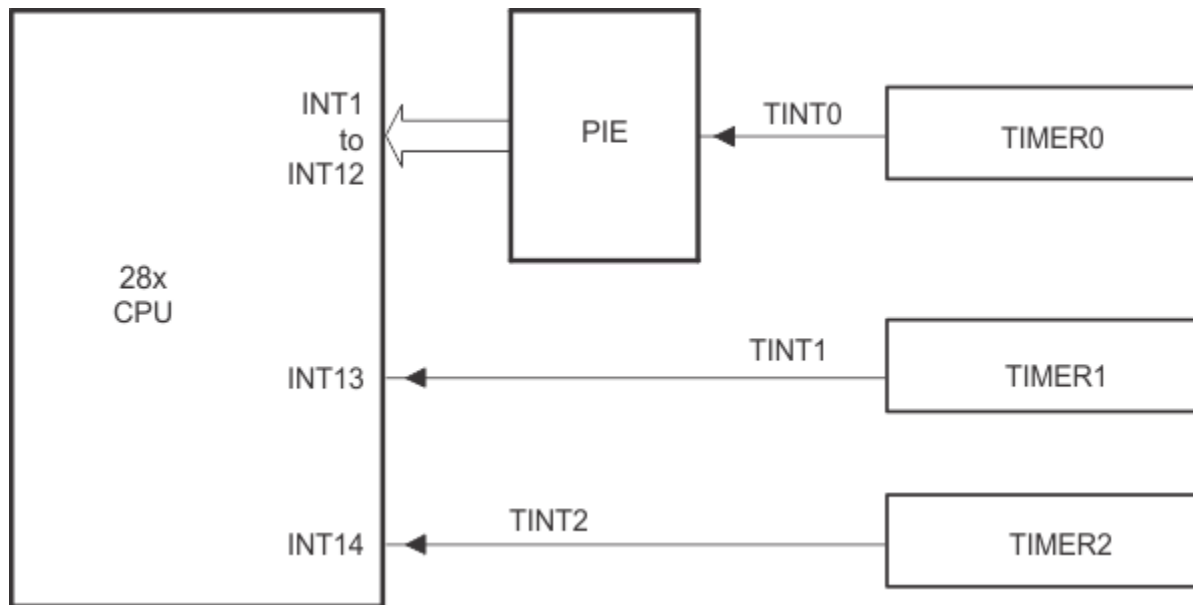

Figure 3-13. CPU Timers

- The timer registers are connected to the memory bus of the C28x processor.
- The CPU Timers are synchronized to SYSCLKOUT.

Figure 3-14. CPU Timer Interrupts Signals and Output Signal

### 3.10 Watchdog Timers

The watchdog module generates an output pulse 512 watchdog-clocks (WDCLKs) wide whenever the 8-bit watchdog up counter has reached its maximum value. The watchdog clock source is INTOSC1. Software must periodically write a 0x55 + 0xAA sequence into the watchdog key register to reset the watchdog counter. The counter can also be disabled. Figure 3-15 shows the various functional blocks within the watchdog module.

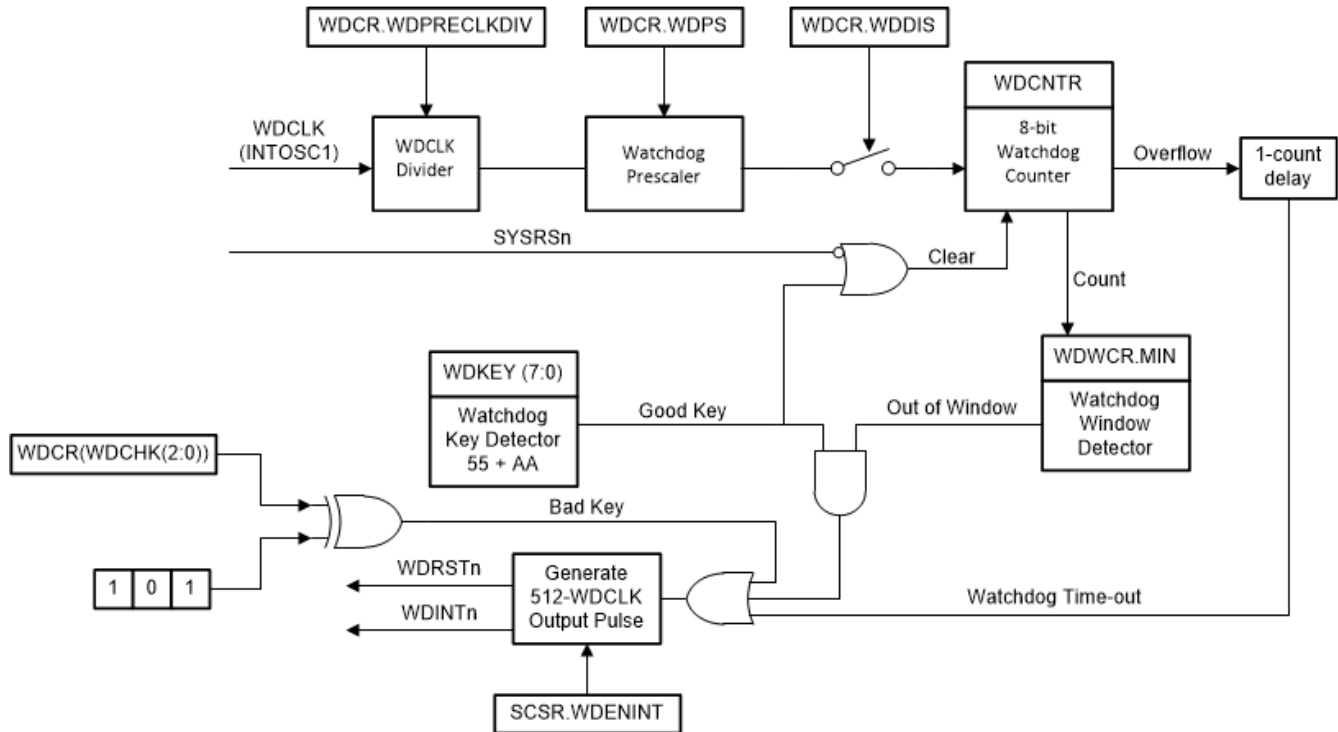

Figure 3-15. CPU Watchdog Timer Module

### 3.10.1 Servicing the Watchdog Timer

The watchdog counter (WDCNTR) is reset when the proper sequence is written to the WDKEY register before the 8-bit watchdog counter overflows. The WDCNTR is reset-enabled when a value of 0x55 is written to the WDKEY. When the next value written to the WDKEY register is 0xAA, then the WDCNTR is reset. Any value written to the WDKEY other than 0x55 or 0xAA causes no action. Any sequence of 0x55 and 0xAA values can be written to the WDKEY without causing a system reset; only a write of 0x55 followed by a write of 0xAA to the WDKEY resets the WDCNTR.

**Table 3-8. Example Watchdog Key Sequences**

Step	Value Written to WDKEY	Result
1	0xAA	No action
2	0xAA	No action
3	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
4	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
5	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
6	0xAA	WDCNTR is reset.
7	0xAA	No action
8	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
9	0xAA	WDCNTR is reset.
10	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
11	0x32	Improper value written to WDKEY. No action, WDCNTR no longer enabled to be reset by next 0xAA.
12	0xAA	No action due to previous invalid value.
13	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
14	0xAA	WDCNTR is reset.

Step 3 in [Table 3-8](#) is the first action that enables the WDCNTR to be reset. The WDCNTR is not actually reset until step 6. Step 8 again re-enables the WDCNTR to be reset and step 9 resets the WDCNTR. Step 10 again re-enables the WDCNTR to be reset. Writing the wrong key value to the WDKEY in step 11 causes no action, however the WDCNTR is no longer enabled to be reset and the 0xAA in step 12 now has no effect.

If the watchdog is configured to reset the device, then a WDCNTR overflow or writing the incorrect value to the WDCR[WDCHK] bits resets the device and set the watchdog flag (WDRSn) in the reset cause register (RESC). After a reset, the program can read the state of this flag to determine whether the reset was caused by the watchdog. After doing this, the program must clear WDRSn to allow subsequent watchdog resets to be detected. Watchdog resets are not prevented when the flag is set.

### 3.10.2 Minimum Window Check

To complement the timeout mechanism, the watchdog also contains an optional "windowing" feature that requires a minimum delay between counter resets. This can help protect against error conditions that bypass large parts of the normal program flow but still include watchdog handling.

To set the window minimum, write the desired minimum watchdog count to the WDWCR register. This value takes effect after the next WDKEY sequence. From then on, any attempt to service the watchdog when WDCNTR is less than WDWCR triggers a watchdog interrupt or reset. When WDCNTR is greater than or equal to WDWCR, the watchdog can be serviced normally.

At reset, the window minimum is zero, which disables the windowing feature.

### 3.10.3 Watchdog Reset or Watchdog Interrupt Mode

The watchdog can be configured in the SCSR register to either reset the device ( $\overline{WDRST}$ ) or assert an interrupt ( $\overline{WDINT}$ ), if the watchdog counter reaches the maximum value. The behavior of each condition is:

- **Reset mode:** If the watchdog is configured to reset the device, then the  $\overline{WDRST}$  signal pulls the device reset ( $\overline{XRS}$ ) pin low for 512 INTOSC1 cycles when the watchdog counter reaches the maximum value.
- **Interrupt mode:** When the watchdog counter expires, the watchdog counter asserts an interrupt by driving the  $\overline{WDINT}$  signal low for 512 INTOSC1 cycles. The falling edge of  $\overline{WDINT}$  triggers a WAKEINT interrupt in the PIE, if the WAKEINT interrupt is enabled. Because the PIE is edge-triggered, re-enabling the WAKEINT interrupt while  $\overline{WDINT}$  is active does not produce a duplicate interrupt.

To avoid unexpected behavior, software must not change the configuration of the watchdog while  $\overline{WDINT}$  is active. For example, changing from interrupt mode to reset mode while  $\overline{WDINT}$  is active immediately resets the device. Disabling the watchdog while  $\overline{WDINT}$  is active causes a duplicate interrupt, if the watchdog is later re-enabled. If a debug reset is issued while  $\overline{WDINT}$  is active, the reset cause register (RESC) shows a watchdog reset. The WDINTS bit in the SCSR register can be read to determine the current state of  $\overline{WDINT}$ .

### 3.10.4 Watchdog Operation in Low-Power Modes

In IDLE mode, the watchdog interrupt ( $\overline{WDINT}$ ) signal can generate an interrupt to the CPU to take the CPU out of IDLE mode. As with any other peripheral, the watchdog interrupt triggers a WAKEINT interrupt in the PIE during IDLE mode. User software must determine which peripheral caused the interrupt.

In STANDBY mode, all of the clocks to the peripherals are turned off within the CPU subsystem. The only peripheral that remains functional is the watchdog since the watchdog module runs off the oscillator clock (OSCCLK). The  $\overline{WDINT}$  signal is applied to the Low Power Modes (LPM) block so that the LPM block can be used to wake the CPU from STANDBY low-power mode. This feature is enabled by setting LPMC.RWDINTE = 1. See [Section 3.11](#) for details.

#### Note

If the watchdog interrupt is used to wake-up from an IDLE or STANDBY low-power mode condition, software must make sure that the  $\overline{WDINT}$  signal goes back high before attempting to reenter the IDLE or STANDBY mode. The  $\overline{WDINT}$  signal is held low for 512 INTOSC1 cycles when the watchdog interrupt is generated. The current state of  $\overline{WDINT}$  can be determined by reading the watchdog interrupt status (WDINTS) bit in the SCSR register. WDINTS follows the state of  $\overline{WDINT}$  by two SYSCLKOUT cycles.

### 3.10.5 Emulation Considerations

The watchdog module behaves as follows under various debug conditions:

CPU Suspended:	When the CPU is suspended, the watchdog clock (WDCLK) is suspended
Run-Free Mode:	When the CPU is placed in run-free mode, then the watchdog module resumes operation as normal.
Real-Time Single-Step Mode:	When the CPU is in real-time single-step mode, the watchdog clock (WDCLK) is suspended. The watchdog remains suspended even within real-time interrupts.
Real-Time Run-Free Mode:	When the CPU is in real-time run-free mode, the watchdog operates as normal.

### 3.11 Low-Power Modes

This device has two clock-gating, low-power modes. All low-power modes are entered by setting the LPMCR register and executing the IDLE instruction. More information about this instruction can be found in the [TMS320C28x CPU and Instruction Set Reference Guide](#).

Low-power modes cannot be entered into while a Flash program or erase is ongoing.

The application can verify the following before entering STANDBY:

1. Check the value of the GPIODAT register of the pin selected for STANDBY(GPIOLPMSEL0/1) prior to entering the Low-Power mode to make sure that the wake event has not already been asserted.
2. The LPMCR.QUALSTDBY register can be set to a value greater than the ratio of INTOSC1/PLLSYSCLK to make sure proper wake up.

#### 3.11.1 IDLE

IDLE is a standard feature of the C28x CPU. In this mode, the CPU clock is gated while all peripheral clocks are left running. IDLE can thus be used to conserve power while a CPU is waiting for peripheral events. When one CPU is in IDLE, there is no effect on the other CPU subsystem.

Any enabled interrupt wakes up the CPU from IDLE mode.

To enter IDLE mode, set LPMCR.LPM to 0x0 and execute the IDLE instruction.

#### 3.11.2 STANDBY

STANDBY is a more aggressive low-power mode that gates both the CPU clock and any peripheral clocks derived from the CPU SYSCLK. The watchdog however, is left active. Like IDLE, this mode affects only one CPU subsystem. The other CPU subsystem and all of the peripherals are unaffected. STANDBY is good for an application where the wake-up signal comes from an external system (or CPU subsystem) rather than a peripheral input.

An NMI (or optionally) a watchdog interrupt or a configured GPIO can wake the CPU from STANDBY mode. Each GPIO from GPIO0-63 can be configured to wake the CPU when the GPIO are driven active low. Upon wakeup, the CPU receives the WAKEINT interrupt if configured.

IPC interrupt 1 (flag 0), an NMI fired to the other CPU, or (optionally) a watchdog interrupt, wakes the CPU subsystem up from STANDBY mode. Any of GPIO0-63 can also be configured to wake up the subsystem when the GPIO is driven active low. Upon wakeup, the CPU receives a WAKEINT interrupt, even if the CPU was woken by an IPCINT1 signal.

#### To enter STANDBY mode:

1. Set LPMCR.LPM to 0x1.
2. Enable the WAKEINT interrupt in the PIE.
3. For watchdog interrupt wakeup, set LPMCR.WDINTE to 1 and configure the watchdog to generate interrupts.
4. For GPIO wakeup, set GPIOLPMSEL0 and GPIOLPMSEL1 to connect the chosen GPIOs to the LPM module, and set LPMCR.QUALSTDBY to select the number of OSCCLK cycles for input qualification.
5. Execute the IDLE instruction to enter STANDBY.

#### To wake up from Standby mode:

1. Configure the desired GPIO to trigger the wakeup.
2. Drive the selected GPIO signal low; the signal must remain low for the number of OSCCLK cycles specified in the QUALSTDBY bits in the LPMCR register. If the signal is sampled high during this period, the count restarts.

At the end of the qualification period, the PLL enables the CLKIN to the CPU and the WAKEINT interrupt is latched in the PIE block. The WAKEINT interrupt can also triggered by IPCINT1 sent from the other CPU and a watchdog interrupt.

The CPU is now out of STANDBY mode and can resume normal execution.

If CPU2 is in STANDBY mode, writing a 1 to the RESET bit of the CPU2RESCTL register has no effect. CPU2 can be reset by any chip-level reset (POR, XRSn, CPU1.WDRSn, or CPU1.NMIWDRSn). Alternately, CPU2 can be woken up by any configured wake-up event.

If CPU2 is in STANDBY mode and the debugger is connected, executing a debug reset on CPU2 has no effect. To wake the CPU2 with the debugger, Click Run, Single Step, or Step over in the Debug toolbar. The CCS IDE prompts the user requesting to bring the CPU out of the low-power mode. Click Yes. This wakes CPU2 from STANDBY and continues execution.

### 3.11.3 HALT

HALT is a global low-power mode that gates almost all system clocks and allows for power-down of oscillators and analog blocks. This mode affects both CPU subsystems. HALT can be used for additional power savings over putting both CPU subsystems in STANDBY, although the options for wakeup are more limited.

Similar to STANDBY, any of GPIO0-63 can be configured to wake up the system from HALT. No other wakeup option is available. However, CPU1 watchdog can still be clocked, and can be configured to produce a watchdog reset if a timeout mechanism is needed. On wakeup, both CPUs receive a WAKEINT interrupt.

#### To enter HALT mode:

1. Disable all interrupts with the exception of the WAKEINT interrupt. The other interrupts can be reenabled after the device is brought out of HALT mode.
2. Put CPU2 into IDLE mode. (Using STANDBY causes a duplicate WAKEINT on CPU2). CPU1 must verify this by checking the LPMSTAT register.
3. Set LPMCR.LPM to 0x2. Set GPIOLPMSEL0 and GPIOLPMSEL1 to connect the chosen GPIOs to the LPM module.
4. Set CLKSRCCTL1.WDHALTI to 1 to keep the CPU1 watchdog active and INTOSC1 and INTOSC2 powered up in HALT.
5. Set CLKSRCCTL1.WDHALTI to 0 to disable the CPU1 watchdog and power down INTOSC1 and INTOSC2 in HALT.
6. Execute the IDLE instruction on CPU1 to enter HALT.

If an interrupt or NMI is received while the IDLE instruction is in the pipeline, the system begins executing the WAKEINT ISR. After HALT wakeup, ISR execution resumes where ISR execution left off.

---

#### Note

Before entering HALT mode, if the system PLL is locked (SYSPLL.LOCKS = 1), the PLL must also be connected to the system clock (PLLCTL1.PLLCLKEN = 1). Otherwise, the device never wakes up.

---

#### To wake up from HALT mode:

1. Drive the selected GPIO low for a minimum 5 $\mu$ s. This activates the CPU1.WAKEINT and CPU2.WAKEINT PIE interrupts.
2. Drive the wake-up GPIO high again to initiate the powering up of the SYSPLL and AUXPLL.
3. Wait 16  $\mu$ s plus 1024 OSCCLK cycles to allow the PLLs to lock and the WAKEINT ISR to be latched.
4. Execute the WAKEINT ISR.

The device is now out of HALT mode and can resume normal execution.

### 3.12 Memory Controller Module

This device has CPU1 subsystem and CPU2 subsystem. This section describes the memory controller used for CPU1 and CPU2 subsystems.

The different RAMs available on CPU1 and CPU2 subsystems have different characteristics. Some are:

- Dedicated to each CPU (M0, M1, and Dx RAMs),
- Shared between the CPU1 and CLA (LSx RAM),
- Shared between the CPU and DMA of both subsystems (GSx RAM), and
- Used to send and receive messages between processors (MSGRAM).
- Used to exchange data between CLA and DMA.

All these RAMs are highly configurable to achieve control for write access and fetch access from different controllers. There are also RAMs - called IPC MSGRAMs - that are used for interprocessor communication. All RAMs are enabled with the ECC or parity feature (both data and address). Some of the dedicated memories are secure memory as well. Refer to [Chapter 5](#) for more details. Each RAM has a controller that takes care of the access protection/security related checks and ECC/Parity features for that RAM. [Figure 3-16](#) shows the configuration of these RAMs.

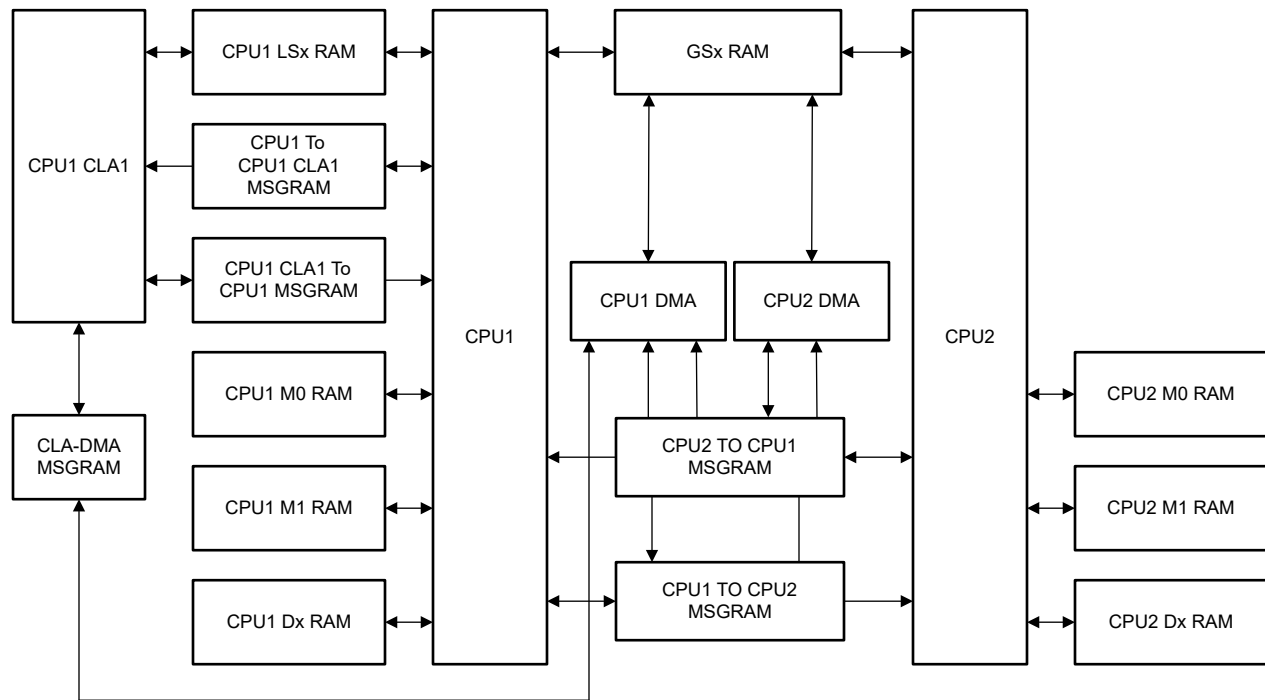

Figure 3-16. Memory Architecture

**Note**

All RAMs on these devices are SRAMs.

### 3.12.1 Dedicated RAM (Dx RAM)

The CPU subsystem has dedicated RAM blocks: M0, M1, and Dx. M0/M1 memories are small blocks of memory that are tightly coupled with the CPU. Only the CPU has access to these memories. No other controllers (including DMA) have any access to these memories. Dx memories are secure blocks and also have the access-protection feature (CPU write/CPU fetch protection). D2-D5 memory blocks are mappable to either of the CPUs. Mapping of D2-D5 memory blocks is accomplished through MCUCNF1 register. When mapped to CPU1, D2-D5 memories cannot be accessed by CPU2. Conversely, when D2-D5 memories are mapped to CPU2, CPU1 does not have access to these memory blocks.

All dedicated RAMs have the ECC feature. All dedicated memories are secure memory (except for M0/M1) and have the access protection (CPU write protection/CPU fetch protection) feature. Each type of access protection for each RAM block can be enabled/disabled by configuring the specific bit in the access protection register, allocated to each subsystem (DxACCPROT).

### 3.12.2 Local Shared RAM (LSx RAM)

RAM blocks that are dedicated to each subsystem and are accessible to the CPU and CLA only, are called local shared RAMs (LSx RAMs). All such memories are secure memory and have the ECC feature. By default, these memories are dedicated to the CPU only, and the user can choose to share these memories with the CLA by appropriately configuring the MSEL\_LSx bit field in the LSxMSEL register. Further, when these memories are shared between the CPU and CLA, the user can choose to use these memories as CLA program memory by configuring the CLAPGM\_LSx bit field in the LSxCLAPGM registers. CPU access to all memory blocks, which are programmed as CLA program memory, are blocked.

All these RAMs have the access protection (CPU write and CPU fetch) feature. Each type of access protection for each RAM block can be enabled or disabled by configuring the specific bit in the local shared RAM access protection registers, mapped to each CPU subsystem. [Table 3-9](#) shows the LSx RAM features.

**Table 3-9. Local Shared RAM**

MSEL_LSx	CLAPGM_LSx	CPUx Allowed Access	CPUx.CLA1 Allowed Access	Comment
00	X	All	-	LSx memory is configured as CPU dedicated RAM
01	0	All	Data Read Data Write	LSx memory is shared between CPU and CLA1
01	1	Emulation Read Emulation Write	Fetch Only Emulation Read Emulation Write	LSx memory is CLA1 program memory

### 3.12.3 Global Shared RAM (GSx RAM)

RAM blocks that are accessible from both the CPU and the respective DMA are called global shared RAMs (GSx RAMs). Each shared RAM can be owned by either CPU subsystem based on the configuration of the respective bits (one bit for each GSx memory) in the GSxMSEL register. When a particular GSx RAM block is owned by the CPU1 subsystem, CPU1 and CPU1.DMA have full access to that RAM block, whereas CPU2 and CPU2.DMA have only read access to that RAM block (no fetch/write access). Similarly, when a particular GSx RAM block is owned by the CPU2 subsystem, CPU1 and CPU1.DMA have only read access (no fetch/write access) to that RAM block, whereas CPU2 and CPU2.DMA have full access to that RAM block. [Table 3-10](#) shows the features of the GSx RAM.

**Table 3-10. Global Shared RAM**

GSxMSEL	CPU1	CPU1	CPU1	CPU1. DMA	CPU1. DMA	CPU2	CPU2	CPU2	CPU2. DMA	CPU2. DMA
	Fetch	Read	Write	Read	Write	Fetch	Read	Write	Read	Write
0	Yes	Yes	Yes	Yes	Yes	No	Yes	No	Yes	No
1	No	Yes	No	Yes	No	Yes	Yes	Yes	Yes	Yes

#### Note

Emulation/Debugger access is allowed from both the CPUs, irrespective of the GSxMSEL setting.

Like other shared RAMs, these RAMs also have different levels of access protection that can be enabled or disabled by configuring specific bits in the GSxACCPROT registers mapped in each subsystem.

Controller select and access protection configuration for each GSx RAM block can be individually locked by the user to prevent further update to these bit fields. The user can also choose to permanently lock the configuration to individual bit fields by setting the specific bit fields in the GSxCOMMIT register (refer to the register description for more details). Once configuration is committed for a particular GSx RAM block, the configuration cannot be changed further until CPUx.SYSRS is issued. Only the CPU1 software can change the controller select configuration by writing into the GSxMSEL register, mapped on the CPU1. The GSxMSEL register, which is mapped to the CPU2 subsystem, is a status register which can only be used by CPU2 software to know the controller ownership for each GSx RAM block.

### 3.12.4 CPU Message RAM (CPU MSG RAM)

These RAM blocks can be used to share data between CPU1 and CPU2. Since these RAMs are used for interprocessor communication, the RAMs are also called IPC RAMs. The CPU MSGRAMs have CPU and DMA read and write access from the CPU subsystem, and has CPU and DMA read only access from the other subsystem.

This RAM has parity.

### 3.12.5 CLA Message RAM (CLA MSGRAM)

These RAM blocks can be used to share data between the CPU and CLA. The CLA has read and write access to the CLA to CPU MSGRAM. The CPU has read and write access to the CPU to CLA MSGRAM. The CPU and CLA both have read access to both MSGRAMs.

This RAM has parity.

### 3.12.6 CLA-DMA MSG RAM

These RAMs blocks can be used to share data between CLA and DMA. The CLA has read and write access to the CLA to DMA MSGRAM. The DMA has read and write access to the DMA to CLA MSGRAM. The CLA and DMA both have read access to both MSGRAMs.

### 3.12.7 Access Arbitration

For a shared RAM, multiple accesses can happen at a given time. The maximum number of accesses to any shared RAM at any given time depends on the type of shared RAM. On this device, a combination of a fixed and round robin scheme is followed to arbitrate multiple access at any given time. Accesses from the same controllers are arbitrated in a fixed priority manner, but the accesses from different controllers are arbitrated using the round robin scheme.

The following is the order of fixed priority for CPU accesses:

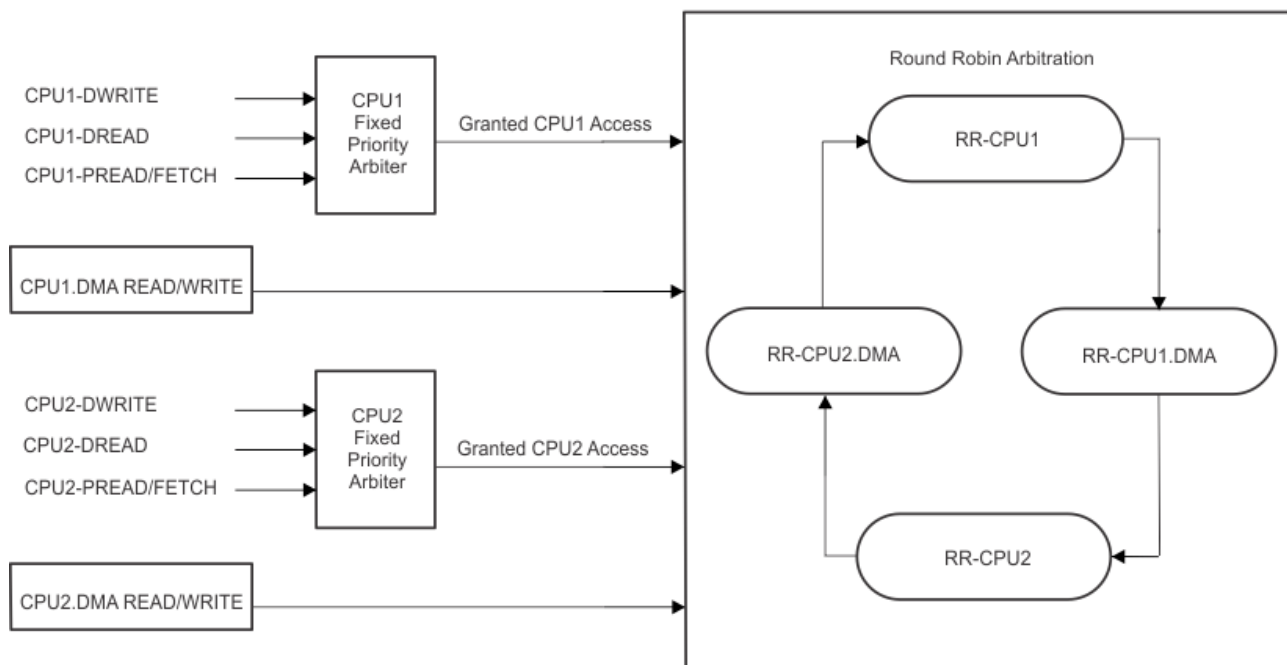

1. Data Write/Program Write
2. Data Read
3. Program Read/Program Fetch

The following is the order of fixed priority for CLA accesses:

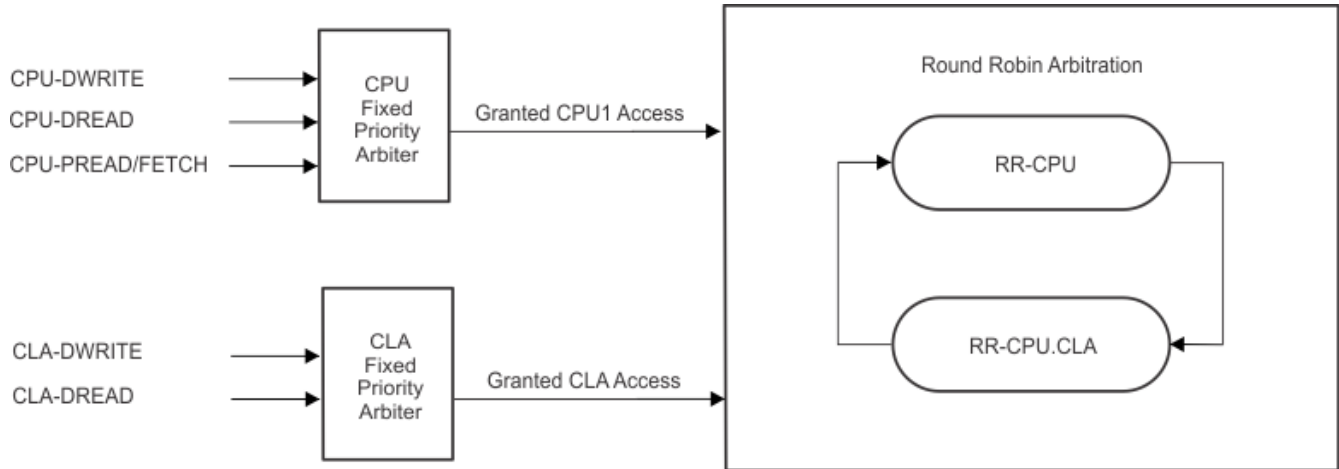

1. Data Write
2. Data Read/Program Fetch

Figure 3-17 represents the arbitration scheme on global shared memories:

Figure 3-18 represents the arbitration scheme on local shared memories.

**Figure 3-17. Arbitration Scheme on Global Shared Memories**

**Figure 3-18. Arbitration Scheme on Local Shared Memories**

### 3.12.8 Access Protection

All RAM blocks on both subsystems have different levels of protection. This feature allows the user to enable or disable specific access to individual RAM blocks from individual controllers. There is no protection for read accesses; hence, reads are always allowed from all the controllers that have access to that RAM block.

The following sections describe the different kinds of protection available for RAM blocks on this device.

#### Note

For debug accesses, all the protections are disabled.

#### 3.12.8.1 CPU Fetch Protection

A CPU has execution permission from a memory, only if that memory is dedicated to that CPU or the respective subsystem is controller for that memory (in case of GSx memory). When fetch accesses are allowed based on the permission, the fetch accesses can be further protected by setting the FETCHPROTx bit of the specific register to 1. If fetch access is done by the CPU to a memory where CPU fetch protection is enabled, a fetch protection violation occurs.

There are two types of fetch protection violations:

- Non-controller CPU fetch protection violation
- Controller CPU fetch protection violation

If a fetch access is made to a memory by a non-controller CPU, the violation is called a non-controller fetch protection violation. If a fetch access is made to a dedicated or shared memory by the controller CPU and FETCHPROTx is set to 1 for that memory, the violation is called a controller CPU fetch protection violation.

If a fetch protection violation occurs, the violation results in an ITRAP for CPU. A flag gets set into the appropriate access violation flag register, and the memory address for which the access violation occurred gets latched into the appropriate CPU fetch access violation address register.

### 3.12.8.2 CPU Write Protection

A CPU has write permission to a memory only if that memory is dedicated to that CPU, or if the respective subsystem is the controller for that memory (in case of GSx memory). When write accesses are allowed based on the permission, the write can be further protected by setting the CPUWRPROTx bit of the specific register to 1. If write access is done by a CPU to memory where the write is protected, a write protection violation occurs.

There are two types of CPU write protection violations:

- Non-controller CPU write protection violation
- Controller CPU write protection violation

If a write access is made to a dedicated or shared memory by the controller CPU and CPUWRPROTx is set to 1 for that memory, the violation is called a controller CPU write protection violation.

If a write protection violation occurs, write gets ignored, a flag gets set into the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched into the appropriate CPU write access violation address register. Also, an access violation interrupt is generated if enabled in the interrupt enable register.

### 3.12.8.3 CPU Read Protection

For local shared RAM, if memory is shared between the CPU and the CLA, the CPU only has access if the memory is configured as data RAM for the CLA. If the data RAM is programmed as program RAM, all the access from the CPU, including a read, are blocked and the violation is considered as a non-controller access violation.

If a read protection violation occurs, a flag gets set into the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched into the appropriate CPU read access violation address register. Also, if enabled in the interrupt enable register, an access violation interrupt is generated.

### 3.12.8.4 CLA Fetch Protection

If local shared RAM is configured as dedicated RAM for the CPU, or if the RAM is configured as data RAM for the CLA, any fetch access from the CLA to that particular LSx RAM results in a CLA fetch protection violation, which is a non-controller access violation.

If a CLA fetch protection violation occurs, the violation results in a MSTOP, a flag gets set into the appropriate access violation flag register, and the memory address for which the access violation occurred gets latched into the appropriate CLA fetch access violation address register. Also, an access violation interrupt is generated to the controller CPU if the interrupt is enabled in the interrupt enable register.

### 3.12.8.5 CLA Write Protection

If local shared RAM is configured as dedicated RAM for the CPU, or if the RAM is configured as program RAM for the CLA, any data write access from the CLA to that particular LSx RAM results in a CLA write protection violation, which is a non-controller access violation. Similarly, any data write access from CLA to CPUTOCLA or DMATTOCLA MSGRAM results in a CLA write protection violation, which is a non-controller access violation.

If a CLA write protection violation occurs, the write gets ignored, a flag gets set into the appropriate access violation flag register, and the memory address for which the access violation occurred gets latched into the appropriate CLA write access violation address register. Also, an access violation interrupt is generated to the controller CPU if the interrupt is enabled in the interrupt enable register.

### 3.12.8.6 CLA Read Protection

If local shared RAM is configured as dedicated RAM for the CPU, or if the local shared RAM is configured as program RAM for the CLA, any data read access from the CLA to that particular LSx RAM results in a CLA read protection violation, which is a non-controller access violation.

If a CLA read protection violation occurs, a flag gets set into the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched into the appropriate CLA read access violation address register. Also, an access violation interrupt is generated to the controller CPU if enabled in the interrupt enable register.

### 3.12.8.7 DMA Write Protection

The CPU1 or CPU2 DMA has write permission to a GSx memory only if the respective subsystem is controller for that memory. When write accesses from a DMA are allowed based on the permission, the write accesses can be further protected by setting the DMAWRPROTx bit of a specific register to 1. If a write access is done by the DMA to a protected memory, a write protection violation occurs.

There are two types of DMA write protection violations:

- Non-controller DMA write protection violation (applicable to GSx RAMs and DMATOC LA MSGRAM)
- Controller DMA write protection violation

If a write access is made to GSx memory by a non-controller DMA, the violation is called a non-controller write protection violation. If a write access is made to a dedicated or shared memory by a controller DMA and DMAWRPROTx is set to 1 for that memory, the violation is called a controller DMA write protection violation.

If a write protection violation occurs on CPU1, the write is ignored and a DMAERR interrupt gets generated, whereas in the case of CPU2, a write is ignored and an access violation interrupt is generated if the interrupt is enabled in the interrupt enable register. A flag gets set in the DMA access violation flag register and the memory address where the violation happened gets latched in the DMA fetch access violation address register. These are dedicated registers for each subsystem.

**Note 1:** All access protections are ignored during debug accesses. Write access to a protected memory goes through when the write access is done using the debugger, irrespective of the write protection configuration for that memory.

**Note 2:** In the case of local shared RAM, if memory is shared between the CPU and the CLA, the CPU only has access if the memory is configured as data RAM for the CLA. If the data RAM is programmed as program RAM, all the access from the CPU (including read) and data access from the CLA is blocked, and the violation is considered a non-controller access violation. If the memory is configured as dedicated to the CPU, all access from the CLA is blocked and the violation is considered a non-controller access violation.

### 3.12.9 Memory Error Detection, Correction, and Error Handling

These devices have memory error detection and correction features to satisfy safety standards requirements. These requirements warrant the addition of detection mechanisms for finite dangerous failures.

In this device, all dedicated RAMs and LSx RAMs support error correction code (ECC) protection and other shared RAMs have parity protection. The ECC scheme used is Single Error Correction Double Error Detection (SECCDED). The parity scheme used is even parity. ECC/Parity covers the data bits stored in memory as well as address.

ECC/Parity calculation is done inside the memory controller module and then calculated. ECC/Parity is written into the memory along with the data. ECC/Parity is computed for 16-bit data; hence, for each 32-bit data, there are three 7-bit ECC codes (or 3-bit parity), two of which are for data and a third one is for the address.

#### 3.12.9.1 Error Detection and Correction

Error detection is done while reading the data from memory. The error detection is performed for data as well as address. For parity memory, only a single-bit error gets detected, whereas in the case of ECC memory, along with a single-bit error, a double-bit error also gets detected. These errors are called correctable error and uncorrectable errors. The following are characteristics of these errors:

- Parity errors are always uncorrectable errors
- Single-bit ECC errors are correctable errors
- Double-bit ECC errors are uncorrectable errors
- Address ECC errors are also uncorrectable errors

Correctable errors get corrected by the memory controller module and then correct data is given back as read data to the controller. The data is also written back into the memory to prevent double-bit error due to another single-bit error at the same memory address.

---

#### Note

ECC/Parity for the address is calculated for the address offset only (based on RAM block size) of the corresponding 32-bit aligned address. In the case of LSx RAM that is a 4KB RAM block, only the 11 LSBs of the 32-bit aligned address are used. So if the address is 0x8F8F, the address ECC (or Parity) is calculated for address 0x78E (11-bit offset of the 32-bit aligned address). Similarly for a 8KB RAM block, the 12-bit address offset is used.

---

### 3.12.9.2 Error Handling

For each correctable error, the count in the correctable error count register increments by one. When the value in this count register becomes equal to the value configured into the correctable error threshold register, an interrupt is generated to the respective CPU, that is, if the interrupt is enabled in the correctable interrupt enable register. The user needs to configure the correctable error threshold register based on the system requirements. Also, the address for which the error occurred, gets latched into the controller-specific status register and a flag gets set. Each of these registers are dedicated for each CPU subsystem.

If there are uncorrectable errors, an NMI gets generated for the respective CPU. In this case, the address for which the error occurred, also gets latched into the controller-specific address status register, and a flag gets set.

[Table 3-11](#) summarizes different error situations that can arise. These need to be handled appropriately in the software, using the status and interrupt indications provided.

**Table 3-11. Error Handling in Different Scenarios**

Access Type	Error Found In	Error Type	Status Indication	Error Notification
Reads	Data read from memory	Uncorrectable Error (Single-bit error for Parity RAMs OR Double bit Error for ECC RAMs)	Yes -CPUx/CPUx.DMA/CPUx.CLA1 CPU/DMA/CLA Read Error Address Register Data returned to CPUx/ CPUx.DMA/CPUx.CLA1 is incorrect	NMI for CPUx access NMI for CPUx.DMA access NMI to CPU for CPUx.CLA1 access
Reads	Data read from memory	Single-bit error for ECC RAMs	Yes - CPUx/CPUx.DMA CPU/DMA Read Error Address Register Increment single error counter	Interrupt when error counter reaches the user programmable threshold for single errors
Reads	Address	Address error	Yes - CPUx/CPUx.DMA/CPUx.CLA1 CPU/DMA/CLA Read Address Error Register Data returned to CPUx/ CPUx.DMA/CPUx.CLA1 is incorrect	NMI to CPU for CPUx access NMI to CPU for CPUx.DMA access NMI to CPU for CPUx.CLA1 access

#### Note

In the case of an uncorrectable error during fetch on the CPU, there is the possibility of getting an ITRAP before an NMI exception, since garbage instructions enter into the CPU pipeline before the NMI gets generated.

During debug accesses, correctable as well as uncorrectable errors are masked.

### 3.12.10 Application Test Hooks for Error Detection and Correction

Since error detection and correction logic is part of safety critical logic, safety applications need to make sure that the logic is always working fine (during run time also). To enable this, different test modes are provided to generate an ECC/parity error in RAM locations. These test modes can be configured in RAM Test registers of different RAM blocks. (for example, for D0 RAM, TEST\_D0 bit in DxTEST register). Different test modes are for different usage. In test mode, the user can modify the data bits (without modifying the ECC/Parity bits) or ECC/Parity bits directly. Using this feature, an ECC/Parity error can be injected into data. Since an uncorrectable error generates NMI, some users can avoid generating this during test mode and one of the test modes (11) is provided where NMI generation gets disabled. This mode is just like the functional mode except NMI generation on an uncorrectable error.

#### Note

The memory map for ECC/Parity bits and data bits are the same. The user must choose a different test mode (10) to access ECC/Parity bits.

The following tables show the bit mapping for the ECC and Parity bits when the bits are read in RAMTEST mode using their respective addresses.

**Table 3-12. Mapping of ECC Bits in Read Data from ECC/Parity Address Map**

Data Bits Location in Read Data	Content (ECC Memory)
6:0	ECC Code for lower 16 bits of data
7	Not Used
14:8	ECC Code for upper 16 bits of data
15	Not Used
22:16	ECC Code for address
31:23	Not Used

**Table 3-13. Mapping of Parity Bits in Read Data from ECC/Parity Address Map**

Data Bits Location in Read Data	Content (Parity Memory)
0	Parity for lower 16 bits of data
7:1	Not Used
8	Parity for upper 16 bits of data
15:9	Not Used
16	Parity for address
31:17	Not Used

Following is the sequence that can be followed to test the ECC/parity logic:

- Set the test mode to 01 or 10, depending on whether data field or ECC/parity field needs to be written.
- Write the data pattern into the memory.
- Set the test mode to 11 to read from memory and exercise the ECC/parity logic.
- Check the test log registers to verify the correctness of the logic.
- The above sequence can be repeated for any number of data patterns.
- Once the test is complete, re-initialize the locations used in test, and set the test mode to 00 that changes the RAM block back into functional mode.

### 3.12.11 ROM Test

ROMs are read-only memory, unlike RAMs, data or parity bits cannot be modified to introduce errors for diagnostic coverage of parity checking logic. The following method is used to check health of parity checking logic in ROMs.

- Added duplicate Parity check logic and feed the same data into duplicate parity checker
- Generate uncorrectable error if parity check status of these two separate parity checkers do not match

The probability of both circuits having fault is unlikely; hence, Parity Errors are certainly detected.

To generate the error, a test bit FORCE\_ERROR is added. When the FORCE\_ERROR bit is set, the parity bit going to one of the party checkers is inverted; thereby, introducing an uncorrectable error. An uncorrectable error is generated only if there is an error on all parity checkers: address, data [15:0], and data [31:16]. This makes sure that all three parity checkers are working as expected. See [Figure 3-19](#).

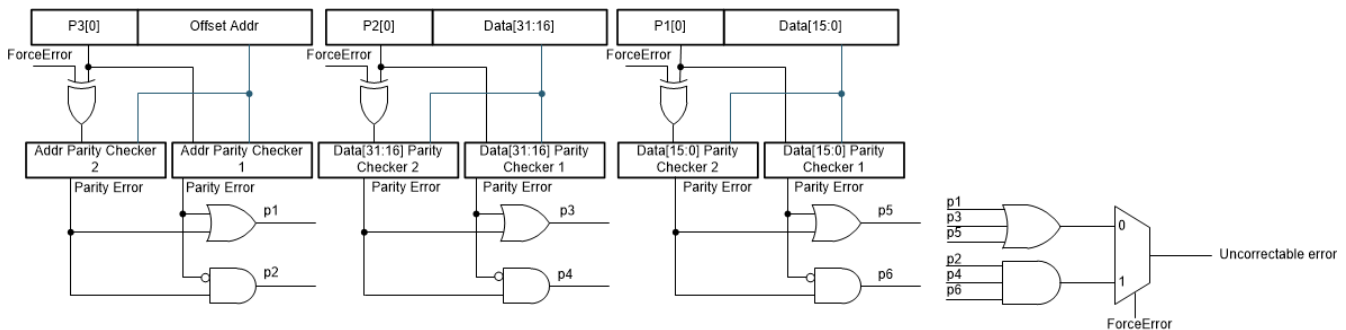

Figure 3-19. ROM Parity Checking Logic

### 3.12.12 RAM Initialization

To make sure that read/fetch from uninitialized RAM locations do not cause ECC or parity errors, the RAM\_INIT feature is provided for each memory block. Using this feature, any RAM block can be initialized with 0x0 data and the respective ECC/Parity bits accordingly. This can be initiated by setting the INIT bit to 1 for the specific RAM block in the INIT registers. To check the status of RAM initialization, software must poll the INITDONE bit for that RAM block in the INITDONE register to be set. Unless this bit gets set, no access must be made to that RAM memory block.

In the case of GSx memory, only the CPU of the subsystem that is configured as the controller for the particular GSx RAM block can initiate the RAM initialization.

#### Note

None of the controllers must access the memory while initialization is taking place. If memory is accessed before RAMINITDONE is set, the memory read/write as well as initialization does not happen correctly.

### 3.13 JTAG

Gel files perform certain initialization tasks. This helps the users in a debug environment. However, when executed standalone (without the emulator connected), the application does not work as expected, since there is no gel file to perform those initializations. For example, the gel file disables the watchdog. If user code does not service the watchdog in the application (or fails to disable the watchdog), there is a difference in how the application behaves with the debugger and without.

Common tasks performed by the gel files (but not boot-ROM):

- On Reset:
  - Disable Flash ECC on some devices.
    - Disabling ECC only when using Flash API functions, see the Flash API User Guide for details. Otherwise, TI suggests to always program ECC and enable ECC-check.
  - Disable Watchdog
  - Enable CLA clock
  - Select real-time mode or C28x mode
- On Restart:
  - Select real-time mode or C28x mode
  - Clear IER and IFR
- On Target Connect:
  - Select real-time mode or C28x mode

For more information, see [C2000 MCU JTAG Connectivity Debug](#).

#### 3.13.1 JTAG Noise and TAP\_STATUS

The TAP\_STATUS register reflects the status of the JTAG TAP at any given time. Normally when no JTAG is connected to the device, the status can be IDLE. In some cases with excessive PCB noise, there can be unwanted TMS and TCK toggles that take JTAG out of the IDLE state. When persistent, this can ultimately lead to unwanted activation of the JTAG Boundary Scan or some other JTAG mode that can interfere with the intended application. To avoid this scenario, place strong enough pull resistors on the board to prevent noise from activating JTAG. As a debug tool, the TAP\_STATUS register can be polled by the application code to detect if this is a cause of device disturbance. The SOFTPRES40[JTAG\_nTRST] register can also be used to reset the JTAG TAP through software. Use this reset register with caution, as this prevents connecting a debugger unless the code qualifies writes to this register with some other GPIO state or other means to distinguish between noise and debugger accesses.

The TAP\_CONTROL register can be used to disable the TAP state machine's control of the device. Using the TAP\_CONTROL register can help to prevent noise from activating JTAG.

### 3.14 Live Firmware Update (LFU)

This device includes hardware hooks to streamline firmware updates. These hardware hooks enable seamless switching from the old firmware to the new firmware without resetting the application.

This section discusses the Live Firmware Update (LFU) and the hardware features present on the device to support LFU.

#### 3.14.1 LFU Background

End equipment like Server Power Supply (PSU) are high availability systems that need to have minimum downtime, even during firmware upgrades. Firmware upgrades are essential to add additional functionality, enhance performance and fix software bugs/vulnerabilities. LFU helps update firmware while the application is running, thus eliminating downtime (with respect to critical real-time interrupts) and also providing a more cost-effective alternative compared to manually updating firmware.

LFU has traditionally been implemented in the C2000 family of MCUs using software-only techniques. This impacts LFU switchover time, which is the time to switchover to new firmware once the transition has begun.

User application code initiates this transition, typically by jumping to an entry point in the new firmware. There, a compiler provided initialization routine specific to LFU is called. This initializes user-specified data variables. When execution arrives in main() of the new application, user application code performs minimal initialization to get the new application running.

### 3.14.2 LFU Switchover Steps

A simplified representation of the LFU switchover is shown in [Figure 3-20](#), and is described in the following steps:

1. In typical systems, a host – typically a PC or another MCU, initiates LFU (depicted as LFU Request) on the application MCU (in this case, the C2000 MCU) that is executing the real-time control application. This initiates the Flash Program sequence in the application MCU. This runs as a background process even as the application MCU continues executing firmware (depicted as Firmware - 1).
2. Since the compiler can move existing PIE vectors and function pointers to new locations between firmware versions, or PIE vectors or function pointers can get added or removed between firmware versions, the user application code needs to manage these properly and efficiently during LFU. In the absence of Flash remapping (where different Flash memory banks can be mapped to the same address), PIE vector table remapping, that is “swapping” and RAM memory block swapping are features supported on the device. Without swapping, the user application code needs to individually update each PIE vector and each function pointer, adding valuable cycles to the LFU switchover time. With swapping, prior to LFU switchover, the user application code can populate a different PIE vector table (depicted as PIE Swap Memory Update) and a different LS RAM region (depicted as LSx Swap Memory Update).
3. When complete, at an appropriate time (depicted as LFU Switchover – waiting for appropriate time), the user application code initiates the transition to new firmware. Once the compiler LFU initialization routine completes and transfers execution to the new application (depicted as Firmware – 2), the user application code needs to perform necessary initialization before the new application can begin running. Since PIE vectors and function pointers have already been populated in the “swap” locations, all that is required is a PIE vector table swap and LSx RAM Memory Swap (depicted as PIE Vector Swap, LSx Memory Swap).

Figure 3-20. Simplified LFU Representation

### 3.14.3 Device Features Supporting LFU

The new hardware capabilities implemented in the device to support LFU are:

1. Multi-Bank Flash
2. PIE Vector Table Swap
3. LS0/LS1 RAM Memory Swap for CPU1
4. D2/D3 RAM Memory Swap for CPU2

#### 3.14.3.1 Multi-Bank Flash

The device has up to three Flash banks, each of size 128KB. With multiple banks, it is possible to Program/Erase a bank while other banks are in read mode.

#### 3.14.3.2 PIE Vector Table Swap

The device contains an additional PIE vector table, in addition to the typical PIE vector table that is present. This allows PIE vector addresses for the new firmware to be populated prior to the LFU switchover. During LFU switchover, a simple swap operation which activates the PIE vector swap table and deactivates the previously active PIE vector table is initiated by user application code, and this operation takes just 1 CPU clock cycle. To initiate the swap, user application code sets `LFUConfig.PieVectorSwap = 1`. The PIE vector table swap features are also implemented on a redundant PIE vector table implemented for safety. Therefore, to implement PIE vector table swap, the sizes of PIE vector memory and redundant PIE vector memory are both doubled.

The changes are summarized in [Figure 3-21](#). In previous devices, PIE vector RAM and redundant PIE vector RAM are present. In this device, these are duplicated. There are now four physical PIE vector RAM memories – Block A, Block B, Block C, and Block D. By default, Block A and Block B are *active*, and are mapped to addresses `0x0000_0D00-0x0000_0EFF` and `0x0100_0D00-0x0100_0EFF` respectively. Block C and Block D are *inactive*, and are mapped to addresses `0x0100_0900-0x0100_0AFF` and `0x0100_0B00-0x0100_0CFF`, respectively.

When user application code initiates a PIE vector table swap by setting `LFUConfig.PieVectorSwap = 1`, Block C and Block D *become active*, and are mapped to addresses `0x0000_0D00-0x0000_0EFF` and `0x0100_0D00-0x0100_0EFF` respectively. Block A and Block B *become inactive*, and are mapped to addresses `0x0100_0900-0x0100_0AFF` and `0x0100_0B00-0x0100_0CFF`, respectively.

Thus, note that the active addresses are always `0x0000_0D00-0x0000_0EFF`, and `0x0100_0D00-0x0100_0EFF` (for redundancy). The inactive addresses are always `0x0100_0900-0x0100_0AFF`, and `0x0100_0B00-0x0100_0CFF` (for redundancy). As mentioned above, prior to the LFU switchover, the user application code needs to write to the inactive addresses with the PIE vector locations corresponding to the new firmware.

The register bit `LFUStatus.PieVectorSwap` provides the status of Pie Vector Swap.

Writes to addresses `0x0000_0D00-0x0000_0EFF` update both the currently active block and the redundant counterpart. Writes to addresses `0x0100_0900-0x0100_0AFF` update both the currently inactive block and the redundant counterpart.

Reads from addresses `0x0000_0D00-0x0000_0EFF` issue reads from both addresses `0x0000_0D00-0x0000_0EFF` and the redundant counterpart `0x0100_0D00-0x0100_0EFF`. The read values are compared and any data mismatches generate the same error response as that of the existing PIE vector fetch mismatch (refer to `PIEVERRADDR`). A read from or write to the redundant PIE vector RAM (`0x0100_0D00-0x0100_0EFF` or `0x0100_0B00-0x0100_0CFF`) impacts only the redundant PIE vector RAM.

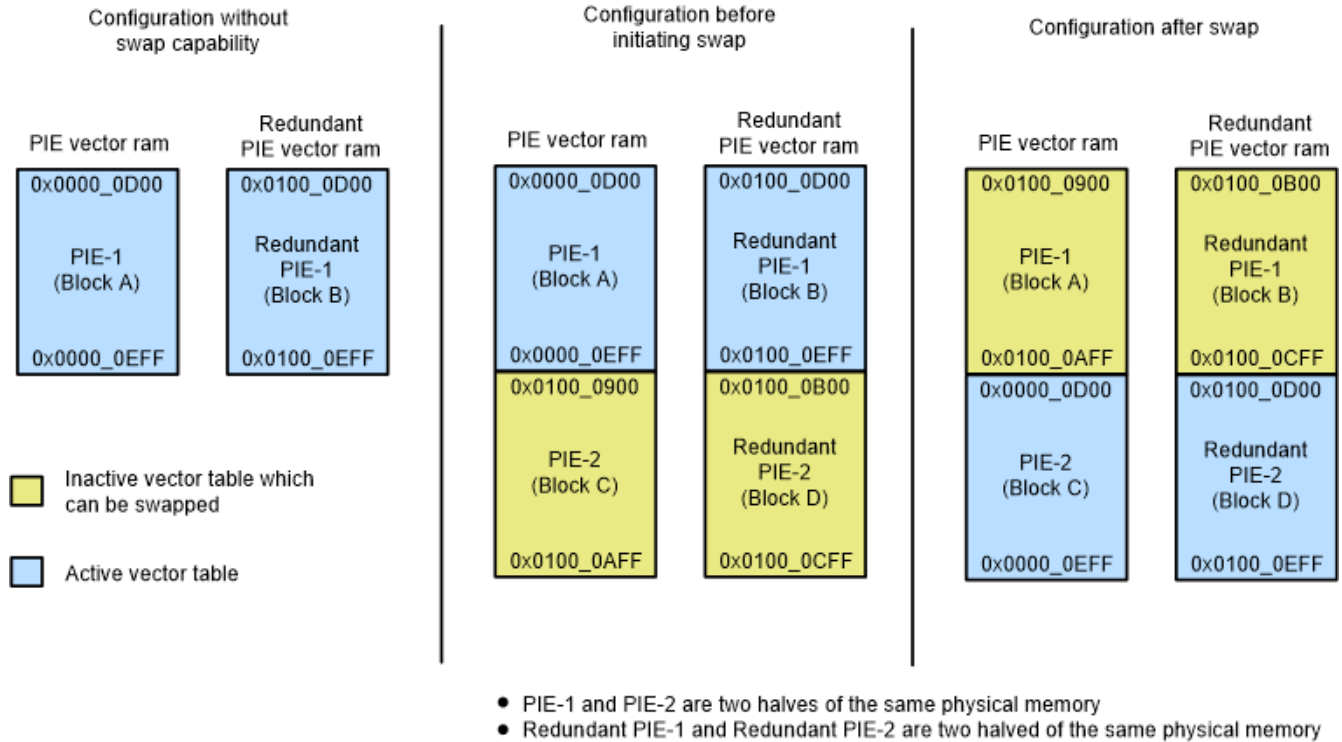

Figure 3-21. PIE Vector Table Swap

### 3.14.3.3 LS0/LS1 RAM Memory Swap for CPU1

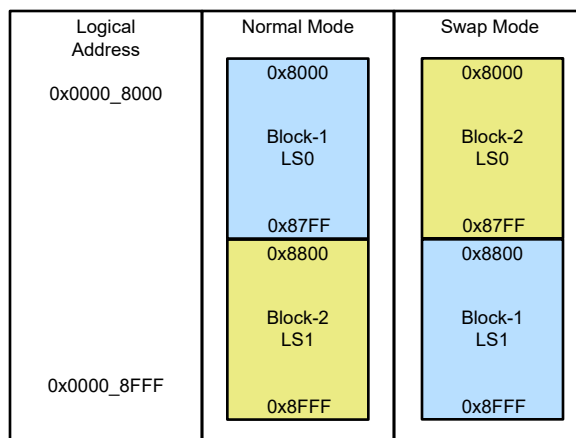

Similar to PIE Vector Table Swap, LS0 and LS1 physical RAM memory blocks can also be swapped. LS0/LS1 memory swapping is for CPU1. The memory architecture is similar to PIE vector table swap, and is shown in Figure 3-22. By default, physical Block 1 is assigned to addresses 0x8000-0x87FF (that is, the address range for LS0), and physical Block 2 is assigned to addresses 0x8800-0x8FFF (that is, the address range for LS1). By configuring LFUConfig.LS01Swap = 1, user application code can execute a swap, where physical *Block 2* is now assigned to addresses 0x8000-0x87FF (that is, the address range for LS0), and physical *Block 1* is now assigned to addresses 0x8800-0x8FFF (that is, the address range for LS1).

If physical memory Block 1 contains function pointers for the current firmware, the same relative locations in physical memory Block 2 can be populated with function pointers for the new firmware prior to LFU switchover. During LFU switchover, a simple swap operation is initiated by user application code, and this operation takes just 1 CPU clock cycle. This allows user application code to always have function pointers in LS0, yet have two different physical blocks that can map to the LS0 address range.

For example, if current firmware contains 10 function pointers present at the start of Block 1 (LS0 address space). If the new firmware contains the same 10 function pointers that now need to be updated, the user application code can place these at the start of Block 2 (LS1 address space) prior to LFU switchover. During LFU switchover, the user application code can execute a LS0/LS1 RAM memory swap, where the physical RAM block previously mapped to the LS1 address space is now mapped to the LS0 address space, and hence can be used seamlessly for function pointer addressing for the new firmware.

The register bit LFUStatus.LS01Swap provides the status of LS0/LS1 RAM memory swap.

**Figure 3-22. LS0/LS1 RAM Memory Swap**

### 3.14.3.3.1 Applicability to CLA LFU

The device does not support a swap table for the CLA task vectors (MVECTs). CLA LFU is implemented typically on the CPU side, where the MVECTs are updated sequentially at an appropriate time. The techniques for when to update the MVECTs are described in the LFU system reference design guide, but is noted that the approach is different from the CPU PIE vector table case, where a simple single cycle swap achieves the switch to the new PIE vector table.

For the LS0/LS1 RAM memory swap feature to be useful for CLA LFU switchover, two conditions need to be satisfied:

- CLA code has to fit into a single LSx block. The MVECT table contains CLA task vectors, whose addresses correspond to locations in the LSx block. For example, if the current firmware CLA code is present in LS0, MVECTs points to various locations in LS0. If the new firmware CLA code is present in LS1, MVECTs points to various locations in LS1.
- When switching over from current to new firmware, the MVECTs needs to be updated, unless the MVECTs reside at the same relative location in both LS0 and LS1. If that is the case, then simply swapping LS0/LS1 RAM memory blocks effectively updates the MVECT table, without the need to sequentially update the MVECTs.

### 3.14.3.4 D2/D3 RAM Memory Swap for CPU2

For CPU2, D2 and D3 physical RAM memory blocks can be swapped. The memory architecture is shown in [Figure 3-23](#). By default, physical Block 1 is assigned to addresses 0x8000-0x9FFF (that is, the address range for D2), and physical Block 2 is assigned to addresses 0xA000-0xCFFF (that is, the address range for D3). By configuring LFUConfig.D23Swap = 1, user application code can execute a swap, where physical *Block 2* is now assigned to addresses 0x8000-0x9FFF (that is, the address range for D2), and physical *Block 1* is now assigned to addresses 0xA000-0xCFFF (that is, the address range for D3).

If physical memory Block 1 contains function pointers for the current firmware, the same relative locations in physical memory Block 2 can be populated with function pointers for the new firmware prior to LFU switchover. During LFU switchover, a simple swap operation is initiated by user application code, and this operation takes just 1 CPU clock cycle. This allows user application code to always have function pointers in D2, yet have two different physical blocks that can map to the D2 address range.

For example, if current firmware contains 10 function pointers present at the start of Block 1 (D2 address space). If the new firmware contains the same 10 function pointers that now need to be updated, the user application code can place these at the start of Block 2 (D3 address space) prior to LFU switchover. During LFU switchover, the user application code can execute a D2/D3 RAM memory swap, where the physical RAM block previously mapped to the D3 address space is now mapped to the D2 address space, and hence can be used seamlessly for function pointer addressing for the new firmware.

The register bit LFUStatus.D23Swap provides the status of D2/D3 RAM memory swap.

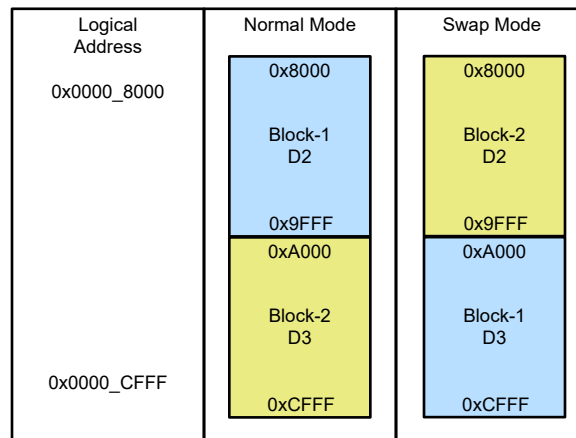

Figure 3-23. D2/D3 RAM Memory Swap

### 3.14.3.5 Additional Points Pertaining to LS0/LS1 and D2/D3 RAM Memory Swap

1. LFU registers can be accessed from both CPU and CLA.
2. Only LS0 and LS1 blocks can be swapped for CPU1 and only D2 and D3 memories can be swapped for CPU2. LS2 to LS9 and DS4, D5 blocks cannot be swapped.
3. LS0/LS1 and D2/D3 blocks have parity protection.
4. For dual core devices, the respective Dx memory (D2, D3, D4, D5) is mapped to CPU2 address space and the LFUConfig.D23Swap bit can be used to swap the D2 and D3 blocks when MCUCNF0.DUAL\_CORE = '1' and MCUCNF1.MSEL\_Dx = '1'. For other configurations, writing to LFUConfig.D23Swap bit does not have any effect.
5. A number of LSx RAM registers are available to the user application code to configure options such as controller select (LSxMSEL.MSEL\_LS0, LSxMSEL.MSEL\_LS1), fetch protect (LSxACCPROT0.FETCHPROT\_LS0, LSxACCPROT0.FETCHPROT\_LS1), write protect (LSxACCPROT0.CPUWRPROT\_LS0, LSxACCPROT0.CPUWRPROT\_LS1), CLA program memory (LSxCLAPGM.CLAPGM\_LS0, LSxCLAPGM.CLAPGM\_LS1). These register bits indicate the status of the memory block that is deemed as LS0 (CPU address 0x8000 to 0x87FF) and LS1 (CPU address 0x8800 to 0x8FFF) at any point of time. When a LS0/LS1 RAM memory swap occurs, the corresponding control/status bits are also automatically swapped.
6. Service all pending errors (access violation, ECC, parity) associated with memory before initiating a LS0/LS1 and D2/D3 RAM memory swap.
7. LS0/LS1 and D2/D3 RAM memory swap must be initiated only after completion of RAM initialization for LS0/LS1 or D2/D3 memories (LSxINITDONE.INITDONE\_LS0 = 1, LSxINITDONE.INITDONE\_LS1 = 1, DxINITDONE.INITDONE\_D2 = 1, DxINITDONE.INITDONE\_D3 = 1).
8. LS0/LS1 RAM memory swap must not be initiated when RAM-test (LSxTEST.TEST\_LS0 = 1 or LSxTEST.TEST\_LS1 = 1) is in progress for LS0 or LS1 blocks. D2/D3 RAM memory swap must not be initiated when RAM-test (DxTEST.TEST\_D2 = 1 or DxTEST.TEST\_D3 = 1) is in progress for D2 or D3 blocks.
9. With DCSM security on the device, in general, LS0/LS1 or D2/D3 RAM blocks can be assigned to different security zones. However, with LS0/LS1 or D2/D3 RAM memory swaps, different physical RAM blocks can get mapped to the same address space. Application software must therefore make sure that both LS0/LS1 or D2/D3 have the same security settings (for example, zone, EXE protection), if there is a plan to implement LS0/LS1 or D2/D3 RAM memory swap. Hardware logic is implemented on the device to prevent swap of LS0/LS1 or D2/D3, if the blocks have different security configurations.
10. To prevent security vulnerabilities, LS0/LS1 or D2/D3 RAM memory swap is not allowed if the memory swap is initiated by code from a different zone. For example,
  - a. if LS0 and LS1 are part of Zone1, swap is not allowed if code that initiates the swap resides in Zone2 or unsecure zone
  - b. if LS0 and LS1 are part of Zone2, swap is not allowed if code that initiates the swap resides in Zone1 or unsecure zone
  - c. if LS0 and LS1 are part of the same zone that is unsecure, swap is allowed in all cases irrespective of where the code that initiates the swap resides
  - d. if LS0 and LS1 are part of the same zone and the zone is unlocked, the swap can be initiated from code residing anywhere (including from the debugger)
11. Once swap is initiated, the swap happens in the next cycle itself, subject to the swap meeting the security requirements mentioned above. After initiation of a swap, application software must check if the swap was correctly configured by checking the LFUStatus.LS01Swap status register. Consistency between LFUStatus.LS01Swap and LFUConfig.LS01Swap helps determine if the swap was correctly configured. If LFUStatus.LS01Swap does not match LFUConfig.LS01Swap, LFUConfig.LS01Swap needs to be cleared by the user application code.
12. Since the logical address accessed by BGCRC changes with LS0/LS1 or D2/D3 RAM memory swap, the computed CRC values for these memories need to be updated after the LS0/LS1 or D2/D3 RAM memory swap.

### 3.14.4 LFU Switchover

After the new firmware has been programmed to Flash, the user application code needs to determine when appropriate to switchover to the new firmware. The techniques to determine this differ between real-time critical firmware running on the CPU and CLA. These techniques are beyond the scope of this document and are described in detail in the LFU system reference design guide.

The device supports two register bits that can be set or reset to indicate that LFU switchover is in progress on the CPU (LFUConfig.LFU\_CPU) and CLA (LFUConfig.LFU\_CLA1). These bits do not impact any hardware logic on the device. For example, LFUConfig.LFU\_CPU can be set by user application code at the start of switchover, and then tested in the initialization code in main(). This can enable only LFU switchover specific initialization to be performed (for example, PIE vector table swap, LS0/LS1 RAM memory swap), while bypassing all other initialization that typically happens after a device reset.

### 3.14.5 LFU Resources

The following are additional LFU resources available.

- [Live Firmware Update Without Device Reset on C2000™ MCUs User's Guide](#)
- [Live Firmware Update With Device Reset on C2000™ MCUs User's Guide](#)
- [Live Firmware Update Reference Design with C2000™ Real-Time MCUs](#)

## 3.15 System Control Register Configuration Restrictions

Memory-mapped registers in System Control operate on the INTOSC1 clock domain; hence, any CPU writes to these registers requires a delay between subsequent writes otherwise the second write can be lost. The application needs to take this into consideration and check the SYNCBUSY and SYNCBUSYWD status registers after every write to the registers that are mentioned in [Table 3-14](#).

**Table 3-14. System Control Registers Impacted**

### 3.16 MCU Configuration (MCUCNFx)

MCU Configuration registers (MCUCNFx) have been implemented to enable customers to emulate a sub-set device on a super-set device. Table 3-15 shows the list of the available MCUCNF registers and the sub-set features that can be emulated. See the MCUCNFx register descriptions for more details. This feature only works when emulating a sub-set device on a super-set device but not the other way around.

**Table 3-15. MCUCNF Registers**

Register	Feature to Modify
MCUCNF0	Dual to Single core
MCUCNF1	D2 - D5 CPU1/CPU2 memory allocation
MCUCNF2	With EtherCAT to no EtherCAT
MCUCNF3	Flash Bank1 sector allocation if bank is present
MCUCNF4	Flash Bank2 sector allocation if bank is present
MCUCNF5	Flash Bank3 sector allocation if bank is present
MCUCNF6	Flash Bank4 sector allocation if bank is present
MCUCNF7	Flash Bank5 sector allocation if bank is present

### 3.17 Software

#### 3.17.1 SYSTL Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location: C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/sysctl

Cloud access to these examples is available at the following link: [dev.ti.com C2000Ware Examples](https://dev.ti.com/C2000Ware/Examples).

##### 3.17.1.1 Missing clock detection (MCD) - SINGLE\_CORE

FILE: sysctl\_ex1\_missing\_clock\_detection.c

This example demonstrates the missing clock detection functionality and the way to handle it. Once the MCD is simulated by disconnecting the OSCCLK to the MCD module an NMI would be generated. This NMI determines that an MCD was generated due to a clock failure which is handled in the ISR.

Before an MCD the clock frequency would be as per device initialization (200Mhz). Post MCD the frequency would move to 10Mhz or INTOSC1.

The example also shows how we can lock the PLL after missing clock, detection, by first explicitly switching the clock source to INTOSC1, resetting the missing clock detect circuit and then re-locking the PLL. Post a re-lock the clock frequency would be 200Mhz but using the INTOSC1 as clock source.

##### External Connections

- None.

##### Watch Variables

- *fail* - Indicates that a missing clock was either not detected or was not handled correctly.
- *mcd\_clkfail\_isr* - Indicates that the missing clock failure caused an NMI to be triggered and called an the ISR to handle it.
- *mcd\_detect* - Indicates that a missing clock was detected.
- *result* - Status of a successful handling of missing clock detection

##### 3.17.1.2 XCLKOUT (External Clock Output) Configuration - SINGLE\_CORE

FILE: sysctl\_ex2\_xclkout.c

This example demonstrates how to configure the XCLKOUT pin for observing internal clocks through an external pin, for debugging and testing purposes.

In this example, we are using INTOSC1 as the XCLKOUT clock source and configuring the divider as 8. Expected frequency of XCLKOUT = (INTOSC1 freq)/8 = 10/8 = 1.25MHz

View the XCLKOUT on GPIO73 using an oscilloscope.

### 3.17.2 MEMCFG Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location: C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/memcfg

Cloud access to these examples is available at the following link: [dev.ti.com C2000Ware Examples](#).

#### 3.17.2.1 Correctable & Uncorrectable Memory Error Handling

FILE: memcfg\_ex1\_error\_handling.c

This example demonstrates error handling in case of various erroneous memory read/write operations. Error handling in case of CPU read/write violations, correctable & uncorrectable memory errors has been demonstrated. Correctable memory errors & violations can generate SYS\_INT interrupt to CPU while uncorrectable errors lead to NMI generation.

##### External Connections

- None

##### Watch Variables

- *testStatusGlobal* - Equivalent to *TEST\_PASS* if test finished correctly, else the value is set to *TEST\_FAIL*
- *errCountGlobal* - Error counter

#### 3.17.2.2 Shared RAM Management (CPU1) - C28X\_DUAL

FILE: memcfg\_ex1\_ram\_management\_cpu1.c

This example shows how to assign shared RAM for use by both the CPU2 and CPU1 core. Shared RAM regions are defined in both the CPU2 and CPU1 linker files. In this example GS0 and GS4 are assigned to/owned by CPU2. The remaining shared RAM regions are owned by CPU1.

In this example, a pattern is written to cpu1RWArray and then an IPC flag is sent to notify CPU2 that data is ready to be read. CPU2 then reads the data from cpu2RArray and writes a modified pattern to cpu2RWArray. Once CPU2 acknowledges the IPC flag, CPU1 reads the data from cpu1RArray and compares with expected result.

A timer ISR is also serviced in both CPUs. The ISRs are copied into the shared RAM region owned by the respective CPUs. Each ISR toggles a GPIO. Watch the GPIOs on an oscilloscope, or if using the controlCARD, watch LED1 and LED2 blink at different rates.

Following are the memory allocation details of CPU Timer interrupt ISRs & read(R)/read write(RW) arrays in CPU1 & CPU2 as configured in the example.

- cpu1RWArray[] is mapped to shared RAM GS1
- cpu1RArray[] is mapped to shared RAM GS0
- cpu2RArray[] is mapped to shared RAM GS1
- cpu2RWArray[] is mapped to shared RAM GS0
- cpuTimer0ISR in CPU2 is copied to shared RAM GS4, toggles LED1
- cpuTimer0ISR in CPU1 is copied to shared RAM GS3, toggles LED2

NOTE: In the default CPU2 linker cmd file, GS4, FLASH\_BANK3 and FLASH\_BANK4 are used for allocating various CPU2 sections. The CPU1 application assigns the ownership of these memory regions to CPU2. Please note that CPU2 .out file can be loaded only after CPU1 completes this configuration

The erase setting (CPU1/CPU2 On-Chip Flash -> erase setting) needs to be configured as selected banks only (Choose the corresponding BANKS allocated for CPUs) or necessary sectors only before loading CPU1/ CPU2.out file (This is applicable only for FLASH configuration)

### Watch Variables

- error Indicates that the data written is not correctly received by the other CPU.

#### 3.17.2.3 Shared RAM Management (CPU2) - C28X\_DUAL

FILE: memcfg\_ex1\_ram\_management\_cpu2.c

This example shows how to assign shared RAM for use by both the CPU2 and CPU1 core. Shared RAM regions are defined in both the CPU2 and CPU1 linker files. In this example GS0 and GS4 are assigned to/owned by CPU2. The remaining shared RAM regions are owned by CPU1.

In this example, a pattern is written to cpu1RWArray and then an IPC flag is sent to notify CPU2 that data is ready to be read. CPU2 then reads the data from cpu2RArray and writes a modified pattern to cpu2RWArray. Once CPU2 acknowledges the IPC flag, CPU1 reads the data from cpu1RArray and compares with expected result.

A timer ISR is also serviced in both CPUs. The ISRs are copied into the shared RAM region owned by the respective CPUs. Each ISR toggles a GPIO. Watch the GPIOs on an oscilloscope, or if using the controlCARD, watch LED1 and LED2 blink at different rates.

Following are the memory allocation details of CPU Timer interrupt ISRs & read(R)/read write(RW) arrays in CPU1 & CPU2 as configured in the example.

- cpu1RWArray[] is mapped to shared RAM GS1
- cpu1RArray[] is mapped to shared RAM GS0
- cpu2RArray[] is mapped to shared RAM GS1
- cpu2RWArray[] is mapped to shared RAM GS0
- cpuTimer0ISR in CPU2 is copied to shared RAM GS4, toggles LED1
- cpuTimer0ISR in CPU1 is copied to shared RAM GS3, toggles LED2

#### 3.17.3 NMI Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location: C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/nmi

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

##### 3.17.3.1 NMI handling - C28X\_DUAL

FILE: nmi\_ex1\_cpu1handling.c

This example demonstrates how to handle an NMI.

The watchdog of CPU2 is configured to reset the core once the watchdog overflows and in the CPU1 the NMI is triggered. The NMI status is read and is verified to be due to CPU2 Watchdog reset. The NMI ISR reboots the CPU2 core and the process is repeated.

NOTE: In the default CPU2 linker cmd file, GS4, FLASH\_BANK3 and FLASH\_BANK4 are used for allocating various CPU2 sections. The CPU1 application assigns the ownership of these memory regions to CPU2. Please note that CPU2 .out file can be loaded only after CPU1 completes this configuration

The erase setting (CPU1/CPU2 On-Chip Flash -> erase setting) needs to be configured as selected banks only (Choose the corresponding BANKS allocated for CPUs) or necessary sectors only before loading CPU1/ CPU2.out file (This is applicable only for FLASH configuration)

### Watch Variables

- nmi\_isr\_count Indicates the number of times the NMI ISR was hit because of CPU2 watchdog reset.

##### 3.17.3.2 Watchdog Reset - C28X\_DUAL

FILE: nmi\_ex1\_cpu2wdreset.c

This example shows how to configure the watchdog to reset CPU2 which will trigger an NMI in CPU1. LED1 is toggled at the start of main indicating CPU reset.

### External Connections

- None.

### Watch Variables

- loopCount - The number of loops performed while not in ISR

### 3.17.4 TIMER Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/timer

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 3.17.4.1 CPU Timers - SINGLE\_CORE

FILE: timer\_ex1\_cputimers.c

This example configures CPU Timer0, 1, and 2 and increments a counter each time the timer asserts an interrupt.

### External Connections

- None

### Watch Variables

- cpuTimer0IntCount
- cpuTimer1IntCount
- cpuTimer2IntCount

#### 3.17.4.2 CPU Timers - SINGLE\_CORE

FILE: timer\_ex2\_cputimers\_syscfg.c

This example configures CPU Timer0, 1, and 2 and increments a counter each time the timer asserts an interrupt.

The interrupt priorities are configured as follows :

- RTINT Threshold = 15
- Timer 0 Interrupt priority = 10 -> RTINT
- Timer 1 Interrupt priority = 20 -> INT
- Timer 2 Interrupt priority = 30 -> INT

Sysconfig inserts the required attributes to the ISR functions to inform the compiler that the function is an interrupt / realtime interrupt.

### External Connections

- None

### Watch Variables

- cpuTimer0IntCount
- cpuTimer1IntCount
- cpuTimer2IntCount

### 3.17.5 WATCHDOG Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/watchdog

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 3.17.5.1 Watchdog - SINGLE\_CORE

FILE: watchdog\_ex1\_service.c

This example shows how to service the watchdog or generate a watchdog interrupt using the watchdog. By default the example will generate a watchdog interrupt. To service the watchdog and not generate the interrupt, uncomment the SysCtl\_serviceWatchdog() line in the main for loop.

#### External Connections

- None.

#### Watch Variables

- ISRCCount - The number of times entered into the watchdog ISR
- loopCount - The number of loops performed while not in ISR

### 3.18 System Control Registers

This section describes the various System Control Registers.

#### 3.18.1 SYSCCTRL Base Address Table

**Table 3-16. SYSCCTRL Base Address Table**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	CPU2	CPU2.DMA	Pipeline Protected
Instance	Structure								
CpuTimer0Regs	CPUTIMER_REGS	CPUTIMER0_BASE	0x0000_0C00	YES	-	-	YES	-	-
CpuTimer1Regs	CPUTIMER_REGS	CPUTIMER1_BASE	0x0000_0C08	YES	-	-	YES	-	-
CpuTimer2Regs	CPUTIMER_REGS	CPUTIMER2_BASE	0x0000_0C10	YES	-	-	YES	-	-
PieCtrlRegs	PIE_CTRL_REGS	PIECTRL_BASE	0x0000_0CE0	YES	-	-	YES	-	-
PieVectTableMain	PIE_VECT_TABLE	PIEVECTTABLEMAIN_BASE	0x0000_0D00	YES	-	-	YES	-	-
PieVectTableExtension	PIE_VECT_TABLE	PIEVECTTABLEEXTENSION_BASE	0x0000_0E00	YES	-	-	YES	-	-
WdRegs	WD_REGS	WD_BASE	0x0000_7000	YES	-	-	YES	-	YES
NmiIntruptRegs	NMI_INTRUPT_REGS	NMI_BASE	0x0000_7060	YES	-	-	YES	-	YES
XintRegs	XINT_REGS	XINT_BASE	0x0000_7070	YES	-	-	YES	-	YES
SyncSocRegs	SYNC_SOC_REGS	SYNCSOC_BASE	0x0000_78F8	YES	-	-	-	-	YES
Cpu1DmaClasrcSelRegs, Cpu2DmaClasrcSelRegs	CPU1_DMA_CLA_SRC_SEL_REGS, CPU2_DMA_CLA_SRC_SEL_REGS	CPU1DMACLASRCSEL_BASE, CPU2DMACLASRCSEL_BASE	0x0000_7980	YES	-	-	YES	-	YES
DevCfgRegs	DEV_CFG_REGS	DEVCFG_BASE	0x0005_D000	YES	-	-	YES	-	YES
ClkCfgRegs	CLK_CFG_REGS	CLKCFG_BASE	0x0005_D200	YES	-	-	YES	-	YES
Cpu1SysRegs, Cpu2SysRegs	CPU1_SYS_REGS, CPU2_SYS_REGS	CPU1SYS_BASE, CPU2SYS_BASE	0x0005_D300	YES	-	-	YES	-	YES
Cpu1SysStatusRegs, Cpu2SysStatusRegs	CPU1_SYS_STATUS_REGS, CPU2_SYS_STATUS_REGS	CPU1SYSSTATUS_BASE, CPU2SYSSTATUS_BASE	0x0005_D400	YES	-	-	YES	-	YES
Cpu1PeriphAcRegs, Cpu2PeriphAcRegs	CPU1_PERIPH_AC_REGS, CPU2_PERIPH_AC_REGS	CPU1PERIPHAC_BASE, CPU2PERIPHAC_BASE	0x0005_D500	YES	-	-	YES	-	YES
MemCfgRegs	MEM_CFG_REGS	MEMCFG_BASE	0x0005_F400	YES	-	-	YES	-	YES

**Table 3-16. SYSCTRL Base Address Table (continued)**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	CPU2	CPU2.DMA	Pipeline Protected
Instance	Structure								
AccessProtectionRegs	<a href="#">ACCESS_PROTECTION_REGS</a>	ACCESSPROTECTION_BASE	0x0005_F500	YES	-	-	YES	-	YES
MemoryErrorRegs	<a href="#">MEMORY_ERROR_REGS</a>	MEMORYERROR_BASE	0x0005_F540	YES	-	-	YES	-	YES
RomWaitStateRegs	<a href="#">ROM_WAIT_STATE_REGS</a>	ROMWAITSTATE_BASE	0x0005_F580	YES	-	-	YES	-	YES
TestErrorRegs	<a href="#">TEST_ERROR_REGS</a>	TESTERROR_BASE	0x0005_F590	YES	-	-	YES	-	YES
UidRegs	<a href="#">UID_REGS</a>	UID_BASE	0x0007_2168	YES	-	-	-	-	-

### 3.18.2 LFU Base Address Table

**Table 3-17. LFU Base Address Table**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	CPU2	CPU2.DMA	Pipeline Protected
Instance	Structure								
Cpu1LfuRegs, Cpu2LfuRegs	<a href="#">CPU1_LFU_REGS</a> , <a href="#">CPU2_LFU_REGS</a>	CPU1LFU_BASE, CPU2LFU_BASE	0x0000_7FE0	YES	-	YES	YES	-	YES

### 3.18.3 CPUTIMER\_REGS Registers

Table 3-18 lists the memory-mapped registers for the CPUTIMER\_REGS registers. All register offset addresses not listed in Table 3-18 should be considered as reserved locations and the register contents should not be modified.

**Table 3-18. CPUTIMER\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	TIM	CPU-Timer, Counter Register		<a href="#">Go</a>
2h	PRD	CPU-Timer, Period Register		<a href="#">Go</a>
4h	TCR	CPU-Timer, Control Register		<a href="#">Go</a>
6h	TPR	CPU-Timer, Prescale Register		<a href="#">Go</a>
7h	TPRH	CPU-Timer, Prescale Register High		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 3-19 shows the codes that are used for access types in this section.

**Table 3-19. CPUTIMER\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
Reset or Default Value		
-n		Value after reset or the default value

### 3.18.3.1 TIM Register (Offset = 0h) [Reset = 0000FFFFh]

TIM is shown in [Figure 3-24](#) and described in [Table 3-20](#).

Return to the [Summary Table](#).

CPU-Timer, Counter Register

**Figure 3-24. TIM Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MSW																LSW															
R/W-0h																R/W-FFFFh															

**Table 3-20. TIM Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	MSW	R/W	0h	<p>CPU-Timer Counter Registers</p> <p>The TIMH register holds the high 16 bits of the current 32-bit count of the timer. The TIMH:TIM decrements by one every (TDDRH:TDDR+1) clock cycles, where TDDRH:TDDR is the timer prescale dividedown value. When the TIMH:TIM decrements to zero, the TIMH:TIM register is reloaded with the period value contained in the PRDH:PRD registers. The timer interrupt (TINT) signal is generated.</p> <p>Reset type: SYSRSn</p>
15-0	LSW	R/W	FFFFh	<p>CPU-Timer Counter Registers</p> <p>The TIM register holds the low 16 bits of the current 32-bit count of the timer. The TIMH:TIM decrements by one every (TDDRH:TDDR+1) clock cycles, where TDDRH:TDDR is the timer prescale dividedown value. When the TIMH:TIM decrements to zero, the TIMH:TIM register is reloaded with the period value contained in the PRDH:PRD registers. The timer interrupt (TINT) signal is generated.</p> <p>Reset type: SYSRSn</p>

### 3.18.3.2 PRD Register (Offset = 2h) [Reset = 0000FFFFh]

PRD is shown in [Figure 3-25](#) and described in [Table 3-21](#).

Return to the [Summary Table](#).

CPU-Timer, Period Register

**Figure 3-25. PRD Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MSW																LSW															
R/W-0h																R/W-FFFFh															

**Table 3-21. PRD Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	MSW	R/W	0h	CPU-Timer Period Registers The PRDH register holds the high 16 bits of the 32-bit period. When the TIMH:TIM decrements to zero, the TIMH:TIM register is reloaded with the period value contained in the PRDH:PRD registers, at the start of the next timer input clock cycle (the output of the prescaler). The PRDH:PRD contents are also loaded into the TIMH:TIM when you set the timer reload bit (TRB) in the Timer Control Register (TCR). Reset type: SYSRSn
15-0	LSW	R/W	FFFFh	CPU-Timer Period Registers The PRD register holds the low 16 bits of the 32-bit period. When the TIMH:TIM decrements to zero, the TIMH:TIM register is reloaded with the period value contained in the PRDH:PRD registers, at the start of the next timer input clock cycle (the output of the prescaler). The PRDH:PRD contents are also loaded into the TIMH:TIM when you set the timer reload bit (TRB) in the Timer Control Register (TCR). Reset type: SYSRSn

### 3.18.3.3 TCR Register (Offset = 4h) [Reset = 0001h]

TCR is shown in [Figure 3-26](#) and described in [Table 3-22](#).

Return to the [Summary Table](#).

CPU-Timer, Control Register

**Figure 3-26. TCR Register**

15		14		13		12		11		10		9		8	
TIF		TIE		RESERVED				FREE		SOFT		RESERVED			
R/W1C-0h		R/W-0h		R-0h				R/W-0h		R/W-0h		R-0h			
7		6		5		4		3		2		1		0	
RESERVED				TRB		TSS		RESERVED							
R-0h				R/W-0h		R/W-0h		R-1h							

**Table 3-22. TCR Register Field Descriptions**

Bit	Field	Type	Reset	Description
15	TIF	R/W1C	0h	CPU-Timer Overflow Flag. TIF indicates whether a timer overflow has happened since TIF was last cleared. TIF is not cleared automatically and does not need to be cleared to enable the next timer interrupt. Reset type: SYSRSn 0h (R/W) = The CPU-Timer has not decremented to zero. Writes of 0 are ignored. 1h (R/W) = This flag gets set when the CPU-timer decrements to zero. Writing a 1 to this bit clears the flag.
14	TIE	R/W	0h	CPU-Timer Interrupt Enable. Reset type: SYSRSn 0h (R/W) = The CPU-Timer interrupt is disabled. 1h (R/W) = The CPU-Timer interrupt is enabled. If the timer decrements to zero, and TIE is set, the timer asserts its interrupt request.
13-12	RESERVED	R	0h	Reserved
11	FREE	R/W	0h	If the FREE bit is set to 1, then, upon a software breakpoint, the timer continues to run. If FREE is 0, then the SOFT bit controls the emulation behavior. Reset type: SYSRSn 0h (R/W) = Stop after the next decrement of the TIMH:TIM (hard stop) (SOFT bit controls the emulation behavior) 1h (R/W) = Free Run (SOFT bit is don't care, counter is free running)
10	SOFT	R/W	0h	If the FREE bit is set to 1, then, upon a software breakpoint, the timer continues to run (that is, free runs). In this case, SOFT is a don't care. But if FREE is 0, then SOFT takes effect. Reset type: SYSRSn 0h (R/W) = Stop after the next decrement of the TIMH:TIM (hard stop). (ONLY if FREE=0, if FREE=1 this bit is don't care) 1h (R/W) = Stop after the TIMH:TIM decrements to 0 (soft stop) In the SOFT STOP mode, the timer generates an interrupt before shutting down (since reaching 0 is the interrupt causing condition). (ONLY if FREE=0, if FREE=1 this bit is don't care)
9-6	RESERVED	R	0h	Reserved

**Table 3-22. TCR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
5	TRB	R/W	0h	Timer reload Reset type: SYSRSn 0h (R/W) = The TRB bit is always read as zero. Writes of 0 are ignored. 1h (R/W) = When you write a 1 to TRB, the TIMH:TIM is loaded with the value in the PRDH:PRD, and the prescaler counter (PSCH:PSC) is loaded with the value in the timer dividedown register (TDDRH:TDDR).
4	TSS	R/W	0h	CPU-Timer stop status bit. TSS is a 1-bit flag that stops or starts the CPU-timer. Reset type: SYSRSn 0h (R/W) = Reads of 0 indicate the CPU-timer is running. To start or restart the CPU-timer, set TSS to 0. At reset, TSS is cleared to 0 and the CPU-timer immediately starts. 1h (R/W) = Reads of 1 indicate that the CPU-timer is stopped. To stop the CPU-timer, set TSS to 1.
3-0	RESERVED	R	1h	Reserved

### 3.18.3.4 TPR Register (Offset = 6h) [Reset = 0000h]

TPR is shown in [Figure 3-27](#) and described in [Table 3-23](#).

Return to the [Summary Table](#).

CPU-Timer, Prescale Register

**Figure 3-27. TPR Register**

15	14	13	12	11	10	9	8
PSC							
R-0h							
7	6	5	4	3	2	1	0
TDDR							
R/W-0h							

**Table 3-23. TPR Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-8	PSC	R	0h	CPU-Timer Prescale Counter. These bits hold the current prescale count for the timer. For every timer clock source cycle that the PSCH:PSC value is greater than 0, the PSCH:PSC decrements by one. One timer clock (output of the timer prescaler) cycle after the PSCH:PSC reaches 0, the PSCH:PSC is loaded with the contents of the TDDRH:TDDR, and the timer counter register (TIMH:TIM) decrements by one. The PSCH:PSC is also reloaded whenever the timer reload bit (TRB) is set by software. The PSCH:PSC can be checked by reading the register, but it cannot be set directly. It must get its value from the timer divide-down register (TDDRH:TDDR). At reset, the PSCH:PSC is set to 0. Reset type: SYSRSn
7-0	TDDR	R/W	0h	CPU-Timer Divide-Down. Every (TDDRH:TDDR + 1) timer clock source cycles, the timer counter register (TIMH:TIM) decrements by one. At reset, the TDDRH:TDDR bits are cleared to 0. To increase the overall timer count by an integer factor, write this factor minus one to the TDDRH:TDDR bits. When the prescaler counter (PSCH:PSC) value is 0, one timer clock source cycle later, the contents of the TDDRH:TDDR reload the PSCH:PSC, and the TIMH:TIM decrements by one. TDDRH:TDDR also reloads the PSCH:PSC whenever the timer reload bit (TRB) is set by software. Reset type: SYSRSn

### 3.18.3.5 TPRH Register (Offset = 7h) [Reset = 0000h]

TPRH is shown in [Figure 3-28](#) and described in [Table 3-24](#).

Return to the [Summary Table](#).

CPU-Timer, Prescale Register High

**Figure 3-28. TPRH Register**

15	14	13	12	11	10	9	8
PSCH							
R-0h							
7	6	5	4	3	2	1	0
TDDRH							
R/W-0h							

**Table 3-24. TPRH Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-8	PSCH	R	0h	See description of TIMERxTPR. Reset type: SYSRSn
7-0	TDDRH	R/W	0h	See description of TIMERxTPR. Reset type: SYSRSn

### 3.18.4 PIE\_CTRL\_REGS Registers

Table 3-25 lists the memory-mapped registers for the PIE\_CTRL\_REGS registers. All register offset addresses not listed in Table 3-25 should be considered as reserved locations and the register contents should not be modified.

**Table 3-25. PIE\_CTRL\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	PIECTRL	ePIE Control Register		<a href="#">Go</a>
1h	PIEACK	Interrupt Acknowledge Register		<a href="#">Go</a>
2h	PIEIER1	Interrupt Group 1 Enable Register		<a href="#">Go</a>
3h	PIEIFR1	Interrupt Group 1 Flag Register		<a href="#">Go</a>
4h	PIEIER2	Interrupt Group 2 Enable Register		<a href="#">Go</a>

(continued)**

Access Type	Code	Description
-n		Value after reset or the default value

### 3.18.4.1 PIECTRL Register (Offset = 0h) [Reset = 0000h]

PIECTRL is shown in [Figure 3-29](#) and described in [Table 3-27](#).

Return to the [Summary Table](#).

ePIE Control Register

**Figure 3-29. PIECTRL Register**

15	14	13	12	11	10	9	8
PIEVECT							
R-0h							
7	6	5	4	3	2	1	0
PIEVECT							ENPIE
R-0h							R/W-0h

**Table 3-27. PIECTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-1	PIEVECT	R	0h	These bits indicate the vector address of the vector fetched from the ePIE vector table. The least significant bit of the address is ignored and only bits 1 to 15 of the address are shown. The vector value can be read by the user to determine which interrupt generated the vector fetch. Note: When a NMI is serviced, the PIEVECT bit-field does not reflect the vector as it does for other interrupts. Reset type: SYSRSn
0	ENPIE	R/W	0h	Enable vector fetching from ePIE block. This bit must be set to 1 for peripheral interrupts to work. All ePIE registers (PIEACK, PIEIFR, PIEIER) can be accessed even when the ePIE block is disabled. Reset type: SYSRSn

### 3.18.4.2 PIEACK Register (Offset = 1h) [Reset = 0000h]

PIEACK is shown in [Figure 3-30](#) and described in [Table 3-28](#).

Return to the [Summary Table](#).

#### Acknowledge Register

When an interrupt propagates from the ePIE to a CPU interrupt line, the interrupt group's PIEACK bit is set. This prevents other interrupts in that group from propagating to the CPU while the first interrupt is handled. Writing a 1 to a PIEACK bit clears it and allows another interrupt from the corresponding group to propagate. ISRs for PIE interrupts should clear the group's PIEACK bit before returning from the interrupt.

Writes of 0 are ignored.

### 3.18.4.3 PIEIER1 Register (Offset = 2h) [Reset = 0000h]

PIEIER1 is shown in [Figure 3-31](#) and described in [Table 3-29](#).

Return to the [Summary Table](#).

#### Interrupt Group 1 Enable Register

These register bits individually enable an interrupt within a group. They behave very much like the bits in the CPU interrupt enable register (IER).

Setting a bit to 1 allows the corresponding interrupt to propagate to the CPU.

Setting a bit to 0 prevents the corresponding interrupt from propagating. Note that a peripheral interrupt signal can still set the PIEIFR bit for the disabled interrupt.

0	INTx1	R/W	0h	Enable for Interrupt 1.1 Reset type: SYSRSn

### 3.18.4.4 PIEIFR1 Register (Offset = 3h) [Reset = 0000h]

PIEIFR1 is shown in [Figure 3-32](#) and described in [Table 3-30](#).

Return to the [Summary Table](#).

#### Interrupt Group 1 Flag Register

These register bits indicate whether each interrupt in the group is currently pending. They behave very much like the bits in the CPU interrupt flag register (IFR).

When a peripheral sends an interrupt, the corresponding bit is set. This bit is cleared when the interrupt propagates to the CPU, at which point PIEACK is set.

NOTE: PIE IFR flags can be written to create software interrupts.

The IFR flag will be cleared on a write of zero. Hence, when the intent is to fire an interrupt it may cause inadvertent cancellation of other interrupts. It is recommended to use this only for testing or with extreme caution in the application code. Reading the PIE IFR registers is safe.

**Figure 3-32. PIEIFR1 Register**

### 3.18.4.10 PIEIFR4 Register (Offset = 9h) [Reset = 0000h]

PIEIFR4 is shown in [Figure 3-38](#) and described in [Table 3-36](#).

Return to the [Summary Table](#).

#### Interrupt Group 4 Flag Register

These register bits indicate whether each interrupt in the group is currently pending. They behave very much like the bits in the CPU interrupt flag register (IFR).

When a peripheral sends an interrupt, the corresponding bit is set. This bit is cleared when the interrupt propagates to the CPU, at which point PIEACK is set.

NOTE: PIE IFR flags can be written to create software interrupts.

The IFR flag will be cleared on a write of zero. Hence, when the intent is to fire an interrupt it may cause inadvertent cancellation of other interrupts. It is recommended to use this only for testing or with extreme caution in the application code. Reading the PIE IFR registers is safe.

### 3.18.4.18 PIEIFR8 Register (Offset = 11h) [Reset = 0000h]

PIEIFR8 is shown in [Figure 3-46](#) and described in [Table 3-44](#).

Return to the [Summary Table](#).

#### Interrupt Group 8 Flag Register

These register bits indicate whether each interrupt in the group is currently pending. They behave very much like the bits in the CPU interrupt flag register (IFR).

When a peripheral sends an interrupt, the corresponding bit is set. This bit is cleared when the interrupt propagates to the CPU, at which point PIEACK is set.

NOTE: PIE IFR flags can be written to create software interrupts.

The IFR flag will be cleared on a write of zero. Hence, when the intent is to fire an interrupt it may cause inadvertent cancellation of other interrupts. It is recommended to use this only for testing or with extreme caution in the application code. Reading the PIE IFR registers is safe.

### 3.18.4.19 PIEIER9 Register (Offset = 12h) [Reset = 0000h]

PIEIER9 is shown in [Figure 3-47](#) and described in [Table 3-45](#).

Return to the [Summary Table](#).

#### Interrupt Group 9 Enable Register

These register bits individually enable an interrupt within a group. They behave very much like the bits in the CPU interrupt enable register (IER).

Setting a bit to 1 allows the corresponding interrupt to propagate to the CPU.

Setting a bit to 0 prevents the corresponding interrupt from propagating. Note that a peripheral interrupt signal can still set the PIEIFR bit for the disabled interrupt.

### 3.18.4.26 PIEIFR12 Register (Offset = 19h) [Reset = 0000h]

PIEIFR12 is shown in [Figure 3-54](#) and described in [Table 3-52](#).

Return to the [Summary Table](#).

#### Interrupt Group 12 Flag Register

These register bits indicate whether each interrupt in the group is currently pending. They behave very much like the bits in the CPU interrupt flag register (IFR).

When a peripheral sends an interrupt, the corresponding bit is set. This bit is cleared when the interrupt propagates to the CPU, at which point PIEACK is set.

NOTE: PIE IFR flags can be written to create software interrupts.

The IFR flag will be cleared on a write of zero. Hence, when the intent is to fire an interrupt it may cause inadvertent cancellation of other interrupts. It is recommended to use this only for testing or with extreme caution in the application code. Reading the PIE IFR registers is safe.

### 3.18.5 WD\_REGS Registers

Table 3-53 lists the memory-mapped registers for the WD\_REGS registers. All register offset addresses not listed in Table 3-53 should be considered as reserved locations and the register contents should not be modified.

**Table 3-53. WD\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
22h	SCSR	System Control & Status Register	EALLOW	<a href="#">Go</a>
23h	WDCNTR	Watchdog Counter Register	EALLOW	<a href="#">Go</a>
25h	WDKEY	Watchdog Reset Key Register	EALLOW	<a href="#">Go</a>
28h	SYNCBUSYWD	SYNCBUSY status for Watchdog Register	EALLOW	<a href="#">Go</a>
29h	WDCR	Watchdog Control Register	EALLOW	<a href="#">Go</a>
2Ah	WDWCR	Watchdog Windowed Control Register	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 3-54 shows the codes that are used for access types in this section.

**Table 3-54. WD\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1S	W1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 3.18.5.1 SCSR Register (Offset = 22h) [Reset = 0005h]

SCSR is shown in [Figure 3-55](#) and described in [Table 3-55](#).

Return to the [Summary Table](#).

System Control & Status Register

**Figure 3-55. SCSR Register**

15	14	13	12	11	10	9	8
RESERVED							
R-0-0h							
7	6	5	4	3	2	1	0
RESERVED					WDINTS	WDENINT	WDOVERRIDE
R-0-0h					R-1h	R/W-0h	R/W1S-1h

**Table 3-55. SCSR Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-3	RESERVED	R-0	0h	Reserved
2	WDINTS	R	1h	Watchdog Interrupt Status This bit indicates the state of the active-low watchdog interrupt signal (synchronized to SYSCLK). If the watchdog interrupt is used to wake the system from a low-power mode, then that mode should only be entered while this bit is high. Likewise, this bit must go high before the watchdog can be safely disabled and re-enabled. Reset type: SYSRSn
1	WDENINT	R/W	0h	Watchdog Interrupt Enable/Reset Disable This bit determines whether the watchdog triggers an interrupt (WAKE/WDOG) or a reset (WDRS) when the counter expires. Reset type: SYSRSn
0	WDOVERRIDE	R/W1S	1h	Watchdog Enable Lock Writing a 1 to this bit clears it and locks the WDDIS bit in the WDCR register. The bit will remain in this state until the next system reset. Reads of this bit return its current value. Writing a 0 to this bit has no effect. Reset type: SYSRSn

### 3.18.5.2 WDCNTR Register (Offset = 23h) [Reset = 0000h]

WDCNTR is shown in [Figure 3-56](#) and described in [Table 3-56](#).

Return to the [Summary Table](#).

Watchdog Counter Register

**Figure 3-56. WDCNTR Register**

7	6	5	4	3	2	1	0
WDCNTR							
R-0h							

**Table 3-56. WDCNTR Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-8	RESERVED	R-0	0h	Reserved
7-0	WDCNTR	R	0h	Watchdog Counter These bits contain the current value of the watchdog counter. This counter increments with each WDCLK (INTOSC1) cycle. If the counter overflows, either an interrupt or a reset is generated based on the value of the WDINTEN bit in the SCSR register. If the correct value is written to the WDKEY register, this counter is reset to zero. Reset type: IORSn

### 3.18.5.3 WDKEY Register (Offset = 25h) [Reset = 0000h]

WDKEY is shown in [Figure 3-57](#) and described in [Table 3-57](#).

Return to the [Summary Table](#).

Watchdog Reset Key Register

**Figure 3-57. WDKEY Register**

Bit	Field	Type	Reset	Description
15-2	RESERVED	R-0	0h	Reserved
1	WDCR	R	0h	This status bit indicates write to the register is in progress 0 : Not BUSY - No synchronization in progress 1 : BUSY - Synchronization is in progress Reset type: SYSRSn
0	BUSY	R	0h	This status bit indicates write to any of the following registers (OR_REDUCE) is in progress or not. WDCR 0 : Not BUSY - No synchronization in progress 1 : BUSY - Synchronization is in progress Reset type: SYSRSn

### 3.18.5.5 WDCR Register (Offset = 29h) [Reset = 0000h]

WDCR is shown in [Figure 3-59](#) and described in [Table 3-59](#).

Return to the [Summary Table](#).

#### Watchdog Control Register

This memory mapped register requires a delay of 69 SYSCLK cycles between subsequent writes to the register, otherwise a second write can be lost. This delay can be realized by adding 69 NOP instructions.

**Figure 3-59. WDCR Register**

15	14	13	12	11	10	9	8
RESERVED				WDPRECLKDIV			
R-0-0h				R/W-0h			
7	6	5	4	3	2	1	0
RESERVED	WDDIS	WDCHK		WDPS			
R/W1S-0h	R/W-0h	R-0/W-0h		R/W-0h			

**Table 3-59. WDCR Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-12	RESERVED	R-0	0h	Reserved
11-8	WDPRECLKDIV	R/W	0h	Watchdog Clock Pre-divider These bits determine the watchdog clock pre-divider, which is the first of the two dividers between INTOSC1 and the watchdog counter clock (WDCLK). The frequency of WDCLK is given by the formulas: $PREDIVCLK = INTOSC1 / \text{Pre-divider}$ $WDCLK = PREDIVCLK / \text{Prescaler}$ The watchdog reset or interrupt pulse is 512 INTOSC1 cycles long, so the counter period must be longer. To guarantee this, the product of the prescaler and pre-divider must be greater than or equal to four. The default pre-divider value is 512. Reset type: IORSn
7	RESERVED	R/W1S	0h	Reserved
6	WDDIS	R/W	0h	Watchdog Disable Setting this bit disables the watchdog module. Clearing this bit enables the watchdog module. This bit can be locked by the WDOVERRIDE bit in the SCSR register. The watchdog is enabled on reset. Reset type: IORSn
5-3	WDCHK	R-0/W	0h	Watchdog Check Bits During any write to this register, these bits must be written with the value 101 (binary). Writing any other value will immediately trigger the watchdog reset or interrupt. Reset type: IORSn
2-0	WDPS	R/W	0h	Watchdog Clock Prescaler These bits determine the watchdog clock prescaler, which is the second of the two dividers between INTOSC1 and the watchdog counter clock (WDCLK). The frequency of WDCLK is given by the formulas: $PREDIVCLK = INTOSC1 / \text{Pre-divider}$ $WDCLK = PREDIVCLK / \text{Prescaler}$ The watchdog reset or interrupt pulse is 512 INTOSC1 cycles long, so the counter period must be longer. To guarantee this, the product of the prescaler and pre-divider must be greater than or equal to four. The default prescaler value is 1. Reset type: IORSn

### 3.18.5.6 WDWCR Register (Offset = 2Ah) [Reset = 0000h]

WDWCR is shown in [Figure 3-60](#) and described in [Table 3-60](#).

Return to the [Summary Table](#).

Watchdog Windowed Control Register

NMIWDCNT							
R-0h							
7	6	5	4	3	2	1	0
NMIWDCNT							
R-0h							

**Table 3-67. NMIWDCNT Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-0	NMIWDCNT	R	0h	<p>NMI Watchdog Counter: This 16-bit incremental counter will start incrementing whenever any one of the enabled FAIL flags are set. If the counter reaches the period value, an NMIRSn signal is fired which will then resets the system. The counter will reset to zero when it reaches the period value and will then restart counting if any of the enabled FAIL flags are set.</p> <p>If no enabled FAIL flag is set, then the counter will reset to zero and remain at zero until an enabled FAIL flag is set.</p> <p>Normally, the software would respond to the NMI interrupt generated and clear the offending FLAG(s) before the NMI watchdog triggers a reset. In some situations, the software may decide to allow the watchdog to reset the device anyway.</p> <p>The counter is clocked at the SYSCLKOUT rate.</p> <p>Reset type: SYSRSn</p>

### 3.18.6.6 NMIWDPRD Register (Offset = 5h) [Reset = FFFFh]

NMIWDPRD is shown in [Figure 3-66](#) and described in [Table 3-68](#).

Return to the [Summary Table](#).

0	ERRORCTL	R/WOnce	0h	0, Writes to ERRORCTL register allowed. 1, Writes to ERRORCTL register is blocked. Writes of 0 to this bit has no effect. Write of 1 will set this bit, cleared only on a SYSRSn. Reset type: SYSRSn

### 3.18.7 XINT\_REGS Registers

Table 3-75 lists the memory-mapped registers for the XINT\_REGS registers. All register offset addresses not listed in Table 3-75 should be considered as reserved locations and the register contents should not be modified.

**Table 3-75. XINT\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	XINT1CR	XINT1 configuration register		<a href="#">Go</a>
1h	XINT2CR	XINT2 configuration register		<a href="#">Go</a>
2h	XINT3CR	XINT3 configuration register		<a href="#">Go</a>
3h	XINT4CR	XINT4 configuration register		<a href="#">Go</a>
4h	XINT5CR	XINT5 configuration register		<a href="#">Go</a>
8h	XINT1CTR	XINT1 counter register		<a href="#">Go</a>
9h	XINT2CTR	XINT2 counter register		<a href="#">Go</a>
Ah	XINT3CTR	XINT3 counter register		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 3-76 shows the codes that are used for access types in this section.

**Table 3-76. XINT\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 3.18.7.1 XINT1CR Register (Offset = 0h) [Reset = 0000h]

XINT1CR is shown in [Figure 3-73](#) and described in [Table 3-77](#).

Return to the [Summary Table](#).

XINT1 configuration register

INTCTR							
R-0h							
7	6	5	4	3	2	1	0
INTCTR							
R-0h							

**Table 3-82. XINT1CTR Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-0	INTCTR	R	0h	This is a free running 16-bit up-counter that is clocked at the SYSCLKOUT rate. The counter value is reset to 0x0000 when a valid interrupt edge is detected and then continues counting until the next valid interrupt edge is detected. The counter must only be reset by the selected POLARITY edge as selected in the respective interrupt control register. When the interrupt is disabled, the counter will stop. The counter is a free-running counter and will wrap around to zero when the max value is reached. The counter is a read only register and can only be reset to zero by a valid interrupt edge or by reset. Reset type: SYSRSn

### 3.18.7.7 XINT2CTR Register (Offset = 9h) [Reset = 0000h]

XINT2CTR is shown in [Figure 3-79](#) and described in [Table 3-83](#).

Return to the [Summary Table](#).

XINT2 counter register

R-0h							
7	6	5	4	3	2	1	0
INTCTR							
R-0h							

**Table 3-84. XINT3CTR Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-0	INTCTR	R	0h	This is a free running 16-bit up-counter that is clocked at the SYSCLKOUT rate. The counter value is reset to 0x0000 when a valid interrupt edge is detected and then continues counting until the next valid interrupt edge is detected. The counter must only be reset by the selected POLARITY edge as selected in the respective interrupt control register. When the interrupt is disabled, the counter will stop. The counter is a free-running counter and will wrap around to zero when the max value is reached. The counter is a read only register and can only be reset to zero by a valid interrupt edge or by reset. Reset type: SYSRSn

### 3.18.8 SYNC\_SOC\_REGS Registers

Table 3-85 lists the memory-mapped registers for the SYNC\_SOC\_REGS registers. All register offset addresses not listed in Table 3-85 should be considered as reserved locations and the register contents should not be modified.

**Table 3-85. SYNC\_SOC\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	SYNCSELECT	Sync Input and Output Select Register	EALLOW	<a href="#">Go</a>
2h	ADCSOCOUTSELECT	External ADCSOC Select Register (PWM1-16)	EALLOW	<a href="#">Go</a>
4h	ADCSOCOUTSELECT1	External ADCSOC Select Register (PWM17-32)	EALLOW	<a href="#">Go</a>
6h	SYNCSOCLOCK	SYNCSEL and EXTADCSOC Select Lock register	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 3-86 shows the codes that are used for access types in this section.

**Table 3-86. SYNC\_SOC\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WOnce	W Once	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 3.18.8.1 SYNCSELECT Register (Offset = 0h) [Reset = E003FFFFh]

SYNCSELECT is shown in [Figure 3-81](#) and described in [Table 3-87](#).

Return to the [Summary Table](#).

### 3.18.9 CPU1\_DMA\_CLA\_SRC\_SEL\_REGS Registers

Table 3-91 lists the memory-mapped registers for the CPU1\_DMA\_CLA\_SRC\_SEL\_REGS registers. All register offset addresses not listed in Table 3-91 should be considered as reserved locations and the register contents should not be modified.

**Table 3-91. CPU1\_DMA\_CLA\_SRC\_SEL\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	CLA1TASKSRCSELLOCK	CLA1 Task Trigger Source Select Lock Register	EALLOW	<a href="#">Go</a>
4h	DMACHSRCSELLOCK	DMA Channel Trigger Source Select Lock Register	EALLOW	<a href="#">Go</a>
6h	CLA1TASKSRCSEL1	CLA1 Task Trigger Source Select Register-1	EALLOW	<a href="#">Go</a>
8h	CLA1TASKSRCSEL2	CLA1 Task Trigger Source Select Register-2	EALLOW	<a href="#">Go</a>
16h	DMACHSRCSEL1	DMA Channel Trigger Source Select Register-1	EALLOW	<a href="#">Go</a>
18h	DMACHSRCSEL2	DMA Channel Trigger Source Select Register-2	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 3-92 shows the codes that are used for access types in this section.

**Table 3-92. CPU1\_DMA\_CLA\_SRC\_SEL\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
WOnce	WOnce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 3.18.9.1 CLA1TASKSRCSELLOCK Register (Offset = 0h) [Reset = 0000000h]

CLA1TASKSRCSELLOCK is shown in [Figure 3-85](#) and described in [Table 3-93](#).

Return to the [Summary Table](#).

### 3.18.10 CPU2\_DMA\_CLA\_SRC\_SEL\_REGS Registers

Table 3-99 lists the memory-mapped registers for the CPU2\_DMA\_CLA\_SRC\_SEL\_REGS registers. All register offset addresses not listed in Table 3-99 should be considered as reserved locations and the register contents should not be modified.

**Table 3-99. CPU2\_DMA\_CLA\_SRC\_SEL\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
4h	DMACHSRCSELLOCK	DMA Channel Trigger Source Select Lock Register	EALLOW	<a href="#">Go</a>
16h	DMACHSRCSEL1	DMA Channel Trigger Source Select Register-1	EALLOW	<a href="#">Go</a>
18h	DMACHSRCSEL2	DMA Channel Trigger Source Select Register-2	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 3-100 shows the codes that are used for access types in this section.

**Table 3-100. CPU2\_DMA\_CLA\_SRC\_SEL\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WOnce	W Once	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 3.18.10.1 DMACHSRCSELLOCK Register (Offset = 4h) [Reset = 0000000h]

DMACHSRCSELLOCK is shown in [Figure 3-91](#) and described in [Table 3-101](#).

Return to the [Summary Table](#).

Complex bit access types are encoded to fit into small table cells. [Table 3-105](#) shows the codes that are used for access types in this section.

**Table 3-105. DEV\_CFG\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s

**Table 3-105. DEV\_CFG\_REGS Access Type Codes (continued)**

Access Type	Code	Description
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
WOnce	W Once	Write Write once
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 3.18.11.1 DEVCFGLOCK1 Register (Offset = 0h) [Reset = 0000000h]

DEVCFGLOCK1 is shown in [Figure 3-94](#) and described in [Table 3-106](#).

Return to the [Summary Table](#).

Lock bit for CPUSELx registers

The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed

Note:

Any SOnce bit in this register, once set can only be cleared through a CPU1.SYSRSn. Write of 0 to any bit of this register has no effect

### 3.18.11.2 DEVCFGLOCK2 Register (Offset = 2h) [Reset = 0000000h]

DEVCFGLOCK2 is shown in [Figure 3-95](#) and described in [Table 3-107](#).

Return to the [Summary Table](#).

Lock bit for DEVCFG registers

Note:

[1] The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed

[2] Any SOnce bit in this register, once set can only be cleared through a CPU1.SYSRSn. Write of 0 to any bit of this register has no effect

### 3.18.11.15 MCUCNFLOCK Register (Offset = 8Ch) [Reset = 0000000h]

MCUCNFLOCK is shown in [Figure 3-108](#) and described in [Table 3-120](#).

Return to the [Summary Table](#).

Lock bit for MCUCNFx registers

The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed

Note:

Any SOnce bit in this register, once set can only be cleared through a CPU1.SYSRSn. Write of 0 to any bit of this register has no effect

**Table 3-145. SOFTPRES40 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	JTAG_nTRST_Key	R-0/W	0h	0xdcaf : Writing this Key value along with 0xA in JTAG_nTRST field causes a JTAG nTRST pulse generated to the JTAG state machine. Any other write does not have impact on the JTAG state machine, bits are self clear when Reset is asserted to JTAG state machine. Reset type: CPU1.SYSRSn, TRSTn
15-4	RESERVED	R-0	0h	Reserved
3-0	JTAG_nTRST	R/W	0h	1010: Writing '1010' along with valid key in JTAG_nTRST_Key takes JTAG TAP to TLR state. Writing any other value or mismatched key does not have any effect on the JTAG TAP reset behavior. Once Reset to JTAG domain is asserted then this field is reset back to 0. Reset type: CPU1.SYSRSn, TRSTn

### 3.18.11.41 CPUSEL0 Register (Offset = F0h) [Reset = 0000000h]

CPUSEL0 is shown in [Figure 3-134](#) and described in [Table 3-146](#).

**Table 3-168. CPU2RESCTL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	KEY	R-0/W	0h	Write to this register succeeds only if this field is written with a value of 0xa5a5 Note: [1] Due to this KEY, only 32-bit writes will succeed (provided the KEY matches). 16-bit writes to the upper or lower half of this register will be ignored Reset type: CPU1.SYSRSn
15-1	RESERVED	R-0	0h	Reserved
0	RESET	R/W	1h	This bit controls the reset input of CPU2 core. 1: CPU2 is held in reset (CPU2.RSn = 0) 0: CPU2 reset is deactivated (CPU2.RSn = 1) Note: [1] If CPU2 is not used at-all by an application, it's advisable to put CPU2 in IDLE mode rather than in reset to save on active power component on the CPU2 subsystem. This is because, all clocks keep toggling when reset is active on the CPU2 sub-system. [2] If CPU2 is in Standby mode, writing to this bit will have no effect. CPU2 may be reset by any Chip-level reset (POR, XRSn, CPU1.WDRSn, or CPU1.NMIWDRSn). Alternately CPU2 may be woken up by any configured wake-up event. Reset type: CPU1.SYSRSn

### 3.18.11.64 RSTSTAT Register (Offset = 13Eh) [Reset = 0000h]

RSTSTAT is shown in [Figure 3-157](#) and described in [Table 3-169](#).

### 3.18.12 CLK\_CFG\_REGS Registers

Table 3-177 lists the memory-mapped registers for the CLK\_CFG\_REGS registers. All register offset addresses not listed in Table 3-177 should be considered as reserved locations and the register contents should not be modified.

**Table 3-177. CLK\_CFG\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	CLKSEM	Clock Control Semaphore Register	EALLOW	<a href="#">Go</a>
2h	CLKCFGLOCK1	Lock bit for CLKCFG registers	EALLOW	<a href="#">Go</a>
8h	CLKSRCCTL1	Clock Source Control register-1	EALLOW	<a href="#">Go</a>
Ah	CLKSRCCTL2	Clock Source Control register-2	EALLOW	<a href="#">Go</a>
Ch	CLKSRCCTL3	Clock Source Control register-3	EALLOW	<a href="#">Go</a>
Eh	SYSPLLCTL1	SYSPLL Control register-1	EALLOW	<a href="#">Go</a>
14h	SYSPLLMULT	SYSPLL Multiplier register	EALLOW	<a href="#">Go</a>
16h	SYSPLLSTS	SYSPLL Status register		<a href="#">Go</a>
18h	AUXPLLCTL1	AUXPLL Control register-1	EALLOW	<a href="#">Go</a>
1Eh	AUXPLLMULT	AUXPLL Multiplier register	EALLOW	<a href="#">Go</a>
20h	AUXPLLSTS	AUXPLL Status register		<a href="#">Go</a>
22h	SYSCLKDIVSEL	System Clock Divider Select register	EALLOW	<a href="#">Go</a>
24h	AUXCLKDIVSEL	Auxillary Clock Divider Select register	EALLOW	<a href="#">Go</a>
26h	PERCLKDIVSEL	Peripheral Clock Divider Select register	EALLOW	<a href="#">Go</a>
28h	XCLKOUTDIVSEL	XCLKOUT Divider Select register	EALLOW	<a href="#">Go</a>
2Ah	CLBCLKCTL	CLB Clocking Control Register	EALLOW	<a href="#">Go</a>
2Ch	LOSPCP	Low Speed Clock Source Prescaler	EALLOW	<a href="#">Go</a>
2Eh	MDCDR	Missing Clock Detect Control Register	EALLOW	<a href="#">Go</a>
30h	X1CNT	10-bit Counter on X1 Clock		<a href="#">Go</a>
32h	XTALCR	XTAL Control Register	EALLOW	<a href="#">Go</a>
3Ah	XTALCR2	XTAL Control Register for pad init	EALLOW	<a href="#">Go</a>
3Ch	CLKFAILCFG	Clock Fail cause Configuration	EALLOW	<a href="#">Go</a>
40h	ETHERCATCLKCTL	EtherCAT Clock Control	EALLOW	<a href="#">Go</a>
42h	SYNCBUSY	Pulse Transfer Sync Busy Status register		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 3-178 shows the codes that are used for access types in this section.

**Table 3-178. CLK\_CFG\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1C	W1C	Write 1 to clear
W1S	W1S	Write 1 to set
WSonce	W Sonce	Write Set once
Reset or Default Value		

**Table 3-178. CLK\_CFG\_REGS Access Type Codes (continued)**

Access Type	Code	Description
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 3.18.12.1 CLKSEM Register (Offset = 0h) [Reset = 0000000h]

CLKSEM is shown in [Figure 3-165](#) and described in [Table 3-179](#).

Return to the [Summary Table](#).

Clock Control Semaphore Register

**Figure 3-165. CLKSEM Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

RESERVED														SEM	
R-0-0h														R/W-0h	

**Table 3-179. CLKSEM Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	KEY	R-0/W	0h	Writing the value 0xa5a5 will allow the writing of the SEM bits, else writes are ignored. Reads will return 0. Note: [1] Due to this KEY, only 32-bit writes will succeed (provided the KEY matches). 16-bit writes to the upper or lower half of this register will be ignored Reset type: N/A
15-2	RESERVED	R-0	0h	Reserved
1-0	SEM	R/W	0h	This register provides a mechanism to acquire all the CLKCFG registers (except this register) by CPU1 or CPU2. A CPU can perform read/writes to any of the CLKCFG registers (except this register) only if it owns the semaphore. Otherwise, writes are ignored and reads will return 0x0. Semaphore State Transitions: A value of 00, 10, 11 gives ownership to CPU1 A value of 01 gives ownership to CPU2. The following are the only state transitions allowed on these bits. 00,11 <-> 01 (allowed by CPU2) 00,11 <-> 10 (allowed by CPU1) If a CPU doesn't own the CLK_CFG_REGS set of registers (as defined by the state of this semaphore), reads from that CPU to all those registers return 0x0 and writes are ignore. Note that this is not true of CLKSEM register. The CLKSEM register's reads and writes are always allowed from both CPU1 and CPU2. Reset type: CPU1.SYSRSn

### 3.18.12.2 CLKCFGLOCK1 Register (Offset = 2h) [Reset = 0000000h]

CLKCFGLOCK1 is shown in [Figure 3-166](#) and described in [Table 3-180](#).

Return to the [Summary Table](#).

Lock bit for CLKCFG registers

Notes:

[1] Any bit in this register, once set can only be cleared through a CPU1.SYSRSn. Write of 0 to any bit of this register has no effect

[2] The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed

### 3.18.12.7 SYSPLLMULT Register (Offset = 14h) [Reset = 0000000h]

SYSPLLMULT is shown in [Figure 3-171](#) and described in [Table 3-185](#).

Return to the [Summary Table](#).

SYSPLL Multiplier register

NOTE: FMULT and IMULT fields must be written at the same time for correct PLL operation.

This memory mapped register requires a delay of 69 SYSCCLK cycles between subsequent writes to the register, otherwise a second write can be lost. This delay can be realized by adding 69 NOP instructions.

Bit	Field	Type	Reset	Description
31-17	RESERVED	R-0	0h	Reserved
16	CLR	R-0/W1C	0h	X1 Counter clear: A write of '1' to this bit field clears the X1CNT and makes it count from 0x0 again (provided X1 clock is ticking). Writes of '0' are ignore to this bit field Reset type: XRSn
15-11	RESERVED	R-0	0h	Reserved
10-0	X1CNT	R	0h	X1 Counter: - This counter increments on every X1 CLOCKS positive-edge. - Once it reaches the values of 0x7ff, it freezes - Before switching from INTOSC2 to X1, application must check this counter and make sure that it has saturated. This will ensure that the Crystal connected to X1/X2 is oscillating. Reset type: XRSn

### 3.18.12.20 XTALCR Register (Offset = 32h) [Reset = 0000005h]

XTALCR is shown in [Figure 3-184](#) and described in [Table 3-198](#).

Return to the [Summary Table](#).

#### XTAL Control Register

This memory mapped register requires a delay of 69 SYSCLK cycles between subsequent writes to the register, otherwise a second write can be lost. This delay can be realized by adding 69 NOP instructions.

Complex bit access types are encoded to fit into small table cells. [Table 3-204](#) shows the codes that are used for access types in this section.

**Table 3-204. CPU1\_SYS\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
WOnce	W Once	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 3.18.13.1 CPUSYSLOCK1 Register (Offset = 0h) [Reset = 0000000h]

CPUSYSLOCK1 is shown in [Figure 3-189](#) and described in [Table 3-205](#).

Return to the [Summary Table](#).

Lock bit for CPUSYS registers

Notes:

[1] Any bit in this register, once set can only be cleared through a CPU1.SYSRSn. Write of 0 to any bit of this register has no effect

[2] The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed

### 3.18.13.2 CPUSYSLOCK2 Register (Offset = 2h) [Reset = 0000000h]

CPUSYSLOCK2 is shown in [Figure 3-190](#) and described in [Table 3-206](#).

Return to the [Summary Table](#).

Lock bit for CPUSYS registers

Notes:

[1] Any bit in this register, once set can only be cleared through a CPU1.SYSRSn. Write of 0 to any bit of this register has no effect

[2] The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed

Complex bit access types are encoded to fit into small table cells. [Table 3-255](#) shows the codes that are used for access types in this section.

**Table 3-255. CPU2\_SYS\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
WOnce	W Once	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 3.18.14.1 CPUSYSLOCK1 Register (Offset = 0h) [Reset = 0000000h]

CPUSYSLOCK1 is shown in [Figure 3-238](#) and described in [Table 3-256](#).

Return to the [Summary Table](#).

Lock bit for CPUSYS registers

Notes:

[1] Any bit in this register, once set can only be cleared through a CPU1.SYSRSn. Write of 0 to any bit of this register has no effect

[2] The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed

### 3.18.15 CPU1\_SYS\_STATUS\_REGS Registers

Table 3-305 lists the memory-mapped registers for the CPU1\_SYS\_STATUS\_REGS registers. All register offset addresses not listed in Table 3-305 should be considered as reserved locations and the register contents should not be modified.

**Table 3-305. CPU1\_SYS\_STATUS\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
10h	SYS_ERR_INT_FLG	Status of interrupts due to multiple different errors in the system.		<a href="#">Go</a>
12h	SYS_ERR_INT_CLR	SYS_ERR_INT_FLG clear register		<a href="#">Go</a>
14h	SYS_ERR_INT_SET	SYS_ERR_INT_FLG set register	EALLOW	<a href="#">Go</a>
16h	SYS_ERR_MASK	SYS_ERR_MASK register	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 3-306 shows the codes that are used for access types in this section.

**Table 3-306. CPU1\_SYS\_STATUS\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1S	W1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 3.18.15.1 SYS\_ERR\_INT\_FLG Register (Offset = 10h) [Reset = 0000000h]

SYS\_ERR\_INT\_FLG is shown in [Figure 3-287](#) and described in [Table 3-307](#).

Return to the [Summary Table](#).

Status of interrupts due to multiple different errors in the system.

### 3.18.16 CPU2\_SYS\_STATUS\_REGS Registers

Table 3-311 lists the memory-mapped registers for the CPU2\_SYS\_STATUS\_REGS registers. All register offset addresses not listed in Table 3-311 should be considered as reserved locations and the register contents should not be modified.

**Table 3-311. CPU2\_SYS\_STATUS\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
10h	SYS_ERR_INT_FLG	Status of interrupts due to multiple different errors in the system.		<a href="#">Go</a>
12h	SYS_ERR_INT_CLR	SYS_ERR_INT_FLG clear register		<a href="#">Go</a>
14h	SYS_ERR_INT_SET	SYS_ERR_INT_FLG set register	EALLOW	<a href="#">Go</a>
16h	SYS_ERR_MASK	SYS_ERR_MASK register	EALLOW	<a href="#">Go</a>
18h	LCM_ERR_FLG	Status register indicating lockstep compare error flag		<a href="#">Go</a>
1Ah	LCM_ERR_FLG_CLR	LCM_ERR_FLG clear register		<a href="#">Go</a>
1Ch	LCM_ERR_FLG_SET	LCM_ERR_FLG set register	EALLOW	<a href="#">Go</a>
1Eh	LCM_ERR_FLG_MASK	LCM_ERR_FLG mask register	EALLOW	<a href="#">Go</a>
20h	REGPARITY_ERR_FLG	Status register indicating register parity error flag		<a href="#">Go</a>
22h	REGPARITY_ERR_FLG_CLR	REGPARITY_ERR_FLG clear register		<a href="#">Go</a>
24h	REGPARITY_ERR_FLG_SET	REGPARITY_ERR_FLG set register	EALLOW	<a href="#">Go</a>
26h	REGPARITY_ERR_FLG_MASK	REGPARITY_ERR_FLG mask register	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 3-312 shows the codes that are used for access types in this section.

**Table 3-312. CPU2\_SYS\_STATUS\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1S	W1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 3.18.16.1 SYS\_ERR\_INT\_FLG Register (Offset = 10h) [Reset = 0000000h]

SYS\_ERR\_INT\_FLG is shown in [Figure 3-291](#) and described in [Table 3-313](#).

Return to the [Summary Table](#).

Status of interrupts due to multiple different errors in the system.

**Table 3-325. CPU1\_PERIPH\_AC\_REGS Registers (continued)**

Offset	Acronym	Register Name	Write Protection	Section
1FEh	PERIPH_AC_LOCK	Lock Register to stop Write access to peripheral Access register.	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. [Table 3-326](#) shows the codes that are used for access types in this section.

**Table 3-326. CPU1\_PERIPH\_AC\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WOnce	W Once	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 3.18.17.1 ADCA\_AC Register (Offset = 0h) [Reset = 00000FFh]

ADCA\_AC is shown in [Figure 3-303](#) and described in [Table 3-327](#).

Return to the [Summary Table](#).

Based on control settings allows Full, Protected Read, No Access to peripheral from corresponding connected controller.

3-2	CLA1_ACC	R/W	3h	Defines Access control definition for the CLA1 as: 11: Full Access for both read and Write 10: Protected RD Access such that FIFOs, Clear on read registers are not changed + No Write Access 01: Reserved 00: No Read/Write Access to peripheral Reset type: XRSn
1-0	CPUx_ACC	R/W	3h	Defines Access control definition for the CPUx as: 11: Full Access for both read and Write 10: Protected RD Access such that FIFOs, Clear on read registers are not changed + No Write Access 01: Reserved 00: No Read/Write Access to peripheral Reset type: XRSn

### 3.18.17.13 CMPSS10\_AC Register (Offset = 22h) [Reset = 00000FFh]

CMPSS10\_AC is shown in [Figure 3-315](#) and described in [Table 3-339](#).

Return to the [Summary Table](#).

Based on control settings allows Full, Protected Read, No Access to peripheral from corresponding connected controller.

3-2	CLA1_ACC	R/W	3h	Defines Access control definition for the CLA1 as: 11: Full Access for both read and Write 10: Protected RD Access such that FIFOs, Clear on read registers are not changed + No Write Access 01: Reserved 00: No Read/Write Access to peripheral Reset type: XRSn
1-0	CPUx_ACC	R/W	3h	Defines Access control definition for the CPUx as: 11: Full Access for both read and Write 10: Protected RD Access such that FIFOs, Clear on read registers are not changed + No Write Access 01: Reserved 00: No Read/Write Access to peripheral Reset type: XRSn

### 3.18.17.26 EPWM10\_AC Register (Offset = 5Ah) [Reset = 00000FFh]

EPWM10\_AC is shown in [Figure 3-328](#) and described in [Table 3-352](#).

Return to the [Summary Table](#).

Based on control settings allows Full, Protected Read, No Access to peripheral from corresponding connected controller.

3-2	CLA1_ACC	R/W	3h	Defines Access control definition for the CLA1 as: 11: Full Access for both read and Write 10: Protected RD Access such that FIFOs, Clear on read registers are not changed + No Write Access 01: Reserved 00: No Read/Write Access to peripheral Reset type: XRSn
1-0	CPUx_ACC	R/W	3h	Defines Access control definition for the CPUx as: 11: Full Access for both read and Write 10: Protected RD Access such that FIFOs, Clear on read registers are not changed + No Write Access 01: Reserved 00: No Read/Write Access to peripheral Reset type: XRSn

### 3.18.17.39 EQEP5\_AC Register (Offset = 78h) [Reset = 00000FFh]

EQEP5\_AC is shown in [Figure 3-341](#) and described in [Table 3-365](#).

Return to the [Summary Table](#).

Based on control settings allows Full, Protected Read, No Access to peripheral from corresponding connected controller.

1-0	CPUx_ACC	R/W	3h	Defines Access control definition for the CPUx as: 11: Full Access for both read and Write 10: Protected RD Access such that FIFOs, Clear on read registers are not changed + No Write Access 01: Reserved 00: No Read/Write Access to peripheral Reset type: XRSn

### 3.18.17.66 PMBUS\_A\_AC Register (Offset = 130h) [Reset = 00000FFh]

PMBUS\_A\_AC is shown in [Figure 3-368](#) and described in [Table 3-392](#).

Return to the [Summary Table](#).

Based on control settings allows Full, Protected Read, No Access to peripheral from corresponding connected controller.

### 3.18.17.80 HRPWM1\_AC Register (Offset = 1B4h) [Reset = 00000FFh]

HRPWM1\_AC is shown in [Figure 3-382](#) and described in [Table 3-406](#).

Return to the [Summary Table](#).

Based on control settings allows Full, Protected Read, No Access to peripheral from corresponding connected controller.

**Table 3-413. CPU2\_PERIPH\_AC\_REGS Registers (continued)**

Offset	Acronym	Register Name	Write Protection	Section
1FEh	PERIPH_AC_LOCK	Lock Register to stop Write access to peripheral Access register.	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. [Table 3-414](#) shows the codes that are used for access types in this section.

**Table 3-414. CPU2\_PERIPH\_AC\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
WOnce	WOnce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 3.18.18.1 ADCA\_AC Register (Offset = 0h) [Reset = 00000FFh]

ADCA\_AC is shown in [Figure 3-389](#) and described in [Table 3-415](#).

Return to the [Summary Table](#).

Based on control settings allows Full, Protected Read, No Access to peripheral from corresponding connected controller.

1-0	CPUx_ACC	R/W	3h	Defines Access control definition for the CPUx as: 11: Full Access for both read and Write 10: Protected RD Access such that FIFOs, Clear on read registers are not changed + No Write Access 01: Reserved 00: No Read/Write Access to peripheral Reset type: XRSn

### 3.18.18.3 ADCC\_AC Register (Offset = 4h) [Reset = 00000FFh]

ADCC\_AC is shown in [Figure 3-391](#) and described in [Table 3-417](#).

Return to the [Summary Table](#).

Based on control settings allows Full, Protected Read, No Access to peripheral from corresponding connected controller.

3-2	CLA1_ACC	R/W	3h	Defines Access control definition for the CLA1 as: 11: Full Access for both read and Write 10: Protected RD Access such that FIFOs, Clear on read registers are not changed + No Write Access 01: Reserved 00: No Read/Write Access to peripheral Reset type: XRSn
1-0	CPUx_ACC	R/W	3h	Defines Access control definition for the CPUx as: 11: Full Access for both read and Write 10: Protected RD Access such that FIFOs, Clear on read registers are not changed + No Write Access 01: Reserved 00: No Read/Write Access to peripheral Reset type: XRSn

### 3.18.18.16 DACC\_AC Register (Offset = 2Ch) [Reset = 00000FFh]

DACC\_AC is shown in [Figure 3-404](#) and described in [Table 3-430](#).

Return to the [Summary Table](#).

Based on control settings allows Full, Protected Read, No Access to peripheral from corresponding connected controller.

3-2	CLA1_ACC	R/W	3h	Defines Access control definition for the CLA1 as: 11: Full Access for both read and Write 10: Protected RD Access such that FIFOs, Clear on read registers are not changed + No Write Access 01: Reserved 00: No Read/Write Access to peripheral Reset type: XRSn
1-0	CPUx_ACC	R/W	3h	Defines Access control definition for the CPUx as: 11: Full Access for both read and Write 10: Protected RD Access such that FIFOs, Clear on read registers are not changed + No Write Access 01: Reserved 00: No Read/Write Access to peripheral Reset type: XRSn

### 3.18.18.29 EPWM13\_AC Register (Offset = 60h) [Reset = 00000FFh]

EPWM13\_AC is shown in [Figure 3-417](#) and described in [Table 3-443](#).

Return to the [Summary Table](#).

Based on control settings allows Full, Protected Read, No Access to peripheral from corresponding connected controller.

3-2	CLA1_ACC	R/W	3h	Defines Access control definition for the CLA1 as: 11: Full Access for both read and Write 10: Protected RD Access such that FIFOs, Clear on read registers are not changed + No Write Access 01: Reserved 00: No Read/Write Access to peripheral Reset type: XRSn
1-0	CPUx_ACC	R/W	3h	Defines Access control definition for the CPUx as: 11: Full Access for both read and Write 10: Protected RD Access such that FIFOs, Clear on read registers are not changed + No Write Access 01: Reserved 00: No Read/Write Access to peripheral Reset type: XRSn

### 3.18.18.55 CLB4\_AC Register (Offset = B6h) [Reset = 00000FFh]

CLB4\_AC is shown in [Figure 3-443](#) and described in [Table 3-469](#).

Return to the [Summary Table](#).

Based on control settings allows Full, Protected Read, No Access to peripheral from corresponding connected controller.

1-0	CPUx_ACC	R/W	3h	Defines Access control definition for the CPUx as: 11: Full Access for both read and Write 10: Protected RD Access such that FIFOs, Clear on read registers are not changed + No Write Access 01: Reserved 00: No Read/Write Access to peripheral Reset type: XRSn

### 3.18.18.69 DCANA\_AC Register (Offset = 140h) [Reset = 00000FFh]

DCANA\_AC is shown in [Figure 3-457](#) and described in [Table 3-483](#).

Return to the [Summary Table](#).

Based on control settings allows Full, Protected Read, No Access to peripheral from corresponding connected controller.

3-2	RESERVED	R/W	3h	Reserved
1-0	CPU1_ACC	R/W	3h	Defines Access control definition for the CPU1 as: 11: Full Access for both read and Write 10: Protected RD Access such that FIFOs, Clear on read registers are not changed + No Write Access 01: Reserved 00: No Read/Write Access to peripheral Reset type: XRSn

### 3.18.18.83 AESA\_AC Register (Offset = 1BCh) [Reset = 00000FFh]

AESA\_AC is shown in [Figure 3-471](#) and described in [Table 3-497](#).

Return to the [Summary Table](#).

Based on control settings allows Full, Protected Read, No Access to peripheral from corresponding connected controller.

**Table 3-501. MEM\_CFG\_REGS Registers (continued)**

Offset	Acronym	Register Name	Write Protection	Section
AAh	PERI_MEM_TEST_LOCK	Peripheral Memory Test Lock Register		<a href="#">Go</a>
ACh	PERI_MEM_TEST_CONTROL	Peripheral Memory Test control Register		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. [Table 3-502](#) shows the codes that are used for access types in this section.

**Table 3-502. MEM\_CFG\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
WOnce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 3.18.19.1 DxLOCK Register (Offset = 0h) [Reset = 0000000h]

DxLOCK is shown in [Figure 3-475](#) and described in [Table 3-503](#).

Return to the [Summary Table](#).

### 3.18.20 ACCESS\_PROTECTION\_REGS Registers

Table 3-545 lists the memory-mapped registers for the ACCESS\_PROTECTION\_REGS registers. All register offset addresses not listed in Table 3-545 should be considered as reserved locations and the register contents should not be modified.

**Table 3-545. ACCESS\_PROTECTION\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	NMAVFLG	Non-Controller Access Violation Flag Register		<a href="#">Go</a>
2h	NMAVSET	Non-Controller Access Violation Flag Set Register	EALLOW	<a href="#">Go</a>
4h	NMAVCLR	Non-Controller Access Violation Flag Clear Register	EALLOW	<a href="#">Go</a>
6h	NMAVINTEN	Non-Controller Access Violation Interrupt Enable Register	EALLOW	<a href="#">Go</a>
8h	NMCPURDAVADDR	Non-Controller CPU Read Access Violation Address		<a href="#">Go</a>
Ah	NMCPUWRAVADDR	Non-Controller CPU Write Access Violation Address		<a href="#">Go</a>
Ch	NMCPUFAVADDR	Non-Controller CPU Fetch Access Violation Address		<a href="#">Go</a>
Eh	NMDMAWRAVADDR	Non-Controller DMA Write Access Violation Address		<a href="#">Go</a>
10h	NMCLA1RDAVADDR	Non-Controller CLA1 Read Access Violation Address		<a href="#">Go</a>
12h	NMCLA1WRAVADDR	Non-Controller CLA1 Write Access Violation Address		<a href="#">Go</a>
14h	NMCLA1FAVADDR	Non-Controller CLA1 Fetch Access Violation Address		<a href="#">Go</a>
1Ch	NMDMARDAVADDR	Non-Controller DMA Read Access Violation Address		<a href="#">Go</a>
20h	MAVFLG	Controller Access Violation Flag Register		<a href="#">Go</a>
22h	MAVSET	Controller Access Violation Flag Set Register	EALLOW	<a href="#">Go</a>
24h	MAVCLR	Controller Access Violation Flag Clear Register	EALLOW	<a href="#">Go</a>
26h	MAVINTEN	Controller Access Violation Interrupt Enable Register	EALLOW	<a href="#">Go</a>
28h	MCPUFAVADDR	Controller CPU Fetch Access Violation Address		<a href="#">Go</a>
2Ah	MCPUWRAVADDR	Controller CPU Write Access Violation Address		<a href="#">Go</a>
2Ch	MDMAWRAVADDR	Controller DMA Write Access Violation Address		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 3-546 shows the codes that are used for access types in this section.

**Table 3-546. ACCESS\_PROTECTION\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1S	W1S	Write 1 to set
Reset or Default Value		

**Table 3-546. ACCESS\_PROTECTION\_REGS Access Type Codes (continued)**

Access Type	Code	Description
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 3.18.20.1 NMAVFLG Register (Offset = 0h) [Reset = 0000000h]

NMAVFLG is shown in [Figure 3-517](#) and described in [Table 3-547](#).

Return to the [Summary Table](#).

### 3.18.21 MEMORY\_ERROR\_REGS Registers

Table 3-566 lists the memory-mapped registers for the MEMORY\_ERROR\_REGS registers. All register offset addresses not listed in Table 3-566 should be considered as reserved locations and the register contents should not be modified.

**Table 3-566. MEMORY\_ERROR\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	UCERRFLG	Uncorrectable Error Flag Register		<a href="#">Go</a>
2h	UCERRSET	Uncorrectable Error Flag Set Register	EALLOW	<a href="#">Go</a>
4h	UCERRCLR	Uncorrectable Error Flag Clear Register	EALLOW	<a href="#">Go</a>
6h	UCCPUREADDR	Uncorrectable CPU Read Error Address		<a href="#">Go</a>
8h	UCDMAREADDR	Uncorrectable DMA Read Error Address		<a href="#">Go</a>
Ah	UCCLA1READDR	Uncorrectable CLA1 Read Error Address		<a href="#">Go</a>
Eh	UCECATRAMADDR	Uncorrectable etherCAT RAM Read Error Address		<a href="#">Go</a>
10h	UCHICAREADDR	Uncorrectable HICA Read Error Address		<a href="#">Go</a>
1Ch	FLUCERRSTATUS	Flash read uncorrectable ecc err status		<a href="#">Go</a>
1Eh	FLCERRSTATUS	Flash read correctable ecc err status		<a href="#">Go</a>
20h	CERRFLG	Correctable Error Flag Register		<a href="#">Go</a>
22h	CERRSET	Correctable Error Flag Set Register	EALLOW	<a href="#">Go</a>
24h	CERRCLR	Correctable Error Flag Clear Register	EALLOW	<a href="#">Go</a>
26h	CCPUREADDR	Correctable CPU Read Error Address		<a href="#">Go</a>
28h	CDMAREADDR	Correctable DMA Read Error Address		<a href="#">Go</a>
2Ah	CCLA1READDR	Correctable CLA1 Read Error Address		<a href="#">Go</a>
2Eh	CERRCNT	Correctable Error Count Register		<a href="#">Go</a>
30h	CERRTHRES	Correctable Error Threshold Value Register	EALLOW	<a href="#">Go</a>
32h	CEINTFLG	Correctable Error Interrupt Flag Status Register		<a href="#">Go</a>
34h	CEINTCLR	Correctable Error Interrupt Flag Clear Register	EALLOW	<a href="#">Go</a>
36h	CEINTSET	Correctable Error Interrupt Flag Set Register	EALLOW	<a href="#">Go</a>
38h	CEINTEN	Correctable Error Interrupt Enable Register	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 3-567 shows the codes that are used for access types in this section.

**Table 3-567. MEMORY\_ERROR\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		

**Table 3-567. MEMORY\_ERROR\_REGS Access Type Codes (continued)**

Access Type	Code	Description
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 3.18.21.1 UCERRFLG Register (Offset = 0h) [Reset = 0000000h]

UCERRFLG is shown in [Figure 3-536](#) and described in [Table 3-568](#).

Return to the [Summary Table](#).

### 3.18.22 ROM\_WAIT\_STATE\_REGS Registers

Table 3-590 lists the memory-mapped registers for the ROM\_WAIT\_STATE\_REGS registers. All register offset addresses not listed in Table 3-590 should be considered as reserved locations and the register contents should not be modified.

**Table 3-590. ROM\_WAIT\_STATE\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	ROMWAITSTATE	ROM Wait State Configuration Register	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 3-591 shows the codes that are used for access types in this section.

**Table 3-591. ROM\_WAIT\_STATE\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 3.18.22.1 ROMWAITSTATE Register (Offset = 0h) [Reset = 0000000h]

ROMWAITSTATE is shown in [Figure 3-558](#) and described in [Table 3-592](#).

Return to the [Summary Table](#).

ROM Wait State Configuration Register

31-16	RESERVED	R	0h	Reserved
15-1	RESERVED	R	0h	Reserved
0	WSDISABLE	R/W	0h	0: ROM Wait State is enabled. CPU accesses to ROM are 1-wait. 1: ROM Wait State is disabled. CPU accesses to ROM are 0-wait. Reset type: SYSRSn

### 3.18.23 TEST\_ERROR\_REGS Registers

Table 3-593 lists the memory-mapped registers for the TEST\_ERROR\_REGS registers. All register offset addresses not listed in Table 3-593 should be considered as reserved locations and the register contents should not be modified.

**Table 3-593. TEST\_ERROR\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	CPU_RAM_TEST_ERROR_STS	Ram Test: Error Status Register		<a href="#">Go</a>
2h	CPU_RAM_TEST_ERROR_STS_CLR	Ram Test: Error Status Clear Register		<a href="#">Go</a>
4h	CPU_RAM_TEST_ERROR_ADDR	Ram Test: Error address register		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 3-594 shows the codes that are used for access types in this section.

**Table 3-594. TEST\_ERROR\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W1S	W1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 3.18.23.1 CPU\_RAM\_TEST\_ERROR\_STS Register (Offset = 0h) [Reset = 0000000h]

CPU\_RAM\_TEST\_ERROR\_STS is shown in [Figure 3-559](#) and described in [Table 3-595](#).

Return to the [Summary Table](#).

31-0	UniqueID	R	Xh	Unique portion of the UID. This identifier will be unique across all devices with the same PARTIDH. Reset type: N/A

### 3.18.24.8 UID\_CHECKSUM Register (Offset = Eh) [Reset = X000000h]

UID\_CHECKSUM is shown in [Figure 3-569](#) and described in [Table 3-607](#).

Return to the [Summary Table](#).

Fletcher checksum of UID\_PSRAND and UID\_UNIQUE registers

**Figure 3-569. UID\_CHECKSUM Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Checksum																															
R-Xh																															

**Table 3-607. UID\_CHECKSUM Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	Checksum	R	Xh	Fletcher checksum of UID_PSRANDx and UID_UNIQUE Reset type: N/A

### 3.18.25 CPU1\_LFU\_REGS Registers

Table 3-608 lists the memory-mapped registers for the CPU1\_LFU\_REGS registers. All register offset addresses not listed in Table 3-608 should be considered as reserved locations and the register contents should not be modified.

**Table 3-608. CPU1\_LFU\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	LFUConfig_CPU1	LFU configuration Register	EALLOW	<a href="#">Go</a>
2h	LFUStatus_CPU1	LFU Configuration Status Register		<a href="#">Go</a>
10h	SWConfig1_SYSRSn	Spare registers reset by SYSRSn	EALLOW	<a href="#">Go</a>
12h	SWConfig2_SYSRSn	Spare registers reset by SYSRSn	EALLOW	<a href="#">Go</a>
14h	SWConfig1_XRSn	Spare registers reset by XRSn	EALLOW	<a href="#">Go</a>
16h	SWConfig2_XRSn	Spare registers reset by XRSn	EALLOW	<a href="#">Go</a>
18h	SWConfig1_PORESETn	Spare registers reset by PORESETn	EALLOW	<a href="#">Go</a>
1Ah	SWConfig2_PORESETn	Spare registers reset by PORESETn	EALLOW	<a href="#">Go</a>
1Ch	LFU_LOCK	LFU Lock Configuration		<a href="#">Go</a>
1Eh	LFU_COMMIT	LFU Commit Configuration		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 3-609 shows the codes that are used for access types in this section.

**Table 3-609. CPU1\_LFU\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WOnce	W Once	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 3.18.25.1 LFUConfig\_CPU1 Register (Offset = 0h) [Reset = 0000000h]

LFUConfig\_CPU1 is shown in [Figure 3-570](#) and described in [Table 3-610](#).

Return to the [Summary Table](#).

### 3.18.26 CPU2\_LFU\_REGS Registers

Table 3-620 lists the memory-mapped registers for the CPU2\_LFU\_REGS registers. All register offset addresses not listed in Table 3-620 should be considered as reserved locations and the register contents should not be modified.

**Table 3-620. CPU2\_LFU\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	LFUConfig_CPU2	LFU configuration Register	EALLOW	<a href="#">Go</a>
2h	LFUStatus_CPU2	LFU Configuration Status Register		<a href="#">Go</a>
10h	SWConfig1_SYSRSn	Spare registers reset by SYSRSn	EALLOW	<a href="#">Go</a>
12h	SWConfig2_SYSRSn	Spare registers reset by SYSRSn	EALLOW	<a href="#">Go</a>
14h	SWConfig1_XRSn	Spare registers reset by XRSn	EALLOW	<a href="#">Go</a>
16h	SWConfig2_XRSn	Spare registers reset by XRSn	EALLOW	<a href="#">Go</a>
18h	SWConfig1_PORESETn	Spare registers reset by PORESETn	EALLOW	<a href="#">Go</a>
1Ah	SWConfig2_PORESETn	Spare registers reset by PORESETn	EALLOW	<a href="#">Go</a>
1Ch	LFU_LOCK	LFU Lock Configuration		<a href="#">Go</a>
1Eh	LFU_COMMIT	LFU Commit Configuration		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 3-621 shows the codes that are used for access types in this section.

**Table 3-621. CPU2\_LFU\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WOnce	W Once	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 3.18.26.1 LFUConfig\_CPU2 Register (Offset = 0h) [Reset = 0000000h]

LFUConfig\_CPU2 is shown in [Figure 3-580](#) and described in [Table 3-622](#).

Return to the [Summary Table](#).

Complex bit access types are encoded to fit into small table cells. Table 3-633 shows the codes that are used for access types in this section.

**Table 3-633. CPU1TOCPU2\_IPC\_REGS\_CPU1VIEW Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1S	W1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value

### 3.18.27.1 CPU1TOCPU2IPCACK Register (Offset = 0h) [Reset = 0000000h]

CPU1TOCPU2IPCACK is shown in [Figure 3-590](#) and described in [Table 3-634](#).

Return to the [Summary Table](#).

**Table 3-634. CPU1TOCPU2IPCACK Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	IPC31	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC31 bit. Reset type: CPU1.SYSRSn
30	IPC30	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC30 bit. Reset type: CPU1.SYSRSn
29	IPC29	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC29 bit. Reset type: CPU1.SYSRSn
28	IPC28	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC28 bit. Reset type: CPU1.SYSRSn
27	IPC27	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC27 bit. Reset type: CPU1.SYSRSn
26	IPC26	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC26 bit. Reset type: CPU1.SYSRSn
25	IPC25	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC25 bit. Reset type: CPU1.SYSRSn
24	IPC24	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC24 bit. Reset type: CPU1.SYSRSn
23	IPC23	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC23 bit. Reset type: CPU1.SYSRSn
22	IPC22	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC22 bit. Reset type: CPU1.SYSRSn
21	IPC21	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC21 bit. Reset type: CPU1.SYSRSn
20	IPC20	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC20 bit. Reset type: CPU1.SYSRSn
19	IPC19	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC19 bit. Reset type: CPU1.SYSRSn

**Table 3-634. CPU1TOCPU2IPCACK Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
18	IPC18	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC18 bit. Reset type: CPU1.SYSRSn
17	IPC17	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC17 bit. Reset type: CPU1.SYSRSn
16	IPC16	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC16 bit. Reset type: CPU1.SYSRSn
15	IPC15	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC15 bit. Reset type: CPU1.SYSRSn
14	IPC14	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC14 bit. Reset type: CPU1.SYSRSn
13	IPC13	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC13 bit. Reset type: CPU1.SYSRSn
12	IPC12	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC12 bit. Reset type: CPU1.SYSRSn
11	IPC11	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC11 bit. Reset type: CPU1.SYSRSn
10	IPC10	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC10 bit. Reset type: CPU1.SYSRSn
9	IPC9	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC9 bit. Reset type: CPU1.SYSRSn
8	IPC8	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC8 bit. Reset type: CPU1.SYSRSn
7	IPC7	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC7 bit. Reset type: CPU1.SYSRSn
6	IPC6	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC6 bit. Reset type: CPU1.SYSRSn
5	IPC5	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC5 bit. Reset type: CPU1.SYSRSn
4	IPC4	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC4 bit. Reset type: CPU1.SYSRSn
3	IPC3	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC3 bit. Reset type: CPU1.SYSRSn
2	IPC2	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC2 bit. Reset type: CPU1.SYSRSn
1	IPC1	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC1 bit. Reset type: CPU1.SYSRSn
0	IPC0	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC0 bit. Reset type: CPU1.SYSRSn

### 3.18.27.2 CPU2TOCPU1IPCSTS Register (Offset = 2h) [Reset = 0000000h]

CPU2TOCPU1IPCSTS is shown in [Figure 3-591](#) and described in [Table 3-635](#).

Return to the [Summary Table](#).

Status of CPU1TOCPU2IPCFLG register

**Table 3-635. CPU2TOCPU1IPCSTS Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	IPC31	R	0h	Indicates to CPU1 if the IPC31 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC31 bit. 0: No IPC31 event was set by CPU2 1: An IPC31 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
30	IPC30	R	0h	Indicates to CPU1 if the IPC30 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC30 bit. 0: No IPC30 event was set by CPU2 1: An IPC30 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
29	IPC29	R	0h	Indicates to CPU1 if the IPC29 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC29 bit. 0: No IPC29 event was set by CPU2 1: An IPC29 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
28	IPC28	R	0h	Indicates to CPU1 if the IPC28 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC28 bit. 0: No IPC28 event was set by CPU2 1: An IPC28 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn

**Table 3-635. CPU2TOCPU1IPCSTS Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
27	IPC27	R	0h	Indicates to CPU1 if the IPC27 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC27 bit. 0: No IPC27 event was set by CPU2 1: An IPC27 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
26	IPC26	R	0h	Indicates to CPU1 if the IPC26 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC26 bit. 0: No IPC26 event was set by CPU2 1: An IPC26 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
25	IPC25	R	0h	Indicates to CPU1 if the IPC25 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC25 bit. 0: No IPC25 event was set by CPU2 1: An IPC25 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
24	IPC24	R	0h	Indicates to CPU1 if the IPC24 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC24 bit. 0: No IPC24 event was set by CPU2 1: An IPC24 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
23	IPC23	R	0h	Indicates to CPU1 if the IPC23 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC23 bit. 0: No IPC23 event was set by CPU2 1: An IPC23 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
22	IPC22	R	0h	Indicates to CPU1 if the IPC22 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC22 bit. 0: No IPC22 event was set by CPU2 1: An IPC22 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
21	IPC21	R	0h	Indicates to CPU1 if the IPC21 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC21 bit. 0: No IPC21 event was set by CPU2 1: An IPC21 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
20	IPC20	R	0h	Indicates to CPU1 if the IPC20 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC20 bit. 0: No IPC20 event was set by CPU2 1: An IPC20 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn

**Table 3-635. CPU2TOCPU1IPCSTS Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
19	IPC19	R	0h	Indicates to CPU1 if the IPC19 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC19 bit. 0: No IPC19 event was set by CPU2 1: An IPC19 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
18	IPC18	R	0h	Indicates to CPU1 if the IPC18 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC18 bit. 0: No IPC18 event was set by CPU2 1: An IPC18 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
17	IPC17	R	0h	Indicates to CPU1 if the IPC17 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC17 bit. 0: No IPC17 event was set by CPU2 1: An IPC17 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
16	IPC16	R	0h	Indicates to CPU1 if the IPC16 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC16 bit. 0: No IPC16 event was set by CPU2 1: An IPC16 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
15	IPC15	R	0h	Indicates to CPU1 if the IPC15 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC15 bit. 0: No IPC15 event was set by CPU2 1: An IPC15 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
14	IPC14	R	0h	Indicates to CPU1 if the IPC14 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC14 bit. 0: No IPC14 event was set by CPU2 1: An IPC14 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
13	IPC13	R	0h	Indicates to CPU1 if the IPC13 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC13 bit. 0: No IPC13 event was set by CPU2 1: An IPC13 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
12	IPC12	R	0h	Indicates to CPU1 if the IPC12 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC12 bit. 0: No IPC12 event was set by CPU2 1: An IPC12 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn

**Table 3-635. CPU2TOCPU1IPCSTS Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
11	IPC11	R	0h	Indicates to CPU1 if the IPC11 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC11 bit. 0: No IPC11 event was set by CPU2 1: An IPC11 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
10	IPC10	R	0h	Indicates to CPU1 if the IPC10 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC10 bit. 0: No IPC10 event was set by CPU2 1: An IPC10 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
9	IPC9	R	0h	Indicates to CPU1 if the IPC9 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC9 bit. 0: No IPC9 event was set by CPU2 1: An IPC9 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
8	IPC8	R	0h	Indicates to CPU1 if the IPC8 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC8 bit. 0: No IPC8 event was set by CPU2 1: An IPC8 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
7	IPC7	R	0h	Indicates to CPU1 if the IPC7 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC7 bit. 0: No IPC7 event was set by CPU2 1: An IPC7 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
6	IPC6	R	0h	Indicates to CPU1 if the IPC6 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC6 bit. 0: No IPC6 event was set by CPU2 1: An IPC6 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
5	IPC5	R	0h	Indicates to CPU1 if the IPC5 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC5 bit. 0: No IPC5 event was set by CPU2 1: An IPC5 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
4	IPC4	R	0h	Indicates to CPU1 if the IPC4 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC4 bit. 0: No IPC4 event was set by CPU2 1: An IPC4 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn

**Table 3-635. CPU2TOCPU1IPCSTS Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
3	IPC3	R	0h	Indicates to CPU1 if the IPC3 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC3 bit. 0: No IPC3 event was set by CPU2 1: An IPC3 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
2	IPC2	R	0h	Indicates to CPU1 if the IPC2 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC2 bit. 0: No IPC2 event was set by CPU2 1: An IPC2 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
1	IPC1	R	0h	Indicates to CPU1 if the IPC1 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC1 bit. 0: No IPC1 event was set by CPU2 1: An IPC1 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
0	IPC0	R	0h	Indicates to CPU1 if the IPC0 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC0 bit. 0: No IPC0 event was set by CPU2 1: An IPC0 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn

### 3.18.27.3 CPU1TOCPU2IPCSET Register (Offset = 4h) [Reset = 0000000h]

CPU1TOCPU2IPCSET is shown in [Figure 3-592](#) and described in [Table 3-636](#).

Return to the [Summary Table](#).

Set CPU1TOCPU2IPCFLG register

**Figure 3-592. CPU1TOCPU2IPCSET Register**

**Table 3-636. CPU1TOCPU2IPCSET Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	IPC31	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC31 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
30	IPC30	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC30 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
29	IPC29	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC29 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
28	IPC28	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC28 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
27	IPC27	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC27 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn

**Table 3-636. CPU1TOCPU2IPCSET Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
26	IPC26	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC26 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
25	IPC25	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC25 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
24	IPC24	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC24 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
23	IPC23	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC23 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
22	IPC22	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC22 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
21	IPC21	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC21 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
20	IPC20	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC20 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
19	IPC19	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC19 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
18	IPC18	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC18 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn

**Table 3-636. CPU1TOCPU2IPCSET Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
17	IPC17	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC17 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
16	IPC16	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC16 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
15	IPC15	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC15 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
14	IPC14	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC14 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
13	IPC13	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC13 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
12	IPC12	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC12 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
11	IPC11	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC11 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
10	IPC10	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC10 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
9	IPC9	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC9 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn

**Table 3-636. CPU1TOCPU2IPCSET Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
8	IPC8	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC8 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
7	IPC7	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC7 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
6	IPC6	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC6 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
5	IPC5	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC5 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
4	IPC4	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC4 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
3	IPC3	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC3 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
2	IPC2	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC2 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
1	IPC1	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC1 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
0	IPC0	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC0 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn

### 3.18.27.4 CPU1TOCPU2IPCCLR Register (Offset = 6h) [Reset = 0000000h]

CPU1TOCPU2IPCCLR is shown in [Figure 3-593](#) and described in [Table 3-637](#).

Return to the [Summary Table](#).

Clear CPU1TOCPU2IPCFLG register

**Table 3-637. CPU1TOCPU2IPCCLR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	IPC31	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC31 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
30	IPC30	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC30 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
29	IPC29	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC29 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
28	IPC28	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC28 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
27	IPC27	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC27 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn

**Table 3-637. CPU1TOCPU2IPCCLR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
26	IPC26	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC26 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
25	IPC25	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC25 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
24	IPC24	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC24 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
23	IPC23	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC23 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
22	IPC22	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC22 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
21	IPC21	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC21 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
20	IPC20	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC20 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
19	IPC19	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC19 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
18	IPC18	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC18 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn

**Table 3-637. CPU1TOCPU2IPCCLR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
17	IPC17	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC17 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
16	IPC16	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC16 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
15	IPC15	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC15 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
14	IPC14	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC14 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
13	IPC13	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC13 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
12	IPC12	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC12 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
11	IPC11	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC11 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
10	IPC10	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC10 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
9	IPC9	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC9 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn

**Table 3-637. CPU1TOCPU2IPCCLR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
8	IPC8	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC8 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
7	IPC7	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC7 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
6	IPC6	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC6 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
5	IPC5	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC5 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
4	IPC4	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC4 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
3	IPC3	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC3 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
2	IPC2	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC2 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
1	IPC1	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC1 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
0	IPC0	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC0 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn

### 3.18.27.5 CPU1TOCPU2IPCFLG Register (Offset = 8h) [Reset = 0000000h]

CPU1TOCPU2IPCFLG is shown in [Figure 3-594](#) and described in [Table 3-638](#).

Return to the [Summary Table](#).

31-0	BOOTMODE	R/W	0h	This register is used by CPU1 to pass a boot mode information to CPU2. The data format is software-defined. It can only be written by CPU1. Reset type: CPU1.SYSRSn

### 3.18.27.18 FLASHCTLSEM Register (Offset = 24h) [Reset = 0000000h]

FLASHCTLSEM is shown in [Figure 3-607](#) and described in [Table 3-651](#).

Return to the [Summary Table](#).

Flash controller access semaphore request register for program/erase

**Figure 3-607. FLASHCTLSEM Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
KEY															
R-0/W-0h															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED														SEM	
R-0-0h														R/W-0h	

**Table 3-651. FLASHCTLSEM Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	KEY	R-0/W	0h	In order to write to the semaphore bits, 0x5a5a must be written to these key bits at the same time. Otherwise, writes are ignored. The key is cleared immediately after writing, so it must be written again for every semaphore change. Reset type: CPU1.SYSRSn
15-2	RESERVED	R-0	0h	Reserved
1-0	SEM	R/W	0h	These bits decide which CPU has control of the flash controller, which allows program/erase access to the flash memory. The possible values are: 00: Read-only state. CPU1 has control of the pump, but CPU2 may seize control at any time. 01: CPU1 has exclusive control of the Flash Controller and of these semaphore bits. CPU1 can relinquish control by setting the bits back to 00. 10: CPU2 has exclusive control of the Flash Controller and of these semaphore bits. CPU2 can relinquish control by setting the bits back to 00. 11: Read-only state. CPU1 has control of the pump, but CPU2 may seize control at any time. Going from 01->10 or 10->01 is not allowed. The semaphore bits [1:0] must be written along with the correct key in bits [31:16]. Note: This field will be reset by the respective CPU resets depending on who owns the Flash Controller. For example if CPU2 is the owner, then CPU2SYSRSN would reset this field. Note: When CPU2SYSRSN asserted, user has to poll for FLASHCTLSEM value 0x0 and then program the FLASHCTLSEM depends on subsequent ownership requirement. Reset type: CPU1.SYSRSn, CPU2.SYSRSn

### 3.18.28 CPU1TOCPU2\_IPC\_REGS\_CPU2VIEW Registers

Table 3-652 lists the memory-mapped registers for the CPU1TOCPU2\_IPC\_REGS\_CPU2VIEW registers. All register offset addresses not listed in Table 3-652 should be considered as reserved locations and the register contents should not be modified.

**Table 3-652. CPU1TOCPU2\_IPC\_REGS\_CPU2VIEW Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	CPU2TOCPU1IPCACK	CPU2TOCPU1IPCACK Register		<a href="#">Go</a>
2h	CPU1TOCPU2IPCSTS	CPU1TOCPU2IPCSTS Register		<a href="#">Go</a>
4h	CPU2TOCPU1IPCSET	CPU2TOCPU1IPCSET Register		<a href="#">Go</a>

**Table 3-655. CPU1TOCPU2IPCSTS Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	IPC31	R	0h	Indicates to CPU2 if the IPC31 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC31 bit. 0: No IPC31 event was set by CPU1 1: An IPC31 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
30	IPC30	R	0h	Indicates to CPU2 if the IPC30 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC30 bit. 0: No IPC30 event was set by CPU1 1: An IPC30 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
29	IPC29	R	0h	Indicates to CPU2 if the IPC29 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC29 bit. 0: No IPC29 event was set by CPU1 1: An IPC29 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
28	IPC28	R	0h	Indicates to CPU2 if the IPC28 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC28 bit. 0: No IPC28 event was set by CPU1 1: An IPC28 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn

**Table 3-655. CPU1TOCPU2IPCSTS Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
27	IPC27	R	0h	Indicates to CPU2 if the IPC27 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC27 bit. 0: No IPC27 event was set by CPU1 1: An IPC27 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
26	IPC26	R	0h	Indicates to CPU2 if the IPC26 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC26 bit. 0: No IPC26 event was set by CPU1 1: An IPC26 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
25	IPC25	R	0h	Indicates to CPU2 if the IPC25 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC25 bit. 0: No IPC25 event was set by CPU1 1: An IPC25 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
24	IPC24	R	0h	Indicates to CPU2 if the IPC24 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC24 bit. 0: No IPC24 event was set by CPU1 1: An IPC24 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
23	IPC23	R	0h	Indicates to CPU2 if the IPC23 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC23 bit. 0: No IPC23 event was set by CPU1 1: An IPC23 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
22	IPC22	R	0h	Indicates to CPU2 if the IPC22 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC22 bit. 0: No IPC22 event was set by CPU1 1: An IPC22 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
21	IPC21	R	0h	Indicates to CPU2 if the IPC21 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC21 bit. 0: No IPC21 event was set by CPU1 1: An IPC21 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
20	IPC20	R	0h	Indicates to CPU2 if the IPC20 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC20 bit. 0: No IPC20 event was set by CPU1 1: An IPC20 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn

**Table 3-655. CPU1TOCPU2IPCSTS Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
19	IPC19	R	0h	Indicates to CPU2 if the IPC19 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC19 bit. 0: No IPC19 event was set by CPU1 1: An IPC19 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
18	IPC18	R	0h	Indicates to CPU2 if the IPC18 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC18 bit. 0: No IPC18 event was set by CPU1 1: An IPC18 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
17	IPC17	R	0h	Indicates to CPU2 if the IPC17 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC17 bit. 0: No IPC17 event was set by CPU1 1: An IPC17 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
16	IPC16	R	0h	Indicates to CPU2 if the IPC16 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC16 bit. 0: No IPC16 event was set by CPU1 1: An IPC16 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
15	IPC15	R	0h	Indicates to CPU2 if the IPC15 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC15 bit. 0: No IPC15 event was set by CPU1 1: An IPC15 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
14	IPC14	R	0h	Indicates to CPU2 if the IPC14 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC14 bit. 0: No IPC14 event was set by CPU1 1: An IPC14 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
13	IPC13	R	0h	Indicates to CPU2 if the IPC13 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC13 bit. 0: No IPC13 event was set by CPU1 1: An IPC13 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
12	IPC12	R	0h	Indicates to CPU2 if the IPC12 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC12 bit. 0: No IPC12 event was set by CPU1 1: An IPC12 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn

**Table 3-655. CPU1TOCPU2IPCSTS Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
11	IPC11	R	0h	Indicates to CPU2 if the IPC11 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC11 bit. 0: No IPC11 event was set by CPU1 1: An IPC11 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
10	IPC10	R	0h	Indicates to CPU2 if the IPC10 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC10 bit. 0: No IPC10 event was set by CPU1 1: An IPC10 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
9	IPC9	R	0h	Indicates to CPU2 if the IPC9 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC9 bit. 0: No IPC9 event was set by CPU1 1: An IPC9 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
8	IPC8	R	0h	Indicates to CPU2 if the IPC8 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC8 bit. 0: No IPC8 event was set by CPU1 1: An IPC8 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
7	IPC7	R	0h	Indicates to CPU2 if the IPC7 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC7 bit. 0: No IPC7 event was set by CPU1 1: An IPC7 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
6	IPC6	R	0h	Indicates to CPU2 if the IPC6 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC6 bit. 0: No IPC6 event was set by CPU1 1: An IPC6 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
5	IPC5	R	0h	Indicates to CPU2 if the IPC5 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC5 bit. 0: No IPC5 event was set by CPU1 1: An IPC5 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
4	IPC4	R	0h	Indicates to CPU2 if the IPC4 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC4 bit. 0: No IPC4 event was set by CPU1 1: An IPC4 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn

**Table 3-655. CPU1TOCPU2IPCSTS Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
3	IPC3	R	0h	Indicates to CPU2 if the IPC3 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC3 bit. 0: No IPC3 event was set by CPU1 1: An IPC3 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
2	IPC2	R	0h	Indicates to CPU2 if the IPC2 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC2 bit. 0: No IPC2 event was set by CPU1 1: An IPC2 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
1	IPC1	R	0h	Indicates to CPU2 if the IPC1 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC1 bit. 0: No IPC1 event was set by CPU1 1: An IPC1 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
0	IPC0	R	0h	Indicates to CPU2 if the IPC0 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC0 bit. 0: No IPC0 event was set by CPU1 1: An IPC0 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn

### 3.18.28.3 CPU2TOCPU1IPCSET Register (Offset = 4h) [Reset = 0000000h]

CPU2TOCPU1IPCSET is shown in [Figure 3-610](#) and described in [Table 3-656](#).

Return to the [Summary Table](#).

Set CPU2TOCPU1IPCFLG register

**Figure 3-610. CPU2TOCPU1IPCSET Register**

31	30	29	28	27	26	25	24

**Table 3-656. CPU2TOCPU1IPCSET Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	IPC31	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC31 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
30	IPC30	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC30 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
29	IPC29	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC29 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
28	IPC28	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC28 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
27	IPC27	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC27 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn

**Table 3-656. CPU2TOCPU1IPCSET Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
26	IPC26	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC26 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
25	IPC25	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC25 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
24	IPC24	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC24 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
23	IPC23	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC23 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
22	IPC22	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC22 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
21	IPC21	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC21 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
20	IPC20	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC20 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
19	IPC19	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC19 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
18	IPC18	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC18 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn

**Table 3-656. CPU2TOCPU1IPCSET Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
17	IPC17	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC17 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
16	IPC16	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC16 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
15	IPC15	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC15 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
14	IPC14	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC14 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
13	IPC13	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC13 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
12	IPC12	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC12 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
11	IPC11	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC11 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
10	IPC10	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC10 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
9	IPC9	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC9 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn

**Table 3-656. CPU2TOCPU1IPCSET Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
8	IPC8	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC8 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
7	IPC7	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC7 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
6	IPC6	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC6 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
5	IPC5	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC5 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
4	IPC4	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC4 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
3	IPC3	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC3 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
2	IPC2	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC2 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
1	IPC1	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC1 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
0	IPC0	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC0 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn

### 3.18.28.4 CPU2TOCPU1IPCCLR Register (Offset = 6h) [Reset = 0000000h]

CPU2TOCPU1IPCCLR is shown in [Figure 3-611](#) and described in [Table 3-657](#).

Return to the [Summary Table](#).

Clear CPU2TOCPU1IPCFLG register

**Figure 3-611. CPU2TOCPU1IPCCLR Register**

**Table 3-657. CPU2TOCPU1IPCCLR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	IPC31	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC31 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
30	IPC30	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC30 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
29	IPC29	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC29 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
28	IPC28	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC28 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
27	IPC27	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC27 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn

**Table 3-657. CPU2TOCPU1IPCCLR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
26	IPC26	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC26 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
25	IPC25	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC25 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
24	IPC24	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC24 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
23	IPC23	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC23 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
22	IPC22	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC22 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
21	IPC21	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC21 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
20	IPC20	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC20 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
19	IPC19	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC19 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
18	IPC18	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC18 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn

**Table 3-657. CPU2TOCPU1IPCCLR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
17	IPC17	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC17 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
16	IPC16	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC16 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
15	IPC15	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC15 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
14	IPC14	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC14 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
13	IPC13	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC13 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
12	IPC12	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC12 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
11	IPC11	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC11 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
10	IPC10	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC10 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
9	IPC9	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC9 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn

**Table 3-657. CPU2TOCPU1IPCCLR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
8	IPC8	R-0/W1S	0h	Writing 1 to this bit clears the CPU2TOCPU1IPCFLG.IPC8 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
7	IPC7	R-0/W1S	0h	Writing 1 to this bit clears the CPU2TOCPU1IPCFLG.IPC7 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
6	IPC6	R-0/W1S	0h	Writing 1 to this bit clears the CPU2TOCPU1IPCFLG.IPC6 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
5	IPC5	R-0/W1S	0h	Writing 1 to this bit clears the CPU2TOCPU1IPCFLG.IPC5 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
4	IPC4	R-0/W1S	0h	Writing 1 to this bit clears the CPU2TOCPU1IPCFLG.IPC4 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
3	IPC3	R-0/W1S	0h	Writing 1 to this bit clears the CPU2TOCPU1IPCFLG.IPC3 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
2	IPC2	R-0/W1S	0h	Writing 1 to this bit clears the CPU2TOCPU1IPCFLG.IPC2 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
1	IPC1	R-0/W1S	0h	Writing 1 to this bit clears the CPU2TOCPU1IPCFLG.IPC1 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
0	IPC0	R-0/W1S	0h	Writing 1 to this bit clears the CPU2TOCPU1IPCFLG.IPC0 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn

### 3.18.28.5 CPU2TOCPU1IPCFLG Register (Offset = 8h) [Reset = 0000000h]

CPU2TOCPU1IPCFLG is shown in [Figure 3-612](#) and described in [Table 3-658](#).

Return to the [Summary Table](#).

CPU2TOCPU1IPCFLG Register

4	IPC4	R	0h	0: No IPC4 event request to CPU1 1: IPC4 event request to CPU1 Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn

**Table 3-658. CPU2TOCPU1IPCFLG Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
3	IPC3	R	0h	0: No IPC3 event request to CPU1 1: IPC3 event request to CPU1 Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
2	IPC2	R	0h	0: No IPC2 event request to CPU1 1: IPC2 event request to CPU1 Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
1	IPC1	R	0h	0: No IPC1 event request to CPU1 1: IPC1 event request to CPU1 Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
0	IPC0	R	0h	0: No IPC0 event request to CPU1 1: IPC0 event request to CPU1 Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn

### 3.18.28.6 IPCCOUNTERL Register (Offset = Ch) [Reset = 0000000h]

IPCCOUNTERL is shown in [Figure 3-613](#) and described in [Table 3-659](#).

Return to the [Summary Table](#).

IPC Counter Low Register

**Figure 3-613. IPCCOUNTERL Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
COUNT																															
R-0h																															

**Table 3-659. IPCCOUNTERL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	COUNT	R	0h	This is the lower 32-bits of free running 64 bit timestamp counter clocked by the PLLSYSCLK. Reset type: CPU1.SYSRSn

### 3.18.28.7 IPCCOUNTERH Register (Offset = Eh) [Reset = 0000000h]

IPCCOUNTERH is shown in [Figure 3-614](#) and described in [Table 3-660](#).

Return to the [Summary Table](#).

IPC Counter High Register

**Figure 3-614. IPCCOUNTERH Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
COUNT																															
R-0h																															

**Table 3-660. IPCCOUNTERH Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	COUNT	R	0h	This is the upper 32-bits of free running 64 bit timestamp counter clocked by the PLLSYSCLK. Reset type: CPU1.SYSRSn

### 3.18.28.8 CPU1TOCPU2IPCRCVCOM Register (Offset = 10h) [Reset = 0000000h]

CPU1TOCPU2IPCRCVCOM is shown in [Figure 3-615](#) and described in [Table 3-661](#).

Return to the [Summary Table](#).

Refelects the value in CPU1TOCPU2IPCSENDCOM Register

**Figure 3-615. CPU1TOCPU2IPCRCVCOM Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
COMMAND																															
R-0h																															

**Table 3-661. CPU1TOCPU2IPCRCVCOM Register Field Descriptions**

BOOTMODE																															
R/W-0h																															

**Table 3-670. CPU1TOCPU2IPCBOOTMODE Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	BOOTMODE	R/W	0h	This register is used by CPU1 to pass a boot mode information to CPU2. The data format is software-defined. It can only be written by CPU1. Reset type: CPU1.SYSRSn

### 3.18.28.18 FLASHCTLSEM Register (Offset = 24h) [Reset = 0000000h]

FLASHCTLSEM is shown in [Figure 3-625](#) and described in [Table 3-671](#).

Return to the [Summary Table](#).

Flash controller access semaphore request register for program/erase

**Figure 3-625. FLASHCTLSEM Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
KEY															
R-0/W-0h															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED														SEM	
R-0-0h														R/W-0h	

**Table 3-671. FLASHCTLSEM Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	KEY	R-0/W	0h	In order to write to the semaphore bits, 0x5a5a must be written to these key bits at the same time. Otherwise, writes are ignored. The key is cleared immediately after writing, so it must be written again for every semaphore change. Reset type: CPU1.SYSRSn
15-2	RESERVED	R-0	0h	Reserved
1-0	SEM	R/W	0h	These bits decide which CPU has control of the flash controller, which allows program/erase access to the flash memory. The possible values are: 00: Read-only state. CPU1 has control of the pump, but CPU2 may seize control at any time. 01: CPU1 has exclusive control of the Flash Controller and of these semaphore bits. CPU1 can relinquish control by setting the bits back to 00. 10: CPU2 has exclusive control of the Flash Controller and of these semaphore bits. CPU2 can relinquish control by setting the bits back to 00. 11: Read-only state. CPU1 has control of the pump, but CPU2 may seize control at any time. Going from 01->10 or 10->01 is not allowed. The semaphore bits [1:0] must be written along with the correct key in bits [31:16]. Note: This field will be reset by the respective CPU resets depending on who owns the Flash Controller. For example if CPU2 is the owner, then CPU2SYSRSn would reset this field. Note: When CPU2SYSRSn asserted, user has to poll for FLASHCTLSEM value 0x0 and then program the FLASHCTLSEM depends on subsequent ownership requirement. Reset type: CPU1.SYSRSn, CPU2.SYSRSn

### 3.18.29 CPU2\_DMA\_CLA\_SRC\_SEL\_REGS Registers

Table 3-672 lists the memory-mapped registers for the CPU2\_DMA\_CLA\_SRC\_SEL\_REGS registers. All register offset addresses not listed in Table 3-672 should be considered as reserved locations and the register contents should not be modified.

**Table 3-672. CPU2\_DMA\_CLA\_SRC\_SEL\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
4h	DMACHSRCSELLOCK	DMA Channel Trigger Source Select Lock Register	EALLOW	<a href="#">Go</a>
16h	DMACHSRCSEL1	DMA Channel Trigger Source Select Register-1	EALLOW	<a href="#">Go</a>
18h	DMACHSRCSEL2	DMA Channel Trigger Source Select Register-2	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 3-673 shows the codes that are used for access types in this section.

**Table 3-673. CPU2\_DMA\_CLA\_SRC\_SEL\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WOnce	W Once	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 3.18.29.1 DMACHSRCSELLOCK Register (Offset = 4h) [Reset = 0000000h]

DMACHSRCSELLOCK is shown in [Figure 3-626](#) and described in [Table 3-674](#).

Return to the [Summary Table](#).

## Chapter 4 ROM Code and Peripheral Booting

---

This chapter explains the boot procedure, the available boot modes, and the various details of the ROM code including memory maps, initializations, reset handling, and status information.

<b>4.1 Introduction</b> .....	<b>1035</b>
<b>4.2 Device Boot Sequence</b> .....	<b>1036</b>
<b>4.3 Device Boot Modes</b> .....	<b>1037</b>
<b>4.4 Device Boot Configurations</b> .....	<b>1039</b>
<b>4.5 Device Boot Flow Diagrams</b> .....	<b>1044</b>
<b>4.6 Device Reset and Exception Handling</b> .....	<b>1049</b>
<b>4.7 Boot ROM Description</b> .....	<b>1051</b>
<b>4.8 Application Notes for Using the Bootloaders</b> .....	<b>1088</b>
<b>4.9 Software</b> .....	<b>1091</b>

## 4.1 Introduction

The purpose of this chapter is to explain the boot read-only memory (ROM) code functionality for the CPU core, including the boot procedure. This chapter also discusses the functions and features of the boot ROM code, and provides details about the ROM memory-map contents. On every reset, the device executes a boot sequence in the ROM depending on the reset type and boot configuration. This sequence initializes the device to run the application code. For the CPU, the boot ROM also contains peripheral bootloaders that can be used to load an application into RAM. These bootloaders can be disabled for safety or security purposes.

See [Table 4-1](#) for details on available boot features for the C28x CPU. Additionally, [Table 4-2](#) shows the sizes of the various ROMs on the device.

For details on the security APIs provided, refer to [Section 4.7.10](#).

Various tables are provided in ROM for use in software library, refer to [Section 4.7.7](#) for more details.

**Table 4-1. Boot System Overview**

Boot Feature	CPU
Initial boot process	Device reset
Boot mode selection	GPIOs
Boot modes supported	Flash boot Secure Flash boot Firmware Update (FWU) Flash boot RAM boot Wait boot
Peripheral boot loaders supported	Parallel IO SCI / Wait CAN CANFD I2C SPI

**Table 4-2. ROM Memory**

ROM	CPU Size
Secure and Unsecure boot ROM	64KB

### 4.1.1 ROM Related Collateral

#### Foundational Materials

- [Bootloading 101](#) (Video)

#### Getting Started Materials

- [Secure BOOT On C2000 Device Application Report](#)

#### Expert Materials

- [C2000 Software Controlled Firmware Update Process Application Report](#)

## 4.2 Device Boot Sequence

[Table 4-3](#) describes the general boot ROM procedure each time the CPU1 core is reset. [Table 4-4](#) describes the general boot ROM procedure each time the CPU2 core is reset.

During boot, boot ROM code updates a boot status location in RAM that details the actions taken during this process. Refer to [Section 4.7.12](#) for more details.

**Table 4-3. CPU1 Boot ROM Sequence**

Step	CPU1 Action
1	Initialize the device C28x CPU and M0/M1 RAM configuration
2	Initialize the device to use stack addressing mode, initialize DP to lower 64k and clear overflow mode bit
3	Trims are loaded from OTP and device configuration registers are programmed
4	On POR, all CPU RAMs (including GSxRAMs) are initialized. Boot continues once the 2KB RAMs are initialized.
5	Non-maskable interrupt (NMI) handling is enabled and DCSM initialization is performed
6	If enabled, the MPOST POR memory test is run. The original clock frequency is NOT restored post MPOST execution.
7	Pull-ups are enabled on unbonded IOs
8	Device calibration is performed, setting the analog trims. Then resets are handled and RAM is checked for initialization completion.
9	The boot mode GPIO pins are polled to determine the boot mode to run. Boot loader is executed based on boot mode/configurations. Refer to <a href="#">Section 4.5.1</a> for a flow chart of the boot sequences.
10	After the application is loaded, the watchdog is enabled before executing application

**Table 4-4. CPU2 Boot ROM Sequence**

Step	CPU1 Action
1	CPU2 release from reset by CPU1 application
2	Once CPU1TOCPU2IPCFLG0 is set, read the CPU1TOCPU2IPCBOOTMODE register. If the bit is not set correctly or has an invalid value, IPC is sent to CPU1 and CPU2 waits forever. Reset CPU2 and set valid values.
3	On POR, all CPU2 RAMs (excluding GSxRAMs) are initialized (the RAMs are split into two initialization groups)
4	NMI is enabled
5	Initialize the device to configure lock step (not enable). This is to initialize the uninitialized flops in the device.
6	Resets are handled
7	Using the value from CPU2 CPU1TOCPU2IPCBOOTMODE register, if “wait for command” mode is specified, a wait loop is entered that waits for CPU1 C28x to update the boot mode and set IPCFLG0. If a boot mode is specified, then boot ROM enables watchdog and boots to the specified boot mode location.
8	When IPCFLG0 is set in “wait for command” mode, watchdog is enabled, and then boot ROM runs the specified boot mode in CPU1TOCPU2IPCBOOTMODE

## 4.3 Device Boot Modes

This section explains the default boot modes, as well as all the available custom boot modes supported on this device. The boot ROM uses the boot mode select, general purpose input/output (GPIO) pins to determine the boot mode configuration.

### 4.3.1 Default Boot Modes

Table 4-5 shows the boot mode options available for selection by the default boot mode select pins. Users have the option to program the device to customize the boot modes selectable in the boot-up table as well as the boot mode select pin GPIOs used.

**Table 4-5. Device Default Boot Modes**

Boot Mode	GPIO72 (Default boot mode select pin 1)	GPIO84 (Default boot mode select pin 0)
Parallel IO	0	0
SCI / Wait Boot <sup>(1)</sup>	0	1
CAN	1	0
Flash / USB <sup>(2)</sup>	1	1

- (1) SCI boot mode is used as a wait boot mode as long as SCI continues to wait for an 'A' or 'a' during the SCI autobaud lock process.  
 (2) On an unprogrammed device, selecting Flash boot when the default Flash entry address is unprogrammed switches the boot mode from Flash boot to USB boot. See Table 4-6 for more details.

**Table 4-6. CPU1 Flash-to-USB Boot Decision Table**

Value at Flash Entry Point Address	Reason for Value	Realized Boot Mode
0x0000 0000	Flash is locked/secured	Boot to Flash
0xFFFF FFFF	Flash is not programmed	USB Boot
Any other value	Flash is programmed	Boot to Flash

Refer to Section 4.4 for details of boot configurations.

Refer to Section 4.7.8.2 for details of the boot modes that use a peripheral boot loader.

Refer to Section 4.7.9 for GPIOs used for selecting the boot modes.

#### Note

All the peripheral boot modes that are supported use the first instance of the peripheral module (SCIA, SPIA, I2CA, CANA, and so forth). Whenever these boot modes are referred to in this chapter, such as SCI boot, the mode is actually referring to the first module instance, which means the SCI boot on the SCIA port. The same applies to the other peripheral boot modes.

### 4.3.2 Custom Boot Modes

Once the user programs a custom boot table in user OTP, an entry in the custom table is used for booting. Users can customize the boot mode select pins in the end system design by programming the BOOTPIN\_CONFIG location in user OTP. This allows customers to use 0, 1, 2, or 3 boot mode select pins as needed. You can also customize the boot definition table and indicate which location to boot from by programming the boot mode definition table in the BOOTDEF location of user OTP. [Table 4-7](#) and [Table 4-8](#) show the options for various boot modes.

---

#### Note

All peripheral boot modes supported below use the first instance of the peripheral modules (that is, SCIA, SPIA, I2CA, and so on).

---

**Table 4-7. CPU1 Boot Modes**

Boot Mode Number	Boot Modes
0	Parallel
1	SCI / Wait
2	CAN
3	Flash
4	Wait
5	RAM
6	SPI
7	I2C
8	CAN-FD
9	USB
10	Secure Flash
11	FWU Flash

**Table 4-8. CPU2 Boot Modes**

Boot Mode Number	Boot Modes
0	Boot from User OTP
1	Copy from CPU1 IPC MSG RAM and boot from CPU2 RAM
3	Flash
4	Wait-for-Command
5	RAM
10	Secure Flash
11	FWU Flash

## 4.4 Device Boot Configurations

This section details what boot configurations are available and how to configure them. This device supports from zero boot mode select pins up to three boot mode select pins and from one configured boot mode up to eight configured boot modes.

To change and configure the device from the default settings to custom settings for your application, use the following process:

1. Determine all the various ways you want application to be able to boot. (For example: Primary boot option of Flash boot for your main application, secondary boot option of CAN boot for firmware updates, tertiary boot option of SCI boot for debugging, and so on.)
2. Based on the number of boot modes needed, determine how many boot mode select pins (BMSPs) are required to select between your selected boot modes. (For example: Two BMSPs are required to select between three boot mode options.)
3. Assign the required BMSPs to a physical GPIO pin. (For example, BMSP0 to GPIO10, BMSP1 to GPIO51, and BMSP2 left as default that is disabled.). Refer to [Section 4.4.1](#) for all the details on performing these configurations.
4. Assign the determined boot mode definitions to indexes in your custom boot table that correlate to the decoded value of the BMSPs. For example, BOOTDEF0 = Boot to Flash, BOOTDEF1 = CAN Boot, BOOTDEF2 = SCI Boot; all other BOOTDEFx remain as default/nothing). Refer to [Section 4.4.2](#) for all the details on setting up and configuring the custom boot mode table.

Additionally, [Section 4.4.3](#) provides some example use cases on how to configure the boot mode select pins and custom boot tables.

#### 4.4.1 Configuring Boot Mode Pins

This section explains how the boot mode select pins are customized by the user, by programming the BOOTPIN-CONFIG location (refer to [Table 4-9](#)), in the user-configurable dual-zone security module (DCSM) OTP. The location in the DCSM OTP is Z1-OTP-BOOTPIN-CONFIG or Z2-OTP-BOOTPIN-CONFIG. When debugging, EMU-BOOTPIN-CONFIG is the emulation equivalent of Z1-OTP-BOOTPIN-CONFIG/Z2-OTP-BOOTPIN-CONFIG, and can be programmed to experiment with different boot modes without writing to OTP. The device can be programmed to use **zero**, **one**, **two**, or **three** boot mode select pins as needed.

---

#### Note

When using Z2-OTP-BOOTPIN-CONFIG, the configurations programmed in this location take priority over the configurations in Z1-OTP-BOOTPIN-CONFIG. It is recommended to use Z1-OTP-BOOTPIN-CONFIG first and then, if OTP configurations need to be altered, switch to using Z2-OTP-BOOTPIN-CONFIG.

---

**Table 4-9. BOOTPIN-CONFIG Bit Fields**

Bit	Name	Description
31:24	Key	Write 0x5A to these 8-bits to tell the boot ROM code that the bits in this register are valid.
23:16	Boot Mode Select Pin 2 (BMSP2)	Refer to BMSP0 description.
15:8	Boot Mode Select Pin 1 (BMSP1)	Refer to BMSP0 description.
7:0	Boot Mode Select Pin 0 (BMSP0)	Set to the GPIO pin to be used during boot (up to 255). 0x0 = GPIO0 0x01 = GPIO1, and so on. Writing 0xFF disables this BMSP and this pin is no longer used to select the boot mode.

---

#### Note

GPIO 224 to 253 are analog pins, but digital inputs are possible on these pins provided the software writes to the GPIOHAMSEL register bits.

The following GPIOs cannot be used as a boot mode select pin. If selected for a particular BMSP, the boot ROM automatically selects the factory default GPIOs for BMSP0 and BMSP1. Factory default for BMSP2 is 0xFF, which disables the BMSP.

- GPIO 14 and GPIO 15 (Not available on any package)
  - GPIO 25 to GPIO 27 (Not available on any package)
  - GPIO 30, GPIO 31, GPIO 34, and GPIO 38 (Not available on any package)
  - GPIO 42 to GPIO 58 (Not available on any package)
  - GPIO 62 to GPIO 223 (Not available on any package)
-

**Table 4-10. Standalone Boot Mode Select Pin Decoding**

BOOTPIN_CONFIG Key	BMSP0	BMSP1	BMSP2	Realized Boot Mode
!= 0x5A	Don't Care	Don't Care	Don't Care	Boot as defined by the factory default BMSPs.
= 0x5A	0xFF	0xFF	0xFF	Boot as defined in the boot table for boot mode 0 (All BMSPs disabled).
	Valid GPIO	0xFF	0xFF	Boot as defined by the value of BMSP0 (BMSP1 and BMSP2 disabled).
	0xFF	Valid GPIO	0xFF	Boot as defined by the value of BMSP1 (BMSP0 and BMSP2 disabled).
	0xFF	0xFF	Valid GPIO	Boot as defined by the value of BMSP2 (BMSP0 and BMSP1 disabled)
	Valid GPIO	Valid GPIO	0xFF	Boot as defined by the values of BMSP0 and BMSP1 (BMSP2 disabled).
	Valid GPIO	0xFF	Valid GPIO	Boot as defined by the values of BMSP0 and BMSP2 (BMSP1 disabled).
	0xFF	Valid GPIO	Valid GPIO	Boot as defined by the values of BMSP1 and BMSP2 (BMSP0 disabled).
	Valid GPIO	Valid GPIO	Valid GPIO	Boot as defined by the values of BMSP0, BMSP1, and BMSP2.
	Invalid GPIO	Valid GPIO	Valid GPIO	BMSP0 is reset to the factory default BMSP0 GPIO. Boot as defined by the values of BMSP0, BMSP1, and BMSP2.
	Valid GPIO	Invalid GPIO	Valid GPIO	BMSP1 is reset to the factory default BMSP1 GPIO. Boot as defined by the values of BMSP0, BMSP1, and BMSP2.
Valid GPIO	Valid GPIO	Invalid GPIO	BMSP2 is reset to the factory default state, which is disabled. Boot as defined by the values of BMSP0 and BMSP1.	

#### Note

When decoding the boot mode, BMSP0 is the least-significant bit and BMSP2 is the most-significant bit of the boot table index value. It is recommended when disabling BMSPs to start with disabling BMSP2. For example, in an instance when only using BMSP2 (BMSP1 and BMSP0 are disabled), then only the boot table indexes of 0 and 4 are selectable. In the instance when using only BMSP0, then the selectable boot table indexes are 0 and 1.

#### 4.4.2 Configuring Boot Mode Table Options

This section explains how to configure the boot definition table, BOOTDEF, for the device and the associated boot options (refer to [Table 4-11](#)). The 64-bit location is located in user-configurable DCSM OTP in the Z1-OTP-BOOTDEF-LOW and Z1-OTP-BOOTDEF-HIGH locations. When debugging, EMU-BOOTDEF-LOW and EMU-BOOTDEF-HIGH are the emulation equivalents of Z1-OTP-BOOTDEF-LOW and Z1-OTP-BOOTDEF-HIGH, and can be programmed to experiment with different boot mode options without writing to OTP. The range of customization to the boot definition table depends on how many boot mode select pins (BMSP) are being used. For example, 0 BMSPs equals to 1 table entry, 1 BMSP equals to 2 table entries, 2 BMSPs equals to 4 table entries, and 3 BMSPs equals to 8 table entries. Refer to [Section 4.4.3](#) for examples on how to setup the BOOTPIN\_CONFIG and BOOTDEF values.

#### Note

The locations Z2-OTP-BOOTDEF-LOW and Z2-OTP-BOOTDEF-HIGH are used instead of Z1-OTP-BOOTDEF-LOW and Z1-OTP-BOOTDEF-HIGH locations when Z2-OTP-BOOTPIN-CONFIG is configured. Refer to [Section 4.4.1](#) for more details on BOOTPIN\_CONFIG usage.

**Table 4-11. BOOTDEF Bit Fields**

BOOTDEF Name	Byte Position	Name	Description
BOOT_DEF0	7:0	[3:0] BOOT_DEF0 Mode	Set the boot mode number from <a href="#">Section 4.3.2</a> . Any unsupported boot mode causes the device to either go to wait boot (debugger connected) or boot to Flash (standalone).
		[7:4] BOOT_DEF0 Options	Set alternate/additional boot options. This can include changing the GPIOs for a particular boot peripheral or specifying a different Flash entry point. Refer to <a href="#">Section 4.7.9</a> for valid BOOTDEF values to set in the table.
BOOT_DEF1	15:8	BOOT_DEF1 Mode/Options	Refer to BOOT_DEF0 description.
BOOT_DEF2	23:16	BOOT_DEF2 Mode/Options	
BOOT_DEF3	31:24	BOOT_DEF3 Mode/Options	
BOOT_DEF4	39:32	BOOT_DEF4 Mode/Options	
BOOT_DEF5	47:40	BOOT_DEF5 Mode/Options	
BOOT_DEF6	55:48	BOOT_DEF6 Mode/Options	
BOOT_DEF7	63:56	BOOT_DEF7 Mode/Options	

### 4.4.3 Boot Mode Example Use Cases

This section demonstrates some use cases for configuring the boot mode select pins and boot modes.

#### 4.4.3.1 Zero Boot Mode Select Pins

This use-case demonstrates a scenario for an application that does not use any boot mode select pins and always has the device boot to Flash.

- Program the BOOTPIN\_CONFIG location in OTP as follows:
  - Set BOOTPIN\_CONFIG.BMSP0 to 0xFF
  - Set BOOTPIN\_CONFIG.BMSP1 to 0xFF
  - Set BOOTPIN\_CONFIG.BMSP2 to 0xFF
  - Set BOOTPIN\_CONFIG.KEY to 0x5A for boot ROM to treat these register bits as valid and use the custom boot table.
- Program the BOOTDEF location options for the device. This essentially sets up a device-specific boot mode table. Refer to [Section 4.7.9](#) for valid BOOTDEF values to set in the table.
  - Set BOOTDEF.BOOTDEF0 to 0x03 for booting to Flash (entry address option 0). This sets Flash boot to boot table index 0.
  - Refer to [Section 4.7.3](#) for the available Flash entry points.

**Table 4-12. Zero Boot Pin Boot Table Result**

Boot Mode Table Number	Boot Mode
0	Flash Boot (0x03)

#### 4.4.3.2 One Boot Mode Select Pin

This use-case demonstrates a scenario for an application using one boot mode select pin to select between booting to Flash or using CAN boot.

- Program the BOOTPIN\_CONFIG location in OTP as follows:
  - Set BOOTPIN\_CONFIG.BMSP0 to a user specified GPIO, such as 0x0 for GPIO0
  - Set BOOTPIN\_CONFIG.BMSP1 to 0xFF
  - Set BOOTPIN\_CONFIG.BMSP2 to 0xFF
  - Set BOOTPIN\_CONFIG.KEY to 0x5A for boot ROM to treat these register bits as valid and use the custom boot table.
- Program the BOOTDEF location options for the device. This essentially sets up a device-specific boot mode table. Refer to [Section 4.7.9](#) for valid BOOTDEF values to set in the table.
  - Set BOOTDEF.BOOTDEF0 to 0x02 for CAN booting. This sets CAN boot to boot table index 0.
  - Set BOOTDEF.BOOTDEF1 to 0x03 for booting to Flash (entry address option 0). This sets Flash boot to boot table index 1.

**Table 4-13. One Boot Pin Boot Table Result**

Boot Mode Table Number	Boot Mode
0	CAN Boot (0x02)
1	Flash Boot (0x03)

#### 4.4.3.3 Three Boot Mode Select Pins

This use-case demonstrates a scenario for an application using three boot mode select pins to select between various boot modes in the custom boot table.

1. Program the BOOTPIN\_CONFIG location in OTP as follows:
  - Set BOOTPIN\_CONFIG.BMSP0 to a user specified GPIO, such as 0x0 for GPIO0
  - Set BOOTPIN\_CONFIG.BMSP1 to a user specified GPIO, such as 0x1 for GPIO1
  - Set BOOTPIN\_CONFIG.BMSP2 to a user specified GPIO, such as 0x2 for GPIO2
  - Set BOOTPIN\_CONFIG.KEY to 0x5A for boot ROM to treat these register bits as valid and use the custom boot table.
2. Program the BOOTDEF location options for the device. This essentially sets up a device-specific boot mode table. Refer to [Section 4.7.9](#) for valid BOOTDEF values to set in the table.
  - Set BOOTDEF.BOOTDEF0 to 0x02 for CAN booting. This sets CAN boot to boot table index 0.
  - Set BOOTDEF.BOOTDEF1 to 0x03 for booting to Flash (entry address option 0). This sets Flash boot to boot table index 1.
  - Set BOOTDEF.BOOTDEF2 to 0x24 for booting to wait boot (alternate option). This sets wait boot to boot table index 2.
  - Set BOOTDEF.BOOTDEF3 to 0x66 for SPI booting (alternate GPIO option 3). This sets SPI boot to boot table index 3.
  - Set BOOTDEF.BOOTDEF4 to 0x43 for booting to Flash (entry address option 2). This sets Flash boot to boot table index 4.

**Table 4-14. Three Boot Pins Boot Table Result**

Boot Mode Table Number	Boot Mode
0	CAN Boot (0x02)
1	Flash Boot (0x03)
2	Wait Boot - Alt (0x24)
3	SPI - Alt3 (0x66)
4	Flash Boot - Alt2 (0x43)
5, 6, 7	Not used in this example

## 4.5 Device Boot Flow Diagrams

This section details the boot flow diagrams for standalone and emulation boot flows.

### 4.5.1 Boot Flow

Upon reset, the CPU follows the boot flow shown in [Figure 4-1](#). Depending on whether a JTAG debugger is connected to the device, the CPU either continues booting following the emulation boot flow or the standalone boot flow.

---

**Note**

Boot on reset (BOR) follows same flow as power on reset (POR).

---

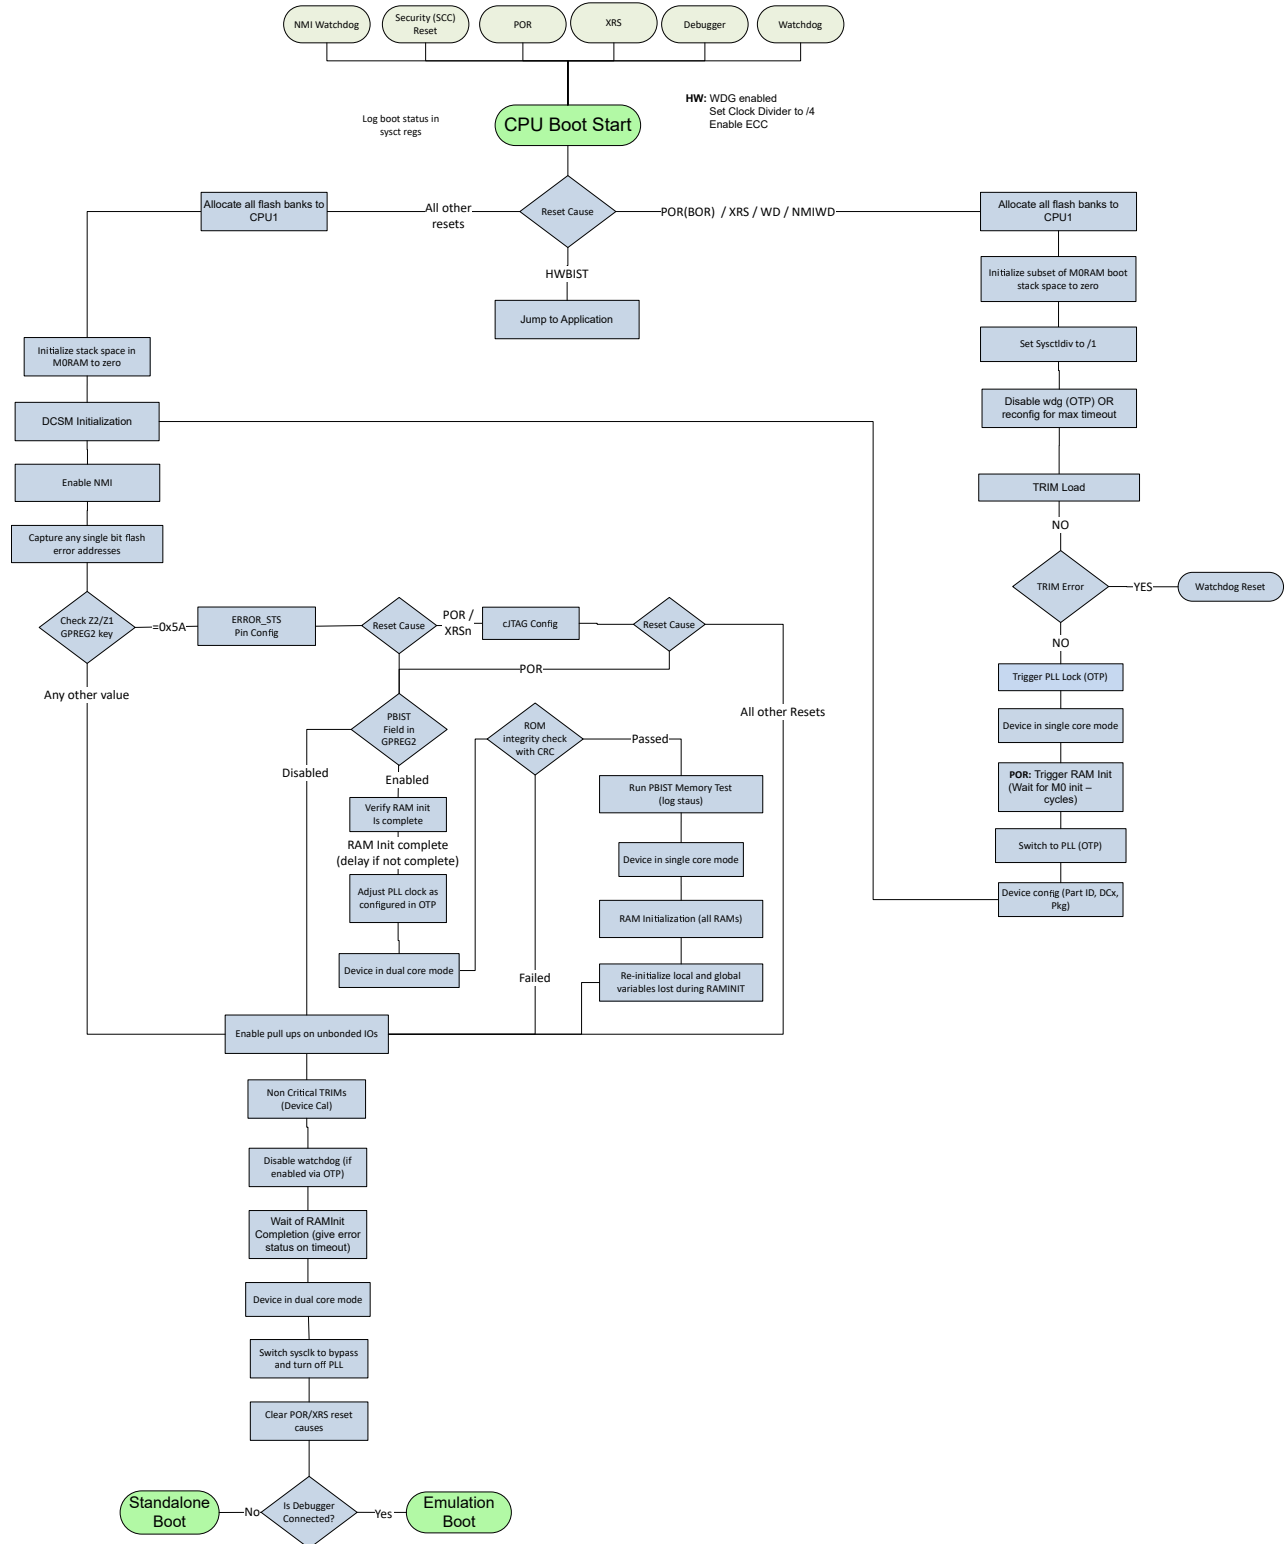

Figure 4-1. Device Boot Flow

### 4.5.2 Emulation Boot Flow

Figure 4-2 shows the emulation boot flow when JTAG debugger is connected.

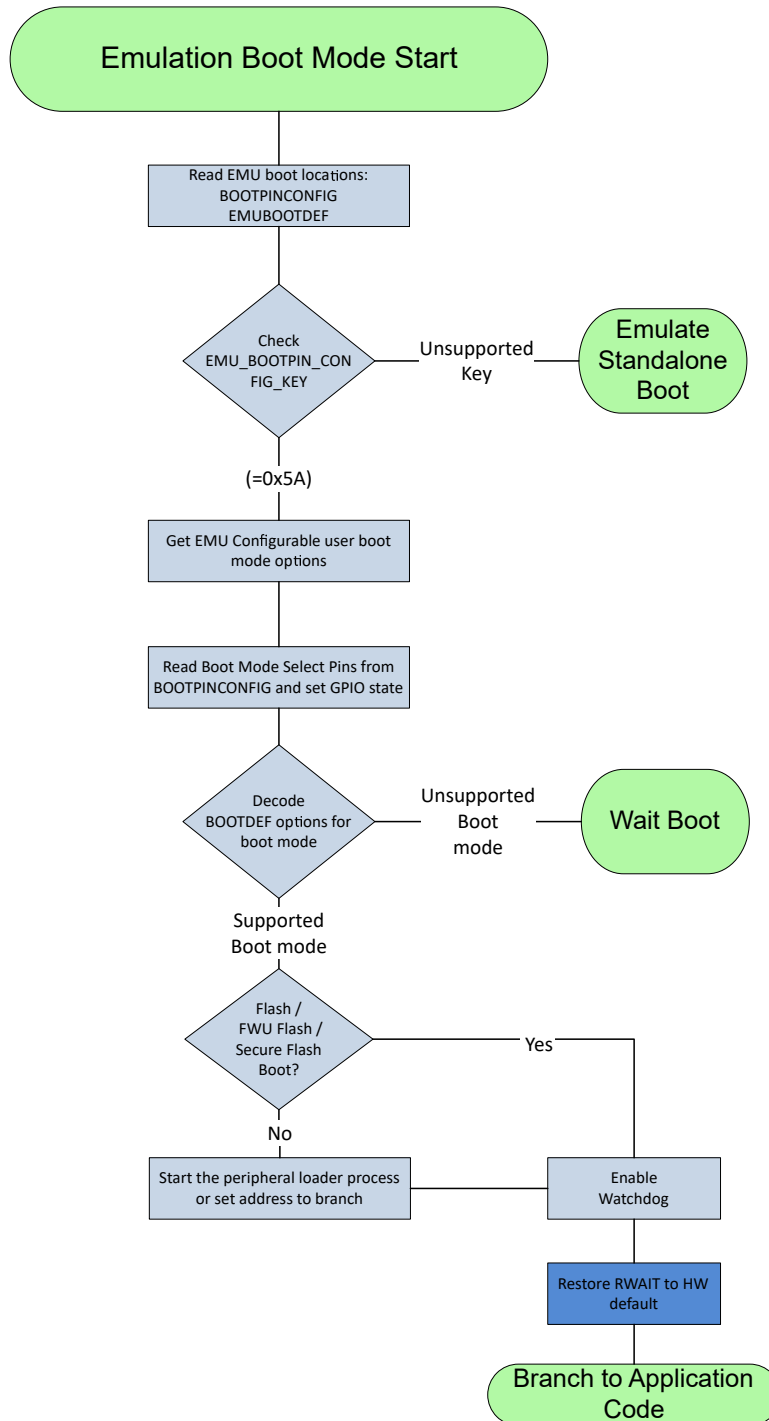

Figure 4-2. Emulation Boot Flow

### 4.5.3 Standalone Boot Flow

Figure 4-3 shows the standalone boot flow for CPU1 and Figure 4-4 shows the standalone boot flow for CPU2 when no JTAG debugger is connected to the device.

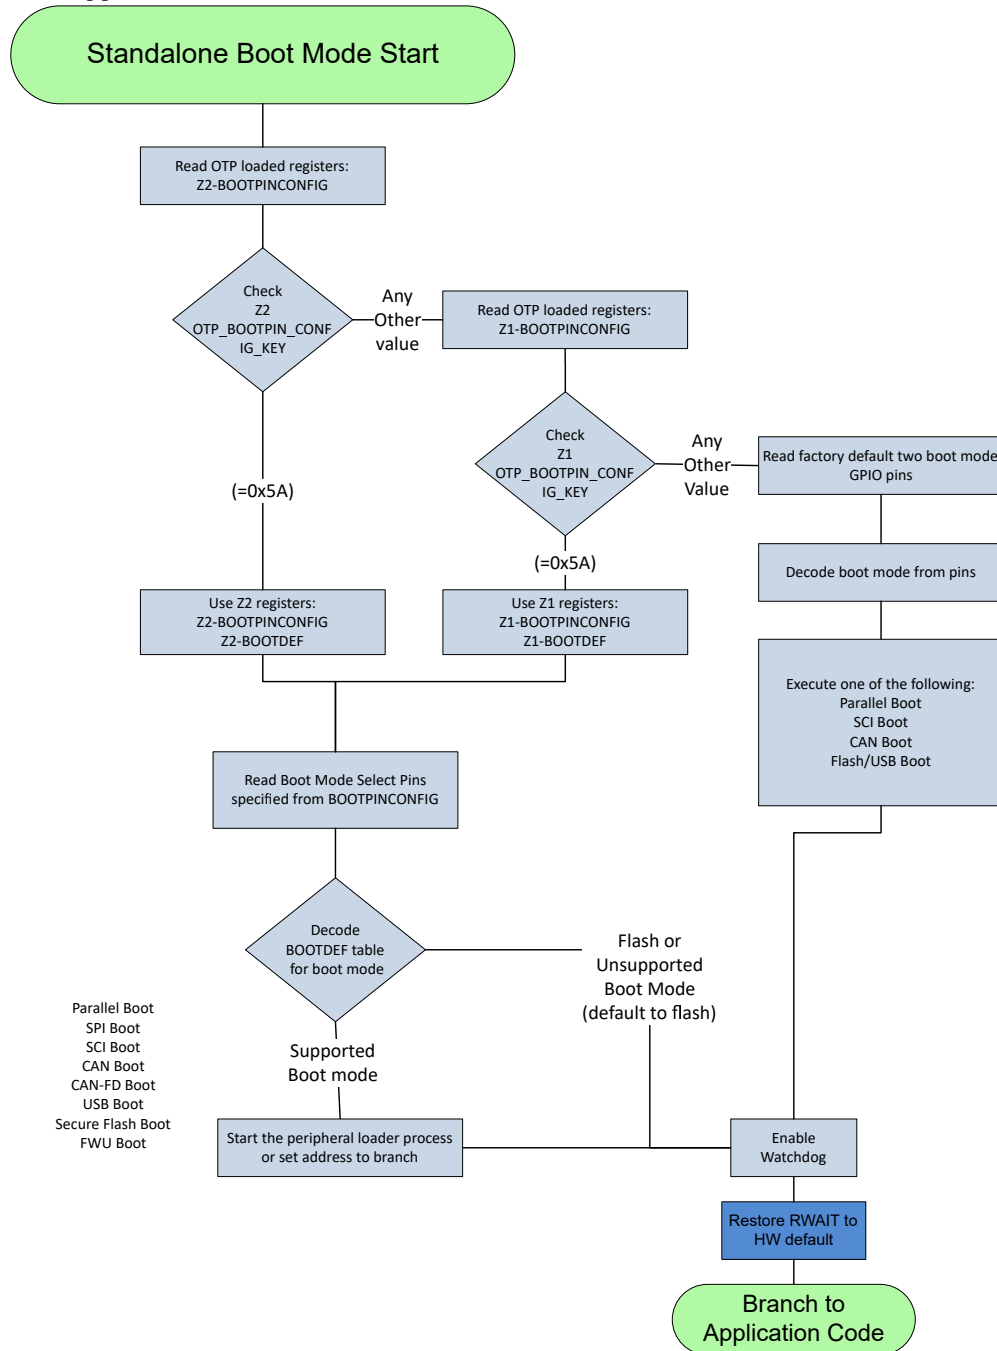

Figure 4-3. CPU1 Standalone Boot Flow

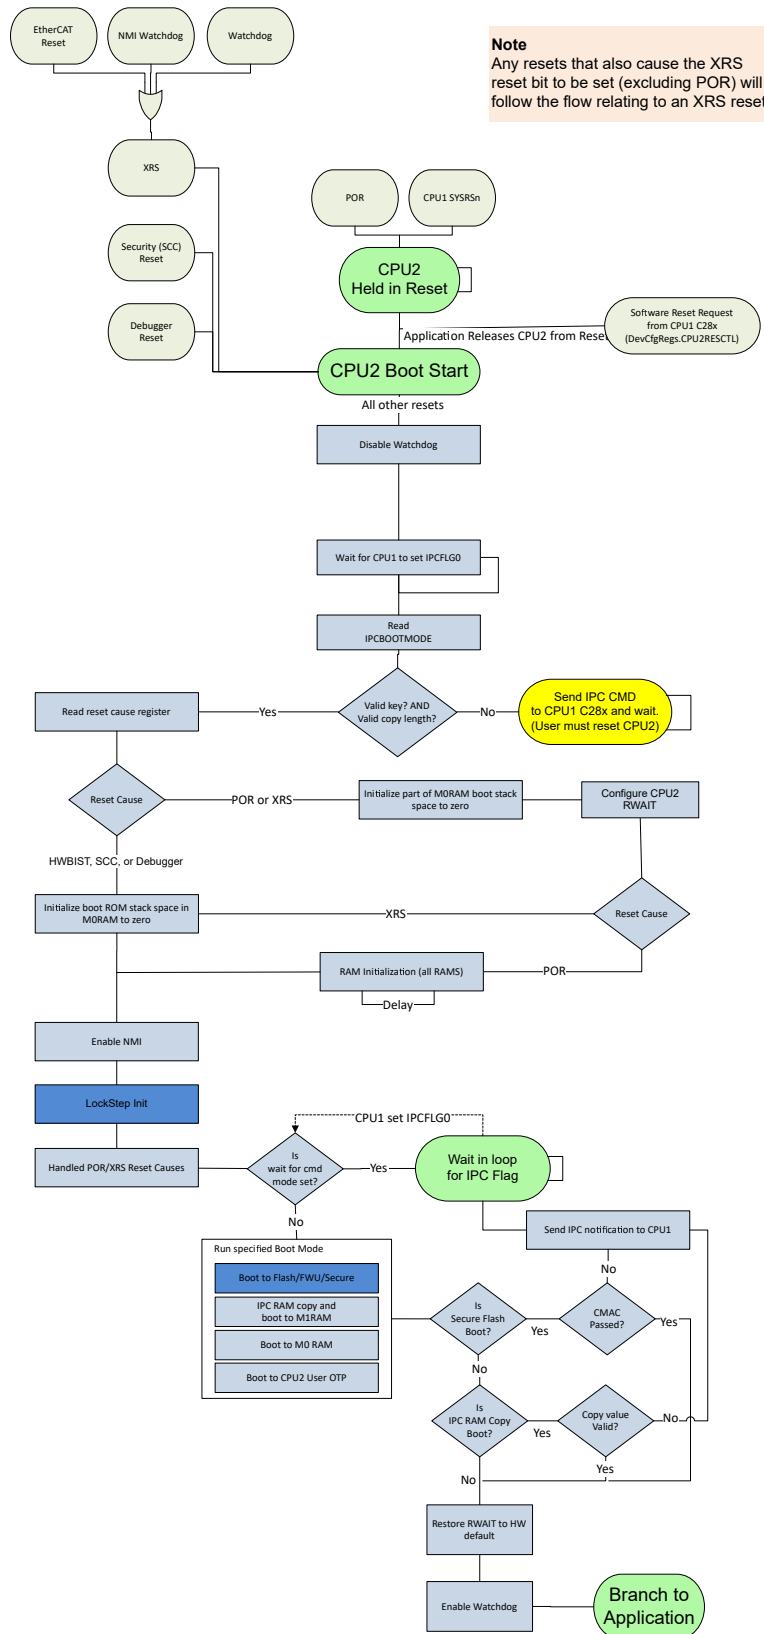

Figure 4-4. CPU2 Standalone Boot Flow

## 4.6 Device Reset and Exception Handling

### 4.6.1 Reset Causes and Handling

Table 4-15 explains the actions each boot ROM performs upon reset for a specific reset cause. The boot ROM flow only explicitly checks for POR and XRS reset cause flags.

**Table 4-15. Boot ROM Reset Causes and Actions**

Reset Source	CPU1 Boot ROM Action	CPU2 Boot ROM Action
Power-On Reset (POR)	<ol style="list-style-type: none"> <li>1. Default boot flow</li> <li>2. Lock PLL and use PLL if configured to do so</li> <li>3. RAM initialization</li> </ol>	<ol style="list-style-type: none"> <li>1. Flash Power Up</li> <li>2. RAM Initialization</li> <li>3. Continue default boot flow</li> </ol>
External Reset ( $\overline{\text{XRS}}$ ) Includes: <ul style="list-style-type: none"> <li>• Watchdog Reset (<math>\overline{\text{WDRS}}</math>)</li> <li>• NMI Watchdog Reset (<math>\overline{\text{NMIWDRS}}</math>)</li> <li>• Simulate External Reset (<math>\text{SIMRESET.XRS}</math>)</li> </ul>	<ol style="list-style-type: none"> <li>1. Default boot flow</li> <li>2. Lock PLL and use PLL if configured to do so</li> </ol>	<ol style="list-style-type: none"> <li>1. Flash Power Up</li> <li>2. Clear boot stack</li> <li>3. Continue default boot flow</li> </ol>
Secure Copy Code Reset ( $\overline{\text{SCCRESET}}$ )	<ol style="list-style-type: none"> <li>1. No change to CLK dividers or RAM</li> <li>2. Clear stack</li> <li>3. Follow default boot</li> </ol>	<ol style="list-style-type: none"> <li>1. Clear boot stack</li> <li>2. Continue default boot flow</li> </ol>
Simulate CPU Reset (SIMRESET)	<ol style="list-style-type: none"> <li>1. No change to CLK dividers or RAM</li> <li>2. Clear stack</li> <li>3. Follow default boot</li> </ol>	<ol style="list-style-type: none"> <li>1. Clear boot stack</li> <li>2. Continue default boot flow</li> </ol>
Debugger Reset ( $\overline{\text{SYSRS}}$ )	<ol style="list-style-type: none"> <li>1. No change to CLK dividers or RAM</li> <li>2. Clear stack</li> <li>3. Follow default boot</li> </ol>	<ol style="list-style-type: none"> <li>1. Clear boot stack</li> <li>2. Continue default boot flow</li> </ol>
HWBIST Reset	<ol style="list-style-type: none"> <li>1. Get application address and branch to application code</li> </ol>	N/A

## 4.6.2 Exceptions and Interrupts Handling

Table 4-16 explains the actions that the boot ROM performs, if any exceptions occur during boot. The philosophy of CPU1 boot ROM is to try and start the application and log the error. The philosophy of CPU2 is to log the error in IPCBOOTSTS register and let CPU1 handle the action.

The boot ROM sets up the NMI handlers and enables NMI on every reset type. For any CPU2 NMI event sources, CPU2 NMI handler clears the NMI flag to stop the NMI watchdog counter and prevent continuous NMIWD resets on CPU2. The error pin goes low or high (depending on the polarity configuration on the error pin and the reset type) temporarily before NMI flag is cleared (shorter width of error pin signal means CPU2 is source of error). CPU2 then updates the boot status and sends IPC to CPU1 for CPU1 to handle the error and reset CPU2.

The CPU error pin can be low or high on an error depending upon the reset and polarity configured for the error pin. For POR, low implies error, whereas on other resets the pin can be low or high depending on the ERROR.POLSEL value configured by the application.

**Table 4-16. Boot ROM Exceptions and Actions**

Exception Event Source	CPU1 Boot ROM Action	CPU2 Boot ROM Action	Event Logged
Clock Fail	Clear the NMI flag and continue to boot	Clear NMI flag, update boot status to CPU1, send error IPC to CPU1, and wait in loop	Yes
RAM/Flash Uncorrectable Error	Reset the device	Clear NMI flag, update boot status to CPU1, send error IPC to CPU1, and wait in loop	Yes
System Debug (ERAD) NMI	Clear the NMI flag and continue to boot	Clear NMI flag, update boot status to CPU1, send error IPC to CPU1, and wait in loop	Yes
RL NMI (CLB)	Clear the NMI flag and continue to boot	Clear NMI flag, update boot status to CPU1, send error IPC to CPU1, and wait in loop	Yes
HWBIST NMI (CLB)	Clear the NMI flag and continue to boot	No action	Yes
ITRAP Exception	Provide program address of where illegal instruction was executed and let the device reset	Send IPC to CPU1 with illegal instruction execution location and wait in loop	Yes
Unsupported PIE Interrupts	Ignore and continue to boot	Ignore and continue to boot	No
OVF (Over Voltage Fault)	Not in the scope of boot code, let the device reset	Not in the scope of boot code, let the device reset	No
Software Error	Software Self-test Error (SW writes to NMI FLAG). Not in the scope of boot code, let the device reset	Software Self-test Error (SW writes to NMI FLAG). Not in the scope of boot code, let the device reset	No
Invalid CPU1TOCPU2IPCBOOTMODE Values On Any Reset	No action	Send IPC to CPU1 and wait in loop	Yes
Lockstep NMI	No action	Send IPC to CPU1 and wait in loop	Yes

## 4.7 Boot ROM Description

This section explains the details regarding the device boot ROMs.

### 4.7.1 Boot ROM Configuration Registers

The boot ROM code involves several memory addresses and registers used during execution. There are two sets of configurations; one for emulation and one for standalone boot flow. The emulation locations located in RAM emulate the OTP configurations and can be written to as many times as needed. The user configurable DCSM OTP locations used in the standalone boot flow program the device OTP and hence can only be written once. [Table 4-17](#) details these locations. For bit field configuration details of BOOTPIN-CONFIG and BOOTDEF, see [Section 4.4.1](#) and [Section 4.4.2](#), respectively.

Additionally, the boot ROM supports boot configurations from DCSM zone 1 and zone 2 GPREG registers. Zone 2 configurations supercede zone 1 configurations, so use zone 1 configurations and use zone 2 when zone 1 is no longer valid.

**Table 4-17. Boot ROM Registers**

Boot Flow	DCSM Register Name	Boot ROM Name	Register Address	User OTP Address
Emulation	-	EMU-BOOTPIN-CONFIG	0x0000 0D00	-
	-	EMU-GPREG2	0x0000 0D02	-
	-	EMU-BOOTDEF-LOW	0x0000 0D04	-
	-	EMU-BOOTDEF-HIGH	0x0000 0D06	-
Standalone (Using Z1)	Z1-GPREG1	Z1-OTP-BOOTPIN-CONFIG	0x0005 F008	0x0007 8008
	Z1-GPREG2	Z1-OTP-BOOT-GPREG2	0x0005 F00A	0x0007 800A
	Z1-GPREG3	Z1-OTP-BOOTDEF-LOW	0x0005 F00C	0x0007 800C
	Z1-GPREG4	Z1-OTP-BOOTDEF-HIGH	0x0005 F00E	0x0007 800E
	Z1-DIAG	Z1-OTP-BOOTDEF-DIAG	0x0005 F03E	0x0007 803E
Standalone (Using Z2)	Z2-GPREG1	Z2-OTP-BOOTPIN-CONFIG	0x0005 F088	0x0007 8208
	Z2-GPREG2	Z2-OTP-BOOT-GPREG2	0x0005 F08A	0x0007 820A
	Z2-GPREG3	Z2-OTP-BOOTDEF-LOW	0x0005 F08C	0x0007 820C
	Z2-GPREG4	Z2-OTP-BOOTDEF-HIGH	0x0005 F08E	0x0007 820E

#### 4.7.1.1 GPREG2 Usage and MPOST Configuration

Table 4-18 explains how the bit field values from the user configurable DCSM OTP location, Z1-OTP-BOOT-GPREG2, are decoded by boot ROM.

#### Note

Z1-GPREG2 shares ECC with Z1-GPREG1, so program both these locations at the same time in user OTP.

**Table 4-18. DCSM Zone GPREG2 Bit Fields**

Bit	Name	Description	Boot ROM Action
31:24	Key	Write 0x5A to indicate to the boot ROM code that the bits in this register are valid.	If user sets to 0x5A, boot ROM uses the values in this register. If set to any other value, boot ROM ignores values in this register.
23:8	Reserved	Reserved	No Action
7:6	MPOST <sup>(1)</sup>	0x0 = Run MPOST with PLL disabled (10MHz internal oscillator) 0x1 = Run MPOST with SYSPLL enabled for 75MHz and AUXPLL enabled for 50MHz 0x2 = Run MPOST with SYSPLL enabled for 150MHz and AUXPLL enabled for 100MHz 0x3 = Disable MPOST	When configured to a valid value, MPOST POR memory self-test is run on all device memories.
5:4	ERROR_STS_PIN	0x0 = GPIO24, MUX Option 13 0x1 = GPIO28, MUX Option 13 0x2 = GPIO29, MUX Option 13 0x3 = ERROR_STS function disabled (default)	This indicates which GPIO pin is supposed to be used as ERROR_PIN and boot ROM configures the mux as such for the said pin. The ERROR_STS pin mux configuration is locked by the boot ROM, but not committed.
3:0	CJTAGNODEID	CJTAGNODEID[3:0]	Boot ROM takes this values and programs the lower 4 bits of the CJTAGNODEID register.

- (1) If MPOST is configured to run with PLL enabled and the PLL fails to lock, then the MPOST run is skipped. This does not apply, if MPOST is configured to use INTOSC2 with PLL disabled.

## 4.7.2 Booting CPU2

This section details the boot up flow for CPU2. This includes the process, how to configure IPCBOOTMODE, and the error IPC commands that CPU2 report to CPU1.

### 4.7.2.1 Boot Up Procedure

The boot configurations for CPU2 is set by the CPU1 application. The CPU1 application configures the clocks for CPU2, sets the boot mode and other parameters in the IPCBOOTMODE register, and releases CPU2 from reset to boot.

CPU2 has two states where the CPU1 can configure the boot mode. The first state occurs before CPU2 boots up and when CPU2 is still in reset. The second state occurs after CPU2 has been released from reset to wait boot mode where the core wait for an IPC flag to be set by CPU1 to indicate that a boot mode has been set in the IPCBOOTMODE register. The procedures that CPU1 must follow are detailed in [Table 4-19](#).

#### Note

Regardless of reset source, CPU2 requires the IPCFLG0 to be set by CPU1 on every reset to confirm the contents of IPCBOOTMODE are valid and continue the boot process.

**Table 4-19. CPU2 Boot Procedure**

CPU2 State	CPU1 Application Actions
Held in Reset	<ol style="list-style-type: none"> <li>1. Configures CPU2 clocks</li> <li>2. Configures the CPU1TOCPU2IPCBOOTMODE register (Refer to <a href="#">Section 4.7.2.2</a> for configuration details)</li> <li>3. Sets CPU1TOCPU2IPCFLG0<sup>(1)</sup></li> <li>4. Releases CPU2 from being held in reset</li> </ol>
In Wait Boot Mode waiting for the IPC Flag	<ol style="list-style-type: none"> <li>1. Configures the CPU1TOCPU2IPCBOOTMODE register (Refer to <a href="#">Section 4.7.2.2</a> for configuration details)</li> <li>2. Sets CPU1TOCPU2IPCFLG0<sup>(1)</sup></li> </ol>

(1) CPU2 acknowledges (ACK) and clears this IPC flag during boot up.

#### 4.7.2.2 IPCBOOTMODE Details

This section details the CPU1TOCPU2IPCBOOTMODE register bit-field configurations and requirements for booting CPU2.

#### Note

If the bit-fields of the CPU1TOCPU2IPCBOOTMODE register are set with invalid values, an error IPC command is sent to CPU1. CPU2 then enter a wait loop where CPU2 wait for CPU1 to re-configure the IPCBOOTMODE register correctly and issue a reset to the respective core.

**Table 4-20. CPU1TOCPU2IPCBOOTMODE Register Details**

Bit	Name	Valid Values	Description
31:24	Key	0x5A	Key must be set for this register to be considered valid.
23:20	Reserved	-	Reserved
19:16	IPC Message RAM Copy Length	0x0 = 0 words (Boot mode not used) 0x1 = 100 words 0x2 = 200 words ... 0x9 = 900 words 0xA = 1000 words <sup>(1)</sup>	Sets the data length (in words) for the "Copy from IPC Message RAM and Boot to M1RAM" boot mode. This is the number of words to be copied from CPU1TOCPU2MSGGRAM1 to CPU2 M1RAM.  If not using this boot mode, set value to 0x0.
15:8	Reserved	-	Reserved
7:0	CPU2 Boot Mode	0x00 = None/Wait Boot 0x01 = IPC Message RAM copy and boot to M1RAM 0x03 = Flash Boot Option 0 (Sector 0) 0x05 = Boot to M0RAM 0x0A = Secure Flash Boot Option 0 (Sector 0) 0x0B = Boot to User OTP 0x23 = Flash Boot Option 1 (Sector 4) 0x2A = Secure Flash Boot Option 1 (Sector 4) 0x43 = Flash Boot Option 2 (Sector 8) 0x4A = Secure Flash Boot Option 2 (Sector 8) 0x63 = Flash Boot Option 3 (Sector 13) 0x6A = Secure Flash Boot Option 3 (Sector 13)	Sets the boot mode for CPU2

(1) Values greater than 0xA are invalid.

#### 4.7.2.3 Error IPC Command Table

This section details the IPC commands that CPU2 can send to CPU1 to notify CPU1 regarding an error that occurred.

#### Note

After CPU2 sends the error IPC command to CPU1, CPU2 sets CPU2TOCPU1IPCFLG0.

**Table 4-21. CPU2 to CPU1 Error IPC Commands**

Description	IPCSENDCOM Value	IPCSENDADDR Value
No Command	0x0000 0000	Not Used
IPCBOOTMODE Values Incorrect	0xFFFF FFFF	Not Used
CPU2 in ITRAP	0xFFFF FFFE	If RAM is accessible, the address for the source of the ITRAP is provided
CPU2 got NMI	0xFFFF FFFA	Not Used
CPU2 Secure Flash CMAC Calculation Failed	0xFFFF FFF9	Not Used

#### 4.7.3 Entry Points

This sections gives details about the entry point addresses for various boot modes. These entry points direct the boot ROM what address to branch to at the end of booting as per the selected boot mode.

[Table 4-22](#) and [Table 4-23](#) give details about the entry point addresses for the Flash boot mode, RAM boot mode, and Secure Flash boot mode.

There are a number of Flash banks assigned to CPU1 by default, which can be allocated to CPU2 by configuring in software. Bank0 is always allocated to CPU1 only. This boot mode selects the memory address in Flash to branch to once boot has completed.

The Secure Flash boot can be executed with PLL enabled to run at 200MHz.

**Table 4-22. Entry Point Addresses for CPU1**

Boot Mode	Option	BOOTDEFx Value	Flash Sector	Address	Packages Supported
Flash	0	0x03	CPU1 Bank 0 Sector 0	0x0008 0000	All
Flash	1	0x23	CPU1 Bank 0 End of Sector 127	0x0009 FFF0	All
Flash	2	0x43	CPU1 Bank 1 Sector 0	0x000A 0000	All
Flash	3	0x63	CPU1 Bank 2 Sector 0	0x000C 0000	All
Flash	4	0x83	CPU1 Bank 3 Sector 0	0x000E 0000	All
Flash	5	0xA3	CPU1 Bank 4 Sector 0	0x0010 0000	All
Flash	6	0xC3	CPU1 Bank 4 End of Sector 127	0x0011 FFF0	All
RAM	RAM	0x05	N/A	0x0000 0000	All
Secure Flash	0	0x0A	CPU1 Bank 0 Sector 0	0x0008 0000	All
Secure Flash	2	0x4A	CPU1 Bank 1 Sector 0	0x000A 0000	All
Secure Flash	3	0x6A	CPU1 Bank 2 Sector 0	0x000C 0000	All
Secure Flash	4	0x8A	CPU1 Bank 3 Sector 0	0x000E 0000	All
Secure Flash	5	0xAA	CPU1 Bank 4 Sector 0	0x0010 0000	All

**Table 4-23. Entry Point Addresses for CPU2**

Boot Mode	Option	BOOTDEFx Value	Flash Sector	Address	Packages Supported
Flash	0	0x03	CPU2 Bank 0 Sector 0	0x0008 0000	All
Flash	1	0x23	CPU2 Bank 0 End of Sector 127	0x0009 FFF0	All
Flash	2	0x43	CPU2 Bank 1 Sector 0	0x000A 0000	All
Flash	3	0x63	CPU2 Bank 2 Sector 0	0x000C 0000	All
Flash	4	0x83	CPU2 Bank 3 Sector 0	0x000E 0000	All
Flash	5	0xA3	CPU2 Bank 4 Sector 0	0x0010 0000	All
Flash	6	0xC3	CPU2 Bank 4 End of Sector 127	0x0011 FFF0	All
RAM	0	0x05	N/A	0x0000 0000	All
Secure Flash	0	0x0A	CPU2 Bank 0 Sector 0	0x0008 0000	All
Secure Flash	2	0x4A	CPU2 Bank 1 Sector 0	0x000A 0000	All
Secure Flash	3	0x6A	CPU2 Bank 2 Sector 0	0x000C 0000	All
Secure Flash	4	0x8A	CPU2 Bank 3 Sector 0	0x000E 0000	All
Secure Flash	5	0xAA	CPU2 Bank 4 Sector 0	0x0010 0000	All

#### 4.7.4 Wait Points

The wait mode puts the CPU in a loop in the boot ROM code and does not branch to the user application code. The device can enter the wait boot mode either through manually being set or because of some issue during boot up. Using the wait boot mode is recommended when using a debugger to avoid any JTAG issues. There is an ESTOP provided for debugging during Wait boot.

**Table 4-24. Wait Boot Options**

Option	BOOTDEFx Value	Watchdog Status	Package Supported
0 (default)	0x04	Enabled	All
1	0x24	Disabled	All

During boot ROM execution, there are situations where the CPU can enter a wait loop in the code. This state can occur for a variety of reasons. [Table 4-25](#) details the address ranges that the CPU PC register value falls between, if the CPU has entered one of these instances.

Following are the actions for entering wait boot mode:

- Wait boot is set by the user as the boot mode.
- Boot mode is unrecognizable and a debugger is connected to the device.
- The emulation BOOTPIN\_CONFIG key isn't equal to 0xA5 or 0x5A.
- An error occurs during emulation boot and the boot mode pins are decoded with a value not recognized as a valid boot mode.

**Table 4-25. Wait Point Addresses**

Address Range	Description
0x003F B714–0x003F B717	In Wait Boot mode
0x003F D3FB–0x003F D403	In SCI Boot waiting on autobaud lock
0x003F FD73–0x003F FE4A	In NMI Handler
0x003F FE4B–0x003F FE78	In ITRAP ISR
0x003F CC6F–0x003F CC73 0x003F CB54–0x003F CB6B	In Parallel Boot waiting for control signal

### 4.7.5 Secure Flash Boot Mode

---

#### Note

The Advanced Encryption Standard (AES) cryptographic hardware-accelerated module has to be with CPU2, while the AES module does secure Flash boot. CPU1 cannot pull this back and CPU1 can take back the AES module only after the CPU2 boot status indicates that the secure Flash boot is completed.

---

Secure Flash boot mode is similar to Flash boot mode in that the boot flow branches to the configured memory address in Flash except only after the Flash memory contents have been authenticated. The Flash authentication uses a Cipher-based Message Authentication Protocol (CMAC) to authenticate 16KB of Flash starting from the configured Flash entry point address. The CMAC calculation requires a user-defined 128-bit key programmed in the CPU User OTP Zone 1 Header OTP CMACKEY bit field. Additionally, the user must calculate the golden CMAC tag based on the 16KB Flash memory range and store the tag along with the user code at a hardcoded address in Flash. During secure Flash boot, the calculated CMAC tag is compared to the user golden CMAC tag in Flash to determine the pass/fail status of the CMAC authentication. When authentication passes, boot flow continues and branches to Flash to begin executing the application. Upon CPU1 secure boot mismatch, the device is reset. Upon CPU2 secure boot mismatch, an IPC is sent to CPU1 and CPU2 returns to “wait for command” mode.

For the available secure Flash boot entry address options, refer to [Section 4.7.3](#).

For generating the secure Flash golden CMAC tag for CPU, refer to the [TMS320C28x Assembly Language Tools User's Guide](#) within section “Using Secure Flash Boot on TMS320F2838x Devices” for instructions.

---

#### Note

Both the CMAC golden signature and CMAC key are stored in the most-significant double format, but each 32-bit section is in little-endian format.

Key: 2B7E 1516 28AE D2A6 ABF7 1588 09CF 4F3C

(MSB is 2B and LSB is 3C)

CMACKEY0 = 0x2B7E 1516

CMACKEY1 = 0x28AE D2A6

CMACKEY2 = 0xABF7 1588

CMACKEY3 = 0x09CF 4F3C

---

#### Note

Make sure that the Flash sector that encompasses the configured Flash entry point and the first 16KB of Flash is assigned to Zone 1 for the core setup for secure Flash boot.

Recommended to use device JTAGLOCK when using secure Flash boot.

---

APIs for CMAC calculation and authentication is provided as part of ROM. Details are available in [Section 4.7.10](#).

**Table 4-26. CPU1 and CPU2 Secure Flash Boot Details**

Details	Location Address
CMAC Signature Address	Flash Entry Point Address + 0x2
CMAC Key Address (128-bit key)	DCSM Z1 OTP CMACKEY0/1/2/3
Flash Entry Point (Bank 0, Sector 0)	0x0008 0000
Flash Entry Point (Bank 1, Sector 0)	0x000A 0000
Flash Entry Point (Bank 2, Sector 0)	0x000C 0000
Flash Entry Point (Bank 3, Sector 0)	0x000E 0000
Flash Entry Point (Bank 4, Sector 0)	0x0010 0000
Address Range for CMAC Calculation	Start: Flash Entry Point Address End: Flash Entry Point Address + 16KB

**Table 4-27. Secure Flash Tag and Key Details**

Name	Address	Details
CMAC Golden Tag (128-bit)	<b>CPU:</b> <i>Flash Entry Point Address + 0x2</i>	Located in Flash, offset from the entry point address, by 2 words (CPU). When CMAC calculations are performed, the golden tag location in memory is considered all 0xFs. Refer to <a href="#">Example 4-1</a> for an example regarding linker configuration on CPU. Lower memory contains the tag's MSW and higher memory contains the LSW.  <b>Example (on CPU):</b> Tag = 0x0011 2233 4455 6677 8899 AABB CCDD EEFF Address 0x0 = 0x0011 2233 Address 0x2 = 0x4455 6677 Address 0x4 = 0x8899 AABB Address 0x6 = 0xCCDD EEFF
CMAC 128-Bit Key	0x0007 8018	Located in CPU Zone 1 User Header OTP (CMACKEY0, CMACKEY1, CMACKEY2, CMACKEY3) CMACKEY0 contains the key's MSW and CMACKEY3 contains the LSW.  <b>Example:</b> Key = 0x0011 2233 4455 6677 8899 AABB CCDD EEFF CMACKEY0 = 0x0011 2233 CMACKEY1 = 0x4455 6677 CMACKEY2 = 0x8899 AABB CMACKEY3 = 0xCCDD EEFF

**Table 4-28. Secure Flash Authentication Failure Actions**

CPU	Action on Failed Authentication
CPU1	1. Emulation only - Halt debugger (ESTOP) 2. Wait in endless loop (for device reset due to watchdog reset)
CPU2	1. Send IPC to CPU1 2. Return to "wait for command" loop

### Example 4-1. Secure Flash CPU1 Linker File Example

```

MEMORY

  .
}

```

## 4.7.6 Memory Maps

### 4.7.6.1 Boot ROM Memory-Maps

Table 4-29 details the ROM memory-map including secure and unsecure ROM.

**Table 4-29. Boot ROM Memory-Map**

Memory	Origin Address	Length (Words)
ROM Signature	0x003F 5000	0x0002
Version	0x003F 5002	0x0004
IQmath Tables	0x003F 5006	0x1674
FPU32 Fast Tables	0x003F 667A	0x081A
FPU64 Fast Tables	0x003F 6E94	0x0D30
FPU32 Twiddle Tables	0x003F 7BC4	0x0DF8
FPU64 Twiddle Tables	0x003F 89BC	0x1BF0
Boot code	0x003F A5AC	0x574A
Interrupt Handlers	0x003F FCF6	0x020E
CRC Table	0x003F FFB6	0x0008
Vector Table	0x003F FFBE	0x0042

### 4.7.6.2 Reserved RAM Memory-Maps

Table 4-30 details memory usage in RAM that is reserved for boot ROM to use. These memory sections can be reserved in the user application.

**Table 4-30. Reserved RAM Memory-Map**

Memory	Description	Origin Address	Length (Words)
RAM	Boot Status, Boot Mode, MPOST Status, Boot Stack	0x0000 0002	0x01C0

### 4.7.7 ROM Tables

[Table 4-31](#) details the boot ROM symbol libraries that can be integrated into an application to use the available ROM functions and tables.

**Table 4-31. ROM Symbol Tables**

ROM Symbols	Library Name	Location
ROM Bootloaders and Functions	F28P65xCPU_BootROM_Symbols	Under <code>/libraries/boot_rom</code> in <a href="#">C2000Ware</a>
FPU32 Tables	F28P65xCPU_BootROM_Symbols	
IQmath	F28P65xCPU_IQMathROM_Symbols	

### 4.7.8 Boot Modes and Loaders

The available boot modes and bootloaders supported on this device are detailed in this section.

#### 4.7.8.1 Boot Modes

This section details the available boot modes that do not involve a peripheral boot loader. [Table 4-32](#) details the available boot modes that do not involve a peripheral boot loader.

**Table 4-32. Boot Mode Availability**

Boot Mode	CPU Support
Flash Boot	C28x CPU
RAM Boot	C28x CPU
Wait Boot	C28x CPU
Secure Flash Boot	C28x CPU

##### 4.7.8.1.1 Flash Boot

Flash boot mode branches to the configured memory address in Flash. Refer to [Section 4.7.3](#) for all the available Flash address options.

##### 4.7.8.1.2 RAM Boot

RAM boot mode branches to the configured memory address in RAM. Refer to [Section 4.7.3](#) for all the available RAM address options.

##### 4.7.8.1.3 Wait Boot

Wait boot mode branches to the memory address as mentioned in [Section 4.7.4](#).

##### 4.7.8.1.4 Secure LFU Flash Boot

Secure LFU Flash boot performs the same Flash bank selection as the non-secure LFU described in [Section 4.7.8.2.9](#). Once the bank entry address is determined, this address + 16KB is authenticated using a CMAC algorithm. The CPUBROM\_verifySecureFlash and CMAC algorithms are reused from the [Section 4.7.5](#) to perform this authentication.

The flow is:

1. Secure LFU boot mode selected.
2. Perform LFU bank selection.
3. Perform CMAC on selected entry address + 16KB.
4. Boot to Flash bank.

To support Secure LFU Flash boot mode, the application image has to have a few fields as shown in [Table 4-33](#).

**Table 4-33. Secure LFU Application Image Format**

Image Address Offset	Content
0x0	Application entry point (32-bit)
0x2	Golden CMAC Tag (128-bits)
0xA	Key (32-bit) Valid Key = 0x5A5A 5A5A
0xC	Firmware version number (32-bit)

**Application entry point:** This is the code execution start address of the image stored in Flash.

**Key:** This 32-bit field determines if this image is valid. The image in a bank is considered valid only if the location contains the value 0x5A5A 5A5A. In case all banks have invalid keys, an error is flagged in boot\_status variable and program jumps to a while loop in standalone boot mode (ESTOP in emulation boot mode).

**Firmware version number:** This 32-bit field is the version number of the application. 0xFFFF FFFF is considered as the initial value and this needs to be decremented after every update. The image with lower version number is the latest application. If all valid images have same version number, then bank-0 (or the lowest numbered bank) is chosen.

**Golden CMAC Tag:** This 128-bit field stores the calculated golden CMAC tag that is used as part of the secure Flash CMAC authentication.

[Table 4-34](#) shows the entry points for CPU1 LFU boot mode.

[Table 4-35](#) shows the entry points for CPU2 LFU boot mode.

**Table 4-34. CPU1 Secure LFU Entry Point Addresses**

Option	BOOTDEFx Value	Bank 0	Bank 1	Bank 2	Bank3	Bank4
0	0x0C	0x0008 0000	0x000A 0000	0x000C 0000	0x000E 0000	0x0010 0000
1	0x2C	0x0008 FFF0	0x000A FFF0	0x000C FFF0	0x000E FFF0	0x0010 FFF0
2	0x4C	0x0009 0000	0x000B 0000	0x000D 0000	0x000F 0000	0x0011 0000

**Table 4-35. CPU2 Secure LFU Entry Point Addresses**

Option	BOOTDEFx Value	Bank 0	Bank 1	Bank 2	Bank3	Bank4
0	0x07	0x0008 0000	0x000A 0000	0x000C 0000	0x000E 0000	0x0010 0000
1	0x27	0x0008 FFF0	0x000A FFF0	0x000C FFF0	0x000E FFF0	0x0010 FFF0
2	0x47	0x0009 0000	0x000B 0000	0x000D 0000	0x000F 0000	0x0011 0000

#### Note

Secure LFU boot mode has the same bank addresses as non-secure LFU boot mode, except boot option 2 is not supported due to CMAC requirements.

For example, if Option 0 with Bank 0 has the application image:

[0008 0000-0008 0001] = Application entry point

[0008 0002-0008 0009] = Golden CMAC Tag

[0008 000A-0008 000B] = Key

[0008 000C-0008 000D] = Firmware version number

#### 4.7.8.2 Bootloaders

This section details the available boot modes that use a peripheral boot loader. For more specific details on the supported data stream structure used by the following bootloaders, refer to [Section 4.8.1](#).

##### 4.7.8.2.1 SCI Boot Mode

The SCI boot mode asynchronously transfers code from SCI-A to internal memory. This boot mode only supports an incoming 8-bit data stream and follows the data flow as shown in [Figure 4-5](#).

**Figure 4-5. Overview of SCI Bootloader Operation**

The device communicates with the external host by communication through the SCI-A peripheral. The autobaud feature of the SCI port is used to lock baud rates with the host. For this reason the SCI loader is very flexible and you can use a number of different baud rates to communicate with the device.

After each data transfer, the bootloader echoes back the 8-bit character received to the host. This allows the host to check that each character was received by the bootloader.

At higher baud rates, the slew rate of the incoming data bits can be affected by transceiver and connector performance. While normal serial communications can work well, this slew rate can limit reliable auto-baud detection at higher baud rates (typically beyond 100k baud) and cause the auto-baud lock feature to fail. To avoid this, the following is recommended:

1. Achieve a baud-lock between the host and SCI bootloader using a lower baud rate.
2. Load the incoming application or custom loader at this lower baud rate.
3. The host can then handshake with the loaded application to set the SCI baud rate register to the desired high baud rate.

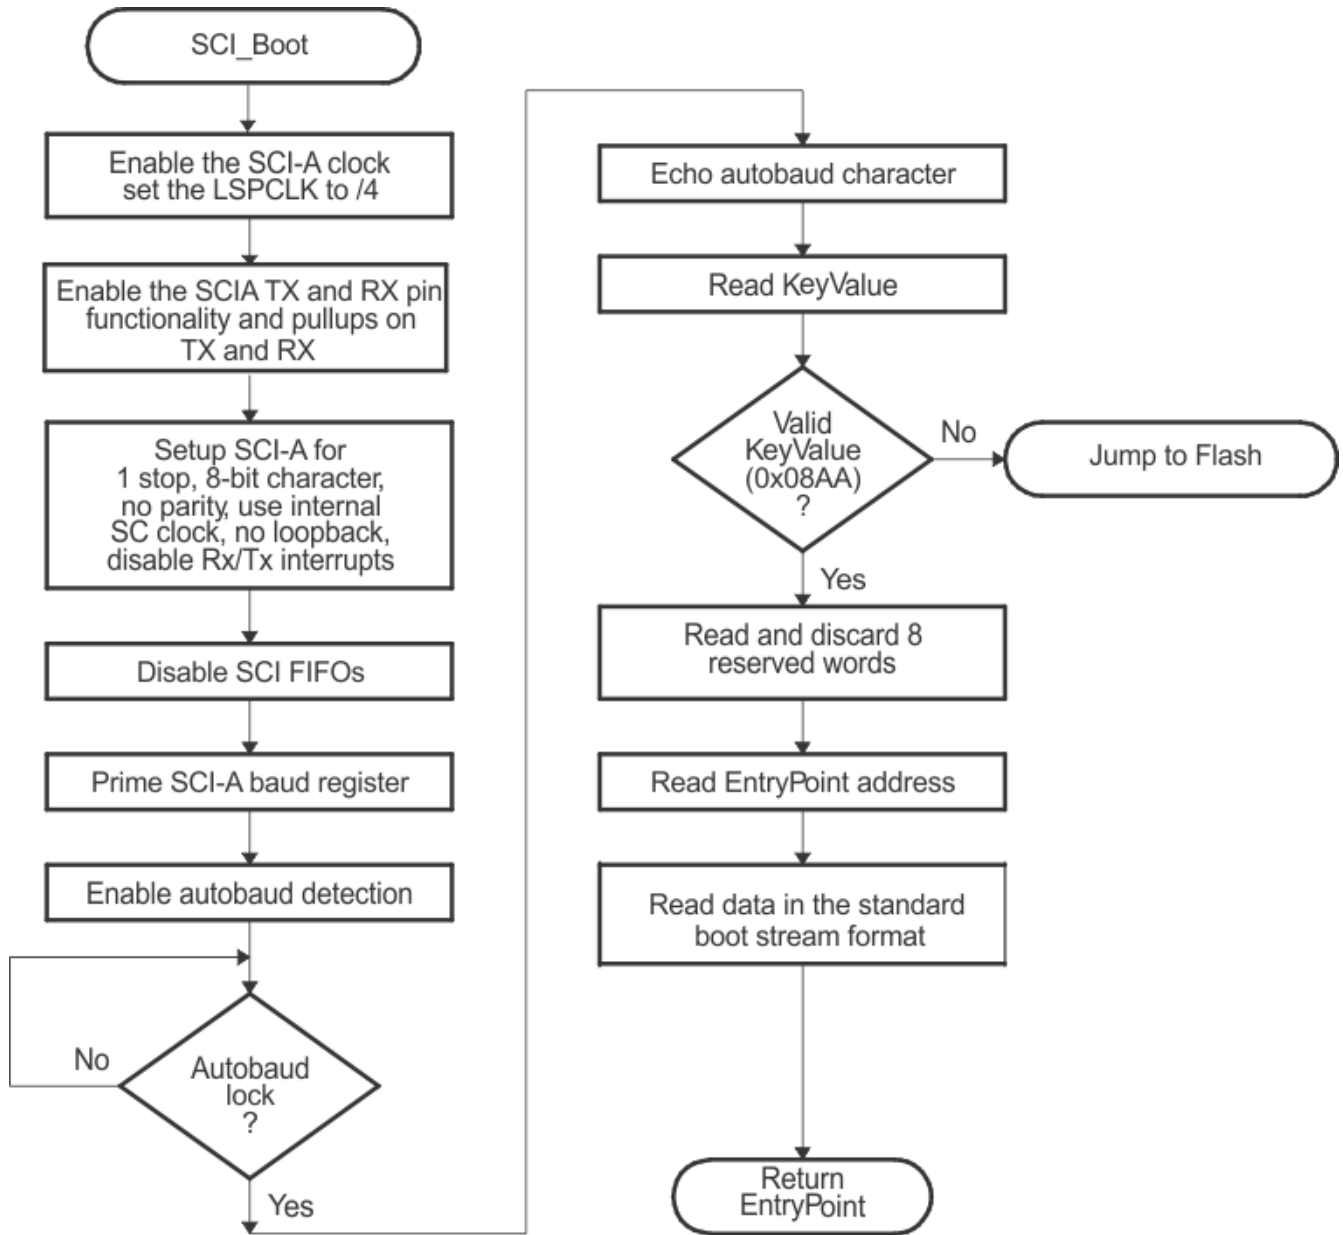

Figure 4-6. Overview of SCI Boot Function

#### 4.7.8.2.2 SPI Boot Mode

The SPI loader expects an SPI-compatible 16-bit or 24-bit addressable serial EEPROM or serial Flash device to be present on the SPI-A pins as shown in Figure 4-7. The SPI bootloader supports an 8-bit data stream and does not support a 16-bit data stream.

**Figure 4-7. Overview of SPI Bootloader Operation**

The SPI boot ROM loader initializes the SPI module to interface to a serial SPI EEPROM or Flash. Devices of this type include, but are not limited to, the Xicor X25320 (4Kx8) and Xicor X25256 (32Kx8) SPI serial SPI EEPROMs and the Atmel AT25F1024A serial Flash.

The SPI boot ROM loader initializes the SPI with the following settings: FIFO enabled, 8-bit character, internal SPICLK controller mode and talk mode, clock phase = 1, polarity = 0, using the slowest baud rate.

If the download is to be performed from an SPI port on another device, then that device must be set up to operate in the peripheral mode and mimic a serial SPI EEPROM. Immediately after entering the SPI\_Boot function, the pin functions for the SPI pins are set to primary and the SPI is initialized. The initialization is done at the slowest speed possible. Once the SPI is initialized and the key value read, specify a change in baud rate or low speed peripheral clock. Table 4-36 shows the 8-bit data stream used by the SPI.

**Table 4-36. SPI 8-Bit Data Stream**

Byte	Contents
1	LSB: AA (KeyValue for memory width = 8-bits)
2	MSB: 08h (KeyValue for memory width = 8-bits)
3	LSB: LOSPCP
4	MSB: SPIBRR
5	LSB: reserved for future use
6	MSB: reserved for future use
...	...

...	...
...	Data for this section.
n	LSB: 00h
n+1	MSB: 00h - indicates the end of the source

The data transfer is done in "burst" mode from the serial SPI EEPROM. The transfer is carried out entirely in byte mode (SPI at 8 bits/character). A step-by-step description of the sequence follows:

1. The SPI-A port is initialized.
2. The GPIO pin, as defined by SPI option configured from [Table 4-53](#), is used as a chip-select for the serial SPI EEPROM or Flash.
3. The SPI-A outputs a read command for the serial SPI EEPROM or Flash.
4. The SPI-A sends the serial SPI EEPROM an address 0x0000; that is, the host requires that the EEPROM or Flash must have the downloadable packet starting at address 0x0000 in the EEPROM or Flash. The loader is compatible with both 16-bit addresses and 24-bit addresses.
5. The next word fetched must match the key value for an 8-bit data stream (0x08AA). The least significant byte of this word is the byte read first and the most significant byte is the next byte fetched. This is true of all word transfers on the SPI. If the key value does not match, then the load is aborted and the bootloader jumps to Flash.
6. The next two bytes fetched can be used to change the value of the low speed peripheral clock register (LOSPCP) and the SPI baud rate register (SPIBRR). The first byte read is the LOSPCP value and the second byte read is the SPIBRR value. The next seven words are reserved for future enhancements. The SPI bootloader reads these seven words and discards them.
7. The next two words makeup the 32-bit entry point address where execution continues after the boot load process is complete. This is typically the entry point for the program being downloaded through the SPI port.
8. Multiple blocks of code and data are then copied into memory from the external serial SPI EEPROM through the SPI port. The blocks of code are organized in the standard data stream structure presented earlier. This is done until a block size of 0x0000 is encountered. At that point in time the entry point address is returned to the calling routine that then exits the bootloader and resumes execution at the address specified.

**Figure 4-8. Data Transfer from EEPROM Flow**

#### 4.7.8.2.3 I2C Boot Mode

The I2C bootloader expects an 8-bit wide I2C-compatible EEPROM device to be present at address 0x50 on the I2C-A bus as shown in [Figure 4-9](#). The EEPROM must adhere to conventional I2C EEPROM protocol, as described in this section, with a 16-bit base address architecture.

**Figure 4-9. EEPROM Device at Address 0x50**

If the download is to be performed from a device other than an EEPROM, then that device must be set up to operate in the target mode and mimic the I2C EEPROM. Immediately after entering the I2C boot function, the GPIO pins are configured for I2C-A operation and the I2C is initialized. The following requirements must be met when booting from the I2C module:

- The input frequency to the device must be in the appropriate range.
- The EEPROM must be at target address 0x50.

The bit-period prescalers (I2CCLKH and I2CCLKL) are configured by the bootloader to run the I2C at a 50 percent duty cycle at 100kHz bit rate (standard I2C mode) when the system clock is 10MHz. These registers can be modified after receiving the first few bytes from the EEPROM. This allows the communication to be increased up to a 400kHz bit rate (fast I2C mode) during the remaining data reads.

Arbitration, bus busy, and target signals are not checked. Therefore, no other controller is allowed to control the bus during this initialization phase. If the application requires another controller during I2C boot mode, that controller must be configured to hold off sending any I2C messages until the application software signals that the software is past the bootloader portion of initialization.

The non-acknowledgment bit is checked only during the first message sent to initialize the EEPROM base address. This is to make sure that an EEPROM is present at address 0x50 before continuing. If an EEPROM is not present, the non-acknowledgment bit is not checked during the address phase of the data read messages (I2C\_Get Word). If a non-acknowledgment is received during the data read messages, the I2C bus hangs. [Table 4-37](#) shows the 8-bit data stream used by the I2C.

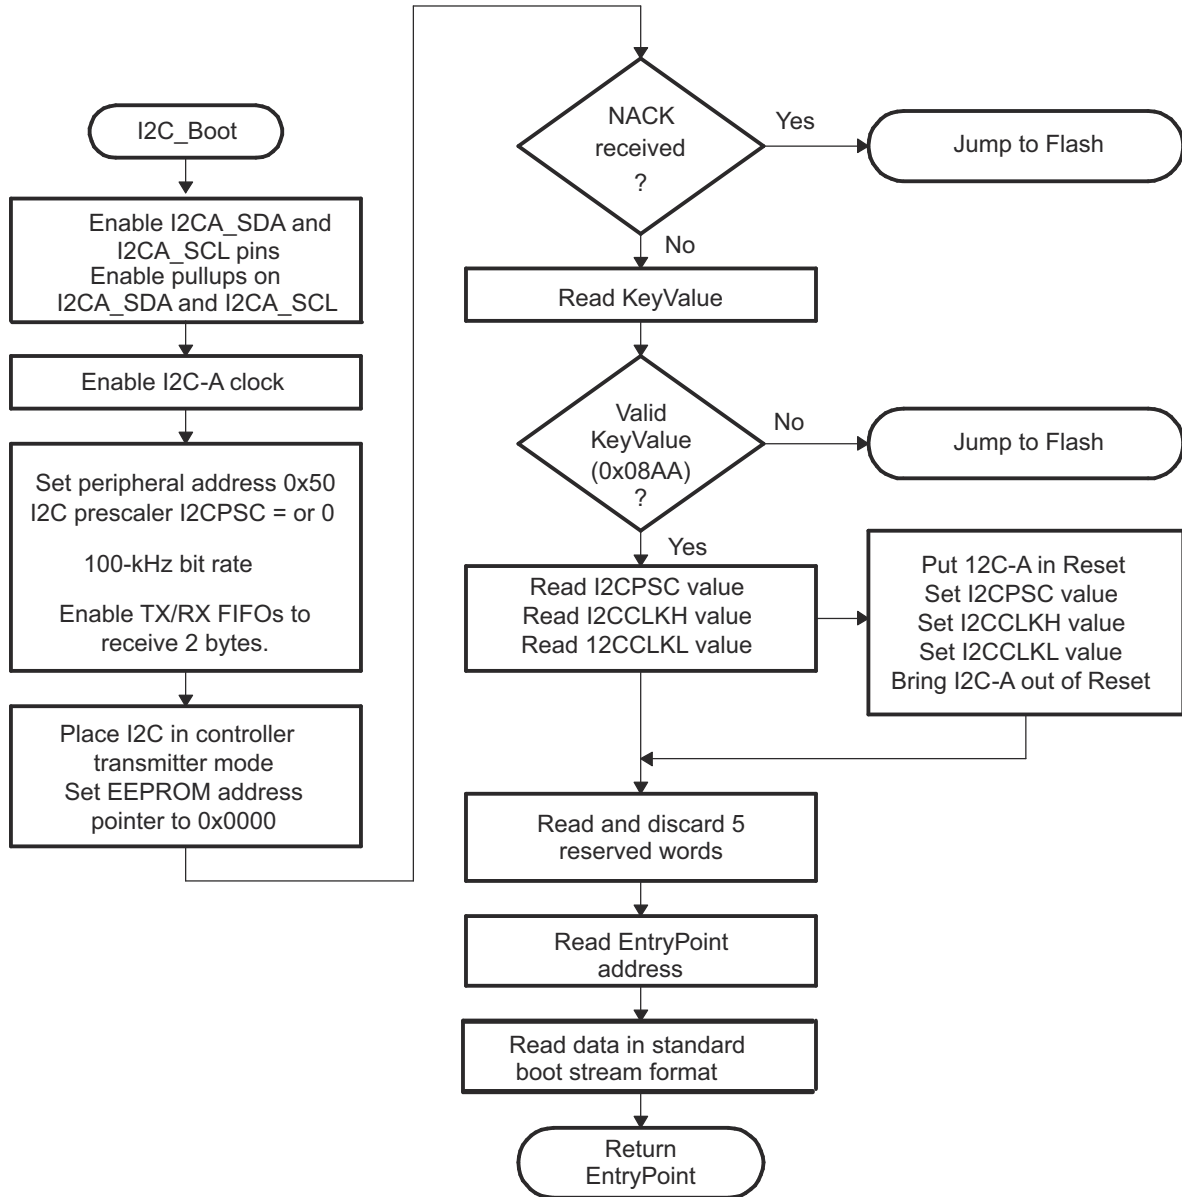

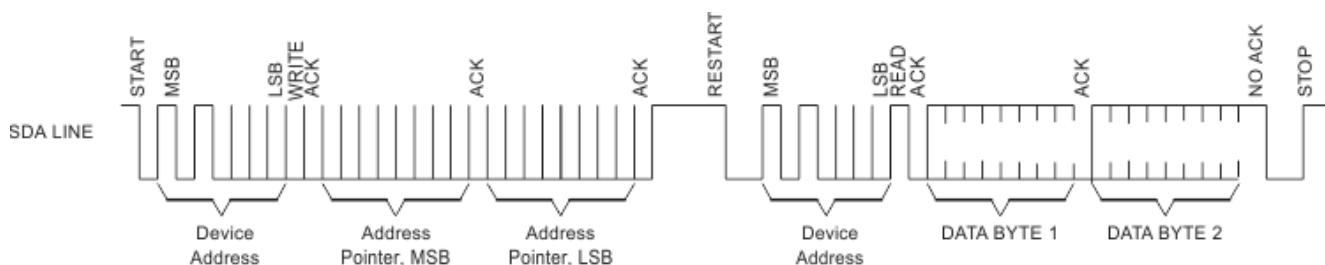

Figure 4-10. Overview of I2C Boot Function

n	LSB: 00h
n+1	MSB: 00h - indicates the end of the source

The I2C EEPROM protocol required by the I2C bootloader is shown in [Figure 4-11](#) and [Figure 4-12](#). The first communication, which sets the EEPROM address pointer to 0x0000 and reads the KeyValue (0x08AA), is shown in [Figure 4-11](#). All subsequent reads are shown in [Figure 4-12](#) and are read two bytes at a time.

**Figure 4-11. Random Read**

**Figure 4-12. Sequential Read**

4.7.8.2.4 Parallel Boot Mode

The parallel general-purpose I/O (GPIO) boot mode asynchronously transfers code from the host to C28x internal memory. Each value is 8-bits long and follows the same data flow as outlined in Figure 4-13.

Figure 4-13. Overview of Parallel GPIO Bootloader Operation

The control subsystem communicates with the external host device by polling/driving the Host Control and 28x control lines. The handshake protocol shown in Figure 4-14 must be used to successfully transfer each word using GPIO [D0:D7]. This protocol is very robust and allows for a slower or faster host to communicate with the controller subsystem.

Two consecutive 8-bit words are read to form a single 16-bit word. The least-significant byte (LSB) is read first followed by the most-significant byte (MSB). In this case, data is read from GPIO[D0:D7].

The device first signals the host that the device is ready to begin data transfer by pulling the 28x control pin low. The host load then initiates the data transfer by pulling the DSP control pin low. The complete handshake protocol is shown in Figure 4-14.

Figure 4-14. Parallel GPIO Bootloader Handshake Protocol

1. The device indicates the device is ready to start receiving data by pulling the 28x control pin low.
2. The bootloader waits until the host puts data on GPIO [D0:D7]. The host signals to the device that data is ready by pulling the host control pin low.
3. The device reads the data and signals the host that the read is complete by pulling the 28x control pin high.
4. The bootloader waits until the host acknowledges the device by pulling the host control pin high.
5. The device again indicates the device is ready for more data by pulling the 28x control pin low.

This process is repeated for each data value to be sent.

The 8-bit data stream is shown in Table 4-38.

Figure 4-15 shows an overview of the parallel GPIO bootloader flow.

**Table 4-38. Parallel GPIO Boot 8-Bit Data Stream**

Bytes		GPIO[D0:D7] (Byte 1 of 2)	GPIO[D0:D7] (Byte 2 of 2)	Description
1	2	AA	08	0x08AA (KeyValue for memory width = 16 bits)
3	4	00	00	8 reserved words (words 2 to 9)
...	...	...	...	...
17	18	00	00	Last reserved word
19	20	BB	00	Entry point PC[22:16]
21	22	DD	CC	Entry point PC[15:0] (PC = 0x00BB CCDD)
23	24	NN	MM	Block size of the first block of data to load = 0xMMNN words
25	26	BB	AA	Destination address of first block Addr[31:16]
27	28	DD	CC	Destination address of first block Addr[15:0] (Addr = 0xAABB CCDD)
29	30	BB	AA	First word of the first block in the source being loaded = 0xAABB
...				...
...				Data for this section.
...				...
.		BB	AA	Last word of the first block of the source being loaded = 0xAABB
.		NN	MM	Block size of the 2nd block to load = 0xMMNN words
.		BB	AA	Destination address of second block Addr[31:16]
.		DD	CC	Destination address of second block Addr[15:0]
.		BB	AA	First word of the second block in the source being loaded
.				...

n+2	n+3	00	00	Block size of 0000h - indicates end of the source program

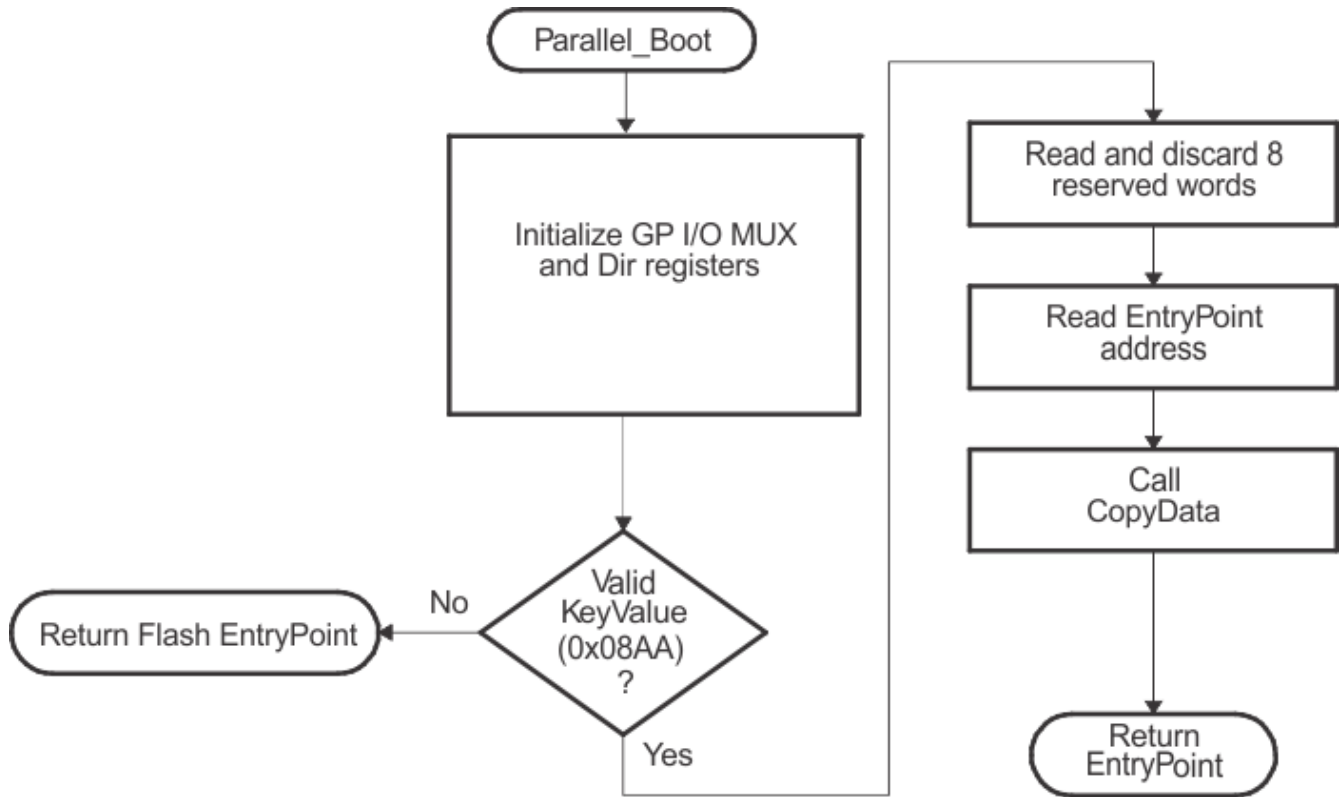

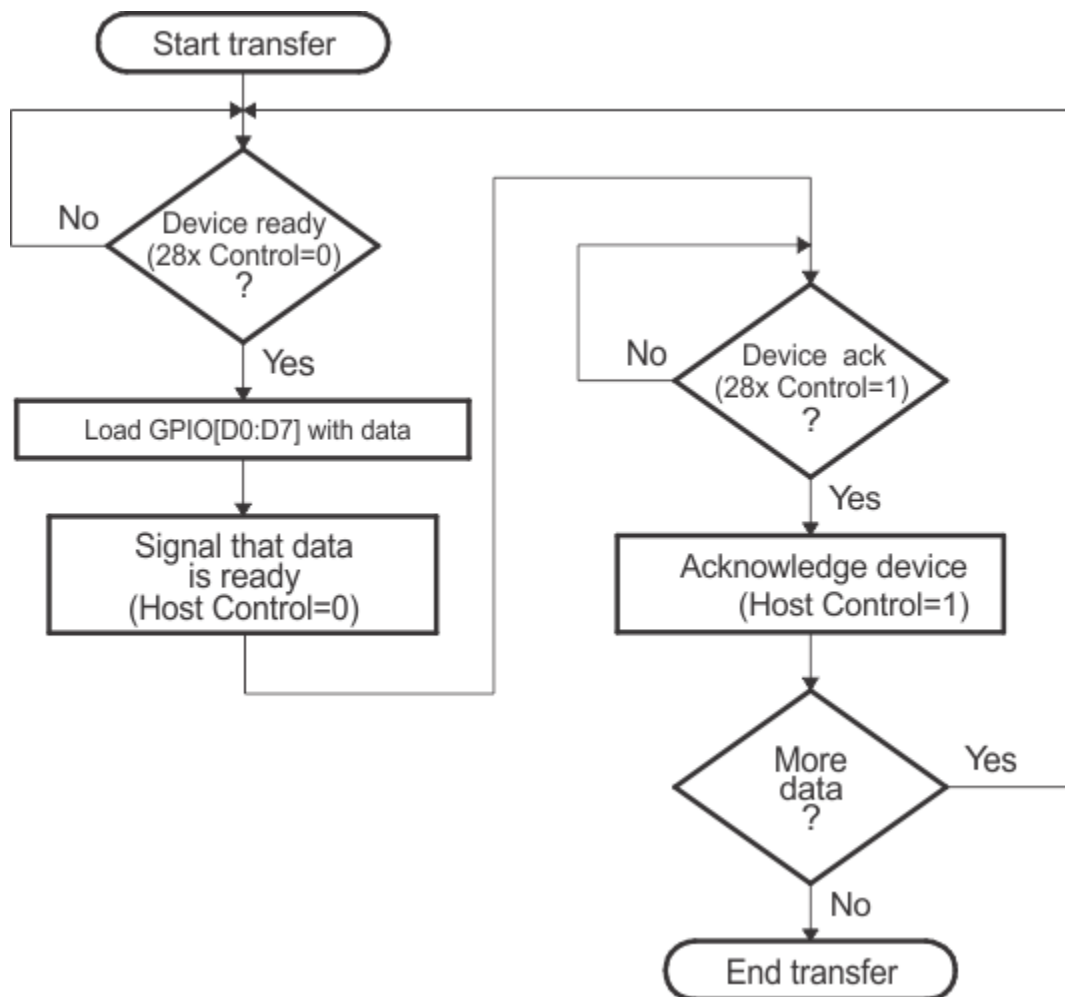

Figure 4-15. Overview of Parallel GPIO Boot Function

Figure 4-16 shows the transfer flow from the host side. The operating speed of the CPU and host are not critical in this mode as the host waits for the device and the device in turn waits for the host. In this manner, the protocol works with both a host running faster and a host running slower than the device.

**Figure 4-16. Parallel GPIO Mode - Host Transfer Flow**

Figure 4-17 shows the flow used to read a single word of data from the parallel port.

The 8-bit routine, shown in Figure 4-17, discards the upper 8 bits of the first read from the port and treats the lower 8 bits masked with D7 in bit position 7 and D6 in bit position 6 as the least-significant byte (LSB) of the word to be fetched. The routine then performs a second read to fetch the most-significant byte (MSB). The routine then combines the MSB and LSB into a single 16-bit value to be passed back to the calling routine.

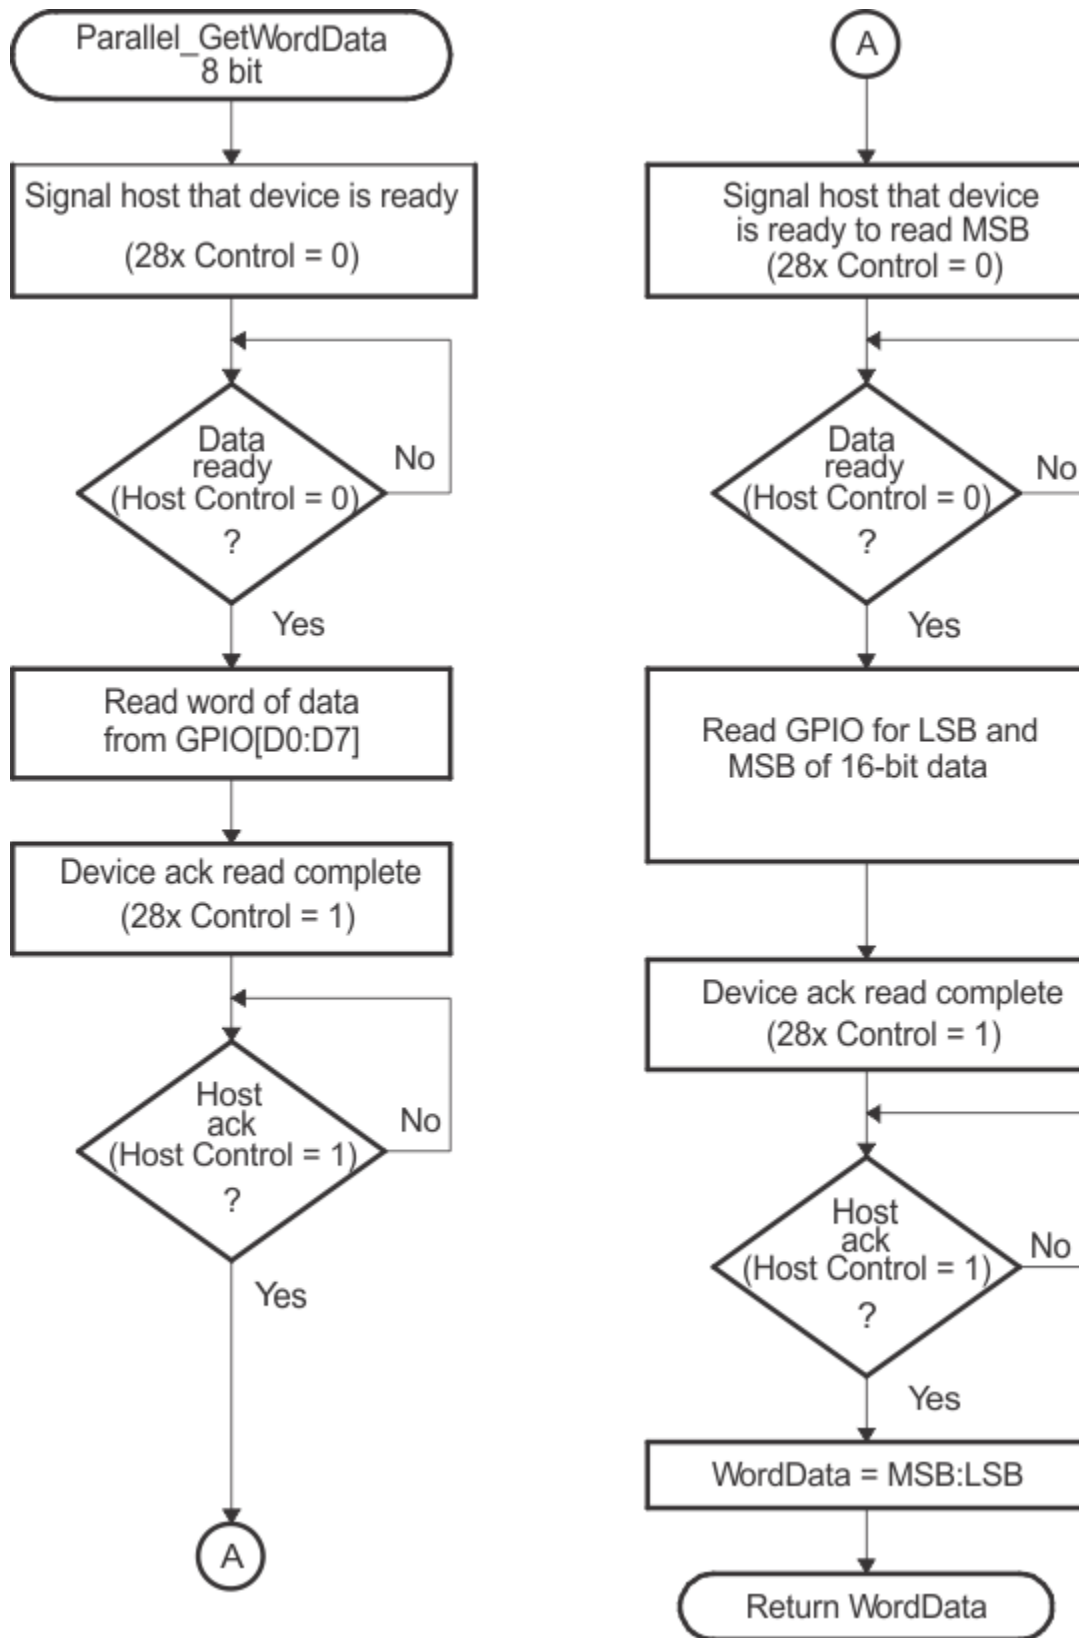

Figure 4-17. 8-Bit Parallel GetWord Function

#### 4.7.8.2.5 CAN Boot Mode

The CAN bootloader asynchronously transfers code from CAN-A to internal memory as shown in [Figure 4-18](#). The host can be any CAN node. The communication is first done with 11-bit standard identifiers (with a MSGID of 0x1) using two bytes per data frame. The host can download a kernel to reconfigure the CAN, if higher data throughput is desired.

#### Note

MCAN and CAN boot can be used with an external oscillator with a 25MHz and 20MHz frequency.

**Figure 4-18. Overview of CAN-A Bootloader Operation**

The bit timing registers are programmed in such a way that a 100kbps bit rate is achieved with a 20MHz external oscillator, as shown in [Table 4-39](#).

**Table 4-39. Bit-Rate Value for External Oscillators**

OSCCLK	SYSCLK	Bit Rate
20MHz	10MHz	100kbps
25MHz	10MHz	100kbps

The SYSCLKOUT values shown are the reset values with the default PLL setting. The BRP and bit-time values are hard-coded to 10 and 20, respectively.

#### Note

The CAN boot loader uses XTAL as the bit clock source and INTOSC2 as the system clock source.

Mailbox 1 is programmed with a standard MSGID of 0x1 for bootloader communication. The CAN host transmits only two bytes at a time, LSB first and MSB next. For example, to transmit the word 0x08AA to the device, transmit AA first, followed by 08. The program flow of the CAN bootloader is identical to the SCI bootloader. The data sequence for the CAN bootloader is shown in [Table 4-40](#).

**Table 4-40. CAN 8-Bit Data Stream**

Bytes	Byte 1 of 2	Byte 2 of 2	Description	
1	2	AA	08	0x08AA (KeyValue for memory width = 16 bits)

#### 4.7.8.2.6 CAN-FD Boot Mode

The CAN-FD bootloader asynchronously transfers code from CAN-FD to internal memory and follows same bootloader execution flow as [Section 4.7.8.2.5](#). The host can be any CAN-FD node. The communication is first done with 11-bit standard identifiers (with a MSGID of 0x1) using two bytes per data frame. The CAN-FD bootloader uses a fixed 64-byte payload size and default bit rate of 1Mbps for nominal phase and 2Mbps for data phase. Bit data timing can be optionally reconfigured after receiving first data segment. The CAN-FD bootloader supports the same debug boot mode and GOIP option-0 as CAN bootloader.

Mailbox 1 is programmed with a standard MSGID of 0x1 for boot-loader communication. The CAN-FD host transmits only two bytes at a time, LSB first and MSB next. For example, to transmit the word 0x08AA to the device, transmit AA first, followed by 08. The program flow of the CAN-FD bootloader is identical to the CAN bootloader. The data sequence for the CAN-FD bootloader is shown in [Table 4-41](#).

**Table 4-41. CAN-FD 8-Bit Data Stream**

Bytes	Byte 1 of 2	Byte 2 of 2	Description	
1	2	AA	08	0x08AA (KeyValue for memory width = 16 bits)
3	4	XX (for example, BB)	XX (for example, AA)	0: Ignored Nonzero: Custom nominal bit register timing [31:16]

.		BB	AA	Destination address of the second block Addr[31:16]
.		DD	CC	Destination address of the second block Addr[15:0]
.		BB	AA	First word of the second block in the source being loaded
.				....
n	n+1	BB	AA	Last word of the last block of the source being loaded (More sections if required)
n+2	n+3	00	00	Block size of 0000h - indicates end of the source program

4.7.8.2.7 USB Boot Mode

Figure 4-19 illustrates the flow for USB boot mode. In USB boot mode, the device enumerates with vendor ID 0x1CBE and product ID 0x00FF. The device descriptor and interface descriptor both show the class as 0xFF (vendor-specific), the subclass as 0x00, and the protocol as 0x00. After enumeration, the device waits for data. Data can be sent using bulk OUT transfers to endpoint 1. The data is interpreted as a series of 8-bit bytes in the standard data stream format described in Section 4.8.1, shown in Table 4-42. No reserved bytes are used. Once the data transfer is complete (block size of 0x0000 sent), the device disconnects from the USB bus, allowing other software to make use of the module if desired.

**Note**

For the USB bootloader, connect 25MHz or 20MHz crystal with up to ±1.5% crystal tolerance.

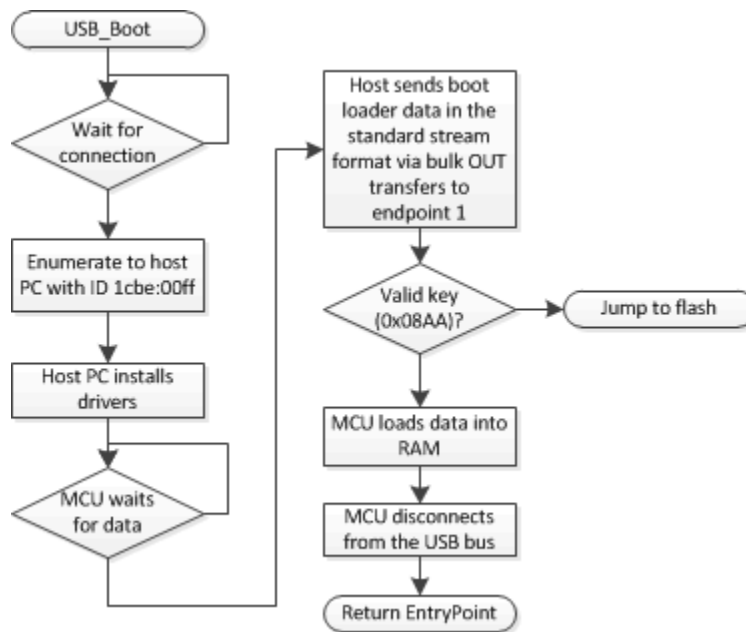

Figure 4-19. USB Boot Flow

**Table 4-42. USB 8-Bit Data Stream**

Bytes	First Byte (LSB)	Second Byte (MSB)	Description
1 2	AA	08	0x08AA (KeyValue for memory width = 16 bits)
3 4	00	00	reserved
5 6	00	00	reserved
7 8	00	00	reserved
9 10	00	00	reserved
11 12	00	00	reserved
13 14	00	00	reserved
15 16	00	00	reserved
17 18	00	00	reserved
19 20	BB	AA	Entry point PC[22:16]
21 22	DD	CC	Entry point PC[15:0] (PC = 0xAABB CCDD)
23 24	NN	MM	Block size of the first block of data to load = 0xMMNN words
25 26	BB	AA	Destination address of the first block Addr[31:16]
27 28	DD	CC	Destination address of the first block Addr[15:0] (Addr = 0xAABB CCDD)
29 30	BB	AA	First word of the first block in the source being loaded = 0xAABB
...			....
...			Data for this section.
...			...
.	BB	AA	Last word of the first block of the source being loaded = 0xAABB
.	NN	MM	Block size of the 2nd block to load = 0xMMNN words
.	BB	AA	Destination address of the second block Addr[31:16]
.	DD	CC	Destination address of the second block Addr[15:0]
.	BB	AA	First word of the second block in the source being loaded
.			...
n n+1	BB	AA	Last word of the last block of the source being loaded (More sections if required)
n+2 n+3	00	00	Block size of 0000h - indicates end of the source program

Implementing PC-side USB software is not trivial. Use the TI-provided tools and drivers to load data in USB boot mode is recommended. Hex and binary files for loader tools can be generated from COFF (.out) files using the hex2000 tool. To produce a plain binary file in the boot loader format, use the following command line:

```
hex2000 -boot -b Program_to_Load.out -o Binary_Loader_Data.dat
```

For more information on hex2000, see the [TMS320C28x Assembly Language Tools User's Guide](#) .

#### Note

INTOSC2 must be enabled before invoking the USB boot loader. If INTOSC2 is not enabled, the boot loader hangs. A debugger reset or SCC reset does not enable INTOSC2, if INTOSC2 has been disabled by the application.

#### 4.7.8.2.8 IPC Message Copy to RAM Boot

IPC message copy to RAM involves copying application code from CPU1 IPC message RAM 1 to CPU2/CM destination RAM for execution. The CPU2 IPC message RAM does not allow for code to be executed. The “CPU1 IPC MSG RAM Copy” boot mode takes an additional value in the IPC boot command in CPU1TOCPU2IPCBOOTMODE, which specifies the length in words to copy out of CPU1 IPC message RAM. The data is copied from unsecure CPU1 IPC message RAM (CPU1TOCPU2MSGRAM1) to CPU2 M1RAM. Once copied, boot ROM branches to M1RAM and the application can begin execution. The maximum copy length size is 1000 words (2000 bytes) and the minimum is 100 words (200 bytes). Refer to [Table 4-43](#) for details regarding configuration and execution flow of this boot mode.

The copy length value specified in CPU1TOCPU2IPCBOOTMODE is checked before running this boot mode and does not execute if the value is out of the valid range. If the value is out of the valid range, an IPC is sent to CPU1 and CPU2 returns to wait-for-command loop. Using M0 RAM can result in boot ROM reserved memory (status variables, stack, and so on) being overwritten when boot mode is used. M1 RAM is used for IPC boot and this boot mode only requires 1000 words. Be aware of any boot mode conflicts if using this boot mode.

**Table 4-43. IPC Message Copy Steps**

Step	Action
1	CPU1 application links CPU2/CM code to copy in either CPU1TOCPU2MSGRAM1 or CPU1TOCMMSGRAM1.
2	CPU1 application configures CPU2/CM IPCBOOTMODE with the copy length and IPC message copy as the boot mode. See <a href="#">Section 4.7.2.2</a> for more IPCBOOTMODE details.
3	Once CPU2/CM is released from reset to boot, CPU2/CM begins copying from CPU1TOCPU2MSGRAM1/ CPU1TOCMMSGRAM1 to their destination RAM. Refer to <a href="#">Table 4-44</a> for destination RAM details.
4	Once the copying is complete, CPU2/CM boot branches to the entry address of the destination RAM and begins executing the application.

**Table 4-44. IPC Message Copy Destination Address**

CPU	RAM	Destination Address Range <sup>(1)</sup> (For maximum copy length of 1000 words)
CPU2	M1RAM	0x0000 0400 to 0x0000 07E6
CM	S0RAM	0x2000 0800 to 0x2000 0FCC

(1) This memory can be allocated and reserved in the CPU2/CM application linker command file when using this boot mode.

#### 4.7.8.2.9 Firmware Update (FWU) Flash Boot

Firmware Update (FWU) boot mode is required to handle the Firmware Update feature. In this boot mode, the boot loader reads the version number from images present in multiple banks and identifies the latest image. The boot ROM then hands off the execution to the application with the latest version. To support FWU boot mode, each Flash bank containing an application image needs a few fields as shown in [Table 4-45](#).

**Table 4-45. FWU Application Image Format**

Image Address Offset	Content
0x0	Application entry point (32-bit)
0xA	Key (32-bit) Valid Key = 0x5A5A 5A5A
0xC	Firmware version number (32-bit)

**Application entry point:** This is the code execution start address of the image stored in Flash.

**Key:** This 32-bit field determines if this image is valid. The image in a bank is considered valid only if the location contains the value 0x5A5A 5A5A. In case all banks have invalid keys, an error is flagged in boot\_status variable and program jumps to a while loop in standalone boot mode (ESTOP in emulation boot mode).

**Firmware version number:** This 32-bit field is the version number of the firmware or application. 0xFFFF FFFF is considered as the initial value and this needs to be decremented after every update. The image with lower version number is the latest application. If all valid images have same version number, then bank-0 (or the lowest numbered bank) is chosen.

For example, if bank-0 has invalid **Key** and bank-1 and bank-2 have valid keys, then the one having the lowest **Firmware version number** is selected for boot. If both are same, then bank-1 is selected.

Table 4-46 shows the entry points for FWU boot mode for CPU1 and Table 4-47 shows the entry points for FWU boot mode for CPU2.

**Table 4-46. CPU1 FWU Entry Point Addresses**

Option	BOOTDEFx Value	Bank 0	Bank 1	Bank 2	Bank 3	Bank 4
0	0x0B	0x0008 0000	0x000A 0000	0x000C 0000	0x000E 0000	0x0010 0000
1	0x2B	0x0008 FFF0	0x000A FFF0	0x000C FFF0	0x000E FFF0	0x0010 FFF0
2	0x4B	0x0009 0000	0x000B 0000	0x000D 0000	0x000F 0000	0x0011 0000
3	0x6B	0x0009 FFF0	0x000B FFF0	0x000D FFF0	0x000F FFF0	0x0011 FFF0

**Table 4-47. CPU2 FWU Entry Point Addresses**

Option	BOOTDEFx Value	Bank 0	Bank 1	Bank 2	Bank 3	Bank 4	Package Supported
0	0x06	0x0008 0000	0x000A 0000	0x000C 0000	0x000E 0000	0x0010 0000	All
1	0x26	0x0008 FFF0	0x000A FFF0	0x000C FFF0	0x000E FFF0	0x0010 FFF0	All
2	0x46	0x0009 0000	0x000B 0000	0x000D 0000	0x000F 0000	0x0011 0000	All
3	0x66	0x0009 FFF0	0x000B FFF0	0x000D FFF0	0x000F FFF0	0x0011 FFF0	All

---

**Note**

The Flash banks can be allocated between CPU1 and CPU2. When a bank is not allocated to a CPU, a read of any address belonging to that bank returns 0.

---

For example, if Option 0 with Bank 0 has the application image:

[0008 0000-0008 0001] = Application entry point

[0008 000A-0008 000B] = Key

[0008 000C-0008 000D] = Firmware version number

### 4.7.9 GPIO Assignments

This section details the GPIOs and boot option values used for boot mode set in the BOOT\_DEF memory location located at Z1-OTP-BOOTDEF-LOW/ Z2-OTP-BOOTDEF-LOW and Z1-OTP-BOOTDEF-HIGH/ Z2-OTP-BOOTDEF-HIGH. Refer to [Section 4.4.2](#) on how to configure BOOT\_DEFx. When selecting a boot mode option, make sure to verify that the necessary pins are available in the pin mux options for the specific device package being used.

Default boot mode GPIO pins:

- Boot mode pin 0 - GPIO84
- Boot mode pin 1 - GPIO72

Guidelines on boot pin selection:

- Avoid pins that have PWM functionality.
- Cannot be analog or USB pins.
- Boot mode select pins and default boot peripheral pins can be available on all packages.
- Avoid JTAG emulation pins and crystal pins.
- Boot mode select pins can be inputs.
- Pins cannot have PHY bootstrap functionality.

**Table 4-48. SCI Boot Options**

Option	BOOTDEF Value	SCITXDA GPIO	SCIRXDA GPIO	Package Supported
0 (default)	0x01	GPIO12	GPIO13	All
1	0x21	GPIO84	GPIO85	All
2	0x41	GPIO36	GPIO35	176-QFP, 169-BGA, 256-BGA

#### 4.7.10 Secure ROM Function APIs

There are a few functions that are available within Secure ROM to be called by the application to perform EXEONLY Flash/RAM tasks in a secure manner.

#### Note

The application can disable interrupts before calling one of the EXEONLY function APIs.

If a vector fetch request is given by the CPU (C28) while the program counter (PC) is within the EXEONLY function API code of the Secure ROM, a reset fires (RSN if from C28). The consequence of this is if an NMI or ITRAP or Bus Fault occurs while the PC is executing one of the EXEONLY API functions, the NMI/ITRAP/Fault cannot be serviced because a reset is fired to the subsystem.

The secure copy code zone 1 function (Table 4-55) allows EXEONLY Flash to be copied to EXEONLY RAM in a secure manner. The source must be from EXEONLY Flash and the destination to EXEONLY RAM. There is no support to copy EXEONLY ROM or EXEONLY RAM to RAM. Both Flash and RAM must be set to EXEONLY and configured for the same zone. Additionally, the copy size must not cross over the Flash sector boundary. Any violations of these requirements results in a failure status returned. Upon successful copy of the data, the number of 16-bit words copied is returned.

**Table 4-55. Secure Copy Code Function**

CPU	Function Prototype	Function Parameters	Function Return Value
CPU (C28x)	<code>uint16_t SecureCopyCodeZ1(uint32_t size, uint16_t *dst, uint16_t *src)</code>	<p><i>size</i> : The number of 16-bit words to copy</p> <p><i>dst</i> : The destination memory address in EXEONLY RAM</p> <p><i>src</i> : The source memory address in EXEONLY Flash</p>	<p>0xFFFF : Returns the number of 16-bit words copied.</p> <p>0x0000 : Indicates one of the following: Copy length is zero; Copy size crosses over Flash sector boundary; Flash and RAM do not belong to the same zone; Flash and RAM are not set to EXEONLY; Error occurred during data copy</p>

The secure CRC calculation zone 1 function (Table 4-56) allows a safety CRC check of EXEONLY memory in a secure manner. The CRC length provided must be a value from 1 to 8 where 1 represents a CRC size of 32 16-bit words and 8 represents a CRC size of 4096 16-bit words. The source address specifies the starting address for the CRC and the destination address is the location that the resulting CRC value is stored. The source and destination memories must be configured for the same zone. Additionally, the CRC length must not cross over the Flash sector or RAM block boundary. Any violations of these requirements results in a failure status returned. Upon successful CRC, the number of 16-bit words CRCed is returned.

**Table 4-56. Secure CRC Calculation Function**

CPU	Function Prototype	Function Parameters	Function Return Value
CPU (C28x)	<code>uint16_t SecureCRCCalcZ1(uint16_t len_id, uint16_t *dst, uint16_t *src)</code>	<p><i>len_id</i> : A number from 1 to 8 that corresponds to length options of 32, 64, 128, 256, 512, 1024, 2048, or 4096 16-bit words</p> <p><i>dst</i> : The destination memory address for resulting CRC</p> <p><i>src</i> : The source memory address to begin CRC calculation</p>	<p>0xFFFF : Returns the number of 16-bit words CRCed</p> <p>0x0000 : Indicates one of the following: Invalid length option; Source address is not modulo of length value; Destination address is not within secure RAM; CRC size crosses over Flash sector or RAM block boundary; The source and destination memory do not belong to the same zone.</p>

The CMAC calculate and compare function (Table 4-57) allows calculation of the CMAC signature of a Flash memory block and compare against a golden signature. This is used in the secure boot mode to authenticate the boot image.

**Table 4-57. CMAC Calculation Function**

CPU	Function Prototype	Function Parameters	Function Return Value
CPU (C28x)	<pre>uint32_t CPU1BROM_calculateCMAC(uint32_t startAddress, uint32_t endAddress, uint32_t signatureAddress)</pre>	<p><b>startAddress:</b> Starting address of memory for which CMAC has to be calculated</p> <p><b>endAddress:</b> Ending address of memory for which CMAC has to be calculated</p> <p><b>signatureAddress:</b> Address of location where golden CMAC signature is stored</p>	<p><b>0xFFFF FFFFU:</b> Calculated CMAC signature did not match golden signature (fail)</p> <p><b>0xA5A5 A5A5U:</b> Memory range provided is not aligned to 128-bit boundary or length is zero</p> <p><b>0xE1E1 E1E1U:</b> AES Engine timed out</p> <p><b>0x0000 0000U:</b> No Error</p>

#### 4.7.11 Clock Initializations

During boot-up, the boot ROM initializes the device clocking, depending upon the reset source, to assist in faster boot time response. Clock configurations are performed on POR and XRS resets only. For all other resets, the boot ROM executes using the clocks that were set up before the reset. PLL is bypassed by default on POR or XRSn and default SYSCLKDIVSEL is set to /1 by hardware on power up.

#### Note

CPU performs clock configurations during boot up. The clock configuration of CPU2 is performed by the CPU1 application before releasing CPU2 to boot. The frequency is not passed to CPU2 as the Flash is already powered up by CPU1 and there is no need to pass the same.

**Table 4-58. CPU Boot Clock Sources**

Source	Frequency	Description
INTOSC2	10MHz	Default clock source
INTOSC1	10MHz	Set as clock source if missing clock is detected at power up or right after device reset.
APLL	190MHz	Boot ROM configures to use PLL output clock. This can be skipped (boot ROM to use INTOSC2) by configuring TI OTP.

**Table 4-59. CPU Clock State After Boot**

Reset Source	Clock State
POR/XRS	1. Using INTOSC2
	2. Modify the SYSCLKDIVSEL based on TRIM configuration (minimum divider is /2)
	3. Power up PLL and set integer multiplier; check PLL Lock status and put PLL output in clock path. This is gated by the OTP configuration
	4. After PLL output is enabled in clock path, CPU executes at PLLOUT/ SYSCLKDIV frequency; this can be configured using the TRIM
All other Resets	Maintain clocks setup before device reset.

### 4.7.12 Boot Status Information

Boot ROM keeps a record of the various actions and events that occur during boot ROM execution. The reason for this is because NMI and other exceptions are enabled by default in the device and must be handled accordingly. Boot ROM stores the boot status information in a RAM location so that the user application can read this boot status and take the necessary actions per application's needs to handle these events.

#### 4.7.12.1 Booting Status

Boot ROM health and booting status for CPU1 and CPU2 is written to a 32-bit address in the respective M0 RAM. This status is cleared on a POR or XRS reset. The previous status is retained on any other reset. For example, clear the status before performing a debugger device reset to view the latest boot ROM actions reflected in the status.

**Table 4-60. CPU1 Boot Status Address**

Description	Address
Boot ROM Status	0x0000 0002

**Table 4-61. CPU1 Boot Status Bit Fields**

Value	Description
0x8000 0000	Boot ROM handled HardWare Built-In Self-Test (HWBIST)
0x4000 0000	Flash 2T Not Ready
0x2000 0000	TRIM Load Error
0x1000 0000	RAM Initialization Error
0x0800 0000	Flash Verification Error
0x0400 0000	DCSM Initialization LP Error
0x0200 0000	DCSM Initialization Invalid LP
0x0100 0000	Boot ROM PLL enabled successfully
0x0080 0000	HWBIST NMI occurred
0x0040 0000	Missing clock NMI occurred
0x0020 0000	PIE Register Parity Error occurred
0x0010 0000	Flash/RAM Uncorrectable Error NMI occurred
0x0008 0000	RL NMI occurred
0x0004 0000	ERAD NMI occurred
0x0002 0000	Boot ROM detected a PIE mismatch
0x0001 0000	Boot ROM detected an ITRAP
0x0000 8000	Boot ROM completed running
0x0000 4000	Watchdog self-test fail
0x0000 2000	Boot ROM handled POR

0x0000 0006	OTP boot started
0x0000 0005	RAM boot started
0x0000 0004	IPC message RAM boot started
0x0000 0003	Secure Flash boot started
0x0000 0002	Flash boot started
0x0000 0001	Boot ROM started running

#### 4.7.12.2 Boot Mode and MPOST (Memory Power On Self-Test) Status

Once the boot mode is decoded during the boot flow, the boot mode value is written to RAM. Additionally when running the MPOST POR memory test, the test result is written to RAM.

For more information, see the [C2000™ Memory Power-On Self-Test \(M-POST\) Application Report](#).

**Table 4-64. Boot Mode and MPOST Status Addresses**

Description	Address
Boot Mode	0x0000 0004
MPOST POR Memory Test Result	0x0000 0008

#### 4.7.13 ROM Version

The ROM revision and release date information is stored at the ROM locations specified in [Table 4-65](#). Reading a revision number value of “0x100” represents version “1.0”, “0x101” represents version “1.1”, and so on. Reading a revision date value of “0x0119” represents “01/19” or “January 2019”.

**Table 4-65. Boot ROM Version Information**

Contents	Address
Revision Number	0x003F 5002
Revision Date	0x003F 5003
Build Number	0x003F 5003

## 4.8 Application Notes for Using the Bootloaders

### 4.8.1 Bootloader Data Stream Structure

This section details the data transfer protocols or stream structures that allow boot data transfer between boot ROM and host device. This data transfer protocol is compatible to the respective bootloaders on C2000 devices.

[Table 4-66](#) and [Example 4-2](#) show the structure of the data stream incoming to the bootloader. The basic structure is the same for all the bootloaders and is based on the C54x source data stream generated by the C54x hex utility. The C28x hex utility (hex2000.exe) has been updated to support this structure. The hex2000.exe utility is included with the C2000 code generation tools. All values in the data stream structure are in hex. Refer to [Section 4.8.2](#) for more details on using the C28x hex utility to convert a project to this format.

The first 16-bit word in the data stream is known as the key value. The key value is used to notify the bootloader the width of the incoming stream: 8 or 16 bits. Note that not all bootloaders accept both 8 and 16-bit streams. Refer to the detailed information on each loader for the valid data stream width. For an 8-bit data stream, the key value is 0x08AA; for a 16-bit stream, the key value is 0x10AA. If a bootloader receives an invalid key value, then the load is aborted.

The next eight words are used to initialize register values or enhance the bootloader by passing values to the bootloader. If a bootloader does not use these values, then the values are reserved for future use and the bootloader simply reads the value and then discards. Currently only the SPI and I2C and parallel bootloaders use these words to initialize registers.

The tenth and eleventh words comprise the 22-bit entry point address. This address is used to initialize the PC after the boot load is complete. This address is most likely the entry point of the program downloaded by the bootloader.

The twelfth word in the data stream is the size of the first data block to be transferred. The size of the block is defined as an 8-bit data stream format. For example, to transfer a block of 20 8-bit data values from an 8-bit data stream, the block size is 0x000A to indicate 10 16-bit words.

The next two words notify the bootloader the destination address of the block of data. Following the size and address are the 16-bit words that makeup that block of data.

This pattern of block size and destination address repeats for each block of data to be transferred. Once all the blocks have been transferred, a block size of 0x0000 signals to the bootloader that the transfer is complete. At this point, the bootloader returns the entry point address to the calling routine, which cleans up and exits. Execution then continues at the entry point address as determined by the input data stream contents.

**Table 4-66. LSB/MSB Loading Sequence in 8-Bit Data Stream**

		Contents	
Byte		LSB (First Byte of 2)	MSB (Second Byte of 2)
1	2	LSB: AA (KeyValue for memory width = 8 bits)	MSB: 08h (KeyValue for memory width = 8 bits)
3	4	LSB: Register initialization value or reserved	MSB: Register initialization value or reserved
5	6	LSB: Register initialization value or reserved	MSB: Register initialization value or reserved
7	8	LSB: Register initialization value or reserved	MSB: Register initialization value or reserved
...	...	...	...
...	...	...	...
17	18	LSB: Register initialization value or reserved	MSB: Register initialization value or reserved
19	20	LSB: Upper half of Entry point PC[23:16]	MSB: Upper half of entry point PC[31:24] (Always 0x00)
21	22	LSB: Lower half of Entry point PC[7:0]	MSB: Lower half of Entry point PC[15:8]
23	24	LSB: Block size in words of the first block to load. If the block size is 0, this indicates the end of the source program; otherwise, another block follows. For example, a block size of 0x000A indicates 10 words or 20 bytes in the block.	MSB: block size
25	26	LSB: MSW destination address, first block Addr[23:16]	MSB: MSW destination address, first block Addr[31:24]
27	28	LSB: LSW destination address, first block Addr[7:0]	MSB: LSW destination address, first block Addr[15:8]
29	30	LSB: First word of the first block being loaded	MSB: First word of the first block being loaded
...	...	...	...
...	...	...	...
.	.	LSB: Last word of the first block to load	MSB: Last word of the first block to load
.	.	LSB: Block size of the second block	MSB: Block size of the second block
.	.	LSB: MSW destination address, second block Addr[23:16]	MSB: MSW destination address, second block Addr[31:24]
.	.	LSB: LSW destination address, second block Addr[7:0]	MSB: LSW destination address, second block Addr[15:8]
.	.	LSB: First word of the second block being loaded	MSB: First word of the second block being loaded
...	...	...	...
...	...	...	...
.	.	LSB: Last word of the second block	MSB: Last word of the second block
.	.	LSB: Block size of the last block	MSB: Block size of the last block
.	.	LSB: MSW of destination address of last block Addr[23:16]	MSB: MSW destination address, last block Addr[31:24]
.	.	LSB: LSW destination address, last block Addr[7:0]	MSB: LSW destination address, last block Addr[15:8]
.	.	LSB: First word of the last block being loaded	MSB: First word of the last block being loaded
...	...	...	...
...	...	...	...
.	.	LSB: Last word of the last block	MSB: Last word of the last block
n	n+1	LSB: 00h	MSB: 00h - indicates the end of the source

### Example 4-2. Data Stream Structure 8-bit

```

AA 08      ; 0x08AA 8bit key value
00 00 00 00 ; 8 reserved words
00 00 00 00
00 00 00 00
00 00 00 00
3F 00 00 80 ; 0x003F8000 EntryAddr, starting point after boot load completes
05 00      ; 0x0005 First block consists of 5 16-bit words
3F 00 10 90 ; 0x003F9010 First block is loaded starting at 0x3F9010
01 00      ; Data loaded = 0x0001 0x0002 0x0003 0x0004 0x0005
02 00
03 00
04 00
05 00
02 00      ; 0x0002 - Second block consists of 2 16bit words
3F 00 00 80 ; 0x003F8000 Second block is loaded starting at 0x3F8000
00 77      ; Data loaded = 0x7700 0x7625
25 76
00 00      ; 0x0000 Size of 0 indicates end of data stream
After load has completed the following memory values are initialized as follows:
Location Value
0x3F9010 0x0001
0x3F9011 0x0002
0x3F9012 0x0003
0x3F9013 0x0004
0x3F9014 0x0005
0x3F8000 0x7700
0x3F8001 0x7625
PC Begins execution at 0x3F8000
  
```

### 4.8.2 The C2000 Hex Utility

To use the features of the bootloader, you must generate a data stream and boot table as described in [Section 4.8.1](#). The hex conversion utility tool, included with the 28x code generation tools, can generate the required data stream including the required boot table. This section describes the hex2000 utility. An example of a file conversion performed by hex2000 is described in [Example 4-3](#).

The hex utility supports creation of the boot table required for the SCI, SPI, I2C, CAN, and parallel I/O loaders. That is, the hex utility adds the required information to the file such as the key value, reserved bits, entry point, address, block start address, block length and terminating value. The contents of the boot table vary slightly depending on the boot mode and the options selected when running the hex conversion utility. The actual file format required by the host (ASCII, binary, hex, and so on) differs from one specific application to another and some additional conversion can be required.

To build the boot table, follow these steps:

1. **Assemble or compile the code.** This creates the object files that are used by the linker to create a single output file.
2. **Link the file.** The linker combines all of the object files into a single output file in common object file format (ELF). The specified linker command file is used by the linker to allocate the code sections to different memory blocks. Each block of the boot table data corresponds to an initialized section in the ELF file. Uninitialized sections are not converted by the hex conversion utility. The following options can be useful:
  - The linker `-m` option can be used to generate a map file. This map file shows all of the sections that were created, the location in memory, and the length. Check this file to make sure that the initialized sections are where you expect them.
  - The linker `-w` option configures the linker to show, if the linker assigned a section to a memory region automatically. For example, if you have a section in your code called `.TI.ramfunc`.
3. **Run the hex conversion utility.** Choose the appropriate options for the desired boot mode and run the hex conversion utility to convert the ELF file produced by the linker to a boot table.

See the [TMS320C28x Assembly Language Tools User's Guide](#) and the [TMS320C28x Optimizing C/C++ Compiler User's Guide](#) for more information on the compiling and linking process.

**Table 4-67** summarizes the hex conversion utility options available for the bootloader. See the [TMS320C28x Assembly Language Tools User's Guide](#) for a detailed description of the hex2000 operations used to generate a boot table. Updates can be made to support the I2C boot. See the Codegen release notes for the latest information.

**Table 4-67. Boot Loader Options**

Option	Description
-boot	Convert all sections into bootable form (use instead of a SECTIONS directive)
-sci8	Specify the source of the bootloader table as the SCI-A port, 8-bit mode
-spi8	Specify the source of the bootloader table as the SPI-A port, 8-bit mode
-gpio8	Specify the source of the bootloader table as the GPIO port, 8-bit mode
-bootorg value	Specify the source address of the bootloader table
-lospcp value	Specify the initial value for the LOSPCP register. This value is used only for the spi8 boot table format and ignored for all other formats. If the value is greater than 0x7F, the value is truncated to 0x7F.
-spibrr value	Specify the initial value for the SPIBRR register. This value is used only for the spi8 boot table format and ignored for all other formats. If the value is greater than 0x7F, the value is truncated to 0x7F.
-e value	Specify the entry point at which to begin execution after boot loading. The value can be an address or a global symbol. This value is optional. The entry point can be defined at compile time using the linker -e option to assign the entry point to a global symbol. The entry point for a C program is normally <code>_c_int00</code> unless defined otherwise by the -e linker option.
-i2c8	Specify the source of the bootloader table as the I2C-A port, 8-bit
-i2cpsc value	Specify the value for the I2CPSC register. This value is loaded and takes effect after all I2C options are loaded, prior to reading data from the EEPROM. This value is truncated to the least-significant eight bits and can be set to maintain an I2C module clock of 7 to 12MHz.
-i2cclk value	Specify the value for the I2CCLKH register. This value is loaded and takes effect after all I2C options are loaded, prior to reading data from the EEPROM.
-i2cclk value	Specify the value for the I2CCLKL register. This value is loaded and takes effect after all I2C options are loaded, prior to reading data from the EEPROM.

### Example 4-3. HEX2000.exe Command Syntax

```
C: HEX2000 GPIO34TOG.OUT -boot -gpio8 -a
where:
- boot Convert all sections into bootable form.
- gpio8 Use the GPIO in 8-bit mode data format. The eCAN
        uses the same data format as the GPIO in 8bit mode.
- a     Select ASCII-Hex as the output format.
```

## 4.9 Software

### 4.9.1 BOOT Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location: `C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/boot`

Cloud access to these examples is available at the following link: [dev.ti.com](https://dev.ti.com) [C2000Ware Examples](#).

Chapter 5  
**Dual Code Security Module (DCSM)**

---

This chapter explains the dual code security module.

<b>5.1 Introduction</b> .....	<b>1093</b>
<b>5.2 Functional Description</b> .....	<b>1093</b>
<b>5.3 Flash and OTP Erase/Program</b> .....	<b>1100</b>
<b>5.4 Secure Copy Code</b> .....	<b>1100</b>

<b>5.6 CSM Impact on Other On-Chip Resources</b> .....	<b>1102</b>
<b>5.7 Incorporating Code Security in User Applications</b> .....	<b>1104</b>
<b>5.8 Software</b> .....	<b>1109</b>
<b>5.9 DCSM Registers</b> .....	<b>1110</b>

## 5.1 Introduction

The dual code security module (DCSM) is a security feature incorporated in this device. The DCSM prevents access and visibility to on-chip secure memories (and other secure resources) by unauthorized persons. The DCSM also prevents duplication and reverse-engineering of proprietary code. The term “secure” means that access to on-chip secure memories and resources is blocked. The term “unsecure” means that access is allowed; that is, the contents of the memory can be read by any means (for example, through a debugging tool such as Code Composer Studio™ IDE).

The CSM has dual-zone security: Zone1 (Z1) and Zone2 (Z2).

### 5.1.1 DCSM Related Collateral

#### Getting Started Materials

- [C2000 DCSM Security Tool Application Report](#)
- [C2000 Unique Device Number Application Report](#)
- [Enhancing Device Security by Using JTAGLOCK Feature Application Report](#)
- [Secure BOOT On C2000 Device Application Report](#)

## 5.2 Functional Description

The security module restricts the CPU access to on-chip secure memory and resources without interrupting or stalling CPU execution. When a read occurs to a secure memory location, the read returns a zero value and CPU execution continues with the next instruction. This, in effect, blocks read and write access to secure memories through the JTAG port.

The code security mechanism offers protection for two zones, Zone1 (Z1) and Zone2 (Z2). The security mechanism for both the zones is identical. Each zone has a dedicated secure resource and allocated secure resource. The following are different secure resources available on this device:

- **OTP:** Each zone has a dedicated secure OTP (USER OTP). This contains the security configurations for the individual zone. If a zone is secure, the USER OTP content (including CSM passwords) can be read (execution not allowed) only if the zone is unlocked using the password match flow (PMF).
- **RAM:** All LSx RAMs can be secure RAM on this device. These RAMs can be allocated to either zone by configuring the respective GRABRAM locations in the USER OTP.
- **Flash Sectors:** Flash sectors of each CPU subsystems can be made secure on this device. Each Flash sector can be allocated to either zone by configuring the respective GRABSECT locations in the bank's USER OTP.
- **Secure ROM:** This device also has secure ROM on each CPU subsystem which is EXEONLY-protected. These ROM contains specific function for the user, provided by TI.

[Table 5-1](#) shows the status of a RAM block/Flash sector based on the configuration in the GRABRAM/GRABSECT register.

The security of each zone is enabled by a 128-bit (four 32-bit words) password (CSM password). The password for each zone is stored in USER OTP. A zone can be unsecured by executing the password match flow (PMF), described in [Section 5.7.4](#).

There are three types of accesses:

- **Data/program reads:** Data reads to secure memory are always blocked unless the program is executing from a memory that belongs to the same zone. Data reads to unsecure memory are always allowed. [Table 5-2](#) shows the levels of security.
- **JTAG access:** JTAG accesses are always blocked when a memory is secure.
- **Instruction fetches (calls, jumps, code executions, ISRs):** Instruction fetches are never blocked.

**CAUTION**

Never program any other values in these fields. Failing any of these conditions for a RAM block/Flash sector makes that RAM block/Flash sector inaccessible.

**Table 5-1. RAM/Flash Status**

Zone 1 GRABRAMx/GRABSECTx Bits	Zone 2 GRABRAMx/GRABSECTx Bits	Ownership and Accessibility
01	10	RAM block/Flash Sector belongs to Zone1
01	11 <sup>(2)</sup>	RAM block/Flash Sector belongs to Zone1
10	01	RAM block/Flash Sector belongs to Zone2
11 <sup>(1)</sup>	01	RAM block/Flash Sector belongs to Zone2
10	10	RAM block/Flash Sector is unsecure
11	11	RAM block/Flash Sector inaccessible if either of the zones is secure (CSM passwords are programmed). User must never leave these values default (11), if CSM passwords are programmed for even one zone.

- (1) Zone1 must be unsecure. Assumption in this case is that user is not using Zone1 so none of the fields, including passwords, in Zone1 USER OTP are programmed by user; hence, Zone1 is always unsecure.
- (2) Zone2 must be unsecure. Assumption in this case is that user is not using Zone2 so none of the fields, including passwords, in Zone2 USER OTP are programmed by user; hence, Zone2 is always unsecure.

**Table 5-2. Security Levels**

PMF Executed With Correct Password?	Operating Mode of the Zone	Program Fetch Location	Security Description
No	Secure	Outside secure memory	Only instruction fetches by the CPU are allowed to secure memory. In other words, code can still be executed, but not read.
No	Secure	Inside secure memory	CPU has full access (except for EXEONLY memories where read is not allowed). JTAG port cannot read the secured memory contents.
Yes	Unsecure	Anywhere	Full access for CPU and JTAG port to secure memory of that zone.

**5.2.1 CSM Passwords**

Unlike earlier C2000™ devices, on this device ALL\_1 value (0x FFFF FFFF, 0x FFFF FFFF, 0x FFFF FFFF, 0x FFFF FFFF) for CSM password for a zone does not unsecure the zone. Instead, if for any zone the CSM password values get loaded as ALL\_1 from USER OTP, the device is in BLOCKED state. Due to this reason, TI programs a few bits in the second 32-bit password value (ZxOTP\_CSMPSWD1) in every zone select block of each zone with value 0. The default value for this password location is chosen in a manner that the respective ECC value remains ALL\_1. Due to this, the CSMPSWD1 value programmed by TI for every zone select block is different. See [Table 5-3](#) for ZxOTP\_CSMPSWD1 value, programmed by TI on every device. Since ECC is not programmed, the user is able to change this value by flipping the bits that are 1 to 0 but leaving the bits that are already programmed by TI as 0. BOOTROM code writes the default password value into the KEYx register to unlock the device as part of device initialization sequence.

If the password locations of a zone have all 128 bits as zeros (ALL\_0), that zone becomes permanently secure (LOCKED state), regardless of the contents of the CSMKEYx registers, which means the zone cannot be unlocked using PMF, see the password match flow described in [Section 5.7.2](#). Therefore, the user can never use ALL\_0 as password. A password of ALL\_0 prevents debug of secure code or reprogramming the Flash sectors. CSMKEYx registers are user-accessible registers that are used to unsecure the zones.

**Table 5-3. Default Value of ZxOTP (Programmed by TI)**

Zone Select Block	Zone1 USER OTP		Zone2 USER OTP	
	Address	Value	Address	Value
JLM_ENABLE (JTAGLOCK)	0x0007 8006	0xFFFF 000F	NA	NA
PSWDLOCK	0x0007 8010	0xFB7F FFFF	0x0007 8210	0x1F7F FFFF
CRCLOCK	0x0007 8012	0x7FFF FFFF	0x0007 8212	0x3FFF FFFF
JTAGPSWDH0	0x0007 8014	0x4BFF FFFF	NA	NA
JTAGPSWDH1	0x0007 8016	0x3FFF FFFF	NA	NA

Zone_Select_Block14	0x0007 81E2 (CSMPSWD1)	0x33FF FFFF	0x0007 83E2 (CSMPSWD1)	0x97FF FFFF
Zone_Select_Block14	0x0007 81FE (JTAGPSWDL1)	0xBD7F FFFF		

### 5.2.2 Emulation Code Security Logic (ECSL)

In addition to the CSM, the emulation code security logic (ECSL) has been implemented using a 64-bit password (part of existing CSM password) for each zone to prevent unauthorized users from stepping through secure code. A halt in secure code while the emulator is connected trips the ECSL and break the emulation connection. To allow emulation of secure code, while maintaining the CSM protection against secure memory reads, you must write the correct 64-bit password into the CSMKEY (0/1) registers, which matches the password value stored in the USER OTP of that zone. This disables the ECSL for the specific zone.

When initially debugging a device with the password locations in OTP programmed (secured), the emulator takes some time to take control of the CPU. During this time, the CPU starts running and can execute an instruction that performs an access to a protected ECSL area and if the CPU is halted when the program counter (PC) is pointing to a secure location, the ECSL trips and causes the emulator connection to be broken.

One answer to this problem is to use the Wait Boot Mode boot option. In this mode, the CPU is in a loop and does not jump to the user application code. Using this BOOTMODE, you can connect to CCS and debug the code.

### 5.2.3 CPU Secure Logic

The CPU Secure Logic (CPUSL) on this device prevents a hacker from reading the CPU registers in a watch window while code is running in a secure zone. All accesses to CPU registers when the PC points to a secure location are blocked by this logic. The only exception to this is read access to the PC. It is highly recommended not to write into the CPU register in this case, because proper code execution can get affected. If the CSM is unlocked using the CSM password match flow, the CPUSL logic also gets disabled.

### 5.2.4 Execute-Only Protection

To achieve a higher level of security on secure Flash sectors and RAM blocks that store critical user code (instruction opcodes), the Execute-Only protection feature is provided. When the Execute-Only protection is turned on for any secure Flash sector or RAM block, data reads to that Flash sector or RAM block are disallowed from any code (even from secure code). Execute-only protection for a Flash sector and RAM block can be turned on by configuring the bit field associated for that particular sector/RAM block in the zone's (which has ownership of that sector/RAM block) EXEONLYSECT and EXEONLYRAM register, respectively.

### 5.2.5 Password Lock

The password locations in USER OTP for each zone can be locked by programming the zone's PSWDLOCK field with any value other than 1111 (0xF) at the PSWDLOCK location in OTP. Until the passwords of a zone are locked, password locations are not secure and can be read from the debugger as well as code running from non-secure memory. This feature can be used by the user to avoid accidental locking of the zone while programming the Flash sectors during the software development phase. On a new device, the value for password lock fields for all zones at the PSWDLOCK location in OTP is 1111, which means the password for all zones is unlocked.

---

#### Note

Password unlock only makes password locations non-secure. All other secure memories remains secure as per security settings. Since password locations are non-secure, anyone can read the password and make the zone unsecure by running through PMF, the user must program the PSWDLOCK locations to lock the password before sending the device in the field.

---

### 5.2.6 JTAGLOCK

To disable the JTAG access on a device to avoid any debug access, use the JTAGLOCK feature on this device. Follow a two step process to enable the JTAGLOCK feature (both steps can be performed at the same time):

1. Program the JTAG passwords. This device has a 128-bit JTAG password that needs to be programmed in Z1 USER OTP. JTAG passwords are split into two parts, JTAGPSWDH and JTAGPSWDL. JTAGPSWDH is part of Z1 USER OTP header and JTAGPSWDL is part of Z1 Zone Select Block (ZSB). What this means is program JTAGPSWDH once and change the JTAGPSWDL multiple times, if needed. The Code Composer Studio™ IDE has an integrated tool that you use to unlock the JTAGLOCK on the device.
2. After programming the JTAG passwords, enable the JTAGLOCK module (JLM) by programming bit [3:0] of Z1OTP\_JLM\_ENABLE with any value other than 0xF. It is recommended to program all four bits with a value 0x0.

### 5.2.7 Link Pointer and Zone Select

For each of the two security zones, a dedicated OTP block exists that holds the configuration related to zone's security. The following are user programmable configurations:

- ZxOTP\_LINKPOINTER1
- ZxOTP\_LINKPOINTER2
- ZxOTP\_LINKPOINTER3
- Z1OTP\_JLM\_ENABLE
- ZxOTP\_GPREG1
- ZxOTP\_GPREG2
- ZxOTP\_GPREG3
- ZxOTP\_GPREG4
- ZxOTP\_PSWDLOCK
- ZxOTP\_CRCLOCK
- Z1OTP\_JTAGPSWDH
- Z1OTP\_CMACKKEY
- ZxOTP\_CSMPSWD0
- ZxOTP\_CSMPSWD1
- ZxOTP\_CSMPSWD2
- ZxOTP\_CSMPSWD3
- ZxOTP\_GRABSECT1
- ZxOTP\_GRABSECT2
- ZxOTP\_GRABSECT3
- ZxOTP\_GRABRAM1
- ZxOTP\_EXEONLYSECT1
- ZxOTP\_EXEONLYSECT2
- ZxOTP\_EXEONLYRAM1
- Z1OTP\_JTAGPSWDL

Since OTP cannot be erased, the following configurations are placed in zone select blocks of each zone's OTP Flash of both the banks:

- ZxOTP\_CSMPSWD0
- ZxOTP\_CSMPSWD1
- ZxOTP\_CSMPSWD2
- ZxOTP\_CSMPSWD3
- ZxOTP\_GRABSECT1
- ZxOTP\_GRABSECT2
- ZxOTP\_GRABSECT3
- ZxOTP\_GRABRAM1
- ZxOTP\_EXEONLYSECT1
- ZxOTP\_EXEONLYSECT2
- ZxOTP\_EXEONLYRAM1
- Z1OTP\_JTAGPSWDL

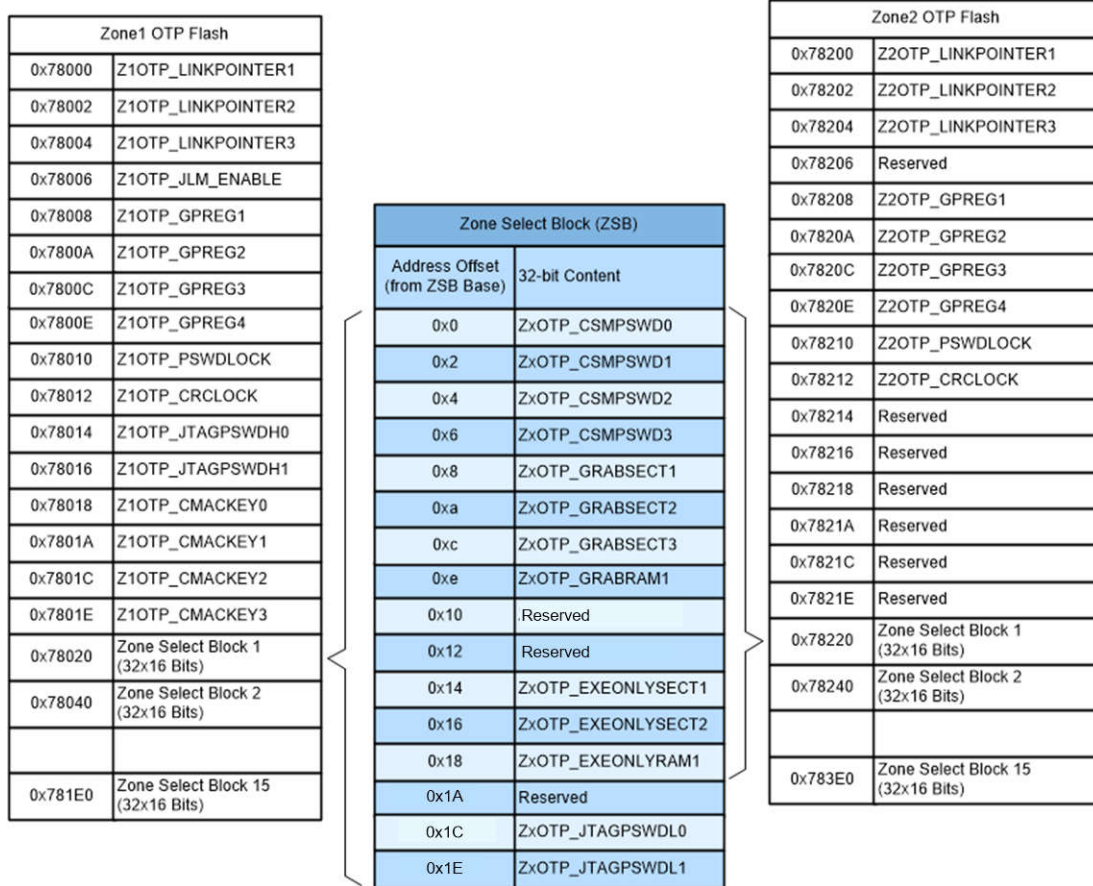

The location of the valid zone select block in OTP is decided based on the value of three 14-bit link pointers (Zx-LINKPOINTERx) programmed in the OTP of each zone. All OTP locations except link pointers and Z1OTP\_JLM\_ENABLE locations are protected with ECC. Since the link pointer locations are not protected with ECC, three link pointers are provided that need to be programmed with the same value. The final value of the link pointer is resolved in hardware, when a dummy read is done to all the link pointers, by comparing all the three values (bit-wise voting logic). Since in OTP, a 1 can be flipped by the user to 0, but a 0 cannot be flipped to a 1 (no erase operation for OTP), the most-significant bit position in the resolved link pointer that is 0 defines the valid base address for the zone select block. While generating the final link pointer value, if the bit pattern is not one of those listed in [Figure 5-1](#), the final link pointer value becomes All\_1 (0xFFFF\_FFFF), which selects the Zone-Select-Block1 (also known as the default zone select block).

Zx-LINKPOINTER	Selected ZSB	Zone1 ZSB Address	Zone2 ZSB Address
32xxxxxxxxxxxxxxxxxxxx111111111111	ZSB1	0x78020	0x78220
32xxxxxxxxxxxxxxxxxxxx111111111110	ZSB2	0x78040	0x78240
32xxxxxxxxxxxxxxxxxxxx111111111100	ZSB3	0x78060	0x78260
32xxxxxxxxxxxxxxxxxxxx1111111111000	ZSB4	0x78080	0x78280
32xxxxxxxxxxxxxxxxxxxx11111111110000	ZSB5	0x780a0	0x782a0
32xxxxxxxxxxxxxxxxxxxx111111111100000	ZSB6	0x780c0	0x782c0
32xxxxxxxxxxxxxxxxxxxx1111111111000000	ZSB7	0x780e0	0x782e0
32xxxxxxxxxxxxxxxxxxxx1111111100000000	ZSB8	0x78100	0x78300
32xxxxxxxxxxxxxxxxxxxx1111111000000000	ZSB9	0x78120	0x78320
32xxxxxxxxxxxxxxxxxxxx1111100000000000	ZSB10	0x78140	0x78340
32xxxxxxxxxxxxxxxxxxxx1111000000000000	ZSB11	0x78160	0x78360
32xxxxxxxxxxxxxxxxxxxx1110000000000000	ZSB12	0x78180	0x78380
32xxxxxxxxxxxxxxxxxxxx1100000000000000	ZSB13	0x781a0	0x783a0
32xxxxxxxxxxxxxxxxxxxx1000000000000000	ZSB14	0x781c0	0x783c0
32xxxxxxxxxxxxxxxxxxxx0000000000000000	ZSB15	0x781e0	0x783e0

**Figure 5-1. Storage of Zone-Select Bits in OTP**

#### Note

Address locations for other security settings that are not part of Zone Select blocks can be programmed only once; therefore, you must program the address locations toward the end of the development cycle.

**Figure 5-2. Location of Zone-Select Block Based on Link-Pointer**

**CAUTION**

USER OTP is ECC protected. You must program the ECC value while programming the security setting in USER OTP. Failing to program the correct ECC value causes the device to be blocked permanently and the device needs to be replaced.

### 5.2.8 C Code Example to Get Zone Select Block Addr for Zone1

```

unsigned long LinkPointer;
unsigned long *ZoneSelBlockPtr;
int Bitpos = 13;
int ZeroFound = 0;
// Read Z1-Linkpointer register of DCSM module.
LinkPointer = *(unsigned long *)0x5F000;
// Bits 31 to 15 as most-significant 0 are reserved LinkPointer options
LinkPointer = LinkPointer << 18;
while ((ZeroFound == 0) && (bitpos > -1))
{
    if ((LinkPointer & 0x80000000) == 0)
    {
        ZeroFound = 1;
        ZoneSelBlockPtr = (unsigned long *) (0x78000 + ((bitpos + 2)*32));
    }
    Else
    {
        bitpos--;
        LinkPointer = LinkPointer << 1;
    }
}
if (ZeroFound == 0)
{
    //Default in case there is no zero found.
    ZoneSelBlockPtr = (unsigned long *)0x78020;
}

```

## 5.3 Flash and OTP Erase/Program

On this device, OTP as well as normal Flash, are secure resources. Each zone has a dedicated OTP, whereas normal Flash sectors can be allocated to any zone based on the value programmed in the GRABSECTx location in OTP. Each zone has 128-bit CSM passwords. Read and write accesses are not allowed to resources assigned to Z1 by code running from memory allocated to Z2 and conversely. Before programming any secure Flash sector, the user must either unlock the zone to which that particular sector belongs using PMF or execute the Flash programming code from secure memory that belongs to the same zone. The same is the case for erasing any secure Flash sector. To program the security settings in OTP Flash, the user must unlock the CSM of the respective zone. Unless the zone is unlocked, security settings in OTP Flash can not be updated. The OTP content cannot be erased.

A semaphore mechanism is provided to avoid the program/erase conflict between Z1 and Z2. A zone needs to grab this semaphore to successfully complete the erase/program operation on the secure Flash sectors allocated to that zone. A semaphore can be grabbed by a zone by writing the appropriate value in the SEM field of the FLSEM register. For further details of this field, see the register description.

## 5.4 Secure Copy Code

In some applications, the user wants to copy the code from secure Flash to secure RAM for better performance. The user cannot do this for EXEONLY Flash sectors because EXEONLY secure memories cannot be read from anywhere. TI provides specific “Secure Copy Code” library functions for ZONE1 to enable the user to copy content from EXEONLY secure Flash sectors to EXEONLY RAM blocks. These functions do the copy-code operation in a highly secure environment and allow a copy to be performed only when the following conditions are met:

- The secure RAM block and the secure Flash sector belong to the same zone.
- Both the secure RAM block and the secure Flash sector have EXEONLY protection enabled.

For further usage of these library functions, see the device-specific Boot ROM documentation.

## 5.5 SecureCRC

Since reads from EXEONLY memories are not allowed, the user cannot calculate the CRC on content in EXEONLY memories using the CRC engine available on this device (for example, VCUCRC, GCRC) or software. In some safety-critical applications, the user has to calculate the CRC even on these memories. To enable this without compromising on security, TI provides specific “SecureCRC” library functions for each zone. These functions do the CRC calculation in highly secure environment and allow a CRC calculation to be performed only when the following conditions are met:

- The source address is modulo the number of words (based on length\_id) for which the CRC needs to be calculated.
- The destination address belongs to the same zone as the source address.

For further usage of these library functions, see the device-specific Boot ROM documentation.

---

### Note

The user must disable all the interrupts before calling the secure functions in ROM. If there is a vector fetch during secure function execution, the CPU gets reset immediately.

---

Disclaimer: The Code Security Module (CSM) included on this device was designed to password protect the data stored in the associated memory and is warranted by Texas Instruments (TI), in accordance with its standard terms and conditions, to conform to TI's published specifications for the warranty period applicable for this device. TI DOES NOT, HOWEVER, WARRANT OR REPRESENT THAT THE CSM CANNOT BE COMPROMISED OR BREACHED OR THAT THE DATA STORED IN THE ASSOCIATED MEMORY CANNOT BE ACCESSED THROUGH OTHER MEANS. MOREOVER, EXCEPT AS SET FORTH ABOVE, TI MAKES NO WARRANTIES OR REPRESENTATIONS CONCERNING THE CSM OR OPERATION OF THIS DEVICE, INCLUDING ANY IMPLIED WARRANTIES OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. IN NO EVENT SHALL TI BE LIABLE FOR ANY CONSEQUENTIAL, SPECIAL, INDIRECT, INCIDENTAL, OR PUNITIVE DAMAGES, HOWEVER CAUSED, ARISING IN ANY WAY OUT OF YOUR USE OF THE CSM OR THIS DEVICE, WHETHER OR NOT TI HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES. EXCLUDED DAMAGES INCLUDE, BUT ARE NOT LIMITED TO LOSS OF DATA, LOSS OF GOODWILL, LOSS OF USE OR INTERRUPTION OF BUSINESS OR OTHER ECONOMIC LOSS.

## 5.6 CSM Impact on Other On-Chip Resources

### CAUTION

The order of initialization matters; hence, if a memory watch window with the USER OTP address is opened in the debugger (CCS IDE), the security initialization can occur in an incorrect order locking the device down. To avoid this, do not keep a memory window with USER OTP address opened in the debugger (CCS IDE) when performing a reset.

### Note

Security initialization is done by BOOTROM code on all the resets (as part of device initialization) that assert SYSRSn. This is not part of the user application code.

On this device, some of the memories are not secure. To avoid any potential hacking when the device is in the default state (post reset), accesses (all types) to all memories (secure as well as non-secure, except BOOT-ROM and OTP ) are disabled until proper security initialization is done. This means that after reset none of the memory resources except BOOT\_ROM and OTP is accessible to the user.

The following steps are required by CPU after reset (any type of reset) to initialize the security on device.

### Security Initialization

- Dummy Read to address location of SECD (0x703F0, TI-reserved register) in TI OTP
- Dummy Read to address location of Z1OTP\_LINKPOINTER1 in Z1 OTP
- Dummy Read to address location of Z1OTP\_LINKPOINTER2 in Z1 OTP
- Dummy Read to address location of Z1OTP\_LINKPOINTER3 in Z1 OTP
- Dummy Read to address location of Z2OTP\_LINKPOINTER1 in Z2 OTP
- Dummy Read to address location of Z2OTP\_LINKPOINTER2 in Z2 OTP
- Dummy Read to address location of Z2OTP\_LINKPOINTER3 in Z2 OTP
- Dummy Read to address location Z1OTP\_JLM\_ENABLE in Z1 OTP
- Dummy Read to address location of Z1OTP\_GPREG1, Z1OTP\_GPREG2, Z1OTP\_GPREG3, Z1OTP\_GPREG4 in Z1 OTP
- Dummy Read to address location of Z1OTP\_PSWDLOCK in Z1 OTP
- Dummy Read to address location of Z1OTP\_CRCLOCK in Z1 OTP
- Dummy Read to address location of Z1OTP\_JTAGPSWDH0, Z1OTP\_JTAGPSWDH1 in Z1 OTP
- Dummy Read to address location of Z2OTP\_GPREG1, Z2OTP\_GPREG2, Z2OTP\_GPREG3, Z2OTP\_GPREG4 in Z2 OTP
- Dummy Read to address location of Z2OTP\_PSWDLOCK in Z2 OTP
- Dummy Read to address location of Z2OTP\_CRCLOCK in Z2 OTP
- Read to memory map register of Z1\_LINKPOINTER in DCSM module to calculate the address of zone select block for Z1
- Dummy read to address location of Z1OTP\_GRABSECT1, Z1OTP\_GRABSECT2, Z1OTP\_GRABSECT3 in Z1 OTP
- Dummy read to address location of Z1OTP\_GRABRAM1
- Dummy read to address location of Z1OTP\_EXEONLYSECT1, Z1OTP\_EXEONLYSECT2 in Z1 OTP
- Dummy read to address location of Z1OTP\_EXEONLYRAM1 in Z1 OTP
- Dummy Read to address location of Z1OTP\_JTAGPSWDL0, Z1OTP\_JTAGPSWDL1 in Z1 OTP
- Read to memory map register of Z2\_LINKPOINTER in DCSM module to calculate the address of zone select block for Z2
- Dummy read to address location of Z2OTP\_GRABSECT1, Z2OTP\_GRABSECT2, Z2OTP\_GRABSECT3 in Z2 OTP
- Dummy read to address location of Z2OTP\_GRABRAM1
- Dummy read to address location of Z2OTP\_EXEONLYSECT1, Z2OTP\_EXEONLYSECT2 in Z2 OTP
- Dummy read to address location of Z2OTP\_EXEONLYRAM1 in Z2 OTP

### 5.6.1 RAMOPEN

RAMOPEN feature on this device enables a user to unsecure all of the secure RAM blocks without unlocking the zone security. Afterward, the RAMs can be converted back into secure RAMs without issuing reset to device. However, the previous contents of the secure RAM are not maintained.

This is a useful feature for Flash programming tools (for example, CCS Flash plugin, serial Flash programmer, and so on), which need to download Flash APIs and data on RAMs to carry out the Flash program/erase operations to unsecure Flash regions. Since debugger and boot loader writes are considered unsecure, the writes require either unsecure RAM or unlocked secure RAM to download the APIs and data to. However, the user can not always have the password required to unlock one or both of the security zones. This can be particularly problematic in a device with limited RAM where the majority of the RAM used during application runtime is designated as secure RAM.

The RAMOPEN feature allows the Flash programming tools to temporarily convert the secured RAM blocks into unsecured RAM blocks to load the API/Data and after Flash program/erase operation is completed, turn them back into secured RAM blocks.

The feature works as:

- RAMOPEN feature is enabled by setting RAMOPENFRC.SET bit to 1
- This clears the content of all the secure RAM (RAMINIT is performed in hardware).
- After completion of RAMINIT operation, RAMOPENSTAT.RAMOPEN bit get set to 1 (RAMOPEN feature is enabled and all secure RAM blocks are unsecure).
- To disable RAMOPEN feature, set RAMOPENCLR.CLEAR bit to 1.
- This again clears the content of all secure RAM (RAMINIT is performed in hardware).
- After completion of RAMINIT operation, RAMOPENSTAT.RAMOPEN bit gets cleared to 0 (RAMOPEN feature is disabled and all secure RAM blocks are again secure).

## 5.7 Incorporating Code Security in User Applications

Code security is typically not required in the development phase of a project. However, security is needed once a robust code is developed for a zone. Before such a code is programmed in the Flash memory, a CSM password must be chosen to secure the zone. Once a CSM password is in place for a zone, the zone is secured (programming a password at the appropriate locations and either performing a device reset or setting the FORCESEC bit (Zx\_CR.31) is the action that secures the device). From that time on, access to debug the contents of secure memory by any means (using JTAG, code running off external/on-chip memory, and so forth) requires a valid password. A password is not needed to run the code out of secure memory (such as in a typical end-user usage); however, access to secure memory contents for debug purposes requires a password.

### 5.7.1 Environments That Require Security Unlocking

The following are the typical situations under which unsecuring the zone can be required:

- Code development using debuggers (such as Code Composer Studio™ IDE). This is the most common environment during the design phase of a product.
- Flash programming using TI's Flash utilities such as Code Composer Studio IDE On-Chip Flash Programmer plug-in or the UniFlash tool. Flash programming is common during code development and testing. Once the user supplies the necessary password, the Flash utilities disable the security logic before attempting to program the Flash. In custom programming that uses the Flash API supplied by TI, unlocking the CSM can be avoided by executing the Flash programming algorithms from secure memory.
- Custom environment defined by the application. In addition to the above, access to secure memory contents can be required in situations such as:
  - Using the on-chip bootloader to load code or data into secure SRAM or to erase and program the Flash.
  - Executing code from on-chip unsecure memory and requiring access to secure memory for the lookup table. This is not a suggested operating condition as supplying the password from external code can compromise code security.

The unsecuring sequence is identical in all the above situations. This sequence is referred to as the password match flow (PMF) for simplicity. [Figure 5-3](#) explains the sequence of operation that is required every time the user attempts to unsecure a particular zone. A code example is listed for clarity.

### 5.7.2 CSM Password Match Flow

Password match flow (PMF) is essentially a sequence of four dummy reads from password locations (PWL) followed by four writes (32-bit writes) to CSMKEY(0/1/2/3) registers. [Figure 5-3](#) shows how PMF helps to initialize the security logic registers and disable security logic.

Figure 5-3. CSM Password Match Flow (PMF)

### 5.7.3 C Code Example to Unsecure C28x Zone1

```
volatile long int *CSM = (volatile long int *)5F090; //CSM register file volatile
long int *CSMPWL = (volatile long int *)0x78020; //CSM Password location (assuming default zone
select block)
volatile int tmp;
int I;
// Read the 128-bits of the CSM password locations (PWL)
//
for (I=0;I<4; I++) tmp = *CSMPWL++;
// Write the 128-bit password to the CSMKEY registers
// If this password matches that stored in the
// CSLPWL, then the CSM becomes unsecure. If the password does not
// match, then the zone remains secure.
// An example password of: // 0x11112222333344445555666677778888 is used.
*CSM++ = 0x22221111; // Register Z1_CSMKEY0 at 0x5F090
*CSM++ = 0x44443333; // Register Z1_CSMKEY1 at 0x5F092
*CSM++ = 0x66665555; // Register Z1_CSMKEY2 at 0x5F094
*CSM++ = 0x88887777; // Register Z1_CSMKEY3 at 0x5F096
```

### 5.7.4 C Code Example to Resecure C28x Zone1

```
volatile int *Z1_CR = 0x5F019; //CSMSCR register
//Set FORCESEC bit
*Z1_CR = 0x8000;
```

### 5.7.5 Environments That Require ECSL Unlocking

The following are the typical situations under which unsecuring can be required:

- The user develops some main IP, and then outsources peripheral functions to a subcontractor who must be able to run the user code during debug and can halt while the main IP code is running. If ECSL is not unlocked, then Code Composer Studio™ IDE connections get disconnected, which can be inconvenient for the user. Note that unlocking ECSL does not enable access to the secure code but only avoids disconnection of Code Composer Studio™ IDE (JTAG).

### 5.7.6 ECSL Password Match Flow

A password match flow (PMF) is essentially a sequence of eight dummy reads from password locations (PWL) followed by two writes to KEY registers. [Figure 5-4](#) shows how the PMF helps to initialize the security logic registers and disable security logic.

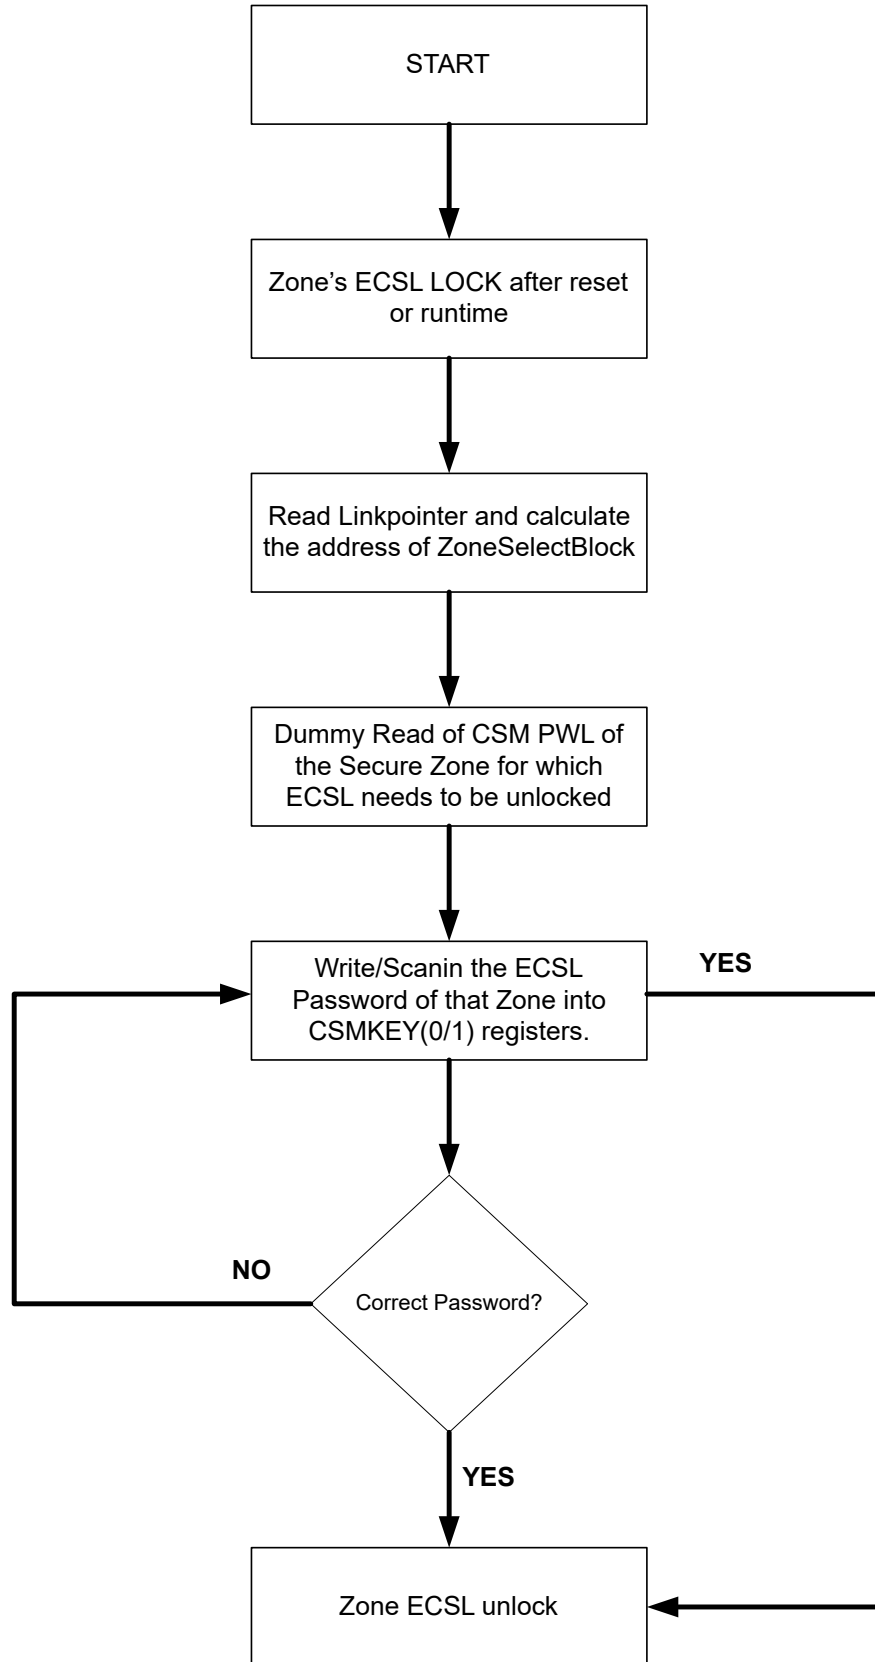

Figure 5-4. ECSSL Password Match Flow (PMF)

### 5.7.7 ECSL Disable Considerations for any Zone

A zone with ECSL enabled must have a predetermined ECSL password stored in the ECSL password locations in Flash (same as lower 64-bits of CSM passwords). Perform the following steps to disable the ECSL for any particular zone:

- Perform a dummy read of CSM password locations of that Zone.
- Write the password into the CSMKEY0/1 registers, corresponding to that Zone.
- If the password is correct, the ECSL gets disabled; otherwise, the ECSL stays enabled.

#### 5.7.7.1 C Code Example to Disable ECSL for C28x Zone1

```
volatile long int *ECSL = (volatile int *)0x5F090; //ECSL register file
volatile long int *ECSLPWL = (volatile int *)0x78028; //ECSL Password location (assuming default
Zone sel block)
volatile int tmp;
int I;
// Read the 64-bits of the password locations (PWL).
for (I=0;I<2; I++) tmp = *ECSLPWL++;
// Write the 64-bit password to the CSMKEYx registers
// If this password matches that stored in the
// CSMPWL, then ECSL gets disabled. If the password does not
// match, then the zone remains secure.
// An example password of: // 0x1111222233334444 is used.
*ECSL++ = 0x22221111; // Register Z1_CSMKEY0 at 0x5F090
*ECSL++ = 0x44443333; // Register Z1_CSMKEY1 at 0x5F092
```

### 5.7.8 Device Unique ID

CPU1 TI OTP contains a 256-bit value that is made up of both random and sequential parts. This value can be used as a seed for code encryption. The starting address of the value is 0x72168. The first 160 bits are random, the next 64 bits are sequential, and the last 32 bits are a checksum value.

## 5.8 Software

### 5.8.1 DCSM Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/dcsm

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 5.8.1.1 Empty DCSM Tool Example

FILE: dcsm\_security\_tool.c

This example is an empty project setup for DCSM Tool and Driverlib development. For guidance refer to: [C2000 DCSM Security Tool](#)

#### 5.8.1.2 DCSM Memory partitioning Example

FILE: dcsm\_ex1\_secure\_memory\_partition.c

This example demonstrates how to configure and use DCSM. It configures the 1st Zone Select Block in the OTP to change the zone passwords and allocates LS0-LS3 to zone 1 & LS4-LS7 to zone 2. Zone1 | Zone2 | LS0-LS3 | LS4-LS7 | In this example, zoning of memories is done by the OTP programming whose values are configured in dcsm\_ex1\_f28p65x\_dcsm\_zxotp.asm while the securing functionalities are done through this file. It writes some data in the zones and checks before locking and after locking and matches with the data set . Ideally after locking zone1, the data set stored in zone1 should not be readable( or reads a 0 value) and zone2 that is not secured matches the written data set. It demonstrates how to lock and and unlock zones by showing where to put the password and how to check if it is secured or unsecured.

#### *External Connections*

- None.

#### *Watch Variables*

- *result* - Status of Secure memory partitioning done through OTP programming.
- *set\_error*, *error\_not\_locked* ,*error\_not\_unlocked* ,*error1* - Count of errors occurring during the execution of the example.
- *Zone1\_Locked\_Array* - Array demonstrating secured memory
- *Unsecure\_mem\_Array* - Array demonstrating Unsecured memory

Before running the example, the below configuration is expected to be done through the dcsm\_ex1\_f28p65x\_dcsm\_zxotp.asm :

- Allocate LS0-LS3 to zone 1 , LS4-LS7 to zone 2 ZSBx\_Z1\_GRABRAM1R 0x000AAA55  
ZSBx\_Z2\_GRABRAM1R 0x000A55AA
- Password of zone 1 is 0xFFFFFFFF4D7FFFFFFFFFFFFFFFFFFFFFFF
- Password of zone 2 is 0xFFFFFFFF1F7FFFFFFFFFFFFFFFFFFFFFFF

DCSM\_unlockZone\*CSM function should not be called in an actual application, should only be used for once to program the OTP memory. Ensure flash data cache is disabled before calling this function.

## 5.9 DCSM Registers

This section describes the various DCSM Registers.

---

### Note

Except for the SECERRSTAT, SECERRCLR, and SECERRFRC registers, all other registers (non-OTP space) are mapped on all three subsystems.

---

### 5.9.1 DCSM Base Address Table

**Table 5-4. DCSM Base Address Table**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	CPU2	CPU2.DMA	Pipeline Protected
Instance	Structure								
DcsmZ1Regs	<a href="#">DCSM_Z1_REGS</a>	DCSM_Z1_BASE	0x0005_F000	YES	-	-	YES	-	YES
DcsmZ2Regs	<a href="#">DCSM_Z2_REGS</a>	DCSM_Z2_BASE	0x0005_F080	YES	-	-	YES	-	YES
DcsmCommonRegs	<a href="#">DCSM_COMMON_REGS</a>	DCSMCOMMON_BASE	0x0005_F0C0	YES	-	-	YES	-	YES
DcsmZ1OtpRegs	<a href="#">DCSM_Z1_OTP</a>	DCSM_Z1OTP_BASE	0x0007_8000	YES	-	-	-	-	-
DcsmZ2OtpRegs	<a href="#">DCSM_Z2_OTP</a>	DCSM_Z2OTP_BASE	0x0007_8200	YES	-	-	-	-	-

### 5.9.2 DCSM\_Z1\_REGS Registers

Table 5-5 lists the memory-mapped registers for the DCSM\_Z1\_REGS registers. All register offset addresses not listed in Table 5-5 should be considered as reserved locations and the register contents should not be modified.

**Table 5-5. DCSM\_Z1\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	Z1_LINKPOINTER	Zone 1 Link Pointer		<a href="#">Go</a>
2h	Z1_OTPSECLOCK	Zone 1 OTP Secure Lock		<a href="#">Go</a>
4h	Z1_JLM_ENABLE	Zone 1 JTAGLOCK Enable Register		<a href="#">Go</a>
6h	Z1_LINKPOINTERERR	Link Pointer Error		<a href="#">Go</a>
8h	Z1_GPREG1	Zone 1 General Purpose Register-1		<a href="#">Go</a>
Ah	Z1_GPREG2	Zone 1 General Purpose Register-2		<a href="#">Go</a>
Ch	Z1_GPREG3	Zone 1 General Purpose Register-3		<a href="#">Go</a>
Eh	Z1_GPREG4	Zone 1 General Purpose Register-4		<a href="#">Go</a>
10h	Z1_CSMKEY0	Zone 1 CSM Key 0		<a href="#">Go</a>
12h	Z1_CSMKEY1	Zone 1 CSM Key 1		<a href="#">Go</a>
14h	Z1_CSMKEY2	Zone 1 CSM Key 2		<a href="#">Go</a>
16h	Z1_CSMKEY3	Zone 1 CSM Key 3		<a href="#">Go</a>
18h	Z1_CR	Zone 1 CSM Control Register		<a href="#">Go</a>
1Ah	Z1_GRABSECT1R	Zone 1 Grab Flash Status Register 1		<a href="#">Go</a>
1Ch	Z1_GRABSECT2R	Zone 1 Grab Flash Status Register 2		<a href="#">Go</a>
1Eh	Z1_GRABSECT3R	Zone 1 Grab Flash Status Register 3		<a href="#">Go</a>
20h	Z1_GRABRAM1R	Zone 1 Grab RAM Status Register 1		<a href="#">Go</a>
22h	Z1_GRABRAM2R	Zone 1 Grab RAM Status Register 2		<a href="#">Go</a>
26h	Z1_EXEONLYSECT1R	Zone 1 Execute Only Flash Status Register 1		<a href="#">Go</a>
28h	Z1_EXEONLYSECT2R	Zone 1 Execute Only Flash Status Register 2		<a href="#">Go</a>
2Ah	Z1_EXEONLYRAM1R	Zone 1 Execute Only RAM Status Register 1		<a href="#">Go</a>
2Eh	Z1_JTAGKEY0	JTAG Unlock Key Register 0		<a href="#">Go</a>
30h	Z1_JTAGKEY1	JTAG Unlock Key Register 1		<a href="#">Go</a>
32h	Z1_JTAGKEY2	JTAG Unlock Key Register 2		<a href="#">Go</a>
34h	Z1_JTAGKEY3	JTAG Unlock Key Register 3		<a href="#">Go</a>
36h	Z1_CMACKKEY0	Secure Boot CMAC Key Status Register 0		<a href="#">Go</a>
38h	Z1_CMACKKEY1	Secure Boot CMAC Key Status Register 1		<a href="#">Go</a>
3Ah	Z1_CMACKKEY2	Secure Boot CMAC Key Status Register 2		<a href="#">Go</a>
3Ch	Z1_CMACKKEY3	Secure Boot CMAC Key Status Register 3		<a href="#">Go</a>
3Eh	Z1_DIAG	Diagnostics Configuration Register		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 5-6 shows the codes that are used for access types in this section.

**Table 5-6. DCSM\_Z1\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
Reset or Default Value

Bit	Field	Type	Reset	Description
31-0	GPREG2	R	0h	This field gets loaded with the contents of Z2OTP_GPREG2 locations in Zone2 USER-OTP when a dummy read is issued to that address. Users can use this register to load any general purpose non-volatile content from USER-OTP of Zone2 Reset type: SYSRSn

### 5.9.3.6 Z2\_GPREG3 Register (Offset = Ch) [Reset = 0000000h]

Z2\_GPREG3 is shown in [Figure 5-40](#) and described in [Table 5-44](#).

Return to the [Summary Table](#).

Zone 2 General Purpose Register-3

**Figure 5-40. Z2\_GPREG3 Register**

**Table 5-44. Z2\_GPREG3 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	GPREG3	R	0h	This field gets loaded with the contents of Z2OTP_GPREG3 locations in Zone2 USER-OTP when a dummy read is issued to that address. Users can use this register to load any general purpose non-volatile content from USER-OTP of Zone2 Reset type: SYSRStn

### 5.9.3.7 Z2\_GPREG4 Register (Offset = Eh) [Reset = 0000000h]

Z2\_GPREG4 is shown in [Figure 5-41](#) and described in [Table 5-45](#).

Return to the [Summary Table](#).

Zone 2 General Purpose Register-4

**Figure 5-41. Z2\_GPREG4 Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
GPREG4

0	EXEONLY_RAM0	R	0h	Value in this field gets loaded from Z2_EXEONLYRAM1[0] when a read is issued to Z2_EXEONLYRAM1 address location in OTP. 0 : Execute-Only protection is enabled for CPU1 LS0 RAM (only if it's allocated to Zone2) 1 : Execute-Only protection is disabled for CPU1 LS0 RAM (only if it's allocated to Zone2) Reset type: SYSRSn

### 5.9.4 DCSM\_COMMON\_REGS Registers

Table 5-59 lists the memory-mapped registers for the DCSM\_COMMON\_REGS registers. All register offset addresses not listed in Table 5-59 should be considered as reserved locations and the register contents should not be modified.

**Table 5-59. DCSM\_COMMON\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	FLSEM	Flash Wrapper Semaphore Register	EALLOW	<a href="#">Go</a>
8h	SECTSTAT1	Flash Sectors Status Register 1		<a href="#">Go</a>
Ah	SECTSTAT2	Flash Sectors Status Register 2		<a href="#">Go</a>
Ch	SECTSTAT3	Flash Sectors Status Register 3		<a href="#">Go</a>
10h	RAMSTAT1	RAM Status Register 1		<a href="#">Go</a>
12h	RAMSTAT2	RAM Status Register 2		<a href="#">Go</a>
18h	SECERRSTAT	Security Error Status Register		<a href="#">Go</a>
1Ah	SECERRCLR	Security Error Clear Register		<a href="#">Go</a>
1Ch	SECERRFRC	Security Error Force Register		<a href="#">Go</a>
1Eh	DENYCODE	Flash Authorization Denial Code		<a href="#">Go</a>
28h	UID_UNIQUE_31_0	Unique Identification Number		<a href="#">Go</a>
2Ah	UID_UNIQUE_63_32	Part Identification High Register		<a href="#">Go</a>
2Ch	PARTIDH	Part Identification High Register		<a href="#">Go</a>
2Eh	PERSEM1	Peripheral Semaphore Register	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 5-60 shows the codes that are used for access types in this section.

**Table 5-60. DCSM\_COMMON\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1S	W1S	Write 1 to set
WOnce	WOnce	Write Write once
WQ	WQ	Write Qualified. A condition must be met for this operation to occur.
Reset or Default Value		
-n		Value after reset or the default value

### 5.9.4.1 FLSEM Register (Offset = 0h) [Reset = 0000000h]

FLSEM is shown in [Figure 5-55](#) and described in [Table 5-61](#).

Return to the [Summary Table](#).

Flash Wrapper Semaphore Register

5-4	GRABTIMER1	R/W	0h	Grab TIMER1 module. Reset type: SYSRSn
3-2	GRABNMIWD	R/W	0h	GRAB NMIWD module. Reset type: SYSRSn

**Table 5-74. PERSEM1 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
1-0	GRABWD	R/W	0h	Grab Watchdog module 00 : Module configuration registers can be written by code running from anywhere without any restriction. 01 : Module configuration registers can be written by code running from Zone1 security zone. 10 : Module configuration registers can be written by code running from Zone2 security zone 11 : Module configuration registers can be written by code running from anywhere without any restriction Allowed State Transitions in this field. 00 TO 11 : Not allowed. 11 TO 00 : Not allowed. 00/11 TO 01 : Code running from Zone1 only can perform this transition. 01 TO 00/11 : Code running from Zone1 only can perform this transition. 00/11 TO 10 : Code running from Zone2 only can perform this transition. 10 TO 00/11 : Code running from Zone2 can perform this transition 10 TO 01 : Not allowed. 01 TO 10 : Not allowed. Reset type: SYSRSn

### 5.9.5 DCSM\_Z1\_OTP Registers

Table 5-75 lists the memory-mapped registers for the DCSM\_Z1\_OTP registers. All register offset addresses not listed in Table 5-75 should be considered as reserved locations and the register contents should not be modified.

**Table 5-75. DCSM\_Z1\_OTP Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	Z1OTP_LINKPOINTER1	Zone 1 Link Pointer1		<a href="#">Go</a>
2h	Z1OTP_LINKPOINTER2	Zone 1 Link Pointer2		<a href="#">Go</a>
4h	Z1OTP_LINKPOINTER3	Zone 1 Link Pointer3		<a href="#">Go</a>
6h	Z1OTP_JLM_ENABLE	Zone 1 JTAGLOCK Enable Register		<a href="#">Go</a>
8h	Z1OTP_GPREG1	Zone 1 General Purpose Register 1		<a href="#">Go</a>
Ah	Z1OTP_GPREG2	Zone 1 General Purpose Register 2		<a href="#">Go</a>
Ch	Z1OTP_GPREG3	Zone 1 General Purpose Register 3		<a href="#">Go</a>
Eh	Z1OTP_GPREG4	Zone 1 General Purpose Register 4		<a href="#">Go</a>
10h	Z1OTP_PSWDLOCK	Secure Password Lock		<a href="#">Go</a>
12h	Z1OTP_CRCLOCK	Secure CRC Lock		<a href="#">Go</a>
14h	Z1OTP_JTAGPSWDH0	JTAG Lock Permanent Password 0		<a href="#">Go</a>
16h	Z1OTP_JTAGPSWDH1	JTAG Lock Permanent Password 1		<a href="#">Go</a>
18h	Z1OTP_CMACKKEY0	Secure Boot CMAC Key 0		<a href="#">Go</a>
1Ah	Z1OTP_CMACKKEY1	Secure Boot CMAC Key 1		<a href="#">Go</a>
1Ch	Z1OTP_CMACKKEY2	Secure Boot CMAC Key 2		<a href="#">Go</a>
1Eh	Z1OTP_CMACKKEY3	Secure Boot CMAC Key 3		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 5-76 shows the codes that are used for access types in this section.

**Table 5-76. DCSM\_Z1\_OTP Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
Reset or Default Value		
-n		Value after reset or the default value

### 5.9.5.1 Z1OTP\_LINKPOINTER1 Register (Offset = 0h) [Reset = FFFFFFFFh]

Z1OTP\_LINKPOINTER1 is shown in [Figure 5-69](#) and described in [Table 5-77](#).

Return to the [Summary Table](#).

Zone 1 Link Pointer1

**Figure 5-69. Z1OTP\_LINKPOINTER1 Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Z1OTP_LINKPOINTER1																															
R-FFFFFFFh																															

**Table 5-77. Z1OTP\_LINKPOINTER1 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	Z1OTP_LINKPOINTER1	R	FFFFFFFh	Zone1 Link Pointer 1 location in USER OTP. Note: [1] ECC comparison is disabled for this location [2] When this value is loaded into DCSM, if the bits[31:14] !=0, device will remain in BLOCKED state. Before shipping parts to customers, TI would change the value of these bits to 0s. Reset type: N/A

### 5.9.5.2 Z1OTP\_LINKPOINTER2 Register (Offset = 2h) [Reset = FFFFFFFFh]

Z1OTP\_LINKPOINTER2 is shown in [Figure 5-70](#) and described in [Table 5-78](#).

Return to the [Summary Table](#).

Zone 1 Link Pointer2

**Figure 5-70. Z1OTP\_LINKPOINTER2 Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R-FFFFFFFh																															

**Table 5-78. Z1OTP\_LINKPOINTER2 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	Z1OTP_LINKPOINTER2	R	FFFFFFFh	Zone1 Link Pointer 2 location in USER OTP. Note: [1] ECC comparison is disabled for this location [2] When this value is loaded into DCSM, if the bits[31:14] !=0, device will remain in BLOCKED state. Before shipping parts to customers, TI would change the value of these bits to 0s. Reset type: N/A

### 5.9.5.3 Z1OTP\_LINKPOINTER3 Register (Offset = 4h) [Reset = FFFFFFFFh]

Z1OTP\_LINKPOINTER3 is shown in [Figure 5-71](#) and described in [Table 5-79](#).

Return to the [Summary Table](#).

Zone 1 Link Pointer3

**Figure 5-71. Z1OTP\_LINKPOINTER3 Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Z1OTP_LINKPOINTER3																															
R-FFFFFFFh																															

**Table 5-79. Z1OTP\_LINKPOINTER3 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	Z1OTP_LINKPOINTER3	R	FFFFFFFh	Zone1 Link Pointer 3 location in USER OTP. Note: [1] ECC comparison is disabled for this location [2] When this value is loaded into DCSM, if the bits[31:14] !=0, device will remain in BLOCKED state. Before shipping parts to customers, TI would change the value of these bits to 0s. Reset type: N/A

#### 5.9.5.4 Z1OTP\_JLM\_ENABLE Register (Offset = 6h) [Reset = FFFFFFFFh]

Z1OTP\_JLM\_ENABLE is shown in [Figure 5-72](#) and described in [Table 5-80](#).

Return to the [Summary Table](#).

Zone 1 JTAGLOCK Enable Register

**Figure 5-72. Z1OTP\_JLM\_ENABLE Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Z1OTP_JLM_ENABLE																															
R-FFFFFFFh																															

**Table 5-80. Z1OTP\_JLM\_ENABLE Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	Z1OTP_JLM_ENABLE	R	FFFFFFFh	Zone1 JLM_ENABLE register location in USER OTP. Note: When this value is loaded into Z1_JLM_ENABLE, if the value is 32-bit all-1s, the JTAGLOCK will be enabled. Before shipping parts to customers, TI will program the default value to 0xFFFF_000F, which will disable the JTAGLOCK feature. Users should program 0xFFFF_0000 to enable the JTAGLOCK feature. Reset type: N/A

### 5.9.5.5 Z1OTP\_GPREG1 Register (Offset = 8h) [Reset = FFFFFFFFh]

Z1OTP\_GPREG1 is shown in [Figure 5-73](#) and described in [Table 5-81](#).

Return to the [Summary Table](#).

Zone 1 General Purpose Register 1

**Figure 5-73. Z1OTP\_GPREG1 Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### 5.9.5.9 Z1OTP\_PSWDLOCK Register (Offset = 10h) [Reset = FFFFFFFFh]

Z1OTP\_PSWDLOCK is shown in [Figure 5-77](#) and described in [Table 5-85](#).

Return to the [Summary Table](#).

Secure Password Lock

**Figure 5-77. Z1OTP\_PSWDLOCK Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Z1OTP_PSWDLOCK																															
R-FFFFFFFh																															

**Table 5-85. Z1OTP\_PSWDLOCK Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	Z1OTP_PSWDLOCK	R	FFFFFFFh	Zone1 password lock location in USER OTP. Note: When this value is loaded into DCSM, if the value is 32-bit all-1s, CSMPSWD will remain locked. Before shipping parts to customers, TI would change the value of this location in such a way that the ECC field remains all-1s and also LSB 4-bits remain 4'b1111. Reset type: N/A

### 5.9.5.10 Z1OTP\_CRCLOCK Register (Offset = 12h) [Reset = FFFFFFFFh]

Z1OTP\_CRCLOCK is shown in [Figure 5-78](#) and described in [Table 5-86](#).

Return to the [Summary Table](#).

Secure CRC Lock

**Figure 5-78. Z1OTP\_CRCLOCK Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Z1OTP_CRCLOCK

31-0	CMACKKEY2	R	FFFFFFFh	Secure Boot CMAC Key 2 (bits 95:64) location in User Z1 OTP. This value is dummy loaded into the CMACKKEY2 register. Reset type: N/A

### 5.9.5.16 Z1OTP\_CMACKKEY3 Register (Offset = 1Eh) [Reset = FFFFFFFFh]

Z1OTP\_CMACKKEY3 is shown in [Figure 5-84](#) and described in [Table 5-92](#).

Return to the [Summary Table](#).

Secure Boot CMAC Key 3

**Figure 5-84. Z1OTP\_CMACKKEY3 Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CMACKKEY3																															
R-FFFFFFFh																															

**Table 5-92. Z1OTP\_CMACKKEY3 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	CMACKKEY3	R	FFFFFFFh	Secure Boot CMAC Key 3 (bits 127:96) location in User Z1 OTP. This value is dummy loaded into the CMACKKEY3 register. Reset type: N/A

### 5.9.6 DCSM\_Z2\_OTP Registers

Table 5-93 lists the memory-mapped registers for the DCSM\_Z2\_OTP registers. All register offset addresses not listed in Table 5-93 should be considered as reserved locations and the register contents should not be modified.

**Table 5-93. DCSM\_Z2\_OTP Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	Z2OTP_LINKPOINTER1	Zone 2 Link Pointer1		<a href="#">Go</a>
2h	Z2OTP_LINKPOINTER2	Zone 2 Link Pointer2		<a href="#">Go</a>
4h	Z2OTP_LINKPOINTER3	Zone 2 Link Pointer3		<a href="#">Go</a>
8h	Z2OTP_GPREG1	Zone 2 General Purpose Register 1		<a href="#">Go</a>
Ah	Z2OTP_GPREG2	Zone 2 General Purpose Register 2		<a href="#">Go</a>
Ch	Z2OTP_GPREG3	Zone 2 General Purpose Register 3		<a href="#">Go</a>
Eh	Z2OTP_GPREG4	Zone 2 General Purpose Register 4		<a href="#">Go</a>
10h	Z2OTP_PSWDLOCK	Secure Password Lock		<a href="#">Go</a>
12h	Z2OTP_CRCLOCK	Secure CRC Lock		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 5-94 shows the codes that are used for access types in this section.

**Table 5-94. DCSM\_Z2\_OTP Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
Reset or Default Value		
-n		Value after reset or the default value

### 5.9.6.1 Z2OTP\_LINKPOINTER1 Register (Offset = 0h) [Reset = FFFFFFFFh]

Z2OTP\_LINKPOINTER1 is shown in [Figure 5-85](#) and described in [Table 5-95](#).

Return to the [Summary Table](#).

Zone 2 Link Pointer1

**Figure 5-85. Z2OTP\_LINKPOINTER1 Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Chapter 6  
**Background CRC-32 (BGCR)**

---

The Background CRC (BGCR) module that helps to identify memory faults and corruption, is discussed in this chapter.

<b>6.1 Introduction</b> .....	<a href="#">1256</a>
<b>6.2 Functional Description</b> .....	<a href="#">1258</a>
<b>6.3 Application of the BGCR</b> .....	<a href="#">1260</a>
<b>6.4 Software</b> .....	<a href="#">1265</a>
<b>6.5 BGCR Registers</b> .....	<a href="#">1266</a>

## 6.1 Introduction

The Background CRC (BGCR) module computes a CRC-32 on a configurable block of memory. The BGCR accomplishes this by fetching the specified block of memory during idle cycles (when the CPU, CLA, or DMA is not accessing the memory block). The calculated CRC-32 value is compared against a golden CRC-32 value to indicate a pass or fail. In essence, the BGCR helps identify memory faults and corruption. There are two BGCR modules, CPU\_CRC and CLA\_CRC. The two BGCR modules differ only in the memories the modules test.

### 6.1.1 BGCR Related Collateral

#### Getting Started Materials

- [CRC Engines in C2000 Devices Application Report](#)

### 6.1.2 Features

The BGCR module has the following features:

- One cycle CRC-32 computation on 32 bits of data
- No CPU bandwidth impact for zero wait state memory
- Minimal CPU bandwidth impact for non-zero wait state memory
- Dual operation modes (CRC-32 mode and scrub mode)
- Watchdog timer to time CRC-32 completion
- Ability to pause and resume CRC-32 computation

### 6.1.3 Block Diagram

Figure 6-1 shows the BGCR block diagram.

**Figure 6-1. BGCR Block Diagram**

### 6.1.4 Memory Wait States and Memory Map

Figure 6-2 shows the memory map of the BGCRC module. M0, M1, D[x]RAM, MSGRAM, LS[x]RAM, and GS[x]RAM are all zero wait-state memories. BGCRC accesses these memories with minimal impact on normal program operation. For instance, if a BGCRC access is being made to a zero wait-state memory in the current cycle, the earliest the operating program can make access to the same memory location is in the next cycle. Similarly for the non-zero wait state memories SECROM, DATAROM and BOOTROM, the worst case delay for functional access after a BGCRC access is the wait-state amount.

Figure 6-2. BGCRC Memory Map

## 6.2 Functional Description

### 6.2.1 Data Read Unit

Once the CRC-32 calculation is started, the BGCRC module continuously reads data from memory as a background process. These reads happen during the idle times (when the CPU or DMA is not accessing the memory block) and so does not impact functional access. The data read unit only reads data if there is no pending functional access. The data read unit begins operation by reading a block of data BGCRC\_CTRL2.BLOCK\_SIZE from address BGCRC\_START\_ADDR. Note that BGCRC\_START\_ADDR must be 0x80 word aligned. For a non-0x80 word aligned BGCRC\_START\_ADDR, the LSB bits are zeroed out to get a 0x80 word aligned BGCRC\_START\_ADDR. For instance, if the programmed BGCRC\_START\_ADDR = 0x1AF3, the internal 0x80 word aligned start address is 0x1A80.

When the data read unit reads a block of data, ECC and parity are checked. Any ECC or parity errors that occur during the read is indicated by setting the respective NMI and generating an interrupt if configured as so. The BGCRC module, however, does not write back the corrected memory contents on the occurrence of a correctable ECC error. Writing back the corrected values is handled by software.

### 6.2.2 CRC-32 Compute Unit

After the data read unit reads a block of data, the data read unit feeds this data to the CRC-32 compute unit. This unit computes the CRC-32 using the standard polynomial  $0x04C11DB7$  ( $x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$ ). The CRC-32 unit retrieves 32-bit of data at a time from the block of data to compute the polynomial. This computation takes 1 cycle. For instance, the CRC-32 calculation for 1KB block of data is 256 cycles, 1 cycle for each of the 256 32-bit chunks. The initial value for the CRC-32 computation can be configured using BGCRC\_SEED.

After the CRC-32 calculation is complete for a data block, the final result is loaded into BGCRC\_RESULT. Note that BGCRC\_RESULT only contains the final calculation for the whole data block; intermediate 32-bit calculations do not update BGCRC\_RESULT. The value in BGCRC\_RESULT is compared against the value in BGCRC\_GOLDEN by hardware and the NMI/Interrupt flags are set accordingly by the CRC notification unit.

Once CRC-32 calculation is commenced, the calculation can be halted by setting BGCRC\_CTRL2.TEST\_HALT to 1010. Clearing this bit resumes CRC-32 calculation from the halt point.

### 6.2.3 CRC Notification Unit

After the CRC-32 compute unit completes the CRC-32 calculation for a block of data or fails to complete the calculation within BGCR\_C\_WD\_MIN and BGCR\_C\_WD\_MAX, if configured, the CRC-32 compute unit sends out a NMI/Interrupt on the occurrence of a pass or fail. In addition, during a data read by the data read unit, if an ECC or parity error occurs, the CRC notification unit can send out a NMI/Interrupt. In the case of an ECC or parity error, the BGCR\_C stops operation and BGCR\_C\_CURR\_ADDR contains the memory address that caused the ECC or parity error. The contents of BGCR\_C\_CURR\_ADDR in addition to the NMI/Interrupt flags can be used to debug a BGCR\_C failure.

#### 6.2.3.1 CPU Interrupt and NMI

The BGCR\_C module has configurable interrupt and NMI lines. NMIs are enabled by default but can be disabled by writing 0xA to BGCR\_C\_CTRL1.NMIDIS register. Conversely, all interrupts are disabled by default but can be enabled by writing 0x7E to BGCR\_C\_INTEN register. When an error occurs in the BGCR\_C, the BGCR\_C can be configured to generate an NMI or interrupt. Since NMIs are enabled by default, all BGCR\_C errors cause an NMI. Figure 6-3 and Figure 6-4 show the NMI and Interrupt lines, respectively.

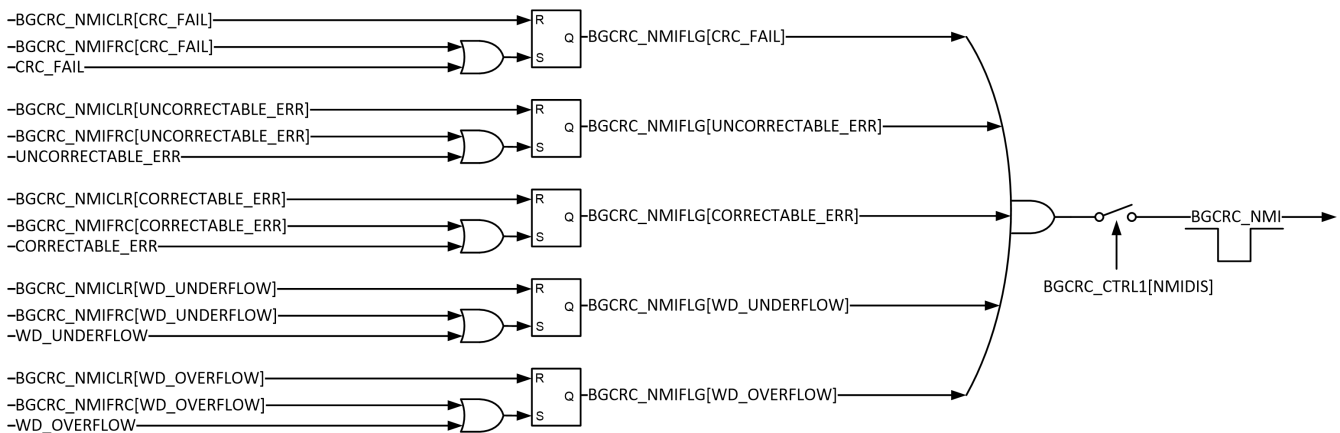

Figure 6-3. BGCR\_C NMI

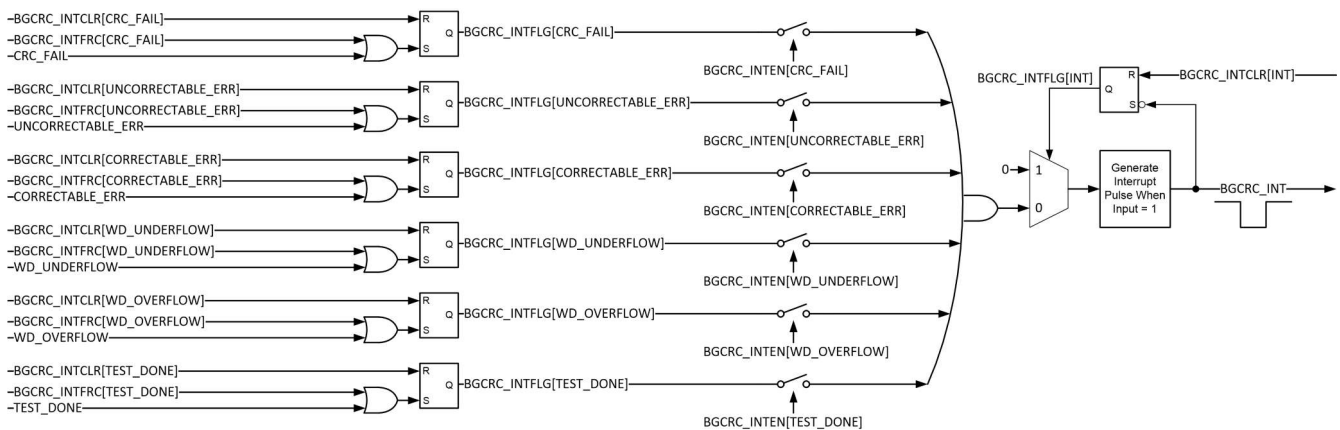

Figure 6-4. BGCR\_C Interrupt

## 6.2.4 Operating Modes

BGCRC module supports two modes of operation: CRC mode and scrub mode. The mode of operation can be configured by clearing or setting the register BGCRC\_CTRL2.SCRUB\_MODE.

### 6.2.4.1 CRC Mode

In CRC mode, the BGCRC module operates as explained in [Section 6.2.2](#). CRC-32 calculation is performed on a block of data and the result compared against a golden value. ECC and parity errors are checked in this mode. Result mismatch, ECC or parity error can trigger an NMI/Interrupt.

### 6.2.4.2 Scrub Mode

In scrub mode, the CRC-32 result is not compared against the golden value and BGCRC\_RESULT register is not updated. ECC and parity errors are also checked in this mode. However unlike CRC mode, NMI/Interrupt are only from ECC or parity error. In scrub mode, Parity and ECC bits of the memory block need to be initialized by the CPU.

## 6.2.5 BGCRC Watchdog

The BGCRC module has an embedded windowed watchdog that is used as a diagnostic to check memory test completion within the expected time window. This can protect against hardware defects that can cause the memory check not to complete in the allotted time, which cannot be caught by the system watchdog as the error can be due to the DMA having continuous access. Windowing also helps detect additional failure modes in the watchdog operation, for example, stuck watchdog.

The BGCRC watchdog is enabled by default and starts when the BGCRC module begins reading from memory. The watchdog can be disabled using the register BGCRC\_WD\_CFG.WDDIS. The BGCRC watchdog counter is a 32-bit counter with the value reflected in BGCRC\_WD\_CNT register. The lower and upper window settings are configured using BGCRC\_WD\_MIN and BGCRC\_WD\_MAX, respectively. BGCRC\_WD\_MIN and BGCRC\_WD\_MAX need to be configured before the test is started and must not be changed while the BGCRC is operating. If configured, an NMI or interrupt is triggered if the memory test fails to complete within the configured time window. The counter stops on completion of the CRC-32 check done, CRC-32 check failure and ECC/Parity errors. The counter is reset when the next memory check begins.

The BGCRC watchdog can be halted by configuring the BGCRC\_WD\_CFG.WDDIS register. After the watchdog resumes from being halted, the counter starts counting from the previous count unless a new memory check operation is initiated. The counter is not halted when CRC-32 computation halts but by default halts during a debug halt. The behavior of the watchdog during emulation can be changed by configuring the appropriate BGCRC registers. In addition, due to the changing nature of memory contents during emulation, it is not recommended to run BGCRC during emulation. CRC-32 computation continues during a watchdog failure and software needs to address this condition.

## 6.2.6 Hardware and Software Faults Protection

The configuration registers are protected using a lock and commit configuration. Each of the configuration registers can be individually locked and committed. The register once locked, can no longer be updated until the lock is removed. However if the register lock is committed, no further writes is permitted until the device is reset. It is recommended to lock the registers after configuration to protect against corruption due to software faults. In addition, registers critical to the module functionality and fault detection are implemented using multi-bit fields to protect against hardware faults.

## 6.3 Application of the BGCRC

This section contains use case scenarios of how the BGCRC module can be configured to test a block of memory. However, the use case scenarios presented are for reference only and do not cover all the possible application scenarios. These use case scenarios can be used as a starting point to configure the BGCRC module for specific applications.

### 6.3.1 Software Configuration

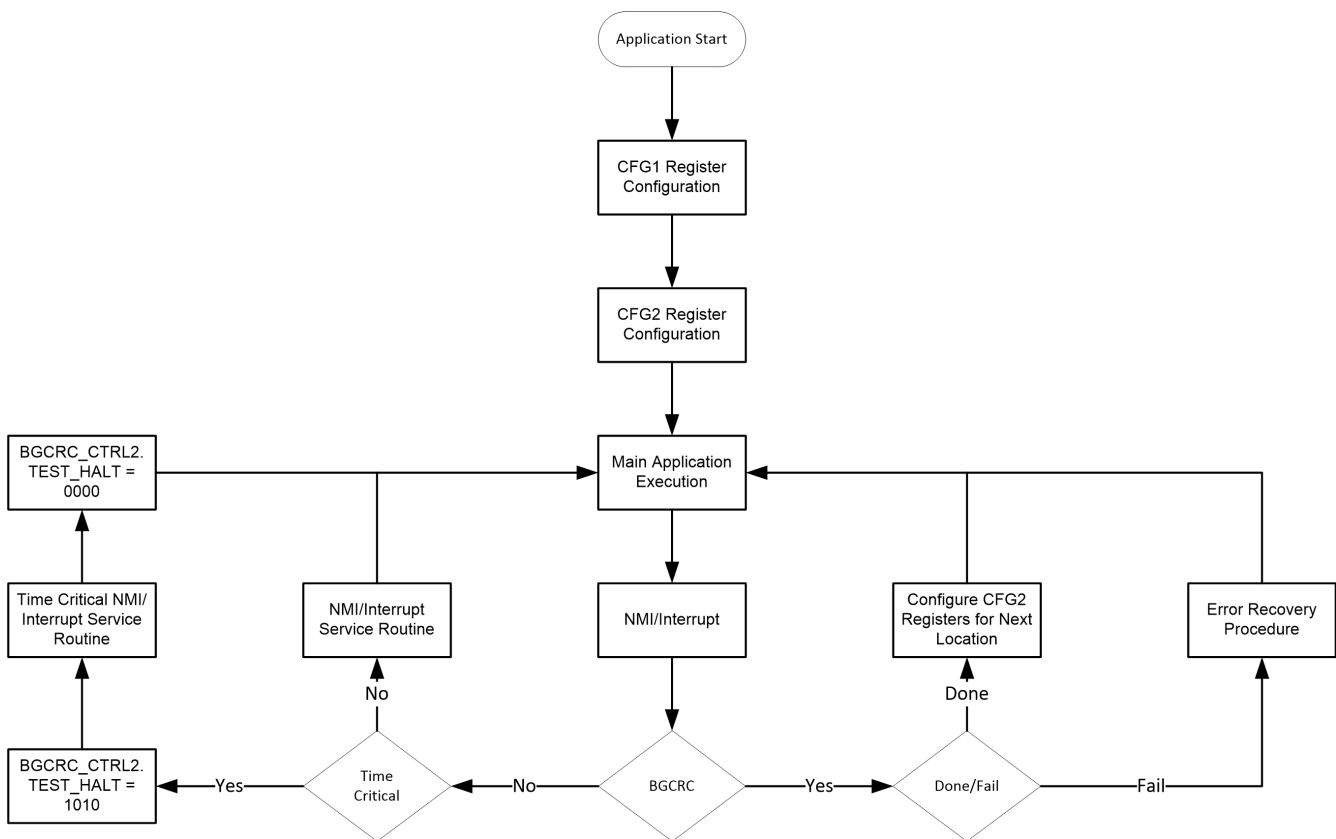

The configuration registers for the BGCRC can be split into three groups (see [Table 6-1](#)):

- **CFG1:** Registers that determine the operating mode and configured at the beginning.
- **CFG2:** Registers that need to be updated during kickoff of a new test.
- **CFG3:** Registers used for test and error management.

CFG1 registers are expected to be locked and committed after initial configuration. It is recommended to lock the CFG2 and CFG3 registers after configuration. [Figure 6-5](#) shows the BGCRC execution sequence.

**Table 6-1. BGCRC Register Groups**

CFG1 - One Time Configuration Registers	CFG2 - Periodic Configuration Registers	CFG3 - Registers Used for Test and Error Management
BGCRC_CTRL1	BGCRC_EN	BGCRC_NMICLR
BGCRC_WD_CFG	BGCRC_CTRL2	BGCRC_INTCLR
BGCRC_INTEN	BGCRC_START_ADDR	BGCRC_NMIFRC
BGCRC_SEED	BGCRC_GOLDEN	BGCRC_INTFRC
	BGCRC_WD_MIN	
	BGCRC_WD_MAX	

**Figure 6-5. BGCRC Execution Sequence Flow**

### **6.3.2 Decision on Error Response Severity**

The error sources for BGCRC are:

- Test completion before BGCRC\_WD\_MIN.
- Test completed after BGCRC\_WD\_MAX.
- Mismatch between the calculated CRC and golden CRC.
- Uncorrectable error during data read (single bit error for parity memory or double bit error for ECC memory).
- Correctable error during memory read (single bit error for ECC memory).

Error severity can be chosen as either NMI or interrupt. By default, error severity is set to NMI. It is not possible to configure error response for each individual error source. The response can be chosen as either interrupt or NMI for all error sources. When error severity is chosen as NMI, ERROR\_STS pin is asserted during an error.

### **6.3.3 Decision of Controller for CLA\_CRC**

CPU\_CRC can only be kicked off by the CPU. However, CLA\_CRC can be kicked off by the CPU or CLA. If BGCRC error severity is chosen as NMI, it is possible to handle the background test using the CLA and error response with the CPU. Once the controller for BGCRC is chosen, it is possible to prevent accesses from other controllers by using the system-level access protection configuration.

### **6.3.4 Execution of Time Critical Code from Wait-Styled Memories**

BGCRC access to functionally wait-stated memories is also wait-stated by the same number. Since it is impossible to predict the next functional access, any ongoing BGCRC access has to complete before functional access is granted. To mitigate delay in functional access, the BGCRC can be halted when time-critical code that accesses the wait-stated memories is in progress. When BGCRC execution is halted, the BGCRC watchdog is not halted. This is consistent with the safety requirement to complete the background test in a predictable window irrespective of the user code. In such scenarios, it is recommended to adjust the upper BGCRC watchdog window limit to account for the halt duration during functional access. However, if required, the BGCRC watchdog can be disabled.

### **6.3.5 BGCRC Execution**

Two notes about BGCRC execution are:

- BGCRC task can run as a background task once kicked off.
- BGCRC task does not impact functional execution for zero-wait stated memories. For memories with higher wait-states, the BGCRC engine can be halted to make functional execution predictable.

[Figure 6-6](#) shows a few examples of BGCRC execution sequences.

CPU\_CRC executed in parallel with functional execution. CRC-32 check can be stalled during time critical ISRs if ISRs require access to non-zero wait-stated memories.
