- **HRCALIBPERIOD:** Calibration period, calibration is stopped when HRSYSCLKCNT is equal to the value in this register.
- **HRSYSCLKCAP:** On a calibration period match, the value of HRSYSCLKCNT is captured into HRSYSCLKCAP.
- **HRCLKCAP:** On a calibration period match, the value of HRCLKCNT is captured into HRCLKCAP.
- **HRCALINT:** An interrupt that occurs on a calibration period match, or when one of the counter registers experiences an overflow condition.

The calibration logic consists of two free-running counters; one clocked by HRCLK(HRCLKCTR) and one clocked by SYSCLK(HRSYSCLKCTR). When HRSYSCLKCTR is equal to HRCALIBPERIOD, the calibration block captures and resets both counter values, then triggers an interrupt, indicating a new scale factor is ready to be calculated. The scale factor can be found by dividing HRSYSCLKCAP by HRCLKCAP (see [Equation 22](#)). A DriverLib function, HRCAP\_getScaleFactor, has been provided to determine the scale factor. This function can be called inside of the calibration interrupt service routine. If one of the counters experiences overflow, the CALPRDCHKSTS flag is set. The full details of the calibration block are described in [Figure 21-20](#).

$$ScaleFactor = \frac{HRSYSCLKCAP}{HRCLKCAP} \quad (22)$$

---

#### Note

- Even with calibration, noise on the 1.2V VDD supply negatively affects the standard deviation of the HRCAP submodule. Care can be taken to make sure that the 1.2V supply is clean, and that noisy internal events such as enabling and disabling clock trees have been minimized while using the HRCAP submodule.
  - When HRCLK > SYSCLK, calibration stops immaturely to mitigate improper calibration, SYSCLK must be set to at least 100MHz.
-

### 21.8.2.4.1 Applying the Scale Factor

A DriverLib function has been provided to apply the scale factor to a capture value, `HRCAP_getEventTimeStampNanoseconds()`. [Equation 23](#) shows how to convert a raw count to seconds without using the DriverLib function.

$$Measurement(ns) = \frac{RawCount \times scaleFactor}{128} * SysClkPrd(ns) \quad (23)$$

**Table 21-2. Scale Factor**

Parameter	Explanation
RawCount	Capture value as read from ECAP_REGS_CAP1-4
ScaleFactor <sup>(1)</sup>	The Scale factor as calculated from <a href="#">Equation 23</a>
128	Constant determined by the hardware of the HRCAP submodule
SysClkPrd(nS)	Period of the system clock
Measurement(nS)	Signal converted to nS

(1) The scale factor is not automatically applied to captured values. The user is required to apply the scale factor to all captured values as shown in [Equation 23](#).

### 21.8.3 Known Exceptions

In HRCAP mode:

- Enabling and disabling core clocks negatively affects the standard deviation of the HRCAP submodule. Do not enable or disable core clocks while taking measurements.
- TSCTR is not writable; however, TSCTR can be reset using `ECCTL2[CTRFILTRESET]`
- Input synchronization is not applicable when using the HRCAP enhancements, because the HRCAP submodule is asynchronous to SYSCLK.
- The Event Filter functionality is not applicable for HRCAP, which defeats the purpose of HRCAP as the Event Filter's output is synchronous to SYSCLK.
- The best practice is to use absolute time mode for high-resolution mode. If time difference mode is used, it can lead to inaccurate results if the fractional value is not taken into consideration for capture events that have reset the time base counter.
  - Actual Capture Value = (Capture Value) – (fractional value of reference event that reset the counter)
- For high-frequency input signals, the CPU can not be able to cope with the speed of the captures. In such a case, one-shot mode is recommended. This mode allows the device to capture up to four edges before waiting to be serviced when the CPU is ready. This is applicable for the eCAP as well; however, in that case the event filter can be used to reduce the rate of captures.

## 21.9 Software

### 21.9.1 ECAP Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
`C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/ecap`

Cloud access to these examples is available at the following link: [dev.ti.com C2000Ware Examples](https://dev.ti.com/C2000Ware/Examples).

#### 21.9.1.1 eCAP APWM Example - SINGLE\_CORE

FILE: `ecap_ex1_apwm.c`

This program sets up the eCAP module in APWM mode. The PWM waveform will come out on GPIO5. The frequency of PWM is configured to vary between 10Hz and 20Hz using the shadow registers to load the next period/compare values.

#### 21.9.1.2 eCAP Capture PWM Example - SINGLE\_CORE

FILE: `ecap_ex2_capture_pwm.c`

This example configures ePWM3A for:

- Up count mode
- Period starts at 500 and goes up to 8000
- Toggle output on PRD

eCAP1 is configured to capture the time between rising and falling edge of the ePWM3A output.

##### *External Connections*

- eCAP1 is on GPIO16
- ePWM1A is on GPIO4
- Connect GPIO4 to GPIO16.

##### *Watch Variables*

- `ecap1PassCount` - Successful captures.
- `ecap1IntCount` - Interrupt counts.

#### 21.9.1.3 eCAP APWM Phase-shift Example - SINGLE\_CORE

FILE: `ecap_ex3_apwm_phase_shift.c`

This program sets up the eCAP1 and eCAP2 modules in APWM mode to generate the two phase-shifted PWM outputs of same duty and frequency value. The frequency, duty and phase values can be programmed of choice by updating the defined macros. By default 10 KHz frequency, 50% duty and 30% phase shift values are used. eCAP2 output leads the eCAP1 output by 30%. GPIO0 and GPIO1 are used as eCAP1/2 outputs and can be probed using analyzer/CRO to observe the waveforms.

#### 21.9.2 HRCAP Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
`C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/hrcap`

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 21.9.2.1 HRCAP Capture and Calibration Example - SINGLE\_CORE

FILE: `hrcap_ex1_capture.c`

This example configures an ECAP to use HRCAP functionality to capture time between edges on input GPIO2.

##### *External Connections*

The user must provide a signal to GPIO2. XCLKOUT has been configured to an output GPIO and can be externally jumped to serve this purpose. See Sysconfig file for XCLKOUT GPIO selected.

##### *Watch Variables*

- `onTime1`, `onTime2`
- `offTime1`, `offTime2`
- `period1`, `period2`

## 21.10 eCAP Registers

This section describes the Enhanced Capture Registers.

### 21.10.1 ECAP Base Address Table

**Table 21-3. ECAP Base Address Table**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	CPU2	CPU2.DMA	Pipeline Protected
Instance	Structure								
ECap1Regs	<a href="#">ECAP_REGS</a>	ECAP1_BASE	0x0000_5200	YES	YES	YES	YES	YES	YES

### 21.10.2 ECAP\_REGS Registers

Table 21-4 lists the memory-mapped registers for the ECAP\_REGS registers. All register offset addresses not listed in Table 21-4 should be considered as reserved locations and the register contents should not be modified.

**Table 21-4. ECAP\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	TSCTR	Time-Stamp Counter		<a href="#">Go</a>
2h	CTRPHS	Counter Phase Offset Value Register		<a href="#">Go</a>
4h	CAP1	Capture 1 Register		<a href="#">Go</a>
6h	CAP2	Capture 2 Register		<a href="#">Go</a>
8h	CAP3	Capture 3 Register		<a href="#">Go</a>
Ah	CAP4	Capture 4 Register		<a href="#">Go</a>
12h	ECCTL0	Capture Control Register 0	EALLOW	<a href="#">Go</a>
14h	ECCTL1	Capture Control Register 1	EALLOW	<a href="#">Go</a>
15h	ECCTL2	Capture Control Register 2	EALLOW	<a href="#">Go</a>
16h	ECEINT	Capture Interrupt Enable Register	EALLOW	<a href="#">Go</a>
17h	ECFLG	Capture Interrupt Flag Register		<a href="#">Go</a>
18h	ECCLR	Capture Interrupt Clear Register		<a href="#">Go</a>
19h	ECFRC	Capture Interrupt Force Register	EALLOW	<a href="#">Go</a>
1Eh	ECAPSYNCINSEL	SYNC source select register	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 21-5 shows the codes that are used for access types in this section.

**Table 21-5. ECAP\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value

### 21.10.2.1 TSCTR Register (Offset = 0h) [Reset = 0000000h]

TSCTR is shown in [Figure 21-21](#) and described in [Table 21-6](#).

Return to the [Summary Table](#).

Time-Stamp Counter

**Figure 21-21. TSCTR Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TSCTR																															
R/W-0h																															

**Table 21-6. TSCTR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	TSCTR	R/W	0h	Active 32-bit counter register that is used as the capture time-base HR mode : 1) This register reads HRCOUNTER value and is not writable 2) can be reset using CTRFILTRRESET 3) Its not synchronized to SYSCLK domain so reads may not be accurate Reset type: SYSRSn

### 21.10.2.2 CTRPHS Register (Offset = 2h) [Reset = 00000000h]

CTRPHS is shown in [Figure 21-22](#) and described in [Table 21-7](#).

Return to the [Summary Table](#).

Counter Phase Offset Value Register

**Figure 21-22. CTRPHS Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CTRPHS																															
R/W-0h																															

**Table 21-7. CTRPHS Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	CTRPHS	R/W	0h	Counter phase value register that can be programmed for phase lag/lead. This register CTRPHS is loaded into TSCTR upon either a SYNCI event or S/W force via a control bit. Used to achieve phase control synchronization with respect to other eCAP and EPWM time-bases. This register is not applicable in HR mode. Reset type: SYSRSn

### 21.10.2.3 CAP1 Register (Offset = 4h) [Reset = 00000000h]

CAP1 is shown in [Figure 21-23](#) and described in [Table 21-8](#).

Return to the [Summary Table](#).

Capture 1 Register

**Figure 21-23. CAP1 Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CAP1																															
R/W-0h																															

**Table 21-8. CAP1 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	CAP1	R/W	0h	This register can be loaded (written) by: <ul style="list-style-type: none"> <li>- Time-Stamp counter value (TSCTR) during a capture event</li> <li>- Software - may be useful for test purposes or initialization</li> <li>- ARPD shadow register (CAP3) when used in APWM mode</li> </ul> Reset type: SYSRSn

### 21.10.2.4 CAP2 Register (Offset = 6h) [Reset = 0000000h]

CAP2 is shown in [Figure 21-24](#) and described in [Table 21-9](#).

Return to the [Summary Table](#).

Capture 2 Register

**Figure 21-24. CAP2 Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CAP2																															
R/W-0h																															

**Table 21-9. CAP2 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	CAP2	R/W	0h	This register can be loaded (written) by: <ul style="list-style-type: none"> <li>- Time-Stamp ( counter value) during a capture event</li> <li>- Software - may be useful for test purposes</li> <li>- ACMP shadow register (CAP4) when used in APWM mode</li> </ul> Reset type: SYSRSn

### 21.10.2.5 CAP3 Register (Offset = 8h) [Reset = 0000000h]

CAP3 is shown in [Figure 21-25](#) and described in [Table 21-10](#).

Return to the [Summary Table](#).

Capture 3 Register

**Figure 21-25. CAP3 Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CAP3																															
R/W-0h																															

**Table 21-10. CAP3 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	CAP3	R/W	0h	In CMP mode, this is a time-stamp capture register. In APWM mode, this is the period shadow (APRD) register. You can update the PWM period value through this register. CAP3 (APRD) shadows CAP1 in this mode. Reset type: SYSRSn

### 21.10.2.6 CAP4 Register (Offset = Ah) [Reset = 0000000h]

CAP4 is shown in [Figure 21-26](#) and described in [Table 21-11](#).

Return to the [Summary Table](#).

Capture 4 Register

**Figure 21-26. CAP4 Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CAP4																															
R/W-0h																															

**Table 21-11. CAP4 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	CAP4	R/W	0h	In CMP mode, this is a time-stamp capture register. In APWM mode, this is the compare shadow (ACMP) register. You can update the PWM compare value via this register. CAP4 (ACMP) shadows CAP2 in this mode. Reset type: SYSRSn

### 21.10.2.7 ECCTL0 Register (Offset = 12h) [Reset = 00000FFh]

ECCTL0 is shown in [Figure 21-27](#) and described in [Table 21-12](#).

Return to the [Summary Table](#).

11	CTRFILTRESET	R-0/W1C	0h	Reset Bit 0h (R) = No effect 1h (W) = Resets event filter, counter, modulo counter and CEVT[1,2,3,4] and CNTOVF , HRERROR flags Note: This provides an ability start capture module from known state in case spurious inputs are captured while ECAP is configured. Reset type: CPU1.SYSRSn
10	APWMPOL	R/W	0h	APWM output polarity select. This is applicable only in APWM operating mode. Reset type: SYSRSn 0h (R/W) = Output is active high (Compare value defines high time) 1h (R/W) = Output is active low (Compare value defines low time)

**Table 21-14. ECCTL2 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
9	CAP_APWM	R/W	0h	CAP/APWM operating mode select Reset type: SYSRSn 0h (R/W) = ECAP module operates in capture mode. This mode forces the following configuration: <ul style="list-style-type: none"> <li>- Inhibits TSCTR resets via CTR = PRD event</li> <li>- Inhibits shadow loads on CAP1 and 2 registers</li> <li>- Permits user to enable CAP1-4 register load</li> <li>- CAPx/APWMx pin operates as a capture input</li> </ul> 1h (R/W) = ECAP module operates in APWM mode. This mode forces the following configuration: <ul style="list-style-type: none"> <li>- Resets TSCTR on CTR = PRD event (period boundary)</li> <li>- Permits shadow loading on CAP1 and 2 registers</li> <li>- Disables loading of time-stamps into CAP1-4 registers</li> <li>- CAPx/APWMx pin operates as a APWM output</li> </ul>
8	SWSYNC	R-0/W1S	0h	Software-forced Counter (TSCTR) Synchronizer. This provides the user a method to generate a synchronization pulse through software. In APWM mode, the synchronization pulse can also be sourced from the CTR = PRD event. Reset type: SYSRSn 0h (R/W) = Writing a zero has no effect. Reading always returns a zero 1h (R/W) = Writing a one forces a TSCTR shadow load of current ECAP module and any ECAP modules down-stream providing the SYNCO_SEL bits are 0,0. After writing a 1, this bit returns to a zero.
7-6	SYNCO_SEL	R/W	0h	Sync-Out Select Reset type: SYSRSn 0h (R/W) = sync out signal is SWSYNC 1h (R/W) = Select CTR = PRD event to be the sync-out signal. Note: Selection CTR = PRD is meaningful only in APWM mode 2h (R/W) = Disable sync out signal 3h (R/W) = Disable sync out signal
5	SYNCI_EN	R/W	0h	Counter (TSCTR) Sync-In select mode Reset type: SYSRSn 0h (R/W) = Disable sync-in option 1h (R/W) = Enable counter (TSCTR) to be loaded from CTRPHS register upon either a SYNCI signal or a S/W force event.
4	TSCTRSTOP	R/W	0h	Time Stamp (TSCTR) Counter Stop (freeze) Control Reset type: SYSRSn 0h (R/W) = TSCTR stopped 1h (R/W) = TSCTR free-running
3	REARM	R-0/W1S	0h	Re-Arming Control. Note: The re-arm function is valid in one shot or continuous mode Reset type: SYSRSn 0h (R/W) = Has no effect (reading always returns a 0) 1h (R/W) = Arms the one-shot sequence as follows: <ol style="list-style-type: none"> <li>1) Resets the Mod4 counter to zero</li> <li>2) Unfreezes the Mod4 counter</li> <li>3) Enables capture register loads</li> </ol>

**Table 21-14. ECCTL2 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
2-1	STOP_WRAP	R/W	3h	<p>Stop value for one-shot mode. This is the number (between 1-4) of captures allowed to occur before the CAP(1-4) registers are frozen, that is, capture sequence is stopped.</p> <p>Wrap value for continuous mode. This is the number (between 1-4) of the capture register in which the circular buffer wraps around and starts again.</p> <p>Notes: STOP_WRAP is compared to Mod4 counter and, when equal, 2 actions occur:</p> <ul style="list-style-type: none"> <li>- Mod4 counter is stopped (frozen)</li> <li>- Capture register loads are inhibited</li> </ul> <p>In one-shot mode, further interrupt events are blocked until re-armed.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Stop after Capture Event 1 in one-shot mode            Wrap after Capture Event 1 in continuous mode.</p> <p>1h (R/W) = Stop after Capture Event 2 in one-shot mode            Wrap after Capture Event 2 in continuous mode.</p> <p>2h (R/W) = Stop after Capture Event 3 in one-shot mode            Wrap after Capture Event 3 in continuous mode.</p> <p>3h (R/W) = Stop after Capture Event 4 in one-shot mode            Wrap after Capture Event 4 in continuous mode.</p>
0	CONT_ONESHT	R/W	0h	<p>Continuous or one-shot mode control (applicable only in capture mode)</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Operate in continuous mode            1h (R/W) = Operate in one-Shot mode</p>

### 21.10.2.10 ECEINT Register (Offset = 16h) [Reset = 0000h]

ECEINT is shown in [Figure 21-30](#) and described in [Table 21-15](#).

Return to the [Summary Table](#).

The interrupt enable bits (CEVT1, ...) block any of the selected events from generating an interrupt. Events will still be latched into the flag bit (ECFLG register) and can be forced/cleared via the ECFRC/ECCLR registers. The proper procedure for configuring peripheral modes and interrupts is as follows:

- Disable global interrupts
- Stop eCAP counter
- Disable eCAP interrupts
- Configure peripheral registers
- Clear spurious eCAP interrupt flags
- Enable eCAP interrupts
- Start eCAP counter
- Enable global interrupts

**Figure 21-30. ECEINT Register**

### 21.10.3 ECAP\_SIGNAL\_MONITORING Registers

Table 21-20 lists the memory-mapped registers for the ECAP\_SIGNAL\_MONITORING registers. All register offset addresses not listed in Table 21-20 should be considered as reserved locations and the register contents should not be modified.

**Table 21-20. ECAP\_SIGNAL\_MONITORING Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	MUNIT_COMMON_CTL	Control registers for monitoring unit {#}	EALLOW	<a href="#">Go</a>
20h	MUNIT_1_CTL	Control registers for monitoring unit 1	EALLOW	<a href="#">Go</a>
22h	MUNIT_1_SHADOW_CTL	Shadow control registers for monitoring unit 1	EALLOW	<a href="#">Go</a>
28h	MUNIT_1_MIN	Min value for monitoring unit 1		<a href="#">Go</a>
2Ah	MUNIT_1_MAX	Max value for monitoring unit 1		<a href="#">Go</a>
2Ch	MUNIT_1_MIN_SHADOW	Shadow register for Min value of monitoring unit 1		<a href="#">Go</a>
2Eh	MUNIT_1_MAX_SHADOW	Shadow register for Max value of monitoring unit 1		<a href="#">Go</a>
30h	MUNIT_1_DEBUG_RANGE_MIN	Observed Min value of check being enabled on monitoring unit 1		<a href="#">Go</a>
32h	MUNIT_1_DEBUG_RANGE_MAX	Observed Max value of check being enabled on monitoring unit 1		<a href="#">Go</a>
40h	MUNIT_2_CTL	Control registers for monitoring unit 2	EALLOW	<a href="#">Go</a>
42h	MUNIT_2_SHADOW_CTL	Shadow control registers for monitoring unit 2	EALLOW	<a href="#">Go</a>
48h	MUNIT_2_MIN	Min value for monitoring unit 2		<a href="#">Go</a>
4Ah	MUNIT_2_MAX	Max value for monitoring unit 2		<a href="#">Go</a>
4Ch	MUNIT_2_MIN_SHADOW	Shadow register for Min value of monitoring unit 2		<a href="#">Go</a>
4Eh	MUNIT_2_MAX_SHADOW	Shadow register for Max value of monitoring unit 2		<a href="#">Go</a>
50h	MUNIT_2_DEBUG_RANGE_MIN	Observed Min value of check being enabled on monitoring unit 2		<a href="#">Go</a>
52h	MUNIT_2_DEBUG_RANGE_MAX	Observed Max value of check being enabled on monitoring unit 2		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 21-21 shows the codes that are used for access types in this section.

**Table 21-21. ECAP\_SIGNAL\_MONITORING Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1S	W1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		

**Table 21-21. ECAP\_SIGNAL\_MONITORING Access Type Codes (continued)**

Access Type	Code	Description
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 21.10.3.1 MUNIT\_COMMON\_CTL Register (Offset = 0h) [Reset = 0000000h]

MUNIT\_COMMON\_CTL is shown in [Figure 21-35](#) and described in [Table 21-22](#).

Return to the [Summary Table](#).

## 21.11 HRCAP Registers

This section describes the High-Resolution Capture Registers.

### 21.11.1 HRCAP Base Address Table

**Table 21-40. HRCAP Base Address Table**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	CPU2	CPU2.DMA	Pipeline Protected
Instance	Structure								
HRCap6Regs	<a href="#">HRCAP_REGS</a>	HRCAP6_BAS E	0x0000_5720	YES	YES	YES	YES	YES	YES
HRCap7Regs	<a href="#">HRCAP_REGS</a>	HRCAP7_BAS E	0x0000_5820	YES	YES	YES	YES	YES	YES

### 21.11.2 HRCAP\_REGS Registers

Table 21-41 lists the memory-mapped registers for the HRCAP\_REGS registers. All register offset addresses not listed in Table 21-41 should be considered as reserved locations and the register contents should not be modified.

**Table 21-41. HRCAP\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	HRCTL	High-Res Control Register	EALLOW	<a href="#">Go</a>
4h	HRINTEN	High-Res Calibration Interrupt Enable Register	EALLOW	<a href="#">Go</a>
6h	HRFLG	High-Res Calibration Interrupt Flag Register		<a href="#">Go</a>
8h	HRCLR	High-Res Calibration Interrupt Clear Register		<a href="#">Go</a>
Ah	HRFRC	High-Res Calibration Interrupt Force Register	EALLOW	<a href="#">Go</a>
Ch	HRCALPRD	High-Res Calibration Period Register	EALLOW	<a href="#">Go</a>
Eh	HRSYSCLKCTR	High-Res Calibration SYSCLK Counter Register		<a href="#">Go</a>
10h	HRSYSCLKCAP	High-Res Calibration SYSCLK Capture Register		<a href="#">Go</a>
12h	HRCLKCTR	High-Res Calibration HRCLK Counter Register		<a href="#">Go</a>
14h	HRCLKCAP	High-Res Calibration HRCLK Capture Register		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 21-42 shows the codes that are used for access types in this section.

**Table 21-42. HRCAP\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value

### 21.11.2.1 HRCTL Register (Offset = 0h) [Reset = 0000000h]

HRCTL is shown in [Figure 21-52](#) and described in [Table 21-43](#).

Return to the [Summary Table](#).

## Chapter 22 Enhanced Pulse Width Modulator (ePWM)

The enhanced pulse width modulator (ePWM) peripheral is a key element in controlling many of the power electronic systems found in both commercial and industrial equipment. These systems include digital motor control, switch mode power supply control, uninterruptible power supplies (UPS), and other forms of power conversion. The ePWM peripheral can also perform a digital-to-analog (DAC) function, where the duty cycle is equivalent to a DAC analog value; it is sometimes referred to as a power DAC.

This chapter is applicable for ePWM type 5. Type 5 EPWM is fully compatible with type 4 EPWM. See the [C2000 Real-Time Control Peripheral Reference Guide](#) for a list of all devices with an ePWM module of the same type, to determine the differences between the types, and for a list of device-specific differences within a type.

## 22.1 Introduction

This chapter includes an overview and information about each submodule:

- [Time Base \(TB\) Submodule](#)
- [Counter Compare \(CC\) Submodule](#)
- [Action Qualifier \(AQ\) Submodule](#)
- [Dead-Band Generator \(DB\) Submodule](#)
- [PWM Chopper \(PC\) Submodule](#)
- [Trip Zone \(TZ\) Submodule](#)
- [Diode Emulation \(DE\) Submodule](#)
- [Minimum Dead-Band \(MINDB\) and Illegal Combo Logic \(ICL\) Submodule](#)
- [Event Trigger \(ET\) Submodule](#)
- [Digital Compare \(DC\) Submodule](#)

The ePWM Type 5 is functionally compatible to Type 4. Type 5 has the following enhancements in addition to the Type 4 features:

- **PWM SYNC Related Enhancements:** Additional external sync option is added in to the EPWMSYNCSEL register. This allows for the configuration of up to 3 independent sync chains with external sync options.
- **Linking and Global Load Enhancements:** DBRED:DBREDHR and DBFED:DBFEDHR have the ability to be linked across ePWM modules.

Global load pulse selection for shadow to active load can now occur when the time-base counter equals CMPCU, CMPCD, CMPDU, or CMPDD.

- **XCMP Complex Waveform Generator:** XCMP mode has been added to allow for generation of multiple ePWM pulses, with high resolution, in a given ePWM cycle. Up to 8 new compare registers are added to achieve this functionality.
- **Digital Compare Submodule Enhancements:** Event detection within the digital compare capture module is able to detect an occurrence of a trip event in a configured time window.

Pulse selection for blanking and capture alignment now includes a blanking window mix selection (BLANKPULSEMIX). This is added for LLC topologies where blanking window settings need to be changed on the fly - providing greater configurability to do this.

- **Trip-Zone Submodule Enhancements:** A CAPEVENT signal can generate a CBC or One-shot trip event.
- **Diode Emulation Submodule:** The diode emulation mode was added to provide hardware features and the necessary hooks into other IPs to implement a robust diode mode sense and control in a noisy environment.
- **Minimum Dead-Band and Illegal Combo Logic Submodule:** The minimum dead-band logic was added to provide the ability to configure the minimum dead-band duration between a complimentary set of ePWMs.

To detect and make sure that under no circumstances, the ePWM states result in potentially hazardous combinations, a Look Up Table (LUT) has been added that can be used to re-configure the ePWM outputs.

- **Event Trigger Submodule Enhancements:** To enable unevenly spaced over-sampling of the ePWM period, the event trigger module trigger select is modified such that multiple events can trigger SOCA, SOCB, and INT events (ETINTMIX).

The ePWM Type 4 is functionally compatible to Type 2 (a Type 3 does not exist). Type 4 has the following enhancements in addition to the Type 2 features:

- **Register Address Map:** Additional registers are required for new features on ePWM Type 4. The ePWM register address space has been remapped for better alignment and easy usage.
- **Delayed Trip Functionality:** Changes have been added to achieve deadband insertion capabilities to support, for example, delayed trip functionality needed for peak current mode control type application scenarios. This has been accomplished by allowing comparator events to go into the Action Qualifier as a trigger event (Events T1 and T2). If comparator T1 / T2 events are used to edit the PWM, changes to the PWM waveform do not take place immediately. Instead, the waveform synchronizes to the next TBCLK.
- **Dead-Band Generator Submodule Enhancements:** Shadowing of the DBCTL register to allow dynamic configuration changes.

- **One Shot and Global Load of Registers:** The ePWM Type 4 allows one shot and global load capability from shadow to active registers to avoid partial loads in, for example, multiphase applications. ePWM Type 4 also allows a programmable prescale of shadow to active load events. ePWM Type 4 Global Load can simplify ePWM software by removing interrupts and making sure that all registers are loaded at the same time.
- **Trip-Zone Submodule Enhancements:** Independent flags have been added to reflect the trip status for each of the TZ sources. Changes have been made to the trip-zone submodule to support certain power converter switching techniques like valley switching.
- **Digital Compare Submodule Enhancements:** Blanking window filter register width has been increased from 8 to 16 bits. DCCAP functionality has been enhanced to provide more programmability.
- **PWM SYNC Related Enhancements:** The ePWM Type 4 allows PWM SYNCOUT generation based on CMPC and CMPD events. These events can also be used for PWMSYNC pulse selection.

The ePWM Type 2 is fully compatible to Type 1. Type 2 has the following enhancements in addition to the Type 1 features:

- **High-Resolution Dead-Band Capability:** High-resolution capability is added to dead-band RED and FED in half-cycle clocking mode.
- **Dead-Band Generator Submodule Enhancements:** The ePWM Type 2 has features to enable both RED and FED on either PWM outputs. Provides increased dead band with 14-bit counters and dead-band / dead-band high-resolution registers are shadowed
- **High-Resolution Extension available on ePWMxB outputs:** Provides the ability to enable high-resolution period and duty cycle control on ePWMxB outputs. This is discussed in more detail in [Section 22.18](#).
- **Counter Compare Submodule Enhancements:** The ePWM Type 2 allows interrupts and SOC events to be generated by additional counter compares CMPC and CMPD.
- **Event Trigger Submodule Enhancements:** Prescaling logic to issue interrupt requests and ADC start of conversion expanded up to every 15 events. This submodule allows software initialization of event counters on SYNC event.
- **Digital Compare Submodule Enhancements:** Digital Compare Trip Select logic [DCTRIPSEL] has up to 12 external trip sources selected by the Input X-BAR logic in addition to an ability to OR all of them (up to 14 [external and internal sources]) to create the respective DCxEVTs.
- **Simultaneous Writes to TBPRD and CMPx Registers:** This feature allows writes to TBPRD, CMPA:CMPAHR, CMPB:CMPBHR, CMPC and CMPD of any ePWM module to be tied to any other ePWM module, and also allows all ePWM modules to be tied to a particular ePWM module if desired.
- **Shadow to Active Load on SYNC of TBPRD and CMP Registers:** This feature supports simultaneous writes of TBPRD and CMPA/B/C/D registers.

An effective PWM peripheral must be able to generate complex pulse width waveforms with minimal CPU overhead or intervention and must be highly programmable and very flexible while being easy to understand and use. The ePWM unit described here addresses these requirements by allocating all needed timing and control resources on a per PWM channel basis. Cross coupling or sharing of resources has been avoided; instead, the ePWM is built up from smaller single channel submodules with separate resources that can operate together as required to form a system. This modular approach results in an orthogonal architecture and provides a more transparent view of the peripheral structure, helping users to understand the operation quickly.

In this document, the letter x within a signal or submodule name is used to indicate a generic ePWM instance on a device. For example, output signals EPWMxA and EPWMxB refer to the output signals from the ePWMx instance. Thus, EPWM1A and EPWM1B belong to ePWM1 and likewise EPWM4A and EPWM4B belong to ePWM4.

## Type0 to Type1 Enhancements

- **Increased Dead-Band Resolution:** Dead-band clocking has been enhanced to allow half-cycle clocking to double resolution.
- **Enhanced Interrupt and SOC Generation:** Interrupts and ADC start-of-conversion can now be generated on both the TBCTR == zero and TBCTR == period events. This feature enables dual edge PWM control. Additionally, the ADC start-of-conversion can be generated from an event defined in the digital compare submodule.
- **High-Resolution Period Capability:** Provides the ability to enable high-resolution period. This is discussed in more detail in [Section 22.18](#).
- **Digital Compare Submodule:** The digital compare submodule enhances the event triggering and trip zone submodules by providing filtering, blanking and improved trip functionality to digital compare signals. Such features are essential for peak current mode control and for support of analog comparators.

---

### Note

The name of the sync signal that goes to the CMPSS has been updated from PWMSYNC to EPWMSYNCPER (SYNCPER/PWMSYNCPER/EPWMxSYNCPER) to avoid confusion with the other EPWM sync signals EPWMSYNCI and EPWMSYNCO. For a description of these signals, see [Table 22-2](#).

### 22.1.2 Submodule Overview

The ePWM module represents one complete PWM channel composed of two PWM outputs: EPWMxA and EPWMxB. Multiple ePWM modules are instanced within a device as shown in [Figure 22-1](#). Each ePWM instance is identical with one exception. Some instances include a hardware extension that allows more precise control of the PWM outputs. This extension is the high-resolution pulse width modulator (HRPWM) and is described in [Section 22.18](#). See the device data sheet to determine which ePWM instances include this feature. Each ePWM module is indicated by a numerical value starting with 1. For example, ePWM1 is the first instance and ePWM3 is the third instance in the system and ePWMx indicates any instance.

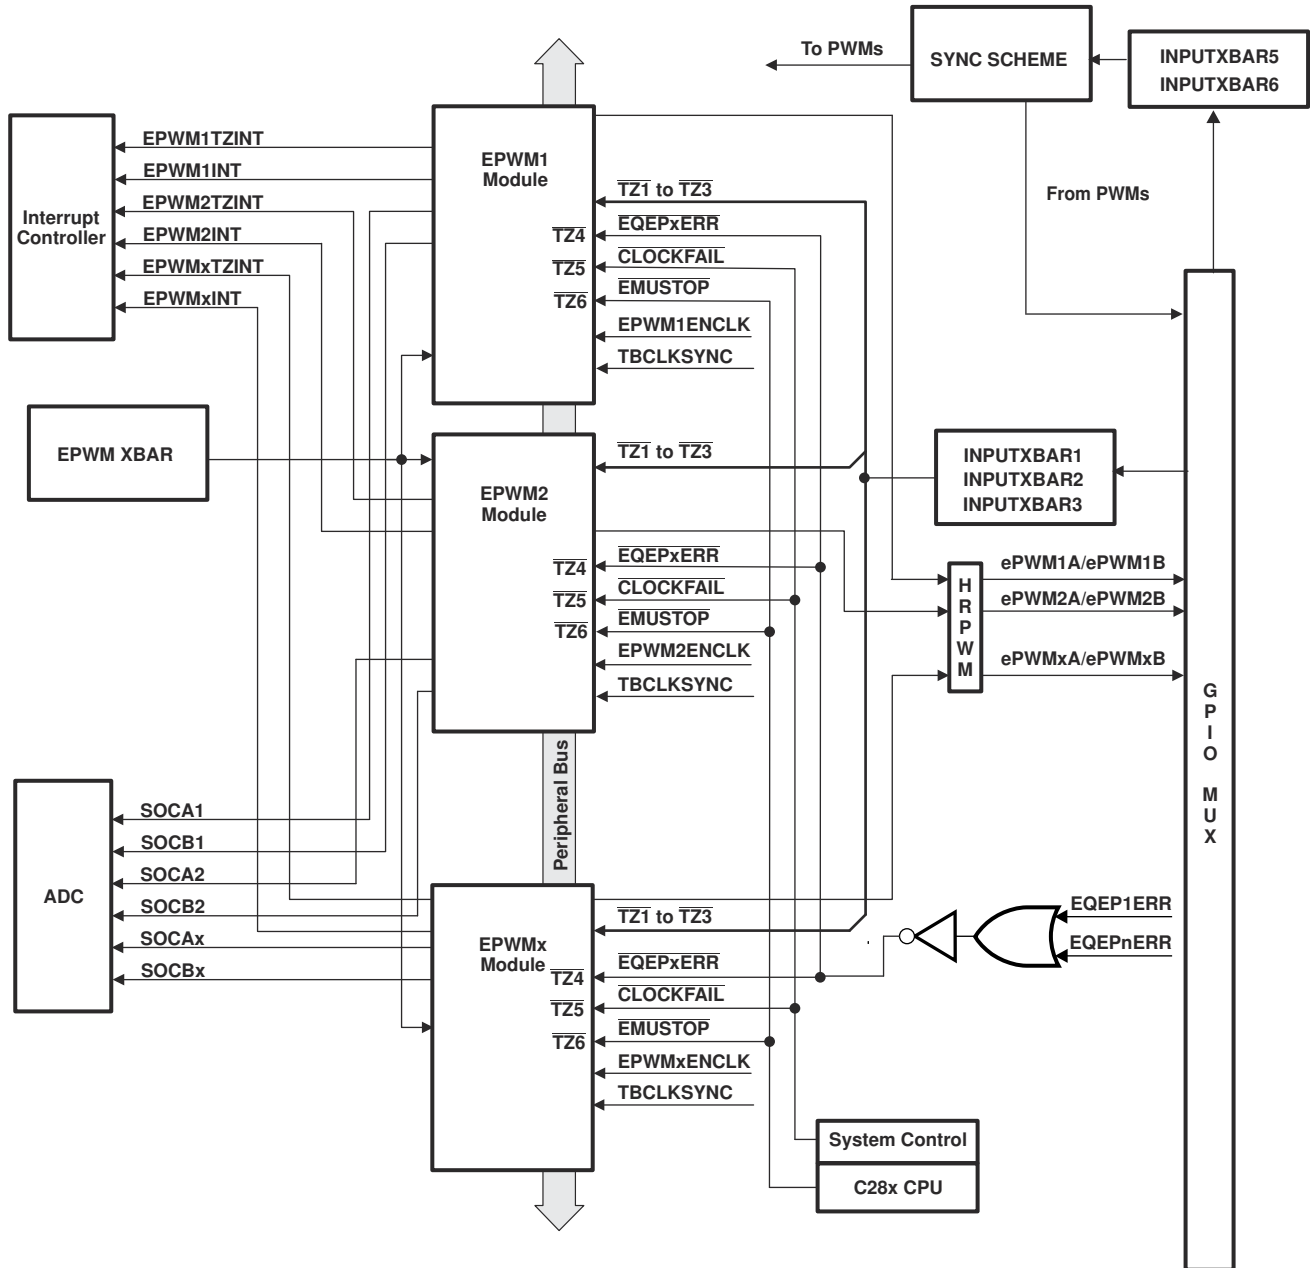

The ePWM modules are chained together by way of a clock synchronization scheme that allows them to operate as a single system when required. Additionally, this synchronization scheme can be extended to the capture peripheral submodules (eCAP). The number of submodules is device-dependent and based on target application needs. Submodules can also operate standalone.

Each ePWM module supports the following features:

- Dedicated 16-bit time-base counter with period and frequency control
- Two PWM outputs (EPWMxA and EPWMxB) that can be used in the following configurations:
  - Two independent PWM outputs with single-edge operation
  - Two independent PWM outputs with dual-edge symmetric operation
  - One independent PWM output with dual-edge asymmetric operation
- Asynchronous override control of PWM signals through software.
- Programmable phase-control support for lag or lead operation relative to other ePWM modules.
- Hardware-locked (synchronized) phase relationship on a cycle-by-cycle basis.
- Dead-band generation with independent rising and falling edge delay control.
- Programmable trip zone allocation of both cycle-by-cycle trip and one-shot trip on fault conditions.
- A trip condition can force either high, low, or high-impedance state logic levels at PWM outputs.
- All events can trigger both CPU interrupts and ADC start of conversion (SOC)
- Programmable event prescaling minimizes CPU overhead on interrupts.
- PWM chopping by high-frequency carrier signal, useful for pulse transformer gate drives.

Each ePWM module is connected to the input/output signals shown in [Figure 22-1](#). The signals are described in detail in subsequent sections.

The order in which the ePWM modules are connected can differ from what is shown in [Figure 22-1](#). See [Section 22.4.3.3](#) for the synchronization scheme for a particular device. Each ePWM module consists of ten submodules and is connected within a system by way of the signals shown in [Figure 22-2](#).

A. This signal exists only on devices with an eQEP submodule.

Figure 22-1. Multiple ePWM Modules

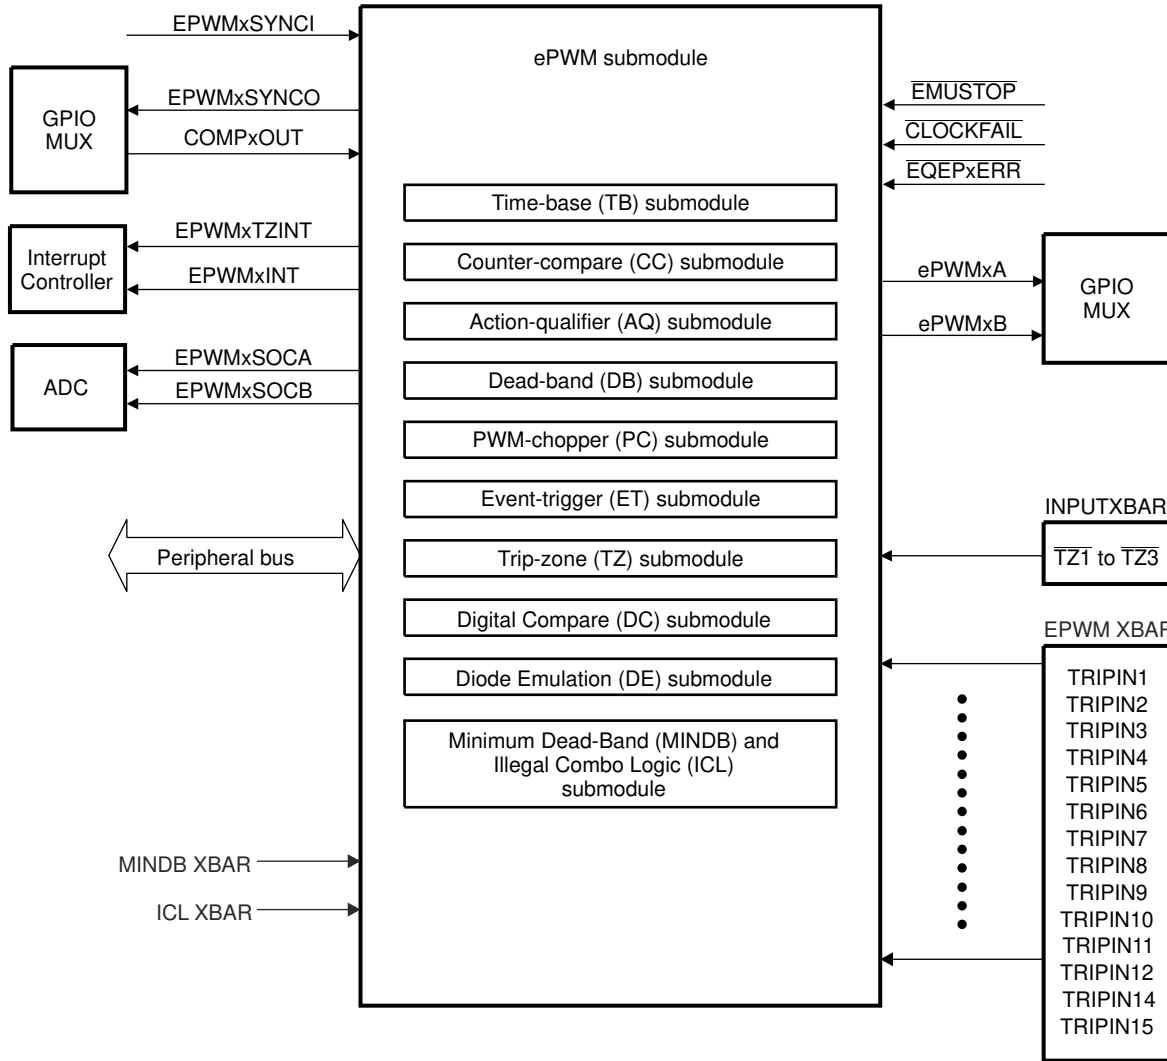

Figure 22-2. Submodules and Signal Connections for an ePWM Module

Figure 22-3 shows more internal details of a single ePWM module. The main signals used by the ePWM module are:

- **PWM output signals (EPWMxA and EPWMxB)**

The PWM output signals are made available external to the device.

- **Trip-zone signals ( $\overline{TZ1}$  to  $\overline{TZ6}$ )**

These input signals alert the ePWM module of fault conditions external to the ePWM module. Each submodule on a device can be configured to either use or ignore any of the trip-zone signals. The  $\overline{TZ1}$  to  $\overline{TZ3}$  trip-zone signals can be configured as asynchronous inputs through the GPIO peripheral using the Input X-BAR logic, refer to Figure 22-75.  $\overline{TZ4}$  is connected to an inverted EQEPx error signal (EQEPxERR), which can be generated from any one of the EQEP submodule (for those devices with an EQEP module).  $\overline{TZ5}$  is connected to the system clock fail logic, and  $\overline{TZ6}$  is connected to the EMUSTOP output from the CPU. This allows configuring a trip action when the clock fails or the CPU halts.

- **Time-base synchronization input (EPWMxSYNCl), output (EPWMxSYNCO), and peripheral (EPWMxSYNCPER) signals**

Each ePWM module can be synchronized with other ePWM modules or other peripherals, using EPWMSYNCINSEL. Each ePWM module can also generate a synchronization output signal. The source of the EPWMxSYNCO can be selected and enabled by EPWMSYNCOEN and TBCTL2.OSHTSYNCPER. For more information, see Section 22.4.3.3.

Each ePWM module also generates another PWMSYNC signal called EPWMxSYNCPER. EPWMxSYNCPER goes to the GPDAC and CMPSS for synchronization purposes. Functionality is configured using the HRPCTL register, but has no relation with the HRPWM. For more information on how EPWMxSYNCPER is used by the GPDAC and CMPSS, see the respective chapters.

- **ADC start-of-conversion signals (EPWMxSOCA and EPWMxSOCB)**

Each ePWM module has two ADC start of conversion signals. Any ePWM module can trigger a start of conversion. Whichever event triggers the start of conversion is configured in the event-trigger submodule of the ePWM.

- **Comparator output signals (COMPxOUT)**

Output signals from the comparator module can be fed through the Input X-BAR and EPWM X-BAR to one or all of the 15 trip inputs [TRIPIN1 - TRIPIN15] and in conjunction with the trip zone signals can generate digital compare events.

- **Peripheral bus**

The peripheral bus is 32-bits wide and allows both 16-bit and 32-bit writes to the ePWM register file.

A. These events are generated by the ePWM Digital Compare (DC) submodule based on the levels of the TRIPIN inputs.

**Figure 22-3. ePWM Modules and Critical Internal Signal Interconnects**

## 22.2 Configuring Device Pins

To connect the device input pins to the module, the Input X-BAR and EPWM X-BAR must be used. Some examples of when an external signal can be needed are TZx, TRIPx, and EXTSYNCIN. Any GPIO on the device can be configured as an input. The GPIO input qualification can be set to asynchronous mode by setting the appropriate GPxQSEL register bits to 11b. The internal pullups can be configured in the GPyPUD register. Since the GPIO mode is used, the GPyINV register can invert the signals.

The GPIO mux registers must be configured for this peripheral. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux, GPIO settings, and XBAR configuration.

## 22.3 ePWM Modules Overview

Ten submodules are included in every ePWM peripheral. Each of these submodules performs specific tasks that can be configured by software.

[Table 22-1](#) lists the key submodules together with a list of the main configuration parameters. For example, if you need to adjust or control the duty cycle of a PWM waveform, see the counter-compare submodule in [Section 22.5](#) for relevant details.

**Table 22-1. Submodule Configuration Parameters**

Submodule	Configuration Parameter or Option
<a href="#">Time Base (TB)</a>	<ul style="list-style-type: none"> <li>• Scale the time-base clock (TBCLK) relative to the ePWM clock (EPWMCLK).</li> <li>• Configure the PWM time-base counter (TBCTR) frequency or period.</li> <li>• Set the mode for the time-base counter:                             <ul style="list-style-type: none"> <li>– count-up mode: used for asymmetric PWM</li> <li>– count-down mode: used for asymmetric PWM</li> <li>– count-up-and-down mode: used for symmetric PWM</li> </ul> </li> <li>• Configure the time-base phase relative to another ePWM module.</li> <li>• Synchronize the time-base counter between modules through hardware or software.</li> <li>• Configure the direction (up or down) of the time-base counter after a synchronization event.</li> <li>• Simultaneous writes to the TBPRD registers on all PWM's corresponding to the configuration on EPWMXLINK.</li> <li>• Configure how the time-base counter behaves when the device is halted by an emulator.</li> <li>• Specify the source for the synchronization output of the ePWM module</li> <li>• Configure one shot and global load of registers in this module.</li> </ul>
<a href="#">Counter Compare (CC)</a>	<ul style="list-style-type: none"> <li>• Specify the PWM duty cycle for output EPWMxA and output EPWMxB</li> <li>• Specify the time at which switching events occur on the EPWMxA or EPWMxB output</li> <li>• Specify the programmable delay for interrupt and SOC generation with additional comparators</li> <li>• Simultaneous writes to the CMPA, CMPB, CMPC, CMPD registers on all PWM's corresponding to the configuration on EPWMXLINK.</li> <li>• Configure one shot and global load of registers in this module.</li> <li>• Generate up to four pulses in one ePWM period through the complex waveform (XCMP) mode feature</li> </ul>

**Table 22-1. Submodule Configuration Parameters (continued)**

Submodule	Configuration Parameter or Option
Action Qualifier (AQ)	<ul style="list-style-type: none"> <li>Specify the type of action taken when a time-base counter-compare, trip-zone submodule, or comparator event occurs: <ul style="list-style-type: none"> <li>No action taken</li> <li>Output EPWMxA and EPWMxB switched high</li> <li>Output EPWMxA and EPWMxB switched low</li> <li>Output EPWMxA and EPWMxB toggled</li> </ul> </li> <li>Force the PWM output state through software control</li> <li>Configure and control the PWM dead band through software</li> <li>Configure one shot and global load of registers in this module.</li> </ul>
Dead-Band Generator (DB)	<ul style="list-style-type: none"> <li>Control of traditional complementary dead-band relationship between upper and lower switches</li> <li>Specify the output rising-edge-delay value</li> <li>Specify the output falling-edge delay value</li> <li>Bypass the dead-band module entirely. **Table 22-1. Submodule Configuration Parameters (continued)**

Submodule	Configuration Parameter or Option
Digital Compare (DC)	<ul style="list-style-type: none"> <li>Enables comparator (COMP) module outputs and trip zone signals which are configured using the Input X-BAR to create events and filtered events</li> <li>Specify event-filtering options to capture TBCTR counter, generate blanking window, or insert delay in PWM output or time-base counter based on captured value.</li> </ul>

## 22.4 Time-Base (TB) Submodule

Each ePWM module has a time-base submodule that determines all of the event timing for the ePWM module. Built-in synchronization logic allows the time-base of multiple ePWM modules to work together as a single system.

Figure 22-4 illustrates the time-base submodule within the ePWM.

**Figure 22-4. Time-Base Submodule**

### 22.4.1 Purpose of the Time-Base Submodule

The time-base submodule can be configured for the following:

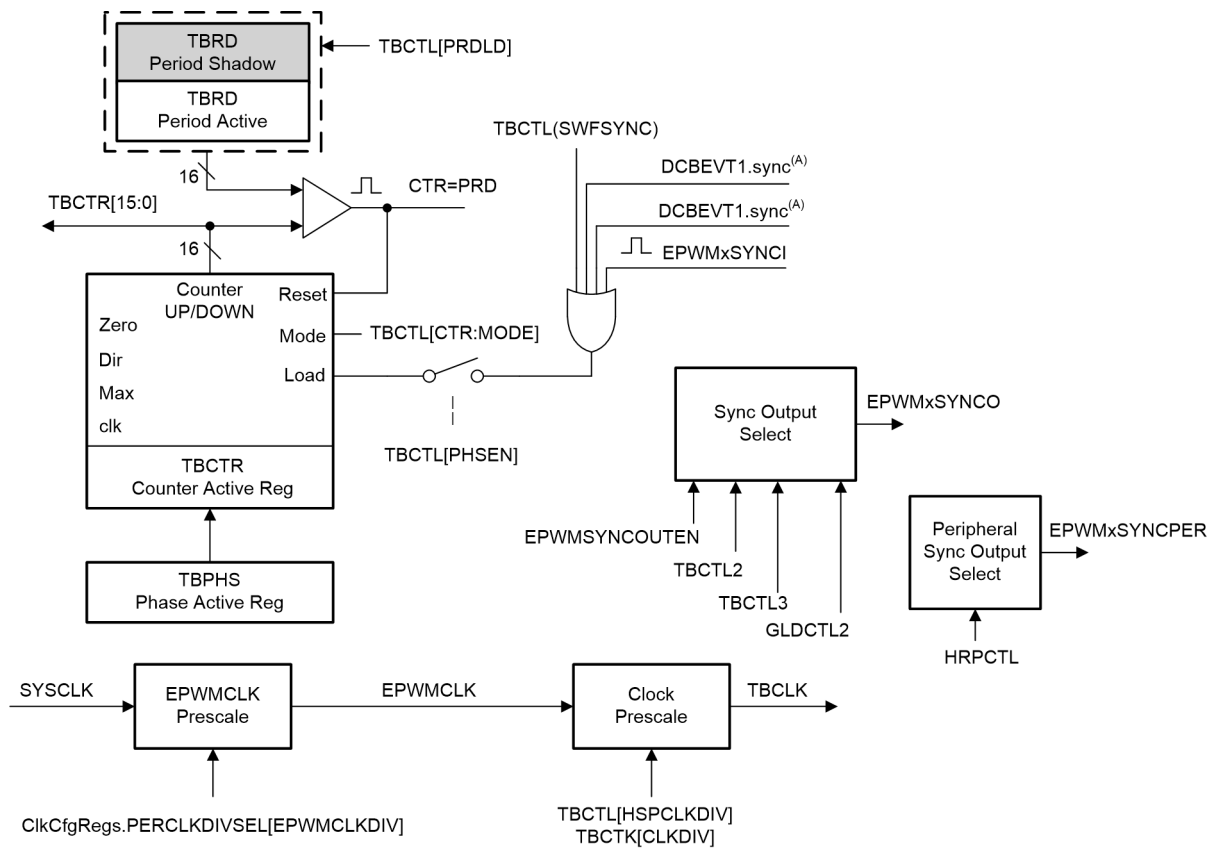

- Specify the ePWM time-base counter (TBCTR) frequency or period to control how often events occur.
- Manage time-base synchronization with other ePWM modules.
- Maintain a phase relationship with other ePWM modules.
- Set the time-base counter to count-up, count-down, or count-up-and-down mode.
- Generate the following events:
  - CTR = PRD: Time-base counter equal to the specified period (TBCTR = TBPRD).
  - CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00).
- Configure the rate of the time-base clock; a prescaled version of the ePWM clock (EPWMCLK). This allows the time-base counter to increment/decrement at a slower rate.

**Note**

If required by the application code to update the TBCTR value through software while the TBCTR is counting, note that the time-base module needs at least 1 TBCLK cycle for the time-base related events to be realized. Hence, the TBCTR can be written with  $TBCTR = PRD - 1$  instead of  $TBCTR = PRD$  (in case the counter is counting up) and can be written as  $TBCTR = 1$  instead of  $TBCTR = 0$  (in case the counter is counting down) for the events to be realized.

**22.4.2 Controlling and Monitoring the Time-Base Submodule**

The block diagram in Figure 22-5 shows the critical signals and registers of the time-base submodule. Table 22-2 provides descriptions of the key signals associated with the time-base submodule.

A. These signals are generated by the digital compare (DC) submodule.

**Figure 22-5. Time-Base Submodule Signals and Registers**

**Table 22-2. Key Time-Base Signals**

Signal	Description
EPWMxSYNCl	Time-base synchronization input.  Input pulse used to synchronize the time-base counter with the counter of other ePWM modules. For more information on all of the signals available for synchronization, see EPWMSYNClNSEL. For information on the synchronization order of a particular device, see <a href="#">Section 22.4.3.3</a> .
EPWMxSYNCO	Time-base synchronization output.  This output pulse is used to synchronize the counter of other ePWM modules. Using EPWMSYNCOOUTEN, TBCTL2, TBCTL3 and GLDCTL2, the source of the output pulse is selected.
EPWMxSYNCPER	Time-base peripheral synchronization output.  This output signal is used to synchronize the GPDAC and CMPSS to the EPWM. The output signal can be configured using the HRPCTL register. Note that this signal has no relation with the HRPWM.
CTR = PRD	Time-base counter equal to the specified period.  This signal is generated whenever the counter value is equal to the active period register value. That is when TBCTR = TBPRD.
CTR = Zero	Time-base counter equal to zero  This signal is generated whenever the counter value is zero. That is when TBCTR equals 0x00.
CTR = CMPB	Time-base counter equal to active counter-compare B register (TBCTR = CMPB).  This event is generated by the counter-compare submodule and used by the synchronization out logic
CTR_dir	Time-base counter direction.  Indicates the current direction of the ePWM's time-base counter. The signal is high when the counter is increasing and the signal is low when the counter is decreasing.
CTR_max	Time-base counter equal max value. (TBCTR = 0xFFFF)  Generated event when the TBCTR value reaches the maximum value. This signal is only used only as a status bit
TBCLK	Time-base clock.  This is a prescaled version of the ePWM clock (EPWMCLK) and is used by all submodules within the ePWM. This clock determines the rate at which time-base counter increments or decrements.

### 22.4.3 Calculating PWM Period and Frequency

The frequency of PWM events is controlled by the time-base period (TBPRD) register and the mode of the time-base counter. Figure 22-6 shows the period ( $T_{pwm}$ ) and frequency ( $F_{pwm}$ ) relationships for the up-count, down-count, and up-down-count time-base counter modes when the period is set to 4 (TBPRD = 4). The time increment for each step is defined by the time-base clock (TBCLK) which is a prescaled version of the ePWM clock (EPWMCLK).

The time-base counter has three modes of operation selected by the time-base control register (TBCTL):

- **Up-Down Count Mode:** In up-down count mode, the time-base counter starts from zero and increments until the period (TBPRD) value is reached. When the period value is reached, the time-base counter then decrements until the counter reaches zero. At this point, the counter repeats the pattern and begins to increment.
- **Up-Count Mode:** In up-count mode, the time-base counter starts from zero and increments until the counter reaches the value in the period register (TBPRD). When the period value is reached, the time-base counter resets to zero and begins to increment once again.
- **Down-Count Mode:** In down-count mode, the time-base counter starts from the period (TBPRD) value and decrements until the counter reaches zero. When the counter reaches zero, the time-base counter is reset to the period value and begins to decrement once again.

Figure 22-6. Time-Base Frequency and Period

### 22.4.3.1 Time-Base Period Shadow Register

The time-base period register (TBPRD) has a shadow register. Shadowing allows the register update to be synchronized with the hardware. The following definitions are used to describe all shadow registers in the ePWM module:

- **Active Register:** The active register controls the hardware and is responsible for actions that the hardware causes or invokes.
- **Shadow Register:** The shadow register buffers provide a temporary holding location for the active register and have no direct effect on any control hardware. At a strategic point in time, the shadow register content is transferred to the active register. This prevents corruption or spurious operation due to the register being asynchronously modified by software.

The memory address of the shadow period register is the same as the active register. Which register is written to or read from is determined by the TBCTL[PRDL] bit. This bit enables and disables the TBPRD shadow register as follows:

- **Time-Base Period Shadow Mode:** The TBPRD shadow register is enabled when TBCTL[PRDL] = 0. Reads from and writes to the TBPRD memory address go to the shadow register. The shadow register contents are transferred to the active register (TBPRD (Active) ← TBPRD (shadow)) when the time-base counter equals zero (TBCTR = 0x00) and/or a sync event as determined by the TBCTL2[PRDLDSYNC] bit. The PRDLDSYNC bit is valid only if TBCTL[PRDL] = 0. By default the TBPRD shadow register is enabled. The sources for the SYNC input is explained in [Section 22.4.3.3](#).

The global load control mechanism can also be used with the time-base period register by configuring the appropriate bits in the global load configuration register (GLDCFG). When global load mode is selected the transfer of contents from shadow register to active register, for all registers that have this mode enabled, occurs at the same event as defined by the configuration bits in Global Shadow to Active Load Control Register (GLDCTL). Global load control mechanism is explained in [Section 22.4.7](#).

- **Time-Base Period Immediate Load Mode:** If immediate load mode is selected (TBCTL[PRDL] = 1), then a read from or a write to the TBPRD memory address goes directly to the active register.

### 22.4.3.2 Time-Base Clock Synchronization

The TBCLKSYNC bit in the peripheral clock enable registers allows all users to globally synchronize all enabled ePWM modules to the time-base clock (TBCLK). When set, all enabled ePWM module clocks are started with the first rising edge of TBCLK aligned. For synchronized TBCLKs, the prescalers for each ePWM module must be set identically.

The proper procedure for enabling ePWM clocks is as follows:

1. Enable ePWM module clocks in the PCLKCRx register
2. Set TBCLKSYNC = 0
3. Configure ePWM modules
4. Set TBCLKSYNC = 1

### 22.4.3.3 Time-Base Counter Synchronization

The ePWM synchronization scheme allows for increased flexibility of synchronization of the ePWM modules. Each ePWM module has a synchronization input (SYNCl), a synchronization output (SYNCO) and a peripheral synchronization output (SYNCPER). In Figure 22-7, EXTSYNClN1 is sourced from INPUTXBAR5 and EXTSYNClN2 is sourced from INPUTXBAR6, which can be configured to select any GPIO as the synchronization input. Refer to Section 22.4.3.4 for a list of all sync inputs including INPUTXBAR5 and INPUTXBAR6. Figure 22-8 shows the sources that can be used for EXTSYNCOU2.

Figure 22-7. Time-Base Counter Synchronization Scheme

**Figure 22-8. ePWM External SYNC Output**
**Note**

See the data sheet for the number of ePWM and eCAP modules available on your specific device.

Each ePWM module can be configured to use or ignore the synchronization input. If the TBCTL[PHSEN] bit is set, then the time-base counter (TBCTR) of the ePWM module is automatically loaded with the phase register (TBPHS) contents when one of the following conditions occur:

- **EPWMxSYNCl: Synchronization Input Pulse:** The value of the phase register is loaded into the counter register when an input synchronization pulse is detected (TBPHS → TBCTR). This operation occurs on the next valid time-base clock (TBCLK) edge.

The delay from internal control module to target modules is given by:

- if (TBCLK = EPWMCLK): 2 x EPWMCLK
- if (TBCLK < EPWMCLK): 1 x TBCLK
- **Software Forced Synchronization Pulse:** Writing a 1 to the TBCTL[SWFSYNC] control bit invokes a software forced synchronization. This pulse is ORed with the synchronization input signal, and therefore has the same effect as a pulse on EPWMxSYNCl.
- **Digital Compare Event Synchronization Pulse:** DCAEVT1 and DCBEVT1 digital compare events can be configured to generate synchronization pulses which have the same affect as EPWMxSYNCl.

**Note**

If the EPWMxSYNCl signal is held high, the sync does not continuously occur. The EPWMxSYNCl is rising edge activated.

### Note

When modifying the TBPHS register during run-time, missed action qualifier events can occur due to sudden jumps in the TBCTR value at the time of the SYNCIN pulse. To recreate the behavior of missed action qualifier events, configure an action qualifier event on a T1 or T2 event on a SYNCIN event. The T1 or T2 action qualifier event must be enabled and disabled during runtime depending on the value of TBPHS.

This feature enables the ePWM module to be automatically synchronized to the time base of another ePWM module. Lead or lag phase control can be added to the waveforms generated by different ePWM modules to synchronize them. In up-down-count mode, the TBCTL[PHSDIR] bit configures the direction of the time-base counter immediately after a synchronization event. The new direction is independent of the direction prior to the synchronization event. The PHSDIR bit is ignored in count-up or count-down modes. See [Figure 22-9](#) through [Figure 22-12](#) for examples.

Clearing the TBCTL[PHSEN] bit configures the ePWM to ignore the synchronization input pulse.

#### 22.4.3.4 ePWM SYNC Selection

[Table 22-3](#) specifies the sources for the ePWM SYNC input and output.

**Table 22-3. ePWM SYNC Selection**

33	FSIRXD_TRIG1
34-63	Reserved

#### 22.4.4 Phase Locking the Time-Base Clocks of Multiple ePWM Modules

The TBCLKSYNC bit can be used to globally synchronize the time-base clocks of all enabled ePWM modules on a device. This bit is part of the device's clock enable registers and is described in the *System Control and Interrupts* section of this manual. When TBCLKSYNC = 0, the time-base clock of all ePWM modules is stopped (default). When TBCLKSYNC = 1, all ePWM time-base clocks are started with the rising edge of TBCLK aligned. For synchronized TBCLKs, the prescaler bits in the TBCTL register of each ePWM module must be set identically. The proper procedure for enabling the ePWM clocks is:

1. Enable the individual ePWM module clocks. This is described in the *System Control and Interrupts* chapter.
2. Set TBCLKSYNC = 0. This stops the time-base clock within any enabled ePWM module.
3. Configure the prescaler values and desired ePWM modes.
4. Set TBCLKSYNC = 1.

#### 22.4.5 Simultaneous Writes to TBPRD and CMPx Registers Between ePWM Modules

For variable frequency applications, there is a need for simultaneous writes of TBPRD and CMPx registers between ePWM modules. This prevents situations where a CTR = 0 or CTR = PRD pulse forces a shadow to active load of these registers before all registers are updated between ePWM modules (resulting in some registers being loaded from new shadow values while others are loaded from old shadow values). To support this, an ePWM register linking scheme for TBPRD:TBPRDHR, CMPA:CMPAHR, CMPB:CMPBHR, CMPC, and CMPD registers between PWM modules has been added.

Refer to the register description for EPWMXLINK to see the linked register bit-field values for corresponding ePWM. An example of using the EPWMXLINK is linking ePWM2 CMPA with CMPA of ePWM1 through ePWM2's EPWMXLINK[CMPLINK] register bit-field. In this case, a write to CMPA of ePWM1 also changes the CMPA value for ePWM2.

#### Note

For devices with multiple CPUs, if the XLINK feature is enabled between ePWM modules, the ePWM modules that require XLINK must be selected for the same core for this feature to work. For example, if CPU2 has ePWM3 selected, and CPU1 has ePWM1 selected and XLINK is enabled on ePWM3 to copy the contents of CPU1's ePWM when written to. A write to CPU1's ePWM does not result in a change in CPU2's ePWM register that has XLINK enabled.

#### 22.4.6 Time-Base Counter Modes and Timing Waveforms

The time-base counter operates in one of four modes:

- Up-count mode that is asymmetrical
- Down-count mode that is asymmetrical
- Up-down-count that is symmetrical
- Frozen where the time-base counter is held constant at the current value

To illustrate the operation of the first three modes, the following timing diagrams show when events are generated and how the time-base responds to an EPWMxSYNCl signal.

Figure 22-9. Time-Base Up-Count Mode Waveforms

Figure 22-10. Time-Base Down-Count Mode Waveforms

**Figure 22-11. Time-Base Up-Down-Count Waveforms, TBCTL[PHSDIR = 0] Count Down On Synchronization Event**

**Figure 22-12. Time-Base Up-Down Count Waveforms, TBCTL[PHSDIR = 1] Count Up On Synchronization Event**

### 22.4.7 Global Load

Figure 22-13 shows the signals and registers associated with the global load feature.

Figure 22-13. Global Load: Signals and Registers

**Note**

The SYNCEVT signal is only propagated through when PHSEN is SET.

When this feature is enabled, the transfer of contents from the shadow register to the active register, for all registers that have this mode enabled, occurs at the same event as defined by the configuration bits in Global Shadow to Active Load Control Register (GLDCTL[GLDMODE]). When GLDCTL[GLD] = 1, shadow to active load event selection bits for individual shadowed registers are ignored and global load mode takes effect for the corresponding registers enabled by GLDCFG[REGx].

When GLDCTL[GLD] = 1 and GLDCFG[REGx] = 0, global load mode does not affect the corresponding register (REGx). Shadow to active load event selection bits for individual shadowed registers decide how the transfer of contents from shadow register to active register takes place.

#### 22.4.7.1 Global Load Pulse Pre-Scalar

This feature provides the capability to choose shadow to active transfers to happen once in 'N' occurrences of selected global load pulse (GLDCTL[GLDMODE]). This pre-scale functionality is not available for registers that cannot or are not configured to use the global load mechanism (that is, GLDCTL[GLD] = 0 or GLDCFG[REGx] = 0).

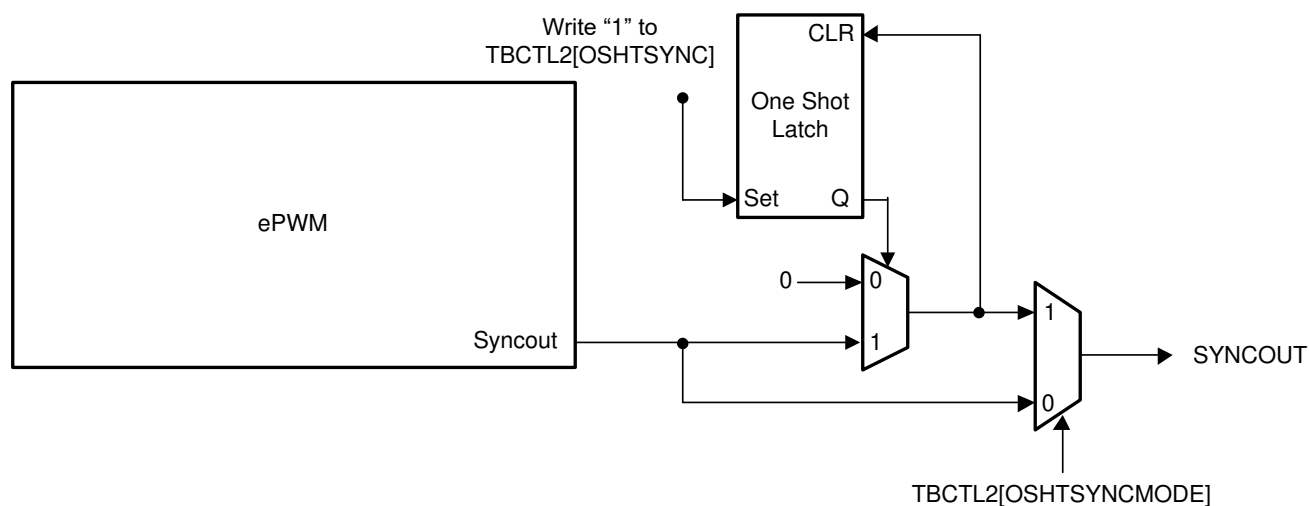

### 22.4.7.2 One-Shot Load Mode

This feature allows users to cause the shadow register to active register transfers to occur once. When  $GLDCTL2[OSHTLD] = 1$  the shadow to active register transfer, for registers that are configured to use the global load mechanism, takes place on the event selected by  $GLDCTL[GLDMODE]$ .

Software force loading of contents from shadow register to active register is possible by using  $GLDCTL2[GFRCLD]$ . The  $GLDCTL2$  register can also be linked across multiple PWM modules by using  $EPWMXLINK[GLDCTL2LINK]$ . This, along with the one-shot load mode feature discussed above, provides a method to correctly update multiple PWM registers in one or more PWM modules at certain PWM events or, if desired, in the same clock cycle. This is very useful in variable frequency applications and/or multi-phase interleaved applications.

### 22.4.7.3 One-Shot Sync Mode

To enable the one-shot sync mode to generate a SYNCOUT pulse, configure the  $TBCTL2[OSHTSYNCMODE]$  bit and set the  $TBCTL2[OSHTSYNC]$  bit as shown in Figure 22-14.

**Figure 22-14. One-Shot Sync Mode**

## 22.5 Counter-Compare (CC) Submodule

Figure 22-15 illustrates the counter-compare submodule within the ePWM.

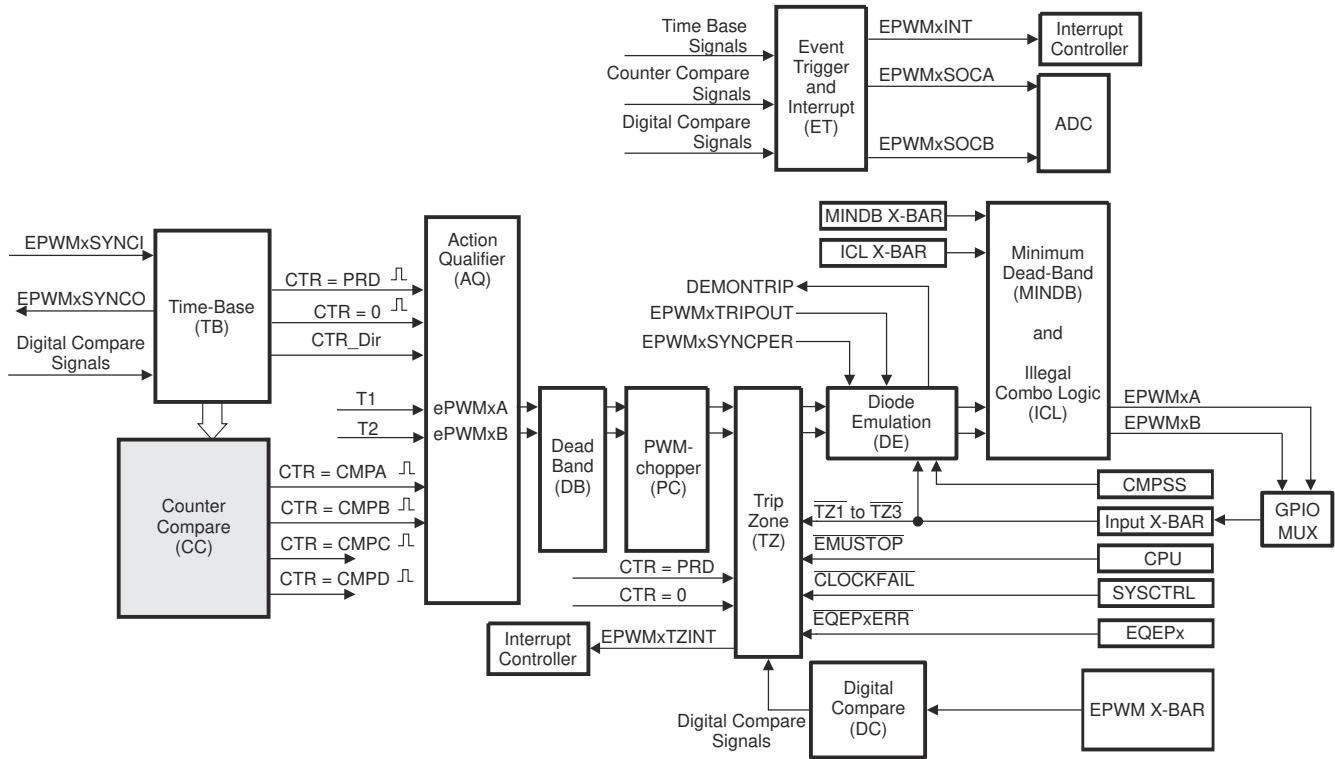

Figure 22-15. Counter-Compare Submodule

### 22.5.1 Purpose of the Counter-Compare Submodule

The counter-compare submodule takes as input the time-base counter value. This value is continuously compared to the counter-compare A (CMPA), counter-compare B (CMPB), counter-compare C (CMPC), and counter-compare D (CMPD) registers. When the time-base counter is equal to one of the compare registers, the counter-compare unit generates an appropriate event.

The counter-compare:

- Generates events based on programmable time stamps using the CMPA, CMPB, CMPC, and CMPD registers:
  - CTR = CMPA: Time-base counter equals counter-compare A register (TBCTR = CMPA)
  - CTR = CMPB: Time-base counter equals counter-compare B register (TBCTR = CMPB)
  - CTR = CMPC: Time-base counter equals counter-compare C register (TBCTR = CMPC)
  - CTR = CMPD: Time-base counter equals counter-compare D register (TBCTR = CMPD)
- Controls the PWM duty cycle, if the action-qualifier submodule is configured appropriately using counter-compare A (CMPA) and counter-compare B (CMPB)
- Shadows new compare values to prevent corruption or glitches during the active PWM cycle

### 22.5.2 Controlling and Monitoring the Counter-Compare Submodule

The counter-compare submodule operation is shown in Figure 22-16.

- A. These events are generated by the ePWM digital compare (DC) submodule based on the levels of the TRIPIN inputs (for example, CMPSSx and TZ signals).

**Figure 22-16. Detailed View of the Counter-Compare Submodule**

### 22.5.3 Operational Highlights for the Counter-Compare Submodule

The counter-compare submodule is responsible for generating events that can be used in the action-qualifier and event-trigger submodules. There are four independent compare events:

1. CTR = CMPA: Time-base counter equal to counter-compare A register (TBCTR = CMPA).
2. CTR = CMPB: Time-base counter equal to counter-compare B register (TBCTR = CMPB).
3. CTR = CMPC: Time-base counter equal to counter-compare C register (TBCTR = CMPC). This event can be used to generate an event in the event trigger submodule only.
4. CTR = CMPD: Time-base counter equal to counter-compare D register (TBCTR = CMPD). This event can be used to generate an event in the event trigger submodule only.

For up-count or down-count mode, each event occurs only once per cycle. For up-down count mode, each event occurs twice per cycle if the compare value is between 0x00-TBPRD; and once per cycle if the compare value is equal to 0x00 or equal to TBPRD. These events are applied to the action-qualifier submodule where the events are qualified by the counter direction and converted into actions if enabled. Refer to [Section 22.6.1](#) for more details.

The counter-compare registers CMPA and CMPB each have an associated shadow register. Shadowing provides a way to keep updates to the registers synchronized with the hardware. When shadowing is used, updates to the active registers only occur at strategic points. This prevents corruption or spurious operation due to the register being asynchronously modified by software. The memory address of the active register and the shadow register is identical. The register that is written to or read from is determined by the CMPCTL[SHDWAMODE] and CMPCTL[SHDWBMODE] bits. These bits enable and disable the CMPC shadow register and CMPD shadow register, respectively. The behavior of the two load modes is:

#### Shadow Mode:

The shadow mode for the CMPA is enabled by clearing the CMPCTL[SHDWAMODE] bit and the shadow register for CMPB is enabled by clearing the CMPCTL[SHDWBMODE] bit. Shadow mode is enabled by default for both CMPA and CMPB.

If the shadow register is enabled then the content of the shadow register is transferred to the active register on one of the following events as specified by the CMPCTL[LOADAMODE], CMPCTL[LOADBMODE], CMPCTL[LOADASYNC], and CMPCTL[LOADBSYNC] register bits:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
- Both CTR = PRD and CTR = Zero
- SYNC event caused by DCAEVT1 or DCBEVT1 or EPWMxSYNCl or TBCTL[SWFSYNC]
- Both SYNC event or a selection made by LOADAMODE/LOADBMODE

Only the active register contents are used by the counter-compare submodule to generate events to be sent to the action-qualifier.

---

#### Note

Refer to [Section 22.6.5](#) for valid configurations of CMPA/CMPB and LOADAMODE/LOADBMODE.

---

#### Immediate Load Mode:

If the immediate load mode is selected (that is, CMPCTL[SHDWAMODE] = 1 or CMPCTL[SHDWBMODE] = 1), then a read from or a write to the register goes directly to the active register.

## Additional Comparators

The counter-compare submodule on ePWMs type 2 and later are responsible for generating two additional independent compare events based on two compare registers, which is fed to Event Trigger submodule:

1. CTR = CMPC: Time-base counter equal to counter-compare C register (TBCTR = CMPC).
2. CTR = CMPD: Time-base counter equal to counter-compare D register (TBCTR = CMPD).

The counter-compare registers CMPC and CMPD each have an associated shadow register. By default this register is shadowed. The memory address of the active register and the shadow register is identical. The value in the active CMPC and CMPD register is compared to the time-base counter (TBCTR). When the values are equal, the counter compare module generates a “time-base counter equal to counter compare C or counter compare D” event respectively. Shadowing of this register is enabled and disabled by the CMPCTL2[SHDWCMODE] and CMPCTL2[SHDWDMODE] bit. These bits enable and disable the CMPC shadow register and CMPD shadow register respectively. The behavior of the two load modes is described below:

### Shadow Mode:

The shadow mode for the CMPC is enabled by clearing the CMPCTL2[SHDWCMODE] bit and the shadow register for CMPD is enabled by clearing the CMPCTL2[SHDWDMODE] bit. Shadow mode is enabled by default for both CMPC and CMPD.

If the shadow register is enabled then the content of the shadow register is transferred to the active register on one of the following events as specified by the CMPCTL2[LOADCMODE], CMPCTL2[LOADDMODE], CMPCTL2[LOADCSYNC], and CMPCTL2[LOADDSYNC] register bits:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
- Both CTR = PRD and CTR = Zero
- SYNC event caused by DCAEVT1 or DCBEVT1 or EPWMxSYNCl or TBCTL[SWFSYNC]
- Both SYNC event or a selection made by LOADCMODE/LOADDMODE

Only the active register contents are used by the counter-compare submodule to generate events to be sent to the action-qualifier.

### Immediate Load Mode:

If the immediate load mode is selected (that is, CMPCTL2[SHDWCMODE] = 1 or CMPCTL2[SHDWDMODE] = 1), then a read from or a write to the register goes directly to the active register.

### Global Load Support

The global load control mechanism can also be used for all counter-compare registers by configuring the appropriate bits in the global load configuration register (GLDCFG). When the global load mode is selected the transfer of contents from shadow register to active register, for all registers that have this mode enabled, occurs at the same event as defined by the configuration bits in the Global Shadow to Active Load Control Register (GLDCTL). The global load control mechanism is explained in [Section 22.4.7](#).

### 22.5.4 Count Mode Timing Waveforms

The counter-compare module can generate compare events in all three count modes:

- Up-count mode: used to generate an asymmetrical PWM waveform.
- Down-count mode: used to generate an asymmetrical PWM waveform.
- Up-down-count mode: used to generate a symmetrical PWM waveform.

To best illustrate the operation of the first three modes, the timing diagrams in [Figure 22-17](#) through [Figure 22-20](#) show when events are generated and how the EPWMxSYNCl signal interacts.

An EPWMxSYNCl external synchronization event can cause a discontinuity in the TBCTR count sequence. This can lead to a compare event being skipped. This skipping is considered normal operation and must be taken into account.

**Figure 22-17. Counter-Compare Event Waveforms in Up-Count Mode**

**Figure 22-18. Counter-Compare Events in Down-Count Mode**

Figure 22-19. Counter-Compare Events In Up-Down-Count Mode, TBCTL[PHSDIR = 0] Count Down On Synchronization Event

Figure 22-20. Counter-Compare Events In Up-Down-Count Mode, TBCTL[PHSDIR = 1] Count Up On Synchronization Event

## 22.6 Action-Qualifier (AQ) Submodule

The action-qualifier submodule has the most important role in waveform construction and PWM generation. The action-qualifier submodule decides which events are converted into various action types, thereby, producing the required switched waveforms at the EPWMxA and EPWMxB outputs.

Figure 22-21 illustrates the action-qualifier submodule within the ePWM.

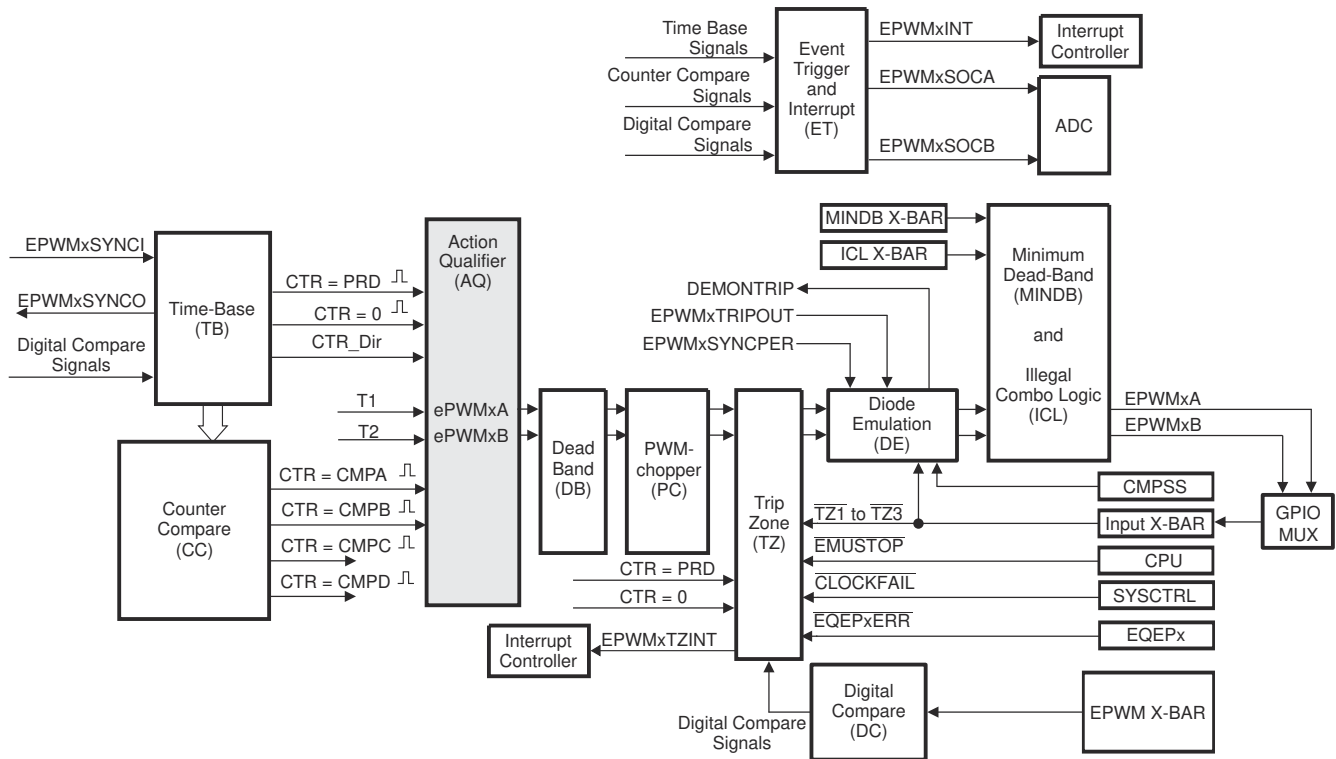

Figure 22-21. Action-Qualifier Submodule

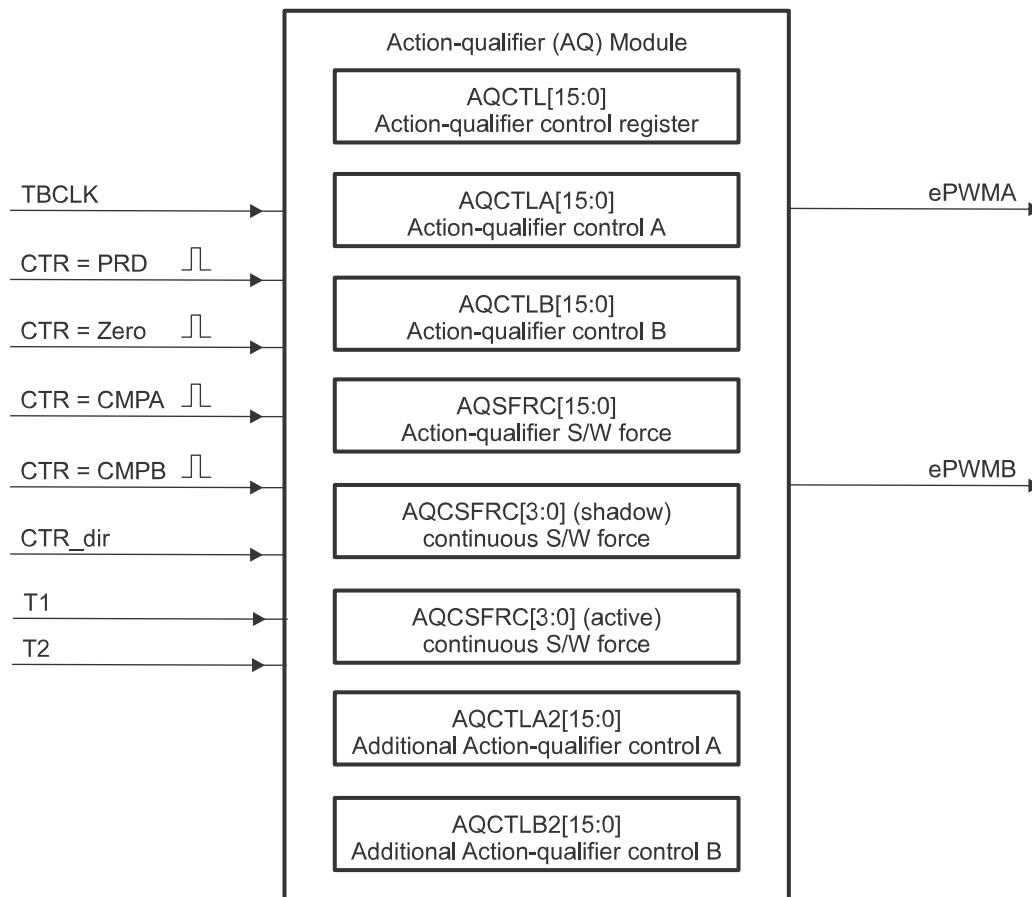

### 22.6.1 Purpose of the Action-Qualifier Submodule

The action-qualifier submodule is responsible for the following:

- Qualifying and generating actions (set, clear, toggle) based on the following events:
  - CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
  - CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
  - CTR = CMPA: Time-base counter equal to the counter-compare A register (TBCTR = CMPA)
  - CTR = CMPB: Time-base counter equal to the counter-compare B register (TBCTR = CMPB)
- T1, T2 events: Trigger events based on comparator, trip or syncin events
- Managing priority when these events occur concurrently
- Providing independent control of events when the time-base counter is increasing and when the time-base counter is decreasing

### 22.6.2 Action-Qualifier Submodule Control and Status Register Definitions

The action-qualifier submodule operation is shown in [Figure 22-22](#) and monitored by way of the registers in [Section 22.20](#).

**Figure 22-22. Action-Qualifier Submodule Inputs and Outputs**

For convenience, the possible input events are summarized again in [Table 22-4](#).

**Table 22-4. Action-Qualifier Submodule Possible Input Events**

Signal	Description	Registers Compared
CTR = PRD	Time-base counter equal to the period value	TBCTR = TBPRD
CTR = Zero	Time-base counter equal to 0	TBCTR = 0x00
CTR = CMPA	Time-base counter equal to the counter-compare A	TBCTR = CMPA
CTR = CMPB	Time-base counter equal to the counter-compare B	TBCTR = CMPB
T1 event	Based on comparator, trip, or syncin events	None
T2 event	Based on comparator, trip, or syncin events	None
Software forced event	Asynchronous event initiated by software	

The software forced action is a useful asynchronous event. This control is handled by the AQSFRC and AQCSFRC registers.

**Note**

If the CSFA is not used in shadow mode, the RLDCSF bit must be configured to disable shadow mode.

The action-qualifier submodule controls how the two outputs EPWMxA and EPWMxB behave when a particular event occurs. The event inputs to the action-qualifier submodule are further qualified by the counter direction (up or down). This allows for independent action on outputs on both the count-up and count-down phases.

The possible actions imposed on outputs EPWMxA and EPWMxB are:

- **Set High:** Set output EPWMxA or EPWMxB to a high level.
- **Clear Low:** Set output EPWMxA or EPWMxB to a low level.
- **Toggle:** If EPWMxA or EPWMxB is currently pulled high, then pull the output low. If EPWMxA or EPWMxB is currently pulled low, then pull the output high.
- **Do Nothing:** Keep outputs EPWMxA and EPWMxB at same level as currently set. Although the "Do Nothing" option prevents an event from causing an action on the EPWMxA and EPWMxB outputs, this event can still trigger interrupts and ADC start of conversion. See the description in [Section 22.13](#) for details.

Actions are specified independently for either output (EPWMxA or EPWMxB). Any or all events can be configured to generate actions on a given output. For example, both CTR = CMPA and CTR = CMPB can operate on output EPWMxA. All qualifier actions are configured using the control registers found in the *ePWM Registers* section.

For clarity, the illustrations in this chapter use a set of symbolic actions. These symbols are summarized in [Figure 22-23](#). Each symbol represents an action as a marker in time. Some actions are fixed in time (zero and period) while the CMPA and CMPB actions are moveable and the time positions are programmed by way of the counter-compare A and B registers, respectively. To turn off or disable an action, use the "Do Nothing option"(the default at reset).

SW force	TB Counter equals			Trigger Events			Actions
	Zero	Comp A	Comp B	Period	T1	T2	
							Do Nothing
							Clear Lo
							Set Hi
							Toggle

**Figure 22-23. Possible Action-Qualifier Actions for EPWMxA and EPWMxB Outputs**

The Action Qualifier Trigger Event Source Selection register (AQTSRCSEL) is used to select the source for T1 and T2 events. T1/T2 selection and configuration of a trip/digital-compare event in Action Qualifier submodule is independent of the configuration of that event in the Trip-Zone submodule. A particular trip event can or cannot

be configured to cause trip action in the Trip Zone submodule, but the same event can be used by the Action Qualifier to generate T1/T2 for controlling PWM generation.

### 22.6.3 Action-Qualifier Event Priority

It is possible for the ePWM action qualifier to receive more than one event at the same time. In this case, events are assigned a priority by the hardware. The general rule is events occurring later in time have a higher priority and software forced events always have the highest priority. The event priority levels for up-down count mode are shown in [Table 22-5](#). A priority level of 1 is the highest priority and level 10 is the lowest. The priority changes slightly depending on the direction of TBCTR.

**Table 22-5. Action-Qualifier Event Priority for Up-Down-Count Mode**

Priority Level	Event If TBCTR is Incrementing TBCTR = Zero up to TBCTR = TBPRD	Event If TBCTR is Decrementing TBCTR = TBPRD down to TBCTR = 1
1 (Highest)	Software forced event	Software forced event
2	T1 on up-count (T1U)	T1 on down-count (T1D)
3	T2 on up-count (T2U)	T2 on down-count (T2D)
4	Counter equals CMPB on up-count (CBU)	Counter equals CMPB on down-count (CBD)
5	Counter equals CMPA on up-count (CAU)	Counter equals CMPA on down-count (CAD)
6 (Lowest)	Counter equals zero	Counter equals period (TBPRD)

[Table 22-6](#) shows the action-qualifier priority for up-count mode. In this case, the counter direction is always defined as up; therefore, down-count events never are taken.

**Table 22-6. Action-Qualifier Event Priority for Up-Count Mode**

Priority Level	Event
1 (Highest)	Software forced event
2	Counter equal to period (TBPRD)
3	T1 on up-count (T1U)
4	T2 on up-count (T2U)
5	Counter equal to CMPB on up-count (CBU)
6	Counter equal to CMPA on up-count (CAU)
7 (Lowest)	Counter equal to Zero

[Table 22-7](#) shows the action-qualifier priority for down-count mode. In this case, the counter direction is always defined as down; therefore, up-count events never are taken.

**Table 22-7. Action-Qualifier Event Priority for Down-Count Mode**

Priority Level	Event
1 (Highest)	Software forced event
2	Counter equal to Zero
3	T1 on down-count (T1D)
4	T2 on down-count (T2D)
5	Counter equal to CMPB on down-count (CBD)
6	Counter equal to CMPA on down-count (CAD)
7 (Lowest)	Counter equal to period (TBPRD)

It is possible to set the compare value greater than the period. In this case, the action takes place as shown in [Table 22-8](#).

**Table 22-8. Behavior if CMPA/CMPB is Greater than the Period**

Counter Mode	Compare on Up-Count Event CAD/CBD	Compare on Down-Count Event CAD/CBD
Up-Count Mode	If $CMPA/CMPB \leq TBPRD$ period, then the event occurs on a compare match ( $TBCTR=CMPA$ or $CMPB$ ). If $CMPA/CMPB > TBPRD$ , then the event does not occur.	Never occurs.
Down-Count Mode	Never occurs.	If $CMPA/CMPB < TBPRD$ , the event occurs on a compare match ( $TBCTR=CMPA$ or $CMPB$ ). If $CMPA/CMPB \geq TBPRD$ , the event occurs on a period match ( $TBCTR=TBPRD$ ).
Up-Down Count Mode	If $CMPA/CMPB < TBPRD$ and the counter is incrementing, the event occurs on a compare match ( $TBCTR=CMPA$ or $CMPB$ ). If $CMPA/CMPB \geq TBPRD$ , the event occurs on a period match ( $TBCTR = TBPRD$ ).	If $CMPA/CMPB < TBPRD$ and the counter is decrementing, the event occurs on a compare match ( $TBCTR=CMPA$ or $CMPB$ ). If $CMPA/CMPB \geq TBPRD$ , the event occurs on a period match ( $TBCTR=TBPRD$ ).

### 22.6.4 AQCTLA and AQCTLB Shadow Mode Operations

To enable Action Qualifier mode changes which must occur at the end of a period even when the phase changes, shadowing of the AQCTLA and AQCTLB registers has been added on ePWMs type 2 and later. Additionally, shadow to active load on SYNC of these registers is supported as well. Shadowing of this register is enabled and disabled by the AQCTL[SHDWAQAMODE] and AQCTL[SHDWAQBMODE] bits. These bits enable and disable the AQCTLA shadow register and AQCTLB shadow register, respectively. The behavior of the two load modes is:

#### Shadow Mode:

The shadow mode for the AQCTLA is enabled by setting the AQCTL[SHDWAQAMODE] bit, and the shadow register for AQCTLB is enabled by setting the AQCTL[SHDWAQBMODE] bit. Shadow mode is disabled by default for both AQCTLA and AQCTLB

If the shadow register is enabled, then the content of the shadow register is transferred to the active register on one of the following events as specified by the AQCTL[LDAQAMODE], AQCTL[LDAQBMODE], AQCTL[LDAQASYNC], and AQCTL[LDAQBSYNC] register bits:

- CTR = PRD: Time-base counter equal to the period ( $TBCTR = TBPRD$ ).
- CTR = Zero: Time-base counter equal to zero ( $TBCTR = 0x00$ )
- Both CTR = PRD and CTR = Zero
- SYNC event caused by DCAEVT1 or DCBEVT1 or EPWMxSYNCl or  $TBCTL[SWFSYNC]$
- Both SYNC event or a selection made by LDAQAMODE/LDAQBMODE

#### Global Load Support

Global load control mechanism can also be used for AQCTLA:AQCTLA2, AQCTLB:AQCTLB2, and AQCSFRC registers by configuring the appropriate bits in the global load configuration register (GLDCFG). When global load mode is selected, the transfer of contents from shadow register to active register for all registers that have this mode enabled, occurs at the same event as defined by the configuration bits in the Global Shadow to Active Load Control Register (GLDCTL). The global load control mechanism is explained in [Section 22.4.7](#).

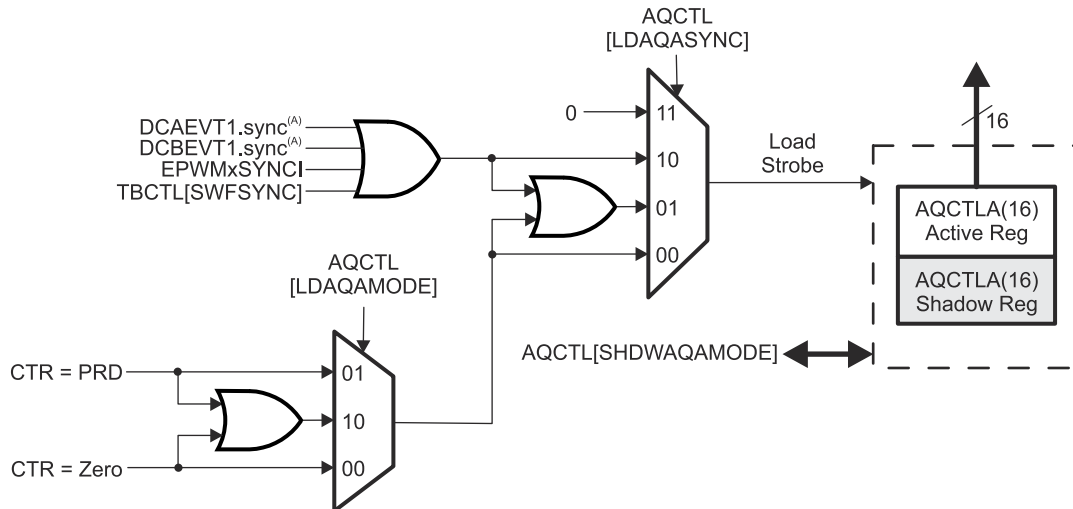

#### Immediate Load Mode:

If the immediate load mode is selected (that is,  $AQCTL[SHDWAQAMODE] = 0$  or  $AQCTL[SHDWAQBMODE] = 0$ ), then a read from or a write to the register goes directly to the active register. See [Figure 22-24](#) and [Figure 22-25](#).

**Note**

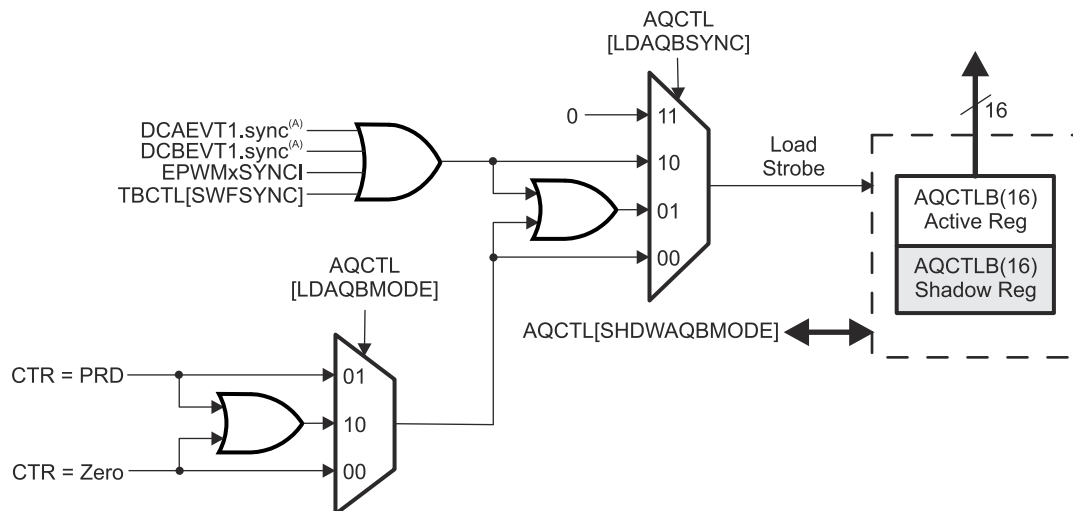

Shadow to Active Load of Action Qualifier Output A/B Control Register [AQCTLA and AQCTLB] on CMPA = 0 or CMPB = 0 boundary

If the Counter-Compare A Register (CMPA) or Counter-Compare B Register (CMPB) is set to a value of 0 and the action qualifier action on AQCTLA and AQCTLB is configured to occur in the same instant as a shadow to active load (that is, CMPA = 0 and AQCTLA shadow to active load on TBCTR = 0 using AQCTL register LDAQAMODE and LDAQAMODE bits), then both events enter contention. It is recommended to use a Non-Zero Counter-Compare when using Shadow to Active Load of Action Qualifier Output A/B Control Register on TBCTR = 0 boundary.

- A. These events are generated by the ePWM digital compare (DC) submodule based on the levels of the TRIPIN inputs (for example, CMPSSx and TZ signals).

**Figure 22-24. AQCTL[SHDWAQAMODE]**

- A. These events are generated by the ePWM digital compare (DC) submodule based on the levels of the TRIPIN inputs (for example, CMPSSx and TZ signals).

**Figure 22-25. AQCTL[SHDWAQBMODE]**

## 22.6.5 Configuration Requirements for Common Waveforms

### Note

The waveforms in this chapter show the behavior of the ePWMs for a static compare register value. In a running system, the active compare registers (CMPA and CMPB) are typically updated from the respective shadow registers once every period. Specify when the update takes place: either when the time-base counter reaches zero or when the time-base counter reaches the period. There are some cases when the action based on the new value can be delayed by one period or the action based on the old value can take effect for an extra period. Some PWM configurations avoid this situation. These include, but are not limited to, the following:

#### Use up-down count mode to generate a symmetric PWM:

- If loading CMPA/CMPB on zero, then use CMPA/CMPB values greater than or equal to 1.
- If loading CMPA/CMPB on period, then use CMPA/CMPB values less than or equal to TBPRD-1.

This means there is always a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

#### Use up-down count mode to generate an asymmetric PWM:

- To achieve 50%-0% asymmetric PWM use the following configuration: Load CMPA/CMPB on period and use the period action to clear the PWM and a compare-up action to set the PWM. Modulate the compare value from 0 to TBPRD to achieve 50%-0% PWM duty.

#### When using up-count mode to generate an asymmetric PWM:

- To achieve 0-100% asymmetric PWM, you **must** load CMPA/CMPB on TBPRD. When CMPA/CMPB is not loaded on TBCTR=PRD, boundary conditions can occur depending on the timing of the write and the value written to CMPA/CMPB. Use the Zero action to set the PWM and a compare-up action to clear the PWM. Modulate the compare value from 0 to TBPRD+1 to achieve 0-100% PWM duty.

#### When using up-count mode to generate an asymmetric PWM with deadband enabled:

- To achieve 0%-100% PWM use the following configuration: When the CMPA value is too close to 0 or PRD such that the following conditions are met ( $CMPX < \text{Deadband}$ ) or ( $CMPX > \text{PRD} - \text{Deadband}$ ), the actions specified by the AQCTL register for CMPX do not take effect. To avoid this, the AQCTL settings must be altered under these conditions only to generate either high or low pulses for both CAU or CAD events (both set or both clear). Make sure that this software update is occurring synchronous to the PWM carrier cycle, and shadow mode is enabled.

#### When using up-down count mode to generate an asymmetric PWM with deadband enabled:

- To achieve 0%-100% PWM use the following configuration: When the CMPA value is too close to 0 or PRD such that the following conditions are met ( $CMPX < \text{Deadband}/2$ ) or ( $CMPX > \text{PRD} - (\text{Deadband})/2$ ), the actions specified by the AQCTL register for CMPX do not take effect. To avoid this, the AQCTL settings must be altered under these conditions only to generate either high or low pulses for both CAU or CAD events (both set or both clear). Make sure that this software update is occurring synchronous to the PWM carrier cycle, and shadow mode is enabled.

See [Using Enhanced Pulse Width Modulator \(ePWM\) Module for 0-100% Duty Cycle Control](#).

Figure 22-26 shows how a symmetric PWM waveform can be generated using the up-down-count mode of the TBCTR. In this mode, 0%-100% DC modulation is achieved by using equal compare matches on the up count and down count portions of the waveform. In the example shown, CMPA is used to make the comparison. When the counter is incrementing, the CMPA match pulls the PWM output high. Likewise when the counter is decrementing, the compare match pulls the PWM signal low. When  $CMPA = 0$ , the PWM signal is high for the entire period giving a 100% duty waveform. When  $CMPA = TBPRD$ , the PWM signal is low achieving 0% duty.

When using this configuration in practice, if loading CMPA/CMPB on zero, then use CMPA/CMPB values greater than or equal to 1. If loading CMPA/CMPB on period, then use CMPA/CMPB values less than or equal to TBPRD-1. This means there is always a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

**Figure 22-26. Up-Down Count Mode Symmetrical Waveform**

The PWM waveforms in [Figure 22-27](#) through [Figure 22-32](#) show some common action-qualifier configurations. Some conventions used in the figures and examples are as follows:

- TBPRD, CMPA, and CMPB refer to the value written in the respective registers. The active register, not the shadow register, is used by the hardware.
- CMPx, refers to either CMPA or CMPB.
- EPWMxA and EPWMxB refer to the output signals from ePWMx
- Up-Down means count-up-and-count-down mode, Up means up-count mode and Down means down-count mode
- Sym = Symmetric, Asym = Asymmetric

- A.  $PWM\ period = (TBPRD + 1) \times T_{TBCLK}$
- B. Duty modulation for EPWMxA is set by CMPA, and is active high (that is, high time duty proportional to CMPA).
- C. Duty modulation for EPWMxB is set by CMPB and is active high (that is, high time duty proportional to CMPB).
- D. The "Do Nothing" actions (X) are shown for completeness, but are not shown on subsequent diagrams.
- E. Actions at zero and period, although appearing to occur concurrently, are actually separated by one TBCLK period. TBCTR wraps from period to 0000.

**Figure 22-27. Up, Single Edge Asymmetric Waveform, with Independent Modulation on EPWMxA and EPWMxB—Active High**

- PWM period =  $(TBPRD + 1) \times T_{TBCLK}$
- Duty modulation for EPWMxA is set by CMPA, and is active low (that is, the low time duty is proportional to CMPA).
- Duty modulation for EPWMxB is set by CMPB and is active low (that is, the low time duty is proportional to CMPB).
- Actions at zero and period, although appearing to occur concurrently, are actually separated by one TBCLK period. TBCTR wraps from period to 0000.

**Figure 22-28. Up, Single Edge Asymmetric Waveform with Independent Modulation on EPWMxA and EPWMxB—Active Low**

- A.  $PWM\ frequency = 1 / ((TBPRD + 1) \times T_{TBCLK})$
- B. Pulse can be placed anywhere within the PWM cycle (0000 - TBPRD)
- C. High time duty proportional to (CMPB - CMPA)

**Figure 22-29. Up-Count, Pulse Placement Asymmetric Waveform With Independent Modulation on EPWMxA**

- A.  $PWM\ period = 2 \times TBPRD \times T_{TBCLK}$
- B. Duty modulation for EPWMxA is set by CMPA, and is active low (that is, the low time duty is proportional to CMPA).
- C. Duty modulation for EPWMxB is set by CMPB and is active low (that is, the low time duty is proportional to CMPB).
- D. Outputs EPWMxA and EPWMxB can drive independent power switches.

**Figure 22-30. Up-Down Count, Dual-Edge Symmetric Waveform, with Independent Modulation on EPWMxA and EPWMxB — Active Low**

- PWM period =  $2 \times \text{TBPRD} \times T_{\text{TBCLK}}$
- Duty modulation for EPWMxA is set by CMPA, and is active low, that is, low time duty proportional to CMPA.
- Duty modulation for EPWMxB is set by CMPB and is active high, that is, high time duty proportional to CMPB.
- Outputs EPWMx can drive upper/lower (complementary) power switches.
- Dead-band = CMPB - CMPA (fully programmable edge placement by software). Note the dead-band module is also available if the more classical edge delay method is required.

**Figure 22-31. Up-Down Count, Dual-Edge Symmetric Waveform, with Independent Modulation on EPWMxA and EPWMxB — Complementary**

- PWM period =  $2 \times \text{TBPRD} \times \text{TBCLK}$
- Rising edge and falling edge can be asymmetrically positioned within a PWM cycle. This allows for pulse placement techniques.
- Duty modulation for EPWMxA is set by CMPA and CMPB.
- Low time duty for EPWMxA is proportional to  $(\text{CMPA} + \text{CMPB})$ .
- To change this example to active high, CMPA and CMPB actions need to be inverted (that is, Clear on CMPA, Set on CMPB).
- Duty modulation for EPWMxB is fixed at 50% (utilizes spare action resources for EPWMxB).

**Figure 22-32. Up-Down Count, Dual-Edge Asymmetric Waveform, with Independent Modulation on EPWMxA—Active Low**

- PWM period =  $2 \times \text{TBPRD} \times \text{TTBCLK}$
- Independent T1 event actions when counter is counting up and when the counter is counting down are used to generate EPWMxA output.
- Independent T2 event actions when counter is counting up and when the counter is counting down are used to generate EPWMxB output.
- TZ1 is selected as the source for T1.
- TZ2 is selected as the source for T2.

**Figure 22-33. Up-Down Count, PWM Waveform Generation Utilizing T1 and T2 Events**

## 22.7 XCMP Complex Waveform Generator Mode

The XCMP complex waveform generator mode is available in the type 5 ePWM and is enabled when XCMPEN is set. The main feature of the XCMP mode is to generate multiple ePWM pulses, with high resolution edge placement if needed, within one ePWM period.

XCMP features include:

- Up to eight counter compare registers XCMP1-XCMP8
- High resolution (HRPWM) edge placement support
- Up-Count counter mode support

---

**Note**

Down-Count and Up-Down-Count counter modes are not supported

---

- Pulse generation is only supported on XCMP1-8 matches (no support for counter events such as PRD and ZRO, or T1/T2 events)
- ePWM module synchronization is not allowed in XCMP mode

---

**Note**

The application software must disable the ePWM synchronization when XCMP mode is enabled.

- XCMP1-8 are loaded through CMPA and CMPB
- The eight XCMPn registers, can be allocated to either CMPA or CMPB through the application software configuration
- XAQCTLA and XAQCTLB registers determine the actions taken on the ePWM output for each XCMP1-8 counter matches
- Up to three ePWM period cycles can be configured at once through three shadow buffers

- Each shadow buffer contains shadow registers for XCMP1-8, XTBPRD, XAQCTLA, XAQCTLB, CMPC, CMPD, and XMINMAX (which is used for CAPEVT signal generation)
- Shadow buffer SHDW2 and SHDW3 can be repeated up to eight times
- All ePWM modules can be linked to trigger the start of their shadow loading at the same time through EPWMXLINKXLOAD

### 22.7.1 XCMP Allocation to CMPA and CMPB

The first criteria that must be selected is whether both EPWM channel A and channel B outputs are required. If both channel A and channel B are required, XCMP registers must be assigned to both CMPA and CMPB. The XCMP<sub>n</sub> registers loaded to CMPA are used for configuring the A channel through XAQCTLA actions. The XCMP<sub>n</sub> registers loaded to CMPB are used for configuring the B channel through XAQCTLB actions.

XCMP allocation to CMPA and CMPB is done through XCMPCTL1.XCMPSPPLIT. If both channel A and channel B are required in the system, then the XCMPCTL1.XCMPSPPLIT must be set. This allows CMPA to use XCMP1-n (where n has a maximum value of 4) while CMPB uses XCMP5-m (where m has a maximum value of 8). If only channel A is needed, then XCMPCTL1.XCMPSPPLIT must be cleared, allowing CMPA to use XCMP1-n (where n has a maximum value of 8), which means up to eight edges can be generated on channel A.

#### Note

The maximum number of edges that channel B can have is four, when XCMP5-8 are allocated to CMPB and all four XCMP5-8 are used by setting the XCMPB\_ALLOC to use all available XCMPs.

XCMPA\_ALLOC and XCMPB\_ALLOC determines how many of the available XCMPs for each CMPA and CMPB must be used in the ePWM configuration.

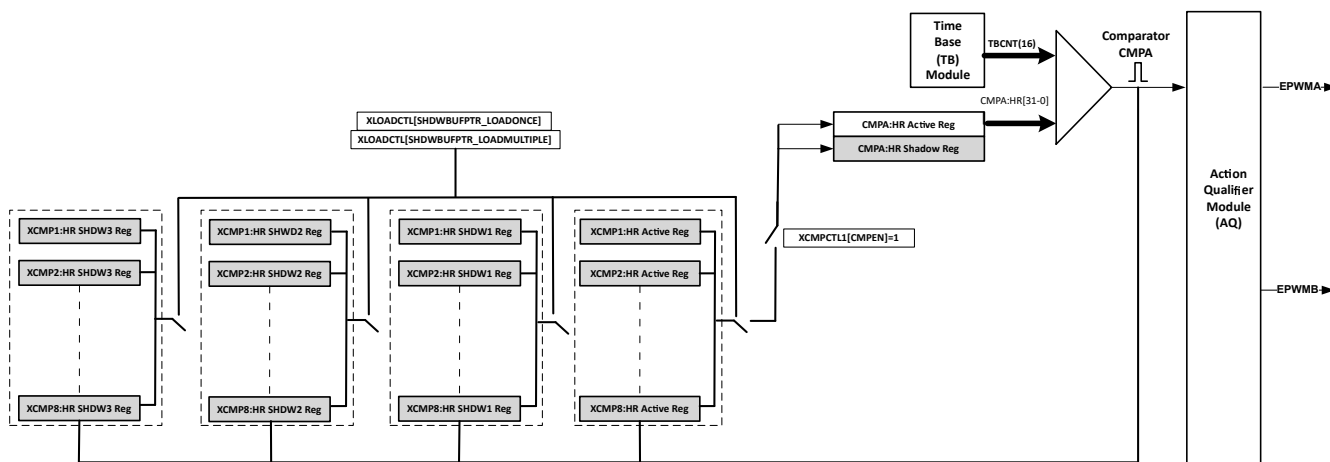

Figure 22-34. Allocate All XCMP1-8 to CMPA

Figure 22-35. XCMP1-4 Allocated to CMPA and XCMP5-8 Allocated to CMPB

### 22.7.2 XCMP Shadow Buffers

Three SHDW buffers are available for XCMP configurations. Each SHDW buffer contains the XCMP1-8 values (CMPA and CMPB values), XTBPDR (TBPRD value), XCMPC (CMPC value), XCMPD (CMPD value), XAQCTLA and XAQCTLB. Each SHDW buffer also contains the XMINMAX values which are used for CAPEVT signal generation.

With the three SHDW buffer (SHDW1, SHDW2 and SHDW3) the values used for the upcoming ePWM period cycles can be buffered.

With XCOMPEN set, the load of the active registers are controlled by the XLOADCTL and XLOAD registers. The shadow to active loading of the registers (other than XMINMAX, XCMPC, XCMPD) are always done three cycles prior to TBCTR==ZERO event. XMINMAX, XCMPC and XCMPD shadow loading is done at TBCTR==PRD.

There are two load modes configured by XLOADCTL[LOADMODE]:

- **LOADONCE** Mode (XLOADCTL[LOADMODE] = 0)
  - In LOADONCE mode, XLOADCTL[SHDWBUFPTR\_LOADONCE] is used to set the pointer location of the shadow buffer.
  - XLOADCTL[SHDWBUFPTR\_LOADONCE] is set by the user and is **NOT** automatically decremented. Upon the occurrence of the first load strobe (write of '1' to XLOAD[STARTLD] bit), active register set is loaded from the XLOADCTL[SHDWBUFPTR\_LOADONCE] SHDW selected by the user. Further load strobes are ignored, and ePWM waveform generation continues with the active register set until next XLOAD[STARTLD] is initiated.
  - When the software sets the XLOAD[STARTLD] bit again, the active register set is loaded from the XLOADCTL[SHDWBUFPTR\_LOADONCE] SHDW selected by the user. If the user wants to initiate a SHDW load from a different shadow register set, then the software can update the XLOADCTL[SHDWBUFPTR\_LOADONCE] register accordingly before setting the XLOADCTL[STARTLD].

- **LOADMULTIPLE Mode** (XLOADCTL[LOADMODE] = 1)
  - XLOADCTL[SHDWBUFPTR\_LOADMULTIPLE] always points to the current shadow register set that is loaded into the active registers set.
  - Setting the XLOAD[STARTLD] bit initiates a load strobe. The SHDW buffer pointer resets to XLOADCTL[SHDWLEVEL] and the corresponding buffer contents are loaded to the active register set. When the next valid load strobe arrives, XLOADCTL[SHDWBUFPTR\_LOADMULTIPLE] is decremented by 1 and the corresponding buffer contents are loaded to the active register set. This continues until the XLOADCTL[SHDWBUFPTR\_LOADMULTIPLE] value reaches 1. At this time SHDW1 values get copied to the active register set. Further load strobes are ignored and the ePWM waveform generation continues with the active register set until next XLOAD[STARTLD] is initiated.
  - Once the XLOADCTL[SHDWBUFPTR\_LOADMULTIPLE] value reaches 1, no further decrements to the this pointer are done until the next STARTLD initiation. This means the XLOADCTL[SHDWBUFPTR\_LOADMULTIPLE] remains at value of '1', indicating that the SHDW1 register set is in use till the next load initiation by user.
  - For a SHDWLEVEL of 3 buffers SHDW3 is loaded first followed by SHDW2 and SHDW1. Then until the next STARTLD write by the software, the SHDW1 values are in use.

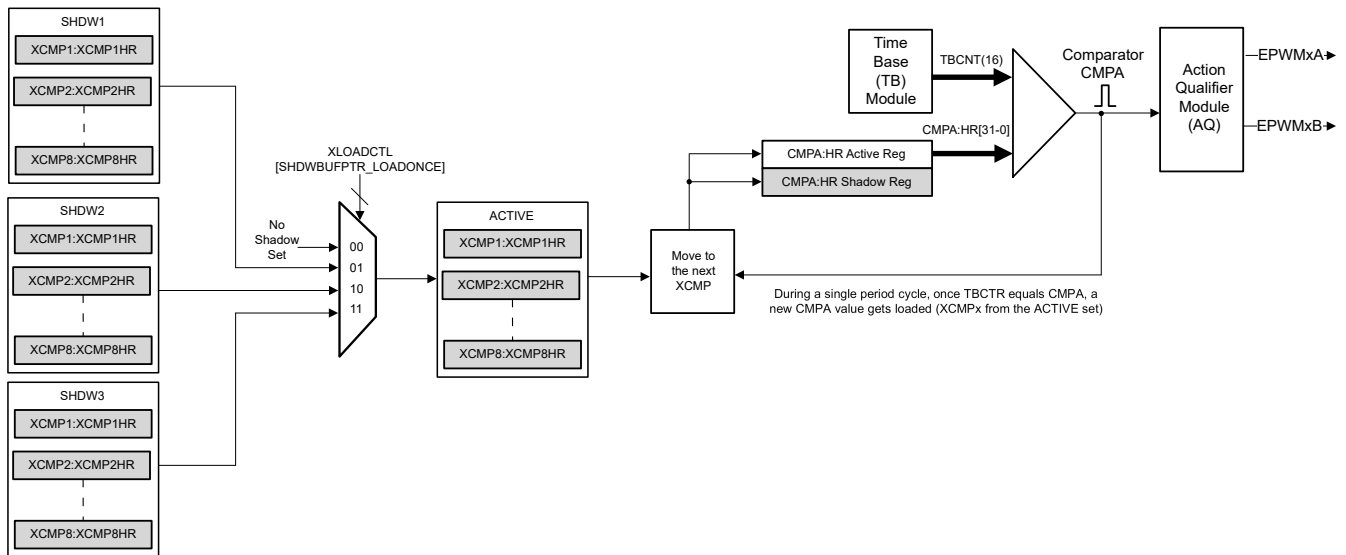

Figure 22-36. XCMP- Load Once Functionality

Figure 22-37. XCMP- Load Multiple Functionality

With this new loading scheme, the global load functionality also changes when using XCMP mode. In this new configuration, once a write to STARLD occurs, the next time the time base counter equals zero or a force load software write occurs, the shadow buffer pointers get reset, based on the load mode (load once or load multiple).

Figure 22-38. Global Load: Signals and Registers

Shadow buffers can also be repeated more than once. Shadow buffer repeat counters are:

- Users can optionally repeat each shadow buffer multiple times. This option sets the repeat count for SHDW2 and SHDW3 buffers before the pointer moves to the SHDW1 buffer. SHDW1 buffer by default repeats until the next load is initiated by the software and hence there is no configurable repeat option for SHDW1 buffer.
- Repeat counter option of the shadow buffers is applicable in LOADMULTIPLE mode. In the LOADONCE mode, user can manually keep track of the repeat counts and move to the SHDW pointer buffer.
- Each shadow buffer has a 3-bit counter. Each buffer can be set to repeat up to 8 times before moving the pointer to the next buffer.
- XLOADCTL[RPTBUF2PRD] and XLOADCTL[RPTBUF3PRD] are used to control the repeat period for each SHDW buffer.

No shadowing can be set by setting the XLOADCTL[SHDWLEVEL] to '0'. In this case, the ACTIVE registers are available for use (XCMP1\_ACTIVE, XCMP2\_ACTIVE, and so on).

### 22.7.3 XCMP Operation

The XCMP complex waveform generation mode is described in this section.

The XCMP mode can be used to generate multiple edges within one ePWM period. The application software must write the location of the ePWM waveform edges to the XCMP registers. Each XCMPn register assigned and used for an ePWM CMPx (CMPA or CMPB) must be spaced out according to the following guidelines to make sure of correct waveform generation.

Figure 22-39 shows an example of four XCMP values being loaded into CMPA during one period cycle and the remaining four XCMP values being used for CMPB. When the action for the last XCMP value loaded into CMPA/CMPB in a period is met, the last value for CMPA/CMPB remains until the next time TBCTR = 0 due to a new shadow set load.

**Figure 22-39. CMPA and CMPB values being loaded from XCMP registers**

Assume XCMP1-3 are assigned and used by CMPA (XCMP4 is not used), and XCMP5-6 are assigned and used by CMPB (XCMP7 and XCMP8 are not used):

- For XCMP1-8 to be split between CMPA and CMPB, software must write  $\text{XCMPCTL1}[\text{XCMPSPPLIT}] = 1$
- For CMPA to only use XCMP1-3, software must write  $\text{XCMPCTL1}[\text{CMPA\_ALLOC}] = 3$
- For CMPB to only use XCMP5-6, software must write  $\text{XCMPCTL1}[\text{CMPB\_ALLOC}] = 6$

For XCMP1-3 in this scenario, since all are used by CMPA, the values written to XCMP1, XCMP2, and XCMP3 must:

- Without high-resolution edge placement requirement:  $\text{XCMP}(n+1) > (\text{XCMP}n) + 1$
- With high-resolution edge placement requirement:  $\text{XCMP}(n+1) > (\text{XCMP}n) + 3$

The requirements above for the minimum difference between  $\text{XCMP}(n+1)$  and  $\text{XCMP}n$  must be met in the application software.

The actions taken for each XCMP1-8 must be configured in XAQCTLA and XAQCTLB.

If shadowing is required then the XCMP1-8, XAQCTLA and XAQCTLB values must be written to the corresponding shadow buffer. As an example, Table 22-9 shows how the shadow buffers are used in LOADMULTIPLE mode.

The SHDW buffers 2 and 3 can also be repeated more than once by using the RPTBUF2PRD and RPTBUF3PRD.

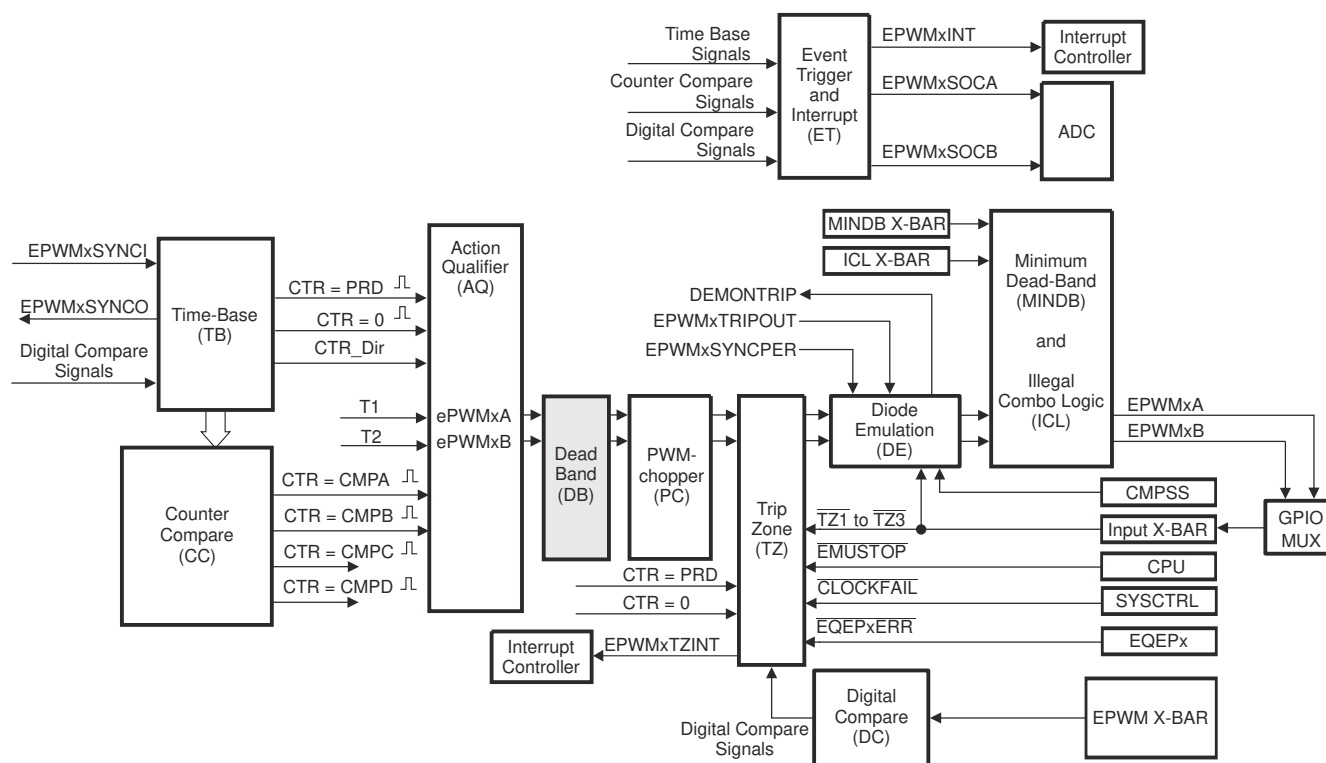

**Table 22-9. SHDW Buffer Loading Example**

	XCMPn, XTBPRD			XTBPRD, TBPRD	XCMPn: XCMPnHR	CMPA: CMPAHR	What happens next?
	SHDW3FULL	SHDW2FULL	SHDW1FULL	Active	Active	Active	
CPU Initialization	Set	Set	Set				Registers initialized by CPU. Load event occurs.
ePWM Cycle 1	Clear	Set	Set	XTBPRD_ SHDW3	XCMPn_ SHDW3	XCMPn_ SHDW3	SHDWBUFPtr set to 3
ePWM Cycle 2	Clear	Clear	Set	XTBPRD_ SHDW2	XCMPn_ SHDW2	XCMPn_ SHDW2	SHDWBUFPtr set to 2
ePWM Cycle 3	Clear	Clear	Clear	XTBPRD_ SHDW1	XCMPn_ SHDW1	XCMPn_ SHDW1	SHDWBUFPtr set to 1
ePWM Cycle 4	Clear	Clear	Clear	XTBPRD_ SHDW1	XCMPn_ SHDW1	XCMPn_ SHDW1	SHDWBUFPtr set to 1 No shadow to active loading from buffer. Operation continues with values in XCMPn_ACTIVE registers.
ePWM Cycle 5	Clear	Clear	Clear	XTBPRD_ SHDW1	XCMPn_ SHDW1	XCMPn_ SHDW1	SHDWBUFPtr set to 1 Continues operation with same values in XCMPn_ACTIVE until the next buffer load event
CPU Load (During ePWM Cycle 5)	Set	Set	Set	XTBPRD_ SHDW1	XCMPn_ SHDW1	XCMPn_ SHDW1	CPU loads new shadow value set. Load event occurs. SHDWBUFPtr set to 3
ePWM Cycle 6	Clear	Set	Set	XTBPRD_ SHDW3	XCMPn_ SHDW3	XCMPn_ SHDW3	SHDWBUFPtr set to 3
ePWM Cycle 7	Clear	Clear	Set	XTBPRD_ SHDW2	XCMPn_ SHDW2	XCMPn_ SHDW2	SHDWBUFPtr set to 2
ePWM Cycle 8	Clear	Clear	Clear	XTBPRD_ SHDW1	XCMPn_ SHDW1	XCMPn_ SHDW1	SHDWBUFPtr set to 1
ePWM Cycle 9	Clear	Clear	Clear	XTBPRD_ SHDW1	XCMPn_ SHDW1	XCMPn_ SHDW1	Continues operation with the same values in XCMPn_ACTIVE until the next buffer load event. SHDWBUFPtr set to 1
ePWM Cycle 10	Set	Set	Set	XTBPRD_ SHDW1	XCMPn_ SHDW1	XCMPn_ SHDW1	CPU loads new shadow register set. Load event occurs. SHDWBUFPtr set to 3

## 22.8 Dead-Band Generator (DB) Submodule

Figure 22-40 illustrates the dead-band submodule within the ePWM.

**Figure 22-40. Dead\_Band Submodule**

### 22.8.1 Purpose of the Dead-Band Submodule

The action-qualifier (AQ) module section discussed how the AQ module can generate the required dead band by having full control over edge placement using both the CMPA and CMPB resources of the ePWM module. However, if the more classical edge delay-based dead band with polarity control is required, then the dead-band submodule described here must be used.

The key functions of the dead-band module are:

- Generating appropriate signal pairs (EPWMxA and EPWMxB) with dead-band relationship from a single EPWMxA input
- Programming signal pairs for:
  - Active high (AH)
  - Active low (AL)
  - Active high complementary (AHC)
  - Active low complementary (ALC)
- Adding programmable delay to rising edges (RED)
- Adding programmable delay to falling edges (FED)
- Can be totally bypassed from the signal path (note dotted lines in diagram)

### 22.8.2 Dead-band Submodule Additional Operating Modes

On type 1 ePWM RED can appear on one channel output and FED can appear on the other channel output.

The following list shows the distinct difference between type 1 and type 4 modules with respect to dead-band operating modes:

- By adding S6, S7, and S8 in [Figure 22-41](#), RED and FED can appear on both the A-channel and B-channel outputs. Additionally, both RED and FED together can be applied to either the A-channel or B-channel outputs to allow B-channel phase shifting with respect to the A-channel.

---

#### Note

Phase shifting B-channel with respect to the A-channel using the dead-band submodule additional operating modes has limitations with respect to the choice of RED and FED delay with respect to the operating duty cycle of the ePWMxA and ePWMxB outputs.

---

- The dead-band counters have also been increased to 14 bits
- Deadband and deadband high-resolution registers are now shadowed
- High-resolution deadband RED and FED have been enabled using the DBREDHR and DBFEDHR registers

---

#### Note

The PWM chopper is not enabled when high-resolution deadband is enabled.

High-resolution deadband RED and FED requires half-cycle clocking mode (DBCTL[HALFCYCLE] = 1).

Cannot have both RED and FED together applied to both ePWMxA and ePWMxB. RED and FED together can be applied only to either OutA OR OutB.

Phase shifting B-channel with respect to the A-channel: When PWMxB is derived from PWMxA using the DEDB\_MODE bit and by delaying rising edge and falling edge by the phase shift amount. When the duty cycle value on PWMxA is less than this phase shift amount, PWMxA's falling edge has precedence over the delayed rising edge for PWMxB. Make sure the duty cycle value of the current waveform applied to the dead-band module is greater than the required phase shift amount.

The Type 4 action qualifier and dead-band outputs of the ePWM module are delayed by one TBCLK cycle in comparison to the Type 2 ePWM module, although the Type 4 behavior is the same as the Type 3 PWM. Both PWMA and PWMB signals are delayed under all circumstances.

---

### Shadow Mode:

The shadow mode for the DBRED is enabled by setting the DBCTL[SHDWDBREDDMODE] bit and the shadow register for DBFED is enabled by setting the DBCTL [SHDWDBFEDMODE] bit. Shadow mode is disabled by default for both DBRED and DBFED

If the shadow register is enabled, then the content of the shadow register is transferred to the active register on one of the following events as specified by the DBCTL [LOADREDDMODE] and DBCTL [LOADFEDMODE] register bits:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
- Both CTR = PRD and CTR = Zero

The DBCTL register can be shadowed. The shadow mode for DBCTL is enabled by setting the DBCTL2[SHDWDBCTLMODE] bit. If the shadow register is enabled then the content of the shadow register is transferred to the active register on one of the following events as specified by the DBCTL2[LOADDBCTLMODE] register bit:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD)
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
- Both CTR = PRD and CTR = Zero

---

#### Note

The application software must enable shadow load mode in the DBCTL[SHDWDBREDDMODE] and DBCTL[SHDWDBFEDMODE] **before** programming values for the DBRED and DBFED registers. If the shadow register is enabled **after** programming the DBRED and DBFED registers, the DBRED and DBFED registers are loaded with a value of 0.

---

### Global Load Support

Global load control mechanism can also be used for DBRED:DBREDHR, DBFED:DBFEDHR, and DBCTL registers by configuring the appropriate bits in the global load configuration register (GLDCFG). When global load mode is selected the transfer of contents from shadow register to active register, for all registers that have this mode enabled, occurs at the same event as defined by the configuration bits in the Global Shadow to Active Load Control Register (GLDCTL). The Global load control mechanism is explained in [Section 22.4.7](#).

---

#### Note

When DBRED/DBFED active is loaded with a new shadow value while DB counters are counting, the new DBRED/DBFED value only affects the NEXT PWMx edge and not the current edge.

A Deadband value of zero cannot be used when the Global Shadow to Active Load is set to occur at CTR=ZERO. Similarly, a Deadband value of PRD cannot be used when the Global Shadow to Active Load is set to occur at CTR=PRD.

---

### Linking DBRED and DBFED

Starting with type 5 EPWM, the DBRED and DBFED values can be linked from one ePWM to another. This allows for simultaneous writes to all linked ePWM registers. For more information, review the EPWMXLINK2 register.

### 22.8.3 Operational Highlights for the Dead-Band Submodule

The configuration options for the dead-band submodule are shown in Figure 22-41.

Figure 22-41. Configuration Options for the Dead-Band Submodule

Although all combinations are supported, not all are typical usage modes. Table 22-10 documents some classical dead-band configurations. These modes assume that the DBCTL[IN\_MODE] is configured such that EPWMxA In is the source for both falling-edge and rising-edge delay. Enhanced, or non-traditional modes can be achieved by changing the input signal source. The modes shown in Table 22-10 fall into the following categories:

- **Mode 1: Bypass both falling-edge delay (FED) and rising-edge delay (RED):** Allows the user to fully disable the dead-band submodule from the PWM signal path.
- **Mode 2-5: Classical Dead-Band Polarity Settings:** These represent typical polarity configurations that can address all the active-high and active-low modes required by available industry power switch gate drivers. The waveforms for these typical cases are shown in Figure 22-42. Note that to generate equivalent waveforms to Figure 22-42, configure the action-qualifier submodule to generate the signal as shown for EPWMxA.
- **Mode 6: Bypass rising-edge delay (RED) and Mode 7: Bypass falling-edge delay (FED):** Finally the last two entries in Table 22-10 show combinations where either the falling-edge delay (FED) or rising-edge delay (RED) blocks are bypassed.

Figure 22-42 shows waveforms for typical cases where  $0% < \text{duty} < 100%$ .

**Table 22-10. Classical Dead-Band Operating Modes**

Mode	Mode Description	DBCTL[POLSEL]		DBCTL[OUT_MODE]	
		S3	S2	S1	S0
1	EPWMxA and EPWMxB Passed Through (No Delay)	X	X	0	0
2	Active High Complementary (AHC)	1	0	1	1
3	Active Low Complementary (ALC)	0	1	1	1
4	Active High (AH)	0	0	1	1
5	Active Low (AL)	1	1	1	1
6	EPWMxA Out = EPWMxA In (No Delay)	0 or 1	0 or 1	0	1
	EPWMxB Out = EPWMxA In with Falling-Edge Delay				
7	EPWMxA Out = EPWMxA In with Rising-Edge Delay	0 or 1	0 or 1	1	0
	EPWMxB Out = EPWMxB In with No Delay				

**Table 22-11. Additional Dead-Band Operating Modes**

Mode Description	DBCTL[DEDB-MODE]	DBCTL[OUTSWAP]	
	S8	S6	S7
EPWMxA and EPWMxB signals are as defined by OUT-MODE bits.	0	0	0
EPWMxA = A-path as defined by OUT-MODE bits.	0	0	1
EPWMxB = A-path as defined by OUT-MODE bits (rising-edge delay or delay-bypassed A-signal path)			
EPWMxA = B-path as defined by OUT-MODE bits (falling-edge delay or delay-bypassed B-signal path)	0	1	0
EPWMxB = B-path as defined by OUT-MODE bits			
EPWMxA = B-path as defined by OUT-MODE bits (falling-edge delay or delay-bypassed B-signal path)	0	1	1
EPWMxB = A-path as defined by OUT-MODE bits (rising-edge delay or delay-bypassed A-signal path)			
Rising-edge delay applied to EPWMxA / EPWMxB as selected by S4 switch (IN-MODE bits) on A signal path only.	0	X	X
Falling-edge delay applied to EPWMxA / EPWMxB as selected by S5 switch (IN-MODE bits) on B signal path only.			
Rising-edge delay and falling-edge delay applied to source selected by S4 switch (IN-MODE bits) and output to B signal path only. <sup>(1)</sup>	1	X	X

- (1) When this bit is set to 1, the user can always either set OUT\_MODE bits such that Apath = InA or set OUTSWAP bits such that EPWMxA=Bpath. Otherwise, EPWMxA is invalid.

**Figure 22-42. Dead-Band Waveforms for Typical Cases (0% < Duty < 100%)**

The dead-band submodule supports independent values for rising-edge (RED) and falling-edge (FED) delays. The amount of delay is programmed using the DBRED and DBFED registers. These are 10-bit registers and the value represents the number of TBCLK (time-base clock) pulses by which a signal edge is delayed. For example, the formula to calculate falling-edge-delay and rising-edge-delay is:

$$FED = DBFED \times T_{TBCLK}$$

$$RED = DBRED \times T_{TBCLK}$$

Where  $T_{TBCLK}$  is the period of TBCLK, the prescaled version of EPWMCLK.

For convenience, delay values for various TBCLK options are shown in [Table 22-12](#). The ePWM input clock frequency that these delay values been computed by is 100MHz.

**Table 22-12. Dead-Band Delay Values in  $\mu$ s as a Function of DBFED and DBRED**

Dead-Band Value		Dead-Band Delay ( $\mu$ s)		
DBFED, DBRED	TBCLK = EPWMCLK/1	TBCLK = EPWMCLK /2	TBCLK = EPWMCLK/4	
1	0.01	0.02	0.04	
5	0.05	0.10	0.20	
10	0.10	0.20	0.40	
100	1.00	2.00	4.00	
200	2.00	4.00	8.00	
400	4.00	8.00	16.00	
500	5.00	10.00	20.00	
600	6.00	12.00	24.00	
700	7.00	14.00	28.00	
800	8.00	16.00	32.00	
900	9.00	18.00	36.00	
1000	10.00	20.00	40.00	

When half-cycle clocking is enabled, the formula to calculate the falling-edge-delay and rising-edge-delay becomes:

$$FED = DBFED \times T_{TBCLK}/2$$

$$RED = DBRED \times T_{TBCLK}/2$$

## 22.9 PWM Chopper (PC) Submodule

The PWM chopper submodule allows a high-frequency carrier signal to modulate the PWM waveform generated by the action-qualifier and dead-band submodules. This capability is important if pulse transformer-based gate drivers to control the power switching elements are needed.

Figure 22-43 illustrates the PWM chopper submodule within the ePWM.

Figure 22-43. PWM Chopper Submodule

### 22.9.1 Purpose of the PWM Chopper Submodule

The key functions of the PWM chopper submodule are:

- Programmable chopping (carrier) frequency
- Programmable pulse width of first pulse
- Programmable duty cycle of second and subsequent pulses
- Can be fully bypassed if not required

### 22.9.2 Operational Highlights for the PWM Chopper Submodule

Figure 22-44 shows the operational details of the PWM chopper submodule. The carrier clock is derived from EPWMCLK. The clock frequency and duty cycle are controlled using the CHPFREQ and CHPDUTY bits in the PCCTL register. The one-shot block is a feature that provides a high energy first pulse to make sure hard and fast power switch turn on, while the subsequent pulses sustain pulses, making sure the power switch remains on. The one-shot width is programmed using the OSHTWTH bits. The PWM chopper submodule can be fully disabled (bypassed) using the CHPEN bit.

Figure 22-44. PWM Chopper Submodule Operational Details

### 22.9.3 Waveforms

Figure 22-45 shows simplified waveforms of the chopping action only; one-shot and duty-cycle control are not shown. Details of the one-shot and duty-cycle control are discussed in the following sections.

Figure 22-45. Simple PWM Chopper Submodule Waveforms Showing Chopping Action Only

### 22.9.3.1 One-Shot Pulse

The width of the first pulse can be programmed to any of 16 possible pulse width values. The width or period of the first pulse is given by:

$$T_{1stpulse} = T_{EPWMCLK} \times 8 \times OSHTWTH$$

Where  $T_{EPWMCLK}$  is the period of the system clock (EPWMCLK) and OSHTWTH is the four control bits (value from 1 to 16)

Figure 22-46 shows the first and subsequent sustaining pulses and Table 22-13 gives the possible pulse width values for a EPWMCLK = 80MHz.

**Figure 22-46. PWM Chopper Submodule Waveforms Showing the First Pulse and Subsequent Sustaining Pulses**

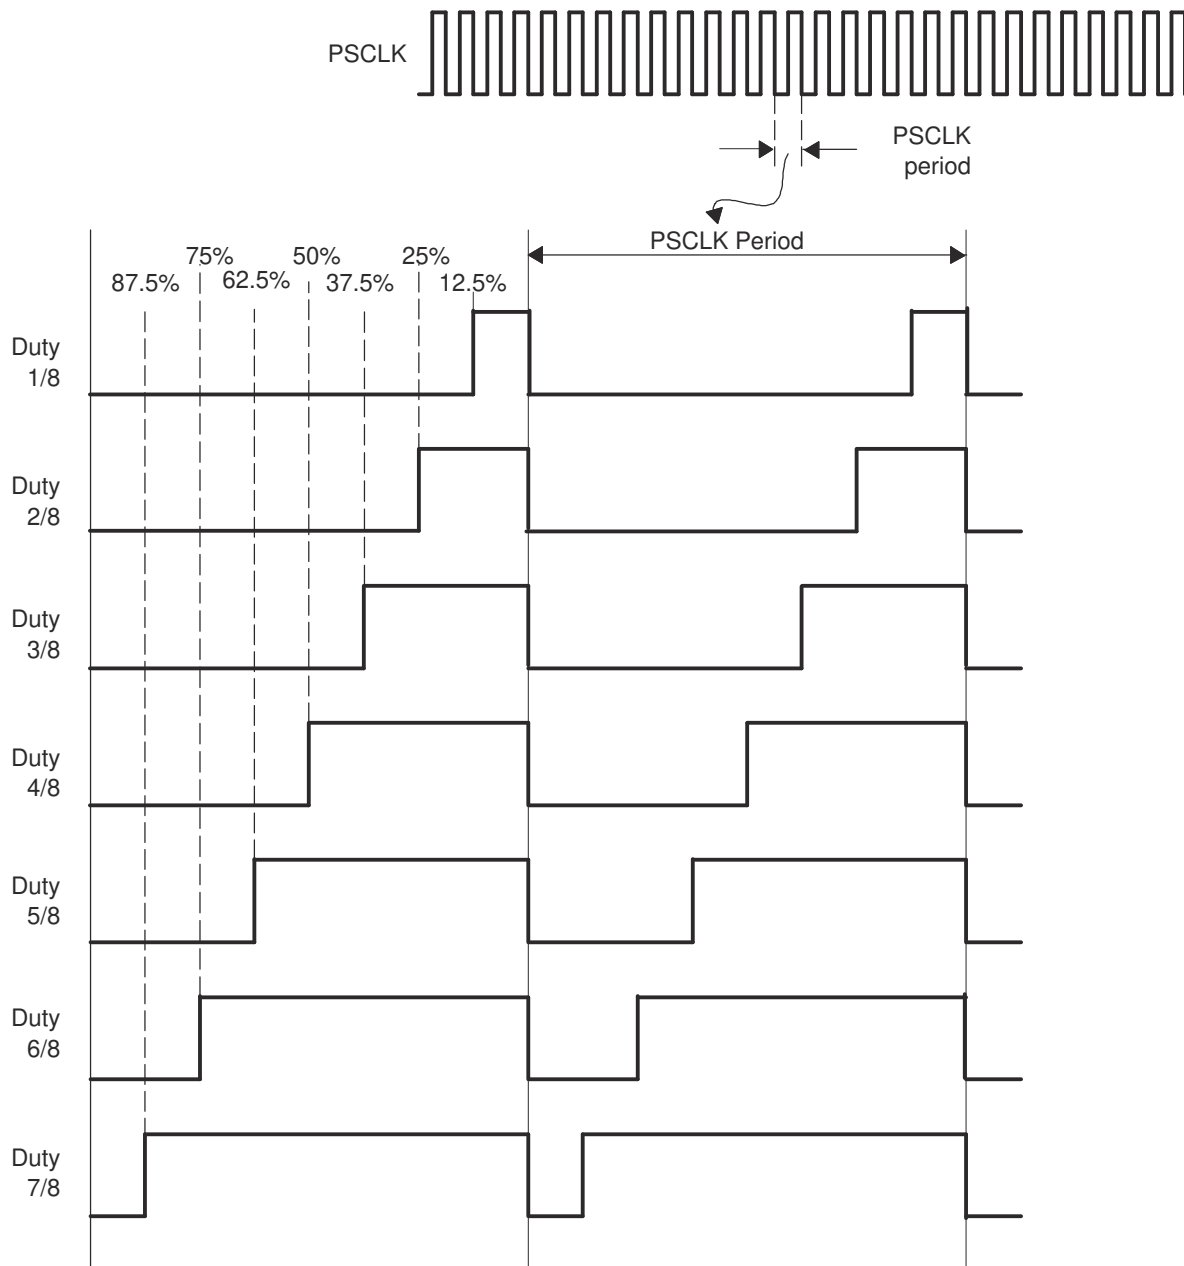

**Table 22-13. Possible Pulse Width Values for EPWMCLK = 80MHz**

OSHTWTH (hex)	Pulse Width (ns)
0	100
1	200
2	300
3	400
4	500
5	600
6	700
7	800
8	900
9	1000
A	1100
B	1200
C	1300
D	1400
E	1500
F	1600

### 22.9.3.2 Duty Cycle Control

Pulse transformer-based gate drive designs need to comprehend the magnetic properties or characteristics of the transformer and associated circuitry. Saturation is one such consideration. To assist the gate drive designer, the duty cycles of the second and subsequent pulses have been made programmable. These sustaining pulses make sure the correct drive strength and polarity is maintained on the power switch gate during the on period, and hence a programmable duty cycle allows a design to be tuned or optimized using software control.

Figure 22-47 shows the duty cycle control that is possible by programming the CHPDUTY bits. One of seven possible duty ratios can be selected ranging from 12.5% to 87.5%.

**Figure 22-47. PWM Chopper Submodule Waveforms Showing the Pulse Width (Duty Cycle) Control of Sustaining Pulses**

## 22.10 Trip-Zone (TZ) Submodule

Each ePWM module is connected to six  $\overline{TZn}$  signals ( $\overline{TZ1}$  to  $\overline{TZ6}$ ).  $\overline{TZ1}$  to  $\overline{TZ3}$  are sourced from the GPIO mux.  $\overline{TZ4}$  is sourced from an inverted EQEPxERR signal on those devices with an EQEP module.  $\overline{TZ5}$  is connected to the system clock fail logic, and  $\overline{TZ6}$  is sourced from the EMUSTOP output from the CPU. These signals indicate external fault or trip conditions, and the ePWM outputs can be programmed to respond accordingly when faults occur.

Figure 22-48 illustrates the trip-zone submodule within the ePWM.

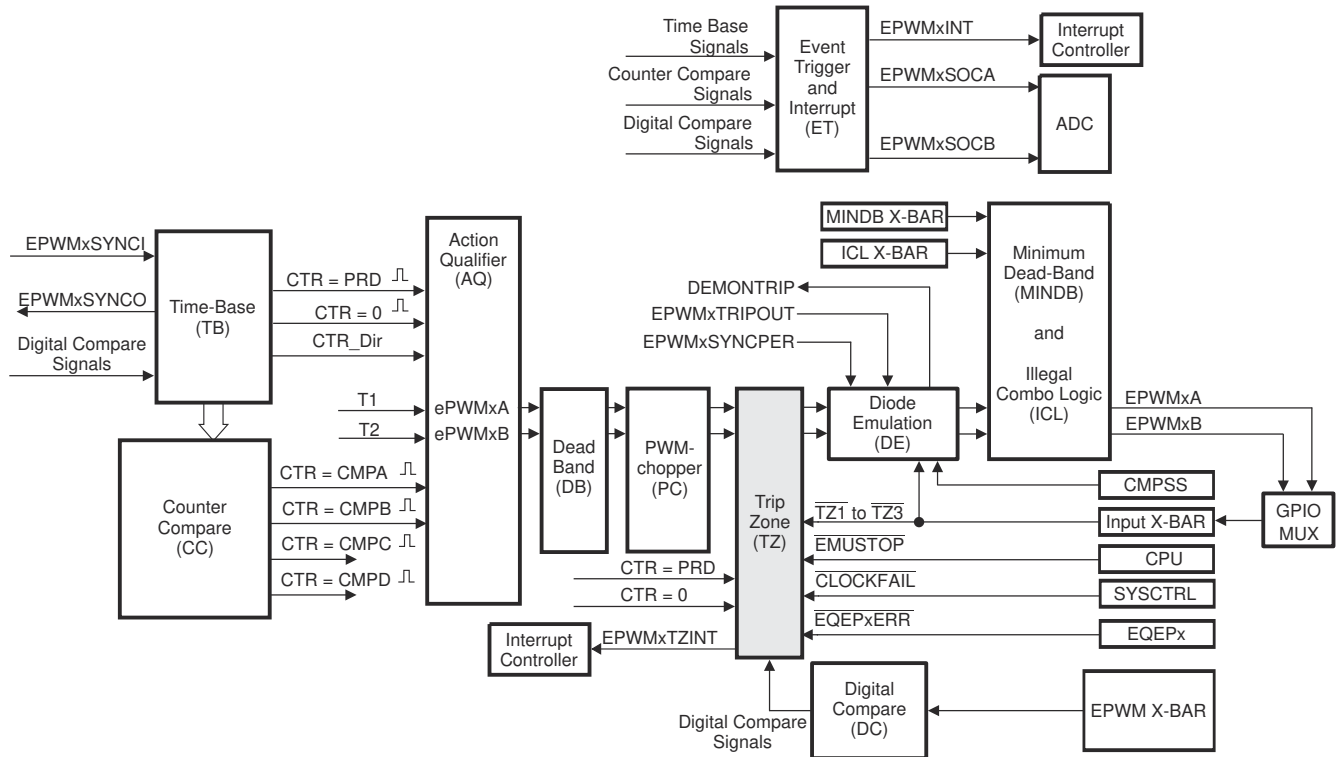

Figure 22-48. Trip-Zone Submodule

### 22.10.1 Purpose of the Trip-Zone Submodule

The key functions of the trip-zone submodule are:

- Trip inputs  $\overline{TZ1}$  to  $\overline{TZ6}$  can be flexibly mapped to any ePWM module.
- Upon a fault condition, outputs EPWMxA and EPWMxB can be forced to one of the following:
  - High
  - Low
  - High-impedance
  - No action taken
- Support for one-shot trip (OSHT) for major short circuits or over-current conditions.
- Support for cycle-by-cycle tripping (CBC) for current limiting operation.
- Support for digital compare tripping (DC) based on state of on-chip analog comparator module outputs and  $\overline{TZ1}$  to  $\overline{TZ3}$  signals.
- Each trip-zone input and digital compare (DC) submodule DCAEVT1/2 or DCBEVT1/2 force event can be allocated to either one-shot or cycle-by-cycle operation.
- Interrupt generation is possible on any trip-zone input.
- Software-forced tripping is also supported.
- The trip-zone submodule can be fully bypassed if the trip-zone submodule is not required.

### 22.10.2 Operational Highlights for the Trip-Zone Submodule

The following sections describe the operational highlights and configuration options for the trip-zone submodule.

The trip-zone signals  $\overline{TZ1}$  to  $\overline{TZ6}$  (also collectively referred to as  $\overline{TZn}$ ) are active-low input signals. When one of these signals goes low, or when a DCAEVT1/2 or DCBEVT1/2 force happens based on the TZDCSEL register event selection, the indication is that a trip event has occurred. Each ePWM module can be individually configured to ignore or use each of the trip-zone signals or DC events. Which trip-zone signals or DC events are used by a particular ePWM module is determined by the TZSEL register for that specific ePWM module. The trip-zone signals can or cannot be synchronized to the ePWMclock (EPWMCLK) and digitally filtered within the GPIO MUX block. A minimum of  $3 \cdot TBCLK$  low pulse width on  $\overline{TZn}$  inputs is sufficient to trigger a fault condition on the ePWM module. If the pulse width is less than this, the trip condition cannot be latched by CBC or OST latches. The asynchronous trip makes sure that if clocks are missing for any reason, the outputs can still be tripped by a valid event present on  $\overline{TZn}$  inputs. The GPIOs or peripherals must be appropriately configured. For more information, see the *System Control and Interrupts* chapter.

Each  $\overline{TZn}$  input can be individually configured to provide either a cycle-by-cycle or one-shot trip event for an ePWM module. DCAEVT1 and DCBEVT1 events can be configured to directly trip an ePWM module or provide a one-shot trip event to the module. Likewise, DCAEVT2 and DCBEVT2 events can also be configured to directly trip an ePWM module or provide a cycle-by-cycle trip event to the module. This configuration is determined by the TZSEL[DCAEVT1/2], TZSEL[DCBEVT1/2], TZSEL[CBCn], and TZSEL[OSHTn] control bits (where n corresponds to the trip input), respectively.

- **Cycle-by-Cycle (CBC):**

When a cycle-by-cycle trip event occurs, the action specified in the TZCTL[TZA] and TZCTL[TZB] bits is carried out immediately on the EPWMxA and EPWMxB outputs. [Table 22-14](#) lists some of the possible actions. Independent actions can be specified based on the occurrence of the event while the counter is counting up or while the counter is counting down by appropriately configuring bits in the TZCTL2 register. Actions specified in the TZCTL2 register take effect only when the ETZE bit in TZCTL2 is set.

Additionally, when a cycle-by-cycle trip event occurs, the cycle-by-cycle trip event flag (TZFLG[CBC]) is set and a EPWMx\_TZINT interrupt is generated when enabled in the TZEINT register and interrupt controller. A corresponding flag for the event that caused the CBC event is also set in register TZCBCFLG.

If the CBC interrupt is enabled using the TZEINT register and DCAEVT2 or DCBEVT2 are selected as CBC trip sources using the TZSEL register, it is not necessary to also enable the DCAEVT2 or DCBEVT2 interrupts in the TZEINT register, as the DC events trigger interrupts through the CBC mechanism.

The specified condition on the inputs is automatically cleared based on the selection made with TZCLR[CBCPULSE] if the trip event is no longer present. Therefore, in this mode, the trip event is cleared or reset every PWM cycle. The TZFLG[CBC] and TZCBCFLG flag bits remain set until the flag bits are manually cleared by writing to the TZCLR[CBC] and TZCBCCLR flag bits. If the cycle-by-cycle trip event is still present when the TZFLG[CBC] and TZCBCFLG register bits are cleared, then these bits are again immediately set.

- **One-Shot (OSHT):**

When a one-shot trip event occurs, the action specified in the TZCTL[TZA] and TZCTL[TZB] bits is carried out immediately on the EPWMxA and EPWMxB output. [Table 22-14](#) lists some of the possible actions. Independent actions can be specified based on the occurrence of the event while the counter is counting up and while the counter is counting down by appropriately configuring bits in TZCTL2 register. Actions specified in TZCTL2 register take effect only when ETZE bit in TZCTL2 is set.

Additionally, when a one-shot trip event occurs, the one-shot trip event flag (TZFLG[OST]) is set and a EPWMx\_TZINT interrupt is generated when enabled in the TZEINT register and interrupt controller. A corresponding flag for the event that caused the OST event is also set in register TZOSTFLG. The one-shot trip condition must be cleared manually by writing to the TZCLR[OST] bit. If desired, the TZOSTFLG register bit can be cleared by manually writing to the corresponding bit in the TZOSTCLR register.

If the one-shot interrupt is enabled using the TZEINT register and DCAEVT1 or DCBEVT1 are selected as OSHT trip sources using the TZSEL register, it is not necessary to also enable the DCAEVT1 or DCBEVT1 interrupts in the TZEINT register, as the DC events trigger interrupts through the OSHT mechanism.

---

#### Note

Clear the TZFLG and TZOSTFLG flags after making sure that the TRIPIN source of the OST has become inactive. Otherwise, if interrupts are enabled, depending on when the flags are cleared, an OST interrupt can occur and the OST flags are zero.

---

- **Digital Compare Events (DCAEVT1/2 and DCBEVT1/2):**

A digital compare DCAEVT1/2 or DCBEVT1/2 event is generated based on a combination of the DCAH/DCAL and DCBH/DCBL signals as selected by the TZDCSEL register. The signals which source the DCAH/DCAL and DCBH/DCBL signals are selected using the DCTRIPSEL register and can be either trip zone input pins or analog comparator CMPSSx signals. For more information on the digital compare submodule signals, see [Section 22.14](#).

When a digital compare event occurs, the action specified in the TZCTL[DCAEVT1/2] and TZCTL[DCBEVT1/2] bits is carried out immediately on the EPWMxA and EPWMxB output. [Table 22-14](#) lists the possible actions. Independent actions can be specified based on the occurrence of the event while the counter is counting up and while the counter is counting down by appropriately configuring bits in TZCTLDCA and TZCTLDCA and TZCTLDCA and TZCTLDCA registers take effect only when ETZE bit in TZCTL2 is set.

In addition, the relevant DC trip event flag (TZFLG[DCAEVT1/2] / TZFLG[DCBEVT1/2]) is set and a EPWMx\_TZINT interrupt is generated when enabled in the TZEINT register and interrupt controller.

The specified condition on the pins is automatically cleared when the DC trip event is no longer present. The TZFLG[DCAEVT1/2] or TZFLG[DCBEVT1/2] flag bit remains set until the flag is manually cleared by writing to the TZCLR[DCAEVT1/2] or TZCLR[DCBEVT1/2] bit. If the DC trip event is still present when the TZFLG[DCAEVT1/2] or TZFLG[DCBEVT1/2] flag is cleared, then the flag is again immediately set.

- **Edge detection within a programmable TBCTR range (CAPEVT):**

An edge detection within a programmable TBCTR range is added in type 5 ePWM. When a CAPIN edge does not occur within a specified range of TBCTR values, the CAPEVT signal is generated. The TBCTR range during which a CAPIN edge must occur is determined by XMINMAX\_ACTIVE register. A gating signal CAPGATE can also be used to gate the CAPIN edge. For more information on the CAPEVT signal, see [Section 22.14.4.4](#).

In addition, the EPWMx\_TZINT interrupt is generated when enabled in the TZEINT register and interrupt controller.

The TZFLG[CAPEVT] flag bit remains set until the flag is manually cleared by writing to the TZCLR[CAPEVT] bit. If the CAPEVT event is still present when the TZFLG[CAPEVT] flag is cleared, then the flag is again immediately set.

The action taken when a trip event occurs can be configured individually for each of the ePWM output pins by way of the TZCTL, TZCTL2, TZCTLDCA, and TZCTLDCB register bit fields. Some of the possible actions, shown in Table 22-14, can be taken on a trip event.

The trip signal generated by the ePWM module can be selected through the TZTRIPOUTSEL register. This register has an ORed version of all the enabled trip signals. The TRIPOUT signal is routed to eCAP Trip Mux, PWM-XBAR and Output-XBAR.

**Figure 22-49. Trip-Zone TRIPOUT Selection**

**Table 22-14. Possible Actions On a Trip Event**

TZCTL Register Bitfield Settings	EPWMxA and EPWMxB	Comment
0,0	High-Impedance	Tripped
0,1	Force to High State	Tripped
1,0	Force to Low State	Tripped
1,1	No Change	Do Nothing. No change is made to the output.

### Example 22-1. Trip-Zone Configurations

#### Scenario A:

A one-shot trip event on  $\overline{TZ1}$  pulls both EPWM1A, EPWM1B low and also forces EPWM2A and EPWM2B high.

- Configure the ePWM1 registers as follows:
  - TZSEL[OSHT1] = 1: enables  $\overline{TZ1}$  as a one-shot event source for ePWM1
  - TZCTL[TZA] = 2: EPWM1A is forced low on a trip event.
  - TZCTL[TZB] = 2: EPWM1B is forced low on a trip event.
- Configure the ePWM2 registers as follows:
  - TZSEL[OSHT1] = 1: enables  $\overline{TZ1}$  as a one-shot event source for ePWM2
  - TZCTL[TZA] = 1: EPWM2A is forced high on a trip event.
  - TZCTL[TZB] = 1: EPWM2B is forced high on a trip event.

#### Scenario B:

A cycle-by-cycle event on  $\overline{TZ5}$  pulls both EPWM1A, EPWM1B low.

A one-shot event on  $\overline{TZ1}$  or  $\overline{TZ6}$  puts EPWM2A into a high impedance state.

- Configure the ePWM1 registers as follows:
  - TZSEL[CBC5] = 1: enables  $\overline{TZ5}$  as a cycle-by-cycle event source for ePWM1
  - TZCTL[TZA] = 2: EPWM1A is forced low on a trip event.
  - TZCTL[TZB] = 2: EPWM1B is forced low on a trip event.
- Configure the ePWM2 registers as follows:
  - TZSEL[OSHT1] = 1: enables  $\overline{TZ1}$  as a one-shot event source for ePWM2
  - TZSEL[OSHT6] = 1: enables  $\overline{TZ6}$  as a one-shot event source for ePWM2
  - TZCTL[TZA] = 0: EPWM2A is put into a high-impedance state on a trip event.
  - TZCTL[TZB] = 3: EPWM2B ignores the trip event.

#### Note

When configuring the GPIOs and INPUT X-BAR/EPWM X-BAR options, be aware that a change in the X-BAR input selections can cause an unwanted event. Therefore, set up the GPIO and X-BAR input configurations before enabling the ePWM Trip-Zone. If a requirement is to change the GPIO/X-BAR configurations while the ePWM Trip-Zone is enabled, the user can turn off the TRIPs by clearing the TZSEL register and reconfiguring the TRIP selection (TZSEL) after the INPUT XBAR selection is changed.

### 22.10.3 Generating Trip Event Interrupts

Figure 22-50 and Figure 22-51 illustrate the trip-zone submodule control and interrupt logic, respectively. DCAEVT1/2 and DCBEVT1/2 signals are described in further detail in Section 22.14.

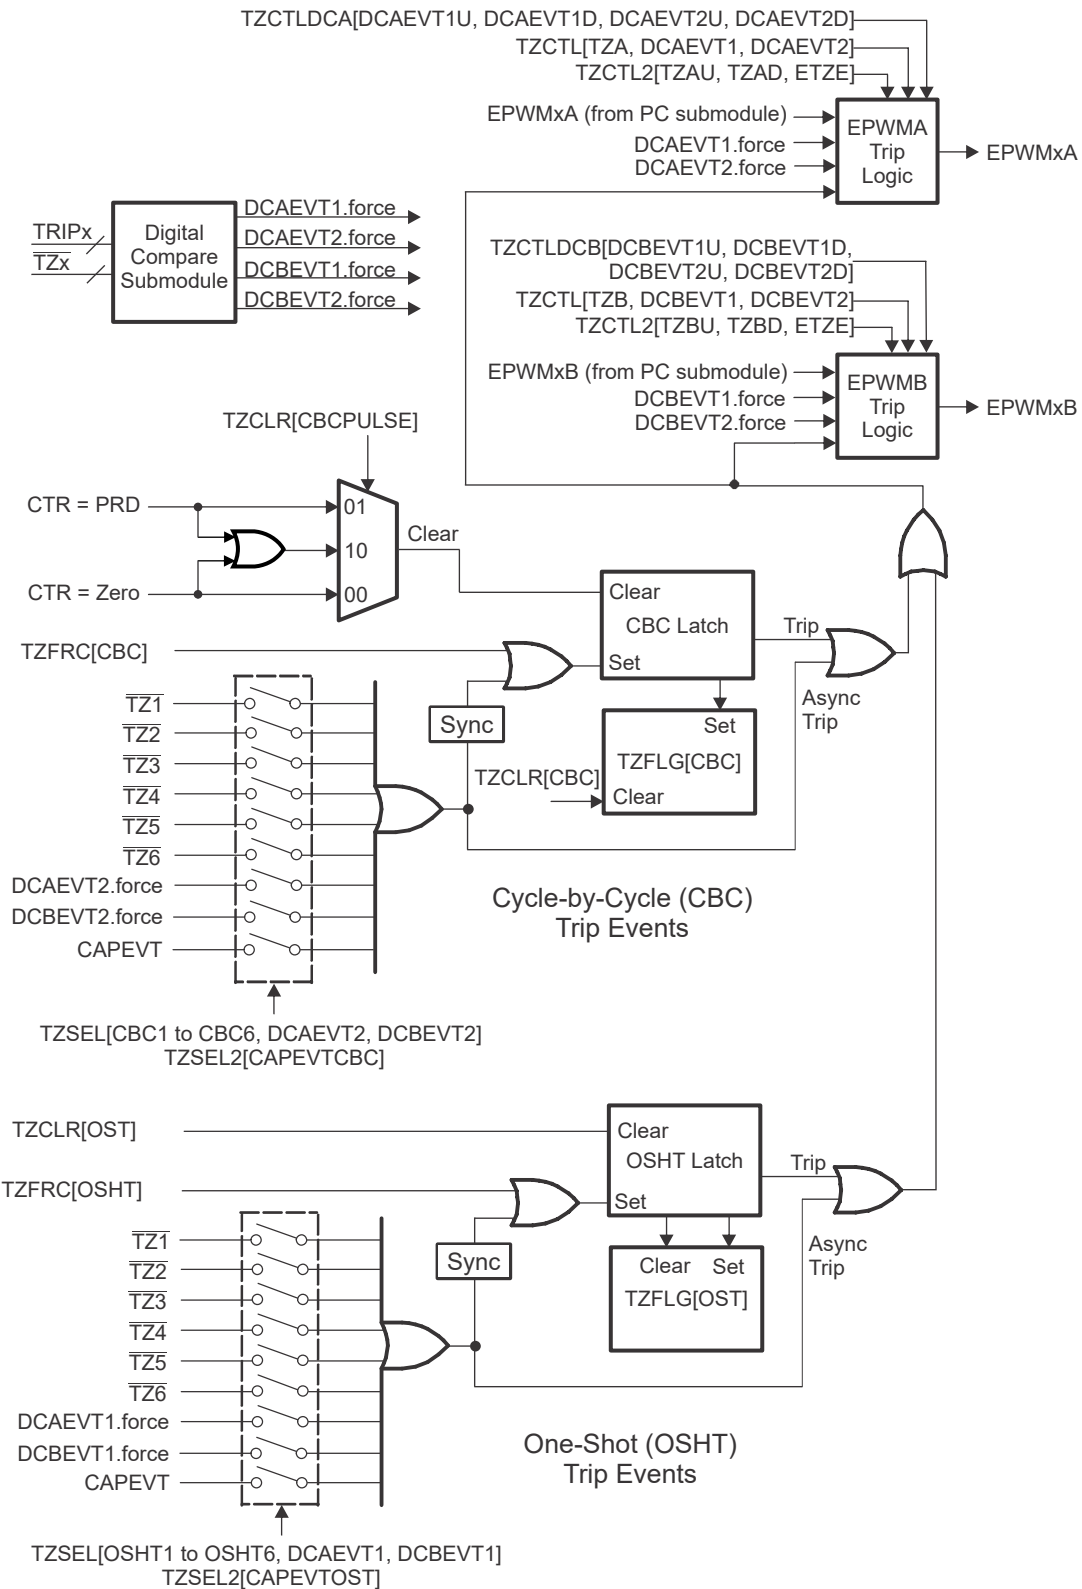

Figure 22-50. Trip-Zone Submodule Mode Control Logic

Figure 22-51. Trip-Zone Submodule Interrupt Logic

The signal CAPEVT is generated from the Capture Control Logic and is available in type 5 EPWM.

These individual flags for the CBC, OST and DCxEVTy can be used to detect the source of the EPWMxTZINT Interrupt. When multiple sources are used to generate the EPWMxTZINT interrupt, reading and clearing the flags takes different actions based on the specific event.

## 22.11 Diode Emulation (DE) Submodule

The purpose of the Diode Emulation logic is to provide hardware features and the necessary hooks into other IPs to implement robust diode mode sense and control in a noisy environment.

Diode Emulation features include:

- Ability to choose any of the comparator outputs as trips to detect entry into DE mode.
- Ability to switch the comparator thresholds, dynamically in hardware upon DE mode entry.
- Two modes of clearing/de-evaluating the DE condition:
  - Software clear
  - Cycle-by-cycle clear on PWMSYNC event
- Configurable source selects of ePWM in DE mode.
- Ability to monitor the DE mode duration and generate a trip event to ePWMs.

Figure 22-52 illustrates the diode emulation submodule within the ePWM.

Figure 22-52. Diode Emulation Submodule

Figure 22-53 shows the interfaces to the DE block. As can be seen from the diagram, DE function is associated with an instance of ePWMx. The EPWMxA and EPWMxB signals from a given instance of ePWM module pass through the associated DE block and minimum dead band logic. In addition to EPWMxA and EPWMxB, two signals, EPWMxA\_DB\_NO\_HR and EPWMxB\_DB\_NO\_HR are tapped from the ePWM modules. These two signals are PWM signals that are tapped before the signals pass through the high-resolution delay lines and come from the dead-band submodule outputs. If high-resolution is not used, then EPWMxA\_DB\_NO\_HR and EPWMxB\_DB\_NO\_HR are just the outputs of the dead-band submodule.

Figure 22-53. Diode Emulation Block Diagram

The DE block can be configured to select one of the comparators or one of the outputs of the Input X-Bar or CLB Input X-Bar, as source of trip signals (TRIPH, TRIPL). The selected comparator is responsible for monitoring the current in the external power converter. Comparator thresholds (High and Low threshold) can be set such that, any breach of these thresholds indicates a need to switch to the DE mode.

Once DE mode is entered, indicated by setting of DEACTIVE flag, the ePWMs sent out of DE block are controlled by configuration registers in the DE block, and are not be the same as ePWMA/B from the associated ePWM instance. Once the DEACTIVE flag is set, the threshold settings of the selected CMPSS are switched to a new set of values (a narrower region). DEACTIVE flag from all of the ePWM instances are hooked up to all the comparator sub-systems (CMPSSy) to enable threshold value switch on DE mode entry. Refer to the CMPSS chapter for more details on how the new threshold values are set.

**22.11.1 DEACTIVE Mode**

DE mode is entered when TRIPH\_OR\_TRIPL signal from the selected comparator (CMPSS) goes high. Once the diode emulation mode is entered, typically TRIPH or TRIPL are set and cleared in a sequence (at a given instance of time, TRIPH is high or TRIPL is high – never both) until the current settles within the threshold band.

**Figure 22-54. DEACTIVE Flag Functionality**

Once the DEACTIVE flag is set, the thresholds on CMPSS are changed to an alternate set of thresholds, and also ePWMA/B out of DE function are being controlled by the DEACTCTL register settings. Figure 22-55 demonstrates an example timing diagram illustrating entry into DE mode.

**Figure 22-55. Example Timing Sequence Illustrating DE Mode Entry**

### 22.11.2 Exiting DE Mode

DE mode can be exited in two ways, based on the DECTL[MODE] setting:

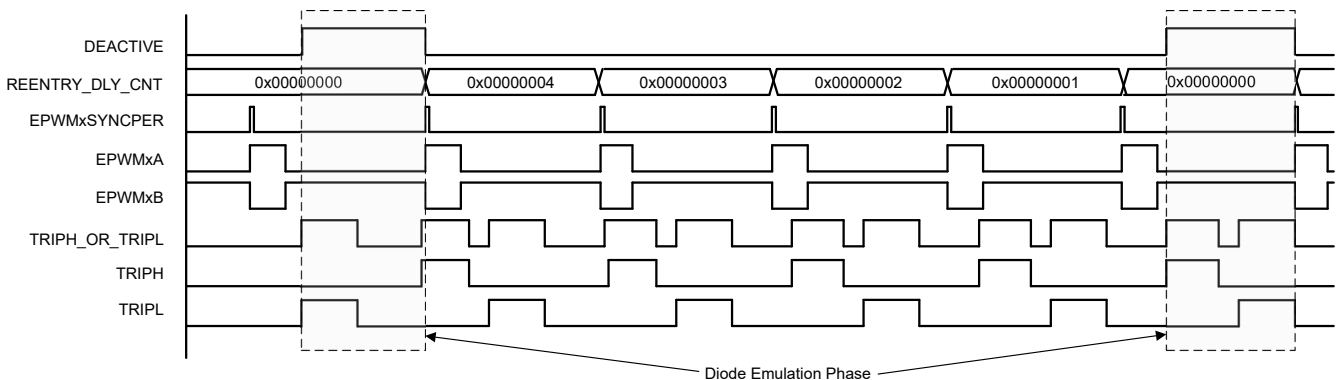

- Software clear of DEACTIVE flag, DECLR[CLR]
- Cycle-by-cycle clear mode, in which TRIPH\_OR\_TRIPL is evaluated on every EPWMxSYNCPER and if the trip condition is not present, then DEACTIVE flag is cleared. [Figure 22-56](#) illustrates the clearing of the DEACTIVE flag based on EPWMxSYNCPER.

**Figure 22-56. Cycle-by-Cycle Mode**

### 22.11.3 Re-Entering DE Mode

Once DE mode is exited, DE mode can be delayed for a certain duration until reentry. This is accomplished by configuring the DECTL[REENTRYDLY] field. REENTRYDLY determines the window in which TRIP signals are prevented from setting the DEACTIVE flag. On a falling edge of DEACTIVE, an internal counter is loaded with the DECTL[REENTRYDLY] value. The counter is decremented on every EPWMxSYNCPER as long as the count value is greater than 0. While the count value is greater than 0, TRIP signals are blocked and DEACTIVE flag is not set even if TRIP events are active.

**Figure 22-57. DE Mode Reentry Sequence**

[Figure 22-58](#) illustrates the circuit driving the EPWMxA/B signals from the DE block. As can be observed, when DEACTIVE flag is not set, EPWMA\_DE, EPWMB\_DE, EPWMA\_DE\_NO\_HR, and EPWMB\_DE\_NO\_HR are driven by EPWMA/B and EPWMA/B\_DB\_NO\_HR respectively. When DEACTIVE flag is set, EPWMA/B\_DE are driven by TRIPH, TRIPL, constant 0, or a constant 1 signal based on the configuration of the DEATCTL[PWMA], DEATCTL[PWMB], DEATCTL[TRIPSELA], DEATCTL[TRIPSELB] fields. When a PWMTRIP signal from the associated ePWM trips, EPWMA/B\_DE are driven by the input PWM signals configured through the DECTL[TRIPENABLE] field.

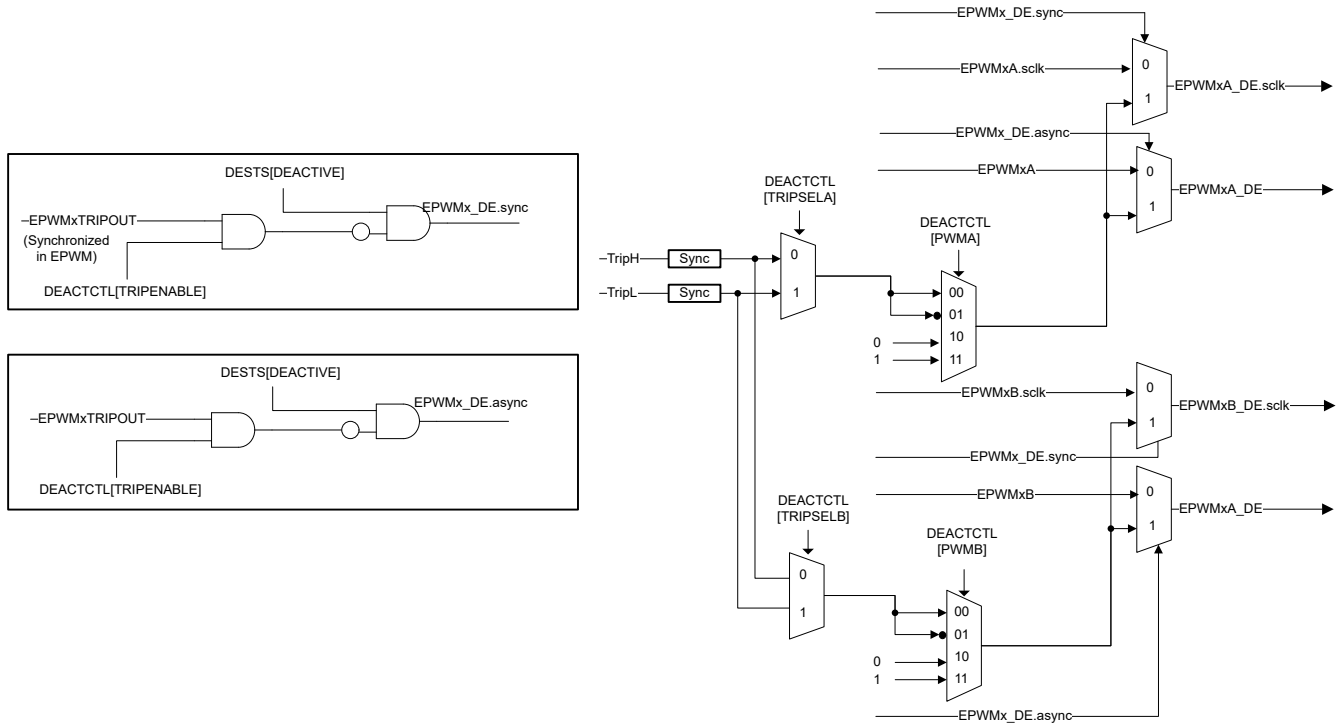

Figure 22-58. Diode Emulation Circuit

Figure 22-59 shows an example waveform, in which DEACTCTL[PWMA] is configured to select TripL as the source, DEACTCTL[PWMB] is configured to select TripH as the source and DEACTCTL[PWMAPOL] and DEACTCTL[PWMBPOL] are both 0.

Figure 22-59. Diode Emulation Mode Timing Diagram

### 22.11.4 DE Monitor

To detect extended DE phase, which is beyond the expected duration, a DE mode monitor counter, DEMONCNT, is provided. This 16-bit counter monitors the frequency of diode mode trip events. The counter if enabled, DEMONCTL[ENABLE], increments on a PWMSYNC event, in steps of DEMONSTEP[INCSTEP] when TRIPH\_OR\_TRIPL is high, and decrements on a PWMSYNC event, in steps of DEMONSTEP[DECSTEP] when TRIPH\_OR\_TRIPL is low. If counter exceeds DEMONTHRES[THRESHOLD], then a DEMONTRIP pulse is generated and the counter is cleared. The counter value is saturated to 0 during an underflow and 0xffff on an overflow. The counter is cleared when DECTL[ENABLE] is cleared.

Figure 22-60. DE Mode Monitor Sequence

## 22.12 Minimum Dead-Band (MINDB) + Illegal Combination Logic (ICL) Submodules

Figure 22-61 illustrates the minimum dead-band and illegal combo submodule within the ePWM.

Figure 22-61. Minimum Dead-Band and Illegal Combo Logic Submodule

### 22.12.1 Minimum Dead-Band (MINDB)

To make sure that the minimum dead band property is not violated, as the application switches between normal mode and DE mode and due to the PWMs potentially switching based on trip inputs, a minimum dead band circuitry show in Figure 22-62 is required.

Figure 22-62. Minimum Dead-Band and Illegal Combo Logic Block Diagram

The minimum dead band block provides the ability to configure the minimum dead band duration between a complimentary set of PWMs.

Minimum dead-band logic involves generating a blocking signal (BLOCKA, BLOCKB) after the falling edge of the EPWMA/B\_DE. These block signals are used to block transition on the other signal. The input to BLOCKA(B) signal generators is configurable. Normally the sources are EPWMA/B\_DB\_NO\_HR. However, there is a provision provided to select any of the MINDB X-BAR outputs. This provides flexibility to support some of the other application scenarios.

The selected source is fed to the BLOCK signal generation logic. Block signal generation involves, detecting the falling edge based on which BLOCK signal goes high and stretching the BLOCK signal for DELAYA/B cycles, which are software configurable.

Figure 22-63. Minimum Dead-Band Block Signal Generation

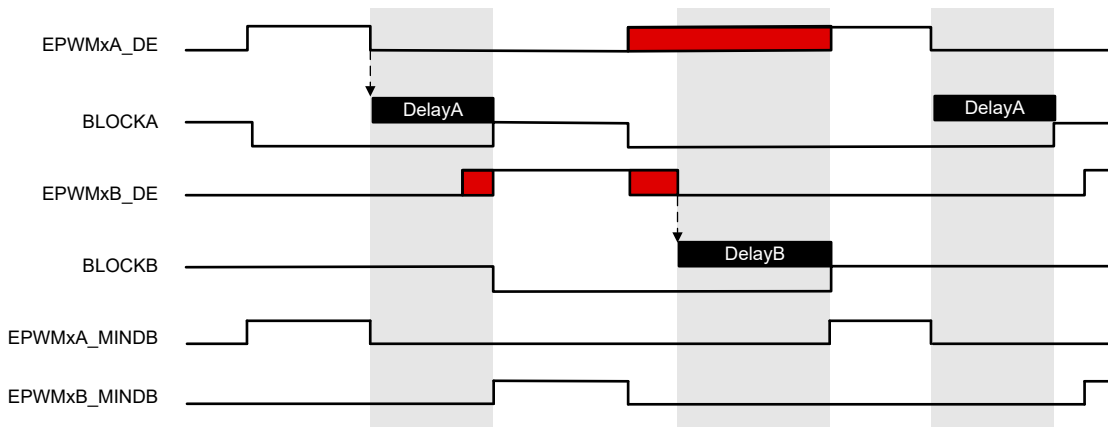

In [Figure 22-64](#) and [Figure 22-65](#), EPWMxA\_DE and BLOCKB are getting ANDed and EPWMxB\_DE and BLOCKA are getting ANDed.

**Note**

Red shade is indicative of incorrect scenario.

**Figure 22-64. Example: Rising Edge on EPWMxA\_DE and EPWMxB\_DE While Delay is Being Applied**

**Figure 22-65. Example: Rising Edge on EPWMxA\_DE while EPWMxB\_DE is Still High**

[Figure 22-66](#) illustrates that a rising edge during the delay application does not affect the BLOCKA generation, same behavior is applied to BLOCKB.

**Figure 22-66. Rising Edge During Delay**

Figure 22-67 showcases what happens when another falling edge occurs during the delay application. In this scenario, BLOCKA stays low until both DELAYA values are complete, same behavior is applied to BLOCKB.

Figure 22-67. Rising Edge and Falling Edge During Delay

### 22.12.2 Illegal Combo Logic (ICL)

As PWM generation logic gets more configurable and the interaction between multiple PWM instances increases, there is potential for corner cases during applications resulting in unintended PWM states. To detect and make sure that under no circumstance, the PWM states result in potentially hazardous combinations, a Look Up Table (LUT) has been added. By default, the LUT logic is bypassed, LUTCTLx[BYPASS]. When not bypassed, based on the combination of values on Input 3 (IN3), Input 2 (IN2), and Input 1 (IN1), the value driven on OUT is determined by the bits in the LUTCTLx [23:16] register. Input 3 into the LUT comes from one of the ICL X-BAR inputs.

Figure 22-68. Illegal Combo Logic Block Diagram

### 22.13 Event-Trigger (ET) Submodule

The key functions of the event-trigger submodule are:

- Receives event inputs generated by the time-base, counter-compare, and digital-compare submodules
- Uses the time-base direction information for up/down event qualification
- Uses prescaling logic to issue interrupt requests and ADC start of conversion at:
  - Every event
  - Every second event
  - Up to every fifteenth event
- Provides full visibility of event generation using event counters and flags
- Allows software forcing of Interrupts and ADC start of conversion

The event-trigger submodule manages the events generated by the time-base submodule, the counter-compare submodule, and the digital-compare submodule to generate an interrupt to the CPU and a start of conversion pulse to the ADC when a selected event occurs.

Figure 22-69 illustrates the event-trigger submodule within the ePWM.

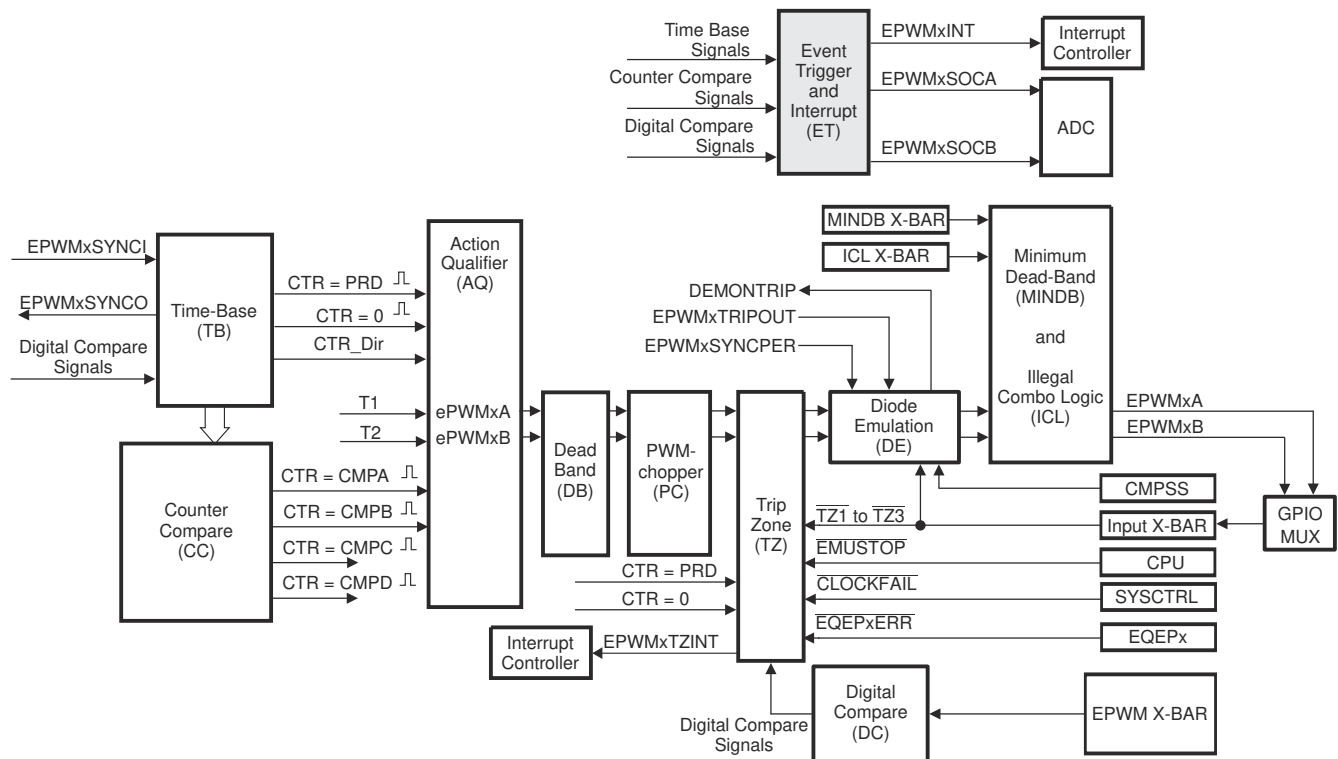

Figure 22-69. Event-Trigger Submodule

### 22.13.1 Operational Overview of the ePWM Event-Trigger Submodule

The event-trigger submodule monitors various event conditions (shown as inputs on the left side of [Figure 22-70](#)) and can be configured to prescale these events before issuing an Interrupt request or an ADC start of conversion. The event-trigger prescaling logic can issue Interrupt requests and ADC start of conversion at:

- Every event
- Every second event
- Up to every fifteenth event

**Figure 22-70. Event-Trigger Submodule Showing Event Inputs and Prescaled Outputs**

- ETSEL - This selects which of the possible events trigger an interrupt or start an ADC conversion.
- ETPS - This programs the event prescaling options mentioned above.
- ETFLG - These are flag bits indicating status of the selected and prescaled events.
- ETCLR - These bits allow clearing the flag bits in the ETFLG register using software.
- ETFRC - These bits allow software forcing of an event. Useful for debugging or software intervention.
- ETINTPS - This programs the interrupt event prescaling options, supporting count and period up to 15 events.
- ETSOCPs - This programs the SOC event prescaling options, supporting count and period up to 15 events.
- ETCNTINITCTL - These bits enable ETCNTINIT initialization using SYNC event or using software force.
- ETCNTINIT - These bits allow initializing INT/SOCA/SOCB counters on SYNC events (or software force) with user programmed value.

A more detailed look at how the various register bits interact with the Interrupt and ADC start of conversion logic are shown in [Figure 22-71](#), [Figure 22-72](#), and [Figure 22-73](#).

[Figure 22-71](#) shows the event-trigger's interrupt generation logic. The interrupt-period (ETPS[INTPRD]) bits specify the number of events required to cause an interrupt pulse to be generated. The choices available are:

- Do not generate an interrupt.
- Generate an interrupt on every event.
- Generate an interrupt on every second event.
- Generate an interrupt on every third event.

The selection made on `ETPS[INTPSEL]` bit determines whether `ETINTPS` register, `INTCNT2` and `INTPRD2` bit fields determine frequency of events (interrupt once every 0-15 events).

The event that can cause an interrupt is configured by the interrupt selection (`ETSEL[INTSEL]`) and (`ETSEL[INTSELCMP]`) bits. The event can be one of the following:

- Time-base counter equal to zero (`TBCTR = 0x00`).
- Time-base counter equal to period (`TBCTR = TBPRD`).
- Time-base counter equal to zero or period (`TBCTR = 0x00 || TBCTR = TBPRD`).
- Time-base counter equal to the compare A register (`CMPA`) when the timer is incrementing.
- Time-base counter equal to the compare A register (`CMPA`) when the timer is decrementing.
- Time-base counter equal to the compare B register (`CMPB`) when the timer is incrementing.
- Time-base counter equal to the compare B register (`CMPB`) when the timer is decrementing.
- Time-base counter equal to the compare C register (`CMPC`) when the timer is incrementing.
- Time-base counter equal to the compare C register (`CMPC`) when the timer is decrementing.
- Time-base counter equal to the compare D register (`CMPD`) when the timer is incrementing.
- Time-base counter equal to the compare D register (`CMPD`) when the timer is decrementing.

The number of events that have occurred can be read from the interrupt event counter `ETPS[INTCNT]` or `ETINTPS[INTCNT2]` register bits based off of the selection made using `ETPS[INTPSEL]`. That is, when the specified event occurs the `ETPS[INTCNT]` or `ETINTPS[INTCNT2]` bits are incremented until the bits reach the value specified by `ETPS[INTPRD]` or `ETINTPS[INTPRD2]` determined again by the selection made in `ETPS[INTPSEL]`. When `ETPS[INTCNT] = ETPS[INTPRD]`, the counter stops counting and the counter output is set. The counter is only cleared when an interrupt is sent to the interrupt controller.

When `ETPS[INTCNT]` reaches `ETPS[INTPRD]`, the following behavior occurs. [The following behavior is also applicable to `ETINTPS[INTCNT2]` and `ETINTPS[INTPRD2]`]:

- If interrupts are enabled, `ETSEL[INTEN] = 1` and the interrupt flag is clear, `ETFLG[INT] = 0`, then an interrupt pulse is generated and the interrupt flag is set, `ETFLG[INT] = 1`, and the event counter is cleared `ETPS[INTCNT] = 0`. The counter begins counting events again.
- If interrupts are disabled, `ETSEL[INTEN] = 0`, or the interrupt flag is set, `ETFLG[INT] = 1`, the counter stops counting events when the counter reaches the period value `ETPS[INTCNT] = ETPS[INTPRD]`.
- If interrupts are enabled, but the interrupt flag is already set, then the counter holds the output high until the `ENTFLG[INT]` flag is cleared. This allows for one interrupt to be pending while one is serviced.

Writing a 0 to the `INTPRD` bits automatically clears the counter (`INTCNT = 0`) and the counter output resets (so no interrupts are generated). For all other writes to `INTPRD`, `INTCNT` retains the previous value. `INTCNT` resets when `INTCNT` overflows. Writing a 1 to the `ETFRC[INT]` bit increments the event counter `INTCNT`. The counter behaves as previously described when `INTCNT = INTPRD`. When `INTPRD = 0`, the counter is disabled and hence no events are detected and the `ETFRC[INT]` bit is also ignored. The same applies to `ETINTPS[INTCNT2]` and `ETINTPS[INTPRD2]`.

The previous definition means that an interrupt on every event, on every second event, or on every third event if using the `INTCNT` and `INTPRD` can be generated. An interrupt on every event up to 15 events if using the `INTCNT2` and `INTPRD2` can be generated.

The `INTCNT2` value can be initialized with the value from `ETCNTINIT[INTINIT]` based on the selection made in `ETCNTINITCTL[INTINITEN]`. When `ETCNTINITCTL[INTINITEN]` is set, then initialization of `INTCNT2` counter with contents of `ETCNTINIT[INTINIT]` on a `SYNC` event or software force is determined by `ETCNTINITCTL[INTINITFRC]`.

### ETINTMIX, ETSOCAMIX and ETSOCBMIX Signals

In type 5 ePWM, the Event-Trigger submodule can generate and use ETINTMIX, ETSOCAMIX and ETSOCBMIX signals.

- **ETINTMIX:** This signal is a generated from the ORed combination of the sources enabled in the ETINTMIXEN register. The ETINTMIX signal can be used as a source for the EPWMxINT interrupt.
- **ETSOCAMIX:** This signal is a generated from the ORed combination of the sources enabled in the ETSOCAMIXEN register. The ETSOCAMIX signal can be used as a source for the EPWMxSOCA trigger signal.
- **ETSOCBMIX:** This signal is a generated from the ORed combination of the sources enabled in the ETSOCBMIXEN register. The ETSOCBMIX signal can be used as a source for the EPWMxSOCB trigger signal.

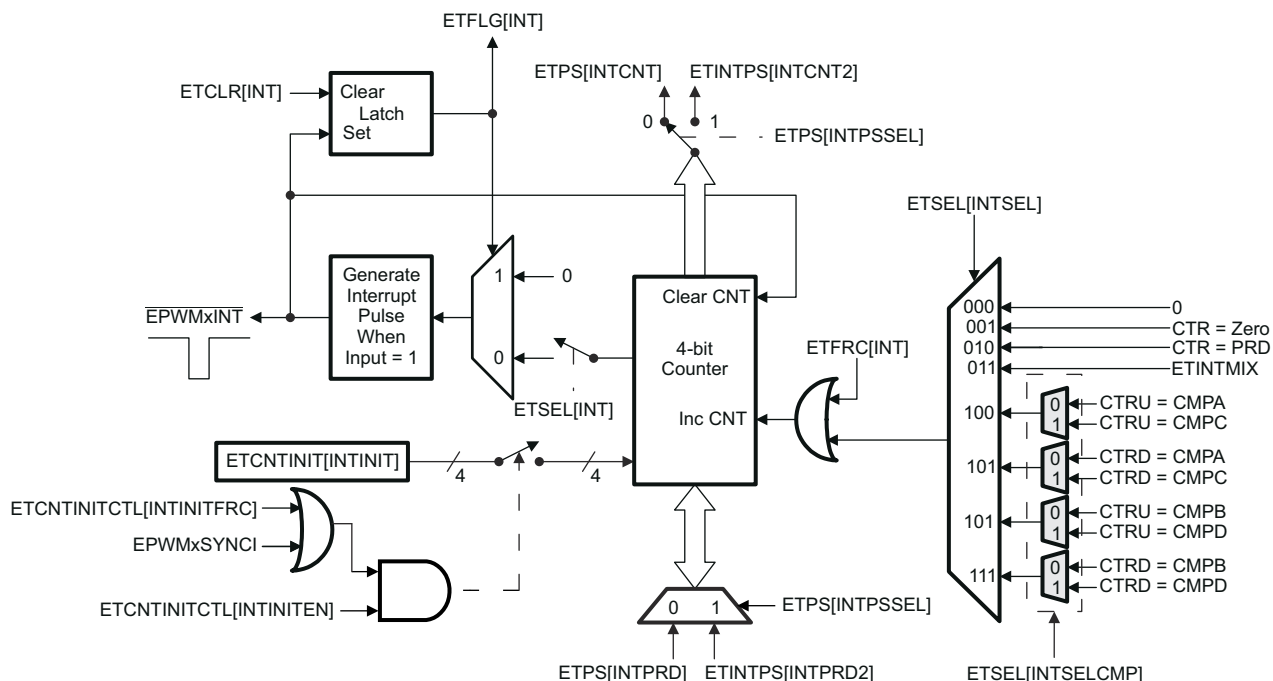

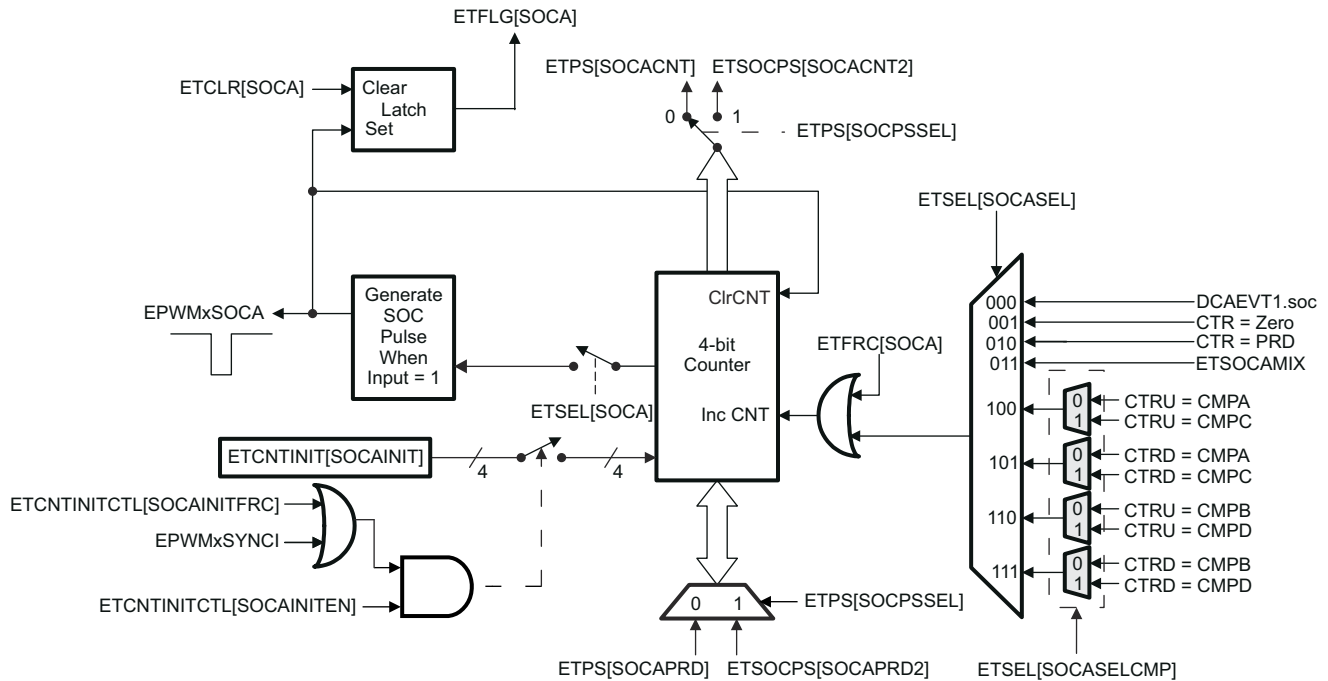

Figure 22-71. Event-Trigger Interrupt Generator

Figure 22-72 shows the operation of the event-trigger's start-of-conversion-A (SOCA) pulse generator. The enhancements include SOCASELCMP and SOCBSELCMP bit fields defined in the ETSEL register enable CMPC and CMPD events respectively to cause a start of conversion. The ETPS[SOCPSSEL] bit field determines whether SOCACNT2 and SOCAPRD2 take control or not. The ETPS[SOCACNT] counter and ETPS[SOCAPRD] period values behave similarly to the interrupt generator except that the pulses are continuously generated. That is, the pulse flag ETFLG[SOCA] is latched when a pulse is generated, but the interrupt generator does not stop further pulse generation. The enable and disable bit ETSEL[SOCAEN] stops pulse generation, but input events can still be counted until the period value is reached as with the interrupt generation logic. The event that triggers an SOCA and SOCB pulse can be configured separately in the ETSEL[SOCASEL] and ETSEL[SOCBSEL] bits. The possible events are the same events that can be specified for the interrupt generation logic with the addition of the DCAEVT1.soc and DCBEVT1.soc event signals from the digital compare (DC) submodule. The SOCACNT2 initialization scheme is very similar to the interrupt generator with respective enable, value initialize and SYNC or software force options.

NOTE: The DCAEVT1.soc signals are generated by the Digital Compare (DC) submodule in [Section 22.14](#).

**Figure 22-72. Event-Trigger SOCA Pulse Generator**

Figure 22-73 shows the operation of the event-trigger's start-of-conversion-B (SOCB) pulse generator. The event-trigger's SOCB pulse generator operates the same way as the SOCA.

NOTE: The DCBEVT1.soc signals are generated by the Digital Compare (DC) submodule in [Section 22.14](#).

**Figure 22-73. Event-Trigger SOCB Pulse Generator**

## 22.14 Digital Compare (DC) Submodule

Figure 22-74 illustrates where the digital compare (DC) submodule signals interface to other submodules in the ePWM system.

The eCAP input signals are sourced from the Input X-BAR signals as shown in Figure 22-75.

On this device, any of the GPIO pins can be flexibly mapped to be the trip-zone input and trip inputs to the trip-zone submodule and digital compare submodule. The Input X-BAR Input Select (INPUTxSELECT) register defines which GPIO pins gets assigned to be the trip-zone inputs / trip inputs.

The digital compare (DC) submodule compares signals external to the ePWM module (for instance, CMPSSx signals from the analog comparators) to directly generate PWM events/actions which then feed to the event-trigger, trip-zone, and time-base submodules. Additionally, blanking window functionality is supported to filter noise or unwanted pulses from the DC event signals.

### Note

The user is responsible for driving the correct state on the selected pin before enabling the clock and configuring the trip input for the respective ePWM peripheral to avoid spurious latch of the TRIP signal.

Figure 22-74. Digital-Compare Submodule High-Level Block Diagram

Figure 22-75. GPIO MUX-to-Trip Input Connectivity

### 22.14.1 Purpose of the Digital Compare Submodule

The key functions of the digital compare submodule are:

- Analog comparator (COMP) module outputs fed through the Input X-BAR, EPWM X-BAR, externally using the GPIO peripheral, interrupt controller signals, ECC error signals, TZ1, TZ2, and TZ3 inputs generate Digital Compare A High/Low (DCAH, DCAL) and Digital Compare B High/Low (DCBH, DCBL) signals.
- DCAH/L and DCBH/L signals trigger events that can then either be filtered or applied directly to the trip-zone, event-trigger, and time-base submodules to:
  - generate a trip zone interrupt
  - generate an ADC start of conversion
  - force an event
  - generate a synchronization event for synchronizing the ePWM module TBCTR.
- Event filtering (blanking window logic) can optionally blank the input signal to remove noise.

### 22.14.2 Enhanced Trip Action Using CMPSS

To allow multiple CMPSS at a time to affect DCA/BEVTx events and trip actions, there is a OR logic to bring together ALL trip inputs (up to 15) from sources external to the ePWM module and feed into DCAH, DCAL, DCBH, and DCBL as a “combinational input” using the DCTRIPSEL register. This is configured by selecting “Trip combination input” (value of 0xF) in the DCTRIPSEL register.

There is a discrete choice of which trip inputs to put through the combinational logic for generating the DCAH, DCAL, DCBH, and DCBL signals. This is achieved using the DCAHTRIPSEL, DCALTRIPSEL, DCBHTRIPSEL, and DCBLTRIPSEL register selections. Inputs selected for combinational input are passed through to the DCTRIPSEL register.

### 22.14.3 Using CMPSS to Trip the ePWM on a Cycle-by-Cycle Basis

When using the CMPSS to trip the ePWM on a cycle-by-cycle basis, steps can be taken to prevent an asserted comparator trip state in one PWM cycle from extending into the following cycle. The CMPSS can be used to signal a trip condition to the downstream ePWM modules. For applications like peak current mode control, only one trip event per PWM cycle is expected. Under certain conditions, it is possible for a sustained or late trip event (arriving near the end of a PWM cycle) to carry over into the next PWM cycle if precautions are not taken. If either the CMPSS Digital Filter or the ePWM Digital Compare (DC) submodule is configured to qualify the comparator trip signal, “N” number of clock cycles of qualification are introduced before the ePWM trip logic can respond to logic changes of the trip signal. Once an ePWM trip condition is qualified, the trip condition remains active for N clock cycles after the comparator trip signal has de-asserted. If a qualified comparator trip signal remains asserted within N clock cycles prior to the end of a PWM cycle, the trip condition is not cleared until after the following PWM cycle has started. Thus, the new PWM cycle detects a trip condition as soon as the cycle begins.

To avoid this undesired trip condition, the application can take steps to make sure that the qualified trip signal seen by the ePWM trip logic is deasserted prior to the end of each PWM cycle. This can be accomplished through various methods:

- Design the system such that a comparator trip is not asserted within N clock cycles prior to the end of the PWM cycle.
- Activate blanking of the comparator trip signal using the ePWM event filter at least two clock cycles prior to the PWMSYNCPER signal and continue blanking for at least N clock cycles into the next PWM cycle.
- If the CMPSS COMPxLATCH path is used, clear the COMPxLATCH at least N clock cycles prior to the end of the PWM cycle. The latch can be cleared by software (using COMPSTCLR) or by generating an early PWMSYNCPER signal. The ePWM modules on this device include the ability to generate PWMSYNCPER upon a CMPC or CMPD match (using HRPCTL) for arbitrary PWMSYNCPER placement within the PWM cycle.

### 22.14.4 Operation Highlights of the Digital Compare Submodule

The following sections describe the operational highlights and configuration options for the digital compare submodule.

#### 22.14.4.1 Digital Compare Events

As described in [Section 22.14.1](#), trip zone inputs ( $\overline{TZ1}$ ,  $\overline{TZ2}$ , and  $\overline{TZ3}$ ) and CMPSSx signals from the analog comparator (COMP) module can be selected using the DCTRISEL bits to generate the Digital Compare A High and Low (DCAH/L) and Digital Compare B High and Low (DCBH/L) signals. Then, the configuration of the TZDCSEL register qualifies the actions on the selected DCAH/L and DCBH/L signals, which generate the DCAEVT1/2 and DCBEVT1/2 events (Event Qualification A and B).

#### Note

The  $\overline{TZn}$  signals, when used as a DCEVT tripping functions, are treated as a normal input signal and can be defined to be active-high or active-low inputs. ePWM outputs are asynchronously tripped when either the  $\overline{TZn}$ , DCAEVTx.force, or DCBEVTx.force signals are active. For the condition to remain latched, a minimum of  $3 \times TBCLK$  sync pulse width is required. If pulse width is  $< 3 \times TBCLK$  sync pulse width, the trip condition can or can not get latched by CBC or OST latches.

The DCAEVT1/2 and DCBEVT1/2 events can then be filtered to provide a filtered version of the event signals (DCEVTFILT) or the filtering can be bypassed. Filtering is discussed further in [Event Filtering](#). Either the DCAEVT1/2 and DCBEVT1/2 event signals or the filtered DCEVTFILT event signals can generate a force to the trip zone module, a TZ interrupt, an ADC SOC, or a PWM sync signal.

- **force signal:** DCAEVT1/2.force signals force trip zone conditions which either directly influence the output on the EPWMxA pin (using TZCTL, TZCTLDCA, TZCTLDCB register configurations) or, if the DCAEVT1/2 signals are selected as one-shot or cycle-by-cycle trip sources (using the TZSEL register), the DCAEVT1/2.force signals can effect the trip action using the TZCTL or TZCTL2 register configurations. The DCBEVT1/2.force signals behaves similarly, but affect the EPWMxB output pin instead of the EPWMxA output pin.

The priority of conflicting actions on the TZCTL, TZCTL2, TZCTLDCA and TZCTLDCB registers is as follows (highest priority overrides lower priority):

Output EPWMxA:

- TZA (highest) -> DCAEVT1 -> DCAEVT2 (lowest)
- TZAU (highest) -> DCAEVT1U -> DCAEVT2U (lowest)
- TZAD (highest) -> DCAEVT1D -> DCAEVT2D (lowest)

Output EPWMxB:

- TZB (highest) -> DCBEVT1 -> DCBEVT2 (lowest)
- TZBU (highest) -> DCBEVT1U -> DCBEVT2U (lowest)
- TZBD (highest) -> DCBEVT1D -> DCBEVT2D (lowest)

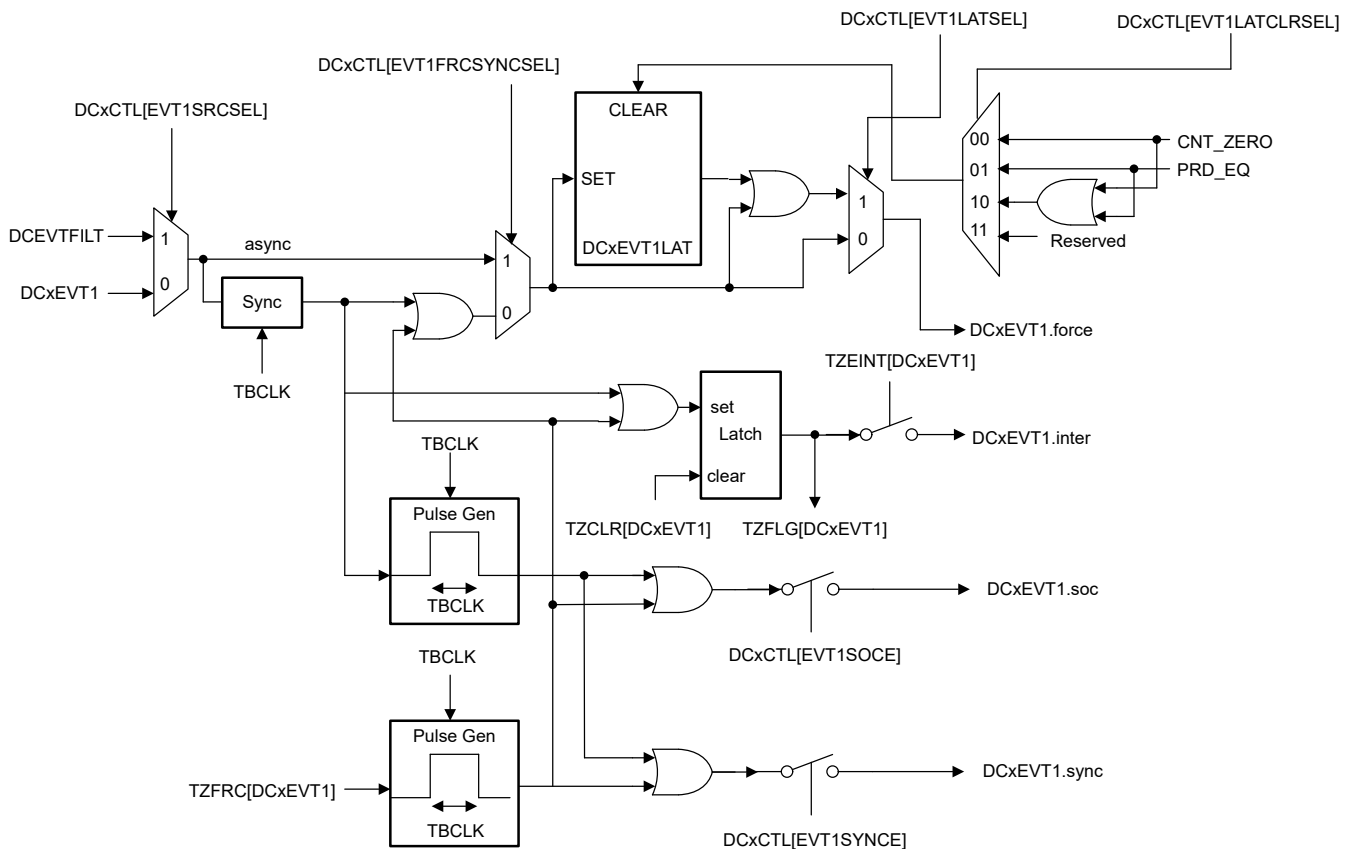

- **interrupt signal:** DCAEVT1/2.interrupt signals generate trip zone interrupts to the interrupt controller. To enable the interrupt, set the DCAEVT1, DCAEVT2, DCBEVT1, or DCBEVT2 bits in the TZEINT register. Once one of these events occurs, an EPWMxTZINT interrupt is triggered, and the corresponding bit in the TZCLR register must be set to clear the interrupt.
- **soc signal:** The DCAEVT1.soc signal interfaces with the event-trigger submodule and can be selected as an event which generates an ADC start-of-conversion-A (SOCA) pulse using the ETSEL[SOCASEL] bit. Likewise, the DCBEVT1.soc signal can be selected as an event which generates an ADC start-of-conversion-B (SOCB) pulse using the ETSEL[SOCBSEL] bit.
- **sync signal:** The DCAEVT1.sync and DCBEVT1.sync events are ORed with the EPWMxSYNCl input signal and the TBCTL[SWFSYNC] signal to generate a synchronization pulse to the time-base counter.

Figure 22-76 and Figure 22-77 show how the DCxEVT1, DCxEVT2, or DCEVTFLT signals are processed to generate the digital compare A and B event force, interrupt, soc and sync signals.

In some of the applications like Phase Shifted Full Bridge (PSFB) Converters, it is required that different actions are taken on a CBC trip event and an OST trip event. This can be achieved using the DCxEVT1LAT.

- This latch can be cleared on CNT = 0, CTR = PRD, and CNT = 0 OR CTR = PRD events based on the setting of DCxCTL.EVTy.LATCLRSEL setting. This is similar to CBC latch clear mechanism.
- DCxEVTy.force signal can be chosen to be either the latched version or the unlatched version based on DCxCTL.EVTyLATSEL value.
- The status of DCxEVTyLAT signal can be accessed by reading DCxCTL.EVTyLAT field.

**Figure 22-76. DCxEVT1 Event Triggering**

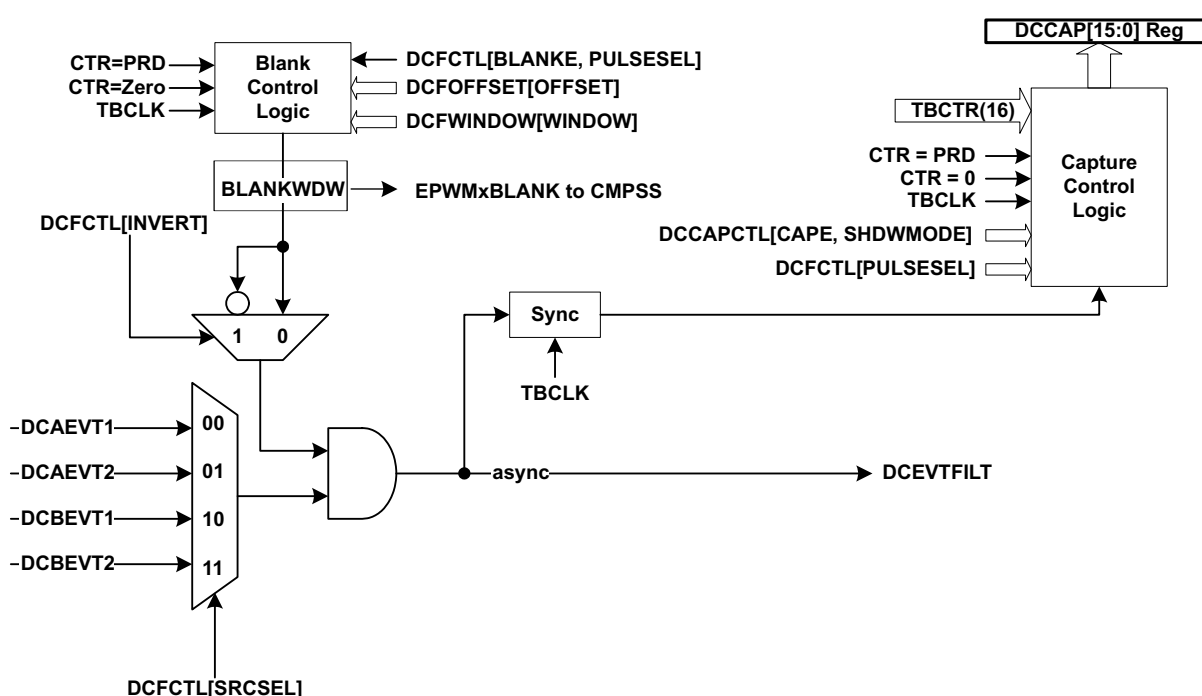

Figure 22-77. DCxEVT2 Event Triggering

### 22.14.4.2 Event Filtering

**Blank Control Logic:** The DCAEVT1/2 and DCBEVT1/2 events can be filtered using event filtering logic to remove noise by optionally blanking events for a certain period of time. This is useful for cases where the analog comparator outputs can be selected to trigger DCAEVT1/2 and DCBEVT1/2 events, and the blank control logic is used to filter out potential noise on the signal prior to tripping the PWM outputs or generating an interrupt or ADC start-of-conversion. Blank control logic is used to define a blanking window, which ignores all event occurrences on the signal while the window is active. The blanking window is configured in the DCFCTL, DCFOFFSET, and DCFWINDOW registers. The DCFCTL register enables the blanking window and aligns the blanking window to either a CTR = PRD pulse or a CTR = 0 pulse or both CTR = PRD and CTR = 0 as specified by DCFCTL[PULSESEL]. DCFCTL[SRCSSEL] selects the DCxEV<sub>Ty</sub> event source for the DCEVTFILT signal. An offset value in TBCLK counts is programmed into the DCFOFFSET register, which determines at what point after the CTR = PRD or CTR = 0 pulse the blanking window starts. The duration of the blanking window, in number of TBCLK counts after the offset counter expires, is written to the DCFWINDOW register. Before and after the blanking window ends, events can generate soc, sync, interrupt, and force signals as before. Figure 22-78 shows the details of the event filtering logic.

**Figure 22-78. Event Filtering**

**Capture Control Logic:** The event filtering can also capture the TBCTR value of the selected DCxEV<sub>Ty</sub> event as configured in the DCCAPCTL register. When capture control logic is enabled, the selected DCxEV<sub>Ty</sub> event triggers capture of the TBCTR to the active register. The CPU reads directly from the active register unless shadow mode is enabled by DCCAPCTL[SHDWMODE]. When shadow mode is enabled, the active register information is copied to shadow register on the event specified by DCFCTL[PULSESEL], and the CPU reads from the shadow register. After the selected DCxEV<sub>Ty</sub> event, no further capture events occur until the event specified by DCCAPCTL[CAPMODE]. The CAPMODE can be configured two ways: (1) no further capture events occur until the event defined by DCFCTL[PULSESEL] or (2) no further capture events occur until the compare-event flag at DCCAPCTL[CAPSTS] is cleared by DCCAPCTL[CAPCLR].

#### Note

You must configure the ePWM blanking window appropriately so that the Trip Input stays valid for at least 3 ePWM cycles after the blanking window has expired.

Figure 22-79 illustrates several timing conditions for the offset and blanking window within an ePWM period. Notice that if the blanking window crosses the CTR = 0 or CTR = PRD boundary, the next window still starts at the same offset value after the CTR = 0 or CTR = PRD pulse.

Figure 22-79. Blanking Window Timing Diagram

### BLANKPULSEMIX and DCCAPMIX Signals

The CAPCTL MUX (available in the Capture Control Logic) and DCFCTL MUX (available for Blank Control Logic and Capture Control Logic) have new options in type 5 ePWM which allows them to select the DCCAPMIX or BLANKPULSEMIX signal respectively.

In type 5 ePWM, the shadow load signal for the Capture Control Logic can be different from the blanking window alignment signal (which is selected by DCFCTL[PULSESEL]). The CAPCTL mux can be configured to use the DCCAPMIX signal

Figure 22-80. BLANKPULSEMIX and DCCAPMIX Signal Source

### 22.14.4.3 Valley Switching

Event filtering depicts the valley switching function along with the event filtering logic described in Event Filtering. This function can be used to achieve programmable valley switching without any additional external circuitry. This module provides an on-chip hardware mechanism that can:

- Capture the oscillation period
- Accurately delay the PWM switching instant
- Allow a programmable number of edges before the delay takes effect
- Provide multiple choices of triggers and events
- Allow easy adaptability for optimum performance under changing system/operating conditions

The DCxEVTy signal needs further processing to support valley switching. Here is a brief description of how valley switching function is enabled:

1. Select one of the DCxEVTy events as input to the valley switching block (DCFCTL[SRSEL]) with an option to add the blanking window (Blank Control Logic). This is where the comparator output (or external input) above is selected as an input to the valley switching block.
2. Configure the edge filter to capture 'n' rising, falling or both edges through the edge selection logic (DCFCTL[EDGEMODE, EDGECOUNT]).
3. Select the correct event to reset and restart the edge filter (VCAPCTL[TRIGSEL]). Edge capturing event is triggered or armed by this selected edge.
4. Enable valley capture logic (VCAPCTL[VCAPE]).
5. Select the start edge that indicates the start of capture for oscillation period measurement (VCNTCFG[STARTEDGE]). This is where the 16-bit counter starts counting.
6. Select the stop edge (VCNTCFG[STOPEDGE]) that indicates the edge at which the 16-bit counter stops counting. The captured counter value (CNTVAL) provides oscillation period information.
  - The STOPEDGE value must always be greater than STARTEDGE value.
7. Configure and apply the captured delay (CNTVAL) to the edge filtered DCxEVTy signal. The CNTVAL value can be applied as is or applied in conjunction with a software programmed value (useful for offset adjustment) (SWVDELVAL) or only a fraction of the delay can be applied with or without SWVDELVAL. This is useful to correctly apply a delay corresponding to the valley point. (VCAPCTL[VDELAYDIV])
8. Configure VCAPCTL[EDGEFILTDLYSEL] to apply hardware delay based on the captured value above.

Once the counter is stopped, counter value is copied into CNTVAL register and counter is reset to zero. No further captures are done until the logic is triggered again by occurrence of event selected by VCAPCTL[TRIGSEL]. In this implementation, the software trigger is used as the source for VCAPCTL[TRIGSEL]. Upon occurrence of the trigger event, irrespective of the current status of the counter, the counter is reset and starts counting from zero upon occurrence of the STARTEDGE. Similarly, upon occurrence of the trigger event, the edge filter is reset and starts counting from zero upon occurrence of the STARTEDGE.

Output from the valley switching block (DCEVTFILT) is then used to synchronize the PWM time-base. The process is shown in [Figure 22-81](#).

---

#### Note

A specific application example showcasing the usage of valley switching hardware and software is available in C2000Ware.

---

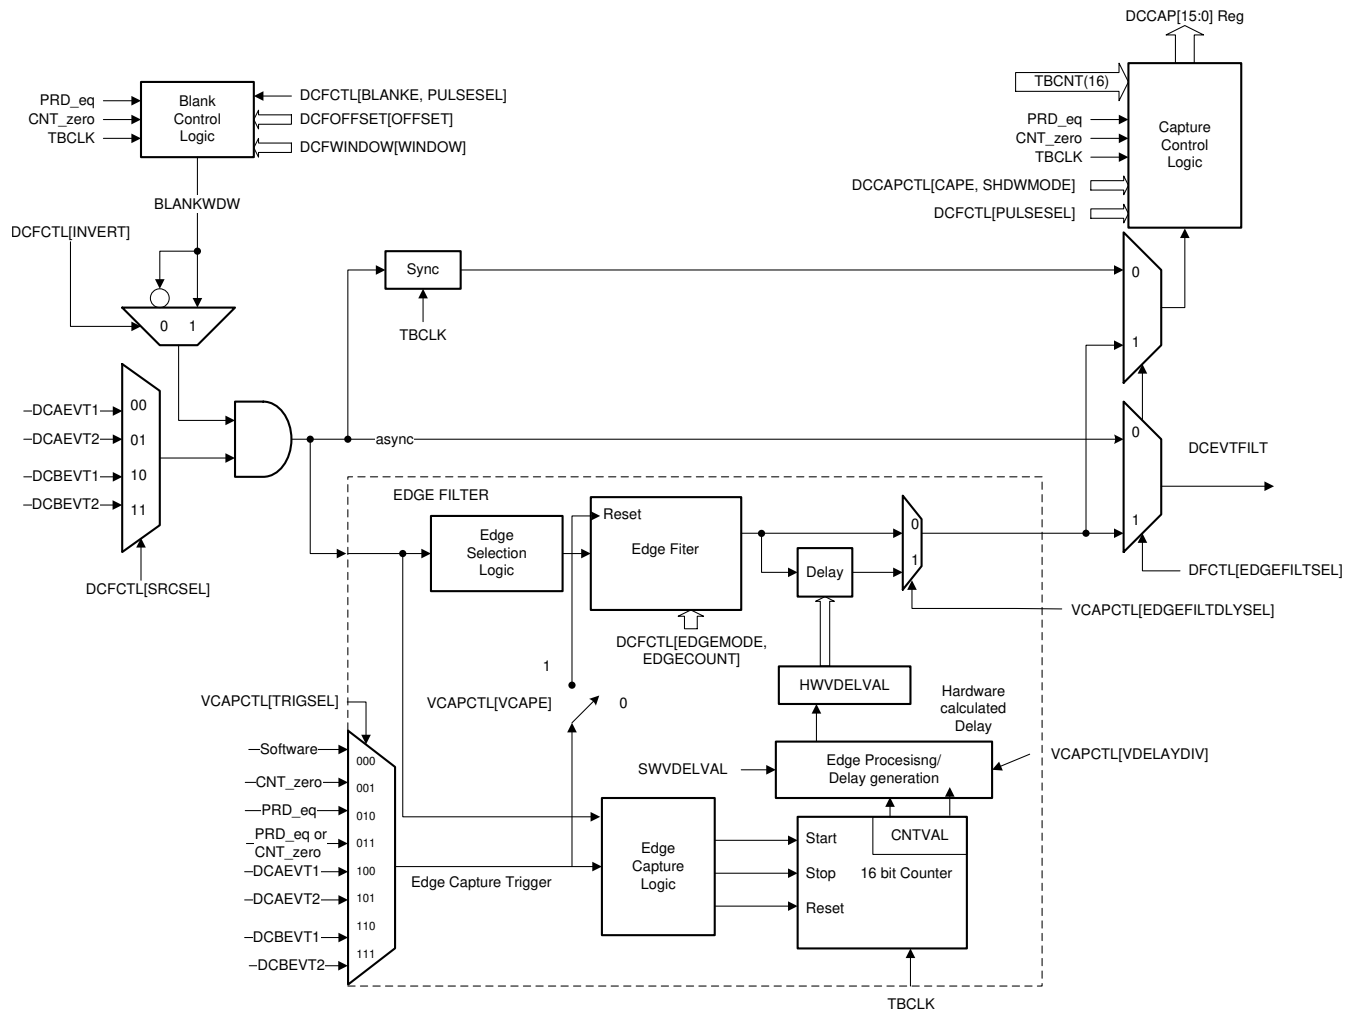

Figure 22-81. Valley Switching

#### 22.14.4.4 Event Detection

This logic is primarily intended to detect an occurrence of a trip event in a configured time window. The window is configured by MIN and MAX values configured in the XMINMAX register sets.

Figure 22-82 indicates the window spread across MIN and MAX bounds and the edge of the chosen signal occurring in that window. The purpose of this block is to detect the occurrence of such edge. If no such edge occurs, this module generates a trip event as well as an interrupt, if configured.

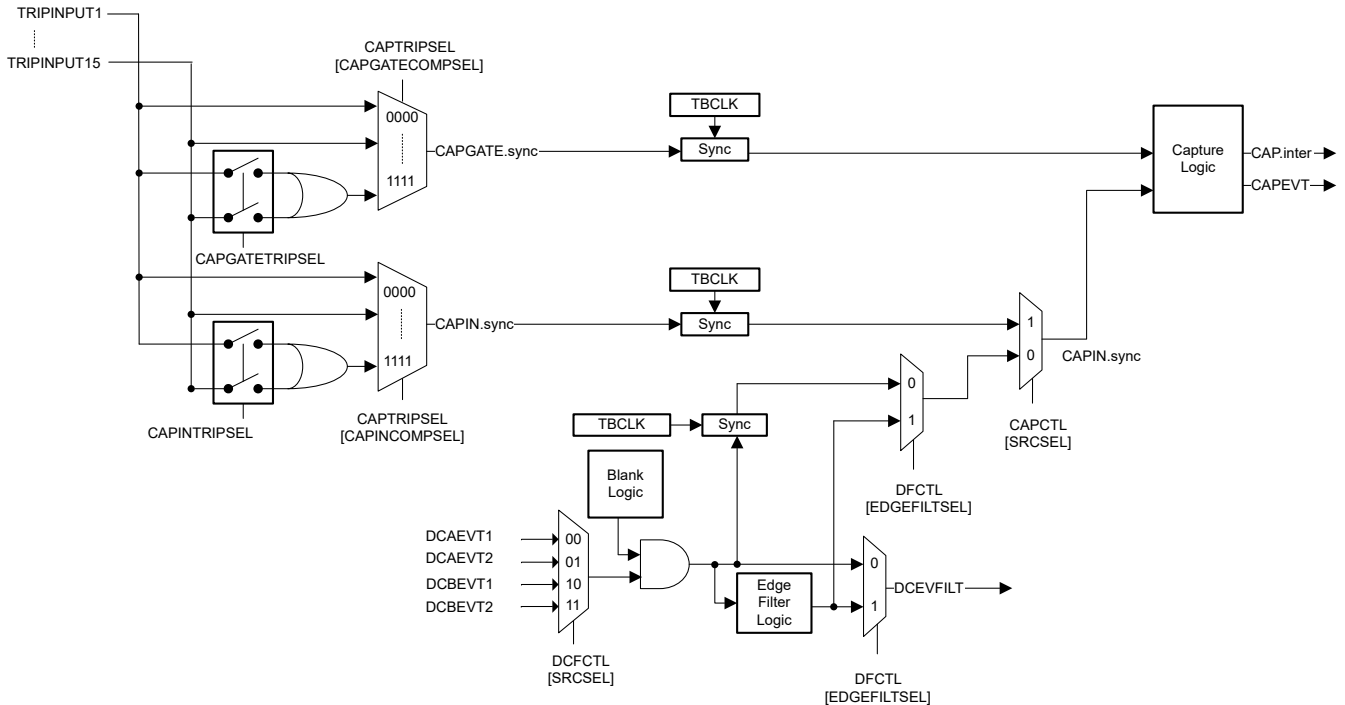

Figure 22-82. MIN, MAX Settings and Window for Capture Event Detection

### 22.14.4.4.1 Input Signal Detection

The CAPTRIPSEL, CAPINTRIPSEL and CAPGATETRIPSEL muxes are used for signal selection. [Figure 22-83](#) shows how the CAPIN and CAPGATE signal source is selected.

**CAPIN Input:** This signal (any input coming from EPWM X-BAR) can be configured as the signal input on which the edge detection logic is performed.

**CAPGATE Input:** This signal (any input coming from EPWM X-BAR) can be configured as the gating signal to Min/Max logic. This signal gates the CAPIN input signal.

**Figure 22-83. CAPIN and CAPGATE Source Selection**

Once selected, [Figure 22-84](#) demonstrates how the CAPGATE and CAPIN signals propagate into the counter capture logic. The logic works in the following way:

- CAPCTL[GATEPOL] is used for the polarity selection of the gating input to be optionally inverted or tied to a 0 or 1.
- CAPCTL[CAPINPOL] can be used to select the edge polarity of CAPIN.sync signal. CAPIN.sync signal is selected from the DCEVFILT options and the CAPIN signal using CAPCTL[SRCSEL] bits.

Figure 22-84. Counter Capture Logic

22.14.4.4.2 MIN and MAX Detection Circuit

The XMINMAX register has XMIN and XMAX fields that can be programmed to set the MIN and MAX limits of the programmable edge detection window. These registers have 3-level buffering similar to the XCMPn registers. The shadow to active loading of these registers is always in sync with the buffer pointers. Any shadow to active loads occur as per the XLOAD register configuration defined for the XCMPn registers such that the MIN and MAX values used are always in line with the corresponding XPRD/XCMPn values used for a given PWM cycle.

Figure 22-85. MIN and MAX Threshold Detection Logic

The logic works in the following way:

- The TBCNT value is continually monitored and compared against the active MIN value. Match of TBCNT to the active MIN value triggers the edge monitoring occurrence.
- When the TBCNT value reached the MIN value, the active LOAD signal is monitored waiting for an edge event to occur.
- If an edge vent occurs before TBCNT reaches the active MAX value, then no further action is taken. The logic resets and TBCNT is compared to the active MIN value again.
- If no edge occurs and TBCNT reaches the active MAX value, then the CAPEVT signal is set high and a CAP interrupt signal can also be generated. The CAPEVT signal needs to be cleared through software for TBCNT to be monitored against the MIN value again.

The Min and Max monitoring is enabled and disabled in three ways:

- By enabling/disabling the circuit via the DCCAPCTL[CAPE] bit
- By the CAPGATE signal which can be sourced from an TRIPINPUT signal to the module.
- By writing the same value into the XMIN and XMAX bits.

Figure 22-86. Capture Logic Boundary Condition

**Note**

Possible boundary condition of MIN/MAX window exceeding the period value: In this case, the XMAX bit can have a value lower than the XMIN bit such that the window can go over the period boundary.

## 22.15 ePWM Crossbar (X-BAR)

Figure 22-87 shows the architecture of the ePWM Crossbar (X-BAR). This module enables selection of various trigger sources into any of the dedicated EPWM trips inputs.

### Note

Refer to the *Crossbar (X-BAR)* chapter for more information on the X-BAR modules, including X-BAR flags.

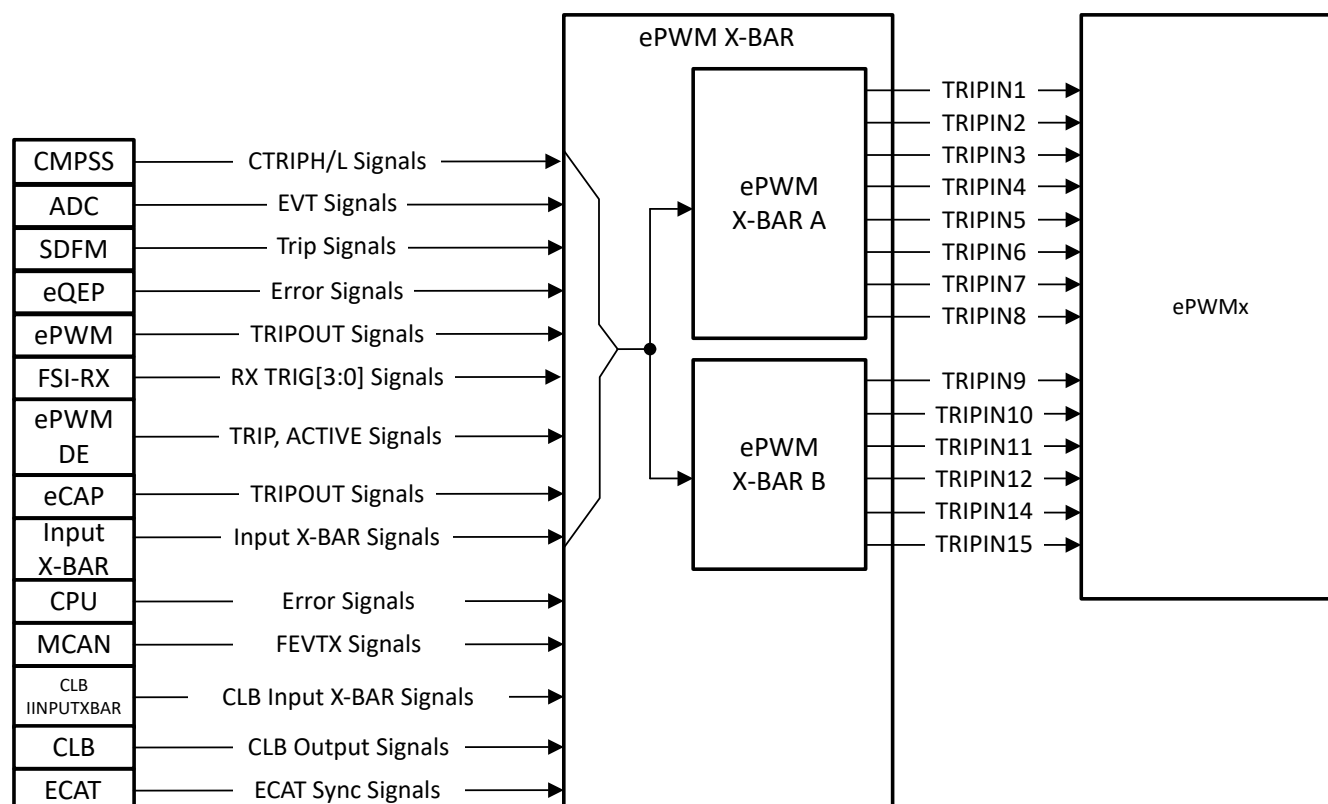

Figure 22-87. ePWM X-BAR

## 22.16 Applications to Power Topologies

An ePWM module has all the local resources necessary to operate completely as a standalone module or to operate in synchronization with other identical ePWM modules.

### 22.16.1 Overview of Multiple Modules

Previously in this chapter, all discussions have described the operation of a single module. To facilitate the understanding of multiple modules working together in a system, the ePWM module described in reference is represented by the more simplified block diagram shown in Figure 22-88. This simplified ePWM block shows only the key resources needed to explain how a multiswitch power topology is controlled with multiple ePWM modules working together.

Figure 22-88. Simplified ePWM Module

### 22.16.2 Key Configuration Capabilities

The key configuration choices available to each module are as follows:

- Options for SyncIn
  - Load own counter with phase register on an incoming sync strobe—enable (EN) switch closed
  - Do nothing or ignore incoming sync strobe—enable switch open
  - Sync flow-through - SyncOut connected to SyncIn
  - Sync Source mode, provides a sync at PWM boundaries—SyncOut connected to CTR = PRD
  - Sync Source mode, provides a sync at any programmable point in time—SyncOut connected to CTR = CMPB
  - Module is in standalone mode and provides no sync to other modules—SyncOut connected to X (disabled)
- Options for SyncOut
  - Sync flow-through - SyncOut connected to SyncIn
  - Sync Source mode, provides a sync at PWM boundaries—SyncOut connected to CTR = PRD
  - Sync Source mode, provides a sync at any programmable point in time—SyncOut connected to CTR = CMPB
  - Module is in standalone mode and provides no sync to other modules—SyncOut connected to X (disabled)

For each choice of SyncOut, a module can also choose to load the counter with a new phase value on a SyncIn strobe input or choose to ignore the value (that is, by the enable switch). Although various combinations are possible, the two most common—Sync Source module and Sync Receiver module modes—are shown in [Figure 22-89](#).

**Figure 22-89. EPWM1 Configured as a Typical Sync Source, EPWM2 Configured as a Sync Receiver**

### 22.16.3 Controlling Multiple Buck Converters With Independent Frequencies

One of the simplest power converter topologies is the buck. A single ePWM module configured as a sync source can control two buck stages with the same PWM frequency. If independent frequency control is required for each buck converter, then one ePWM module must be allocated for each converter stage. Figure 22-90 shows four buck stages, each running at independent frequencies. In this case, all four ePWM modules are configured as Sync Sources and no synchronization is used. Figure 22-91 shows the waveforms generated by the setup shown in Figure 22-90; note that only three waveforms are shown, although there are four stages.

A.  $\phi = X$  indicates value in phase register is a "don't care"

**Figure 22-90. Control of Four Buck Stages. Here  $F_{PWM1} \neq F_{PWM2} \neq F_{PWM3} \neq F_{PWM4}$**

Figure 22-91. Buck Waveforms for Control of Four Buck Stages (Note: Only three bucks shown here)

### 22.16.4 Controlling Multiple Buck Converters With Same Frequencies

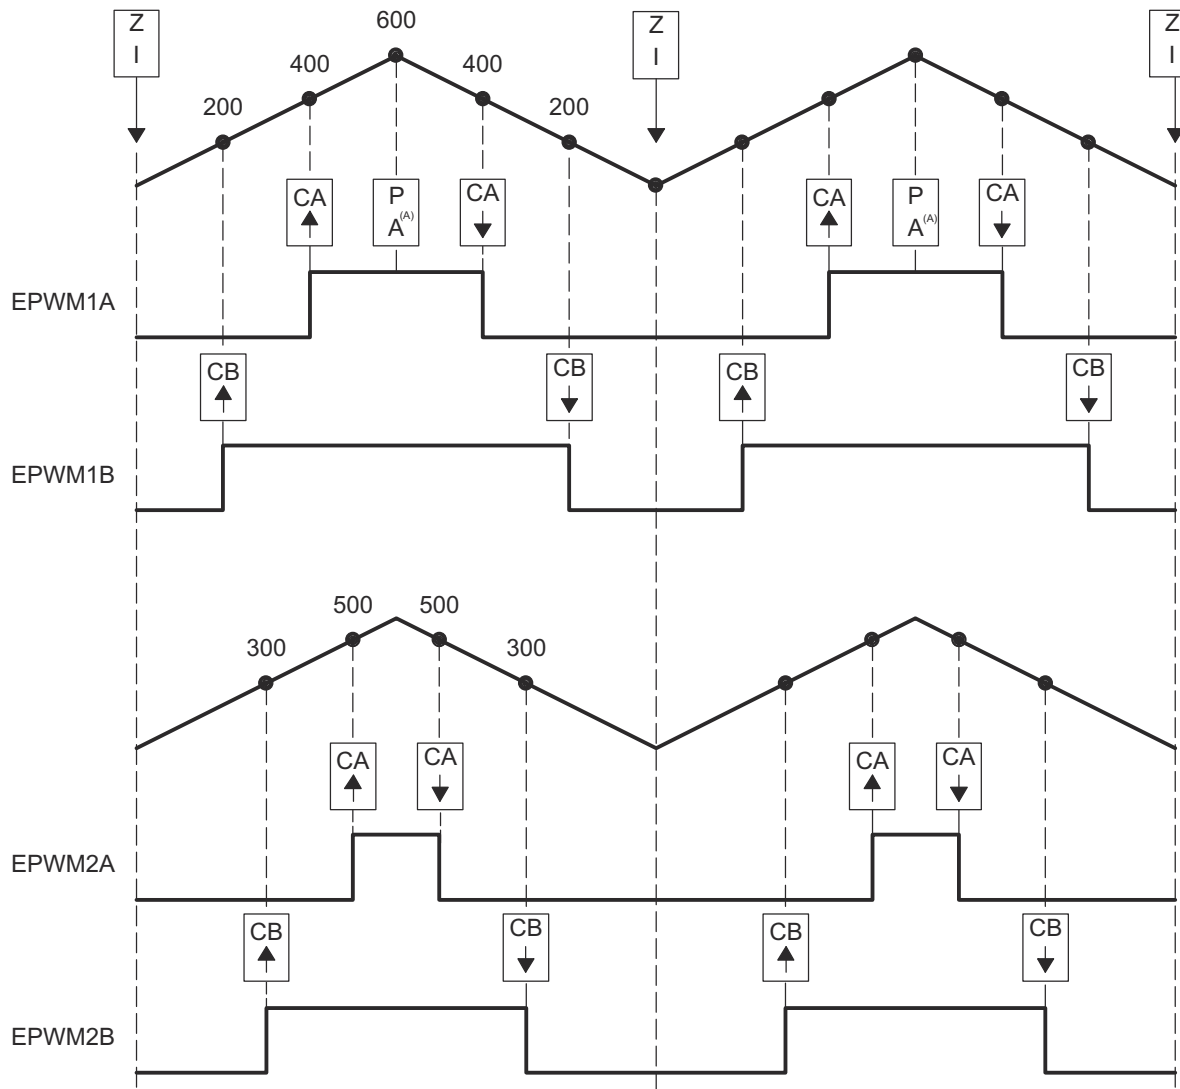

If synchronization is a requirement, ePWM module 2 is configured as a sync receiver and operates at integer multiple (N) frequencies of module 1. The sync signal from sync source to sync receiver makes sure these modules remain locked. Figure 22-92 shows such a configuration; Figure 22-93 shows the waveforms generated by the configuration.

A.  $\phi = X$  indicates value in phase register is a "don't care"

**Figure 22-92. Control of Four Buck Stages. (Note:  $F_{PWM2} = N \times F_{PWM1}$ )**

A. Starts ADC conversion.

**Figure 22-93. Buck Waveforms for Control of Four Buck Stages (Note:  $F_{PWM2} = F_{PWM1}$ )**

### 22.16.5 Controlling Multiple Half H-Bridge (HNB) Converters

Topologies that require control of multiple switching elements can also be addressed with these same ePWM modules. It is possible to control a Half-H bridge stage with a single ePWM module. This control can be extended to multiple stages. Figure 22-94 shows control of two synchronized Half-H bridge stages where stage 2 can operate at integer multiple (N) frequencies of stage 1. Figure 22-95 shows the waveforms generated by the configuration shown in Figure 22-94.

ePWM module 2 (sync receiver) is configured for Sync flow-through; if required, this configuration allows for a third Half-H bridge to be controlled by ePWM module 3 and also, most importantly, to remain in synchronization with sync source ePWM module 1.

Figure 22-94. Control of Two Half-H Bridge Stages ( $F_{PWM2} = N \times F_{PWM1}$ )

Figure 22-95. Half-H Bridge Waveforms for Control of Two Half-H Bridge Stages (Note: Here  $F_{PWM2} = F_{PWM1}$ )

### 22.16.6 Controlling Dual 3-Phase Inverters for Motors (ACI and PMSM)

The idea of multiple modules controlling a single power stage can be extended to the 3-phase inverter case. In such a case, six switching elements are controlled using three PWM modules, one for each leg of the inverter. Each leg must switch at the same frequency and all legs must be synchronized. A sync receivers configuration easily addresses this requirement. Figure 22-96 shows how six PWM modules control two independent 3-phase inverters; each running a motor.

As in the cases shown in the previous sections, we have a choice of running each inverter at a different frequency (module 1 and module 4 are sync sources as in Figure 22-96), or both inverters can be synchronized by using one sync source (module 1) and five sync receivers. In this case, the frequency of modules 4, 5, and 6 (all equal) can be integer multiples of the frequency for modules 1, 2, and 3 (also all equal).

Figure 22-96. Control of Dual 3-Phase Inverter Stages as Is Commonly Used in Motor Control

Figure 22-97. 3-Phase Inverter Waveforms for Control of Dual 3-Phase Inverter Stages (Only One Inverter Shown)

### 22.16.7 Practical Applications Using Phase Control Between PWM Modules

So far, none of the examples have made use of the phase register (TBPHS). It has either been set to zero or a don't care. However, by programming appropriate values into TBPHS, multiple PWM modules can address another class of power topologies that rely on phase relationship between legs (or stages) for correct operation. As described in the time-base submodule section, a PWM module can be configured to allow a SyncIn pulse to cause the TBPHS register to be loaded into the TBCTR register. To illustrate this concept, [Figure 22-98](#) shows a sync source and sync receiver module with a phase relationship of 120° (that is, the sync receiver leads the sync source).

**Figure 22-98. Configuring Two PWM Modules for Phase Control**

[Figure 22-99](#) shows the associated timing waveforms for this configuration. Here, TBPRD = 600 for both sync source and sync receiver. For the sync receiver, TBPHS = 200 (that is,  $200/600 \times 360^\circ = 120^\circ$ ). Whenever the sync source generates a SyncIn pulse (CTR = PRD), the value of TBPHS = 200 is loaded into the sync receiver TBCTR register so the sync receiver time-base is always leading the sync source time-base by 120°.

**Figure 22-99. Timing Waveforms Associated with Phase Control Between Two Modules**

### 22.16.8 Controlling a 3-Phase Interleaved DC/DC Converter

A popular power topology that makes use of phase-offset between modules is shown in [Figure 22-100](#). This system uses three PWM modules, with module 1 configured as the sync source. To work, the phase relationship between adjacent modules must be  $F = 120^\circ$ . This is achieved by setting the sync receiver TBPHS registers 2 and 3 with values of  $1/3$  and  $2/3$  of the period value, respectively. For example, if the period register is loaded with a value of 600 counts, then  $TBPHS(\text{sync receiver } 2) = 200$  and  $TBPHS(\text{sync receiver } 3) = 400$ . Both sync receiver modules are synchronized to the sync source module 1.

This concept can be extended to four or more phases, by setting the TBPHS values appropriately. The following formula gives the TBPHS values for N phases:

$$TBPHS(N,M) = (TBPRD/N) \times (M - 1)$$

Where:

N = number of phases

M = PWM module number

For example, for the 3-phase case (N = 3), TBPRD = 600,

$TBPHS(3,2) = (600/3) \times (2 - 1) = 200$  (that is, Phase value for Sync Receiver module 2)

$TBPHS(3,3) = 400$  (that is, Phase value for Sync Receiver module 3)

[Figure 22-101](#) shows the waveforms for the configuration in [Figure 22-100](#).

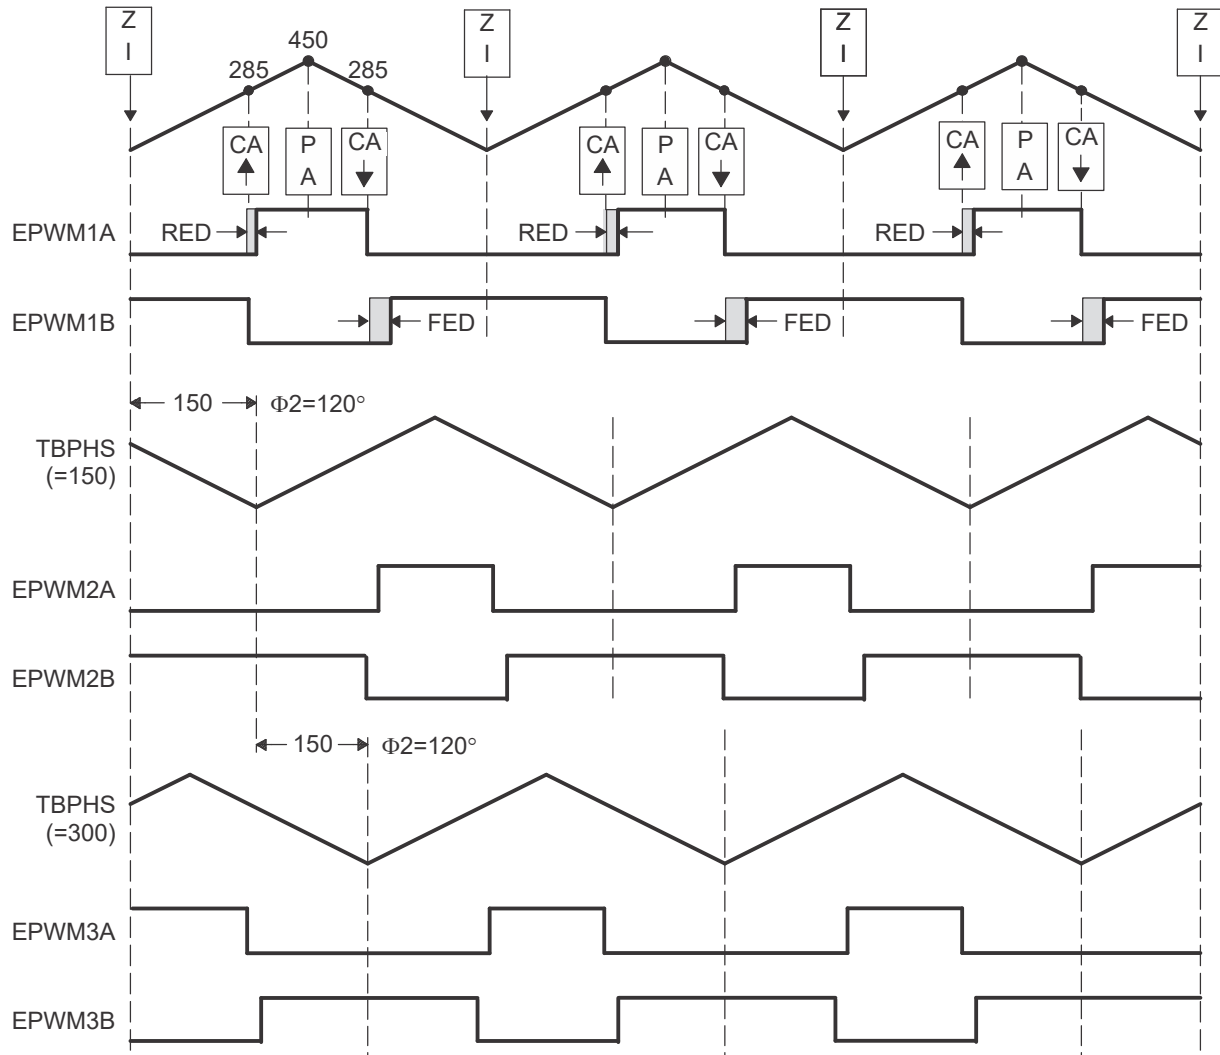

Figure 22-100. Control of 3-Phase Interleaved DC/DC Converter

**Figure 22-101. 3-Phase Interleaved DC/DC Converter Waveforms for Control of 3-Phase Interleaved DC/DC Converter**

### 22.16.9 Controlling Zero Voltage Switched Full Bridge (ZVSFB) Converter

The example given in [Figure 22-102](#) assumes a static or constant phase relationship between legs (modules). In such a case, control is achieved by modulating the duty cycle. It is also possible to dynamically change the phase value on a cycle-by-cycle basis. This feature lends to controlling a class of power topologies known as *phase-shifted full bridge*, or *zero voltage switched full bridge*. Here the controlled parameter is not duty cycle (this is kept constant at approximately 50 percent); instead it is the phase relationship between legs. Such a system can be implemented by allocating the resources of two PWM modules to control a single power stage, which in turn requires control of four switching elements. [Figure 22-103](#) shows a sync source and sync receiver module combination synchronized together to control a full H-bridge. In this case, both sync source and sync receiver modules are required to switch at the same PWM frequency. The phase is controlled by using the sync receiver phase register (TBPHS). The sync source phase register is not used and therefore can be initialized to zero.

**Figure 22-102. Control of Full-H Bridge Stage ( $F_{PWM2} = F_{PWM1}$ )**

Figure 22-103. ZVS Full-H Bridge Waveforms

### 22.16.10 Controlling a Peak Current Mode Controlled Buck Module

Peak current control techniques offer a number of benefits like automatic over current limiting, fast correction for input voltage variations and reducing magnetic saturation. Figure 22-104 shows the use of ePWM1A along with the on-chip analog comparator for buck converter topology. The output current is sensed through a current sense resistor and fed to the positive terminal of the on-chip comparator. The internal programmable 12-bit DAC can be used to provide a reference peak current at the negative terminal of the comparator. Alternatively, an external reference can be connected at this input. The comparator output is an input to the Digital compare sub-module. The ePWM module is configured in such a way so as to trip the ePWM1A output as soon as the sensed current reaches the peak reference value. A cycle-by-cycle trip mechanism is used. Figure 22-105 shows the waveforms generated by the configuration.

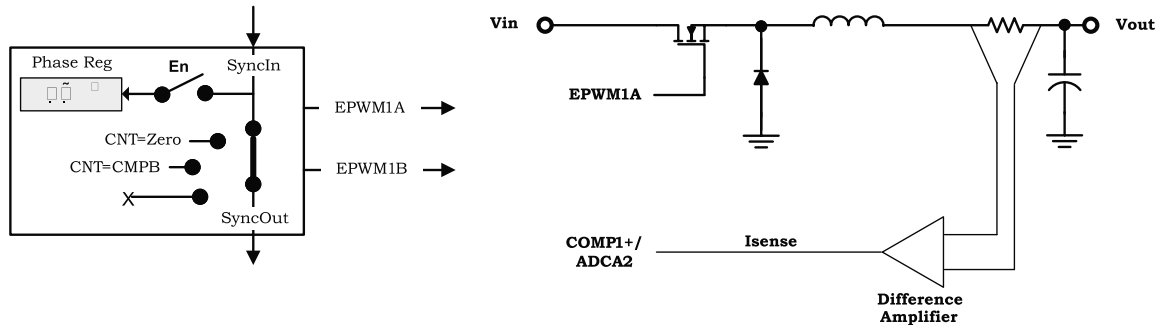

Figure 22-104. Peak Current Mode Control of Buck Converter

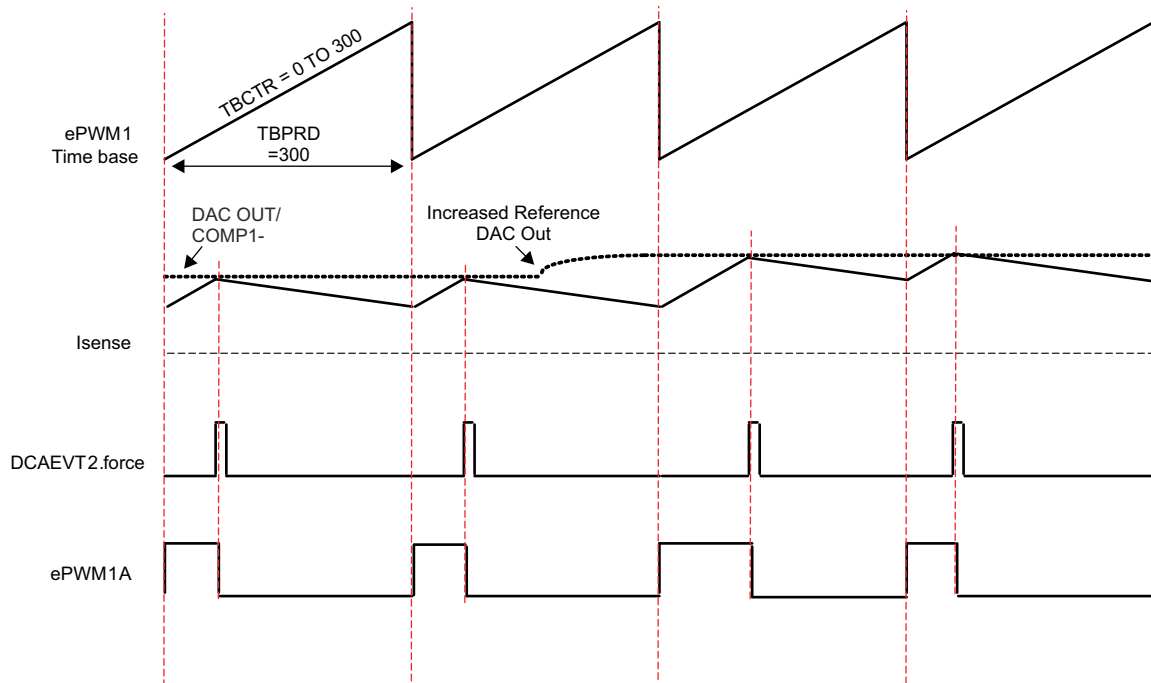

Figure 22-105. Peak Current Mode Control Waveforms for Control of Buck Converter

### 22.16.11 Controlling H-Bridge LLC Resonant Converter

Various topologies of resonant converters are well-known in the field of power electronics for many years. In addition to these, H-bridge LLC resonant converter topology has recently gained popularity in many consumer electronics applications where high efficiency and power density are required. In this example, single channel configuration of ePWM1 is detailed, yet the configuration can easily be extended to multichannel. Here the controlled parameter is not duty cycle (this is kept constant at approximately 50 percent); instead the parameter is frequency. Although the deadband is not controlled and kept constant as 300ns (that is, 30 at 100MHz TBCLK), the user can update the deadband in real time to enhance the efficiency by adjusting enough time delay for soft switching.

NOTE  $\Theta = X$  indicates value in phase register is a "don't care"

Figure 22-106. Control of Two Resonant Converter Stages

**P I** Indicates this event triggers an interrupt

**CB A** Indicates this event triggers an ADC start of conversion

Figure 22-107. H-Bridge LLC Resonant Converter PWM Waveforms

## 22.17 Register Lock Protection

The register lock protection mechanism is added to protect the critical ePWM registers from being corrupted by accidental writes in case of runaway code. The register EPWMLOCK contains the definition of Lock bits (Table 22-17 shows the lock bits and the corresponding registers). This register also has a KEY field; writes to this register succeed only if the KEY field is written with a value of 0xa5a5. Refer to the register descriptions for more details.

**Table 22-17. Lock Bits and Corresponding Registers**

Bit Field	Definition	Registers Locked
HRLOCK	HRPWM Register Set Lock	HRCNFG, HRPWR, HRMSTEP, HRPCTL
GLLOCK	Global Load Register Set Lock	GLDCTL, GLDCFG
TZCFGLOCK	TripZone Register Set Lock	TZSEL, TZDCSEL, TZCTL, TZCTL2, TZCTLDCA, TZCTLDCB, TZEINT
TZCLRLOCK	TripZone Clear Register Set Lock	TZCLR, TZCBCCLR, TZOSTCLR, TZFRC
DCLOCK	Digital Compare Register Set Lock	DCTRIPSEL, DCACTL, DCBCTL, DCFCTL, DCCAPCTL, DCAHTRIPSEL, DCALTRIPSEL, DCBHTRIPSEL, DCBLTRIPSEL

### Note

Due to the presence of the KEY field in the same register, only 32-bit writes succeed if the KEY matches. The 16-bit writes to the upper or lower half of this register are ignored.

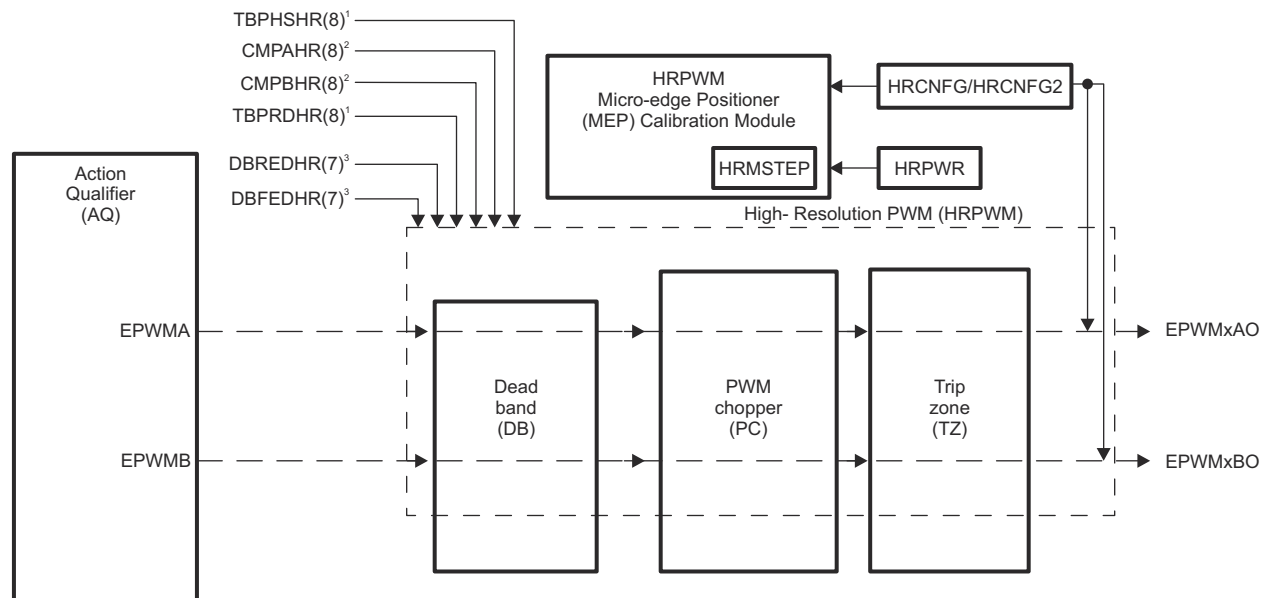

## 22.18 High-Resolution Pulse Width Modulator (HRPWM)

Figure 22-108 shows a block diagram of the HRPWM. This module extends the time resolution capabilities of the conventionally derived digital pulse width modulator (PWM). HRPWM is typically used when PWM resolution falls below approximately 9-10 bits. The key features of HRPWM are:

- Extended time resolution capability
- Used in both duty cycle and phase-shift control methods
- Finer time granularity control or edge positioning using extensions to the Compare A, Compare B and Phase registers
- Implemented using the A and B signal path of PWM, that is, on the EPWMxA and EPWMxB output
- Dead band high-resolution control for falling and rising edge delay in half cycle clocking operation
- Self-check diagnostics software mode to check if the micro edge positioner (MEP) logic is running how designed
- Enables high-resolution output swapping on the EPWMxA and EPWMxB output
- Enables high-resolution output on EPWMxB signal output using inversion of EPWMxA signal output
- Enables high-resolution period, duty and phase control on the EPWMxA and EPWMxB output on devices with an ePWM module

### Note

See the device data sheet to determine if your device has an ePWM module with high-resolution period support.

- A. From ePWM Time-base (TB) submodule  
 B. From ePWM counter-compare (CC) submodule  
 C. From ePWM Deadband (DB) submodule

**Figure 22-108. HRPWM Block Diagram**

The ePWM peripheral is used to perform a function mathematically equivalent to a digital-to-analog converter (DAC). As shown in Figure 22-109, the effective resolution for conventionally generated PWM is a function of PWM frequency (or period) and system clock frequency.

Figure 22-109. Resolution Calculations for Conventionally Generated PWM

If the required PWM operating frequency does not offer sufficient resolution in PWM mode, consider using HRPWM. As an example of improved performance offered by HRPWM, Table 22-18 shows resolution in bits for various PWM frequencies. These values assume a MEP step size of 180ps. See the device data sheet for typical and maximum performance specifications for the MEP.

Table 22-18. Resolution for PWM and HRPWM

PWM Frequency (kHz)	Regular Resolution (PWM) 100MHz EPWMCLK		High Resolution (HRPWM)	
	Bits	%	Bits	%
20	12.3	0.02	18.1	0.000
50	11	0.05	16.8	0.001
100	10	0.1	15.8	0.002
150	9.4	0.15	15.2	0.003
200	9	0.2	14.8	0.004
250	8.6	0.25	14.4	0.005
500	7.6	0.5	13.4	0.009
1000	6.6	1	12.4	0.018
1500	6.1	1.5	11.9	0.027
2000	5.6	2	11.4	0.036

Although each application can differ, typical low-frequency PWM operation (below 250kHz) does not require HRPWM. HRPWM capability is most useful for high-frequency PWM requirements of power conversion topologies such as:

- Single-phase buck, boost, and flyback
- Multiphase buck, boost, and flyback
- Phase-shifted full bridge
- Direct modulation of D-Class power amplifiers

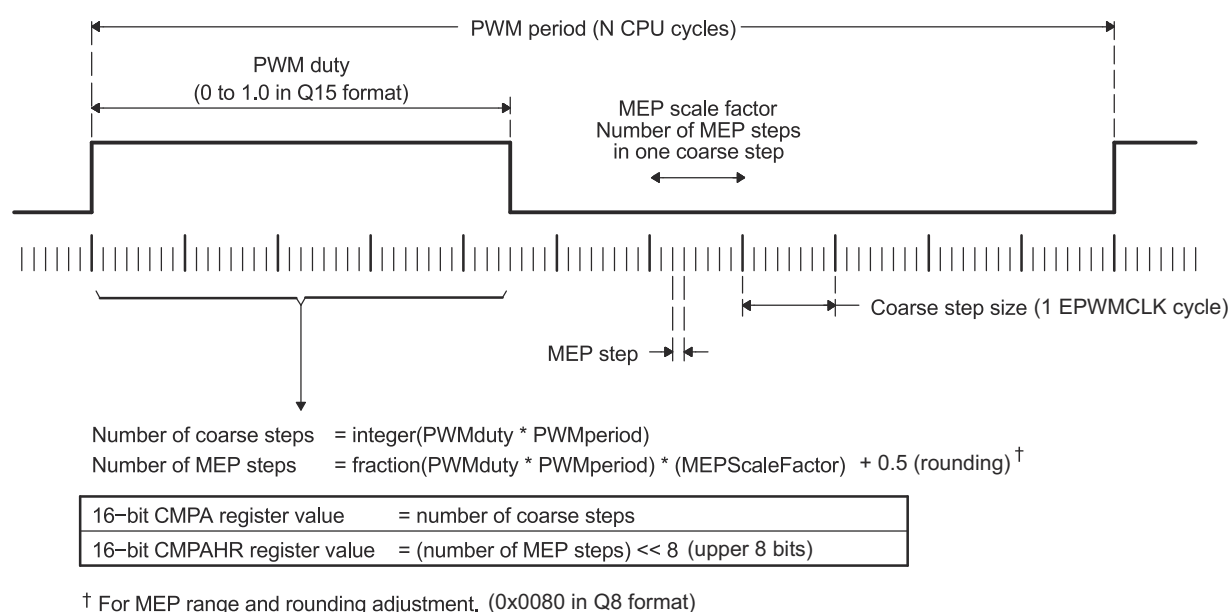

### 22.18.1 Operational Description of HRPWM

The HRPWM is based on micro-edge positioner (MEP) technology. MEP logic is capable of positioning an edge very finely by sub-dividing one coarse system clock of a conventional PWM generator. The time step accuracy is on the order of 150ps. See the device data sheet for the typical MEP step size on a particular device. The HRPWM also has a self-check software diagnostics mode to check if the MEP logic is running as designed under all operating conditions. Details on software diagnostics and functions are in [Section 22.18.1.7](#).

[Figure 22-110](#) shows the relationship between one coarse system clock and edge position in terms of MEP steps, which are controlled using an 8-bit field in the Compare A extension register (CMPAHR). The same operating logic applies to CMPBHR as well.

To generate an HRPWM waveform, configure the ePWM registers to generate a conventional PWM of a given frequency and polarity. The HRPWM works together with the ePWM registers to extend edge resolution. Although many programming combinations are possible, only a few are needed and practical. These methods are described in [Section 22.18.1.8](#).

**Figure 22-110. Operating Logic Using MEP**

#### 22.18.1.1 Controlling the HRPWM Capabilities

The MEP of the HRPWM is controlled by six extension registers. These HRPWM registers are concatenated with the 16-bit TBPHS, TBPRD, CMPA, CMPBM, DBREDM, and DBFEDM registers used to control PWM operation.

- TBPHSHR - Time Base Phase High Resolution Register
- CMPAHR - Counter Compare A High Resolution Register; CMPAHR is for use with the AQ output of Channel A, and is not related to CMPA
- TBPRDHR - Time Base Period High Resolution Register. (available on some devices)
- CMPBHR - Counter Compare B High Resolution Register; CMPBHR is for use with the AQ output of Channel B, and is not related to CMPB
- DBREDHR - Dead-band Generator Rising Edge Delay High Resolution Register
- DBFEDHR - Dead-band Generator Falling Edge Delay High Resolution Register

A. Dependent upon your device, these registers can be mirrored and can be written to at two different memory locations.

**Figure 22-111. HRPWM Extension Registers and Memory Configuration**

**Note**

HRPWM capabilities on Deadband Rising Edge Delay and Falling Edge Delay is applicable only during dead band half cycle clocking Operation. The number of MEP steps is half in size [bits 15:9] than duty and phase high-resolution registers for the same reason.

A minimum of 4 cycles difference (including the HR component) between adjacent XCMP values must be maintained to make sure of minimum pulse width when HR is enabled. A difference of less than 4 cycles would result in incorrect HR placement.

HRPWM capabilities are controlled using the Channel A and B PWM signal path. HRPWM support on the Dead band signal path is available by properly configuring the HRCNFG2 register. shows how the HRPWM interfaces with the 8-bit extension registers.

### 22.18.1.2 HRPWM Source Clock

Each HRPWM module is clocked from the respective EPWMxCLK. HRCAL has a separate clock. For example, HRPWM1 is sourced from EPWM1CLK while HRPWM2 is clocked from the EPWM2CLK. Figure 22-112 shows the HRCAL and HRPWM modules are sourced from the respective ePWM clock source.

**Figure 22-112. HRPWM and HRCAL Source Clock**

### 22.18.1.3 Configuring the HRPWM

Once the ePWM has been configured to provide conventional PWM of a given frequency and polarity, the HRPWM is configured by programming the HRCNFG register in that particular ePWM module's register space. This register provides the following configuration options:

- Edge Mode** The MEP can be programmed to provide precise position control on the rising edge (RE), falling edge (FE) or both edges (BE) at the same time. FE and RE are used for power topologies requiring duty cycle control (CMPA or CMPB high-resolution control), while BE is used for topologies requiring phase shifting, for example, phase shifted full bridge (TBPHS or TBPRD high-resolution control).
- Control Mode** The MEP is programmed to be controlled either from the CMPAHR/CMPBHR register in case of duty cycle control or the TBPHSHR register (phase control). RE or FE control mode can be used with the CMPAHR or CMPBHR register. BE control mode can be used with the TBPHSHR register. When the MEP is controlled from the TBPRDHR register (period control), the duty cycle and phase can also be controlled using the respective high-resolution registers.
- Shadow Mode** This mode provides the same shadowing (double buffering) option as in regular PWM mode. This option is valid only when operating from the CMPAHR, CMPBHR, and TBPRDHR registers and can be chosen to be the same as the regular load option for the CMPA/CMPB register. If TBPHSHR is used, then this option has no effect.
- High-Resolution B Signal Control** The B signal path of an ePWM channel can generate a high-resolution output by outputting an inverted version of the high-resolution ePWMxA signal on the ePWMxB pin. A Type 2 or Type 4 HRPWM module can also enable high-resolution features on the B signal path independently of the A signal path as well.
- Swap ePWMxA and ePWMxB Outputs** This mode enables the swapping of the high-resolution A and B outputs. The mode selection allows either A and B Outputs Unchanged or A Output Comes Out On B and B Output Comes Out On A.

**Auto-  
conversion  
Mode**

This mode is used in conjunction with the scale factor optimization (SFO) software only. For a type 4 HRPWM module, below is a description of the Auto-conversion Mode taking CMPAHR as an example. If auto-conversion is enabled,  $CMPAHR = \text{fraction}(PWMduty \times PWMperiod) \ll 8$ . The scale factor optimization software calculates the MEP scale factor in the background code and automatically updates the HRMSTEP register with the calculated number of MEP steps per coarse step. The MEP Calibration Module then uses the values in the HRMSTEP and CMPAHR registers to automatically calculate the appropriate number of MEP steps represented by the fractional duty cycle and moves the high-resolution ePWM signal edge accordingly. If auto-conversion is disabled, the CMPAHR register behaves like a type 0 HRPWM module and  $CMPAHR = (\text{fraction}(PWMduty \times PWMperiod) \times \text{MEP Scale Factor} + 0.5) \ll 8$ . All calculations need to be performed by your code in this mode, and the HRMSTEP register is ignored. Auto-conversion for high-resolution period has the same behavior as auto-conversion for high-resolution duty cycle. Auto-conversion must always be enabled for high-resolution period mode.

---

**Note**

If the HRPWM module is configured in UP-DOWN counter mode, the shadow mode for the HRPWM registers must be set to load on both ZERO AND PERIOD. New values from the user are loaded to the shadow registers only at CTR = ZERO, but the shadow mode of for the registers must be set to both ZERO AND PERIOD. The CTR = PRD event is used for specific internal logic inside the HRPWM module.

Auto-conversion Mode performs the calculation for CMPBHR, DBREDHR, and DBFEDHR. The scale factor optimization software calculates the MEP scale factor in the background code and automatically updates the HRMSTEP register with the calculated number of MEP steps per coarse step. The MEP Calibration Module then uses the values in the HRMSTEP and CMPBHR or DBREDHR/DBFEDHR register to automatically calculate the appropriate number of MEP steps represented by the fractional components and moves the high-resolution ePWM signal edge accordingly. If auto-conversion is disabled, CMPBHR behaves the same as CMPAHR.  $CMPBHR = (\text{fraction}(PWMduty \times PWMperiod) \times \text{MEP Scale Factor} + 0.5) \ll 8$ .

---

**Linking CMPBHR to CMPAHR**

Starting with EPWM Type 5, the user has the option to link the CMPBHR value to the CMPAHR value. This allows for EPWM channel A and EPWM channel B outputs to both be controlled by CMPAHR. This feature is enabled through CMPCTL.LINKDUTYHR register. This feature is commonly used when the HRPWM is configured for complimentary output mode.

### 22.18.1.4 Configuring High-Resolution in Deadband Rising-Edge and Falling-Edge Delay

Once the ePWM has been configured to provide conventional PWM of a given frequency, polarity, and dead band enabled in half-cycle clocking mode, the high-resolution operation on dead band RED and FED lines are enabled by programming the HRCNFG2 register in that particular ePWM module register space. This register provides the following configuration options:

- Edge Mode** The MEP can be programmed to provide precise position control on the dead band rising edge (RED), dead band falling edge (FED), or both edges (rising edge of DBRED signal and falling edge of DBFED signal) at the same time.
- Control Mode** Selects the time event that loads the shadow value in the active register for DBRED and DBFED in high-resolution mode. Select the pulse to match the selection in the ePWM DBCTL[LOADREDMODE] and DBCTL[LOADFEDMODE] bits.

### 22.18.1.5 Principle of Operation

The MEP logic is capable of placing an edge in one of 255 (8 bits) discrete time steps (see the device data sheet for typical MEP step size). The MEP works with the TBM and CCM registers to be certain that time steps are applied and that edge placement accuracy is maintained over a wide range of PWM frequencies, system clock frequencies, and other operating conditions. Table 22-19 shows the typical range of operating frequencies supported by the HRPWM.

**Table 22-19. Relationship Between MEP Steps, PWM Frequency, and Resolution**

System (MHz)	MEP Steps Per EPWMCLK <sup>(1)</sup> <sup>(2)</sup> <sup>(3)</sup>	PWM Minimum (Hz) <sup>(4)</sup>	PWM Maximum (MHz)	Resolution at Maximum (Bits) <sup>(5)</sup>
60.0	93	916	3.00	10.9
70.0	79	1068	3.50	10.6
80.0	69	1221	4.00	10.4
90.0	62	1373	4.50	10.3
100.0	56	1526	5.00	10.1

(1) TBCLK = EPWMCLK.

(2) Table data based on a MEP time resolution of 180ps (this is an example value. See the device data sheet for MEP limits)

(3) MEP steps applied =  $T_{EPWMCLK}/180ps$  in this example.

(4) PWM minimum frequency is based on a maximum period value, (TBPRD = 65535). PWM mode is asymmetrical up-count.

(5) Resolution in bits is given for the maximum PWM frequency stated.

22.18.1.5.1 Edge Positioning

Note

The following example is presented using the [CMPA:CMPAHR] register combination. The theory of operation and equations are the same, if intending to use the [CMPBM:CMPBHRM] for duty cycle control.

In a typical power control loop, a digital controller issues a duty command, usually expressed in a per unit or percentage terms. Assume that for a particular operating point, the demanded duty cycle is 0.405 or 40.5% on time and the required converter PWM frequency is 1.25MHz. In conventional PWM generation with a system clock of 100MHz, the duty cycle choices are in the vicinity of 40.5%. As shown in Figure 22-113, a compare value of 32 counts (duty = 40%) is the closest to 40.5% that can be attained. This is equivalent to an edge position of 320ns instead of the desired 324ns. This data is shown in Table 22-20.

By utilizing the MEP, an edge position much closer to the desired point of 324ns can be achieved. Table 22-20 shows that in addition to the CMPA value, 22 steps of the MEP (CMPAHR register) positions the edge at 323.96ns, resulting in almost zero error. In this example, assume that the MEP has a step resolution of 180ps.

Figure 22-113. Required PWM Waveform for a Requested Duty = 40.5%

Table 22-20. CMPA versus Duty (left), and [CMPA:CMPAHR] versus Duty (right)

CMPA (count) <sup>(1) (2) (3)</sup>	Duty (%)	High Time (ns)	CMPA (count)	CMPAHR (count)	Duty (%)	High Time (ns)
28	35.0	280	32	18	40.405	323.24
29	36.3	290	32	19	40.428	323.42
30	37.5	300	32	20	40.450	323.60
31	38.8	310	32	21	40.473	323.78
32	40.0	320	32	22	40.495	323.96
33	41.3	330	32	23	40.518	324.14
34	42.5	340	32	24	40.540	324.32
			32	25	40.563	324.50
Required			32	26	40.585	324.68
32.40	40.5	324	32	27	40.608	324.86

- (1) Assumed MEP step size for the above example = 180ps. See the device-specific data sheet for typical and maximum MEP values.
- (2) TBCLK = 100MHz, 10ns
- (3) For a PWM Period register value of 80 counts, PWM Period = 80 × 10ns = 800ns, PWM frequency = 1/800ns = 1.25MHz

### 22.18.1.5.2 Scaling Considerations

The mechanics of how to position an edge precisely in time has been demonstrated using the resources of the standard CMPA and MEP (CMPAHR) registers. In a practical application, however, it is necessary to seamlessly provide the CPU a mapping function from a per-unit (fractional) duty cycle to a final integer (non-fractional) representation that is written to the [CMPA:CMPAHR] register combination.

To do this, first examine the scaling or mapping steps involved. It is common in control software to express duty cycle in a per-unit or percentage basis. This has the advantage of performing all needed math calculations without concern for the final absolute duty cycle, expressed in clock counts or high time in nanoseconds (ns). Furthermore, it makes the code more transportable across multiple converter types running different PWM frequencies.

To implement the mapping scheme, a two-step scaling procedure is required.

#### Assumptions for this example:

TBCLK	=	10ns (100MHz)
PWM frequency	=	1.25MHz (1/800ns)
Required PWM duty cycle, <b>PWMDuty</b>	=	0.405 (40.5%)
PWM period in terms of coarse steps, <b>PWMPeriod</b> (800ns/10ns)	=	80
Number of MEP steps per coarse step at 180ps (10ns/180ps), <b>MEP_ScaleFactor</b>	=	55
Value to keep CMPAHR within the range of 1-255 and fractional rounding constant (default value)	=	0.5 (0080h in Q8 format)

#### Step 1: Percentage Integer Duty value conversion for CMPA register

CMPA register value	=	$\text{int}(\text{PWMDuty} * \text{PWMPeriod})$ ; int means integer part
	=	$\text{int}(0.405 * 80)$
	=	$\text{int}(32.4)$
CMPA register value	=	32 (20h)

#### Step 2: Fractional value conversion for CMPAHR register

CMPAHR	=	$(\text{frac}(\text{PWMDuty} * \text{PWMPeriod}) * \text{MEP\_ScaleFactor} + 0.5) \ll 8$ ; frac means fractional part
	=	$(\text{frac}(32.4) * 55 + 0.5) \ll 8$ ; Shifting is to move the value to the high byte of CMPAHR.
	=	$(0.4 * 55 + 0.5) \ll 8$
	=	$(22 + 0.5) \ll 8$
	=	$22.5 * 256$ ; Shifting left by 8 is the same as multiplying by 256.
	=	5760 (1680h)
CMPAHR	=	1680h CMPAHR value = 1600h (lower 8 bits are ignored by hardware).

---

### Note

If the AUTOCONV bit (HRCNFG.6) is set and the MEP\_ScaleFactor is in the HRMSTEP register, then CMPAHR / CMPBHR register value =  $\text{frac}(\text{PWMDuty} * \text{PWMperiod} << 8)$ . The rest of the conversion calculations are performed automatically in hardware, and the correct MEP-scaled signal edge appears on the ePWM channel output. If AUTOCONV is not set, the above calculations must be performed by software.

The MEP scale factor (MEP\_ScaleFactor) varies with the system clock and DSP operating conditions. TI provides an MEP scale factor optimizing (SFO) software C function, which uses the built in diagnostics in each HRPWM and returns the best scale factor for a given operating point.

The scale factor varies slowly over a limited range so the optimizing C function can be run very slowly in a background loop.

The CMPA, CMPB, CMPAHR and CMPBHR registers are configured in memory so that the 32-bit data capability of the CPU can write this as a single concatenated value, that is, [CMPA:CMPAHR], [CMPB:CMPBHR], and so on.

The mapping scheme has been implemented in both C and assembly, as shown in [Section 22.18.1.8](#). The actual implementation takes advantage of the 32-bit CPU architecture and is somewhat different from the steps shown in [Section 22.18.1.5.2](#).

For time-critical control loops where every cycle counts, the assembly version is recommended. This is a cycle optimized function (11 EPWMCLK cycles) that takes a Q15 duty value as input and writes a single [CMPA:CMPAHR] value.

---

#### 22.18.1.5.3 Duty Cycle Range Limitation

In high-resolution mode, the MEP is not active for 100% of the PWM period and becomes operational:

- Three EPWMCLK cycles after the period starts when high-resolution period (TBPRDHR) control is not enabled.
- When high-resolution period (TBPRDHR) control is enabled using the HRPCTL register:
  - In up-count mode: three EPWMCLK cycles after the period starts until three EPWMCLK cycles before the period ends.
  - In up-down count mode: when counting up, three cycles after CTR = 0 until three cycles before CTR = PRD, and when counting down, three cycles after CTR = PRD until three cycles before CTR = 0.
- When using DBREDHR or DBFEDHR, DBRED or DBFED (the register corresponding to the edge with high-resolution displacement) must be greater than or equal to 7.

Duty cycle range limitations are illustrated in [Figure 22-114](#) to [Figure 22-117](#). This limitation imposes a duty cycle limit on the MEP. For example, precision edge control is not available all the way down to 0% duty cycle. When high-resolution period control is disabled, regular PWM duty control is fully operational down to 0% duty cycle despite the unavailability of HRPWM features in the first three cycles. In most applications, this cannot be an issue as the controller regulation point is usually not designed to be close to 0% duty cycle. To better understand the useable duty cycle range, see [Table 22-21](#). When high-resolution period control is enabled (HRPCTL[HRPE] = 1), the duty cycle must not fall within the restricted range; otherwise, there can be undefined behavior on the ePWMxA output.

**Figure 22-114. Low % Duty Cycle Range Limitation Example (HRPCTL[HRPE] = 0)**

**Table 22-21. Duty Cycle Range Limitation for Three EPWMCLK/TBCLK Cycles**

PWM Frequency <sup>(1)</sup> (kHz)	3 Cycles Minimum Duty	3 Cycles Maximum Duty <sup>(2)</sup>
200	0.6%	99.4%
400	1.2%	98.8%
600	1.8%	98.2%
800	2.4%	97.6%
1000	3%	97%
1200	3.6%	96.4%
1400	4.2%	95.8%
1600	4.8%	95.2%
1800	5.4%	94.6%
2000	6%	94%

(1) EPWMCLK = TBCLK = 100MHz

(2) This limitation applies only if high-resolution period (TBPRDHR) control is enabled.

If the application demands HRPWM operation below the minimum duty cycle limitation, then the HRPWM can be configured to operate in count-down mode with the rising edge position (REP) controlled by the MEP when high-resolution period is disabled (HRPCTL[HRPE] = 0). This is illustrated in [Figure 22-115](#). In this configuration, the minimum duty cycle limitation is no longer an issue. However, there is a maximum duty limitation with same percent numbers as given in [Table 22-21](#).

#### CAUTION

If the application has enabled high-resolution period control (HRPCTL[HRPE] = 1), the duty cycle must not fall within the restricted range; otherwise, there can be undefined behavior on the ePWM output.

Figure 22-115. High % Duty Cycle Range Limitation Example (HRPCTL[HRPE] = 0)

Figure 22-116. Up-Count Duty Cycle Range Limitation Example (HRPCTL[HRPE] = 1)

Figure 22-117. Up-Down Count Duty Cycle Range Limitation Example (HRPCTL[HRPE] = 1)

### 22.18.1.5.4 High-Resolution Period

High-resolution period control using the MEP logic is supported on devices with a Type 1 ePWM module or greater.

#### Note

When high-resolution period control is enabled, on ePWMxA only, and not ePWMxB output and conversely, the non high-resolution output has  $\pm 1$  TBCLK cycle jitter in up-count mode and  $\pm 2$  TBCLK cycle jitter in up-down count mode.

The scaling procedure described for duty cycle in [Section 22.18.1.5.2](#) applies for high-resolution period as well:

#### Assumptions for this example:

TBCLK	= 10ns (100MHz)
Required PWM frequency	= 175kHz (period of 571.428)
Number of MEP steps per coarse step at 180ps (10ns/180ps), (MEP_ScaleFactor)	= 55
Value to keep TBPRDHR within range of 1-255 and fractional rounding constant (default value)	= 0.5 (0080h in Q8 format)

#### Problem:

In up-count mode:

- If TBPRD = 571, then PWM frequency = 174.82kHz (period =  $(571+1) * T_{TBCLK}$ ).
- If TBPRD = 570, then PWM frequency = 175.13kHz (period =  $(570+1) * T_{TBCLK}$ ).

In up-down count mode:

- If TBPRD = 286, then PWM frequency = 174.82kHz (period =  $(286*2) * T_{TBCLK}$ ).
- If TBPRD = 285, then PWM frequency = 175.44kHz (period =  $(285*2) * T_{TBCLK}$ ).

#### Solution:

With 55 MEP steps per coarse step at 180ps each:

#### Step 1: Percentage Integer Period value conversion for TBPRD register

Integer period value	= $571 * T_{TBCLK}$
	= $\text{int}(571.428) * T_{TBCLK}$
	= $\text{int}(\text{PWMperiod}) * T_{TBCLK}$

In up-count mode:

TBPRD	= 570 (TBPRD = period value - 1)
	= 023Ah

In up-down count mode:

TBPRD	= 285 (TBPRD = period value/2)
	= 011Dh

## Step 2: Fractional value conversion for TBPRDHR register

In up-count mode:

$$\text{TBPRDHR register value} = (\text{frac}(\text{PWMperiod}) * \text{MEP\_ScaleFactor} + 0.5)$$

If auto-conversion enabled and HRMSTEP =

$$\text{MEP\_ScaleFactor value (55):} = \text{frac}(\text{PWMperiod}) \ll 8 \text{ (Shifting is to move the value to the high byte of TBPRDHR)}$$

$$\begin{aligned} \text{TBPRDHR register value} &= \text{frac}(571.428) \ll 8 \\ &= 0.428 \times 256 \\ &= 6D00\text{h} \end{aligned}$$

The auto-conversion then automatically performs the calculation, such that TBPRDHR MEP delay is scaled by hardware to:

$$\begin{aligned} &= ((\text{TBPRDHR}(15:0) \gg 8) \times \text{HRMSTEP} + 80\text{h}) \ll 8 \\ &= (006D\text{h} \times 55 + 80\text{h}) \gg 8 \\ &= (17EB\text{h}) \gg 8 \end{aligned}$$

$$\text{Period MEP delay} = 0017\text{h MEP Steps}$$

In up-down count mode:

$$\text{TBPRDHR register value} = (\text{frac}(\text{PWMperiod}) * \text{MEP\_ScaleFactor} + 0.5)$$

If auto-conversion enabled and HRMSTEP =

$$\text{MEP\_ScaleFactor value (55):} = \text{frac}(\text{PWMperiod} / 2) \ll 8 \text{ (Shifting is to move the value to the high byte of TBPRDHR)}$$

$$\begin{aligned} \text{TBPRDHR register value} &= \text{frac}(285.714) \ll 8 \\ &= 0.714 \times 256 \\ &= B600\text{h} \end{aligned}$$

The auto-conversion then automatically performs the calculation, such that TBPRDHR MEP delay is scaled by hardware to:

$$\begin{aligned} &= (00B6\text{h} \times 55 + 80\text{h}) \gg 8 \\ &= (279A\text{h}) \gg 8 \end{aligned}$$

$$\text{Period MEP delay} = 0027\text{h MEP Steps}$$

#### 22.18.1.5.4.1 High-Resolution Period Configuration

To use high-resolution period, the ePWMx module must be initialized in the exact order presented.

The following steps use CMPA with shadow registers and the corresponding HRCNFG bits for high-resolution operation on EPWMxA. For high-resolution operation on EPWMxB, make the appropriate substitutions with the B channel fields.

1. Enable ePWMx clock
2. Enable HRPWM clock
3. Disable TBCLKSYNC
4. Configure ePWMx registers - AQ, TBPRD, CC, and so on.
  - ePWMx can only be configured for up-count or up-down count modes. High-resolution period is not compatible with down-count mode.
  - TBPRD and CC registers must be configured for shadow loads.
  - CMPCTL[LOADAMODE]
    - In up-count mode: CMPCTL[LOADAMODE] = 1 (load on CTR = PRD)
    - In up-down count mode: CMPCTL[LOADAMODE] = 2 (load on CTR = 0 or CTR = PRD)
5. Configure the HRCNFG register such that:
  - HRCNFG[HRLOAD] = 2 (load on either CTR = 0 or CTR = PRD)
  - HRCNFG[AUTOCONV] = 1 (Enable auto-conversion)
  - HRCNFG[EDGMODE] = 3 (MEP control on both edges)
6. For TBPHS:TBPHSHR synchronization with high-resolution period, set both HRPCTL[TBPSHRLOADE] = 1 and TBCTL[PHSEN] = 1. In up-down count mode these bits must be set to 1 regardless of the contents of TBPHSHR.
7. Enable high-resolution period control (HRPCTL[HRPE] = 1)
8. Enable TBCLKSYNC
9. TBCTL[SWFSYNC] = 1
10. HRMSTEP must contain an accurate MEP scale factor (# of MEP steps per EPWMCLK coarse step) because auto-conversion is enabled. The MEP scale factor can be acquired using the SFO() function described in [Section 22.18.2](#).
11. To control high-resolution period, write to the TBPRDHR(M) registers.

---

#### Note

When high-resolution period mode is enabled, an EPWMxSYNC pulse introduces  $\pm 1$ -2 cycle jitter to the PWM ( $\pm 1$  cycle in up-count mode and  $\pm 2$  cycle in up-down count mode). For this reason, EPWMxSYNCO source cannot be set to CTR = 0 or CTR = CMPB. Otherwise, the jitter occurs on every PWM cycle with the synchronization pulse.

When EPWMxSYNCl is EPWMxSYNCO source, a software synchronization pulse can be issued only once during high-resolution period initialization. If a software sync pulse is applied while the PWM is running, the jitter appears on the PWM output at the time of the sync pulse.

---

### 22.18.1.6 Deadband High-Resolution Operation

---

#### Note

In up-count mode, the dead-band module is not available when any high-resolution mode is enabled.

---

#### Assumptions for this example:

System clock	= 10ns (100MHz)
Deadband enabled in half-cycle mode, TBCLK = EPWMCLK	
Required PWM frequency	1.33MHz (1/750ns)
Required PWM duty cycle	0.5 (50%)
Required Deadband Rising-Edge Delay	5% over duty
Required Deadband Rising-Edge Delay in ns	$(0.05 * 375ns) = 18.75ns$

---

#### Note

Similar to the duty cycle restrictions when using HRPWM, the DBRED and DBFED values must be greater than 3 to use high-resolution deadband.

---

#### Deadband delay values as a function of DBFED and DBRED:

When half-cycle clocking is enabled, the formula to calculate the falling-edge delay (FED) and rising-edge delay (RED) becomes:

$$FED = DBFED * TBCLK / 2$$

$$RED = DBRED * TBCLK / 2$$

#### DBRED and DBFED calculated values:

Required Deadband Rising-Edge Delay in ns = 18.75ns

$$DBRED = RED / (TBCLK / 2)$$

$$DBRED = 18.75ns/5ns$$

$$DBRED \text{ Required} = 3.75ns$$

With 55 MEP steps per coarse step at 180ps each:

**Step 1: Integer Deadband value conversion for DBREDM register**

Integer DBRED value	= int (RED / (TBCLK / 2))
	= int (3.75)
DBRED	= 3

**Step 2: Fractional value conversion for Deadband high-resolution register DBREDHR**

DBREDHR register value	= (frac(DBRED Required) * MEP_ScaleFactor + 0.5) << 8 (Shifting is to move the value to the high byte of DBREDHR)
	= (frac (3.75) * 55 + 0.5) << 8
	= (0.75 * 55 + 0.5) << 8
	= (41.75) * 256 Shifting left by 8 is the same as multiplying by 256.
DBREDHR value	= 29C0h MEP Steps
	Hardware ignores lower 9 bits in the above calculated DBREDHR value

---

**Note**

If the AUTOCONV bit (HRCNFG.6) is set and the MEP\_ScaleFactor is in the HRMSTEP register, then DBREDHR:DBRED = frac((required DB value) < <8). The rest of the conversion calculations are performed automatically in hardware, and the correct MEP-scaled signal edge appears on the ePWM channel output. If AUTOCONV is not set, the above calculations must be performed by software.

---

**22.18.1.7 Scale Factor Optimizing Software (SFO)**

The micro edge positioner (MEP) logic is capable of placing an edge in one of 255 discrete time steps. As previously mentioned, the size of these steps is on the order of 150ps (see the device data sheet for typical MEP step size on your device). The MEP step size varies based on worst-case process parameters, operating temperature, and voltage. MEP step size increases with decreasing voltage and increasing temperature and decreases with increasing voltage and decreasing temperature. Applications that use the HRPWM feature can use the TI-supplied MEP scale factor optimization (SFO) software function. The SFO function helps to dynamically determine the number of MEP steps per EPWMCLK period while the HRPWM is in operation.

To utilize the MEP capabilities effectively, the correct value for the MEP scaling factor needs to be known by the software. To accomplish this, the HRPWM module has built in self-check and diagnostic capabilities that can be used to determine the optimum MEP scale factor value for any operating condition. TI provides a C-callable library containing one SFO function that utilizes this hardware and determines the optimum MEP scale factor. As such, MEP control and diagnostics registers are reserved for TI use.

A detailed description of the SFO library - SFO\_TI\_Build\_V8.lib software can be found in [SFO Library Software - SFO TI\\_Build\\_V8.lib](#).

### 22.18.1.8 HRPWM Examples Using Optimized Assembly Code

The best way to understand how to use the HRPWM capabilities is through two real examples:

1. Simple buck converter using asymmetrical PWM (count-up) with active high polarity.
2. DAC function using simple R+C reconstruction filter.

The following examples all have initialization and configuration code written in C. To make these easier to understand, the #defines shown below are used.

[Example 22-2](#) assumes MEP step size of 150ps and does not use the SFO library.

#### Example 22-2. #Defines for HRPWM Header Files

```
// HRPWM (High Resolution PWM) //
=====
// HRCNFG
#define HR_Disable 0x0
#define HR_REP 0x1 // Rising Edge position
#define HR_FEP 0x2 // Falling Edge position
#define HR_BEP 0x3 // Both Edge position #define HR_CMP 0x0 // CMPAHR controlled
#define HR_PHS 0x1 // TBPHSHR controlled #define HR_CTR_ZERO 0x0 // CTR = Zero event
#define HR_CTR_PRD 0x1 // CTR = Period event
#define HR_CTR_ZERO_PRD 0x2 // CTR = ZERO or Period event
#define HR_NORM_B 0x0 // Normal ePWMxB output
#define HR_INVERT_B 0x1 // ePWMxB is inverted ePWMxA output
```

### 22.18.1.8.1 Implementing a Simple Buck Converter

In this example, the PWM requirements are:

- PWM frequency = 1MHz (that is, TBPRD = 100)
- PWM mode = asymmetrical, up-count
- Resolution = 12.7 bits (with a MEP step size of 150ps)

Figure 22-118 and Figure 22-119 show the required PWM waveform. As explained previously, configuration for the ePWM1 module is almost identical to the normal case except that the appropriate MEP options need to be enabled/selected.

**Figure 22-118. Simple Buck Controlled Converter Using a Single PWM**

**Figure 22-119. PWM Waveform Generated for Simple Buck Controlled Converter**

The example code shown consists of two main parts:

- Initialization code (executed once)
- Run time code (typically executed within an ISR)

Example 22-3 shows the Initialization code. The first part is configured for conventional PWM. The second part sets up the HRPWM resources.

This example assumes MEP step size of 150ps and does not use the SFO library.

Example 22-4 shows an assembly example of run-time code for the HRPWM buck converter.

### Example 22-3. HRPWM Buck Converter Initialization Code

```

void HrBuckDrvCnf(void)
{
// Config for conventional PWM first
EPwm1Regs.TBCTL.bit.PRDL = TB_IMMEDIATE;           // set Immediate load
EPwm1Regs.TBPRD = 100;                             // Period set for 1000kHz PWM
hrbuck_period = 200;                                // Used for Q15 to Q0 scaling
EPwm1Regs.TBCTL.bit.CTRMODE = TB_COUNT_UP;         // EPWM1 is the Sync Source
EPwm1Regs.TBCTL.bit.PHSEN = TB_DISABLE;

EPwm1Regs.TBCTL.bit.HSPCLKDIV = TB_DIV1;
EPwm1Regs.TBCTL.bit.CLKDIV = TB_DIV1;
// Note: ChB is initialized here only for comparison purposes, it is not required

EPwm1Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO;
EPwm1Regs.CMPCTL.bit.SHDWAMODE = CC_SHADOW;
EPwm1Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO;      // optional
EPwm1Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW;       // optional
EPwm1Regs.AQCTLA.bit.ZRO = AQ_SET;
EPwm1Regs.AQCTLA.bit.CAU = AQ_CLEAR;
EPwm1Regs.AQCTLB.bit.ZRO = AQ_SET;                // optional
EPwm1Regs.AQCTLB.bit.CBU = AQ_CLEAR;              // optional
// Now configure the HRPWM resources
EALLOW;                                           // Note these registers are protected
                                                    // and act only on ChA
EPwm1Regs.HRCNFG.all = 0x0;                       // clear all bits first
EPwm1Regs.HRCNFG.bit.EDGMODE = HR_FEP;            // Control Falling Edge Position
EPwm1Regs.HRCNFG.bit.CTLMODE = HR_CMP;            // CMPAHR controls the MEP
EPwm1Regs.HRCNFG.bit.HRLOAD = HR_CTR_ZERO;        // Shadow load on CTR=Zero
EDIS;
MEP_ScaleFactor = 66*256;                          // Start with typical Scale Factor
                                                    // value for 100MHz
                                                    // Note: Use SFO functions to update
                                                    // MEP_ScaleFactor dynamically
}

```

### Example 22-4. HRPWM Buck Converter Run-Time Code

```

EPWM1_BASE .set 0x6800
CMPAHR1 .set EPWM1_BASE+0x8
;=====
HRBUCK_DRV; (can execute within an ISR or loop)
;=====
    MOVW DP, #_HRBUCK_In
    MOVL XAR2,@_HRBUCK_In      ; Pointer to Input Q15 Duty (XAR2)
    MOVL XAR3,#CMPAHR1        ; Pointer to HRPWM CMPA reg (XAR3)

; Output for EPWM1A (HRPWM)
    MOV T,*XAR2 ; T <= Duty
    MPYU ACC,T,@_hrbuck_period ; Q15 to Q0 scaling based on Period
    MOV T,@_MEP_ScaleFactor    ; MEP scale factor (from optimizer s/w)
    MPYU P,T,@AL               ; P <= T * AL, Optimizer scaling
    MOVH @AL,P                 ; AL <= P, move result back to ACC
    ADD ACC, #0x080            ; MEP range and rounding adjustment
    MOVL *XAR3,ACC             ; CMPA: CMPAHR(31:8) <= ACC

; Output for EPWM1B (Regular Res) Optional - for comparison purpose only
    MOV *+XAR3[2],AH           ; Store ACCH to regular CMPB

```

### 22.18.1.8.2 Implementing a DAC Function Using an R+C Reconstruction Filter

In this example, the PWM requirements are:

- PWM frequency = 400kHz (that is, TBPRD = 250)
- PWM mode = Asymmetrical, Up-count
- Resolution = 14 bits (MEP step size = 150ps)

Figure 22-120 and Figure 22-121 show the DAC function and the required PWM waveform. As explained previously, configuration for the ePWM1 module is almost identical to the normal case except that the appropriate MEP options need to be enabled/selected.

**Figure 22-120. Simple Reconstruction Filter for a PWM-based DAC**

**Figure 22-121. PWM Waveform Generated for the PWM DAC Function**

The example code shown consists of two main parts:

- Initialization code (executed once)
- Run time code (typically executed within an ISR)

This example assumes a typical MEP\_SP and does not use the SFO library.

[Example 22-5](#) shows the Initialization code. The first part is configured for conventional PWM. The second part sets up the HRPWM resources.

[Example 22-6](#) shows an assembly example of run-time code that can execute in a high-speed ISR loop.

### Example 22-5. PWM DAC Function Initialization Code

```

void HrPwmDacDrvCnf(void)
{
// Config for conventional PWM first
EPwm1Regs.TBCTL.bit.PRDL = TB_IMMEDIATE;           // Set Immediate load
EPwm1Regs.TBPRD = 250;                             // Period set for 400kHz PWM
hrDAC_period = 250;                                 // Used for Q15 to Q0 scaling
EPwm1Regs.TBCTL.bit.CTRMODE = TB_COUNT_UP;
EPwm1Regs.TBCTL.bit.PHSEN = TB_DISABLE;           // EPWM1 is the Sync Source

EPwm1Regs.TBCTL.bit.HSPCLKDIV = TB_DIV1;
EPwm1Regs.TBCTL.bit.CLKDIV = TB_DIV1;
// Note: ChB is initialized here only for comparison purposes, it is not required

EPwm1Regs.CMPCTL.bit.LOADAMODE = CC_CTR_ZERO;
EPwm1Regs.CMPCTL.bit.SHDWAMODE = CC_SHADOW;
EPwm1Regs.CMPCTL.bit.LOADBMODE = CC_CTR_ZERO;    // optional
EPwm1Regs.CMPCTL.bit.SHDWBMODE = CC_SHADOW;     // optional

EPwm1Regs.AQCTLA.bit.ZRO = AQ_SET;
EPwm1Regs.AQCTLA.bit.CAU = AQ_CLEAR;
EPwm1Regs.AQCTLB.bit.ZRO = AQ_SET;              // optional
EPwm1Regs.AQCTLB.bit.CBU = AQ_CLEAR;           // optional
// Now configure the HRPWM resources
EALLOW;                                         // Note these registers are protected
                                                // and act only on ChA.
EPwm1Regs.HRCNFG.all = 0x0;                    // Clear all bits first
EPwm1Regs.HRCNFG.bit.EDGMODE = HR_FEP;        // Control falling edge position
EPwm1Regs.HRCNFG.bit.CTLMODE = HR_CMP;        // CMPAHR controls the MEP.
EPwm1Regs.HRCNFG.bit.HRLOAD = HR_CTR_ZERO;    // Shadow load on CTR=Zero.
EDIS;
MEP_ScaleFactor = 66*256;                       // Start with typical Scale Factor
                                                // value for 100MHz.
                                                // Use SFO functions to update MEP_ScaleFactor
                                                // dynamically.
}

```

### Example 22-6. PWM DAC Function Run-Time Code

```

EPWM1_BASE .set 0x6800
CMPAHR1 .set EPWM1_BASE+0x8
;=====
HRPWM_DAC_DRV; (can execute within an ISR or loop)
;=====
    MOVW DP, #_HRDAC_In
    MOVL XAR2,@_HRDAC_In           ; Pointer to input Q15 duty (XAR2)
    MOVL XAR3,#CMPAHR1            ; Pointer to HRPWM CMPA reg (XAR3)

; Output for EPWM1A (HRPWM
    MOV T,*XAR2                    ; T <= duty
    MPY ACC,T,@_hrDAC_period       ; Q15 to Q0 scaling based on period
    ADD ACC,@_hrDAC_period<<15    ; Offset for bipolar operation
    MOV T,@_MEP_ScaleFactor        ; MEP scale factor (from optimizer s/w)
    MPYU P,T,@AL                   ; P <= T * AL, optimizer scaling
    MOVH @AL,P                     ; AL <= P, move result back to ACC
    ADD ACC,#0x080                 ; MEP range and rounding adjustment
    MOVL *XAR3,ACC                 ; CMPA: CMPAHR(31:8) <= ACC

; Output for EPWM1B (Regular Res) Optional - for comparison purpose only
    MOV *+XAR3[2],AH               ; Store ACCH to regular CMPB

```

## 22.18.2 SFO Library Software - SFO\_TI\_Build\_V8.lib

Table 22-22 lists several features of the SFO\_TI\_Build\_V8.lib library.

**Table 22-22. SFO Library Features**

	SFO_TI_Build_V8.lib	Unit
Completion-checking?	Yes	Function return value
Typical cycles required for SFO() to update MEP_ScaleFactor if called repetitively without interrupts	130,000	EPWMCLK cycles

### 22.18.2.1 Scale Factor Optimizer Function - int SFO()

This routine drives the micro-edge positioner (MEP) calibration module to run SFO diagnostics and determine the appropriate MEP scale factor (number of MEP steps per coarse EPWMCLK step) for a device at any given time.

If EPWMCLK = TBCLK = 100MHz and assuming the MEP step size is 150ps, the typical scale factor value at 100MHz = 66 MEP steps per TBCLK unit (10ns)

The function returns a MEP scale factor value:

MEP\_ScaleFactor = Number of MEP steps per EPWMCLK

#### Constraints when using this function:

- SFO() can be used with a minimum EPWMCLK = TBCLK = 50MHz. MEP diagnostics logic uses EPWMCLK and not TBCLK, so the EPWMCLK restriction is an important constraint. Below 50MHz with device process variation, the MEP step size can decrease under cold temperature and high core voltage conditions to such a point that 255 MEP steps do not span an entire EPWMCLK cycle.
- At any time, SFO() can be called to run SFO diagnostics on the MEP calibration module.

#### Usage:

- SFO() can be called at any time in the background while the ePWM channels are running in HRPWM mode. The scale factor result obtained can be applied to all ePWM channels running in HRPWM mode because the function makes use of the diagnostics logic in the MEP calibration module (which runs independently of ePWM channels).
- This routine returns a 1 when calibration is finished and a new scale factor has been calculated or returns a 0 if calibration is still running. The routine returns a 2 if there is an error, and the MEP\_ScaleFactor is greater than the maximum 255 fine steps per coarse EPWMCLK cycle. In this case, the HRMSTEP register maintains the last MEP scale factor value less than 256 for auto conversion.
- All ePWM modules operating in HRPWM incur only a 3 EPWMCLK cycle minimum duty cycle limitation when high-resolution period control is not used. If high-resolution period control is enabled, there is an additional duty cycle limitation 3-EPWMCLK cycles before the end of the PWM period (see [Section 22.18.1.5.3](#)).
- The SFO() function also updates the HRMSTEP register with the scale factor result. If the HRCNFG[AUTOCONV] bit is set, the application software is responsible only for setting  $CMPAHR = \text{fraction}(\text{PWMduty} * \text{PWMperiod}) \ll 8$  or  $CMPBHR = \text{fraction}(\text{PWMduty} * \text{PWMperiod}) \ll 8$  or  $TBPRDHR = \text{fraction}(\text{PWMperiod})$  while running SFO() in the background. The MEP Calibration Module then uses the values in the HRMSTEP and CMPAHR/CMPBHR/TBPRDHR register to automatically calculate the appropriate number of MEP steps represented by the fractional duty cycle or period and move the high-resolution ePWM signal edge accordingly.
- If the HRCNFG[AUTOCONV] bit is clear, the HRMSTEP register is ignored. The application software needs to perform the necessary calculations manually so that:
  - $CMPAHR = (\text{fraction}(\text{PWMduty} * \text{PWMperiod}) * \text{MEP Scale Factor}) \ll 8 + 0x080$ .
  - Similar behavior applies for TBPHSHR, CMPBHR, DBREDHR, and DBFEDHR. Auto-conversion must be enabled when using TBPRDHR.

The following code snippet shows how to use the HRPWM DUTY using driverlib functions.

```
float32_t dutyFine = 85.62;
float32_t count = (dutyFine * (float32_t)(EPWM_TIMER_TBPRD << 8))/100;
uint32_t compCount = (count);
HRPWM_setCounterCompareValue(EPWM1_BASE, HRPWM_COUNTER_COMPARE_A, compCount);
HRPWM_setCounterCompareValue(EPWM1_BASE, HRPWM_COUNTER_COMPARE_B, compCount);
```

The routine can be run as a background task in a slow loop requiring negligible CPU cycles. The repetition rate at which an SFO function needs to be executed depends on the application's operating environment. As with all digital CMOS devices, temperature and supply voltage variations have an effect on MEP operation. However, in most applications these parameters vary slowly and therefore is often sufficient to execute the SFO function once every 5 to 10 seconds. If more rapid variations are expected, then execution can be performed more frequently to match the application. Note there is no high limit restriction on the SFO function repetition rate; hence, the SFO function can execute as quickly as the background loop is capable.

While using the HRPWM feature, HRPWM logic is not active for the first 3 EPWMCLK cycles of the PWM period (and the last 3 EPWMCLK cycles of the PWM period if TBPRDHR is used). While running the application in this configuration, if high-resolution period control is disabled (HRPCTL[HRPE = 0]) and the CMPA/CMPB register value is less than 3 cycles, then the CMPAHR/CMPBHR register must be cleared to zero. If high-resolution period control is enabled (HRPCTL[HRPE = 1]), the CMPA register value must not fall below 3 or above TBPRD-3. This can avoid any unexpected transitions on the PWM signal.

### 22.18.2.2 Software Usage

The software library function SFO(), calculates the MEP scale factor for the HRPWM-supported ePWM modules. The scale factor is an integer value in the range 1-255, and represents the number of micro step edge positions available for a system clock period. The scale factor value is returned in an integer variable called MEP\_ScaleFactor. For example, see [Table 22-23](#).

**Table 22-23. Factor Values**

Software Function call	Functional Description	Updated Variables
SFO()	Returns MEP scale factor in the HRMSTEP register	MEP_ScaleFactor and HRMSTEP register.

To use the HRPWM feature of the ePWMs, it is recommended that the SFO function be used as described here.

#### Step 1. Add "Include" Files

The SFO\_V8.h file needs to be included as follows. This include file is mandatory while using the SFO library function. For the SFO() to operate, the appropriate (Device)\_Device.h and (Device)\_Epwm\_defines.h must be included in the project. These include files are optional if customized header files are used in the end applications.

#### Example 22-7. A Sample of How to Add "Include" Files

```
#include "F28x7x_Device.h" // F28x7x Headerfile
#include "F28x7x_EPwm_defines.h" // init defines
#include "SFO_v8.h" // SFO lib functions (needed for HRPWM)
```

## Step 2. Element Declaration

Declare an integer variable for the scale factor value as shown below.

### Example 22-8. Declaring an Element

```
int MEP_ScaleFactor = 0; //scale factor value
volatile struct EPWM_REGS *ePWM[] = {0, &EPwm1Regs, &EPwm2Regs, &EPwm3Regs,
&EPwm4Regs};
```

## Step 3. MEP\_ScaleFactor Initialization

The SFO() function does not require a starting scale factor value in MEP\_ScaleFactor. Prior to using the MEP\_ScaleFactor variable in application code, SFO() can be called to drive the MEP calibration module to calculate an MEP\_ScaleFactor value.

As part of the one-time initialization code prior to using MEP\_ScaleFactor, include the following:

### Example 22-9. Initializing With a Scale Factor Value

```
MEP_ScaleFactor initialized using function SFO ()
while (SFO() == 0) {} // MEP_ScaleFactor calculated by MEP Cal Module
```

## Step 4. Application Code

While the application is running, fluctuations in both device temperature and supply voltage can be expected. To be sure that good Scale Factors are used for each ePWM module, the SFO function can be re-run periodically as part of a slower back-ground loop. Some examples of this are shown here.

### Note

See the HRPWM\_SFO example in the device-specific C/C++ header files and peripheral examples available from the TI website.

### Example 22-10. SFO Function Calls

```
main ()
{
    int status;
    // User code
    // ePWM1, 2, 3, 4 are running in HRPWM mode
    // The status variable returns 1 once a new MEP_ScaleFactor has been
    // calculated by the MEP Calibration Module running SFO
    // diagnostics.
    status = SFO();
    if(status==2) {ESTOP0;} // The function returns a 2 if MEP_ScaleFactor is greater
    // than the maximum 255 allowed (error condition)
}
```

## 22.19 Software

### 22.19.1 EPWM Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/epwm

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 22.19.1.1 ePWM Trip Zone - SINGLE\_CORE

FILE: epwm\_ex1\_trip\_zone.c

This example configures ePWM1 and ePWM2 as follows

- ePWM1 has TZ1 as one shot trip source
- ePWM2 has TZ1 as cycle by cycle trip source

Initially tie TZ1 high. During the test, monitor ePWM1 or ePWM2 outputs on a scope. Pull TZ1 low to see the effect.

##### *External Connections*

- ePWM1A is on GPIO0
- ePWM2A is on GPIO2
- TZ1 is on GPIO12

This example also makes use of the Input X-BAR. GPIO12 (the external trigger) is routed to the input X-BAR, from which it is routed to TZ1.

The TZ-Event is defined such that ePWM1A will undergo a One-Shot Trip and ePWM2A will undergo a Cycle-By-Cycle Trip.

#### 22.19.1.2 ePWM Up Down Count Action Qualifier - SINGLE\_CORE

FILE: epwm\_ex2\_updown\_aq.c

This example configures ePWM1, ePWM2, ePWM3 to produce a waveform with independent modulation on ePWMxA and ePWMxB.

The compare values CMPA and CMPB are modified within the ePWM's ISR.

The TB counter is in up/down count mode for this example.

View the ePWM1A/B(GPIO0 & GPIO1), ePWM2A/B(GPIO2 & GPIO3) and ePWM3A/B(GPIO4 & GPIO5) waveforms on oscilloscope.

#### 22.19.1.3 ePWM Synchronization - SINGLE\_CORE

FILE: epwm\_ex3\_synchronization.c

This example configures ePWM1, ePWM2, ePWM3 and ePWM4 as follows

- ePWM1 without phase shift as sync source
- ePWM2 with phase shift of 300 TBCLKs
- ePWM3 with phase shift of 600 TBCLKs
- ePWM4 with phase shift of 900 TBCLKs

##### *External Connections*

- GPIO0 EPWM1A
- GPIO1 EPWM1B
- GPIO2 EPWM2A
- GPIO3 EPWM2B
- GPIO4 EPWM3A
- GPIO5 EPWM3B
- GPIO6 EPWM4A

- GPIO7 EPWM4B

*Watch Variables*

- None.

**22.19.1.4 ePWM Digital Compare - SINGLE\_CORE**

FILE: epwm\_ex4\_digital\_compare.c

This example configures ePWM1 as follows

- ePWM1 with DCAEVT1 forcing the ePWM output LOW
- GPIO25 is used as the input to the INPUT XBAR INPUT1
- INPUT1 (from INPUT XBAR) is used as the source for DCAEVT1
- GPIO25's PULL-UP resistor is enabled, in order to test the trip, PULL this pin to GND

*External Connections*

- GPIO0 EPWM1A
- GPIO1 EPWM1B
- GPIO25 TZ1, pull this pin low to trip the ePWM

*Watch Variables*

- None.

**22.19.1.5 ePWM Digital Compare Event Filter Blanking Window - SINGLE\_CORE**

FILE: epwm\_ex5\_digital\_compare\_event\_filter.c

This example configures ePWM1 as follows

- ePWM1 with DCAEVT1 forcing the ePWM output LOW
- GPIO25 is used as the input to the INPUT XBAR INPUT1
- INPUT1 (from INPUT XBAR) is used as the source for DCAEVT1
- GPIO25's PULL-UP resistor is enabled, in order to test the trip, PULL this pin to GND
- ePWM1 with DCBEVT1 forcing the ePWM output LOW
- GPIO25 is used as the input to the INPUT XBAR INPUT1
- INPUT1 (from INPUT XBAR) is used as the source for DCAEVT1
- GPIO25's PULL-UP resistor is enabled, in order to test the trip, PULL this pin to GND
- DCBEVT1 uses the filtered version of DCBEVT1
- The DCFILT signal uses the blanking window to ignore the DCBEVT1 for the duration of DC Blanking window

*External Connections*

- GPIO0 EPWM1A
- GPIO1 EPWM1B
- GPIO25 TRIPIN1, pull this pin low to trip the ePWM

*Watch Variables*

- None.

**22.19.1.6 ePWM Valley Switching - SINGLE\_CORE**

FILE: epwm\_ex6\_valley\_switching.c

This example configures ePWM1 as follows

- ePWM1 with DCAEVT1 forcing the ePWM output LOW
- GPIO25 is used as the input to the INPUT XBAR INPUT1
- INPUT1 (from INPUT XBAR) is used as the source for DCAEVT1
- GPIO25 is set to output and toggled in the main loop to trip the PWM
- ePWM1 with DCBEVT1 forcing the ePWM output LOW
- GPIO25 is used as the input to the INPUT XBAR INPUT1
- INPUT1 (from INPUT XBAR) is used as the source for DCAEVT1

- GPIO25 is set to output and toggled in the main loop to trip the PWM
- DCBEVT1 uses the filtered version of DCBEVT1
- The DCFILT signal uses the valley switching module to delay the
- DCFILT signal by a software defined DELAY value.

#### *External Connections*

- GPIO0 EPWM1A
- GPIO1 EPWM1B
- GPIO25 TRIPIN1 (Output Pin, toggled through software)

#### *Watch Variables*

- None.

### **22.19.1.7 ePWM Digital Compare Edge Filter - SINGLE\_CORE**

FILE: epwm\_ex7\_edge\_filter.c

This example configures ePWM1 as follows

- ePWM1 with DCBEVT2 forcing the ePWM output LOW as a CBC source
- GPIO25 is used as the input to the INPUT XBAR INPUT1
- INPUT1 (from INPUT XBAR) is used as the source for DCBEVT2
- GPIO25 is set to output and toggled in the main loop to trip the PWM
- The DCBEVT2 is the source for DCFILT
- The DCFILT will count edges of the DCBEVT2 and generate a signal to to trip the ePWM on the 4th edge of DCBEVT2

#### *External Connections*

- GPIO0 EPWM1A
- GPIO1 EPWM1B
- GPIO25 TRIPIN1 (Output Pin, toggled through software)

#### *Watch Variables*

- None.

### **22.19.1.8 ePWM Deadband - SINGLE\_CORE**

FILE: epwm\_ex8\_deadband.c

This example configures ePWM1 through ePWM6 as follows

- ePWM1 with Deadband disabled (Reference)
- ePWM2 with Deadband Active High
- ePWM3 with Deadband Active Low
- ePWM4 with Deadband Active High Complimentary
- ePWM5 with Deadband Active Low Complimentary
- ePWM6 with Deadband Output Swap (switch A and B outputs)

#### *External Connections*

- GPIO0 EPWM1A
- GPIO1 EPWM1B
- GPIO2 EPWM2A
- GPIO3 EPWM2B
- GPIO4 EPWM3A
- GPIO5 EPWM3B
- GPIO6 EPWM4A
- GPIO7 EPWM4B
- GPIO8 EPWM5A
- GPIO9 EPWM5B
- GPIO14 EPWM6A

- GPIO11 EPWM6B

#### *Watch Variables*

- None.

#### **22.19.1.9 ePWM DMA - SINGLE\_CORE**

FILE: epwm\_ex9\_dma.c

This example configures ePWM1 and DMA as follows:

- ePWM1 is set up to generate PWM waveforms
- DMA5 is set up to update the CMPAHR, CMPA, CMPBHR and CMPB every period with the next value in the configuration array. This allows the user to create a DMA enabled fifo for all the CMPx and CMPxHR registers to generate unconventional PWM waveforms.
- DMA6 is set up to update the TBPHSHR, TBPHS, TBPRDHR and TBPRD every period with the next value in the configuration array.
- Other registers such as AQCTL can be controlled through the DMA as well by following the same procedure. (Not used in this example)

#### *External Connections*

- GPIO0 EPWM1A
- GPIO1 EPWM1B

#### *Watch Variables*

- None.

#### **22.19.1.10 ePWM Chopper - SINGLE\_CORE**

FILE: epwm\_ex10\_chopper.c

This example configures ePWM1, ePWM2, ePWM3 and ePWM4 as follows

- ePWM1 with Chopper disabled (Reference)
- ePWM2 with chopper enabled at 1/8 duty cycle
- ePWM3 with chopper enabled at 6/8 duty cycle
- ePWM4 with chopper enabled at 1/2 duty cycle with One-Shot Pulse enabled

#### *External Connections*

- GPIO0 EPWM1A
- GPIO1 EPWM1B
- GPIO2 EPWM2A
- GPIO3 EPWM2B
- GPIO4 EPWM3A
- GPIO5 EPWM3B
- GPIO6 EPWM4A
- GPIO7 EPWM4B

#### *Watch Variables*

- None.

#### **22.19.1.11 EPWM Configure Signal - SINGLE\_CORE**

FILE: epwm\_ex11\_configure\_signal.c

This example configures ePWM1, ePWM2, ePWM3 to produce signal of desired frequency and duty. It also configures phase between the configured modules.

Signal of 10kHz with duty of 0.5 is configured on ePWMxA & ePWMxB with ePWMxB inverted. Also, phase of 120 degree is configured between ePWM1 to ePWM3 signals.

During the test, monitor ePWM1, ePWM2, and/or ePWM3 outputs on an oscilloscope.

- ePWM1A is on GPIO0
- ePWM1B is on GPIO1
- ePWM2A is on GPIO2
- ePWM2B is on GPIO3
- ePWM3A is on GPIO4
- ePWM3B is on GPIO5

#### 22.19.1.12 Realization of Monoshot mode - SINGLE\_CORE

FILE: epwm\_ex12\_monoshot\_mode.c

This example showcases how to generate monoshot PWM output based on external trigger i.e. generating just a single pulse output on receipt of an external trigger. And the next pulse will be generated only when the next trigger comes. The example utilizes external synchronization and T1 action qualifier event features to achieve the desired output.

ePWM1 is used to generate the monoshot output and ePWM2 is used as an external trigger for that. No external connections are required as ePWM2A is fed as the trigger using Input X-BAR automatically.

ePWM1 is configured to generate a single pulse of 0.5us when received an external trigger. This is achieved by enabling the phase synchronization feature and configuring EPWMxSYNCl as EXTSYNClN1. And this EPWMxSYNCl is also configured as T1 event of action qualifier to set output HIGH while "CTR = PRD" action is used to set output LOW.

ePWM2 is configured to generate a 100 KHz signal with a duty of 1% (to simulate a rising edge trigger) which is routed to EXTSYNClN1 using Input XBAR.

Observe GPIO0 (EPWM1A : Monoshot Output) and GPIO2(EPWM2 : External Trigger) on oscilloscope.

#### 22.19.1.13 EPWM Action Qualifier (epwm\_up\_aq) - SINGLE\_CORE

FILE: epwm\_ex13\_up\_aq.c

This example configures ePWM1, ePWM2, ePWM3 to produce an waveform with independent modulation on EPWMxA and EPWMxB.

The compare values CMPA and CMPB are modified within the ePWM's ISR.

The TB counter is in up count mode for this example.

View the EPWM1A/B(GPIO0 & GPIO1), EPWM2A/B(GPIO2 & GPIO3) and EPWM3A/B(GPIO4 & GPIO5) waveforms via an oscilloscope.

#### 22.19.1.14 ePWM XCMP Mode - SINGLE\_CORE

FILE: epwm\_ex15\_xcmp\_multiple\_edges.c

(Note - base frequency and duty cycle of all ePWM's are 50 KHz and 50% respectively. Value of TBPRD = 1999)  
This example configures ePWM1, ePWM2, ePWM4, ePWM6 and ePWM8 as follows

- ePWM1A is allocated all XCMP1-8 registers. ePWM1B has no output.
  - New duty cycle = 50%, new frequency = 200 KHz
  - No Shadow registers used
- ePWM2A is allocated XCMP1-4 and ePWM2B is allocated XCMP5-8 registers.
  - A and B waveforms are complimentary
  - New duty cycle = 50%, new frequency = 100 KHz
  - No Shadow registers used
- ePWM4 is configured same as ePWM2 with Minimum Deadband.
  - Minimum Deadband of 200 SYSCLK cycles provided ( $200 * (1/200 \text{ MHz}) = 1 \text{ micro second}$ )
  - This implies dead band of 1 us is visible on output of ePWM4A and ePWM4B after their falling edge
  - New duty cycle = 40%, new frequency = 100 KHz
- ePWM6A is allocated XCMP1-4 registers.

- 3 Shadow register sets used with LOADMULTIPLE mode
- Shadow set 2 repeated 2 times, Shadow set 3 repeated 4 times
- ISR to update all Shadow registers with new values after they repeat
- This means Shadow3 is active for 5 periods, Shadow2 is active for 3 periods and Shadow1 is active for 1 period before their new values are visible in output
- ePWM8A is allocated XCMP1-4 registers.
  - 3 Shadow register sets used with LOADONCE mode
  - Only Shadow set 3 is loaded from every period
  - ISR updates Shadow 3 register with new values every 5 periods

#### External Connections

- ePWM1A is on GPIO0
- ePWM2A is on GPIO2 and ePWM2B is on GPIO3
- ePWM4A is on GPIO6 and ePWM4B is on GPIO7
- ePWM6A is on GPIO14
- ePWM8A is on GPIO10
- Monitor GPIO24 for ePWM6A new Shadow register value loading
- Monitor GPIO25 for ePWM8A new Shadow register value loading

Shadow register updations for ePWM6 and ePWM8:

- Only XCMP1 and XCMP4 are updated
- Update values are +/- 20 TBCTR steps depending on direction of updation
- GPIO24 is toggled every 9 cycles for ePWM6 after cycling through all Shadow buffers and loading new values Similarly GPIO25 is toggled every 5 cycles for ePWM8

#### 22.19.1.15 ePWM Event Detection - SINGLE\_CORE

FILE: epwm\_ex16\_event\_detection.c

(Note - base frequency and duty cycle of all ePWM's are 50 KHz and 50% respectively. Value of TBPRD = 1999)  
This example configures ePWM1 and ePWM2 in identical fashion with XCMP1-8 allocated to channel A. No shadow registers are used.

- XCMP1 = 250, XMP2 = 500, XCMP3 = 750 ..... XCMP 8 = 1750.
- In ePWM1, XMIN = 300 and XMAX = 400.
  - This window has no edge and generates a CAPEVT pulse every period.
- In ePWM2, XMIN = 300 and XMAX = 600.
  - This window has an edge and doesn't generate CAPEVT pulse signal.

#### External Connections

- ePWM1A is on GPIO0
- ePWM2A is on GPIO2
- ePWM1 Tripout is on GPIO24
- ePWM2 Tripout is on GPIO25
- LED1 is on GPIO31 (For control card)
- LED2 is on GPIO34 (For control card)

CAPIN and CAPGATE signals are both sourced as Trip4 for ePWM1 and Trip5 for ePWM2. Trip4 and Trip5 are routed from the INPUT X-BAR through EPWM-XBAR which feeds into the Digital Compare submodule. CAPEVT signal is used as Tripout and Trip-Zone interrupt source.

For ePWM1, Trip-Zone ISR configured to make LED1 blink 1 second on/off. For ePWM2, Trip-Zone ISR configured to make LED2 turn on if an interrupt ever occurs.

#### 22.19.2 HRPWM Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/hrpwm

Cloud access to these examples is available at the following link: [dev.ti.com C2000Ware Examples](https://dev.ti.com/C2000Ware/Examples).

#### 22.19.2.1 HRPWM Duty Control with SFO

FILE: `hrpwm_ex1_duty_sfo.c`

This example modifies the MEP control registers to show edge displacement for high-resolution period with ePWM in Up count mode due to the HRPWM control extension of the respective ePWM module.

This example calls the following TI's MEP Scale Factor Optimizer (SFO) software library V8 functions:

*int SFO();*

- updates MEP\_ScaleFactor dynamically when HRPWM is in use
- updates HRMSTEP register (exists only in EPwm1Regs register space) with MEP\_ScaleFactor value
- returns 2 if error: MEP\_ScaleFactor is greater than maximum value of 255 (Auto-conversion may not function properly under this condition)
- returns 1 when complete for the specified channel
- returns 0 if not complete for the specified channel

This example is intended to explain the HRPWM capabilities. The code can be optimized for code efficiency. Refer to TI's Digital power application examples and TI Digital Power Supply software libraries for details.

##### *External Connections*

- Monitor ePWM1/2/3/4 A/B pins on an oscilloscope.

#### 22.19.2.2 HRPWM Slider

FILE: `hrpwm_ex2_slider.c`

This example modifies the MEP control registers to show edge displacement due to HRPWM. Control blocks of the respective ePWM module channel A and B have fine edge movement due to HRPWM logic.

Monitor ePWM1 A/B pins on an oscilloscope.

#### 22.19.2.3 HRPWM Period Control

FILE: `hrpwm_ex3_prd_updown_sfo.c`

This example modifies the MEP control registers to show edge displacement for high-resolution period with ePWM in Up-Down count mode due to the HRPWM control extension of the respective ePWM module.

This example calls the following TI's MEP Scale Factor Optimizer (SFO) software library V8 functions:

*int SFO();*

- updates MEP\_ScaleFactor dynamically when HRPWM is in use
- updates HRMSTEP register (exists only in EPwm1Regs register space) with MEP\_ScaleFactor value
- returns 2 if error: MEP\_ScaleFactor is greater than maximum value of 255 (Auto-conversion may not function properly under this condition)
- returns 1 when complete for the specified channel
- returns 0 if not complete for the specified channel

This example is intended to explain the HRPWM capabilities. The code can be optimized for code efficiency. Refer to TI's Digital power application examples and TI Digital Power Supply software libraries for details.

##### *External Connections*

- Monitor ePWM1/2/3/4 A/B pins on an oscilloscope.

#### 22.19.2.4 HRPWM Duty Control with UPDOWN Mode

FILE: `hrpwm_ex4_duty_updown_sfo.c`

This example calls the following TI's MEP Scale Factor Optimizer (SFO) software library V8 functions:

*int SFO();*

- updates MEP\_ScaleFactor dynamically when HRPWM is in use
- updates HRMSTEP register (exists only in EPwm1Regs register space) with MEP\_ScaleFactor value
- returns 2 if error: MEP\_ScaleFactor is greater than maximum value of 255 (Auto-conversion may not function properly under this condition)
- returns 1 when complete for the specified channel
- returns 0 if not complete for the specified channel

This example is intended to explain the HRPWM capabilities. The code can be optimized for code efficiency. Refer to TI's Digital power application examples and TI Digital Power Supply software libraries for details.

#### *External Connections*

- Monitor ePWM1/2/3/4 A/B pins on an oscilloscope.

#### **22.19.2.5 HRPWM Slider Test**

FILE: hrpwm\_ex5\_slider\_qformat.c

This example modifies the MEP control registers to show edge displacement due to HRPWM. Control blocks of the respective ePWM module channel A and B will have fine edge movement due to HRPWM logic. Load the hrpwm\_slider.gel file. Select the HRPWM\_eval from the GEL menu. A FineDuty slider graphics will show up in CCS. Load the program and run. Use the Slider to and observe the EPWM edge displacement for each slider step change. This explains the MEP control on the EPwmxA channels.

Monitor ePWM1 & ePWM2 A/B pins on an oscilloscope.

#### **22.19.2.6 HRPWM Duty Up Count**

FILE: hrpwm\_ex6\_duty\_sfo\_qformat.c

This example modifies the MEP control registers to show edge displacement for high-resolution period with ePWM in Up count mode due to the HRPWM control extension of the respective ePWM module.

This example calls the following TI's MEP Scale Factor Optimizer (SFO) software library V8 functions:

*int SFO();*

- updates MEP\_ScaleFactor dynamically when HRPWM is in use
- updates HRMSTEP register (exists only in EPwm1Regs register space) with MEP\_ScaleFactor value
- returns 2 if error: MEP\_ScaleFactor is greater than maximum value of 255 (Auto-conversion may not function properly under this condition)
- returns 1 when complete for the specified channel
- returns 0 if not complete for the specified channel

This example is intended to explain the HRPWM capabilities. The code can be optimized for code efficiency. Refer to TI's Digital power application examples and TI Digital Power Supply software libraries for details.

To run this example:

1. Run this example at maximum SYSCLKOUT
2. Activate Real time mode
3. Run the code

#### *External Connections*

- Monitor ePWM1/2 A/B pins on an oscilloscope.

#### *Watch Variables*

- status - Example run status
- updateFine - Set to 1 use HRPWM capabilities and observe in fine MEP steps(default) Set to 0 to disable HRPWM capabilities and observe in coarse SYSCLKOUT cycle steps

#### **22.19.2.7 HRPWM Period Up-Down Count**

FILE: hrpwm\_ex7\_prd\_updown\_sfo\_qformat.c

This example modifies the MEP control registers to show edge displacement for high-resolution period with ePWM in Up-Down count mode due to the HRPWM control extension of the respective ePWM module.

This example calls the following TI's MEP Scale Factor Optimizer (SFO) software library V8 functions:

```
int SFO();
```

- updates MEP\_ScaleFactor dynamically when HRPWM is in use
- updates HRMSTEP register (exists only in EPwm1Regs register space) with MEP\_ScaleFactor value
- returns 2 if error: MEP\_ScaleFactor is greater than maximum value of 255 (Auto-conversion may not function properly under this condition)
- returns 1 when complete for the specified channel
- returns 0 if not complete for the specified channel

This example is intended to explain the HRPWM capabilities. The code can be optimized for code efficiency. Refer to TI's Digital power application examples and TI Digital Power Supply software libraries for details.

To run this example:

1. Run this example at maximum SYSCLKOUT
2. Activate Real time mode
3. Run the code

#### External Connections

- Monitor ePWM1/2 A/B pins on an oscilloscope.

#### Watch Variables

- updateFine - Set to 1 use HRPWM capabilities and observe in fine MEP steps(default) Set to 0 to disable HRPWM capabilities and observe in coarse SYSCLKOUT cycle steps

## 22.20 ePWM Registers

This section describes the Enhanced Pulse Width Modulator registers.

### 22.20.1 EPWM Base Address Table

**Table 22-24. EPWM Base Address Table**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	CPU2	CPU2.DMA	Pipeline Protected
Instance	Structure								
EPwm17Regs	<a href="#">EPWM_REGS</a>	EPWM17_BASE	0x0000_2C00	YES	YES	YES	YES	YES	YES
EPwm17XcmpRegs	<a href="#">EPWM_XCMP_REGS</a>	EPWM17XCMP_BASE	0x0000_2D00	YES	YES	YES	YES	YES	YES
EPwm17DeRegs	<a href="#">DE_REGS</a>	EPWM17DE_BASE	0x0000_2DC0	YES	YES	YES	YES	YES	YES
EPwm17MinDbLutRegs	<a href="#">MINDB_LUT_REGS</a>	EPWM17MINDBLUT_BASE	0x0000_2DE0	YES	YES	YES	YES	YES	YES
EPwm18Regs	<a href="#">EPWM_REGS</a>	EPWM18_BASE	0x0000_2E00	YES	YES	YES	YES	YES	YES
EPwm18XcmpRegs	<a href="#">EPWM_XCMP_REGS</a>	EPWM18XCMP_BASE	0x0000_2F00	YES	YES	YES	YES	YES	YES

Complex bit access types are encoded to fit into small table cells. [Table 22-26](#) shows the codes that are used for access types in this section.

**Table 22-26. EPWM\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1C	W1C	Write 1 to clear
W1S	W1S	Write 1 to set
WOnce	WOnce	Write Write once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 22.20.2.1 TBCTL Register (Offset = 0h) [Reset = 0083h]

TBCTL is shown in [Figure 22-122](#) and described in [Table 22-27](#).

Return to the [Summary Table](#).

Time Base Control Register

**Figure 22-122. TBCTL Register**

15	14	13	12	11	10	9	8
FREE_SOFT		PHSDIR	CLKDIV			HSPCLKDIV	
R/W-0h		R/W-0h	R/W-0h			R/W-1h	
7	6	5	4	3	2	1	0
HSPCLKDIV	SWFSYNC	RESERVED		PRDL	PHSEN	CTRMODE	
R/W-1h	R-0/W1S-0h	R-0h		R/W-0h	R/W-0h	R/W-3h	

**Table 22-27. TBCTL Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-14	FREE_SOFT	R/W	0h	Emulation Mode Bits. These bits select the behavior of the ePWM time-base counter during emulation events 00: Stop after the next time-base counter increment or decrement 01: Stop when counter completes a whole cycle: - Up-count mode: stop when the time-base counter = period (TBCTR = TBPRD) - Down-count mode: stop when the time-base counter = 0x00 (TBCTR = 0x00) - Up-down-count mode: stop when the time-base counter = 0x00 (TBCTR = 0x00) 1x: Free run Reset type: SYSRSn
13	PHSDIR	R/W	0h	Phase Direction Bit This bit is only used when the time-base counter is configured in the up-down-count mode. The PHSDIR bit indicates the direction the time-base counter (TBCTR) will count after a synchronization event occurs and a new phase value is loaded from the phase (TBPHS) register. This is irrespective of the direction of the counter before the synchronization event. In the up-count and down-count modes this bit is ignored. 0: Count down after the synchronization event. 1: Count up after the synchronization event. Reset type: SYSRSn
12-10	CLKDIV	R/W	0h	Time Base Clock Pre-Scale Bits These bits select the time base clock pre-scale value (TBCLK = EPWMCLK/(HSPCLKDIV * CLKDIV): 000: /1 (default on reset) 001: /2 010: /4 011: /8 100: /16 101: /32 110: /64 111: /128 Reset type: SYSRSn

**Table 22-27. TBCTL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
9-7	HSPCLKDIV	R/W	1h	High Speed Time Base Clock Pre-Scale Bits These bits determine part of the time-base clock prescale value. $TBCLK = EPWMCLK / (HSPCLKDIV \times CLKDIV)$ . This divisor emulates the HSPCLK in the TMS320x281x system as used on the Event Manager (EV) peripheral. 000: /1 001: /2 (default on reset) 010: /4 011: /6 100: /8 101: /10 110: /12 111: /14 Reset type: SYSRSn
6	SWFSYNC	R-0/W1S	0h	Software Forced Sync Pulse 0: Writing a 0 has no effect and reads always return a 0. 1: Writing a 1 forces a one-time synchronization pulse to be generated. SWFSYNC can be enabled to affect EPWMxSYNCO by setting the EPWMSYNCOOUTEN.SWEN bit. Reset type: SYSRSn
5-4	RESERVED	R	0h	Reserved
3	PRDL	R/W	0h	Active Period Reg Load from Shadow Select 0: The period register (TBPRD) is loaded from its shadow register when the time-base counter, TBCTR, is equal to zero and/or a sync event as determined by the TBCTL2[PRDLDSYNC] bit. A write/read to the TBPRD register accesses the shadow register. 1: Immediate Mode (Shadow register bypassed): A write or read to the TBPRD register accesses the active register. Reset type: SYSRSn
2	PHSEN	R/W	0h	Counter Reg Load from Phase Reg Enable 0: Do not load the time-base counter (TBCTR) from the time-base phase register (TBPHS). 1: Allow Counter to be loaded from the Phase register (TBPHS) and shadow to active load events when an EPWMxSYNCl input signal occurs or a software-forced sync signal, see bit 6. Reset type: SYSRSn
1-0	CTRM	R/W	3h	Counter Mode The time-base counter mode is normally configured once and not changed during normal operation. If you change the mode of the counter, the change will take effect at the next TBCLK edge and the current counter value shall increment or decrement from the value before the mode change. These bits set the time-base counter mode of operation as follows: 00: Up-count mode 01: Down-count mode 10: Up-down count mode 11: Freeze counter operation (default on reset) Reset type: SYSRSn

### 22.20.2.2 TBCTL2 Register (Offset = 1h) [Reset = 0000h]

TBCTL2 is shown in [Figure 22-123](#) and described in [Table 22-28](#).

Return to the [Summary Table](#).

Time Base Control Register 2

R/W-0h		R/W-0h		R/W-0h				R/W-0h		R/W-0h		R/W-0h			
7		6		5		4		3		2		1		0	
LOADREDMODE				IN_MODE				POLSEL				OUT_MODE			
R/W-0h				R/W-0h				R/W-0h				R/W-0h			

**Table 22-36. DBCTL Register Field Descriptions**

Bit	Field	Type	Reset	Description
15	HALFCYCLE	R/W	0h	Half Cycle Clocking Enable Bit 0: Full cycle clocking enabled. The dead-band counters are clocked at the TBCLK rate. 1: Half cycle clocking enabled. The dead-band counters are clocked at TBCLK*2. Reset type: SYSRSn
14	DEDB_MODE	R/W	0h	Dead Band Dual-Edge B Mode Control (S8 switch) 0: Rising edge delay applied to InA/InB as selected by S4 switch (IN-MODE bits) on A signal path only. Falling edge delay applied to InA/InB as selected by S5 switch (INMODE bits) on B signal path only. 1: Rising edge delay and falling edge delay applied to source selected by S4 switch (INMODE bits) and output to B signal path only. Note: When this bit is set to 1, user should always either set OUT_MODE bits such that Apath = InA OR OUTSWAP bits such that OutA=Bpath otherwise, OutA will be invalid. Reset type: SYSRSn
13-12	OUTSWAP	R/W	0h	Dead Band Output Swap Control Bit 13 controls the S6 switch and bit 12 controls the S7 switch. 00: OutA and OutB signals are as defined by OUT-MODE bits. 01: OutA = A-path as defined by OUT-MODE bits. OutB = A-path as defined by OUT-MODE bits (rising edge delay or delay-bypassed A signal path). 10: OutA = B-path as defined by OUT-MODE bits (falling edge delay or delay-bypassed B signal path). OutB = B-path as defined by OUT-MODE bits. 11: OutA = B-path as defined by OUT-MODE bits (falling edge delay or delay-bypassed B signal path). OutB = A-path as defined by OUT-MODE bits (rising edge delay or delay-bypassed A signal path). Reset type: SYSRSn
11	SHDWDBFEDMODE	R/W	0h	FED Dead-Band Load Mode 0: Immediate mode. Only the active DBFED register is used. All writes/reads via the CPU directly access the active register for immediate 'FED dead-band action.' 1: Shadow mode. Operates as a double buffer. All writes via the CPU access Shadow register. Default at Reset is Immediate mode (for compatibility with legacy). Reset type: SYSRSn

**Table 22-36. DBCTL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
10	SHDWDBREDMODE	R/W	0h	RED Dead-Band Load Mode 0: Immediate mode. Only the active DBRED register is used. All writes/reads via the CPU directly access the active register for immediate 'RED dead-band action.' 1: Shadow mode. Operates as a double buffer. All writes via the CPU access Shadow register. Default at Reset is Immediate mode (for compatibility with legacy). Reset type: SYSRSn
9-8	LOADFEDMODE	R/W	0h	Active DBFED Load from Shadow Select Mode 00: Load on Counter = 0 (CNT_eq) 01: Load on Counter = Period (PRD_eq) 10: Load on either Counter = 0, or Counter = Period 11: Freeze (no loads possible) Note: has no effect in Immediate mode. Reset type: SYSRSn
7-6	LOADREDMODE	R/W	0h	Active DBRED Load from Shadow Select Mode 00: Load on Counter = 0 (CNT_eq) 01: Load on Counter = Period (PRD_eq) 10: Load on either Counter = 0, or Counter = Period 11: Freeze (no loads possible) Note: has no effect in Immediate mode. Reset type: SYSRSn
5-4	IN_MODE	R/W	0h	Dead-Band Input Mode Control Bit 5 controls the S5 switch and bit 4 controls the S4 switch shown. This allows you to select the input source to the falling-edge and rising-edge delay. To produce classical dead-band waveforms the default is EPWMxA In is the source for both falling and rising-edge delays. 00: EPWMxA In (from the action-qualifier) is the source for both falling-edge and rising-edge delay. 01: EPWMxB In (from the action-qualifier) is the source for rising-edge delayed signal. EPWMxA In (from the action-qualifier) is the source for falling-edge delayed signal. 10: EPWMxA In (from the action-qualifier) is the source for rising-edge delayed signal. EPWMxB In (from the action-qualifier) is the source for falling-edge delayed signal. 11: EPWMxB In (from the action-qualifier) is the source for both rising-edge delay and falling-edge delayed signal. Reset type: SYSRSn
3-2	POLSEL	R/W	0h	Polarity Select Control Bit 3 controls the S3 switch and bit 2 controls the S2 switch. This allows you to selectively invert one of the delayed signals before it is sent out of the dead-band submodule. The following descriptions correspond to classical upper/lower switch control as found in one leg of a digital motor control inverter. These assume that DBCTL[OUT_MODE] = 1,1 and DBCTL[IN_MODE] = 0x0. Other enhanced modes are also possible, but not regarded as typical usage modes. 00: Active high (AH) mode. Neither EPWMxA nor EPWMxB is inverted (default). 01: Active low complementary (ALC) mode. EPWMxA is inverted. 10: Active high complementary (AHC). EPWMxB is inverted. 11: Active low (AL) mode. Both EPWMxA and EPWMxB are inverted. Reset type: SYSRSn

**Table 22-36. DBCTL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
1-0	OUT_MODE	R/W	0h	Dead-Band Output Mode Control Bit 1 controls the S1 switch and bit 0 controls the S0 switch. 00: DBM is fully disabled or by-passed. In this mode the POLSEL and IN-MODE bits have no effect. 01: Apath = InA (delay is by-passed for A signal path) Bpath = FED (Falling Edge Delay in B signal path) 10: Apath = RED (Rising Edge Delay in A signal path) Bpath = InB (delay is by-passed for B signal path) 11: DBM is fully enabled (i.e. both RED and FED active) Reset type: SYSRSn

### 22.20.2.11 DBCTL2 Register (Offset = Dh) [Reset = 0000h]

DBCTL2 is shown in [Figure 22-132](#) and described in [Table 22-37](#).

Return to the [Summary Table](#).

**Table 22-45. HRPCTL Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-7	RESERVED	R-0	0h	Reserved
6-4	PWMSYNCSELX	R/W	0h	Extended selection bits for EPWMSYNCPER 000: EPWMSYNCPER is defined by PWMSYNCSEL - > default condition (compatible with previous EPWM versions) 001: Reserved 010: Reserved 011: Reserved 100: CTR = CMPC, Count direction Up 101: CTR = CMPC, Count direction Down 110: CTR = CMPD, Count direction Up 111: CTR = CMPD, Count direction Down Reset type: SYSRSn
3	RESERVED	R/W	0h	Reserved
2	TBPHSHRLOADE	R/W	0h	TBPHSHR Load Enable This bit allows you to synchronize ePWM modules with a high-resolution phase on a SYNCIN, TBCTL[SWFSYNC] or digital compare event. This allows for multiple ePWM modules operating at the same frequency to be phase aligned with high-resolution. 0: Disables synchronization of high-resolution phase on a SYNCIN, TBCTL[SWFSYNC] or digital compare event: 1: Synchronize the high-resolution phase on a SYNCIN, TBCTL[SWFSYNC] or digital comparator synchronization event. The phase is synchronized using the contents of the high-resolution phase TBPHSHR register. The TBCTL[PHESEN] bit which enables the loading of the TBCTR register with TBPHS register value on a SYNCIN or TBCTL[SWFSYNC] event works independently. However, users need to enable this bit also if they want to control phase in conjunction with the high-resolution period feature. This bit and the TBCTL[PHESEN] bit must be set to 1 when high-resolution period is enabled for up-down count mode even if TBPHSHR = 0x0000. This bit does not need to be set when only high-resolution duty is enabled. Reset type: SYSRSn
1	PWMSYNCSEL	R/W	0h	PWMSYNC Source Select Bit: This bit selects the source for the EPWMSYNCPER signal that goes to the CMPSS and GPDAC: 0 CTR = PRD: Time-base counter equal to period (TBCTR = TBPRD) 1 CTR = zero: Time-base counter equal to zero (TBCTR = 0x00) Reset type: SYSRSn

**Table 22-45. HRPCTL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
0	HRPE	R/W	0h	High Resolution Period Enable Bit 0: High resolution period feature disabled. In this mode the ePWM behaves as a Type 4 ePWM. 1: High resolution period enabled. In this mode the HRPWM module can control high-resolution of both the duty and frequency. When high-resolution period is enabled, TBCTL[CTRMODE] = 0,1 (down-count mode) is not supported. Reset type: SYSRSn

### 22.20.2.20 TRREM Register (Offset = 2Eh) [Reset = 0000h]

TRREM is shown in [Figure 22-141](#) and described in [Table 22-46](#).

Return to the [Summary Table](#).

High Resolution Period Control Register

Fields in this register related to HRPWM are only applicable on EPWM modules with HRPWM capabilities.

TBPRD							
R/W-0h							
7	6	5	4	3	2	1	0
TBPRD							
R/W-0h							

**Table 22-63. TBPRD Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-0	TBPRD	R/W	0h	Time Base Period Register These bits determine the period of the time-base counter. This sets the PWM frequency. Shadowing of this register is enabled and disabled by the TBCTL[PRDL] bit. By default this register is shadowed. - If TBCTL[PRDL] = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the active register will be loaded from the shadow register when the time-base counter equals zero. - If TBCTL[PRDL] = 1, then the shadow is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware. - The active and shadow registers share the same memory map address. Reset type: SYSRSn

### 22.20.2.38 CMPA Register (Offset = 6Ah) [Reset = 0000000h]

CMPA is shown in [Figure 22-159](#) and described in [Table 22-64](#).

Return to the [Summary Table](#).

Counter Compare A Register

**Figure 22-159. CMPA Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CMPA																CMPAHR															
R/W-0h																R/W-0h															

**Table 22-64. CMPA Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	CMPA	R/W	0h	<p>Compare A Register</p> <p>The value in the active CMPA register is continuously compared to the time-base counter (TBCTR). When the values are equal, the counter-compare module generates a 'time-base counter equal to counter compare A' event. This event is sent to the action-qualifier where it is qualified and converted it into one or more actions. These actions can be applied to either the EPWMxA or the EPWMxB output depending on the configuration of the AQCTLA and AQCTLB registers. The actions that can be defined in the AQCTLA and AQCTLB registers include:</p> <ul style="list-style-type: none"> <li>- Do nothing</li> <li>- Clear: Pull the EPWMxA and/or EPWMxB signal low</li> <li>- Set: Pull the EPWMxA and/or EPWMxB signal high</li> <li>- Toggle the EPWMxA and/or EPWMxB signal</li> </ul> <p>Shadowing of this register is enabled and disabled by the CMPCTL[SHDWAMODE] bit. By default this register is shadowed.</p> <ul style="list-style-type: none"> <li>- If CMPCTL[SHDWAMODE] = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the CMPCTL[LOADAMODE] bit field determines which event will load the active register from the shadow register.</li> <li>- Before a write, the CMPCTL[SHDWAFULL] bit can be read to determine if the shadow register is currently full.</li> <li>- If CMPCTL[SHDWAMODE] = 1, then the shadow register is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware.</li> <li>- In either mode, the active and shadow registers share the same memory map address.</li> </ul> <p>Reset type: SYSRSn</p>
15-0	CMPAHR	R/W	0h	<p>Compare A HRPWM Extension Register</p> <p>The UPPER 8-bits contain the high-resolution portion (most significant 8-bits) of the counter-compare A value. CMPA:CMPAHR can be accessed in a single 32-bit read/write. Shadowing is enabled and disabled by the CMPCTL[SHDWAMODE] bit as described for the CMPA register.</p> <p>The lower 8 bits in this register are ignored</p> <p>Reset type: SYSRSn</p>

### 22.20.2.39 CMPB Register (Offset = 6Ch) [Reset = 0000000h]

CMPB is shown in [Figure 22-160](#) and described in [Table 22-65](#).

Return to the [Summary Table](#).

Compare B Register

Bit	Field	Type	Reset	Description
15-8	RESERVED	R-0	0h	Reserved
7	CAPEVT	R	0h	Latched Status Flag for Capture Event 0: Indicates no trip event has occurred on CAPEVT 1: Indicates a trip event has occurred for the event defined for CAPEVT Reset type: SYSRSn
6	DCBEVT2	R	0h	Latched Status Flag for Digital Compare Output B Event 2 0: Indicates no trip event has occurred on DCBEVT2 1: Indicates a trip event has occurred for the event defined for DCBEVT2 Reset type: SYSRSn
5	DCBEVT1	R	0h	Latched Status Flag for Digital Compare Output B Event 1 0: Indicates no trip event has occurred on DCBEVT1 1: Indicates a trip event has occurred for the event defined for DCBEVT1 Reset type: SYSRSn
4	DCAEVT2	R	0h	Latched Status Flag for Digital Compare Output A Event 2 0: Indicates no trip event has occurred on DCAEVT2 1: Indicates a trip event has occurred for the event defined for DCAEVT2 Reset type: SYSRSn
3	DCAEVT1	R	0h	Latched Status Flag for Digital Compare Output A Event 1 0: Indicates no trip event has occurred on DCAEVT1 1: Indicates a trip event has occurred for the event defined for DCAEVT1 Reset type: SYSRSn
2	OST	R	0h	Latched Status Flag for A One-Shot Trip Event 0: No one-shot trip event has occurred. 1: Indicates a trip event has occurred on a pin selected as a one-shot trip source. This bit is cleared by writing the appropriate value to the TZCLR register. Reset type: SYSRSn

**Table 22-78. TZFLG Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
1	CBC	R	0h	Latched Status Flag for Cycle-By-Cycle Trip Event 0: No cycle-by-cycle trip event has occurred. 1: Indicates a trip event has occurred on a signal selected as a cycle-by-cycle trip source. The TZFLG[CBC] bit will remain set until it is manually cleared by the user. If the cycle-by-cycle trip event is still present when the CBC bit is cleared, then CBC will be immediately set again. The specified condition on the signal is automatically cleared when the ePWM time-base counter reaches zero (TBCTR = 0x00) if the trip condition is no longer present. The condition on the signal is only cleared when the TBCTR = 0x00 no matter where in the cycle the CBC flag is cleared. This bit is cleared by writing the appropriate value to the TZCLR register. Reset type: SYSRSn
0	INT	R	0h	Latched Trip Interrupt Status Flag 0: Indicates no interrupt has been generated. 1: Indicates an EPWMx_TZINT PIE interrupt was generated because of a trip condition. No further EPWMx_TZINT PIE interrupts will be generated until this flag is cleared. If the interrupt flag is cleared when either CBC or OST is set, then another interrupt pulse will be generated. Clearing all flag bits will prevent further interrupts. This bit is cleared by writing the appropriate value to the TZCLR register. Reset type: SYSRSn

### 22.20.2.53 TZCBCFLG Register (Offset = 94h) [Reset = 0000h]

R-0/W1S-0h	R-0/W1S-0h	R-0/W1S-0h	R-0/W1S-0h	R-0/W1S-0h	R-0/W1S-0h	R-0/W1S-0h	R-0/W1S-0h

**Table 22-81. TZCLR Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-14	CBCPULSE	R/W	0h	Clear Pulse for Cycle-By-Cycle (CBC) Trip Latch This bit field determines which pulse clears the CBC trip latch. 00: CTR = zero pulse clears CBC trip latch. (Same as legacy designs.) 01: CTR = PRD pulse clears CBC trip latch. 10: CTR = zero or CTR = PRD pulse clears CBC trip latch. 11: CBC trip latch is not cleared Reset type: SYSRSn
13-8	RESERVED	R-0	0h	Reserved
7	CAPEVT	R-0/W1S	0h	Clear Flag for Capture Event 0: Writing 0 has no effect. This bit always reads back 0. 1: Writing 1 clears the CAPEVT event trip condition. Reset type: SYSRSn
6	DCBEVT2	R-0/W1S	0h	Clear Flag for Digital Compare Output B Event 2 0: Writing 0 has no effect. This bit always reads back 0. 1: Writing 1 clears the DCBEVT2 event trip condition. Reset type: SYSRSn
5	DCBEVT1	R-0/W1S	0h	Clear Flag for Digital Compare Output B Event 1 0: Writing 0 has no effect. This bit always reads back 0. 1: Writing 1 clears the DCBEVT1 event trip condition. Reset type: SYSRSn
4	DCAEVT2	R-0/W1S	0h	Clear Flag for Digital Compare Output A Event 2 0: Writing 0 has no effect. This bit always reads back 0. 1: Writing 1 clears the DCAEVT2 event trip condition. Reset type: SYSRSn
3	DCAEVT1	R-0/W1S	0h	Clear Flag for Digital Compare Output A Event 1 0: Writing 0 has no effect. This bit always reads back 0. 1: Writing 1 clears the DCAEVT1 event trip condition. Reset type: SYSRSn
2	OST	R-0/W1S	0h	Clear Flag for One-Shot Trip (OST) Latch 0: Has no effect. Always reads back a 0. 1: Clears this Trip (set) condition. Reset type: SYSRSn
1	CBC	R-0/W1S	0h	Clear Flag for Cycle-By-Cycle (CBC) Trip Latch 0: Has no effect. Always reads back a 0. 1: Clears this Trip (set) condition. Reset type: SYSRSn

**Table 22-81. TZCLR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
0	INT	R-0/W1S	0h	Global Interrupt Clear Flag 0: Has no effect. Always reads back a 0. 1: Clears the trip-interrupt flag for this ePWM module (TZFLG[INT]). NOTE: No further EPWMx_TZINT PIE interrupts will be generated until the flag is cleared. If the TZFLG[INT] bit is cleared and any of the other flag bits are set, then another interrupt pulse will be generated. Clearing all flag bits will prevent further interrupts. Reset type: SYSRSn

### 22.20.2.56 TZCBCCLR Register (Offset = 98h) [Reset = 0000h]

TZCBCCLR is shown in [Figure 22-177](#) and described in [Table 22-82](#).

Return to the [Summary Table](#).

3-2	INTCNT	R	0h	<p>ePWM Interrupt Event (EPWMx_INT) Counter Register</p> <p>These bits indicate how many selected ETSEL[INTSEL] events have occurred. These bits are automatically cleared when an interrupt pulse is generated. If interrupts are disabled, ETSEL[INT] = 0 or the interrupt flag is set, ETFLG[INT] = 1, the counter will stop counting events when it reaches the period value ETPS[INTCNT] = ETPS[INTPRD].</p> <p>00: No events have occurred.</p> <p>01: 1 event has occurred.</p> <p>10: 2 events have occurred.</p> <p>11: 3 events have occurred.</p> <p>Reset type: SYSRSn</p>

**Table 22-87. ETPS Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
1-0	INTPRD	R/W	0h	<p>ePWM Interrupt (EPWMx_INT) Period Select</p> <p>These bits determine how many selected ETSEL[INTSEL] events need to occur before an interrupt is generated. To be generated, the interrupt must be enabled (ETSEL[INT] = 1). If the interrupt status flag is set from a previous interrupt (ETFLG[INT] = 1) then no interrupt will be generated until the flag is cleared via the ETCLR[INT] bit. This allows for one interrupt to be pending while another is still being serviced. Once the interrupt is generated, the ETPS[INTCNT] bits will automatically be cleared.</p> <p>Writing a INTPRD value that is the same as the current counter value will trigger an interrupt if it is enabled and the status flag is clear. Writing a INTPRD value that is less than the current counter value will result in an undefined state. If a counter event occurs at the same instant as a new zero or non-zero INTPRD value is written, the counter is incremented.</p> <p>00: Disable the interrupt event counter. No interrupt will be generated and ETFRC[INT] is ignored.</p> <p>01: Generate an interrupt on the first event INTCNT = 01 (first event)</p> <p>10: Generate interrupt on ETPS[INTCNT] = 1,0 (second event)</p> <p>11: Generate interrupt on ETPS[INTCNT] = 1,1 (third event)</p> <p>Reset type: SYSRSn</p>

RESERVED												SHDWMODE		CAPE	
R-0-0h												R/W-0h		R/W-0h	

**Table 22-102. DCCAPCTL Register Field Descriptions**

Bit	Field	Type	Reset	Description
15	CAPMODE	R/W	0h	<p>Counter Capture Mode</p> <p>0: When a DCEVTFILT occurs and the counter capture is enabled, then the current TBCNT value is captured in the active register. When the respective trip event occurs, further trip (capture) events are ignored until the next PRD_eq or CNT_zero event (as selected by the PULSESEL bit in the DCFCTL register) re-triggers the capture mechanism.</p> <p>If active mode is enabled, via SHDWMODE bit in DCCAPCTL register, CPU reads of this register will return the active register value.</p> <p>If shadow mode is enabled, via SHDWMODE bit in DCCAPCTL register, the active register is copied to the shadow register on the PRD_eq or CNT_zero event (whichever is selected by PULSESEL bit in DCFCTL register). CPU reads of this register will return the shadow register value.</p> <p>1: When a DCEVTFILT occurs and the counter capture is enabled, then the current TBCNT value is captured in the active register. When the respective trip event occurs - it will set the CAPSTS flag and further trip (capture) events are ignored until this bit is cleared. CAPSTS can be cleared by writing to CAPCLR bit in DCCAPCTL register and it re-triggers the capture mechanism.</p> <p>If active mode is enabled, via SHDWMODE bit in DCCAPCTL register, CPU reads of this register will return the active register value.</p> <p>If shadow mode is enabled, via SHDWMODE bit in DCCAPCTL register, the active register is copied to the shadow register on the PRD_eq or CNT_zero event (whichever is selected by PULSESEL bit in DCFCTL register). CPU reads of this register will return the shadow register value.</p> <p>Reset type: SYSRSn</p>
14	CAPCLR	R-0/W1S	0h	<p>DC Capture Latched Status Clear Flag</p> <p>0: Writing a 0 has no effect.</p> <p>1: Writing a 1 will clear this CAPSTS (set) condition.</p> <p>Reset type: SYSRSn</p>
13	CAPSTS	R	0h	<p>Latched Status Flag for Capture Event</p> <p>0: No DC capture event occurred.</p> <p>1: A DC capture event has occurred.</p> <p>Reset type: SYSRSn</p>
12-2	RESERVED	R-0	0h	Reserved

**Table 22-102. DCCAPCTL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
1	SHDWMODE	R/W	0h	TBCTR Counter Capture Shadow Select Mode 0: Enable shadow mode. The DCCAP active register is copied to shadow register on a TBCTR = TBPRD or TBCTR = zero event as defined by the DCFCTL[PULSESEL] bit. CPU reads of the DCCAP register will return the shadow register contents. 1: Active Mode. In this mode the shadow register is disabled. CPU reads from the DCCAP register will always return the active register contents. Reset type: SYSRSn
0	CAPE	R/W	0h	TBCTR Counter Capture Enable/Disable 0: Disable the time-base counter capture. 1: Enable the time-base counter capture. Reset type: SYSRSn

### 22.20.2.77 DCFOFFSET Register (Offset = C9h) [Reset = 0000h]

DCFOFFSET is shown in [Figure 22-198](#) and described in [Table 22-103](#).

Return to the [Summary Table](#).

Digital Compare Filter Offset Register

**Figure 22-198. DCFOFFSET Register**

15	14	13	12	11	10	9	8
DCFOFFSET							
R/W-0h							
7	6	5	4	3	2	1	0
DCFOFFSET							
R/W-0h							

**Table 22-103. DCFOFFSET Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-0	DCFOFFSET	R/W	0h	Blanking Window Offset These 16-bits specify the number of TBCLK cycles from the blanking window reference to the point when the blanking window is applied. The blanking window reference is either period or zero as defined by the DCFCTL[PULSESEL] bit. This offset register is shadowed and the active register is loaded at the reference point defined by DCFCTL[PULSESEL]. The offset counter is also initialized and begins to count down when the active register is loaded. When the counter expires, the blanking window is applied. If the blanking window is currently active, then the blanking window counter is restarted. Reset type: SYSRSn

### 22.20.2.78 DCFOFFSETCNT Register (Offset = CAh) [Reset = 0000h]

DCFOFFSETCNT is shown in [Figure 22-199](#) and described in [Table 22-104](#).

Return to the [Summary Table](#).

Digital Compare Filter Offset Counter Register

**Figure 22-199. DCFOFFSETCNT Register**

15	14	13	12	11	10	9	8
DCFOFFSETCNT							
R-0h							
7	6	5	4	3	2	1	0
DCFOFFSETCNT							
R-0h							

**Table 22-104. DCFOFFSETCNT Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-0	DCFOFFSETCNT	R	0h	Blanking Offset Counter These 16-bits are read only and indicate the current value of the offset counter. The counter counts down to zero and then stops until it is re-loaded on the next period or zero event as defined by the DCCTL[PULSESEL] bit. The offset counter is not affected by the free/soft emulation bits. That is, it will always continue to count down if the device is halted by an emulation stop. Reset type: SYSRSn

### 22.20.2.79 DCFWINDOW Register (Offset = CBh) [Reset = 0000h]

DCFWINDOW is shown in [Figure 22-200](#) and described in [Table 22-105](#).

Return to the [Summary Table](#).

Digital Compare Filter Window Register

**Figure 22-200. DCFWINDOW Register**

15	14	13	12	11	10	9	8
DCFWINDOW							
R/W-0h							
7	6	5	4	3	2	1	0
DCFWINDOW							
R/W-0h							

**Table 22-105. DCFWINDOW Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-0	DCFWINDOW	R/W	0h	Blanking Window Width 00h: No blanking window is generated. 01-FFFFh: Specifies the width of the blanking window in TBCLK cycles. The blanking window begins when the offset counter expires. When this occurs, the window counter is loaded and begins to count down. If the blanking window is currently active and the offset counter expires, the blanking window counter is not restarted and the blanking window is cut short prematurely. Care should be taken to avoid this situation. The blanking window can cross a PWM period boundary. Reset type: SYSRSn

### 22.20.2.80 DCFWINDOWCNT Register (Offset = CCh) [Reset = 0000h]

DCFWINDOWCNT is shown in [Figure 22-201](#) and described in [Table 22-106](#).

Return to the [Summary Table](#).

Digital Compare Filter Window Counter Register

**Figure 22-201. DCFWINDOWCNT Register**

7	6	5	4	3	2	1	0
DCCAP							
R-0h							

**Table 22-109. DCCAP Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-0	DCCAP	R	0h	Digital Compare Time-Base Counter Capture To enable time-base counter capture, set the DCCAPCLT[CAPE] bit to 1. If enabled, reflects the value of the time-base counter (TBCTR) on the low to high edge transition of a filtered (DCEVTFLT) event. Further capture events are ignored until the next period or zero as selected by the DCFCTL[PULSESEL] bit. Shadowing of DCCAP is enabled and disabled by the DCCAPCTL[SHDWMODE] bit. By default this register is shadowed. - If DCCAPCTL[SHDWMODE] = 0, then the shadow is enabled. In this mode, the active register is copied to the shadow register on the TBCTR = TBPRD or TBCTR = zero as defined by the DCFCTL[PULSESEL] bit. CPU reads of this register will return the shadow register value. - If DCCAPCTL[SHDWMODE] = 1, then the shadow register is disabled. In this mode, CPU reads will return the active register value. The active and shadow registers share the same memory map address. Reset type: SYSRSn

### 22.20.2.84 DCAHTRIPSEL Register (Offset = D2h) [Reset = 0000h]

DCAHTRIPSEL is shown in [Figure 22-205](#) and described in [Table 22-110](#).

Complex bit access types are encoded to fit into small table cells. [Table 22-122](#) shows the codes that are used for access types in this section.

**Table 22-122. EPWM\_XCMP\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1S	W1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 22.20.3.1 XCMPCTL1 Register (Offset = 0h) [Reset = 0000000h]

XCMPCTL1 is shown in [Figure 22-216](#) and described in [Table 22-123](#).

Return to the [Summary Table](#).

R-0-0h						R-0/W1S-0h	R-0/W1S-0h

**Table 22-125. XLOAD Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-2	RESERVED	R-0	0h	Reserved
1	FRCLD	R-0/W1S	0h	Force reload event in one shot mode : 1: Writing a 1 to this bit turn force one load event at the input of the event pre-scale counter as shown in the diagram below. This bit is intended to be used for testing and/or software force loading of the events in global load mode. 0: Writing of 0 will be ignored. Always reads back a 0. Reset type: SYSRSn
0	STARTLD	R-0/W1S	0h	Enable reload event : 1: Writing a 1 to this bit turn the one shot latch condition ON. Upon occurrence of a chosen load strobe, one shadow to active reload occurs and the latch will be cleared. Hence writing '1' to this bit would allow load strobe event to pass through and block further strobe events. 0: Writing of 0 will be ignored. Always reads back a 0. Reset type: SYSRSn

### 22.20.3.4 EPWMXLINKXLOAD Register (Offset = Eh) [Reset = 00000XXh]

15-0	XMAX_SHDW3	R/W	0h	The value in the XMAX_SHDW3 register is loaded into XMAX_ACTIVE register when shadow to active load occurs. Reset type: SYSRSn

### 22.20.4 DE\_REGS Registers

Table 22-184 lists the memory-mapped registers for the DE\_REGS registers. All register offset addresses not listed in Table 22-184 should be considered as reserved locations and the register contents should not be modified.

**Table 22-184. DE\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	DECTL	DE control register		<a href="#">Go</a>
2h	DECOMPSEL	DE comparator source select register		<a href="#">Go</a>
4h	DEACTCTL	DE Action Control		<a href="#">Go</a>
6h	DESTS	DE Status register		<a href="#">Go</a>
8h	DEFRC	DE Status force register		<a href="#">Go</a>
Ah	DECLR	DE Status clear register		<a href="#">Go</a>
10h	DEMONCNT	DE trip monitor counter		<a href="#">Go</a>
12h	DEMONCTL	DE monitor mode control		<a href="#">Go</a>
14h	DEMONSTEP	DE monitor counter step		<a href="#">Go</a>
16h	DEMONTHRES	DE monitor counter threshold		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 22-185 shows the codes that are used for access types in this section.

**Table 22-185. DE\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 22.20.4.1 DECTL Register (Offset = 0h) [Reset = 0000000h]

DECTL is shown in [Figure 22-277](#) and described in [Table 22-186](#).

Return to the [Summary Table](#).

DE control register

### 22.20.5 MINDB\_LUT\_REGS Registers

Table 22-196 lists the memory-mapped registers for the MINDB\_LUT\_REGS registers. All register offset addresses not listed in Table 22-196 should be considered as reserved locations and the register contents should not be modified.

**Table 22-196. MINDB\_LUT\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	MINDBCFCG	Minimum dead band configuration register.		<a href="#">Go</a>
2h	MINDBDLY	Minimum dead band delay register		<a href="#">Go</a>
10h	LUTCTLA	LUT control register on PWMA		<a href="#">Go</a>
12h	LUTCTLB	LUT control register on PWMB		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 22-197 shows the codes that are used for access types in this section.

**Table 22-197. MINDB\_LUT\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 22.20.5.1 MINBCFG Register (Offset = 0h) [Reset = 0000000h]

MINBCFG is shown in [Figure 22-287](#) and described in [Table 22-198](#).

Return to the [Summary Table](#).

Minimum dead band configuration register.

### 22.20.6 HRPWMCAL\_REGS Registers

Table 22-202 lists the memory-mapped registers for the HRPWMCAL\_REGS registers. All register offset addresses not listed in Table 22-202 should be considered as reserved locations and the register contents should not be modified.

**Table 22-202. HRPWMCAL\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
21h	HRPWR	HRPWM Power Register	EALLOW	<a href="#">Go</a>
26h	HRMSTEP	HRPWM MEP Step Register	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 22-203 shows the codes that are used for access types in this section.

**Table 22-203. HRPWMCAL\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 22.20.6.1 HRPWR Register (Offset = 21h) [Reset = 0000h]

HRPWR is shown in [Figure 22-291](#) and described in [Table 22-204](#).

Return to the [Summary Table](#).

HRPWM Power Register

This register is only accessible on EPWM modules with HRPWM capabilities.

**Figure 22-291. HRPWR Register**

## Enhanced Quadrature Encoder Pulse (eQEP)

---

The enhanced Quadrature Encoder Pulse (eQEP) module described here is a Type 2 eQEP. See the [C2000 Real-Time Control Peripheral Reference Guide](#) for a list of all devices with a module of the same type to determine the differences between types and for a list of device-specific differences within a type.

The enhanced quadrature encoder pulse (eQEP) module is used for direct interface with a linear or rotary incremental encoder to get position, direction, and speed information from a rotating machine for use in a high-performance motion and position-control system.

### 23.1 Introduction

An incremental encoder disk is patterned with a track of slots along the periphery, as shown in Figure 23-1. These slots create an alternating pattern of dark and light lines. The disk count is defined as the number of dark and light line pairs that occur per revolution (lines per revolution). As a rule, a second track is added to generate a signal that occurs once per revolution (index signal: QEPI), which can be used to indicate an absolute position. Encoder manufacturers identify the index pulse using different terms such as index, marker, home position, and zero reference

Figure 23-1. Optical Encoder Disk

To derive direction information, the lines on the disk are read out by two different photo-elements that "look" at the disk pattern with a mechanical shift of 1/4 the pitch of a line pair between them. This shift is detected with a reticle or mask that restricts the view of the photo-element to the desired part of the disk lines. As the disk rotates, the two photo-elements generate signals that are shifted 90° out of phase from each other. These are commonly called the quadrature QEPA and QEPB signals. The clockwise direction for most encoders is defined as the QEPA channel going positive before the QEPB channel and conversely, as shown in Figure 23-2.

Figure 23-2. QEP Encoder Output Signal for Forward/Reverse Movement

The encoder wheel typically makes one revolution for every revolution of the motor, or the wheel can be at a geared rotation ratio with respect to the motor. Therefore, the frequency of the digital signal coming from the QEPA and QEPB outputs varies proportionally with the velocity of the motor. For example, a 2000-line encoder

directly coupled to a motor running at 5000 revolutions-per-minute (rpm) results in a frequency of 166.6kHz, so by measuring the frequency of either the QEPA or QEPB output, the processor can determine the velocity of the motor.

Quadrature encoders from different manufacturers come with two forms of index pulse (gated index pulse or ungated index pulse) as shown in Figure 23-3. A nonstandard form of index pulse is ungated. In the ungated configuration, the index edges are not necessarily coincident with A and B signals. The gated index pulse is aligned to any of the four quadrature edges and width of the index pulse and can be equal to a quarter, half, or full period of the quadrature signal.

**Figure 23-3. Index Pulse Example**

Some typical applications of shaft encoders include robotics and computer input in the form of a mouse. Inside your mouse you can see where the mouse ball spins a pair of axles (a left/right, and an up/down axle). These axles are connected to optical shaft encoders that effectively tell the computer how fast and in what direction the mouse is moving.

**General Issues:** Estimating velocity from a digital position sensor is a cost-effective strategy in motor control. Two different first order approximations for velocity can be written as:

$$v(k) \approx \frac{x(k) - x(k - 1)}{T} = \frac{\Delta X}{T} \quad (24)$$

$$v(k) \approx \frac{X}{t(k) - t(k - 1)} = \frac{X}{\Delta T} \quad (25)$$

where:

- $v(k)$  = Velocity at time instant  $k$
- $x(k)$  = Position at time instant  $k$
- $x(k-1)$  = Position at time instant  $k-1$
- $T$  = Fixed unit time or inverse of velocity calculation rate
- $\Delta X$  = Incremental position movement in unit time
- $t(k)$  = Time instant " $k$ "
- $t(k-1)$  = Time instant " $k-1$ "
- $X$  = Fixed unit position
- $\Delta T$  = Incremental time elapsed for unit position movement

[Equation 24](#) is the conventional approach to velocity estimation and requires a time base to provide a unit time event for velocity calculation. Unit time is basically the inverse of the velocity calculation rate.

The encoder count (position) is read once during each unit time event. The quantity  $[x(k) - x(k-1)]$  is formed by subtracting the previous reading from the current reading. Then the velocity estimate is computed by multiplying by the known constant  $1/T$  (where  $T$  is the constant time between unit time events and is known in advance).

Estimation based on [Equation 24](#) has an inherent accuracy limit directly related to the resolution of the position sensor and the unit time period  $T$ . For example, consider a 500 line-per-revolution quadrature encoder with a velocity calculation rate of 400Hz. When used for position, the quadrature encoder gives a four-fold increase in resolution; in this case, 2000 counts-per-revolution. The minimum rotation that can be detected is, therefore, 0.0005 revolutions, which gives a velocity resolution of 12rpm when sampled at 400Hz. While this resolution can be satisfactory at moderate or high speeds, for example 1% error at 1200rpm, this resolution clearly proves inadequate at low speeds. In fact, at speeds below 12rpm, the speed estimate is erroneously zero much of the time.

At low speed, [Equation 25](#) provides a more accurate approach. It requires a position sensor that outputs a fixed interval pulse train, such as the aforementioned quadrature encoder. The width of each pulse is defined by motor speed for a given sensor resolution. [Equation 25](#) can be used to calculate motor speed by measuring the elapsed time between successive quadrature pulse edges. However, this method suffers from the opposite limitation, as does [Equation 24](#). A combination of relatively large motor speeds and high sensor resolution makes the time interval  $\Delta T$  small, and thus more greatly influenced by the timer resolution. This can introduce considerable error into high-speed estimates.

For systems with a large speed range (that is, speed estimation is needed at both low and high speeds), one approach is to use [Equation 25](#) at low speed and have the DSP software switch over to [Equation 24](#) when the motor speed rises above some specified threshold.

## **23.2 Configuring Device Pins**

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

For proper operation of the eQEP module, input GPIO pins must be configured using the GPxQSELn registers for synchronous input mode (with or without qualification). The asynchronous mode cannot be used for eQEP input pins. The internal pullups can be configured in the GPyPUD register.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

## 23.3 Description

This section provides the eQEP inputs, memory map, and functional description.

### 23.3.1 EQEP Inputs

The eQEP inputs include two pins for quadrature-clock mode or direction-count mode, an index (or 0 marker), and a strobe input. The eQEP module requires that the QEPA, QEPB, and QEPI inputs are synchronized to SYCLK prior to entering the module. The application code can enable the synchronous GPIO input feature on any eQEP-enabled GPIO pins (see the *General-Purpose Input/Output (GPIO)* chapter for more details).

- **QEPA/XCLK and QEPB/XDIR:** These two pins can be used in quadrature-clock mode or direction-count mode.
  - Quadrature-clock Mode: The eQEP encoders provide two square wave signals (A and B) 90 electrical degrees out of phase. This phase relationship is used to determine the direction of rotation of the input shaft and number of eQEP pulses from the index position to derive the relative position information. For forward or clockwise rotation, QEPA signal leads QEPB signal and conversely. The quadrature decoder uses these two inputs to generate quadrature-clock and direction signals.
  - Direction-count Mode: In direction-count mode, direction and clock signals are provided directly from the external source. Some position encoders have this type of output instead of quadrature output. The QEPA pin provides the clock input and the QEPB pin provides the direction input.
- **QEPI: Index or Zero Marker:** The eQEP encoder uses an index signal to assign an absolute start position from which position information is incrementally encoded using quadrature pulses. This pin is connected to the index output of the eQEP encoder to optionally reset the position counter for each revolution. This signal can be used to initialize or latch the position counter on the occurrence of a desired event on the index pin.
- **QEPS: Strobe Input:** This general-purpose strobe signal can initialize or latch the position counter on the occurrence of a desired event on the strobe pin. This signal is typically connected to a sensor or limit switch to notify that the motor has reached a defined position.

Input signals to the eQEP (QEPA, QEPB, QEPI and QEPS) can come from multiple sources; that is, device pin, CMPSSx, or PWMXBARx. One typical use case is if SinCos transducers are used in the motor control system to estimate the position of motor shaft and Index signal is coming from traditional rotary encoder, source of the eQEP signals (QEPA, QEPB and QEPI) can be configured as output of CMPSSx that decodes the Sin, Cos, and Index signals. [Figure 23-4](#) illustrates the use case.

Selection of the source of Input signals (QEPA, QEPB, and QEPI) is user-configurable through the QEPSRCSEL register as shown in [Table 23-1](#).

---

**Note**

Configuration of QEPSRCSEL register to select the source of QEPA, QEPB, and QEPI signals can lead to unexpected transition on these signals, which can cause an undesirable outcome if eQEP is already running. Make sure that the eQEP is disabled before configuring the QEPSRCSEL register for input signals.

---

### 23.3.2 Functional Description

The eQEP peripheral contains the following major functional units (as shown in Figure 23-5):

- Programmable input qualification for each pin (part of the GPIO MUX)
- Quadrature decoder unit (QDU)
- Position counter and control unit for position measurement (PCCU)
- Quadrature edge-capture unit for low-speed measurement (QCAP)
- Unit time base for speed/frequency measurement (UTIME)
- Watchdog timer for detecting stalls (QWDOG)
- Quadrature Mode Adapter (QMA)

### 23.4 Quadrature Decoder Unit (QDU)

Figure 23-6 shows a functional block diagram of the QDU.

Figure 23-6. Functional Block Diagram of Decoder Unit

#### 23.4.1 Position Counter Input Modes

Clock and direction input to the position counter is selected using QDECCTL[QSRC] bits, based on interface input requirement as follows:

- Quadrature-count mode
- Direction-count mode
- UP-count mode
- DOWN-count mode

**23.4.1.1 Quadrature Count Mode**

The quadrature decoder generates the direction and clock to the position counter in quadrature count mode.

**Direction Decoding** The direction decoding logic of the eQEP circuit determines which one of the sequences (QEPA, QEPB) is the leading sequence and accordingly updates the direction information in the QEPSTS[QDF] bit. [Table 23-3](#) and [Figure 23-7](#) show the direction decoding logic in truth table and state machine form. Both edges of the QEPA and QEPB signals are sensed to generate count pulses for the position counter. Therefore, the frequency of the clock generated by the eQEP logic is four times that of each input sequence. [Figure 23-8](#) shows the direction decoding and clock generation from the eQEP input signals.

**Table 23-3. Quadrature Decoder Truth Table**

Previous Edge	Present Edge	QDIR	QPOSCNT
QA↑	QB↑	UP	Increment
	QB↓	DOWN	Decrement
	QA↓	TOGGLE	Increment or Decrement
QA↓	QB↓	UP	Increment
	QB↑	DOWN	Decrement
	QA↑	TOGGLE	Increment or Decrement
QB↑	QA↑	DOWN	Decrement
	QA↓	UP	Increment
	QB↓	TOGGLE	Increment or Decrement
QB↓	QA↓	DOWN	Decrement
	QA↑	UP	Increment
	QB↑	TOGGLE	Increment or Decrement

**Figure 23-7. Quadrature Decoder State Machine**

**Figure 23-8. Quadrature-clock and Direction Decoding**

**Phase Error Flag** In normal operating conditions, quadrature inputs QEPA and QEPB is 90 degrees out of phase. The phase error flag (PHE) is set in the QFLG register and the QPOSCNT value can be incorrect and offset by multiples of 1 or 3. That is, when edge transition is detected simultaneously on the QEPA and QEPB signals to optionally generate interrupts. State transitions marked by dashed lines in [Figure 23-7](#) are invalid transitions that generate a phase error.

**Count Multiplication** The eQEP position counter provides 4x times the resolution of an input clock by generating a quadrature-clock (QCLK) on the rising/falling edges of both eQEP input clocks (QEPA and QEPB) as shown in [Figure 23-8](#).

**Reverse Count** In normal quadrature count operation, QEPA input is applied to the QA input of the quadrature decoder and the QEPB input is applied to the QB input of the quadrature decoder. Reverse counting is enabled by setting the SWAP bit in the QDECCTL register. This swaps the input to the quadrature decoder; thereby, reversing the counting direction.

### 23.4.1.2 Direction-Count Mode

Some position encoders provide direction and clock outputs, instead of quadrature outputs. In such cases, direction-count mode can be used. The QEPA input provides the clock for the position counter and the QEPB input has the direction information. The position counter is incremented on every rising edge of a QEPA input when the direction input is high, and decremented when the direction input is low.

### 23.4.1.3 Up-Count Mode

The counter direction signal is hard-wired for up-count and the position counter is used to measure the frequency of the QEPA input. Clearing the QDECCTL[XCR] bit enables clock generation to the position counter on both edges of the QEPA input; thereby, increasing the measurement resolution by a factor of 2x. In up-count mode, we recommend that the application not configure QEPB as a GPIO mux option, or make sure that a signal edge is not generated on the QEPB input.

### 23.4.1.4 Down-Count Mode

The counter direction signal is hardwired for a down-count and the position counter is used to measure the frequency of the QEPA input. Clearing the QDECCTL[XCR] bit enables clock generation to the position counter on both edges of a QEPA input, thereby increasing the measurement resolution by a factor of 2x. In down-count mode, the application must not configure QEPB as a GPIO mux option or make sure that a signal edge is not generated on the QEPB input.

### 23.4.2 eQEP Input Polarity Selection

Each eQEP input can be inverted using QDECCTL[8:5] control bits. As an example, setting the QDECCTL[QIP] bit inverts the index input.

### 23.4.3 Position-Compare Sync Output

The enhanced eQEP peripheral includes a position-compare unit that is used to generate the position-compare sync signal on compare match between the position-counter register (QPOSCNT) and the position-compare register (QPOSCMP). This sync signal can be output using an index pin or strobe pin of the EQEP peripheral.

Setting the QDECCTL[SOEN] bit enables the position-compare sync output and the QDECCTL[SPSEL] bit selects either an eQEP index pin or an eQEP strobe pin.

## 23.5 Position Counter and Control Unit (PCCU)

The position-counter and control unit provides two configuration registers (QEPCTL and QPOSCTL) for setting up position-counter operational modes, position-counter initialization/latch modes and position-compare logic for sync signal generation.

### 23.5.1 Position Counter Operating Modes

Position-counter data can be captured in different manners. In some systems, the position counter is accumulated continuously for multiple revolutions and the position-counter value provides the position information with respect to the known reference. An example of this is the quadrature encoder mounted on the motor controlling the print head in the printer. Here the position counter is reset by moving the print head to the home position and then the position counter provides absolute position information with respect to home position.

In other systems, the position counter is reset on every revolution using index pulse, and the position counter provides a rotor angle with respect to the index pulse position.

The position counter can be configured to operate in following four modes

- Position-Counter Reset on Index Event
- Position-Counter Reset on Maximum Position
- Position-Counter Reset on the first Index Event
- Position-Counter Reset on Unit Time Out Event (Frequency Measurement)

In all the above operating modes, the position counter is reset to 0 on overflow and to the QPOSMAX register value on underflow. Overflow occurs when the position counter counts up after the QPOSMAX value. Underflow occurs when the position counter counts down after 0. The Interrupt flag is set to indicate overflow/underflow in QFLG register.

### 23.5.1.1 Position Counter Reset on Index Event (QEPCTL[PCRM] = 00)

If the index event occurs during the forward movement, then the position counter is reset to 0 on the next eQEP clock. If the index event occurs during the reverse movement, then the position counter is reset to the value in the QPOS MAX register on the next eQEP clock.

The first index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (QEPSTS[FIMF]) and direction on the first index event marker (QEPSTS[FIDF]) in QEPSTS registers, the eQEP peripheral also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for index event reset operation.

For example, if the first reset operation occurs on the falling edge of QEPB during the forward direction, then all the subsequent reset must be aligned with the falling edge of QEPB for the forward rotation and on the rising edge of QEPB for the reverse rotation as shown in Figure 23-9.

The position-counter value is latched to the QPOSILAT register and direction information is recorded in the QEPSTS[QDLF] bit on every index event marker. The position-counter error flag (QEPSTS[PCEF]) and error interrupt flag (QFLG[PCE]) are set if the latched value is not equal to 0 or QPOS MAX. The position-counter error flag (QEPSTS[PCEF]) is updated on every index event marker and an interrupt flag (QFLG[PCE]) is set on error that can be cleared only through software.

The index event latch configuration QEPCTL[IEL] must be configured to 00 or 11 when pcrm = 0 and the position counter error flag/interrupt flag are generated only in index event reset mode. The position counter value is latched into the IPOS LAT register on every index marker.

**Figure 23-9. Position Counter Reset by Index Pulse for 1000-Line Encoder (QPOS MAX = 3999 or 0xF9F)**

#### Note

In case of a boundary condition where the time period between the Index Event and the previous QCLK edge is less than SYSCLK period, then QPOSCNT gets reset to zero or QPOS MAX in the same SYSCLK cycle and does not wait for the next QCLK edge to occur.

**23.5.1.2 Position Counter Reset on Maximum Position (QEPCTL[PCRM] = 01)**

If the position counter is equal to QPOS MAX, then the position counter is reset to 0 on the next eQEP clock for forward movement and position counter overflow flag is set. If the position counter is equal to ZERO, then the position counter is reset to QPOS MAX on the next QEP clock for reverse movement and position-counter underflow flag is set. Figure 23-10 shows the position-counter reset operation in this mode.

The first index marker fields (QEPSTS[FIDF] and QEPSTS[FIMF]) are not applicable in this mode.

**Figure 23-10. Position Counter Underflow/Overflow (QPOS MAX = 4)**

**23.5.1.3 Position Counter Reset on the First Index Event (QEPCTL[PCRM] = 10)**

If the index event occurs during forward movement, then the position counter is reset to 0 on the next eQEP clock. If the index event occurs during the reverse movement, then the position counter is reset to the value in the QPOS MAX register on the next eQEP clock. Note that this is done only on the first occurrence and subsequently the position-counter value is not reset on an index event; rather, the position-counter value is reset based on the maximum position as described in Section 23.5.1.2.

The first index marker fields (QEPSTS[FIDF] and QEPSTS[FIMF]) are not applicable in this mode.

### 23.5.1.4 Position Counter Reset on Unit Time-out Event (QEPCTL[PCRM] = 11)

In this mode, QPOSCNT is set to 0 or QPOMAX, depending on the direction mode selected by QDECCTL[QSRC] bits on a unit time event. This is useful for frequency measurement.

### 23.5.2 Position Counter Latch

The eQEP index and strobe input can be configured to latch the position counter (QPOSCNT) into QPOSILAT and QPOSSLAT, respectively, on occurrence of a definite event on these pins.

#### 23.5.2.1 Index Event Latch

In some applications, it is not desirable to reset the position counter on every index event and instead it can be required to operate the position counter in full 32-bit mode (QEPCTL[PCRM] = 01 and QEPCTL[PCRM] = 10 modes).

In such cases, the eQEP position counter can be configured to latch on the following events and direction information is recorded in the QEPSTS[QDLF] bit on every index event marker.

- Latch on Rising edge (QEPCTL[IEL] = 01)
- Latch on Falling edge (QEPCTL[IEL] = 10)
- Latch on Index Event Marker (QEPCTL[IEL] = 11)

This is particularly useful as an error checking mechanism to check if the position counter accumulated the correct number of counts between index events. As an example, the 1000-line encoder must count 4000 times when moving in the same direction between the index events.

The index event latch interrupt flag (QFLG[IEL]) is set when the position counter is latched to the QPOSILAT register. The index event latch configuration bits (QEPCTL[IEL]) are ignored when QEPCTL[PCRM] = 00.

#### Latch on Rising Edge (QEPCTL[IEL] = 01)

The position-counter value (QPOSCNT) is latched to the QPOSILAT register on every rising edge of an index input.

#### Latch on Falling Edge (QEPCTL[IEL] = 10)

The position-counter value (QPOSCNT) is latched to the QPOSILAT register on every falling edge of index input.

#### Latch on Index Event Marker/Software Index Marker (QEPCTL[IEL] = 11)

The first index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (QEPSTS[FIMF]) and the direction on the first index event marker (QEPSTS[FIDF]) in the QEPSTS registers. The eQEP peripheral also remembers the quadrature edge on the first index marker so that the same relative quadrature transition is used for latching the position counter (QEPCTL[IEL] = 11).

Figure 23-11 shows the position counter latch using an index event marker.

Figure 23-11. Software Index Marker for 1000-line Encoder (QEPCTL[IEL] = 1)

### 23.5.2.2 Strobe Event Latch

The position-counter value is latched to the QPOSSLAT register on the rising edge of the strobe input by clearing the QEPCTL[SEL] bit.

If the QEPCTL[SEL] bit is set, then the position-counter value is latched to the QPOSSLAT register on the rising edge of the strobe input for forward direction, and on the falling edge of the strobe input for reverse direction as shown in Figure 23-12.

The strobe event latch interrupt flag (QFLG[SEL]) is set when the position counter is latched to the QPOSSLAT register.

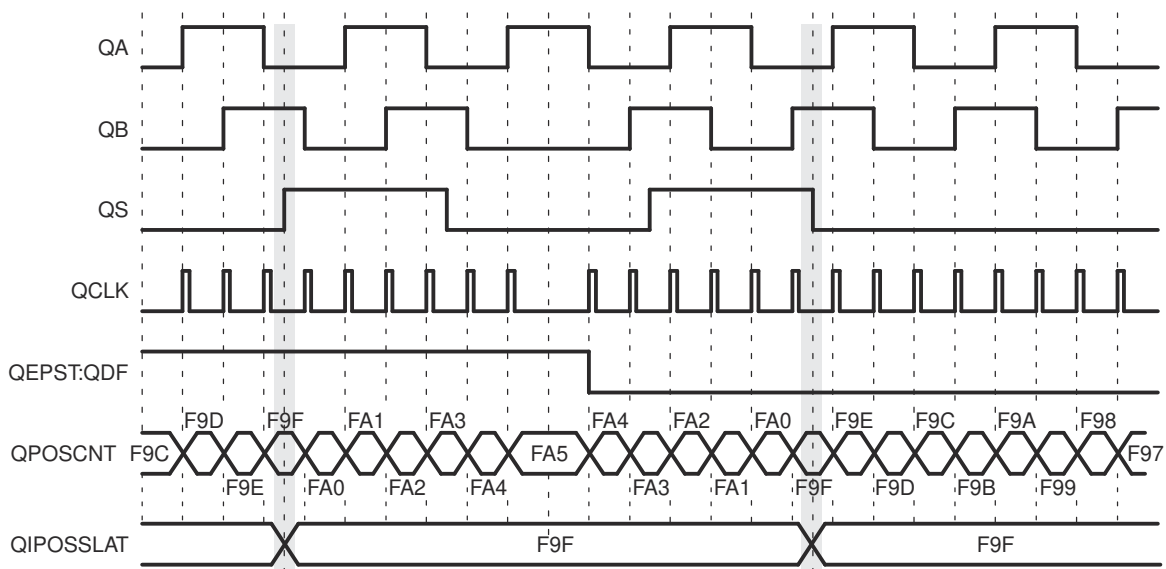

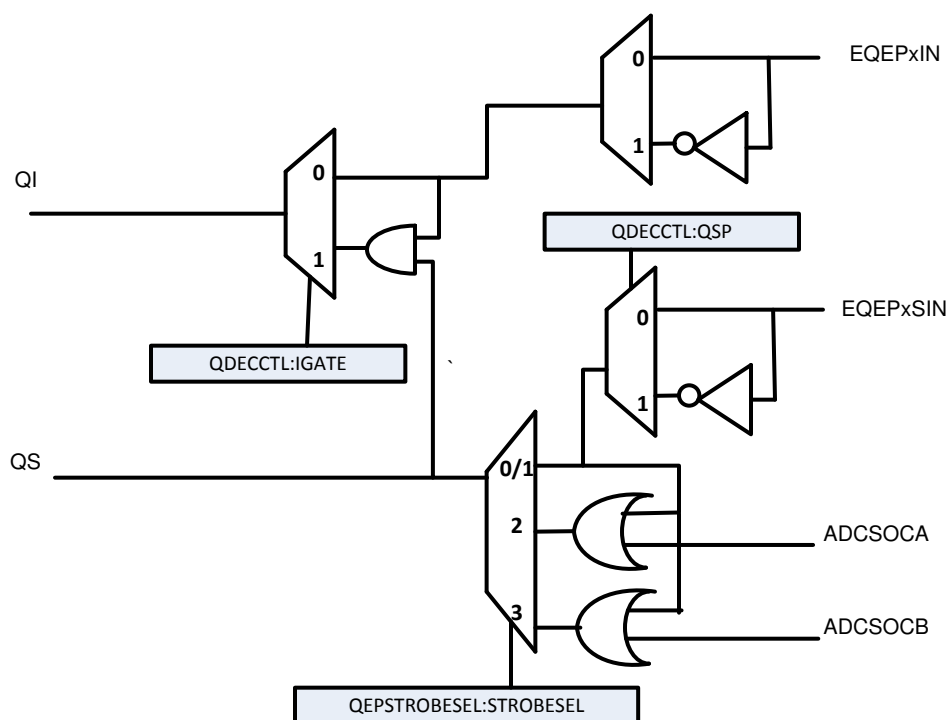

Figure 23-12. Strobe Event Latch (QEPCTL[SEL] = 1)

There is an added feature on Type 2.0 eQEP where position-counter value can also be latched on ADCSOCA and ADCSOCB events by configuring the register QEPSTROBESEL.STROBESEL as shown in Figure 23-13. To use the ADCSOCA/B events for the QS signal, configuration of the QEPSRCSEL.QEPSSEL to be non-zero is needed..

**Figure 23-13. Latching Position Counter on ADCSOCA/ADCSOCB Event**

### 23.5.3 Position Counter Initialization

The position counter can be initialized using the following events:

- Index event
- Strobe event
- Software initialization

<b>Index Event Initialization (IEI)</b>	The QEPI index input can be used to trigger the initialization of the position counter at the rising or falling edge of the index input. If the QEPCTL[IEI] bits are 10, then the position counter (QPOSCNT) is initialized with a value in the QPOSINIT register on the rising edge of index input. Conversely, if the QEPCTL[IEI] bits are 11, initialization is on the falling edge of the index input.
<b>Strobe Event Initialization (SEI)</b>	If the QEPCTL[SEI] bits are 10, then the position counter is initialized with a value in the QPOSINIT register on the rising edge of strobe input.  If QEPCTL[SEL] bits are 11, then the position counter is initialized with a value in the QPOSINIT register on the rising edge of strobe input for forward direction and on the falling edge of strobe input for reverse direction.
<b>Software Initialization (SWI)</b>	The position counter can be initialized in software by writing a 1 to the QEPCTL[SWI] bit. This bit is not automatically cleared. While the bit is still set, if a 1 is written to the bit again, the position counter is re-initialized.

### 23.5.4 eQEP Position-compare Unit

The eQEP peripheral includes a position-compare unit that is used to generate a sync output and interrupt on a position-compare match. Figure 23-14 shows a diagram. The position-compare (QPOSCMP) register is shadowed and shadow mode can be enabled or disabled using the QPOSCTL[PSSHDW] bit. If the shadow mode is not enabled, the CPU writes directly to the active position compare register.

Figure 23-14. eQEP Position-compare Unit

In shadow mode, you can configure the position-compare unit (QPOSCTL[PCLOAD]) to load the shadow register value into the active register on the following events, and to generate the position-compare ready (QFLG[PCR]) interrupt after loading.

- Load on compare match
- Load on position-counter zero event

The position-compare match (QFLG[PCM]) is set when the position-counter value (QPOSCNT) matches with the active position-compare register (QPOSCMP) and the position-compare sync output of the programmable pulse width is generated on compare-match to trigger an external device.

For example, if QPOSCMP = 2, the position-compare unit generates a position-compare event on 1 to 2 transitions of the eQEP position counter for forward counting direction and on 3 to 2 transitions of the eQEP position counter for reverse counting direction (see Figure 23-15).

See the register section for the layout of the eQEP Position-Compare Control Register (QPOSCTL) and description of the QPOSCTL bit fields.

**Figure 23-15. eQEP Position-compare Event Generation Points**

The pulse stretcher logic in the position-compare unit generates a programmable position-compare sync pulse output on the position-compare match. In the event of a new position-compare match while a previous position-compare pulse is still active, then the pulse stretcher generates a pulse of specified duration from the new position-compare event as shown in [Figure 23-16](#).

**Figure 23-16. eQEP Position-compare Sync Output Pulse Stretcher**

## 23.6 eQEP Edge Capture Unit

The eQEP peripheral includes an integrated edge capture unit to measure the elapsed time between the unit position events as shown in [Figure 23-17](#). This feature is typically used for low-speed measurement using the following formula:

$$v(k) = \frac{X}{t(k) - t(k - 1)} = \frac{X}{\Delta T} \quad (26)$$

where:

- X = Unit position is defined by integer multiple of quadrature edges (see [Figure 23-18](#))
- $\Delta T$  = Elapsed time between unit position events
- v(k) = Velocity at time instant "k"

The eQEP capture timer (QCTMR) runs from prescaled SYSCLKOUT and the prescaler is programmed by the QCAPCTL[CCPS] bits. The capture timer (QCTMR) value is latched into the capture period register (QCPRD) on every unit position event and then the capture timer is reset, a flag is set in QEPSTS:UPEVNT to indicate that new value is latched into the QCPRD register. Software can check this status flag before reading the period register for low speed measurement, and clear the flag by writing 1.

Time measurement ( $\Delta T$ ) between unit position events is correct if the following conditions are met:

- No more than 65,535 counts have occurred between unit position events.
- No direction change between unit position events.

If the QEP capture timer overflows between unit position events, then the timer sets the QEP capture overflow flag (QEPSTS[COEF]) in the status register and the QCPRDLAT register is set to 0xFFFF. If direction change occurs between the unit position events, then the error flag is set in the status register (QEPSTS[CDEF]) and the QCPRDLAT register is set to 0xFFFF.

The Capture Timer (QCTMR) and Capture Period register (QCPRD) can be configured to latch on the following events:

- CPU read of QPOSCNT register
- Unit time-out event

If the QEPCTL[QCLM] bit is cleared, then the capture timer and capture period values are latched into the QCTMRLAT and QCPRDLAT registers, respectively, when the CPU reads the position counter (QPOSCNT).

If the QEPCTL[QCLM] bit is set, then the position counter, capture timer, and capture period values are latched into the QPOSLAT, QCTMRLAT and QCPRDLAT registers, respectively, on unit time out.

[Figure 23-19](#) shows the capture unit operation along with the position counter.

Figure 23-17. eQEP Edge Capture Unit

**CAUTION**

The QCAPCTL[UPPS] prescaler cannot be modified dynamically (such as switching the unit event prescaler from QCLK/4 to QCLK/8). Doing so can result in undefined behavior. The QCAPCTL[CCPS] prescaler can be modified dynamically (such as switching CAPCLK prescaling mode from SYSCLK/4 to SYSCLK/8) only after the capture unit is disabled.

N = Number of quadrature periods selected using QCAPCTL[UPPS] bits

Figure 23-18. Unit Position Event for Low Speed Measurement (QCAPCTL[UPPS] = 0010)

Figure 23-19. eQEP Edge Capture Unit - Timing Details

Velocity calculation equation:

$$v(k) = \frac{x(k) - x(k - 1)}{T} = \frac{\Delta X}{T} \quad (27)$$

where:

- $v(k)$  = Velocity at time instant  $k$
- $x(k)$  = Position at time instant  $k$
- $x(k-1)$  = Position at time instant  $k-1$
- $T$  = Fixed unit time or inverse of velocity calculation rate
- $\Delta X$  = Incremental position movement in unit time
- $X$  = Fixed unit position
- $\Delta T$  = Incremental time elapsed for unit position movement
- $t(k)$  = Time instant " $k$ "
- $t(k-1)$  = Time instant " $k-1$ "

Unit time ( $T$ ) and unit period ( $X$ ) are configured using the QUPRD and QCAPCTL[UPPS] registers. Incremental position output and incremental time output is available in the QOSLAT and QCPRDLAT registers.

Parameter	Relevant Register to Configure or Read the Information
$T$	Unit Period Register (QUPRD)
$\Delta X$	Incremental Position = QOSLAT( $k$ ) - QOSLAT( $k-1$ )
$X$	Fixed-unit position defined by sensor resolution and QCAPCTL[UPPS] bits
$\Delta T$	Capture Period Latch (QCPRDLAT)

### 23.7 eQEP Watchdog

The eQEP peripheral contains a 16-bit watchdog timer (Figure 23-20) that monitors the quadrature clock to indicate proper operation of the motion-control system. The eQEP watchdog timer is clocked from SYSCLKOUT/64 and the quadrature clock event (pulse) resets the watchdog timer. If no quadrature clock event is detected until a period match (QWDPRD = QWDTMR), then the watchdog timer times out and the watchdog interrupt flag is set (QFLG[WTO]). The time-out value is programmable through the watchdog period register (QWDPRD).

Figure 23-20. eQEP Watchdog Timer

### 23.8 eQEP Unit Timer Base

The eQEP peripheral includes a 32-bit timer (QUTMR) that is clocked by SYSCLKOUT to generate periodic interrupts for velocity calculations, see Figure 23-21. Whenever the unit timer (QUTMR) matches the unit period register (QUPRD), the eQEP peripheral resets the unit timer (QUTMR) and also generates the unit time out interrupt flag (QFLG[UTO]). The unit timer gets reset whenever timer value equals to configured period value.

The eQEP peripheral can be configured to latch the position counter, capture timer, and capture period values on a unit time out event so that latched values are used for velocity calculation as described in Section 23.6.

Figure 23-21. eQEP Unit Timer Base

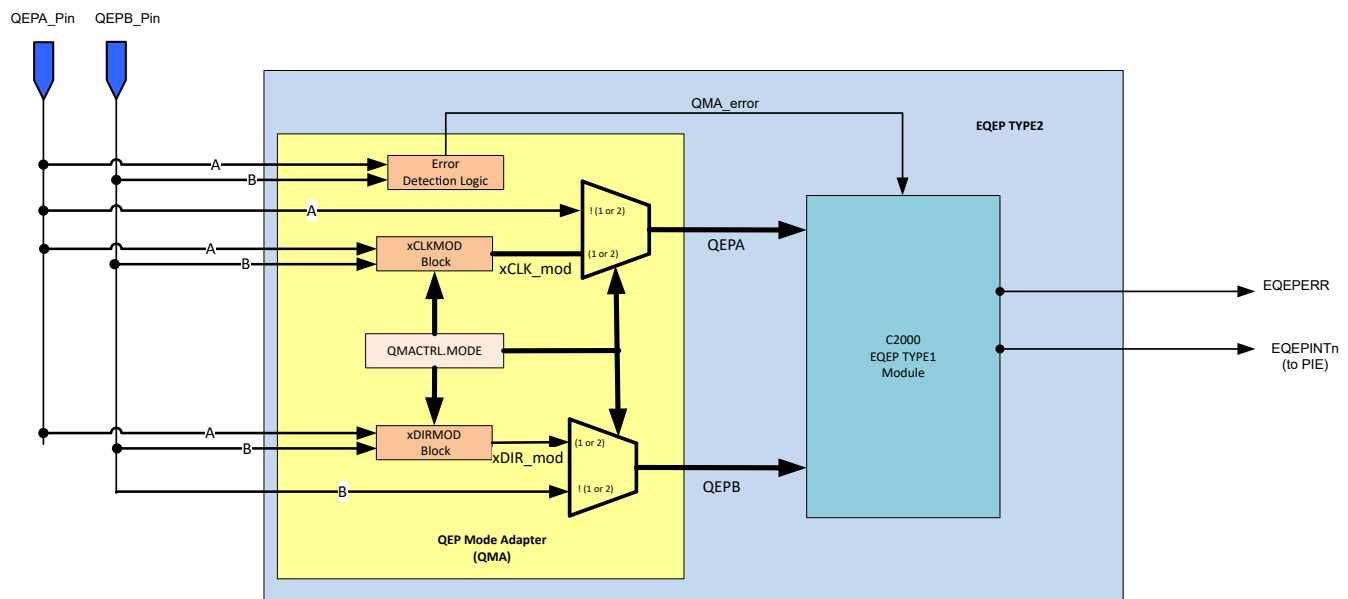

## 23.9 QMA Module

The QEP Mode Adapter (QMA) is designed to extend the C2000™ eQEP module capabilities to support the additional modes described. [Figure 23-22](#) depicts how the QMA module is integrated into the eQEP module.

At reset, by default QMA logic is bypassed and the EQEPA and EQEPB inputs from the pins go directly into the eQEP module. When QMA module is enabled by configuring the QMACTRL[MODE] register, the EQEPA and EQEPB input are processed by this module and modified version of EQEPA and EQEPB signals are sent to the eQEP module. The QMA module requires the eQEP module to be configured in the Direction-Count mode and generates a clock signal on EQEPA input and direction signal on EQEPB input as needed for the proper operation of the intended mode.

- The xCLKMOD block inside the QMA module looks at the transitions on external EQEPA and EQEPB signals to generate the clock signal on the EQEPA input to the eQEP module.
- The xDIRMOD block inside the QMA module looks at the transitions on external EQEPA and EQEPB signals to generate the direction signal on the EQEPB input to the eQEP module.

The QMA module has error detection logic to detect illegal transitions on EQEPA and EQEPB input signals. The QMA module's error and interrupt are integrated inside the eQEP module as described in [Section 23.10](#). In addition, the QMACTRL register configuration can be locked using the QMALOCK register. Refer to the register description for more details.

**Figure 23-22. QMA Module Block Diagram**

### 23.9.1 Modes of Operation

The QMA module can be operated in the following modes by configuring the QMACTRL register:

- QMA Mode-1 (QMACTRL[MODE] = 1)
- QMA Mode-2 (QMACTRL[MODE] = 2)

#### 23.9.1.1 QMA Mode-1 (QMACTRL[MODE] = 1)

This mode is used when the default state of EQEPA and EQEPB inputs is high. In this mode, outputs of QMA correspond to the following as shown in [Figure 23-23](#):

- EQEPA Output of QMA is the AND of EQEPA and EQEPB inputs coming from the pin
- EQEPB Output of QMA is the direction signal generated by QMA based on EQEPA and EQEPB inputs

**Figure 23-23. QMA Mode-1**

### 23.9.1.2 QMA Mode-2 (QMACTRL[MODE] = 2)

This mode is used when the default state of EQEPA and EQEPB inputs is low. In this mode, outputs of QMA correspond to the following as shown in Figure 23-24:

- EQEPA Output of QMA is the OR of EQEPA and EQEPB inputs coming from the pin
- EQEPB Output of QMA is the direction signal generated by QMA based on EQEPA and EQEPB inputs

Figure 23-24. QMA Mode-2

### 23.9.2 Interrupt and Error Generation

The error detection logic detects illegal transitions on EQEPA and EQEPB signals and generates an error signal. This error signal can be used to generate eQEP interrupt and error output. Refer to Section 23.10 for details.

### 23.10 eQEP Interrupt Structure

Figure 23-25 shows how the interrupt mechanism works in the eQEP module.

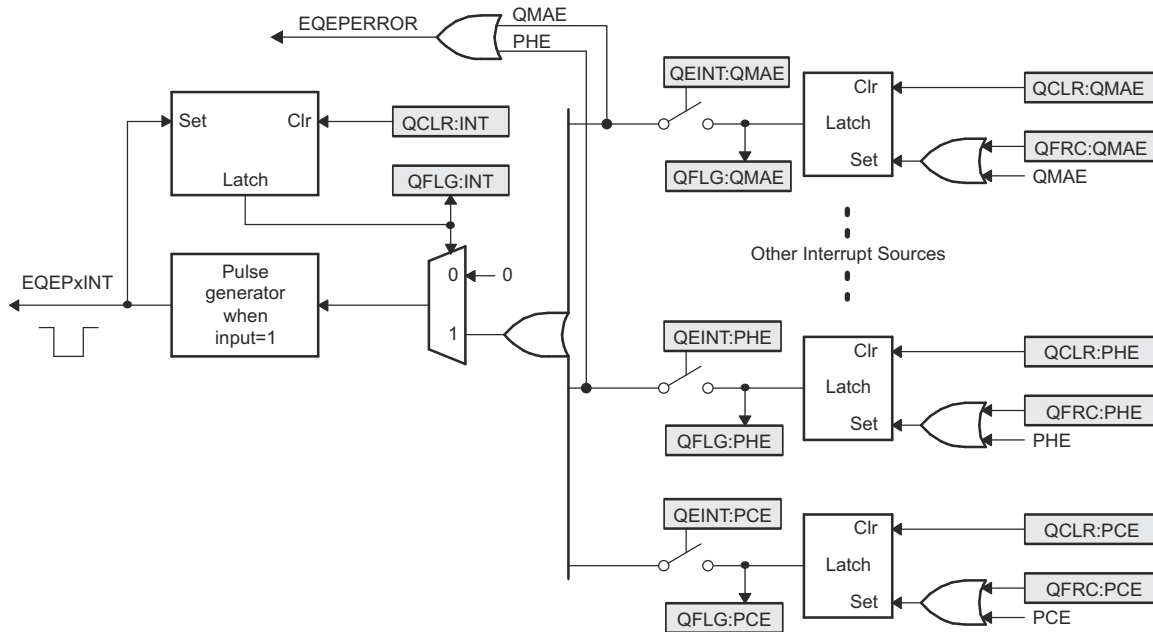

Figure 23-25. eQEP Interrupt Generation

Eleven interrupt events (PCE, PHE, QDC, WTO, PCU, PCO, PCR, PCM, SEL, IEL and UTO) can be generated. The interrupt control register (QEINT) is used to enable/disable individual interrupt event sources. The interrupt flag register (QFLG) indicates if any interrupt event has been latched and contains the global interrupt flag bit (INT).

An interrupt pulse is generated to PIE when:

1. Interrupt is enabled for eQEP event inside QEINT register
2. Interrupt flag for eQEP event inside QFLG register is set, and
3. Global interrupt status flag bit QFLG[INT] had been cleared for previously generated interrupt event. The interrupt service routine needs to clear the global interrupt flag bit and the serviced event, by way of the interrupt clear register (QCLR), before any other interrupt pulses are generated. If either flags inside the QFLG register are not cleared, further interrupt events do not generate an interrupt to PIE. You can force an interrupt event by way of the interrupt force register (QFRC), which is useful for test purposes.

## 23.11 Software

### 23.11.1 EQEP Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
 C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/eqep

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 23.11.1.1 Frequency Measurement Using eQEP via unit timeout interrupt - SINGLE\_CORE

FILE: eqep\_ex2\_freq\_cal\_interrupt.c

This example will calculate the frequency of an input signal using the eQEP module. ePWM1A is configured to generate this input signal with a frequency of 5 kHz. EQEP unit timeout is set which will generate an interrupt every *UNIT\_PERIOD* microseconds and frequency calculation occurs continuously

The configuration for this example is as follows

- PWM frequency is specified as 5000Hz
- UNIT\_PERIOD is specified as 10000 us
- Min frequency is  $(1/(2*10ms))$  i.e 50Hz
- Highest frequency can be  $(2^{32}/((2*10ms)))$
- Resolution of frequency measurement is 50hz

*freq* : Frequency Measurement is obtained by counting the external input pulses for UNIT\_PERIOD (unit timer set to 10 ms).

#### External Connections

- Connect GPIO20/eQEP1A to GPIO0/ePWM1A

#### Watch Variables

- *freq* - Frequency measurement using position counter/unit time out
- *pass* - If measured frequency matches with PWM frequency then pass = 1 else 0

#### 23.11.1.2 Motor speed and direction measurement using eQEP via unit timeout interrupt - SINGLE\_CORE

FILE: eqep\_ex5\_speed\_dir\_motor.c

This example can be used to sense the speed and direction of motor using eQEP in quadrature encoder mode. ePWM1A is configured to simulate motor encoder signals with frequency of 5 kHz on both A and B pins with 90 degree phase shift (so as to run this example without motor). EQEP unit timeout is set which will generate an interrupt every *UNIT\_PERIOD* microseconds and speed calculation occurs continuously based on the direction of motor

The configuration for this example is as follows

- PWM frequency is specified as 5000Hz
- UNIT\_PERIOD is specified as 10000 us
- Simulated quadrature signal frequency is 20000Hz (4 \* 5000)
- Encoder holes assumed as 1000
- Thus Simulated motor speed is 300rpm (5000 \* (60 / 1000))

*freq* : Simulated quadrature signal frequency measured by counting the external input pulses for UNIT\_PERIOD (unit timer set to 10 ms). *speed* : Measure motor speed in rpm *dir* : Indicates clockwise (1) or anticlockwise (-1)

#### External Connections (if motor encoder signals are simulated by ePWM)

- Connect GPIO20/eQEP1A to GPIO0/ePWM1A
- Connect GPIO21/eQEP1B to GPIO1/ePWM1B With motor
- Comment in "MOTOR" in includes
- Connect GPIO20/eQEP1A to encoder A output
- Connect GPIO21/eQEP1B to encoder B output

#### Watch Variables

- *freq* : Simulated motor frequency measurement is obtained by counting the external input pulses for UNIT\_PERIOD (unit timer set to 10 ms).
- *speed* : Measure motor speed in rpm
- *dir* : Indicates clockwise (1) or anticlockwise (-1)
- *pass* - If measured quadrature frequency matches with i.e. input quadrature frequency (4 \* PWM frequency) then pass = 1 else fail = 1 (\*\* only when "MOTOR" is commented out)

## 23.12 eQEP Registers

This section describes the Enhanced Quadrature Encoder Pulse Registers.

### 23.12.1 EQEP Base Address Table

**Table 23-4. EQEP Base Address Table**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	CPU2	CPU2.DMA	Pipeline Protected
Instance	Structure								
EQep1Regs	<a href="#">EQEP_REGS</a>	EQEP1_BASE	0x0000_5080	YES	YES	YES	YES	YES	YES

34h	QMACTRL	QMA Control register		<a href="#">Go</a>
36h	QEPRCSEL	QEP Source Select Register		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 23-6 shows the codes that are used for access types in this section.

**Table 23-6. EQEP\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear

**Table 23-6. EQEP\_REGS Access Type Codes (continued)**

Access Type	Code	Description
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 23.12.2.1 QPOSCNT Register (Offset = 0h) [Reset = 0000000h]

QPOSCNT is shown in [Figure 23-26](#) and described in [Table 23-7](#).

Return to the [Summary Table](#).

Position Counter

**Figure 23-26. QPOSCNT Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
QPOSCNT																															
R/W-0h																															

**Table 23-7. QPOSCNT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	QPOSCNT	R/W	0h	Position Counter This 32-bit position counter register counts up/down on every eQEP pulse based on direction input. This counter acts as a position integrator whose count value is proportional to position from a give reference point. This Register acts as a Read ONLY register while counter is counting up/down. Note: It is recommended to only write to the position counter register (QPOSCNT) during initialization, i.e. when the eQEP position counter is disabled (QPEN bit of QEPCTL is zero). Once the position counter is enabled (QPEN bit is one), writing to the eQEP position counter register (QPOSCNT) may cause unexpected results. Reset type: SYSRSn

### 23.12.2.2 QPOSINIT Register (Offset = 2h) [Reset = 0000000h]

QPOSINIT is shown in [Figure 23-27](#) and described in [Table 23-8](#).

Return to the [Summary Table](#).

Position Counter Init

**Figure 23-27. QPOSINIT Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
QPOSINIT																															
R/W-0h																															

**Table 23-8. QPOSINIT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	QPOSINIT	R/W	0h	Position Counter Init This register contains the position value that is used to initialize the position counter based on external strobe or index event. The position counter can be initialized through software. Writes to this register should always be full 32-bit writes. Reset type: SYSRSn

### 23.12.2.3 QPOSMAX Register (Offset = 4h) [Reset = 0000000h]

QPOSMAX is shown in [Figure 23-28](#) and described in [Table 23-9](#).

Return to the [Summary Table](#).

Maximum Position Count

**Figure 23-28. QPOSMAX Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
QPOSMAX																															
R/W-0h																															

**Table 23-9. QPOSMAX Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	QPOSMAX	R/W	0h	Maximum Position Count This register contains the maximum position counter value. Writes to this register should always be full 32-bit writes. Reset type: SYSRSn

### 23.12.2.4 QPOSCMP Register (Offset = 6h) [Reset = 00000000h]

QPOSCMP is shown in [Figure 23-29](#) and described in [Table 23-10](#).

Return to the [Summary Table](#).

Position Compare

**Figure 23-29. QPOSCMP Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
QPOSCMP																															
R/W-0h																															

**Table 23-10. QPOSCMP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	QPOSCMP	R/W	0h	Position Compare The position-compare value in this register is compared with the position counter (QPOSCNT) to generate sync output and/or interrupt on compare match. Writes to this register should always be full 32-bit writes. Reset type: SYSRSn

### 23.12.2.5 QPOSILAT Register (Offset = 8h) [Reset = 00000000h]

QPOSILAT is shown in [Figure 23-30](#) and described in [Table 23-11](#).

Return to the [Summary Table](#).

Index Position Latch

**Figure 23-30. QPOSILAT Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
QPOSILAT

### 23.12.2.8 QUTMR Register (Offset = Eh) [Reset = 0000000h]

QUTMR is shown in [Figure 23-33](#) and described in [Table 23-14](#).

Return to the [Summary Table](#).

QEP Unit Timer

**Figure 23-33. QUTMR Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
QUTMR																															
R/W-0h																															

**Table 23-14. QUTMR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	QUTMR	R/W	0h	QEP Unit Timer This register acts as time base for unit time event generation. When this timer value matches the unit time period value a unit time event is generated. Writes to this register should always be full 32-bit writes. Reset type: SYSRSn

### 23.12.2.9 QUPRD Register (Offset = 10h) [Reset = 0000000h]

QUPRD is shown in [Figure 23-34](#) and described in [Table 23-15](#).

Return to the [Summary Table](#).

QEP Unit Period

**Figure 23-34. QUPRD Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
QUPRD																															
R/W-0h																															

**Table 23-15. QUPRD Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	QUPRD	R/W	0h	QEP Unit Period This register contains the period count for the unit timer to generate periodic unit time events. These events latch the eQEP position information at periodic intervals and optionally generate an interrupt. Writes to this register should always be full 32-bit writes. Reset type: SYSRSn

### 23.12.2.10 QWDTMR Register (Offset = 12h) [Reset = 0000h]

QWDTMR is shown in [Figure 23-35](#) and described in [Table 23-16](#).

Return to the [Summary Table](#).

QEP Watchdog Timer

**Figure 23-35. QWDTMR Register**

13-12	PCRM	R/W	0h	Position counter reset Reset type: SYSRSn 0h (R/W) = Position counter reset on an index event 1h (R/W) = Position counter reset on the maximum position 2h (R/W) = Position counter reset on the first index event 3h (R/W) = Position counter reset on a unit time event
11-10	SEI	R/W	0h	Strobe event initialization of position counter Reset type: SYSRSn 0h (R/W) = Does nothing (action disabled) 1h (R/W) = Does nothing (action disabled) 2h (R/W) = Initializes the position counter on rising edge of the QEPS signal 3h (R/W) = Clockwise Direction: Initializes the position counter on the rising edge of QEPS strobe Counter Clockwise Direction: Initializes the position counter on the falling edge of QEPS strobe

**Table 23-19. QEPCTL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
9-8	IEI	R/W	0h	Index event init of position count Reset type: SYSRSn 0h (R/W) = Do nothing (action disabled) 1h (R/W) = Do nothing (action disabled) 2h (R/W) = Initializes the position counter on the rising edge of the QEPI signal (QPOSCNT = QPOSINIT) 3h (R/W) = Initializes the position counter on the falling edge of QEPI signal (QPOSCNT = QPOSINIT)
7	SWI	R/W	0h	Software init position counter Reset type: SYSRSn 0h (R/W) = Do nothing (action disabled) 1h (R/W) = Initialize position counter (QPOSCNT=QPOSINIT). This bit is not cleared automatically
6	SEL	R/W	0h	Strobe event latch of position counter Reset type: SYSRSn 0h (R/W) = The position counter is latched on the rising edge of QEPS strobe (QPOSSLAT = POSCCNT). Latching on the falling edge can be done by inverting the strobe input using the QSP bit in the QDECCTL register 1h (R/W) = Clockwise Direction: Position counter is latched on rising edge of QEPS strobe Counter Clockwise Direction: Position counter is latched on falling edge of QEPS strobe
5-4	IEL	R/W	0h	Index event latch of position counter (software index marker) Reset type: SYSRSn 0h (R/W) = Reserved 1h (R/W) = Latches position counter on rising edge of the index signal 2h (R/W) = Latches position counter on falling edge of the index signal 3h (R/W) = Software index marker. Latches the position counter and quadrature direction flag on index event marker. The position counter is latched to the QPOSILAT register and the direction flag is latched in the QEPSTS[QDLF] bit. This mode is useful for software index marking.
3	QPEN	R/W	0h	Quadrature position counter enable/software reset Reset type: SYSRSn 0h (R/W) = Reset the eQEP peripheral internal operating flags/read-only registers. Control/configuration registers are not disturbed by a software reset. When QPEN is disabled, some flags in the QFLG register do not get reset or cleared and show the actual state of that flag. 1h (R/W) = eQEP position counter is enabled
2	QCLM	R/W	0h	QEP capture latch mode Reset type: SYSRSn 0h (R/W) = Latch on position counter read by CPU. Capture timer and capture period values are latched into QCTMRLAT and QCPRDLAT registers when CPU reads the QPOSCNT register. 1h (R/W) = Latch on unit time out. Position counter, capture timer and capture period values are latched into QPOSILAT, QCTMRLAT and QCPRDLAT registers on unit time out.
1	UTE	R/W	0h	QEP unit timer enable Reset type: SYSRSn 0h (R/W) = Disable eQEP unit timer 1h (R/W) = Enable unit timer
0	WDE	R/W	0h	QEP watchdog enable Reset type: SYSRSn 0h (R/W) = Disable the eQEP watchdog timer 1h (R/W) = Enable the eQEP watchdog timer

**23.12.2.14 QCAPCTL Register (Offset = 16h) [Reset = 0000h]**

## Chapter 24

# Sigma Delta Filter Module (SDFM)

---

The sigma delta filter module (SDFM) is a four-channel digital filter designed specifically for current measurement and resolver position decoding in motor control applications. Each input channel can receive an independent delta-sigma ( $\Delta\Sigma$ ) modulator bit stream. The bit streams are processed by four individually-programmable digital decimation filters. The filter set includes a fast comparator (secondary filter) for immediate digital threshold comparisons for over-current and under-current monitoring, and zeros crossing detection.

### 24.1.2 Features

SDFM features include:

- Eight external pins per SDFM module
  - Four sigma-delta data input pins per SDFM module (SD-Dx, where x = 1 to 4)
  - Four sigma-delta clock input pins per SDFM module (SD-Cx, where x = 1 to 4)
- Different configurable modulator clock modes supported:
  - Mode 0: Modulator clock rate equals the modulator data rate.
- Four independent, configurable secondary filter (comparator) units per SDFM module:
  - Four different filter type selection (Sinc1/Sinc2/SincFast/Sinc3) options available
  - Ability to detect over-value condition, under-value condition, and Threshold-crossing conditions
    1. Two independent Higher Threshold comparators (used to detect over-value condition)
    2. Two independent Lower Threshold comparators (used to detect under-value condition)
    3. One independent Threshold-Crossing comparator (used to measure duty cycle/frequency with eCAP)
  - OSR value for comparator filter unit (COSR) programmable from 1 to 32
- Four independent configurable primary filter (data filter) units per SDFM module:
  - Four different filter type selection (Sinc1/Sinc2/SincFast/Sinc3) options available
  - OSR value for data filter unit (DOSR) programmable from 1 to 256
  - Ability to enable or disable (or both) individual filter module
  - Ability to synchronize all four independent filters of an SDFM module by using the Main Filter Enable (MFE) bit or by using PWM signals
- Data filter output can be represented in either 16 bits or 32 bits.
- Data filter unit has a programmable mode FIFO to reduce interrupt overhead. The FIFO has the following features:
  - The primary filter (data filter) has a 16-deep x 32-bit FIFO.
  - The FIFO can interrupt the CPU after programmable number of data-ready events.
  - FIFO Wait-for-Sync feature: Ability to ignore data-ready events until the PWM synchronization signal (SDSYNC) is received. Once the SDSYNC event is received, the FIFO is populated on every data-ready event.
  - Data filter output can be represented in either 16 bits or 32 bits.
- PWMx.SOCA/SOCB can be configured to serve as SDSYNC source on a per-data-filter-channel basis.
- PWMs can be used to generate a modulator clock for sigma-delta modulators.
- Configurable Input Qualification available for both SD-Cx and SD-Dx
- Ability to use one filter channel clock (SD-C1) to provide clock to other filter clock channels.
- Configurable digital filter available on comparator filter events to blankout comparator events caused by spurious noise

### 24.1.3 Block Diagram

Each SDFM module has four independent filter modules. These filter modules are identical and can be configured independently. Each individual filter module has the following units:

- Input control unit
- Primary filter (data filter) unit
- Secondary filter (comparator filter) unit with 4 independent comparators

Figure 24-2 shows the SDFM module block diagram. The SDFM port operation is configured and controlled by the registers listed in Section 24.12.

Figure 24-2. Sigma Delta Filter Module (SDFM) Block Diagram

Each filter module shown in Figure 24-3 has a primary (data) filter and a secondary (comparator) filter pair that receives the same bit stream. Except for the input bit stream, both the primary and secondary filter are completely independent of each other. Each of these filter modules can be independently configured. So, in a SDFM module, there is a total of four primary filters and four secondary filters.

Figure 24-3. Block Diagram of One Filter Module

## 24.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

For proper SDFM operation, use the following GPIO input qualification. Other GPIO qualifications are not supported.

- GPIO Input qualification is ASYNC, make sure to check the SDFM Electrical Data and Timing (Using ASYNC) requirement is met and be aware of the following caution message. SDFM Input Qualification feature is used to provide protection against random noise glitches.
- **Recommended option:** GPIO Input qualification = 3-sample GPIO Input Qualification. This option provides additional hardware protection against occasional random noise glitches. When GPIO Input qualification is a 3-sample window, make sure to check that the SDFM Electrical Data and Timing (Using 3-Sample GPIO Input Qualification) requirement is met and be aware of the following caution message and note.

### CAUTION

The SDFM clock inputs (SDx\_Cy pins) directly clock the SDFM module. Any glitches or ringing noise on these inputs can corrupt the SDFM module operation. Special precautions must be taken on these signals to make sure of a clean and noise-free signal that meets SDFM timing requirements. Precautions such as series termination for ringing due to any impedance mismatch of the clock driver and spacing of traces from other noisy signals are recommended.

### Note

The SDFM module expects SD-Dx to change on the falling edge of SD-Cx and strobes for SD-Dx on the rising edge. But some SD-modulators in the market change SD-Dx on the rising edge and expect SDFM to strobe for data on the falling edge. In such cases, the GPIO inversion feature (GPxINV) is used on SD-Cx pin to change polarity and make it compatible with the SDFM.

The SDFM Qualified GPIO (3-sample) option provides protection against SDFM module corruption due to occasional random noise glitches on the SDx\_Cy pin that can result in a false comparator trip and filter output.

The SDFM Qualified GPIO (3-sample) option does not provide protection against persistent violations of the above timing requirements. Timing violations results in data corruption proportional to the number of bits that violate the requirements.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

## 24.3 Input Qualification

Impulse noise sources such as EMI, crosstalk, and so on, has the possibility of corrupting SDCLK and SDDATA bit streams, resulting in corrupted SDFM filtered data. This impulse noise effects can be mitigated when using the input qualification feature that synchronizes SDCLK/SDDATA signals with PLLRAWCLK. By default, both SDCLK and SDDATA bit stream are not synchronized. SDCLK can be synchronized to PLLRAWCLK by setting SDCTLPARAMx.SDCLKSYNC = 1 and SDDATA can be synchronized to PLLRAWCLK by setting SDCTLPARAMx.SDDATASYNC = 1. [Figure 24-4](#) shows optional Input Qualification option on SDCLK and SDDATA lines.

**Figure 24-4. Input Qualification on SD-Cx and SD-Dx**

### Note

Using GPIO input synchronization when SDFM input qualification feature is enabled can cause unexpected results. The user must make sure that the GPIO pin is configured for asynchronous in this case.

## 24.4 Input Control Unit

The input control unit receives sigma delta modulated data and a sigma delta modulated clock. The modulated data received is captured and passed on to the data filter unit and comparator unit. This unit can be configured to receive the modulated data in Mode 0. [Table 24-1](#) and [Figure 24-5](#) show how SDCTLPARAMx.MOD bits can be configured in Mode 0.

**Table 24-1. Modulator Clock Modes**

Modulator Mode [MOD]	Description
0	The modulator clock is running with the modulator data rate. The modulator data is strobed at every rising edge of the modulator clock.
1	Reserved
2	Reserved
3	Reserved

### Note

To achieve the maximum value, the sigma-delta modulator has to be operated at absolute maximum positive or negative full scale, which is outside of the recommended full scale range of 80% of most sigma-delta modulators.

Mode 0 Operation

**Figure 24-5. Different Modulator Modes Supported**

## 24.5 SDFM Clock Control

In systems, the modulator clock can be generated using PWMs. Assuming all the SD-CLKs see the same delay on board traces, you can potentially use just one clock to clock multiple filters; thereby, saving on the number of pins used for SDFM. To enable this, Filter1 SDCLK (SD-C1) can possibly apply to other filter channels if required. The SDCTLPARAMx.SDCLKSEL register bit field can be configured to select filter channel SDCLK. See [Figure 24-6](#) to view this feature.

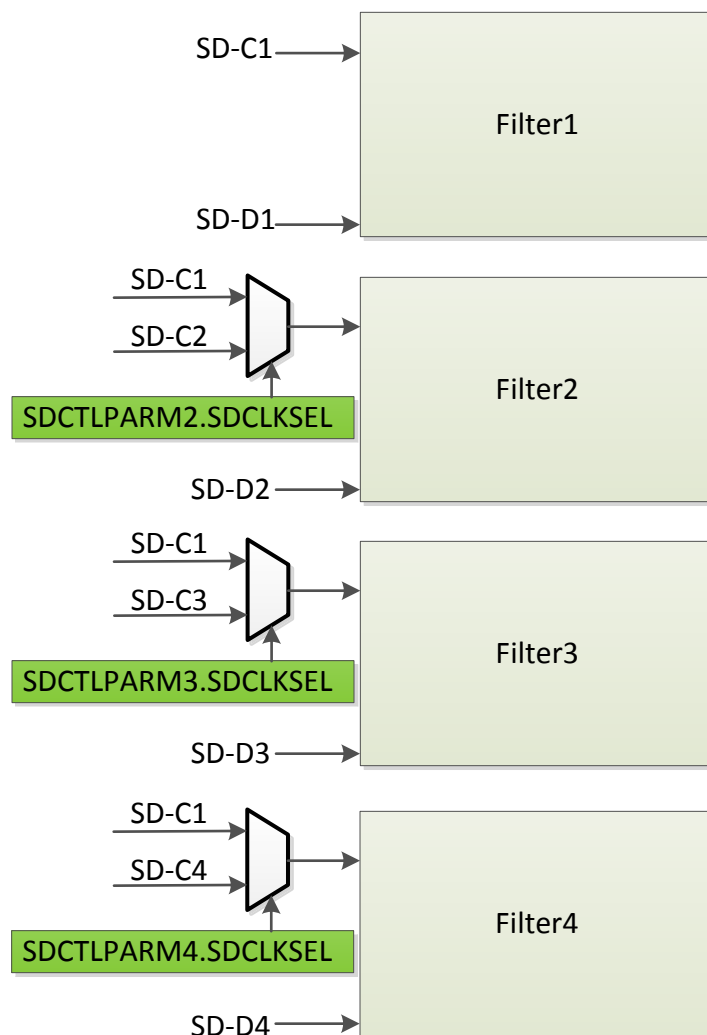

Figure 24-6. SDFM Clock Control

### 24.6 Sinc Filter

Both the comparator filter and data filter available in SDFM have the Sinc<sup>N</sup> filter as the core. The Sinc<sup>N</sup> filter is essentially a low-pass filter that converts the input bit stream into digital data by digital filtering and decimation. This filtered digital data represents analog input given to the sigma delta modulator. Simplified Sinc<sup>N</sup> architecture consists of cascaded integrators and differentiators separated by a down-sampler as shown in Figure 24-7. The Z-transfer function of the Sinc filter of order N is shown in Figure 24-8.

Figure 24-7. Simplified Sinc Filter Architecture

$$H(Z) = \left[ \frac{1 - Z^{-OSR}}{1 - Z^{-1}} \right]^N$$

N = Order of Sinc filter  
 OSR = Over Sampling Ratio

Figure 24-8. Z-Transform of Sinc Filter of Order N

Effective resolution of the Sinc filter (ENOB) depends upon filter type, OSR and sigma-delta modulator frequency. Typically, higher resolution or ENOB can be achieved by higher OSR for a given filter type; however, the tradeoff is increased filter delay. It is important to choose the right sigma delta modulator by studying the optimal speed versus resolution tradeoff. Refer to the corresponding sigma delta modulator data sheet to determine the effective resolution for a given Sinc filter configuration. Figure 24-9 shows the frequency response of different filter structures when OSR = 32 and when the sigma delta modulator frequency is 10MHz.

Figure 24-9. Frequency Response of Different Sinc Filters

The order of different sinc filter is shown in [Table 24-2](#).

**Table 24-2. Order of Sinc Filter**

Filter Type	Order of Sinc Filter
Sinc1	1
Sinc2	2
Sinc3	3
SincFast	3

### 24.6.1 Data Rate and Latency of the Sinc Filter

The data rate of the sinc filter (filter throughput) represented in samples/sec is calculated by the following formula:

$$\text{Data rate of Sinc filter} = \frac{\text{Modulator data rate}}{\text{OSR}} \quad (28)$$

The latency of the sinc filter represented in secs is defined as the amount of time taken by a sinc filter type to deliver the correct filtered output upon initiation. For a given filter type, latency is calculated by the following formula:

$$\text{Latency of Sinc filter} = \frac{\text{Order of Sinc filter}}{\text{Data rate of Sinc filter}} \quad (29)$$

#### **Example configuration:**

Sinc filter type = sinc3  
 Modulator data rate = 10MHz  
 OSR = 256  
 Data rate of Sinc Filter = 10MHz/256 = 39.1K samples/second  
 Sinc filter latency = 76.8µs

Sinc filter type = sinc2  
 Modulator data rate = 10MHz  
 OSR = 256  
 Data rate of Sinc Filter = 10MHz/256 = 39.1K samples/second  
 Sinc filter latency = 51.2µs

## 24.7 Data (Primary) Filter Unit

The data filter is a configurable Sinc filter which supports the following filter types: Sinc1, Sinc2, Sinc3, and SincFast. The data filter OSR (DOSR) settings can be configured from 1 to 256 and is independent of the comparator filter. Effective resolution of the data filter (ENOB) depends upon Data filter type, DOSR, and sigma-delta modulator frequency. By default, the data filter is disabled and setting of SDDFPARMx.FEN = 1 enables the data filter. The data filter output is represented in 26-bit signed integer in two's complement format. This filter unit translates a low input signal as '-1' and a high input signal as '1'. The resulting calculation gives both positive and negative values for the output of the data filter. [Table 24-3](#) shows the different full scale values that the data filter can store using different OSRs.

See [Section 24.6.1](#) to understand how to calculate data rate and latency of data filter.

**Table 24-3. Peak Data Values for Different DOSR/Filter Combinations**

DOSR	Sinc1	Sinc2	Sinc3	SincFast
x	x	$x^2$	$x^3$	$2x^2$
4	-4 to 4	-16 to 16	-64 to 64	-32 to 32
8	-8 to 8	-64 to 64	-512 to 512	-128 to 128
16	-16 to 16	-256 to 256	-4096 to 4096	-512 to 512
32	-32 to 32	-1024 to 1024	-32,768 to 32,768	-2048 to 2048
64	-64 to 64	-4096 to 4096	-262,144 to 262,144	-8192 to 8192
128	-128 to 128	-16,384 to 16,384	-2,097,152 to 2,097,152	-32,768 to 32,768
256	-256 to 256	-65,536 to 65,536	-16,777,216 to 16,777,216	-131,072 to 131,072

### 24.7.1 32-bit or 16-bit Data Filter Output Representation

The data filter output can be represented in either 32-bit or 16-bit format.

#### 32-bit data filter representation:

- When SDDPARMx.DR = 1, data filter output is represented in 32-bit format. Writes to shift control bits do not have any bearing on the output of the data filter in this configuration.

#### 16-bit data filter representation:

- By default, data filter output is represented in 16-bit format
- When SDDPARMx.DR = 0, data filter output is represented in 16-bit format. But it is the responsibility of the user to configure the corresponding shift control bits in the SDDPARMx register to control which 16-bit part of the 32-bit word is sent to the register map.

For example, for the data filter configuration below:

- Filter type = Sinc3
- OSR = 128
- SDDPARMx.DR = 0

The data filter with a 26-bit signed output value can be in the range of  $-2,097,152$  to  $2,097,152$ . But, 16-bit signed output supports values only from  $-32,768$  to  $32,767$ . Therefore, it is required to configure shift control bits (SDDPARMx.SH) to 7 to represent the data filter output correctly in 16-bit format. [Table 24-4](#) shows the configuration settings of shift control bits for different OSR and filter types.

**Table 24-4. Shift Control Bit Configuration Settings**

OSR	Sinc1	Sinc2	SincFast	Sinc3
1 to 31	0	0	0	0
32 to 40	0	0	0	1
41 to 50	0	0	0	2
51 to 63	0	0	0	3
64 to 80	0	0	0	4
81 to 101	0	0	0	5
102 to 127	0	0	0	6
128 to 161	0	0	1	7
162 to 181	0	0	1	8
182 to 203	0	1	2	8
204 to 255	0	1	2	9
256	0	2	3	10

#### CAUTION

Configuring shift control bits incorrectly results in getting an incorrect 16-bit data filter output.

### 24.7.2 Data FIFO

Each primary (data) filter channel has a 16-level deep, 32-bit FIFO.

FIFOs can be configured to collect a programmable number of data filter samples before issuing data-ready interrupt. This reduces the number of data-ready interrupts generated and resulting interrupt overhead for managed data flow.

By default, FIFO operation is disabled. FIFOs can be enabled by setting SDFIFOCTLx.FFEN = 1. When FIFO is enabled, each data-ready event from the data filter populates the FIFO, and the status of the FIFO at any given time is updated in the SDFIFOCTLx.SDFFST bit field.

### Setting up FIFO to interrupt after receiving programmable number of data ready events:

- Enable SDFM FIFO (Set SDFIFOCTLx.FFEN = 1)
- Enable SDFM FIFO interrupt (Set SDFIFOCTLx.FFIEN = 1)
- Configure SDFIFOCTLx.SDFFIL bit field to any value between 0 to 16
- Configure SDFM data ready event to interrupt on FIFO interrupt (SDFFINT) (Set SDFFINTx = 1)
- Select data-ready interrupt source is SDFFINTx (DRINTx = SDFFINTx) (SDFIFOCTLx.DRINTSEL = 1)

When the SDFIFOCTLx.SDFFST >= SDFIFOCTLx.SDFFIL condition is met, the SDIFLG.SDFFINTx bit is set and an interrupt is generated on the DRINTx. SDIFLG.SDFFINTx flag can be cleared by setting the SDIFLGCLR.SDFFINTx bit field.

### Wait for Sync feature:

The FIFO wait for sync feature can be used to ignore data-ready events from the data filter until the SDSYNC (from PWM) event is triggered.

By default, the Wait for Sync feature is disabled. This feature can be enabled by setting SDSYNcx.WTSYNcEN = 1

### When the wait for sync feature is disabled:

FIFOs get populated on every data ready event until the FIFO gets full (or) when SDFIFOCTLx.SDFFST >= SDFIFOCTLx.SDFFIL.

### When the wait for sync feature enabled:

FIFOs do not get populated on every data ready event until the FIFO receives a SDSYNC event. On a SYSYNC event, the FIFO sets SDSYNcx.WTSYNcFLG = 1 and data ready events from the primary filter start populating the FIFO until either the FIFOs get full or when SDFIFOCTLx.SDFFST >= SDFIFOCTLx.SDFFIL. WTSYNcFLG can be cleared either automatically or manually.

When WTSYNcFLG = 0, FIFOs contents are frozen and subsequent data ready events do not populate FIFO until next SDSYNC event.

### WTSYNcFLG automatic clear mode:

By default, this mode is enabled. When SDSYNcx.WTScLREN = 1, WTSYNcFLG is automatically cleared on SDFFINT event.

### WTSYNcFLG manual clear mode:

Setting SDSYNcx.WTSYNcCLR = 1 can be used to clear WTSYNcFLG manually.

### Clearing FIFO contents:

FIFO contents can be cleared by any of the following methods:-

- Disabling FIFO clear FIFO contents. This can be done by clearing SDFIFOCTLx.FFEN = 0.
- Disabling Primary filter clear FIFO contents. This can be done by either clearing SDDFPARMx.FEN = 0 (or) by clearing SDMFILEN.MFE = 0.
- FIFO contents can also be automatically cleared upon receiving the SDSYNC event. By default, this feature is disabled and this feature can be enabled by setting FIFO Clear-on-SDSYNC enable (SDSYNcx.FFSYNcCLREN = 1).

**Note:** The above feature is only enabled when wait for sync feature is enabled (SDSYNcx.WTSYNcEN = 1).

### FIFO debug access behavior:

Debug access of the SDDATFIFOx registers does not affect the FIFO pointers. On a CPU/CLA/DMA access to the SDDATFIFOx register, the FIFO read pointers advance to the next available entry in the FIFO.

### 24.7.3 SDSYNC Event

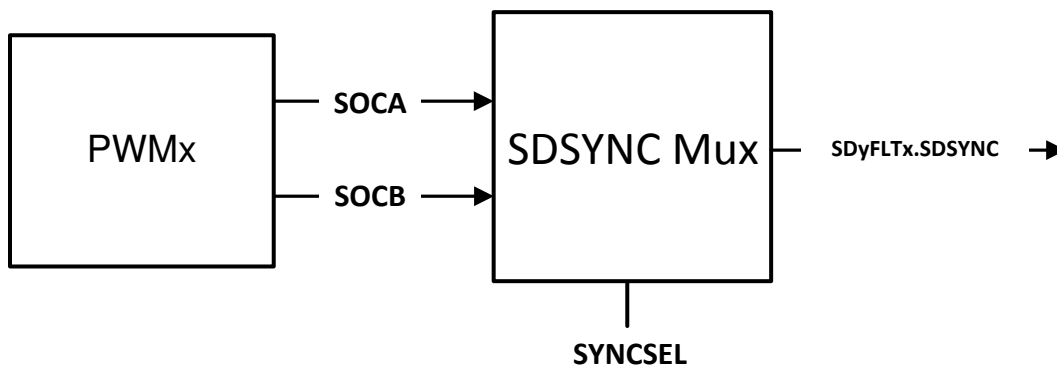

Primary (data) filters can be synchronized with respect to the PWM event (called SDSYNC event). The SDSYNC signal from the PWM module is used to reset the DOSR counter. This feature is by default disabled and can be enabled by setting `SDDFPARMx.SDSYNCEN = 1`. Each primary filter can be synchronized from any of the available PWMx SOCA/SOCB signals (see [Table 24-5](#)). The `SDSYNCx.SDSYNCSEL` bits allow the user to configure which PWM signal provides the SDSYNC pulse to the primary filter. [Figure 24-10](#) shows how device PWM signals are connected to the SDFM modules.

**Table 24-5. SDSYNCx.SYNCSEL**

SDSYNCxSYNCSEL	Input Signal
0	EPWM1_SOCA

**Figure 24-10. SDSYNC Event**

Because of the inherent architecture of the Sinc filter (Sinc1, Sinc2, Sinc3, SincFast), the first few samples, depending upon filter type, are incorrect. [Table 24-6](#) shows the number of incorrect samples on the following conditions:

- When Sinc filter is enabled and configured for first time.
- When Sinc filter is disabled and re-enabled or reconfigured in the middle of operation.
- When data filter receives SDSYNC event from PWM.

**Table 24-6. Number of Incorrect Samples Tabulated**

Filter Type	Number of Incorrect Samples After the Filter is Enabled and Configured
Sinc1	No incorrect sample.
Sinc2	The first sample of the Sinc2 filter is incorrect.
SincFast	The first two samples of the SincFast filter are incorrect.
Sinc3	The first two samples of the Sinc3 filter are incorrect.

**CAUTION**

SDFM comparator interrupts can be enabled only after providing sufficient settling time to make sure the comparator filter does not trip on these incorrect samples. Therefore, SDFM comparator interrupts (CEVT1 and CEVT2) can be enabled only after a sufficient delay is provided after the comparator filter is configured. This sufficient delay is calculated by adding the latency of the comparator filter and 5 SD-Cx clock cycles.

## 24.8 Comparator (Secondary) Filter Unit

Most control systems require protection of the system by tripping the PWM in case the current or voltage goes out of bounds. The primary purpose of the secondary (comparator) filter is to allow the user to monitor input conditions with a fast settling time. This allows the user to trip PWMs to protect the system from potential damage.

---

### Note

The secondary (comparator) filter cannot be synchronized with respect to the PWM event (SDSYNC event).

---

The comparator filter is a configurable Sinc filter that supports the following filter types: Sinc1, Sinc2, Sinc3, and SincFast. The comparator OSR (COSR) settings can be configured from 1 to 32 and is independent of the data filter. Effective resolution of the comparator filter (ENOB) depends upon the comparator filter type, COSR, and sigma-delta modulator frequency. By default, the comparator filter is disabled and setting SDCPARMx.CEN = 1 enables the comparator filter. The comparator filter output is represented in 16-bit unsigned format. This filter unit translates a low input signal as 0 and a high input signal as 1. The resulting calculations give only positive values for the output of the comparator filter. [Table 24-7](#) shows the different full-scale values that the comparator filter can store using different OSRs.

**Table 24-7. Peak Data Values for Different OSR/Filter Combinations**

OSR	Sinc1	Sinc2	Sinc3	SincFast
x	0 to x	0 to x <sup>2</sup>	0 to x <sup>3</sup>	0 to 2x <sup>2</sup>
4	0 to 4	0 to 16	0 to 64	0 to 32
8	0 to 8	0 to 64	0 to 512	0 to 128
16	0 to 16	0 to 256	0 to 4096	0 to 512
32	0 to 32	0 to 1024	0 to 32,768	0 to 2048

See [Section 24.6.1](#) to understand how to calculate data rate and latency of comparator filter.

The output of the comparator filter is memory-mapped and can be read in the SDCDATAx register. This register, SDCDATAx, is updated every COSR number of SD-Cx cycles. The comparator filter digital output is connected to digital comparators explained below.

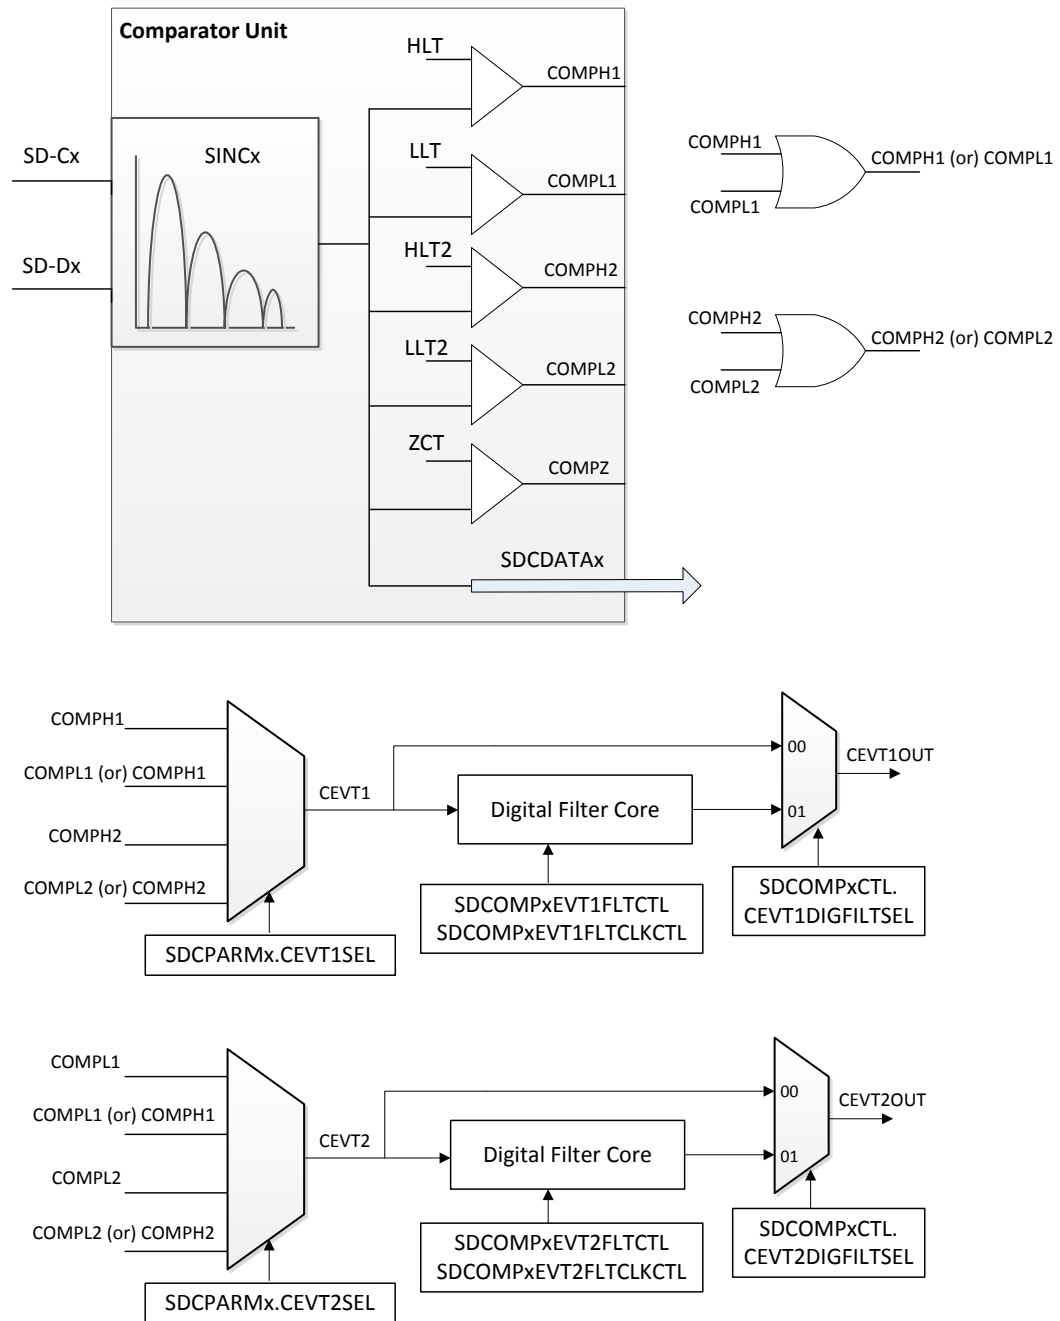

Figure 24-11. Comparator Unit Structure

### 24.8.1 Higher Threshold (HLT) Comparators

- High threshold comparator can be used to detect over-value condition.
- When comparator data  $\geq$  higher threshold register, a high threshold event is generated.
- Higher threshold comparator events except for COMPHZx can be configured to trigger following events: CPU interrupt, CLA task, PWM trip.
- This device has three high threshold :
  - **Higher Threshold 1 (HLT1) Comparator:**
    - When comparator data  $\geq$  (SDFLTxCMPH1.HLT), HLT1 comparator generates COMPH1 event.
    - The COMPH1 event is connected to both CEVT1 and CEVT2.
  - **Higher Threshold 2 (HLT2) Comparator:**
    - When comparator data  $\geq$  (SDFLTxCMPH2.HLT), HLT2 comparator generates COMPH2 event.
    - The COMPH2 event is connected to both CEVT1 and CEVT2.
  - **Higher Threshold (HTLZ) Comparator:**
    - When comparator data  $\geq$  (SDFLT1CMPHZ.CMPHZ), it can generate a Higher Threshold (B) event (COMPHZx) and sets the corresponding SDSTATUS.HZx flag. But, this event cannot be configured to generate SDFM interrupt (SDx\_ERR). The COMPHZ signals from HTLZ comparator are connected to CLB XBAR.

### 24.8.2 Lower Threshold (LLT) Comparators

- The low threshold comparator can be used to detect under-value condition.
- When comparator data  $\leq$  Lower Threshold register, a low threshold event is generated.
- Lower threshold comparator events can be configured to trigger following events: CPU interrupt, CLA task, PWM trip.
- Lower threshold comparator events can be used in conjunction with ECAP to measure the frequency / duty cycle of Threshold crossing
- This device has two low threshold comparators. .
  - **Lower Threshold 1 (LLT1) Comparator**
    - When comparator data  $\leq$  (SDFLTxCMPL1.LLT), the LLT1 comparator generates COMPL1 event.
    - The COMPL1 event is connected to both CEVT1 and CEVT2.
  - **Lower Threshold 2 (LLT2) Comparator**
    - When comparator data  $\leq$  (SDFLTxCMPL2.LLT), LLT2 comparator generates COMPL2 event.
    - The COMPL2 event is connected to both CEVT1 and CEVT2.

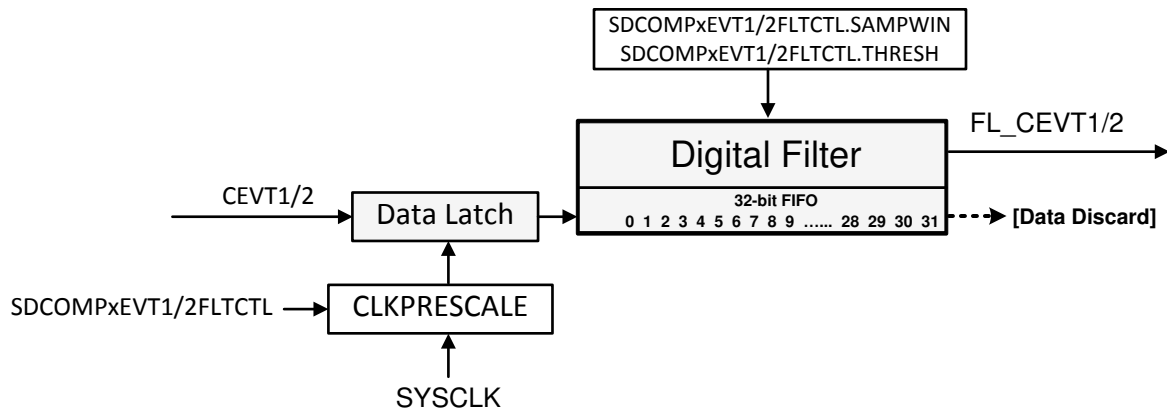

### 24.8.3 Digital Filter

The digital filter works on a window of FIFO samples ( $SAMPWIN + 1$ ) taken from the input. The filter output resolves to the majority value of the sample window, where majority is defined by the threshold (THRESH) value. If the majority threshold is not satisfied, the filter output remains unchanged.

For proper operation, the value of THRESH must be greater than  $SAMPWIN / 2$ .

A prescale function (CLKPRESCALE) determines the filter sampling rate, where the filter FIFO captures one sample every CLKPRESCALE system clocks. Old data from the FIFO is discarded.

A conceptual model of the digital filter is shown in [Figure 24-12](#).

**Figure 24-12. Digital Filter**

Equivalent C code of the filter implementation is:

```

if (FILTER_OUTPUT == 0) {
    if (Num_1s_in_SAMPWIN >= THRESH) {
        FILTER_OUTPUT = 1;
    }
}
else {
    if (Num_0s_in_SAMPWIN >= THRESH) {
        FILTER_OUTPUT = 0;
    }
}
    
```

#### Filter Initialization Sequence

To make sure of proper operation of the digital filter, the following initialization sequence is recommended:

1. Configure the digital filter parameters for operation:
  - Set SAMPWIN for the number of samples to monitor in the FIFO window.
  - Set THRESH for the threshold required for majority qualification.
  - Set CLKPRESCALE for the digital filter clock prescale value.
2. Initialize the sample values in the digital FIFO window by setting FILINIT = 1.

## 24.9 Theoretical SDFM Filter Output

The following equations can be used to derive a theoretical filter output of an SDFM filter output for both a comparator filter and a data filter.

$$\text{Density of ones in bitstream} = \frac{\text{Input Voltage} + V_{\text{clipping}}}{2 \times V_{\text{clipping}}} \quad (30)$$

Where:

- $V_{\text{clipping}}$  = maximum differential voltage input range of modulator
- Input voltage = Differential input voltage applied to the modulator

$$\begin{aligned} \text{Comparator Filter Output (Theoretical)} = \\ \text{Density of ones in bitstream} \times \text{Maximum Filter Output (FilterType, COSR)} \end{aligned} \quad (31)$$

$$\text{FilterOutput} = \left\{ \frac{\text{absolute}(\text{Input voltage})}{V_{\text{clipping}}} \right\} \times \text{Maximum Filter Output (FilterType, DOSR)} \quad (32)$$

$$\text{Data Filter Output}_{32\text{bit}}(\text{Theoretical}) = \begin{cases} \text{FilterOutput} & \text{if Input Voltage is +ve voltage} \\ 2\text{'s complement} & \text{if input voltage is -ve voltage} \\ \text{of FilterOutput} & \end{cases} \quad (33)$$

$$\begin{aligned} \text{Data Filter Output}_{16\text{bit}}(\text{Theoretical}) = \\ \text{Data Filter Output}_{32\text{bit}}(\text{Theoretical}) \gg \text{Shift value}(\text{FilterType, OSR}) \end{aligned} \quad (34)$$

For example, when using the AMC1306x25 modulator:

AMC1306x25	Vclipping = Input voltage (AINP - AINN) =	320mV 100mV
SDFM filter settings	Filter type = Comparator OSR (COSR) = Data filter OSR (DOSR) =	3 32 100

Density of 1s in bit stream	Using <a href="#">Equation 30</a>	0.65625
Comparator filter output Filter type = Sinc3 COSR = 32	Using <a href="#">Equation 31</a>	21504
Data filter output (32-bit) Filter type = Sinc3 DOSR = 100	Using <a href="#">Equation 32</a> and <a href="#">Equation 33</a>	312500
Data filter output (32-bit) Filter type = Sinc3 DOSR = 100 (Right shift by 5)	Using <a href="#">Equation 34</a>	9765

## 24.10 Interrupt Unit

Each SDFM can generate five CPU interrupts such as SDFM Error (SDy\_ERR) and SDFM data ready (SDy\_DRINT1 / SDy\_DRINT2, SDy\_DRINT3, SDy\_DRINT4) interrupts for each filter module.

### 24.10.1 SDFM (SDyERR) Interrupt Sources

Figure 24-13 shows the structure of SDy\_ERR interrupt. SDy\_ERR interrupt can be triggered by any of these 16 events.

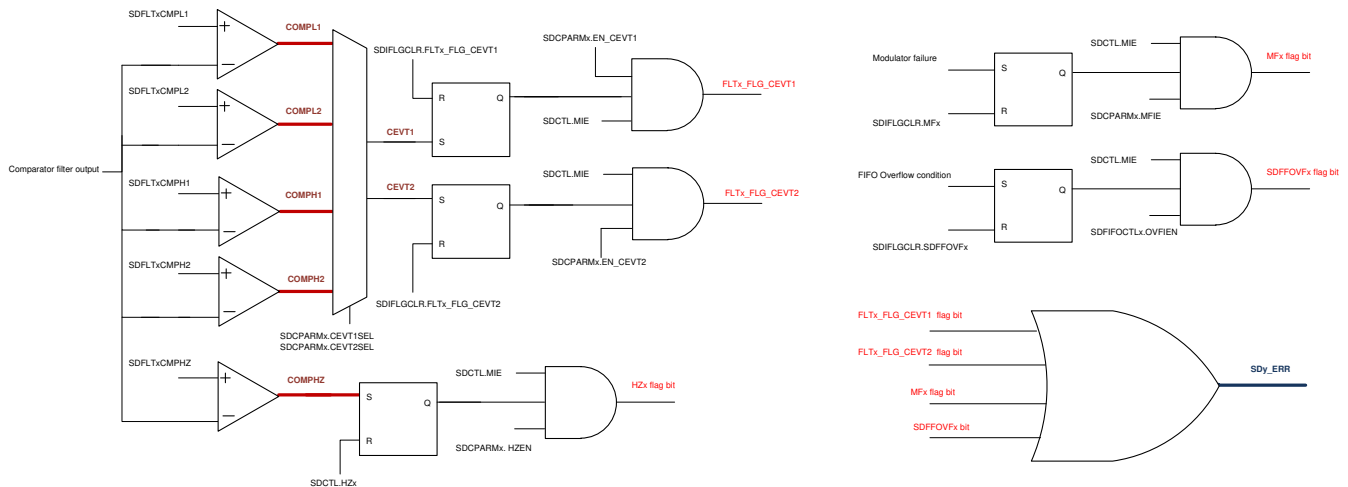

Figure 24-13. SDFM Error (SD\_ERR) Interrupt Sources

#### 1. Comparator Event1 (CEVT1)

CEVT1 events from any of the four comparator filter module can trigger CPU interrupt. This event can be configured to trigger SDy\_ERR interrupt only if below configurations are made:

- Enable Main interrupt enable (SDCTL.MIE = 1)
- Enable comparator Event1 interrupt (SDCPARMx.EN\_CEVT1 = 1)

On a CEVT1 event, SDIFLG.FLTx\_FLG\_CEVT1 flag bit is set. This flag bit can only be reset if the corresponding bit in SDIFLGCLR register is set and if the interrupt source is no longer active.

#### 2. Comparator Event2 (CEVT2)

CEVT2 events from any of the four comparator filter module can trigger CPU interrupt. This event can be configured to trigger SDy\_ERR interrupt only if below configurations are made:

- Enable Main interrupt enable (SDCTL.MIE = 1)
- Enable comparator event1 interrupt (SDCPARMx.EN\_CEVT2 = 1)

On a CEVT2 event, SDIFLG.FLTx\_FLG\_CEVT2 flag bit is set. This flag bit can only be reset if the corresponding bit in SDIFLGCLR register is set and if the interrupt source is no longer active.

#### 3. Modulator Failure (MFx) event

Modulator failures (MFx) are generated when SD-Cx goes missing. The modulator clock is considered missing if SD-Cx does not toggle for 64-SYSCLKs. MFx events from any of the four filter modules can trigger CPU interrupt. This event can be configured to trigger SDy\_ERR interrupt only if below configurations are made:

- Enable Main Interrupt Enable (SDCTL.MIE = 1)
- Enable modulator clock failure interrupt source (SDCPARMx.MFIE = 1)

On a MFx event, SDIFLG.MFx flag bit is set. This flag bit can only be reset if the corresponding bit in SDIFLGCLR register is set and if the interrupt source is no longer active.

#### 4. FIFO overflow (SDFFOVx) event

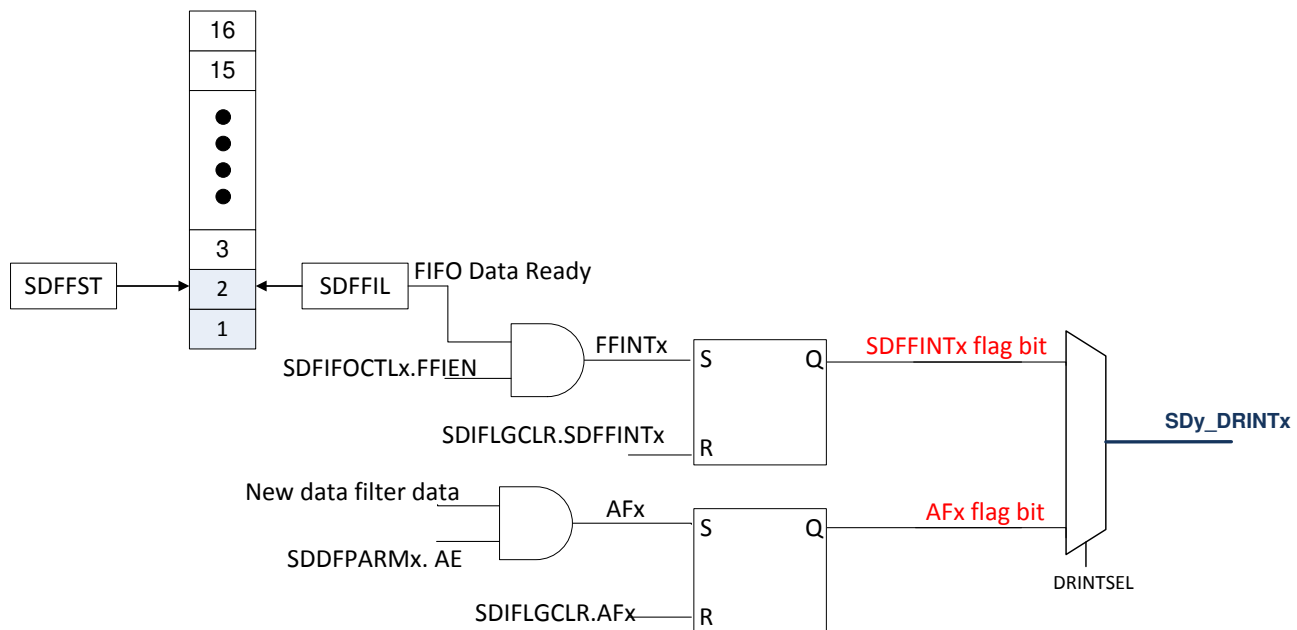

The number of filter data available in FIFO at any given point can be tracked in SDFIFOCTLx.SDFFST. If the number of words received in FIFO is greater than Max FIFO depth (16), SDFFOVx event is generated. SDFFOVx events from any of the four filter modules can trigger CPU interrupt. This event can be configured to trigger SDy\_ERR interrupt, only if below configurations are made:

- Enable SDFM FIFO (Set SDFIFOCTLx.FFEN = 1)
- Enable SDFM FIFO overflow interrupt (Set SDFIFOCTLx.OVFIEN = 1) and
- Enable Main interrupt enable (Set SDCTL.MIE = 1)

On a SDFFOVx event, all subsequent data (primary) filter data is lost and is not stored in FIFO. SDIFLG.SDFFOVx flag bit is set on a FIFO overflow event and this bit can be cleared if the corresponding bit in SDIFLGCLR register is set and if the interrupt source is no longer active.

##### 24.10.2 Data Ready (DRINT) Interrupt Sources

Figure 24-14 shows the structure of interrupt SDy\_DRINTx interrupt. Each SDy\_DRINTx interrupt is triggered by corresponding Data Filter channel.

**Figure 24-14. SDFM Data Ready (SDy\_DRINTx) Interrupt**

## 24.11 Software

### 24.11.1 SDFM Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/sdfm

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 24.11.1.1 SDFM Filter Sync CPU

FILE: `sdfm_ex1_filter_sync_cpuread.c`

In this example, SDFM filter data is read by CPU in SDFM ISR routine. The SDFM configuration is shown below:

- SDFM used in this example - SDFM1
- Input control mode selected - MODE0
- Comparator settings
  - Sinc3 filter selected
  - OSR = 32
  - HLT = 0x7FFF (Higher threshold setting)
  - LLT = 0x0000(Lower threshold setting)
- Data filter settings
  - All the 4 filter modules enabled
  - Sinc3 filter selected
  - OSR = 128
  - All the 4 filters are synchronized by using MFE (Master Filter enable bit)
  - Filter output represented in 16 bit format
  - In order to convert 25 bit Data filter into 16 bit format user needs to right shift by 7 bits for Sinc3 filter with OSR = 128
- Interrupt module settings for SDFM filter
  - All the 4 higher threshold comparator interrupts disabled
  - All the 4 lower threshold comparator interrupts disabled
  - All the 4 modulator failure interrupts disabled
  - All the 4 filter will generate interrupt when a new filter data is available.

#### External Connections

- SDFM\_PIN\_MUX\_OPTION1 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4,SDx-C4) on GPIO16-GPIO31
- SDFM\_PIN\_MUX\_OPTION2 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4,SDx-C4) on GPIO48-GPIO63
- SDFM\_PIN\_MUX\_OPTION3 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4,SDx-C4) on GPIO122-GPIO137

#### Watch Variables

- *filter1Result* - Output of filter 1
- *filter2Result* - Output of filter 2
- *filter3Result* - Output of filter 3
- *filter4Result* - Output of filter 4

#### 24.11.1.2 SDFM Filter Sync CLA

FILE: `sdfm_ex2_filter_sync_claread.c`

In this example, SDFM filter data is read by CLA in Cla1Task1. The SDFM configuration is shown below:

- SDFM1 used in this example.For using SDFM2, few modifications would be needed in the example.
- MODE0 Input control mode selected
- Comparator settings

- Sinc3 filter selected
- OSR = 32
- hlt = 0x7FFF (Higher threshold setting)
- llt = 0x0000(Lower threshold setting)
- Data filter settings
  - All the 4 filter modules enabled
  - Sinc3 filter selected
  - OSR = 256
  - All the 4 filters are synchronized by using MFE (Master Filter enable bit)
  - Filter output represented in 16 bit format
  - In order to convert 25 bit Data filter into 16 bit format user needs to right shift by 10 bits for Sinc3 filter with OSR = 256
- Interrupt module settings for SDFM filter
  - All the 4 higher threshold comparator interrupts disabled
  - All the 4 lower threshold comparator interrupts disabled
  - All the 4 modulator failure interrupts disabled
  - All the 4 filter will generate interrupt when a new filter data is available

#### External Connections

- SDFM\_PIN\_MUX\_OPTION1 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4,SDx-C4) on GPIO16-GPIO31
- SDFM\_PIN\_MUX\_OPTION2 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4,SDx-C4) on GPIO48-GPIO63
- SDFM\_PIN\_MUX\_OPTION3 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4,SDx-C4) on GPIO122-GPIO137

#### Watch Variables

- *filter1Result* - Output of filter 1
- *filter2Result* - Output of filter 2
- *filter3Result* - Output of filter 3
- *filter4Result* - Output of filter 4

#### 24.11.1.3 SDFM Filter Sync DMA

FILE: `sdfm_ex3_filter_sync_dmaread.c`

In this example, SDFM filter data is read by DMA. The SDFM configuration is shown below:

- SDFM1 used in this example. For using SDFM2, few modifications would be needed in the example.
- MODE0 Input control mode selected
- Comparator settings
  - Sinc3 filter selected
  - OSR = 32
  - hlt = 0x7FFF (Higher threshold setting)
  - llt = 0x0000(Lower threshold setting)
- Data filter settings
  - All the 4 filter modules enabled
  - Sinc3 filter selected
  - OSR = 256
  - All the 4 filters are synchronized by using MFE (Master Filter enable bit)
  - Filter output represented in 16 bit format
  - In order to convert 25 bit Data filter into 16 bit format user needs to right shift by 10 bits for Sinc3 filter with OSR = 256
- Interrupt module settings for SDFM filter
  - All the 4 higher threshold comparator interrupts disabled

- All the 4 lower threshold comparator interrupts disabled
- All the 4 modulator failure interrupts disabled
- All the 4 filter will generate interrupt when a new filter data is available

#### External Connections

- SDFM\_PIN\_MUX\_OPTION1 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4,SDx-C4) on GPIO16-GPIO31
- SDFM\_PIN\_MUX\_OPTION2 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4,SDx-C4) on GPIO48-GPIO63
- SDFM\_PIN\_MUX\_OPTION3 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4,SDx-C4) on GPIO122-GPIO137

#### Watch Variables

- *filter1Result* - Output of filter 1
- *filter2Result* - Output of filter 2
- *filter3Result* - Output of filter 3
- *filter4Result* - Output of filter 4

#### 24.11.1.4 SDFM PWM Sync

FILE: `sdfm_ex4_pwm_sync_cpuread.c`

In this example, SDFM filter data is read by CPU in SDFM ISR routine. The SDFM configuration is shown below:

- SDFM1 is used in this example. For using SDFM2, few modifications would be needed in the example.
- MODE0 Input control mode selected
- Comparator settings
  - Sinc3 filter selected
  - OSR = 32
  - hlt = 0x7FFF (Higher threshold setting)
  - llt = 0x0000(Lower threshold setting)

#### Data filter settings

- All the 4 filter modules enabled
- Sinc3 filter selected
- OSR = 256
- All the 4 filters are synchronized by using PWM (Master Filter enable bit)
- Filter output represented in 16 bit format
- In order to convert 25 bit Data filter into 16 bit format user needs to right shift by 10 bits for Sinc3 filter with OSR = 256

#### Interrupt module settings for SDFM filter

- All the 4 higher threshold comparator interrupts disabled
- All the 4 lower threshold comparator interrupts disabled
- All the 4 modulator failure interrupts disabled
- All the 4 filter will generate interrupt when a new filter data is available

#### External Connections

- SDFM\_PIN\_MUX\_OPTION1 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4,SDx-C4) on GPIO16-GPIO31
- SDFM\_PIN\_MUX\_OPTION2 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4,SDx-C4) on GPIO48-GPIO63
- SDFM\_PIN\_MUX\_OPTION3 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4,SDx-C4) on GPIO122-GPIO137

#### Watch Variables

- *filter1Result* - Output of filter 1
- *filter2Result* - Output of filter 2

- *filter3Result* - Output of filter 3
- *filter4Result* - Output of filter 4

#### 24.11.1.5 SDFM Type 1 Filter FIFO

FILE: `sdm_ex5_type1_filter_fifo_cpuread.c`

This example configures SDFM1 filter in type 1 to demonstrate data read through CPU in FIFO & non-FIFO mode. Data filter is configured in mode 0 to select SINC3 filter with OSR of 256. Filter output is configured for 16-bit format and data shift of 10 is used.

This example demonstrates the FIFO usage if enabled. FIFO length is set at 16 and data ready interrupt is configured to be triggered when FIFO is full. In this example, SDFM filter data is read by CPU in SDFM Data Ready ISR routine.

##### *External Connections*

- SDFM\_PIN\_MUX\_OPTION1 Connect Sigma-Delta streams(SD1-D1, SD1-C1) to (GPIO16, GPIO17)
- SDFM\_PIN\_MUX\_OPTION2 Connect Sigma-Delta streams(SD1-D1, SD1-C1) to (GPIO48, GPIO49)
- SDFM\_PIN\_MUX\_OPTION3 Connect Sigma-Delta streams(SD1-D1, SD1-C1) to (GPIO122, GPIO123)

##### *Watch Variables*

- *filter1Result* - Output of filter 1

#### 24.11.1.6 SDFM Filter Sync CLA

FILE: `sdm_ex6_FIFO_freeze_claread.c`

In this example, SDFM FIFO will not be filled until a SDSYNC event. On a SDSYNC event, SDFM data filter output will start filling FIFO and stop filling after programmable number 'N' of FIFO is filled.

SDy-C1 (Filter1 channel clock) is internally configured to connected SDy-C2 / SDy-C3 / SDy-C4 SDFM configuration is shown below:

- SDFM1 used in this example. For using SDFM2, few modifications would be needed in the example.
- MODE0 Input control mode selected
- Comparator settings
  - Sinc3 filter selected
  - OSR = 32
  - hlt = 0x7FFF (Higher threshold setting)
  - llt = 0x0000 (Lower threshold setting)
- Data filter settings
  - All the 4 filter modules enabled
  - Sinc3 filter selected
  - OSR = 256
  - All the 4 filters are synchronized by using MFE (Master Filter enable bit)
  - Filter output represented in 16 bit format
  - In order to convert 25 bit Data filter into 16 bit format user needs to right shift by 10 bits for Sinc3 filter with OSR = 256
- Interrupt module settings for SDFM filter
  - All the 4 higher threshold comparator interrupts disabled
  - All the 4 lower threshold comparator interrupts disabled
  - All the 4 modulator failure interrupts disabled
  - All the 4 filter will generate interrupt when a new filter data is available

##### *External Connections*

- SDFM\_PIN\_MUX\_OPTION1 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4, SDx-C4) on GPIO16-GPIO31
- SDFM\_PIN\_MUX\_OPTION2 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4, SDx-C4) on GPIO48-GPIO63

- SDFM\_PIN\_MUX\_OPTION3 Connect Sigma-Delta streams to (SDx-D1, SDx-C1 to SDx-D4,SDx-C4) on GPIO122-GPIO137

*Watch Variables*

- *filter1Result* - Output of filter 1
- *filter2Result* - Output of filter 2
- *filter3Result* - Output of filter 3
- *filter4Result* - Output of filter 4

## 24.12 SDFM Registers

This section describes the Sigma Delta Filter Module registers.

### 24.12.1 SDFM Base Address Table

**Table 24-8. SDFM Base Address Table**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	CPU2	CPU2.DMA	Pipeline Protected
Instance	Structure								
Sdfm1Regs	<a href="#">SDFM_REGS</a>	SDFM1_BASE	0x0000_5E00	YES	YES	YES	YES	YES	YES
Sdfm2Regs	<a href="#">SDFM_REGS</a>	SDFM2_BASE	0x0000_5E80	YES	YES	YES	YES	YES	YES
Sdfm3Regs	<a href="#">SDFM_REGS</a>	SDFM3_BASE	0x0000_5F00	YES	YES	YES	YES	YES	YES
Sdfm4Regs	<a href="#">SDFM_REGS</a>	SDFM4_BASE	0x0000_5F80	YES	YES	YES	YES	YES	YES

### 24.12.2 SDFM\_REGS Registers

Table 24-9 lists the memory-mapped registers for the SDFM\_REGS registers. All register offset addresses not listed in Table 24-9 should be considered as reserved locations and the register contents should not be modified.

**Table 24-9. SDFM\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	SDIFLG	SD Interrupt Flag Register		<a href="#">Go</a>
2h	SDIFLGCLR	SD Interrupt Flag Clear Register		<a href="#">Go</a>
4h	SDCTL	SD Control Register	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. [Table 24-10](#) shows the codes that are used for access types in this section.

**Table 24-10. SDFM\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1S	W1S	Write 1 to set
WOnce	WOnce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 24.12.2.1 SDIFLG Register (Offset = 0h) [Reset = 0000000h]

SDIFLG is shown in [Figure 24-15](#) and described in [Table 24-11](#).

Return to the [Summary Table](#).

SD Interrupt Flag Register

### 24.12.2.2 SDIFLGCLR Register (Offset = 2h) [Reset = 0000000h]

SDIFLGCLR is shown in [Figure 24-16](#) and described in [Table 24-12](#).

Return to the [Summary Table](#).

SD Module Interrupt Flag Clear Bits:

Writing a '1' will clear the respective flag bit in the SDIFLG register.

Writes of '0' are ignored.

Note: If user writes a '1' to clear a bit on the same cycle that the hardware is trying to set the bit to '1', then hardware has priority and the bit will not be cleared.

Bit	Field	Type	Reset	Description
15	RESERVED	R-0	0h	Reserved
14-0	HLT2	R/W	7FFFh	Second Unsigned high-level threshold for the comparator filter output. Reset type: SYSRSn

### 24.12.2.58 SDFLT4CMPHZ Register (Offset = 4Ch) [Reset = 0000h]

SDFLT4CMPHZ is shown in [Figure 24-72](#) and described in [Table 24-68](#).

Return to the [Summary Table](#).

High-level (Z) Threshold Register for Ch4

**Figure 24-72. SDFLT4CMPHZ Register**

15	14	13	12	11	10	9	8
RESERVED	HLTZ						
R-0-0h				R/W-0h			
7	6	5	4	3	2	1	0
HLTZ							
R/W-0h							

**Table 24-68. SDFLT4CMPHZ Register Field Descriptions**

Bit	Field	Type	Reset	Description
15	RESERVED	R-0	0h	Reserved
14-0	HLTZ	R/W	0h	Unsigned High-level threshold (Z) for the comparator filter output. Primarily intended for detecting 'zero'-crossing events. Unlike the primary comparator SDCMPHx, it does not have the ability to generate an interrupt. Reset type: SYSRSn

### 24.12.2.59 SDFIFOCTL4 Register (Offset = 4Dh) [Reset = 0000h]

SDFIFOCTL4 is shown in [Figure 24-73](#) and described in [Table 24-69](#).

Return to the [Summary Table](#).

FIFO Control Register for Ch4

**Figure 24-73. SDFIFOCTL4 Register**

15		14		13		12		11		10		9		8

## Chapter 25 Controller Area Network (CAN)

This chapter describes the Controller Area Network (CAN) module. CAN is a serial communications protocol that efficiently supports distributed real-time control with a high level of reliability. The CAN module supports bit rates up to 1 Mbit/s and is compliant with the ISO11898-1 (CAN 2.0B) protocol specification.

Further information can be found in:

- [Calculator for CAN Bit Timing Parameters Application Report](#)
- [Programming Examples and Debug Strategies for the DCAN Module Application Report](#)
- [Configurable Error Generator for Controller Area Network Application Report](#)

## 25.1 Introduction

This device uses the CAN IP known as DCAN.

### 25.1.1 DCAN Related Collateral

### 25.1.2 Features

The CAN module implements the following features:

- Complies with ISO11898-1 (Bosch® CAN protocol specification 2.0 A and B)
- Bit rates up to 1Mbps
- Multiple clock sources
- 32 message objects (“message objects” are also referred to as “mailboxes” in this document; the two terms are used interchangeably)
- Individual identifier mask for each message object
- Programmable FIFO mode for message objects
- Programmable loop-back modes for self-test operation
- Suspend mode for debug support
- Software module reset
- Automatic bus-on, after bus-off state by a programmable 32-bit timer
- Two interrupt lines

---

#### Note

For a CAN bit clock of 200MHz, the smallest bit rate possible is 7.8125kbps.

Depending on the timing settings used, the accuracy of the on-chip zero-pin oscillator (specified in the data sheet) may not meet the requirements of the CAN protocol. In this situation, an external clock source must be used.

---

25.1.3 Block Diagram

Figure 25-1 shows a block diagram of the CAN module. Following is a description of some of the main blocks.

Figure 25-1. CAN Block Diagram

**25.1.3.1 CAN Core**

The CAN core consists of the CAN Protocol Controller and the Rx/Tx Shift register. The CAN core handles all ISO 11898-1 protocol functions.

**25.1.3.2 Message Handler**

The message handler is a state machine that controls the data transfer between the single-port Message RAM and the CAN Core's Rx/Tx Shift register. The message handler also handles acceptance filtering and the interrupt request generation as programmed in the control registers.

**25.1.3.3 Message RAM**

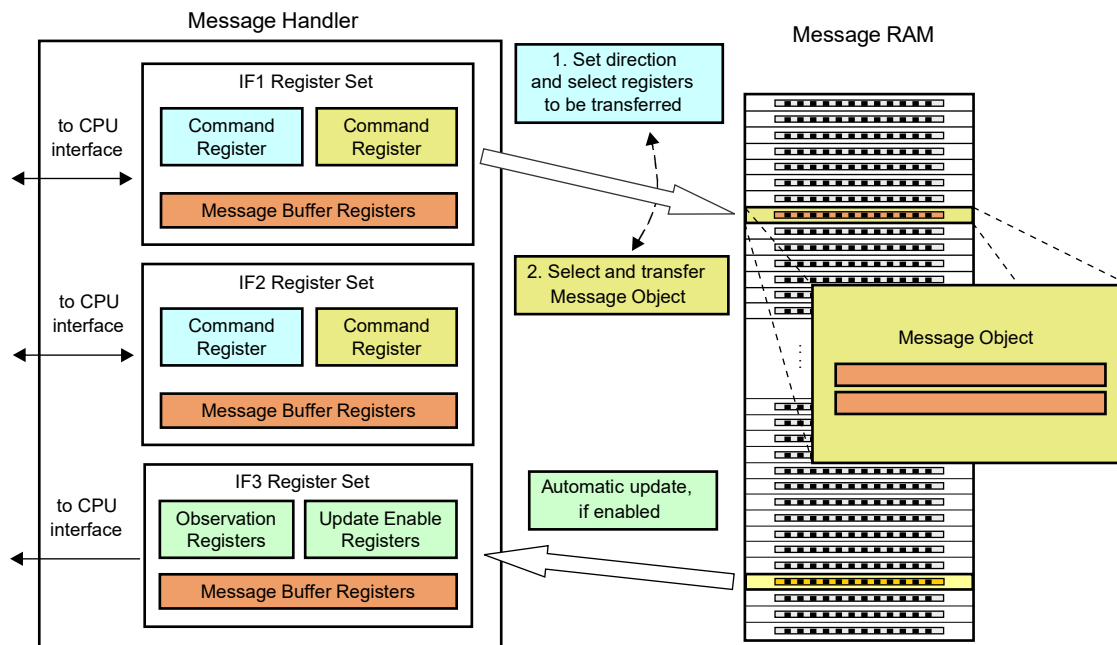

The CAN message RAM enables the storage of 32 CAN messages.

**25.1.3.4 Registers and Message Object Access (IFx)**

Data consistency is provided by indirect accesses to the message objects. During normal operation, all CPU accesses to the message RAM are done through Interface registers. The IFx registers can be thought of as a "window" through which the message objects (mailboxes) are accessed.

Three Interface register sets control the CPU read and write accesses to the Message RAM, see [Figure 25-2](#). There are two Interface register sets for read/write access (IF1 and IF2) and one Interface register set for read access only (IF3). See also [Section 25.13](#). The Interface registers have the same word length as the message RAM.

In a dedicated test mode, the message RAM is memory-mapped and can be directly accessed.

**Figure 25-2. Accessing Message Objects Through IFx Registers**

## 25.2 Functional Description

The CAN module performs CAN protocol communication according to ISO 11898-1. The bit rate can be programmed to values up to 1Mbps. A CAN transceiver chip is required for the connection to the physical layer (CAN bus).

For communication on a CAN network, individual message objects can be configured. The message objects and identifier masks are stored in the Message RAM.

All functions concerning the handling of messages are implemented in the message handler. These functions are: acceptance filtering; the transfer of messages between the CAN Core and the Message RAM; and the handling of transmission requests .

The register set of the CAN can be accessed directly by the CPU through the module interface. These registers are used to control and configure the CAN core and the message handler, and to access the message RAM.

### 25.2.1 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some I/O functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification must be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pull-ups can be configured in the GPyPUD register.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

### 25.2.2 Address/Data Bus Bridge

The CAN module uses a special addressing scheme to support byte accesses. It is recommended to only use 32-bit accesses to the CAN registers using the *HWREG\_BP()* macro that uses the *\_\_byte\_peripheral\_32()* intrinsic. If 16-bit accesses are to be used, the lower 16-bits must be written to the register's address, and the upper 16-bits must be written to the register's address plus 2.

Because of the bus bridge, the view of the CAN module's register space through the Code Composer Studio™ (CCS) IDE memory window does not always match the actual addressing. When the view mode is 32-bit or 16-bit, even addresses are effectively duplicated; odd addresses can be ignored. When the view mode is 8-bit, even addresses from within the CAN module are duplicated into the odd addresses in the CCS memory view; odd addresses from the module are not displayed.

**Table 25-1. CAN Register Access from Software**

CAN Register Space			C28x 8-Bit		C28x 16-Bit		C28x 32-Bit	
Address	Name	Data	Access	Data	Access	Data	Address	Data

## 25.3 Operating Modes

### 25.3.1 Initialization

The initialization mode is entered either by software (by setting the **Init** bit in the CAN\_CTL register), by hardware reset, or by going bus-off. While the Init bit is set, the message transfer from and to the CAN bus is stopped, and the status of the CAN\_TX output is recessive (high). The CAN error counters are not updated. Setting the Init bit does not change any other configuration register.

To initialize the CAN controller, the CPU has to configure the CAN bit timing and those message objects that are used for CAN communication. Message objects that are not needed, can be deactivated with the MsgVal bits cleared.

The access to the Bit Timing Register for the configuration of the bit timing is enabled when both **Init** and CCE bits in the CAN Control register are set.

Clearing the Init bit finishes the software initialization. Afterwards, the bit stream processor (BSP) synchronizes to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive recessive bits (= Bus Idle) before the BSP can take part in bus activities and start the message transfer. For more details, see [Section 25.12](#).

The initialization of the message objects is independent of the Init bit; however, all message objects must be configured with particular identifiers or set to "not-valid" before the message transfer is started.

It is possible to change the configuration of message objects during normal operation by the CPU. After setup and subsequent transfer of message object from interface registers to message RAM, the acceptance filtering is applied to it when the modified message object number is same or smaller than the previously found message object. This makes sure of data consistency even when changing message objects; for example, while there is a pending CAN frame reception.

### 25.3.2 CAN Message Transfer (Normal Operation)

Once the CAN is initialized and the Init bit is reset to zero, the CAN Core synchronizes to the CAN bus and is ready for communication.

Received messages are stored into the appropriate message objects, if the messages pass acceptance filtering. The whole message (MSGID, DLC, and up to 8 data bytes) is stored into the message object. As a consequence, for example, if the identifier mask is used, the MSGID bits that are masked to "don't care" can change in the message object when a received message is stored.

The CPU can read or write each message at any time using the interface registers, as the message handler provides data consistency in case of concurrent accesses.

Messages to be transmitted can be updated by the CPU. If a permanent message object (MSGID, control bits set up during configuration, and setup for multiple CAN transfers) exists for the message, it is possible to only update the data bytes. If several transmit messages must be assigned to one message object, the whole message object has to be configured before the transmission of this message is requested.

The transmission of multiple message objects can be requested at the same time. The message objects are subsequently transmitted, according to the internal priority. Messages can be updated or set to "not valid" at any time, even if a requested transmission is still pending. However, the data bytes are discarded if a message is updated before a pending transmission has started.

Depending on the configuration of the message object, a transmission can be automatically requested by the reception of a remote frame with a matching identifier.

#### 25.3.2.1 Disabled Automatic Retransmission

According to the CAN Specification (see ISO11898, 6.3.3 Recovery Management), the CAN provides a mechanism to automatically retransmit frames that have lost arbitration or have been disturbed by errors during transmission. The frame transmission service is not confirmed to the user before the transmission is successfully completed.

By default, this automatic retransmission is enabled and can be disabled by setting the DAR bit in the CAN control register. Further details to this mode are provided in [Section 25.11.3](#).

#### 25.3.2.2 Auto-Bus-On

After the CAN has entered the bus-off state, the CPU can start a bus-off-recovery sequence by resetting the *Init* bit. If this is not done, the module stays in the bus-off state.

The CAN provides an automatic auto-bus-on feature that is enabled by the ABO bit. If set, the CAN automatically starts the bus-off-recovery sequence. The sequence can be delayed by a user-defined number of clock cycles.

---

#### Note

If the CAN module goes Bus-Off due to multiple CAN bus errors, the CAN module stops all bus activities and automatically sets the Init bit. Once the Init bit is cleared by the application (or due to the auto-bus-on feature), the device waits for 129 occurrences of Bus Idle (equal to 129 \* 11 consecutive recessive bits) before resuming normal operation. The Bus-Off recovery sequence cannot be shortened by setting or resetting the Init bit. At the end of the bus-off recovery sequence, the error counters reset. After the Init bit is reset, each time when a sequence of 11 recessive bits is monitored, a Bit0 Error code is written to the Error and Status Register. This enables the CPU to check whether the CAN bus is stuck at dominant or continuously disturbed, and to monitor the proceeding of the Bus-Off recovery sequence.

---

### 25.3.3 Test Modes

The CAN module provides several test modes that are mainly intended for self-test purposes. Figure 25-3 aids in understanding the various test modes. Figure 25-3 must be viewed as representative of the module behavior, and not as a gate-accurate implementation of the module. Figure 25-3 does not include the GPIO muxing or the I/O buffers.

For all test modes, the Test bit in the CAN control register needs to be set to 1 to enable write access to the CAN\_TEST register.

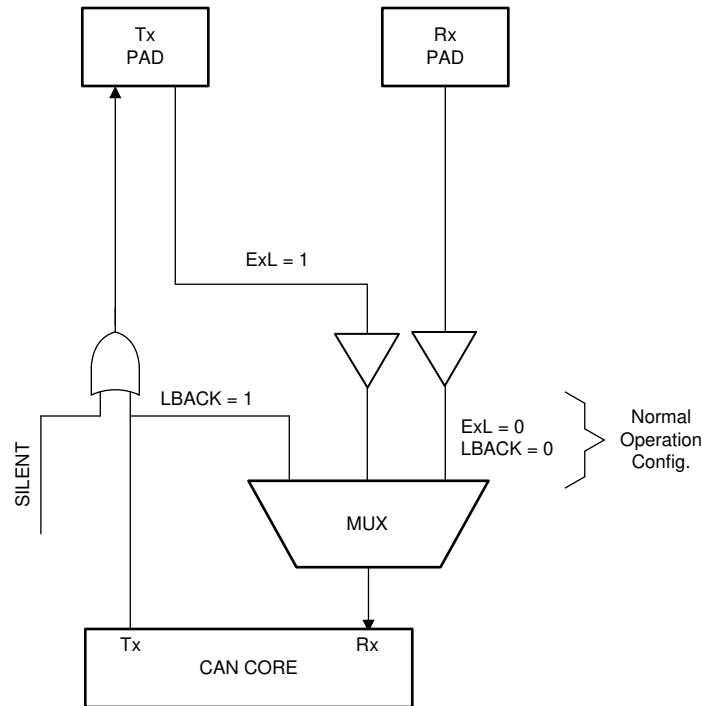

Figure 25-3. CAN\_MUX

### 25.3.3.1 Silent Mode

The silent mode can be used to analyze the traffic on the CAN bus without affecting the CAN by sending dominant bits (for example, acknowledge bit, overload flag, active error flag). The CAN is still able to receive valid data frames and valid remote frames, but the CAN does not send any dominant bits. However, the received frames are internally routed to the CAN Core.

Figure 25-4 shows the connection of signals CAN\_TX and CAN\_RX to the CAN core in silent mode. Silent mode can be activated by setting the Silent bit in test register (CAN\_TEST), to 1. In ISO 11898-1, the silent mode is called the bus monitoring mode.

Figure 25-4. CAN Core in Silent Mode

### 25.3.3.2 Loopback Mode

The loopback mode is mainly intended for hardware self-test functions. In this mode, the CAN core uses internal feedback from Tx output to Rx input. Transmitted messages are treated as received messages, and can be stored into message objects if the messages pass acceptance filtering. The actual value of the CAN\_RX input pin is disregarded by the CAN core. Transmitted messages still can be monitored at the CAN\_TX pin.

To be independent from external stimulation, the CAN core ignores acknowledge errors (recessive bit sampled in the acknowledge slot of a data/remote frame) in loopback mode.

Figure 25-5 shows the connection of signals CAN\_TX and CAN\_RX to the CAN core in loopback mode. Loopback mode can be activated by setting the LBack bit in the CAN\_TEST register to 1.

#### Note

In loopback mode, the signal path from the CAN core to the Tx pin, and the signal path from the Tx pin back to the CAN core are disregarded. For including these into the testing, see Section 25.3.3.3.

**Figure 25-5. CAN Core in Loopback Mode**

### 25.3.3.3 External Loopback Mode

The external loopback mode is similar to the loopback mode; however, the external loopback mode includes the signal path from the CAN core to the Tx pin, and the signal path from the Tx pin back to the CAN core. When the external loopback mode is selected, the CAN core is connected to the input buffer of the Tx pin. With this configuration, the Tx pin IO circuit can be tested. External loopback mode can be activated by setting the ExL bit in Test Register to 1.

Figure 25-6 shows the connection of signals CAN\_TX and CAN\_RX to the CAN Core in external loopback mode.

**Note**

When loopback mode is active (LBack bit set), the ExL bit is ignored.

Figure 25-6. CAN Core in External Loopback Mode

### 25.3.3.4 Loopback Combined with Silent Mode

It is also possible to combine loopback mode and silent mode by setting bits LBack and Silent at the same time. The CAN hardware can be tested without affecting the CAN network. In this mode, the CAN\_RX pin is disconnected from the CAN core and no dominant bits are sent on the CAN\_TX pin.

Figure 25-7 shows the connection of the signals CAN\_TX and CAN\_RX to the CAN Core in case of the combination of loopback mode with silent mode.

Figure 25-7. CAN Core in Loopback Combined with Silent Mode

## 25.4 Multiple Clock Source

The *System Control and Interrupts* chapter and the device data sheet provide more information on how to configure the relevant clock source registers in the system module.

### Note

The CAN core has to be programmed to at least 8 clock cycles per bit time. To achieve a transfer rate of 1Mbps an oscillator frequency of 8MHz or higher has to be used.

## 25.5 Interrupt Functionality

Interrupts can be generated on two interrupt lines: CAN0INT and CAN1INT. These lines can be enabled by setting the IE0 and IE1 bits, respectively, in the CAN Control register.

The CAN provides three groups of interrupt sources: message object interrupts, status change interrupts, and error interrupts. The source of an interrupt can be determined by the interrupt identifiers Int0ID and Int1ID in the Interrupt register. When no interrupt is pending, the register holds the value zero. Each interrupt line remains active until the dedicated field in the Interrupt register (Int0ID or Int1ID) again reaches zero (this means the cause of the interrupt is reset), or until IE0 and IE1 are reset. The value 0x8000 in the Int0ID field indicates that an interrupt is pending because the CAN core has updated (not necessarily changed) the Error and Status Register (Error Interrupt or Status Interrupt). This interrupt has the highest priority. The CPU can update (reset) the status bits RxOk, TxOk, and LEC by reading the Error and Status Register, but a write access of the CPU never generates or resets an interrupt.

Values between 1 and the number of the last message object indicates that the source of the interrupt is one of the message objects. INT0ID and INT1ID point to the pending message interrupt with the highest priority. The Message Object 1 has the highest priority, the last message object has the lowest priority.

An interrupt service routine that reads the message from the interrupt source can also read the message and reset the message object's IntPnd at the same time (ClrIntPnd bit in the IF1 or IF2 Command register). When IntPnd is cleared, the Interrupt register points to the next message object with a pending interrupt.

The CAN module features a module-level interrupt enable and acknowledge mechanism. To enable the CAN0 and CAN1 interrupts, you must set the appropriate bits in the CAN\_GLB\_INT\_EN register. When handling an interrupt, the individual message or status change flag must be cleared prior to acknowledging the interrupt using CAN\_GLB\_INT\_CLR and PIEACK.

### 25.5.1 Message Object Interrupts

Message object interrupts are generated by events from the message objects. They are controlled by the flags IntPND, TxIE and RxIE which are described in [Section 25.14.1](#). Message object interrupts can be routed to the CAN0INT or CAN1INT line, which is controlled by the Interrupt Multiplexer register.

Note that writing to the IntPnd bit in the CAN\_IFnMCTL registers can force an interrupt.

### 25.5.2 Status Change Interrupts

The events RxOk, TxOk, and LEC in the Error and Status register belong to the status change interrupts. The status change interrupt group can be enabled by the SIE bit in the CAN Control Register. If SIE is set, a status change interrupt is generated at each CAN frame, independent of bus errors or valid CAN communication, and also independent of the Message RAM configuration. Status Change interrupts can only be routed to interrupt line CAN0INT which has to be enabled by setting IE0 in the CAN\_CTL Register.

### 25.5.3 Error Interrupts

The events PER, BOff and EWarn, belong to the error interrupts. The error interrupt group can be enabled by setting bit EIE. Also, error interrupts can only be routed to interrupt line CAN0INT, which has to be enabled by setting IE0 in the CAN\_CTL register.

### 25.5.4 Peripheral Interrupt Expansion (PIE) Module Nomenclature for DCAN Interrupts

[Table 25-3](#) shows the Peripheral Interrupt Expansion (PIE) module nomenclature for the interrupts.

**Table 25-3. PIE Module Nomenclature for Interrupts**

Interrupt	CANA	CANB
CANINT0	CANA_0	CANB_0
CANINT1	CANA_1	CANB_1

### 25.5.5 Interrupt Topologies

Interrupt topologies for CAN are illustrated in Figure 25-8 and Figure 25-9. Mailbox interrupts for transmit and receive operations can be routed to both CANINT0 and CANINT1. However, error and status interrupts can only be routed to CANINT0.

Figure 25-8. CAN Interrupt Topology 1

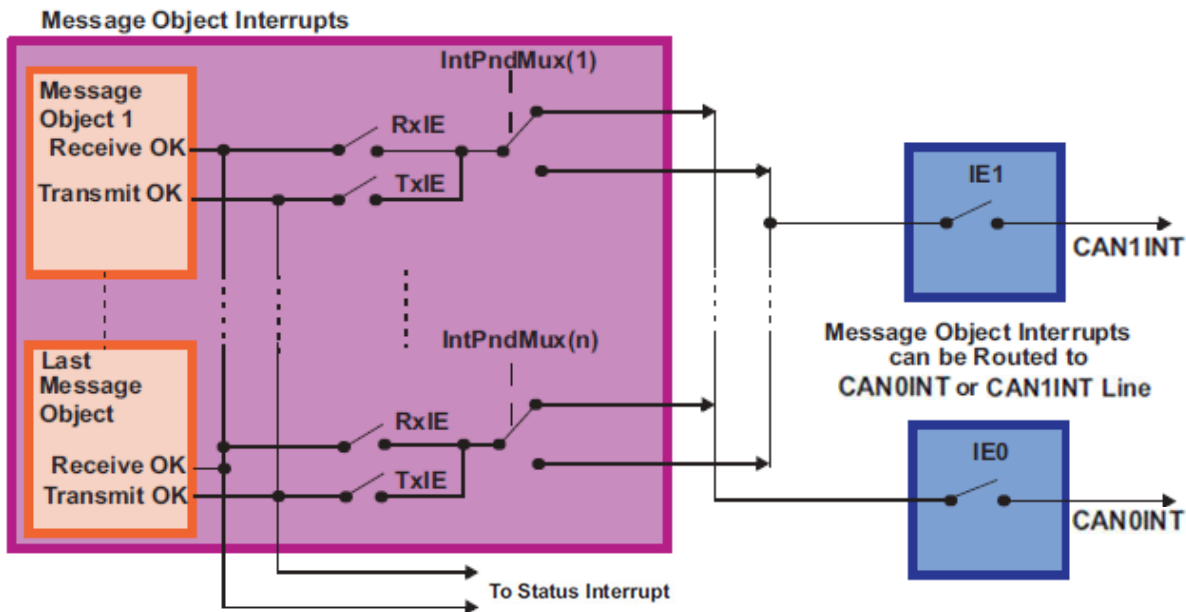

Figure 25-9. CAN Interrupt Topology 2

## 25.6 DMA Functionality

The CAN module provides three DMA trigger outputs, one for each of the three Interface Registers IF1, IF2 and IF3. These can be enabled using the DE1, DE2, and DE3 bits in the CAN\_CTL register.

The Update of IF1 and IF2 registers is initiated by a write access to the IF1 and IF2 Command registers, respectively. Once enabled, setting the DMAactive bit in the IF1CMD or IF2CMD registers cause a DMA request the next time the corresponding interface becomes available.

The IF3 registers content can be automatically updated on reception of CAN messages in message objects which are programmed for automatic IF3 update. That is, when IF3 DMA requests are enabled, all IF3 updates trigger a DMA request.

When a DCAN internal IFx update is complete, a DMA request is activated and stays active until the first access to one of the relevant IFx registers; that is, DMA requests are cleared after the first read or write access to an IF register set.

## 25.7 Parity Check Mechanism

The CAN provides a parity check mechanism to make sure data integrity of the message RAM data. For each word (32 bits) in Message RAM, one parity bit is calculated.

Parity information is stored in the Message RAM on write accesses and is checked against the stored parity bit from Message RAM on read accesses.

The parity check functionality can be enabled or disabled by the PMD bit field in the CAN control register. In case of a disabled parity check, the parity bits in message RAM are left unchanged on write access to the data area and no check is done on read access.

If parity checking is enabled, parity bits are automatically generated and checked by the CAN. A parity bit is set if the modulo-2-sum of the data bits is 1. This means that if the parity bit is set, then there are an odd number of 1 bits in the data.

### 25.7.1 Behavior on Parity Error

On any read access to Message RAM, for example, during the start of a CAN frame transmission, the parity of the message object is checked. If a parity error is detected, the PER bit in the Error and Status register is set. If error interrupts are enabled, an interrupt can also be generated. To avoid the transmission of invalid data over the CAN bus, the MsgVal bit of the message object is reset.

The message object data can be read by the CPU, independently of parity errors. Thus, the application has to make sure that the read data is valid, for example, by immediately checking the Parity Error Code register on parity error interrupt.

## 25.8 Debug Mode

The module supports the usage of an external debug unit by providing functions like pausing CAN activities and making message RAM content accessible from the debugger. Debug mode is entered automatically when an external debugger is connected and the core is halted.

Before entering Debug mode, the circuit waits until a transmission is started, a reception is finished, or the Bus idle state is recognized. If the IDS bit is set, the debugger immediately interrupts the current transmission or reception. Afterwards, the CAN enters Debug mode, indicated by the InitDbg flag, in the CAN Control register. During debug mode, all CAN registers can be accessed. Reading reserved bits returns a 0; writing to reserved bits has no effect. Also, the message RAM is memory-mapped, so this allows the external debug unit to read the message RAM. For the memory organization (see [Section 25.14.3](#)).

---

### Note

During debug mode, the Message RAM cannot be accessed using the IFx register sets.

Writing to control registers in Debug mode can influence the CAN state machine and further message handling.

---

For debug support, the auto clear functionality of the following CAN registers is disabled:

- Error and Status register (clear of status flags by read)
- IF1/IF2 Command registers

## 25.9 Module Initialization

After hardware reset, the Init bit in the CAN Control register is set and all CAN protocol functions are disabled. The configuration of the bit timing and of the message objects must be completed before the CAN protocol functions are enabled.

For the configuration of the message objects, see [Section 25.10](#).

For the configuration of the Bit Timing, see [Section 25.12.2](#).

The bits MsgVal, NewDat, IntPnd, and TxRqst of the message objects are reset to 0 by a hardware reset. The configuration of a message object is done by programming Mask, Arbitration, Control and Data bits of one of the IF1/IF2 Interface register sets to the desired values. By writing the message object number to bits [7:0] of the corresponding IF1/IF2 Command register, the IF1/IF2 Interface Register content is loaded into the addressed message object in the Message RAM.

The configuration of the bit timing requires that the CCE bit in the CAN Control register is set additionally to Init. This is not required for the configuration of the message objects.

When the Init bit in the CAN Control register is cleared, the CAN Protocol Controller state machine of the CAN Core and the message handler State Machine start to control the CAN's internal data flow. Received messages which pass the acceptance filtering are stored into the Message RAM; messages with pending transmission request are loaded into the CAN Core's Shift register and are transmitted using the CAN bus.

The CPU can enable the interrupt lines (setting IE0 and IE1 to 1) at the same time when the CPU clears Init and CCE. The status interrupts EIE and SIE can be enabled simultaneously.

The CAN communication can be controlled interrupt-driven or in polling mode. The Interrupt Register points to those message objects with IntPnd = 1. The register is updated even if the interrupt lines to the CPU are disabled (IE0 and IE1 are 0).

The CPU can poll all MessageObject's NewDat and TxRqst bits in parallel from the NewData registers and the Transmission Request registers. Polling can be made easier if all Transmit Objects are grouped at the low numbers; all Receive Objects are grouped at the high numbers.

## 25.10 Configuration of Message Objects

The entire Message RAM must be configured before the end of the initialization; however, it is also possible to change the configuration of message objects during CAN communication.

### 25.10.1 Configuration of a Transmit Object for Data Frames

Figure 25-10 shows how a transmit object can be initialized.

**Figure 25-10. Initialization of a Transmit Object**

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	1	0	0	0	appl.	0	appl.	0

- The arbitration bits (ID[28:0] and Xtd bit) are given by the application. The arbitration bits define the identifier and type of the outgoing message. If an 11-bit Identifier (standard frame) is used (Xtd = 0), the Identifier is programmed to ID[28:18]. In this case, ID[17:0] can be ignored.
- The data registers (DLC[3:0] and Data0-7) are given by the application. TxRqst and RmtEn must not be set before the data is valid.
- If the TxIE bit is set, the IntPnd bit is set after a successful transmission of the message object.
- If the RmtEn bit is set, a matching received remote frame causes the TxRqst bit to be set; the remote frame is autonomously answered by a data frame.
- The Mask bits (Msk[28:0], UMask, MXtd, and MDir bits) can be used (UMask = 1) to allow groups of remote frames with similar identifiers to set the TxRqst bit. The Dir bit must not be masked. For details, see [Section 25.11.8](#). Identifier masking must be disabled (UMask = 0) if no remote frames are allowed to set the TxRqst bit (RmtEn = 0).

### 25.10.2 Configuration of a Transmit Object for Remote Frames

It is not necessary to configure transmit objects for the transmission of remote frames. Setting TxRqst for a receive object causes the transmission of a remote frame with the same identifier as the data frame for which this receive object is configured.

### 25.10.3 Configuration of a Single Receive Object for Data Frames

Figure 25-11 shows how a receive object for data frames can be initialized.

**Figure 25-11. Initialization of a Single Receive Object for Data Frames**

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	0	0	0	appl.	0	0	0	0

- The arbitration bits (ID[28:0] and Xtd bit) are given by the application. The arbitration bits define the identifier and type of accepted received messages. If an 11-bit Identifier (Standard Frame) is used (Xtd = 0), the Identifier is programmed to ID[28:18]. In this case, ID[17:0] can be ignored. When a data frame with an 11-bit Identifier is received, ID[17:0] is set to 0.
- When the message handler stores a data frame in the message object, the message handler stores the received data length code and the corresponding number of data bytes. If the data length code is less than 8, the remaining bytes of the message object can be overwritten by non-specified values.
- The mask bits (Msk[28:0], UMask, MXtd, and MDir bits) can be used (UMask = 1) to allow groups of data frames with similar identifiers to be accepted. The Dir bit must not be masked in typical applications. If some bits of the Mask bits are set to "don't care", the corresponding bits of the Arbitration Register are overwritten by the bits of the stored data frame.
- If the RxIE bit is set, the IntPnd bit is set when a received data frame is accepted and stored in the message object.
- If the TxRqst bit is set, the transmission of a remote frame with the same identifier as stored in the Arbitration bits is triggered. The content of the Arbitration bits can change if the Mask bits are used (UMask = 1) for acceptance filtering.

### 25.10.4 Configuration of a Single Receive Object for Remote Frames

Figure 25-12 shows how a receive object for remote frames can be initialized.

**Figure 25-12. Initialization of a Single Receive Object for Remote Frames**

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	1	0	0	appl.	0	0	0	0

- Receive objects for remote frames can be used to monitor remote frames on the CAN bus. The remote frame stored in the receive object does not trigger the transmission of a data frame. Receive objects for remote frames can be expanded to a FIFO buffer, see [Section 25.10.5](#).
- UMask must be set to 1. The Mask bits (Msk[28:0], UMask, MXtd, and MDir bits) can be set to "must-match" or to "don't care", to allow groups of remote frames with similar identifiers to be accepted. The Dir bit must not be masked in typical applications. For details, see [Section 25.11.8](#).
- The arbitration bits (ID[28:0] and Xtd bit) can be given by the application. The arbitration bits define the identifier and type of accepted received remote frames. If some bits of the Mask bits are set to "don't care", the corresponding bits of the arbitration bits are overwritten by the bits of the stored remote frame. If an 11-bit Identifier (standard frame) is used (Xtd = 0), the Identifier is programmed to ID[28:18]. In this case, ID[17:0] can be ignored. When a remote frame with an 11-bit Identifier is received, ID[17:0] is set to 0.
- The data length code (DLC[3:0]) can be given by the application. When the message handler stores a remote frame in the message object, the message handler stores the received data length code. The data bytes of the message object remain unchanged.
- If the RxIE bit is set, the IntPnd bit is set when a received remote frame is accepted and stored in the message object.

### 25.10.5 Configuration of a FIFO Buffer

With the exception of the EoB bit, the configuration of receive objects belonging to a FIFO buffer is the same as the configuration of a single receive object.

To concatenate multiple message objects to form a FIFO, the identifiers and masks (if used) of these message objects are programmed to matching values. Due to the implicit priority of the message objects, the message object with the lowest number is the first message object of the FIFO buffer. The EoB bit of all message objects of a FIFO buffer except the last one must be programmed to 0. The EoB bit of the last message object of a FIFO buffer is set to 1, configuring the last message object as the end of the block.

## 25.11 Message Handling

When initialization is finished, the CAN module synchronizes to the traffic on the CAN bus. The CAN module does acceptance filtering on received messages and stores those frames that are accepted into the designated message objects. The application must update the data of the messages to be transmitted and to enable and request the transmission. The transmission is requested automatically when a matching remote frame is received.

The application can read messages that are received and accepted. Messages that are not read before the next messages are accepted for the same message object are overwritten. Messages can be read interrupt-driven or after polling of NewDat.

### 25.11.1 Message Handler Overview

The message handler state machine controls the data transfer between the Rx/Tx Shift Register of the CAN Core and the Message RAM. The message handler state machine performs the following tasks:

- Data transfer from Message RAM to CAN Core (messages to be transmitted).
- Data transfer from CAN Core to the Message RAM (received messages).
- Data transfer from CAN Core to the Acceptance Filtering unit.
- Scanning of Message RAM for a matching message object (acceptance filtering).
- Scanning the same message object after being changed by IF1/IF2 registers when priority is same or higher as message the object found by last scanning.
- Handling of TxRqst flags.
- Handling of interrupt flags.

The message handler registers contains status flags of all message objects grouped into the following topics:

- Transmission request flags
- New data flags
- Interrupt pending flags
- Message valid registers

Instead of collecting above listed status information of each message object using IFx registers separately, these message handler registers provide a fast and easy way to get an overview, for example, about all pending transmission requests.

All message handler registers are read-only.

### 25.11.2 Receive/Transmit Priority

The receive/transmit priority for the message objects is attached to the message number, not to the CAN identifier. Message object 1 has the highest priority, while message object 32 has the lowest priority. If more than one transmission request is pending, the requests are serviced according to the priority of the corresponding message object, so for example, messages with the highest priority can be placed in the message objects with the lowest numbers.

The acceptance filtering for received data frames or remote frames is also done in ascending order of message objects, so a frame that has been accepted by a message object cannot be accepted by another message object with a higher message number. The last message object can be configured to accept any data frame or remote frame that was not accepted by any other message object, for nodes that need to log the complete message traffic on the CAN bus.

### 25.11.3 Transmission of Messages in Event Driven CAN Communication

If the shift register of the CAN Core is ready for loading and if there is no data transfer between the IFx registers and Message RAM, the MsgVal bits in the Message Valid register and the TxRqst bits in the transmission request register are evaluated. The valid message object with the highest priority pending transmission request is loaded into the shift register by the message handler and the transmission is started. The message object's NewDat bit is reset.

After a successful transmission and if no new data was written to the message object (NewDat = 0) since the start of the transmission, the TxRqst bit is reset. If TxIE is set, IntPnd is set after a successful transmission. If the CAN has lost the arbitration or if an error occurred during the transmission, the message is retransmitted as soon as the CAN bus is free again. If meanwhile the transmission of a message with higher priority has been requested, the messages are transmitted in the order of the priority.

If automatic retransmission mode is disabled by setting the DAR bit in the CAN control register, the behavior of bits TxRqst and NewDat in the Message Control register of the Interface register set is as follows:

- When a transmission starts, the TxRqst bit of the respective Interface register set is reset, while bit NewDat remains set.
- When the transmission has been successfully completed, the NewDat bit is reset.

When a transmission failed (lost arbitration or error) bit NewDat remains set. To restart the transmission, the application has to set TxRqst again.

Received remote frames do not require a receive object for storage. The remote frames automatically trigger the transmission of a data frame, if the *RmtEn* bit is set in the matching Transmit Object.

#### 25.11.4 Updating a Transmit Object

The CPU can update the data bytes of a transmit object any time using the IF1 and IF2 interface registers; neither MsgVal nor TxRqst need to be reset before the update.

Even if only a part of the data bytes are to be updated, all four bytes in the corresponding IF1/IF2 Data A register or IF1/IF2 Data B register must be valid before the content of that register is transferred to the message object. Either the CPU has to write all four bytes into the IF1/IF2 Data register or the message object is transferred to the IF1/IF2 Data Register before the CPU writes the new data bytes.

When only the data bytes are updated, first 0x87 can be written to bits [23:16] of the Command register and then the number of the message object is written to bits [7:0] of the Command register, concurrently updating the data bytes and setting TxRqst with NewDat.

To prevent the reset of TxRqst at the end of a transmission that can already be in progress while the data is updated, NewDat has to be set together with TxRqst in event driven CAN communication. For details see [Section 25.11.3](#).

When NewDat is set together with TxRqst, NewDat is reset as soon as the new transmission has started.

#### 25.11.5 Changing a Transmit Object

If the number of implemented message objects is not sufficient to be used as permanent message objects only, the transmit objects can be managed dynamically. The CPU can write the whole message (arbitration, control, and data) into the Interface register. The bits [23:16] of the Command register can be set to 0xB7 for the transfer of the whole message object content into the message object. Neither MsgVal nor TxRqst need to be reset before this operation.

If a previously requested transmission of this message object is not completed but already in progress, the transmission is continued; however, the transmission is not repeated if the transmission is disturbed.

To update only the data bytes of a message being transmitted, set bits [23:16] of the Command register to 0x87.

---

#### Note

After the update of the transmit object, the interface register set contains a copy of the actual contents of the object, including the part that had not been updated.

---

### 25.11.6 Acceptance Filtering of Received Messages

When the arbitration and control bits (Identifier + IDE + RTR + DLC) of an incoming message is completely shifted into the shift register of the CAN Core, the message handler starts to scan the message RAM for a matching valid message object:

- The acceptance filtering unit is loaded with the arbitration bits from the CAN Core shift register.
- Then the arbitration and mask bits (including MsgVal, UMask, NewDat, and EoB) of Message Object 1 are loaded into the Acceptance Filtering unit and are compared with the arbitration bits from the shift register. This is repeated for all following message objects until a matching message object is found, or until the end of the Message RAM is reached.
- If a match occurs, the scanning is stopped and the message handler proceeds depending on the type of the frame (data frame or remote frame) received.

### 25.11.7 Reception of Data Frames

The message handler stores the message from the CAN Core shift register into the respective message object in the Message RAM. Not only the data bytes, but all arbitration bits and the data length code are stored into the corresponding message object. This makes sure that the data bytes stay associated to the identifier even if arbitration mask registers are used.

The NewDat bit is set to indicate that new data (not yet seen by the CPU) has been received. The CPU must reset the NewDat bit when the CPU reads the message object. If at the time of the reception the NewDat bit was already set, MsgLst is set to indicate that the previous data (not seen by the CPU) is lost. If the RxIE bit is set, the IntPnd bit is set, causing the Interrupt Register to point to this message object.

The TxRqst bit of this message object is reset to prevent the transmission of a remote frame, while the requested data frame has just been received.

### 25.11.8 Reception of Remote Frames

When a remote frame is received, three different configurations of the matching message object are considered:

1. Dir = 1 (direction = transmit), RmtEn = 1, UMask = 1 or 0  
The TxRqst bit of this message object is set at the reception of a matching remote frame. The rest of the message object remains unchanged.
2. Dir = 1 (direction = transmit), RmtEn = 0, UMask = 0  
The remote frame is ignored, this message object remains unchanged.
3. Dir = 1 (direction = transmit), RmtEn = 0, UMask = 1  
The remote frame is treated similar to a received data frame. At the reception of a matching remote frame, the TxRqst bit of this message object is reset. The arbitration and control bits (Identifier + IDE + RTR + DLC) from the shift register are stored in the message object in the Message RAM and the NewDat bit of this message object is set. The data bytes of the message object remain unchanged

### 25.11.9 Reading Received Messages

The CPU can read a received message any time using the IFx interface registers, the data consistency is provided by the message handler state machine.

Typically the CPU writes 0x7F to bits [23:16] and then the number of the message object to bits [7:0] of the Command Register. That combination transfers the whole received message from the Message RAM into the Interface Register set. Additionally, the bits NewDat and IntPnd are cleared in the Message RAM (not in the Interface Register set). The values of these bits in the Message Control Register always reflect the status before resetting the bits.

If the message object uses masks for acceptance filtering, the arbitration bits show which of the different matching messages has been received.

The actual value of NewDat shows whether a new message has been received since the last time when this message object was read. The actual value of MsgLst shows whether more than one message have been received since the last time when this message object was read. MsgLst is not automatically reset.

#### **25.11.10 Requesting New Data for a Receive Object**

By means of a remote frame, the CPU can request another CAN node to provide new data for a receive object. Setting the TxRqst bit of a receive object causes the transmission of a remote frame with the receive object's identifier. This remote frame triggers the other CAN node to start the transmission of the matching data frame. If the matching data frame is received before the remote frame can be transmitted, the TxRqst bit is automatically reset.

Setting the TxRqst bit without changing the contents of a message object requires the value 0x84 in bits [23:16] of the Command Register.

#### **25.11.11 Storing Received Messages in FIFO Buffers**

Several message objects can be grouped to form one or more FIFO Buffers. Each FIFO Buffer configured to store received messages with a particular (group of) Identifiers. Arbitration and Mask registers of the FIFO Buffer's message objects are identical. The EoB (End of Buffer) bits of all but the last of the FIFO Buffer's message objects are 0, in the last bit the EoB bit is 1.

Received messages with identifiers matching to a FIFO Buffer are stored into a message object of this FIFO Buffer, starting with the message object with the lowest message number.

When a message is stored into a message object of a FIFO Buffer the NewDat bit of this message object is set. By setting NewDat while EoB is 0, the message object is locked for further write accesses by the message handler until the CPU has cleared the NewDat bit.

Messages are stored into a FIFO Buffer until the last message object of this FIFO Buffer is reached. If none of the preceding message objects is released by writing NewDat to 0, all further messages for this FIFO Buffer are written into the last message object of the FIFO Buffer (EoB = 1) and therefore overwrite previous messages in this message object.

#### **25.11.12 Reading from a FIFO Buffer**

Several messages can be accumulated in a set of message objects that are concatenated to form a FIFO buffer before the application program is required (to avoid the loss of data) to empty the buffer. A FIFO buffer of length N stores N-1 plus the last received message since the last time the FIFO buffer was cleared. A FIFO buffer is cleared by reading and resetting the NewDat bits of all the message objects, starting at the FIFO object with the lowest message number. This can be done in a subroutine following the example shown in [Figure 25-13](#).

---

#### **Note**

All message objects of a FIFO buffer needs to be read and cleared before the next batch of messages can be stored. Otherwise, true FIFO functionality cannot be maintained, since the message objects of a partly read buffer are refilled according to the normal (descending) priority.

---

Reading from a FIFO Buffer message object and resetting the NewDat bit is handled the same way as reading from a single message object.

Figure 25-13. CPU Handling of a FIFO Buffer (Interrupt Driven)

## 25.12 CAN Bit Timing

The CAN supports bit rates up to 1000kBit/s.

Each CAN node has a clock generator, typically derived from a crystal oscillator. The bit timing parameters can be configured individually for each CAN node, creating a common Bit rate even though the CAN nodes' oscillator periods ( $F_{osc}$ ) can be different.

The frequencies of these oscillators are not absolutely stable. Small variations are caused by changes in temperature or voltage and by deteriorating components. As long as the variations remain inside a specific oscillator tolerance range ( $df$ ), the CAN nodes are able to compensate for the different bit rates by resynchronizing to the bit stream.

In many cases, the CAN bit synchronization amends a faulty configuration of the CAN bit timing to such a degree that only occasionally an error frame is generated. In the case of arbitration, when two or more CAN nodes simultaneously try to transmit a frame, a misplaced sample point can cause one of the transmitters to become error passive.

The analysis of such sporadic errors requires a detailed knowledge of the CAN bit synchronization inside a CAN node and of the CAN nodes' interaction on the CAN bus.

Even if minor errors in the configuration of the CAN bit timing do not result in immediate failure, the performance of a CAN network can be reduced significantly.

### 25.12.1 Bit Time and Bit Rate

According to the CAN specification, the Bit time is divided into four segments (see [Figure 25-14](#)):

- Synchronization Segment (Sync\_Seg)
- Propagation Time Segment (Prop\_Seg)
- Phase Buffer Segment 1 (Phase\_Seg1)
- Phase Buffer Segment 2 (Phase\_Seg2)

**Figure 25-14. Bit Timing**

Each segment consists of a specific number of time quanta. The length of one time quantum ( $t_q$ ), which is the basic time unit of the bit time, is given by the CAN\_CLK and the Baud Rate Prescalers (BRPE and BRP). With these two Baud Rate Prescalers combined, divider values from 1 to 1024 can be programmed:

$$t_q = \text{Baud Rate Prescaler} / \text{CAN\_CLK}$$

Apart from the fixed length of the synchronization segment, these numbers are programmable. [Table 25-4](#) describes the minimum programmable ranges required by the CAN protocol.

A given bit rate can be met by different bit time configurations.

**Table 25-4. Programmable Ranges Required by CAN Protocol**

Parameter	Range	Remark
Sync_Seg	1 $t_q$ (fixed)	Synchronization of bus input to CAN_CLK
Prop_Seg	[1 ... 8] $t_q$	Compensates for the physical delay times
Phase_Seg1	[1 ... 8] $t_q$	Can be lengthened temporarily by synchronization
Phase_Seg2	[1 ... 8] $t_q$	Can be shortened temporarily by synchronization
Synchronization Jump Width (SJW)	[1 ... 4] $t_q$	Cannot be longer than either phase buffer segment

**Note**

For proper functionality of the CAN network, the physical delay times and the oscillator's tolerance range must be considered.

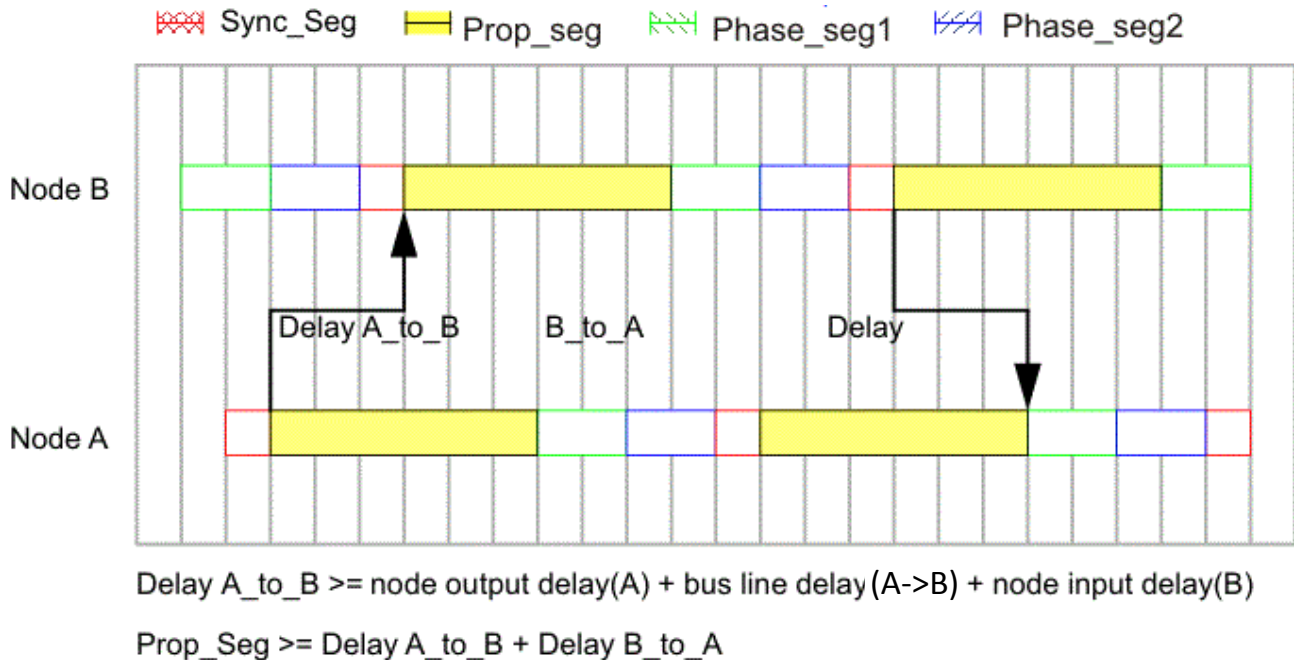

**25.12.1.1 Synchronization Segment**

The Synchronization Segment (Sync\_Seg) is the part of the bit time where edges of the CAN bus level are expected to occur. If an edge occurs outside of Sync\_Seg, the distance to the Sync\_Seg is called the phase error of this edge.

**25.12.1.2 Propagation Time Segment**

This part of the bit time is used to compensate physical delay times within the CAN network. These delay times consist of the signal propagation time on the bus and the internal delay time of the CAN nodes.

Any CAN node synchronized to the bit stream on the CAN bus can be out of phase with the transmitter of the bit stream, caused by the signal propagation time between the two nodes. The CAN protocol's nondestructive bitwise arbitration and the dominant acknowledge bit provided by receivers of CAN messages require that a CAN node transmitting a bit stream must also be able to receive dominant bits transmitted by other CAN nodes that are synchronized to that bit stream. The example in Figure 25-15 shows the phase shift and propagation times between two CAN nodes.

**Figure 25-15. Propagation Time Segment**

In this example, both nodes A and B are transmitters performing an arbitration for the CAN bus. Node A has sent a Start of Frame bit less than one bit time earlier than node B, therefore node B has synchronized to the received edge from recessive to dominant. Since node B has received this edge delay ( $A\_to\_B$ ) after the bit has been transmitted, node B's bit timing segments are shifted with regard to node A. Node B sends an identifier with higher priority, so node B wins the arbitration at a specific identifier bit when node B transmits a dominant bit while node A transmits a recessive bit. The dominant bit transmitted by node B arrives at node A after the delay ( $B\_to\_A$ ).

Due to oscillator tolerances, the actual position of node A's Sample Point can be anywhere inside the nominal range of node A's Phase Buffer Segments, so the bit transmitted by node B must arrive at node A before the start of Phase\_Seg1. This condition defines the length of Prop\_Seg.

If the edge from recessive to dominant transmitted by node B arrives at node A after the start of Phase\_Seg1, node A can potentially sample a recessive bit instead of a dominant bit, resulting in a bit error and the destruction of the current frame by an error flag.

This error only occurs when two nodes arbitrate for the CAN bus, which have oscillators of opposite ends of the tolerance range and are separated by a long bus line; this is an example of a minor error in the bit timing configuration (Prop\_Seg too short) that causes sporadic bus errors.

Some CAN implementations provide an optional 3-Sample Mode. The CAN module on this device does not. In this mode, the CAN bus input signal passes a digital low-pass filter, using three samples and a majority logic to determine the valid bit value. This results in an additional input delay of  $1 t_q$ , requiring a longer Prop\_Seg.

### 25.12.1.3 Phase Buffer Segments and Synchronization

The phase buffer segments (Phase\_Seg1 and Phase\_Seg2) and the synchronization jump width (SJW) are used to compensate for the oscillator tolerance.

The phase buffer segments surround the sample point. The phase buffer segments can be lengthened or shortened by synchronization.

The synchronization jump width (SJW) defines how far the resynchronizing mechanism can move the sample point inside the limits defined by the phase buffer segments to compensate for edge phase errors.

Synchronizations occur on edges from recessive to dominant. The purpose is to control the distance between edges and sample points.

Edges are detected by sampling the actual bus level in each time quantum and comparing the sample with the bus level at the previous sample point. A synchronization can be done only if a recessive bit was sampled at the previous sample point and if the actual time quantum's bus level is dominant.

An edge is synchronous if the edge occurs inside of Sync\_Seg; otherwise, the distance to the Sync\_Seg is the edge phase error, measured in time quanta. If the edge occurs before Sync\_Seg, the phase error is negative; else, the phase error is positive.

Two types of synchronization exist: hard synchronization and resynchronization. A hard synchronization is done once at the start of a frame; inside a frame, only resynchronization is possible.

- **Hard Synchronization:** After a hard synchronization, the bit time is restarted with the end of Sync\_Seg, regardless of the edge phase error. Thus hard synchronization forces the edge which has caused the hard synchronization to lie within the synchronization segment of the restarted bit time.
- **Bit Resynchronization:** Resynchronization leads to a shortening or lengthening of the bit time such that the position of the sample point is shifted with regard to the edge.

When the phase error of the edge that causes resynchronization is positive, Phase\_Seg1 is lengthened. If the magnitude of the phase error is less than SJW, Phase\_Seg1 is lengthened by the magnitude of the phase error; else, Phase\_Seg1 is lengthened by SJW.

When the phase error of the edge that causes resynchronization is negative, Phase\_Seg2 is shortened. If the magnitude of the phase error is less than SJW, Phase\_Seg2 is shortened by the magnitude of the phase error; else, Phase\_Seg2 is shortened by SJW.

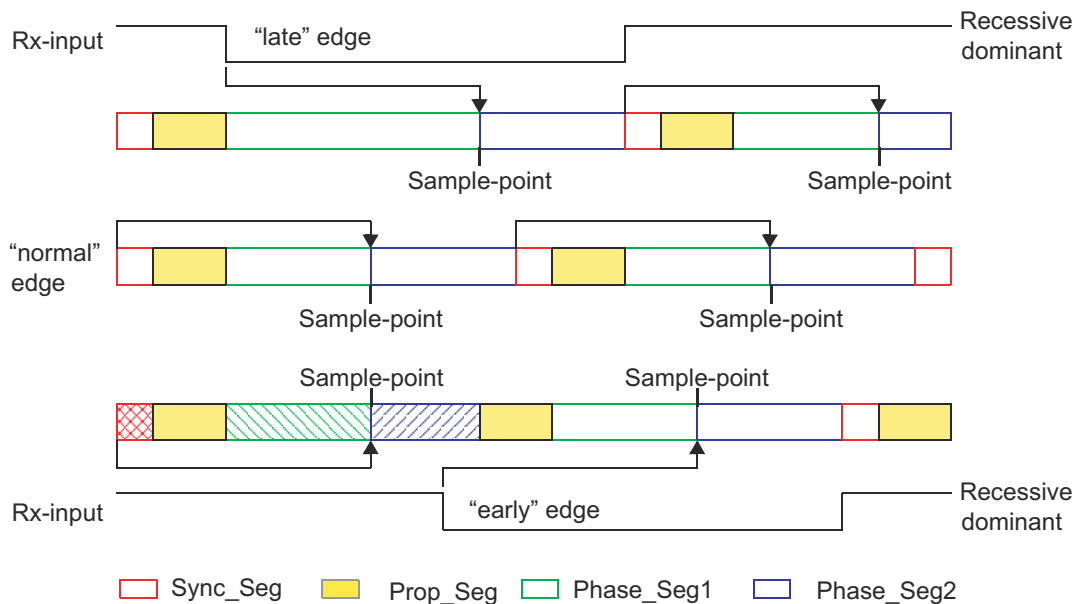

If the magnitude of the phase error of the edge is less than or equal to the programmed value of SJW, the results of hard synchronization and resynchronization are the same. If the magnitude of the phase error is larger than SJW, the resynchronization cannot compensate the phase error completely, and an error of (phase error - SJW) remains.

Only one synchronization can be done between two sample points. The synchronizations maintain a minimum distance between edges and sample points, giving the bus level time to stabilize and filtering out spikes that are shorter than (Prop\_Seg + Phase\_Seg1).

Apart from noise spikes, most synchronizations are caused by arbitration. All nodes synchronize "hard" on the edge transmitted by the "leading" transceiver that started transmitting first, but due to propagation delay times, the nodes cannot become completely synchronized. The "leading" transmitter does not necessarily win the arbitration; therefore, the receivers must synchronize themselves to different transmitters that subsequently "take the lead" and that are differently synchronized to the previously "leading" transmitter. The same happens at the acknowledge field, where the transmitter and some of the receivers must synchronize to the receiver that "takes the lead" in the transmission of the dominant acknowledge bit.

Synchronizations after the end of the arbitration are caused by oscillator tolerance, when the differences in the oscillator's clock periods of transmitter and receivers sum up during the time between synchronizations (at most 10 bits). These summarized differences cannot be longer than the SJW, limiting the oscillator's tolerance range.

The examples in Figure 25-16 show how the phase buffer segments are used to compensate for phase errors. There are three drawings of each two consecutive bit timings. The upper drawing shows the synchronization on a "late" edge, the lower drawing shows the synchronization on an "early" edge, and the middle drawing is the reference without synchronization.

**Figure 25-16. Synchronization on Late and Early Edges**

In the first example, an edge from recessive to dominant occurs at the end of Prop\_Seg. The edge is "late" since the edge occurs after the Sync\_Seg. Reacting to the "late" edge, Phase\_Seg1 is lengthened so that the distance from the edge to the sample point is the same as from the Sync\_Seg to the sample point if no edge had occurred. The phase error of this "late" edge is less than SJW, so it is fully compensated and the edge from dominant to recessive at the end of the bit, which is one nominal bit time long, occurs in the Sync\_Seg.

In the second example, an edge from recessive to dominant occurs during Phase\_Seg2. The edge is "early" since it occurs before a Sync\_Seg. Reacting to the "early" edge, Phase\_Seg2 is shortened and Sync\_Seg is omitted, so that the distance from the edge to the sample point is the same as from a Sync\_Seg to the sample point if no edge had occurred. As in the previous example, the magnitude of this "early" edge's phase error is less than SJW, so it is fully compensated.

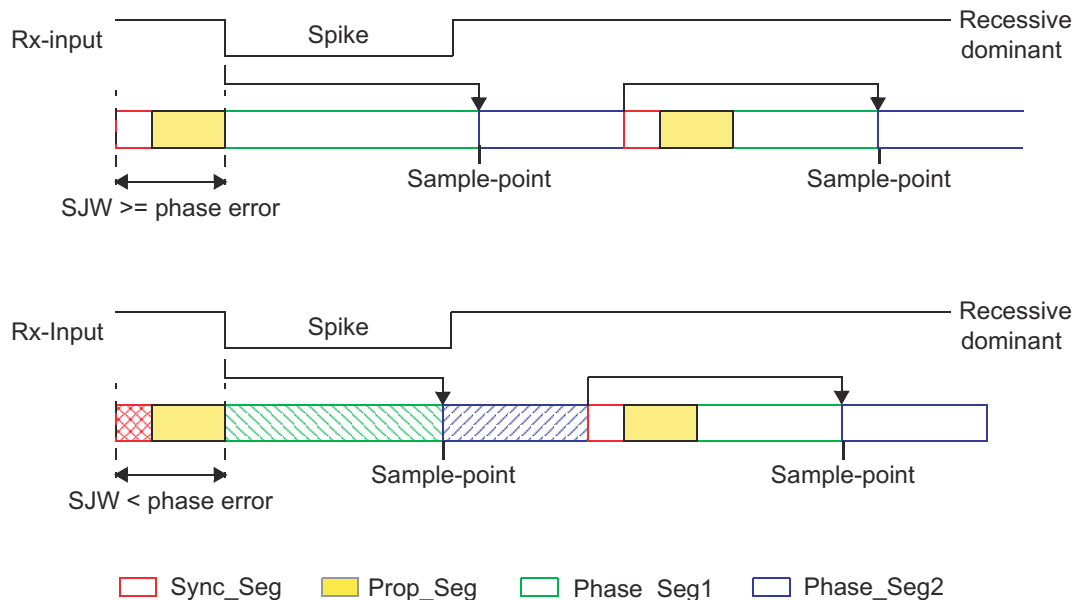

The phase buffer segments are lengthened or shortened temporarily only; at the next bit time, the segments return to the nominal programmed values.

In these examples, the bit timing is seen from the point of view of the CAN implementation's state machine, where the bit time starts and ends at the sample points. The state machine omits Sync\_Seg when synchronizing on an "early" edge because the state machine cannot subsequently redefine that time quantum of Phase\_Seg2 where the edge occurs to be the Sync\_Seg.

The examples in [Figure 25-17](#) show how short dominant noise spikes are filtered by synchronizations. In both examples, the spike starts at the end of Prop\_Seg and has the length of (Prop\_Seg + Phase\_Seg1).

In the first example, the synchronization jump width is greater than or equal to the phase error of the spike's edge from recessive to dominant. Therefore the sample point is shifted after the end of the spike; a recessive bus level is sampled.

In the second example, SJW is shorter than the phase error, so the sample point cannot be shifted far enough; the dominant spike is sampled as actual bus level.

**Figure 25-17. Filtering of Short Dominant Spikes**

#### 25.12.1.4 Oscillator Tolerance Range

With the introduction of CAN protocol version 1.2, the option to synchronize on edges from dominant to recessive became obsolete. Only edges from recessive to dominant are considered for synchronization. The protocol update to version 2.0 (A and B) had no influence on the oscillator tolerance.

The tolerance range  $df$  for an oscillator's frequency  $f_{osc}$  around the nominal frequency  $f_{nom}$  with:

$$(1 - df) * f_{nom} \leq f_{osc} \leq (1 + df) * f_{nom}$$

depends on the proportions of Phase\_Seg1, Phase\_Seg2, SJW, and the bit time. The maximum tolerance  $df$  is defined by two conditions (both must be met):

$$df \leq \frac{\min(Tseg1, Tseg2)}{2((13 \times bit\ time) - Tseg2)}$$

$$df \leq \frac{SJW}{20 \times bit\_time}$$

You must consider that SJW cannot be larger than the smaller of the phase buffer segments and that the propagation time segment limits that part of the bit time that can be used for the phase buffer segments.

The combination Prop\_Seg = 1 and Phase\_Seg1 = Phase\_Seg2 = SJW = 4 allows the largest possible oscillator tolerance of 1.58%. This combination with a Propagation Time Segment of only 10% of the bit time is not for short bit times; the combination can be used for bit rates of up to 125kBit/s (bit time = 8 $\mu$ s) with a bus length of 40 meters.

#### 25.12.2 Configuration of the CAN Bit Timing

In the CAN, the bit timing configuration is programmed in two register bytes, additionally a third byte for a baud rate prescaler extension of 4 bits (BRPE) is provided. The sum of Prop\_Seg and Phase\_Seg1 (as TSEG1) is combined with Phase\_Seg2 (as TSEG2) in one byte, SJW and BRP (plus BRPE in third byte) are combined in the other byte (see [Figure 25-18](#)).

In this bit timing register, the components TSEG1, TSEG2, SJW, and BRP are programmed to a numerical value that is one less than the functional value; so instead of values in the range of [1...n], values in the range of [0...n-1] are programmed. That way, for example, SJW (functional range of [1...4]) is represented by only two bits.

Therefore the length of the bit time is either:

- (programmed values) [TSEG1 + TSEG2 + 3]  $t_q$
- (functional values) [Sync\_Seg + Prop\_Seg + Phase\_Seg1 + Phase\_Seg2]  $t_q$

The data in the Bit Timing Register is the configuration input of the CAN protocol controller. The baud rate prescaler (configured by BRPE/BRP) defines the length of the time quantum (the basic time unit of the bit time); the bit timing logic (configured by TSEG1, TSEG2, and SJW) defines the number of time quanta in the bit time.

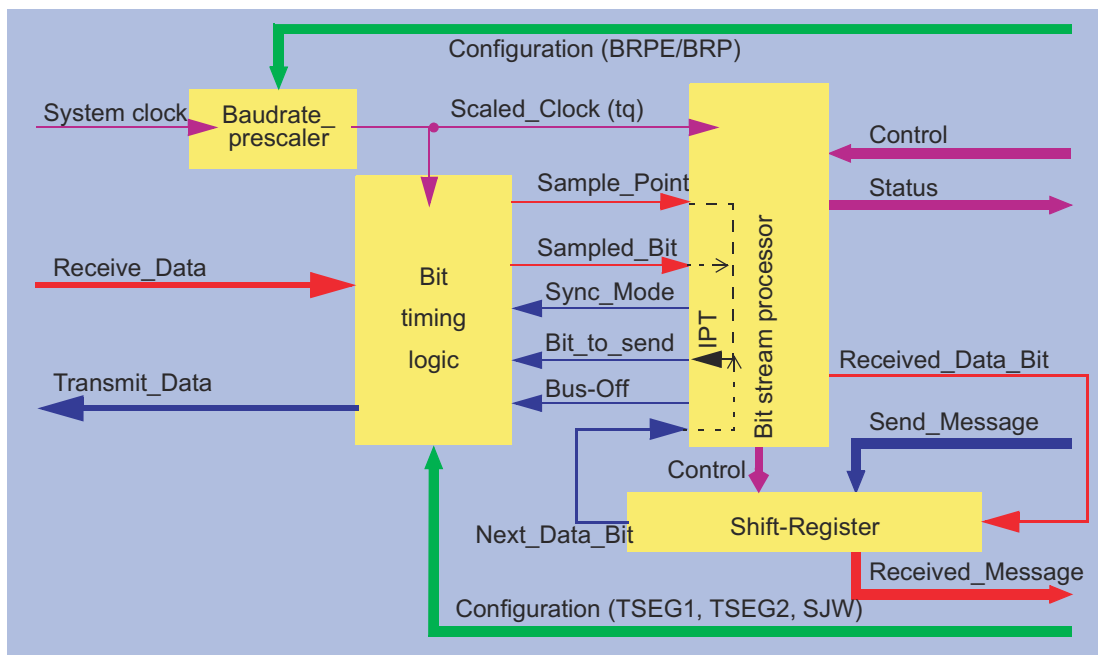

The processing of the bit time, the calculation of the position of the Sample Point, and occasional synchronizations are controlled by the Bit timing state machine, which is evaluated once each time quantum. The rest of the CAN protocol controller, the Bit Stream Processor (BSP) state machine, is evaluated once each bit time, at the Sample Point.

The Shift register serializes the messages to be sent and parallelizes received messages. Loading and shifting is controlled by the BSP.

The BSP translates messages into frames and conversely. The BSP generates and discards the enclosing fixed format bits, inserts and extracts stuff bits, calculates and checks the CRC code, performs the error management, and decides which type of synchronization is to be used. It is evaluated at the sample point and processes the sampled bus input bit. The time after the sample point that is needed to calculate the next bit to be sent (for example, data bit, CRC bit, stuff bit, error flag, or idle) is called the Information Processing Time (IPT), which is  $0 t_q$  for the CAN.

Generally, the IPT is CAN controller specific, but cannot be longer than  $2 t_q$ . The IPT length is the lower limit of the programmed length of Phase\_Seg2. In case of a synchronization, Phase\_Seg2 can be shortened to a value less than IPT, which does not affect bus timing.

**Figure 25-18. Structure of the CAN Core's CAN Protocol Controller**

### 25.12.2.1 Calculation of the Bit Timing Parameters

Usually, the calculation of the bit timing configuration starts with a desired bit rate or bit time. The resulting Bit time (1/Bit rate) must be an integer multiple of the CAN clock period.

---

#### Note

8MHz is the minimum CAN clock frequency required to operate the CAN at a bit rate of 1MBit/s.

---

The bit time can consist of 8 to 25 time quanta. The length of the time quantum  $t_q$  is defined by the Baud Rate Prescaler with  $t_q = (\text{Baud Rate Prescaler}) / \text{CAN\_CLK}$ . Several combinations can lead to the desired bit time, allowing iterations of the following steps.

The first part of the bit time to be defined is the Prop\_Seg. The length depends on the delay times measured in the system. A maximum bus length as well as a maximum node delay has to be defined for expandable CAN bus systems. The resulting time for Prop\_Seg is converted into time quanta (rounded up to the nearest integer multiple of  $t_q$ ).

The Sync\_Seg is 1  $t_q$  long (fixed), leaving  $(\text{bit time} - \text{Prop\_Seg} - 1) t_q$  for the two Phase Buffer Segments. If the number of remaining  $t_q$  is even, the Phase Buffer Segments have the same length,  $\text{Phase\_Seg2} = \text{Phase\_Seg1}$ ; else,  $\text{Phase\_Seg2} = \text{Phase\_Seg1} + 1$ .

The minimum nominal length of Phase\_Seg2 has to be regarded as well. Phase\_Seg2 cannot be shorter than the Information Processing Time of any node in the network, which is device dependent and can be in the range of  $[0 \text{ to } 2] t_q$ .

The length of the synchronization jump width is set to the maximum value, which is the minimum of 4 and Phase\_Seg1.

The oscillator tolerance range necessary for the resulting configuration is calculated by the formulas given in [Section 25.12.1.4](#).

If more than one configurations are possible to reach a certain bit rate, choose the configuration that allows the highest oscillator tolerance range.

CAN nodes with different clocks require different configurations to come to the same bit rate. The calculation of the propagation time in the CAN network, based on the nodes with the longest delay times, is done once for the whole network.

The CAN system oscillator tolerance range is limited by the node with the lowest tolerance range.

The calculation can show that bus length or bit rate has to be decreased or that the oscillator frequency stability has to be increased to find a protocol compliant configuration of the CAN bit timing.

The resulting configuration is written into the Bit Timing register:

$$(\text{Phase\_Seg2}-1) \& (\text{Phase\_Seg1} + \text{Prop\_Seg} - 1) \& (\text{SynchronizationJumpWidth} - 1) \& (\text{Prescaler} - 1)$$

### 25.12.2.2 Example for Bit Timing at High Baudrate

In this example, the frequency of CAN\_CLK is 10MHz, BRP is 0, the bit rate is 1MBit/s.

$t_q$	100ns =	$t_{CAN\_CLK}$
delay of bus driver	90ns =	
delay of receiver circuit	40ns =	
delay of bus line (40m)	220ns =	
$t_{Prop}$	700ns =	$2 \times \text{delays} = 7 \times t_q$
$t_{SJW}$	100ns =	$1 \times t_q$
$t_{TSeg1}$	800ns =	$t_{Prop} + t_{SJW}$
$t_{TSeg2}$	100ns =	Information Processing Time + $1 \times t_q$
$t_{Sync-Seg}$	100ns =	$1 \times t_q$
bit time	1000ns =	$t_{Sync-Seg} + t_{TSeg1} + t_{TSeg2}$
tolerance for CAN_CLK	0.35% =	$\frac{\min(Tseg1, Tseg2)}{2((13 \times \text{bit time}) - Tseg2)}$
		$= \frac{0.1 \mu s}{2((13 \times 1 \mu s) - 0.1 \mu s)}$

In this example, the concatenated bit time parameters are  $(1-1)_3 \& (8-1)_4 \& (1-1)_2 \& (1-1)_6$ , so the Bit Timing Register is programmed to = 0x0000 0700.

### 25.12.2.3 Example for Bit Timing at Low Baudrate

In this example, the frequency of CAN\_CLK is 2MHz, BRP is 1, the bit rate is 100KBit/s.

$t_q$	1 $\mu$ s =	$2 \times t_{CAN\_CLK}$
delay of bus driver	200ns =	
delay of receiver circuit	80ns =	
delay of bus line (40m)	220ns =	
$t_{Prop}$	1 $\mu$ s =	$1 \times t_q$
$t_{SJW}$	4 $\mu$ s =	$4 \times t_q$
$t_{TSeg1}$	5 $\mu$ s =	$t_{Prop} + t_{SJW}$
$t_{TSeg2}$	4 $\mu$ s =	Information Processing Time + $4 \times t_q$
$t_{Sync-Seg}$	1 $\mu$ s =	$1 \times t_q$
bit time	10 $\mu$ s =	$t_{Sync-Seg} + t_{TSeg1} + t_{TSeg2}$
tolerance for CAN_CLK	1.58% =	$\frac{\min(Tseg1, Tseg2)}{2((13 \times \text{bit time}) - Tseg2)}$
		$= \frac{4 \mu s}{2((13 \times 10 \mu s) - 4 \mu s)}$

In this example, the concatenated bit time parameters are  $(4-1)_3 \& (5-1)_4 \& (4-1)_2 \& (2-1)_6$ , so the Bit Timing register is programmed to = 0x0000 34C1.

## 25.13 Message Interface Register Sets

The interface register sets control the CPU read and write accesses to the Message RAM. There are two interface register sets for read and write access (IF1 and IF2) and one Interface Register Set for read access only (IF3).

Due to the structure of the Message RAM, it is not possible to change single bits or bytes of a message object. Instead, always a complete message object in the Message RAM is accessed. Therefore the data transfer from the IF1/IF2 registers to the Message RAM requires the message handler to perform a read-modify-write cycle. First those parts of the message object that are not to be changed are read from the Message RAM into the Interface Register set, and after the update the whole content of the Interface Register set is written into the message object.

After the partial write of a message object, those parts of the Interface Register set that are not selected in the Command Register are set to the actual contents of the selected message object. After the partial read of a message object, those parts of the Interface Register set that are not selected in the Command Register are left unchanged.

By buffering the data to be transferred, the Interface Register sets avoid conflicts between concurrent CPU accesses to the Message RAM and CAN message reception and transmission. A complete message object (see [Section 25.14.1](#)) or parts of the message object can be transferred between the Message RAM and the IF1/IF2 Register set in one single transfer. This transfer, performed in parallel on all selected parts of the message object, maintains the data consistency of the CAN message.

There is one condition that can cause a write access to the message RAM to be lost. If `MsgVal = 1` for the message object that is accessed and CAN communication is ongoing, a transfer from the IFx register to message RAM can be lost. The reason this can happen is that the IFx register write to the message RAM occurs in between a read-modify-write access of the Host Message Handler when in the process of receiving a message for the same message object.

To avoid this issue with receive mail boxes, reset `MsgVal` before changing any of the following: `Id28-0`, `Xtd`, `Dir`, `DLC3-0`, `RxIE`, `TxIE`, `RmtEn`, `EoB`, `Umask`, `Msk28-0`, `MXtd`, and `MDir`.

To avoid this issue with transmit mail boxes, reset `MsgVal` before changing any of the following: `Dir`, `RxIE`, `TxIE`, `RmtEn`, `EoB`, `Umask`, `Msk28-0`, `MXtd`, and `MDir`. Other fields not listed above, like `Data`, can be changed without fear of losing a write to the message RAM.

### 25.13.1 Message Interface Register Sets 1 and 2 (IF1 and IF2)

The IF1 and IF2 register sets allow data transfers to and from the message objects. The IFxCMD register for an interface control the direction of the data transfer. If the IFxCMD register is set to write, then the message object fields selected by the IFxCMD register are overwritten by values taken from the other IFx registers. If the IFxCMD register is set to read, then the message object fields selected by the IFxCMD register is copied from the message object to the other IFx registers. The interfaces allow for transfers of a complete message object as well as individual parts. The transfer begins with the desired message object number is written to bits 7:0 of the IFxCMD register.

When the CPU initiates a data transfer between the IF1/IF2 registers and Message RAM, the message handler sets the Busy bit in the respective Command Register to 1. After the transfer has completed, the Busy bit is set back to 0 (see [Figure 25-19](#)).

**Figure 25-19. Data Transfer Between IF1 / IF2 Registers and Message RAM**

### 25.13.2 Message Interface Register Set 3 (IF3)

The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from Message RAM by CPU. The automatic update functionality can be programmed for each message object (see the IF3 Update Enable register).

All valid message objects in Message RAM that are configured for automatic update are checked for active NewDat flags. If such a message object is found, the message objects are transferred to the IF3 register, controlled by IF3 Observation register. If more than one NewDat flag is active, the message object with the lowest number has the highest priority for automatic IF3 update.

The NewDat bit in the message object is reset by a transfer to IF3.

#### Note

The IF3 register set cannot be used for transferring data into message objects.

## 25.14 Message RAM

The CAN Message RAM contains message objects and parity bits for the message objects. There are 32 message objects in the Message RAM.

During normal operation, accesses to the Message RAM are performed using the Interface Register sets, and the CPU cannot directly access the Message RAM.

The Interface Register sets IF1 and IF2 provide indirect read/write access from the CPU to the Message RAM. The IF1 and IF2 register sets can buffer control and user data to be transferred to and from the message objects.

The third Interface Register set IF3 can be configured to automatically receive control and user data from the Message RAM when a message object has been updated after reception of a CAN message. The CPU does not need to initiate the transfer from Message RAM to IF3 Register set.

The message handler avoids potential conflicts between concurrent accesses to Message RAM and CAN frame reception/transmission.

The message RAM can only be accessed in debug mode. The message RAM base address is 0x1000 above the base address of the CAN peripheral.

### 25.14.1 Structure of Message Objects

Figure 25-20 shows the structure of a message object.

The grayed fields are those parts of the message object which are represented in dedicated registers. For example, the transmit request flags of all message objects are represented in centralized transmit request registers.

**Figure 25-20. Structure of a Message Object**

Message Object												
UMask	Msk[28:0]	MXtd	MDir	EoB	unused	NewDat	MsgLst	RxIE	TxE	IntPnd	RmtEn	TxRqst
MsgVal	ID[28:0]	Xtd	Dir	DLC[3:0]	Data 0	Data 1	Data 2	Data 3	Data 4	Data 5	Data 6	Data 7

**Table 25-5. Message Object Field Descriptions**

Name	Value	Description
MsgVal	0	The message object is ignored by the message handler.
	1	The message object is to be used by the message handler. Note: This bit can be kept at level 1 even when the identifier bits ID[28:0], the control bits Xtd, Dir, or the data length code DLC[3:0] are changed.
UMask	0	Mask bits (Msk[28:0], MXtd and MDir) are ignored and not used for acceptance filtering.
	1	Mask bits are used for acceptance filtering. Note: If the UMask bit is set to 1, the message object's mask bits are programmed during initialization of the message object before MsgVal is set to 1.
ID[28:0]	ID[28:0]	29-bit ("extended") identifier bits
	ID[28:18]	11-bit ("standard") identifier bits

**Table 25-5. Message Object Field Descriptions (continued)**

Name	Value	Description
Msk[28:0]	0	The corresponding bit in the message identifier is not used for acceptance filtering (don't care).
	1	The corresponding bit in the message identifier is used for acceptance filtering. Note: The bit functionality in the DCAN module is the opposite of the Local Acceptance Mask bit functionality in the eCAN module found in older C28x devices, where a 1 means the corresponding bit is not used for filtering, and a 0 means the bit is used.
Xtd	0	The 11-bit ("standard") identifier is used for this message object.
	1	The 29-bit ("extended") identifier is used for this message object.
MXtd	0	The extended identifier bit (IDE) has no effect on the acceptance filtering.
	1	The extended identifier bit (IDE) is used for acceptance filtering. Note: When 11-bit ("standard") Identifiers are used for a message object, the identifiers of received data frames are written into bits ID[28:18]. For acceptance filtering, only these bits together with mask bits Msk[28:18] are considered.
Dir	0	Direction = receive: On TxRqst, a remote frame with the identifier of this message object is transmitted. On reception of a data frame with matching identifier, the message is stored in this message object.
	1	Direction = transmit: On TxRqst, a data frame is transmitted. On reception of a remote frame with matching identifier, the TxRqst bit of this message object is set (if RmtEn = 1).
MDir	0	The message direction bit (Dir) has no effect on the acceptance filtering.
	1	The message direction bit (Dir) is used for acceptance filtering.
EOB	0	The message object is part of a FIFO Buffer block and is not the last message object of this FIFO Buffer block.
	1	The message object is a single message object or the last message object in a FIFO Buffer Block. Note: This bit is used to concatenate multiple message objects to build a FIFO Buffer. For single message objects (not belonging to a FIFO Buffer), this bit must always be set to 1.
NewDat	0	No new data has been written into the data bytes of this message object by the message handler since the last time when this flag was cleared by the CPU.
	1	The message handler or the CPU has written new data into the data bytes of this message object.
MsgLst	0	Message Lost (only valid for Message Objects with direction = receive) No message was lost since the last time when this bit was reset by the CPU.
	1	The message handler stored a new message into this message object when NewDat was still set, so the previous message has been overwritten.
RxIE	0	IntPnd is not triggered after the successful reception of a frame.
	1	IntPnd is triggered after the successful reception of a frame.
TxIE	0	IntPnd is not triggered after the successful transmission of a frame.
	1	IntPnd is triggered after the successful transmission of a frame.
IntPnd	0	Interrupt Pending This message object is not the source of an interrupt.
	1	This message object is the source of an interrupt. The Interrupt Identifier in the Interrupt Register point to this message object, if there is no other interrupt source with higher priority.

**Table 25-5. Message Object Field Descriptions (continued)**

Name	Value	Description
RmtEn	0	Remote Enable At the reception of a remote frame, TxRqst is not changed.
	1	At the reception of a remote frame, TxRqst is set. Note: See <a href="#">Section 25.11.8</a> for details on the setup of RmtEn and UMask for remote frames.
TxRqst	0	Transmit Request This message object is not waiting for a transmission.
	1	The transmission of this message object is requested and is not yet done.
DLC[3:0]	0-8	Data length code Data frame has 0-8 data bytes.
	9-15	Data frame has 8 data bytes. Note: The data length code of a message object must be defined to the same value as in the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame, the message handler writes the DLC to the value given by the received message.
Data 0		1st data byte of a CAN data frame
Data 1		2nd data byte of a CAN data frame
Data 2		3rd data byte of a CAN data frame
Data 3		4th data byte of a CAN data frame
Data 4		5th data byte of a CAN data frame
Data 5		6th data byte of a CAN data frame
Data 6		7th data byte of a CAN data frame
Data 7		8th data byte of a CAN data frame Note: Byte Data 0 is the first data byte shifted into the shift register of the CAN core during a reception, byte Data 7 is the last. When the message handler stores a data frame, the message handler writes all the eight data bytes into a message object. If the data length code is less than 8, the remaining bytes of the message object can be overwritten by undefined values.

### 25.14.2 Addressing Message Objects in RAM

The starting location of a particular message object in RAM is:

$$\text{Message RAM base address} + (\text{message object number}) * 0x20$$

This means that Message Object 1 starts at offset 0x0020; Message Object 2 starts at offset 0x0040, and so on.

#### Note

A 0 is not a valid message object number. At address 0x0000, the last message object (32) (with the lowest priority) is located. Writing to the address of an unimplemented message object can overwrite an implemented message object.

Message Object number 1 has the highest priority.

**Table 25-6. Message RAM Addressing in Debug Mode**

Message Object Number	Offset From Base Address	Word Number	Debug Mode <sup>(1)</sup>
last implemented (here:32)	0x0000	1	Parity
	0x0004	2	MXtd,MDir,Mask
	0x0008	3	Xtd,Dir,ID
	0x000C	4	Ctrl
	0x0010	5	Data Bytes 3-0
	0x0014	6	Data Bytes 7-4
1	0x0020	1	Parity
	0x0024	2	MXtd,MDir,Mask
	0x0028	3	Xtd,Dir,ID
	0x002C	4	Ctrl
	0x0030	5	Data Bytes 3-0
	0x0034	6	Data Bytes 7-4
2	0x0040	1	Parity
	0x0044	2	MXtd,MDir,Mask
	0x0048	3	Xtd,Dir,ID
	0x004C	4	Ctrl
	0x0050	5	Data Bytes 3-0
	0x0054	6	Data Bytes 7-4
...	...	...	...
31	0x03E0	1	Parity
	0x03E4	2	MXtd,MDir,Mask
	0x03E8	3	Xtd,Dir,ID
	0x03EC	4	Ctrl
	0x03F0	5	Data Bytes 3-0
	0x03F4	6	Data Bytes 7-4

(1) See [Section 25.14.3](#).

### 25.14.3 Message RAM Representation in Debug Mode

In debug mode, the Message RAM is memory-mapped. This allows the external debug unit to access the Message RAM.

#### Note

During debug mode, the Message RAM cannot be accessed using the IFx register sets.

**Figure 25-21. Message RAM Representation in Debug Mode**

## 25.15 Software

### 25.15.1 CAN Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/can

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 25.15.1.1 CAN Dual Core Example - C28X\_DUAL

FILE: can\_cpu1\_allocate\_to\_cpu2.c

This example demonstrates how to allocate DCAN peripheral using CPU1 so that it can be operated using CPU2.

In the default CPU2 linker cmd file, GS4, FLASH\_BANK3 and FLASH\_BANK4 are used for allocating various CPU2 sections. The CPU1 application assigns the ownership of these memory regions to CPU2. Please note that CPU2 .out file can be loaded only after CPU1 completes this configuration. The erase setting (CPU1/CPU2 On-Chip Flash -> erase setting) needs to be configured as selected banks only (Choose the corresponding BANKS allocated for CPUs) or necessary sectors only before loading CPU1/CPU2.out file (This is applicable only for FLASH configuration)

##### *External Connections*

- None.

##### *Watch Variables*

- None.

#### 25.15.1.2 CAN External Loopback

FILE: can\_ex1\_loopback.c

This example shows the basic setup of CAN to transmit and receive messages on the CAN bus. The CAN peripheral is configured to transmit messages with a specific CAN ID. A message is then transmitted once per second, using a simple delay loop for timing. The message that is sent is a 2 byte message that contains an incrementing pattern.

This example sets up the CAN controller in External Loopback test mode. Data transmitted is visible on the CANTXA pin and is received internally back to the CAN Core. Please refer to details of the External Loopback Test Mode in the CAN Chapter in the Technical Reference Manual. Refer to [Programming Examples and Debug Strategies for the DCAN Module](#) for useful information about this example

##### *External Connections*

- None.

##### *Watch Variables*

- msgCount - A counter for the number of successful messages received
- txMsgData - An array with the data being sent
- rxMsgData - An array with the data that was received

#### 25.15.1.3 CAN External Loopback - C28X\_DUAL

FILE: can\_ex1\_cpu2\_loopback.c

This example sets up the CAN controller in External Loopback test mode using CPU2. The CAN peripheral is configured to transmit messages with a specific CAN ID. A message is then transmitted once per second, using a simple delay loop for timing. The message that is sent is a 4 byte message that contains an incrementing pattern. A CAN interrupt handler is used to confirm message transmission and count the number of messages that have been sent.

This example sets up the CAN controller in External Loopback test mode. Data transmitted is visible on the CANTXA pin and is received internally back to the CAN Core. Please refer to details of the External Loopback

Test Mode in the CAN Chapter in the Technical Reference Manual. Refer to [Programming Examples and Debug Strategies for the DCAN Module](#) for useful information about this example

#### External Connections

- None.

#### Watch Variables

- msgCount - A counter for the number of messages received
- txMsgData - An array with the data being sent
- rxMsgData - An array with the data that was received

#### 25.15.1.4 CAN External Loopback with Interrupts

FILE: can\_ex2\_loopback\_interrupts.c

This example shows the basic setup of CAN to transmit and receive messages on the CAN bus. The CAN peripheral is configured to transmit messages with a specific CAN ID. A message is then transmitted once per second, using a simple delay loop for timing. The message that is sent is a 4 byte message that contains an incrementing pattern. A CAN interrupt handler is used to confirm message transmission and count the number of messages that have been sent.

This example sets up the CAN controller in External Loopback test mode. Data transmitted is visible on the CANTXA pin and is received internally back to the CAN Core. Please refer to details of the External Loopback Test Mode in the CAN Chapter in the Technical Reference Manual. Refer to [Programming Examples and Debug Strategies for the DCAN Module](#) for useful information about this example

#### External Connections

- None.

#### Watch Variables

- txMsgCount - A counter for the number of messages sent
- rxMsgCount - A counter for the number of messages received
- txMsgData - An array with the data being sent
- rxMsgData - An array with the data that was received
- errorFlag - A flag that indicates an error has occurred

#### 25.15.1.5 CAN External Loopback with Interrupts - C28X\_DUAL

FILE: can\_ex2\_cpu2\_loopback\_interrupts.c

This example sets up the CAN controller in External Loopback test mode using CPU2. The CAN peripheral is configured to transmit messages with a specific CAN ID. A message is then transmitted once per second, using a simple delay loop for timing. The message that is sent is a 4 byte message that contains an incrementing pattern. A CAN interrupt handler is used to confirm message transmission and count the number of messages that have been sent.

This example sets up the CAN controller in External Loopback test mode. Data transmitted is visible on the CANTXA pin and is received internally back to the CAN Core. Please refer to details of the External Loopback Test Mode in the CAN Chapter in the Technical Reference Manual. Refer to [Programming Examples and Debug Strategies for the DCAN Module](#) for useful information about this example

#### External Connections

- None.

#### Watch Variables

- txMsgCount - A counter for the number of messages sent
- rxMsgCount - A counter for the number of messages received
- txMsgData - An array with the data being sent
- rxMsgData - An array with the data that was received

- errorFlag - A flag that indicates an error has occurred

#### 25.15.1.6 CAN External Loopback with DMA

FILE: can\_ex4\_loopback\_dma.c

This example sets up the CAN module to transmit and receive messages on the CAN bus. The CAN module is set to transmit a 4 byte message internally. An interrupt is used to assert the DMA request line which then triggers the DMA to transfer the received data from the CAN interface register to the receive buffer array. A data check is performed once the transfer is complete.

This example sets up the CAN controller in External Loopback test mode. Data transmitted is visible on the CANTXA pin and is received internally back to the CAN Core. Please refer to details of the External Loopback Test Mode in the CAN Chapter in the Technical Reference Manual. Please refer to the appnote Programming Examples and Debug Strategies for the DCAN Module ([www.ti.com/lit/SPRACE5](http://www.ti.com/lit/SPRACE5)) for useful information about this example

##### External Connections

- None.

##### Watch Variables

- txMsgCount - A counter for the number of messages sent
- rxMsgCount - A counter for the number of messages received
- txMsgData - An array with the data being sent
- rxMsgData - An array with the data that was received

#### 25.15.1.7 CAN Transmit and Receive Configurations

FILE: can\_ex5\_transmit\_receive.c

This example shows the basic setup of CAN to transmit or receive messages on the CAN bus with a specific Message ID. The CAN Controller is configured according to the selection of the define.

When the TRANSMIT define is selected, the CAN Controller acts as a Transmitter and sends data to the second CAN Controller connected externally. If TRANSMIT is not defined the CAN Controller acts as a Receiver and waits for message to be transmitted by the External CAN Controller. Refer to [Programming Examples and Debug Strategies for the DCAN Module](#) for useful information about this example

CAN modules on the device need to be connected to via CAN transceivers. *Hardware Required*

- A C2000 board with CAN transceiver.

##### External Connections

- ControlCARD CANA is on DEVICE\_GPIO\_PIN\_CANTXA (CANTXA)
- and DEVICE\_GPIO\_PIN\_CANRXA (CANRXA)

##### Watch Variables Transmit \Configuration

- MSGCOUNT - Adjust to set the number of messages
- txMsgCount - A counter for the number of messages sent
- txMsgData - An array with the data being sent
- errorFlag - A flag that indicates an error has occurred
- rxMsgCount - Has the initial value as No. of Messages to be received and decrements with each message.

#### 25.15.1.8 CAN Error Generation Example

FILE: can\_ex6\_error\_generation.c

This example demonstrates the ways of handling CAN Error conditions. It generates the CAN Packets and sends them over GPIO. It is looped back externally to be received in CAN module. The CAN Interrupt service routine reads the Error status and demonstrates how different Error conditions can be detected.

Change ERR\_CFG define to the different Error Scenarios and run the example. The corresponding Error Flag will be set in status variable of canalSR() routine. Uses a CPU Timer (Timer 0) for periodic timer interrupt.

of CANBITRATE uSec On the Timer interrupt it sends the required CAN Frame type with the specified error conditions CAN modules on the device need to be connected to via CAN transceivers. Please refer to the application note titled "Configurable Error Generator for Controller Area Network" at [Configurable Error Generator for Controller Area Network](#) for further details on this example

#### External Connections

- ControlCARD GPIOTX\_PIN should be connected to
- DEVICE\_GPIO\_PIN\_CANRXA(CANRXA)

#### Watch Variables Transmit \Configuration

- status - variable in canaISR for checking error Status

#### 25.15.1.9 CAN Remote Request Loopback

FILE: can\_ex7\_loopback\_tx\_rx\_remote\_frame.c

This example shows the basic setup of CAN in order to transmit a remote frame and get a response for the remote frame and store it in a receive Object. The CAN peripheral is configured to transmit remote request frame and a remote answer frame messages with a specific CAN ID. Message object 3 is configured to transmit a remote request. Message object 2 is configured as a remote answer object with filter mask such that it accepts remote frame with any message ID and transmit's remote answer with message ID 7 and data length 8. Message object 1 is configured as a received object with filter message ID 7 so as to store the remote answer data transmitted by message object 2.

This example sets up the CAN controller in External Loopback test mode. Data transmitted is visible on the CANTXA pin and is received internally back to the CAN Core. Please refer to details of the External Loopback Test Mode in the CAN Chapter in the Technical Reference Manual.

#### External Connections

- None.

#### Watch Variables

- txMsgData - An array with the data being sent
- rxMsgData - An array with the data that was received

#### 25.15.1.10 CAN example that illustrates the usage of Mask registers

FILE: can\_ex8\_mask.c

This example initializes CAN module A for Reception. When a frame with a matching filter criterion is received, the data is copied in mailbox 1 and LED is toggled a few times and the code gets ready for the next frame. If a message of any other MSGID is received, an ACK is provided Completion of reception is determined by polling CAN\_NDAT\_21 register. No interrupts are used. Refer to [Programming Examples and Debug Strategies for the DCAN Module](#) for useful information about this example

#### Hardware Required

- An external CAN node that transmits to CAN-A on the C2000 MCU

#### Watch Variables

- rxMsgCount - A counter for the number of messages received
- rxMsgData - An array with the data that was received

## 25.16 CAN Registers

This section describes the Controller Area Network registers.

### 25.16.1 CAN Base Address Table

**Table 25-7. CAN Base Address Table**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	CPU2	CPU2.DMA	Pipeline Protected
Instance	Structure								
CanaRegs	<a href="#">CAN_REGS</a>	CANA_BASE	0x0004_8000	YES	YES	-	YES	YES	YES

### 25.16.2 CAN\_REGS Registers

Table 25-8 lists the memory-mapped registers for the CAN\_REGS registers. All register offset addresses not listed in Table 25-8 should be considered as reserved locations and the register contents should not be modified.

**Table 25-8. CAN\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	CAN_CTL	CAN Control Register		<a href="#">Go</a>
4h	CAN_ES	Error and Status Register		<a href="#">Go</a>
8h	CAN_ERRC	Error Counter Register		<a href="#">Go</a>
Ch	CAN_BTR	Bit Timing Register		<a href="#">Go</a>
10h	CAN_INT	Interrupt Register		<a href="#">Go</a>

98h	CAN_NDAT_X	CAN New Data Register		<a href="#">Go</a>
9Ch	CAN_NDAT_21	CAN New Data 2_1 Register		<a href="#">Go</a>
ACh	CAN_IPEN_X	CAN Interrupt Pending Register		<a href="#">Go</a>
B0h	CAN_IPEN_21	CAN Interrupt Pending 2_1 Register		<a href="#">Go</a>
C0h	CAN_MVAL_X	CAN Message Valid Register		<a href="#">Go</a>
C4h	CAN_MVAL_21	CAN Message Valid 2_1 Register		<a href="#">Go</a>
D8h	CAN_IP_MUX21	CAN Interrupt Multiplexer 2_1 Register		<a href="#">Go</a>
100h	CAN_IF1CMD	IF1 Command Register		<a href="#">Go</a>
104h	CAN_IF1MSK	IF1 Mask Register		<a href="#">Go</a>
108h	CAN_IF1ARB	IF1 Arbitration Register		<a href="#">Go</a>
10Ch	CAN_IF1MCTL	IF1 Message Control Register		<a href="#">Go</a>
110h	CAN_IF1DATA	IF1 Data A Register		<a href="#">Go</a>
114h	CAN_IF1DATB	IF1 Data B Register		<a href="#">Go</a>
120h	CAN_IF2CMD	IF2 Command Register		<a href="#">Go</a>
124h	CAN_IF2MSK	IF2 Mask Register		<a href="#">Go</a>
128h	CAN_IF2ARB	IF2 Arbitration Register		<a href="#">Go</a>
12Ch	CAN_IF2MCTL	IF2 Message Control Register		<a href="#">Go</a>
130h	CAN_IF2DATA	IF2 Data A Register		<a href="#">Go</a>
134h	CAN_IF2DATB	IF2 Data B Register		<a href="#">Go</a>
140h	CAN_IF3OBS	IF3 Observation Register		<a href="#">Go</a>
144h	CAN_IF3MSK	IF3 Mask Register		<a href="#">Go</a>
148h	CAN_IF3ARB	IF3 Arbitration Register		<a href="#">Go</a>
14Ch	CAN_IF3MCTL	IF3 Message Control Register		<a href="#">Go</a>
150h	CAN_IF3DATA	IF3 Data A Register		<a href="#">Go</a>
154h	CAN_IF3DATB	IF3 Data B Register		<a href="#">Go</a>
160h	CAN_IF3UPD	IF3 Update Enable Register		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. [Table 25-9](#) shows the codes that are used for access types in this section.

**Table 25-9. CAN\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 25.16.2.1 CAN\_CTL Register (Offset = 0h) [Reset = 00001401h]

CAN\_CTL is shown in [Figure 25-22](#) and described in [Table 25-10](#).

Return to the [Summary Table](#).

This register is used for configuring the CAN module in terms of interrupts, parity, debug-mode behavior etc.

**Figure 25-22. CAN\_CTL Register**

**Table 25-10. CAN\_CTL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
16	INITDBG	R	0h	Debug Mode Status Bit: This bit indicates the internal init state for a debug access 0 Not in debug mode, or debug mode requested but not entered. 1 Debug mode requested and internally entered the CAN module is ready for debug accesses. Reset type: SYSRSn
15	SWR	R-0/W1C	0h	Software Reset Enable Bit: This bit activates the software reset. 0 Normal Operation. 1 Module is forced to reset state. This bit will get cleared automatically one clock cycle after execution of software reset. Note: To execute software reset, the following procedure is necessary: 1. Set INIT bit to shut down CAN communication. 2. Set SWR bit. Note: This bit is write-protected by Init bit. If module is reset using the SWR bit, no user configuration is lost. Only status bits get reset along with logic which needs to be reset for the next CAN transaction. If module is reset using SOFTPRES register, entire module will get reset, including configuration registers. Reset type: SYSRSn
14	RESERVED	R	0h	Reserved
13-10	PMD	R/W	5h	Parity on/off 0101 Parity function disabled Any other value - Parity function enabled Reset type: SYSRSn
9	ABO	R/W	0h	Auto-Bus-On Enable 0 The Auto-Bus-On feature is disabled 1 The Auto-Bus-On feature is enabled Reset type: SYSRSn
8	IDS	R/W	0h	Interruption Debug Support Enable 0 When Debug mode is requested, the CAN module will wait for a started transmission or reception to be completed before entering Debug mode 1 When Debug mode is requested, the CAN module will interrupt any transmission or reception, and enter Debug mode immediately. Reset type: SYSRSn
7	Test	R/W	0h	Test Mode Enable 0 Disable Test Mode (Normal operation) 1 Enable Test Mode Reset type: SYSRSn
6	CCE	R/W	0h	Configuration Change Enable 0 The CPU has no write access to the configuration registers. 1 The CPU has write access to the configuration registers (when Init bit is set). Reset type: SYSRSn
5	DAR	R/W	0h	Disable Automatic Retransmission 0 Automatic Retransmission of 'not successful' messages enabled. 1 Automatic Retransmission disabled. Reset type: SYSRSn
4	RESERVED	R	0h	Reserved
3	EIE	R/W	0h	Error Interrupt Enable 0 Disabled - PER, BOff and EWarn bits cannot generate an interrupt. 1 Enabled - PER, BOff and EWarn bits can generate an interrupt at CANINT0 line and affect the Interrupt Register. Reset type: SYSRSn

**Table 25-10. CAN\_CTL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
2	SIE	R/W	0h	Status Change Interrupt Enable 0 Disabled - RxOk, TxOk and LEC bits cannot generate an interrupt. 1 Enabled - RxOk, TxOk and LEC can generate an interrupt on the CANINT0 line Reset type: SYSRSn
1	IE0	R/W	0h	Interrupt line 0 Enable 0 CANINT0 is disabled. 1 CANINT0 is enabled. Interrupts will assert CANINT0 line to 1 line remains active until pending interrupts are processed. Reset type: SYSRSn
0	Init	R/W	1h	Initialization Mode This bit is used to keep the CAN module inactive during bit timing configuration and message RAM initialization. It is set automatically during a bus off event. Clearing this bit will not shorten the bus recovery time. 0 CAN module processes messages normally 1 CAN module ignores bus activity Reset type: SYSRSn

### 25.16.2.2 CAN\_ES Register (Offset = 4h) [Reset = 0000007h]

CAN\_ES is shown in [Figure 25-23](#) and described in [Table 25-11](#).

Return to the [Summary Table](#).

This register indicates error conditions, if any, of the CAN module. Interrupts are generated by PER, BOff and EWarn bits (if EIE bit in CAN Control Register is set) and by RxOk, TxOk, and LEC bits (if SIE bit in CAN Control Register is set). A change of bit EPass will not generate an Interrupt.

Reading the Error and Status Register clears the PER, RxOk and TxOk bits and sets the LEC to value '7'. Additionally, the Status Interrupt value (0x8000) in the Interrupt Register will be replaced by the next lower priority interrupt value.

For debug support, the auto clear functionality of Error and Status Register (clear of status flags by read) is disabled when in Debug/Suspend mode.

10	RESERVED	R	0h	Reserved
9	RESERVED	R	0h	Reserved
8	PER	R	0h	Parity Error Detected: This bit will be reset after the CPU reads the register. 0 No parity error has been detected since last read access. 1 The parity check mechanism has detected a parity error in the Message RAM. Reset type: SYSRSn
7	BOff	R	0h	Bus-off Status Bit: 0 The CAN module is not in Bus-Off state. 1 The CAN module is in Bus-Off state. Reset type: SYSRSn
6	EWarn	R	0h	Warning State Bit: 0 Both error counters are below the error warning limit of 96. 1 At least one of the error counters has reached the error warning limit of 96. Reset type: SYSRSn
5	EPass	R	0h	Error Passive State 0 On CAN Bus error, the CAN could send active error frames. 1 The CAN Core is in the error passive state as defined in the CAN Specification. Reset type: SYSRSn

**Table 25-11. CAN\_ES Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
4	RxOk	R	0h	<p>Reception status Bit: This bit indicates the status of reception. The bit will be reset after the CPU reads the register.</p> <p>0 No message has been successfully received since the last time when this bit was read by the CPU. This bit is never reset by CAN internal events.</p> <p>1 A message has been successfully received since the last time when this bit was reset by a read access of the CPU. This bit will be set independent of the result of acceptance filtering.</p> <p>Reset type: SYSRSn</p>
3	TxOk	R	0h	<p>Transmission status Bit: This bit indicates the status of transmission. The bit will be reset after the CPU reads the register.</p> <p>0 No message has been successfully transmitted since the last time when this bit was read by the CPU. This bit is never reset by CAN internal events.</p> <p>1 A message has been successfully transmitted (error free and acknowledged by at least one other node) since the last time when this bit was cleared by a read access of the CPU.</p> <p>Reset type: SYSRSn</p>
2-0	LEC	R	7h	<p>Last Error Code</p> <p>The LEC field indicates the type of the last error on the CAN bus. This field will be cleared to '0' when a message has been transferred (reception or transmission) without error. This field will be reset to '7' whenever the CPU reads the register.</p> <p>0 No Error</p> <p>1 Stuff Error: More than five equal bits in a row have been detected in a part of a received message where this is not allowed.</p> <p>2 Form Error: A fixed format part of a received frame has the wrong format.</p> <p>3 Ack Error: The message this CAN Core transmitted was not acknowledged by another node.</p> <p>4 Bit1 Error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value '1'), but the monitored bus value was dominant.</p> <p>5 Bit0 Error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (logical value '0'), but the monitored bus level was recessive. During Bus-Off recovery, this status is set each time a sequence of 11 recessive bits has been monitored. This enables the CPU to monitor the proceeding of the Bus-Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed).</p> <p>6 CRC Error: In a received message, the CRC check sum was incorrect. (CRC received for an incoming message does not match the calculated CRC for the received data).</p> <p>7 No CAN bus event was detected since the last time when CPU has read the Error and Status Register. Any read access to the Error and Status Register re-initializes the LEC to value '7'.</p> <p>Reset type: SYSRSn</p>

### 25.16.2.3 CAN\_ERRC Register (Offset = 8h) [Reset = 0000000h]

CAN\_ERRC is shown in [Figure 25-24](#) and described in [Table 25-12](#).

Return to the [Summary Table](#).

This register reflects the value of the Transmit and Receive error counters

**Figure 25-24. CAN\_ERRC Register**

7-0	TEC	R	0h	Transmit Error Counter Actual state of the Transmit Error Counter. (values from 0 to 255). Reset type: SYSRSn

### 25.16.2.4 CAN\_BTR Register (Offset = Ch) [Reset = 00002301h]

CAN\_BTR is shown in [Figure 25-25](#) and described in [Table 25-13](#).

Return to the [Summary Table](#).

This register is used to configure the bit-timing parameters for the CAN module. This register is only writable if CCE and Init bits in the CAN Control Register are set.

The CAN bit time may be programmed in the range of 8 to 25 time quanta.

The CAN time quantum may be programmed in the range of 1 to 1024 CAN\_CLK periods.

A message interrupt is cleared by clearing the mailbox's IntPnd bit. Among the message interrupts, the mailbox's interrupt priority decreases with increasing message number.</p> <p>Reset type: SYSRSn</p>
15-0	INT0ID	R	0h	<p>Interrupt 0 Cause</p> <p>0x0000 - No interrupt is pending.</p> <p>0x0001 - 0x0020 - Number of message object which caused the interrupt.</p> <p>0x0021 - 0x7FFF - Unused.</p> <p>0x8000 - Error and Status Register value is not 0x07.</p> <p>0x8001 - 0xFFFF - Unused.</p> <p>If several interrupts are pending, the CAN Interrupt Register will point to the pending interrupt with the highest priority.</p> <p>Note: The CANINT0 interrupt line remains active until INT0ID reaches value 0 (the cause of the interrupt is reset) or until IE0 is cleared. The Status Interrupt has the highest priority. Among the message interrupts, the message object's interrupt priority decreases with increasing message number.</p> <p>Reset type: SYSRSn</p>

### 25.16.2.6 CAN\_TEST Register (Offset = 14h) [Reset = 0000000h]

CAN\_TEST is shown in [Figure 25-27](#) and described in [Table 25-15](#).

Return to the [Summary Table](#).

This register is used to configure the various test options supported. For all test modes, the Test bit in CAN Control Register needs to be set to one. If Test bit is set, the RDA, EXL, Tx1, Tx0, LBack and Silent bits are writable. Bit Rx monitors the state of CANRX pin and therefore is only readable. All Test Register functions are disabled when Test bit is cleared.

Note: Setting Tx[1:0] other than '00' will disturb message transfer.

Note: When the internal loop back mode is active (bit LBack is set), bit EXL will be ignored.

### 25.16.2.7 CAN\_PERR Register (Offset = 1Ch) [Reset = 0000XXh]

CAN\_PERR is shown in [Figure 25-28](#) and described in [Table 25-16](#).

Return to the [Summary Table](#).

This register indicates the Word/Mailbox number where a parity error has been detected. If a parity error is detected, the PER flag will be set in the Error and Status Register. This bit is not reset by the parity check mechanism

it must be reset by reading the Error and Status Register. In addition to the PER flag, the Parity Error Code Register will indicate the memory area where the parity error has been detected. If more than one word with a parity error was detected, the highest word number with a parity error will be displayed. After a parity error has been detected, the register will hold the last error code until power is removed.

**Figure 25-28. CAN\_PERR Register**

### 25.16.2.8 CAN\_RAM\_INIT Register (Offset = 40h) [Reset = 0000005h]

CAN\_RAM\_INIT is shown in [Figure 25-29](#) and described in [Table 25-17](#).

Return to the [Summary Table](#).

This register is used to initialize the Mailbox RAM. It clears the entire mailbox RAM, including the MsgVal bits.

**Figure 25-29. CAN\_RAM\_INIT Register**

This function has to be enabled by setting bit ABO in CAN Control Register.</p> <p>The Auto-Bus-On timer is realized by a 32-bit counter which starts to count down to zero when the module goes Bus-Off. The counter will be reloaded with the preload value of the ABO Time register after this phase.</p> <p>NOTE: On write access to the CAN Control register while Auto-Bus-On timer is running, the Auto-Bus-On procedure will be aborted.</p> <p>NOTE: During Debug mode, running Auto-Bus-On timer will be paused.</p> <p>Reset type: SYSRSn</p>

### 25.16.2.13 CAN\_TXRQ\_X Register (Offset = 84h) [Reset = 0000000h]

CAN\_TXRQ\_X is shown in [Figure 25-34](#) and described in [Table 25-22](#).

Return to the [Summary Table](#).

With these bits, the CPU can detect if one or more bits in the CAN Transmission Request 21 Register (CAN\_TXRQ\_21) is set. Each bit in this register represents a group of eight mailboxes. If at least one of the TxRqst bits of these message objects is set, the corresponding bit in this register will be set.

### 25.16.2.14 CAN\_TXRQ\_21 Register (Offset = 88h) [Reset = 0000000h]

CAN\_TXRQ\_21 is shown in [Figure 25-35](#) and described in [Table 25-23](#).

Return to the [Summary Table](#).

This register holds the TxRqst bits of the mailboxes. By reading out these bits, the CPU can check for pending transmission requests. The TxRqst bit in a specific mailbox can be set/reset by the CPU via the IF1/IF2 message interface registers, or by the message handler after reception of a remote frame or after a successful transmission.

**Figure 25-35. CAN\_TXRQ\_21 Register**

### 25.16.2.21 CAN\_IP\_MUX21 Register (Offset = D8h) [Reset = 0000000h]

CAN\_IP\_MUX21 is shown in [Figure 25-42](#) and described in [Table 25-30](#).

Return to the [Summary Table](#).

The IntMux bit determines for each mailbox, which of the two interrupt lines (CANINT0 or CANINT1) will be asserted when the IntPnd bit of that mailbox is set. Both interrupt lines can be globally enabled or disabled by setting or clearing IE0 and IE1 bits in CAN Control Register. This will also affect the INT0ID or INT1ID flags in the Interrupt Register.

**Figure 25-42. CAN\_IP\_MUX21 Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### 25.16.2.22 CAN\_IF1CMD Register (Offset = 100h) [Reset = 0000001h]

CAN\_IF1CMD is shown in [Figure 25-43](#) and described in [Table 25-31](#).

Return to the [Summary Table](#).

The IF1/IF2 Command Registers configure and initiate the transfer between the IF1/IF2 Register sets and the Message RAM. It is configurable which portions of the message object should be transferred. A transfer is started when the CPU writes the message number to bits [7:0] of the IF1/IF2 Command Register. With this write operation, the Busy bit is automatically set to '1' to indicate that a transfer is in progress. After 4 to 14 clock cycles, the transfer between the Interface Register and the Message RAM will be completed and the Busy bit is cleared. The maximum number of cycles is needed when the message transfer coincides with a CAN message transmission, acceptance filtering, or message storage.

If the CPU writes to both IF1/IF2 Command Registers consecutively (request of a second transfer while first transfer is still in progress), the second transfer will start after the first one has been completed. The following points must be borne in mind while writing to this register: (1) Do not write zeros to the whole register. (2) Write to the register in a single 32-bit write or write the upper 16-bits before writing to the lower 16-bits.

Note: While Busy bit is one, IF1/IF2 Register sets are write protected.

Note: For debug support, the auto clear functionality of the IF1/IF2 Command Registers (clear of DMAActive flag by R/W, for devices with DMA support) is disabled during Debug/Suspend mode.

Note: If an invalid Message Number is written to bits [7:0] of the IF1/IF2 Command Register, the Message Handler may access an implemented (valid) message object instead.

### 25.16.2.23 CAN\_IF1MSK Register (Offset = 104h) [Reset = FFFFFFFFh]

CAN\_IF1MSK is shown in [Figure 25-44](#) and described in [Table 25-32](#).

Return to the [Summary Table](#).

The bits of the IF1/IF2 Mask Registers mirror the mask bits of a message object.

Note: While Busy bit of IF1/IF2 Command Register is one, IF1/IF2 Register Set is write-protected.

Note: This bit is write protected by Busy bit. Reset type: SYSRSn

### 25.16.2.24 CAN\_IF1ARB Register (Offset = 108h) [Reset = 0000000h]

CAN\_IF1ARB is shown in [Figure 25-45](#) and described in [Table 25-33](#).

Return to the [Summary Table](#).

The bits of the IF1/IF2 Arbitration Registers mirror the arbitration bits of a message object. The Arbitration bits ID[28:0], Xtd, and Dir are used to define the identifier and type of outgoing messages and (together with the Mask bits Msk[28:0], MXtd, and MDir) for acceptance filtering of incoming messages.

A received message is stored into the valid message object with matching identifier and Direction = receive (Data Frame) or Direction = transmit (Remote Frame).

Extended frames can be stored only in message objects with Xtd = one, standard frames in message objects with Xtd = zero.

If a received message (Data Frame or Remote Frame) matches more than one valid message objects, it is stored into the one with the lowest message number.

Note: While Busy bit of IF1/IF2 Command Register is one, IF1/IF2 Register Set is write-protected.

### 25.16.2.25 CAN\_IF1MCTL Register (Offset = 10Ch) [Reset = 0000000h]

CAN\_IF1MCTL is shown in [Figure 25-46](#) and described in [Table 25-34](#).

Return to the [Summary Table](#).

The bits of the IF1/IF2 Message Control Registers mirror the message control bits of a message object. This register has control/status bits pertaining to interrupts, acceptance mask, remote frames and FIFO option.

3-0	DLC	R/W	0h	Data length code 0-8 Data frame has 0-8 data bytes. 9-15 Data frame has 8 data bytes. Note: The data length code of a message object must be defined the same as in all the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame, it will write the DLC to the value given by the received message. Note: This bit is write protected by Busy bit. Reset type: SYSRSn

### 25.16.2.26 CAN\_IF1DATA Register (Offset = 110h) [Reset = 0000000h]

CAN\_IF1DATA is shown in [Figure 25-47](#) and described in [Table 25-35](#).

Return to the [Summary Table](#).

This register provides a window to the data bytes of the CAN message. The data bytes of CAN messages are stored in the IF1/IF2 registers in the following order. In a CAN Data Frame, Data 0 is the first, and Data 7 is the last byte to be transmitted or received. In CAN's serial bit stream, the MSB of each byte will be transmitted first. All bits in this register are write-protected by the Busy bit.

### 25.16.2.28 CAN\_IF2CMD Register (Offset = 120h) [Reset = 0000001h]

CAN\_IF2CMD is shown in [Figure 25-49](#) and described in [Table 25-37](#).

Return to the [Summary Table](#).

The IF1/IF2 Command Registers configure and initiate the transfer between the IF1/IF2 Register sets and the Message RAM. It is configurable which portions of the message object should be transferred. A transfer is started when the CPU writes the message number to bits [7:0] of the IF1/IF2 Command Register. With this write operation, the Busy bit is automatically set to '1' to indicate that a transfer is in progress. After 4 to 14 clock cycles, the transfer between the Interface Register and the Message RAM will be completed and the Busy bit is cleared. The maximum number of cycles is needed when the message transfer coincides with a CAN message transmission, acceptance filtering, or message storage.

If the CPU writes to both IF1/IF2 Command Registers consecutively (request of a second transfer while first transfer is still in progress), the second transfer will start after the first one has been completed. The following points must be borne in mind while writing to this register: (1) Do not write zeros to the whole register. (2) Write to the register in a single 32-bit write or write the upper 16-bits before writing to the lower 16- bits.

Note: While Busy bit is one, IF1/IF2 Register sets are write protected.

Note: For debug support, the auto clear functionality of the IF1/IF2 Command Registers (clear of DMAActive flag by R/W, for devices with DMA support) is disabled during Debug/Suspend mode.

Note: If an invalid Message Number is written to bits [7:0] of the IF1/IF2 Command Register, the Message Handler may access an implemented (valid) message object instead.

### 25.16.2.29 CAN\_IF2MSK Register (Offset = 124h) [Reset = FFFFFFFFh]

CAN\_IF2MSK is shown in [Figure 25-50](#) and described in [Table 25-38](#).

Return to the [Summary Table](#).

The bits of the IF1/IF2 Mask Registers mirror the mask bits of a message object.

Note: While Busy bit of IF1/IF2 Command Register is one, IF1/IF2 Register Set is write-protected.

**Figure 25-50. CAN\_IF2MSK Register**

### 25.16.2.30 CAN\_IF2ARB Register (Offset = 128h) [Reset = 0000000h]

CAN\_IF2ARB is shown in [Figure 25-51](#) and described in [Table 25-39](#).

Return to the [Summary Table](#).

The bits of the IF1/IF2 Arbitration Registers mirror the arbitration bits of a message object. The Arbitration bits ID[28:0], Xtd, and Dir are used to define the identifier and type of outgoing messages and (together with the Mask bits Msk[28:0], MXtd, and MDir) for acceptance filtering of incoming messages.

A received message is stored into the valid message object with matching identifier and Direction = receive (Data Frame) or Direction = transmit (Remote Frame).

Extended frames can be stored only in message objects with Xtd = one, standard frames in message objects with Xtd = zero.

If a received message (Data Frame or Remote Frame) matches more than one valid message objects, it is stored into the one with the lowest message number.

Note: While Busy bit of IF1/IF2 Command Register is one, IF1/IF2 Register Set is write-protected.

### 25.16.2.31 CAN\_IF2MCTL Register (Offset = 12Ch) [Reset = 0000000h]

CAN\_IF2MCTL is shown in [Figure 25-52](#) and described in [Table 25-40](#).

Return to the [Summary Table](#).

The bits of the IF1/IF2 Message Control Registers mirror the message control bits of a message object. This register has control/status bits pertaining to interrupts, acceptance mask, remote frames and FIFO option.

Note: This bit is used to concatenate multiple message objects to build a FIFO Buffer. For single message objects (not belonging to a FIFO Buffer), this bit must always be set to one. Note: This bit is write protected by Busy bit. Reset type: SYSRSn
6-4	RESERVED	R	0h	Reserved
3-0	DLC	R/W	0h	Data length code 0-8 Data frame has 0-8 data bytes. 9-15 Data frame has 8 data bytes. Note: The data length code of a message object must be defined the same as in all the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame, it will write the DLC to the value given by the received message. Note: This bit is write protected by Busy bit. Reset type: SYSRSn

### 25.16.2.32 CAN\_IF2DATA Register (Offset = 130h) [Reset = 0000000h]

CAN\_IF2DATA is shown in [Figure 25-53](#) and described in [Table 25-41](#).

Return to the [Summary Table](#).

This register provides a window to the data bytes of the CAN message. The data bytes of CAN messages are stored in the IF1/IF2 registers in the following order. In a CAN Data Frame, Data 0 is the first, and Data 7 is the last byte to be transmitted or received. In CAN's serial bit stream, the MSB of each byte will be transmitted first. All bits in this register are write-protected by the Busy bit.

### 25.16.2.34 CAN\_IF3OBS Register (Offset = 140h) [Reset = 0000000h]

CAN\_IF3OBS is shown in [Figure 25-55](#) and described in [Table 25-43](#).

Return to the [Summary Table](#).

The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from Message RAM by CPU.

The observation flags (Bits [4:0]) in the IF3 Observation register are used to determine, which data sections of the IF3 Interface Register set have to be read in order to complete a DMA read cycle. After all marked data sections are read, the DCAN is enabled to update the IF3 Interface Register set with new data.

Any access order of single bytes or half-words is supported. When using byte or half-word accesses, a data section is marked as completed, if all bytes are read.

Note: If IF3 Update Enable is used and no Observation flag is set, the corresponding message objects will be copied to IF3 without activating the DMA request line and without waiting for DMA read accesses.

A write access to this register aborts a pending DMA cycle by resetting the DMA line and enables updating of IF3 Interface Register set with new data. To avoid data inconsistency, the DMA controller should be disabled before reconfiguring IF3 observation register. The status of the current read-cycle can be observed via status flags (Bits [12:8]).

With this, the observation status bits and the IF3Upd bit could be used by the application to realize the notification about new IF3 content in polling or interrupt mode

The Interrupt Identifier in the Interrupt Register will point to this message object if there is no other interrupt source with higher priority. Reset type: SYSRSn
12	UMask	R	0h	Use Acceptance Mask 0 Mask ignored 1 Use Mask (Msk[28:0], MXtd, and MDir) for acceptance filtering If the UMask bit is set to one, the message object's mask bits have to be programmed during initialization of the message object before MsgVal is set to one. Reset type: SYSRSn

**Table 25-46. CAN\_IF3MCTL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
11	TxE	R	0h	Transmit Interrupt Enable 0 IntPnd will not be triggered after the successful transmission of a frame. 1 IntPnd will be triggered after the successful transmission of a frame. Reset type: SYSRSn
10	RxE	R	0h	Receive Interrupt Enable 0 IntPnd will not be triggered after the successful reception of a frame. 1 IntPnd will be triggered after the successful reception of a frame. Reset type: SYSRSn
9	RmtEn	R	0h	Remote Enable 0 At the reception of a remote frame, TxRqst is not changed. 1 At the reception of a remote frame, TxRqst is set. Reset type: SYSRSn
8	TxRqst	R	0h	Transmit Request 0 This message object is not waiting for a transmission. 1 The transmission of this message object is requested and is not yet done. Reset type: SYSRSn
7	EoB	R	0h	End of Block 0 The message object is part of a FIFO Buffer block and is not the last message object of the FIFO Buffer block. 1 The message object is a single message object or the last message object in a FIFO Buffer Block. Note: This bit is used to concatenate multiple message objects to build a FIFO Buffer. For single message objects (not belonging to a FIFO Buffer), this bit must always be set to one. Reset type: SYSRSn
6-4	RESERVED	R	0h	Reserved
3-0	DLC	R	0h	Data length code 0-8 Data frame has 0-8 data bytes. 9-15 Data frame has 8 data bytes. Note: The data length code of a message object must be defined the same as in all the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame, it will write the DLC to the value given by the received message. Reset type: SYSRSn

### 25.16.2.38 CAN\_IF3DATA Register (Offset = 150h) [Reset = 0000000h]

CAN\_IF3DATA is shown in [Figure 25-59](#) and described in [Table 25-47](#).

Return to the [Summary Table](#).

This register provides a window to the data bytes of the CAN message.

**Figure 25-59. CAN\_IF3DATA Register**

### 25.16.2.40 CAN\_IF3UPD Register (Offset = 160h) [Reset = 0000000h]

CAN\_IF3UPD is shown in [Figure 25-61](#) and described in [Table 25-49](#).

Return to the [Summary Table](#).

The automatic update functionality of the IF3 register set can be configured for each message object. A message object is enabled for automatic IF3 update, if the dedicated IF3UpdEn flag is set. This means that an active NewDat flag of this message object (e.g due to reception of a CAN frame) will trigger an automatic copy of the whole message object to IF3 register set. Note: IF3 Update enable should not be set for transmit objects.

**Figure 25-61. CAN\_IF3UPD Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**EtherCAT® Subordinate Device Controller (ESC)**

This chapter describes the implementation and integration of the Ethernet for Control Automation Technology (EtherCAT®) Subordinate Device Controller (ESC). The ESC can be mapped to any CPU subsystem (default access mapped to CPU1 subsystem), and thus any of these subsystems can run the ESC stack and application software to implement an ESC node.

On this device, the CPU1 is the main subsystem. If the intention is to use a different CPU subsystem as the owner of the ESC, then certain ESC subsystem configurations can only be done by the CPU1 during initialization before allocating the ownership of the ESC peripheral to the other CPU subsystem. These details are explained in this chapter.

Information about the EtherCAT standards and working principles can be found these documents:

- EtherCAT ET1100 Data sheet
- EtherCAT ESC Hardware Data sheet (Section I)
- EtherCAT IP Core for Xilinx™ FPGAs

Refer to [Section 26.1.11](#) for details on EtherCAT IP errata provided from Beckhoff® Automation.

## 26.1 Introduction

Ethernet for Control Automation Technology (EtherCAT®) is an Ethernet-based fieldbus system, invented by Beckhoff® Automation and is standardized in IEC 61158. All the SubordinateDevice (or SubDevice) nodes connected to the bus interpret, process, and modify the data addressed to them "on the fly", without having to buffer the frame inside the node. This real-time behavior, frame processing, and forwarding requirements are implemented by the EtherCAT SubDevice controller (ESC) hardware. EtherCAT does not require software interaction for data transmission inside the SubDevices. EtherCAT only defines the MAC layer while the higher layer protocols and stack are implemented in software on the microcontrollers connected to the ESC.

The EtherCAT:

- Involves MainDevice (or MDevice) and SubordinateDevice (SubDevice) setup where SubDevice nodes are physically connected
- Specializes in precise, low jitter synchronization across SubDevice nodes
- Uses IEEE 802.3 Ethernet physical layer and standard Ethernet frames

A list of relevant terms and definitions are listed in [Table 26-1](#).

**Table 26-1. Abbreviations**

Name	Definition
CPU1	Main CPU1 subsystem on this MCU
CPU2	CPU2 subsystem on this MCU
DIGIO	Digital IO profile
ENI	EtherCAT Network Information
ESC	EtherCAT SubordinateDevice Controller
ESCSS or SS	Subsystem (specifically referring to EtherCAT Subsystem on this device)
ESI	EtherCAT SubordinateDevice Information
ET1100	Beckhoff EtherCAT SubordinateDevice controller
ETG	EtherCAT Technical Group
EtherCAT	Ethernet for Control Automation Technology
FMMU	Fieldbus Memory Management Units
HAL	Hardware Abstraction Layer
MII	Medium Independent Interface
NMIWDRS	NMI Watchdog Reset
PDI	Processor Data Interface
POR	Power-on-Reset
SSC	EtherCAT SubordinateDevice Stack Code
SII	SubordinateDevice Information Interface
WDRS	Watchdog Reset
XRS	External Reset

### 26.1.2 ESC Features

The ESC on this MCU provides the following functionality.

- Up to 2 MII ports to connect to EtherCAT PHYs
- Process data interface (PDI) through 16-bit asynchronous interface (ASYN16)
- 64-bit distributed clocking.
  - Sync output signals to synchronize device events and latch input signals supporting time stamping for events.
  - Distributed clock features of SYNC0/1 (o/ps) and LATCH0/1 able to synchronize GPIOs and allow inputs from any GPIOs as well as other muxing options for internal device events.
- 8 Field bus Memory Management Units (FMMUs)
  - Supports all native types of RD/, WR/, RDWR, and built-in features of bit- and byte-addressing
- 8 Sync Managers
- I2C EEPROM interface
- Up-to 32 general-purpose inputs and 32 general-purpose outputs
- 2 SYNC and 2 LATCH signals connected to GPIO pads
- 16KB RAM with parity

### 26.1.3 ESC Subsystem Integrated Features

In addition to the ESC features, the following are the device-specific features provided by the integration of the ESC to the MCU:

- ESC access allocation to either CPU1 subsystem or CPU2 subsystem during initialization
- EtherCAT reset request from MainDevice can be routed to NMI or general interrupt controller on MCU
- RAM Parity error routed to NMI on MCU
- DMA access to EtherCAT RAM
- Up to 32 GPI (general-purpose inputs) and up to 32 GPO (general-purpose outputs) feature integrated in addition to 16-bit ASYNC PDI interface
- Interface to CLB
- I2C internal loopback feature for EEPROM Emulation
- Distributed clock feature of SYNC0 and SYNC1 able to synchronize PWMs, generate interrupt and DMA requests, trigger ECAP capture, or allow external component action through GPIO access
- EtherCAT SYNC0 and SYNC1 pulse can trigger a CLA task
- Distributed clock feature of LATCH0 and LATCH1 allowing inputs from any GPIO or PWM crossbar triggers

### 26.1.4 F28P65x ESC versus Beckhoff ET1100

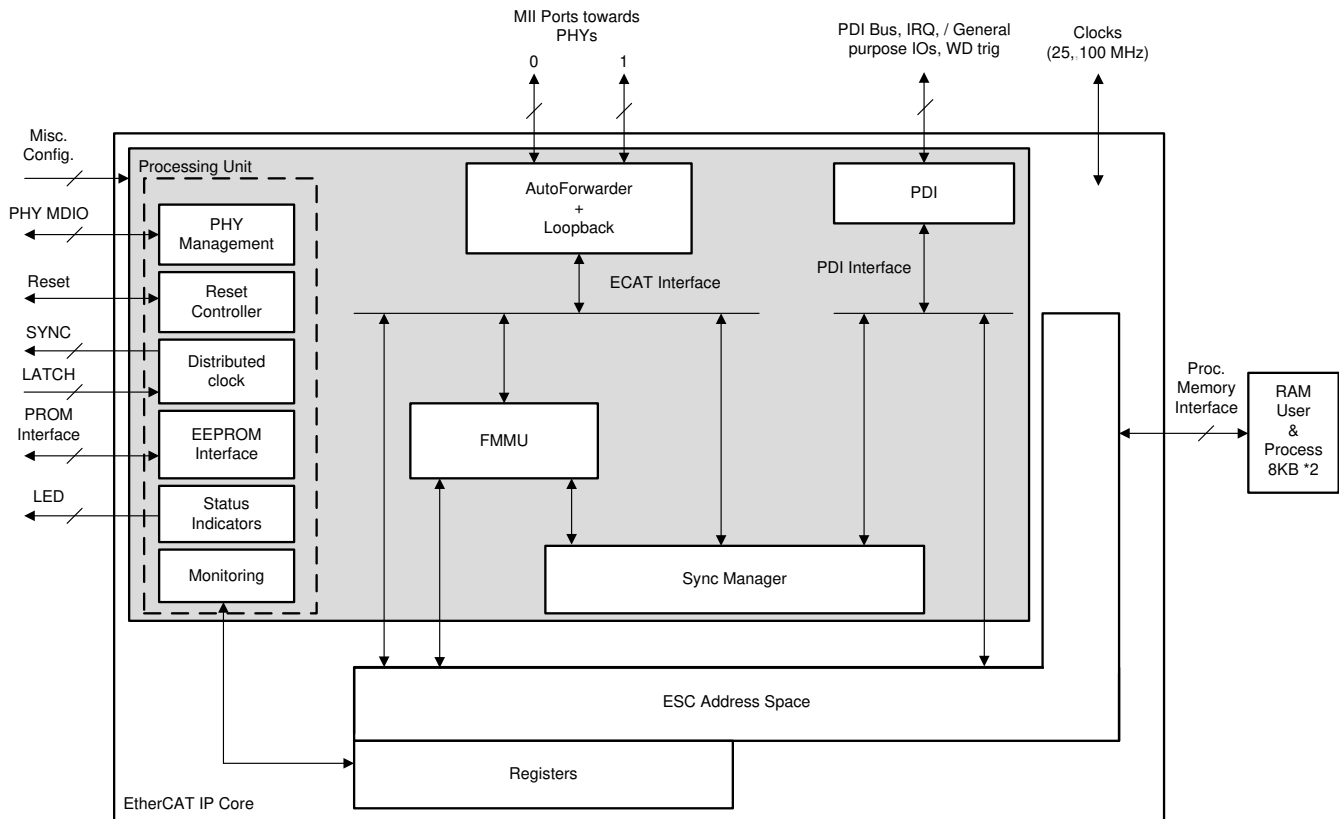

Table 26-2 details a comparison between the F28P65x ESC IP Core implementation and the Beckhoff's ET1100 ESC.

**Table 26-2. F28P65x ESC versus Beckhoff ET1100**

Feature	F28P65x ESC	Beckhoff ET1100
Transmission Speed	100Mbit/s	100Mbit/s
Number of Ports	2 (MII Only)	4 (MII or EBUS)
FMMUs	8	8
SyncManagers	8	8
RAM (KByte)	16KB	8KB
Distributed Clocks	Yes, 64-bit	Yes, 64-bit
EBUS Support	No	Yes
Process Data Interfaces (PDI)	16-bit ASYNC	Digital I/O SPI 8-bit ASYNC/SYNC 16-bit ASYNC/SYNC

### 26.1.5 EtherCAT IP Block Diagram

Figure 26-1 shows the general functionality of etherCAT IP from Beckhoff. This chapter discusses how the etherCAT IP is integrated into the MCU.

**Figure 26-1. EtherCAT IP Block Diagram**

### 26.1.6 ESC Functional Blocks

The following introduces each of the sub-blocks. For more details, refer to the Beckhoff EtherCAT documentation.

#### 26.1.6.1 Interface to EtherCAT MainDevice

The EtherCAT MainDevice is a remote entity normally implemented through the device with ethernet switch capability. Beckhoff suggests using either a standard ethernet physical layer interface through MII or RMII protocol, or using a low-voltage differential pair signaling with EBUS protocol. Per Beckhoff specification, up to 4 PHY ports can be supported. In this MCU, implementation of ESC:

- Only MII is supported for Ethernet PHY interface
- ESC supports only 2 PHY ports

#### 26.1.6.2 Process Data Interface

Process data interface (PDI) is a connection from the ESC IP to the microcontroller and SubordinateDevice application. The implementation of the ESC on this MCU supports a 16-bit asynchronous interface (ASYNC16) to the local host only

#### 26.1.6.3 General-Purpose Inputs and Outputs

Since this MCU does not support digital I/O PDI interface, the ESC supports general-purpose I/O that allows 32 GPI and 32 GPO signals. These EtherCAT GPI/GPOs can be programmed to be either driven by (or drive) device I/O pins or be driven by (or drive) the same I/O pins after qualifying them using internal events. Refer to [Section 26.2.9](#) for more details.

#### 26.1.6.4 EtherCAT Processing Unit (EPU)

The EtherCAT Processing Unit (EPU) receives, analyzes, and processes the EtherCAT data stream. The EPU is logically located between port 0 and port 1. The main purpose of the EPU is to enable and coordinate access to the internal registers and the memory space of the ESC, which can be addressed both from the EtherCAT MainDevice and from the local application by way of the Processor Data Interface (PDI). Data exchange between the MainDevice and SubordinateDevice application is comparable to a dual-ported memory (process memory), enhanced by special functions; for example, for consistency checking (SyncManager) and data mapping (FMMU). The EPU contains the main function blocks of the EtherCAT SubordinateDevices besides Auto-Forwarding, Loop-back function, and PDI.

- **Auto-Forwarder:**
  - The Auto-forwarder function includes receiving EtherCAT frame, checksum computation and verification, timestamp capture for received frames, and forwarding to Loop-back component.
- **Loop-back Function:**
  - For the two-port implementation on this device, port 3 and port 2 are looped back by design, as shown in [Figure 26-2](#).
  - Port 0 is a special port that is always connected to the MainDevice while designing the topology. At egress, port 0 acts as a terminal point for the network connected downstream; hence, any circulating packets get dropped at port 0 in the event of port 0 being looped-back.
  - In the event of a network or link loss downstream to the ESC port 1, the packets end in loopback.

**Figure 26-2. Two-port ESC Description**

**Figure 26-3. Two-port Block Diagram in EtherCAT Topology**

#### 26.1.6.5 Fieldbus Memory Management Unit (FMMU)

The fieldbus memory management unit (FMMU) maps the logical addresses of the memory elements in ESC to a physical address that allows the remote EtherCAT MainDevice to address registers and process RAM as one memory-map that can be accessed across the EtherCAT network. Mapping can be done up-to bit-wise mapping.

#### 26.1.6.6 Sync Manager

The integrity and security of the data in dual-port memory across the MainDevice and local application is maintained by the sync manager. The sync manager allows data to be accessed as buffered or mailbox, where either there is definite read and write space or sequence defined for both of the MainDevice entities.

#### 26.1.6.7 Monitoring

The monitoring unit contains error counters and watchdogs. The watchdogs are used for observing communication and returning to a safe state in case of an error. Error counters are used for error detection and analysis.

#### 26.1.6.8 Reset Controller

The reset controller aggregates the internal/external resets as well as asserts the reset to external pin, which can be connected to device pin to reset companion devices on the board.

### 26.1.6.9 PHY Management

The PHY control is maintained through the MDIO interface which allows the configuration of the PHYs and enabling advanced features of link detection, if present, be enabled.

### 26.1.6.10 Distributed Clock (DC)

Distributed clocks (DC) allows the tracked time at ESC be synchronized across the EtherCAT network, which makes precisely timed events possible throughout the network. Events can be realized with triggers from ESC outputs that are programmed to create a toggle at a certain absolute time tracked by the ESC or through sampling of timestamp of certain system event inputs to ESC that can further be used for synchronizing the time.

- Refer to [Section 26.2.10](#) for more details.

### 26.1.6.11 EEPROM

Every ESC requires non-volatile memory to store the configuration contents of the ESI (EtherCAT SubordinateDevice Information) that are accessed by the MainDevice normally before enabling the ESC in the network. Size of the memory is configurable with a minimum of 1K bit up to 4M bit are supported depending on the ESC. This non-volatile memory is supported in simplest form by the ESC IP core as serial access EEPROM.

- For ESI EEPROM Layout and mandatory information, refer to the ESC Hardware Data Sheet Section I - Technology (ethercat\_esc\_datasheet\_sec1\_technology) document provided by Beckhoff/ETG at [www.beckhoff.com](http://www.beckhoff.com).
- EEPROM is supported using the I2C interface on this device and is further explained in [Section 26.2.8](#).

### 26.1.6.12 Status / LEDs

ESC supports the status indication of application activity, link status and link errors which can be utilized for visual status indication through LEDs.

### 26.1.7 EtherCAT Physical Layer

ESC devices with Ethernet Physical Layer are able to support MII interfaces, RMI interfaces, and EBUS interfaces. Since RMI PHYs include TX FIFOs, the RMI PHYs increase the packet forwarding delay of an ESC device as well as the jitter. RMI as an Ethernet Physical Layer is not supported on this device due to these reasons and therefore only the MII interface is supported.

- On this device, only MII is supported (RMI and EBUS are not supported)
- Refer to the **ESC Application Note - PHY Selection Guide (an\_phy\_selection\_guide)** provided by Beckhoff/ETG at [www.beckhoff.com](http://www.beckhoff.com) for additional PHY selection details.

Table 26-3 depicts the number of pins needed for MII interface for two ports.

**Table 26-3. EtherCAT Physical Layer Signals**

Pin	Number of Pins for 2 Ports	MII	Direction	Description
nMII_Link	2	Yes	IN	Input signal provided by the PHY, if a 100Mbps (full duplex) link is established
RX_CLK	2	Yes	IN	Receive Clock
RX_DV	2	Yes	IN	Receive Data valid
RX_DATA[1:0]	4	Yes	IN	Receive Data
RX_DATA[3:2]	4	Yes	IN	Receive Data
RX_ERR	2	Yes	IN	Receive error
TX_CLK <sup>(1)</sup>	2	Optional	IN	Transmit Clock
TX_ENA	2	Yes	OUT	Transmit Enable
TX_DATA[1:0]	4	Yes	OUT	Transmit Data
TX_DATA[3:2]	4	Yes	OUT	Transmit Data
MCLK	1	Yes	OUT	MII Interface clock
MDIO	1	Yes	BI-Directional	MII Interface Data
<b>Total Pins:</b>	28 (required) + 2 (optional)			

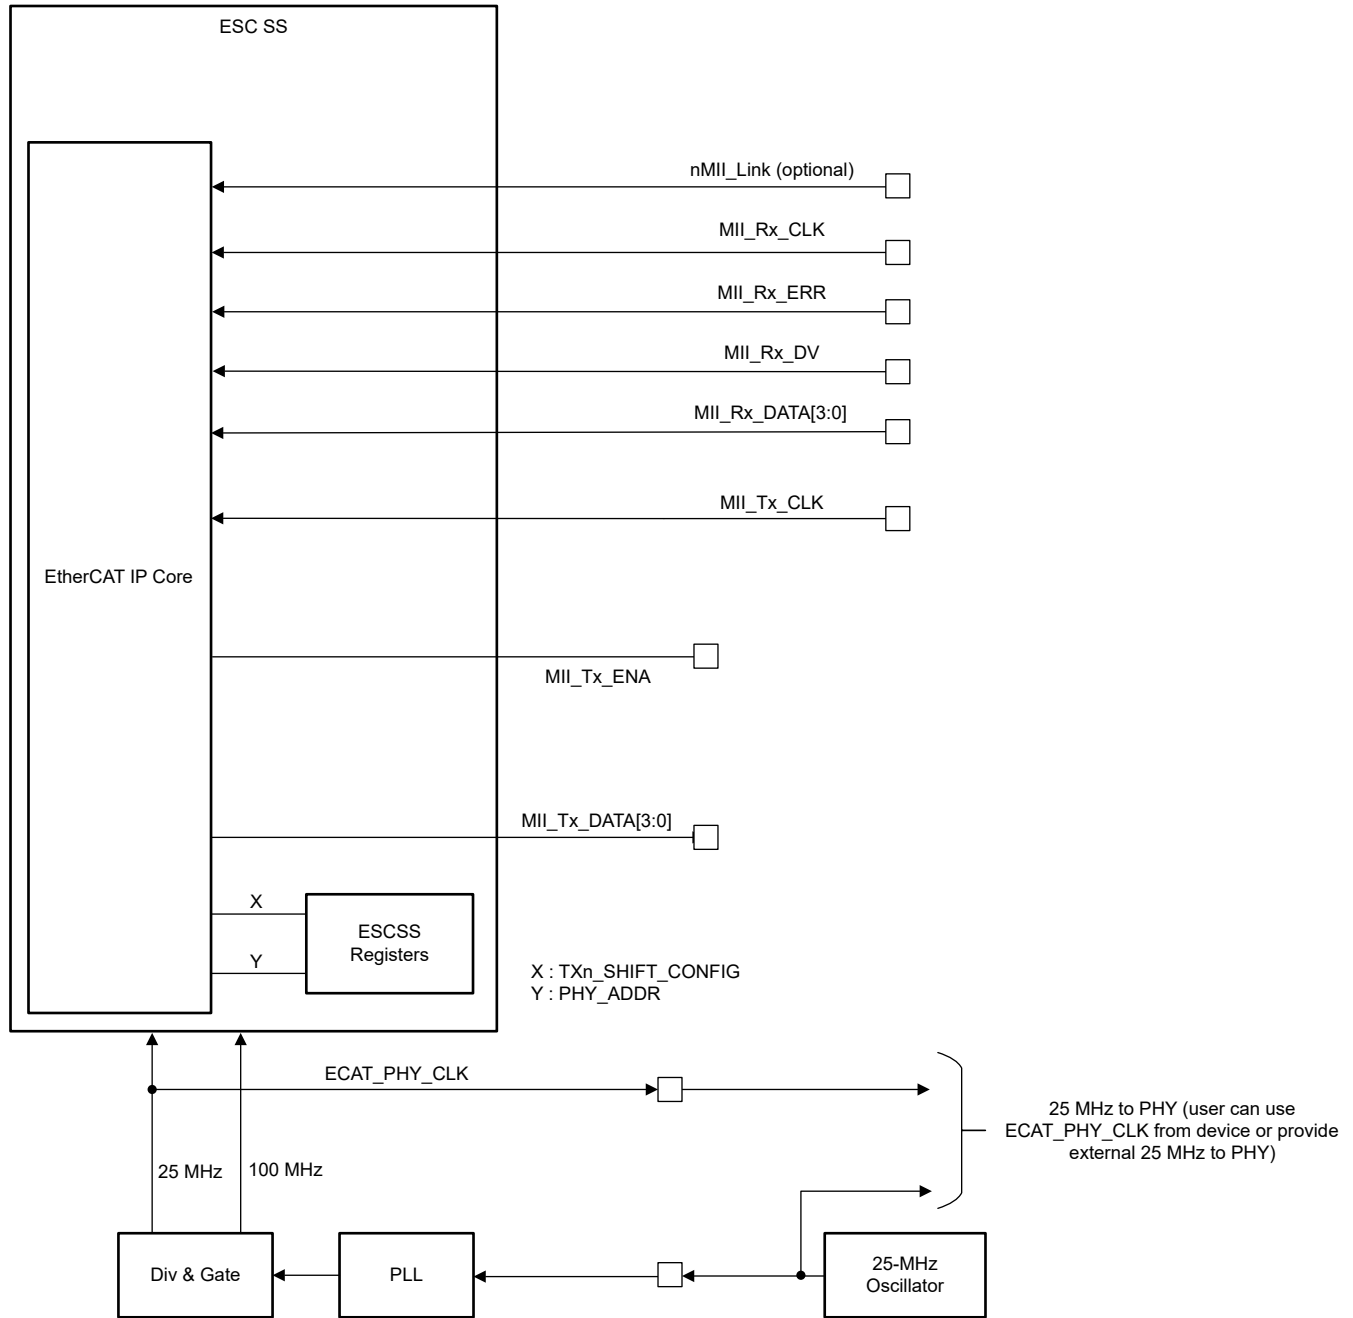

- (1) The TX\_CLK signal is optional when using the TX\_SHIFT register for manual compensation; however, it is recommended to route the TX\_CLK signals to the MII ports for improved accuracy and to avoid the need for manual compensation.

#### 26.1.7.1 MII Interface

Ethernet IEEE802.3 specified MII interface is supported with possible minor variation in clocking to optimize the clock delay to operate the Tx FIFO. Unlike regular integration of Tx clock being sourced by the PHY, the ESC implementation allows the common source clock between PHY and ESC be used for Tx logic. The option is selected by manual Tx shift compensation which allows Tx-Data and Tx-En be compensated in steps of 10 ns to meet the timing requirements of data sampling at the PHY.

The following signals are used by the ESC to connect to an Ethernet PHY. The MDIO pins are not shown in Figure 26-4, as these pins are covered in the next section.

The MII signals TX\_ERR, COL and CRS are not used by the ESC. These are not available on the MCU for EtherCAT.

Note: The PHY reset signal is also not shown in the diagram.

**Figure 26-4. ESC PHY Interface Diagram**

If an ESC MII interface is not used, LINK\_MII has to be tied to the logic value high that indicates no link. RX\_CLK, RXD, RX\_ER, and especially RX\_DV are connected to GND and this is taken care of by design internally when the functional IO mux for the RX pins is not configured when the IP is out of reset. The TX outputs can be left unconnected, by not configuring the Functional IO mux for respective EtherCAT functionality, unless the TX outputs are used for ESC configuration.

### 26.1.7.2 PHY Management Interface

Most ESCs with MII/RMII ports use the MII management interface for communication with the Ethernet PHYs. Most ESCs do not use the management interface for link detection or configuration of link modes. For link detection, it is recommended that the ESC use a separate signal (LINK\_MII). The MII management interface can be used by the EtherCAT MainDevice – or the local MCU. Enhanced MII link detection uses the management interface for restarting auto-negotiation after communication errors occurred.

On this ESC, it is possible to make use of the MII management interface for link detection and PHY configuration.

#### Note

Note that the EtherCAT link status through the MII management interface option must be enabled only if a Gigabit PHY is to be supported; the EtherCAT link must not be enabled if needing to support both 10/100 and Gigabit PHY. For this reason, the link status through the MII management interface is disabled on this ESC. Instead, use the LINKACT or PHY MII\_LINK signals for link status purposes.

Note: The MDIO must have a pull-up resistor (4.7 kOhm recommended) externally. MCLK is driven rail-to-rail, idle value is high.

**Figure 26-5. PHY Management Interface Connectivity**

#### 26.1.7.2.1 PHY Address Configuration

The ESC typically addresses the Ethernet PHYs using the logical port number plus the PHY address offset. The Ethernet PHY addresses must correspond with the logical port number, so PHY addresses 0 and 1 are used.

A PHY address offset of 0 to 31 can be applied, which moves the PHY addresses to any consecutive address range. The ESC module expects logical port 0 to have PHY address 0 plus the PHY address offset. The PHY address offset can be selected in register ESCSS\_MISC\_CONFIG.PHY\_ADDR[4:0].

#### 26.1.7.2.2 PHY Reset Signal

The PHY reset signal is generated out of the ESC module. If required to release both, the PHY and ESC module synchronous out of reset, this signal can be used. Since there are no pull devices active on the MCU during and after reset, a pull down resistor must be added on this signal on the board level.

In some case, PHYs can be released from reset after releasing the ESC module. To generate a delay, the pin for nPHY\_RESET can be used as an I/O and must be switched later to the alternate output function.

### 26.1.7.2.3 PHY Clock

The PHY Clock connectivity is shown in [Figure 26-4](#). On this MCU, the user has an option to clock the PHY using the ESCSS\_PHY\_CLK signal if needed; otherwise, the user can choose to provide an external 25MHz source to the PHY and ESC (both must be clocked from the same source). For more details regarding providing PHY clock, refer to [Section 26.2.6.2](#) and see the EtherCAT data sheet from Beckhoff.

---

#### Note

Beckhoff documents strict accuracy (ppm) requirements for the shared 25MHz ESC and PHY clock. Special care must be taken within a design to make sure the EtherCAT clocking requirements are met. Relying on external components (oscillator and clock buffer) for the 25MHz source are recommended. Validation of a design during normal operating conditions can be necessary to confirm clocking requirements are adequately met, especially if using the ESCSS\_PHY\_CLK signal.

---

### 26.1.8 EtherCAT Protocol

EtherCAT uses standard IEEE 802.3 Ethernet frames, thus a standard network controller can be used and no special hardware is required on the MainDevice side. EtherCAT has a reserved EtherType of 0x88A4 that distinguishes this from other Ethernet frames. Thus, EtherCAT can run in parallel to other Ethernet protocols.

- EtherCAT does not need the IP protocol; however, the EtherCAT can be encapsulated in IP/UDP.
- The ESC processes the frame in hardware; therefore, communication performance is independent from processor power.

An EtherCAT frame is subdivided into the EtherCAT frame header followed by one or more EtherCAT datagrams. At least one EtherCAT datagram has to be in the frame. Only EtherCAT frames with Type 1 in the EtherCAT Header are currently processed by the ESCs. The ESCs also support IEEE802.1Q VLAN Tags, although the VLAN Tag contents are not evaluated by the ESC.

- If the minimum Ethernet frame size requirement is not fulfilled, padding bytes are added. Otherwise, the EtherCAT frame is exactly as large as the sum of all EtherCAT datagrams plus EtherCAT frame header.
- For further reading, including details on network time or network propagation delay, refer to the ESC Hardware Data Sheet Section I - Technology (ethercat\_esc\_datasheet\_sec1\_technology) document provided by Beckhoff/ETG at [www.beckhoff.com](http://www.beckhoff.com).

### 26.1.9 EtherCAT State Machine (ESM)

The EtherCAT State Machine (ESM) is responsible for the coordination of the MainDevice and SubordinateDevice applications at start up and during operation. State changes are typically initiated by requests from the MainDevice. The state changes are acknowledged by the local application after the associated operations have been executed. Unsolicited state changes of the local application are also possible.

There are four states (see [Figure 26-6](#)) an ESC can support, plus one optional state:

- Initialize (Init)
- Pre-Operational
- Safe-Operational
- Operational
- Bootstrap (Optional)

**Figure 26-6. EtherCAT State Machine**
**Note**

Not all state changes are possible, for example, the transition from Init to Operational requires the following sequence: Init → Pre-Operational → Safe-Operational → Operational.

**26.1.10 More Information on EtherCAT**

- For further information on EtherCAT, refer to the EtherCAT specifications, available from the EtherCAT Technology Group (ETG, [www.ethercat.org](http://www.ethercat.org)).
- Refer to the IEC standard “Digital data communications for measurement and control – Fieldbus for use in industrial control systems”, IEC 61158 Type 12: EtherCAT, available from the IEC ([www.iec.ch](http://www.iec.ch)).
- Documentation on Beckhoff Automation ESC are available at the Beckhoff website ([www.beckhoff.com](http://www.beckhoff.com)), for example, data sheets, application notes, and ASIC pinout configuration tools.

**26.1.11 Beckhoff® Automation EtherCAT IP Errata**

Table 26-4 details the Beckhoff®Automation errata of the EtherCAT IP integrated onto this device.

**Table 26-4. EtherCAT IP Errata**

Errata Number	Description
ER#156	WKC increment for reading reserved FMMU registers (+0xD-+0xF)
ER#158	WKC increment for writing 0x0914-0x0917
ER#162	ESC DL Control (0x0101) loop setting Auto-Close (01): if port waits for write access to be opened, the temporary loop bit (0x0100[1]) is not taken into account when a write command to ESC DL Control occurs.
ER#164	EEPROM FSM cannot accept another command within 1680 ns after finishing a previous command
ER#165	EtherCAT reset register 0x0040 cannot be written using VLAN tagged frames, because state is reset due to double ECAT_CLEAR. VLAN tagged frames are rarely used for EtherCAT.
ER#168	Changing SyncSignal cycle times during activation can lead to extremely long cycle times, resulting from (intermediate) violation of the minimum delay between two consecutive pulses. For example, changing Sync1 from a few ns before Sync0 to a few ns after Sync0 results in a missed Sync1 time, which can take up to several 32/64-bit turn-arounds until the next pulse occurs. Changing cycle time from PDI can result in usage of intermediate, inconsistent values, which can result in unwanted cycle times or extremely long delays as above.

**26.2 ESC and ESCSS Description**

This section details the aspects of the ESC integration in the MCU. On this MCU, the ESC is integrated such that the ESC is accessed by either the CPU1 (main) subsystem or the CPU2 subsystem. The MCU with the ESC functions as an EtherCAT SubordinateDevice device.

Figure 26-7 shows the ESC on this MCU.

Figure 26-7. ESC Integration on MCU

**Table 26-5. ESC Integration Figure Sections**

Inputs Outputs	<a href="#">General Purpose Inputs and Outputs</a>
Physical Layer	<a href="#">EtherCAT Physical Layer</a>
EEPROM	<a href="#">SubordinateDevice Node Configuration and EEPROM</a>

There are various actions that the controlling processor (CPU1/CPU2) needs to perform in response to actions initiated by the EtherCAT MainDevice meant for this particular SubordinateDevice . All these interactions take place through one of the following:

- The 16-bit asynchronous interface through which registers and RAM of the EtherCAT IP are read/written.
- An interrupt request going from the ESC to the Local Host (CPU1 or CPU2).
- SYNC0 and SYNC1 pulses generated by the ESC that are used as triggers for initiating further action.
- LATCH0 and LATCH1 that are sampled by the ESC.
- EtherCAT general-purpose inputs and outputs.

### 26.2.1 ESC RAM Parity and Memory Address Maps

This section details the ESC RAM parity logic, CPU1 ESC memory address map, and CPU2 ESC memory address map.

#### 26.2.1.1 ESC RAM Parity Logic

The ESC RAM has parity logic to make sure the data integrity of the contents. The byte-wide parity is implemented, as PDI accesses to RAM can be done byte wide. To make sure that errors in parity logic itself do not mask the memory error, redundant parity generation logic is used. The parity generated by both logics is compared to make sure safe operation of the memory accesses. Use the INITIATE\_MEM\_INIT bit from the ESCSS register to trigger the memory initialization.

#### 26.2.1.2 CPU1 and CPU2 ESC Memory Address Map

When the ESC is allocated to CPU1 and CPU2, [Table 26-6](#) is the memory-map and associated details.

**Table 26-6. ESC Address Map on CPU1/CPU2**

Memory-Map Region	Memory Region	Accessed Through	Parity Scheme	DMA Access	CLA Access	Security	Access/Bus
DPRAM memory-map (16KB)	0x0005 0800 - 0x0005 27FF	PDI interface of ESC	1 parity bit for 8 bits of data	Yes	No	No	Async
ESC registers	0x0005 0000 - 0x0005 07FF	PDI interface of ESC	No	No	No	No	Async
ESCSS registers <sup>(1)</sup>	0x0005 7E00 - 0x0005 7FFF	Direct access	No	No	No	No	VBUS32

(1) When register access protection is enabled, all write accesses are blocked; however, a violation interrupt is not generated in the event of an attempted write access.

### 26.2.2 Local Host Communication

Figure 26-8 shows how the ESC and ESC subsystem connects to the local host subsystem. The local host subsystem can include the CPU (CPU1 or CPU2) of the device and the DMA engine as the bus controller accessing the ESC. This local host subsystem is acting upon the commands that are sent by the EtherCAT MainDevice in the form of EtherCAT datagrams.

The 16-bit asynchronous interface and the interrupt request line are the main channels through which the local host subsystem interacts with the ESC. The interrupt request line can be used to trigger actions based on ESC internal events, exception conditions or time synchronized events. The DMA engine is used to transfer the contents from the process data memory to system RAM on any of these events. The user application needs to select the events that act as interrupts or DMA requests. The mask and clear events for the interrupt causes are configured to be accessed by the CPU/Co-processor that is controlling the ESC.

Figure 26-8. Interaction of ESCSS with the CPU Subsystem

### 26.2.2.1 Byte Accessibility Through PDI

The ESC has a few registers which need byte wide access to affect the functionality. The EtherCAT implementation on this MCU is as follows:

- CPU1 and CPU2 support 16-bit accesses only
- 

### 26.2.2.2 Software Details for Operation Across Clock Domains

The registers accessible from the CPU are in the system clock domain and are synchronized to the PDI clock before being used within the EtherCAT IP. Given the frequency ratios and different styles of synchronization schemes, the application needs to assume there is a delay in getting the values transferred from one domain to other. Such a delay can vary based on the frequency of system clock and type of synchronizer used in the path.

For example, a system clock of 200MHz and ESCSS running at 100MHz requires at least 10 clock-system clock cycles delay before values are affected on the other side. If a write occurs to the PDI and some other action is performed elsewhere (not involving the PDI), then the software must perform a simple read to make sure that the write is complete.

### 26.2.3 Debug Emulation Mode Operation

There are two aspects of the EtherCAT IP operation that need to be considered from a debug emulation stand point.

- **CPU Halted Condition:**
  - **CPU1:** For any operation from the EtherCAT IP that is based off an interrupt request, it is quite important that this interrupt is marked as a real-time interrupt and the debugger must be halted in RealTime mode. If the CPU is halted without taking the above precaution, then the EtherCAT IP can only be active for those parts where servicing the interrupt is not required (For example, GPIO and SYNC0/1 output triggers can all function unaffected).
  - **CPU2** Does not apply. CPU2 does not have real-time debug and remains in halt mode until released by the run command, regardless of interrupt request assertions.
- **Debugger Writes/Reads of EtherCAT IP registers/memories Condition:** The EtherCAT IP does not have any mechanism to identify a debug initiated read/write. Debug accesses to the registers or the ESC RAM can affect the state of the EtherCAT IP. This is addressed by the following:
  - **CPU1/CPU2:** The ENABLE\_DEBUG\_ACCESS bit must be set in the ESCSS Access Control Register to enable user access to the ESC RAM and EtherCAT registers for the purpose of debug. By default, this is disabled.

### 26.2.4 ESC SubSystem

The EtherCAT SubordinateDevice Controller SubSystem (ESCSS) wraps the ESC core with required register configurations and required logic for different functions of the EtherCAT and RAM (ESC RAM). This section covers the ESCSS integration aspects. [Figure 26-9](#) shows the EtherCAT subsystem integration.

- **ESCSS configuration registers interface** is the port for accessing the critical device level configurations which are a must have for the ESCSS to function.
- **ESCSS register interface** has control and status registers including SYNC, LATCH configurations, interrupt related controls, and GPIO related controls.
- **PDI Async interface** is a 16-bit wide data interface that allows the local application to access the registers internal to the EtherCAT IP Core as well as the dual-port memory (ESC RAM) through the SyncManager and the FMMUs.

Figure 26-9. ESCSS Wrapper

#### 26.2.4.1 CPU1 Bus Interface

Interface to the CPU1 core is retained at the ESCSS boundary as a native mem32 interface that connects the RD and WR ports independently to all of the SubordinateDevice entities within the ESCSS.

- CPU1 MEM32 RD and WR ports: Configuration Registers, Control/Status Registers, PDI
- CPU1 DMA MEM32 RD and WR ports: PDI (access to ESC RAM only)

#### 26.2.4.2 CPU2 Bus Interface

The CPU2 interface involves a bus that is arbitrated between the CPU2 and DMA accesses to the PDI .

- CPU2 bus ports: Configuration Registers, Control/Status Registers, PDI
- DMA ports: PDI (access to ESC RAM only)

## 26.2.5 Interrupts and Interrupt Mapping

The ESC has one interrupt line that can be connected to the local host (CPU1 or CPU2) that is called PDI IRQ from the ESC. Besides this, there are other interrupt causes generated within the ESCSS. These are aggregated to a total of 4 interrupt lines that are connected to the local host core.

**Table 26-7** summarizes these exceptions and the mapping. There are 4 interrupt lines provided for ESCSS which are: ECATSS\_Intr, RESET\_OUT\_Intr, SYNC0\_Intr and SYNC1\_Intr. Each of these causes have an independent set of mask/clear/set controls and raw/masked interrupt status flags. This allows independent cause servicing on the exception event with flexibility to mask or service the desired set of causes. All these interrupts are mapped onto PIE on CPU1 and CPU2. Refer to the *System Control and Interrupts* chapter for details on the interrupt numbers.

In the event that the same exception is available to the multiple bus MainDevice cores of the local host CPU, the application software is expected to make sure that clearing of the RIS is a software synchronized event between those MainDevices and there is no stale exceptions pending for one controller while the other clears the RIS. In other words, there is no separate exception cause (RIS/MIS) copy per MainDevice but are common interrupt registers for the local host across MainDevices.

**Table 26-7. Service Request Generation Map**

Source	Description	MainDevice				
		CPU1	CLA	CPU1 DMA	CPU2	DMA
EtherCAT IRQ	AL Event Request of the ESC	ECATSS_ intr	ECATSS_ intr	Not Available	ECATSS_ intr	Not Available
PDI Interface Timeout Error	PDI Interface WatchDog timeout error	ECATSS_ intr	ECATSS_ intr	Not Available	ECATSS_ intr	Not Available
EtherCAT RESET_OUT Event	RESET_OUT can be programmed as interrupt to the CPU to either complete the reset sequence with required pre-steps if an or acknowledge the reset request in some other way. Given the high priority nature of the signal independent interrupt line is allocated	RESET_OUT_Intr	RESET_OUT_Intr	Not Available	RESET_OUT_Intr	Not Available
SYNC0 Event	Precise time event 2, can be used to start routine SYNC1_Intron cores or data transfer using DMA. Given the precise time and priority of these interrupts a separate interrupt line is dedicated.	SYNC0_Intr	SYNC0_Intr	SYNC_DMAReq	SYNC0_Intr	SYNC_DMAReq
SYNC1 Event	Precise time event 1, can be used to start routine on cores or data transfer using DMA. Given the precise time and priority of these interrupts a separate interrupt line is dedicated.	SYNC1_Intr	SYNC1_Intr	SYNC_DMAReq	SYNC1_Intr	SYNC_DMAReq

## 26.2.6 Power, Clocks, and Resets

This section details the ESCSS power requirements, clocking, and resets. The EtherCAT IP has 2 clock ports and one reset output. Since the PLLs, dividers, and gating is implemented as part of system control, this setup is always handled by CPU1 during the initialization sequence.

### 26.2.6.1 Power

The ESC module is inside the main power domain like other peripherals and there are no special considerations about the power-up or power-down sequences that need to be taken. Refer to the *System Control and Interrupts* chapter for different power modes.

### 26.2.6.2 Clocking

Two functional clock inputs are defined for the ESC: CLK25 (25MHz) and CLK100 (100MHz).

EtherCAT functional clock inputs CLK25 and CLK100 are sourced by the MCU clocking module either using SYSPLL or AUXPLL. At the SoC level, you have multiple options to choose from regarding what inputs are used for the SYSPLL or AUXPLL.

- Due to the 25ppm requirement for EtherCAT, an external oscillator of 25MHz is suggested to be used as the main clock source.
- A less accurate clock than 25ppm limits the ability of the ESC to act as the network reference clock. For practical reasons, clock accuracy must be the same or better than the Ethernet clock source that is 50ppm.

#### Note

- CLK25 and CLK100 are used for the ESC core operation. These two clocks and the clocks to the PHY **must have a common source**, which establishes a deterministic phase relationship between PHY clocks and ESC clocks.
- In MII mode, the 25MHz RX clock is sourced by the PHY while the TX clock from the PHY is optional (which effectively saves a pin). The phase differential between the PHY TX clock and CLK25 can be compensated to the TX data and TX EN using the manual compensation mode in increments of 10ns. Connecting the TX clock avoids the need to perform the manual compensation.

Figure 26-10 shows the clocks connectivity. Refer to the *System Control and Interrupts* chapter for additional details of the PLL source selections and clock dividers.

Figure 26-10. Clocking of ESC

In the case of a low-accuracy clock (up to 100ppm) being used, a clock accuracy of 25ppm cannot be feasible, then the following restrictions apply:

- RX FIFO size cannot be reduced lower than 7 (default for 100ppm), which in turn affects the latency of the transfer as the transfer starts after half of the FIFO full threshold, thus resulting in a RX Delay.
- This ECS cannot be used as the first SubordinateDevice from the MainDevice in the network, as typically the first SubordinateDevice from the MainDevice is treated as the reference clock for the distributed clocks functionality.
- The number of iterations required for synchronizing clocks (specially the drift computation) increases.

### 26.2.6.3 Resets

This section describes the ESCSS sources of reset. There are other conditional reset sources that can impact ESCSS and those include all the device level reset sources including: device pin reset “XRSN” or software initiated device level reset “SYSRSn”.

---

#### Note

Whenever the device comes out of reset, software must execute the following sequence to make sure that PHY can see the full stretching of the reset:

1. Configure the EtherCAT GPIOs
2. Put the ESCSS into soft reset
3. Bring the ESCSS out of soft reset

Refer to [Section 26.3](#) more information on proper software procedure.

---

#### 26.2.6.3.1 Chip-Level Reset

Chip-level resets (such as POR, XRS, WDRS, or NMIWDRS) are a MainDevice reset that resets the entire device including the ESC.

#### 26.2.6.3.2 EtherCAT Soft Resets

ESSCS can be reset by three soft reset mechanisms, including:

- System control level software programmable (SOFTPRES23) that is reset only by chip-level and EtherCAT resets. Default keeps the ESC in reset that is released by the local application after setting the ESC ready for operation.
- Reset by a particular command sequence from the remote EtherCAT MainDevice.
- Reset by a particular command sequence from the local host application. (CPU2 core only)

#### 26.2.6.3.3 Reset Out (RESET\_OUT)

Multiple reset sources of ESCSS are combined to make the reset vector that drives the EtherCAT and companion devices (PHYs) on this MCU. The RESET\_OUT is asserted only when configured to be a reset. If configured as an interrupt or NMI, the local host completes the reset.

By default, RESET\_OUT performs no action and must be setup to cause the reset to the EtherCAT core and PHY. The input events to RESET\_OUT include the remote EtherCAT MainDevice, local host application, and EtherCAT soft reset.

When the intent is to perform a reset to the ESCSS and the device, the following options are available to reset the device after software has given a reset to the ESCSS:

- Use the system control SIMRESET register to generate a device reset.
- Use the watchdog or NMIWD to generate a device reset.

### 26.2.7 LED Controls

There are four LED outputs from the ESC that can be routed out of GPIO to indicate different status of the ESC. [Table 26-8](#) is the recommendation for applications on the usage, especially for the pin sensitive systems that can support this and still meet the intent. All the LED functions are routed to the peripheral pin mux and the user must configure the LEDs as per the available pins.

**Table 26-8. Status LED Options and Priority**

LED	Priority Order	Function	Recommendation	Usage Priority
RUN	5	Shows the status of ESC state machine with different blinking patterns.	In the case where color LEDs are not supported, then this needs to be supported.	Must
ERR <sup>(1)</sup>	4	Indicates the Error in ESC operation.	In the case where color LEDs are not supported, then at least the Error status needs to be reported.	Must
STATE	2	Combination of the RUN and ERR LED.	Not supported on this device.	-
LINKACT0 (ESC_LED_LINK0_ACTIVE)	3	Link Active Status for link towards the MainDevice.	Link Status on MainDevice side (Port0) is important to know, if the ESC and network downstream is part of the network or not. The prior ESC loopbacks, if this node fails. The status on this LED eases the debug.	Desired
LINKACT1 (ESC_LED_LINK1_ACTIVE)	1	Link Active status for link towards Network side.	The Link status on the network side (Port 1) is critical from continuity through the ESC point; hence, this is kept highest priority status reporting.	Must

(1) Driven by software and not the ESC on this device.

The PHY MII\_LINK (ESC\_PHYx\_LINKSTATUS) indication is an indication from PHY and does not indicate if the established link meets the characteristics including auto-negotiation as required by EtherCAT. Hence, the indication may not be a true status indication; however, it is critical to shorten reaction time in the event of link loss that is crucial for redundancy operation. Using LINKACT LEDs (LED\_LINKx\_ACTIVE) for the status output and MII\_LINK (ESC\_PHYx\_LINKSTATUS) for the status input is the best usage; however, using the LEDs are not practical to sacrifice 4 pins. The tradeoff of whether MII\_LINK is used as a link status LED or LINKACT is used depends on link loss reaction time requirements and available number of GPIOs for the system.

The PHY MII\_LINK (ESC\_PHYx\_LINKSTATUS) signal is an active-low signal input to the C2000 ESC. It is possible to use the GPxINV register to invert the signal's polarity before the signal enters the ESC, if the system hardware cannot provide the desired polarity for this signal.

The LINKACT LEDs (LED\_LINKx\_ACTIVE) is an output signal of the ESC intended to control an LED for link indication.

**Table 26-9. LINKACT and PHY MII\_LINK States**

Link State	LINKACTx (LED_LINKx_ACTIVE) State	PHY MII_LINK (ESC_PHYx_LINKSTATUS) State
No Link	0 (LOW)	1 (HIGH)
Link WITHOUT Activity	1 (HIGH)	0 (LOW)
Link WITH Activity	Toggling / Blinking	0 (LOW)

---

**Note**

The EtherCAT link status through the MII management interface option must be enabled if only a Gigabit PHY is to be supported and must not be enabled if needing to support both 10/100 and Gigabit PHY. For this reason, the link status through MII management interface is disabled on this ESC. Instead, use the LINKACT or PHY MII\_LINK signals for link status purposes.

---

### 26.2.8 SubordinateDevice Node Configuration and EEPROM

The ESC requires non-volatile memory (for example, an EEPROM with I2C interface), which is referred to as the SubordinateDevice Information Interface (SII) memory, to store the EtherCAT SubordinateDevice Information (ESI) data.

The ESI data contains information about the SubordinateDevice device identification, supported features, and other network accessible properties.

---

**Note**

The ESI XML file is generated from Beckhoff's SubordinateDevice Stack Code (SSC) tool.

---

- **EtherCAT SubordinateDevice**

- Uses the SII upon power-on or reset to load configuration data into the EtherCAT SubordinateDevice configuration registers.

- **EtherCAT MainDevice**

- During development, the MainDevice is used to program the device SII memory with the ESI data.
- When the ESI file isn't provided to the MainDevice, the MainDevice reads the device SII memory upon boot-up to determine the SubordinateDevice device properties such as the process data and their mapping options, the supported mailbox protocols including optional features, as well as the supported modes of synchronization.

### 26.2.9 General-Purpose Inputs and Outputs

The ESC subsystem implementation on this MCU supports 32 general-purpose inputs (GPI) and 32 general-purpose outputs (GPO) in addition to the PDI.

These GPI/GPOs provide an advantage for embedded applications over discrete components because the GPI/GPOs can selectively drive or sense GPIOs in a time controlled manner. For example, it can be a sensor/actuator control, status read, LED status update, and so on. The following section describes the integration and usage of this feature.

#### 26.2.9.1 General-Purpose Inputs

General-purpose inputs are connected to the device GPIO pin mux through an input buffer with an option to directly connect the asynchronous input flowing directly into the ECS or through a ESCSS register pipeline, which can hold the value stable while the value is captured within the ESC. The state of the GPI can be captured based on the following events:

- **Start-of-Frame (SOF):** Contents can be ready for capture in the frame if requested by the MainDevice
- **SYNC0/1:** Contents captured on a precise time tick
- **LATCH0/1:** Contents synchronized with LATCHIN read (allows simultaneous input and timestamp capture)

The ESCSS\_GPIN\_DAT register, containing the contents of the GPIN data, is available for reading from host CPU to allow debug access. Additionally, ESCSS\_GPIN\_DAT allows CPU writes for being used GPIN override purposes such as in place of using GPIOs.

GPIs are divided into 4 sets: GPIO:7, GPI8:15, GPI16:23, and GPI24:31, for clocking the capture trigger, which means the same capture trigger has to be used for the IOs within a set. Thus, either a bus can be formed out of these or individual IOs which need to be aggregated under common trigger can be combined in one set. This allows limited freedom of trigger selection for inputs. Selection of which Inputs (ESCSS\_GPIN\_SEL) and outputs (ESCSS\_GPOUT\_SEL) can be connected to GPIO is possible at each single IO level.

Figure 26-11 shows the integration of the GPI feature.

Figure 26-11. ESCSS General-Purpose Inputs Integration

**Note**

For software: The write data gets reflected on the ESCSS\_GPIN\_DAT read path only when one of the configured events, like SOF, SYNC0/1, and so on, is seen as configured after a few cycles of that event getting generated. Additionally, the copy of ESCSS\_GPIN\_DAT register readable by the CPU is provided without synchronization; therefore, multiple reads must be performed to confirm a stable value before using the value.

**26.2.9.2 General-Purpose Output**

General-purpose outputs are connected to the device GPIO pin mux through an output buffer with an option to directly connect from the ESC IP core registers to the external world or through a ESCSS register pipeline, which can hold the output value stable. The state of the GPO can be set based on the following events:

- **End-of-Frame:** Contents can be updated by the MainDevice from the last received frame
- **SYNC0/1:** Contents can be updated based on a precise time tick
- **Watchdog Trigger:** Contents can be updated based on the last successful access to process data memory

The ESCSS\_GPOUT\_DAT register, containing the contents of the GPO data, is available for reading from host CPU to allow debug access or to read in place of GPIOs.

GPOs are divided into 4 sets: GPI0:7, GPI8:15, GPI16:23, and GPI24:31, for clocking the output trigger, which means the same output trigger has to be used for the IOs within a set. Thus, either a bus can be formed out of these or individual IOs which need to be aggregated under common trigger can be combined in one set. This allows limited freedom of trigger selection for inputs. Selection of which inputs (ESCSS\_GPIN\_SEL) and outputs (ESCSS\_GPOUT\_SEL) can be connected to GPIO is possible at each single IO level.

Figure 26-12 shows the integration of the GPO feature.

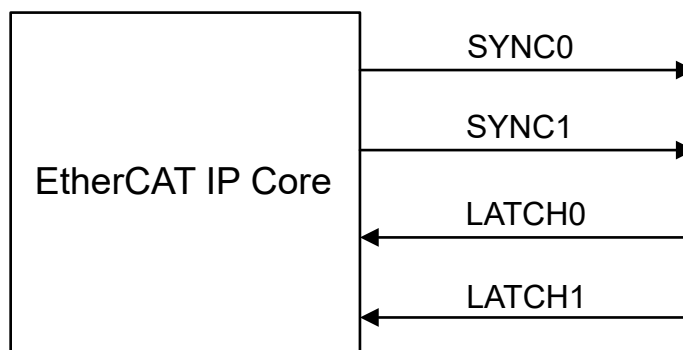

**Figure 26-12. ESCSS General-Purpose Output Integration**

**Note**

In Figure 26-12, the synchronization between CLK100 or CLK25 with respect to SysClk is not shown and is implicit by design. The local host can adjust for the synchronization delays as required while processing the data in either direction.

**26.2.10 Distributed Clocks – Sync and Latch**

Distributed clocks (DC) is a differentiating feature of the EtherCAT network. Distributed clocks allows all the SubordinateDevice nodes in the EtherCAT network to be bound in a tight margin of time to synchronize the events and the EtherCAT MainDevice command.

**Figure 26-13. ESC SYNC and LATCH**

This feature has sub-features as listed below. To enable the utility of these features at the application level, the related signals of DC are integrated tightly with the C2000 control loop logic, as well as, an external component that can be a possible implementation to trigger/latch other components on the board. This section explains the integration of these signals and related nuances of usage.

**Distributed clock features:**

- Clock Synchronization
- Sync Signal Generation
- Latch Signal event capture

Apart from usage for control loop synchronizations, these features are also used to synchronize the system and network time. These include the following:

- **System Time PDI Controlled:** Synchronize system time between two different EtherCAT networks.
- **Communication Timing:** To synchronize SubordinateDevice communication with sync signals, output or input events, and so on.

For further reading, including details on network time or network propagation delay, refer to the **ESC Hardware Data Sheet Section I - Technology (ethercat\_esc\_datasheet\_sec1\_technology)** document provided by Beckhoff/ETG at [www.beckhoff.com](http://www.beckhoff.com).

#### 26.2.10.1 Clock Synchronization

DC clock synchronization is the ability and procedure of the ESC to maintain the copy of the reference clock based on local clock (internal 64-bit time base) and other adjustment as derived by the procedure. The reference clock is the most accurate clock in the system and is typically held by one of the SubordinateDevices (Topologically first one after MainDevice is preferred). This time-base has a higher accuracy requirement and needs to periodically synchronize with an absolute time source like GPS or any other maintained time-base as in IEEE1588 network.

The synchronization order is as follows:

1. The MainDevice maintains a MainDevice clock that is either the absolute time synchronized or controls the reference clock.
2. The MainDevice queries the ESC time-base based on topology information and timestamps to determine the drift of the local clock for each ESC with regards to the reference clock.
3. The MainDevice programs the clock drift adjustments in each respective ESC.
4. With further periodic queries of the local clock, the MainDevice determines the drift of the local clock and keeps adjusting the clock so as to maintain the copies of the reference clocks on each ESCs in a tight limit.

While the ESC requires two clocks of 25MHz and 100MHz, the 100MHz clock is used for the internal time-base and supports the best accuracy possible. Refer to [Section 26.2.6.2](#) for more details on clocking.

#### 26.2.10.2 SYNC Signals

Sync signals are precise time controlled signals and are able to trigger time synchronized actions of the MainDevice. CPU core and DMA engine triggers are configured independently for every end point. The following sections describe ESC signal integration and various control triggers in the device.

**Figure 26-14. SYNC0 Signal Modes**

- **SYNC0:** SYNC0 is the primary trigger and can be generated in either a cyclic (periodic event generation like rise edge at every x period) or one-shot mode. Furthermore, these modes can be either with or without acknowledge, such that when enabled with acknowledge mode, the next event is not generated until the acknowledgment is received from the controlling MainDevice. If the acknowledgment is delayed, the event is skipped and the next periodic event is generated. Remember that the acknowledgment can be part of the interrupt servicing from the PDI and such a delay in triggering the next event is acceptable since the servicing routine can accordingly take action for the period elapsed. These modes are shown in [Figure 26-14](#).
- **SYNC1:** The SYNC1 generation follows the SYNC0 generation with a programmable delay and depending upon the delay time defined, SYNC1 can or cannot generate the pulse since the predefined delay from the SYNC0 event is newly measured only after the SYNC1 event (except for the start).

**Note**

- The SYNC0/1 when used in a system clock domain is stretched to at least 3 clock-wide pulse.
- When ESC goes through a reset, the SYNC outputs triggering external device events need to be kept at a safe value. At reset, the output values are 0 and this can be an active state when the reset occurs; therefore, the corresponding care of usage from the remote device must be taken.

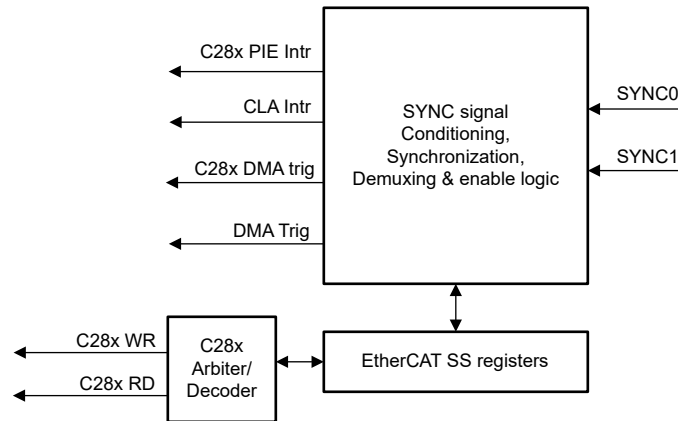

**26.2.10.2.1 Seeking Host Intervention**

SYNC can be used to initiate the action from the local host or related DMA engine that can respond with control action or data transfers from the ESC IP.

These actions can be selectively initiated in terms of:

- Interrupts to CPU cores (CPU1, CLA, or CPU2)
- DMA requests to DMA cores (CPU1 DMA and CPU2 DMA)

Figure 26-15 depicts the SYNC connection diagram to the CPU subsystems.

**Figure 26-15. SYNC Integration for the HOST Intervention**

Table 26-10 shows the Host Intervention selections, control and information that helps applications to route and handle the SYNC signals for respective Host intervention.

**Table 26-10. ESC SYNC Integration Map**

Destination	Source	Enable	Mask	Clear	Source Clock	Destination Clock	Destination Signaling
C28x PIE Interrupt	SYNC0	ESCSS_SYNC0_CONFIG[0]	ESCSS_INTR_MASK[0]	ESCSS_INTR_CLR[0]	ECAT.100MHz	C28x.SysClk	Pulse
C28x PIE Interrupt	SYNC1	ESCSS_SYNC1_CONFIG[0]	ESCSS_INTR_MASK[1]	ESCSS_INTR_CLR[1]	ECAT.100MHz	C28x.SysClk	Pulse
CLA Interrupt	SYNC0	ESCSS_SYNC0_CONFIG[1]	NA	NA	ECAT.100MHz	C28x.SysClk	Pulse
CLA Interrupt	SYNC1	ESCSS_SYNC1_CONFIG[1]	NA	NA	ECAT.100MHz	C28x.SysClk	Pulse
C28x DMA Trigger	SYNC0	ESCSS_SYNC0_CONFIG[2]	NA	NA	ECAT.100MHz	C28x.SysClk	Pulse
C28x DMA Trigger	SYNC1	ESCSS_SYNC1_CONFIG[2]	NA	NA	ECAT.100MHz	C28x.SysClk	Pulse
DMA Trigger	SYNC0	ESCSS_SYNC0_CONFIG[4]	NA	NA	ECAT.100MHz	CPU2.SysClk	Pulse/Level
DMA Trigger	SYNC1	ESCSS_SYNC1_CONFIG[4]	NA	NA	ECAT.100MHz	CPU2.SysClk	Pulse/Level

The difference between Enable and Mask is that Enable allows the conditioned and synchronized interrupt to be routed to the raw interrupt/trigger cause register, while Mask is a software control to allow raising an interrupt or not. Disabling the SYNC0 and SYNC1 on a respective trigger can lose any events that happen until SYNC0 and SYNC1 are enabled again.

### Regarding the CLA:

- The CLA does not have access to EtherCAT, so the CLA does not have the MASK and Clear controls; however, the trigger starts the action on the CLA processing which, upon completion, must be acknowledged by CPU1 to clear the cause.

### Regarding the DMA:

- The DMA triggers do not have Mask and Clear capabilities, as typically there is no feedback mechanism from the DMA to clear the trigger cause.
- [Figure 26-16](#) is the symbolic view of DMA request source select. If a given source event triggers multiple events across different MainDevices, then the software has to make sure there is a status exchange before the cause is cleared.

**Figure 26-16. SYNC Event Muxing for Different Host DMA Triggers**

### 26.2.10.3 LATCH Signals

Latch inputs to the ESC can be used to capture the time-stamp or register the GPI inputs. Two latch inputs are available. Latch enables external events:

- To take a system time snapshot of the EtherCAT network, measure time, or schedule further operations.
- To capture the status of the GPI inputs either as the status of connected external components or as part of control flow.

Both of the Latch inputs can be independently configured to operate on either the rising or falling edge of the signal. The LATCH events can be individually assigned either for the PDI control or EtherCAT controller control. Additionally, one shot or continuous mode is supported.

- In **one shot mode**, the next capture of the timestamp is done on a qualifying LATCH event only after the previous event is acknowledged.
- In **continuous mode**, timestamps are successively captured on a qualifying event, regardless of a preceding event being read or not.

Figure 26-17 depicts the different sources for the LATCH0/1 so as to fulfill the application requirements. These are explained for possible use.

Figure 26-17. ESC Latch Input Integration

The details of connections and mux select to these muxes is shown in [Table 26-11](#) and selection is possible individually for each of the LATCH0 or LATCH1 signal.

**Table 26-11. ESC LATCH0/1 Trigger Table**

### 26.2.10.3.1 Timestamping

Timestamping allows the local application or remote EtherCAT MainDevice to measure the time events and plan the subsequent controls.

#### Timestamping: Device Internal Events

- Enable timestamping and logging of internal device events coming from control logic
- The same outputs of the EPWM crossbar that connect to the 8 EPWMs can be used as 8 input signals (PWMXBAROUT0-PWMXBAROUT7) for time stamping
- Note that there is no independent option for Latch muxing as far as EPWM cross-bar inputs are concerned; unless one of the TRIP outputs are not used in control loop and such a crossbar output is dedicated for LATCH0/1 toggle

#### Timestamping: External Events

- Enable external board components apart from the MCU to trigger timestamp capture
- For example, timestamp a periodic event or pulse/edge event from a sensor when the sensor data is read or accessed
- Connecting the LATCH0/1 controls through the input crossbar allows timestamp capture based on any selected GPIO toggle (such as GPTRIP15 or GPTRIP16)
  - Two GPTRIPs are provided for independent GPIO choice for LATCH0 and LATCH1
  - GPTRIP1, 2, and 3 allow the same functionality; however, those can be utilized for EPWM trip zone functions where pins can or cannot need to match. In the case of a trip zone based on GPTRIP is to be latched, one of these inputs can be used.

#### Timestamping: Device Exception Events

- Log and timestamp exception events within the device (example: NMI exceptions) and periodically collect information to find out systemic issues in the system
- Can be used by local application and the remote MainDevice to diagnose or debug the system
- On CPU1, ERAD can be used to analyze particular accesses or data patterns/counts on the CPU bus. Refer to the *Embedded Real-time Analysis and Diagnostic (ERAD)* chapter for further information

### 26.2.10.4 Device Control and Synchronization

The primary advantage of DC functionality is when used in conjunction with device control functions. The precisely timed pulse/edge nature of the SYNC allows the ESC to synchronize the internal resources like PWMs, ECAPs (for capture as well as PWM) with remote system components. The following are the connections which are available for applications to program for allowing this synchronization.

#### 26.2.10.4.1 Synchronization of PWM

The PWM Sync-chain on the MCU can be triggered either by the device external inputs from the GPIO via input cross-bar or the PWM internal events when the chain is programmed appropriately. The SYNC0/1 inputs in this implementation also act as the external sync inputs to the PWM sync-chain. The integration is shown in [Figure 26-18](#).

The additional select register added to the trigger crossbar register allows independent programming of the EXTSYNCx from either GPTRIP or SYNC0/1.

**Figure 26-18. SYNC Integration for Control Functions - PWM SYNC**

#### 26.2.10.4.2 ECAP SYNC Inputs

ECAP supports accurate time capture of events that can be relatively checked against the series of events in vicinity and used for the control loop action. Additionally, ECAP has inbuilt capability of limited PWM action that can be triggered based on the selected input. Hence, the SYNC0/1 are also connected to ECAP input mux. The exact select value/vector for SYNC0/1 is defined in the *Enhanced Capture (eCAP)* chapter.

**Figure 26-19. SYNC Integration for Control Functions – ECAP**

### 26.2.10.4.3 SYNC Signal Conditioning and Rerouting

SYNC0/SYNC1 generation modes can generate various waveform patterns to create different trigger conditions. The SYNC0/1 signals are routed to the CLB, which can make conditional and delay based waveforms. Using the CLB, these signals can be processed for additional uses based on the application.

Additionally, this integration also allows routing SYNC0/1 signals with or without processing to other destinations within the device that are not explicitly connected. Details of the CLB input mux selects are explained in the *Configurable Logic Block (CLB)* chapter.

**Figure 26-20. SYNC Integration for Signal Conditioning – CLB**

## 26.3 Software Initialization Sequence and Allocating Ownership

This section details the software initialization sequence when configuring CPU1 or CPU2 as ESC owner. The CPU2 sequence includes details on allocating ownership of the ESC peripheral.

**Table 26-12. CPU1 Software Initialization Sequence**

Step	Action
1	General device initialization (configure clock, enable PLL, enable peripheral clocks except EtherCAT)
2	Configure Aux Clock for EtherCAT (if using Aux clock as source)
3	Configure GPIOs for EtherCAT (set pin configurations, set GPIO qualification mode, set pad configuration)
4	Initialize interrupts and register ISR handlers
5	Set EtherCAT clock source and divider. Then configure if EtherCAT PHY is clocked from device or external PHY clock.
6	Configure the EEPROM size
7	Bring ESC out of reset using system control register
8	Perform EtherCAT memory initialization and wait until memory initialization is complete
9	(Optional) Enable debug access to the EtherCAT registers
10	(Optional) Check that EEPROM loaded successfully
11	EtherCAT subsystem configurations for interrupt masking, SYNCx connections, and so on <sup>(1)</sup>

(1) Applications must make sure that ESC outputs are in a safe state until the EEPROM is loaded and that SYNC and LATCH are configured only after the EEPROM is loaded.

**Table 26-13. CPU2 Software Initialization Sequence**

Step	Core	Action
1	CPU1	General device initialization (configure clock, enable PLL, enable peripheral clocks except EtherCAT)
2	CPU1	Assign RAMs and Flash Banks to CPU2
3	CPU1	Bring CPU2 out of reset using system control register
4	CPU1	Configure GPIOs for EtherCAT (set pin configurations, set GPIO qualification mode, set pad configuration)
5	CPU1	Configure Aux Clock for EtherCAT (if using Aux clock as source)
6	CPU1	Set EtherCAT source and clock divider. Then configure if EtherCAT PHY is clocked from device or external PHY clock
7	CPU1	Reset ESC using system control register
8	CPU1	Bring ESC out of reset using system control register
9	CPU1	Configure EtherCAT EEPROM Size
10	CPU1	Reset ESC using system control register
11	CPU1	Allocate ESC to CPU2
12	CPU2	Initialize Interrupts and Register ISR Handlers
13	CPU2	Perform EtherCAT memory initialization and wait until memory initialization is complete
14	CPU2	(Optional) Enable debug access to the EtherCAT registers
15	CPU2	(Optional) Check that EEPROM Loaded successfully
16	CPU2	EtherCAT subsystem configurations for interrupt masking, SYNCx connections and so on <sup>(1)</sup>

- (1) Applications must make sure that ESC outputs are in a safe state until the EEPROM is loaded and that SYNC and LATCH are configured only after the EEPROM is loaded.

## 26.4 ESC Configuration Constants

The following is EtherCAT IP core configurations that are static by design.

**Table 26-14. ESC Configuration Constants Table**

Name	Value
ESC Type	0x91
Revision	0x0
Build	0x0
FMMU Supported	0x8
SyncManagers	0x8
RAM Size	0x10
Port Descriptor	0xF
ESC Features Supported	0x1CC
Product ID	0x0
Vendor ID	0x0

**Table 26-15. ESC IP Register Constants Table**

EtherCAT IP Register	Offset Address	Value <sup>(1)</sup>
PDI 8/16Bit asynchronous Microcontroller configuration	0x0150	0x00
Sync/Latch PDI configuration	0x0151	0x66
Pulse Length of SyncSignals	0x0982/0x0983	0x000A

- (1) These values are not changed or overwritten by EEPROM contents.

## 26.5 EtherCAT IP Registers

The EtherCAT IP (IP core) register details are included as part of Beckhoff documentation.

**Table 26-16. EtherCAT IP Register Documentation**

Document	Beckhoff ESC Type	Link
ESC Hardware Data Sheet - Section II - Register Description (ethercat_esc_datasheet_sec2_registers)	EtherCAT IP Core	<a href="http://www.beckhoff.com">www.beckhoff.com</a>

### 26.5.1 ETHERCAT Base Address Table

**Table 26-17. ETHERCAT Base Address Table**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	CPU2	CPU2.DMA	Pipeline Protected
Instance	Structure								
EscssRegs	<a href="#">ESCSS_REGS</a>	ESC_SS_BASE	0x0005_7E00	YES	-	-	YES	-	YES
EscssConfigRegisters	<a href="#">ESCSS_CONFIG_REGS</a>	ESC_SS_CONFIG_BASE	0x0005_7F00	YES	-	-	YES	-	YES

## 26.5.2 ESCSS\_REGS Registers

Table 26-18 lists the memory-mapped registers for the ESCSS\_REGS registers. All register offset addresses not listed in Table 26-18 should be considered as reserved locations and the register contents should not be modified.

**Table 26-18. ESCSS\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	ESCSS_IPREVNUM	IP Revision Number		<a href="#">Go</a>
2h	ESCSS_INTR_RIS	EtherCATSS Interrupt Raw Status		<a href="#">Go</a>
4h	ESCSS_INTR_MASK	EtherCATSS Interrupt Mask		<a href="#">Go</a>
6h	ESCSS_INTR_MIS	EtherCATSS Masked Interrupt Status		<a href="#">Go</a>
8h	ESCSS_INTR_CLR	EtherCATSS Interrupt Clear		<a href="#">Go</a>
Ah	ESCSS_INTR_SET	EtherCATSS Interrupt Set to emulate		<a href="#">Go</a>
Ch	ESCSS_LATCH_SEL	Select for Latch0/1 inputs and LATCHIN input		<a href="#">Go</a>
Eh	ESCSS_ACCESS_CTRL	PDI interface access control config.		<a href="#">Go</a>
10h	ESCSS_GPIN_DAT	GPIN data capture for debug & override		<a href="#">Go</a>
12h	ESCSS_GPIN_PIPE	GPIN pipeline select		<a href="#">Go</a>
14h	ESCSS_GPIN_GRP_CAP_SEL	GPIN pipe group capture trigger		<a href="#">Go</a>
16h	ESCSS_GPOUT_DAT	GPOUT data capture for debug & override		<a href="#">Go</a>
18h	ESCSS_GPOUT_PIPE	GPOUT pipeline select		<a href="#">Go</a>
1Ah	ESCSS_GPOUT_GRP_CAP_SEL	GPOUT pipe group capture trigger		<a href="#">Go</a>
1Ch	ESCSS_MEM_TEST	Memory Test Control		<a href="#">Go</a>
1Eh	ESCSS_RESET_DEST_CONFIG	ResetOut impact or destination config	LOCK	<a href="#">Go</a>
20h	ESCSS_SYNC0_CONFIG	SYNC0 Configuration for various triggers	LOCK	<a href="#">Go</a>
22h	ESCSS_SYNC1_CONFIG	SYNC1 Configuration for various triggers	LOCK	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 26-19 shows the codes that are used for access types in this section.

**Table 26-19. ESCSS\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1C	W1C	Write 1 to clear
W1S	W1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value

### 26.5.2.1 ESCSS\_IPRENUM Register (Offset = 0h) [Reset = 0000000h]

ESSC\_IPRENUM is shown in [Figure 26-21](#) and described in [Table 26-20](#).

Return to the [Summary Table](#).

IP Revision number showing the Major & Minor IP versions 4 bit each

**Figure 26-21. ESCSS\_IPRENUM Register**

Reset type: ECAT.IPRSn
3	DMA_DONE_MIS	R	0h	Indicates Masked Interrupt status of the past event on DMA Done, until RIS is cleared by ESCSS_INTR_CLR 0: No pending DMA Done interrupt. 1: DMA Done Event has triggered the interrupt/DMA trigger and it's pending. This is MASK qualified RIS such that application can select to service or suppress the interrupt cause behind this. Upon reset or upon RIS clear through ESCSS_INTR_CLR this field is cleared. Reset type: ECAT.IPRSn

**Table 26-23. ESCSS\_INTR\_MIS Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
2	IRQ_MIS	R	0h	Indicates Masked Interrupt status of the past event on EtherCATSS IRQ, until RIS is cleared by ESCSS_INTR_CLR 0: No pending EtherCATSS IRQ interrupt. 1: EtherCATSS IRQ Event has triggered the interrupt and it's pending. This is MASK qualified RIS such that application can select to service or suppress the interrupt cause behind this. Upon reset or upon RIS clear through ESCSS_INTR_CLR this field is cleared. Reset type: ECAT.IPRS <sub>n</sub>
1	SYNC1_MIS	R	0h	Indicates Masked Interrupt status of the past event on SYNC0, until RIS is cleared by ESCSS_INTR_CLR 0: No pending SYNC1 interrupt. 1: SYNC1 Event has triggered the interrupt/DMA trigger and it's pending. This is MASK qualified RIS such that application can select to service or suppress the interrupt cause behind this. Upon reset or upon RIS clear through ESCSS_INTR_CLR this field is cleared. Reset type: ECAT.IPRS <sub>n</sub>
0	SYNC0_MIS	R	0h	Indicates Masked Interrupt status of the past event on SYNC0, until RIS is cleared by ESCSS_INTR_CLR 0: No pending SYNC0 interrupt. 1: SYNC0 Event has triggered the interrupt/DMA trigger and it's pending. This is MASK qualified RIS such that application can select to service or suppress the interrupt cause behind this. Upon reset or upon RIS clear through ESCSS_INTR_CLR this field is cleared. Reset type: ECAT.IPRS <sub>n</sub>

### 26.5.2.5 ESCSS\_INTR\_CLR Register (Offset = 8h) [Reset = 0000000h]

ESSCS\_INTR\_CLR is shown in [Figure 26-25](#) and described in [Table 26-24](#).

Return to the [Summary Table](#).

Individual Interrupt cause clear register

**Table 26-27. ESCSS\_ACCESS\_CTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-28	RESERVED	R-0	0h	Reserved
27-16	TIMEOUT_COUNT	R/W	0h	This is the cycle count in SYSCLK cycles after which an access on the EtherCAT Async interface will be aborted and CPU will be given back a READY. Reset type: ECAT.IPRSn
15-11	RESERVED	R-0	0h	Reserved
10	ENABLE_PARALLEL_PORT_ACCESS	R/W	1h	Enabled memory accesses through the parallel port interface. 0: Memory accesses using parallel port are not allowed to go through. 1: Memory accesses using parallel port are allowed through the Bridge. Reset type: ECAT.IPRSn
9	ENABLE_DEBUG_ACCESS	R/W	0h	Enabled debug accesses through the PDI interface. 0: Debug accesses are not allowed to go through. 1: Debug accesses are allowed through the Bridge. Bridge logic will ensure that access will not hang. Reset type: ECAT.IPRSn
8	RESERVED	R/W	0h	Reserved
7	EN_TIMEOUT	R/W	0h	Enables the Timeout features which counts programmed number of Sys clocks before the Local host aborts the transaction. 0: Timeout feature is not enabled on PDI interface. 1: The timeout counter starts counting upon BUSY is asserted by EtherCAT IP. Reset type: ECAT.IPRSn
6-0	WAIT_STATES	R/W	0h	This is the predefined minimum number of wait-states which the VBUS bridge will put out accesses on the 16-bit Async interface. Reset type: ECAT.IPRSn

### 26.5.2.9 ESCSS\_GPIN\_DAT Register (Offset = 10h) [Reset = 0000000h]

ESSCS\_GPIN\_DAT is shown in [Figure 26-29](#) and described in [Table 26-28](#).

Return to the [Summary Table](#).

GPI data status for debug & override

**Figure 26-29. ESCSS\_GPIN\_DAT Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
GPIN_DAT																															
R/W-0h																															

**Table 26-28. ESCSS\_GPIN\_DAT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	GPIN_DAT	R/W	0h	Local GPIN data register connects to GPIN pipelined register for debug & override purposes. Note: The copy of this register readable by the CPU is provided without synchronization, therefore multiple reads should be performed to confirm a stable value before using it. Reset type: ECAT.IPRSn

### 26.5.2.10 ESCSS\_GPIN\_PIPE Register (Offset = 12h) [Reset = 0000000h]

ESSCSS\_GPIN\_PIPE is shown in [Figure 26-30](#) and described in [Table 26-29](#).

Return to the [Summary Table](#).

Register to select raw PAD input or pipelined input be presented to ESC.

**Figure 26-30. ESCSS\_GPIN\_PIPE Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
GPI_PIPE																															
R/W-0h																															

**Table 26-29. ESCSS\_GPIN\_PIPE Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	GPI_PIPE	R/W	0h	Enables the connection of GPIN to EtherCATSS through pipelined register as against the direct from IO. 0: The connection is directly from the IO pad 1: Connection is through the pipelined register which is captured on programmed event. Reset type: ECAT.IPRS <sub>n</sub>

### 26.5.2.11 ESCSS\_GPIN\_GRP\_CAP\_SEL Register (Offset = 14h) [Reset = 0000000h]

ESSSS\_GPIN\_GRP\_CAP\_SEL is shown in [Figure 26-31](#) and described in [Table 26-30](#).

Return to the [Summary Table](#).

Register to configure trigger select for the group of 8 IOs together.

### 26.5.3 ESCSS\_CONFIG\_REGS Registers

Table 26-38 lists the memory-mapped registers for the ESCSS\_CONFIG\_REGS registers. All register offset addresses not listed in Table 26-38 should be considered as reserved locations and the register contents should not be modified.

**Table 26-38. ESCSS\_CONFIG\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	ESCSS_CONFIG_LOCK	EtherCATSS Configuration Lock		<a href="#">Go</a>
2h	ESCSS_MISC_IO_CONFIG	RESET_IN, EEPROM IO connections select	LOCK	<a href="#">Go</a>
4h	ESCSS_PHY_IO_CONFIG	Control Register of ESCSS		<a href="#">Go</a>
6h	ESCSS_SYNC_IO_CONFIG	SYNC Signals IO configurations	LOCK	<a href="#">Go</a>
8h	ESCSS_LATCH_IO_CONFIG	LATCH inputs IO pad select	LOCK	<a href="#">Go</a>
Ah	ESCSS_GPIN_SEL	GPIN Select between IO PAD & tieoff	LOCK	<a href="#">Go</a>
Eh	ESCSS_GPOUT_SEL	GPOUT IO pad connect select	LOCK	<a href="#">Go</a>
12h	ESCSS_LED_CONFIG	Selection of LED o/p connect to IO pad	LOCK	<a href="#">Go</a>
14h	ESCSS_MISC_CONFIG	Miscellaneous Configuration	LOCK	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 26-39 shows the codes that are used for access types in this section.

**Table 26-39. ESCSS\_CONFIG\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
WOnce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value

### 26.5.3.1 ESCSS\_CONFIG\_LOCK Register (Offset = 0h) [Reset = 0000000h]

ESSCS\_CONFIG\_LOCK is shown in [Figure 26-39](#) and described in [Table 26-40](#).

Return to the [Summary Table](#).

Lock bit for EtherCAT configuration registers

Chapter 27  
**Fast Serial Interface (FSI)**

---

This chapter contains a general description of the Fast Serial Interface (FSI) module. The FSI is a serial peripheral capable of reliable high-speed communication across isolation barriers.

<b>27.1 Introduction</b> .....	<b>4556</b>
<b>27.2 System-level Integration</b> .....	<b>4557</b>
<b>27.3 FSI Functional Description</b> .....	<b>4565</b>
<b>27.4 FSI Programing Guide</b> .....	<b>4594</b>
<b>27.5 Software</b> .....	<b>4597</b>
<b>27.6 FSI Registers</b> .....	<b>4598</b>

## 27.1 Introduction

The Fast Serial Interface (FSI) module is a serial communication peripheral capable of reliable high-speed communication across isolation devices. Galvanic isolation devices are used in situations where two different electronic circuits, which do not have common power and ground connections, must exchange information. Though isolation devices facilitate these signal communications, isolation devices can also introduce a large delay on the signal lines and add skew between the signals. The FSI is designed specifically to make sure reliable high-speed communication for system scenarios that involve communication across isolation barriers without adding components.

The FSI consists of independent transmitter (FSITX) and receiver (FSIRX) cores. The FSITX and FSIRX cores are configured and operated independently.

For additional information on the FSI module, refer to [Fast Serial Interface \(FSI\) Skew Compensation](#) .

### 27.1.2 FSI Features

The FSI module includes the following features:

- Independent transmitter and receiver cores
- Source-synchronous transmission
- Double Data Rate (DDR)
- One or two data lines
- Programmable data length
- Skew adjustment block to compensate for board and system delay mismatches
- Frame error detection
- Programmable frame tagging for message filtering
- Hardware ping to detect line breaks during communication (ping watchdog)
- Two interrupts per FSI core
- Externally-triggered frame generation
- Hardware- or software-calculated CRC
- Embedded ECC computation module
- Register write protection
- FSI-SPI compatibility mode (limited features available)
- Tag match notifications

## 27.2 System-level Integration

This section describes the device-level integration of the FSI module. Some of the features can require additional configuration of modules that are not within the scope of this chapter, the details can be found elsewhere in this TRM.

### 27.2.1 CPU Interface

The following diagrams show the CPU interface of each FSI module.

A. The signals connected to the trigger muxes are described in [Section 27.2.6](#).

**Figure 27-1. FSI Transmitter (FSITX) CPU Interface**

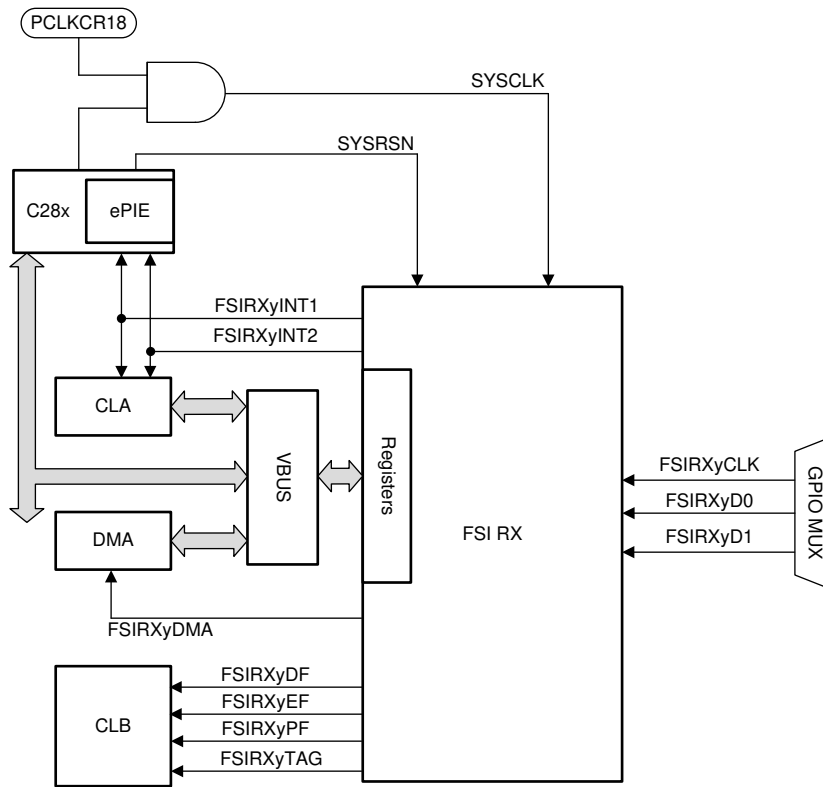

Figure 27-2. FSI Receiver (FSIRX) CPU Interface with CLB

### 27.2.2 Signal Description

FSI is a point-to-point communication protocol. Hence, an FSI transmitter core communicates directly to a single FSI receiver core. Similarly, an FSI receiver core receives data from a single FSI transmitter core.

Each FSI core has three signals: one clock and two data signals. Data is always transmitted or received with the most-significant bit of each frame field being first. If multilane transmissions are not used, the TXD1 and RXD1 signals can be left unconnected and the GPIOs repurposed for other application needs. [Table 27-1](#) and [Table 27-2](#) describe the various signals that can be selected by the PADCONFIG register to be brought out to device pins.

#### CAUTION

The maximum RXCLK rate is SYSCLK/2 and must not exceed this limit.

**Table 27-1. FSI Receiver Core Signals**

Signal Name	Direction	Description	Inactive Level <sup>(1)</sup>
RXCLK	Input	This is the receive clock input signal for the FSI receive module. This must be connected to TXCLK of the transmitting FSI module.	Logic High
RXD0	Input	This is the primary data input line for reception. This must be connected to the TXD0 of the transmitting FSI module.	Logic High
RXD1	Input	This is an additional data input line for reception. This signal must be connected to the TXD1 of the transmitting FSI module to use multilane transmission.	Logic High

(1) Inactive level refers to the state of the pin while the module is not actively receiving data.

**Table 27-2. FSI Transmitter Core Signals**

Signal Name	Direction	Description	Inactive Level <sup>(1)</sup>
TXCLK	Output	This is the transmit clock and is driven by the FSI transmit module.  During a transmission, four clock edges are transmitted before the start of frame phase (preamble) and four clock edges follow the last bit of the frame (postamble). Data is transmitted on both edges of the clock.  In FSI-SPI compatibility mode, the preamble and the post frame clock edges are not transmitted. Data is transmitted only on one edge of the clock. Data transmits on rising edge and received on falling edge of the clock.	Logic High
TXD0	Output	This is the primary data output line for transmission and is driven by the FSI transmit module.  When the FSI is configured for multilane transmission, TXD0 contains all the even numbered bits of the data and CRC bytes. Other frame fields such as frame type, start-of-frame, tag, and end-of-frame are transmitted in full.	Logic High
TXD1	Output	This is an additional data output line for transmission, if the FSI is configured for multilane transmission. This signal is driven by the FSI transmit module.  During transmission, the data bits are split between TXD0 and TXD1. TXD1 contains all the odd numbered bits of the data and CRC bytes. This applies only to the data words and the CRC bytes. Other data frame related information like Frame Type, Start-of-Frame, Tag and End-of-frame, the state of this line are identical to TXD0.	Logic High

(1) Inactive level refers to the state of the pin while the module is not actively transmitting, or held in reset.

### 27.2.2.1 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification must be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 0x3. The internal pullups can be configured in the GPyPUD register. See the *General Purpose Input-Output (GPIO)* chapter for more details on the GPIO mux and settings.

### 27.2.3 FSI Interrupts

Each FSI module contains multiple interrupt sources that can be assigned to two different interrupt vectors: INT1 and INT2. Each interrupt source has an associated status flag, force, and clear bits in the EVT\_STS, EVT\_FRC, and the EVT\_CLR registers, respectively.

Each interrupt can be assigned to either interrupt vector, INT1 and INT2, to allow for two priority levels. Alternately, the interrupt source can be prevented from generating any interrupt, though the status flag can still be set and monitored by software. The transmitter events are assigned to either interrupt vector in the TX\_INT\_CTRL register. The receiver events are assigned an interrupt vector using RX\_INT1\_CTRL and RX\_INT2\_CTRL registers. If an interrupt is not required, make sure the bit is not set in the respective INT\_CTRL register.

#### 27.2.3.1 Transmitter Interrupts

The transmitter can generate the following interrupts:

- **Frame Done (FRAME\_DONE):** This event indicates that FSI has completed transmitting a frame.
- **Buffer Underrun (BUF\_UNDERRUN):** This event indicates that the transmit buffer has experienced underrun. Buffer underrun occurs when the transmitter tries to read data from a location which has not yet be written to by the CLA, CPU, or DMA.
- **Buffer Overrun (BUF\_OVERRUN):** The buffer overrun interrupt is generated when the buffer has experienced overrun. Buffer overrun can occur if a piece of data is overwritten before the data has been transmitted.
- **Ping Frame Triggered (PING\_TRIGGERED):** The ping frame triggered interrupt is generated when the ping frame has been triggered. This bit is set when the ping counter has timed out or an external ping trigger event has occurred.

### 27.2.3.2 Receiver Interrupts

The receiver core is capable of generating interrupts from many different events:

- **Ping Watchdog Timeout (PING\_WD\_TO):** This event indicates that the ping watchdog timer has timed out. The receiver has not received a valid frame within the time period specified in the RX\_PING\_WD\_REF register.
- **Frame Watchdog Timeout (FRAME\_WD\_TO):** This event indicates that the frame watchdog timer has timed out. The conditions of this timeout are set using the RX\_FRAME\_WD\_CTRL register. As soon as the start of frame phase is detected, the frame watchdog counter starts counting from 0. The end of frame phase must complete by the time the watchdog counter reaches the reference value. If this does not happen, the watchdog times out and this event is generated. If this event occurs, the receiver must undergo a soft reset and subsequent resynchronization to resume proper operation.
- **CRC Error (CRC\_ERR):** This error indicates that a CRC error has occurred. A CRC error is generated when the received CRC and the computed CRC do not match.
- **Frame Type Error (TYPE\_ERR):** This error indicates that an invalid frame type has been received. If this error occurs, the receiver must undergo a soft reset and subsequent resynchronization to resume proper operation.
- **End-of-Frame Error (EOF\_ERR):** This error indicates that an invalid end-of-frame bit pattern has been received. If this error occurs, the receiver must undergo a soft reset and subsequent resynchronization to resume proper operation.
- **Receive Buffer Overrun (BUF\_OVERRUN):** This event indicates that an overrun condition has occurred in the receive buffer.
- **Receive Buffer Underrun (BUF\_UNDERRUN):** This event indicates that an underrun condition has occurred in the receive buffer. This condition occurs when software reads an empty buffer.
- **Frame Done (FRAME\_DONE):** This event indicates that a valid frame has been received without error.
- **Error Frame Received (ERR\_FRAME):** This event indicates that an error frame has been received.
- **Ping Frame Received (PING\_FRAME):** This event indicates that a ping frame has been received.
- **Frame Overrun (FRAME\_OVERRUN):** This event indicates that a new frame has been received while the FRAME\_DONE flag was still set.
- **Data Frame Received (DATA\_FRAME):** This event indicates that a data frame has been received.
- **Ping Tag Matched (PING\_TAG\_MATCH):** This event indicates that a ping frame with a matching tag has been received.
- **Data Tag Matched (DATA\_TAG\_MATCH):** This event indicates that a data frame with a matching tag has been received.
- **Error Tag Matched (ERROR\_TAG\_MATCH):** This event indicates that an error frame with a matching tag has been received.

### 27.2.3.3 Configuring Interrupts

To configure interrupts on the FSI, the application must select the interrupt vector for each desired event using the TX\_INT\_CTRL register for the transmitter, and RX\_INT1\_CTRL and RX\_INT2\_CTRL registers for the receiver. There is no module-level interrupt enable bit to configure.

---

#### Note

If an event is registered for both interrupt vectors, both interrupts fire. There are no hardware checks for overlapping interrupt vector assignments.

---

#### 27.2.3.4 Handling Interrupts

Inside the interrupt service routine (ISR), the user must clear the event flag using the EVT\_CLR register and then acknowledge the CPU interrupt.

If the one event occurs multiple times before the corresponding bit is cleared by software, no new interrupt is generated.

If multiple events occur simultaneously, or very close in time, it is possible to handle multiple conditions within a single interrupt. Each flag is independently set by hardware and must be cleared by application software. If multiple different events occur, the ISR can handle each in whatever order is deemed necessary by the application. It is not advisable to clear the full interrupt status register in every ISR. This can cause the application to miss events that can be detrimental to the application. A sample sequence for handling interrupts on the receiver follows; the transmitter routine is similar.

- On receiving an interrupt, copy the current state of the receive event and error status flag register (RX\_EVT\_STS) into a local snapshot variable.
- Read all of the bits from the snapshot to determine the events that require action.
- Perform the necessary actions for each of the events seen in the snapshot.
- Write to the receive event and error clear register (RX\_EVT\_CLR) with the snapshot to clear only those interrupts that were set at the beginning of the ISR.
- Repeat this sequence for every generated ISR.

There is a chance that another event occurred during the just-handled ISR since only the snapshot of events was handled and then cleared; an event flag can still be set at the end of the ISR. As soon as the ISR completes, a new interrupt is generated and this flag is still set and can be handled accordingly.

Software accesses tied to multiple events and handled within the same ISR can cause race conditions that cause the software to not function as desired. For example, it is recommended to use different interrupt lines if the user wants to enable events for both ping and data frames. If both events are handled within the same interrupt line, the software can only respond to one of the events if both events occur close in time.

#### 27.2.4 CLA Task Triggering

In addition to generating interrupt vectors to the PIE, both interrupts lines for each module TX\_INT1, TX\_INT2, RX\_INT1, and RX\_INT2 can be assigned to trigger CLA tasks. Refer to the Configuration options table for the list of all sources capable of CLA task triggering. The configuration and use of CLA tasks are described in the CLA Tasks and Interrupt Vectors section in the *Control Law Accelerator (CLA)* chapter. The CLA has access to the entire FSI register map. This allows the CLA to manage the FSI independently from the CPU, freeing it up for other tasks.

#### 27.2.5 DMA Interface

Both the transmitter and receiver are capable of using the DMA for automatic data transfers. The DMA trigger is independent from the interrupt signals. DMA events are only triggered on the completion of a data frame.

The transmitter DMA trigger is enabled by setting TX\_DMA\_CTRL.DMA\_EVT\_EN to 1. The transmitter must also set TX\_OPER\_CTRL\_LO.START\_MODE to 0x2 to allow either a write to the TX\_FRAME\_CTRL.START bit or to the TX\_FRAME\_TAG\_UDATA register to start the transmission.

The receiver DMA trigger is enabled by setting RX\_DMA\_CTRL.DMA\_EVT\_EN to 1.

Refer to [Section 27.3.2](#) and [Section 27.3.3](#) for more DMA information specific to each FSI Module.

### 27.2.6 External Frame Trigger Mux

The FSI has two muxes connected to the transmitter module. These muxes are used to select triggers to start ping frames, and generic frames. These muxes are independently configured for each type of frame. The application can select one trigger source per frame type. Use of these triggers are optional.

The external ping frame trigger is configured by setting TX\_PING\_CTRL.EXT\_TRIG\_SEL to the index of the desired trigger. TX\_PING\_CTRL.EXT\_TRIG\_EN must also be set to allow the trigger to generate a ping frame.

The generic frame trigger is configured by setting TX\_OPER\_CTRL\_HI.EXT\_TRIG\_SEL to the index of the desired trigger. TX\_OPER\_CTRL\_LO.START\_MODE must be set to 0x1 for a frame to be transmitted by an external trigger.

#### Note

Triggers generated by the CLB and EPWM XBAR are asynchronous and must be at least 3 SYSCLKs wide.

## 27.3 FSI Functional Description

### 27.3.1 Introduction to Operation

The Fast Serial Interface Transmitter and Receiver modules (FSI\_TX/FSI\_RX) are two completely independent modules on the device. Each module has an independent set of control registers, clocking, and interrupts. The following sections describe the frame format and the various initialization and configuration procedures for both the transmitter and receiver.

### 27.3.2 FSI Transmitter Module

The FSI transmitter module handles the framing of data, CRC generation, and signal generation of TXCLK, TXD0, and TXD1, as well as interrupt generation. The operation of the transmitter core is controlled and configured through programmable control registers. The transmitter control registers allow the CPU (or the CLA) to program, control, and monitor the operation of the FSI receiver. The transmit data buffer is accessible by the CPU, CLA, and the DMA.

The transmitter has the following features:

- Automated ping frame generation
- Externally triggered ping frames
- Externally triggered data frames
- Software-configurable frame lengths
- 16-word data buffer
- Data buffer underrun and overrun detection
- Hardware-generated CRC on data bits
- Software ECC calculation on select data
- DMA support
- CLA task triggering

Figure 27-3 shows the high-level block diagram of the FSI transmitter. Figure 27-4 shows the block diagram of the transmitter core submodule.

The following sections describe the various aspects of the FSI transmitter in detail.

**Figure 27-3. FSI Transmitter Block Diagram**

Figure 27-4. FSI Transmitter Core Block Diagram

### 27.3.2.1 Initialization

On the first initialization or after a module reset due to an underrun condition, the transmitter module executes the following initialization sequence to start or resume transmit operations.

1. Initialize the transmitter clock by setting TX\_CLK\_CTRL.CLK\_RST to 1 and subsequently clearing the bit.
2. Set the clock to the transmitter core to PLLRAWCLK by setting TX\_OPER\_CTRL\_LO.SEL\_PLLCLK to 1.
3. Set the clock prescaler value to the desired rate by writing to TX\_CLK\_CTRL.PRESCALE\_VAL.
4. Enable the transmitter clock divider by setting TX\_CLK\_CTRL.CLK\_EN to 1.
5. Assert the transmitter module soft reset by writing 0xA501 to TX\_MAIN\_CTRL.
6. Wait four TXCLK cycles.
7. Release the transmitter core from reset by writing 0xA500 to TX\_MAIN\_CTRL.

After initialization and configuration, the transmitter module synchronizes with the receiver module before transmitting. The synchronization sequence is described in [Section 27.4.1](#).

**CAUTION**

Do not change TX\_CLK\_CTRL.PRESCALE\_VAL while the clock is enabled (TX\_CLK\_CTRL.CLK\_EN = 1). Doing so can cause undefined behavior.

### 27.3.2.2 FSI\_TX Clocking

The transmitter core registers and control logic run off of the device system clock (SYSCLK).

The FSI Transmit Clock (TXCLK) is derived from PLLRAWCLK. PLLRAWCLK is divided down by configuring the clock prescaler value (TX\_CLK\_CTRL.PRESCALE\_VAL) then setting the clock divider enable bit (TX\_CLK\_CTRL.CLK\_EN). The clock prescaler value can be set to divide PLLRAWCLK by 1 (TX\_CLK\_CTRL.PRESCALE\_VAL = 0x0 or 0x1) through 255 (TX\_CLK\_CTRL.PRESCALE\_VAL = 0xFF). Though TXCLK and SYSCLK are both derived from PLLRAWCLK, TXCLK is asynchronous with respect to SYSCLK.

#### **CAUTION**

TXCLK must never be configured to be faster than SYSCLK/2.

### 27.3.2.3 Transmitting Frames

On the transmitter, the ping frame is the only frame that can be set up and transmitted without any further software or DMA intervention. Ping frames can be transmitted by any (or all) of the three sources: automatic ping timer, software, or external triggers.

Each available frame type can be sent multiple ways. Generically, the following steps must be executed before the frame is sent. These steps can be executed in any order before the start condition is set.

1. Configure the frame type
2. Set the frame tag
3. If the frame to be sent is a data frame:
  - Set the user data
  - Write to the data buffer
  - Set the word length if the frame is a software defined frame length
4. Set the start condition

#### **Note**

Transmit Frame Start Restriction:

A new frame transmission can be initiated by one of the methods selected in the TX\_OPER\_CTRL\_LO.START\_MODE bits. If there is already a PING frame transmission taking place, due to a hardware initiated PING timer, the new frame transmission begins as soon as the on-going PING transmission is completed.

Once a START of frame has been initiated, the next START of frame is recognized when the first frame has started transmitting the End-of-Frame (EOF) field. If a new START trigger arrives before the current transmission has reached the EOF field, the trigger is lost without a notification.

#### **Note**

There is no hardware check implemented to check whether the type field written by software is valid or not. If an invalid type is used and a frame transmission is initiated, the behavior is:

- The transmitted frame structure is exactly like an NWORD data frame. The size of the data frame is determined by the value in the TX\_FRAME\_CTRL.N\_WORDS register.
- The frame type field of the transmitted data frame is transmitted as programmed. If this is received by an FSI receiver, a Type error is generated.

This mechanism can be used for force a Type error in a received frame for testing purposes.

The following sections describe the specific configuration for each frame type and start condition.

### 27.3.2.3.1 Software Triggered Frames

The most basic way to transmit a data frame is through software. Each step must be handled by the application. To send a data frame using software, the following steps must be executed. Steps 1-6 can be executed in any order before setting TX\_FRAME\_CTRL.START. Some fields do not need to be reconfigured for every transmission. The frame tag, user data, and frame type are sticky and are retransmitted in the subsequent frame unless modified by software.

1. Write the data to be transmitted to the next location of the transmit data buffer.
2. Set TX\_FRAME\_CTRL.FRAME\_TYPE to the appropriate value for the type of frame to be transmitted.
3. Set TX\_FRAME\_CTRL.N\_WORDS to 1 less than the number of words to be transmitted if TX\_FRAME\_CTRL.FRAME\_TYPE is set to 0011, the frame type of the software-defined length data frame. That is, if 16 words are transmitted, N = 16, set TX\_FRAME\_CTRL.N\_WORDS to 15.
4. When the frame is assembled before transmitting, the FSITX hardware calculates the CRC to be transmitted. If TX\_OPER\_CTRL\_LO.SW\_CRC is 1, the application can calculate a custom CRC value and then set TX\_USER\_CRC to the result.
5. Set TX\_FRAME\_TAG\_UDATA.FRAME\_TAG to the desired tag.
6. Set TX\_FRAME\_TAG\_UDATA.USER\_DATA to the desired user data.
7. Set TX\_FRAME\_CTRL.START to 1 to initiate the transmission of the data frame.

Once the frame transmission has started, the TX\_FRAME\_CTRL.START is cleared by hardware. To monitor if the frame has completed, the software can poll TX\_EVT\_STS.FRAME\_DONE.

### 27.3.2.3.2 Externally Triggered Frames

The transmitter can transmit frames when triggered by an external source. See [Section 27.2.6](#) for more information on the available external triggers.

To transmit frames using an external trigger, the application must follow the same procedure as described in [Section 27.3.2.3.1](#). The only difference is that in Step 7, the start condition is automatically set when the external trigger condition is met rather than by software.

Note that by externally triggering frames, the frame information to be sent is pulled from the same registers described in the previous section. Because of this, it is possible to send any type of frame from an external trigger including ping, error, and data frames. Also, there is no hardware mechanism by which the FSI can determine if multiple triggers occur. The FSITX takes the data as is, and the application software makes sure that this data has been updated as necessary.

Using TX\_EVT\_STS fields either by polling or by interrupts, the application can populate or update the frame information to be sent in the next frame

### 27.3.2.3.3 Ping Frame Generation

Assuming the FSI transmitter has already been properly initialized, the following sequences can be used to configure and send ping frames.

#### 27.3.2.3.3.1 Automatic Ping Frames

To generate periodic ping frames, the following steps must be followed:

1. Initialize the ping counter by writing 1 to TX\_PING\_CTRL.CNT\_RST.
2. Set the desired ping tag to TX\_PING\_TAG.TAG.
3. Set the ping timer reference value to TX\_PING\_TO\_REF.TO\_REF.
4. Enable the ping timer by writing 1 to TX\_PING\_CTRL.TIMER\_EN.

The ping timer is a free-running counter that counts up from 0. The current value of the ping timer counter is found in TX\_PING\_TO\_CNT. When the current value of TX\_PING\_TO\_CNT matches the reference value TX\_PING\_TO\_REF.TO\_REF, the TX\_EVT\_STS.PING\_TRIGGERED is set. TX\_PING\_TO\_CNT resets to 0 and resumes counting until the next match has occurred or the ping timer is halted by software (TX\_PING\_CTRL.TIMER\_EN is set to 0).

### 27.3.2.3.3.2 Software Triggered Ping Frame

Software can also manually generate a ping frame. The process for sending a ping frame with software is very similar to sending the other types of frames. The following steps must be followed:

1. Set TX\_FRAME\_CTRL.FRAME\_TYPE to 0000'b to denote that the frame being sent is a Ping Frame.
2. Set TX\_FRAME\_TAG\_UDATA.FRAME\_TAG to the desired value.
3. Write 1 to TX\_FRAME\_CTRL.START. This starts the transmission.

Once the frame transmission has started, the TX\_FRAME\_CTRL.START is cleared by hardware. To monitor if the frame has completed, the software can poll TX\_EVT\_STS.FRAME\_DONE.

### 27.3.2.3.3.3 Externally Triggered Ping Frame

The last source for generating ping frames is an external trigger. One of up to 32 different triggers can be selected. See [Section 27.2.6](#) for the list of input sources.

#### **CAUTION**

Ping frames can be triggered by both an external trigger source and the internal ping timer. If TX\_PING\_CTRL.EXT\_TRIG\_EN is set to 1, the external trigger source takes precedence and the ping timer is ignored.

### 27.3.2.3.4 Transmitting Frames with DMA

The FSI transmitter can send data that is continuously applied with the DMA. A DMA trigger is generated every time a data frame transmission is completed. This is concurrent with the FRAME\_DONE signal that sets the TX\_EVT\_STS.FRAME\_DONE flag.

To transmit continuous data with the DMA, some configurations need to be made on the transmitter:

First, set TX\_DMA\_CTRL.DMA\_EVT\_EN to 1. This allows the DMA trigger to propagate to the DMA module. Next, TX\_OPER\_CTRL\_LO.START\_MODE must be set to 0x2. The transmitter is now able to start a transmission using a software write to TX\_FRAME\_CTRL.START or TX\_FRAME\_TAG\_UDATA..

The DMA must also be configured properly for the FSI to send the data. One way of using the DMA to continuously feed the transmit buffer is:

- Set up two DMA channels to be triggered by the same FSI transmitter and DMA trigger.
- Configure one channel to fill the transmit buffer.
- Configure the other channel to set the frame tag and user data fields
- Since the FSI transmit buffer is a 16-word circular buffer, make sure the DMA channel servicing the data buffer wraps the after 16 words are copied.

#### **Note**

Because the frame tag and user data must be written in to initiate the transmission of the frame, use two consecutive DMA channels. This makes sure that the DMA channels are always executed in sequence. The DMA channel servicing the data buffer must be the lower numbered channel and the tag/user data channel must be the next. For example, configure DMA channel 3 to service the data buffer, and configure DMA channel 4 to service the tag and user data.

### 27.3.2.4 Transmit Buffer Management

The FSI transmitter has a 16-word buffer that the FSI transmitter pulls data to transmit. This buffer is implemented as a circular buffer, not a FIFO, so some care must be taken to properly interpret buffer overrun and underrun, as well as the TX\_BUF\_PTR\_STS register. These flags and pointers work under the assumption that the software or DMA is using the buffer as a circular buffer. This mode of operation is the only way that the overrun, underrun, and pointer status are meaningful. If data is being sourced by the DMA and there is some other periodic trigger mechanism trying to initiate transfers, underrun becomes a critical error. If an underrun happens, a buffer went out of sync. This not only affects the current transfer, but can also affect all future transfers due to the ring buffer. Under such conditions, the underrun needs a soft reset to cleanly recover. Alternately, the software can manually stop the transmitting, reset the buffer pointers, clear the remaining error conditions, and then restart transmission. The software method involves a few steps, while the soft reset is a single action and makes sure of a full reset of the control registers.

Due to the flexibility of the transmit buffer, software can implement a simple ping-pong buffer or randomly load and send from any location of the buffer. If the buffer is used in this manner, error flags and status fields can be ignored without adversely affecting the transmitter capability. Additionally, the CURR\_WORD\_CNT is also invalid if used in this way. The application can set the buffer pointer manually by writing the 4-bit index to TX\_BUF\_PTR\_LOAD. This forces the transmitter to start picking the data from the indicated location in the buffer.

### 27.3.2.5 CRC Submodule

The FSI transmitter can supply the CRC to the frame being transmitted through the embedded hardware CRC submodule or by supplying a user-defined value. This is controlled by setting TX\_OPER\_CTRL\_LO.SW\_CRC appropriately.

If hardware CRC generation is selected (TX\_OPER\_CTRL\_LO.SW\_CRC = 0, the default), the CRC is computed by hardware on the data and user data fields using the CRC polynomial  $0x7 (x^8 + x^2 + x + 1)$ . The transmitter module automatically computes the CRC on the data fields without user intervention when the frame is transmitted. For more information on how the CRC is generated by the CRC submodule, refer to [Section 27.3.7](#).

If software CRC generation is selected (TX\_OPER\_CTRL\_LO.SW\_CRC = 1), the CRC must be computed by software and placed in the TX\_USER\_CRC register. The next frame to be transmitted uses the value placed in the TX\_USER\_CRC register in place of the CRC value generated by the hardware.

As the TX\_USER\_CRC register is software-programmable, the application can use this field as an extra data field for application-specific purposes. If TX\_USER\_CRC is used in this manner, the CRC detection on the receiver is not valid and must be ignored.

### 27.3.2.6 Conditions in Which the Transmitter Must Undergo a Soft Reset

Unlike the receiver, there are no detectable errors that require a soft reset. A buffer overrun or underrun interrupt can or cannot require a soft reset to resume proper operation. This determination is up to the application software. Refer to [Section 27.3.2.4](#) for more information on the transmit buffer.

### 27.3.2.7 Reset

The entire transmitter module and all transmitter registers are reset by SYSRSn. The transmitter core is reset by SYSRSn or by writing a 1 to TX\_MAIN\_CTRL.CORE\_RST.

A module reset causes the registers to be reset to the default state.

### 27.3.3 FSI Receiver Module

The receiver module interfaces to the FSI clock (RXCLK), and data lines (RXD0 and RXD1) after the data lines pass through an optional programmable delay line. The receiver core handles the data framing, CRC computation, and frame-related error checking. The receiver bit clock and state machine are run by the RXCLK input, which is asynchronous to the device system clock.

The receiver control registers allow the CPU (or the CLA) to program, control, and monitor the operation of the FSI receiver. The receive data buffer is accessible by the CPU, CLA, and the DMA.

The receiver core has the following features:

- 16-word data buffer
- Multiple supported frame types
- Ping frame watchdog
- Frame watchdog
- CRC calculation and comparison in hardware
- ECC detection
- Programmable delay line control on incoming signals
- DMA support
- CLA task triggering
- FSI-SPI compatibility mode

Figure 27-5 provides a high-level overview of the internal modules present in the FSI receiver. Figure 27-6 shows a view of the FSI receiver core submodule. Not all data paths and internal connections are shown.

The following sections describe the various aspects of the FSI receiver module.

**Figure 27-5. FSI Receiver Block Diagram**

**Figure 27-6. FSI Receiver Core Block Diagram**

### 27.3.3.1 Initialization

On the first initialization or after a module reset following any frame error, the receiver module asserts and releases the receiver core reset bit (RX\_MAIN\_CTRL.CORE\_RST) prior to any other initialization. Once the receiver module is initialized, the following steps are executed:

1. If required, assign interrupt sources to the necessary interrupt line.
2. If required, configure the ping watchdog to periodically check for an active link to the transmitter. See [Section 27.3.3.4](#) for configuration details.
3. If required, configure the frame watchdog to make sure that each frame is received within a predetermined window. See [Section 27.3.3.5](#) for configuration details.
4. Initialize the receive buffer pointer by writing to the RX\_BUF\_PTR\_LOAD register. Received data is placed into the buffer starting with the address loaded in this register.
5. Make sure all errors and flags have been cleared from the RX\_EVT\_STS register.

At this point the receiver is ready to receive any incoming frames. Software can now either poll on the RX\_EVT\_STS register for various conditions. For example, when the RX\_EVT\_STS.FRAME\_DONE and no other flags are set, the receiver has successfully received a frame without error.

Next, the application configures the various features such as the ping and frame watchdogs, DMA, external triggering, and so on. These features are described in subsequent sections. The receiver module is now ready to synchronize with the transmitter then begin reception. The synchronization sequence is described in [Section 27.4.1](#).

### 27.3.3.2 FSI\_RX Clocking

The receiver module registers and control logic are clocked by the device system clock (SYSCLK). The receiver state machine is clocked by the receiver input clock pin (RXCLK).

#### CAUTION

RXCLK must never be faster than SYSCLK.

### 27.3.3.3 Receiving Frames

Once the receiver has been properly configured and synchronized, incoming messages are handled as described below. Note that there is no equivalent to a chip-select signal to gate incoming data. Every valid clock edge latches data into the receiver.

The header information of the received frame is placed in the respective register fields.

- `RX_FRAME_INFO.FRAME_TYPE` contains the received frame type.
- `RX_FRAME_TAG_UDATA.FRAME_TAG` contains the received frame tag.
- `RX_FRAME_TAG_UDATA.USER_DATA` contains the received user data.

If any error conditions occur during reception such as a CRC mismatch, frame error, frame timeout, buffer overrun, or ping watchdog timeout, the corresponding flag is set in the `RX_EVT_STS` register.

#### Note

If at any point during operation a frame error occurs, the receiver module must be reset and re-synchronized with the transmitter before the next frame can be successfully received. The follow errors are classified as frame errors:

- Type error
- CRC error
- End of frame error

#### 27.3.3.3.1 Receiving Frames with DMA

The FSI receiver can continuously receive data and move the data from the receiver buffer with the DMA. A DMA trigger is generated every time a data frame has been received. This is concurrent with the `FRAME_DONE` signal that sets the `RX_EVT_STS.FRAME_DONE` flag. To receive continuous data with the DMA, some configurations need to be made on the receiver.

First, set `RX_DMA_CTRL.DMA_EVT_EN` to 1. This allows the DMA trigger to propagate to the DMA module. The receiver is now able to trigger a DMA event upon the reception of a data frame.

The DMA must also be configured properly for the FSI to receive the data. One way for using the receiver to continuously feed the DMA is:

- Set up two DMA channels to be triggered by the FSI Receiver DMA Trigger.
- Configure one DMA channel to copy data from the receive buffer to a larger data buffer.
- Configure the next DMA channel to copy the received frame tag and user data to another data buffer.
- Since the FSI receive buffer is a 16-word circular buffer, make sure the DMA channel servicing the data buffer wraps after 16 words are copied.

Unlike the transmitter, there is no requirement to have the DMA channel that is handling the data buffer execute before the DMA channel handling the received tag and user data.

### 27.3.3.4 Ping Frame Watchdog

The ping frame watchdog is a hardware-enabled automatic error detection of the connection status to the transmitter. This watchdog monitors the time elapsed between ping frames. If the transmitter has been set up to periodically send out a ping frame, the receiver can be set up to monitor whether this frame has been received within a specified amount of time. If the time between ping frames has exceeded the programmed number of clock cycles, an event is triggered that can generate an interrupt or be monitored by software.

This watchdog has a dedicated counter that is reset and restarted upon the successful reception of a ping frame. The watchdog counter is incremented at the rate of SYSCLK. Optionally, the watchdog can be configured to be reset upon the successful reception of any frame. This option allows the receiver to monitor for any successful frame to indicate that the connection is still alive and the transmitter is still functioning as expected.

To configure the ping frame watchdog for operation:

1. Reset the ping watchdog counter by setting `RX_PING_WD_CTRL.PING_WD_RST` to 1 and then subsequently clearing the bit to 0.
2. Set `RX_OPER_CTRL.PING_WD_RST_MODE` to the desired watchdog reset event, set to 0 for ping frames only or set to 1 for any frame.
3. Set `RX_PING_WD_REF` to the maximum time between frames. Add 10 additional SYSCLK cycles to account for clock synchronization.
4. Enable the ping watchdog by setting `RX_PING_WD_CTRL.PING_EN` to 1.

The ping watchdog is now enabled and can now monitor for ping frames.

If the `RX_PING_WD_CNT` value reaches the value programmed in `RX_PING_WD_REF`, the `RX_EVT_STS.PING_WD_TO` flag is set. If configured, an interrupt can be generated on this event.

### 27.3.3.5 Frame Watchdog

The frame watchdog is an additional feature the receiver can use to monitor for any error conditions. This dedicated watchdog monitors the duration for a single frame to be received. The watchdog starts incrementing at the time the receiver detects a proper start of frame condition. If the end of frame condition is not detected within the expected number of SYSCLK cycles, the frame watchdog is triggered that can generate an interrupt or be monitored by software.

This watchdog is automatically started and stopped at the start-of-frame and end-of-frame conditions, respectively. The frame watchdog is connected to SYSCLK.

To configure the frame watchdog for operation:

1. Reset the frame watchdog counter by setting `RX_FRAME_WD_CTRL.FRAME_WD_CNT_RST` to 1 and then subsequently clearing the bit to 0.
2. Set `RX_FRAME_WD_REF.FRAME_WD_REF` to the maximum number of SYSCLK cycles expected to be in the longest frame that can be received. Add an additional 10 SYSCLK cycles to account for clock synchronization.
3. Enable the frame watchdog by setting `RX_FRAME_WD_CTRL.FRAME_WD_CNT_EN` to 1.

The frame watchdog is now enabled and can detect a failed frame.

If the `RX_FRAME_WD_CNT` reaches the value programmed in `RX_FRAME_WD_REF`, the `RX_EVT_STS.FRAME_WD_TO` flag is set. If enabled, an interrupt can be generated on this event.

If the frame watchdog interrupt ever occurs, the receiver core is in an invalid state to receive a new transmission. The only way to recover from a frame watchdog time out is to undergo a soft reset, and subsequently resynchronizing with the transmitter.

### 27.3.3.6 Delay Line Control

The receiver module has a programmable delay line on each of the external signal inputs: RXCLK, RXD0, and RXD1. The delay elements introduce delays on the respective lines. This is to facilitate adjustment for signal delays introduced by system level components such as signal buffers, ferrite beads, isolators, and so on, or board delays such as uneven trace lengths, long cable length, and so on. The length of the delay is controlled by setting the RX\_DLY\_LINE\_CTRL register values for each line. By default, no delay is introduced by the delay line elements. The delay values must only be adjusted while the FSIRX is held in soft reset, making sure that there are no active transmissions during this process. Figure 27-7 shows a representation of the delay line circuitry for the input signals. The implementation for RXCLK, RXD0, and RXD1 are replicas of this diagram. All circuits behave similarly.

**Figure 27-7. Delay Line Control Circuit**

For more information on skew compensation, refer to [Fast Serial Interface \(FSI\) Skew Compensation](#).

The FSITX module also has a delay line control circuitry that is placed before the FSITX signals (TXCLK, TXD0, and TXD1) are sent to the TDM signal selection mux (controlled by the SEL\_TDM\_PATH signal). The TX\_DLY\_LINE\_CTRL register determines the length of the delay for each output line.

### 27.3.3.7 Buffer Management

The FSI receiver has a 16-word buffer that the data is copied to when the data has been received. This buffer is implemented as a circular buffer, not a FIFO, so some care must be taken to properly interpret buffer overrun and underrun as well as the RX\_BUF\_PTR\_STS register. These flags and pointers work under the assumption that the software or DMA is using the buffer as a circular buffer. If the receiver state machine enters into an erroneous state, there is no way for software to cleanly handle this because there is no specified receive clock. For the receiver to detect a clean resynchronization, the state machine needs to be operational and not in the error state. The only way to recover from the error state is to reset the entire receiver module. For overrun and underrun, the receiver can no longer verify that values in the buffer are valid. As such, the best way to recover is to reset the FSI and resynchronize with the transmitter.

Due to the flexibility of the receive buffer, it is possible for software to implement a simple ping-pong buffer, or to randomly receive and read from any location of the buffer. If the buffer is used in this manner, these flags and status fields can be ignored without adversely affecting the receiver capability. Additionally, the CURR\_WORD\_CNT is also invalid if used in this way. The application can set the buffer pointer manually by writing the 4-bit index to RX\_BUF\_PTR\_LOAD. This forces the receiver to start storing the received data starting at the indicated location in the buffer.

### 27.3.3.8 CRC Submodule

The receive module automatically calculates the CRC on the incoming data. The received CRC value is placed into `RX_CRC_INFO.RX_CRC`. The CRC value calculated by hardware on the received data is placed into `RX_CRC_INFO.CALC_CRC`. These values are compared by hardware and `RX_EVT_STS.CRC_ERROR` is set if there is a mismatch. The receiver can generate an interrupt based on `RX_EVT_STS.CRC_ERROR` if enabled.

Since the CRC is only used in data frames, the values found in `RX_CRC_INFO.RX_CRC` and `RX_CRC_INFO.CALC_CRC` are undefined during ping and error frames.

For more information on how the CRC is calculated, refer to [Section 27.3.7](#).

If the transmitting module is sending a software-defined CRC value (`FSITX.TX_OPER_CTRL_LO.SW_CRC = 1`), the receiver module triggers a CRC error event if the received value does not match the hardware-calculated value. As this is an application-level decision, the FSIRX can safely disregard the CRC error event. Application software needs to calculate and verify the incoming CRC using the same custom algorithm used on the transmitter and act appropriately.

The CRC field can also be used as an application-specific value, not a CRC. The application can use the `RX_CRC_INFO.RX_CRC` as required. All CRC errors and flags can be ignored in this situation.

### 27.3.3.9 Using the Zero Bits of the Receiver Tag Registers

The receiver tag registers (receiver frame tag and user data (`RX_FRAME_TAG_UDATA`) register and receiver ping tag (`RX_PING_TAG`) register) have the least-significant bit set to 0. The actual received tag is in the bit positions 4:1. The reason for this is to facilitate user software to create a table of functions that can be called depending on the tag value. A function pointer needs a 32-bit storage space and, hence, each successive pointer is offset by 2. If the first pointer is at address  $x$ , then the second pointer is at address  $x + 2$ , the third at address  $x + 4$ , and so on. By keeping the LSB to 0, the five bits of the tag register (bits 4:0) can now be directly used as an index into a table of function pointers.

### 27.3.3.10 Conditions in Which the Receiver Must Undergo a Soft Reset

The receiver receives data on every clock edge. While there are specific patterns that determine the start of a frame, and denote the end of a frame, these patterns are able to occur at any point during normal operation inside of the frame. If there ever is a point at which the receiver fails to detect a successful frame, the module must be reset to make sure that subsequent frames are received properly.

When any of the following errors occur in a received frame, the receiver can be required to be reset and resynchronized with the transmitter:

- Frame type error
- End of frame error
- Ping frame watchdog timeout
- Frame watchdog timeout
- Receiver in an invalid state due to noisy clock

The receiver core status (`RX_VIS_1.RX_CORE_STS`) can be monitored to determine if the receiver core has entered into an error state requiring a soft reset to resume communication. Incorrect frame type and end of frame errors always cause this bit to become set. A soft reset is required in these cases. A frame watchdog timeout always requires a reset due to the fact that the receiver state machine is still expecting more information when the watchdog timed out. `RX_CORE_STS` can be used to determine if a noise event was the cause of the failed frame. The ping frame watchdog also does not cause `RX_CORE_STS` to be set. Similar to the frame watchdog, a corrupt receiver may not be the reason for the ping frame to have timed out. The transmitter could have gone offline and never sent a ping frame. Alternately, during idle time, a noise event could have occurred, thereby putting the receiver into a corrupt state. As the receiver is able to detect this during the ping frame watchdog timeout interrupt handler, this type of event is not lost and the application can act appropriately.

As the receiver is clocked by RXCLK, not SYSCCLK, a noisy clock or data line can cause some internal design constraints to be violated, putting the receiver core logic into undefined states. Make sure that the clock and data lines satisfy the Electrical Characteristics and timing requirements of the FSI module found in the device data sheet. Failure to do so can cause the receiver state machine to go into an unrecoverable error state. The receiver can only be recovered by undergoing a soft reset. To determine the state of the receiver core after an unexpected frame error, the application must check the receiver core status bit.

In addition to the above errors, buffer overrun or underrun can warrant a soft reset to resynchronize with the local application software. Refer to [Section 27.3.3.8](#) for more information on the receive buffers. The requirement of resetting the receiver due to overrun or underrun is up to the application.

After the receiver has been placed into soft reset, the application must notify the other device's transmitter to begin a new synchronization phase. The simplest way to achieve this is through a ping or error frame sent with a designated tag. If the application is not using the FSITX on the device with the detected error, some other method must be established. The other device must stop transmitting and begin a new synchronization phase.

#### 27.3.3.11 FSI\_RX Reset

The receiver module and the registers are reset by SYSRSn. The receiver core is reset by SYSRSn or by writing a 1 to RX\_MAIN\_CTRL.CORE\_RST.

A module reset causes the registers to be reset to the default state. After a module reset, the receiver module must be re-initialized and the data link re-established.

#### 27.3.4 Frame Format

The FSI module transmits and receives information in frames. Each frame contains multiple phases where different information can be found. The number of phases as well as the total length of the frame varies depending on the frame type being transmitted. Frames can be as short as 16-bits long for a ping or error frame or 288-bits long for a 16-word data frame.

In normal transmission mode, there are four preamble clock edges before the start of the frame and four post-frame clock edges (postamble). Data is transmitted on both edges of the clock (double data rate). The basic frame structure is shown in [Table 27-4](#). Each phase of the frame (such as start-of-frame, frame type, and so on) is transmitted with the most-significant bit first. [Table 27-4](#) describes the basic frame structure used by the FSI and adapted according to which frame type is transmitted.

**Table 27-4. Basic Frame Structure**

Idle State	Preamble	Start of Frame	Frame Type	User Data	Data Words	CRC Byte	Frame Tag	End of Frame	Postamble	Idle State
	1111	1001	4 bits	8 bits	1-16 words	8 bits	4 bits	0110	1111	

The FSI also supports a FSI-SPI compatibility mode. The SPI compatible frame structure is similar to a standard FSI frame, but there are differences. Refer to [Section 27.3.13](#) for more information on how to configure and use the FSI-SPI compatibility mode.

---

#### Note

One word of the FSI refers to 16 bits.

The terms “frame” and “packet” can be used interchangeably to describe the signaling format of the FSI.

---

### 27.3.4.1 FSI Frame Phases

The different phases of the frame structure are described in detail.

- **Idle State:** During the idle state, the clock and data lines are driven high, the inactive state.
- **Preamble:** The preamble phase contains four clock edges (or two complete clock pulses) with the data signals held in the high state. These clock edges serve to flush the receiver logic and prepare the receiver logic for receiving a new frame. This phase is not present in SPI compatibility mode.
- **Start of Frame:** The start of frame phase contains two clock pulses with four bits, 1001, transmitted on the data lines.
- **Frame Type:** The frame type phase contains two clock pulses with the 4-bit frame type code being transmitted on the data lines. The different frame types are described in detail in [Section 27.3.4.2](#). The transmitter must set the TX\_FRAME\_CTRL.FRAME\_TYPE field before transmitting a frame. The received frame type is stored in the RX\_FRAME\_INFO.FRAME\_TYPE.
- **User Data:** The user data phase contains a fully user-configurable data field. There are no restrictions on how this field is used. This phase is only available in data frames. The user data to be transmitted is set by writing to TX\_FRAME\_TAG\_UDATA.USER\_DATA. The received user data is stored in RX\_FRAME\_TAG\_UDATA.USER\_DATA.
- **Data:** The data phase contains the data that is being transmitted. The data is pulled from the transmit buffer of the transmitter and is placed in the receive buffer of the receiver. Word 0 is transmitted first. This phase is only present in data frames. Depending on the type of frame transmitted, this can contain anywhere between 1 and 16 words depending on the frame type selected. More information on data frames is found in [Section 27.3.4.2.3](#).
- **CRC Byte:** The CRC byte contains the CRC of the transmitted data. The value present in this phase can be sourced from either hardware or software based on the TX\_OPER\_CTRL\_LO.SW\_CRC bit. Refer to the module-specific section of the CRC Submodule for more information on the CRC is generated or used, for the transmitter and receiver modules respectively. The CRC byte is only present in data frames.
- **Frame Tag:** The frame tag contains the 4-bit user-defined frame tag. There are no restrictions on how this field is used in an application. The transmitter supplies this tag into the TX\_FRAME\_TAG\_UDATA.FRAME\_TAG bits for data frames. Ping frames use the tag defined in TX\_PING\_TAG.TAG. The receiver can access the received frame tag in RX\_FRAME\_TAG\_UDATA.FRAME\_TAG.
- **End of Frame:** The end of frame contains four clock edges with four bits, 0110, transmitted on the data lines.
- **Postamble:** The postamble contains four additional clock edges with the data lines held in the high state. After the postamble, the clock and data lines are driven high (inactive state). This phase is not present in FSI-SPI compatibility mode.

### 27.3.4.2 Frame Types

The FSI hardware can generate and handle many predefined frame types. The different frame types can be used by the application to signal different types of events or convey different information to the receiver. The different frame types influence which phases and data fields to include in the transmitted frames.

[Table 27-5](#) provides a short overview of the different frame types used by the FSI. Each frame type is described in more detail in the following subsections.

**Table 27-5. Frame Types and the 4-bit Codes**

Frame Type	4-bit Frame Code	Description
PING	0000	Used typically for checking line integrity. A ping frame can be sent either by software or automatically by hardware.
ERROR	1111	Used typically during error conditions or any condition where one side wants to signal the other side for attention. However, the user software can use an error frame for any purpose.
DATA_1_WORD	0100	1 word data packet (16 bits of data)
DATA_2_WORD	0101	2 word data packet (32 bits of data)
DATA_4_WORD	0110	4 word data packet (64 bits of data)
DATA_6_WORD	0111	6 word data packet (96 bits of data)
DATA_N_WORD	0011	N(1-16) word data packet where software has programmed the number of the data words in a designated register. Both transmitter and receiver modules must have the same value programmed.
Reserved	0001, 0010, and 1000-1110	Reserved

#### 27.3.4.2.1 Ping Frames

Ping frames are one of the most basic frames that can be generated by the FSI. [Table 27-6](#) shows the structure of the ping frames.

**Table 27-6. Ping Frame**

Idle State	Preamble	SOF	Frame Type	Frame Tag	EOF	Postamble	Idle State
	1111	1001	0000	xxxx	0110	1111	

The ping frame type is always 0000. The frame tag is defined by the application. Separate frame tags exist for timer and software initiated ping frames. No data or CRC is transmitted in a ping frame.

The main purpose of the ping frame is to periodically send a notification to the receiver to make sure an active connection between the transmitter and receiver. The transmitter and receiver cores implement different features to allow the ping frame to operate as a line break detect feature.

On the transmitter, the ping frame is the only frame that can be set up and transmitted without any further software or DMA intervention. Ping frames can be transmitted by any (or all) of the three sources: automatic ping timer, software, or external triggers. See [Section 27.3.2.3.3](#) for information on how the transmitter configures and sends the ping frames.

The receiver has a ping watchdog that can detect if a ping frame has not been received in a predetermined window. This allows the receiver to know if the connection between the receiver and the transmitter has been broken. See [Section 27.3.3.4](#) for information on how the receiver handles ping frames.

### 27.3.4.2.2 Error Frames

Error frames are similar to ping frames in that there are no data fields transmitted. Despite the naming of this frame as an “error frame,” the usage of it is up to the application, as no restrictions are placed on how and when this type of frame is transmitted. [Table 27-7](#) shows the structure of an error frame.

**Table 27-7. Error Frame**

Idle State	Preamble	SOF	Frame Type	Frame Tag	EOF	Postamble	Idle State
	1111	1001	1111	xxxx	0110	1111	

The structure of the error frame is the same as a ping frame. No data or CRC values are transmitted. The frame type is 1111 for all error frames, and the frame tag is defined by software in the TX\_FRAME\_TAG\_UDATA register.

The receiver can detect if an error frame has been received based on the frame type field. Because of this, the receiver can read the incoming frame tag from the RX\_FRAME\_TAG\_UDATA register and act on up to 16 different conditions.

### 27.3.4.2.3 Data Frames

Data frames are the most complex frames. As the name indicates, these frames are used to transfer data. [Table 27-8](#) shows the general structure of data frames.

**Table 27-8. Data Frame**

Idle State	Preamble	SOF	Frame Type	User Data	Data Words	CRC Byte	Frame Tag	EOF	Postamble	Idle State
	1111	1001	0xxx	xxxx xxxx	1-16 words	xxxx xxxx	xxxx	0110	1111	

The frame type field reflects the 4-bit code of the frame type. A list of frame types can be seen in [Table 27-5](#). The number of the data words transmitted is determined by the frame type chosen.

There are four fixed-length data frames supported by the frame type: 1 word, 2 words, 4 words, and 6 words.

Additionally, there is a user-defined data length frame type where the number of data words is fixed by software. Anywhere from 1 to 16 words can be transmitted in this frame type. This length must be configured in the N\_WORDS field of the transmitter’s TX\_FRAME\_CTRL register and receiver’s RX\_OPER\_CTRL register.

### 27.3.4.3 Multi-Lane Transmission

The FSI is capable of transmitting and receiving data on two parallel data lines. When enabled, data bits are split between the data lines while the start of frame, frame type, frame tag, and end of frame fields are identical and complete on each line. The user data, data, and CRC fields are split between the data lines. Starting with the most-significant bit, the odd-numbered bits appear on D0 and even-numbered bits appear on D1.

In the following example, assume the following:

8-bit user data: u7u6u5u4u3u2u1u0

16-bit data: d15d14d13d12...d1d0

8-bit CRC: c7c6c5c4c3c2c1c0

**Table 27-9. Multi-Lane Frame Format**

Idle State	Preamble	SOF	Frame Type	User Data	Data Words	CRC Byte	Frame Tag	EOF	Postamble	Idle State
TXD0	1111	1001	0011	u7u5u3u1	d15d13...d1	c7c5c3c1	xxxx	0110	1111	
TXD1	1111	1001	0011	u6u4u2u0	d14d12...d0	c6c4c2c0	xxxx	0110	1111	

### 27.3.5 Flush Sequence

Every time there is a soft reset of the receiver, the receiver requires a flush sequence from the transmitter before the receiver can receive and decode frames. The receiver core has an asynchronous reset mechanism that allows the receive module to be reset even in the absence of the receive clocks. However, due to the design, this reset is released synchronous to the receive clock (RXCLK). Thus, the receiver requires five full clock pulses to be able to come out of reset. Sending the flush pattern makes sure that these clock edges are received and any subsequent frames sent to the receiver are correctly interpreted.

The flush sequence consists of a single toggle on both of the data lines as well as five consecutive pulses on the clock line.

If the FSI receiver is receiving data from a standard SPI, a data word of 0xFFFF from the SPI has the same effect as a flush sequence.

Figure 27-8 shows a sample plot of the flush sequence.

**Figure 27-8. Flush Sequence Signals**

### 27.3.6 Internal Loopback

The transmitter and receiver cores can be connected together internally to allow for development and debug. This is achieved by setting `RX_MAIN_CTRL.INT_LOOPBACK` to 1. Internal loopback routes the signals from the corresponding transmitter to the appropriate receiver pin. No configuration needs to be done in the transmitter.

Figure 27-9 shows the signal connections with internal loopback.

In this device, there are two FSI transmitter cores (A and B), and four receiver cores (A, B, C, and D). When using loopback mode, FSITXA can be used in loopback mode with FSIRXA and FSIRXC. At the same time, FSITXB can be used in loopback mode with FSIRXB and FSIRXD.

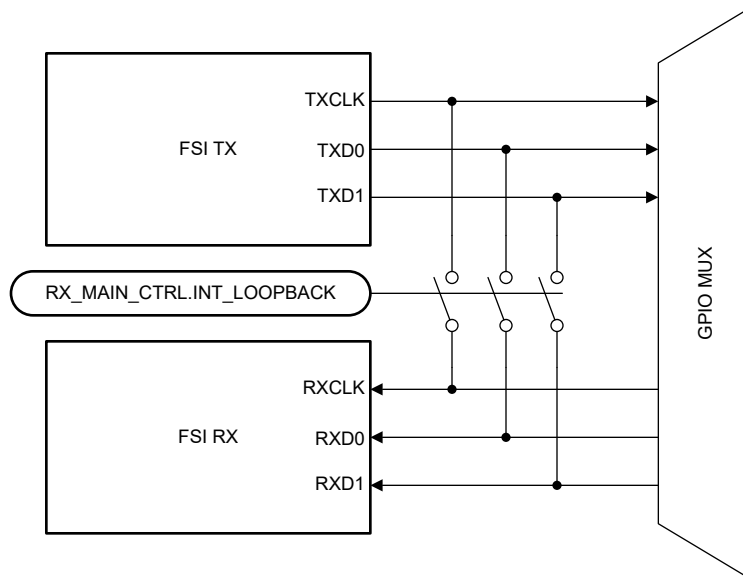

Figure 27-9. FSI with Internal Loopback

Table 27-10. Loopback Connections

TX Module	RX Modules
FSIA TX	FSIA RX, FSIC RX
FSIB TX	FSIB RX, FSID RX

### 27.3.7 CRC Generation

The FSI uses CRC-8 with the polynomial 0x07 for the internal hardware CRC generation. This polynomial is also represented as  $x^8+x^2+x+1$ .

For example, for a 2-word data packet the following calculation occurs:

Data-1 = 0x4433

Data-0 = 0x2211

User Data = 0xAA

The CRC is computed with the bytes being taken in the following order (first to last):

0xAA – Byte 0, User Data

0x11 – Byte 1, Data-0, Least-significant byte

0x22 – Byte 2, Data-0, Most-significant byte

0x33 – Byte 3, Data-1, Least-significant byte

0x44 – Byte 4, Data-1, Most-significant byte

### 27.3.8 ECC Module

The FSI module comes with a 16-bit or 32-bit ECC computation module in both the transmitter and receiver. Use of this module is optional.

Note that the ECC is independent and unrelated to the hardware CRC computation module present in both the transmitter and receiver cores.

The following example shows a scenario in which the application requires ECC be calculated and transmitted on a 2-word data frame.

In the FSITX module:

1. Configure the ECC module for 32-bit data by setting TX\_OPER\_CTRL\_HI.ECC\_SEL to 1.
2. Write the data to the TX\_ECC\_DATA register as well as the transmit buffer.
3. Read TX\_ECC\_VAL Register. This register contains the 8-bit ECC value calculated on the data.
4. Copy the 8-bit data from TX\_ECC\_VAL to TX\_FRAME\_TAG\_UDATA.USER\_DATA.
5. Set the Start Condition to begin the transmission.

The reverse process is followed on the FSIRX module. Once the data frame is received, user software can do the following:

1. Copy the data from the receive buffer to the RX\_ECC\_DATA register.
2. Copy the received user data that contains the transmitted ECC value from RX\_FRAME\_TAG\_UDATA.USER\_DATA to the RX\_ECC\_VAL register.
3. Read the RX\_ECC\_LOG register. This contains the result of the ECC computation using the RX\_ECC\_DATA and RX\_ECC\_VAL registers.
  - a. If no ECC errors were detected, RX\_ECC\_LOG is 0. The correct data is available in RX\_ECC\_SEC\_DATA.
  - b. If a single bit error was detected, RX\_ECC\_LOG.SBE is 1. The autocorrected data is available in RX\_ECC\_SEC\_DATA.
  - c. If multiple bit errors occurred, RX\_ECC\_LOG.MBE is 1. The data in RX\_ECC\_SEC\_DATA is invalid and must not be used.

Using a 2-word data frame plus using the user data for the ECC is one possible implementation for ECC detection. Another option is to use a larger data frame and allocate one of the data words to be the ECC value.

### 27.3.9 Tag Matching

The FSI receiver core has the capability of generating an interrupt when the received data or ping frame's tag matches the reference tag in RX\_FRAME\_TAG\_CMP or RX\_PING\_TAG\_CMP, respectively.

Each tag compare register allows the user to not only select a reference tag (TAG\_REF) but also set up a mask (TAG\_MASK) to ignore specified bits in the reference tag. For tag matching to be enabled, the CMP\_EN bit must be set. When the tag compare is enabled and a successful match occurs, the PING\_TAG\_MATCH, the DATA\_TAG\_MATCH or the ERROR\_TAG\_MATCH in RX\_EVT\_ERR\_STATUS is set. The corresponding match register status can be cleared by writing to RX\_EVT\_ERR\_CLEAR. Also, if required to set the match register status in software, the user must do so by writing to the RX\_EVT\_ERR\_SET register.

The tag matching scheme is not a filtering scheme. Tag matching is only a notification scheme to alert the user when a specific tag is detected in a data or ping frame. Both RX\_INTR\_EVT\_CTRL\_1 and RX\_INTR\_EVT\_CTRL\_2 interrupts can be set up to generate an interrupt when a tag match event occurs.

Another feature used when tag matching is enabled is the broadcast feature. The broadcast feature can be enabled by setting the BRDCST\_EN in RX\_FRAME\_TAG\_CMP or RX\_PING\_TAG\_CMP. When broadcast mode is enabled, the third bit of the tag is treated as a broadcast bit. If the received tag has a third bit set, then the tag is treated as a match regardless of the other tag bit comparisons. Note that a match caused by TAG\_REF and TAG\_MASK is also considered a match.

Note that the tag matching scheme is not a filtering scheme. For example, if tag matching is enabled and a frame is received with a non-matching tag, the frame is still saved in the buffer and the corresponding event status bits (FRAME\_DONE, DATA\_FRAME\_RCVD) is set.

Tag matching is required in multi-peripheral TDM configurations as described in [Section 27.3.11](#); however, tag matching can also be used in single-peripheral configurations as needed.

### 27.3.10 User Data Filtering (UDATA Matching)

The FSI receiver core has the capability of filtering data frames and only receive packets when received data UDATA (user data) matches the reference UDATA in RX\_UDATA\_FILTER.

The UDATA filter compare register allows you to not only select a reference UDATA (UDATA\_REF) but also set up a mask (UDATA\_MASK) to ignore specified bits in the reference user data. For user data filtering to be enabled, the RX\_MAIN\_CTRL.DATA\_FILTER\_EN bit must be set. When the user data filtering is enabled, only a successful match allows the packet to be received in the FSIRX circular buffer and all non-matching packets are ignored.

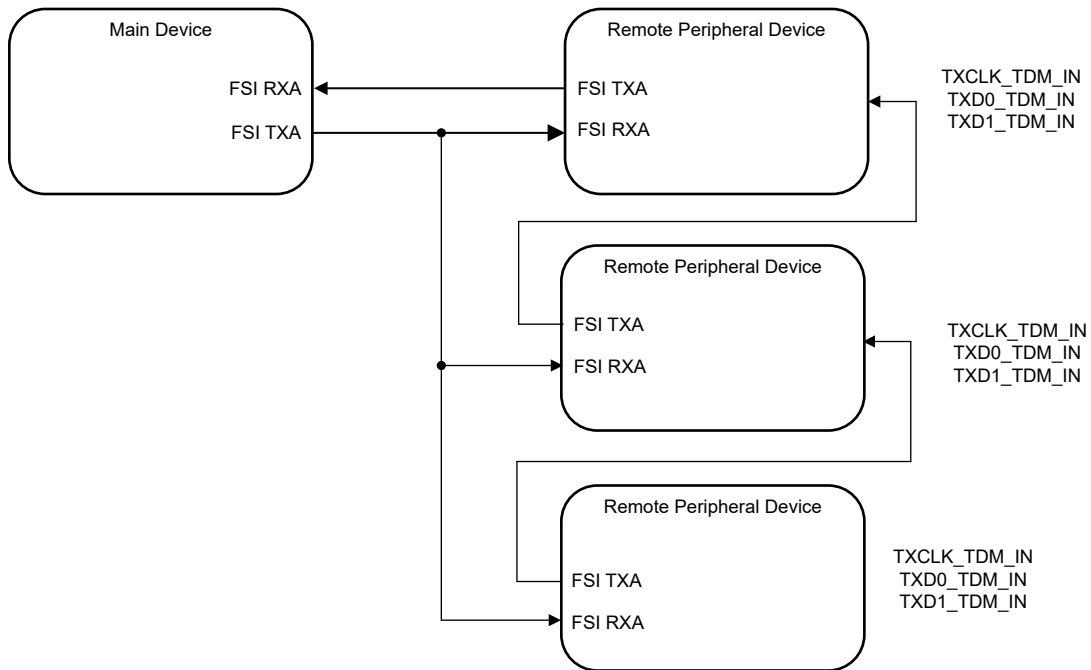

The user data matching scheme is a filtering scheme.

User data filtering is used in multi-peripheral configurations as described in [Section 27.3.11](#); however, user data filtering can be used in single-peripheral configurations as needed.

### 27.3.11 TDM Configurations

The FSI module in this device supports multi-node TDM configurations, whereas a single main device can control multiple remote node devices. To use the FSI module in the multi-node TDM configuration described, the remote node device must utilize tag matching and user data filtering.

This multi-node TDM configuration is supported in the FSI module through time-division multiplexing. When TDM is enabled, each remote node device must also have tag matching enabled. [Figure 27-10](#) shows a scheme where a single main device is communicating with multiple remote node devices. All FSI receive modules in the remote node devices are directly connected to the main device transmit module. The transmit modules of the remote node devices are chained serially such that each transmit module is connected to the next remote node device and the last remote node device output connects to the main device receive module. Each remote node device decides, based on the received frame's tag, whether to transmit the data or to enter bypass mode where the previous remote node device transmit module directly connects to the next remote node device. This is done by using the FSI transmit module TDM\_IN.

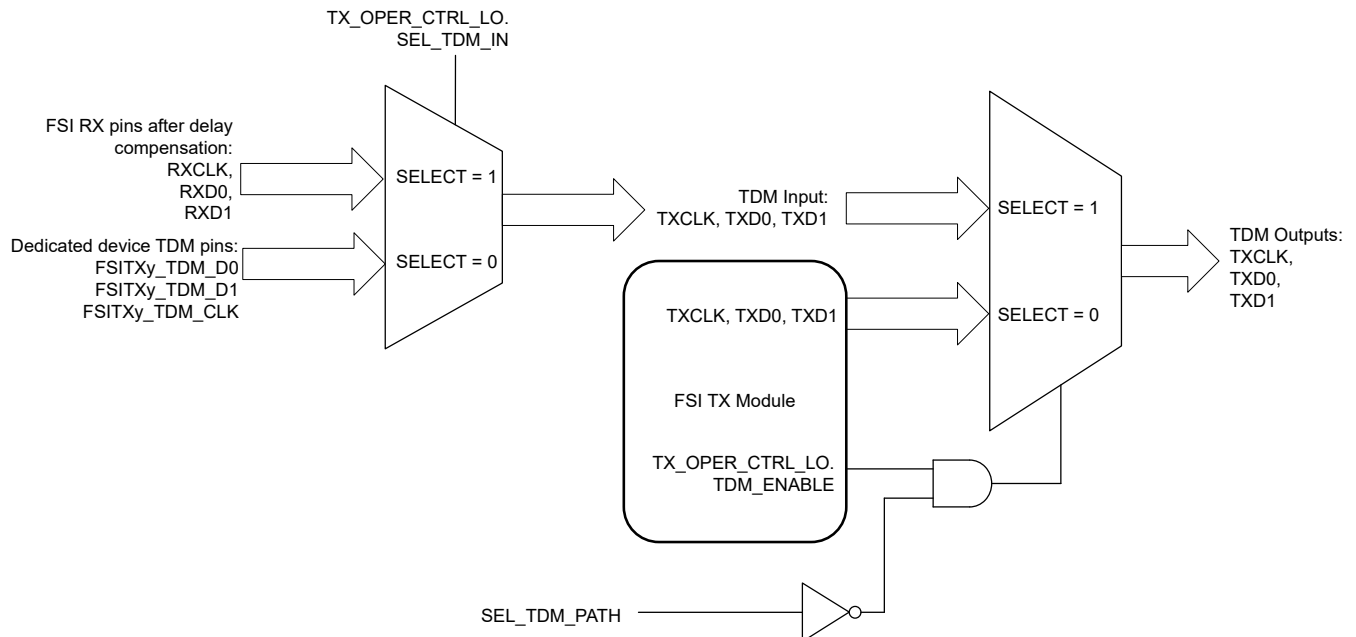

**Figure 27-10. FSI Multi-Node TDM Configuration**

**Note**

FSI C and FSI D are not part of the TDM connections.

When an FSI transmitter module is used in TDM mode, TXCLK\_TDM\_IN, TXD0\_TDM\_IN and TXD1\_TDM\_IN pins are used if the transmitter is required to enter bypass mode. Figure 27-11 shows how the FSI module operates when in multi-node TDM mode.

**Figure 27-11. FSI Transmitter Multi-Node TDM Multiplexing**

The SEL\_TDM\_PATH signal is sourced from the CLB module. The CLB module also generates the transmit trigger for the FSI transmitter. The CLB module must be configured to decide when to generate the FSI transmit trigger based on the status of the data, ping, and frame tag match generated by the FSI receiver module. The FSITX module must be configured to transmit on an external trigger and the corresponding CLB trigger input must be selected. In a broadcast scenario (FSI tag match notifies all remote node devices that a match has occurred), the CLB module inside each remote node device generates a trigger and SEL\_TDM\_PATH signal. The main key here is that the trigger and the SEL\_TDM\_PATH signal must be generated at a different time interval in a non-overlapping manner. Figure 27-12 shows an example of FSI transmit triggers and the multi-node TDM SEL\_TDM\_PATH signals generated by the RX\_TRIGx signal or the CLB module of the remote node devices in a broadcast scenario.

**Figure 27-12. Generated Signals for FSI Multi-Node TDM Configuration**

The TXCLK\_TDM\_IN, TXD0\_TDM\_IN, and TXD1\_TDM\_IN for the FSI transmit modules available in this device are shown in Table 27-11.

**Table 27-11. FSI TDM Inputs**

FSI Transmit Module	TXCLK_TDM_IN	TXD0_TDM_IN	TXD1_TDM_IN
FSITXA	FSIRXB RXCLK	FSIRXB RXD0	FSIRXB RXD1
FSITXB	FSIRXA RXCLK	FSIRXA RXD0	FSIRXA RXD1

The FSI transmit modules are configured to use the external triggers generated by the CLB to initiate the transmission. Through appropriate configurations, the logic is designed to work assuming that only one TDM trigger is generated until the transmission is completed. In the case where there is another trigger before the current transmission is completed, an error is flagged in the TX\_EVT\_ERR\_STATUS register. Figure 27-13 shows the connections between CLB, FSITX, and FSIRX modules.

**Figure 27-13. FSI and CLB Multi-Node TDM Connections**

In Figure 27-10, the main device is connected to three remote node devices. The main device uses FSITXA to transmit frames to the three remote node devices. Each remote node device receives every frame, using the FSIRXA. The remote node devices are chained together using the FSITXA output and FSIRXB inputs (configured as FSITXA TDM input). When a remote node device receives a frame using the FSIRXA, the device checks the tag of the frame to see if the tag matches the specified reference value in the tag compare register. When a match does occur, the CLB module configures the FSITXA of the remote node device to select the local FSITXA outputs as the source for the output pins. However, if a match does not occur, the FSITXA of the remote node device is configured to enter bypass mode. There, the device selects the FSITXA TDM inputs (which is FSIRXB) to be passed on to the output pins.

In this case, when a frame is transmitted by the main device and the frame tag is matched only in one of the remote node devices, all other devices with non-matching tags enter the bypass mode to allow the main device to receive frames from the chosen remote node device.

### 27.3.12 FSI Trigger Generation

The RX\_TRIGx external trigger can be used to initiate FSITX transmission. RX\_TRIG0 must be used if TDM mode (multi-node configuration) is required. RX\_TRIG0 must be used as the trigger source for start of transmission while the programmable stretch width RX\_TRIG0 signal is used as the SEL\_TDM\_PATH signal (which decides whether the local FSITX is active or put in bypass mode).

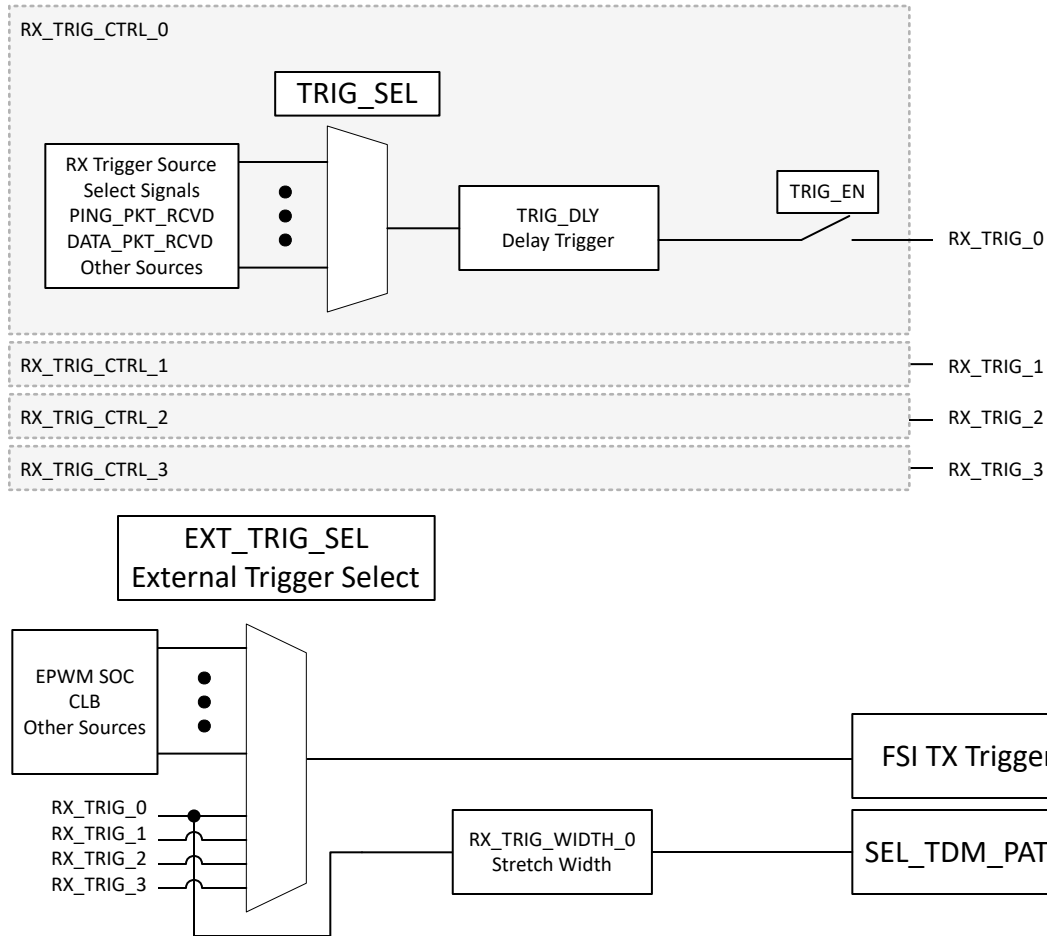

Figure 27-14. RX\_TRIGx FSI Trigger

The signal source for the RX\_TRIGx signal is selected through the RX\_TRIG\_CTRL\_x.TRIG\_SEL bits, as listed in [Table 27-12](#).

Table 27-12. RX\_TRIGx Trigger Select Signals

RX_TRIG_CTRLx.TRIG_SEL	Selected Signal
0	Ping Packet Received
1	Data Packet Received
2	Error Packet Received
3	Ping Frame Tag Match Occurred
4	Data Frame Tag Match Occurred
5	Error Frame Tag Match Occurred
6	Frame Done
7	Reserved
8 to 15	Reserved

The RX\_TRIGx signals can optionally be delayed (this can be used in TDM scenarios) through the RX\_TRIG\_CTRL\_x.TRIG\_DLY.

### 27.3.13 FSI-SPI Compatibility Mode

The FSI supports a SPI compatibility mode. While the FSI can communicate with a standard SPI module, the FSI supports a limited configuration. The features of this compatibility mode are:

- Data transmits on rising edge and receive on falling edge of the clock.
- Only 16-bit word size is supported.
- TXD1 is driven like an active-low, chip-select signal. The signal is low for the duration for the full frame transmission.
- No receiver chip-select input is required. RXD1 is not used. Data is shifted into the receiver on every active clock edge.
- No preamble or postamble clocks are transmitted. All signals return to the IDLE state after the frame phase is finished.
- It is not possible to transmit in the SPI peripheral configuration because the FSI TXCLK cannot take an external clock source.

Table 27-13 lists the frame structure of the FSI-SPI compatibility mode. Each frame phase is present in this mode. If the FSI is transmitting to a standard SPI module, the SPI must decode the frame structure. Similarly, if the FSI is configured as a SPI peripheral, the standard SPI must encode the transmission to be sent.

**Table 27-13. FSI-SPI Compatibility Frame Structure**

Idle State	Start of Frame	Frame Type	User Data	Data Words	CRC byte <sup>(1)</sup>	Frame Tag	End of Frame	Idle State
	1001	4 bits	8 bits	1-16 words	8 bits	4 bits	0110	

(1) The CRC byte is present only in data frames.

Because of the requirement that the standard SPI module encodes the various frame data, this limits the type of modules that can be connected to the FSI in SPI mode. The paired SPI module must have enough functionality to encode and decode the frames.

If the FSI is transmitted to a standard 16-bit SPI, the data is arranged in the following manner. The example provided in Table 27-14 assumes a DATA\_2\_WORD frame has been sent.

**Table 27-14. Contents of Data Received by a Standard SPI**

SPI Data	Data Contents
SPI word 0	1001, 0100, 8-bit User Data
SPI word 1	Data word 1
SPI word 2	Data word 2
SPI word 3	8-bit CRC, 4-bit Frame Tag, 0110

**27.3.13.1 Available SPI Modes**

There are a few wiring schemes available for the FSI to use when communicating with an SPI module.

**27.3.13.1.1 FSITX as SPI Controller, Transmit Only**

The FSITX can operate as an independent SPI controller module. In this condition, TXCLK is connected to SPICLK, TXD0 is connected to SPIPICO, and TXD1 is connected to  $\overline{\text{SPIPTE}}$ , the chip select.

**Figure 27-15. FSITX as SPI Controller, Transmit Only**

When the FSI is an SPI transmitter, the application has the ability to check for frame errors, line breaks, CRC errors, and ECC checks on data. These are all encoded by hardware in every FSI frame. The SPI receiver requires some software to act upon this information.

**Table 27-15. FSI as Controller Transmitter, SPI as Peripheral Receiver**

Capability	Availability	Comment
Framing checks on the data frames	Yes	Can be implemented in software on the SPI receiver.
Ability to detect line breaks	Yes	Can be implemented in software on the SPI receiver but requires additional software overhead such as a timer or watchdog.
CRC check	Yes	Can be implemented in software on the SPI receiver. For devices that have VCRC, this is more efficient.
ECC on data	Yes	Can be implemented in software on the SPI receiver
Detection of abruptly terminated frames	No	
Double edge data rate	No	
Recovery from glitches on signal lines between frames	No	
Skew adjustment on signal lines	No	

**27.3.13.1.1.1 Initialization**

To configure the FSITX module to be an SPI controller for transmit only, proceed through the standard FSITX initialization procedure. Before releasing the FSITX from reset, set TX\_OPER\_CTRL\_LO.SPI\_MODE to 1. This enables the SPI clocking scheme and signaling structure.

**27.3.13.1.1.2 Operation**

The operation of the FSITX module in FSI-SPI Compatibility mode is the same as if the module is in standard FSI mode. The application can utilize the frame timer, ping frames, external frame triggers, and so on. Refer to [Section 27.3.2](#) for more information on each of these features.

### 27.3.13.1.2 FSIRX as SPI Peripheral, Receive Only

The FSIRX can operate as an independent SPI peripheral module. In this usage, RXCLK is connected to SPICLK and RXD0 is connected to SPIPICO. RXD1 is unused. There is no requirement for a chip select signal to be used when connected to the FSIRX. This is because the FSIRX responds to any incoming clock edge. If there is any noise or unwanted clock transitions, a flush sequence is required to resynchronize the FSIRX module with the controller.

**Figure 27-16. FSIRX as SPI Peripheral, Receive Only**

When the FSI is an SPI receiver communicating with an SPI transmitter, the application has the ability to detect frame errors, line breaks, CRC errors, ECC checks on data, as well as abruptly terminated frames. Note that the FSI can handle all of this in hardware, but the SPI transmitter must encode the information into the data to be transmitted.

**Table 27-16. SPI as Controller Transmitter, FSI as Peripheral Receiver**

Capability	Availability	Comment
Framing checks on the data frames	Yes	Standard on FSI
Ability to detect line breaks	Yes	Can be implemented in software on the SPI transmitter but requires the use of a timer or watchdog in the transmitting SPI device.
CRC check	Yes	Can be implemented in software on the SPI transmitter.
ECC on data	Yes	Can be implemented in software on the SPI transmitter.
Detection of abruptly terminated frames	Yes	This is accomplished with the FSI setting up the frame watchdog counter.
Double edge data rate	No	
Recovery from glitches on signal lines between frames	Yes	Whenever glitches occur on either the clock or data lines in between transmissions, the initial flush pattern of a frame discards the effects of these glitches and causes the receiver to resynchronize when the real "start-of-frame" pattern is seen. So, the ability to reject glitches in between frames is very high.
Skew adjustment on signal lines	Yes	The FSI receiver has the ability to add delays to the incoming signal lines.

#### 27.3.13.1.2.1 Initialization

To configure the FSIRX module to be an SPI peripheral for receiving only, proceed through the standard FSIRX initialization procedure. Before releasing the FSIRX from reset, set `RX_OPER_CTRL.SPI_MODE` to 1. This enables the SPI clocking scheme and signaling structure.

#### 27.3.13.1.2.2 Operation

The operation of the FSIRX module in FSI-SPI compatibility mode is the same as if the module is in standard FSI mode. The application can utilize the Frame and Ping Watchdogs, CRC and ECC checks, and so on. Refer to [Section 27.3.3](#) for more information on each of these features.

### 27.3.13.1.3 FSITX and FSIRX Emulating a Full Duplex SPI Controller

In this configuration, the FSITX is the controller clock. The FSITX module drives TXCLK (SPICLK), TXD0 (SPIPICO), and TXD1 (SPISTE/chip select) to the SPI peripheral. The SPIPOCI signal is connected back to the RXD0 signal. RXCLK can be applied either using the internal SPI pairing feature or externally wired, depending on the application requirements. Since the FSITX and RX modules are independent, the FSIRX can also be thought of as an additional SPI peripheral. Some software logic is required for the FSI to emulate an SPI controller fully.

Figure 27-17. FSITX and FSIRX as SPI Controller, Full Duplex

#### 27.3.13.1.3.1 Initialization

To configure both FSITX and RX modules for full duplex SPI controller operation, follow the initialization instructions for each module described in the preceding sections. Both FSITX and RX modules must set the respective SPI\_MODE bits. This enables the SPI clocking scheme and signaling structures.

If internal clock loopback is desired, the FSIRX module must also set RX\_MAIN\_CTRL.SPI\_PAIRING to 1. This internally connects TXCLK to RXCLK. If using internal clock loopback, the GPIO used for RXCLK can be reallocated to other application requirements.

If the application requires an external clock loopback, make sure that TXCLK is connected to RXCLK. This is required if the SPI peripheral is across an isolation barrier and there is latency between TXCLK being launched and SPIPOCI data being received on RXD0.

#### 27.3.13.1.3.2 Operation

In this mode of operation, some higher level software must be written to emulate a full SPI controller module. There is no path for the transmit module to determine what the receive module received. Both the TX and RX modules are still able to utilize the various other features available, such as the ping frame timer, ping frame and frame watchdogs, CRC and ECC error checkers, and so on. The procedure for configuring these features is described elsewhere in this document.

## 27.4 FSI Programming Guide

This section describes various operational sequences and features for the FSI.

### 27.4.1 Establishing the Communication Link

Once the transmitter and receiver modules have been configured, some synchronization must occur before the modules exchange data. Since the receiver accepts data on any clock transition, the receiver core logic must be flushed to properly interpret the start of a new, valid frame. This is especially true when the FSI modules reside on separate devices and are possibly isolated.

The following example provides a suggested approach for establishing a clean communication link on two separate devices that power up in an arbitrary order. Note that this is only a sample synchronization. Depending on application requirements, a different approach can be followed. The single, most important aspect of synchronization is to make sure that the receiver is properly flushed and ready to receive a complete frame without error. How to achieve this is up to the application.

Figure 27-18 shows the connection of the devices in this example. While there is no true concept of a main device or a remote device node in the FSI protocol, the example uses this nomenclature as a simple way to describe the data flow.

**Figure 27-18. Point to Point Connection**

Device 1 is the main node; it is the driver of the initialization sequence. Device 2 is the remote node; it responds to the main device commands. In this example, as well as in a real world use-case, neither the main device nor the remote device knows precisely when the other is ready to receive communication.

Sample sequences for both the main device and remote device are provided in the following subsections.

#### 27.4.1.1 Establishing the Communication Link from the Main Device

The following sequence is an example of how the main device node establishes the communication link with the remote device without external signals outside of the standard communication link.

1. Assert the core reset to both the FSITX and FSIRX modules, and then deassert the resets.
2. Configure the transmitter and receiver for desired operation.
3. Set up the receiver interrupts to detect an incoming transmission.
4. Begin the ping loop:
  - Send the flush sequence.
  - Send a ping frame with the frame tag 0000.
  - Wait for some time. (determined by application)
  - If the FSIRX has received a valid ping frame, continue; else, iterate the loop again.
  - If the received ping frame tag was 0001, continue; else, iterate the loop again.
5. Send a ping frame with the frame tag 0001.

At this point, both the main transmit and receive channels have successfully received a frame from the remote counterparts. The link has been established and standard application communication can begin.

#### 27.4.1.2 Establishing the Communication Link from the Remote Device

The following sequence is an example of how the remote device node establishes the communication link with the main device without external signals outside of the standard communication link.

1. Apply the core reset to both the FSITX and FSIRX modules, and then release the reset.
2. Configure the transmitter and receiver for desired operation.
3. Set up the receiver interrupts to detect an incoming transmission.
4. Wait for a receiver interrupt.
5. If the FSIRX has received a valid ping frame, continue; else, return to step 4.
6. If the received frame tag was 0000, continue; else, discard the transmission and return to step 4.
7. Send the flush sequence.
8. Send a ping frame with the frame tag 0001.
9. Wait for a receiver interrupt.
10. If the FSIRX has received a valid ping frame, continue; else, return to step 4.
11. If the received ping frame tag was 0001, continue; else, if the received frame tag was 0000, return to step 9.  
This can happen if a second ping frame was already in transit before receiving the remote device response in step 8.

At this point, both the transmit and receive modules have successfully received ping frames from the main counterparts. The link has been established and regular communication can now proceed. The application can configure periodic ping frames from the transmitter, initialize the receiver ping and frame watchdogs, and begin the communication required by the application.

### 27.4.2 Register Protection

Both the FSITX and FSIRX modules contain control registers that have embedded write protection. This is accomplished through EALLOW, register keys, and a main register lock. These protections make sure that no spurious writes or unintentional modifications to these registers are accepted. For the list of registers with write protections available and the register and bit descriptions, refer to the *FSI Registers* section..

#### EALLOW Protection

EALLOW is a device-level register protection, refer to the *EALLOW Protection* section of the *System Control and Interrupts* chapter for more information on EALLOW. For those registers with EALLOW protection, the EALLOW bit is set before modifying the register. The application then clears the EALLOW bit to re-enable the write protection when access to EALLOW-protected registers are complete.

#### Register Key Protection

In addition to EALLOW, some bits in the FSI registers are protected by a key. To write to these bits, the key must be written at the same time. For example, to put the transmitter core into reset, TX\_MAIN\_CTRL.CORE\_RST must be set. To do this, write 0xA501 to TX\_MAIN\_CTRL, where 0xA500 is the KEY value, and 0x0001 is the CORE\_RST value. Refer to the *Registers* section for more information on which registers have write keys added.

#### Control Register Lock Protection

There also exists a main lock to prevent any modifications to the control registers. There is an independent lock for each FSI module. For the list of registers that are protected by this control register lock, refer to the *Registers* section. The control register lock prevents any writes to the control registers until the lock is released. To set the control register lock, write 0xA501 to RX\_LOCK\_CTRL and TX\_LOCK\_CTRL for the receiver and transmitter, respectively.

The control register lock cannot be disabled by the application until a SYSRSn has been asserted. This can occur at the device level, or by writing to the appropriate peripheral soft reset register (DEV\_CFG\_REGS.SOFTPRESx) for the FSI module. Refer to [Section 27.3.2.7](#) for more information on SYSRSn.

### 27.4.3 Emulation Mode

There is no specific emulation mode or configuration supported. The FSI cores are always in free running mode. CPU halts do not have any effect on the operation of the FSI. Reads of registers and data buffers by the debugger do not affect any flags or status of the data buffers.

If you want to stop the operation of either FSI module when the debugger halts, the following steps are required:

1. Set the debugger to real-time emulation mode.
2. Mark the FSI interrupt group as a time-critical interrupt. That is, enable the corresponding bit in the DBGIER register.
3. The ISR can check the DSTAT register and to determine if the ISR was called when the debugger was halted.
4. FSI operations can be disabled and the ISR can branch to a debug-specific halt location.

## 27.5 Software

### 27.5.1 FSI Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/fsi

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 27.5.1.1 FSI Loopback:CPU Control - SINGLE\_CORE

FILE: fsi\_ex1\_loopback\_cpucontrol.c

Example sets up infinite data frame transfers where trigger happens through *CPU*. Automatic(Hw triggered) Ping frame transmission is also setup along with data.

User can edit some of configuration parameters as per usecase. These are as below. Default values can be referred in code where these globals are defined

- *txUserData* - User data to be sent with Data frame
- *txDataFrameTag* - Frame tag used for Data transfers
- *txPingFrameTag* - Frame tag used for Ping transfers

For any errors during transfers i.e. *error* events such as Frame Overrun, Underrun, Watchdog timeout and CRC/EOF/TYPE errors, execution will stop immediately and status variables can be looked into for more details. Execution will also stop for any mismatch between received data and sent ones and also if transfers takes unusually long time(detected through software counters - txTimeOutCntr and rxTimeOutCntr)

#### External Connections

- None.

#### Watch Variables

- *dataFrameCntr* Number of Data frame transfered
- *error* Non zero for transmit/receive data mismatch

#### 27.5.1.2 FSI data transfers upon CPU Timer event - SINGLE\_CORE

FILE: fsi\_ex2\_periodic\_frame.c

Example sets up infinite data frame transfers where trigger comes from ISR handling the periodic CPU Timer event. Automatic(Hw triggered) Ping frame transmission is also setup along with data.

CPU Timer0 is chosen for setting up periodic timer events. User can choose any other Timer-1/Timer-2 as well.

Automatic(Hw triggered) Ping frame transmission is also setup along with data.

If there are any comparison failures during transfers or any of error event occurs, execution will stop.

#### External Connections

- None

#### Watch Variables

- *dataFrameCntr* Number of Data frame transfered
- *error* Non zero for transmit/receive data mismatch

## 27.6 FSI Registers

This section describes the Fast Serial Interface Registers. The FSI module contains two distinct sets of registers. One for the FSI receiver and one for the FSI transmitter.

### 27.6.1 FSI Base Address Table

**Table 27-17. FSI Base Address Table**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	CPU2	CPU2.DMA	Pipeline Protected
Instance	Structure								
FsiTxaRegs	<a href="#">FSI_TX_REGS</a>	FSITXA_BASE	0x0000_6600	YES	YES	YES	YES	YES	YES
FsiRxaRegs	<a href="#">FSI_RX_REGS</a>	FSIRXA_BASE	0x0000_6680	YES	YES	YES	YES	YES	YES
FsiTxbRegs	<a href="#">FSI_TX_REGS</a>	FSITXB_BASE	0x0000_6700	YES	YES	YES	YES	YES	YES
FsiRxbRegs	<a href="#">FSI_RX_REGS</a>	FSIRXB_BASE	0x0000_6780	YES	YES	YES	YES	YES	YES
FsiRxcRegs	<a href="#">FSI_RX_REGS</a>	FSIRXC_BASE	0x0000_6880	YES	YES	YES	YES	YES	YES
FsiRxdRegs	<a href="#">FSI_RX_REGS</a>	FSIRXD_BASE	0x0000_6980	YES	YES	YES	YES	YES	YES

## 27.6.2 FSI\_TX\_REGS Registers

Table 27-18 lists the memory-mapped registers for the FSI\_TX\_REGS registers. All register offset addresses not listed in Table 27-18 should be considered as reserved locations and the register contents should not be modified.

**Table 27-18. FSI\_TX\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	TX_MAIN_CTRL	Transmit main control register	EALLOW	<a href="#">Go</a>
2h	TX_CLK_CTRL	Transmit clock control register	EALLOW and LOCK	<a href="#">Go</a>
4h	TX_OPER_CTRL_LO	Transmit operation control register low	EALLOW and LOCK	<a href="#">Go</a>
5h	TX_OPER_CTRL_HI	Transmit operation control register high	EALLOW and LOCK	<a href="#">Go</a>
6h	TX_FRAME_CTRL	Transmit frame control register		<a href="#">Go</a>
7h	TX_FRAME_TAG_UDATA	Transmit frame tag and user data register		<a href="#">Go</a>
8h	TX_BUF_PTR_LOAD	Transmit buffer pointer control load register	EALLOW	<a href="#">Go</a>
9h	TX_BUF_PTR_STS	Transmit buffer pointer control status register		<a href="#">Go</a>
Ah	TX_PING_CTRL	Transmit ping control register	EALLOW and LOCK	<a href="#">Go</a>
Bh	TX_PING_TAG	Transmit ping tag register		<a href="#">Go</a>
Ch	TX_PING_TO_REF	Transmit ping timeout counter reference	EALLOW and LOCK	<a href="#">Go</a>
Eh	TX_PING_TO_CNT	Transmit ping timeout current count		<a href="#">Go</a>
10h	TX_INT_CTRL	Transmit interrupt event control register	EALLOW and LOCK	<a href="#">Go</a>
11h	TX_DMA_CTRL	Transmit DMA event control register	EALLOW and LOCK	<a href="#">Go</a>
12h	TX_LOCK_CTRL	Transmit lock control register	EALLOW and LOCK	<a href="#">Go</a>
14h	TX_EVT_STS	Transmit event and error status flag register		<a href="#">Go</a>
16h	TX_EVT_CLR	Transmit event and error clear register	EALLOW	<a href="#">Go</a>
17h	TX_EVT_FRC	Transmit event and error flag force register	EALLOW	<a href="#">Go</a>
18h	TX_USER_CRC	Transmit user-defined CRC register		<a href="#">Go</a>
20h	TX_ECC_DATA	Transmit ECC data register		<a href="#">Go</a>
22h	TX_ECC_VAL	Transmit ECC value register		<a href="#">Go</a>
24h	TX_DLYLINE_CTRL	Transmit delay Line control register	EALLOW and LOCK	<a href="#">Go</a>
40h + formula	TX_BUF_BASE_y	Base address for transmit buffer		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 27-19 shows the codes that are used for access types in this section.

**Table 27-19. FSI\_TX\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		

**Table 27-19. FSI\_TX\_REGS Access Type Codes (continued)**

Access Type	Code	Description
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 27.6.2.1 TX\_MAIN\_CTRL Register (Offset = 0h) [Reset = 0000h]

TX\_MAIN\_CTRL is shown in [Figure 27-19](#) and described in [Table 27-20](#).

Return to the [Summary Table](#).

Transmit main control register

**Figure 27-19. TX\_MAIN\_CTRL Register**

15	14	13	12	11	10	9	8
KEY							
W-0h							
7	6	5	4	3	2	1	0
RESERVED						FLUSH	CORE_RST
R-0h						R/W-0h	R/W-0h

**Table 27-20. TX\_MAIN\_CTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-8	KEY	W	0h	Write Key In order to write to any bit in this register, 0xA5 must be written to this field at the same time. Otherwise, writes are ignored. The key is cleared immediately after writing, so it must be written again for every change to this register. Reset type: SYSRSn
7-2	RESERVED	R	0h	Reserved
1	FLUSH	R/W	0h	Flush Operation Start bit This bit will cause the transmitter to initiate a flush pattern of a single toggle on the TXD0 and TXD1 followed by five full cycles of TXCLK. This bit should be written only when the CORE_RST bit is 0 and the clock to the Transmitter core is turned on. 0h (R/W) = Clear this bit. 1h (R/W) = Setting this bit will initiate flush sequence. To properly execute a flush sequence, Set FLUSH to 1, wait for five TXCLK cycles then clear FLUSH to 0. Note: The KEY field must contain 0xA5 for any write to this bit to take effect. The software must keep this bit set to 1 for at least five TXCLK cycles before setting it back to 0. Reset type: SYSRSn
0	CORE_RST	R/W	0h	Transmitter Main Core Reset bit This bit controls the transmitter main core reset. In order to send any frame, this bit must be cleared. 0h (R/W) = Transmitter core is not in reset and can transmit frames. 1h (R/W) = Transmitter core is held in reset. Note: The KEY field must contain 0xA5 for any write to this bit to take effect. Reset type: SYSRSn

### 27.6.2.2 TX\_CLK\_CTRL Register (Offset = 2h) [Reset = 0000h]

TX\_CLK\_CTRL is shown in [Figure 27-20](#) and described in [Table 27-21](#).

Return to the [Summary Table](#).

Transmit clock control register

**Figure 27-20. TX\_CLK\_CTRL Register**

15	14	13	12	11	10	9	8

**Table 27-21. TX\_CLK\_CTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-10	RESERVED	R	0h	Reserved
9-2	PRESCALE_VAL	R/W	0h	<p>Clock Divider Prescale Value</p> <p>The input clock is divided by this 8-bit value and fed into the transmitter core. This divided clock is the rate at which TXCLK will operate.</p> <p>0h (R/W) = Reserved</p> <p>1h (R/W) = Input clock / 1</p> <p>2h (R/W) = Input clock / 2</p> <p>3h (R/W) = Input clock / 3</p> <p>4h (R/W) = Input clock / 4</p> <p>...</p> <p>FFh (R/W) = Input clock / 255</p> <p>TXCLKIN = Input clock / PRESCALE_VAL</p> <p>In FSI mode: TXCLK = TXCLKIN / 2</p> <p>In SPI mode: TXCLK = TXCLKIN</p> <p>Reset type: SYSRSn</p>
1	CLK_EN	R/W	0h	<p>Clock Divider Enable bit</p> <p>This bit will enable and disable the input clock divider and start the clock to the transmitter core.</p> <p>0h (R/W) = The input clock divider is not enabled and the clock is not connected to the transmitter core.</p> <p>1h (R/W) = The input clock to the transmitter core is being divided by the PRESCALE_VAL and enabled.</p> <p>Reset type: SYSRSn</p>
0	CLK_RST	R/W	0h	<p>Clock Divider Reset bit</p> <p>This bit will reset the clock counter in the clock divider.</p> <p>0h (R/W) = The clock divider is set based on the value in PRESCALE_VAL. The input clock will be divided by PRESCALE_VAL if CLK_EN is set.</p> <p>1h (R/W) = The clock divider will be reset to 0 and will stay reset until software writes a 0 to this bit.</p> <p>Reset type: SYSRSn</p>

### 27.6.2.3 TX\_OPER\_CTRL\_LO Register (Offset = 4h) [Reset = 0000h]

TX\_OPER\_CTRL\_LO is shown in [Figure 27-21](#) and described in [Table 27-22](#).

Return to the [Summary Table](#).

Transmit operation control register low

**Figure 27-21. TX\_OPER\_CTRL\_LO Register**

15	14	13	12	11	10	9	8
RESERVED					SEL_TDM_IN	TDM_ENABLE	SEL_PLLCLK
R-0h					R/W-0h	R/W-0h	R/W-0h

PING_TO_MODE	SW_CRC	START_MODE			SPI_MODE	DATA_WIDTH	
R/W-0h	R/W-0h	R/W-0h			R/W-0h	R/W-0h	

**Table 27-22. TX\_OPER\_CTRL\_LO Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-11	RESERVED	R	0h	Reserved
10	SEL_TDM_IN	R/W	0h	Input TDM port Select bit This bit selects the input port for the transmitter core between the TDM input pins or the RX module. When this bit is '0', the inputs selected for TDM are from the TDM input pins. When this bit is '1', then inputs selected for TDM are from the RX module. Reset type: SYSRSn
9	TDM_ENABLE	R/W	0h	Transmit TDM Mode Enable bit. This bit enables the TDM Mode for multi-remote TDM operation. 0h (R/W) Transmit TDM Mode is not enabled. 1h (R/W) Transmit TDM Mode is enabled. Reset type: SYSRSn
8	SEL_PLLCLK	R/W	0h	Input Clock Select bit This bit selects the input clock source for the transmitter core. 0h (R/W) = SYSCLK is the source of the transmitter clock into the clock prescaler. 1h (R/W) = PLLRAWCLK is the source of the transmitter core clock into the clock prescaler. Reset type: SYSRSn
7	PING_TO_MODE	R/W	0h	Ping Counter Reset Mode Select bit This bit selects when the ping counter will reset. 0h (R/W) = The ping counter will reset and restart only on hardware initiated ping frames, when ping counter has timed out. 1h (R/W) = The ping counter will reset and restart on any software initiated frame as well as a ping counter timeout Reset type: SYSRSn
6	SW_CRC	R/W	0h	CRC Source Select bit This bit selects the source of the CRC value that is transmitted. 0h (R/W) = The transmitted CRC value is computed by hardware. 1h (R/W) = The transmitted CRC value is sourced from the value programmed in the TX_USER_CRC register. Reset type: SYSRSn

**Table 27-22. TX\_OPER\_CTRL\_LO Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
5-3	START_MODE	R/W	0h	<p>Transmission Start Mode Select bit</p> <p>These bits select the method by which a new frame transmission is started.</p> <p>0h (R/W) = Only a software write to TX_FRAME_CTRL.START initiate a new transmission.</p> <p>1h (R/W) = The configured external trigger will initiate a new transmission.</p> <p>2h (R/W) = Either writing to TX_FRAME_CTRL.START or the TX_FRAME_TAG_UDATA register will initiate a new transmission. All other combinations of bits are illegal and reserved for future use.</p> <p>Reset type: SYSRSn</p>
2	SPI_MODE	R/W	0h	<p>SPI Mode Select bit</p> <p>This bit enables and disables SPI compatibility mode.</p> <p>0h (R/W) = FSI is in normal mode of operation.</p> <p>1h (R/W) = FSI is operating in SPI compatibility mode.</p> <p>Reset type: SYSRSn</p>
1-0	DATA_WIDTH	R/W	0h	<p>Transmit Data Width Select bits</p> <p>These bits define the number of data lines used by the transmitter.</p> <p>0h (R/W) = Data will be transmitted on one data line (TXD0)</p> <p>1h (R/W) = Data will be transmitted on two data lines (TXD0 and TXD1). The format of the data is described in the preceding chapter.</p> <p>2h, 3h (R/W) = Reserved</p> <p>Reset type: SYSRSn</p>

### 27.6.2.4 TX\_OPER\_CTRL\_HI Register (Offset = 5h) [Reset = 0000h]

TX\_OPER\_CTRL\_HI is shown in [Figure 27-22](#) and described in [Table 27-23](#).

Return to the [Summary Table](#).

Transmit operation control register high

**Figure 27-22. TX\_OPER\_CTRL\_HI Register**

15	14	13	12	11	10	9	8
RESERVED			EXT_TRIG_SEL

**Table 27-23. TX\_OPER\_CTRL\_HI Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-14	RESERVED	R	0h	Reserved
13-7	EXT_TRIG_SEL	R/W	0h	External Trigger Select bit These bits define which of the 128 external inputs will be used as the source for the external input trigger. 00h (R/W) = Trigger 1 is the source. 01h (R/W) = Trigger 2 is the source. 02h (R/W) = Trigger 3 is the source. ... 7Fh (R/W) = Trigger 128 is the source. Reset type: SYSRSn
6	ECC_SEL	R/W	0h	ECC Data Width Select bit This bit selects between 16-bit and 32-bit ECC computation. 0h (R/W) = 32-bit ECC is used. 1h (R/W) = 16-bit ECC is used. Reset type: SYSRSn
5	FORCE_ERR	R/W	0h	Error Frame Force bit This bit will force the the CRC value of the transmitted data frame to 0 whenever there is a buffer overrun or underrun condition. This can be used to force a corrupted CRC as the data is not guaranteed to be reliable. The receiver will treat the data as invalid and can handle this as needed. Note: DO NOT use FORCE_ERR if using the SW CRC mode (FSI Transmit). 0h (R/W) = The CRC will not be forced to 0. 1h (R/W) = The CRC will be forced to 0 in a buffer overrun or underrun condition. Reset type: SYSRSn
4-0	RESERVED	R	0h	Reserved

### 27.6.2.5 TX\_FRAME\_CTRL Register (Offset = 6h) [Reset = 0000h]

TX\_FRAME\_CTRL is shown in [Figure 27-23](#) and described in [Table 27-24](#).

Return to the [Summary Table](#).

Transmit frame control register

**Figure 27-23. TX\_FRAME\_CTRL Register**

15	14	13	12	11	10	9	8
START	RESERVED						
R/W-0h				R-0h			
7	6	5	4	3	2	1	0
N_WORDS				FRAME_TYPE			
R/W-0h				R/W-0h			

**Table 27-24. TX\_FRAME\_CTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
15	START	R/W	0h	Start Transmission bit This bit will cause the FSI to start transmitting the next frame. 0h (R/W) = Writing a 0 to this bit will have no effect. 1h (R/W) = Start the next transmission. This bit will be cleared by hardware. Reset type: SYSRSn
14-8	RESERVED	R	0h	Reserved
7-4	N_WORDS	R/W	0h	Number of Words to be Transmitted This field defines the number of words which will be transmitted in a DATA_N_WORD frame. This is a user-defined field that must match the corresponding field in the receiver. Set this bitfield to be one less than the number of words to be transmitted. 0h (R/W) = 1 data word frame (16-bit data). 1h (R/W) = 2 data word frame (32-bit data). .. Fh (R/W) = 16 data word frame (256-bit data). Reset type: SYSRSn
3-0	FRAME_TYPE	R/W	0h	Transmit Frame Type This field determines the type of frame that will be transmitted next. 0000b (R/W) = Ping Frame. This frame can be sent either by software or automatically by hardware. 0100b (R/W) = DATA_1_WORD Frame. One word data frame (16-bit data). 0101b (R/W) = DATA_2_WORD Frame. Two word data frame (32-bit data). 0110b (R/W) = DATA_4_WORD Frame. Four word data frame (64-bit data). 0111b (R/W) = DATA_6_WORD Frame. Six word data frame (96-bit data). 0011b (R/W) = DATA_N_WORD Frame. The N_WORDS field will determine the number of words (1 to 16) to be sent. Both the transmitter and receiver must have the same value programmed. 1111b (R/W) = Error Frame. This frame can be used during error conditions or any condition where the transmitter wants to notify the receiver of a high priority status. However, the user software is at liberty to use this for any purpose. 0001b, 0010b, and 1000b through 1110b are Reserved and should not be used. Reset type: SYSRSn

### 27.6.2.6 TX\_FRAME\_TAG\_UDATA Register (Offset = 7h) [Reset = 0000h]

TX\_FRAME\_TAG\_UDATA is shown in [Figure 27-24](#) and described in [Table 27-25](#).

Return to the [Summary Table](#).

Transmit frame tag and user data register

**Figure 27-24. TX\_FRAME\_TAG\_UDATA Register**

**Table 27-28. TX\_PING\_CTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-10	RESERVED	R	0h	Reserved
9-3	EXT_TRIG_SEL	R/W	0h	External Trigger Select bits This bitfield will select one of the 128 external trigger inputs to as the source to generate a ping frame. A ping frame will only be generated if the EXT_TRIG_EN bit is set. 0h (R/W) = Trigger 1 will be used to generate a ping frame. 1h (R/W) = Trigger 2 will be used to generate a ping frame. .. 7Fh (R/W) = Trigger 128 will be used to generate a ping frame. Reset type: SYSRSn
2	EXT_TRIG_EN	R/W	0h	External Trigger Enable bit This bit will allow the external trigger logic to generate a ping frame. 0h (R/W) = External triggers will not be used to generate ping frames. 1h (R/W) = The selected external trigger (selected by EXT_TRIG_SEL bits) will be able to generate a ping frame. The ping timer will be ignored if this bit is set. Reset type: SYSRSn
1	TIMER_EN	R/W	0h	Ping Timer Enable bit This bit will enable the ping timer for generating periodic ping frames. 0h (R/W) = The ping timer is disabled and will not generate ping frames. 1h (R/W) = The ping timer is enabled and can be used to generate ping frames. Once the timer count reaches the value set by the TX_PING_TO_REF register, it will initiate a ping frame transmission. Note: If the ping timer is used, EXT_TRIG_EN should not be set as it will override this function. Reset type: SYSRSn
0	CNT_RST	R/W	0h	Ping Counter Reset bit Writing a 1 to this bit will reset the ping counter to 0. The counter will stay in reset as long as this bit is set to 1. This bit needs to be cleared to 0 to use the counter. 0h (R/W) = Clear the CNT_RST. 1h (R/W) = The ping counter will be reset to 0. Reset type: SYSRSn

### 27.6.2.10 TX\_PING\_TAG Register (Offset = Bh) [Reset = 0000h]

TX\_PING\_TAG is shown in [Figure 27-28](#) and described in [Table 27-29](#).

Return to the [Summary Table](#).

Transmit ping tag register

**Figure 27-28. TX\_PING\_TAG Register**

RESERVED							
R-0h							
7	6	5	4	3	2	1	0
RESERVED				TAG			
R-0h				R/W-0h			

**Table 27-29. TX\_PING\_TAG Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-4	RESERVED	R	0h	Reserved
3-0	TAG	R/W	0h	Ping Frame Tag This field contains a 4-bit tag which will be sent in any ping frame that is initiated by an external trigger or the ping timer. This field is user-defined and can be set based on the application requirement. If a ping frame is generated manually, the transmitted tag will be from TX_FRAME_TAG_UDATA.FRAME_TAG, not this value. Reset type: SYSRSn

### 27.6.2.11 TX\_PING\_TO\_REF Register (Offset = Ch) [Reset = 0000000h]

TX\_PING\_TO\_REF is shown in [Figure 27-29](#) and described in [Table 27-30](#).

Return to the [Summary Table](#).

Transmit ping timeout counter reference

**Figure 27-29. TX\_PING\_TO\_REF Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TO_REF																															
R/W-0h																															

**Table 27-30. TX\_PING\_TO\_REF Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	TO_REF	R/W	0h	Ping Timer Reference Value. This is the 32-bit reference value for the ping timer. The timer will increment the counter starting from 0. When the reference value is reached, it will generate a timeout event, triggering a ping frame transmission. The counter will then reset to 0 and continue counting. Reset type: SYSRSn

**27.6.2.12 TX\_PING\_TO\_CNT Register (Offset = Eh) [Reset = 0000000h]**

TX\_PING\_TO\_CNT is shown in [Figure 27-30](#) and described in [Table 27-31](#).

Return to the [Summary Table](#).

Transmit ping timeout current count

**Figure 27-30. TX\_PING\_TO\_CNT Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TO_CNT																															
R-0h																															

**Table 27-31. TX\_PING\_TO\_CNT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	TO_CNT	R	0h	Ping Timer Counter Value This register contains the current value of the ping timer counter. After reset, this counter will increment until it reaches the reference value (TX_PING_TO_REF), at which point it generates a ping frame transmission. After this point, the counter will reset to 0 and continue counting. This is a free-running counter Reset type: SYSRSn

### 27.6.2.13 TX\_INT\_CTRL Register (Offset = 10h) [Reset = 0000h]

TX\_INT\_CTRL is shown in [Figure 27-31](#) and described in [Table 27-32](#).

Return to the [Summary Table](#).

Transmit interrupt event control register

Complex bit access types are encoded to fit into small table cells. [Table 27-44](#) shows the codes that are used for access types in this section.

**Table 27-44. FSI\_RX\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 27.6.3.1 RX\_MAIN\_CTRL Register (Offset = 0h) [Reset = 0000h]

RX\_MAIN\_CTRL is shown in [Figure 27-42](#) and described in [Table 27-45](#).

Return to the [Summary Table](#).

Receive main control register

**Figure 27-42. RX\_MAIN\_CTRL Register**

15	14	13	12	11	10	9	8
KEY							
W-0h							
7	6	5	4	3	2	1	0
RESERVED			DATA_FILTER_ EN	INPUT_ISOLAT E	SPI_PAIRING	INT_LOOPBAC K	CORE_RST
R-0h			R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

**Table 27-45. RX\_MAIN\_CTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-8	KEY	W	0h	Write Key. In order to write to this register, 0xA5 must be written to this field at the same time. Otherwise, writes are ignored. The key is cleared immediately after writing, so it must be written again for every change to this register. Reset type: SYSRSn
7-5	RESERVED	R	0h	Reserved
4	DATA_FILTER_EN	R/W	0h	Data Filter Enable Bit. 0h (R/W) = Data filtering is disabled. 1h (R/W) = Data filtering is enabled. Reset type: SYSRSn
3	INPUT_ISOLATE	R/W	0h	When set to 1, the FSI RX inputs (RXCLK, RXD0 and RXD1) will be isolated from what is driven from the device pins and will be held at inactive level of '1'. This isolation facilitates the user to switch the RX inputs to a different set of device pins and hence any potential glitch that could occur during the process of switching will not affect the RX module itself. Reset type: SYSRSn
2	SPI_PAIRING	R/W	0h	Clock Pairing for SPI-like Behavior Enable bit This bit enables the internal clock pairing with the FSI TX module. This feature internally connects the TXCLK to RXCLK allowing the FSI TX module, acting as a SPI controller, to clock data into the receiver and out of the transmitter like a standard SPI module. This configuration is valid when the Module is in SPI mode only (RX_OPER_CTRL.SPI_MODE = 1) 0h (R/W) = SPI clock pairing is not enabled. 1h (R/W) = SPI clock pairing is enabled. The RXCLK will be internally connected to the TXCLK of the corresponding FSI module. Note: The KEY field must contain 0xA5 for any write to this bit to take effect. Reset type: SYSRSn

**Table 27-45. RX\_MAIN\_CTRL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
1	INT_LOOPBACK	R/W	0h	<p>Internal Loopback Enable bit</p> <p>This bit enables the internal loopback functionality of the FSI receiver. By enabling this bit, a mux will select the signals coming directly from the corresponding FSI transmitter module rather than from the pins.</p> <p>0h (R/W) = Internal loopback is disabled. The FSI RX module will receive signals coming from the pins.</p> <p>1h (R/W) = Internal loopback is enabled. The FSI RX module will receive signals from the directly from FSI TX module rather than the pins.</p> <p>Note: The KEY field must contain 0xA5 for any write to this bit to take effect.</p> <p>Reset type: SYSRSn</p>
0	CORE_RST	R/W	0h	<p>Receiver Main Core Reset bit</p> <p>This bit controls the receiver main core reset. In order to receive any frame, this bit must be cleared.</p> <p>Note: For reset to take effect, the FSI RX module must be held in reset for at least 4 SYSCLK cycles.</p> <p>0h (R/W) = Receiver core is not in reset and can receive frames.</p> <p>1h (R/W) = Receiver core is held in reset.</p> <p>Note: The KEY field must contain 0xA5 for any write to this bit to take effect.</p> <p>Reset type: SYSRSn</p>

### 27.6.3.2 RX\_OPER\_CTRL Register (Offset = 4h) [Reset = 0000h]

RX\_OPER\_CTRL is shown in [Figure 27-43](#) and described in [Table 27-46](#).

Return to the [Summary Table](#).

Receive operation control register

Bit	Field	Type	Reset	Description
15-9	RESERVED	R	0h	Reserved
8	PING_WD_RST_MODE	R/W	0h	<p>Ping Watchdog Timeout Mode Select bit</p> <p>This bit selects the mode by which the ping watchdog counter is reset. The watchdog counter can be reset and restarted only by ping frames or by any received frame.</p> <p>0h (R/W) = The ping watchdog counter will reset and restart only by ping frames.</p> <p>1h (R/W) = The ping watchdog counter will reset and restart by any received frame.</p> <p>Reset type: SYSRSn</p>
7	ECC_SEL	R/W	0h	<p>ECC Data Width Select bit</p> <p>This bit selects between whether the ECC computation is done on 16-bit or 32-bit words.</p> <p>0h (R/W) = 32-bit ECC is used.</p> <p>1h (R/W) = 16-bit ECC is used.</p> <p>Reset type: SYSRSn</p>
6-3	N_WORDS	R/W	0h	<p>Number of Words to Receive</p> <p>This field defines the number of words which will be received in a DATA_N_WORD frame. This is a user-defined field that must match the corresponding field in the transmitter. Set this bitfield to be one less than the number of words to be received. This value is only applicable when the frame type received is DATA_N_WORD.</p> <p>0h (R/W) = 1 data word frame (16-bit data).</p> <p>1h (R/W) = 2 data word frame (32-bit data).</p> <p>..</p> <p>Fh (R/W) = 16 data word frame (256-bit data).</p> <p>Reset type: SYSRSn</p>
2	SPI_MODE	R/W	0h	<p>SPI Mode Enable bit</p> <p>This bit enables and disables the SPI compatibility mode of the FSI RX. The received data must be formatted as an FSI frame in order for the data to properly be received. SPI compatibility mode will allow FSI RX to receive data that is sent using SPI signal format. Refer to the applicable section in the FSI TRM chapter for more information.</p> <p>0h (R/W) = FSI is in normal mode of operation.</p> <p>1h (R/W) = FSI is operating in SPI compatibility mode.</p> <p>Reset type: SYSRSn</p>

**Table 27-46. RX\_OPER\_CTRL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
1-0	DATA_WIDTH	R/W	0h	Receive Data Width Select bit These bits decide the number of data lines used for receiving data. 0h (R/W) = Data will be received on one data line, RXD0. 1h (R/W) = Data will be received on two data lines, RXD0 and RXD1. 2h, 3h (R/W) = Reserved Reset type: SYSRSn

### 27.6.3.3 RX\_FRAME\_INFO Register (Offset = 6h) [Reset = 0000h]

RX\_FRAME\_INFO is shown in [Figure 27-44](#) and described in [Table 27-47](#).

Return to the [Summary Table](#).

Receive frame control register

### 27.6.3.21 RX\_LOCK\_CTRL Register (Offset = 1Eh) [Reset = 0000h]

RX\_LOCK\_CTRL is shown in [Figure 27-62](#) and described in [Table 27-65](#).

Return to the [Summary Table](#).

Receive lock control register

**Figure 27-62. RX\_LOCK\_CTRL Register**

15	14	13	12	11	10	9	8
KEY							
W-0h							
7	6	5	4	3	2	1	0
RESERVED							LOCK
R-0h							R/W-0h

**Table 27-65. RX\_LOCK\_CTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-8	KEY	W	0h	Write Key. In order to write to this register, 0xA5 must be written to this field at the same time. Otherwise, writes are ignored. The key is cleared immediately after writing, so it must be written again for every change to this register. Reset type: SYSRSn
7-1	RESERVED	R	0h	Reserved
0	LOCK	R/W	0h	Control Register Lock Enable bit This bit locks the contents of all the receive control registers that support a lock protection. Once locked, further writes will not take effect until SYSRS unlocks the register. Once set, further writes even to this bit will be ignored. 0h (R/W) = Receive control registers can be modified and are not locked. 1h (R/W) = Receive control registers are locked and cannot be modified until this bit is cleared by SYSRS. Any further writes to this bit are ignored. Note: The KEY field must contain 0xA5 for any write to this bit to take effect. Reset type: SYSRSn

### 27.6.3.22 RX\_ECC\_DATA Register (Offset = 20h) [Reset = 00000000h]

RX\_ECC\_DATA is shown in [Figure 27-63](#) and described in [Table 27-66](#).

Return to the [Summary Table](#).

Receive ECC data register

**Figure 27-63. RX\_ECC\_DATA Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATA_HIGH																DATA_LOW															
R/W-0h																R/W-0h															

**Table 27-66. RX\_ECC\_DATA Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	DATA_HIGH	R/W	0h	Upper 16 bits of ECC Data Writing to this bitfield will cause the ECC logic to compute the ECC(SEC-DED) the entire 32-bit register and update TX_ECC_VAL register with the results. Software should write to these 16 bits of the register in a 32-bit write when needing to compute ECC for 32-bits for the full TX_ECC_DATA register. Reset type: SYSRSn
15-0	DATA_LOW	R/W	0h	Lower 16 bits of ECC Data Writing to this bitfield will cause the ECC logic to compute the ECC(SEC-DED) for these 16 bits and update the TX_ECC_VAL register with the results. Software should write to these register bits as a 16-bit write when needing to compute ECC for 16-bits. Reset type: SYSRSn

**27.6.3.23 RX\_ECC\_VAL Register (Offset = 22h) [Reset = 0000h]**

RX\_ECC\_VAL is shown in [Figure 27-64](#) and described in [Table 27-67](#).

Return to the [Summary Table](#).

Receive ECC value register

**Figure 27-64. RX\_ECC\_VAL Register**

15	14	13	12	11	10	9	8
RESERVED							
R-0h							
7	6	5	4	3	2	1	0

## Chapter 28 Inter-Integrated Circuit Module (I2C)

This chapter describes the features and operation of the inter-integrated circuit (I2C) module. The I2C module provides an interface between one of these devices and devices compliant with the NXP Semiconductors Inter-IC bus (I2C bus) specification version 2.1, and connected by way of an I2C bus. External components attached to this 2-wire serial bus can transmit/receive 1- to 8-bit data to/from the device through the I2C module. This chapter assumes the reader is familiar with the I2C bus specification.

### Note

A unit of data transmitted or received by the I2C module can have fewer than 8 bits; however, for convenience, a unit of data is called a data byte throughout this chapter. The number of bits in a data byte is selectable by way of the BC bits of the mode register, I2CMDR.

<b>28.1 Introduction</b> .....	<b>4680</b>
<b>28.2 Configuring Device Pins</b> .....	<b>4685</b>
<b>28.3 I2C Module Operational Details</b> .....	<b>4685</b>
<b>28.4 Interrupt Requests Generated by the I2C Module</b> .....	<b>4696</b>
<b>28.5 Resetting or Disabling the I2C Module</b> .....	<b>4700</b>
<b>28.6 Software</b> .....	<b>4701</b>
<b>28.7 I2C Registers</b> .....	<b>4702</b>

## 28.1 Introduction

The I2C module supports any target or controller I2C-compatible device. [Figure 28-1](#) shows an example of multiple I2C modules connected for a two-way transfer from one device to other devices.

**Figure 28-1. Multiple I2C Modules Connected**

### 28.1.2 Features

The I2C module has the following features:

- Compliance with the NXP Semiconductors I2C bus specification (version 2.1):
  - Support for 8-bit format transfers
  - 7-bit and 10-bit addressing modes
  - General call
  - START byte mode
  - Support for multiple controller-transmitters and target-receivers
  - Support for multiple target-transmitters and controller-receivers
  - Combined controller transmit/receive and receive/transmit mode
  - Data transfer rate from 10kbps up to 400kbps (Fast-mode)
- Receive FIFO and Transmitter FIFO (16-deep x 8-bit FIFO)
- Supports two ePIE interrupts:
  - I2Cx Interrupt – Any of the following events can be configured to generate an I2Cx interrupt:
    - Transmit-data ready
    - Receive-data ready
    - Register-access ready
    - No-acknowledgment received
    - Arbitration lost
    - Stop condition detected
    - Addressed as target
  - I2Cx\_FIFO interrupts:
    - Transmit FIFO interrupt
    - Receive FIFO interrupt
- Module enable and disable capability
- Free data format mode

### 28.1.3 Features Not Supported

The I2C module does not support:

- High-speed mode (Hs-mode)
- CBUS-compatibility mode

### 28.1.4 Functional Overview

Each device connected to an I2C bus is recognized by a unique address. Each device can operate as either a transmitter or a receiver, depending on the function of the device. A device connected to the I2C bus can also be considered as the controller or the target when performing data transfers. A controller device is the device that initiates a data transfer on the bus and generates the clock signals to permit that transfer. During this transfer, any device addressed by this controller is considered a target. The I2C module supports the multi-controller mode, in which one or more devices capable of controlling an I2C bus can be connected to the same I2C bus.

For data communication, the I2C module has a serial data pin (SDA) and a serial clock pin (SCL), as shown in [Figure 28-2](#). These two pins carry information between the C28x device and other devices connected to the I2C bus. The SDA and SCL pins are both bidirectional and each must be connected to a positive supply voltage using a pull-up resistor. When the bus is free, both pins are high. The driver of these two pins has an open-drain configuration to perform the required wired-AND function.

There are two major transfer techniques:

- **Standard Mode:** Send exactly *n* data values, where *n* is a value you program in an I2C module register. See the I2CCNT register in the *I2C Registers* section for more information.
- **Repeat Mode:** Keep sending data values until you use software to initiate a STOP condition or a new START condition. See the I2CMDR register in the *I2C Registers* section for RM bit information.

The I2C module consists of the following primary blocks:

- A serial interface: one data pin (SDA) and one clock pin (SCL)
- Data registers and FIFOs to temporarily hold receive data and transmit data traveling between the SDA pin and the CPU
- Control and status registers
- A peripheral bus interface to enable the CPU to access the I2C module registers and FIFOs.
- A clock synchronizer to synchronize the I2C input clock (from the device clock generator) and the clock on the SCL pin, and to synchronize data transfers with controllers of different clock speeds
- A prescaler to divide down the input clock that is driven to the I2C module
- A noise filter on each of the two pins, SDA and SCL
- An arbitrator to handle arbitration between the I2C module (when the I2C module is a controller) and another controller
- Interrupt generation logic, so that an interrupt can be sent to the CPU
- FIFO interrupt generation logic, so that FIFO access can be synchronized to data reception and data transmission in the I2C module

[Figure 28-2](#) shows the four registers used for transmission and reception in non-FIFO mode. The CPU writes data for transmission to I2CDXR and reads received data from I2CDRR. When the I2C module is configured as a transmitter, data written to I2CDXR is copied to I2CXSR and shifted out on the SDA pin one bit at a time. When the I2C module is configured as a receiver, received data is shifted into I2CRSR and then copied to I2CDRR.

Figure 28-2. I2C Module Conceptual Block Diagram

### 28.1.5 Clock Generation

The I2C module clock determines the frequency at which the I2C module operates. A programmable prescaler in the I2C module divides down the SYSCLK to produce the I2C module clock and this I2C module clock is divided further to produce the I2C controller clock on the SCL pin. Figure 28-3 shows the clock generation diagram for I2C module.

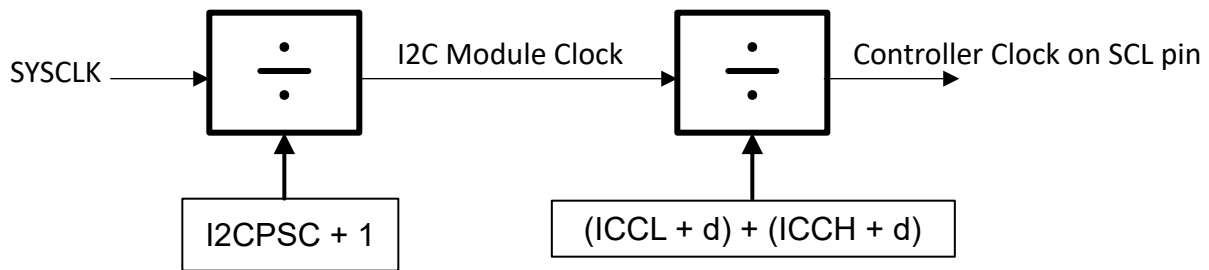

Figure 28-3. Clocking Diagram for the I2C Module

#### Note

To meet all of the I2C protocol timing specifications, the I2C module clock must be between 7 to 12MHz.

To specify the divide-down value, initialize the IPSC field of the prescaler register, I2CPSC. The resulting frequency is:

$$\text{I2C Module Clock (Fmod)} = \frac{\text{SYSCLK}}{(\text{I2CPSC} + 1)} \quad (35)$$

The prescaler must be initialized only while the I2C module is in the reset state (IRS = 0 in I2CMDR). The prescaled frequency takes effect only when IRS is changed to 1. Changing the IPSC value while IRS = 1 has no effect.

The controller clock appears on the SCL pin when the I2C module is configured to be a controller on the I2C bus. This clock controls the timing of communication between the I2C module and a target. As shown in Figure 28-3, a second clock divider in the I2C module divides down the module clock to produce the controller clock. The clock divider uses the ICCL value of I2CCLKL to divide down the low portion of the module clock signal and uses the ICCH value of I2CCLKH to divide down the high portion of the module clock signal. See Section 28.1.6 for the controller clock frequency equation.

### 28.1.6 I2C Clock Divider Registers (I2CCLKL and I2CCLKH)

As explained in Section 28.1.5, when the I2C module is a controller, the I2C module clock is divided down further to use as the controller clock on the SCL pin. As shown in Figure 28-4, the shape of the controller clock depends on two divide-down values:

- ICCL in I2CCLKL. For each controller clock cycle, ICCL determines the amount of time the signal is low.
- ICCH in I2CCLKH. For each controller clock cycle, ICCH determines the amount of time the signal is high.

**Figure 28-4. Roles of the Clock Divide-Down Values (ICCL and ICCH)**

#### 28.1.6.1 Formula for the Controller Clock Period

The controller clock period ( $T_{\text{mst}}$ ) is a multiple of the period of the I2C Module Clock ( $T_{\text{mod}}$ ):

$$\text{Controller Clock period (Tmst)} = \frac{[(\text{ICCH} + d) + (\text{ICCL} + d)]}{\text{I2C Module Clock (Fmod)}} \quad (36)$$

where  $d$  depends on the divide-down value IPSC, as shown in Table 28-1. IPSC is described in the I2CPSC register.

**Table 28-1. Dependency of Delay  $d$  on the Divide-Down Value IPSC**

IPSC	$d$
0	7
1	6
Greater than 1	5

## 28.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification must be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups can be configured in the GPyPUD register.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

## 28.3 I2C Module Operational Details

This section provides an overview of the I2C bus protocol and how it is implemented.

### 28.3.1 Input and Output Voltage Levels

One clock pulse is generated by the controller device for each data bit transferred. Due to a variety of different technology devices that can be connected to the I2C bus, the levels of logic 0 (low) and logic 1 (high) are not fixed and depend on the associated level of  $V_{DD}$ . For details, see the device data sheet.

### 28.3.2 Selecting Pullup Resistors

The chosen pullup resistor must meet the I2C standard timings. In most circumstances, 2.2k $\Omega$  of total bus resistance to VDDIO is sufficient. The value of the pullup resistance used on both the SCL and SDA pins be matched is also recommended. For evaluating pullup resistor values for a particular design, see the [I2C Bus Pullup Resistor Calculation Application Report](#).

### 28.3.3 Data Validity

The data on SDA must be stable during the high period of the clock (see [Figure 28-5](#)). The high or low state of the data line, SDA, must change only when the clock signal on SCL is low.

Figure 28-5. Bit Transfer on the I2C bus

### 28.3.4 Operating Modes

The I2C module has four basic operating modes to support data transfers as a controller and as a target. See [Table 28-2](#) for the names and descriptions of the modes.

If the I2C module is a controller, the I2C module begins as a controller-transmitter and typically transmits an address for a particular target. When giving data to the target, the I2C module must remain a controller-transmitter. To receive data from a target, the I2C module must be changed to the controller-receiver mode.

If the I2C module is a target, the I2C module begins as a target-receiver and typically sends acknowledgment when the I2C module recognizes the target address from a controller. If the controller is sending data to the I2C module, the module must remain a target-receiver. If the controller has requested data from the I2C module, the module must be changed to the target-transmitter mode.

**Table 28-2. Operating Modes of the I2C Module**

Operating Mode	Description
Target-receiver mode	The I2C module is a target and receives data from a controller. All targets begin in this mode. In this mode, serial data bits received on SDA are shifted in with the clock pulses that are generated by the controller. As a target, the I2C module does not generate the clock signal, but can hold SCL low while the intervention of the device is required (RSFULL = 1 in I2CSTR) after a byte has been received. See <a href="#">Section 28.3.8</a> for more details.
Target-transmitter mode	The I2C module is a target and transmits data to a controller. This mode can be entered only from the target-receiver mode; the I2C module must first receive a command from the controller. When using any of the 7-bit/10-bit addressing formats, the I2C module enters the target-transmitter mode if the target address byte is the same as the address (in I2COAR) and the controller has transmitted R/ $\bar{W}$ = 1. As a target-transmitter, the I2C module then shifts the serial data out on SDA with the clock pulses that are generated by the controller. While a target, the I2C module does not generate the clock signal, but it can hold SCL low while the intervention of the device is required (XSMT = 0 in I2CSTR) after a byte has been transmitted. See <a href="#">Section 28.3.8</a> for more details.
Controller-receiver mode	The I2C module is a controller and receives data from a target. This mode can be entered only from the controller-transmitter mode; the I2C module must first transmit a command to the target. When using any of the 7-bit/10-bit addressing formats, the I2C module enters the controller-receiver mode after transmitting the target address byte and R/ $\bar{W}$ = 1. Serial data bits on SDA are shifted into the I2C module with the clock pulses generated by the I2C module on SCL. The clock pulses are inhibited and SCL is held low when the intervention of the device is required (RSFULL = 1 in I2CSTR) after a byte has been received.
Controller-transmitter mode	The I2C module is a controller and transmits control information and data to a target. All controllers begin in this mode. In this mode, data assembled in any of the 7-bit/10-bit addressing formats is shifted out on SDA. The bit shifting is synchronized with the clock pulses generated by the I2C module on SCL. The clock pulses are inhibited and SCL is held low when the intervention of the device is required (XSMT = 0 in I2CSTR) after a byte has been transmitted.

To summarize, SCL is held low in the following conditions:

- When an overrun condition is detected (RSFULL = 1), in Target-receiver mode.
- When an underflow condition is detected (XSMT = 0), in Target-transmitter mode.

I2C target nodes accept and provide data when the I2C controller node requests data.

- To release SCL in target-receiver mode, read data from I2CDRR.
- To release SCL in target-transmitter mode, write data to I2CDXR.
- To force a release without handling the data, reset the module using the I2CMDR.IRS bit.

**Table 28-3. Controller-Transmitter/Receiver Bus Activity Defined by the RM, STT, and STP Bits of I2CMDR**

RM	STT	STP	Bus Activity <sup>(1)</sup>	Description
0	0	0	None	No activity
0	0	1	P	STOP condition
0	1	0	S-A-D..(n)..D.	START condition, target address, n data bytes (n = value in I2CCNT)
0	1	1	S-A-D..(n)..D-P	START condition, target address, n data bytes, STOP condition (n = value in I2CCNT)
1	0	0	None	No activity
1	0	1	P	STOP condition
1	1	0	S-A-D-D-D.	Repeat mode transfer: START condition, target address, continuous data transfers until STOP condition or next START condition
1	1	1	None	Reserved bit combination (No activity)

(1) S = START condition; A = Address; D = Data byte; P = STOP condition;

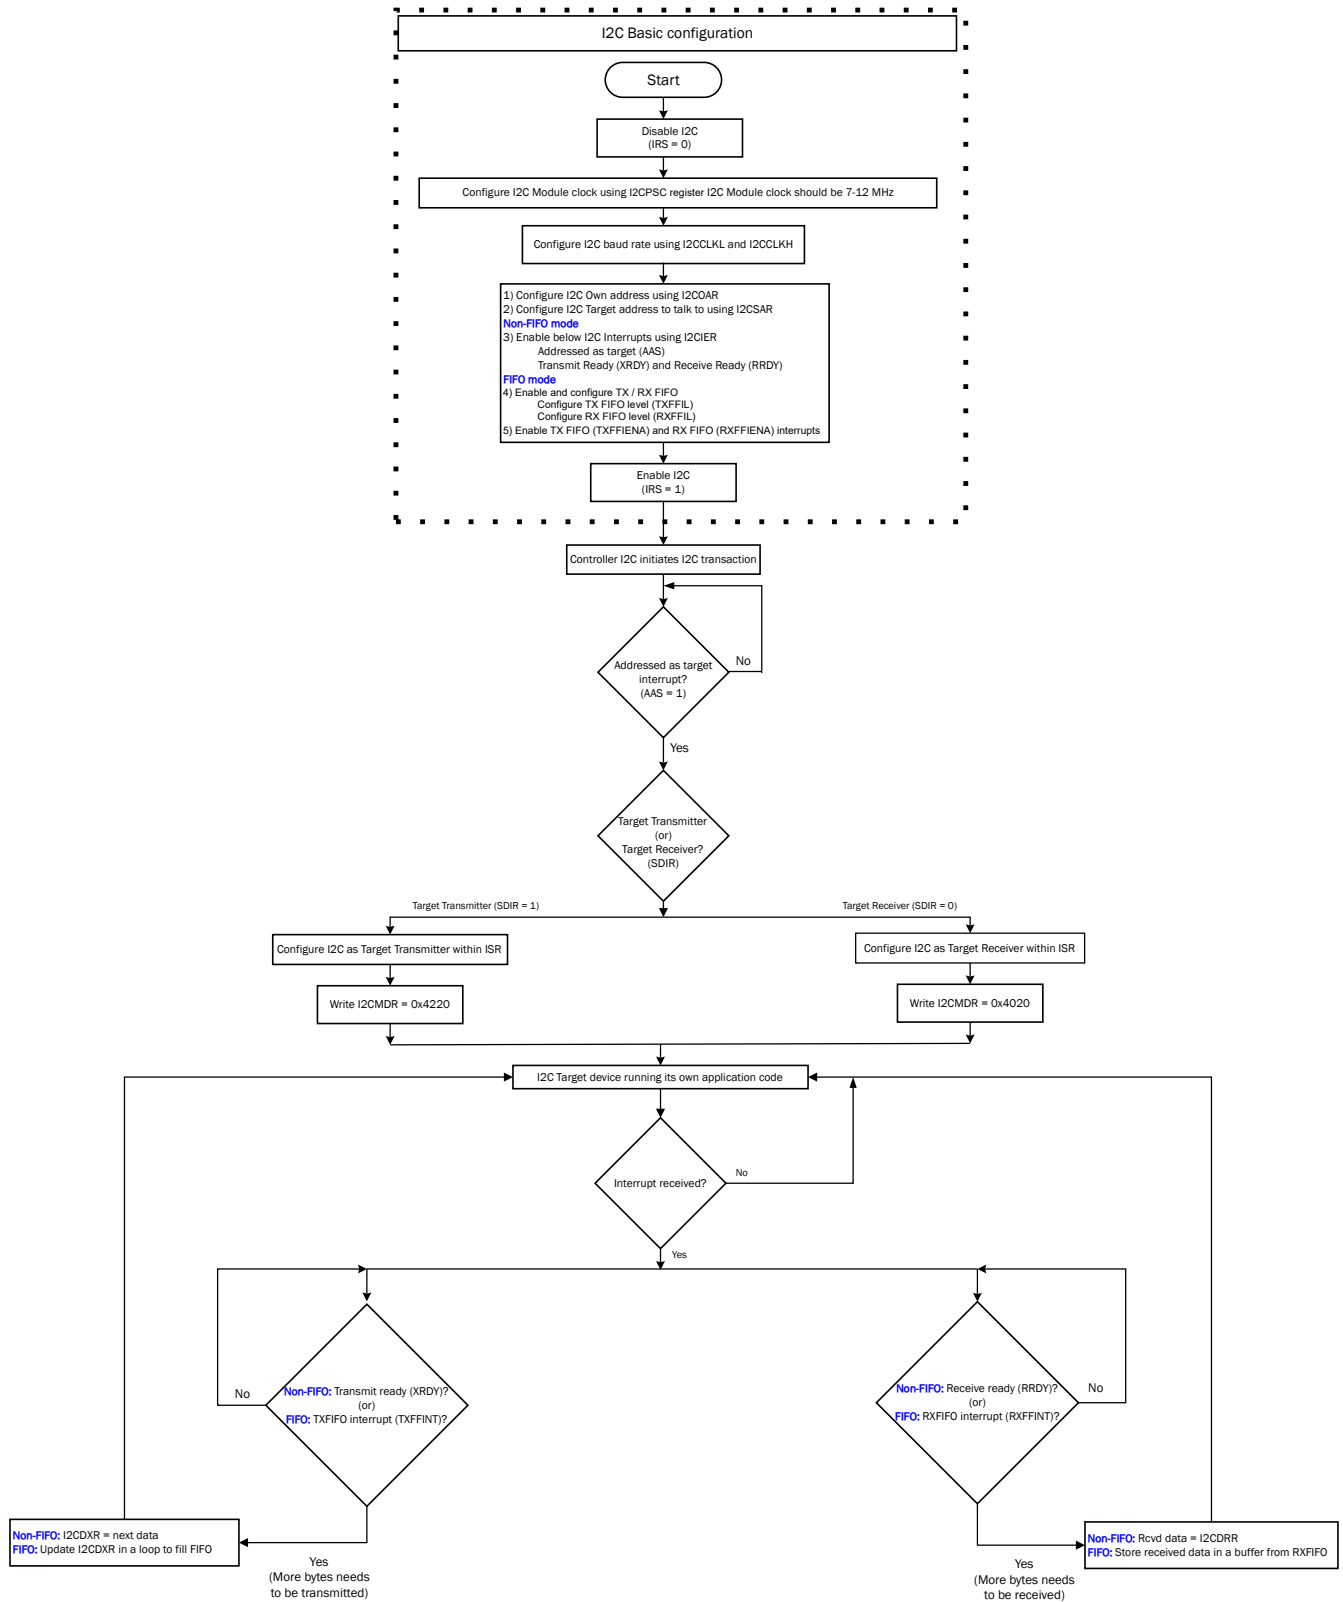

Figure 28-6. I2C Target TX / RX Flowchart

Figure 28-7. I2C Controller TX / RX Flowchart

### 28.3.5 I2C Module START and STOP Conditions

START and STOP conditions can be generated by the I2C module when the module is configured to be a controller on the I2C bus. As shown in [Figure 28-8](#):

- The START condition is defined as a high-to-low transition on the SDA line while SCL is high. A controller drives this condition to indicate the start of a data transfer.
- The STOP condition is defined as a low-to-high transition on the SDA line while SCL is high. A controller drives this condition to indicate the end of a data transfer.

**Figure 28-8. I2C Module START and STOP Conditions**

After a START condition and before a subsequent STOP condition, the I2C bus is considered busy, and the bus busy (BB) bit of I2CSTR is 1. Between a STOP condition and the next START condition, the bus is considered free, and BB is 0.

For the I2C module to start a data transfer with a START condition, the controller mode bit (MST) and the START condition bit (STT) in I2CMDR must both be 1. For the I2C module to end a data transfer with a STOP condition, the STOP condition bit (STP) must be set to 1. When the BB bit is set to 1 and the STT bit is set to 1, a repeated START condition is generated. For a description of I2CMDR and the bits (including MST, STT, and STP), see [Section 28.7](#).

The I2C peripheral cannot detect a START or STOP condition while in reset (IRS = 0). The BB bit remains in the cleared state (BB = 0) while the I2C peripheral is in reset (IRS = 0). When the I2C peripheral is taken out of reset (IRS set to 1), the BB bit does not correctly reflect the I2C bus status until a START or STOP condition is detected.

Follow these steps before initiating the first data transfer with I2C:

1. After taking the I2C peripheral out of reset by setting the IRS bit to 1, wait a period larger than the total time taken for the longest data transfer in the application. By waiting for a period of time after I2C comes out of reset, make sure that at least one START or STOP condition has occurred on the I2C bus and has been captured by the BB bit. After this period, the BB bit correctly reflects the state of the I2C bus.
2. Check the BB bit and verify that BB = 0 (bus not busy) before proceeding.
3. Begin data transfers.

Not resetting the I2C peripheral in between transfers makes sure that the BB bit reflects the actual bus status. If users must reset the I2C peripheral in between transfers, repeat steps 1 through 3 every time the I2C peripheral is taken out of reset.

### 28.3.6 Non-repeat Mode versus Repeat Mode

#### Non-repeat mode:

- When I2CMDR.RM = 0, I2C module is configured in non-repeat mode.
- I2CCNT register determines the number of bytes to be transmitted or received.
- If STP = 0 in I2CMDR, the ARDY bit is set when the internal data counter counts down to 0.
- If STP = 1, ARDY bit does not get set and I2C module generates a STOP condition when the internal data counter counts down to 0.

---

#### Note

In non-repeat mode (RM = 0), if I2CCNT is set to 0, I2C state machine expects to transmit or receive 65536 bytes and not 0 bytes.

---

#### Repeat mode:

- When I2CMDR.RM = 1, I2C module is configured in repeat mode.
- I2CCNT register contents do not determine the number of bytes to be transmitted or received.
- Number of bytes to be transmitted or received can be controlled by software.
- ARDY bit gets set at end of transmission and reception of each byte.

---

#### Note

Once you start I2C transaction in non-repeat mode or repeat mode, you cannot switch into another mode until the I2C transaction is completed with a STOP condition.

---

### 28.3.7 Serial Data Formats

Figure 28-9 shows an example of a data transfer on the I2C bus. The I2C module supports 1 to 8-bit data values. In Figure 28-9, 8-bit data is transferred. Each bit put on the SDA line equates to 1 pulse on the SCL line, and the values are always transferred with the most significant bit (MSB) first. The number of data values that can be transmitted or received is unrestricted. The serial data format used in Figure 28-9 is the 7-bit addressing format. The I2C module supports the formats shown in Figure 28-10 through Figure 28-12 and described in the paragraphs that follow the figures.

---

#### Note

In Figure 28-9 through Figure 28-12, n = the number of data bits (from 1 to 8) specified by the bit count (BC) field of I2CMDR.

---

**Figure 28-9. I2C Module Data Transfer (7-Bit Addressing with 8-bit Data Configuration Shown)**

### 28.3.7.1 7-Bit Addressing Format

The 7-bit addressing format is the default format after reset. Disabling expanded address (I2CMDR.XA = 0) and free data format (I2CMDR.FDF = 0) enables 7-bit addressing format.

In this format (see Figure 28-10), the first byte after a START condition (S) consists of a 7-bit target address followed by a R/W bit. R/W determines the direction of the data:

- R/W = 0: The I2C controller writes (transmits) data to the addressed target. This can be achieved by setting I2CMDR.TRX = 1 (Transmitter mode)
- R/W = 1: The I2C controller reads (receives) data from the target. This can be achieved by setting I2CMDR.TRX = 0 (Receiver mode)

An extra clock cycle dedicated for acknowledgment (ACK) is inserted after each byte. If the ACK bit is inserted by the target after the first byte from the controller, it is followed by n bits of data from the transmitter (controller or target, depending on the R/W bit). n is a number from 1 to 8 determined by the bit count (BC) field of I2CMDR. After the data bits have been transferred, the receiver inserts an ACK bit.

**Figure 28-10. I2C Module 7-Bit Addressing Format (FDF = 0, XA = 0 in I2CMDR)**

### 28.3.7.2 10-Bit Addressing Format

The 10-bit addressing format can be enabled by setting expanded address (I2CMDR.XA = 1) and disabling free data format (I2CMDR.FDF = 0).

The 10-bit addressing format (see Figure 28-11) is similar to the 7-bit addressing format, but the controller sends the target address in two separate byte transfers. The first byte consists of 11110b, the two MSBs of the 10-bit target address, and R/W. The second byte is the remaining 8 bits of the 10-bit target address. The target must send acknowledgment after each of the two byte transfers. Once the controller has written the second byte to the target, the controller can either write data or use a repeated START condition to change the data direction. For more details about using 10-bit addressing, see the NXP Semiconductors I2C bus specification.

**Figure 28-11. I2C Module 10-Bit Addressing Format (FDF = 0, XA = 1 in I2CMDR)**

### 28.3.7.3 Free Data Format

The free data format can be enabled by setting I2CMDR. FDF = 1.

In this format (see [Figure 28-12](#)), the first byte after a START condition (S) is a data byte. An ACK bit is inserted after each data byte, which can be from 1 to 8 bits, depending on the BC field of I2CMDR. No address or data-direction bit is sent. Therefore, the transmitter and the receiver must both support the free data format, and the direction of the data must be constant throughout the transfer.

**Figure 28-12. I2C Module Free Data Format (FDF = 1 in I2CMDR)**

#### Note

The free data format is not supported in the digital loopback mode (I2CMDR.DLB = 1).

**Table 28-4. How the MST and FDF Bits of I2CMDR Affect the Role of the TRX Bit of I2CMDR**

MST	FDF	I2C Module State	Function of TRX
0	0	In target mode but not free data format mode	TRX is a don't care. Depending on the command from the controller, the I2C module responds as a receiver or a transmitter.
0	1	In target mode and free data format mode	The free data format mode requires that the I2C module remains the transmitter or the receiver throughout the transfer. TRX identifies the role of the I2C module: TRX = 1: The I2C module is a transmitter. TRX = 0: The I2C module is a receiver.
1	0	In controller mode but not free data format mode	TRX = 1: The I2C module is a transmitter. TRX = 0: The I2C module is a receiver.
1	1	In controller mode and free data format mode	TRX = 0: The I2C module is a receiver. TRX = 1: The I2C module is a transmitter.

### 28.3.7.4 Using a Repeated START Condition

I2C controller can communicate with multiple target addresses without having to give up control of the I2C bus by driving a STOP condition. This can be achieved by driving another START condition at the end of each data type. The repeated START condition can be used with the 7-bit addressing and 10-bit addressing. [Figure 28-13](#) shows a repeated START condition in the 7-bit addressing format.

**Figure 28-13. Repeated START Condition (in This Case, 7-Bit Addressing Format)**

#### Note

In [Figure 28-13](#), n = the number of data bits (from 1 to 8) specified by the bit count (BC) field of I2CMDR.

### 28.3.8 Clock Synchronization

Under normal conditions, only one controller device generates the clock signal, SCL. During the arbitration procedure, however, there are two or more controllers and the clock must be synchronized so that the data output can be compared. [Figure 28-14](#) illustrates the clock synchronization. The wired-AND property of SCL means that a device that first generates a low period on SCL overrules the other devices. At this high-to-low transition, the clock generators of the other devices are forced to start a low period. The SCL is held low by the device with the longest low period. The other devices that finish the low periods must wait for SCL to be released, before starting the high periods. A synchronized signal on SCL is obtained, where the slowest device determines the length of the low period and the fastest device determines the length of the high period.

If a device pulls down the clock line for a longer time, the result is that all clock generators must enter the wait state. In this way, a target slows down a fast controller and the slow device creates enough time to store a received byte or to prepare a byte to be transmitted.

**Figure 28-14. Synchronization of Two I2C Clock Generators During Arbitration**

### 28.3.9 Arbitration

If two or more controller-transmitters attempt to start a transmission on the same bus at approximately the same time, an arbitration procedure is invoked. The arbitration procedure uses the data presented on the serial data bus (SDA) by the competing transmitters. Figure 28-15 illustrates the arbitration procedure between two devices. The first controller-transmitter that releases the SDA line high is overruled by another controller-transmitter that drives the SDA low. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. If two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

If the I2C module is the losing controller, the I2C module switches to the target-receiver mode, sets the arbitration lost (ARBL) flag, and generates the arbitration-lost interrupt request.

If during a serial transfer the arbitration procedure is still in progress when a repeated START condition or a STOP condition is transmitted to SDA, the controller-transmitters involved must send the repeated START condition or the STOP condition at the same position in the format frame. Arbitration is not allowed between:

- A repeated START condition and a data bit
- A STOP condition and a data bit
- A repeated START condition and a STOP condition

**Figure 28-15. Arbitration Procedure Between Two Controller-Transmitters**

### 28.3.10 Digital Loopback Mode

The I2C module support a self-test mode called digital loopback, which is enabled by setting the DLB bit in the I2CMDR register. In this mode, data transmitted out of the I2CDXR register is received in the I2CDRR register. The data follows an internal path, and takes n cycles to reach I2CDRR, where:

$$n = 8 * (\text{SYSCLK}) / (\text{I2C module clock (Fmod)})$$

The transmit clock and the receive clock are the same. The address seen on the external SDA pin is the address in the I2COAR register. Figure 28-16 shows the signal routing in digital loopback mode.

**Figure 28-16. Pin Diagram Showing the Effects of the Digital Loopback Mode (DLB) Bit**

**Note**

The free data format (I2CMDR.FDF = 1) is not supported in digital loopback mode.

### 28.3.11 NACK Bit Generation

When the I2C module is a receiver (controller or target), the I2C module can acknowledge or ignore bits sent by the transmitter. To ignore any new bits, the I2C module must send a no-acknowledge (NACK) bit during the acknowledge cycle on the bus. [Table 28-5](#) summarizes the various ways you can allow the I2C module to send a NACK bit.

#### Note

When a NACK is sent, the following occurs:

1. The STP in I2CMR is cleared
2. SCL is held low
3. The NACK in I2CSTR is set

**Table 28-5. Ways to Generate a NACK Bit**

I2C Module Condition	NACK Bit Generation Options
Target-receiver modes	Allow an overrun condition (RSFULL = 1 in I2CSTR) Reset the module (IRS = 0 in I2CMR) Set the NACKMOD bit of I2CMR before the rising edge of the last data bit you intend to receive
Controller-receiver mode AND Repeat mode (RM = 1 in I2CMR)	Generate a STOP condition (STP = 1 in I2CMR) Reset the module (IRS = 0 in I2CMR) Set the NACKMOD bit of I2CMR before the rising edge of the last data bit you intend to receive
Controller-receiver mode AND Nonrepeat mode (RM = 0 in I2CMR)	If STP = 1 in I2CMR, allow the internal data counter to count down to 0 and thus force a STOP condition If STP = 0, make STP = 1 to generate a STOP condition Reset the module (IRS = 0 in I2CMR) Set STP = 1 to generate a STOP condition Set the NACKMOD bit of I2CMR before the rising edge of the last data bit you intend to receive

### 28.4 Interrupt Requests Generated by the I2C Module

Each I2C module can generate two CPU interrupts.

1. Basic I2C interrupt: Possible basic I2C interrupt sources that can trigger this interrupt are described in [Section 28.4.1](#).
2. I2C FIFO interrupt: Possible I2C FIFO interrupt sources that can trigger this interrupt are described in [Section 28.4.2](#)

### 28.4.1 Basic I2C Interrupt Requests

The I2C module generates the interrupt requests described in [Table 28-6](#). As shown in [Figure 28-17](#), all requests are multiplexed through an arbiter to a single I2C interrupt request to the CPU. Each interrupt request has a flag bit in the status register (I2CSTR) and an enable bit in the interrupt enable register (I2CIER). When one of the specified events occurs, the flag bit is set. If the corresponding enable bit is 0, the interrupt request is blocked. If the enable bit is 1, the request is forwarded to the CPU as an I2C interrupt.

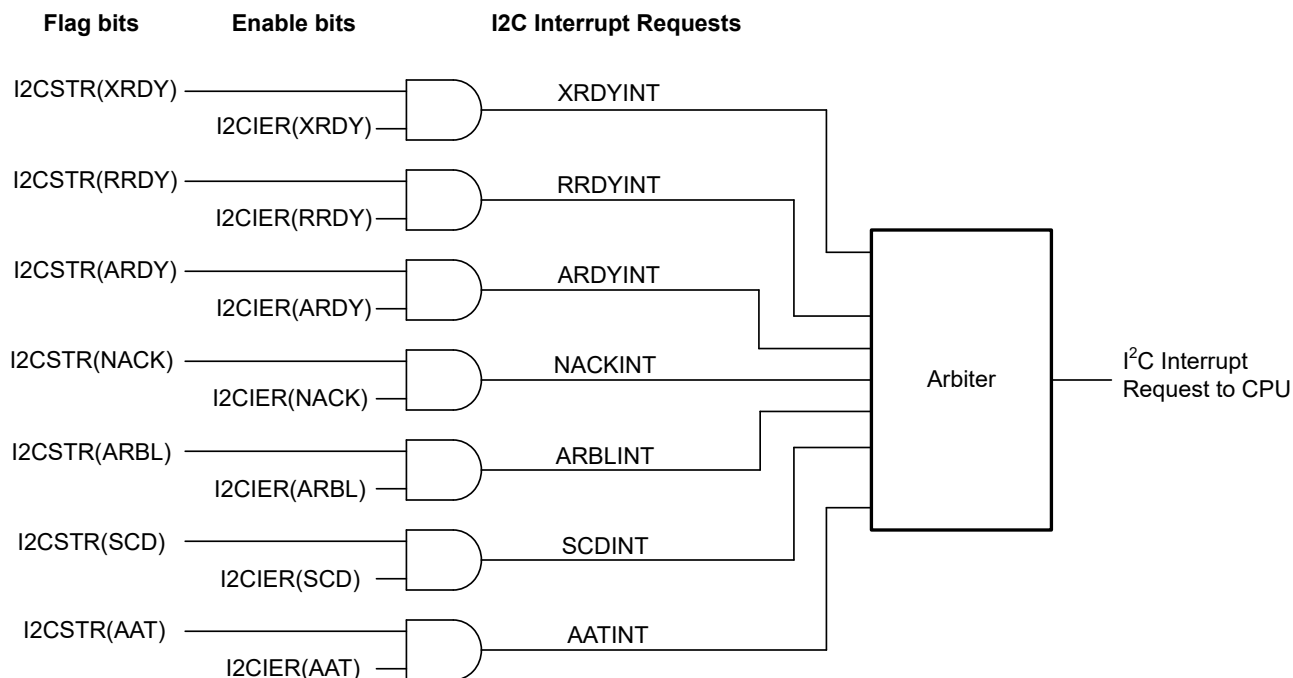

The I2C interrupt is one of the maskable interrupts of the CPU. As with any maskable interrupt request, if the request is properly enabled in the CPU, the CPU executes the corresponding interrupt service routine (I2CINT1A\_ISR). The I2CINT1A\_ISR for the I2C interrupt can determine the interrupt source by reading the interrupt source register, I2CISRC. Then the I2CINT1A\_ISR can branch to the appropriate subroutine.

After the CPU reads I2CISRC, the following events occur:

1. The flag for the source interrupt is cleared in I2CSTR. Exception: The ARDY, RRDY, and XRDY bits in I2CSTR are not cleared when I2CISRC is read. To clear one of these bits, write a 1 to the bit.
2. The arbiter determines which of the remaining interrupt requests has the highest priority, writes the code for that interrupt to I2CISRC, and forwards the interrupt request to the CPU.

**Table 28-6. Descriptions of the Basic I2C Interrupt Requests**

I2C Interrupt Request	Interrupt Source
XRDYINT	<p>Transmit ready condition: The data transmit register (I2CDXR) is ready to accept new data because the previous data has been copied from I2CDXR to the transmit shift register (I2CXSR).</p> <p>As an alternative to using XRDYINT, the CPU can poll the XRDY bit of the status register, I2CSTR. XRDYINT must not be used when in FIFO mode. Use the FIFO interrupts instead.</p>
RRDYINT	<p>Receive ready condition: The data receive register (I2CDRR) is ready to be read because data has been copied from the receive shift register (I2CRSR) to I2CDRR.</p> <p>As an alternative to using RRDYINT, the CPU can poll the RRDY bit of I2CSTR. RRDYINT must not be used when in FIFO mode. Use the FIFO interrupts instead.</p>
ARDYINT	<p>Register-access ready condition: The I2C module registers are ready to be accessed because the previously programmed address, data, and command values have been used.</p> <p>The specific events that generate ARDYINT are the same events that set the ARDY bit of I2CSTR.</p> <p>As an alternative to using ARDYINT, the CPU can poll the ARDY bit.</p>
NACKINT	<p>No-acknowledgment condition: The I2C module is configured as a controller-transmitter and did not received acknowledgment from the target-receiver.</p> <p>As an alternative to using NACKINT, the CPU can poll the NACK bit of I2CSTR.</p>
ARBLINT	<p>Arbitration-lost condition: The I2C module has lost an arbitration contest with another controller-transmitter.</p> <p>As an alternative to using ARBLINT, the CPU can poll the ARBL bit of I2CSTR.</p>
SCDINT	<p>Stop condition detected: A STOP condition was detected on the I2C bus.</p> <p>As an alternative to using SCDINT, the CPU can poll the SCD bit of the status register, I2CSTR.</p>
AASINT	<p>Addressed as target condition: The I2C has been addressed as a target device by another controller on the I2C bus.</p> <p>As an alternative to using AASINT, the CPU can poll the AAS bit of the status register, I2CSTR.</p>

**Figure 28-17. Enable Paths of the I2C Interrupt Requests**

The priorities of the basic I2C interrupt requests are listed in order of highest priority to lowest priority:

1. ARBLINT
2. NACKINT
3. ARDYINT
4. RRDYINT
5. XRDYINT
6. SCDINT
7. AATINT

The normal transmit interrupt timing makes it possible for stale data to remain in the transmit buffer if a transaction is aborted in the middle of a byte. To avoid this, set the FCM bit in the I2CEMDR register. When this bit is set, the transmit data ready interrupt is generated only when data is required for a bus transaction. In controller mode, the interrupt is first generated when the ACK of the address byte is received. In target mode, the interrupt is first generated when the address is matched. Further interrupts are generated when the data is ACKed. In this mode, XRDY is asserted at the same time as the transmit ready interrupt.

The I2C module has a backwards compatibility bit (BC) in the I2CEMDR register. The timing diagram in demonstrates the effect the backwards compatibility bit has on I2C module registers and interrupts when configured as a target-transmitter.

Target Transmitter

Figure 28-18. Backwards Compatibility Mode and Forward Compatibility Bit, Target Transmitter

### 28.4.2 I2C FIFO Interrupts

In addition to the seven basic I2C interrupts, the transmit and receive FIFOs each contain the ability to generate an interrupt (I2CINT2A). The transmit FIFO can be configured to generate an interrupt after transmitting a defined number of bytes, up to 16. The receive FIFO can be configured to generate an interrupt after receiving a defined number of bytes, up to 16. These two interrupt sources are ORed together into a single maskable CPU interrupt. Figure 28-19 shows the structure of I2C FIFO interrupt. The interrupt service routine can then read the FIFO interrupt status flags to determine from which source the interrupt came. See the I2C transmit FIFO register (I2CFFTX) and the I2C receive FIFO register (I2CFFRX) descriptions.

**Figure 28-19. I2C FIFO Interrupt**

### 28.5 Resetting or Disabling the I2C Module

You can reset or disable the I2C module in two ways:

- Write 0 to the I2C reset bit (IRS) in the I2C mode register (I2CMR). All status bits (in I2CSTR) are forced to the default values, and the I2C module remains disabled until IRS is changed to 1. The SDA and SCL pins are in the high-impedance state.
- Initiate a device reset by driving the  $\overline{\text{XRS}}$  pin low. The entire device is reset and is held in the reset state until you drive the pin high. When the  $\overline{\text{XRS}}$  pin is released, all I2C module registers are reset to the default values. The IRS bit is forced to 0, which resets the I2C module. The I2C module stays in the reset state until you write 1 to IRS.

The IRS must be 0 while you configure or reconfigure the I2C module. Forcing IRS to 0 can be used to save power and to clear error conditions.

## 28.6 Software

### 28.6.1 I2C Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
 C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/i2c

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 28.6.1.1 I2C Digital Loopback with FIFO Interrupts - SINGLE\_CORE

FILE: i2c\_ex1\_loopback.c

This program uses the internal loopback test mode of the I2C module. Both the TX and RX I2C FIFOs and their interrupts are used. The pinmux and I2C initialization is done through the sysconfig file.

A stream of data is sent and then compared to the received stream. The sent data looks like this:

```
0000 0001
0001 0002
0002 0003
....
00FE 00FF
00FF 0000
etc..
```

This pattern is repeated forever.

##### *External Connections*

- None

##### *Watch Variables*

- *sData* - Data to send
- *rData* - Received data
- *rDataPoint* - Used to keep track of the last position in the receive stream for error checking

#### 28.6.1.2 I2C EEPROM - SINGLE\_CORE

FILE: i2c\_ex2\_eeprom.c

This program will write 1-14 words to EEPROM and read them back. The data written and the EEPROM address written to are contained in the message structure, *i2cMsgOut*. The data read back will be contained in the message structure *i2cMsgIn*.

##### *External Connections*

- Connect external I2C EEPROM at address 0x50
- Connect DEVICE\_GPIO\_PIN\_SDAA on to external EEPROM SDA (serial data) pin
- Connect DEVICE\_GPIO\_PIN\_SCL on to external EEPROM SCL (serial clock) pin

##### *Watch Variables*

- *i2cMsgOut* - Message containing data to write to EEPROM
- *i2cMsgIn* - Message containing data read from EEPROM

#### 28.6.1.3 I2C Digital External Loopback with FIFO Interrupts - SINGLE\_CORE

FILE: i2c\_ex3\_external\_loopback.c

This program uses the I2CA and I2CB modules for achieving external loopback. The I2CA TX FIFO and the I2CB RX FIFO are used along with their interrupts.

A stream of data is sent on I2CA and then compared to the received stream on I2CB. The sent data looks like this:

```
0000 0001
0001 0002
```

0002 0003

....

00FE 00FF

00FF 0000

etc..

This pattern is repeated forever.

#### *External Connections*

- Connect SCLA(DEVICE\_GPIO\_PIN\_SCLA) to SCLB (DEVICE\_GPIO\_PIN\_SCLB)
- and SDAA(DEVICE\_GPIO\_PIN\_SDAA) to SDAB (DEVICE\_GPIO\_PIN\_SDAB)
- Connect DEVICE\_GPIO\_PIN\_LED1 to an LED used to depict data transfers.

#### *Watch Variables*

- *sData* - Data to send
- *rData* - Received data
- *rDataPoint* - Used to keep track of the last position in the receive stream for error checking

#### **28.6.1.4 I2C Extended Clock Stretching Controller TX - SINGLE\_CORE**

FILE: i2c\_ex7\_clock\_stretching\_controller\_tx.c

This program uses the extended clock stretching mode of the I2C module. Both the TX and RX I2C Non-FIFOs and their interrupts are used.

A stream of data is sent and then compared to the received stream.

#### **28.6.1.5 I2C Extended Clock Stretching Target RX - SINGLE\_CORE**

FILE: i2c\_ex7\_clock\_stretching\_target\_rx.c

This program uses the extended clock stretching mode of the I2C module. Both the TX and RX I2C Non-FIFOs and their interrupts are used.

A stream of data is sent and then compared to the received stream.

## **28.7 I2C Registers**

This Section describes the I2C Registers.

### **28.7.1 I2C Base Address Table**

**Table 28-7. I2C Base Address Table**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	CPU2	CPU2.DMA	Pipeline Protected
Instance	Structure								
I2caRegs	<a href="#">I2C_REGS</a>	I2CA_BASE	0x0000_7300	YES	-	-	YES	-	YES
I2cbRegs	<a href="#">I2C_REGS</a>	I2CB_BASE	0x0000_7340	YES	-	-	YES	-	YES

### 28.7.2 I2C\_REGS Registers

Table 28-8 lists the memory-mapped registers for the I2C\_REGS registers. All register offset addresses not listed in Table 28-8 should be considered as reserved locations and the register contents should not be modified.

**Table 28-8. I2C\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	I2COAR	I2C Own address		<a href="#">Go</a>
1h	I2CIER	I2C Interrupt Enable		<a href="#">Go</a>
2h	I2CSTR	I2C Status		<a href="#">Go</a>
3h	I2CCLKL	I2C Clock low-time divider		<a href="#">Go</a>
4h	I2CCLKH	I2C Clock high-time divider		<a href="#">Go</a>
5h	I2CCNT	I2C Data count		<a href="#">Go</a>
6h	I2CDRR	I2C Data receive		<a href="#">Go</a>
7h	I2CTAR	I2C TARGET address		<a href="#">Go</a>
8h	I2CDXR	I2C Data Transmit		<a href="#">Go</a>
9h	I2CMDR	I2C Mode		<a href="#">Go</a>
Ah	I2CISRC	I2C Interrupt Source		<a href="#">Go</a>
Bh	I2CEMDR	I2C Extended Mode		<a href="#">Go</a>
Ch	I2CPSC	I2C Prescaler		<a href="#">Go</a>
20h	I2CFFTX	I2C FIFO Transmit		<a href="#">Go</a>
21h	I2CFFRX	I2C FIFO Receive		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 28-9 shows the codes that are used for access types in this section.

**Table 28-9. I2C\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 28.7.2.1 I2COAR Register (Offset = 0h) [Reset = 0000h]

I2COAR is shown in [Figure 28-20](#) and described in [Table 28-10](#).

Return to the [Summary Table](#).

The I2C own address register (I2COAR) is a 16-bit register. The I2C module uses this register to specify its own TARGET address, which distinguishes it from other TARGETs connected to the I2C-bus. If the 7-bit addressing mode is selected (XA = 0 in I2CMDR), only bits 6-0 are used write 0s to bits 9-7.

**Figure 28-20. I2COAR Register**

15	14	13	12	11	10	9	8
RESERVED						OAR	
R-0h						R/W-0h	
7	6	5	4	3	2	1	0
OAR							
R/W-0h							

**Table 28-10. I2COAR Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-10	RESERVED	R	0h	Reserved
9-0	OAR	R/W	0h	In 7-bit addressing mode (XA = 0 in I2CMDR): 00h-7Fh Bits 6-0 provide the 7-bit TARGET address of the I2C module. Write 0s to bits 9-7. In 10-bit addressing mode (XA = 1 in I2CMDR): 000h-3FFh Bits 9-0 provide the 10-bit TARGET address of the I2C module. Reset type: SYSRSn

### 28.7.2.2 I2CIER Register (Offset = 1h) [Reset = 0000h]

I2CIER is shown in [Figure 28-21](#) and described in [Table 28-11](#).

Return to the [Summary Table](#).

I2CIER is used by the CPU to individually enable or disable I2C interrupt requests.

**Figure 28-21. I2CIER Register**

Bit	Field	Type	Reset	Description
15-7	RESERVED	R	0h	Reserved
6	AAT	R/W	0h	Addressed as TARGET interrupt enable Reset type: SYSRSn 0h (R/W) = Interrupt request disabled 1h (R/W) = Interrupt request enabled
5	SCD	R/W	0h	Stop condition detected interrupt enable Reset type: SYSRSn 0h (R/W) = Interrupt request disabled 1h (R/W) = Interrupt request enabled
4	XRDY	R/W	0h	Transmit-data-ready interrupt enable bit. This bit should not be set when using FIFO mode. Reset type: SYSRSn 0h (R/W) = Interrupt request disabled 1h (R/W) = Interrupt request enabled
3	RRDY	R/W	0h	Receive-data-ready interrupt enable bit. This bit should not be set when using FIFO mode. Reset type: SYSRSn 0h (R/W) = Interrupt request disabled 1h (R/W) = Interrupt request enabled
2	ARDY	R/W	0h	Register-access-ready interrupt enable Reset type: SYSRSn 0h (R/W) = Interrupt request disabled 1h (R/W) = Interrupt request enabled
1	NACK	R/W	0h	No-acknowledgment interrupt enable Reset type: SYSRSn 0h (R/W) = Interrupt request disabled 1h (R/W) = Interrupt request enabled
0	ARBL	R/W	0h	Arbitration-lost interrupt enable Reset type: SYSRSn 0h (R/W) = Interrupt request disabled 1h (R/W) = Interrupt request enabled

### 28.7.2.3 I2CSTR Register (Offset = 2h) [Reset = 0410h]

I2CSTR is shown in [Figure 28-22](#) and described in [Table 28-12](#).

Return to the [Summary Table](#).

The I2C status register (I2CSTR) is a 16-bit register used to determine which interrupt has occurred and to read status information.

**Figure 28-22. I2CSTR Register**

15	14	13	12	11	10	9	8
RESERVED	TDIR	NACKSNT	BB	RSFULL	XSMT	AAT	AD0

**Table 28-12. I2CSTR Register Field Descriptions**

Bit	Field	Type	Reset	Description
15	RESERVED	R	0h	Reserved
14	TDIR	R/W1C	0h	TARGET direction bit Reset type: SYSRSn 0h (R/W) = I2C is not addressed as a TARGET transmitter. TDIR is cleared by one of the following events: - It is manually cleared. To clear this bit, write a 1 to it. - Digital loopback mode is enabled. - A START or STOP condition occurs on the I2C bus. 1h (R/W) = I2C is addressed as a TARGET transmitter.
13	NACKSNT	R/W1C	0h	NACK sent bit. This bit is used when the I2C module is in the receiver mode. One instance in which NACKSNT is affected is when the NACK mode is used (see the description for NACKMOD in Reset type: SYSRSn 0h (R/W) = NACK not sent. NACKSNT bit is cleared by any one of the following events: - It is manually cleared. To clear this bit, write a 1 to it. - The I2C module is reset (either when 0 is written to the IRS bit of I2CMDR or when the whole device is reset). 1h (R/W) = NACK sent: A no-acknowledge bit was sent during the acknowledge cycle on the I2C-bus.
12	BB	R	0h	Bus busy bit. BB indicates whether the I2C-bus is busy or is free for another data transfer. See the paragraph following the table for more information Reset type: SYSRSn 0h (R/W) = Bus free. BB is cleared by any one of the following events: - The I2C module receives or transmits a STOP bit (bus free). - The I2C module is reset. 1h (R/W) = Bus busy: The I2C module has received or transmitted a START bit on the bus.

**Table 28-12. I2CSTR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
11	RSFULL	R	0h	<p>Receive shift register full bit.</p> <p>RSFULL indicates an overrun condition during reception. Overrun occurs when new data is received into the shift register (I2CRSR) and the old data has not been read from the receive register (I2CDRR). As new bits arrive from the SDA pin, they overwrite the bits in I2CRSR. The new data will not be copied to ICDRR until the previous data is read.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No overrun detected. RSFULL is cleared by any one of the following events:</p> <ul style="list-style-type: none"> <li>- I2CDRR is read by the CPU. Emulator reads of the I2CDRR do not affect this bit.</li> <li>- The I2C module is reset.</li> </ul> <p>1h (R/W) = Overrun detected</p>
10	XSMT	R	1h	<p>Transmit shift register empty bit.</p> <p>XSMT = 0 indicates that the transmitter has experienced underflow. Underflow occurs when the transmit shift register (I2CXSR) is empty but the data transmit register (I2CDXR) has not been loaded since the last I2CDXR-to-I2CXSR transfer. The next I2CDXR-to-I2CXSR transfer will not occur until new data is in I2CDXR. If new data is not transferred in time, the previous data may be re-transmitted on the SDA pin.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Underflow detected (empty)</p> <p>1h (R/W) = No underflow detected (not empty). XSMT is set by one of the following events:</p> <ul style="list-style-type: none"> <li>- Data is written to I2CDXR.</li> <li>- The I2C module is reset</li> </ul>
9	AAT	R	0h	<p>Addressed-as-TARGET bit</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = In the 7-bit addressing mode, the AAT bit is cleared when receiving a NACK, a STOP condition, or a repeated START condition. In the 10-bit addressing mode, the AAT bit is cleared when receiving a NACK, a STOP condition, or by a TARGET address different from the I2C peripheral's own TARGET address.</p> <p>1h (R/W) = The I2C module has recognized its own TARGET address or an address of all zeros (general call).</p>
8	AD0	R	0h	<p>Address 0 bits</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = AD0 has been cleared by a START or STOP condition.</p> <p>1h (R/W) = An address of all zeros (general call) is detected.</p>
7	RESERVED	R	0h	Reserved
6	BYTESENT	R/W1C	0h	<p>Byte Transmit over indication.</p> <p>BYTESENT is set when the CONTROLLER/TARGET has successfully sent the byte on SCL/SDA lines. This is diagnostic register which needs to be explicitly cleared by Software. In case not cleared the stale status would keep reflecting as no automated clear incorporated to avoid corner conditions.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = The I2C module has not finished transmitting the next data byte. BYTESENT is cleared by any one of the following events:</p> <ul style="list-style-type: none"> <li>- It is manually cleared. To clear this bit, write a 1 to it.</li> <li>- The I2C module is reset.</li> </ul> <p>1h (R/W) = The I2C module has completed the transmission of a byte.</p>

**Table 28-12. I2CSTR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
5	SCD	R/W1C	0h	<p>Stop condition detected bit.</p> <p>SCD is set when the I2C sends or receives a STOP condition. The I2C module delays clearing of the I2CMDR[STP] bit until the SCD bit is set.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = STOP condition not detected since SCD was last cleared. SCD is cleared by any one of the following events:</p> <ul style="list-style-type: none"> <li>- I2CISRC is read by the CPU when it contains the value 110b (stop condition detected). Emulator reads of the I2CISRC do not affect this bit.</li> <li>- SCD is manually cleared. To clear this bit, write a 1 to it.</li> <li>- The I2C module is reset.</li> </ul> <p>1h (R/W) = A STOP condition has been detected on the I2C bus.</p>
4	XRDY	R	1h	<p>Transmit-data-ready interrupt flag bit. When not in FIFO mode, XRDY indicates that the data transmit register (I2CDXR) is ready to accept new data.</p> <p>FCM=0 : When the previous data has been copied from I2CDXR to the transmit shift register (I2CXSR). The CPU can poll XRDY or use the XRDY interrupt request When in FIFO mode, use TXFFINT instead.</p> <p>FCM=1: XRDY is asserted only when next data is required it gets deasserted with write to I2CDXR. Both Polling and interrupt based data transfers are allowed in the FCM mode.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = I2CDXR not ready. XRDY is cleared when data is written to I2CDXR.</p> <p>1h (R/W) = I2CDXR ready: Data has been copied from I2CDXR to I2CXSR.</p> <p>XRDY is also forced to 1 when the I2C module is reset.</p>
3	RRDY	R/W1C	0h	<p>Receive-data-ready interrupt flag bit.</p> <p>When not in FIFO mode, RRDY indicates that the data receive register (I2CDRR) is ready to be read because data has been copied from the receive shift register (I2CRSR) to I2CDRR. The CPU can poll RRDY or use the RRDY interrupt request When in FIFO mode, use RXFFINT instead.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = I2CDRR not ready. RRDY is cleared by any one of the following events:</p> <ul style="list-style-type: none"> <li>- I2CDRR is read by the CPU. Emulator reads of the I2CDRR do not affect this bit.</li> <li>- RRDY is manually cleared. To clear this bit, write a 1 to it.</li> <li>- The I2C module is reset.</li> </ul> <p>1h (R/W) = I2CDRR ready: Data has been copied from I2CRSR to I2CDRR.</p>
2	ARDY	R/W1C	0h	<p>Register-access-ready interrupt flag bit (only Applicable when the I2C module is in the CONTROLLER mode).</p> <p>ARDY indicates that the I2C module registers are ready to be accessed because the previously programmed address, data, and command values have been used. The CPU can poll ARDY or use the ARDY interrupt request</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = The registers are not ready to be accessed. ARDY is cleared by any one of the following events:</p> <ul style="list-style-type: none"> <li>- The I2C module starts using the current register contents.</li> <li>- ARDY is manually cleared. To clear this bit, write a 1 to it.</li> <li>- The I2C module is reset.</li> </ul> <p>1h (R/W) = The registers are ready to be accessed.</p> <p>In the nonrepeat mode (RM = 0 in I2CMDR): If STP = 0 in I2CMDR, the ARDY bit is set when the internal data counter counts down to 0. If STP = 1, ARDY is not affected (instead, the I2C module generates a STOP condition when the counter reaches 0).</p> <p>In the repeat mode (RM = 1): ARDY is set at the end of each byte transmitted from I2CDXR.</p>

**Table 28-12. I2CSTR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
1	NACK	R/W1C	0h	<p>No-acknowledgment interrupt flag bit.</p> <p>NACK applies when the I2C module is a CONTROLLER transmitter. NACK indicates whether the I2C module has detected an acknowledge bit (ACK) or a noacknowledge bit (NACK) from the TARGET receiver. The CPU can poll NACK or use the NACK interrupt request.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = ACK received/NACK not received. This bit is cleared by any one of the following events:</p> <ul style="list-style-type: none"> <li>- An acknowledge bit (ACK) has been sent by the TARGET receiver.</li> <li>- NACK is manually cleared. To clear this bit, write a 1 to it.</li> <li>- The CPU reads the interrupt source register (I2CISRC) and the register contains the code for a NACK interrupt. Emulator reads of the I2CISRC do not affect this bit.</li> <li>- The I2C module is reset.</li> </ul> <p>1h (R/W) = NACK bit received. The hardware detects that a no-acknowledge (NACK) bit has been received.</p> <p>Note: While the I2C module performs a general call transfer, NACK is 1, even if one or more TARGETs send acknowledgment.</p>
0	ARBL	R/W1C	0h	<p>Arbitration-lost interrupt flag bit (only applicable when the I2C module is a CONTROLLER-transmitter).</p> <p>ARBL primarily indicates when the I2C module has lost an arbitration contest with another CONTROLLERtransmitter. The CPU can poll ARBL or use the ARBL interrupt request.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Arbitration not lost. AL is cleared by any one of the following events:</p> <ul style="list-style-type: none"> <li>- AL is manually cleared. To clear this bit, write a 1 to it.</li> <li>- The CPU reads the interrupt source register (I2CISRC) and the register contains the code for an AL interrupt. Emulator reads of the I2CISRC do not affect this bit.</li> <li>- The I2C module is reset.</li> </ul> <p>1h (R/W) = Arbitration lost. AL is set by any one of the following events:</p> <ul style="list-style-type: none"> <li>- The I2C module senses that it has lost an arbitration with two or more competing transmitters that started a transmission almost simultaneously.</li> <li>- The I2C module attempts to start a transfer while the BB (bus busy) bit is set to 1.</li> </ul> <p>When AL becomes 1, the CNT and STP bits of I2CMDR are cleared, and the I2C module becomes a TARGET-receiver.</p>

### 28.7.2.4 I2CCLKL Register (Offset = 3h) [Reset = 0000h]

I2CCLKL is shown in [Figure 28-23](#) and described in [Table 28-13](#).

Return to the [Summary Table](#).

### 28.7.2.6 I2CCNT Register (Offset = 5h) [Reset = 0000h]

I2CCNT is shown in [Figure 28-25](#) and described in [Table 28-15](#).

Return to the [Summary Table](#).

I2CCNT is a 16-bit register used to indicate how many data bytes to transfer when the I2C module is configured as a transmitter, or to receive when configured as a CONTROLLER receiver. In the repeat mode (RM = 1), I2CCNT is not used.

The value written to I2CCNT is copied to an internal data counter. The internal data counter is decremented by 1 for each byte transferred (I2CCNT remains unchanged). If a STOP condition is requested in the CONTROLLER mode (STP = 1 in I2CMDR), the I2C module terminates the transfer with a STOP condition when the countdown is complete (that is, when the last byte has been transferred).

**Figure 28-25. I2CCNT Register**

R/W-0h							

**Table 28-15. I2CCNT Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-0	I2CCNT	R/W	0h	Data count value. I2CCNT indicates the number of data bytes to transfer or receive. If a STOP condition is specified (STP=1) then I2CCNT will decrease after each byte is sent until it reaches zero, which in turn will generate a STOP condition. The value in I2CCNT is a don't care when the RM bit in I2CMDR is set to 1. Reset type: SYSRSn 0h (R/W) = data count value is 65536 1h (R/W) = data count value is 1 2h (R/W) = data count value is 2 FFFFh (R/W) = data count value is 65535

### 28.7.2.7 I2CDRR Register (Offset = 6h) [Reset = 0000h]

I2CDRR is shown in [Figure 28-26](#) and described in [Table 28-16](#).

Return to the [Summary Table](#).

I2CDRR is a 16-bit register used by the CPU to read received data. The I2C module can receive a data byte with 1 to 8 bits. The number of bits is selected with the bit count (BC) bits in I2CMMDR. One bit at a time is shifted in from the SDA pin to the receive shift register (I2CRSR). When a complete data byte has been received, the I2C module copies the data byte from I2CRSR to I2CDRR. The CPU cannot access I2CRSR directly.

If a data byte with fewer than 8 bits is in I2CDRR, the data value is right-justified, and the other bits of I2CDRR(7-0) are undefined. For example, if BC = 011 (3-bit data size), the receive data is in I2CDRR(2-0), and the content of I2CDRR(7-3) is undefined.

When in the receive FIFO mode, the I2CDRR register acts as the receive FIFO buffer.

### 28.7.2.8 I2CTAR Register (Offset = 7h) [Reset = 03FFh]

I2CTAR is shown in [Figure 28-27](#) and described in [Table 28-17](#).

Return to the [Summary Table](#).

The I2C TARGET address register (I2CSAR) is a 16-bit register for storing the next TARGET address that will be transmitted by the I2C module when it is a CONTROLLER. The SAR field of I2CSAR contains a 7-bit or 10-bit TARGET address. When the I2C module is not using the free data format (FDF = 0 in I2CMDR), it uses this address to initiate data transfers with a TARGET, or TARGETs. When the address is nonzero, the address is for a particular TARGET. When the address is 0, the address is a general call to all TARGETs. If the 7-bit addressing mode is selected (XA = 0 in I2CMDR), only bits 6-0 of I2CSAR are used write 0s to bits 9-7.

Write 0s to bits 9-7. In 10-bit addressing mode (XA = 1 in I2CMDR): 000h-3FFh Bits 9-0 provide the 10-bit TARGET address that the I2C module transmits when it is in the CONTROLLER transmitter mode. Reset type: SYSRSn

### 28.7.2.9 I2CDXR Register (Offset = 8h) [Reset = 0000h]

I2CDXR is shown in [Figure 28-28](#) and described in [Table 28-18](#).

Return to the [Summary Table](#).

The CPU writes transmit data to I2CDXR. This 16-bit register accepts a data byte with 1 to 8 bits. Before writing to I2CDXR, specify how many bits are in a data byte by loading the appropriate value into the bit count (BC) bits of I2CMR. When writing a data byte with fewer than 8 bits, make sure the value is right-aligned in I2CDXR. After a data byte is written to I2CDXR, the I2C module copies the data byte to the transmit shift register (I2CXSR). The CPU cannot access I2CXSR directly. From I2CXSR, the I2C module shifts the data byte out on the SDA pin, one bit at a time.

When in the transmit FIFO mode, the I2CDXR register acts as the transmit FIFO buffer.

Bit	Field	Type	Reset	Description
15	NACKMOD	R/W	0h	<p>NACK mode bit. This bit is only applicable when the I2C module is acting as a receiver.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = In the TARGET-receiver mode: The I2C module sends an acknowledge (ACK) bit to the transmitter during each acknowledge cycle on the bus. The I2C module only sends a no-acknowledge (NACK) bit if you set the NACKMOD bit.</p> <p>In the CONTROLLER-receiver mode: The I2C module sends an ACK bit during each acknowledge cycle until the internal data counter counts down to 0. At that point, the I2C module sends a NACK bit to the transmitter. To have a NACK bit sent earlier, you must set the NACKMOD bit</p> <p>1h (R/W) = In either TARGET-receiver or CONTROLLER-receiver mode: The I2C module sends a NACK bit to the transmitter during the next acknowledge cycle on the bus. Once the NACK bit has been sent, NACKMOD is cleared.</p> <p>Important: To send a NACK bit in the next acknowledge cycle, you must set NACKMOD before the rising edge of the last data bit.</p>
14	FREE	R/W	0h	<p>This bit controls the action taken by the I2C module when a debugger breakpoint is encountered.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = When I2C module is CONTROLLER: If SCL is low when the breakpoint occurs, the I2C module stops immediately and keeps driving SCL low, whether the I2C module is the transmitter or the receiver. If SCL is high, the I2C module waits until SCL becomes low and then stops.</p> <p>When I2C module is TARGET: A breakpoint forces the I2C module to stop when the current transmission/reception is complete.</p> <p>1h (R/W) = The I2C module runs free that is, it continues to operate when a breakpoint occurs.</p>
13	STT	R/W	0h	<p>START condition bit (only applicable when the I2C module is a CONTROLLER). The RM, STT, and STP bits determine when the I2C module starts and stops data transmissions (see Table 9-6). Note that the STT and STP bits can be used to terminate the repeat mode, and that this bit is not writable when IRS = 0.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = In the CONTROLLER mode, STT is automatically cleared after the START condition has been generated.</p> <p>1h (R/W) = In the CONTROLLER mode, setting STT to 1 causes the I2C module to generate a START condition on the I2C-bus</p>
12	RESERVED	R	0h	Reserved

**Table 28-19. I2CMDR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
11	STP	R/W	0h	<p>STOP condition bit (only applicable when the I2C module is a CONTROLLER).</p> <p>In the CONTROLLER mode, the RM,STT, and STP bits determine when the I2C module starts and stops data transmissions. Note that the STT and STP bits can be used to terminate the repeat mode, and that this bit is not writable when IRS=0. When in non-repeat mode, at least one byte must be transferred before a stop condition can be generated. The I2C module delays clearing of this bit until after the I2CSTR[SCD] bit is set. To avoid disrupting the I2C state machine, the user must wait until this bit is clear before initiating a new message.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = STP is automatically cleared after the STOP condition has been generated</p> <p>1h (R/W) = STP has been set by the device to generate a STOP condition when the internal data counter of the I2C module counts down to 0.</p>
10	CNT	R/W	0h	<p>CONTROLLER mode bit.</p> <p>CNT determines whether the I2C module is in the TARGET mode or the CONTROLLER mode. CNT is automatically changed from 1 to 0 when the I2C CONTROLLER generates a STOP condition</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = TARGET mode. The I2C module is a TARGET and receives the serial clock from the CONTROLLER.</p> <p>1h (R/W) = CONTROLLER mode. The I2C module is a CONTROLLER and generates the serial clock on the SCL pin.</p>
9	TRX	R/W	0h	<p>Transmitter mode bit.</p> <p>When relevant, TRX selects whether the I2C module is in the transmitter mode or the receiver mode.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Receiver mode. The I2C module is a receiver and receives data on the SDA pin.</p> <p>1h (R/W) = Transmitter mode. The I2C module is a transmitter and transmits data on the SDA pin.</p>
8	XA	R/W	0h	<p>Expanded address enable bit.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = 7-bit addressing mode (normal address mode). The I2C module transmits 7-bit TARGET addresses (from bits 6-0 of I2CTAR), and its own TARGET address has 7 bits (bits 6-0 of I2COAR).</p> <p>1h (R/W) = 10-bit addressing mode (expanded address mode). The I2C module transmits 10-bit TARGET addresses (from bits 9-0 of I2CTAR), and its own TARGET address has 10 bits (bits 9-0 of I2COAR).</p>
7	RM	R/W	0h	<p>Repeat mode bit (only applicable when the I2C module is a CONTROLLER-transmitter or CONTROLLER-receiver).</p> <p>The RM, STT, and STP bits determine when the I2C module starts and stops data transmissions</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Nonrepeat mode. The value in the data count register (I2CCNT) determines how many bytes are received/transmitted by the I2C module.</p> <p>1h (R/W) = Repeat mode. A data byte is transmitted each time the I2CDXR register is written to (or until the transmit FIFO is empty when in FIFO mode) until the STP bit is manually set. The value of I2CCNT is ignored. The ARDY bit/interrupt can be used to determine when the I2CDXR (or FIFO) is ready for more data, or when the data has all been sent and the CPU is allowed to write to the STP bit.</p>

**Table 28-19. I2CMDR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
6	DLB	R/W	0h	Digital loopback mode bit. Reset type: SYSRSn 0h (R/W) = Digital loopback mode is disabled. 1h (R/W) = Digital loopback mode is enabled. For proper operation in this mode, the CNT bit must be 1. In the digital loopback mode, data transmitted out of I2CDXR is received in I2CDRR after n device cycles by an internal path, where: $n = ((I2C \text{ input clock frequency/module clock frequency}) \times 8)$ The transmit clock is also the receive clock. The address transmitted on the SDA pin is the address in I2COAR. Note: The free data format (FDF = 1) is not supported in the digital loopback mode.
5	IRS	R/W	0h	I2C module reset bit. Reset type: SYSRSn 0h (R/W) = The I2C module is in reset/disabled. When this bit is cleared to 0, all status bits (in I2CSTR) are set to their default values. 1h (R/W) = The I2C module is enabled. This has the effect of releasing the I2C bus if the I2C peripheral is holding it.
4	STB	R/W	0h	START byte mode bit. This bit is only applicable when the I2C module is a CONTROLLER. As described in version 2.1 of the Philips Semiconductors I2C-bus specification, the START byte can be used to help a TARGET that needs extra time to detect a START condition. When the I2C module is a TARGET, it ignores a START byte from a CONTROLLER, regardless of the value of the STB bit. Reset type: SYSRSn 0h (R/W) = The I2C module is not in the START byte mode. 1h (R/W) = The I2C module is in the START byte mode. When you set the START condition bit (STT), the I2C module begins the transfer with more than just a START condition. Specifically, it generates: <ol style="list-style-type: none"> <li>1. A START condition</li> <li>2. A START byte (0000 0001b)</li> <li>3. A dummy acknowledge clock pulse</li> <li>4. A repeated START condition</li> </ol> Then, as normal, the I2C module sends the TARGET address that is in I2CTAR.
3	FDF	R/W	0h	Free data format mode bit. Reset type: SYSRSn 0h (R/W) = Free data format mode is disabled. Transfers use the 7-/10-bit addressing format selected by the XA bit. 1h (R/W) = Free data format mode is enabled. Transfers have the free data (no address) format described in Section 9.2.5. The free data format is not supported in the digital loopback mode (DLB=1).

**Table 28-19. I2CMDR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
2-0	BC	R/W	0h	<p>Bit count bits.</p> <p>BC defines the number of bits (1 to 8) in the next data byte that is to be received or transmitted by the I2C module. The number of bits selected with BC must match the data size of the other device. Notice that when BC = 000b, a data byte has 8 bits. BC does not affect address bytes, which always have 8 bits.</p> <p>Note: If the bit count is less than 8, receive data is right-justified in I2CDRR(7-0), and the other bits of I2CDRR(7-0) are undefined. Also, transmit data written to I2CDXR must be right-justified</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = 8 bits per data byte            1h (R/W) = 1 bit per data byte            2h (R/W) = 2 bits per data byte            3h (R/W) = 3 bits per data byte            4h (R/W) = 4 bits per data byte            5h (R/W) = 5 bits per data byte            6h (R/W) = 6 bits per data byte            7h (R/W) = 7 bits per data byte</p>

### 28.7.2.11 I2CISRC Register (Offset = Ah) [Reset = 0000h]

I2CISRC is shown in [Figure 28-30](#) and described in [Table 28-20](#).

Return to the [Summary Table](#).

The I2C interrupt source register (I2CISRC) is a 16-bit register used by the CPU to determine which event generated the I2C interrupt.

**Figure 28-30. I2CISRC Register**

Bit	Field	Type	Reset	Description
15-2	RESERVED	R	0h	Reserved
1	FCM	R/W	0h	Forward Compatibility mode. This bit when programmed brings the functionality of Tx request only when Tx data required regardless of data status in Tx buffer for non-FIFO mode. This register affects the XRDY behavior hence needs to be set after releasing the IRS (I2CMDR[5]). Reset type: SYSRSn 0h (R/W) = Legacy functionality of requesting Tx data upon buffer copy to shift register or upon start condition is active. Stale data is reused after illegal start, ARB Lost, NACK conditions. 1h (R/W) = New functionality of requesting data only upon ACK (address/data) is active.
0	BC	R/W	1h	Backwards compatibility mode. This bit affects the timing of the transmit status bits (XRDY and XSMT) in the I2CSTR register when in TARGET transmitter mode. Reset type: SYSRSn 0h (R/W) = See the 'Backwards Compatibility Mode Bit, TARGET Transmitter' Figure for details. 1h (R/W) = See the 'Backwards Compatibility Mode Bit, TARGET Transmitter' Figure for details.

### 28.7.2.13 I2CPSC Register (Offset = Ch) [Reset = 0000h]

I2CPSC is shown in [Figure 28-32](#) and described in [Table 28-22](#).

Return to the [Summary Table](#).

The I2C prescaler register (I2CPSC) is a 16-bit register (see [Figure 14-21](#)) used for dividing down the I2C input clock to obtain the desired module clock for the operation of the I2C module. See the device-specific data manual for the supported range of values for the module clock frequency.

IPSC must be initialized while the I2C module is in reset (IRS = 0 in I2CMDR). The prescaled frequency takes effect only when IRS is changed to 1. Changing the IPSC value while IRS = 1 has no effect.

**Figure 28-32. I2CPSC Register**

R-0h	R-0/W1S-0h	R/W-0h	R/W-0h					

**Table 28-23. I2CFFTX Register Field Descriptions**

Bit	Field	Type	Reset	Description
15	RESERVED	R	0h	Reserved
14	I2CFFEN	R/W	0h	I2C FIFO mode enable bit. This bit must be enabled for either the transmit or the receive FIFO to operate correctly. Reset type: SYSRSn 0h (R/W) = Disable the I2C FIFO mode. 1h (R/W) = Enable the I2C FIFO mode.
13	TXFFRST	R/W	0h	Transmit FIFO Reset Reset type: SYSRSn 0h (R/W) = Reset the transmit FIFO pointer to 0000 and hold the transmit FIFO in the reset state. 1h (R/W) = Enable the transmit FIFO operation.
12-8	TXFFST	R	0h	Contains the status of the transmit FIFO: xxxxx Transmit FIFO contains xxxxx bytes. 00000 Transmit FIFO is empty. Note: Since these bits are reset to zero, the transmit FIFO interrupt flag will be set when the transmit FIFO operation is enabled and the I2C is taken out of reset. This will generate a transmit FIFO interrupt if enabled. To avoid any detrimental effects from this, write a one to the TXFFINTCLR once the transmit FIFO operation is enabled and the I2C is taken out of reset. Reset type: SYSRSn
7	TXFFINT	R	0h	Transmit FIFO interrupt flag. This bit cleared by a CPU write of a 1 to the TXFFINTCLR bit. If the TXFFIENA bit is set, this bit will generate an interrupt when it is set. Reset type: SYSRSn 0h (R/W) = Transmit FIFO interrupt condition has not occurred. 1h (R/W) = Transmit FIFO interrupt condition has occurred.
6	TXFFINTCLR	R-0/W1S	0h	Transmit FIFO Interrupt Flag Clear Reset type: SYSRSn 0h (R/W) = Writes of zeros have no effect. Reads return a 0. 1h (R/W) = Writing a 1 to this bit clears the TXFFINT flag.
5	TXFFIENA	R/W	0h	Transmit FIFO Interrupt Enable Reset type: SYSRSn 0h (R/W) = Disabled. TXFFINT flag does not generate an interrupt when set. 1h (R/W) = Enabled. TXFFINT flag does generate an interrupt when set.

**Table 28-23. I2CFFTX Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
4-0	TXFFIL	R/W	0h	<p>Transmit FIFO interrupt level.</p> <p>These bits set the status level that will set the transmit interrupt flag. When the TXFFST4-0 bits reach a value equal to or less than these bits, the TXFFINT flag will be set. This will generate an interrupt if the TXFFIENA bit is set. Because the I2C on this device has a 16-level transmit FIFO, these bits cannot be configured for an interrupt of more than 16 FIFO levels.</p> <p>Reset type: SYSRSn</p>

### 28.7.2.15 I2CFFRX Register (Offset = 21h) [Reset = 0000h]

I2CFFRX is shown in [Figure 28-34](#) and described in [Table 28-24](#).

Return to the [Summary Table](#).

The I2C receive FIFO register (I2CFFRX) is a 16-bit register that contains the control and status bits for the receive FIFO mode of operation on the I2C peripheral.

**Figure 28-34. I2CFFRX Register**

15	14	13	12	11	10	9	8	
RESERVED		RXFFRST	RXFFST					
R-0h		R/W-0h	R-0h					
7	6	5	4	3	2	1	0	
RXFFINT	RXFFINTCLR	RXFFIENA	RXFFIL					
R-0h	R-0/W1S-0h	R/W-0h	R/W-0h					

**Table 28-24. I2CFFRX Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-14	RESERVED	R	0h	Reserved
13	RXFFRST	R/W	0h	I2C receive FIFO reset bit Reset type: SYSRSn 0h (R/W) = Reset the receive FIFO pointer to 0000 and hold the receive FIFO in the reset state. 1h (R/W) = Enable the receive FIFO operation.
12-8	RXFFST	R	0h	Contains the status of the receive FIFO: xxxxx Receive FIFO contains xxxxx bytes 00000 Receive FIFO is empty. Reset type: SYSRSn
7	RXFFINT	R	0h	Receive FIFO interrupt flag. This bit cleared by a CPU write of a 1 to the RXFFINTCLR bit. If the RXFFIENA bit is set, this bit will generate an interrupt when it is set Reset type: SYSRSn 0h (R/W) = Receive FIFO interrupt condition has not occurred. 1h (R/W) = Receive FIFO interrupt condition has occurred.
6	RXFFINTCLR	R-0/W1S	0h	Receive FIFO interrupt flag clear bit. Reset type: SYSRSn 0h (R/W) = Writes of zeros have no effect. Reads return a zero. 1h (R/W) = Writing a 1 to this bit clears the RXFFINT flag.
5	RXFFIENA	R/W	0h	Receive FIFO interrupt enable bit. Reset type: SYSRSn 0h (R/W) = Disabled. RXFFINT flag does not generate an interrupt when set. 1h (R/W) = Enabled. RXFFINT flag does generate an interrupt when set.
4-0	RXFFIL	R/W	0h	Receive FIFO interrupt level. These bits set the status level that will set the receive interrupt flag. When the RXFFST4-0 bits reach a value equal to or greater than these bits, the RXFFINT flag is set. This will generate an interrupt if the RXFFIENA bit is set. Note: Since these bits are reset to zero, the receive FIFO interrupt flag will be set if the receive FIFO operation is enabled and the I2C is taken out of reset. This will generate a receive FIFO interrupt if enabled. To avoid this, modify these bits on the same instruction as or prior to setting the RXFFRST bit. Because the I2C on this device has a 16-level receive FIFO, these bits cannot be configured for an interrupt of more than 16 FIFO levels. Reset type: SYSRSn

Chapter 29

## **Power Management Bus Module (PMBus)**

---

This chapter describes the features and operation of the Power Management Bus (PMBus) module.

<b>29.1 Introduction</b> .....	<b>4729</b>
<b>29.2 Configuring Device Pins</b> .....	<b>4730</b>
<b>29.3 Target Mode Operation</b> .....	<b>4731</b>
<b>29.4 Controller Mode Operation</b> .....	<b>4742</b>
<b>29.5 PMBUS Registers</b> .....	<b>4752</b>

## 29.1 Introduction

The PMBus module provides an interface between the microcontroller and devices compliant with the SMI Forum PMBus Specification Part I version 1.0 and Part II version 1.1. The PMBus is based on SMBus, which uses a similar physical layer to the I2C. This chapter assumes you are familiar with the PMBus, SMBus, and I2C bus specifications.

### 29.1.1 PMBUS Related Collateral

#### Foundational Materials

#### Expert Materials

- [9 things you need to know about PMBus Point-of-Load Power \(Video\)](#)

### 29.1.2 Features

The PMBus module has the following features:

- Compliance with the SMI Forum PMBus Specification (Part I v1.0 and Part II v1.1)
- Support for controller and target modes
- Support for I2C modes
- Support for three speeds:
  - Standard Mode: Up to 100kHz
  - Fast Mode: Up to 400kHz
- Packet error checking
- CONTROL and ALERT signals
- Clock high and low time-outs
- Four-byte transmit and receive buffers
- One maskable interrupt, which can be generated by several conditions:
  - Receive data ready
  - Transmit buffer empty
  - Target address received
  - End of message
  - ALERT input asserted
  - Clock low time-out
  - Clock high time-out
  - Bus free

### 29.1.3 Block Diagram

Figure 29-1 shows the block diagram for PMBus. The PMBus module handles the lower levels of the PMBus protocol. In addition to controlling signal levels and timing, parsing addresses, and buffering data, the PMBus module also directly supports complex transactions such as Read Word and Process Call.

There are four PMBus signals:

- **SCL** is the bus clock. SCL is normally controlled by the controller, but can be held low by a target to delay a transaction and allow more time for processing.
- **SDA** is the bidirectional data line.
- **CONTROL** is a target input that can trigger an interrupt. CONTROL can be used to shut down a target device.
- **ALERT** is a target output/controller input that allows a target to request attention from the controller.

The SDA and SCL timings produced by the module are derived from SYSCLK. To comply with the PMBus timing specs, the bit clock divider must be set by way of the PMBTIMCLK register to provide a bit clock of 10MHz or less.

Figure 29-1. PMBus Module Block Diagram

## 29.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification is set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups are configured in the GPyPUD register.

### Note

The GPIO configuration register GPyODR must be set to normal mode when the PMBus is used. The open-drain operation for PMBus is managed by the PMBus module

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

## 29.3 Target Mode Operation

This section describes the configuration and operation of the PMBus module in target mode.

### 29.3.1 Configuration

To configure the module, write a clock divider to the PMBCTRL register's CLKDIV field to produce a bit clock frequency of less than 10MHz. To activate target mode, set the TARGET\_EN bit in the PMBCTRL register. Next, set up the PMBTCR register. The following options are configurable:

- Target address and mask (TARGET\_ADDR and TARGET\_MASK): Sets the target address and mask for message acceptance.
- Manual target address acknowledgment (MAN\_TARGET\_ACK): When enabled, allows software to decide whether to acknowledge (ACK) an address. When disabled, the decision to ACK is made automatically based on the target address and mask.
- PEC enable (PEC\_ENA): Set this bit if Packet Error Checking (PEC) is used on the bus.
- Manual command byte acknowledgment (MAN\_CMD): Similar to manual target acknowledgment, setting this bit allows software to decide whether to acknowledge (ACK) a command byte.
- Number of bytes to acknowledge automatically (RX\_BYTE\_ACK\_CNT): This is normally set to the maximum value, which allows the entire receive buffer to be used. However, smaller values can be used if the application requires that erroneous messages be detected and not acknowledged (NACKed) as soon as possible.

Manual acknowledgment is done by writing a one to the PMBACK register. Even with automatic acknowledgment, some writes to PMBACK are required. If the message (not including the address) is longer than 4 bytes, each packet of 4 bytes must be acknowledged. The PMBus module stretches the clock (hold the clock low) until an ACK is issued. The module then pulls the data line low and releases the clock, providing the ACK signal to the controller.

If the complete message or the last part of the message is less than 4 bytes (or the RX\_BYTE\_ACK\_CNT limit), do not write to PMBACK.

Writing a zero to the PMBACK bit sends a NACK. This can only be done when the module is waiting for an acknowledgment. If a zero is written at any other time, the NACK is issued during the next message.

### 29.3.2 Message Handling

This section describes some of the message types for PMBus and how to determine which message type is being received in target mode. This section is oriented toward the most efficient mode of operation – with automatic address and command acknowledgment and is also oriented toward having Packet Error Checking (PEC) enabled.

If automatic address acknowledgment is disabled, all messages start by setting the TARGET\_ADDR\_READY bit high. Read commands have two instructions one for the read and one for the write. If automatic command acknowledgment is enabled, the DATA READY bit is set high, as well. If the message has no PEC, the number of bytes available is n-1. For example with PEC, a QUICK COMMAND has one byte. With no PEC, a QUICK COMMAND has zero bytes.

Note that the byte count does not increment as bytes arrive. No bits are set in the PMBST register until a stop message is received, the receive buffer is full, or a fault occurs. Then, all appropriate bit values are placed in the register together. All that is necessary to receive a quick command is to ACK the message by writing a one to the PMBACK register.

#### 29.3.2.1 Quick Command

Quick Commands ([Figure 29-2](#)) received by the PMBus module in target mode require a simple acknowledgment of the received device address. In automatic address acknowledge mode, the module processes the quick command without firmware interaction. Upon receipt of the end of message, the firmware has the option to read the received address in the PMBHTA register. In manual address acknowledge mode, the address is acknowledged by writing to the PMBACK register.

**Figure 29-2. Quick Command Message**

### 29.3.2.2 Send Byte

A Send Byte message (Figure 29-3) consists of the device address, a single data byte, and an optional PEC byte. To process the PEC byte correctly, PEC processing must be enabled in the PMBTCR register. In automatic address acknowledge mode, the data and optional PEC byte are acknowledged without firmware interaction. The module generates an End of Message interrupt, reads the status register and finds the data ready indication bit set. In manual mode, the address is acknowledged by the firmware, while the remaining data and PEC bytes are acknowledged by the module.

The PMBus module stores Data Byte #0 into the PMBRXBUF register. The data byte is stored into bits 7-0. In non-PEC mode, the RX Byte Count in the PMBSTS register indicates one byte received. If PEC processing is enabled, the PEC byte is also stored into the PMBRXBUF register, with the PEC byte residing in bits 15-8. The RX Byte Count in the PMBSTS register indicates two bytes received. The PEC Valid bit in the PMBSTS register indicates the validity of the received PEC byte.

When a Send Byte message is received, the Data Ready bit is set along with the EOM and, assuming that the PEC is valid, the PEC valid bit. The read byte count (RD\_BYTE\_COUNT) register contains a 2. All that is necessary to receive a send byte command is to ACK the message by writing a 1 to the PMBACK register. Before doing the ACK, read the byte from the lowest byte of the PMBRXBUF register.

**Figure 29-3. Send Byte Message With and Without PEC**

### 29.3.2.3 Receive Byte

A Receive Byte message (Figure 29-4) consists of the device address, a single data byte, and an optional PEC byte. In automatic address acknowledge mode, the firmware receives a data request interrupt following reception of the target address. The data byte to be sent to the controller is stored into bits 7-0 of the PMBTXBUF register and Transmit Byte Count bits within the PMBTCR register are set to a value of 1. If PEC processing is enabled, the Transmit PEC bit (bit 19) within the PMBTCR register is set to 1, along with the Enable PEC bit (bit 15). The module automatically appends the calculated PEC byte at the completion of the message.

**Figure 29-4. Receive Byte Message With and Without PEC**

### 29.3.2.4 Write Byte and Write Word

The Write Byte and Write Word messages (Figure 29-5) consist of a target address, a command word, transmitted data bytes and an optional PEC byte. In automatic address acknowledge mode, the data bytes and optional PEC byte are acknowledged without firmware interaction. The acknowledgment of the command word is configured through the PMBTCCR register. The firmware receives an End of Message interrupt in all cases except for Write Word with PEC message, reads the status register and finds the data ready indication bit set.

In the case of a Write Word with PEC byte message, the data ready interrupt is enabled after receiving 4 bytes (command byte, the 2 data bytes and the PEC byte). The firmware reads the data from the PMBRXBUF register and must write the PMBACK register to acknowledge back to the controller. The PMBus module holds SCL low until the firmware responds to the received data.

In all other cases, the EOM interrupt is received and data can be read from the PMBRXBUF register. The firmware is not required to send an acknowledgment back to the controller.

The Write Byte message looks exactly the same as the Send Byte, except the RD\_BYTE\_COUNT register contains a 3. The Write Word message has a RD\_BYTE\_COUNT of 4.

**Figure 29-5. Write Byte and Write Word Messages With and Without PEC**

### 29.3.2.5 Read Byte and Read Word

The Read Byte and Read Word messages (Figure 29-6) consist of a target address, a command word, received data bytes from a target, and an optional PEC byte. Address and command acknowledgment is configured through the PMBTCR register. In automatic mode, the PMBus module provides a data ready and data request interrupt following receipt of a repeated start and target address. The received command byte is found in bits 7-0 of the PMBRXBUF register. The firmware responds to the data request by programming the data bytes into the PMBTXBUF register and the TX Byte Count bits in the PMBTCR register. If PEC processing is enabled, the Transmit PEC bit must also be asserted. An EOM interrupt indicates completion of the message to the Controller.

When the repeated start (Sr) signal is received, the Data Ready bit is asserted with a RD\_BYTE\_COUNT of 1. At this point, the operation cannot be distinguished from a group command Send Byte message. When the same device address is sent out with a read, the Data Request bit is asserted. If data has already been written to the PMTXBUF register before the Device Address is received, the Data Request bit is not asserted. So if group commands are also expected, read the Data Ready with a RD\_BYTE\_COUNT of 1, and then wait and see whether the next event is an EOM or a Data Request. If the event is an EOM, the command must be processed as a group send byte. If the event is a Data Request, the command must be processed as a read. Depending on the command, the event can be a read byte, word, or block. If the PMBus module is polled, both the Data Ready and the Data Request bits can possibly be set between polling intervals. This must be considered in the design of the firmware.

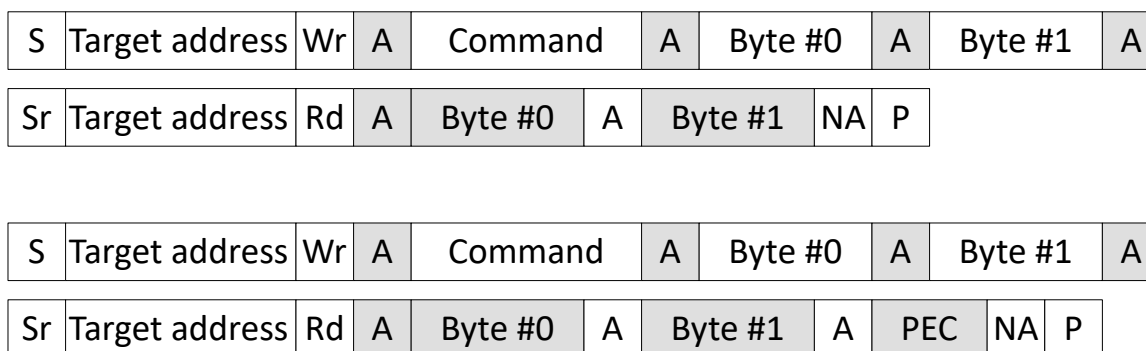

Once the read command is recognized, you must respond by writing data to the PMBTXBUF register. Make sure that the values in the PMBTCR register are correct. The transmit byte count and PEC bit must be set appropriately. For a read byte, the transmit byte count can be loaded with a 1. If the transmission of a PEC byte is desired, the TX\_PEC bit must be set. After this, the data can be written to PMBTXBUF, which starts the transmission. All bytes must be written to PMBTXBUF at the same time. After the controller receives the message, the controller NACKs the last byte to indicate that the correct number of bytes have been received. This causes the EOM bit to be set in the PMBSTS register, indicating to the firmware that the Read Byte message is complete.

**Figure 29-6. Read Byte and Read Word Messages With and Without PEC**

### 29.3.2.6 Process Call

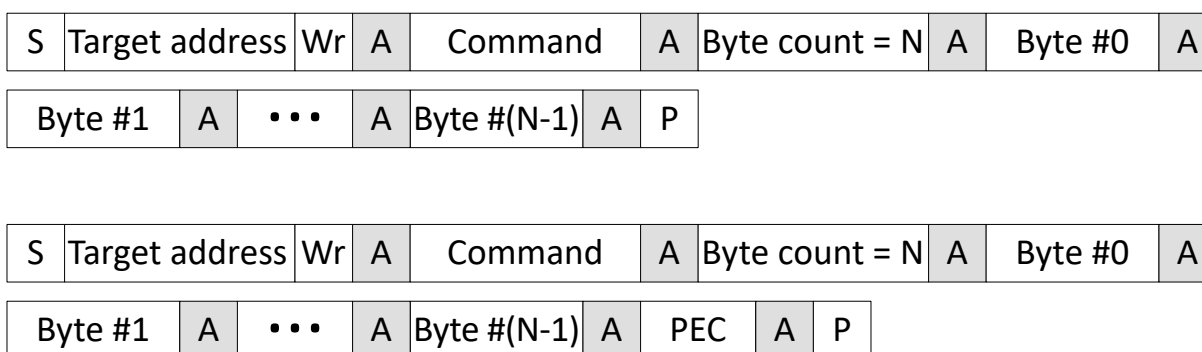

The Process Call (Figure 29-7) protocol consists of a Write Word message, followed by a Read Word message, without a stop condition between the two messages. Address and command acknowledgment is configured through the PMBTCR register. In automatic mode, following receipt of the repeated start and target address, the PMBus module provides a data ready and a data request interrupt. The repeated start bit is set in the PMBSTS register to indicate the receipt of the first part of the Process Call message. The received command byte is found in bits 7-0 of the PMBRXBUF register, while the two data bytes received from the controller can be found in bits 23-8. Upon receipt of the repeated start and a data request from the module, the firmware programs the PMBTXBUF with the 2 data bytes to be sent to the controller. If PEC processing is enabled, the Transmit PEC bit within the PMBTCR register is asserted. The EOM interrupt indicates the read word portion of the Process Call message has been completed by the module.

**Figure 29-7. Process Call Message With and Without PEC**

### 29.3.2.7 Block Write

The Block Write (Figure 29-8) protocol is similar to Write Word in structure, except that there are more than 2 data bytes in the message. Following the receipt of the command byte, the block length and 2 data bytes, the PMBus module provides a data ready interrupt. The module waits for the firmware to read the received data and program the acknowledge register. While waiting for an ACK from the firmware, the module drives the clock line low, stalling the bus. The data ready interrupts continue for the duration of the message at a frequency of every 4 data bytes. The number of bytes received can be found within the PMBSTS register. At the end of the message, less than 4 bytes can be stored in the PMBRXBUF register. The PEC Valid bit can be checked to determine if the received PEC value is accurate.

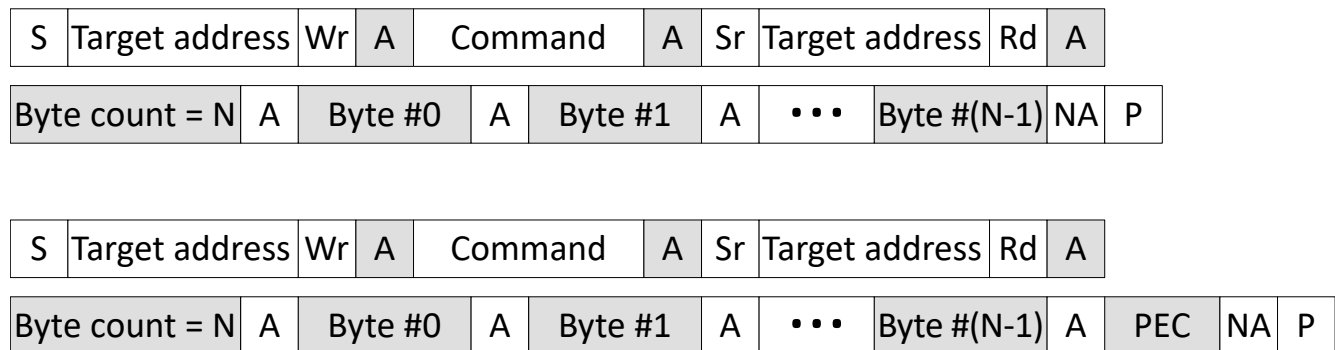

**Figure 29-8. Block Write Message With and Without PEC**

### 29.3.2.8 Block Read

The Block Read (Figure 29-9) protocol is similar to a Read Word in structure, except that there are more than 2 data bytes in the message. Following the receipt of the repeated target address, a data ready and data request interrupt is generated by the PMBus module. The command byte received from the controller can be found in bits 7-0 of the PMBRXBUF register. The SCL line is held low until the firmware programs data bytes into the PMBTXBUF register. The firmware is required to load the block length into bits 7-0 of the PMBTXBUF register during the initial programming of the register. After 4 bytes have been transmitted, the module issues a data request interrupt and holds SCL low again until the firmware has programmed additional data into the PMBTXBUF register.

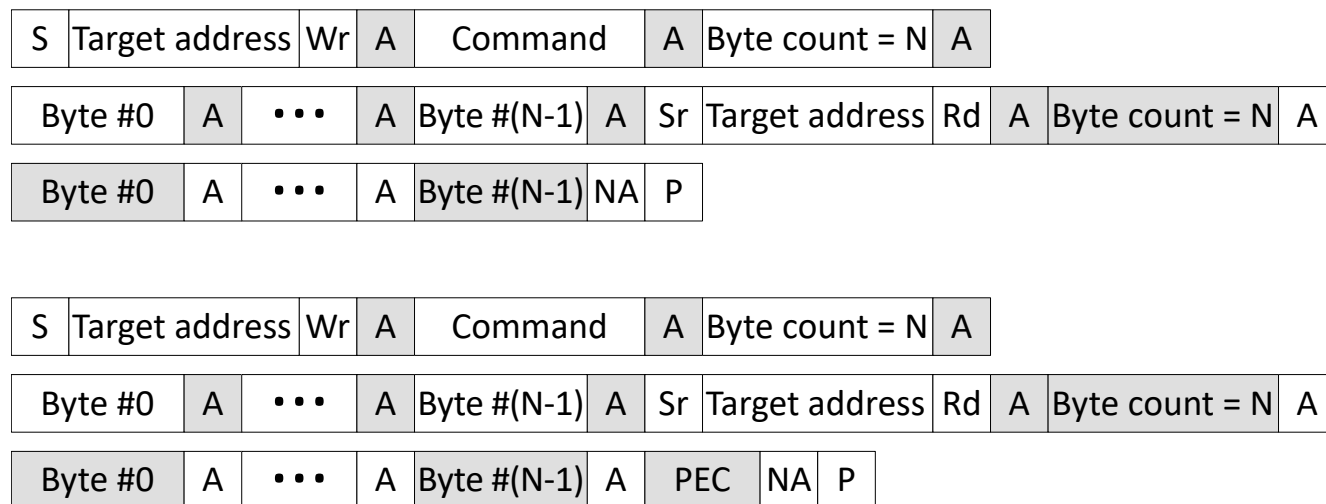

Block read starts the same as Read Word or Read Byte, but TX\_COUNT is loaded with a 4 the first time, and TX\_PEC is not set. Instead of waiting for an EOM after the first transmission, the firmware instead waits for a Data Request, indicating that the controller is ready for more data. Until the last 4 or less bytes, the firmware simply writes a 4 to TX\_COUNT and then writes the 4 bytes to PMBTXBUF. TX\_PEC is left cleared. Then when the last 4 or fewer bytes are to be transmitted, the firmware writes out the appropriate byte count, sets the TX\_PEC bit, and writes the data to PMBTXBUF. The PMBus module writes out the data, followed by the PEC, and then the EOM bit is set when the controller NACKs the PEC.

**Figure 29-9. Block Read Message With and Without PEC**

### 29.3.2.9 Block Write-Block Read Process Call

The Block Write-Block Read Process Call (Figure 29-10) protocol combines the Block Write and Block Read protocols, removing the stop condition between the two messages. The processing of the Block Read-Block Write Process Call message is similar to the mode of operation for the Process Call message. After acknowledgment of the address and command bytes, the PMBus module generates a data ready interrupt upon detection of 4 data bytes or a repeated start condition. After receiving the repeated start, the firmware is required to load transmit data to send to the controller. Bits 7-0 of the initial programming of the PMBTXBUF register must represent the byte count of the block data sent to the controller.

**Figure 29-10. Block Write-Block Read Process Call Message With and Without PEC**

### 29.3.2.10 Alert Response

The Alert Response Message (Figure 29-11) is utilized when the controller detects an alert condition from a target on the PMBus. In automatic address acknowledge mode, upon detection of the Alert Response Address, the PMBus module provides an acknowledgment to the controller and sends the programmed target address within the PMBTCR register. The module only responds to the message if the Alert En bit within PMBCTRL register has been previously set. After receiving the Alert Response message, the module clears the alert condition and the enable bit within the PMBCTRL register.

In manual address acknowledge mode, the firmware must read the received address from the PMBRXBUF register and transmit the desired target address back to the controller. The PMBCTRL register must be reprogrammed to disable the Alert En bit used to initiate the Alert Response message from the controller.

**Figure 29-11. Alert Response Message**

### 29.3.2.11 Extended Command

The PMBus module provides support for extended commands that allow for an extra 256 command codes. Both command bytes are stored in the PMBRXBUF register along with the data bytes. In recognizing the extended command messages, the Repeated Start bit and the Rd Byte Count Bits within the PMBSTS register are utilized. For Extended Command Write Byte and Write Word messages (Figure 29-12), the two command bytes are stored in bits 15-0 of the PMBRXBUF register. The initial command byte must hold the command extension code, representing utilization of the extended command protocol. The Repeated Start bit is also set, received after the retransmission of the device address. The Rd Byte Count equals 3 for an Ext Cmd Write Byte message and 4 for an Ext Cmd Write Word message.

For the Extended Command Read Byte and Read Word messages (Figure 29-13), the module generates a data ready and data request interrupt following reception of the repeated device address. The two command bytes are found in bits 15-0 of the PMBRXBUF register, with the initial command byte matching the command extension code. The firmware is required to load transmit data to complete the message back to the controller.

Figure 29-12. Extended Command Write Byte and Write Word Messages With and Without PEC

**Figure 29-13. Extended Command Read Byte and Read Word Messages With and Without PEC**

### 29.3.2.12 Group Command

The PMBus module supports the Group Command protocol. The Group Command (Figure 29-14) protocol is used to send commands to more than one device within the same message. When devices on the bus detect the stop condition at the conclusion of the Group Command message, the received commands are executed concurrently. Following address and command acknowledgment, the module provides a data ready interrupt upon detection of 4 data bytes or the transmission of a repeated start on the bus. The firmware must wait for the EOM interrupt before processing the received command, as required by the use of the Group Command message.

For Group Commands, the data ready bit is set as soon as the repeated start is received. The data can then be read into memory. But the data must not be acted upon until the EOM bit is set, which occurs when all of the messages have been received. Other than this delayed EOM, there is no difference for the target firmware in receiving a Group Command than any other write message.

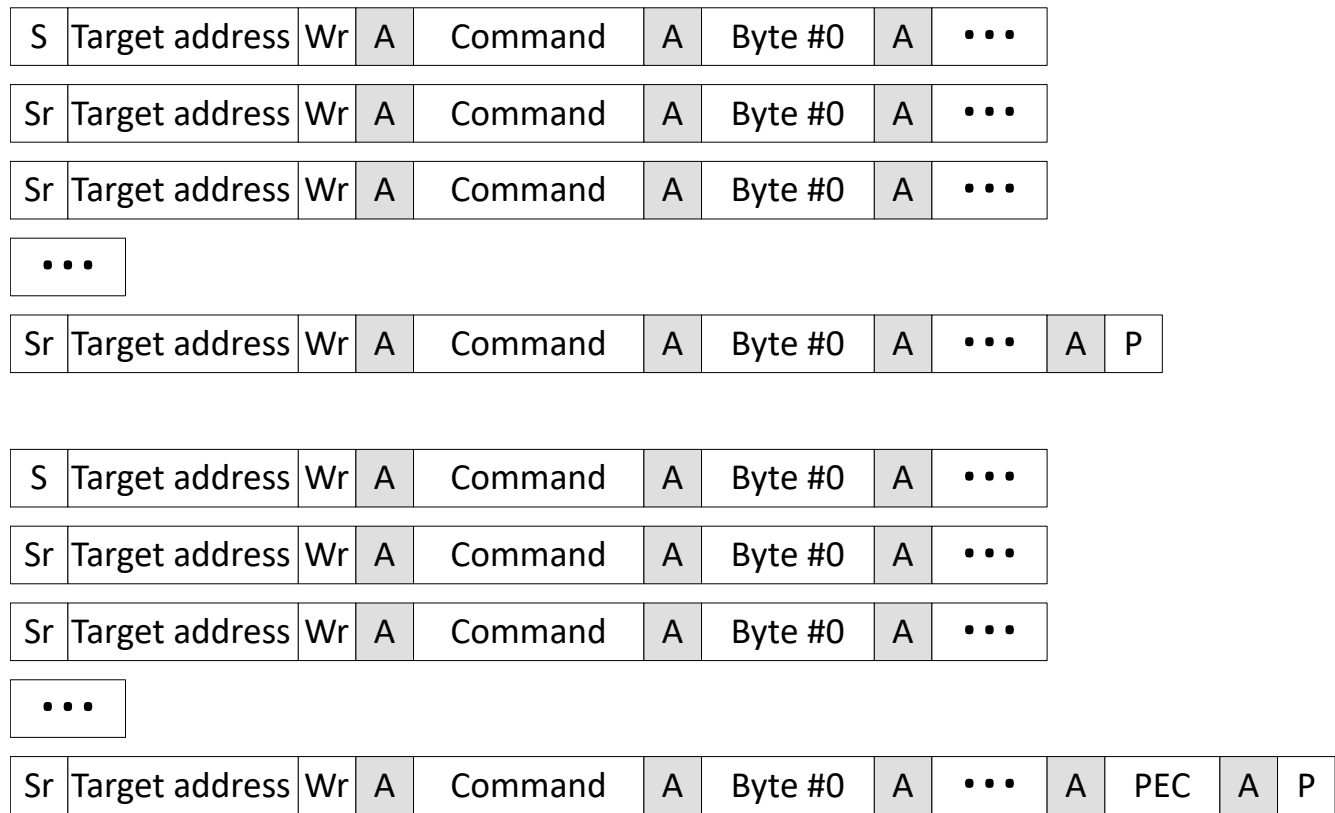

Figure 29-14. Group Command Message With and Without PEC

## 29.4 Controller Mode Operation

This section describes the configuration and operation of the PMBus module in controller mode.

### 29.4.1 Configuration

First, write a clock divider to the PMBCTRL register CLKDIV field to produce a bit clock frequency of less than 10MHz. To activate controller mode, set the CONTROLLER\_EN bit and clear the TARGET\_EN bit in the PMBCTRL register. For each transaction, set up the PMBCCR register. The following options are configurable:

- Target address (TARGET\_ADDR): Sets the target address for the next transaction.
- PEC enable (PEC\_ENA): If Packet Error Checking (PEC) is used on the bus, set this bit.
- Extended command code enable (EXT\_CMD): When set, uses two bytes for commands.
- Command code enable (CMD\_ENA): When set, sends a command byte at the start of the transaction.
- Byte count (BYTE\_COUNT): Determines the number of data bytes to transfer. This does not include the block length byte, which is generated automatically when needed.
- Special command enables (GRP\_CMD and PRC\_CALL): Enables special behavior for group commands and process calls.

Writing to the PMBCCR register starts a transfer.

Manual acknowledgment of received data is not needed.

### 29.4.2 Message Handling

This section describes the behavior and required configuration for each command type.

#### 29.4.2.1 Quick Command

Quick commands (Figure 29-15) are initiated in controller mode by simply programming the desired target device address into the PMBCCR. The byte count within the PMBCCR register is configured to 0 bytes by writing all zeros to bits 15-8. Upon transmission of the device address, the PMBus module monitors the target acknowledgment of the address. If the address is not acknowledged, the NACK bit within the status register is enabled and the PMBus module automatically sends a stop condition on the bus to terminate the message. If the address is acknowledged, a data request is issued to the processor. The firmware writes a zero to the PMBACK to terminate the message, forcing the PMBus modules to write a stop condition onto the bus.

**Figure 29-15. Quick Command Message**

### 29.4.2.2 Send Byte

A Send Byte message (Figure 29-16) consists of the device address, a single data byte, and an optional PEC byte. To initiate a Send Byte message, the data byte to be transmitted to the target is loaded into bits 7-0 of the PMBTXBUF register. The PMBCCR register is configured with the device address. To transmit a PEC byte with the message, the PEC\_EN bit within the PMBCCR register is asserted high when the address is programmed.

After programming the PMBCCR register, the PMBus module transmits the Send Byte message. The firmware can wait for an End of Message interrupt from the PMBus module. Upon receipt of the EOM interrupt, the PMBSTS register is read to verify the target properly acknowledged the transmitted data.

**Figure 29-16. Send Byte Message With and Without PEC**

### 29.4.2.3 Receive Byte

A Receive Byte message (Figure 29-17) consists of the device address, a single data byte, and an optional PEC byte. Data is being read from the target in a Receive Byte message. To initiate a Receive Byte message, the firmware programs the device address, the R/W bit and the optional PEC\_EN into the PMBCCR register. The R/W bit is enabled high to indicate a read message type (data transmitted from target to controller).

After programming the PMBCCR register, the PMBus module transmits the Receive Byte message. The firmware can wait for an End of Message interrupt from the PMBus module to verify the accuracy of the message transmission. Upon receipt of the EOM interrupt, the PMBSTS register is read to verify proper target acknowledgment of the device address and to determine if any data is available for reading in the PMBRXBUF register. If PEC\_EN was asserted in the PMBCCR register, the PEC\_VALID bit in the PMBSTS register is also checked to make sure a proper PEC byte was received from the target with the received data.

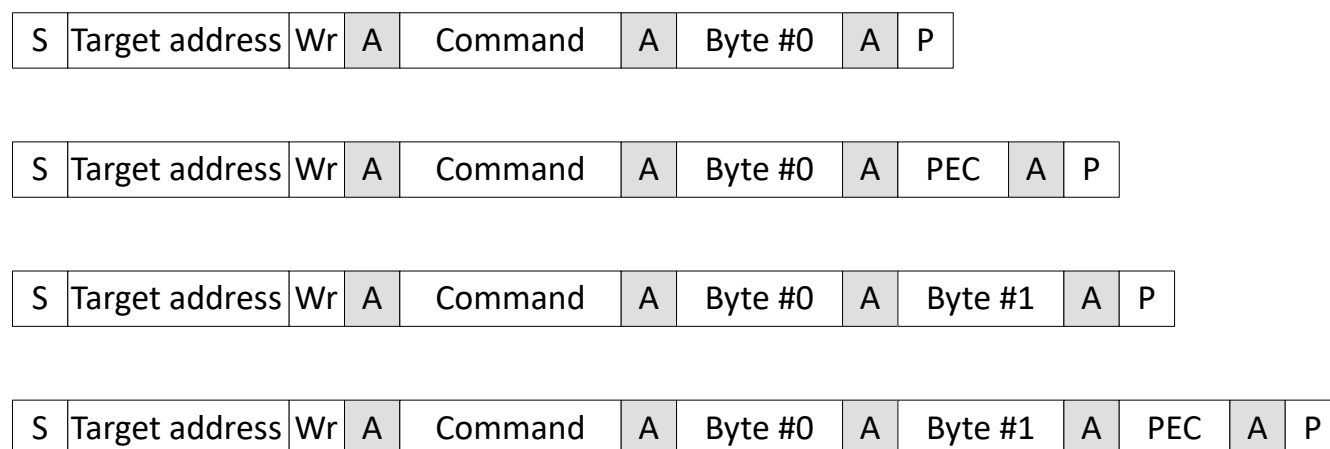

**Figure 29-17. Receive Byte Message With and Without PEC**

#### 29.4.2.4 Write Byte and Write Word

The Write Byte and Write Word messages (Figure 29-18) consist of a device address, a command byte, transmitted data bytes, and an optional PEC byte. Write Byte messages include a single byte, while the Write Word messages support transmission of 2 bytes to the corresponding target module. Similar to the Send Byte protocol, the PMBCCR register is configured to send 1 or 2 bytes, the CMD\_EN bit is set to enable command byte transmission and the optional PEC\_EN bit is set.

With the command byte transmission enabled, the format of the PMBTXBUF register differs from the Send Byte protocol. In bits 7-0, the firmware must program the command byte to be sent to the target. The data bytes are programmed into bits 15-8 and bits 23-16.

After programming the PMBCCR register, the PMBus module transmits the Write Byte/Word message. The firmware can wait for an End of Message interrupt from the module to verify the accuracy of the message transmission. The PMBSTS register indicates if the target acknowledged the message properly.

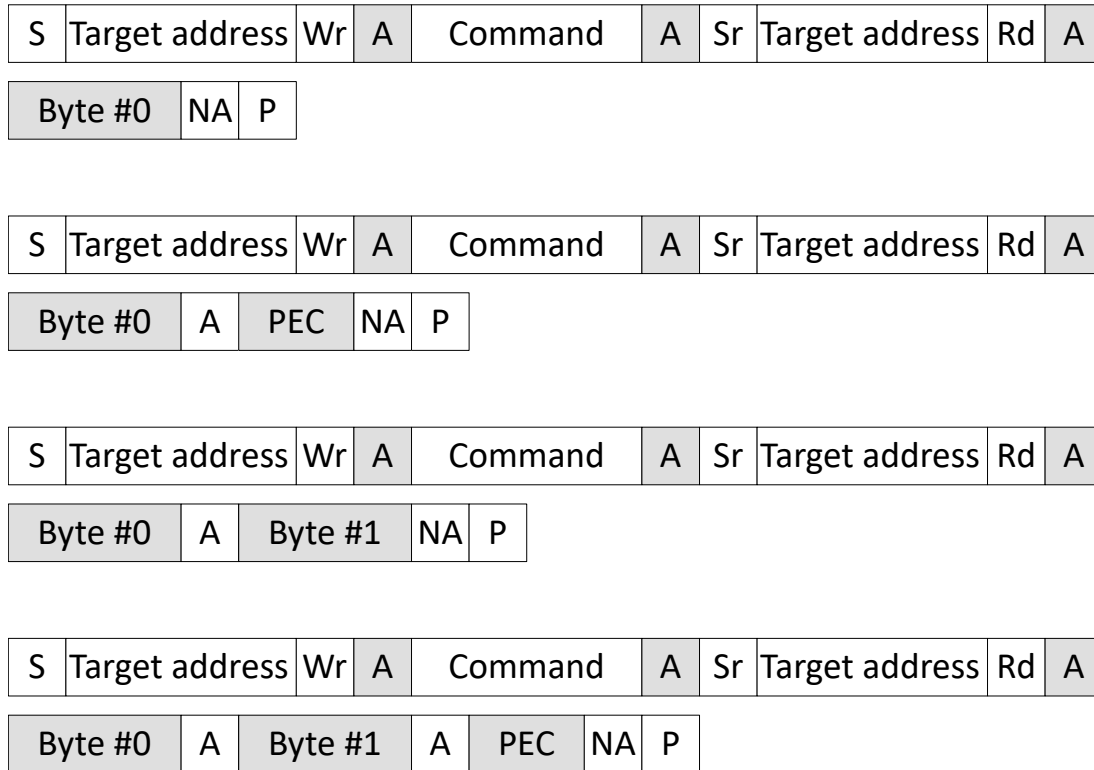

**Figure 29-18. Write Byte and Write Word Messages With and Without PEC**

### 29.4.2.5 Read Byte and Read Word

The Read Byte and Read Word messages (Figure 29-19) consist of a device address, a command byte, received data bytes from a target, and an optional PEC byte. Read Byte messages include a single byte, while the Read Word message protocol supports receipt of 2 bytes from the target. Similar to the Receive Byte Protocol, the PMBCCR register is configured to receive 1 or 2 bytes, the CMD\_EN bit is set and the PEC\_EN is configured to expect or not expect a PEC byte appended to the message. The PMBus module automatically terminates the message after the expected number of bytes is received from the target or if the target does not properly acknowledge any portion of the message.

In addition to programming the PMBCCR register, the firmware is expected to load the command byte into bits 7-0 of the PMBTXBUF register. Any data received from the target is found in the PMBRXBUF register.

**Figure 29-19. Read Byte and Read Word Messages With and Without PEC**

### 29.4.2.6 Process Call

The Process Call (Figure 29-20) protocol consists of a Write Word message, followed by a Read Word message, without a stop condition between the two messages. A PEC byte can be appended to the read data from the target as an option to the message protocol. The PMBCCR register includes a PRC\_CALL bit, which enables the transmission of a Process Call message onto the PMBus. The PMBus module automatically generates a repeated start condition and initiates the Read Word portion of the message when the process call bit is enabled.

To complete the Write Word portion of the Process Call, the PMBTXBUF register is loaded with the command byte in bits 7-0 and the data bytes are loaded into bits 23-8 of the register.

After programming the PMBCCR register, the PMBus module transmits the Process Call Message. The firmware can wait for an End of Message interrupt from the module to determine the validity of the message. Upon the receipt of the EOM, the PMBSTS register can indicate the receipt of 2 bytes from the Read Word portion of the Process Call message and the status of the target acknowledgment of the transmit data. If PEC processing is enabled, the PEC\_VAL bit within the PMBSTS register indicates the accuracy of the PEC byte received from the target during the Read Word part of the message.

The PRC\_CALL bit within the PMBCCR register must be disabled for the next non-Process Call message. Note that any write to the PMBCCR register initiates a message, so reconfiguration of the controller is not recommended until the firmware requires a new message to be transmitted.

**Figure 29-20. Process Call Message With and Without PEC**

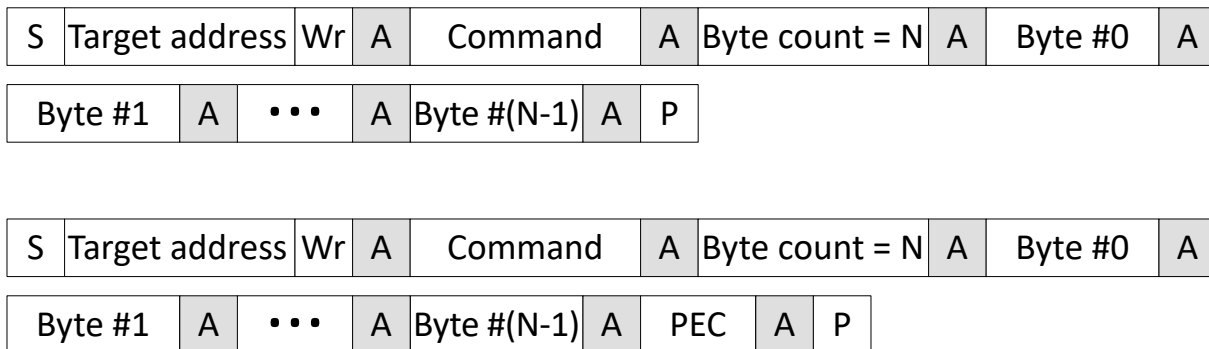

### 29.4.2.7 Block Write

The Block Write (Figure 29-21) protocol is similar to a Write Word in structure, with the exception of transmission of more than 2 data bytes in the message. Additionally, the first data byte following the command byte specifies the length of the block of data bytes. As with a majority of the message protocols, the PEC byte can be appended to the end of the write data to the target.

To initiate a Block Write message on the bus, the PMBCCR register is programmed with the block length in the Byte Count bits. The block length is the number of data bytes, excluding the command byte and the first data byte that contains the block length. The PMBus module automatically inserts the block length into the message, if the number of data bytes specified by the firmware exceeds 2. The initial write data is loaded into the PMBTXBUF register. With bits 7-0 representing the command byte, the remaining 3 bytes represent the first 3 data bytes following the block length.

Following programming of the PMBCCR register, the Block Write message is transmitted. If the block length exceeds 3 bytes, the PMBus module provides a data request interrupt, indicating the need for additional data bytes in the PMBTXBUF register. The PMBus module assumes that if more than 4 bytes are needed to complete the message, the firmware utilizes all 4 bytes when programming the PMBTXBUF register. If less than 4 bytes are needed to finish the Block Write message, the firmware only needs to program the appropriate bits of the PMBTXBUF register.

Upon completion of the message, the PMBus module issues an EOM interrupt. The PMBSTS register can be checked to verify the target accepted the block of write data.

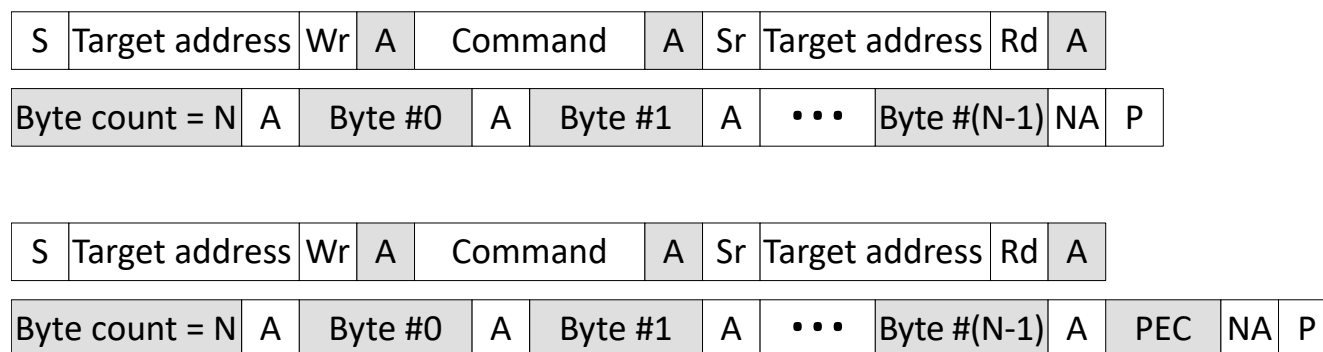

**Figure 29-21. Block Write Message With and Without PEC**

### 29.4.2.8 Block Read

The Block Read (Figure 29-22) protocol is similar to a Read Word in structure, with the exception that there are more than 2 data bytes received from the target. The first data byte transmitted by the target represents the block length of the data being written by the target. If PEC processing is enabled, the target appends a PEC byte to the end of the message.

To initiate a Block Read message on the PMBus, the PMBCCR register is programmed with the block length in the Byte Count bits. This count excludes the command byte, any target address and the block length bytes in the message. The command byte to be transmitted to the target is written into bits 7-0 of the PMBTXBUF register prior to the programming of the PMBCCR register.

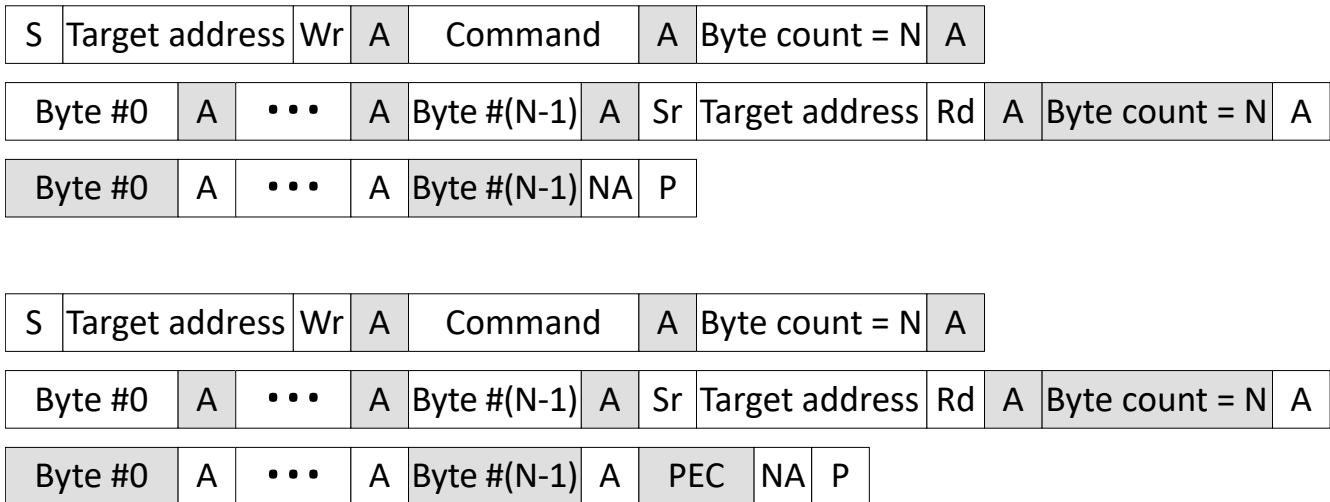

After configuring the PMBCCR register, the Block Read message is transmitted. The module interrupts the firmware upon receipt of 4 data bytes from the target. If the block length is 3, the EOM interrupt is received concurrently with the data ready interrupt. Otherwise, only a data ready interrupt is asserted, indicating 4 bytes are ready for reading by the firmware. At the end of the message, less than 4 bytes can be stored in the PMBRXBUF register. The RX Byte Count bits in the PMBSTS register indicate the number of bytes available in the final data transfer. The firmware can verify the received PEC upon detection of the End of Message interrupt.

**Figure 29-22. Block Read Message With and Without PEC**

**29.4.2.9 Block Write-Block Read Process Call**

The Block Write-Block Read Process Call (Figure 29-23) protocol combines the Block Write and Block Read protocols, removing the stop condition between the two messages. The operation of the controller is similar to a Block Write operation. Loading the block length into the byte count bits of the PMBCCR register provides the length of the Block Write portion of the message. In addition, the PRC\_CALL bit within the PMBCCR register must be enabled. Upon completion of the Block Write part of the message, the PMBus module automatically issues a Repeated Start condition on the PMBus and starts transmission of the Block Read portion of the message. Operation of the PMBus module after the Repeated Start condition is the same as a simple Block Read Message.

**Figure 29-23. Block Write-Block Read Process Call Message With and Without PEC**

**29.4.2.10 Alert Response**

The Alert Response Message (Figure 29-24) is utilized when the controller detects an alert condition from a target. In controller mode, the Alert Response Message is simply a Receive Byte message with PEC disabled and the target address set to 0xC (Alert Response address). The PMBus module detects the alert condition on an input and interrupts the firmware indicating the assertion of an alert condition (target desires to communicate with the controller). Programming the PMBCCR register with the Alert Response address initiates the Alert Response message and provides the device address of the target requesting service. The device address is found in the PMBRXBUF register following receipt of the EOM interrupt.

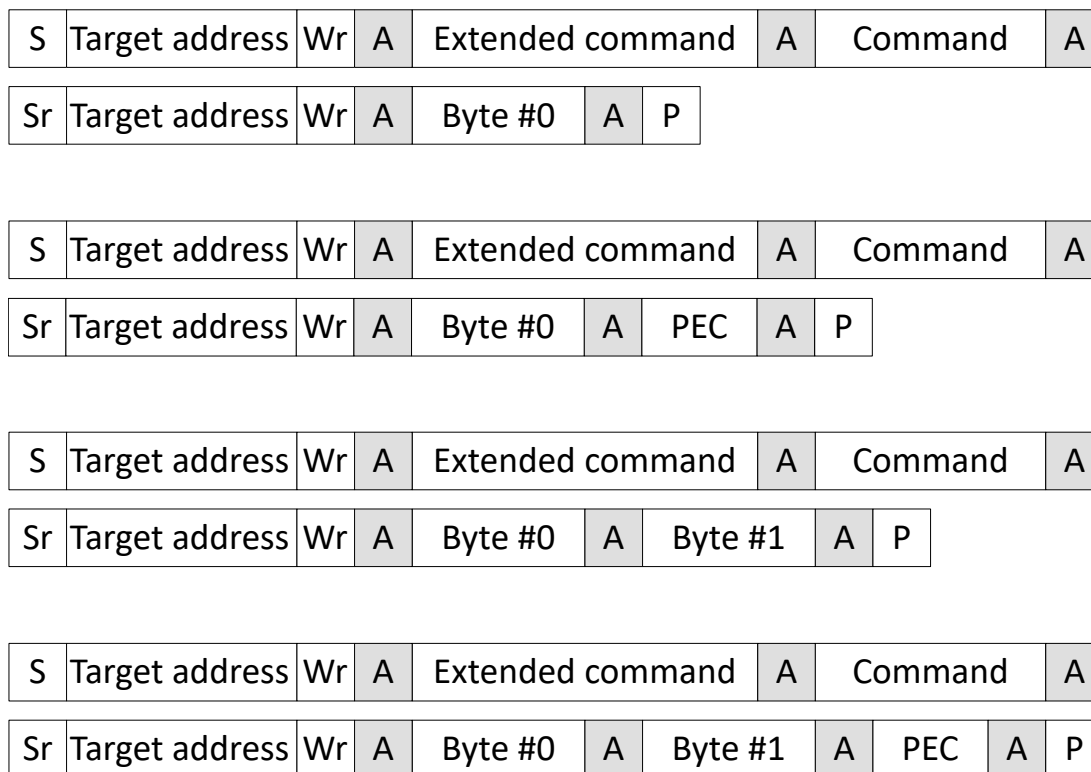

**Figure 29-24. Alert Response Message**

### 29.4.2.11 Extended Command

The PMBus module provides support for extended commands which allow for an extra 256 command codes. By asserting the EXT\_CMD bit within the PMBCCR register, two command bytes are transmitted on the message protocol. Extended commands can be added to the Write Byte and Write Word (Figure 29-25) and the Read Byte and Read Word (Figure 29-26) protocols. Operation of the PMBus module in extended command mode is similar to these formats. In programming the write data or first part of the read message, the second command byte is loaded into bits 15-8 of the PMBTXBUF register with the remaining data bytes. The remaining operation of the module is identical to the previous protocols, except for the inclusion of a Repeated Start condition and target address in the write messages. No support is required by firmware for these additional bytes in the write messages. The module interprets the EXT\_CMD bit and makes the appropriate format changes.

**Figure 29-25. Extended Command Write Byte and Write Word Messages With and Without PEC**

**Figure 29-26. Extended Command Read Byte and Read Word Messages With and Without PEC**

### 29.4.2.12 Group Command

The Group Command (Figure 29-27) protocol is used to send commands to more than one device within the same message. When devices on the bus detect the stop condition at the conclusion of the Group Command message, the received commands are executed concurrently. To initiate a Group Command, the GRP\_CMD bit within the PMBCCR register must be set when programming the target address for the first device in the message. The rest of the message is processed as a write byte/word message. At the conclusion of the first part of the Group Command message, the firmware programs the next device address in the PMBCCR register. The PMBus module sends a repeated start on the bus and begins the next part of the message. When programming the last device address of the Group Command message, the firmware must disable the GRP\_CMD bit when programming the PMBCCR register.

Figure 29-27. Group Command Message With and Without PEC

## 29.5 PMBUS Registers

This Section describes the PMBUS Registers.

### 29.5.1 PMBUS Base Address Table

Table 29-1. PMBUS Base Address Table

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	CPU2	CPU2.DMA	Pipeline Protected
Instance	Structure								
PmbusaRegs	<a href="#">PMBUS_REGS</a>	PMBUSA_BAS E	0x0000_6400	YES	YES	YES	YES	YES	YES

### 29.5.2 PMBUS\_REGS Registers

Table 29-2 lists the memory-mapped registers for the PMBUS\_REGS registers. All register offset addresses not listed in Table 29-2 should be considered as reserved locations and the register contents should not be modified.

**Table 29-2. PMBUS\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	PMBCCR	PMBUS CONTROLLER Mode Control Register	EALLOW	<a href="#">Go</a>
2h	PMBTXBUF	PMBUS Transmit Buffer		<a href="#">Go</a>
4h	PMBRXBUF	PMBUS Receive buffer		<a href="#">Go</a>
6h	PMBACK	PMBUS Acknowledge Register		<a href="#">Go</a>
8h	PMBSTS	PMBUS Status Register		<a href="#">Go</a>
Ah	PMBINTM	PMBUS Interrupt Mask Register	EALLOW	<a href="#">Go</a>
Ch	PMBTCR	PMBUS TARGET Mode Configuration Register	EALLOW	<a href="#">Go</a>
Eh	PMBHTA	PMBUS Hold TARGET Address Register		<a href="#">Go</a>
10h	PMBCTRL	PMBUS Control Register	EALLOW	<a href="#">Go</a>
12h	PMBTIMCTL	PMBUS Timing Control Register	EALLOW	<a href="#">Go</a>
14h	PMBTIMCLK	PMBUS Clock Timing Register	EALLOW	<a href="#">Go</a>
16h	PMBTIMSTSETUP	PMBUS Start Setup Time Register	EALLOW	<a href="#">Go</a>
18h	PMBTIMBIDLE	PMBUS Bus Idle Time Register	EALLOW	<a href="#">Go</a>
1Ah	PMBTIMLOWTIMEOUT	PMBUS Clock Low Timeout Value Register	EALLOW	<a href="#">Go</a>
1Ch	PMBTIMHIGHTIMEOUT	PMBUS Clock High Timeout Value Register	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 29-3 shows the codes that are used for access types in this section.

**Table 29-3. PMBUS\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
RC	R C	Read to Clear
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 29.5.2.1 PMBCCR Register (Offset = 0h) [Reset = 0000000h]

PMBCCR is shown in [Figure 29-28](#) and described in [Table 29-4](#).

Return to the [Summary Table](#).

PMBUS CONTROLLER Mode Control Register

**Figure 29-28. PMBCCR Register**

**Table 29-4. PMBCCR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-21	RESERVED	R	0h	Reserved
20	PRC_CALL	R/W	0h	0 = Default state for all messages besides Process Call message 1 = Enables transmission of Process Call message Reset type: SYSRSn
19	GRP_CMD	R/W	0h	0 = Default state for all messages besides Group Command message 1 = Enables transmission of Group Command message Reset type: SYSRSn
18	PEC_ENA	R/W	0h	0 = Disables PEC processing 1 = Enables PEC byte transmission/reception Reset type: SYSRSn
17	EXT_CMD	R/W	0h	0 = Use 1 byte for Command Code 1 = Use 2 bytes for Command Code Reset type: SYSRSn
16	CMD_ENA	R/W	0h	0 = Disables use of command code on CONTROLLER initiated messages 1 = Enables use of command code on CONTROLLER initiated messages Reset type: SYSRSn
15-8	BYTE_COUNT	R/W	0h	Indicates number of data bytes transmitted in current message. Byte count does not include any device addresses, command words or block lengths in block messages. In block messages, the PMBus Interface automatically inserts the block length into the message based on the byte count setting. The firmware only needs to load the address, command words and data to be transmitted. PMBus Interface supports byte writes up to 255 bytes. Reset type: SYSRSn

**Table 29-4. PMBCCR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
7-1	TARGET_ADDR	R/W	0h	Specifies the address of the TARGET to which the current message is directed towards. Reset type: SYSRSn
0	RW	R/W	0h	0 = Message is a write transaction (data from CONTROLLER to TARGET) 1 = Message is a read transaction (data from TARGET to CONTROLLER) Reset type: SYSRSn

### 29.5.2.2 PMBTXBUF Register (Offset = 2h) [Reset = 0000000h]

PMBTXBUF is shown in [Figure 29-29](#) and described in [Table 29-5](#).

Return to the [Summary Table](#).

PMBUS Transmit Buffer

15	14	13	12	11	10	9	8
PEC_ENA	TARGET_MASK						
R/W-0h	R/W-7Fh						
7	6	5	4	3	2	1	0
MAN_TARGET_ACK	TARGET_ADDR						
R/W-0h	R/W-7Ch						

**Table 29-10. PMBTCR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-23	RESERVED	R	0h	Reserved
22-21	RX_BYTE_ACK_CNT	R/W	3h	Configures number of data bytes to automatically acknowledge when receiving data in TARGET mode. 00 = 1 byte received by TARGET. Firmware is required to manually acknowledge every received byte. 01 = 2 bytes received by TARGET. Hardware automatically acknowledges the first received byte. Firmware is required to manually acknowledge after the second received byte. 10 = 3 bytes received by TARGET. Hardware automatically acknowledges the first 2 received bytes. Firmware is required to manually acknowledge after the third received byte. 11 = 4 bytes received by TARGET. Hardware automatically acknowledges the first 3 received bytes. Firmware is required to manually acknowledge after the fourth received byte Reset type: SYSRSn
20	MAN_CMD	R/W	0h	0 = TARGET automatically acknowledges received command code 1 = Data Request flag generated after receipt of command code, firmware required to issue ACK to continue message Reset type: SYSRSn
19	TX_PEC	R/W	0h	Asserted when the TARGET needs to send a PEC byte at end of message. PMBus Interface will transmit the calculated PEC byte after transmitting the number of data bytes indicated by TX Byte Cnt(Bits 18:16). Reset type: SYSRSn

**Table 29-10. PMBTCR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
18-16	TX_COUNT	R/W	0h	0 = No bytes valid 1 = One byte valid, Byte #0 (Bits 7:0 of Transmit Data Register) 2 = Two bytes valid, Bytes #0 and #1 (Bits 15:0 of Transmit Data Register) 3 = Three bytes valid, Bytes #0-2 (Bits 23:0 of Transmit Data Register) 4 = Four bytes valid, Bytes #0-3 (Bits 31:0 of Transmit Data Register) Reset type: SYSRSn
15	PEC_ENA	R/W	0h	0 = PEC processing disabled 1 = PEC processing enabled Reset type: SYSRSn
14-8	TARGET_MASK	R/W	7Fh	Used in address detection, the TARGET mask enables acknowledgement of multiple device addresses by the TARGET. Writing a '0' to a bit within the TARGET mask enables the corresponding bit in the TARGET address to be either '1' or '0' and still allow for a match. Writing a '0' to all bits in the mask enables the PMBus Interface to acknowledge any device address. Upon power-up, the TARGET mask defaults to 7Fh, indicating the TARGET will only acknowledge the address programmed into the TARGET Address (Bits 6-0). Reset type: SYSRSn
7	MAN_TARGET_ACK	R/W	0h	0 = TARGET automatically acknowledges device address specified in TARGET_ADDR, Bits 6:0 1 = Enables the Manual TARGET Address Acknowledgement Mode. Firmware is required to read received address and acknowledge on every message Note: When bit 31 (I2C_mode) of PMBCTRL register is set it is recommended to use manual acknowledging of TARGET address only (MAN_TARGET_ACK =1). Reset type: SYSRSn
6-0	TARGET_ADDR	R/W	7Ch	Configures the current device address of the TARGET. Used in automatic TARGET address acknowledge mode (default mode). The PMBus Interface will compare the received device address with the value stored in the TARGET Address bits and the mask configured in the TARGET Mask bits. If matching, the TARGET will acknowledge the device address. Reset type: SYSRSn

### 29.5.2.8 PMBHTA Register (Offset = Eh) [Reset = 0000000h]

PMBHTA is shown in [Figure 29-35](#) and described in [Table 29-11](#).

Return to the [Summary Table](#).

## Chapter 30 Serial Communications Interface (SCI)

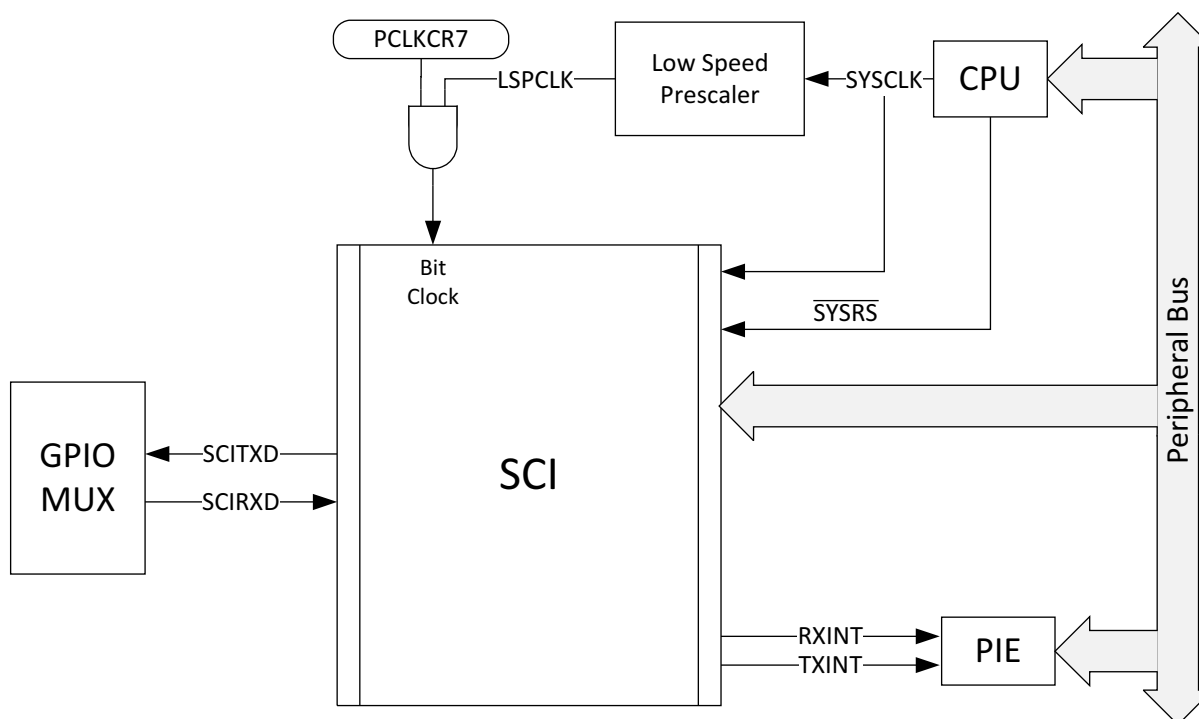

This chapter describes the features and operation of the serial communication interface (SCI) module. SCI is a two-wire asynchronous serial port, commonly known as a UART. The SCI modules support digital communications between the CPU and other asynchronous peripherals that use the standard non-return-to-zero (NRZ) format. The SCI receiver and transmitter each have a -level deep FIFO for reducing servicing overhead, and each has a separate enable and interrupt bits. Both can be operated independently for half-duplex communication, or simultaneously for full-duplex communication.

To specify data integrity, the SCI checks received data for break detection, parity, overrun, and framing errors. The bit rate is programmable to different speeds through a 16-bit baud-select register.

## 30.1 Introduction

The SCI interfaces are shown in [Figure 30-1](#).

**Figure 30-1. SCI CPU Interface**

### 30.1.1 Features

Features of the SCI module include:

- Two external pins (both pins can be used as GPIO, if not used for SCI):
  - SCITXD: SCI transmit-output pin
  - SCIRXD: SCI receive-input pin
- Baud rate programmable to 64K different rates
- Data-word format
  - One start bit
  - Data-word length programmable from one to eight bits
  - Optional even/odd/no parity bit
  - One or two stop bits
  - An extra bit to distinguish addresses from data (address bit mode only)
- Four error-detection flags: parity, overrun, framing, and break detection
- Two wake-up multiprocessor modes: idle-line and address bit
- Half- or full-duplex operation
- Double-buffered receive and transmit functions
- Transmitter and receiver operations can be accomplished through interrupt-driven or polled algorithms with status flags
- Separate enable bits for transmitter and receiver interrupts (except BRKDT)
- NRZ (non-return-to-zero) format

Enhanced features include:

- Auto-baud-detect hardware logic
- -level transmit/receive FIFO

### 30.1.2 SCI Related Collateral

#### Foundational Materials

- [C2000 Academy - SCI](#)
- [One Minute RS-485 Introduction \(Video\)](#)
- [RS-232, RS-422, RS-485: What Are the Differences? \(Video\)](#)

### 30.1.3 Block Diagram

Figure 30-2 shows the SCI module block diagram. The SCI port operation is configured and controlled by the registers listed in [Section 30.15](#).

## 30.2 Architecture

The major elements used in full-duplex operation are shown in [Figure 30-2](#) and include:

- A transmitter (TX) and the major registers (upper half of [Figure 30-2](#)):
  - SCITXBUF — transmitter data buffer register. Contains data (loaded by the CPU) to be transmitted
  - TXSHF register — transmitter shift register. Accepts data from register SCITXBUF and shifts data onto the SCITXD pin, one bit at a time
- A receiver (RX) and the major registers (lower half of [Figure 30-2](#)):
  - RXSHF register — receiver shift register. Shifts data in from SCIRXD pin, one bit at a time
  - SCIRXBUF — receiver data buffer register. Contains data to be read by the CPU. Data from a remote processor is loaded into register RXSHF and then into registers SCIRXBUF and SCIRXEMU
- A programmable baud generator
- Control and status registers

The SCI receiver and transmitter can operate either independently or simultaneously.

## 30.3 SCI Module Signal Summary

A summarized description of each SCI signal name is shown in [Table 30-1](#).

**Table 30-1. SCI Module Signal Summary**

Signal Name	Description
<b>External signals</b>	
SCIRXD	SCI Asynchronous Serial Port receive data
SCITXD	SCI Asynchronous Serial Port transmit data
<b>Control</b>	
Baud clock	LSPCLK Prescaled clock
<b>Interrupt signals</b>	
TXINT	Transmit interrupt
RXINT	Receive interrupt

Figure 30-2. Serial Communications Interface (SCI) Module Block Diagram

### 30.4 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification must be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups can be configured in the GPyPUD register.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

### 30.5 Multiprocessor and Asynchronous Communication Modes

The SCI has two multiprocessor protocols, the idle-line multiprocessor mode (see [Section 30.8](#)) and the address-bit multiprocessor mode (see [Section 30.9](#)). These protocols allow efficient data transfer between multiple processors.

The SCI offers the universal asynchronous receiver/transmitter (UART) communications mode for interfacing with many popular peripherals. The asynchronous mode (see [Section 30.10](#)) requires two lines to interface with many standard devices such as terminals and printers that use RS-232-C formats. Data transmission characteristics include:

- One start bit
- One to eight data bits
- An even/odd parity bit or no parity bit
- One or two stop bits

### 30.6 SCI Programmable Data Format

SCI data, both receive and transmit, is in NRZ (non-return-to-zero) format. The NRZ data format, shown in Figure 30-3, consists of:

- One start bit
- One to eight data bits
- An even/odd parity bit (optional)
- One or two stop bits
- An extra bit to distinguish addresses from data (address-bit mode only)

The basic unit of data is called a character and is one to eight bits in length. Each character of data is formatted with a start bit, one or two stop bits, and optional parity and address bits. A character of data with formatting information is called a frame and is shown in Figure 30-3.

**Figure 30-3. Typical SCI Data Frame Formats**

To program the data format, use the SCICCR register. The bits used to program the data format are shown in Table 30-2.

**Table 30-2. Programming the Data Format Using SCICCR**

Bits	Bit Name	Designation	Functions
2-0	SCICCHAR	SCICCR.2:0	Select the character (data) length (one to eight bits).
5	PARITYENA (ENABLE)	SCICCR.5	Enables the parity function if set to 1, or disables the parity function if cleared to 0.
6	PARITY (EVEN/ODD)	SCICCR.6	If parity is enabled, selects odd parity if cleared to 0; even parity if set to 1.
7	STOPBITS	SCICCR.7	Determines the number of stop bits transmitted—one stop bit if cleared to 0 or two stop bits if set to 1.

## 30.7 SCI Multiprocessor Communication

The multiprocessor communication format allows one processor to efficiently send blocks of data to other processors on the same serial link. On one serial line, there can be only one transfer at a time. In other words, there can be only one talker on a serial line at a time.

### Address Byte

The first byte of a block of information that the talker sends contains an address byte that is read by all listeners. Only listeners with the correct address can be interrupted by the data bytes that follow the address byte. The listeners with an incorrect address remain uninterrupted until the next address byte.

### Sleep Bit

All processors on the serial link set the SCI SLEEP bit (bit 2 of SCICTL1) to 1 so that the processor is interrupted only when the address byte is detected. When the processor reads a block address that corresponds to the CPU device address as set by your application software, your program must clear the SLEEP bit to enable the SCI to generate an interrupt on receipt of each data byte.

Although the receiver still operates when the SLEEP bit is 1, the receiver does not set RXRDY, RXINT, or any of the receiver error status bits to 1 unless the address byte is detected and the address bit in the received frame is a 1 (applicable to address-bit mode). The SCI does not alter the SLEEP bit; your software must alter the SLEEP bit.

#### 30.7.1 Recognizing the Address Byte

A processor recognizes an address byte differently, depending on the multiprocessor mode used. For example:

- The idle-line mode ([Section 30.8](#)) leaves a quiet space before the address byte. This mode does not have an extra address/data bit and is more efficient than the address-bit mode for handling blocks that contain more than 10 bytes of data. The idle-line mode must be used for typical non-multiprocessor SCI communication.
- The address-bit mode ([Section 30.9](#)) adds an extra bit (that is, an address bit) into every byte to distinguish addresses from data. This mode is more efficient in handling many small blocks of data because, unlike the idle mode, this mode does not wait between blocks of data. However, at a high transmit speed, the program is not fast enough to avoid a 10-bit idle in the transmission stream.

#### 30.7.2 Controlling the SCI TX and RX Features

The multiprocessor mode is software selectable using the ADDR/IDLE MODE bit (SCICCR, bit 3). Both modes use the TXWAKE flag bit (SCICTL1, bit 3), RXWAKE flag bit (SCIRXST, bit1), and the SLEEP flag bit (SCICTL1, bit 2) to control the SCI transmitter and receiver features of these modes.

#### 30.7.3 Receipt Sequence

In both multiprocessor modes, the receive sequence is as follows:

1. At the receipt of an address block, the SCI port wakes up and requests an interrupt (bit number 1 RX/BK INT ENA-of SCICTL2 must be enabled to request an interrupt in non-FIFO mode of operation. In FIFO mode, RXFFINT serves this purpose and to enable this, RXFFINTEN in SCIFFRX register must be enabled with RXFFIL in the same register set to 1). The SCI reads the first frame of the block, which contains the destination address.
2. A software routine is entered through the interrupt and checks the incoming address. This address byte is checked against the device address byte stored in memory.
3. If the check shows that the block is addressed to the device CPU, the CPU clears the SLEEP bit and reads the rest of the block. If not, the software routine exits with the SLEEP bit still set, and does not receive interrupts until the next block start.

## 30.8 Idle-Line Multiprocessor Mode

In the idle-line multiprocessor protocol (ADDR/IDLE MODE bit = 0), blocks are separated by having a longer idle time between the blocks than between frames in the blocks. An idle time of ten or more high-level bits after a frame indicates the start of a new block. The time of a single bit is calculated directly from the baud value (bits per second). The idle-line multiprocessor communication format is shown in Figure 30-4 (ADDR/IDLE MODE bit is bit 3 of SCICCR).

**Figure 30-4. Idle-Line Multiprocessor Communication Format**

### 30.8.1 Idle-Line Mode Steps

The steps followed by the idle-line mode:

1. SCI wakes up after receipt of the block-start signal.
2. The processor recognizes the next SCI interrupt.
3. The interrupt service routine compares the received address (sent by a remote transmitter) to the ISR address.
4. If the CPU is being addressed, the service routine clears the SLEEP bit and receives the rest of the data block.
5. If the CPU is not being addressed, the SLEEP bit remains set. This lets the CPU continue to execute the main program without being interrupted by the SCI port until the next detection of a block start.

#### Note

In IDLE mode, if the SCI is taking greater than 10 bit periods to read all the RXDATA from the FIFO, the SCI can miss the immediate block start to be detected.

The RXWAKE logic asserts only one time when the SCI identifies 10 bit periods of IDLE. The SCI does not assert again if RXBUF is read (which clears the WAKE condition) even if the line continues to be idle after RXBUF read.

So, if the ISR is taking more than 10 bit periods of time to read all the RXDATA from the FIFO using RXBUF, the SCI can miss to detect the next block start. This is applicable for both FIFO and Non-FIFO mode when the CPU takes greater than 10 bit clocks of SCI to read the data from RXBUF/ FIFO.

To avoid this, either of the following is recommended:

- Set SCICTL1.SWRESET after reading all RX data at the end of the ISR.
- Read and check the RXWAKE status bit before reading the RXBUF register. If RXWAKE is set, do not set the SLEEP bit for RX at the end of the ISR.

### 30.8.2 Block Start Signal

There are two ways to send a block-start signal:

- **Method 1:** Deliberately leave an idle time of ten bits or more by delaying the time between the transmission of the last frame of data in the previous block and the transmission of the address frame of the new block.
- **Method 2:** The SCI port first sets the TXWAKE bit (SCICTL1, bit 3) to 1 before writing to the SCITXBUF register. This sends an idle time of exactly 11 bits. In this method, the serial communications line is not idle any longer than necessary. (A don't care byte has to be written to SCITXBUF after setting TXWAKE, and before sending the address, so as to transmit the idle time.)

### 30.8.3 Wake-Up Temporary (WUT) Flag

Associated with the TXWAKE bit is the wake-up temporary (WUT) flag. WUT is an internal flag, double-buffered with TXWAKE. When TXSHF is loaded from SCITXBUF, WUT is loaded from TXWAKE, and the TXWAKE bit is cleared to 0. This arrangement is shown in [Figure 30-5](#).

Figure 30-5. Double-Buffered WUT and TXSHF

#### 30.8.3.1 Sending a Block Start Signal

To send out a block-start signal of exactly one frame time during a sequence of block transmissions:

1. Write a 1 to the TXWAKE bit.
2. Write a data word (content not important: a don't care) to the SCITXBUF register (transmit data buffer) to send a block-start signal. (The first data word written is suppressed while the block-start signal is sent out and ignored after that.) When the TXSHF (transmit shift register) is free again, SCITXBUF contents are shifted to TXSHF, the TXWAKE value is shifted to WUT, and then TXWAKE is cleared.

Because TXWAKE was set to a 1, the start, data, and parity bits are replaced by an idle period of 11 bits transmitted following the last stop bit of the previous frame.

3. Write a new address value to SCITXBUF.

A don't-care data word must first be written to register SCITXBUF so that the TXWAKE bit value can be shifted to WUT. After the don't-care data word is shifted to the TXSHF register, the SCITXBUF (and TXWAKE, if necessary) can be written to again because TXSHF and WUT are both double-buffered.

### 30.8.4 Receiver Operation

The receiver operates regardless of the SLEEP bit. However, the receiver neither sets RXRDY nor the error status bits, nor does the receiver request a receive interrupt until an address frame is detected.

### 30.9 Address-Bit Multiprocessor Mode

In the address-bit protocol (ADDR/IDLE MODE bit = 1), frames have an extra bit called an address bit that immediately follows the last data bit. The address bit is set to 1 in the first frame of the block and to 0 in all other frames. The idle period timing is irrelevant (see Figure 30-6).

#### 30.9.1 Sending an Address

The TXWAKE bit value is placed in the address bit. During transmission, when the SCITXBUF register and TXWAKE are loaded into the TXSHF register and WUT respectively, TXWAKE is reset to 0 and WUT becomes the value of the address bit of the current frame. Thus, to send an address:

1. Set the TXWAKE bit to 1 and write the appropriate address value to the SCITXBUF register.

When this address value is transferred to the TXSHF register and shifted out, the address bit is sent as a 1. This flags the other processors on the serial link to read the address.

2. Write to SCITXBUF and TXWAKE after TXSHF and WUT are loaded. (Can be written to immediately since both TXSHF and WUT are both double-buffered.)
3. Leave the TXWAKE bit set to 0 to transmit non-address frames in the block.

#### Note

As a general rule, the address-bit format is typically used for data frames of 11 bytes or less. This format adds one bit value (1 for an address frame, 0 for a data frame) to all data bytes transmitted. The idle-line format is typically used for data frames of 12 bytes or more.

Figure 30-6. Address-Bit Multiprocessor Communication Format

### 30.10 SCI Communication Format

The SCI asynchronous communication format uses either single line (one way) or two line (two way) communications. In this mode, the frame consists of a start bit, one to eight data bits, an optional even/odd parity bit, and one or two stop bits (shown in Figure 30-7). There are eight SCICLK periods per data bit.

The receiver begins operation on receipt of a valid start bit. A valid start bit is identified by four consecutive internal SCICLK periods of zero bits as shown in Figure 30-7. If any bit is not zero, then the processor starts over and begins looking for another start bit.

For the bits following the start bit, the processor determines the bit value by making three samples in the middle of the bits. These samples occur on the fourth, fifth, and sixth SCICLK periods, and bit-value determination is on a majority (two out of three) basis. Figure 30-7 illustrates the asynchronous communication format for this with a start bit showing where a majority vote is taken.

Since the receiver synchronizes to frames, the external transmitting and receiving devices do not use a synchronized serial clock. The clock can be generated locally.

Figure 30-7. SCI Asynchronous Communications Format

### 30.10.1 Receiver Signals in Communication Modes

Figure 30-8 illustrates an example of receiver signal timing that assumes the following conditions:

- Address-bit wake-up mode (address bit does not appear in idle-line mode)
- Six bits per character

**Figure 30-8. SCI RX Signals in Communication Modes**

**Notes:**

1. Flag bit RXENA (SCICTL1, bit 0) goes high to enable the receiver.
2. Data arrives on the SCIRXD pin, start bit detected.
3. Data is shifted from RXSHF to the receiver buffer register (SCIRXBUF); an interrupt is requested. Flag bit RXRDY (SCIRXST, bit 6) goes high to signal that a new character has been received.
4. The program reads SCIRXBUF; flag RXRDY is automatically cleared.
5. The next byte of data arrives on the SCIRXD pin; the start bit is detected, then cleared.
6. Bit RXENA is brought low to disable the receiver. Data continues to be assembled in RXSHF but is not transferred to the receiver buffer register.

### 30.10.2 Transmitter Signals in Communication Modes

Figure 30-9 illustrates an example of transmitter signal timing that assumes the following conditions:

- Address-bit wake-up mode (address bit does not appear in idle-line mode)
- Three bits per character

**Figure 30-9. SCI TX Signals in Communications Mode**

**Notes:**

1. Bit TXENA (SCICTL1, bit 1) goes high, enabling the transmitter to send data.
2. SCITXBUF is written to; thus, (1) the transmitter is no longer empty, and (2) TXRDY goes low.
3. The SCI transfers data to the shift register (TXSHF). The transmitter is ready for a second character (TXRDY goes high), and the transmitter requests an interrupt (to enable an interrupt, bit TX INT ENA — SCICTL2, bit 0 — must be set).
4. The program writes a second character to SCITXBUF after TXRDY goes high (item 3). (TXRDY goes low again after the second character is written to SCITXBUF.)
5. Transmission of the first character is complete. Transfer of the second character to shift register TXSHF begins.
6. Bit TXENA goes low to disable the transmitter; the SCI finishes transmitting the current character.
7. Transmission of the second character is complete; transmitter is empty and ready for new character.

### 30.11 SCI Port Interrupts

The SCI receiver and transmitter can be interrupt controlled. The SCICTL2 register has one flag bit (TXRDY) that indicates active interrupt conditions, and the SCIRXST register has two interrupt flag bits (RXRDY and BRKDT), plus the RX ERROR interrupt flag that is a logical-OR of the FE, OE, BRKDT, and PE conditions. The transmitter and receiver have separate interrupt-enable bits. When not enabled, the interrupts are not asserted; however, the condition flags remain active, reflecting transmission and receipt status.

The SCI has independent peripheral interrupt vectors for the receiver and transmitter. Peripheral interrupt requests can be either high priority or low priority. This is indicated by the priority bits that are output from the peripheral to the PIE controller. When both RX and TX interrupt requests are made at the same priority level, the receiver always has higher priority than the transmitter, reducing the possibility of receiver overrun.

The operation of peripheral interrupts is described in the Peripheral Interrupts section of the *System Control and Interrupts* chapter.

- If the RX/BK INT ENA bit (SCICTL2, bit 1) is set, the receiver peripheral interrupt request is asserted when one of the following events occurs:
  - The SCI receives a complete frame and transfers the data in the RXSHF register to the SCIRXBUF register. This action sets the RXRDY flag (SCIRXST, bit 6) and initiates an interrupt.
  - A break detect condition occurs (the SCIRXD is low for 9.625 bit periods following a missing stop bit). This action sets the BRKDT flag bit (SCIRXST, bit 5) and initiates an interrupt.
- If the TX INT ENA bit (SCICTL2.0) is set, the transmitter peripheral interrupt request is asserted whenever the data in the SCITXBUF register is transferred to the TXSHF register, indicating that the CPU can write to SCITXBUF; this action sets the TXRDY flag bit (SCICTL2, bit 7) and initiates an interrupt.

---

#### Note

Interrupt generation due to the RXRDY and BRKDT bits is controlled by the RX/BK INT ENA bit (SCICTL2, bit 1). Interrupt generation due to the RX ERROR bit is controlled by the RX ERR INT ENA bit (SCICTL1, bit 6).

---

### 30.11.1 Break Detect

A "break" signal (also called a "break detect" or "break sequence") can be sent to the module to signal to the bus a specific condition. This break signal is defined as a low pulse of a certain amount of time, typically at least 1 packet wide (including a missed stop bit). The SCI has two main methods for detecting a "break" signal sent on the line, with certain limitations for each.

The first for break detect method involves reading the SCIRXST.BRKDT bit. A break condition that triggers the BRKDT bit occurs when the SCI receiver data line (SCIRXD) remains continuously low for at least 9.625 bits, beginning after a missing first stop bit. If the SCIRX line goes high at any point during the 9.625 bits then the SCI does not flag a break detect. To trigger the first stop bit missed, the typical method is to hold the RX line low for:

- 1 start bit
- 8 data bits
- (optional) 1 address bit
- (optional) 1 parity bit
- 1 stop bit
- 9.625 bits of additional time held low

This is a total of 19.625 (systems using no parity or address bit), 20.625 (systems using either parity or address bit but not both), or 21.625 (systems using both parity and address bit) bit times held low.

The second method for break detect is to instead use the SCIRXST.FE, SCIRXST.PE and SCIRXBUF.SAR bits to detect a break signal of 10 or 11 bits of low. ISR code can use the following combination of flags and received data to determine if a break detect occurred:

- Break signal = 11 bits low (requires parity enabled)
  - FE == 1
  - PE == 1 for odd parity, PE == 0 for even parity
  - SCIRXBUF.SAR (received character) == 0x00
- Break signal = 10 bits low (requires parity disabled)
  - FE == 1
  - SCIRXBUF.SAR (received character) == 0x00

### 30.12 SCI Baud Rate Calculations

The internally generated serial clock is determined by the low-speed peripheral clock (LSPCLK) and the baud-select registers. The SCI uses the 16-bit value of the baud-select registers to select one of the 64K different serial clock rates possible for a given LSPCLK.

See the bit descriptions in the baud-select registers, for the formula to use when calculating the SCI asynchronous baud. [Table 30-3](#) shows the baud-select values for common SCI bit rates. LSPCLK/16 is the maximum baud rate. For example, if LSPCLK is 100MHz, then the maximum baud rate is 6.25Mbps.

**Table 30-3. Asynchronous Baud Register Values for Common SCI Bit Rates**

Baud Rate	LSPCLK Clock Frequency, 100MHz		
	BRR	Actual Baud Rate	% Error
2400	5207 (1457h)	2400	0
4800	2603 (A2Bh)	4800	0
9600	1301 (515h)	9601	0.01
19200	650 (28Ah)	19201	0.01
38400	324 (144h)	38462	0.16

### 30.13 SCI Enhanced Features

The C28x SCI features autobaud detection and transmit/receive FIFO. The following section explains the FIFO operation.

#### 30.13.1 SCI FIFO Description

The following steps explain the FIFO features and help with programming the SCI with FIFOs.

1. **Reset.** At reset the SCI powers up in standard SCI mode and the FIFO function is disabled. The FIFO registers SCIFFTX, SCIFFRX, and SCIFFCT remain inactive.
2. **Standard SCI.** The standard SCI modes work normally with TXINT/RXINT interrupts as the interrupt source for the module.
3. **FIFO enable.** FIFO mode is enabled by setting the SCIFFEN bit in the SCIFFTX register. SCIRST can reset the FIFO mode at any stage of the operation.
4. **Active registers.** All the SCI registers and SCI FIFO registers (SCIFFTX, SCIFFRX, and SCIFFCT) are active.
5. **Interrupts.** FIFO mode has two interrupts; transmit FIFO (TXINT) and receive FIFO (RXINT). The RXINT is the common interrupt for SCI FIFO receive, receive error, and receive FIFO overflow conditions. The TXINT of the standard SCI is disabled and this interrupt serves as SCI transmit FIFO interrupt.
6. **Buffers.** Transmit and receive buffers are supplemented with two 16-level FIFOs. The transmit FIFO registers are 8-bits wide and receive FIFO registers are 10-bits wide. The one-word transmit buffer (SCITXBUF) of the standard SCI functions as a transition buffer before the transmit FIFO and shift register. SCITXBUF is loaded into either the FIFO (when FIFO is enabled) or the TXSHF (when FIFO is disabled). When FIFO is enabled, SCITXBUF loads into the FIFO only after the last bit of the shift register is shifted out, so SCITXBUF cannot be treated as an additional level of buffer. With the FIFO enabled, TXSHF is directly loaded from the FIFO (not TXBUF) after an optional delay value (SCIFFCT). When FIFO mode is enabled for SCI, characters written to SCITXBUF are queued in to SCI-TXFIFO and the characters received in SCI-RXFIFO can be read using SCIRXBUF.
7. **Delayed transfer.** The rate that words in the FIFO are transferred to the transmit shift register is programmable. The SCIFFCT register bits (7–0) FFTXDLY7–FFTXDLY0 define the delay between the word transfer. The delay is defined in the number SCI baud clock cycles. The 8 bit register can define a minimum delay of 0 baud clock cycles and a maximum of 256-baud clock cycles. With zero delay, the SCI module can transmit data in continuous mode with the FIFO words shifting out back to back. With the 256 clock delay the SCI module can transmit data in a maximum delayed mode with the FIFO words shifting out with a delay of 256 baud clocks between each words. The programmable delay facilitates communication with slow SCI/UARTs with little CPU intervention.
8. **FIFO status bits.** Both the transmit and receive FIFOs have status bits TXFFST or RXFFST (bits 12–8) that define the number of words available in the FIFOs at any time. The transmit FIFO reset bit TXFIFO and receive reset bit RXFIFO reset the FIFO pointers to zero when these bits are cleared to 0. The FIFOs resumes operation from start once these bits are set to 1.
9. **Programmable interrupt levels.** Both transmit and receive FIFO can generate CPU interrupts. The interrupt trigger is generated whenever the transmit FIFO status bits TXFFST (bits 12–8) match (less than or equal to) the interrupt trigger level bits TXFFIL (bits 4–0). This provides a programmable interrupt trigger for transmit and receive sections of the SCI. Default value for these trigger level bits is 0x11111 for receive FIFO and 0x00000 for transmit FIFO, respectively.

Figure 30-10 and Table 30-4 explain the operation/configuration of SCI interrupts in nonFIFO/FFO mode.

Figure 30-10. SCI FIFO Interrupt Flags and Enable Logic

Table 30-4. SCI Interrupt Flags

FIFO Options <sup>(1)</sup>	SCI Interrupt Source	Interrupt Flags	Interrupt Enables	FIFO Enable SCIFFENA	Interrupt Line
SCI without FIFO	Receive error	RXERR <sup>(2)</sup>	RXERRINTENA	0	RXINT
	Receive break	BRKDT	RX/BKINTENA	0	RXINT
	Data receive	RXRDY	RX/BKINTENA	0	RXINT
	Transmit empty	TXRDY	TXINTENA	0	TXINT
SCI with FIFO	Receive error and receive break	RXERR	RXERRINTENA	1	RXINT
	FIFO receive	RXFFIL	RXFFIENA	1	RXINT
	Transmit empty	TXFFIL	TXFFIENA	1	TXINT
Auto-baud	Auto-baud detected	ABD	Don't care	x	TXINT

(1) FIFO mode TXSHF is directly loaded after delay value, TXBUF is not used.

(2) RXERR can be set by BRKDT, FE, OE, PE flags. In FIFO mode, BRKDT interrupt is only through RXERR flag.

### 30.13.2 SCI Auto-Baud

Most SCI modules do not have an auto-baud detect logic built-in hardware. These SCI modules are integrated with embedded controllers whose clock rates are dependent on PLL reset values. Often embedded controller clocks change after final design. In the enhanced feature set this module supports an autobaud-detect logic in hardware. The following section explains the enabling sequence for autobaud-detect feature.

### 30.13.3 Autobaud-Detect Sequence

Bits ABD and CDC in SCIFFCT control the autobaud logic. The SCIRST bit can be enabled to make autobaud logic work.

If ABD is set while CDC is 1, which indicates auto-baud alignment, SCI transmit FIFO interrupt occurs (TXINT). After the interrupt service, the CDC bit must be cleared by software. If CDC remains set even after interrupt service, there can be no repeat interrupts.

1. Enable autobaud-detect mode for the SCI by setting the CDC bit (bit 13) in SCIFFCT and clearing the ABD bit (bit 15) by writing a 1 to ABDCLR bit (bit 14).
2. Initialize the baud register to be 1 or less than a baud rate limit of 500Kbps.
3. Allow SCI to receive either character "A" or "a" from a host at the desired baud rate. If the first character is either "A" or "a", the autobaud-detect hardware detects the incoming baud rate and sets the ABD bit.
4. The auto-detect hardware updates the baud rate register with the equivalent baud value hex. The logic also generates an interrupt to the CPU.
5. Respond to the interrupt clear ADB bit by writing a 1 to ABD CLR (bit 14) of SCIFFCT register and disable further autobaud locking by clearing CDC bit by writing a 0.
6. Read the receive buffer for character "A" or "a" to empty the buffer and buffer status.
7. If ABD is set while CDC is 1, which indicates autobaud alignment, the SCI transmit FIFO interrupt occurs (TXINT). After the interrupt service, the CDC bit must be cleared by software.

---

#### Note

At higher baud rates, the slew rate of the incoming data bits can be affected by transceiver and connector performance. While normal serial communications can work well, this slew rate can limit reliable autobaud detection at higher baud rates (typically beyond 100k baud) and cause the auto-baudlock feature to fail.

To avoid this, the following is recommended:

- Achieve a baud-lock between the host and C28x SCI boot loader using a lower baud rate.
  - The host can then handshake with the loaded C28x application to set the SCI baud rate register to the desired higher baud rate.
- 

## 30.14 Software

### 30.14.1 SCI Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/sci

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 30.14.1.1 Tune Baud Rate via UART Example

FILE: `baud_tune_via_uart.c`

This example demonstrates the process of tuning the UART/SCI baud rate of a C2000 device based on the UART input from another device. As UART does not have a clock signal, reliable communication requires baud rates to be reasonably matched. This example addresses cases where a clock mismatch between devices is greater than is acceptable for communications, requiring baud compensation between boards. As reliable communication only requires matching the EFFECTIVE baud rate, it does not matter which of the two boards

executes the tuning (the board with the less-accurate clock source does not need to be the one to tune; as long as one of the two devices tunes to the other, then proper communication can be established).

To tune the baud rate of this device, SCI data (of the desired baud rate) must be sent to this device. The input SCI baud rate must be within the +/- MARGINPERCENT of the TARGETBAUD chosen below. These two variables are defined below, and should be chosen based on the application requirements. Higher MARGINPERCENT will allow more data to be considered "correct" in noisy conditions, and may decrease accuracy. The TARGETBAUD is what was expected to be the baud rate, but due to clock differences, needs to be tuned for better communication robustness with the other device.

NOTE: Lower baud rates have more granularity in register options, and therefore tuning is more affective at these speeds.

This example project has support for migration across our C2000 device families. If you are wanting to build this project from launchpad or controlCARD, please specify in the .syscfg file the board you're using. At any time you can select another device to migrate this example. *External Connections* for Control Card

- SCIA\_RX/eCAP1 is on GPIO9, connect to incoming SCI communications
- SCIA\_TX is on GPIO8, for observation externally

#### Watch Variables

- *avgBaud* - Baud rate that was detected and set after tuning

#### 30.14.1.2 SCI FIFO Digital Loop Back

FILE: sci\_ex1\_loopback.c

This program uses the internal loop back test mode of the peripheral. Other than boot mode pin configuration, no other hardware configuration is required. The pinmux and SCI modules are configured through the sysconfig file.

This test uses the loopback test mode of the SCI module to send characters starting with 0x00 through 0xFF. The test will send a character and then check the receive buffer for a correct match.

This example project has support for migration across our C2000 device families. If you are wanting to build this project from launchpad or controlCARD, please specify in the .syscfg file the board you're using. At any time you can select another device to migrate this example. *Watch Variables*

- *loopCount* - Number of characters sent
- *errorCount* - Number of errors detected
- *sendChar* - Character sent
- *receivedChar* - Character received

#### 30.14.1.3 SCI Digital Loop Back with Interrupts

FILE: sci\_ex2\_loopback\_interrupts.c

This test uses the internal loop back test mode of the peripheral. Other than boot mode pin configuration, no other hardware configuration is required. Both interrupts and the SCI FIFOs are used.

A stream of data is sent and then compared to the received stream. The SCI-A sent data looks like this:

```
00 01
01 02
02 03
....
FE FF
FF 00
etc..
```

The pattern is repeated forever.

#### Watch Variables

- *sDataA* - Data being sent
- *rDataA* - Data received

- *rDataPointA* - Keep track of where we are in the data stream. This is used to check the incoming data

#### 30.14.1.4 SCI Echoback

FILE: sci\_ex3\_echoback.c

This test receives and echo-backs data through the SCI-A port.

A terminal such as 'putty' can be used to view the data from the SCI and to send information to the SCI. Characters received by the SCI port are sent back to the host.

*Running the Application* Open a COM port with the following settings using a terminal:

- Find correct COM port
- Bits per second = 9600
- Data Bits = 8
- Parity = None
- Stop Bits = 1
- Hardware Control = None

The program will print out a greeting and then ask you to enter a character which it will echo back to the terminal.

*Watch Variables*

- loopCounter - the number of characters sent

*External Connections*

Connect the USB cable from Control card J1:A to PC

#### 30.14.1.5 stdout redirect example

FILE: sci\_ex4\_stdout\_redirect.c This test transmits data through the SCI-A port to a terminal

A terminal such as 'putty' can be used to view the data from the SCI. Characters received by the SCI port are sent back to the host.

*Running the Application* Open a COM port with the following settings using a terminal:

- Find correct COM port
- Bits per second = 9600
- Data Bits = 8
- Parity = None
- Stop Bits = 1
- Hardware Control = None

The program will print out three sentences: one to the SCIA, one to CCS, and a final one to SCIA.

*External Connections*

Connect the SCI-A port to a PC via a transceiver and cable.

- DEVICE\_GPIO\_PIN\_SCIRXDA is SCI\_A-RXD (Connect to Pin3, PC-TX, of serial DB9 cable)
- DEVICE\_GPIO\_PIN\_SCITXDA is SCI\_A-TXD (Connect to Pin2, PC-RX, of serial DB9 cable)

## 30.15 SCI Registers

The section describes the Serial Communication Interface module registers.

### 30.15.1 SCI Base Address Table

**Table 30-5. SCI Base Address Table**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	CPU2	CPU2.DMA	Pipeline Protected
Instance	Structure

### 30.15.2 SCI\_REGS Registers

Table 30-6 lists the memory-mapped registers for the SCI\_REGS registers. All register offset addresses not listed in Table 30-6 should be considered as reserved locations and the register contents should not be modified.

**Table 30-6. SCI\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	SCICCR	Communications control register		<a href="#">Go</a>
1h	SCICTL1	Control register 1		<a href="#">Go</a>
2h	SCIHBAUD	Baud rate (high) register		<a href="#">Go</a>
3h	SCILBAUD	Baud rate (low) register		<a href="#">Go</a>
4h	SCICTL2	Control register 2		<a href="#">Go</a>
5h	SCIRXST	Receive status register		<a href="#">Go</a>
6h	SCIRXEMU	Receive emulation buffer register		<a href="#">Go</a>
7h	SCIRXBUF	Receive data buffer		<a href="#">Go</a>
9h	SCITXBUF	Transmit data buffer		<a href="#">Go</a>
Ah	SCIFFTX	FIFO transmit register		<a href="#">Go</a>
Bh	SCIFFRX	FIFO receive register		<a href="#">Go</a>
Ch	SCIFFCT	FIFO control register		<a href="#">Go</a>
Fh	SCIPRI	SCI priority control		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 30-7 shows the codes that are used for access types in this section.

**Table 30-7. SCI\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value

### 30.15.2.1 SCICCR Register (Offset = 0h) [Reset = 0000h]

SCICCR is shown in [Figure 30-11](#) and described in [Table 30-8](#).

Return to the [Summary Table](#).

SCICCR defines the character format, protocol, and communications mode used by the SCI.

**Figure 30-11. SCICCR Register**

15	14	13	12	11	10	9	8
RESERVED

R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h		

**Table 30-8. SCICCR Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-8	RESERVED	R	0h	Reserved
7	STOPBITS	R/W	0h	SCI number of stop bits. This bit specifies the number of stop bits transmitted. The receiver checks for only one stop bit. Reset type: SYSRSn 0h (R/W) = One stop bit 1h (R/W) = Two stop bits
6	PARITY	R/W	0h	SCI parity odd/even selection. If the PARITY ENABLE bit (SCICCR, bit 5) is set, PARITY (bit 6) designates odd or even parity (odd or even number of bits with the value of 1 in both transmitted and received characters). Reset type: SYSRSn 0h (R/W) = Odd parity 1h (R/W) = Even parity
5	PARITYENA	R/W	0h	SCI parity enable. This bit enables or disables the parity function. If the SCI is in the addressbit multiprocessor mode (set using bit 3 of this register), the address bit is included in the parity calculation (if parity is enabled). For characters of less than eight bits, the remaining unused bits should be masked out of the parity calculation. Reset type: SYSRSn 0h (R/W) = Parity disabled no parity bit is generated during transmission or is expected during reception 1h (R/W) = Parity is enabled
4	LOOPBKENA	R/W	0h	Loop Back test mode enable. This bit enables the Loop Back test mode where the Tx pin is internally connected to the Rx pin. Reset type: SYSRSn 0h (R/W) = Loop Back test mode disabled 1h (R/W) = Loop Back test mode enabled

**Table 30-8. SCICCR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
3	ADDRIDLE_MODE	R/W	0h	<p>SCI multiprocessor mode control bit.</p> <p>This bit selects one of the multiprocessor protocols. Multiprocessor communication is different from the other communication modes because it uses SLEEP and TXWAKE functions (bits SCICTL1, bit 2 and SCICTL1, bit 3, respectively). The idle-line mode is usually used for normal communications because the address-bit mode adds an extra bit to the frame. The idle-line mode does not add this extra bit and is compatible with RS-232 type communications.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Idle-line mode protocol selected 1h (R/W) = Address-bit mode protocol selected</p>
2-0	SCICCHAR	R/W	0h	<p>Character-length control bits 2-0.</p> <p>These bits select the SCI character length from one to eight bits. Characters of less than eight bits are right-justified in SCIRXBUF and SCIRXEMU and are padded with leading zeros in SCIRXBUF. SCITXBUF doesn't need to be padded with leading zeros.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = SCICCHAR_LENGTH_1 1h (R/W) = SCICCHAR_LENGTH_2 2h (R/W) = SCICCHAR_LENGTH_3 3h (R/W) = SCICCHAR_LENGTH_4 4h (R/W) = SCICCHAR_LENGTH_5 5h (R/W) = SCICCHAR_LENGTH_6 6h (R/W) = SCICCHAR_LENGTH_7 7h (R/W) = SCICCHAR_LENGTH_8</p>

### 30.15.2.2 SCICTL1 Register (Offset = 1h) [Reset = 0000h]

SCICTL1 is shown in [Figure 30-12](#) and described in [Table 30-9](#).

Return to the [Summary Table](#).

SCICTL1 controls the receiver/transmitter enable, TXWAKE and SLEEP functions, and the SCI software reset.

**Figure 30-12. SCICTL1 Register**

15	14	13	12	11	10	9	8
RESERVED

**Table 30-9. SCICTL1 Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-7	RESERVED	R	0h	Reserved
6	RXERRINTENA	R/W	0h	SCI receive error interrupt enable. Setting this bit enables an interrupt if the RX ERROR bit (SCIRXST, bit 7) becomes set because of errors occurring. Reset type: SYSRSn 0h (R/W) = Receive error interrupt disabled 1h (R/W) = Receive error interrupt enabled
5	SWRESET	R/W	0h	SCI software reset (active low). Writing a 0 to this bit initializes the SCI state machines and operating flags (registers SCICTL2 and SCIRXST) to the reset condition. This reset will not reset the FIFO pointers or flush out the data in TX/RX FIFO. If you need to clear the FIFO then perform SWRESET + TXFFINT + RXFFINT or refer to a channel reset SCIFFTX[SCIRST]. The SW RESET bit does not affect any of the configuration bits. All affected logic is held in the specified reset state until a 1 is written to SW RESET (the bit values following a reset are shown beneath each register diagram in this section). Thus, after a system reset, re-enable the SCI by writing a 1 to this bit. Clear this bit after a receiver break detect (BRKDT flag, bit SCIRXST, bit 5). SW RESET affects the operating flags of the SCI, but it neither affects the configuration bits nor restores the reset values. Once SW RESET is asserted, the flags are frozen until the bit is deasserted. The affected flags are as follows: Value After SW SCI Flag Register Bit RESET 1 TXRDY SCICTL2, bit 7 1 TX EMPTY SCICTL2, bit 6 0 RXWAKE SCIRXST, bit 1 0 PE SCIRXST, bit 2 0 OE SCIRXST, bit 3 0 FE SCIRXST, bit 4 0 BRKDT SCIRXST, bit 5 0 RXRDY SCIRXST, bit 6 0 RX ERROR SCIRXST, bit 7 Reset type: SYSRSn 0h (R/W) = Writing a 0 to this bit initializes the SCI state machines and operating flags (registers SCICTL2 and SCIRXST) to the reset condition. 1h (R/W) = After a system reset, re-enable the SCI by writing a 1 to this bit. There is no time requirement to meet before writing a one to this bit after writing a zero.
4	RESERVED	R	0h	Reserved

**Table 30-9. SCICTL1 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
3	TXWAKE	R/W	0h	<p>SCI transmitter wake-up method select.</p> <p>The TXWAKE bit controls selection of the data-transmit feature, depending on which transmit mode (idle-line or address-bit) is specified at the ADDR/IDLE MODE bit (SCICCR, bit 3)</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Transmit feature is not selected. In idle-line mode: write a 1 to TXWAKE, then write data to register SCITXBUF to generate an idle period of 11 data bits In address-bit mode: write a 1 to TXWAKE, then write data to SCITXBUF to set the address bit for that frame to 1</p> <p>1h (R/W) = Transmit feature selected is dependent on the mode, idle-line or address-bit: TXWAKE is not cleared by the SW RESET bit (SCICTL1, bit 5)</p> <p>it is cleared by a system reset or the transfer of TXWAKE to the WUT flag.</p>
2	SLEEP	R/W	0h	<p>SCI sleep.</p> <p>The TXWAKE bit controls selection of the data-transmit feature, depending on which transmit mode (idle-line or address-bit) is specified at the ADDR/IDLE MODE bit (SCICCR, bit 3). In a multiprocessor configuration, this bit controls the receiver sleep function. Clearing this bit brings the SCI out of the sleep mode. The receiver still operates when the SLEEP bit is set however, operation does not update the receiver buffer ready bit (SCIRXST, bit 6, RXRDY) or the error status bits (SCIRXST, bit 5-2: BRKDT, FE, OE, and PE) unless the address byte is detected. SLEEP is not cleared when the address byte is detected.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Sleep mode disabled</p> <p>1h (R/W) = Sleep mode enabled</p>
1	TXENA	R/W	0h	<p>SCI transmitter enable.</p> <p>Data is transmitted through the SCITXD pin only when TXENA is set. If reset, transmission is halted but only after all data previously written to SCITXBUF has been sent. Data written into SCITXBUF when TXENA is disabled will not be transmitted even if the TXENA is enabled later.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Transmitter disabled</p> <p>1h (R/W) = Transmitter enabled</p>
0	RXENA	R/W	0h	<p>SCI receiver enable.</p> <p>Data is received on the SCIRXD pin and is sent to the receiver shift register and then the receiver buffers. This bit enables or disables the receiver (transfer to the buffers).</p> <p>Clearing RXENA stops received characters from being transferred to the two receiver buffers and also stops the generation of receiver interrupts. However, this will not stop RX errors from triggering interrupts. To disable interrupts from RX errors use the RXERRINTENA bit. To stop propagation of the BRKDT interrupt use the RXBKINTENA bit.</p> <p>The receiver shift register can continue to assemble characters even while RXENA is cleared. Thus, if RXENA is set during the reception of a character, the complete character will be transferred into the receiver buffer registers, SCIRXEMU and SCIRXBUF.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Prevent received characters from transfer into the SCIRXEMU and SCIRXBUF receiver buffers</p> <p>1h (R/W) = Send received characters to SCIRXEMU and SCIRXBUF</p>

### 30.15.2.3 SCIHBAUD Register (Offset = 2h) [Reset = 0000h]

SCIHBAUD is shown in [Figure 30-13](#) and described in [Table 30-10](#).

Return to the [Summary Table](#).

The values in SCIHBAUD and SCILBAUD specify the baud rate for the SCI.

Bit	Field	Type	Reset	Description
15-8	RESERVED	R	0h	Reserved
7-0	BAUD	R/W	0h	SCI 16-bit baud selection Registers SCIHBAUD (MSbyte). The internally-generated serial clock is determined by the low speed peripheral clock (LSPCLK) signal and the two baud-select registers. The SCI uses the 16-bit value of these registers to select one of 64K serial clock rates for the communication modes. $BRR = (SCIHBAUD \ll 8) + (SCILBAUD)$ The SCI baud rate is calculated using the following equation: $SCI \text{ Asynchronous Baud} = LSPCLK / ((BRR + 1) * 8)$ Alternatively, $BRR = LSPCLK / (SCI \text{ Asynchronous Baud} * 8) - 1$ Note that the above formulas are applicable only when $0 < BRR < 65536$ . If $BRR = 0$ , then $SCI \text{ Asynchronous Baud} = LSPCLK / 16$ Where: BRR = the 16-bit value (in decimal) in the baud-select registers Reset type: SYSRSn

### 30.15.2.4 SCILBAUD Register (Offset = 3h) [Reset = 0000h]

SCILBAUD is shown in [Figure 30-14](#) and described in [Table 30-11](#).

Return to the [Summary Table](#).

The values in SCIHBAUD and SCILBAUD specify the baud rate for the SCI.

### 30.15.2.5 SCICTL2 Register (Offset = 4h) [Reset = 00C0h]

SCICTL2 is shown in [Figure 30-15](#) and described in [Table 30-12](#).

Return to the [Summary Table](#).

SCICTL2 enables the receive-ready, break-detect, and transmit-ready interrupts as well as transmitter-ready and -empty flags.

**Figure 30-15. SCICTL2 Register**

15	14	13	12	11	10	9	8

**Table 30-12. SCICTL2 Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-8	RESERVED	R	0h	Reserved
7	TXRDY	R	1h	Transmitter buffer register ready flag. When set, this bit indicates that the transmit data buffer register, SCITXBUF, is ready to receive another character. Writing data to the SCITXBUF automatically clears this bit. When set, this flag asserts a transmitter interrupt request if the interrupt-enable bit, TX INT ENA (SCICTL2.0), is also set. TXRDY is set to 1 by enabling the SW RESET bit (SCICTL1.5) or by a system reset. Reset type: SYSRSn 0h (R/W) = SCITXBUF is full 1h (R/W) = SCITXBUF is ready to receive the next character
6	TXEMPTY	R	1h	Transmitter empty flag. This flag's value indicates the contents of the transmitter's buffer register (SCITXBUF) and shift register (TXSHF). An active SW RESET (SCICTL1.5), or a system reset, sets this bit. This bit does not cause an interrupt request. Reset type: SYSRSn 0h (R/W) = Transmitter buffer or shift register or both are loaded with data 1h (R/W) = Transmitter buffer and shift registers are both empty
5-2	RESERVED	R	0h	Reserved
1	RXBKINTENA	R/W	0h	Receiver-buffer/break interrupt enable. This bit controls the interrupt request caused by either the RXRDY flag or the BRKDT flag (bits SCIRXST.6 and .5) being set. However, RX/BK INT ENA does not prevent the setting of these flags. Reset type: SYSRSn 0h (R/W) = Disable RXRDY/BRKDT interrupt 1h (R/W) = Enable RXRDY/BRKDT interrupt

**Table 30-12. SCICTL2 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
0	TXINTENA	R/W	0h	<p>SCITXBUF-register interrupt enable.</p> <p>This bit controls the interrupt request caused by the setting of TXRDY flag bit (SCICTL2.7). However, it does not prevent the TXRDY flag from being set (which indicates SCITXBUF is ready to receive another character).</p> <p>0 Disable TXRDY interrupt 1 Enable TXRDY interrupt.</p> <p>In non-FIFO mode, a dummy (or a valid) data has to be written to SCITXBUF for the first transmit interrupt to occur. This is the case when you enable the transmit interrupt for the first time and also when you re-enable (disable and then enable) the transmit interrupt. If TXINTENA is enabled after writing the data to SCITXBUF, it will not generate an interrupt.</p> <p>Reset type: SYSRSn 0h (R/W) = Disable TXRDY interrupt 1h (R/W) = Enable TXRDY interrupt</p>

### 30.15.2.6 SCIRXST Register (Offset = 5h) [Reset = 0000h]

SCIRXST is shown in [Figure 30-16](#) and described in [Table 30-13](#).

Return to the [Summary Table](#).

SCIRXST contains seven bits that are receiver status flags (two of which can generate interrupt requests). Each time a complete character is transferred to the receiver buffers (SCIRXEMU and SCIRXBUF), the status flags are updated.

**Figure 30-16. SCIRXST Register**

15	14	13	12	11	10	9	8

**Table 30-13. SCIRXST Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-8	RESERVED	R	0h	Reserved
7	RXERROR	R	0h	SCI receiver error flag. The RX ERROR flag indicates that one of the error flags in the receiver status register is set. RX ERROR is a logical OR of the break detect, framing error, overrun, and parity error enable flags (bits 5-2: BRKDT, FE, OE, and PE). A 1 on this bit will cause an interrupt if the RX ERR INT ENA bit (SCICTL1.6) is set. This bit can be used for fast error-condition checking during the interrupt service routine. This error flag cannot be cleared directly it is cleared by an active SW RESET, channel reset (SCIRST), or by a system reset. Reset type: SYSRSn 0h (R/W) = No error flags set 1h (R/W) = Error flag(s) set
6	RXRDY	R	0h	SCI receiver-ready flag. When a new character is ready to be read from the SCIRXBUF register, the receiver sets this bit, and a receiver interrupt is generated if the RX/BK INT ENA bit (SCICTL2.1) is a 1. RXRDY is cleared by a reading of the SCIRXBUF register, by an active SW RESET, channel reset (SCIRST), or by a system reset. Reset type: SYSRSn 0h (R/W) = No new character in SCIRXBUF 1h (R/W) = Character ready to be read from SCIRXBUF

**Table 30-13. SCIRXST Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
5	BRKDT	R	0h	<p>SCI break-detect flag.</p> <p>The SCI sets this bit when a break condition occurs. A break condition occurs when the SCI receiver data line (SCIRXD) remains continuously low for at least 9.625 bits, beginning after a missing first stop bit. If the SCIRX line goes high at any point during the 9.625 bits then the SCI will not flag a break detect. In order to trigger the first stop bit missed, the typical method is to hold the RX line low for 1 start bit, 8 data bits, 1 optional address bit, 1 optional parity bit, 1 stop bit, and 9.625 bits of additional time held low. This is a total of 19.625 (no parity/address bit), 20.625 (either parity or address bit), or 21.625 (both parity and address bit) bit times.</p> <p>To instead detect a 'break seq' or 'break sequence' of 11 bits of low voltage level (0), ISR code can use the following combination of flags and received data: FE==1 &amp;&amp; PE==1 &amp;&amp; SCIRXBUF.SAR (received character)==0x00. This assumes parity enabled and odd parity set. With even parity, PE==0 instead. The detection of 11 bits of low/0 can be reduced to 10 bits of low if no parity bit is used (then PE flag does not matter to detect the sequence).</p> <p>The occurrence of a break causes a receiver interrupt to be generated if the RX/BK INT ENA bit is a 1, but it does not cause the receiver buffer to be loaded.</p> <p>A BRKDT interrupt can occur even if the receiver SLEEP bit is set to 1.</p> <p>BRKDT is cleared by an active SW RESET, SCIRST bit, or by a system reset. It is not cleared by receipt of a character after the break is detected.</p> <p>If Break Detect (BRKDT) is set, then RXRDY won't be set and there will be no further interrupts after the first interrupt where there is an error detected if a SW reset, channel reset, or system reset is not performed. In order to receive more characters, the SCI must be reset by toggling the SW RESET bit, channel reset (SCIRST), or by a system reset.</p> <p>NOTE: If your system is susceptible to break detects, ensure that you have a pull-up resistor on the SCI-RX pin to provide proper return-to-high signal behavior and noise immunity.</p> <p>NOTE: To monitor a break detect, place an oscilloscope on the C2000 SCI-RX line and monitor for a low-signal greater than 9.625 bits wide. If this is found and a break is not expected, please correct the software in the other device that is transmitting to this C2000 device. There should never be a low-signal greater than 9.625 bits wide on the SCI-RX line of the C2000 device unless a break detect is being transmitted purposely.</p> <p>Reset type: SYSRSn            0h (R/W) = No break condition            1h (R/W) = Break condition occurred</p>
4	FE	R	0h	<p>SCI framing-error flag.</p> <p>The SCI sets this bit when an expected stop bit is not found. Only the first stop bit is checked. The missing stop bit indicates that synchronization with the start bit has been lost and that the character is incorrectly framed. The FE bit is reset by a clearing of the SW RESET bit, channel reset (SCIRST), or by a system reset. NOTE: FE will be flagged prior to BRKDT, except when RX is in sleep mode. In sleep mode, when there is no RX WAKEUP and RXD line is low for greater than 10 bits, BRKDT will be flagged while FE will not be flagged.</p> <p>Reset type: SYSRSn            0h (R/W) = No framing error detected            1h (R/W) = Framing error detected</p>

**Table 30-13. SCIRXST Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
3	OE	R	0h	SCI overrun-error flag. The SCI sets this bit when a character is transferred into registers SCIRXEMU and SCIRXBUF before the previous character is fully read by the CPU or DMAC. The previous character is overwritten and lost. The OE flag bit is reset by an active SW RESET, channel reset (SCIRST), or a system reset. Reset type: SYSRSn 0h (R/W) = No overrun error detected 1h (R/W) = Overrun error detected
2	PE	R	0h	SCI parity-error flag. This flag bit is set when a character is received with a mismatch between the number of 1s and its parity bit. The address bit is included in the calculation. If parity generation and detection is not enabled, the PE flag is disabled and read as 0. The PE bit is reset by an active SW RESET, channel reset (SCIRST), or a system reset. Reset type: SYSRSn 0h (R/W) = No parity error or parity is disabled 1h (R/W) = Parity error is detected
1	RXWAKE	R	0h	Receiver wake-up-detect flag Reset type: SYSRSn 0h (R/W) = No detection of a receiver wake-up condition 1h (R/W) = A value of 1 in this bit indicates detection of a receiver wake-up condition. In the address-bit multiprocessor mode (SCICCR.3 = 1), RXWAKE reflects the value of the address bit for the character contained in SCIRXBUF. In the idle-line multiprocessor mode, RXWAKE is set if the SCIRXD data line is detected as idle. RXWAKE is a read-only flag, cleared by one of the following: <ul style="list-style-type: none"> <li>- The transfer of the first byte after the address byte to SCIRXBUF (only in non-FIFO mode)</li> <li>- The reading of SCIRXBUF</li> <li>- An active SW RESET</li> <li>- Channel reset (SCIRST)</li> <li>- A system reset</li> </ul>
0	RESERVED	R	0h	Reserved

### 30.15.2.7 SCIRXEMU Register (Offset = 6h) [Reset = 0000h]

SCIRXEMU is shown in [Figure 30-17](#) and described in [Table 30-14](#).

Return to the [Summary Table](#).

Normal SCI data-receive operations read the data received from the SCIRXBUF register. The SCIRXEMU register is used principally by the emulator (EMU) because it can continuously read the data received for screen updates without clearing the RXRDY flag. SCIRXEMU is cleared by a system reset. This is the register that should be used in an emulator watch window to view the contents of the SCIRXBUF register. SCIRXEMU is not physically implemented

it is just a different address location to access the SCIRXBUF register without clearing the RXRDY flag.

**Table 30-15. SCIRXBUF Register Field Descriptions**

Bit	Field	Type	Reset	Description
15	SCIFFFE	R	0h	SCIFFFE. SCI FIFO Framing error flag bit (applicable only if the FIFO is enabled) Note: 'SCIFFFE' is meant to serve as a flag for the specific set of data being received/read in the SCIRXBUF register. Each set of data received into the FIFO will have this information. The 'FE' bit within the SCIRXST register can be thought of as high level error flag where the flag will get set if any data that has been received has a framing error. Reset type: SYSRSn 0h (R/W) = No frame error occurred while receiving the character, in bits 7-0. This bit is associated with the character on the top of the FIFO. 1h (R/W) = A frame error occurred while receiving the character in bits 7-0. This bit is associated with the character on the top of the FIFO.
14	SCIFFPE	R	0h	SCIFFPE. SCI FIFO parity error flag bit (applicable only if the FIFO is enabled) Note: 'SCIFFPE' is meant to serve as a flag for the specific set of data being received/read in the SCIRXBUF register. Each set of data received into the FIFO will have this information. The 'PE' bit within the SCIRXST register can be thought of as high level error flag where the flag will get set if any data that has been received has a parity error. Note: If the parity is changed in the middle of data reception, the SCI module will not reinterpret the data with the new parity or other settings that may have changed. Therefore, changing the parameter, the FIFO should be cleared or the user should acknowledge that there will most likely be errors in the data caused by the change. Note: If RX parity errors are occurring intermittently this could be due to the length of the SCI ISR. To help prevent this, ensure that interrupt nesting is limited, increase the SCI interrupt priority, and move as much of the processing as possible out of the ISR (to reduce ISR time to the absolute minimum). Reset type: SYSRSn 0h (R/W) = No parity error occurred while receiving the character, in bits 7-0. This bit is associated with the character on the top of the FIFO. 1h (R/W) = A parity error occurred while receiving the character in bits 7-0. This bit is associated with the character on the top of the FIFO.
13-8	RESERVED	R	0h	Reserved

7-0	SAR	R	0h	Receive Character bits Reset type: SYSRSn

### 30.15.2.9 SCITXBUF Register (Offset = 9h) [Reset = 0000h]

SCITXBUF is shown in [Figure 30-19](#) and described in [Table 30-16](#).

Return to the [Summary Table](#).

Data bits to be transmitted are written to SCITXBUF. These bits must be rightjustified because the leftmost bits are ignored for characters less than eight bits long. The transfer of data from this register to the TXSHF transmitter shift register sets the TXRDY flag (SCICTL2.7), indicating that SCITXBUF is ready to receive another set of data. If bit TXINTENA (SCICTL2.0) is set, this data transfer also causes an interrupt.

7	TXFFINT	R	0h	<p>Transmit FIFO interrupt</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = TXFIFO interrupt has not occurred, read-only bit</p> <p>1h (R/W) = TXFIFO interrupt has occurred, read-only bit</p>

**Table 30-17. SCIFFTX Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
6	TXFFINTCLR	R-0/W1S	0h	Transmit FIFO clear Reset type: SYSRSn 0h (R/W) = Write 0 has no effect on TXFIFINT flag bit, Bit reads back a zero 1h (R/W) = Write 1 to clear TXFFINT flag in bit 7
5	TXFFIENA	R/W	0h	Transmit FIFO interrupt enable Reset type: SYSRSn 0h (R/W) = TX FIFO interrupt is disabled 1h (R/W) = TX FIFO interrupt is enabled. This interrupt is triggered whenever the transmit FIFO status (TXFFST) bits match (equal to or less than) the interrupt trigger level bits TXFFIL (bits 4-0).
4-0	TXFFIL	R/W	0h	TXFFIL4-0 Transmit FIFO interrupt level bits. The transmit FIFO generates an interrupt whenever the FIFO status bits (TXFFST4-0) are less than or equal to the FIFO level bits (TXFFIL4-0). The maximum value that can be assigned to these bits to generate an interrupt cannot be more than the depth of the TX FIFO. The default value of these bits after reset is 00000b. Users should set TXFFIL to best fit their application needs by weighing between the CPU overhead to service the ISR and the best possible usage of SCI bus bandwidth. Reset type: SYSRSn

### 30.15.2.11 SCIFFRX Register (Offset = Bh) [Reset = 201Fh]

SCIFFRX is shown in [Figure 30-21](#) and described in [Table 30-18](#).

Return to the [Summary Table](#).

SCIFFRX controls the receive FIFO interrupt, receive FIFO reset, and status of the receive FIFO overflow.

**Figure 30-21. SCIFFRX Register**

15	14	13	12	11	10	9	8

12-8	RXFFST	R	0h	<p>FIFO status</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Receive FIFO is empty            1h (R/W) = Receive FIFO has 1 words            2h (R/W) = Receive FIFO has 2 words            3h (R/W) = Receive FIFO has 3 words            4h (R/W) = Receive FIFO has 4 words            5h (R/W) = Receive FIFO has 5 words            6h (R/W) = Receive FIFO has 6 words            7h (R/W) = Receive FIFO has 7 words            8h (R/W) = Receive FIFO has 8 words            9h (R/W) = Receive FIFO has 9 words            Ah (R/W) = Receive FIFO has 10 words            Bh (R/W) = Receive FIFO has 11 words            Ch (R/W) = Receive FIFO has 12 words            Dh (R/W) = Receive FIFO has 13 words            Eh (R/W) = Receive FIFO has 14 words            Fh (R/W) = Receive FIFO has 15 words            10h (R/W) = Receive FIFO has 16 words</p>
7	RXFFINT	R	0h	<p>Receive FIFO interrupt</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = RXFIFO interrupt has not occurred, read-only bit            1h (R/W) = RXFIFO interrupt has occurred, read-only bit</p>
6	RXFFINTCLR	W	0h	<p>Receive FIFO interrupt clear</p> <p>Note: Both RXFFIL and RXFFOVF flags are ORed together, so they need to be cleared at the same time (RXFFINTCLR &amp; RXFFOVRCLR) during overflow scenarios else it will prevent further interrupts from occurring.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Write 0 has no effect on RXFIFINT flag bit. Bit reads back a zero.            1h (R/W) = Write 1 to clear RXFFINT flag in bit 7</p>
5	RXFFIENA	R/W	0h	<p>Receive FIFO interrupt enable</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = RX FIFO interrupt is disabled            1h (R/W) = RX FIFO interrupt is enabled. This interrupt is triggered whenever the receive FIFO status (RXFFST) bits match (equal to or greater than) the interrupt trigger level bits RXFFIL (bits 4-0).</p>
4-0	RXFFIL	R/W	1Fh	<p>Receive FIFO interrupt level bits</p> <p>The receive FIFO generates an interrupt whenever the FIFO status bits (RXFFST4-0) are greater than or equal to the FIFO level bits (RXFFIL4-0). The maximum value that can be assigned to these bits to generate an interrupt cannot be more than the depth of the RX FIFO. The default value of these bits after reset is 11111b. Users should set RXFFIL to best fit their application needs by weighing between the CPU overhead to service the ISR and the best possible usage of received SCI data.</p> <p>Reset type: SYSRSn</p>

### 30.15.2.12 SCIFFCT Register (Offset = Ch) [Reset = 0000h]

SCIFFCT is shown in [Figure 30-22](#) and described in [Table 30-19](#).

Return to the [Summary Table](#).

SCIFFCT contains the status of auto-baud detect, clears the auto-baud flag, and calibrate for A-detect bit.

**Figure 30-22. SCIFFCT Register**

15	14	13	12	11	10	9	8
ABD	ABDCLR	CDC	RESERVED				
R-0h	W-0h	R/W-0h	R-0h				
7	6	5	4	3	2	1	0
FFTXDLY							
R/W-0h							

**Table 30-19. SCIFFCT Register Field Descriptions**

Bit	Field	Type	Reset	Description
15	ABD	R	0h	Auto-baud detect (ABD) bit Reset type: SYSRSn 0h (R/W) = Auto-baud detection is not complete. 'A','a' character has not been received successfully. 1h (R/W) = Auto-baud hardware has detected 'A' or 'a' character on the SCI receive register. Auto-detect is complete.
14	ABDCLR	W	0h	ABD-clear bit Reset type: SYSRSn 0h (R/W) = Write 0 has no effect on ABD flag bit. Bit reads back a zero. 1h (R/W) = Write 1 to clear ABD flag in bit 15.
13	CDC	R/W	0h	CDC calibrate A-detect bit Reset type: SYSRSn 0h (R/W) = Disables auto-baud alignment 1h (R/W) = Enables auto-baud alignment
12-8	RESERVED	R	0h	Reserved
7-0	FFTXDLY	R/W	0h	FIFO transfer delay. These bits define the delay between every transfer from FIFO transmit bufferto transmit shift register. The delay is defined in the number of SCI serial baud clock cycles. The 8 bit register could define a minimum delay of 0 baud clock cycles and a maximum of 256 baud clock cycles In FIFO mode, the buffer (TXBUF) between the shift register and the FIFO should be filled only after the shift register has completed shifting of the last bit. This is required to pass on the delay between transfers to the data stream. In FIFO mode, TXBUF should not be treated as one additional level of buffer. The delayed transmit feature will help to create an auto-flow scheme without RTS/CTS controls as in standard UARTS. When SCI is configured for one stop-bit, delay introduced by FFTXDLY between one frame and the next frame is equal to number of baud clock cycles that FFTXDLY is set to. When SCI is configured for two stop-bits, delay introduced by FFTXDLY between one frame and the next frame is equal to number of baud clock cycles that FFTXDLY is set to minus 1. Reset type: SYSRSn

### 30.15.2.13 SCIPRI Register (Offset = Fh) [Reset = 0000h]

SCIPRI is shown in [Figure 30-23](#) and described in [Table 30-20](#).

Return to the [Summary Table](#).

SCIPRI determines what happens when an emulation suspend event occurs.

**Figure 30-23. SCIPRI Register**

Chapter 31  
**Serial Peripheral Interface (SPI)**

---

This chapter describes the serial peripheral interface (SPI) which is a high-speed synchronous serial input and output (I/O) port that allows a serial bit stream of programmed length (one to 16 bits) to be shifted into and out of the device at a programmed bit-transfer rate. The SPI is normally used for communications between the MCU controller and external peripherals or another controller. Typical applications include external I/O or peripheral expansion using devices such as shift registers, display drivers, and analog-to-digital converters (ADCs). Multi-device communications are supported by the controller or peripheral operation of the SPI. The port supports a 16-level, receive and transmit FIFO for reducing CPU servicing overhead.

<b>31.1 Introduction</b> .....	<b>4820</b>
<b>31.2 System-Level Integration</b> .....	<b>4822</b>
<b>31.3 SPI Operation</b> .....	<b>4826</b>
<b>31.4 Programming Procedure</b> .....	<b>4837</b>
<b>31.5 Software</b> .....	<b>4843</b>
<b>31.6 SPI Registers</b> .....	<b>4845</b>

## 31.1 Introduction

### 31.1.1 Features

The SPI module features include:

- SPIOCI: SPI peripheral-output/controller-input pin
- SPIICO: SPI peripheral-input/controller-output pin
- SPIPTE : SPI peripheral transmit-enable pin
- SPICLK: SPI serial-clock pin

---

#### Note

All four pins can be used as GPIO if the SPI module is not used.

---

- Two operational modes: Controller and Peripheral
- Baud rate: 125 different programmable rates. The maximum baud rate that can be employed is limited by the maximum speed of the I/O buffers used on the SPI pins. See the device data sheet for more details.
- Data word length: 1 to 16 data bits
- Four clocking schemes (controlled by clock polarity and clock phase bits) include:
  - Falling edge without phase delay: SPICLK active-high. SPI transmits data on the falling edge of the SPICLK signal and receives data on the rising edge of the SPICLK signal.
  - Falling edge with phase delay: SPICLK active-high. SPI transmits data one half-cycle ahead of the falling edge of the SPICLK signal and receives data on the falling edge of the SPICLK signal.
  - Rising edge without phase delay: SPICLK inactive-low. SPI transmits data on the rising edge of the SPICLK signal and receives data on the falling edge of the SPICLK signal.
  - Rising edge with phase delay: SPICLK inactive-low. SPI transmits data one half-cycle ahead of the rising edge of the SPICLK signal and receives data on the rising edge of the SPICLK signal.
- Simultaneous receive and transmit operation (transmit function can be disabled in software)
- Transmitter and receiver operations are accomplished through either interrupt- driven or polled algorithm
- DMA support
- Delayed transmit control
- 16-level transmit/receive FIFO
- High-speed mode
- 3-wire SPI mode
- SPIPTE inversion for digital audio interface receive mode on devices with two SPI modules

#### Getting Started Materials

- [SPI: Microcontroller overview](#) (Video)

### 31.1.3 Block Diagram

Figure 31-1 shows the SPI CPU interfaces.

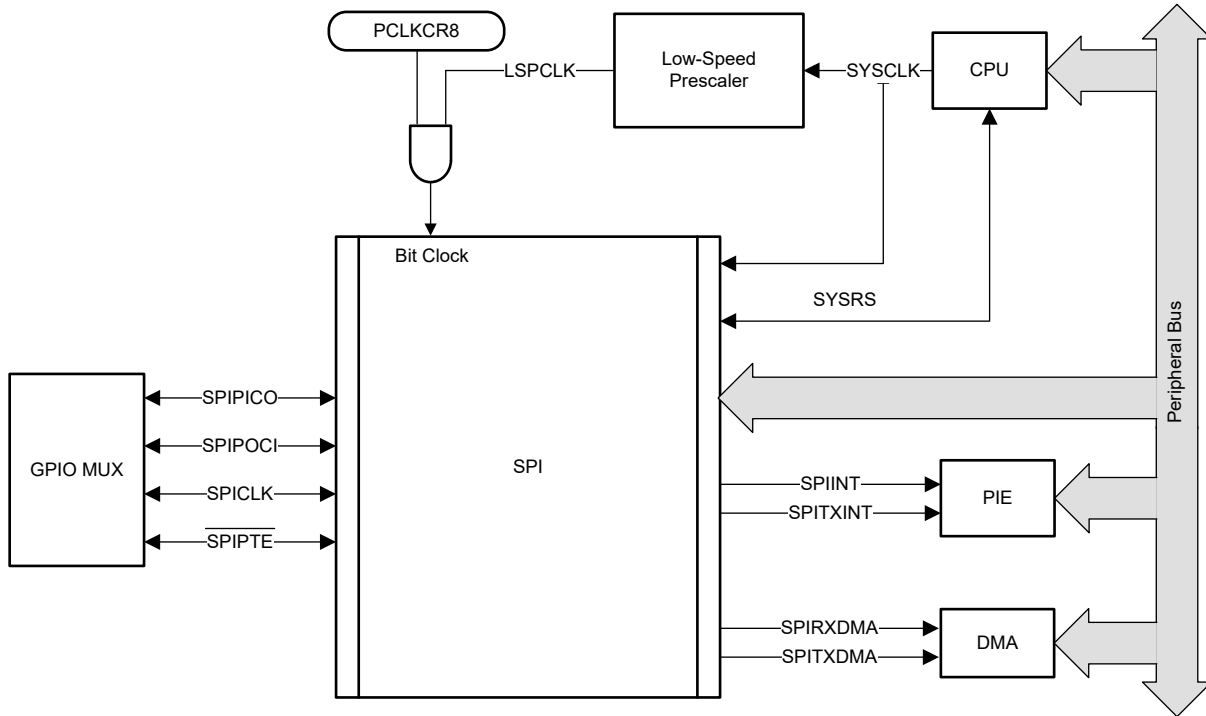

Figure 31-1. SPI CPU Interface

## 31.2 System-Level Integration

This section describes the various functionality that is applicable to the device integration. These features require configuration of other modules in the device that are not within the scope of this chapter.

### 31.2.1 SPI Module Signals

[Table 31-1](#) classifies and provides a summary of the SPI module signals.

**Table 31-1. SPI Module Signal Summary**

Signal Name	Description
<b>External Signals</b>	
SPICLK	SPI clock
SPIPICO	SPI peripheral in, controller out
SPIPOCI	SPI peripheral out, controller in
$\overline{\text{SPIPTE}}$	SPI peripheral transmit enable
<b>Control</b>	
SPI Clock Rate	LSPCLK
<b>Interrupt Signals</b>	
SPIINT/SPIRXINT	Transmit interrupt/ Receive Interrupt in non FIFO mode (referred to as SPIINT) Receive interrupt in FIFO mode
SPITXINT	Transmit interrupt in FIFO mode
<b>DMA Triggers</b>	
SPITXDMA	Transmit request to DMA
SPIRXDMA	Receive request to DMA

### Special Considerations

The  $\overline{\text{SPIPTE}}$  signal provides the ability to gate any spurious clock and data pulses when the SPI is in peripheral mode. A HIGH logic signal on  $\overline{\text{SPIPTE}}$  does not allow the peripheral to receive data. This prevents the SPI peripheral from losing synchronization with the controller. TI does not recommend that the  $\overline{\text{SPIPTE}}$  always be tied to the active state.

If the SPI peripheral does ever lose synchronization with the controller, toggling SPISWRESET resets the internal bit counter as well as the various status flags in the module. By resetting the bit counter, the SPI interprets the next clock transition as the first bit of a new transmission. The register bit fields that are reset by SPISWRESET are found in [Section 31.6](#).

### Configuring a GPIO to Emulate $\overline{\text{SPIPTE}}$

In many systems, a SPI controller can be connected to multiple SPI peripherals using multiple instances of  $\overline{\text{SPIPTE}}$ . Though this SPI module does not natively support multiple  $\overline{\text{SPIPTE}}$  signals, it is possible to emulate this behavior in software using GPIOs. In this configuration, the SPI must be configured as the controller. Rather than using the GPIO Mux to select  $\overline{\text{SPIPTE}}$ , the application can configure pins to be GPIO outputs, one GPIO per SPI peripheral. Before transmitting any data, the application can drive the desired GPIO to the active state. Immediately after the transmission has been completed, the GPIO chip select can be driven to the inactive state. This process can be repeated for many peripherals that share the SPICLK, SPIPICO, and SPIPOCI lines.

### 31.2.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification must be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups can be configured in the GPyPUD register.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

#### 31.2.2.1 GPIOs Required for High-Speed Mode

The high-speed mode of the SPI is available on the specified GPIO mux options in the device data sheet. To enable the high-speed enhancements, set SPICCR.HS\_MODE to 1. Make sure that the capacitive loading on the pin does not exceed the value stated in the device data sheet.

When not operating in high-speed mode or if the capacitive loading on the pins exceed the value stated in the device data sheet, SPICCR.HS\_MODE can be set to 0.

### 31.2.3 SPI Interrupts

This section includes information on the available interrupts present in the SPI module. The SPI module contains two interrupt lines: SPIINT/SPIRXINT and SPITXINT. When the SPI is operating in non-FIFO mode, all available interrupts are routed together to generate the single SPIINT interrupt. When FIFO mode is used, both SPIRXINT and SPITXINT can be generated.

#### SPIINT/SPIRXINT

When the SPI is operating in non-FIFO mode, the interrupt generated is called SPIINT. If FIFO enhancements are enabled, the interrupt is called SPIRXINT. These interrupts share the same interrupt vector in the Peripheral Interrupt Expansion (PIE) block.

In non-FIFO mode, two conditions can trigger an interrupt: a transmission is complete (INT\_FLAG), or there is overrun in the receiver (OVERRUN\_FLAG). Both of these conditions share the same interrupt vector: SPIINT.

The transmission complete flag (INT\_FLAG) indicates that the SPI has completed sending or receiving the last bit and is ready to be serviced. At the same time this bit is set, the received character is placed in the receiver buffer (SPIRXBUF). The INT\_FLAG generates an interrupt on the SPIINT vector if the SPIINTENA bit is set.

The receiver overrun flag (OVERRUN\_FLAG) indicates that a transmit or receive operation has completed before the previous character has been read from the buffer. The OVERRUN\_FLAG generates an interrupt on the SPIINT vector if the OVERRUNINTENA bit is set and OVERRUN\_FLAG was previously cleared.

In FIFO mode, the SPI can interrupt the CPU upon a match condition between the current receive FIFO status (RXFFST) and the receive FIFO interrupt level (RXFFIL). If RXFFST is greater than or equal to RXFFIL, the receive FIFO interrupt flag (RXFFINT) is set. SPIRXINT is triggered in the PIE block, if RXFFINT is set and the receive FIFO interrupt is enabled (RXFFIENA = 1).

#### SPITXINT

The SPITXINT interrupt is not available when the SPI is operating in non-FIFO mode.

In FIFO mode, the SPITXINT behavior is similar to the SPIRXINT. SPITXINT is generated upon a match condition between the current transmit FIFO status (TXFFST) and the transmit FIFO interrupt level (TXFFIL). If TXFFST is less than or equal to TXFFIL, the transmit FIFO interrupt flag (TXFFINT) is set. SPITXINT is triggered in the PIE block, if TXFFINT is set and the transmit FIFO interrupt is enabled in the SPI module (TXFFIENA = 1).

[Figure 31-2](#) and [Table 31-2](#) show how these control bits influence the SPI interrupt generation.

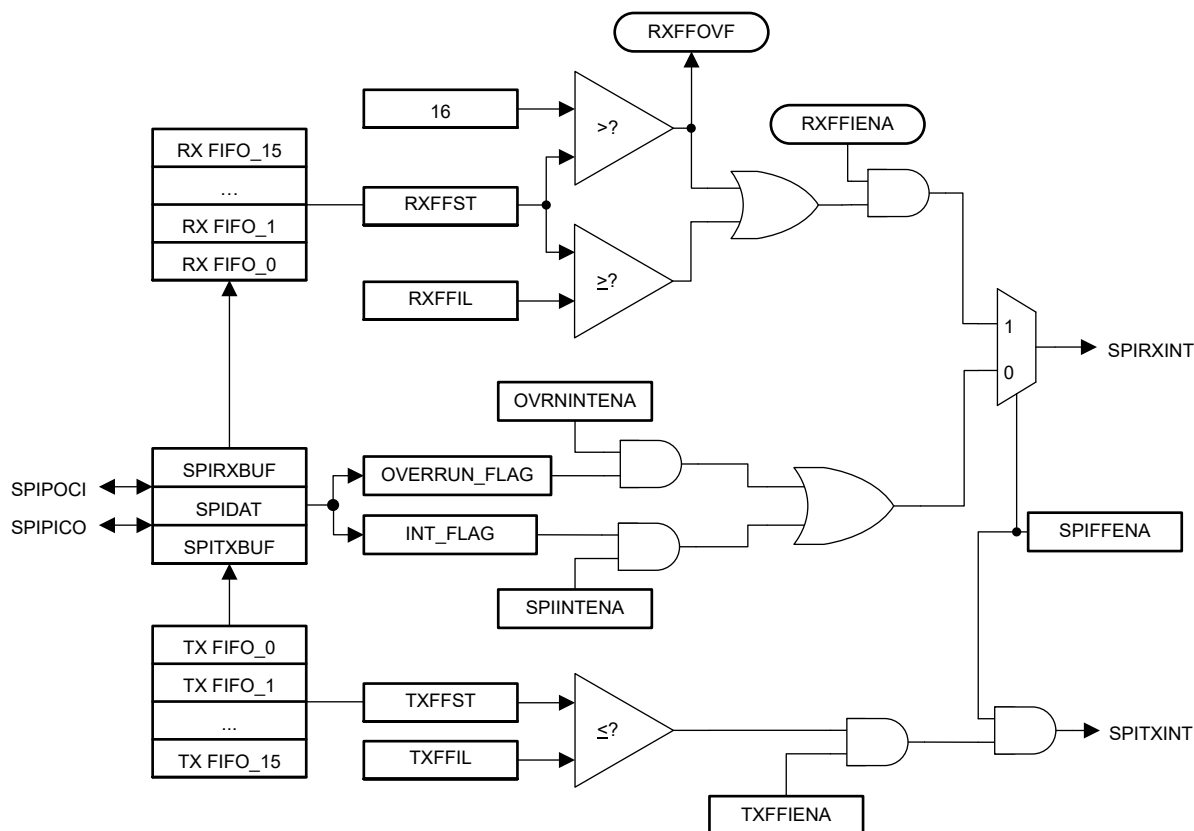

Figure 31-2. SPI Interrupt Flags and Enable Logic Generation

Table 31-2. SPI Interrupt Flag Modes

FIFO Options	SPI Interrupt Source	Interrupt Flags	Interrupt Enables	FIFO Enable (SPIFFENA)	Interrupt Line <sup>(1)</sup>
SPI without FIFO	Receive overrun	RXOVRN	OVRNINTENA	0	SPIRXINT
	Data receive	SPIINT	SPIINTENA	0	SPIRXINT
	Transmit empty	SPIINT	SPIINTENA	0	SPIRXINT
SPI FIFO mode	FIFO receive	RXFFIL	RXFFIENA	1	SPIRXINT
	Transmit empty	TXFFIL	TXFFIENA	1	SPITXINT

(1) In non-FIFO mode, SPIRXINT is the same name as the SPIINT interrupt in C28x devices.

### 31.2.4 DMA Support

Both the CPU and DMA have access to the SPI data registers using the internal peripheral bus. This access is limited to 16-bit register reads and writes. Each SPI module can generate two DMA events, SPITXDMA and SPIRXDMA. The DMA events are controlled by configuring the SPIFFTX.TXFFIL and SPIFFRX.RXFFIL appropriately. SPITXDMA activates when TXFFST is less than the interrupt level (TXFFIL). SPIRXDMA activates when RXFFST is greater than or equal to the interrupt level (RXFFIL).

The SPI must have FIFO enhancements enabled for the DMA triggers to be generated.

For more information on configuring the SPI for DMA transfers, refer to [Section 31.3.8](#).

Figure 31-3 is a block diagram showing the DMA trigger generation from the SPI module.

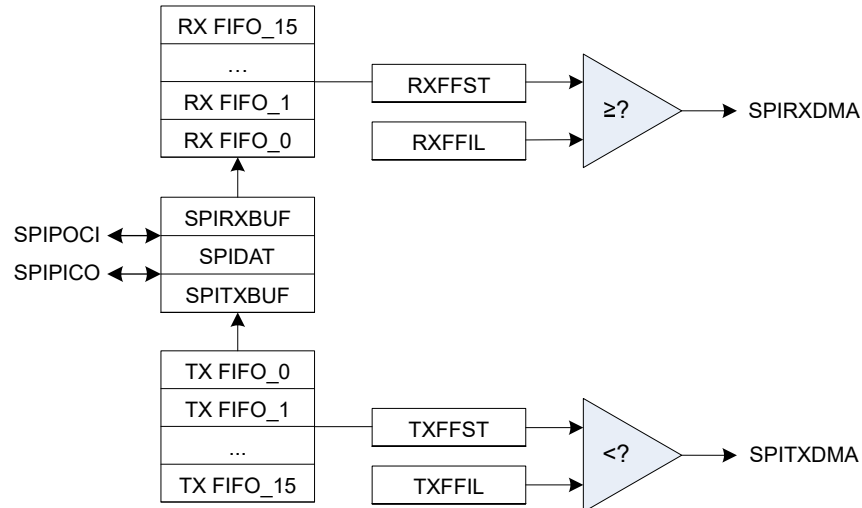

Figure 31-3. SPI DMA Trigger Diagram

### 31.3 SPI Operation

This section describes the various modes of operation of the SPI. Included are explanations of the operational modes, interrupts, data format, clock sources, and initialization. Typical timing diagrams for data transfers are given.

#### 31.3.1 Introduction to Operation

Figure 31-4 shows typical connections of the SPI for communications between two controllers: a controller and a peripheral.

The controller transfers data by sending the SPICLK signal. For both the peripheral and the controller, data is shifted out of the shift registers on one edge of the SPICLK and latched into the shift register on the opposite SPICLK clock edge. If the CLK\_PHASE bit is high, data is transmitted and received a half-cycle before the SPICLK transition. As a result, both controllers send and receive data simultaneously. The application software determines whether the data is meaningful or dummy data. There are three possible methods for data transmission:

- Controller sends data; peripheral sends dummy data.
- Controller sends data; peripheral sends data.
- Controller sends dummy data; peripheral sends data.

The controller can initiate data transfer at any time because the controller controls the SPICLK signal. The software, however, determines how the controller detects when the peripheral is ready to broadcast data.

The SPI operates in controller or peripheral mode. The CONTROLLER\_PERIPHERAL bit selects the operating mode and the source of the SPICLK signal.

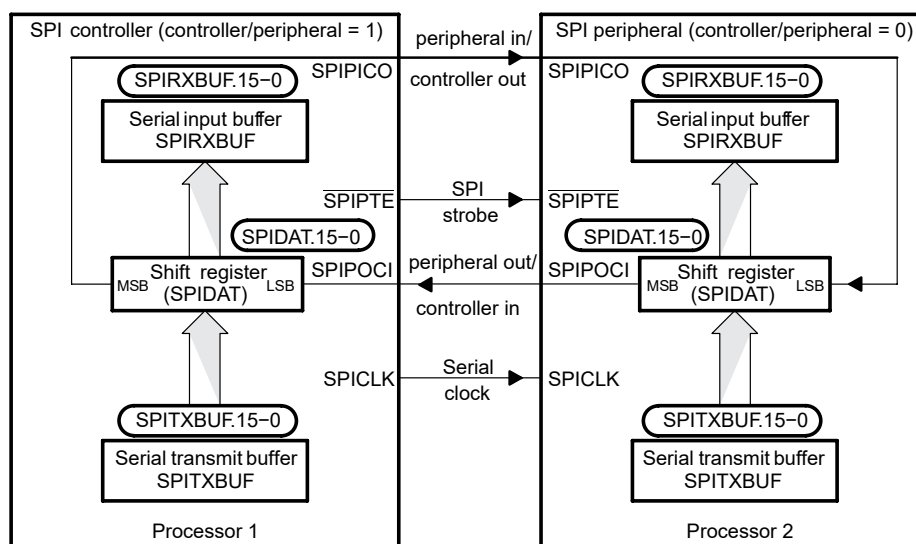

Figure 31-4. SPI Controller/Peripheral Connection

### 31.3.2 Controller Mode

In controller mode (CONTROLLER\_PERIPHERAL = 1), the SPI provides the serial clock on the SPICLK pin for the entire serial communications network. Data is output on the SPIPICO pin and latched from the SPIPOCI pin.

The SPIBRR register determines both the transmit and receive bit transfer rate for the network. SPIBRR can select 125 different data transfer rates.

Data written to SPIDAT or SPITXBUF initiates data transmission on the SPIPICO pin, MSB (most-significant bit) first. Simultaneously, received data is shifted through the SPIPOCI pin into the LSB (least-significant bit) of SPIDAT. When the selected number of bits has been transmitted, the received data is transferred to the SPIRXBUF (buffered receiver) for the CPU to read. Data is stored right-justified in SPIRXBUF.

When the specified number of data bits has been shifted through SPIDAT, the following events occur:

- SPIDAT contents are transferred to SPIRXBUF.
- INT\_FLAG bit is set to 1.
- If there is valid data in the transmit buffer SPITXBUF, as indicated by the transmit buffer full flag (BUFFULL\_FLAG), this data is transferred to SPIDAT and is transmitted; otherwise, SPICLK stops after all bits have been shifted out of SPIDAT.
- If the SPIINTENA bit is set to 1, an interrupt is asserted.

In a typical application, the  $\overline{\text{SPIPTE}}$  pin serves as a chip-enable pin for a SPI peripheral device. This pin is driven low by the controller before transmitting data to the peripheral and is taken high after the transmission is complete.

[Figure 31-5](#) is a block diagram of the SPI in controller mode. The block diagram shows the basic control blocks available in SPI controller mode.

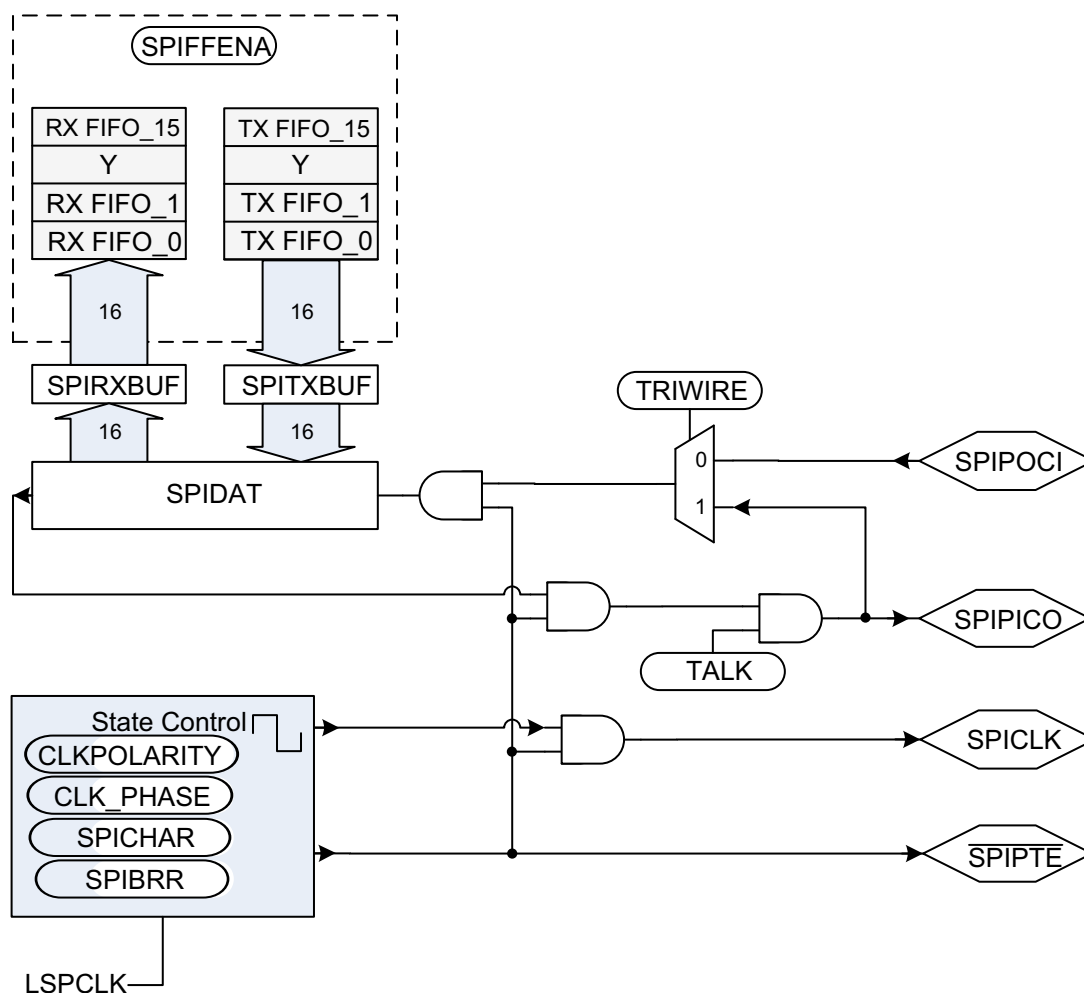

Figure 31-5. SPI Module Controller Configuration

### 31.3.3 Peripheral Mode

In peripheral mode (`CONTROLLER_PERIPHERAL = 0`), data shifts out on the SPIPOCI pin and in on the SPIPICO pin. The SPICLK pin is used as the input for the serial shift clock, which is supplied from the external network controller. The transfer rate is defined by this clock. The SPICLK input frequency can be no greater than the LSPCLK frequency divided by 4.

Data written to SPIDAT or SPITXBUF is transmitted to the network when appropriate edges of the SPICLK signal are received from the network controller. A character written to the SPITXBUF register is copied to the SPIDAT register when all bits of the current character in SPIDAT have been shifted out. If no character was previously copied to SPIDAT, then any character written to SPITXBUF is immediately copied to SPIDAT. If a character was previously copied to SPIDAT, any data written to SPITXBUF is not copied to SPIDAT until the current character in SPIDAT has been shifted out. To receive data, the SPI waits for the network controller to send the SPICLK signal and then shifts the data on the SPIPICO pin into SPIDAT. If data is to be transmitted by the peripheral simultaneously, and SPIDAT has not been previously loaded, the character must be written to SPITXBUF before the beginning of the SPICLK signal.

When the TALK bit is cleared, data transmission is disabled, and the output line (SPIPOCI) is put into the high-impedance state. If this occurs while a transmission is active, the current character is completely transmitted even though SPIPOCI is forced into the high-impedance state. This makes sure that the SPI is still able to

receive incoming data correctly. This TALK bit allows many peripheral devices to be tied together on the network, but only one peripheral at a time is allowed to drive the SPIPOCI line.

The  $\overline{\text{SPIPTE}}$  pin operates as the peripheral-select pin. An active-low signal on the  $\overline{\text{SPIPTE}}$  pin allows the peripheral SPI to transfer data to the serial data line; an inactive-high signal causes the peripheral SPI serial shift register to stop and the serial output pin to be put into the high-impedance state. This allows many peripheral devices to be tied together on the network, although only one peripheral device is selected at a time.

Figure 31-6 is a block diagram of the SPI in peripheral mode. The block diagram shows the basic control blocks available in SPI peripheral mode.

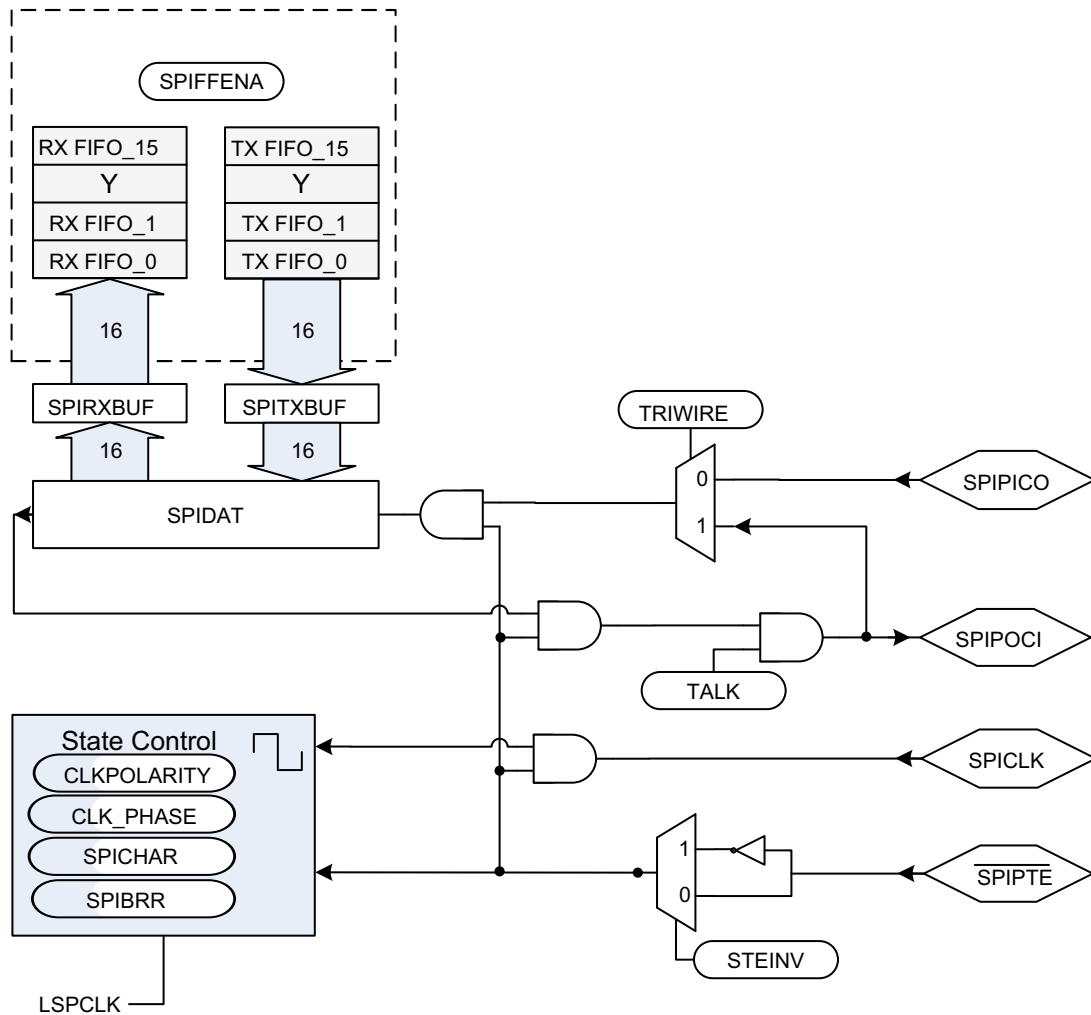

Figure 31-6. SPI Module Peripheral Configuration

### 31.3.4 Data Format

The four-bit SPICHR register field specifies the number of bits in the data character (1 to 16). This information directs the state control logic to count the number of bits received or transmitted to determine when a complete character has been processed.

The following statements apply to characters with fewer than 16 bits:

- Data must be left-justified when written to SPIDAT and SPITXBUF.
- Data read back from SPIRXBUF is right-justified.
- SPIRXBUF contains the most recently received character, right-justified, plus any bits that remain from previous transmission(s) that have been shifted to the left (shown in [Example 31-1](#)).

#### Example 31-1. Transmission of Bit from SPIRXBUF

Conditions:

1. Transmission character length = 1 bit (specified in SPICHR bits)
2. The current value of SPIDAT = 737Bh

SPIDAT (before transmission)																	
	0	1	1	1	0	0	1	1	0	1	1	1	1	0	1	1	
SPIDAT (after transmission)																	
(TXed) 0 ←	1	1	1	0	0	1	1	0	1	1	1	1	0	1	1	x <sup>(1)</sup>	← (RXed)
SPIRXBUF (after transmission)																	
	1	1	1	0	0	1	1	0	1	1	1	1	0	1	1	x <sup>(1)</sup>	

(1) x = 1, if SPIPOCI data is high; x = 0, if SPIPOCI data is low; controller mode is assumed.

### 31.3.5 Baud Rate Selection

The SPI module supports 125 different baud rates and four different clock schemes. Depending on whether the SPI clock is in peripheral or controller mode, the SPICLK pin can receive an external SPI clock signal or provide the SPI clock signal, respectively.

- In the peripheral mode, the SPI clock is received on the SPICLK pin from the external source and can be no greater than the LSPCLK frequency divided by 4.
- In the controller mode, the SPI clock is generated by the SPI and is output on the SPICLK pin and can be no greater than the LSPCLK frequency divided by 4.

---

#### Note

The baud rate must be configured to not exceed the maximum rated GPIO toggle frequency. Refer to the device data sheet for the maximum GPIO toggle frequency.

---

[Example 31-2](#) shows how to determine the SPI baud rates.

[Example 31-3](#) shows how to calculate the baud rate of the SPI module in standard SPI mode (`HS_MODE = 0`).

#### Example 31-2. Baud Rate Determination

For SPIBRR = 3 to 127:

$$\text{SPI Baud Rate} = \frac{\text{LSPCLK}}{(\text{SPIBRR} + 1)}$$

For SPIBRR = 0, 1, or 2:

$$\text{SPI Baud Rate} = \frac{\text{LSPCLK}}{4}$$

where:

LSPCLK = Low-speed peripheral clock frequency of the device

SPIBRR = Contents of the SPIBRR in the controller SPI device

To determine what value to load into SPIBRR, you must know the device system clock (LSPCLK) frequency (that is device-specific) and the baud rate at which you are operating.

#### Example 31-3. Baud Rate Calculation in Non-High Speed Mode (`HS_MODE = 0`)

$$\begin{aligned} \text{SPI Baud Rate} &= \frac{\text{LSPCLK}}{\text{SPIBRR} + 1} \quad \text{LSPCLK} = 50 \text{ MHz} \\ &= \frac{50 \times 10^6}{3 + 1} \\ &= 12.5 \text{ Mbps} \end{aligned}$$

### 31.3.6 SPI Clocking Schemes

The clock polarity select bit (CLKPOLARITY) and the clock phase select bit (CLK\_PHASE) control four different clocking schemes on the SPICLK pin. CLKPOLARITY selects the active edge, either rising or falling, of the clock. CLK\_PHASE selects a half-cycle delay of the clock. The four different clocking schemes are:

- Falling Edge Without Delay. The SPI transmits data on the falling edge of the SPICLK and receives data on the rising edge of the SPICLK.
- Falling Edge With Delay. The SPI transmits data one half-cycle ahead of the falling edge of the SPICLK signal and receives data on the falling edge of the SPICLK signal.
- Rising Edge Without Delay. The SPI transmits data on the rising edge of the SPICLK signal and receives data on the falling edge of the SPICLK signal.
- Rising Edge With Delay. The SPI transmits data one half-cycle ahead of the rising edge of the SPICLK signal and receives data on the rising edge of the SPICLK signal.

The selection procedure for the SPI clocking scheme is shown in [Table 31-3](#). Examples of these four clocking schemes relative to transmitted and received data are shown in [Figure 31-7](#).

**Table 31-3. SPI Clocking Scheme Selection Guide**

SPICLK Scheme	CLKPOLARITY <sup>(1)</sup>	CLK_PHASE <sup>(1)</sup>
Rising edge without delay	0	0
Rising edge with delay	0	1
Falling edge without delay	1	0
Falling edge with delay	1	1

(1) The description of CLK\_PHASE and CLKPOLARITY differs between manufacturers. For proper operation, select the desired waveform to determine the clock phase and clock polarity settings.

**Note:** Previous data bit

**Figure 31-7. SPICLK Signal Options**

SPICLK symmetry is retained only when the result of  $(SPIBRR + 1)$  is an even value. When  $(SPIBRR + 1)$  is an odd value and  $SPIBRR$  is greater than 3, SPICLK becomes asymmetrical. The low pulse of SPICLK is one LSPCLK cycle longer than the high pulse when  $CLKPOLARITY$  bit is clear (0). When  $CLKPOLARITY$  bit is set to 1, the high pulse of the SPICLK is one LSPCLK cycle longer than the low pulse, as shown in [Figure 31-8](#).

**Figure 31-8. SPI: SPICLK-LSPCLK Characteristic when  $(BRR + 1)$  is Odd,  $BRR > 3$ , and  $CLKPOLARITY = 1$**

### 31.3.7 SPI FIFO Description

The following steps explain the FIFO features and help with programming the SPI FIFOs:

- Reset.** At reset the SPI powers up in standard SPI mode and the FIFO function is disabled. The FIFO registers SPIFFTX, SPIFFRX and SPIFFCT remain inactive.
- Standard SPI.** The standard 28x SPI mode works with SPIINT/SPIRXINT as the interrupt source.
- Mode change.** FIFO mode is enabled by setting the SPIFFENA bit to 1 in the SPIFFTX register. SPIRST can reset the FIFO mode at any stage of the operation.
- Active registers.** All the SPI registers and SPI FIFO registers SPIFFTX, SPIFFRX, and SPIFFCT are active.
- Interrupts.** FIFO mode has two interrupts: one for the transmit FIFO, SPITXINT; one for the receive FIFO, SPIRXINT. SPIRXINT is the common interrupt for SPI FIFO receive, receive error and receive FIFO overflow conditions. The single SPIINT for both transmit and receive sections of the standard SPI are disabled and this interrupt is serviced as SPI receive FIFO interrupt. For more information, refer to [Section 31.2.3](#).
- Buffers.** Transmit and receive buffers are each supplemented with a -word FIFO. The one-word transmit buffer (SPITXBUF) of the standard SPI functions as a transition buffer between the transmit FIFO and shift register. The one-word transmit buffer is loaded from transmit FIFO only after the last bit of the shift register is shifted out.
- Delayed transfer.** The rate at which transmit words in the FIFO are transferred to transmit shift register is programmable. The SPIFFCT register bits (7–0) FFTXDLY7–FFTXDLY0 define the delay between the word transfer. The delay is defined in number SPI serial clock cycles. The 8-bit register can define a minimum delay of 0 SPICLK cycles and a maximum of 255 SPICLK cycles. With zero delay, the SPI module can transmit data in continuous mode with the FIFO words shifting out back to back. With the 255 clock delay, the SPI module can transmit data in a maximum delayed mode with the FIFO words shifting out with a delay of 255 SPICLK cycles between each words. The programmable delay facilitates glueless interface to various slow SPI peripherals, such as EEPROMs, ADC, DAC, and so on.
- FIFO status bits.** Both transmit and receive FIFOs have status bits TXFFST or RXFFST that define the number of words available in the FIFOs at any time. The transmit FIFO reset bit (TXFIFO) and receive reset bit (RXFIFO) reset the FIFO pointers to zero when these bits are set to 1. The FIFOs resume operation from start once these bits are cleared to zero.
- Programmable interrupt levels.** Both transmit and receive FIFOs can generate CPU interrupts and DMA triggers. The transmit interrupt (SPITXINT) is generated whenever the transmit FIFO status bits (TXFFST) match (less than or equal to) the interrupt trigger level bits (TXFFIL). The receive interrupt (SPIRXINT) is generated whenever the receive FIFO status bits (RXFFST) match (greater than or equal to) the interrupt trigger level RXFFIL. This provides a programmable interrupt trigger for transmit and receive sections of the SPI. The default value for these trigger level bits is 0x11111 for receive FIFO and 0x00000 for transmit FIFO, respectively.

### 31.3.8 SPI DMA Transfers

#### 31.3.8.1 Transmitting Data Using SPI with DMA

When using the DMA with the TX FIFO, the DMA Burst Size (DMA\_BURST\_SIZE) must be no greater than 16 - TXFFIL, to prevent the DMA from writing to an already full FIFO. This leads to data loss and is not recommended.

For complete data transmission, follow these steps:

1. Calculate the total number of words to be transmitted. [NUM\_WORDS]
2. Decide the transmit FIFO level. [TXFFIL]
3. Calculate the total number of DMA transfers. [DMA\_TRANSFER\_SIZE]
4. Calculate the size of the DMA Burst. [DMA\_BURST\_SIZE]
5. Configure DMA using calculated values.
6. Configure SPI with FIFO using the calculated values.

To transfer 128 words to SPI using the DMA:

NUM\_WORDS: 128

TXFFIL: 8

DMA\_TRANSFER\_SIZE:  $(\text{NUM\_WORDS} / \text{TXFFIL}) - 1 = (128/8) - 1 = 15$  (16 transfers)

DMA\_BURST\_SIZE:  $(16 - \text{TXFFIL}) - 1 = (16 - 8) - 1 = 7$  (8 words per burst)

---

#### Note

Avoid setting TXFFIL to 0h or 10h to make sure of proper DMA configuration.

---

#### 31.3.8.2 Receiving Data Using SPI with DMA

When using the DMA with the RX FIFO, the DMA Burst Size (BURST\_SIZE) must be no greater than RXFFIL to prevent the DMA from reading from an empty FIFO. To make sure that the DMA correctly receives all data from the RX FIFO, the DMA Burst Size can equal RXFFIL and also be an integer divisor of the total number of SPI transmissions.

For complete data reception, follow these steps:

1. Calculate the total number of words to be received. [NUM\_WORDS]
2. Calculate the necessary FIFO level [RXFFIL]
3. Calculate the total number of DMA transfers. [DMA\_TRANSFER\_SIZE]
4. Calculate the size of the DMA Burst. [DMA\_BURST\_SIZE]
5. Configure DMA using the calculated values.
6. Configure SPI with FIFO using the calculated values.

To receive 200 words from SPI using the DMA:

NUM\_WORDS = 200

RXFFIL: 4

DMA\_TRANSFER\_SIZE:  $(\text{NUM\_WORDS} / \text{RXFFIL}) - 1 = (200/4) - 1 = 49$  (50 transfers)

DMA\_BURST\_SIZE = RXFFIL - 1 = 3 (4 words per burst)

---

#### Note

Avoid setting RXFFIL to 0h to make sure proper DMA configuration.

---

### 31.3.9 SPI High-Speed Mode

The SPI module is capable of reaching full-duplex communication speeds up to LSPCLK/4 (where LSPCLK equals SYSCLK). For the maximum rated speed, refer to the device data sheet.

To achieve the maximum full-duplex speeds, the following restrictions are placed on the design:

- Single controller to single peripheral configuration is supported.
- Loading on the pins must not exceed the value stated in the device data sheet.

When configuring the GPIOs to support high-speed mode, refer to [Section 31.2.2.1](#) for more information.

### 31.3.10 SPI 3-Wire Mode Description

SPI 3-wire mode allows for SPI communication over three pins instead of the normal four pins.

In controller mode, if the TRIWIRE bit is set, enabling 3-wire SPI mode, SPIPICOx becomes the bi-directional SPICOCIx (SPI controller out, controller in) pin, and SPIPOCix is no longer used by the SPI. In peripheral mode, if the TRIWIRE bit is set, SPIPOCix becomes the bi-directional SPIPIPOx (SPI peripheral in, peripheral out) pin, and SPIPICOx is no longer used by the SPI.

[Table 31-4](#) indicates the pin function differences between 3-wire and 4-wire SPI mode for a controller and peripheral SPI.

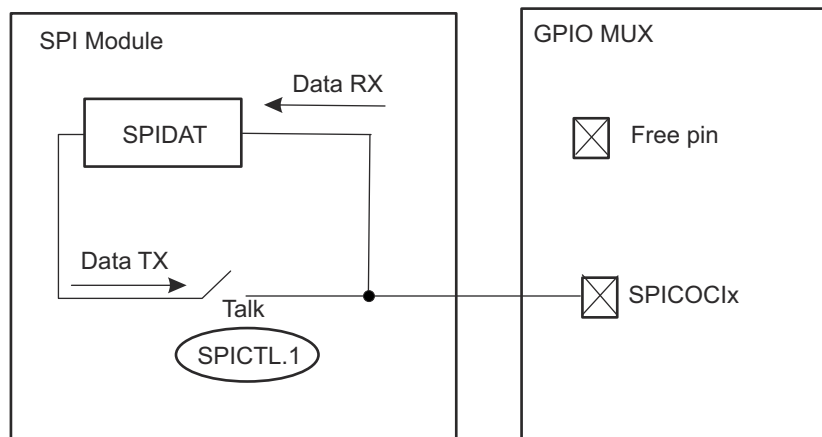

**Table 31-4. 4-wire versus 3-wire SPI Pin Functions**

4-wire SPI	3-wire SPI (Controller)	3-wire SPI (Peripheral)
SPICLKx	SPICLKx	SPICLKx
SPISTEx	SPISTEx	SPISTEx
SPIPICOx	SPICOCIx	Free
SPIPOCix	Free	SPIPIPOx

Because in 3-wire mode, the receive and transmit paths within the SPI are connected, any data transmitted by the SPI module is also received. The application software must take care to perform a dummy read to clear the SPI data register of the additional received data.

The TALK bit plays an important role in 3-wire SPI mode. The bit must be set to transmit data and cleared prior to reading data. In controller mode, to initiate a read, the application software must write dummy data to the SPI data register (SPIDAT or SPIRXBUF) while the TALK bit is cleared (no data is transmitted out the SPICOCi pin) before reading from the data register.

[Figure 31-9](#) and [Figure 31-10](#) illustrate 3-wire controller and peripheral mode.

**Figure 31-9. SPI 3-wire Controller Mode**

**Figure 31-10. SPI 3-wire Peripheral Mode**

Table 31-5 indicates how data is received or transmitted in the various SPI modes while the TALK bit is set or cleared.

**Table 31-5. 3-Wire SPI Pin Configuration**

Pin Mode	SPIPRI[TRIWIRE]	SPICTL[TALK]	SPIPICO	SPIPOCI
<b>Controller Mode</b>				
4-wire	0	X	TX	RX
3-pin mode	1	0	RX	Disconnect from SPI
		1	TX/RX	
<b>Peripheral Mode</b>				
4-wire	0	X	RX	TX
3-pin mode	1	0	Disconnect from SPI	RX
		1		TX/RX

## 31.4 Programming Procedure

This section describes the procedure for configuring the SPI for the various modes of operation.

### 31.4.1 Initialization Upon Reset

A system reset forces the SPI peripheral into the following default configuration:

- Unit is configured as a peripheral module (CONTROLLER\_PERIPHERAL = 0)
- Transmit capability is disabled (TALK = 0)
- Data is latched at the input on the falling edge of the SPICLK signal
- Character length is assumed to be one bit
- SPI interrupts are disabled
- Data in SPIDAT is reset to 0000h

### 31.4.2 Configuring the SPI

This section describes the procedure in which to configure the SPI module for operation. To prevent unwanted and unforeseen events from occurring during or as a result of initialization changes, clear the SPISWRESET bit before making initialization changes, and then set this bit after initialization is complete. While the SPI is held in reset (SPISWRESET = 0), configuration can be changed in any order. The following list shows the SPI configuration procedure in a logical order. However, the SPI registers can be written with single 16-bit writes, so the order is not required with the exception of SPISWRESET.

---

#### Note

Do not change the SPI configuration when communication is in progress.

---

To change the SPI configuration:

1. Clear the SPI Software Reset bit (SPISWRESET) to 0 to force the SPI to the reset state.
2. Configure the SPI as desired:
  - Select either controller or peripheral mode (CONTROLLER\_PERIPHERAL).
  - Choose SPICLK polarity and phase (CLKPOLARITY and CLK\_PHASE).
  - Set the desired baud rate (SPIBRR).
  - Enable high-speed mode, if desired (HS\_MODE).
  - Set the SPI character length (SPICHR).
  - Clear the SPI Flags (OVERRUN\_FLAG, INT\_FLAG).
  - Enable  $\overline{\text{SPIPTE}}$  inversion (STEINV), if needed.
  - Enable 3-wire mode (TRIWIRE), if needed.
  - If using FIFO enhancements:
    - Enable the FIFO enhancements (SPIFFENA).
    - Clear the FIFO Flags (TXFFINTCLR, RXFFOVFCLR, and RXFFINTCLR).
    - Release transmit and receive FIFO resets (TXFIFO and RXFIFORESET).
    - Release SPI FIFO channels from reset (SPIRST).
3. If interrupts are used:
  - In non-FIFO mode, enable the receiver overrun and/or SPI interrupts (OVERRUNINTENA and SPIINTENA).
  - In FIFO mode, set the transmit and receive interrupt levels (TXFFIL and RXFFIL) then enable the interrupts (TXFFIENA and RXFFIENA).
4. Set SPISWRESET to 1 to release the SPI from the reset state.

### 31.4.3 Configuring the SPI for High-Speed Mode

To achieve the maximum rated speeds, the following settings must be made. This example assumes that the device is operating at 100MHz.

Set LSPCLK equal to SYSCLK:

```
ClkCfgRegs.LOSPCP.bit.LSPCLKDIV = 0;
```

Select the appropriate Pin Mux options in GPIO\_CTRL\_REGS.

During the SPI configuration procedure:

Set HS\_MODE to 1.

```
SPIARegs.SPICCR.bit.HS_MODE = 0x1;
```

Set SPIBRR to 3.  $SPICLK = LSPCLK / (SPIBRR + 1) = 25\text{MHz}$

```
SPIARegs.SPIBRR = 0x3;
```

There are no other differences in the configuration from normal SPI operation. Sending and receiving data, DMA operation, and interrupts operates without change.

### 31.4.4 Data Transfer Example

The timing diagram shown in [Figure 31-11](#) shows an SPI data transfer between two devices using a character length of five bits with the SPICLK being symmetrical.

The timing diagram with SPICLK asymmetrical ([Figure 31-8](#)) shares similar characterizations with [Figure 31-11](#) except that the data transfer is one LSPCLK cycle longer per bit during the low pulse (CLKPOLARITY = 0) or during the high pulse (CLKPOLARITY = 1) of the SPICLK.

[Figure 31-11](#) is applicable for 8-bit SPI only and is not for C28x devices that are capable of working with 16-bit data. The figure is shown for illustrative purposes only.

- A. Peripheral writes 0D0h to SPIDAT and waits for the controller to shift out the data.
- B. Controller sets the peripheral SPIPTE signal low (active).
- C. Controller writes 058h to SPIDAT, which starts the transmission procedure.
- D. First byte is finished and sets the interrupt flags.
- E. Peripheral reads 0Bh from the SPIRXBUF (right-justified).
- F. Peripheral writes 04Ch to SPIDAT and waits for the controller to shift out the data.
- G. Controller writes 06Ch to SPIDAT, which starts the transmission procedure.
- H. Controller reads 01Ah from the SPIRXBUF (right-justified).
- I. Second byte is finished and sets the interrupt flags.
- J. Controller reads 89h and the peripheral reads 8Dh from the respective SPIRXBUF. After the user software masks off the unused bits, the controller receives 09h and the peripheral receives 0Dh.
- K. Controller clears the peripheral SPIPTE signal high (inactive).

**Figure 31-11. Five Bits per Character**

### 31.4.5 SPI 3-Wire Mode Code Examples

In addition to the normal SPI initialization, to configure the SPI module for 3-wire mode, the TRIWIRE bit (SPIPRI.0) must be set to 1. After initialization, there are several considerations to take into account when transmitting and receiving data in 3-wire controller and peripheral mode. The following examples demonstrate these considerations.

In 3-wire controller mode, SPICLKx,  $\overline{\text{SPIPTEx}}$ , and SPIPICOx pins must be configured as SPI pins (SPIPOCIx pin can be configured as non-SPI pin). When the controller transmits, the controller receives the data the controller transmits (because SPIPICOx and SPIPOCIx are connected internally in 3-wire mode). Therefore, the junk data received must be cleared from the receive buffer every time data is transmitted.

#### Example 31-4. 3-Wire Controller Mode Transmit

```

uint16 data;
uint16 dummy;
    SpiaRegs.SPICTL.bit.TALK = 1;           // Enable Transmit path
    SpiaRegs.SPITXBUF = data; // Controller transmits data
    while(SpiaRegs.SPISTS.bit.INT_FLAG !=1) {} // waits until data rx'd
    dummy = SpiaRegs.SPIRXBUF;             // Clears junk data because
                                           // rx'd same data as tx'd
    
```

To receive data in 3-wire controller mode, the controller must clear the TALK (SPICTL.1) bit to 0 to close the transmit path and then transmit dummy data to initiate the transfer from the peripheral. Because the TALK bit is 0, unlike in transmit mode, the controller dummy data does not appear on the SPIPICOx pin, and the controller does not receive the dummy data. Instead, the data from the peripheral is received by the controller.

#### Example 31-5. 3-Wire Controller Mode Receive

```

uint16 rdata;
uint16 dummy;
    SpiaRegs.SPICTL.bit.TALK = 0;           // Disable Transmit path
    SpiaRegs.SPITXBUF = dummy;             // Send dummy to start tx
    // NOTE: because TALK = 0, data does not tx onto SPIPICOA pin
    while(SpiaRegs.SPISTS.bit.INT_FLAG !=1) {} // wait until data received
    rdata = SpiaRegs.SPIRXBUF;             // Controller reads data
    
```

In 3-wire peripheral mode, SPICLKx, SPISTEx, and SPIPOCIx pins must be configured as SPI pins (SPIPICOx pin can be configured as non-SPI pin). Like in controller mode, when transmitting, the peripheral receives the data transmitted and must clear this junk data from the receive buffer.

#### Example 31-6. 3-Wire Peripheral Mode Transmit

```

uint16 data;
uint16 dummy;
    SpiaRegs.SPICTL.bit.TALK = 1;           // Enable Transmit path
    SpiaRegs.SPITXBUF = data;             // Peripheral transmits data
    while(SpiaRegs.SPISTS.bit.INT_FLAG !=1) {} // wait until data rx'd
    dummy = SpiaRegs.SPIRXBUF;             // Clears junk data
    
```

As in 3-wire controller mode, the TALK bit must be cleared to 0. Otherwise, the peripheral receives data normally.

**Example 31-7. 3-Wire Peripheral Mode Receive**

```
uint16 rdata;
SpiRegs.SPCTL.bit.TALK = 0; // Disable Transmit path
while(SpiRegs.SPISTS.bit.INT_FLAG !=1) {} // waits until data rx'd
rdata = SpiRegs.SPIRXBUF; // Peripheral reads data
```

### 31.4.6 SPI STEINV Bit in Digital Audio Transfers

On those devices with two SPI modules, enabling the STEINV bit on one of the SPI modules allows the pair of SPIs to receive both left and right-channel digital audio data in peripheral mode. The SPI module that receives a normal active-low  $\overline{\text{SPIPTE}}$  signal stores right-channel data, and the SPI module that receives an inverted active-high  $\overline{\text{SPIPTE}}$  signal stores left-channel data from the controller. To receive digital audio data from a digital audio interface receiver, the SPI modules can be connected as shown in Figure 31-12.

**Note**

This configuration is only applicable to peripheral mode (CONTROLLER\_PERIPHERAL = 0). When the SPI is configured as controller (CONTROLLER\_PERIPHERAL = 1), the STEINV bit has no effect on the  $\overline{\text{SPIPTE}}$  pin.

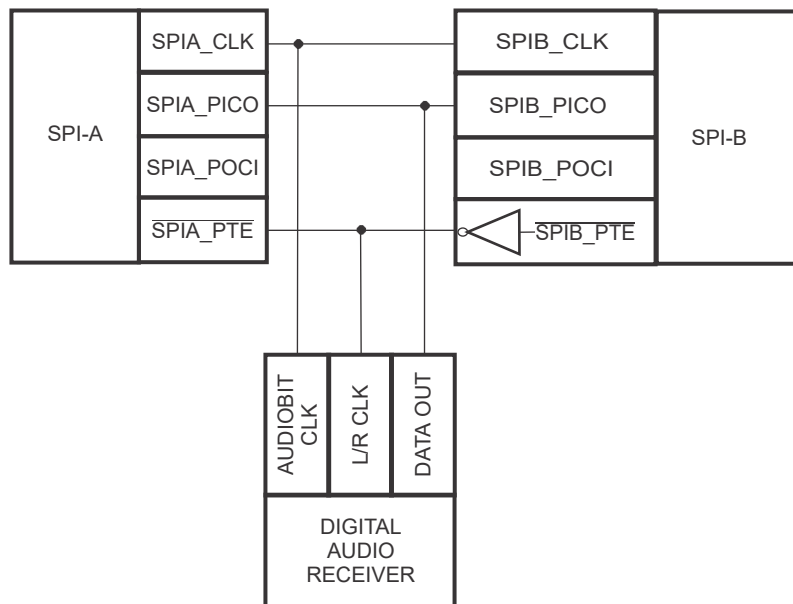

Figure 31-12. SPI Digital Audio Receiver Configuration Using Two SPIs

Standard C28x SPI timing requirements limit the number of digital audio interface formats supported using the 2-SPI configuration with the STEINV bit. See the device data sheet electrical specifications for SPI timing requirements. With the SPI clock phase configured such that the CLKPOLARITY bit is 0 and the CLK\_PHASE bit is 1 (data latched on rising edge of clock), standard right-justified digital audio interface data format is supported as shown in Figure 31-13.

Figure 31-13. Standard Right-Justified Digital Audio Data Format

## 31.5 Software

### 31.5.1 SPI Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/spi

Cloud access to these examples is available at the following link: [dev.ti.com](https://dev.ti.com) [C2000Ware Examples](#).

#### 31.5.1.1 SPI Digital Loopback - SINGLE\_CORE

FILE: spi\_ex1\_loopback.c

This program uses the internal loopback test mode of the SPI module. This is a very basic loopback that does not use the FIFOs or interrupts. A stream of data is sent and then compared to the received stream. The pinmux and SPI modules are configured through the sysconfig file.

The sent data looks like this:

```
0000 0001 0002 0003 0004 0005 0006 0007 .... FFFE FFFF 0000
```

This pattern is repeated forever.

##### *External Connections*

- None

##### *Watch Variables*

- *sData* - Data to send
- *rData* - Received data

#### 31.5.1.2 SPI Digital Loopback with FIFO Interrupts - SINGLE\_CORE

FILE: spi\_ex2\_loopback\_fifo\_interrupts.c

This program uses the internal loopback test mode of the SPI module. Both the SPI FIFOs are used, and SPI RX interrupt is used.

A stream of data is sent and then compared to the received stream. The sent data looks like this:

```
0000 0001
```

```
0001 0002
```

```
0002 0003
```

```
....
```

```
FFFE FFFF
```

```
FFFF 0000
```

```
etc..
```

This pattern is repeated forever.

Note : The SPI peripheral generates level interrupts, which should be cleared in ISR to avoid generating false pending interrupt on clear edge, followed by some wait cycles

##### *External Connections*

- None

##### *Watch Variables*

- *sData* - Data to send
- *rData* - Received data
- *rDataPoint* - Used to keep track of the last position in the receive stream for error checking

#### 31.5.1.3 SPI Digital External Loopback without FIFO Interrupts - SINGLE\_CORE

FILE: spi\_ex3\_external\_loopback.c

This program uses the external loopback between two SPI modules. Both the SPI FIFOs and interrupts are not used in this example. SPIA is configured as a peripheral and SPI B is configured as controller. This

example demonstrates full duplex communication where both controller and peripheral transmits and receives data simultaneously.

#### *External Connections*

-GPIO16 and GPIO63 - SPIPICO -GPIO17 and GPIO25 - SPIPOCI -GPIO34 and GPIO26 - SPICLK -GPIO61 and GPIO27 - SPISTE

#### *Watch Variables*

- *TxData\_SPIA* - Data send from SPIA (peripheral)
- *TxData\_SPIB* - Data send from SPIB (controller)
- *RxData\_SPIA* - Data received by SPIA (peripheral)
- *RxData\_SPIB* - Data received by SPIB (controller)

#### **31.5.1.4 SPI Digital External Loopback with FIFO Interrupts - SINGLE\_CORE**

FILE: spi\_ex4\_external\_loopback\_fifo\_interrupts.c

This program uses the external loopback between two SPI modules. Both the SPI FIFOs are used. SPI-A is configured as a peripheral and receives data from SPI-B which is configured as a controller. SPI-A RX interrupt is used.

A stream of data is sent and then compared to the received stream. The sent data looks like this:

```
0000 0001
0001 0002
0002 0003
```

....

```
FFFF FFFF
FFFF 0000
```

etc..

This pattern is repeated forever.

Note : The SPI peripheral generates level interrupts, which should be cleared in ISR to avoid generating false pending interrupt on clear edge, followed by some wait cycles

#### *External Connections*

-GPIO16 and GPIO63 - SPIPICO -GPIO17 and GPIO25 - SPIPOCI -GPIO34 and GPIO26 - SPICLK -GPIO61 and GPIO27 - SPISTE

#### *Watch Variables*

- *sData* - Data to send
- *rData* - Received data
- *rDataPoint* - Used to keep track of the last position in the receive stream for error checking

#### **31.5.1.5 SPI Digital Loopback with DMA - SINGLE\_CORE**

FILE: spi\_ex5\_loopback\_dma.c

This program uses the internal loopback test mode of the SPI module. Both DMA interrupts and the SPI FIFOs are used. When the SPI transmit FIFO has enough space (as indicated by its FIFO level interrupt signal), the DMA will transfer data from global variable *sData* into the FIFO. This will be transmitted to the receive FIFO via the internal loopback.

When enough data has been placed in the receive FIFO (as indicated by its FIFO level interrupt signal), the DMA will transfer the data from the FIFO into global variable *rData*.

When all data has been placed into *rData*, a check of the validity of the data will be performed in one of the DMA channels' ISRs.

#### *External Connections*

- None

### Watch Variables

- *sData* - Data to send
- *rData* - Received data

## 31.6 SPI Registers

This section describes the Serial Peripheral Interface registers. It is important to note that the SPI registers only allow 16-bit accesses.

### 31.6.1 SPI Base Address Table

**Table 31-6. SPI Base Address Table**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	CPU2	CPU2.DMA	Pipeline Protected
Instance	Structure								
SpiaRegs	<a href="#">SPI_REGS</a>	SPIA_BASE	0x0000_6100	YES	YES	YES	YES	YES	YES
SpibRegs	<a href="#">SPI_REGS</a>	SPIB_BASE	0x0000_6110	YES	YES	YES	YES	YES	YES
SpicRegs	<a href="#">SPI_REGS</a>	SPIC_BASE	0x0000_6120	YES	YES	YES	YES	YES	YES
SpidRegs	<a href="#">SPI_REGS</a>	SPID_BASE	0x0000_6130	YES	YES	YES	YES	YES	YES

### 31.6.2 SPI\_REGS Registers

Table 31-7 lists the memory-mapped registers for the SPI\_REGS registers. All register offset addresses not listed in Table 31-7 should be considered as reserved locations and the register contents should not be modified.

**Table 31-7. SPI\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	SPICCR	SPI Configuration Control Register		<a href="#">Go</a>
1h	SPICTL	SPI Operation Control Register		<a href="#">Go</a>
2h	SPISTS	SPI Status Register		<a href="#">Go</a>
4h	SPIBRR	SPI Baud Rate Register		<a href="#">Go</a>
6h	SPIRXEMU	SPI Emulation Buffer Register		<a href="#">Go</a>
7h	SPIRXBUF	SPI Serial Input Buffer Register		<a href="#">Go</a>
8h	SPITXBUF	SPI Serial Output Buffer Register		<a href="#">Go</a>
9h	SPIDAT	SPI Serial Data Register		<a href="#">Go</a>
Ah	SPIFFTX	SPI FIFO Transmit Register		<a href="#">Go</a>
Bh	SPIFFRX	SPI FIFO Receive Register		<a href="#">Go</a>
Ch	SPIFFCT	SPI FIFO Control Register		<a href="#">Go</a>
Fh	SPIPRI	SPI Priority Control Register		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 31-8 shows the codes that are used for access types in this section.

**Table 31-8. SPI\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
RC	R C	Read to Clear
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
Reset or Default Value		
-n		Value after reset or the default value

### 31.6.2.1 SPICCR Register (Offset = 0h) [Reset = 0000h]

SPICCR is shown in [Figure 31-14](#) and described in [Table 31-9](#).

Return to the [Summary Table](#).

SPICCR controls the setup of the SPI for operation.

**Figure 31-14. SPICCR Register**

RESERVED							
R-0h							
7	6	5	4	3	2	1	0
SPISWRESET	CLKPOLARITY	HS_MODE	SPI1BK	SPICCHAR			
R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h			

**Table 31-9. SPICCR Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-8	RESERVED	R	0h	Reserved
7	SPISWRESET	R/W	0h	<p>SPI Software Reset</p> <p>When changing configuration, you should clear this bit before the changes and set this bit before resuming operation.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Initializes the SPI operating flags to the reset condition. Specifically, the RECEIVER OVERRUN Flag bit (SPISTS.7), the SPI INT FLAG bit (SPISTS.6), and the TXBUF FULL Flag bit (SPISTS.5) are cleared. SPIPTE will become inactive. SPICLK will be immediately driven to 0 regardless of the clock polarity. The SPI configuration remains unchanged.</p> <p>1h (R/W) = SPI is ready to transmit or receive the next character. When the SPI SW RESET bit is a 0, a character written to the transmitter will not be shifted out when this bit is set. A new character must be written to the serial data register. SPICLK will be returned to its inactive state one SPICLK cycle after this bit is set.</p>
6	CLKPOLARITY	R/W	0h	<p>Shift Clock Polarity</p> <p>This bit controls the polarity of the SPICLK signal. CLOCK POLARITY and POLARITY CLOCK PHASE (SPICTL.3) control four clocking schemes on the SPICLK pin.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Data is output on rising edge and input on falling edge. When no SPI data is sent, SPICLK is at low level. The data input and output edges depend on the value of the CLOCK PHASE bit (SPICTL.3) as follows:</p> <ul style="list-style-type: none"> <li>- CLOCK PHASE = 0: Data is output on the rising edge of the SPICLK signal. Input data is latched on the falling edge of the SPICLK signal.</li> <li>- CLOCK PHASE = 1: Data is output one half-cycle before the first rising edge of the SPICLK signal and on subsequent falling edges of the SPICLK signal. Input data is latched on the rising edge of the SPICLK signal.</li> </ul> <p>1h (R/W) = Data is output on falling edge and input on rising edge. When no SPI data is sent, SPICLK is at high level. The data input and output edges depend on the value of the CLOCK PHASE bit (SPICTL.3) as follows:</p> <ul style="list-style-type: none"> <li>- CLOCK PHASE = 0: Data is output on the falling edge of the SPICLK signal. Input data is latched on the rising edge of the SPICLK signal.</li> <li>- CLOCK PHASE = 1: Data is output one half-cycle before the first falling edge of the SPICLK signal and on subsequent rising edges of the SPICLK signal. Input data is latched on the falling edge of the SPICLK signal.</li> </ul>

**Table 31-9. SPICCR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
5	HS_MODE	R/W	0h	<p>High Speed Mode Enable Bits</p> <p>This bit determines if the High Speed mode is enabled. The correct GPIOs should be selected in the GPxGMUX/GPxMUX registers.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = SPI High Speed mode disabled. This is the default value after reset.</p> <p>1h (R/W) = SPI High Speed mode enabled,</p>
4	SPILBK	R/W	0h	<p>SPI Loopback Mode Select</p> <p>Loopback mode allows module validation during device testing. This mode is valid only in CONTROLLER mode of the SPI.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = SPI loopback mode disabled. This is the default value after reset.</p> <p>1h (R/W) = SPI loopback mode enabled, PICO/POCI lines are connected internally. Used for module self-tests.</p>
3-0	SPICHR	R/W	0h	<p>Character Length Control Bits</p> <p>These four bits determine the number of bits to be shifted in or SPI CHAR0 out as a single character during one shift sequence.</p> <p>SPICHR = Word length - 1</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = 1-bit word</p> <p>1h (R/W) = 2-bit word</p> <p>7h (R/W) = 8-bit word</p> <p>Fh (R/W) = 16-bit word</p>

### 31.6.2.2 SPICTL Register (Offset = 1h) [Reset = 0000h]

SPICTL is shown in [Figure 31-15](#) and described in [Table 31-10](#).

Return to the [Summary Table](#).

SPICTL controls data transmission, the SPI's ability to generate interrupts, the SPICLK phase, and the operational mode (PERIPHERAL or CONTROLLER).

**Figure 31-15. SPICTL Register**

**Table 31-10. SPICTL Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-5	RESERVED	R	0h	Reserved
4	OVERRUNINTENA	R/W	0h	<p>Overrun Interrupt Enable</p> <p>Overrun Interrupt Enable. Setting this bit causes an interrupt to be generated when the RECEIVER_OVERRUN Flag bit (SPISTS.7) is set by hardware. Interrupts generated by the RECEIVER_OVERRUN Flag bit and the SPI_INT_FLAG bit (SPISTS.6) share the same interrupt vector.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Disable RECEIVER_OVERRUN interrupts.</p> <p>1h (R/W) = Enable RECEIVER_OVERRUN interrupts.</p>
3	CLK_PHASE	R/W	0h	<p>SPI Clock Phase Select</p> <p>This bit controls the phase of the SPICLK signal. CLOCK_PHASE and CLOCK_POLARITY (SPICCR.6) make four different clocking schemes possible (see clocking figures in SPI chapter). When operating with CLOCK_PHASE high, the SPI (CONTROLLER or PERIPHERAL) makes the first bit of data available after SPIDAT is written and before the first edge of the SPICLK signal, regardless of which SPI mode is being used.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Normal SPI clocking scheme, depending on the CLOCK_POLARITY bit (SPICCR.6).</p> <p>1h (R/W) = SPICLK signal delayed by one half-cycle. Polarity determined by the CLOCK_POLARITY bit.</p>
2	CONTROLLER_PERIPHERAL	R/W	0h	<p>SPI Network Mode Control</p> <p>This bit determines whether the SPI is a network CONTROLLER or PERIPHERAL. After SPI reset, SPI is automatically configured as a PERIPHERAL</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = SPI is configured as a PERIPHERAL.</p> <p>1h (R/W) = SPI is configured as a CONTROLLER.</p>

**Table 31-10. SPICTL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
1	TALK	R/W	0h	<p><b>Transmit Enable</b>                      The TALK bit can disable data transmission (CONTROLLER or PERIPHERAL) by placing the serial data output in the high-impedance state. If this bit is disabled during a transmission, the transmit shift register continues to operate until the previous character is shifted out. When the TALK bit is disabled, the SPI is still able to receive characters and update the status flags. TALK is cleared (disabled) by a system reset.</p> <p>Reset type: SYSRSn                      0h (R/W) = Disables transmission:                      - PERIPHERAL mode operation: If not previously configured as a general-purpose I/O pin, the SPIPOCI pin will be put in the high-impedance state.                      - CONTROLLER mode operation: If not previously configured as a general-purpose I/O pin, the SPIPICO pin will be put in the high-impedance state.                      1h (R/W) = Enables transmission For the 4-pin option, ensure to enable the receiver's SPIPTEn input pin.</p>
0	SPIINTENA	R/W	0h	<p><b>SPI Interrupt Enable</b>                      This bit controls the SPI's ability to generate a transmit/receive interrupt. The SPI INT FLAG bit (SPISTS.6) is unaffected by this bit.</p> <p>Reset type: SYSRSn                      0h (R/W) = Disables the interrupt.                      1h (R/W) = Enables the interrupt.</p>

### 31.6.2.3 SPISTS Register (Offset = 2h) [Reset = 0000h]

SPISTS is shown in [Figure 31-16](#) and described in [Table 31-11](#).

Return to the [Summary Table](#).

SPISTS contains interrupt and status bits.

**Figure 31-16. SPISTS Register**

15	14	13	12	11	10	9	8
RESERVED							
R-0h							
7	6	5	4	3	2	1	0
OVERRUN_FL AG	INT_FLAG	BUFFULL_FL AG	RESERVED				
W1C-0h	RC-0h	R-0h	R-0h				

**Table 31-11. SPISTS Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-8	RESERVED	R	0h	Reserved
7	OVERRUN_FLAG	W1C	0h	<p>SPI Receiver Overrun Flag</p> <p>This bit is a read/clear-only flag. The SPI hardware sets this bit when a receive or transmit operation completes before the previous character has been read from the buffer. The bit is cleared in one of three ways:</p> <ul style="list-style-type: none"> <li>- Writing a 1 to this bit</li> <li>- Writing a 0 to SPI SW RESET (SPICCR.7)</li> <li>- Resetting the system</li> </ul> <p>If the OVERRUN INT ENA bit (SPICTL.4) is set, the SPI requests only one interrupt upon the first occurrence of setting the RECEIVER OVERRUN Flag bit. Subsequent overruns will not request additional interrupts if this flag bit is already set. This means that in order to allow new overrun interrupt requests the user must clear this flag bit by writing a 1 to SPISTS.7 each time an overrun condition occurs. In other words, if the RECEIVER OVERRUN Flag bit is left set (not cleared) by the interrupt service routine, another overrun interrupt will not be immediately re-entered when the interrupt service routine is exited.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = A receive overrun condition has not occurred.</p> <p>1h (R/W) = The last received character has been overwritten and therefore lost (when the SPIRXBUF was overwritten by the SPI module before the previous character was read by the user application).</p> <p>Writing a '1' will clear this bit. The RECEIVER OVERRUN Flag bit should be cleared during the interrupt service routine because the RECEIVER OVERRUN Flag bit and SPI INT FLAG bit (SPISTS.6) share the same interrupt vector. This will alleviate any possible doubt as to the source of the interrupt when the next byte is received.</p>

**Table 31-11. SPISTS Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
6	INT_FLAG	RC	0h	<p>SPI Interrupt Flag</p> <p>SPI INT FLAG is a read-only flag. Hardware sets this bit to indicate that the SPI has completed sending or receiving the last bit and is ready to be serviced. This flag causes an interrupt to be requested if the SPI INT ENA bit (SPICTL.0) is set. The received character is placed in the receiver buffer at the same time this bit is set. This bit is cleared in one of three ways:</p> <ul style="list-style-type: none"> <li>- Reading SPIRXBUF</li> <li>- Writing a 0 to SPI SW RESET (SPICCR.7)</li> <li>- Resetting the system</li> </ul> <p>Note: This bit should not be used if FIFO mode is enabled. The internal process of copying the received word from SPIRXBUF to the Receive FIFO will clear this bit. Use the FIFO status, or FIFO interrupt bits for similar functionality.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No full words have been received or transmitted. 1h (R/W) = Indicates that the SPI has completed sending or receiving the last bit and is ready to be serviced.</p>
5	BUFFULL_FLAG	R	0h	<p>SPI Transmit Buffer Full Flag</p> <p>This read-only bit gets set to 1 when a character is written to the SPI Transmit buffer SPITXBUF. It is cleared when the character is automatically loaded into SPIDAT when the shifting out of a previous character is complete.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Transmit buffer is not full. 1h (R/W) = Transmit buffer is full.</p>
4-0	RESERVED	R	0h	Reserved

### 31.6.2.4 SPIBRR Register (Offset = 4h) [Reset = 0000h]

SPIBRR is shown in [Figure 31-17](#) and described in [Table 31-12](#).

Return to the [Summary Table](#).

SPIBRR contains the bits used for baud-rate selection.

**Figure 31-17. SPIBRR Register**

**Table 31-12. SPIBRR Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-7	RESERVED	R	0h	Reserved
6-0	SPI_BIT_RATE	R/W	0h	<p>SPI Baud Rate Control</p> <p>These bits determine the bit transfer rate if the SPI is the network SPI BIT RATE 0 CONTROLLER. There are 125 data-transfer rates (each a function of the CPU clock, LSPCLK) that can be selected. One data bit is shifted per SPICLK cycle. (SPICLK is the baud rate clock output on the SPICLK pin.)</p> <p>If the SPI is a network PERIPHERAL, the module receives a clock on the SPICLK pin from the network CONTROLLER. Therefore, these bits have no effect on the SPICLK signal. The frequency of the input clock from the CONTROLLER should not exceed the PERIPHERAL SPI's LSPCLK signal divided by 4.</p> <p>In CONTROLLER mode, the SPI clock is generated by the SPI and is output on the SPICLK pin. The SPI baud rates are determined by the following formula:</p> <p>For SPIBRR = 3 to 127: SPI Baud Rate = LSPCLK / (SPIBRR + 1)</p> <p>For SPIBRR = 0, 1, or 2: SPI Baud Rate = LSPCLK / 4</p> <p>Reset type: SYSRSn</p> <p>3h (R/W) = SPI Baud Rate = LSPCLK/4</p> <p>4h (R/W) = SPI Baud Rate = LSPCLK/5</p> <p>7Eh (R/W) = SPI Baud Rate = LSPCLK/127</p> <p>7Fh (R/W) = SPI Baud Rate = LSPCLK/128</p>

### 31.6.2.5 SPIRXEMU Register (Offset = 6h) [Reset = 0000h]

SPIRXEMU is shown in [Figure 31-18](#) and described in [Table 31-13](#).

Return to the [Summary Table](#).

SPIRXEMU contains the received data. Reading SPIRXEMU does not clear the SPI INT FLAG bit of SPISTS. This is not a real register but a dummy address from which the contents of SPIRXBUF can be read by the emulator without clearing the SPI INT FLAG.

**Figure 31-18. SPIRXEMU Register**

15	14	13	12	11	10	9	8
ERXBn							
R-0h							
7	6	5	4	3	2	1	0
ERXBn							
R-0h							

**Table 31-13. SPIRXEMU Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-0	ERXBn	R	0h	Emulation Buffer Received Data SPIRXEMU functions almost identically to SPIRXBUF, except that reading SPIRXEMU does not clear the SPI INT FLAG bit (SPISTS.6). Once the SPIDAT has received the complete character, the character is transferred to SPIRXEMU and SPIRXBUF, where it can be read. At the same time, SPI INT FLAG is set. This mirror register was created to support emulation. Reading SPIRXBUF clears the SPI INT FLAG bit (SPISTS.6). In the normal operation of the emulator, the control registers are read to continually update the contents of these registers on the display screen. SPIRXEMU was created so that the emulator can read this register and properly update the contents on the display screen. Reading SPIRXEMU does not clear the SPI INT FLAG bit, but reading SPIRXBUF clears this flag. In other words, SPIRXEMU enables the emulator to emulate the true operation of the SPI more accurately. It is recommended that you view SPIRXEMU in the normal emulator run mode. Reset type: SYSRSn

### 31.6.2.6 SPIRXBUF Register (Offset = 7h) [Reset = 0000h]

SPIRXBUF is shown in [Figure 31-19](#) and described in [Table 31-14](#).

Return to the [Summary Table](#).

SPIRXBUF contains the received data. Reading SPIRXBUF clears the SPI INT FLAG bit in SPISTS. If FIFO mode is enabled, reading this register will also decrement the RXFFST counter in SPIFFRX.

**Figure 31-19. SPIRXBUF Register**

15	14	13	12	11	10	9	8

R-0h							
7	6	5	4	3	2	1	0
RXBn							
R-0h							

**Table 31-14. SPIRXBUF Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-0	RXBn	R	0h	Received Data Once SPIDAT has received the complete character, the character is transferred to SPIRXBUF, where it can be read. At the same time, the SPI INT FLAG bit (SPISTS.6) is set. Since data is shifted into the SPI's most significant bit first, it is stored right-justified in this register. Reset type: SYSRSn

### 31.6.2.7 SPITXBUF Register (Offset = 8h) [Reset = 0000h]

SPITXBUF is shown in [Figure 31-20](#) and described in [Table 31-15](#).

Return to the [Summary Table](#).

SPITXBUF stores the next character to be transmitted. Writing to this register sets the TX BUF FULL Flag bit in SPISTS. When the transmission of the current character is complete, the contents of this register are automatically loaded in SPIDAT and the TX BUF FULL Flag is cleared. If no transmission is currently active, data written to this register falls through into the SPIDAT register and the TX BUF FULL Flag is not set. In CONTROLLER mode, if no transmission is currently active, writing to this register initiates a transmission in the same manner that writing to SPIDAT does.

Bit	Field	Type	Reset	Description
15-0	TXBn	R/W	0h	Transmit Data Buffer This is where the next character to be transmitted is stored. When the transmission of the current character has completed, if the TX BUF FULL Flag bit is set, the contents of this register is automatically transferred to SPIDAT, and the TX BUF FULL Flag is cleared. Writes to SPITXBUF must be left-justified. Reset type: SYSRSn

### 31.6.2.8 SPIDAT Register (Offset = 9h) [Reset = 0000h]

SPIDAT is shown in [Figure 31-21](#) and described in [Table 31-16](#).

Return to the [Summary Table](#).

SPIDAT is the transmit and receive shift register. Data written to SPIDAT is shifted out (MSB) on subsequent SPICLK cycles. For every bit (MSB) shifted out of the SPI, a bit is shifted into the LSB end of the shift register.

**Figure 31-21. SPIDAT Register**

SDATn							
R/W-0h							

**Table 31-16. SPIDAT Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-0	SDATn	R/W	0h	Serial Data Shift Register - It provides data to be output on the serial output pin if the TALK bit (SPICTL.1) is set. - When the SPI is operating as a CONTROLLER, a data transfer is initiated. When initiating a transfer, check the CLOCK POLARITY bit (SPICCR.6) described in Section 10.2.1.1 and the CLOCK PHASE bit (SPICTL.3) described in Section 10.2.1.2, for the requirements. In CONTROLLER mode, writing dummy data to SPIDAT initiates a receiver sequence. Since the data is not hardware-justified for characters shorter than sixteen bits, transmit data must be written in left-justified form, and received data read in right-justified form. Reset type: SYSRSn

### 31.6.2.9 SPIFFTX Register (Offset = Ah) [Reset = A000h]

SPIFFTX is shown in [Figure 31-22](#) and described in [Table 31-17](#).

Return to the [Summary Table](#).

SPIFFTX contains both control and status bits related to the output FIFO buffer. This includes FIFO reset control, FIFO interrupt level control, FIFO level status, as well as FIFO interrupt enable and clear bits.

**Figure 31-22. SPIFFTX Register**

15	14	13	12	11	10	9	8

7-0	TXDLY	R/W	0h	<p>FIFO Transmit Delay Bits</p> <p>These bits define the delay between every transfer from FIFO transmit buffer to transmit shift register. The delay is defined in number SPI serial clock cycles. The 8-bit register could define a minimum delay of 0 serial clock cycles and a maximum of 255 serial clock cycles. In FIFO mode, the buffer (TXBUF) between the shift register and the FIFO should be filled only after the shift register has completed shifting of the last bit. This is required to pass on the delay between transfers to the data stream. In the FIFO mode TXBUF should not be treated as one additional level of buffer.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = The next word in the TX FIFO buffer is transferred to SPITXBUF immediately upon completion of transmission of the previous word.</p> <p>1h (R/W) = The next word in the TX FIFO buffer is transferred to SPITXBUF1 serial clock cycle after completion of transmission of the previous word.</p> <p>2h (R/W) = The next word in the TX FIFO buffer is transferred to SPITXBUF 2 serial clock cycles after completion of transmission of the previous word.</p> <p>FFh (R/W) = The next word in the TX FIFO buffer is transferred to SPITXBUF 255 serial clock cycles after completion of transmission of the previous word.</p>

### 31.6.2.12 SPIPRI Register (Offset = Fh) [Reset = 0000h]

SPIPRI is shown in [Figure 31-25](#) and described in [Table 31-20](#).

Return to the [Summary Table](#).

SPIPRI controls auxillary functions for the SPI including emulation control, SPIPTE inversion, and 3-wire control.

**Figure 31-25. SPIPRI Register**

15	14	13	12	11	10	9	8

Bit	Field	Type	Reset	Description
15-7	RESERVED	R	0h	Reserved
6	RESERVED	R/W	0h	Reserved
5	SOFT	R/W	0h	Emulation Soft Run This bit only has an effect when the FREE bit is 0. Reset type: SYSRSn 0h (R/W) = Transmission stops midway in the bit stream while TSUSPEND is asserted. Once TSUSPEND is deasserted without a system reset, the remainder of the bits pending in the DATBUF are shifted. Example: If SPIDAT has shifted 3 out of 8 bits, the communication freezes right there. However, if TSUSPEND is later deasserted without resetting the SPI, SPI starts transmitting from where it had stopped (fourth bit in this case) and will transmit 8 bits from that point. 1h (R/W) = If the emulation suspend occurs before the start of a transmission, (that is, before the first SPICLK pulse) then the transmission will not occur. If the emulation suspend occurs after the start of a transmission, then the data will be shifted out to completion. When the start of transmission occurs is dependent on the baud rate used. Standard SPI mode: Stop after transmitting the words in the shift register and buffer. That is, after TXBUF and SPIDAT are empty. In FIFO mode: Stop after transmitting the words in the shift register and buffer. That is, after TX FIFO and SPIDAT are empty.
4	FREE	R/W	0h	Emulation Free Run These bits determine what occurs when an emulation suspend occurs (for example, when the debugger hits a breakpoint). The peripheral can continue whatever it is doing (free-run mode) or, if in stop mode, it can either stop immediately or stop when the current operation (the current receive/transmit sequence) is complete. Reset type: SYSRSn 0h (R/W) = Emulation mode is selected by the SOFT bit 1h (R/W) = Free run, continue SPI operation regardless of suspend or when the suspend occurred.
3-2	RESERVED	R	0h	Reserved

**Table 31-20. SPIPRI Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
1	PTEINV	R/W	0h	SPIPTEn Inversion Bit On devices with 2 or more SPI modules, inverting the SPIPTE signal on one of the modules allows the device to receive left and right-channel digital audio data. This bit is only applicable to PERIPHERAL mode. Writing to this bit while configured as CONTROLLER (CONTROLLER_PERIPHERAL = 1) has no effect Reset type: SYSRSn 0h (R/W) = SPIPTEn is active low (normal) 1h (R/W) = SPIPTE is active high (inverted)
0	TRIWIRE	R/W	0h	SPI 3-wire Mode Enable Reset type: SYSRSn 0h (R/W) = Normal 4-wire SPI mode. 1h (R/W) = 3-wire SPI mode enabled. The unused pin becomes a GPIO pin. In CONTROLLER mode, the SPIPICO pin becomes the SPICOC1 (CONTROLLER receive and transmit) pin and SPIPOC1 is free for non-SPI use. In PERIPHERAL mode, the SPIPOC1 pin becomes the SPIPIPO (PERIPHERAL receive and transmit) pin and SPIPICO is free for non-SPI use.

Chapter 32  
**Universal Serial Bus (USB) Controller**

---

This chapter discusses the features and functions of the universal serial bus (USB) controller.

<b>32.1 Introduction</b> .....	<b>4867</b>
<b>32.2 Functional Description</b> .....	<b>4870</b>
<b>32.3 Initialization and Configuration</b> .....	<b>4881</b>
<b>32.4 USB Global Interrupts</b> .....	<b>4882</b>
<b>32.5 Software</b> .....	<b>4882</b>
<b>32.6 USB Registers</b> .....	<b>4885</b>

## 32.1 Introduction

The USB controller operates as a full-speed function controller during point-to-point communications with the USB host. The controller complies with the USB 2.0 standard, which includes SUSPEND and RESUME signaling. The USB controller has thirty-two endpoints, one-half of them being for IN transactions and one-half of them being for OUT transactions. One IN and one OUT endpoint are fixed-function endpoints used for control transfers; the others are defined by firmware. A dynamically sizeable FIFO supports queuing multiple packets. Software-controlled connect and disconnect allow flexibility during USB device startup.

### 32.1.1 Features

The USB module has the following features:

- Complies with USB-IF certification standards
- USB 2.0 full-speed (12Mbps) operation in host and device modes as well as low-speed (1.5Mbps) operation in host mode
- Integrated PHY
- Three transfer types: Control, Interrupt, and Bulk
- 32 endpoints
  - One dedicated control IN endpoint and one dedicated control OUT endpoint
  - Fifteen configurable IN endpoints and fifteen configurable OUT endpoints
- 4KB dedicated endpoint memory

### 32.1.3 Block Diagram

The USB block diagram is shown in Figure 32-1.

Figure 32-1. USB Block Diagram

#### 32.1.3.1 Signal Description

The USB controller requires a total of three signals (D+, D-, and  $V_{BUS}$ ) to operate in device mode and two signals (D+, D-) to operate in embedded host mode. Because of the differential signaling needed for USB, the D+ and D- pins have special buffers to support USB. As such, the position on the chip is not user-selectable. The D+ and D- pins at reset are, by default, GPIOs and must be configured before being used as USB function pins. Bits 10 and 11 in the GPIO B Analog Mode Select register (GPBAMSEL) must be set to choose the USB function. The signals USB bus voltage ( $V_{BUS}$ ), external power enable (EPEN), and power fault (PFLT) are not hardwired to any pin and some applications require these signals be implemented in software using a GPIO. Software that implements these signals is available in the USB software library.

#### 32.1.3.2 VBus Recommendations

Most applications do not need to monitor  $V_{BUS}$ . Because of this, a dedicated  $V_{BUS}$  monitoring pin was not included on this microcontroller. If you are designing a bus-powered device application or an embedded host application, you do not need to monitor  $V_{BUS}$ . If you are designing a self-powered device, you need to actively monitor the state of the  $V_{BUS}$  pin to make sure compliance with the USB specification. In Section 7.1.5 and Section 7.2.1 of the USB Specification Revision 2.0™:

- "The voltage source on the [speed identification] pull-up resistor must be derived from or controlled by the power supplied on the USB cable such that when  $V_{BUS}$  is removed, the pull-up resistor does not supply current on the data line to which it is attached.
- When  $V_{BUS}$  is removed, the device must remove power from the D+/D- pull-up resistor within 10 seconds.
- Later in the timing tables (Section 7.3.2) of the USB Specification 2.0, it is also stated that the D+/D- pull-up resistor must be applied within 100 ms of  $V_{BUS}$  reaching a valid level."

Meeting the above specification is easy because of the slow timing requirements. The hardware part of the  $V_{BUS}$  monitoring is discussed in this chapter. The corresponding software is discussed briefly, but for examples and an explanation, consult the USB software guide.

The pins of this microcontroller are not 5V tolerant, and because of this, the  $V_{BUS}$  signal cannot be directly connected to a GPIO pin. Directly connecting 5V to a pin of the microcontroller destroys the I/O buffer of the pin and possibly more of the chip. The most cost-effective way of making any pin capable of reading a 5V input is to use a series resistance in conjunction with the ESD diode clamps already present inside the device on every pin. Also, use a 100kohm series resistor between the  $V_{BUS}$  signal and the pin chosen to monitor the pin. A diagram of this setup is shown in [Figure 32-2](#).

In [Figure 32-2](#), if  $V_{BUS}$  is above 3.3V or below 0V, one of the ESD clamp diodes is forward-biased, allowing current to flow through the 100kohm resistor. The purpose of the diode clamps is to protect the pins of the microcontroller from very short over voltage spikes of a high magnitude. The diode clamps do this by clamping the voltage excursion to one of the supply rails. We are effectively requiring the ESD clamps to do the same thing the clamps were designed to do, but instead of a short high magnitude pulse, we are giving the clamps a long low magnitude static value using the 100kohm resistor.

Any pin that has digital input and output functionality can potentially be used to monitor  $V_{BUS}$ , but the use of an interrupt-capable GPIO is recommended. A pin that does not have external interrupt capability can also be used, but the input state of the pin must be polled periodically by the application software to make sure appropriate action is taken whenever  $V_{BUS}$  is applied or removed. If an interrupt-capable GPIO is chosen, the GPIO can be configured to generate an interrupt on both the rising and falling edge. More information on external interrupts can be found in the *System Control and Interrupts* chapter. Example code that implements  $V_{BUS}$  monitoring using external interrupts and takes the appropriate actions is documented in the USB Software Guide and can be found in the associated USB software package.

Figure 32-2. USB Scheme

## 32.2 Functional Description

The USB controller can be configured to act as either a dedicated host or device. However, when the USB controller is acting as a self-powered device, a GPIO input or analog comparator input must be connected to  $V_{BUS}$  and configured to generate an interrupt when the  $V_{BUS}$  level drops. This interrupt is used to disable the pullup resistor on the USB0DP signal.

---

### Note

When a USB is used in the system, the minimum system frequency is 30MHz.

---

### 32.2.1 Operation as a Device

This section describes how the USB controller performs when the USB controller is being used as a USB device. IN endpoints, OUT endpoints, entry into and exit from SUSPEND mode, and recognition of start of frame (SOF) are all described.

When in device mode, IN transactions are controlled by the endpoint transmit interface and uses the transmit endpoint registers for the given endpoint. OUT transactions are handled with the endpoints receive interface and use the receive endpoint registers for the given endpoint. When configuring the size of the FIFOs for endpoints, take into account the maximum packet size for an endpoint. Note the following:

- Bulk endpoints must be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used (described further in the following section).
- Interrupt endpoints must be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used.
- It is also possible to specify a separate control endpoint for a USB device. However, in most cases the USB device must use the dedicated control endpoint on the USB controller's endpoint 0.

#### 32.2.1.1 Control and Configurable Endpoints

When operating as a device, the USB controller provides two dedicated control endpoints (IN and OUT). The remaining available configurable endpoints (one-half IN and one-half OUT) can be used for communications with a host controller. The endpoint number and direction associated with an endpoint is directly related to the register designation. For example, when the Host is transmitting to endpoint 1, all configuration and data is in the endpoint 1 transmit register interface. Endpoint 0 is a dedicated control endpoint used for all control transactions to endpoint 0 during enumeration or when any other control requests are made to endpoint 0. Endpoint 0 uses the first 64 bytes of the USB controller's FIFO RAM as a shared memory for both IN and OUT transactions. The remaining six endpoints can be configured as control, bulk, or interrupt endpoints. The six endpoints can be treated as three configurable IN and three configurable OUT endpoints. The endpoint pairs are not required to have the same type for the IN and OUT endpoint configuration. For example, the OUT portion of an endpoint pair can be a bulk endpoint, while the IN portion of that endpoint pair can be an interrupt endpoint. The address and size of the FIFOs attached to each endpoint can be modified to fit the application's needs.

### 32.2.1.1.1 IN Transactions as a Device

When operating as a USB device, data for IN transactions is handled through the FIFOs attached to the transmit endpoints. The sizes of the FIFOs for the configurable IN endpoints are determined by the USB Transmit FIFO Start Address (USBTXFIFOADD) register. The maximum size of a data packet that can be placed in a transmit endpoint's FIFO for transmission is programmable and is determined by the value written to the USB Maximum Transmit Data Endpoint n (USBTXMAXPn) register for that endpoint. The endpoint's FIFO can also be configured to use double-packet or single-packet buffering. When double-packet buffering is enabled, two data packets can be buffered in the FIFO, which also requires that the FIFO is at least two packets in size. When double-packet buffering is disabled, only one packet can be buffered, even if the packet size is less than half the FIFO size.

---

#### Note

The maximum packet size set for any endpoint must not exceed the FIFO size. The USBTXMAXPn register cannot be written to while data is in the FIFO as unexpected results can occur.

---

### Single-Packet Buffering

If the size of the transmit endpoint's FIFO is less than twice the maximum packet size for this endpoint (as set in the USB Transmit Dynamic FIFO Sizing (USBTXFIFOSZ) register), only one packet can be buffered in the FIFO and single-packet buffering is required. When each packet is completely loaded into the transmit FIFO, the TXRDY bit in the USB Transmit Control and Status Endpoint n Low (USBTXCSRLn) register must be set. If the AUTOSET bit in the USB Transmit Control and Status Endpoint n High (USBTXCSRHn) register is set, the TXRDY bit is automatically set when a maximum-sized packet is loaded into the FIFO. For packet sizes less than the maximum, the TXRDY bit must be set manually. When the TXRDY bit is set, either manually or automatically, the packet is ready to be sent. When the packet has been successfully sent, both TXRDY and FIFONE are cleared, and the appropriate transmit endpoint interrupt signaled. At this point, the next packet can be loaded into the FIFO.

### Double-Packet Buffering

If the size of the transmit endpoint's FIFO is at least twice the maximum packet size for this endpoint, two packets can be buffered in the FIFO and double-packet buffering is allowed. As each packet is loaded into the transmit FIFO, the TXRDY bit in the USBTXCSRLn register must be set. If the AUTOSET bit in the USBTXCSRHn register is set, the TXRDY bit is automatically set when a maximum-sized packet is loaded into the FIFO. For packet sizes less than the maximum, TXRDY must be set manually. When the TXRDY bit is set, either manually or automatically, the packet is ready to be sent. After the first packet is loaded, TXRDY is immediately cleared and an interrupt is generated. A second packet can now be loaded into the transmit FIFO and TXRDY set again (either manually or automatically if the packet is the maximum size). At this point, both packets are ready to be sent. After each packet has been successfully sent, TXRDY is automatically cleared and the appropriate transmit endpoint interrupt signaled to indicate that another packet can now be loaded into the transmit FIFO. The state of the FIFONE bit in the USBTXCSRLn register at this point indicates how many packets can be loaded. If the FIFONE bit is set, then another packet is in the FIFO and only one more packet can be loaded. If the FIFONE bit is clear, then no packets are in the FIFO and two more packets can be loaded.

---

#### Note

Double-packet buffering is disabled if an endpoint's corresponding EPn bit is set in the USB Transmit Double Packet Buffer Disable (USBTXDPKTBUFDIS) register. This bit is set by default, so the bit must be cleared to enable double-packet buffering.

---

### 32.2.1.1.2 Out Transactions as a Device

When in device mode, OUT transactions are handled through the USB controller receive FIFOs. The sizes of the receive FIFOs for the configurable OUT endpoints are determined by the USB Receive FIFO Start Address (USBRXFIFOADD) register. The maximum amount of data received by an endpoint in any packet is determined by the value written to the USB Maximum Receive Data Endpoint n (USBRXMAXPn) register for that endpoint. When double-packet buffering is enabled, two data packets can be buffered in the FIFO. When double-packet buffering is disabled, only one packet can be buffered even if the packet is less than half the FIFO size.

---

#### Note

In all cases, the maximum packet size must not exceed the FIFO size.

---

### Single-Packet Buffering

If the size of the receive endpoint FIFO is less than twice the maximum packet size for an endpoint, only one data packet can be buffered in the FIFO and single-packet buffering is required. When a packet is received and placed in the receive FIFO, the RXRDY and FULL bits in the USB Receive Control and Status Endpoint n Low (USBRXCSRL[n]) register are set and the appropriate receive endpoint is signaled, indicating that a packet can now be unloaded from the FIFO. After the packet has been unloaded, the RXRDY bit must be cleared to allow further packets to be received. This action also generates the acknowledge signaling to the Host controller. If the AUTOCL bit in the USB Receive Control and Status Endpoint n High (USBRXCSRH[n]) register is set and a maximum-sized packet is unloaded from the FIFO, the RXRDY and FULL bits are cleared automatically. For packet sizes less than the maximum, RXRDY must be cleared manually.

### Double-Packet Buffering

If the size of the receive endpoint FIFO is at least twice the maximum packet size for the endpoint, two data packets can be buffered and double-packet buffering can be used. When the first packet is received and loaded into the receive FIFO, the RXRDY bit in the USBRXCSRL[n] register is set and the appropriate receive endpoint interrupt is signaled to indicate that a packet can now be unloaded from the FIFO.

---

#### Note

The FULL bit in USBRXCSRL[n] is not set when the first packet is received. The FULL bit is only set if a second packet is received and loaded into the receive FIFO.

---

After each packet has been unloaded, the RXRDY bit must be cleared to allow further packets to be received. If the AUTOCL bit in the USBRXCSRH[n] register is set and a maximum-sized packet is unloaded from the FIFO, the RXRDY bit is cleared automatically. For packet sizes less than the maximum, RXRDY must be cleared manually. If the FULL bit is set when RXRDY is cleared, the USB controller first clears the FULL bit, then sets RXRDY again to indicate that there is another packet waiting in the FIFO to be unloaded.

---

#### Note

Double-packet buffering is disabled if an endpoint's corresponding EPn bit is set in the USB Receive Double Packet Buffer Disable (USBRXDPKTBUFDIS) register. This bit is set by default, so the bit must be cleared to enable double-packet buffering.

---

### 32.2.1.1.3 Scheduling

The device has no control over the scheduling of transactions as scheduling is determined by the Host controller. The USB controller can set up a transaction at any time. The USB controller waits for the request from the Host controller and generates an interrupt when the transaction is complete or if the transaction was terminated due to some error. If the Host controller makes a request and the device controller is not ready, the USB controller sends a busy response (NAK) to all requests until the USB controller is ready.

### 32.2.1.1.4 Additional Actions

The USB controller responds automatically to certain conditions on the USB bus or actions by the Host controller such as when the USB controller automatically stalls a control transfer or unexpected zero length OUT data packets.

#### Stalled Control Transfer

The USB controller automatically issues a STALL handshake to a control transfer under the following conditions:

1. The Host sends more data during an OUT data phase of a control transfer than was specified in the device request during the SETUP phase. This condition is detected by the USB controller when the Host sends an OUT token (instead of an IN token) after the last OUT packet has been unloaded and the DATAEND bit in the USB Control and Status Endpoint 0 Low (USBCSRL0) register has been set.
2. The Host requests more data during an IN data phase of a control transfer than was specified in the device request during the SETUP phase. This condition is detected by the USB controller when the Host sends an IN token (instead of an OUT token) after the CPU has cleared TXRDY and set DATAEND in response to the ACK issued by the Host to what must have been the last packet.
3. The Host sends more than USBRXMAXPn bytes of data with an OUT data token.
4. The Host sends more than a zero length data packet for the OUT STATUS phase.

#### Zero Length OUT Data Packets

A zero-length OUT data packet is used to indicate the end of a control transfer. In normal operation, such packets must only be received after the entire length of the device request has been transferred. However, if the Host sends a zero-length OUT data packet before the entire length of device request has been transferred, the Host is signaling the premature end of the transfer. In this case, the USB controller automatically flushes any IN token ready for the data phase from the FIFO and sets the DATAEND bit in the USBCSRL0 register.

#### Setting the Device Address

When a Host is attempting to enumerate the USB device, the Host requests that the device change the address from zero to some other value. The address is changed by writing the value that the Host requested to the USB Device Functional Address (USBFADDR) register. However, care must be taken when writing to USBFADDR to avoid changing the address before the transaction is complete. This register must only be set after the SET\_ADDRESS command is complete. Like all control transactions, the transaction is only complete after the device has left the STATUS phase. In the case of a SET\_ADDRESS command, the transaction is completed by responding to the IN request from the Host with a zero-byte packet. Once the device has responded to the IN request, the USBFADDR register must be programmed to the new value as soon as possible to avoid missing any new commands sent to the new address.

---

#### Note

If the USBFADDR register is set to the new value as soon as the device receives the OUT transaction with the SET\_ADDRESS command in the packet, it changes the address during the control transfer. In this case, the device does not receive the IN request that allows the USB transaction to exit the STATUS phase of the control transfer because it is sent to the old address. As a result, the Host does not get a response to the IN request, and the Host fails to enumerate the device.

---

### 32.2.1.1.5 Device Mode Suspend

When no activity has occurred on the USB bus for 3ms, the USB controller automatically enters SUSPEND mode. If the SUSPEND interrupt has been enabled in the USB Interrupt Enable (USBIE) register, an interrupt is generated at this time. When in SUSPEND mode, the PHY also goes into SUSPEND mode. When RESUME signaling is detected, the USB controller exits SUSPEND mode and takes the PHY out of SUSPEND. If the RESUME interrupt is enabled, an interrupt is generated. The USB controller can also be forced to exit SUSPEND mode by setting the RESUME bit in the USB Power (USBPOWER) register. When this bit is set, the USB controller exits SUSPEND mode and drives RESUME signaling onto the bus. The RESUME bit must be cleared after 10ms (a maximum of 15ms) to end RESUME signaling. To meet USB power requirements, the controller can be put into Deep Sleep mode that keeps the controller in a static state.

### 32.2.1.1.6 Start of Frame

When the USB controller is operating in device mode, the USB receives a Start-Of-Frame (SOF) packet from the Host once every millisecond. When the SOF packet is received, the 11-bit frame number contained in the packet is written into the USB Frame Value (USBFRAME) register, and an SOF interrupt is also signaled and can be handled by the application. Once the USB controller has started to receive SOF packets, the USB expects one every millisecond. If no SOF packet is received after 1.00358ms, the packet is assumed to have been lost, and the USBFRAME register is not updated. The USB controller continues and resynchronizes these pulses to the received SOF packets when these packets are successfully received again.

### 32.2.1.1.7 USB Reset

When the USB controller is in device mode and a RESET condition is detected on the USB bus, the USB controller automatically performs the following actions:

- Clears the USBFADDR register
- Clears the USB Endpoint Index (USBEPIDX) register
- Flushes all endpoint FIFOs
- Clears all control/status registers
- Enables all endpoint interrupts
- Generates a RESET interrupt

### 32.2.1.1.8 Connect/Disconnect

The USB controller connection to the USB bus is handled by software. The USB PHY can be switched between normal mode and non-driving mode by setting or clearing the SOFTCONN bit of the USBPOWER register. When the SOFTCONN bit is set, the PHY is placed in the normal mode, and the USB0DP/USB0DM lines of the USB bus are enabled. At the same time, the USB controller is placed into a state that does not respond to any USB signaling except a USB RESET. When the SOFTCONN bit is cleared, the PHY is put into non-driving mode, USB0DP and USB0DM are tristated, and the USB controller appears to other devices on the USB bus as if the USB controller has been disconnected. The non-driving mode is the default so the USB controller appears disconnected until the SOFTCONN bit has been set. The application software can then choose when to set the PHY into the normal mode. Systems with a lengthy initialization procedure can use this to make sure that initialization is complete, and the system is ready to perform enumeration before connecting to the USB bus. Once the SOFTCONN bit has been set, the USB controller can be disconnected by clearing this bit.

---

#### Note

The USB controller does not generate an interrupt when the device is connected to the Host. However, an interrupt is generated when the Host terminates a session.

---

### 32.2.2 Operation as a Host

When the USB controller is operating in Host mode, the USB controller can either be used for point-to-point communications with another USB device or, when attached to a hub, for communication with multiple devices. Full-speed and low-speed USB devices are supported, both for point-to-point communication and for operation through a hub. The USB controller automatically carries out the necessary transaction translation needed to allow a low-speed or full-speed device to be used with a USB 2.0 hub. Control, bulk, and interrupt transactions are supported. This section describes the USB controller's actions when the USB controller is being used as a USB Host. Configuration of IN endpoints, OUT endpoints, entry into and exit from SUSPEND mode, and RESET are all described.

When in Host mode, IN transactions are controlled by an endpoint's receive interface. All IN transactions use the receive endpoint registers and all OUT endpoints use the transmit endpoint registers for a given endpoint. As in device mode, the FIFOs for endpoints must take into account the maximum packet size for an endpoint.

- Bulk endpoints must be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used (described further in the following section).
- Interrupt endpoints must be the size of the maximum packet (up to 64 bytes) or twice the maximum packet size if double buffering is used.
- It is also possible to specify a separate control endpoint to communicate with a device. However, in most cases the USB controller must use the dedicated control endpoint to communicate with a device's endpoint 0.

#### 32.2.2.1 Endpoint Registers

The endpoint registers are used to control the USB endpoint interfaces which communicate with devices that are connected. The endpoints consist of a dedicated control IN endpoint and a dedicated control OUT endpoint. The remaining available endpoints are configurable, with one-half of them being OUT endpoints, and one-half of them being IN endpoints. See [Section 32.1.1](#) for the number of available endpoints on this device.

The dedicated control interface can only be used for control transactions to endpoint 0 of devices. These control transactions are used during enumeration or other control functions that communicate using endpoint 0 of devices. This control endpoint shares the first 64 bytes of the USB controller's FIFO RAM for IN and OUT transactions. The remaining IN and OUT interfaces can be configured to communicate with control, bulk, or interrupt endpoints.

These USB interfaces can be used to simultaneously schedule as many as 15 independent OUT and 15 independent IN transactions to any endpoints on any device. The IN and OUT controls are paired together in the same set of registers for the respective endpoints. However, the IN and OUT controls can be configured to communicate with different types of endpoints and different endpoints on devices. For example, the first pair of endpoint controls can be split so that the OUT portion is communicating with a device's bulk OUT endpoint 1, while the IN portion is communicating with a device's interrupt IN endpoint 2.

Before accessing any device, whether for point-to-point communications or for communications using a hub, the relevant USB Receive Functional Address Endpoint  $n$  (USB<sub>RX</sub>FUNCADDR<sub>n</sub>) or USB Transmit Functional Address Endpoint  $n$  (USB<sub>TX</sub>FUNCADDR<sub>n</sub>) registers must be set for each receive or transmit endpoint to record the address of the device being accessed.

The USB controller also supports connections to devices through a USB hub by providing a register that specifies the hub address and port of each USB transfer. The FIFO address and size are customizable and can be specified for each USB IN and OUT transfer. Customization includes allowing one FIFO per transaction, sharing a FIFO across transactions, and allowing for double-buffered FIFOs.

### 32.2.2.2 IN Transactions as a Host

IN transactions are handled in a similar manner to the way in which OUT transactions are handled when the USB controller is in device mode except that the transaction first must be initiated by setting the REQPKT bit in the USBCSRL0 register, indicating to the transaction scheduler that there is an active transaction on this endpoint. The transaction scheduler then sends an IN token to the target device. When the packet is received and placed in the receive FIFO, the RXRDY bit in the USBCSRL0 register is set, and the appropriate receive endpoint interrupt is signaled to indicate that a packet can now be unloaded from the FIFO.

When the packet has been unloaded, RXRDY must be cleared. The AUTOCL bit in the USBRXCSRHn register can be used to have RXRDY automatically cleared when a maximum-sized packet has been unloaded from the FIFO. The AUTORQ bit in USBRXCSRHn causes the REQPKT bit to be automatically set when the RXRDY bit is cleared. When the RXRDY bit is cleared, the controller sends an acknowledge to the device. When there is a known number of packets to be transferred, the USB Request Packet Count in Block Transfer Endpoint n (USBRQPKTCOUNTn) register associated with the endpoint must be configured to the number of packets to be transferred. The USB controller decrements the value in the USBRQPKTCOUNTn register following each request. When the USBRQPKTCOUNTn value decrements to 0, the AUTORQ bit is cleared to prevent any further transactions being attempted. For cases where the size of the transfer is unknown, USBRQPKTCOUNTn must be cleared. AUTORQ then remains set until cleared by the reception of a short packet (that is, less than the MAXLOAD value in the USBRXMAXPn register) such as can occur at the end of a bulk transfer.

If the device responds to a bulk or interrupt IN token with a NAK, the USB Host controller keeps retrying the transaction until any NAK Limit that has been set has been reached. If the target device responds with a STALL, however, the USB Host controller does not retry the transaction but sets the STALLED bit in the USBCSRL0 register. If the target device does not respond to the IN token within the required time, or the packet contained a CRC or bit-stuff error, the USB Host controller retries the transaction. If after three attempts the target device has still not responded, the USB Host controller clears the REQPKT bit and sets the ERROR bit in the USBCSRL0 register.

### 32.2.2.3 OUT Transactions as a Host

OUT transactions are handled in a similar manner to the way in which IN transactions are handled when the USB controller is in device mode. The TXRDY bit in the USBTXCSRLn register must be set as each packet is loaded into the transmit FIFO. Again, setting the AUTOSET bit in the USBTXCSRHn register automatically sets TXRDY when a maximum-sized packet has been loaded into the FIFO.

If the target device responds to the OUT token with a NAK, the USB Host controller keeps retrying the transaction until the NAK Limit that has been set has been reached. However, if the target device responds with a STALL, the USB controller does not retry the transaction but interrupts the main processor by setting the STALLED bit in the USBTXCSRLn register. If the target device does not respond to the OUT token within the required time, or the packet contained a CRC or bit-stuff error, the USB Host controller retries the transaction. If after three attempts the target device has still not responded, the USB controller flushes the FIFO and sets the ERROR bit in the USBTXCSRLn register.

#### 32.2.2.4 Transaction Scheduling

Scheduling of transactions is handled automatically by the USB Host controller. The Host controller allows configuration of the endpoint communication scheduling based on the type of endpoint transaction. Interrupt transactions can be scheduled to occur in the range of every frame to every 255 frames in 1 frame increments. Bulk endpoints do not allow scheduling parameters, but do allow for a NAK timeout in the event an endpoint on a device is not responding.

The USB controller maintains a frame counter. If the target device is a full-speed device, the USB controller automatically sends an SOF packet at the start of each frame and increments the frame counter. If the target device is a low-speed device, a K state is transmitted on the bus to act as a keep-alive to stop the low-speed device from going into SUSPEND mode.

After the SOF packet has been transmitted, the USB Host controller cycles through all the configured endpoints looking for active transactions. An active transaction is defined as a receive endpoint for which the REQPKT bit is set or a transmit endpoint for which the TXRDY bit and/or the FIFONE bit is set.

An interrupt transaction is started if the transaction is found on the first scheduler cycle of a frame and if the interval counter for that endpoint has counted down to zero. As a result, only one interrupt transaction occurs per endpoint every  $n$  frames, where  $n$  is the interval set using the USB Host Transmit Interval Endpoint  $n$  (USBTXINTERVAL[ $n$ ]) or USB Host Receive Interval Endpoint  $n$  (USBRXINTERVAL[ $n$ ]) register for that endpoint.

An active bulk transaction starts immediately, provided sufficient time is left in the frame to complete the transaction before the next SOF packet is due. If the transaction must be retried (for example, because a NAK was received or the target device did not respond), then the transaction is not retried until the transaction scheduler has first checked all the other endpoints for active transactions. This process makes sure that an endpoint that is sending a lot of NAKs does not block other transactions on the bus. The controller also allows the user to specify a limit to the length of time for NAKs to be received from a target device before the endpoint times out.

### 32.2.2.5 USB Hubs

The following setup requirements apply to the USB Host controller only if it is used with a USB hub. When a full- or low-speed device is connected to the USB controller using a USB 2.0 hub, details of the hub address and the hub port also must be recorded in the corresponding USB Receive Hub Address Endpoint  $n$  (USBRXHUBADDR $n$ ) and USB Receive Hub Port Endpoint  $n$  (USBRXHUBPORT $n$ ) or the USB Transmit Hub Address Endpoint  $n$  (USBTXHUBADDR $n$ ) and USB Transmit Hub Port Endpoint  $n$  (USBTXHUBPORT $n$ ) registers. In addition, the speed at which the device operates (full or low) must be recorded in the USB Type Endpoint 0 (USBTYP0) (endpoint 0), USB Host Configure Transmit Type Endpoint  $n$  (USBTXTYPE $n$ ), or USB Host Configure Receive Type Endpoint  $n$  (USBRXTYPE $n$ ) registers for each endpoint that is accessed by the device.

For hub communications, the settings in these registers record the current allocation of the endpoints to the attached USB devices. To maximize the number of devices supported, the USB Host controller allows this allocation to be changed dynamically by simply updating the address and speed information recorded in these registers. Any changes in the allocation of endpoints to device functions must be made following the completion of any on-going transactions on the endpoints affected.

### 32.2.2.6 Babble

The USB Host controller does not start a transaction until the bus has been inactive for at least the minimum inter-packet delay. The controller also does not start a transaction unless it can be finished before the end of the frame. If the bus is still active at the end of a frame, then the USB Host controller assumes that the target device to which it is connected has malfunctioned, and the USB controller suspends all transactions and generates a babble interrupt.

### 32.2.2.7 Host SUSPEND

If the SUSPEND bit in the USBPOWER register is set, the USB Host controller completes the current transaction then stops the transaction scheduler and frame counter. No further transactions are started and no SOF packets are generated.

To exit SUSPEND mode, set the RESUME bit and clear the SUSPEND bit. While the RESUME bit is set, the USB Host controller generates RESUME signaling on the bus. After 20ms, the RESUME bit must be cleared, at which point the frame counter and transaction scheduler start. The Host supports the detection of a remote wake-up.

### 32.2.2.8 USB RESET

If the RESET bit in the USBPOWER register is set, the USB Host controller generates USB RESET signaling on the bus. The RESET bit must be set for at least 20ms to make sure of correct resetting of the target device. After the CPU has cleared the bit, the USB Host controller starts the frame counter and transaction scheduler.

### 32.2.2.9 Connect/Disconnect

A session is started by setting the SESSION bit in the USB device Control (USBDEVCTL) register, enabling the USB controller to wait for a device to be connected. When a device is detected, a connect interrupt is generated. The speed of the device that has been connected can be determined by reading the USBDEVCTL register where the FSDEV bit is set for a full-speed device, and the LSDEV bit is set for a low-speed device. The USB controller must generate a RESET to the device, and then the USB Host controller can begin device enumeration. If the device is disconnected while a session is in progress, a disconnect interrupt is generated.

### 32.2.3 DMA Operation

The USB module DMA trigger signals are not supported on this device. The DMA controller can be used to read and write the USB FIFOs using software triggering. See the *Direct Memory Access (DMA)* chapter for more details about programming the DMA controller. See the *USB DMA Event Trigger* advisory in the device errata for more information.

### 32.2.4 Address/Data Bus Bridge

This USB controller was originally designed to connect to an ARM AHB bus, but has been modified to function with the C28x device bus architecture. The modifications made are largely invisible to the user application, but there are some things to note.

- The USB memory space is 8 bits wide, while the C28x memory space is 16 bits wide.
- 32- and 16-bit accesses (r/w) are completely transparent to the user application code, no changes need be made.
- The C28x core only supports 8 bit accesses through a byte intrinsic type. This can be used to perform 8 bit reads or writes to the USB controller.
  - `int &__byte(int *array, unsigned int byte_index);`
  - `*array = ptr to address to access, byte_index = always 0 (for USB)`  
See [Table 32-1](#) for example.
  - See the [TMS320C28x Optimizing C/C++ Compiler User's Guide](#) and the [TMS320C28x Assembly Language Tools User's Guide](#)
- Because of the bridge, the memory view of the USB controller memory space in CCS is not a 1:1 representation of what is in the controller
  - When the view mode is
    - 32 bit or 16 bit, even address are effectively duplicated, ignore odd addresses.
    - 8 bit, even addresses from within the controller are duplicated into odd address in the view window; odd addresses from within the controller are not displayed.  
See [Table 32-2](#) for example.

**Table 32-1. USB Memory Access from Software**

USB Controller Memory			C28x 8 Bit	
Address	Register Name	Data	Access	Data
0x00	FADDR	0x00	__byte((int *)0x00,0)	0x0000

### 32.3 Initialization and Configuration

To use the USB controller, the peripheral clock must be enabled using the System Control module PCLKCR11 register. In addition, the USB PHY signals must be connected to the respective pins using the GPIO module GPBAMSEL register. Set bits 10 and 11 for USB0DM (GPIO42) and USB0DP (GPIO43).

Set up the auxiliary PLL so a 60MHz output clock is provided to the USB module. This fixed frequency is required for all USB operations. See the *System Control and Interrupts* chapter for more details.

In host mode, the USB controller is responsible for supplying power to the bus. To avoid incorrectly supplying voltage to the bus, the external power control signal, USB0EPEN, must be kept inactive on start-up. This can be done by connecting the USB0EPEN and USB0PFLT pins to the USB controller as soon as possible.

#### 32.3.1 Pin Configuration

To give more flexibility, the signals External Power Enable (EPEN) and Power Fault (PFLT) were not implemented in hardware and the user must implement these signals in software. Examples of how to implement these signals in software can be found in the [USB Software Guide](#) located in C2000Ware in the \libraries\communications\usb\ directory.

When using the device controller portion of the USB controller in a system that also provides host functionality, the power to  $V_{BUS}$  must be disabled to allow the external host controller to supply power. Usually, the EPEN signal is used to control the external regulator and must be negated to avoid having two devices driving the  $V_{BUS}$  power pin on the USB connector.

When the USB controller is acting as a host, the USB controller is in control of two signals that are attached to an external voltage supply that provides power to  $V_{BUS}$ . The Host controller uses the EPEN signal to enable or disable power to the  $V_{BUS}$  pin on the USB connector. An input pin, PFLT, provides feedback when there has been a power fault on  $V_{BUS}$ . The PFLT signal can be configured to either automatically negate the EPEN signal to disable power, or the PFLT signal can generate an interrupt to the interrupt controller to allow software to handle the power fault condition. The polarity and actions related to both EPEN and PFLT are fully configurable in the USB controller. The controller also provides interrupts on device insertion and removal to allow the Host controller code to respond to these external events.

### 32.3.2 Endpoint Configuration

To start communication in Host or device mode, the endpoint registers must first be configured. In Host mode, this configuration establishes a connection between an endpoint register and an endpoint on a device. In device mode, an endpoint must be configured before enumerating to the Host controller.

In both cases, the endpoint 0 configuration is limited because the endpoint is a fixed-function, fixed-FIFO-size endpoint. In device and Host modes, the endpoint requires little setup but does require a software-based state machine to progress through the setup, data, and status phases of a standard control transaction. In device mode, the configuration of the remaining endpoints is done once before enumerating and then only changed if an alternate configuration is selected by the Host controller. In Host mode, the endpoints must be configured to operate as control, bulk, or interrupt mode. Once the type of endpoint is configured, a FIFO area must be assigned to each endpoint. In the case of bulk, control and interrupt endpoints, each has a maximum of 64 bytes per transaction. The maximum packet size for the given endpoint must be set prior to sending or receiving data.

Configuring each endpoint's FIFO involves reserving a portion of the overall USB FIFO RAM to each endpoint. The total FIFO RAM available is 4 Kbytes with the first 64 bytes reserved for endpoint 0. The endpoint's FIFO must be at least as large as the maximum packet size. The FIFO can also be configured as a double-buffered FIFO so that interrupts occur at the end of each packet and allow filling the other half of the FIFO.

If operating as a device, the USB device controller's soft connect must be enabled when the device is ready to start communications, indicating to the host controller that the device is ready to start the enumeration process. If operating as a Host controller, the device soft connect must be disabled and power must be provided to  $V_{BUS}$  using the USB0EPEN signal.

## 32.4 USB Global Interrupts

Global interrupt enable, flag, and clear registers have been added to make sure that no interrupt is missed. The USB interrupt can be enabled or blocked using the INTEN bit. The INTFLG bit indicates whether an interrupt has occurred or not. Finally, the INTFLGCLR bit clears the INTFLG when a value of 1 is written to the field.

## 32.5 Software

### 32.5.1 USB Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location: C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/usb

Cloud access to these examples is available at the following link: [dev.ti.com C2000Ware Examples](#).

#### 32.5.1.1 USB CDC serial example

FILE: usb\_ex1\_dev\_serial.c

This example application turns the evaluation kit into a virtual serial port when connected to the USB host system. The application supports the USB Communication Device Class, Abstract Control Model to redirect SCIA traffic to and from the USB host system.

Connect USB cables from your PC to both the mini and microUSB connectors on the controlCARD. Figure out what COM ports your controlCARD is enumerating (typically done using Device Manager in Windows) and open a serial terminal to each of with the settings 115200 Baud 8-N-1. Characters typed in one terminal should be echoed in the other and vice versa.

A driver information (INF) file for use with Windows XP, Windows 7 and Windows 10 can be found in the windows\_drivers directory.

#### 32.5.1.2 USB HID Mouse Device

FILE: usb\_ex2\_dev\_mouse.c

This example application turns the evaluation board into a USB mouse supporting the Human Interface Device class. After loading and running the example simply connect the PC to the controlCARDs microUSB port using a USB cable, and the mouse pointer will move in a square pattern for the duration of the time it is plugged in.

SCIA, connected to the FTDI virtual COM port and running at 115200, 8-N-1, is used to display messages from this application.

### 32.5.1.3 USB Device Keyboard

FILE: `usb_ex3_dev_keyboard.c`

This example application turns the evaluation board into a USB keyboard supporting the Human Interface Device class. The global variable `ui32Button` should be modified to wake up the USB. Care should be taken to ensure that the active window can safely receive the text; enter is not pressed at any point so no actions are attempted by the host if a terminal window is used.

The device implemented by this application also supports USB remote wake up allowing it to request the host to reactivate a suspended bus. If the bus is suspended (as indicated on the application display), updating `ui32Button` will request a remote wakeup assuming the host has not specifically disabled such requests.

To run the example compile the project, load to the target, and run the example. After the example is running, connect a USB cable from the PC to the microUSB port on the controlCARD. Modify `ui32Button` value in the expressions window and then focus should be on the window so that we can receive keyboard input (i.e. NotePad).

### 32.5.1.4 USB Generic Bulk Device

FILE: `usb_ex4_dev_bulk.c`

This example provides a generic USB device offering simple bulk data transfer to and from the host. The device uses a vendor-specific class ID and supports a single bulk IN endpoint and a single bulk OUT endpoint. Data received from the host is assumed to be ASCII text and it is echoed back with the case of all alphabetic characters swapped.

SCIA, connected to the FTDI virtual COM port and running at 115200, 8-N-1, is used to display messages from this application.

A Windows INF file for the device is provided under the windows drivers directory. This INF contains information required to install the WinUSB subsystem on WindowsXP, Windows 7 and Windows 10. WinUSB is a Windows subsystem allowing user mode applications to access the USB device without the need for a vendor-specific kernel mode driver.

A sample Windows command-line application, `usb_bulk_example`, illustrating how to connect to and communicate with the bulk device is also provided. Project files are included to allow the examples to be built using Microsoft VisualStudio. Source code for this application can be found in directory `~/C2000Ware/utilities/tools/{Device}/usb_bulk_example/Release`

### 32.5.1.5 USB HID Mouse Host

FILE: `usb_ex5_host_mouse.c`

This application demonstrates the handling of a USB mouse attached to the evaluation kit. Once attached, the position of the mouse pointer and the state of the mouse buttons are output to the display.

SCIA, which is connected to the FTDI virtual serial port on the controlCARD board, is configured for 115200 bits per second, and 8-N-1 mode. When a HID compliant mouse is connected to the microUSB port on the top of the controlCARD, position and button information will be displayed to the console.

### 32.5.1.6 USB HID Keyboard Host

FILE: `usb_ex6_host_keyboard.c`

This example application demonstrates how to support a USB keyboard attached to the evaluation kit board. The display will show if a keyboard is currently connected and the current state of the Caps Lock key on the keyboard that is connected on the bottom status area of the screen. Pressing any keys on the keyboard will cause them to be sent out the SCI at 115200 baud with no parity, 8 bits and 1 stop bit. Any keyboard that supports the USB HID BIOS protocol should work with this demo application.

To run the example you should connect a HID compliant keyboard to the microUSB port on the top of the controlCARD and open up a serial terminal with the above settings to view the characters typed on the keyboard.

### 32.5.1.7 USB Mass Storage Class Host

FILE: `usb_ex7_host_msc.c`

This example application demonstrates reading a file system from a USB mass storage class device. It makes use of FatFs, a FAT file system driver. It provides a simple command console via the SCI for issuing commands to view and navigate the file system on the mass storage device.

The first SCI, which is connected to the FTDI virtual serial port on the controlCARD board, is configured for 115200 bits per second, and 8-N-1 mode. When the program is started a message will be printed to the terminal. Type `help` for command help.

After loading and running the example, open a serial terminal with the above settings to open the command prompt. Then connect a USB MSC device to the microUSB port on the top of the controlCARD.

For additional details about FatFs, see the following site: [FatFs - Generic FAT Filesystem Module](#)

### 32.5.1.8 USB Dual Detect

FILE: `usb_ex8_dual_detect.c`

This program uses a GPIO to do ID detection. If a host is connected to the device's USB port, the stack will switch to device mode and enumerate as mouse. If a mouse device is connected to the device's USB port, the stack will switch to host mode and display the mouse movement and button press information in a serial terminal.

### 32.5.1.9 USB Throughput Bulk Device Example (`usb_ex9_throughput_dev_bulk`)

FILE: `usb_ex9_dev_bulk_throughput.c`

This example provides a throughput numbers of bulk data transfer to and from the host. The device uses a vendor-specific class ID and supports a single bulk IN Endpoint and a single bulk OUT Endpoint.

SCIA, connected to the FTDI virtual COM port and running at 115200, 8-N-1, is used to display messages from this application.

A Windows INF file for the device is provided under the windows drivers directory. This INF contains information required to install the WinUSB subsystem on WindowsXP, Windows 7 and Windows 10. This is present in `utilities/windows_drivers`.

A sample Windows command-line application, `usb_throughput_bulk_example`, illustrating how to connect to and communicate with the bulk device is also provided. Project files are included to allow the examples to be built using Microsoft VisualStudio. Source code for this application can be found in directory `~/utilities/tools/usb_throughput_bulk_example/Release`.

After running the example in CCS Connect the USB Micro to the PC. Then the example will wait to receive data from the application. Run the `usb_throughput_bulk` example, the throughput and Data Packets Transferred.

### 32.5.1.10 USB HUB Host example

FILE: `usb_ex10_host_hub.c`

This example application demonstrates how to support a USB keyboard and USB Mouse with a USB Hub. The display will show the connected devices on the USB hub.

To run the example you should connect a USB Hub to the microUSB port on the top of the controlCARD and open up a serial terminal with the above settings to view the characters typed on the keyboard. Allow the example to run with the hub connected and then connect the USB Host Mouse or Keyboard.

When a USB Mouse is connected on the Hub the position of the mouse pointer and the state of the mouse buttons are output to the display. Similarly when a USB Keyboard is connected, any key press on the keyboard will cause them to be sent out the SCI at 115200 baud with no parity, 8 bits and 1 stop bit.

This example is for depicting the usage of Hub.

There are some limitations in this example :

1. The Example fails to recognize the USB Hub and the device if the Mouse/Keyboard is already connected to the USB Hub and the Hub is connected to the Micro USB of the Control Card.
2. The same port should not be used to connect a Keyboard and mouse.

## 32.6 USB Registers

### 32.6.1 USB Base Address Table

**Table 32-3. USB Base Address Table**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	CPU2	CPU2.DMA	Pipeline Protected
Instance	Structure								
UsbRegs	<a href="#">USB_REGS</a>	USBA_BASE	0x0004_0000	YES	YES	-	YES	YES	YES

### 32.6.2 USB\_REGS Registers

Table 32-4 lists the memory-mapped registers for the USB\_REGS registers. All register offset addresses not listed in Table 32-4 should be considered as reserved locations and the register contents should not be modified.

**Table 32-4. USB\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	USBFADDR	USB Device Functional Address		<a href="#">Go</a>
1h	USBPOWER	USB Power		<a href="#">Go</a>
2h	USBTXIS	USB Transmit Interrupt Status		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. [Table 32-5](#) shows the codes that are used for access types in this section.

**Table 32-5. USB\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		

**Table 32-5. USB\_REGS Access Type Codes (continued)**

Access Type	Code	Description
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 32.6.2.1 USBFADDR Register (Offset = 0h) [Reset = 00h]

USBFADDR is shown in [Figure 32-3](#) and described in [Table 32-6](#).

Return to the [Summary Table](#).

USB Device Functional Address

ISOUP	SOFT_CONN	RESERVED		RESET	RESUME	SUSPEND	PWRDNPHY
R/W-0h	R/W-0h	R-0h		R/W-0h	R/W-0h	R/W-0h	R/W-0h

**Table 32-7. USBPOWER Register Field Descriptions**

Bit	Field	Type	Reset	Description
7	ISOUP	R/W	0h	Isochronous Update Reset type: SYSRSn 0h (R/W) = Host Mode - Reserved Device Mode - No effect 1h (R/W) = Host Mode - Reserved Device Mode - The USB controller waits for an SOF token from the time the TXRDY bit is set in the USBTXCSRLn register before sending the packet. If an IN token is received before an SOF token, then a zerolength data packet is sent.
6	SOFT_CONN	R/W	0h	Soft Connect/Disconnect Reset type: SYSRSn 0h (R/W) = Host Mode - Reserved Device Mode - The USB D+/D- lines are tri-stated. 1h (R/W) = Host Mode - Reserved Device Mode - The USB D+/D- lines are enabled.
5-4	RESERVED	R	0h	Reserved
3	RESET	R/W	0h	Enable Reset Signaling Reset type: SYSRSn 0h (R/W) = Ends RESET signaling on the bus. 1h (R/W) = Enables RESET signaling on the bus.
2	RESUME	R/W	0h	Enable Resume Signaling. The bit should be cleared by software 20 ms after being set. Reset type: SYSRSn 0h (R/W) = Ends RESUME signaling on the bus. 1h (R/W) = Enables RESUME signaling when the Device is in SUSPEND mode.
1	SUSPEND	R/W	0h	Enable Suspend Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Enables SUSPEND mode.
0	PWRDNPHY	R/W	0h	Power Down PHY Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Powers down the internal USB PHY.

### 32.6.2.3 USBTXIS Register (Offset = 2h) [Reset = 0000h]

USBTXIS is shown in [Figure 32-5](#) and described in [Table 32-8](#).

Return to the [Summary Table](#).

USB Transmit Interrupt Status

**Table 32-14. USBFRAME Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-11	RESERVED	R	0h	Reserved
10-0	FRAME	R	0h	Frame Number Reset type: SYSRSn

### 32.6.2.10 USBEPIDX Register (Offset = Eh) [Reset = 00h]

USBEPIDX is shown in [Figure 32-12](#) and described in [Table 32-15](#).

Return to the [Summary Table](#).

USB Endpoint Index

**Figure 32-12. USBEPIDX Register**

7	6	5	4	3	2	1	0
RESERVED				EPIDX			
R-0h				R/W-0h			

**Table 32-15. USBEPIDX Register Field Descriptions**

Bit	Field	Type	Reset	Description
7-4	RESERVED	R	0h	Reserved
3-0	EPIDX	R/W	0h	Endpoint Index. This bit field configures which endpoint is accessed when reading or writing to one of the USB controller's indexed registers. A value of 0x0 corresponds to Endpoint 0 and a value of 0xF corresponds to Endpoint 15. Reset type: SYSRSn

### 32.6.2.11 USBTEST Register (Offset = Fh) [Reset = 00h]

USBTEST is shown in [Figure 32-13](#) and described in [Table 32-16](#).

Return to the [Summary Table](#).

USB Test Mode

**Figure 32-13. USBTEST Register**

7	6	5	4	3	2	1	0
FORCEH	FIFOACC	FORCEFS	RESERVED				
R/W-0h	R/W-0h	R/W-0h	R-0h				

**Table 32-16. USBTEST Register Field Descriptions**

Bit	Field	Type	Reset	Description
7	FORCEH	R/W	0h	Force Host Mode. While in this mode, status of the bus connection may be read using the DEV bit of the USBDEVCTL register. The operating speed is determined from the FORCEFS bit. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Forces the USB controller to enter Host mode when the SESSION bit is set, regardless of whether the USB controller is connected to any peripheral. The state of the USB0DP and USB0DM signals is ignored. The USB controller then remains in Host mode until the SESSION bit is cleared, even if a Device is disconnected. If the FORCEH bit remains set, the USB controller re-enters Host mode the next time the SESSION bit is set.
6	FIFOACC	R/W	0h	FIFO Access Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Transfers the packet in the endpoint 0 transmit FIFO to the endpoint 0 receive FIFO.
5	FORCEFS	R/W	0h	Force Full Speed Upon Reset Reset type: SYSRSn 0h (R/W) = The USB controller operates at Low Speed. 1h (R/W) = Forces the USB controller into Full-Speed mode upon receiving a USB RESET.
4-0	RESERVED	R	0h	Reserved

### 32.6.2.12 USBFIFO0 Register (Offset = 20h) [Reset = 0000000h]

USBFIFO0 is shown in [Figure 32-14](#) and described in [Table 32-17](#).

Return to the [Summary Table](#).

USB FIFO Endpoint 0

**Figure 32-14. USBFIFO0 Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**Table 32-21. USBDEVCTL Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-8	RESERVED	R	0h	Reserved
7	DEV	R	0h	Device Mode Reset type: SYSRSn 0h (R/W) = The USB controller is operating on the OTG A side of the cable. 1h (R/W) = The USB controller is operating on the OTG B side of the cable. Only valid while a session is in progress.
6	FSDEV	R/W	1h	Full Speed Device Detected Reset type: SYSRSn 0h (R/W) = A full-speed Device has not been detected on the port. 1h (R/W) = A full-speed Device has been detected on the port.
5	LSDEV	R	0h	Low Speed Device Detected Reset type: SYSRSn 0h (R/W) = A low-speed Device has not been detected on the port. 1h (R/W) = A low-speed Device has been detected on the port.
4-3	VBUS	R/W	1h	Vbus Level Reset type: SYSRSn 0h (R/W) = Above AValid, below VBusValid. VBUS is detected as above 1.5 V and below 4.75 V. 1h (R/W) = Above VBusValid. VBUS is detected as above 4.75 V.
2	HOST	R/W	1h	Host Mode Reset type: SYSRSn 0h (R/W) = The USB controller is acting as a Device. 1h (R/W) = The USB controller is acting as a Host. Only valid while a session is in progress.
1	HOSTREQ	R/W	1h	When set, the USB controller will initiate the Host Negotiation when Suspend mode is entered. It is cleared when Host Negotiation is completed. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Initiates the Host Negotiation when SUSPENDmode is entered.

**Table 32-21. USBDEVCTL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
0	SESSION	R	0h	Session Start/End Reset type: SYSRSn 0h (R/W) = When operating as a Host: When cleared by software, this bit ends a session. When operating as a Device: The USB controller has ended a session. When the USB controller is in SUSPEND mode, this bit may be cleared by software to perform a software disconnect. 1h (R/W) = When operating as a Host: When set by software, this bit starts a session. When operating as a Device: The USB controller has started a session. When set by software, the Session Request Protocol is initiated. Clearing this bit when the USB controller is not suspended results in undefined behavior.

### 32.6.2.17 USBTXFIFOSZ Register (Offset = 62h) [Reset = 00h]

USBTXFIFOSZ is shown in [Figure 32-19](#) and described in [Table 32-22](#).

Return to the [Summary Table](#).

### 32.6.2.21 USBCONTIM Register (Offset = 7Ah) [Reset = 11h]

USBCONTIM is shown in [Figure 32-23](#) and described in [Table 32-26](#).

Return to the [Summary Table](#).

USB Connect Timing

**Figure 32-23. USBCONTIM Register**

7	6	5	4	3	2	1	0
WTCON				WTID			
R/W-1h				R/W-1h			

**Table 32-26. USBCONTIM Register Field Descriptions**

Bit	Field	Type	Reset	Description
7-4	WTCON	R/W	1h	The wait ID field configures the delay required from the enable of the ID detection to when the ID value is valid, in units of 4.369 ms. The default corresponds to 52.43 ms. Reset type: SYSRSn
3-0	WTID	R/W	1h	The connect wait field configures the wait required to allow for the user's connect/disconnect filter, in units of 533.3 ns. The default corresponds to 2.667 us. Reset type: SYSRSn

### 32.6.2.22 USBFSEOF Register (Offset = 7Dh) [Reset = 77h]

USBFSEOF is shown in [Figure 32-24](#) and described in [Table 32-27](#).

Return to the [Summary Table](#).

USB Full-Speed Last Transaction to End of Frame Timing

**Figure 32-24. USBFSEOF Register**

7	6	5	4	3	2	1	0
FSEOFG							
R/W-77h							

**Table 32-27. USBFSEOF Register Field Descriptions**

Bit	Field	Type	Reset	Description
7-0	FSEOFG	R/W	77h	The full-speed end-of-frame gap field is used during full-speed transactions to configure the gap between the last transaction and the End-of-Frame (EOF), in units of 533.3 ns. The default corresponds to 63.46 us. Reset type: SYSRSn

### 32.6.2.23 USBLSEOF Register (Offset = 7Eh) [Reset = 72h]

USBLSEOF is shown in [Figure 32-25](#) and described in [Table 32-28](#).

Return to the [Summary Table](#).

USB Low-Speed Last Transaction to End of Frame Timing

### 32.6.2.45 USBCSRL0 Register (Offset = 102h) [Reset = 00h]

USBCSRL0 is shown in [Figure 32-47](#) and described in [Table 32-50](#).

Return to the [Summary Table](#).

USB Control and Status Endpoint 0 Low

**Figure 32-47. USBCSRL0 Register**

7	6	5	4	3	2	1	0
SETENDC_NAKTO	RXRDYC_STATUS	STALL_RQPKT	SETEND_ERROR	DATAEND_SETUP	STALLED	TXRDY	RXRDY
W1C-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

**Table 32-50. USBCSRL0 Register Field Descriptions**

Bit	Field	Type	Reset	Description
7	SETENDC_NAKTO	W1C	0h	NAK Timeout. Software must clear this bit to allow the endpoint to continue. Reset type: SYSRSn 0h (R/W) = No timeout 1h (R/W) = Indicates that endpoint 0 is halted following the receipt of NAK responses for longer than the time set by the USBNAKLMT register
6	RXRDYC_STATUS	R/W	0h	Status Packet. Setting this bit ensures that the DT bit is set in the USBCSRH0 register so that a DATA1 packet is used for the STATUS stage transaction. Reset type: SYSRSn 0h (R/W) = No transaction 1h (R/W) = The Endpoint 1 transmit interrupt is asserted.
5	STALL_RQPKT	R/W	0h	Request Packet. This bit is cleared when the RXRDY bit is set. Reset type: SYSRSn 0h (R/W) = No request 1h (R/W) = Initiates a STATUS stage transaction. This bit must be set at the same time as the TXRDY or REQPKT bit is set. This bit is automatically cleared when the STATUS stage is over.
4	SETEND_ERROR	R/W	0h	Error. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = No error 1h (R/W) = Three attempts have been made to perform a transaction with no response from the peripheral. The EP0 bit in the USBTXIS register is also set in this situation.
3	DATAEND_SETUP	R/W	0h	Setup Packet. Setting this bit always clears the DT bit in the USBCSRH0 register to send a DATA0 packet. Reset type: SYSRSn 0h (R/W) = Sends an OUT token. 1h (R/W) = Sends a SETUP token instead of an OUT token for the transaction. This bit should be set at the same time as the TXRDY bit is set.
2	STALLED	R/W	0h	Endpoint Stalled. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = No handshake has been received. 1h (R/W) = A STALL handshake has been received

**Table 32-50. USBCSRL0 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
1	TXRDY	R/W	0h	Transmit Packet Ready. If both the TXRDY and SETUP bits are set, a setup packet is sent. If just TXRDY is set, an OUT packet is sent. Reset type: SYSRSn 0h (R/W) = No transmit packet is ready. 1h (R/W) = Software sets this bit after loading a data packet into the TX FIFO. The EP0 bit in the USBTXIS register is also set in this situation.
0	RXRDY	R/W	0h	Receive Packet Ready. Software must clear this bit after the packet has been read from the FIFO to acknowledge that the data has been read from the FIFO. Reset type: SYSRSn 0h (R/W) = No receive packet has been received. 1h (R/W) = Indicates that a data packet has been received in the RX FIFO. The EP0 bit in the USBTXIS register is also set in this situation.

### 32.6.2.46 USBCSRH0 Register (Offset = 103h) [Reset = 00h]

USBCSRH0 is shown in [Figure 32-48](#) and described in [Table 32-51](#).

Return to the [Summary Table](#).

USB Control and Status Endpoint 0 High

**Figure 32-48. USBCSRH0 Register**

7	6	5	4	3	2	1	0
RESERVED					DTWE	DT	FLUSH
R-0h					R/W-0h	R/W-0h	R/W-0h

**Table 32-51. USBCSRH0 Register Field Descriptions**

Bit	Field	Type	Reset	Description
7-3	RESERVED	R	0h	Reserved
2	DTWE	R/W	0h	Data Toggle Write Enable. This bit is automatically cleared once the new value is written. Reset type: SYSRSn 0h (R/W) = The DT bit cannot be written. 1h (R/W) = Enables the current state of the endpoint 0 data toggle to be written (see DT bit).
1	DT	R/W	0h	Data Toggle. When read, this bit indicates the current state of the endpoint 0 data toggle. If DTWE is set, this bit may be written with the required setting of the data toggle. If DTWE is Low, this bit cannot be written. Care should be taken when writing to this bit as it should only be changed to RESET USB endpoint 0. Reset type: SYSRSn
0	FLUSH	R/W	0h	Flush FIFO. This bit is automatically cleared after the flush is performed. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Flushes the next packet to be transmitted/read from the endpoint 0 FIFO. The FIFO pointer is reset and the TXRDY/RXRDY bit is cleared. Note: This bit should only be set when TXRDY/RXRDY is set. At other times, it may cause data to be corrupted..

### 32.6.2.47 USBCOUNT0 Register (Offset = 108h) [Reset = 00h]

USBCOUNT0 is shown in [Figure 32-49](#) and described in [Table 32-52](#).

Return to the [Summary Table](#).

USB Receive Byte Count Endpoint 0

**Figure 32-49. USBCOUNT0 Register**

Bit	Field	Type	Reset	Description
15-11	RESERVED	R	0h	Reserved
10-0	MAXLOAD	R/W	0h	Maximum Payload specifies the maximum payload in bytes per transaction. Reset type: SYSRSn

### 32.6.2.51 USBTXCSRL1 Register (Offset = 112h) [Reset = 00h]

USBTXCSRL1 is shown in [Figure 32-53](#) and described in [Table 32-56](#).

Return to the [Summary Table](#).

USB Transmit Control and Status Endpoint 1 Low

**Figure 32-53. USBTXCSRL1 Register**

7	6	5	4	3	2	1	0
NAKTO	CLRDT	STALLED	STALL_SETUP	FLUSH	UNDRN_ERRO R1	FIFONE	TXRDY
R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

**Table 32-56. USBTXCSRL1 Register Field Descriptions**

Bit	Field	Type	Reset	Description
7	NAKTO	R/W	0h	NAK Timeout. Software must clear this bit to allow the endpoint to continue. Reset type: SYSRSn 0h (R/W) = No timeout 1h (R/W) = Bulk endpoints only: Indicates that the transmit endpoint is halted following the receipt of NAK responses for longer than the time set by the NAKLMT field in the USBTXINTERVAL[n] register.
6	CLRDT	R/W	0h	Clear DataToggle Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Writing a 1 to this bit clears the DT bit in the USBTXCSRH[n] register.
5	STALLED	R/W	0h	Endpoint Stalled. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = A STALL handshake has not been received 1h (R/W) = Indicates that a STALL handshake has been received. When this bit is set, any DMA request that is in progress is stopped, the FIFO is completely flushed, and the TXRDY bit is cleared.
4	STALL_SETUP	R/W	0h	Setup Packet. Reset type: SYSRSn 0h (R/W) = No SETUP token is sent. 1h (R/W) = Sends a SETUP token instead of an OUT token for the transaction. This bit should be set at the same time as the TXRDY bit is set. Note: Setting this bit also clears the DT bit in the USBTXCSRH[n] register.
3	FLUSH	R/W	0h	Flush FIFO. This bit can be set simultaneously with the TXRDY bit to abort the packet that is currently being loaded into the FIFO. Note that if the FIFO is double-buffered, FLUSH may have to be set twice to completely clear the FIFO. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Flushes the latest packet from the endpoint transmit FIFO. The FIFO pointer is reset and the TXRDY bit is cleared. The EPn bit in the USBTXIS register is also set in this situation. Note: This bit should only be set when the TXRDY bit is set. At other times, it may cause data to be corrupted.

**Table 32-56. USBTXCSRL1 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
2	UNDRN_ERROR1	R/W	0h	Error. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = No error 1h (R/W) = Three attempts have been made to send a packet and no handshake packet has been received. The TXRDY bit is cleared, the EPn bit in the USBTXIS register is set, and the FIFO is completely flushed in this situation. Note: This bit is valid only when the endpoint is operating in Bulk or Interrupt mode.
1	FIFONE	R/W	0h	FIFO Not Empty Reset type: SYSRSn 0h (R/W) = The FIFO is empty 1h (R/W) = At least one packet is in the transmit FIFO.
0	TXRDY	R/W	0h	Transmit Packet Ready. This bit is cleared automatically when a data packet has been transmitted. The EPn bit in the USBTXIS register is also set at this point. TXRDY is also automatically cleared prior to loading a second packet into a double-buffered FIFO. Reset type: SYSRSn 0h (R/W) = No transmit packet is ready. 1h (R/W) = Software sets this bit after loading a data packet into the TX FIFO.

### 32.6.2.52 USBTXCSRH1 Register (Offset = 113h) [Reset = 00h]

USBTXCSRH1 is shown in [Figure 32-54](#) and described in [Table 32-57](#).

Return to the [Summary Table](#).

USB Transmit Control and Status Endpoint 1 High

**Figure 32-54. USBTXCSRH1 Register**

7	6	5	4	3	2	1	0
AUTOSET	ISO	MODE	DMAEN	FDT	DMAMOD	DTWE	DT
R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

**Table 32-57. USBTXCSRH1 Register Field Descriptions**

Bit	Field	Type	Reset	Description
7	AUTOSET	R/W	0h	Auto Set Reset type: SYSRSn 0h (R/W) = The TXRDY bit must be set manually. 1h (R/W) = Enables the TXRDY bit to be automatically set when data of the maximum packet size (value in USBTXMAXP[n]) is loaded into the transmit FIFO. If a packet of less than the maximum packet size is loaded, then the TXRDY bit must be set manually.
6	ISO	R/W	0h	Isochronous Transfers Reset type: SYSRSn 0h (R/W) = Enables the transmit endpoint for bulk or interrupt transfers. 1h (R/W) = Enables the transmit endpoint for isochronous transfers.
5	MODE	R/W	0h	Mode Note: This bit only has an effect when the same endpoint FIFO is used for both transmit and receive transactions. Reset type: SYSRSn 0h (R/W) = Enables the endpoint direction as RX. 1h (R/W) = Enables the endpoint direction as TX.
4	DMAEN	R/W	0h	DMA Request Enable Note: Three TX and three /RX endpoints can be connected to the DMA module. If this bit is set for a particular endpoint, the DMAATX, DMABTX, or DMACTX field in the USB DMA Select (USBDMASEL) register must be programmed correspondingly Reset type: SYSRSn 0h (R/W) = Disables the DMA request for the transmit endpoint. 1h (R/W) = Enables the DMA request for the transmit endpoint.
3	FDT	R/W	0h	Force Data Toggle Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Forces the endpoint DT bit to switch and the data packet to be cleared from the FIFO, regardless of whether an ACK was received. This bit can be used by interrupt transmit endpoints that are used to communicate rate feedback for isochronous endpoints. Note: This bit should only be set when the TXRDY bit is set. At other times, it may cause data to be corrupted.
2	DMAMOD	R/W	0h	DMA Request Mode Reset type: SYSRSn 0h (R/W) = An interrupt is generated after every DMA packet transfer. 1h (R/W) = An interrupt is generated only after the entire DMA transfer is complete. Note: This bit is valid only when the endpoint is operating in Bulk or Interrupt mode.

**Table 32-57. USBTXCSRH1 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
1	DTWE	R/W	0h	Data Toggle Write Enable. This bit is automatically cleared once the new value is written. Reset type: SYSRSn 0h (R/W) = The DT bit cannot be written. 1h (R/W) = Enables the current state of the transmit endpoint data to be written (see DT bit).
0	DT	R/W	0h	Data Toggle. When read, this bit indicates the current state of the transmit endpoint data toggle. If DTWE is High, this bit can be written with the required setting of the data toggle. If DTWE is Low, any value written to this bit is ignored. Care should be taken when writing to this bit as it should only be changed to RESET the transmit endpoint. Reset type: SYSRSn

### 32.6.2.53 USBRXMAXP1 Register (Offset = 114h) [Reset = 0000h]

USBRXMAXP1 is shown in [Figure 32-55](#) and described in [Table 32-58](#).

Return to the [Summary Table](#).

10-0	MAXLOAD	R/W	0h	Maximum Payload specifies the maximum payload in bytes per transaction. Reset type: SYSRSn

### 32.6.2.54 USBRXCSRL1 Register (Offset = 116h) [Reset = 00h]

USBRXCSRL1 is shown in [Figure 32-56](#) and described in [Table 32-59](#).

Return to the [Summary Table](#).

USB Receive Control and Status Endpoint 1 Low

**Figure 32-56. USBRXCSRL1 Register**

7	6	5	4	3	2	1	0
CLRDT	STALLED	STALLREQPKT	FLUSH	DATAERRNAK TO	OVERERROR1	FULL	RXRDY
W1C-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

**Table 32-59. USBRXCSRL1 Register Field Descriptions**

Bit	Field	Type	Reset	Description
7	CLRDT	W1C	0h	Clear Data Toggle. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Writing a 1 to this bit clears the DT bit in the USBRXCSRH[n] register.
6	STALLED	R/W	0h	Endpoint Stalled. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = No handshake has been received. 1h (R/W) = A STALL handshake has been received. The EPn bit in the USBRXIS register is also set.
5	STALLREQPKT	R/W	0h	Request Packet. This bit is cleared when the RXRDY bit is set. Reset type: SYSRSn 0h (R/W) = No request 1h (R/W) = Requests an IN transaction.
4	FLUSH	R/W	0h	Flush FIFO. If the FIFO is double-buffered, FLUSH may have to be set twice to completely clear the FIFO. Note: This bit should only be set when the RXRDY bit is set. At other times, it may cause data to be corrupted. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Flushes the next packet to be read from the endpoint receive FIFO. The FIFO pointer is reset and the RXRDY bit is cleared
3	DATAERRNAKTO	R/W	0h	Data Error / NAK Timeout Reset type: SYSRSn 0h (R/W) = Normal operation 1h (R/W) = Isochronous endpoints only: Indicates that RXRDY is set and the data packet has a CRC or bit-stuff error. This bit is cleared when RXRDY is cleared. Bulk endpoints only: Indicates that the receive endpoint is halted following the receipt of NAK responses for longer than the time set by the NAKLMT field in the USBRXINTERVAL[n] register. Software must clear this bit to allow the endpoint to continue.
2	OVERERROR1	R/W	0h	Error. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = No error 1h (R/W) = Three attempts have been made to receive a packet and no data packet has been received. The Epn bit in the USBRXIS register is set in this situation.
1	FULL	R/W	0h	FIFO Full Reset type: SYSRSn 0h (R/W) = The receive FIFO is not full. 1h (R/W) = No more packets can be loaded into the receive FIFO.

**Table 32-59. USBRXCSRL1 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
0	RXRDY	R/W	0h	Receive Packet Ready. If the AUTOCLR bit in the USBRXCSRH[n] register is set, then the this bit is automatically cleared when a packet of USBRXMAXP[n] bytes has been unloaded from the receive FIFO. If the AUTOCLR bit is clear, or if packets of less than the maximum packet size are unloaded, then software must clear this bit manually when the packet has been unloaded from the receive FIFO Reset type: SYSRSn 0h (R/W) = No data packet has been received. 1h (R/W) = Indicates that a data packet has been received. The EPn bit in the USBTXIS register is also set in this situation

### 32.6.2.55 USBRXCSRH1 Register (Offset = 117h) [Reset = 00h]

USBRXCSRH1 is shown in [Figure 32-57](#) and described in [Table 32-60](#).

Return to the [Summary Table](#).

USB Receive Control and Status Endpoint 1 High

**Figure 32-57. USBRXCSRH1 Register**

7	6	5	4	3	2	1	0
AUTOCL	ISOAUTORQ	DMAEN	DISNYETPIDERR	DMAMOD	DTWE	DT	RESERVED
W1C-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

**Table 32-60. USBRXCSRH1 Register Field Descriptions**

Bit	Field	Type	Reset	Description
7	AUTOCL	W1C	0h	Auto Clear Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Enables the RXRDY bit to be automatically cleared when a packet of USBRXMAXP[n] bytes has been unloaded from the receive FIFO. When packets of less than the maximum packet size are unloaded, RXRDY must be cleared manually. Care must be taken when using DMA to unload the receive FIFO as data is read from the receive FIFO in 4-byte chunks regardless of the value of the MAXLOAD field in the USBRXMAXP[n] register,
6	ISOAUTORQ	R/W	0h	Auto Request Note: This bit is automatically cleared when a short packet is received. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Enables the REQPKT bit to be automatically set when the RXRDY bit is cleared
5	DMAEN	R/W	0h	DMA Request Enable Note: Three TX and three RX endpoints can be connected to the DMA module. If this bit is set for a particular endpoint, the DMAARX, DMABRX, or DMACRX field in the USB DMA Select (USBDMASEL) register must be programmed correspondingly Reset type: SYSRSn 0h (R/W) = Disables the DMA request for the receive endpoint. 1h (R/W) = Enables the DMA request for the receive endpoint.
4	DISNYETPIDERR	R/W	0h	PID Error. This bit is ignored in bulk or interrupt transactions. Reset type: SYSRSn 0h (R/W) = No error 1h (R/W) = Indicates a PID error in the received packet of an isochronous transaction.
3	DMAMOD	R/W	0h	DMAMOD Note: This bit must not be cleared either before or in the same cycle as the above DMAEN bit is cleared. Reset type: SYSRSn 0h (R/W) = An interrupt is generated after every DMA packet transfer. 1h (R/W) = An interrupt is generated only after the entire DMA transfer is complete.
2	DTWE	R/W	0h	Data Toggle Write Enable. This bit is automatically cleared once the new value is written. Reset type: SYSRSn 0h (R/W) = The DT bit cannot be written. 1h (R/W) = Enables the current state of the receive endpoint data to be written (see DT bit).

**Table 32-60. USBRXCSRH1 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
1	DT	R/W	0h	Data Toggle. When read, this bit indicates the current state of the receive data toggle. If DTWE is High, this bit may be written with the required setting of the data toggle. If DTWE is Low, any value written to this bit is ignored. Care should be taken when writing to this bit as it should only be changed to RESET the receive endpoint. Reset type: SYSRSn
0	RESERVED	R/W	0h	Reserved

### 32.6.2.56 USBRXCOUNT1 Register (Offset = 118h) [Reset = 0000h]

USBRXCOUNT1 is shown in [Figure 32-58](#) and described in [Table 32-61](#).

Return to the [Summary Table](#).

### 32.6.2.62 USBTXCSRL2 Register (Offset = 122h) [Reset = 00h]

USBTXCSRL2 is shown in [Figure 32-64](#) and described in [Table 32-67](#).

Return to the [Summary Table](#).

USB Transmit Control and Status Endpoint 2 Low

**Figure 32-64. USBTXCSRL2 Register**

7	6	5	4	3	2	1	0
NAKTO	CLRDT	STALLED	STALL_SETUP	FLUSH	UNDRNERROR 2	FIFONE	TXRDY
R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

**Table 32-67. USBTXCSRL2 Register Field Descriptions**

Bit	Field	Type	Reset	Description
7	NAKTO	R/W	0h	NAK Timeout. Software must clear this bit to allow the endpoint to continue. Reset type: SYSRSn 0h (R/W) = No timeout 1h (R/W) = Bulk endpoints only: Indicates that the transmit endpoint is halted following the receipt of NAK responses for longer than the time set by the NAKLMT field in the USBTXINTERVAL[n] register.
6	CLRDT	R/W	0h	Clear DataToggle Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Writing a 1 to this bit clears the DT bit in the USBTXCSRH[n] register.
5	STALLED	R/W	0h	Endpoint Stalled. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = A STALL handshake has not been received 1h (R/W) = Indicates that a STALL handshake has been received. When this bit is set, any DMA request that is in progress is stopped, the FIFO is completely flushed, and the TXRDY bit is cleared.
4	STALL_SETUP	R/W	0h	Setup Packet. Reset type: SYSRSn 0h (R/W) = No SETUP token is sent. 1h (R/W) = Sends a SETUP token instead of an OUT token for the transaction. This bit should be set at the same time as the TXRDY bit is set. Note: Setting this bit also clears the DT bit in the USBTXCSRH[n] register.
3	FLUSH	R/W	0h	Flush FIFO. This bit can be set simultaneously with the TXRDY bit to abort the packet that is currently being loaded into the FIFO. Note that if the FIFO is double-buffered, FLUSH may have to be set twice to completely clear the FIFO. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Flushes the latest packet from the endpoint transmit FIFO. The FIFO pointer is reset and the TXRDY bit is cleared. The EPn bit in the USBTXIS register is also set in this situation. Note: This bit should only be set when the TXRDY bit is set. At other times, it may cause data to be corrupted.

**Table 32-67. USBTXCSRL2 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
2	UNDRNERROR2	R/W	0h	Error. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = No error 1h (R/W) = Three attempts have been made to send a packet and no handshake packet has been received. The TXRDY bit is cleared, the EPn bit in the USBTXIS register is set, and the FIFO is completely flushed in this situation. Note: This bit is valid only when the endpoint is operating in Bulk or Interrupt mode.
1	FIFONE	R/W	0h	FIFO Not Empty Reset type: SYSRSn 0h (R/W) = The FIFO is empty 1h (R/W) = At least one packet is in the transmit FIFO.
0	TXRDY	R/W	0h	Transmit Packet Ready. This bit is cleared automatically when a data packet has been transmitted. The EPn bit in the USBTXIS register is also set at this point. TXRDY is also automatically cleared prior to loading a second packet into a double-buffered FIFO. Reset type: SYSRSn 0h (R/W) = No transmit packet is ready. 1h (R/W) = Software sets this bit after loading a data packet into the TX FIFO.

### 32.6.2.63 USBTXCSRH2 Register (Offset = 123h) [Reset = 00h]

USBTXCSRH2 is shown in [Figure 32-65](#) and described in [Table 32-68](#).

Return to the [Summary Table](#).

USB Transmit Control and Status Endpoint 2 High

**Figure 32-65. USBTXCSRH2 Register**

7	6	5	4	3	2	1	0
AUTOSET	ISO	MODE	DMAEN	FDT	DMAMOD	DTWE	DT
R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

**Table 32-68. USBTXCSRH2 Register Field Descriptions**

Bit	Field	Type	Reset	Description
7	AUTOSET	R/W	0h	Auto Set Reset type: SYSRSn 0h (R/W) = The TXRDY bit must be set manually. 1h (R/W) = Enables the TXRDY bit to be automatically set when data of the maximum packet size (value in USBTXMAXP[n]) is loaded into the transmit FIFO. If a packet of less than the maximum packet size is loaded, then the TXRDY bit must be set manually.
6	ISO	R/W	0h	Isochronous Transfers Reset type: SYSRSn 0h (R/W) = Enables the transmit endpoint for bulk or interrupt transfers. 1h (R/W) = Enables the transmit endpoint for isochronous transfers.
5	MODE	R/W	0h	Mode Note: This bit only has an effect when the same endpoint FIFO is used for both transmit and receive transactions. Reset type: SYSRSn 0h (R/W) = Enables the endpoint direction as RX. 1h (R/W) = Enables the endpoint direction as TX.
4	DMAEN	R/W	0h	DMA Request Enable Note: Three TX and three /RX endpoints can be connected to the DMA module. If this bit is set for a particular endpoint, the DMAATX, DMABTX, or DMACTX field in the USB DMA Select (USBDMASEL) register must be programmed correspondingly Reset type: SYSRSn 0h (R/W) = Disables the DMA request for the transmit endpoint. 1h (R/W) = Enables the DMA request for the transmit endpoint.
3	FDT	R/W	0h	Force Data Toggle Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Forces the endpoint DT bit to switch and the data packet to be cleared from the FIFO, regardless of whether an ACK was received. This bit can be used by interrupt transmit endpoints that are used to communicate rate feedback for isochronous endpoints. Note: This bit should only be set when the TXRDY bit is set. At other times, it may cause data to be corrupted.
2	DMAMOD	R/W	0h	DMA Request Mode Reset type: SYSRSn 0h (R/W) = An interrupt is generated after every DMA packet transfer. 1h (R/W) = An interrupt is generated only after the entire DMA transfer is complete. Note: This bit is valid only when the endpoint is operating in Bulk or Interrupt mode.

**Table 32-68. USBTXCSRH2 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
1	DTWE	R/W	0h	Data Toggle Write Enable. This bit is automatically cleared once the new value is written. Reset type: SYSRSn 0h (R/W) = The DT bit cannot be written. 1h (R/W) = Enables the current state of the transmit endpoint data to be written (see DT bit).
0	DT	R/W	0h	Data Toggle. When read, this bit indicates the current state of the transmit endpoint data toggle. If DTWE is High, this bit can be written with the required setting of the data toggle. If DTWE is Low, any value written to this bit is ignored. Care should be taken when writing to this bit as it should only be changed to RESET the transmit endpoint. Reset type: SYSRSn

### 32.6.2.64 USBRXMAXP2 Register (Offset = 124h) [Reset = 0000h]

USBRXMAXP2 is shown in [Figure 32-66](#) and described in [Table 32-69](#).

Return to the [Summary Table](#).

### 32.6.2.65 USBRXCSRL2 Register (Offset = 126h) [Reset = 00h]

USBRXCSRL2 is shown in [Figure 32-67](#) and described in [Table 32-70](#).

Return to the [Summary Table](#).

USB Receive Control and Status Endpoint 2 Low

**Figure 32-67. USBRXCSRL2 Register**

7	6	5	4	3	2	1	0
CLRDT	STALLED	STALLREQPKT	FLUSH	DATAERRNAK TO	OVERERROR2	FULL	RXRDY
W1C-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

**Table 32-70. USBRXCSRL2 Register Field Descriptions**

Bit	Field	Type	Reset	Description
7	CLRDT	W1C	0h	Clear Data Toggle. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Writing a 1 to this bit clears the DT bit in the USBRXCSRH[n] register.
6	STALLED	R/W	0h	Endpoint Stalled. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = No handshake has been received. 1h (R/W) = A STALL handshake has been received. The EPn bit in the USBRXIS register is also set.
5	STALLREQPKT	R/W	0h	Request Packet. This bit is cleared when the RXRDY bit is set. Reset type: SYSRSn 0h (R/W) = No request 1h (R/W) = Requests an IN transaction.
4	FLUSH	R/W	0h	Flush FIFO. If the FIFO is double-buffered, FLUSH may have to be set twice to completely clear the FIFO. Note: This bit should only be set when the RXRDY bit is set. At other times, it may cause data to be corrupted. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Flushes the next packet to be read from the endpoint receive FIFO. The FIFO pointer is reset and the RXRDY bit is cleared
3	DATAERRNAKTO	R/W	0h	Data Error / NAK Timeout Reset type: SYSRSn 0h (R/W) = Normal operation 1h (R/W) = Isochronous endpoints only: Indicates that RXRDY is set and the data packet has a CRC or bit-stuff error. This bit is cleared when RXRDY is cleared. Bulk endpoints only: Indicates that the receive endpoint is halted following the receipt of NAK responses for longer than the time set by the NAKLMT field in the USBRXINTERVAL[n] register. Software must clear this bit to allow the endpoint to continue.
2	OVERERROR2	R/W	0h	Error. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = No error 1h (R/W) = Three attempts have been made to receive a packet and no data packet has been received. The Epn bit in the USBRXIS register is set in this situation.
1	FULL	R/W	0h	FIFO Full Reset type: SYSRSn 0h (R/W) = The receive FIFO is not full. 1h (R/W) = No more packets can be loaded into the receive FIFO.

**Table 32-70. USBRXCSRL2 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
0	RXRDY	R/W	0h	Receive Packet Ready. If the AUTOCLR bit in the USBRXCSRH[n] register is set, then the this bit is automatically cleared when a packet of USBRXMAXP[n] bytes has been unloaded from the receive FIFO. If the AUTOCLR bit is clear, or if packets of less than the maximum packet size are unloaded, then software must clear this bit manually when the packet has been unloaded from the receive FIFO Reset type: SYSRSn 0h (R/W) = No data packet has been received. 1h (R/W) = Indicates that a data packet has been received. The EPn bit in the USBTXIS register is also set in this situation

### 32.6.2.66 USBRXCSRH2 Register (Offset = 127h) [Reset = 00h]

USBRXCSRH2 is shown in [Figure 32-68](#) and described in [Table 32-71](#).

Return to the [Summary Table](#).

USB Receive Control and Status Endpoint 2 High

**Figure 32-68. USBRXCSRH2 Register**

Bit	Field	Type	Reset	Description
15-11	RESERVED	R	0h	Reserved
10-0	MAXLOAD	R/W	0h	Maximum Payload specifies the maximum payload in bytes per transaction. Reset type: SYSRSn

### 32.6.2.73 USBTXCSRL3 Register (Offset = 132h) [Reset = 00h]

USBTXCSRL3 is shown in [Figure 32-75](#) and described in [Table 32-78](#).

Return to the [Summary Table](#).

USB Transmit Control and Status Endpoint 3 Low

**Figure 32-75. USBTXCSRL3 Register**

7	6	5	4	3	2	1	0
NAKTO	CLRDT	STALLED	STALL_SETUP	FLUSH	UNDRNERROR 3	FIFONE	TXRDY
R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

**Table 32-78. USBTXCSRL3 Register Field Descriptions**

Bit	Field	Type	Reset	Description
7	NAKTO	R/W	0h	NAK Timeout. Software must clear this bit to allow the endpoint to continue. Reset type: SYSRSn 0h (R/W) = No timeout 1h (R/W) = Bulk endpoints only: Indicates that the transmit endpoint is halted following the receipt of NAK responses for longer than the time set by the NAKLMT field in the USBTXINTERVAL[n] register.
6	CLRDT	R/W	0h	Clear DataToggle Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Writing a 1 to this bit clears the DT bit in the USBTXCSRH[n] register.
5	STALLED	R/W	0h	Endpoint Stalled. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = A STALL handshake has not been received 1h (R/W) = Indicates that a STALL handshake has been received. When this bit is set, any DMA request that is in progress is stopped, the FIFO is completely flushed, and the TXRDY bit is cleared.
4	STALL_SETUP	R/W	0h	Setup Packet. Reset type: SYSRSn 0h (R/W) = No SETUP token is sent. 1h (R/W) = Sends a SETUP token instead of an OUT token for the transaction. This bit should be set at the same time as the TXRDY bit is set. Note: Setting this bit also clears the DT bit in the USBTXCSRH[n] register.
3	FLUSH	R/W	0h	Flush FIFO. This bit can be set simultaneously with the TXRDY bit to abort the packet that is currently being loaded into the FIFO. Note that if the FIFO is double-buffered, FLUSH may have to be set twice to completely clear the FIFO. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Flushes the latest packet from the endpoint transmit FIFO. The FIFO pointer is reset and the TXRDY bit is cleared. The EPn bit in the USBTXIS register is also set in this situation. Note: This bit should only be set when the TXRDY bit is set. At other times, it may cause data to be corrupted.

**Table 32-78. USBTXCSRL3 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
2	UNDRNERROR3	R/W	0h	Error. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = No error 1h (R/W) = Three attempts have been made to send a packet and no handshake packet has been received. The TXRDY bit is cleared, the EPn bit in the USBTXIS register is set, and the FIFO is completely flushed in this situation. Note: This bit is valid only when the endpoint is operating in Bulk or Interrupt mode.
1	FIFONE	R/W	0h	FIFO Not Empty Reset type: SYSRSn 0h (R/W) = The FIFO is empty 1h (R/W) = At least one packet is in the transmit FIFO.
0	TXRDY	R/W	0h	Transmit Packet Ready. This bit is cleared automatically when a data packet has been transmitted. The EPn bit in the USBTXIS register is also set at this point. TXRDY is also automatically cleared prior to loading a second packet into a double-buffered FIFO. Reset type: SYSRSn 0h (R/W) = No transmit packet is ready. 1h (R/W) = Software sets this bit after loading a data packet into the TX FIFO.

### 32.6.2.74 USBTXCSRH3 Register (Offset = 133h) [Reset = 00h]

USBTXCSRH3 is shown in [Figure 32-76](#) and described in [Table 32-79](#).

Return to the [Summary Table](#).

USB Transmit Control and Status Endpoint 3 High

**Figure 32-76. USBTXCSRH3 Register**

7	6	5	4	3	2	1	0
AUTOSET	ISO	MODE	DMAEN	FDT	DMAMOD	DTWE	DT
R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

**Table 32-79. USBTXCSRH3 Register Field Descriptions**

Bit	Field	Type	Reset	Description
7	AUTOSET	R/W	0h	Auto Set Reset type: SYSRSn 0h (R/W) = The TXRDY bit must be set manually. 1h (R/W) = Enables the TXRDY bit to be automatically set when data of the maximum packet size (value in USBTXMAXP[n]) is loaded into the transmit FIFO. If a packet of less than the maximum packet size is loaded, then the TXRDY bit must be set manually.
6	ISO	R/W	0h	Isochronous Transfers Reset type: SYSRSn 0h (R/W) = Enables the transmit endpoint for bulk or interrupt transfers. 1h (R/W) = Enables the transmit endpoint for isochronous transfers.
5	MODE	R/W	0h	Mode Note: This bit only has an effect when the same endpoint FIFO is used for both transmit and receive transactions. Reset type: SYSRSn 0h (R/W) = Enables the endpoint direction as RX. 1h (R/W) = Enables the endpoint direction as TX.
4	DMAEN	R/W	0h	DMA Request Enable Note: Three TX and three /RX endpoints can be connected to the DMA module. If this bit is set for a particular endpoint, the DMAATX, DMABTX, or DMACTX field in the USB DMA Select (USBDMASEL) register must be programmed correspondingly Reset type: SYSRSn 0h (R/W) = Disables the DMA request for the transmit endpoint. 1h (R/W) = Enables the DMA request for the transmit endpoint.
3	FDT	R/W	0h	Force Data Toggle Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Forces the endpoint DT bit to switch and the data packet to be cleared from the FIFO, regardless of whether an ACK was received. This bit can be used by interrupt transmit endpoints that are used to communicate rate feedback for isochronous endpoints. Note: This bit should only be set when the TXRDY bit is set. At other times, it may cause data to be corrupted.
2	DMAMOD	R/W	0h	DMA Request Mode Reset type: SYSRSn 0h (R/W) = An interrupt is generated after every DMA packet transfer. 1h (R/W) = An interrupt is generated only after the entire DMA transfer is complete. Note: This bit is valid only when the endpoint is operating in Bulk or Interrupt mode.

**Table 32-79. USBTXCSRH3 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
1	DTWE	R/W	0h	Data Toggle Write Enable. This bit is automatically cleared once the new value is written. Reset type: SYSRSn 0h (R/W) = The DT bit cannot be written. 1h (R/W) = Enables the current state of the transmit endpoint data to be written (see DT bit).
0	DT	R/W	0h	Data Toggle. When read, this bit indicates the current state of the transmit endpoint data toggle. If DTWE is High, this bit can be written with the required setting of the data toggle. If DTWE is Low, any value written to this bit is ignored. Care should be taken when writing to this bit as it should only be changed to RESET the transmit endpoint. Reset type: SYSRSn

### 32.6.2.75 USBRXMAXP3 Register (Offset = 134h) [Reset = 0000h]

USBRXMAXP3 is shown in [Figure 32-77](#) and described in [Table 32-80](#).

Return to the [Summary Table](#).

### 32.6.2.76 USBRXCSRL3 Register (Offset = 136h) [Reset = 00h]

USBRXCSRL3 is shown in [Figure 32-78](#) and described in [Table 32-81](#).

Return to the [Summary Table](#).

USB Receive Control and Status Endpoint 3 Low

**Figure 32-78. USBRXCSRL3 Register**

7	6	5	4	3	2	1	0
CLRDT	STALLED	STALLREQPKT	FLUSH	DATAERRNAK TO	OVERERROR3	FULL	RXRDY
W1C-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

**Table 32-81. USBRXCSRL3 Register Field Descriptions**

Bit	Field	Type	Reset	Description
7	CLRDT	W1C	0h	Clear Data Toggle. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Writing a 1 to this bit clears the DT bit in the USBRXCSRH[n] register.
6	STALLED	R/W	0h	Endpoint Stalled. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = No handshake has been received. 1h (R/W) = A STALL handshake has been received. The EPn bit in the USBRXIS register is also set.
5	STALLREQPKT	R/W	0h	Request Packet. This bit is cleared when the RXRDY bit is set. Reset type: SYSRSn 0h (R/W) = No request 1h (R/W) = Requests an IN transaction.
4	FLUSH	R/W	0h	Flush FIFO. If the FIFO is double-buffered, FLUSH may have to be set twice to completely clear the FIFO. Note: This bit should only be set when the RXRDY bit is set. At other times, it may cause data to be corrupted. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Flushes the next packet to be read from the endpoint receive FIFO. The FIFO pointer is reset and the RXRDY bit is cleared
3	DATAERRNAKTO	R/W	0h	Data Error / NAK Timeout Reset type: SYSRSn 0h (R/W) = Normal operation 1h (R/W) = Isochronous endpoints only: Indicates that RXRDY is set and the data packet has a CRC or bit-stuff error. This bit is cleared when RXRDY is cleared. Bulk endpoints only: Indicates that the receive endpoint is halted following the receipt of NAK responses for longer than the time set by the NAKLMT field in the USBRXINTERVAL[n] register. Software must clear this bit to allow the endpoint to continue.
2	OVERERROR3	R/W	0h	Error. Software must clear this bit. Reset type: SYSRSn 0h (R/W) = No error 1h (R/W) = Three attempts have been made to receive a packet and no data packet has been received. The Epn bit in the USBRXIS register is set in this situation.
1	FULL	R/W	0h	FIFO Full Reset type: SYSRSn 0h (R/W) = The receive FIFO is not full. 1h (R/W) = No more packets can be loaded into the receive FIFO.

**Table 32-81. USBRXCSRL3 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
0	RXRDY	R/W	0h	Receive Packet Ready. If the AUTOCLR bit in the USBRXCSRH[n] register is set, then the this bit is automatically cleared when a packet of USBRXMAXP[n] bytes has been unloaded from the receive FIFO. If the AUTOCLR bit is clear, or if packets of less than the maximum packet size are unloaded, then software must clear this bit manually when the packet has been unloaded from the receive FIFO Reset type: SYSRSn 0h (R/W) = No data packet has been received. 1h (R/W) = Indicates that a data packet has been received. The EPn bit in the USBTXIS register is also set in this situation

### 32.6.2.77 USBRXCSRH3 Register (Offset = 137h) [Reset = 00h]

USBRXCSRH3 is shown in [Figure 32-79](#) and described in [Table 32-82](#).

Return to the [Summary Table](#).

USB Receive Control and Status Endpoint 3 High

**Figure 32-79. USBRXCSRH3 Register**

7	6	5	4	3	2	1	0

W1C-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

**Table 32-82. USBRXCSRH3 Register Field Descriptions**

Bit	Field	Type	Reset	Description
7	AUTOCL	W1C	0h	Auto Clear Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Enables the RXRDY bit to be automatically cleared when a packet of USBRXMAXP[n] bytes has been unloaded from the receive FIFO. When packets of less than the maximum packet size are unloaded, RXRDY must be cleared manually. Care must be taken when using DMA to unload the receive FIFO as data is read from the receive FIFO in 4-byte chunks regardless of the value of the MAXLOAD field in the USBRXMAXP[n] register,
6	ISOAUTORQ	R/W	0h	Auto Request Note: This bit is automatically cleared when a short packet is received. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Enables the REQPKT bit to be automatically set when the RXRDY bit is cleared
5	DMAEN	R/W	0h	DMA Request Enable Note: Three TX and three RX endpoints can be connected to the DMA module. If this bit is set for a particular endpoint, the DMAARX, DMABRX, or DMACRX field in the USB DMA Select (USBDMASEL) register must be programmed correspondingly Reset type: SYSRSn 0h (R/W) = Disables the DMA request for the receive endpoint. 1h (R/W) = Enables the DMA request for the receive endpoint.
4	DISNYETPIDERR	R/W	0h	PID Error. This bit is ignored in bulk or interrupt transactions. Reset type: SYSRSn 0h (R/W) = No error 1h (R/W) = Indicates a PID error in the received packet of an isochronous transaction.
3	DMAMOD	R/W	0h	DMAMOD Note: This bit must not be cleared either before or in the same cycle as the above DMAEN bit is cleared. Reset type: SYSRSn 0h (R/W) = An interrupt is generated after every DMA packet transfer. 1h (R/W) = An interrupt is generated only after the entire DMA transfer is complete.
2	DTWE	R/W	0h	Data Toggle Write Enable. This bit is automatically cleared once the new value is written. Reset type: SYSRSn 0h (R/W) = The DT bit cannot be written. 1h (R/W) = Enables the current state of the receive endpoint data to be written (see DT bit).

**Table 32-82. USBRXCSRH3 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
1	DT	R/W	0h	Data Toggle. When read, this bit indicates the current state of the receive data toggle. If DTWE is High, this bit may be written with the required setting of the data toggle. If DTWE is Low, any value written to this bit is ignored. Care should be taken when writing to this bit as it should only be changed to RESET the receive endpoint. Reset type: SYSRSn
0	RESERVED	R/W	0h	Reserved

### 32.6.2.78 USBRXCOUNT3 Register (Offset = 138h) [Reset = 0000h]

USBRXCOUNT3 is shown in [Figure 32-80](#) and described in [Table 32-83](#).

Return to the [Summary Table](#).

RESERVED						PFLTACT	
R-0h						R/W-0h	
7	6	5	4	3	2	1	0
RESERVED	PFLTAEN	PFLTSEN	PFLTEN	RESERVED	EPENDE	EPEN	
R-0h	R/W-0h	R/W-0h	R/W-0h	R-0h	R/W-0h	R/W-0h	

**Table 32-93. USBEPC Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	Reserved
15-10	RESERVED	R	0h	Reserved
9-8	PFLTACT	R/W	0h	Power Fault Action. This bit field specifies how the USB0EPEN signal is changed when detecting a USB power fault Reset type: SYSRSn 0h (R/W) = Unchanged. USB0EPEN is controlled by the combination of the EPEN and EPENDE bits. 1h (R/W) = Tristate. USB0EPEN is undriven (tristate). 2h (R/W) = Low. USB0EPEN is driven Low. 3h (R/W) = High. USB0EPEN is driven High.
7	RESERVED	R	0h	Reserved
6	PFLTAEN	R/W	0h	Power Fault Action Enable. This bit specifies whether a USB power fault triggers any automatic corrective action regarding the driven state of the USB0EPEN signal. Reset type: SYSRSn 0h (R/W) = Disabled. USB0EPEN is controlled by the combination of the EPEN and EPENDE bits. 1h (R/W) = Enabled. The USB0EPEN output is automatically changed to the state specified by the PFLTACT field.
5	PFLTSEN	R/W	0h	Power Fault Sense. This bit specifies the logical sense of the USB0PFLT input signal that indicates an error condition. The complementary state is the inactive state. Reset type: SYSRSn 0h (R/W) = Low Fault. If USB0PFLT is driven Low, the power fault is signaled internally (if enabled by the PFLTEN bit). 1h (R/W) = High Fault. If USB0PFLT is driven High, the power fault is signaled internally (if enabled by the PFLTEN bit).

**Table 32-93. USBEPC Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
4	PFLTEN	R/W	0h	Power Fault Input Enable. This bit specifies whether the USB0PFLT input signal is used in internal logic. Reset type: SYSRSn 0h (R/W) = Not Used. The USB0PFLT signal is ignored. 1h (R/W) = Used. The USB0PFLT signal is used internally
3	RESERVED	R	0h	Reserved
2	EPENDE	R/W	0h	EPEN Drive Enable. This bit specifies whether the USB0EPEN signal is driven or undriven (tristate). When driven, the signal value is specified by the EPEN field. When not driven, the EPEN field is ignored and the USB0EPEN signal is placed in a high-impedance state. The USB0EPEN signal is undriven at reset because the sense of the external power supply enable is unknown. By adding the high-impedance state, system designers can bias the power supply enable to the disabled state using a large resistor (100 kOhm) and later configure and drive the output signal to enable the power supply. Reset type: SYSRSn 0h (R/W) = Not Driven. The USB0EPEN signal is high impedance. 1h (R/W) = Driven. The USB0EPEN signal is driven to the logical value specified by the value of the EPEN field.
1-0	EPEN	R/W	0h	External Power Supply Enable Configuration. This bit field specifies and controls the logical value driven on the USB0EPEN signal. Reset type: SYSRSn 0h (R/W) = Power Enable Active Low. The USB0EPEN signal is driven Low if the EPENDE bit is set. 1h (R/W) = Power Enable Active High. The USB0EPEN signal is driven High if the EPENDE bit is set. 2h (R/W) = Power Enable High if VBUS Low. The USB0EPEN signal is driven High when the A device is not recognized. 3h (R/W) = Power Enable High if VBUS High. The USB0EPEN signal is driven High when the A device is recognized.

### 32.6.2.89 USBEPCRIS Register (Offset = 404h) [Reset = 0000000h]

USBEPCRIS is shown in [Figure 32-91](#) and described in [Table 32-94](#).

Return to the [Summary Table](#).

USB External Power Control Raw Interrupt Status

**Figure 32-91. USBEPCRIS Register**

Chapter 33

# Advanced Encryption Standard (AES) Accelerator

---

This section describes the Advanced Encryption Standard (AES) cryptographic hardware-accelerated module.

<b>33.1 Introduction</b> .....	<b>5051</b>
<b>33.2 AES Operating Modes</b> .....	<b>5055</b>
<b>33.3 Extended and Combined Modes of Operations</b> .....	<b>5065</b>
<b>33.4 AES Module Programming Guide</b> .....	<b>5066</b>
<b>33.5 Software</b> .....	<b>5071</b>
<b>33.6 AES Registers</b> .....	<b>5072</b>

### 33.1 Introduction

This section introduces the Advanced Encryption Standard (AES), and describes the AES main functions and connections in the device.

The AES module provides hardware-accelerated data encryption and decryption operations based on a binary key. The AES is a symmetric cipher module that supports a 128-, 192-, or 256-bit key in hardware for encryption and decryption. The AES module is based on a symmetric algorithm, which means that the encryption and decryption keys are identical. To encrypt data means to convert the data from plain text to an unintelligible form called cipher text. Decrypting cipher text converts previously encrypted data to the original plain text form. The main features of the AES accelerator are:

AES encrypt and decrypt operations are supported by:

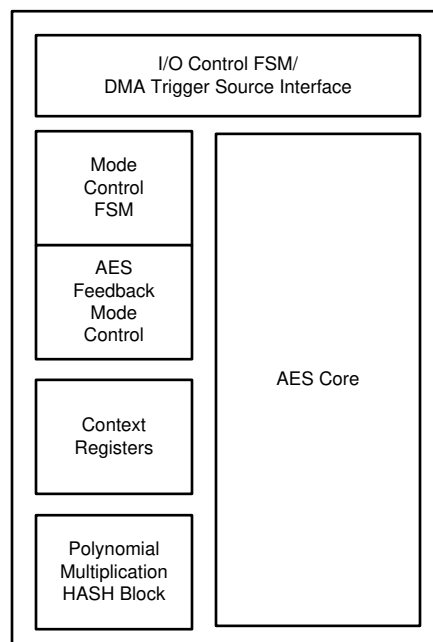

- Galois/Counter mode (GCM), with basic GHASH operation
- Counter mode with CBC-MAC (CCM)
- XTS mode

The following feedback operating modes are available:

- Electronic code book mode (ECB)
- Cipher block chaining mode (CBC)
- Counter mode (CTR)
- Cipher feedback mode (CFB), 128-bit
- F8 mode
- Key sizes: 128, 192, and 256 bits
- Support for CBC\_MAC and Fedora 9 (F9) authentication modes
- Basic GHASH operation (when selecting no encryption)
- Key scheduling in hardware
- Support for  $\mu$ DMA transfers
- Fully synchronous design

#### 33.1.1 AES Block Diagram

Figure 33-1 shows the AES block diagram. A single-core or dual-interface architecture is used.

**Figure 33-1. AES Block Diagram**

AES is an efficient implementation of the Rijndael cipher (the AES algorithm) and a 128-bit polynomial multiplication (referred to here as GHASH, according to the AES-GCM specification). Rijndael is a block cipher in which each data block is 128 bits. The polynomial multiplication multiplies two 128-bit vectors using the smallest 128-bit irreducible polynomial, represented by the following 128-bit string: {0 120}||10000111. The two implementations are combined into the AES wide-bus engine.

Depending on the availability of context and data, the AES wide-bus engine is automatically triggered to process the data. The AES wide-bus engine is directly connected to the context and data registers, so that the AES engine can immediately start processing when all data is available. The AES wide-bus engine also interfaces to the I/O control FSM/ $\mu$ DMA request interface.

AES comprises the following major functional blocks:

- Global control FSM and  $\mu$ DMA interface
- Register interface module
- The AES wide-bus engine

The AES wide-bus engine, which is the major top-level component, comprises the following functional blocks:

- Mode control FSM: Manages the data flow to and from the AES wide-bus engine and starts each encryption or decryption operation
- Feedback modes: The logic that implements the various feedback modes supported by AES.
- GHASH core: The polynomial multiplication algorithm used for AES-GCM
- AES key scheduler: Generates AES encryption and decryption (round) keys
- AES encryption core: The AES encryption algorithm
- AES decryption core: The AES decryption algorithm
- Substitution-boxes (S-Boxes): Contain AES S-Box  $GF(2^8)$  implementations

AES encryption requires a specific number of rounds, depending on the key length. The supported key lengths are 128-, 192-, and 256-bit, which require 10, 12, and 14 rounds, respectively, or 32-, 38-, and 44-clock cycles, respectively, because {number of clock cycles} =  $2 + 3 \times$  {number of rounds}.

The larger key lengths provide greater encryption strength at the expense of additional rounds, and therefore reduced throughput. The overall throughput of the AES executing polynomial multiplication is adjusted based on the overall cryptographic performance. The AES module contains one ECB core and a dedicated 32-cycle polynomial multiplication module for performing GHASH operations. Polynomial multiplication operates in parallel with the AES core, if data is available for both modules.

Depending on the key size (128, 192, or 256 bits), this core requires 32-, 38-, or 44-clock cycles to process one 128-bit data block. While one data block processes, the next block can be preloaded immediately. When a block is preloaded, the previous block must finish before additional data can be loaded. Therefore, when the pipeline is full, sequential data blocks can be passed every 32-, 38-, or 44-clock cycles.

### 33.1.1.1 Interfaces

The interface signals to the AES module can be grouped into the following categories:

- Clock enable
- DMA and interrupt interface, used to request new context and packet data or to indicate available result data (encrypted or decrypted data, or authentication result)
- Functional register interface

### 33.1.1.2 AES Subsystem

The AES subsystem interfaces with the DMA module as shown in [Table 33-1](#). Input/output context and data ports from the AES directly feed to the DMA trigger source. Two interrupt registers are included, AES\_GLB\_INT\_FLG and AES\_GLB\_INT\_CLR. AES\_GLB\_INT\_FLG, that provide the status of the secure interrupt generated by the AES while AES\_GLB\_INT\_CLR clears the flag. AES only allows word access. Non-word access (not 32-bit access) generates an interrupt and is aggregated in SYS\_ERR.

**Table 33-1. AES Subsystem DMA Interface**

Request	DMA Trigger Source
Context Output	AES_ContextIn
Context Input	AES_ContextOut
Data Output	AES_DataOut
Data Input	AES_DataIn

### 33.1.1.3 AES Wide-Bus Engine

The AES wide-bus engine performs the cryptographic operations. The composition of the AES core follows:

#### AES Key Scheduler

The AES key scheduler generates the round keys. During each round, a new subkey is generated from the input key to be XORed with the data. Round keys are generated arbitrarily and parallel to data processing to minimize register requirements.

For encryption operations, the key sequencer transfers the initial key data to the AES core. For decryption operations, the key scheduler must provide the final subkey to the AES core so the AES can generate the subkeys in reverse order.

#### AES Encryption Core

The AES encryption core implements the Rijndael algorithm as specified in [FIPS-197]. This core operates on the input block and performs the required substitution, shift, and mix operations. For each round, the encryption core receives the proper round key from the AES key scheduler. A fundamental component of the AES algorithm is the S-Box. The S-Box provides a unique 8-bit output for each 8-bit input. This implementation of the AES encryption core has a 64-bit data path.

#### AES Decryption Core

The architecture of the AES decryption core is generally the same as the architecture of the encryption core. One difference is that the generation of round keys for decryption requires an initial conversion of the input key (always supplied by the host in the form of an encryption key) to the corresponding decryption key. This conversion is done by performing a dummy encryption operation and storing the final round key as a decryption key. The key scheduler is then reversed to generate the round keys for the decryption operation. Consequently, for each sequence of decryption operations under the same key, a single throughput reduction equal to the time to encrypt a single block occurs. Once a decryption key is generated, subsequent decryption operations with the same key use this generated decryption key directly.

#### AES Feedback Mode Block

The AES feedback mode block buffers the feedback parameters and controls the various feedback modes. For more information about the ECB, CBC, CTR, and CFB modes of operation, see the NIST-SP800-38A specification.

CTR implements the standard incrementing function, as described in the NIST-SP800-38A specification, with  $m$  set to 16 or a multiple of 32.

AES-XTS mode requires a polynomial multiplication for initialization vector (IV) generation of the AES operation. This multiplication can be simplified when the first result is available due to the definition and use of the block number within a unit. The input for the polynomial multiplication is not directly  $j$ , but  $\alpha^j$ , where  $\alpha = x^2$  in the  $GF(2^{128})$  domain.

In addition, f8 encryption/decryption mode and f9 and (X)CBC-MAC authentication modes are available.

## GHASH Block

The data sequencer manages the data flow to and from the AES core. For data input, the data sequencer monitors the input buffer until a 16-byte block is available. If the AES core is idle, the data sequencer writes this data block to the internal working registers of the AES core, thus clearing the buffer for the next block.

After completing an encryption or decryption operation, the data sequencer writes the AES output to the output buffer. If the output buffer is full at the time of completion, the AES core is held until the buffer clears. Although the data sequencer is designed to support uninterrupted packet encryption, the host must properly manage the input and output packet buffers to achieve designed performance.

### 33.1.2 AES Algorithm

The AES algorithm generates block ciphers. The AES block size is 16 bytes. The AES keys can be coded on 128, 192, or 256 bits. The larger key sizes provide a higher level of security, but at the cost of a moderate decrease in throughput.

For the AES algorithm:

- The length of the input and output blocks is 128 bits. The block length is represented by  $N_b = 4$ , which reflects the number of 32-bit words.
- The length of the cipher key ( $K$ ) is 128, 192, or 256 bits. The key length is represented by  $N_k = 4, 6, \text{ or } 8$ , which reflects the number of 32-bit words in the cipher key.
- The number of rounds to be performed during the execution of the algorithm depends on the key size. The number of rounds is represented by  $N_r$ , where  $N_r = 10$  when  $N_k = 4$  (128-bit key);  $N_r = 12$  when  $N_k = 6$  (192-bit key); and  $N_r = 14$  when  $N_k = 8$  (256-bit key).

Table 33-2 lists the combinations of keys, blocks, and rounds.

**Table 33-2. Key-Block-Round Combinations**

Key	Key Length ( $N_k$ )	Block Size ( $N_b$ )	Number of Rounds ( $N_r$ )
128 bits	4	4	10
192 bits	6	4	12
256 bits	8	4	14

The AES algorithm for cipher and inverse cipher uses a round function composed of four different byte-oriented transformations:

- Byte substitution using a substitution table (S-Box): This transformation is a nonlinear byte substitution that operates independently on each byte of the state (the state is an intermediate processed block of 128 bits inside the AES; the state is arranged as an array of  $[4 \times N_k]$  bytes) using an S-Box. This S-Box transformation is reversible.
- Shifting rows of the state array by different offsets: In this transformation, the bytes in the last three rows of the state are cyclically shifted over different numbers of bytes (offsets). The first row ( $\textcircled{0}$ ) is not shifted.
- Mixing the data within each column of the state array: This transformation operates on the state column-by-column, treating each column as a 4-term polynomial. The columns are considered polynomials over  $GF(2^8)$  and multiplied modulo  $x^4 + 1$  with a fixed polynomial  $a(x)$ .
- Adding a round key to the state: In this transformation, a round key is added to the state by a simple bitwise XOR operation. Each round key consists of  $N_b$  words from the key schedule.

The AES algorithm takes the cipher key ( $K$ ) and performs a key expansion routine to generate a key schedule. The key expansion generates a total of  $N_b \times (N_r + 1)$  words: The algorithm requires an initial set of  $N_b$  words, and each  $N_r$  round requires  $N_b$  words of key data. The resulting key schedule consists of a linear array of 4-byte words, denoted  $[w_i]$ , with  $i$  in the range  $0 \leq i \leq N_b \times (N_r + 1)$ .

### 33.2 AES Operating Modes

#### 33.2.1 GCM Operation

Figure 33-2 shows one round of a GCM operation for encryption and decryption. A 32-bit counter is used as IV (as it is for CTR mode). The data is encrypted in the same way as in CTR mode, by XORing the cryptographic core output with the input. After the encryption/decryption, the ciphertext is XORed with the intermediate authentication result. The XORed result is used as input for the polynomial multiplication to create the next (intermediate) authentication result. For more information about the GCM protocol, see Section 33.3.1.

Figure 33-2. AES - GCM Operation

### 33.2.2 CCM Operation

Figure 33-3 shows one round of a CCM (counter with CBC-MAC) operation for encryption and decryption. A 32-bit counter is used as IV (as it is for CTR mode). The data is encrypted in the same way as in CTR mode, by XORing the cryptographic core output with the input. Immediately after the encryption operation, the plaintext is XORed with the intermediate authentication result. The XOR result is used as input for a second encryption operation to calculate the next (intermediate) authentication result.

**Figure 33-3. AES - CCM Operation**

### 33.2.3 XTS Operation

Figure 33-4 shows the XTS mode of operation for encryption and decryption. The input to the cryptographic core is XORed with the IV; the output of the cryptographic core is XORed with the same IV. For decryption, the cryptographic core operates in reverse, but the XOR operations are the same.

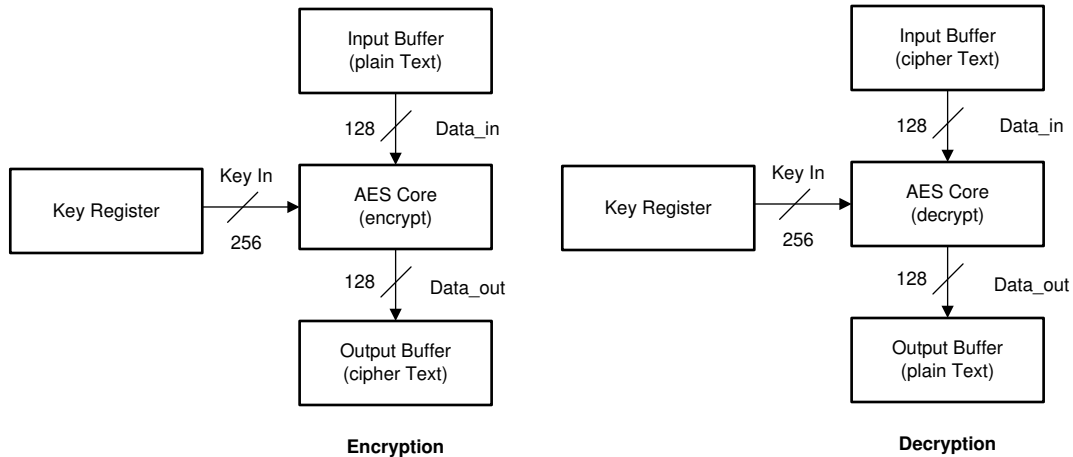

Figure 33-4. AES - XTS Operation

**Note**

The IV is created with an initial encryption, followed by an LFSR operation for each new block.

### 33.2.4 ECB Feedback Mode

Figure 33-5 shows the basic ECB feedback mode of operation, where the input data is passed directly to the basic cryptographic core and the output is passed directly to the output buffer. For decryption, the cryptographic core operates in reverse: the decryption data path is used for data processing, whereas encryption uses the encryption data path.

**Figure 33-5. AES - ECB Feedback Mode**

### 33.2.5 CBC Feedback Mode

Figure 33-6 shows the CBC feedback mode of operation, where the input data is XORed with the IV before it is passed to the basic cryptographic core. The output of the cryptographic core passes directly to the output buffer and becomes the next IV.

The operation is reversed for decryption, resulting in an XOR at the output of the cryptographic core. The input cipher text of the current operation is the IV for the next operation.

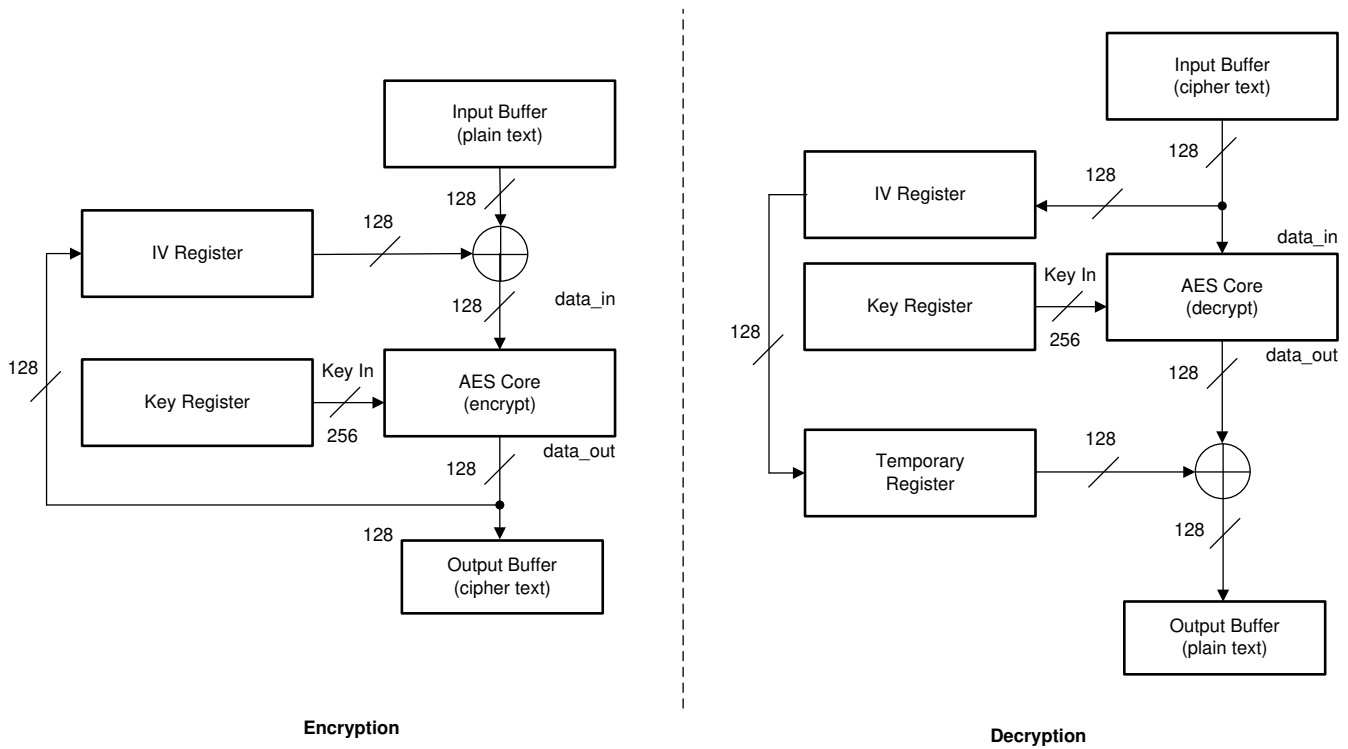

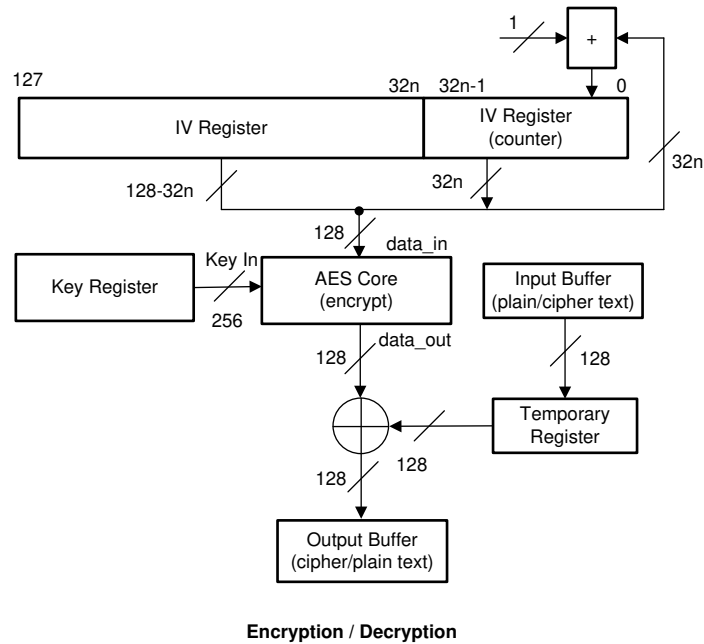

Figure 33-6. AES - CBC Feedback Mode

### 33.2.6 CTR and ICM Feedback Modes

Figure 33-7 shows the counter feedback (CTR/ICM) mode of operation. This operation encrypts the IV. The output of the cryptographic core (encrypted IV) is XORed with the data, thus creating the output result.

The IV is built out of two components: a fixed part and a counter part. The counter part is incremented with each block. The counter width is selectable per context and can be 16, 32, 64, 96, or 128 bits wide. In this mode, encryption and decryption use the same operation.

**Figure 33-7. AES Encryption With CTR/ICM Mode**

#### Note

The value for  $n$  can be 1, 2, 3, or 4 for CTR mode and is  $\frac{1}{2}$  for ICM mode.

### 33.2.7 CFB Mode

Figure 33-8 shows the full block (128 bits) CFB mode of operation for encryption and decryption. The input for the cryptographic core is the IV; the result is XORed with the data. The result is fed back through the IV register as the next input for the cryptographic core. The decryption operation is reversed, but the cryptographic core still performs encryption.

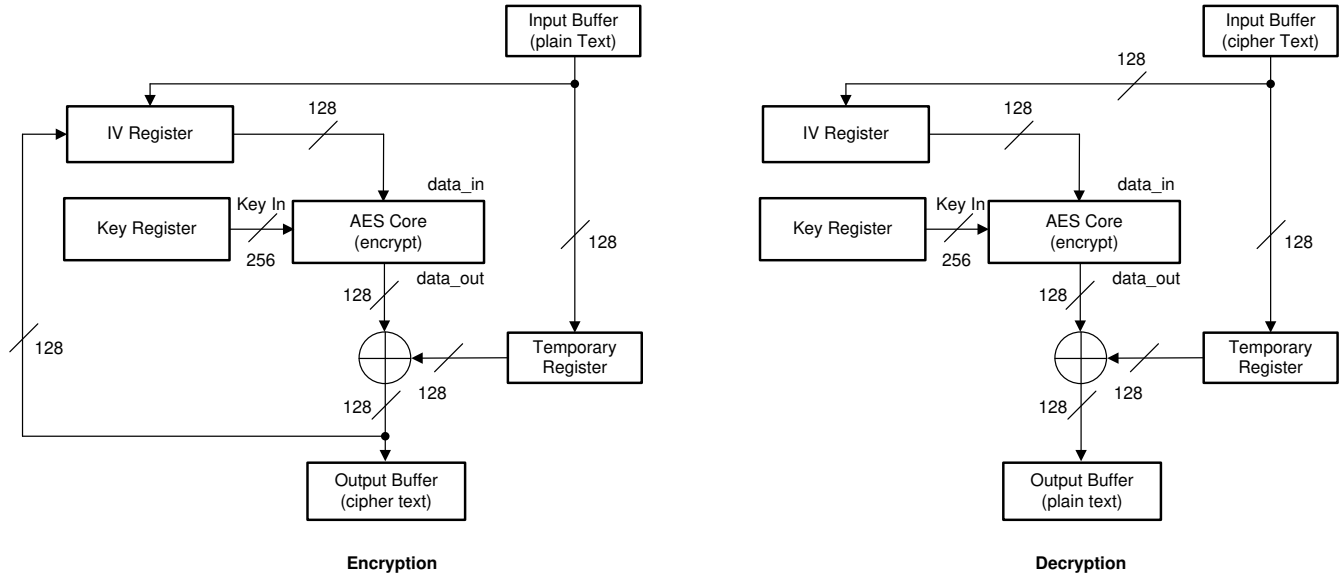

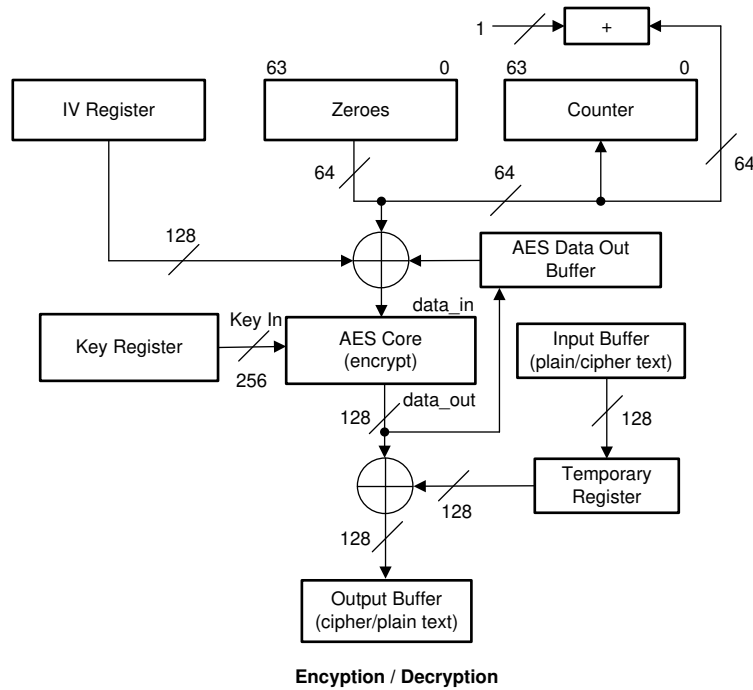

Figure 33-8. AES - CFB Feedback Mode

### 33.2.8 F8 Mode

Figure 33-9 shows the F8 feedback mode of operation for encryption and decryption. The input to the cryptographic core is the result of the XOR operation of the previous cryptographic core output, a constant IV, and a block counter. The output of the cryptographic core is XORed with the input to create the result. In this mode, encryption and decryption use the same operations.

**Figure 33-9. AES - F8 Mode**

### 33.2.9 F9 Operation

Figure 33-10 shows the F9 authentication mode of operation, where the input to the cryptographic core is XORed with the IV, and the output is XORed with the previous result to create the next result. The cryptographic core output is fed back as IV for the next block. The result is the output of the last XOR operation of the cryptographic core output.

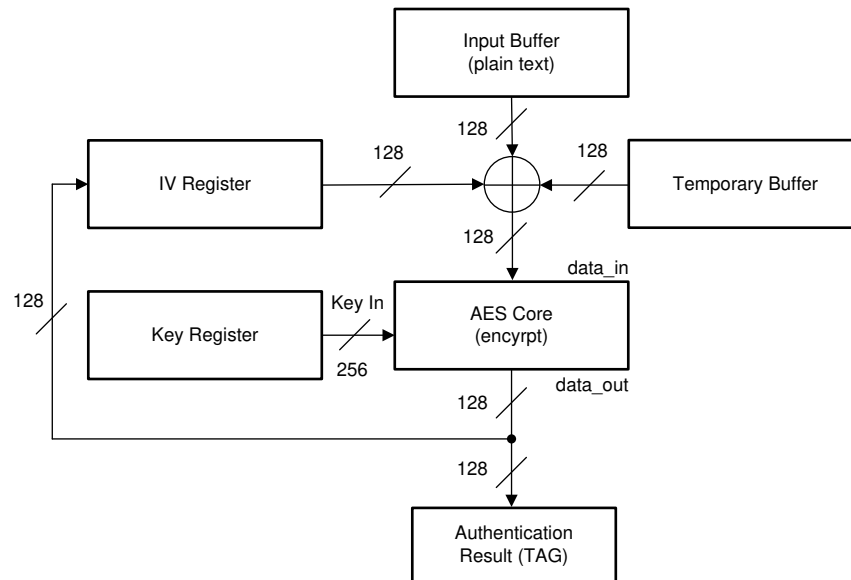

Figure 33-10. AES - F9 Operation

### 33.2.10 CBC-MAC Operation

Figure 33-11 shows the CBC-MAC authentication mode of operation, where the input to the cryptographic core is XORed with the IV. The cryptographic core output is then fed back as IV for the next block. The last data input block is XORed with an additional input value stored in the temporary buffer; this can be any precalculated value and is dependent on the alignment of the last input block. The result is the cryptographic core output of the last encryption operation.

**Figure 33-11. AES - CBC-MAC Authentication Mode**

### 33.3 Extended and Combined Modes of Operations

This section describes the protocols (or autonomous precalculations) supported by the AES wide-bus engine.

#### 33.3.1 GCM Protocol Operation

A GCM protocol operation is a combined operation consisting of encryption or decryption, and authentication. A part of the input data stream can be authenticated only, while normally most of the input data is encrypted or decrypted and authenticated. The authentication-only data must always be in front of the data requiring encryption. Within GCM, the authentication-only data is called the additional authentication data (AAD). The AAD is fetched independently of other data.

The intermediate (temporary) result data is used as input to the remaining authentication operation. Because the authentication operation does not require the cryptographic core but only the polynomial multiplication, encryption, decryption, and authentication can be performed in parallel. After encryption of the last data block, additional polynomial multiplication and encryption are required to authenticate a 128-bit-long vector and finally encrypt the authentication result.

#### 33.3.2 CCM Protocol Operation

The CCM protocol operation is a combined operation consisting of encryption or decryption, and authentication. The authentication and encryption or decryption operations use the cryptographic core; these operations are executed sequentially on the AES core. A part of the data stream can require authentication only. The authentication-only data must always be in front of the data requiring encryption.

Authentication starts with the encryption of a predefined block B0. This block consists of flags, nonce, and message length. The next blocks contain the authentication data length concatenated with the authentication-only data. After processing the authentication-only data, the encryption or decryption operations are performed, each followed by the related authentication of the plaintext data block (which equals the input in the case of encryption, and the output in the case of decryption). The final authentication result must be encrypted using the output of the encryption of the IV block A0. This block contains the IV (consisting of flags and nonce) concatenated with the counter, which is zero for A0.

#### 33.3.3 Hardware Requests

The AES module can assert a DMA request for context in, context out, input data, or output data read. The AES DMA Interrupt Mask (AES\_DMAIM) register can be set to generate interrupts during the following events:

- Context In DMA request (Cin)
- Context Out DMA request (Cout)
- Data In DMA request (Din)
- Data Out DMA request (Dout)

The AES module can be programmed to assert an interrupt when the DMA has completed the last transfer.

If context and data transfers are to be handled through software, then the AES Interrupt Enable (AES\_IRQENABLE) register can be used to enable interrupt triggering when context out, context in, data in, or data out is ready. The AES Interrupt Status (AES\_IRQSTATUS) register indicates when an interrupt is triggered, as listed in [Table 33-3](#).

**Table 33-3. Interrupts and Events**

Event	Description
AES_IRQSTATUS[3]: CONTEXT_OUT	Context output interrupt
AES_IRQSTATUS[2]: DATA_OUT	Data output interrupt
AES_IRQSTATUS[1]: DATA_IN	Data input interrupt
AES_IRQSTATUS[0]: CONTEXT_IN	Context input interrupt

## 33.4 AES Module Programming Guide

### 33.4.1 AES Low-Level Programming Models

This section describes the low-level hardware programming sequences for configuring and using the AES module.

#### 33.4.1.1 Global Initialization

The following list describes the requirements for initializing the AES and associated modules.

1. Specify the size of the keys by programming the KEY\_SIZE bit field in the AES\_CTRL register.
2. Load the AES Key 1 (AES\_KEY1\_n) register.
3. Load the AES Key 2 (AES\_KEY2\_n) register if it is used by the configuration mode.
4. Configure the AES for the appropriate encryption or decryption mode (see [Section 33.4.1.2](#)).
5. Select encryption or decryption by programming the DIRECTION bit in the AES Control (AES\_CTRL) register.

#### 33.4.1.2 AES Operating Modes Configuration

The following sections list the initialization subsequences for the available encryption and decryption modes:

##### Subsequence: Initialize CCM AES Core Mode

The steps to initialize CCM mode follow:

1. Define the width of the length field and the length of the authentication field by programming the CCM\_L and CCM\_M bit fields in the AES\_CTRL register.
2. Enable counter mode by setting the CTR bit in the AES\_CTRL register.
3. Load the authentication data length in the AUTH field of the AES Authentication Data Length (AES\_AUTH\_LENGTH) register.
4. Select the IV counter by programming the CTR\_WIDTH field in the AES\_CTRL register.
5. Load the AES Initialization Vector Input n (AES\_IV\_IN\_n) registers.

##### Subsequence: Initialize GCM AES Core Mode

The steps to enable GCM mode follow:

1. Enable counter mode by setting the CTR bit in the AES\_CTRL register.
2. Load the authentication data length in the AUTH field of the AES Authentication Data Length (AES\_AUTH\_LENGTH) register.
3. Select the IV counter by programming the CTR\_WIDTH field in the AES\_CTRL register.
4. Load the AES Initialization Vector Input n (AES\_IV\_IN\_n) registers.

##### Subsequence: Initialize CBC-MAC AES Core Mode

The steps to initialize CBC-MAC mode follow:

1. Enable CBC-MAC mode by setting the CBCMAC bit in the AES\_CTRL register.
2. Select encryption mode by setting the DIRECTION bit in the AES\_CTRL register.
3. Load the AES Initialization Vector Input n (AES\_IV\_IN\_n) registers.

**Subsequence: Initialize F9 AES Core Mode**

The steps to configure the AES for F9 mode follow:

1. Enable F9 mode by setting the F9 bit in the AES\_CTRL register.
2. Set the key size to 128 bits by programming the KEY\_SIZE field to 0x1 in the AES\_CTRL register.
3. Load the AES Initialization Vector Input n (AES\_IV\_IN\_n) registers.

**Subsequence: Initialize F8 AES Core Mode**

The steps to configure the AES for F8 mode follow:

1. Enable F8 mode by setting the F8 bit in the AES\_CTRL register.
2. Select the counter width by programming the CTR\_WIDTH field in the AES\_CTRL register.
3. Set the key size to 128 bits by setting the KEY\_SIZE field to 0x1 in the AES\_CTRL register.
4. Load the AES Initialization Vector Input n (AES\_IV\_IN\_n) registers.

**Subsequence: Initialize XTS AES Core Mode**

The steps to configure XTS mode follow:

1. Enable XTS mode by configuring the XTS field in the AES\_CTRL register.
2. If the XTS field in the AES\_CTRL register indicates that the AAD length is required, load the AAD length in the AES\_AUTH\_LENGTH register.
3. Load the AES Initialization Vector Input n (AES\_IV\_IN\_n) registers.

**Subsequence: Initialize CFB AES Core Mode**

The steps to initialize the AES code for CFB mode follow:

1. Enable CFB mode by setting the CFB bit in the AES\_CTRL register.
2. Load the AES Initialization Vector Input n (AES\_IV\_IN\_n) registers.

**Subsequence: Initialize ICM AES Core Mode**

The steps to initialize the AES code for ICM mode follow:

1. Enable ICM mode by setting the ICM bit in the AES\_CTRL register.
2. Configure for a 16-bit counter by programming the CTR\_WIDTH field to 0x0 in the AES\_CTRL register.
3. Load the AES Initialization Vector Input n (AES\_IV\_IN\_n) registers.

**Subsequence: Initialize CTR AES Core Mode**

The steps to initialize CTR mode follow:

1. Enable CTR mode by setting the CTR bit in the AES\_CTRL register.
2. Select counter width by programming the CTR\_WIDTH in the AES\_CTRL register.
3. Load the AES Initialization Vector Input n (AES\_IV\_IN\_n) registers.

**Subsequence: Initialize CBC AES Core Mode**

The steps to configure CBC mode follow:

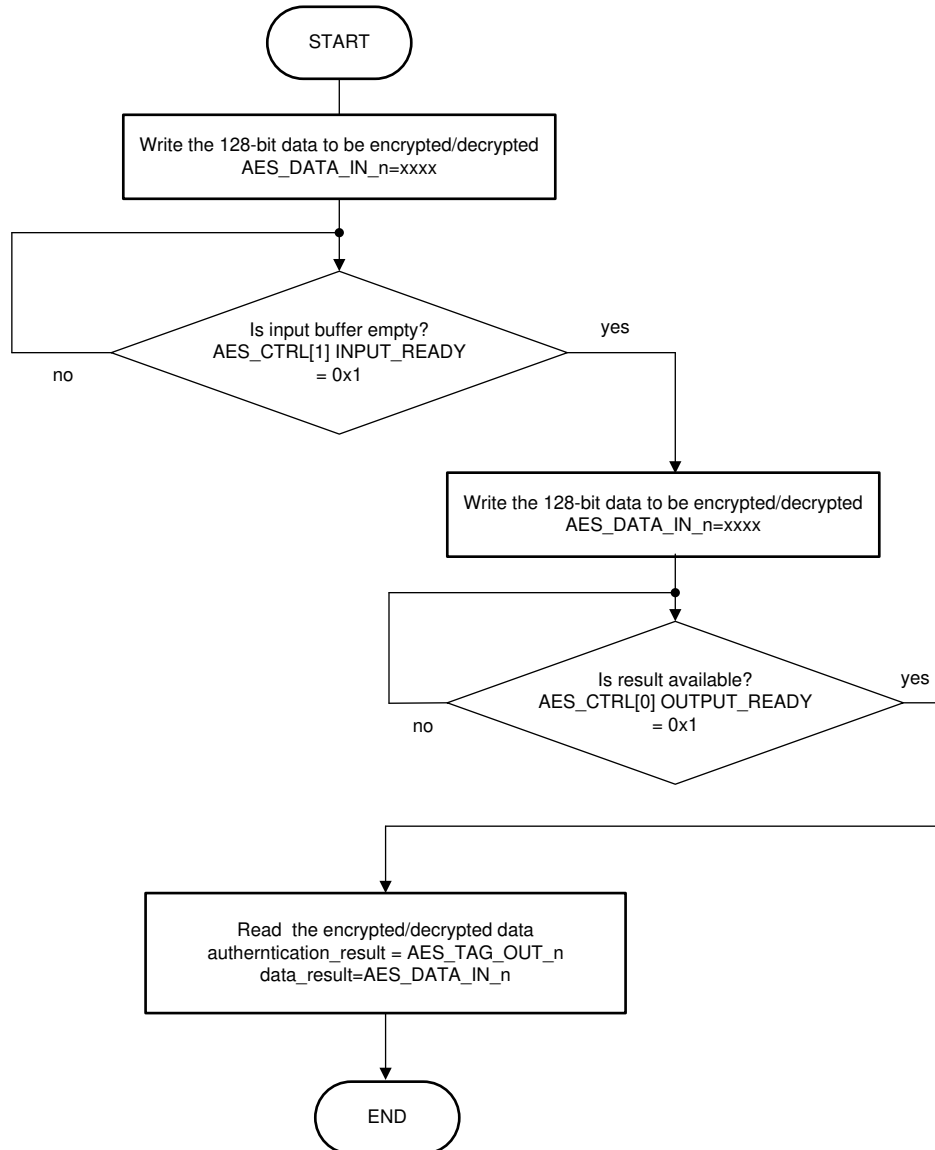

1. Enable CBC mode by setting the MODE bit in the AES\_CTRL register.
2. Load the AES Initialization Vector Input n (AES\_IV\_IN\_n) registers.

### 33.4.1.3 AES Mode Configurations

#### AES Polling Mode

Main Sequence: AES Polling Mode – [Figure 33-12](#) shows AES polling mode. The registers used in AES polling mode follow:

- AES Data RW Plaintext/Ciphertext 0 (AES\_DATA\_IN\_OUT\_0) registers
- AES Control (AES\_CTRL) register
- AES Hash Tag Out 0 (AES\_TAG\_OUT\_0) register

**Figure 33-12. AES Polling Mode**

## AES Interrupt Mode

The application can use software interrupts to control the flow of Context In, Context Out, Data In, and Data Out requests. To enable these interrupts

1. First, initialize the device by following the initialization sequences described in [Section 33.4.1.1](#) and [Section 33.4.1.2](#).
2. When the device has been initialized, the application can enable the AES module interrupts through the AES Interrupt Enable (AES\_IRQENABLE) register.
3. Load the input buffers, AES\_DATA\_IN\_OUT\_n, with data.

---

### Note

If the application uses interrupt mode, an interrupt is generated for each block of processed data. To support larger data flow, mode must be used and the bits in the AES\_IRQENABLE register must be cleared.

---

## AES DMA Mode

When AES DMA mode is enabled, the AES\_IRQENABLE register must be cleared. To enable the to transfer data, follow these steps:

The input buffer registers, AES\_DATA\_IN\_OUT\_n, are now loaded.

### 33.4.1.4 AES Events Servicing

#### Interrupt Servicing

This section describes the event servicing of the module. [Figure 33-13](#) shows the AES interrupt service. The registers used during event servicing follow:

- AES\_IRQSTATUS
- AES\_KEY1\_n
- AES\_KEY2\_n
- AES\_IV\_IN\_n
- AES\_DATA\_IN\_OUT\_n
- AES\_TAG\_OUT\_n
- AES\_IRQENABLE

**Figure 33-13. AES Interrupt Service**

## 33.5 Software

### 33.5.1 AES Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/aes

Cloud access to these examples is available at the following link: [dev.ti.com C2000Ware Examples](#).

#### 33.5.1.1 AES ECB Encryption Example

FILE: aes\_ex1\_ecb\_encrypt.c

This example encrypts block cipher-text using AES128 in ECB mode. It does the encryption first without DMA and then with DMA. The results are checked after each operation.

##### *External Connections*

- None

##### *Watch Variables*

- *errCountGlobal* - Error Counter. It should be zero.
- *testStatusGlobal* - Test status. It should be equal to PASS.

#### 33.5.1.2 AES ECB De-cryption Example

FILE: aes\_ex2\_ecb\_decrypt.c

This example de-crypts block cipher-text using AES128 in ECB mode. It does the de-cryption first without DMA and then with DMA. The results are checked after each operation.

##### *External Connections*

- None

##### *Watch Variables*

- *errCountGlobal* - Error Counter. It should be zero.
- *testStatusGlobal* - Test status. It should be equal to PASS.

#### 33.5.1.3 AES GCM Encryption Example

FILE: aes\_ex3\_gcm\_encrypt.c

This example encrypts block cipher-text using AES128 in GCM mode. It does the encryption first without DMA and then with DMA. The results are checked after each operation.

##### *External Connections*

- None

##### *Watch Variables*

- *errorCountGlobal* - Error Counter. It should be zero.
- *testStatusGlobal* - Test status. It should be equal to PASS.

#### 33.5.1.4 AES GCM Decryption Example

FILE: aes\_ex4\_gcm\_decrypt.c

This example decrypts block cipher-text using AES128 in GCM mode. It does the decryption first without DMA and then with DMA. The results are checked after each operation.

##### *External Connections*

- None

##### *Watch Variables*

- *errorCountGlobal* - Error Counter. It should be zero.
- *testStatusGlobal* - Test status. It should be equal to PASS.

## 33.6 AES Registers

The following sections are register descriptions for the AES Subsystem and AES Peripheral Core.

### 33.6.1 AES Base Address Table

**Table 33-4. AES Base Address Table**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	CPU2	CPU2.DMA	Pipeline Protected
Instance	Structure								
AesaRegs	<a href="#">AES_REGS</a>	AESA_BASE	0x0004_2000	YES	YES	-	YES	YES	YES
AesaSsRegs	<a href="#">AES_SS_REGS</a>	AESA_SS_BASE	0x0004_2C00	YES	YES	-	YES	YES	YES

### 33.6.2 AES\_REGS Registers

Table 33-5 lists the memory-mapped registers for the AES\_REGS registers. All register offset addresses not listed in Table 33-5 should be considered as reserved locations and the register contents should not be modified.

**Table 33-5. AES\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	AES_KEY2_6	XTS Second Key or CBC-MAC Third Key		<a href="#">Go</a>
4h	AES_KEY2_7	XTS Second Key or CBC-MAC Third Key		<a href="#">Go</a>
8h	AES_KEY2_4	XTS/CCM Second Key or CBC-MAC Third Key		<a href="#">Go</a>
Ch	AES_KEY2_5	XTS Second Key or CBC-MAC Third Key		<a href="#">Go</a>
10h	AES_KEY2_2	XTS/CCM/CBC-MAC Second Key or Hash Key Input		<a href="#">Go</a>
14h	AES_KEY2_3	XTS/CCM/CBC-MAC Second Key or Hash Key Input		<a href="#">Go</a>
18h	AES_KEY2_0	XTS/CCM/CBC-MAC Second Key or Hash Key Input		<a href="#">Go</a>
1Ch	AES_KEY2_1	XTS/CCM/CBC-MAC Second Key or Hash Key Input		<a href="#">Go</a>
20h	AES_KEY1_6	Key		<a href="#">Go</a>
24h	AES_KEY1_7	Key		<a href="#">Go</a>
28h	AES_KEY1_4	Key		<a href="#">Go</a>
2Ch	AES_KEY1_5	Key		<a href="#">Go</a>
30h	AES_KEY1_2	Key		<a href="#">Go</a>
34h	AES_KEY1_3	Key		<a href="#">Go</a>
38h	AES_KEY1_0	Key		<a href="#">Go</a>
3Ch	AES_KEY1_1	Key		<a href="#">Go</a>
40h	AES_IV_IN_OUT_0	Initialization Vector 0		<a href="#">Go</a>
44h	AES_IV_IN_OUT_1	Initialization Vector 1		<a href="#">Go</a>
48h	AES_IV_IN_OUT_2	Initialization Vector 2		<a href="#">Go</a>
4Ch	AES_IV_IN_OUT_3	Initialization Vector 3		<a href="#">Go</a>
50h	AES_CTRL	Input/Output Buffer Control and Mode Selection		<a href="#">Go</a>
54h	AES_C_LENGTH_0	Crypto Data Length 0		<a href="#">Go</a>
58h	AES_C_LENGTH_1	Crypto Data Length 1		<a href="#">Go</a>
5Ch	AES_AUTH_LENGTH	AAD Data Length		<a href="#">Go</a>
60h	AES_DATA_IN_OUT_0	Data Word 0		<a href="#">Go</a>
64h	AES_DATA_IN_OUT_1	Data Word 1		<a href="#">Go</a>
68h	AES_DATA_IN_OUT_2	Data Word 2		<a href="#">Go</a>
6Ch	AES_DATA_IN_OUT_3	Data Word 3		<a href="#">Go</a>
70h	AES_TAG_OUT_0	Hash Result 0		<a href="#">Go</a>
74h	AES_TAG_OUT_1	Hash Result 1		<a href="#">Go</a>
78h	AES_TAG_OUT_2	Hash Result 2		<a href="#">Go</a>
7Ch	AES_TAG_OUT_3	Hash Result 3		<a href="#">Go</a>
80h	AES_REV	Module Revision Number		<a href="#">Go</a>
84h	AES_SYSCONFIG	System Configuration		<a href="#">Go</a>
88h	AES_SYSSTATUS	Reset Status		<a href="#">Go</a>
8Ch	AES_IRQSTATUS	Interrupt Status		<a href="#">Go</a>
90h	AES_IRQENABLE	Interrupt Enable		<a href="#">Go</a>
94h	AES_DIRTY_BITS	Accessed / Dirty Bits		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. [Table 33-6](#) shows the codes that are used for access types in this section.

**Table 33-6. AES\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1S	W1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 33.6.2.1 AES\_KEY2\_6 Register (Offset = 0h) [Reset = 0000000h]

AES\_KEY2\_6 is shown in [Figure 33-14](#) and described in [Table 33-7](#).

Return to the [Summary Table](#).

Secure Host Interface Bank

**Figure 33-14. AES\_KEY2\_6 Register**

**Table 33-27. AES\_CTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	CTXTRDY	R	1h	Context Data Registers Ready Value Description 0 The context data registers are not ready to be overwritten. 1 The context data registers can be overwritten and the host is permitted to write the next context. Reset type: PER.RESET
30	SVCTXTRDY	R	0h	AES TAG/IV Block(s) Ready This bit is only asserted if the SAVE_CONTEXT bit is set to 1. This bit is mutual exclusive with the CTXTRDY bit. Value Description 0 AES authentication TAG and/or IV block(s) is/are not available. 1 Indicates the AES authentication TAG and /or IV block(s) is/are available for the host to retrieve. Reset type: PER.RESET
29	SAVE_CONTEXT	R/W	0h	TAG or Result IV Save If this bit is set, the CONTEXT_OUT interrupt bit is set in the AES_IRQSTATUS register if the operation is finished and related signals are enabled. Value Description 0 No effect. 1 Indicates an authentication TAG of result IV needs to be stored as a result context. Reset type: PER.RESET
28-25	RESERVED	R	0h	Reserved

**Table 33-27. AES\_CTRL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
24-22	CCM_M	R/W	0h	Counter with CBC-MAC (CCM) Defines M which indicates the length of the authentication field for CCM operations the authentication field length equals two times the sum of CCM-M plus one. The AES Engine always returns a 128-bit authentication field, of which the M least significant bytes are valid. All values are supported. Reset type: PER.RESET
21-19	CCM_L	R/W	0h	Indicates the width of the length field for CCM operations the length field in bytes equals the value of CMM-L plus one. Supported values for L are: Value Description 0x0 width = 0 0x1 width = 2 0x2 reserved 0x3 width = 4 0x4 - 0x6 reserved 0x7 width = 8 Reset type: PER.RESET
18	CCM	R/W	0h	AES-CCM Mode Enable Value Description 0 AES-CCM mode is not enabled. 1 AES-CCM mode enabled. This is a combined mode, using AES for both authentication and encryption. No additional mode selection is required. Reset type: PER.RESET
17-16	GCM	R/W	0h	AES-GCM Mode Enable This is a combined mode, using the Galois field-multiplier $GF(2^{128})$ for authentication and AES-CTR mode for encryption the bits specify the GCM mode. Value Description 0x0 No operation 0x1 GHASH with H loaded and Y0-encrypted forced to zero 0x2 GHASH with H loaded and Y0-encrypted calculated internally 0x3 Autonomous GHASH (both H and Y0-encrypted calculated internally) Reset type: PER.RESET
15	CBCMAC	R/W	0h	AES-CBC MAC Enable The DIRECTION bit must be set to 1 for this mode. Value Description 0 AES-CBC MAC mode is not enabled. 1 AES-CBC MAC mode enabled. Reset type: PER.RESET
14	F9	R/W	0h	AES f9 Mode Enable The AES key size must be set to 128-bit for this mode. Value Description 0 f9 mode is not enabled 1 f9 mode is enabled. Reset type: PER.RESET
13	F8	R/W	0h	AES f8 Mode Enable, The KEY_SIZE must be set to 128-bit for this mode. Value Description 0 AES f8 mode is not enabled. 1 AES f8 mode is enabled. Reset type: PER.RESET

**Table 33-27. AES\_CTRL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
12-11	XTS	R/W	0h	AES-XTS Operation Enable The bits specify the XTS mode. Value Description 0x0 No operation 0x1 Previous/intermediate tweak value and j loaded (value is loaded via IV, j is loaded via the AAD length register) 0x2 Key2, n and j are loaded (n is loaded via IV, j is loaded via the AAD length register) 0x3 Key2 and n are loaded j=0 (n is loaded via IV) Reset type: PER.RESET
10	CFB	R/W	0h	Full block AES cipher feedback mode (CFB128) Enable Value Description 0 AES-CFB mode is not enabled. 1 AES-CFB mode is enabled. Reset type: PER.RESET
9	ICM	R/W	0h	AES Integer Counter Mode (ICM) Enable This is a counter mode with a 16-bit wide counter. Value Description 0 AES-ICM mode is not enabled. 1 AES-ICM mode is enabled. Reset type: PER.RESET
8-7	CTR_WIDTH	R/W	0h	AES-CTR Mode Counter Width Value Description 0x0 Counter is 32 bits 0x1 Counter is 64 bits 0x2 Counter is 96 bits 0x3 Counter is 128 bits Reset type: PER.RESET
6	CTR	R/W	0h	Counter Mode This bit must also be set for GCM and CCM mode, when encryption/decryption is required. Value Description 0 Counter mode is not enabled. 1 Counter mode is enabled. Reset type: PER.RESET
5	MODE	R/W	0h	ECB/CBC Mode Value Description 0 ECB mode 1 CBC mode Reset type: PER.RESET
4-3	KEY_SIZE	R/W	0h	Key Size Value Description 0x0 reserved 0x1 Key is 128 bits 0x2 Key is 192 bits 0x3 Key is 256 bits Reset type: PER.RESET

**Table 33-27. AES\_CTRL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
2	DIRECTION	R/W	0h	Encryption/Decryption Selection If set to =1, an encrypt operation is performed. If set to 0, a decrypt operation is performed. DIRECTION Value Description 0 Decryption is selected. 1 Encryption is selected. Reset type: PER.RESET
1	INPUT_READY	R	0h	Input Ready Status Value Description 0 Input buffer is not empty. 1 Indicates that the 16-byte input buffer is empty, and the host is permitted to write the next block of data. Reset type: PER.RESET
0	OUTPUT_READY	R	0h	Output Ready Status Value Description 0 No AES output block is available. 1 An AES output block is available for the host to retrieve. Reset type: PER.RESET

### 33.6.2.22 AES\_C\_LENGTH\_0 Register (Offset = 54h) [Reset = 0000000h]

**Table 33-30. AES\_AUTH\_LENGTH Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	AUTH	R-0/W	0h	<p>Bits [31:0] of the authentication length register store the authentication data length in bytes for combined modes only (GCM or CCM)</p> <p>Supported AAD-lengths for CCM are from 0 to <math>(2^{16} - 2^8)</math> bytes. For GCM any value up to <math>(2^{32} - 1)</math> bytes can be used. Once processing with this context is started, this length decrements to zero.</p> <p>A write to this register triggers the engine to start using this context for GCM and CCM.</p> <p>For XTS this register is optionally used to load 'j'. Loading of 'j' is only required if 'j' != 0. 'j' is a 28-bit value and must be written to bits [31-4] of this register. 'j' represents the sequential number of the 128-bit block inside the data unit. For the first block in a unit, this value is zero. It is not required to provide a 'j' for each new data block within a unit. Note that it is possible to start with a 'j' unequal to zero refer to Table 4 for more details.</p> <p>For a Host read operation, these registers return all-zeroes.</p> <p>Reset type: PER.RESET</p>

### 33.6.2.25 AES\_DATA\_IN\_OUT\_0 Register (Offset = 60h) [Reset = 0000000h]

AES\_DATA\_IN\_OUT\_0 is shown in [Figure 33-38](#) and described in [Table 33-31](#).

Return to the [Summary Table](#).

Secure Host Interface Bank

**Table 33-31. AES\_DATA\_IN\_OUT\_0 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	DATA	R/W	0h	The Data Input/Output Registers buffer the input/output data blocks to/from the AES Engine. Notice that the data input buffer (AES_DATA_IN_n) and data output buffer (AES_DATA_OUT_n) are mapped to the same address locations. Writes to these addresses load the Input Buffer while reads pull from the Output Buffer. Therefore, for write access, the data input buffer is written for read access, the data output buffer is read. The data input buffer must be written prior to starting an operation. The data output buffer contains valid data on completion of an operation. All writes from, and reads to, these registers are tracked independently per direction and HIB. Therefore, any 128-bit data block can be split over multiple 32-bit word transfers, which can be mixed with other transfers over the external interface. Reset type: PER.RESET

### 33.6.2.26 AES\_DATA\_IN\_OUT\_1 Register (Offset = 64h) [Reset = 0000000h]

AES\_DATA\_IN\_OUT\_1 is shown in [Figure 33-39](#) and described in [Table 33-32](#).

Return to the [Summary Table](#).

0	S_ACCESS	R/W1S	0h	AES Access Bit This bit must be written to a 1 to clear. Value Description 0 No AES registers have been read. 1 Indicates when any of the AES_x registers have been read (except for the AES_DIRTYBITS register). Reset type: PER.RESET

### 33.6.3 AES\_SS\_REGS Registers

Table 33-45 lists the memory-mapped registers for the AES\_SS\_REGS registers. All register offset addresses not listed in Table 33-45 should be considered as reserved locations and the register contents should not be modified.

**Table 33-45. AES\_SS\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
4h	AES_GLB_INT_FLG	AES Global Interrupt Flag Register		<a href="#">Go</a>
8h	AES_GLB_INT_CLR	AES Global Interrupt Clear Register		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 33-46 shows the codes that are used for access types in this section.

**Table 33-46. AES\_SS\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 33.6.3.1 AES\_GLB\_INT\_FLG Register (Offset = 4h) [Reset = 0000000h]

AES\_GLB\_INT\_FLG is shown in [Figure 33-52](#) and described in [Table 33-47](#).

Return to the [Summary Table](#).

The AES\_GLB\_INT\_FLG register contains the current status of the AES interrupt

Bit	Field	Type	Reset	Description
31-1	RESERVED	R	0h	Reserved
0	INT_FLG	R	0h	Global Interrupt Flag for AES INT. This bit determines whether the SINTREQUEST is generated by AES This bit can be cleared by writing a 1 to the corresponding bit in the AES_GLB_INT_CLR register. Reset type: SYSRSn

### 33.6.3.2 AES\_GLB\_INT\_CLR Register (Offset = 8h) [Reset = 0000000h]

AES\_GLB\_INT\_CLR is shown in [Figure 33-53](#) and described in [Table 33-48](#).

Return to the [Summary Table](#).

The AES\_GLB\_INT\_CLR register is used to clear the interrupt flags in AES\_GLB\_INT\_FLG register.

## 34.1 Introduction

The Embedded Pattern Generator (EPG) module is a customizable pattern and clock generator that can serve many test and application scenarios that require a simple pattern generator or a periodic clock generator. The EPG module can also be used to capture an incoming serial stream of data.

### 34.1.1 Features

Features of the EPG module are:

- Clock generation:
  - Independent clock generation and clock division
  - Synchronous clock generation with programmable offsets
  - Can generate clocks to act as source for external modulator and internal demodulator for the SDFM
- Pattern generation:
  - Independent serial data stream generation
  - Serial data stream and the associated clock generation
  - Ability to skew clock with respect to serial data
  - Synchronous data stream with programmable offset with respect to one another
  - Can generate waveforms for loopback test of communication peripherals
  - Useful as diagnostics test if not already built-in

The EPG output signals are connected to GPIOs or other peripherals inside the device. The EPG inputs act as shift register inputs to capture incoming serial data streams. This allows the EPG to be configured as a custom serial module. The EPG is also capable of generating interrupts that are used to supply the pattern generators with new data or signal the completion of a generated pattern.

### 34.1.2 EPG Block Diagram

Figure 34-1 shows the EPG overview block diagram.

**Figure 34-1. EPG Overview Block Diagram**

Figure 34-2 shows the EPG block diagram.

Figure 34-2. EPG Detailed Block Diagram

**Note**

The number of available EPGx SIGGEN modules for each device can be different. This diagram shows an EPG with 2 SIGGEN modules (SIGGEN0 and SIGGEN1). Refer to the EPG\_REGS register description to see how many SIGGEN modules are available for a specific device.

The EPG input clock (EPGCLK) is sourced from PERx.SYSCLK.

### 34.2 Clock Generator Modules

The clock generator modules use the EPG input clock and generate four output clocks, see [Figure 34-3](#). Each of the four output clocks (CLKOUT0 to CLKOUT3) has a DCLK and a GCLK version. The EPG clock division results in a gated, GCLK, version of the EPG input clock which are named CLKOUT0\_GCLK to CLKOUT3\_GCLK. The other version, DCLK (CLKOUT0\_DCLK to CLKOUT3\_DCLK), have the same period but with an approximately 50% duty cycle. The clock generation takes place using the divider settings CLKDIVx\_CTL0.PRD, and clock offset settings CLKDIVx\_CLK.CLK<sub>y</sub>OFFSET. The RUNCLOCK signal generated by the clock stop logic determines when the clock generation is started and stopped.

The clock divider counter is a simple up counter, which has a period determined by CLKDIVx\_CTL0.PRD. This divider counter begins counting when RUNCLOCK is set. The CLKOUT0 to CLKOUT4 GCLKs are gated versions of the CLKIN (EPG input clock). The clock gates are enabled when the counter value matches the corresponding clock offsets. In the case where RUNCLOCK is cleared, the clock gates are disabled and the counter is set to zero.

**Note**

The CLKDIVx\_CTL0.PRD register can only be written when GCTL0.EN is 0.

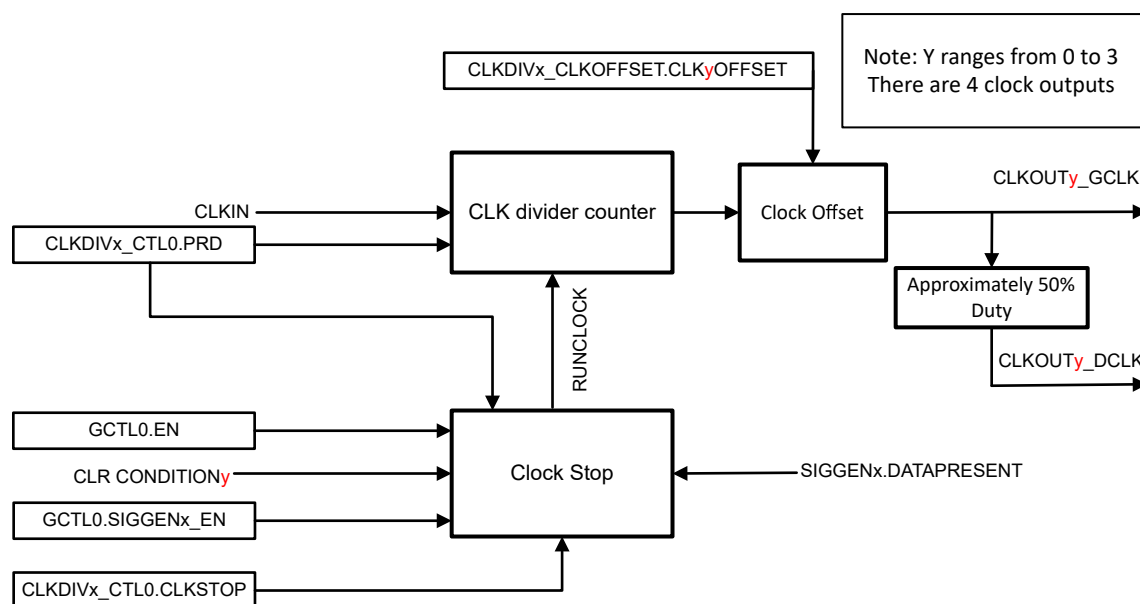

Figure 34-3. EPG Clock Generator

#### 34.2.1 DCLK (50% duty cycle clock)

The CLKOUT<sub>y</sub>\_DCLK is generated by setting the clock output for half the clock divider period. When CLKDIVx\_CTL0.PRD is set to zero, CLKOUT<sub>y</sub>\_DCLK is the same as the input clock.

### 34.2.2 Clock Stop

Figure 34-4 shows how the Clock Stop module sets and clears the RUNCLOCK signal.

Figure 34-4. EPG Clock Stop

In signal generator modes, GCTL0.SIGGENx\_EN bit is cleared when BIT\_LENGTH shifts (or rotates) is completed. This makes sure that data is not shifted out. In addition, clock generation (generation of CLKOUT0 to CLKOUT3) also is stopped to make sure that sampling of input data does not continue after BIT\_LENGTH shifts when GCTL0.SIGGENx\_EN is cleared to 0.

The RUNCLOCK signal has to be high for the clock generation circuitry to be active. When GCTL0.SIGGENx\_EN is cleared, the clock generation can be selected to stop on the falling edge of CLKOUT0 to CLKOUT3.

The clock stop module operates as follow:

- RUNCLOCK is asserted as soon as both GCTL0.SIGGENx\_EN and GCTL0.EN are set.
- RUN\_CLOCK\_FF is set when both GCTL0.SIGGENx\_EN and GCTL0.EN are set and CLKDIVx\_CTL0.PRD is not zero.
- When GCTL0.SIGGENx\_EN is cleared, RUN\_CLOCK\_FF is not cleared immediately. This makes sure that RUNCLOCK remains set and the clock generation circuitry remains enabled.
- When SIGGENx.DATA0 and SIGGENx.DATA1 are not filled with data before the next shift sequence (repeat shift modes) and signal generator is waiting for data to be written, clocks are stopped.
- The RUN\_CLOCK\_FF can be cleared on the falling edge of CLKOUT0 to CLKOUT3 based on the configuration of CLKSTOP field.
- Clearing GCTL0.EN clears RUN\_CLOCK\_FF unconditionally.

### 34.3 Signal Generator Module

The signal generator module is the main component of the EPG and generates the data stream that follows custom patterns. Figure 34-5 shows the main components. This module has 8 output ports DATATRANOUT0 to DATATRANOUT7. The two registers SIGGENx\_DATA1 and SIGGENx\_DATA0 constitute a 64-bit bus named DATA[63:0]. DATATRANIN[63:0], which is used for all the data transform operations, can be DATA[63:0] or bit reversed DATA (when SIGGENx\_CTL0.BRIN bit is set). The DATATRANOUT0 to DATATRANOUT7 are connected to DATATRANIN0 to DATATRANIN7 when the signal generator is not in BIT\_BANG mode. In BIT\_BANG mode, DATATRANOUT0 to DATATRANOUT7 are connected to DATATRANIN0, DATATRANIN8, and DATATRANIN16 to DATATRANIN56.

In addition to generating data outputs, one of the 8 EPGIN inputs can act as data input to SIGGENx\_DATAy registers. In Figure 34-5, the EPGIN\_MUX block illustrates the mechanism used to capture the input data stream. This enables one to capture a data input stream using EPG module.

Data transformation is done on the DATATRANIN bus, and is determined by the configured mode (SIGGENx\_CTL0.MODE), provided GCTL0.EN and GCTL0.SIGGENx\_EN are both set. If either of these enable bits are 0, then the data output of the transform block is the same as the input. The transformed output is bit reversed when SIGGENx\_CTL0.BROUT bit is set. Conditions under which the DATA active register (SIGGENx\_DATA0\_ACTIVE and SIGGENx\_DATA1\_ACTIVE) are:

- Loaded from SIGGENx\_DATA1 and SIGGENx\_DATA0
- Directly updated on a memory mapped write to SIGGENx\_DATA1 and SIGGENx\_DATA0
- Holds the current data

**Table 34-1. SIGGENx Active Register Loading**

Condition	SIGGENx_DATA1_ACTIVE DATA ACTIVE Register [63:32]	SIGGENx_DATA0_ACTIVE DATA ACTIVE Register [31:0]
Memory mapped write to SIGGENx_DATA0 register and GCTL0.SIGGENx_EN is 0	No updates	Updated with the value written to SIGGENx_DATA0 register
Memory mapped write to SIGGENx_DATA1 register and GCTL0.SIGGENx_EN is 0.	Updated with the value written to SIGGENx_DATA1 register	No updates
"BITLENGTH" number of shifts are done, and Mode is SHIFT_RIGHT_REPEAT or SHIFT_LEFT_REPEAT, and BITLENGTH <= 32, and Either SIGGENx_DATA0 or SIGGENx_DATA1 has been updated	Copy SIGGENx_DATA1 register content	Copy SIGGENx_DATA0 register content
"BITLENGTH" number of shifts are done, and Mode is SHIFT_RIGHT_REPEAT or SHIFT_LEFT_REPEAT, and BITLENGTH >= 32, and Both SIGGENx_DATA0 and SIGGENx_DATA1 have been updated	Copy SIGGENx_DATA1 register contents	Copy SIGGENx_DATA0 register contents
"BITLENGTH" number of shifts are done, and Mode is SHIFT_RIGHT_REPEAT or SHIFT_LEFT_REPEAT, and BITLENGTH <= 32, and Neither SIGGENx_DATA0, nor SIGGENx_DATA1 has been updated	Hold the current value, no shifts	Hold the current value, no shifts
"BITLENGTH" number of shifts are done, and Mode is SHIFT_RIGHT_REPEAT or SHIFT_LEFT_REPEAT, and BITLENGTH >= 32, and Neither SIGGENx_DATA0, nor SIGGENx_DATA1 has not been updated	Hold the current value, no shifts	Hold the current value, no shifts
All other conditions	Updates based on current mode of operation	Updates based on current mode of operation

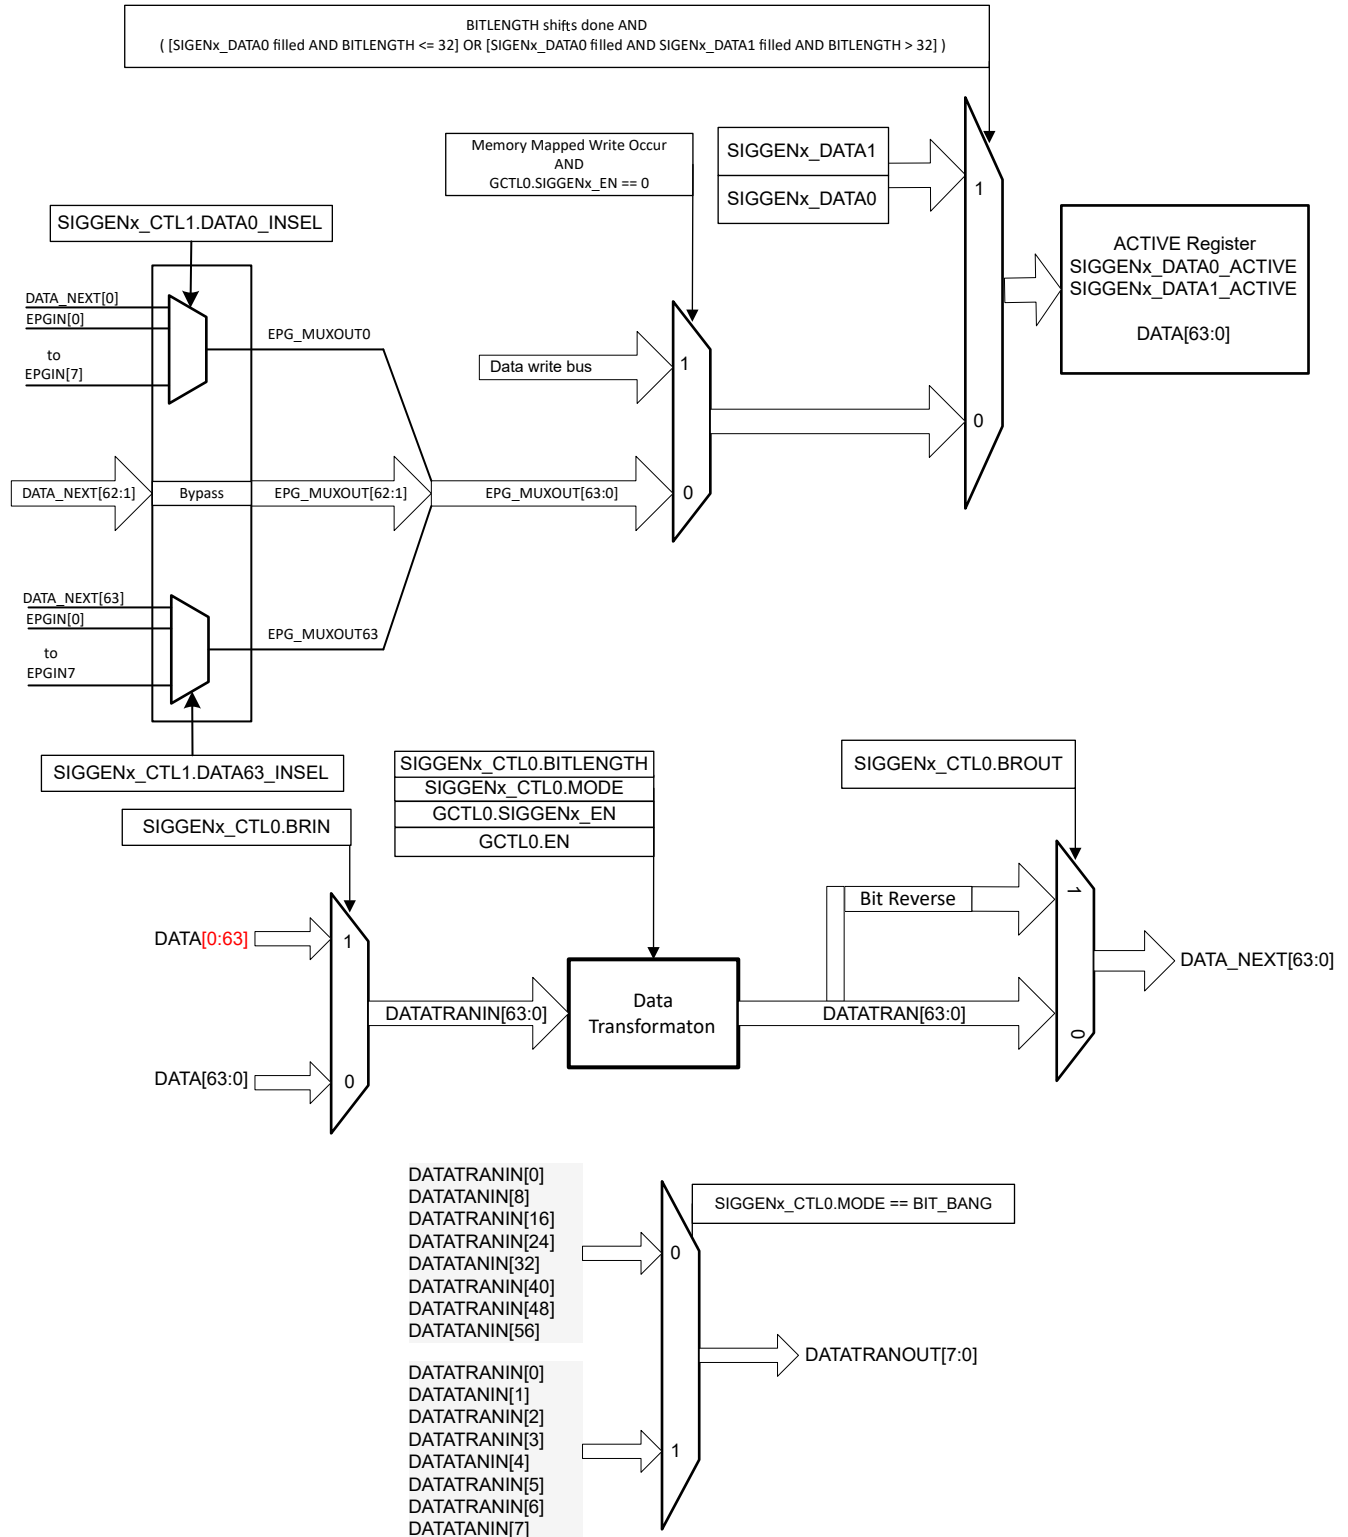

Figure 34-5. EPG Signal Generator Detailed Overview

Following are the possible data transformations:

**Bit-bang mode:** In this mode, DATATRAN[63:0] is the same as DATATRANIN[63:0].

**Shift right once mode:** In this mode, DATATRAN[63:0] = {0,DATATRANIN[63:1]}. After SIGENx\_CTL0.BITLENGTH shifts, SIGENx\_CTL0.EN is cleared.

**Shift right repeat mode:** In this mode, DATATRAN[63:0] = {0,DATATRANIN[63:1]}. After SIGENx\_CTL0.BITLENGTH shifts, load the data as per [Table 34-1](#).

**Rotate right once mode:** In this mode, DATATRAN[63:0] = {DATATRANIN[0],DATATRANIN[63:1]}. After SIGENx\_CTL0.BITLENGTH shifts, active register is loaded from the {DATA1,DATA0} register, and SIGENx\_CTL0.EN is cleared.

**Rotate right repeat:** This mode is same as rotate right once, except that SIGENx\_CTL0.EN is not cleared upon SIGENx\_CTL0.BITLENGTH rotates.

**Shift left once mode:** In this mode, DATATRAN[63:0] = {DATATRANIN[62:1],0}. After SIGENx\_CTL0.BITLENGTH shifts, SIGENx\_CTL0.EN is cleared.

**Shift left repeat mode:** In this mode, DATATRAN[63:0] = {DATATRANIN[62:1],0}. After SIGENx\_CTL0.BITLENGTH shifts, load the data as per [Table 34-1](#).

**Rotate left once mode:** In this mode, DATATRAN[63:0] = {DATATRANIN[62:1],DATATRANIN[63]}. After SIGENx\_CTL0.BITLENGTH shifts, active register is loaded from the {DATA1,DATA0} register, and SIGENx\_CTL0.EN is cleared.

**Rotate left repeat:** This mode is same as rotate left once, except that SIGENx\_CTL0.EN is not cleared upon SIGENx\_CTL0.BITLENGTH rotates.

---

#### Note

SIGGENx\_CTL0.MODE and SIGGENx\_CTL.BITWIDTH must only be updated when GCTL0.SIGGENx\_EN is 0.

---

### 34.4 EPG Peripheral Signal Mux Selection

EPG DATAINx signals are connected to input signal sources from other peripherals. The EPG DATAINx signal sources are listed in [Table 34-2](#).

EPGOUT0 to EPGOUT7 can override peripheral input signals connected to DATAINx. For example, the peripheral CAN RX input signal can be overwritten by EPGOUTx. DATAINx can be passed to DATAOUTx untouched, if EPG is not required, or the DATAINx can be replaced with EPGOUTy ( $y = x\%8$ ). The EPGMXSEL0 and EPGMXSEL1 registers must be configured to select the source of the DATAOUTx signals. Also, EPGOUTx signals can be connected to GPIOs through the Output XBARs and CLB Output XBARs, while EPGINx signals can be connected to the Input XBARs.

### 34.5 Application Software Notes

The following points are important considerations when utilizing the EPG:

- SIGGENx\_CTL0.MODE and SIGGENx\_CTL0.BITLENGTH can only be written to when SIGGENx\_CTL0.EN is 0
- CLKDIVx\_CTL0.PRD register can be written, when GCTL0.EN is 0
- GCTL0.EN can be enabled before GCTL0.SIGGENx\_EN

## 34.6 EPG Example Use Cases

This section provides example register configurations for different EPG use cases.

### Note

Some examples can require more than one SIGGEN module. Check the device registers or data sheet for the number of available SIGGEN modules.

### 34.6.1 EPG Example: Synchronous Clocks with Offset

[Example 34-1](#) register configuration generates 4 clocks, all synchronous to one another with edges offset by 2 clock cycles. In [Example 34-1](#), a clock divide value of 12 is used.

#### Example 34-1. Synchronous Clocks with Offset Register Configuration

Register	Value	Selected Mode
<b>Epg1MuxRegs</b>		
EPGMXSEL0.SEL0	0x1	Select EPGOUT0 to drive DATAOUT[0]
EPGMXSEL0.SEL1	0x1	Select EPGOUT1 to drive DATAOUT[1]
EPGMXSEL0.SEL2	0x1	Select EPGOUT2 to drive DATAOUT[2]
EPGMXSEL0.SEL3	0x1	Select EPGOUT3 to drive DATAOUT[3]
<b>Epg1Regs</b>		
<b>Global Settings</b>		
GCTL0.EPGOUT0SEL	0x0	Selects signal mux output on EPGOUT0
GCTL0.EPGOUT1SEL	0x0	Selects signal mux output on EPGOUT1
GCTL0.EPGOUT2SEL	0x0	Selects signal mux output on EPGOUT2
GCTL0.EPGOUT3SEL	0x0	Selects signal mux output on EPGOUT3
GCTL3.EPGOUT0_SIGOUTSEL	0x0	Select SIGGEN0.OUT[0] on EPGOUT0
GCTL3.EPGOUT1_SIGOUTSEL	0x1	Select SIGGEN0.OUT[1] on EPGOUT1
GCTL3.EPGOUT2_SIGOUTSEL	0x2	Select SIGGEN0.OUT[2] on EPGOUT2
GCTL3.EPGOUT3_SIGOUTSEL	0x3	Select SIGGEN0.OUT[3] on EPGOUT3
GCTL1.SIGGEN0_CLKSEL	0x0	Select CLKOUT0 of CLKGEN0 as the clock source of SIGGEN0
<b>CLKGEN0 Setting</b>		
CLKDIV0_CTL0.PRD	0x0	Divide by 1
CLKDIV0_CLKOFFSET.CLK0OFFSET	0x0	No offset
<b>SIGGEN0 Mode and Bit Length Configuration</b>		
SIGGEN0_CTL0.BITLENGTH	0xC	Configure bit length to 12 to get a divide-by-12 clock.
SIGGEN0_CTL0.MODE	0x3	Configure the mode to rotate right repeat mode to generate a periodic waveform.
SIGGEN0_DATA0[11:0]	0000 0111 1110	Initialize the 12 bits to 6 ones and 6 zeroes, which makes sure of a 50% duty cycle clock.
SIGGEN0_DATA0[27:16]	0001 1111 1000	Create a 2-cycle offset with respect to first clock.
SIGGEN0_DATA1[11:0]	0111 1110 0000	Create a 4-cycle offset with respect to first clock.
SIGGEN0_DATA1[27:16]	1111 1000 0001	Create a 6-cycle offset with respect to first clock.

### 34.6.2 EPG Example: Serial Data Bit Stream (LSB first)

**Example 34-2** register configuration shifts out a data word, the data rate is set to divide by 8 and the LSB is shifted out first. After 32 shifts are completed, an interrupt is generated for further sequencing.

#### **Example 34-2. Serial Data Bit Stream (LSB first) Register Configuration**

Register	Value	Selected Mode
<b>Epg1MuxRegs</b>		
EPGMXSEL0.SEL0	0x1	Select EPGOUT0 to drive DATAOUT[0]
<b>Epg1Regs</b>		
<b>Global Settings</b>		
GCTL1.SIGGEN0_CLKSEL	0x0	Select CLKOUT0 of CLKGEN0 as the clock source of SIGGEN0
<b>CLKGEN0 Setting</b>		
CLKDIV0_CTL0.PRD	0x7	Divide by 8
CLKDIV0_CLKOFFSET.CLK0OFFSET	0x0	No offset
<b>SIGGEN0 Mode and Bit Length Configuration</b>		
SIGGEN0_CTL0.BITLENGTH	0x20	Do 32 shifts.
SIGGEN0_CTL0.MODE	0x1	Configure the mode to shift right once mode. Generates an interrupt after 32 shifts.
SIGGEN0_DATA0[15:0]	0xAA55	Data to be shifted out
SIGGEN0_DATA0[31:16]	0xCCCC	Data to be shifted out
SIGGEN0_DATA1[15:0]	0xAA55	Data to be shifted out
SIGGEN0_DATA1[31:16]	0x55AA	Data to be shifted out

### 34.6.3 EPG Example: Serial Data Bit Stream (MSB first)

**Example 34-3** register configuration shifts out a data word, the data rate is set to divide by 8 and MSB is shifted out first. After 32 shifts are complete, an interrupt is generated for further sequencing.

#### Example 34-3. Serial Data Bit Stream (MSB first) Register Configuration

Register	Value	Selected Mode
<b>Epg1MuxRegs</b>		
EPGMXSEL0.SEL0	0x1	Select EPGOUT0 to drive DATAOUT[0]
<b>Epg1Regs</b>		
<b>Global Settings</b>		
GCTL0.EPGOUT0SEL	0x0	Selects signal mux output on EPGOUT0
GCTL3.EPGOUT0_SIGOUTSEL	0x4	Select SIGGEN0.OUT[4] on EPGOUT0, on 64-bit reversal, 31 bit appears on 32 bit (hence, configuring to 4).
GCTL1.SIGGEN0_CLKSEL	0x0	Select CLKOUT0 of CLKGEN0 as the clock source of SIGGEN0
<b>CLKGEN0 Setting</b>		
CLKDIV0_CTL0.PRD	0x7	Divide by 8
CLKDIV0_CLKOFFSET.CLK0OFFSET	0x0	No offset
<b>SIGGEN0 Mode and Bit Length Configuration</b>		
SIGGEN0_CTL0.BITLENGTH	0x20	Do 32 shifts.
SIGGEN0_CTL0.MODE	0x1	Configure the mode to shift right once mode. Generates an interrupt after 32 shifts.
SIGGEN0_CTL0.BRIN	0x1	Reverse the bits to the data transform block to make sure that the MSB is transmitted first.
SIGGEN0_CTL0.BROUT	0x1	Reverse the data back and store in the register
SIGGEN0_DATA0[15:0]	0xAA55	Data to be shifted out
SIGGEN0_DATA0[31:16]	0xCCCC	Data to be shifted out
SIGGEN0_DATA1[15:0]	0xAA55	Data to be shifted out
SIGGEN0_DATA1[31:16]	0x55AA	Data to be shifted out

### 34.6.4 EPG Example: Clock and Data Pair

**Example 34-4** register configuration shifts out a data word, also an associated clock is generated to latch the data (EPGOUT1), the data rate is set to divide by 8 and MSB is shifted out first. After 32 shifts are complete, an interrupt is generated for further sequencing.

#### Example 34-4. Clock and Data Pair Register Configuration

Register	Value	Selected Mode
<b>Epg1MuxRegs</b>		
EPGMXSEL0.SEL0	0x1	Select EPGOUT0 to drive DATAOUT[0]
EPGMXSEL0.SEL1	0x1	Select EPGOUT1 to drive DATAOUT[1]
<b>Epg1Regs</b>		
<b>Global Settings</b>		
GCTL0.EPGOUT0SEL	0x0	Selects signal mux output on EPGOUT0
GCTL3.EPGOUT0_SIGOUTSEL	0x4	Select SIGGEN0.OUT[4] on EPGOUT0, on 64-bit reversal, 31 bit appears on 32 bit (hence, configuring to 4).
GCTL0.EPGOUT1SEL	0x0	Selects signal mux output on EPGOUT1
GCTL3.EPGOUT1_SIGOUTSEL	0x8	Select SIGGEN1.OUT[0] on EPGOUT1.
GCTL1.SIGGEN0_CLKSEL	0x0	Select CLKOUT0 of CLKGEN0 as the clock source of SIGGEN0
GCTL1.SIGGEN1_CLKSEL	0x4	Select CLKOUT0 of CLKGEN1 as the clock source of SIGGEN1
<b>CLKGEN0 Setting</b>		
CLKDIV0_CTL0.PRD	0x7	Divide by 8
CLKDIV0_CLKOFFSET.CLK0OFFSET	0x0	No offset
CLKDIV1_CTL0.PRD	0x3	Divide by 4
<b>SIGGEN0 Mode and Bit Length Configuration</b>		
SIGGEN0_CTL0.BITLENGTH	0x20	Do 32 shifts.
SIGGEN0_CTL0.MODE	0x1	Configure the mode to shift right once mode. Generates an interrupt after 32 shifts.
SIGGEN0_CTL0.BRIN	0x1	Reverse the bits to the data transform block to make sure that the MSB is transmitted first.
SIGGEN0_CTL0.BROUT	0x1	Reverse the data back and store in the register
SIGGEN0_DATA0[15:0]	0xAA55	Data to be shifted out
SIGGEN0_DATA0[31:16]	0xCCCC	Data to be shifted out
SIGGEN0_DATA1[15:0]	0xAA55	Data to be shifted out
SIGGEN0_DATA1[31:16]	0x55AA	Data to be shifted out
<b>SIGGEN1 Mode and Bit Length Configuration</b>		
SIGGEN1_CTL0.BITLENGTH	0x2	Set bit length to 2 to generate a 50% duty clock.
SIGGEN1_CTL0.MODE	0x3	Configure the mode to rotate right repeat mode. Generates a 50% duty cycle clock.
SIGGEN1_DATA0[15:0]	0x2	Data to be shifted out

### 34.6.5 EPG Example: Clock and Skewed Data Pair

Example 34-5 register configuration shows the data shifted out is skewed by few a EPG input clock cycles.

#### Example 34-5. Clock and Skewed Data Pair Register Configuration

Register	Value	Selected Mode
<b>Epg1MuxRegs</b>		
EPGMXSEL0.SEL0	0x1	Select EPGOUT0 to drive DATAOUT[0]
EPGMXSEL0.SEL1	0x1	Select EPGOUT1 to drive DATAOUT[1]
<b>Epg1Regs</b>		
<b>Global Settings</b>		
GCTL0.EPGOUT0SEL	0x0	Selects signal mux output on EPGOUT0
GCTL3.EPGOUT0_SIGOUTSEL	0x4	Select SIGGEN0.OUT[4] on EPGOUT0, on 64-bit reversal, 31 bit appears on 32 bit (hence, configuring to 4).
GCTL0.EPGOUT1SEL	0x0	Selects signal mux output on EPGOUT1
GCTL3.EPGOUT1_SIGOUTSEL	0x8	Select SIGGEN1.OUT[0] on EPGOUT1.
GCTL1.SIGGEN0_CLKSEL	0x0	Select CLKOUT0 of CLKGEN0 as the clock source of SIGGEN0
GCTL1.SIGGEN1_CLKSEL	0x4	Select CLKOUT0 of CLKGEN1 as the clock source of SIGGEN1
<b>CLKGEN0 Setting</b>		
CLKDIV0_CTL0.PRD	0x7	Divide by 8
CLKDIV0_CLKOFFSET.CLK0OFFSET	0x2	Offset of 2 cycles.
CLKDIV1_CTL0.PRD	0x3	Divide by 4
<b>SIGGEN0 Mode and Bit Length Configuration</b>		
SIGGEN0_CTL0.BITLENGTH	0x20	Do 32 shifts.
SIGGEN0_CTL0.MODE	0x1	Configure the mode to shift right once mode. Generates an interrupt after 32 shifts.
SIGGEN0_CTL0.BRIN	0x1	Reverse the bits to the data transform block to make sure that the MSB is transmitted first.
SIGGEN0_CTL0.BROUT	0x1	Reverse the data back and store in the register
SIGGEN0_DATA0[15:0]	0xAA55	Data to be shifted out
SIGGEN0_DATA0[31:16]	0xCCCC	Data to be shifted out
SIGGEN0_DATA1[15:0]	0xAA55	Data to be shifted out
SIGGEN0_DATA1[31:16]	0x55AA	Data to be shifted out
<b>SIGGEN1 Mode and Bit Length Configuration</b>		
SIGGEN1_DATA0[15:0]	0x2	Data to be shifted out
SIGGEN1_CTL0.BITLENGTH	0x2	Set bit length to 2 to generate a 50% duty clock.
SIGGEN1_CTL0.MODE	0x3	Configure the mode to rotate right repeat mode. Generates a 50% duty cycle clock.

### 34.6.6 EPG Example: Capturing Serial Data with a Known Baud Rate

**Example 34-6** register configuration captures a 32-bit data stream. The data is generated from SIGGEN0 and captured in SIGGEN1 (EPGOUT0 looped back as EPGIN0). The clock to SIGGEN1 is offset by a few cycles to reliably capture the data.

#### Example 34-6. Capturing Serial Data with a Known Baud Rate Register Configuration

Register	Value	Selected Mode
<b>Epg1MuxRegs</b>		
EPGMXSEL0.SEL0	0x1	Select EPGOUT0 to drive DATAOUT[0]
EPGMXSEL0.SEL1	0x1	Select EPGOUT1 to drive DATAOUT[1]
<b>Epg1Regs</b>		
<b>Global Settings</b>		
GCTL0.EPGOUT0SEL	0x0	Selects signal mux output on EPGOUT0
GCTL3.EPGOUT0_SIGOUTSEL	0x4	Select SIGGEN0.OUT[4] on EPGOUT0, on 64-bit reversal, 31 bit appears on 32 bit (hence, configuring to 4).
GCTL0.EPGOUT1SEL	0x0	Selects signal mux output on EPGOUT1
GCTL3.EPGOUT1_SIGOUTSEL	0x8	Select SIGGEN1.OUT[0] on EPGOUT1.
GCTL1.SIGGEN0_CLKSEL	0x0	Select CLKOUT0 of CLKGEN0 as the clock source of SIGGEN0
GCTL1.SIGGEN1_CLKSEL	0x4	Select CLKOUT0 of CLKGEN1 as the clock source of SIGGEN1
<b>CLKGEN0 Setting</b>		
CLKDIV0_CTL0.PRD	0x7	Divide by 8
CLKDIV0_CLKOFFSET.CLK0OFFSET	0x0	No offset
CLKDIV1_CTL0.PRD	0x7	Divide by 8
CLKDIV1_CLKOFFSET.CLK0OFFSET	0x2	Offset the capture clock by a few cycles to capture the data reliably.
<b>SIGGEN0 Mode and Bit Length Configuration</b>		
SIGGEN0_CTL0.BITLENGTH	0x20	Do 32 shifts, data out looped back to EPGIN[0] to demonstrate the data capture function.
SIGGEN0_CTL0.MODE	0x1	Configure the mode to shift right once mode. Generates an interrupt after 32 shifts.
SIGGEN0_CTL0.BRIN	0x0	Reverse the bits to the data transform block to make sure that the MSB is transmitted first.
SIGGEN0_CTL0.BROUT	0x0	Reverse the data back and store in the register
SIGGEN_DATA0[15:0]	0xAA55	Data to be shifted out
SIGGEN_DATA0[31:16]	0xCCCC	Data to be shifted out
SIGGEN_DATA1[15:0]	0xAA55	Data to be shifted out
SIGGEN_DATA1[31:16]	0x55AA	Data to be shifted out
<b>SIGGEN1 Mode and Bit Length Configuration</b>		
SIGGEN1_CTL0.BITLENGTH	0x32	Set bit length to 2 to generate a 50% duty clock.
SIGGEN1_CTL0.MODE	0x4	Configure the mode to shift left once mode. To capture the data pattern on EPGIN[0].
SIGGEN1_CTL1.DATA0_INSEL	0x1	Select EPGIN[0] as the data input of bit 0.
SIGGEN1_DATA0	0x0	Clear the data contents. Holds 0xAA55 3333 at the end of 32 shifts.

### 34.7 EPG Interrupt

EPG interrupt can be generated on “BIT\_LENGTH” shifts or rotates, or “BIT\_LENGTH/2” shifts or rotates. Interrupts can be generated in any of the signal generator modes.

The GINTSTS, GINTEN, GINTCLR, and GINTFRC registers are used to configure the EPG interrupt, as shown in Figure 34-7.

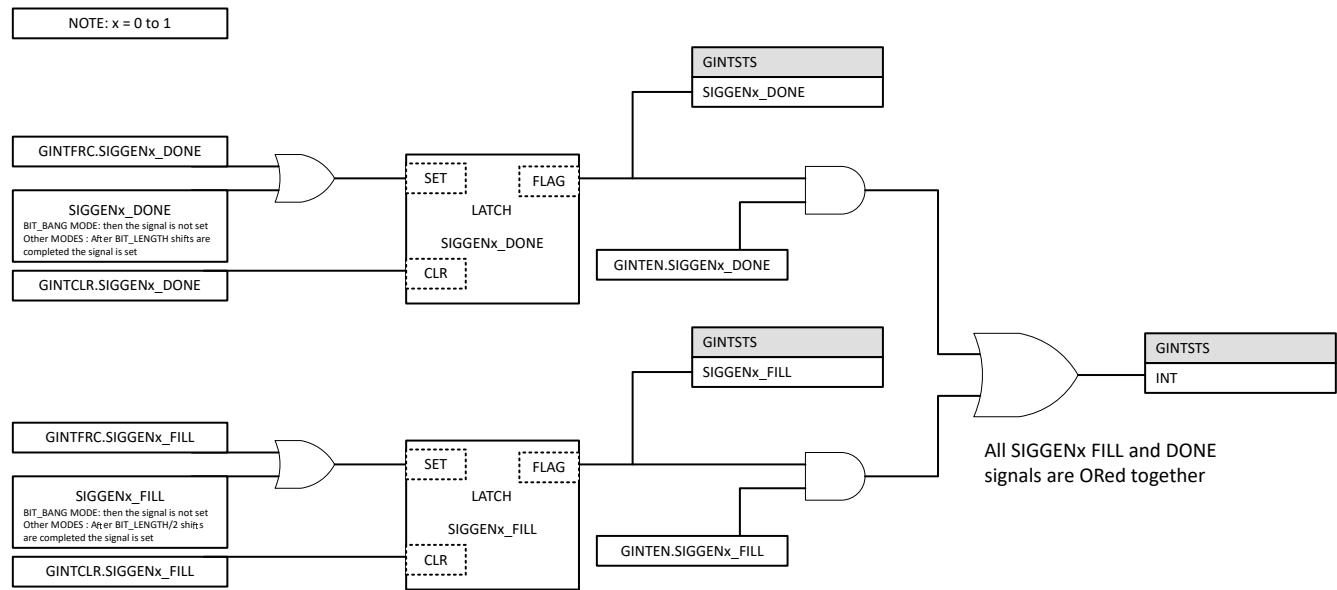

Figure 34-7. EPG Interrupt

### 34.8 Software

#### 34.8.1 EPG Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location: C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/epg

Cloud access to these examples is available at the following link: [dev.ti.com C2000Ware Examples](#).

##### 34.8.1.1 EPG Generating Synchronous Clocks - SINGLE\_CORE

FILE: epg\_ex1\_generate\_clocks.c

This example shows how to generate 2 synchronous clocks with edges being offset by 2 clock cycles. It configures Signal Generator to shift a periodic data. Generated Clock has period EPG CLOCK/6.

##### External Connections

- None. Signal is generated on GPIO 24, 3. Can be visualized through oscilloscope.

##### Watch Variables

- sigGenActiveData - Active Data of signal generator transform output

##### 34.8.1.2 EPG Generating Two Offset Clocks - SINGLE\_CORE

FILE: epg\_ex2\_generate\_two\_offset\_clocks.c

This example generates two offset clocks using the CLKGEN (CLKDIV) modules. For more information on this example, visit: [Designing With the C2000 Embedded Pattern Generator \(EPG\)](#)

##### External Connections

- None. Signal is generated on GPIO 24, 3. Can be visualized through oscilloscope.

### 34.8.1.3 EPG Generating Two Offset Clocks With SIGGEN - SINGLE\_CORE

FILE: `epg_ex3_generate_two_offset_clocks_with_siggen.c`

This example generates two offset clocks using the SIGGEN module. For more information on this example, visit: [Designing With the C2000 Embedded Pattern Generator \(EPG\)](#)

#### External Connections

- None. Signal is generated on GPIO 24, 3. Can be visualized through oscilloscope.

### 34.8.1.4 EPG Generate Serial Data - SINGLE\_CORE

FILE: `epg_ex4_generate_serial_data.c`

This example generates SPICLK and SPI DATA signals using the SIGGEN module. For more information on this example, visit: [Designing With the C2000 Embedded Pattern Generator \(EPG\)](#)

#### External Connections

- None. Signal is generated on GPIO 24, 3. Can be visualized through oscilloscope.

### 34.8.1.5 EPG Generate Serial Data Shift Mode - SINGLE\_CORE

FILE: `epg_ex5_generate_serial_data_shift_mode.c`

This example generates SPICLK and SPI DATA signals using the SIGGEN module in SHIFT mode. For more information on this example, visit: [Designing With the C2000 Embedded Pattern Generator \(EPG\)](#)

#### External Connections

- None. Signal is generated on GPIO 24, 3. Can be visualized through oscilloscope.

## 34.9 EPG Registers

The following sections are register descriptions for the Embedded Pattern Generator (EPG) module.

### 34.9.1 EPG Base Address Table

**Table 34-5. EPG Base Address Table**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	CPU2	CPU2.DMA	Pipeline Protected
Instance	Structure								
EPGRegs	<a href="#">EPG_REGS</a>	EPG_BASE	0x0005_EC00	YES	-	-	YES	-	YES
EPGMuxRegs	<a href="#">EPG_MUX_REGS</a>	EPGMUX_BASE	0x0005_ECD0	YES	-	-	YES	-	YES

### 34.9.2 EPG\_REGS Registers

Table 34-6 lists the memory-mapped registers for the EPG\_REGS registers. All register offset addresses not listed in Table 34-6 should be considered as reserved locations and the register contents should not be modified.

**Table 34-6. EPG\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	GCTL0	EPG Global control register 0		<a href="#">Go</a>
2h	GCTL1	EPG Global control register 1		<a href="#">Go</a>
4h	GCTL2	EPG Global control register 2		<a href="#">Go</a>
6h	GCTL3	EPG Global control register 3		<a href="#">Go</a>
8h	EPGLOCK	EPG LOCK Register		<a href="#">Go</a>
Ah	EPGCOMMIT	EPG COMMIT register		<a href="#">Go</a>
Ch	GINTSTS	EPG Global interrupt status register.		<a href="#">Go</a>
Eh	GINTEN	EPG Global interrupt enable register.		<a href="#">Go</a>
10h	GINTCLR	EPG Global interrupt clear register.		<a href="#">Go</a>
12h	GINTFRC	EPG Global interrupt force register.		<a href="#">Go</a>
18h	CLKDIV0_CTL0	Clock divider 0's control register 0		<a href="#">Go</a>
1Eh	CLKDIV0_CLKOFFSET	Clock divider 0's clock offset value		<a href="#">Go</a>
24h	CLKDIV1_CTL0	Clock divider 1's control register 0		<a href="#">Go</a>
2Ah	CLKDIV1_CLKOFFSET	Clock divider 1's clock offset value		<a href="#">Go</a>
30h	SIGGEN0_CTL0	Signal generator 0's control register 0		<a href="#">Go</a>
32h	SIGGEN0_CTL1	Signal generator 0's control register 1		<a href="#">Go</a>
38h	SIGGEN0_DATA0	Signal generator 0's data register 0		<a href="#">Go</a>
3Ah	SIGGEN0_DATA1	Signal generator 0's data register 1		<a href="#">Go</a>
3Ch	SIGGEN0_DATA0_ACTIVE	Signal generator 0's data active register 0		<a href="#">Go</a>
3Eh	SIGGEN0_DATA1_ACTIVE	Signal generator 0's data active register 1		<a href="#">Go</a>
50h	REVISION	IP Revision tie-off value		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 34-7 shows the codes that are used for access types in this section.

**Table 34-7. EPG\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1C	W1C	Write 1 to clear
W1S	W1S	Write 1 to set
WOnce	WOnce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		

**Table 34-7. EPG\_REGS Access Type Codes (continued)**

Access Type	Code	Description
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 34.9.2.1 GCTL0 Register (Offset = 0h) [Reset = 0000000h]

GCTL0 is shown in [Figure 34-8](#) and described in [Table 34-8](#).

Return to the [Summary Table](#).

23-16	BITLENGTH	R/W	0h	Defines the number bits which participates in the shift rotate operations. Reset type: SYSRSn
15-7	RESERVED	R	0h	Reserved
6	BROUT	R/W	0h	0 : No bit reversal on data output from data transform block 1 : Perform bit reversal on data output from data transform block Reset type: SYSRSn
5	BRIN	R/W	0h	0 : No bit reversal on data input of data transform block 1 : Perform bit reversal on data input of data transform block Reset type: SYSRSn
4	RESERVED	R	0h	Reserved

**Table 34-22. SIGGEN0\_CTL0 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
3-0	MODE	R/W	0h	<p>0 : BIT_BANG mode, The value written into DATA0 and DATA1 registers appear on the signal generator outputs as is.</p> <p>1 : SHIFT_RIGHT_ONCE mode, The data value written into (DATA1,DATA0) registers are shifted right by 1 on every clock. Shifting operations stops when BITLENGTH shifts are done and SIGGEN0_CTL0.EN bit is cleared.</p> <p>2 : ROTATE_RIGHT_ONCE, The data value written into (DATA1,DATA0) registers are rotated right by 1 on every clock. Rotation happens within (DATA1,DATA0)[BITLENGTH-1:0] Rotate operations stops when BITLENGTH shifts are done and SIGGEN0_CTL0.EN bit is cleared.</p> <p>3 : ROTATE_RIGHT_REPEAT, The data value written into (DATA1,DATA0) registers are rotated right by 1 on every clock. Rotation happens within (DATA1,DATA0)[BITLENGTH-1:0] Rotate operations continue until SIGGEN0_CTL0.EN bit is cleared.</p> <p>4 : SHIFT_LEFT_ONCE mode, The data value written into (DATA1,DATA0) registers are shifted left by 1 on every clock. Shifting operations stops when BITLENGTH shifts are done and SIGGEN0_CTL0.EN bit is cleared.</p> <p>5 : ROTATE_LEFT_ONCE, The data value written into (DATA1,DATA0) registers are rotated left by 1 on every clock. Rotation happens within (DATA1,DATA0)[BITLENGTH-1:0] Rotate operations stops when BITLENGTH shifts are done and SIGGEN0_CTL0.EN bit is cleared.</p> <p>6 : ROTATE_LEFT_REPEAT, The data value written into (DATA1,DATA0) registers are rotated left by 1 on every clock. Rotation happens within (DATA1,DATA0)[BITLENGTH-1:0] Rotate operations continue until SIGGEN0_CTL0.EN bit is cleared.</p> <p>7 : SHIFT_RIGHT_REPEAT mode, The data value written into (DATA1,DATA0) registers are shifted right by 1 on every clock. Shifting operations stops when SIGGEN0_CTL0.EN bit is cleared.</p> <p>8 : SHIFT_LEFT_REPEAT mode, The data value written into (DATA1,DATA0) registers are shifted left by 1 on every clock. Shifting operations stops when SIGGEN0_CTL0.EN bit is cleared.</p> <p>Reset type: SYSRSn</p>

### 34.9.2.16 SIGGEN0\_CTL1 Register (Offset = 32h) [Reset = 0000000h]

SIGGEN0\_CTL1 is shown in [Figure 34-23](#) and described in [Table 34-23](#).

Return to the [Summary Table](#).

Signal generator 0's control register 1

**Figure 34-23. SIGGEN0\_CTL1 Register**

29-28	RESERVED	R-0	0h	Reserved
27-16	FUNC	R	1h	Functional Release Number Reflects software-compatibility. If there is no software compatibility, a unique func number is assigned for compatible modules, the same number is maintained. Reset type: SYSRSn
15-11	RESERVED	R	1h	Reserved
10-8	MAJOR	R	0h	Major Revision Number Represents major changes to the module (e.g. entirely new features are added/changed). The major revision number for this module. Reset type: SYSRSn
7-6	CUSTOM	R	0h	Custom Module Number Indicates a special version of the module. May not be supported by standard software. Reset type: SYSRSn
5-0	MINOR	R	1h	Minor Revision Number Represents minor changes to the module (e.g. enhancements to existing features). The minor revision number for this module. Reset type: SYSRSn

### 34.9.3 EPG\_MUX\_REGS Registers

Table 34-29 lists the memory-mapped registers for the EPG\_MUX\_REGS registers. All register offset addresses not listed in Table 34-29 should be considered as reserved locations and the register contents should not be modified.

**Table 34-29. EPG\_MUX\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	EPGMXSEL0	EPG Mux select register 0		<a href="#">Go</a>
Ch	EPGMXSELLOCK	EPG Mux select register lock		<a href="#">Go</a>
Eh	EPGMXSELCOMMIT	EPG Mux select register commit		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 34-30 shows the codes that are used for access types in this section.

**Table 34-30. EPG\_MUX\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
WOnce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 34.9.3.1 EPGMXSEL0 Register (Offset = 0h) [Reset = 0000000h]

Chapter 35

# Modular Controller Area Network (MCAN)

---

This chapter describes the Modular Controller Area Network (MCAN). MCAN supports both classic CAN and CAN FD protocols.

<b>35.1 MCAN Introduction</b> .....	<b>5181</b>
<b>35.2 MCAN Environment</b> .....	<b>5182</b>
<b>35.3 CAN Network Basics</b> .....	<b>5183</b>
<b>35.4 MCAN Integration</b> .....	<b>5184</b>
<b>35.5 MCAN Functional Description</b> .....	<b>5186</b>
<b>35.6 Software</b> .....	<b>5223</b>
<b>35.7 MCAN Registers</b> .....	<b>5223</b>

### 35.1 MCAN Introduction

The Controller Area Network (CAN) is a serial communications protocol that efficiently supports distributed real-time control with a high level of reliability. CAN has high immunity to electrical interference and the ability to detect various type of errors. In CAN, many short messages are broadcast to the entire network, which provides data consistency in every node of the system.

The MCAN module supports both classic CAN and CAN FD (CAN with flexible data-rate) protocols. The CAN FD feature allows higher throughput and increased payload per data frame. Classic CAN and CAN FD devices can coexist on the same network without any conflict provided that partial network transceivers, which can detect and ignore CAN FD without generating bus errors, are used by the classic CAN devices. The MCAN module is compliant to ISO 11898-1:2015.

#### Note

The availability of the CAN FD feature is dependent on the device's part number. Refer to the device data sheet for more information.

Figure 35-1 shows an overview of the MCAN module.

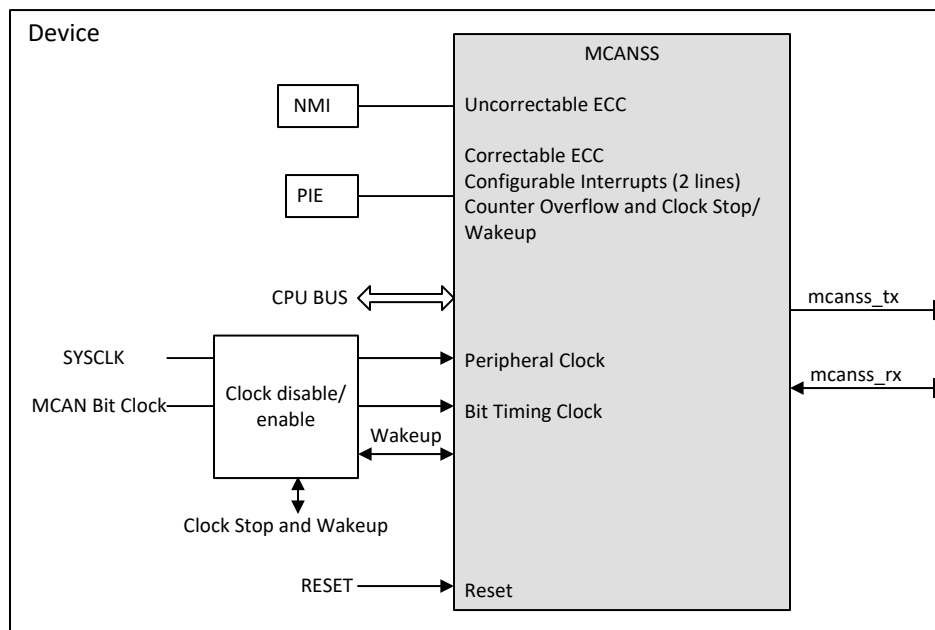

Figure 35-1. MCAN Module Overview

#### 35.1.1 MCAN Related Collateral

##### Foundational Materials

- [C2000 Academy - MCAN](#)
- [CAN and CAN FD Overview](#) (Video)
- [CAN and CAN FD Protocol](#) (Video)

##### Getting Started Materials

- [Getting Started with the MCAN \(CAN FD\) Module Application Report](#)

### 35.1.2 MCAN Features

The MCAN module implements the following features:

- Conforms with CAN Protocol 2.0 A, B and ISO 11898-1:2015
- Full CAN FD support (up to 64 data bytes)
- AUTOSAR and SAE J1939 support
- Up to 32 dedicated transmit buffers
- Configurable transmit FIFO, up to 32 elements
- Configurable transmit queue, up to 32 elements
- Configurable transmit Event FIFO, up to 32 elements
- Up to 64 dedicated receive buffers
- Two configurable receive FIFOs, up to 64 elements each
- Up to 128 filter elements
- Loop-back mode for self-test
- Maskable interrupt (two configurable interrupt lines, correctable ECC, counter overflow, and clock stop or wakeup)
- Non-maskable interrupt (uncorrectable ECC)
- Two clock domains (CAN clock and host clock)
- ECC check for Message RAM
- Clock stop and wakeup support
- Timestamp counter
- 1-Mbps nominal bit rate, 5-Mbps data bit rate

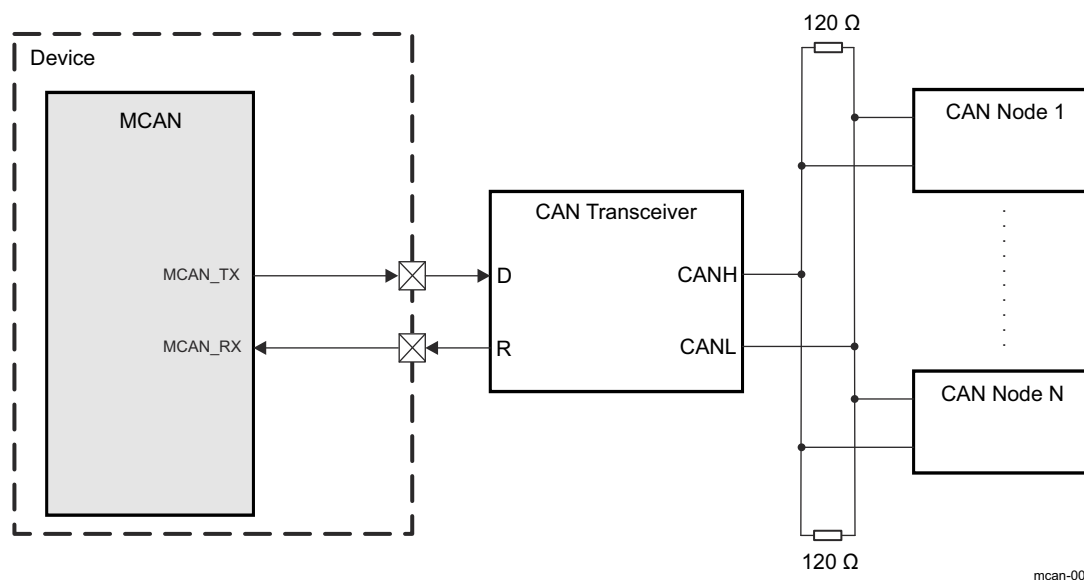

Non-supported features:

- Host bus firewall
- Clock calibration
- Debug over CAN

### 35.2 MCAN Environment

The CAN network physical layer consists of a two-wire differential bus, usually twisted pair, and provides a high level of interference immunity. An external CAN transceiver IC is needed to access the bus.

Figure 35-2 shows typical MCAN wiring. Table 35-1 describes the external signals of the MCAN module.

**Figure 35-2. MCAN Typical Bus Wiring**

**Table 35-1. MCAN I/O Description**

Module Signal	I/O	Description	Value at Reset
MCAN_RX	Input	Serial data input from external CAN transceiver.	HiZ
MCAN_TX	Output	Serial data output to external CAN transceiver.	HiZ

**Note**

See the *Terminal Configurations and Functions* section in the device data sheet and the *General-Purpose Input/Output (GPIO)* chapter to configure this peripheral to be connected to the device pins.

### 35.3 CAN Network Basics

The network basics are:

- The CAN bus is a 2-wire differential bus using non-return-to-zero (NRZ) encoding and has two states:
  - Recessive state (logical 1)
  - Dominant state (logical 0)
- When the bus is idle, any node can initiate a transmission to any other node (or nodes). When two or more nodes (ECUs) attempt to transmit at the same time, a non-destructive arbitration technique makes sure messages are sent in order of priority and no messages are lost.
- The message transmission is multicast. Data messages transmitted are identifier-based, not address-based.
- The content of the message is labeled by the identifier that is unique throughout the network (for example: RPM, temperature, position, pressure, and so forth).
- All nodes on the network receive the message and each performs an acceptance test on the identifier. If the message is relevant, the message is processed; otherwise, the message is ignored.
- The unique identifier also determines the priority of the message (the lower the numerical value of the identifier, the higher the priority).
- Data is transmitted and received using message frames, consisting of the following basic fields:
  - Arbitration field
  - Control field
  - Data field (up to 8 bytes for classical CAN and up to 64 bytes for CAN FD)
  - CRC field
  - ACK field

For more information, see *ISO 11898-1:2015: CAN data link layer and physical signaling*.

### 35.4 MCAN Integration

Figure 35-3 shows the integration of the MCAN module in the device.

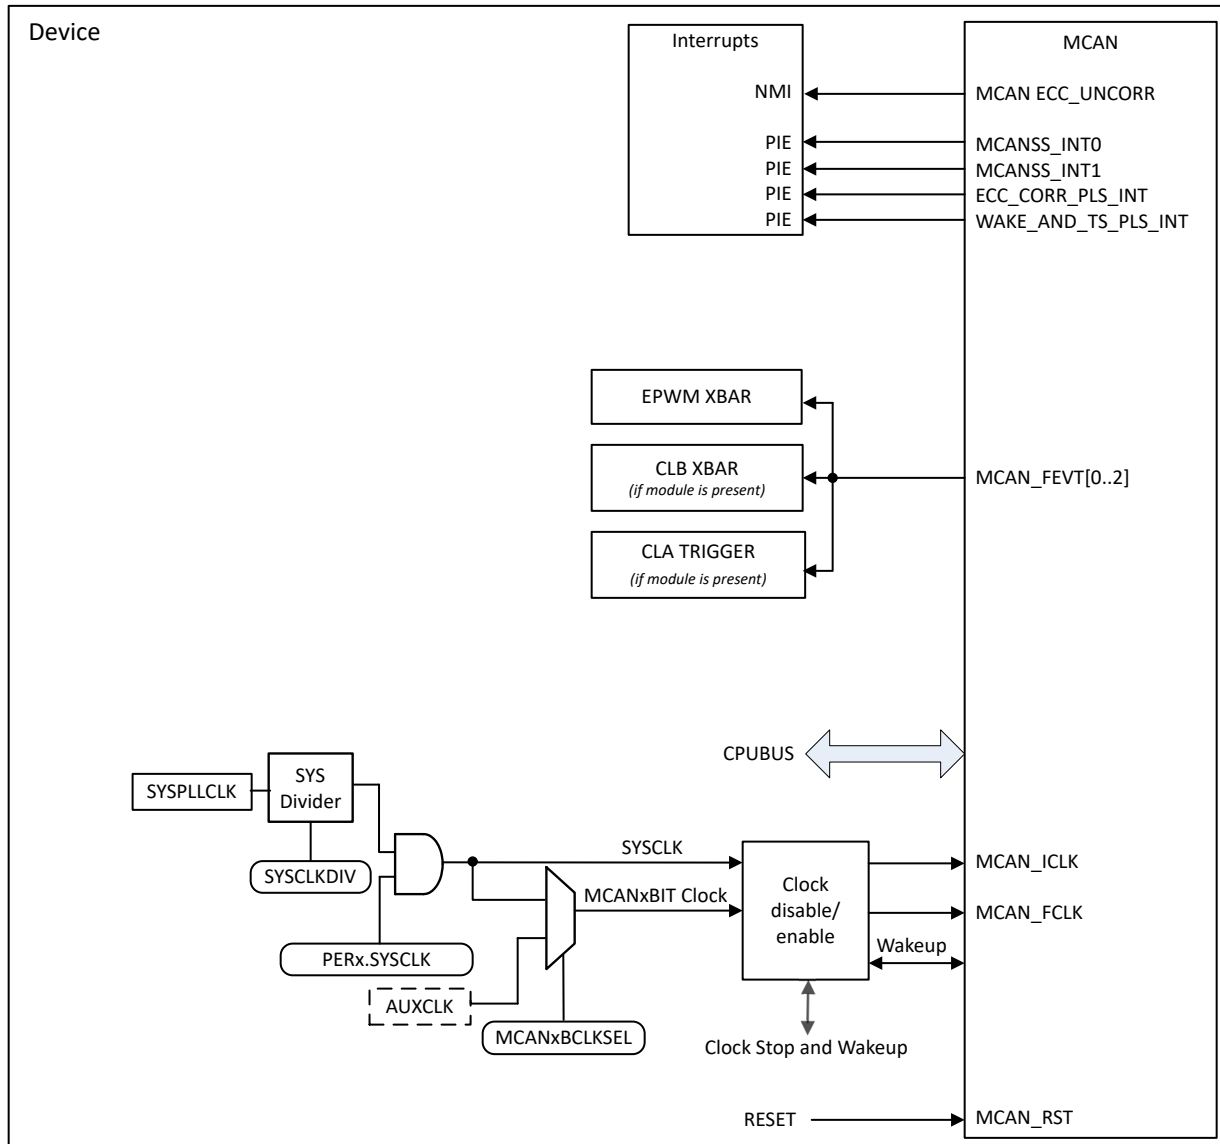

Figure 35-3. MCAN Integration

Table 35-2 and Table 35-3 summarize the integration of the MCAN module in the device.

**Table 35-2. MCAN Clocks and Resets**

Destination Signal Name	Source Signal Name	Description
<b>Clocks</b>		
MCAN_ICLK	SYSCLK	Interface clock for the MCAN module
MCAN_FCLK	MCANxBIT Clock	Bit timing clock for MCAN
<b>Resets</b>		
MCAN_RST	RESET	Asynchronous reset signal to the MCAN module

**Table 35-3. MCAN Hardware Requests**

Interrupt Requests <sup>(1)</sup>		
Source Signal Name	Description	
MCANSS_INT0	MCAN interrupt 0	
MCANSS_INT1	MCAN interrupt 1	
ECC_CORR_PLS_INT	MCAN ECC interrupt	
WAKE_AND_TS_PLS_INT	MCAN timestamp and wakeup interrupt	
MCAN_IRQ_ECC_UNCORR	MCAN ECC uncorrectable interrupt	
Filter Event Connections		
Source Signal Name	Trigger Input	Description
MCAN_FEVT0	EPWM XBAR <sup>(2)</sup> CLB XBAR <sup>(3)</sup> CLA Trigger <sup>(4)</sup>	MCAN RX Filter Event 1
MCAN_FEVT1	EPWM XBAR <sup>(2)</sup> CLB XBAR <sup>(3)</sup> CLA Trigger <sup>(4)</sup>	MCAN RX Filter Event 2
MCAN_FEVT2	EPWM XBAR <sup>(2)</sup> CLB XBAR <sup>(3)</sup> CLA Trigger <sup>(4)</sup>	MCAN RX Filter Event 3

 (2) See the ePWM XBAR Mux Configuration table in the *Crossbar (X-BAR)* chapter for the trigger position.  
 (3) See the CLB X-BAR Mux Configuration table in the *Crossbar (X-BAR)* chapter for the trigger position.  
 (4) See the Configuration Options table in the *Control Law Accelerator (CLA)* chapter for the trigger value.

### Note

For more information about the CLA\_triggers, see the *Control Law Accelerator (CLA)* chapter.

For more information about the CLB XBAR, see the *Configurable Logic Block (CLB)* chapter.

For more information about the ePWM XBAR module, see the *Enhanced Pulse Width Modulator (ePWM)* chapter.

### 35.5 MCAN Functional Description

The MCAN module performs CAN protocol communication according to ISO 11898-1:2015. The data bit rate can be programmed to values up to 5Mbps. Additional transceiver hardware is required for the connection to the physical layer (CAN bus).

For communication on a CAN network, individual message frames can be configured. The message frames and identifier masks are stored in the Message RAM.

All functions concerning the handling of messages are implemented in the Message Handler.

The register set of the MCAN module can be accessed directly using the module interface. These registers are used to control and configure the CAN core and the Message Handler, and to access the Message RAM.

Figure 35-4 shows the MCAN module block diagram, followed by the description of the MCAN module blocks.

**Figure 35-4. MCAN Block Diagram**

- **CAN Core:** The CAN core consists of the CAN protocol controller and the Rx/Tx shift register. The CAN handles all ISO 11898-1:2015 protocol functions and supports 11-bit and 29-bit identifiers.
- **Message Handler:** the Message Handler (Rx Handler and Tx Handler) is a state machine that controls the data transfer between the single-ported Message RAM and the CAN core's Rx/Tx shift register. The Message Handler also handles the acceptance filtering and Interrupt generation as programmed in the control registers.
- **Message RAM:** the main purpose of the Message RAM is to store Rx/Tx messages, Tx Event elements, and Message ID Filter elements (for more information, see [Section 35.5.16](#)).
- **Message RAM Interface:** enables a connection between the Message RAM and the other blocks in the MCAN module.
- **Registers and Message Object Access:** Data consistency is provided by indirect accesses to the message objects. During normal operation, all software and DMA accesses to the Message RAM are done through interface registers. The interface registers have the same word-length as the Message RAM.
- **Module Interface:** The MCAN module registers are accessed by the user's software through a 32-bit peripheral bus interface.
- **Clocking:** Two clocks are provided to the MCAN module: the peripheral synchronous clock (interface clock - MCAN\_ICLK) and the peripheral asynchronous clock (functional clock - MCAN\_FCLK).
- **Extension Interface:** All selected internal status and control signals are routed to this interface (except for the indication signals of configuration change enable bit (MCAN\_CCCR.CCE) and Interrupt Register bits (MCAN\_IR).

### 35.5.1 Module Clocking Requirements

Two clocks are provided to the MCAN module:

- Host Clock : peripheral synchronous clock (MCAN\_ICLK) as the general module clock source, and
- CAN Clock: peripheral asynchronous clock (MCAN\_FCLK) provided to the CAN core for generating the CAN bit timing.

Within the MCAN module, there is a synchronization mechanism implemented to make sure there is safe data transfer between the two clock domains. There is synchronization between the signals from the Host clock domain to the CAN clock domain and conversely, and between the reset signal (MCAN\_RST) to the Host clock domain and to the CAN clock domain.

---

#### Note

MCAN\_ICLK must always be higher or equal to MCAN\_FCLK, to achieve a stable functionality of the MCAN module:  $f_{ICLK} \geq f_{FCLK}$

---

The CAN-FD supports higher speeds of operation and as such has more stringent timing requirements than the classic CAN. For performance, TI recommends using the lowest N-divider value that maintains a working PLL REF\_CLK for the system. Lower N-divider values increase the loop bandwidth of the PLL, which in turn improves timing margins for CAN-FD.

### 35.5.2 Interrupt Requests

The MCAN module generates interrupt requests and is configured using the Host CPU. The Suspend mode prevents the interrupt requests from propagating to the Host CPU. The MCAN core has two interrupt lines and 30 internal interrupt sources. Each source can be configured to drive one of the two interrupt lines. The interrupts are level high interrupts. The MCAN core provides two interrupt requests (MCANSS\_INT0 and MCANSS\_INT1).

For more information, see the following registers:

- Interrupt Register (MCAN\_IR)
- Interrupt Enable (MCAN\_IE)
- Interrupt Line Select (MCAN\_ILS)
- Interrupt Line Enable (MCAN\_ILE)

The MCAN module supports External Timestamp Counter. The External Timestamp Counter produces an interrupt when the count rolls over (see [Section 35.5.10.1](#)).

For more information, see the following registers:

- Interrupt Clear Shadow Register (MCANSS\_ICS)
- Interrupt Raw Status Register (MCANSS\_IRS)
- Interrupt Enable Clear Shadow Register (MCANSS\_IECS)
- Interrupt Enable Register (MCANSS\_IE)
- Interrupt Enable Status Register (MCANSS\_IES)
- End Of Interrupt Register (MCANSS\_EOI)
- External Timestamp Prescaler Register (MCANSS\_EXT\_TS\_PRESCALER)
- External Timestamp Unserviced Interrupts Counter Register (MCANSS\_EXT\_TS\_UNSERVICED\_INTR\_CNTR)

To clear IRQ\_INT0, IRQ\_INT1, and TS\_WAKE interrupts, write to the EOI bit field for the corresponding interrupt number that is described in the MCANSS\_EOI register. When the MCAN is used by the CPU, in addition to clearing the interrupt sources, clear the interrupt by writing 1 to PIEACK register in the bit position for group 9 (refer to the *PIE Channel Mapping* section of the *System Control and Interrupts* chapter) for successive MCAN interrupts to be recognized.

The MCAN module is capable of issuing an ECC interrupt. After clearing the ECC interrupt source, the application software must also write a 1 to the EOI registers (MCANERR\_SEC\_EOI.EOI\_WR/MCANERR\_DED\_EOI.EOI\_WR). For more information, see [Section 35.5.12.2](#).

### 35.5.3 Operating Modes

The operating modes are discussed in the following sections.

#### 35.5.3.1 Software Initialization

A software initialization begins when the MCAN\_CCCR.INIT bit is set to 1. This is done either by software or by a hardware reset, when an uncorrected bit error is detected in the Message RAM, or by going to a Bus\_Off state. While the MCAN\_CCCR.INIT bit is set, the message transfer is stopped and the status of the output TX pin is recessive (high). The counters of the Error Management Logic (EML) are unchanged. Setting the MCAN\_CCCR.INIT bit does not change any configuration register. Resetting the MCAN\_CCCR.INIT bit finishes the software initialization. After waiting for the occurrence of a sequence of 11 consecutive recessive bits (indication for Bus\_Idle state) the message transfer starts.

Access to the MCAN configuration registers is only enabled when both MCAN\_CCCR.INIT and MCAN\_CCCR.CCE bits are set (write protection).

The MCAN\_CCCR.CCE bit can only be set/reset while the MCAN\_CCCR.INIT = 1. The MCAN\_CCCR.CCE bit is automatically reset when the MCAN\_CCCR.INIT bit is reset.

The following registers are reset when the MCAN\_CCCR.CCE bit is set:

- MCAN\_HPMS - High Priority Message Status
- MCAN\_RXF0S - Rx FIFO 0 Status
- MCAN\_RFX1S - Rx FIFO 1 Status
- MCAN\_TXFQS - Tx FIFO/Queue Status
- MCAN\_TXBRP - Tx Buffer Request Pending
- MCAN\_TXBTO - Tx Buffer Transmission Occurred
- MCAN\_TXBCF - Tx Buffer Cancellation Finished
- MCAN\_TXEFS - Tx Event FIFO Status

The Timeout Counter value MCAN\_TOCV.TOC field is preset to the value configured by the MCAN\_TOCC.TOP field when the MCAN\_CCCR.CCE bit is set.

In addition, the Tx Handler and Rx Handler are held in idle state while MCAN\_CCCR.CCE = 1.

The following registers are only writable while MCAN\_CCCR.CCE = 0

- MCAN\_TXBAR - Tx Buffer Add Request
- MCAN\_TXBCR - Tx Buffer Cancellation Request

MCAN\_CCCR.TEST and MCAN\_CCCR.MON bits can only be set by the Host CPU while MCAN\_CCCR.INIT = 1 and MCAN\_CCCR.CCE = 1. Both bits are reset at any time. The MCAN\_CCCR.DAR bit can only be set/reset while MCAN\_CCCR.INIT = 1 and MCAN\_CCCR.CCE = 1.

[Table 35-4](#) shows the steps to configure the MCAN module.

**Table 35-4. Steps to Configure MCAN Module**

Step	Operation	Description	Pseudo Code
1	Initialize MCAN_CCCR	Set MCAN_CCCR.INIT bit and check that the bit has been set	INIT = 1; If INIT ≠ 1, wait until set
2	Unlock protected registers	Set MCAN_CCCR.CCE bit	CCE = 1;
3	Configure CAN mode	Set MCAN_CCCR.FDOE bit to CAN FD	FDOE = 1 for CAN FD FDOE = 0 for Classic CAN
4	Configure Bit Rate Switching	Set MCAN_CCCR.BRSE bit	BRSE = 1 for bit rate switching BRSE = 0 for no bit rate switching
5	Set nominal bit timing <sup>(1)</sup>	Set MCAN_NBTP register	
6	Lock protected registers	Clear MCAN_CCCR.CCE bit	CCE = 0;

**Table 35-4. Steps to Configure MCAN Module (continued)**

Step	Operation	Description	Pseudo Code
7	Return MCAN module to normal operation	Clear MCAN_CCCR.INIT bit and check that the bit has been cleared	INIT = 0; If INIT ≠ 0, wait until cleared

(1) See the MCAN\_NBTP register on how to program CAN bit timing in the *MCAN\_REGS Registers* section.

**35.5.3.2 Normal Operation**

Once the MCAN module is initialized and the MCAN\_CCCR.INIT bit is reset to zero, the MCAN module synchronizes to the CAN bus and is ready for communication. After passing the acceptance filtering, received messages including Message Identifier (ID) and Data Length Code (DLC) are stored into a dedicated Rx Buffer or into Rx FIFO 0/Rx FIFO 1.

For messages to be transmitted, dedicated Tx buffers, and a Tx FIFO or a Tx queue can be initialized or updated.

**Note**

The automated transmission upon reception of remote frames is not supported.

**35.5.3.3 CAN FD Operation**

The CAN FD standard allows extended frames to be sent, up to 64 data bytes in a single frame at a higher bit rate for the data phase of a frame, up to 5Mbps. The CAN FD standard introduces the ability to switch from one bit rate to another. Extended Data Length (EDL), as shown in [Figure 35-5](#) and described in [Table 35-5](#), sets a data length of up to 8 or 64 data bytes. Bit Rate Switching (BRS) indicates whether two bit rates (the data phase is transmitted at a different bit rate compared to the arbitration phase) are enabled.

\* 17 bit CRC for data fields with up to 16 bytes

mcan-004a

**Figure 35-5. CAN FD Frame**

**Table 35-5. CAN FD Frame Description**

Bit	Description
SOF	Start of Frame
IDE	Identifier extension (for 29 bit extended ID)
FDF	Flexible Data Format
BRS	Bit Rate Switching
ESI	Error Status Indicator
DLC	Data Length Code
CRC	Cyclic Redundancy check

There are two variants of CAN FD frame transmission:

- CAN FD frame transmission without bit rate switching
- CAN FD frame transmission where control field, data field, and CRC field are transmitted with a higher bit rate than the beginning and the end of the frame

The previously reserved bit in CAN frames with 11-bit identifiers and the first previously reserved bit in CAN frames with 29-bit identifiers are now decoded as the FDF bit. In the CAN frames, FDF = recessive (logical 1) signifies a CAN FD frame, FDF = dominant (logical 0) signifies a Classic CAN frame. In a CAN FD frame, the two bits following FDF - res and BRS, decide whether the bit rate inside of this CAN FD frame is switched. A CAN FD bit rate switch is signified by res = dominant and BRS = recessive. Note that the coding of res = recessive is reserved for future expansion of the protocol. If the MCAN module receives a frame with FDF = recessive and res = recessive, the MCAN signals a Protocol Exception Event by setting the MCAN\_PSR.PXE bit. When Protocol Exception Handling is enabled (MCAN\_CCCR.PXHD = 0), this causes the operation state to change from Receiver (MCAN\_PSR.ACT = 10) to Integrating (MCAN\_PSR.ACT = 00) at the next sample point. In case Protocol Exception Handling is disabled (MCAN\_CCCR.PXHD = 1), the MCAN treats a recessive bit as an error and responds with an error frame.

CAN FD operation is enabled by programming the MCAN\_CCCR.FDOE bit. If MCAN\_CCCR.FDOE = 1, transmission and reception of CAN FD frames is enabled. Transmission and reception of Classic CAN frames is always possible. Whether a CAN FD frame or a Classic CAN frame is transmitted can be configured using the FDF bit in the respective Tx Buffer element.

With MCAN\_CCCR.FDOE = 0, received frames are interpreted as Classic CAN frames, which leads to the transmission of an error frame when receiving a CAN FD frame. When CAN FD operation is disabled, no CAN FD frames are transmitted even if the FDF bit of a Tx Buffer element is set. The MCAN\_CCCR.FDOE and MCAN\_CCCR.BRSE bits can only be changed while the MCAN\_CCCR.INIT and MCAN\_CCCR.CCE bits are both set. With MCAN\_CCCR.FDOE = 0, the setting of bits FDF and BRS is ignored and frames are transmitted in Classic CAN format.

With MCAN\_CCCR.FDOE = 1 and MCAN\_CCCR.BRSE = 0, only FDF bit of a Tx Buffer element is evaluated. With MCAN\_CCCR.FDOE = 1 and MCAN\_CCCR.BRSE = 1, transmission of CAN FD frames with bit rate switching is enabled. All Tx Buffer elements with bits FDF and BRS set are transmitted in CAN FD format with bit rate switching.

A mode change during CAN operation is only recommended under the following conditions:

- The failure rate in the CAN FD data phase is significantly higher than in the CAN FD arbitration phase. In this case, disable the CAN FD bit rate switching option for transmissions.
- During system startup, all nodes are transmitting Classic CAN messages until verified that the nodes are able to communicate in CAN FD format. If this is true, all nodes switch to CAN FD operation.
- Wakeup messages in CAN Partial Networking must be transmitted in Classic CAN format.
- End-of-line programming in case not all nodes are CAN FD capable. Non CAN FD nodes are held in Silent mode until programming has completed. Then all nodes switch back to Classic CAN communication.

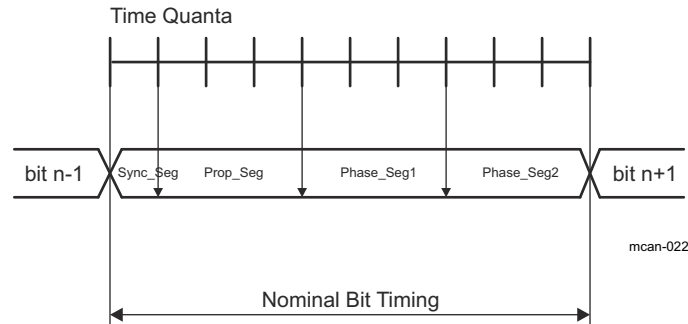

The coding of the DLC in the CAN FD format differs from the standard CAN format. The DLC codes 0 to 8 have the same coding as in standard CAN (0 to 8 data bytes), the codes 9 to 15, which in standard CAN all code a data field of 8 bytes, are coded according to [Table 35-6](#).

**Table 35-6. DLC Coding in CAN FD**

DLC	9	10	11	12	13	14	15
Number of Data Bytes	12	16	20	24	32	48	64

For CAN FD frames, the bit timing is switched inside the frame after the BRS (Bit Rate Switch) bit in case this bit is recessive. In the CAN FD arbitration phase, before the BRS bit, the nominal CAN bit timing (see [Figure 35-6](#)) is used as configured by the Nominal Bit Timing and Prescaler Register (MCAN\_NBTP). In the following CAN FD data phase, the data phase bit timing is used as configured by the Data Bit Timing and Prescaler Register

(MCAN\_DBTP). The bit timing is switched back from the data phase timing at the CRC delimiter or when an error is detected, whichever occurs first.

**Figure 35-6. CAN Bit Timing**

The maximum configurable data phase bit timing depends on the CAN clock frequency (MCAN\_FCLK).

Example: with MCAN\_FCLK = 20MHz and the shortest configurable bit time of 4  $t_q$  (time quanta), the bit rate in the data phase is 5Mbit/s.

In both data frame formats, CAN FD and CAN FD with bit rate switching, the value of the Error Status Indicator (ESI) bit depends on the transmitter error state (see MCAN\_PSR.RESI bit) monitored at the start of the transmission. If the transmitter has an error passive flag, the ESI bit is transmitted recessive; else, the ESI bit is transmitted dominant.

### 35.5.4 Transmitter Delay Compensation

#### 35.5.4.1 Description

When only one CAN FD node is transmitting and all other nodes are receivers, the length of the bus line has no impact. When transmitting using the TX pin, the MCAN module receives the transmitted data from the CAN transceiver using the RX pin. The received data is delayed. If the transmitter delay is greater than TSEG1 (time segment before sample point), a bit error is detected.

The MCAN module provides a delay compensation mechanism to compensate for the transmitter delay. The compensation mechanism enables transmission with higher bit rates during the CAN FD data phase independent of the delay of a specific CAN transceiver. Without transmitter delay compensation the bit rate in the data phase is limited by the transmitter delay.

The mechanism enables configurations where the data bit time is shorter than the transmitter delay (it is described in detail in ISO 11898-1:2015). The transmitter delay compensation is enabled by setting the MCAN\_DBTP.TDC bit to 1.

The delayed transmit data is compared against the received data at the Secondary Sample Point (SSP) to check for bit errors during the data phase of transmitting nodes. If a bit error is detected, the transmitter reacts on this bit error at the next following regular sample point. During the arbitration phase, the delay compensation is always disabled.

The received bit is compared against the transmitted bit at the SSP. The SSP position is defined as the sum of the measured delay from the MCAN's transmit output TX pin through the transceiver to the receive input RX pin plus the transmitter delay compensation offset configured by the MCAN\_TDCR.TDCO field (see [Figure 35-7](#)). The transmitter delay compensation offset is used to adjust the position of the SSP inside the received bit (example: half of the bit time in the data phase). The position of the SSP is rounded down to the next integer number of  $mtq$ .

The actual transmitter delay compensation value can be checked by reading the MCAN\_PSR.TDCV field. This field is cleared when the MCAN\_CCCR\_INIT bit is set and is updated at each transmission of CAN FD frame while the MCAN\_DBTP.TDC bit is set.

mcan-005

**Figure 35-7. Transmitter Delay Measurement**

### 35.5.4.2 Transmitter Delay Compensation Measurement

When transmitter delay compensation is enabled (by programming `MCAN_DBTP.TDC = 1`), the measurement is started within each transmitted CAN FD frame at the falling edge of FDF bit to bit r0. The measurement is stopped when this edge is seen at the receive input RX pin of the transmitter. The resolution of this measurement is one mtq (see [Figure 35-7](#)). The mtq (minimum time quantum) dimension is equal to the CAN clock period (`MCAN_FCLK`).

The use of a transmitter delay compensation filter window can be enabled by programming the `MCAN_TDCR.TDCF` field. This filter feature defines a minimum value for the SSP position to avoid the case in which a dominant glitch inside the received FDF bit ends the delay compensation measurement before the falling edge of the received res bit, resulting in an early taken SSP position. Dominant edges on the RX pin that result in an earlier SSP position are ignored for transmitter delay measurement. The measurement is stopped when the SSP position is at least `MCAN_TDCR.TDCF` field and the RX pin is low.

The following boundary conditions must be considered:

- The sum of the measured delay from the TX pin to the RX pin and the configured transmitter delay compensation offset (`MCAN_TDCR.TDCO` field) is less than 6 bit-times in the data phase.
- The sum of the measured delay from the TX pin to the RX pin and the configured transmitter delay compensation offset (`MCAN_TDCR.TDCO`) field is less than or equal to 127 mtq. In case this sum exceeds 127 mtq, the maximum value of 127 mtq is used for transmitter delay compensation.
- The data phase ends at the sample point of the CRC delimiter, that stops checking of receive bits at the SSPs.

### 35.5.5 Restricted Operation Mode

In restricted operation mode, the CAN node is able to receive data and remote frames and to give acknowledgment to valid frames, but the node does not send data frames, remote frames, active error frames, or overload frames. In case of an error condition or overload condition, the node does not send dominant bits; instead the node waits for the occurrence of bus idle condition to resynchronize to the CAN communication. The receive and transmit error counters (MCAN\_ECR.REC and MCAN\_ECR.TEC) are frozen while CAN error logging (MCAN\_ECR.CEL) is active. The Host CPU can set the MCAN module into Restricted Operation Mode by setting the MCAN\_CCCR.ASM bit. The bit can only be set by the Host CPU at any time when both MCAN\_CCCR.CCE and MCAN\_CCCR.INIT bits are set to 1.

The restricted operation mode is automatically entered when the Tx Handler is not able to read data from the Message RAM in time. To leave restricted operation mode, the Host CPU has to reset the MCAN\_CCCR.ASM bit. This mode can be used in applications that adapt themselves to different CAN bit rates. In this case, the application tests different bit rates and leaves the restricted operation mode after the node has received a valid frame.

#### Note

The Restricted Operation Mode must not be combined with the Loop Back Mode.

### 35.5.6 Bus Monitoring Mode

Entering bus monitoring mode is done by setting the MCAN\_CCCR.MON bit to 1. In this mode (see ISO 11898-1:2015, *Bus Monitoring* section), the MCAN module is able to receive valid data and remote frames, but cannot start a transmission. The MCAN module sends only recessive bits on the CAN bus. If the MCAN module is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the MCAN module monitors this dominant bit, although the CAN bus can remain in recessive state. In bus monitoring mode, the MCAN\_TXBRP register is held in reset state. The bus monitoring mode can be used to analyze the traffic on a CAN bus without affecting the bus by the transmission of dominant bits. [Figure 35-8](#) shows the connection of the TX and RX signals to the MCAN module in bus monitoring mode.

Figure 35-8. Connection of Signals in Bus Monitoring Mode

### 35.5.7 Disabled Automatic Retransmission (DAR) Mode

According to the CAN Specification (see ISO11898-1:2015, *Recovery Management* section), the MCAN module provides means for automatic retransmission of frames that have lost arbitration or that have been disturbed by errors during transmission. By default automatic retransmission is enabled (see the MCAN\_CCCR.DAR bit).

#### 35.5.7.1 Frame Transmission in DAR Mode

In DAR mode, the automatic retransmission of frames that have lost arbitration or that have been disturbed by errors during transmission is disabled. A Tx buffer's Tx Request Pending (MCAN\_TXBRP[xx]) TRPx bit is reset after successful transmission, when a transmission has not yet been started at the point of cancellation, has been aborted due to lost arbitration, or when an error occurred during frame transmission.

Successful transmission:

- Corresponding Tx Buffer Transmission Occurred (MCAN\_TXBTO[xx]) TOx bit is set
- Corresponding Tx Buffer Cancellation Finished (MCAN\_TXBCF[xx]) CFx bit is not set

Successful transmission in spite of cancellation:

- Corresponding Tx Buffer Transmission Occurred (MCAN\_TXBTO[xx]) TOx bit is set
- Corresponding Tx Buffer Cancellation Finished (MCAN\_TXBCF[xx]) CFx bit is set

Arbitration lost or frame transmission disturbed:

- Corresponding Tx Buffer Transmission Occurred (MCAN\_TXBTO[xx]) TOx bit is not set
- Corresponding Tx Buffer Cancellation Finished (MCAN\_TXBCF[xx]) CFx bit is set

In the case of a successful frame transmission, and if storage of Tx events is enabled, a Tx Event FIFO element is written with Event Type ET = 10 (transmission in spite of cancellation).

### 35.5.8 Clock Stop Mode

Entering clock stop mode is controlled by the input clock stop request signal or MCAN\_CCCR.CSR bit. As long as the clock stop request signal is active, the MCAN\_CCCR.CSR bit is read as 1. When all pending transmission requests have completed, the MCAN module waits until bus idle state is detected. Then the MCAN module sets the MCAN\_CCCR.INIT to 1 to prevent any further CAN transfers. The MCAN module acknowledges that the module is ready for power down by setting the output clock stop acknowledge signal to 1 and the MCAN\_CCCR.CSA bit to 1. In this state, before the clocks are switched off, further register accesses can be made. A write access to the MCAN\_CCCR.INIT bit has no effect. Now the module clock inputs MCAN\_ICLK and MCAN\_FCLK can be switched off.

To leave power-down mode, the application has to turn on the module clocks before resetting the input clock stop request signal respectively the MCAN\_CCCR.CSR flag bit. The MCAN acknowledges this by resetting the output clock stop acknowledge signal respectively the MCAN\_CCCR.CSA flag bit. Afterwards, the application can restart CAN communication by resetting the MCAN\_CCCR.INIT bit.

Restoring the clocks from clock stop mode needs to be done according to how the clock stop was initiated.

The MCAN module supports two external clock stop modes:

- Immediate
- Graceful

In a graceful clock stop mode when the clock stop request is asserted, the MCAN core responds with a clock stop acknowledge when all pending Tx messages have been processed and an Idle line had been detected. The MCAN\_CCCR.INIT bit is set, the MCAN core goes and stays Idle.

The automatic wakeup feature is enabled by setting the MCANSS\_CTRL.AUTOWAKEUP and MCANSS\_CTRL.WAKEUPREQEN bits to 1 (for more information, see [Section 35.5.8.2](#)). When an external clock stop request is removed and no suspend request is active, a read-modify-write to the MCAN\_CCCR.INIT bit is performed to clear the bit.

### 35.5.8.1 Suspend Mode

The MCAN module supports two suspend modes:

- Immediate
- Graceful

In a graceful suspend mode (see the MCANSS\_CTRL.DBGSUSP\_FREE bit) when the suspend request is asserted, a clock stop request to the MCAN core is performed. The MCAN core responds with a clock stop acknowledge when all pending Tx messages have been processed and an Idle line had been detected. At that point, the MCAN\_CCCR.INIT bit is set and the MCAN core stays Idle. The suspend state can be verified by reading the MCAN\_CCCR.INIT bit.

The automatic wakeup feature is enabled by setting the MCANSS\_CTRL.AUTOWAKEUP and MCANSS\_CTRL.WAKEUPREQEN bits to 1 (for more information, see [Section 35.5.8.2](#)). When suspend request is removed, if no external clock stop request is active, a read-modify-write to the MCAN\_CCCR.INIT bit is performed to clear the bit.

During suspend mode the auto-clear feature is disabled. The following register fields have an auto-clear feature:

- MCAN\_ECR.CEL
- MCAN\_PSR.LEC
- MCAN\_PSR.DLEC
- MCAN\_PSR.RESI
- MCAN\_PSR.RBRS
- MCAN\_PSR.RFDF
- MCAN\_PSR.PXE

### 35.5.8.2 Wakeup Request

Issuing a clock stop request puts the MCAN module into power-down mode (Sleep Mode). During transition from IDLE to ACTIVE, if the MCANSS\_CTRL.AUTOWAKEUP and MCANSS\_CTRL.WAKEUPREQEN bits are enabled, after the MCAN Core responds to the removal of the clock stop request with removing the clock stop acknowledge, a read-modify-write is issued to clear the MCAN\_CCCR.INIT bit and the MCAN core resumes operation.

If the MCANSS\_CTRL.WAKEUPREQEN bit is set, the MCAN module provides a wakeup request on the following wakeup event:

- The receive RX pin is dominant (logical 0)

The wakeup request is deasserted when any of the following conditions occur:

- Clock stop request is removed and clock stop acknowledge is deasserted
- A reset is applied to the MCAN module

**Figure 35-9. Auto Wakeup Enabled Exit from Power Down**

### 35.5.9 Test Modes

The MCAN\_TEST register write access is enabled by setting the test mode enable MCAN\_CCCR.TEST bit to 1. The MCAN\_TEST register allows the configuration of the test modes and test functions.

The transmit (TX) pin has four different output functions which can be selected by programming the MCAN\_TEST.TX field. The default function is the serial data output. The pin can also be driven with a constant dominant or recessive value. It is also possible to drive the sample-point signal to monitor the bit-timing.

The actual value of the receive (RX) pin can be monitored from MCAN\_TEST.RX bit. Both functions can be used to check the physical layer. Due to the synchronization mechanism between the CAN clock (MCANx\_FCLK) and Host clock (MCANx\_ICLK) domain, there can be a delay of several Host clock periods between writing to the MCAN\_TEST.TX field until the new configuration is visible at the output TX pin. This applies also when reading input RX pin by way of the MCAN\_TEST.RX bit.

#### Note

Test modes can be used for self-test only. The software control for TX pin interferes with all CAN protocol functions. It is not recommended to use test modes for an application.

#### 35.5.9.1 External Loop Back Mode

The MCAN module can be set into external loop back mode by programming MCAN\_TEST.LBCK to 1. In loop back mode, the MCAN treats the transmitted messages as received messages and stores the messages (if the messages pass acceptance filtering) into an Rx Buffer or an Rx FIFO. [Figure 35-10](#) shows the connection of the TX and RX pins to the MCAN module in external loop back mode.

This mode is provided for hardware self-test. To be independent from external stimulation, the MCAN module ignores acknowledge errors (recessive bit sampled in the acknowledge slot of a data/remote frame) in loop back mode. In this mode, the MCAN module performs an internal feedback from the Tx output to the Rx input. The actual value of the RX input pin is disregarded by the MCAN module. The transmitted messages are monitored at the TX pin.

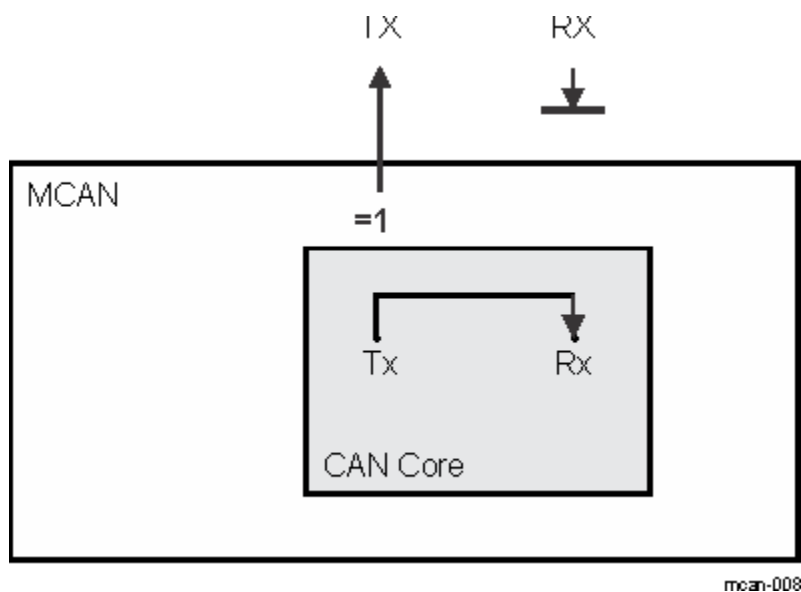

Figure 35-10. External Loop Back Mode

### 35.5.9.2 Internal Loop Back Mode

The MCAN module can be set into internal loop back mode by programming MCAN\_TEST.LBCK and MCAN\_CCCR.MON bits to 1. The internal loop back mode is used for a Hot Self-test. The Hot Self-test allows the MCAN module to be tested without affecting a running CAN system connected to the TX and RX pins. In this mode, the RX pin is disconnected from the MCAN module and the TX pin is held recessive. Figure 35-11 shows the connection of the TX and RX pins to the MCAN module in internal loop back mode.

**Figure 35-11. Internal Loop Back Mode**

### 35.5.10 Timestamp Generation

The MCAN module has integrated a 16-bit wrap-around counter for timestamp generation. The timestamp counter prescaler MCAN\_TSCC.TCP field can be configured to clock the counter in multiples of CAN bit times (1-16). The counter is readable by way of the MCAN\_TSCV.TSC field. A write access to the MCAN\_TSCV register resets the counter to zero. When the timestamp counter wraps around the interrupt MCAN\_IR.TSW flag is set. On start of a frame reception/transmission the counter value is captured and stored into the timestamp section of an Rx Buffer/Rx FIFO (RXTS[15:0]) or Tx Event FIFO (TXTS[15:0]) element. For more information, see [Section 35.5.16](#).

### 35.5.10.1 External Timestamp Counter

For CAN FD operation mode, the MCAN core requires an external timestamp counter (see Figure 35-12). An externally generated 16-bit vector can substitute the integrated 16-bit CAN bit time counter (internal timestamp counter) for receive and transmit timestamp generation. An external 16-bit timestamp counter can be used by programming the MCAN\_TSCC.TSS field.

The external timestamp counter uses the interface clock (MCANx\_ICLK) as a reference clock. The MCAN core accepts a 16-bit timestamp. A 24-bit prescaler provides a programmable resolution for the timestamp (see MCANSS\_EXT\_TS\_PRESCALER.PRESCALER bit field). The external timestamp counter can be enabled or disabled through the MCANSS\_CTRL.EXT\_TS\_CNTR\_EN bit. When disabled, the counter is reset back to zero. While enabled, the counter keeps incrementing. When the timestamp rolls over, the MCAN\_IRQ\_TS interrupt is generated.

When the timestamp rolls over, the MCANSS\_IRS register is set. The MCANSS\_IE register can be affected by writing to the MCANSS\_IESS register to set or to the MCANSS\_IECS register to clear. The MCANSS\_IESS register is a shadow register mapped to the same address as the MCANSS\_IE register. The level interrupt is a reflection of both MCANSS\_IRS and MCANSS\_IE being set. The MCANSS\_IES register reflects the level interrupt. When a rollover event occurs, the interrupt counter is incremented. Writing to the MCANSS\_ICS register to clear the MCANSS\_IRS register also decrements the interrupt counter. Writing to the MCANSS\_EOI register issues another pulse, if the interrupt counter is not zero.

The rollover event can be artificially simulated by software through writing to the Interrupt Set Shadow register (MCANSS\_ISS). The MCANSS\_ISS register is a shadow register mapped to the same address as the MCANSS\_IRS register.

mcan-021

Figure 35-12. External Timestamp Counter Interrupt

### 35.5.11 Timeout Counter

The MCAN module has an integrated 16-bit timeout counter. The timeout counter is used to signal timeout conditions for the Rx FIFO 0, Rx FIFO 1, and Tx Event FIFO Message RAM elements. The timeout counter is configured using the MCAN\_TOCC register and is enabled using the MCAN\_TOCC.ETOC bit. The timeout counter operates as down-counter and uses the same prescaler programmed by the MCAN\_TSCC.TCP field as the timestamp counter. The actual counter value can be monitored from the MCAN\_TOCV.TOC field. The timeout counter can be started only when MCAN\_CCCR.INIT = 0 and stopped when MCAN\_CCCR.INIT = 1 (example: when the MCAN enters Bus\_Off state). The operation mode is selected by the MCAN\_TOCC.TOS field. When continuous mode is selected, the counter starts when MCAN\_CCCR.INIT = 0, a write to the MCAN\_TOCV register presets the counter to the value configured by the MCAN\_TOCC.TOP field and continues down-counting.

In case the timeout counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by the MCAN\_TOCC.TOP field. Down-counting is started when the first FIFO element is stored. Writing to the MCAN\_TOCV register has no effect. When the counter reaches zero, the interrupt MCAN\_IR.TOO flag is set.

In continuous mode, the counter is immediately restarted at the value configured by the MCAN\_TOCC.TOP field.

---

#### Note

The clock signal for the timeout counter is derived from the CAN core sample point signal. Therefore, the point in time where the timeout counter is decremented can vary due to the synchronization/re-synchronization mechanism of the CAN core. If the baud rate switch feature in CAN FD is used, the timeout counter is clocked differently in arbitration and data field.

---

### 35.5.12 Safety

The Message Memory is wrapped in an ECC wrapper providing SECDED parity functionality. The ECC wrapper is controlled by an ECC aggregator.

#### 35.5.12.1 ECC Wrapper

The ECC wrapper provides single error correction (SEC) and double error detection (DED) parity to the message memory content. The ECC wrapper has side band signals for error notification. The ECC Wrapper implements an error injection test mode.

The error correction is done using a lazy write back. When an error is detected, the error is noted in a FIFO queue that waits for an access gap to write the data back and refresh the memory. If a transaction writes new data to the compromised entry before the lazy write back completes, the write back is discarded.

#### 35.5.12.2 ECC Aggregator

This section describes the functional details of the ECC aggregator module.

##### 35.5.12.2.1 ECC Aggregator Overview

The ECC aggregator module supports the following general features:

- Provides a mechanism to control and monitor the ECC RAM in the MCAN module.
- Provides software access to all the ECC related registers.
- Supports software readable status of ECC single/double-bit errors and associated info such as RAM address and data bits that are in error.
- Aggregates level pending status from the ECC RAM into a single interrupt to the Host CPU.

The following feature is not supported:

- Statistics such as tracking the number of single and double-bit errors. If needed, these operations can be handled by software.

### 35.5.12.2.2 ECC Aggregator Registers

There are three groups of registers in the ECC aggregator module:

- **Global registers:** Aggregator Revision Register (MCANERR\_REV), ECC Vector Register (MCANERR\_VECTOR), Misc Status Register (MCANERR\_STAT), ECC Control Register (MCANERR\_CTRL), and ECC Wrapper Revision Register (MCANERR\_WRAP\_REV).
- **Control and status registers:** ECC Error Control Registers (MCANERR\_ERR\_CTRL1 and MCANERR\_ERR\_CTRL2) and ECC Error Status Registers (MCANERR\_ERR\_STAT1, MCANERR\_ERR\_STAT2, and MCANERR\_ERR\_STAT3).
- **Interrupt registers:** interrupt status, interrupt enable set, interrupt enable clear, and EOI (End Of Interrupt) registers that are part of a standard interrupt module. For more information, see the following registers:
  - MCANERR\_SEC\_EOI
  - MCANERR\_SEC\_STATUS
  - MCANERR\_SEC\_ENABLE\_SET
  - MCANERR\_SEC\_ENABLE\_CLR
  - MCANERR\_DED\_EOI
  - MCANERR\_DED\_STATUS
  - MCANERR\_DED\_ENABLE\_SET
  - MCANERR\_DED\_ENABLE\_CLR

### 35.5.12.3 Reads to ECC Control and Status Registers

The reads to the ECC control and status registers are triggered by writing a 'read message' to the ECC Vector Register as:

- Software writes value (the ECC RAM ID) to the MCANERR\_VECTOR.ECC\_VECTOR field to select the ECC RAM for control or status.
- Software writes 1 to the MCANERR\_VECTOR.RD\_SVBUS bit to trigger a read.
- Software writes read address to the MCANERR\_VECTOR.RD\_SVBUS\_ADDRESS field.
- Software then polls the MCANERR\_VECTOR.RD\_SVBUS\_DONE bit to check if the bit is 1. This bit indicates that the read operation has completed.
- Software reads the data from the ECC control or status register. The following clock cycle (MCAN\_ICLK) returns the read data.

### 35.5.12.4 ECC Interrupts

The ECC aggregator module aggregates the level pending status from the ECC RAM into a single EOI-handshake based interrupt to the Host CPU. Software is expected to follow the sequence described:

- Software enables the interrupts for the ECC RAM by writing to the MCANERR\_SEC\_ENABLE\_SET/MCANERR\_DED\_ENABLE\_SET register.
- Software writes the ECC RAM ID in the MCANERR\_VECTOR.ECC\_VECTOR.
- Software writes the MCANERR\_VECTOR.RD\_SVBUS bit to trigger the read.
- Software writes the MCANERR\_ERR\_STAT1 register address to the MCANERR\_VECTOR.RD\_SVBUS\_ADDRESS field. Software needs to load the 'read message' in the rMCANERR\_VECTOR register again, if the software needs to read the MCANERR\_ERR\_STAT2 register.
- Software polls the MCANERR\_VECTOR.RD\_SVBUS\_DONE bit. When this bit is set, a read of the MCANERR\_ERR\_STAT1/MCANERR\_ERR\_STAT2 register is performed.
- After the interrupt has been serviced, software clears the interrupt status by writing to the MCANERR\_ERR\_STAT1.CLR\_ECC\_SEC or MCANERR\_ERR\_STAT1.CLR\_ECC\_DED bit depending on the type of the ECC error.
- Software polls the MCANERR\_ERR\_STAT1 register to verify that the status bit has been cleared.
- Software writes to the MCANERR\_SEC\_EOI/MCANERR\_DED\_EOI register to clear the interrupt.
- After clearing the ECC interrupt source, the application software must also write 1 to the MCANERR\_SEC\_EOI.EOI\_WR/MCANERR\_DED\_EOI.EOI\_WR bits.

### 35.5.13 Rx Handling

The Rx Handler controls the following operations:

- Acceptance filtering
- The transfer of received messages to the Rx buffers or to one of the two Rx FIFOs (Rx FIFO 0 or Rx FIFO 1)
- Rx FIFO Put and Get Index operations

#### 35.5.13.1 Acceptance Filtering

The MCAN module employs two sets of acceptance filters - one set for standard and one set for extended identifiers. These filters can be assigned to an Rx Buffer or to one of the two Rx FIFOs.

The main features of the filter elements are:

- Each filter element can be configured as:
  - Range filter (from - to)
  - Filter for specific IDs (for one or two dedicated IDs)
  - Classic bit mask filter
- Each filter element can be enabled/disabled individually
- Each filter element can be configured for acceptance or rejection filtering
- Filters are checked sequentially and execution (acceptance filtering procedure) stops at the first matching filter element or when the end of the filter list is reached

Related configuration registers are:

- Global Filter Configuration (MCAN\_GFC) register
- Standard ID Filter Configuration (MCAN\_SIDFC) register
- Extended ID Filter Configuration (MCAN\_XIDFC) register
- Extended ID AND Mask (MCAN\_XIDAM) register

Depending on the configuration of the filter element (see SFEC/EFEC in [Section 35.5.16](#)) if filter matches, one of the following actions is performed:

- Received frame is stored in FIFO 0 or FIFO 1
- Received frame is stored in Rx Buffer
- Received frame is stored in Rx Buffer and generation of pulse at filter event pin is performed. This is high level single MCAN\_ICLK pulse.
- Received frame is rejected
- Set High Priority Message interrupt flag MCAN\_IR.HPM
- Set High Priority Message interrupt flag MCAN\_IR.HPM and store received frame in FIFO 0 or FIFO 1

Acceptance filtering starts when complete Message ID is received. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If a filter element matches - the Rx Handler starts writing the received message data in portions of 32-bit to the matching Rx Buffer or Rx FIFO. If an error condition occurs (for example: CRC error), this message is rejected with the following impact on the affected Rx Buffer or Rx FIFO:

- Rx Buffer: New Data flag (MCAN\_NDAT1/MCAN\_NDAT2) of matching Rx Buffer is not set, but Rx Buffer (partly) overwritten with received data (for error type, see MCAN\_PSR.LEC and MCAN\_PSR.DLEC fields, respectively).
- Rx FIFO: Put index of matching Rx FIFO is not updated, but related Rx FIFO element (partly) overwritten with received data (for error type, see MCAN\_PSR.LEC and MCAN\_PSR.DLEC fields, respectively). If matching Rx FIFO is configured to operate in overwrite mode, the boundary conditions described in [Section 35.5.13.2.2](#) must be considered.

---

#### Note

When an accepted message is written to one of the two Rx FIFOs, or into an Rx Buffer, the unmodified received identifier is stored independent of the filters used. The result of the acceptance filter process is strongly depending on the sequence of configured filter elements.

---

### 35.5.13.1.1 Range Filter

Each filter element can be configured to operate as Range Filter (Standard Filter Type SFT = 00/Extended Filter Type EFT = 00). The filter matches for all received message frames with IDs in the range from SFID1 to SFID2 (SFID2 ≥ SFID1) respectively in the range from EFID1 to EFID2 (EFID2 ≥ EFID1). For more information see [Section 35.5.16.5](#) and [Section 35.5.16.6](#).

There are two options for range filtering of extended frames:

- Extended Filter Type EFT = 00: The Extended ID AND Mask (MCAN\_XIDAM) is used for Range Filtering. The Message ID of received frames is ANDed with the Extended ID AND Mask (MCAN\_XIDAM) before the range filter is applied.
- Extended Filter Type EFT = 11: The Extended ID AND Mask (MCAN\_XIDAM) is not used for Range Filtering.

### 35.5.13.1.2 Filter for Specific IDs

Each filter element can be configured to filter one or two dedicated Message IDs (Standard Filter Type SFT = 01/Extended Filter Type EFT = 01). To filter only one specific Message ID, the filter element has to be configured with SFID1 = SFID2 respectively EFID1 = EFID2. For more information, see [Section 35.5.16.5](#) and [Section 35.5.16.6](#).

### 35.5.13.1.3 Classic Bit Mask Filter

Classic bit mask filtering can filter groups of Message IDs (Standard Filter Type SFT = 10/Extended Filter Type EFT = 10). This is done by masking single bits of a received Message ID. In this case SFID1/EFID1 element is used as Message ID filter, while the SFID2/EFID2 element is used as filter mask.

A 0 bit at the filter mask (SFID2/EFID2) masks out the corresponding bit position of the configured Message ID filter (SFID1/EFID1) and the value of the received Message ID at that bit position is not relevant for acceptance filtering. Only those bits of the received Message ID where the corresponding mask bits are 1 are relevant for acceptance filtering.

There are two interesting cases:

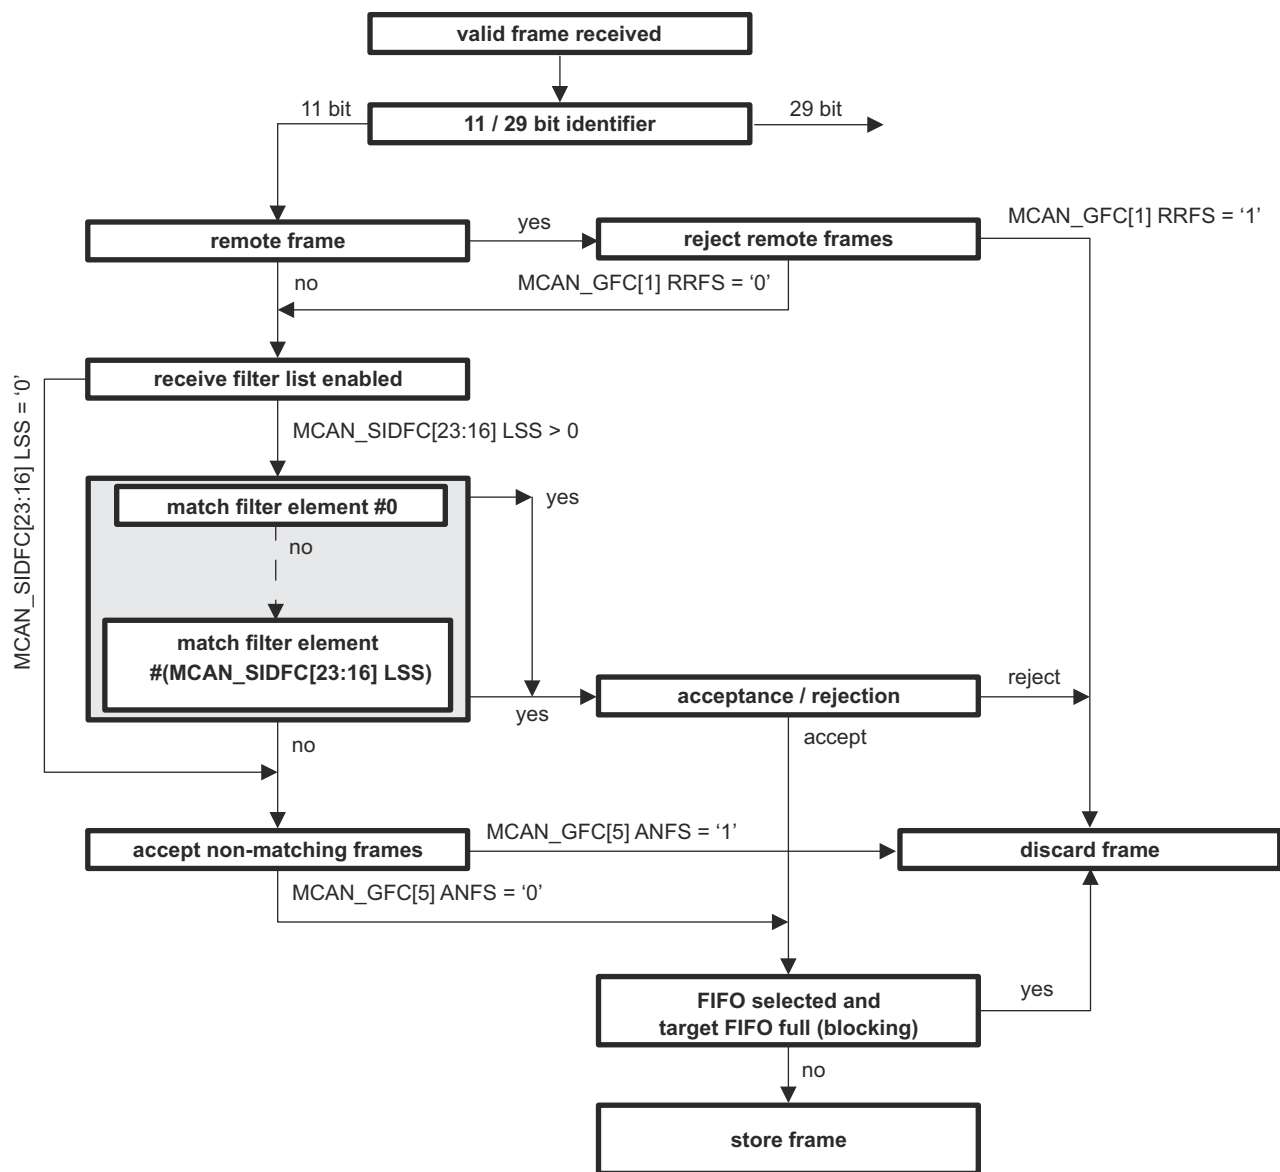

- All mask bits are 1: a match occurs only when the received Message ID and the configured Message ID filter are identical.
- All mask bits are 0: all Message IDs match.

35.5.13.1.4 Standard Message ID Filtering

Figure 35-13 shows the standard Message ID (11-bit ID) filtering flow. Section 35.5.16.5 describes the standard Message ID filter element.

The Remote Transmission Request (RTR) and Extended Identifier (XTD) bits of the received frames are compared against the list of configured filter elements. This is controlled by the following registers:

- Global Filter Configuration (MCAN\_GFC) register
- Standard ID Filter Configuration (MCAN\_SIDFC) register

mcan-009

Figure 35-13. Standard Message ID Filter Path

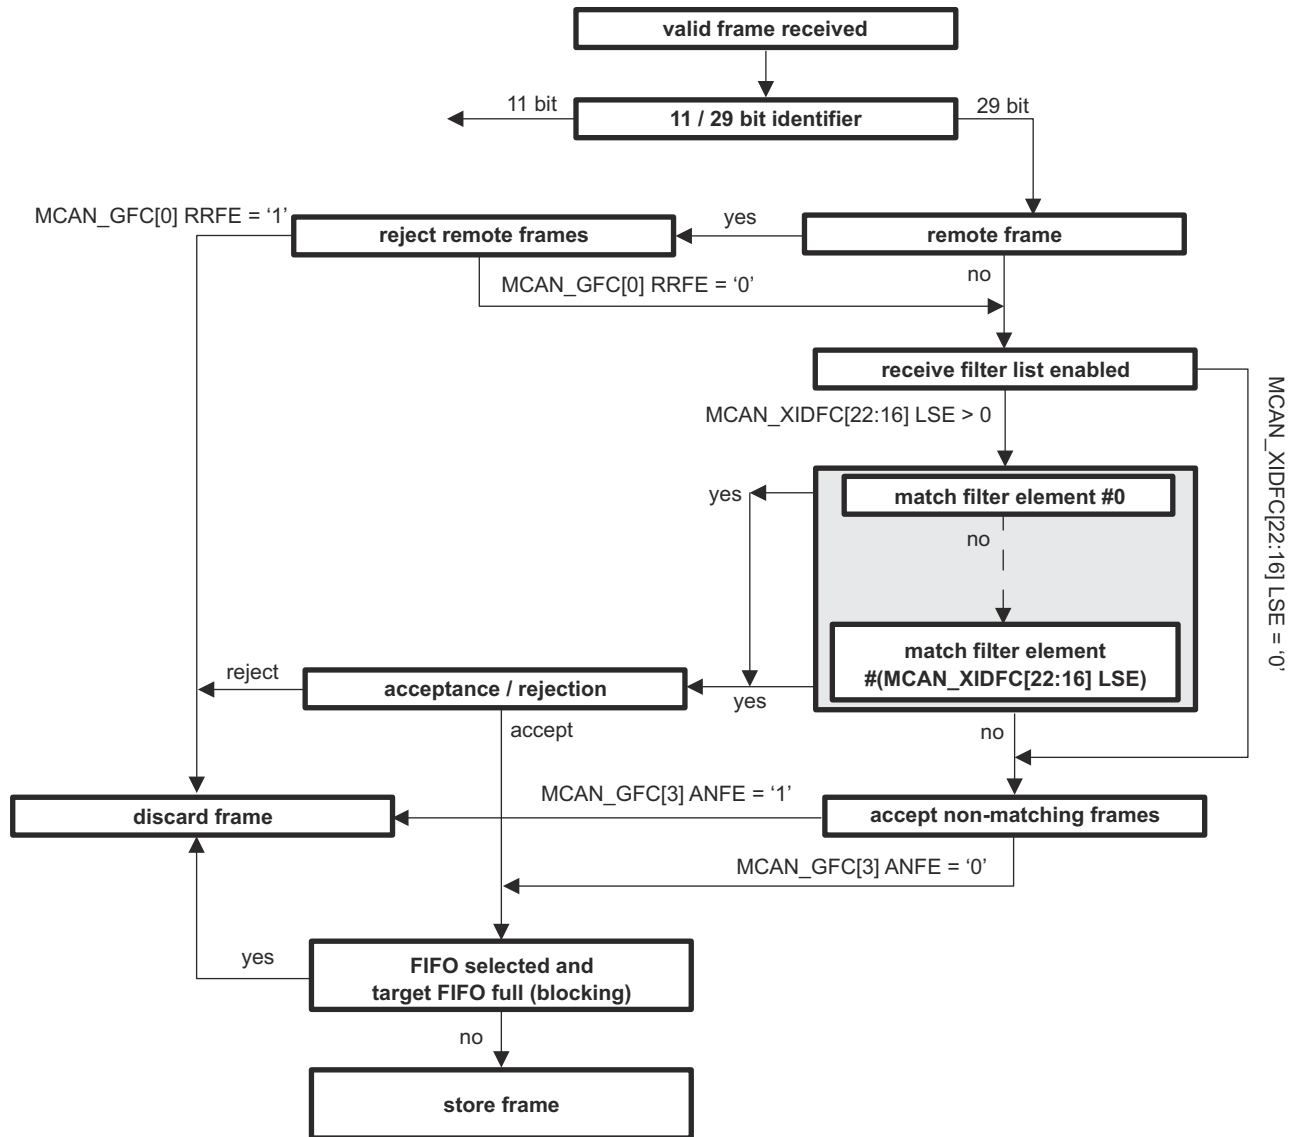

35.5.13.1.5 Extended Message ID Filtering

Figure 35-14 shows the extended Message ID (29-bit ID) filtering flow. Section 35.5.16.6 describes the extended Message ID filter element.

The Remote Transmission Request (RTR) and Extended Identifier (XTD) bits of the received frames are compared against the list of configured filter elements. This is controlled by the following registers:

- Global Filter Configuration (MCAN\_GFC) register
- Extended ID Filter Configuration (MCAN\_XIDFC) register

Note that before the filter list is executed, the received identifier is ANDed with the Extended ID AND Mask (MCAN\_XIDAM).

mcan-010

Figure 35-14. Extended Message ID Filter Path

### 35.5.13.2 Rx FIFOs

The configuration of the Rx FIFOs (Rx FIFO 0 and Rx FIFO 1) can be done by way of the MCAN\_RXF0C and MCAN\_RXF1C registers. Each Rx FIFO can be configured to store up to 64 received messages.

After acceptance filtering the received messages that passed are transferred to the Rx FIFO. The filter mechanisms available for the Rx FIFO 0 and Rx FIFO 1 are described in [Section 35.5.13.1](#). The Rx FIFO element is described in [Section 35.5.16.2](#).

The Rx FIFO watermark can be used to prevent an Rx FIFO overflow. If the Rx FIFO fill level reaches the Rx FIFO watermark configured by the MCAN\_RXFnC[30:24].FnWM bit (where: n = 0 or 1), an interrupt flag MCAN\_IR.RF0W/MCAN\_IR.RF1W is set.

When the Rx FIFO Put Index reaches the Rx FIFO Get Index (MCAN\_RXFnS[21:16].FnPI = MCAN\_RXFnS[13:8].FnGI), an Rx FIFO Full condition is signaled by the MCAN\_RXFnS[24].FnF status bit and interrupt flag MCAN\_IR.RF0F/MCAN\_IR.RF1F is set. [Figure 35-15](#) shows Rx FIFO Status. The FIFOs fill level is presented in the MCAN\_RXFnS[6:0].FnFL field (the number of elements stored in Rx FIFO).

mcan-011

**Figure 35-15. Rx FIFO Status**

Rx FIFOs start address in the Message RAM (MCAN\_RXFnC[15:2].FnSA field) has to be configured when reading from an Rx FIFO (Rx FIFO Get Index - MCAN\_RXFnS[13:8].FnGI). [Table 35-7](#) presents Rx Buffer/Rx FIFO Element Size for different Rx Buffer/Rx FIFO Data Field Size which is configured by way of the MCAN\_RXESC register.

**Table 35-7. Rx Buffer/Rx FIFO Element Size**

MCAN_RXESC Register RBDS/F0DS/F1DS Bits	Data Field [bytes]	FIFO Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

### 35.5.13.2.1 Rx FIFO Blocking Mode

The Rx FIFO blocking mode is the default operation mode for the Rx FIFOs and is configured by  $MCAN\_RXFnC[31].FnOM = 0$ .

If an Rx FIFO full condition is reached ( $MCAN\_RXFnS[21:16].FnPI = MCAN\_RXFnS[13:8].FnGI$ ), no further messages are written to the corresponding Rx FIFO until at least one message has been read out and the Rx FIFO Get Index has been incremented. An Rx FIFO full condition is signaled by the  $MCAN\_RXFnS[24].FnF = 1$  and interrupt flag  $MCAN\_IR.RF0F/MCAN\_IR.RF1F$  is set.

In case a message is received while the corresponding Rx FIFO is full, this message is rejected and the message lost condition is signaled by  $MCAN\_RXFnS[25].RFnL = 1$  and interrupt flag  $MCAN\_IR.RF0L/MCAN\_IR.RF1L$  is set.

### 35.5.13.2.2 Rx FIFO Overwrite Mode

The Rx FIFO overwrite mode is configured by  $MCAN\_RXFnC[31].FnOM = 1$ . When an Rx FIFO full condition is reached ( $MCAN\_RXFnS[21:16].FnPI = MCAN\_RXFnS[13:8].FnGI$ ) signaled by  $MCAN\_RXFnS[24].FnF = 1$ , the next accepted message for the FIFO overwrites the oldest FIFO message. Put index/Get index are both incremented by one.

In overwrite mode if an Rx FIFO full condition is signaled, reading of the Rx FIFO elements starts at least at get index + 1. The reason for this is a received message is written to the Message RAM (Put index) while the Host CPU is reading from the Message RAM (Get index). In this case, inconsistent data can be read from the respective Rx FIFO element. The problem is solved by adding an offset to the Get index when reading from the Rx FIFO. The offset depends on how fast the Host CPU accesses the Rx FIFO. Figure 35-16 shows an offset of two with respect to the Get index when reading the Rx FIFO. In this case, the two messages stored in element 1 and 2 are lost.

After reading from the Rx FIFO, the number of the last element read has to be written to the Rx FIFO Acknowledge Index  $MCAN\_RXFnA[5:0].FnAI$ . This increments the get index to that element number. In case the Put index has not been incremented to this Rx FIFO element, the Rx FIFO full condition is reset ( $MCAN\_RXFnS[24].FnF = 0$ ).

Figure 35-16. Rx FIFO Overflow Handling

### 35.5.13.3 Dedicated Rx Buffers

The MCAN supports up to 64 dedicated Rx buffers. The start address of the Rx buffers section in the Message RAM is configured by way of the MCAN\_RXBC.RBSA field. To store in an Rx Buffer a Standard or Extended Message ID Filter Element with SFEC/EFEC = 111 and SFID2/EFID2[10:9] = 00 has to be configured (see [Section 35.5.16.5](#) and [Section 35.5.16.6](#)).

After a received message has been accepted by a filter element, the message is stored into the Rx Buffer in the Message RAM referenced by the filter element (the format is the same as for an Rx FIFO element). In addition, the flag MCAN\_IR.DRX (message stored in Dedicated Rx Buffer) is set.

[Table 35-8](#) shows an example filter configuration for Rx buffers.

**Table 35-8. Example Filter Configuration for Rx Buffers**

Filter Element	SFID1[10:0] EFID1[28:0]	SFID2[10:9] EFID2[10:9]	SFID2[5:0] EFID2[5:0]
0	ID message 1	00	00 0000
1	ID message 2	00	00 0001
2	ID message 3	00	00 0010

After the last word of a matching received message has been written to the Message RAM, the respective New Data flag in register MCAN\_NDAT1/MCAN\_NDAT1 is set. As long as the New Data flag is set, the respective Rx Buffer is locked against updates from received matching frames. The New Data flags must be reset by the Host CPU by writing a 1 to the respective bit position.

While an Rx buffer New Data flag is set, a Message ID Filter Element referencing this specific Rx Buffer does not match, causing the acceptance filtering to continue. Following Message ID Filter Elements can cause the received message to be stored into another Rx Buffer, into an Rx FIFO, or the message can be rejected, depending on filter configuration.

#### 35.5.13.3.1 Rx Buffer Handling

Rx Buffer Handling include the following steps:

- Reset interrupt flag MCAN\_IR.DRX
- Read New Data registers
- Read messages from Message RAM
- Reset New Data flags of processed messages

### 35.5.14 Tx Handling

The Tx handler is used to handle the Tx requests. The Tx handler controls the transfer of transmit messages from the dedicated Tx buffers, the Tx FIFO, and the Tx Queue to the CAN Core, the Tx Event FIFO, and the Put and Get Index operations. The MCAN module supports up to 32 Tx buffers. These Tx buffers can be configured as dedicated Tx buffers, Tx FIFO, or Tx Queue and as combination of dedicated Tx buffers/Tx FIFO or dedicated Tx buffers/Tx Queue. For each Tx Buffer element Classical CAN or CAN FD transmission mode can be configured. [Section 35.5.16.3](#) describes the Tx Buffer Element. [Table 35-9](#) shows the possible configurations for message transmission.

**Table 35-9. Possible Configurations for Message Transmission**

MCAN_CCCR Register		Tx Buffer Element		Frame Transmission
BRSE	FDOE	FDL	BRS	
ignored	0	ignored	ignored	Classic CAN
0	1	0	ignored	Classic CAN
0	1	1	ignored	CAN FD without bit rate switching
1	1	0	ignored	Classic CAN
1	1	1	0	CAN FD without bit rate switching
1	1	1	1	CAN FD with bit rate switching

When the Tx Buffer Request Pending (MCAN\_TXBRP) register is updated, or when a transmission has been started the Tx Handler starts scanning to check for the highest priority pending Tx request. The Tx Buffer with the lowest Message ID has highest priority.

---

**Note**

AUTOSAR requires at least three Tx Queue buffers and support of transmit cancellation.

---

### 35.5.14.1 Transmit Pause

The transmit pause feature is intended for use in CAN networks where the CAN Message IDs are specific and cannot easily be changed. These Message IDs can have a higher priority than other defined Message IDs, while in a specific application the relative priority can be inverse. This allows for a case where one ECU sends a burst of CAN messages that cause another ECU CAN messages to be delayed (paused).

The transmit pause feature is enabled by the MCAN\_CCCR.TXP bit. By default this bit is disabled (MCAN\_CCCR.TXP = 0). Each time after successfully transmitted message, a pause for two CAN bit times occurs before the start of the next transmission. This allows the other CAN nodes in the network to transmit messages even if the Message IDs have lower priority.

### 35.5.14.2 Dedicated Tx Buffers

Dedicated Tx buffers are intended for message transmission under complete control of the Host CPU.

There are two options:

- Each dedicated Tx Buffer is configured with a specific Message ID.
- Two or more dedicated Tx buffers are configured with the same Message ID. In this case the Tx Buffer with the lowest buffer number is transmitted first.

After the data section has been updated, a transmission is requested by an Add Request. This is done using the MCAN\_TXBAR[x]ARn bit (where x = 0 to 31). The requested messages arbitrate internally with messages from an optional Tx FIFO or Tx Queue and externally with messages on the CAN bus, and are sent out according to the Message ID.

**Table 35-10** shows Tx Buffer/Tx FIFO/Tx Queue Element Size. A Dedicated Tx Buffer allocates element size 32-bit words in the Message RAM. The start address of a dedicated Tx Buffer in the Message RAM is calculated by adding transmit buffer index from 0 to 31 (MCAN\_TXFQS.TFQP) × Element size to the Tx Buffer start address MCAN\_TXBC.TBSA field.

**Table 35-10. Tx Buffer, Tx FIFO, Tx Queue Element Size**

MCAN_TXESC.TBDS	Data Field (bytes)	Element Size (RAM Words)
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

### 35.5.14.3 Tx FIFO

Tx FIFO mode is configured by setting bit MCAN\_TXBC.TFQM = 0. The stored in the Tx FIFO messages are transmitted starting with the message referenced by the Get Index MCAN\_TXFQS.TFGI field. After each transmission the Get Index is incremented until the Tx FIFO is empty. The Tx FIFO Free Level MCAN\_TXFQS.TFFL field indicates the number of the available free Tx FIFO elements. The Tx FIFO allows transmission of messages with the same Message ID from different Tx buffers in the order these messages have been written to the Tx FIFO.

New transmit messages must be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index MCAN\_TXFQS.TFQP field. After each Add Request (MCAN\_TXBAR[x] ARn = 1), the Put Index is incremented to the next free Tx FIFO element. When the Put Index reaches the Get Index (MCAN\_TXFQS.TFQP = MCAN\_TXFQS.TFGI), Tx FIFO Full condition is signaled by bit MCAN\_TXFQS.TFQF = 1. In this case, no further messages must be written to the Tx FIFO until the next message is transmitted and the Get Index is incremented.

The number of requested Tx buffers must not exceed the number of free Tx buffers, as indicated by the Tx FIFO Free Level MCAN\_TXFQS.TFFL field.

In case a transmission request for the Tx Buffer referenced by the Get Index is canceled, the Get Index is incremented to the next Tx Buffer with pending transmission request and the Tx FIFO Free Level MCAN\_TXFQS.TFFL field is recalculated. In case transmission cancellation is applied to any other Tx Buffer, the Get Index and the FIFO Free Level remain unchanged.

A Tx FIFO element allocates element size 32-bit words in the Message RAM (see [Table 35-10](#)). The start address of the next available (free) Tx FIFO Buffer is calculated by adding Tx FIFO/Queue Put Index MCAN\_TXFQS.TFQP (from 0 to 31) × Element Size to the Tx Buffer Start Address MCAN\_TXBC.TBSA field.

### 35.5.14.4 Tx Queue

Tx Queue mode is configured by setting bit MCAN\_TXBC.TFQM = 1. The stored in the Tx Queue messages are transmitted starting with the highest priority message (lowest Message ID). In case two or more Queue buffers are configured with the same Message ID, the Queue Buffer with the lowest buffer number is transmitted first.

New transmit messages must be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index MCAN\_TXFQS.TFQP field. Each Add Request cyclically increments the Put Index to the next free Tx Buffer. In case of Tx Queue Full condition (MCAN\_TXFQS.TFQF = 1), the Put Index is not valid and no further message must be written to the Tx Queue until at least one of the requested messages is sent out or a pending transmission request is canceled.

The application can use the MCAN\_TXBRP register instead of the Put Index and can place messages to any Tx Buffer without pending transmission request.

A Tx Queue Buffer allocates element size 32-bit words in the Message RAM (see [Table 35-10](#)). The start address of the next available (free) Tx Queue Buffer is calculated by adding Tx FIFO/Queue Put Index MCAN\_TXFQS.TFQP (from 0 to 31) × Element Size to the Tx Buffer Start Address MCAN\_TXBC.TBSA field.

### 35.5.14.5 Mixed Dedicated Tx Buffers/Tx FIFO

For this combination the Tx buffers section in the Message RAM is separated in two parts:

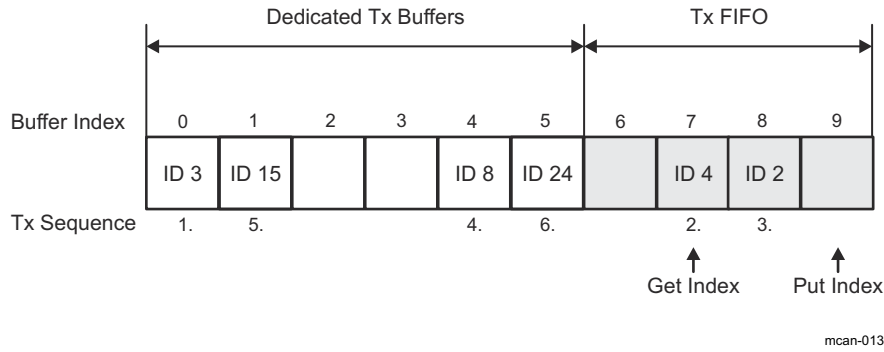

- Dedicated Tx buffers: the number of Dedicated Tx buffers is configured by the MCAN\_TXBC.NDTB field
- Tx FIFO: the number of Tx buffers assigned to the Tx FIFO is configured by the MCAN\_TXBC.TFQS field

If the MCAN\_TXBC.TFQS field is empty (zero) - only Dedicated Tx buffers are used.

Tx prioritization:

- Scan Dedicated Tx buffers and oldest pending Tx FIFO Buffer (referenced by the MCAN\_TXFQS.TFGI field)
- Buffer with lowest Message ID gets highest priority and is transmitted next

[Figure 35-17](#) shows Mixed Dedicated Tx buffers/Tx FIFO example.

**Figure 35-17. Mixed Dedicated Tx Buffers /Tx FIFO (example)**

**35.5.14.6 Mixed Dedicated Tx Buffers/Tx Queue**

For this combination the Tx buffers section in the Message RAM is separated in two parts:

- Dedicated Tx buffers: the number of Dedicated Tx buffers is configured by the MCAN\_TXBC.NDTB field
- Tx Queue: the number of Tx buffers assigned to the Tx Queue is configured by the MCAN\_TXBC.TFQS field

If MCAN\_TXBC.TFQS field is empty (zero) - only Dedicated Tx buffers are used.

Tx prioritization:

- Scan all Tx buffers with activated transmission request
- Tx Buffer with lowest Message ID gets highest priority and is transmitted next

Figure 35-18 shows Mixed Dedicated Tx buffers/Tx Queue example.

**Figure 35-18. Mixed Dedicated Tx Buffers /Tx Queue (example)**

**35.5.14.7 Transmit Cancellation**

This feature is especially intended for gateway and AUTOSAR based applications. The Host CPU can cancel a requested transmission from a dedicated Tx Buffer or a Tx Queue Buffer by setting bit MCAN\_TXBCR[n].CRn = 1 (where n = 0 to 31). The corresponding bit position n is equivalent to the number of the Tx buffer.

Transmit cancellation is not intended for Tx FIFO operation.

Successful cancellation is signaled by setting the corresponding bit of the MCAN\_TXBCF register (MCAN\_TXBCF[n].CFn = 1).

If transmission from a Tx Buffer is already ongoing and a transmit cancellation is requested, the corresponding MCAN\_TXBRP[n].TRPn bit remains set as long as the transmission is in progress. If the transmission was

successful, the corresponding MCAN\_TXBTO[n].TON and MCAN\_TXBCF[n].CFn bits are set. If the transmission was not successful, only the corresponding bit MCAN\_TXBCF[n].CFn = 1.

---

#### Note

If a pending transmission is canceled immediately before this transmission has started, a short time window occurs where no transmission is started even if another message is also pending in this node. This can enable another node to transmit a message that can have a lower priority than the second message in this node.

---

#### 35.5.14.8 Tx Event Handling

To support Tx Event Handling, the Message RAM has implemented a Tx Event FIFO section. Up to 32 Tx Event FIFO elements can be configured. [Section 35.5.16.4](#) describes the Tx Event FIFO element. After message transmission on the CAN bus, Message ID and Timestamp are stored in a Tx Event FIFO element. To link a Tx Event to a Tx Event FIFO element, the Message Marker from the transmitted Tx Buffer is copied into the Tx Event FIFO element.

A Tx Event FIFO full condition is signaled by the MCAN\_IR.TEFF bit. In this case no further elements are written to the Tx Event FIFO until at least one element has been read out and the Tx Event FIFO Get Index has been incremented (MCAN\_TXEFS.EFGI). In case a Tx Event occurs while the Tx Event FIFO is full, this event is rejected and interrupt flag MCAN\_IR.TEFL bit is set.

The Tx Event FIFO watermark can be configured to avoid a Tx Event FIFO overflow. When the Tx Event FIFO fill level reaches the Tx Event FIFO watermark configured by the MCAN\_TXEFC.EFWM field, interrupt flag MCAN\_IR.TEFW is set. When reading from the Tx Event FIFO, two times the Tx Event FIFO Get Index MCAN\_TXEFS.EFGI field has to be added to the Tx Event FIFO start address MCAN\_TXEFC.EFSA field.

#### 35.5.15 FIFO Acknowledge Handling

The Get Indices of the two Rx FIFOs (Rx FIFO 0 or Rx FIFO 1) and the Tx Event FIFO are controlled by writing to the corresponding FIFO Acknowledge Index (see MCAN\_RXF0A, MCAN\_RXF1A, and MCAN\_TXEFA). Writing to the FIFO Acknowledge Index sets the FIFO Get Index to the FIFO Acknowledge Index plus one and, thereby, updates the FIFO Fill Level.

There are two use cases:

- A single element has been read from the FIFO: the Get Index value is written to the FIFO Acknowledge Index.
- A sequence of elements has been read from the FIFO: the Get Index value (Index of the last element read) is written to the FIFO Acknowledge Index at the end of that read sequence.

The Host CPU has free access to the Message RAM. Special care has to be taken when reading FIFO elements in an arbitrary order (Get Index not considered). This can be useful when reading a High Priority Message from one of the two Rx FIFOs. In this case, the FIFO Acknowledge Index must not be written because this sets the Get Index to a wrong position and also changes the FIFO's Fill Level. In this case, some of the older FIFO elements can be lost.

---

#### Note

The application has to make sure that a valid value is written to the FIFO Acknowledge Index. The MCAN module does not check for erroneous values.

---

#### 35.5.16 Message RAM

The MCAN module has a Message RAM. The main purpose of the Message RAM is to store:

- Received Messages
- Transmit Messages
- Tx Event Elements
- Message ID Filter Elements

### 35.5.16.1 Message RAM Configuration

The MCAN module is configured to allocate up to 1024 words in the Message RAM. The Message RAM has a width of 32 bits.

The address ranges of the Message RAMs is from 0x0005 9000 to 0x0005 9FFF and from 0x0005 B000 to 0x0005 BFFF.

The Message RAM is capable to include each of the sections listed in [Figure 35-19](#). It is not necessary to configure each of the sections (a section in the Message RAM can be 0) and there is no restriction with respect to the sequence of the sections. For parity checking or ECC, a respective number of bits has to be added to each word. When the MCAN module addresses the Message RAM, the MCAN addresses 32-bit words. The start addresses are configurable and are 32-bit word addresses.

The element size can be configured for:

- Rx FIFO 0, by way of the MCAN\_RXESC.F0DS field
- Rx FIFO, 1 by way of the MCAN\_RXESC.F1DS field
- Rx buffers, by way of the MCAN\_RXESC.RBDS field
- Tx buffers, by way of the MCAN\_TXESC.TBDS field

**Figure 35-19. Message RAM Configuration**

The Host CPU configures the following information in the Message RAM:

- Start addresses of the memory sections
- Number of elements in each section
- The size of the elements in some sections

**Note**

The MCAN module does not check for errors in the Message RAM configuration. The configuration of the start addresses of the different sections and the number of elements of each section has to be done carefully. This prevents falsification or loss of data.

### 35.5.16.2 Rx Buffer and FIFO Element

Up to 64 Rx buffers and two Rx FIFOs can be configured in the Message RAM. Each Rx FIFO section can be configured to store up to 64 received messages. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field by way of the MCAN\_RXESC register.

Figure 35-20 shows the Rx Buffer/Rx FIFO element structure. Table 35-11 shows the Rx Buffer/Rx FIFO element field descriptions.

**Figure 35-20. Rx Buffer/Rx FIFO Element Structure**

**Table 35-11. Rx Buffer/Rx FIFO Element Field Descriptions**

Word	Bits	Field Name	Description
	31	ESI	Error State Indicator <ul style="list-style-type: none"> <li>• 0x0: Transmitting node is error active</li> <li>• 0x1: Transmitting node is error passive</li> </ul>
	30	XTD	Extended Identifier Signals to the Host CPU whether the received frame has a standard or extended identifier. <ul style="list-style-type: none"> <li>• 0x0: 11-bit standard identifier</li> <li>• 0x1: 29-bit extended identifier</li> </ul>
R0	29	RTR	Remote Transmission Request Signals to the Host CPU whether the received frame is a data frame or a remote frame. <ul style="list-style-type: none"> <li>• 0x0: Received frame is a data frame</li> <li>• 0x1: Received frame is a remote frame</li> </ul> <p><b>Note:</b> There are no remote frames in CAN FD format. In case a CAN FD frame was received (FDF = 1), RTR bit reflects the state of the reserved r1 bit (RES[23]). In CAN FD frames (FDF = 1), the dominant RRS (Remote Request Substitution) bit replaces the RTR (Remote Transmission Request) bit.</p>
	28:0	ID[28:0]	Identifier Standard or extended identifier depending on XTD bit. A standard identifier is stored into ID[28:18].

**Table 35-11. Rx Buffer/Rx FIFO Element Field Descriptions (continued)**

Word	Bits	Field Name	Description
R1	31	ANMF	Accepted Non-matching Frame Acceptance of non-matching frames can be enabled using the MCAN_GFC.ANFS and MCAN_GFC.ANFE fields. <ul style="list-style-type: none"> <li>0x0: Received frame matching filter index FIDX field</li> <li>0x1: Received frame did not match any Rx filter element</li> </ul>
	30:24	FIDX[6:0]	Filter Index 0x0-0x7F (0-127): Index of matching Rx acceptance filter element (invalid if ANMF = 1). Range is 0 to MCAN_SIDFC.LSS - 1 respectively MCAN_XIDFC.LSE - 1.
	23:22	RES	Reserved
	21	FDF	FD Format <ul style="list-style-type: none"> <li>0x0: Standard frame format</li> <li>0x1: CAN FD frame format (new DLC-coding and CRC)</li> </ul>
	20	BRS	Bit Rate Switch <ul style="list-style-type: none"> <li>0x0: Frame received without bit rate switching</li> <li>0x1: Frame received with bit rate switching</li> </ul>
	19:16	DLC[3:0]	Data Length Code <ul style="list-style-type: none"> <li>0x0-0x8 (0-8): CAN + CAN FD: received frame has 0-8 data bytes</li> <li>0x9-0xF (9-15): CAN: received frame has 8 data bytes</li> <li>0x9-0xF (9-15): CAN FD: received frame has 12/16/20/24/32/48/64 data bytes</li> </ul>
R2	15:0	RXTS[15:0]	Rx Timestamp Timestamp Counter value captured on start of frame reception. Resolution depending on configuration of the Timestamp Counter Prescaler MCAN_TSCC.TCP.
	31:24	DB3[7:0]	Data Byte 3
	23:16	DB2[7:0]	Data Byte 2
	15:8	DB1[7:0]	Data Byte 1
R3	7:0	DB0[7:0]	Data Byte 0
	31:24	DB7[7:0]	Data Byte 7
	23:16	DB6[7:0]	Data Byte 6
	15:8	DB5[7:0]	Data Byte 5
Rn	7:0	DB4[7:0]	Data Byte 4
	...	...	...
	31:24	DBm[7:0]	Data Byte m
	23:16	DBm-1[7:0]	Data Byte m-1
Rn	15:8	DBm-2[7:0]	Data Byte m-2
	7:0	DBm-3[7:0]	Data Byte m-3

**Note**

Depending on the configuration of the element size (MCAN\_RXESC), between two and sixteen 32-bit words (Rn = 3-17) are used for storage of a CAN message's data field.

### 35.5.16.3 Tx Buffer Element

The Tx buffers section can be configured to hold dedicated Tx buffers as well as a Tx FIFO/Tx Queue. In case that the Tx buffers section is shared by dedicated Tx buffers and a Tx FIFO/Tx Queue, the dedicated Tx buffers start at the beginning of the Tx buffers section followed by the buffers assigned to the Tx FIFO or Tx Queue. The Tx Handler makes difference between dedicated Tx buffers and Tx FIFO/Tx Queue by way of the MCAN\_TXBC.TFQS and MCAN\_TXBC.NDTB fields. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field by way of the MCAN\_TXESC register.

Figure 35-21 shows the Tx Buffer element structure. Table 35-12 shows the Tx Buffer element field descriptions.

**Figure 35-21. Tx Buffer Element Structure**

**Table 35-12. Tx Buffer Element Field Descriptions**

Word	Bits	Field Name	Description
			Error State Indicator
	31	ESI	<ul style="list-style-type: none"> <li>0x0: ESI bit in CAN FD format depends only on error passive flag</li> <li>0x1: ESI bit in CAN FD format transmitted recessive</li> </ul> <p><b>Note:</b> The ESI bit of the transmit buffer is ORed with the error passive flag to decide the value of the ESI bit in the transmitted CAN FD frame. As required by the CAN FD protocol specification, an error active node can optionally transmit the ESI bit recessive, but an error passive node always transmits the ESI bit recessive.</p>
T0	30	XTD	Extended Identifier <ul style="list-style-type: none"> <li>0x0: 11-bit standard identifier</li> <li>0x1: 29-bit extended identifier</li> </ul>
	29	RTR	Remote Transmission Request <ul style="list-style-type: none"> <li>0x0: Transmit data frame</li> <li>0x1: Transmit remote frame</li> </ul> <p><b>Note:</b> When RTR = 1, the MCAN module transmits a remote frame according to ISO11898-1:2015, even if the MCAN_CCCR.FDOE bit enables the transmission in CAN FD format.</p>
	28:0	ID[28:0]	Identifier Standard or extended identifier depending on XTD bit. A standard identifier has to be written to ID[28:18].

**Table 35-12. Tx Buffer Element Field Descriptions (continued)**

	15:8	DBm-2[7:0]	Data Byte m-2
	7:0	DBm-3[7:0]	Data Byte m-3

**Note**

Depending on the configuration of the element size (MCAN\_TXESC), between two and sixteen 32-bit words (Tn = 3-17) are used for storage of a CAN message's data field.

### 35.5.16.4 Tx Event FIFO Element

Each element stores information about transmitted messages. By reading the Tx Event FIFO the Host CPU gets this information in the order the messages were transmitted. Status information about the Tx Event FIFO can be obtained from the MCAN\_TXEFS register.

Figure 35-22 shows the Tx Event FIFO element structure. Table 35-13 shows the Tx Event FIFO element field descriptions.

mcan-018

**Figure 35-22. Tx Event FIFO Element Structure**

	15:0	TXTS[15:0]	Tx Timestamp Timestamp Counter value captured on start of frame transmission. Resolution depending on configuration of the Timestamp Counter Prescaler MCAN_TSCC.TCP filed.

**35.5.16.5 Standard Message ID Filter Element**

Up to 128 filter elements can be configured for 11-bit standard IDs. When accessing a Standard Message ID Filter element, the element address is the Filter List Standard Start Address MCAN\_SIDFC.FLSSA field plus the index of the filter element (0-127).

[Figure 35-23](#) shows the Standard Message ID Filter element structure. [Table 35-14](#) shows the Standard Message ID Filter element field descriptions.

**Figure 35-23. Standard Message ID Filter Element Structure**

**Table 35-14. Standard Message ID Filter Element Field Descriptions**

Word	Bits	Field Name	Description
S0	31:30	SFT[1:0]	Standard Filter Type <ul style="list-style-type: none"> <li>0x0: Range filter from SFID1 to SFID2 (SFID2 ≥ SFID1)</li> <li>0x1: Dual ID filter for SFID1 or SFID2</li> <li>0x2: Classic filter: SFID1 = filter; SFID2 = mask</li> <li>0x3: Filter element disabled</li> </ul> <p><b>Note:</b> With SFT = 11 the filter element is disabled and the acceptance filtering continues (same behavior as with SFEC = 000)</p>
			Standard Filter Element Configuration All enabled filter elements are used for acceptance filtering of standard frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If SFEC = 100, 101, or 110 match sets interrupt flag MCAN_IR.HPM and, if enabled, an interrupt is generated. In this case, the MCAN_HPMS register is updated with the status of the priority match. <ul style="list-style-type: none"> <li>0x0: Disable filter element</li> <li>0x1: Store in Rx FIFO 0 if filter matches</li> <li>0x2: Store in Rx FIFO 1 if filter matches</li> <li>0x3: Reject ID if filter matches</li> <li>0x4: Set priority if filter matches</li> <li>0x5: Set priority and store in FIFO 0 if filter matches</li> <li>0x6: Set priority and store in FIFO 1 if filter matches</li> <li>0x7: Store into Rx Buffer , configuration of SFT[1:0] ignored</li> </ul>
	26:16	SFID1[10:0]	Standard Filter ID 1 When filtering for Rx buffers this field defines the ID of a standard message to be stored. The received identifiers must match exactly, no masking mechanism is used.
	15:11	RES	Reserved
	10:0	SFID2[10:0]	Standard Filter ID 2 This bit field has a different meaning depending on the configuration of SFEC: <ul style="list-style-type: none"> <li>SFEC = 001 - 110: Second ID of standard ID filter element</li> <li>SFEC = 111: Filter for Rx buffers</li> </ul>
			This field is decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence. <ul style="list-style-type: none"> <li>0x0: Store message into an Rx Buffer</li> <li>0x1: Debug Message A</li> <li>0x2: Debug Message B</li> <li>0x3: Debug Message C</li> </ul> <p><b>Note:</b> Debug feature is not supported.</p>
		SFID2[8:6]	This field is used to control the filter event pins at the Extension Interface. A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one MCAN_ICKL period in case the filter matches. <p><b>Note:</b> Only two filter event pins are supported.</p>
		SFID2[5:0]	This field defines the offset to the Rx Buffer Start Address MCAN_RXBC.RBSA field for storage of a matching message.

### 35.5.16.6 Extended Message ID Filter Element

Up to 64 filter elements can be configured for 29-bit extended IDs. When accessing an Extended Message ID Filter element, the element address is the Filter List Extended Start Address MCAN\_XIDFC.FLESA field plus two times the index of the filter element (0-63).

Figure 35-24 shows the Extended Message ID Filter element structure. Table 35-15 shows the Extended Message ID Filter element field descriptions.

Figure 35-24. Extended Message ID Filter Element Structure

Table 35-15. Extended Message ID Filter Element Field Descriptions

Word	Bits	Field Name	Description
F0	31:29	EFEC[2:0]	<p>Extended Filter Element Configuration</p> <p>All enabled filter elements are used for acceptance filtering of extended frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If EFEC = 100, 101, or 110 match sets interrupt flag MCAN_IR.HPM and, if enabled, an interrupt is generated. In this case, the MCAN_HPMS register is updated with the status of the priority match.</p> <ul style="list-style-type: none"> <li>0x0: Disable filter element</li> <li>0x1: Store in Rx FIFO 0 if filter matches</li> <li>0x2: Store in Rx FIFO 1 if filter matches</li> <li>0x3: Reject ID if filter matches</li> <li>0x4: Set priority if filter matches</li> <li>0x5: Set priority and store in FIFO 0 if filter matches</li> <li>0x6: Set priority and store in FIFO 1 if filter matches</li> <li>0x7: Store into Rx Buffer or as debug message, configuration of EFT[1:0] ignored</li> </ul>
	28:0	EFID1[28:0]	<p>Extended Filter ID 1</p> <p>First ID of extended ID filter element.</p> <p>When filtering for Rx buffers this field defines the ID of an extended message to be stored. The received identifiers must match exactly, only XIDAM masking mechanism (see Section 35.5.13.1.5) is used.</p>

**Table 35-15. Extended Message ID Filter Element Field Descriptions (continued)**

Word	Bits	Field Name	Description

			29
	28:0	EFID2[28:0]	Extended Filter ID 2 This bit field has a different meaning depending on the configuration of EFEC: <ul style="list-style-type: none"> <li>EFEC = 001 - 110: Second ID of extended ID filter element</li> <li>EFEC = 111: Filter for Rx buffers</li> </ul>
		EFID2[10:9]	This field decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence. <ul style="list-style-type: none"> <li>0x0: Store message into an Rx Buffer</li> <li>0x1: Debug Message A</li> <li>0x2: Debug Message B</li> <li>0x3: Debug Message C</li> </ul> <b>Note:</b> Debug feature is not supported.
		EFID2[8:6]	This field is used to control the filter event pins at the Extension Interface. A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one MCAN_ICKL period in case the filter matches. <b>Note:</b> Only two filter event pins are supported.
		EFID2[5:0]	This field defines the offset to the Rx Buffer Start Address MCAN_RXBC.RBSA field for storage of a matching message.

## 35.6 Software

### 35.6.1 MCAN Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location: C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/mcan

Cloud access to these examples is available at the following link: [dev.ti.com C2000Ware Examples](#).

#### 35.6.1.1 MCAN Loopback with Interrupts Example Using SYSCONFIG Tool - SINGLE\_CORE

FILE: mcan\_ex1\_loopback\_interrupts.c

This example illustrates the MCAN Loopback functionality. The internal loopback mode is entered. The message transmitted would be received by the node. The last address of memory is used for the Rx buffer. Peripheral configuration is done through SYSCONFIG

##### External Connections

- None.

##### Watch Variables

- error - Checks if there is an error that occurred when the data was sent using internal loopback.

#### 35.6.1.2 MCAN Loopback with Polling Example Using SYSCONFIG Tool - SINGLE\_CORE

FILE: mcan\_ex2\_loopback\_polling.c

This example illustrates the MCAN Loopback functionality. The internal loopback mode is entered. The message transmitted would be received by the node. The last address of memory is used for the Rx buffer. Peripheral configuration is done through SYSCONFIG

##### External Connections

- None.

##### Watch Variables

- error - Checks if there is an error that occurred when the data was sent using internal loopback.

## 35.7 MCAN Registers

This Section describes the MCAN Registers.

### 35.7.1 MCAN Base Address Table

**Table 35-16. MCAN Base Address Table**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	CPU2	CPU2.DMA	Pipeline Protected
Instance	Structure								
-	-	MCANA_DRIVER_BASE	0x0005_9000	YES	YES	-	YES	YES	YES
McanaSsRegs	<a href="#">MCANSS_REGS</a>	MCANASS_BASE	0x0005_A400	YES	-	-	YES	-	YES
McanaRegs	<a href="#">MCAN_REGS</a>	MCANA_BASE	0x0005_A600	YES	-	-	YES	-	YES
McanaErrorRegs	<a href="#">MCAN_ERROR_REGS</a>	MCANA_ERROR_BASE	0x0005_A800	YES	-	-	YES	-	YES
-	-	MCANB_DRIVER_BASE	0x0005_B000	YES	YES	-	YES	YES	YES
McanbSsRegs	<a href="#">MCANSS_REGS</a>	MCANBSS_BASE	0x0005_C400	YES	-	-	YES	-	YES
McanbRegs	<a href="#">MCAN_REGS</a>	MCANB_BASE	0x0005_C600	YES	-	-	YES	-	YES
McanbErrorRegs	<a href="#">MCAN_ERROR_REGS</a>	MCANB_ERROR_BASE	0x0005_C800	YES	-	-	YES	-	YES

### 35.7.2 MCANSS\_REGS Registers

Table 35-17 lists the memory-mapped registers for the MCANSS\_REGS registers. All register offset addresses not listed in Table 35-17 should be considered as reserved locations and the register contents should not be modified.

**Table 35-17. MCANSS\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	MCANSS_PID	MCAN Subsystem Revision Register		<a href="#">Go</a>
2h	MCANSS_CTRL	MCAN Subsystem Control Register		<a href="#">Go</a>
4h	MCANSS_STAT	MCAN Subsystem Status Register		<a href="#">Go</a>
6h	MCANSS_ICS	MCAN Subsystem Interrupt Clear Shadow Register		<a href="#">Go</a>
8h	MCANSS_IRS	MCAN Subsystem Interrupt Raw Status Register		<a href="#">Go</a>
Ah	MCANSS_IECS	MCAN Subsystem Interrupt Enable Clear Shadow Register		<a href="#">Go</a>
Ch	MCANSS_IE	MCAN Subsystem Interrupt Enable Register		<a href="#">Go</a>
Eh	MCANSS_IES	MCAN Subsystem Interrupt Enable Status		<a href="#">Go</a>
10h	MCANSS_EOI	MCAN Subsystem End of Interrupt		<a href="#">Go</a>
12h	MCANSS_EXT_TS_PRESCALER	MCAN Subsystem External Timestamp Prescaler 0		<a href="#">Go</a>
14h	MCANSS_EXT_TS_UNSERVICED_INTR_CNTR	MCAN Subsystem External Timestamp Unserviced Interrupts Counter		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 35-18 shows the codes that are used for access types in this section.

**Table 35-18. MCANSS\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1C	W1C	Write 1 to clear
W1S	W1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value

### 35.7.2.1 MCANSS\_PID Register (Offset = 0h) [Reset = 68E05101h]

MCANSS\_PID is shown in [Figure 35-25](#) and described in [Table 35-19](#).

Return to the [Summary Table](#).

MCAN Subsystem Revision Register

**Figure 35-25. MCANSS\_PID Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SCHEME		RESERVED			MODULE_ID

RESERVED				MAJOR			RESERVED		MINOR						
R-Ah				R-1h			R-0h		R-1h						

**Table 35-19. MCANSS\_PID Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-30	SCHEME	R	1h	PID Register Scheme Reset type: SYSRSn
29-28	RESERVED	R	2h	Reserved
27-16	MODULE_ID	R	8E0h	Module Identification Number Reset type: SYSRSn
15-11	RESERVED	R	Ah	Reserved
10-8	MAJOR	R	1h	Major Revision of the MCAN Subsystem Reset type: SYSRSn
7-6	RESERVED	R	0h	Reserved
5-0	MINOR	R	1h	Minor Revision of the MCAN Subsystem Reset type: SYSRSn

### 35.7.2.2 MCANSS\_CTRL Register (Offset = 2h) [Reset = 0000008h]

MCANSS\_CTRL is shown in [Figure 35-26](#) and described in [Table 35-20](#).

Return to the [Summary Table](#).

MCAN Subsystem Control Register

**Figure 35-26. MCANSS\_CTRL Register**

Bit	Field	Type	Reset	Description
31-1	RESERVED	R	0h	Reserved
0	EXT_TS_CNTR_OVFL	R	0h	External Timestamp Counter Overflow Interrupt Enable Status. To set, use the CANSS_IE.EXT_TS_CNTR_OVFL bit. To clear, use the MCANSS_IECS.EXT_TS_CNTR_OVFL bit. 0 External timestamp counter overflow interrupt is not enabled 1 External timestamp counter overflow interrupt is enabled Reset type: SYSRSn

### 35.7.2.9 MCANSS\_EOI Register (Offset = 10h) [Reset = 00000000h]

MCANSS\_EOI is shown in [Figure 35-33](#) and described in [Table 35-27](#).

Return to the [Summary Table](#).

MCAN Subsystem End of Interrupt

**Figure 35-33. MCANSS\_EOI Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED														EOI																	
R-0h														R-0/W1S-0h																	

**Table 35-27. MCANSS\_EOI Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	Reserved
7-0	EOI	R-0/W1S	0h	End of Interrupt. A write to this register will clear the associated interrupt. If the unserviced interrupt counter is > 1, another interrupt is generated. 0x00 External TS Interrupt is cleared 0x01 MCAN[0] interrupt is cleared 0x02 MCAN[1] interrupt is cleared Other writes are ignored. Reset type: SYSRSn

### 35.7.2.10 MCANSS\_EXT\_TS\_PRESCALER Register (Offset = 12h) [Reset = 0000000h]

MCANSS\_EXT\_TS\_PRESCALER is shown in [Figure 35-34](#) and described in [Table 35-28](#).

Return to the [Summary Table](#).

MCAN Subsystem External Timestamp Prescaler 0

**Figure 35-34. MCANSS\_EXT\_TS\_PRESCALER Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								PRESCALER																							
R-0h								R/W-0h																							

**Table 35-28. MCANSS\_EXT\_TS\_PRESCALER Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	RESERVED	R	0h	Reserved
23-0	PRESCALER	R/W	0h	External Timestamp Prescaler Reload Value. The external timestamp count rate is the host (system) clock rate divided by this value, except in the case of 0. A zero value in this bit field will act identically to a value of 0x000001. Reset type: SYSRSn

### 35.7.2.11 MCANSS\_EXT\_TS\_UNSERVICED\_INTR\_CNTR Register (Offset = 14h) [Reset = 0000000h]

MCANSS\_EXT\_TS\_UNSERVICED\_INTR\_CNTR is shown in [Figure 35-35](#) and described in [Table 35-29](#).

Return to the [Summary Table](#).

MCAN Subsystem External Timestamp Unserviced Interrupts Counter

**Figure 35-35. MCANSS\_EXT\_TS\_UNSERVICED\_INTR\_CNTR Register**

31	30	29	28	27	26	25	24

R-0h							
7	6	5	4	3	2	1	0
RESERVED				EXT_TS_INTR_CNTR			
R-0h				R-0h			

**Table 35-29. MCANSS\_EXT\_TS\_UNSERVICED\_INTR\_CNTR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-5	RESERVED	R	0h	Reserved
4-0	EXT_TS_INTR_CNTR	R	0h	External Timestamp Counter Unserviced Rollover Interrupts. If this value is > 1, an MCANSS_EOI write of '1' to bit 0 will issue another interrupt. The status of this bit field is affected by the MCANSS_IRS.EXT_TS_CNTR_OVFL bit field. Reset type: SYSRSn

### 35.7.3 MCAN\_REGS Registers

Table 35-30 lists the memory-mapped registers for the MCAN\_REGS registers. All register offset addresses not listed in Table 35-30 should be considered as reserved locations and the register contents should not be modified.

**Table 35-30. MCAN\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	MCAN_CREL	MCAN Core Release Register		<a href="#">Go</a>
2h	MCAN_ENDN	MCAN Endian Register		<a href="#">Go</a>
6h	MCAN_DBTP	MCAN Data Bit Timing and Prescaler Register		<a href="#">Go</a>
8h	MCAN_TEST	MCAN Test Register		<a href="#">Go</a>
Ah	MCAN_RWD	MCAN RAM Watchdog		<a href="#">Go</a>
Ch	MCAN_CCCR	MCAN CC Control Register		<a href="#">Go</a>
Eh	MCAN_NBTP	MCAN Nominal Bit Timing and Prescaler Register		<a href="#">Go</a>
10h	MCAN_TSCC	MCAN Timestamp Counter Configuration		<a href="#">Go</a>
12h	MCAN_TSCV	MCAN Timestamp Counter Value		<a href="#">Go</a>
14h	MCAN_TOCC	MCAN Timeout Counter Configuration		<a href="#">Go</a>
16h	MCAN_TOCV	MCAN Timeout Counter Value		<a href="#">Go</a>
20h	MCAN_ECR	MCAN Error Counter Register		<a href="#">Go</a>
22h	MCAN_PSR	MCAN Protocol Status Register		<a href="#">Go</a>
24h	MCAN_TDCR	MCAN Transmitter Delay Compensation Register		<a href="#">Go</a>
28h	MCAN_IR	MCAN Interrupt Register		<a href="#">Go</a>
2Ah	MCAN_IE	MCAN Interrupt Enable		<a href="#">Go</a>
2Ch	MCAN_ILS	MCAN Interrupt Line Select		<a href="#">Go</a>
2Eh	MCAN_ILE	MCAN Interrupt Line Enable		<a href="#">Go</a>

6Ah	MCAN_TXBCR	MCAN Tx Buffer Cancellation Request		<a href="#">Go</a>
6Ch	MCAN_TXBTO	MCAN Tx Buffer Transmission Occurred		<a href="#">Go</a>

**Table 35-30. MCAN\_REGS Registers (continued)**

Offset	Acronym	Register Name	Write Protection	Section
6Eh	MCAN_TXBCF	MCAN Tx Buffer Cancellation Finished		<a href="#">Go</a>
70h	MCAN_TXBTIE	MCAN Tx Buffer Transmission Interrupt Enable		<a href="#">Go</a>
72h	MCAN_TXBCIE	MCAN Tx Buffer Cancellation Finished Interrupt Enable		<a href="#">Go</a>
78h	MCAN_TXEFC	MCAN Tx Event FIFO Configuration		<a href="#">Go</a>
7Ah	MCAN_TXEFS	MCAN Tx Event FIFO Status		<a href="#">Go</a>
7Ch	MCAN_TXEFA	MCAN Tx Event FIFO Acknowledge		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. [Table 35-31](#) shows the codes that are used for access types in this section.

**Table 35-31. MCAN\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
RC	R C	Read to Clear
RS	R S	Read to Set
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1SQ	W 1S Q	Write 1 to set Qualified. A condition must be met for this operation to occur.
WQ	W Q	Write Qualified. A condition must be met for this operation to occur.
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 35.7.3.1 MCAN\_CREL Register (Offset = 0h) [Reset = 32380608h]

MCAN\_CREL is shown in [Figure 35-36](#) and described in [Table 35-32](#).

Return to the [Summary Table](#).

MCAN Core Release Register

**Figure 35-36. MCAN\_CREL Register**

Bit	Field	Type	Reset	Description
31-0	ETV	R	87654321h	Endianess Test Value. Reading the constant value maintained in this register allows software to determine the endianness of the host CPU. Reset type: SYSRSn

### 35.7.3.3 MCAN\_DBTP Register (Offset = 6h) [Reset = 0000A33h]

MCAN\_DBTP is shown in [Figure 35-38](#) and described in [Table 35-34](#).

Return to the [Summary Table](#).

This register is only writable if bits CCCR.CCE and CCCR.INIT are set. The CAN bit time may be programmed in the range of 4 to 49 time quanta. The CAN time quantum may be programmed in the range of 1 to 32  $m\_can\_cclk$  periods.  $tq = (DBRP + 1) mtq$ .

DTSEG1 is the sum of Prop\_Seg and Phase\_Seg1. DTSEG2 is Phase\_Seg2.

Therefore the length of the bit time is (programmed values) [DTSEG1 + DTSEG2 + 3] tq or (functional values) [Sync\_Seg + Prop\_Seg + Phase\_Seg1 + Phase\_Seg2] tq.

The Information Processing Time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point.

3-0	DSJW	R/WQ	3h	Data Resynchronization Jump Width. Valid values are 0 to 15. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used. Qualified Write is possible only with CCCR.CCE='1' and CCCR.INIT='1'. Reset type: SYSRSn

### 35.7.3.4 MCAN\_TEST Register (Offset = 8h) [Reset = 00000X0h]

MCAN\_TEST is shown in [Figure 35-39](#) and described in [Table 35-35](#).

Return to the [Summary Table](#).

Write access to the Test Register has to be enabled by setting bit CCCR.TEST to '1'. All Test Register functions are set to their reset values when bit CCCR.TEST is reset.

Loop Back Mode and software control of the internal CAN TX pin are hardware test modes. Programming of TX != '00' may disturb the message transfer on the CAN bus.

The bit can be reset by SW at any time. 0 Bus Monitoring Mode is disabled 1 Bus Monitoring Mode is enabled Qualified Write 1 to Set is possible only with CCCR.CCE='1' and CCCR.INIT='1'. Reset type: SYSRSn
4	CSR	R/W	0h	Clock Stop Request 0 No clock stop is requested 1 Clock stop requested. When clock stop is requested, first INIT and then CSA will be set after all pending transfer requests have been completed and the CAN bus reached idle. Reset type: SYSRSn
3	CSA	R	0h	Clock Stop Acknowledge 0 No clock stop acknowledged 1 MCAN may be set in power down by stopping the Host and CAN clocks Reset type: SYSRSn
2	ASM	R/W1SQ	0h	Restricted Operation Mode. Bit ASM can only be set by SW when both CCE and INIT are set to '1'. The bit can be reset by SW at any time. 0 Normal CAN operation 1 Restricted Operation Mode active Qualified Write 1 to Set is possible only with CCCR.CCE='1' and CCCR.INIT='1'. Reset type: SYSRSn

**Table 35-37. MCAN\_CCCR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
1	CCE	R/WQ	0h	Configuration Change Enable 0 The CPU has no write access to the protected configuration registers 1 The CPU has write access to the protected configuration registers (while CCCR.INIT = '1') Qualified Write is possible only with CCCR.CCE='1' and CCCR.INIT='1'. Reset type: SYSRSn
0	INIT	R/W	1h	Initialization 0 Normal Operation 1 Initialization is started Note: Due to the synchronization mechanism between the two clock domains, there may be a delay until the value written to INIT can be read back. Therefore the programmer has to assure that the previous value written to INIT has been accepted by reading INIT before setting INIT to a new value. Reset type: SYSRSn

### 35.7.3.7 MCAN\_NBTP Register (Offset = Eh) [Reset = 06000A03h]

MCAN\_NBTP is shown in [Figure 35-42](#) and described in [Table 35-38](#).

Return to the [Summary Table](#).

This register is only writable if bits CCCR.CCE and CCCR.INIT are set. The CAN bit time may be programmed in the range of 4 to 385 time quanta. The CAN time quantum may be programmed in the range of 1 to 512  $m\_can\_clk$  periods.  $tq = (NBRP + 1) mtq$ .

NTSEG1 is the sum of Prop\_Seg and Phase\_Seg1. NTSEG2 is Phase\_Seg2.

Therefore the length of the bit time is (programmed values)  $[NTSEG1 + NTSEG2 + 3] tq$  or (functional values)  $[Sync\_Seg + Prop\_Seg + Phase\_Seg1 + Phase\_Seg2] tq$ .

The Information Processing Time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point.

Note: With a CAN clock of 8 MHz, the reset value of 0x06000A03 configures the MCAN for a bit rate of 500 kBit/s.

**Table 35-44. MCAN\_PSR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-23	RESERVED	R	0h	Reserved
22-16	TDCV	R	0h	Transmitter Delay Compensation Value. Position of the secondary sample point, defined by the sum of the measured delay from the internal CAN TX signal to the internal CAN RX signal and TDCR.TDCO. The SSP position is, in the data phase, the number of mtq between the start of the transmitted bit and the secondary sample point. Valid values are 0 to 127 mtq. Reset type: SYSRSn
15	RESERVED	R	0h	Reserved
14	PXE	RC	0h	Protocol Exception Event 0 No protocol exception event occurred since last read access 1 Protocol exception event occurred Reset type: SYSRSn
13	RFDF	RC	0h	Received a CAN FD Message. This bit is set independent of acceptance filtering. 0 Since this bit was reset by the CPU, no CAN FD message has been received 1 Message in CAN FD format with FDF flag set has been received Reset type: SYSRSn
12	RBRS	RC	0h	BRS Flag of Last Received CAN FD Message. This bit is set together with RFDF, independent of acceptance filtering. 0 Last received CAN FD message did not have its BRS flag set 1 Last received CAN FD message had its BRS flag set Reset type: SYSRSn
11	RESI	RC	0h	ESI Flag of Last Received CAN FD Message. This bit is set together with RFDF, independent of acceptance filtering. 0 Last received CAN FD message did not have its ESI flag set 1 Last received CAN FD message had its ESI flag set Reset type: SYSRSn

**Table 35-44. MCAN\_PSR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
10-8	DLEC	RS	7h	Data Phase Last Error Code. Type of last error that occurred in the data phase of a CAN FD format frame with its BRS flag set. Coding is the same as for LEC. This field will be cleared to zero when a CAN FD format frame with its BRS flag set has been transferred (reception or transmission) without error. Reset type: SYSRSn
7	BO	R	0h	Bus_Off Status 0 The M_CAN is not Bus_Off 1 The M_CAN is in Bus_Off state Reset type: SYSRSn
6	EW	R	0h	Warning Status 0 Both error counters are below the Error_Warning limit of 96 1 At least one of error counter has reached the Error_Warning limit of 96 Reset type: SYSRSn
5	EP	R	0h	Error Passive 0 The M_CAN is in the Error_Active state. It normally takes part in bus communication and sends an active error flag when an error has been detected 1 The M_CAN is in the Error_Passive state Reset type: SYSRSn
4-3	ACT	R	0h	Node Activity. Monitors the module's CAN communication state. 00 Synchronizing - node is synchronizing on CAN communication 01 Idle - node is neither receiver nor transmitter 10 Receiver - node is operating as receiver 11 Transmitter - node is operating as transmitter Note: ACT is set to '00' by a Protocol Exception Event. Reset type: SYSRSn

**Table 35-44. MCAN\_PSR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
2-0	LEC	RS	7h	<p>Last Error Code. The LEC indicates the type of the last error to occur on the CAN bus. This field will be cleared to '0' when a message has been transferred (reception or transmission) without error.</p> <p>0 No Error: No error occurred since LEC has been reset by successful reception or transmission.</p> <p>1 Stuff Error: More than 5 equal bits in a sequence have occurred in a part of a received message where this is not allowed.</p> <p>2 Form Error: A fixed format part of a received frame has the wrong format.</p> <p>3 AckError: The message transmitted by the MCAN was not acknowledged by another node.</p> <p>4 Bit1Error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value '1'), but the monitored bus value was dominant.</p> <p>5 Bit0Error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (data or identifier bit logical value '0'), but the monitored bus value was recessive. During Bus_Off recovery this status is set each time a sequence of 11 recessive bits has been monitored. This enables the CPU to monitor the proceeding of the Bus_Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed).</p> <p>6 CRCErr: The CRC check sum of a received message was incorrect. The CRC of an incoming message does not match with the CRC calculated from the received data.</p> <p>7 NoChange: Any read access to the Protocol Status Register re-initializes the LEC to '7'. When the LEC shows the value '7', no CAN bus event was detected since the last CPU read access to the Protocol Status Register.</p> <p>Note: When a frame in CAN FD format has reached the data phase with BRS flag set, the next CAN event (error or valid frame) will be shown in DLEC instead of LEC. An error in a fixed stuff bit of a CAN FD CRC sequence will be shown as a Form Error, not Stuff Error.</p> <p>Note: The Bus_Off recovery sequence (see ISO 11898-1:2015) cannot be shortened by setting or resetting CCCR.INIT. If the device goes Bus_Off, it will set CCCR.INIT of its own accord, stopping all bus activities. Once CCCR.INIT has been cleared by the CPU, the device will then wait for 129 occurrences of Bus Idle (129 * 11 consecutive recessive bits) before resuming normal operation. At the end of the Bus_Off recovery sequence, the Error Management Counters will be reset. During the waiting time after the resetting of CCCR.INIT, each time a sequence of 11 recessive bits has been monitored, a Bit0Error code is written to PSR.LEC, enabling the CPU to readily check up whether the CAN bus is stuck at dominant or continuously disturbed and to monitor the Bus_Off recovery sequence. ECR.REC is used to count these sequences.</p> <p>Reset type: SYSRSn</p>

### 35.7.3.14 MCAN\_TDCR Register (Offset = 24h) [Reset = 0000000h]

MCAN\_TDCR is shown in [Figure 35-49](#) and described in [Table 35-45](#).

Return to the [Summary Table](#).

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	Reserved
15	RESERVED	R	0h	Reserved
14-8	TDCO	R/WQ	0h	Transmitter Delay Compensation Offset. Offset value defining the distance between the measured delay from the internal CAN TX signal to the internal CAN RX signal and the secondary sample point. Valid values are 0 to 127 mtq. Qualified Write is possible only with CCCR.CCE='1' and CCCR.INIT='1'. Reset type: SYSRSn
7	RESERVED	R	0h	Reserved
6-0	TDCF	R/WQ	0h	Transmitter Delay Compensation Filter Window Length. Defines the minimum value for the SSP position, dominant edges on the internal CAN RX signal that would result in an earlier SSP position are ignored for transmitter delay measurement. The feature is enabled when TDCF is configured to a value greater than TDCO. Valid values are 0 to 127 mtq. Qualified Write is possible only with CCCR.CCE='1' and CCCR.INIT='1'. Reset type: SYSRSn

### 35.7.3.15 MCAN\_IR Register (Offset = 28h) [Reset = 80000000h]

MCAN\_IR is shown in [Figure 35-50](#) and described in [Table 35-46](#).

Return to the [Summary Table](#).

The flags are set when one of the listed conditions is detected (edge-sensitive). The flags remain set until the Host clears them. A flag is cleared by writing a '1' to the corresponding bit position. Writing a '0' has no effect. A hard reset will clear the register. The configuration of IE controls whether an interrupt is generated. The configuration of ILS controls on which interrupt line an interrupt is signalled.

Bit	Field	Type	Reset	Description
23	EP	R/W1C	0h	Error Passive 0 Error_Passive status unchanged 1 Error_Passive status changed Reset type: SYSRSn
22	ELO	R/W1C	0h	Error Logging Overflow 0 CAN Error Logging Counter did not overflow 1 Overflow of CAN Error Logging Counter occurred Reset type: SYSRSn
21	BEU	R/W1C	0h	Bit Error Uncorrected. Message RAM bit error detected, uncorrected. This bit is set when a double bit error is detected by the ECC aggregator attached to the Message RAM. An uncorrected Message RAM bit error sets CCCR.INIT to '1'. This is done to avoid transmission of corrupted data. 0 No bit error detected when reading from Message RAM 1 Bit error detected, uncorrected (e.g. parity logic) Reset type: SYSRSn
20	RESERVED	R	0h	Reserved
19	DRX	R/W1C	0h	Message Stored to Dedicated Rx Buffer. The flag is set whenever a received message has been stored into a dedicated Rx Buffer. 0 No Rx Buffer updated 1 At least one received message stored into an Rx Buffer Reset type: SYSRSn
18	TOO	R/W1C	0h	Timeout Occurred 0 No timeout 1 Timeout reached Reset type: SYSRSn
17	MRAF	R/W1C	0h	Message RAM Access Failure. The flag is set, when the Rx Handler: - has not completed acceptance filtering or storage of an accepted message until the arbitration field of the following message has been received. In this case acceptance filtering or message storage is aborted and the Rx Handler starts processing of the following message. - was not able to write a message to the Message RAM. In this case message storage is aborted. In both cases the FIFO put index is not updated resp. the New Data flag for a dedicated Rx Buffer is not set, a partly stored message is overwritten when the next message is stored to this location. The flag is also set when the Tx Handler was not able to read a message from the Message RAM in time. In this case message transmission is aborted. In case of a Tx Handler access failure the MCAN is switched into Restricted Operation Mode. To leave Restricted Operation Mode, the Host CPU has to reset CCCR.ASM. 0 No Message RAM access failure occurred 1 Message RAM access failure occurred Reset type: SYSRSn

### 35.7.3.17 MCAN\_ILS Register (Offset = 2Ch) [Reset = 0000000h]

MCAN\_ILS is shown in [Figure 35-52](#) and described in [Table 35-48](#).

Return to the [Summary Table](#).

The Interrupt Line Select register assigns an interrupt generated by a specific interrupt flag from the Interrupt Register to one of the two module interrupt lines. For interrupt generation the respective interrupt line has to be enabled via ILE.EINT0 and ILE.EINT1.

31-29	RESERVED	R	0h	Reserved
28-0	EIDM	R/WQ	1FFFFFFh	Extended ID Mask. For acceptance filtering of extended frames the Extended ID AND Mask is ANDed with the Message ID of a received frame. Intended for masking of 29-bit IDs in SAE J1939. With the reset value of all bits set to one the mask is not active. Qualified Write is possible only with CCCR.CCE='1' and CCCR.INIT='1'. Reset type: SYSRSn

### 35.7.3.23 MCAN\_HPMS Register (Offset = 4Ah) [Reset = 0000000h]

MCAN\_HPMS is shown in [Figure 35-58](#) and described in [Table 35-54](#).

Return to the [Summary Table](#).

This register is updated every time a Message ID filter element configured to generate a priority event matches. This can be used to monitor the status of incoming high priority messages and to enable fast access to these messages.

**Table 35-68. MCAN\_TXBRP Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
0	TRP0	R	0h	<p>Transmission Request Pending 0.</p> <p>Each Tx Buffer has its own Transmission Request Pending bit. The bits are set via register TXBAR. The bits are reset after a requested transmission has completed or has been cancelled via register TXBCR.</p> <p>TXBRP bits are set only for those Tx Buffers configured via TXBC. After a TXBRP bit has been set, a Tx scan is started to check for the pending Tx request with the highest priority (Tx Buffer with lowest Message ID).</p> <p>A cancellation request resets the corresponding transmission request pending bit of register TXBRP. In case a transmission has already been started when a cancellation is requested, this is done at the end of the transmission, regardless whether the transmission was successful or not. The cancellation request bits are reset directly after the corresponding TXBRP bit has been reset.</p> <p>After a cancellation has been requested, a finished cancellation is signalled via TXBCF</p> <ul style="list-style-type: none"> <li>- after successful transmission together with the corresponding TXBTO bit</li> <li>- when the transmission has not yet been started at the point of cancellation</li> <li>- when the transmission has been aborted due to lost arbitration</li> <li>- when an error occurred during frame transmission</li> </ul> <p>In DAR mode all transmissions are automatically cancelled if they are not successful. The corresponding TXBCF bit is set for all unsuccessful transmissions.</p> <p>0 No transmission request pending 1 Transmission request pending</p> <p>Note: TXBRP bits which are set while a Tx scan is in progress are not considered during this particular Tx scan. In case a cancellation is requested for such a Tx Buffer, this Add Request is cancelled immediately, the corresponding TXBRP bit is reset.</p> <p>Reset type: SYSRSn</p>

### 35.7.3.38 MCAN\_TXBAR Register (Offset = 68h) [Reset = 0000000h]

MCAN\_TXBAR is shown in [Figure 35-73](#) and described in [Table 35-69](#).

Return to the [Summary Table](#).

**Table 35-76. MCAN\_TXEFS Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-26	RESERVED	R	0h	Reserved
25	TEFL	R	0h	Tx Event FIFO Element Lost. This bit is a copy of interrupt flag IR.TEFL. When IR.TEFL is reset, this bit is also reset. 0 No Tx Event FIFO element lost 1 Tx Event FIFO element lost, also set after write attempt to Tx Event FIFO of size zero. Reset type: SYSRSn
24	EFF	R	0h	Event FIFO Full 0 Tx Event FIFO not full 1 Tx Event FIFO full Reset type: SYSRSn
23-21	RESERVED	R	0h	Reserved
20-16	EFPI	R	0h	Event FIFO Put Index. Tx Event FIFO write index pointer, range 0 to 31. Reset type: SYSRSn
15-13	RESERVED	R	0h	Reserved
12-8	EFGI	R	0h	Event FIFO Get Index. Tx Event FIFO read index pointer, range 0 to 31. Reset type: SYSRSn
7-6	RESERVED	R	0h	Reserved
5-0	EFFL	R	0h	Event FIFO Fill Level. Number of elements stored in Tx Event FIFO, range 0 to 32. Reset type: SYSRSn

### 35.7.3.46 MCAN\_TXEFA Register (Offset = 7Ch) [Reset = 0000000h]

MCAN\_TXEFA is shown in [Figure 35-81](#) and described in [Table 35-77](#).

Return to the [Summary Table](#).

MCAN Tx Event FIFO Acknowledge

**Figure 35-81. MCAN\_TXEFA Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																											EFAI				
R-0h																											R/W-0h				

**Table 35-77. MCAN\_TXEFA Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-5	RESERVED	R	0h	Reserved
4-0	EFAI	R/W	0h	Event FIFO Acknowledge Index. After the Host has read an element or a sequence of elements from the Tx Event FIFO it has to write the index of the last element read from Tx Event FIFO to EFAI. This will set the Tx Event FIFO Get Index TXEFS.EFGI to EFAI + 1 and update the Event FIFO Fill Level TXEFS.EFFL. Reset type: SYSRSn

### 35.7.4 MCAN\_ERROR\_REGS Registers

Table 35-78 lists the memory-mapped registers for the MCAN\_ERROR\_REGS registers. All register offset addresses not listed in Table 35-78 should be considered as reserved locations and the register contents should not be modified.

**Table 35-78. MCAN\_ERROR\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	MCANERR_REV	MCAN Error Aggregator Revision Register		<a href="#">Go</a>
4h	MCANERR_VECTOR	MCAN ECC Vector Register		<a href="#">Go</a>
6h	MCANERR_STAT	MCAN Error Misc Status		<a href="#">Go</a>
8h	MCANERR_WRAP_REV	MCAN ECC Wrapper Revision Register		<a href="#">Go</a>
Ah	MCANERR_CTRL	MCAN ECC Control		<a href="#">Go</a>
Ch	MCANERR_ERR_CTRL1	MCAN ECC Error Control 1 Register		<a href="#">Go</a>
Eh	MCANERR_ERR_CTRL2	MCAN ECC Error Control 2 Register		<a href="#">Go</a>
10h	MCANERR_ERR_STAT1	MCAN ECC Error Status 1 Register		<a href="#">Go</a>
12h	MCANERR_ERR_STAT2	MCAN ECC Error Status 2 Register		<a href="#">Go</a>
14h	MCANERR_ERR_STAT3	MCAN ECC Error Status 3 Register		<a href="#">Go</a>
1Eh	MCANERR_SEC_EOI	MCAN Single Error Corrected End of Interrupt Register		<a href="#">Go</a>
20h	MCANERR_SEC_STATUS	MCAN Single Error Corrected Interrupt Status Register		<a href="#">Go</a>
40h	MCANERR_SEC_ENABLE_SET	MCAN Single Error Corrected Interrupt Enable Set Register		<a href="#">Go</a>
60h	MCANERR_SEC_ENABLE_CLR	MCAN Single Error Corrected Interrupt Enable Clear Register		<a href="#">Go</a>
9Eh	MCANERR_DED_EOI	MCAN Double Error Detected End of Interrupt Register		<a href="#">Go</a>
A0h	MCANERR_DED_STATUS	MCAN Double Error Detected Interrupt Status Register		<a href="#">Go</a>
C0h	MCANERR_DED_ENABLE_SET	MCAN Double Error Detected Interrupt Enable Set Register		<a href="#">Go</a>
E0h	MCANERR_DED_ENABLE_CLR	MCAN Double Error Detected Interrupt Enable Clear Register		<a href="#">Go</a>
100h	MCANERR_AGGR_ENABLE_SET	MCAN Error Aggregator Enable Set Register		<a href="#">Go</a>
102h	MCANERR_AGGR_ENABLE_CLR	MCAN Error Aggregator Enable Clear Register		<a href="#">Go</a>
104h	MCANERR_AGGR_STATUS_SET	MCAN Error Aggregator Status Set Register		<a href="#">Go</a>
106h	MCANERR_AGGR_STATUS_CLR	MCAN Error Aggregator Status Clear Register		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 35-79 shows the codes that are used for access types in this section.

**Table 35-79. MCAN\_ERROR\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1C	W1C	Write 1 to clear

**Table 35-79. MCAN\_ERROR\_REGS Access Type Codes (continued)**

Access Type	Code	Description
W1S	W 1S	Write 1 to set
WD	W D	Write Decrement. Decrements the specified bit field by the amount written.
WI	W I	Write Increment. Increments the specified bit field by the amount written.
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 35.7.4.1 MCANERR\_REV Register (Offset = 0h) [Reset = 66A0EA00h]

MCANERR\_REV is shown in [Figure 35-82](#) and described in [Table 35-80](#).

Return to the [Summary Table](#).

MCAN Error Aggregator Revision Register

### 35.7.4.2 MCANERR\_VECTOR Register (Offset = 4h) [Reset = 0000000h]

MCANERR\_VECTOR is shown in [Figure 35-83](#) and described in [Table 35-81](#).

Return to the [Summary Table](#).

Each error detection and correction (EDC) controller has a bank of error registers (offsets 0x10 - 0x3B) associated with it. These registers are accessed via an internal serial bus (SVBUS). To access them through the ECC aggregator the controller ID desired must be written to the ECC\_VECTOR field, together with the RD\_SVBUS trigger and RD\_SVBUS\_ADDRESS bit field. This initiates the serial read which consummates by setting the RD\_SVBUS\_DONE bit. At this point the addressed register may be read by a normal CPU read of the appropriate offset address.

**Figure 35-83. MCANERR\_VECTOR Register**

Bit	Field	Type	Reset	Description
31-25	RESERVED	R	0h	Reserved
24	RD_SVBUS_DONE	R	0h	Read Completion Flag Reset type: SYSRSn
23-16	RD_SVBUS_ADDRESS	R/W	0h	Read Address Offset Reset type: SYSRSn
15	RD_SVBUS	R-0/W1S	0h	Read Trigger Reset type: SYSRSn
14-11	RESERVED	R	0h	Reserved
10-0	ECC_VECTOR	R/W	0h	ECC RAM ID. Each error detection and correction (EDC) controller has a bank of error registers (offsets 0x10 - 0x3B) associated with it. These registers are accessed via an internal serial bus (SVBUS). To access them through the ECC aggregator the controller ID desired must be written to the ECC_VECTOR field, together with the RD_SVBUS trigger and RD_SVBUS_ADDRESS bit field. This initiates the serial read which consummates by setting the RD_SVBUS_DONE bit. At this point the addressed register may be read by a normal CPU read of the appropriate offset address. 0x000 Message RAM ECC controller is selected Others Reserved (do not use) Subsequent writes through the SVBUS (offsets 0x10 - 0x3B) have a delayed completion. To avoid conflicts, perform a read back of a register within this range after writing. Reset type: SYSRSn

### 35.7.4.3 MCANERR\_STAT Register (Offset = 6h) [Reset = 0000002h]

MCANERR\_STAT is shown in [Figure 35-84](#) and described in [Table 35-82](#).

Return to the [Summary Table](#).

Bit	Field	Type	Reset	Description
31-9	RESERVED	R	0h	Reserved
8	CHECK_SVBUS_TIMEOUT	R/W	1h	Enables Serial VBUS timeout mechanism Reset type: SYSRSn
7	RESERVED	R/W	1h	Reserved
6	ERROR_ONCE	R/W	0h	If this bit is set, the FORCE_SEC/FORCE_DED will inject an error to the specified row only once. The FORCE_SEC bit will be cleared once a writeback happens. If writeback is not enabled, this error will be cleared the cycle following the read when the data is corrected. For double-bit errors, the FORCE_DED bit will be cleared the cycle following the double-bit error. Any subsequent reads will not force an error. Reset type: SYSRSn
5	FORCE_N_ROW	R/W	0h	Enable single/double-bit error on the next RAM read, regardless of the MCANERR_ERR_CTRL1.ECC_ROW setting. For write through mode, this applies to writes as well as reads. Reset type: SYSRSn
4	FORCE_DED	R/W	0h	Force double-bit error. Cleared the cycle following the error if ERROR_ONCE is asserted. For write through mode, this applies to writes as well as reads. MCANERR_ERR_CTRL1 and MCANERR_ERR_CTRL2 should be configured prior to setting this bit. Reset type: SYSRSn
3	FORCE_SEC	R/W	0h	Force single-bit error. Cleared on a writeback or the cycle following the error if ERROR_ONCE is asserted. For write through mode, this applies to writes as well as reads. MCANERR_ERR_CTRL1 and MCANERR_ERR_CTRL2 should be configured prior to setting this bit. Reset type: SYSRSn

**Table 35-84. MCANERR\_CTRL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
2	ENABLE_RMW	R/W	1h	Enable read-modify-write on partial word writes Reset type: SYSRSn
1	ECC_CHECK	R/W	1h	Enable ECC Check. ECC is completely bypassed if both ECC_ENABLE and ECC_CHECK are '0'. Reset type: SYSRSn
0	ECC_ENABLE	R/W	1h	Enable ECC Generation Reset type: SYSRSn

### 35.7.4.6 MCANERR\_ERR\_CTRL1 Register (Offset = Ch) [Reset = 00000000h]

MCANERR\_ERR\_CTRL1 is shown in [Figure 35-87](#) and described in [Table 35-85](#).

Return to the [Summary Table](#).

This register is accessed through the ECC aggregator via an internal serial bus. To access, the appropriate procedure must be first followed in the MCAN ECC Vector Register.

**Figure 35-87. MCANERR\_ERR\_CTRL1 Register**

**Table 35-87. MCANERR\_ERR\_STAT1 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	ECC_BIT1	R	0h	ECC Error Bit Position. Indicates the bit position in the RAM data that is in error on an SEC error. Only valid on an SEC error. 0 Bit 0 is in error 1 Bit 1 is in error 2 Bit 2 is in error 3 Bit 3 is in error ... 31 Bit 31 is in error >32 Invalid Reset type: SYSRSn
15	CLR_CTRL_REG_ERROR	R/W1S	0h	Writing a '1' clears the CTRL_REG_ERROR bit Reset type: SYSRSn
14-13	RESERVED	R/WD	0h	Reserved
12	CLR_ECC_OTHER	R/W1C	0h	Writing a '1' clears the ECC_OTHER bit. Reset type: SYSRSn
11-10	CLR_ECC_DED	R/WD	0h	Clear ECC_DED. A write of a non-zero value to this bit field decrements the ECC_DED bit field by the value provided. Reset type: SYSRSn
9-8	CLR_ECC_SEC	R/WD	0h	Clear ECC_SEC. A write of a non-zero value to this bit field decrements the ECC_SEC bit field by the value provided. Reset type: SYSRSn
7	CTRL_REG_ERROR	R/W1S	0h	Control Register Error. A bit field in the control register is in an ambiguous state. This means that the redundancy registers have detected a state where not all values are the same and has defaulted to the reset state. S/W needs to re-write these registers to a known state. A write of 1 will set this interrupt flag. Reset type: SYSRSn
6-5	RESERVED	R/WI	0h	Reserved

**Table 35-87. MCANERR\_ERR\_STAT1 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
4	ECC_OTHER	R/W1S	0h	SEC While Writeback Error Status 0 No SEC error while writeback pending 1 Indicates that successive single-bit errors have occurred while a writeback is still pending Reset type: SYSRSn
3-2	ECC_DED	R/WI	0h	Double Bit Error Detected Status. A 2-bit saturating counter of the number of DED errors that have occurred since last cleared. 0 No double-bit error detected 1 One double-bit error was detected 2 Two double-bit errors were detected 3 Three double-bit errors were detected A write of a non-zero value to this bit field increments it by the value provided. Reset type: SYSRSn
1-0	ECC_SEC	R/WI	0h	Single Bit Error Corrected Status. A 2-bit saturating counter of the number of SEC errors that have occurred since last cleared. 0 No single-bit error detected 1 One single-bit error was detected and corrected 2 Two single-bit errors were detected and corrected 3 Three single-bit errors were detected and corrected A write of a non-zero value to this bit field increments it by the value provided. Reset type: SYSRSn

### 35.7.4.9 MCANERR\_ERR\_STAT2 Register (Offset = 12h) [Reset = 0000000h]

MCANERR\_ERR\_STAT2 is shown in [Figure 35-90](#) and described in [Table 35-88](#).

Return to the [Summary Table](#).

This register is accessed through the ECC aggregator via an internal serial bus. To access, the appropriate procedure must be first followed in the MCAN ECC Vector Register.

# Universal Asynchronous Receiver/Transmitter (UART)

---

This chapter describes the Universal Asynchronous Receivers/Transmitters (UARTs).

<b>36.1 Introduction</b> .....	<b>5345</b>
<b>36.2 Functional Description</b> .....	<b>5345</b>

## 36.1 Introduction

The UART module performs the functions of parallel-to-serial and serial-to-parallel conversions.

### 36.1.1 Features

The Universal Asynchronous Receiver/Transmitter (UART) module in this device contains the following features:

- Programmable baud-rate generator allowing speeds up to 12.5Mbps for regular speed (divide by 16) and 25Mbps for high speed (divide by 8)
- Separate 16-deep and 8-bit wide transmit (TX) and receive (RX) FIFOs to reduce CPU interrupt service loading
- Programmable FIFO length, including 1-byte deep operation providing conventional double-buffered interface
- FIFO trigger levels of  $\frac{1}{8}$ ,  $\frac{1}{4}$ ,  $\frac{1}{2}$ ,  $\frac{3}{4}$ , and  $\frac{7}{8}$
- Standard asynchronous communication bits for start, stop, and parity
- Line-break generation and detection
- Fully programmable serial interface characteristics
  - 5, 6, 7, or 8 data bits
  - Even, odd, stick, or no parity bit generation and detection
  - 1 or 2 stop bit generation
- IrDA serial-IR (SIR) encoder and decoder providing
  - Programmable use of IrDA SIR or UART input/output
  - Support of IrDA SIR encoder and decoder functions for data rates up to 115.2kbps half-duplex
  - Support of normal 3/16 and low-power (1.41 to 2.23 $\mu$ s) bit durations
  - Programmable internal clock generator enabling division of reference clock by 1 to 256 for low-power mode bit duration
- EIA-485 9-bit support
- Standard FIFO-level and End-of-Transmission (EOT) interrupts
- Efficient transfers using Direct Memory Access Controller (DMA)
  - Separate channels for transmit and receive
  - Receive single request asserted when data is in the FIFO; burst request asserted at programmed FIFO level
  - Transmit single request asserted when there is space in the FIFO; burst request asserted at programmed FIFO level
- SYSCLK (200MHz maximum) is used to generate the baud clock.

### 36.1.2 Block Diagram

Figure 36-1 shows the UART block diagram.

## 36.2 Functional Description

The UART module performs the functions of parallel-to-serial and serial-to-parallel conversions. The UART module is similar in functionality to a 16C550 UART, but is not register-compatible.

The UART is configured for transmit or receive through the TXE and RXE bits of the UART Control (UARTCTL) register. Transmit and receive are both enabled out of reset. Before any control registers are programmed, the UART must be disabled by clearing the UARTEN bit in UARTCTL. If the UART is disabled during a TX or RX operation, the current transaction is completed prior to the UART stopping.

The UART module also includes a serial IR (SIR) encoder and decoder block that can be connected to an infrared transceiver to implement an IrDA SIR physical layer. The SIR function is programmed using the UARTCTL register.

Figure 36-1. UART Module Block Diagram

### 36.2.1 Transmit and Receive Logic

The transmit logic performs parallel-to-serial conversion on the data read from the transmit FIFO. The control logic outputs the serial bit stream beginning with a start bit and followed by the data bits (LSB first), parity bit, and the stop bits according to the programmed configuration in the control registers. See Figure 36-2 for details.

The receive logic performs serial-to-parallel conversion on the received bit stream after a valid start pulse has been detected. Overrun, parity, frame error checking, and line-break detection are also performed, and the status accompanies the data that is written to the receive FIFO.

Figure 36-2. UART Character Frame

### 36.2.2 Baud-Rate Generation

The baud-rate divisor is a 22-bit number consisting of a 16-bit integer and a 6-bit fractional part. The number formed by these two values is used by the baud-rate generator to determine the bit period. Having a fractional baud-rate divisor allows the UART to generate all the standard baud rates.

The 16-bit integer is loaded through the UART Integer Baud-Rate Divisor (UARTIBRD) register and the 6-bit fractional part is loaded with the UART Fractional Baud-Rate Divisor (UARTFBRD) register. The baud-rate divisor (BRD) has the following relationship to the system clock (where BRDI is the integer part of the BRD, and BRDF is the fractional part, separated by a decimal place.)

$$\text{BRD} = \text{BRDI} + \text{BRDF} = \text{UARTSysClk} / (\text{ClkDiv} \times \text{Baud Rate})$$

where

UARTSysClk is the system clock (SYSCLK) connected to the UART, and ClkDiv is either 16 (if HSE in UARTCTL is clear) or 8 (if HSE in UARTCTL is set).

By default, this is the main system clock (SYSCLK).

The 6-bit fractional number (that is to be loaded into the DIVFRAC bit field in the UARTFBRD register) can be calculated by taking the fractional part of the baud-rate divisor, multiplying by 64, and adding 0.5 to account for rounding errors:

$$\text{UARTFBRD}[\text{DIVFRAC}] = \text{integer}(\text{BRDF} \times 64 + 0.5)$$

The UART generates an internal baud-rate reference clock at 8× or 16× the baud-rate (referred to as Baud8 and Baud16, depending on the setting of the HSE bit [bit 5] in UARTCTL). This reference clock is divided by 8 or 16 to generate the transmit clock, and is used for error detection during receive operations.

Along with the UART Line Control High Byte (UARTLCRH) register, the UARTIBRD and UARTFBRD registers form an internal 30-bit register. This internal register is only updated when a write operation to UARTLCRH is performed, so any changes to the baud-rate divisor must be followed by a write to the UARTLCRH register for the changes to take effect.

To update the baud-rate registers, there are four possible sequences:

- UARTIBRD write, UARTFBRD write, and UARTLCRH write
- UARTFBRD write, UARTIBRD write, and UARTLCRH write
- UARTIBRD write and UARTLCRH write
- UARTFBRD write and UARTLCRH write

### 36.2.3 Data Transmission

Data received or transmitted is stored in two 16-byte FIFOs, though the receive FIFO has an extra four bits per character for status information. For transmission, data is written into the transmit FIFO. If the UART is enabled, the UART causes a data frame to start transmitting with the parameters indicated in the UARTLCRH register. Data continues to be transmitted until there is no data left in the transmit FIFO. The BUSY bit in the UART Flag (UARTFR) register is asserted as soon as data is written to the transmit FIFO (that is, if the FIFO is non-empty) and remains asserted while data is being transmitted. The BUSY bit is negated only when the transmit FIFO is empty, and the last character has been transmitted from the shift register, including the stop bits. The UART can indicate that the UART is busy even though the UART is no longer enabled.

When the receiver is idle (the UnRx signal is continuously 1), and the data input goes Low (a start bit has been received), the receive counter begins running and data is sampled on the eighth cycle of Baud16 or fourth cycle of Baud8 depending on the setting of the HSE bit (bit 5) in UARTCTL (described in [Section 36.2.1](#)).

The start bit is valid and recognized if the UnRx signal is still low on the eighth cycle of Baud16 (HSE clear) or the fourth cycle of Baud8 (HSE set), otherwise the start bit is ignored. After a valid start bit is detected, successive data bits are sampled on every 16th cycle of Baud16 or eighth cycle of Baud8 (that is, one bit period later) according to the programmed length of the data characters and value of the HSE bit in UARTCTL. The parity bit is then checked if parity mode is enabled. Data length and parity are defined in the UARTLCRH register.

Lastly, a valid stop bit is confirmed if the UnRx signal is High, otherwise a framing error has occurred. When a full word is received, the data is stored in the receive FIFO along with any error bits associated with that word.

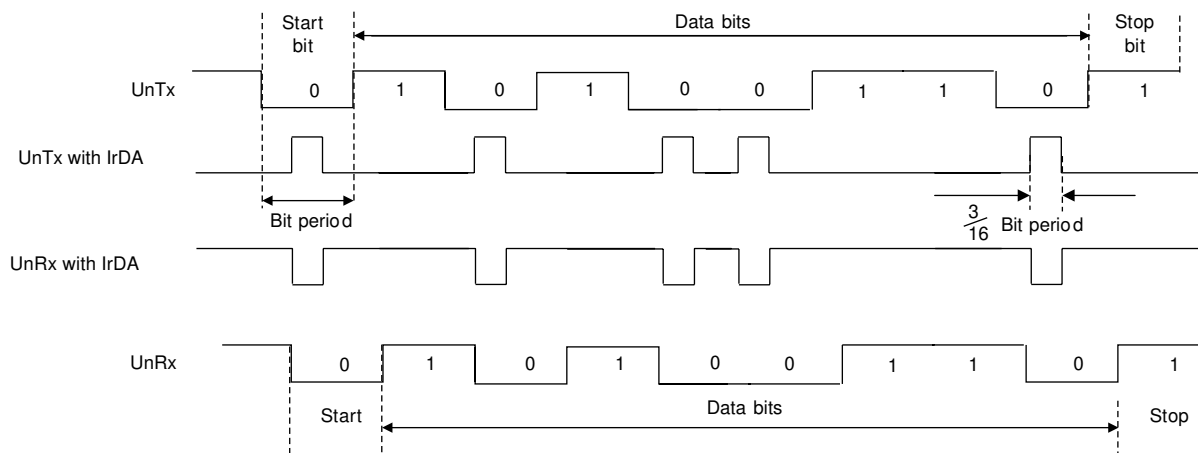

### 36.2.4 Serial IR (SIR)

The UART peripheral includes an IrDA SIR encoder and decoder block. The IrDA SIR block provides functionality that converts between an asynchronous UART data stream and a half-duplex serial SIR interface. No analog processing is performed on-chip. The role of the SIR block is to provide a digital encoded output and decoded input to the UART. When enabled, the SIR block uses the UnTx and UnRx pins for the SIR protocol. These signals must be connected to an infrared transceiver to implement an IrDA SIR physical layer link. The SIR block can receive and transmit, but the SIR block is only half-duplex so the SIR block cannot do both at the same time. Transmission must be stopped before data can be received. The IrDA SIR physical layer specifies a minimum 10ms delay between transmission and reception. The SIR block has two modes of operation:

- In normal IrDA mode, a zero logic level is transmitted as a high pulse of 3/16th duration of the selected baud rate bit period on the output pin, while logic one levels are transmitted as a static low signal. These levels control the driver of an infrared transmitter, sending a pulse of light for each zero. On the reception side, the incoming light pulses energize the photo transistor base of the receiver, pulling the output low and driving the UART input pin low.
- In low-power IrDA mode, the width of the transmitted infrared pulse is set to three times the period of the internally generated IrLPBaud16 signal (1.63μs, assuming a nominal 1.8432MHz frequency) by changing the appropriate bit in the UARTCTL register.

Whether the device is in normal or low-power IrDA mode, a start bit is deemed valid if the decoder is still low one period of IrLPBaud16 after the low was first detected. This enables a normal-mode UART to receive data from a low-power mode UART that can transmit pulses as small as 1.41μs. Thus, for both low-power and normal mode operation, the ILPDVSR field in the UARTILPR register must be programmed such that  $1.42\text{MHz} < f_{\text{IrLPBaud16}} < 2.12\text{MHz}$ , resulting in a low-power pulse duration of 1.41 to 2.11μs (three times the period of IrLPBaud16). The minimum frequency of IrLPBaud16 make sure that pulses less than one period of IrLPBaud16 are rejected, but pulses greater than 1.4μs are accepted as valid pulses.

[Figure 36-3](#) shows the UART transmit and receive signals, with and without IrDA modulation.

**Figure 36-3. IrDA Data Modulation**

In both normal and low-power IrDA modes:

- During transmission, the UART data bit is used as the base for encoding
- During reception, the decoded bits are transferred to the UART receive logic

The IrDA SIR physical layer specifies a half-duplex communication link, with a minimum 10ms delay between transmission and reception. This delay must be generated by software because the delay is not automatically supported by the UART. The delay is required because the infrared receiver electronics can become biased or even saturated from the optical power coupled from the adjacent transmitter LED. This delay is known as latency or receiver setup time.

### 36.2.5 9-Bit UART Mode

The UART provides a 9-bit mode that is enabled with the 9BITEN bit in the UART9BITADDR register. This feature is useful in a multi-drop configuration of the UART, where a single transmitter connected to multiple receivers can communicate with a particular receiver through the address or set of addresses along with a qualifier for an address byte. All the receivers check for the address qualifier in the place of the parity bit and, if set, then compare the byte received with the preprogrammed address. If the address matches, then the receiver receives or sends further data. If the address does not match, the receiver drops the address byte and any subsequent data bytes. If the UART is in 9-bit mode, then the receiver operates with no parity mode. The address can be predefined to match with the received byte and the address can be configured with the UART9BITADDR register. The matching can be extended to a set of addresses using the address mask in the UART9BITAMASK register. By default, the UART9BITAMASK is 0xFF, meaning that only the specified address is matched.

When not finding a match, the rest of the data bytes with the ninth bit cleared are dropped. If a match is found, then an interrupt is generated to the NVIC for further action. The subsequent data bytes with the cleared ninth bit are stored in the FIFO. Software can mask this interrupt in case DMA or FIFO operations are enabled for this instance and processor intervention is not required. All the send transactions with 9-bit mode are data bytes and the ninth bit is cleared. Software can override the ninth bit to be set (to indicate address) by overriding the parity settings to sticky parity with odd parity enabled for a particular byte. To match the transmission time with correct parity settings, the address byte can be transmitted as a single then a burst transfer. The transmit FIFO does not hold the address/data bit; hence, software can enable the address bit appropriately.

### 36.2.6 FIFO Operation

The UART has two 16-deep 8-bit wide FIFOs; one for transmit and one for receive. Both FIFOs are accessed by way of the UART Data (UARTDR) register. Read operations of the UARTDR register return a 12-bit value consisting of eight data bits and four error flags while write operations place 8-bit data in the transmit FIFO.

Out of reset, both FIFOs are disabled and act as 1 byte-deep holding registers. The FIFOs are enabled by setting the FEN bit in the UARTLCRH register.

FIFO status can be monitored through the UART Flag (UARTFR) register and the UART Receive Status (UARTRSR) register. Hardware monitors empty, full, and overrun conditions. The UARTFR register contains empty and full flags (TXFE, TXFF, RXFE, and RXFF bits), and the UARTRSR register shows overrun status with the OE bit. If the FIFOs are disabled, the empty and full flags are set according to the status of the 1 byte-deep holding registers.

The trigger points, at which the FIFOs generate interrupts, is controlled by way of the UART Interrupt FIFO Level Select (UARTIFLS) register. Both FIFOs can be individually configured to trigger interrupts at different levels. Available configurations include  $\frac{1}{8}$ ,  $\frac{1}{4}$ ,  $\frac{1}{2}$ ,  $\frac{3}{4}$ , and  $\frac{7}{8}$ . For example, if the  $\frac{1}{4}$  option is selected for the receive FIFO, the UART generates a receive interrupt after four data bytes are received. Out of reset, both FIFOs are configured to trigger an interrupt at the  $\frac{1}{2}$  mark.

### 36.2.7 Interrupts

The UART can generate interrupts when the following conditions are observed:

- Overrun error
- Break error
- Parity error
- Framing error
- Receive time-out
- Transmit (when condition defined in the TXIFLSEL bit in the UARTIFLS register is met, or if the EOT bit in UARTCTL is set, when the last bit of all transmitted data leaves the serializer)
- Receive (when condition defined in the RXIFLSEL bit in the UARTIFLS register is met)

All of the interrupt events are ORed together before being sent to the interrupt controller, so the UART can only generate a single interrupt request to the controller at any given time. Software can service multiple interrupt events in a single interrupt service routine by reading the UART Masked Interrupt Status (UARTMIS) register.

The interrupt events that can trigger a controller-level interrupt are defined in the UART Interrupt Mask (UARTIM) register by setting the corresponding IM bits. If interrupts are not used, the raw interrupt status is visible by way of the UART Raw Interrupt Status (UARTRIS) register.

---

#### Note

For receive time-out, the RTIM bit in the UARTIM register must be set to see the RTMIS and RTRIS status in the UARTMIS and UARTRIS registers.

---

Interrupts are always cleared (for the UARTMIS and UARTRIS registers) by writing a 1 to the corresponding bit in the UART Interrupt Clear (UARTICR) register. Additionally, write a 1 to the INT\_FLG\_CLR field of the UART\_GLB\_INT\_CLR register to clear the global interrupt flag and receive further UART interrupts.

The receive time-out interrupt is asserted when the receive FIFO is not empty, and no further data is received over a 32-bit period when the HSE bit is clear or over a 64-bit period when the HSE bit is set. The receive time-out interrupt is cleared either when the FIFO becomes empty through reading all the data (or by reading the holding register), or when a 1 is written to the corresponding bit in the UARTICR register.

The receive interrupt changes state when one of the following events occurs:

- If the FIFOs are enabled and the receive FIFO reaches the programmed trigger level, the RXRIS bit is set. The receive interrupt is cleared by reading data from the receive FIFO until the receive FIFO becomes less than the trigger level, or by clearing the interrupt by writing a 1 to the RXIC bit.
- If the FIFOs are disabled (have a depth of one location) and data is received thereby filling the location, the RXRIS bit is set. The receive interrupt is cleared by performing a single read of the receive FIFO, or by clearing the interrupt by writing a 1 to the RXIC bit.

The transmit interrupt changes state when one of the following events occurs:

- If the FIFOs are enabled and the transmit FIFO progresses through the programmed trigger level, the TXRIS bit is set. The transmit interrupt is based on a transition through level, therefore the FIFO must be written past the programmed trigger level otherwise no further transmit interrupts are generated. The transmit interrupt is cleared by writing data to the transmit FIFO until the transmit FIFO becomes greater than the trigger level, or by clearing the interrupt by writing a 1 to the TXIC bit.
- If the FIFOs are disabled (have a depth of one location) and there is no data present in the transmitters single location, the TXRIS bit is set. The transmit interrupt is cleared by performing a single write to the transmit FIFO, or by clearing the interrupt by writing a 1 to the TXIC bit.

### 36.2.8 Loopback Operation

The UART can be placed into an internal loopback mode for diagnostic or debug work by setting the LBE bit in the UARTCTL register. In loopback mode, data transmitted on the UnTx output is received on the UnRx input. Note that the LBE bit must be set before the UART is enabled.

### 36.2.9 DMA Operation

The UART provides an interface to the DMA controller with separate channels for transmit and receive. The DMA operation of the UART is enabled through the UART DMA Control (UARTDMACTL) register. When DMA operation is enabled, the UART asserts a DMA request on the receive or transmit channel when the associated FIFO can transfer data. To trigger the DMA with the UART trigger sources, the UART FIFOs on the corresponding channel must be enabled. DMA operation does not work in non-FIFO mode.

For the receive channel, a transfer request is asserted whenever the amount of data in the receive FIFO is at or above the FIFO trigger level configured in the UARTIFLS register.

For the transmit channel, a request is asserted whenever the transmit FIFO contains fewer characters than the FIFO trigger level. The single and burst DMA transfer requests are handled automatically by the DMA controller depending on how the DMA channel is configured. When using the DMA to transfer 16-bit or 32-bit data to UARTDR for a transmit, only the least-significant 8-bits are transmitted.

To enable DMA operation for the receive channel, set the RXDMAE bit of the DMA Control (UARTDMACTL) register. To enable DMA operation for the transmit channel, set the TXDMAE bit of the UARTDMACTL register. The UART can also be configured to stop using DMA for the receive channel if a receive error occurs. If the DMAERR bit of the UARTDMACR register is set and a receive error occurs, the DMA receive requests are automatically disabled. This error condition can be cleared by clearing the appropriate UART error interrupt.

When the DMA is finished transferring data to the TX FIFO or from the RX FIFO, a dma\_done signal is sent to the UART to indicate completion. The dma\_done status is indicated through the DMATXRIS and DMARXIS bits of the UARTRIS register. An interrupt can be generated from these status bits by setting the DMATXIM and DMARXIM bits in the UARTIM register.

---

#### Note

The DMATXRIS bit can be used to indicate the completion of data transfer from the DMA to the TX FIFO. To indicate transfer completion from the serializer of the UART, the EOT bit can be enabled in the UARTCTL register.

---

See the *Direct Memory Access (DMA)* chapter for more details about programming the DMA controller.

### 36.2.9.1 Receiving Data Using UART with DMA

When using the DMA with the RX FIFO, the DMA Burst Size [DMA\_BURST\_SIZE] must equal the number of bytes used to trigger the FIFO level interrupt defined by RXIFLSEL in UARTIFLS. For example, a level of 1/8 is triggered by 2 bytes or more present in the FIFO, so DMA\_BURST\_SIZE = 2. To make sure that the DMA correctly receives all data from the RX FIFO, the DMA Burst Size also must be an integer divisor of the total number of UART receives. For complete data reception, follow these steps:

1. Decide the total number of words to be received. [BUFFER\_SIZE]
2. Decide the necessary FIFO level [UART\_BUFFER\_SIZE] and set RXIFSEL accordingly.
3. Calculate the number of DMA transfers. [DMA\_TRANSFER\_SIZE = BUFFER\_SIZE / UART\_BUFFER\_SIZE]
4. Set the DMA Burst Size [DMA\_BURST\_SIZE] equal to the UART\_BUFFER\_SIZE.
5. Configure DMA using the calculated values and use the UART peripheral trigger as the trigger source.

To receive 120 words from the UART using the DMA:

BUFFER\_SIZE = 120

UART\_BUFFER\_SIZE = 12

RXIFSEL: UART\_BUFFER\_SIZE / 16 = 3/4

DMA\_TRANSFER\_SIZE: BUFFER\_SIZE / UART\_BUFFER\_SIZE = 120/12 = 10

DMA\_BURST\_SIZE: UART\_BUFFER\_SIZE = 12

(1 burst = 12 words, 1 transfer = 10 bursts, 120 words received with each transfer)

### 36.2.9.2 Transmitting Data Using UART with DMA

When using the DMA with the TX FIFO, the DMA Burst Size [DMA\_BURST\_SIZE] must equal 16 - the number of bytes used to trigger the FIFO level interrupt defined by TXIFSEL in UARTIFLS. For example, a level of 1/8 is triggered by having 14 bytes or less present in the FIFO, so DMA\_BURST\_SIZE = 16 - 14 = 2. To make sure that the DMA writes all data correctly to the TX FIFO, the DMA Burst Size must also be an integer divisor of the total number of UART transmissions. For complete data transmission, follow these steps:

1. Decide the total number or words to be transmitted. [BUFFER\_SIZE]
2. Decide the necessary FIFO level [UART\_BUFFER\_SIZE] and set TXIFSEL accordingly.
3. Calculate the number of DMA transfers. [DMA\_TRANSFER\_SIZE = BUFFER\_SIZE / UART\_BUFFER\_SIZE]
4. Calculate the DMA Burst Size [DMA\_BURST\_SIZE] to equal 16 - UART\_BUFFER\_SIZE.
5. Configure the DMA using the calculated values and use UART peripheral trigger as the trigger source.

---

#### Note

For a BUFFER\_SIZE less than or equal to 16, a software trigger can alternatively be used.

---

To transmit 120 words from the UART using the DMA:

BUFFER\_SIZE = 120

UART\_BUFFER\_SIZE = 12

TXIFSEL: 1 - (UART\_BUFFER\_SIZE / 16) = 1 - 3/4 = 1/4

DMA\_TRANSFER\_SIZE: (BUFFER\_SIZE / UART\_BUFFER\_SIZE) = (120/12) = 10

DMA\_BURST\_SIZE: UART\_BUFFER\_SIZE = 12

(1 burst = 12 words, 1 transfer = 10 bursts, 120 words transmitted with each transfer)

### 36.3 Initialization and Configuration

To enable and initialize the UART, perform the following steps:

1. Disable the UART by clearing the UARTEN bit in the UARTCTL register.
2. Write the integer portion of the BRD to the UARTIBRD register.
3. Write the fractional portion of the BRD to the UARTFBRD register.
4. Write the desired serial parameters to the UARTLCRH register.
5. Optionally, configure the DMA channel (see the *Direct Memory Access (DMA)* chapter and enable the DMA options in the UARTDMACTL register.
6. Enable the UART by setting the UARTEN bit in the UARTCTL register.

### 36.4 Software

#### 36.4.1 UART Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/uart

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

##### 36.4.1.1 UART Loopback - SINGLE\_CORE

FILE: uart\_ex1\_loopback.c

Simple UART internal loopback example

The sent data looks like this:

```
00 01 02 03 .... FE FF 00
```

This pattern is repeated forever.

##### *External Connections*

- None

##### *Watch Variables*

- *sData* - Data to send
- *rData* - Received data

Note: Avoid keeping the memory browser open while the execution is in progress.

##### 36.4.1.2 UART Loopback with Interrupt - SINGLE\_CORE

FILE: uart\_ex2\_loopback\_fifo\_interrupts.c

UART internal loopback w/ interrupt example Receive interrupt with FIFO is used.

A stream of data is sent and then compared to the received stream. The sent data looks like this:

```
00 01
```

```
01 02
```

```
02 03
```

```
....
```

```
FE FF
```

```
FF 00
```

```
etc..
```

The pattern is repeated forever.

##### *External Connections*

- None

##### *Watch Variables*

- *sData* - Data to send

- *rData* - Received data

Note: Avoid keeping the memory browser open while the execution is in progress.

### 36.4.1.3 UART Loopback with DMA - SINGLE\_CORE

FILE: `uart_ex3_loopback_dma.c`

This program uses the internal loopback test mode of the UART module. Both DMA interrupts and UART FIFOs are used. When the UART transmit FIFO has enough space (as indicated by its FIFO level interrupt signal), the DMA will transfer data from global variable `sData` into the FIFO. This will be transmitted to the receive FIFO via the internal loopback.

When enough data has been placed in the receive FIFO (as indicated by its FIFO level interrupt signal), the DMA will transfer the data from the FIFO into global variable `rData`.

When all data has been placed into `rData`, a check of the validity of the data will be performed in one of the DMA channels' ISRs.

#### External Connections

- None

#### Watch Variables

- *sData* - Data to send
- *rData* - Received data

## 36.5 UART Registers

This section describes the Connectivity Manager Universal Asynchronous Interface Registers.

### 36.5.1 UART Base Address Table

**Table 36-1. UART Base Address Table**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	CPU2	CPU2.DMA	Pipeline Protected
Instance	Structure								
UartaRegs, UartaWriteRegs	<a href="#">UART_REGS_WRITE</a>	UARTA_BASE, UARTAWRITE_BASE	0x0006_A000	YES	YES	-	YES	YES	YES
UartbRegs, UartbWriteRegs	<a href="#">UART_REGS_WRITE</a>	UARTB_BASE, UARTBWRITE_BASE	0x0006_A800	YES	YES	-	YES	YES	YES

### 36.5.2 UART\_REGS Registers

Table 36-2 lists the memory-mapped registers for the UART\_REGS registers. All register offset addresses not listed in Table 36-2 should be considered as reserved locations and the register contents should not be modified.

**Table 36-2. UART\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	UARTDR	UART Data		<a href="#">Go</a>
2h	UARTRSR	UART Receive Status/Error Clear		<a href="#">Go</a>
Ch	UARTFR	UART Flag		<a href="#">Go</a>
10h	UARTILPR	UART IrDA Low-Power Register		<a href="#">Go</a>

7FCh	UARTPCellID2	UART PrimeCell Identification 2		<a href="#">Go</a>
7FEh	UARTPCellID3	UART PrimeCell Identification 3		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 36-3 shows the codes that are used for access types in this section.

**Table 36-3. UART\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		

**Table 36-3. UART\_REGS Access Type Codes (continued)**

Access Type	Code	Description
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 36.5.2.1 UARTDR Register (Offset = 0h) [Reset = 0000000h]

UARTDR is shown in [Figure 36-4](#) and described in [Table 36-4](#).

Return to the [Summary Table](#).

**IMPORTANT:** This register is read sensitive. This register is the data register (the interface to the FIFOs). For transmitted data, if the FIFO is enabled, data written to this location is pushed onto the transmit FIFO. If the FIFO is disabled, data is stored in the transmitter holding register (the bottom word of the transmit FIFO). A write to this register initiates a transmission from the UART. For received data, if the FIFO is enabled, the data byte and the 4-bit status (break, frame, parity, and overrun) is pushed onto the 12-bit wide receive FIFO. If the FIFO is disabled, the data byte and status are stored in the receiving holding register (the bottom word of the receive FIFO). The received data can be retrieved by reading this register.

**Figure 36-4. UARTDR Register**

7-0	DATA	R/W	0h	<p>Data Transmitted or Received</p> <p>Data that is to be transmitted via the UART is written to this field. When read, this field contains the data that was received by the UART.</p> <p>For transmitted data, if the FIFO is enabled, data written to this location is pushed onto the transmit FIFO. If the FIFO is disabled, data is stored in the transmitter holding register (the bottom word of the transmit FIFO). A write to this register initiates a transmission from the UART.</p> <p>For received data, if the FIFO is enabled, the data byte and the 4-bit status (break, frame, parity, and overrun) is pushed onto the 12-bit wide receive FIFO. If the FIFO is disabled, the data byte and status are stored in the receiving holding register (the bottom word of the receive FIFO). The received data can be retrieved by reading this register.</p> <p>Reset type: PER.RESET</p>

### 36.5.2.2 UARTRSR Register (Offset = 2h) [Reset = 0000000h]

UARTRSR is shown in [Figure 36-5](#) and described in [Table 36-5](#).

Return to the [Summary Table](#).

The UARTRSR/UARTECR register is the receive status register/error clear register.

In addition to the UARTDR register, receive status can also be read from the UARTRSR register.

If the status is read from this register, then the status information corresponds to the entry read from UARTDR prior to reading UARTRSR. The status information for overrun is set immediately when an overrun condition occurs.

The UARTRSR register cannot be written.

A write of any value to the UARTECR register clears the framing, parity, break, and overrun errors.

All the bits are cleared on reset.

**Figure 36-5. UARTRSR Register**

31-4	RESERVED	R	0h	Reserved
3	OE	R	0h	UART Overrun Error 0 No data has been lost due to a FIFO overrun. 1 New data was received when the FIFO was full, resulting in data loss. This bit is cleared by a write to UARTECR. The FIFO contents remain valid because no further data is written when the FIFO is full, only the contents of the shift register are overwritten. The CPU must read the data in order to empty the FIFO. Reset type: PER.RESET
2	BE	R	0h	UART Break Error 0 No break condition has occurred 1 A break condition has been detected, indicating that the receive data input was held Low for longer than a full-word transmission time (defined as start, data, parity, and stop bits). This bit is cleared to 0 by a write to UARTECR. In FIFO mode, this error is associated with the character at the top of the FIFO. When a break occurs, only one 0 character is loaded into the FIFO. The next character is only enabled after the receive data input goes to a 1 (marking state) and the next valid start bit is received. Reset type: PER.RESET
1	PE	R	0h	UART Parity Error 0 No parity error has occurred 1 The parity of the received data character does not match the parity defined by bits 2 and 7 of the UARTLCRH register. This bit is cleared to 0 by a write to UARTECR. Reset type: PER.RESET

**Table 36-5. UARTSR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
0	FE	R	0h	UART Framing Error 0 No framing error has occurred 1 The received character does not have a valid stop bit (a valid stop bit is 1). This bit is cleared to 0 by a write to UARTECR. In FIFO mode, this error is associated with the character at the top of the FIFO. Reset type: PER.RESET

### 36.5.2.3 UARTFR Register (Offset = Ch) [Reset = 0000090h]

UARTFR is shown in [Figure 36-6](#) and described in [Table 36-6](#).

Return to the [Summary Table](#).

The UARTFR register is the flag register. After reset, the TXFF, RXFF, and BUSY bits are 0, and TXFE and RXFE bits are 1.

### 36.5.2.4 UARTILPR Register (Offset = 10h) [Reset = 0000000h]

UARTILPR is shown in [Figure 36-7](#) and described in [Table 36-7](#).

Return to the [Summary Table](#).

The UARTILPR register stores the 8-bit low-power counter divisor value used to derive the low-power SIR pulse width clock.

**Figure 36-7. UARTILPR Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																ILPDVSR															
R-0h																R/W-0h															

**Table 36-7. UARTILPR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	Reserved
7-0	ILPDVSR	R/W	0h	<p>IrDA Low-Power Divisor</p> <p>This field contains the 8-bit low-power divisor value. The UARTILPR register stores the 8-bit low-power counter divisor value used to derive the low-power SIR pulse width clock by dividing down the system clock (SysClk). All the bits are cleared when reset.</p> <p>The internal IrLPBaud16 clock is generated by dividing down SysClk according to the low-power divisor value written to UARTILPR. The duration of SIR pulses generated when low-power mode is enabled is three times the period of the IrLPBaud16 clock. The low-power divisor value is calculated as follows:</p> $\text{ILPDVSR} = \text{SysClk} / \text{FIrLPBaud16}$ <p>where FIrLPBaud16 is nominally 1.8432 MHz. Because the IrLPBaud16 clock is used to sample transmitted data irrespective of mode, the ILPDVSR field must be programmed in both low power and normal mode, such that FIrLPBaud16 is between 1.42 and 2.12 MHz, resulting in a low-power pulse duration of 1.41-2.11 us (three times the period of IrLPBaud16). The minimum frequency of IrLPBaud16 ensures that pulses less than one period of IrLPBaud16 are rejected, but pulses greater than 1.4 us are accepted as valid pulses.</p> <p>Note: Zero is an illegal value. Programming a zero value results in no IrLPBaud16 pulses being generated</p> <p>Reset type: PER.RESET</p>

### 36.5.2.5 UARTIBRD Register (Offset = 12h) [Reset = 0000000h]

UARTIBRD is shown in [Figure 36-8](#) and described in [Table 36-8](#).

Return to the [Summary Table](#).

The UARTIBRD register is the integer part of the baud-rate divisor value. All the bits are cleared on reset. The minimum possible divide ratio is 1 (when UARTIBRD=0), in which case the UARTFBRD register is ignored. When changing the UARTIBRD register, the new value does not take effect until transmission/reception of the current character is complete. Any changes to the baud-rate divisor must be followed by a write to the UARTLCRH register.

**Figure 36-8. UARTIBRD Register**

15-0	DIVINT	R/W	0h	Integer Baud-Rate Divisor The minimum possible divide ratio is 1 (when UARTIBRD=0), in which case the UARTFBRD register is ignored. When changing the UARTIBRD register, the new value does not take effect until transmission/reception of the current character is complete. Any changes to the baud-rate divisor must be followed by a write to the UARTLCRH register. Reset type: PER.RESET

### 36.5.2.6 UARTFBRD Register (Offset = 14h) [Reset = 0000000h]

UARTFBRD is shown in [Figure 36-9](#) and described in [Table 36-9](#).

Return to the [Summary Table](#).

The UARTFBRD register is the fractional part of the baud-rate divisor value. All the bits are cleared on reset. When changing the UARTFBRD register, the new value does not take effect until transmission/reception of the current character is complete. Any changes to the baud-rate divisor must be followed by a write to the UARTLCRH register. See 'Baud-Rate Generation' on page 1165 for configuration details.

5-0	DIVFRAC	R/W	0h	Fractional Baud-Rate Divisor The UARTFBRD register is the fractional part of the baud-rate divisor value. All the bits are cleared on reset. When changing the UARTFBRD register, the new value does not take effect until transmission/reception of the current character is complete. Any changes to the baud-rate divisor must be followed by a write to the UARTLCRH register. Reset type: PER.RESET

### 36.5.2.7 UARTLCRH Register (Offset = 16h) [Reset = 0000000h]

UARTLCRH is shown in [Figure 36-10](#) and described in [Table 36-10](#).

Return to the [Summary Table](#).

The UARTLCRH register is the line control register. Serial parameters such as data length, parity, and stop bit selection are implemented in this register.

When updating the baud-rate divisor (UARTIBRD and/or UARTIFRD), the UARTLCRH register must also be written. The write strobe for the baud-rate divisor registers is tied to the UARTLCRH register.

7	SPS	R/W	0h	UART Stick Parity Select UART Stick Parity Select 0 Stick parity is disabled (default) 1 Stick parity is enabled. When bits 1, 2, and 7 of UARTLCRH are set, the parity bit is transmitted and checked as a 0. When bits 1 and 7 are set and 2 is cleared, the parity bit is transmitted and checked as a 1. Reset type: PER.RESET
6-5	WLEN	R/W	0h	UART Word Length The bits indicate the number of data bits transmitted or received in a frame as follows: 0x0 5 bits (default) 0x1 6 bits 0x2 7 bits 0x3 8 bits Reset type: PER.RESET
4	FEN	R/W	0h	UART Enable FIFOs 0 The FIFOs are disabled. The FIFOs become 1-byte-deep holding registers. 1 The transmit and receive FIFO buffers are enabled (FIFO mode). Reset type: PER.RESET
3	STP2	R/W	0h	UART Two Stop Bits Select 0 One stop bit is transmitted at the end of a frame. 1 Two stop bits are transmitted at the end of a frame. The receive logic does not check for two stop bits being received. Reset type: PER.RESET

**Table 36-10. UARTLCRH Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
2	EPS	R/W	0h	UART Even Parity Select 0 Odd parity is performed, which checks for an odd number of 1s. 1 Even parity generation and checking is performed during transmission and reception, which checks for an even number of 1s in data and parity bits. This bit has no effect when parity is disabled by the PEN bit. Reset type: PER.RESET
1	PEN	R/W	0h	UART Parity Enable 0 Parity is disabled and no parity bit is added to the data frame. 1 Parity checking and generation is enabled. Reset type: PER.RESET
0	BRK	R/W	0h	UART Send Break 0 Normal use. 1 A Low level is continually output on the UnTx signal, after completing transmission of the current character. For the proper execution of the break command, software must set this bit for at least two frames (character periods). Reset type: PER.RESET

### 36.5.2.8 UARTCTL Register (Offset = 18h) [Reset = 0000300h]

UARTCTL is shown in [Figure 36-11](#) and described in [Table 36-11](#).

Return to the [Summary Table](#).

The UARTCTL register is the control register. All the bits are cleared on reset except for the Transmit Enable (TXE) and Receive Enable (RXE) bits, which are set.

To enable the UART module, the UARTEN bit must be set. If software requires a configuration change in the module, the UARTEN bit must be cleared before the configuration changes are written. If the UART is disabled during a transmit or receive operation, the current transaction is completed prior to the UART stopping.

Reset type: PER.RESET
3	RESERVED	R/W	0h	Reserved
2	SIRLP	R/W	0h	UART SIR Low-Power Mode This bit selects the IrDA encoding mode. 0 Low-level bits are transmitted as an active High pulse with a width of 3/16th of the bit period. 1 The UART operates in SIR Low-Power mode. Low-level bits are transmitted with a pulse width which is 3 times the period of the IrLPBaud16 input signal, regardless of the selected bit rate. Setting this bit uses less power, but might reduce transmission distances. Reset type: PER.RESET
1	SIREN	R/W	0h	UART SIR Enable 0 Normal operation. 1 The IrDA SIR block is enabled, and the UART will transmit and receive data using SIR protocol. Reset type: PER.RESET
0	UARTEN	R/W	0h	UART Enable 0 The UART is disabled. 1 The UART is enabled. If the UART is disabled in the middle of transmission or reception, it completes the current character before stopping. Reset type: PER.RESET

### 36.5.2.9 UARTIFLS Register (Offset = 1Ah) [Reset = 0000012h]

UARTIFLS is shown in [Figure 36-12](#) and described in [Table 36-12](#).

Return to the [Summary Table](#).

The UARTIFLS register is the interrupt FIFO level select register. You can use this register to define the FIFO level at which the TXRIS and RXRIS bits in the UARTRIS register are triggered.

The interrupts are generated based on a transition through a level rather than being based on the level. That is, the interrupts are generated when the fill level progresses through the trigger level.

For example, if the receive trigger level is set to the half-way mark, the interrupt is triggered as the module is receiving the 9th character.

Therefore, changing the trigger level does not trigger an interrupt using the new level until another character is received.

Out of reset, the TXIFLSEL and RXIFLSEL bits are configured so that the FIFOs trigger an interrupt at the half-way mark.

**Figure 36-12. UARTIFLS Register**

2-0	TXIFLSEL	R/W	2h	Value Description 0x0 TX FIFO less than or equal to 1/8 full - at least 14 empty spots 0x1 TX FIFO less than or equal to 1/4 full - at least 12 empty spots 0x2 TX FIFO less than or equal to 1/2 full - at least 8 empty spots (default) 0x3 TX FIFO less than or equal to 3/4 full - at least 4 empty spots 0x4 TX FIFO less than or equal to 7/8 full - at least 2 empty spots 0x5-0x7 Reserved Note: If the EOT bit in UARTCTL is set, the transmit interrupt is generated once the FIFO is completely empty and all data including stop bits have left the transmit serializer. In this case, the setting of TXIFLSEL is ignored. Reset type: PER.RESET

### 36.5.2.10 UARTIM Register (Offset = 1Ch) [Reset = 0000000h]

UARTIM is shown in [Figure 36-13](#) and described in [Table 36-13](#).

Return to the [Summary Table](#).

The UARTIM register is the interrupt mask set/clear register.

On a read, this register gives the current value of the mask on the relevant interrupt. Setting a bit allows the corresponding raw interrupt signal to be routed to the interrupt controller. Clearing a bit prevents the raw interrupt signal from being sent to the interrupt controller.

### 36.5.2.15 UART\_GLB\_INT\_EN Register (Offset = 40h) [Reset = 0000000h]

UART\_GLB\_INT\_EN is shown in [Figure 36-18](#) and described in [Table 36-18](#).

Return to the [Summary Table](#).

The UART\_GLB\_INT\_EN register is used to enable interrupt from UART to PIE

### 36.5.2.16 UART\_GLB\_INT\_FLG Register (Offset = 42h) [Reset = 0000000h]

UART\_GLB\_INT\_FLG is shown in [Figure 36-19](#) and described in [Table 36-19](#).

Return to the [Summary Table](#).

The UART\_GLB\_INT\_FLG register contains the current status of the UART interrupt

0	INT_FLG	R	0h	Global Interrupt Flag for UART INT. This bit determines whether the SINTREQUEST is generated by UART This bit can be cleared by writing a 1 to the corresponding bit in the UART_GLB_INT_CLR register. Reset type: SYSRSn

### 36.5.2.17 UART\_GLB\_INT\_CLR Register (Offset = 44h) [Reset = 0000000h]

UART\_GLB\_INT\_CLR is shown in [Figure 36-20](#) and described in [Table 36-20](#).

Return to the [Summary Table](#).

The UART\_GLB\_INT\_CLR register is used to clear the interrupt flags in UART\_GLB\_INT\_FLG register.

### 36.5.2.18 UART9BITADDR Register (Offset = 52h) [Reset = 0000000h]

UART9BITADDR is shown in [Figure 36-21](#) and described in [Table 36-21](#).

Return to the [Summary Table](#).

The UART9BITADDR register is used to write the specific address that should be matched with the receiving byte when the 9-bit Address Mask (UART9BITAMASK) is set to 0xFF. This register is used in conjunction with UART9BITAMASK to form a match for address-byte received.

14-8	RESERVED	R	0h	Reserved
7-0	ADDR	R/W	0h	Self Address for 9-Bit Mode This field contains the address that should be matched when UART9BITAMASK is 0xFF. Reset type: PER.RESET

### 36.5.2.19 UART9BITAMASK Register (Offset = 54h) [Reset = 00000FFh]

UART9BITAMASK is shown in [Figure 36-22](#) and described in [Table 36-22](#).

Return to the [Summary Table](#).

The UART9BITAMASK register is used to enable the address mask for 9-bit mode. The address bits are masked to create a set of addresses to be matched with the received address byte.

**Figure 36-22. UART9BITAMASK Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### 36.5.3 UART\_REGS\_WRITE Registers

Table 36-36 lists the memory-mapped registers for the UART\_REGS\_WRITE registers. All register offset addresses not listed in Table 36-36 should be considered as reserved locations and the register contents should not be modified.

**Table 36-36. UART\_REGS\_WRITE Registers**

Offset	Acronym	Register Name	Write Protection	Section
2h	UARTECR	UART Error Clear		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 36-37 shows the codes that are used for access types in this section.

**Table 36-37. UART\_REGS\_WRITE Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 36.5.3.1 UARTECR Register (Offset = 2h) [Reset = 0000000h]

UARTECR is shown in [Figure 36-36](#) and described in [Table 36-38](#).

Return to the [Summary Table](#).

The UARTECR register is the error clear register.

In addition to the UARTDR register, receive status can also be read from the UARTRSR register. If the status is read from this register, then the status information corresponds to the entry read from UARTDR prior to reading UARTRSR. The status information for overrun is set immediately when an overrun condition occurs.

The UARTRSR register cannot be written.

A write of any value to the UARTECR register clears the framing, parity, break, and overrun errors. All the bits are cleared on reset.

**Figure 36-36. UARTECR Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## Chapter 37

# Local Interconnect Network (LIN)

---

This chapter describes the local interconnect network (LIN) module. Since this module can also operate like a conventional serial communications interface (SCI) port, this module is referred to as the SCI/LIN module in this document. In SCI compatibility mode, this module is functionally compatible to the standalone SCI module. However, since the SCI/LIN module uses a different register/bit structure, code written for this module cannot be directly ported to the standalone SCI module and conversely.

This module can be configured to operate in either SCI (UART) or LIN mode.

## 37.1 LIN Overview

The SCI/LIN is compliant to the LIN 2.1 protocol specified in the *LIN Specification Package*. The SCI/LIN module can be programmed to work either as an SCI or as a LIN. The SCI hardware features are augmented to achieve LIN compatibility.

The SCI module is a universal asynchronous receiver-transmitter (UART) that implements the standard non-return to zero format.

The LIN standard is based on the SCI (UART) serial data link format. The communication concept is single-commander/multiple-responder with a message identification for multicast transmission between any network nodes.

Throughout the chapter, compatibility mode refers to SCI mode functionality of the SCI/LIN module. [Section 37.2](#) explains about the SCI functionality and [Section 37.3](#) explains about the LIN functionality. Though the registers are common for LIN and SCI, the register descriptions has notes to identify the register and bit usage in different modes.

### 37.1.1 SCI Features

The following are the features of the SCI module:

- Standard universal asynchronous receiver-transmitter (UART) communication
- Supports full- or half-duplex operation
- Standard non-return to zero (NRZ) format
- Double-buffered receive and transmit functions in compatibility mode
- Supports two individually enabled interrupt lines: level 0 and level 1
- Configurable frame format of 3 to 13 bits per character based on the following:
  - Data word length programmable from one to eight bits
  - Additional address bit in address-bit mode
  - Parity programmable for zero or one parity bit, odd or even parity
  - Stop programmable for one or two stop bits
- Asynchronous communication mode
- Two multiprocessor communication formats allow communication between more than two devices
- Sleep mode is available to free CPU resources during multiprocessor communication and then wake up to receive an incoming message
- The 24-bit programmable baud rate supports  $2^{24}$  different baud rates provide high accuracy baud rate selection
- At 100MHz peripheral clock, 3.125Mbps is the maximum baud rate achievable
- Capability to use direct memory access (DMA) for transmit and receive data
- Five error flags and seven status flags provide detailed information regarding SCI events
- Two external pins: LINRX and LINTX
- Multibuffered receive and transmit units

---

#### Note

The SCI/LIN module is functionally compatible with the C2000™ SCI modules, but not directly software compatible due to different register control structures.

The SCI/LIN module does not support UART hardware flow control. This feature can be implemented in software using a general-purpose I/O pin.

The SCI/LIN module does not support isosynchronous mode as there is no SCICLK pin.

---

### 37.1.2 LIN Features

The following are the features of the LIN module:

- Compatibility with LIN 1.3 , 2.0, and 2.1 protocols
- Configurable baud rate up to 20 kbps
- Two external pins: LINRX and LINTX.
- Multibuffered receive and transmit units
- Identification masks for message filtering
- Automatic commander header generation
  - Programmable synchronization break field
  - Synchronization field
  - Identifier field
- Responder Automatic Synchronization
  - Synchronization break detection
  - Optional baud rate update
  - Synchronization validation
- $2^{31}$  programmable transmission rates with 7 fractional bits
- Wakeup on LINRX dominant level from transceiver
- Automatic wakeup support
  - Wakeup signal generation
  - Expiration times on wakeup signals
- Automatic bus idle detection
- Error detection
  - Bit error
  - Bus error
  - No-response error
  - Checksum error
  - Synchronization field error
  - Parity error
- Capability to use Direct Memory Access (DMA) for transmit and receive data.
- 2 interrupt lines with priority encoding for:
  - Receive
  - Transmit
  - ID, error, and status
- Support for LIN 2.0 checksum
- Enhanced synchronizer finite state machine (FSM) support for frame processing
- Enhanced handling of extended frames
- Enhanced baud rate generator
- Update wakeup/go to sleep

### 37.1.4 Block Diagram

The SCI/LIN module contains the core SCI block with added sub-blocks to support LIN protocol.

The three major components of the SCI Module are:

- **Transmitter (TX)** contains two major registers to perform the double-buffering:
  - The transmitter data buffer register (SCITD) contains data loaded by the CPU to be transferred to the shift register for transmission.
  - The transmitter shift register (SCITXSHF) loads data from the data buffer (SCITD) and shifts data onto the LINTX pin, one bit at a time.
- **Baud Clock Generator**
  - A programmable baud generator produces a baud clock scaled from the input clock VCLK
  - LIN VCLK is based on the SYSCLK frequency. VCLK input from SYSCLK and can be divided by 1, 2, or 4 using the CLK\_CFG\_REGS PERCLKDIVSEL.LINxCLKDIV field for each LIN module individually. By default, VCLK input is SYSCLK divided by 2
- **Receiver (RX)** contains two major registers to perform the double-buffering:
  - The receiver shift register (SCIRXSHF) shifts data in from the LINRX pin one bit at a time and transfers completed data into the receive data buffer.
  - The receiver data buffer register (SCIRD) contains received data transferred from the receiver shift register

The SCI receiver and transmitter are double-buffered, and each has a separate enable and interrupt bits. The receiver and transmitter can each be operated independently or simultaneously in full duplex mode.

To maintain data integrity, the SCI checks the data the SCI receives for breaks, parity, overrun, and framing errors. The bit rate (baud) is programmable to over 16 million different rates through a 24-bit baud-select register. [Figure 37-1](#) shows the detailed SCI block diagram.

The SCI/LIN module is based on the standalone SCI with the addition of an error detector (parity calculator, checksum calculator, and bit monitor), a mask filter, a synchronizer, and a multibuffered receiver and transmitter. The SCI interface, the DMA control sub-blocks and the baud generator are modified as part of the hardware enhancements for LIN compatibility. [Figure 37-2](#) shows the SCI/LIN block diagram.

Figure 37-1. SCI Block Diagram

Figure 37-2. SCI/LIN Block Diagram

## 37.2 Serial Communications Interface Module

### 37.2.1 SCI Communication Formats

The SCI module can be configured to meet the requirements of many applications. Because communication formats vary depending on the specific application, many attributes of the SCI/LIN are user configurable. The configuration options are:

- SCI Frame format
- SCI Timing modes
- SCI Baud rate
- SCI Multiprocessor modes

#### 37.2.1.1 SCI Frame Formats

The SCI uses a programmable frame format. All frames consist of the following:

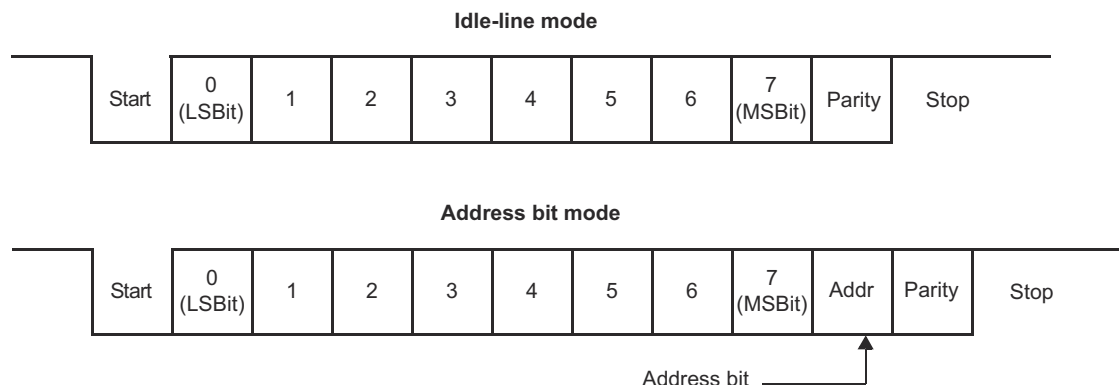

- One start bit
- One to eight data bits
- Zero or one address bit
- Zero or one parity bit
- One or two stop bits

The frame format for both the transmitter and receiver is programmable through the bits in the SCIGCR1 register. Both receive and transmit data is in nonreturn to zero (NRZ) format, which means that the transmit and receive lines are at logic high when idle. Each frame transmission begins with a start bit, in which the transmitter pulls the SCI line low (logic low). Following the start bit, the frame data is sent and received least significant bit first (LSB).

An address bit is present in each frame if the SCI is configured to be in address-bit mode but is not present in any frame if the SCI is configured for idle-line mode. The format of frames with and without the address bit is illustrated in [Figure 37-3](#).

A parity bit is present in every frame when the PARITY ENA bit is set. The value of the parity bit depends on the number of one bits in the frame and whether odd or even parity has been selected using the PARITY ENA bit. Both examples in [Figure 37-3](#) have parity enabled.

All frames include one stop bit, which is always a high level. This high level at the end of each frame is used to indicate the end of a frame to make sure synchronization between communicating devices. Two stop bits are transmitted, if the STOP bit in SCIGCR1 register is set. The examples shown in [Figure 37-3](#) use one stop bit per frame.

**Figure 37-3. Typical SCI Data Frame Formats**

### 37.2.1.2 SCI Asynchronous Timing Mode

The SCI can be configured to use the asynchronous timing mode using TIMING MODE bit in SCIGCR1 register.

The asynchronous timing mode uses only the receive and transmit data lines to interface with devices using the standard universal asynchronous receiver-transmitter (UART) protocol.

In the asynchronous timing mode, each bit in a frame has a duration of 16 SCI baud clock periods. Each bit therefore consists of 16 samples (one for each clock period). When the SCI is using asynchronous mode, the baud rates of all communicating devices must match as closely as possible. Receive errors result from devices communicating at different baud rates.

With the receiver in the asynchronous timing mode, the SCI detects a valid start bit if the first four samples after a falling edge on the LINRX pin are of logic level 0. As soon as a falling edge is detected on LINRX, the SCI assumes that a frame is being received and synchronizes to the bus.

To prevent interpreting noise as Start bit SCI expects LINRX line to be low for at least four contiguous SCI baud clock periods to detect a valid start bit. The bus is considered idle if this condition is not met. When a valid start bit is detected, the SCI determines the value of each bit by sampling the LINRX line value during the seventh, eighth, and ninth SCI baud clock periods. A majority vote of these three samples is used to determine the value stored in the SCI receiver shift register. By sampling in the middle of the bit, the SCI reduces errors caused by propagation delays and rise and fall times and data line noises. Figure 37-4 illustrates how the receiver samples a start bit and a data bit in asynchronous timing mode.

The transmitter transmits each bit for a duration of 16 SCI baud clock periods. During the first clock period for a bit, the transmitter shifts the value of that bit onto the LINTX pin. The transmitter then holds the current bit value on LINTX for 16 SCI baud clock periods.

Figure 37-4. Asynchronous Communication Bit Timing

### 37.2.1.3 SCI Baud Rate

The SCI/LIN has an internally generated serial clock determined by the peripheral VCLK and the prescalers P and M in this register. The SCI uses the 24-bit integer prescaler P value in the BRS register to select the required baud rates. The additional 4-bit fractional divider M refines the baud rate selection.

In asynchronous timing mode, the SCI generates a baud clock according to the following formula:

$$SCICLK \text{ Frequency} = \frac{VCLK \text{ Frequency}}{P + 1 + \frac{M}{16}}$$

$$\text{Asynchronous baud value} = \frac{SCICLK \text{ Frequency}}{16}$$

For P = 0,

$$\text{Asynchronous baud value} = \frac{VCLK \text{ Frequency}}{32}$$

### 37.2.1.3.1 Superfractional Divider, SCI Asynchronous Mode

The superfractional divider is available in SCI asynchronous mode (idle-line and address-bit mode). Building on the 4-bit fractional divider M (BRS[27:24]), the superfractional divider uses an additional 3-bit modulating value (see [Table 37-2](#)). The bits with a 1 in the table have an additional VCLK period added to the  $T_{bit}$ . If the character length is more than 10, then the modulation table is a rolled-over version of the original table ([Table 37-1](#)), as shown in [Table 37-2](#).

The baud rate varies over a data field to average according to the BRS[30:28] value by a “d” fraction of the peripheral internal clock:  $0 < d < 1$ . See [Figure 37-5](#) for a simple Average “d” calculation based on “U” value (BRS[30:28]).

The instantaneous bit time is expressed in terms of  $T_{VCLK}$  as follows:

For all P other than 0, and all M and d (0 or 1),

$$T^{i bit} = \left[ 16 \left( P + 1 + \frac{M}{16} \right) + d \right] T_{VCLK}$$

For P = 0,  $T_{bit} = 32T_{VCLK}$

The averaged bit time is expressed in terms of  $T_{VCLK}$  as follows:

For all P other than 0, and all M and d ( $0 < d < 1$ ),

$$T^{a bit} = \left[ 16 \left( P + 1 + \frac{M}{16} \right) + d \right] T_{VCLK}$$

For P = 0,  $T_{bit} = 32T_{VCLK}$

**Table 37-1. Superfractional Bit Modulation for SCI Mode (Normal Configuration)**

#### 37.2.1.4 SCI Multiprocessor Communication Modes

In some applications, the SCI can be connected to more than one serial communication device. In such a multiprocessor configuration, several frames of data can be sent to all connected devices or to an individual device. In the case of data sent to an individual device, the receiving devices must determine when the devices are being addressed. When a message is not intended for them, the devices can ignore the following data. When only two devices make up the SCI network, addressing is not needed, so multiprocessor communication schemes are not required.

SCI supports two multiprocessor communication modes which can be selected using COMM MODE bit:

- Idle-Line Mode
- Address Bit Mode

When the SCI is not used in a multiprocessor environment, software can consider all frames as data frames. In this case, the only distinction between the idle-line and address-bit modes is the presence of an extra bit (the address bit) in each frame sent with the address-bit protocol.

The SCI allows full-duplex communication where data can be sent and received using the transmit and receive pins simultaneously. However, the protocol used by the SCI assumes that only one device transmits data on the same bus line at any one time. No arbitration is done by the SCI.

### 37.2.1.4.1 Idle-Line Multiprocessor Modes

In idle-line multiprocessor mode, a frame that is preceded by an idle period (10 or more idle bits) is an address frame. A frame that is preceded by fewer than 10 idle bits is a data frame. Figure 37-6 illustrates the format of several blocks and frames with idle-line mode.

There are two ways to transmit an address frame using idle-line mode:

**Method 1:** In software, deliberately leave an idle period between the transmission of the last data frame of the previous block and the address frame of the new block.

**Method 2:** Configure the SCI to automatically send an idle period between the last data frame of the previous block and the address frame of the new block.

Although Method 1 is only accomplished by a delay loop in software, Method 2 can be implemented by using the transmit buffer and the TXWAKE bit in the following manner:

Step 1: Write a 1 to the TXWAKE bit.

Step 2: Write a dummy data value to the SCITD register. This triggers the SCI to begin the idle period as soon as the transmitter shift register is empty.

Step 3: Wait for the SCI to clear the TXWAKE flag.

Step 4: Write the address value to SCITD.

As indicated by Step 3, software can wait for the SCI to clear the TXWAKE bit. However, the SCI clears the TXWAKE bit at the same time the SCI sets TXRDY (that is, transfers data from SCITD into SCITXSHF). Therefore, if the TX INT ENA bit is set, the transfer of data from SCITD to SCITXSHF causes an interrupt to be generated at the same time that the SCI clears the TXWAKE bit. If this interrupt method is used, software is not required to poll the TXWAKE bit waiting for the SCI to clear the bit.

When idle-line multiprocessor communications are used, software must make sure that the idle time exceeds 10 bit periods before addresses (using one of the methods mentioned above), and software must also make sure that data frames are written to the transmitter quickly enough to be sent without a delay of 10 bit periods between frames. Failure to comply with these conditions results in data interpretation errors by other devices receiving the transmission.

**Figure 37-6. Idle-Line Multiprocessor Communication Format**

**37.2.1.4.2 Address-Bit Multiprocessor Mode**

In the address-bit protocol, each frame has an extra bit immediately following the data field called an address bit. A frame with the address bit set to 1 is an address frame; a frame with the address bit set to 0 is a data frame. The idle period timing is irrelevant in this mode. Figure 37-7 illustrates the format of several blocks and frames with the address-bit mode.

When address-bit mode is used, the value of the TXWAKE bit is the value sent as the address bit. To send an address frame, software must set the TXWAKE bit. This bit is cleared as the contents of the SCITD are shifted from the TXWAKE register so that all frames sent are data except when the TXWAKE bit is written as a 1.

No dummy write to SCITD is required before an address frame is sent in address-bit mode. The first byte written to SCITD after the TXWAKE bit is written to 1 is transmitted with the address bit set when address-bit mode is used.

**Figure 37-7. Address-Bit Multiprocessor Communication Format**

### 37.2.1.5 SCI Multibuffered Mode

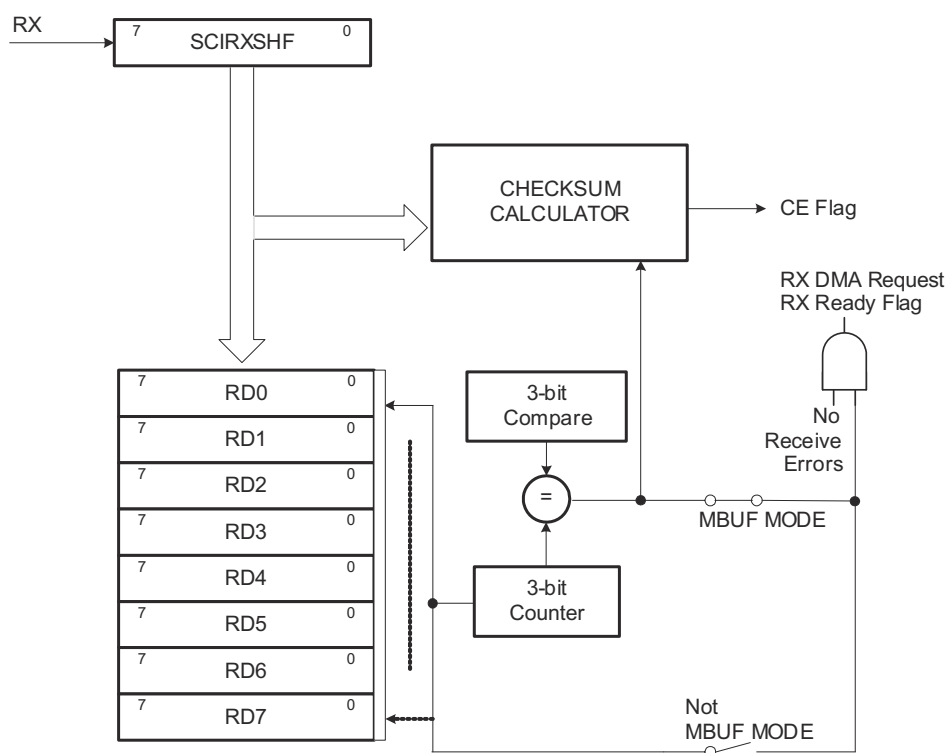

To reduce CPU load when receiving or transmitting data in interrupt mode or DMA mode, the SCI/LIN module has eight separate receive and transmit buffers. Multibuffered mode is enabled by setting the MBUF MODE bit.

The multibuffer 3-bit counter counts the data bytes transferred from the SCIRXSHF register to the RDy receive buffers and TDy transmit buffers register to SCITXSHF register. The 3-bit compare register contains the number of data bytes expected to be received or transmitted. The LENGTH value in SCIFORMAT register indicates the expected length and is used to load the 3-bit compare register.

A receive interrupt (RX interrupt; see the SCIINTVECT0 and SCIINTVECT1 registers), and a receive ready RXRDY flag set in SCIFLR register, as well as a DMA request (RXDMA) can occur after receiving a response if there are no response receive errors for the frame (such as, there is, frame error, and overrun error).

A transmit interrupt (TX interrupt), and a transmit ready flag (TXRDY flag in SCIFLR register), and a DMA request (TXDMA) can occur after transmitting a response.

Figure 37-8 and Figure 37-9 show the receive and transmit multibuffer functional block diagram, respectively.

**Figure 37-8. Receive Buffers**

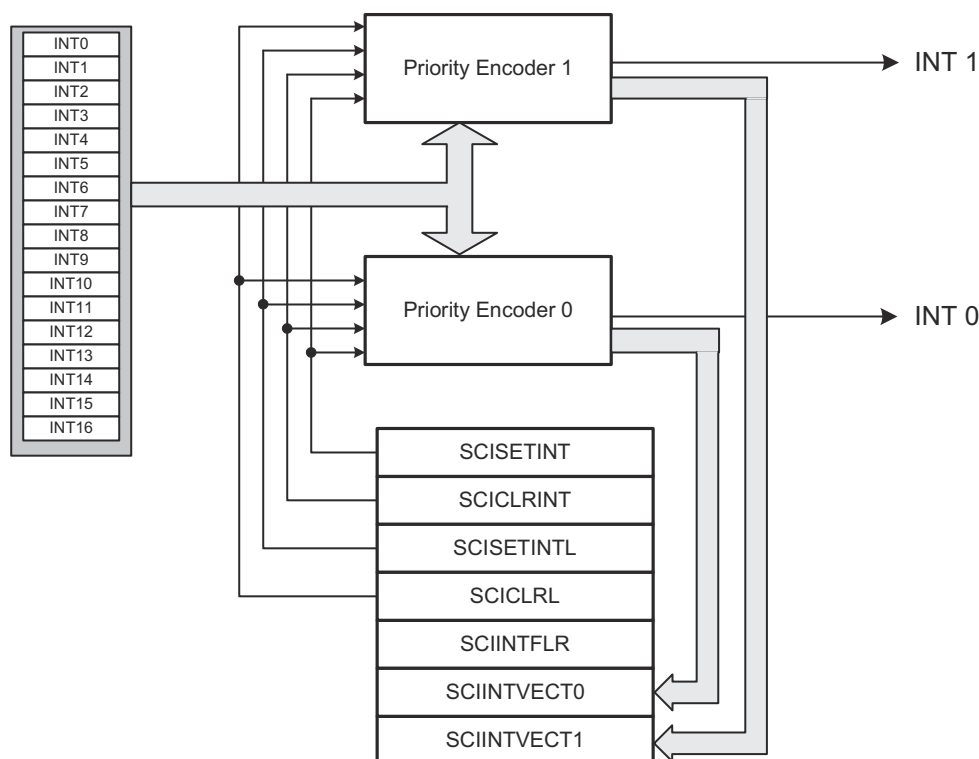

Figure 37-9. Transmit Buffers

### 37.2.2 SCI Interrupts

The SCI/LIN module has two interrupt lines, level 0 and level 1, to the vectored interrupt manager (VIM) module (see [Figure 37-10](#)). Two offset registers SCIINTVECT0 and SCIINTVECT1 determine which flag triggered the interrupt according to the respective priority encoders. Each interrupt condition has a bit to enable/disable the interrupt in the SCISSETINT and SCICLRINT registers, respectively.

Each interrupt also has a bit that can be set as interrupt level 0 (INT0) or as interrupt level 1 (INT1). By default, interrupts are in interrupt level 0. SCISSETINTLVL sets a given interrupt to level 1. SCICLEARINTLVL resets a given interrupt level to the default level 0.

The interrupt vector registers SCIINTVECT0 and SCIINTVECT1 return the vector of the pending interrupt line INT0 or INT1. If more than one interrupt is pending, the interrupt vector register holds the highest priority interrupt.

**Figure 37-10. General Interrupt Scheme**

Figure 37-11. Interrupt Generation for Given Flags

### 37.2.2.1 Transmit Interrupt

To use transmit interrupt functionality, SETTXINT bit must be enabled and SET\_TX\_DMA bit must be cleared in the SCISSETINT register. The transmit ready (TXRDY) flag is set when the SCI transfers the contents of SCITD/TDy to the shift register, SCITXSHF. The TXRDY flag indicates that SCITD/TDy is ready to be loaded with more data. In addition, the SCI sets the TX EMPTY bit if both the SCITD/TDy and SCITXSHF registers are empty. If the SETTXINT bit is set, then a transmit interrupt is generated when the TXRDY flag goes high. The transmit interrupt is not generated immediately after setting the SETTXINT bit unlike the transmit DMA request. The transmit interrupt is generated only after the first transfer from SCITD/TDy to SCITXSHF, that is first data has to be written to SCITD/TDy before any interrupt gets generated. To transmit further data, data can be written to SCITD/TDy in the transmit interrupt service routine.

Writing data to the SCITD/TDy register clears the TXRDY bit. When this data has been moved to the SCITXSHF register, the TXRDY bit is set again. The interrupt request can be suspended by setting the CLRTXINT bit in the SCICLEARINT register; however, when the SETTXINT bit is again set to 1, the TXRDY interrupt is asserted again. The transmit interrupt request can be eliminated until the next series of values is written to SCITD/TDy, by disabling the transmitter using the TXENA bit, by a software reset SWnRST, or by a device hardware reset.

### 37.2.2.2 Receive Interrupt

The receive ready (RXRDY) flag is set when the SCI transfers newly received data from SCIRXSHF to SCIRD/RDy. The RXRDY flag therefore indicates that the SCI has new data to be read. Receive interrupts are enabled by the SETRXINT bit in the SCISSETINT register. If the SETRXINT is set when the SCI sets the RXRDY flag, then a receive interrupt is generated. The received data can be read in the Interrupt Service routine.

On a device with a DMA controller, the SET\_RX\_DMA bit in the SCISSETINT register must be cleared to select interrupt functionality.

### 37.2.2.3 WakeUp Interrupt

SCI sets the WAKEUP flag if bus activity on the RX line either prevents power-down mode from being entered, or RX line activity causes an exit from power-down mode. If enabled (SCISSETINT.SETWAKEUPINT is set), the wakeup interrupt is triggered once the WAKEUP flag in the SCIFLR register is set.

### 37.2.2.4 Error Interrupts

The following error detections are supported with an interrupt by the SCI module:

- Parity errors (PE)
- Frame errors (FE)
- Break Detect errors (BRKDT)
- Overrun errors (OE)
- Bit errors (BE)

There are 16 interrupt sources in the SCI/LIN module. In SCI mode, 8 interrupts are supported, as listed in [Table 37-5](#).

If all of these errors (PE, FE, BRKDT, OE, BE) are flagged, an interrupt for the flagged errors is generated if enabled. A message is valid for both the transmitter and the receiver, if there is no error detected until the end of the frame. Each of these flags is located in the receiver status (SCIFLR) register ([Table 37-6](#) and [Table 37-7](#)).

**Table 37-5. SCI/LIN Interrupts**

Offset <sup>(1)</sup>	Interrupt	Applicable to SCI	Applicable to LIN
0	No interrupt	-	-
1	Wakeup	Yes	Yes
2	Inconsistent-sync-field error (ISFE)	No	Yes
3	Parity error (PE)	Yes	Yes
4	ID	No	Yes
5	Physical bus error (PBE)	No	Yes
6	Frame error (FE)	Yes	Yes
7	Break detect (BRKDT)	Yes	No
8	Checksum error (CE)	No	Yes
9	Overrun error (OE)	Yes	Yes
10	Bit error (BE)	Yes	Yes
11	Receive	Yes	Yes
12	Transmit	Yes	Yes
13	No-response error (NRE)	No	Yes
14	Timeout after wakeup signal (150ms)	No	Yes
15	Timeout after three wakeup signals (1.5s)	No	Yes
16	Timeout (Bus Idle, 4s)	No	Yes

(1) Offset 1 is the highest priority. Offset 16 is the lowest priority.

**Table 37-6. SCI Receiver Status Flags**

SCI Flag	Register	Bit	Value After Reset <sup>(1)</sup>
CE	SCIFLR	29	0
ISFE	SCIFLR	28	0
NRE	SCIFLR	27	0
FE	SCIFLR	26	0
OE	SCIFLR	25	0
PE	SCIFLR	24	0
RXWAKE	SCIFLR	12	0
RXRDY	SCIFLR	9	0
BUSY	SCIFLR	3	0
IDLE	SCIFLR	2	1
WAKEUP	SCIFLR	1	0
BRKDT	SCIFLR	0	0

(1) The flags are frozen with the reset value while SWnRST = 0.

**Table 37-7. SCI Transmitter Status Flags**

SCI Flag	Register	Bit	Value After Reset <sup>(1)</sup>
BE	SCIFLR	31	0
PBE	SCIFLR	30	0
TXWAKE	SCIFLR	10	0
TXEMPTY	SCIFLR	11	1
TXRDY	SCIFLR	8	1

(1) The flags are frozen with the reset value while SWnRST = 0.

### 37.2.3 SCI DMA Interface

DMA requests for receive (RXDMA request) and transmit (TXDMA request) are available for the SCI/LIN module. The DMA must be configured to transfer to/from the SCITD/SCIRD register if multibuffer mode is disabled (MБУFMODE in the SCIGCR1 register is cleared), and to/from the TDy/RDy registers if multibuffer mode is enabled (MБУFMODE in the SCIGCR1 register is set.)

#### 37.2.3.1 Receive DMA Requests

This DMA functionality is enabled/disabled by the CPU using the SETRXDMA/CLRRXDMA bits, respectively.

In multibuffered SCI mode with DMA enabled, the receiver loads the RDy buffers for each received character. RXDMA request is triggered once the last character of the programmed number of characters (LENGTH) are received and copied to the corresponding RDy buffer successfully.

If the multibuffer option is disabled, then DMA requests are generated on a byte-per-byte basis.

In multiprocessor mode, the SCI can generate receiver interrupts for address frames and DMA requests for data frames or DMA requests for both. This is controlled by the SET\_RX\_DMA\_ALL bit.

In multiprocessor mode with the SLEEP bit set, no DMA request is generated for received data frames. The software must clear the SLEEP bit before data frames can be received.

#### 37.2.3.2 Transmit DMA Requests

DMA functionality is enabled/disabled by the CPU with SET\_TX\_DMA/CLR\_TX\_DMA bits, respectively.

In multibuffered SCI mode once TXRDY bit is set or after a transmission of programmed number of characters (LENGTH) (up to eight data bytes stored in the transmit buffers (TDy) in the LINTD0 and LINTD1 registers), a DMA request is generated to reload the transmit buffer for the next transmission. If the multibuffer option is disabled, then DMA requests are generated on a byte-per-byte basis.

### 37.2.4 SCI Configurations

Before the SCI sends or receives data, the SCI registers can be properly configured. Upon power-up or a system-level reset, each bit in the SCI registers is set to a default state. The registers are writable only after the RESET bit in the SCIGCR0 register is set to 1. Of particular importance is the SWnRST bit in the SCIGCR1 register. The SWnRST is an active-low bit initialized to 0 and keeps the SCI in a reset state until the bit is programmed to 1. Therefore, all SCI configuration can be completed before a 1 is written to the SWnRST bit.

The following list details the configuration steps that software can perform prior to the transmission or reception of data. As long as the SWnRST bit is cleared to 0 the entire time that the SCI is being configured, the order in which the registers are programmed is not important.

- Enable SCI by setting the RESET bit to 1.
- Clear the SWnRST bit to 0 before SCI is configured.
- Select the desired frame format by programming the SCIGCR1 register.
- Set both the RX FUNC and TX FUNC bits in SCIPIO0 to 1 to configure the LINRX and LINTX pins for SCI functionality.
- Select the baud rate to be used for communication by programming the BRS register.
- Set the CLOCK bit in SCIGCR1 to 1 to select the internal clock.
- Set the CONT bit in SCIGCR1 to 1 to make SCI not halt for an emulation breakpoint until the current reception or transmission is complete (this bit is used only in an emulation environment).
- Set the LOOP BACK bit in SCIGCR1 to 1 to connect the transmitter to the receiver internally (this feature is used to perform a self-test).
- Set the RXENA bit in SCIGCR1 to 1, if data is to be received.
- Set the TXENA bit in SCIGCR1 to 1, if data is to be transmitted.
- Set the SWnRST bit to 1 after SCI is configured.
- Perform receiving or transmitting data (see [Section 37.2.4.1](#) or [Section 37.2.4.2](#)).

#### 37.2.4.1 Receiving Data

The SCI receiver is enabled to receive messages, if both the RX FUNC bit and the RXENA bit are set to 1. If the RX FUNC bit is not set, the LINRX pin functions as a general-purpose I/O pin rather than as an SCI function pin.

SCI module can receive data in one of the following modes:

- Single-Buffer (Normal) Mode
- Multibuffer Mode

After a valid idle period is detected, data is automatically received as the data arrives on the LINRX pin.

##### 37.2.4.1.1 Receiving Data in Single-Buffer Mode

Single-buffer mode is selected when the MBUFMODE bit in SCIGCR1 is cleared to 0. In this mode, SCI sets the RXRDY bit when the SCI transfers newly received data from SCIRXSHF to SCIRD. The RXRDY bit is cleared after the new data in SCIRD has been read. Also, as data is transferred from SCIRXSHF to SCIRD, the FE, OE, or PE flags are set if any of these error conditions were detected in the received data. These error conditions are supported with configurable interrupt capability. The wakeup and break-detect status bits are also set if one of these errors occurs, but the bits do not necessarily occur at the same time that new data is being loaded into SCIRD.

You can receive data by:

1. Polling the Receive Ready Flag
2. Receive Interrupt
3. DMA

In polling method, software can poll for the RXRDY bit and read the data from the SCIRD register once the RXRDY bit is set high. The CPU is unnecessarily overloaded by selecting the polling method. To avoid this, you can use either the interrupt or DMA method. To use the interrupt method, set the SETRXINT bit. To use the DMA method, set the SET\_RX\_DMA bit. Either an interrupt or a DMA request is generated the moment the RXRDY bit is set.

#### 37.2.4.1.2 Receiving Data in Multibuffer Mode

Multibuffer mode is selected when the MBUFMODE bit in SCIGCR1 is set to 1. In this mode, SCI sets the RXRDY bit after receiving the programmed number of data in the receive buffer, the complete frame. The error condition detection logic is similar to the single-buffer mode, except that this logic monitors for the complete frame. Like single-buffer mode, use the polling, DMA, or interrupt method to read the data. The RXRDY bit is automatically cleared after the new data in SCIRD has been read.

#### 37.2.4.2 Transmitting Data

The SCI transmitter is enabled if both the TXFUNC bit and the TXENA bit are set to 1. If the TXFUNC bit is not set, the LINTX pin functions as a general-purpose I/O pin rather than as an SCI function pin. Any value written to the SCITD/TDy before TXENA is set to 1 is not transmitted. Both of these control bits allow for the SCI transmitter to be held inactive independently of the receiver.

The SCI module can transmit data in one of the following modes:

- Single-Buffer (Normal) Mode
- Multibuffered or Buffered SCI Mode

##### 37.2.4.2.1 Transmitting Data in Single-Buffer Mode

Single-buffer mode is selected when the MBUFMODE bit in SCIGCR1 is cleared to 0. In this mode, the SCI waits for data to be written to SCITD, transfers the data to SCITXSHF, and transmits the data. The TXRDY and TXEMPTY bits indicate the status of the transmit buffers. That is, when the transmitter is ready for data to be written to SCITD, the TXRDY bit is set. Additionally, if both SCITD and SCITXSHF are empty, then the TXEMPTY bit is also set.

You can transmit data by:

1. Polling the Transmit Ready Flag
2. Transmit Interrupt
3. DMA

With the polling method, software can poll for the TXRDY bit to go high before writing the data to the SCITD register. The CPU is unnecessarily overloaded by selecting the polling method. To avoid this, you can use the interrupt or DMA method. To use the interrupt method, the SETTXINT bit is set. To use the DMA method, the SET\_TX\_DMA bit is set. Either an interrupt or a DMA request is generated the moment the TXRDY bit is set. When the SCI has completed transmission of all pending frames, the SCITXSHF register and SCITD are empty, the TXRDY bit is set, and an interrupt/DMA request is generated, if enabled. Because all data has been transmitted, the interrupt/DMA request must be halted. This can either be done by disabling the transmit interrupt (CLRTXINT) / DMA request (CLRTXDMA bit), or by disabling the transmitter (clear TXENA bit).

---

#### Note

The TXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0 or SCIINTVECT1 register.

---

##### 37.2.4.2.2 Transmitting Data in Multibuffer Mode

Multibuffer mode is selected when the MBUFMODE bit in SCIGCR1 is set to 1. Like single-buffer mode, you can use the polling, DMA, or interrupt method to write the data to be transmitted. The transmitted data has to be written to the SCITD registers. The SCI waits for data to be written to the SCITD register and then transfers the programmed number of bytes to SCITXSHF to transmit one by one automatically.

### 37.2.5 SCI Low-Power Mode

The SCI/LIN can be put in either local or global low-power mode. Global low-power mode is asserted by the system and is not controlled by the SCI/LIN. During global low-power mode, all clocks to the SCI/LIN are turned off so the module is completely inactive.

Local low-power mode is asserted by setting the POWERDOWN bit; setting this bit stops the clocks to the SCI/LIN internal logic and the module registers. Setting the POWERDOWN bit causes the SCI to enter local low-power mode and clearing the POWERDOWN bit causes SCI/LIN to exit from local low-power mode. All the registers are accessible during local power-down mode as any register access enables the clock to SCI for that particular access alone.

The wakeup interrupt is used to allow the SCI to exit low-power mode automatically when a low level is detected on the LINRX pin and also this clears the POWERDOWN bit. If wakeup interrupt is disabled, then the SCI/LIN immediately enters low-power mode whenever it is requested and also any activity on the LINRX pin does not cause the SCI to exit low-power mode.

---

#### Note

##### Enabling Local Low-Power Mode During Receive and Transmit

If the wakeup interrupt is enabled and low-power mode is requested while the receiver is receiving data, then the SCI immediately generates a wakeup interrupt to clear the powerdown bit and prevents the SCI from entering low-power mode and thus completes the current reception. Otherwise, if the wakeup interrupt is disabled, then the SCI completes the current reception and then enters the low-power mode.

---

#### 37.2.5.1 Sleep Mode for Multiprocessor Communication

When the SCI receives data and transfers that data from SCIRXSHF to SCIRD, the RXRDY bit is set and if SETRXINT is set, the SCI also generates an interrupt. The interrupt triggers the CPU to read the newly received frame before another one is received. In multiprocessor communication modes, this default behavior can be enhanced to provide selective indication of new data. When the SCI receives an address frame that does not match the address, the device can ignore the data following this non-matching address until the next address frame by using sleep mode. Sleep mode can be used with both idle-line and address-bit multiprocessor modes.

If sleep mode is enabled by the SLEEP bit, then the SCI transfers data from SCIRXSHF to SCIRD only for address frames. Therefore, in sleep mode, all data frames are assembled in the SCIRXSHF register without being shifted into the SCIRD and without initiating a receive interrupt or DMA request. Upon reception of an address frame, the contents of the SCIRXSHF are moved into SCIRD, and the software must read SCIRD and determine if the SCI is being addressed by comparing the received address against the address previously set in the software and stored somewhere in memory (the SCI does not have hardware available for address comparison). If the SCI is being addressed, the software must clear the SLEEP bit so that the SCI loads SCIRD with the data of the data frames that follow the address frame.

When the SCI has been addressed and sleep mode has been disabled (in software) to allow the receipt of data, the SCI can check the RXWAKE bit (SCIFLR.12) to determine when the next address has been received. The bit is set to 1, if the current value in SCIRD is an address; the bit is set to 0, if SCIRD contains data. If the RXWAKE bit is set, then software can check the address in SCIRD against the address. If SCIRD is still being addressed, then sleep mode can remain disabled; otherwise, the SLEEP bit can be set again.

Following is a sequence of events typical of sleep mode operation:

- The SCI is configured and both sleep mode and receive actions are enabled.
- An address frame is received and a receive interrupt is generated.
- Software compares the received address frame against that set by software and determines that the SCI is not being addressed, so the value of the SLEEP bit is not changed.
- Several data frames are shifted into SCIRXSHF, but no data is moved to SCIRD and no receive interrupts are generated.
- A new address frame is received and a receive interrupt is generated.
- Software compares the received address frame against that set by software and determines that the SCI is being addressed and clears the SLEEP bit.
- Data shifted into SCIRXSHF is transferred to SCIRD, and a receive interrupt is generated after each data frame is received.
- In each interrupt routine, software checks RXWAKE to determine if the current frame is an address frame.
- Another address frame is received, RXWAKE is set, software determines that the SCI is not being addressed and sets the SLEEP bit back to 1. No receive interrupts are generated for the data frames following this address frame.

By ignoring data frames that are not intended for the device, fewer interrupts are generated. Otherwise, these interrupts require CPU intervention to read data that is of no significance to this specific device. Using sleep mode can help free some CPU resources.

Except for the RXRDY flag, the SCI continues to update the receiver status flags (see [Table 37-6](#)) while sleep mode is active. In this way, if an error occurs on the receive line, an application can immediately respond to the error and take the appropriate corrective action.

Because the RXRDY bit is not updated for data frames when sleep mode is enabled, the SCI can enable sleep mode and use a polling algorithm if desired. In this case, when RXRDY is set, software knows that a new address has been received. If the SCI is not being addressed, then the software can not change the value of the SLEEP bit and can continue to poll RXRDY.

## 37.3 Local Interconnect Network Module

### 37.3.1 LIN Communication Formats

The SCI/LIN module can be used in LIN mode or SCI mode. The enhancements for baud generation, DMA controls, and additional receive/transmit buffers necessary for LIN mode operation are also part of the enhanced buffered SCI module. LIN mode is selected by enabling the LINMODE bit in SCIGCR1 register.

---

#### Note

The SCI/LIN is built around the SCI platform and uses a similar sampling scheme: 16 samples for each bit with majority vote on samples 8, 9, and 10. For the START bit, the first three samples are used.

---

The SCI/LIN control registers are located at the SCI/LIN base address. For a detailed description of each register, see [Section 37.7](#).

#### 37.3.1.1 LIN Standards

For compatibility with LIN2.0 standard the following additional features are implemented over LIN1.3:

1. Support for LIN 2.0 checksum
2. Enhanced synchronizer FSM support for frame processing
3. Enhanced handling of extended frames
4. Enhanced baud rate generator
5. Update wakeup/go to sleep

The LIN module covers the CPU performance-consuming features, defined in the *LIN Specification Package* Revision 1.3 and 2.0 by hardware. The Commander Mode of LIN module is compatible with LIN 2.1 standard.

### 37.3.1.2 Message Frame

The LIN protocol defines a message frame format, shown in Figure 37-12. Each frame includes one commander header, one response, one in-frame response space, and inter-byte spaces. In-frame-response and inter-byte spaces can be 0.

There is no arbitration in the definition of the LIN protocol; therefore, multiple responder nodes responding to a header can be detected as an error.

The LIN bus is a single-channel wired-AND bus. The bus has a binary level: either dominant for a value of 0 or recessive for a value of 1.

Figure 37-12. LIN Protocol Message Frame Format: Commander Header and Responder Peripheral Response

#### 37.3.1.2.1 Message Header

The header of a message is initiated by a commander (see Figure 37-13) and consists of a three field-sequence:

- The synchronization break field signaling the beginning of a message
- The synchronization field conveying bit rate information of the LIN bus
- The identification field denoting the content of a message

Figure 37-13. Header 3 Fields: Synch Break, Synch, and ID

### 37.3.1.2.2 Response

The format of the response is as illustrated in [Figure 37-14](#). There are two types of fields in a response: data and checksum. The data field consists of exactly one data byte, one start bit, and one stop bit, for a total of 10 bits. The LSB is transmitted first. The checksum field consists of one checksum byte, one start bit and one stop bit. The checksum byte is the inverted modulo-256 sum over all data bytes in the data fields of the response.

**Figure 37-14. Response Format of LIN Message Frame**

The format of the response is a stream of N data fields and one checksum field. Typically N is from 1 to 8, with the exception of the extended command frames ([Section 37.3.1.6](#)). The length N of the response is indicated either with the optional length control bits of the ID Field (this is used in standards earlier than LIN 1.x); see [Table 37-8](#), or by LENGTH value in SCIFORMAT[18:16] register; see [Table 37-9](#). The SCI/LIN module supports response lengths from 1 to 8 bytes in compliance with LIN 2.0.

**Table 37-8. Response Length Info Using IDBYTE Field Bits [5:4] for LIN Standards Earlier than v1.3**

ID5	ID4	Number of Data Bytes
0	0	2
0	1	2
1	0	4
1	1	8

**Table 37-9. Response Length with SCIFORMAT[18:16] Programming**

SCIFORMAT[18:16]	Number of Bytes
000	1
001	2
010	3
011	4
100	5
101	6
110	7
111	8

### 37.3.1.3 Synchronizer

The synchronizer has three major functions in the messaging between commander and responder nodes. The synchronizer generates the commander header data stream, the synchronizer synchronizes to the LIN bus for responding, and the synchronizer locally detects timeouts. A bit rate is programmed using the prescalers in the BRSR register to match the indicated LIN\_speed value in the LIN description file.

The LIN synchronizer performs the following functions: commander header signal generation, responder detection and synchronization to message header with optional baud rate adjustment, response transmission timing and timeout control.

The LIN synchronizer is capable of detecting an incoming break and initializing communication at all times.

### 37.3.1.4 Baud Rate

The transmission baud rate of any node is configured by the CPU at the beginning; this defines the bit time  $T_{bit}$ . The bit time is derived from the fields P and M in the baud rate selection register (BRSR). There is an additional 3-bit fractional divider value, field U in the BRSR register, which further fine-tunes the data-field baud rate.

The ranges for the prescaler values in the BRSR register are:

$$P = 0, 1, 2, 3, \dots, 2^{24} - 1$$

$$M = 0, 1, 2, \dots, 15$$

$$U = 0, 1, 2, 3, 4, 5, 6, 7$$

The P, M, and U values in the BRSR register are user programmable. The P and M dividers can be used for both SCI mode and LIN mode to select a baud rate. The U value is an additional 3-bit value determining that “ $a T_{VCLK}$ ” (with  $a = 0, 1$ ) is added to each  $T_{bit}$  as explained in [Section 37.3.1.4.2](#). If the ADAPT bit is set and the LIN peripheral is in adaptive baud rate mode, then all these divider values are automatically obtained during header reception when the synchronization field is measured.

The LIN protocol defines baud rate boundaries as:

$$1\text{kHz} \leq F_{LINCLK} \leq 20\text{kHz}$$

All transmitted bits are shifted in and out at  $T_{bit}$  periods.

#### 37.3.1.4.1 Fractional Divider

The M field of the BRSR register modifies the integer prescaler P for fine tuning of the baud rate. The M value adds in increments of 1/16 of the P value.

The bit time,  $T_{bit}$  is expressed in terms of the VCLK period  $T_{VCLK}$  as follows:

For all P other than 0, and all M,

$$T_{bit} = 16 \left( P + 1 + \frac{M}{16} \right) T_{VCLK}$$

For  $P = 0$  :  $T_{bit} = 32T_{VCLK}$

Therefore, the LINCLK frequency is given by:

$$F_{\text{LINCLK}} = \frac{F_{\text{VCLK}}}{16(P+1 + \frac{M}{16})} \quad \text{For all } P \text{ other than zero}$$

$$F_{\text{LINCLK}} = \frac{F_{\text{VCLK}}}{32} \quad \text{For } P = 0$$

### 37.3.1.4.2 Superfractional Divider

The superfractional divider scheme applies to the following modes:

- LIN commander mode (sync field + identifier field + response field + checksum field)
- LIN responder mode (response field + checksum field)

#### 37.3.1.4.2.1 Superfractional Divider In LIN Mode

Building on the 4-bit fractional divider M (BRSR[27:24], the superfractional divider uses an additional 3-bit modulating value, illustrated in [Table 37-10](#). The sync field (0x55), the identifier field, and the response field can all be seen as 8-bit data bytes flanked by a start bit and a stop bit. The bits with a 1 in the table have an additional VCLK period added to the  $T_{\text{bit}}$ . In LIN commander mode, bit modulation applies to sync field + identifier field + response field. In LIN responder mode, bit modulation applies to identifier field + response field.

**Table 37-10. Superfractional Bit Modulation for LIN Commander Mode and Responder Mode**

BRSR[30:28]	Start Bit	D[0]	D[1]	D[2]	D[3]	D[4]	D[5]	D[6]	D[7]	Stop Bit
0h	0	0	0	0	0	0	0	0	0	0
1h	1	0	0	0	0	0	0	0	1	0
2h	1	0	0	0	1	0	0	0	1	0
3h	1	0	1	0	1	0	0	0	1	0
4h	1	0	1	0	1	0	1	0	1	0
5h	1	1	1	0	1	0	1	0	1	1
6h	1	1	1	0	1	1	1	0	1	1
7h	1	1	1	1	1	1	1	0	1	1

The baud rate varies over a LIN data field to average according to the BRSR[30:28] value by a  $d$  fraction of the peripheral internal clock:  $0 < d < 1$ .

The instantaneous bit time is expressed in terms of  $T_{\text{VCLK}}$  as follows:

For all  $P$  other than 0, and all  $M$  and  $d$  (0 or 1),

$$T^{\text{bit}} = \left[ 16 \left( P + 1 + \frac{M}{16} \right) + d \right] T_{\text{VCLK}}$$

For  $P = 0$ ,  $T_{\text{bit}} = 32T_{\text{VCLK}}$

The averaged bit time is expressed in terms of  $T_{VCLK}$  as follows:

For all  $P$  other than 0, and all  $M$  and  $d$  ( $0 < d < 1$ ),

$$T^{a}bit = \left[ 16 \left( P + 1 + \frac{M}{16} \right) + d \right] T_{VCLK}$$

For  $P = 0$ ,  $T_{bit} = 32T_{VCLK}$

### 37.3.1.5 Header Generation

Automatic generation of the LIN protocol header data stream is supported without CPU interaction. The CPU or the DMA triggers the LIN state machine to generate a message header. A commander node initiates header generation on the CPU or DMA writes to the IDBYTE in the LINID register. The header is always sent by the commander to initiate a LIN communication and consists of three fields: synchronization break field, synchronization field, and identification field, as seen in [Figure 37-15](#).

#### Note

The LIN protocol uses the parity bits in the identifier. The control length bits are optional to the LIN protocol.

**Figure 37-15. Message Header in Terms of  $T_{bit}$**

- The break field consists of two components:
  - The synchronization break (SYNCH BREAK) consists of a minimum of 13 (dominant) low bits to a maximum of 20 dominant bits. The sync break length can be extended from the minimum with the 3-bit SBREAK value in the LINCOMP register.
  - The synchronization break delimiter (SDEL) consists of a minimum of 1 (recessive) high bit to a maximum of 4 recessive bits. The delimiter marks the end of the synchronization break field. The sync break delimiter length depends on the 2-bit SDEL value in the LINCOMP register.
- The synchronization field (SYNCH FIELD) consists of one start bit, byte 0x55, and a stop bit. SYNCH FIELD is used to convey  $T_{bit}$  information and resynchronize LIN bus nodes.
- The identifier field ID byte can use 6 bits as an identifier, with optional length control and two optional bits as parity of the identifier. The identifier parity is used and checked if the PARITYENA bit is set. If length control bits are not used, then there can be a total of 64 identifiers plus parity. If neither length control or parity are used there can be up to 256 identifiers. See [Figure 37-16](#) for an illustration of the ID field.

**Note**
**Optional Control Length Bits**

The control length bits only apply to LIN standards prior to LIN 1.3. IDBYTE field conveys response length information if compliant to standards earlier than LIN1.3. The SCIFORMAT register stores the length of the response for later versions of the LIN protocol.

**Figure 37-16. ID Field**
**Note**

If the LIN module, configured as a responder in multibuffer mode, is in the process of transmitting data while a new header comes in, the module can end up responding with the data from the previous interrupted response (not the data corresponding to the new ID). To avoid this scenario, the following procedure can be used:

1. Check for the Bit Error (BE) during the response transmission. If the BE flag is set, this indicates that a collision has happened on the LIN bus (here because of the new Synch Break).
2. In the Bit Error ISR, configure the TD0 and TD1 registers with the next set of data to be transmitted on a TX Match for the incoming ID. Before writing to TD0/TD1 make sure that there was not already an update because of a Bit Error; otherwise, TD0/TD1 can be written twice for one ID.
3. Once the complete ID is received, based on the match, the newly configured data is transmitted by the node.

### 37.3.1.5.1 Event Triggered Frame Handling

The LIN 2.0 protocol uses event-triggered frames that can occasionally cause collisions. Event-triggered frames are handled in software.

If no responder answers to an event triggered frame header, the commander node sets the NRE flag, and a NRE interrupt occurs if enabled. If a collision occurs, a frame error and checksum error can arise before the NRE error. Those errors are flagged and the appropriate interrupts occur, if enabled.

Frame errors and checksum errors depend on the behavior and synchronization of the responding responders. If the responders are totally synchronized and stop transmission once the collision occurred, it is possible that only the NRE error is flagged despite the occurrence of a collision. To detect if there has been a reception of one byte before the NRE error is flagged, the BUS BUSY flag can be used as an indicator.

The BUS BUSY flag is set on the reception of the first bit of the header and remains set until the header reception is complete, and again is set on the reception of the first bit of the response. In the case of a collision, the flag is cleared in the same cycle as the NRE flag is set.

Software can implement the following sequence:

- Once the reception of the header is done (poll for RXID flag), wait for the BUS BUSY flag to get set or the NRE flag to get set.
- If the BUS BUSY flag is not set before the NRE flag, then a true no response is the case (no data has been transmitted onto the bus).
- If the BUS BUSY flag gets set, then wait for the NRE flag to get set or for successful reception. If the NRE flag is set, then a collision has occurred on the bus.

Even in the case of a collision, the received (corrupted) data is accessible in the RX buffers; registers LINRD0 and LINRD1.

### 37.3.1.5.2 Header Reception and Adaptive Baud Rate

A responder node baud rate can optionally be adjusted to the detected bit rate as an option to the LIN module. The adaptive baud rate option is enabled by setting the ADAPT bit. During header reception, a responder measures the baud rate during detection of the synch field. If ADAPT bit is set, then the measured baud rate is compared to the responder node programmed baud rate and adjusted to the LIN bus baud rate if necessary.

The responder node adjusts to any measured baud rate that is within  $\pm 10\%$  of the programmed baud rate. For example, if the expected baud rate is programmed at 20kbps, the responder node detects any baud rate between 18kbps and 22kbps and adjusts accordingly. The MBRSR register prescaler is determined by the following formula:

$$MBR = \frac{F_{VCLK}}{1.1 \times F_{LINCLK}}$$

The LIN synchronizer determines two measurements: BRK\_count and BAUD\_count ([Figure 37-17](#)). These values are always calculated during the Header reception for synch field validation ([Figure 37-18](#)).

**Figure 37-17. Measurements for Synchronization**

By measuring the values BRK\_count and BAUD\_count, a valid sync break sequence can be detected as described in [Figure 37-18](#). The four numbered events in [Figure 37-17](#) signal the start/stop of the synchronizer counter. The synchronizer counter uses VCLK as the time base.

The synchronizer counter is used to measure the sync break relative to the detecting node  $T_{bit}$ . For a responder node receiving the sync break, a threshold of  $11 T_{bit}$  is used as required by the LIN protocol. For detection of the dominant data stream of the sync break, the synchronizer counter is started on a falling edge and stopped on a rising edge of the LINRX. On detection of the sync break delimiter, the synchronizer counter value is saved and then reset.

On detection of five consecutive falling edges, the BAUD\_count is measured. Bit timing calculation and consistency to required accuracy is implemented following the recommendations of LIN revision 2.0. A responder node can calculate a single  $T_{bit}$  time by division of BAUD\_count by 8. In addition, for consistency between the detected edges the following is evaluated:

$$BAUD\_count + BAUD\_count \gg 2 + BAUD\_count \gg 3 \leq BRK\_count$$

The BAUD\_count value is shifted 3 times to the right and rounded using the first insignificant bit to obtain a  $T_{bit}$  unit. If the ADAPT bit is set, then the detected baud rate is compared to the programmed baud rate.

During the header reception processing as illustrated in [Figure 37-18](#), if the measured BRK\_count value is less than  $11 T_{bit}$ , the sync break is not valid according to the protocol for a fixed rate. If the ADAPT bit is set, then the MBRS register is used for measuring BRK\_count and BAUD\_count values and automatically adjusts to any allowed LIN bus rate (refer to *LIN Specification Package 2.0*).

#### Note

In adaptive mode, the MBRS divider can be set to allow a maximum baud rate that is not more than 10% above the expected operating baud rate in the LIN network. Otherwise, a 0x00 data byte can mistakenly be detected as a sync break.

The break-threshold relative to the responder node is  $11 T_{bit}$ . The break is  $13 T_{bit}$  as specified in LIN v1.3.

Figure 37-18. Synchronization Validation Process and Baud Rate Adjustment

If the synch field is not detected within the given tolerances, the inconsistent-sync-field-error (ISFE) flag is set. An ISFE interrupt is generated, if enabled by the respective bit in the SCISSETINT register. The ID byte can be received after the synch field validation was successful. Any time a valid break (larger than  $11 T_{bit}$ ) is detected, the receiver state machine can reset to reception of this new frame. This reset condition is only valid during response state, not if an additional synch break occurs during header reception.

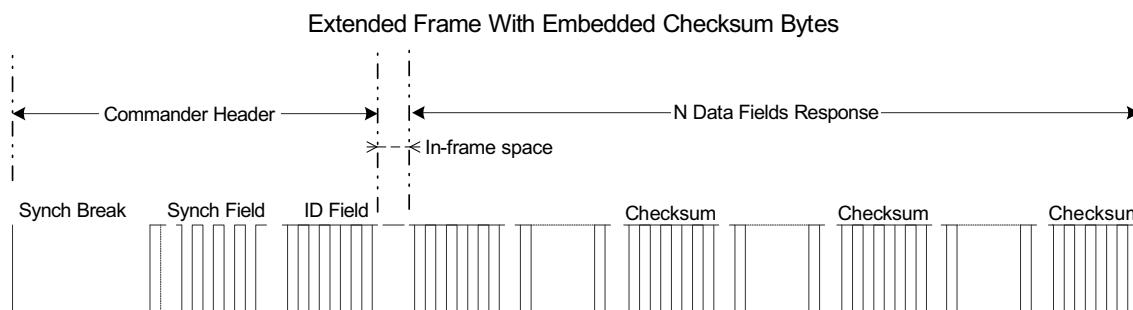

#### Note

When an inconsistent synch field (ISFE) error occurs, suggested action for the application is to reset the SWnRST bit and set the SWnRST bit to make sure that the internal state machines are back to the normal states.

### 37.3.1.6 Extended Frames Handling

The LIN protocol 2.0 and prior includes two extended frames with identifiers 62 (user-defined) and 63 (reserved extended). The response data length of the user-defined frame (ID 62, or 0x3E) is unlimited. The length for this identifier is set at network configuration time to be shared with the LIN bus nodes.

Extended frame communication is triggered on reception of a header with identifier 0x3E; see [Figure 37-19](#). Once the extended frame communication is triggered, unlike normal frames, this communication needs to be stopped before issuing another header. To stop the extended frame communication the STOP EXT FRAME bit must be set.

**Figure 37-19. Optional Embedded Checksum in Response for Extended Frames**

An ID interrupt is generated (if enabled and there is a match) on reception of ID 62 (0x3E). This interrupt allows the CPU using a software counter to keep track of the bytes that are being sent out and decides when to calculate and insert a checksum byte (recommended at periodic rates). To handle this procedure, SC bit is used. A write to the send checksum bit SC initiates an automatic send of the checksum byte. The last data field can always be a checksum in compliance with the LIN protocol.

The periodicity of the checksum insertion, defined at network configuration time, is used by the receiving node to evaluate the checksum of the ongoing message, and has the benefit of enhanced reliability.

For the sending node, the checksum is automatically embedded each time the send checksum bit SC is set. For the receiving node, the checksum is compared each time the compare checksum bit CC is set; see [Figure 37-20](#).

#### Note

The LIN 2.0 enhanced checksum does not apply to the reserved identifiers. The reserved identifiers always use the classic checksum.

**Figure 37-20. Checksum Compare and Send for Extended Frames**

### 37.3.1.7 Timeout Control

Any LIN node listening to the bus and expecting a response initiated from a commander node can flag a no-response error timeout event. The LIN protocol defines four types of timeout events, which are all handled by the hardware of the LIN module. The four LIN protocol events are:

- No-response timeout error
- Bus idle detection
- Timeout after wakeup signal
- Timeout after three wakeup signals

#### 37.3.1.7.1 No-Response Error (NRE)

The no-response error occurs when any node expecting a response waits for  $T_{FRAME\_MAX}$  time and the message frame is not fully completed within the maximum length allowed,  $T_{FRAME\_MAX}$ . After this time, a no-response error (NRE) is flagged in the NRE bit of the SCIFLR register. An interrupt is triggered, if enabled.

As specified in the LIN 1.3 standard, the minimum time to transmit a frame is:

$$T_{FRAME\_MIN} = T_{HEADER\_MIN} + T_{DATA\_FIELD} + T_{CHECKSUM\_FIELD} = 44 + 10N$$

where N = number of data fields.

And the maximum time frame is given by:

$$T_{FRAME\_MAX} = T_{FRAME\_MIN} * 1.4 = (44 + 10N) * 1.4$$

The timeout value  $T_{FRAME\_MAX}$  is derived from the N number of data fields value, see [Table 37-11](#). The N value is either embedded in the header ID field for messages or is part of the description file. In the latter case, the 3-bit CHAR value in SCIFORMAT register indicates the value for N.

#### Note

The length coding of the ID field does not apply to two extended frame identifiers, ID fields of 0x3E (62) and 0x3F (63). In these cases, the ID field can be followed by an arbitrary number of data byte fields. Also, the LIN 2.0 protocol specification mentions that ID field 0x3F (63) cannot be used. For these two cases, the NRE is not handled by the LIN hardware.

**Table 37-11. Timeout Values in  $T_{bit}$  Units**

N	$T_{DATA\_FIELD}$	$T_{FRAME\_MIN}$	$T_{FRAME\_MAX}$
1	10	54	76
2	20	64	90
3	30	74	104
4	40	84	118
5	50	94	132
6	60	104	146
7	70	114	160
8	80	124	174

### 37.3.1.7.2 Bus Idle Detection

The second type of timeout can occur when a node detects an inactive LIN bus: no transitions between recessive and dominant values are detected on the bus. This happens after a minimum of 4 seconds (this is 80,000  $F_{LINCLK}$  cycles with the fastest bus rate of 20kbps). If a node detects no activity in the bus as the TIMEOUT bit is set, assume that the LIN bus is in sleep mode. Application software can use the Timeout flag to determine when the LIN bus is inactive and put the LIN into sleep mode by writing the POWERDOWN bit.

#### Note

After the timeout was flagged, a SWnRESET must be asserted before entering Low-Power Mode. This is required to reset the receiver in case that an incomplete frame is on the bus before the idle period.

### 37.3.1.7.3 Timeout After Wakeup Signal and Timeout After Three Wakeup Signals

The third and fourth types of timeout are related to the wakeup signal. A node initiating a wakeup must expect a header from the commander within a defined amount of time: timeout after wakeup signal. See [Section 37.4.3](#) for more details.

### 37.3.1.8 TXRX Error Detector (TED)

The following sources of error are detected by the TXRX error detector logic (TED). The TED logic consists of a bit monitor, an ID parity checker, and a checksum error. The following errors are detected:

- Bit errors (BE)
- Physical bus errors (PBE)
- Identifier parity errors (PE)
- Checksum errors (CE)

All of these errors (BE, PBE, PE, CE) are flagged. An interrupt for the flagged errors is generated if enabled. A message is valid for both the transmitter and the receiver if there is no error detected until the end of the frame.

37.3.1.8.1 Bit Errors

A bit error (BE) is detected at the bit time when the bit value that is monitored is different from the bit value that is sent. A bit error is indicated by the BE flag in SCIFLR. After signaling a BE, the transmission is aborted no later than the next byte. The bit monitor makes sure that the transmitted bit in LINTX is the correct value on the LIN bus by reading back on the LINRX pin as shown in Figure 37-21.

Note

If a bit occurs due to receiving a header during a responder response, NRE/TIMEOUT flag is not set for the new frame.

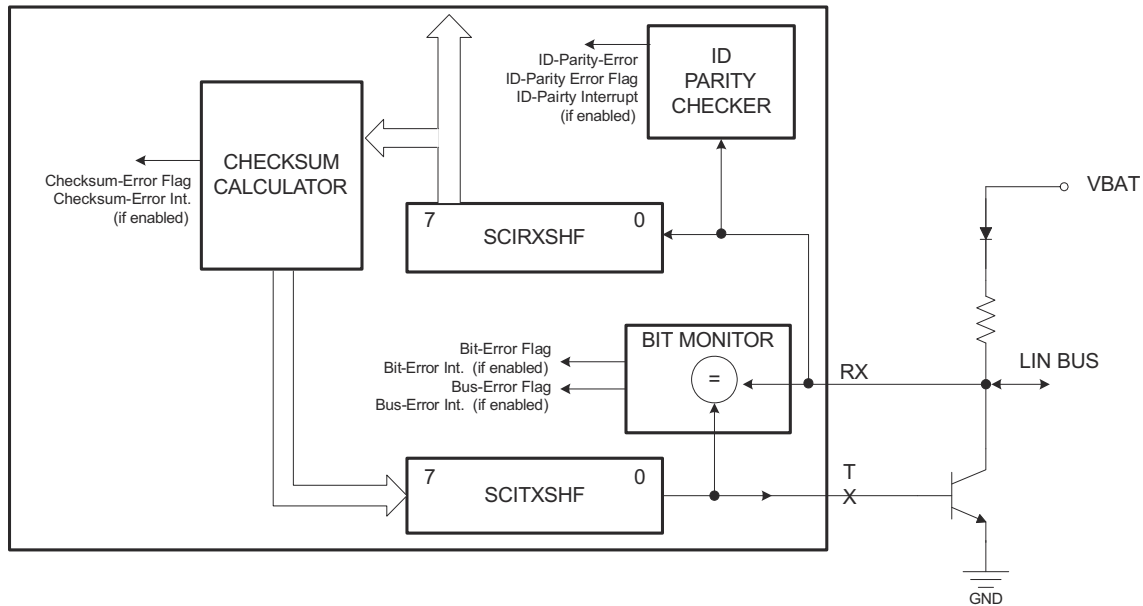

Figure 37-21. TXRX Error Detector

37.3.1.8.2 Physical Bus Errors

A Physical Bus Error (PBE) has to be detected by a commander, if no valid message can be generated on the bus (bus shorted to GND or VBAT). The bit monitor detects a PBE during the header transmission, if no Synch Break can be generated (for example, because of a bus shortage to VBAT) or if no Synch Break delimiter can be generated (for example, because of a bus shortage to GND). Once the Sync Break Delimiter was validated, all other deviations between the monitored and the sent bit value are flagged as Bit Errors (BE) for this frame.

37.3.1.8.3 ID Parity Errors

If parity is enabled, an ID parity error (PE) is detected if any of the two parity bits of the sent ID byte are not equal to the calculated parity on the receiver node. The two parity bits are generated using the following mixed parity algorithm:

$$P0 = ID0 \oplus ID1 \oplus ID2 \oplus ID4 \text{ (even Parity)}$$

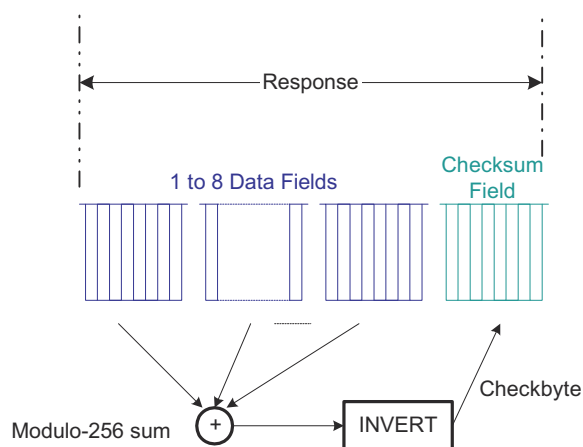

$$P1 = ID1 \oplus ID3 \oplus ID4 \oplus ID5 \text{ (odd Parity)}$$

If an ID-parity error is detected, the ID-parity error is flagged, and the received ID is not valid. See Section 37.3.1.9 for details.

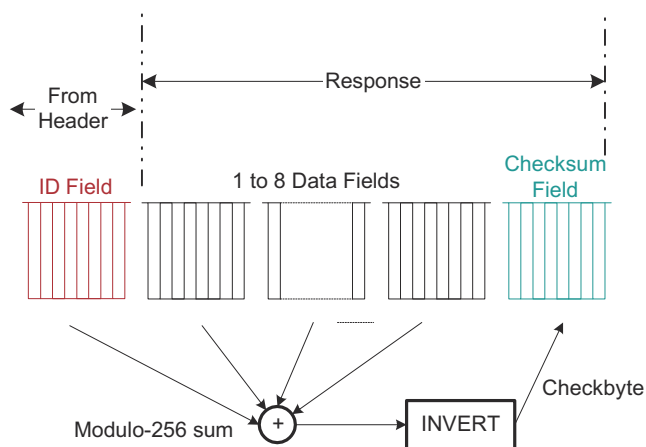

### 37.3.1.8.4 Checksum Errors

A checksum error (CE) is detected and flagged at the receiving end, if the calculated modulo-256 sum over all received data bytes (including the ID byte if the enhanced checksum type) plus the checksum byte does not result in 0xFF. The modulo-256 sum is calculated over each byte by adding with carry, where the carry bit of each addition is added to the LSB of the resulting sum.

For the transmitting node, the checksum byte sent at the end of a message is the inverted sum of all the data bytes (see Figure 37-22) for classic checksum implementation. The checksum byte is the inverted sum of the identifier byte and all the data bytes (see Figure 37-23) for the LIN 2.0 compliant enhanced checksum implementation. The classic checksum implementation can always be used for reserved identifiers 60 to 63; therefore, the CTYPE bit is overridden in this case. For signal-carrying-frame identifiers (0 to 59) the type of checksum used depends on the CTYPE bit.

**Figure 37-22. Classic Checksum Generation at Transmitting Node**

**Figure 37-23. LIN 2.0-Compliant Checksum Generation at Transmitting Node**

### 37.3.1.9 Message Filtering and Validation

Message filtering uses the entire identifier to determine which nodes participate in a response, either receiving or transmitting a response. Therefore, two acceptance masks are used as shown in Figure 37-24. During header reception, all nodes filter the ID-Field (ID-Field is the part of the header explained in Figure 37-16) to determine whether the nodes transmit a response or receive a response for the current message. There are two masks for message ID filtering: one to accept a response reception, the other to initiate a response transmission. See Figure 37-24. All nodes compare the received ID to the identifier stored in the ID-Responder Task BYTE of the LINID register and use the RX ID MASK and the TX ID MASK fields in the LINMASK register to filter the bits of the identifier that can not be compared.

If there is an RX match with no parity error and the RXENA bit is set, there is an ID RX flag and an interrupt is triggered if enabled. If there is a TX match with no parity error and the TXENA bit is set, there is an ID TX flag and an interrupt is triggered if enabled in the SCISSETINT register.

The masked bits become "don't cares" for the comparison. To build a mask for a set of identifiers, an XOR function can be used.

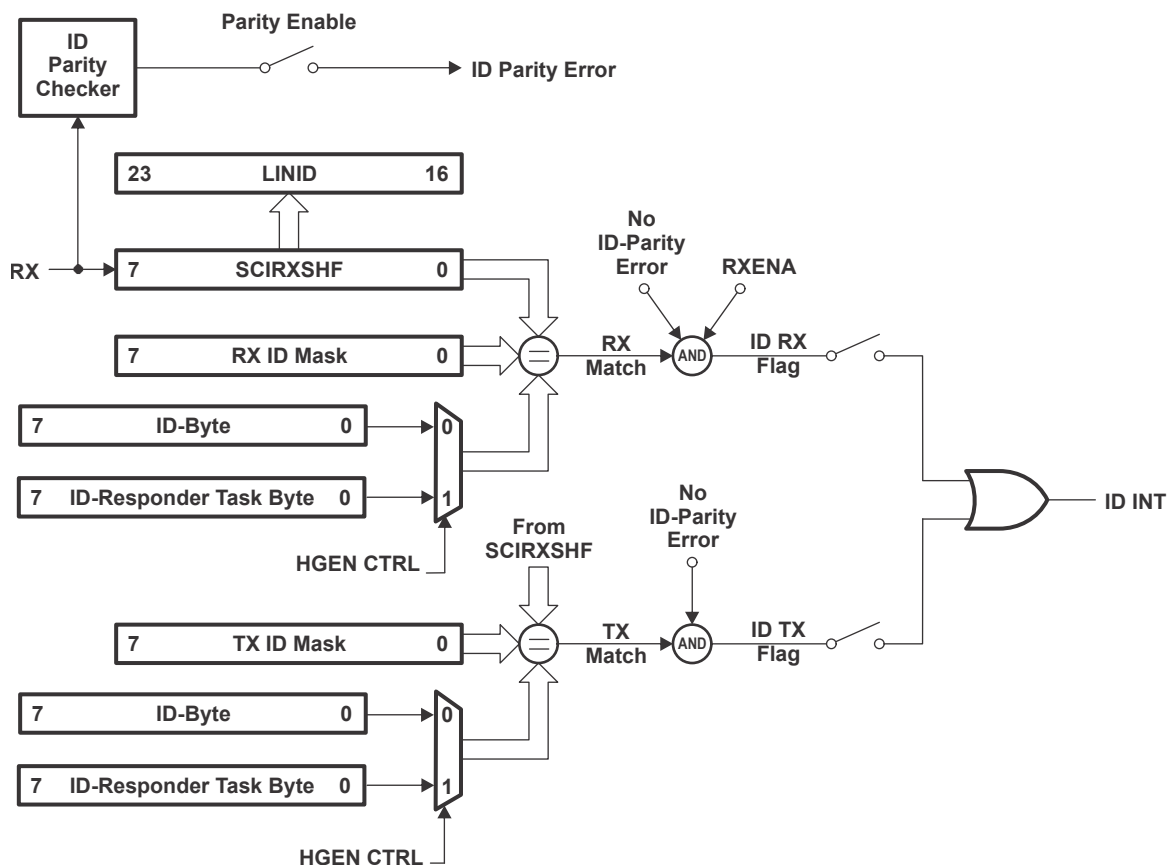

Figure 37-24. ID Reception, Filtering, and Validation

For example, to build a mask to accept IDs 0x26 and 0x25 using LINID[7:0] = 0x20; that is, compare 5 most-significant bits (MSBs) and filter 3 least-significant bits (LSBs), the acceptance mask can be:

$$(0x26 + 0x25) \oplus 0x20 = 0x07$$

A mask of all zeros compares all bits of the received identifier in the shift register with the ID-BYTE in LINID[7:0]. If HGEN CTRL is set to 1, a mask of 0xFF always causes a match. A mask of all 1s filters all bits of the received identifier, and thus there is an ID match regardless of the content of the ID-Responder Task BYTE field in the LINID register.

---

#### Note

When the HGEN CTRL bit = 0, the LIN nodes compare the received ID to the ID-BYTE field in the LINID register, and use the RX ID MASK and the TX ID MASK in the LINMASK register to filter the bits of the identifier that can not be compared.

If there is an RX match with no parity error and the RXENA bit is set, there is an ID RX flag and an interrupt is triggered if enabled. A mask of all 0s compares all bits of the received identifier in the shift register with the ID-BYTE field in LINID[7:0]. A mask of all 1s filters all bits of the received identifier and there is no match.

---

#### If HGEN CTRL = 1:

- Received ID is compared with the ID-Responder Task byte, using the RXID mask and the TXID mask.
- A mask of all 1s always result in a match.
- A mask of all 0s means all the bits must be the same to result in a match.
- If a mask has some bits that are 1s, then those bits are not used for the filtering criterion.

#### If HGEN CTRL = 0:

- Received ID is compared with the ID byte, using the RXID mask and the TXID mask.
- A mask of all 1s results in no match.
- A mask of all 0s means all the bits must be the same to result in a match.
- If a mask has some bits that are 1s, then those bits are not used for the filtering criterion.

During header reception, the received identifier is copied to the Received ID field LINID[23:16]. If there is no parity error and there is either a TX match or an RX match, then the corresponding TX or RX ID flag is set. If the ID interrupt is enabled, then an ID interrupt is generated.

After the ID interrupt is generated, the CPU can read the Received ID field LINID[23:16] and determine what response to load into the transmit buffers.

---

#### Note

When byte 0 is written to TD0 (LINTD0[31:24]), the response transmission is automatically generated.

---

In multibuffer mode, the TXRDY flag is set when all the response data bytes and checksum byte are copied to the shift register SCITXSHF. In non-multibuffer mode, the TXRDY flag is set each time a byte is copied to the SCITXSHF register, and also for the last byte of the frame after the checksum byte is copied to the SCITXSHF register.

In multibuffer mode, the TXEMPTY flag is set when both the transmit buffers TDy and the SCITXSHF shift register are emptied and the checksum has been sent. In non-multibuffer mode, TXEMPTY is set each time TD0 and SCITXSHF are emptied, except for the last byte of the frame where the checksum byte must also be transmitted.

If parity is enabled, all responder receiving nodes validate the identifier using all eight bits of the received ID byte. The SCI/LIN flags a corrupted identifier if an ID-parity error is detected.

### 37.3.1.10 Receive Buffers

To reduce CPU load when receiving a LIN N-byte (with N = 1–8) response in interrupt mode or DMA mode, the SCI/LIN module has eight receive buffers. These buffers can store an entire LIN response in the RDy receive buffers. [Figure 37-8](#) illustrates the receive buffers.

The checksum byte following the data bytes is validated by the internal checksum calculator. The checksum error (CE) flag indicates a checksum error and a CE interrupt is generated if enabled in the SCISSETINT register.

The multibuffer 3-bit counter counts the data bytes transferred from the SCIRXSHF register to the RDy receive buffers if multibuffer mode is enabled, or to RD0 if multibuffer mode is disabled. The 3-bit compare register contains the number of data bytes expected to be received. In cases where the IDBYTE field does not convey message length (see *Note: Optional Control Length Bits* in [Section 37.3.1.5](#)), the LENGTH value, indicates the expected length and is used to load the 3-bit compare register. Whether the length control field or the LENGTH value is used is selectable with the COMMMODE bit.

A receive interrupt, and a receive ready RXRDY flag, and a DMA request (RXDMA) can occur after receiving a response, if there are no response receive errors for the frame (such as, there is no checksum error, frame error, and overrun error). The checksum byte is compared before acknowledging a reception. A DMA request can be generated for each received byte or for the entire response depending on whether the multibuffer mode is enabled or not (MБУFMODE bit).

---

#### Note

In multibuffer mode following are the scenarios associated with clearing the RXRDY flag bit:

1. The RXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0/1 register.
  2. For LENGTH less than or equal to 4, Read to RD0 register clears the RXRDY flag.
  3. For LENGTH greater than 4, Read to RD1 register clears the RXRDY flag.
-

### 37.3.1.11 Transmit Buffers

To reduce the CPU load when transmitting a LIN N-byte (with N = 1–8) response in interrupt mode or DMA mode, the SCI/LIN module has 8 transmit buffers, TD0–TD7 in LINTD0 and LINTD1. With these transmit buffers, an entire LIN response field can be preloaded in the TDy transmit buffers. Optionally, a DMA transfer can be done on a byte-per-byte basis when multibuffer mode is not enabled (MБУFMODE bit). [Figure 37-9](#) illustrates the transmit buffers.

The multibuffer 3-bit counter counts the data bytes transferred from the TDy transmit buffers register if multibuffer mode is enabled, or from TD0 to SCITXSHF if multibuffer mode is disabled. The 3-bit compare register contains the number of data bytes expected to be transmitted. If the ID field is not used to convey message length (see *Note: Optional Control Length Bits* in [Section 37.3.1.5](#)), the LENGTH value indicates the expected length and is used instead to load the 3-bit compare register. Whether the length control field or the LENGTH value is used is selectable with the COMMMODE bit.

A transmit interrupt (TX interrupt) and a transmit ready flag (TXRDY flag), as well as a DMA request (TXDMA) can occur after transmitting a response. A DMA request can be generated for each transmitted byte or for the entire response depending on whether multibuffer mode is enabled or not (MБУFMODE bit).

The checksum byte is automatically generated by the checksum calculator and sent after the data-fields transmission is finished. The multibuffer 3-bit counter counts the data bytes transferred from the TDy buffers into the SCITXSHF register.

---

#### Note

The transmit interrupt request can be eliminated until the next series of data is written into the transmit buffers LINTD0 and LINTD1, by disabling the corresponding interrupt using the SCICLRINT register or by disabling the transmitter using the TXENA bit.

---

### 37.3.2 LIN Interrupts

LIN and SCI modes have a common interrupt block, as explained in Section 37.2.2. There are 16 interrupt sources in the SCI/LIN module, with 8 of them being LIN mode only, as seen in Table 37-5.

A LIN message frame indicating the timing and sequence of the LIN interrupts that can occur is shown in Figure 37-25.

Figure 37-25. LIN Message Frame Showing LIN Interrupt Timing and Sequence

### 37.3.3 Servicing LIN Interrupts

When servicing an interrupt, clear the corresponding flag in the flag register (SCIFLR) before clearing the global interrupt (LIN\_GLB\_INT\_CLR). The ISR can follow the guidelines below. This prevents any spurious or duplicate interrupt from occurring.

- Clear the LIN interrupt flag in the SCIFLR register.
- Read the LIN interrupt status register to make sure the flag is cleared.
- Clear the global interrupt flag bit in LIN\_GLB\_INT\_CLR.

#### Note

The transmit interrupt is generated before the LIN transmitter is ready to accept new data. Inside of the LIN transmit ISR, the software can wait until the buffer is completely empty before loading the next data. This can be done by polling for the Bus Busy Flag (SCIFLR.BUSY) to be 0.

### 37.3.4 LIN DMA Interface

The LIN DMA interface uses the SCI DMA interface logic. DMA requests for receive (RXDMA request) and transmit (TXDMA request) are available for the SCI/LIN module. There are two modes for DMA transfers depending on whether multibuffer mode is enabled or not using the multibuffer enable control bit (MБУFMODE).

---

#### Note

Do not use the DMA to transmit data to multiple peripheral IDs. Writing to the LINID register initiates a new transmission. The DMA writes to the LINID register before the LIN state machine is ready to accept the new ID. Doing so causes the LIN to miss this transmission.

---

#### 37.3.4.1 LIN Receive DMA Requests

In LIN mode, when the multibuffer option is enabled, if a received response (up to eight data bytes) is transferred to the receive buffers (RDy), then a DMA request is generated. If the multibuffer option is disabled, then DMA requests are generated on a byte-per-byte basis until all the expected response data fields are received. This DMA functionality is enabled and disabled using the SET\_RX\_DMA and CLRRXDMA bits, respectively.

#### 37.3.4.2 LIN Transmit DMA Requests

In LIN mode with the multibuffer option enabled, after a transmission (up to eight data bytes stored in the transmit buffers (TDy) in the LINTD0 and LINTD1 registers), a DMA request is generated to reload the transmit buffer for the next transmission. If the multibuffer option is disabled, then DMA requests are generated on a byte-per-byte basis until all bytes are transferred. This DMA functionality is enabled and disabled using the SET\_TX\_DMA and CLRTXDMA bits, respectively.

### 37.3.5 LIN Configurations

The following list details the configuration steps that software can perform prior to the transmission or reception of data in LIN mode. As long as the SWnRST bit in the SCIGCR1 register is cleared to 0 the entire time that the LIN is being configured, the order in which the registers are programmed is not important.

- Enable LIN by setting RESET bit (SCIGCR0.0).
- Clear SWnRST to 0 before configuring the LIN (SCIGCR1.7).
- Enable the LINRX and LINTX pins by setting the RXFUNC and TXFUNC bits.
- Select LIN mode by programming the LINMODE bit (SCIGCR1.6).
- Select commander or responder mode by programming the CLOCK bit.
- Select the desired frame format (checksum, parity, length control) by programming SCIGCR1.
- Select multibuffer mode by programming MБУFMODE bit (SCIGCR1.10).
- Select the baud rate to be used for communication by programming BRSR.
- Set the maximum baud rate to be used for communication by programming MBRSR.
- Set the CONT bit to make LIN not halt for an emulation breakpoint until the LIN current reception or transmission is complete (this bit is used only in an emulation environment).
- Set LOOPBACK bit (SCIGCR1.16) to connect the transmitter to the receiver internally if needed (this feature is used to perform a self-test).
- Select the receiver enable RXENA bit (SCIGCR1.24), if data is to be received.
- Select the transmit enable TXENA bit (SCIGCR1.25), if data is to be transmitted.
- Select the RXIDMASK and the TXIDMASK fields in the LINMASK register.
- Set SWnRST (SCIGCR1.7) to 1 after the LIN is configured.
- Receive or Transmit data (see [Section 37.3.1.9](#), [Section 37.3.5.1](#), and [Section 37.3.5.2](#)).

---

#### Note

If TXENA is set and the SWnRST is released, the LIN immediately generates a new DMA request but not a new transmit interrupt request. If using interrupts, the first transmission must be started with software by writing data to the transmit buffer, followed by writing the chosen ID to the LINID register to initiate the transmission.

---

### 37.3.5.1 Receiving Data

The LIN receiver is enabled to receive messages if both the RXFUNC bit and the RXENA bit are set to 1. If the RXFUNC bit is not set, the LINRX pin functions as a general-purpose I/O pin rather than as a LIN function pin.

The IDRXFLAG in the SCIFLR register is set after a valid LINID is received with an RX Match. An ID interrupt is then generated, if enabled.

#### 37.3.5.1.1 Receiving Data in Single-Buffer Mode

Single-buffer mode is selected when the MBUFMODE bit is cleared to 0. In this mode, LIN sets the RXRDY bit when the LIN transfers newly received data from SCIRXSHF to RD0. The SCI clears the RXRDY bit after the new data in RD0 has been read. Also, as data is transferred from SCIRXSHF to RD0, the LIN sets the FE, OE, or PE flags if any of these error conditions were detected in the received data. These error conditions are supported with configurable interrupt capability.

You can receive data by:

1. Polling Receive Ready Flag
2. Receive Interrupt
3. DMA

In polling method, software can poll for the RXRDY bit and read the data from RD0 byte of the LINRD0 register once the RXRDY bit is set high. The CPU is unnecessarily overloaded by selecting the polling method. To avoid this, you can use the interrupt or DMA method. To use the interrupt method, the SETRXINT bit is set. To use the DMA method, the SET\_RX\_DMA bit must be set. Either an interrupt or a DMA request is generated the moment the RXRDY bit is set. If the checksum scheme is enabled by setting the Compare Checksum (CC) bit to 1, the checksum is compared on the byte that is currently being received, which is expected to be the checksum byte. The CC bit is cleared once the checksum is received. A CE is immediately flagged, if there is a checksum error.

#### 37.3.5.1.2 Receiving Data in Multibuffer Mode

Multibuffer mode is selected when the MBUFMODE bit is set to 1. In this mode, LIN sets the RXRDY bit after receiving the programmed number of data in the receive buffer and the checksum field, the complete frame. The error condition detection logic is similar to the single-buffer mode, except that this logic monitors for the complete frame. Like single-buffer mode, you can use the polling, DMA, or interrupt method to read the data. The received data has to be read from the LINRD0 and LINRD1 registers, based on the number of bytes. For a LENGTH less than or equal to 4, a read from the LINRD0 register clears the RXRDY flag. For a LENGTH greater than 4, a read from the LINRD1 register clears the RXRDY flag. If the checksum scheme is enabled by setting the Compare Checksum (CC) bit to 1 during the reception of the data, then the byte that is received after the reception of the programmed number of data bytes indicated by the LENGTH field is treated as a checksum byte. The CC bit is cleared once the checksum is received and compared.

### 37.3.5.2 Transmitting Data

The LIN transmitter is enabled if both the TXFUNC bit and the TXENA bit are set to 1. If the TXFUNC bit is not set, the LINTX pin functions as a general-purpose I/O pin rather than as a LIN function pin. Any value written to the TD0 before the TXENA bit is set to 1 is not transmitted. Both of these control bits allow for the LIN transmitter to be held inactive independently of the receiver.

The IDTXFLAG bit in the SCIFLR register is set after a valid LIN ID is received with a TX Match. An ID interrupt is then generated, if enabled.

### 37.3.5.2.1 Transmitting Data in Single-Buffer Mode

Single-buffer mode is selected when the MBUFMODE bit is cleared to 0. In this mode, LIN waits for data to be written to TD0, transfers the data to SCITXSHF, and transmits the data. The TXRDY and TXEMPTY bits indicate the status of the transmit buffers. That is, when the transmitter is ready for data to be written to TD0, the TXRDY bit is set. Additionally, if both TD0 and SCITXSHF are empty, then the TXEMPTY bit is also set.

You can transmit data by:

1. Polling Transmit Ready Flag
2. Transmit Interrupt
3. DMA

In polling method, software can poll for the TXRDY bit to go high before writing the data to the TD0. The CPU is unnecessarily overloaded by selecting the polling method. To avoid this, you can use the interrupt or DMA method. To use the interrupt method, the SETXINT bit is set. To use the DMA method, the SET\_TX\_DMA bit is set. Either an interrupt or a DMA request is generated the moment the TXRDY bit is set. When the LIN has completed transmission of all pending frames, the SCITXSHF register and the TD0 are empty, the TXRDY bit is set, and an interrupt/DMA request is generated, if enabled. Because all data has been transmitted, the interrupt/DMA request can be halted. This can either be done by disabling the transmit interrupt (CLRTXINT) / DMA request (CLRTXDMA bit) or by disabling the transmitter (clear TXENA bit). If the checksum scheme is enabled by setting the Send Checksum (SC) bit to 1, the checksum byte is sent after the current byte transmission. The SC bit is cleared after the checksum byte has been transmitted.

---

#### Note

The TXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0 or SCIINTVECT1 register.

---

### 37.3.5.2.2 Transmitting Data in Multibuffer Mode

Multibuffer mode is selected when the MBUFMODE bit is set to 1. Like single-buffer mode, you can use the polling, DMA, or interrupt method to write the data to be transmitted. The transmitted data has to be written to the LINTD0 and LINTD1 registers, based on the number of bytes. LIN waits for data to be written to Byte 0 (TD0) of the LINTD0 register and transfers the programmed number of bytes to SCITXSHF to transmit one by one automatically. If the checksum scheme is enabled by setting the Send Checksum (SC) bit to 1, the checksum is sent after transmission of the last byte of the programmed number of data bytes, indicated by the LENGTH field. The SC bit is cleared after the checksum byte has been transmitted.

## 37.4 Low-Power Mode

The SCI/LIN module can be put in either local or global low-power mode. Global low-power mode is asserted by the system and is not controlled by the SCI/LIN module. During global low-power mode, all clocks to the SCI/LIN are turned off so the module is completely inactive. If global low-power mode is requested while the receiver is receiving data, then the SCI/LIN completes the current reception and then enters the low-power mode, that is, module enters low-power mode only when Busy bit (SCIFLR.3) is cleared.

The LIN module can enter low-power mode either when there was no activity on the LINRX pin for more than 4 seconds (this can be either a constant recessive or dominant level) or when a Sleep Command frame was received. Once the Timeout flag (SCIFLR.4) was set or once a Sleep Command was received, the POWERDOWN bit (SCIGCR2.0) must be set by the application software to make the module enter local low-power mode. A wakeup signal terminates the sleep mode of the LIN bus.

**Note**

**Enabling Local Low-Power Mode During Receive and Transmit**

If the wakeup interrupt is enabled and low-power mode is requested while the receiver is receiving data, then the SCI/LIN immediately generates a wakeup interrupt to clear the power-down bit. Thus, the SCI/LIN is prevented from entering low-power mode and completes the current reception. Otherwise, if the wakeup interrupt is disabled, the SCI/LIN completes the current reception and then enters the low-power mode.

**37.4.1 Entering Sleep Mode**

In LIN protocol, a sleep command is used to broadcast the sleep mode to all nodes. The sleep command consists of a diagnostic commander request frame with identifier 0x3C (60), with the first data field as 0x00. There must be no activity in the bus once all nodes receive the sleep command: the bus is in sleep mode.

Local low-power mode is asserted by setting the POWERDOWN bit; setting this bit stops the clocks to the SCI/LIN internal logic and registers. Clearing the POWERDOWN bit causes SCI/LIN to exit from local low-power mode. All the registers are accessible during local power-down mode. If a register is accessed in low-power mode, this access results in enabling the clock to the module for that particular access alone.

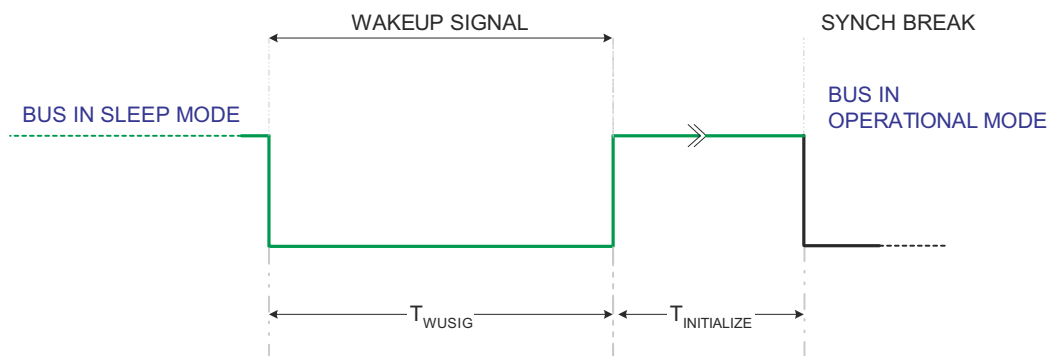

**37.4.2 Wakeup**

The wakeup interrupt is used to allow the SCI/LIN module to automatically exit a low-power mode. A SCI/LIN wakeup is triggered when a low level is detected on the receive RX pin, and this clears the POWERDOWN bit.

**Note**

If the wakeup interrupt is disabled, then the SCI/LIN enters low-power mode whenever the SCI/LIN is requested to do so, but a low level on the receive RX pin does not cause the SCI/LIN to exit low-power mode.

In LIN mode, any node can terminate sleep mode by sending a wakeup signal, see [Figure 37-26](#). A responder node that detects the bus in sleep mode, and with a wakeup request pending, sends a wakeup signal. The wakeup signal is a dominant value on the LIN bus for  $T_{WUSIG}$ ; this is at least 5  $T_{bits}$  for the LIN bus baud rates. The wakeup signal is generated by sending a 0xF0 byte containing 5 dominant  $T_{bits}$  and 5 recessive  $T_{bits}$ .

$0.25ms \leq T_{WUSIG} \leq 5ms$

**Figure 37-26. Wakeup Signal Generation**

Assuming a bus with no noise or loading effects, a write of 0xF0 to TD0 loads the transmitter to meet the wakeup signal timing requirement for  $T_{WUSIG}$ . Then, setting the GENWU bit transmits the preloaded value in TD0 for a wakeup signal transmission.

#### Note

The GENWU bit can be set/reset only when SWnRST is set to 1 and the node is in power-down mode. The bit is cleared on a valid synch break detection. A commander sending a wakeup request, exits power-down mode upon reception of the wakeup pulse. The bit is cleared on a SWnRST. This can be used to stop a commander from sending further wakeup requests.

---

The TI TPIC1021 LIN transceiver, upon receiving a wakeup signal, translates it to the microcontroller for wakeup with a dominant level on the RX pin, or a signal to the voltage regulator. While the POWERDOWN bit is set, if the LIN module detects a recessive-to-dominant edge (falling edge) on the RX pin, the LIN module generates a wakeup interrupt if enabled in the SCISSETINT register.

According to LIN protocol 2.0, the TI TPIC1021 LIN transceiver detecting a dominant level on the bus longer than 150ms detects it as a wakeup request. The LIN responder is ready to listen to the bus in less than 100ms ( $T_{INITIALIZE} < 100\text{ms}$ ) after a dominant-to-recessive edge (end-of-wakeup signal).

#### 37.4.3 Wakeup Timeouts

The LIN protocol defines the following timeouts for a wakeup sequence. After a wakeup signal has been sent to the bus, all nodes wait for the commander to send a header. If no synch field is detected before 150ms (3,000 cycles at 20kHz) after a wakeup signal is transmitted, a new wakeup is sent by the same node that requested the first wakeup. This sequence is not repeated more than two times. After three attempts to wake up the LIN bus, wakeup signal generation is suspended for a 1.5s (30,000 cycles at 20kHz) period after three breaks.

#### Note

To achieve compatibility to LIN1.3 timeout conditions, the MBRS register must be set to make sure that the LIN 2.0 (real-time-based) timings meet the LIN 1.3 bit time base. A node triggering the wakeup can set the MBRS register accordingly to meet the targeted time as  $128 \text{ Tbits} \times \text{programmed prescaler}$ .

The LIN handles the wakeup expiration times defined by the LIN protocol with a hardware implementation.

---

### 37.5 Emulation Mode

In emulation mode, the CONT bit determines how the SCI/LIN operates when the program is suspended. The SCI/LIN counters are affected by this bit during debug mode. when set, the counters are not stopped and when cleared, the counters are stopped debug mode.

Any reads in emulation mode to a SCI/LIN register do not have any effect on the flags in the SCIFLR register.

#### Note

When emulation mode is entered during the Frame transmission or reception of the frame and CONT bit is not set, Communication is not expected to be successful. The suggested usage is to set CONT bit during emulation mode for successful communication.

---

## 37.6 Software

### 37.6.1 LIN Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
 C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/lin

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 37.6.1.1 LIN Internal Loopback with Interrupts - SINGLE\_CORE

FILE: lin\_ex1\_loopback\_interrupt.c

This example configures the LIN module in commander mode for internal loopback with interrupts. The module is setup to perform 8 data transmissions with different transmit IDs and varying transmit data. Upon reception of an ID header, an interrupt is triggered on line 0 and an interrupt service routine (ISR) is called. The received data is then checked for accuracy.

##### *External Connections*

- None.

##### *Watch Variables*

- txData - An array with the data being sent
- rxData - An array with the data that was received
- result - The example completion status (PASS = 0xABCD, FAIL = 0xFFFF)
- level0Count - The number of line 0 interrupts
- level1Count - The number of line 1 interrupts

#### 37.6.1.2 LIN SCI Mode Internal Loopback with Interrupts - SINGLE\_CORE

FILE: lin\_ex2\_sci\_loopback.c

This example configures the LIN module in SCI mode for internal loopback with interrupts. The LIN module performs as a SCI with a set character and frame length in a non-multi-buffer mode. The module is setup to continuously transmit a character, wait to receive that character, and repeat.

##### *External Connections*

- None.

##### *Watch Variables*

- rxCount - The number of RX interrupts
- transmitChar - The character being transmitted
- receivedChar - The character received

#### 37.6.1.3 LIN SCI MODE Internal Loopback with DMA - SINGLE\_CORE

FILE: lin\_ex3\_sci\_dma.c

This example configures the LIN module in SCI mode for internal loopback with the use of the DMA. The LIN module performs as SCI with a set character and frame length in multi-buffer mode. When the transmit buffers in the LINTD0 and LINTD1 registers have enough space, the DMA will transfer data from global variable sData into those transmit registers. Once the received buffers in the LINRD0 and LINRD1 registers contain data, the DMA will transfer the data into the global variable rdata.

When all data has been placed into rData, a check of the validity of the data will be performed in one of the DMA channels' ISRs.

##### *External Connections*

- None

##### *Watch Variables*

- sData - Data to send

- *rData* - Received data

#### 37.6.1.4 LIN Internal Loopback without interrupts (polled mode) - SINGLE\_CORE

FILE: lin\_ex4\_loopback\_polling.c

This example configures the LIN module in commander mode for internal loopback without interrupts. The module is setup to perform 8 data transmissions with different transmit IDs and varying transmit data. Waits for reception of an ID header. The received data is then checked for accuracy.

##### External Connections

- None.

##### Watch Variables

- txData - An array with the data being sent
- rxData - An array with the data that was received
- result - The example completion status (PASS = 0xABCD, FAIL = 0xFFFF)

#### 37.6.1.5 LIN SCI MODE (Single Buffer) Internal Loopback with DMA - SINGLE\_CORE

FILE: lin\_ex5\_sci\_dma\_single\_buffer.c

This example configures the LIN module in SCI mode for internal loopback with the use of the DMA. The LIN module performs as SCI with a set character and frame length in single-buffer compatibility mode. When the transmit buffer i.e. the SCITD register is free, the DMA will transfer data from global variable sData into this register. Once the received buffer, i.e. the SCIRD register contains data, the DMA will transfer the data into the global variable rdata.

When all data has been placed into rData, a check of the validity of the data will be performed in one of the DMA channels' ISRs.

##### External Connections

- None

##### Watch Variables

- sData - Data to send
- rData - Received data

## 37.7 SCI/LIN Registers

The SCI/LIN module registers are based on the SCI registers, with added functionality registers enabled by the LIN MODE bit in the SCIGCR1 register.

These registers are accessible in 32-bit reads or writes. The SCI/LIN is controlled and accessed through the registers listed in the following sections. Among the features that can be programmed are the LIN protocol mode, communication and timing modes, baud rate value, frame format, DMA requests, and interrupt configuration.

### 37.7.1 LIN Base Address Table

**Table 37-12. LIN Base Address Table**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	CPU2	CPU2.DMA	Pipeline Protected
Instance	Structure								
LinaRegs	<a href="#">LIN_REGS</a>	LINA_BASE	0x0000_6E00	YES	YES	YES	YES	YES	YES
LinbRegs	<a href="#">LIN_REGS</a>	LINB_BASE	0x0000_6F00	YES	YES	YES	YES	YES	YES

### 37.7.2 LIN\_REGS Registers

Table 37-13 lists the memory-mapped registers for the LIN\_REGS registers. All register offset addresses not listed in Table 37-13 should be considered as reserved locations and the register contents should not be modified.

**Table 37-13. LIN\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	SCIGCR0	Global Control Register 0		<a href="#">Go</a>
4h	SCIGCR1	Global Control Register 1		<a href="#">Go</a>
8h	SCIGCR2	Global Control Register 2		<a href="#">Go</a>
Ch	SCISSETINT	Interrupt Enable Register		<a href="#">Go</a>
10h	SCICLEARINT	Interrupt Disable Register		<a href="#">Go</a>
14h	SCISSETINTLVL	Set Interrupt Level Register		<a href="#">Go</a>
18h	SCICLEARINTLVL	Clear Interrupt Level Register		<a href="#">Go</a>
1Ch	SCIFLR	Flag Register		<a href="#">Go</a>
20h	SCIINTVECT0	Interrupt Vector Offset Register 0		<a href="#">Go</a>
24h	SCIINTVECT1	Interrupt Vector Offset Register 1		<a href="#">Go</a>
28h	SCIFORMAT	Length Control Register		<a href="#">Go</a>
2Ch	BRSR	Baud Rate Selection Register		<a href="#">Go</a>
30h	SCIED	Emulation buffer Register		<a href="#">Go</a>
34h	SCIRD	Receiver data buffer Register		<a href="#">Go</a>
38h	SCITD	Transmit data buffer Register		<a href="#">Go</a>
3Ch	SCPIO0	Pin control Register 0		<a href="#">Go</a>
44h	SCPIO2	Pin control Register 2		<a href="#">Go</a>
60h	LINCOMP	Compare register		<a href="#">Go</a>
64h	LINRD0	Receive data register 0		<a href="#">Go</a>
68h	LINRD1	Receive data register 1		<a href="#">Go</a>
6Ch	LINMASK	Acceptance mask register		<a href="#">Go</a>
70h	LINID	LIN ID Register		<a href="#">Go</a>
74h	LINTD0	Transmit Data Register 0		<a href="#">Go</a>
78h	LINTD1	Transmit Data Register 1		<a href="#">Go</a>
7Ch	MBSR	Maximum Baud Rate Selection Register		<a href="#">Go</a>
90h	IODFTCTRL	IODFT for LIN		<a href="#">Go</a>
E0h	LIN_GLB_INT_EN	LIN Global Interrupt Enable Register		<a href="#">Go</a>
E4h	LIN_GLB_INT_FLG	LIN Global Interrupt Flag Register		<a href="#">Go</a>
E8h	LIN_GLB_INT_CLR	LIN Global Interrupt Clear Register		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 37-14 shows the codes that are used for access types in this section.

**Table 37-14. LIN\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear

**Table 37-14. LIN\_REGS Access Type Codes (continued)**

Access Type	Code	Description
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 37.7.2.1 SCIGCR0 Register (Offset = 0h) [Reset = 0000000h]

SCIGCR0 is shown in [Figure 37-27](#) and described in [Table 37-15](#).

Return to the [Summary Table](#).

The SCIGCR0 register defines the module reset.

**Figure 37-27. SCIGCR0 Register**

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	Reserved
15-1	RESERVED	R	0h	Reserved
0	RESET	R/W	0h	This bit resets the SCI/LIN module. This bit is effective in LIN or SCI-compatible mode.. This bit affects the reset state of the SCI/LIN module. Reset type: SYSRSn 0h (R/W) = SCI/LIN module is in held in reset. 1h (R/W) = SCI/LIN module is out of reset.

### 37.7.2.2 SCIGCR1 Register (Offset = 4h) [Reset = 0000000h]

SCIGCR1 is shown in [Figure 37-28](#) and described in [Table 37-16](#).

Return to the [Summary Table](#).

The SCIGCR1 register defines the frame format, protocol, and communication mode used by the SCI.

**Figure 37-28. SCIGCR1 Register**

**Table 37-16. SCIGCR1 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-26	RESERVED	R	0h	Reserved
25	TXENA	R/W	0h	Transmit enable. This bit is effective in LIN and SCI modes. Data is transferred from SCITD or the TDy (with y=0, 1,...7) buffers in LIN mode to the SCITXSHF shift out register only when the TXENA bit is set. Note: Data written to SCITD or the transmit multi-buffer before TXENA is set is not transmitted. If TXENA is cleared while transmission is ongoing, the data previously written to SCITD is sent (including the checksum byte in LIN mode). Reset type: SYSRSn 0h (R/W) = Disable transfers from SCITD or TDy to SCITXSHF 1h (R/W) = Enable transfers of data from SCITD or TDy to SCITXSHF

**Table 37-16. SCIGCR1 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
24	RXENA	R/W	0h	<p>Receive enable.</p> <p>This bit is effective in LIN or SCI-compatible mode. RXENA allows or prevents the transfer of data from SCIRXSHF to SCIRD or the receive multibuffers.</p> <p>Note: Clearing RXENA stops received characters from being transferred into the receive buffer or multi-buffers, prevents the RX status flags (see Table 7) from being updated by receive data, and inhibits both receive and error interrupts. However, the shift register continues to assemble data regardless of the state of RXENA.</p> <p>Note: If RXENA is cleared before the time the reception of a frame is complete, the data from the frame is not transferred into the receive buffer.</p> <p>Note: If RXENA is set before the time the reception of a frame is complete, the data from the frame is transferred into the receive buffer. If RXENA is set while SCIRXSHF is in the process of assembling a frame, the status flags are not guaranteed to be accurate for that frame. To ensure that the status flags correctly reflect what was detected on the bus during a particular frame, RXENA should be set before the detection of that frame</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Prevents the receiver from transferring data from the shift buffer to the receive buffer or multi-buffers</p> <p>1h (R/W) = Allows the receiver to transfer data from the shift buffer to the receive buffer or multi-buffers</p>
23-18	RESERVED	R	0h	Reserved
17	CONT	R/W	0h	<p>Continue on suspend.</p> <p>This bit has an effect only when a program is being debugged with an emulator, and it determines how the SCI/LIN operates when the program is suspended. This bit affects the LIN counters. When this bit is set, the counters are not stopped during debug. When this bit is cleared, the counters are stopped during debug.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = When debug mode is entered, the SCI/LIN state machine is frozen. Transmissions and LIN counters are halted and resume when debug mode is exited.</p> <p>1h (R/W) = When debug mode is entered, the SCI/LIN continues to operate until the current transmit and receive functions are complete.</p>
16	LOOPBACK	R/W	0h	<p>Loopback bit.</p> <p>This bit is effective in LIN or SCI-compatible mode. The self-checking option for the SCI/LIN can be selected with this bit. If the LINTX and LINRX pins are configured with SCI/LIN functionality, then the LINTX pin is internally connected to the LINRX pin. Externally, during loop back operation, the LINTX pin outputs a high value and the LINRX pin is in a high-impedance state. If this bit value is changed while the SCI/LIN is transmitting or receiving data, errors may result.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Loopback mode is disabled.</p> <p>1h (R/W) = Loopback mode is enabled.</p>
15-14	RESERVED	R	0h	Reserved
13	STOPEXTFRAME	R/W	0h	<p>Stop extended frame communication.</p> <p>This bit is effective in LIN mode only. This bit can be written only during extended frame communication. When the extended frame communication is stopped, this bit is cleared automatically.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No effect</p> <p>1h (R/W) = Extended frame communication will be stopped, once current frame transmission/reception is completed.</p>

**Table 37-16. SCIGCR1 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
12	HGENCTRL	R/W	0h	<p>HGEN control bit.</p> <p>This bit is effective in LIN mode only. This bit controls the type of mask filtering comparison.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = ID filtering using ID-Byte.</p> <p>RECEIVEDID and IDBYTE fields in the LINID register are used for detecting a match (using TX/RXMASK values). Mask of 0xFF in LINMASK register will result in NO match.</p> <p>1h (R/W) = ID filtering using ID-RESPONDERTask byte (Recommended).</p> <p>RECEIVEDID and IDRESPONDERTASKBYTE fields in the LINID register are used for detecting a match (using TX/RXMASK values). Mask of 0xFF in LINMASK register will result in ALWAYS match</p>
11	CTYPE	R/W	0h	<p>Checksum type.</p> <p>This bit is effective in LIN mode only. This bit controls the type of checksum to be used: classic or enhanced.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Classic checksum is used.</p> <p>This checksum is compatible with LIN 1.3 Responder nodes. The classic checksum contains the modulo-256 sum with carry over all data bytes. Frames sent with Identifier 60 (0x3C) to 63 (0x3F) must always use the classic checksum.</p> <p>1h (R/W) = Enhanced checksum is used.</p> <p>The enhanced checksum is compatible with LIN 2.0 and newer Responder nodes. The enhanced checksum contains the modulo-256 sum with carry over all data bytes AND the protected Identifier.</p>
10	MBUFMODE	R/W	0h	<p>Multibuffer mode.</p> <p>This bit is effective in LIN or SCI-compatible mode. This bit controls receive/transmit buffer usage, that is, whether the RX/TX multibuffers are used or a single register, RD0/TD0, is used.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = The multi-buffer mode is disabled.</p> <p>1h (R/W) = The multi-buffer mode is enabled.</p>
9	ADAPT	R/W	0h	<p>Adapt mode enable.</p> <p>This mode is effective in LIN mode only. This bit has an effect during the detection of the Sync Field. There are two LIN protocol bit rate modes that could be enabled with this bit according to the Node capability file definition: automatic or select. Software and network configuration will decide which of the previous two modes. When this bit is cleared, the LIN 2.0 protocol fixed bit rate should be used. If the ADAPT bit is set, a LIN Responder node detecting the baudrate will compare it to the prescalers in BRSR register and update it if they are different. The BRSR register will be updated with the new value. If this bit is not set there will be no adjustment to the BRSR register. This field is writable in LIN mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Automatic baudrate adjustment is disabled.</p> <p>1h (R/W) = Automatic baudrate adjustment is enabled.</p>

**Table 37-16. SCIGCR1 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
8	SLEEP	R/W	0h	<p>SCI sleep.</p> <p>SCI compatibility mode only. In a multiprocessor configuration, this bit controls the receive sleep function. Clearing this bit brings the SCI out of sleep mode.</p> <p>The receiver still operates when the SLEEP bit is set however, RXRDY is updated and SCIRD is loaded with new data only when an address frame is detected. The remaining receiver status flags are updated and an error interrupt is requested if the corresponding interrupt enable bit is set, regardless of the value of the SLEEP bit. In this way, if an error is detected on the receive data line while the SCI is asleep, software can promptly deal with the error condition. The SLEEP bit is not automatically cleared when an address byte is detected.</p> <p>This field is writable in SCI mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Sleep mode is disabled.</p> <p>1h (R/W) = Sleep mode is enabled.</p>
7	SWnRST	R/W	0h	<p>Software reset (active low).</p> <p>This bit is effective in LIN or SCI-compatible mode. The SCI/LIN should only be configured while SWnRST = 0.</p> <p>Only the following configuration bits can be changed in runtime (i.e., while SWnRESET = 1):</p> <ul style="list-style-type: none"> <li>- STOP EXT Frame (SCIGCR1[13])</li> <li>- CC bit (SCIGCR2[17])</li> <li>- SC bit (SCIGCR2[16])</li> </ul> <p>Reset type: SYSRSn</p> <p>0h (R/W) = The SCI/LIN is in its reset state no data will be transmitted or received. Writing a 0 to this bit initializes the SCI/LIN state machines and operating flags. All affected logic is held in the reset state until a 1 is written to this bit.</p> <p>1h (R/W) = The SCI/LIN is in its ready state transmission and reception can occur. After this bit is set to 1, the configuration of the module should not change.</p>
6	LINMODE	R/W	0h	<p>LIN mode</p> <p>This bit controls the mode of operation of the module.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = LIN mode is disabled SCI compatibility mode is enabled.</p> <p>1h (R/W) = LIN mode is enabled SCI compatibility mode is disabled.</p>
5	CLK_COMMANDER	R/W	0h	<p>SCI internal clock enable or LIN Commander/Responder configuration.</p> <p>In the SCI mode, this bit enables the clock to the SCI module. In LIN mode, this bit determines whether a LIN node is a Responder or Commander.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = SCI-compatible mode: Reserved.</p> <p>LIN mode: The module is in Responder mode.</p> <p>1h (R/W) = SCI-compatible mode: Enable clock to the SCI module. LIN mode: The node is in Commander mode.</p>
4	STOP	R/W	0h	<p>SCI number of stop bits.</p> <p>This bit is effective in SCI-compatible mode only.</p> <p>Note: The receiver checks for only one stop bit. However in idle-line mode, the receiver waits until the end of the second stop bit (if STOP = 1) to begin checking for an idle period.</p> <p>This field is writable in SCI mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = One stop bit is used.</p> <p>1h (R/W) = Two stop bits are used.</p>

**Table 37-16. SCIGCR1 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
3	PARITY	R/W	0h	<p>SCI parity odd/even selection.</p> <p>This bit is effective in SCI-compatible mode only. If the PARITY ENA bit (SCIGCR1.2) is set, PARITY designates odd or even parity. The parity bit is calculated based on the data bits in each frame and the address bit (in address-bit mode). The start and stop fields in the frame are not included in the parity calculation.</p> <p>This field is writable in SCI mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Odd parity is used. The SCI transmits and expects to receive a value in the parity bit that makes odd the total number of bits in the frame with the value of 1.</p> <p>1h (R/W) = Even parity is used. The SCI transmits and expects to receive a value in the parity bit that makes even the total number of bits in the frame with the value of 1.</p>
2	PARITYENA	R/W	0h	<p>Parity enable.</p> <p>Enables or disables the parity function.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = SCI-compatible mode: Parity disabled no parity bit is generated during transmission or is expected during reception.</p> <p>LIN mode: ID-parity verification is disabled.</p> <p>1h (R/W) = SCI compatible mode: Parity enabled. A parity bit is generated during transmission and is expected during reception.</p> <p>LIN mode: ID-parity verification is enabled.</p>
1	TIMINGMODE	R/W	0h	<p>SCI timing mode bit.</p> <p>This bit is effective in SCI-compatible mode only. It must be set to 1 when the SCI mode is used. This bit configures the SCI for asynchronous operation.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Reserved.</p> <p>1h (R/W) = Must be set to 1 when module is configured for SCI operation</p>
0	COMMMODE	R/W	0h	<p>SCI/LIN communication mode bit.</p> <p>In compatibility mode, it selects the SCI communication mode. In LIN mode it selects length control option for ID-field bits ID4 and ID5.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = SCI-compatible mode: Idle-line mode is used.</p> <p>LIN mode: ID4 and ID5 are not used for length control.</p> <p>1h (R/W) = SCI-compatible mode: Address-bit mode is used.</p> <p>LIN mode: ID4 and ID5 are used for length control.</p>

### 37.7.2.3 SCIGCR2 Register (Offset = 8h) [Reset = 0000000h]

SCIGCR2 is shown in [Figure 37-29](#) and described in [Table 37-17](#).

Return to the [Summary Table](#).

The SCIGCR2 register is used to send or compare a checksum byte during extended frames, to generate a wakeup and for low-power mode control of the LIN module.

**Figure 37-29. SCIGCR2 Register**

Bit	Field	Type	Reset	Description
31-18	RESERVED	R	0h	Reserved
17	CC	R/W	0h	<p>Compare Checksum.</p> <p>This mode is effective in LIN mode only. This bit is used by the receiver for extended frames to trigger a checksum compare. The user will initiate this transaction by writing a one to this bit.</p> <p>In non multibuffer mode, once the CC bit is set, the checksum will be compared on the byte that is currently being received, expected to be the checkbyte.</p> <p>During Multi-buffer mode, following are the scenarios associated with the CC bit :</p> <ul style="list-style-type: none"> <li>- If CC bit is set during the reception of the data, then the byte that is received after the reception of the programmed no. of data bytes indicated by SCIFORMAT[18:16], is treated as a checksum byte.</li> <li>- If CC bit is set during the IDLE period (i.e. during inter-frame space), then the next immediate byte will be treated as a checksum byte.</li> </ul> <p>A CE will immediately be flagged if there is a checksum error.</p> <p>This bit is automatically cleared once the checksum is successfully compared.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No effect</p> <p>1h (R/W) = Compare checksum on expected checkbyte</p>

**Table 37-17. SCIGCR2 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
16	SC	R/W	0h	Send Checksum This mode is effective in LIN mode only. This bit is used by the transmitter with extended frames to send a checkbyte. In non multibuffer mode the checkbyte will be sent after the current byte transmission. In multibuffer mode the checkbyte will be sent after the last byte count, indicated by the SCIFORMAT[18:16]. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = No checkbyte will be sent. 1h (R/W) = A checkbyte will be sent. This bit will automatically get cleared after the checkbyte is transmitted. The checksum will not be sent if this bit is set before transmitting the very first byte, that is, during interframe space.
15-9	RESERVED	R	0h	Reserved
8	GENWU	R/W	0h	Generate wakeup signal. This bit controls the generation of a wakeup signal, by transmitting the TDO buffer value. This bit is cleared on reception of a valid sync break. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Transmit TDO for wakeup. This bit will be cleared on a SWnRST (SCIGCR1.7)
7-1	RESERVED	R	0h	Reserved
0	POWERDOWN	R/W	0h	Power down. This bit is effective in LIN or SCI-compatible mode. When the powerdown bit is set, the SCI/LIN module attempts to enter local low-power mode. If the POWERDOWN bit is set while the receiver is actively receiving data and the wakeup interrupt is disabled, then the SCI/LIN will delay low-power mode from being entered until completion of reception. In LIN mode the user may set the POWERDOWN bit on Sleep Command reception or on idle bus detection (more than 4 seconds, i.e. 80,000 cycles at 20kHz) Reset type: SYSRSn 0h (R/W) = Normal operation 1h (R/W) = Request local low-power mode

### 37.7.2.4 SCISSETINT Register (Offset = Ch) [Reset = 0000000h]

SCISSETINT is shown in [Figure 37-30](#) and described in [Table 37-18](#).

Return to the [Summary Table](#).

The SCISSETINT register is used to enable the various interrupts available in the LIN module.

**Table 37-18. SCISSETINT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	SETBEINT	R/W1S	0h	Set bit error interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN module to generate an interrupt when there is a bit error. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
30	SETPBEINT	R/W1S	0h	Set physical bus error interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN module to generate an interrupt when a physical bus error occurs. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
29	SETCEINT	R/W1S	0h	Set checksum-error Interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN module to generate an interrupt when there is a checksum error. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
28	SETISFEINT	R/W1S	0h	Set inconsistent-sync-field-error interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN module to generate an interrupt when there is an inconsistent sync field error. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.

**Table 37-18. SCISSETINT Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
27	SETNREINT	R/W1S	0h	Set no-response-error interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN module to generate an interrupt when a no-response error occurs. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
26	SETFEINT	R/W1S	0h	Set framing-error interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit enables the SCI/LIN module to generate an interrupt when a framing error occurs. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
25	SETOEINT	R/W1S	0h	Set overrun-error interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit enables the SCI/LIN module to generate an interrupt when an overrun error occurs. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
24	SETPEINT	R/W1S	0h	Set parity interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit enables the SCI/LIN module to generate an interrupt when a parity error occurs. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
23-19	RESERVED	R	0h	Reserved
18	SET_RX_DMA_ALL	R/W1S	0h	Set receiver DMA for Address & Data frames. This bit is effective in LIN or SCI-compatible mode for devices with a DMA module. To enable RX DMA request for address and data frames this bit must be set. If it is cleared, RX interrupt request is generated for address frames and DMA requests are generated for data frames. Reset type: SYSRSn 0h (R/W) = Receiver DMA request is disabled for address frames (RX interrupt request is enabled for address frames). Writing a 0 to this bit has no effect. 1h (R/W) = Receiver DMA request is enabled for address and data frames
17	SET_RX_DMA	R/W1S	0h	Set receiver DMA. This bit is effective in LIN or SCI-compatible mode for devices with a DMA module. To enable DMA requests for the receiver this bit must be set. If it is cleared, interrupt requests are generated depending on SETRXINT. Reset type: SYSRSn 0h (R/W) = Receiver DMA request is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Receiver DMA request is enabled.
16	SET_TX_DMA	R/W1S	0h	Set transmit DMA. This bit is effective in LIN or SCI-compatible mode for devices with a DMA module. To enable DMA requests for the transmitter, this bit must be set. If it is cleared, interrupt requests are generated depending on SETTXINT. Reset type: SYSRSn 0h (R/W) = Transmit DMA request is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Transmit DMA request is enabled

**Table 37-18. SCISSETINT Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
15-14	RESERVED	R	0h	Reserved
13	SETIDINT	R/W1S	0h	Set Identification interrupt. This bit is effective in LIN mode only. This bit is set to enable interrupt once a valid matching identifier is received. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
12-10	RESERVED	R	0h	Reserved
9	SETRXINT	R/W1S	0h	Set Receiver interrupt. Setting this bit enables the SCI/LIN to generate a receive interrupt after a frame has been completely received and the data is being transferred from SCIRXSHF to SCIRD. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
8	SETTXINT	R/W1S	0h	Set Transmitter interrupt. Setting this bit enables the SCI/LIN to generate a transmit interrupt as data is being transferred from SCITD to SCITXSHF and the TXRDY bit is being set. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
7	SETTOA3WUSINT	R/W1S	0h	Set Timeout After 3 Wakeup Signals interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN to generate an interrupt when there is a timeout after 3 wakeup signals have been sent. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
6	SETTOAWUSINT	R/W1S	0h	Set Timeout After Wakeup Signal interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN to generate an interrupt when there is a timeout after one wakeup signal has been sent. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
5	RESERVED	R	0h	Reserved
4	SETTIMEOUTINT	R/W1S	0h	Set timeout interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN to generate an interrupt when no LIN bus activity (bus idle) occurs for at least 4 seconds. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
3-2	RESERVED	R	0h	Reserved

**Table 37-18. SCISSETINT Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
1	SETWAKEUPINT	R/W1S	0h	Set wake-up interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit enables the SCI/LIN to generate a wake-up interrupt and thereby exit low-power mode. The wake-up interrupt is asserted on falling edge of the wake-up pulse. If enabled, the wake-up interrupt is asserted when local low-power mode is requested while the receiver is busy or if a low level is detected on the SCIRX pin during low-power mode. Wake-up interrupt is not asserted upon a wakeup pulse if the module is not in power down mode. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
0	SETBRKDTINT	R/W1S	0h	Set break-detect interrupt. This bit is effective in SCI-compatible mode only. Setting this bit enables the SCI/LIN to generate an interrupt if a break condition is detected on the LINRX pin. This field is writable in SCI mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.

### 37.7.2.5 SCICLEARINT Register (Offset = 10h) [Reset = 0000000h]

SCICLEARINT is shown in [Figure 37-31](#) and described in [Table 37-19](#).

Return to the [Summary Table](#).

The SCICLEARINT register is used to disable the enabled interrupts without accessing the SCISSETINT register.

**Table 37-19. SCICLEARINT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	CLRBEINT	R/W1C	0h	Clear Bit Error Interrupt. This bit is effective in LIN mode only. Setting this bit disables the bit error interrupt. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.
30	CLRPBEINT	R/W1C	0h	Clear Physical Bus Error Interrupt. This bit is effective in LIN mode only. Setting this bit disables the physical-bus error interrupt. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.
29	CLRCEINT	R/W1C	0h	Clear checksum-error Interrupt. This bit is effective in LIN mode only. Setting this bit disables the checksum-error interrupt. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.
28	CLRISFEINT	R/W1C	0h	Clear Inconsistent-Sync-Field-Error Interrupt. This bit is effective in LIN mode only. Setting this bit disables the ISFE interrupt. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.

**Table 37-19. SCICLEARINT Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
27	CLRNREINT	R/W1C	0h	Clear No-Response-Error Interrupt. This bit is effective in LIN mode only. Setting this bit disables the no-response error interrupt. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.
26	CLRFEINT	R/W1C	0h	Clear Framing-Error Interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit disables framing-error interrupt. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.
25	CLROEINT	R/W1C	0h	Clear Overrun-Error Interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit disables the overrun interrupt. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.
24	CLRPEINT	R/W1C	0h	Clear Parity Interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit disables the parity error interrupt. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.

**Table 37-20. SCISSETINTLVL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	SETBEINTLVL	R/W1S	0h	Set Bit Error interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the Bit Error interrupt level to the INT1 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.
30	SETPBEINTLVL	R/W1S	0h	Set Physical Bus Error interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the Physical Bus Error interrupt level to the INT1 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.
29	SETCEINTLVL	R/W1S	0h	Set Checksum-error interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the Checksum-error interrupt level to the INT1 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.
28	SETISFEINTLVL	R/W1S	0h	Set Inconsistent-Sync-Field-Error interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the Inconsistent-Sync-Field-Error interrupt level to the INT1 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.

**Table 37-20. SCISSETINTLVL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
27	SETNREINTLVL	R/W1S	0h	Set No-Response-Error interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the No-Response-Error interrupt level to the INT1 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.
26	SETFEINTLVL	R/W1S	0h	Set Framing-Error interrupt level. This bit is effective in LIN or SCI-compatible mode. Writing to this bit maps the Framing-Error interrupt level to the INT1 line. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.
25	SETOEINTLVL	R/W1S	0h	Set Overrun-Error Interrupt Level. This bit is effective in LIN or SCI-compatible mode. Writing to this bit maps the Overrun-Error interrupt level to the INT1 line. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.
24	SETPEINTLVL	R/W1S	0h	Set Parity Error interrupt level. This bit is effective in LIN or SCI-compatible mode. Writing to this bit maps the Parity error interrupt level to the INT1 line. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.
23-19	RESERVED	R	0h	Reserved
18	RESERVED	R	0h	Reserved
17-16	RESERVED	R	0h	Reserved
15-14	RESERVED	R	0h	Reserved
13	SETIDINTLVL	R/W1S	0h	Set ID interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the ID interrupt level to the INT1 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.
12-10	RESERVED	R	0h	Reserved
9	SETRXINTOVO	R/W1S	0h	Set Receiver interrupt level. This bit is effective in LIN or SCI-compatible mode. Writing to this bit maps the receiver interrupt level to the INT1 line. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.
8	SETTXINTLVL	R/W1S	0h	Set Transmitter interrupt level. This bit is effective in LIN or SCI-compatible mode. Writing to this bit maps the transmitter interrupt level to the INT1 line. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.
7	SETTOA3WUSINTLVL	R/W1S	0h	Set Timeout After 3 Wakeup Signals interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the timeout after 3 wakeup signals interrupt level to the INT1 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.

**Table 37-20. SCISSETINTLVL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
6	SETTOAWUSINTLVL	R/W1S	0h	Set Timeout After Wakeup Signal interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the the timeout after wakeup interrupt level to the INT1 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.
5	RESERVED	R	0h	Reserved
4	SETTIMEOUTINTLVL	R/W1S	0h	Set Timeout interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the timeout interrupt level to the INT1 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.
3-2	RESERVED	R	0h	Reserved
1	SETWAKEUPINTLVL	R/W1S	0h	Set Wake-up interrupt level. This bit is effective in LIN or SCI-compatible mode. Writing to this bit maps the Wake-up interrupt level to the INT1 line. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.
0	SETBRKDTINTLVL	R/W1S	0h	Set Break-detect interrupt level. This bit is effective in SCI-compatible mode only. Writing to this bit maps the Break-detect interrupt level to the INT1 line. This field is writable in SCI mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.

### 37.7.2.7 SCICLEARINTLVL Register (Offset = 18h) [Reset = 0000000h]

SCICLEARINTLVL is shown in [Figure 37-33](#) and described in [Table 37-21](#).

Return to the [Summary Table](#).

The SCICLEARINTLVL register is used to map individual interrupt sources to the INT0 line.

**Table 37-21. SCICLEARINTLVL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	CLRBEINTLVL	R/W1C	0h	Clear Bit Error interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the Bit Error interrupt level to the INT0 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.
30	CLRPBEINTLVL	R/W1C	0h	Clear Physical Bus Error interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the Physical Bus Error interrupt level to the INT0 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.
29	CLRCEINTLVL	R/W1C	0h	Clear Checksum-error interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the Checksum-error interrupt level to the INT0 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.
28	CLRISFEINTLVL	R/W1C	0h	Clear Inconsistent-Sync-Field-Error interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the Inconsistent-Sync-Field-Error interrupt level to the INT0 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.

**Table 37-21. SCICLEARINTLVL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
27	CLRNREINTLVL	R/W1C	0h	Clear No-Response-Error interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the No-Response-Error interrupt level to the INT0 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.
26	CLRFEINTLVL	R/W1C	0h	Clear Framing-Error interrupt level. This bit is effective in LIN or SCI-compatible mode. Writing to this bit maps the Framing-Error interrupt level to the INT0 line. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.
25	CLROEINTLVL	R/W1C	0h	Clear Overrun-Error Interrupt Level. This bit is effective in LIN or SCI-compatible mode. Writing to this bit maps the Overrun-Error interrupt level to the INT0 line. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.
24	CLRPEINTLVL	R/W1C	0h	Clear Parity Error interrupt level. This bit is effective in LIN or SCI-compatible mode. Writing to this bit maps the Parity Error interrupt level to the INT0 line. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.
23-19	RESERVED	R	0h	Reserved
18	RESERVED	R	0h	Reserved
17-16	RESERVED	R	0h	Reserved
15-14	RESERVED	R	0h	Reserved
13	CLRIDINTLVL	R/W1C	0h	Clear ID interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the ID interrupt level to the INT0 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.
12-10	RESERVED	R	0h	Reserved
9	CLRRXINTLVL	R/W1C	0h	Clear Receiver interrupt level. This bit is effective in LIN or SCI-compatible mode. Writing to this bit maps the receiver interrupt level to the INT0 line. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.
8	CLRTXINTLVL	R/W1C	0h	Clear Transmitter interrupt level. This bit is effective in LIN or SCI-compatible mode. Writing to this bit maps the transmitter interrupt level to the INT0 line. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.

**Table 37-21. SCICLEARINTLVL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
7	CLRTOA3WUSINTLVL	R/W1C	0h	Clear Timeout After 3 Wakeup Signals interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the timeout after 3 wakeup signals interrupt level to the INTO line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INTO line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INTO and clear this bit.
6	CLRTOAWUSINTLVL	R/W1C	0h	Clear Timeout After Wakeup Signal interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the the timeout after wakeup interrupt level to the INTO line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INTO line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INTO and clear this bit.
5	RESERVED	R	0h	Reserved
4	CLRTIMEOUTINTLVL	R/W1C	0h	Clear Timeout interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the timeout interrupt level to the INTO line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INTO line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INTO and clear this bit.
3-2	RESERVED	R	0h	Reserved
1	CLRWAKEUPINTLVL	R/W1C	0h	Clear Wake-up interrupt level. This bit is effective in LIN or SCI-compatible mode. Writing to this bit maps the Wake-up interrupt level to the INTO line. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INTO line. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INTO and clear this bit.
0	CLBRKDTINTLVL	R/W1C	0h	Clear Break-detect interrupt level. This bit is effective in SCI-compatible mode only. Writing to this bit maps the Break-detect interrupt level to the INTO line. This field is writable in SCI mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INTO line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INTO and clear this bit.

### 37.7.2.8 SCIFLR Register (Offset = 1Ch) [Reset = 0000904h]

SCIFLR is shown in [Figure 37-34](#) and described in [Table 37-22](#).

Return to the [Summary Table](#).

The SCIFLR register indicates the current status of the various interrupt sources of the LIN module.

**Table 37-22. SCIFLR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	BE	R/W1C	0h	Bit Error Flag. This bit is effective in LIN mode only. This bit is set when there has been a bit error. This is detected by the bit monitor in the internal bit monitor. This bit is cleared by: <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- System reset</li> <li>- Writing a 1 to this bit</li> <li>- Reception of a new sync break</li> </ul> This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = No bit error detected. 1h (R/W) = Bit error detected.
30	PBE	R/W1C	0h	Physical Bus Error Flag. This bit is effective in LIN mode only. This bit is set when there has been a physical bus error. This is detected by the bit monitor in TED. This bit is cleared by: <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- System reset</li> <li>- Writing a 1 to this bit</li> <li>- Reception of a new sync break</li> </ul> Note: this PBE will only be flagged if no sync break can be generated. (because of a bus shortage to VBAT) or if no sync break delimiter can be generated (because of a bus shortage to GND). This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = No physical bus error detected. 1h (R/W) = Physical bus error detected.

**Table 37-22. SCIFLR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
29	CE	R/W1C	0h	<p>Checksum Error Flag.</p> <p>This bit is effective in LIN mode only. This bit is set when there is checksum error detected by a receiving node. The type of checksum to be used depends on the SCIGCR1.CTYPE bit. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- System reset</li> <li>- Writing a 1 to this bit</li> <li>- Reception of a new sync break</li> </ul> <p>This field is writable in LIN mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No Checksum error detected. 1h (R/W) = Checksum error detected.</p>
28	ISFE	R/W1C	0h	<p>Inconsistent Sync Field Error Flag.</p> <p>This bit is effective in LIN mode only. This bit is set when there has been an inconsistent Sync Field error detected by the synchronizer during header reception. See the 'Header Reception and Adaptive Baudrate' section for more information. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- System reset</li> <li>- Writing a 1 to this bit</li> <li>- Reception of a new sync break</li> </ul> <p>This field is writable in LIN mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No Inconsistent Sync Field error detected. 1h (R/W) = Inconsistent Sync Field error detected.</p>
27	NRE	R/W1C	0h	<p>No-Response Error Flag.</p> <p>This bit is effective in LIN mode only. This bit is set when there is no response to a Commander's header completed within TFRAME_MAX. This timeout period is applied for message frames of unknown length (identifiers 0 to 61). This error is detected by the synchronizer of the module. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- System reset</li> <li>- Writing a 1 to this bit</li> <li>- Reception of a new sync break</li> </ul> <p>This field is writable in LIN mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No No-Response error detected. 1h (R/W) = No-Response error detected.</p>

**Table 37-22. SCIFLR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
26	FE	R/W1C	0h	<p>Framing error flag.</p> <p>This bit is effective in LIN or SCI-compatible mode. This bit is set when an expected stop bit is not found. In SCI compatible mode, only the first stop bit is checked. The missing stop bit indicates that synchronization with the start bit has been lost and that the character is incorrectly framed. Detection of a framing error causes the SCI to generate an error interrupt if the RXERR INT ENA bit is set. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- System reset</li> <li>- Writing a 1 to this bit</li> </ul> <p>- Reception of a new character (SCI-compatible mode), or frame (LIN mode)</p> <p>In multibuffer mode the frame is defined in the SCIFORMAT register.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No framing error detected. 1h (R/W) = Framing error detected.</p>
25	OE	R/W1C	0h	<p>Overrun error flag.</p> <p>This bit is effective in LIN or SCI-compatible mode. This bit is set when the transfer of data from SCIRXSHF to SCIRD overwrites unread data already in SCIRD or the RDy buffers. Detection of an overrun error causes the LIN to generate an error interrupt if the SET OE INT bit is one. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- System reset</li> <li>- Writing a 1 to this bit</li> </ul> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No overrun error detected. 1h (R/W) = Overrun error detected.</p>
24	PE	R/W1C	0h	<p>Parity error flag.</p> <p>This bit is effective in LIN or SCI-compatible mode. This bit is set when a parity error is detected in the received data. In SCI address-bit mode, the parity is calculated on the data and address bit fields of the received frame. In idle-line mode, only the data is used to calculate parity. An error is generated when a character is received with a mismatch between the number of 1s and its parity bit. For more information on parity checking, see the 'SCI Global Control Register (SCIGCR1)' description. If the parity function is disabled (that is, SCIGCR1.2 = 0), the PE flag is disabled and read as 0. Detection of a parity error causes the LIN to generate an error interrupt if the SET PE INT bit = 1. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- System reset</li> <li>- Reception of a new character (SCI-compatible mode) or frame (LIN mode)</li> <li>- Writing a 1 to this bit</li> </ul> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No parity error or parity disabled. 1h (R/W) = Parity error detected.</p>
23-16	RESERVED	R	0h	Reserved
15	RESERVED	R	0h	Reserved

**Table 37-22. SCIFLR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
14	IDRXFLAG	R/W1C	0h	<p>Identifier On Receive Flag.</p> <p>This bit is effective in LIN mode only. This flag is set once an identifier is received with an RX match and no ID-parity error. See the 'Message Filtering and Validation' section for more details. When this flag is set it indicates that a new valid identifier has been received on an RX match. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- System reset</li> <li>- Reading the LINID register</li> <li>- Writing a 1 to this bit</li> </ul> <p>This field is writable in LIN mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No valid ID received. 1h (R/W) = Valid ID RX received in LINID[23:16] on RX match.</p>
13	IDTXFLAG	R/W1C	0h	<p>Identifier On Transmit Flag.</p> <p>This bit is effective in LIN mode only. This flag is set once an identifier is received with a TX match and no ID-parity error. See the 'Message Filtering and Validation' section for more details. When this flag is set it indicates that a new valid identifier has been received on a TX match. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- Setting SWnRESET</li> <li>- System reset</li> <li>- Reading the LINID register</li> <li>- Writing a 1 to this bit</li> </ul> <p>This field is writable in LIN mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No valid ID received. 1h (R/W) = Valid ID received in LINID[23:16] on TX match.</p>
12	RXWAKE	R	0h	<p>Receiver wakeup detect flag.</p> <p>This bit is effective in SCI-compatible mode only. The SCI sets this bit to indicate that the data currently in SCIRD is an address. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- RESET bit</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- System reset</li> <li>- Receipt of a data frame</li> </ul> <p>This bit is writable in SCI mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = The data in SCIRD is not an address. 1h (R/W) = The data in SCIRD is an address.</p> <p>See [1] Section 3.4.4, Sleep Mode for Multiprocessor Communication, on page 16 for more information on using the RXWAKE bit with sleep mode.</p>

**Table 37-22. SCIFLR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
11	TXEMPTY	R	1h	<p>Transmitter Empty flag.</p> <p>The value of this flag indicates the contents of the transmitter's buffer register(s) (SCITD/TDy) and shift register (SCITXSHF). In multibuffer mode, this flag indicates the value of the TDx registers and shift register (SCITXSHF). In non multibuffer mode, this flag indicates the value of LINTD0 (byte) and shift register (SCITXSHF). This bit is set by:</p> <ul style="list-style-type: none"> <li>- RESET bit (SCIGCR0.0)</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- System reset.</li> </ul> <p>Note: This bit does not cause an interrupt request.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Compatible mode or LIN with no multibuffer: Transmitter buffer or shift register (or both) are loaded with data.</p> <p>In LIN mode using multibuffer mode: Multibuffer or shift register (or all) are loaded with data.</p> <p>1h (R/W) = Compatible mode or LIN with no multibuffer: Transmitter buffer and shift registers are both empty.</p> <p>In LIN mode using multibuffer mode: Multibuffer and shift registers are all empty.</p>
10	TXWAKE	R/W	0h	<p>SCI transmitter wakeup method select.</p> <p>This bit is effective in SCI-compatible mode only. The TXWAKE bit controls whether the data in SCITD should be sent as an address or data frame using multiprocessor communication format. This bit is set to 1 or 0 by software before a byte is written to SCITD and is cleared by the SCI when data is transferred from SCITD to SCITXSHF or by a system reset. TXWAKE is not cleared by the SWnRESET bit (SCIGCR1.7).</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Address-bit mode: Frame to be transmitted will be data (address bit = 0).</p> <p>Idle-line mode: Frame to be transmitted will be data.</p> <p>1h (R/W) = Address-bit mode: Frame to be transmitted will be an address (address bit=1).</p> <p>Idle-line mode: Following frame to be transmitted will be an address (writing a 1 to this bit followed by writing dummy data to the SCITD will result in a idle period of 11 bit periods before the next frame is transmitted).</p>
9	RXRDY	R/W1C	0h	<p>Receiver ready flag.</p> <p>In SCI compatibility mode, the receiver sets this bit to indicate that the SCIRD contains new data and is ready to be read by the CPU. In LIN mode, RXRDY is set once a valid frame is received in multibuffer mode, a valid frame being a message frame received with no errors. In non multibuffer mode RXRDY is set for each received byte and will be set for the last byte of the frame if there are no errors. The SCI/LIN generates a receive interrupt when RXRDY flag bit is set if the interrupt-enable bit is set (SCISSETINT.9). RXRDY is cleared by:</p> <ul style="list-style-type: none"> <li>- RESET bit (SCIGCR0.0)</li> <li>- Setting the SWnRESET</li> <li>- System reset</li> <li>- Writing a 1 to this bit</li> <li>- Reading SCIRD in while in SCI compatibility mode</li> <li>- Reading last data byte RDY of the response in LIN mode</li> </ul> <p>Note: The RXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0/1 register.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No new data in SCIRD/RDy.</p> <p>1h (R/W) = New data ready to be read from SCIRD.</p>

**Table 37-22. SCIFLR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
8	TXRDY	R	1h	<p>Transmitter buffer register ready flag.</p> <p>When set, this bit indicates that the transmit buffer(s) register (SCITD in compatibility mode and LINTD0, LINTD1 in MBUF mode) is/are ready to get another character from a CPU write.</p> <p>In SCI compatibility mode, writing data to SCITD automatically clears this bit. In LIN mode, this bit is cleared once byte 0 (TD0) is written to LINTD0. This bit is set after the data of the TX buffer are shifted into the SCITXSHF register. For devices with a DMA module, this event can trigger a transmit DMA event if the DMA enable bit is set. This bit is set to 1 by:</p> <ul style="list-style-type: none"> <li>- RESET bit (SCIGCR0.0)</li> <li>- Setting the SWnRESET (SCIGCR1.7)</li> <li>- System reset</li> </ul> <p>Note: The TXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0/1 register.</p> <p>Note: The transmit interrupt request can be eliminated until the next series of data is written into the transmit buffers LINTD0 and LINTD1, by disabling the corresponding interrupt via the SCICLEARINT register or by disabling the transmitter via the TXENA bit (SCIGCR1.25=0).</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Compatible mode: SCITD is full.</p> <p>LIN mode: The multibuffers are full.</p> <p>1h (R/W) = Compatible mode: SCITD is ready to receive the next character.</p> <p>LIN mode: The multibuffers are ready to receive the next character(s).</p>
7	TOA3WUS	R/W1C	0h	<p>Timeout After 3 Wakeup Signals flag.</p> <p>This bit is effective in LIN mode only. This flag is set if there is no Sync Break received after 3 wakeup signals and a period of 1.5 seconds have passed. Such expiration time is used before issuing another round of wakeup signals. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- System reset</li> <li>- Writing a 1 to this bit</li> </ul> <p>This field is writable in LIN mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No timeout after 3 wakeup signals.</p> <p>1h (R/W) = Timeout after 3 wakeup signals and 1.5s time.</p>
6	TOAWUS	R/W1C	0h	<p>Timeout After Wakeup Signal flag.</p> <p>This bit is effective in LIN mode only. This bit is set if there is no Sync Break received after a wakeup signal has been sent. A minimum of 150 ms expiration time is used before issuing another wakeup signal. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- System reset</li> <li>- Writing a 1 to this bit</li> </ul> <p>This field is writable in LIN mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No timeout after one wakeup signal (150 ms).</p> <p>1h (R/W) = Timeout after one wakeup signal.</p>
5	RESERVED	R	0h	Reserved

**Table 37-22. SCIFLR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
4	TIMEOUT	R/W1C	0h	<p>LIN Bus IDLE timeout flag.</p> <p>This bit is effective in LIN mode only. This bit is set if there is no LIN bus activity for at least 4 seconds. LIN bus activity being a transition from recessive to dominant. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- System reset</li> <li>- Writing a 1 to this bit</li> </ul> <p>This field is writable in LIN mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No bus idle detected. 1h (R/W) = LIN bus idle detected.</p>
3	BUSY	R	0h	<p>Bus BUSY flag.</p> <p>This bit is effective in LIN mode and SCI-compatible mode. This bit indicates whether the receiver is in the process of receiving a frame. As soon as the receiver detects the beginning of a start bit, the BUSY bit is set to 1. When the reception of a frame is complete, the BUSY bit is cleared. If SET WAKEUP INT is set and power down is requested while this bit is set, the SCI/LIN automatically prevents low-power mode from being entered and generates wakeup interrupt. The BUSY bit is controlled directly by the SCI receiver but can be cleared by:</p> <ul style="list-style-type: none"> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- System reset.</li> </ul> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Receiver is not currently receiving a frame. 1h (R/W) = Receiver is currently receiving a frame.</p>
2	IDLE	R	1h	<p>SCI receiver in idle state.</p> <p>This bit is effective in SCI-compatible mode only. While this bit is set, the SCI looks for an idle period to resynchronize itself with the bit stream. The receiver does not receive any data while the bit is set. The bus must be idle for 11 bit periods to clear this bit. The SCI enters this state:</p> <ul style="list-style-type: none"> <li>- After a system reset</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- After coming out of power down</li> </ul> <p>This bit is writable in SCI mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Idle period detected, the SCI is ready to receive. 1h (R/W) = Idle period not detected, the SCI will not receive any data.</p>
1	WAKEUP	R/W1C	0h	<p>Wake-up flag.</p> <p>This bit is effective in LIN mode only. This bit is set by the SCI/LIN when receiver or transmitter activity has taken the module out of power-down mode. An interrupt is generated if the SET WAKEUP INT bit (SCISSETINT.1) is set. This bit is cleared by:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register.</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- System reset</li> <li>- Writing a 1 to this bit.</li> </ul> <p>This field is writable in LIN mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = Do not wake up from power-down mode. 1h (R/W) = Wake up from power-down mode.</p>

**Table 37-22. SCIFLR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
0	BRKDT	R/W1C	0h	<p>SCI break-detect flag.</p> <p>This bit is effective in SCI-compatible mode only. This bit is set when the SCI detects a break condition on the LINRX pin. A break condition occurs when the LINRX pin remains continuously low for at least 10 bits after a missing first stop bit, that is, after a framing error. Detection of a break condition causes the SCI to generate an error interrupt if the BRKDT INT ENA bit is set. The BRKDT bit is cleared by the following:</p> <ul style="list-style-type: none"> <li>- Reading the corresponding interrupt offset in the SCIINTVECT0/1 register.</li> <li>- Setting the SWnRESET bit (SCIGCR1.7)</li> <li>- RESET bit (SCIGCR0.0)</li> <li>- System reset</li> <li>- By writing a 1 to this bit.</li> </ul> <p>This bit is writable in SCI mode only.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No break condition detected. 1h (R/W) = Break condition detected.</p>

### 37.7.2.9 SCIINTVECT0 Register (Offset = 20h) [Reset = 0000000h]

SCIINTVECT0 is shown in [Figure 37-35](#) and described in [Table 37-23](#).

Return to the [Summary Table](#).

The SCIINTVECT0 register indicates the offset for the INT0 interrupt line.

**Figure 37-35. SCIINTVECT0 Register**

30-28	U	R/W	0h	Superfractional Divider Selection. (U) These bits are an additional fractional part for the baudrate specification. These bits allow a super fine tuning of the fractional baudrate with 7 more intermediate values for each of the M fractional divider values. See the Superfractional Divider section for more details. Reset type: SYSRSn
27-24	M	R/W	0h	SCI/LIN 4-bit Fractional Divider Selection. (M) These bits are effective in LIN or SCI asynchronous mode. These bits are used to select a baud rate for the SCI/LIN module, and they are a fractional part for the baud rate specification. The M divider allows fine-tuning of the baud rate over the P prescaler with 15 additional intermediate values for each of the P integer values. Reset type: SYSRSn
23-16	SCI_LIN_PSH	R/W	0h	PRESCALER P (High Bits). SCI/LIN 24-bit Integer Prescaler Selection. These bits are used to select a baudrate for the SCI/LIN module. These bits are effective in LIN mode and SCI compatible mode. The SCI/LIN has an internally generated serial clock determined by the LIN module input clock and the prescalers P and M in this register. The SCI/LIN uses the 24-bit integer prescaler P value to select 1 of over 16,700,000 available baud rates. The additional 4-bit fractional prescaler M refines the baudate selection. Reset type: SYSRSn

**Table 37-26. BRSR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
15-0	SCI_LIN_PSL	R/W	0h	PRESCALER P (Low Bits). SCI/LIN 24-bit Integer Prescaler Selection. These bits are used to select a baudrate for the SCI/LIN module. These bits are effective in LIN mode and SCI compatible mode. The SCI/LIN has an internally generated serial clock determined by the LIN module input clock and the prescalers P and M in this register. The SCI/LIN uses the 24-bit integer prescaler P value to select 1 of over 16,700,000 available baud rates. The additional 4-bit fractional prescaler M refines the baudrate selection. Reset type: SYSRSn

### 37.7.2.13 SCIED Register (Offset = 30h) [Reset = 0000000h]

SCIED is shown in [Figure 37-39](#) and described in [Table 37-27](#).

Return to the [Summary Table](#).

The SCIED register is a duplicate copy of SCIRD register that has no affect on the RXRDY flag for use with an emulator.

**Figure 37-39. SCIED Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**Table 37-28. SCIRD Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	Reserved
7-0	RD	R	0h	Received Data. This bit is effective in SCI-compatible mode only. When a frame has been completely received, the data in the frame is transferred from the receiver shift register SCIRXSHF to this register. As this transfer occurs, the RXRDY flag is set and a receive interrupt is generated if RX INT ENA (SCISSETINT0.9) is set. When the data is read from SCIRD, the RXRDY flag is automatically cleared. When the SCI receives data that is fewer than eight bits in length, it loads the data into this register in a left justified format padded with trailing zeros. Therefore, your software should perform a logical shift on the data by the correct number of positions to make it right justified. Reset type: SYSRSn

### 37.7.2.15 SCITD Register (Offset = 38h) [Reset = 0000000h]

SCITD is shown in [Figure 37-41](#) and described in [Table 37-29](#).

Return to the [Summary Table](#).

The SCITD register is where data to be transmitted is written to by application software.

**Figure 37-41. SCITD Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																TD

15-8	RD6	R	0h	8-bit Receive Buffer 6. Each response data-byte that is received in the SCIRXSHFT register is transferred to the corresponding RDy register according to the number of bytes received. Reset type: SYSRSn
7-0	RD7	R	0h	8-bit Receive Buffer 7. Each response data-byte that is received in the SCIRXSHFT register is transferred to the corresponding RDy register according to the number of bytes received. Reset type: SYSRSn

### 37.7.2.21 LINMASK Register (Offset = 6Ch) [Reset = 0000000h]

LINMASK is shown in [Figure 37-47](#) and described in [Table 37-35](#).

Return to the [Summary Table](#).

The LINMASK register is used to configure the masks used for filtering incoming ID messages for receive and transmit frames.

**Figure 37-47. LINMASK Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								RXIDMASK								RESERVED								TXIDMASK							
R-0h								R/W-0h								R-0h								R/W-0h							

**Table 37-35. LINMASK Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	RESERVED	R	0h	Reserved
23-16	RXIDMASK	R/W	0h	Receive ID mask. This field is effective in LIN mode only. This 8-bit mask is used for filtering an incoming ID message and compare it to the ID-byte. A compare match of the received ID with the RX ID mask will set the ID RX flag and trigger and ID interrupt if enabled. A 0 bit in the mask indicates that bit is compared to the ID-byte. A 1 bit in the mask indicates that that bit is filtered and therefore not used in the compare. When HGENCTRL is set to 1, this field must be set to 0xFF if the complete ID must be compared. Reset type: SYSRSn
15-8	RESERVED	R	0h	Reserved
7-0	TXIDMASK	R/W	0h	Transmit ID mask. This field is effective in LIN mode only. This 8-bit mask is used for filtering an incoming ID message and comparing it to the ID-byte. A compare match of the received ID with the TX ID Mask will set the ID TX flag and trigger an ID interrupt if enabled. A 0 bit in the mask indicates that bit is compared to the ID-byte. A 1 bit in the mask indicates that bit is filtered and therefore not used for the compare. When HGENCTRL is set to 1, this field must be set to 0xFF if the complete ID must be compared. Reset type: SYSRSn

### 37.7.2.22 LINID Register (Offset = 70h) [Reset = 0000000h]

LINID is shown in [Figure 37-48](#) and described in [Table 37-36](#).

Return to the [Summary Table](#).

The LINID register contains the identification fields for LIN communication.

NOTE: For software compatibility with future LIN modules, the HGEN CTRL bit must be set to 1, the RX ID MASK field must be set to FFh, and the TX ID MASK field must be set to FFh.

**Figure 37-48. LINID Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

IDRESPONDERTASKBYTE								IDBYTE							
R/W-0h								R/W-0h							

**Table 37-36. LINID Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	RESERVED	R	0h	Reserved
23-16	RECEIVEDID	R	0h	Received ID. This bit is effective in LIN mode only. This byte contains the current message identifier. During header reception the received ID is copied from the SCIRXSHF register to this byte if there is no ID-parity error and there has been an RX/TX match. Note: If a framing error (FE) is detected during ID reception, the received ID will also not be copied to the LINID register. Reset type: SYSRSn
15-8	IDRESPONDERTASKBYTE	R/W	0h	ID Responder Task byte. This field is effective in LIN mode only. This byte contains the identifier to which the received ID of an incoming header will be compared in order to decide whether a RX response, a TX response, or no action needs to be done by the LIN node. These bits are writable in LIN mode only. Reset type: SYSRSn
7-0	IDBYTE	R/W	0h	ID byte. This field is effective in LIN mode only. This byte is the LIN mode message ID. On a Commander node, a write to this register by the CPU initiates a header transmission. For a Responder task, this byte is used for message filtering when HGENCTRL (SCIGCR1.12) is '0'. These bits are writable in LIN mode only. Reset type: SYSRSn

### 37.7.2.23 LINTD0 Register (Offset = 74h) [Reset = 0000000h]

LINTD0 is shown in [Figure 37-49](#) and described in [Table 37-37](#).

Return to the [Summary Table](#).

The LINTD0 register contains the lower 4 bytes of the data to be transmitted.

NOTE: TD<x-1> is equivalent to Data byte <x> of the LIN frame.

**Figure 37-49. LINTD0 Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit	Field	Type	Reset	Description
31-24	TD0	R/W	0h	8-bit Transmit Buffer 0. Byte 0 to be transmitted is written into this register and then copied to SCITXSHF for transmission. Once byte 0 is written in TDO buffer, transmission will be initiated. Reset type: SYSRSn
23-16	TD1	R/W	0h	8-bit Transmit Buffer 1. Byte 1 to be transmitted is written into this register and then copied to SCITXSHF for transmission. Reset type: SYSRSn
15-8	TD2	R/W	0h	8-bit Transmit Buffer 2. Byte 2 to be transmitted is written into this register and then copied to SCITXSHF for transmission. Reset type: SYSRSn
7-0	TD3	R/W	0h	8-bit Transmit Buffer 3. Byte 3 to be transmitted is written into this register and then copied to SCITXSHF for transmission. Reset type: SYSRSn

### 37.7.2.24 LINTD1 Register (Offset = 78h) [Reset = 0000000h]

LINTD1 is shown in [Figure 37-50](#) and described in [Table 37-38](#).

Return to the [Summary Table](#).

The LINTD1 register contains the upper 4 bytes of the data to be transmitted.

NOTE: TD<x-1> is equivalent to Data byte <x> of the LIN frame.

**Figure 37-50. LINTD1 Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

31-24	TD4	R/W	0h	8-bit Transmit Buffer 4. Byte 4 to be transmitted is written into this register and then copied to SCITXSHF for transmission. Reset type: SYSRSn
23-16	TD5	R/W	0h	8-bit Transmit Buffer 5. Byte 5 to be transmitted is written into this register and then copied to SCITXSHF for transmission. Reset type: SYSRSn
15-8	TD6	R/W	0h	8-bit Transmit Buffer 6. Byte 6 to be transmitted is written into this register and then copied to SCITXSHF for transmission. Reset type: SYSRSn
7-0	TD7	R/W	0h	8-bit Transmit Buffer 7. Byte 7 to be transmitted is written into this register and then copied to SCITXSHF for transmission. Reset type: SYSRSn

### 37.7.2.25 MBRSR Register (Offset = 7Ch) [Reset = 0000DACH]

MBRSR is shown in [Figure 37-51](#) and described in [Table 37-39](#).

Return to the [Summary Table](#).

The MBRSR register is used to configure the expected maximum baud rate of the LIN network.

**Figure 37-51. MBRSR Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED													MBR																		
R-0h													R/W-DACH																		

**Table 37-39. MBRSR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-13	RESERVED	R	0h	Reserved
12-0	MBR	R/W	DACH	<p>Maximum Baud Rate Prescaler.</p> <p>This field is effective in LIN mode only. This 13-bit prescaler is used during the synchronization phase (see the 'Header Reception and Adaptive Baudrate' section) of a responder module if the ADAPT bit is set. In this way, a SCI/LIN responder using automatic or select bit rate modes detects any LIN bus legal rate automatically if the measured baud rate is within <math>\pm 10\%</math> of the programmed baud rate. The MBR value should be programmed to allow a maximum baud rate that is not more than 10% above the expected operating baud rate in the LIN network. Otherwise a s 0x00 data byte could mistakenly be detected as sync break.</p> <p>The default value is for a 70MHz VCLK and ~18kbps expected baud rate. (0xDAC).</p> <p>This MBR prescaler is used by the wake-up and idle time counters for a constant expiration time relative to a 20kHz rate.</p> <p><math>MBR = VCLK \text{ Frequency} / (1.1 * \text{Expected Baud Rate Frequency})</math></p> <p>Note: The MBR field must be written with a 13-bit value. If the calculated MBR exceeds <math>2^{13} = 8192</math>, either the baud rate or the VCLK frequency must be adjusted for valid operation.</p> <p>Reset type: SYSRSn</p>

### 37.7.2.26 IODFTCTRL Register (Offset = 90h) [Reset = 00000500h]

IODFTCTRL is shown in [Figure 37-52](#) and described in [Table 37-40](#).

Return to the [Summary Table](#).

The IODFTCTRL register is used to emulate various error and test conditions.

**Figure 37-52. IODFTCTRL Register**

31	30	29	28	27	26	25	24
BERRENA	PBERRENA	CERRENA	ISFERRENA	RESERVED	FERRENA	PERRENA	BRKDTERREN A

**Table 37-40. IODFTCTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	BERRENA	R/W	0h	Bit Error Enable bit. This bit is effective in LIN mode only. This bit is used to create a Bit error. When this bit is set, the bit received is ORed with 1 and passed to the Bit monitor circuitry. Reset type: SYSRSn
30	PBERRENA	R/W	0h	Physical Bus Error Enable bit. This bit is effective in LIN mode only. This bit is used to create a Physical Bus Error. When this bit is set, the bit received during Sync Break field transmission is ORed with 1 and passed to the Bit monitor circuitry. Reset type: SYSRSn
29	CERRENA	R/W	0h	Checksum Error Enable bit. This bit is effective in LIN mode only. This bit is used to create a checksum error. When this bit is set, the polarity of the CTYPE (checksum type) in the receive checksum calculator is changed so that a checksum error is generated. Reset type: SYSRSn
28	ISFERRENA	R/W	0h	Inconsistent Sync Field Error Enable bit. This bit is effective in LIN mode only. This bit is used to create an ISF error. When this bit is set, the bit widths in the sync field are varied so that the ISF check fails and the error flag is set. Reset type: SYSRSn
27	RESERVED	R	0h	Reserved
26	FERRENA	R/W	0h	This bit is used to create a Frame Error. This bit is effective in SCI-compatible mode only. When this bit is set, the stop bit received is ANDed with '0' and passed to the stop bit check circuitry. Reset type: SYSRSn

**Table 37-40. IODFTCTRL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
25	PERRENA	R/W	0h	Compatible Mode only This bit is effective in SCI-compatible mode only. This bit is used to create a Parity Error. When this bit is set, in compatible mode, the parity bit received is toggled so that a parity error occurs. Reset type: SYSRSn
24	BRKDTERRRENA	R/W	0h	Compatible Mode only This bit is effective in SCI-compatible mode only. This bit is used to create BRKDT error (SCI mode only). When this bit is set, the stop bit of the frame is ANDed with '0' and passed to the RSM so that a frame error occurs. Then the RX Pin is forced to continuous low for 10 Tbits so that a BRKDT error occurs. Reset type: SYSRSn
23-21	RESERVED	R/W	0h	Reserved
20-19	PINSAMPLEMASK	R/W	0h	Pin sample mask. These bits define the sample number at which the TX Pin value that is being transmitted will be inverted to verify the receive pin samples correctly with the majority detection circuitry. Note: During IODFT mode testing for the pin sample mask, the prescaler P must be programmed to be greater than 2. Reset type: SYSRSn 0h (R/W) = No Mask 1h (R/W) = Invert the TX Pin value at TBIT_CENTER 2h (R/W) = Invert the TX Pin value at TBIT_CENTER + SCLK 3h (R/W) = Invert the TX Pin value at TBIT_CENTER + 2 SCLK
18-16	TXSHIFT	R/W	0h	Transmit shift. These bits define the delay by which the value on LINTX is delayed so that the value on LINRX is asynchronous. (Not applicable to Start Bit) Reset type: SYSRSn 0h (R/W) = No Delay 1h (R/W) = Delay by 1 SCLK 2h (R/W) = Delay by 2 SCLK 3h (R/W) = Delay by 3 SCLK 4h (R/W) = Delay by 4 SCLK 5h (R/W) = Delay by 5 SCLK 6h (R/W) = Delay by 6 SCLK 7h (R/W) = Delay by 7 SCLK
15-12	RESERVED	R	0h	Reserved
11-8	IODFTENA	R/W	5h	IO DFT Enable Key This field is used to enable the IODFT mode of the SCI/LIN module for testing. 7-2	RESERVED	R	0h	Reserved

**Table 37-40. IODFTCTRL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
1	LPBENA	R/W	0h	Module loopback enable. In analog loopback mode the complete communication path through the I/Os can be tested, whereas in digital loopback mode the I/O buffers are excluded from this path. Reset type: SYSRSn 0h (R/W) = Digital loopback is enabled. 1h (R/W) = Analog loopback is enabled in module I/O DFT mode (when IODFTENA = 1010)
0	RXPENA	R/W	0h	Module Analog loopback through receive pin enable. This bit defines whether the I/O buffers for the transmit or the receive pin are included in the communication path in analog loopback mode only. Reset type: SYSRSn 0h (R/W) = Analog loopback through the transmit pin is enabled. 1h (R/W) = Analog loopback through the receive pin is enabled.

### 37.7.2.27 LIN\_GLB\_INT\_EN Register (Offset = E0h) [Reset = 0000000h]

LIN\_GLB\_INT\_EN is shown in [Figure 37-53](#) and described in [Table 37-41](#).

Return to the [Summary Table](#).

The LIN\_GLB\_INT\_EN register is used to enable the INT0 and INT1 interrupt lines to propagate to the PIE block.

Bit	Field	Type	Reset	Description
31-2	RESERVED	R	0h	Reserved
1	INT1_FLG	R	0h	Global Interrupt Flag for LIN INT1. This bit indicates if an interrupt was generated to the PIE due to an enabled interrupt on the INT1 interrupt line. Refer to the LIN Interrupt Status Register for the condition that generated the interrupt. This bit can be cleared by writing a 1 to the corresponding bit in the LIN_GLB_INT_CLR register. Reset type: SYSRSn 0h (R/W) = No interrupt is active on the INT1 line. 1h (R/W) = An interrupt was generated due to an enabled interrupt on the INT1 interrupt line.
0	INT0_FLG	R	0h	Global Interrupt Flag for LIN INT0. This bit indicates if an interrupt was generated to the PIE due to an enabled interrupt on the INT0 interrupt line. Refer to the LIN Interrupt Status Register for the condition that generated the interrupt. This bit can be cleared by writing a 1 to the corresponding bit in the LIN_GLB_INT_CLR register. Reset type: SYSRSn 0h (R/W) = No interrupt is active on the INT0 line. 1h (R/W) = An interrupt was generated due to an enabled interrupt on the INT0 interrupt line.

### 37.7.2.29 LIN\_GLB\_INT\_CLR Register (Offset = E8h) [Reset = 0000000h]

LIN\_GLB\_INT\_CLR is shown in [Figure 37-55](#) and described in [Table 37-43](#).

Return to the [Summary Table](#).

The LIN\_GLB\_INT\_CLR register is used to clear the interrupt flags in LIN\_GLB\_INT\_FLG register.

### 38.1 Introduction

Hardware module integrity during run-time is a critical functional safety requirement. Hardware Redundancy implemented by the lockstep CPU architecture (two CPUs executing the same function and the output of the CPUs are continuously compared) is a proven method for achieving high diagnostic coverage for both permanent and transient faults. The Lockstep Comparator Module (LCM) is implemented to compare output from the CPU to detect permanent and transient faults.

#### 38.1.1 Features

The LCM implements the following features:

- Pipelined architecture
- Redundant comparison
- Self-test capability
  - Match and mismatch test
  - Error forcing capability
- Temporal redundancy: The operation of the two modules is skewed by two cycles to address the issue of common cause failures like failure of clock, power, and so on. This makes sure of temporal redundancy.
- Spatial redundancy: In the lockstep architecture, module instances are redundantly instantiated and the outputs are compared. Redundant instantiation provides spatial redundancy.
- Non-delayed functional output path to provide non-delayed CPU execution for the system (while still having temporal redundancy).
- Register protection of critical memory mapped registers of the module, using a parity scheme.

#### 38.1.2 Block Diagram

Figure 38-1 shows the LCM block diagram.

Figure 38-1. LCM Block Diagram

#### Note

The *Module* described in this block diagram can be either a CPU (for example, CPU1) or a peripheral (for example, DMA) depending on availability for the device.

## 38.2 Enabling LCM Comparators

### Note

The redundant module is automatically enabled at boot.

To enable the LCM comparators upon device startup or after reset, perform the following steps at the beginning of the user application code:

1. Lock the LSEN configuration using the following bit:
  - CPU\_SYS\_REGS[CPUSYSLOCK2.LSEN = 1]
2. Enable the comparator for the desired modules using the following bit:
  - LCM\_REGS[LCM\_CONTROL.CMPEN = 1]
  - Lockstep compare begins the immediate next cycle.

**Note:** The lockstep comparison is enabled by this write and cannot be disabled again without a reset.

## 38.3 Disabling LCM Redundant Module

In systems that do not require the redundant module for functional safety requirements, the LCM redundant module can be disabled for additional power savings. To disable the LCM comparators upon device startup or after reset, the following steps must be taken at the beginning of the user application code:

1. Disable the redundant module using the following bit:
  - CPU\_SYS\_REGS[LSEN.Enable = 0]

**Note:** The redundant lockstep module is disabled by this write and cannot be re-enabled without a reset.

2. (Optional) Lock the LSEN configuration using the following bit:
  - CPU\_SYS\_REGS[CPUSYSLOCK2.LSEN = 1]

## 38.4 LCM Error Handling

Upon an error generated by the LCM module, a system-level NMI is triggered. The LCM error can be triggered by any of the following:

- Functional failure: LCM detecting an error (functional failure between the two modules).
- Self-test failure: LCM self-test failure detected (functional failure on one or both of the modules).
- Force Compare Error Request: Running LCM\_CONTROL.CMPx\_ERR\_FORCE to force a compare error.
  - If the force compare error test passes, the LCM module generates an NMI. Inside the NMI routine, to differentiate between a functional failure of the device and a "force compare error test" induced failure, the LCM\_STATUS.CMPx\_ERR\_FORCE\_DONE flag can be read. This bit determines if the error-force test completed successfully (bit = 1, test complete) or never ran (bit = 0, test not completed). If the test never ran, then the NMI was triggered by an actual functional failure.

To determine the specific cause of the LCM error-induced NMI, the LCM\_STATUS register bits can be read. Particularly:

- CMP\_FAIL
- STPASS
- CMPx\_ERR\_FORCE\_PASS
- CMPx\_ERR\_FORCE\_DONE

For details on system-level NMIs vector locations and interrupt-handling, see the *System Control and Interrupts* chapter.

### 38.5 LCM Error Flags

SYS\_STATUS\_REGS[LCM\_ERR\_FLG] register contains individual LCM module error flags as well as global error event flag indicating lockstep compare error status.

On occurrence of a lockstep module compare error :

1. Sets the individual compare module flag in LCM\_ERR\_FLG register
2. Sets the Global error (GERR) event flag in LCM\_ERR\_FLG register
3. NMI is generated, no further NMI's are fired until GERR flag is cleared

For clearing the status flags user writes to SYS\_STATUS\_REGS[LCM\_ERR\_FLG\_CLR] register. When GERR(Global Error) flag is cleared with the source flags still set, another NMI is generated, therefore user is recommended to clear the source flags before clearing GERR flag.

Optionally user can set the individual module LCM flags in SYS\_STATUS\_REGS[LCM\_ERR\_FLG] register by writing key and respective bits in SYS\_STATUS\_REGS[LCM\_ERR\_FLG\_SET] register simultaneously.

---

#### Note

Only a 32-bit write to the LCM\_ERR\_FLG\_SET register succeeds in updating the fields of this register provided the correct value is written to KEY field simultaneously.

---

### 38.6 Debug Mode with LCM

Lockstep comparison is disabled automatically during debug/emulation mode of the device. However, some items are still available when a debugger is connected:

- Code can continue to be debugged even though lockstep compare is disabled with a debugger connection.
- Self-test logic (match test and mismatch test) is still accessible with debugger connected.
- Clock and inputs to the secondary module are not impacted, and continue to get delayed clock and delayed inputs.

The status of the debugger connection is readable from the status register, specifically the LCM\_REGS[LCM\_STATUS.DBGCON] bit.

To re-initialize the lockstep compare module (after debugger is disconnected), a reset is required. This reset is called using a system reset requested from the debugger which in turn generates an XRSn in the device.

### 38.7 Register Parity Error Protection

The following critical LCM registers are protected by a parity scheme:

- LCM\_CONTROL
- LCM\_STATUS
- LCM\_LOCK
- LCM\_COMMIT

The parity scheme provides one parity bit per byte of data in the corresponding registers. Updates to any of the constantly-monitored registers causes an update to the parity bit. A single bit fault can therefore immediately flag an error. If the parity check determines a parity error has occurred, a dedicated error output line from the LCM module flags an error to the system.

All register parity errors (from the LCM) are combined into a single NMI to the NMIWD module as REGPARITYERR. The status of the register parity error specific to the LCM can also be viewed in the SYS\_STATUS\_REGS[REGPARITY\_ERR\_FLG.LCMx] bits.

Upon a parity error detection, SYSRSN must be asserted and the LCM\_REGS[LCM\_STATUS\_CLEAR] register must then be cleared using the a write of 1 to all appropriate bits in the register.

Details on the self-test capability of the register parity error test are explained in [Section 38.8.3](#).

## 38.8 Functional Logic

This section describes the various logical blocks within the LCM that contribute to the goal of improved diagnostic coverage.

### 38.8.1 Comparator Logic

To implement lockstep scheme, a comparator block is needed. The comparator block compares the delayed version of relevant outputs of the primary module and the equivalent outputs of the secondary (redundant) module. This provides immunity towards the common cause failures like loss of power, clock failures, etc.

The LCM has two instantiations of the comparator block to provide redundancy of the comparator block. This enables availability of one comparator block during self-test of the other comparator block and also provides additional failure protection capability for the comparator logic.

Although the lockstep secondary (redundant) module is enabled upon startup, lockstep comparison must be enabled in software.

Once lockstep compare is enabled in software, the comparison is performed continuously every cycle, from the immediate next cycle. Any difference between the primary and secondary modules generates an error signal from the LCM to the SoC. The corresponding register bit is also set (LCM\_STATUS.CMP\_FAIL).

CPU reset (or any higher-level resets) disables the lockstep comparators, requiring re-enabling of the comparator in software.

### 38.8.2 Self-Test Logic

The self-test of the comparator has two different modes:

- Match Test
- Mismatch Test

These two tests are run together. Self-test is initiated by setting the appropriate register bit (LCM\_CONTROL.STEN). When the self-test is initiated, the two different modes are executed on the two comparators one after the other. A self-test error triggers error aggregator logic at the SoC. A failed self-test also generates an NMI.

Redundant instantiation of the comparator block allows for one instantiation to be conducting a self-test while the other instantiation is active and performing the comparison check.

Self-test can also be performed before the comparator block is enabled in software.

Execution of the self-test is stopped immediately on failure. If either comparator fails the self-test, a status bit (LCM\_STATUS.STPASS) is 0 instead of being set to 1.

During self-test, the LCM\_STATUS.STACTIVE bit has a value of 1. Another self-test or compare error force must not be started until completion of the self-test, as indicated by LCM\_STATUS.STDONE = 1.

The following subsections describe functionality of each of the individual test modes, Mismatch Test and Match Test.

### 38.8.2.1 Match Test Mode

The match test mode checks to make sure identical inputs on each comparator provide passing outputs. This makes sure that the comparator inputs and comparators themselves are working correctly and that a fault is successfully propagated to the module output.

This test is executed using two different patterns fed to the two inputs of each comparator (bit) in the comparator block: {0,0} and {1,1}. Both inputs can provide a passing output to the comparator since both patterns are providing identical inputs to both inputs of the comparator. This tests output-stuck-at-one, input-stuck-at-one, and input-stuck-at-zero issues. [Table 38-1](#) shows the test execution sequence for a single comparator in the comparator block.

**Table 38-1. Match Test Simplified Example**

Clock Cycle	A Input (Primary Module) of Comparator	B Input (Secondary Module) of Comparator	Output
0	0	0	0
1	1	1	0

### 38.8.2.2 Mismatch Test Mode

The mismatch test mode creates an error output of 1 on each individual comparator (bit) within the comparator block, one at a time. This makes sure that all comparators in the block are working correctly and that a fault is successfully propagated to the module output.

This test is executed using a walking 1s pattern to test for output-stuck-at-zero issues. The walking 1s pattern is where all comparators in the comparator block are zero except for one of the comparators.

For example, the primary module has a 1 at the spot that the secondary module has a 0. This can force an intentional error.

This is repeated for every comparator in the block, with the 1 being set on both modules. The passing scenario for this is that all comparators see a mismatch, flagging a mismatch each iteration. See [Figure 38-2](#) for a simplified illustration of how this is implemented for a comparator block with 8 comparators (not the number used in the actual design).

Cycle #	Secondary Module Signal								Primary Module Signal								Output	
	7 (n)	6	5	4	3	2	1	0	7 (n)	6	5	4	3	2	1	0		
0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

**Figure 38-2. Mismatch Test Simplified Example**

### 38.8.3 Error Injection Tests

There are two error injection tests available for the LCM:

- Comparator Error Force Test
- Register Parity Error Injection Test

Each error injection test is run individually, as described in the following subsections.

#### 38.8.3.1 Comparator Error Force Test

The LCM has the capability to force a fault to check the error signaling path between the LCM and error aggregation logic at the device level (for example, NMIWD). This test is executed separately from the self-test, and is executed on the primary and redundant comparators individually through separate calls.

---

#### Note

- The lockstep comparator must be enabled to execute this test.
  - Once this self-test is triggered, another self-test or compare error force request must not be triggered again until the current test is completed, as indicated by `LCM_STATUS.STDONE == 1`.
- 

Execution of this self-test is started by setting the appropriate bit: `LCM_CONTROL.CMPx_ERR_FORCE`, where `x` is the number designator of the redundant comparator to be tested.

Upon execution of this one-cycle-long test, the LCM asserts a lockstep comparison error signal to the device. The normal functional compare fail flag (`LCM_STATUS.CMP_FAIL`) is not set by this test mode.

The following bits are set by the test:

- `LCM_STATUS` register:
  - `CMPx_ERR_FORCE_DONE` bit - 1 when the test is completed.
    - This bit must be cleared before running the test again for comparator "x".
  - `CMPx_ERR_FORCE_PASS` bit - 1 when the test passes.
    - This bit must be cleared before running the test again for comparator "x".

Because the test triggers an NMI on a test pass, the "DONE" flag allows the cause to be determined by either a functional fail or an error forcing test fail.

#### 38.8.3.2 Register Parity Error Test

An error can be injected into the register parity error protection that exists for critical LCM registers, to test for latent faults. This error is inserted by forcing a particular byte to output a failing parity state to the system. This then triggers an NMI to the NMIWD, and also set the `SYS_STATUS_REGS[REGPARITY_ERR_FLG]` bits.

The test can be executed by running setting the `LCM_REGS[PARITY_TEST.TESTEN]` bits to the appropriate value.

Once the `TESTEN` register bits are set, the actual registers are no longer accessible in the memory map. Instead, the one bit parity error status values are accessible for every byte in the registers. Parity is computed for every byte, and the corresponding parity pass/fail value is available at the bit 0 location of every byte, in-place. A 0 in the bit 0 location corresponds to a pass; a 1 in the bit 0 location corresponds to a fail.

To actually inject an error, the value 1 can then be written to the bit 0 location of any byte. This inverts the stored parity value, and therefore inject an error into the parity test mechanism. Note that this propagates as an NMI like an actual parity error, and must therefore be handled within the parity error NMI.

## 38.9 LCM Registers

The following sections are register descriptions for the Lockstep Compare Module (LCM).

### 38.9.1 LCM Base Address Table

**Table 38-2. LCM Base Address Table**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	CPU2	CPU2.DMA	Pipeline Protected
Instance	Structure								
LCM_CPU2Regs	<a href="#">LCM_REGS</a>	LCM_CPU2_BASE	0x0004_C800	-	-	-	YES	-	YES
LCM_CPU2.DMA1Regs	<a href="#">LCM_REGS</a>	LCM_CPU2.DMA1_BASE	0x0004_E800	-	-	-	YES	-	YES

### 38.9.2 LCM\_REGS Registers

Table 38-3 lists the memory-mapped registers for the LCM\_REGS registers. All register offset addresses not listed in Table 38-3 should be considered as reserved locations and the register contents should not be modified.

**Table 38-3. LCM\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	REVISION	IP Revision tie-off value		<a href="#">Go</a>
8h	LCM_CONTROL	LCM Control configuration	PARITY	<a href="#">Go</a>
20h	LCM_STATUS	LCM status register	PARITY	<a href="#">Go</a>
28h	LCM_STATUS_CLEAR	LCM Status clear register		<a href="#">Go</a>
68h	PARITY_TEST	Enabling the parity test feature		<a href="#">Go</a>
70h	LCM_LOCK	LCM lock configuration	PARITY	<a href="#">Go</a>
78h	LCM_COMMIT	LCM commit configuration	PARITY	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 38-4 shows the codes that are used for access types in this section.

**Table 38-4. LCM\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1C	W1C	Write 1 to clear
WOnce	WOnce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 38.9.2.1 REVISION Register (Offset = 0h) [Reset = 4000000h]

REVISION is shown in [Figure 38-3](#) and described in [Table 38-5](#).

Return to the [Summary Table](#).

IP Revision tie-off value

Bit	Field	Type	Reset	Description
31-22	RESERVED	R	0h	Reserved
21	CMP2_ERR_FORCE	R-0/W	0h	0: configuration is ignored 1: comparator-2 lockstep compare error is forced (i) Once the bit is configured, comparator-2 compare error output will be asserted for one cycle. This feature is used to check the error propagation path from comparator2 compare error output to the observation point defined in system control (ii) The test shall be triggered only after enabling the lockstep feature. (iii) It is not possible to execute this test with debugger connected. (iv) The test cannot be executed if there is pending functional failure or test failure (i.e. test cannot be executed when LCM_STATUS.cmp_fail = 1 or (LCM_STATUS.stpass = 0 and LCM_STATUS.stdone = 1) or (LCM_STATUS.cmp1_err_force_pass = 0 and LCM_STATUS.cmp1_err_force_done = 1) or (LCM_STATUS.cmp2_err_force_pass = 0 and LCM_STATUS.cmp2_err_force_done = 1) (v) LCM_STATUS.cmp2_err_force_done and LCM_STATUS.cmp2_err_force_pass flags need to be cleared before initiating the test a 2nd time. Reset type: SYSRSn
20	RESERVED	R	0h	Reserved

**Table 38-6. LCM\_CONTROL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
19	CMP1_ERR_FORCE	R-0/W	0h	0: configuration is ignored 1: comparator-1 lockstep compare error is forced (i) Once the bit is configured, comparator-1 compare error output will be asserted for one cycle. This feature is used to check the error propagation path from comparator1 compare error output to the observation point defined in system control. (ii) The test shall be triggered only after enabling the lockstep feature. (iii) It is not possible to execute this test with debugger connected. (iv) The test cannot be executed if there is pending functional failure or test failure (i.e. test cannot be executed when LCM_STATUS.cmp_fail = 1 or (LCM_STATUS.stpass = 0 and LCM_STATUS.stdone = 1) or (LCM_STATUS.cmp1_err_force_pass = 0 and LCM_STATUS.cmp1_err_force_done = 1) or (LCM_STATUS.cmp2_err_force_pass = 0 and LCM_STATUS.cmp2_err_force_done = 1) (v) LCM_STATUS.cmp1_err_force_done and LCM_STATUS.cmp1_err_force_pass flags need to be cleared before initiating the test a 2nd time. Reset type: SYSRSn
18-17	RESERVED	R	0h	Reserved
16	STEN	R-0/W	0h	0: configuration is ignored 1: self-test enabled (i) Self-test sequence will start when the bit is configured to a value of 1. The test shall be triggered only after enabling the lockstep feature. Lockstep feature shall not be disabled when the test is in progress. (ii) Once the test is initiated, both the comparators will be tested one after the other. It should be possible to execute this test with debugger connected (iii) The test can be triggered only after the previous execution of self-test is complete (i.e. ensuring by checking LCM_STATUS.stdone = 1) (iv) The test cannot be executed if there is pending functional failure or test failure (i.e. test cannot be executed when LCM_STATUS.cmp_fail = 1 or (LCM_STATUS.stpass = 0 and LCM_STATUS.stdone = 1) or (LCM_STATUS.cmp1_err_force_pass = 0 and LCM_STATUS.cmp1_err_force_done = 1) or (LCM_STATUS.cmp2_err_force_pass = 0 and LCM_STATUS.cmp2_err_force_done = 1) (v) LCM_STATUS.stdone and LCM_STATUS.stpass flags need to be cleared before initiating the test a 2nd time. (vi) Device shouldn't enter any low power modes when self-test is in progress Reset type: SYSRSn
15-1	RESERVED	R-0/W	0h	Reserved

**Table 38-6. LCM\_CONTROL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
0	COMPEN	R/W	0h	0: Lockstep compare disabled 1: Lockstep compare enabled Note: (1) Mentions of 'dual module' below are only applicable to systems that support dual modules. Datasheet will explicitly state this functionality if it exists. (2) The configuration to decide whether IP is in lockstep configuration, dual module configuration or single module configuration comes from system control. (3) This bit will have impact only when the IP is configured in lockstep mode (i.e. not in single module or dual module mode) (4) Device is expected to work in either lockstep mode or dual module mode. Switching between modes is not supported except the one time switching from lockstep mode to dual-core mode. (5) User must ensure that LCM_STATUS register should not indicate a failure (i.e. cmp_fail = 1, stpass = 0, cmp1_err_force_pass = 0, cmp2_err_force_pass = 0) at the time of enabling the lockstep compare. Reset type: SYSRSn

### 38.9.2.3 LCM\_STATUS Register (Offset = 20h) [Reset = 0000001h]

LCM\_STATUS is shown in Figure 38-5 and described in Table 38-7.

• Changed <a href="#">Table 35-3</a> .....	5184
• Added second paragraph and formula in <a href="#">Section 37.3.1.5.2</a> .....	5433

## IMPORTANT NOTICE AND DISCLAIMER

TI PROVIDES TECHNICAL AND RELIABILITY DATA (INCLUDING DATA SHEETS), DESIGN RESOURCES (INCLUDING REFERENCE DESIGNS), APPLICATION OR OTHER DESIGN ADVICE, WEB TOOLS, SAFETY INFORMATION, AND OTHER RESOURCES "AS IS" AND WITH ALL FAULTS, AND DISCLAIMS ALL WARRANTIES, EXPRESS AND IMPLIED, INCLUDING WITHOUT LIMITATION ANY IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE OR NON-INFRINGEMENT OF THIRD PARTY INTELLECTUAL PROPERTY RIGHTS.

These resources are intended for skilled developers designing with TI products. You are solely responsible for (1) selecting the appropriate TI products for your application, (2) designing, validating and testing your application, and (3) ensuring your application meets applicable standards, and any other safety, security, regulatory or other requirements.

These resources are subject to change without notice. TI grants you permission to use these resources only for development of an application that uses the TI products described in the resource. Other reproduction and display of these resources is prohibited. No license is granted to any other TI intellectual property right or to any third party intellectual property right. TI disclaims responsibility for, and you will fully indemnify TI and its representatives against, any claims, damages, costs, losses, and liabilities arising out of your use of these resources.

TI's products are provided subject to [TI's Terms of Sale](#) or other applicable terms available either on [ti.com](https://www.ti.com) or provided in conjunction with such TI products. TI's provision of these resources does not expand or otherwise alter TI's applicable warranties or warranty disclaimers for TI products.

TI objects to and rejects any additional or different terms you may have proposed.
