CLA\_CRC executed in parallel with other CLA tasks. This can cause delay in functional execution.

Functional tasks prioritized over CLA\_CRC tasks. CLA\_CRC will be stalled by functional tasks to avoid delays in functional execution.

**Figure 6-6. BGCR Execution Sequence Example**

### 6.3.6 Debug/Error Response for BGCR Errors

The BGCR error severity can be decoded by reading the BGCR\_INTFLG or BGCR\_NMIFLG. The errors can be:

- **WD\_OVERFLOW/WD\_UNDERFLOW:** The test did not complete in the programmed window. System timing needs to be checked to understand reason for non-completion of the test. BGCR\_CURR\_ADDR and BGCR\_WD\_CNT indicate how far the test progressed.
- **UNCORRECTABLE\_ERR:** BGCR\_CURR\_ADDR contains the address of the memory location causing the error. This error is due to single bit failure for Parity SRAM or double bit failure for ECC SRAM. The memory location can be reloaded (if possible, for cases where code is copied from Flash) to see if the problem resolves. If the problem persists, the problem can be a permanent defect.
- **CORRECTABLE\_ERR:** This error is due to single bit failure for ECC SRAM. If the problem location is accessed again (execution from the location for execute only memory or reading the location in other cases), the expectation is that the single bit error is corrected. If the single bit error is not corrected, this can be an indication of a permanent defect.
- **CRC\_FAIL:** This indicates a failure in the computation of the CRC-32 value. This error does not occur in scrub mode. For SRAMs with protection, in the absence of code bugs, this error is less likely since the error is most often manifest as a correctable/uncorrectable error. Code bugs can cause failure if the code inadvertently writes to a wrong address thus causing a CRC-32 error.

### 6.3.7 BGCRC Golden CRC-32 Value Computation

The C28x is a little-endian, 16-bit word addressable CPU. Therefore, the 32-bit value of 0x12345678 stored at address 0x100 is stored in the C28x memory as shown in [Table 6-2](#).

**Table 6-2. Data Address Location Example 1**

Address	0x100	0x101
Data	0x5678	0x1234

The BGCRC order of byte calculations of the above example is 0x78, 0x56, 0x34, 0x12 and yields 0x6A330D2D. The 32-bit polynomial 0x04C11DB7 is used with an initialization vector of 0x00000000. The following code snippet shows the effective bit processing. Processing for all 32-bits within a word occurs in a single cycle within the BGCRC hardware.

```

seed = 0x0UL; //Initialize with Seed
poly = 0x04C11DB7UL; //32-Bit Polynomial
crc32 = seed;

for(i=0; i<dataSize; i++)
{
    byteSwappedData = ((data[i] & 0x000000FF) << 24) |
                      = ((data[i] & 0x0000FF00) << 8) |
                      = ((data[i] & 0x00FF0000) >> 8) |
                      = ((data[i] & 0xFF000000) >> 24);

    crc32 = byteSwappedData^crc32;
    for(j=0; j<32; j++)
    {
        if(crc32 & 0x80000000) crc32 = (crc32 << 1)^poly;
        else crc32 = crc32 << 1;

        crc32 = crc32 & 0xFFFFFFFF;
    }
}
    
```

A second example ([Table 6-3](#)) with two 32-bit words, 0x12345678 and 0x9ABCDEF0 at address 0x100 and 0x102 successively, calculates the bytes in the order 0x78, 0x56, 0x34, 0x12, 0xDE, 0xBC, and 0x9A and yield 0x7E0B4164.

**Table 6-3. Data Address Location Example 2**

Address	0x100	0x101	0x102	0x103
Data	0x5678	0x1234	0xDEF0	0x9ABC

All data input to the BGCRC must align to a 32-bit boundary, both in the starting address and the size. It is possible to include 16-bit data within the span of data; however, when the data is read by the BGCRC, it always assume 32-bits and conform to the above calculation order. For example, if two 16-bit words (0xA0B1 and 0xC2D3) were placed in between the previous two 32-bit words ([Table 6-4](#)), the calculations are performed in byte order 0x78, 0x56, 0x34, 0x12, 0xB1, 0xA0, 0xD3, 0xC2, 0xF0, 0xDE, 0xBC, and 0x9A and yield 0x2AEFD987.

**Table 6-4. Data Address Location Example 3**

Address	0x100	0x101	0x102	0x103	0x104	0x105
Data	0x5678	0x1234	0xA0B1	0xC2D3	0xDEF0	0x9ABC

## 6.4 Software

### 6.4.1 BGCRC Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/bgcr

Cloud access to these examples is available at the following link: [dev.ti.com C2000Ware Examples](#).

#### 6.4.1.1 BGCRC CPU Interrupt Example

FILE: bgcrc\_ex1\_cpuinterrupt.c

This example demonstrates how to configure and trigger BGCRC from the CPU. BGCRC module is configured for 1 KB of GS0 RAM which is programmed with a known data. The pre-computed CRC value is used as the golden CRC value. Interrupt is generated once the computation is done and checks if no error flags are raised. Calculation uses the 32-bit polynomial 0x04C11DB7 and seed value 0x00000000.

##### *External Connections*

- None.

##### *Watch Variables*

- pass - This should be 1.
- runStatus - BGCRC running status. This will be BGCRC\_ACTIVE if the module is running, BGCRC\_IDLE if the module is idle

#### 6.4.1.2 BGCRC Example with Watchdog and Lock

FILE: bgcrc\_ex2\_cpugc\_crc\_basic.c

This example demonstrates how to configure and trigger BGCRC from the CPU. It also showcases how to configure the CRC watchdog and lock the registers after configuring the module. The watchdog is used as a diagnostic to check memory test completion within the expected time window. An error signal is generated if the test does not complete in the specified time window.

The module is configured for 1kB of GS0 RAM which is programmed with random data. The golden CRC value for comparison is computed using software method. Interrupt is generated once the computation is done and checks if no error flags are raised. The NMI is enabled and is triggered if an error is detected.

##### *External Connections*

- None.

##### *Watch Variables*

- pass
- bgcrcDone

#### 6.4.1.3 CLA-BGCRC Example in CRC mode

FILE: bgcrc\_ex3\_clabgc\_crcmode.c

This example demonstrates how to configure and trigger CLABGCRC from the CPU. It also showcases how to configure the CRC watchdog and lock the registers after configuring the module. The watchdog is used as a diagnostic to check memory test completion within the expected time window. An error signal is generated if the test does not complete in the specified time window.

The module is configured for 1kB of CLA ROM memory. The golden CRC value for comparison is computed using software method. Interrupt is generated once the computation is done and checks if no error flags are raised. The NMI is enabled and is triggered if an error is detected.

##### *External Connections*

- None.

##### *Watch Variables*

- pass
- bgcrcDone

#### 6.4.1.4 CLA-BGCR Example in Scrub Mode

FILE: bgcrc\_ex4\_clabgcr\_scrubmode.c

This example demonstrates how to configure and trigger CLA-BGCR in Scrub mode. In Scrub mode, CRC of data is not compared with the golden CRC. Error check is done using the ECC/Parity logic. It also showcases how to configure the CRC watchdog and lock the registers after configuring the module. The watchdog is used as a diagnostic to check memory test completion within the expected time window. An error signal is generated if the test does not complete in the specified time window.

The module is configured for 256 bytes of CLA ROM memory. Interrupt is generated once the computation is done and checks if no error flags are raised. The NMI is enabled and is triggered if an error is detected.

#### External Connections

- None.

#### Watch Variables

- pass
- bgcrcDone

## 6.5 BGCR Registers

This section describes the Background CRC registers.

### 6.5.1 BGCR Base Address Table

**Table 6-5. BGCR Base Address Table**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	CPU2	CPU2.DMA	Pipeline Protected
Instance	Structure								
BgcrCpuRegs	BGCR_REGS	BGCR_CPU_BASE	0x0000_6340	YES	-	-	YES	-	YES
BgcrClaRegs	BGCR_REGS	BGCR_CLA_BASE	0x0000_6380	YES	-	YES	-	-	YES

## 6.5.2 BGCR\_REG Registers

Table 6-6 lists the memory-mapped registers for the BGCR\_REG registers. All register offset addresses not listed in Table 6-6 should be considered as reserved locations and the register contents should not be modified.

**Table 6-6. BGCR\_REG Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	BGCR_EN	BGCR Enable	EALLOW	<a href="#">Go</a>
2h	BGCR_CTRL1	BGCR Control register 1	EALLOW	<a href="#">Go</a>
4h	BGCR_CTRL2	BGCR Control register 2	EALLOW	<a href="#">Go</a>
6h	BGCR_START_ADDR	Start address for the BGCR check	EALLOW	<a href="#">Go</a>
8h	BGCR_SEED	Seed for CRC calculation	EALLOW	<a href="#">Go</a>
Eh	BGCR_GOLDEN	Golden CRC to be compared against	EALLOW	<a href="#">Go</a>
10h	BGCR_RESULT	CRC calculated		<a href="#">Go</a>
12h	BGCR_CURR_ADDR	Current address register		<a href="#">Go</a>
1Ch	BGCR_WD_CFG	BGCR windowed watchdog configuration	EALLOW	<a href="#">Go</a>
1Eh	BGCR_WD_MIN	BGCR windowed watchdog min value	EALLOW	<a href="#">Go</a>
20h	BGCR_WD_MAX	BGCR windowed watchdog max value	EALLOW	<a href="#">Go</a>
22h	BGCR_WD_CNT	BGCR windowed watchdog count		<a href="#">Go</a>
2Ah	BGCR_NMIFLG	BGCR NMI flag register		<a href="#">Go</a>
2Ch	BGCR_NMICLR	BGCR NMI flag clear register	EALLOW	<a href="#">Go</a>
2Eh	BGCR_NMIFRC	BGCR NMI flag force register	EALLOW	<a href="#">Go</a>
34h	BGCR_INTEN	Interrupt enable	EALLOW	<a href="#">Go</a>
36h	BGCR_INTFLG	Interrupt flag		<a href="#">Go</a>
38h	BGCR_INTCLR	Interrupt flag clear	EALLOW	<a href="#">Go</a>
3Ah	BGCR_INTFRC	Interrupt flag force	EALLOW	<a href="#">Go</a>
3Ch	BGCR_LOCK	BGCR register map lock configuration	EALLOW	<a href="#">Go</a>
3Eh	BGCR_COMMIT	BGCR register map commit configuration	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 6-7 shows the codes that are used for access types in this section.

**Table 6-7. BGCR\_REG Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1S	W1S	Write 1 to set
WOnce	WOnce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value

### 6.5.2.1 BGCR\_EN Register (Offset = 0h) [Reset = 0000000h]

BGCR\_EN is shown in [Figure 6-7](#) and described in [Table 6-8](#).

Return to the [Summary Table](#).

BGCR Enable

**Figure 6-7. BGCR\_EN Register**

31	30	29	28	27	26	25	24

Bit	Field	Type	Reset	Description
31-20	RESERVED	R-0	0h	Reserved
19-16	SCRUB_MODE	R/W	0h	Scrub mode configuration 1010 : Scrub mode, CRC of data is not compared with the golden CRC. Error check is done using the ECC/Parity logic. Any other value: CRC value is compared with golden CRC at the end in addition to the data correctness check by ECC/Parity logic. Notes: 1010 configuration is used for scrub mode (for data memories) where the memory value is read and ECC/Parity logic is used for the error detection. BGCR_RESULT.CRC_VALUE is not updated in this configuration. Reset type: CPUx.SYSRSn
15-12	TEST_HALT	R/W	0h	Halt Bit : 1010 : Module operation is stopped Any other value : CRC calculation will continue/resume from where it was halted Notes: BGCR_EN.START = 1010 configuration with TEST_HALT = 1010 will halt the CRC calculation. The new check will resume when TEST_HALT is configured to a value other than 1010 Reset type: CPUx.SYSRSn
11-10	RESERVED	R-0	0h	Reserved
9-0	BLOCK_SIZE	R/W	0h	Configures the block size for the check 0x0 : 256 Byte (default) 0x1 : 512 Byte 0x2 : 768 Byte 0x3 : 1KB ... 0x3FF : 256KB (0xn : (n+1)*256Byte) Reset type: CPUx.SYSRSn

### 6.5.2.4 BGCR\_START\_ADDR Register (Offset = 6h) [Reset = 0000000h]

BGCR\_START\_ADDR is shown in [Figure 6-10](#) and described in [Table 6-11](#).

Return to the [Summary Table](#).

Start address for the BGCR check

**Figure 6-10. BGCR\_START\_ADDR Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
START_ADDRESS																															
R/W-0h																															

**Table 6-11. BGCR\_START\_ADDR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	START_ADDRESS	R/W	0h	START_ADDRESS indicates the start point of the test. (For CPU_CRC, this will be the CPU address. For CLA_CRC, this will be the CLA address where the memory is mapped) Reset type: CPUx.SYSRSn

### 6.5.2.5 BGCRC\_SEED Register (Offset = 8h) [Reset = 0000000h]

BGCRC\_SEED is shown in [Figure 6-11](#) and described in [Table 6-12](#).

Return to the [Summary Table](#).

Seed for CRC calculation

**Figure 6-11. BGCRC\_SEED Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SEED																															
R/W-0h																															

**Table 6-12. BGCRC\_SEED Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	SEED	R/W	0h	Initial value of CRC, this value is copied to the CRC register on triggering CRC calculation by writing to START bit. Reset type: CPUx.SYSRSn

### 6.5.2.6 BGCR\_GOLDEN Register (Offset = Eh) [Reset = 0000000h]

BGCR\_GOLDEN is shown in [Figure 6-12](#) and described in [Table 6-13](#).

Return to the [Summary Table](#).

Golden CRC to be compared against

**Figure 6-12. BGCR\_GOLDEN Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CRC_VALUE

### 6.5.2.7 BGCR\_RESULT Register (Offset = 10h) [Reset = 00000000h]

BGCR\_RESULT is shown in [Figure 6-13](#) and described in [Table 6-14](#).

Return to the [Summary Table](#).

CRC calculated

**Figure 6-13. BGCR\_RESULT Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CRC_VALUE																															
R-0h																															

**Table 6-14. BGCR\_RESULT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	CRC_VALUE	R	0h	CRC result register This register value will be updated only on the completion of CRC check on a block of data as programmed by BGCR_CTRL2.BLOCK_SIZE. Reset type: CPUx.SYSRSn

### 6.5.2.8 BGCR\_Curr\_Addr Register (Offset = 12h) [Reset = 0000000h]

BGCR\_Curr\_Addr is shown in [Figure 6-14](#) and described in [Table 6-15](#).

Return to the [Summary Table](#).

Current address register

**Figure 6-14. BGCR\_Curr\_Addr Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CURRENT_ADDR																															
R-0h																															

**Table 6-15. BGCR\_Curr\_Addr Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	CURRENT_ADDR	R	0h	Current address from where the data is fetched. During a failure, the CURRENT_ADDR field indicates the value from where the last fetch happened. Reset type: CPUx.SYSRSn

### 6.5.2.9 BGCRD\_WD\_CFG Register (Offset = 1Ch) [Reset = 0000000h]

BGCRD\_WD\_CFG is shown in [Figure 6-15](#) and described in [Table 6-16](#).

Return to the [Summary Table](#).

BGCRD windowed watchdog configuration

**Figure 6-15. BGCRD\_WD\_CFG Register**

## Chapter 7 Control Law Accelerator (CLA)

---

The Control Law Accelerator (CLA) is an independent, fully-programmable, 32-bit floating-point math processor that brings concurrent control-loop execution to the C28x family. The low interrupt latency of the CLA allows the CLA to read ADC samples "just-in-time." This significantly reduces the ADC sample to output delay to enable faster system response and higher MHz control loops. By using the CLA to service time-critical control loops, the main CPU is free to perform other system tasks such as communications and diagnostics. This chapter provides an overview of the architectural structure and components of the control law accelerator.

<b>7.1 Introduction</b> .....	<b>1296</b>

## 7.1 Introduction

The Control Law Accelerator extends the capabilities of the C28x CPU by adding parallel processing. Time-critical control loops serviced by the CLA can achieve low ADC sample to output delay. Thus, the CLA enables faster system response and higher frequency control loops. Utilizing the CLA for time-critical tasks frees up the main CPU to perform other system and communication functions concurrently.

### 7.1.1 Features

The following is a list of major features of the CLA:

- C compilers are available for CLA software development.
- Clocked at the same rate as the main CPU (SYSCLKOUT).
- An independent architecture allowing CLA algorithm execution independent of the main C28x CPU.
  - Complete bus architecture:
    - Program Address Bus (PAB) and Program Data Bus (PDB)
    - Data Read Address Bus (DRAB), Data Read Data Bus (DRDB), Data Write Address Bus (DWAB), and Data Write Data Bus (DWDB)
  - Independent eight stage pipeline.
  - 16-bit program counter (MPC)
  - Four 32-bit result registers (MR0-MR3)
  - Two 16-bit auxiliary registers (MAR0, MAR1)
  - Status register (MSTF)
- Instruction set includes:
  - IEEE single-precision (32-bit) floating-point math operations
  - Floating-point math with parallel load or store
  - Floating-point multiply with parallel add or subtract
  - 1/X and 1/sqrt(X) estimations
  - Data type conversions.
  - Conditional branch and call
  - Data load/store operations
- The CLA program code can consist of up to eight tasks or interrupt service routines, or seven tasks and a main background task.
  - The start address of each task is specified by the MVECT registers.
  - No limit on task size as long as the tasks fit within the configurable CLA program memory space.
  - One task is serviced at a time until completion. There is no nesting of tasks.
  - Upon task completion a task-specific interrupt is flagged within the PIE.
  - When a task finishes the next highest-priority pending task is automatically started.
  - The Type-2 CLA can have a main task that runs continuously in the background, while other high priority events trigger a foreground task.
- Task trigger mechanisms:
  - C28x CPU using the IACK instruction
  - Task1 to Task8: up to 256 possible trigger sources from peripherals connected to the shared bus on which the CLA assumes secondary ownership.
  - Task8 can be set to be the background task, while Tasks 1 through 7 take peripheral triggers.
- Memory and Shared Peripherals:
  - Two dedicated message RAMs for communication between the CLA and the main CPU.
  - Two dedicated message RAMs for communication between the CLA and the DMA.
  - The C28x CPU can map CLA program and data memory to the main CPU space or CLA space.

**Figure 7-1. CLA Block Diagram**

## 7.2 CLA Interface

This section describes how the C28x main CPU can interface to the CLA and conversely.

### 7.2.1 CLA Memory

The CLA can access three types of memory: program, data and message RAMs. The behavior and arbitration for each type of memory is described in this chapter. The CLA RAMs are protected by the DCSM module. Refer to the *Dual Code Security Module (DCSM)* section of the *System Control and Interrupts* chapter for more details on the security scheme.

- **CLA Program Memory**

The CLA program can be loaded with any of the local shared memories (LSxRAM). At reset, all memory blocks are mapped to the CPU. While mapped to the CPU space, the CPU can copy the CLA program code into the memory. During debug, the memory can also be loaded directly by the Code Composer Studio™ IDE.

Once the memory is initialized with CLA code, the CPU maps the memory to the CLA program space by:

1. Assigning ownership of the memory block to the CLA by writing a 1 to the memory block's MemCfgRegs.LSxMSEL[MSEL\_LSx] bit.
2. Specifying the memory block as a code block for the CLA by writing a 1 to the MemCfgRegs.LSxCLAPGM[CLAPGM\_LSx] bit.

When a memory block is configured as CLA program memory, debug accesses are allowed only on cycles where the CLA is not fetching a new instruction. A detailed explanation of the memory configurations and access arbitration (CPU, CLA, and DEBUG) process can be found in the *Memory Controller Module* section of the *System Control and Interrupts* chapter.

All CLA program fetches are performed as 32-bit read operations and all opcodes must be aligned to an even address. Since all CLA opcodes are 32-bits, this alignment occurs naturally.

- **CLA Data Memory**

Any of the device's LSxRAMs can serve as data memory blocks to the CLA. At reset, all blocks are mapped to the CPU memory space, whereby the CPU can initialize the memory with data tables, coefficients, and so on, for the CLA to use.

Once the memory is initialized with CLA data, the CPU maps the memory to the CLA data space by:

1. Assigning ownership of the memory block to the CLA by writing a 1 to the memory block's MemCfgRegs.LSxMSEL[MSEL\_LSx] bit.
2. Specifying the memory block as a data block for the CLA by writing a 0 to the MemCfgRegs.LSxCLAPGM[CLAPGM\_LSx] bit. The value of this bit at reset is 0.

When a memory block is configured as CLA data memory, CLA read and write accesses are arbitrated along with CPU accesses. The user has the option of turning on CPU fetch or write protection to the memory by writing to the appropriate bits of the MemCfgRegs.LSxACCPROT registers. A detailed explanation of the memory configurations and access arbitration (CPU, CLA, and DEBUG) process can be found in the *Memory Controller Module* section of the *System Control and Interrupts* chapter.

- **CLA Shared Message RAMs**

There are two memory blocks for data sharing and communication between the CLA and the CPU. The message RAMs are always mapped to both CPU and CLA memory spaces, and only data access is allowed; no program fetches can be performed.

- **CLA to CPU Message RAM:** The CLA can use this block to pass data to the CPU. This block is both readable and writable by the CLA. This block is also readable by the CPU but writes by the CPU are ignored.
- **CPU to CLA Message RAM:** The CPU can use this block to pass data and messages to the CLA. This message RAM is both readable and writable by the CPU. The CLA can perform reads but writes by the CLA are ignored.

### 7.2.2 CLA Memory Bus

The CLA has dedicated bus architecture similar to that of the C28x CPU where there are separate program read, data read, and data write buses. Thus, there can be simultaneous instruction fetch, data read, and data write in a single cycle. Like the C28x CPU, the CLA expects memory logic to align any 32-bit read or write to an even address. If the address-generation logic generates an odd address, the CLA can begin reading or writing at the previous even address. This alignment does not affect the address values generated by the address-generation logic.

- **CLA Program Bus**

The CLA program bus has an access range of 32K 32-bit instructions. Since all CLA instructions are 32 bits, this bus always fetches 32 bits at a time and the opcodes must be even-word aligned. The amount of program space available for the CLA is limited to the number of available LSxRAM blocks. This number is device-dependent and can be described in the data sheet.

- **CLA Data Read Bus**

The CLA data read bus has a 64K x 16 address range. The bus can perform 16 or 32-bit reads and can automatically stall if there are memory access conflicts. The data read bus has access to both the message RAMs, CLA data memory, and the shared peripherals.

- **CLA Data Write Bus**

The CLA data write bus has a 64K x 16 address range. This bus can perform 16 or 32-bit writes. The bus can automatically stall if there are memory access conflicts. The data write bus has access to the CLA to CPU message RAM, CLA data memory, and the shared peripherals.

### 7.2.3 Shared Peripherals and EALLOW Protection

For a given CPU subsystem, the CPU, CLA, and DMA can share access to some peripherals. There is a 3-way arbitration among the different peripherals that is described in [Section 7.3](#). Each peripheral has an access control register with two bit fields, CPU<sub>n</sub>AC, CLAnAC, and DMA<sub>n</sub>AC (n being the instance) that determine what kind of access is given to that particular peripheral.

---

#### Note

The CLA read access time to the bus is 2-wait states while write access is 0-wait.

---

Refer to the device data sheet for the list of peripherals connected to the bus.

Several peripheral control registers are protected from spurious 28x CPU writes by the EALLOW protection mechanism. These same registers are also protected from spurious CLA writes. The EALLOW bit in the CPU status register 1 (ST1) indicates the state of protection for the CPU. Likewise, the MEALLOW bit in the CLA status register (MSTF) indicates the state of write protection for the CLA. The MEALLOW CLA instruction enables write access by the CLA to EALLOW protected registers. Likewise, the MEDIS CLA instruction disables write access. This way the CLA can enable and disable write access independent of the CPU.

The ADC offers the option to generate an early interrupt pulse at the start of a sample conversion. If this option is used to start an ADC-triggered CLA task, use the intervening cycles until the completion of the conversion to perform preliminary calculations or loads and stores before finally reading the ADC value. The CLA pipeline activity for this scenario is shown in [Section 7.5](#).

### 7.2.4 CLA Tasks and Interrupt Vectors

The CLA program code is divided up into tasks or interrupt service routines. Tasks do not have a fixed starting location or length. The CLA program memory can be divided up as desired. The CLA uses the contents of the interrupt vectors (MVECT1 to MVECT8) to determine where a task begins; tasks are terminated by the MSTOP instruction.

The CLA supports eight tasks. Task 1 has the highest priority and task 8 has the lowest priority. The Type-2 CLA offers the option of setting the lowest priority task, for example, task 8, as a background task that, once triggered, runs continuously until the user either terminates the task or resets the CLA or the device. The remaining tasks, 1 through 7, maintain the priority levels and interrupt the background task when triggered.

The background task is enabled by setting the BGEN bit in the MCTLBGRND register; this causes the hardware to disable task 8 in the MIER register. The background task derives the interrupt vector from the MVECTBGRND register instead of MVECT8.

A task can be requested by a peripheral interrupt or by software:

- **Peripheral interrupt trigger**

Each task can be triggered by software-selectable interrupt sources. The trigger for each task is defined by writing an appropriate value to the DmaClaSrcSelRegs.CLA1TASKSRCSELx[TASKx] bit field. Each option specifies an interrupt source from a specific peripheral on the shared bus. The peripheral interrupt triggers are listed in [Table 7-1](#).

For example, task 1 (MVECT1) can be set to trigger on EPWMINT1 by writing 36 to DmaClaSrcSelRegs.CLA1TASKSRCSEL1.TASK1. To disable the triggering of a task by a peripheral, set the DmaClaSrcSelRegs.CLA1TASKSRCSELx[TASKx] bit field to 0. Note that a CLA task only triggers on a level transition (an edge) of the configured interrupt source.

- **Software Trigger**

CPU software can trigger tasks by writing to the MIFRC register or by the IACK instruction. Using the IACK instruction is more efficient because the instruction does not require the need to issue an EALLOW to set MIFR bits. Set the MCTL[JACKE] bit to enable the IACK feature. Each bit in the operand of the IACK instruction corresponds to a task. For example, IACK #0x0001 sets bit 0 in the MIFR register to start task 1. Likewise, IACK #0x0003 set bits 0 and 1 in the MIFR register to start task 1 and task 2.

- **Background Task**

The Type-2 CLA allows the use of Task 8 as a background task that runs continuously until Task 8 disables the task or resets the device (or the CLA using a soft reset). The background task vector is given by the MVECTBGRND register and the operation is controlled by the MCTLBGRND register; the task is enabled by setting the BGEN bit to 1. Then start the task through software by writing a 1 to the BGSTART bit (TRIGEN must be 0), or through a peripheral by setting the TRIGEN bit to 1 and then setting the trigger source in the bit-field, DmaClaSrcSelRegs.CLA1TASKSRCSEL2.bit.TASK8. By default, the background task is interruptible; the highest priority pending task is executed first. When a task completes and there are not any pending tasks, the execution returns to the background task. The CLA keeps track of the branching point by saving the return address to the MVECTBGRNDACTIVE register, and then popping this address to the MPC when execution returns. Choose to make sections of the background task uninterruptible by possibly doing this with the MSETC BGINTM assembly instruction.

Subsequently, enabling interrupts with the MCLRC BGINTM instruction.

The background interrupt mask bit, BGINTM, can be queried in the MSTSBGRND register. This register also provides the current status of the background task. If the task is currently executing, the RUN bit is set to 1, if another trigger for the background task is received while the task has already started, the overflow (BGOVF) bit is set.

The CLA has a fetch mechanism and can run and execute a task independently of the CPU. Only one task is serviced at a time; there is no nesting of tasks unless the background task is enabled, then one level of nesting is possible. The task currently running is indicated in the MIRUN register; if the background task is enabled and running, the task is reflected in the MSTSBGRND register (the RUN bit).

Interrupts that have been received but not yet serviced are indicated in the flag register (MIFR). If an interrupt request from a peripheral is received and that same task is already flagged, then the overflow flag bit is set. Overflow flags remain set until the flags are cleared by the CPU. If the CLA is idle (no task is currently running) or is executing the background task, then the highest priority interrupt request that is both flagged (MIFR) and enabled (MIER) starts.

The flow is as follows:

1. The associated RUN register bit is set (MIRUN) and the flag bit (MIFR) is cleared.
2. The CLA begins execution at the location indicated by the associated interrupt vector (MVECTx). MVECT contains the absolute 16-bit address of the task in the lower 64K memory space. If a task is interrupting the background task then the current program address is stored in the MVECTBGRNDACTIVE register before execution jumps to the task; this saved address is restored to the MPC when the task completes and execution returns to the background task.
3. The CLA executes instructions until the MSTOP instruction is found. This indicates the end of the task.
4. The MIRUN bit is cleared.
5. The task-specific interrupt to the PIE is issued. This informs the main CPU that the task has completed.
6. The CLA returns to idle (or to the background task, if enabled). Once a task completes the next highest-priority pending task is automatically serviced and this sequence repeats.

### 7.2.5 CLA Software Interrupt to CPU

The CLA can issue a software interrupt to the C28x CPU at any point in the code through the use of the CLA1SOFTINTEN and CLA1INTFRC registers. See [Section 7.8](#) for a description of these registers. If a software interrupt is selected for a CLA task, then an end-of-task interrupt is not issued to the C28x CPU when that task completes.

## 7.3 CLA, DMA, and CPU Arbitration

Typically, CLA activity is independent of the CPU activity. Under the circumstance where the CLA, DMA, or CPU attempt to concurrently access memory or a peripheral register within the same interface, an arbitration procedure occurs. This section describes this arbitration.

The arbitration follows a fixed arbitration scheme with highest priority first:

1. DMA WRITE
2. DMA READ
3. CLA WRITE
4. CLA READ
5. CPU WRITE
6. CPU READ

Refer to the Memory Controller Module section of the *System Control and Interrupts* chapter.

### 7.3.1 CLA Message RAM

Message RAMs consist of four blocks:

- CLA to CPU Message RAM
- CPU to CLA Message RAM
- DMA to CLA Message RAM
- CLA to DMA Message RAM

These blocks are useful for passing data between the CLA and CPU or CLA and DMA. No opcode fetches, from either the CLA or CPU, are allowed from the message RAMs. A write protection violation is not generated if the CLA attempts to write to the CPU to CLA or DMA to CLA message RAM, but the write is ignored. The arbitration scheme for the message RAMs are the same as those for the shared memories, described in the Memory Controller Module section of the *System Control and Interrupts* chapter.

The message RAMs have the following characteristics:

- CLA to CPU Message RAM:
  - The following accesses are allowed:
    - CPU reads
    - CLA data reads and writes
    - CPU debug reads and writes
  - The following accesses are ignored:
    - CPU writes
- CPU to CLA Message RAM:
  - The following accesses are allowed:
    - CPU reads and writes
    - CLA reads
    - CPU debug reads and writes
  - The following accesses are ignored:
    - CLA writes

### 7.3.2 CLA Program Memory

The behavior of the program memory depends on the state of the MMEMCFG[PROGE] bit. This bit controls whether the memory is mapped to CLA space or CPU space.

- **MMEMCFG[PROGE] == 0**

In this case, the memory is mapped to the CPU. The CLA is halted and no tasks can be incoming.

- Any CLA fetch is treated as an illegal opcode condition as described in [Section 7.4.4](#). This condition does not occur, if the proper procedure is followed to map the program memory.
- CLA reads and writes cannot occur
- The memory block behaves as any normal RAM block mapped to CPU memory space.

Priority of accesses are (highest priority first):

1. CPU data write, program write, debug write
2. CPU data read, program read, debug read
3. CPU fetch, program read

- **MMEMCFG[PROGE] == 1**

In this case, the memory block is mapped to CLA space. The CPU can only make debug accesses.

- CLA reads and writes cannot occur
- CLA fetches are allowed
- CPU fetches return 0 that is an illegal opcode and causes an ITRAP interrupt.
- CPU data reads and program reads return 0
- CPU data writes and program writes are ignored

Priority of accesses are (highest priority first):

1. CLA fetch
2. CPU debug write
3. CPU debug read

---

#### Note

Because the CLA fetch has higher priority than CPU debug reads, there is a possibility for the CLA to permanently block debug accesses if the CLA is executing in a loop. This can occur when initially developing CLA code due to a bug. To avoid this issue, the program memory returns all 0x0000 for CPU debug reads (ignore writes) when the CLA is running. When the CLA is halted or idle, then normal CPU debug read and write access can be performed.

---

### 7.3.3 CLA Data Memory

There are independent data memory blocks. The behavior of the data memory depends on the state of the MMEMCFG[RAM0E] MMEMCFG[RAM1E] bits. These bits determine whether the memory blocks are mapped to CLA space or CPU space.

- **MMEMCFG[RAMxE] == 0**

In this case the memory block is mapped to the CPU.

- CLA fetches cannot occur to this block.
- CLA reads return 0.
- CLA writes are ignored.
- The memory block behaves as any normal RAM block mapped to the CPU memory space.

Priority of accesses are (highest priority first):

1. CPU data write/program write/debug access write
2. CPU data read/debug access read
3. CPU fetch/program read

- **MMEMCFG[RAMxE] == 1**

In this case the memory block is mapped to CLA space. The CPU can make only debug accesses.

- CLA fetches cannot occur to this block.
- CLA read and CLA writes are allowed.
- CPU fetches return 0
- CPU data reads and program reads return 0.
- CPU data writes and program writes are ignored.

Priority of accesses are (highest priority first):

1. CLA data write
2. CPU debug write
3. CPU debug read
4. CLA read

### 7.3.4 Peripheral Registers (ePWM, HRPWM, Comparator)

Accesses to the registers follow these rules:

- If both the CPU and CLA request access at the same time, then the CLA has priority and the main CPU is stalled.
- If a CPU access is in-progress and another CPU access is pending, then the CLA has priority over the pending CPU access. In this case, the CLA access begins when the current CPU access completes.
- While a CPU access is in-progress, any incoming CLA access is stalled.
- While a CLA access is in-progress, any incoming CPU access is stalled.
- A CPU write operation has priority over a CPU read operation.
- A CLA write operation has priority over a CLA read operation.
- If the CPU is performing a read-modify-write operation and the CLA performs a write to the same location, the CLA write can be lost if the operation occurs in-between the CPU read and write. For this reason, do not mix CPU and CLA accesses to same location.

## 7.4 CLA Configuration and Debug

This section discusses the steps necessary to configure and debug the CLA.

### 7.4.1 Building a CLA Application

The control law accelerator can be programmed in either CLA assembly code, using the instructions described in [Section 7.7](#), or a reduced subset of the C language. CLA assembly code resides in the same project with C28x code. The only restriction is the CLA code must be in the assembly section. This can be easily done using the `.sect` assembly directive. This does not prevent CLA and C28x code from being linked into the same memory region in the linker command file.

System and CLA initialization are performed by the main CPU. This can typically be done in C or C++ but can also include C28x assembly code. The main CPU also copies the CLA code to the program memory and, if needed, initialize the CLA data RAMs. Once system initialization is complete and the application begins, the CLA services the interrupts using the CLA assembly code (or tasks). The main CPU can perform other tasks concurrently with CLA program execution.

The CLA Type 2 requires Codegen V16.9.1.LTS or later with the compiler switch: `--cla_support=cla2`.

### 7.4.2 Typical CLA Initialization Sequence

A typical CLA initialization sequence is performed by the main CPU as described in this section.

- Copy CLA code into the CLA program RAM:** The source for the CLA code can initially reside in the Flash or a data stream from a communications peripheral or anywhere the main CPU can access. The debugger can also be used to load code directly to the CLA program RAM during development.
- Initialize CLA data RAM, if necessary:** Populate the CLA data RAM with any required data coefficients or constants.
- Configure the CLA registers:** Configure the CLA registers, but keep interrupts disabled until later (leave MIER = 0):
  - Enable the CLA peripheral clock using the assigned PCLKCRn register:** The peripheral clock control (PCLKCRn) registers are defined in the *System Control and Interrupts* chapter.
  - Populate the CLA task interrupt vectors:**
    - MVECT1 to MVECT8  
 Each vector needs to be initialized with the start address of the task to be executed when the CLA receives the associated interrupt. This address is the full 16-bit starting address of the task in the lower 64K section of memory.
    - MVECT1 to MVECT7, and MVECTBGRND  
 When using the background task, the vector (MVECTBGRND) must be loaded with the start address of the task in lower 64K of memory. Note that Task 8 is ignored when the background task is enabled.
  - Select the task interrupt sources:** For each task select the interrupt source in the CLA1TASKSRCSELx register. If a task is software triggered, select no interrupt. Since the background task takes the place of Task 8, the task uses the same peripheral trigger source as task 8.
  - Enable IACK to start a task from software, if desired:** To enable the IACK instruction to start a task set the MCTL[IACKE] bit. Using the IACK instruction avoids having to set and clear the EALLOW bit. If the background task is enabled, the IACK bit for task 8 is ignored; the user must, instead, write to the BGSTART bit of the MCTLBGRND register to start the background task (TRIGEN can be 0 to avoid a peripheral trigger from causing an overflow, for example, MSTSBGRND.BGOVF is set to 1).
  - Map CLA data RAM to CLA space, if necessary:** Map the data RAM to the CLA space by first, assigning ownership of the memory block to the CLA by writing a 1 to the memory block's MemCfgRegs.LSxMSEL[MSEL\_LSx] bit, and then specifying the memory block as a CLA data block by writing a 0 to the MemCfgRegs.LSxCLAPGM[CLAPGM\_LSx] bit. When an LSx memory is configured as a CLA data memory, the CLA read/write accesses are arbitrated along with CPU accesses. The user has the option of turning on CPU fetch or write protection to the memory by writing to the appropriate bits of the MemCfgRegs.LSxACCPROTx registers.

- **Map CLA program RAM to CLA space:** Map the CLA program RAM to CLA space by first assigning ownership of the memory block to the CLA by writing a 1 to the memory block's MemCfgRegs.LSxMSEL[MSEL\_LSx] bit, and then specifying the memory block as CLA code memory by writing a 1 to the MemCfgRegs.LSxCLAPGM[CLAPGM\_LSx] bit. When an LSx memory is configured as CLA program memory, only debug accesses are allowed on cycles in which the CLA is not fetching a new instruction.
- 4. **Initialize the PIE vector table and registers:** When a CLA task completes, the associated interrupt in the PIE is flagged. The CLA overflow and underflow flags also have associated interrupts within the PIE.
- 5. **Enable CLA tasks/interrupts:** Set appropriate bits in the interrupt enable register (MIER) to allow the CLA to service interrupts. Note that a CLA task only triggers on a level transition (a falling edge) of the configured interrupt source. If a peripheral is enabled and an interrupt fires before the CLA is configured, then the CLA does not recognize the interrupt edge and does not respond. To avoid this, configure the CLA before the peripherals or clear any pending peripheral interrupts before setting bits in the MIER register.
- 6. **Initialize other peripherals:** Initialize any peripherals (such as ePWM, ADC, and others) that generate interrupt triggers for enabled CLA tasks.

The CLA is now ready to service interrupts and the message RAMs can be used to pass data between the CPU and the CLA. Mapping of the CLA program and data RAMs typically occurs only during the initialization process. If the RAM mapping needs to be changed after initialization, the CLA interrupts must be disabled and all tasks must be completed (by checking the MIRUN register) prior to modifying the RAM ownership.

### 7.4.3 Debugging CLA Code

Debugging the CLA code is a simple process that occurs independently of the main CPU. The type 2 CLA adds a true software breakpoint feature.

#### 7.4.3.1 Software Breakpoint Support (MDEBUGSTOP1)

The MDEBUGSTOP1 instruction is meant to be used as a software breakpoint; the instruction on which the execution must halt is replaced with this instruction.

The MDEBUGSTOP1 and MDEBUGSTOP instructions differ in how the CLA pipeline is treated. When halted, the MDEBUGSTOP1 instruction flushes all the instructions that have already been fetched; on a single-step or run-free command, the CLA refetches the same instruction that the CLA replaced. [Table 7-2](#) illustrates the pipeline behavior.

**Table 7-2. Pipeline Behavior of the MDEBUGSTOP1 Instruction**

Cycles	F1	F2	D1	D2	R1	R2	E	W	Comments
1	i1								
2	i2	i1							
3	i3	i2	i1						
4	i4	i3	i2	i1					
5	MDEBUG STOP1	i4	i3	i2	i1				
6	i6	MDEBUG STOP1	i4	i3	i2	i1			
7	i7	i6	MDEBUG STOP1	i4	i3	i2	i1		
9	i8	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	i4	i3	i2	i1	CLA halted
10	i5(MDEBUGSTOP1)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	i4	i3	i2	CLA step/run
11	i6	i5(MDEBUGSTOP1)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	i4	i3	CLA step/run
12	i7	i6	i5(MDEBUGSTOP1)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	i4	CLA step/run

**Table 7-2. Pipeline Behavior of the MDEBUGSTOP1 Instruction (continued)**

Cycles	F1	F2	D1	D2	R1	R2	E	W	Comments
13	i8	i7	i6	i5(MDEBUGSTOP1)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	Flushed (MNOP)	CLA step/run

A software breakpoint is placed at instruction i5. The instruction, i5, is then replaced with MDEBUGSTOP1. Execution takes 3 cycles for the MDEBUGSTOP1 to reach the D2 phase at which point the instructions i6, i7, and i8 that were previously fetched are now flushed from the pipeline. The instruction, i5, is then refetched and execution continues as before.

#### 7.4.3.2 Legacy Breakpoint Support (MDEBUGSTOP)

##### 1. Insert a breakpoint in CLA code

Insert a CLA breakpoint (MDEBUGSTOP instruction) into the code where the CLA is to halt, then rebuild and reload the code. Because the CLA does not flush the pipeline when in single-step, the MDEBUGSTOP instruction must be inserted as part of the code. The debugger cannot insert the MDEBUGSTOP instruction as needed.

If CLA breakpoints are not enabled, then the MDEBUGSTOP instruction is ignored and is treated as a MNOP. The MDEBUGSTOP instruction can be placed anywhere in the CLA code as long as the MDEBUGSTOP instruction is not within three instructions of a MBCNDD, MCCNDD, or MRCNDD instruction. When programming in C, the user can use the `__mdebugstop()` intrinsic instead; the compiler makes sure that the placement of the MDEBUSTOP instruction in the generated assembly does not violate any of the pipeline restrictions.

##### 2. Enable CLA breakpoints

Enable the CLA breakpoints in the debugger. In the Code Composer Studio™ IDE, this is done by connecting to the CLA core (or tap) from the debug perspective. Breakpoints are disabled when the core is disconnected.

##### 3. Start the task

There are three ways to start the task:

- The peripheral can assert an interrupt,
- The main CPU can execute an IACK instruction, or
- The user can manually write to the MIFRC register in the debugger window

When the task starts, the CLA executes instructions until the MDEBUGSTOP is in the D2 phase of the pipeline. At this point, the CLA halts and the pipeline is frozen. The MPC register reflects the address of the MDEBUGSTOP instruction.

#### 4. Single-step the CLA code

Once halted, the user can single-step the CLA code. The behavior of a CLA single-step is different than the main C28x. When issuing a CLA single-step, the pipeline is clocked only one cycle and then again frozen. On the C28x CPU, the pipeline is flushed for each single-step.

Run to the next MDEBUGSTOP or to the end of the task. If another task is pending, the task automatically starts when run to the end of the task.

---

#### Note

A CLA fetch has higher priority than CPU debug reads. For this reason, the CLA to permanently block CPU debug accesses if the CLA is executing in a loop is possible. This can occur when initially developing CLA code due to a bug that causes an infinite loop. To avoid locking up the main CPU, the program memory returns all 0x0000 for CPU debug reads when the CLA is running. When the CLA is halted or idle, then normal CPU debug read and write access to CLA program memory can be performed.

If the CLA gets caught in an infinite loop, use a soft or hard reset to exit the condition. A debugger reset also exits the condition.

---

There are special cases that can occur when single-stepping a task such that the program counter, MPC, reaches the MSTOP instruction at the end of the task.

- **MPC halts at or after the MSTOP with a task already pending**

If single-stepping or halted in "task A" and "task B" comes in before the MPC reaches the MSTOP, then "task B" starts if continuing to step through the MSTOP instruction. Basically, if "task B" is pending before the MPC reaches MSTOP in "task A" then there is no issue in "task B" starting and no special action is required.

- **MPC halts at or after the MSTOP with no task pending**

In this case, if single-stepped or halted in "task A" and the MPC has reached the MSTOP with no tasks pending. If "task B" comes in at this point, "task B" is flagged in the MIFR register but "task B" can or cannot start if continuing to single-step through the MSTOP instruction of "task A."

Depending on exactly when the new task comes in, to reliably start "task B", perform a soft reset and reconfigure the MIER bits. Once this is done, start single-stepping "task B."

This case can be handled slightly differently if there is control over when "task B" comes in (for example, using the IACK instruction to start the task). In this case, the task is single-stepped or halted in "task A" and the MPC has reached the MSTOP with no tasks pending. Before forcing "task B," run free to force the CLA out of the debug state. Once this is done, force "task B" and continue debugging.

#### 5. Disable CLA breakpoints, if desired

In the Code Composer Studio™ IDE, disable the CLA breakpoints by disconnecting the CLA core in the debug perspective. Make sure to first issue a run or reset; otherwise, the CLA is halted and no other tasks start.

#### 7.4.4 CLA Illegal Opcode Behavior

If the CLA fetches an opcode that does not correspond to a legal instruction, the CLA behaves as follows:

- The CLA halts with the illegal opcode in the D2 phase of the pipeline as if a breakpoint. This occurs whether CLA breakpoints are enabled or not.
- The CLA issues the task-specific interrupt to the PIE.
- The MIRUN bit for the task remains set.

Further single-stepping is ignored once execution halts due to an illegal op-code. To exit this situation, issue either a soft or hard reset of the CLA as described in [Section 7.4.5](#).

### 7.4.5 Resetting the CLA

There are times when resetting the CLA is needed. For example, during code debug the CLA can enter an infinite loop due to a code bug. The CLA has two types of resets: hard and soft. Both of these resets can be performed by the debugger or by the main CPU.

- **Hard Reset** Writing a 1 to the MCTL[HARDRESET] bit performs a hard reset of the CLA. The behavior of a hard reset is the same as a system reset (using  $\overline{XRS}$  or the debugger). In this case, all CLA configuration and execution registers can be set to the default state and CLA execution halts.
- **Soft Reset** Writing a 1 to the MCTL[SOFTRESET] bit performs a soft reset of the CLA. If a task is executing, the task halts and the associated MIRUN bit is cleared. All bits within the interrupt enable (MIER) register are also cleared, so that no new tasks start. In addition, the background task start bit (MCTLBGRN.BGSTART) and trigger enable bit (MCTLBGRND.TRIGEN) are reset. The MVECTBGRNACTIVE is set to the value of MVECTBGRND, and the status register (MSTSBGRND) is also reset.

## 7.5 Pipeline

This section describes the CLA pipeline stages and presents cases where pipeline alignment must be considered.

### 7.5.1 Pipeline Overview

The CLA pipeline is very similar to the C28x pipeline with eight stages:

1. **Fetch 1 (F1):** During the F1 stage the program read address is placed on the CLA program address bus.
2. **Fetch 2 (F2):** During the F2 stage the instruction is read using the CLA program data bus.
3. **Decode 1 (D1):** During D1 the instruction is decoded.
4. **Decode 2 (D2):** Generate the data read address. Changes to MAR0 and MAR1 due to post-increment using indirect addressing takes place in the D2 phase. Conditional branch decisions are also made at this stage based on the MSTF register flags.
5. **Read 1 (R1):** Place the data read address on the CLA data-read address bus. If a memory conflict exists, the R1 stage is stalled.
6. **Read 2 (R2):** Read the data value using the CLA data read data bus.
7. **Execute (EXE):** Execute the operation. Changes to MAR0 and MAR1 due to loading an immediate value or value from memory take place in this stage.
8. **Write (W):** Place the write address and write data on the CLA write data bus. If a memory conflict exists, the W stage is stalled.

### 7.5.2 CLA Pipeline Alignment

The majority of the CLA instructions do not require any special pipeline considerations. This section lists the few operations that do require special consideration.

- **Write Followed by Read**

In both the C28x pipeline and the CLA pipeline, the read operation occurs before the write. This means that if a read operation immediately follows a write, then the read completes first as shown in [Table 7-3](#). In most cases this does not cause a problem since the contents of one memory location does not depend on the state of another. For accesses to peripherals where a write to one location can affect the value in another location, the code must wait for the write to complete before issuing the read as shown in [Table 7-4](#).

This behavior is different for the C28x CPU. For the C28x CPU, any write followed by read to the same location is protected by what is called write-followed-by-read protection. This protection automatically stalls the pipeline so that the write completes before the read. In addition, some peripheral frames are protected such that a C28x CPU write to one location within the frame always completes before a read to the frame. The CLA does not have this protection mechanism. Instead, the code must wait to perform the read.

**Table 7-3. Write Followed by Read - Read Occurs First**

Instruction	F1	F2	D1	D2	R1	R2	E	W
I1 MMOV16 @Reg1, MR3	I1							
I2 MMOV16 MR2, @Reg2	I2	I1						
		I2	I1					
			I2	I1				
				I2	I1			
					I2	I1		
						I2	I1	
							I2	I1

**Table 7-4. Write Followed by Read - Write Occurs First**

Instruction	F1	F2	D1	D2	R1	R2	E	W
I1 MMOV16 @Reg1, MR3	I1							
I2	I2	I1						
I3	I3	I2	I1					
I4	I4	I3	I2	I1				
I5 MMOV16 MR2, @Reg2	I5	I4	I3	I2	I1			
		I5	I4	I3	I2	I1		
			I5	I4	I3	I2	I1	
				I5	I4	I3	I2	I1
					I5	I4	I3	I1
						I5	I4	I1
							I5	I1

- **Delayed Conditional instructions: MBCNDD, MCCNDD, and MRCNDD**

Referring to [Example 7-1](#), the following applies to delayed conditional instructions:

- **I1:** I1 is the last instruction that can effect the CNDF flags for the branch, call, or return instruction. The CNDF flags are tested in the D2 phase of the pipeline. That is, a decision is made whether to branch or not when MBCNDD, MCCNDD, or MRCNDD is in the D2 phase.
- **I2, I3, and I4:** The three instructions preceding MBCNDD can change the MSTF flags but have no effect on whether the MBCNDD instruction branches or not. This is because the flag modification occurs after the D2 phase of the branch, call, or return instruction. These three instructions must not be a MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.
- **I5, I6, and I7:** The three instructions following a branch, call, or return are always executed irrespective of whether the condition is true or not. These instructions must not be MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.

For a more detailed description, refer to the description for [MBCNDD](#) , [MCCNDD](#) , and [MRCNDD](#) .

**Example 7-1. Code Fragment For MBCNDD, MCCNDD, or MRCNDD**

```

<Instruction 1>      ; I1 Last instruction that can affect flags for
                    ;   the branch, call or return operation
<Instruction 2>      ; I2 Cannot be stop, branch, call or return
<Instruction 3>      ; I3 Cannot be stop, branch, call or return
<Instruction 4>      ; I4 Cannot be stop, branch, call or return
<branch/call/ret>    ; MBCNDD, MCCNDD or MRCNDD
                    ; I5-I7: Three instructions after are always
                    ;   executed whether the branch/call or return is
                    ;   taken or not
<Instruction 5>      ; I5 Cannot be stop, branch, call or return
<Instruction 6>      ; I6 Cannot be stop, branch, call or return
<Instruction 7>      ; I7 Cannot be stop, branch, call or return
<Instruction 8>      ; I8
<Instruction 9>      ; I9
....

```

- **Stop or Halting a Task: MSTOP and MDEBUGSTOP**

The MSTOP and MDEBUGSTOP instructions cannot be placed three instructions before or after a conditional branch, call or return instruction (MBCNDD, MCCNDD, or MRCNDD). Refer to [Example 7-1](#). To single-step through a branch/call or return, insert the MDEBUGSTOP at least four instructions back and step from there.

### • Loading MAR0 or MAR1

A load of auxiliary register MAR0 or MAR1 occurs in the EXE phase of the pipeline. Any post increment of MAR0 or MAR1 using indirect addressing occurs in the D2 phase of the pipeline. Referring to [Example 7-2](#), the following applies when loading the auxiliary registers:

- **I1 and I2:** The two instructions following the load instruction use the value in MAR0 or MAR1 before the update occurs.
- **I3:** Loading of an auxiliary register occurs in the EXE phase while updates due to post-increment addressing occur in the D2 phase. Thus I3 cannot use the auxiliary register or there is a conflict. In the case of a conflict, the update due to address-mode post increment wins and the auxiliary register is not updated with #\_X.
- **I4:** Starting with the 4th instruction MAR0 or MAR1 has the new value.

#### **Example 7-2. Code Fragment for Loading MAR0 or MAR1**

```

; Assume MAR0 is 50 and #_X is 20

MMOV16 MAR0, #_X ; Load MAR0 with address of X (20)
<Instruction 1> ; I1 uses the old value of MAR0 (50)
<Instruction 2> ; I2 uses the old value of MAR0 (50)
<Instruction 3> ; I3 Cannot use MAR0
<Instruction 4> ; I4 uses the new value of MAR0 (20)
<Instruction 5> ; I5 uses the new value of MAR0 (20)
....

```

### • Background Task Interrupted Close to a Branch

When the background task is running, if another task request happens (and MSTSBGRND.BGINTM is not set), then the following sequence of operations happen.

- A check is made to determine if the following instructions are not in the pipeline (D2 – R2).
  - MBCNDD
  - MCCNDD
  - MRCNDD

If any of the above instructions are present in the pipeline, the back ground task continues to execute until such time when the condition is satisfied. Once the condition is satisfied, the following actions are performed:

- The MPC value of the D1 phase instruction is saved to the MVECTBGRNDACTIVE register.
- The run status bit of the background task (MSTSBGRND.RUNSTS) is cleared.
- An MSTOP instruction is forced into the D2 phase of the pipeline; causing the background task to terminate.

When the background task terminates, the CLA picks the next highest pending task and begins execution. Note that while the background task is pending, the background task has the lowest priority and, therefore, yields to any other pending task. Once all pending non-background tasks have completed execution, the CLA restores the program counter (MPC), that is, loads the address from the MVECTBGRNDACTIVE register to the MPC, sets the background status to RUN (MSTSBGRND.RUN = 1), and continues execution from that point.

- **MSTOP in the Background Task**

If an MSTOP instruction occurs in the D1 phase while the background task is running, the following sequence of operations happens:

- The RUN bit (MSTSBGRND.RUN) is cleared.
- The address stored in MVECTBGRND is copied over to MVECTBGRNDACTIVE.
- An interrupt, signaling the background task has completed execution, is generated. This interrupt signal is ANDed with the interrupt from Task 8 and fed to the PIE. Note that if an illegal instruction occurs inside the background task, the interrupt for task 8 is fired.
- When the background task terminates, the CLA resumes arbitration among the pending tasks.

### 7.5.2.1 ADC Early Interrupt to CLA Response

The ADC can be configured to generate an early interrupt pulse before the ADC conversion completes. If this option is used to start a CLA task, the CLA is able to read the result as soon as the conversion result is available in the ADC result register. This combination of just-in-time sampling along with the low interrupt response of the CLA enable faster system response and higher frequency control loops. The CLA task trigger to first instruction fetch interrupt latency is 4 cycles.

Timings for ADC conversions are shown in the timing diagrams of the ADC chapter. If the ADCCLK is a divided down version of the SYSCLK, the user has to account for the conversion time in SYSCLK cycles.

For example, if using the 12-bit ADC with ADCCLK at SYSCLK / 4, the ADC can take  $10.5 \text{ ADCCLK} \times 4 \text{ SYSCLK} = 42 \text{ SYSCLK}$  cycles to complete a conversion. If using the ADC in 16-bit mode at the same ADCCLK, the ADC can take  $29.5 \text{ ADCCLK} \times 4 \text{ SYSCLK} = 118 \text{ SYSCLK}$  cycles, and so on.

From a CLA perspective, the pipeline activity is shown in [Table 7-5](#) for an N-cycle (SYSCLK) ADC conversion. The N-2 instruction arrives in the R2 phase just in time to read the result register. While the prior instructions enter the R2 phase of the pipeline too soon to read the conversion, the instructions can be efficiently used for pre-processing calculations needed by the task.

**Table 7-5. ADC to CLA Early Interrupt Response**

ADC Activity	CLA Activity	F1	F2	D1	D2	R1	R2	E	W
Sample									
Sample									
...									
Sample									
Conversion <sub>(Cycle 1)</sub>	Interrupt Received								
Conversion <sub>(Cycle 2)</sub>	Task Startup

Conversion <sub>(Cycle N-4)</sub>	I <sub>(Cycle N-4)</sub>	I <sub>(Cycle N-4)</sub>	I <sub>(Cycle N-5)</sub>	I <sub>(Cycle N-6)</sub>	I <sub>(Cycle N-7)</sub>	I <sub>(Cycle N-8)</sub>	I <sub>(Cycle N-9)</sub>		
Conversion <sub>(Cycle N-3)</sub>	I <sub>(Cycle N-3)</sub>	I <sub>(Cycle N-3)</sub>	I <sub>(Cycle N-4)</sub>	I <sub>(Cycle N-5)</sub>	I <sub>(Cycle N-6)</sub>	I <sub>(Cycle N-7)</sub>	I <sub>(Cycle N-8)</sub>		
Conversion <sub>(Cycle N-2)</sub>	<b>Read RESULT</b>	<b>Read RESULT</b>	I <sub>(Cycle N-3)</sub>	I <sub>(Cycle N-4)</sub>	I <sub>(Cycle N-5)</sub>	I <sub>(Cycle N-6)</sub>	I <sub>(Cycle N-7)</sub>		
Conversion <sub>(Cycle N-1)</sub>			<b>Read RESULT</b>	I <sub>(Cycle N-3)</sub>	I <sub>(Cycle N-4)</sub>	I <sub>(Cycle N-5)</sub>	I <sub>(Cycle N-6)</sub>		
Conversion <sub>(Cycle N-0)</sub>				<b>Read RESULT</b>	I <sub>(Cycle N-3)</sub>	I <sub>(Cycle N-4)</sub>	I <sub>(Cycle N-5)</sub>		
Conversion Complete					<b>Read RESULT</b>	I <sub>(Cycle N-3)</sub>	I <sub>(Cycle N-4)</sub>		
RESULT Latched						<b>Read RESULT</b>	I <sub>(Cycle N-3)</sub>		
<b>RESULT Available</b>							<b>Read RESULT</b>		

The ADCINTCYCLE register of the ADC can be programmed by the application to adjust the generation of the interrupt pulse to align with the ADC read operation. For example, if the first instruction in the task reads the ADC and the conversion time is N SYSCLK cycles, then the delay programmed is  $(N-2) - 4 = N-6$ .

### 7.5.3 Parallel Instructions

Parallel instructions are single opcodes that perform two operations in parallel. The following types of parallel instructions are available: math operation in parallel with a move operation, or two math operations in parallel. Both operations complete in a single cycle and there are no special pipeline alignment requirements.

#### Example 7-3. Math Operation with Parallel Load

```

; MADDF32 || MMOV32 instruction: 32-bit floating-point add with parallel move
; MADDF32 is a 1 cycle operation
; MMOV32 is a 1 cycle operation
; MADDF32 MR0, MR1, #2 ; MR0 = MR1 + 2,
|| MMOV32 MR1, @val ; MR1 gets the contents of val
; <-- MMOV32 completes here (MR1 is valid)
; <-- DDF32 completes here (MR0 is valid)
MMPYF32 MR0, MR0, MR1 ; Any instruction, can use MR1 and/or MR0

```

#### Example 7-4. Multiply with Parallel Add

```

; MMPYF32 || MADDF32 instruction: 32-bit floating-point multiply with parallel add
; MMPYF32 is a 1 cycle operation
; MADDF32 is a 1 cycle operation
; MMPYF32 MR0, MR1, MR3 ; MR0 = MR1 * MR3
|| MADDF32 MR1, MR2, MR0 ; MR1 = MR2 + MR0 (Uses value of MR0 before MMPYF32)
; <-- MMPYF32 and MADDF32 complete here (MR0 and MR1 are valid)
MMPYF32 MR1, MR1, MR0 ; Any instruction, can use MR1 and/or MR0

```

### 7.5.4 CLA Task Execution Latency

The CLA task execution latency depends on the state of the system:

- CLA task trigger of new task (normal or background) without background task active:

Task takes 8 cycles from CLA task trigger to first instruction of task to reach the D2 phase of pipeline.

#### Note

If background task has been configured in the system, then the compiler during code compilation adds context save instructions at the start of each regular task and restore instructions at end of each task so that register content can be saved and restored in case a background task is executing while the regular task is triggered. When a regular task is entered, this compiler-generated context save instruction is the first instruction of the task.

- CLA task trigger of normal task when background task is active:

Task takes 9 cycles from CLA task trigger to first instruction of normal task to reach the D2 phase of pipeline. There is a difference of one clock cycle to force the MSTOP in the D2 phase of the background task before the task exits as compared to a new task trigger without the background task active.

#### Note

If the MBCNDD/MCCNDD/MRCNDD instructions in the background task are in the D2 phase of the pipeline when a new task gets triggered, the task takes a minimum of 3 more cycles to complete these uninterruptible instructions adding to the delay.

- Returning to background task from normal task:

The task takes 5 cycles to return from a normal task to resume the background task instruction at the D2 phase of the pipeline.

## 7.6 Software

### 7.6.1 CLA Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/cla

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 7.6.1.1 CLA arcsine(x) using a lookup table (cla\_asin\_cpu01)

FILE: cla\_asin\_ls8\_9.c

In this example, Task 1 of the CLA will calculate the arcsine of an input argument in the range (-1.0 to 1.0) using a lookup table.

Note that since this example does not use background CLA task, the compile flag `cla_background_task` is turned off for this project. Set this flag as on to enable background CLA task. The option is available in Project Properties -> C2000 Build -> C2000 Compiler -> Advanced Options -> Runtime Model Options.

##### Memory Allocation

- CLA1 Math Tables (RAMLS0)
  - CLAasinTable - Lookup table
- CLA1 to CPU Message RAM
  - fResult - Result of the lookup algorithm
- CPU to CLA1 Message RAM
  - fVal - Sample input to the lookup algorithm

##### Watch Variables

- fVal - Argument to task 1
- fResult - Result of arcsin(fVal)

#### 7.6.1.2 CLA arcsine(x) using a lookup table (cla\_asin\_cpu01)

FILE: cla\_ex1\_asin.c

In this example, Task 1 of the CLA will calculate the arcsine of an input argument in the range (-1.0 to 1.0) using a lookup table.

Note that since this example does not use background CLA task, the compile flag `cla_background_task` is turned off for this project. Set this flag as on to enable background CLA task. The option is available in Project Properties -> C2000 Build -> C2000 Compiler -> Advanced Options -> Runtime Model Options.

##### Memory Allocation

- CLA1 Math Tables (RAMLS1)
  - CLAasinTable - Lookup table
- CLA1 to CPU Message RAM
  - fResult - Result of the lookup algorithm
- CPU to CLA1 Message RAM
  - fVal - Sample input to the lookup algorithm

##### Watch Variables

- fVal - Argument to task 1
- fResult - Result of arcsin(fVal)

#### 7.6.1.3 CLA arctangent(x) using a lookup table (cla\_atan\_cpu01)

FILE: cla\_ex2\_atan.c

In this example, Task 1 of the CLA will calculate the arctangent of an input argument using a lookup table.

Note that since this example does not use background CLA task, the compile flag `cla_background_task` is turned off for this project. Set this flag as on to enable background CLA task. The option is available in Project Properties -> C2000 Build -> C2000 Compiler -> Advanced Options -> Runtime Model Options.

#### Memory Allocation

- CLA1 Math Tables (RAMLS1)
  - CLAatan2Table - Lookup table
- CLA1 to CPU Message RAM
  - fResult - Result of the lookup algorithm
- CPU to CLA1 Message RAM
  - fNum - Numerator of sample input
  - fDen - Denominator of sample input

#### Watch Variables

- fVal - Argument to task 1
- fResult - Result of  $\arctan(fVal)$

#### 7.6.1.4 CLA background nesting task

FILE: `cla_ex3_background_nesting_task.c`

This example configures CLA task 1 to be triggered by EPWM1 running at 2 Hz (period = 0.5s). A background task is configured to be triggered by CPU timer running at .5 Hz (period = 2s). CLA task 1 toggles LED1 at the start and end of the task and the background task toggles LED2 at the start and end of the task. Background task will be preempted by Task1 and hence LED1 will be toggling even while LED2 is ON.

Note that the compile flag `cla_background_task` is turned on in this project. Enabling background task adds additional context save/restore cycles during task switching thus increasing the overall trigger-to-task latency. If the application does not use the background CLA task, it is recommended to turn this flag off for better performance. The option is available in Project Properties -> C2000 Build -> C2000 Compiler -> Advanced Options -> Runtime Model Options.

#### External Connections

- None

#### Watch Variables

- None

#### 7.6.1.5 Controlling PWM output using CLA

FILE: `cla_ex4_pwm_control.c`

This example showcases how to update PWM signal output using CLA. EPWM1 is configured to generate complementary signals on both of its channels of fixed frequency 100 KHz. EPWM4 is configured to trigger a periodic CLA control task of frequency 10 KHz. The CLA task implements a very simple logic to vary the duty of the EPWM1 outputs by increasing it by 0.1 in every iteration and maintaining it in the range of 0.1-0.9. For actual use-cases, the control logic could be modified to much more complex depending upon the application. The other CLA task (CLA task 8) is triggered by software at beginning to initialize the CLA global variables

#### External Connections

- Observe GPIO0 (EPWM1A) on oscilloscope
- Observe GPIO1 (EPWM1B) on oscilloscope

#### Watch Variables

- duty

#### 7.6.1.6 Just-in-time ADC sampling with CLA

FILE: `cla_ex5_adc_just_in_time.c`

This example showcases how to utilize early-interrupt feature of ADC in combination with the low interrupt response of CLA to enable faster system response and achieve high frequency control loops. EPWM1 is configured to generate a PWM output signal of frequency 1 MHz and this is also used to trigger the ADC sampling at each cycle. ADCA is configured to sample the input on Channel 0 and to generate the early interrupt at the end of S/H + offset cycles. This interrupt is used to trigger the CLA control task. The CLA task implements the control logic to update the duty of the PWM output based on reading the ADC sample data just-in-time i.e. as soon as the ADC results gets latched. The early interrupt feature and low interrupt latency of CLA allows to do some pre-processing as well before reading the ADC data and still completes updating the PWM output before the next interrupts comes in i.e. data read and PWM update is done within a 1 MHz cycle. For illustration purposes, 3-point moving average filter is used to simulate some processing and few steps of the filtering code are done before reading the ADC result which we consider as pre-processing code. The ADC interrupt offset is programmed based on the cycles consumed by the pre-processing code.

The calculation for interrupt offset value is as follows :-  
 -ADC acquisition cycles programmed = 10 SYSCCLKS  
 -Conversion time for 12-bit data = 10.5 ADCCLKS = N = 42 SYSCCLKS  
 -CLA task trigger to first instruction in Fetch delay = 4  
 -Let the interrupt offset value be 'x'  
 -The code inside CLA control task before ADC read takes below cycles :  
 Setting up profiling gpio : 3 cycles  
 Pre-processing : 13 cycles  
 Total = 3 + 13 = 16 cycles

As described in device TRM, in order to read just-in-time the total delay before reading ADC should be (N-2) cycles = 40 i.e. :  $x + 4 + 16 = 40$  :  $x = 20$

NOTE :- The optimization is off for this project and the cycles quoted above corresponds to that case.

GPIO2 is used for profiling purposes. GPIO2 is set at the beginning of CLA task 1 and is reset at the end of the task. Thus ON time of GPIO2 indicates the CLA activity. In order to validate the example functionality, observe the GPIO0 (PWM output) and GPIO2 (profiling GPIO) on CRO. The cycles difference between the rising edge of the GPIO0 and GPIO2 indicate the total delay from the time of ADC trigger to setting up of profiling GPIO inside CLA task which should be around 44 cycles (220 ns) based on the above calculation.

#### External Connections

- Provide constant DC input on ADCA0 for quick validation. GND -> Should observe PWM output duty = 0.1  
3.3V -> Should observe PWM output duty = 0.9 Can also provide analog input in range 0 - 3.3V upto  $f_s / 10 = 100$  KHz for observing continuous duty variations
- Observe GPIO0 on oscilloscope
- Observe GPIO2 on oscilloscope

#### Watch Variables

- None

#### 7.6.1.7 Optimal offloading of control algorithms to CLA

FILE: cla\_ex6\_cpu\_offloading.c

This example showcases how to optimally offload the control algorithms from CPU to CLA in order to meet the system requirements. In this example, two control loops are simulated, the faster one (loop1) running at 200 KHz and the slower one (loop2) running at 20 KHz. Loop1 senses the first parameter at ADCA Channel 0, runs the PI controller to achieve the target and contributes to the duty of EPWM1A output with 80% weightage. Loop2 senses the second parameter at ADCB Channel 2, runs the PI controller and contributes to the duty of EPWM1A output with 20% weightage. It is important to note that since these are just software simulated control loops but there is no actual physical process involved and hence updating the duty is not going to have any affect on sampled inputs. ADCA is configured to oversample the first parameter using SOCs 0-3 to suppress the noise and similarly ADCB is used to oversample the second parameter. EPWM4 and EPWM5 are configured to trigger the ADCA and ADCB sampling at loop1 and loop2 frequencies respectively. Once the conversion of all 4 SOCs complete, a CPU ISR or a CLA task is triggered based on the user-configuration. There is also a background task running in the main loop which disables the entire system including PWM output and the control loops when "system\_OFF" is set to 1. The system gets enabled again once "system\_OFF" is restored back to 0. By default system\_OFF is set to 0 but it's value can be updated dynamically by adding it to expression window and writing to it. DCL library is included in the project to make use of optimal PI controllers used in both the loops.

User-configurable pre-defined symbol "run\_loop1\_cla" has been added to the project options in order to specify whether to run the loop1 on C28x or CLA. GPIO2 and GPIO3 are used to profile the execution of loop1 and loop2.

For run\_loop1\_cla == 0 i.e. both loops running on CPU -> Loop1 Utilization = ~77.5% (measured using profiling GPIO2) -> Loop2 Utilization = ~6% (measured using profiling GPIO3) -> Background task in a while loop -> Total CPU utilization is greater than Utilization bound (UB) Hence the system is non-schedulable, lower priority task (Loop2) execution never completes (no toggling observed on GPIO3) and also background task never gets chance to execute

For run\_loop1\_cla == 1 i.e. high frequency control loop (loop1) is offloaded to CLA while loop2 runs on CPU -> Loop1 Utilization (CLA) = ~73% -> Loop2 Utilization (CPU) = ~6% -> Total CPU utilization has come down to just ~6% Hence the system is perfectly schedulable, no miss happens for any of the loops and offloading of loop1 to CLA saves CPU bandwidth to execute background tasks as well

For quick inspection of the example functionality, constant DC HIGH/LOW inputs can be provided to the analog channels instead of varying analog voltages. The target value for both the loops are set as some intermediate value i.e. 3500 corresponds to ~2.8V. Now since the sensed inputs are constant and not same as target so the controller outputs will get saturated soon to either 1 or 0. Thus the "duty" variable can take only fixed values based on the equations used in the loops. Infact the duty output would be very intuitive, for instance if both inputs are LOW(GND), the controller will try to produce the maximum duty as the target is higher than sensed value hence the duty should be  $1.0(0.2 + 0.8)$  but will get saturated to 0.9(the maximum value defined). Similarly if both inputs are made HIGH, the duty will be 0.1 (the minimum saturation value defined). The final duty table is shown below :

#### *External Connections*

- Observe GPIO2 (Loop1 Profiling) on oscilloscope
- Observe GPIO3 (Loop2 Profiling) on oscilloscope
- Observe GPIO0 (EPWM1A Output) on oscilloscope
- Provide constant HIGH(3.3V)/LOW(0V) on both ADCA Ch0 and ADCB Ch2 for quick validation, the following duty value should be observable at EPWM1A for various combinations if the system is perfectly schedulable i.e. both loops gets chance to execute properly :- A0 B2 duty GND GND 0.9 3.3V GND 0.2 GND 3.3V 0.8 3.3V 3.3V 0.1 Note :- The optimization is OFF for this project and all the profiling data quoted above corresponds to this case.

#### **7.6.1.8 Handling shared resources across C28x and CLA**

FILE: cla\_ex7\_shared\_resource\_handling.c

This example showcases how to handle shared resource challenges across C28x and CLA. As the peripherals are shared between CLA and the CPU, overlapping read-modify-write to the registers by them can lead to data race conditions ultimately leading to data violation or incorrect functionality. In this example, CPU ISR and CLA tasks runs independently. CPU ISR gets triggered by EPWM4 @10KHz and toggles the EPWM1B output via software by controlling CSFB bits of AQCSFRC. CLA task gets triggered by EPWM5 @100KHz and toggles the EPWM1A output via software by controlling CSFA bits of AQCSFRC. Thus in this process both CPU and CLA do read-modify -write to AQCSFRC register independently at different frequencies so there is chance of race condition and updates due to one of them can get lost/. overwritten. This can be clearly observed by updating "phase\_shift\_ON" to 0U and probing the EPWM1A and 1B outputs on a scope.

This is a standard critical section problem and can be handled by software handshaking mechanism like mutex etc. But most of the real-time control applications are time-sensitive and cannot afford addition software overhead hence this example suggests an alternative hardware based technique to avoid shared resource conflicts between CPU and CLA. The phase shifting mechanism of the EPWM modules is utilized to schedule the CLA task and CPU ISR as desired. EPWM4 generates a synchronous pulse every ZERO event and provides a phase shift of 20 cycles to EPWM5. This way both CLA task and C28x ISR runs at original frequencies i.e. 100KHz and 10KHz but CLA task leads with a phase offset of 20 cycles wrt CPU ISR. Hence concurrent read-modify-writes to AQCSFRC never happens and the EPWM1A and EPWM1B outputs behave as desired i.e. consistent 50 KHz PWM output on EPWM1A and 5 KHz PWM output on EPWM1B with a duty ~50% on

both should be generated. In order to utilize this phase shifting mechanism in this example, please make sure "phase\_shift\_ON" is set to 1.

#### *External Connections*

- Observe GPIO0 (EPWM1A Output) on oscilloscope
- Observe GPIO1 (EPWM1B Output) on oscilloscope
- Observe GPIO2 (CLA Task Profiling) on oscilloscope
- Observe GPIO3 (CPU ISR Profiling) on oscilloscope

Note :- The phase offset value can easily be configured by updating TBPHS register to schedule the CLA task and C28x ISR as desired depending upon the application need so as to avoid overlapping register writes by CPU and CLA

Note :- The optimization is on and set to O2 for the project and all the results quoted correspond to this case.

## 7.7 Instruction Set

This section describes the assembly language instructions of the control law accelerator. Also described are parallel operations, conditional operations, resource constraints, and addressing modes. The instructions listed here are independent from C28x and C28x+FPU instruction sets.

### 7.7.1 Instruction Descriptions

This section gives detailed information on the instruction set. Each instruction presents the following information:

- Operands
- Opcode
- Description
- Exceptions
- Pipeline
- Examples
- See also

The example INSTRUCTION is shown to familiarize you with the way each instruction is described. The example describes the kind of information you find in each part of the individual instruction description and where to obtain more information. CLA instructions follow the same format as the C28x instructions; the source operands are always on the right and the destination operands are on the left.

The explanations for the syntax of the operands used in the instruction descriptions for the CLA are given in [Table 7-6](#).

**Table 7-6. Operand Nomenclature**

Symbol	Description
#16FHi	16-bit immediate (hex or float) value that represents the upper 16-bits of an IEEE 32-bit floating-point value. Lower 16-bits of the mantissa are assumed to be zero.
#16FHiHex	16-bit immediate hex value that represents the upper 16-bits of an IEEE 32-bit floating-point value. Lower 16-bits of the mantissa are assumed to be zero.
#16FLoHex	A 16-bit immediate hex value that represents the lower 16-bits of an IEEE 32-bit floating-point value
#32Fhex	32-bit immediate value that represents an IEEE 32-bit floating-point value
#32F	Immediate float value represented in floating-point representation
#0.0	Immediate zero
#SHIFT	Immediate value of 1 to 32 used for arithmetic and logical shifts.
addr	Opcode field indicating the addressing mode
CNDF	Condition to test the flags in the MSTF register
FLAG	Selected flags from MSTF register (OR) 8 bit mask indicating which floating-point status flags to change
MAR0	Auxiliary register 0
MAR1	Auxiliary register 1
MARx	Either MAR0 or MAR1
mem16	16-bit memory location accessed using direct, indirect, or offset addressing modes
mem32	32-bit memory location accessed using direct, indirect, or offset addressing modes
MRa	MR0 to MR3 registers
MRb	MR0 to MR3 registers
MRc	MR0 to MR3 registers
MRd	MR0 to MR3 registers
MRe	MR0 to MR3 registers
MRf	MR0 to MR3 registers
MSTF	CLA Floating-point Status Register
shift	Opcode field indicating the number of bits to shift.
VALUE	Flag value of 0 or 1 for selected flag (OR) 8 bit mask indicating the flag value; 0 or 1

Each instruction has a table that gives a list of the operands and a short description. Instructions always have the destination operands first followed by the source operands.

**Table 7-7. INSTRUCTION dest, source1, source2 Short Description**

	Description
dest1	Description for the 1st operand for the instruction
source1	Description for the 2nd operand for the instruction
source2	Description for the 3rd operand for the instruction
Opcode	This section shows the opcode for the instruction
Description	Detailed description of the instruction execution is described. Any constraints on the operands imposed by the processor or the assembler are discussed.
Restrictions	Any constraints on the operands or use of the instruction imposed by the processor are discussed.
Pipeline	This section describes the instruction in terms of pipeline cycles as described in <a href="#">Section 7.5</a>
Example	Examples of instruction execution. If applicable, register and memory values are given before and after instruction execution. Some examples are code fragments while other examples are full tasks that assume the CLA is correctly configured and the main CPU has passed the CLA data.
Operands	Each instruction has a table that gives a list of the operands and a short description. Instructions always have the destination operands first followed by the source operands.

### 7.7.2 Addressing Modes and Encoding

The CLA uses the same address to access data and registers as the main CPU. For example, if the main CPU accesses an ePWM register at address 0x00 6800, then the CLA accesses the register using address 0x6800. Since all CLA accessible memory and registers are within the low 64k x 16 of memory, only the low 16-bits of the address are used by the CLA.

To address the CLA data memory, message RAMs and shared peripherals, the CLA supports two addressing modes:

- Direct addressing mode: Uses the address of the variable or register directly.
- Indirect addressing with 16-bit post increment. This mode uses either XAR0 or XAR1.

The CLA does not use a data page pointer or a stack pointer. The two addressing modes are encoded as shown [Table 7-8](#).

**Table 7-8. Addressing Modes**

Addressing Mode	'addr' Opcode Field Encode <sup>(1)</sup>	Description
@dir	0000	<p><b>Direct Addressing Mode</b></p> <p>Example 1: MMOV32 MR1, @_VarA</p> <p>Example 2: MMOV32 MR1, @_EPwm1Regs.CMPA.all</p> <p>In this case, the 'mmmm mmmm mmmm mmmm' opcode field is populated with the 16-bit address of the variable. This is the low 16-bits of the address to access the variable using the main CPU.</p> <p>For example, @_VarA populates the address of the variable VarA. and @_EPwm1Regs.CMPA.all populates the address of the CMPA register.</p>
*MAR0[#imm16]++	0001	<p><b>MAR0 Indirect Addressing with 16-bit Immediate Post Increment</b></p> <p><b>MAR1 Indirect Addressing with 16-bit Immediate Post Increment</b></p> <p>addr = MAR0 (or MAR1) Access memory using the address stored in MAR0 (or MAR1). MAR0 (or MAR1) += #imm16 Then post increment MAR0 (or MAR1) by #imm16.</p> <p>Example 1: MMOV32 MR0, *MAR0[2]++</p> <p>Example 2: MMOV32 MR1, *MAR1[-2]++</p> <p>For a post increment of 0, the assembler accepts both *MAR0 and *MAR0[0]++.</p> <p>The 'mmmm mmmm mmmm mmmm' opcode field is populated with the signed 16-bit pointer offset. For example, if #imm16 is 2, then the opcode field is 0x0002. Likewise, if #imm16 is -2, then the opcode field is 0xFFFFE.</p> <p>If addition of the 16-bit immediate causes overflow, then the value wraps around on a 16-bit boundary.</p>
*MAR1[#imm16]++	0010	
*MAR0+[#imm16]	0101	<p><b>MAR0 Offset Addressing with 16-bit Immediate Offset</b></p> <p><b>MAR1 Offset Addressing with 16-bit Immediate Offset</b></p> <p>addr = MAR0 (or MAR1) + #imm16 to the base location</p> <p>Add the offset #imm16 address stored in MAR0(MAR1) to access the desired memory location</p> <p>Example 1: MMOV32 MR0, *MAR0+[2]</p> <p>Example 1: MMOV32 MR1, *MAR1+[-2]</p> <p>The 'mmmm mmmm mmmm mmmm' opcode field is populated with the signed 16-bit pointer offset. For example, if #imm16 is 2, then the opcode field is 0x0002. Likewise, if #imm16 is -2, then the opcode field is 0xFFFFE.</p> <p>If the addition of the 16-bit immediate causes overflow, the value wraps around on a 16-bit boundary.</p>
*MAR1+[#imm16]	0110	

(1) Values not shown are reserved.

Encoding for the shift fields in the MASR32, MLSR32 and ML32 instructions is shown in [Table 7-9](#).

**Table 7-9. Shift Field Encoding**

Shift Value	'shift' Opcode Field Encode
1	0000
2	0001
3	0010
....	....
32	1111

For instructions that use MRx (where x can be 'a' through 'f') as operands, the trailing alphabet appears in the opcode as a two-bit field. For example:

```
MMPYF32 MRa, MRb, MRc ||
MADDF32 MRd, MRe, MRf
```

whose opcode is,

```
LSW: 0000 ffee ddcc bbaa
MSW: 0111 1010 0000 0000
```

The two-bit field specifies one of four working registers according to [Table 7-10](#).

**Table 7-10. Operand Encoding**

Two-Bit Field	Working Register
00	MR0
01	MR1
10	MR2
11	MR3

[Table 7-11](#) shows the condition field encoding for conditional instructions such as MNEGF, MSWAPF, MBCNDD, MCCNDD, and MRCNDD.

**Table 7-11. Condition Field Encoding**

Encode <sup>(1)</sup>	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF <sup>(2)</sup>	Unconditional with flag modification	None

(1) Values not shown are reserved.

(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

### 7.7.3 Instructions

The instructions are listed alphabetically.

---

#### Instruction Set Summary

<b>MABSF32 MRa, MRb</b> — 32-Bit Floating-Point Absolute Value.....	1331
<b>MADD32 MRa, MRb, MRc</b> — 32-Bit Integer Add.....	1332
<b>MADDF32 MRa, #16FHi, MRb</b> — 32-Bit Floating-Point Addition.....	1333
<b>MADDF32 MRa, MRb, #16FHi</b> — 32-Bit Floating-Point Addition.....	1335
<b>MADDF32 MRa, MRb, MRc</b> — 32-Bit Floating-Point Addition.....	1337
<b>MADDF32 MRd, MRe, MRf   MMOV32 mem32, MRa</b> — 32-Bit Floating-Point Addition with Parallel Move....	1338
<b>MADDF32 MRd, MRe, MRf   MMOV32 MRa, mem32</b> — 32-Bit Floating-Point Addition with Parallel Move...	1339
<b>MAND32 MRa, MRb, MRc</b> — Bitwise AND.....	1341
<b>MASR32 MRa, #SHIFT</b> — Arithmetic Shift Right.....	1342
<b>MBCNDD 16BitDest {, CNDF}</b> — Branch Conditional Delayed.....	1344
<b>MCCNDD 16BitDest {, CNDF}</b> — Call Conditional Delayed.....	1349
<b>MCLRC BGINTM</b> — Clear Background Task Interrupt Mask.....	1353
<b>MCMP32 MRa, MRb</b> — 32-Bit Integer Compare for Equal, Less Than or Greater Than.....	1354
<b>MCMPF32 MRa, MRb</b> — 32-Bit Floating-Point Compare for Equal, Less Than or Greater Than.....	1356
<b>MCMPF32 MRa, #16FHi</b> — 32-Bit Floating-Point Compare for Equal, Less Than or Greater Than.....	1357
<b>MDEBUGSTOP</b> — Debug Stop Task.....	1359
<b>MDEBUGSTOP1</b> — Software Breakpoint.....	1360
<b>MEALLOW</b> — Enable CLA Write Access to EALLOW Protected Registers.....	1361
<b>MEDIS</b> — Disable CLA Write Access to EALLOW Protected Registers.....	1362
<b>MEINVF32 MRa, MRb</b> — 32-Bit Floating-Point Reciprocal Approximation.....	1363
<b>MEISQRTF32 MRa, MRb</b> — 32-Bit Floating-Point Square-Root Reciprocal Approximation.....	1365
<b>MF32TOI16 MRa, MRb</b> — Convert 32-Bit Floating-Point Value to 16-Bit Integer.....	1367
<b>MF32TOI16R MRa, MRb</b> — Convert 32-Bit Floating-Point Value to 16-Bit Integer and Round.....	1368
<b>MF32TOI32 MRa, MRb</b> — Convert 32-Bit Floating-Point Value to 32-Bit Integer.....	1369
<b>MF32TOUI16 MRa, MRb</b> — Convert 32-Bit Floating-Point Value to 16-bit Unsigned Integer .....	1371
<b>MF32TOUI16R MRa, MRb</b> — Convert 32-Bit Floating-Point Value to 16-bit Unsigned Integer and Round.....	1372
<b>MF32TOUI32 MRa, MRb</b> — Convert 32-Bit Floating-Point Value to 32-Bit Unsigned Integer .....	1373
<b>MFRACF32 MRa, MRb</b> — Fractional Portion of a 32-Bit Floating-Point Value.....	1374
<b>MI16TOF32 MRa, MRb</b> — Convert 16-Bit Integer to 32-Bit Floating-Point Value .....	1375
<b>MI16TOF32 MRa, mem16</b> — Convert 16-Bit Integer to 32-Bit Floating-Point Value .....	1376
<b>MI32TOF32 MRa, mem32</b> — Convert 32-Bit Integer to 32-Bit Floating-Point Value .....	1377
<b>MI32TOF32 MRa, MRb</b> — Convert 32-Bit Integer to 32-Bit Floating-Point Value .....	1378
<b>MLSL32 MRa, #SHIFT</b> — Logical Shift Left.....	1379
<b>MLSR32 MRa, #SHIFT</b> — Logical Shift Right.....	1381
<b>MMACF32 MR3, MR2, MRd, MRe, MRf   MMOV32 MRa, mem32</b> — 32-Bit Floating-Point Multiply and Accumulate with Parallel Move.....	1382
<b>MMAXF32 MRa, MRb</b> — 32-Bit Floating-Point Maximum.....	1385
<b>MMAXF32 MRa, #16FHi</b> — 32-Bit Floating-Point Maximum.....	1387
<b>MMINF32 MRa, MRb</b> — 32-Bit Floating-Point Minimum.....	1389
<b>MMINF32 MRa, #16FHi</b> — 32-Bit Floating-Point Minimum.....	1391
<b>MMOV16 MARx, MRa, #16I</b> — Load the Auxiliary Register with MRa + 16-bit Immediate Value.....	1393

**MBSF32 MRa, MRb****32-Bit Floating-Point Absolute Value****Operands**

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

**Opcode**

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1110 0010 0000
```

**Description**

The absolute value of MRb is loaded into MRa. Only the sign bit of the operand is modified by the MBSF32 instruction.

```
if (MRb < 0) {MRa = -MRb};
else {MRa = MRb};
```

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified as follows:

```
NF = 0;
ZF = 0;
if ( MRa(30:23) == 0) ZF = 1;
```

**Pipeline**

This is a single-cycle instruction.

**Example**

```
MMOVIZ MR0, #-2.0 ; MR0 = -2.0 (0xc0000000)
MBSF32 MR0, MR0 ; MR0 = 2.0 (0x40000000), ZF = NF = 0
MMOVIZ MR0, #5.0 ; MR0 = 5.0 (0x40A00000)
MBSF32 MR0, MR0 ; MR0 = 5.0 (0x40A00000), ZF = NF = 0
MMOVIZ MR0, #0.0 ; MR0 = 0.0
MBSF32 MR0, MR0 ; MR0 = 0.0 ZF = 1, NF = 0
```

**MADD32 MRa, MRb, MRc****32-Bit Integer Add****Operands**

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point destination register (MR0 to MR3)
MRc	CLA floating-point destination register (MR0 to MR3)

**Opcode**

```
LSW: 0000 0000 000cc bbaa
MSW: 0111 1110 1100 0000
```

**Description**

32-bit integer addition of MRb and MRc.

```
MRa(31:0) = MRb(31:0) + MRc(31:0);
```

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; };
```

**Pipeline**

This is a single-cycle instruction.

**Example**

```
; Given A = (int32)1
; B = (int32)2
; C = (int32)-7
;
; Calculate Y2 = A + B + C
;
_Cla1Task1:
    MMOV32 MR0, @_A      ; MR0 = 1 (0x00000001)
    MMOV32 MR1, @_B      ; MR1 = 2 (0x00000002)
    MMOV32 MR2, @_C      ; MR2 = -7 (0xFFFFFFFF9)
    MADD32 MR3, MR0, MR1 ; A + B
    MADD32 MR3, MR2, MR3 ; A + B + C = -4 (0xFFFFFFFFC)
    MMOV32 @_y2, MR3     ; Store y2
    MSTOP                ; end of task
```

**MADDF32 MRa, #16FHi, MRb**
**32-Bit Floating-Point Addition**
**Operands**

MRa	CLA floating-point destination register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0.
MRb	CLA floating-point source register (MR0 to MR3)

**Opcode**

```
LSW: IIII IIII IIII IIII
MSW: 0111 0111 1100 bbaa
```

**Description**

Add MRb to the floating-point value represented by the immediate operand. Store the result of the addition in MRa.

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. #16FHi is most useful for representing constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler accepts either a hex or float as the immediate value. That is, the value -1.5 can be represented as #-1.5 or #0xBFC0.

```
MRa = MRb + #16FHi:0;
```

This instruction can also be written as MADDF32 MRa, MRb, #16FHi.

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

**Pipeline**

This is a single-cycle instruction.

**Example**

```
; Add to MR1 the value 2.0 in 32-bit floating-point format
; Store the result in MR0
MADDF32 MR0, #2.0, MR1 ; MR0 = 2.0 + MR1
; Add to MR3 the value -2.5 in 32-bit floating-point format
; Store the result in MR2
MADDF32 MR2, #-2.5, MR3 ; MR2 = -2.5 + MR3
; Add to MR3 the value 0x3FC00000 (1.5)
; Store the result in MR3
MADDF32 MR3, #0x3FC0, MR3 ; MR3 = 1.5 + MR3
```

**MADDF32 MRa, MRb, MRc**
**32-Bit Floating-Point Addition**
**Operands**

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
MRc	CLA floating-point source register (MR0 to MR3)

**Opcode**

```
LSW: 000 0000 00cc bbaa
MSW: 0111 1100 0010 0000
```

**Description**

Add the contents of MRc to the contents of MRb and load the result into MRa.

```
MRa = MRb + MRc;
```

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

**Pipeline**

This is a single-cycle instruction.

**Example**

```
; Given M1, X1, and B1 are 32-bit floating-point numbers
; Calculate Y1 = M1*X1+B1
;
;
_Cla1Task1:
  MMOV32 MR0,@M1      ; Load MR0 with M1

**MADDF32 MRd, MRe, MRf||MMOV32 mem32, MRa****32-Bit Floating-Point Addition with Parallel Move****Operands**

MRd	CLA floating-point destination register for the MADDF32 (MR0 to MR3)
MRe	CLA floating-point source register for the MADDF32 (MR0 to MR3)
MRf	CLA floating-point source register for the MADDF32 (MR0 to MR3)
mem32	32-bit memory location accessed using one of the available addressing modes. This is the destination of the MMOV32.
MRa	CLA floating-point source register for the MMOV32 (MR0 to MR3)

**Opcode**

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0101 ffee ddaa addr
```

**Description**

Perform an MADDF32 and a MMOV32 in parallel. Add MRf to the contents of MRe and store the result in MRd. In parallel move the contents of MRa to the 32-bit location mem32.

```
MRd = MRe + MRf;
[mem32] = MRa;
```

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

**Pipeline**

Both MADDF32 and MMOV32 complete in a single cycle.

**Example**

```
; Given A, B, and C are 32-bit floating-point numbers
; Calculate Y2 = (A * B)
;           Y3 = (A * B) + C
;
;
_cla1Task2:
  MMOV32  MR0, @_A      ; Load MR0 with A
  MMOV32  MR1, @_B      ; Load MR1 with B
  MMPYF32 MR1, MR1, MR0 ; Multiply A*B
  || MMOV32 MR0, @_C      ; and in parallel load MR0 with C
  MADDF32 MR1, MR1, MR0 ; Add (A*B) to C
  || MMOV32 @_Y2, MR1    ; and in parallel store A*B
  MMOV32  @_Y3, MR1    ; Store the A*B + C
  MSTOP                ; end of task
```

**MADDF32 MRd, MRe, MRf ||MMOV32 MRa, mem32**
**32-Bit Floating-Point Addition with Parallel Move**
**Operands**

MRd	CLA floating-point destination register for the MADDF32 (MR0 to MR3). MRd cannot be the same register as MRa.
MRe	CLA floating-point source register for the MADDF32 (MR0 to MR3)
MRf	CLA floating-point source register for the MADDF32 (MR0 to MR3)
MRa	CLA floating-point destination register for the MMOV32 (MR0 to MR3). MRa cannot be the same register as MRd.
mem32	32-bit memory location accessed using one of the available addressing modes. This is the source for the MMOV32.

**Opcode**

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0001 ffee ddaa addr
```

**Description**

Perform an MADDF32 and a MMOV32 operation in parallel. Add MRf to the contents of MRe and store the result in MRd. In parallel move the contents of the 32-bit location mem32 to MRa.

```
MRd = MRe + MRf;
MRa = [mem32];
```

**Restrictions**

The destination register for the MADDF32 and the MMOV32 must be unique. That is, MRa and MRd cannot be the same register.

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

The MMOV32 Instruction sets the NF and ZF flags as follows:

```
NF = MRa(31);
ZF = 0;
if(MRa(30:23) == 0) { ZF = 1; NF = 0; };
```

**Pipeline**

The MADDF32 and the MMOV32 both complete in a single cycle.

MADDF32 MRd, MRe, MRf ||MMOV32 MRa, mem32 (continued)

### 32-Bit Floating-Point Addition with Parallel Move

#### Example 1

```

; Given A, B, and C are 32-bit floating-point numbers
; Calculate Y1 = A + 4B
;           Y2 = A + C
;
;
;_Cla1Task1:
  MMOV32 MR0, @A          ; Load MR0 with A

**MAND32 MRa, MRb, MRc****Bitwise AND****Operands**

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
MRc	CLA floating-point source register (MR0 to MR3)

**Opcode**

```
LSW: 0000 0000 00cc bbaa
MSW: 0111 1100 0110 0000
```

**Description**

Bitwise AND of MRb with MRc.

```
MRa(31:0) = MRb(31:0) AND MRc(31:0);
```

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; }
```

**Pipeline**

This is a single-cycle instruction.

**Example**

```

**MASR32 MRa, #SHIFT****Arithmetic Shift Right****Operands**

MRa	CLA floating-point source/destination register (MR0 to MR3)
#SHIFT	Number of bits to shift (1 to 32)

**Opcode**

```
LSW: 0000 0000 0shi ftaa
MSW: 0111 1011 0100 0000
```

**Description**

Arithmetic shift right of MRa by the number of bits indicated. The number of bits can be 1 to 32.

```
MARa(31:0) = Arithmetic Shift(MARa(31:0) by #SHIFT bits);
```

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; }
```

**Pipeline**

This is a single-cycle instruction.

**Example**

```
; Given m2 = (int32)32
; x2 = (int32)64
; b2 = (int32)-128
;
; calculate
; m2 = m2/2
; x2 = x2/4
; b2 = b2/8
;
_Cla1Task2:
  MMOV32 MR0, @_m2 ; MR0 = 32 (0x00000020)
  MMOV32 MR1, @_x2 ; MR1 = 64 (0x00000040)
  MMOV32 MR2, @_b2 ; MR2 = -128 (0xFFFFFFFF80)
  MASR32 MR0, #1 ; MR0 = 16 (0x00000010)
  MASR32 MR1, #2 ; MR1 = 16 (0x00000010)
  MASR32 MR2, #3 ; MR2 = -16 (0xFFFFFFFFF0)
  MMOV32 @_m2, MR0 ; store results
  MMOV32 @_x2, MR1
  MMOV32 @_b2, MR2
  MSTOP ; end of task
```

**MBCNDD 16BitDest {, CNDF}*****Branch Conditional Delayed*****Operands**

16BitDest	16-bit destination if condition is true
CNDF	Optional condition tested

**Opcode**

```
LSW: dest dest dest dest
MSW: 0111 1001 1000 cndf
```

**Description**

If the specified condition is true, then branch by adding the signed 16BitDest value to the MPC value. Otherwise, continue without branching. If the address overflows, the address wraps around. Therefore, a value of "0xFFFFE" puts the MPC back to the MBCNDD instruction.

Refer to the Pipeline section for important information regarding this instruction.

```
if (CNDF == TRUE) MPC += 16BitDest;
```

CNDF is one of the following conditions:

Encode <sup>(1)</sup>	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF <sup>(2)</sup>	Unconditional with flag modification	None

(1) Values not shown are reserved.

(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

**Restrictions**

The MBCNDD instruction is not allowed three instructions before or after a MBCNDD, MCCNDD, or MRCNDD instruction. Refer to the Pipeline section for more information.

**Flags**

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**MBCNDD 16BitDest {, CNDF} (continued)**
***Branch Conditional Delayed***
**Pipeline**

The MBCNDD instruction alone is a single-cycle instruction. As shown in [Table 7-12](#), 6 instruction slots are executed for each branch; 3 slots before the branch instruction (I2-I4) and 3 slots after the branch instruction (I5-I7). The total number of cycles for a branch taken or not taken depends on the usage of these slots. That is, the number of cycles depends on how many slots are filled with a MNOP as well as which slots are filled. The effective number of cycles for a branch can, therefore, range from 1 to 7 cycles. The number of cycles for a branch taken cannot be the same as for a branch not taken.

Referring to [Table 7-12](#) and [Table 7-13](#), the instructions before and after MBCNDD have the following properties:

- **I1**
  - I1 is the last instruction that can effect the CNDF flags for the MBCNDD instruction. The CNDF flags are tested in the D2 phase of the pipeline. That is, a decision is made whether to branch or not when MBCNDD is in the D2 phase.
  - There are no restrictions on the type of instruction for I1.
- **I2, I3, and I4**
  - The three instructions proceeding MBCNDD can change MSTF flags but have no effect on whether the MBCNDD instruction branches or not. This is because the flag modification occurs after the D2 phase of the MBCNDD instruction.
  - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.
- **I5, I6, and I7**
  - The three instructions following MBCNDD are always executed irrespective of whether the branch is taken or not.
  - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.

```

<Instruction 1> ; I1 Last instruction that can affect flags for

[MCCNDD 16BitDest, CNDF](#)  
[MRCNDD CNDF](#)

**MCCNDD 16BitDest {, CNDF}**
**Call Conditional Delayed**
**Operands**

16BitDest	16-bit destination if condition is true
CNDF	Optional condition to be tested

**Opcode**

```
LSW: dest dest dest dest
MSW: 0111 1001 1001 cndf
```

**Description**

If the specified condition is true, then store the return address in the RPC field of MSTF and make the call by adding the signed 16BitDest value to the MPC value. Otherwise, continue code execution without making the call. If the address overflows, the address wraps around. Therefore a value of "0xFFFFE" puts the MPC back to the MCCNDD instruction.

Refer to the Pipeline section for important information regarding this instruction.

```
if (CNDF == TRUE)
{
    RPC = return address;
    MPC += 16BitDest;
};
```

CNDF is one of the following conditions:

Encode <sup>(1)</sup>	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF <sup>(2)</sup>	Unconditional with flag modification	None

(1) Values not shown are reserved.

(2) This is the default operation if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

**Restrictions**

The MCCNDD instruction is not allowed three instructions before or after a MBCNDD, MCCNDD, or MRCNDD instruction. Refer to the Pipeline section for more details.

**Flags**

This instruction does not modify flags in the MSTF register.

**MCCNDD 16BitDest {, CNDF} (continued)**
**Call Conditional Delayed**

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**Pipeline**

The MCCNDD instruction alone is a single-cycle instruction. As shown in [Table 7-14](#), 6 instruction slots are executed for each call; 3 before the call instruction (I2-I4) and 3 after the call instruction (I5-I7). The total number of cycles for a call taken or not taken depends on the usage of these slots. That is, the number of cycles depends on how many slots are filled with a MNOP as well as which slots are filled. The effective number of cycles for a call can, therefore, range from 1 to 7 cycles. The number of cycles for a call taken cannot be the same as for a call not taken.

Referring to the following code fragment and the pipeline diagrams in [Table 7-14](#) and [Table 7-15](#), the instructions before and after MCCNDD have the following properties:

- **I1**
  - I1 is the last instruction that can effect the CNDF flags for the MCCNDD instruction. The CNDF flags are tested in the D2 phase of the pipeline. That is, a decision is made whether to branch or not when MCCNDD is in the D2 phase.
  - There are no restrictions on the type of instruction for I1.
- **I2, I3, and I4**
  - The three instructions proceeding MCCNDD can change MSTF flags but have no effect on whether the MCCNDD instruction makes the call or not. This is because the flag modification occurs after the D2 phase of the MCCNDD instruction.
  - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.
- **I5, I6, and I7**
  - The three instructions following MBCNDD are always executed irrespective of whether the branch is taken or not.
  - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.

**MCLRC BGINTM*****Clear Background Task Interrupt Mask*****Operands**

None	This instruction does not have any operands
------	---

**Opcode**

LSW: 0000 0000 0000 0000
MSW: 0111 1111 0111 0000

**Description**

This instruction clears the background task interrupt mask (BGINTM) bit in the MSTSBGRND register, allowing any code thereafter to be interrupted by a higher priority task. This instruction clears the BGINTM bit at the end of the D2 phase.

**Note**

This instruction does not require the MEALLOW bit to be asserted before or deasserted after clearing BGINTM.

**Flags**

This instruction does not modify flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**Pipeline**

This is a single-cycle instruction.

**Example**

MCLRC BGINTM	; Allow the background task to be ; interrupted by clearing the ; MSTSBGRND.BGINTM bit
--------------	--

**See also**

[MSETC BGINTM](#)

**MCMP32 MRa, MRb****32-Bit Integer Compare for Equal, Less Than or Greater Than****Operands**

MRa	CLA floating-point source register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

**Opcode**

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1111 0010 0000
```

**Description**

Set ZF and NF flags on the result of MRa - MRb where MRa and MRb are 32-bit integers. For a floating-point compare, refer to [MCMPF32](#).

**Note**

A known hardware issue exists in the MCMP32 instruction. Signed-integer comparisons using MCMP32 alone set the status bits in a way that is not useful for comparison when the difference between the two operands is too large, such as when the inputs have opposite sign and are near the extreme 32-bit signed values. This affects both signed and unsigned integer comparisons.

The compiler (version 18.1.5.LTS or higher) has implemented a workaround for this issue. The compiler checks the upper bits of the operands by performing a floating point comparison before proceeding to do the integer comparison or subtraction.

The compiler flag `--cla_signed_compare_workaround` enables this workaround.

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
If(MRa == MRb) {ZF=1; NF=0;}
If(MRa > MRb) {ZF=0; NF=0;}
If(MRa < MRb) {ZF=0; NF=1;}
```

**Pipeline**

This is a single-cycle instruction.

**Example**

```
; Behavior of ZF and NF flags for different comparisons
;
; Given A = (int32)1
; B = (int32)2
; C = (int32)-7
;
MMOV32 MR0, @_A ; MR0 = 1 (0x00000001)
MMOV32 MR1, @_B ; MR1 = 2 (0x00000002)
MMOV32 MR2, @_C ; MR2 = -7 (0xFFFFFFFF9)
MCMP32 MR2, MR2 ; NF = 0, ZF = 1
MCMP32 MR0, MR1 ; NF = 1, ZF = 0
MCMP32 MR1, MR0 ; NF = 0, ZF = 0
```

**MCMPF32 MRa, MRb****32-Bit Floating-Point Compare for Equal, Less Than or Greater Than****Operands**

MRa	CLA floating-point source register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

**Opcode**

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1101 0000 0000
```

**Description**

Set ZF and NF flags on the result of MRa - MRb. The MCMPF32 instruction is performed as a logical compare operation. This is possible because of the IEEE format offsetting the exponent. Basically the bigger the binary number, the bigger the floating-point value.

Special cases for inputs:

- Negative zero is treated as positive zero.
- A denormalized value is treated as positive zero.
- Not-a-Number (NaN) is treated as infinity.

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified as follows:

```
If(MRa == MRb) {ZF=1; NF=0;}
If(MRa > MRb) {ZF=0; NF=0;}
If(MRa < MRb) {ZF=0; NF=1;}
```

**Pipeline**

This is a single-cycle instruction.

**Example**

```
; Behavior of ZF and NF flags for different comparisons
MMOVIZ MR1, #-2.0 ; MR1 = -2.0 (0xc0000000)
MMOVIZ MR0, #5.0 ; MR0 = 5.0 (0x40A00000)
MCMPF32 MR1, MR0 ; ZF = 0, NF = 1
MCMPF32 MR0, MR1 ; ZF = 0, NF = 0
MCMPF32 MR0, MR0 ; ZF = 1, NF = 0
```

[MMINF32 MRa, MRb](#)

**MCMPF32 MRa, #16FHi****32-Bit Floating-Point Compare for Equal, Less Than or Greater Than****Operands**

MRa	CLA floating-point source register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0.

**Opcode**

```
LSW: IIII IIII IIII IIII
MSW: 0111 1000 1100 00aa
```

**Description**

Compare the value in MRa with the floating-point value represented by the immediate operand. Set the ZF and NF flags on (MRa - #16FHi:0).

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. This addressing mode is most useful for constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler accepts either a hex or float as the immediate value. That is, -1.5 can be represented as #-1.5 or #0xBFC0.

The MCMPF32 instruction is performed as a logical compare operation. This is possible because of the IEEE floating-point format offsets the exponent. Basically the bigger the binary number, the bigger the floating-point value.

Special cases for inputs:

- Negative zero is treated as positive zero.
- Denormalized value is treated as positive zero.
- Not-a-Number (NaN) is treated as infinity.

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified as follows:

```
If(MRa == #16FHi:0) {ZF=1, NF=0;}
If(MRa > #16FHi:0) {ZF=0, NF=0;}
If(MRa < #16FHi:0) {ZF=0, NF=1;}
```

**Pipeline**

This is a single-cycle instruction

**Example 1**

```
; Behavior of ZF and NF flags for different comparisons
MMOVIZ MR1, #-2.0 ; MR1 = -2.0 (0xC0000000)
MMOVIZ MR0, #5.0 ; MR0 = 5.0 (0x40A00000)
MCMPF32 MR1, #-2.2 ; ZF = 0, NF = 0
MCMPF32 MR0, #6.5 ; ZF = 0, NF = 1
MCMPF32 MR0, #5.0 ; ZF = 1, NF = 0
```

## MDEBUGSTOP

### *Debug Stop Task*

#### Operands

none	This instruction does not have any operands
------	---

#### Opcode

LSW: 0000 0000 0000 0000
MSW: 0111 1111 0110 0000

#### Description

When CLA breakpoints are enabled, the MDEBUGSTOP instruction is used to halt a task so that the task can be debugged. That is, MDEBUGSTOP is the CLA breakpoint. If CLA breakpoints are not enabled, the MDEBUGSTOP instruction behaves like a MNOP. Unlike the MSTOP, the MIRUN flag is not cleared and an interrupt is not issued. A single-step or run operation continues execution of the task.

#### Restrictions

The MDEBUGSTOP instruction cannot be placed 3 instructions before or after a [MBCNDD](#) , [MCCNDD](#) , or [MRCNDD](#) instruction.

#### Flags

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

#### Pipeline

This is a single-cycle instruction.

#### See also

[MSTOP](#) , [MDEBUGSTOP1](#)

**MDEBUGSTOP1****Software Breakpoint****Operands**

none	This instruction does not have any operands
------	---

**Opcode**

LSW: 0000 0000 0000 0000
MSW: 0111 1111 0011 0000

**Description**

The instruction at which a software breakpoint is placed is replaced by the MDEBUGSTOP1 instruction. The instruction halts execution once the instruction reaches the D2 phase in the pipeline; at that point, the subsequent instructions that were fetched, after the halt, are flushed from the pipeline. The replace instruction is re-fetched after this and execution continues normally (either in run or step mode).

See [Section 7.4.3](#) for a detailed explanation of the operation.

**Restrictions**

The MDEBUGSTOP1 instruction cannot be placed 3 instructions before or after a [MBCNDD](#) , [MCCNDD](#) , or [MRCNDD](#) instruction.

**Flags**

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**Pipeline**

This is a single-cycle instruction.

**See also**

## MEALLOW

### Enable CLA Write Access to EALLOW Protected Registers

#### Operands

none	This instruction does not have any operands
------	---

#### Opcode

LSW: 0000 0000 0000 0000
MSW: 0111 1111 1001 0000

#### Description

This instruction sets the MEALLOW bit in the CLA status register MSTF. When this bit is set, the CLA is allowed write access to EALLOW protected registers. To again protect against CLA writes to protected registers, use the MEDIS instruction.

MEALLOW and MEDIS only control CLA write access; reads are allowed even if MEALLOW has not been executed. MEALLOW and MEDIS are also independent from the main CPU's EALLOW/EDIS. This instruction does not modify the EALLOW bit in the main CPU's status register. The MEALLOW bit in MSTF only controls access for the CLA while the EALLOW bit in the ST1 register only controls access for the main CPU.

As with EALLOW, the MEALLOW bit is overridden using the JTAG port, allowing full control of register accesses during debug from Code Composer Studio.

#### Flags

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

#### Pipeline

This is a single-cycle instruction.

#### Example

```

; C header file including definition of
; the EPwm1Regs structure
;
; The ePWM TZSEL register is EALLOW protected
;
.cdecls C,LIST,"CLAShared.h"
...
_Cla1Task1:
...
MEALLOW                ; Allow CLA write access
MMOV16 @_EPwm1Regs.TZSEL.all, MR3 ; write to TZSEL
MEDIS                  ; Disallow CLA write access
...
...
MSTOP

```

#### See also

[MEDIS](#)

**MEDIS*****Disable CLA Write Access to EALLOW Protected Registers*****Operands**

none	This instruction does not have any operands
------	---

**Opcode**

LSW: 0000 0000 0000 0000
MSW: 0111 1111 1011 0000

**Description**

This instruction clears the MEALLOW bit in the CLA status register MSTF. When this bit is clear, the CLA is not allowed write access to EALLOW-protected registers. To enable CLA writes to protected registers, use the MEALLOW instruction.

MEALLOW and MEDIS only control CLA write access; reads are allowed even if MEALLOW has not been executed. MEALLOW and MEDIS are also independent from the main CPU's EALLOW/EDIS. This instruction does not modify the EALLOW bit in the main CPU's status register. The MEALLOW bit in MSTF only controls access for the CLA while the EALLOW bit in the ST1 register only controls access for the main CPU.

As with EALLOW, the MEALLOW bit is overridden using the JTAG port, allowing full control of register accesses during debug from the Code Composer Studio™ IDE.

**Flags**

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**Pipeline**

This is a single-cycle instruction.

**Example**

```

; C header file including definition of
; the EPwm1Regs structure
;
; The ePWM TZSEL register is EALLOW protected
;
.cdecls C,LIST,"CLAShared.h"
...
_Cla1Task1:
...
MEALLOW                ; Allow CLA write access
MMOV16 @_EPwm1Regs.TZSEL.all, MR3 ; write to TZSEL
MEDIS                  ; Disallow CLA write access
...
...
MSTOP

```

**MEINVF32 MRa, MRb****32-Bit Floating-Point Reciprocal Approximation****Operands**

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

**Opcode**

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1111 0000 0000
```

**Description**

This operation generates an estimate of  $1/X$  in 32-bit floating-point format accurate to approximately 8 bits. This value can be used in a Newton-Raphson algorithm to get a more accurate answer. That is:

```
Ye = Estimate(1/X);
Ye = Ye*(2.0 - Ye*X);
Ye = Ye*(2.0 - Ye*X);
```

After two iterations of the Newton-Raphson algorithm, you get an exact answer accurate to the 32-bit floating-point format. On each iteration, the mantissa bit accuracy approximately doubles. The MEINVF32 operation does not generate a negative zero, DeNorm, or NaN value.

```
MRa = Estimate of 1/MRb;
```

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MEINVF32 generates an underflow condition.
- LVF = 1 if MEINVF32 generates an overflow condition.

**Pipeline**

This is a single-cycle instruction.

**MEINVF32 MRa, MRb (continued)**
**32-Bit Floating-Point Reciprocal Approximation**
**Example**

```

; Calculate Num/Den using a Newton-Raphson algorithm for 1/Den
; Ye = Estimate(1/X)
; Ye = Ye*(2.0 - Ye*X)
; Ye = Ye*(2.0 - Ye*X)
;
;

**Opcode**

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1110 0100 0000
```

**Description**

This operation generates an estimate of  $1/\sqrt{X}$  in 32-bit floating-point format accurate to approximately 8 bits. This value can be used in a Newton-Raphson algorithm to get a more accurate answer. That is:

```
Ye = Estimate(1/sqrt(X));
Ye = Ye*(1.5 - Ye*Ye*X/2.0);
Ye = Ye*(1.5 - Ye*Ye*X/2.0);
```

After 2 iterations of the Newton-Raphson algorithm, you get an exact answer accurate to the 32-bit floating-point format. On each iteration, the mantissa bit accuracy approximately doubles. The MEISQRTF32 operation does not generate a negative zero, DeNorm, or NaN value.

```
MRa = Estimate of 1/sqrt (MRb);
```

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MEISQRTF32 generates an underflow condition.
- LVF = 1 if MEISQRTF32 generates an overflow condition.

**MF32TOUI16 MRa, MRb**
**Convert 32-Bit Floating-Point Value to 16-bit Unsigned Integer**
**Operands**

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

**Opcode**

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1110 1010 0000
```

**Description**

Convert the 32-bit floating point value in MRb to an unsigned 16-bit integer value and truncate to zero. The result is stored in MRa. To instead round the integer to the nearest even value, use the MF32TOUI16R instruction.

```
MRa(15:0) = F32TOUI16(MRb);
MRa(31:16) = 0x0000;
```

**Flags**

This instruction does not affect any flags:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**Pipeline**

This is a single-cycle instruction.

**Example**

```
MMOVIZ    MR0, #9.0      ; MR0 = 9.0 (0x41100000)
MF32TOUI16 MR1, MR0      ; MR1(15:0) = MF32TOUI16(MR0) = 9 (0x0009)
              ; MR1(31:16) = 0x0000
MMOVIZ    MR2, #-9.0     ; MR2 = -9.0 (0xc1100000)
MF32TOUI16 MR3, MR2      ; MR3(15:0) = MF32TOUI16(MR2) = 0 (0x0000)
              ; MR3(31:16) = 0x0000
```

**MF32TOUI16R MRa, MRb****Convert 32-Bit Floating-Point Value to 16-bit Unsigned Integer and Round****Operands**

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

**Opcode**

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1110 1100 0000
```

**Description**

Convert the 32-bit floating-point value in MRb to an unsigned 16-bit integer and round to the closest even value. The result is stored in MRa. To instead truncate the converted value, use the MF32TOUI16 instruction.

```
MRa(15:0) = MF32TOUI16round(MRb);
MRa(31:16) = 0x0000;
```

**Flags**

This instruction does not affect any flags:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**Pipeline**

This is a single-cycle instruction.

**Example**

```
MMOVIZ      MR0, #0x412C    ; MR0 = 0x412C
MMOVXI      MR0, #0xCCCCD   ; MR0 = 0xCCCCD ; MR0 = 10.8 (0x412CCCCD)
MF32TOUI16R MR1, MR0        ; MR1(15:0) = MF32TOUI16round(MR0) = 11 (0x000B)
                ; MR1(31:16) = 0x0000
MMOVF32     MR2, #-10.8     ; MR2 = -10.8 (0x0xC12CCCCD)
MF32TOUI16R MR3, MR2        ; MR3(15:0) = MF32TOUI16round(MR2) = 0 (0x0000)
                ; MR3(31:16) = 0x0000
```

**MLSL32 MRa, #SHIFT****Logical Shift Left****Operands**

MRa	CLA floating-point source/destination register (MR0 to MR3)
#SHIFT	Number of bits to shift (1 to 32)

**Opcode**

```
LSW: 0000 0000 0shi ftaa
MSW: 0111 1011 1100 0000
```

**Description**

Logical shift-left of MRa by the number of bits indicated. The number of bits can be 1 to 32.

```
MARa(31:0) = Logical Shift Left(MARa(31:0) by #SHIFT bits);
```

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; }
```

**Pipeline**

This is a single-cycle instruction.

**Example**

```
; Given m2 = (int32)32
; x2 = (int32)64
; b2 = (int32)-128
;
; calculate:
; m2 = m2*2
; x2 = x2*4
; b2 = b2*8
;
_Cla1Task3:
  MMOV32 MR0, @_m2 ; MR0 = 32 (0x00000020)
  MMOV32 MR1, @_x2 ; MR1 = 64 (0x00000040)
  MMOV32 MR2, @_b2 ; MR2 = -128 (0xFFFFF80)
  MLSL32 MR0, #1 ; MR0 = 64 (0x00000040)
  MLSL32 MR1, #2 ; MR1 = 256 (0x00000100)
  MLSL32 MR2, #3 ; MR2 = -1024 (0xFFFFFC00)
  MMOV32 @_m2, MR0 ; Store results
  MMOV32 @_x2, MR1
  MMOV32 @_b2, MR2
  MSTOP ; end of task
```

MLSL32 MRa, #SHIFT (continued)

**Logical Shift Left**

**MLSR32 MRa, #SHIFT****Logical Shift Right****Operands**

MRa	CLA floating-point source/destination register (MR0 to MR3)
#SHIFT	Number of bits to shift (1 to 32)

**Opcode**

```
LSW: 0000 0000 0shi ftaa
MSW: 0111 1011 1000 0000
```

**Description**

Logical shift-right of MRa by the number of bits indicated. The number of bits can be 1 to 32. Unlike the arithmetic shift (MASR32), the logical shift does not preserve the number's sign bit. Every bit in the operand is moved the specified number of bit positions, and the vacant bit positions are filled in with zeros.

```
MARa(31:0) = Logical Shift Right(MARa(31:0) by #SHIFT bits);
```

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1;}
```

**Pipeline**

This is a single-cycle instruction.

**Example**

```
; illustrate the difference between MASR32 and MLSR32
MMOVIZ MR0, #0xAAAA ; MR0 = 0xAAAA5555
MMOVXI MR0, #0x5555
MMOV32 MR1, MR0 ; MR1 = 0xAAAA5555
MMOV32 MR2, MR0 ; MR2 = 0xAAAA5555
MASR32 MR1, #1 ; MR1 = 0xD5552AAA
MLSR32 MR2, #1 ; MR2 = 0x55552AAA
MASR32 MR1, #1 ; MR1 = 0xEAAA9555
MLSR32 MR2, #1 ; MR2 = 0x2AAA9555
MASR32 MR1, #6 ; MR1 = 0xFFAAA555
MLSR32 MR2, #6 ; MR2 = 0x00AAA555
```

**MMACF32 MR3, MR2, MRd, MRe, MRf ||MMOV32 MRa, mem32**
**32-Bit Floating-Point Multiply and Accumulate with Parallel Move**
**Operands**

MR3	floating-point destination/source register MR3 for the add operation
MR2	CLA floating-point source register MR2 for the add operation
MRd	CLA floating-point destination register (MR0 to MR3) for the multiply operation MRd cannot be the same register as MRa
MRe	CLA floating-point source register (MR0 to MR3) for the multiply operation
MRf	CLA floating-point source register (MR0 to MR3) for the multiply operation
MRa	CLA floating-point destination register for the MMOV32 operation (MR0 to MR3). MRa cannot be MR3 or the same register as MRd.
mem32	32-bit source for the MMOV32 operation

**Opcode**

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0011 ffee ddaa addr
```

**Description**

Multiply and accumulate the contents of floating-point registers and move from register to memory. The destination register for the MMOV32 cannot be the same as the destination registers for the MMACF32.

```
MR3 = MR3 + MR2;
MRd = MRe * MRf;
MRa = [mem32];
```

**Restrictions**

The destination registers for the MMACF32 and the MMOV32 must be unique. That is, MRa cannot be MR3 and MRa cannot be the same register as MRd.

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MMACF32 (add or multiply) generates an underflow condition.
- LVF = 1 if MMACF32 (add or multiply) generates an overflow condition.

MMOV32 sets the NF and ZF flags as follows:

```
NF = MRa(31);
ZF = 0;
if(MRa(30:23) == 0) { ZF = 1; NF = 0; }
```

**Pipeline**

MMACF32 and MMOV32 complete in a single cycle.

**MMACF32 MR3, MR2, MRd, MRe, MRf ||MMOV32 MRa, mem32 (continued)**
**32-Bit Floating-Point Multiply and Accumulate with Parallel Move**
**Example 1**

```

; Perform 5 multiply and accumulate operations:
;
; X and Y are 32-bit floating-point arrays
;
; 1st multiply: A = X0 * Y0
; 2nd multiply: B = X1 * Y1
; 3rd multiply: C = X2 * Y2
; 4th multiply: D = X3 * Y3
; 5th multiply: E = X3 * Y3
;
; Result = A + B + C + D + E
;
_Cla1Task1:

**32-Bit Floating-Point Maximum**
**Operands**

MRa	CLA floating-point source/destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

**Opcode**

```
LSW: 0000 0000 0000 bbaa
MSW: 0111 1101 0010 0000
```

**Description**

```
if(MRa < MRb) MRa = MRb;
```

Special cases for the output from the MMAXF32 operation:

- NaN output is converted to infinity
- A denormalized output is converted to positive zero.

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The ZF and NF flags are configured on the result of the operation, not the result stored in the destination register.

```
if(MRa == MRb) {ZF=1; NF=0;}
if(MRa > MRb) {ZF=0; NF=0;}
if(MRa < MRb) {ZF=0; NF=1;}
```

**Pipeline**

This is a single-cycle instruction.

**Example 1**

```
MMOVIZ MR0, #5.0 ; MR0 = 5.0 (0x40A00000)

**MMAXF32 MRa, #16FHi**
**32-Bit Floating-Point Maximum**
**Operands**

MRa	CLA floating-point source/destination register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0.

**Opcode**

```
LSW: IIII IIII IIII IIII
MSW: 0111 1001 0000 00aa
```

**Description**

Compare MRa with the floating-point value represented by the immediate operand. If the immediate value is larger, then load the value into MRa.

```
if(MRa < #16FHi:0) MRa = #16FHi:0;
```

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. This addressing mode is most useful for constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler accepts either a hex or float as the immediate value. That is, -1.5 can be represented as #-1.5 or #0xBFC0.

Special cases for the output from the MMAXF32 operation:

- NaN output is converted to infinity
- A denormalized output is converted to positive zero.

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The ZF and NF flags are configured on the result of the operation, not the result stored in the destination register.

```
if(MRa == #16FHi:0) {ZF=1; NF=0;}
if(MRa > #16FHi:0) {ZF=0; NF=0;}
if(MRa < #16FHi:0) {ZF=0; NF=1;}
```

**Pipeline**

This is a single-cycle instruction.

**Example**

```
MMOVIZ MR0, #5.0 ; MR0 = 5.0 (0x40A00000)
MMOVIZ MR1, #4.0 ; MR1 = 4.0 (0x40800000)
MMOVIZ MR2, #-1.5 ; MR2 = -1.5 (0xBFC00000)
MMAXF32 MR0, #5.5 ; MR0 = 5.5, ZF = 0, NF = 1
MMAXF32 MR1, #2.5 ; MR1 = 4.0, ZF = 0, NF = 0
MMAXF32 MR2, #-1.0 ; MR2 = -1.0, ZF = 0, NF = 1
MMAXF32 MR2, #-1.0 ; MR2 = -1.5, ZF = 1, NF = 0
```

**MMOV16 MARx, MRa, #16I****Load the Auxiliary Register with MRa + 16-bit Immediate Value****Operands**

MARx	Auxiliary register MAR0 or MAR1
MRa	CLA Floating-point register (MR0 to MR3)
#16I	16-bit immediate value

**Opcode**

```
LSW: IIII IIII IIII IIII (opcode of MMOV16 MAR0, MRa, #16I)
MSW: 0111 1111 1101 00AA
LSW: IIII IIII IIII IIII (opcode of MMOV16 MAR1, MRa, #16I)
MSW: 0111 1111 1111 00AA
```

**Description**

Load the auxiliary register, MAR0 or MAR1, with MRa(15:0) + 16-bit immediate value. Refer to the Pipeline section for important information regarding this instruction.

```
MARX = MRa(15:0) + #16I;
```

**Flags**

This instruction does not modify flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**Pipeline**

This is a single-cycle instruction. The load of MAR0 or MAR1 occurs in the EXE phase of the pipeline. Any post increment of MAR0 or MAR1 using indirect addressing occurs in the D2 phase of the pipeline. Therefore, the following applies when loading the auxiliary registers:

- **I1 and I2**

The two instructions following MMOV16 use MAR0 or MAR1 before the update occurs. Thus, these two instructions use the old value of MAR0 or MAR1.

- **I3**

Loading of an auxiliary register occurs in the EXE phase while updates due to post-increment addressing occur in the D2 phase. Thus, I3 cannot use the auxiliary register or there is a conflict. In the case of a conflict, the update due to address-mode post increment wins and the auxiliary register is not updated with #\_X.

- **I4**

Starting with the 4th instruction, MAR0 or MAR1 is the new value loaded with MMOV16.

```
; Assume MAR0 is 50, MR0 is 10, and #_X is 20
MMOV16 MAR0, MR0, #_X ; Load MAR0 with address of x (20) + MR0 (10)
<Instruction 1> ; I1 Uses the old value of MAR0 (50)
<Instruction 2> ; I2 Uses the old value of MAR0 (50)
<Instruction 3> ; I3 Cannot use MAR0
<Instruction 4> ; I4 Uses the new value of MAR0 (30)
<Instruction 5> ; I5
```

**MMOV16 MARx, mem16****Load MAR1 with 16-bit Value****Operands**

MARx	CLA auxiliary register MAR0 or MAR1
mem16	16-bit destination memory accessed using one of the available addressing modes

**Opcode**

```
LSW: mmmm mmmm mmmm mmmm (Opcode for MMOV16 MAR0, mem16)
MSW: 0111 0110 0000 addr
LSW: mmmm mmmm mmmm mmmm (Opcode for MMOV16 MAR1, mem16)
MSW: 0111 0110 0100 addr
```

**Description**

Load MAR0 or MAR1 with the 16-bit value pointed to by mem16. Refer to the Pipeline section for important information regarding this instruction.

```
MAR1 = [mem16];
```

**Flags**

No flags MSTF flags are affected.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**Pipeline**

This is a single-cycle instruction. The load of MAR0 or MAR1 occurs in the EXE phase of the pipeline. Any post increment of MAR0 or MAR1 using indirect addressing occurs in the D2 phase of the pipeline. Therefore, the following applies when loading the auxiliary registers:

- **I1 and I2**

The two instructions following MMOV16 use MAR0 or MAR1 before the update occurs. Thus, these two instructions use the old value of MAR0 or MAR1.

- **I3**

Loading of an auxiliary register occurs in the EXE phase while updates due to post-increment addressing occur in the D2 phase. Thus, I3 cannot use the auxiliary register or there is a conflict. In the case of a conflict, the update due to address-mode post increment, the auxiliary register is not updated with #\_X.

- **I4**

Starting with the 4th instruction, MAR0 or MAR1 is the new value loaded with MMOV16.

```
; Assume MAR0 is 50 and @_X is 20
MMOV16 MAR0, @_X ; Load MAR0 with the contents of x (20)
<Instruction 1> ; I1 Uses the old value of MAR0 (50)
<Instruction 2> ; I2 Uses the old value of MAR0 (50)
<Instruction 3> ; I3 Cannot use MAR0

[MMOV32 mem32, MSTF](#)

**MMOV32 mem32, MSTF****Move 32-Bit MSTF Register to Memory****Operands**

MSTF	Floating-point status register
mem32	32-bit destination memory

**Opcode**

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0111 0111 0100 addr
```

**Description**

Copy the CLA floating-point status register, MSTF, to memory.

```
[mem32] = MSTF;
```

**Flags**

This instruction does not modify flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**Pipeline**

This is a single-cycle instruction.

One of the uses of this instruction is to save off the return PC (RPC) prior to calling a function. The decision to jump to a function is made when the MCCNDD is in the decode2 (D2) phase of the pipeline; the RPC is also updated in this phase. The actual jump occurs 3 cycles later when MCCNDD enters the execution (E) phase. You must save the old RPC before MCCNDD updates in the D2 phase; that is, save MSTF 3 instructions prior to the function call.

**Example**

The following example illustrates the pipeline flow for the context save (of the flags and RPC) prior to a function call. The first column in the comments shows the pipeline stages for the MMOV32 instruction while the second column pertains to the MCCNDD instruction.

```
MMOV32 @_temp, MSTF ; D2 | |
MNOP                ; R1 | F1 | MCCNDD is fetched
MNOP                ; R2 | F2 |
MNOP                ; E  | D1 |
MCCNDD _bar, UNC    ; W  | D2 | old RPC written to memory,
                   ;   |   | RPC updated with MPC+1
MNOP                ;   | R1 |
MNOP                ;   | R2 |
MNOP                ;   | E  | execution branches to _bar
```

[MMOV32 mem32, MRa](#)

**MMOV32 MRa, mem32 {, CNDF}**
**Conditional 32-Bit Move**
**Operands**

MRa	CLA floating-point destination register (MR0 to MR3)
mem32	32-bit memory location accessed using one of the available addressing modes
CNDF	Optional condition

**Opcode**

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0111 00cn dfaa addr
```

**Description**

If the condition is true, then move the 32-bit value referenced by mem32 to the floating-point register indicated by MRa.

```
if (CNDF == TRUE) MRa = [mem32];
```

CNDF is one of the following conditions:

Encode <sup>(1)</sup>	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF <sup>(2)</sup>	Unconditional with flag modification	None

(1) Values not shown are reserved.

(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

```
if(CNDF == UNCF)
{
  NF = MRa(31);
  ZF = 0;
  if(MRa(30:23) == 0) { ZF = 1; NF = 0; }
}
else No flags modified;
```

**MMOV32 MRa, mem32 {, CNDF} (continued)**
**Conditional 32-Bit Move**

---

**Pipeline**

This is a single-cycle instruction.

**Example**

```

; Given A, B, X, M1 and M2 are 32-bit floating-point numbers
;
; if(A == B) calculate Y = X*M1
; if(A! = B) calculate Y = X*M2
;
_Cla1Task5:
    MMOV32    MR0, @_A

**See also**
[MMOV32 MRa, mem32 {,CNDF}](#)

**MMOVF32 MRa, #32F****Load the 32-Bits of a 32-Bit Floating-Point Register****Operands**

This instruction is an alias for the MMOVIZ and MMOVXI instructions. The second operand is translated by the assembler such that the instruction becomes:

```
MMOVIZ MRa, #16FHiHex MMOVXI MRa, #16FLoHex
```

MRa	CLA floating-point destination register (MR0 to MR3)
#32F	Immediate float value represented in floating-point representation

**Opcode**

```
LSW: IIII IIII IIII IIII (opcode of MMOVIZ MRa, #16FHiHex)
MSW: 0111 1000 0100 00aa
LSW: IIII IIII IIII IIII (opcode of MMOVXI MRa, #16FLoHex)
MSW: 0111 1000 1000 00aa
```

**Description**

This instruction accepts the immediate operand only in floating-point representation. To specify the immediate value as a hex value (IEEE 32-bit floating-point format), use the MOVI32 MRa, #32FHex instruction.

Load the 32-bits of MRa with the immediate float value represented by #32F.

#32F is a float value represented in floating-point representation. The assembler only accepts a float value represented in floating-point representation. That is, 3.0 can only be represented as #3.0 (#0x40400000 results in an error).

```
MRa = #32F;
```

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**Pipeline**

Depending on #32F, this instruction takes one or two cycles. If all of the lower 16-bits of the IEEE 32-bit floating-point format of #32F are zeros, then the assembler converts MMOVF32 into only an MMOVIZ instruction. If the lower 16-bits of the IEEE 32-bit floating-point format of #32F are not zeros, then the assembler converts MMOVF32 into MMOVIZ and MMOVXI instructions.

**Example**

```
MMOVF32 MR1, #3.0      ; MR1 = 3.0 (0x40400000)
                       ; Assembler converts this instruction as
                       ; MMOVIZ MR1, #0x4040
MMOVF32 MR2, #0.0      ; MR2 = 0.0 (0x00000000)
                       ; Assembler converts this instruction as
                       ; MMOVIZ MR2, #0x0
MMOVF32 MR3, #12.265   ; MR3 = 12.625 (0x41443D71)
                       ; Assembler converts this instruction as
                       ; MMOVIZ MR3, #0x4144
                       ; MMOVXI MR3, #0x3D71
```

**MMOVI16 MARx, #16I****Load the Auxiliary Register with the 16-Bit Immediate Value****Operands**

MARx	Auxiliary register MAR0 or MAR1
#16I	16-bit immediate value

**Opcode**

```

LSW: IIII IIII IIII IIII (opcode of MMOVI16 MAR0, #16I)
MSW: 0111 1111 1100 0000
LSW: IIII IIII IIII IIII (opcode of MMOVI16 MAR1, #16I)
MSW: 0111 1111 1110 0000

```

**Description**

Load the auxiliary register, MAR0 or MAR1, with a 16-bit immediate value. Refer to the Pipeline section for important information regarding this instruction.

```
MARx = #16I;
```

**Flags**

This instruction does not modify flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**Pipeline**

This is a single-cycle instruction. The immediate load of MAR0 or MAR1 occurs in the EXE phase of the pipeline. Any post increment of MAR0 or MAR1 using indirect addressing occurs in the D2 phase of the pipeline. Therefore, the following applies when loading the auxiliary registers:

- **I1 and I2**

The two instructions following MMOVI16 use MAR0 or MAR1 before the update occurs. Thus, these two instructions use the old value of MAR0 or MAR1.

- **I3**

Loading of an auxiliary register occurs in the EXE phase while updates due to post-increment addressing occur in the D2 phase. Thus, I3 cannot use the auxiliary register or there is a conflict. In the case of a conflict, the update due to address-mode post increment, the auxiliary register is not updated with #\_X.

- **I4**

Starting with the 4th instruction, MAR0 or MAR1 is the new value loaded with MMOVI16.

```

; Assume MAR0 is 50 and #_X is 20
MMOVI16 MAR0, #_X          ; Load MAR0 with address of X (20)
<Instruction 1>             ; I1 Uses the old value of MAR0 (50)
<Instruction 2>             ; I2 Uses the old value of MAR0 (50)
<Instruction 3>             ; I3 Cannot use MAR0
<Instruction 4>             ; I4 Uses the new value of MAR0 (20)
<Instruction 5>             ; I5
....

```

**MMOVI16 MARx, #16I (continued)**

I6	I6	I5	I4	I3	I2	I1	MMOVI16	

**MMOVI32 MRa, #32FHex****Load the 32-Bits of a 32-Bit Floating-Point Register with the Immediate****Operands**

MRa	Floating-point register (MR0 to MR3)
#32FHex	A 32-bit immediate value that represents an IEEE 32-bit floating-point value.

This instruction is an alias for the MMOVIZ and MMOVXI instructions. The second operand is translated by the assembler such that the instruction becomes:

```
MMOVIZ MRa, #16FHiHex
MMOVXI MRa, #16FLoHex
```

**Opcode**

```
LSW: IIII IIII IIII IIII (opcode of MMOVIZ MRa, #16FHiHex)
MSW: 0111 1000 0100 00aa
LSW: IIII IIII IIII IIII (opcode of MMOVXI MRa, #16FLoHex)
MSW: 0111 1000 1000 00aa
```

**Description**

This instruction only accepts a hex value as the immediate operand. To specify the immediate value with a floating-point representation, use the MMOVF32 MRa, #32F instruction.

Load the 32-bits of MRa with the immediate 32-bit hex value represented by #32FHex.

#32FHex is a 32-bit immediate hex value that represents the IEEE 32-bit floating-point value of a floating-point number. The assembler only accepts a hex immediate value. That is, 3.0 can only be represented as #0x40400000 (#3.0 results in an error).

```
MRa = #32FHex;
```

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**Pipeline**

Depending on #32FHex, this instruction takes one or two cycles. If all of the lower 16-bits of #32FHex are zeros, then the assembler converts MOV32 to an MMOVIZ instruction. If the lower 16-bits of #32FHex are not zeros, then the assembler converts MOV32 to MMOVIZ and MMOVXI instructions.

**MMOV132 MRa, #32FHex (continued)**
***Load the 32-Bits of a 32-Bit Floating-Point Register with the Immediate***
**Example**

```

MOVI32 MR1, #0x40400000 ; MR1 = 0x40400000
                        ; Assembler converts this instruction as
                        ; MMOVIZ MR1, #0x4040
MOVI32 MR2, #0x00000000 ; MR2 = 0x00000000
                        ; Assembler converts this instruction as
                        ; MMOVIZ MR2, #0x0
MOVI32 MR3, #0x40004001 ; MR3 = 0x40004001
                        ; Assembler converts this instruction as
                        ; MMOVIZ MR3, #0x4000
                        ; MMOVXI MR3, #0x4001
MOVI32 MR0, #0x00004040 ; MR0 = 0x00004040
                        ; Assembler converts this instruction as
                        ; MMOVIZ MR0, #0x0000
                        ; MMOVXI MR0, #0x4040
  
```

**MMOVIZ MRa, #16FHi****Load the Upper 16-Bits of a 32-Bit Floating-Point Register****Operands**

MRa	Floating-point register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0.

**Opcode**

```
LSW: IIII IIII IIII IIII
MSW: 0111 1000 0100 00aa
```

**Description**

Load the upper 16-bits of MRa with the immediate value #16FHi and clear the low 16-bits of MRa.

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. The assembler only accepts a decimal or hex immediate value. That is, -1.5 can be represented as #-1.5 or #0xBFC0.

MMOVIZ is useful for loading a floating-point register with a constant in which the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). If a constant requires all 32-bits of a floating-point register to be initialized, then use MMOVIZ along with the MMOVXI instruction.

```
MRa(31:16) = #16FHi;
MRa(15:0) = 0;
```

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**Pipeline**

This is a single-cycle instruction.

**Example**

```
; Load MR0 and MR1 with -1.5 (0xBFC00000)
MMOVIZ MR0, #0xBFC0 ; MR0 = 0xBFC00000 (1.5)
MMOVIZ MR1, #-1.5 ; MR1 = -1.5 (0xBFC00000)
; Load MR2 with pi = 3.141593 (0x40490FDB)
MMOVIZ MR2, #0x4049 ; MR2 = 0x40490000
MMOVXI MR2, #0x0FDB ; MR2 = 0x40490FDB
```

**MMOVZ16 MRa, mem16**
**Load MRx with 16-Bit Value**
**Operands**

MRa	CLA floating-point destination register (MR0 to MR3)
mem16	16-bit source memory location

**Opcode**

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0111 0101 10aa addr
```

**Description**

Move the 16-bit value referenced by mem16 to the floating-point register indicated by MRa.

```
MRa(31:16) = 0;
MRa(15:0) = [mem16];
```

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = 0;
if (MRa(31:0) == 0) { ZF = 1; }
```

**Pipeline**

This is a single-cycle instruction.

**MMOVXI MRa, #16FLoHex*****Move Immediate Value to the Lower 16-Bits of a Floating-Point Register*****Operands**

MRa	CLA floating-point register (MR0 to MR3)
#16FLoHex	A 16-bit immediate hex value that represents the lower 16-bits of an IEEE 32-bit floating-point value. The upper 16-bits are not modified.

**Opcode**

```
LSW: IIII IIII IIII IIII
MSW: 0111 1000 1000 00aa
```

**Description**

Load the lower 16-bits of MRa with the immediate value #16FLoHex. #16FLoHex represents the lower 16-bits of an IEEE 32-bit floating-point value. The upper 16-bits of MRa are not modified. MMOVXI can be combined with the MMOVIZ instruction to initialize all 32-bits of a MRa register.

```
MRa(15:0) = #16FLoHex;
MRa(31:16) = Unchanged;
```

**Flags**

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**Pipeline**

This is a single-cycle instruction.

**Example**

```
; Load MR0 with pi = 3.141593 (0x40490FDB)
MMOVIZ    MR0,#0x4049    ; MR0 = 0x40490000

[MMPYF32 MRa, MRb, MRc](#)

**MMPYF32 MRa, MRb, MRc||MADDF32 MRd, MRe, MRf**
**32-Bit Floating-Point Multiply with Parallel Add**
**Operands**

MRa	CLA floating-point destination register for MMPYF32 (MR0 to MR3) MRa cannot be the same register as MRd
MRb	CLA floating-point source register for MMPYF32 (MR0 to MR3)
MRC	CLA floating-point source register for MMPYF32 (MR0 to MR3)
MRd	CLA floating-point destination register for MADDF32 (MR0 to MR3) MRd cannot be the same register as MRa
MRe	CLA floating-point source register for MADDF32 (MR0 to MR3)
MRf	CLA floating-point source register for MADDF32 (MR0 to MR3)

**Opcode**

```
LSW: 0000 ffee ddcc bbaa
MSW: 0111 1010 0000 0000
```

**Description**

Multiply the contents of two floating-point registers with parallel addition of two registers.

```
MRa = MRb * MRC;
MRd = MRe + MRf;
```

**Restrictions**

The destination register for the MMPYF32 and the MADDF32 must be unique. That is, MRa cannot be the same register as MRd.

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MMPYF32 or MADDF32 generates an underflow condition.
- LVF = 1 if MMPYF32 or MADDF32 generates an overflow condition.

**Pipeline**

Both MMPYF32 and MADDF32 complete in a single cycle.

MRf	CLA floating-point source register for MMPYF32 (MR0 to MR3)
MRa	CLA floating-point destination register for MMOV32 (MR0 to MR3) MRa cannot be the same register as MRd
mem32	32-bit memory location accessed using one of the available addressing modes. This is the source of MMOV32.

**Opcode**

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0000 ffee ddaa addr
```

**Description**

Multiply the contents of two floating-point registers and load another.

```
MRd = MRe * MRf;
MRa = [mem32];
```

**Restrictions**

The destination register for the MMPYF32 and the MMOV32 must be unique. That is, MRa cannot be the same register as MRd.

**Flags**

This instruction modifies the following flags in the MSTF register..

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MMPYF32 generates an underflow condition.
- LVF = 1 if MMPYF32 generates an overflow condition.

The MMOV32 instruction sets the NF and ZF flags as follows:

```
NF = MRa(31);
ZF = 0;
if(MRa(30:23) == 0) { ZF = 1; NF = 0; }
```

**Pipeline**

Both MMPYF32 and MMOV32 complete in a single cycle.

**Example 1**

```

**MNEGF32 MRa, MRb{, CNDF}**
**Conditional Negation**
**Operands**

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
CNDF	Condition tested

**Opcode**

```
LSW: 0000 0000 cndf bbaa
MSW: 0111 1010 1000 0000
```

**Description**

```
if (CNDF == true) {MRa = - MRb; }
else {MRa = MRb; }
```

CNDF is one of the following conditions:

Encode <sup>(1)</sup>	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF <sup>(2)</sup>	Unconditional with flag modification	None

(1) Values not shown are reserved.

(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF, and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

**Pipeline**

This is a single-cycle instruction.

**MRCNDD {CNDF}*****Return Conditional Delayed*****Operands**

CNDF	Optional condition
------	--------------------

**Opcode**

LSW: 0000 0000 0000 0000
MSW: 0111 1001 1010 cndf

**Description**

If the specified condition is true, then the RPC field of MSTF is loaded into MPC and fetching continues from that location. Otherwise, program fetches continue without the return.

Refer to the Pipeline section for important information regarding this instruction.

<code>if (CNDF == TRUE) MPC = RPC;</code>
---

CNDF is one of the following conditions:

Encode <sup>(1)</sup>	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF <sup>(2)</sup>	Unconditional with flag modification	None

(1) Values not shown are reserved.

(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

**Flags**

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**Pipeline**

The MRCNDD instruction is a single-cycle instruction. As shown in [Table 7-19](#), 6 instruction slots are executed for each return; 3 slots before the return instruction (d5-d7) and 3 slots after the return instruction (d8-d10). The total number of cycles for a return taken or not taken depends on the usage of these slots. That is, the number of cycles depends on how many slots are filled with a MNOP as well as which slots are filled.

**MRCNDD {CNDF} (continued)**
***Return Conditional Delayed***

The effective number of cycles for a return can, therefore, range from 1 to 7 cycles. The number of cycles for a return taken cannot be the same as for a return not taken.

Referring to the following code fragment and the pipeline diagrams in [Table 7-19](#) and [Table 7-20](#), the instructions before and after MRCNDD have the following properties:

```

;
;
<Instruction 1> ; I1 Last instruction that can affect flags for
; the MCCNDD operation
<Instruction 2> ; I2 Cannot be stop, branch, call or return
<Instruction 3> ; I3 Cannot be stop, branch, call or return
<Instruction 4> ; I4 Cannot be stop, branch, call or return
MCCNDD _func, NEQ ; Call to func if not equal to zero
; Three instructions after MCCNDD are always
; executed whether the call is taken or not
<Instruction 5> ; I5 Cannot be stop, branch, call or return
<Instruction 6> ; I6 Cannot be stop, branch, call or return
<Instruction 7> ; I7 Cannot be stop, branch, call or return
<Instruction 8> ; I8 The address of this instruction is saved
; in the RPC field of the MSTF register.
; Upon return this value is loaded into MPC
; and fetching continues from this point.
<Instruction 9> ; I9
<Instruction 10> ; I10
....
....
_func:
<Destination 1> ; d1 Can be any instruction
<Destination 2> ; d2
<Destination 3> ; d3
<Destination 4> ; d4 Last instruction that can affect flags for
; the MRCNDD operation
<Destination 5> ; d5 Cannot be stop, branch, call or return
<Destination 6> ; d6 Cannot be stop, branch, call or return
<Destination 7> ; d7 Cannot be stop, branch, call or return
MRCNDD NEQ ; Return to <Instruction 8> if not equal to zero
; Three instructions after MRCNDD are always
; executed whether the return is taken or not
<Destination 8> ; d8 Cannot be stop, branch, call or return
<Destination 9> ; d9 Cannot be stop, branch, call or return
<Destination 10> ; d10 Cannot be stop, branch, call or return
<Destination 11> ; d11
<Destination 12> ; d12
....
....
MSTOP
....
    
```

- **d4**
  - d4 is the last instruction that can effect the CNDF flags for the MRCNDD instruction. The CNDF flags are tested in the D2 phase of the pipeline. That is, a decision is made whether to return or not when MRCNDD is in the D2 phase.
  - There are no restrictions on the type of instruction for d4.
- **d5, d6, and d7**
  - The three instructions proceeding MRCNDD can change MSTF flags but have no effect on whether the MRCNDD instruction makes the return or not. This is because the flag modification occurs after the D2 phase of the MRCNDD instruction.
  - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.
- **d8, d9, and d10**
  - The three instructions following MRCNDD are always executed irrespective of whether the return is taken or not.

**MRCNDD {CNDF} (continued)**
**Return Conditional Delayed**

- These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD, or MRCNDD.

**Table 7-19. Pipeline Activity for MRCNDD, Return Not Taken**

**MSETC BGINTM*****Set Background Task Interrupt Mask*****Operands**

none	This instruction does not have any operands
------	---

**Opcode**

LSW: 0000 0000 0000 0000
MSW: 0111 1111 0101 0000

**Description**

This instruction sets the background task interrupt mask (BGINTM) bit in the MSTSBGRND register, making any code thereafter uninterruptible. No other higher priority task is able to interrupt the background task until the BGINTM is cleared. This instruction sets the BGINTM bit at the end of the D2 phase.

This instruction does not require the MEALLOW bit to be asserted before, or de-asserted after, setting BGINTM.

**Flags**

This instruction does not modify the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**Pipeline**

This is a single-cycle instruction.

**Example**

MSETC BGINTM	;	Set the MSTSBGRND.BGINTM bit
	;	to prevent any other tasks from
	;	interrupting the background task

**See also**

[MCLRC BGINTM](#)

## MSETFLG FLAG, VALUE

### Set or Clear Selected Floating-Point Status Flags

#### Operands

FLAG	8-bit mask indicating which floating-point status flags to change.
VALUE	8-bit mask indicating the flag value: 0 or 1.

#### Opcode

```
LSW: FFFF FFFF VVVV VVVV
MSW: 0111 1001 1100 0000
```

#### Description

The MSETFLG instruction is used to set or clear selected floating-point status flags in the MSTF register. The FLAG field is an 11-bit value that indicates which flags are changed. That is, if a FLAG bit is set to 1, that flag is changed; all other flags are not modified. The bit mapping of the FLAG field is:

9	8	7	6	5	4	3	2	1	0
RNDF 32	Reserved		TF	Reserved		ZF	NF	LUF	LVF

The VALUE field indicates the value the flag can be set to: 0 or 1.

#### Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	Yes	Yes	Yes	Yes	Yes

Any flag can be modified by this instruction. The MEALLOW and RPC fields cannot be modified with this instruction.

#### Pipeline

This is a single-cycle instruction.

#### Example

To make it easier and legible, the assembler accepts a FLAG=VALUE syntax for the MSETFLG operation as:

```
MSETFLG RNDF32=0, TF=0, NF=1; FLAG = 11000100; VALUE = 00XXX1XX;
```

#### See also

## MSTOP

### Stop Task

#### Operands

none	This instruction does not have any operands
------	---

#### Opcode

LSW: 0000 0000 0000 0000
MSW: 0111 1111 1000 0000

#### Description

The MSTOP instruction must be placed to indicate the end of each task. In addition, placing MSTOP in unused memory locations within the CLA program RAM can be useful for debugging and preventing run away CLA code. When MSTOP enters the D2 phase of the pipeline, the MIRUN flag for the task is cleared and the associated interrupt is flagged in the PIE vector table.

There are three special cases that can occur when single-stepping a task such that the MPC reaches the MSTOP instruction.

1. If you are single-stepping or halted in "task A" and "task B" comes in before the MPC reaches the MSTOP, then "task B" starts if you continue to step through the MSTOP instruction. Basically, if "task B" is pending before the MPC reaches MSTOP in "task A" then there is no issue in "task B" starting and no special action is required.
2. In this case, you have single-stepped or halted in "task A" and the MPC has reached the MSTOP with no tasks pending. If "task B" comes in at this point, "task B" is flagged in the MIFR register but "task B" can or cannot start if you continue to single-step through the MSTOP instruction of "task A". It depends on exactly when the new task comes in. To reliably start "task B", perform a soft reset and reconfigure the MIER bits. Once this is done, you can start single-stepping "task B".
3. Case 2 can be handled slightly differently if there is control over when "task B" comes in (for example using the IACK instruction to start the task). In this case you have single-stepped or halted in "task A" and the MPC has reached the MSTOP with no tasks pending. Before forcing "task B", run free to force the CLA out of the debug state. Once this is done you can force "task B" and continue debugging.

#### Restrictions

The MSTOP instruction cannot be placed 3 instructions before or after a [MBCNDD](#) , [MCCNDD](#) , or [MRCNDD](#) instruction.

#### Flags

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**MSTOP (continued)**
**Stop Task**
**Pipeline**

This is a single-cycle instruction. [Table 7-21](#) shows the pipeline behavior of the MSTOP instruction. The MSTOP instruction cannot be placed with 3 instructions of a [MBCNDD](#) , [MCCNDD](#) , or [MRCNDD](#) instruction.

**Table 7-21. Pipeline Activity for MSTOP**

Instruction	F1	F2	D1	D2	R1	R2	E	W
I1	I1

**MSUB32 MRa, MRb, MRc****32-Bit Integer Subtraction****Operands**

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point destination register (MR0 to MR3)
MRc	CLA floating-point destination register (MR0 to MR3)

**Opcode**

```
LSW: 0000 0000 00cc bbaa
MSW: 0111 1100 1110 0000
```

**Description**

32-bit integer addition of MRb and MRc.

```
MARa(31:0) = MARb(31:0) - MRC(31:0);
```

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified as follows:

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; }
```

**Pipeline**

This is a single-cycle instruction.

**Example**

```
; Given A = (int32)1
;         B = (int32)2
;         C = (int32)-7
;
;
; Calculate Y2 = A - B - C
;

**MSUBF32 MRa, MRb, MRc**
**32-Bit Floating-Point Subtraction**
**Operands**

MRa	CLA floating-point destination register (MR0 to R1)
MRb	CLA floating-point source register (MR0 to R1)
MRc	CLA floating-point source register (MR0 to R1)

**Opcode**

```
LSW: 0000 0000 00cc bbaa
MSW: 0111 1100 0100 0000
```

**Description**

Subtract the contents of two floating-point registers

```
MRa = MRb - MRc;
```

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MSUBF32 generates an underflow condition.
- LVF = 1 if MSUBF32 generates an overflow condition.

**Pipeline**

This is a single-cycle instruction.

**Example**

```
; Given A, B, and C are 32-bit floating-point numbers
; Calculate Y2 = A + B - C
;
;
_Cla1Task5:
  MMOV32  MR0, @_A      ; Load MR0 with A

**MSUBF32 MRa, #16FHi, MRb****32-Bit Floating-Point Subtraction****Operands**

MRa	CLA floating-point destination register (MR0 to R1)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The lower 16-bits of the mantissa are assumed to be all 0.
MRb	CLA floating-point source register (MR0 to R1)

**Opcode**

```
LSW: IIII IIII IIII IIII
MSW: 0111 1000 0000 baaa
```

**Description**

Subtract MRb from the floating-point value represented by the immediate operand. Store the result of the addition in MRa.

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The lower 16-bits of the mantissa are assumed to be all 0. #16FHi is most useful for representing constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler accepts either a hex or float as the immediate value. That is, the value -1.5 can be represented as #-1.5 or #0xBFC0.

```
MRa = #16FHi:0 - MRb;
```

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MSUBF32 generates an underflow condition.
- LVF = 1 if MSUBF32 generates an overflow condition.

**Pipeline**

This is a single-cycle instruction.

**MSUBF32 MRd, MRe, MRf ||MMOV32 MRa, mem32****32-Bit Floating-Point Subtraction with Parallel Move****Operands**

MRd	CLA floating-point destination register (MR0 to MR3) for the MSUBF32 operation MRd cannot be the same register as MRa
MRe	CLA floating-point source register (MR0 to MR3) for the MSUBF32 operation
MRf	CLA floating-point source register (MR0 to MR3) for the MSUBF32 operation
MRa	CLA floating-point destination register (MR0 to MR3) for the MMOV32 operation MRa cannot be the same register as MRd
mem32	32-bit memory location accessed using one of the available addressing modes. Source for the MMOV32 operation.

**Opcode**

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0010 ffee ddaa addr
```

**Description**

Subtract the contents of two floating-point registers and move from memory to a floating-point register.

```
MRd = MRe - MRf;
MRa = [mem32];
```

**Restrictions**

The destination register for the MSUBF32 and the MMOV32 must be unique. That is, MRa cannot be the same register as MRd.

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MSUBF32 generates an underflow condition.
- LVF = 1 if MSUBF32 generates an overflow condition.

The MMOV32 instruction sets the NF and ZF flags.

**Pipeline**

Both MSUBF32 and MMOV32 complete in a single cycle.

**Example**

```
NF = MRa(31);
ZF = 0;
if(MRa(30:23) == 0) { ZF = 1; NF = 0; }
```

```

**Description**

Conditional swap of MRa and MRb.

```
if (CNDF == true) swap MRa and MRb;
```

CNDF is one of the following conditions:

Encode <sup>(1)</sup>	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF <sup>(2)</sup>	Unconditional with flag modification	None

(1) Values not shown are reserved.

(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

No flags affected

**Pipeline**

This is a single-cycle instruction.

**MSWAPF MRa, MRb {, CNDF} (continued)**
**Conditional Swap**
**Example**

```

; X is an array of 32-bit floating-point values
; and has length elements. Find the maximum value in
; the array and store the value in Result
;
; Note: MCMPPF32 and MSWAPF can be replaced by MMAXF32
;
_Cla1Task1:
  MMOV16    MAR1, #_X          ; Start address
  MUI16TOF32 MR0, @_len       ; Length of the array
  MNOP      ; delay for MAR1 load
  MNOP      ; delay for MAR1 load
  MMOV32    MR1, *MAR1[2]++    ; MR1 = X0
LOOP
  MMOV32    MR2, *MAR1[2]++    ; MR2 = next element
  MCMPPF32  MR2, MR1           ; Compare MR2 with MR1
  MSWAPF    MR1, MR2, GT       ; MR1 = MAX(MR1, MR2)
  MADD32    MR0, MR0, #-1.0    ; Decrement the counter
  MCMPPF32  MR0, #0.0         ; Set/clear flags for MBCNDD
  MNOP
  MNOP
  MNOP
  MBCNDD    LOOP, NEQ         ; Branch if not equal to zero
  MMOV32    @_Result, MR1     ; Always executed
  MNOP      ; Always executed
  MNOP      ; Always executed
  MSTOP

```

**MTESTTF CNDF****Test MSTF Register Flag Condition****Operands**

CNDF	Condition to test based on MSTF flags
------	---------------------------------------

**Opcode**

```
LSW: 0000 0000 0000 cndf
MSW: 0111 1111 0100 0000
```

**Description**

Test the CLA floating-point condition and if true, set the MSTF[TF] flag. If the condition is false, clear the MSTF[TF] flag. This is useful for temporarily storing a condition for later use.

```
if (CNDF == true) TF = 1;
else TF = 0;
```

CNDF is one of the following conditions:

Encode <sup>(1)</sup>	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF <sup>(2)</sup>	Unconditional with flag modification	None

(1) Values not shown are reserved.

(2) This is the default operation, if no CNDF field is specified. This condition allows the ZF and NF flags to be modified when a conditional operation is executed. All other conditions do not modify these flags.

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	Yes	No	No	No	No

```
TF = 0;
if (CNDF == true) TF = 1;
```

Note: If (CNDF == UNC or UNCF), the TF flag is set to 1.

**Pipeline**

This is a single-cycle instruction.

**MTESTTF CNDF (continued)**
**Test MSTF Register Flag Condition**
**Example**

```

; if (State == 0.1)
;   RampState = RampState || RAMPMASK
; else if (State == 0.01)
;   CoastState = CoastState || COASTMASK
; else
;   SteadyState = SteadyState || STEADYMASK
;
_Cla1Task2:
  MMOV32   MR0, @_State
  MCMPF32  MR0, #0.1           ; Affects flags for 1st MBCNDD (A)
  MCMPF32  MR0, #0.01         ; Check used by 2nd MBCNDD (B)
  MTESTTF  EQ                 ; Store EQ flag in TF for 2nd MBCNDD (B)
  MNOP
  MBCNDD   _Skip1, NEQ        ; (A) If State != 0.1, go to Skip1
  MMOV32   MR1, @_RampState   ; Always executed
  MMOVXI   MR2, #RAMPMASK     ; Always executed
  MOR32    MR1, MR2           ; Always executed
  MMOV32   @_RampState, MR1   ; Execute if (A) branch not taken
  MSTOP    ; end of task if (A) branch not taken
_Skip1:
  MMOV32   MR3, @_SteadyState
  MMOVXI   MR2, #STEADYMASK
  MOR32    MR3, MR2
  MBCNDD   _Skip2, NTF        ; (B) if State != .01, go to Skip2
  MMOV32   MR1, @_CoastState  ; Always executed
  MMOVXI   MR2, #COASTMASK    ; Always executed
  MOR32    MR1, MR2           ; Always executed
  MMOV32   @_CoastState, MR1  ; Execute if (B) branch not taken
  MSTOP    ; end of task if (B) branch not taken
_Skip2:
  MMOV32   @_SteadyState, MR3  ; Executed if (B) branch taken
  MSTOP

```

**MUI16TOF32 MRa, mem16****Convert Unsigned 16-Bit Integer to 32-Bit Floating-Point Value****Operands**

MRa	CLA floating-point destination register (MR0 to MR3)
mem16	16-bit source memory location

**Opcode**

```
LSW: mmmm mmmm mmmm mmmm
MSW: 0111 0101 01aa addr
```

**Description**

When converting F32 to I16/UI16 data format, the MF32TOI16/UI16 operation truncates to zero while the MF32TOI16R/UI16R operation rounds to the nearest (even) value.

```
MRa = UI16TOF32[mem16];
```

**Flags**

This instruction does not affect any flags:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

**Pipeline**

This is a single-cycle instruction.

**MXOR32 MRa, MRb, MRc****Bitwise Exclusive Or****Operands**

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
MRc	CLA floating-point source register (MR0 to MR3)

**Opcode**

```
LSW: 0000 0000 00cc bbaa
MSW: 0111 1100 1010 0000
```

**Description**

Bitwise XOR of MRb with MRc.

```
MARa(31:0) = MARb(31:0) XOR MRC(31:0);
```

**Flags**

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; }
```

**Pipeline**

This is a single-cycle instruction.

**Example**

```
MMOVIZ MR0, #0x5555 ; MR0 = 0x5555AAAA
MMOVXI MR0, #0xAAAA
MMOVIZ MR1, #0x5432 ; MR1 = 0x5432FEDC
MMOVXI MR1, #0xFEDC
; 0101 XOR 0101 = 0000 (0)
; 0101 XOR 0100 = 0001 (1)
; 0101 XOR 0011 = 0110 (6)
; 0101 XOR 0010 = 0111 (7)
; 1010 XOR 1111 = 0101 (5)
; 1010 XOR 1110 = 0100 (4)
; 1010 XOR 1101 = 0111 (7)
; 1010 XOR 1100 = 0110 (6)
MXOR32 MR2, MR1, MR0 ; MR3 = 0x01675476

## 7.8 CLA Registers

This section describes the Control Law Accelerator registers.

### 7.8.1 CLA Base Address Table

**Table 7-22. CLA Base Address Table**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	CPU2	CPU2.DMA	Pipeline Protected
Instance	Structure								
ClA1OnlyRegs	<a href="#">CLA_ONLY_REGS</a>	CLA1_ONLY_BASE	0x0000_0C00	-	-	YES	-	-	-
ClA1SoftIntRegs	<a href="#">CLA_SOFTINT_REGS</a>	CLA1_SOFTINT_BASE	0x0000_0CE0	-	-	YES	-	-	-
ClA1Regs	<a href="#">CLA_REGS</a>	CLA1_BASE	0x0000_1400	YES	-	-	-	-	-

## 7.8.2 CLA\_ONLY\_REGS Registers

Table 7-23 lists the memory-mapped registers for the CLA\_ONLY\_REGS registers. All register offset addresses not listed in Table 7-23 should be considered as reserved locations and the register contents should not be modified.

**Table 7-23. CLA\_ONLY\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
80h	_MVECTBGRNDACTIVE	Active register for MVECTBGRND.	EALLOW	<a href="#">Go</a>
C0h	_MPSACTL	CLA PSA Control Register	EALLOW	<a href="#">Go</a>
C2h	_MPSA1	CLA PSA1 Register	EALLOW	<a href="#">Go</a>
C4h	_MPSA2	CLA PSA2 Register	EALLOW	<a href="#">Go</a>
E0h	SOFTINTEN	CLA Software Interrupt Enable Register		<a href="#">Go</a>
E2h	SOFTINTFRC	CLA Software Interrupt Force Register		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 7-24 shows the codes that are used for access types in this section.

**Table 7-24. CLA\_ONLY\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1S	W1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 7.8.2.1 \_MVECTBGRNDACTIVE Register (Offset = 80h) [Reset = 0000h]

\_MVECTBGRNDACTIVE is shown in [Figure 7-2](#) and described in [Table 7-25](#).

Return to the [Summary Table](#).

Gives the current interrupted MPC value of the background task, if the background task was running and interrupted, or reflects the MVECTBGRND value, if MCTLBGRND.BGSTART bit is 0.

**Figure 7-2. \_MVECTBGRNDACTIVE Register**

15	14	13	12	11	10	9	8

Writes to this register should only be made when PSA2 is stopped. Register value is cleared to zero by reset or by writing to the MPSA2CLEAR bit in the MPSACTL register. Reset type: SYSRSn

### 7.8.2.5 SOFTINTEN Register (Offset = E0h) [Reset = 0000h]

SOFTINTEN is shown in [Figure 7-6](#) and described in [Table 7-29](#).

Return to the [Summary Table](#).

Enables the ability to generate CLA task interrupt from within the task, by writing to SOFTINTFRC register. SOFTINTFRC register can only be written from CLA.

**Figure 7-6. SOFTINTEN Register**

0	TASK1	R/W	0h	0: End-Of-Task Interrupt is fired for the respective task 1: Enable Software Interrupt for the respective task. End-of-Task interrupt is not sent to CPU in this case. Note: SOFTINTEN register is read only in the CPU memory map. Reset type: SYSRSn

### 7.8.2.6 SOFTINTFRC Register (Offset = E2h) [Reset = 0000h]

SOFTINTFRC is shown in [Figure 7-7](#) and described in [Table 7-30](#).

Return to the [Summary Table](#).

Writing a value of 1 in a bit will generate the corresponding task interrupt.

**Figure 7-7. SOFTINTFRC Register**

1	TASK2	R-0/W1S	0h	Write of '1' will generate a CLA software interrupt to the CPU for the corresponding task. Write of '0' has no effect. Reset type: SYSRSn
0	TASK1	R-0/W1S	0h	Write of '1' will generate a CLA software interrupt to the CPU for the corresponding task. Write of '0' has no effect. Reset type: SYSRSn

### 7.8.3 CLA\_SOFTINT\_REGS Registers

Table 7-31 lists the memory-mapped registers for the CLA\_SOFTINT\_REGS registers. All register offset addresses not listed in Table 7-31 should be considered as reserved locations and the register contents should not be modified.

**Table 7-31. CLA\_SOFTINT\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	SOFTINTEN	CLA Software Interrupt Enable Register		<a href="#">Go</a>
2h	SOFTINTFRC	CLA Software Interrupt Force Register		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 7-32 shows the codes that are used for access types in this section.

**Table 7-32. CLA\_SOFTINT\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1S	W1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 7.8.3.1 SOFTINTEN Register (Offset = 0h) [Reset = 0000h]

SOFTINTEN is shown in [Figure 7-8](#) and described in [Table 7-33](#).

Return to the [Summary Table](#).

Enables the ability to generate CLA task interrupt from within the task, by writing to SOFTINTFRC register. SOFTINTFRC register can only be written from CLA.

**Figure 7-8. SOFTINTEN Register**

6	TASK7	R/W	0h	0: End-Of-Task Interrupt is fired for the respective task 1: Enable Software Interrupt for the respective task. End-of-Task interrupt is not sent to CPU in this case. Note: SOFTINTEN register is read only in the CPU memory map. Reset type: SYSRSn
5	TASK6	R/W	0h	0: End-Of-Task Interrupt is fired for the respective task 1: Enable Software Interrupt for the respective task. End-of-Task interrupt is not sent to CPU in this case. Note: SOFTINTEN register is read only in the CPU memory map. Reset type: SYSRSn
4	TASK5	R/W	0h	0: End-Of-Task Interrupt is fired for the respective task 1: Enable Software Interrupt for the respective task. End-of-Task interrupt is not sent to CPU in this case. Note: SOFTINTEN register is read only in the CPU memory map. Reset type: SYSRSn
3	TASK4	R/W	0h	0: End-Of-Task Interrupt is fired for the respective task 1: Enable Software Interrupt for the respective task. End-of-Task interrupt is not sent to CPU in this case. Note: SOFTINTEN register is read only in the CPU memory map. Reset type: SYSRSn
2	TASK3	R/W	0h	0: End-Of-Task Interrupt is fired for the respective task 1: Enable Software Interrupt for the respective task. End-of-Task interrupt is not sent to CPU in this case. Note: SOFTINTEN register is read only in the CPU memory map. Reset type: SYSRSn
1	TASK2	R/W	0h	0: End-Of-Task Interrupt is fired for the respective task 1: Enable Software Interrupt for the respective task. End-of-Task interrupt is not sent to CPU in this case. Note: SOFTINTEN register is read only in the CPU memory map. Reset type: SYSRSn

**Table 7-33. SOFTINTEN Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
0	TASK1	R/W	0h	0: End-Of-Task Interrupt is fired for the respective task 1: Enable Software Interrupt for the respective task. End-of-Task interrupt is not sent to CPU in this case. Note: SOFTINTEN register is read only in the CPU memory map. Reset type: SYSRSn

### 7.8.3.2 SOFTINTFRC Register (Offset = 2h) [Reset = 0000h]

SOFTINTFRC is shown in [Figure 7-9](#) and described in [Table 7-34](#).

Return to the [Summary Table](#).

Writing a value of 1 in a bit will generate the corresponding task interrupt. This register is only accessible by the CLA (not the CPU).

**Figure 7-9. SOFTINTFRC Register**

38h	_MR2	CLA Floating-Point Result Register 2		<a href="#">Go</a>
3Ch	_MR3	CLA Floating-Point Result Register 3		<a href="#">Go</a>
42h	_MPSACTL	CLA PSA Control Register	EALLOW	<a href="#">Go</a>
44h	_MPSA1	CLA PSA1 Register	EALLOW	<a href="#">Go</a>
46h	_MPSA2	CLA PSA2 Register	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 7-36 shows the codes that are used for access types in this section.

**Table 7-36. CLA\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		

**Table 7-36. CLA\_REGS Access Type Codes (continued)**

Access Type	Code	Description
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 7.8.4.1 MVECT1 Register (Offset = 0h) [Reset = 0000h]

MVECT1 is shown in [Figure 7-10](#) and described in [Table 7-37](#).

Return to the [Summary Table](#).

Each CLA interrupt has its own interrupt vector (MVECT1 to MVECT8). This interrupt vector points to the first instruction of the associated task. When a task begins, the CLA will start fetching instructions at the location indicated by the appropriate MVECT register .

**Figure 7-10. MVECT1 Register**

**Table 7-37. MVECT1 Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-0	MVECT	R/W	0h	MPC Start Address: These bits specify the start address for the given interrupt (task). The address range of the CLA with a 16-bit MVECT is 64Kx16 words or 32K CLA instructions. There is one MVECT register per interrupt (task). Interrupt 1 uses MVECT1, interrupt 2 uses MVECT2 and so forth. Note: While the CLA is running or executing a task, the CPU can change the MVECT values.. Reset type: SYSRSn

### 7.8.4.2 MVECT2 Register (Offset = 1h) [Reset = 0000h]

MVECT2 is shown in [Figure 7-11](#) and described in [Table 7-38](#).

Return to the [Summary Table](#).

Each CLA interrupt has its own interrupt vector (MVECT1 to MVECT8). This interrupt vector points to the first instruction of the associated task. When a task begins, the CLA will start fetching instructions at the location indicated by the appropriate MVECT register .

**Figure 7-11. MVECT2 Register**

15-0	MVECT	R/W	0h	<p>MPC Start Address: These bits specify the start address for the given interrupt (task). The address range of the CLA with a 16-bit MVECT is 64Kx16 words or 32K CLA instructions.</p> <p>There is one MVECT register per interrupt (task). Interrupt 1 uses MVECT1, interrupt 2 uses MVECT2 and so forth.</p> <p>Note: While the CLA is running or executing a task, the CPU can change the MVECT values..</p> <p>Reset type: SYSRSn</p>

### 7.8.4.3 MVECT3 Register (Offset = 2h) [Reset = 0000h]

MVECT3 is shown in [Figure 7-12](#) and described in [Table 7-39](#).

Return to the [Summary Table](#).

Each CLA interrupt has its own interrupt vector (MVECT1 to MVECT8). This interrupt vector points to the first instruction of the associated task. When a task begins, the CLA will start fetching instructions at the location indicated by the appropriate MVECT register .

**Figure 7-12. MVECT3 Register**

Bit	Field	Type	Reset	Description
15-0	MVECT	R/W	0h	MPC Start Address: These bits specify the start address for the given interrupt (task). The address range of the CLA with a 16-bit MVECT is 64Kx16 words or 32K CLA instructions. There is one MVECT register per interrupt (task). Interrupt 1 uses MVECT1, interrupt 2 uses MVECT2 and so forth. Note: While the CLA is running or executing a task, the CPU can change the MVECT values.. Reset type: SYSRSn

#### 7.8.4.4 MVECT4 Register (Offset = 3h) [Reset = 0000h]

MVECT4 is shown in [Figure 7-13](#) and described in [Table 7-40](#).

Return to the [Summary Table](#).

Each CLA interrupt has its own interrupt vector (MVECT1 to MVECT8). This interrupt vector points to the first instruction of the associated task. When a task begins, the CLA will start fetching instructions at the location indicated by the appropriate MVECT register .

**Figure 7-13. MVECT4 Register**

There is one MVECT register per interrupt (task). Interrupt 1 uses MVECT1, interrupt 2 uses MVECT2 and so forth. Note: While the CLA is running or executing a task, the CPU can change the MVECT values.. Reset type: SYSRSn

#### 7.8.4.6 MVECT6 Register (Offset = 5h) [Reset = 0000h]

MVECT6 is shown in [Figure 7-15](#) and described in [Table 7-42](#).

Return to the [Summary Table](#).

Each CLA interrupt has its own interrupt vector (MVECT1 to MVECT8). This interrupt vector points to the first instruction of the associated task. When a task begins, the CLA will start fetching instructions at the location indicated by the appropriate MVECT register .

**Figure 7-15. MVECT6 Register**

There is one MVECT register per interrupt (task). Interrupt 1 uses MVECT1, interrupt 2 uses MVECT2 and so forth. Note: While the CLA is running or executing a task, the CPU can change the MVECT values.. Reset type: SYSRSn

#### 7.8.4.8 MVECT8 Register (Offset = 7h) [Reset = 0000h]

MVECT8 is shown in [Figure 7-17](#) and described in [Table 7-44](#).

Return to the [Summary Table](#).

Each CLA interrupt has its own interrupt vector (MVECT1 to MVECT8). This interrupt vector points to the first instruction of the associated task. When a task begins, the CLA will start fetching instructions at the location indicated by the appropriate MVECT register .

**Figure 7-17. MVECT8 Register**

The address range of the CLA with a 16-bit MVECT is 64Kx16 words or 32K CLA instructions.</p> <p>There is one MVECT register per interrupt (task). Interrupt 1 uses MVECT1, interrupt 2 uses MVECT2 and so forth.</p> <p>Note: While the CLA is running or executing a task, the CPU can change the MVECT values..</p> <p>Reset type: SYSRSn</p>

### 7.8.4.9 MCTL Register (Offset = 10h) [Reset = 0000h]

MCTL is shown in [Figure 7-18](#) and described in [Table 7-45](#).

Return to the [Summary Table](#).

Control Register

**Figure 7-18. MCTL Register**

15	14	13	12	11	10	9	8
RESERVED							
R-0h							
7	6	5	4	3	2	1	0
RESERVED					IACKE	SOFTRESET	HARDRESET
R-0h					R/W-0h	R-0/W1S-0h	R-0/W1S-0h

**Table 7-45. MCTL Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-3	RESERVED	R	0h	Reserved
2	IACKE	R/W	0h	<p>IACK Operation Enable Bit: Writing a '1' to this bit will enable the IACK operation for setting the MIFR bits in the same manner as the MIFRC register (write of '1' will set respective MIFR bit). At reset, this feature is disabled.</p> <p>This feature enables the C28 CPU to efficiently trigger a task.</p> <p>Note: IACK operation should ignore EALLOW status of C28 core when accessing the MIFRC register.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = The CLA ignores the IACK instruction. (default)</p> <p>1h (R/W) = Enable the main CPU to use the IACK #16bit instruction to set MIFR bits in the same manner as writing to the MIFRC register. Each bit in the operand, #16bit, corresponds to a bit in the MIFRC register. Using IACK has the advantage of not having to first set the EALLOW bit. This allows the main CPU to efficiently trigger a CLA task through software.</p> <p>Examples IACK #0x0001 Write a 1 to MIFRC bit 0 to force task 1</p> <p>IACK #0x0003 Write a 1 to MIFRC bit 0 and 1 to force task 1 and task 2</p>
1	SOFTRESET	R-0/W1S	0h	<p>Soft Reset Bit: Writing a '1' to this bit will stop a current task, clear the RUN flag and also clear all bits in the MIER register. Writes of '0' are ignored and reads always return a '0'.</p> <p>Note: After issuing SOFTRESET command, user should wait at least 1 clock cycle before attempting to write to MIER register.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = This bit always reads back 0 and writes of 0 are ignored.</p> <p>1h (R/W) = Writing a 1 will cause a soft reset of the CLA. This will stop the current task, clear the MIRUN flag and clear all bits in the MIER register. After a soft reset you must wait at least 1 SYSCLKOUT cycle before reconfiguring the MIER bits. If these two operations are done back-to-back then the MIER bits will not get set.</p>
0	HARDRESET	R-0/W1S	0h	<p>Hard Reset Bit: Writing a '1' to this bit will cause a HARD reset on the CLA. The behavior of a HARD reset is the same as a system reset SYSRSn on the CLA. Writes of '0' are ignored and reads always return a '0'.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = This bit always reads back 0 and writes of 0 are ignored.</p> <p>1h (R/W) = Writing a 1 will cause a hard reset of the CLA. This will set all CLA registers to their default state.</p>

#### 7.8.4.10 \_MVECTBGRNDACTIVE Register (Offset = 1Bh) [Reset = 0000h]

\_MVECTBGRNDACTIVE is shown in [Figure 7-19](#) and described in [Table 7-46](#).

Return to the [Summary Table](#).

Gives the current interrupted MPC value of the background task, if the background task was running and interrupted, or reflects the MVECTBGRND value, if MCTLBGRND.BGSTART bit is 0.

**Figure 7-19. \_MVECTBGRNDACTIVE Register**

Bit	Field	Type	Reset	Description
15-0	i16	R	0h	Gives the current interrupted MPC value of the background task, if the background task was running and interrupted, or reflects the MVECTBGRND value, if MCTLBGRND.BGSTART bit is 0. Reset type: SYSRSn

### 7.8.4.11 SOFTINTEN Register (Offset = 1Ch) [Reset = 0000h]

SOFTINTEN is shown in [Figure 7-20](#) and described in [Table 7-47](#).

Return to the [Summary Table](#).

Enables the ability to generate CLA task interrupt from within the task, by writing to SOFTINTFRC register. SOFTINTFRC register can only be written from CLA. Only reads are allowed from CPU. Writes are not allowed from CPU.

### 7.8.4.15 MIFR Register (Offset = 20h) [Reset = 0000h]

MIFR is shown in [Figure 7-24](#) and described in [Table 7-51](#).

Return to the [Summary Table](#).

Each bit in the interrupt flag register corresponds to a CLA task. The corresponding bit is automatically set when the task request is received from the peripheral interrupt. The bit can also be set by the main CPU writing to the MIFRC register or using the IACK instruction to start the task. To use the IACK instruction to begin a task first enable this feature in the MCTL register. If the bit is already set when a new peripheral interrupt is received, then the corresponding overflow bit will be set in the MIOVF register.

The corresponding MIFR bit is automatically cleared when the task begins execution. This will occur if the interrupt is enabled in the MIER register and no other higher priority task is pending. The bits can also be cleared manually by writing to the MICLR register. Writes to the MIFR register are ignored.

### 7.8.4.16 MIOVF Register (Offset = 21h) [Reset = 0000h]

MIOVF is shown in [Figure 7-25](#) and described in [Table 7-52](#).

Return to the [Summary Table](#).

Each bit in the overflow flag register corresponds to a CLA task. The bit is set when an interrupt overflow event has occurred for the specific task. An overflow event occurs when the MIFR register bit is already set when a new interrupt is received from a peripheral source. The MIOVF bits are only affected by peripheral interrupt events. They do not respond to a task request by the main CPU IACK instruction or by directly setting MIFR bits. The overflow flag will remain latched and can only be cleared by writing to the overflow flag clear (MICLROVF) register. Writes to the MIOVF register are ignored.

0	INT1	R	0h	<p>These bits, when set to '1', indicate an interrupt overflow event occurred. Such an event occurs when the IFR bit is already set. An overflow event remains latched and respective bits can only be cleared by writing to the MIOVF register.</p> <p>If the MIFR bit is being cleared by a new task on the same cycle as a new peripheral interrupt occurs, the overflow flag will not be affected and the respective MIFR bit will be set.</p> <p>If the MIOVF bit is being cleared by the MIOVF register on the same cycle as the overflow bit is being set by hardware, then the hardware will have priority.</p> <p>Notes: [1] The MIOVF bits are only affected by peripheral interrupt events. Forcing an interrupt using the MIFRC or IACK operation will not set the overflow flag even if the MIFR bit is set.</p> <p>Reset type: SYSRSn            0h (R/W) = A task 1 interrupt overflow has not occurred (default)            1h (R/W) = A task 1 interrupt overflow has occurred</p>

### 7.8.4.17 MIFRC Register (Offset = 22h) [Reset = 0000h]

MIFRC is shown in [Figure 7-26](#) and described in [Table 7-53](#).

Return to the [Summary Table](#).

The interrupt force register can be used by the main CPU to start tasks through software. Writing a 1 to a MIFRC bit will set the corresponding bit in the MIFR register. Writes of 0 are ignored and reads always return 0. The IACK #16bit operation can also be used to start tasks and has the same effect as the MIFRC register. To enable IACK to set MIFR bits you must first set the MCTL[IACKE] bit. Using IACK has the advantage of not having to first set the EALLOW bit. This allows the main CPU to efficiently trigger CLA tasks through software.

### 7.8.4.18 MICLR Register (Offset = 23h) [Reset = 0000h]

MICLR is shown in [Figure 7-27](#) and described in [Table 7-54](#).

Return to the [Summary Table](#).

Normally bits in the MIFR register are automatically cleared when a task begins. The interrupt flag clear register can be used to instead manually clear bits in the interrupt flag (MIFR) register. Writing a 1 to a MICLR bit will clear the corresponding bit in the MIFR register. Writes of 0 are ignored and reads always return 0.

### 7.8.4.20 MIER Register (Offset = 25h) [Reset = 0000h]

MIER is shown in [Figure 7-29](#) and described in [Table 7-56](#).

Return to the [Summary Table](#).

Setting the bits in the interrupt enable register (MIER) allow an incoming interrupt or main CPU software to start the corresponding CLA task. Writing a 0 will block the task, but the interrupt request will still be latched in the flag register (MIFLG). Setting the MIER register bit to 0 while the corresponding task is executing will have no effect on the task. The task will continue to run until it hits the MSTOP instruction. When a soft reset is issued, the MIER bits are cleared. There should always be at least a 1 SYSCLKOUT delay between issuing the soft reset and reconfiguring the MIER bits.

### 7.8.4.21 MIRUN Register (Offset = 26h) [Reset = 0000h]

MIRUN is shown in [Figure 7-30](#) and described in [Table 7-57](#).

Return to the [Summary Table](#).

The interrupt run status register (MIRUN) indicates which task is currently executing. Only one MIRUN bit will ever be set to a 1 at any given time. The bit is automatically cleared when the task completes and the respective interrupt is fed to the peripheral interrupt expansion (PIE) block of the device. This lets the main CPU know when a task has completed. The main CPU can stop a currently running task by writing to the MCTL[SOFTRESET] bit. This will clear the MIRUN flag and stop the task. In this case no interrupt will be generated to the PIE.

**Figure 7-30. MIRUN Register**

### 7.8.4.25 \_MSTF Register (Offset = 2Eh) [Reset = 0000000h]

\_MSTF is shown in [Figure 7-34](#) and described in [Table 7-61](#).

Return to the [Summary Table](#).

The CLA status register (MSTF) reflects the results of different operations. These are the basic rules for the flags:

- Zero and negative flags are cleared or set based on:
- floating-point moves to registers
- the result of compare, minimum, maximum, negative and absolute value operations
- the integer result of operations such as MMOV16, MAND32, MOR32, MXOR32, MCMP32, MASR32, MLSR32
- Overflow and underflow flags are set by floating-point math instructions such as multiply, add, subtract and 1/x. These flags may also be connected to the peripheral interrupt expansion (PIE) block on your device. This can be useful for debugging underflow and overflow conditions within an application.

## 8.1 Introduction

The configurable logic block (CLB) is a collection of configurable blocks that can be inter-connected using software to implement custom digital logic functions. The CLB is able to enhance existing peripherals through a set of crossbar interconnections, which provide a high level of connectivity to existing control peripherals such as enhanced pulse width modulators (ePWM), enhanced capture modules (eCAP), and enhanced quadrature encoder pulse modules (eQEP). The crossbars also allow the CLB to be connected to external GPIO pins. In this way, the CLB can be configured to interact with device peripherals to perform small logical functions such as simple PWM generators, or to implement custom serial data exchange protocols.

The CLB peripheral is configured through the CLB tool. For more information on the CLB tool, available examples, application reports, and user's guide, refer to the following location in your C2000WARE package (C2000Ware\_2\_00\_00\_03 and higher): C2000WARE\_INSTALL\_LOCATION\utilities\clb\_tool\clb\_syscfg\doc

## 8.2 Description

The CLB subsystem contains a number of identical tiles. There are four such tiles in the CLB subsystem; other devices can contain more or fewer tiles. Tiles are numbered 1 to N, where N is the total tile count on the device. Each tile contains combinational and sequential logic blocks, as well as other dedicated hardware to be described later in this document. [Figure 8-1](#) shows the structure of the CLB subsystem in the device.

The tile contains the core logic, providing the logic reconfiguration capability. Each CLB tile is associated with a separate CPU interface, which contains the registers needed to control and configure the logic in the tile. The CPU interface also contains data transfer buffers that can be used as part of the configurable logic to exchange data with the rest of the device. [Figure 8-2](#) shows the connections between the tile, the CPU interface, and the device.

Figure 8-1. Block Diagram of the CLB Subsystem in the Device

Figure 8-2. Block Diagram of a CLB Tile and CPU Interface

### 8.2.1 CLB Clock

In this device, the CLB clock is called CLBx clock that can be enabled or disabled by SYSCTL\_PERIPH\_CLK\_CLBx through the SysCtl\_enablePeripheral function. The maximum frequency is 150MHz and the clock can be enabled and configured by modifying the CLBx clock.

**Note**

When in SYNC mode at clock frequencies above 100MHz, PIPELINE mode must be enabled. When in ASYNC mode at clock frequencies above 120MHz, PIPELINE mode must be enabled.

Figure 8-3. CLB Clocking

The CLB TILE clock and CLB register clock can be in ASYNC/SYNC mode with the SYSCLK. An example CLB clock configuration is shown in Table 8-1. Check the device data sheet for details on clocking specifications.

Table 8-1. Example CLB Clocking Configuration

Clock	SYNC Mode (CLKMODECLBx = 0)	ASYNC Mode (CLKMODECLBx = 1)	
		TILECLKDIV = 1	TILECLKDIV = 0
CLB Register Clock	SYSCLK	SYSCLK	SYSCLK
CLB TILE Clock	SYSCLK	SYSCLK / 2	SYSCLK

Starting with CLB Type 2, a clock prescaler module is available. The prescaler module can generate a prescaled version of the CLB clock signal that can be used as an input to the CLB TILE's counter.

**Note**

The prescaler logic does not change the actual clocking speed of the CLB. The prescaler generates a strobe (that can toggle at the defined prescaled rate) that is made available as another input signal to the CLB logic and the strobe is only used when required.

The prescaler module is shown in Figure 8-4.

Figure 8-4. CLB Clock Prescalar

### 8.3 CLB Input/Output Connection

#### 8.3.1 Overview

There are four instances of the CLB module in the device. Each CLB instance has a common set of input signals referred to as global input signals. Additionally, each CLB instance has a specific set of input signals that are unique to each instance, and are referred to as local input signals. Each of the eight inputs of a CLB can be chosen from any of the global input signals or the local input signals.

**Note**

Signals routed into the CLB using the XBAR must be synchronized within the CLB.

#### 8.3.2 CLB Input Selection

Each CLB module has eight inputs that are applied to the reconfigurable logic cell. Each of these inputs can be selectively driven by a predefined set of signals. A two-level mux structure allows each input of each CLB instance to select a signal.

Figure 8-5. GPIO to CLB Tile Connections

A set of signals is common to all the CLB instances. These are referred to as global inputs in Figure 8-6. A separate set of signals is unique to each instance of the CLB. These are referred to as local inputs in Figure 8-6.

Registers `CLB_LCL_MUX_SEL_1` and `CLB_LCL_MUX_SEL_2` control the local mux selection for each of the eight inputs. The mux control registers `CLB_GLBL_MUX_SEL_1` and `CLB_GLBL_MUX_SEL_2` control the global mux selection for each of the eight inputs.

The local mux select value of 0 causes the selected global mux input signal to be connected to the corresponding CLB Input. For example, setting `CLB_LCL_MUX_SEL_IN_0 = 0` and `CLB_GLBL_MUX_SEL_IN_0 = 8` causes the global mux input number 8 to be connected to CLB Input 0. The input filter feature can be used to enable edge detection on the CLB inputs. The input filter feature can also synchronize the input with the CLB clock.

The global mux settings are shown in Table 8-2 and Table 8-3. The local input mux settings are shown in Table 8-4 and Table 8-5.

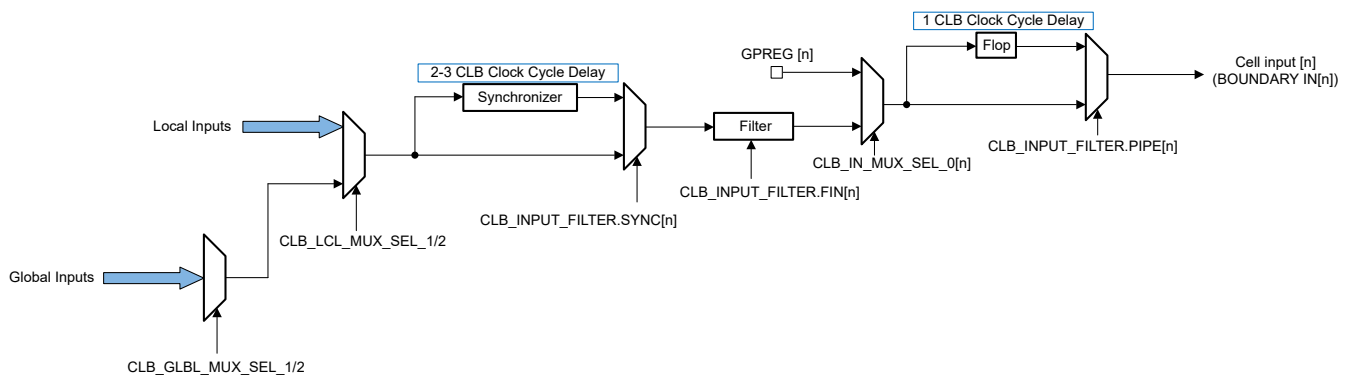

Figure 8-6. CLB Input Mux and Filter

Figure 8-7 shows an example of how to use synchronization for an asynchronous signal, in this case the ePWM signal. Figure 8-8 shows an instance of using input pipelining for a synchronous signal, which here is the ePWM TBCLK signal. Note that these two input configurations are not used simultaneously, and each have a cycle delay that adds to the input path.

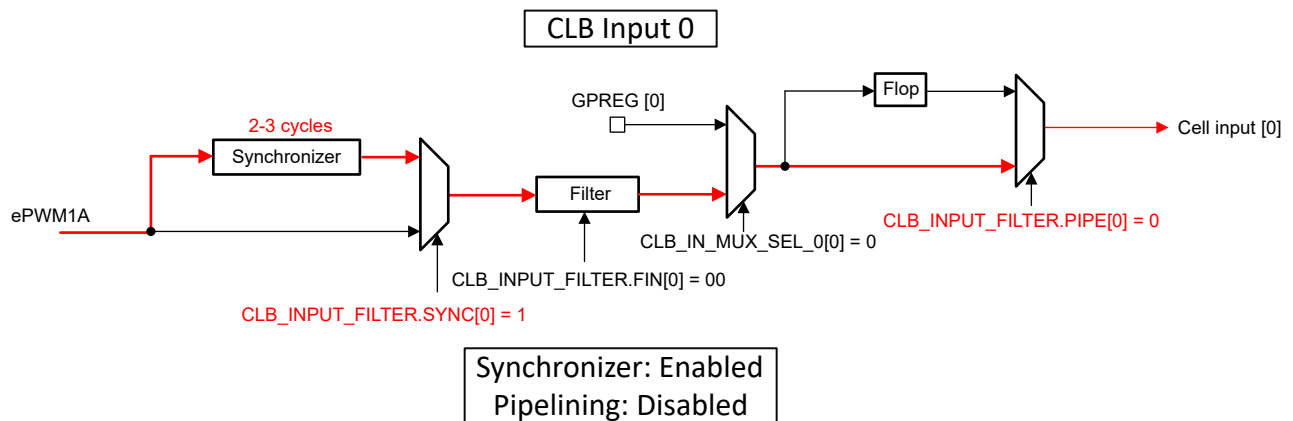

Figure 8-7. CLB Input Synchronization Example

Figure 8-8. CLB Input Pipelining Example

Note

If a signal in the following table indicates that synchronization is required, then the CLB input synchronizer must be enabled using the appropriate SYNC bit in the CLB\_INPUT\_FILTER register. This synchronization adds a 2-3 CLB clock cycle delay to the input. This delay is either 2 or 3 cycles and is not predictable. There is a potential for a metastability hazard, if the indicated signals are not first synchronized before going into the CLB tile. This metastability can cause errors dependent on voltage, temperature, and wafer fab process. Note that this requirement is in addition to and separate from GPIO input synchronization.

If a signal in the following table indicates that synchronization is not required, as the signal is already synchronous, then pipelining is required and must be enabled using the PIPE bit in the CLB\_INPUT\_FILTER register. This pipelining adds a 1 CLB clock cycle delay to the input. This is not to be mistaken with the PIPELINE\_EN bit in the CLB\_LOAD\_EN register, which controls pipelining of the CLB operations in the HLC and counter blocks. This PIPELINE\_EN bit is also used when the device is run above 100MHz. Having synchronization and pipelining both enabled or both disabled is not recommended. Enabling both synchronization and pipelining introduces a delay of more than 2-3 CLB clock cycles on the signal path. Disabling both allows the completely asynchronous signal to be routed as an input.

Table 8-2. Global Signals and Mux Selection

Select Value	CLB1 Input	CLB2 Input	CLB3 Input	CLB4 Input	Synchronization Requirement

**Note**

EPWMxA\_OE and EPWMxB\_OE refer to trip outputs from the respective EPWM module.

EPWMxA\_AQ and EPWMxB\_AQ refer to the output of the AQ submodule in the respective EPWM module.

EPWMxA\_DB and EPWMBx\_DB refer to the output of the DB submodule in the respective EPWM module.

### Note

If a signal in the following table indicates that synchronization is required, then the CLB input synchronizer must be enabled using the appropriate SYNC bit in the CLB\_INPUT\_FILTER register. This synchronization adds a 2-3 CLB clock cycle delay to the input. This delay is either 2 or 3 cycles and is not predictable. There is a potential for a metastability hazard, if the indicated signals are not first synchronized before going into the CLB tile. This metastability can cause errors dependent on voltage, temperature, and wafer fab process. Note that this requirement is in addition to and separate from GPIO input synchronization.

If a signal in the following table indicates that synchronization is not required, as the signal is already synchronous, then pipelining is required and must be enabled using the PIPE bit in the CLB\_INPUT\_FILTER register. This pipelining adds a 1 CLB clock cycle delay to the input. This is not to be mistaken with the PIPELINE\_EN bit in the CLB\_LOAD\_EN register, which controls pipelining of the CLB operations in the HLC and counter blocks. Having synchronization and pipelining both enabled or both disabled is not recommended. Enabling both synchronization and pipelining introduces a delay of more than 2-3 CLB clock cycles on the signal path. Disabling both allows the completely asynchronous signal to be routed as an input.

The GPREG is accessible by the CPU and the bits of this register can be used as BOUNDARY INPUTs for the CLB Tiles. For example, CLB1s GPREG[0] can be used as BOUNDARY IN0 (Cell Input 0) for the corresponding CLB Tile.

To connect multiple tiles to each other, you can use the CLBx OUT4/5 and connect to CLBy BOUNDARY INz through the CLB X-BAR and the Global Signals Mux.

Another option is to connect the CLBx OUT0-7 to a GPIO and then use the INPUT X-BAR to bring the signal back in to the device and connect to the CLBy BOUNDARY INz through the CLB X-BAR and the Global Signals Mux.

To use GPIOs as inputs to the CLB, you must utilize the Input X-BAR and the CLB X-BAR. [Figure 8-5](#) shows how GPIOs can be used as inputs to the CLB tiles.

### 8.3.3 CLB Output Selection

The eight outputs of the CLB are replicated to create 32 output signals. Each of these outputs has a separate enable bit defined in the CLB output enable register, CLB\_OUT\_EN. The CLB outputs go to the ePWM, eCAP, eQEP and the crossbar module in the device. This allows the user to enhance the functionality of these modules with the CLB. [Figure 8-9](#) shows the CLB outputs.

The user has the capability to disable updated to the CLB\_OUT\_EN register by blocking access to the register through setting the CLB\_MISC\_ACCESS\_CTRL.BLKEN bit. The eight outputs are replicated to generate a total of 32 outputs (shown in [Figure 8-9](#)). Some of these new outputs can be used for TILE to TILE connection through the CLB Global Mux inputs.

---

#### Note

The output from OUTLUT0 is connected to OUT0, OUT8, OUT16, and OUT24. While the signal is the same, each OUTy has access to a different peripheral as shown in [Section 8.3.4](#). Likewise, OUTLUT1 is connected to OUT1, OUT9, OUT17, and OUT25, and are the same signal.

CLBx\_OUT12 through CLBx\_OUT15 are unregistered and asynchronous to the CLB clock.

---

Figure 8-9. CLB Outputs

### 8.3.4 CLB Output Signal Multiplexer

Each CLB output signal passes through an external multiplexer that intersects a specific peripheral signal, see [Figure 8-10](#). The output of the multiplexer is connected to the destination of the original peripheral signal and the default multiplexer setting is that the peripheral signal is passed through. The multiplexer is controlled by bit[n] in the CLB output enable register CLB\_OUT\_EN.

**Figure 8-10. CLB Output Signal Multiplexer**

For example, if the CLB1 OUT0 must override the EPWM1A signal, the OUPUT ENABLE bit for OUT0 must be set to 1.

[Table 8-6](#) and [Table 8-7](#) shows the allocation of peripheral signals and the CLB outputs.

**Note**

When not explicitly specified in the table above, refer to corresponding IP chapters for exact CLB Output destinations (that is, FSI, ECAP, XBAR connections).

---

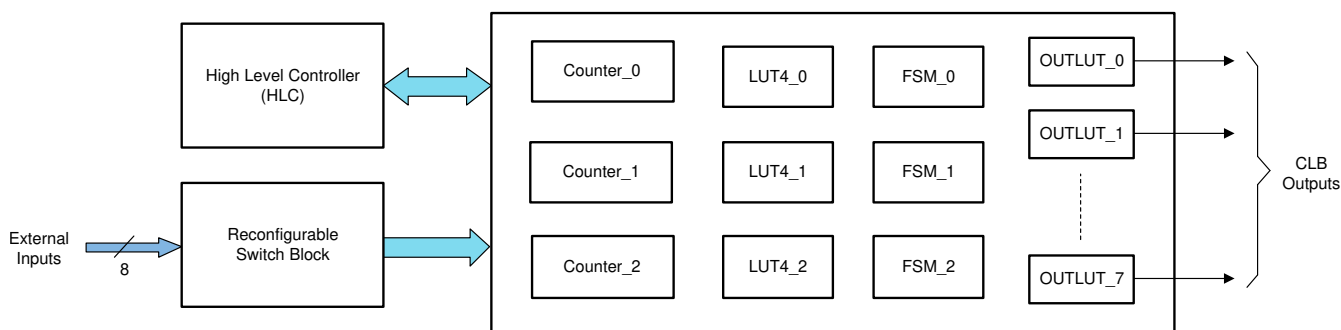

## 8.4 CLB Tile

The purpose of the CLB tile is to provide the logic reconfiguration capability of the CLB. The CLB tile contains the following submodules:

- **Counter:** The counter submodule can be configured as an adder, a counter, or a shifter. When functioning as an adder, the counter submodule can either add or subtract. When functioning as a counter, the counter submodule can count up or count down. When functioning as a shifter, the counter submodule can shift left or shift right. The counter event inputs, as well as the reset input, can be freely connected to any of the other submodules in the same tile. Starting with CLB Type 2, the counter module can also operate as a serializer or linear feedback shift register. There are three counters in each tile.
- **LUT4:** The LUT4 submodule has a 4-input look-up table functionality and is capable of realizing any combinatorial Boolean equation of up to four inputs. There are three LUT4 submodules in each CLB tile.
- **FSM:** The Finite State Machine (FSM) submodule can be configured either as a single four-state finite state machine, or as two independent two-state finite state machines. The FSM accepts two external inputs, and generates two state outputs and one combination output. When not used as a state machine, the FSM submodule can accept two external inputs and function as a 4-input LUT. There are three FSM submodules in each CLB tile.
- **Output LUT:** The output LUT is a 3-input lookup table submodule capable of realizing any combinatorial Boolean equation of up to three inputs. There are eight such blocks in a CLB tile, each associated with one of the tile outputs.
- **Asynchronous Output Conditioning Block:** The primary purpose of the Asynchronous Output Conditioning (AOC) block is to provide asynchronous conditioning capabilities on the TILE outputs or directly on the inputs of the TILE.
- **High Level Controller:** The High Level Controller (HLC) submodule is an event-driven block that can handle up to four concurrent events. The event can be an activity on any of the other block outputs. A predefined set of operations is executed when each event occurs. The HLC also provides a data exchange and interrupt mechanism to the CPU subsystem. There are four working registers (R0, R1, R2, and R3) that can be used for basic operations, and to modify or set up values for the three counter blocks. Unlike the other submodules, there is only one HLC in each CLB tile.
- **Static Switch Block:** The static switch block provides dynamic connectivity between all of the blocks listed above. Submodules can be connected by the user, with the only restriction that the submodules must not form a combinational loop within the tile.

A CLB tile consists of three sets each of the counter block, FSM, and LUT4, one high-level controller, and eight output LUT blocks. The submodule numbering is shown in [Figure 8-11](#).

The functionality of the LUT submodules is configured using a register field containing the binary pattern of the output of the desired look-up table. For example, a 4-input LUT has 16 possible input permutations, each of which corresponds to a desired binary 0 or 1 at the output. The register field can, therefore, be 16-bits in length, with each bit representing the desired result of a binary pattern. Input pattern sequences start at 0000 and continue sequentially to 1111. A similar method is used to encode the 16-bit state equations in the FSM submodule.

**Figure 8-11. CLB Tile Submodules**

### 8.4.1 Static Switch Block

The Static Switch Block provides the configurable connectivity between the submodules in the CLB tile. The outputs of all the submodules and the eight external inputs are connected to a common internal bus inside the tile. Every input port has a 32-to-1 multiplexer and an associated 5-bit selection value that allows the user to select one of the inputs on the bus. The only restrictions are certain signals (described below) that are tied off in the design to prevent creation of accidental combinatorial loops.

**Table 8-8. Output Table**

Bit Position	Signal Connection	Comment
0	Always 0	This select value is used to tie an input to 0.
1	COUNTER_0 MATCH2	
2	COUNTER_0 ZERO	
3	COUNTER_0 MATCH1	
4	FSM_0 STATE_BIT_0	
5	FSM_0 STATE_BIT_1	
6	FSM_0 LUT output	
7	LUT4_0 output	
8	Always 1	This select value is used to tie an input to 1.
9	COUNTER_1 MATCH2	
10	COUNTER_1 ZERO	
11	COUNTER_1 MATCH1	
12	FSM_1 STATE_BIT_0	
13	FSM_1 STATE_BIT_1	
14	FSM_1 LUT output	
15	LUT4_1 output	
16	Always '0'	
17	COUNTER_2 MATCH2	
18	COUNTER_2 ZERO	
19	COUNTER_2 MATCH1	
20	FSM_2 STATE_BIT_0	
21	FSM_2 STATE_BIT_1	
22	FSM_2 LUT output	
23	LUT4_2 output	
24	External Input 0	
25	External Input 1	
26	External Input 2	
27	External Input 3	
28	External Input 4	
29	External Input 5	
30	External Input 6	
31	External Input 7	

**Table 8-9. Input Table**

Module Name	Port Name	Description
Counter Block	RESET	Acts as an active high reset when used as a counter
	MODE_0	Acts as an enable when used as a counter. The counter counts only when this input is 1.
	MODE_1	Acts as a direction control when used as a counter. If this input is 1, then the counter counts up; else, the counter counts down.
LUT	IN0	Input 0 of the 4-input LUT.
	IN1	Input 1 of the 4-input LUT.
	IN2	Input 2 of the 4-input LUT.
	IN3	Input 3 of the 4-input LUT.
FSM	EXT_IN0	Input 0 of the FSM block.
	EXT_IN1	Input 1 of the FSM block.
	EXTRA_EXT_IN0	Extra external input 0 of the FSM block. This input matters only if configured in the LUT mode.
	EXTRA_EXT_IN1	Extra external input 1 of the FSM block. This input matters only if configured in the LUT mode.

The static switch block allows the user to define the input connection of any submodule to come from any of the outputs in [Table 8-8](#). It is therefore easy to create a combinatorial loop. To prevent this, certain paths are broken in the input path of each submodule. These port positions are tied to 0, as shown in [Table 8-10](#).

**Table 8-10. Ports Tied Off to Prevent Combinatorial Loops**

Module Name	Ports of Input MUX Tied Off to 0 to Prevent Combinatorial Loops
LUT_0	LUT_0 , LUT_1, and LUT_2 output, FSM_0, FSM_1, and FSM_2 output.
FSM_0	LUT_1 and LUT_2 output, FSM_0, FSM_1, and FSM_2 output.
LUT_1	LUT_1 and LUT_2 output, FSM_1 and FSM_2 output.
FSM_1	LUT_2 output, FSM_1 and FSM_2 output.
LUT_2	LUT_2 output, FSM_2 output.
FSM_2	FSM_2 output.

### 8.4.2 Counter Block

#### 8.4.2.1 Counter Description

The counter block is a complex functional submodule that can be configured either as a counter, an adder, or a shifter. Apart from the normal operational control, this block has a dedicated EVENT input, which can trigger an addition, subtraction or shift operation, or load data into the counter register. The inputs to the counter submodule are shown in Figure 8-12.

Figure 8-12. Counter Block

### 8.4.2.2 Counter Operation

At the heart of the counter block is a 32-bit count register. This register can either be loaded statically before counting commences, or dynamically at run time. The operation of the counter submodule is determined by the inputs described below. Note that each of the inputs can be connected to the outputs of any of the other blocks in the CLB tile. These connections are made by configuring the static switch block.

The counter inputs are:

- **RESET:** This is the highest priority input and takes precedence over all other inputs. The input is level sensitive and as long as the input remains high, the counter resets to 0 on the next clock cycle.
- **MODE\_0:** This input is an enable for the counter. The counter begins counting (up or down depending on the MODE\_1 setting) only when this input is high. If this input is low, then no counting takes place.
- **MODE\_1:** This input is the direction control for the counter. If this input is high, then the counter increments on every clock cycle where MODE\_0 is high. If this input is low, then the counter decrements on every clock cycle where MODE\_0 is high. The counter wraps around to 0x0000 0000 after 0xFFFF FFFF when counting up. The counter wraps around to 0xFFFF FFFF after 0x0000 0000 when counting down. The only exception to this is when an EVENT occurs at exactly the same time, causing a different value to be loaded into the counter.
- **EVENT:** This input is defined for the purpose of triggering actions in the counter based on certain events. The event can be any of the outputs of the other blocks or an external input to the tile. The counter's static control inputs define the behavior of the counter on an active event. An active event is defined as a rising edge on the EVENT input. The counter can be configured to perform one of the following actions:
  - Load a predefined 32-bit value from the LOAD VALUE register into the count register
  - Shift the contents of the counter register left or right by a predefined amount between 0 and 31
  - Add or subtract a predefined 32-bit value. Addition and subtraction are treated as 32-bit unsigned operations and there is no saturation.

Note that the effect of a rising edge on the EVENT input only lasts for one cycle. On the next cycle, the counter operation continues based on the MODE\_0, MODE\_1, and RESET inputs.

MATCH1 REF and MATCH2 REF are 32-bit reference values that are used to generate the MATCH1 and MATCH2 outputs. The MATCH1 output becomes active high whenever the counter register value matches the 32-bit MATCH1 REF value. MATCH2 behaves in a similar manner in relation to the MATCH2 REF register. The reference values for MATCH1 and MATCH2 can either be setup once before the start of operation, or can be modified dynamically. The High Level Controller can load desired values into the MATCH1 REF and MATCH2 REF registers.

Note that the counter load and match registers are not memory-mapped. For more information, see [Section 8.5.2](#).

The three logic outputs of the counter block are:

- **ZERO:** This output goes high whenever the counter register is 0.
- **MATCH1:** This output goes high whenever the counter register is equal to the MATCH1 REF input register.
- **MATCH2:** This output goes high whenever the counter register is equal to the MATCH2 REF input register.

The operation of the counter block is controlled by the CFG\_MISC\_CTRL register. The following three bits of this register are relevant for each counter. The “x” below refers to the counter instance; 0, 1, or 2. For more information, see the CLB\_MISC\_CONTROL register description located in [Section 8.10](#).

- COUNT\_EVENT\_CTRL\_x: This bit defines whether the counter performs an addition or a shift on an event. A value of 0 means that on an event, the counter loads the static value; 1 means an add/shift operation is performed. This bit must be 0 for indirect loads and HLC loads of the counter to take effect.
- COUNT\_ADD\_SHIFT\_x. 1 means add, 0 means shift.
- COUNT\_DIR\_x. 1 means left shift or add. 0 means right shift or subtract.

Table 8-11 shows the logical operation of the counter block in terms of the inputs and control register bits. Count up and down modes are the normal operation with EVENT = 0. The operations on the CNTVAL register are:

Load:  $CNTVAL = EVENT\_LOAD\_VAL$

Shift right:  $CNTVAL = CNTVAL \gg EVENT\_LOAD\_VAL$

Shift left:  $CNTVAL = CNTVAL \ll EVENT\_LOAD\_VAL$

Subtract:  $CNTVAL = CNTVAL - EVENT\_LOAD\_VAL$

Add:  $CNTVAL = CNTVAL + EVENT\_LOAD\_VAL$

**Table 8-11. Counter Block Operating Modes**

EVENT	MODE_0	MODE_1	COUNT_EVENT_CTRL_x	COUNT_ADD_SHIFT_x	COUNT_DIR_x	Action on CNTVAL
0	0	0	X	X	X	None
0	0	1	X	X	X	None
0	1	0	X	X	X	Count down
0	1	1	X	X	X	Count up
1	X	X	0	X	X	Load
1	X	X	1	0	0	Shift right
1	X	X	1	0	1	Shift left
1	X	X	1	1	0	Subtract
1	X	X	1	1	1	Add

#### 8.4.2.3 Serializer Mode

Starting with CLB Type 2, the Counter module can operate as a serializer. In this mode of operation, this module acts as a shift register (also referred to as a serializer). In serializer mode of operation, the EVENT input is used to shift one bit of data into the serializer. Either of MATCH1 and MATCH2 can be configured to send out the shift register data. Using the MATCH1/2\_TAP\_SEL bit of CLB\_COUNT\_MATCH\_TAP\_SEL, any bit position of the counter can be brought out on the MATCH1/MATCH2 outputs. The shifting and direction of the counter in this mode is controlled by MODE\_0 (enable) and MODE\_1 (direction).

To enable the Serializer mode, CLB\_MISC\_CONTROL.COUNT\_SERIALIZER\_0 (for Counter 0) must be set.

#### 8.4.2.4 Linear Feedback Shift Register (LFSR) Mode

Starting with CLB Type 2, the Counter module operates as a linear feedback shift register. By configuring the characteristics of the LFSR, the counter module is used to compute the CRC on a serial bit stream. The polynomial for LFSR is in the MATCH2 reference register. The feedback bit position is in the MATCH1 reference register.

To enable the LFSR mode, CLB\_MISC\_CONTROL.COUNT\_SERIALIZER\_0 (for Counter 0) must be set along with COUNT0\_LFSR\_EN.

There are two types of LFSR that can be selected by changing the MODE1 value (0 or 1), as shown in [Figure 8-13](#).

Structure for LFSR Type 1 (MODE\_1 = 0)

CNT\_VAL is the 32-bit counter's active register  
 CNT\_VAL\_next is the 32-bit value to be written into CNT\_VAL on the next active cycle  
 (clock edge when MODE\_0 == 1)  
 LFSR\_MSB = CNT\_VAL[MATCH1\_REF[4:0]]  
 Poly[31:0] is MATCH2\_REF which acts as the CRC polynomial

Structure for LFSR Type 2 (MODE\_1 = 1)

CNT\_VAL is the 32-bit counter register  
 CNT\_VAL\_next is the 32-bit value to be written into CNT\_VAL on the next active cycle  
 (clock edge when MODE\_0 == 1)  
 LFSR\_MSB = CNT\_VAL[MATCH1\_REF[4:0]]  
 Poly[31:0] is MATCH2\_REF which acts as the CRC polynomial

Figure 8-13. LFSR Modes

### 8.4.3 FSM Block

The Finite State Machine (FSM) block provides the ability to build programmable finite state machines with up to four states. The FSM block has two register bits and two external inputs, and can be programmed either as two 2-state machines or as a single 4-state machine. For additional flexibility, there are two auxiliary inputs (EXTRA\_EXT\_IN0 and EXTRA\_EXT\_IN1) that can be used to create larger combinational functions by giving up a state functionality. The structure of the FSM is shown in Figure 8-14.

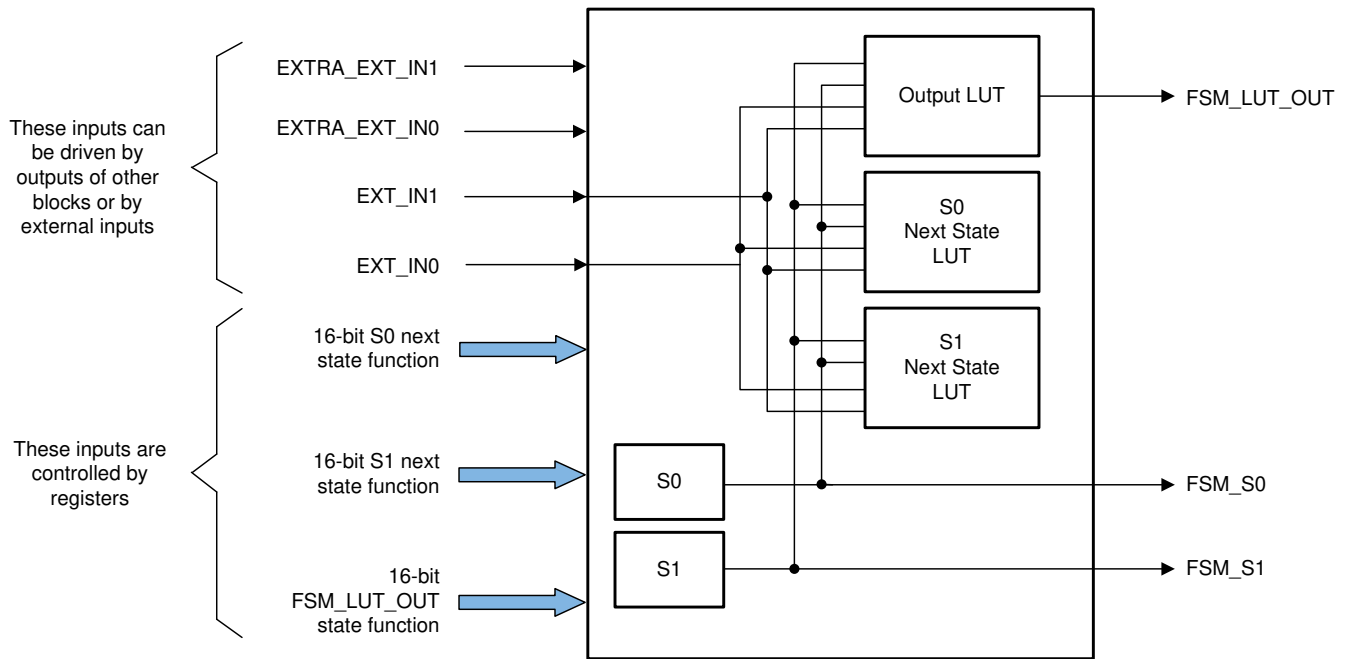

Figure 8-14. FSM Block

The signals and functionality of the FSM block are:

- **EXT\_IN0 and EXT\_IN1:** These are the two external inputs that can be used to control the output FSM\_LUT\_OUT or either of the states S0 and S1.
- **S0 and S1** are two state bits that have independent state control equations.
- **16-bit S0 equation** defines a function (EXT\_IN1, EXT\_IN0, S1, S0). The four bits in the order defined are used as an index into the 16-bit register to decide the next state of S0.
- **16-bit S1 equation** defines a function (EXT\_IN1, EXT\_IN0, S1, S0). The four bits in the order defined are used as an index into the 16-bit register to decide the next state of S1.
- **16-bit output equation** defines a function (EXT\_IN1, EXT\_IN0, S1, S0). The four bits in the order defined are used as an index into the 16-bit register to decide the output value of FSM\_LUT\_OUT. An additional level of configurability is provided such that FSM\_LUT\_OUT can use extra inputs in case the states S0 and S1 are unused.

One extra bit is used to select EXTRA\_EXT\_IN0 instead of S0. One extra bit is used to select EXTRA\_EXT\_IN1 instead of S1. Using these, one can effectively build 3-input or a 4-input LUT for the FSM\_LUT\_OUT by giving up one or two state bits, respectively.

The CFG\_MISC\_CTRL register controls the operation of the FSM block. Two bits in this register are used for each FSM Block to determine whether the FSM output LUT function uses the state variable S0/S1, or the corresponding extra external input signal FSM\_EXTRA\_EXT\_INx. A 0 means use the state bit, and a 1 means use the FSM\_EXTRA\_EXT\_IN0 / FSM\_EXTRA\_EXT\_IN1 signal.

**Figure 8-15. FSM LUT Block**

### 8.4.4 LUT4 Block

This is a simple four input Look-Up table (LUT) block with inputs IN0, IN1, IN2, and IN3 (see [Figure 8-16](#)). Any combinatorial Boolean equation using the four inputs can be realized by programming the 16-bit control register associated with each LUT4 block. For more information, see the LUT4 register descriptions located in [Section 8.10](#).

Figure 8-16. LUT4 Block

### 8.4.5 Output LUT Block

The output LUT block ([Figure 8-17](#)) is very similar in functionality to the LUT4 block, except that the output LUT block has three inputs. Unlike the other sub blocks, the outputs of these blocks are meant to go out of the tile and hence cannot be used by any other block within the tile. Any combinatorial function of the three inputs can be realized by the output LUT block. For more information, see the output LUT register descriptions located in [Section 8.10](#).

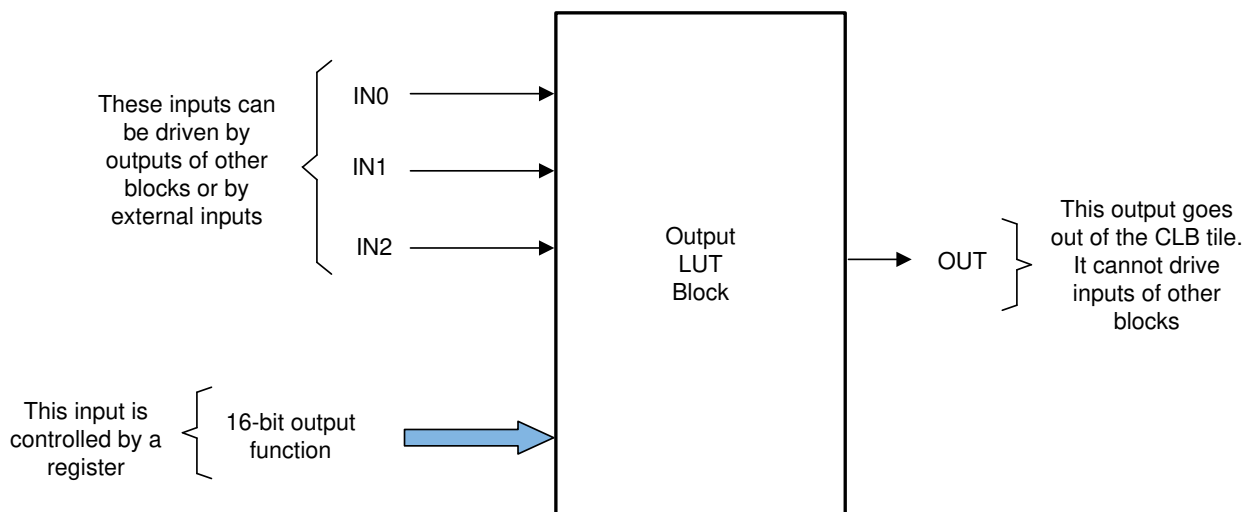

Figure 8-17. Output LUT Block

### 8.4.6 Asynchronous Output Conditioning (AOC) Block

The logic in the AOC block is organized into three stages with the inputs passing through different types of logic modification at each stage before proceeding to the next level. This is shown in [Figure 8-18](#).

There are 8 inputs to this block. Each of these 8 inputs can pick the corresponding BOUNDARY input to the CLB or the CLB TILE output (for example, the INPUT 0 of the AOC block can choose between CLB BOUNDARY INPUT0 and CLB TILE OUTPUT 0). If the CLB TILE OUTPUT 0 is selected, the CLB TILE OUTPUT 0 is always registered before being sent to the subsequent asynchronous signal conditioning stages. In each of the three stages, there is always an option to do nothing and just send the signal as is to the next stage (bypass).

**Stage 1:** The input signal can be inverted before sending the signal to the next stage.

**Stage 2:** The signal coming from Stage 1 can be GATED with a gating control signal. The gating control signal can either be from a software register or can be any of the CLB TILE outputs. The GATING function can be a logical AND, OR, or XOR.

**Stage 3:** The input signal can be used to either set or clear the output on the rising edge of the signal. This is a purely asynchronous set/clear that occurs without needing any clocks. The release control signal, when high, restores the output to the default state (HIGH if asynchronous clear is selected and LOW if asynchronous set is selected). The release control signal can be either from a software register or can be any of the CLB TILE outputs. Optionally, instead of any of the asynchronous set and clear operations, the input signal can just be delayed by a clock cycle.

The interaction of the CLB TILE and the AOC block is shown in [Figure 8-19](#).

Figure 8-18. AOC Block

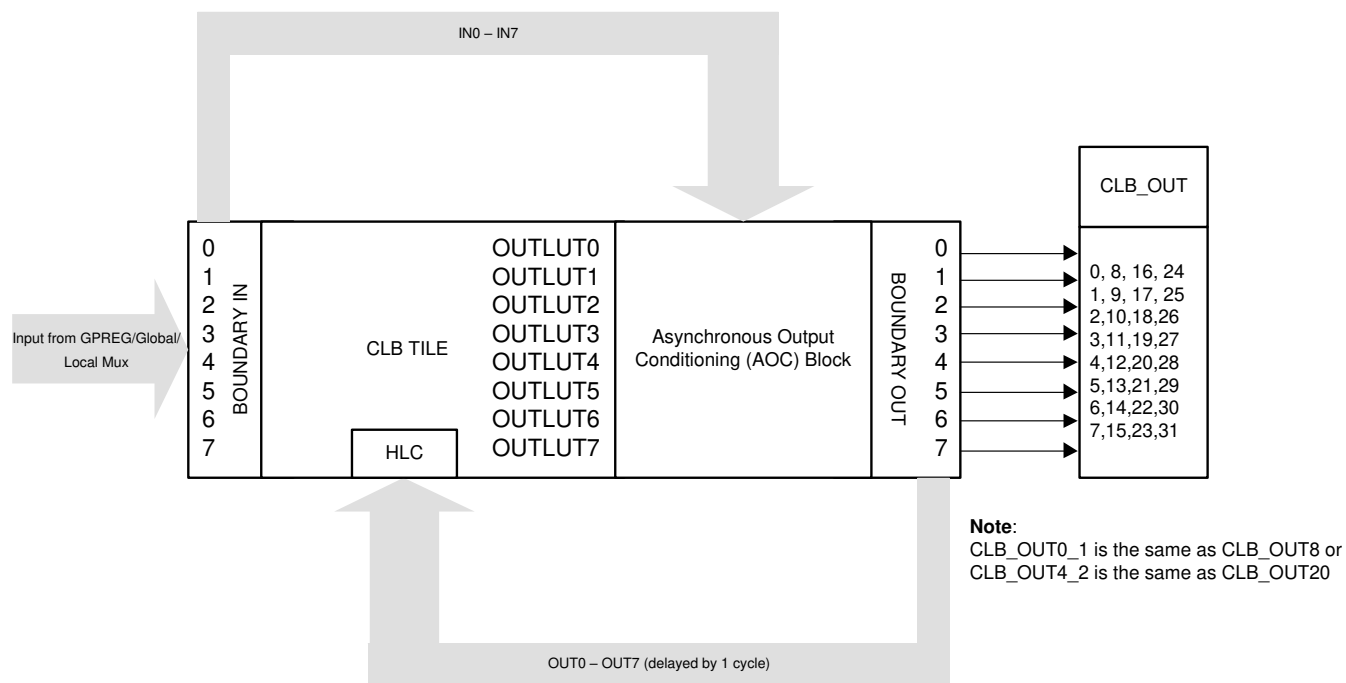

Figure 8-19. AOC Block and The CLB TILE

**Note**

Only CLB\_OUT12 to CLB\_OUT15 can be used as ASYNC outputs. This is the same as CLB\_OUT4\_1 to CLB\_OUT7\_1. GPIO Output XBAR can be used to route the OUT4\_1 and OUT5\_1 ASYNC outputs to GPIOs.

### 8.4.7 High Level Controller (HLC)

The High Level Controller (HLC) is significantly more complex than the other blocks in the CLB tile. The HLC performs two main functions:

- Provides a means of communication and data exchange with the rest of the device. This is done through two methods: a global access path to four general purpose HLC registers (R0 through R3) and PUSH and PULL FIFOs between the CPU and the HLC. The general-purpose HLC registers are designed to only be written to during device configuration time. To avoid unexpected behavior, the HLC registers must not be written to during run-time operation. The PUSH and PULL FIFOs are the primary avenues of data exchange during run-time, refer to [Section 8.4.7.4](#) for more information.
- Provides a programmable, event-based action system, which performs computation, manipulation of logic functionality, and data movement. In other words, events can be configured to trigger a predefined set of actions in the CLB tile, or to initiate data exchange with the rest of the device.

The architecture of the HLC is shown in [Figure 8-20](#). The HLC is an event-based system capable of handling up to four simultaneous events that can be selected from any outputs of the other blocks within the tile or from an external input.

Figure 8-20. High Level Controller Block

### 8.4.7.1 High Level Controller Events

Each of the four HLC events has a dedicated address from which instructions are executed. Events are selected from the set of signals listed in [Table 8-12](#). The lowest numbered event (Event 0) has the highest priority, and the highest numbered event (Event 3) has the lowest priority.

**Table 8-12. HLC Event List**

Index	HLC Event Mux
0	Always 0
1	COUNTER_0 MATCH2
2	COUNTER_0 ZERO
3	COUNTER_0 MATCH1
4	FSM_0 STATE_BIT_0
5	FSM_0 STATE_BIT_1
6	FSM_0 LUT output
7	LUT4_0 output
8	Always 1
9	COUNTER_1 MATCH2
10	COUNTER_1 ZERO
11	COUNTER_1 MATCH1
12	FSM_1 STATE_BIT_0
13	FSM_1 STATE_BIT_1
14	FSM_1 LUT output
15	LUT4_1 output
16	Always '0'
17	COUNTER_2 MATCH2
18	COUNTER_2 ZERO
19	COUNTER_2 MATCH1
20	FSM_2 STATE_BIT_0
21	FSM_2 STATE_BIT_1

31	CLB_ASYNC_OUT_7.INVERTED

### 8.4.7.2 High Level Controller Instructions

The instruction memory supports up to eight instructions per event. Each instruction sequence gets triggered on the rising edge of the corresponding event. Starting with CLB Type 2, the option to trigger the execution of instructions using both falling edge and rising edge is available.

The HLC memory supports up to eight instructions per event, starting at the beginning of the fixed address range shown in [Table 8-14](#). An instruction sequence is triggered on the rising edge of the corresponding event. If two or more events occur simultaneously, the associated instruction sequences each are executed sequentially in priority order.

**Table 8-14. HLC Instruction Address Ranges**

Address	Instructions for
00000 to 00111	Event 0
01000 to 01111	Event 1
10000 to 10111	Event 2
11000 to 11111	Event 3

The HLC instruction format is shown in [Table 8-15](#).

**Table 8-15. HLC Instruction Format**

Last Instruction Bit	5-Bit Opcode	3-Bit Source	3-Bit Destination
This bit when set to 1 stops execution after the current instruction.	MOV 00000	Source can be R0, R1, R2, R3, C0, C1, C2.	Destination can be R0, R1, R2, R3, C0, C1, C2.  Note that for ADD/SUB instructions, only R0, R1, R2, or R3 can be the destination.
	MOV_T1 00001		
	MOV_T2 00010		
	PUSH 00011		
	PULL 00100		
	ADD 00101		
	SUB 00110		
INTR 00111			

R0, R1, R2, and R3 are four 32-bit general-purpose registers in the HLC. C0, C1, and C2 are three counter registers present in the CLB tile. <Src> is used to indicate the source and <Dest> is used to indicate the destination. [Table 8-16](#) describes the HLC instructions.

**Table 8-16. HLC Instruction Description**

Instruction	Description
ADD <Src>, <Dest>	This instruction performs an unsigned 32-bit addition. <Dest> = <Dest> + <Src>. The <Src> can be R0, R1, R2, R3, C0, C1, or C2. The <Dest> can only be R0, R1, R2, or R3.
INTR <6-bit constant>	This instruction flags an interrupt through the CPU interface. The 6-bit constant is stored in the interrupt flag register CLB_INTR_TAG_REG. If multiple INTR instructions are called consecutively, only the first one has an effect. When multiple INTR calls are needed, each can be separated by other HLC instructions to make sure the interrupt calls take effect.
<b>Note</b>	
Starting with CLB Type 2, NMI can be generated by the CLB. This feature is DISABLED by default and must be enabled ( <b>CLB_LOAD_EN.NMI_EN</b> ).	
MOV <Src>, <Dest>	This instruction moves <Src> to <Dest>. Both <Src> and <Dest> can be any of R0, R1, R2, R3, C0, C1, or C2. The COUNT_EVENT_CTRL_x bit must be configured to load (that is, 0) for indirect loads and HLC loads of the counter to take effect.

**Table 8-16. HLC Instruction Description (continued)**

Instruction	Description
MOV_T1 <Src>, <Dest>	<p>This instruction moves &lt;Src&gt; to the Match1 register of the &lt;Dest&gt; counter. &lt;Src&gt; can be any of the registers R0, R1, R2, R3, or the counter values associated with C0, C1, or C2. &lt;Dest&gt; is the Match1 register of any of the counters C0, C1, or C2. Examples are:</p> <ul style="list-style-type: none"> <li>This instruction moves the count value in C1 into register R0: MOV_T1 C1 R0</li> <li>This instruction moves the value in R2 into the Match1 register of counter C0: MOV_T1 R2 C0</li> </ul>
MOV_T2 <Src>, <Dest>	<p>This instruction is similar to MOV_T1. The instruction moves &lt;Src&gt; to the Match2 register of the &lt;Dest&gt; counter. &lt;Src&gt; can be any of the registers R0, R1, R2, R3, or the counter values associated with C0, C1, or C2. &lt;Dest&gt; is the Match2 register of any of the counters C0, C1, or C2.</p>
PULL <Dest>	<p>This instruction transfers data from the data exchange pull memory buffer in the CPU interface to the &lt;Dest&gt; register. &lt;Dest&gt; can be any of R0, R1, R2, or R3. The PULL instruction is used as seen from the High Level Controller and a PULL operation reads (pulls) data from an internal 4-word FIFO.</p>
PUSH <Src>	<p>This instruction transfers data from &lt;Src&gt; to the data exchange push memory buffer in the CPU interface. &lt;Src&gt; can be any of R0, R1, R2, R3, C0, C1, or C2. The PUSH instruction is used as seen from the High Level Controller and pushes data into an internal 4 word FIFO.</p>
SUB <Src>, <Dest>	<p>This instruction performs an unsigned 32-bit subtraction. &lt;Dest&gt; = &lt;Dest&gt; - &lt;Src&gt;. The &lt;Src&gt; can be R0, R1, R2, R3, C0, C1, or C2. The &lt;Dest&gt; can only be R0, R1, R2, or R3.</p>

MOV, MOV\_T1, MOV\_T2, ADD, SUB, and INTR instructions take one cycle to execute. PUSH and PULL require two cycles to execute. Note that the PUSH and PULL instructions are pipeline protected, meaning that a register can be used immediately after a PUSH/PULL to that register.

For multiple events triggered simultaneously, if the last instruction in the higher priority event is a PUSH or a PULL, there is an additional cycle delay between the end of the higher priority event and the start of the next event. If the last instruction is not a PUSH or PULL, then there is no cycle delay between the events.

#### 8.4.7.3 <Src> and <Dest>

Three bits are used to encode the <Src> and <Dest> registers as shown in [Table 8-17](#).

**Table 8-17. HLC Register Encoding**

Bits	Register
000	R0
001	R1
010	R2
011	R3
100	C0
101	C1
110	C2

#### 8.4.7.4 Operation of the PUSH and PULL Instructions (Overflow and Underflow Detection)

The PUSH and PULL operations of the HLC are intended for data exchange with the host system. There are separate FIFO buffers for PUSH and PULL operations. For example, a series of PUSH operations write to successive locations in a linearly mapped-memory buffer. The PUSH buffer and the PULL buffer are mapped at address offsets shown in the *Registers* section.

The CPU can read from and write to the PUSH and PULL buffers, respectively, to exchange data with the HLC. Data pushed by the HLC is read by the CPU from the PUSH buffers. Data sent from the CPU to the HLC is written by the CPU to the PULL buffer and is read by the HLC using the PULL instruction.

Refer to *clb\_ex13\_push\_pull* for guidance on properly using the PUSH and PULL buffers. To make use of one of the CLB inputs as a GPREG, have this input indicate when data is written to the FIFO by the CPU.

There are separate PUSH and PULL address pointers that increment each time the HLC performs a PUSH or PULL operation. These address pointers are also memory-mapped so that the CPU can determine the value. These address pointers are also writable and can be reset by the CPU at any time.

Overflow and underflow detection is done by simply reading the values of the PUSH and PULL address pointers.

In the CLB module of the device, the depth of the PUSH and PULL FIFOs is four 32-bit words each. If the CPU starts a fresh data transfer to the PULL buffers and sees the address pointer greater than four, then an underflow has occurred since the HLC has pulled more data than the number of words written by the CPU into the buffer.

## 8.5 CPU Interface

### 8.5.1 Register Description

There are three classes of registers that are used to control and configure the CLB tile. This specification only describes the offset addresses of the registers. The absolute register addresses are different for each CLB tile. The three instances of the various blocks (LUT4, FSM, and Counter Block) are numbered 0, 1, and 2.

- **Logic configuration registers (0x000 – 0x0FF):** These registers control the core reconfiguration logic for the tile. All registers in this group are EALLOW protected and also protected by the LOCK register.
- **Top level control registers (0x100 – 0x1FF):** These registers are used for top level and device related control of the CLB. These registers typically control mux selects for inputs, global enables, and so forth, and are accessible by normal memory mapped access. Some of these registers have EALLOW and LOCK protection.
- **Data exchange registers (0x200 – 0x3FF):** These registers are used to exchange data between the CLB and the rest of the device. The registers are accessible by normal memory-mapped access and no EALLOW or LOCK protection exists.

---

#### Note

EALLOW protection means that the write access to the register is enabled only when the EALLOW instruction has been executed prior to the write access. The complementary EDIS instruction disables access to all registers protected in this way. For more information, see [Section 8.10](#).

---

### 8.5.2 Non-Memory Mapped Registers

The memory-mapped CLB registers are described later in this chapter; however, many of the CLB resources including counters, the instruction memory of the High Level Controller, and the HLC general-purpose registers (R0 through R3) are only indirectly accessible through a local interface bus and are not memory-mapped. These registers are accessible through the two memory-mapped registers CLB\_LOAD\_DATA and CLB\_LOAD\_ADDR. Note that the general-purpose registers R0 through R3 must only be written to during configuration-time and are not intended to be written to during run-time. Writes during run-time can lead to unexpected behavior. If run-time data exchange is desired, refer to [Section 8.4.7.4](#).

Load the data to be written into the CLB\_LOAD\_DATA register, then load the appropriate address into CLB\_LOAD\_ADDR to determine where this data is written. Writing a 1 to bit position 0 in the CLB\_LOAD\_EN register then causes an internal write operation to be triggered. The address allocation for the CLB\_LOAD\_ADDR register is shown in [Table 8-18](#).

---

#### Note

The COUNT\_EVENT\_CTRL\_x bit must be configured to load (that is, 0) for indirect loads and for HLC loads of the counter to take effect.

---

**Table 8-18. Non-Memory Mapped Register Addresses**

Address (Binary)	Resource
000000 to 000010	Counter 0 to 2 Load value
000100 to 000110	Counter 0 to 2 Match1 value
001000 to 001010	Counter 0 to 2 Match2 value
001100 to 001111	R0 to R3 of High Level Controller
100000 to 100111	Instructions for Event 0
101000 to 101111	Instructions for Event 1
110000 to 110111	Instructions for Event 2
111000 to 111111	Instructions for Event 3

---

Use the following steps to load the value 0x11223344 into the general purpose R0 register:

1. Write 0x11223344 to CLB\_LOAD\_DATA.
2. Write 0xc to CLB\_LOAD\_ADDR.
3. Write 0x1 to CLB\_LOAD\_EN.

---

#### Note

Even though HLC registers are accessible by the CPU, your application code needs to make sure that no other CLB internal logics are updating the same HLC register at the same time, causing a race condition.

---

### 8.6 DMA Access

The DMA does not have access to the CLB memory-mapped registers, including the PUSH and PULL FIFO registers. For more information, refer to [Section 8.10](#).

## 8.7 CLB Data Export Through SPI RX Buffer

For a continuous export of data from the CLB peripherals, SPI RX buffers can be used. CLB data can be exported through the SPI RX buffers without CPU/CLA interventions.

For the F28P65x devices, CLB1 to CLB4 have access to SPIA to SPID, respectively, as shown in [Table 8-19](#).

**Table 8-19. CLB to SPI RX Access**

CLB Instance	SPI Instance
CLB1	SPIA
CLB2	SPIB
CLB3	SPIC
CLB4	SPID

When the CLB to SPI data exporting is enabled, 16-bit data can be exported from CLB to SPI RX buffers. The 32-bit HLC R0 register is the data that is exported to the SPI RX buffers. The user can select which 16-bit range of the HLC R0 is exported by configuring the `CLB_SPI_DATA_CTRL_HI.SHIFT`. The CLB also controls when HLC R0 data must be transferred to the SPI RX buffer through `CLB_SPI_DATA_CTRL_HI.STRB` that selects one of the HLC event signals from the static switch block.

When CLB to SPI data exporting is required, note:

- The selected SPI transmit functionality is not affected.
- Even though the data is being pushed into the SPI RX buffers by the CLB, the SPI RX interrupt and the DMA trigger for SPI RX in the respective peripherals must be configured.
- The SPI can resume normal operation when the CLB to SPI data exporting is disabled.

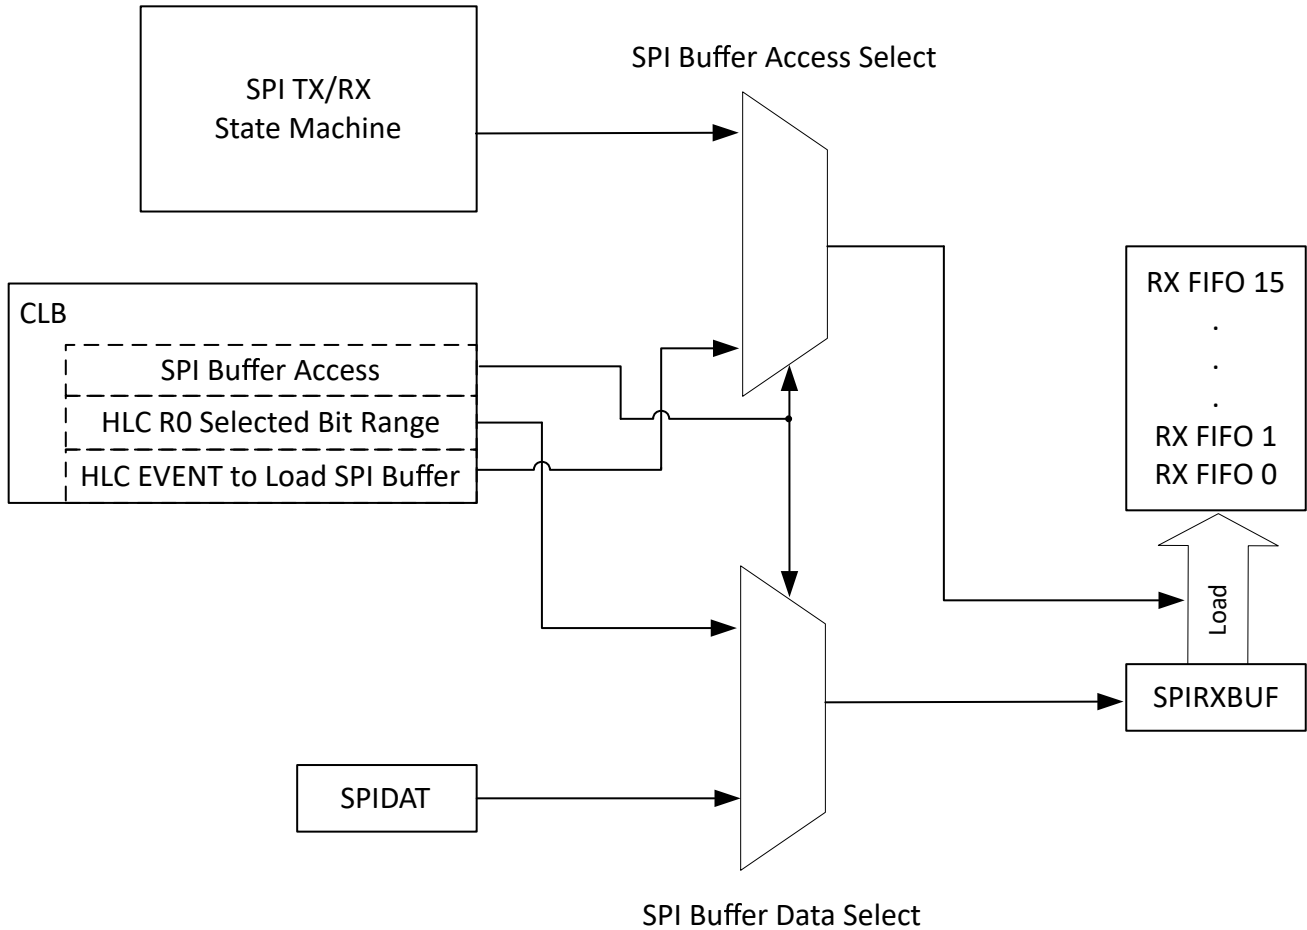

Figure 8-21. CLB Control of SPI RX Buffer

### 8.8 CLB Pipeline Mode

When operating the CLB TILE at frequencies higher than 100MHz, the Pipeline mode MUST be enabled. When CLB Pipeline mode is enabled, the operations of the HLC and COUNTER modules are changed.

- When operating at higher frequencies that require Pipeline mode to be enabled, the pipelined versions of the the CLB CELL OUTPUTs are brought into the HLC. The Pipeline mode causes the CELL outputs delayed by 1 clock cycle to be used as the source of the HLC event triggers.
- In Pipeline mode, the COUNTER module's add/sub/shift operations, which are triggered by an event, use the value of the counter in the previous clock cycle (pipelined).

To enable the CLB Pipeline mode, set the `CLB_LOAD_EN.PIPELINE_EN`.

## 8.9 Software

### 8.9.1 CLB Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/clb

Cloud access to these examples is available at the following link: [dev.ti.com C2000Ware Examples](https://dev.ti.com/C2000Ware/Examples).

#### 8.9.1.1 CLB Empty Project

FILE: empty.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

#### 8.9.1.2 CLB Combinational Logic

FILE: clb\_ex1\_combinatorial\_logic.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

The objective of this example is to prevent simultaneous high or low outputs on a PWM pair. PWM modules 1 and 2 are configured to generate identical waveforms based on a fixed frequency up-count mode.

#### 8.9.1.3 CLB GPIO Input Filter

FILE: clb\_ex2\_gpio\_input\_filter.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

This example demonstrates use of finite state machines (FSMs) and counters to implement a simple 'glitch' filter which might, for example, be applied to an incoming GPIO signal to remove unwanted short duration pulses.

#### 8.9.1.4 CLB Auxiliary PWM

FILE: clb\_ex3\_auxiliary\_pwm.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

This example configures a CLB tile as an auxiliary PWM generator. The example uses combinatorial logic (LUTs), state machines (FSMs), counters, and the high level controller (HLC) to demonstrate the PWM output generation capabilities using CLB.

#### 8.9.1.5 CLB PWM Protection

FILE: clb\_ex4\_pwm\_protection.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

This example extends the features of example 1 to ensure an active high complementary pair PWM configuration always operates with a minimum value of dead-band irrespective of how the generating PWM module is configured. The example illustrates the configuration of four separate PWM tiles to implement PWM protection on four PWM modules. The outputs of PWM modules 1 to 4 are operated on by CLB tiles 1 to 4, respectively.

#### 8.9.1.6 CLB Event Window

FILE: clb\_ex5\_event\_window.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

This example uses the counter, FSM, and HLC sub-modules of the CLB to implement an event timing feature which detects whether an interrupt service routine takes too long to respond to an interrupt. The example configures four PWM modules to operate in up-count mode and generate a low-to-high edge on a timer zero match event. The zero match event also triggers a PWM ISR which, for the purposes of this example, contains a dummy payload of variable length. At the end of the ISR, a write operation takes place to a CLB GP register to indicate the ISR has ended.

#### 8.9.1.7 CLB Signal Generator

FILE: clb\_ex6\_siggen.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

This example uses CLB1 to generate a rectangular wave and CLB2 to check the rectangular wave generated by CLB1 doesn't exceed the defined duty cycle and period limits.

#### 8.9.1.8 CLB State Machine

FILE: clb\_ex7\_state\_machine.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\Designing With the C2000 CLB.pdf This application report describes the process of creating this CLB example and can be used as guidance on designing custom logic with the CLB. This example uses all submodules inside a CLB TILE in order to implement a complete system.

#### 8.9.1.9 CLB External Signal AND Gate

FILE: clb\_ex8\_external\_signal\_AND\_gate.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

In this example, two external signals from two GPIOs are passed through the Input X-BAR and the CLB X-BAR to the CLB TILE. Inside the CLB module these two signals are ANDED. The output of the AND gate is then exported to a GPIO, using Output X-BAR.

#### 8.9.1.10 CLB Timer

FILE: clb\_ex9\_timer.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

In this example, a COUNTER module is used to create timed events. The use of the GP Register is shown. Through setting/clearing the bits in the GP register, the timer is started, stopped or changes direction. The output of the timer event (1-clock cycle) is exported to a GPIO. Interrupts are generated from the timer event using the HLC module. A GPIO is also toggled inside the CLB ISR. The indirect CLB register access is used to update the timer's event match value and the active counter register to modify the frequency of the timer.

#### 8.9.1.11 CLB Timer Two States

FILE: clb\_ex10\_timer\_two\_states.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

In this example, the timer is setup the same as the previous example. The difference is the use of the FSM submodule to toggle the output of the CLB which is then exported to a GPIO. The FSM module acts as a single bit memory block. Interrupts are setup in the same format as the previous example. The interrupt delay of the CLB can be seen by comparing the output of the CLB and the GPIO toggled in the ISR.

#### 8.9.1.12 CLB Interrupt Tag

FILE: clb\_ex11\_interrupt\_tag.c

For the detailed description of this example, please refer to:

C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

In this example, a timer is setup with two different match values. These two events are used by the HLC submodule to generate interrupts. The interrupt TAG is used to differentiate between the interrupt generated due to the match1 event of the CLB counter and the match2 event of the CLB counter.

#### 8.9.1.13 CLB Output Intersect

FILE: clb\_ex12\_output\_intersect.c

For the detailed description of this example, please refer to:

C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

In this example, the CLB module is set up the same as the external\_AND\_gate example. However, instead of the output being exported to the GPIO using Output X-BAR, the output is exported to the GPIO by replacing the output of ePWM1. This is done by configuring the GPIO for EPWM1A output, followed by enabling output intersection.

#### 8.9.1.14 CLB PUSH PULL

FILE: clb\_ex13\_push\_pull.c

For the detailed description of this example, please refer to:

C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

In this example, the use of the PUSH-PULL interface is shown. Multiple COUNTER submodules, HLC submodule, FSM submodules, and OUTLUT submodules are used. The PUSH-PULL interface is used alongside the GP register to update the COUNTER submodules' event frequencies.

#### 8.9.1.15 CLB Multi Tile

FILE: clb\_ex14\_multi\_tile.c

For the detailed description of this example, please refer to:

C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

In this example the output of a CLB TILE is passed to the input of another CLB TILE. The output of the second CLB TILE is then exported to a GPIO, showcasing how two CLB TILES can be used in series.

#### 8.9.1.16 CLB Tile to Tile Delay

FILE: clb\_ex15\_tile\_to\_tile\_delay.c

For the detailed description of this example, please refer to:

C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

In this example the output of a GPIO is taken into the CLB TILE through INPUT XBAR and the CLB XBAR. The signal is forwarded by the TILE to the next TILE. This time the signal only goes through the CLB XBAR and NOT the Input XBAR. This is done to show that delays are added when the signals are passed from TILE to TILE and the delay is NOT characterized. The user should always avoid passing signals with timing requirements between tiles. The COUNTER modules inside the CLBs will count the amount of delay in cycles.

#### 8.9.1.17 CLB Glue Logic

FILE: clb\_ex16\_glue\_logic.c

For the detailed description of this example, please refer to :

C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

In this example the user is walked through how to migrate custom logic from an FPGA/CPLD to C2000™ microcontrollers.

#### 8.9.1.18 CLB based One-shot PWM

FILE: clb\_ex17\_one\_shot\_pwm.c

For the detailed description of this example, please refer to :  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

#### **8.9.1.19 CLB AOC Control**

FILE: clb\_ex18\_aoc.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

In this example the Asynchronous Output Conditioning block is used to asynchronously AND gate the input signals to the CLB. This module is only available for CLB types 2 and up.

#### **8.9.1.20 CLB AOC Release Control**

FILE: clb\_ex19\_aoc\_release\_control.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

In this example the Asynchronous Output Conditioning block is used to asynchronously set/release the input signals to the CLB. This module is only available for CLB types 2 and up.

#### **8.9.1.21 CLB XBARs**

FILE: clb\_ex20\_clxbars.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

In this example the CLB INPUTXBAR and CLB OUTPUTXBAR are used to take input signals from GPIOs into the CLB TILES and take output signal from the TILE to GPIOs. The availability of these XBARs are device dependent.

#### **8.9.1.22 CLB AOC Control**

FILE: clb\_ex21\_clockprescalar\_nmi.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

In this example the clock prescalar of the CLB module is used to divide down the CLB clock and use it as an input to the TILE logic. Also the HLC module is used to generate NMI interrupts. This module is only available for CLB types 2 and up.

#### **8.9.1.23 CLB Serializer**

FILE: clb\_ex22\_serializer.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

In this example the CLB COUNTER is used in serializer mode to act as a shift register. This module is only available for CLB types 2 and up.

#### **8.9.1.24 CLB LFSR**

FILE: clb\_ex23\_lfsr.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

In this example the CLB COUNTER module is used in Linear Feedback Shift Register (LFSR) mode. This module is only available for CLB types 2 and up.

### 8.9.1.25 CLB Lock Output Mask

FILE: clb\_ex24\_lock\_output\_mask.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

In this example the lock output mask feature of the CLB is used to lock the selected output signal override settings. This module is only available for CLB types 3 and up.

### 8.9.1.26 CLB INPUT Pipeline Mode

FILE: clb\_ex25\_input\_pipeline.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

In this example the CLB Input Pipeline mode is enable to delay the input signal by a clock cycle. This module is only available for CLB types 3 and up.

### 8.9.1.27 CLB Clocking and PIPELINE Mode

FILE: clb\_ex26\_clocking\_pipeline.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

In this example the CLB pipeline mode is enable and affects the behavior of the CLB COUNTERs and HLC. This module is only available for CLB types 3 and up.

### 8.9.1.28 CLB SPI Data Export

FILE: clb\_ex27\_spi\_data\_export.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

In this example the high speed data export feature of the CLB is used and one of the HLC registers is exported out of the CLB module using the SPI RX buffer. This module is only available for CLB types 3 and up.

### 8.9.1.29 CLB SPI Data Export DMA

FILE: clb\_ex28\_spi\_data\_export\_dma.c

For the detailed description of this example, please refer to:  
C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

In this example the high speed data export feature of the CLB is used and one of the HLC registers is exported out of the CLB module using the SPI RX buffer. The data received in the SPI RX buffer is transferred to memory using DMA. This module is only available for CLB types 3 and up.

### 8.9.1.30 CLB Trip Zone Timestamp

FILE: clb\_ex29\_timestamp.c

This example displays how to timestamp interrupts generated by the CLB. An interrupt is generated when ePWM1 is tripped.

ePWM1 is configured to be interrupted by TZ1 and TZ2, both one shot trip sources.

The CLB is configured as follows:

- COUNTER0 and COUNTER1 continually count when the program begins.
- COUNTER0 timestamps TZ1 and COUNTER1 timestamps TZ2.
- COUNTER2 increments once when COUNTER0/COUNTER1 overflows using LUT2.
- FSM0/1 are configured to sync counters and stop COUNTER0/1 when an interrupt is received.
- TZ1 (GPIO12) and TZ2 (GPIO13) are routed as inputs through CLBXBAR.

- BOUNDARY.boundaryInput0 denotes TZ1. On rising edge, HLC issues an interrupt with tag 12.
- BOUNDARY.in1 denotes TZ2. On rising edge, HLC issues an interrupt with tag 13.
- BOUNDARY.boundaryInput7 serves as a simultaneous enable for COUNTER0/1 to begin counting.

TZ1 is tripped when GPIO12 is connected to GND. TZ2 is tripped when GPIO13 is connected to GND. When an interrupt occurs, the interrupt handler determines the initial trip source and stores this value in a variable 'initialTripZone'.

View these variables in Debug Expressions tab:

initialTripZone: stores the first TZ to have been tripped tz1Counter64bit: stores the counter value at the instant that TZ1 is tripped. tz2Counter64bit: stores the counter value at the instant that TZ2 is tripped.

### 8.9.1.31 CLB CRC

FILE: clb\_ex30\_cyclic\_redundancy\_check.c

For the detailed description of this example, please refer to:

C2000Ware\_PATH\utilities\clb\_tool\clb\_syscfg\doc\CLB Tool Users Guide.pdf

In this example, the CLB module is used to perform the cyclic redundancy check (C.R.C.) with twelve messages in bits checked with ten different CRC polynomials.

First element passed in is message length, second is the message stored in input\_data

This example is only available for CLB types 2 and up.

The known values in the output\_data are compared with expected values from the CLB-based CRC calculation. A total of 120 messages are verified, and the number of matching messages are displayed in passCount

Variables to add to Watch Expressions in debug view: passCount - number of messages that match between generated and known CRC values failCount - number of messages that fail the CRC value verification

### 8.9.1.32 CLB TDM Serial Port

FILE: clb\_ex31\_tdm\_serial\_port.c

For the detailed description of this example, please refer to: How to Implement Custom Serial Interfaces Using the Configurable Logic Block (CLB) Application Note (SPRAD62).

In this example a single CLB tile is used to input a TDM stream and generate a TDM output stream. The CLB generates a CPU interrupt when four 32-bit words are received. The CPU can load four 32-bit values to the CLB FIFO for transmission. The CLB and CPU are configured to run at their maximum speed.

This example is only available on C2000 MCU devices with CLB types 2 and up.

#### External Connections

TDM Input Signal GPIO pin FSYNC\_IN GPIO00 BCLK\_IN GPIO01 DATA1\_IN GPIO02

TDM Output Signal GPIO pin FSYNC\_OUT GPIO04 BCLK\_OUT GPIO05 DATA1\_OUT GPIO06

### 8.9.1.33 CLB LED Driver

FILE: clb\_ex32\_led\_driver.c

For the detailed description of this example, please refer to: How to Implement Custom Serial Interfaces Using the Configurable Logic Block (CLB) Application Note (SPRAD62).

In this example two CLB tiles are used to communicate with an LP5891-Q1 LED driver. One CCSI bus is used to transmit data using the CCSI bus protocol, while a second tile is used to receive data from the CCSI bus. The C28x CPU communicates with the CLB logic through a hardware-abstraction layer (HAL). This example also utilizes a PWM to generate the required CCSI clocks, and a timer to generate periodic sync events to the LED driver.

This example is only available on C2000 MCU devices with CLB types 2 and up.

## 8.10 CLB Registers

This section describes the Configurable Logic Block Registers.

### 8.10.1 CLB Base Address Table

**Table 8-20. CLB Base Address Table**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	CPU2	CPU2.DMA	Pipeline Protected
Instance	Structure								
Clb1LogicCfg Regs	<a href="#">CLB_LOGIC_CONFIG_REGS</a>	CLB1_LOGICCFG_BASE	0x0000_2000	YES	-	YES	YES	-	YES
Clb1LogicCtrl Regs	<a href="#">CLB_LOGIC_CONTROL_REGS</a>	CLB1_LOGICCTRL_BASE	0x0000_2100	YES	-	YES	YES	-	YES
Clb1DataExch Regs	<a href="#">CLB_DATA_EXCHANGE_REGS</a>	CLB1_DATAEXCH_BASE	0x0000_2180	YES	-	YES	YES	-	YES
Clb2LogicCfg Regs	<a href="#">CLB_LOGIC_CONFIG_REGS</a>	CLB2_LOGICCFG_BASE	0x0000_2200	YES	-	YES	YES	-	YES

### 8.10.2 CLB\_LOGIC\_CONFIG\_REGS Registers

Table 8-21 lists the memory-mapped registers for the CLB\_LOGIC\_CONFIG\_REGS registers. All register offset addresses not listed in Table 8-21 should be considered as reserved locations and the register contents should not be modified.

**Table 8-21. CLB\_LOGIC\_CONFIG\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
2h	CLB_COUNT_RESET	Counter Block RESET	EALLOW, LOCK	<a href="#">Go</a>
4h	CLB_COUNT_MODE_1	Counter Block MODE_1	EALLOW, LOCK	<a href="#">Go</a>
6h	CLB_COUNT_MODE_0	Counter Block MODE_0	EALLOW, LOCK	<a href="#">Go</a>
8h	CLB_COUNT_EVENT	Counter Block EVENT	EALLOW, LOCK	<a href="#">Go</a>
Ah	CLB_FSM_EXTRA_IN0	FSM Extra EXT_IN0	EALLOW, LOCK	<a href="#">Go</a>
Ch	CLB_FSM_EXTERNAL_IN0	FSM EXT_IN0	EALLOW, LOCK	<a href="#">Go</a>
Eh	CLB_FSM_EXTERNAL_IN1	FSM_EXT_IN1	EALLOW, LOCK	<a href="#">Go</a>
10h	CLB_FSM_EXTRA_IN1	FSM Extra_EXT_IN1	EALLOW, LOCK	<a href="#">Go</a>
12h	CLB_LUT4_IN0	LUT4_0/1/2 IN0 input source	EALLOW, LOCK	<a href="#">Go</a>
14h	CLB_LUT4_IN1	LUT4_0/1/2 IN1 input source	EALLOW, LOCK	<a href="#">Go</a>
16h	CLB_LUT4_IN2	LUT4_0/1/2 IN2 input source	EALLOW, LOCK	<a href="#">Go</a>
18h	CLB_LUT4_IN3	LUT4_0/1/2 IN3 input source	EALLOW, LOCK	<a href="#">Go</a>
1Ch	CLB_FSM_LUT_FN1_0	LUT function for FSM Unit 1 and Unit 0	EALLOW, LOCK	<a href="#">Go</a>
1Eh	CLB_FSM_LUT_FN2	LUT function for FSM Unit 2	EALLOW, LOCK	<a href="#">Go</a>
20h	CLB_LUT4_FN1_0	LUT function for LUT4 block of Unit 1 and 0	EALLOW, LOCK	<a href="#">Go</a>
22h	CLB_LUT4_FN2	LUT function for LUT4 block of Unit 2	EALLOW, LOCK	<a href="#">Go</a>
24h	CLB_FSM_NEXT_STATE_0	FSM Next state equations for Unit 0	EALLOW, LOCK	<a href="#">Go</a>
26h	CLB_FSM_NEXT_STATE_1	FSM Next state equations for Unit 1	EALLOW, LOCK	<a href="#">Go</a>
28h	CLB_FSM_NEXT_STATE_2	FSM Next state equations for Unit 2	EALLOW, LOCK	<a href="#">Go</a>
2Ah	CLB_MISC_CONTROL	Static controls for Ctr,FSM	EALLOW, LOCK	<a href="#">Go</a>
2Ch	CLB_OUTPUT_LUT_0	Inp Sel, LUT fns for Out0	EALLOW, LOCK	<a href="#">Go</a>
2Eh	CLB_OUTPUT_LUT_1	Inp Sel, LUT fns for Out1	EALLOW, LOCK	<a href="#">Go</a>
30h	CLB_OUTPUT_LUT_2	Inp Sel, LUT fns for Out2	EALLOW, LOCK	<a href="#">Go</a>
32h	CLB_OUTPUT_LUT_3	Inp Sel, LUT fns for Out3	EALLOW, LOCK	<a href="#">Go</a>
34h	CLB_OUTPUT_LUT_4	Inp Sel, LUT fns for Out4	EALLOW, LOCK	<a href="#">Go</a>
36h	CLB_OUTPUT_LUT_5	Inp Sel, LUT fns for Out5	EALLOW, LOCK	<a href="#">Go</a>
38h	CLB_OUTPUT_LUT_6	Inp Sel, LUT fns for Out6	EALLOW, LOCK	<a href="#">Go</a>
3Ah	CLB_OUTPUT_LUT_7	Inp Sel, LUT fns for Out7	EALLOW, LOCK	<a href="#">Go</a>
3Ch	CLB_HLC_EVENT_SEL	Event Selector register for the High Level controller	EALLOW, LOCK	<a href="#">Go</a>
3Eh	CLB_COUNT_MATCH_TAP_SEL	Counter tap values for match1 and match2 outputs	EALLOW, LOCK	<a href="#">Go</a>
40h	CLB_OUTPUT_COND_CTRL_0	Output conditioning control for output 0	EALLOW, LOCK	<a href="#">Go</a>
42h	CLB_OUTPUT_COND_CTRL_1	Output conditioning control for output 1	EALLOW, LOCK	<a href="#">Go</a>
44h	CLB_OUTPUT_COND_CTRL_2	Output conditioning control for output 2	EALLOW, LOCK	<a href="#">Go</a>
46h	CLB_OUTPUT_COND_CTRL_3	Output conditioning control for output 3	EALLOW, LOCK	<a href="#">Go</a>
48h	CLB_OUTPUT_COND_CTRL_4	Output conditioning control for output 4	EALLOW, LOCK	<a href="#">Go</a>
4Ah	CLB_OUTPUT_COND_CTRL_5	Output conditioning control for output 5	EALLOW, LOCK	<a href="#">Go</a>
4Ch	CLB_OUTPUT_COND_CTRL_6	Output conditioning control for output 6	EALLOW, LOCK	<a href="#">Go</a>
4Eh	CLB_OUTPUT_COND_CTRL_7	Output conditioning control for output 7	EALLOW, LOCK	<a href="#">Go</a>
50h	CLB_MISC_ACCESS_CTRL	Miscellaneous Access and enable control	EALLOW, LOCK	<a href="#">Go</a>

**Table 8-21. CLB\_LOGIC\_CONFIG\_REGS Registers (continued)**

Offset	Acronym	Register Name	Write Protection	Section
51h	CLB_SPI_DATA_CTRL_HI	CLB to SPI buffer control High	EALLOW, LOCK	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. [Table 8-22](#) shows the codes that are used for access types in this section.

**Table 8-22. CLB\_LOGIC\_CONFIG\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1C	W1C	Write 1 to clear
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 8.10.2.1 CLB\_COUNT\_RESET Register (Offset = 2h) [Reset = 0000000h]

CLB\_COUNT\_RESET is shown in [Figure 8-22](#) and described in [Table 8-23](#).

Return to the [Summary Table](#).

Counter Block RESET

**Figure 8-22. CLB\_COUNT\_RESET Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit	Field	Type	Reset	Description
15-13	RESERVED	R/W1C	0h	Reserved
12-8	SHIFT	R/W1C	0h	This is a 5 bit value which denotes the first bit position of register R0 from which the Least Significant Bit of the output data should start. 00000 Output data is R0[15:0] 00001 Output data is R0[16:1] 00010 Output data is R0[17:2] 00011 Output data is R0[18:3] ... ... 10000 Output data is R0[31:16] Reset type: SYSRSn
7	STRB_DEL	R/W1C	0h	0 Selected strobe event goes directly to SPI module 1 Selected strobe event is delayed by 4 CLB clock cycles to SPI module (This is done to facilitate use of STROBE as the same event to initiate a HLC task that can get the required data on to R0 for SPI data transfer before Strobe becomes valid at SPI block) Reset type: SYSRSn
6-5	RESERVED	R/W1C	0h	Reserved
4-0	STRB	R/W1C	0h	This is a 5 bit value which selects one of the HLC_EVENT inputs to be treated as the data_valid strobe Reset type: SYSRSn

### 8.10.3 CLB\_LOGIC\_CONTROL\_REGS Registers

Table 8-63 lists the memory-mapped registers for the CLB\_LOGIC\_CONTROL\_REGS registers. All register offset addresses not listed in Table 8-63 should be considered as reserved locations and the register contents should not be modified.

**Table 8-63. CLB\_LOGIC\_CONTROL\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	CLB_LOAD_EN	Global enable & indirect load enable control, only Global Enable Bit is LOCK protected	LOCK	<a href="#">Go</a>
2h	CLB_LOAD_ADDR	Indirect address		<a href="#">Go</a>
4h	CLB_LOAD_DATA	Data for indirect loads		<a href="#">Go</a>
6h	CLB_INPUT_FILTER	Input filter selection for both edge detection and synchronizers	LOCK	<a href="#">Go</a>
8h	CLB_IN_MUX_SEL_0	Input selection to decide between Signals and GP register	LOCK	<a href="#">Go</a>
Ah	CLB_LCL_MUX_SEL_1	Input Mux selection for local mux	LOCK	<a href="#">Go</a>
Ch	CLB_LCL_MUX_SEL_2	Input Mux selection for local mux	LOCK	<a href="#">Go</a>
Eh	CLB_BUF_PTR	PUSH and PULL pointers		<a href="#">Go</a>
10h	CLB_GP_REG	General purpose register for CELL inputs		<a href="#">Go</a>
12h	CLB_OUT_EN	CELL output enable register		<a href="#">Go</a>
14h	CLB_GLBL_MUX_SEL_1	Global Mux select for CELL inputs	LOCK	<a href="#">Go</a>
16h	CLB_GLBL_MUX_SEL_2	Global Mux select for CELL inputs	LOCK	<a href="#">Go</a>
18h	CLB_PRESCALE_CTRL	Prescaler register control	LOCK	<a href="#">Go</a>
20h	CLB_INTR_TAG_REG	Interrupt Tag register		<a href="#">Go</a>
22h	CLB_LOCK	Lock control register	EALLOW	<a href="#">Go</a>
24h	CLB_HLC_INSTR_READ_PTR	HLC instruction read pointer		<a href="#">Go</a>
26h	CLB_HLC_INSTR_VALUE	HLC instruction read value		<a href="#">Go</a>
2Eh	CLB_DBG_OUT_2	Visibility for CLB inputs and final asynchronous outputs		<a href="#">Go</a>
30h	CLB_DBG_R0	R0 of High level Controller		<a href="#">Go</a>
32h	CLB_DBG_R1	R1 of High level Controller		<a href="#">Go</a>
34h	CLB_DBG_R2	R2 of High level Controller		<a href="#">Go</a>
36h	CLB_DBG_R3	R3 of High level Controller		<a href="#">Go</a>
38h	CLB_DBG_C0	Count of Unit 0		<a href="#">Go</a>
3Ah	CLB_DBG_C1	Count of Unit 1		<a href="#">Go</a>
3Ch	CLB_DBG_C2	Count of Unit 2		<a href="#">Go</a>
3Eh	CLB_DBG_OUT	Outputs of various units in the Cell		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 8-64 shows the codes that are used for access types in this section.

**Table 8-64. CLB\_LOGIC\_CONTROL\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
R-1	R -1	Read Returns 1s
Write Type		

**Table 8-64. CLB\_LOGIC\_CONTROL\_REGS Access Type Codes (continued)**

Access Type	Code	Description
W	W	Write
W1C	W 1C	Write 1 to clear
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 8.10.3.1 CLB\_LOAD\_EN Register (Offset = 0h) [Reset = 0000h]

CLB\_LOAD\_EN is shown in [Figure 8-62](#) and described in [Table 8-65](#).

Return to the [Summary Table](#).

Global enable & indirect load enable control, only Global Enable Bit is LOCK protected

**Figure 8-62. CLB\_LOAD\_EN Register**

15	14	13	12	11	10	9	8
RESERVED							
R-0-0h							
7	6	5	4	3	2	1	0
RESERVED			PIPELINE_EN	NMI_EN	STOP	GLOBAL_EN	LOAD_EN
R-0-0h			R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

**Table 8-65. CLB\_LOAD\_EN Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-5	RESERVED	R-0	0h	Reserved
4	PIPELINE_EN	R/W	0h	This bit controls pipelining of all the CLB operations in HLC and Counter blocks. Pipelined operation is enabled when this bit is set to 1. Reset type: SYSRSn
3	NMI_EN	R/W	0h	This bit controls the generation of NMI along with the interrupt whenever a INTR operation is executed by the HLC. NMI generation is disabled by default. It will be enabled when this bit is set to 1. Reset type: SYSRSn
2	STOP	R/W	0h	This bit defines the behaviour of the sequential elements in the CELL during debug HALTs of the CPU. If this bit is set to 0, the debug HALT condition is ignored. Reset type: SYSRSn
1	GLOBAL_EN	R/W	0h	This bit is a global enable signal for the logic in the CELL. This also acts as a soft reset for the CELL logic. CLB outputs (including LUTs and OUTLUTs) will be gated when this bit is cleared from 1 to 0, i.e., the CLB outputs will be low when GLOBAL_EN is low. Additionally, the FSM and AOC blocks will also be reset. Note that when this bit goes low, the COUNTER blocks and HLC are simply halted, but they will NOT be reset internally. This allows the ability to preload these submodules when GLOBAL_EN is 0. This bit is normally set after all the other configuration settings are completed. This bit is LOCK protected. Reset type: SYSRSn
0	LOAD_EN	R/W	0h	A write with this bit set to 1 will pulse the Load Enable signal for the indirect register loads in the CELL. Reset type: SYSRSn

### 8.10.3.2 CLB\_LOAD\_ADDR Register (Offset = 2h) [Reset = 0000000h]

CLB\_LOAD\_ADDR is shown in [Figure 8-63](#) and described in [Table 8-66](#).

Return to the [Summary Table](#).

Indirect address

RESERVED		TAP				STRB	CLKEN	
R-0-0h		R/W-0h				R/W-0h	R/W-0h	

**Table 8-77. CLB\_PRESCALE\_CTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	PRESCALE	R/W	0h	16-bit Value of prescaler to be used for the counter as reference to reset when reaching this value. The counter is a simple incrementing counter which will count up to the reference value and reset to 0 and this cycle will continue as long as the counter is enabled. This 16-bit register value is used as a reference for the 16-bit counter to reset to zero whenever count reaches this value. Reset type: SYSRSn
15-6	RESERVED	R-0	0h	Reserved
5-2	TAP	R/W	0h	TAP Select value. These 4 bits will be used as a select to tap one of the 16 register bit position of the counter as the output. 0000 selects Counter Bit position 0 0001 selects Counter Bit position 1 .... 1111 selects Counter Bit position 15 Reset type: SYSRSn
1	STRB	R/W	0h	When set to 0, a strobe output will be sent out whenever the counter value matches the PRESCALE_VALUE. When set to 1, the output of the counter register bit position as selected by TAP_SELECT_VALUE will be sent out. Reset type: SYSRSn
0	CLKEN	R/W	0h	Enable the prescale clock/strobe generator. A 16-bit counter is used to either generate a strobe or send out a selected counter bit position to the CLB CELL. This is meant to be a general purpose strobe/prescaled clock which can be used by the CELL logic if needed. This will be sent to the CELL through one of the LCL_IN MUX ports. Reset type: SYSRSn

### 8.10.3.14 CLB\_INTR\_TAG\_REG Register (Offset = 20h) [Reset = 0000h]

CLB\_INTR\_TAG\_REG is shown in [Figure 8-75](#) and described in [Table 8-78](#).

Return to the [Summary Table](#).

Interrupt Tag register

### 8.10.4 CLB\_DATA\_EXCHANGE\_REGS Registers

Table 8-91 lists the memory-mapped registers for the CLB\_DATA\_EXCHANGE\_REGS registers. All register offset addresses not listed in Table 8-91 should be considered as reserved locations and the register contents should not be modified.

**Table 8-91. CLB\_DATA\_EXCHANGE\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	CLB_PUSH	CLB_PUSH FIFO Registers (from HLC)		<a href="#">Go</a>
40h	CLB_PULL	CLB_PULL FIFO Registers (TO HLC)		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 8-92 shows the codes that are used for access types in this section.

**Table 8-92. CLB\_DATA\_EXCHANGE\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 8.10.4.1 CLB\_PUSH Register (Offset = 0h) [Reset = 00000000h]

CLB\_PUSH is shown in [Figure 8-88](#) and described in [Table 8-93](#).

Chapter 9  
**Dual-Clock Comparator (DCC)**

---

This chapter describes the Dual-Clock Comparator (DCC) module.

<b>9.1 Introduction</b> .....	<b>1669</b>
<b>9.2 Module Operation</b> .....	<b>1670</b>
<b>9.3 Interrupts</b> .....	<b>1676</b>
<b>9.4 Software</b> .....	<b>1677</b>
<b>9.5 DCC Registers</b> .....	<b>1678</b>

## 9.1 Introduction

The dual-clock comparator module is used for evaluating and monitoring the clock input based on a second clock, which can be a more accurate and reliable version. This instrumentation is used to detect faults in clock source or clock structures, thereby enhancing the system's safety metrics.

### 9.1.1 Features

The main features of each of the DCC modules are:

- Allows the application to make sure that a fixed ratio is maintained between frequencies of two clock signals.
- Supports the definition of a programmable tolerance window in terms of the number of reference clock cycles.
- Supports continuous monitoring without requiring application intervention.
- Supports a single-sequence mode for spot measurements.
- Allows the selection of a clock source for each of the counters, resulting in several specific use cases.

### 9.1.2 Block Diagram

Figure 9-1 shows how the DCC connects to the rest of the system. Figure 9-2 shows the main concept of the DCC module.

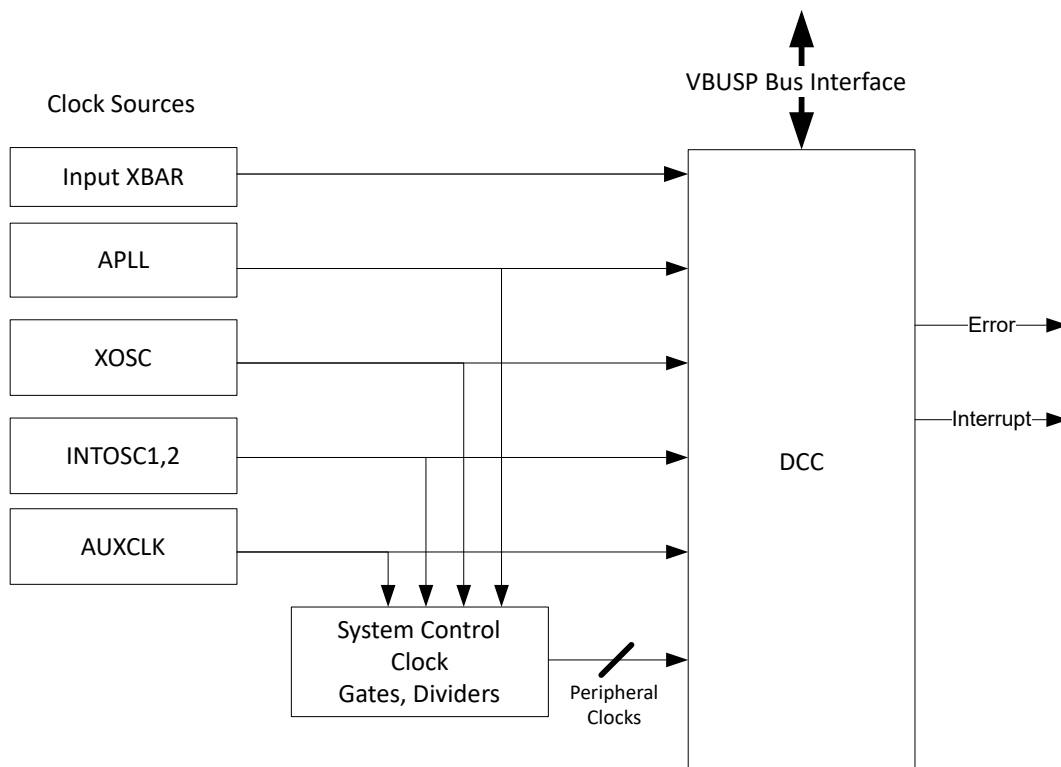

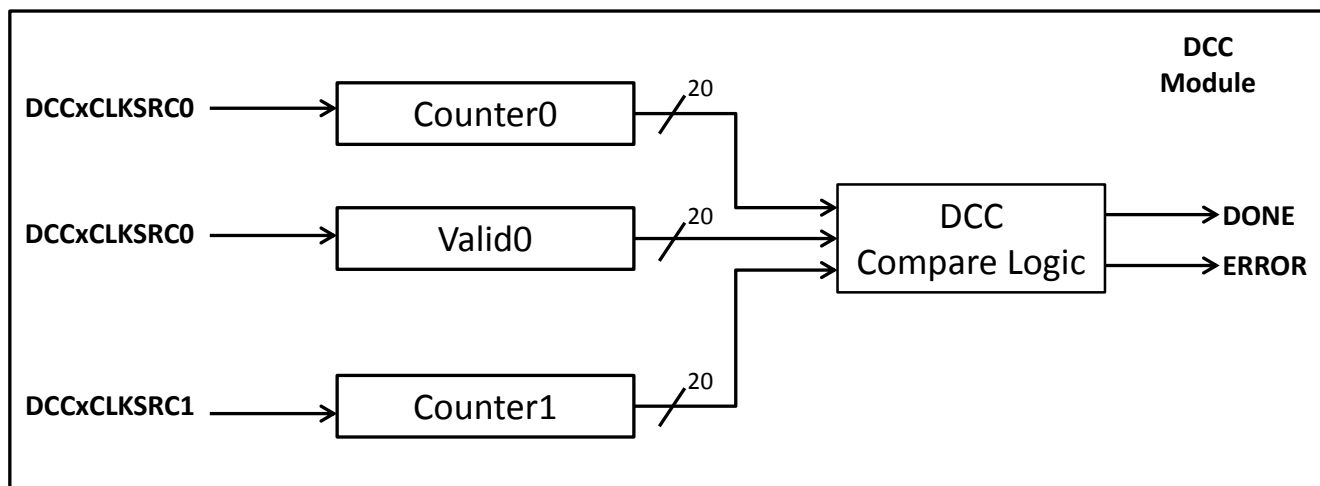

Figure 9-1. DCC Module Overview

**Figure 9-2. DCC Operation**

## 9.2 Module Operation

As shown in [Figure 9-2](#), DCC contains three counters – Counter0, Valid0 and Counter1. Initially, all counters are loaded with the user-defined, pre-load value. Counter0 and Counter1 start decrementing once the DCC is enabled at rates determined by the frequencies of Clock0 and Clock1, respectively. When Counter0 equals 0 (expires), the Valid0 counter decrements at a rate determined by Clock0. If Counter1 decrements to 0 in the valid window, then no error is generated and Clock1 is considered to be good within allowable tolerance as configured by the user.

### 9.2.1 Configuring DCC Counters

Counter0 and Counter1 are configured based on the ratio between the frequencies of Clock0 and Clock1 ( $F_{clk1} \times \text{Counter0} = F_{clk0} \times \text{Counter1}$ ). The Valid0 counter provides tolerance and is configured based on the error in DCC. Since Clock0 and Clock1 are asynchronous, the start and stop of the counters do not occur synchronously. Hence, while configuring the counters, two different sources of errors must be accounted for:

- DCC Errors due to the asynchronous timing of Clock0 and Clock1: this depends on the frequency of Clock0 and Clock1:
  - If  $F_{clk1} > F_{clk0}$ , then Async. Error (in Clock0 cycles) =  $2 + 2 \times (F_{sysclk}/F_{clk0})$
  - If  $F_{clk1} < F_{clk0}$ , then Async. Error (in Clock0 cycles) =  $2 \times (F_{clk0}/F_{clk1}) + 2 \times (F_{sysclk}/F_{clk0})$
  - If  $F_{clk1}$  is unknown, then Async. Error (in Clock0 cycles) =  $2 + 2 \times (F_{sysclk}/F_{clk0})$
- Digitization Error = 8 Clock0 cycles

#### DCC Error (in Clock0 Cycles) = Async. Error + Digitization Error

DCC error shows up as a frequency error for clock under measurement. This error is DCC induced and does not represent error in frequency of clock under measurement. The application needs to take this into consideration while configuring the counters, and determine a desirable tolerance for DCC error that defines the window of measurement. To illustrate:

#### Window (in Clock0 Cycles) = (DCC Error)/(0.01 × Tolerance)

For example, if DCC Error is 10 and the tolerance desired is  $\pm 0.1\%$ , then:

$$\text{Window (in Clock0 Cycles)} = 10 / (0.01 \times 0.1) = 10000$$

Based on above formula for Window, if the desired tolerance is low, then the counter values are large and increase the window of measurement. This means that counter values for a tolerance of 0.1% are larger than that of 0.2%. So, based on the application defined tolerance, define the window of measurement in terms of Clock0 cycles.

The clock under measurement can have an allowed frequency error. If this error is expected, then the error can also be accounted while configuring counters. For example, if measuring INTOSC1/2 frequency using an external crystal as a reference clock, the allowable tolerance of INTOSC1/2 (for example,  $\pm 1\%$ ) can be accounted for and factored into the counter configuration. The formula is:

$$\text{Frequency Error Allowed (in Clock0 Cycles)} = \text{Window} \times (\text{Allowable Frequency Tolerance (in \%)} / 100)$$

$$\text{Total Error (in Clock0 Cycles)} = \text{DCC Error} + \text{Frequency Error Allowed}$$

The following equations are used to configure counter values:

$$\text{Counter0 (DCCNTSEED0)} = \text{Window} - \text{Total Error}$$

$$\text{Valid0 (DCCVALIDSEED0)} = 2 \times \text{Total Error}$$

$$\text{Counter1 (DCCNTSEED1)} = \text{Window} \times (F_{clk1}/F_{clk0})$$

#### Note

Counter1 is a 20-bit counter, so the maximum possible value cannot exceed 1048575. If the value does exceed, then increase the desired Tolerance for DCC error, so that Window of measurement is lowered. The following formula can be used to compute minimum tolerance possible:

$$\text{Tolerance (\%)} = (100 \times \text{DCC Error} \times (F_{clk1}/F_{clk0})) / 1048575$$

### 9.2.2 Single-Shot Measurement Mode

The DCC module can be programmed to count down one time by enabling the single-shot mode. In this mode, the DCC stops operating when the down counter0 and the valid counter0 reach 0.

At the end of one sequence of counting down in this single-shot mode, the DCC gets disabled automatically, which prevents further counting. This mode is typically used for spot-checking the frequency of a signal.

#### Example-1: Validating PLLRAWCLK frequency

A practical example of the usage is to validate the PLL output clock frequency using the XTAL as the reference clock. Assume XTAL is 10MHz, PLL output frequency is 100MHz, SYSCLK is 100MHz, allowable Frequency Tolerance is 0.1%, and DCC Tolerance required is 0.1%. The measurement sequence proceeds as follows:

- Set Clock0 source for Counter0 and Valid0 as XTAL, and Clock1 source for Counter1 as PLL output clock.
- Based on the equations defined in [Section 9.2.1](#), calculated seed values for Counters can be Counter0 = 29940; Valid0 = 120; Counter1 = 300000
- Once the DCC is enabled, the counters Counter0 and Counter1 both start counting down from the seed values.
- When Counter0 reaches zero, Counter0 automatically triggers the Valid0 counter.
- When Valid0 reaches zero and Counter1 is not zero, an ERROR status flag is set and a "DCC error" is sent to the PIE. Counter1 is frozen so that the counter stops counting down any further. The application can enable an interrupt to be generated from the PIE whenever this DCC error is indicated.
- The application then needs to clear the ERROR status flag and restart the DCC module so that the module is ready for the next spot measurement.

If there is no error generated at the end of the sequence, then the DONE status flag is set and a DONE interrupt is generated. The application must clear the DONE flag before restarting the DCC.

#### Error Conditions:

An error condition is generated by any one of the following:

1. Counter1 counts down to 0 before Counter0 reaches 0. This means that Clock1 is faster than expected, or Clock0 is slower than expected. This error includes the case when Clock0 is stuck at 1 or 0.
2. Counter1 does not reach 0 even when Counter0 and Valid0 have both reached 0. This means that Clock1 is slower than expected. This error includes the case when Clock1 is stuck at 1 or 0.

Any error freezes the counters from counting. An application can then read out the counter values to help determine what caused the error.

### Example-2: Measuring AUXCLKIN frequency

Another example of single-shot mode is to measure the frequency of AUXCLKIN (unknown frequency) using INTOSC1 (10MHz) as the reference clock and SYSClk is 10MHz. The measurement sequence proceeds as follows:

- Set Clock0 source for Counter0 and Valid0 as INTOSC1 (10MHz), and Clock1 source for Counter1 as AUXCLKIN.
- Now configure counter values using equations in [Section 9.2.1](#). For tolerance = ±0.1%, Total Error = 10 clock0 cycles; Window = 10000 clock0 cycles; Counter0 = 9990; Valid0 = 20. Since Clock1 frequency (Fclk1) is unknown, the Counter1 value can be set to the maximum value, 1048575 (0xFFFFF).
- Once the DCC is enabled, the counters Counter0 and Counter1 both start counting down from the seed values.
- Since Counter1 is set to the maximum value, 1048575, the counter does not expire when Counter0 and Valid0 have expired. This generates an error that is expected and the application ignores this error and uses Counter1 values to compute the frequency of Clock1 (Fclk1).
- Knowing the frequency of Clock0 (INTOSC1), Fclk0 = 10MHz, and using [Equation 1](#), the frequency of AUXCLKIN, Fclk1, can be measured:

$$F_{clk1} = \frac{F_{clk0} \times (1048575 - Meas. Counter1)}{(Counter0 + Valid0)} = \frac{10 \times (1048575 - Meas. Counter1)}{(9990 + 20)} \quad (1)$$

### 9.2.3 Continuous Monitoring Mode

In this mode, the DCC is used by the application to make sure that two clock signals maintain the correct frequency ratio. Suppose the application wants to make sure that the PLL output signal always maintains a fixed frequency relationship with the XTAL:

- In this case, the application can use the XTAL as the Clock0 signal (for Counter0 and Valid0) and the PLL output as the Clock1 (for Counter1).
- The seed values of Counter0, Valid0 and Counter1 are selected based on the equations defined in [Section 9.2.1](#) such that if the actual frequencies of Clock0 and Clock1 are equal to the expected frequencies, then the Counter1 reaches zero during the count down of the Valid0 counter.
- If the Counter1 reaches zero during the count down of the Valid0 counter, then all the counters (Counter0, Valid0, Counter1) are reloaded with the initial seed values.
- This sequence of counting down and checking then continues as long as there is no error, or until the DCC module is disabled.
- The counters must get reloaded if the application resets and restarts the DCC module.

#### Error Conditions:

An error condition is generated by one of the following:

1. Counter1 counts down to 0 before Counter0 reaches 0. This means that Clock1 is faster than expected or Clock0 is slower than expected. This condition includes the case when Clock0 is stuck at 1 or 0.
2. Counter1 does not reach 0 even when Counter0 and Valid0 have both reached 0. This means that Clock1 is slower than expected. This condition includes the case when Clock1 is stuck at 1 or 0.

Any error freezes the counters from counting. An application can then read out the counter values to help determine what caused the error.

### 9.2.4 Error Conditions

While operating in continuous mode, the counters get reloaded with the seed values and continue counting down under the following conditions:

- The module is reset or restarted by the application, OR
- Counter0, Valid 0, and Counter1 all reach 0 without any error.

**Figure 9-3. Counter Relationship**

**Figure 9-4. Clock1 Slower Than Clock0 - Results in an Error and Stops Counting**

**Figure 9-5. Clock1 Faster Than Clock0 - Results in an Error and Stops Counting**

**Figure 9-6. Clock1 Not Present - Results in an Error and Stops Counting**

**Figure 9-7. Clock0 Not Present - Results in an Error and Stops Counting**

### 9.3 Interrupts

DCC generates an interrupt on either of two events:

- DCC finishes counting and all the counters expire within a defined window indicating DONE operation, provided `DCCGCTRL.DONENA = 1`.
- DCC finishes counting with error where counters do not expire in a defined window. This indicates an ERROR event, and sets an interrupt provided `DCCGCTRL.ERRENA = 1`.

## 9.4 Software

### 9.4.1 DCC Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/dcc

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 9.4.1.1 DCC Single shot Clock verification - SINGLE\_CORE

FILE: dcc\_ex1\_single\_shot\_verification.c

This program uses the XTAL oscillator as a reference clock to verify the frequency of the PLL.

The Dual-Clock Comparator Module 1 is used for the clock verification. The clocksource0 is the reference clock (Fclk0 = 20Mhz) and the clocksource1 is the clock that needs to be verified (Fclk1 = 200Mhz). Seed is the value that gets loaded into the Counter.

Please refer to the TRM for details on counter seed values to be set.

##### *External Connections*

- None

##### *Watch Variables*

- *result* - Status of the clock verification

#### 9.4.1.2 DCC Single shot Clock measurement - SINGLE\_CORE

FILE: dcc\_ex2\_single\_shot\_measurement.c

This program demonstrates Single Shot measurement of the INTOSC1 clock post trim using XTAL as the reference clock.

The Dual-Clock Comparator Module 1 is used for the clock measurement. The clocksource0 is the reference clock (Fclk0 = 20Mhz) and the clocksource1 is the clock that needs to be measured (Fclk1 = 10Mhz). Since the frequency of clock1 needs to be measured, an initial seed is set to the max value of the counter.

Please refer to the TRM for details on counter seed values to be set.

##### *External Connections*

- None

##### *Watch Variables*

- *result* - Status if the INTOSC1 clock measurement completed successfully.
- *meas\_freq1* - measured clock frequency, in this case for INTOSC1.

#### 9.4.1.3 DCC Continuous clock monitoring - SINGLE\_CORE

FILE: dcc\_ex3\_continuous\_monitoring\_of\_clock.c

This program demonstrates continuous monitoring of PLL Clock in the system using INTOSC1 as the reference clock. This would trigger an error signal on any error, causing the decrement/ reload of counters to stop. The Dual-Clock Comparator Module 1 is used for the clock monitoring. The clocksource0 is the reference clock (Fclk0 = 10Mhz) and the clocksource1 is the clock that needs to be monitored (Fclk1 = 200Mhz). The clock0 and clock1 seed are set automatically by the error tolerances defined in the sysconfig file included in this project. For the sake of demo an un-realistic tolerance is assumed to generate an error on continuous monitoring.

Please refer to the TRM for details on counter seed values to be set. Note : When running in flash configuration it is good to do a reset & restart after loading the example to remove any stale flags/states.

##### *External Connections*

- None

##### *Watch Variables*

- *result* - Status of the PLLRAW clock monitoring
- *cnt0* - Counter0 Value measure when error is generated
- *cnt1* - Counter1 Value measure when error is generated
- *valid* - Valid0 Value measure when error is generated

## 9.5 DCC Registers

This section describes the Dual Clock Comparator Registers.

### Note

The DCC is used by Boot ROM; hence, the register values can be different than the hardware reset value. You need to make sure to configure the values of these registers to the desired value before enabling the DCC.

### 9.5.1 DCC Base Address Table

**Table 9-1. DCC Base Address Table**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	CPU2	CPU2.DMA	Pipeline Protected
Instance	Structure								
Dcc0Regs	<a href="#">DCC_REGS</a>	DCC0_BASE	0x0005_E700	YES	-	-	YES	-	YES
Dcc1Regs	<a href="#">DCC_REGS</a>	DCC1_BASE	0x0005_E740	YES	-	-	YES	-	YES
Dcc2Regs	<a href="#">DCC_REGS</a>	DCC2_BASE	0x0005_E780	YES	-	-	YES	-	YES

### 9.5.2 DCC\_REGS Registers

Table 9-2 lists the memory-mapped registers for the DCC\_REGS registers. All register offset addresses not listed in Table 9-2 should be considered as reserved locations and the register contents should not be modified.

**Table 9-2. DCC\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	DCCGCTRL	Starts / stops the counters. Clears the error signal.		<a href="#">Go</a>
8h	DCCCNTSEED0	Seed value for the counter attached to Clock Source 0.		<a href="#">Go</a>
Ch	DCCVALIDSEED0	Seed value for the timeout counter attached to Clock Source 0.		<a href="#">Go</a>
10h	DCCCNTSEED1	Seed value for the counter attached to Clock Source 1.		<a href="#">Go</a>
14h	DCCSTATUS	Specifies the status of the DCC Module.		<a href="#">Go</a>
18h	DCCCNT0	Value of the counter attached to Clock Source 0.		<a href="#">Go</a>
1Ch	DCCVALID0	Value of the valid counter attached to Clock Source 0.		<a href="#">Go</a>
20h	DCCCNT1	Value of the counter attached to Clock Source 1.		<a href="#">Go</a>
24h	DCCCLKSRC1	Selects the clock source for Counter 1.		<a href="#">Go</a>
28h	DCCCLKSRC0	Selects the clock source for Counter 0.		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 9-3 shows the codes that are used for access types in this section.

**Table 9-3. DCC\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
R-1	R -1	Read Returns 1s
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 9.5.2.1 DCCGCTRL Register (Offset = 0h) [Reset = 00005555h]

DCCGCTRL is shown in [Figure 9-8](#) and described in [Table 9-4](#).

Return to the [Summary Table](#).

Starts / stops the counters. Clears the error signal.

**Figure 9-8. DCCGCTRL Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Chapter 10  
**Direct Memory Access (DMA)**

---

The direct memory access (DMA) module provides a hardware method of transferring data between peripherals and memory without intervention from the CPU; thereby, freeing up bandwidth for other system functions. Additionally, the DMA has the capability to orthogonally rearrange the data as the data is transferred as well as “ping-pong” data between buffers. These features are useful for structuring data into blocks for CPU processing.

## 10.1 Introduction

The strength of a controller is not measured purely in processor speed, but in total system capabilities. As a part of the equation, any time the CPU bandwidth for a given function can be reduced, the greater the system capabilities. Many times applications spend a significant amount of the bandwidth moving data, whether moving data from off-chip memory to on-chip memory, from a peripheral such as an analog-to-digital converter (ADC) to RAM, or from one peripheral to another. Furthermore, many times this data comes in a format that is not conducive to the optimum processing powers of the CPU. The DMA module described in this chapter has the ability to free up CPU bandwidth and rearrange the data into a pattern for more streamlined processing.

The DMA module is an event-based machine, meaning the DMA module requires a peripheral or software trigger to start a DMA transfer. Although the DMA module can be made into a periodic time-driven machine by configuring a timer as the DMA trigger source, there is no mechanism within the module to start memory transfers periodically. The DMA module has six independent DMA channels that can be configured separately and each channel contains an independent PIE interrupt to let the CPU know when a DMA transfer has either started or completed. Five of the six channels are exactly the same, while Channel 1 has the ability to be configured at a higher priority than the others. At the heart of the DMA is a state machine and tightly coupled address control logic. This address control logic allows for rearrangement of the block of data during the transfer as well as the process of ping-ponging data between buffers. Each of these features is discussed in detail in this chapter.

### 10.1.1 Features

DMA features include:

- Six channels with independent PIE interrupts
- Each DMA channel can be triggered from multiple peripheral trigger sources independently
- Word Size: 16-bit or 32-bit (SPI limited to 16-bit)
- Throughput: 3 cycles/word without arbitration

### 10.1.2 Block Diagram

Figure 10-1 shows a device-level block diagram of the DMA.

Figure 10-1. DMA Block Diagram

## 10.2 Architecture

### 10.2.1 Peripheral Interrupt Event Trigger Sources

Each DMA Channel can be configured to trigger by software and other peripheral triggers events. DMACHSRCSELx register can be used to configure DMA Trigger sources for each DMA channel. CHx.MODE.PERINTSEL register bit field can be set to channel number (CHx.MODE.PERINTSEL = x) as shown in [Figure 10-2](#). Included in these DMA Trigger sources are five external interrupt signals that can be connected to most of the general-purpose input/output (GPIO) pins on the device. This adds significant flexibility to the event trigger capabilities. Upon receipt of a peripheral interrupt event signal, the DMA automatically sends a clear signal to the interrupt source so that subsequent interrupt events occur.

---

#### Note

To use the system-level DMA Trigger source selection, the DMA internal trigger source selection configuration for each channel can be done using the DMACHSRCSELx register and the CHx.MODE.PERINTSEL register. See [Table 10-1](#) or the DMACHSRCSELx register definition for a complete list of DMA trigger sources.

---

Regardless of the value of the MODE.CHx[PERINTSEL] bit field, software can always force a trigger by using the CONTROL.CHx[PERINTFRC] bit. Likewise, software can always clear a pending DMA trigger using the CONTROL.CHx[PERINTCLR] bit.

Once a particular peripheral trigger event sets a channel's PERINTFLG bit, the bit remains pending until the priority logic of the state machine starts the burst transfer for that channel. Once the burst transfer starts, the flag is cleared. If a new peripheral trigger event is generated while a burst is in progress, the burst completes before responding to the new peripheral trigger event (after proper prioritization). If a third peripheral trigger event occurs before the pending event is serviced, an error flag is set in the CONTROL.CHx[OVRFLG] bit. If a peripheral trigger event occurs at the same time as the latched flag is being cleared, the trigger event has priority and the PERINTFLG remains set.

[Figure 10-3](#) shows a diagram of the trigger select circuit.

[Table 10-1](#) shows the peripheral trigger source options that are available for each channel.

### 10.2.2 DMA Bus

The DMA bus architecture consists of a 32-bit address bus, a 32-bit data read bus, and a 32-bit data write bus. Memories and register locations connected to the DMA bus by way of interfaces that sometimes share resources with the CPU memory or peripheral bus.

### 10.3 Address Pointer and Transfer Control

The DMA state machine is, at the most basic level, two nested loops.

#### Burst (Inner) Loop:

The burst (inner) loop transfers a programmable number of words set by (BURST\_SIZE + 1) register when a DMA channel trigger (Peripheral or Software trigger) is received. The BURST\_SIZE register allows a maximum of 32 sixteen-bit words to be transferred in one burst. Each DMA channel supports both 16-bit or 32-bit word burst that can be controlled by MODE.DATASIZE bit field. Each DMA channel contains a shadowed address pointer for the source (SRC\_ADDR\_SHADOW) and the destination (DST\_ADDR\_SHADOW) address. At the beginning of each transfer, the shadowed version of each pointer is copied into the respective active (SRC\_ADDR\_ACTIVE or DST\_ADDR\_ACTIVE) register. During the burst loop, after each word is transferred, the signed value contained in the appropriate source or destination BURST\_STEP register is added to the active register:

$$\text{SRC\_ADDR\_ACTIVE} = \text{SRC\_ADDR\_ACTIVE} + \text{SRC\_BURST\_STEP}$$

$$\text{DST\_ADDR\_ACTIVE} = \text{DST\_ADDR\_ACTIVE} + \text{DST\_BURST\_STEP}$$

The burst (inner) loop transfers a burst of data when a DMA Channel Trigger (Peripheral or Software trigger) is received.

#### Transfer (Outer) Loop:

The Transfer (outer) loop transfers a programmable number of bursts set by (TRANSFER\_SIZE + 1) register for each channel. Since TRANSFER\_SIZE is a 16-bit register, the total size of a transfer allowed is well beyond any practical requirement. During the transfer loop, after each burst is complete, there are two methods that can be used to modify the active address pointer:

**Method 1** (Default): When address wrapping is disabled (SRC\_WRAP\_SIZE or DST\_WRAP\_SIZE is greater than TRANSFER\_SIZE), active address pointer is updated as shown below

$$\text{SRC\_ADDR\_ACTIVE} = \text{SRC\_ADDR\_ACTIVE} + \text{SRC\_TRANSFER\_STEP}$$

$$\text{DST\_ADDR\_ACTIVE} = \text{DST\_ADDR\_ACTIVE} + \text{DST\_TRANSFER\_STEP}$$

**Method 2:** Address wrapping gets enabled when SRC\_WRAP\_SIZE or DST\_WRAP\_SIZE is less than TRANSFER\_SIZE. This allows the channel to wrap multiple times within a single transfer. When the number of bursts is equal to (SRC/DST\_WRAP\_SIZE + 1) register, the state machine modifies the active address pointers as:

$$\text{SRC\_BEG\_ADDR\_ACTIVE} = \text{SRC\_BEG\_ADDR\_ACTIVE} + \text{SRC\_WRAP\_STEP}$$

$$\text{DST\_BEG\_ADDR\_ACTIVE} = \text{DST\_BEG\_ADDR\_ACTIVE} + \text{DST\_WRAP\_STEP}$$

$$\text{SRC\_ADDR\_ACTIVE} = \text{SRC\_BEG\_ADDR\_ACTIVE}$$

$$\text{DST\_ADDR\_ACTIVE} = \text{DST\_BEG\_ADDR\_ACTIVE}$$

At the end of DMA transfer, DMA can have transferred (BURST\_SIZE + 1) x (TRANSFER\_SIZE + 1) words.

### OneShot Mode:

OneShot mode is disabled by default.

When OneShot mode is disabled ( $\text{MODE.CHx}[\text{ONESHOT}] = 0$ ), DMA transfers one burst  $[(\text{BURST\_SIZE} + 1)$  words] of data each time a DMA Channel Trigger is received. After the burst is completed, the state machine moves on to the next pending channel in the priority scheme, even if another trigger for the channel just completed is pending. This feature keeps any single channel from monopolizing the DMA bus.

When OneShot mode is enabled ( $\text{MODE.CHx}[\text{ONESHOT}] = 1$ ), DMA transfers all the bursts  $[(\text{BURST\_SIZE} + 1) \times (\text{TRANSFER\_SIZE} + 1)$  words] on a single DMA channel trigger. Be careful when using this mode, since this can create a condition where one trigger uses up the majority of the DMA bandwidth.

### Continuous Mode:

Continuous mode is disabled by default.

When Continuous mode is disabled ( $\text{MODE.CHx}[\text{CONTINUOUS}] = 0$ ), DMA state machine disables channel after all bursts in a transfer loop ( $\text{TRANSFER\_COUNT} = 0$ ) are complete. The channel must be re-enabled by setting the RUN bit in the CONTROL register before another transfer can be started on that channel.

When Continuous mode is enabled ( $\text{MODE.CHx}[\text{CONTINUOUS}] = 1$ ), DMA state machine keep channel active even after all bursts in a transfer loop ( $\text{TRANSFER\_COUNT} = 0$ ) are complete.

Each DMA channel can trigger an EPIE interrupt for each DMA transfer either at start of DMA transfer or end of DMA transfer using  $\text{MODE.CHx}[\text{CHINTMODE}]$  bit.

**Source/Destination Address Pointers (SRC/DST\_ADDR)** The value written into the shadow register is the start address of the first location where data is read or written to.

At the beginning of a transfer the shadow register ( $\text{SRC/DST\_ADDR\_SHADOW}$ ) is copied into the active register ( $\text{SRC/DST\_ADDR\_ACTIVE}$ ). The active register performs as the current address pointer.

**Source/Destination Begin Address Pointers (SRC/DST\_BEG\_ADDR)** This is the wrap pointer.

The value written into the shadow register ( $\text{SRC/DST\_BEG\_ADDR\_SHADOW}$ ) is loaded into the active register ( $\text{SRC/DST\_BEG\_ADDR\_ACTIVE}$ ) at the start of a transfer. On a wrap condition, the active register ( $\text{SRC/DST\_BEG\_ADDR\_ACTIVE}$ ) is incremented by the signed value in the appropriate  $\text{SRC/DST\_WRAP\_STEP}$  register prior to being loaded into the active register ( $\text{SRC/DST\_ADDR\_ACTIVE}$ ).

For each channel, the transfer process can be controlled with the following size values:

**Source and Destination Burst Size (BURST\_SIZE)**

This specifies the number of words to be transferred in a burst.

This value is loaded into the BURST\_COUNT register at the beginning of each burst. The BURST\_COUNT decrements each word that is transferred and when the register reaches a zero value, the burst is complete, indicating that the next channel can be serviced. The behavior of the current channel is defined by the ONE\_SHOT bit in the MODE register. The maximum size of the burst is dictated by the type of peripheral. For the ADC, the burst size can be all 16 registers (if all 16 registers are used). For RAM, the burst size can be up to the maximum allowed by the BURST\_SIZE register, which is 32. See [Table 10-2](#) to understand how BURST\_SIZE register affects the number of 16-bit words transferred with respect to DATASIZE.

**Table 10-2. BURSTSIZE versus DATASIZE Behavior**

BURSTSIZE	Number of 16-bit words transferred in	
	DataSize = 16-bit data	DataSize = 32-bit data
0	1	2
1	2	2
2	3	4
3	4	4
4	5	6
5	6	6
6	7	8
7	8	8
8	9	10
9	10	10
10	11	12
11	12	12
*	*	*
*	*	*
*	*	*
30	31	32
31	32	32

**Source and Destination Transfer Size (TRANSFER\_SIZE)**

This specifies the number of bursts to be transferred per CPU interrupt (if enabled).

Whether this interrupt is generated at the beginning or the end of the transfer is defined in the CHINTMODE bit in the MODE register. Whether the channel remains enabled or not after the transfer is completed is defined by the CONTINUOUS bit in the MODE register. The TRANSFER\_SIZE register is loaded into the TRANSFER\_COUNT register at the beginning of each transfer. The TRANSFER\_COUNT register keeps track of how many bursts of data the channel has transferred and when the register reaches zero, the DMA transfer is complete.

**Source/Destination Wrap Size (SRC/DST\_WRAP\_SIZE)** This specifies the number of bursts to be transferred before the current address pointer wraps around to the beginning.

This feature is used to implement a circular addressing type function. This value is loaded into the appropriate SRC/DST\_WRAP\_COUNT register at the beginning of each transfer. The SRC/DST\_WRAP\_COUNT registers keep track of how many bursts of data the channel has transferred and when the registers reach zero, the wrap procedure is performed on the appropriate source or destination address pointer. A separate size and count register is allocated for source and destination pointers. To disable the wrap function, assign the value of these registers to be larger than the TRANSFER\_SIZE.

---

#### Note

The value written to the SIZE registers is one less than the intended size. So, to transfer three 16-bit words, the value 2 can be placed in the SIZE register.

Regardless of the state of the DATASIZE bit, the value specified in the SIZE registers are for 16-bit addresses. So, to transfer three 32-bit words, the value 5 can be placed in the SIZE register.

---

For each source/destination pointer, the address changes can be controlled with the following step values:

**Source/Destination Burst Step (SRC/DST\_BURST\_STEP)** Within each burst transfer, the address source and destination step sizes are specified by these registers.

This value is a signed 2s compliment number so that the address pointer can be incremented or decremented as required. If no increment is desired, such as when accessing the data receive or transmit registers in a communication peripheral, the value of these registers can be set to zero.

**Source/Destination Transfer Step (SRC/DST\_TRANSFER\_STEP)** This specifies the address offset to start the next burst transfer after completing the current burst transfer.

This is used in cases where registers or data memory locations are spaced at constant intervals. This value is a signed 2s compliment number so that the address pointer can be incremented or decremented as required.

**Source/Destination Wrap Step (SRC/DST\_WRAP\_STEP)** When the wrap counter reaches zero, this value specifies the number of words to add/subtract from the SRC/DST\_BEG\_ADDR pointer and hence sets the new start address.

This implements a circular type of addressing mode, useful in many applications. This value is a signed 2s compliment number so that the address pointer can be incremented or decremented as required.

---

#### Note

Regardless of the state of the DATASIZE bit, the value specified in the STEP registers are for 16-bit addresses. So, to increment one 32-bit address, a value of 2 can be placed in these registers.

---

**Channel Interrupt Mode (CHINTMODE)** This mode bit selects whether the DMA interrupt from the respective channel is generated at the beginning of a new transfer or at the end of the transfer.

If implementing a ping-pong buffer scheme with continuous mode of operation, then the interrupt can be generated at the beginning, just after the working registers are copied to the shadow set. If the DMA does not operate in continuous mode, then the interrupt is typically generated at the end when the transfer is complete.

All of the previous features and modes are shown in [Figure 10-4](#). The following items are in reference to [Figure 10-4](#).

- The *HALT* points represent where the channel halts operation when interrupted by a high priority channel 1 trigger, or when the HALT command is set, or when an emulation halt is issued and the FREE bit is cleared to 0.
- The SRC/DST\_ADDR\_ACTIVE registers are not affected by SRC/DST\_BEG\_ADDR\_ACTIVE at the start of a transfer. SRC/DST\_BEG\_ADDR\_ACTIVE only affects the SRC/DST\_ADDR\_ACTIVE registers on a wrap. Following is what happens when a transfer first starts:
  - SRC/DST\_BEG\_ADDR\_SHADOW remains unchanged.
  - SRC/DST\_ADDR\_SHADOW remains unchanged.
  - SRC/DST\_BEG\_ADDR\_ACTIVE = SRC/DST\_BEG\_ADDR\_SHADOW
  - SRC/DST\_ADDR\_ACTIVE = SRC/DST\_ADDR\_SHADOW
- The active registers get updated when a wrap occurs. The shadow registers remain unchanged. Specifically:
  - SRC/DST\_BEG\_ADDR\_SHADOW remains unchanged.
  - SRC/DST\_ADDR\_SHADOW remains unchanged.
  - SRC/DST\_BEG\_ADDR\_ACTIVE += SRC/DST\_WRAP\_STEP
  - SRC/DST\_ADDR\_ACTIVE = SRC/DST\_BEG\_ADDR\_ACTIVE
- The best way to remember this is:
  - The shadow registers never change except by software.
  - The active registers never change except by hardware, and a shadow register is only copied into the active register, never an active register by another name.

Figure 10-4. DMA State Diagram

### 10.4 Pipeline Timing and Throughput

In addition to the pipeline there are a few other behaviors of the DMA that affect the total throughput:

- A 1-cycle delay is added at the beginning of each burst
- A 1-cycle delay is added when returning from a CH1 high-priority interrupt
- Collisions with the CPU can add delay slots
- 32-bit transfers run at double the speed of a 16-bit transfer (takes the same amount of time to transfer a 32-bit word as to transfer a 16-bit word)

For example, to transfer 128 16-bit words from GS0 RAM to GS3 RAM, a channel can be configured to transfer 8 bursts of 16 words/burst. This gives:

$$8 \text{ bursts} * [(3 \text{ cycles/word} * 16 \text{ words/burst}) + 1] = 392 \text{ cycles}$$

If instead the channel were configured to transfer the same amount of data 32 bits at a time (the word size is configured to 32 bits), the transfer can take:

$$8 \text{ bursts} * [(3 \text{ cycles/word} * 8 \text{ words/burst}) + 1] = 200 \text{ cycles}$$

The DMA module consists of a 3-stage pipeline as shown in [Figure 10-5](#) and [Figure 10-6](#).

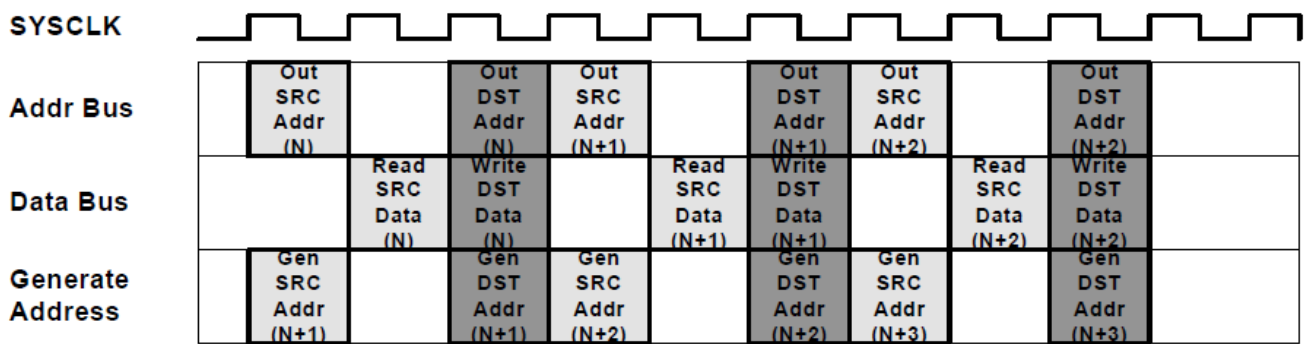

Figure 10-5. 3-Stage Pipeline DMA Transfer

Figure 10-6. 3-stage Pipeline with One Read Stall

## 10.5 CPU and CLA Arbitration

Typically, DMA activity is independent of CPU and CLA activity. However, when the DMA and CPU (or CLA) try to access the same peripheral at the same time, an arbitration procedure is required to resolve the conflict. All instances of the same peripheral type conflict with each other. For instance, CAN-A and CAN-B conflict. Accesses to global shared RAM, across different instances, do not have this conflict. Different peripheral types can share a bus interface, which creates further opportunities for conflicts. These bus interfaces are:

- Peripheral frame 1: ePWM, eCAP, eQEP, CMPSS, DAC , SDFM
- Peripheral frame 2: PMBus, SPI , FSI

**Conflict Example:** The CLA is accessing DAC-A while the DMA is simultaneously accessing DAC-B.

**Conflict Example:** The CPU is accessing an SPI FIFO while the DMA is simultaneously accessing a PMBus register.

**Non-conflict Example:** The CPU is accessing a shared ePWM while the DMA is accessing an SPI.

**Non-conflict Example:** The CPU is accessing GS0 while the DMA is accessing GS1

The exception to all this is the ADC result registers, which are duplicated for each bus controller. The CPU, DMA, and CLA can all simultaneously read these result registers with no stalls or arbitration needed for any controller.

A DMA transfer consists of four phases: send source address, read source data, send destination address, and write destination data (see [Section 10.4](#)). Suppose CPU accesses a peripheral/memory causing conflict in middle of a DMA transfer, CPU is stalled till the current DMA access is complete and not until the completion of whole DMA transfer.

The following priority schemes are implemented for the various interfaces on the device:

- The priority scheme for GSx RAM accesses is round-robin.
- The ADC results are duplicated for CPU, CLA, and DMA so that no arbitration is needed when reading the result registers. This allows all controllers to access the ADC result registers simultaneously without delay.

---

### Note

If the CPU is performing a read-modify-write operation and the DMA performs a write to the same location, the DMA write can be lost if the operation occurs in between the CPU read and the CPU write. Avoid mixing CPU writes with DMA writes to the same locations.

---

Arbitration within DMA channels is based on a round-robin priority or Channel 1 high-priority scheme described in [Section 10.6](#).

## 10.6 Channel Priority

Two priority schemes exist when determining channel priority: Round-robin mode and Channel 1 high-priority mode.

### 10.6.1 Round-Robin Mode

In this mode, all channels have *equal* priority and each enabled channel is serviced in round-robin fashion as:

$$\text{CH1} \rightarrow \text{CH2} \rightarrow \text{CH3} \rightarrow \text{CH4} \rightarrow \text{CH5} \rightarrow \text{CH6} \rightarrow \text{CH1} \rightarrow \text{CH2} \rightarrow \dots$$

In the case above, after each channel has transferred a burst of words, the next channel is serviced. The user can specify the size of the burst for each channel. Once CH6 (or the last enabled channel) has been serviced, and no other channels are pending, the round-robin state machine enters an idle state.

From the idle state, channel 1 (if enabled) is always serviced first. However, if the DMA is currently processing another channel *x*, all other pending channels between *x* and the end of the round are serviced before CH1. All the channels are of *equal* priority. For instance, take an example where CH1, CH4, and CH5 are enabled in round-robin mode and CH4 is currently being processed. Then CH1 and CH5 both receive an interrupt trigger from the respective peripherals before CH4 completes. CH1 and CH5 are now both pending. When CH4 completes the burst, CH5 is serviced next. Only after CH5 completes is CH1 serviced. Upon completion of CH1, if there are no more channels pending, the round-robin state machine enters an idle state.

A more complicated example is:

- Assume all channels are enabled, and the DMA is in an idle state,
- Initially a trigger occurs on CH1, CH3, and CH5 on the same cycle,
- When the CH1 burst transfer starts, requests from CH3 and CH5 are pending,
- Before completion of the CH1 burst, the DMA receives a request from CH2. Now the pending requests are from CH2, CH3, and CH5,
- After completing the CH1 burst, CH2 is serviced since this channel is next in the round-robin scheme after CH1.
- After the burst from CH2 is finished, the CH3 burst is serviced, followed by CH5 burst.
- Now while the CH5 burst is being serviced, the DMA receives a request from CH1, CH3, and CH6.
- The burst from CH6 starts after the completion of the CH5 burst, since this channel is the next channel after CH5 in the round-robin scheme.
- This is followed by the CH1 burst and then the CH3 burst
- After the CH3 burst finishes, assuming no more triggers have occurred, the round-robin state machine enters an idle state.

The round-robin state machine can be reset to the idle state using the DMACTRL[PRIORITYRESET] bit.

### 10.6.2 Channel 1 High-Priority Mode

In this mode, Channel 1 has high priority over all the other channels. Channels 2 to 6 have equal priority and each enabled channel is serviced in a round-robin fashion.

Higher priority: CH1

Lower priority: CH2 → CH3 → CH4 → CH5 → CH6 → CH2 → ...

Given an example where CH1, CH4, and CH5 are enabled in Channel 1 high-priority mode and CH4 is currently being processed. Then CH1 and CH5 both receive an interrupt trigger from the respective peripherals before CH4 completes. CH1 and CH5 are now both pending. When the current CH4 word transfer is completed, regardless of whether the DMA has completed the entire CH4 burst, CH4 execution is suspended and CH1 is serviced. After the CH1 burst completes, CH4 resumes execution.

Upon completion of CH4, CH5 is serviced. After CH5 completes, if there are no more channels pending, the round-robin state machine enters an idle state.

Typically Channel 1 is used in this mode for the ADC, since the data rate is so high. However, Channel 1 high-priority mode can be used in conjunction with any peripheral.

#### Note

High-priority mode and ONESHOT mode cannot be used at the same time on Channel 1. Other channels can use ONESHOT mode when Channel 1 is in high-priority mode.

### 10.7 Overrun Detection Feature

The DMA contains overrun detection logic. When a peripheral event trigger is received by the DMA, the PERINTFLG bit in the CONTROL register is set, pending the channel to the DMA state machine. When the burst for that channel is started, the PERINTFLG is cleared. If however, between the time that the PERINTFLG bit is set by an event trigger and cleared by the start of the burst, an additional event trigger arrives, the second trigger is lost. This condition sets the OVRFLG bit in the CONTROL register as in Figure 10-7. If the overrun interrupt is enabled, the channel interrupt is generated to the PIE module.

**Figure 10-7. Overrun Detection Logic**

## 10.8 Software

### 10.8.1 DMA Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/dma

Cloud access to these examples is available at the following link: [dev.ti.com C2000Ware Examples](https://dev.ti.com/C2000Ware/Examples).

#### 10.8.1.1 DMA GSRAM Transfer (dma\_ex1\_gsram\_transfer)

FILE: dma\_ex1\_gsram\_transfer.c

This example uses one DMA channel to transfer data from a buffer in RAMGS0 to a buffer in RAMGS1. The example sets the DMA channel PERINTFRC bit repeatedly until the transfer of 16 bursts (where each burst is 8 16-bit words) has been completed. When the whole transfer is complete, it will trigger the DMA interrupt.

: This example project has support for migration across our C2000 device families. If you are wanting to build this project from launchpad or controlCARD, please specify in the .syscfg file the board you're using. At any time you can select another device to migrate this example. *Watch Variables*

- *sData* - Data to send
- *rData* - Received data

#### 10.8.1.2 DMA Transfer Shared Peripheral - C28X\_DUAL

FILE: dma\_ex1\_shared\_periph\_cpu1.c

This example shows how to initiate a DMA transfer on CPU1 from a shared peripheral which is owned by CPU2. In this specific example, a timer ISR is used on CPU2 to initiate a SPI transfer which will trigger the CPU1 DMA. CPU1's DMA will then in turn update the ePWM1 CMPA value for the PWM which it owns. The PWM output can be observed on the GPIO pins. It is recommended to run the c28x1 core first, followed by the C28x2 core.

NOTE: In the default CPU2 linker cmd file, GS4, FLASH\_BANK3 and FLASH\_BANK4 are used for allocating various CPU2 sections. The CPU1 application assigns the ownership of these memory regions to CPU2. Please note that CPU2 .out file can be loaded only after CPU1 completes this configuration

The erase setting (CPU1/CPU2 On-Chip Flash -> erase setting) needs to be configured as selected banks only (Choose the corresponding BANKS allocated for CPUs) or necessary sectors only before loading CPU1/ CPU2.out file (This is applicable only for FLASH configuration)

*Watch Pins*

- GPIO0 and GPIO1 - ePWM output can be viewed with oscilloscope

#### 10.8.1.3 DMA Transfer for Shared Peripheral Example (CPU2) - C28X\_DUAL

FILE: dma\_ex1\_shared\_periph\_cpu2.c

This example shows how to initiate a DMA transfer on CPU1 from a shared peripheral that is owned by CPU2. In this specific example, a timer ISR is used on CPU2 to initiate a SPI transfer that triggers the CPU1 DMA. CPU1 DMA then updates the ePWM1 CMPA value for the PWM that the DMA owns. The PWM output can be observed on the GPIO pins. It is recommended to run the c28x1 core first, followed by the C28x2 core.

#### 10.8.1.4 DMA GSRAM Transfer (dma\_ex2\_gsram\_transfer)

FILE: dma\_ex2\_gsram\_transfer.c

This example uses one DMA channel to transfer data from a buffer in RAMGS0 to a buffer in RAMGS1. The example sets the DMA channel PERINTFRC bit repeatedly until the transfer of 16 bursts (where each burst is 8 16-bit words) has been completed. When the whole transfer is complete, it will trigger the DMA interrupt.

*Watch Variables*

- *sData* - Data to send

## 10.9 DMA Registers

This section describes the C28x Direct Memory Access Registers.

### 10.9.1 DMA Base Address Table

**Table 10-3. DMA Base Address Table**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	CPU2	CPU2.DMA	Pipeline Protected
Instance	Structure								
DmaRegs	<a href="#">DMA_REGS</a>	DMA_BASE	0x0000_1000	YES	-	-	YES	-	-
Dmach1Regs	<a href="#">DMA_CH_REGS</a>	DMA_CH1_BA SE	0x0000_1020	YES	-	-	YES	-	-
Dmach2Regs	<a href="#">DMA_CH_REGS</a>	DMA_CH2_BA SE	0x0000_1040	YES	-	-	YES	-	-
Dmach3Regs	<a href="#">DMA_CH_REGS</a>	DMA_CH3_BA SE	0x0000_1060	YES	-	-	YES	-	-
Dmach4Regs	<a href="#">DMA_CH_REGS</a>	DMA_CH4_BA SE	0x0000_1080	YES	-	-	YES	-	-
Dmach5Regs	<a href="#">DMA_CH_REGS</a>	DMA_CH5_BA SE	0x0000_10A0	YES	-	-	YES	-	-
Dmach6Regs	<a href="#">DMA_CH_REGS</a>	DMA_CH6_BA SE	0x0000_10C0	YES	-	-	YES	-	-

### 10.9.2 DMA\_REGS Registers

Table 10-4 lists the memory-mapped registers for the DMA\_REGS registers. All register offset addresses not listed in Table 10-4 should be considered as reserved locations and the register contents should not be modified.

**Table 10-4. DMA\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	DMACTRL	DMA Control Register	EALLOW	<a href="#">Go</a>
1h	DEBUGCTRL	Debug Control Register	EALLOW	<a href="#">Go</a>
4h	PRIORITYCTRL1	Priority Control 1 Register	EALLOW	<a href="#">Go</a>
6h	PRIORITYSTAT	Priority Status Register	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 10-5 shows the codes that are used for access types in this section.

**Table 10-5. DMA\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value

### 10.9.2.1 DMACTRL Register (Offset = 0h) [Reset = 0000h]

DMACTRL is shown in [Figure 10-8](#) and described in [Table 10-6](#).

Return to the [Summary Table](#).

DMA Control Register

**Figure 10-8. DMACTRL Register**

15	14	13	12	11	10	9	8
RESERVED							
R-0h							
7	6	5	4	3	2	1	0
RESERVED						PRIORITYRES ET	HARDRESET
R-0h						R-0/W1S-0h	R-0/W1S-0h

**Table 10-6. DMACTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-2	RESERVED	R	0h	Reserved
1	PRIORITYRESET	R-0/W1S	0h	<p>The priority reset bit resets the round-robin state machine when a 1 is written. Service starts from the first enabled channel. Writes of 0 are ignored and this bit always reads back a 0.</p> <p>When a 1 is written to this bit, any pending burst transfer completes before resetting the channel priority machine. If CH1 is configured as a high-priority channel, and this bit is written to while CH1 is servicing a burst, both the CH1 burst and the next pending low-priority burst are completed before the state machine is reset.</p> <p>If CH1 is high-priority, the state machine restarts from CH2 (or the next highest enabled channel).</p> <p>Reset type: SYSRSn</p>
0	HARDRESET	R-0/W1S	0h	<p>Writing a 1 to the hard reset bit resets the whole DMA and aborts any current access (similar to applying a device reset). Writes of 0 are ignored and this bit always reads back a 0.</p> <p>For a soft reset, a bit is provided for each channel to perform a gentler reset. Refer to the channel control registers.</p> <p>When writing to this bit, there is a one cycle delay before it takes effect. Hence, a one-cycle delay (such as a NOP instruction) is required in software before attempting to access any other DMA register.</p> <p>Reset type: SYSRSn</p>

### 10.9.2.2 DEBUGCTRL Register (Offset = 1h) [Reset = 0000h]

DEBUGCTRL is shown in [Figure 10-9](#) and described in [Table 10-7](#).

Return to the [Summary Table](#).

Debug Control Register

**Figure 10-9. DEBUGCTRL Register**

15	14	13	12	11	10	9	8
FREE	RESERVED						
R/W-0h	R-0h						
7	6	5	4	3	2	1	0
RESERVED							
R-0h							

**Table 10-7. DEBUGCTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
15	FREE	R/W	0h	Emulation Control This bit specifies the action when an emulation halt event occurs. Reset type: SYSRSn 0h (R/W) = The DMA completes the current read-write operation, then halts. 1h (R/W) = The DMA continues running during an emulation halt.
14-0	RESERVED	R	0h	Reserved

### 10.9.2.3 PRIORITYCTRL1 Register (Offset = 4h) [Reset = 0000h]

PRIORITYCTRL1 is shown in [Figure 10-10](#) and described in [Table 10-8](#).

Return to the [Summary Table](#).

Priority Control 1 Register

**Figure 10-10. PRIORITYCTRL1 Register**

15	14	13	12	11	10	9	8
RESERVED							
R-0h							
7	6	5	4	3	2	1	0
RESERVED							CH1PRIORITY
R-0h							R/W-0h

**Table 10-8. PRIORITYCTRL1 Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-1	RESERVED	R	0h	Reserved
0	CH1PRIORITY	R/W	0h	DMA Channel 1 Priority This bit selects whether CH1 has high priority or not. The priority can only be changed when all channels are disabled. A priority reset should be performed before restarting channels after changing priority Reset type: SYSRSn 0h (R/W) = CH1 has the same priority as the other channels 1h (R/W) = CH1 has a higher priority than the other channels

### 10.9.2.4 PRIORITYSTAT Register (Offset = 6h) [Reset = 0000h]

PRIORITYSTAT is shown in [Figure 10-11](#) and described in [Table 10-9](#).

Return to the [Summary Table](#).

Priority Status Register

**Figure 10-11. PRIORITYSTAT Register**

15	14	13	12	11	10	9	8
RESERVED							
R-0h							
7	6	5	4	3	2	1	0

**Table 10-9. PRIORITYSTAT Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-7	RESERVED	R	0h	Reserved
6-4	ACTIVESTS_SHADOW	R	0h	<p>Active Channel Status Shadow</p> <p>These bits are only meaningful when CH1 is in high-priority mode. When CH1 is serviced, the ACTIVESTS bits are copied to the shadow bits and indicate which channel was interrupted by CH1. When CH1 service is completed, the shadow bits are copied back to the ACTIVESTS bits. If this bit field is zero or the same as the ACTIVESTS bit field, then no channel is pending due to a CH1 interrupt. When CH1 is not a higher priority channel, these bits should be ignored.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No channel is active            1h (R/W) = CH 1            2h (R/W) = CH 2            3h (R/W) = CH 3            4h (R/W) = CH 4            5h (R/W) = CH 5            6h (R/W) = CH 6            7h (R/W) = Reserved</p>
3	RESERVED	R	0h	Reserved
2-0	ACTIVESTS	R	0h	<p>Active Channel Status</p> <p>These bits indicate which channel (if any) is currently active or performing a transfer.</p> <p>Reset type: SYSRSn</p> <p>0h (R/W) = No channel is active            1h (R/W) = CH 1            2h (R/W) = CH 2            3h (R/W) = CH 3            4h (R/W) = CH 4            5h (R/W) = CH 5            6h (R/W) = CH 6            7h (R/W) = Reserved</p>

### 10.9.3 DMA\_CH\_REGS Registers

Table 10-10 lists the memory-mapped registers for the DMA\_CH\_REGS registers. All register offset addresses not listed in Table 10-10 should be considered as reserved locations and the register contents should not be modified.

**Table 10-10. DMA\_CH\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	MODE	Mode Register	EALLOW	<a href="#">Go</a>
1h	CONTROL	Control Register	EALLOW	<a href="#">Go</a>
2h	BURST_SIZE	Burst Size Register	EALLOW	<a href="#">Go</a>
3h	BURST_COUNT	Burst Count Register	EALLOW	<a href="#">Go</a>
4h	SRC_BURST_STEP	Source Burst Step Register	EALLOW	<a href="#">Go</a>
5h	DST_BURST_STEP	Destination Burst Step Register	EALLOW	<a href="#">Go</a>
6h	TRANSFER_SIZE	Transfer Size Register	EALLOW	<a href="#">Go</a>
7h	TRANSFER_COUNT	Transfer Count Register	EALLOW	<a href="#">Go</a>
8h	SRC_TRANSFER_STEP	Source Transfer Step Register	EALLOW	<a href="#">Go</a>
9h	DST_TRANSFER_STEP	Destination Transfer Step Register	EALLOW	<a href="#">Go</a>
Ah	SRC_WRAP_SIZE	Source Wrap Size Register	EALLOW	<a href="#">Go</a>
Bh	SRC_WRAP_COUNT	Source Wrap Count Register	EALLOW	<a href="#">Go</a>
Ch	SRC_WRAP_STEP	Source Wrap Step Register	EALLOW	<a href="#">Go</a>
Dh	DST_WRAP_SIZE	Destination Wrap Size Register	EALLOW	<a href="#">Go</a>
Eh	DST_WRAP_COUNT	Destination Wrap Count Register	EALLOW	<a href="#">Go</a>
Fh	DST_WRAP_STEP	Destination Wrap Step Register	EALLOW	<a href="#">Go</a>
10h	SRC_BEG_ADDR_SHADOW	Source Begin Address Shadow Register	EALLOW	<a href="#">Go</a>
12h	SRC_ADDR_SHADOW	Source Address Shadow Register	EALLOW	<a href="#">Go</a>
14h	SRC_BEG_ADDR_ACTIVE	Source Begin Address Active Register	EALLOW	<a href="#">Go</a>
16h	SRC_ADDR_ACTIVE	Source Address Active Register	EALLOW	<a href="#">Go</a>
18h	DST_BEG_ADDR_SHADOW	Destination Begin Address Shadow Register	EALLOW	<a href="#">Go</a>
1Ah	DST_ADDR_SHADOW	Destination Address Shadow Register	EALLOW	<a href="#">Go</a>
1Ch	DST_BEG_ADDR_ACTIVE	Destination Begin Address Active Register	EALLOW	<a href="#">Go</a>
1Eh	DST_ADDR_ACTIVE	Destination Address Active Register	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 10-11 shows the codes that are used for access types in this section.

**Table 10-11. DMA\_CH\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1S	W1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value

### 10.9.3.1 MODE Register (Offset = 0h) [Reset = 0000h]

MODE is shown in [Figure 10-12](#) and described in [Table 10-12](#).

Return to the [Summary Table](#).

Mode Register

**Figure 10-12. MODE Register**

15		14		13		12		11		10		9		8	
CHINTE	DATASIZE	RESERVED	RESERVED	CONTINUOUS	ONESHOT	CHINTMODE	PERINTE								
R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h								
7		6		5		4		3		2		1		0	
OVRINTE	RESERVED			PERINTSEL											
R/W-0h	R-0h			R/W-0h											

**Table 10-12. MODE Register Field Descriptions**

Bit	Field	Type	Reset	Description
15	CHINTE	R/W	0h	Channel Interrupt Enable Bit This bit enables the DMA channel's CPU interrupt. Reset type: SYSRSn 0h (R/W) = Interrupt disabled 1h (R/W) = Interrupt enabled
14	DATASIZE	R/W	0h	Data Size Mode Bit This bit determines whether the DMA channel transfers 16 bits or 32 bits of data per read/write operation. Regardless of this setting, all data lengths and offsets in other DMA registers refer to 16-bit words. The pointer step increments must be configured to accommodate 32-bit words. Reset type: SYSRSn 0h (R/W) = 16-bit data transfer size 1h (R/W) = 32-bit data transfer size
13	RESERVED	R/W	0h	Reserved
12	RESERVED	R/W	0h	Reserved
11	CONTINUOUS	R/W	0h	Continuous Mode Bit If this bit is set to 1, then the channel re-initializes when TRANSFER_COUNT is zero and waits for the next event trigger. Otherwise, the DMA stops and clears the RUNSTS bit. Reset type: SYSRSn
10	ONESHOT	R/W	0h	One Shot Mode If this bit is set to 1, each peripheral event trigger causes the channel to perform an entire transfer. Otherwise, the channel only performs one burst per trigger. Reset type: SYSRSn
9	CHINTMODE	R/W	0h	Channel Interrupt Generation Mode This bit specifies when the DMA channel generates a CPU interrupt for a transfer. Reset type: SYSRSn 0h (R/W) = Generate interrupt at beginning of new transfer 1h (R/W) = Generate interrupt at end of transfer.
8	PERINTE	R/W	0h	Peripheral Event Trigger Enable This bit enables peripheral event triggers on the DMA channel. Reset type: SYSRSn 0h (R/W) = Peripheral event trigger disabled. Neither the selected peripheral nor software can start a DMA burst. 1h (R/W) = Peripheral event trigger enabled.

**Table 10-12. MODE Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
7	OVRINTE	R/W	0h	Overflow Interrupt Enable The bit determines whether the DMA module generates a CPU interrupt when it detects an overflow event. Reset type: SYSRSn 0h (R/W) = Overflow interrupt disabled 1h (R/W) = Overflow interrupt enabled
6-5	RESERVED	R	0h	Reserved
4-0	PERINTSEL	R/W	0h	Peripheral Event Trigger Source Select These are legacy bits and should be set to the channel number. The actual source selection is done via the DMACHSRCSELn registers, which are part of the DMA_CLA_SRC_SEL_REGS group. Reset type: SYSRSn

### 10.9.3.2 CONTROL Register (Offset = 1h) [Reset = 0000h]

CONTROL is shown in [Figure 10-13](#) and described in [Table 10-13](#).

Return to the [Summary Table](#).

Control Register

**Figure 10-13. CONTROL Register**

15	14	13	12	11	10	9	8
RESERVED	OVRFLG	RUNSTS	BURSTSTS	TRANSFERSTS	RESERVED	RESERVED	PERINTFLG
R-0h	R-0h	R-0h	R-0h	R-0h	R-0h	R-0h	R-0h
7	6	5	4	3	2	1	0
ERRCLR	RESERVED	RESERVED	PERINTCLR	PERINTFRC	SOFTRESET	HALT	RUN
R-0/W1S-0h	R-0/W1S-0h	R-0/W1S-0h	R-0/W1S-0h	R-0/W1S-0h	R-0/W1S-0h	R-0/W1S-0h	R-0/W1S-0h

**Table 10-13. CONTROL Register Field Descriptions**

Bit	Field	Type	Reset	Description
15	RESERVED	R	0h	Reserved
14	OVRFLG	R	0h	Overflow Flag This bit indicates that a peripheral event trigger was received while PERINTFLG was already set. It can be cleared by writing to the ERRCLR bit. Reset type: SYSRSn 0h (R/W) = No overflow detected 1h (R/W) = Overflow detected
13	RUNSTS	R	0h	Run Status Flag This bit indicates that the DMA channel is ready to respond to peripheral event triggers. This bit is set when a 1 is written to the RUN bit. It is cleared when a transfer completes (TRANSFER_COUNT = 0) and continuous mode is disabled, or when the HARDRESET, SOFTRESET, or HALT bit is set. Reset type: SYSRSn 0h (R/W) = The channel is disabled 1h (R/W) = The channel is enabled
12	BURSTSTS	R	0h	Burst Status Flag This bit is set when a DMA burst begins. The BURST_COUNT is set to the BURST_SIZE. This bit is cleared when BURST_COUNT reaches zero, or when the HARDRESET or SOFTRESET bit is set. Reset type: SYSRSn 0h (R/W) = No burst activity 1h (R/W) = The DMA is currently servicing or suspending a burst transfer from this channel
11	TRANSFERSTS	R	0h	Transfer Status Flag This bit is set when a DMA transfer begins. The address registers are copied to the shadow set and the TRANSFER_COUNT is set to the TRANSFER_SIZE. This bit is cleared when TRANSFER_COUNT reaches zero, or when the HARDRESET or SOFTRESET bit is set. Reset type: SYSRSn 0h (R/W) = No transfer activity 1h (R/W) = The channel is currently in the middle of a transfer regardless of whether a burst of data is actively being transferred or not
10	RESERVED	R	0h	Reserved
9	RESERVED	R	0h	Reserved

**Table 10-13. CONTROL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
8	PERINTFLG	R	0h	Peripheral Event Trigger Flag This bit indicates whether a peripheral event trigger has arrived. This bit is automatically cleared when the first burst transfer begins. Reset type: SYSRSn 0h (R/W) = Waiting for event trigger 1h (R/W) = Event trigger pending
7	ERRCLR	R-0/W1S	0h	Clear Error Writing a 1 to this bit will clear the OVRFLG bit. This is normally done when initializing the DMA module or if an overflow condition is detected. If an overflow event occurs at the same time this bit is set, the overrun has priority and the OVRFLG bit is set. Reset type: SYSRSn
6	RESERVED	R-0/W1S	0h	Reserved
5	RESERVED	R-0/W1S	0h	Reserved
4	PERINTCLR	R-0/W1S	0h	Clear Peripheral Event Trigger Writing a 1 to this bit clears PERINTFLG, which cancels a pending event trigger. This is normally done when initializing the DMA module. If an event trigger arrives at the same time this bit is set, the trigger has priority and PERINTFLG is set. Reset type: SYSRSn
3	PERINTFRC	R-0/W1S	0h	Force Peripheral Event Trigger If the PERINTE bit of the MODE register is set, writing a 1 to this bit sets PERINTFLG, which triggers a DMA burst. This bit can be used to start a DMA transfer in software. Reset type: SYSRSn
2	SOFTRESET	R-0/W1S	0h	Channel Soft Reset Writing a 1 to this bit places the channel into its default state after the current read/write access has completed: RUNSTS = 0 TRANSFERSTS = 0 BURSTSTS = 0 BURST_COUNT = 0 TRANSFER_COUNT = 0 SRC_WRAP_COUNT = 0 DST_WRAP_COUNT = 0 When writing to this bit, there is a one cycle delay before it takes effect. Hence, a one-cycle delay (such as a NOP instruction) is required in software before attempting to access any other DMA register. Reset type: SYSRSn
1	HALT	R-0/W1S	0h	Halt Channel Writing a 1 to this bit halts the DMA channel in its current state after any ongoing read/write access has completed. Reset type: SYSRSn
0	RUN	R-0/W1S	0h	Run Channel Writing a 1 to this bit enables the DMA channel and sets the RUNSTS bit to 1. This bit is also used to resume after a channel halt. The RUN bit is typically used to start the DMA channel after configuration. The channel will then wait for the first peripheral event trigger (PERINTFLG == 1) to start a burst. Reset type: SYSRSn

### 10.9.3.3 BURST\_SIZE Register (Offset = 2h) [Reset = 0000h]

BURST\_SIZE is shown in [Figure 10-14](#) and described in [Table 10-14](#).

Return to the [Summary Table](#).

Burst Size Register

**Figure 10-14. BURST\_SIZE Register**

### 10.9.4 DMA\_CLA\_SRC\_SEL\_REGS Registers

Table 10-36 lists the memory-mapped registers for the DMA\_CLA\_SRC\_SEL\_REGS registers. All register offset addresses not listed in Table 10-36 should be considered as reserved locations and the register contents should not be modified.

**Table 10-36. DMA\_CLA\_SRC\_SEL\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	CLA1TASKSRCSELLOCK	CLA1 Task Trigger Source Select Lock Register	EALLOW	<a href="#">Go</a>
4h	DMACHSRCSELLOCK	DMA Channel Trigger Source Select Lock Register	EALLOW	<a href="#">Go</a>
6h	CLA1TASKSRCSEL1	CLA1 Task Trigger Source Select Register-1	EALLOW	<a href="#">Go</a>
8h	CLA1TASKSRCSEL2	CLA1 Task Trigger Source Select Register-2	EALLOW	<a href="#">Go</a>
16h	DMACHSRCSEL1	DMA Channel Trigger Source Select Register-1	EALLOW	<a href="#">Go</a>
18h	DMACHSRCSEL2	DMA Channel Trigger Source Select Register-2	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 10-37 shows the codes that are used for access types in this section.

**Table 10-37. DMA\_CLA\_SRC\_SEL\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
WOnce	W Once	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 10.9.4.1 CLA1TASKSRCSELLOCK Register (Offset = 0h) [Reset = 0h]

CLA1TASKSRCSELLOCK is shown in [Figure 10-36](#) and described in [Table 10-38](#).

Return to the [Summary Table](#).

Chapter 11  
**External Memory Interface (EMIF)**

---

This chapter describes the external memory interface (EMIF).

Further information can be found in the following documents:

[Accessing External SDRAM on the TMS320F2837x/2807x Microcontrollers Using C/C++ Application Report](#)

[Design and Usage Guidelines for the C2000™ External Memory Interface \(EMIF\) Application Report](#)

<b>11.1 Introduction</b> .....	1755
<b>11.2 EMIF Module Architecture</b> .....	1758
<b>11.3 Example Configuration</b> .....	1788
<b>11.4 Software</b> .....	1797
<b>11.5 EMIF Registers</b> .....	1799

## 11.1 Introduction

This device supports one EMIF module — EMIF1, as shown in [Figure 11-1](#).

[Table 11-1](#) gives the configuration for the EMIF module.

**Figure 11-1. EMIF Module Overview**

**Table 11-1. Configuration for the EMIF1 Module**

	EMIF1
Maximum Data Width	32
Maximum Address Width	22 (Some of EMIF1 pins are muxed with each other. Refer to <a href="#">Section 11.2.11</a> for usage)
SDRAM CSx Support	1 (CS0)
ASRAM CSx Support	3 (CS2/CS3/CS4)

### Note

Subsequent sections in this chapter provide the details on the generic EMIF module. Unless otherwise specified, pin names are used from EMIF1 to define the functionality.

### 11.1.1 Purpose of the Peripheral

This EMIF memory controller is compliant with the JESD21-C SDR SDRAM memories utilizing a 32-bit/16-bit data bus. The purpose of this EMIF is to provide a means for the CPU to connect to a variety of external devices including:

- Single data rate (SDR) SDRAM
- Asynchronous devices including NOR Flash and SRAM

A common use for the EMIF is to interface with both a Flash device and an SDRAM device simultaneously. [Section 11.3](#) contains an example of operating the EMIF in this configuration.

### 11.1.2 EMIF Related Collateral

#### Foundational Materials

- [C2000 Academy - EMIF](#)

#### Getting Started Materials

- [Design and Usage Guidelines for the C2000 External Memory Interface \(EMIF\) Application Report](#)

### 11.1.3 Features

The EMIF controller includes many features to enhance the ease and flexibility of connecting to the external SDR SDRAM and asynchronous devices.

#### 11.1.3.1 Asynchronous Memory Support

The EMIF controller supports asynchronous:

- SRAM memories
- NOR Flash memories

There is an external wait input that allows slower asynchronous memories to extend the memory access. The EMIF module supports more than one chip select (enable). Each chip select has the following individually programmable attributes:

- Data bus width
- Read cycle timings: setup, hold, strobe
- Write cycle timings: setup, hold, strobe
- Bus turnaround time
- Extended wait option with programmable timeout
- Select strobe option

#### 11.1.3.2 Synchronous DRAM Memory Support

The EMIF module supports 16-bit/32-bit SDRAM in addition to the asynchronous memories listed in [Section 11.1.3.1](#). The EMIF module has a single SDRAM chip select. SDRAM configurations that are supported are:

- One, two and four bank SDRAM devices
- Devices with eight, nine, ten, and eleven column address
- CAS latency of two or three clock cycles
- 16-bit/32-bit data bus width
- 3.3V LVCMOS interface

Additionally, the EMIF supports placing the SDRAM in self-refresh and power-down modes. The self-refresh mode allows the SDRAM to be put in a low-power state while still retaining memory contents, since the SDRAM continues to refresh itself even without clocks from the microcontroller. The power-down mode achieves even lower power, except the microcontroller must periodically wake up and issue refreshes if data retention is required.

Note that the EMIF module does not support mobile SDRAM devices.

### 11.1.4 Functional Block Diagram

Figure 11-2 shows the connections between the EMIF and the internal requesters, along with the external EMIF pins. Section 11.2.2 contains a description of the entities internal to the MCU that can send requests to the EMIF, along with their prioritization. Section 11.2.3 describes the EMIF external pins and summarizes their purpose when interfacing with the SDRAM and asynchronous devices.

Figure 11-2. EMIF Functional Block Diagram

### 11.1.5 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification must be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups can be configured in the GPyPUD register.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

## 11.2 EMIF Module Architecture

This section provides details about the architecture and operation of the EMIF. Both the SDRAM and asynchronous interface are covered, along with other system-related configurations such as clock control.

### 11.2.1 EMIF Clock Control

The EMIF clock is output on the pin and must be used when interfacing to external SDRAM devices. The EMIF module gets the PLLSYSCLK clock domain as the input. The user can choose to run the EMIF at PLLSYSCLK/1 or PLLSYSCLK/2 clock frequency by configuring the field in the PERCLKDIVSEL register in the *Clock Control* module.

### 11.2.2 EMIF Requests

Different sources within the MCU can make requests to the EMIF. These requests consist of accesses to the SDRAM memory, the asynchronous memory, and the EMIF registers. The EMIF can process only one request at a time. Therefore, a high performance controller arbitration block exists within the MCU to provide prioritized requests from the different sources to the EMIF. The sources are:

- CPU1
- CPU1.DMA

If a request is submitted from two or more sources simultaneously, the crossbar switch forwards the highest priority request to the EMIF first. Upon completion of a request, the controller arbitration block again evaluates the pending requests and forwards the highest priority pending request to the EMIF.

The controller arbitration block always allows RD access from any of the controller. But for WR access (or execute access), the controller arbitration block only allows access of controller from a CPU subsystem that takes controller ownership of the EMIF module based on the configuration in the EMIF1MSEL register in the *Memory Controller* module.

When the EMIF receives a request, it is possible that the request is not immediately processed. In some cases, the EMIF performs one or more auto-refresh cycles before processing the request. For details on the EMIF internal arbitration between performing requests and performing auto-refresh cycles, see [Section 11.2.13](#).

### 11.2.3 EMIF Signal Descriptions

This section describes the function of each of the EMIF signals.

**Table 11-2. EMIF Pins Used to Access Both SDRAM and Asynchronous Memories**

Pins	I/O	Description
EM1D[x:0]	I/O	<b>EMIF data bus.</b>
EM1A[x:0]	O	<b>EMIF address bus.</b> When interfacing to an SDRAM device, these pins are primarily used to provide the row and column address to the SDRAM. The mapping from the internal program address to the external values placed on these pins is found in <a href="#">Table 11-14</a> . EM1A[10] is also used during the PRE command to select which banks to deactivate. When interfacing to an asynchronous device, these pins are used in conjunction with the EM1BA pins to form the address that is sent to the device. The mapping from the internal program address to the external values placed on these pins is found in <a href="#">Section 11.2.6.1</a> .
EM1BA[1:0]	O	<b>EMIF bank address.</b> When interfacing to an SDRAM device, these pins are used to provide the bank address inputs to the SDRAM. The mapping from the internal program address to the external values placed on these pins is found in <a href="#">Table 11-14</a> . When interfacing to an asynchronous device, these pins are used in conjunction with the EM1A pins to form the address that is sent to the device. The mapping from the internal program address to the external values placed on these pins is found in <a href="#">Section 11.2.6.1</a> .
EM1DQM[x:0]	O	<b>Active-low byte enables.</b> When interfacing to SDRAM, these pins are connected to the DQM pins of the SDRAM to individually enable/disable each of the bytes in a data access. When interfacing to an asynchronous device, these pins are connected to byte enables. See <a href="#">Section 11.2.6</a> for details.
EM1WE	O	<b>Active-low write enable.</b> When interfacing to SDRAM, this pin is connected to the nWE pin of the SDRAM and is used to send commands to the device. When interfacing to an asynchronous device, this pin provides a signal which is active-low during the strobe period of an asynchronous write access cycle.

**Table 11-3. EMIF Pins Specific to SDRAM**

Pins	I/O	Description
EM1CS0	O	<b>Active-low chip enable pin for SDRAM devices.</b> This pin is connected to the chip-select pin of the attached SDRAM device and is used for enabling/disabling commands. By default, EMIF keeps this SDRAM chip select active, even if EMIF is not interfaced with an SDRAM device. This pin is deactivated when accessing the asynchronous memory bank and is reactivated on completion of the asynchronous access.
EM1RAS	O	<b>Active-low row address strobe pin.</b> This pin is connected to the nRAS pin of the attached SDRAM device and is used for sending commands to the device.
EM1CAS	O	<b>Active-low column address strobe pin.</b> This pin is connected to the nCAS pin of the attached SDRAM device and is used for sending commands to the device.
EM1SDCKE	O	<b>Clock enable pin.</b> This pin is connected to the CKE pin of the attached SDRAM device and is used for issuing the SELF REFRESH command which places the device in self-refresh mode. See <a href="#">Section 11.2.5.7</a> for details.
EM1CLK	O	<b>SDRAM clock pin.</b> This pin is connected to the CLK pin of the attached SDRAM device. See <a href="#">Section 11.2.1</a> for details on the clock signal.

**Table 11-4. EMIF Pins Specific to Asynchronous Memory**

Pins	I/O	Description
EM1CS[4:2]	O	<b>Active-low chip enable pins for asynchronous devices.</b> These pins are meant to be connected to the chip-select pins of the attached asynchronous device. These pins are active only during accesses to the asynchronous memory.
EM1WAIT	I	<b>Wait input with programmable polarity.</b> A connected asynchronous device can extend the strobe period of an access cycle by asserting the EM1WAIT input to EMIF as described in <a href="#">Section 11.2.6.6</a> . To enable this functionality, the EW bit in the asynchronous 1 configuration register (ASYNC_CS2_CFG) must be set to 1. In addition, the WP0 bit in ASYNC_CS2_CFG must be configured to define the polarity of the EM1WAIT pin.
EM1OE	O	<b>Active-low pin enable for asynchronous devices.</b> This pin provides a signal which is active-low during the strobe period of an asynchronous read access cycle.
EM1RNW	O	<b>EMIF asynchronous read/write control.</b> This pin stays high during reads and stays low during writes (same duration as CS).

### 11.2.4 EMIF Signal Multiplexing Control

Several EMIF signals are multiplexed with other functions on this microcontroller. Refer to the multiplexing section of the *General-Purpose Input/Output (GPIO)* chapter for more information on how to enable the output of these EMIF signals.

### 11.2.5 SDRAM Controller and Interface

The EMIF controller provides a glueless interface to most standard SDR SDRAM devices and supports features like self-refresh mode and prioritized refresh. In addition, the EMIF controller provides flexibility through programmable parameters such as the refresh rate, CAS latency, and many SDRAM timing parameters. The following sections include details on how to interface and properly configure the EMIF to perform read and write operations to externally connected SDR SDRAM devices. Also, [Section 11.3](#) provides a detailed example of interfacing the EMIF to a common SDRAM device.

#### 11.2.5.1 SDRAM Commands

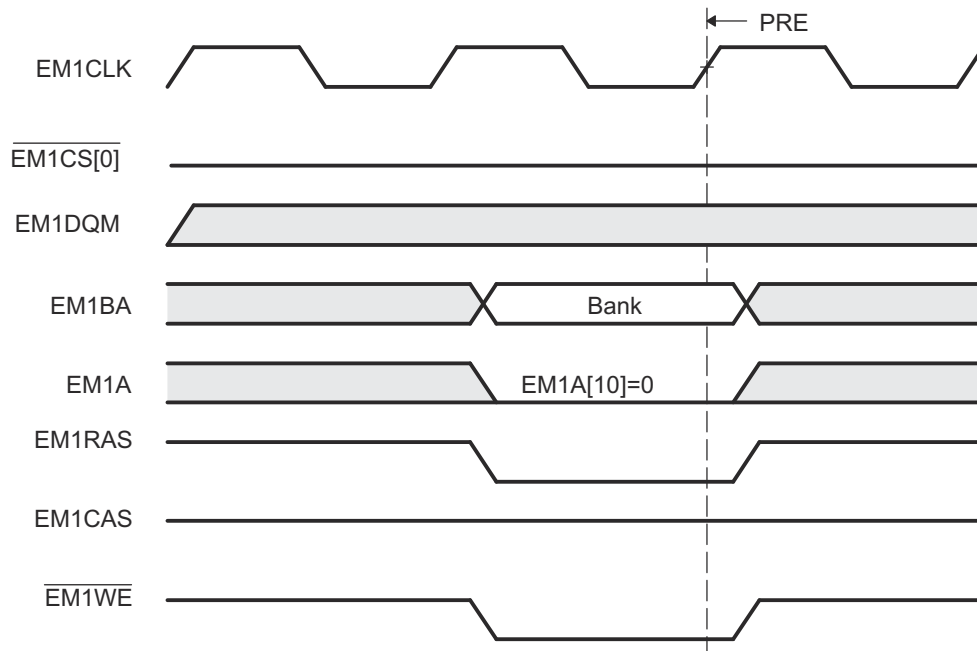

The EMIF controller supports the SDRAM commands described in [Table 11-5](#). [Table 11-6](#) shows the truth table for the SDRAM commands, and an example timing waveform of the PRE command is shown in [Figure 11-3](#). EM1A[10] is pulled low in this example to deactivate only the bank specified by the EM1BA pins.

**Table 11-5. EMIF SDRAM Commands**

Command	Function
PRE	<b>Precharge.</b> Depending on the value of EM1A[10], the PRE command either deactivates the open row in all banks (EM1A[10] = 1) or only the bank specified by the EM1BA[1:0] pins (EM1A[10] = 0).
ACTV	<b>Activate.</b> The ACTV command activates the selected row in a particular bank for the current access.
READ	<b>Read.</b> The READ command outputs the starting column address and signals the SDRAM to begin the burst read operation. Address EM1A[10] is always pulled low to avoid auto precharge. This allows for better bank interleaving performance.
WRT	<b>Write.</b> The WRT command outputs the starting column address and signals the SDRAM to begin the burst write operation. Address EM1A[10] is always pulled low to avoid auto precharge. This allows for better bank interleaving performance.
BT	<b>Burst terminate.</b> The BT command is used to truncate the current read or write burst request. On this device, all the SDRAM accesses are single access except when EMIF controller splits a single access into multiple access (for example, a 32-bit access from CPU is split into two 16-bit accesses if external SDRAM device is 16 bit (NM =1)).
LMR	<b>Load mode register.</b> The LMR command sets the mode register of the attached SDRAM devices and is only issued during the SDRAM initialization sequence described in <a href="#">Section 11.2.5.4</a> .
REFR	<b>Auto refresh.</b> The REFR command signals the SDRAM to perform an auto refresh according to the internal address.
SLFR	<b>Self refresh.</b> The self-refresh command places the SDRAM into self-refresh mode, during which the SDRAM provides a clock signal and auto refresh cycles.
NOP	<b>No operation.</b> The NOP command is issued during all cycles in which one of the above commands is not issued.

**Table 11-6. Truth Table for SDRAM Commands**

SDRAM Pins:	CKE	nCS	nRAS	nCAS	nWE	BA[1:0]	A[12:11]	A[10]	A[9:0]
EMIF Pins:	EM1SDCKE	$\overline{\text{EM1CS}}[0]$	EM1RAS	EM1CAS	$\overline{\text{EM1WE}}$	EM1BA[1:0]	EM1A[12:11]	EM1A[10]	EM1A[9:0]

**Figure 11-3. Timing Waveform of SDRAM PRE Command**

### 11.2.5.2 Interfacing to SDRAM

The EMIF supports a glueless interface to SDRAM devices with the following characteristics:

- Pre-charge bit is A[10]
- The number of column address bits is 8, 9, 10, or 11.
- The number of row address bits is 13, 14, 15, or 16.
- The number of internal banks is 1, 2, or 4.

Figure 11-4 shows an interface between the EMIF and a  $2\text{M} \times 16 \times 4$  bank SDRAM device, and Figure 11-5 shows an interface between the EMIF and a  $512\text{K} \times 16 \times 2$  bank SDRAM device. For devices supporting 16-bit interface, refer to Table 11-7 for list of commonly-supported SDRAM devices and the required connections for the address pins.

**Figure 11-4. EMIF to  $2\text{M} \times 16 \times 4$  Bank SDRAM Interface**

**Figure 11-5. EMIF to  $512\text{K} \times 16 \times 2$  Bank SDRAM Interface**

**Table 11-7. 16-bit EMIF Address Pin Connections**

SDRAM Size	Width	Banks	Device	Address Pins
16M bits	×16	2	SDRAM	A[10:0]
			EMIF	EM1A[10:0]
64M bits	×16	4	SDRAM	A[11:0]
			EMIF	EM1A[11:0]
128M bits	×16	4	SDRAM	A[11:0]
			EMIF	EM1A[11:0]
256M bits	×16	4	SDRAM	A[12:0]
			EMIF	EM1A[12:0]
512M bits	×16	4	SDRAM	A[12:0]
			EMIF	EM1A[12:0]

### 11.2.5.3 SDRAM Configuration Registers

The operation of the EMIF SDRAM interface is controlled by programming the appropriate configuration registers. This section describes the purpose and function of each configuration register, but [Section 11.5](#) can be referred to for a more detailed description of each register, including the default registers values and bit-field positions. The following tables list the four such configuration registers, along with a description of each of their programmable fields.

---

#### Note

Writing to any of the fields: NM, CL, IBANK, and PAGESIZE in the SDRAM configuration register (SDRAM\_CR) causes the EMIF to abandon whatever the EMIF is currently doing and trigger the SDRAM initialization procedure described in [Section 11.2.5.4](#).

---

**Table 11-8. Description of the SDRAM Configuration Register (SDRAM\_CR)**

Parameter	Description
SR	This bit controls entering and exiting of the self-refresh mode
PD	This bit controls entering and exiting of the power-down mode. If both SR and PD bits are set, the EMIF goes into self-refresh mode.
PDWR	Perform refreshes during power down. Writing a 1 to this bit causes the EMIF to exit the power-down state and issue an AUTO REFRESH command every time Refresh May level is set. This bit must be set along with PD when entering power-down mode.
NM	<b>Narrow Mode.</b> This bit defines the width of the data bus between the EMIF and the attached SDRAM device. When set to 1, the data bus is set to 16-bits. When set to 0, the data bus is set to 32-bits.
CL	<b>CAS latency.</b> This field defines the number of clock cycles between when an SDRAM issues a READ command and when the first piece of data appears on the bus. The value in this field is sent to the attached SDRAM device using the LOAD MODE REGISTER command during the SDRAM initialization procedure as described in <a href="#">Section 11.2.5.4</a> . Only, values of 2h (CAS latency = 2) and 3h (CAS latency = 3) are supported and must be written to this field. While updating the CL field, BIT11_9LOCK bit field must be set to 1 simultaneously.
IBANK	<p><b>Number of Internal SDRAM Banks.</b> This field defines the number of banks inside the attached SDRAM devices in the following way:</p> <ul style="list-style-type: none"> <li>• When IBANK = 0, 1 internal bank is used</li> <li>• When IBANK = 1h, 2 internal banks are used</li> <li>• When IBANK = 2h, 4 internal banks are used</li> </ul> <p>This field value affects the mapping of logical addresses to the SDRAM row, column, and bank addresses. See <a href="#">Section 11.2.5.11</a> for details.</p>
PAGESIZE	<p><b>Page Size.</b> This field defines the internal page size of the attached SDRAM devices in the following way:</p> <ul style="list-style-type: none"> <li>• When PAGESIZE = 0, 256-word pages are used</li> <li>• When PAGESIZE = 1h, 512-word pages are used</li> <li>• When PAGESIZE = 2h, 1024-word pages are used</li> <li>• When PAGESIZE = 3h, 2048-word pages are used</li> </ul> <p>This field value affects the mapping of logical addresses to the SDRAM row, column, and bank addresses. See <a href="#">Section 11.2.5.11</a> for details.</p>

**Table 11-9. Description of the SDRAM Refresh Control Register (SDRAM\_RCR)**

Parameter	Description
RR	<p><b>Refresh Rate.</b> This field controls the rate at which attached SDRAM devices are refreshed. The following equation can be used to determine the required value of RR for an SDRAM device:</p> <ul style="list-style-type: none"> <li>• <math>RR = f_{EM1CLK} / (\text{Required SDRAM Refresh Rate})</math></li> </ul> <p>More information about the operation of the SDRAM refresh controller is found in <a href="#">Section 11.2.5.6</a>.</p>

**Table 11-10. Description of the SDRAM Timing Register (SDRAM\_TR)**

Parameter	Description
T_RFC	<b>SDRAM Timing Parameters.</b> These fields configure the EMIF to comply with the AC timing requirements of the attached SDRAM devices. This allows the EMIF to avoid violating SDRAM timing constraints and to more efficiently schedule operations. More details about each of these parameters can be found in the SDRAM_TR register description. These parameters must be set to satisfy the corresponding timing requirements found in the SDRAM data sheet.
T_RP	
T_RCD	
T_WR	
T_RAS	
T_RC	
T_RRD	

**Table 11-11. Description of the SDRAM Self Refresh Exit Timing Register (SDR\_EXT\_TMNG)**

Parameter	Description
T_XS	<b>Self Refresh Exit Parameter.</b> The T_XS field of this register informs the EMIF about the minimum number of EM1CLK cycles required between exiting self-refresh and issuing any command. This parameter must be set to satisfy the $t_{XSR}$ value for the attached SDRAM device.

#### 11.2.5.4 SDRAM Auto-Initialization Sequence

The EMIF automatically performs an SDRAM initialization sequence, regardless of whether the EMIF is interfaced to an SDRAM device, when either of the following two events occur:

- The EMIF comes out of reset. No memory accesses to the SDRAM and asynchronous interfaces are performed until this auto-initialization is complete.
- A write is performed to any of the three least-significant bytes of the SDRAM configuration register (SDRAM\_CR)

An SDRAM initialization sequence consists of the following steps:

1. If the initialization sequence is activated by a write to SDRAM\_CR, and if any of the SDRAM banks are open, the EMIF issues a PRE command with EM1A[10] held high to indicate all banks. This is done so that the maximum ACTV to PRE timing for an SDRAM is not violated.
2. The EMIF drives EM1SDCKE high and begins continuously issuing NOP commands until eight SDRAM refresh intervals have elapsed. An SDRAM refresh interval is equal to the value of the RR field of the SDRAM refresh control register (SDRAM\_RCR), divided by the frequency of EM1CLK ( $RR/f_{EM1CLK}$ ). This step is used to avoid violating the power-up constraint of most SDRAM devices that requires 200 $\mu$ s (sometimes 100 $\mu$ s) between receiving stable Vdd and CLK and the issuing of a PRE command. Depending on the frequency of EM1CLK, this step can be insufficient to avoid violating the SDRAM constraint. See [Section 11.2.5.5](#) for more information.
3. After the refresh intervals have elapsed, the EMIF issues a PRE command with EM1A[10] held high to indicate all banks.
4. The EMIF issues eight AUTO REFRESH commands.
5. The EMIF issues the LMR command with the EM1A[9:0] pins set as described in [Table 11-12](#).
6. Finally, the EMIF performs a refresh cycle, which consists of the following steps:
  - a. Issuing a PRE command with EM1A[10] held high if any banks are open
  - b. Issuing an REF command

**Table 11-12. SDRAM LOAD MODE REGISTER Command**

EM1A[9:7]	EM1A[6:4]	EM1A[3]	EM1A[2:0]
0 (Write bursts are of the programmed burst length in EM1A[2:0])	These bits control the CAS latency of the SDRAM and are set according to CL field in the SDRAM configuration register (SDRAM_CR) as follows: <ul style="list-style-type: none"> <li>• If CL = 2, EM1A[6:4] = 2h (CAS latency = 2)</li> <li>• If CL = 3, EM1A[6:4] = 3h (CAS latency = 3)</li> </ul>	0 (Sequential Burst Type. Interleaved Burst Type not supported)	These bits control the burst length of the SDRAM and are set according to the NM field in the SDRAM configuration register (SDRAM_CR) as follows: <ul style="list-style-type: none"> <li>• If NM = 0, EM1A[2:0] = 2h (Burst Length = 4)</li> <li>• If NM = 1, EM1A[2:0] = 3h (Burst Length = 8)</li> </ul>

### 11.2.5.5 SDRAM Configuration Procedure

There are two different SDRAM configuration procedures. Although the EMIF automatically performs the SDRAM initialization sequence described in [Section 11.2.5.4](#) when coming out of reset, follow one of the procedures before performing any EMIF memory requests.

Procedure A must be followed if the SDRAM power-up constraint was not violated during the SDRAM auto-initialization sequence detailed in [Section 11.2.5.4](#) on coming out of Reset. The SDRAM power-up constraint specifies that 200µs (sometimes 100µs) must exist between receiving stable Vdd and CLK and the issuing of a PRE command.

Procedure B must be followed if the SDRAM power-up constraint was violated. The 200µs (100µs) SDRAM power-up constraint is violated, if the frequency of EM1CLK is greater than 50MHz (100MHz for 100µs SDRAM power-up constraint) during SDRAM Auto-Initialization Sequence. Procedure B must be followed if there is any doubt that the power-up constraint was not met.

**Procedure A** — Following is the procedure to be followed if the SDRAM power-up constraint was not violated:

1. Place the SDRAM into self-refresh mode by setting the SR bit of SDRAM\_CR to 1. The SDRAM can be placed into self-refresh mode when changing the frequency of the EM1CLK to avoid incurring the 200µs power-up constraint again.
2. Configure the desired EMIF1 clock (EM1CLK) frequency. The frequency of the memory clock must meet the timing requirements in the SDRAM manufacturer's documentation and the timing limitations shown in the electrical specifications of the device data sheet.
3. Remove the SDRAM from self-refresh mode by clearing the SR bit of the SDRAM\_CR to 0.
4. Program SDRAM\_TR and SDR\_EXT\_TMNG to satisfy the timing requirements for the attached SDRAM device. The timing parameters must be taken from the SDRAM data sheet.
5. Program the RR field of SDRAM\_RCR to match that of the attached device's refresh interval. See [Section 11.2.5.6.1](#) details on determining the appropriate value.
6. Program the SDRAM\_CR to match the characteristics of the attached SDRAM device. This causes the auto-initialization sequence in [Section 11.2.5.4](#) to be re-run. This second initialization generally takes much less time due to the increased frequency of EM1CLK.

**Procedure B** — Following is the procedure to be followed if the SDRAM power-up constraint was violated:

1. Configure the desired EM1CLK clock frequency. The frequency of the memory clock must meet the timing requirements in the SDRAM manufacturer's documentation and the timing limitations shown in the electrical specifications of the device data sheet.
2. Program SDRAM\_TR and SDR\_EXT\_TMNG to satisfy the timing requirements for the attached SDRAM device. The timing parameters must be taken from the SDRAM data sheet.
3. Program the RR field of the SDRAM\_RCR such that the following equation is satisfied:  $(RR \times 8) / (f_{EM1CLK}) > 200\mu s$  (sometimes 100µs). For example, an EM1CLK frequency of 100MHz requires setting RR to 2501 (9C5h) or higher to meet a 200µs constraint.
4. Program the SDRAM\_CR to match the characteristics of the attached SDRAM device. This causes the auto-initialization sequence in [Section 11.2.5.4](#) to be re-run with the new value of RR.
5. Perform a read from the SDRAM to make sure that step 5 of this procedure occurs after the initialization process has completed. Alternatively, wait for 200µs instead of performing a read.
6. Finally, program the RR field to match that of the attached device's refresh interval. See [Section 11.2.5.6.1](#) details on determining the appropriate value.

After following the above procedure, the EMIF is ready to perform accesses to the attached SDRAM device.

### 11.2.5.6 EMIF Refresh Controller

An SDRAM device requires that each of the rows be refreshed at a minimum required rate. The EMIF can meet this constraint by performing auto refresh cycles at or above this required rate. An auto-refresh cycle consists of issuing a PRE command to all banks of the SDRAM device followed by issuing a REFR command. To inform the EMIF of the required rate for performing auto refresh cycles, the RR field of the SDRAM refresh control register (SDRAM\_RCR) must be programmed. The EMIF uses this value along with two internal counters to automatically perform auto refresh cycles at the required rate. The auto-refresh cycles cannot be disabled, even if the EMIF is not interfaced with an SDRAM. The remainder of this section details the EMIF's refresh scheme and provides an example for determining the appropriate value to place in the RR field of the SDRAM\_RCR.

The two counters used to perform auto-refresh cycles are a 13-bit refresh interval counter and a 4-bit refresh backlog counter. At reset and upon writing to the RR field, the refresh interval counter is loaded with the value from RR field and begins decrementing, by one, each EMIF clock cycle. When the refresh interval counter reaches zero, the following actions occur:

- The refresh interval counter is reloaded with the value from the RR field and restarts decrementing.
- The 4-bit refresh backlog counter increments unless the counter has already reached the maximum value.

The refresh backlog counter records the number of auto refresh cycles that the EMIF currently has outstanding. This counter is decremented by one each time an auto refresh cycle is performed and incremented by one each time the refresh interval counter expires. The refresh backlog counter saturates at the values of 0000b and 1111b. The EMIF uses the refresh backlog counter to determine the urgency with which an auto refresh cycle must be performed. The four levels of urgency are described in [Table 11-13](#). This refresh scheme allows the required refreshes to be performed with minimal impact on access requests.

**Table 11-13. Refresh Urgency Levels**

Urgency Level	Refresh Backlog Counter Range	Action Taken
Refresh May	1-3	An auto-refresh cycle is performed only if the EMIF has no requests pending and none of the SDRAM banks are open.
Refresh Release	4-7	An auto-refresh cycle is performed if the EMIF has no requests pending, regardless of whether any SDRAM banks are open.
Refresh Need	8-11	An auto-refresh cycle is performed at the completion of the current access unless there are read requests pending.
Refresh Must	12-15	Multiple auto-refresh cycles are performed at the completion of the current access until the Refresh Release urgency level is reached. At that point, the EMIF can begin servicing any new read or write requests.

### 11.2.5.6.1 Determining the Appropriate Value for the RR Field

The value that must be programmed into the RR field of the SDRAM\_RCR must can be calculated by using the frequency of the EM1CLK signal ( $f_{EM1CLK}$ ) and the required refresh rate of the SDRAM ( $f_{Refresh}$ ). The following formula can be used:

$$RR = f_{EM1CLK} / f_{Refresh}$$

The SDRAM data sheet often communicates the required SDRAM Refresh Rate in terms of the number of REFR commands required in a given time interval. The required SDRAM Refresh Rate in the formula above can therefore be calculated by dividing the number of required cycles per time interval ( $n_{cycles}$ ) by the time interval given in the data sheet ( $t_{Refresh\ Period}$ ):

$$f_{Refresh} = n_{cycles} / t_{Refresh\ Period}$$

Combining these formulas, the value that must be programmed into the RR field can be computed as:

$$RR = f_{EM1CLK} \times t_{Refresh\ Period} / n_{cycles}$$

The following example illustrates calculating the value of RR. Given that:

- $f_{EM1CLK} = 100\text{MHz}$  (frequency of EMIF clock)
- $t_{Refresh\ Period} = 64\text{ms}$  (required refresh interval of the SDRAM)
- $n_{cycles} = 8192$  (number of cycles in a refresh interval for the SDRAM)

RR can be calculated as:

$$RR = 100\text{MHz} \times 64\text{ms}/8192$$

$$RR = 781.25$$

$$RR = 782\text{ cycles} = 30\text{Eh cycles}$$

### 11.2.5.7 Self-Refresh Mode

The EMIF can be programmed to enter the self-refresh state by setting the SR bit of SDRAM\_CR to 1. This causes the EMIF to issue the SLFR command after completing any outstanding SDRAM access requests and clearing the refresh backlog counter by performing one or more auto refresh cycles. This places the attached SDRAM device into self-refresh mode in which the EMIF consumes a minimal amount of power while performing the refresh cycles.

While in the self-refresh state, the EMIF continues to service asynchronous bank requests and register accesses as normal, with one caveat. The EMIF does not park the data bus following a read to asynchronous memory while in the self-refresh state. Instead, the EMIF tri-states the data bus. Therefore, it is not recommended to perform asynchronous read operations while the EMIF is in the self-refresh state to prevent floating inputs on the data bus. More information about data bus parking can be found in [Section 11.2.7](#).

The EMIF exits from the self-refresh state, if either of the following events occur:

- The SR bit of SDRAM\_CR is cleared to 0.
- An SDRAM accesses is requested.

The EMIF exits from the self-refresh state by driving EM1SDCKE high and performing an auto refresh cycle.

The attached SDRAM device must also be placed into self-refresh mode when changing the frequency of EM1CLK. If the frequency of EM1CLK changes while the SDRAM is not in self-refresh mode, Procedure B in [Section 11.2.5.5](#) must be followed to reinitialize the device.

#### 11.2.5.8 Power-Down Mode

To support low-power modes, the EMIF can be requested to issue a POWER DOWN command to the SDRAM by setting the PD bit in the SDRAM configuration register (SDRAM\_CR). When this bit is set, the EMIF continues normal operation until all outstanding memory access requests have been serviced and the SDRAM refresh backlog (if there is one) has been cleared. At this point, the EMIF enters the power-down state. Upon entering this state, the EMIF issues a POWER DOWN command (same as a NOP command but driving the EM1SDCKE low on the same cycle). The EMIF then maintains the EM1SDCKE low until the EMIF exits the power-down state.

Since the EMIF services the refresh backlog before the EMIF enters the power-down state, all internal banks of the SDRAM are closed (precharged) prior to issuing the POWER DOWN command. Therefore, the EMIF only supports precharge power-down. The EMIF does not support active power-down, where internal banks of the SDRAM are open (active) before the POWER DOWN command is issued.

During the power-down state, the EMIF services the SDRAM, asynchronous memory, and register accesses as normal, returning to the power-down state upon completion.

The PDWR bit in the SDRAM\_CR indicates whether the EMIF must perform refreshes in power-down state. If the PDWR bit is set, the EMIF exits the power-down state every time the Refresh Must level is set, performs AUTO REFRESH commands to the SDRAM, and returns back to the power-down state. This evenly distributes the refreshes to the SDRAM in power-down state. If the PDWR bit is not set, the EMIF does not perform any refreshes to the SDRAM. Therefore, the data integrity of the SDRAM is not maintained upon power-down exit, if the PDWR bit is not set.

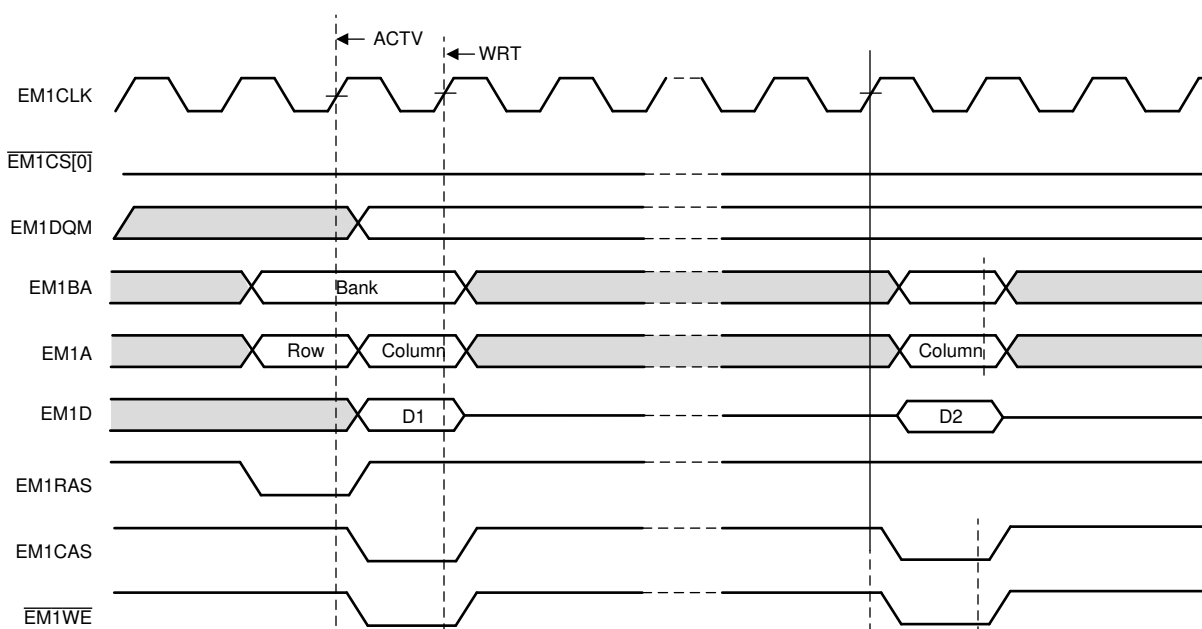

If the PD bit is cleared while in the power-down state, the EMIF comes out of the power-down state. The EMIF:

- Drives EM1SDCKE high
- Enters the idle state

### 11.2.5.9 SDRAM Read Operation

When the EMIF receives a read request to the SDRAM from one of the requesters listed in [Section 11.2.2](#), the EMIF performs one or more read access cycles. A read access cycle begins with the issuing of the ACTV command to select the desired bank and row of the SDRAM device. After the row has been opened, the EMIF proceeds to issue a READ command while specifying the desired bank and column address. EM1A[10] is held low during the READ command to avoid auto-precharging. The READ command signals the SDRAM device to output data from the specified address while EMIF issues NOP commands. Following a READ command, the CL field of the SDRAM configuration register (SDRAM\_CR) defines how many delay cycles are present before the read data appears on the data bus. This is referred to as the CAS latency.

[Figure 11-6](#) shows the signal waveforms for a basic SDRAM read operation in which multiple data is read from a single page. On this device, burst accesses are not supported; hence, the EMIF issues a READ command for each data access. Only when the EMIF SDRAM interface is configured to 16-bit by setting the NM bit of the SDRAM configuration register (SDRAM\_CR) to 1 and CPU (or any other controller) does a 32-bit READ access, a burst access is issued with a size of two.

**Figure 11-6. Timing Waveform for Basic SDRAM Read Operation**

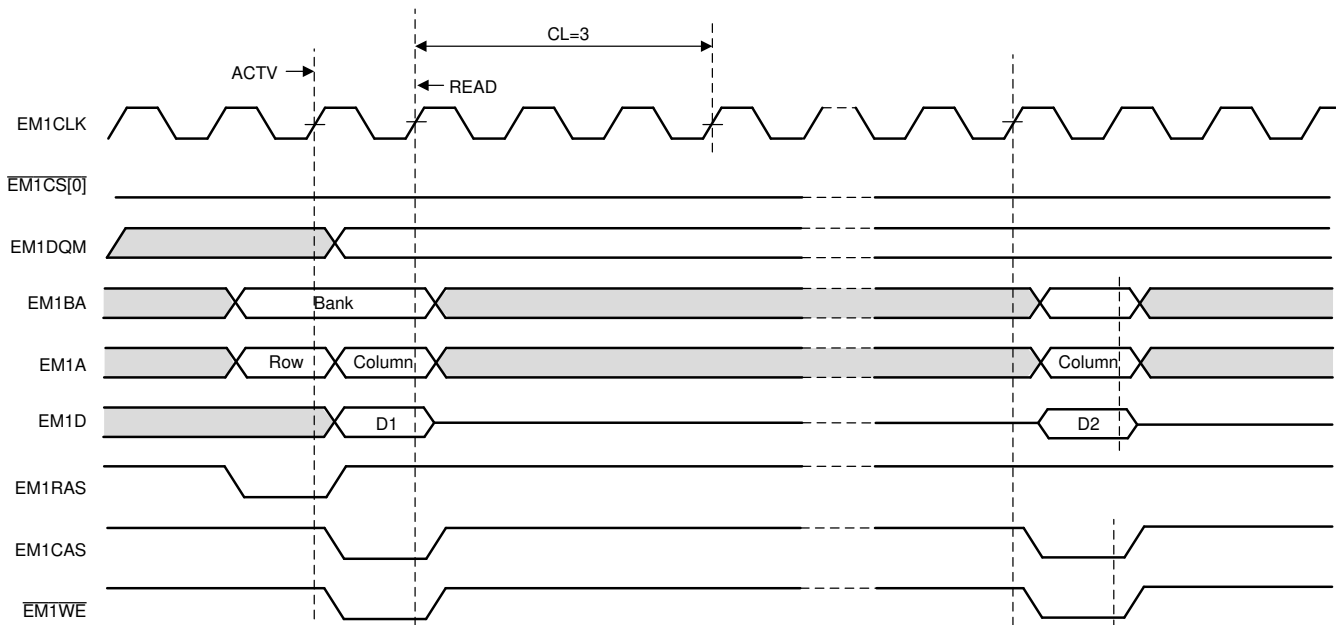

Several other pins are also active during a read access. The EM1DQM[x:0] pins are driven low during the READ commands and are kept low during the NOP commands that correspond to the burst request. The state of the other EMIF pins during each command can be found in [Table 11-6](#).

The EMIF schedules the commands based on the timing information that is provided to the EMIF in the SDRAM timing register (SDRAM\_TR). The values for the timing parameters in this register must be chosen to satisfy the timing requirements listed in the SDRAM data manual. The EMIF uses this timing information to avoid violating any timing constraints related to issuing commands. This is commonly accomplished by inserting NOP commands between various commands during an access. Refer to the register description of SDRAM\_TR in the SDTIMER register for more details on the various timing parameters.

### 11.2.5.10 SDRAM Write Operations

When the EMIF receives a write request to SDRAM from one of the requesters listed in [Section 11.2.2](#), the EMIF performs one or more write-access cycles. A write-access cycle begins with the issuing of the ACTV command to select the desired bank and row of the SDRAM device. After the row has been opened, the EMIF proceeds to issue a WRT command while specifying the desired bank and column address. EM1A[10] is held low during the WRT command to avoid auto-precharging. The WRT command signals the SDRAM device to start writing the given data to the specified address while the EMIF issues NOP commands. On this device, burst accesses are not supported; hence, the EMIF issues a WRITE command for each data access. Only when the EMIF SDRAM interface is configured to 16-bit by setting the NM bit of the SDRAM configuration register (SDRAM\_CR) to 1 and CPU (or any other controller) does a 32bit WRITE access, a burst access is issued with size of two.

Figure 11-7 shows the signal waveforms for a basic SDRAM write operation.

**Figure 11-7. Timing Waveform for Basic SDRAM Write Operation**

The EMIF truncates a series of bursting data if the remaining addresses of the burst are not part of the write request. The EMIF can truncate the burst in three ways:

- By issuing another WRT to the same page
- By issuing a PRE command to prepare for accessing a different page of the same bank
- By issuing a BT command to prepare for accessing a page in a different bank

Several other pins are also active during a write access. The EM1DQM[x:0] pins are driven to select which bytes of the data word are written to the SDRAM device. The pins are also used to mask out entire undesired data words during a burst access. The state of the other EMIF pins during each command can be found in [Table 11-6](#).

The EMIF schedules the commands based on the timing information that is provided to the EMIF in the SDRAM timing register (SDRAM\_TR). The values for the timing parameters in this register must be chosen to satisfy the timing requirements listed in the SDRAM data sheet. The EMIF uses this timing information to avoid violating any timing constraints related to issuing commands. This is commonly accomplished by inserting NOP commands during various cycles of an access. Refer to the register description of SDRAM\_TR in the SDTMR register for more details on the various timing parameters.

### 11.2.5.11 Mapping from Logical Address to EMIF Pins

When the EMIF receives an SDRAM access request, the EMIF must convert the address of the access into the appropriate signals to send to the SDRAM device. The details of this address mapping are shown in [Table 11-14](#) for 32-bit operation and in [Table 11-15](#) for 16-bit operation. Using the settings of the IBANK and PAGESIZE fields of the SDRAM configuration register (SDRAM\_CR), the EMIF determines which bits of the logical address are mapped to the SDRAM row, column, and bank addresses.

As the logical address is incremented by one halfword (16-bit operation), the column address is likewise incremented by one until a page boundary is reached. When the logical address increments across a page boundary, the EMIF moves into the same page in the next bank of the attached device by incrementing the bank address EM1BA and resetting the column address. The page in the previous bank is left open until necessary to close the page. This method of traversal through the SDRAM banks helps maximize the number of open banks inside of the SDRAM and results in an efficient use of the device. There is no limitation on the number of banks that can be open at one time, but only one page within a bank can be open at a time.

The EMIF uses the EM1DQM[3:0] pins during a WRT command to mask out selected bytes or entire words. The EM1DQM[3:0] pins are always low during a READ command.

**Table 11-14. Mapping from Logical Address to EMIF Pins for 32-bit SDRAM**

IBANK	PAGESIZE	Logical Address														
		31:27	26	25	24	23	22	21:14	13	12	11	10	9	8:1	0	
0	0	-						Row Address						Col Address	EM1DQM[2]/EM1DQM[3]	
1	0	-						Row Address						EM1BA[0]	Col Address	EM1DQM[2]/EM1DQM[3]
2	0	-						Row Address						EM1BA[1:0]	Col Address	EM1DQM[2]/EM1DQM[3]
0	1	-						Row Address						Column Address		EM1DQM[2]/EM1DQM[3]
1	1	-						Row Address						EM1BA[0]	Column Address	EM1DQM[2]/EM1DQM[3]
2	1	-						Row Address						EM1BA[1:0]	Column Address	EM1DQM[2]/EM1DQM[3]
0	2	-						Row Address						Column Address		EM1DQM[2]/EM1DQM[3]
1	2	-						Row Address						EM1BA[0]	Column Address	EM1DQM[2]/EM1DQM[3]
2	2	-						Row Address						EM1BA[1:0]	Column Address	EM1DQM[2]/EM1DQM[3]
0	3	-						Row Address						Column Address		EM1DQM[2]/EM1DQM[3]
1	3	-						Row Address						EM1BA[0]	Column Address	EM1DQM[2]/EM1DQM[3]
2	3	-						Row Address						EM1BA[1:0]	Column Address	EM1DQM[2]/EM1DQM[3]

**Table 11-15. Mapping from Logical Address to EMIF Pins for 16-bit SDRAM**

IBANK	PAGESIZE	Logical Address													
		31:26	25	24	23	22	21	20:13	12	11	10	9	8	7:0	
0	0	-						Row Address						Col Address	
1	0	-						Row Address						EM1BA[0]	Col Address
2	0	-						Row Address						EM1BA[1:0]	Col Address
0	1	-						Row Address						Column Address	
1	1	-						Row Address						EM1BA[0]	Column Address
2	1	-						Row Address						EM1BA[1:0]	Column Address
0	2	-						Row Address						Column Address	
1	2	-						Row Address						EM1BA[0]	Column Address
2	2	-						Row Address						EM1BA[1:0]	Column Address
0	3	-						Row Address						Column Address	
1	3	-						Row Address						EM1BA[0]	Column Address
2	3	-						Row Address						EM1BA[1:0]	Column Address

**Note**

The upper bit of the row address is used only when addressing 256-Mbit and 512-Mbit SDRAM memories.

**11.2.6 Asynchronous Controller and Interface**

The EMIF easily interfaces to a variety of asynchronous devices including NOR Flash and SRAM. The EMIF can be operated in two major modes (see Table 11-16):

- Normal Mode
- Select Strobe Mode

**Table 11-16. Normal Mode vs. Select Strobe Mode**

Mode	Function of EM1DQM pins	Operation of EM1CS[4:2]
Normal Mode	Byte enables	Active during the entire asynchronous access cycle
Select Strobe Mode	Byte enables	Active only during the strobe period of an access cycle

The first mode of operation is normal mode, in which the EM1DQM pins of the EMIF function as byte enables. In this mode, the  $\overline{\text{EM1CS}}[4:2]$  pins behave as typical chip select signals, remaining active for the duration of the asynchronous access. See Section 11.2.6.1 for an example interface with multiple 8-bit devices.

The second mode of operation is select strobe mode, in which the  $\overline{\text{EM1CS}}[4:2]$  pins act as a strobe, active only during the strobe period of an access. In this mode, the EM1DQM pins of the EMIF function as standard byte enables for reads and writes. A summary of the differences between the two modes of operation are shown in Table 11-16. Refer to Section 11.2.6.4 for the details of asynchronous operations in normal mode, and to Section 11.2.6.5 for the details of asynchronous operations in select strobe mode. The EMIF hardware defaults to normal mode, but can be manually switched to select strobe mode by setting the SS bit in the asynchronous  $m$  ( $m = 1, 2, 3, \text{ or } 4$ ) configuration register (CENCFG) ( $n = 2, 3, \text{ or } 4$ ). Throughout the chapter,  $m$  can hold the values 1, 2, 3 or 4; and  $n$  can hold the values 2, 3, or 4.

The EMIF also provides configurable cycle timing parameters and an extended wait mode that allows the connected device to extend the strobe period of an access cycle. The following sections describe the features related to interfacing with external asynchronous devices.

**11.2.6.1 Interfacing to Asynchronous Memory**

Figure 11-8 shows the EMIF's external pins used in interfacing with an asynchronous device. In  $\overline{\text{EM1CS}}[n]$ ,  $n = 2, 3, \text{ or } 4$ .

**Figure 11-8. EMIF Asynchronous Interface**

Of special note is the connection between the EMIF and the external device's address bus. The EMIF address pin EM1A[0] always provides the least-significant bit of a 32-bit word address. Therefore, when interfacing to a 16-bit or 8-bit asynchronous device, the EM1BA[1] and EM1BA[0] pins provide the least-significant bits of the halfword or byte address, respectively. Figure 11-9 and Figure 11-10 show the mapping between the EMIF and the connected device's data and address pins for various programmed data bus widths. The data bus width can be configured in the asynchronous  $n$  configuration register (ASYNC\_CS $n$ \_CR).

Figure 11-10 shows an interface between the EMIF and an external memory with byte enables. The EMIF must be operated in either normal mode or select strobe mode when using this interface, so that the EM1DQM signals operate as byte enables.

a) EMIF to 8-bit memory interface

b) EMIF to 16-bit memory interface

**Figure 11-9. EMIF to 8-bit/16-bit Memory Interface**

**Figure 11-10. Common Asynchronous Interface**

### 11.2.6.2 Accessing Larger Asynchronous Memories

If a device such as a large asynchronous Flash needs to be attached to the EMIF, then GPIO pins can be used to control the Flash device upper address lines.

### 11.2.6.3 Configuring EMIF for Asynchronous Accesses

The operation of the EMIF's asynchronous interface can be configured by programming the appropriate register fields. The reset value and bit position for each register field can be found in [Section 11.5](#). The following tables list the register fields that can be programmed and describe the purpose of each field. These registers can be programmed prior to accessing the external memory, and the transfer following a write to these registers uses the new configuration.

**Table 11-17. Description of the Asynchronous *m* Configuration Register (ASYNC\_CS<sub>*n*</sub>\_CR)**

Parameter	Description
SS	<p><b>Select Strobe mode.</b> This bit selects the EMIF's mode of operation in the following way:</p> <ul style="list-style-type: none"> <li>SS = 0 selects Normal Mode <ul style="list-style-type: none"> <li>EM1DQM pins function as byte enables</li> <li><math>\overline{\text{EM1CS}}[4:2]</math> active for duration of access</li> </ul> </li> <li>SS = 1 selects Select Strobe Mode <ul style="list-style-type: none"> <li>EM1DQM pins function as byte enables</li> <li><math>\overline{\text{EM1CS}}[4:2]</math> acts as a strobe.</li> </ul> </li> </ul>
EW	<p><b>Extended Wait Mode enable.</b></p> <ul style="list-style-type: none"> <li>EW = 0 disables extended wait mode</li> <li>EW = 1 enables extended wait mode</li> </ul> <p>When set to 1, the EMIF enables the extended wait mode in which the strobe width of an access cycle can be extended in response to the assertion of the EM1WAIT pin. The WP<sub><i>n</i></sub> bit in the asynchronous wait cycle configuration register (ASYNC_WCCR) controls the polarity of the EM1WAIT pin. See <a href="#">Section 11.2.6.6</a> for more details on this mode of operation.</p>
W_SETUP/R_SETUP	<p><b>Read/Write setup widths.</b></p> <p>These fields define the number of EMIF clock cycles of setup time for the address pins (EM1A), byte enables (EM1DQM), and asynchronous chip enable (<math>\overline{\text{EM1CS}}[4:2]</math>) before the read strobe pin (EM103) or write strobe pin (EM1WE) falls, minus one cycle. For writes, the W_SETUP field also defines the setup time for the data pins (EM1D). Refer to the asynchronous device's data sheet to determine the appropriate setting for this field.</p>
W_STROBE/R_STROBE	<p><b>Read/Write strobe widths.</b></p> <p>These fields define the number of EMIF clock cycles between the falling and rising of the read strobe pin (EM103) or write strobe pin (EM1WE<sub><i>n</i></sub>), minus one cycle. If Extended Wait Mode is enabled by setting the EW field in the asynchronous <i>n</i> configuration register (ASYNC_CS<sub><i>n</i></sub>_CR), these fields must be set to a value greater than zero. Refer to the data manual of the external asynchronous device to determine the appropriate setting for this field.</p>
W_HOLD/R_HOLD	<p><b>Read/Write hold widths.</b></p> <p>These fields define the number of EMIF clock cycles of hold time for the address pins (EM1A and EM1BA), byte enables (EM1DQM), and asynchronous chip enable (<math>\overline{\text{EM1CS}}[4:2]</math>) after the read strobe pin (EM103) or write strobe pin (<math>\overline{\text{EM1WE}}</math>) rises, minus one cycle. For writes, the W_HOLD field also defines the hold time for the data pins (EM1D). Refer to the data manual of the external asynchronous device to determine the appropriate setting for this field.</p>
TA	<p><b>Minimum turnaround time.</b></p> <p>This field defines the minimum number of EMIF clock cycles between asynchronous reads and writes, minus one cycle. The purpose of this feature is to avoid contention on the bus. The value written to this field also determines the number of cycles that are inserted between asynchronous accesses and SDRAM accesses. Refer to the data manual of the external asynchronous device to determine the appropriate setting for this field.</p>

**Table 11-17. Description of the Asynchronous *m* Configuration Register (ASYNC\_CS<sub>n</sub>\_CR) (continued)**

Parameter	Description
ASIZE	<p><b>Asynchronous Device Bus Width.</b> This field determines the data bus width of the asynchronous interface in the following way:</p> <ul style="list-style-type: none"> <li>ASIZE = 0 selects an 8-bit bus</li> <li>ASIZE = 1 selects a 16-bit bus</li> <li>ASIZE = 2 selects a 32-bit bus</li> </ul> <p>The configuration of ASIZE determines the function of the EM1A and EM1BA pins as described in <a href="#">Section 11.2.6.1</a>. This field also determines the number of external accesses required to fulfill a request generated by one of the sources mentioned in <a href="#">Section 11.2.2</a>. For example, a request for a 32-bit word requires four external access when ASIZE = 0. Refer to the data manual of the external asynchronous device to determine the appropriate setting for this field.</p>

**Table 11-18. Description of the Asynchronous Wait Cycle Configuration Register (ASYNC\_WCCR)**

Parameter	Description
WP <sub>n</sub>	<p><b>EM_WAIT Polarity.</b></p> <ul style="list-style-type: none"> <li>WP<sub>n</sub> = 0 selects active-low polarity</li> <li>WP<sub>n</sub> = 1 selects active-high polarity</li> </ul> <p>When set to 1, the EMIF waits if the EM1WAIT pin is high. When cleared to 0, the EMIF waits if the EM1WAIT pin is low. The EMIF must have the Extended Wait Mode enabled for the EM1WAIT pin to affect the width of the strobe period.</p>
MAX_EXT_WAIT	<p><b>Maximum Extended Wait Cycles.</b> This field configures the number of EMIF clock cycles the EMIF waits for the EM1WAIT pin to be deactivated during the strobe period of an access cycle. The maximum number of EMIF clock cycles the EMIF waits is determined by the following formula: Maximum Extended Wait Cycles = (MAX_EXT_WAIT + 1) × 16 If the EM1WAIT pin is not deactivated within the time specified by this field, the EMIF resumes the access cycle, registering whatever data is on the bus and proceeding to the hold period of the access cycle. This situation is referred to as an Asynchronous Timeout. An Asynchronous Timeout generates an interrupt, if the interrupt has been enabled in the EMIF interrupt mask set register (INT_MSK_SET). Refer to <a href="#">Section 11.2.9.1</a> for more information about EMIF interrupts.</p>

**Table 11-19. Description of EMIF Interrupt Mask Set Register (INT\_MSK\_SET)**

Parameter	Description
WR_MASK_SET	<p><b>Wait Rise Mask Set.</b> Writing a 1 enables an interrupt to be generated when a rising edge on EM1WAIT occurs.</p>
AT_MASK_SET	<p><b>Asynchronous Timeout Mask Set.</b> Writing a 1 to this bit enables an interrupt to be generated when an Asynchronous Timeout occurs.</p>

**Table 11-20. Description of EMIF Interrupt Mast Clear Register (INT\_MSK\_CLR)**

Parameter	Description
WR_MASK_CLR	<b>Wait Rise Mask Clear.</b> Writing a 1 to this bit disables the interrupt, clearing the WR_MASK_SET bit in EMIF interrupt mask set register (INT_MSK_SET).
AT_MASK_CLR	<b>Asynchronous Timeout Mask Clear.</b> Writing a 1 to this bit prevents an interrupt from being generated when an Asynchronous Timeout occurs.

**Note**

The EMIF performs SDRAM refreshes even if the SDRAM interface is not used. If using only the ASRAM interface, then SDRAM refreshes impact the ASRAM performance. To avoid this, set PD = 1 in the SDRAM\_CR register (Emif1Regs.SDRAM\_CR.PD = 1). This bit can be updated only if there are no pending EMIF accesses.

**11.2.6.4 Read and Write Operations in Normal Mode**

Normal mode is the asynchronous interface default mode of operation. Normal mode is selected when the SS bit in the asynchronous  $n$  configuration register (ASYNC\_CS $n$ \_CR) is cleared to 0. In this mode, the EM1DQM pins operate as byte enables. [Section 11.2.6.4.1](#) and [Section 11.2.6.4.2](#) explain the details of read and write operations while in normal mode.

**11.2.6.4.1 Asynchronous Read Operations (Normal Mode)****Note**

During an entire asynchronous read operation, the EM1WE pin is driven high.

An asynchronous read is performed when any of the requesters mentioned in [Section 11.2.2](#) request a read from the attached asynchronous memory. After the request is received, a read operation is initiated once the request becomes the EMIF's highest priority task, according to the priority scheme detailed in [Section 11.2.13](#). In the event that the read request cannot be serviced by a single access cycle to the external device, multiple access cycles are performed by EMIF until the entire request is fulfilled. The details of an asynchronous read operation in normal mode are described in [Table 11-21](#). Also, [Figure 11-11](#) shows an example timing diagram of a basic read operation.

**Table 11-21. Asynchronous Read Operation in Normal Mode**

Time Interval	Pin Activity in Normal Mode
Turnaround period	Once the read operation becomes the highest priority task for EMIF, the EMIF waits for the programmed number of turn-around cycles before proceeding to the setup period of the operation. The number of wait cycles is taken directly from the TA field of the asynchronous $n$ configuration register (ASYNC_CS $n$ _CR). Between each access (write or read), the EMIF inserts two cycles of delay even though TA field is programmed as 0. After the EMIF has waited for the turnaround cycles to complete, the EMIF again checks to make sure that the read operation is still the highest priority task. If so, the EMIF proceeds to the setup period of the operation. If the read operation is no longer the highest priority task, the EMIF terminates the operation.
Start of the setup period	The following actions occur at the start of the setup period: <ul style="list-style-type: none"> <li>The setup, strobe, and hold values are set according to the R_SETUP, R_STROBE, and R_HOLD values in ASYNC_CS<math>n</math>_CR.</li> <li>The address pins EM1A and EM1BA become valid and carry the values described in <a href="#">Section 11.2.6.1</a>.</li> <li>EM1CS[4:2] falls to enable the external device (if not already low from a previous operation)</li> </ul>

**Table 11-21. Asynchronous Read Operation in Normal Mode (continued)**

Time Interval	Pin Activity in Normal Mode
Strobe period	<p>The following actions occur during the strobe period of a read operation:</p> <ol style="list-style-type: none"> <li>1. <math>\overline{\text{EM1OE}}</math> falls at the start of the strobe period</li> <li>2. On the rising edge of the clock that is concurrent with the end of the strobe period:                             <ul style="list-style-type: none"> <li>• <math>\overline{\text{EM1OE}}</math> rises</li> <li>• The data on the EM1Dx bus is sampled by EMIF.</li> </ul> </li> </ol> <p>In <a href="#">Figure 11-11</a>, EM1WAIT is inactive. If EM1WAIT is instead activated, the strobe period can be extended by the external device to give it more time to provide the data. <a href="#">Section 11.2.6.6</a> contains more details on using the EM1WAIT pin.</p>
End of the hold period	<p>At the end of the hold period:</p> <ul style="list-style-type: none"> <li>• The address pins EM1A and EM1BA become invalid</li> <li>• <math>\overline{\text{EM1CS}}[4:2]</math> rises (if no more operations are required to complete the current request)</li> </ul> <p>The EMIF can be required to issue additional read operations to a device with a small data bus width to complete an entire word access. In this case, the EMIF immediately re-enters the setup period to begin another operation without incurring the turn-round cycle delay. The setup, strobe, and hold values are not updated in this case. If the entire word access has been completed, the EMIF returns to the previous state unless another asynchronous request has been submitted and is currently the highest priority task. If this is the case, EMIF instead enters directly into the turnaround period for the pending read or write operation.</p>

**Figure 11-11. Timing Waveform of an Asynchronous Read Cycle in Normal Mode**

### 11.2.6.4.2 Asynchronous Write Operations (Normal Mode)

#### Note

During an entire asynchronous write operation, the EM1OE pin is driven high.

An asynchronous write is performed when any of the requesters mentioned in [Section 11.2.2](#) request a write to memory in the asynchronous bank of EMIF. After the request is received, a write operation is initiated once the request becomes the EMIF's highest priority task, according to the priority scheme detailed in [Section 11.2.13](#). In the event that the write request cannot be serviced by a single access cycle to the external device, multiple access cycles are performed by the EMIF until the entire request is fulfilled. The details of an asynchronous write operation in normal mode are described in [Table 11-22](#). Also, [Figure 11-12](#) shows an example timing diagram of a basic write operation.

**Table 11-22. Asynchronous Write Operation in Normal Mode**

Time Interval	Pin Activity in Normal Mode
Turnaround period	Once the write operation becomes the highest priority task for the EMIF, the EMIF waits for the programmed number of turn-around cycles before proceeding to the setup period of the operation. The number of wait cycles is taken directly from the TA field of the asynchronous <i>n</i> configuration register (ASYNC_CS <i>n</i> _CR). Between each access (write or read) EMIF inserts two cycles of delay even though TA field is programmed as 0. After the EMIF has waited for the turn-around cycles to complete, the EMIF again checks to make sure that the write operation is still the highest priority task. If so, the EMIF proceeds to the setup period of the operation. If the write operation is no longer the highest priority task, EMIF terminates the operation.
Start of the setup period	The following actions occur at the start of the setup period: <ul style="list-style-type: none"> <li>The setup, strobe, and hold values are set according to the W_SETUP, W_STROBE, and W_HOLD values in ASYNC_CS<i>n</i>_CR.</li> <li>The address pins EM1A and EM1BA and the data pins EM1D<i>x</i> become valid. The EM1A and EM1BA pins carry the values described in <a href="#">Section 11.2.6.1</a>.</li> <li><math>\overline{\text{EM1CS}}[4:2]</math> falls to enable the external device (if not already low from a previous operation).</li> </ul>
Strobe period	The following actions occur at the start of the strobe period of a write operation: <ol style="list-style-type: none"> <li><math>\overline{\text{EM1WE}}</math> falls</li> <li>The EM1DQM pins become valid as byte enables.</li> </ol> <p>The following actions occur on the rising edge of the clock that is concurrent with the end of the strobe period:</p> <ol style="list-style-type: none"> <li><math>\overline{\text{EM1WE}}</math> rises</li> <li>The EM1DQM pins deactivate</li> </ol> <p>In <a href="#">Figure 11-12</a>, EM1WAIT is inactive. If EM1WAIT is instead activated, the strobe period can be extended by the external device to give it more time to accept the data. <a href="#">Section 11.2.6.6</a> contains more details on using the EM1WAIT pin.</p>
End of the hold period	At the end of the hold period: <ul style="list-style-type: none"> <li>The address pins EM1A<i>x</i> and EM1BA<i>x</i> become invalid</li> <li>The data pins become invalid</li> <li><math>\overline{\text{EM1CS}}[n]</math> (<i>n</i> = 2, 3, or 4) rises (if no more operations are required to complete the current request)</li> </ul> <p>The EMIF can be required to issue additional write operations to a device with a small data bus width to complete an entire word access. In this case, the EMIF immediately re-enters the setup period to begin another operation without incurring the turnaround cycle delay. The setup, strobe, and hold values are not updated in this case. If the entire word access has been completed, the EMIF returns to the previous state unless another asynchronous request has been submitted and is currently the highest priority task. If this is the case, the EMIF instead enters directly into the turnaround period for the pending read or write operation.</p>

Figure 11-12. Timing Waveform of an Asynchronous Write Cycle in Normal Mode

### 11.2.6.5 Read and Write Operation in Select Strobe Mode

Select Strobe mode is the EMIF's second mode of operation. Select Strobe mode is selected when the SS bit of the asynchronous  $n$  configuration register (ASYNC\_CS $_n$ \_CR) is set to 1. In this mode, the EM1DQM pins operate as byte enables and the  $\overline{\text{EM1CS}}[n]$  ( $n = 2, 3, \text{ or } 4$ ) pin is only active during the strobe period of an access cycle. [Section 11.2.6.4.1](#) and [Section 11.2.6.4.2](#) explain the details of read and write operations while in select strobe mode.

#### 11.2.6.5.1 Asynchronous Read Operations (Select Strobe Mode)

##### Note

During the entirety of an asynchronous read operation, the EM1WEn pin is driven high.

An asynchronous read is performed when any of the requesters mentioned in [Section 11.2.2](#) request a read from the attached asynchronous memory. After the request is received, a read operation is initiated once the request becomes the EMIF's highest priority task, according to the priority scheme detailed in [Section 11.2.13](#). In the event that the read request cannot be serviced by a single access cycle to the external device, multiple access cycles are performed by the EMIF until the entire request is fulfilled. The details of an asynchronous read operation in select strobe mode are described in [Table 11-23](#). Also, [Figure 11-13](#) shows an example timing diagram of a basic read operation.

**Table 11-23. Asynchronous Read Operation in Select Strobe Mode**

Time Interval	Pin Activity in Select Strobe Mode
Turnaround period	Once the read operation becomes the highest priority task for the EMIF, the EMIF waits for the programmed number of turnaround cycles before proceeding to the setup period of the operation. The number of wait cycles is taken directly from the TA field of the asynchronous $n$ configuration register (ASYNC_CS $_n$ _CR). Between each access (Write or Read) EMIF inserts two cycles of delay even though TA field is programmed as 0. After the EMIF has waited for the turn-around cycles to complete, the EMIF again checks to make sure that the read operation is still the highest priority task. If so, the EMIF proceeds to the setup period of the operation. If the read operation is no longer the highest priority task, the EMIF terminates the operation.
Start of the setup period	The following actions occur at the start of the setup period: <ul style="list-style-type: none"> <li>The setup, strobe, and hold values are set according to the R_SETUP, R_STROBE, and R_HOLD values in ASYNC_CS<math>_n</math>_CR.</li> <li>The address pins EM1A and EM1BA become valid and carry the values described in <a href="#">Section 11.2.6.1</a>.</li> <li>The EM1DQM pins become valid as byte enables.</li> </ul>
Strobe period	The following actions occur during the strobe period of a read operation: <ol style="list-style-type: none"> <li><math>\overline{\text{EM1CS}}[n]</math> (<math>n = 2, 3, \text{ or } 4</math>) and <math>\overline{\text{EM1OE}}</math> fall at the start of the strobe period</li> <li>On the rising edge of the clock that is concurrent with the end of the strobe period: <ul style="list-style-type: none"> <li><math>\overline{\text{EM1CS}}[n]</math> (<math>n = 2, 3, \text{ or } 4</math>) and <math>\overline{\text{EM1OE}}</math> rise</li> <li>The data on the EM1D bus is sampled by EMIF.</li> </ul> </li> </ol> <p>In <a href="#">Figure 11-13</a>, EM1WAIT is inactive. If EM1WAIT is instead activated, the strobe period can be extended by the external device to give more time to provide the data. <a href="#">Section 11.2.6.6</a> contains more details on using the EM1WAIT pin.</p>
End of the hold period	At the end of the hold period: <ul style="list-style-type: none"> <li>The address pins EM1A and EM1BA become invalid</li> <li>The EM1DQM pins become invalid</li> </ul> <p>The EMIF can be required to issue additional read operations to a device with a small data bus width to complete an entire word access. In this case, the EMIF immediately re-enters the setup period to begin another operation without incurring the turnaround cycle delay. The setup, strobe, and hold values are not updated in this case. If the entire word access has been completed, the EMIF returns to the previous state unless another asynchronous request has been submitted and is currently the highest priority task. If this is the case, the EMIF instead enters directly into the turnaround period for the pending read or write operation.</p>

Figure 11-13. Timing Waveform of an Asynchronous Read Cycle in Select Strobe Mode

### 11.2.6.5.2 Asynchronous Write Operations (Select Strobe Mode)

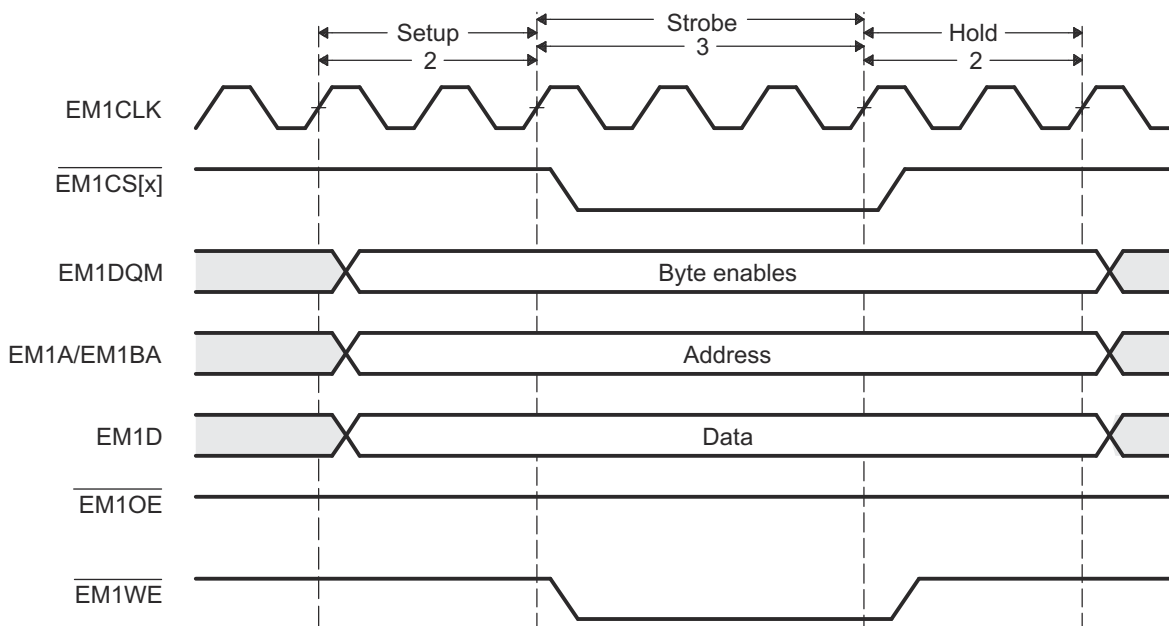

#### Note

During the entirety of an asynchronous write operation, the  $\overline{\text{EM1OE}}$  pin is driven high.

An asynchronous write is performed when any of the requesters mentioned in [Section 11.2.2](#) request a write to memory in the asynchronous bank of EMIF. After the request is received, a write operation is initiated once the request becomes the EMIF's highest priority task, according to the priority scheme detailed in [Section 11.2.13](#). In the event that the write request cannot be serviced by a single access cycle to the external device, multiple access cycles are performed by the EMIF until the entire request is fulfilled. The details of an asynchronous write operation in select strobe mode are described in [Table 11-24](#). Also, [Figure 11-14](#) shows an example timing diagram of a basic write operation.

**Table 11-24. Asynchronous Write Operation in Select Strobe Mode**

Time Interval	Pin Activity in Select Strobe Mode
Turnaround period	<p>Once the write operation becomes the highest priority task for the EMIF, the EMIF waits for the programmed number of turnaround cycles before proceeding to the setup period of the operation. The number of wait cycles is taken directly from the TA field of the asynchronous <i>n</i> configuration register (ASYNC_CS<sub>n</sub>_CR). Between each access (Write or Read) EMIF inserts two cycles of delay even though TA field is programmed as 0.</p> <p>After the EMIF has waited for the turnaround cycles to complete, the EMIF again checks to make sure that the write operation is still the highest priority task. If so, the EMIF proceeds to the setup period of the operation. If the write operation is no longer the highest priority task, the EMIF terminates the operation.</p>
Start of the setup period	<p>The following actions occur at the start of the setup period:</p> <ul style="list-style-type: none"> <li>The setup, strobe, and hold values are set according to the W_SETUP, W_STROBE, and W_HOLD values in ASYNC_CS<sub>n</sub>_CR.</li> <li>The address pins EM1A and EM1BA and the data pins EM1D become valid. The EM1A and EM1BA pins carry the values described in <a href="#">Section 11.2.6.1</a>.</li> <li>The EM1DQM pins become active as byte enables.</li> </ul>
Strobe period	<p>The following actions occur at the start of the strobe period of a write operation:</p> <ul style="list-style-type: none"> <li><math>\overline{\text{EM1CS}}[n]</math> (<i>n</i> = 2, 3, or 4) and <math>\overline{\text{EM1WE}}</math> fall</li> </ul> <p>The following actions occur on the rising edge of the clock which is concurrent with the end of the strobe period:</p> <ul style="list-style-type: none"> <li><math>\overline{\text{EM1CS}}[n]</math> (<i>n</i> = 2, 3, or 4) and <math>\overline{\text{EM1WE}}</math> rise</li> </ul> <p>In <a href="#">Figure 11-14</a>, EM1WAIT is inactive. If EM1WAIT is instead activated, the strobe period can be extended by the external device to give more time to accept the data. <a href="#">Section 11.2.6.6</a> contains more details on using the EM1WAIT pin.</p>
End of the hold period	<p>At the end of the hold period:</p> <ul style="list-style-type: none"> <li>The address pins EM1A and EM1BA become invalid</li> <li>The data pins become invalid</li> <li>The EM1DQM pins become invalid</li> </ul> <p>The EMIF can be required to issue additional write operations to a device with a small data bus width to complete an entire word access. In this case, the EMIF immediately re-enters the setup period to begin another operation without incurring the turnaround cycle delay. The setup, strobe, and hold values are not updated in this case. If the entire word access has been completed, the EMIF returns to the previous state unless another asynchronous request has been submitted and is currently the highest priority task. If this is the case, the EMIF instead enters directly into the turnaround period for the pending read or write operation.</p>

**Figure 11-14. Timing Waveform of an Asynchronous Write Cycle in Select Strobe Mode**

#### 11.2.6.6 Extended Wait Mode and the EM1WAIT Pin

The EMIF supports the extended wait mode. This is a mode that the external asynchronous device can assert control over the length of the strobe period. The extended wait mode can be entered by setting the EW bit in the asynchronous  $n$  configuration register (ASYNC\_CS $n$ \_CR ( $n = 2, 3, \text{ or } 4$ )). When this bit is set, the EMIF monitors the EM1WAIT pin to determine if the attached device wishes to extend the strobe period of the current access cycle beyond the programmed number of clock cycles.

When the EMIF detects that the EM1WAIT pin has been asserted, the EMIF begins inserting extra strobe cycles into the operation until the EM1WAIT pin is deactivated by the external device. The EMIF then returns to the last cycle of the programmed strobe period and the operation proceeds as usual from this point. Refer to the device data sheet for details on the timing requirements of the EM1WAIT signal.

The EM1WAIT pin cannot be used to extend the strobe period indefinitely. The programmable MAX\_EXT\_WAIT field in the asynchronous wait cycle configuration register (AWCC) determines the maximum number of EM1CLK cycles the strobe period can be extended beyond the programmed length. When the counter expires, the EMIF proceeds to the hold period of the operation regardless of the state of the EM1WAIT pin. The EMIF can also generate an interrupt upon expiration of this counter. See [Section 11.2.9.1](#) for details on enabling this interrupt.

For the EMIF to function properly in the extended wait mode, the WP $n$  bit of AWCC must be programmed to match the polarity of the EM1WAIT pin. In the reset state of 1, the EMIF inserts wait cycles when the EM1WAIT pin is sampled high. When set to 0, the EMIF inserts wait cycles only when EM1WAIT is sampled low. This programmability allows for a glueless connection to larger variety of asynchronous devices.

Finally, a restriction is placed on the strobe period timing parameters when operating in extended wait mode. Specifically, the sum of the W\_SETUP and W\_STROBE fields must be greater than four, and the sum of the R\_SETUP and R\_STROBE fields must be greater than four for the EMIF to recognize the EM1WAIT pin has been asserted. The W\_SETUP, W\_STROBE, R\_SETUP, and R\_STROBE fields are in ASYNC\_CS $n$ \_CR.

### 11.2.7 Data Bus Parking

The EMIF always drives the data bus to the previous write data value when the EMIF is idle. This feature is called data bus parking. Only when the EMIF issues a read command to the external memory does the EMIF stop driving the data bus. After the EMIF latches the last read data, the EMIF immediately parks the data bus again.

The one exception to this behavior occurs after performing an asynchronous read operation while the EMIF is in the self-refresh state. In this situation, the read operation is not followed by the EMIF parking the data bus. Instead, the EMIF tri-states the data bus. Therefore, it is not recommended to perform asynchronous read operations while the EMIF is in the self-refresh state, to prevent floating inputs on the data bus. External pull-ups, such as 10-kohm resistors, must be placed on the 16 EMIF data bus pins (that do not have internal pull-ups) if required to perform reads in this situation. The precise resistor value must be chosen so that the worst case combined off-state leakage currents do not cause the voltage levels on the associated pins to drop below the high-level input voltage requirement.

For information about the self-refresh state, see [Section 11.2.5.7](#).

### 11.2.8 Reset and Initialization Considerations

The EMIF memory controller has two active-low reset signals, `CHIP_RST_n` and `MOD_G_RST_n`. Both these reset signals are driven by the device system reset signal. This device does not offer the flexibility to reset just the EMIF state machine without also resetting the EMIF controller's memory-mapped registers. As soon as the device system reset is released (driven high), the EMIF memory controller immediately begins its initialization sequence. Command and data stored in the EMIF memory controller FIFOs are lost. Refer to [Section 11.2](#) for more information on conditions that can cause a device system reset to be asserted.

When system reset is released, the EMIF automatically begins running the SDRAM initialization sequence described in [Section 11.2.5.4](#). Even though the initialization procedure is automatic, a special procedure, found in [Section 11.2.5.5](#) must still be followed.

### 11.2.9 Interrupt Support

The EMIF supports a single interrupt to the CPU. [Section 11.2.9.1](#) details the generation and internal masking of EMIF interrupts.

#### 11.2.9.1 Interrupt Events

There are three conditions that can cause the EMIF to generate an interrupt to the CPU. These conditions are:

- A rising edge on the EM1WAIT signal (wait rise interrupt)
- An asynchronous time out
- Usage of unsupported addressing mode (line trap interrupt)

The wait rise interrupt occurs when a rising edge is detected on EM1WAIT signal. This interrupt generation is not affected by the `WPn` bit in the asynchronous wait cycle configuration register (`ASYNC_WCCR`). The asynchronous time out interrupt condition occurs when the attached asynchronous device fails to deassert the EM1WAIT pin within the number of cycles defined by the `MAX_EXT_WAIT` bit in `AWCC` (this happens only in extended wait mode). The EMIF supports only linear incrementing and cache line wrap addressing modes. If an access request for an unsupported addressing mode is received, the EMIF sets the `LT` bit in the EMIF interrupt raw register (`INT_RAW`) and treats the request as a linear incrementing request.

Only when the interrupt is enabled by setting the appropriate bit (`WR_MASK_SET/AT_MASK_SET/LT_MASK_SET`) in the EMIF interrupt mask set register (`INT_MSK_SET`) to 1, is the interrupt sent to the CPU. Once enabled, the interrupt can be disabled by writing a 1 to the corresponding bit in the EMIF interrupt mask clear register (`INT_MSK_CLR`). The bit fields in both the `INT_MSK_SET` and `INT_MSK_CLR` can be used to indicate whether the interrupt is enabled. When the interrupt is enabled, the corresponding bit field in both the `INT_MSK_SET` and `INT_MSK_CLR` have a value of 1; when the interrupt is disabled, the corresponding bit field has a value of 0.

The EMIF interrupt raw register (INT\_RAW) and the IF interrupt mask register (INT\_MSK) indicate the status of each interrupt. The appropriate bit (WR/AT/LT) in INT\_RAW is set when the interrupt condition occurs, whether or not the interrupt has been enabled. However, the appropriate bit (WR\_MASKED/AT\_MASKED/LT\_MASKED) in INT\_MSK is set only when the interrupt condition occurs and the interrupt is enabled. Writing a 1 to the bit in INT\_RAW clears the INT\_RAW bit as well as the corresponding bit in INT\_MSK. [Table 11-25](#) contains a brief summary of the interrupt status and control bit fields. See [Section 11.5](#) for complete details on the register fields.

**Table 11-25. Interrupt Monitor and Control Bit Fields**

Register Name	Bit Name	Description
EMIF interrupt raw register (INT_RAW)	WR	This bit is set when a rising edge on the EM1WAIT signal occurs. Writing a 1 clears the WR bit as well as the WR_MASKED bit in INT_MSK.
	AT	This bit is set when an asynchronous timeout occurs. Writing a 1 clears the AT bit as well as the AT_MASKED bit in INT_MSK.
	LT	This bit is set when an unsupported addressing mode is used. Writing a 1 clears LT bit as well as the LT_MASKED bit in INT_MSK.
EMIF interrupt mask register (INT_MSK)	WR_MASKED	This bit is set only when a rising edge on the EM1WAIT signal occurs and the interrupt has been enabled by writing a 1 to the WR_MASK_SET bit in INT_MSK_SET.
	AT_MASKED	This bit is set only when an asynchronous timeout occurs and the interrupt has been enabled by writing a 1 to the AT_MASK_SET bit in INT_MSK_SET.
	LT_MASKED	This bit is set only when line trap interrupt occurs and the interrupt has been enabled by writing a 1 to the LT_MASK_SET bit in INT_MSK_SET.
EMIF interrupt mask set register (INT_MSK_SET)	WR_MASK_SET	Writing a 1 to this bit enables the wait rise interrupt.
	AT_MASK_SET	Writing a 1 to this bit enables the asynchronous timeout interrupt.
	LT_MASK_SET	Writing a 1 to this bit enables the line trap interrupt.
EMIF interrupt mask clear register (INT_MSK_CLR)	WR_MASK_CLR	Writing a 1 to this bit disables the wait rise interrupt.
	AT_MASK_CLR	Writing a 1 to this bit disables the asynchronous timeout interrupt.
	LT_MASK_CLR	Writing a 1 to this bit disables the line trap interrupt.

### 11.2.10 DMA Event Support

The EMIF memory controller is a DMA target peripheral and therefore does not generate DMA events. Data read and write requests can be made directly, by controllers and the DMA.

### 11.2.11 EMIF Signal Multiplexing

For details on the EMIF signal multiplexing, see the *GPIO* chapter, I/O Multiplexing Module section, of this technical reference manual.

### 11.2.12 Memory Map

For information describing the device memory-map, see the data sheet.

### 11.2.13 Priority and Arbitration

[Section 11.2.2](#) describes the external prioritization and arbitration among requests from different sources within the microcontroller. The result of this external arbitration is that only one request is presented to the EMIF at a time. Once the EMIF completes a request, the external arbiter then provides the EMIF with the next pending request.

Internally, the EMIF undertakes memory device transactions according to a strict priority scheme. The highest priority events are:

- A device reset.
- A write to any of the three least significant bytes of the SDRAM configuration register (SDRAM\_CR).

Either of these events causes the EMIF to immediately commence the initialization sequence as described in [Section 11.2.5.4](#).

Once the EMIF has completed its initialization sequence, the EMIF performs memory transactions according to the following priority scheme (highest priority listed first):

1. If the EMIF's backlog refresh counter is at the Refresh Must urgency level, the EMIF performs multiple SDRAM auto-refresh cycles until the Refresh Release urgency level is reached.
2. If an SDRAM or asynchronous read has been requested, the EMIF performs a read operation.
3. If the EMIF's backlog refresh counter is at the Refresh Need urgency level, the EMIF performs an SDRAM auto-refresh cycle.
4. If an SDRAM or asynchronous write has been requested, the EMIF performs a write operation.
5. If the EMIF's backlog refresh counter is at the Refresh May or Refresh Release urgency level, the EMIF performs an SDRAM auto-refresh cycle.
6. If the value of the SR bit in SDRAM\_CR has been set to 1, the EMIF enters the self-refresh state as described in [Section 11.2.5.7](#).

After taking one of the actions listed above, the EMIF then returns to the top of the priority list to determine the next action.

Because the EMIF does not issue auto-refresh cycles when in the self-refresh state, the above priority scheme does not apply when in this state. See [Section 11.2.5.7](#) for details on the operation of the EMIF when in the self-refresh state.

### 11.2.14 System Considerations

This section describes various system considerations to keep in mind when operating the EMIF.

#### 11.2.14.1 Asynchronous Request Times

In a system that interfaces to both SDRAM and asynchronous memory, the asynchronous requests must not take longer than the smaller of the following two values:

- $t_{RAS}$  (typically 120 $\mu$ s) - to avoid violating the maximum time allowed between issuing an ACTV and PRE command to the SDRAM.
- $t_{Refresh\ Rate} \times 11$  (typically 15.7 $\mu$ s  $\times$  11 = 172.7 $\mu$ s) - to avoid refresh violations on the SDRAM.

The length of an asynchronous request is controlled by multiple factors, the primary factor being the number of access cycles required to complete the request. For example, an asynchronous request for 4 bytes requires four access cycles using an 8-bit data bus and only two access cycle using a 16-bit data bus. The maximum request size that the EMIF can be sent is 16 words; therefore, the maximum number of access cycles per memory request is 64 when the EMIF is configured with an 8-bit data bus. The length of the individual access cycles that make up the asynchronous request is determined by the programmed setup, strobe, hold, and turnaround values, but can also be extended with the assertion of the EM1WAIT input signal up to a programmed maximum limit. The user must make sure that an entire asynchronous request does not exceed the timing values listed above when also interfacing to an SDRAM device. This can be done by limiting the asynchronous timing parameters.

### 11.2.15 Power Management

Power dissipation from the EMIF memory controller can be managed by following methods:

- Self-refresh mode
- Power-down mode
- Gating input clocks to the module off

Gating input clocks off to the EMIF memory controller achieves higher power savings when compared to the power savings of self-refresh or power down mode. The input clock to EMIF can be turned off through the use of the Global Clock Module (GCM). Before gating clocks off, the EMIF memory controller must place the SDR SDRAM memory in self-refresh mode. If the external memory requires a continuous clock, the VCLK3 clock domain must not be turned off because this can result in data corruption. See the following subsections for the proper procedures to follow when stopping EMIF memory controller clocks.

#### 11.2.15.1 Power Management Using Self-Refresh Mode

The EMIF memory controller can be placed into a self-refresh state in order to place the attached SDRAM devices into self-refresh mode, which consumes less power for most SDRAM devices. In this state, the attached SDRAM device uses an internal clock to perform its own auto refresh cycles. This maintains the validity of the data in the SDRAM without the need for any external commands. Refer to [Section 11.2.5.7](#) for more details on placing the EMIF into the self-refresh state.

#### 11.2.15.2 Power Management Using Power Down Mode

In the power down mode, the EMIF drives EM1SDCKE low to lower the power consumption. EM1SDCKE goes high when there is a need to send refresh (REFR) commands, after which EM1SDCKE is again driven low. EM1SDCKE remains low until any request arrives. Refer to [Section 11.2.5.8](#) for more details on placing the EMIF in power-down mode.

### 11.2.16 Emulation Considerations

The EMIF remains fully functional during emulation halts in order to allow emulation access to external memory.

## 11.3 Example Configuration

This section presents an example of interfacing the EMIF1 to both an SDR SDRAM device and an asynchronous Flash device.

### 11.3.1 Hardware Interface

[Figure 11-15](#) shows the hardware interface between the EMIF, a Samsung K4S641632H-TC(L)70 64Mb SDRAM device, and a SHARP LH28F800BJE-PTTL90 8Mb Flash memory. The connection between EMIF and the SDRAM is straightforward, but the connection between the EMIF and the Flash deserves a detailed look.

The address inputs for the Flash are provided by three sources. The A[18:0] address inputs are provided by a combination of the EM1A and EM1BA pins according to [Section 11.2.6.1](#), and a set of GPIO pins. The RD/nBY signal from Flash is connected to EM1WAIT pin of the EMIF.

Finally, this example configuration connects the  $\overline{\text{EM1WE}}$  pin to the nWE input of the Flash and operates the EMIF in select strobe mode.

Figure 11-15. Example Configuration Interface

### 11.3.2 Software Configuration

The following sections describe how to configure the EMIF registers and bit fields to interface the EMIF with the Samsung K4S641632H-TC(L)70 SDRAM and the SHARP LH28F800BJE-PTTL90 8Mb Flash memory.

#### 11.3.2.1 Configuring the SDRAM Interface

This section describes how to configure the EMIF to interface with the Samsung K4S641632H-TC(L)70 SDRAM with a clock frequency of  $f_{EM1CLK} = 100\text{MHz}$ . Procedure A described in Section 11.2.5.5 is followed that assumes that the SDRAM power-up timing constraints were met during the SDRAM auto-initialization sequence after reset.

##### 11.3.2.1.1 PLL Programming for EMIF to K4S641632H-TC(L)70 Interface

If the system PLL is programmed to provide a SYSCLK frequency  $> 100\text{MHz}$ , then configure the EMIF1CLKDIV field in the PERSYSCLKDIVSEL register to make  $EM1CLK = SYSCLK/2$  (default configuration). Before doing this, the SDRAM must be placed in self-refresh mode by setting the SR bit in the SDRAM configuration register. Once the EM1CLK frequency has been configured, remove the SDRAM from self-refresh by clearing the SR bit in SDRAM\_CR.

Table 11-26. SR Field Value For EMIF to K4S641632H-TC(L)70 Interface

Field	Value	Purpose
SR	1 then 0	To place the EMIF into the self-refresh state

### 11.3.2.1.2 SDRAM Timing Register (SDRAM\_TR) Settings for EMIF to K4S641632H-TC(L)70 Interface

The fields of the SDRAM timing register (SDRAM\_TR) must be programmed first as described in [Table 11-27](#) to satisfy the required timing parameters for the K4S641632H-TC(L)70. Based on these calculations, a value of 6111 4610h must be written to the SDRAM\_TR. [Figure 11-16](#) shows a graphical description of how the SDRAM\_TR must be programmed.

**Table 11-27. SDRAM\_TR Field Calculations for EMIF to K4S641632H-TC(L)70 Interface**

Field Name	Formula	Value from K4S641632H-TC(L)70 Data Sheet	Value Calculated for Field
T_RFC	$T\_RFC \geq (t_{RFC} \times f_{EM1CLK}) - 1$	$t_{RC} = 68\text{ns}$ (minimum) <sup>(1)</sup>	6
T_RP	$T\_RP \geq (t_{RP} \times f_{EM1CLK}) - 1$	$t_{RP} = 20\text{ns}$ (minimum)	1
T_RCD	$T\_RCD \geq (t_{RCD} \times f_{EM1CLK}) - 1$	$t_{RCD} = 20\text{ns}$ (minimum)	1
T_WR	$T\_WR \geq (t_{WR} \times f_{EM1CLK}) - 1$	$t_{RDL} = 2 \text{ CLK} = 20\text{ns}$ (minimum) <sup>(2)</sup>	1
T_RAS	$T\_RAS \geq (t_{RAS} \times f_{EM1CLK}) - 1$	$t_{RAS} = 49\text{ns}$ (minimum)	4
T_RC	$T\_RC \geq (t_{RC} \times f_{EM1CLK}) - 1$	$t_{RC} = 68\text{ns}$ (minimum)	6
T_RRD	$T\_RRD \geq (t_{RRD} \times f_{EM1CLK}) - 1$	$t_{RRD} = 14\text{ns}$ (minimum)	1

(1) The Samsung data sheet does not specify a  $t_{RFC}$  value. Instead, Samsung specifies  $t_{RC}$  as the minimum auto refresh period.

(2) The Samsung data sheet does not specify a  $t_{WR}$  value. Instead, Samsung specifies  $t_{RDL}$  as last data in to row precharge minimum delay.

**Figure 11-16. SDRAM Timing Register (SDRAM\_TR)**

31	30	29	28	27	26	24	23	22	21	20	19	18	17	16

### 11.3.2.1.3 SDRAM Self Refresh Exit Timing Register (SDR\_EXT\_TMNG) Settings for EMIF to K4S641632H-TC(L)70 Interface

The SDRAM self-refresh exit timing register (SDSRETR) must be programmed second to satisfy the  $t_{XSR}$  timing requirement from the K4S641632H-TC(L)70 data sheet. [Table 11-28](#) shows the calculation of the proper value to program into the T\_XS field of this register. Based on this calculation, a value of 6h must be written to the SDSRETR. [Figure 11-17](#) shows how the SDSRETR must be programmed.

**Table 11-28. RR Calculation for EMIF to K4S641632H-TC(L)70 Interface**

Field Name	Formula	Value from K4S641632H-TC(L)70 Data Sheet	Value Calculated for Field
T_XS	$T_{XS} \geq (t_{XSR} \times f_{EM1CLK}) - 1$	$t_{RC} = 68\text{ns}$ (minimum) <sup>(1)</sup>	6

(1) The Samsung data sheet does not specify a  $t_{XSR}$  value. Instead, Samsung specifies  $t_{RC}$  as the minimum required time after CKE going high to complete self-refresh exit.

**Figure 11-17. SDRAM Self Refresh Exit Timing Register (SDR\_EXT\_TMNG)**

### 11.3.2.1.4 SDRAM Refresh Control Register (SDRAM\_RCR) Settings for EMIF to K4S641632H-TC(L)70 Interface

The SDRAM refresh control register (SDRAM\_RCR) can next be programmed to satisfy the required refresh rate of the K4S641632H-TC(L)70. [Table 11-29](#) shows the calculation of the proper value to program into the RR field of this register. Based on this calculation, a value of 61Ah must be written to the SDRAM\_RCR. [Figure 11-18](#) shows how the SDRAM\_RCR must be programmed.

**Table 11-29. RR Calculation for EMIF to K4S641632H-TC(L)70 Interface**

Field Name	Formula	Values	Value Calculated for Field
RR	$RR \leq f_{EM1CLK} \times t_{Refresh\ Period} / n_{cycles}$	From SDRAM data sheet: $t_{Refresh\ Period} = 64\text{ms}$ ; $n_{cycles} = 4096$ EMIF clock rate: $f_{EM1CLK} = 100\text{MHz}$	$RR = 1562$ cycles = 61Ah cycles

**Figure 11-18. SDRAM Refresh Control Register (SDRAM\_RCR)**

### 11.3.2.1.5 SDRAM Configuration Register (SDRAM\_CR) Settings for EMIF to K4S641632H-TC(L)70 Interface

Finally, the fields of the SDRAM configuration register (SDRAM\_CR) must be programmed as described in [Table 11-30](#) to properly interface with the K4S641632H-TC(L)70 device. Based on these settings, a value of 4720h must be written to the SDRAM\_CR. [Figure 11-19](#) shows how the SDRAM\_CR must be programmed. The EMIF is now ready to perform read and write accesses to the SDRAM.

**Table 11-30. SDRAM\_CR Field Values For EMIF to K4S641632H-TC(L)70 Interface**

Field	Value	Purpose
SR	0	To avoid placing the EMIF into the self-refresh state
NM	1	To configure the EMIF for a 16-bit data bus
CL	011b	To select a CAS latency of 3
BIT11_9LOCK	1	To allow the CL field to be written
IBANK	010b	To select 4 internal SDRAM banks
PAGESIZE	0	To select a page size of 256 words

**Figure 11-19. SDRAM Configuration Register (SDRAM\_CR)**

### 11.3.2.2 Configuring the Flash Interface

This section describes how to configure the EMIF to interface with the SHARP LH28F800BJE-PTTL90 8Mb Flash memory with a clock frequency of  $f_{EM1CLK} = 100\text{MHz}$ .

#### 11.3.2.2.1 Asynchronous 1 Configuration Register (ASYNC\_CS2\_CFG) Settings for EMIF to LH28F800BJE-PTTL90 Interface

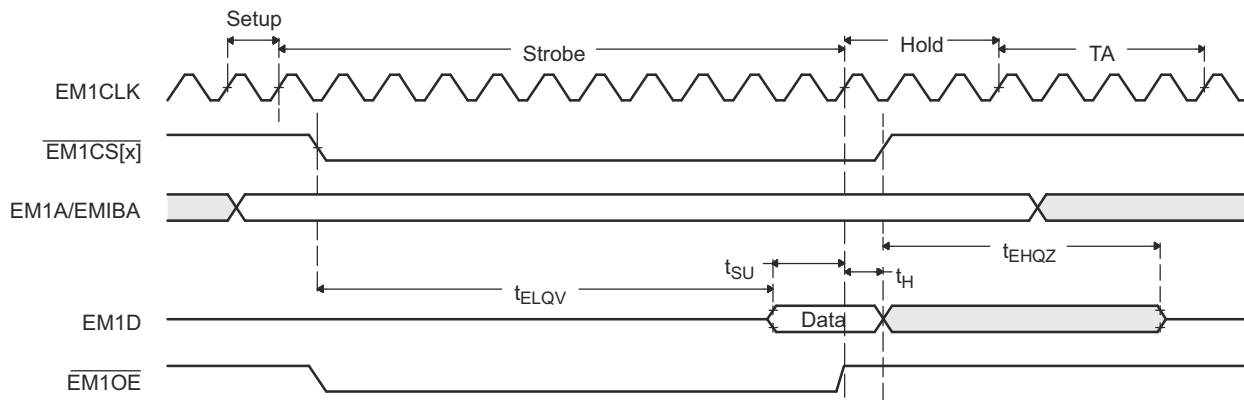

The asynchronous 1 configuration register (ASYNC\_CS2\_CFG) is the only register that is necessary to program for this asynchronous interface. The SS bit must be set to 1 to enable select strobe command and the ASIZE field can be set to 1 to select a 16-bit interface. The other fields in this register control the shaping of the EMIF signals, and the proper values can be determined by referring to the AC Characteristics in the Flash data sheet and the device data sheet. [Table 11-31](#) and [Table 11-32](#) show the pertinent AC Characteristics for reads and writes to the Flash device, and [Figure 11-20](#) and [Figure 11-21](#) show the associated timing waveforms. Finally, [Figure 11-22](#) shows programming the ASYNC\_CS2\_CFG with the calculated values.

**Table 11-31. AC Characteristics for a Read Access**

AC Characteristic	Device	Definition	Minimum	Maximum	Unit
$t_{SU}$	EMIF	Setup time, read EM1D before EM1OE high	15		ns
$t_H$	EMIF	Data hold time, read EM1D after EM1OE high	0		ns
$t_{ELQV}$	Flash	nCE to Output Delay		90	ns
$t_{EHQZ}$	Flash	nCE High to Output in High Impedance		55	ns

**Table 11-32. AC Characteristics for a Write Access**

AC Characteristic	Device	Definition	Minimum	Maximum	Unit
$t_{AVAV}$	Flash	Write Cycle Time	90		ns
$t_{ELEH}$	Flash	nCE Pulse Width Low	50		ns
$t_{EHEL}$	Flash	nCE Pulse Width High (not shown in <a href="#">Figure 11-21</a> )	30		ns

**Figure 11-20. LH28F800BJE-PTTL90 to EMIF Read Timing Waveforms**

**Figure 11-21. LH28F800BJE-PTTL90 to EMIF Write Timing Waveforms**

The R\_STROBE field must be set to meet the following equation:

$$R\_STROBE \geq (t_{ELQV} + t_{SU}) \times f_{EM1CLK} - 1$$

$$R\_STROBE \geq (90\text{ns} + 15\text{ns}) \times 200\text{MHz} - 1$$

$$R\_STROBE \geq 20$$

$$R\_STROBE = 20$$

The R\_HOLD field must be large enough to satisfy EMIF Data hold time,  $t_H$ :

$$R\_HOLD \geq t_H \times f_{EM1CLK} - 1$$

$$R\_HOLD \geq 0\text{ns} \times 200\text{MHz} - 1$$

$$R\_HOLD \geq -1$$

The R\_HOLD field must also combine with the TA field to satisfy the Flash nCE High to Output in High Impedance time,  $t_{EHQZ}$ :

$$R\_HOLD + TA \geq t_{EHQZ} \times f_{EM1CLK} - 2$$

$$R\_HOLD + TA \geq 55\text{ns} \times 200\text{MHz} - 2$$

$$R\_HOLD + TA \geq 9$$

The largest value that can be programmed into the TA field is 3h, therefore the following values must be used:

$$R\_HOLD = 6$$

$$TA = 3$$

For Writes, the W\_STROBE field must be set to satisfy the Flash nCE Pulse Width constraint,  $t_{ELEH}$ :

$$W\_STROBE \geq t_{ELEH} \times f_{EM1CLK} - 1$$

$$W\_STROBE \geq 50\text{ns} \times 200\text{MHz} - 1$$

$$W\_STROBE \geq 9$$

The W\_SETUP and W\_HOLD fields must combine to satisfy the Flash nCE Pulse Width High constraint,  $t_{\text{EHEL}}$ :

$$W\_SETUP + W\_HOLD \geq t_{\text{EHEL}} \times f_{\text{EM1CLK}} - 2$$

$$W\_SETUP + W\_HOLD \geq 30\text{ns} \times 200\text{MHz} - 2$$

$$W\_SETUP + W\_HOLD \geq 4$$

In addition, the entire Write access length must satisfy the Flash minimum Write Cycle Time,  $t_{\text{AVAV}}$ :

$$W\_SETUP + W\_STROBE + W\_HOLD \geq t_{\text{AVAV}} \times f_{\text{EM1CLK}} - 3$$

$$W\_SETUP + W\_STROBE + W\_HOLD \geq 90\text{ns} \times 200\text{MHz} - 3$$

$$W\_SETUP + W\_STROBE + W\_HOLD \geq 15$$

Solving the above equations for the Write fields results in the following:

$$W\_SETUP = 4$$

$$W\_STROBE = 10$$

$$W\_HOLD = 1$$

Adding a 5ns (1 cycle) margin to each of the periods (excluding TA that is already at the maximum) in this example produces the following recommended values:

$$W\_SETUP = 5h$$

$$W\_STROBE = 8h$$

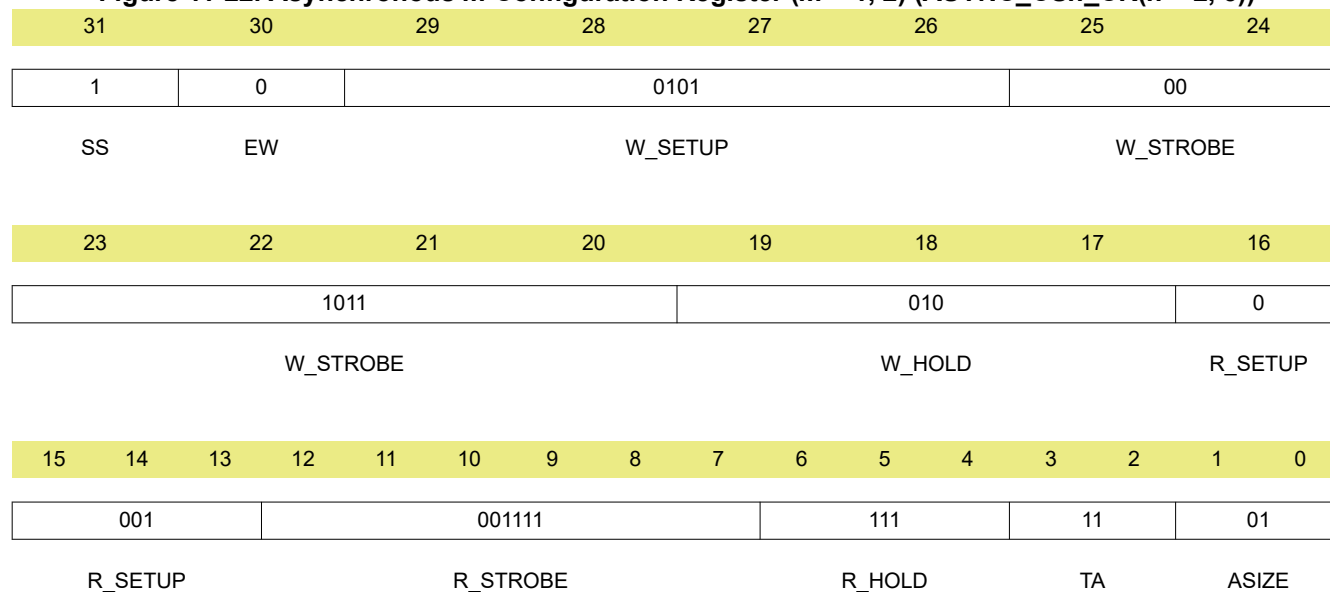

$$W\_HOLD = 2h$$

$$R\_SETUP = 1h$$

$$R\_STROBE = 15h$$

$$R\_HOLD = 7h$$

$$TA = 3h$$

**Figure 11-22. Asynchronous  $m$  Configuration Register ( $m = 1, 2$ ) (ASYNC\_CS $n$ \_CR( $n = 2, 3$ ))**

## 11.4 Software

### 11.4.1 EMIF Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
 C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/emif

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 11.4.1.1 Pin setup for EMIF module accessing ASRAM.

FILE: emif\_asram\_pin\_setup.c

This example configures pins for EMIF in ASYNC mode.

#### 11.4.1.2 EMIF1 ASYNC module accessing 16bit ASRAM.

FILE: emif\_ex1\_16bit\_asram.c

This example configures EMIF1 in 16bit ASYNC mode and uses CS2 as chip enable.

##### External Connections

- External ASRAM memory (CY7C1041CV33 -10ZSXA) daughter card

##### Watch Variables

- *testStatusGlobal* - Equivalent to *TEST\_PASS* if test finished correctly, else the value is set to *TEST\_FAIL*
- *errCountGlobal* - Error counter

#### 11.4.1.3 EMIF1 module accessing 16bit ASRAM as code memory.

FILE: emif\_ex2\_16bit\_asram\_codemem.c

This example configures EMIF1 in 16bit ASYNC mode and uses CS2 as chip enable. This example enables use of ASRAM as code memory.

##### External Connections

- External ASRAM memory (CY7C1041CV33 -10ZSXA) daughter card

##### Watch Variables

- *testStatusGlobal* - Equivalent to *TEST\_PASS* if test finished correctly, else the value is set to *TEST\_FAIL*
- *errCountGlobal* - Error counter

#### 11.4.1.4 EMIF1 module accessing 16bit SDRAM using memcpy\_fast\_far().

FILE: emif\_ex3\_16bit\_sdram\_far.c

This example configures EMIF1 in 16bit SYNC mode and uses CS0 as chip enable. It will first write to an array in the SDRAM and then read it back using the FPU function, `memcpy_fast_far()`, for both operations.

The buffer in SDRAM will be placed in the `.farbss` memory on account of the fact that its assigned the attribute "far" indicating it lies beyond the 22-bit program address space. The compiler will take care to avoid using instructions such as `PREAD`, which uses the Program Read Bus, or addressing modes restricted to the lower 22-bit space when accessing data with the attribute "far".

The memory space beyond 22-bits must be treated as data space for load/store operations only. The user is cautioned against using this space for either instructions or working memory. *External Connections*

- External SDR-SDRAM memory (MT48LC32M16A2 -75) daughter card

##### Watch Variables

- *testStatusGlobal* - Equivalent to *TEST\_PASS* if test finished correctly, else the value is set to *TEST\_FAIL*
- *errCountGlobal* - Error counter

#### 11.4.1.5 EMIF1 module accessing 16bit SDRAM then puts into Self Refresh mode before entering Low Power Mode.

FILE: emif\_ex4\_16bit\_sdram\_far\_lpm.c

This example configures EMIF1 in 16bit SYNC mode and uses CS0 as chip enable. This example puts SDRAM into self refresh before entering standby mode. Watchdog timer is configured to trigger WAKEINT interrupt.

As soon as the watchdog timer expires, the device should wake up, SDRAM should come out of self refresh mode and GPIO11 can be observed to toggle.

#### External Connections

- External SDR-SDRAM memory (MT48LC32M16A2 -75) daughter card

#### Watch Variables

- *testStatusGlobal* - Equivalent to *TEST\_PASS* if test finished correctly, else the value is set to *TEST\_FAIL*
- *errCountGlobal* - Error counter

#### 11.4.1.6 EMIF1 module accessing 32bit SDRAM using DMA.

FILE: emif\_ex5\_16bit\_sdram\_dma.c

This example configures EMIF1 in 16bit SYNC(SDRAM) mode and uses CS0 as chip enable. It will first write to an array in the SDRAM and then read it back, using the DMA for both operations.

The buffer in SDRAM will be placed in the .farbss memory on account of the fact that its assigned the attribute "far" indicating it lies beyond the 22-bit program address space. The compiler will take care to avoid using instructions such as PREAD, which uses the Program Read Bus, or addressing modes restricted to the lower 22-bit space when accessing data with the attribute "far".

The memory space beyond 22-bits must be treated as data space for load/store operations only. The user is cautioned against using this space for either instructions or working memory. *External Connections*

- External SDR-SDRAM (Micron MT48LC32M16A2 "P -75 C") daughter card.

#### Watch Variables

- *testStatusGlobal* - Equivalent to *TEST\_PASS* if test finished correctly, else the value is set to *TEST\_FAIL*
- *errCountGlobal* - Error counter

#### 11.4.1.7 EMIF1 module accessing 16bit SDRAM using alternate address mapping.

FILE: emif\_ex6\_16bit\_sdram\_nonfar.c

This example configures EMIF1 in 16bit SYNC mode and uses CS0 as chip enable. It will first write to an array in the SDRAM and then read it back.

The buffer in SDRAM will be placed in the emif\_cs0\_nonfar memory section which is dual mapped with CS2 memory range. This has been done to keep the SDRAM memory range within 22-bit address range in order to generate optimal code. EMIF1 Async RAM accesses will not be issued at the same time and program space reads & fetches will be allowed to SDRAM in non-far range.

#### External Connections

- External SDR-SDRAM memory (MT48LC32M16A2 -75) daughter card

#### Watch Variables

- *testStatusGlobal* - Equivalent to *TEST\_PASS* if test finished correctly, else the value is set to *TEST\_FAIL*
- *errCountGlobal* - Error counter

## 11.5 EMIF Registers

This section describes the External Memory Interface Registers.

### 11.5.1 EMIF Base Address Table

**Table 11-33. EMIF Base Address Table**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	CPU2	CPU2.DMA	Pipeline Protected
Instance	Structure								
EMIF1Regs	<a href="#">EMIF_REGS</a>	EMIF1_BASE	0x0004_7000	YES	-	-	YES	-	YES
Emif1ConfigRegisters	<a href="#">EMIF1_CONFIG_REGS</a>	EMIF1CONFIG_BASE	0x0005_F4C0	YES	-	-	YES	-	YES

### 11.5.2 EMIF\_REGS Registers

Table 11-34 lists the memory-mapped registers for the EMIF\_REGS registers. All register offset addresses not listed in Table 11-34 should be considered as reserved locations and the register contents should not be modified.

**Table 11-34. EMIF\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	RCSR	Revision Code and Status Register		<a href="#">Go</a>
2h	ASYNC_WCCR	Async Wait Cycle Config Register		<a href="#">Go</a>
4h	SDRAM_CR	SDRAM (EMxCS0n) Config Register		<a href="#">Go</a>
6h	SDRAM_RCR	SDRAM Refresh Control Register		<a href="#">Go</a>
8h	ASYNC_CS2_CR	Async 1 (EMxCS2n) Config Register		<a href="#">Go</a>
Ah	ASYNC_CS3_CR	Async 2 (EMxCS3n) Config Register		<a href="#">Go</a>
Ch	ASYNC_CS4_CR	Async 3 (EMxCS4n) Config Register		<a href="#">Go</a>
10h	SDRAM_TR	SDRAM Timing Register		<a href="#">Go</a>
18h	TOTAL_SDRAM_AR	Total SDRAM Accesses Register		<a href="#">Go</a>
1Ah	TOTAL_SDRAM_ACTR	Total SDRAM Activate Register		<a href="#">Go</a>
1Eh	SDR_EXT_TMNG	SDRAM SR/PD Exit Timing Register		<a href="#">Go</a>
20h	INT_RAW	Interrupt Raw Register		<a href="#">Go</a>
22h	INT_MSK	Interrupt Masked Register		<a href="#">Go</a>
24h	INT_MSK_SET	Interrupt Mask Set Register		<a href="#">Go</a>
26h	INT_MSK_CLR	Interrupt Mask Clear Register		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 11-35 shows the codes that are used for access types in this section.

**Table 11-35. EMIF\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 11.5.2.1 RCSR Register (Offset = 0h) [Reset = 4000205h]

RCSR is shown in [Figure 11-23](#) and described in [Table 11-36](#).

Return to the [Summary Table](#).

Revision Code and Status Register

**Table 11-38. SDRAM\_CR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	SR	R/W	0h	Self Refresh. Writing a 1 to this bit will cause connected SDRAM devices to be placed into Self Refresh mode and the EMIF to enter the self refresh state. In this state the EMIF will service all asynchronous memory accesses immediately but any SDRAM access will take at least $t_{ras} + 1$ cycles due to the time required for the SDRAM devices to out of Self Refresh mode. If an SDRAM access immediately follows the setting of the sr bit, the access will take $t_{ras} + t_{xs} + 2$ cycles. If both sr and pd bits are set, the EMIF will go into Self Refresh. Reset type: SYSRSn
30	PD	R/W	0h	Power Down. Writing a 1 to this bit will cause connected SDRAM devices to be placed into Power Down mode. If both sr and pd bits are set, the EMIF will go into Self Refresh. Reset type: SYSRSn
29	PDWR	R/W	0h	Perform refreshes during Power Down. Writing a 1 to this bit will cause the EMIF to exit the power down state and issue an AUTO REFRESH command every time Refresh May level is set. Reset type: SYSRSn
28-26	RESERVED	R	0h	Reserved
25-23	RESERVED	R/W	0h	Reserved
22-20	RESERVED	R/W	0h	Reserved
19	RESERVED	R/W	0h	Reserved
18-17	RESERVED	R/W	0h	Reserved
16	RESERVED	R/W	0h	Reserved
15	RESERVED	R	0h	Reserved

**Table 11-38. SDRAM\_CR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
14	NM	R/W	0h	Narrow mode. Set to 1 when system bus width to memory bus width is 2:1 for SDR SDRAM. Set to 0 when system bus width to memory bus width is 1:1 for SDR SDRAM. A write to this field will cause the EMIF to start the SDRAM initialization sequence. Reset type: SYSRSn
13	RESERVED	R/W	0h	Reserved
12	RESERVED	R/W	0h	Reserved
11-9	CL	R/W	3h	The value of this field defines the CAS latency to be used when accessing connected SDRAM devices. Only CAS latencies of 2 (cl = 2) and 3 (cl = 3) are supported. A write to this field will cause the EMIF to start the SDRAM initialization sequence. Reset type: SYSRSn
8	BIT_11_9_LOCK	R-0/W1S	0h	Bits 11 to 9 can only be written if this bit is set to 1. Reset type: SYSRSn
7	RESERVED	R	0h	Reserved
6-4	IBANK	R/W	2h	Defines number of banks inside connected SDRAM devices: 000: 1 bank SDRAM devices. 001: 2 bank SDRAM devices. 010: 4 bank SDRAM devices. 011: Reserved. 1xx: Reserved. A write to this field will cause the EMIF to start the SDRAM initialization sequence. Reset type: SYSRSn
3	RESERVED	R/W	0h	Reserved
2-0	PAGESIGE	R/W	0h	Defines the internal page size of connected SDRAM devices: 000: 256-word pages requiring 8 column address bits. 001: 512-word pages requiring 9 column address bits. 010: 1024-word pages requiring 10 column address bits. 011: 2048-word pages requiring 11 column address bits. 1xx: Reserved. A write to this field will cause the EMIF to start the SDRAM initialization sequence. Reset type: SYSRSn

### 11.5.2.4 SDRAM\_RCR Register (Offset = 6h) [Reset = 0000080h]

SDRAM\_RCR is shown in [Figure 11-26](#) and described in [Table 11-39](#).

Return to the [Summary Table](#).

### 11.5.3 EMIF1\_CONFIG\_REGS Registers

Table 11-51 lists the memory-mapped registers for the EMIF1\_CONFIG\_REGS registers. All register offset addresses not listed in Table 11-51 should be considered as reserved locations and the register contents should not be modified.

**Table 11-51. EMIF1\_CONFIG\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	EMIF1LOCK	EMIF1 Config Lock Register	EALLOW	<a href="#">Go</a>
2h	EMIF1COMMIT	EMIF1 Config Lock Commit Register	EALLOW	<a href="#">Go</a>
4h	EMIF1MSEL	EMIF1 Controller Sel Register	EALLOW	<a href="#">Go</a>
8h	EMIF1ACCPROTO	EMIF1 Config Register 0	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 11-52 shows the codes that are used for access types in this section.

**Table 11-52. EMIF1\_CONFIG\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WOnce	W Once	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 11.5.3.1 EMIF1LOCK Register (Offset = 0h) [Reset = 0000000h]

## 12.1 Introduction to Flash and OTP Memory

Flash is an electrically erasable/programmable nonvolatile memory that can be programmed and erased many times to ease code development. Flash memory can be used primarily as a program memory for the core, and secondarily as static data memory.

This section describes the proper sequence to configure the wait states and operating mode of Flash. This section also includes information on Flash and OTP power modes, how to improve Flash performance by enabling the Flash prefetch/cache mode, and the SECDED safety feature.

### 12.1.1 FLASH Related Collateral

#### Foundational Materials

- [C2000 Academy - FLASH](#)
- [Embedded Flash Memory](#) (Video)

#### Getting Started Materials

- [Serial Flash Programming of C2000 Microcontrollers Application Report](#)
- [\[FAQ\] FAQ for Flash ECC usage in C2000 devices - Includes ECC test mode, Linker ECC options:](#)
- [\[FAQ\] FAQ on Flash API usage for C2000 devices](#)
- [\[FAQ\] Flash - How to modify an application from RAM configuration to Flash configuration?](#)
- [\[FAQ\] How can we improve the Flash tool performance?](#)
- [\[FAQ\] TI C2000 Device Programming Tools and Services](#)

### 12.1.2 Features

Features of Flash memory include:

- Up to five Flash banks, which can be allocated to either CPU1 or CPU2 at boot time (refer to device data sheet for the number and size of Flash banks);
- One Flash Wrapper controlling up to five Flash banks (Bank0, 1, 2, 3, 4);
- Simultaneous read from two Flash banks by two CPUs
- Program or erase one Flash bank while simultaneously reading two Flash banks;
- 128-bit wide Flash programming;
- Configurable Flash programming options, with ECC support;
- Multiple sectors, with the ability to erase individual/specific sectors while leaving others programmed;
- User-programmable locations in user-configurable DCSM OTP (also referred to as USER OTP), for configuring security, OTP boot mode and boot mode selection pins (if the user is unable to use factory-default boot mode select pins);
- Code prefetch mechanism and data cache for enhanced performance;
- Configurable wait states to achieve the best performance at a given clock frequency;
- Safety Features:
  - SECDED: Single-error correction and double-error detection is supported;
  - Address bits are included in ECC;
  - Test mode to check the health of ECC logic;
- Integrated Flash program and erase state machine in the Flash Wrapper:
  - Simple Flash API algorithms;
  - Fast erase and program times (refer to the device data sheet for details);
- Dual Code Security Module (DCSM) to prevent unauthorized access to the Flash (refer to the *Dual Code Security Module (DCSM)* chapter for details).

### 12.1.3 Flash Tools

Texas Instruments provides the following tools for Flash:

- Code Composer Studio™ (CCS) IDE - the development environment with integrated Flash plugin. TI recommends performing a debug reset and restart after programming the code into Flash using CCS.
- Flash API Library - a set of software peripheral functions to erase/program Flash
- UniFlash - standalone tool to erase/program/verify the Flash content through JTAG. No CCS is required.
- Users must check and install available updates for CCS On-Chip Flash Plugin and UniFlash tools.

### 12.1.4 Default Flash Configuration

The following are Flash module configuration settings at power-up:

- Flash Bank and Pump are powered up on device reset.
- ECC is enabled
- Wait-states are set to the maximum (0xF)
- Code-prefetch mechanism and data cache are disabled

During the boot process, the boot ROM performs a dummy read of the Code Security Module (CSM) password locations in the OTP. This read is performed to unlock a new device that has no password stored in the device, so that Flash programming or loading of code into CSM-protected SRAM can be performed. On devices with a password, this read has no effect and the device remains locked.

User application software must initialize wait-states using the FRDCNTL register, and configure cache/prefetch features using the FRD\_INTF\_CTRL register, to achieve optimum system performance. Software that configures Flash settings like wait-states, cache/prefetch features, and so on, must be executed only from RAM memory, **not** from Flash memory.

---

#### Note

Before initializing wait-states, turn off the pre-fetch and data caching in the FRD\_INTF\_CTRL register.

## 12.2 Flash Bank, OTP, and Pump

This device includes up to five Flash banks. In addition, there is one-time programmable Flash memory (OTP) in each Flash bank. Flash and OTP are uniformly mapped in both program and data memory space.

There are two OTP regions. The first OTP region, TI-OTP, contains manufacturing information, trims, Flash operation settings, and other device data. TI-OTP can be read by the user application, but TI-OTP cannot be programmed or erased. The second OTP region, USER-OTP, is primarily used for programming device security (DCSM module) settings. USER-OTP can be programmed only once and cannot be erased afterwards. For information on the memory-map, Flash bank sizes, TI-OTP, USER-OTP, and corresponding ECC locations, refer to the device data sheet.

The *Location of Zone-Select Block Based on Link-Pointer* figure in the *Dual Code Security Module (DCSM)* chapter shows the user-programmable OTP locations in CPU1 USER-OTP. For more information on the functionality of these fields, refer to the *ROM Code and Peripheral Booting* chapter and the *Dual Code Security Module (DCSM)* chapter.

### 12.3 Flash Wrapper

The CPU interfaces with the Flash wrapper, which interfaces with the Flash banks and the pump (see [Figure 12-1](#)). The Flash wrapper has the following primary features:

- Provides a simple interface for software to program or erase the Flash memory.
- Provides an interface for the CPU to read Flash data, including data caching and prefetch features.
- Performs ECC error checking and correction, and generates interrupts when an error is detected.
- Provides the capability to prevent unwanted bank program or erase operations.

Figure 12-1. Flash Interface Block Diagram

## 12.4 Flash and OTP Memory Performance

Flash read or instruction fetch accesses can be classified either as a Flash access (access to an address location in Flash), or an OTP access (access to an address location in OTP).

When the CPU performs an access to a Flash memory address, data is returned after (RWAIT+1) SYSCLK cycles.

For a USER-OTP access, data is returned after 11 SYSCLK cycles.

RWAIT defines the number of random access wait states, and is configured using the RWAIT field in the FRDCNTL register. At reset, RWAIT defaults to a worst-case wait state count (15), and therefore must be initialized to the appropriate number of wait states to improve performance, based on the CPU clock frequency and the access time of the Flash. The Flash supports zero-wait accesses when RWAIT is set to zero, when the CPU clock frequency is low enough to accommodate the Flash access time.

For a given system clock frequency, configure RWAIT using the following formula:

For C28x Flash Bank:  $RWAIT = \text{ceiling}[(SYSCLK/FCLK)-1]$

where SYSCLK is the system operating frequency for CPU1 and CPU2, and FCLK is the clock frequency for Flash.

FCLK must be  $\leq FCLK_{max}$ , the allowed maximum Flash clock frequency at RWAIT = 0.

If RWAIT results in a fractional value when calculated using the above formula, round up RWAIT to the nearest integer.

## 12.5 Flash Read Interface

This section provides details about the data read modes to access Flash bank/OTP and the configuration registers that control the read interface. In addition to a standard read mode, the Flash wrapper has a built-in prefetch and cache mechanism to allow increased clock speeds and CPU throughput wherever applicable.

### 12.5.1 C28x-Flash Read Interface

#### 12.5.1.1 Standard Read Mode

Standard read mode is the default Flash read mode after reset. In this mode, the code prefetch mechanism and data cache are disabled. When standard read mode is active, every read access to Flash is decoded by the Flash wrapper to fetch the data from the addressed location, and the data is returned after RWAIT+1 cycles (except User OTP).

Flash data buffers associated with the prefetch mechanism and data cache are bypassed in standard read mode; therefore, every access to the Flash/OTP is used by the CPU immediately, and every access creates a unique Flash bank access.

Standard read mode is the recommended mode for lower system frequency operation, where RWAIT can be set to zero to provide single-cycle access operation. The Flash wrapper can operate at higher frequencies using standard read mode, at the expense of adding wait states. At higher system frequencies, it is recommended to enable the data cache and prefetch mechanisms to improve performance. Refer to the device data sheet to determine the maximum Flash frequency allowed in standard read mode (that is, maximum Flash clock frequency with RWAIT = 0,  $FCLK_{MAX}$ ).

### 12.5.1.2 Prefetch Mode

Flash memory is typically used to store application code. During code execution, instructions are fetched from contiguous memory addresses, except when a discontinuity occurs. Usually, the portion of the code that resides in contiguous address locations makes up the majority of the application code, and is referred to as linear code. To improve the performance of linear code execution, a Flash prefetch mechanism has been implemented. Figure 12-2 illustrates how this mode functions.

The prefetch mechanism does a look-ahead prefetch on linear address increments, starting from the address of the last instruction fetch. The Flash prefetch mechanism is disabled by default. To enable prefetch mode, set the PREFETCH\_EN bit in the FRD\_INTF\_CTRL register, or call the Flash\_enablePrefetch() driverlib function.

Each instruction fetch from the Flash or OTP reads out 128 bits. The starting address of the access from Flash is automatically aligned to a 128-bit boundary, such that the instruction location is within the 128 bits to be fetched. When Flash prefetch mode is enabled, the 128 bits read from the instruction fetch are stored in a 128-bit wide by 2-level deep instruction prefetch buffer. The contents of this prefetch buffer are then sent to the CPU for processing as required.

Up to four 32-bit or eight 16-bit instructions can reside within a single 128-bit access. The majority of C28x instructions are 16 bits, so for every 128-bit instruction fetch from the Flash bank there are up to eight instructions in the prefetch buffer ready to process through the CPU. During the time to process these instructions, the Flash prefetch mechanism automatically initiates another access to the Flash bank to prefetch the next 128 bits. The Flash prefetch mechanism works in the background to keep the instruction prefetch buffers as full as possible. Using this technique, the overall efficiency of sequential code execution from Flash or OTP is improved significantly.

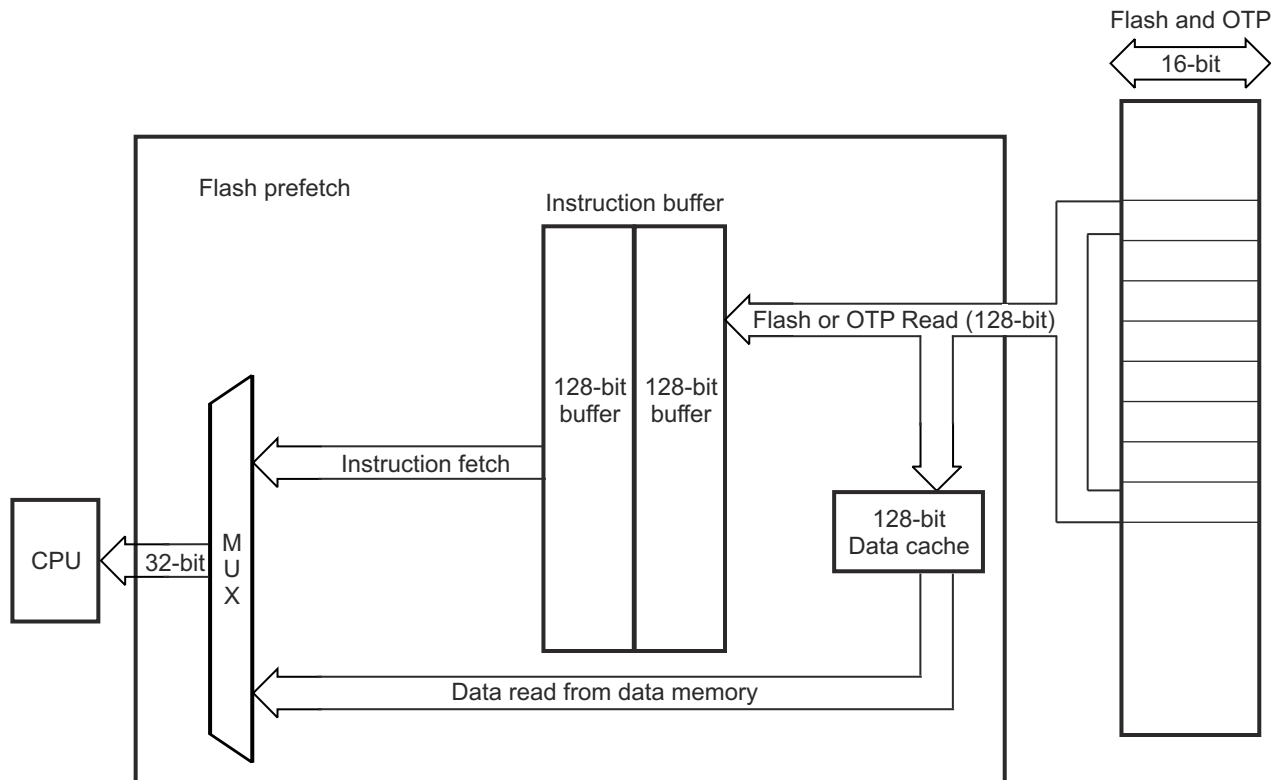

Figure 12-2. Flash Prefetch Mode

The Flash prefetch is aborted only when there is a code discontinuity caused by executing an instruction such as a branch, function call, or loop. When this occurs, the prefetch mechanism is aborted, and the contents of the prefetch buffer are flushed. There are two possible scenarios when this occurs:

1. If the destination address is within the Flash or OTP, the prefetch aborts and then resumes at the destination address.
2. If the destination address is outside of the Flash and OTP, the prefetch is aborted, and begins again only when the code branches back into the Flash or OTP. The Flash prefetch mechanism only applies to instruction fetches from program space. Data reads from data memory and from program memory do not utilize the prefetch mechanism and thus bypass the prefetch buffer. For example, instructions such as MAC, DMAC, and PREAD read a data value from program memory. When such a read happens, the prefetch buffer is bypassed, but the buffer is not flushed. If an instruction prefetch is already in progress when a data read operation is initiated, then the data read is stalled until the prefetch completes.

Note that the prefetch mechanism gets bypassed when RWAIT is configured as zero.

### 12.5.1.3 Data Cache

In addition to the prefetch mechanism, a data cache of 128-bits wide has been implemented to improve data space read performance. This data cache is separate from the instruction prefetch buffer, and is used for data reads only. Whenever a data read access is performed by the CPU to a Flash bank address, if the data located at that address is not presently loaded into the data cache, then the Flash wrapper reads 128 bits of data from the Flash bank and stores the data in the data cache. This data is eventually sent to the CPU for processing. The starting address of the Flash bank access is automatically aligned to a 128-bit boundary, such that the requested address location is within the 128 bits to be read from the bank.

The data cache is disabled by default at reset. To enable the data cache, set the DATA\_CACHE\_EN bit in the FRD\_INTF\_CTRL register, or call the `Flash_enableCache()` driverlib function. Note that the data cache gets bypassed when RWAIT is set to zero.

---

#### Note

The data cache does not get updated on a debugger access, or when a read to the ECC memory-mapped region is performed.

---

### 12.5.1.4 Flash Read Operation

There are a few important points to keep in mind when using Flash or OTP memory:

- Reads of USER OTP locations are hardwired for 9 wait states. The RWAIT bits have no effect on these locations.
- CPU writes to Flash or OTP memory addresses are ignored, and complete within a single cycle. Flash memory can only be modified by issuing program or erase commands, using the Flash API.
- When a security zone is in the locked state, and the respective password lock bits are not all ones, then:
  - Data reads to Zx-CSMPSWD return zero;
  - Program space reads to Zx-CSMPSWD return zero; and
  - Program fetches to Zx-CSMPSWD return zero.
- When the Code Security Module (CSM) is secured, reads to Flash or OTP memory addresses from outside the secure zone take the same number of cycles as a normal access. However, the read operation returns zero.
- The arbitration scheme in the Flash wrapper prioritizes CPU accesses in the fixed priority order of data space read (highest priority), program space read, and program fetches/program prefetches (lowest priority).
- When Flash state machine is activated for erase or program operations, the contents of the prefetch buffer and data cache are automatically flushed.

---

#### Note

ECC checks are performed on data read from Flash before the data is stored in the prefetch buffer or data cache. Once data has entered the cache or buffer, there are no further ECC checks performed.

---

## 12.6 Flash Erase and Program

Flash memory can be programmed either by using the CCS Flash plug-in or by using the UniFlash application. If these methods are not feasible in an application, the Flash API can be used. The Flash memory can be programmed, erased, and verified only by using the Flash API library. These functions are written, compiled and validated by Texas Instruments. The Flash module contains a Flash state machine (FSM) to perform program and erase operations.

The recommended flow for programming Flash is:  
Erase → Program → Verify

### 12.6.1 Flash Controller Access Semaphore

Both CPU1 and CPU2 have the ability to perform program and erase operations on any of the Flash banks present in the device, but only one CPU can access the Flash wrapper at a given time for programming or erase. The Flash controller access semaphore determines which CPU has control of the Flash wrapper, and can be configured by writing to the FLASHCTLSEM register. This register is present in the IPC register address spaces for both CPUs.

In the default state, CPU1 has control of the Flash wrapper. Either CPU can grab the semaphore for exclusive access. While one CPU has grabbed the semaphore for exclusive access, the other CPU cannot grab the semaphore or access the Flash wrapper until the owner CPU has relinquished control. [Table 12-1](#) describes the FLASHCTLSEM register values and their corresponding states.

While the Flash wrapper is owned by a CPU, that CPU's reset also resets the semaphore register. In the default state, the semaphore register is reset by CPU1.SYSRSn.

**Table 12-1. Flash Controller Access Semaphore States**

SEM Value	Description
00, 11	CPU1 has control of the Flash wrapper, but CPU2 can seize control at any time.
01	CPU1 has exclusive control of the Flash wrapper. CPU1 can relinquish control by setting SEM back to 00.
10	CPU2 has exclusive control of the Flash wrapper. CPU2 can relinquish control by setting SEM back to 00.

### 12.6.2 Erase

When the target Flash is erased, the Flash reads as all 1s. This state is called 'blank.' The erase function must be executed before programming. The user cannot skip erase on sectors that read as 'blank' because these sectors can require additional erasing due to marginally erased bits columns. The FSM provides an Erase Sector command to erase the target sector. The erase function erases the data and the ECC together. Bank erase is also supported in this device.

### 12.6.3 Program

The Flash wrapper provides a command to program the Flash and User OTP. This command is also used to program ECC check bits.

### Note

The main array Flash programming must be aligned to 64-bit address boundaries, and each 64-bit word can only be programmed once per write/erase cycle.

The DCSM OTP programming must be aligned to 128-bit address boundaries and each 128-bit word can only be programmed once. The exceptions are:

- The DCSM Zx-LINKPOINTER1 and Zx-LINKPOINTER2 values in the DCSM OTP can be programmed together and can be programmed one bit at a time as required by the DCSM operation.
- The DCSM Zx-LINKPOINTER3 values in the DCSM OTP can be programmed one bit at a time as required by the DCSM operation.

To avoid exceeding data retention capability limits, do not perform more than 64 program operations on the same Flash word line before performing an erase operation. Each Flash word line consists of sixteen 128-bit words (256 bytes). This limit is especially important to observe when writing to one-time-programmable Flash regions, such as the User OTP.

#### 12.6.4 Verify

After programming, the user must perform verify using API function `Fapi_doVerify()`. This function verifies the Flash contents against supplied data.

Application software typically perform a CRC check of the Flash memory contents during power-up and at regular intervals during runtime (as needed). Apart from this, ECC logic, when enabled (enabled by default), catches single-bit errors, double-bit errors, and address errors whenever the CPU reads/fetches from a Flash address.

#### 12.7 Error Correction Code (ECC) Protection

There are two ECC blocks (ECC64\_H and ECC64\_L) inside the Flash Read Interface. These ECC blocks correct single-bit Flash read errors, and can detect uncorrectable errors of two or more bits. The ECC blocks are also capable of detecting address errors. The ECC blocks operate using eight user-calculated ECC check bits associated with each 64-bit wide data word and the corresponding 128-bit memory-aligned address. Users must program these ECC check bits into ECC memory space, along with Flash data during the Flash programming operation. Refer to the device data sheet for the Flash/OTP ECC memory-map.

The ECC bits for a given Flash address and 64-bit data word can be calculated using the Flash API; however, TI recommends using the `AutoEccGeneration` option available in the Flash Plugin or API to auto-calculated and program ECC bits. The Flash API uses hardware ECC logic in the device to generate the ECC data for the given Flash data. The Flash Plugin, the Flash programming tool integrated with the Code Composer Studio™ IDE, uses the Flash API to generate and program ECC data.

Figure 12-3 illustrates the ECC logic inputs and outputs.

During an instruction fetch or a data read operation, the 19 most-significant address bits (the three least-significant bits of address are not considered), together with the 64-bit data/8-bit ECC read-out of Flash banks/ECC memory-map area, pass through the ECC logic, and the eight check bits are produced in ECC block. These eight calculated ECC check bits are then XORed with the stored check bits (user programmed check bits) associated with the address and the read data. The 8-bit output is decoded inside the ECC block to determine one of three conditions:

- No error occurred
- A correctable error (single bit data error) occurred
- A non-correctable error (double bit data error or address error) occurred

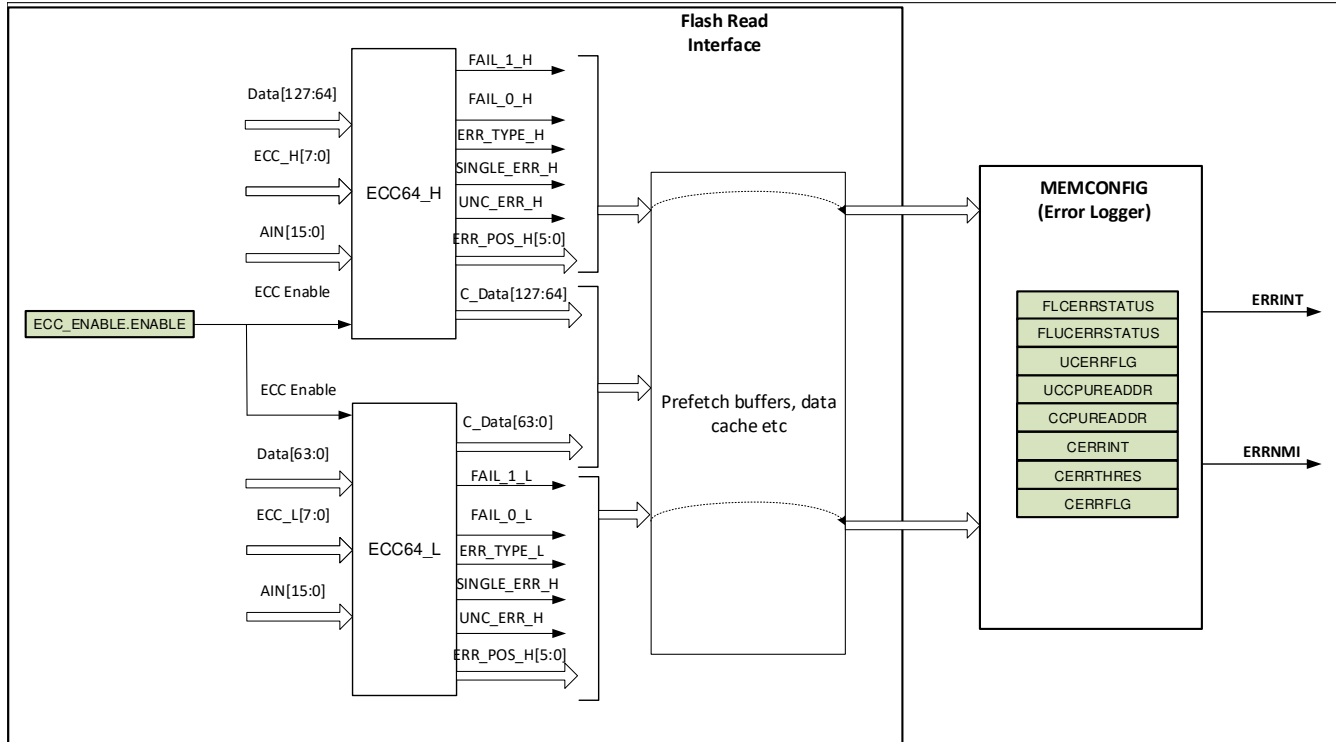

Figure 12-3. ECC Logic Inputs and Outputs

A single-bit error in the address field is considered to be a non-correctable error.

**Note**

Since ECC is calculated for an entire 64-bit data word, a non 64-bit read such as a byte read or a half-word read still forces the entire 64-bit data word to be read and calculated, even though only the byte or half-word is actually used by the CPU.

The ECC feature is enabled by default at reset, and can be enabled or disabled by writing to the ECC\_ENABLE register. ECC logic is automatically bypassed when the 64 data bits and associated ECC bits fetched from the bank are either all ones or all zeros.

**12.7.1 Single-Bit Data Error**

This section provides information for both single-bit data errors and single-bit ECC check bit errors. If there is a single bit flip (0 to 1 or 1 to 0) in Flash data or in ECC data, then the error is considered as a single-bit data error. The SECDED module detects and corrects single-bit errors, if any, in the 64-bit Flash data or eight ECC check bits read from the Flash/ECC memory map before the read data is provided to the CPU.

When SECDED finds and corrects single bit data errors, the following information is logged in the ECC registers if the ECC feature is enabled:

- Address where the error occurred: if the single-bit error occurs in the lower 64 bits of a 128-bit memory-aligned Flash data word, the address of the lower 64-bit word is captured in the SINGLE\_ERR\_ADDR\_LOW register. If the single-bit error occurs in the upper 64 bits of the 128-bit data word, then the address of the upper 64-bit word is captured in the SINGLE\_ERR\_ADDR\_HIGH register.
- Whether the error occurred in data bits or ECC bits: the ERR\_TYPE\_L and ERR\_TYPE\_H bit fields in the ERR\_POS register indicate whether the error occurred in data bits or ECC bits of the lower 64 bits, or the upper 64 bits respectively, of a 128-bit memory-aligned Flash data word.

- Bit position at which the error occurred: the ERR\_POS\_L and ERR\_POS\_H bit fields in the ERR\_POS register indicate the bit position of the error in the lower 64 bits/lower 8-bit ECC, or the upper 64 bits/upper 8-bit ECC respectively, of a 128-bit memory-aligned Flash data word.
- Whether the corrected value is 0 (FAIL\_0\_L, FAIL\_0\_H flags in ERR\_STATUS register).
- Whether the corrected value is 1 (FAIL\_1\_L, FAIL\_1\_H flags in ERR\_STATUS register).
- A single bit error counter that increments on every single bit error occurrence (ERR\_CNT register) until a user-configurable threshold (see ERR\_THRESHOLD) is met.
- A flag that gets set when one or more single-bit errors occurs after ERR\_CNT equals ERR\_THRESHOLD (SINGLE\_ERR\_INT\_FLG flag in the ERR\_INTFLG register).

When the ERR\_CNT value equals ERR\_THRESHOLD+1, and a single bit error occurs, the Flash module sets the SINGLE\_ERR\_INT flag and generates an interrupt signal. To enable propagation of the generated interrupt pulse to the CPU, the user application must enable the FLASH\_CORRECTABLE\_ERROR channel in the C28 Peripheral Interrupt Expansion module (PIE). The interrupt signal remains high until the application clears the SINGLE\_ERR\_INTFLG flag by writing to the SINGLE\_ERR\_INTCLR bit in the ERR\_INTCLR register. The Flash module cannot generate any further FLASH\_CORRECTABLE\_ERROR interrupt signals to the PIE/CPU until SINGLE\_ERR\_INTFLG is cleared, as this is an edge-based interrupt.

When multiple single-bit errors have been detected by ECC logic, the contents of the Flash ECC registers reflect the most recent ECC error. When multiple single-bit errors have been detected, both FAIL\_0\_L and FAIL\_1\_L (or FAIL\_0\_H and FAIL\_1\_H) can be set, indicating that single-bit fail0/fail1 occurred in different 64-bit aligned addresses.

Although ECC is calculated on 64-bit basis, a read of any address location within a 128-bit aligned Flash data word causes the single-bit error flag to get set, if there is a single-bit error in both or in either the lower 64 or upper 64 bits (or corresponding ECC check bits) of that 128-bit data word.

### 12.7.2 Uncorrectable Error

Uncorrectable errors include address errors and double-bit errors in data or ECC. When the ECC logic finds uncorrectable errors, the following information is logged in ECC registers if the ECC feature is enabled:

- Address where the error occurred: if the uncorrectable error occurs in the lower 64 bits of a 128-bit memory-aligned Flash data word, the lower 64-bit memory-aligned address is captured in the UNC\_ERR\_ADDR\_LOW register. If the uncorrectable error occurs in the upper 64 bits of a 128-bit memory-aligned Flash data word, the upper 64-bit memory-aligned address is captured in the UNC\_ERR\_ADDR\_HIGH register.
- A flag is set indicating that an uncorrectable error occurred – the UNC\_ERR\_L and UNC\_ERR\_H flags in the ERR\_STATUS register indicate the uncorrectable error occurrence in the lower 64 bits/lower 8-bit ECC, or the upper 64 bits/upper 8-bit ECC, respectively, of a 128-bit memory-aligned Flash data word.
- A flag is set indicating that an uncorrectable error interrupt is generated (UNC\_ERR\_INTFLG in ERR\_INTFLG register).

When an uncorrectable error occurs, the Flash module sets the UNC\_ERR\_INTFLG bit and generates an uncorrectable error interrupt. This uncorrectable error interrupt generates a non-maskable interrupt (NMI), if enabled, in the CPU. If an uncorrectable error interrupt flag is not cleared by writing to the UNC\_ERR\_INTCLR bit in the ERR\_INTCLR register, the Flash module cannot generate new uncorrectable interrupt signals, as this is an edge-based interrupt.

Although ECC is calculated on 64-bit basis, a read of any address location within a 128-bit aligned Flash word causes the uncorrectable error flag to get set, and an uncorrectable error interrupt/NMI to occur, when there is a uncorrectable error in both or in either the lower 64 bits or upper 64 bits (or corresponding ECC check bits) of that 128-bit data word.

### 12.7.3 Mechanism to Check the Correctness of ECC Logic

To make sure the correctness of the ECC logic, a redundant ECC logic block for each of the ECC64\_L and ECC64\_H checkers is used. Each 64-bit ECC checker block and the corresponding redundant checker block receive the same inputs. The output of each 64-bit checker block is bitwise XORed with the output of the corresponding redundant checker block; a non-zero output from this comparison generates an uncorrectable error (UNC\_ERR) signal. This redundancy makes sure that any fault in ECC logic circuits can be detected and trigger an NMI.

A mechanism has been added to enable self-testing of the ECC logic for additional diagnostic coverage. To use this mechanism, configure the ECC\_TEST\_EN field in the FECC\_CTRL register. A value of 01 in ECC\_TEST\_EN injects a single-bit error into the redundant ECC logic upon a Flash read access, and a value of 11 injects a double-bit error upon a Flash read access. This causes an output comparison failure. In this mode, the diagnostic outputs of each of the high and low comparators (DIAG\_H and DIAG\_L) are captured in the FLUCERRSTATUS Memconfig register.

---

#### Note

When ECC self-test is enabled and CPU issues a read access to the Flash, ECC errors are captured in the data cache and prefetch buffers. TI recommends that application software disables caching while performing diagnostic checks.

---

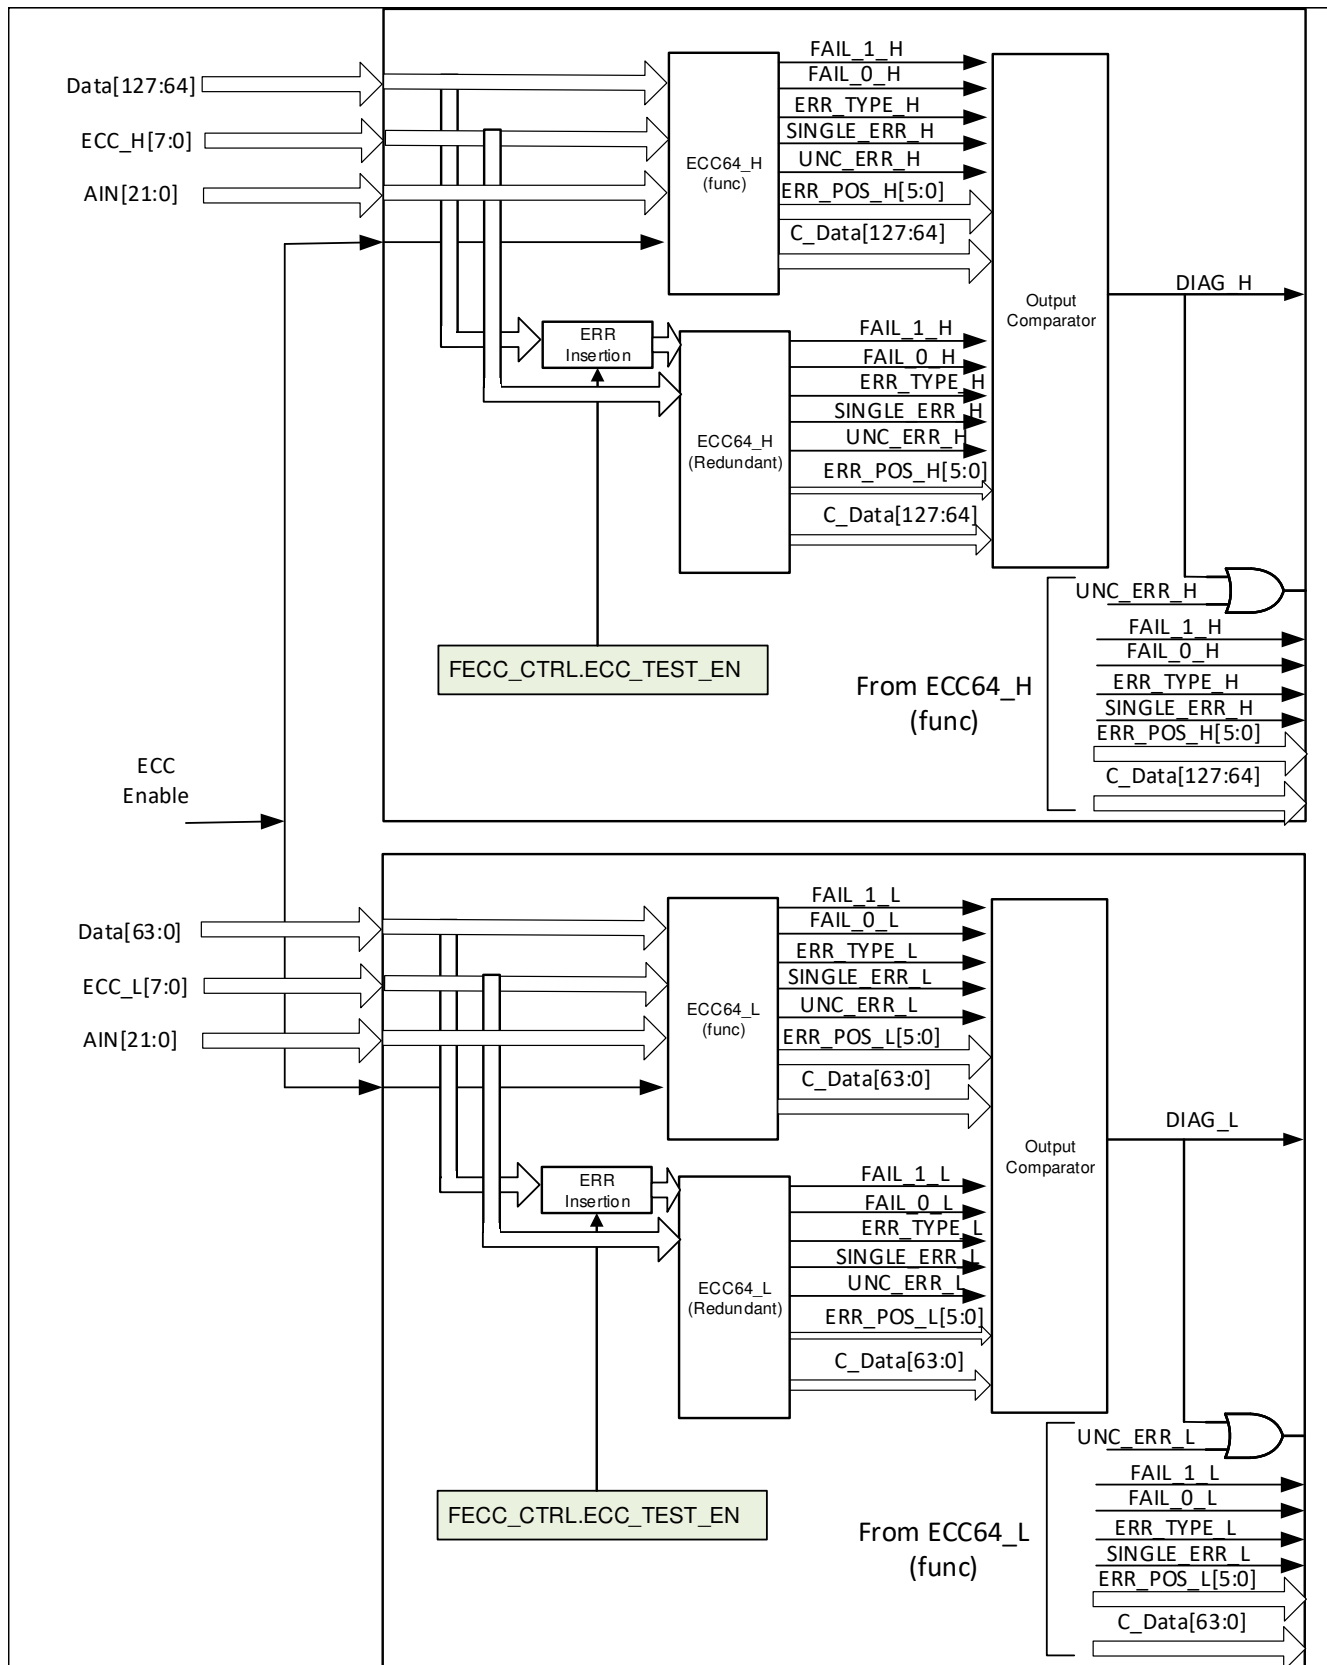

Figure 12-4. Testing ECC Logic

## 12.8 Reserved Locations Within Flash and OTP

When allocating code and data to Flash and OTP memory, keep the following reserved locations in mind:

- The entire OTP has reserved user-configurable locations for security and boot process. For more details on the functionality of these fields, refer to the *ROM Code and Peripheral Booting* chapter and the *Dual Code Security Module (DCSM)* chapter.
- Refer to the *ROM Code and Peripheral Booting* chapter for reserved locations in Flash for real-time operating system usage and a boot-to-Flash entry point. A boot-to-Flash entry point is reserved for an entry-into-Flash branch instruction. When the boot-to-Flash boot option is used, the boot ROM jumps to this address in Flash. If you program a branch instruction here, that redirects code execution to the entry point of the application.

## 12.9 Migrating an Application from RAM to Flash

To migrate an existing application that is configured to run from RAM to a Flash-based linker configuration, follow these steps:

1. Replace the RAM linker command file with a Flash linker command file. For examples of Flash-based linker command files, see the `device_support\<device>\common\cmd` directory.
2. When modifying the Flash-based linker command file, be sure to map any initialized sections to Flash memory regions.
3. Make sure the boot mode pins are configured for Flash boot. This tells the boot ROM to redirect execution to the application programmed into Flash memory after boot code execution is complete. For more information on boot mode configuration, see *Detailed Description > Device Boot Modes* in the device data sheet.
4. When the device is configured for Flash boot, the boot ROM redirects execution to the Flash entry point location (defined as `BEGIN` in TI-provided Flash linker command files) at the end of boot code execution. Make sure there is a branch instruction at the Flash entry point to your code initialization (for example, `_c_int00`) function. In the C2000Ware examples, the entry point code is specified in the `codestartbranch.asm` file.
5. To achieve best performance for Flash execution, configure the Flash wait states as per the device operating clock frequency, as specified in the device data sheet. In addition, enable prefetch mode and data cache mode. Calling the `Flash_initModule()` driverlib function achieves these steps. Note that code that initializes the Flash module must execute from a RAM location. This is accomplished by assigning the Flash initialization function to the `.TI.ramfunc` section. In the linker command file, map this section to Flash for load, and RAM for execution. The example cmd files provided in C2000Ware show how to do this correctly.
6. For any functions that require 0- or 1-wait state performance, be sure to map to RAM for execution in the linker command file, similar to the Flash initialization function. The `.TI.ramfunc` section in the TI-provided Flash linker command files accomplishes this purpose.
7. Align all code and data sections to 128-bit address boundaries when mapping to Flash memory, using the `ALIGN` directive in the linker command file.
8. For EABI executable formats, define all uninitialized sections mapped to RAM as `NOINIT` sections (using the directive `"type=NOINIT"`) in the linker command file.
9. Be sure to program ECC bits correctly for the Flash application image. Keep the `AutoEccGeneration` option enabled in the Code Composer Studio Flash Plugin or UniFlash GUI.

## 12.10 Procedure to Change the Flash Control Registers

During Flash configuration, no accesses to the Flash or OTP can be in progress. This includes instructions still in the CPU pipeline, data reads, and instruction prefetch operations. To be sure that no access takes place during the configuration change, follow the procedure shown below for any code that modifies the Flash control registers.

1. Start executing application code from RAM/Flash/OTP.
2. Branch to or call the Flash configuration code (that writes to Flash control registers) in RAM. This is required to properly flush the CPU pipeline before the configuration change. The function that changes the Flash configuration cannot execute from the Flash or OTP and must reside in RAM.
3. Execute the Flash configuration code (located in RAM) that writes to Flash control registers like FRDCNTL, FRD\_INTF\_CTRL, and so on.
4. At the end of the Flash configuration code execution, wait eight cycles to let the write instructions propagate through the CPU pipeline. This must be done before the return-from-function call is made.
5. Return to the calling function that resides in RAM or Flash/OTP and continue execution.

## 12.11 Software

### 12.11.1 FLASH Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/flash

Cloud access to these examples is available at the following link: [dev.ti.com C2000Ware Examples](https://dev.ti.com/C2000Ware/Examples).

#### 12.11.1.1 Flash Programming with 512-bit AutoECC, DataAndECC, DataOnly and EccOnly - C28X\_DUAL

FILE: flashapi\_cpu1\_512bitprogramming.c

This example demonstrates how to program Flash banks using API's following options

1. AutoEcc generation
2. DataOnly and EccOnly
3. DataAndECC

CPU1 example must be loaded and executed before CPU2 example. Only CPU1 is able to set the BankMuxSel and GSxMSel registers for CPU2. For both CPU1 and CPU2 load, make sure to set the correct Erase settings for bank selection. *External Connections*

- None.

#### *Watch Variables*

- None.

#### 12.11.1.2 Flash Programming with AutoECC, DataAndECC, DataOnly and EccOnly - C28X\_DUAL

FILE: flashapi\_cpu2\_128bitprogramming.c

This example demonstrates how to program Flash using API's following options

1. AutoEcc generation
2. DataOnly and EccOnly
3. DataAndECC

NOTE: CPU1 example must be loaded and executed before CPU2 example. Only CPU1 is able to set the BankMuxSel and GSxMSel registers for CPU2. For both CPU1 and CPU2 load, make sure to set the correct Erase settings for bank selection.

#### *External Connections*

- None.

#### *Watch Variables*

- None.

### 12.11.1.3 Flash Programming with 512-bit AutoECC, DataAndECC, DataOnly and EccOnly - C28X\_DUAL

FILE: flashapi\_cpu2\_512bitprogramming.c

This example demonstrates how to program Flash banks using API's following options

1. AutoEcc generation
2. DataOnly and EccOnly
3. DataAndECC

CPU1 example must be loaded and executed before CPU2 example. Only CPU1 is able to set the BankMuxSel and GSxMSel registers for CPU2. For both CPU1 and CPU2 load, make sure to set the correct Erase settings for bank selection. *External Connections*

- None.

#### Watch Variables

- None.

### 12.11.1.4 Flash Programming with AutoECC, DataAndECC, DataOnly and EccOnly - C28X\_DUAL

FILE: flashapi\_cpu1\_128bitprogramming.c

This example demonstrates how to program Flash using API's following options

1. AutoEcc generation
2. DataOnly and EccOnly
3. DataAndECC

NOTE: CPU1 example must be loaded and executed before CPU2 example. Only CPU1 is able to set the BankMuxSel and GSxMSel registers for CPU2. For both CPU1 and CPU2 load, make sure to set the correct Erase settings for bank selection.

#### External Connections

- None.

#### Watch Variables

- None.

## 12.12 Flash Registers

This section describes the Flash Module Registers.

### 12.12.1 FLASH Base Address Table

**Table 12-2. FLASH Base Address Table**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	CPU2	CPU2.DMA	Pipeline Protected
Instance	Structure								
Flash0CtrlRegs	FLASH_CTRL_REGS	FLASH0CTRL_BASE	0x0005_F800	YES	-	-	YES	-	YES
Flash0EccRegs	FLASH_ECC_REGS	FLASH0ECC_BASE	0x0005_FB00	YES	-	-	YES	-	YES

### 12.12.2 FLASH\_CTRL\_REGS Registers

Table 12-3 lists the memory-mapped registers for the FLASH\_CTRL\_REGS registers. All register offset addresses not listed in Table 12-3 should be considered as reserved locations and the register contents should not be modified.

**Table 12-3. FLASH\_CTRL\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	FRDCNTL	Flash Read Control Register	EALLOW	<a href="#">Go</a>
4h	FLPROT	Flash program/erase protect register	EALLOW	<a href="#">Go</a>
180h	FRD_INTF_CTRL	Flash Read Interface Control Register	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 12-4 shows the codes that are used for access types in this section.

**Table 12-4. FLASH\_CTRL\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 12.12.2.1 FRDCNTL Register (Offset = 0h) [Reset = 0F000F00h]

FRDCNTL is shown in [Figure 12-5](#) and described in [Table 12-5](#).

Return to the [Summary Table](#).

**Embedded Real-time Analysis and Diagnostic (ERAD)**

This chapter describes the features and operation of the embedded real-time analysis and diagnostic (ERAD) module. The ERAD module enhances the debug and system analysis capabilities of the device. The debug and system analysis enhancements provided by the ERAD module are implemented external to the CPU. The ERAD module consists of the enhanced bus comparator (EBC) units, the system event counter (SEC) units, and the cyclic redundancy check (CRC) units. The EBC units are used to generate hardware breakpoints, hardware watch points, and other output events. The SEC units are used to analyze and profile the system. The CRC units monitor CPU buses and compute the CRC when the self-test code is executed. This capability aids in achieving simpler, non-intrusive and interruptible self-test mechanisms with the Software Test Library (STL). The ERAD module is accessible both by the debugger and the application software, which significantly increases the debug capabilities of many real-time systems, especially in situations where the debugger is not connected.

## 13.1 Introduction

The ERAD module is shown in [Figure 13-1](#).

The ERAD enhances the debug and system analysis capabilities of the device external to the CPU. The CPU has two analysis resources; Analysis Unit 1 (AU1) and Analysis Unit 2 (AU2). The first analysis unit counts events or monitors address buses. The second analysis unit monitors address and data buses. The two analysis units can be configured for hardware breakpoints or hardware watch points, and additionally the first analysis unit can be configured as a benchmark counter or event counter. The ERAD module further expands this capability to provide additional hardware breakpoints, hardware watch points, and counters for profiling, as well as other advanced features. The ERAD module can be utilized by the debugger, and also by the application software. For many real-time systems, it is not always possible to connect a debugger and perform an intrusive debug. Under these situations, the user's code has the ability to set up and control the ERAD module to debug and profile the system without disturbing the end application.

The ERAD module consists of eight enhanced bus comparator (EBC) units and four system event counter (SEC) units. The EBC units monitor buses and generate output events. The SEC units can be used with EBC units to profile and analyze the system. These units are described in detail in the following sections.

**Figure 13-1. ERAD Overview**

## 13.2 Enhanced Bus Comparator Unit

The Enhanced Bus Comparator (EBC) units connect to the CPU using a direct memory interface. This includes the program address and data buses, the data address, write and read data buses, debug qualifiers for memory access, and the ability to set breakpoints, watch points, and trace points on the CPU. Typically, the EBC is owned and controlled by the debugger application (for example, Code Composer Studio™ IDE). A user application running on the CPU can also configure and use the EBC units to generate events and interrupts for real-time diagnostic purposes. Note that ownership is exclusive—the debugger and application software cannot simultaneously control an EBC unit. For more information on EBC unit ownership, see [Section 13.4](#).

The EBC units have the following capabilities:

- Generate hardware breakpoints
- Generate hardware watch points
- Generate trace tags for instruction fetch matches and generate real-time interrupts (RTOSINT)
- Monitor data address and read and write buses and generate real-time interrupts (RTOSINT)
- Generate event outputs that can be used by other modules.

The following features are not supported by the EBC units:

- Chained breakpoints
- Ability to monitor DMA transfers
- Ability to monitor CLA buses

Each EBC unit has the capability to monitor a range of addresses by defining masks and generating outputs based on greater than, less than, or equal events.

The EBC units can also be used with the System Event Counter (SEC) units for system or code profiling and analysis purposes.

### 13.2.1 Enhanced Bus Comparator Unit Operations

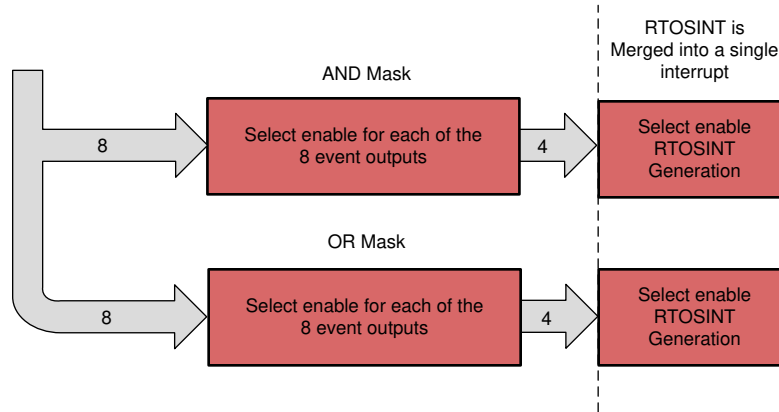

The following operations are supported by each EBC unit:

- **Hardware Breakpoints:** The EBC unit generates a breakpoint tag when the specified instruction address is accessed on the program address bus. When the instruction reaches the DECODE-2 (D2) stage of the pipeline, the CPU is halted.
- **Watch Points:** A watch point detects a read or write to specified locations in data memory, and halts the CPU. Unlike hardware breakpoints, watch points do not have precise timing for halting the CPU—this is entirely dependent on the current state of the CPU pipeline. The CPU halts at the next interruptible boundary.
- **Program Trace:** Program traces are very similar to hardware breakpoints. The difference here is that instead of halting the CPU, a program trace generates a real-time interrupt (RTOSINT) when the instruction reaches the D2 stage of the pipeline. If the instruction is discarded in the fetch buffer due to discontinuity, no RTOSINT is generated.
- **Data Trace:** A data trace is similar to a watch point, except that a data trace generates a real-time interrupt (RTOSINT) instead of halting the CPU on an access to the specified data memory.

Note that hardware breakpoints only halt the CPU if a debugger is connected.

### 13.2.2 Event Masking and Exporting

The events generated by different EBC units can be combined using OR and AND logic to generate new events as required. There are four AND and four OR combinations that can be exported using masks to suppress undesired events. These events can be configured to generate an RTOSINT. In addition, the AND and OR events can also be used to qualify CRC computation using the cyclic redundancy check unit. The AND and OR events are also available as inputs to the system event counter unit for event counting and system profiling.

**Figure 13-2. EBC Units Event Masking**

To use the AND and OR masks:

1. Configure the `GLBL_EVENT_AND_MASK` and `GLBL_OR_EVENT_MASK` registers to select the desired EBC unit outputs for any of the available four masks.
2. To enable an RTOSINT for the configured mask, write 1 to the corresponding bit in the `GLBL_AND_EVENT_INT_MASK` or `GLBL_OR_EVNT_INT_MASK` register.
3. To use the mask output as an input to the system event counter unit, configure the `CTM_INPUT_SEL` register with the mux value for the desired mask. The input mux values are listed in [Section 13.3.1.4](#).
4. To use the mask output as a qualifier to the CRC unit, configure the `CRC_QUALIFIER` register.

For example, to generate a real-time interrupt on MASK1 when EBC units 2, 3, AND 6 events are triggered, write 0x46 to `GLBL_EVENT_AND_MASK`, and then write 0x1 to `GLBL_AND_EVENT_INT_MSK`.

### 13.3 System Event Counter Unit

The SEC units provide system profiling, analysis, and debug capability. The SEC units contain counters that can enhance the debug and profiling process in various types of system scenarios such as:

- Profiling code segments
- Counting duration between specified memory reads and writes
- Counting system events (such as interrupts)
- Counting duration between system events
- System timer
- Measuring the number of wait states in code segments
- Measuring the maximum amount of time spent in between a pair of events, measured over multiple iterations
- Chaining counters to link events or create larger counters

Furthermore, the SEC unit has the capability to:

- Function as a counter capable of counting:
  - Any of the match events generated by the EBC units.
  - Events generated by the EBC units. These events can be used to start and stop the counting.
  - System events including the interrupts to the interrupt controller, and timer interrupts. These system events can be used to start and stop the counting.
  - More information on the input sources for the SEC units can be found in [Section 13.3.1.4](#).
- Generate an interrupt or a watch point if the count reaches a reference value.
- Perform counter operation in one of the following two modes:
  - Duration mode: The counter counts the CPU cycles as long as the event is active.
  - Event mode: The counter counts only the positive edge of the event signal. This is effectively counting the number of times the event transitions from inactive to active.

#### 13.3.1 System Event Counter Modes

The following are the operating modes of the SEC unit. The counters are initialized to zero when the SEC module receives a reset input signal, and always count up.

- Continuous Count: In this mode, the counter continues to count as specified by the input selector. The counter can count the CPU cycles without any events selected. In this mode, the module can be used as a software-controlled SYSCLK counter. Continuous mode is active when SEC\_CNTL.START\_STOP\_MODE and SEC\_REF are both set to 0.
- Timer Mode Count: In this mode, the counter counts up to a set reference value, defined in the SEC\_REF register. Upon reaching the reference value, the counter generates an event that can send an interrupt to the CPU or generate a watch point. The RST\_ON\_MATCH bit in the SEC\_CNTL register configures the counter to either continue incrementing or reset when a match event occurs.
- Start-Stop Count: In this mode, two events are configured to act as start and stop indicators to the counter. The counter commences counting only when the defined start event occurs. The counter then continues to count up until the stop event occurs. Once the first start event has occurred, further start events are ignored until the stop event occurs.

In any of the counter modes of operation, there is a possibility that the 32-bit counter value overflows. If an overflow occurs, the counter value resets to zero and continues to count up, and the OVERFLOW bit in the SEC\_STATUS register is set high. The OVERFLOW bit remains high until either the counter is reset, or the application writes 1 to the OVERFLOW bit of the SEC\_STATUSCLEAR register.

### 13.3.1.1 Counting Active Levels Versus Edges

The SEC units can be configured to either count active levels or edges of the selected inputs.

Each SEC unit has eight inputs from the EBC units and many inputs from other events in the device. Each SEC unit can be configured to count any of the input events or just count up on every cycle. For example, if an input event occurs and is active for 25 cycles, the SEC unit counter increments only by 1 in event mode; whereas in the duration mode, the counter increments by 25.

### 13.3.1.2 Max Mode

Max mode is also supported by the SEC units. This mode allows the user to detect the maximum count that has occurred during various count iterations in start-stop mode. For example, a user can set up the counter in the start-stop count mode to count the duration of a critical code loop. Every time the stop event occurs and the counter stops, the counter value is checked against the current MAX\_COUNT present in the register. If the new value is greater, then the MAX\_COUNT register is updated. The counter always resets to zero at the stop event and is ready to start counting on the next start event. Therefore, the MAX\_COUNT contains the maximum number of cycles that occurred between the start and stop condition over many iterations.

### 13.3.1.3 Cumulative Mode

The SEC units can be used to yield the cumulative count over several start and stop events. In this mode, unlike Max mode, the counter does not reset due to a stop event. Instead, the counter stops counting and resumes counting when a start event occurs. In cumulative count mode, the MAX\_COUNT is not valid.

### 13.3.1.4 Input Signal Selection

The SEC inputs can be selected from various signals from in the system to enable debug and system analysis. Figure 13-3 shows the SEC inputs. Each event selector MUX can select from various signals on in the system. These signals are shown in Table 13-1.

### 13.3.2 Reset on Event

Resetting the counters on external events is also possible. Additionally all the counter event outputs are applied back to each of counter input MUX, which selects the event that can be used as a reset input. When enabled, an active high on the reset input causes the counter to reset. This gives a powerful feature that allows setting up threshold monitors. This can be used to flag an interrupt or a watch point, if the distance between two events crosses a certain threshold.

### 13.3.3 Operation Conditions

The SEC units count accurately only when the CPU is operating in normal conditions. If the counters are running and capturing the CPU cycles while the CPU is controlled through the debugger to single-step through the code, then the result can differ from when the CPU was executing the code in normal conditions.

### 13.4 ERAD Ownership, Initialization and Reset

Although the features of the ERAD module are typically used by the debugger, user applications can also take advantage of the capabilities to monitor buses and generate interrupts and events. There are three possible ownership scenarios:

1. The user elects to give ownership of the ERAD module to the application software or the debugger.
2. Both the application code and the debugger share use of the ERAD module. Only the current owner of the module (application code or debugger) is allowed to use the module at a given time. When ownership is shared between application and debugger, the user application has the responsibility of resolving any ownership conflicts.
3. There is no ERAD owner. In this mode, both application code and debugger can access the module at any given time. The software, both on the application side and the debugger side, to resolve any potential conflicts is critical. An example scenario in this mode can be for the debugger to use some of the EBC and SEC units, while the application software uses the remaining units.

The ERAD module initializes the internal states and all registers to the initial/reset states under the following conditions:

- At power-on-reset (POR)
- With DCON and SYSRSN
  - Debug logic disconnected when the debugger owns the module
  - Functional reset when application owns the module

## 13.5 ERAD Programming Sequence

The ERAD module can be used to set hardware breakpoints and hardware watch points. The programming sequences to set hardware breakpoints, hardware watch points, or to use the timers to profile and analyze the system are described in this section. The same sequences can be used by both the debugger software and user application code.

Refer to the Driverlib example projects in C2000Ware for JavaScript files to configure the ERAD module. Example projects are also available to showcase the usage of these script files. These examples can be found in the `driverlib\28p65x\examples\erad` directory under the C2000Ware installation directory.

### 13.5.1 Hardware Breakpoint and Hardware Watch Point Programming Sequence

The programming sequence is identical when using the EBC units, regardless of whether the debug software or the application is programming the units. A typical programming sequence for a unit is:

- Read and make sure the ownership is set as expected; if not, acquire the ownership before proceeding further if required.
- Make sure the unit is in IDLE mode.
- Set up the address reference, mask, bus select and stop bits.
- Enable the corresponding module bit in the global enable register.
- Once the usage is completed, write 1 to clear the `EVENT_FIRED` sticky bit. This takes the module back to the enabled state.

The example programming sequences for hardware breakpoints and hardware watch points are:

Set a hardware breakpoint on address 0x201000:

- Read `OWNER` to confirm ownership.
- Read `EBC_STATUS` to confirm the module is in IDLE state.
- Write 0x0 to `EBC_MASKH/MASKL`.
- Write 0x201000 to `EBC_REFH/REFL`.
- Set `HWBP_CNTL.STOP = 1` and `HWBP_CNTL.BUS_SEL = 0000 (PAB)`. If a trace is to be generated instead of a breakpoint, set `HWBP_CNTL.STOP = 0`.
- Enable the corresponding module bit in the EBC enable register.

Set a hardware watch point on read of addresses from 0x121010 to 0x12101F:

- Read `OWNER` to confirm ownership.
- Read `EBC_STATUS` to confirm the module is in IDLE state.
- Write 0xF to `EBC_MASKH/MASKL`.
- Write 0x121010 to `EBC_REFH/REFL`.
- Write `HWBP_CNTL.STOP = 1` and `HWBP_CNTL.BUS_SEL = 0011 (DRAB)`. If an `RTOSINTn` is to be generated instead of a watch point, set `HWBP_CNTL.STOP = 0`.
- Enable the corresponding module bit in the global enable register.

Set a hardware watch point on write to address 0xFF10101A:

- Read `OWNER` to confirm ownership
- Read `EBC_STATUS` to confirm the module is in IDLE state
- Write 0x0 to `EBC_MASKH/MASKL`
- Write 0xFF10101A to `EBC_REFH/REFL`
- Write `HWBP_CNTL.STOP = 1`, `HWBP_CNTL.BUS_SEL = 0010 (DWAB)`. If an `RTOSINTn` is to be generated instead of a watch point, set `HWBP_CNTL.STOP = 0`.
- Enable the corresponding module bit in the global enable register.

### 13.5.2 Timer and Counter Programming Sequence

The programming sequence is identical when using the SEC units, regardless of whether the debug software or the application is programming the units. Typical programming sequence for a unit is:

- Read and make sure the ownership is set as expected. If not, acquire the ownership before proceeding further if required.
- Make sure the unit is in IDLE mode.
- Set up the counter reference, counter registers (clear/reset if a clean start is required).
- Enable the corresponding module bit in the enable register.
- Once the usage is completed, write 1 to clear the EVENT\_FIRED sticky bit. This takes the module back to the enabled state.

Set up a free running counter:

- Read and make sure the ownership is set as expected. If not, acquire the ownership before proceeding further, if required.
- Read SEC\_STATUS to confirm that the module is in IDLE state.
- Write 0x0 to CNT\_INP\_SEL\_EN.
- Write 0x0 to SEC\_CNTL.
- Enable the module in the SEC\_CNTL.EN register.

Set up the counter to count the duration spent between addresses 0x1000 and 0x1210:

- Read and make sure the ownership is set as expected. If not, acquire the ownership before proceeding further, if required.
- Read SEC\_STATUS to confirm that the module is in IDLE state.
- Set up the EBC unit 1 to generate an event for VPC = 0x1000.
- Set up the EBC unit 2 to generate an event for VPC = 0x1210.
- Set up the start and stop input selects to use comparator event 1 and 2, respectively. This is achieved by writing CTM\_INPUT\_SEL.STA\_INP\_SEL = 0x0 and CTM\_INPUT\_SEL\_2.STO\_INP\_SEL = 0x1.
- Enable the counter in the START\_STOP\_MODE of operation. This is achieved by writing CTM\_CNTL.START\_STOP\_MODE = 1.
- Enable the module in the SEC\_CNTL.EN register.

Set up the counter to count the number of times a function at address 0x2010 is called and fire an interrupt if this count reaches 0x300:

- Read and make sure the ownership is set as expected. If not, acquire the ownership before proceeding further, if required.
- Read SEC\_STATUS to confirm that the module is in IDLE state.
- Set up the EBC unit 1 to generate an event for VPC = 0x2010.
- Setup the counter to select comparator event 1 as the event to count. This is achieved by writing CTM\_INPUT\_SEL.CNT\_INP\_SEL = 0 and CTM\_CNTL.CNT\_INP\_SEL\_EN = 1.
- Write 0x300 SEC\_REF.
- Enable the counter in the EDGE\_LEVEL, and also allow the counter to generate an interrupt when the count matches the reference. This is achieved by writing 0x42 to SEC\_CNTL.
- Enable the module in the SEC\_CNTL.EN register.

### 13.6 Cyclic Redundancy Check Unit

The cyclic redundancy check (CRC) units monitor CPU buses and compute CRC when the self-test code is executed. This capability aids in achieving simpler, non-intrusive and interruptible self-test mechanisms with Software Test Library (STL). Each CRC unit is used to monitor a different CPU interface. For example, CRC unit 1 is used to monitor the Program Counter, while CRC unit 2 is used to monitor the data read address bus. [Table 13-2](#) identifies the CPU interface monitored by each of the CRC units.

**Table 13-2. CPU Interfaces Monitored by CRC Units**

CRC Unit	CPU Interface
CRC Unit 1	Program Counter Register
CRC Unit 2	Data Read Address Bus
CRC Unit 3	Data Read Data Bus
CRC Unit 4	Data Write Address Bus
CRC Unit 5	Data Write Data Bus
CRC Unit 6	Instruction Register Value (Unsecured)
CRC Unit 7	Instruction Register Value (Secure-Zone 1)
CRC Unit 8	Instruction Register Value (Secure-Zone 2)

The main purpose of the CRC units is to make sure that the CPU functionally remains intact when the CRC unit is executing the same software test library over multiple iterations. This is done by comparing the computed CRC values after each iteration, with a pre-computed golden value.

CRC units 7 and 8 are intended to compute the instruction register values for secure-zone 1 and secure-zone 2 instruction execution. Computed CRC values for the a given secure-zone is available only for accesses originating from that zone.

**13.6.1 CRC Unit Qualifier**

By default, all the valid events on a given interface enables a CRC unit for computation. However there are optional qualifiers that can be used to gate the CRC computation when valid events occur. If required, these qualifiers can be generated by masking the EBC units events. The AND/OR masks discussed in [Section 13.2.2](#) are used to generate these qualifiers. Refer to the CRC\_QUALIFIER register for a full list of available qualifiers. [Figure 13-4](#) shows the connection between EBC event masking and exporting with the CRC qualifiers.

EBC units have the capability to monitor the Program Counter, data writes and data reads. CRC units can use the EBC units to decide when the check values can be calculated. For example, if required to calculate the check values only when the CPU is executing a specific function, the user can set up an EBC unit to monitor the PC and generate a CRC qualifier when that function is executed. This allows the CRC unit to calculated the check value only when desired.

**Figure 13-4. Event Masking and Exporting for CRC Qualifiers**

### 13.6.2 CRC Unit Programming Sequence

The following sequence can be used to initialize a CRC unit to calculate the check value for the corresponding CPU interface.

1. Initialize the CRC unit by writing a 1 to the corresponding CRC\_INIT field in the CRC\_GLOBAL\_CTRL register.
2. Configure the seed value (if required) using CRC\_SEED register (CRC\_EN can be 0 for when modifying the CRC\_SEED register).
3. Configure the CRC\_QUALIFIER register if additional qualification from EBC units is required; If not additional qualification is not required, set the CRC\_QUALIFIER register to 0.
4. Enable the CRC unit by setting the CRC\_EN to 1 at the beginning of the software for which the CRC calculation is done.
5. Disable the CRC unit by setting the CRC\_EN to 0 at the end of the software for which the CRC calculation is done.
6. Read the CRC\_CURRENT register to record the computed CRC. This check value can be compared with previous check values to make sure no changes have occurred.
7. Repeat steps 1-7 periodically as needed.

---

#### Note

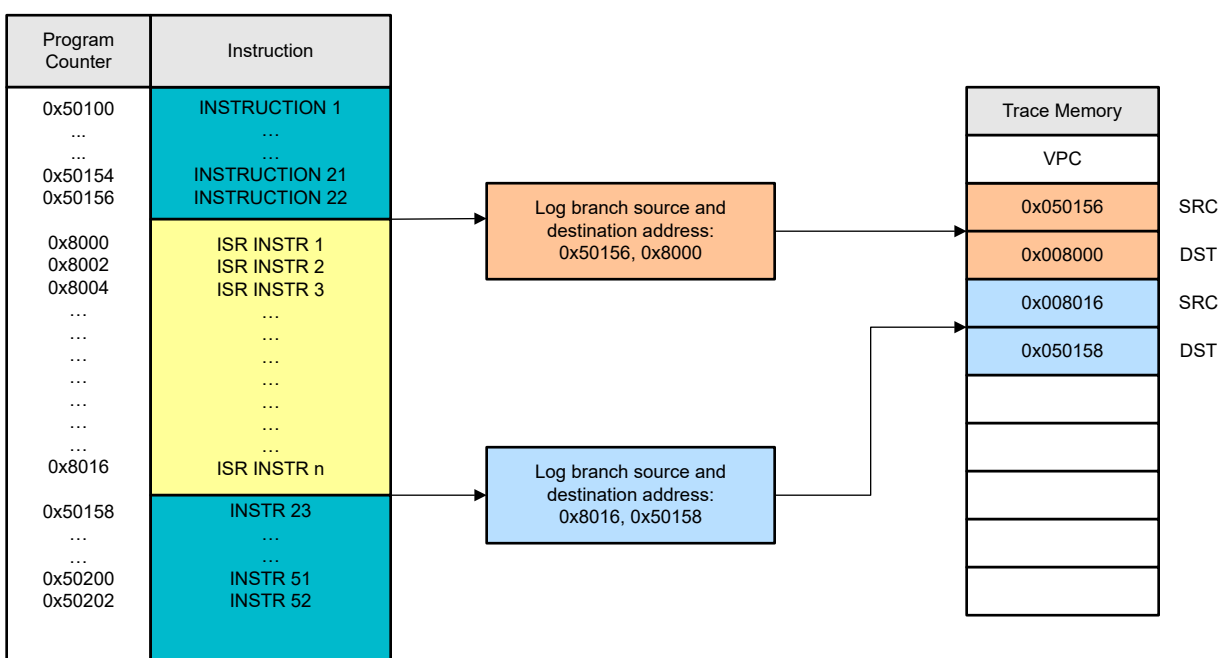

Sufficient NOP's must be added immediately after the CRC submodule is enabled to make sure the pipeline contains predictable code as soon as the CRC is enabled. Similarly, sufficient NOP's must be added before the CRC submodule is disabled. Disabling the CRC write access takes a few cycles, therefore there must be predictable code in the pipeline stages until the write takes place.

---

## 13.7 Program Counter Trace

The Program Counter (PC) Trace module can be used to keep track of PC discontinuities or jumps, as a means to trace an entire program execution sequence over a period of time. When trace is completed or stopped, trace data can be read out using a debugger and analyzed to reconstruct the code execution sequence. The PC Trace module provides multiple modes and controls to govern when to trace and when not to trace. The trace module is tightly coupled with the Enhanced Bus Comparator, the System Event Counter Unit, and certain critical system level event signals.

Trace data is stored in an addressable memory buffer that can be read by software or a debugger. The trace data stored in this buffer includes additional status information on trace validity that can be used to correctly reconstruct the code execution system. For each discontinuity, two PC values are stored: the source of the discontinuity, and the destination. [Figure 13-5](#) illustrates the operation of the PC trace module. The trace buffer is a circular buffer with overflow: when the buffer becomes full, new trace data is written starting from the top of the buffer, and an overflow status bit is set.

**Figure 13-5. PC Trace Operation**

### 13.7.1 Functional Block Diagram

Figure 13-6 describes the device PC trace architecture. The trace module is tightly coupled with the CPU, and receives the current program counter (VPC), program address (PAB), and various qualifying signals from the CPU interface. The Trace core captures these values whenever a PC discontinuity (for example, branch operation) is detected. The DCSM also interfaces with the PC Trace module, providing security zone data to prevent unauthorized trace information from being exposed in trace memory. The PC Trace module interfaces with the Enhanced Bus Comparator Unit and System Event Counter Unit, providing the ability to select events from these units as triggers to start a trace, stop a trace, or determine the bounding conditions for a windowed trace operation.

The Trace Core qualifies trace source and destination addresses, and stores these addresses sequentially in the trace memory buffer. Additionally, the Trace Core can generate hit events every time a new trace is stored in the memory buffer; this event signal is connected to the ERAD counter block so that the number of entries in the buffer can be tracked. This counter value can in turn be used to create a STOP event at a predefined threshold.

#### Note

Discontinuities that arise due to block repeats (RPTB instruction blocks) are not captured by the PC trace module.

Debugger accesses are always treated as unsecure accesses. Unlike other ERAD components, there is no concept of debug or application ownership in the PC Trace module.

The Trace Core generates a trace hit event for a discontinuity arising from a speculative instruction fetch, even if the fetched instruction does not reach the execution phase in the CPU pipeline. As a result, the BUFFER\_FULL signal can be set prematurely due to a speculative prefetch. The user can always safely discard the oldest discontinuity pair present in the memory buffer when a full buffer is detected, to mitigate this scenario.

Figure 13-6. PC Trace Block Diagram

### 13.7.2 Trace Qualification Modes

There are three modes of trace qualification available:

1. Normal mode: In this mode, trace is enabled without any qualifiers. Trace control happens purely through software writing to the PCTRACE\_GLOBAL register. When operating PC Trace in normal mode, The PCTRACE\_LOGPC\_SOFTENABLE captures the program counter value at the point when PCTRACE\_GLOBAL.EN is set to 1, and the PCTRACE\_LOGPC\_SOFTDISABLE register captures the program counter value at the point PCTRACE\_GLOBAL.EN is set to 0.
2. Windowed Trace mode: In windowed mode, PC Trace can be activated or stopped based on the value of a signal coming from the Event Bus Comparator, System Event Counter, or other system events. The WINDOWED\_INP\_SEL field in the PCTRACE\_QUAL1 register specifies the input signal used to qualify PC Trace operation in windowed mode. By default trace is active when the input signal is high and inactive when the input signal is low; this behavior can be reversed by setting the PCTRACE\_QUAL1.WINDOWED\_INP\_INV bit high.
3. Start-Stop mode: In this mode, one input signal starts the PC trace operation, and a different input signal stops the trace operation. Event Bus Comparator signals, System Event Counter signals and other system event signals can be used as inputs to start or stop the PC Trace. The START\_INP\_SEL and STOP\_INP\_SEL fields in the PCTRACE\_QUAL2 register specify the input signals used to qualify PC Trace operation in start-stop mode. Once a start event arrives and PC trace operation begins, the PC Trace module ignores all further start events until a stop event is received. Trace start and stop operations are triggered on the rising edge of the input event; this behavior can be reversed by setting the START\_INP\_INV and STOP\_INP\_INV bits in the PCTRACE\_QUAL1 register.

To set the PC Trace operation mode, write to the TRACE\_MODE bit in the PCTRACE\_QUAL1 register.

### 13.7.3 Trace Memory

PC Trace memory is a 32-bit-wide read-only memory buffer that holds each 31-bit PC value, together with a security BLOCKED status bit. The memory-map section of the device data sheet specifies the size of the PC Trace memory buffer. Trace memory entries are stored in pairs: the discontinuity source and destination addresses. [Table 13-3](#) describes the bit field structure of each trace memory entry.

**Table 13-3. Trace Memory Entry Bit Fields**

Bits	Field Name	Description
31:1	PROGRAM_COUNTER	Program counter source or destination address value where discontinuity occurred
0	BLOCKED	1 = PROGRAM_COUNTER[31:1] is invalid due to security permissions 0 = PROGRAM_COUNTER[31:1] is valid

#### Note

For addresses that are blocked due to security zone restrictions, the PROGRAM\_COUNTER value is set to 0.

Trace memory is intended solely for debug purposes and does not have parity or Error Correction Code (ECC) support.

### 13.7.4 Trace Input Signal Conditioning

The PC Trace module provides input conditioning options for signals that are used to qualify operation in Start-Stop or Windowed modes. For each of these (START, STOP, WINDOWED), there is a two-stage synchronizer for asynchronous input signals, and an inverter. The PC Trace input conditioning options are controllable using the PCTRACE\_QUAL1 register with the following bits:

- **WINDOWED\_INP\_INV:** This bit inverts the input signal for Windowed trace mode selected in WINDOWED\_INP\_SEL. When set to 1, the trace operation starts on the falling edge of the input, and stops on the rising edge of the input. When this bit is set to 0, the trace operation starts on the rising edge of the input, and stops on the falling edge of the input.
- **START\_INP\_INV:** This bit inverts the input signal for trace START operation selected in PCTRACE\_QUAL2.START\_INP\_SEL. When set to 1, the trace operation starts on the falling edge of the input. When this bit is set to 0, the trace operation starts on the rising edge of the input.
- **STOP\_INP\_INV:** This bit inverts the input signal for trace STOP operation selected in PCTRACE\_QUAL2.STOP\_INP\_SEL. When set to 1, the trace operation stops on the falling edge of the input. When this bit is set to 0, the trace operation stops on the rising edge of the input.

Figure 13-7 describes the signal conditioning circuit available for each input qualifier signal.

**Figure 13-7. Trace Qualifier Input Conditioning Circuit**

### 13.7.5 PC Trace Software Operation

An example software sequence to perform PC Trace operation is as follows:

1. Initialize the PC Trace module by writing 1 to PCTRACE\_GLOBAL.INIT. The trace initialize operation resets the buffer pointer and overflow flags, and clears the values of the PCTRACE\_LOGPC\_SOFTENABLE and PCTRACE\_LOGPC\_SOFTDISABLE registers.
2. Start the PC Trace operation by writing 1 to PCTRACE\_GLOBAL.EN.
3. Execute the desired code sequence to be profiled.
4. Stop the PC Trace operation by writing 0 to PCTRACE\_GLOBAL.EN. This step is optional, as the PC Trace buffer can be read while trace operation is active.
5. To determine if there are valid entries in the trace buffer and how many:
  - a. Examine the buffer pointer by reading PCTRACE\_BUFFER.PTR. If the pointer value is 0, then no discontinuities have been detected since PC Trace was initialized. A non-zero value indicates the number of locations in the buffer that contain valid entries. For instance, PTR = 4 indicates that locations 0, 1, 2, and 3 contain valid entries (SRC, DST, SRC, DST).
  - b. Examine the BUFFER\_FULL bit in the PCTRACE\_BUFFER register. If BUFFER\_FULL = 1, then the following possibilities apply:
    - If PTR = 0, then the buffer is simply full and contains the maximum number of entries possible.
    - If PTR > 0, then a buffer overflow has occurred. The value of PTR indicates by how many entries the buffer has overflowed: this is a circular buffer.
6. Read PCTRACE\_LOGPC\_SOFTENABLE (and optionally PCTRACE\_LOGPC\_SOFTDISABLE) if needed to determine the bounding addresses of the trace operation, in case the code sequence being traced does not begin or end at a discontinuity boundary (for example, partial function trace).
7. Trace discontinuities are recorded in the trace buffer in pairs (SRC, DST). Use this data to reconstruct the code execution sequence. While reading the trace buffer, be sure to examine the BLOCKED status bit to confirm the validity of each trace entry.

### 13.7.6 Trace Operation in Debug Mode

PC Trace is designed to capture data while the CPU is executing code. Debugger operations such as halt, step, and manual PC modification can compromise the reliability of PC trace data collection. Only use or interpret PC Trace data in the context of a continuous CPU run without debugger interruption or intervention.

CPU execution does not preclude debugger operation of the PC trace module if the debugger owns the PCTRACE module. While the CPU is running and executing code, the debugger can read and write PC Trace registers, read the trace buffer, and enable or disable PC trace operation. Debugger can update the PC Trace registers if debugger owns PCTRACE module. The PCTRACE\_LOGPC\_SOFTENABLE and PCTRACE\_LOGPC\_SOFTDISABLE registers record the start and stop PC addresses to provide accurate trace window information during manual trace starts or stops triggered by writing to the PCTRACE\_GLOBAL.EN bit.

## 13.8 Software

### 13.8.1 ERAD Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/erad

Cloud access to these examples is available at the following link: [dev.ti.com](http://dev.ti.com) [C2000Ware Examples](#).

#### 13.8.1.1 ERAD Profiling Interrupts

FILE: erad\_ex1\_profileinterrupts.c

This example configures CPU Timer0, 1, and 2 to be profiled using the ERAD module. Included is a JavaScript file, `profile_interrupts.js`, which is used with the scripting console to program ERAD registers and view profiling data.

To properly use the provided ERAD script, the following variables must be set in the scripting environment prior to launching the ERAD script:

- `var PROJ_NAME = "erad_debugger_ex1_profileinterrupts"`
- `var PROJ_WKSPC_LOC = "<proj_workspace_path>"`
- `var PROJ_CONFIG = "<name of active configuration [CPU1_FLASH|CPU1_RAM]>"`

To run the ERAD script, use the following command in the scripting console:

- `loadJSFile("<proj_workspace_path>\\\erad_debugger_ex1_profileinterrupts\\erad_ex1_profile_interrupts.js", 0);`

The included JavaScript file, `erad_ex1_profile_interrupts.js`, uses Debug Server Scripting (DSS) features. For information on using the DSS, please visit: [http://software-dl.ti.com/ccs/esd/documents/users\\_guide/sdto\\_dss\\_handbook.html](http://software-dl.ti.com/ccs/esd/documents/users_guide/sdto_dss_handbook.html)

Note that the script must be run after loading and running the `.out` on the C28x core. Only CPU timer 2 ISR is profiled in this example.

This example uses 2 HW breakpoints and 4 counters:

- `HWBP_1` : PC = start address of `cpuTimer2ISR`
- `HWBP_2` : PC = end address of `cpuTimer2ISR`
- `CTM_1` : Used to count the `cpuTimer2ISR` execution cycles. Configured in start-stop mode with start event as `HWBP_1` and stop event as `HWBP_2`
- `CTM_2` : Used to count the number of times the system event `TIMER2_TINT2` has occurred. Configured in rising-edge count mode with counting input as system event `TIMER2_TINT2 (INP_SEL[25])`
- `CTM_3` : Used to count the number of times `cpuTimer2ISR` executes. Configured in rising-edge count mode with counting input as `HWBP_1 (INP_SEL[0])`
- `CTM_4` : Used to count the latency from the system event `TIMER2_TINT2` to `cpuTimer2ISR` entry. Configured in start-stop mode with start event as `TIMER2_TINT2` and stop event as `HWBP_1`

#### External Connections

- None

#### Watch Variables

- `cpuTimer0IntCount`
- `cpuTimer1IntCount`
- `cpuTimer2IntCount`

#### Profiling Script Output

- Current ISR cycle count (`CTM_1`)
- Max ISR cycle count (maximum value of `CTM_1`)
- Interrupt occurrence count (`CTM_2`)
- ISR execution count (`CTM_3`)

- ISR entry delay cycle count (maximum value of CTM\_4)

Note that the large difference between Interrupt occurrence count (CTM\_2) and ISR execution count (CTM\_3) is because the ISR takes more number of cycles than the actual interrupt period. ISR entry delay cycle count will also be higher due to the same reason.

### 13.8.1.2 ERAD Profile Function

FILE: erad\_ex1\_profile\_function.c

This example uses BUSCOMP1, BUSCOMP2 and COUNTER1 of the ERAD module to profile a function (delayFunction). It calculates the CPU cycles taken between the the start address of the function to the end address of the function

Two dummy variable are written to inside the function - startCount and endCount. BUSCOMP3, BUSCOMP4 and COUNTER2 are used to profile the time taken between the access to startCount variable till the access to endCount variable.

Both the counters are setup to operate in START-STOP mode and count the number of CPU cycles spend between the respective bus comparator events.

#### *Watch Variables*

- cycles\_Function - the maximum number of cycles between the start of function to the end of function
- cycles\_Data - the maximum number of cycles taken between accessing startCount variable to endCount variable

#### *External Connections*

None

### 13.8.1.3 ERAD Profile Function

FILE: erad\_ex1\_profile\_function\_syscfg.c

This example uses BUSCOMP1, BUSCOMP2 and COUNTER1 of the ERAD module to profile a function (delayFunction). It calculates the CPU cycles taken between the the start address of the function to the end address of the function

Two dummy variable are written to inside the function - startCount and endCount. BUSCOMP3, BUSCOMP4 and COUNTER2 are used to profile the time taken between the access to startCount variable till the access to endCount variable.

Both the counters are setup to operate in START-STOP mode and count the number of CPU cycles spend between the respective bus comparator events.

#### *Watch Variables*

- cycles\_Function - the maximum number of cycles between the start of function to the end of function
- cycles\_Data - the maximum number of cycles taken between accessing startCount variable to endCount variable

#### *External Connections*

None

### 13.8.1.4 ERAD HWBP Monitor Program Counter

FILE: erad\_ex2\_bus\_monitor.c

In this example, the function delayFunction is called multiple times. The function does read and writes to the global variables startCount and endCount.

The BUSCOMP1 and COUNTER1 is used to count the number of times the function delayFunction was invoked. BUSCOMP2 is used to generate an interrupt when there is read access to the startCount variable and BUSCOMP3 is used to generate an interrupt when there is a write access to the endCount variable

#### *Watch Variables*

- funcCount - number of times the function delayFunction was invoked
- isrCount - number of times the ISR was invoked

#### External Connections

- None

#### 13.8.1.5 ERAD HWBP Monitor Program Counter

FILE: erad\_ex2\_bus\_monitor\_syscfg.c

In this example, the function delayFunction is called multiple times. The function does read and writes to the global variables startCount and endCount.

The BUSCOMP1 and COUNTER1 is used to count the number of times the function delayFunction was invoked. BUSCOMP2 is used to generate an interrupt when there is read access to the startCount variable and BUSCOMP3 is used to generate an interrupt when there is a write access to the endCount variable

#### Watch Variables

- funcCount - number of times the function delayFunction was invoked
- isrCount - number of times the ISR was invoked

#### External Connections

- None

#### 13.8.1.6 ERAD Profile Function

FILE: erad\_ex2\_profilefunction.c

This example contains a basic FIR calculation and sorting algorithm to help demonstrate the function profiling capability of the ERAD peripheral. A number of FIR sums are calculated within a loop and are then sorted using the insertion sort algorithm. Cycle counts of both the FIR calculations and the sorting algorithm are output to the screen through the scripting console. In this example, it can be seen that sorting the data takes up a majority of the CPU cycles executed in this program.

To properly use the provided ERAD script, the following variables must be set in the scripting environment prior to launching the ERAD script:

- var PROJ\_NAME = "erad\_debugger\_ex2\_profilefunction"
- var PROJ\_WKSPC\_LOC = "<proj\_workspace\_path>"
- var PROJ\_CONFIG = "<name of active configuration [CPU1\_FLASH|CPU1\_RAM]>"

To run the ERAD script, use the following command in the scripting console:

- loadJSFile("<proj\_workspace\_path>\erad\_debugger\_ex2\_profilefunction\erad\_ex2\_profile\_function.js", 0);

Note that the script must be run after loading and running the .out on the C28x core.

The included JavaScript file, erad\_ex2\_profile\_function.js, uses Debug Server Scripting (DSS) features. For information on using the DSS, please visit: [http://software-dl.ti.com/ccs/esd/documents/users\\_guide/sdto\\_dss\\_handbook.html](http://software-dl.ti.com/ccs/esd/documents/users_guide/sdto_dss_handbook.html)

This example uses 4 HW breakpoints and 2 counters:

- HWBP\_1 : PC = start address of performFIR
- HWBP\_2 : PC = end address of performFIR
- HWBP\_3 : PC = start address of sortMax
- HWBP\_4 : PC = end address of sortMax
- CTM\_1 : Used to count the performFIR execution cycles. Configured in start-stop mode with start event as HWBP\_1 and stop event as HWBP\_2
- CTM\_2 : Used to count the sortMax execution cycles. Configured in start-stop mode with start event as HWBP\_3 and stop event as HWBP\_4

#### External Connections

- None.

#### Watch Variables

- FIR\_iterationCounter - A counter for the number of times FIR calculation and sorting was performed

#### Profiling Script Output

- Current FIR cycle count (CTM\_1)
- Max FIR cycle count (maximum value of CTM\_1)
- Current sorting function cycle count (CTM\_2)
- Max sorting function cycle count (maximum value of CTM\_2)

Note that the the counters are reset after the stop event. The counter value remains 0 till the next start event occurs. The javascript continuously reads the counter value in a while(1) and hence the current counter may return 0.

#### 13.8.1.7 ERAD HWBP Stack Overflow Detection

FILE: erad\_ex3\_stack\_overflow\_detect.c

This example uses BUSCOMP1 to monitor the stack. The Bus comparator is set to monitor the data write access bus and generate an RTOS interrupt CPU when a write is detected to end of the STACK within a threshold.

#### Watch Variables

- functionCallCount - the number of times the recursive function overflowing the STACK is called.
- x indicates that the ISR has been entered

#### External Connections

None

#### 13.8.1.8 ERAD HWBP Stack Overflow Detection

FILE: erad\_ex3\_stack\_overflow\_detect\_syscfg.c

This example uses BUSCOMP1 to monitor the stack. The Bus comparator is set to monitor the data write access bus and generate an RTOS interrupt CPU when a write is detected to end of the STACK within a threshold.

#### Watch Variables

- functionCallCount - the number of times the recursive function overflowing the STACK is called.
- x indicates that the ISR has been entered

#### External Connections

None

#### 13.8.1.9 ERAD Stack Overflow

FILE: erad\_ex3\_stackoverflow.c

This example shows the basic setup of CAN in order to transmit and receive messages on the CAN bus. The CAN peripheral is configured to transmit messages with a specific CAN ID. A message is then transmitted once per second, using a simple delay loop for timing. The message that is sent is a 2 byte message that contains an incrementing pattern.

This example sets up the CAN controller in External Loopback test mode. Data transmitted is visible on the CANTXA pin and is received internally back to the CAN Core.

A buffer is created to store message history up to 50 messages for the duration of the program. A logic error is intentionally made to allow the buffer to overflow, eventually causing a stack overflow. The included JavaScript file, stack\_overflow.js, programs ERAD registers in order to detect the stack overflow and halt the CPU once the illegal write is made. The illegal write is made after 507 messages are received.

To properly use the provided ERAD script, the following variables must be set in the scripting environment prior to launching the ERAD script:

- var PROJ\_NAME = "erad\_debugger\_ex3\_stackoverflow"
- var PROJ\_WKSPC\_LOC = <proj\_workspace\_path>

To run the ERAD script, use the following command in the scripting console:

- loadJSFile("<proj\_workspace\_path>\lerad\_debugger\_ex3\_stackoverflow\lerad\_ex3\_stack\_overflow.js", 0);

Note that the script must be run after loading and running the .out on the C28x core.

The included JavaScript file, erad\_ex3\_stack\_overflow.js, uses Debug Server Scripting (DSS) features. For information on using the DSS, please visit: [http://software-dl.ti.com/ccs/esd/documents/users\\_guide/sdto\\_dss\\_handbook.html](http://software-dl.ti.com/ccs/esd/documents/users_guide/sdto_dss_handbook.html)

This example uses 1 HW watchpoint :

- HWBP\_1 : Data Write Address Bus = Stack end address + 1

#### External Connections

- None.

#### Watch Variables

- msgCount - A counter for the number of successful messages received
- txMsgData - An array with the data being sent
- rxMsgData - An array with the data that was received
- msgHistoryBuff - An array meant to store the last 50 messages received

#### Profiling Script Output

- "STACK OVERFLOW detected. Halting CPU." will be printed in the scripting console when a stack overflow occurs (that is, when the watchpoint is hit)

#### 13.8.1.10 ERAD Profile Interrupts CLA

FILE: erad\_ex4\_profileinterrupts\_cla.c

This example configures EPWM1A to run at 1 KHz (period = 1 ms) to trigger a start-of-conversion on ADC channel A0. This channel will, in turn, sample EPWM4A which is set to run at 100Hz. At the end-of-conversion the ADC interrupt is fired. The interrupt signal will be used to trigger a CLA task that runs an FIR filter. The filter is designed to be low pass with a cutoff frequency of 100Hz; it will remove the odd harmonics in the input signal smoothing the square wave to a sinusoidal shape. The CLA background task will continuously buffer the filtered output in a circular buffer.

This example also utilizes the ERAD peripheral to profile the Interrupt Service Routine (ISR) cla1ISR1 (on the C28x core). The ISR contains a loop that simulates storing a random amount of data to a location in order to introduce variability into the cycle measurements. The ERAD peripheral is also configured to count the number of times the system event CLA\_INTERRUPT1 occurs.

To properly use the provided ERAD script, the following variables must be set in the scripting environment prior to launching the ERAD script:

- var PROJ\_NAME = "erad\_debugger\_ex4\_profileinterrupts\_cla"
- var PROJ\_WKSPC\_LOC = "<proj\_workspace\_path>"
- var PROJ\_CONFIG = "<name of active configuration [CPU1\_FLASH|CPU1\_RAM]>"

To run the ERAD script, use the following command in the scripting console:

- loadJSFile("<proj\_workspace\_path>\lerad\_debugger\_ex4\_profileinterrupts\_cla\lerad\_ex4\_profile\_interrupts\_cla.js", 0);

Note that the script must be run after loading and running the .out on the C28x core.

The included JavaScript file, erad\_ex4\_profile\_interrupts\_cla.js, uses Debug Server Scripting (DSS) features. For information on using the DSS, please visit: [http://software-dl.ti.com/ccs/esd/documents/users\\_guide/sdto\\_dss\\_handbook.html](http://software-dl.ti.com/ccs/esd/documents/users_guide/sdto_dss_handbook.html)

This example uses 4 HW breakpoints and 2 counters:

- HWBP\_1 : PC = start address of cla1Isr1
- HWBP\_2 : PC = end address of cla1Isr1
- CTM\_1 : Used to count the cla1Isr1 execution cycles. Configured in start-stop mode with start event as HWBP\_1 and stop event as HWBP\_2
- CTM\_2 : Used to count the number of times the system event CLA\_INTERRUPT1 event has occurred. Configured in rising-edge count mode with counting input as system event CLA\_INTERRUPT1 (INP\_SEL[26])

#### *External Connections*

- connect A0 to EPWM4A

#### *Watch Variables*

- ISR\_count - A counter that signifies how many times cla1ISR1 executes

#### *Profiling Script Output*

- Current ISR cycle count (CTM\_1)
- Max ISR cycle count (maximum value of CTM\_1)
- Interrupt occurrence count (CTM\_2)

#### **13.8.1.11 ERAD Profiling Interrupts**

FILE: erad\_ex4\_profile\_interrupt.c

This example shows how an ISR can be profiled by ERAD. The CPU timer generates interrupts periodically. We set up the counters to count the CPU cycles elapsed while executing the ISR, to count the number of interrupts, the number of ISR executions and the CPU cycles elapsed between the interrupt and the execution of the ISR.

This example uses 2 bus comparators and 4 counters:

- BUSCOMP\_1 : PC = start address of cpuTimer1ISR
- BUSCOMP\_2 : PC = address of cpuTimer1IntCount variable access. This specifies the end address of the code of interest.
- COUNTER\_1 : Used to count the cpuTimer1ISR execution cycles. Configured in start-stop mode with start event as BUSCOMP\_1 and stop event as BUSCOMP\_2
- COUNTER\_2 : Used to count the number of times the system event TIMER1\_TINT1 has occurred. Configured in rising-edge count mode with counting input as system event TIMER1\_TINT1
- COUNTER\_3 : Used to count the number of times cputimer2ISR executes. Configured in rising-edge count mode with counting input as BUSCOMP\_1
- COUNTER\_4 : Used to count the latency from the system event TIMER1\_TINT1 to cpuTimer1ISR entry. Configured in start-stop mode with start event as TIMER1\_TINT1 and stop event as BUSCOMP\_1

We configure the COUNTER1 to generate an interrupt once it reaches a threshold value.

#### *External Connections*

- None

#### *Profiling Output*

- Current ISR cycle count (COUNTER\_1)
- Interrupt occurrence count (COUNTER\_2)
- ISR execution count (COUNTER\_3)
- ISR entry delay cycle count (maximum value of COUNTER\_4)
- x - To show that the ISR executed

#### **13.8.1.12 ERAD Profiling Interrupts**

FILE: erad\_ex4\_profile\_interrupt\_syscfg.c

This example shows how an ISR can be profiled by ERAD. The CPU timer generates interrupts periodically. We set up the counters to count the CPU cycles elapsed while executing the ISR, to count the number of interrupts, the number of ISR executions and the CPU cycles elapsed between the interrupt and the execution of the ISR.

This example uses 2 bus comparators and 4 counters:

- BUSCOMP\_1 : PC = start address of cpuTimer1ISR
- BUSCOMP\_2 : PC = address of cpuTimer1IntCount variable access. This specifies the end address of the code of interest.
- COUNTER\_1 : Used to count the cpuTimer1ISR execution cycles. Configured in start-stop mode with start event as BUSCOMP\_1 and stop event as BUSCOMP\_2
- COUNTER\_2 : Used to count the number of times the system event TIMER1\_TINT1 has occurred. Configured in rising-edge count mode with counting input as system event TIMER1\_TINT1
- COUNTER\_3 : Used to count the number of times cputimer2ISR executes. Configured in rising-edge count mode with counting input as BUSCOMP\_1
- COUNTER\_4 : Used to count the latency from the system event TIMER1\_TINT1 to cpuTimer1ISR entry. Configured in start-stop mode with start event as TIMER1\_TINT1 and stop event as BUSCOMP\_1

We configure the COUNTER1 to generate an interrupt once it reaches a threshold value.

#### *External Connections*

- None

#### *Profiling Output*

- Current ISR cycle count (COUNTER\_1)
- Interrupt occurrence count (COUNTER\_2)
- ISR execution count (COUNTER\_3)
- ISR entry delay cycle count (maximum value of COUNTER\_4)
- x - To show that the ISR executed

#### **13.8.1.13 ERAD MEMORY ACCESS RESTRICT**

FILE: erad\_ex5\_restricted\_write\_detect.c

This example uses BUSCOMP1 to monitor the Data Write Address Bus. It monitors the bus and generates an RTOS interrupt if a certain region of memory is accessed by the PC. The user may disable the Bus Comparator to access that region.

Use the COM port (Baud=9600) to try to write to the restricted area.

#### *Watch Variables*

- x : stores the number of times the region of memory is accessed

#### *External Connections*

- None

#### **13.8.1.14 ERAD INTERRUPT ORDER**

FILE: erad\_ex6\_interrupt\_order.c

This example uses a COUNTER to monitor the sequence of ISRs executed. An interrupt is generated if the ISRs executed are not in the expected order. The expected order is CPUTimer0, then CPUTimer1 and then CPUTimer2

The counter is configured in Start-Stop Mode to count the number of times CPUTimer interrupt occurs between the CPUTimer1 interrupt and CPUTimer2 ISRs. Ideally, this count should be zero if the interrupts are occurring in the expected order. we configure a threshold value of 1 to generate an RTOS interrupt. This indicates that the CPUTimer2 interrupt has come out of order.

For demonstration purposes, this example disables CPUTimer1 to simulate this error.

#### *Watch Variables*

- `cpuTimer0IntCount`: Number of executions of ISR0
- `cpuTimer1IntCount`: Number of executions of ISR1
- `cpuTimer2IntCount`: Number of executions of ISR2

#### *External Connections*

- None

#### **13.8.1.15 ERAD AND CLB**

FILE: `erad_ex7_reg_write_clb.c`

This example uses 4 BUS COMPARATORS of ERAD along with the CLB. One bus comparator monitors a write to x, another one monitors a write to y. The other two monitor a write of 0x1 and 0x0. By using the LUTs in the CLB1 tile, we can monitor a write of 0x1 to x or 0x0 to x. These are used to change the state of FSM2 in the CLB1 tile. If y is accessed before writing a 0x1 to x, an interrupt is generated and y is changed to 0x0 again. The LED2 indicates when access to y is allowed(it is off at this point) The LED1 indicates if an invalid access is attempted. A COUNTER in ERAD is used to count the number of access attempts to y.

#### *Watch Variables*

- y
- x
- a - counts the number of access attempts to y

#### *External Connections*

None

#### **13.8.1.16 ERAD PWM PROTECTION**

FILE: `erad_ex8_pwm_protection.c`

This example uses a BUS COMPARATOR and the CLB to detect the event when the delay between the interrupt and the ISR execution is longer than expected. The PWM output is also tripped in this case.

#### *Watch Variables*

- `adcAResults` stores the results of the conversions from the ADC

#### *External Connections*

- Monitor the PWM output (GPIO0)

## 13.9 ERAD Registers

This section describes the Embedded Real-Time Analysis and Diagnostic Registers.

### 13.9.1 ERAD Base Address Table

**Table 13-4. ERAD Base Address Table**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	CPU2	CPU2.DMA	Pipeline Protected
Instance	Structure								
EradGlobalRegs	<a href="#">ERAD_GLOBAL_REGS</a>	ERAD_GLOBAL_BASE	0x0005_E800	YES	-	-	YES	-	YES

### 13.9.2 ERAD\_GLOBAL\_REGS Registers

Table 13-5 lists the memory-mapped registers for the ERAD\_GLOBAL\_REGS registers. All register offset addresses not listed in Table 13-5 should be considered as reserved locations and the register contents should not be modified.

**Table 13-5. ERAD\_GLOBAL\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	GLBL_EVENT_STAT	Global Event Status Register		<a href="#">Go</a>
2h	GLBL_HALT_STAT	Global Halt Status Register		<a href="#">Go</a>
4h	GLBL_ENABLE	Global Enable Register	EALLOW	<a href="#">Go</a>
6h	GLBL_CTM_RESET	Global Counter Reset	EALLOW	<a href="#">Go</a>
8h	GLBL_NMI_CTL	Global Debug NMI control	EALLOW	<a href="#">Go</a>
Ah	GLBL_OWNER	Global Ownership	EALLOW	<a href="#">Go</a>
Ch	GLBL_EVENT_AND_MASK	Global Bus Comparator Event AND Mask Register	EALLOW	<a href="#">Go</a>
Eh	GLBL_EVENT_OR_MASK	Global Bus Comparator Event OR Mask Register	EALLOW	<a href="#">Go</a>
10h	GLBL_AND_EVENT_INT_MASK	Global AND Event Interrupt Mask Register	EALLOW	<a href="#">Go</a>
12h	GLBL_OR_EVENT_INT_MASK	Global OR Event Interrupt Mask Register	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 13-6 shows the codes that are used for access types in this section.

**Table 13-6. ERAD\_GLOBAL\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value

### 13.9.2.1 GLBL\_EVENT\_STAT Register (Offset = 0h) [Reset = 0000h]

GLBL\_EVENT\_STAT is shown in [Figure 13-8](#) and described in [Table 13-7](#).

Return to the [Summary Table](#).

This register contains one bit for each of the bus comparator modules and the counter modules that are present in a device. Each bit directly reflects the state of the EVENT\_FIRED bit of the corresponding module. This facilitates software to just read one register and find out if any of the debug modules had fired.

**Figure 13-8. GLBL\_EVENT\_STAT Register**

15	14	13	12	11	10	9	8
RESERVED				CTM4	CTM3	CTM2	CTM1
R-0h				R-0h	R-0h	R-0h	R-0h
7	6	5	4	3	2	1	0
HWBP8	HWBP7	HWBP6	HWBP5	HWBP4	HWBP3	HWBP2	HWBP1

**Table 13-7. GLBL\_EVENT\_STAT Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-12	RESERVED	R	0h	Reserved
11	CTM4	R	0h	This bit directly reflects the state of the EVENT_FIRED bit of the Counter unit 4. 0 No Event 1 Event Fired Reset type: ERAD_RESET
10	CTM3	R	0h	This bit directly reflects the state of the EVENT_FIRED bit of the Counter unit 3. 0 No Event 1 Event Fired Reset type: ERAD_RESET
9	CTM2	R	0h	This bit directly reflects the state of the EVENT_FIRED bit of the Counter unit 2. 0 No Event 1 Event Fired Reset type: ERAD_RESET
8	CTM1	R	0h	This bit directly reflects the state of the EVENT_FIRED bit of the Counter unit 1. 0 No Event 1 Event Fired Reset type: ERAD_RESET
7	HWBP8	R	0h	This bit directly reflects the state of the EVENT_FIRED bit of the Enhanced Bus Comparator (EBC) unit 8. 0 No Event 1 Event Fired Reset type: ERAD_RESET
6	HWBP7	R	0h	This bit directly reflects the state of the EVENT_FIRED bit of the Enhanced Bus Comparator (EBC) unit 7. 0 No Event 1 Event Fired Reset type: ERAD_RESET
5	HWBP6	R	0h	This bit directly reflects the state of the EVENT_FIRED bit of the Enhanced Bus Comparator (EBC) unit 6. 0 No Event 1 Event Fired Reset type: ERAD_RESET

**Table 13-7. GLBL\_EVENT\_STAT Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
4	HWBP5	R	0h	This bit directly reflects the state of the EVENT_FIRED bit of the Enhanced Bus Comparator (EBC) unit 5. 0 No Event 1 Event Fired Reset type: ERAD_RESET
3	HWBP4	R	0h	This bit directly reflects the state of the EVENT_FIRED bit of the Enhanced Bus Comparator (EBC) unit 4. 0 No Event 1 Event Fired Reset type: ERAD_RESET
2	HWBP3	R	0h	This bit directly reflects the state of the EVENT_FIRED bit of the Enhanced Bus Comparator (EBC) unit 3. 0 No Event 1 Event Fired Reset type: ERAD_RESET
1	HWBP2	R	0h	This bit directly reflects the state of the EVENT_FIRED bit of the Enhanced Bus Comparator (EBC) unit 2. 0 No Event 1 Event Fired Reset type: ERAD_RESET
0	HWBP1	R	0h	This bit directly reflects the state of the EVENT_FIRED bit of the Enhanced Bus Comparator (EBC) unit 1. 0 No Event 1 Event Fired Reset type: ERAD_RESET

### 13.9.2.2 GLBL\_HALT\_STAT Register (Offset = 2h) [Reset = 0000h]

GLBL\_HALT\_STAT is shown in [Figure 13-9](#) and described in [Table 13-8](#).

Return to the [Summary Table](#).

This register contains one bit for each of the bus comparator modules and the counter modules that are present in a device. Each bit directly reflects the state of the EVENT\_FIRED status bit. This facilitates software to just read one register and find out if any of the debug modules have fired.

**Figure 13-9. GLBL\_HALT\_STAT Register**

### 13.9.2.3 GLBL\_ENABLE Register (Offset = 4h) [Reset = 0000h]

GLBL\_ENABLE is shown in [Figure 13-10](#) and described in [Table 13-9](#).

Return to the [Summary Table](#).

This register contains one bit for each of the bus comparator modules and the counter modules that are present in a device. Each bit directly acts as a global enable for the corresponding module. This bit has to be set to 1 for the module to be functional.

**Figure 13-10. GLBL\_ENABLE Register**

### 13.9.2.4 GLBL\_CTM\_RESET Register (Offset = 6h) [Reset = 0000h]

GLBL\_CTM\_RESET is shown in [Figure 13-11](#) and described in [Table 13-10](#).

Return to the [Summary Table](#).

This register contains one bit for each of the counter modules that are present in a device. Each bit directly acts as a reset for the counters for the corresponding module. (It does not affect anything else except resetting the counter.

Example: If the counter was previously incrementing before reset, then on a reset event the counter gets reset and continues to increment again).

0	CTM1	R-0/W	0h	This bit directly resets the state the Counter unit 1. 0 No Effect 1 Reset Reset type: ERAD_RESET

### 13.9.2.5 GLBL\_NMI\_CTL Register (Offset = 8h) [Reset = 0000h]

GLBL\_NMI\_CTL is shown in [Figure 13-12](#) and described in [Table 13-11](#).

Return to the [Summary Table](#).

This register contains one bit for each of the bus comparator modules and the counter modules that can cause an NMI to the CPU. When the corresponding bit of a unit is set to 1, then if an event occurs from that module, then an NMI will be generated.

**Figure 13-12. GLBL\_NMI\_CTL Register**

### 13.9.3 ERAD\_HWBP\_REGS Registers

Table 13-17 lists the memory-mapped registers for the ERAD\_HWBP\_REGS registers. All register offset addresses not listed in Table 13-17 should be considered as reserved locations and the register contents should not be modified.

**Table 13-17. ERAD\_HWBP\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	HWBP_MASK	HWBP (EBC) Mask Register	EALLOW	<a href="#">Go</a>
2h	HWBP_REF	HWBP (EBC) Reference Register	EALLOW	<a href="#">Go</a>
4h	HWBP_CLEAR	HWBP (EBC) Clear Register	EALLOW	<a href="#">Go</a>
6h	HWBP_CNTL	HWBP (EBC) Control Register	EALLOW	<a href="#">Go</a>
7h	HWBP_STATUS	HWBP (EBC) Status Register	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 13-18 shows the codes that are used for access types in this section.

**Table 13-18. ERAD\_HWBP\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value

### 13.9.3.1 HWBP\_MASK Register (Offset = 0h) [Reset = 0000000h]

HWBP\_MASK is shown in [Figure 13-18](#) and described in [Table 13-19](#).

Return to the [Summary Table](#).

HWBP (EBC) Mask Register

**Figure 13-18. HWBP\_MASK Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MASK																															
R/W-0h																															

**Table 13-19. HWBP\_MASK Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	MASK	R/W	0h	This register contains address mask for comparison. The contents of this register are used along with the reference register to determine the address match. The equation used to determine a match is as follows. Match is true if, $(\text{address} \mid \text{mask}) == (\text{ref} \mid \text{mask})$ This register is writable by CPU only if application owns the unit and if EALLOW is set. Otherwise, the writes are ignored. The register is writable by the debugger only if the debugger owns this unit. Otherwise, the writes are ignored. Reset type: ERAD_RESET

### 13.9.3.2 HWBP\_REF Register (Offset = 2h) [Reset = 0000000h]

HWBP\_REF is shown in [Figure 13-19](#) and described in [Table 13-20](#).

Return to the [Summary Table](#).

HWBP (EBC) Reference Register

**Figure 13-19. HWBP\_REF Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REF																															
R/W-0h																															

**Table 13-20. HWBP\_REF Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	REF	R/W	0h	<p>This register contains the reference address for comparison. The contents of this register are used along with the mask register to determine the address match. The equation used to determine a match is as follows. Match is true if,</p> $(\text{address}   \text{mask}) == (\text{ref}   \text{mask})$ <p>This register is writable by CPU only if application owns the unit and if EALLOW is set. Otherwise, the writes are ignored. The register is writable by the debugger only if the debugger owns this unit. Otherwise, the writes are ignored.</p> <p>Reset type: ERAD_RESET</p>

### 13.9.3.3 HWBP\_CLEAR Register (Offset = 4h) [Reset = 0000h]

HWBP\_CLEAR is shown in [Figure 13-20](#) and described in [Table 13-21](#).

Return to the [Summary Table](#).

HWBP (EBC) Clear Register

**Figure 13-20. HWBP\_CLEAR Register**

15	14	13	12	11	10	9	8
RESERVED							
R-0h							
7	6	5	4	3	2	1	0
RESERVED							EVENT_CLR
R-0h							R-0/W-0h

**Table 13-21. HWBP\_CLEAR Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-1	RESERVED	R	0h	Reserved
0	EVENT_CLR	R-0/W	0h	Event Clear register: 0 No action. 1 A write with this bit set to 1 will clear the sticky EVENT_FIRED bit in the HWBP_STATUS register and bring the Breakpoint Module statemachine status back to IDLE. Reads of this bit position will always return a 0. Reset type: ERAD_RESET

### 13.9.3.4 HWBP\_CNTL Register (Offset = 6h) [Reset = 0000h]

HWBP\_CNTL is shown in [Figure 13-21](#) and described in [Table 13-22](#).

Return to the [Summary Table](#).

HWBP (EBC) Control Register

**Figure 13-21. HWBP\_CNTL Register**

15	14	13	12	11	10	9	8
RESERVED			RESERVED		RESERVED	COMP_MODE

R/W-0h	R/W-0h	R/W-0h	R/W-0h			R-0h	

**Table 13-22. HWBP\_CNTL Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-12	RESERVED	R	0h	Reserved
11	RESERVED	R/W	0h	Reserved
10	RESERVED	R	0h	Reserved
9-7	COMP_MODE	R/W	0h	Enhanced Bus Comparator (EBC) compare modes: 000 Regular masked compare HWBP_MSK will be ignored for the following modes: 100 Bus value GT HWBP_REF 101 Bus value GE HWBP_REF 110 Bus value LT HWBP_REF 111 Bus value LE HWBP_REF GT means Greater Than GE means Greater or Equal LT means Less Than LE means Lesser or Equal Reset type: ERAD_RESET
6	RTOSINT	R/W	0h	This bit decides whether the Enhanced Bus Comparator (EBC) unit will generate RTOSINTn interrupt when event matches occur. Note that the event outputs will always be generated regardless of the state of this bit. 0 The Enhanced Bus Comparator (EBC) unit will not cause any action towards the CPU. 1 The Enhanced Bus Comparator (EBC) unit will assert RTOSINTn for matching data accesses and trace tags for matching program fetches. Reset type: ERAD_RESET
5	STOP	R/W	0h	This bit decides whether the Enhanced Bus Comparator (EBC) unit will generate CPU halting signals when event matches occur. Note that the event outputs will always be generated regardless of the state of this bit. 0 The Enhanced Bus Comparator (EBC) unit will not cause any action towards halting the CPU. 1 The Enhanced Bus Comparator (EBC) unit will assert ANASTOP for matching data accesses and break tags for matching program fetches. These can cause the CPU to HALT Reset type: ERAD_RESET

**Table 13-22. HWBP\_CNTL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
4-1	BUS_SEL	R/W	0h	These bits are used to select which CPU buses will be used for comparison to generate the match events. For each bus selected, the corresponding strobes will automatically be selected to determine valid accesses. 0000 PAB for instruction fetches 0001 VPC 0010 DWAB for data write accesses 0011 DRAB for data read accesses 0100 DWDB for write data match 0101 DRDB for read data match 0110 VPC Instruction aligned match 0111 VPC R1 aligned match 1000 VPC R2 aligned match 1001 VPC W aligned match All other combinations are RESERVED. Reset type: ERAD_RESET
0	RESERVED	R	0h	Reserved

### 13.9.3.5 HWBP\_STATUS Register (Offset = 7h) [Reset = 0400h]

HWBP\_STATUS is shown in [Figure 13-22](#) and described in [Table 13-23](#).

Return to the [Summary Table](#).

HWBP (EBC) Status Register

**Figure 13-22. HWBP\_STATUS Register**

15	14	13	12	11	10	9	8
STATUS		MODULE_ID					
R-0h		R-4h					
7	6	5	4	3	2	1	0
RESERVED							EVENT_FIRED
R-0h							R-0h

**Table 13-23. HWBP\_STATUS Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-14	STATUS	R	0h	Bus comparator status: 00 Idle 10 Enabled 11 Completed Reset type: ERAD_RESET
13-8	MODULE_ID	R	4h	These bits are always a constant representing a unique identification for the Enhanced Bus Comparator (EBC) unit. Reset type: ERAD_RESET
7-1	RESERVED	R	0h	Reserved
0	EVENT_FIRED	R	0h	This is a sticky bit which gets set every time the HWBP (EBC) unit generates a match event. This will be used by software to figure out whether this HWBP module fired an event or not. This bit will get cleared by writing a '1' to bit 0 of the HWBP_CLEAR register. Reset type: ERAD_RESET

### 13.9.4 ERAD\_COUNTER\_REGS Registers

Table 13-24 lists the memory-mapped registers for the ERAD\_COUNTER\_REGS registers. All register offset addresses not listed in Table 13-24 should be considered as reserved locations and the register contents should not be modified.

**Table 13-24. ERAD\_COUNTER\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	CTM_CNTL	Counter Control Register	EALLOW	<a href="#">Go</a>
1h	CTM_STATUS	Counter Status Register	EALLOW	<a href="#">Go</a>
2h	CTM_REF	Counter Reference Register	EALLOW	<a href="#">Go</a>
4h	CTM_COUNT	Counter Current Value Register	EALLOW	<a href="#">Go</a>
6h	CTM_MAX_COUNT	Counter Max Count Value Register	EALLOW	<a href="#">Go</a>
8h	CTM_INPUT_SEL	Counter Input Select Register	EALLOW	<a href="#">Go</a>
9h	CTM_CLEAR	Counter Clear Register	EALLOW	<a href="#">Go</a>
Ah	CTM_INPUT_SEL_2	Counter Input Select Extension Register	EALLOW	<a href="#">Go</a>
Bh	CTM_INPUT_COND	Counter Input Conditioning Register	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 13-25 shows the codes that are used for access types in this section.

**Table 13-25. ERAD\_COUNTER\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value

### 13.9.4.1 CTM\_CNTL Register (Offset = 0h) [Reset = 0000h]

CTM\_CNTL is shown in [Figure 13-23](#) and described in [Table 13-26](#).

Return to the [Summary Table](#).

Counter Control Register

**Figure 13-23. CTM\_CNTL Register**

15	14	13	12	11	10	9	8
RESERVED				CNT_INP_SEL_EN	RST_EN	RESERVED	START_STOP_CUMULATIVE
R-0h				R/W-0h	R/W-0h	R-0h	R/W-0h
7	6	5	4	3	2	1	0
RTOSINT	STOP	RESERVED	RST_ON_MAT_CH	EVENT_MODE	START_STOP_MODE	RESERVED	
R/W-0h	R/W-0h	R-0h	R/W-0h	R/W-0h	R/W-0h	R-0h	

**Table 13-26. CTM\_CNTL Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-12	RESERVED	R	0h	Reserved
11	CNT_INP_SEL_EN	R/W	0h	0 = Disable using the input_select register for the count input. The counter will always count CPU cycles. 1 = Enable using the input_select register for the count input. The counter will count the event selected by the count input register. Reset type: ERAD_RESET
10	RST_EN	R/W	0h	This bit decides if the reset input is enabled or not. Setting this to 1 will cause the counter to reset to zero whenever the selected reset input goes active high. No event will be generated when the counter is reset. Setting this bit to 0 will cause the counter to ignore the reset inputs. Reset type: ERAD_RESET
9	RESERVED	R	0h	Reserved
8	START_STOP_CUMULATIVE	R/W	0h	This bit decides whether the counter counts to give the cumulative cycle count for 'n' number of successive start stop events or clears the counter on every stop event to record the MAX_COUNT across successive start stop sequences. 0 When in START_STOP mode counter gets cleared on every stop event and MAX_COUNT records the max value 1 When in START_STOP mode counter keeps counting between successive start stop events to generate a cumulative count w/o clearing the counter on any stop events. MAX_COUNT register is invalid when this bit is set. Reset type: ERAD_RESET
7	RTOSINT	R/W	0h	This bit decides whether the counter module will generate RTOSINTn interrupt when count value matches the reference. Note that the event outputs will always be generated regardless of the state of this bit. 0 The counter unit will not cause any action towards the CPU. 1 The counter unit will assert RTOSINTn when the count value matches the reference value. Reset type: ERAD_RESET

**Table 13-26. CTM\_CNTL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
6	STOP	R/W	0h	This bit decides whether the counter module will generate a watchpoint to the CPU when the count value matches the reference. Note that the event outputs will always be generated regardless of the state of this bit. 0 The counter unit will not generate a watchpoint. 1 The counter unit will assert ANASTOP when the count value matches the reference. Reset type: ERAD_RESET
5	RESERVED	R	0h	Reserved
4	RST_ON_MATCH	R/W	0h	This bit is used to decide whether the counter will reset to zero once it reaches the reference value. 0 Counter will stay at the reference value and the counter will go to COMPLETED state and further counting will be stopped. 1 The counter will reset to zero once it reaches the match value and will stay enabled. Reset type: ERAD_RESET
3	EVENT_MODE	R/W	0h	This bit is used to decide whether the counter will count the level of the event or the edge of the event. 0 Counter will increment the count as long as the count input is active high. 1 The counter will count only on the rising edge of the count input. Reset type: ERAD_RESET
2	START_STOP_MODE	R/W	0h	This bit is used to decide whether the counter will count in the START_STOP mode or not. 0 Normal count mode. The counter will not depend on the START and STOP events 1 This is the START-STOP mode of the counter. The counter will start counting only after the START input has been asserted. It will continue to count the selected event till the STOP event is seen. Reset type: ERAD_RESET
1-0	RESERVED	R	0h	Reserved

### 13.9.4.2 CTM\_STATUS Register (Offset = 1h) [Reset = 0010h]

CTM\_STATUS is shown in [Figure 13-24](#) and described in [Table 13-27](#).

Return to the [Summary Table](#).

Counter Status Register

**Figure 13-24. CTM\_STATUS Register**

15	14	13	12	11	10	9	8
STATUS				MODULE_ID			
R-0h				R-4h			
7	6	5	4	3	2	1	0
MODULE_ID						OVERFLOW	EVENT_FIRED
R-4h						R-0h	R-0h

**Table 13-27. CTM\_STATUS Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-12	STATUS	R	0h	Counter unit status, 00 Idle 10 Enabled 11 Completed Reset type: ERAD_RESET
11-2	MODULE_ID	R	4h	These bits are always a constant representing a unique identification for the trigger unit. Reset type: ERAD_RESET
1	OVERFLOW	R	0h	This is a sticky bit which gets set every time the counter overflows and wraps around after reaching 0xffffffff. This bit will get cleared by writing a '1' to bit 9 of the CTM_CNTL register. Reset type: ERAD_RESET
0	EVENT_FIRED	R	0h	This is a sticky bit which gets set every time the CTM unit generates a match event. This will be used by software to figure out whether this CTM module fired an event or not. This bit will get cleared by writing a '1' to bit 9 of the CTM_CNTL register. Reset type: ERAD_RESET

### 13.9.4.3 CTM\_REF Register (Offset = 2h) [Reset = 0000000h]

CTM\_REF is shown in [Figure 13-25](#) and described in [Table 13-28](#).

Return to the [Summary Table](#).

Counter Reference Register

**Figure 13-25. CTM\_REF Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REF																															
R/W-0h																															

**Table 13-28. CTM\_REF Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	REF	R/W	0h	This register contains the counter reference value for comparison. The counter will generate an event if the count value matches the reference register (considering both upper and lower half of the register). This register is writable by CPU only if application owns the unit and if EALLOW is set. Otherwise, the writes are ignored. The register is writable by the debugger only if the debugger owns this unit. Otherwise, the writes are ignored. Reference match is enabled only when a non zero value is programmed on one of the REF register. Reset type: ERAD_RESET

### 13.9.4.4 CTM\_COUNT Register (Offset = 4h) [Reset = 0000000h]

CTM\_COUNT is shown in [Figure 13-26](#) and described in [Table 13-29](#).

Return to the [Summary Table](#).

Counter Current Value Register

**Figure 13-26. CTM\_COUNT Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
COUNT																															
R/W-0h																															

**Table 13-29. CTM\_COUNT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	COUNT	R/W	0h	<p>This register contains the current count value.</p> <p>The counter will generate an event if the count value matches the reference register (considering both upper and lower half of the register).</p> <p>This register is writable by CPU only if application owns the unit and if EALLOW is set. Otherwise, the writes are ignored.</p> <p>The register is writable by the debugger only if the debugger owns this unit. Otherwise, the writes are ignored.</p> <p>Reset type: ERAD_RESET</p>

### 13.9.4.5 CTM\_MAX\_COUNT Register (Offset = 6h) [Reset = 0000000h]

CTM\_MAX\_COUNT is shown in [Figure 13-27](#) and described in [Table 13-30](#).

Return to the [Summary Table](#).

Counter Max Count Value Register

**Figure 13-27. CTM\_MAX\_COUNT Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MAX_COUNT																															
R/W-0h																															

**Table 13-30. CTM\_MAX\_COUNT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	MAX_COUNT	R/W	0h	This register contains the maximum recorded counter value. This is relevant only in the Start Stop mode of operation. This register is writable by CPU only if application owns the unit and if EALLOW is set. Otherwise, the writes are ignored. The register is writable by the debugger only if the debugger owns this unit. Otherwise, the writes are ignored. Reset type: ERAD_RESET

### 13.9.4.6 CTM\_INPUT\_SEL Register (Offset = 8h) [Reset = 0000h]

CTM\_INPUT\_SEL is shown in [Figure 13-28](#) and described in [Table 13-31](#).

Return to the [Summary Table](#).

Counter Input Select Register

**Figure 13-28. CTM\_INPUT\_SEL Register**

4-0	CRC_QUALIFIER	R/W	0h	0000 = No Qualifier, every valid event is qualified for CRC computation 00001 = CRC Compute Qualified by HWBP_EVENT1 00010 = CRC Compute Qualified by HWBP_EVENT2 00011 = CRC Compute Qualified by HWBP_EVENT3 00100 = CRC Compute Qualified by HWBP_EVENT4 00101 = CRC Compute Qualified by HWBP_EVENT5 00110 = CRC Compute Qualified by HWBP_EVENT6 00111 = CRC Compute Qualified by HWBP_EVENT7 01000 = CRC Compute Qualified by HWBP_EVENT8 01001 = CRC Compute Qualified by HWBP_EVENT_OR1 01010 = CRC Compute Qualified by HWBP_EVENT_OR2 01011 = CRC Compute Qualified by HWBP_EVENT_OR3 01100 = CRC Compute Qualified by HWBP_EVENT_OR4 01101 = CRC Compute Qualified by HWBP_EVENT_AND1 01110 = CRC Compute Qualified by HWBP_EVENT_AND2 01111 = CRC Compute Qualified by HWBP_EVENT_AND3 10000 = CRC Compute Qualified by HWBP_EVENT_AND4 Others = No Qualifier, every valid event is qualified for CRC computation Reset type: SYSRSn

### 13.9.7 PCTRACE\_REGS Registers

Table 13-43 lists the memory-mapped registers for the PCTRACE\_REGS registers. All register offset addresses not listed in Table 13-43 should be considered as reserved locations and the register contents should not be modified.

**Table 13-43. PCTRACE\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	PCTRACE_GLOBAL	PCTRACE_GLOBAL	EALLOW	<a href="#">Go</a>
1h	PCTRACE_BUFFER	PCTRACE_BUFFER	EALLOW	<a href="#">Go</a>
2h	PCTRACE_QUAL1	PCTRACE_QUAL1	EALLOW	<a href="#">Go</a>
4h	PCTRACE_QUAL2	PCTRACE_QUAL2	EALLOW	<a href="#">Go</a>
6h	PCTRACE_LOGPC_SOFTENABLE	PCTRACE_LOGPC_SOFTENABLE	EALLOW	<a href="#">Go</a>
8h	PCTRACE_LOGPC_SOFTDISABLE	PCTRACE_LOGPC_SOFTDISABLE	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 13-44 shows the codes that are used for access types in this section.

**Table 13-44. PCTRACE\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value

### 13.9.7.1 PCTRACE\_GLOBAL Register (Offset = 0h) [Reset = 0000h]

PCTRACE\_GLOBAL is shown in [Figure 13-36](#) and described in [Table 13-45](#).

Return to the [Summary Table](#).

Global Control Register

**Figure 13-36. PCTRACE\_GLOBAL Register**

15	14	13	12	11	10	9	8
RESERVED							INIT
R-0h							R-0/W-0h
7	6	5	4	3	2	1	0
RESERVED							EN
R-0h							R/W-0h

**Table 13-45. PCTRACE\_GLOBAL Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-9	RESERVED	R	0h	Reserved
8	INIT	R-0/W	0h	0 = No action 1 = Trace module is initialized for a fresh trace start with buffer pointer reset and overflow flags cleared along with SOFT_START_PC and SOFT_STOP_PC Reads of this bit position always returns zero Reset type: SYSRSn
7-1	RESERVED	R	0h	Reserved
0	EN	R/W	0h	0 = PC Trace Disabled 1 = PC Trace Enabled Reset type: SYSRSn

### 13.9.7.2 PCTRACE\_BUFFER Register (Offset = 1h) [Reset = 0000h]

PCTRACE\_BUFFER is shown in [Figure 13-37](#) and described in [Table 13-46](#).

Return to the [Summary Table](#).

Trace Buffer pointer register

**Figure 13-37. PCTRACE\_BUFFER Register**

15	14	13	12	11	10	9	8
BUFFER_FULL		RESERVED				PTR	
R-0h		R-0h				R-0h	
7	6	5	4	3	2	1	0
				PTR			
				R-0h			

**Table 13-46. PCTRACE\_BUFFER Register Field Descriptions**

Bit	Field	Type	Reset	Description
15	BUFFER_FULL	R	0h	0 = Trace Buffer Never became full/Overflowed after init 1 = Indicates Trace Buffer became full/Overflowed This bit also gets cleared when INIT is performed via PCTRACE_GLOBAL.INIT Reset type: SYSRSn
14-10	RESERVED	R	0h	Reserved
9-0	PTR	R	0h	Current Pointer to the Trace Buffer. If BUFFER_FULL=0 a. PTR=0 => there is no trace data in buffer ) b. PTR=2,4,6. indicates there is fresh trace data in buffer Buffer pointer gets incremented by 2 for every new trace storage, since two 32-bit values get stored for every discontinuity. For ex : 2 => Locations 0,1 of trace buffer have valid data (SRC,DST) 4 => Locations 0,1,2,3 have valid data (SRC,DST,SRC,DST) and so on If BUFFER_FULL = 1 a. PTR = 0 => buffer is just full b. PTR = non-zero value, then the buffer had overflowed and PTR points to how much it has overflowed. Discontinuities start from PTR (oldest discontinuity trace) to the end of buffer and then follows back to 0 and then until PTR-1(most recent discontinuity trace). This acts more like a circular buffer. These bits also gets cleared when INIT is performed via PCTRACE_GLOBAL.INIT Reset type: SYSRSn

### 13.9.7.3 PCTRACE\_QUAL1 Register (Offset = 2h) [Reset = 0000000h]

PCTRACE\_QUAL1 is shown in [Figure 13-38](#) and described in [Table 13-47](#).

Return to the [Summary Table](#).

Trace Qualifier register 1

21-0	PC_SOFTDISABLE	R	0h	These bits reflect the value of PC when trace module enable bit was last written with '0' (PCTRACE_GLOBAL.EN). These registers are primarily used by ccs drivers while displaying the trace to give a logical end to where tracing block was disabled. This register also gets cleared when INIT is performed via PCTRACE_GLOBAL.INIT Reset type: SYSRSn

### 13.9.8 PCTRACE\_BUFFER\_REGS Registers

Table 13-51 lists the memory-mapped registers for the PCTRACE\_BUFFER\_REGS registers. All register offset addresses not listed in Table 13-51 should be considered as reserved locations and the register contents should not be modified.

**Table 13-51. PCTRACE\_BUFFER\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h + formula	PCTRACE_BUFFER_BASE_y	PCTRACE_BUFFER_BASE		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 13-52 shows the codes that are used for access types in this section.

**Table 13-52. PCTRACE\_BUFFER\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 13.9.8.1 PCTRACE\_BUFFER\_BASE\_y Register (Offset = 0h + formula) [Reset = 0000000h]

PCTRACE\_BUFFER\_BASE\_y is shown in Figure 13-42 and described in Table 13-53.

Return to the [Summary Table](#).

Trace Buffer Base address

Offset = 0h + (y \* 2h); where y = 0h to 3FFh

Chapter 14

## General-Purpose Input/Output (GPIO)

---

The GPIO module controls the device's digital multiplexing, which uses shared pins to maximize application flexibility. The pins are named by the general-purpose I/O name (for example, GPIO0, GPIO25, GPIO58). These pins can be individually selected to operate as digital I/O (also called GPIO mode), or connected to one of several peripheral I/O signals. The input signals can be qualified to remove unwanted noise.

## 14.1 Introduction

Up to twelve independent peripheral signals are multiplexed on a single GPIO-enabled pin in addition to the CPU-controlled I/O capability. Each pin output can be controlled by either a peripheral or one of the CPU controllers.

There are up to 8 possible I/O ports:

- Port A consists of GPIO0-GPIO31
- Port B consists of GPIO32-GPIO63
- Port C consists of GPIO64-GPIO95
- Port D consists of GPIO96-GPIO127
- Port E consists of GPIO128-GPIO159
- Port F consists of GPIO160-GPIO191
- Port G consists of GPIO192-GPIO223
- Port H consists of GPIO224-GPIO255

---

### Note

Some GPIO and I/O ports can be unavailable on particular devices. See the *GPIO Registers* section for available GPIO and I/O ports.

---

Figure 14-1 shows the GPIO logic for a single pin.

---

### Note

The USB PHY pin muxing is not shown in Figure 14-1. For more details on USB pins, see Section 14.7.

---

There are two key features to note in Figure 14-1. The first is that the input and output paths are entirely separate, connecting only at the pin. The second is that peripheral muxing takes place far from the pin. As a result, for both CPUs and CLAs to read the physical state of the pin independent of CPU controlling and peripheral muxing is possible. Likewise, external interrupts can be generated from peripheral activity. All pin options such as input qualification and open-drain output are valid for all controllers and peripherals. However, the peripheral muxing, CPU muxing, and pin options can only be configured by CPU1. Table 14-1 provides details of GPIO registers accessible by different controllers.

A separate configuration is required for the USB signals. See Section 14.7 for details.

---

### Note

In open-drain mode, the GPIO does not drive the pin high, the GPIO can only pull the pin low. Instead, use an external pull-up to the bus voltage to drive the high level. When open-drain mode is enabled, the value in the GPyDAT register still controls the pin state. Writing a value of 1 turns off the driver to allow the external pull-up to control the pin; writing a value of 0 pulls the pin to ground. The open-drain configuration is automatically used by peripherals such as I2C and PMBus (no need to enable open-drain mode locally). This mode can also be set manually by writing to the GPyODR register and can be used when there are multiple nodes on the same net to avoid the pin contention that a push-pull driver can cause.

---

### 14.2 Configuration Overview

I/O pin configuration consists of several steps:

1. **Plan the device pin-out:** Make a list of all required peripherals for the application. Using the peripheral mux information in the device data sheet, choose which GPIOs to use for the peripheral signals. Decide which of the remaining GPIOs to use as inputs and outputs for each CPU and CLA.

Once the peripheral muxing has been chosen, implement the mux by writing the appropriate values to the GPyMUX1/2 and GPyGMUX1/2 registers. When changing the GPyGMUX value for a pin, always set the corresponding GPyMUX bits to zero first to avoid glitching in the muxes. By default, all pins are general-purpose I/Os, not peripheral signals.

2. **(Optional) Enable internal pullup resistors:** To enable or disable the pullup resistors, write to the appropriate bits in the GPIO pullup disable registers (GPyPUD). All pullups are disabled by default. Pullups can be used to keep input pins in a known state when there is no external signal driving them.
3. **Select input qualification:** If the pin is used as an input, specify the required input qualification, if any. The input qualification sampling period is selected in the GPyCTRL registers, while the type of qualification is selected in the GPyQSEL1 and GPyQSEL2 registers. By default, all qualification is synchronous with a sampling period equal to PLLSYSCLK. For an explanation of input qualification, see [Section 14.6](#).
4. **Select the direction of any general-purpose I/O pins:** For each pin configured as a GPIO, specify the direction of the pin as either input or output using the GPyDIR registers. By default, all GPIO pins are inputs. Before changing a pin to an output, load the output latch with the value to be driven by writing that value to the GPySET, GPyCLEAR, or GPyDAT registers. Once the latch is loaded, write to GPyDIR to change the pin direction. By default, all output latches are zero.

The GPyDAT\_R register can be used to read what value was written to the GPyDAT register.

5. **Select low-power mode wake-up sources:** GPIOs 0-63 can be used to wake the system up from low power modes. To select one or more GPIOs for wake-up, write to the appropriate bits in the GPIOLPMSEL0 and GPIOLPMSEL1 registers. These registers are part of the CPU system register space. For more information on low-power modes and GPIO wake-up, see the Low-Power Modes section in the *System Control and Interrupts* chapter.
6. **Select external interrupt sources:** Configuring external interrupts is a two-step process. First, the interrupts themselves must be enabled and the polarity must be configured using the XINTnCR registers. Second, the XINT1-5 GPIO pins must be set by selecting the sources for Input X-BAR signals 4, 5, 6, 13, and 14, respectively. For more information on the Input X-BAR architecture, see the *Crossbar (X-BAR)* chapter.

### 14.3 Digital Inputs on ADC Pins (AIOs)

Some GPIOs are multiplexed with analog pins and only have digital input functionality. These are also referred to as AIOs. Pins with only an AIO option on this port can only function in input mode. See the device data sheet for list of AIO signals. By default, these pins function as analog pins and the GPIOs are in a high-impedance state. The GPxAMSEL register is used to configure these pins for digital or analog operation.

#### Note

If digital signals with sharp edges (high  $dv/dt$ ) are connected to the AIOs, cross-talk can occur with adjacent analog signals. Therefore, limit the edge rate of signals connected to AIOs if adjacent channels are being used for analog functions.

### 14.4 Digital Inputs and Outputs on ADC Pins (AGPIOs)

Some GPIOs are multiplexed with analog pins and have digital input and output functionality. These are also referred to as AGPIOs. Unlike AIOs, AGPIOs have full input and output capability. By default, the AGPIOs are not connected and must be configured. [Table 14-2](#) shows how to configure the AGPIOs. To enable the analog functionality, set the register AGPIOTRlX from analog subsystem. To enable the digital functionality, set the register GPxAMSEL from the *General-Purpose Input/Output (GPIO)* chapter.

**Table 14-2. AGPIO Configuration**

AGPIOTRlX.GPIOy (Default = 0)	GPxAMSEL.GPIOy (Default = 1)	Pin Connected To:	
		ADC	GPIOy
0	0	-	Yes
<b>0</b>	<b>1</b>	- <sup>(1)</sup>	- <sup>(1)</sup>
1	0	-	Yes
1	1	Yes	-

(1) By default there are no signals connected to AGPIO pins. One of the other rows in the table must be chosen for pin functionality.

#### Note

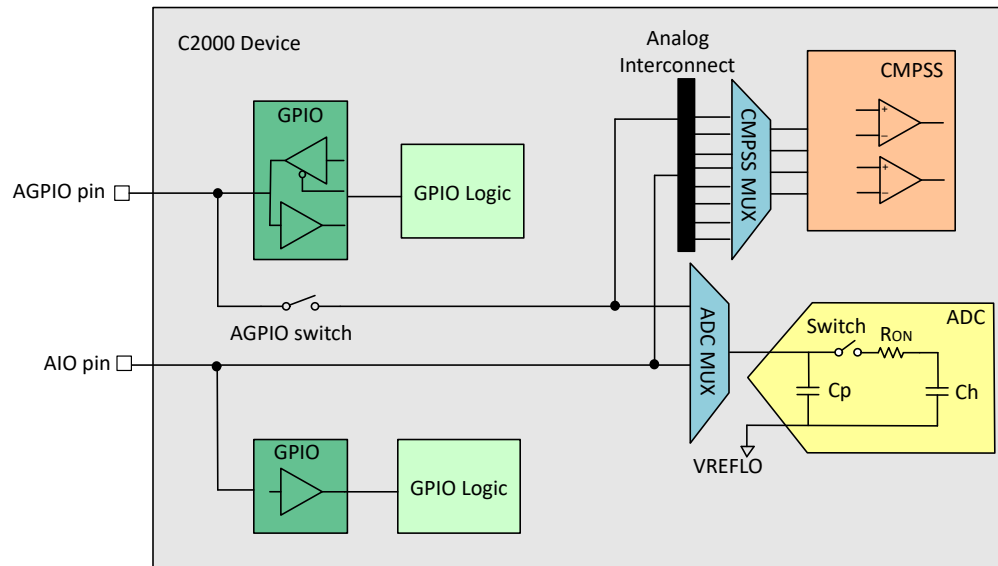

If digital signals with sharp edges (high  $dv/dt$ ) are connected to the AGPIOs, cross-talk can occur with adjacent analog signals. The user must therefore limit the edge rate of signals connected to AGPIOs, if adjacent channels are being used for analog functions.

The general schematic of analog subsystem with AGPIO implementation is illustrated in [Figure 14-2](#). The combinations of use cases for a specific analog input pin need special consideration are shown in [Table 14-3](#). The AGPIO analog pin path contains an extra series switch of 53Ω. This creates a low capacitance isolated node shared by the ADC and CMPSS Comparator as shown in [Figure 14-2](#). This node can be disturbed when the ADC samples the channel (depending on the prior voltage stored on the ADC sample and hold capacitor), and this disturbance can cause a false CMPSS event of up to 50ns. As shown in [Table 14-3](#), special considerations or workarounds need to be used for the combination of CMPSS Input, ADC Sampling, and AGPIO. To accommodate this potential disturbance the following workarounds can be implemented:

1. Use a different pin (that is AIO pin type) for analog channels which need both ADC and CMPSS together.
2. Use the CMPSS Digital Filter with a setting of 50ns or greater, which filters the temporary disturbance.
3. Precondition the sample and hold capacitor of the ADC so the disturbance does not cause a false trip. For example, perform a dummy read of a 3.3V connection from a different channel on the ADC immediately before the impacted channel is read so the disturbance is in the positive direction, away from the false trip. The opposite dummy read of a 0V signal can be used if the false trip is inverted in polarity.

**Table 14-3. The Combinations of Use Cases for a Specific Analog Input Pin**

Function Used on a Specific Analog Pin	Component Used				
CMPSS Comparator Input	Yes	-	Yes	-	Yes
ADC Sampling	Yes	Yes	-	Yes	Yes
AGPIO Analog Pin Type	Yes	Yes	Yes	-	-
AIO Analog Pin Type	-	-	-	Yes	Yes
<b>Result</b>	<b>Workaround needed</b>		<b>No special analysis or workaround needed</b>		

**Figure 14-2. Analog Subsystem Block Diagram with AGPIO Implementation**

## 14.5 Digital General-Purpose I/O Control

The values on the pins that are configured as GPIO can be changed by using the following registers.

- **GPyDAT Registers**

Each I/O port has one data register. Each bit in the data register corresponds to one GPIO pin. No matter how the pin is configured (GPIO or peripheral function), the corresponding bit in the data register reflects the current state of the pin after qualification. Writing to the GPyDAT register clears or sets the corresponding output latch and if the pin is enabled as a general-purpose output (GPIO output), the pin is also driven either low or high. If the pin is not configured as a GPIO output, then the value is latched but the pin is not driven. Only if the pin is later configured as a GPIO output is the latched value driven onto the pin.

When using the GPyDAT register to change the level of an output pin, be cautious to not accidentally change the level of another pin. For example, to change the output latch level of GPIOA0 by writing to the GPADAT register bit 0 using a read-modify-write instruction, a problem can occur if another I/O port A signal changes level between the read and the write stage of the instruction. Following is an analysis of why this happens:

The GPyDAT registers reflect the state of the pin, not the latch. This means the register reflects the actual pin value. However, there is a lag between when the register is written to when the new pin value is reflected back in the register. This can pose a problem when this register is used in subsequent program statements to alter the state of GPIO pins. An example is shown below where two program statements attempt to drive two different GPIO pins that are currently low to a high state.

If Read-Modify-Write operations are used on the GPyDAT registers, because of the delay between the output and the input of the first instruction (I1), the second instruction (I2) reads the old value and writes the value back.

```
GpioDataRegs.GPADAT.bit.GPIO1 = 1; //I1 performs read-modify-write of GPADAT
GpioDataRegs.GPADAT.bit.GPIO2 = 1; //I2 also a read-modify-write of GPADAT
//GPADAT gets the old value of GPIO1 due to the delay
```

The second instruction waits for the first to finish the write due to the write-followed-by-read protection on this peripheral frame. There is some lag, however, between the write of (I1) and the GPyDAT bit reflecting the new value (1) on the pin. During this lag, the second instruction reads the old value of GPIO1 (0) and writes the value back along with the new value of GPIO2 (1). Therefore, GPIO1 pin stays low.

One answer is to put some NOPs between instructions. A better answer is to use the GPySET/GPyCLEAR/GPyTOGGLE registers instead of the GPyDAT registers. These registers always read back a 0 and writes of 0 have no effect. Only bits that need to be changed can be specified without disturbing any other bits that are currently in the process of changing.

- **GPyDAT\_R Registers**

The GPyDAT\_R registers are read only registers that return the value written to the GPyDAT registers instead of pin status. Writes to these registers have no effect.

- **GPySET Registers**

The set registers are used to drive specified GPIO pins high without disturbing other pins. Each I/O port has one set register and each bit corresponds to one GPIO pin. The set registers always read back 0. If the corresponding pin is configured as an output, then writing a 1 to that bit in the set register sets the output latch high and the corresponding pin is driven high. If the pin is not configured as a GPIO output, then the value is latched but the pin is not driven. Only if the pin is later configured as a GPIO output is the latched value driven onto the pin. Writing a 0 to any bit in the set registers has no effect.

- **GPYCLEAR Registers**

The clear registers are used to drive specified GPIO pins low without disturbing other pins. Each I/O port has one clear register. The clear registers always read back 0. If the corresponding pin is configured as a general-purpose output, then writing a 1 to the corresponding bit in the clear register clears the output latch and the pin is driven low. If the pin is not configured as a GPIO output, then the value is latched but the pin is not driven. Only if the pin is later configured as a GPIO output is the latched value driven onto the pin. Writing a 0 to any bit in the clear registers has no effect.

- **GPYTOGGLE Registers**

The toggle registers are used to drive specified GPIO pins to the opposite level without disturbing other pins. Each I/O port has one toggle register. The toggle registers always read back 0. If the corresponding pin is configured as an output, then writing a 1 to that bit in the toggle register flips the output latch and pulls the corresponding pin in the opposite direction. That is, if the output pin is driven low, then writing a 1 to the corresponding bit in the toggle register pulls the pin high. Likewise, if the output pin is high, then writing a 1 to the corresponding bit in the toggle register pulls the pin low. If the pin is not configured as a GPIO output, then the value is latched but the pin is not driven. Only if the pin is later configured as a GPIO output is the latched value driven onto the pin. Writing a 0 to any bit in the toggle registers has no effect.

## 14.6 Input Qualification

The input qualification scheme has been designed to be very flexible. Select the type of input qualification for each GPIO pin by configuring the GPYQSEL1 and GPYQSEL2 registers. In the case of a GPIO input pin, the qualification can be specified as only synchronized to SYSCLKOUT or qualification by a sampling window. For pins that are configured as peripheral inputs, the input can also be asynchronous in addition to synchronized to SYSCLKOUT or qualified by a sampling window. The remainder of this section describes the options available.

### 14.6.1 No Synchronization (Asynchronous Input)

This mode is used for peripherals where input synchronization is not required or the peripheral performs the synchronization. Examples include communication ports McBSP, SCI, SPI, and I<sup>2</sup>C. In addition, the ePWM trip zone ( $\overline{TZn}$ ) signals can function independent of the presence of SYSCLKOUT.

---

#### Note

Using input synchronization when the peripheral performs the synchronization can cause unexpected results. The user must make sure that the GPIO pin is configured for asynchronous in this case.

---

### 14.6.2 Synchronization to SYSCLKOUT Only

This is the default qualification mode of all the pins at reset. In this mode, the input signal is only synchronized to the system clock (SYSCLKOUT). Because the incoming signal is asynchronous, a SYSCLKOUT period of delay is needed for the input to the device to be changed. No further qualification is performed on the signal.

### 14.6.3 Qualification Using a Sampling Window

In this mode, the signal is first synchronized to the system clock (SYSCLKOUT) and then qualified by a specified number of cycles before the input is allowed to change. Figure 14-3 and Figure 14-4 show how the input qualification is performed to eliminate unwanted noise. Two parameters are specified by the user for this type of qualification: 1) the sampling period, or how often the signal is sampled, and 2) the number of samples to be taken.

Figure 14-3. Input Qualification Using a Sampling Window

#### Time between samples (sampling period):

To qualify the signal, the input signal is sampled at a regular period. The sampling period is specified by the user and determines the time duration between samples, or how often the signal is sampled, relative to the CPU clock (SYSCLKOUT).

The sampling period is specified by the qualification period (QUALPRDn) bits in the GPxCTRL register. The sampling period is configurable in groups of 8 input signals. For example, GPIO0 to GPIO7 use GPxCTRL[QUALPRD0] setting and GPIO8 to GPIO15 use GPxCTRL[QUALPRD1]. Table 14-4 and Table 14-5 show the relationship between the sampling period or sampling frequency and the GPxCTRL[QUALPRDn] setting.

Table 14-4. Sampling Period

Sampling Period	
If GPxCTRL[QUALPRDn] = 0	$1 \times T_{\text{SYSCLKOUT}}$
If GPxCTRL[QUALPRDn] $\neq$ 0	$2 \times \text{GPxCTRL[QUALPRDn]} \times T_{\text{SYSCLKOUT}}$
Where $T_{\text{SYSCLKOUT}}$ is the period in time of SYSCLKOUT	

Table 14-5. Sampling Frequency

Sampling Frequency	
If GPxCTRL[QUALPRDn] = 0	$f_{\text{SYSCLKOUT}}$
If GPxCTRL[QUALPRDn] $\neq$ 0	$f_{\text{SYSCLKOUT}} \times 1 \div (2 \times \text{GPxCTRL[QUALPRDn]})$
Where $f_{\text{SYSCLKOUT}}$ is the frequency of SYSCLKOUT	

From these equations, the minimum and maximum time between samples can be calculated for a given SYSCLKOUT frequency:

**Example: Maximum Sampling Frequency:**

If GPxCTRL[QUALPRDn] = 0

then the sampling frequency is  $f_{\text{SYSCLKOUT}}$

If, for example,  $f_{\text{SYSCLKOUT}} = 60\text{MHz}$

then the signal is sampled at 60MHz or one sample every 16.67ns.

**Example: Minimum Sampling Frequency:**

If GPxCTRL[QUALPRDn] = 0xFF (255)

then the sampling frequency is  $f_{\text{SYSCLKOUT}} \times 1 \div (2 \times \text{GPxCTRL[QUALPRDn]})$

If, for example,  $f_{\text{SYSCLKOUT}} = 60\text{MHz}$

then the signal is sampled at  $60\text{MHz} \times 1 \div (2 \times 255)$  (117.647kHz) or one sample every 8.5 $\mu\text{s}$ .

**Number of samples:**

The number of times the signal is sampled is either three samples or six samples as specified in the qualification selection (GPYQSEL1, GPYQSEL2) registers. When three or six consecutive cycles are the same, then the input change is passed through to the device.

**Total Sampling-Window Width:**

The sampling window is the time during which the input signal is sampled as shown in [Figure 14-4](#). By using the equation for the sampling period, along with the number of samples to be taken, the total width of the window can be determined.

For the input qualifier to detect a change in the input, the level of the signal must be stable for the duration of the sampling-window width or longer.

The number of sampling periods within the window is always one less than the number of samples taken. For a three-sample window, the sampling-window width is two sampling-periods wide where the sampling period is defined in [Table 14-4](#). Likewise, for a six-sample window, the sampling-window width is five sampling-periods wide. [Table 14-6](#) and [Table 14-7](#) show the calculations used to determine the total sampling-window width based on GPxCTRL[QUALPRDn] and the number of samples taken.

**Table 14-6. Case 1: Three-Sample Sampling-Window Width**

Total Sampling-Window Width	
If GPxCTRL[QUALPRDn] = 0	$2 \times T_{\text{SYSCLKOUT}}$
If GPxCTRL[QUALPRDn] $\neq$ 0	$2 \times 2 \times \text{GPxCTRL[QUALPRDn]} \times T_{\text{SYSCLKOUT}}$
Where $T_{\text{SYSCLKOUT}}$ is the period in time of SYSCLKOUT	

**Table 14-7. Case 2: Six-Sample Sampling-Window Width**

Total Sampling-Window Width	
If GPxCTRL[QUALPRDn] = 0	$5 \times T_{\text{SYSCLKOUT}}$
If GPxCTRL[QUALPRDn] $\neq$ 0	$5 \times 2 \times \text{GPxCTRL[QUALPRDn]} \times T_{\text{SYSCLKOUT}}$
Where $T_{\text{SYSCLKOUT}}$ is the period in time of SYSCLKOUT	

**Note**

The external signal change is asynchronous with respect to both the sampling period and SYSCLKOUT. Due to the asynchronous nature of the external signal, the input must be held stable for a time greater than the sampling-window width to make sure the logic detects a change in the signal. The extra time required can be up to an additional sampling period +  $T_{SYSCLKOUT}$ .

The required duration for an input signal to be stable for the qualification logic to detect a change is described in the data sheet.

**Example Qualification Window:**

For the example shown in Figure 14-4, the input qualification has been configured as follows:

- $GPxQSEL1/2 = 1,0$ . This indicates a six-sample qualification.
- $GPxCTRL[QUALPRDn] = 1$ . The sampling period is  $t_w(SP) = 2 \times GPxCTRL[QUALPRDn] \times T_{SYSCLKOUT} = 2 \times T_{SYSCLKOUT}$ .

This configuration results in the following:

- The width of the sampling window is:

$$t_w(IQSW) = 5 \times t_w(SP) = 5 \times 2 \times GPxCTRL[QUALPRDn] \times T_{SYSCLKOUT} = 5 \times 2 \times T_{SYSCLKOUT}$$

- If, for example,  $T_{SYSCLKOUT} = 16.67ns$ , then the duration of the sampling window is:

$$\text{Sampling period, } t_w(SP) = 2 \times T_{SYSCLKOUT} = 2 \times 16.67ns = 33.3ns$$

$$\text{Sampling window, } t_w(IQSW) = 5 \times t_w(SP) = 5 \times 33.3ns = 166.7ns$$

- To account for the asynchronous nature of the input relative to the sampling period and SYSCLKOUT, up to a single additional sampling period and SYSCLK period is required to detect a change in the input signal. For this example:

$$t_w(IQSW) + t_w(SP) + T_{SYSCLKOUT} = 166.7ns + 33.3ns + 16.67ns = 216.7ns$$

- In Figure 14-4, the glitch (A) is shorter than the qualification window and is ignored by the input qualifier.

A. This glitch will be ignored by the input qualifier. The QUALPRD bit field specifies the qualification sampling period. It can vary from 00 to 0xFF. If QUALPRD = 00, then the sampling period is 1 SYSCLKOUT cycle. For any other value "n", the qualification sampling period in 2n SYSCLKOUT cycles (i.e., at every 2n SYSCLKOUT cycles, the GPIO pin will be sampled).  
 B. The qualification period selected via the GPxCTRL register applies to groups of 8 GPIO pins.  
 C. The qualification block can take either three or six samples. The QUAL\_SEL Register selects which sample mode is used.  
 D. In the example shown, for the qualifier to detect the change, the input should be stable for 10 SYSCLKOUT cycles or greater. In other words, the inputs should be stable for (5 x QUALPRD x 2) SYSCLKOUT cycles. That would ensure 5 sampling periods for detection to occur. Since external signals are driven asynchronously, an 13-SYSCLKOUT-wide pulse ensures reliable recognition.

**Figure 14-4. Input Qualifier Clock Cycles**

## 14.7 USB Signals

The USB module on this device has an internal physical layer transceiver (PHY). The I/O signals are not normal digital signals, and as a result, the signals do not connect to the pins through the normal GPIO mux path. Instead, a special analog mux is used. To connect the USB signals to the device pins, set the GPyAMSEL bits appropriately. See the data sheet for which GPIOs are associated with the USB signals USBDM and USBDP. See [Section 14.11](#) for correct GPyAMSEL register bits to set. Do not enable pullups or any other special pin option when using the USB signals.

## 14.8 GPIO and Peripheral Muxing

### 14.8.1 GPIO Muxing

Up to twelve different peripheral functions are multiplexed to each pin along with a general-purpose input/output (GPIO) function. This allows you to choose the peripheral mix and pinout that works best for your particular application. Refer to [Table 14-8](#) for muxing combinations and definitions.

### 14.8.2 Peripheral Muxing

For example, multiplexing for the GPIO6 pin is controlled by writing to GPAGMUX[13:12] and GPAMUX[13:12]. By writing to these bits, GPIO6 is configured as either a general-purpose digital I/O or one of several different peripheral functions. An example of GPyGMUX and GPyMUX selection and options for a single GPIO are shown in [Table 14-9](#).

#### Note

The following table is for example only. Refer to the device data sheet to check the availability of GPIO6 on this device. If GPIO6 is available, the functions mentioned in the table may not match the actual functions available. See [Section 14.8.1](#) for correct list of GPIOs and corresponding mux options for this device.

**Table 14-9. GPIO and Peripheral Muxing**

GPAGMUX1[13:12]	GPAMUX1[13:12]	Pin Functionality
00	00	GPIO6
00	01	Peripheral 1
00	10	Peripheral 2
00	11	Peripheral 3
01	00	GPIO6
01	01	Peripheral 4
01	10	Peripheral 5
01	11	
10	00	GPIO6
10	01	
10	10	Peripheral 6
10	11	Peripheral 7
11	00	GPIO6
11	01	Peripheral 8
11	10	Peripheral 9
11	11	Peripheral 10

The devices have different multiplexing schemes. If a peripheral is not available on a particular device, that mux selection is reserved on that device and must not be used.

#### CAUTION

If a reserved GPIO mux configuration that is not mapped to either a peripheral or GPIO mode is selected, the state of the pin is undefined and the pin is driven. Unimplemented configurations are for future expansion and must not be selected. In the device mux table (see the data sheet), these options are indicated as Reserved or left blank.

Some peripherals can be assigned to more than one pin by way of the mux registers. For example, OUTPUTXBAR1 can be assigned to GPIOs p, q, or r (where p, q, and r are example GPIO numbers), depending on individual system requirements. An example of this is shown in [Table 14-10](#).

#### Note

The following table is for example only. Bit ranges cannot correspond to OUTPUTXBAR1 on this device. See [Section 14.8.1](#) for correct list of GPIOs and corresponding mux options for this device.

If none or more than one of the GPIO pins is configured as peripheral input pins, then that GPIO is set to a hard-wired default value.

**Table 14-10. Peripheral Muxing (Multiple Pins Assigned)**

GMUX Configuration	MUX Configuration	
Choice 1: GPIOp	GPyGMUX1[5:4] = 01	GPyMUX1[5:4] = 01
or Choice 2: GPIOq	GPyGMUX2[17:16] = 00	GPyMUX2[17:16] = 01
or Choice 3: GPIOr	GPyGMUX1[7:6] = 01	GPyMUX1[7:6] = 01

## 14.9 Internal Pullup Configuration Requirements

On reset, GPIOs are in input mode and have the internal pullups disabled. An un-driven input can float to a mid-rail voltage and cause wasted shoot-through current on the input buffer. The user must always put each GPIO in one of these configurations:

- Input mode and driven on the board by another component to a level above  $V_{ih}$  or below  $V_{il}$
- Input mode with GPIO internal pullup enabled
- Output mode

On devices with lesser pin count packages, pull-ups on unbonded GPIOs are by default enabled to prevent floating inputs. The user must take care to avoid disabling these pullups in the application code.

On devices with larger pin count packages, the pullups for any internally unbonded GPIO must be enabled to prevent floating inputs. TI has provided functions in controlSUITE/C2000Ware that users can call to enable the pullup on any unbonded GPIO for the package in use. This function, `GPIO_EnabledUnbondedIOPullups()`, resides in the `(Device)_Sysctrl.c` file and is called by default from `InitSysCtrl()`. The user must take care to avoid disabling these pullups in the application code.

## 14.10 Software

### 14.10.1 GPIO Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location: `C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/gpio`

Cloud access to these examples is available at the following link: [dev.ti.com C2000Ware Examples](#).

#### 14.10.1.1 Device GPIO Toggle - SINGLE\_CORE

FILE: `gpio_ex1_toggle.c`

Configures the device GPIO through the sysconfig file. The GPIO pin is toggled in the infinite loop.

#### 14.10.1.2 XINT/XBAR example - SINGLE\_CORE

FILE: `gpio_ex2_interrupt.c`

This example demonstrates the XINT feature in SysConfig by using it in conjunction with the input and output XBARs. The GPIO is toggled and connected to the input XBAR, while simultaneously triggering an external interrupt. The interrupt increments a counter which can be observed in the watch window. In addition to triggering an interrupt, the input signal is routed from the input XBAR to the output XBAR so that the output can be observed via oscilloscope or logic analyzer on a separate pin.

*Watch Variables*

- *counter* - Number of interrupts generated

### 14.10.2 LED Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location: `C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/led`

Cloud access to these examples is available at the following link: [dev.ti.com C2000Ware Examples](#).

#### 14.10.2.1 LED Blinky Example - MULTI\_CORE

FILE: `led_ex1_blinky_cpu1_cpu3_multi_c29x1.c`

This example demonstrates how to blink a LED using CPU1 and blink another LED using CPU3 (`led_ex1_blinky_cpu1_cpu3_multi_c29x3.c`). It is recommended to run the C29x1 core first, followed by the C29x3 core. Once the C29x1 configures and releases CPU3 out of reset, the program stops, connect to the CPU3 target now and load the C29x3 .out.

*External Connections*

- None.

*Watch Variables*

- None.

**14.10.2.2 LED Blinky Example (CPU1,CPU3) - MULTI\_CORE**

FILE: led\_ex1\_blinky\_cpu1\_cpu3\_multi\_c29x3.c

This example demonstrates how to blink an LED using CPU3. Once the C29x1 configures and releases CPU3 out of reset, the program stops, connect to the CPU3 target now and load this C29x3 .out.

*External Connections*

- None.

*Watch Variables*

- None.

**14.10.2.3 LED Blinky example - SINGLE\_CORE**

FILE: led\_ex1\_blinky.c

This example demonstrates how to blink an LED. The device GPIO is configured through the sysconfig file. The GPIO pin is toggled in an infinite loop.

**14.10.2.4 LED Blinky Example (CPU1|CPU2|CPU3) - MULTI\_CORE**

FILE: led\_ex2\_blinky\_cpu1\_cpu2\_cpu3\_multi\_c29x1.c

This example demonstrates how to configure LEDs using CPU1 and blink two LEDs using CPU2 (led\_ex2\_blinky\_cpu1\_cpu2\_cpu3\_multi\_c29x2.c) and CPU3 (led\_ex2\_blinky\_cpu1\_cpu2\_cpu3\_multi\_c29x3.c). It is recommended to run the C29x1 core first, followed by C29x2 and C29x3 cores. Once the C29x1 configures and releases CPU2/CPU3 out of reset, the program stops, connect to the targets now and load the .out

*External Connections*

- None.

*Watch Variables*

- None.

**14.10.2.5 LED Blinky Example (CPU2) - MULTI\_CORE**

FILE: led\_ex2\_blinky\_cpu1\_cpu2\_cpu3\_multi\_c29x2.c

This example demonstrates how to blink an LED using CPU2.

*External Connections*

- None.

*Watch Variables*

- None.

**14.10.2.6 LED Blinky Example (CPU3) - MULTI\_CORE**

FILE: led\_ex2\_blinky\_cpu1\_cpu2\_cpu3\_multi\_c29x3.c

This example demonstrates how to blink an LED using CPU3.

*External Connections*

- None.

*Watch Variables*

- None.

## 14.11 GPIO Registers

This section describes the General-Purpose Input/Output Registers.

### 14.11.1 GPIO Base Address Table

**Table 14-11. GPIO Base Address Table**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	CPU2	CPU2.DMA	Pipeline Protected
Instance	Structure								
GpioCtrlRegs	<a href="#">GPIO_CTRL_REGS</a>	GPIOCTRL_BASE	0x0000_7C00	YES	-	-	-	-	YES
GpioDataRegs	<a href="#">GPIO_DATA_REGS</a>	GPIODATA_BASE	0x0000_7F00	YES	-	YES	YES	-	YES
GpioDataReadRegs	<a href="#">GPIO_DATA_READ_REGS</a>	GPIODATAREAD_BASE	0x0000_7F80	YES	-	YES	YES	-	YES

### 14.11.2 GPIO\_CTRL\_REGS Registers

Table 14-12 lists the memory-mapped registers for the GPIO\_CTRL\_REGS registers. All register offset addresses not listed in Table 14-12 should be considered as reserved locations and the register contents should not be modified.

**Table 14-12. GPIO\_CTRL\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	GPACTRL	GPIO A Qualification Sampling Period Control (GPIO0 to 31)	EALLOW	<a href="#">Go</a>
2h	GPAQSEL1	GPIO A Qualifier Select 1 Register (GPIO0 to 15)	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. [Table 14-13](#) shows the codes that are used for access types in this section.

**Table 14-13. GPIO\_CTRL\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
WOnce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 14.11.2.1 GPMCTRL Register (Offset = 0h) [Reset = 0000000h]

GPMCTRL is shown in [Figure 14-5](#) and described in [Table 14-14](#).

Return to the [Summary Table](#).

GPIO A Qualification Sampling Period Control (GPIO0 to 31)

**Figure 14-5. GPMCTRL Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

#### 14.11.2.4 GPAMUX1 Register (Offset = 6h) [Reset = 0000000h]

GPAMUX1 is shown in [Figure 14-8](#) and described in [Table 14-17](#).

Return to the [Summary Table](#).

GPIO A Mux 1 Register (GPIO0 to 15)  
Defines pin-muxing selection for GPIO.

Notes:

The respective GPyGMUXn.GPIOz must be configured prior to this register to avoid intermediate peripheral selects being mapped to the GPIO. Refer to GPIO chapter for more details.

**Figure 14-8. GPAMUX1 Register**

### 14.11.2.5 GPAMUX2 Register (Offset = 8h) [Reset = 0000000h]

GPAMUX2 is shown in [Figure 14-9](#) and described in [Table 14-18](#).

Return to the [Summary Table](#).

GPIO A Mux 2 Register (GPIO16 to 31)

Defines pin-muxing selection for GPIO.

Notes:

The respective GPyGMUXn.GPIOz must be configured prior to this register to avoid intermediate peripheral selects being mapped to the GPIO. Refer to GPIO chapter for more details.

**Figure 14-9. GPAMUX2 Register**

### 14.11.2.6 GPADIR Register (Offset = Ah) [Reset = 0000000h]

GPADIR is shown in [Figure 14-10](#) and described in [Table 14-19](#).

Return to the [Summary Table](#).

GPIO A Direction Register (GPIO0 to 31)

Controls direction of GPIO pins when the specified pin is configured in GPIO mode.

0: Configures pin as input.

1: Configures pin as output.

Reading the register returns the current value of the register setting.

**Figure 14-10. GPADIR Register**

### 14.11.2.7 GPAPUD Register (Offset = Ch) [Reset = FFFFFFFFh]

GPAPUD is shown in [Figure 14-11](#) and described in [Table 14-20](#).

Return to the [Summary Table](#).

GPIO A Pull Up Disable Register (GPIO0 to 31)

Disables the Pull-Up on GPIO.

0: Enables the Pull-Up.

1: Disables the Pull-Up.

Reading the register returns the current value of the register setting.

Note:

[1] The Pull-Ups on the GPIO pins are disabled asynchronously when IORSn signal is low.

### 14.11.2.8 GPAINV Register (Offset = 10h) [Reset = 0000000h]

GPAINV is shown in [Figure 14-12](#) and described in [Table 14-21](#).

Return to the [Summary Table](#).

GPIO A Input Polarity Invert Registers (GPIO0 to 31)

Selects between non-inverted and inverted GPIO input to the device.

0: selects non-inverted GPIO input

1: selects inverted GPIO input

Reading the register returns the current value of the register setting.

**Figure 14-12. GPAINV Register**

### 14.11.2.9 GPAODR Register (Offset = 12h) [Reset = 0000000h]

GPAODR is shown in [Figure 14-13](#) and described in [Table 14-22](#).

Return to the [Summary Table](#).

GPIO A Open Drain Output Register (GPIO0 to GPIO31)

Selects between normal and open-drain output for the GPIO pin.

0: Normal Output

1: Open Drain Output

Reading the register returns the current value of the register setting.

Note:

[1] In the Open Drain output mode, if the buffer is configured for output mode, a 0 value to be driven out comes out on the on the PAD while a 1 value to be driven out tri-states the buffer.

### 14.11.2.10 GPAGMUX1 Register (Offset = 20h) [Reset = 0000000h]

GPAGMUX1 is shown in [Figure 14-14](#) and described in [Table 14-23](#).

Return to the [Summary Table](#).

GPIO A Peripheral Group Mux (GPIO0 to 15)

Defines pin-muxing selection for GPIO.

Notes:

[1]For complete pin-mux selection on GPIOx, GPAMUXy.GPIOx configuration is also required.

**Figure 14-14. GPAGMUX1 Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

**Table 14-23. GPAGMUX1 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-30	GPIO15	R/W	0h	Defines pin-muxing selection for GPIO Reset type: SYSRSn
29-28	GPIO14	R/W	0h	Defines pin-muxing selection for GPIO Reset type: SYSRSn
27-26	GPIO13	R/W	0h	Defines pin-muxing selection for GPIO Reset type: SYSRSn
25-24	GPIO12	R/W	0h	Defines pin-muxing selection for GPIO Reset type: SYSRSn
23-22	GPIO11	R/W	0h	Defines pin-muxing selection for GPIO Reset type: SYSRSn
21-20	GPIO10	R/W	0h	Defines pin-muxing selection for GPIO Reset type: SYSRSn
19-18	GPIO9	R/W	0h	Defines pin-muxing selection for GPIO Reset type: SYSRSn
17-16	GPIO8	R/W	0h	Defines pin-muxing selection for GPIO Reset type: SYSRSn
15-14	GPIO7	R/W	0h	Defines pin-muxing selection for GPIO Reset type: SYSRSn
13-12	GPIO6	R/W	0h	Defines pin-muxing selection for GPIO Reset type: SYSRSn
11-10	GPIO5	R/W	0h	Defines pin-muxing selection for GPIO Reset type: SYSRSn
9-8	GPIO4	R/W	0h	Defines pin-muxing selection for GPIO Reset type: SYSRSn
7-6	GPIO3	R/W	0h	Defines pin-muxing selection for GPIO Reset type: SYSRSn
5-4	GPIO2	R/W	0h	Defines pin-muxing selection for GPIO Reset type: SYSRSn
3-2	GPIO1	R/W	0h	Defines pin-muxing selection for GPIO Reset type: SYSRSn

**Table 14-23. GPAGMUX1 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
1-0	GPIO0	R/W	0h	Defines pin-muxing selection for GPIO Reset type: SYSRSn

### 14.11.2.11 GPAGMUX2 Register (Offset = 22h) [Reset = 0000000h]

GPAGMUX2 is shown in [Figure 14-15](#) and described in [Table 14-24](#).

Return to the [Summary Table](#).

GPIO A Peripheral Group Mux (GPIO16 to 31)

Defines pin-muxing selection for GPIO.

Notes:

[1]For complete pin-mux selection on GPIOx, GPAMUXy.GPIOx configuration is also required.

**Figure 14-15. GPAGMUX2 Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W-0h				R/W-0h				R/W-0h				R/W-0h			

**Table 14-28. GPACSEL4 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-28	GPIO31	R/W	0h	Selects which controller's GPIODAT/SET/CLEAR/TOGGLE registers control this GPIO pin Reset type: SYSRSn
27-24	GPIO30	R/W	0h	Selects which controller's GPIODAT/SET/CLEAR/TOGGLE registers control this GPIO pin Reset type: SYSRSn
23-20	GPIO29	R/W	0h	Selects which controller's GPIODAT/SET/CLEAR/TOGGLE registers control this GPIO pin Reset type: SYSRSn
19-16	GPIO28	R/W	0h	Selects which controller's GPIODAT/SET/CLEAR/TOGGLE registers control this GPIO pin Reset type: SYSRSn
15-12	GPIO27	R/W	0h	Selects which controller's GPIODAT/SET/CLEAR/TOGGLE registers control this GPIO pin Reset type: SYSRSn
11-8	GPIO26	R/W	0h	Selects which controller's GPIODAT/SET/CLEAR/TOGGLE registers control this GPIO pin Reset type: SYSRSn
7-4	GPIO25	R/W	0h	Selects which controller's GPIODAT/SET/CLEAR/TOGGLE registers control this GPIO pin Reset type: SYSRSn
3-0	GPIO24	R/W	0h	Selects which controller's GPIODAT/SET/CLEAR/TOGGLE registers control this GPIO pin Reset type: SYSRSn

### 14.11.2.16 GPALOCK Register (Offset = 3Ch) [Reset = 0000000h]

GPALOCK is shown in [Figure 14-20](#) and described in [Table 14-29](#).

Return to the [Summary Table](#).

GPIO A Lock Configuration Register (GPIO0 to 31)

GPIO Configuration Lock for GPIO.

0: Bits in GPyMUX1, GPyMUX2, GPyDIR, GPyINV, GPyODR, GPyAMSEL, GPyGMUX1, GPyGMUX2 and GPyCSELx register which control the same pin can be changed

1: Locks changes to the bits in GPyMUX1, GPyMUX2, GPyDIR, GPyINV, GPyODR, GPyAMSEL, GPyGMUX1, GPyGMUX2 and GPyCSELx registers which control the same pin

**Figure 14-20. GPALOCK Register**

### 14.11.2.17 GPACR Register (Offset = 3Eh) [Reset = 0000000h]

GPACR is shown in [Figure 14-21](#) and described in [Table 14-30](#).

Return to the [Summary Table](#).

GPIO A Lock Commit Register (GPIO0 to 31)

GPIO Configuration Lock Commit for GPIO:

1: Locks changes to the bit in GPyLOCK register which controls the same pin

0: Bit in the GPyLOCK register which controls the same pin can be changed

**Figure 14-21. GPACR Register**

#### 14.11.2.21 GPBMUX1 Register (Offset = 46h) [Reset = 0000CC0h]

GPBMUX1 is shown in [Figure 14-25](#) and described in [Table 14-34](#).

Return to the [Summary Table](#).

GPIO B Mux 1 Register (GPIO32 to 47)

Defines pin-muxing selection for GPIO.

Notes:

The respective GPyGMUXn.GPIOz must be configured prior to this register to avoid intermediate peripheral selects being mapped to the GPIO. Refer to GPIO chapter for more details.

**Figure 14-25. GPBMUX1 Register**

### 14.11.2.23 GPBDIR Register (Offset = 4Ah) [Reset = 0000000h]

GPBDIR is shown in [Figure 14-27](#) and described in [Table 14-36](#).

Return to the [Summary Table](#).

GPIO B Direction Register (GPIO32 to 63)

Controls direction of GPIO pins when the specified pin is configured in GPIO mode.

0: Configures pin as input.

1: Configures pin as output.

Reading the register returns the current value of the register setting.

#### 14.11.2.24 GPBPUD Register (Offset = 4Ch) [Reset = FFFFFFFFh]

GPBPUD is shown in [Figure 14-28](#) and described in [Table 14-37](#).

Return to the [Summary Table](#).

GPIO B Pull Up Disable Register (GPIO32 to 63)

Disables the Pull-Up on GPIO.

0: Enables the Pull-Up.

1: Disables the Pull-Up.

Reading the register returns the current value of the register setting.

Note:

[1] The Pull-Ups on the GPIO pins are disabled asynchronously when IORSn signal is low.

#### 14.11.2.25 GPBINV Register (Offset = 50h) [Reset = 0000000h]

GPBINV is shown in [Figure 14-29](#) and described in [Table 14-38](#).

Return to the [Summary Table](#).

GPIO B Input Polarity Invert Registers (GPIO32 to 63)

Selects between non-inverted and inverted GPIO input to the device.

0: selects non-inverted GPIO input

1: selects inverted GPIO input

Reading the register returns the current value of the register setting.

**Figure 14-29. GPBINV Register**

### 14.11.2.26 GPBODR Register (Offset = 52h) [Reset = 0000000h]

GPBODR is shown in [Figure 14-30](#) and described in [Table 14-39](#).

Return to the [Summary Table](#).

GPIO B Open Drain Output Register (GPIO32 to GPIO63)

Selects between normal and open-drain output for the GPIO pin.

0: Normal Output

1: Open Drain Output

Reading the register returns the current value of the register setting.

Note:

[1] In the Open Drain output mode, if the buffer is configured for output mode, a 0 value to be driven out comes out on the on the PAD while a 1 value to be driven out tri-states the buffer.

### 14.11.2.27 GPBAMSEL Register (Offset = 54h) [Reset = 0000000h]

GPBAMSEL is shown in [Figure 14-31](#) and described in [Table 14-40](#).

Return to the [Summary Table](#).

GPIO B Analog Mode Select register (GPIO32 to GPIO63)

Selects between digital and analog functionality for GPIO pins.

0: The analog function of the pin is disabled and the pin is capable of digital functions as specified by the other GPIO configuration registers

1: The analog function of the pin is enabled and the pin is capable of analog functions

Reading the register returns the current value of the register setting.

Note:

[1] This register and bits are only valid for GPIO signals that share analog function through a unified I/O pad. For all the IOs, t

Bit	Field	Type	Reset	Description
1-0	GPIO32	R/W	0h	Defines pin-muxing selection for GPIO Reset type: SYSRSn

### 14.11.2.29 GPBGMUX2 Register (Offset = 62h) [Reset = 0000000h]

GPBGMUX2 is shown in [Figure 14-33](#) and described in [Table 14-42](#).

Return to the [Summary Table](#).

GPIO B Peripheral Group Mux (GPIO48 to 63)

Defines pin-muxing selection for GPIO.

Notes:

[1]For complete pin-mux selection on GPIOx, GPAMUXy.GPIOx configuration is also required.

**Figure 14-33. GPBGMUX2 Register**

3-0	GPIO56	R/W	0h	Selects which controller's GPIODAT/SET/CLEAR/TOGGLE registers control this GPIO pin Reset type: SYSRSn

#### 14.11.2.34 GPBLOCK Register (Offset = 7Ch) [Reset = 0000000h]

GPBLOCK is shown in [Figure 14-38](#) and described in [Table 14-47](#).

Return to the [Summary Table](#).

GPIO B Lock Configuration Register (GPIO32 to 63)

GPIO Configuration Lock for GPIO.

0: Bits in GPyMUX1, GPyMUX2, GPyDIR, GPyINV, GPyODR, GPyAMSEL, GPyGMUX1, GPyGMUX2 and GPyCSELx register which control the same pin can be changed

1: Locks changes to the bits in GPyMUX1, GPyMUX2, GPyDIR, GPyINV, GPyODR, GPyAMSEL, GPyGMUX1, GPyGMUX2 and GPyCSELx registers which control the same pin

**Figure 14-38. GPBLOCK Register**

1-0	GPIO80	R/W	0h	Select input qualification type for GPIO80: 0,0,Sync 0,1,Qualification (3 samples) 1,0,Qualification (6 samples) 1,1,Async (no Sync or Qualification) Reset type: SYSRSn

### 14.11.2.39 GPCMUX1 Register (Offset = 86h) [Reset = 0000000h]

GPCMUX1 is shown in [Figure 14-43](#) and described in [Table 14-52](#).

Return to the [Summary Table](#).

GPIO C Mux 1 Register (GPIO64 to 79)

Defines pin-muxing selection for GPIO.

Notes:

The respective GPyGMUXn.GPIOz must be configured prior to this register to avoid intermediate peripheral selects being mapped to the GPIO. Refer to GPIO chapter for more details.

**Figure 14-43. GPCMUX1 Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Field	Type	Reset	Description
1-0	GPIO80	R/W	0h	Defines pin-muxing selection for GPIO Reset type: SYSRSn

#### 14.11.2.41 GPCDIR Register (Offset = 8Ah) [Reset = 0000000h]

GPCDIR is shown in [Figure 14-45](#) and described in [Table 14-54](#).

Return to the [Summary Table](#).

GPIO C Direction Register (GPIO64 to 95)

Controls direction of GPIO pins when the specified pin is configured in GPIO mode.

0: Configures pin as input.

1: Configures pin as output.

Reading the register returns the current value of the register setting.

**Figure 14-45. GPCDIR Register**

#### 14.11.2.42 GPCPUD Register (Offset = 8Ch) [Reset = FFFFFFFFh]

GPCPUD is shown in [Figure 14-46](#) and described in [Table 14-55](#).

Return to the [Summary Table](#).

GPIO C Pull Up Disable Register (GPIO64 to 95)

Disables the Pull-Up on GPIO.

0: Enables the Pull-Up.

1: Disables the Pull-Up.

Reading the register returns the current value of the register setting.

Note:

[1] The Pull-Ups on the GPIO pins are disabled asynchronously when IORSn signal is low.

#### 14.11.2.43 GPCINV Register (Offset = 90h) [Reset = 0000000h]

GPCINV is shown in [Figure 14-47](#) and described in [Table 14-56](#).

Return to the [Summary Table](#).

GPIO C Input Polarity Invert Registers (GPIO64 to 95)

Selects between non-inverted and inverted GPIO input to the device.

0: selects non-inverted GPIO input

1: selects inverted GPIO input

Reading the register returns the current value of the register setting.

**Figure 14-47. GPCINV Register**

#### 14.11.2.44 GPCODR Register (Offset = 92h) [Reset = 0000000h]

GPCODR is shown in [Figure 14-48](#) and described in [Table 14-57](#).

Return to the [Summary Table](#).

GPIO C Open Drain Output Register (GPIO64 to GPIO95)

Selects between normal and open-drain output for the GPIO pin.

0: Normal Output

1: Open Drain Output

Reading the register returns the current value of the register setting.

Note:

[1] In the Open Drain output mode, if the buffer is configured for output mode, a 0 value to be driven out comes out on the on the PAD while a 1 value to be driven out tri-states the buffer.

### 14.11.2.51 GPCLOCK Register (Offset = BCh) [Reset = 0000000h]

GPCLOCK is shown in [Figure 14-55](#) and described in [Table 14-64](#).

Return to the [Summary Table](#).

GPIO C Lock Configuration Register (GPIO64 to 95)

GPIO Configuration Lock for GPIO.

0: Bits in GPyMUX1, GPyMUX2, GPyDIR, GPyINV, GPyODR, GPyAMSEL, GPyGMUX1, GPyGMUX2 and GPyCSELx register which control the same pin can be changed

1: Locks changes to the bits in GPyMUX1, GPyMUX2, GPyDIR, GPyINV, GPyODR, GPyAMSEL, GPyGMUX1, GPyGMUX2 and GPyCSELx registers which control the same pin

**Figure 14-55. GPCLOCK Register**

### 14.11.2.56 GPDMUX1 Register (Offset = C6h) [Reset = 0000000h]

GPDMUX1 is shown in [Figure 14-60](#) and described in [Table 14-69](#).

Return to the [Summary Table](#).

GPIO D Mux 1 Register (GPIO96 to 111)

Defines pin-muxing selection for GPIO.

Notes:

The respective GPyGMUXn.GPIOz must be configured prior to this register to avoid intermediate peripheral selects being mapped to the GPIO. Refer to GPIO chapter for more details.

### 14.11.2.57 GPDMUX2 Register (Offset = C8h) [Reset = 0000000h]

GPDMUX2 is shown in [Figure 14-61](#) and described in [Table 14-70](#).

Return to the [Summary Table](#).

GPIO D Mux 2 Register (GPIO112 to 127)

Defines pin-muxing selection for GPIO.

Notes:

The respective GPyGMUXn.GPIOz must be configured prior to this register to avoid intermediate peripheral selects being mapped to the GPIO. Refer to GPIO chapter for more details.

### 14.11.2.58 GPDDIR Register (Offset = CAh) [Reset = 0000000h]

GPDDIR is shown in [Figure 14-62](#) and described in [Table 14-71](#).

Return to the [Summary Table](#).

GPIO D Direction Register (GPIO96 to 127)

Controls direction of GPIO pins when the specified pin is configured in GPIO mode.

0: Configures pin as input.

1: Configures pin as output.

Reading the register returns the current value of the register setting.

### 14.11.2.59 GPDPU Register (Offset = CCh) [Reset = FFFFFFFFh]

GPDPU is shown in [Figure 14-63](#) and described in [Table 14-72](#).

Return to the [Summary Table](#).

GPIO D Pull Up Disable Register (GPIO96 to 127)

Disables the Pull-Up on GPIO.

0: Enables the Pull-Up.

1: Disables the Pull-Up.

Reading the register returns the current value of the register setting.

Note:

[1] The Pull-Ups on the GPIO pins are disabled asynchronously when IORSn signal is low.

### 14.11.2.60 GPDINV Register (Offset = D0h) [Reset = 0000000h]

GPDINV is shown in [Figure 14-64](#) and described in [Table 14-73](#).

Return to the [Summary Table](#).

GPIO D Input Polarity Invert Registers (GPIO96 to 127)

Selects between non-inverted and inverted GPIO input to the device.

0: selects non-inverted GPIO input

1: selects inverted GPIO input

Reading the register returns the current value of the register setting.

### 14.11.2.61 GPDODR Register (Offset = D2h) [Reset = 0000000h]

GPDODR is shown in [Figure 14-65](#) and described in [Table 14-74](#).

Return to the [Summary Table](#).

GPIO D Open Drain Output Register (GPIO96 to GPIO127)

Selects between normal and open-drain output for the GPIO pin.

0: Normal Output

1: Open Drain Output

Reading the register returns the current value of the register setting.

Note:

[1] In the Open Drain output mode, if the buffer is configured for output mode, a 0 value to be driven out comes out on the on the PAD while a 1 value to be driven out tri-states the buffer.

### 14.11.2.75 GPEDIR Register (Offset = 10Ah) [Reset = 0000000h]

GPEDIR is shown in [Figure 14-79](#) and described in [Table 14-88](#).

Return to the [Summary Table](#).

GPIO E Direction Register (GPIO128 to 159)

Controls direction of GPIO pins when the specified pin is configured in GPIO mode.

0: Configures pin as input.

1: Configures pin as output.

Reading the register returns the current value of the register setting.

### 14.11.2.76 GPEPUD Register (Offset = 10Ch) [Reset = FFFFFFFFh]

GPEPUD is shown in [Figure 14-80](#) and described in [Table 14-89](#).

Return to the [Summary Table](#).

GPIO E Pull Up Disable Register (GPIO128 to 159)

Disables the Pull-Up on GPIO.

0: Enables the Pull-Up.

1: Disables the Pull-Up.

Reading the register returns the current value of the register setting.

Note:

[1] The Pull-Ups on the GPIO pins are disabled asynchronously when IORSn signal is low.

### 14.11.2.77 GPEINV Register (Offset = 110h) [Reset = 0000000h]

GPEINV is shown in [Figure 14-81](#) and described in [Table 14-90](#).

Return to the [Summary Table](#).

GPIO E Input Polarity Invert Registers (GPIO128 to 159)

Selects between non-inverted and inverted GPIO input to the device.

0: selects non-inverted GPIO input

1: selects inverted GPIO input

Reading the register returns the current value of the register setting.

### 14.11.2.78 GPEODR Register (Offset = 112h) [Reset = 0000000h]

GPEODR is shown in [Figure 14-82](#) and described in [Table 14-91](#).

Return to the [Summary Table](#).

GPIO E Open Drain Output Register (GPIO128 to GPIO159)

Selects between normal and open-drain output for the GPIO pin.

0: Normal Output

1: Open Drain Output

Reading the register returns the current value of the register setting.

Note:

[1] In the Open Drain output mode, if the buffer is configured for output mode, a 0 value to be driven out comes out on the on the PAD while a 1 value to be driven out tri-states the buffer.

9-8	GPIO164	R/W	0h	Select input qualification type for GPIO164: 0,0,Sync 0,1,Qualification (3 samples) 1,0,Qualification (6 samples) 1,1,Async (no Sync or Qualification) Reset type: SYSRSn
7-6	GPIO163	R/W	0h	Select input qualification type for GPIO163: 0,0,Sync 0,1,Qualification (3 samples) 1,0,Qualification (6 samples) 1,1,Async (no Sync or Qualification) Reset type: SYSRSn
5-4	GPIO162	R/W	0h	Select input qualification type for GPIO162: 0,0,Sync 0,1,Qualification (3 samples) 1,0,Qualification (6 samples) 1,1,Async (no Sync or Qualification) Reset type: SYSRSn
3-2	GPIO161	R/W	0h	Select input qualification type for GPIO161: 0,0,Sync 0,1,Qualification (3 samples) 1,0,Qualification (6 samples) 1,1,Async (no Sync or Qualification) Reset type: SYSRSn
1-0	GPIO160	R/W	0h	Select input qualification type for GPIO160: 0,0,Sync 0,1,Qualification (3 samples) 1,0,Qualification (6 samples) 1,1,Async (no Sync or Qualification) Reset type: SYSRSn

### 14.11.2.89 GPFQSEL2 Register (Offset = 144h) [Reset = 0000000h]

GPFQSEL2 is shown in [Figure 14-93](#) and described in [Table 14-102](#).

Return to the [Summary Table](#).

GPIO F Qualifier Select 2 Register (GPIO176 to 191)

Input qualification type:

0,0 Sync

0,1 Qualification (3 samples)

1,0 Qualification (6 samples)

1,1 Async (no Sync or Qualification)

### 14.11.2.90 GPFMUX1 Register (Offset = 146h) [Reset = 0000000h]

GPFMUX1 is shown in [Figure 14-94](#) and described in [Table 14-103](#).

Return to the [Summary Table](#).

GPIO F Mux 1 Register (GPIO160 to 175)

Defines pin-muxing selection for GPIO.

Notes:

The respective GPyGMUXn.GPIOz must be configured prior to this register to avoid intermediate peripheral selects being mapped to the GPIO. Refer to GPIO chapter for more details.

### 14.11.2.92 GPFDIR Register (Offset = 14Ah) [Reset = 0000000h]

GPFDIR is shown in [Figure 14-96](#) and described in [Table 14-105](#).

Return to the [Summary Table](#).

GPIO F Direction Register (GPIO160 to 191)

Controls direction of GPIO pins when the specified pin is configured in GPIO mode.

0: Configures pin as input.

1: Configures pin as output.

Reading the register returns the current value of the register setting.

### 14.11.2.93 GPFPU Register (Offset = 14Ch) [Reset = FFFFFFFFh]

GPFPU is shown in [Figure 14-97](#) and described in [Table 14-106](#).

Return to the [Summary Table](#).

GPIO F Pull Up Disable Register (GPIO160 to 191)

Disables the Pull-Up on GPIO.

0: Enables the Pull-Up.

1: Disables the Pull-Up.

Reading the register returns the current value of the register setting.

Note:

[1] The Pull-Ups on the GPIO pins are disabled asynchronously when IORSn signal is low.

#### 14.11.2.94 GPFINV Register (Offset = 150h) [Reset = 0000000h]

GPFINV is shown in [Figure 14-98](#) and described in [Table 14-107](#).

Return to the [Summary Table](#).

GPIO F Input Polarity Invert Registers (GPIO160 to 191)

Selects between non-inverted and inverted GPIO input to the device.

0: selects non-inverted GPIO input

1: selects inverted GPIO input

Reading the register returns the current value of the register setting.

### 14.11.2.95 GPFODR Register (Offset = 152h) [Reset = 0000000h]

GPFODR is shown in [Figure 14-99](#) and described in [Table 14-108](#).

Return to the [Summary Table](#).

GPIO F Open Drain Output Register (GPIO160 to GPIO191)

Selects between normal and open-drain output for the GPIO pin.

0: Normal Output

1: Open Drain Output

Reading the register returns the current value of the register setting.

Note:

[1] In the Open Drain output mode, if the buffer is configured for output mode, a 0 value to be driven out comes out on the on the PAD while a 1 value to be driven out tri-states the buffer.

### 14.11.2.96 GPFGMUX1 Register (Offset = 160h) [Reset = 0000000h]

GPFGMUX1 is shown in [Figure 14-100](#) and described in [Table 14-109](#).

Return to the [Summary Table](#).

GPIO F Peripheral Group Mux (GPIO160 to 175)

Defines pin-muxing selection for GPIO.

Notes:

[1]For complete pin-mux selection on GPIOx, GPAMUXy.GPIOx configuration is also required.

### 14.11.2.107 GPGMUX1 Register (Offset = 186h) [Reset = 0000000h]

GPGMUX1 is shown in [Figure 14-111](#) and described in [Table 14-120](#).

Return to the [Summary Table](#).

GPIO G Mux 1 Register (GPIO192 to 207)

Defines pin-muxing selection for GPIO.

Notes:

The respective GPyGMUXn.GPIOz must be configured prior to this register to avoid intermediate peripheral selects being mapped to the GPIO. Refer to GPIO chapter for more details.

### 14.11.2.109 GPGDIR Register (Offset = 18Ah) [Reset = 0000000h]

GPGDIR is shown in [Figure 14-113](#) and described in [Table 14-122](#).

Return to the [Summary Table](#).

GPIO G Direction Register (GPIO192 to 223)

Controls direction of GPIO pins when the specified pin is configured in GPIO mode.

0: Configures pin as input.

1: Configures pin as output.

Reading the register returns the current value of the register setting.

**Figure 14-113. GPGDIR Register**

### 14.11.2.110 GPGPUD Register (Offset = 18Ch) [Reset = FFFFFFFFh]

GPGPUD is shown in [Figure 14-114](#) and described in [Table 14-123](#).

Return to the [Summary Table](#).

GPIO G Pull Up Disable Register (GPIO192 to 223)

Disables the Pull-Up on GPIO.

0: Enables the Pull-Up.

1: Disables the Pull-Up.

Reading the register returns the current value of the register setting.

Note:

[1] The Pull-Ups on the GPIO pins are disabled asynchronously when IORSn signal is low.

### 14.11.2.111 GPGINV Register (Offset = 190h) [Reset = 0000000h]

GPGINV is shown in [Figure 14-115](#) and described in [Table 14-124](#).

Return to the [Summary Table](#).

GPIO G Input Polarity Invert Registers (GPIO192 to 223)

Selects between non-inverted and inverted GPIO input to the device.

0: selects non-inverted GPIO input

1: selects inverted GPIO input

Reading the register returns the current value of the register setting.

**Figure 14-115. GPGINV Register**

### 14.11.2.112 GPGODR Register (Offset = 192h) [Reset = 0000000h]

GPGODR is shown in [Figure 14-116](#) and described in [Table 14-125](#).

Return to the [Summary Table](#).

GPIO G Open Drain Output Register (GPIO92 to 223)

Selects between normal and open-drain output for the GPIO pin.

0: Normal Output

1: Open Drain Output

Reading the register returns the current value of the register setting.

Note:

[1] In the Open Drain output mode, if the buffer is configured for output mode, a 0 value to be driven out comes out on the on the PAD while a 1 value to be driven out tri-states the buffer.

### 14.11.2.113 GPGAMSEL Register (Offset = 194h) [Reset = 0000000h]

GPGAMSEL is shown in [Figure 14-117](#) and described in [Table 14-126](#).

Return to the [Summary Table](#).

GPIO G Analog Mode Select register (GPIO192 to 223)

Selects between digital and analog functionality for GPIO pins.

0: The analog function of the pin is disabled and the pin is capable of digital functions as specified by the other GPIO configuration registers

1: The analog function of the pin is enabled and the pin is capable of analog functions

Reading the register returns the current value of the register setting.

Note:

[1] This register and bits are only valid for GPIO signals that share analog function through a unified I/O pad. For all the IOs, t

### 14.11.2.125 GPHMUX1 Register (Offset = 1C6h) [Reset = 0000000h]

GPHMUX1 is shown in [Figure 14-129](#) and described in [Table 14-138](#).

Return to the [Summary Table](#).

GPIO H Mux 1 Register (GPIO224 to 239)

Defines pin-muxing selection for GPIO.

Notes:

The respective GPyGMUXn.GPIOz must be configured prior to this register to avoid intermediate peripheral selects being mapped to the GPIO. Refer to GPIO chapter for more details.

### 14.11.2.126 GPHMUX2 Register (Offset = 1C8h) [Reset = 0000000h]

GPHMUX2 is shown in [Figure 14-130](#) and described in [Table 14-139](#).

Return to the [Summary Table](#).

GPIO H Mux 2 Register (GPIO240 to 255)

Defines pin-muxing selection for GPIO.

Notes:

The respective GPyGMUXn.GPIOz must be configured prior to this register to avoid intermediate peripheral selects being mapped to the GPIO. Refer to GPIO chapter for more details.

### 14.11.2.127 GPHDIR Register (Offset = 1CAh) [Reset = 0000000h]

GPHDIR is shown in [Figure 14-131](#) and described in [Table 14-140](#).

Return to the [Summary Table](#).

GPIO H Direction Register (GPIO224 to 255)

Controls direction of GPIO pins when the specified pin is configured in GPIO mode.

0: Configures pin as input.

1: Configures pin as output.

Reading the register returns the current value of the register setting.

### 14.11.2.128 GPHPUD Register (Offset = 1CCh) [Reset = FFFFFFFh]

GPHPUD is shown in [Figure 14-132](#) and described in [Table 14-141](#).

Return to the [Summary Table](#).

GPIO H Pull Up Disable Register (GPIO224 to 255)

Disables the Pull-Up on GPIO.

0: Enables the Pull-Up.

1: Disables the Pull-Up.

Reading the register returns the current value of the register setting.

Note:

[1] The Pull-Ups on the GPIO pins are disabled asynchronously when IORSn signal is low.

### 14.11.2.129 GPHINV Register (Offset = 1D0h) [Reset = 0000000h]

GPHINV is shown in [Figure 14-133](#) and described in [Table 14-142](#).

Return to the [Summary Table](#).

GPIO H Input Polarity Invert Registers (GPIO224 to 255)

Selects between non-inverted and inverted GPIO input to the device.

0: selects non-inverted GPIO input

1: selects inverted GPIO input

Reading the register returns the current value of the register setting.

### 14.11.2.130 GPHODR Register (Offset = 1D2h) [Reset = 0000000h]

GPHODR is shown in [Figure 14-134](#) and described in [Table 14-143](#).

Return to the [Summary Table](#).

GPIO H Open Drain Output Register (GPIO224 to GPIO255)

Selects between normal and open-drain output for the GPIO pin.

0: Normal Output

1: Open Drain Output

Reading the register returns the current value of the register setting.

Note:

[1] In the Open Drain output mode, if the buffer is configured for output mode, a 0 value to be driven out comes out on the on the PAD while a 1 value to be driven out tri-states the buffer.

### 14.11.2.131 GPHAMSEL Register (Offset = 1D4h) [Reset = FFFFFFFh]

GPHAMSEL is shown in [Figure 14-135](#) and described in [Table 14-144](#).

Return to the [Summary Table](#).

GPIO H Analog Mode Select register (GPIO224 to GPIO255)

Selects between digital and analog functionality for GPIO pins.

0: The analog function of the pin is disabled and the pin is capable of digital functions as specified by the other GPIO configuration registers

1: The analog function of the pin is enabled and the pin is capable of analog functions

Reading the register returns the current value of the register setting.

Note:

[1] This register and bits are only valid for GPIO signals that share analog function through a unified I/O pad. For all the IOs, t

### 14.11.3 GPIO\_DATA\_REGS Registers

Table 14-153 lists the memory-mapped registers for the GPIO\_DATA\_REGS registers. All register offset addresses not listed in Table 14-153 should be considered as reserved locations and the register contents should not be modified.

**Table 14-153. GPIO\_DATA\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	GPADAT	GPIO A Data Register (GPIO0 to 31)		<a href="#">Go</a>
2h	GPASET	GPIO A Data Set Register (GPIO0 to 31)		<a href="#">Go</a>
4h	GPACLEAR	GPIO A Data Clear Register (GPIO0 to 31)		<a href="#">Go</a>
6h	GPATOGGLE	GPIO A Data Toggle Register (GPIO0 to 31)		<a href="#">Go</a>
8h	GPBDAT	GPIO B Data Register (GPIO32 to 63)		<a href="#">Go</a>
Ah	GPBSET	GPIO B Data Set Register (GPIO32 to 63)		<a href="#">Go</a>
Ch	GPBCLEAR	GPIO B Data Clear Register (GPIO32 to 63)		<a href="#">Go</a>
Eh	GPBTOGGLE	GPIO B Data Toggle Register (GPIO32 to 63)		<a href="#">Go</a>
10h	GPCDAT	GPIO C Data Register (GPIO64 to 95)		<a href="#">Go</a>
12h	GPCSET	GPIO C Data Set Register (GPIO64 to 95)		<a href="#">Go</a>
14h	GPCCLEAR	GPIO C Data Clear Register (GPIO64 to 95)		<a href="#">Go</a>
16h	GPCTOGGLE	GPIO C Data Toggle Register (GPIO64 to 95)		<a href="#">Go</a>
18h	GPDDAT	GPIO D Data Register (GPIO96 to 127)		<a href="#">Go</a>
1Ah	GPDSET	GPIO D Data Set Register (GPIO96 to 127)		<a href="#">Go</a>
1Ch	GPDCLEAR	GPIO D Data Clear Register (GPIO96 to 127)		<a href="#">Go</a>
1Eh	GPDTOGGLE	GPIO D Data Toggle Register (GPIO96 to 127)		<a href="#">Go</a>
20h	GPEDAT	GPIO E Data Register (GPIO128 to 159)		<a href="#">Go</a>
22h	GPESET	GPIO E Data Set Register (GPIO128 to 159)		<a href="#">Go</a>
24h	GPECLEAR	GPIO E Data Clear Register (GPIO128 to 159)		<a href="#">Go</a>
26h	GPETOGGLE	GPIO E Data Toggle Register (GPIO128 to 159)		<a href="#">Go</a>
28h	GPFDAT	GPIO F Data Register (GPIO160 to 191)		<a href="#">Go</a>
2Ah	GPFSET	GPIO F Data Set Register (GPIO160 to 191)		<a href="#">Go</a>
2Ch	GPFCLEAR	GPIO F Data Clear Register (GPIO160 to 191)		<a href="#">Go</a>
2Eh	GPFTOGGLE	GPIO F Data Toggle Register (GPIO160 to 191)		<a href="#">Go</a>
30h	GPGDAT	GPIO G Data Register (GPIO192 to 223)		<a href="#">Go</a>
32h	GPGSET	GPIO G Data Set Register (GPIO192 to 223)		<a href="#">Go</a>
34h	GPGCLEAR	GPIO G Data Clear Register (GPIO192 to 223)		<a href="#">Go</a>
36h	GPGTOGGLE	GPIO G Data Toggle Register (GPIO192 to 223)		<a href="#">Go</a>
38h	GPHDAT	GPIO H Data Register (GPIO224 to 255)		<a href="#">Go</a>
3Ah	GPHSET	GPIO H Data Set Register (GPIO224 to 255)		<a href="#">Go</a>
3Ch	GPHCLEAR	GPIO H Data Clear Register (GPIO224 to 255)		<a href="#">Go</a>
3Eh	GPHTOGGLE	GPIO H Data Toggle Register (GPIO224 to 255)		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 14-154 shows the codes that are used for access types in this section.

**Table 14-154. GPIO\_DATA\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s

**Table 14-154. GPIO\_DATA\_REGS Access Type Codes (continued)**

Access Type	Code	Description
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 14.11.3.1 GPADAT Register (Offset = 0h) [Reset = 0000000h]

GPADAT is shown in [Figure 14-144](#) and described in [Table 14-155](#).

Return to the [Summary Table](#).

#### GPIO A Data Register (GPIO0 to 31)

Reading this register indicates the current status of the GPIO pin, irrespective of which mode the pin is in. Writing to this register will set the GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero.

#### DESIGNER NOTE:

[1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the GPIODAT register.

### 14.11.3.2 GPASET Register (Offset = 2h) [Reset = 0000000h]

GPASET is shown in [Figure 14-145](#) and described in [Table 14-156](#).

Return to the [Summary Table](#).

GPIO A Data Set Register (GPIO0 to 31)

Writing a 1 will force GPIO output data latch to 1.

Writes of 0 are ignored.

Always reads back a 0.

**Figure 14-145. GPASET Register**

### 14.11.3.4 GPATOGGLE Register (Offset = 6h) [Reset = 0000000h]

GPATOGGLE is shown in [Figure 14-147](#) and described in [Table 14-158](#).

Return to the [Summary Table](#).

GPIO A Data Toggle Register (GPIO0 to 31)

Writing a 1 will toggle GPIO0 output data latch 1 to 0 or 0 to 1.

Writes of 0 are ignored.

Always reads back a 0.

### 14.11.3.5 GPBDAT Register (Offset = 8h) [Reset = 0000000h]

GPBDAT is shown in [Figure 14-148](#) and described in [Table 14-159](#).

Return to the [Summary Table](#).

GPIO B Data Register (GPIO32 to 63)

Reading this register indicates the current status of the GPIO pin, irrespective of which mode the pin is in. Writing to this register will set the GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero.

DESIGNER NOTE:

[1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the GPIODAT register.

### 14.11.3.9 GPCDAT Register (Offset = 10h) [Reset = 0000000h]

GPCDAT is shown in [Figure 14-152](#) and described in [Table 14-163](#).

Return to the [Summary Table](#).

GPIO C Data Register (GPIO64 to 95)

Reading this register indicates the current status of the GPIO pin, irrespective of which mode the pin is in. Writing to this register will set the GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero.

DESIGNER NOTE:

[1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the

### 14.11.3.10 GPCSET Register (Offset = 12h) [Reset = 0000000h]

GPCSET is shown in [Figure 14-153](#) and described in [Table 14-164](#).

Return to the [Summary Table](#).

GPIO C Data Set Register (GPIO64 to 95)

Writing a 1 will force GPIO output data latch to 1.

Writes of 0 are ignored.

Always reads back a 0.

### 14.11.3.12 GPCTOGGLE Register (Offset = 16h) [Reset = 0000000h]

GPCTOGGLE is shown in [Figure 14-155](#) and described in [Table 14-166](#).

Return to the [Summary Table](#).

GPIO C Data Toggle Register (GPIO64 to 95)

Writing a 1 will toggle GPIO0 output data latch 1 to 0 or 0 to 1.

Writes of 0 are ignored.

Always reads back a 0.

### 14.11.3.13 GPDDAT Register (Offset = 18h) [Reset = 00000000h]

GPDDAT is shown in [Figure 14-156](#) and described in [Table 14-167](#).

Return to the [Summary Table](#).

#### GPIO D Data Register (GPIO96 to 127)

Reading this register indicates the current status of the GPIO pin, irrespective of which mode the pin is in. Writing to this register will set the GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero.

#### DESIGNER NOTE:

[1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the GPIODAT register.

### 14.11.3.15 GPD CLEAR Register (Offset = 1Ch) [Reset = 0000000h]

GPD CLEAR is shown in [Figure 14-158](#) and described in [Table 14-169](#).

Return to the [Summary Table](#).

GPIO D Data Clear Register (GPIO96 to 127)

Writing a 1 will force GPIO0 output data latch to 0.

Writes of 0 are ignored.

Always reads back a 0.

### 14.11.3.17 GPEDAT Register (Offset = 20h) [Reset = 0000000h]

GPEDAT is shown in [Figure 14-160](#) and described in [Table 14-171](#).

Return to the [Summary Table](#).

GPIO E Data Register (GPIO128 to 159)

Reading this register indicates the current status of the GPIO pin, irrespective of which mode the pin is in. Writing to this register will set the GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero.

DESIGNER NOTE:

[1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the

### 14.11.3.20 GPETOGGLE Register (Offset = 26h) [Reset = 0000000h]

GPETOGGLE is shown in [Figure 14-163](#) and described in [Table 14-174](#).

Return to the [Summary Table](#).

GPIO E Data Toggle Register (GPIO128 to 159)

Writing a 1 will toggle GPIO0 output data latch 1 to 0 or 0 to 1.

Writes of 0 are ignored.

Always reads back a 0.

### 14.11.3.21 GPFDAT Register (Offset = 28h) [Reset = 0000000h]

GPFDAT is shown in [Figure 14-164](#) and described in [Table 14-175](#).

Return to the [Summary Table](#).

GPIO F Data Register (GPIO160 to 191)

Reading this register indicates the current status of the GPIO pin, irrespective of which mode the pin is in. Writing to this register will set the GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero.

DESIGNER NOTE:

[1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the

### 14.11.3.25 GPGDAT Register (Offset = 30h) [Reset = 0000000h]

GPGDAT is shown in [Figure 14-168](#) and described in [Table 14-179](#).

Return to the [Summary Table](#).

GPIO G Data Register (GPIO192 to 223)

Reading this register indicates the current status of the GPIO pin, irrespective of which mode the pin is in. Writing to this register will set the GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero.

DESIGNER NOTE:

[1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the

### 14.11.3.29 GPHDAT Register (Offset = 38h) [Reset = 0000000h]

GPHDAT is shown in [Figure 14-172](#) and described in [Table 14-183](#).

Return to the [Summary Table](#).

GPIO H Data Register (GPIO224 to 255)

Reading this register indicates the current status of the GPIO pin, irrespective of which mode the pin is in. Writing to this register will set the GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero.

DESIGNER NOTE:

[1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the

### 14.11.3.30 GPHSET Register (Offset = 3Ah) [Reset = 0000000h]

GPHSET is shown in [Figure 14-173](#) and described in [Table 14-184](#).

Return to the [Summary Table](#).

GPIO H Data Set Register (GPIO224 to 255)

Writing a 1 will force GPIO output data latch to 1.

Writes of 0 are ignored.

Always reads back a 0.

### 14.11.3.32 GPHTOGGLE Register (Offset = 3Eh) [Reset = 0000000h]

GPHTOGGLE is shown in [Figure 14-175](#) and described in [Table 14-186](#).

Return to the [Summary Table](#).

GPIO H Data Toggle Register (GPIO224 to 255)

Writing a 1 will toggle GPIO0 output data latch 1 to 0 or 0 to 1.

Writes of 0 are ignored.

Always reads back a 0.

#### 14.11.4 GPIO\_DATA\_READ\_REGS Registers

Table 14-187 lists the memory-mapped registers for the GPIO\_DATA\_READ\_REGS registers. All register offset addresses not listed in Table 14-187 should be considered as reserved locations and the register contents should not be modified.

**Table 14-187. GPIO\_DATA\_READ\_REGS Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	GPADAT_R	GPIO A Data Read Register		<a href="#">Go</a>
2h	GPBDAT_R	GPIO B Data Read Register		<a href="#">Go</a>
4h	GPCDAT_R	GPIO C Data Read Register		<a href="#">Go</a>
6h	GPDDAT_R	GPIO D Data Read Register		<a href="#">Go</a>
8h	GPEDAT_R	GPIO E Data Read Register		<a href="#">Go</a>
Ah	GPFDAT_R	GPIO F Data Read Register		<a href="#">Go</a>
Ch	GPGDAT_R	GPIO G Data Read Register		<a href="#">Go</a>
Eh	GPHDAT_R	GPIO H Data Read Register		<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 14-188 shows the codes that are used for access types in this section.

**Table 14-188. GPIO\_DATA\_READ\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

#### 14.11.4.1 GPADAT\_R Register (Offset = 0h) [Reset = 0000000h]

GPADAT\_R is shown in [Figure 14-176](#) and described in [Table 14-189](#).

Return to the [Summary Table](#).

GPIO A Data Read Register.

Returns the contents of what was written to the GPADAT register on a read, write to this register has no effect

**Figure 14-176. GPADAT\_R Register**

Chapter 15  
**Interprocessor Communication (IPC)**

---

The Interprocessor Communications (IPC) module allows communication between the two CPU subsystems.

<b>15.1 Introduction</b> .....	<b>2307</b>
<b>15.2 Message RAMs</b> .....	<b>2308</b>
<b>15.3 IPC Flags and Interrupts</b> .....	<b>2308</b>
<b>15.4 IPC Command Registers</b> .....	<b>2308</b>
<b>15.5 Free-Running Counter</b> .....	<b>2308</b>
<b>15.6 IPC Communication Protocol</b> .....	<b>2309</b>
<b>15.7 Software</b> .....	<b>2310</b>
<b>15.8 IPC Registers</b> .....	<b>2311</b>

## 15.1 Introduction

This section details the IPC features that each CPU can use to request and share information. The IPC features are:

- Message RAMs
- IPC flags and interrupts
- IPC command registers
- Flash pump semaphore
- Clock configuration semaphore
- Free-running counter

All IPC features are independent of each other, and most do not require any specific data format.

There are also two registers for boot mode and status communication. Please refer to the boot ROM chapter for more information on these registers.

Figure 15-1 shows the design structure of the IPC module.

Figure 15-1. IPC Module Architecture

## 15.2 Message RAMs

There are two dedicated 2-kB blocks of message RAM. Each CPU and the DMA have read and write access to one RAM and read-only access to the other RAM, as shown in [Table 15-1](#).

Reading or writing a message RAM does not trigger any events on the remote CPU.

**Table 15-1. IPC Message RAM Read/Write Access**

	CPU1	CPU2	CPU1 DMA	CPU2 DMA
CPU1 to CPU2 (1K x 16, address 0x03A000)	R/W	R	R/W	R
CPU2 to CPU1 (1K x 16, address 0x03B000)	R	R/W	R	R/W

## 15.3 IPC Flags and Interrupts

There are 32 IPC event signals in each direction between the CPU pairs. These signals can be used for flag-based event polling. With the C28x core, four of them (IPC0 - IPC3) can be configured to generate IPC interrupts on the remote CPU.

## 15.4 IPC Command Registers

The IPC command registers provide a simple and flexible way for the CPUs to exchange more complex messages. Each CPU has eight dedicated registers; four for sending messages and four for receiving messages. The register names were chosen to support a simple command/response protocol, but can be used for any purpose. Only the read/write permissions are determined by hardware; the data format is entirely software-defined.

For sending messages, each CPU has three writable registers and one read-only register. Those same registers are accessible on the remote CPU as three read-only registers and one writable register. [Table 15-2](#) shows the command registers.

**Table 15-2. IPC Command Registers**

Local Register Name	Local CPU	Remote CPU	Remote Register Name
IPCSENDCOM	R/W	R	IPCRCVCOM
IPCSENDADDR	R/W	R	IPCRCVADDR
IPCSENDATA	R/W	R	IPCRCVDATA
IPCREPLY	R	R/W	IPCREPLY

## 15.5 Free-Running Counter

A 64-bit free-running counter is present in the device and can be used to timestamp IPC events between processors. The counter is clocked by PLLSYSCLK and reset by SYSRSn. The counter is implemented as two 32-bit registers, IPCCOUNTERH and IPCCOUNTERL. When IPCCOUNTERL is read, the value of IPCCOUNTERH is saved. A subsequent read to IPCCOUNTERH returns this saved value. Therefore, the user must always read IPCCOUNTERL first then read IPCCOUNTERH next. This design prevents race conditions due to IPCCOUNTERL overflowing between reads of the two registers.

The free-running counter stops only when emulation is suspended (when debugger hits a breakpoint) on all CPUs. If any core is executing, the counter runs.

## 15.6 IPC Communication Protocol

This section describes the hardware support options for IPC communication between the two CPUs. These options can be used independently or in combination. All flag definitions and data formats are entirely user-defined.

- The flag system supports event-based communication via interrupts and register polling.
  - CPUx can raise an IPC event by writing to any of the 32 bits of the IPCSET register. This sets the corresponding bits in the CPUx IPCFLG register and CPUy IPCSTS register.
  - CPUy can signal the response to the event by setting the appropriate bit in the IPCACK register. This clears the corresponding bits in the CPUx IPCFLG register and the CPUy IPCSTS register.
  - If CPUx needs to cancel an event, CPUx can set the appropriate bit in the IPCCLR register. This has the same effect as CPUy writing to IPCACK.
  - Flags 0–3 (set using IPCSET[3:0]) fire interrupts to the remote CPU. The remote CPU must configure the ePIE module properly to receive an IPC interrupt. Flags 4–31 (set using IPCSET[31:4]) do not produce interrupts. Multiple flags can be set, acknowledged, and cleared simultaneously.
- The command registers support sending several distinct pieces of information and are named COM, ADDR, DATA, and REPLY for convenience only and can hold whatever data the application needs.
  - CPUx can write data to the IPCSENDCOM, IPCSENDADDR, and IPCSENDATA registers. CPUy receives these in the IPCRECVCOM, IPCRECVADDR, and IPCRECVDATA registers.
  - CPUy can respond by writing to the IPCREPLY register. CPUx receives this data in the IPCREPLY register.
- There is an additional pair of command-like registers offered for boot-time IPC or any other convenient use — IPCBOOTMODE and IPCBOOTSTS. Both CPUs can read these registers. CPUx can only write to IPCBOOTMODE, and CPUy can only write to IPCBOOTSTS.
- There are two shared memories for passing large amounts of data between the CPUs. Each CPU has a writable memory for sending data and a read-only memory for receiving data.
- Here is an example of how to use these features together. CPUx needs some data from CPUy's LS RAM. The data is at CPUy address 0x9400 and is 0x80 16-bit words long. The protocol can be implemented like this:
  - CPUx writes 0x1 to IPCSENDCOM, defined in software to mean "copy data from address". CPUx writes the address (0x9400) to IPCSENDADDR and the data length (0x80) to IPCSENDATA.
  - CPUx writes to IPCSET[3] and IPCSET[16]. Here, IPC flag 3 is configured to send an interrupt and IPCSET[16] is defined in software to indicate an incoming command. CPUx begins polling for IPCFLG[3] to go low.
  - CPUy receives the interrupt. In the interrupt handler, CPUy checks IPCSTS, finds that flag 16 is set, and runs a command processor.
  - CPUy reads the command (0x1) from IPCRECVCOM, the address (0x9400) from IPCRECVADDR, and the data length (0x80) from IPCRECVDATA. CPUy then copies the LS RAM data to an empty space in the writable shared memory starting at offset 0x210.
  - CPUy writes the shared memory address (0x210) to the IPCLOCALREPLY register. CPUy then writes to IPCACK[16] and IPCACK[3] to clear the flags and indicate completion of the command. CPUy's work is done.
  - CPUx sees IPCFLG[3] go low. CPUx reads IPCREMOTEREPLY to get the shared memory offset of the copied data (0x210).

## 15.7 Software

### 15.7.1 IPC Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:  
C2000Ware\_VERSION#/driverlib/DEVICE\_GPN/examples/CORE\_IF\_MULTICORE/ipc

Cloud access to these examples is available at the following link: [dev.ti.com C2000Ware Examples](https://dev.ti.com/C2000Ware/Examples/).

#### 15.7.1.1 IPC basic message passing example with interrupt - MULTI\_CORE

FILE: ipc\_ex1\_basic\_cpu1\_cpu2\_multi\_c29x1.c

This example demonstrates how to configure IPC and pass information from C29x1 to C29x2 core without message queues. It is recommended to run the C29x1 core first, followed by the C29x2 core.

When using CCS for debugging the Multi-core example, after launching the debug session, connect to CPU1, load the c29x2.out followed by c29x1.out After the program is loaded, run CPU1. Once c29x1 configures and releases CPU2 out of reset, the program stops, connect to the CPU2 target now and load the symbols for c29x2.out.

In the default CPU2 linker cmd file, LPAX and LDAX RAMs are used for allocating various CPU2 sections. The CPU1 application assigns the ownership of these memory regions to CPU2 by using SysConfig. Please note that CPU2 .out file can be loaded only after CPU1 completes this configuration. The erase setting (CPU1/CPU2 On-Chip Flash -> erase setting) needs to be configured as selected banks only (Choose the corresponding BANKS allocated for CPUs) or necessary sectors only before loading CPU1/CPU2.out file (This is applicable only for FLASH configuration)

##### External Connections

- None.

##### Watch Variables

- pass

#### 15.7.1.2 IPC basic message passing example with interrupt - MULTI\_CORE

FILE: ipc\_ex1\_basic\_cpu1\_cpu2\_multi\_c29x2.c

This example demonstrates how to configure IPC and pass information from C29x1 to C29x2 core without message queues. It is recommended to run the C29x1 core first, followed by the C29x2 core.

In the default CPU2 linker cmd file, LPAX and LDAX RAMs are used for allocating various CPU2 sections. The CPU1 application assigns the ownership of these memory regions to CPU2 by using SysConfig. Please note that CPU2 .out file can be loaded only after CPU1 completes this configuration. The erase setting (CPU1/CPU2 On-Chip Flash -> erase setting) needs to be configured as selected banks only (Choose the corresponding BANKS allocated for CPUs) or necessary sectors only before loading CPU1/CPU2.out file (This is applicable only for FLASH configuration)

#### 15.7.1.3 IPC basic message passing example with interrupt - MULTI\_CORE

FILE: ipc\_ex2\_basic\_cpu1\_cpu3\_multi\_c29x1.c

This example demonstrates how to configure IPC and pass information from C29x1 to C29x3 core without message queues. It is recommended to run the C29x1 core first, followed by the C29x3 core. Once the C29x1 configures and releases CPU3 out of reset, the program stops, connect to the CPU3 target now and load the C29x3 .out.

When using CCS for debugging the Multi-core example, after launching the debug session, connect to CPU1, load the c29x3.out followed by c29x1.out. After the program is loaded, run CPU1. Once c29x1 configures and releases CPU3 out of reset, the program stops, connect to the CPU3 target now and load the symbols for c29x3.out.

In the default CPU3 linker cmd file, CPAX and CDAX RAMs are used for allocating various CPU3 sections. The CPU1 application assigns the ownership of these memory regions to CPU3 by using SysConfig. Please note that CPU3 .out file can be loaded only after CPU1 completes this configuration. The erase setting (CPU1/CPU3 On-Chip Flash -> erase setting) needs to be configured as selected banks only (Choose the corresponding BANKS allocated for CPUs) or necessary sectors only before loading CPU1/CPU3.out file (This is applicable only for FLASH configuration)

#### External Connections

- None.

#### Watch Variables

- pass

#### 15.7.1.4 IPC basic message passing example with interrupt - MULTI\_CORE

FILE: ipc\_ex2\_basic\_cpu1\_cpu3\_multi\_c29x3.c

This example demonstrates how to configure IPC and pass information from C29x1 to C29x3 core without message queues. It is recommended to run the C29x1 core first, followed by the C29x3 core. Once the C29x1 configures and releases CPU3 out of reset, the program stops, connect to the CPU3 target now and load this C29x3 .out.

In the default CPU3 linker cmd file, LPAX and LDAX RAMs are used for allocating various CPU3 sections. The CPU1 application assigns the ownership of these memory regions to CPU3 by using SysConfig. Please note that CPU3 .out file can be loaded only after CPU1 completes this configuration. The erase setting (CPU1/CPU3 On-Chip Flash -> erase setting) needs to be configured as selected banks only (Choose the corresponding BANKS allocated for CPUs) or necessary sectors only before loading CPU1/CPU3.out file (This is applicable only for FLASH configuration)

## 15.8 IPC Registers

This section describes the Interprocessor Communication Registers.

### 15.8.1 IPC Base Address Table

**Table 15-3. IPC Base Address Table**

Bit Field Name		DriverLib Name	Base Address	CPU1	CPU1.DMA	CPU1.CLA1	CPU2	CPU2.DMA	Pipeline Protected
Instance	Structure								
Cpu1toCpu2IpcRegs	<a href="#">CPU1TOCPU2_IPC_REGS_CPU1VIEW</a>	IPC_CPUXTOCP UX_BASE	0x0005_CE00	YES	-	-	-	-	YES
Cpu2toCpu1IpcRegs	<a href="#">CPU1TOCPU2_IPC_REGS_CPU2VIEW</a>	IPC_CPUXTOCP UX_BASE	0x0005_CE00	-	-	-	YES	-	YES

### 15.8.2 CPU1TOCPU2\_IPC\_REGS\_CPU1VIEW Registers

Table 15-4 lists the memory-mapped registers for the CPU1TOCPU2\_IPC\_REGS\_CPU1VIEW registers. All register offset addresses not listed in Table 15-4 should be considered as reserved locations and the register contents should not be modified.

**Table 15-4. CPU1TOCPU2\_IPC\_REGS\_CPU1VIEW Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	CPU1TOCPU2IPCACK	CPU1TOCPU2IPCACK Register		<a href="#">Go</a>
2h	CPU2TOCPU1IPCSTS	CPU2TOCPU1IPCSTS Register		<a href="#">Go</a>
4h	CPU1TOCPU2IPCSET	CPU1TOCPU2IPCSET Register		<a href="#">Go</a>
6h	CPU1TOCPU2IPCCLR	CPU1TOCPU2IPCCLR Register		<a href="#">Go</a>
8h	CPU1TOCPU2IPCFLG	CPU1TOCPU2IPCFLG Register		<a href="#">Go</a>
Ch	IPCCOUNTERL	IPCCOUNTERL Register		<a href="#">Go</a>
Eh	IPCCOUNTERH	IPCCOUNTERH Register		<a href="#">Go</a>
10h	CPU1TOCPU2IPCSENDCOM	CPU1TOCPU2IPCSENDCOM Register		<a href="#">Go</a>
12h	CPU1TOCPU2IPCSENDADDR	CPU1TOCPU2IPCSENDADDR Register		<a href="#">Go</a>
14h	CPU1TOCPU2IPCSENDATA	CPU1TOCPU2IPCSENDATA Register		<a href="#">Go</a>
16h	CPU2TOCPU1IPCREPLY	CPU2TOCPU1IPCREPLY Register		<a href="#">Go</a>
18h	CPU2TOCPU1IPCRCVCOM	CPU2TOCPU1IPCRCVCOM Register		<a href="#">Go</a>
1Ah	CPU2TOCPU1IPCRCVADDR	CPU2TOCPU1IPCRCVADDR Register		<a href="#">Go</a>
1Ch	CPU2TOCPU1IPCRCVDATA	CPU2TOCPU1IPCRCVDATA Register		<a href="#">Go</a>
1Eh	CPU1TOCPU2IPCREPLY	CPU1TOCPU2IPCREPLY Register		<a href="#">Go</a>
20h	CPU2TOCPU1IPCBOOTSTS	CPU2TOCPU1IPCBOOTSTS Register		<a href="#">Go</a>
22h	CPU1TOCPU2IPCBOOTMODE	CPU1TOCPU2IPCBOOTMODE Register		<a href="#">Go</a>
24h	FLASHCTLSEM	FLASHCTLSEM Register	EALLOW	<a href="#">Go</a>

Complex bit access types are encoded to fit into small table cells. Table 15-5 shows the codes that are used for access types in this section.

**Table 15-5. CPU1TOCPU2\_IPC\_REGS\_CPU1VIEW  
Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1S	W1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value

### 15.8.2.1 CPU1TOCPU2IPCACK Register (Offset = 0h) [Reset = 0000000h]

CPU1TOCPU2IPCACK is shown in [Figure 15-2](#) and described in [Table 15-6](#).

Return to the [Summary Table](#).

CPU1TOCPU2IPCACK Register

**Figure 15-2. CPU1TOCPU2IPCACK Register**

31	30	29	28	27	26	25	24
IPC31	IPC30	IPC29	IPC28	IPC27	IPC26	IPC25	IPC24
R-0/W1S-0h	R-0/W1S-0h	R-0/W1S-0h	R-0/W1S-0h	R-0/W1S-0h	R-0/W1S-0h	R-0/W1S-0h	R-0/W1S-0h
23	22	21	20	19	18	17	16
IPC23	IPC22	IPC21	IPC20	IPC19	IPC18	IPC17	IPC16
R-0/W1S-0h	R-0/W1S-0h	R-0/W1S-0h	R-0/W1S-0h	R-0/W1S-0h	R-0/W1S-0h	R-0/W1S-0h	R-0/W1S-0h

**Table 15-6. CPU1TOCPU2IPCACK Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	IPC31	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC31 bit. Reset type: CPU1.SYSRSn
30	IPC30	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC30 bit. Reset type: CPU1.SYSRSn
29	IPC29	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC29 bit. Reset type: CPU1.SYSRSn
28	IPC28	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC28 bit. Reset type: CPU1.SYSRSn
27	IPC27	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC27 bit. Reset type: CPU1.SYSRSn
26	IPC26	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC26 bit. Reset type: CPU1.SYSRSn
25	IPC25	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC25 bit. Reset type: CPU1.SYSRSn
24	IPC24	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC24 bit. Reset type: CPU1.SYSRSn
23	IPC23	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC23 bit. Reset type: CPU1.SYSRSn
22	IPC22	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC22 bit. Reset type: CPU1.SYSRSn
21	IPC21	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC21 bit. Reset type: CPU1.SYSRSn
20	IPC20	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC20 bit. Reset type: CPU1.SYSRSn
19	IPC19	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC19 bit. Reset type: CPU1.SYSRSn

**Table 15-6. CPU1TOCPU2IPCAK Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
18	IPC18	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC18 bit. Reset type: CPU1.SYSRSn
17	IPC17	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC17 bit. Reset type: CPU1.SYSRSn
16	IPC16	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC16 bit. Reset type: CPU1.SYSRSn
15	IPC15	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC15 bit. Reset type: CPU1.SYSRSn
14	IPC14	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC14 bit. Reset type: CPU1.SYSRSn
13	IPC13	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC13 bit. Reset type: CPU1.SYSRSn
12	IPC12	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC12 bit. Reset type: CPU1.SYSRSn
11	IPC11	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC11 bit. Reset type: CPU1.SYSRSn
10	IPC10	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC10 bit. Reset type: CPU1.SYSRSn
9	IPC9	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC9 bit. Reset type: CPU1.SYSRSn
8	IPC8	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC8 bit. Reset type: CPU1.SYSRSn
7	IPC7	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC7 bit. Reset type: CPU1.SYSRSn
6	IPC6	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC6 bit. Reset type: CPU1.SYSRSn
5	IPC5	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC5 bit. Reset type: CPU1.SYSRSn
4	IPC4	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC4 bit. Reset type: CPU1.SYSRSn
3	IPC3	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC3 bit. Reset type: CPU1.SYSRSn
2	IPC2	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC2 bit. Reset type: CPU1.SYSRSn
1	IPC1	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC1 bit. Reset type: CPU1.SYSRSn
0	IPC0	R-0/W1S	0h	Writing 1 to this bit, will clear CPU2TOCPU1IPCFLG.IPC0 bit. Reset type: CPU1.SYSRSn

### 15.8.2.2 CPU2TOCPU1IPCSTS Register (Offset = 2h) [Reset = 0000000h]

CPU2TOCPU1IPCSTS is shown in [Figure 15-3](#) and described in [Table 15-7](#).

Return to the [Summary Table](#).

Status of CPU1TOCPU2IPCFLG register

**Figure 15-3. CPU2TOCPU1IPCSTS Register**

**Table 15-7. CPU2TOCPU1IPCSTS Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	IPC31	R	0h	Indicates to CPU1 if the IPC31 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC31 bit. 0: No IPC31 event was set by CPU2 1: An IPC31 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
30	IPC30	R	0h	Indicates to CPU1 if the IPC30 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC30 bit. 0: No IPC30 event was set by CPU2 1: An IPC30 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
29	IPC29	R	0h	Indicates to CPU1 if the IPC29 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC29 bit. 0: No IPC29 event was set by CPU2 1: An IPC29 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
28	IPC28	R	0h	Indicates to CPU1 if the IPC28 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC28 bit. 0: No IPC28 event was set by CPU2 1: An IPC28 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn

**Table 15-7. CPU2TOCPU1IPCSTS Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
27	IPC27	R	0h	Indicates to CPU1 if the IPC27 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC27 bit. 0: No IPC27 event was set by CPU2 1: An IPC27 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
26	IPC26	R	0h	Indicates to CPU1 if the IPC26 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC26 bit. 0: No IPC26 event was set by CPU2 1: An IPC26 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
25	IPC25	R	0h	Indicates to CPU1 if the IPC25 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC25 bit. 0: No IPC25 event was set by CPU2 1: An IPC25 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
24	IPC24	R	0h	Indicates to CPU1 if the IPC24 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC24 bit. 0: No IPC24 event was set by CPU2 1: An IPC24 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
23	IPC23	R	0h	Indicates to CPU1 if the IPC23 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC23 bit. 0: No IPC23 event was set by CPU2 1: An IPC23 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
22	IPC22	R	0h	Indicates to CPU1 if the IPC22 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC22 bit. 0: No IPC22 event was set by CPU2 1: An IPC22 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
21	IPC21	R	0h	Indicates to CPU1 if the IPC21 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC21 bit. 0: No IPC21 event was set by CPU2 1: An IPC21 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
20	IPC20	R	0h	Indicates to CPU1 if the IPC20 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC20 bit. 0: No IPC20 event was set by CPU2 1: An IPC20 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn

**Table 15-7. CPU2TOCPU1IPCSTS Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
19	IPC19	R	0h	Indicates to CPU1 if the IPC19 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC19 bit. 0: No IPC19 event was set by CPU2 1: An IPC19 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
18	IPC18	R	0h	Indicates to CPU1 if the IPC18 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC18 bit. 0: No IPC18 event was set by CPU2 1: An IPC18 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
17	IPC17	R	0h	Indicates to CPU1 if the IPC17 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC17 bit. 0: No IPC17 event was set by CPU2 1: An IPC17 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
16	IPC16	R	0h	Indicates to CPU1 if the IPC16 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC16 bit. 0: No IPC16 event was set by CPU2 1: An IPC16 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
15	IPC15	R	0h	Indicates to CPU1 if the IPC15 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC15 bit. 0: No IPC15 event was set by CPU2 1: An IPC15 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
14	IPC14	R	0h	Indicates to CPU1 if the IPC14 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC14 bit. 0: No IPC14 event was set by CPU2 1: An IPC14 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
13	IPC13	R	0h	Indicates to CPU1 if the IPC13 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC13 bit. 0: No IPC13 event was set by CPU2 1: An IPC13 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
12	IPC12	R	0h	Indicates to CPU1 if the IPC12 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC12 bit. 0: No IPC12 event was set by CPU2 1: An IPC12 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn

**Table 15-7. CPU2TOCPU1IPCSTS Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
11	IPC11	R	0h	Indicates to CPU1 if the IPC11 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC11 bit. 0: No IPC11 event was set by CPU2 1: An IPC11 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
10	IPC10	R	0h	Indicates to CPU1 if the IPC10 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC10 bit. 0: No IPC10 event was set by CPU2 1: An IPC10 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
9	IPC9	R	0h	Indicates to CPU1 if the IPC9 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC9 bit. 0: No IPC9 event was set by CPU2 1: An IPC9 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
8	IPC8	R	0h	Indicates to CPU1 if the IPC8 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC8 bit. 0: No IPC8 event was set by CPU2 1: An IPC8 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
7	IPC7	R	0h	Indicates to CPU1 if the IPC7 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC7 bit. 0: No IPC7 event was set by CPU2 1: An IPC7 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
6	IPC6	R	0h	Indicates to CPU1 if the IPC6 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC6 bit. 0: No IPC6 event was set by CPU2 1: An IPC6 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
5	IPC5	R	0h	Indicates to CPU1 if the IPC5 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC5 bit. 0: No IPC5 event was set by CPU2 1: An IPC5 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
4	IPC4	R	0h	Indicates to CPU1 if the IPC4 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC4 bit. 0: No IPC4 event was set by CPU2 1: An IPC4 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn

**Table 15-7. CPU2TOCPU1IPCSTS Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
3	IPC3	R	0h	Indicates to CPU1 if the IPC3 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC3 bit. 0: No IPC3 event was set by CPU2 1: An IPC3 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
2	IPC2	R	0h	Indicates to CPU1 if the IPC2 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC2 bit. 0: No IPC2 event was set by CPU2 1: An IPC2 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
1	IPC1	R	0h	Indicates to CPU1 if the IPC1 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC1 bit. 0: No IPC1 event was set by CPU2 1: An IPC1 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
0	IPC0	R	0h	Indicates to CPU1 if the IPC0 event flag was set by CPU2. Reflects the state of CPU2TOCPU1IPCFLG.IPC0 bit. 0: No IPC0 event was set by CPU2 1: An IPC0 event was set by CPU2 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn

### 15.8.2.3 CPU1TOCPU2IPCSET Register (Offset = 4h) [Reset = 0000000h]

CPU1TOCPU2IPCSET is shown in [Figure 15-4](#) and described in [Table 15-8](#).

Return to the [Summary Table](#).

Set CPU1TOCPU2IPCFLG register

**Figure 15-4. CPU1TOCPU2IPCSET Register**

**Table 15-8. CPU1TOCPU2IPCSET Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	IPC31	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC31 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
30	IPC30	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC30 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
29	IPC29	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC29 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
28	IPC28	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC28 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
27	IPC27	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC27 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn

**Table 15-8. CPU1TOCPU2IPCSET Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
26	IPC26	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC26 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
25	IPC25	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC25 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
24	IPC24	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC24 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
23	IPC23	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC23 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
22	IPC22	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC22 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
21	IPC21	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC21 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
20	IPC20	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC20 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
19	IPC19	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC19 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
18	IPC18	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC18 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn

**Table 15-8. CPU1TOCPU2IPCSET Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
17	IPC17	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC17 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
16	IPC16	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC16 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
15	IPC15	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC15 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
14	IPC14	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC14 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
13	IPC13	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC13 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
12	IPC12	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC12 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
11	IPC11	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC11 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
10	IPC10	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC10 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
9	IPC9	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC9 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn

**Table 15-8. CPU1TOCPU2IPCSET Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
8	IPC8	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC8 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
7	IPC7	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC7 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
6	IPC6	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC6 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
5	IPC5	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC5 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
4	IPC4	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC4 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
3	IPC3	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC3 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
2	IPC2	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC2 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
1	IPC1	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC1 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
0	IPC0	R-0/W1S	0h	Writing 1 to this bit sets the CPU1TOCPU2IPCFLG.IPC0 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn

### 15.8.2.4 CPU1TOCPU2IPCCLR Register (Offset = 6h) [Reset = 0000000h]

CPU1TOCPU2IPCCLR is shown in [Figure 15-5](#) and described in [Table 15-9](#).

Return to the [Summary Table](#).

Clear CPU1TOCPU2IPCFLG register

**Figure 15-5. CPU1TOCPU2IPCCLR Register**

**Table 15-9. CPU1TOCPU2IPCCLR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	IPC31	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC31 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
30	IPC30	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC30 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
29	IPC29	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC29 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
28	IPC28	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC28 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
27	IPC27	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC27 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn

**Table 15-9. CPU1TOCPU2IPCCLR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
26	IPC26	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC26 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
25	IPC25	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC25 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
24	IPC24	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC24 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
23	IPC23	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC23 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
22	IPC22	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC22 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
21	IPC21	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC21 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
20	IPC20	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC20 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
19	IPC19	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC19 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
18	IPC18	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC18 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn

**Table 15-9. CPU1TOCPU2IPCCLR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
17	IPC17	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC17 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
16	IPC16	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC16 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
15	IPC15	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC15 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
14	IPC14	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC14 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
13	IPC13	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC13 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
12	IPC12	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC12 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
11	IPC11	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC11 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
10	IPC10	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC10 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
9	IPC9	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC9 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn

**Table 15-9. CPU1TOCPU2IPCCLR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
8	IPC8	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC8 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
7	IPC7	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC7 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
6	IPC6	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC6 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
5	IPC5	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC5 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
4	IPC4	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC4 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
3	IPC3	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC3 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
2	IPC2	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC2 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
1	IPC1	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC1 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
0	IPC0	R-0/W1S	0h	Writing 1 to this bit clear the CPU1TOCPU2IPCFLG.IPC0 event flag for CPU2. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn

### 15.8.2.5 CPU1TOCPU2IPCFLG Register (Offset = 8h) [Reset = 0000000h]

CPU1TOCPU2IPCFLG is shown in [Figure 15-6](#) and described in [Table 15-10](#).

Return to the [Summary Table](#).

CPU1TOCPU2IPCFLG Register

**Table 15-20. CPU1TOCPU2IPCREPLY Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	RDATA	R/W	0h	This is a general purpose register used to send a reply to CPU2 to CPU1 command from CPU1. Note: This register is not writable from CPU2. Reset type: CPU1.SYSRSn

### 15.8.2.16 CPU2TOCPU1IPCBOOTSTS Register (Offset = 20h) [Reset = 0000000h]

CPU2TOCPU1IPCBOOTSTS is shown in [Figure 15-17](#) and described in [Table 15-21](#).

Return to the [Summary Table](#).

CPU2 to CPU1 BOOT Status

**Figure 15-17. CPU2TOCPU1IPCBOOTSTS Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BOOTSTS																															
R/W-0h																															

**Table 15-21. CPU2TOCPU1IPCBOOTSTS Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	BOOTSTS	R/W	0h	This register is used by CPU2 to pass the boot Status to CPU1. The data format is software-defined. It can only be written by CPU2. Reset type: CPU2.SYSRSn

### 15.8.2.17 CPU1TOCPU2IPCBOOTMODE Register (Offset = 22h) [Reset = 0000000h]

CPU1TOCPU2IPCBOOTMODE is shown in [Figure 15-18](#) and described in [Table 15-22](#).

Return to the [Summary Table](#).

CPU1 to CPU2 BOOT Mode setting

**Figure 15-18. CPU1TOCPU2IPCBOOTMODE Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BOOTMODE																															
R/W-0h																															

**Table 15-22. CPU1TOCPU2IPCBOOTMODE Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	BOOTMODE	R/W	0h	This register is used by CPU1 to pass a boot mode information to CPU2. The data format is software-defined. It can only be written by CPU1. Reset type: CPU1.SYSRSn

### 15.8.2.18 FLASHCTLSEM Register (Offset = 24h) [Reset = 0000000h]

FLASHCTLSEM is shown in [Figure 15-19](#) and described in [Table 15-23](#).

Return to the [Summary Table](#).

Flash controller access semaphore request register for program/erase

**Figure 15-19. FLASHCTLSEM Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
KEY															
R-0/W-0h															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED														SEM	
R-0-0h														R/W-0h	

**Table 15-23. FLASHCTLSEM Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	KEY	R-0/W	0h	In order to write to the semaphore bits, 0x5a5a must be written to these key bits at the same time. Otherwise, writes are ignored. The key is cleared immediately after writing, so it must be written again for every semaphore change. Reset type: CPU1.SYSRSn
15-2	RESERVED	R-0	0h	Reserved
1-0	SEM	R/W	0h	These bits decide which CPU has control of the flash controller, which allows program/erase access to the flash memory. The possible values are: 00: Read-only state. CPU1 has control of the pump, but CPU2 may seize control at any time. 01: CPU1 has exclusive control of the Flash Controller and of these semaphore bits. CPU1 can relinquish control by setting the bits back to 00. 10: CPU2 has exclusive control of the Flash Controller and of these semaphore bits. CPU2 can relinquish control by setting the bits back to 00. 11: Read-only state. CPU1 has control of the pump, but CPU2 may seize control at any time. Going from 01->10 or 10->01 is not allowed. The semaphore bits [1:0] must be written along with the correct key in bits [31:16]. Note: This field will be reset by the respective CPU resets depending on who owns the Flash Controller. For example if CPU2 is the owner, then CPU2SYSRSN would reset this field. Note: When CPU2SYSRSN asserted, user has to poll for FLASHCTLSEM value 0x0 and then program the FLASHCTLSEM depends on subsequent ownership requirement. Reset type: CPU1.SYSRSn, CPU2.SYSRSn

### 15.8.3 CPU1TOCPU2\_IPC\_REGS\_CPU2VIEW Registers

Table 15-24 lists the memory-mapped registers for the CPU1TOCPU2\_IPC\_REGS\_CPU2VIEW registers. All register offset addresses not listed in Table 15-24 should be considered as reserved locations and the register contents should not be modified.

**Table 15-24. CPU1TOCPU2\_IPC\_REGS\_CPU2VIEW Registers**

Offset	Acronym	Register Name	Write Protection	Section
0h	CPU2TOCPU1IPCACK	CPU2TOCPU1IPCACK Register		<a href="#">Go</a>
2h	CPU1TOCPU2IPCSTS	CPU1TOCPU2IPCSTS Register		<a href="#">Go</a>
4h	CPU2TOCPU1IPCSET	CPU2TOCPU1IPCSET Register		<a href="#">Go</a>

21	IPC21	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC21 bit. Reset type: CPU2.SYSRSn
20	IPC20	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC20 bit. Reset type: CPU2.SYSRSn
19	IPC19	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC19 bit. Reset type: CPU2.SYSRSn

**Table 15-26. CPU2TOCPU1IPCACK Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
18	IPC18	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC18 bit. Reset type: CPU2.SYSRSn
17	IPC17	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC17 bit. Reset type: CPU2.SYSRSn
16	IPC16	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC16 bit. Reset type: CPU2.SYSRSn
15	IPC15	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC15 bit. Reset type: CPU2.SYSRSn
14	IPC14	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC14 bit. Reset type: CPU2.SYSRSn
13	IPC13	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC13 bit. Reset type: CPU2.SYSRSn
12	IPC12	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC12 bit. Reset type: CPU2.SYSRSn
11	IPC11	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC11 bit. Reset type: CPU2.SYSRSn
10	IPC10	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC10 bit. Reset type: CPU2.SYSRSn
9	IPC9	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC9 bit. Reset type: CPU2.SYSRSn
8	IPC8	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC8 bit. Reset type: CPU2.SYSRSn
7	IPC7	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC7 bit. Reset type: CPU2.SYSRSn
6	IPC6	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC6 bit. Reset type: CPU2.SYSRSn
5	IPC5	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC5 bit. Reset type: CPU2.SYSRSn
4	IPC4	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC4 bit. Reset type: CPU2.SYSRSn
3	IPC3	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC3 bit. Reset type: CPU2.SYSRSn
2	IPC2	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC2 bit. Reset type: CPU2.SYSRSn
1	IPC1	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC1 bit. Reset type: CPU2.SYSRSn
0	IPC0	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC0 bit. Reset type: CPU2.SYSRSn

### 15.8.3.2 CPU1TOCPU2IPCSTS Register (Offset = 2h) [Reset = 0000000h]

CPU1TOCPU2IPCSTS is shown in [Figure 15-21](#) and described in [Table 15-27](#).

Return to the [Summary Table](#).

Status of CPU2TOCPU1IPCFLG register

**Figure 15-21. CPU1TOCPU2IPCSTS Register**

31	30	29	28	27	26	25	24

**Table 15-27. CPU1TOCPU2IPCSTS Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	IPC31	R	0h	Indicates to CPU2 if the IPC31 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC31 bit. 0: No IPC31 event was set by CPU1 1: An IPC31 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
30	IPC30	R	0h	Indicates to CPU2 if the IPC30 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC30 bit. 0: No IPC30 event was set by CPU1 1: An IPC30 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
29	IPC29	R	0h	Indicates to CPU2 if the IPC29 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC29 bit. 0: No IPC29 event was set by CPU1 1: An IPC29 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
28	IPC28	R	0h	Indicates to CPU2 if the IPC28 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC28 bit. 0: No IPC28 event was set by CPU1 1: An IPC28 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn

**Table 15-27. CPU1TOCPU2IPCSTS Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
27	IPC27	R	0h	Indicates to CPU2 if the IPC27 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC27 bit. 0: No IPC27 event was set by CPU1 1: An IPC27 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
26	IPC26	R	0h	Indicates to CPU2 if the IPC26 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC26 bit. 0: No IPC26 event was set by CPU1 1: An IPC26 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
25	IPC25	R	0h	Indicates to CPU2 if the IPC25 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC25 bit. 0: No IPC25 event was set by CPU1 1: An IPC25 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
24	IPC24	R	0h	Indicates to CPU2 if the IPC24 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC24 bit. 0: No IPC24 event was set by CPU1 1: An IPC24 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
23	IPC23	R	0h	Indicates to CPU2 if the IPC23 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC23 bit. 0: No IPC23 event was set by CPU1 1: An IPC23 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
22	IPC22	R	0h	Indicates to CPU2 if the IPC22 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC22 bit. 0: No IPC22 event was set by CPU1 1: An IPC22 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
21	IPC21	R	0h	Indicates to CPU2 if the IPC21 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC21 bit. 0: No IPC21 event was set by CPU1 1: An IPC21 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
20	IPC20	R	0h	Indicates to CPU2 if the IPC20 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC20 bit. 0: No IPC20 event was set by CPU1 1: An IPC20 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn

**Table 15-27. CPU1TOCPU2IPCSTS Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
19	IPC19	R	0h	Indicates to CPU2 if the IPC19 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC19 bit. 0: No IPC19 event was set by CPU1 1: An IPC19 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
18	IPC18	R	0h	Indicates to CPU2 if the IPC18 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC18 bit. 0: No IPC18 event was set by CPU1 1: An IPC18 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
17	IPC17	R	0h	Indicates to CPU2 if the IPC17 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC17 bit. 0: No IPC17 event was set by CPU1 1: An IPC17 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
16	IPC16	R	0h	Indicates to CPU2 if the IPC16 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC16 bit. 0: No IPC16 event was set by CPU1 1: An IPC16 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
15	IPC15	R	0h	Indicates to CPU2 if the IPC15 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC15 bit. 0: No IPC15 event was set by CPU1 1: An IPC15 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
14	IPC14	R	0h	Indicates to CPU2 if the IPC14 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC14 bit. 0: No IPC14 event was set by CPU1 1: An IPC14 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
13	IPC13	R	0h	Indicates to CPU2 if the IPC13 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC13 bit. 0: No IPC13 event was set by CPU1 1: An IPC13 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
12	IPC12	R	0h	Indicates to CPU2 if the IPC12 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC12 bit. 0: No IPC12 event was set by CPU1 1: An IPC12 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn

**Table 15-27. CPU1TOCPU2IPCSTS Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
11	IPC11	R	0h	Indicates to CPU2 if the IPC11 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC11 bit. 0: No IPC11 event was set by CPU1 1: An IPC11 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
10	IPC10	R	0h	Indicates to CPU2 if the IPC10 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC10 bit. 0: No IPC10 event was set by CPU1 1: An IPC10 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
9	IPC9	R	0h	Indicates to CPU2 if the IPC9 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC9 bit. 0: No IPC9 event was set by CPU1 1: An IPC9 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
8	IPC8	R	0h	Indicates to CPU2 if the IPC8 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC8 bit. 0: No IPC8 event was set by CPU1 1: An IPC8 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
7	IPC7	R	0h	Indicates to CPU2 if the IPC7 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC7 bit. 0: No IPC7 event was set by CPU1 1: An IPC7 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
6	IPC6	R	0h	Indicates to CPU2 if the IPC6 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC6 bit. 0: No IPC6 event was set by CPU1 1: An IPC6 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
5	IPC5	R	0h	Indicates to CPU2 if the IPC5 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC5 bit. 0: No IPC5 event was set by CPU1 1: An IPC5 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
4	IPC4	R	0h	Indicates to CPU2 if the IPC4 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC4 bit. 0: No IPC4 event was set by CPU1 1: An IPC4 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn

**Table 15-27. CPU1TOCPU2IPCSTS Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
3	IPC3	R	0h	Indicates to CPU2 if the IPC3 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC3 bit. 0: No IPC3 event was set by CPU1 1: An IPC3 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
2	IPC2	R	0h	Indicates to CPU2 if the IPC2 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC2 bit. 0: No IPC2 event was set by CPU1 1: An IPC2 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
1	IPC1	R	0h	Indicates to CPU2 if the IPC1 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC1 bit. 0: No IPC1 event was set by CPU1 1: An IPC1 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn
0	IPC0	R	0h	Indicates to CPU2 if the IPC0 event flag was set by CPU1. Reflects the state of CPU1TOCPU2IPCFLG.IPC0 bit. 0: No IPC0 event was set by CPU1 1: An IPC0 event was set by CPU1 Notes [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU1.SYSRSn

### 15.8.3.3 CPU2TOCPU1IPCSET Register (Offset = 4h) [Reset = 0000000h]

CPU2TOCPU1IPCSET is shown in [Figure 15-22](#) and described in [Table 15-28](#).

Return to the [Summary Table](#).

Set CPU2TOCPU1IPCFLG register

**Figure 15-22. CPU2TOCPU1IPCSET Register**

31	30	29	28	27	26	25	24

**Table 15-28. CPU2TOCPU1IPCSET Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	IPC31	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC31 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
30	IPC30	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC30 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
29	IPC29	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC29 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
28	IPC28	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC28 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
27	IPC27	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC27 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn

**Table 15-28. CPU2TOCPU1IPCSET Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
26	IPC26	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC26 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
25	IPC25	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC25 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
24	IPC24	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC24 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
23	IPC23	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC23 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
22	IPC22	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC22 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
21	IPC21	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC21 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
20	IPC20	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC20 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
19	IPC19	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC19 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
18	IPC18	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC18 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn

**Table 15-28. CPU2TOCPU1IPCSET Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
17	IPC17	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC17 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
16	IPC16	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC16 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
15	IPC15	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC15 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
14	IPC14	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC14 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
13	IPC13	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC13 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
12	IPC12	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC12 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
11	IPC11	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC11 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
10	IPC10	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC10 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
9	IPC9	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC9 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn

**Table 15-28. CPU2TOCPU1IPCSET Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
8	IPC8	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC8 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
7	IPC7	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC7 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
6	IPC6	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC6 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
5	IPC5	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC5 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
4	IPC4	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC4 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
3	IPC3	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC3 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
2	IPC2	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC2 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
1	IPC1	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC1 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
0	IPC0	R-0/W1S	0h	Writing 1 to this bit sets the CPU2TOCPU1IPCFLG.IPC0 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn

### 15.8.3.4 CPU2TOCPU1IPCCLR Register (Offset = 6h) [Reset = 0000000h]

CPU2TOCPU1IPCCLR is shown in [Figure 15-23](#) and described in [Table 15-29](#).

Return to the [Summary Table](#).

Clear CPU2TOCPU1IPCFLG register

**Table 15-29. CPU2TOCPU1IPCCLR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	IPC31	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC31 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
30	IPC30	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC30 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
29	IPC29	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC29 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
28	IPC28	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC28 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
27	IPC27	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC27 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn

**Table 15-29. CPU2TOCPU1IPCCLR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
26	IPC26	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC26 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
25	IPC25	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC25 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
24	IPC24	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC24 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
23	IPC23	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC23 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
22	IPC22	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC22 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
21	IPC21	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC21 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
20	IPC20	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC20 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
19	IPC19	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC19 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
18	IPC18	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC18 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn

**Table 15-29. CPU2TOCPU1IPCCLR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
17	IPC17	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC17 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
16	IPC16	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC16 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
15	IPC15	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC15 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
14	IPC14	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC14 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
13	IPC13	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC13 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
12	IPC12	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC12 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
11	IPC11	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC11 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
10	IPC10	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC10 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
9	IPC9	R-0/W1S	0h	Writing 1 to this bit clear the CPU2TOCPU1IPCFLG.IPC9 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn

**Table 15-29. CPU2TOCPU1IPCCLR Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
8	IPC8	R-0/W1S	0h	Writing 1 to this bit clears the CPU2TOCPU1IPCFLG.IPC8 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
7	IPC7	R-0/W1S	0h	Writing 1 to this bit clears the CPU2TOCPU1IPCFLG.IPC7 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
6	IPC6	R-0/W1S	0h	Writing 1 to this bit clears the CPU2TOCPU1IPCFLG.IPC6 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
5	IPC5	R-0/W1S	0h	Writing 1 to this bit clears the CPU2TOCPU1IPCFLG.IPC5 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
4	IPC4	R-0/W1S	0h	Writing 1 to this bit clears the CPU2TOCPU1IPCFLG.IPC4 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
3	IPC3	R-0/W1S	0h	Writing 1 to this bit clears the CPU2TOCPU1IPCFLG.IPC3 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
2	IPC2	R-0/W1S	0h	Writing 1 to this bit clears the CPU2TOCPU1IPCFLG.IPC2 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
1	IPC1	R-0/W1S	0h	Writing 1 to this bit clears the CPU2TOCPU1IPCFLG.IPC1 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn
0	IPC0	R-0/W1S	0h	Writing 1 to this bit clears the CPU2TOCPU1IPCFLG.IPC0 event flag for CPU1. Writing 0 has no effect. Notes: [1] IPC event flags 0-7 will trigger interrupts. Reset type: CPU2.SYSRSn

### 15.8.3.5 CPU2TOCPU1IPCFLG Register (Offset = 8h) [Reset = 0000000h]

CPU2TOCPU1IPCFLG is shown in [Figure 15-24](#) and described in [Table 15-30](#).

Return to the [Summary Table](#).

### 15.8.3.18 FLASHCTLSEM Register (Offset = 24h) [Reset = 0000000h]

FLASHCTLSEM is shown in [Figure 15-37](#) and described in [Table 15-43](#).

Return to the [Summary Table](#).

Flash controller access semaphore request register for program/erase

**Figure 15-37. FLASHCTLSEM Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
KEY															
R-0/W-0h															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED														SEM	
R-0-0h														R/W-0h	

**Table 15-43. FLASHCTLSEM Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	KEY	R-0/W	0h	In order to write to the semaphore bits, 0x5a5a must be written to these key bits at the same time. Otherwise, writes are ignored. The key is cleared immediately after writing, so it must be written again for every semaphore change. Reset type: CPU1.SYSRSn
15-2	RESERVED	R-0	0h	Reserved
1-0	SEM	R/W	0h	These bits decide which CPU has control of the flash controller, which allows program/erase access to the flash memory. The possible values are: 00: Read-only state. CPU1 has control of the pump, but CPU2 may seize control at any time. 01: CPU1 has exclusive control of the Flash Controller and of these semaphore bits. CPU1 can relinquish control by setting the bits back to 00. 10: CPU2 has exclusive control of the Flash Controller and of these semaphore bits. CPU2 can relinquish control by setting the bits back to 00. 11: Read-only state. CPU1 has control of the pump, but CPU2 may seize control at any time. Going from 01->10 or 10->01 is not allowed. The semaphore bits [1:0] must be written along with the correct key in bits [31:16]. Note: This field will be reset by the respective CPU resets depending on who owns the Flash Controller. For example if CPU2 is the owner, then CPU2SYSRSN would reset this field. Note: When CPU2SYSRSN asserted, user has to poll for FLASHCTLSEM value 0x0 and then program the FLASHCTLSEM depends on subsequent ownership requirement. Reset type: CPU1.SYSRSn, CPU2.SYSRSn

The crossbars (referred to as X-BAR throughout this chapter) provide flexibility to connect device inputs, outputs, and internal resources in a variety of configurations.

The device contains a total of eight X-BARs:

- Input X-BAR
- CLB Input X-BAR
- Output X-BAR
- CLB Output X-BAR
- CLB X-BAR
- ePWM X-BAR
- MINDB X-BAR
- ICL X-BAR

Each of the X-BARs is named according to where the X-BAR takes signals. For example, the Input X-BAR and CLB Input X-BAR bring external signals “in” to the device. The Output X-BAR and CLB Output X-BAR take internal signals “out” of the device to a GPIO. The CLB X-BAR and ePWM X-BAR take signals to the CLB and ePWM modules, respectively.

<b>16.1 Input X-BAR, ICL XBAR, MINDB XBAR, and CLB Input X-BAR</b> .....	<b>2381</b>
<b>16.2 ePWM , CLB, and GPIO Output X-BAR</b> .....	<b>2388</b>
<b>16.3 XBAR Registers</b> .....	<b>2400</b>

## 16.1 Input X-BAR, ICL XBAR, MINDB XBAR, and CLB Input X-BAR

On this device, the Input X-BAR is used to route signals from a GPIO to many different IP blocks such as the ADC, eCAP, ePWM, and external interrupts. The input of each Input X-BAR instance (INPUTx) can be any GPIO, while the output of each instance connects to various IP blocks in the device. The digital input of AIOs are also available as inputs to the Input X-BAR. This flexibility relieves some of the constraints on peripheral muxing by allowing the user to connect any GPIO to the specified outputs of each Input X-BAR instance. Note that the GPIO selected by the Input X-BAR can be configured as either an input or an output. The Input X-BAR simply connects the signal on the input buffer to the output of the selected Input X-BAR instance. Therefore, you can do things such as route the output of an ePWM to the eCAP module for a frequency test).

The Input X-BAR is configured by way of the INPUTxSELECT registers. The destinations for each INPUTx are shown in [Figure 16-1](#) and [Table 16-1](#). For additional details on how each Input X-BAR connects to other IP blocks throughout the device, look for references to Input X-BAR in the chapter associated with that IP. Note that the destinations of each INPUTx are fixed and are not user-configurable. For more information on configuring the Input X-BAR, see the INPUT\_XBAR\_REGS register definitions in the *XBAR Registers* section.

---

### Note

All input sources to the generic XBAR can be active high.

The minimum input pulse width required for ePWM, CLB XBAR (CLB Clocks required), SYSCLK for Output XBAR, and CLB Output XBAR is 3 ticks of the respective clocks.

---

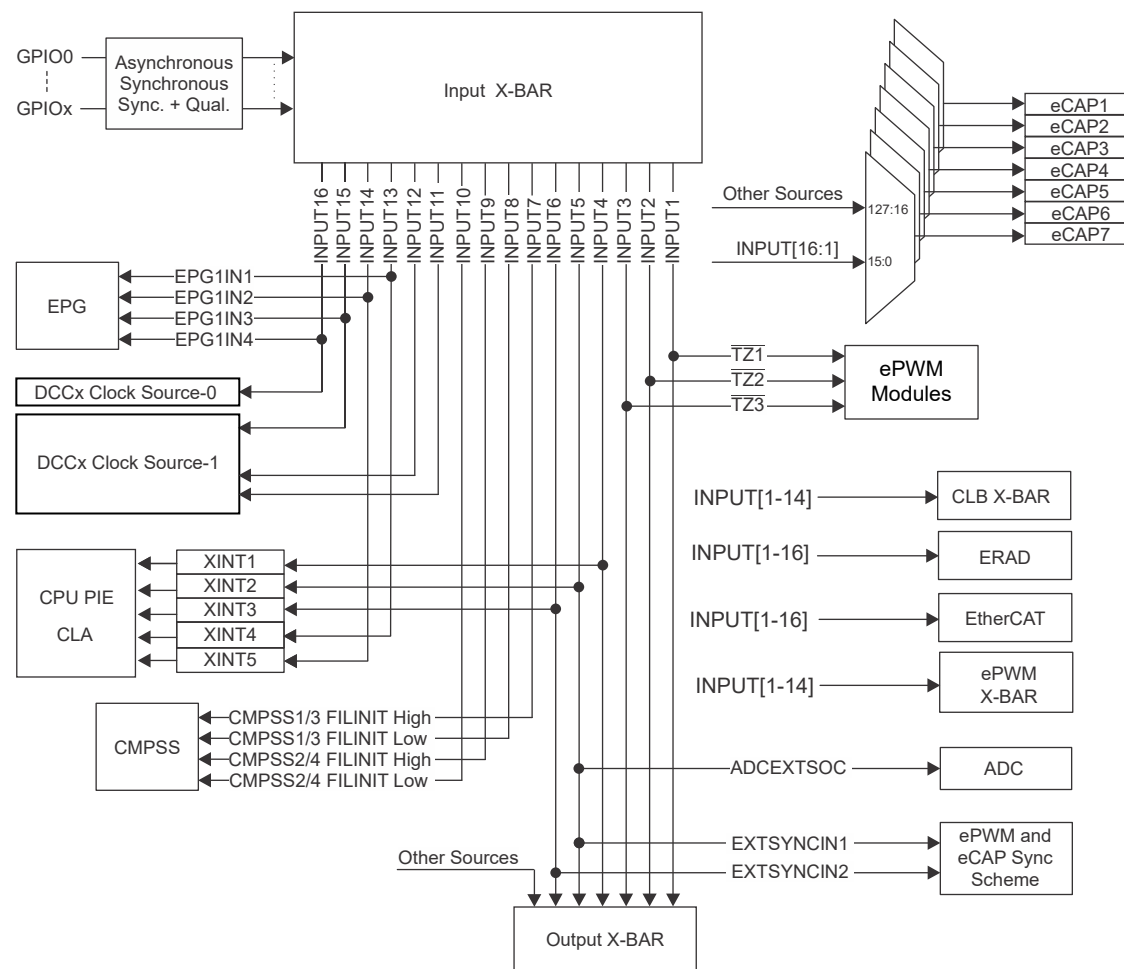

Figure 16-1. Input X-BAR

**Note**

INPUTXBARx, INPUTXBAR\_INPUTx, and INPUTx (when referenced in the context of Input X-BAR) are equivalent in all C2000 software and documentation.

**Table 16-1. Input X-BAR Destinations**

### 16.1.1 CLB Input X-BAR

The CLB Input X-BAR is architecturally identical to the Input X-BAR. The only difference is the destination for each INPUTx. The destination for each INPUTx is only the CLB Tiles as shown in . This allows for GPIOs to be accessed by the CLB tiles without using the combination of Input X-BAR and CLB X-BAR.

#### Note

Signals routed into the CLB using the XBAR must be synchronized within the CLB.

**Table 16-2. CLB Input X-BAR Destinations**

### 16.1.2 ICL and MINDB X-BAR

The Illegal Combo Logic (ICL) X-BAR and Minimum Dead-band (MINDB) X-BAR are used to route various EPWM signals and CLB outputs from to the Minimum Dead-band and Illegal Combination Logic sub-module of the EPWM. Both X-BARs are architecturally identical to the Input X-BAR, in the sense that only one input to each X-BAR can be routed to the output. The difference is the inputs to the X-BARs, which come from the EPWM and CLB modules rather than GPIOs. The inputs for each ICL X-BAR are listed in [Table 16-3](#). The inputs for each MINDB X-BAR are listed in [Table 16-4](#).

## 16.2 ePWM , CLB, and GPIO Output X-BAR

This section describes the ePWM , CLB, and GPIO Output X-BAR. Remember that the minimum input pulse width required for ePWM, CLB XBAR (CLB Clocks required), SYSCLK for Output XBAR, and CLB Output XBAR is 3 ticks of the respective clocks.

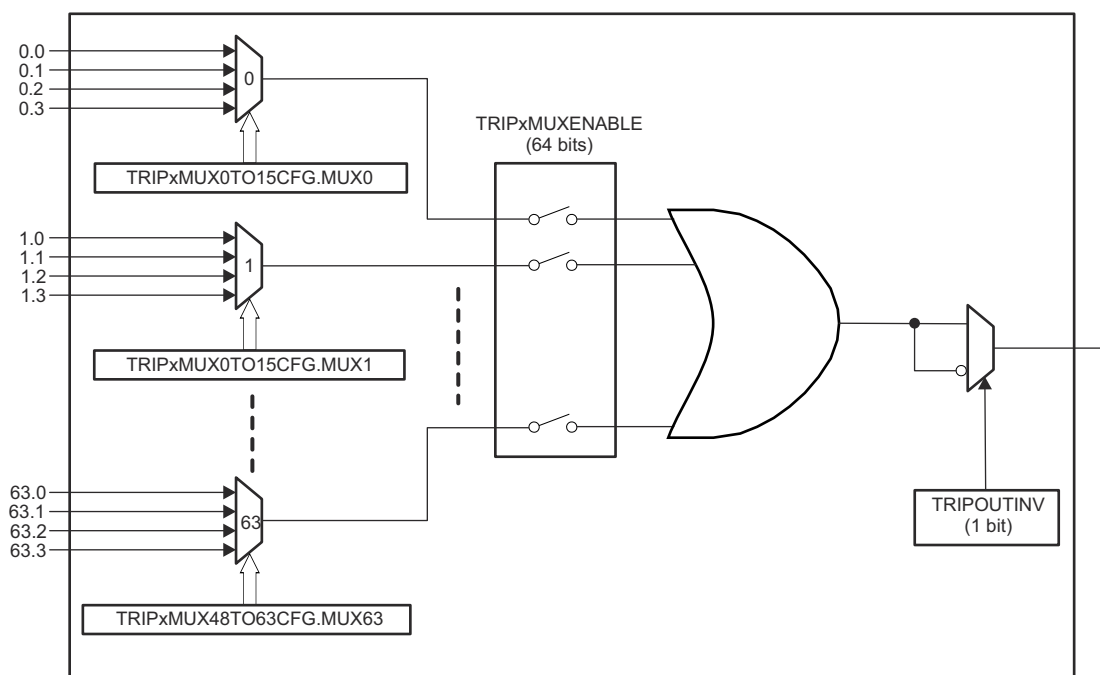

### 16.2.1 ePWM X-BAR

The ePWM X-BAR brings signals to the ePWM modules. Specifically, the ePWM X-BAR is connected to the Digital Compare (DC) submodule of each ePWM module for actions such as tripzones and syncing. Refer to the *Enhanced Pulse Width Modulator (ePWM)* chapter for more information on additional ways the DC submodule can be used. Figure 16-3 shows the architecture of the ePWM X-BAR. Note that the architecture of the ePWM X-BAR is identical to the architecture of the GPIO Output X-BAR (with the exception of the output latch).

#### 16.2.1.1 ePWM X-BAR Architecture

The ePWM X-BAR has eight outputs that are routed to each ePWM module. There are two instances of ePWM X-BAR (ePWM X-BAR A and ePWM X-BAR B), resulting in 16 outputs total. Figure 16-3 represents the architecture of a single output, but this output is identical to the architecture of all of the other outputs.

First, determine the signals that can be passed to the ePWM by referencing Table 16-5. Select up to one signal per mux for each TRIPx output. Select the inputs to ePWM X-BAR using the TRIPxMUX0TO15CFG, TRIPxMUX16TO31CFG, TRIPxMUX32TO47CFG, and TRIPxMUX48TO63CFG registers. To pass any signal through to the ePWM, enable the signal using the TRIPxMUXENABLE register. All signals that are enabled are logically ORed before being passed on to the respective TRIPx signal on the ePWM. To optionally invert the signal, use the TRIPxOUTINV register.

**Figure 16-3. ePWM X-BAR Architecture - Single Output**

### Note

Do not use "Reserved" signals in your application.

There are two instances of the ePWM X-BAR (ePWM X-BAR A and ePWM X-BAR B). [Table 16-5](#) describes the inputs to the ePWM X-BARs, which are identical for both instances. Each instance has 8 outputs. The outputs of ePWM X-BAR A are connected to trips 1-8 of each ePWM instance, while outputs 1-4 and output 6-7 of ePWM X-BAR B are connected to trips 9-12 and trips 14-15 of each ePWM instance, respectively. Note that outputs 5 and 8 of ePWM X-BAR B are not connected to any ePWM trip source.

## 16.2.2 CLB X-BAR

The CLB X-BAR brings signals to the CLB modules. Figure 16-4 shows the architecture of the CLB X-BAR. Note that the architecture of the CLB X-BAR is identical to the architecture of the GPIO Output X-BAR (with the exception of the output latch).

### 16.2.2.1 CLB X-BAR Architecture

The CLB X-BAR has eight outputs that are routed to each CLB module. Figure 16-4 represents the architecture of a single output, but the output is identical to the architecture of all of the other outputs.

First, determine the signals that can be passed to the CLB by referencing Table 16-6. Select up to one signal per mux (31 total muxes) for each AUXSIGx output. Select the inputs to each mux using the AUXSIGxMUX0TO15CFG and AUXSIGxMUX16TO31CFG registers. To pass any signal through to the CLB, enable the mux in the AUXSIGxMUXENABLE register. All muxes that are enabled are logically ORed before being passed on to the respective AUXSIGx signal on the CLB. To optionally invert the signal, use the AUXSIGOUTINV register.

### 16.2.3 GPIO Output X-BAR

The GPIO Output X-BAR takes signals from inside the device and brings them out to a GPIO. Figure 16-6 shows the architecture of the GPIO Output X-BAR. The X-BAR contains eight outputs and each contains at least one position on the GPIO mux, denoted as OUTPUTXBARx. The X-BAR allows the selection of a single input or a logical-OR of many inputs.

#### 16.2.3.1 GPIO Output X-BAR Architecture

The GPIO Output X-BAR has eight outputs that are routed to the GPIO module. Figure 16-6 represents the architecture of a single output, but this output is identical to the architecture of all of the other outputs. Note that the architecture of the Output X-BAR (with the exception of the output latch) is similar to the architecture of the ePWM X-BAR.

First, determine the signals that can be passed to the GPIO by referencing Table 16-7. Select up to one signal per mux (64 total muxes) for each OUTPUTXBARx output. Select the inputs to each mux using the OUTPUTxMUX0TO15CFG, OUTPUTxMUX16TO31CFG, OUTPUTxMUX32TO47 and OUTPUTxMUX48TO63 registers. To pass any signal through to the GPIO, enable the mux in the OUTPUTxMUXENABLE register. All muxes that are enabled are logically ORed before being passed on to the respective OUTPUTx signal on the GPIO module. To optionally invert the signal, use the OUTPUTINV register. The final output is only recognized on the GPIO if the proper OUTPUTx muxing options are selected using the GPIO registers.

**Figure 16-6. GPIO Output X-BAR Architecture**

**Note**

Do not use "Reserved" signals in your application.

### 16.2.5 X-BAR Flags

With the exception of the CMPSS signals, the ePWM X-BAR and the Output X-BAR have all of the same input signals. Due to the inputs being similar between the ePWM X-BAR, CLB X-BAR, and Output X-BAR, all X-BAR modules leverage a single set of input flags to indicate which input signals have been triggered. This allows software to check the input flags when an event occurs. See [Figure 16-7](#) for more information. There is a bit allocated for each input signal in one of the XBARFLGx registers. The flag remains set until cleared through the appropriate XBARCLR<sub>x</sub> register.

---

#### Note

Not all input sources are routed to all X-BAR modules. Refer to the X-BAR specific configuration tables for exact connections.

---

Complex bit access types are encoded to fit into small table cells. [Table 16-11](#) shows the codes that are used for access types in this section.

**Table 16-11. EPWM\_XBAR\_REGS Access Type Codes**

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WOnce	W Once	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

### 16.3.2.1 OUT1MUX0TO15CFG Register (Offset = 0h) [Reset = 0000000h]

OUT1MUX0TO15CFG is shown in [Figure 16-8](#) and described in [Table 16-12](#).

Return to the [Summary Table](#).

Bit	Field	Type	Reset	Description
31-30	MUX63	R/W	0h	Select Bits for EPWM-XBAR OUT1MUX63: 00 : Select .0 input for MUX63 01 : Select .1 input for MUX63 10 : Select .2 input for MUX63 11 : Select .3 input for MUX63 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
29-28	MUX62	R/W	0h	Select Bits for EPWM-XBAR OUT1MUX62: 00 : Select .0 input for MUX62 01 : Select .1 input for MUX62 10 : Select .2 input for MUX62 11 : Select .3 input for MUX62 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
27-26	MUX61	R/W	0h	Select Bits for EPWM-XBAR OUT1MUX61: 00 : Select .0 input for MUX61 01 : Select .1 input for MUX61 10 : Select .2 input for MUX61 11 : Select .3 input for MUX61 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
25-24	MUX60	R/W	0h	Select Bits for EPWM-XBAR OUT1MUX60: 00 : Select .0 input for MUX60 01 : Select .1 input for MUX60 10 : Select .2 input for MUX60 11 : Select .3 input for MUX60 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
23-22	MUX59	R/W	0h	Select Bits for EPWM-XBAR OUT1MUX59: 00 : Select .0 input for MUX59 01 : Select .1 input for MUX59 10 : Select .2 input for MUX59 11 : Select .3 input for MUX59 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
21-20	MUX58	R/W	0h	Select Bits for EPWM-XBAR OUT1MUX58: 00 : Select .0 input for MUX58 01 : Select .1 input for MUX58 10 : Select .2 input for MUX58 11 : Select .3 input for MUX58 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 16-15. OUT1MUX48TO63CFG Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
19-18	MUX57	R/W	0h	Select Bits for EPWM-XBAR OUT1MUX57: 00 : Select .0 input for MUX57 01 : Select .1 input for MUX57 10 : Select .2 input for MUX57 11 : Select .3 input for MUX57 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
17-16	MUX56	R/W	0h	Select Bits for EPWM-XBAR OUT1MUX56: 00 : Select .0 input for MUX56 01 : Select .1 input for MUX56 10 : Select .2 input for MUX56 11 : Select .3 input for MUX56 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
15-14	MUX55	R/W	0h	Select Bits for EPWM-XBAR OUT1MUX55: 00 : Select .0 input for MUX55 01 : Select .1 input for MUX55 10 : Select .2 input for MUX55 11 : Select .3 input for MUX55 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
13-12	MUX54	R/W	0h	Select Bits for EPWM-XBAR OUT1MUX54: 00 : Select .0 input for MUX54 01 : Select .1 input for MUX54 10 : Select .2 input for MUX54 11 : Select .3 input for MUX54 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
11-10	MUX53	R/W	0h	Select Bits for EPWM-XBAR OUT1MUX53: 00 : Select .0 input for MUX53 01 : Select .1 input for MUX53 10 : Select .2 input for MUX53 11 : Select .3 input for MUX53 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
9-8	MUX52	R/W	0h	Select Bits for EPWM-XBAR OUT1MUX52: 00 : Select .0 input for MUX52 01 : Select .1 input for MUX52 10 : Select .2 input for MUX52 11 : Select .3 input for MUX52 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
7-6	MUX51	R/W	0h	Select Bits for EPWM-XBAR OUT1MUX51: 00 : Select .0 input for MUX51 01 : Select .1 input for MUX51 10 : Select .2 input for MUX51 11 : Select .3 input for MUX51 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5-4	MUX50	R/W	0h	Select Bits for EPWM-XBAR OUT1MUX50: 00 : Select .0 input for MUX50 01 : Select .1 input for MUX50 10 : Select .2 input for MUX50 11 : Select .3 input for MUX50 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 16-15. OUT1MUX48TO63CFG Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
3-2	MUX49	R/W	0h	Select Bits for EPWM-XBAR OUT1MUX49: 00 : Select .0 input for MUX49 01 : Select .1 input for MUX49 10 : Select .2 input for MUX49 11 : Select .3 input for MUX49 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
1-0	MUX48	R/W	0h	Select Bits for EPWM-XBAR OUT1MUX48: 00 : Select .0 input for MUX48 01 : Select .1 input for MUX48 10 : Select .2 input for MUX48 11 : Select .3 input for MUX48 Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

### 16.3.2.5 OUT2MUX0TO15CFG Register (Offset = 8h) [Reset = 0000000h]

OUT2MUX0TO15CFG is shown in [Figure 16-12](#) and described in [Table 16-16](#).

Return to the [Summary Table](#).

Bit	Field	Type	Reset	Description
19	MUX51	R/W	0h	Selects the output of MUX51 to drive OUT1 of EPWM-XBAR 0: Respective output of MUX51 is disabled to drive the OUT1 of EPWM-XBAR 1: Respective output of MUX51 is enabled to drive the OUT1 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
18	MUX50	R/W	0h	Selects the output of MUX50 to drive OUT1 of EPWM-XBAR 0: Respective output of MUX50 is disabled to drive the OUT1 of EPWM-XBAR 1: Respective output of MUX50 is enabled to drive the OUT1 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
17	MUX49	R/W	0h	Selects the output of MUX49 to drive OUT1 of EPWM-XBAR 0: Respective output of MUX49 is disabled to drive the OUT1 of EPWM-XBAR 1: Respective output of MUX49 is enabled to drive the OUT1 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
16	MUX48	R/W	0h	Selects the output of MUX48 to drive OUT1 of EPWM-XBAR 0: Respective output of MUX48 is disabled to drive the OUT1 of EPWM-XBAR 1: Respective output of MUX48 is enabled to drive the OUT1 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
15	MUX47	R/W	0h	Selects the output of MUX47 to drive OUT1 of EPWM-XBAR 0: Respective output of MUX47 is disabled to drive the OUT1 of EPWM-XBAR 1: Respective output of MUX47 is enabled to drive the OUT1 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
14	MUX46	R/W	0h	Selects the output of MUX46 to drive OUT1 of EPWM-XBAR 0: Respective output of MUX46 is disabled to drive the OUT1 of EPWM-XBAR 1: Respective output of MUX46 is enabled to drive the OUT1 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
13	MUX45	R/W	0h	Selects the output of MUX45 to drive OUT1 of EPWM-XBAR 0: Respective output of MUX45 is disabled to drive the OUT1 of EPWM-XBAR 1: Respective output of MUX45 is enabled to drive the OUT1 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
12	MUX44	R/W	0h	Selects the output of MUX44 to drive OUT1 of EPWM-XBAR 0: Respective output of MUX44 is disabled to drive the OUT1 of EPWM-XBAR 1: Respective output of MUX44 is enabled to drive the OUT1 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 16-45. OUT1MUXENABLE32TO64 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
11	MUX43	R/W	0h	Selects the output of MUX43 to drive OUT1 of EPWM-XBAR 0: Respective output of MUX43 is disabled to drive the OUT1 of EPWM-XBAR 1: Respective output of MUX43 is enabled to drive the OUT1 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
10	MUX42	R/W	0h	Selects the output of MUX42 to drive OUT1 of EPWM-XBAR 0: Respective output of MUX42 is disabled to drive the OUT1 of EPWM-XBAR 1: Respective output of MUX42 is enabled to drive the OUT1 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
9	MUX41	R/W	0h	Selects the output of MUX41 to drive OUT1 of EPWM-XBAR 0: Respective output of MUX41 is disabled to drive the OUT1 of EPWM-XBAR 1: Respective output of MUX41 is enabled to drive the OUT1 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
8	MUX40	R/W	0h	Selects the output of MUX40 to drive OUT1 of EPWM-XBAR 0: Respective output of MUX40 is disabled to drive the OUT1 of EPWM-XBAR 1: Respective output of MUX40 is enabled to drive the OUT1 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
7	MUX39	R/W	0h	Selects the output of MUX39 to drive OUT1 of EPWM-XBAR 0: Respective output of MUX39 is disabled to drive the OUT1 of EPWM-XBAR 1: Respective output of MUX39 is enabled to drive the OUT1 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
6	MUX38	R/W	0h	Selects the output of MUX38 to drive OUT1 of EPWM-XBAR 0: Respective output of MUX38 is disabled to drive the OUT1 of EPWM-XBAR 1: Respective output of MUX38 is enabled to drive the OUT1 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5	MUX37	R/W	0h	Selects the output of MUX37 to drive OUT1 of EPWM-XBAR 0: Respective output of MUX37 is disabled to drive the OUT1 of EPWM-XBAR 1: Respective output of MUX37 is enabled to drive the OUT1 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
4	MUX36	R/W	0h	Selects the output of MUX36 to drive OUT1 of EPWM-XBAR 0: Respective output of MUX36 is disabled to drive the OUT1 of EPWM-XBAR 1: Respective output of MUX36 is enabled to drive the OUT1 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 16-45. OUT1MUXENABLE32TO64 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
3	MUX35	R/W	0h	Selects the output of MUX35 to drive OUT1 of EPWM-XBAR 0: Respective output of MUX35 is disabled to drive the OUT1 of EPWM-XBAR 1: Respective output of MUX35 is enabled to drive the OUT1 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
2	MUX34	R/W	0h	Selects the output of MUX34 to drive OUT1 of EPWM-XBAR 0: Respective output of MUX34 is disabled to drive the OUT1 of EPWM-XBAR 1: Respective output of MUX34 is enabled to drive the OUT1 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
1	MUX33	R/W	0h	Selects the output of MUX33 to drive OUT1 of EPWM-XBAR 0: Respective output of MUX33 is disabled to drive the OUT1 of EPWM-XBAR 1: Respective output of MUX33 is enabled to drive the OUT1 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
0	MUX32	R/W	0h	Selects the output of MUX32 to drive OUT1 of EPWM-XBAR 0: Respective output of MUX32 is disabled to drive the OUT1 of EPWM-XBAR 1: Respective output of MUX32 is enabled to drive the OUT1 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

### 16.3.2.35 OUT2MUXENABLE Register (Offset = 44h) [Reset = 0000000h]

OUT2MUXENABLE is shown in [Figure 16-42](#) and described in [Table 16-46](#).

Return to the [Summary Table](#).

ePWM XBAR Mux Enable for Output2

**Table 16-46. OUT2MUXENABLE Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	MUX31	R/W	0h	Selects the output of MUX31 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX31 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX31 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
30	MUX30	R/W	0h	Selects the output of MUX30 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX30 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX30 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
29	MUX29	R/W	0h	Selects the output of MUX29 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX29 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX29 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
28	MUX28	R/W	0h	Selects the output of MUX28 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX28 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX28 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 16-46. OUT2MUXENABLE Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
27	MUX27	R/W	0h	Selects the output of MUX27 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX27 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX27 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
26	MUX26	R/W	0h	Selects the output of MUX26 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX26 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX26 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
25	MUX25	R/W	0h	Selects the output of MUX25 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX25 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX25 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
24	MUX24	R/W	0h	Selects the output of MUX24 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX24 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX24 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
23	MUX23	R/W	0h	Selects the output of MUX23 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX23 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX23 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
22	MUX22	R/W	0h	Selects the output of MUX22 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX22 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX22 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
21	MUX21	R/W	0h	Selects the output of MUX21 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX21 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX21 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
20	MUX20	R/W	0h	Selects the output of MUX20 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX20 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX20 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 16-46. OUT2MUXENABLE Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
19	MUX19	R/W	0h	Selects the output of MUX19 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX19 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX19 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
18	MUX18	R/W	0h	Selects the output of MUX18 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX18 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX18 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
17	MUX17	R/W	0h	Selects the output of MUX17 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX17 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX17 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
16	MUX16	R/W	0h	Selects the output of MUX16 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX16 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX16 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
15	MUX15	R/W	0h	Selects the output of MUX15 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX15 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX15 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
14	MUX14	R/W	0h	Selects the output of MUX14 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX14 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX14 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
13	MUX13	R/W	0h	Selects the output of MUX13 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX13 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX13 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
12	MUX12	R/W	0h	Selects the output of MUX12 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX12 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX12 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 16-46. OUT2MUXENABLE Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
11	MUX11	R/W	0h	Selects the output of MUX11 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX11 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX11 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
10	MUX10	R/W	0h	Selects the output of MUX10 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX10 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX10 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
9	MUX9	R/W	0h	Selects the output of MUX9 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX9 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX9 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
8	MUX8	R/W	0h	Selects the output of MUX8 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX8 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX8 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
7	MUX7	R/W	0h	Selects the output of MUX7 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX7 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX7 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
6	MUX6	R/W	0h	Selects the output of MUX6 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX6 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX6 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5	MUX5	R/W	0h	Selects the output of MUX5 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX5 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX5 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
4	MUX4	R/W	0h	Selects the output of MUX4 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX4 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX4 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 16-46. OUT2MUXENABLE Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
3	MUX3	R/W	0h	Selects the output of MUX3 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX3 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX3 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
2	MUX2	R/W	0h	Selects the output of MUX2 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX2 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX2 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
1	MUX1	R/W	0h	Selects the output of MUX1 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX1 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX1 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
0	MUX0	R/W	0h	Selects the output of MUX0 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX0 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX0 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

### 16.3.2.36 OUT2MUXENABLE32TO64 Register (Offset = 46h) [Reset = 0000000h]

OUT2MUXENABLE32TO64 is shown in [Figure 16-43](#) and described in [Table 16-47](#).

Return to the [Summary Table](#).

23	MUX55	R/W	0h	Selects the output of MUX55 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX55 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX55 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
22	MUX54	R/W	0h	Selects the output of MUX54 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX54 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX54 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
21	MUX53	R/W	0h	Selects the output of MUX53 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX53 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX53 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
20	MUX52	R/W	0h	Selects the output of MUX52 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX52 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX52 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 16-47. OUT2MUXENABLE32TO64 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
19	MUX51	R/W	0h	Selects the output of MUX51 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX51 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX51 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
18	MUX50	R/W	0h	Selects the output of MUX50 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX50 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX50 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
17	MUX49	R/W	0h	Selects the output of MUX49 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX49 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX49 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
16	MUX48	R/W	0h	Selects the output of MUX48 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX48 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX48 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
15	MUX47	R/W	0h	Selects the output of MUX47 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX47 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX47 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
14	MUX46	R/W	0h	Selects the output of MUX46 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX46 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX46 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
13	MUX45	R/W	0h	Selects the output of MUX45 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX45 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX45 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
12	MUX44	R/W	0h	Selects the output of MUX44 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX44 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX44 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 16-47. OUT2MUXENABLE32TO64 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
11	MUX43	R/W	0h	Selects the output of MUX43 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX43 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX43 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
10	MUX42	R/W	0h	Selects the output of MUX42 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX42 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX42 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
9	MUX41	R/W	0h	Selects the output of MUX41 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX41 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX41 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
8	MUX40	R/W	0h	Selects the output of MUX40 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX40 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX40 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
7	MUX39	R/W	0h	Selects the output of MUX39 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX39 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX39 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
6	MUX38	R/W	0h	Selects the output of MUX38 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX38 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX38 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5	MUX37	R/W	0h	Selects the output of MUX37 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX37 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX37 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
4	MUX36	R/W	0h	Selects the output of MUX36 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX36 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX36 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 16-47. OUT2MUXENABLE32TO64 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
3	MUX35	R/W	0h	Selects the output of MUX35 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX35 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX35 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
2	MUX34	R/W	0h	Selects the output of MUX34 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX34 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX34 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
1	MUX33	R/W	0h	Selects the output of MUX33 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX33 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX33 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
0	MUX32	R/W	0h	Selects the output of MUX32 to drive OUT2 of EPWM-XBAR 0: Respective output of MUX32 is disabled to drive the OUT2 of EPWM-XBAR 1: Respective output of MUX32 is enabled to drive the OUT2 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

### 16.3.2.37 OUT3MUXENABLE Register (Offset = 48h) [Reset = 0000000h]

OUT3MUXENABLE is shown in [Figure 16-44](#) and described in [Table 16-48](#).

Return to the [Summary Table](#).

Bit	Field	Type	Reset	Description
27	MUX59	R/W	0h	Selects the output of MUX59 to drive OUT3 of EPWM-XBAR 0: Respective output of MUX59 is disabled to drive the OUT3 of EPWM-XBAR 1: Respective output of MUX59 is enabled to drive the OUT3 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
26	MUX58	R/W	0h	Selects the output of MUX58 to drive OUT3 of EPWM-XBAR 0: Respective output of MUX58 is disabled to drive the OUT3 of EPWM-XBAR 1: Respective output of MUX58 is enabled to drive the OUT3 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
25	MUX57	R/W	0h	Selects the output of MUX57 to drive OUT3 of EPWM-XBAR 0: Respective output of MUX57 is disabled to drive the OUT3 of EPWM-XBAR 1: Respective output of MUX57 is enabled to drive the OUT3 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
24	MUX56	R/W	0h	Selects the output of MUX56 to drive OUT3 of EPWM-XBAR 0: Respective output of MUX56 is disabled to drive the OUT3 of EPWM-XBAR 1: Respective output of MUX56 is enabled to drive the OUT3 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
23	MUX55	R/W	0h	Selects the output of MUX55 to drive OUT3 of EPWM-XBAR 0: Respective output of MUX55 is disabled to drive the OUT3 of EPWM-XBAR 1: Respective output of MUX55 is enabled to drive the OUT3 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
22	MUX54	R/W	0h	Selects the output of MUX54 to drive OUT3 of EPWM-XBAR 0: Respective output of MUX54 is disabled to drive the OUT3 of EPWM-XBAR 1: Respective output of MUX54 is enabled to drive the OUT3 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
21	MUX53	R/W	0h	Selects the output of MUX53 to drive OUT3 of EPWM-XBAR 0: Respective output of MUX53 is disabled to drive the OUT3 of EPWM-XBAR 1: Respective output of MUX53 is enabled to drive the OUT3 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
20	MUX52	R/W	0h	Selects the output of MUX52 to drive OUT3 of EPWM-XBAR 0: Respective output of MUX52 is disabled to drive the OUT3 of EPWM-XBAR 1: Respective output of MUX52 is enabled to drive the OUT3 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 16-49. OUT3MUXENABLE32TO64 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
19	MUX51	R/W	0h	Selects the output of MUX51 to drive OUT3 of EPWM-XBAR 0: Respective output of MUX51 is disabled to drive the OUT3 of EPWM-XBAR 1: Respective output of MUX51 is enabled to drive the OUT3 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
18	MUX50	R/W	0h	Selects the output of MUX50 to drive OUT3 of EPWM-XBAR 0: Respective output of MUX50 is disabled to drive the OUT3 of EPWM-XBAR 1: Respective output of MUX50 is enabled to drive the OUT3 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
17	MUX49	R/W	0h	Selects the output of MUX49 to drive OUT3 of EPWM-XBAR 0: Respective output of MUX49 is disabled to drive the OUT3 of EPWM-XBAR 1: Respective output of MUX49 is enabled to drive the OUT3 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
16	MUX48	R/W	0h	Selects the output of MUX48 to drive OUT3 of EPWM-XBAR 0: Respective output of MUX48 is disabled to drive the OUT3 of EPWM-XBAR 1: Respective output of MUX48 is enabled to drive the OUT3 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
15	MUX47	R/W	0h	Selects the output of MUX47 to drive OUT3 of EPWM-XBAR 0: Respective output of MUX47 is disabled to drive the OUT3 of EPWM-XBAR 1: Respective output of MUX47 is enabled to drive the OUT3 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
14	MUX46	R/W	0h	Selects the output of MUX46 to drive OUT3 of EPWM-XBAR 0: Respective output of MUX46 is disabled to drive the OUT3 of EPWM-XBAR 1: Respective output of MUX46 is enabled to drive the OUT3 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
13	MUX45	R/W	0h	Selects the output of MUX45 to drive OUT3 of EPWM-XBAR 0: Respective output of MUX45 is disabled to drive the OUT3 of EPWM-XBAR 1: Respective output of MUX45 is enabled to drive the OUT3 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
12	MUX44	R/W	0h	Selects the output of MUX44 to drive OUT3 of EPWM-XBAR 0: Respective output of MUX44 is disabled to drive the OUT3 of EPWM-XBAR 1: Respective output of MUX44 is enabled to drive the OUT3 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 16-49. OUT3MUXENABLE32TO64 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
11	MUX43	R/W	0h	Selects the output of MUX43 to drive OUT3 of EPWM-XBAR 0: Respective output of MUX43 is disabled to drive the OUT3 of EPWM-XBAR 1: Respective output of MUX43 is enabled to drive the OUT3 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
10	MUX42	R/W	0h	Selects the output of MUX42 to drive OUT3 of EPWM-XBAR 0: Respective output of MUX42 is disabled to drive the OUT3 of EPWM-XBAR 1: Respective output of MUX42 is enabled to drive the OUT3 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
9	MUX41	R/W	0h	Selects the output of MUX41 to drive OUT3 of EPWM-XBAR 0: Respective output of MUX41 is disabled to drive the OUT3 of EPWM-XBAR 1: Respective output of MUX41 is enabled to drive the OUT3 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
8	MUX40	R/W	0h	Selects the output of MUX40 to drive OUT3 of EPWM-XBAR 0: Respective output of MUX40 is disabled to drive the OUT3 of EPWM-XBAR 1: Respective output of MUX40 is enabled to drive the OUT3 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
7	MUX39	R/W	0h	Selects the output of MUX39 to drive OUT3 of EPWM-XBAR 0: Respective output of MUX39 is disabled to drive the OUT3 of EPWM-XBAR 1: Respective output of MUX39 is enabled to drive the OUT3 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
6	MUX38	R/W	0h	Selects the output of MUX38 to drive OUT3 of EPWM-XBAR 0: Respective output of MUX38 is disabled to drive the OUT3 of EPWM-XBAR 1: Respective output of MUX38 is enabled to drive the OUT3 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5	MUX37	R/W	0h	Selects the output of MUX37 to drive OUT3 of EPWM-XBAR 0: Respective output of MUX37 is disabled to drive the OUT3 of EPWM-XBAR 1: Respective output of MUX37 is enabled to drive the OUT3 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
4	MUX36	R/W	0h	Selects the output of MUX36 to drive OUT3 of EPWM-XBAR 0: Respective output of MUX36 is disabled to drive the OUT3 of EPWM-XBAR 1: Respective output of MUX36 is enabled to drive the OUT3 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 16-49. OUT3MUXENABLE32TO64 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
3	MUX35	R/W	0h	Selects the output of MUX35 to drive OUT3 of EPWM-XBAR 0: Respective output of MUX35 is disabled to drive the OUT3 of EPWM-XBAR 1: Respective output of MUX35 is enabled to drive the OUT3 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
2	MUX34	R/W	0h	Selects the output of MUX34 to drive OUT3 of EPWM-XBAR 0: Respective output of MUX34 is disabled to drive the OUT3 of EPWM-XBAR 1: Respective output of MUX34 is enabled to drive the OUT3 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
1	MUX33	R/W	0h	Selects the output of MUX33 to drive OUT3 of EPWM-XBAR 0: Respective output of MUX33 is disabled to drive the OUT3 of EPWM-XBAR 1: Respective output of MUX33 is enabled to drive the OUT3 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
0	MUX32	R/W	0h	Selects the output of MUX32 to drive OUT3 of EPWM-XBAR 0: Respective output of MUX32 is disabled to drive the OUT3 of EPWM-XBAR 1: Respective output of MUX32 is enabled to drive the OUT3 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

### 16.3.2.39 OUT4MUXENABLE Register (Offset = 4Ch) [Reset = 0000000h]

OUT4MUXENABLE is shown in [Figure 16-46](#) and described in [Table 16-50](#).

Return to the [Summary Table](#).

ePWM XBAR Mux Enable for Output4

**Figure 16-46. OUT4MUXENABLE Register**

**Table 16-50. OUT4MUXENABLE Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	MUX31	R/W	0h	Selects the output of MUX31 to drive OUT4 of EPWM-XBAR 0: Respective output of MUX31 is disabled to drive the OUT4 of EPWM-XBAR 1: Respective output of MUX31 is enabled to drive the OUT4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
30	MUX30	R/W	0h	Selects the output of MUX30 to drive OUT4 of EPWM-XBAR 0: Respective output of MUX30 is disabled to drive the OUT4 of EPWM-XBAR 1: Respective output of MUX30 is enabled to drive the OUT4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
29	MUX29	R/W	0h	Selects the output of MUX29 to drive OUT4 of EPWM-XBAR 0: Respective output of MUX29 is disabled to drive the OUT4 of EPWM-XBAR 1: Respective output of MUX29 is enabled to drive the OUT4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
28	MUX28	R/W	0h	Selects the output of MUX28 to drive OUT4 of EPWM-XBAR 0: Respective output of MUX28 is disabled to drive the OUT4 of EPWM-XBAR 1: Respective output of MUX28 is enabled to drive the OUT4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

**Table 16-50. OUT4MUXENABLE Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
27	MUX27	R/W	0h	Selects the output of MUX27 to drive OUT4 of EPWM-XBAR 0: Respective output of MUX27 is disabled to drive the OUT4 of EPWM-XBAR 1: Respective output of MUX27 is enabled to drive the OUT4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
26	MUX26	R/W	0h	Selects the output of MUX26 to drive OUT4 of EPWM-XBAR 0: Respective output of MUX26 is disabled to drive the OUT4 of EPWM-XBAR 1: Respective output of MUX26 is enabled to drive the OUT4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
25	MUX25	R/W	0h	Selects the output of MUX25 to drive OUT4 of EPWM-XBAR 0: Respective output of MUX25 is disabled to drive the OUT4 of EPWM-XBAR 1: Respective output of MUX25 is enabled to drive the OUT4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
24	MUX24	R/W	0h	Selects the output of MUX24 to drive OUT4 of EPWM-XBAR 0: Respective output of MUX24 is disabled to drive the OUT4 of EPWM-XBAR 1: Respective output of MUX24 is enabled to drive the OUT4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
23	MUX23	R/W	0h	Selects the output of MUX23 to drive OUT4 of EPWM-XBAR 0: Respective output of MUX23 is disabled to drive the OUT4 of EPWM-XBAR 1: Respective output of MUX23 is enabled to drive the OUT4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
22	MUX22	R/W	0h	Selects the output of MUX22 to drive OUT4 of EPWM-XBAR 0: Respective output of MUX22 is disabled to drive the OUT4 of EPWM-XBAR 1: Respective output of MUX22 is enabled to drive the OUT4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
21	MUX21	R/W	0h	Selects the output of MUX21 to drive OUT4 of EPWM-XBAR 0: Respective output of MUX21 is disabled to drive the OUT4 of EPWM-XBAR 1: Respective output of MUX21 is enabled to drive the OUT4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
20	MUX20	R/W	0h	Selects the output of MUX20 to drive OUT4 of EPWM-XBAR 0: Respective output of MUX20 is disabled to drive the OUT4 of EPWM-XBAR 1: Respective output of MUX20 is enabled to drive the OUT4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
