Complex bit access types are encoded to fit into small table cells. Table 34-78 shows the codes that are used for access types in this section.

Table 34-78. MCAN_ERROR_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set

Table 34-78. MCAN_ERROR_REGS Access Type Codes (continued)

Access Type	Code	Description
WD	W D	Write Decrement. Decrements the specified bit field by the amount written.
WI	W I	Write Increment. Increments the specified bit field by the amount written.
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

34.7.4.1 MCANERR_REV Register (Offset = 0h) [Reset = 66A0EA00h]

MCANERR_REV is shown in Figure 34-82 and described in Table 34-79.

Return to the Summary Table.

34.7.4.2 MCANERR_VECTOR Register (Offset = 8h) [Reset = 00000000h]

MCANERR_VECTOR is shown in Figure 34-83 and described in Table 34-80.

Return to the Summary Table.

Each error detection and correction (EDC) controller has a bank of error registers (offsets 0x10 - 0x3B) associated with it. These registers are accessed via an internal serial bus (SVBUS). To access them through the ECC aggregator the controller ID desired must be written to the ECC_VECTOR field, together with the RD_SVBUS trigger and RD_SVBUS_ADDRESS bit field. This initiates the serial read which consummates by setting the RD_SVBUS_DONE bit. At this point the addressed register may be read by a normal CPU read of the appropriate offset address.

Table 34-83. MCANERR_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-9	RESERVED	R	0h	Reserved
8	CHECK_SVBUS_TIMEOUT	R/W	1h	Enables Serial VBUS timeout mechanism Reset type: SYSRSn
7	RESERVED	R/W	1h	Reserved
6	ERROR_ONCE	R/W	0h	If this bit is set, the FORCE_SEC/FORCE_DED will inject an error to the specified row only once. The FORCE_SEC bit will be cleared once a writeback happens. If writeback is not enabled, this error will be cleared the cycle following the read when the data is corrected. For double-bit errors, the FORCE_DED bit will be cleared the cycle following the double-bit error. Any subsequent reads will not force an error. Reset type: SYSRSn
5	FORCE_N_ROW	R/W	0h	Enable single/double-bit error on the next RAM read, regardless of the MCANERR_ERR_CTRL1.ECC_ROW setting. For write through mode, this applies to writes as well as reads. Reset type: SYSRSn
4	FORCE_DED	R/W	0h	Force double-bit error. Cleared the cycle following the error if ERROR_ONCE is asserted. For write through mode, this applies to writes as well as reads. MCANERR_ERR_CTRL1 and MCANERR_ERR_CTRL2 should be configured prior to setting this bit. Reset type: SYSRSn
3	FORCE_SEC	R/W	0h	Force single-bit error. Cleared on a writeback or the cycle following the error if ERROR_ONCE is asserted. For write through mode, this applies to writes as well as reads. MCANERR_ERR_CTRL1 and MCANERR_ERR_CTRL2 should be configured prior to setting this bit. Reset type: SYSRSn

Table 34-83. MCANERR_CTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
2	ENABLE_RMW	R/W	1h	Enable read-modify-write on partial word writes Reset type: SYSRSn
1	ECC_CHECK	R/W	1h	Enable ECC Check. ECC is completely bypassed if both ECC_ENABLE and ECC_CHECK are '0'. Reset type: SYSRSn
0	ECC_ENABLE	R/W	1h	Enable ECC Generation Reset type: SYSRSn

34.7.4.6 MCANERR_ERR_CTRL1 Register (Offset = 18h) [Reset = 00000000h]

MCANERR_ERR_CTRL1 is shown in Figure 34-87 and described in Table 34-84.

Return to the Summary Table.

This register is accessed through the ECC aggregator via an internal serial bus. To access, the appropriate procedure must be first followed in the MCAN ECC Vector Register.

Chapter 35

EtherCAT® SubordinateDevice Controller (ESC)

This chapter describes the implementation and integration of the Ethernet for Control Automation Technology (EtherCAT®) SubordinateDevice Controller (ESC). The ESC can be mapped to any CPU subsystem (default access mapped to CPU1 subsystem), and thus any of these subsystems can run the ESC stack and application software to implement an ESC node.

On this device, the CPU1 is the main subsystem. If the intention is to use a different CPU subsystem as the owner of the ESC, then certain ESC subsystem configurations can only be done by the CPU1 during initialization before allocating the ownership of the ESC peripheral to the other CPU subsystem. These details are explained in this chapter.

Information about the EtherCAT standards and working principles can be in found these documents:

- EtherCAT ET1100 Data sheet
- EtherCAT ESC Hardware Data sheet (Section I)
- EtherCAT IP Core for Xilinx™ FPGAs

Refer to Section 35.1.11 for details on EtherCAT IP errata provided from Beckhoff ® Automation.

35.1 Introduction

Ethernet for Control Automation Technology (EtherCAT®) is an Ethernet-based fieldbus system, invented by Beckhoff ® Automation and is standardized in IEC 61158. All the SubordinateDevice (or SubDevice) nodes connected to the bus interpret, process, and modify the data addressed to them "on the fly", without having to buffer the frame inside the node. This real-time behavior, frame processing, and forwarding requirements are implemented by the EtherCAT SubDevice controller (ESC) hardware. EtherCAT does not require software interaction for data transmission inside the SubDevices. EtherCAT only defines the MAC layer while the higher layer protocols and stack are implemented in software on the microcontrollers connected to the ESC.

The EtherCAT:

- Involves MainDevice (or MDevice) and SubordinateDevice (SubDevice) setup where SubDevice nodes are physically connected
- Specializes in precise, low jitter synchronization across SubDevice nodes
- Uses IEEE 802.3 Ethernet physical layer and standard Ethernet frames

A list of relevant terms and definitions are listed in Table 35-1.

Table 35-1. Abbreviations

Name	Definition
CPU1	Main CPU1 subsystem on this MCU
CPU2	CPU2 subsystem on this MCU
CPU3	CPU3 subsystem on this MCU
DIGIO	Digital IO profile
ENI	EtherCAT Network Information
ESC	EtherCAT SubordinateDevice Controller
ESCSS or SS	Subsystem (specifically referring to EtherCAT Subsystem on this device)
ESI	EtherCAT SubordinateDevice Information
ET1100	Beckhoff EtherCAT SubordinateDevice controller
ETG	EtherCAT Technical Group
EtherCAT	Ethernet for Control Automation Technology
FMMU	Fieldbus Memory Management Units
HAL	Hardware Abstraction Layer
MII	Medium Independent Interface
NMIWDRS	NMI Watchdog Reset
PDI	Processor Data Interface
POR	Power-on-Reset
SSC	EtherCAT SubordinateDevice Stack Code
SII	SubordinateDevice Information Interface
WDRS	Watchdog Reset
XRS	External Reset

35.1.1 EtherCAT Related Collateral

Foundational Materials

- C29x Academy - Ethernet for Control Automation Technology (EtherCAT)

35.1.2 ESC Features

The ESC on this MCU provides the following functionality.

- Up to 2 MII ports to connect to EtherCAT PHYs
- Process data interface (PDI) through 16-bit asynchronous interface (ASYNC16)
- 64-bit distributed clocking.
  - Sync output signals to synchronize device events and latch input signals supporting time stamping for events.
  - Distributed clock features of SYNC0/1 (o/ps) and LATCH0/1 able to synchronize GPIOs and allow inputs from any GPIOs as well as other muxing options for internal device events.
- 8 Field bus Memory Management Units (FMMUs)
  - Supports all native types of RD/, WR/, RDWR, and built-in features of bit- and byte-addressing
- 8 Sync Managers
- I2C EEPROM interface
- Up-to 32 general-purpose inputs and 32 general-purpose outputs
- 2 SYNC and 2 LATCH signals connected to GPIO pads
- 16KB RAM with parity

35.1.3 ESC Subsystem Integrated Features

In addition to the ESC features, the following are the device-specific features provided by the integration of the ESC to the MCU:

- ESC access allocation to CPU1 subsystem, CPU2 subsystem, or CPU3 subsystem during initialization
- EtherCAT reset request from MainDevice can be routed to NMI or general interrupt controller on MCU
- RAM Parity error routed to NMI on MCU
- RTDMA access to EtherCAT RAM
- Up to 32 GPI (general-purpose inputs) and up to 32 GPO (general-purpose outputs) feature integrated in addition to 16-bit ASYNC PDI interface
- Interface to CLB
- I2C internal loopback feature for EEPROM Emulation
- Distributed clock feature of SYNC0 and SYNC1 able to synchronize PWMs, generate interrupt and RTDMA requests, trigger ECAP capture, or allow external component action through GPIO access
- EtherCAT SYNC0 and SYNC1 pulse can trigger a CLA task
- Distributed clock feature of LATCH0 and LATCH1 allowing inputs from any GPIO or PWM crossbar triggers

35.1.4 ESC versus Beckhoff ET1100

Table 35-2 details a comparison between the ESC IP Core implementation and the Beckhoff's ET1100 ESC.

Table 35-2. ESC versus Beckhoff ET1100

Feature	ESC	Beckhoff ET1100
Transmission Speed	100Mbit/s	100Mbit/s
Number of Ports	2 (MII Only)	4 (MII or EBUS)
FMMUs	8	8
SyncManagers	8	8
RAM (KByte)	16KB	8KB
Distributed Clocks	Yes, 64-bit	Yes, 64-bit
EBUS Support	No	Yes
Process Data Interfaces (PDI)	16-bit ASYNC	Digital I/O SPI 8-bit ASYNC/SYNC 16-bit ASYNC/SYNC

35.1.5 EtherCAT IP Block Diagram

Figure 35-1 shows the general functionality of etherCAT IP from Beckhoff. This chapter discusses how the etherCAT IP is integrated into the MCU.

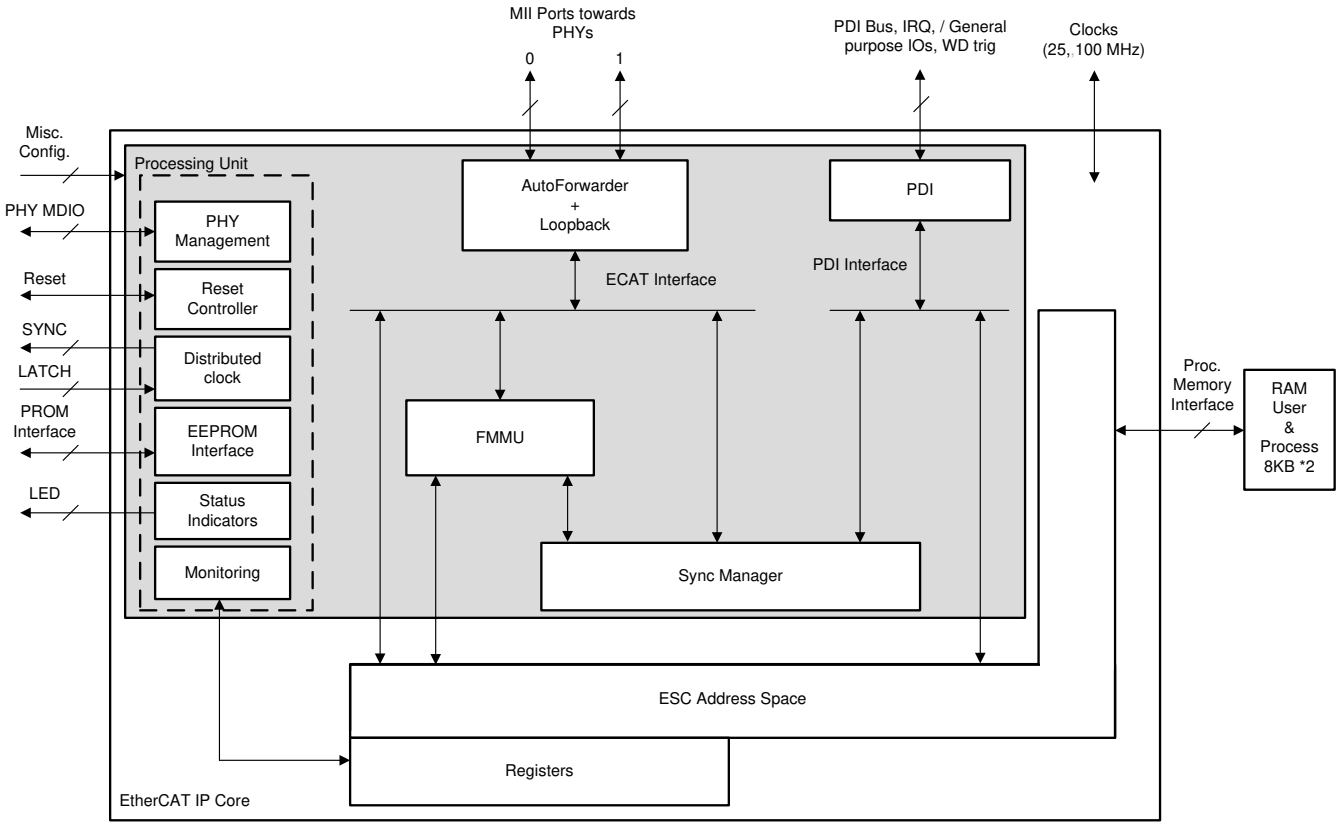

Figure 35-1. EtherCAT IP Block Diagram

35.1.6 ESC Functional Blocks

The following introduces each of the sub-blocks. For more details, refer to the Beckhoff EtherCAT documentation.

35.1.6.1 Interface to EtherCAT MainDevice

The EtherCAT MainDevice is a remote entity normally implemented through the device with ethernet switch capability. Beckhoff suggests using either a standard ethernet physical layer interface through MII or RMII protocol, or using a low-voltage differential pair signaling with EBUS protocol. Per Beckhoff specification, up to 4 PHY ports can be supported. In this MCU, implementation of ESC:

- Only MII is supported for Ethernet PHY interface
- ESC supports only 2 PHY ports

35.1.6.2 Process Data Interface

Process data interface (PDI) is a connection from the ESC IP to the microcontroller and SubordinateDevice application. The implementation of the ESC on this MCU supports a 16-bit asynchronous interface (ASYNC16) to the local host only

35.1.6.3 General-Purpose Inputs and Outputs

Since this MCU does not support digital I/O PDI interface, the ESC supports general-purpose I/O that allows 32 GPI and 32 GPO signals. These EtherCAT GPI/GPOs can be programmed to be either driven by (or drive) device I/O pins or be driven by (or drive) the same I/O pins after qualifying them using internal events. Refer to Section 35.2.9 for more details.

35.1.6.4 EtherCAT Processing Unit (EPU)

The EtherCAT Processing Unit (EPU) receives, analyzes, and processes the EtherCAT data stream. The EPU is logically located between port 0 and port 1. The main purpose of the EPU is to enable and coordinate access to the internal registers and the memory space of the ESC, which can be addressed both from the EtherCAT MainDevice and from the local application by way of the Processor Data Interface (PDI). Data exchange between the MainDevice and SubordinateDevice application is comparable to a dual-ported memory (process memory), enhanced by special functions; for example, for consistency checking (SyncManager) and data mapping (FMMU). The EPU contains the main function blocks of the EtherCAT SubordinateDevices besides Auto-Forwarding, Loop-back function, and PDI.

- **Auto-Forwarder:**
  - The Auto-forwarder function includes receiving EtherCAT frame, checksum computation and verification, timestamp capture for received frames, and forwarding to Loop-back component.
- **Loop-back Function:**
  - For the two-port implementation on this device, port 3 and port 2 are looped back by design, as shown in Figure 35-2.
  - Port 0 is a special port that is always connected to the MainDevice while designing the topology. At egress, port 0 acts as a terminal point for the network connected downstream; hence, any circulating packets get dropped at port 0 in the event of port 0 being looped-back.
  - In the event of a network or link loss downstream to the ESC port 1, the packets end in loopback.

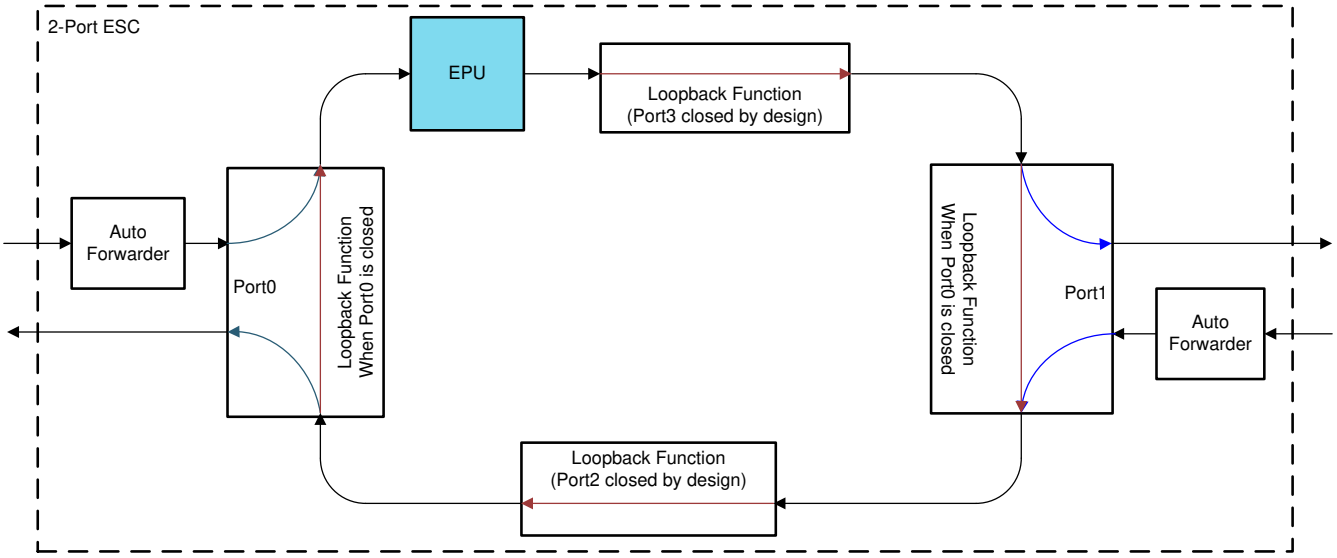

Figure 35-2. Two-port ESC Description

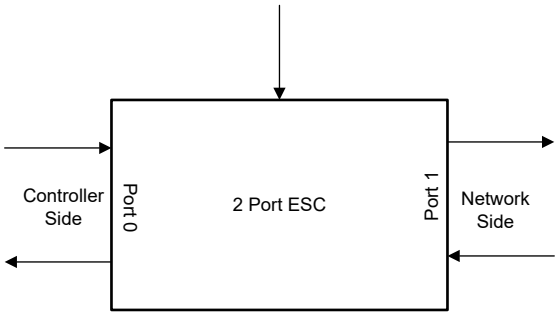

Figure 35-3. Two-port Block Diagram in EtherCAT Topology

35.1.6.5 Fieldbus Memory Management Unit (FMMU)

The fieldbus memory management unit (FMMU) maps the logical addresses of the memory elements in ESC to a physical address that allows the remote EtherCAT MainDevice to address registers and process RAM as one memory-map that can be accessed across the EtherCAT network. Mapping can be done up-to bit-wise mapping.

35.1.6.6 Sync Manager

The integrity and security of the data in dual-port memory across the MainDevice and local application is maintained by the sync manager. The sync manager allows data to be accessed as buffered or mailbox, where either there is definite read and write space or sequence defined for both of the MainDevice entities.

35.1.6.7 Monitoring

The monitoring unit contains error counters and watchdogs. The watchdogs are used for observing communication and returning to a safe state in case of an error. Error counters are used for error detection and analysis.

35.1.6.8 Reset Controller

The reset controller aggregates the internal/external resets as well as asserts the reset to external pin, which can be connected to device pin to reset companion devices on the board.

35.1.6.9 PHY Management

The PHY control is maintained through the MDIO interface which allows the configuration of the PHYs and enabling advanced features of link detection, if present, be enabled.

35.1.6.10 Distributed Clock (DC)

Distributed clocks (DC) allows the tracked time at ESC be synchronized across the EtherCAT network, which makes precisely timed events possible throughout the network. Events can be realized with triggers from ESC outputs that are programmed to create a toggle at a certain absolute time tracked by the ESC or through sampling of timestamp of certain system event inputs to ESC that can further be used for synchronizing the time.

- Refer to Section 35.2.10 for more details.

35.1.6.11 EEPROM

Every ESC requires non-volatile memory to store the configuration contents of the ESI (EtherCAT SubordinateDevice Information) that are accessed by the MainDevice normally before enabling the ESC in the network. Size of the memory is configurable with a minimum of 1K bit up to 4M bit are supported depending on the ESC. This non-volatile memory is supported in simplest form by the ESC IP core as serial access EEPROM.

- For ESI EEPROM Layout and mandatory information, refer to the ESC Hardware Data Sheet Section I - Technology (ethercat_esc_datasheet_sec1_technology) document provided by Beckhoff/ETG at www.beckhoff.com.
- EEPROM is supported using the I2C interface on this device and is further explained in Section 35.2.8.

35.1.6.12 Status / LEDs

ESC supports the status indication of application activity, link status and link errors which can be utilized for visual status indication through LEDs.

35.1.7 EtherCAT Physical Layer

ESC devices with Ethernet Physical Layer are able to support MII interfaces, RMII interfaces, and EBUS interfaces. Since RMII PHYs include TX FIFOs, the RMII PHYs increase the packet forwarding delay of an ESC device as well as the jitter. RMII as an Ethernet Physical Layer is not supported on this device due to these reasons and therefore only the MII interface is supported.

- On this device, only MII is supported (RMII and EBUS are not supported)
- Refer to the **ESC Application Note - PHY Selection Guide (an_phy_selection_guide)** provided by Beckhoff/ETG at www.beckhoff.com for additional PHY selection details.

Table 35-3 depicts the number of pins needed for MII interface for two ports.

Table 35-3. EtherCAT Physical Layer Signals

Pin	Number of Pins for 2 Ports	MII	Direction	Description
nMII_Link	2	Yes	IN	Input signal provided by the PHY, if a 100Mbps (full duplex) link is established
RX_CLK	2	Yes	IN	Receive Clock
RX_DV	2	Yes	IN	Receive Data valid
RX_DATA[1:0]	4	Yes	IN	Receive Data
RX_DATA[3:2]	4	Yes	IN	Receive Data
RX_ERR	2	Yes	IN	Receive error
TX_CLK(1)	2	Optional	IN	Transmit Clock
TX_ENA	2	Yes	OUT	Transmit Enable
TX_DATA[1:0]	4	Yes	OUT	Transmit Data
TX_DATA[3:2]	4	Yes	OUT	Transmit Data
MCLK	1	Yes	OUT	MII Interface clock
MDIO	1	Yes	BI-Directional	MII Interface Data
Total Pins:	28 (required) + 2 (optional)			

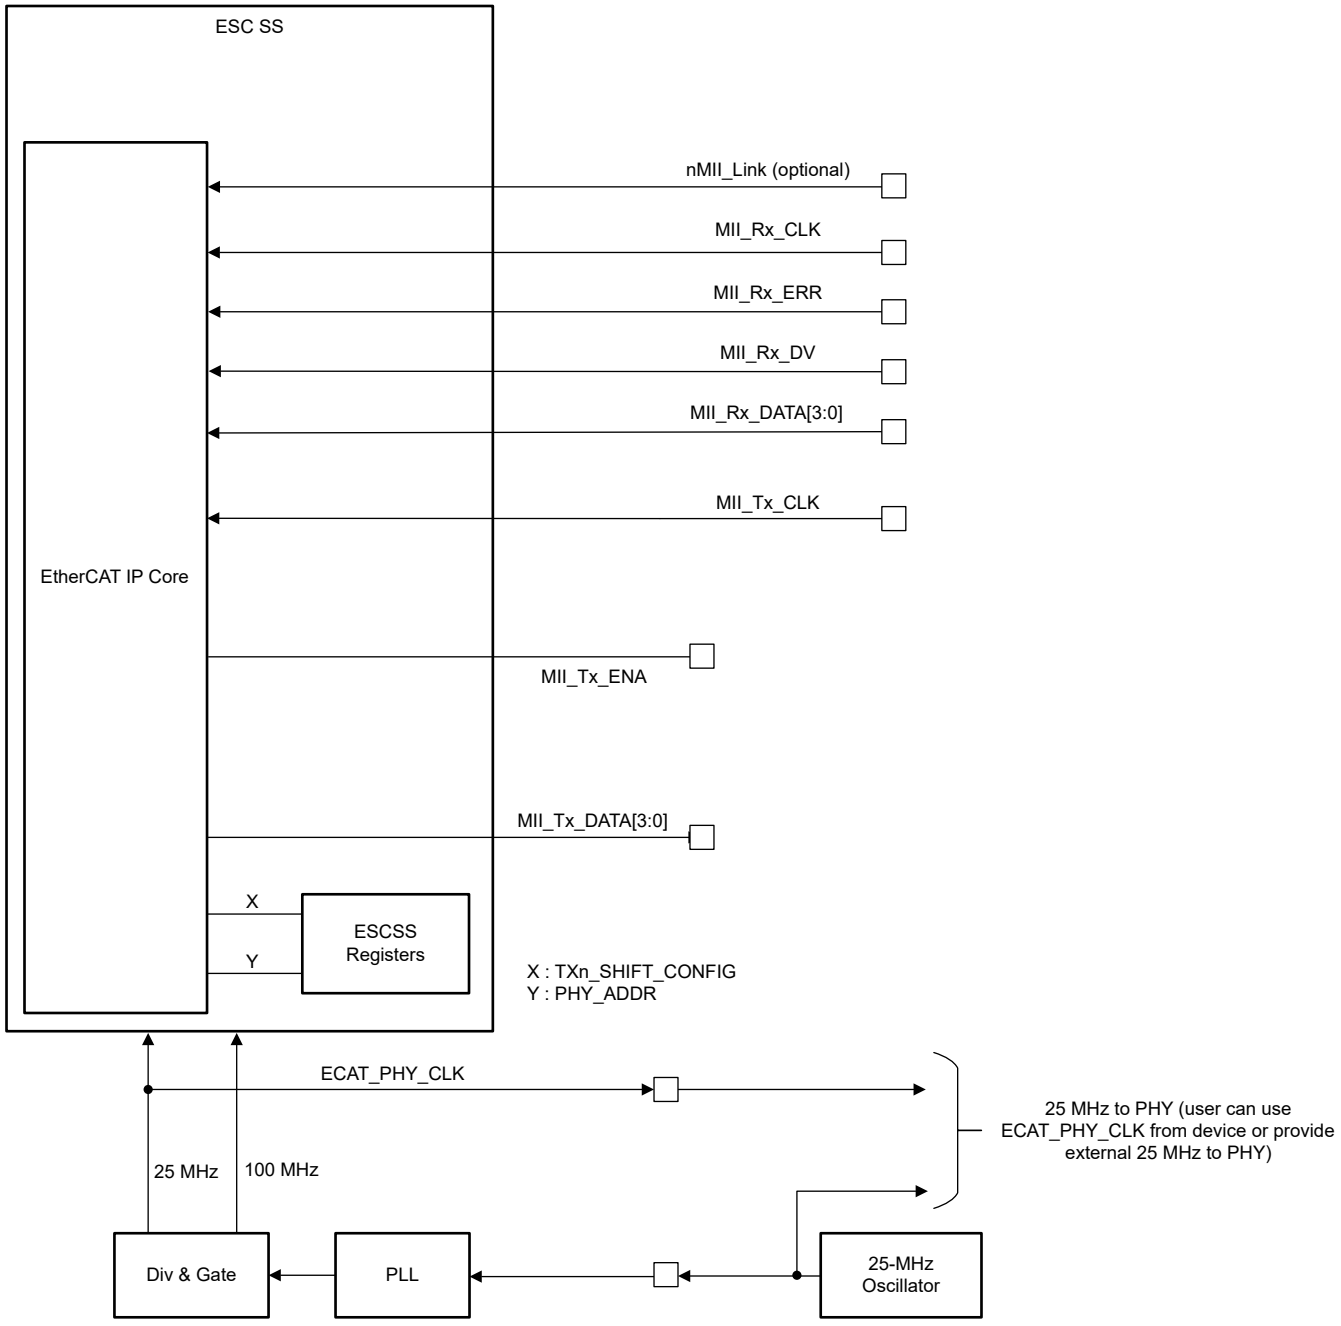
(1) The TX_CLK signal is optional when using the TX_SHIFT register for manual compensation; however, it is recommended to route the TX_CLK signals to the MII ports for improved accuracy and to avoid the need for manual compensation.

35.1.7.1 MII Interface

Ethernet IEEE802.3 specified MII interface is supported with possible minor variation in clocking to optimize the clock delay to operate the Tx FIFO. Unlike regular integration of Tx clock being sourced by the PHY, the ESC implementation allows the common source clock between PHY and ESC be used for Tx logic. The option is selected by manual Tx shift compensation which allows Tx-Data and Tx-En be compensated in steps of 10 ns to meet the timing requirements of data sampling at the PHY.

The following signals are used by the ESC to connect to an Ethernet PHY. The MDIO pins are not shown in Figure 35-4, as these pins are covered in the next section.

The MII signals TX_ERR, COL and CRS are not used by the ESC. These are not available on the MCU for EtherCAT.



Note: The PHY reset signal is also not shown in the diagram.

Figure 35-4. ESC PHY Interface Diagram

If an ESC MII interface is not used, LINK_MII has to be tied to the logic value high that indicates no link. RX_CLK, RXD, RX_ER, and especially RX_DV are connected to GND and this is taken care of by design internally when the functional IO mux for the RX pins is not configured when the IP is out of reset. The TX outputs can be left unconnected, by not configuring the Functional IO mux for respective EtherCAT functionality, unless the TX outputs are used for ESC configuration.

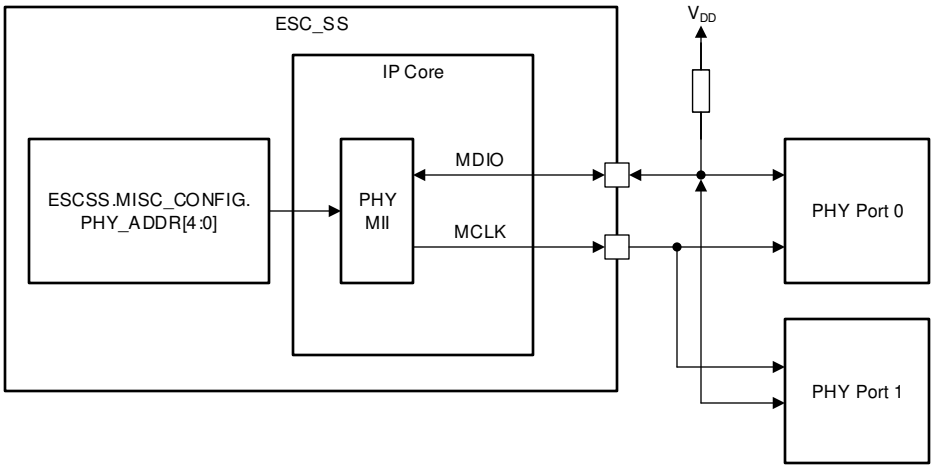
35.1.7.2 PHY Management Interface

Most ESCs with MII/RMII ports use the MII management interface for communication with the Ethernet PHYs. Most ESCs do not use the management interface for link detection or configuration of link modes. For link detection, it is recommended that the ESC use a separate signal (LINK_MII). The MII management interface can be used by the EtherCAT MainDevice – or the local MCU. Enhanced MII link detection uses the management interface for restarting auto-negotiation after communication errors occurred.

On this ESC, it is possible to make use of the MII management interface for link detection and PHY configuration.

Note

Note that the EtherCAT link status through the MII management interface option must be enabled only if a Gigabit PHY is to be supported; the EtherCAT link must not be enabled if needing to support both 10/100 and Gigabit PHY. For this reason, the link status through the MII management interface is disabled on this ESC. Instead, use the LINKACT or PHY MII_LINK signals for link status purposes.



Note: The MDIO must have a pull-up resistor (4.7 kOhm recommended) externally. MCLK is driven rail-to-rail, idle value is high.

Figure 35-5. PHY Management Interface Connectivity

35.1.7.2.1 PHY Address Configuration

The ESC typically addresses the Ethernet PHYs using the logical port number plus the PHY address offset. The Ethernet PHY addresses must correspond with the logical port number, so PHY addresses 0 and 1 are used.

A PHY address offset of 0 to 31 can be applied, which moves the PHY addresses to any consecutive address range. The ESC module expects logical port 0 to have PHY address 0 plus the PHY address offset. The PHY address offset can be selected in register ESCSS_MISC_CONFIG.PHY_ADDR[4:0].

35.1.7.2.2 PHY Reset Signal

The PHY reset signal is generated out of the ESC module. If required to release both, the PHY and ESC module synchronous out of reset, this signal can be used. Since there are no pull devices active on the MCU during and after reset, a pull down resistor must be added on this signal on the board level.

In some case, PHYs can be released from reset after releasing the ESC module. To generate a delay, the pin for nPHY_RESET can be used as an I/O and must be switched later to the alternate output function.

35.1.7.2.3 PHY Clock

The PHY Clock connectivity is shown in Figure 35-4. On this MCU, the user has an option to clock the PHY using the ESCSS_PHY_CLK signal if needed; otherwise, the user can chose to provide an external 25MHz source to the PHY and ESC (both must be clocked from the same source). For more details regarding providing PHY clock, refer to Section 35.2.6.2 and see the EtherCAT data sheet from Beckhoff.

Note

Beckhoff documents strict accuracy (ppm) requirements for the shared 25MHz ESC and PHY clock. Special care must be taken within a design to make sure the EtherCAT clocking requirements are met. Relying on external components (oscillator and clock buffer) for the 25MHz source are recommended. Validation of a design during normal operating conditions can be necessary to confirm clocking requirements are adequately met, especially if using the ESCSS_PHY_CLK signal.

35.1.8 EtherCAT Protocol

EtherCAT uses standard IEEE 802.3 Ethernet frames, thus a standard network controller can be used and no special hardware is required on the MainDevice side. EtherCAT has a reserved EtherType of 0x88A4 that distinguishes this from other Ethernet frames. Thus, EtherCAT can run in parallel to other Ethernet protocols.

- EtherCAT does not need the IP protocol; however, the EtherCAT can be encapsulated in IP/UDP.
- The ESC processes the frame in hardware; therefore, communication performance is independent from processor power.

An EtherCAT frame is subdivided into the EtherCAT frame header followed by one or more EtherCAT datagrams. At least one EtherCAT datagram has to be in the frame. Only EtherCAT frames with Type 1 in the EtherCAT Header are currently processed by the ESCs. The ESCs also support IEEE802.1Q VLAN Tags, although the VLAN Tag contents are not evaluated by the ESC.

- If the minimum Ethernet frame size requirement is not fulfilled, padding bytes are added. Otherwise, the EtherCAT frame is exactly as large as the sum of all EtherCAT datagrams plus EtherCAT frame header.
- For further reading, including details on network time or network propagation delay, refer to the ESC Hardware Data Sheet Section I - Technology (ethercat_esc_datasheet_sec1_technology) document provided by Beckhoff/ETG at www.beckhoff.com.

35.1.9 EtherCAT State Machine (ESM)

The EtherCAT State Machine (ESM) is responsible for the coordination of the MainDevice and SubordinateDevice applications at start up and during operation. State changes are typically initiated by requests from the MainDevice. The state changes are acknowledged by the local application after the associated operations have been executed. Unsolicited state changes of the local application are also possible.

There are four states (see Figure 35-6) an ESC can support, plus one optional state:

- Initialize (Init)
- Pre-Operational
- Safe-Operational
- Operational
- Bootstrap (Optional)

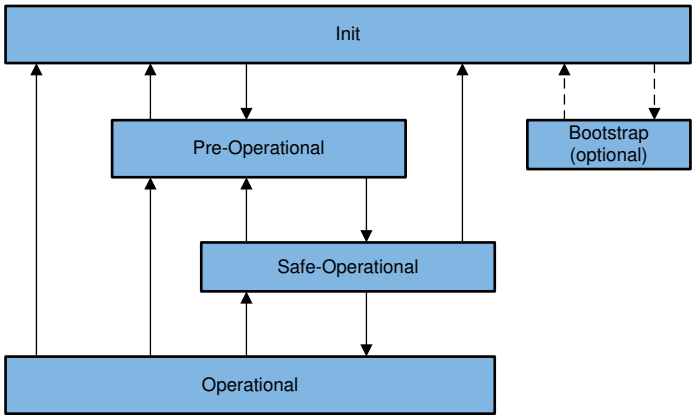


Figure 35-6. EtherCAT State Machine

Note

Not all state changes are possible, for example, the transition from Init to Operational requires the following sequence: Init → Pre-Operational → Safe-Operational → Operational.

35.1.10 More Information on EtherCAT

- For further information on EtherCAT, refer to the EtherCAT specifications, available from the EtherCAT Technology Group (ETG, www.ethercat.org).
- Refer to the IEC standard “Digital data communications for measurement and control – Fieldbus for use in industrial control systems”, IEC 61158 Type 12: EtherCAT, available from the IEC (www.iec.ch).
- Documentation on Beckhoff Automation ESC are available at the Beckhoff website (www.beckhoff.com), for example, data sheets, application notes, and ASIC pinout configuration tools.

35.1.11 Beckhoff® Automation EtherCAT IP Errata

Table 35-4 details the Beckhoff ®Automation errata of the EtherCAT IP integrated onto this device.

Table 35-4. EtherCAT IP Errata

Errata Number	Description
ER#156	WKC increment for reading reserved FMMU registers (+0xD-+0xF)
ER#158	WKC increment for writing 0x0914-0x0917
ER#162	ESC DL Control (0x0101) loop setting Auto-Close (01): if port waits for write access to be opened, the temporary loop bit (0x0100[1]) is not taken into account when a write command to ESC DL Control occurs.
ER#164	EEPROM FSM cannot accept another command within 1680 ns after finishing a previous command
ER#165	EtherCAT reset register 0x0040 cannot be written using VLAN tagged frames, because state is reset due to double ECAT_CLEAR. VLAN tagged frames are rarely used for EtherCAT.
ER#168	Changing SyncSignal cycle times during activation can lead to extremely long cycle times, resulting from (intermediate) violation of the minimum delay between two consecutive pulses. For example, changing Sync1 from a few ns before Sync0 to a few ns after Sync0 results in a missed Sync1 time, which can take up to several 32/64-bit turn-arounds until the next pulse occurs. Changing cycle time from PDI can result in usage of intermediate, inconsistent values, which can result in unwanted cycle times or extremely long delays as above.

35.2 ESC and ESCSS Description

This section details the aspects of the ESC integration in the MCU. On this MCU, the ESC is integrated such that the ESC is accessed by either the CPU1 (main) subsystem or the CPU2 or the CPU3 subsystem. The MCU with the ESC functions as an EtherCAT SubordinateDevice device.

Figure 35-7 shows the ESC on this MCU.

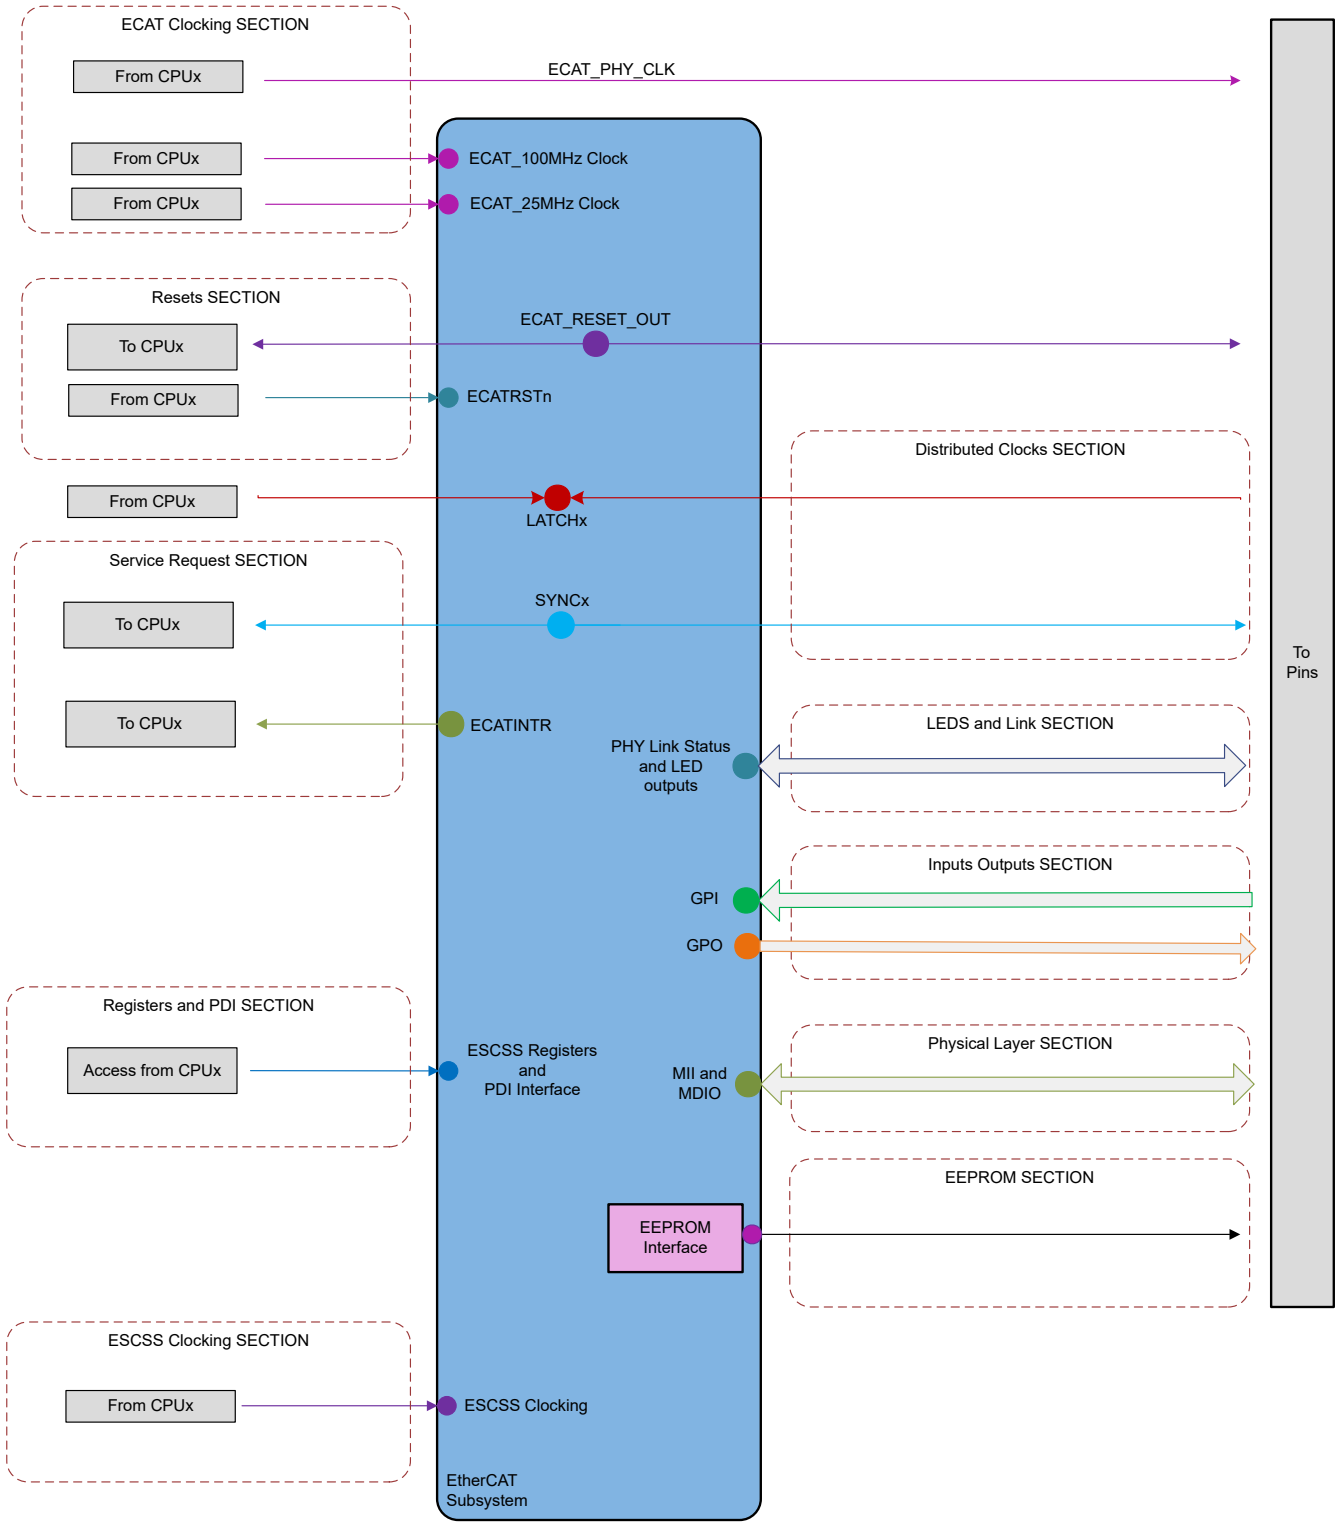

Figure 35-7. ESC Integration on MCU

Table 35-5. ESC Integration Figure Sections

ESC Figure Sections	More Information Links
ECAT/ESCSS Clocking	ESC Clocking
Resets	ESCSS Resets
Service Request	SYNC Signals Interrupts and Interrupt Mapping
Registers and PDI	ESC SubSystem
Distributed Clocks	Distributed Clocks - Sync and Latch
LEDS and Link	LED Controls
Inputs Outputs	General Purpose Inputs and Outputs
Physical Layer	EtherCAT Physical Layer
EEPROM	SubordinateDevice Node Configuration and EEPROM

There are various actions that the controlling processor (CPU1/CPU2/CPU3) needs to perform in response to actions initiated by the EtherCAT MainDevice meant for this particular SubordinateDevice . All these interactions take place through one of the following:

- The 16-bit asynchronous interface through which registers and RAM of the EtherCAT IP are read/written.
- An interrupt request going from the ESC to the Local Host (CPU1 or CPU2 or CPU3).
- SYNC0 and SYNC1 pulses generated by the ESC that are used as triggers for initiating further action.
- LATCH0 and LATCH1 that are sampled by the ESC.
- EtherCAT general-purpose inputs and outputs.

35.2.1 ESC RAM Parity and Memory Address Maps

This section details the ESC RAM parity logic, CPU1 ESC memory address map, and CPU2 ESC memory address map.

35.2.1.1 ESC RAM Parity Logic

The ESC RAM has parity logic to make sure the data integrity of the contents. The byte-wide parity is implemented, as PDI accesses to RAM can be done byte wide. To make sure that errors in parity logic itself do not mask the memory error, redundant parity generation logic is used. The parity generated by both logics is compared to make sure safe operation of the memory accesses. Use the INITIATE_MEM_INIT bit from the ESCSS register to trigger the memory initialization.

35.2.1.2 CPU1 ESC Memory Address Map

When the ESC is allocated to CPU1, Table 35-6 is the memory map and associated details.

Table 35-6. ESC Address Map on CPU1

Memory Map Region	Memory Region	Accessed Through	Parity Scheme	RTDMA Access	CLA Access	CPU2 Access	Security	Access/ Bus
DPRAM memory map (16KB)	0x0005 0800 - 0x0005 27FF	PDI interface of ESC	1 parity bit for 8 bits of data	Yes	No	No	No	Async
ESC Registers	0x0005 0000 - 0x0005 07FF	PDI Interface of ESC	No	No	No	No	No	Async
ESCSS Registers(1)	0x0005 7E00 - 0x0005 7FFF	Direct Access	No	No	No	No	No	VBUS32

(1) When register access protection is enabled, all write accesses are blocked; however, a violation interrupt is not generated in the event of an attempted write access.

35.2.1.3 CPU2 ESC Memory Address Map

When ESC is allocated to CPU2, Table 35-7 is the memory map and features.

Table 35-7. ESC Address Map on CPU2

Memory Map Region	Memory Region	Accessed Through	Parity Scheme	RTDMA Access	Bus/Protocol	Security
ESC RAM memory map (16KB)	0x400A 1000 - 0x400A 4FFF	PDI interface of ESC	1 parity bit for 8 bits of data	Yes	System/PDI	No
ESC Registers	0x400A 0000 – 0x400A 0FFF	PDI	No	No	System/PDI	No
ESC_SS Registers	0x400A FC00 – 0x400A FFFF	Direct Access	No	No	System/VBUSP	No

35.2.2 Local Host Communication

Figure 35-8 shows how the ESC and ESC subsystem connects to the local host subsystem. The local host subsystem can include the CPU (CPU1 or) of the device and the RTDMA engine as the bus controller accessing the ESC. This local host subsystem is acting upon the commands that are sent by the EtherCAT MainDevice in the form of EtherCAT datagrams.

The 16-bit asynchronous interface and the interrupt request line are the main channels through which the local host subsystem interacts with the ESC. The interrupt request line can be used to trigger actions based on ESC internal events, exception conditions or time synchronized events. The RTDMA engine is used to transfer the contents from the process data memory to system RAM on any of these events. The user application needs to select the events that act as interrupts or RTDMA requests. The mask and clear events for the interrupt causes are configured to be accessed by the CPU/Co-processor that is controlling the ESC.

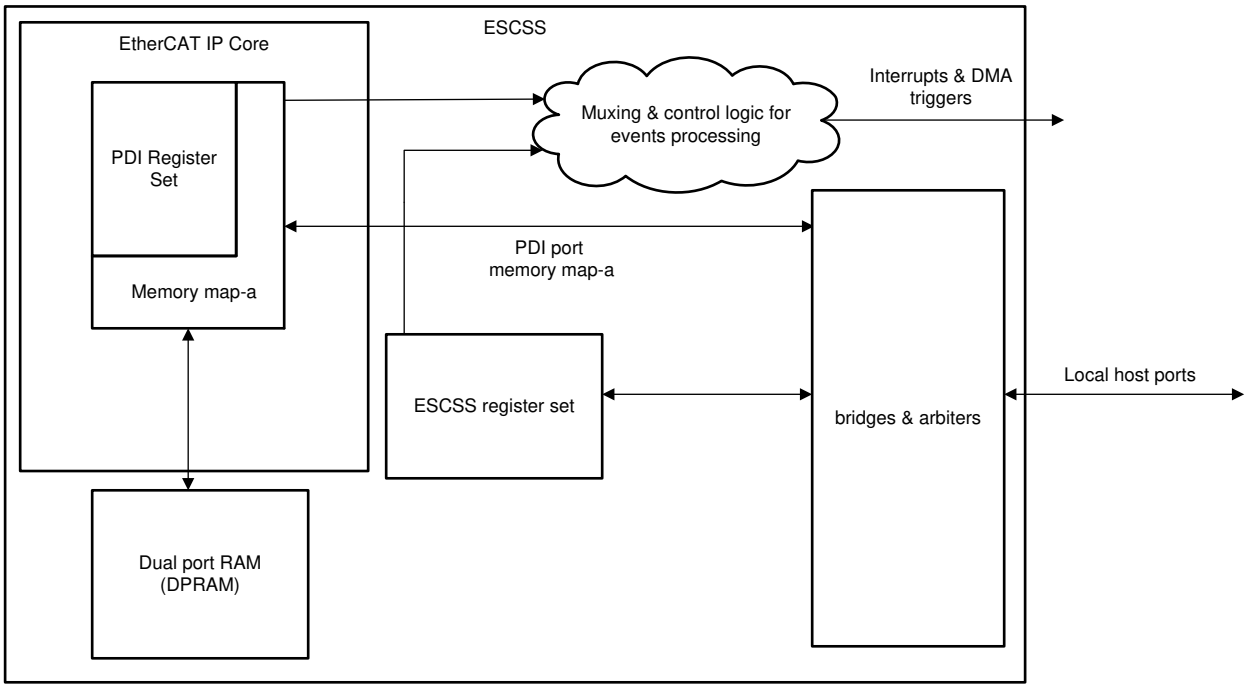

Figure 35-8. Interaction of ESCSS with the CPU Subsystem

35.2.2.1 Byte Accessibility Through PDI

The ESC has a few registers which need byte wide access to affect the functionality. The EtherCAT implementation on this MCU is as follows:

- CPUs support byte accesses

35.2.2.2 Software Details for Operation Across Clock Domains

The registers accessible from the CPU are in the system clock domain and are synchronized to the PDI clock before being used within the EtherCAT IP. Given the frequency ratios and different styles of synchronization schemes, the application needs to assume there is a delay in getting the values transferred from one domain to other. Such a delay can vary based on the frequency of system clock and type of synchronizer used in the path.

For example, a system clock of 200MHz and ESCSS running at 100MHz requires at least 10 clock-system clock cycles delay before values are affected on the other side. If a write occurs to the PDI and some other action is performed elsewhere (not involving the PDI), then the software must perform a simple read to make sure that the write is complete.

35.2.3 Debug Emulation Mode Operation

There are two aspects of the EtherCAT IP operation that need to be considered from a debug emulation stand point.

- **Debugger Writes/Reads of EtherCAT IP registers/memories Condition:** The EtherCAT IP does not have any mechanism to identify a debug initiated read/write. Debug accesses to the registers or the ESC RAM can affect the state of the EtherCAT IP. This is addressed by the following:
  - **CPU1/CPU2/CPU3:** The ENABLE_DEBUG_ACCESS bit must be set in the ESCSS Access Control Register to enable user access to the ESC RAM and EtherCAT registers for the purpose of debug. By default, this is disabled.

35.2.4 ESC SubSystem

The EtherCAT SubordinateDevice Controller SubSystem (ESCSS) wraps the ESC core with required register configurations and required logic for different functions of the EtherCAT and RAM (ESC RAM). This section covers the ESCSS integration aspects. Figure 35-9 shows the EtherCAT subsystem Integration.

- **ESCSS configuration registers interface** is the port for accessing the critical device level configurations which are a must have for the ESCSS to function.
- **ESCSS register interface** has control and status registers including SYNC, LATCH configurations, interrupt related controls, and GPIO related controls.
- **PDI Async interface** is a 16-bit wide data interface that allows the local application to access the registers internal to the EtherCAT IP Core as well as the dual-port memory (ESC RAM) through the SyncManager and the FMMUs.

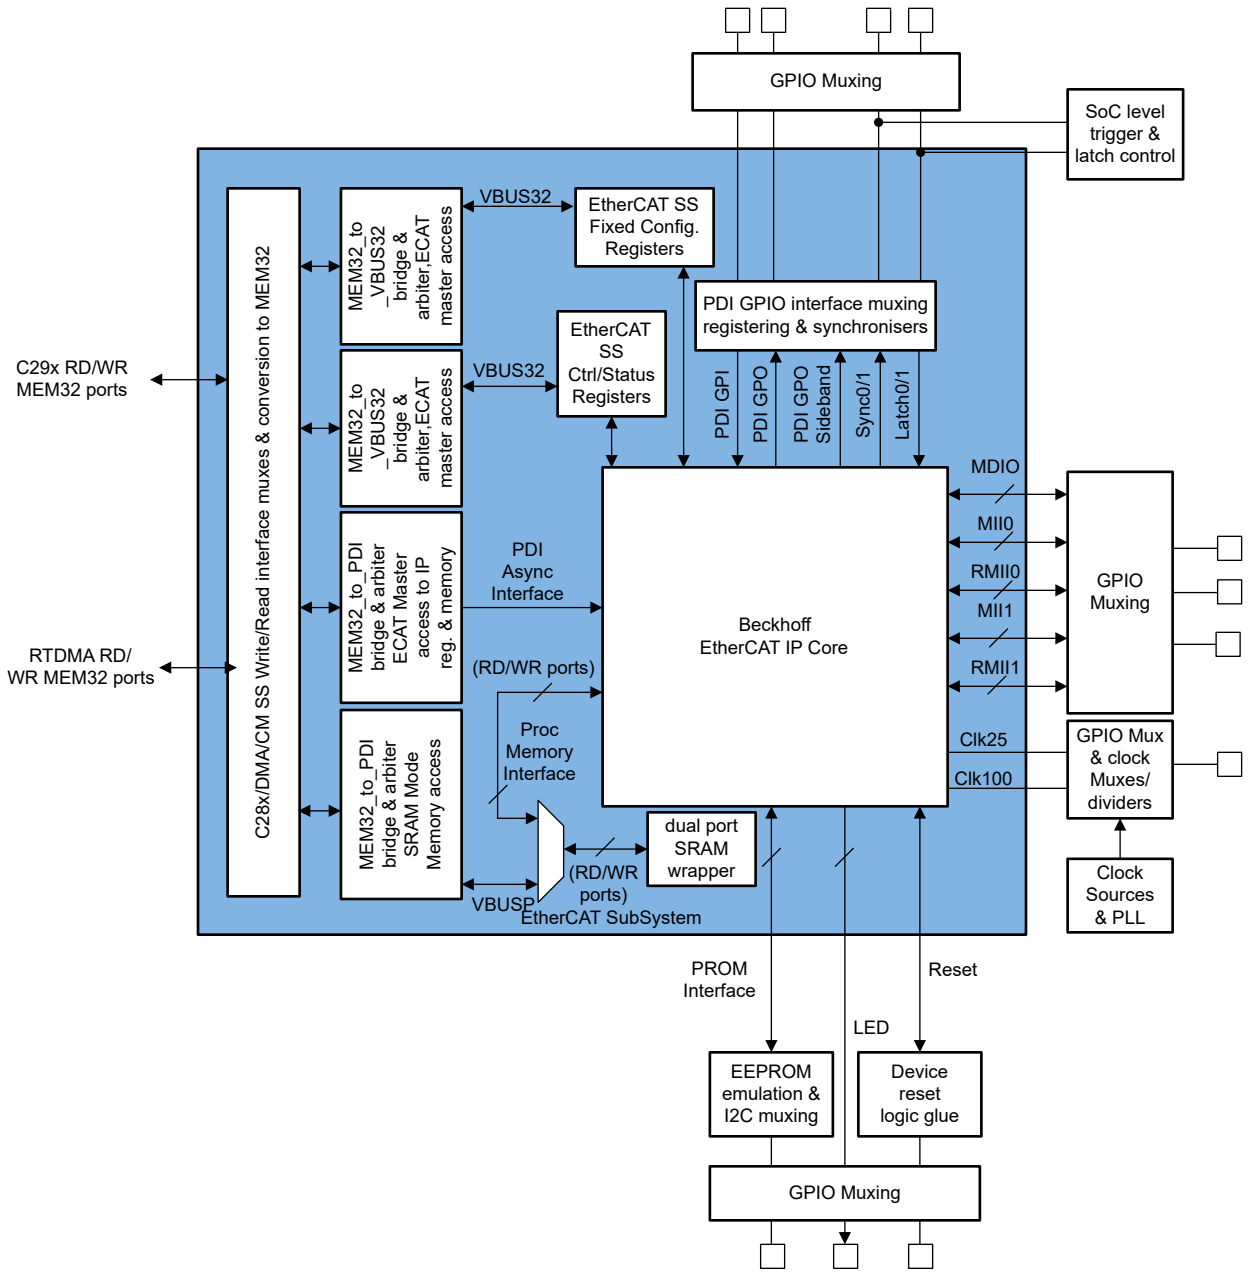

Figure 35-9. ESCSS Wrapper

35.2.4.1 CPU1 Bus Interface

Interface to the CPU1 core is retained at the ESCSS boundary as a native mem32 interface that connects the RD and WR ports independently to all of the SubordinateDevice entities within the ESCSS.

- CPU1 MEM32 RD and WR ports: Configuration Registers, Control/Status Registers, PDI
- CPU1 RTDMA MEM32 RD and WR ports: PDI (access to ESC RAM only)

35.2.4.2 CPU2/CPU3 Bus Interface

The CPU2/CPU3 interfaces involve a bus that is arbitrated between the CPU2/CPU3 and RTDMA accesses to the PDI .

- CPU2/CPU3 bus ports: Configuration Registers, Control/Status Registers, PDI

- RTDMA ports: PDI (access to ESC RAM only)

35.2.5 Interrupts and Interrupt Mapping

The ESC has one interrupt line that can be connected to the local host (CPU1 or CPU2 or CPU3) that is called PDI IRQ from the ESC. Besides this, there are other interrupt causes generated within the ESCSS. These are aggregated to a total of 4 interrupt lines that are connected to the local host core.

Table 35-8 summarizes these exceptions and the mapping. There are 4 interrupt lines provided for ESCSS which are: ECATSS_Intr, RESET_OUT_Intr, SYNC0_Intr and SYNC1_Intr. Each of these causes have an independent set of mask/clear/set controls and raw/masked interrupt status flags. This allows independent cause servicing on the exception event with flexibility to mask or service the desired set of causes. All these interrupts are mapped onto PIPE on CPU1, CPU2, and CPU3. Refer to the *System Control and Interrupts* chapter for details on the interrupt numbers.

In the event that the same exception is available to the multiple bus MainDevice cores of the local host CPU, the application software is expected to make sure that clearing of the RIS is a software synchronized event between those MainDevices and there is no stale exceptions pending for one controller while the other clears the RIS. In other words, there is no separate exception cause (RIS/MIS) copy per MainDevice but are common interrupt registers for the local host across MainDevices.

Table 35-8. Service Request Generation Map

Source	Description	MainDevice				
		CPU1	CLA	CPU1 RTDMA	CPU2/CPU3	RTDMA
EtherCAT IRQ	AL Event Request of the ESC	ECATSS_ intr	ECATSS_ intr	Not Available	ECATSS_ intr	Not Available
PDI Interface Timeout Error	PDI Interface WatchDog timeout error	ECATSS_ intr	ECATSS_ intr	Not Available	ECATSS_ intr	Not Available
EtherCAT RESET_ OUT Event	RESET_OUT can be programmed as interrupt to the CPU to either complete the reset sequence with required pre-steps if an or acknowledge the reset request in some other way. Given the high priority nature of the signal independent interrupt line is allocated	RESET_ OUT_Intr	RESET_ OUT_Intr	Not Available	RESET_ OUT_Intr	Not Available
SYNC0 Event	Precise time event 2, can be used to start routine SYNC1_Intron cores or data transfer using RTDMA. Given the precise time and priority of these interrupts a separate interrupt line is dedicated.	SYNC0_ Intr	SYNC0_ Intr	SYNC_ DMAReq	SYNC0_ Intr	SYNC_ DMAReq
SYNC1 Event	Precise time event 1, can be used to start routine on cores or data transfer using RTDMA. Given the precise time and priority of these interrupts a separate interrupt line is dedicated.	SYNC1_ Intr	SYNC1_ Intr	SYNC_ DMAReq	SYNC1_ Intr	SYNC_ DMAReq

35.2.6 Power, Clocks, and Resets

This section details the ESCSS power requirements, clocking, and resets. The EtherCAT IP has 2 clock ports and one reset output. Since the PLLs, dividers, and gating is implemented as part of system control, this setup is always handled by CPU1 during the initialization sequence.

35.2.6.1 Power

The ESC module is inside the main power domain like other peripherals and there are no special considerations about the power-up or power-down sequences that need to be taken. Refer to the *System Control and Interrupts* chapter for different power modes.

35.2.6.2 Clocking

Two functional clock inputs are defined for the ESC: CLK25 (25MHz) and CLK100 (100MHz).

EtherCAT functional clock inputs CLK25 and CLK100 are sourced by the MCU clocking module either using SYSPLL or AUXPLL. At the SoC level, you have multiple options to choose from regarding what inputs are used for the SYSPLL or AUXPLL.

- Due to the 25ppm requirement for EtherCAT, an external oscillator of 25MHz is suggested to be used as the main clock source.
- A less accurate clock than 25ppm limits the ability of the ESC to act as the network reference clock. For practical reasons, clock accuracy must be the same or better than the Ethernet clock source that is 50ppm.

Note

- CLK25 and CLK100 are used for the ESC core operation. These two clocks and the clocks to the PHY **must have a common source**, which establishes a deterministic phase relationship between PHY clocks and ESC clocks.
- In MII mode, the 25MHz RX clock is sourced by the PHY while the TX clock from the PHY is optional (which effectively saves a pin). The phase differential between the PHY TX clock and CLK25 can be compensated to the TX data and TX EN using the manual compensation mode in increments of 10ns. Connecting the TX clock avoids the need to perform the manual compensation.

Figure 35-10 shows the clocks connectivity. Refer to the *System Control and Interrupts* chapter for additional details of the PLL source selections and clock dividers.

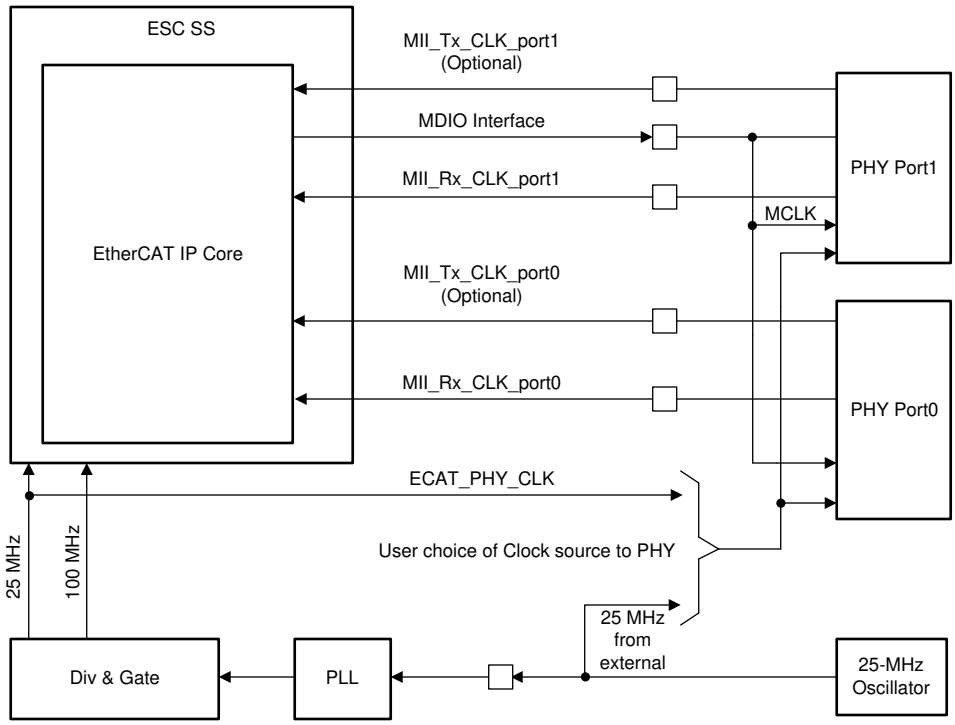

Figure 35-10. Clocking of ESC

In the case of a low-accuracy clock (up to 100ppm) being used, a clock accuracy of 25ppm cannot be feasible, then the following restrictions apply:

- RX FIFO size cannot be reduced lower than 7 (default for 100ppm), which in turn affects the latency of the transfer as the transfer starts after half of the FIFO full threshold, thus resulting in a RX Delay.
- This ECS cannot be used as the first SubordinateDevice from the MainDevice in the network, as typically the first SubordinateDevice from the MainDevice is treated as the reference clock for the distributed clocks functionality.
- The number of iterations required for synchronizing clocks (specially the drift computation) increases.

35.2.6.3 Resets

This section describes the ESCSS sources of reset. There are other conditional reset sources that can impact ESCSS and those include all the device level reset sources including: device pin reset “XRSN” or software initiated device level reset “SYSRSn”.

Note

Whenever the device comes out of reset, software must execute the following sequence to make sure that PHY can see the full stretching of the reset:

1. Configure the EtherCAT GPIOs
2. Put the ESCSS into soft reset
3. Bring the ESCSS out of soft reset

Refer to Section 35.3 more information on proper software procedure.

35.2.6.3.1 Chip-Level Reset

Chip-level resets (such as POR, XRS, WDRS, or NMIWDRS) are a MainDevice reset that resets the entire device including the ESC.

35.2.6.3.2 EtherCAT Soft Resets

ESCSS can be reset by three soft reset mechanisms, including:

- System control level software programmable (SOFTPRES23) that is reset only by chip-level and EtherCAT resets. Default keeps the ESC in reset that is released by the local application after setting the ESC ready for operation.
- Reset by a particular command sequence from the remote EtherCAT MainDevice.
- Reset by a particular command sequence from the local host application. (core only)

35.2.6.3.3 Reset Out (RESET_OUT)

Multiple reset sources of ESCSS are combined to make the reset vector that drives the EtherCAT and companion devices (PHYs) on this MCU. The RESET_OUT is asserted only when configured to be a reset. If configured as an interrupt or NMI, the local host completes the reset.

By default, RESET_OUT performs no action and must be setup to cause the reset to the EtherCAT core and PHY. The input events to RESET_OUT include the remote EtherCAT MainDevice, local host application, and EtherCAT soft reset.

When the intent is to perform a reset to the ESCSS and the device, the following options are available to reset the device after software has given a reset to the ESCSS:

- Use the system control SIMRESET register to generate a device reset.
- Use the watchdog or NMIWD to generate a device reset.

35.2.7 LED Controls

There are four LED outputs from the ESC that can be routed out of GPIO to indicate different status of the ESC. Table 35-9 is the recommendation for applications on the usage, especially for the pin sensitive systems that can support this and still meet the intent. All the LED functions are routed to the peripheral pin mux and the user must configure the LEDs as per the available pins.

Table 35-9. Status LED Options and Priority

LED	Priority Order	Function	Recommendation	Usage Priority
RUN	5	Shows the status of ESC state machine with different blinking patterns.	In the case where color LEDs are not supported, then this needs to be supported.	Must
ERR(1)	4	Indicates the Error in ESC operation.	In the case where color LEDs are not supported, then at least the Error status needs to be reported.	Must
STATE	2	Combination of the RUN and ERR LED.	Not supported on this device.	-
LINKACT0 (ESC_LED_LINK0_ACTIVE)	3	Link Active Status for link towards the MainDevice.	Link Status on MainDevice side (Port0) is important to know, if the ESC and network downstream is part of the network or not. The prior ESC loopbacks, if this node fails. The status on this LED eases the debug.	Desired
LINKACT1 (ESC_LED_LINK1_ACTIVE)	1	Link Active status for link towards Network side.	The Link status on the network side (Port 1) is critical from continuity through the ESC point; hence, this is kept highest priority status reporting.	Must

(1) Driven by software and not the ESC on this device.

The PHY MII_LINK (ESC_PHYx_LINKSTATUS) indication is an indication from PHY and does not indicate if the established link meets the characteristics including auto-negotiation as required by EtherCAT. Hence, the indication may not be a true status indication; however, it is critical to shorten reaction time in the event of link loss that is crucial for redundancy operation. Using LINKACT LEDs (LED_LINKx_ACTIVE) for the status output and MII_LINK (ESC_PHYx_LINKSTATUS) for the status input is the best usage; however, using the LEDs are not practical to sacrifice 4 pins. The tradeoff of whether MII_LINK is used as a link status LED or LINKACT is used depends on link loss reaction time requirements and available number of GPIOs for the system.

The PHY MII_LINK (ESC_PHYx_LINKSTATUS) signal is an active-low signal input to the C2000 ESC. It is possible to use the GPxINV register to invert the signal's polarity before the signal enters the ESC, if the system hardware cannot provide the desired polarity for this signal.

The LINKACT LEDs (LED_LINKx_ACTIVE) is an output signal of the ESC intended to control an LED for link indication.

Table 35-10. LINKACT and PHY MII_LINK States

Link State	LINKACTx (LED_LINKx_ACTIVE) State	PHY MII_LINK (ESC_PHYx_LINKSTATUS) State
No Link	0 (LOW)	1 (HIGH)
Link WITHOUT Activity	1 (HIGH)	0 (LOW)
Link WITH Activity	Toggling / Blinking	0 (LOW)

Note

The EtherCAT link status through the MII management interface option must be enabled if only a Gigabit PHY is to be supported and must not be enabled if needing to support both 10/100 and Gigabit PHY. For this reason, the link status through MII management interface is disabled on this ESC. Instead, use the LINKACT or PHY MII_LINK signals for link status purposes.

35.2.8 SubordinateDevice Node Configuration and EEPROM

The ESC requires non-volatile memory (for example, an EEPROM with I2C interface), which is referred to as the SubordinateDevice Information Interface (SII) memory, to store the EtherCAT SubordinateDevice Information (ESI) data.

The ESI data contains information about the SubordinateDevice device identification, supported features, and other network accessible properties.

Note

The ESI XML file is generated from Beckhoff's SubordinateDevice Stack Code (SSC) tool.

- **EtherCAT SubordinateDevice**
  - Uses the SII upon power-on or reset to load configuration data into the EtherCAT SubordinateDevice configuration registers.
- **EtherCAT MainDevice**
  - During development, the MainDevice is used to program the device SII memory with the ESI data.
  - When the ESI file isn't provided to the MainDevice, the MainDevice reads the device SII memory upon boot-up to determine the SubordinateDevice device properties such as the process data and their mapping options, the supported mailbox protocols including optional features, as well as the supported modes of synchronization.

35.2.9 General-Purpose Inputs and Outputs

The ESC subsystem implementation on this MCU supports 32 general-purpose inputs (GPI) and 32 general-purpose outputs (GPO) in addition to the PDI.

These GPI/GPOs provide an advantage for embedded applications over discrete components because the GPI/GPOs can selectively drive or sense GPIOs in a time controlled manner. For example, it can be a sensor/actuator control, status read, LED status update, and so on. The following section describes the integration and usage of this feature.

35.2.9.1 General-Purpose Inputs

General-purpose inputs are connected to the device GPIO pin mux through an input buffer with an option to directly connect the asynchronous input flowing directly into the ECS or through a ESCSS register pipeline, which can hold the value stable while the value is captured within the ESC. The state of the GPI can be captured based on the following events:

- **Start-of-Frame (SOF):** Contents can be ready for capture in the frame if requested by the MainDevice
- **SYNC0/1:** Contents captured on a precise time tick
- **LATCH0/1:** Contents synchronized with LATCHIN read (allows simultaneous input and timestamp capture)

The ESCSS_GPIN_DAT register, containing the contents of the GPIN data, is available for reading from host CPU to allow debug access. Additionally, ESCSS_GPIN_DAT allows CPU writes for being used GPIN override purposes such as in place of using GPIOs.

GPIs are divided into 4 sets: GPI0:7, GPI8:15, GPI16:23, and GPI24:31, for clocking the capture trigger, which means the same capture trigger has to be used for the IOs within a set. Thus, either a bus can be formed out of these or individual IOs which need to be aggregated under common trigger can be combined in one set. This allows limited freedom of trigger selection for inputs. Selection of which Inputs (ESCSS_GPIN_SEL) and outputs (ESCSS_GPOUT_SEL) can be connected to GPIO is possible at each single IO level.

Figure 35-11 shows the integration of the GPI feature.

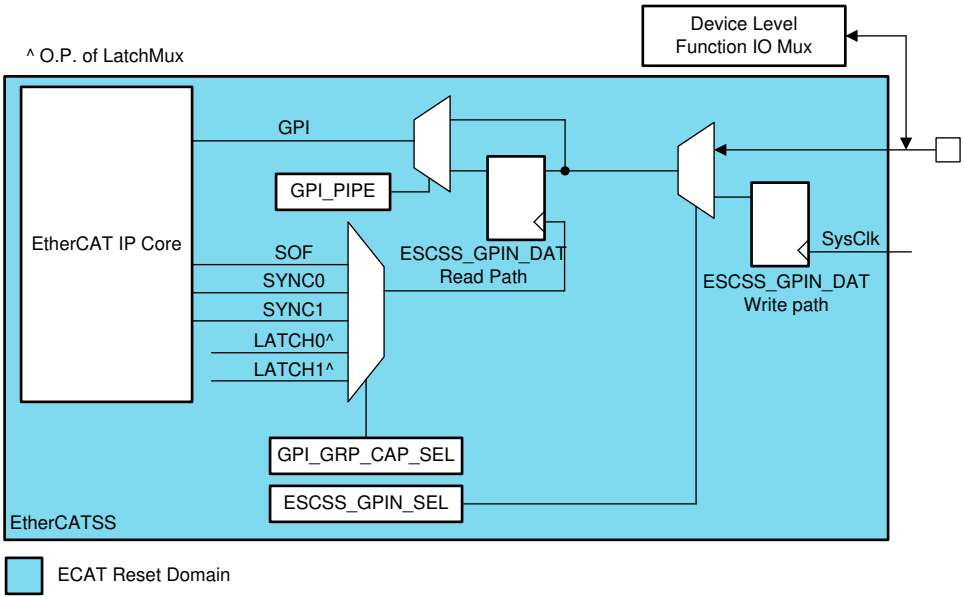

Figure 35-11. ESCSS General-Purpose Inputs Integration

Note

For software: The write data gets reflected on the ESCSS_GPIN_DAT read path only when one of the configured events, like SOF, SYNC0/1, and so on, is seen as configured after a few cycles of that event getting generated. Additionally, the copy of ESCSS_GPIN_DAT register readable by the CPU is provided without synchronization; therefore, multiple reads must be performed to confirm a stable value before using the value.

35.2.9.2 General-Purpose Output

General-purpose outputs are connected to the device GPIO pin mux through an output buffer with an option to directly connect from the ESC IP core registers to the external world or through a ESCSS register pipeline, which can hold the output value stable. The state of the GPO can be set based on the following events:

- **End-of-Frame:**Contents can be updated by the MainDevice from the last received frame
- **SYNC0/1:** Contents can be updated based on a precise time tick
- **Watchdog Trigger:** Contents can be updated based on the last successful access to process data memory

The ESCSS_GPOUT_DAT register, containing the contents of the GPO data, is available for reading from host CPU to allow debug access or to read in place of GPIOs.

GPOs are divided into 4 sets: GPI0:7, GPI8:15, GPI16:23, and GPI24:31, for clocking the output trigger, which means the same output trigger has to be used for the IOs within a set. Thus, either a bus can be formed out of these or individual IOs which need to be aggregated under common trigger can be combined in one set. This allows limited freedom of trigger selection for inputs. Selection of which inputs (ESCSS_GPIN_SEL) and outputs (ESCSS_GPOUT_SEL) can be connected to GPIO is possible at each single IO level.

Figure 35-12 shows the integration of the GPO feature.

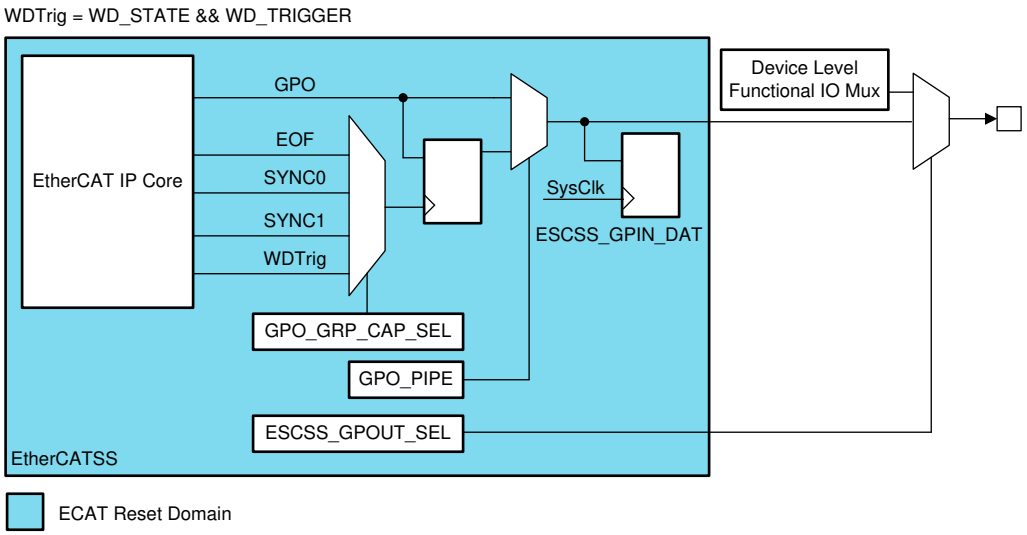

Figure 35-12. ESCSS General-Purpose Output Integration

Note

In Figure 35-12, the synchronization between CLK100 or CLK25 with respect to SysClk is not shown and is implicit by design. The local host can adjust for the synchronization delays as required while processing the data in either direction.

35.2.10 Distributed Clocks – Sync and Latch

Distributed clocks (DC) is a differentiating feature of the EtherCAT network. Distributed clocks allows all the SubordinateDevice nodes in the EtherCAT network to be bound in a tight margin of time to synchronize the events and the EtherCAT MainDevice command.

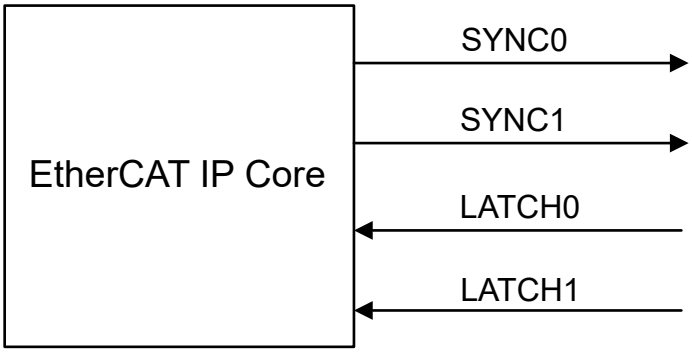

Figure 35-13. ESC SYNC and LATCH

This feature has sub-features as listed below. To enable the utility of these features at the application level, the related signals of DC are integrated tightly with the C2000 control loop logic, as well as, an external component that can be a possible implementation to trigger/latch other components on the board. This section explains the integration of these signals and related nuances of usage.

Distributed clock features:

- Clock Synchronization
- Sync Signal Generation
- Latch Signal event capture

Apart from usage for control loop synchronizations, these features are also used to synchronize the system and network time. These include the following:

- **System Time PDI Controlled:** Synchronize system time between two different EtherCAT networks.
- **Communication Timing:** To synchronize SubordinateDevice communication with sync signals, output or input events, and so on.

For further reading, including details on network time or network propagation delay, refer to the **ESC Hardware Data Sheet Section I - Technology (ethercat_esc_datasheet_sec1_technology)** document provided by Beckhoff/ETG at www.beckhoff.com.

35.2.10.1 Clock Synchronization

DC clock synchronization is the ability and procedure of the ESC to maintain the copy of the reference clock based on local clock (internal 64-bit time base) and other adjustment as derived by the procedure. The reference clock is the most accurate clock in the system and is typically held by one of the SubordinateDevices (Topologically first one after MainDevice is preferred). This time-base has a higher accuracy requirement and needs to periodically synchronize with an absolute time source like GPS or any other maintained time-base as in IEEE1588 network.

The synchronization order is as follows:

1. The MainDevice maintains a MainDevice clock that is either the absolute time synchronized or controls the reference clock.
2. The MainDevice queries the ESC time-base based on topology information and timestamps to determine the drift of the local clock for each ESC with regards to the reference clock.
3. The MainDevice programs the clock drift adjustments in each respective ESC.
4. With further periodic queries of the local clock, the MainDevice determines the drift of the local clock and keeps adjusting the clock so as to maintain the copies of the reference clocks on each ESCs in a tight limit.

While the ESC requires two clocks of 25MHz and 100MHz, the 100MHz clock is used for the internal time-base and supports the best accuracy possible. Refer to Section 35.2.6.2 for more details on clocking.

35.2.10.2 SYNC Signals

Sync signals are precise time controlled signals and are able to trigger time synchronized actions of the MainDevice. CPU core and RTDMA engine triggers are configured independently for every end point. The following sections describe ESC signal integration and various control triggers in the device.

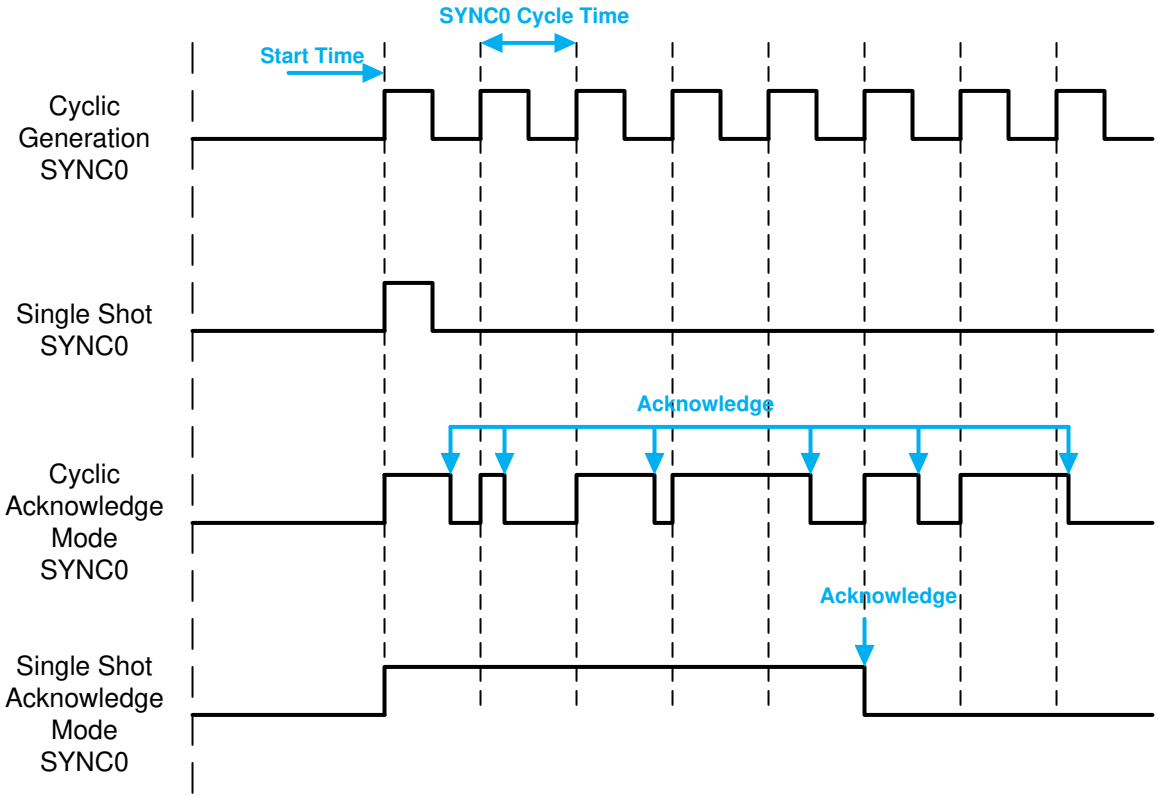

Figure 35-14. SYNC0 Signal Modes

- **SYNC0:** SYNC0 is the primary trigger and can be generated in either a cyclic (periodic event generation like rise edge at every x period) or one-shot mode. Furthermore, these modes can be either with or without acknowledge, such that when enabled with acknowledge mode, the next event is not generated until the acknowledgment is received from the controlling MainDevice. If the acknowledgment is delayed, the event is skipped and the next periodic event is generated. Remember that the acknowledgment can be part of the interrupt servicing from the PDI and such a delay in triggering the next event is acceptable since the servicing routine can accordingly take action for the period elapsed. These modes are shown in Figure 35-14.
- **SYNC1:** The SYNC1 generation follows the SYNC0 generation with a programmable delay and depending upon the delay time defined, SYNC1 can or cannot generate the pulse since the predefined delay from the SYNC0 event is newly measured only after the SYNC1 event (except for the start).

Note

- The SYNC0/1 when used in a system clock domain is stretched to at least 3 clock-wide pulse.
- When ESC goes through a reset, the SYNC outputs triggering external device events need to be kept at a safe value. At reset, the output values are 0 and this can be an active state when the reset occurs; therefore, the corresponding care of usage from the remote device must be taken.

35.2.10.2.1 Seeking Host Intervention

SYNC can be used to initiate the action from the local host or related RTDMA engine that can respond with control action or data transfers from the ESC IP.

These actions can be selectively initiated in terms of:

- Interrupts to CPU cores (CPU1, CLA, or CPU2)
- RTDMA requests to RTDMA cores (CPU1 RTDMA and CPU2 RTDMA)

Figure 35-15 depicts the SYNC connection diagram to the CPU subsystems.

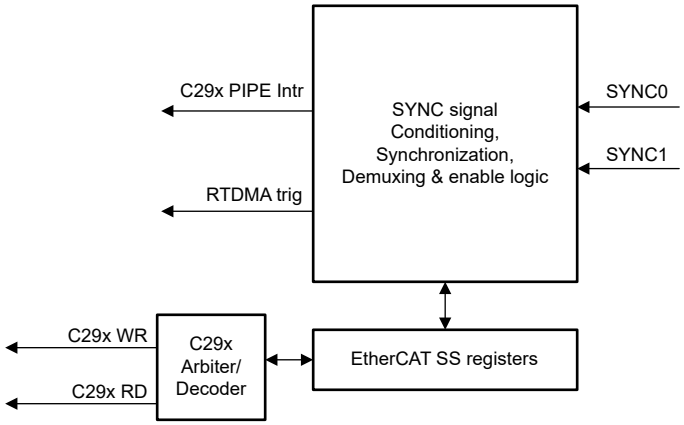

Figure 35-15. SYNC Integration for the HOST Intervention

Table 35-11 shows the Host Intervention selections, control and information that helps applications to route and handle the SYNC signals for respective Host intervention.

Table 35-11. ESC SYNC Integration Map

Destination	Source	Enable	Mask	Clear	Source Clock	Destination Clock	Destination Signaling
C29x Interrupt Controller Interrupt	SYNC0	ESCSS_SYNC0_ CONFIG[0]	ESCSS_INTR_ MASK[0]	ESCSS_INTR_ CLR[0]	ECAT.100MHz	C28x.SysClk	Pulse
C29x Interrupt Controller Interrupt	SYNC1	ESCSS_SYNC1_ CONFIG[0]	ESCSS_INTR_ MASK[1]	ESCSS_INTR_ CLR[1]	ECAT.100MHz	C28x.SysClk	Pulse
CLA Interrupt	SYNC0	ESCSS_SYNC0_ CONFIG[1]	NA	NA	ECAT.100MHz	C28x.SysClk	Pulse
CLA Interrupt	SYNC1	ESCSS_SYNC1_ CONFIG[1]	NA	NA	ECAT.100MHz	C28x.SysClk	Pulse
C29x RTDMA Trigger	SYNC0	ESCSS_SYNC0_ CONFIG[2]	NA	NA	ECAT.100MHz	C28x.SysClk	Pulse
C29x RTDMA Trigger	SYNC1	ESCSS_SYNC1_ CONFIG[2]	NA	NA	ECAT.100MHz	C28x.SysClk	Pulse
RTDMA Trigger	SYNC0	ESCSS_SYNC0_ CONFIG[4]	NA	NA	ECAT.100MHz	CPU2.SysClk	Pulse/Level
RTDMA Trigger	SYNC1	ESCSS_SYNC1_ CONFIG[4]	NA	NA	ECAT.100MHz	CPU2.SysClk	Pulse/Level

The difference between Enable and Mask is that Enable allows the conditioned and synchronized interrupt to be routed to the raw interrupt/trigger cause register, while Mask is a software control to allow raising an interrupt or not. Disabling the SYNC0 and SYNC1 on a respective trigger can loose any events that happen until SYNC0 and SYNC1 are enabled again.

Regarding the CLA:

- The CLA does not have access to EtherCAT, so the CLA does not have the MASK and Clear controls; however, the trigger starts the action on the CLA processing which, upon completion, must be acknowledged by CPU1 to clear the cause.

Regarding the RTDMA:

- The RTDMA triggers do not have Mask and Clear capabilities, as typically there is no feedback mechanism from the RTDMA to clear the trigger cause.
- Figure 35-16 is the symbolic view of RTDMA request source select. If a given source event triggers multiple events across different MainDevices, then the software has to make sure there is a status exchange before the cause is cleared.

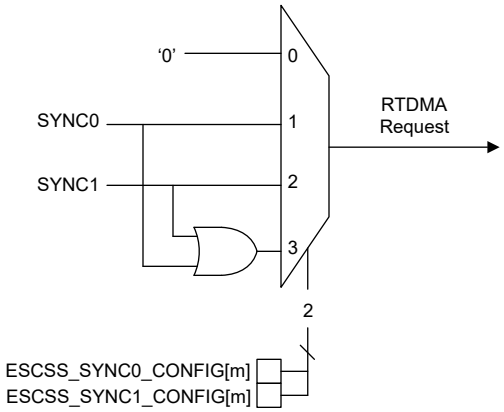

Figure 35-16. SYNC Event Muxing for Different Host RTDMA Triggers

35.2.10.3 LATCH Signals

Latch inputs to the ESC can be used to capture the time-stamp or register the GPI inputs. Two latch inputs are available. Latch enables external events:

- To take a system time snapshot of the EtherCAT network, measure time, or schedule further operations.
- To capture the status of the GPI inputs either as the status of connected external components or as part of control flow.

Both of the Latch inputs can be independently configured to operate on either the rising or falling edge of the signal. The LATCH events can be individually assigned either for the PDI control or EtherCAT controller control. Additionally, one shot or continuous mode is supported.

- In **one shot mode**, the next capture of the timestamp is done on a qualifying LATCH event only after the previous event is acknowledged.
- In **continuous mode**, timestamps are successively captured on a qualifying event, regardless of a preceding event being read or not.

Figure 35-17 depicts the different sources for the LATCH0/1 so as to fulfill the application requirements. These are explained for possible use.

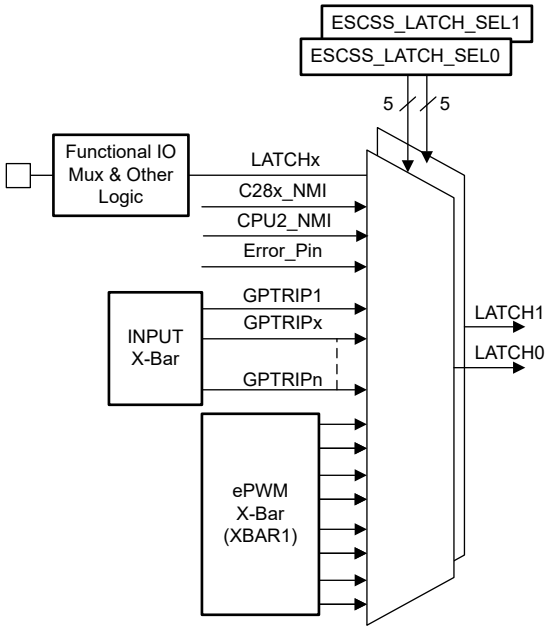

Figure 35-17. ESC Latch Input Integration

The details of connections and mux select to these muxes is shown in Table 35-12 and selection is possible individually for each of the LATCH0 or LATCH1 signal.

Table 35-12. ESC LATCH0/1 Trigger Table

35.2.10.3.1 Timestamping

Timestamping allows the local application or remote EtherCAT MainDevice to measure the time events and plan the subsequent controls.

Timestamping: Device Internal Events

- Enable timestamping and logging of internal device events coming from control logic
- The same outputs of the EPWM crossbar that connect to the 8 EPWMs can be used as 8 input signals (PWMXBAROUT0-PWMXBAROUT7) for time stamping
- Note that there is no independent option for Latch muxing as far as EPWM cross-bar inputs are concerned; unless one of the TRIP outputs are not used in control loop and such a crossbar output is dedicated for LATCH0/1 toggle

Timestamping: External Events

- Enable external board components apart from the MCU to trigger timestamp capture
- For example, timestamp a periodic event or pulse/edge event from a senor when the sensor data is read or accessed
- Connecting the LATCH0/1 controls through the input crossbar allows timestamp capture based on any selected GPIO toggle (such as GPTRIP15 or GPTRIP16)
  - Two GPTRIPs are provided for independent GPIO choice for LATCH0 and LATCH1
  - GPTRIP1, 2, and 3 allow the same functionality; however, those can be utilized for EPWM trip zone functions where pins can or cannot need to match. In the case of a trip zone based on GPTRIP is to be latched, one of these inputs can be used.

Timestamping: Device Exception Events

- Log and timestamp exception events within the device (example: NMI exceptions) and periodically collect information to find out systemic issues in the system
- Can be used by local application and the remote MainDevice to diagnose or debug the system
- On CPU1, ERAD can be used to analyze particular accesses or data patterns/counts on the CPU bus. Refer to the *Embedded Real-time Analysis and Diagnostic (ERAD)* chapter for further information

35.2.10.4 Device Control and Synchronization

The primary advantage of DC functionality is when used in conjunction with device control functions. The precisely timed pulse/edge nature of the SYNC allows the ESC to synchronize the internal resources like PWMs, ECAPs (for capture as well as PWM) with remote system components. The following are the connections which are available for applications to program for allowing this synchronization.

35.2.10.4.1 Synchronization of PWM

The PWM Sync-chain on the MCU can be triggered either by the device external inputs from the GPIO via input cross-bar or the PWM internal events when the chain is programmed appropriately. The SYNC0/1 inputs in this implementation also act as the external sync inputs to the PWM sync-chain. The integration is shown in Figure 35-18.

The additional select register added to the trigger crossbar register allows independent programming of the EXTSYNCx from either GPTRIP or SYNC0/1.

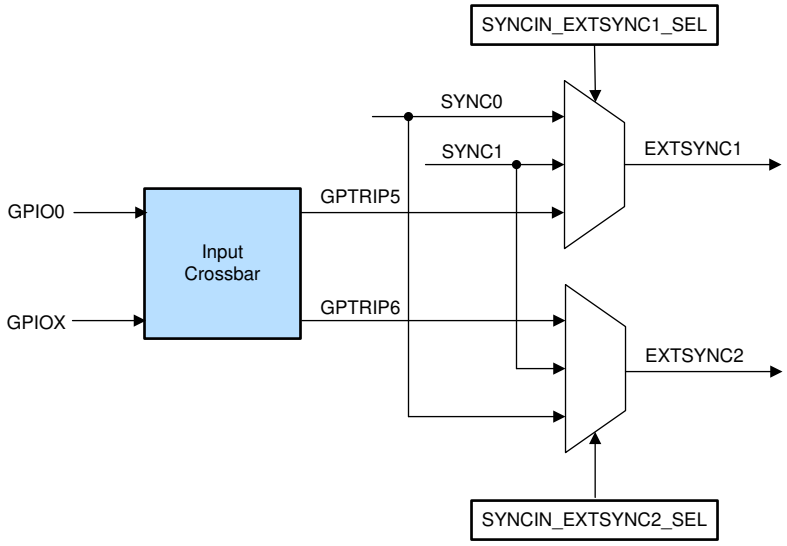

Figure 35-18. SYNC Integration for Control Functions - PWM SYNC

35.2.10.4.2 ECAP SYNC Inputs

ECAP supports accurate time capture of events that can be relatively checked against the series of events in vicinity and used for the control loop action. Additionally, ECAP has inbuilt capability of limited PWM action that can be triggered based on the selected input. Hence, the SYNC0/1 are also connected to ECAP input mux. The exact select value/vector for SYNC0/1 is defined in the *Enhanced Capture (eCAP)* chapter.

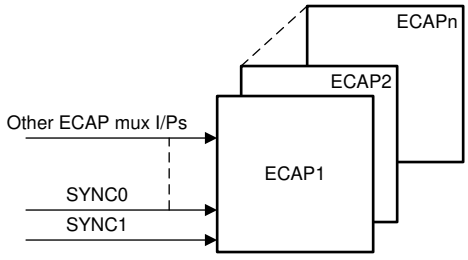

Figure 35-19. SYNC Integration for Control Functions – ECAP

35.2.10.4.3 SYNC Signal Conditioning and Rerouting

SYNC0/SYNC1 generation modes can generate various waveform patterns to create different trigger conditions. The SYNC0/1 signals are routed to the CLB, which can make conditional and delay based waveforms. Using the CLB, these signals can be processed for additional uses based on the application.

Additionally, this integration also allows routing SYNC0/1 signals with or without processing to other destinations within the device that are not explicitly connected. Details of the CLB input mux selects are explained in the *Configurable Logic Block (CLB)* chapter.

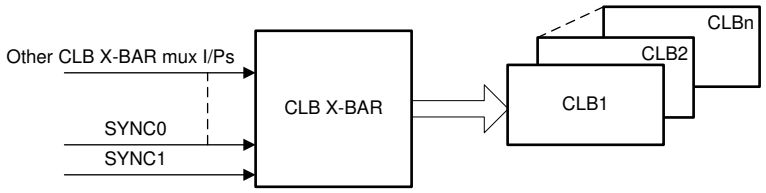

Figure 35-20. SYNC Integration for Signal Conditioning – CLB

35.3 Software Initialization Sequence and Allocating Ownership

This section details the software initialization sequence when configuring CPU1 or CPU2 as ESC owner. The CPU2 sequence includes details on allocating ownership of the ESC peripheral.

Table 35-13. CPU1 Software Initialization Sequence

Step	Action
1	General device initialization (configure clock, enable PLL, enable peripheral clocks except EtherCAT)
2	Configure Aux Clock for EtherCAT (if using Aux clock as source)
3	Configure GPIOs for EtherCAT (set pin configurations, set GPIO qualification mode, set pad configuration)
4	Initialize interrupts and register ISR handlers
5	Set EtherCAT clock source and divider. Then configure if EtherCAT PHY is clocked from device or external PHY clock.
6	Configure the EEPROM size
7	Bring ESC out of reset using system control register
8	Perform EtherCAT memory initialization and wait until memory initialization is complete
9	(Optional) Enable debug access to the EtherCAT registers
10	(Optional) Check that EEPROM loaded successfully
11	EtherCAT subsystem configurations for interrupt masking, SYNCx connections, and so on(1)

(1) Applications must make sure that ESC outputs are in a safe state until the EEPROM is loaded and that SYNC and LATCH are configured only after the EEPROM is loaded.

Table 35-14. CPU2 Software Initialization Sequence

Step	Core	Action
1	CPU1	General device initialization (configure clock, enable PLL, enable peripheral clocks except EtherCAT)
2	CPU1	Assign RAMs and Flash Banks to CPU2/CPU3
3	CPU1	Bring CPU2 out of reset using system control register
4	CPU1	Configure GPIOs for EtherCAT (set pin configurations, set GPIO qualification mode, set pad configuration)
5	CPU1	Configure Aux Clock for EtherCAT (if using Aux clock as source)
6	CPU1	Set EtherCAT source and clock divider. Then configure if EtherCAT PHY is clocked from device or external PHY clock
7	CPU1	Reset ESC using system control register
8	CPU1	Bring ESC out of reset using system control register
9	CPU1	Configure EtherCAT EEPROM Size
10	CPU1	Reset ESC using system control register
11	CPU1	Allocate ESC to CPU2/CPU3
12	CPU2/CPU3	Initialize Interrupts and Register ISR Handlers
13	CPU2/CPU3	Perform EtherCAT memory initialization and wait until memory initialization is complete
14	CPU2/CPU3	(Optional) Enable debug access to the EtherCAT registers
15	CPU2/CPU3	(Optional) Check that EEPROM Loaded successfully
16	CPU2/CPU3	EtherCAT subsytem configurations for interrupt masking, SYNCx connections and so on(1)

(1) Applications must make sure that ESC outputs are in a safe state until the EEPROM is loaded and that SYNC and LATCH are configured only after the EEPROM is loaded.

35.4 ESC Configuration Constants

The following is EtherCAT IP core configurations that are static by design.

Table 35-15. ESC Configuration Constants Table

Name	Value
ESC Type	0x91
Revision	0x0
Build	0x0
FMMU Supported	0x8
SyncManagers	0x8
RAM Size	0x10
Port Descriptor	0xF
ESC Features Supported	0x1CC
Product ID	0x0
Vendor ID	0x0

Table 35-16. ESC IP Register Constants Table

EtherCAT IP Register	Offset Address	Value(1)
PDI 8/16Bit asynchronous Microcontroller configuration	0x0150	0x00
Sync/Latch PDI configuration	0x0151	0x66
Pulse Length of SyncSignals	0x0982/0x0983	0x000A

(1) These values are not changed or overwritten by EEPROM contents.

35.5.2 ETHERNET Examples

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/ethernet

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

35.6 ETHERCAT Registers

This Section describes the ETHERCAT Registers.

35.6.1 ETHERCAT Base Address Table

Table 35-18. ETHERCAT Base Address Table

Structure	DriverLib Name	Base Address	Frame Applicable	CPU1	CPU2	CPU3	RTDMA1	RTDMA2	HSM	Pipeline Protected
ESCSS_REGS	ESC_SS_BASE	0x3038_8000	-	YES	YES	YES	YES	YES	-	YES
ESCSS_CONFIG_REGS	ESC_SS_CONFIG_BASE	0x3038_8200	-	YES	YES	YES	YES	YES	-	YES

35.6.2 ESCSS_REGS Registers

Table 35-19 lists the memory-mapped registers for the ESCSS_REGS registers. All register offset addresses not listed in Table 35-19 should be considered as reserved locations and the register contents should not be modified.

Table 35-19. ESCSS_REGS Registers

Offset	Acronym	Register Name	Protection
0h	ESCSS_IPREVNUM	IP Revision Number	
4h	ESCSS_INTR_RIS	EtherCATSS Interrupt Raw Status	
8h	ESCSS_INTR_MASK	EtherCATSS Interrupt Mask	
Ch	ESCSS_INTR_MIS	EtherCATSS Masked Interrupt Status	
10h	ESCSS_INTR_CLR	EtherCATSS Interrupt Clear	
14h	ESCSS_INTR_SET	EtherCATSS Interrupt Set to emulate	
18h	ESCSS_LATCH_SEL	Select for Latch0/1 inputs and LATCHIN input	
1Ch	ESCSS_ACCESS_CTRL	PDI interface access control config.	
20h	ESCSS_GPIN_DAT	GPIN data capture for debug & override	
24h	ESCSS_GPIN_PIPE	GPIN pipeline select	
28h	ESCSS_GPIN_GRP_CAP_SEL	GPIN pipe group capture trigger	
2Ch	ESCSS_GPOUT_DAT	GPOUT data capture for debug & override	
30h	ESCSS_GPOUT_PIPE	GPOUT pipeline select	
34h	ESCSS_GPOUT_GRP_CAP_SEL	GPOUT pipe group capture trigger	
38h	ESCSS_MEM_TEST	Memory Test Control	
3Ch	ESCSS_RESET_DEST_CONFIG	ResetOut impact or destination config	LOCK
40h	ESCSS_SYNC0_CONFIG	SYNC0 Configuration for various triggers	LOCK
44h	ESCSS_SYNC1_CONFIG	SYNC1 Configuration for various triggers	LOCK

Complex bit access types are encoded to fit into small table cells. Table 35-20 shows the codes that are used for access types in this section.

Table 35-20. ESCSS_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value

35.6.2.1 ESCSS_IPREVNUM Register (Offset = 0h) [Reset = 00000000h]

ESCSS_IPREVNUM is shown in Figure 35-21 and described in Table 35-21.

Return to the Summary Table.

IP Revision number showing the Major & Minor IP versions 4 bit each

Table 35-22. ESCSS_INTR_RIS Register Field Descriptions

Bit	Field	Type	Reset	Description
31-6	RESERVED	R-0	0h	Reserved
5	MASTER_RESET_RIS	R	0h	Indicates Raw Status of the EtherCAT Master Reset event , until cleared by ESCSS_INTR_CLR 0: EtherCAT Master Reset Event did not happen since last IP reset or last clear of this bit and ECAT Master reset programmed to be Interrupt to local host. 1: EtherCAT Master Reset Event has occured. This status gets updated regardless of interrupt mask, it is registered on the EtherCATSS clock domain, sticky and remains active till cleared using ESCSS_INTR_CLR. If simultaneous clear & incoming event on same clock edge the incoming event registering has priority and clear does not have effect. Information of this event is lost if ECAT Master event is programmed to be reset IP. Reset type: ECAT.IPRSn
4	TIMEOUT_ERR_RIS	R	0h	Indicates Raw Status of the past event on PDI access timeout Error, until cleared by ESCSS_INTR_CLR 0: PDI Access Timeout Error Event did not happen since reset or last clear of this bit. 1: PDI Access Timeout Error Event has triggered the interrupt/DMA trigger. This status gets updated regardless of interrupt mask as long as Timeout is enabled, it is registered on the EtherCATSS clock domain, sticky and remains active till cleared using ESCSS_INTR_CLR. If simultaneous clear & incoming event on same clock edge the incoming event registering has priority and clear does not have effect. Reset type: ECAT.IPRSn

Table 35-22. ESCSS_INTR_RIS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	DMA_DONE_RIS	R	0h	Indicates Raw Status of the past event on DMA Done, until cleared by ESCSS_INTR_CLR 0: DMA Done Event did not happen since reset or last clear of this bit. 1: DMA Done Event has triggered the interrupt/DMA trigger. This status gets updated regardless of interrupt mask, it is registered on the EtherCATSS clock domain, sticky and remains active till cleared using ESCSS_INTR_CLR. If simultaneous clear & incoming event on same clock edge the incoming event registering has priority and clear does not have effect. Reset type: ECAT.IPRSn
2	IRQ_RIS	R	0h	Indicates Raw Status of the past event on EtherCATSS IRQ, until cleared by ESCSS_INTR_CLR 0: EtherCATSS IRQ Event did not happen since reset or last clear of this bit. 1: EtherCATSS IRQ Event has triggered the interrupt/DMA trigger. This status gets updated regardless of interrupt mask, it is registered on the EtherCATSS clock domain, sticky and remains active till cleared using ESCSS_INTR_CLR. If simultaneous clear & incoming event on same clock edge the incoming event registering has priority and clear does not have effect. Reset type: ECAT.IPRSn
1	SYNC1_RIS	R	0h	Indicates Raw Status of the past event on SYNC1, until cleared by ESCSS_INTR_CLR 0: SYNC1 Event did not happen since reset or last clear of this bit. 1: SYNC1 Event has triggered the interrupt/DMA trigger. This status gets updated regardless of interrupt mask, it is registered on the EtherCATSS clock domain, sticky and remains active till cleared using ESCSS_INTR_CLR. If simultaneous clear & incoming event on same clock edge the incoming event registering has priority and clear does not have effect. Reset type: ECAT.IPRSn
0	SYNC0_RIS	R	0h	Indicates Raw Status of the past event on SYNC0, until cleared by ESCSS_INTR_CLR 0: SYNC0 Event did not happen since reset or last clear of this bit. 1: SYNC0 Event has triggered the interrupt/DMA trigger. This status gets updated regardless of interrupt mask, it is registered on the EtherCATSS clock domain, sticky and remains active till cleared using ESCSS_INTR_CLR. If simultaneous clear & incoming event on same clock edge the incoming event registering has priority and clear does not have effect. Reset type: ECAT.IPRSn

35.6.2.3 ESCSS_INTR_MASK Register (Offset = 8h) [Reset = 00000000h]

ESCSS_INTR_MASK is shown in Figure 35-23 and described in Table 35-23.

Return to the Summary Table.

Allows to mask individual interrupt cause impacting the interrupt

Bit	Field	Type	Reset	Description
31-6	RESERVED	R-0	0h	Reserved
5	MASTER_RESET_MASK	R/W	0h	Masks EtherCAT Master reset event against any effect on interrupts or other CPU Interrupts. 1: EtherCAT Master Reset affects the interrupt/DMA trigger. 0: EtherCAT Master Reset masked and does not affect Interrupt. Reset type: ECAT.IPRSn
4	TIMEOUT_ERR_MASK	R/W	0h	Masks PDI access timeout Error to have effect on interrupts or other CPU Interrupts. 1: PDI Access Timeout Errors affects the interrupt/DMA trigger. 0: PDI Access Timeout Errors masked and does not affect Interrupt. Reset type: ECAT.IPRSn
3	DMA_DONE_MASK	R/W	0h	Masks DMA Done status update to have effect on interrupts or other CPU Interrupts. 1: DMA Done affects the interrupt/DMA trigger. 0: DMA Done masked and does not affect Interrupt. Raw DMA Done status is updated regardless of this setting. Reset type: ECAT.IPRSn
2	IRQ_MASK	R/W	0h	Masks EtherCATSS IRQ to have effect on interrupts or other CPU/DMA triggers. 1: EtherCATSS IRQ affects the interrupt/DMA trigger. 0: EtherCATSS IRQ masked and does not affect Interrupt/DMA trigger. Raw EtherCATSS IRQ status is updated regardless of this setting. Reset type: ECAT.IPRSn
1	SYNC1_MASK	R/W	0h	Masks SYNC1 to have effect on interrupts or other CPU/DMA triggers as programmed in HOST_TRIG_MAP registers. 1: SYNC1 affects the interrupt/DMA trigger. 0: SYNC1 masked and does not affect Interrupt/DMA trigger. Raw SYNC1 status is updated regardless of this setting. Reset type: ECAT.IPRSn

Table 35-23. ESCSS_INTR_MASK Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	SYNC0_MASK	R/W	0h	Masks SYNC0 to have effect on interrupts or other CPU/DMA triggers as programmed in HOST_TRIG_MAP registers. 1: SYNC0 affects the interrupt/DMA trigger. 0: SYNC0 masked and does not affect Interrupt/DMA trigger. Raw SYNC0 status is updated regardless of this setting. Reset type: ECAT.IPRSn

35.6.2.4 ESCSS_INTR_MIS Register (Offset = Ch) [Reset = 00000000h]

ESCSS_INTR_MIS is shown in Figure 35-24 and described in Table 35-24.

Return to the Summary Table.

Registers the Msked Interrupt status of different interrupt triggers. This is AND of RIS & MASK of respective fields

Table 35-24. ESCSS_INTR_MIS Register Field Descriptions

Bit	Field	Type	Reset	Description
31-6	RESERVED	R-0	0h	Reserved
5	MASTER_RESET_MIS	R	0h	Indicates Masked Interrupt status of the past event on EtherCAT Master Reset, until RIS cleared by ESCSS_INTR_CLR or by Reset. 0: No pending EtherCAT Master Reset interrupt, if configured and unmasked. 1: EtherCAT Master Reset Event has triggered the interrupt/DMA trigger and it's pending. This is MASK qualified RIS such that application can select to service or suppress the interrupt cause behind this. Upon reset or upon RIS clear through ESCSS_INTR_CLR this field is cleared. Reset type: ECAT.IPRSn
4	TIMEOUT_ERR_MIS	R	0h	Indicates Masked Interrupt status of the past event on PDI Access Timeout Error, until RIS cleared by ESCSS_INTR_CLR 0: No pending PDI Access Timeout Error interrupt. 1: PDI Access Timeout Error Event has triggered the interrupt/DMA trigger and it's pending. This is MASK qualified RIS such that application can select to service or suppress the interrupt cause behind this. Upon reset or upon RIS clear through ESCSS_INTR_CLR this field is cleared. Reset type: ECAT.IPRSn
3	DMA_DONE_MIS	R	0h	Indicates Masked Interrupt status of the past event on DMA Done, until RIS is cleared by ESCSS_INTR_CLR 0: No pending DMA Done interrupt. 1: DMA Done Event has triggered the interrupt/DMA trigger and it's pending. This is MASK qualified RIS such that application can select to service or suppress the interrupt cause behind this. Upon reset or upon RIS clear through ESCSS_INTR_CLR this field is cleared. Reset type: ECAT.IPRSn

Table 35-24. ESCSS_INTR_MIS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
2	IRQ_MIS	R	0h	Indicates Masked Interrupt status of the past event on EtherCATSS IRQ, until RIS is cleared by ESCSS_INTR_CLR 0: No pending EtherCATSS IRQ interrupt. 1: EtherCATSS IRQ Event has triggered the interrupt and it's pending. This is MASK qualified RIS such that application can select to service or suppress the interrupt cause behind this. Upon reset or upon RIS clear through ESCSS_INTR_CLR this field is cleared. Reset type: ECAT.IPRSn
1	SYNC1_MIS	R	0h	Indicates Masked Interrupt status of the past event on SYNC0, until RIS is cleared by ESCSS_INTR_CLR 0: No pending SYNC1 interrupt. 1: SYNC1 Event has triggered the interrupt/DMA trigger and it's pending. This is MASK qualified RIS such that application can select to service or suppress the interrupt cause behind this. Upon reset or upon RIS clear through ESCSS_INTR_CLR this field is cleared. Reset type: ECAT.IPRSn
0	SYNC0_MIS	R	0h	Indicates Masked Interrupt status of the past event on SYNC0, until RIS is cleared by ESCSS_INTR_CLR 0: No pending SYNC0 interrupt. 1: SYNC0 Event has triggered the interrupt/DMA trigger and it's pending. This is MASK qualified RIS such that application can select to service or suppress the interrupt cause behind this. Upon reset or upon RIS clear through ESCSS_INTR_CLR this field is cleared. Reset type: ECAT.IPRSn

35.6.2.5 ESCSS_INTR_CLR Register (Offset = 10h) [Reset = 00000000h]

ESCSS_INTR_CLR is shown in Figure 35-25 and described in Table 35-25.

Return to the Summary Table.

35.6.3 ESCSS_CONFIG_REGS Registers

Table 35-39 lists the memory-mapped registers for the ESCSS_CONFIG_REGS registers. All register offset addresses not listed in Table 35-39 should be considered as reserved locations and the register contents should not be modified.

Table 35-39. ESCSS_CONFIG_REGS Registers

Offset	Acronym	Register Name	Protection
0h	ESCSS_CONFIG_LOCK	EtherCATSS Configuration Lock	
4h	ESCSS_MISC_IO_CONFIG	RESET_IN, EEPROM IO connections select	LOCK
8h	ESCSS_PHY_IO_CONFIG	Control Register of ESCSS	
Ch	ESCSS_SYNC_IO_CONFIG	SYNC Signals IO configurations	LOCK
10h	ESCSS_LATCH_IO_CONFIG	LATCH inputs IO pad select	LOCK
14h	ESCSS_GPIN_SEL	GPIN Select between IO PAD & tieoff	LOCK
1Ch	ESCSS_GPOUT_SEL	GPOUT IO pad connect select	LOCK
24h	ESCSS_LED_CONFIG	Selection of LED o/p connect to IO pad	LOCK
28h	ESCSS_MISC_CONFIG	Miscelleneous Configuration	LOCK

Complex bit access types are encoded to fit into small table cells. Table 35-40 shows the codes that are used for access types in this section.

Table 35-40. ESCSS_CONFIG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value

35.6.3.1 ESCSS_CONFIG_LOCK Register (Offset = 0h) [Reset = 00000000h]

ESCSS_CONFIG_LOCK is shown in Figure 35-39 and described in Table 35-41.

Return to the Summary Table.

4	EEPROM_SIZE	R/W	0h	This bit will be hooked up to the EEPROM_SIZE input of the EtherCAT IP . This is set to 0 for EEPROMs of size 16K bits or lower. This is set to 1 for EEPROMs of size above 16K bits. Reset type: ECAT.XRSn
3-2	TX1_SHIFT_CONFIG	R/W	0h	Two bit TX_SHIFT configuration in terms of 10ns counts for port0. This is the shift added to TX_ENA & TX_DATA to match delay of PHY TX_CLK w.r.t. device internal clock. Reset type: ECAT.XRSn
1-0	TX0_SHIFT_CONFIG	R/W	0h	Two bit TX_SHIFT configuration in terms of 10ns counts for port0. This is the shift added to TX_ENA & TX_DATA to match delay of PHY TX_CLK w.r.t. device internal clock. Reset type: ECAT.XRSn

Chapter 36

Fast Serial Interface (FSI)

This chapter contains a general description of the Fast Serial Interface (FSI) module. The FSI is a serial peripheral capable of reliable high-speed communication across isolation barriers.

36.1 Introduction

The Fast Serial Interface (FSI) module is a serial communication peripheral capable of reliable high-speed communication across isolation devices. Galvanic isolation devices are used in situations where two different electronic circuits, which do not have common power and ground connections, must exchange information. Though isolation devices facilitate these signal communications, isolation devices can also introduce a large delay on the signal lines and add skew between the signals. The FSI is designed specifically to make sure reliable high-speed communication for system scenarios that involve communication across isolation barriers without adding components.

The FSI consists of independent transmitter (FSITX) and receiver (FSIRX) cores. The FSITX and FSIRX cores are configured and operated independently.

For additional information on the FSI module, refer to *Fast Serial Interface (FSI) Skew Compensation*.

36.1.2 FSI Features

The FSI module includes the following features:

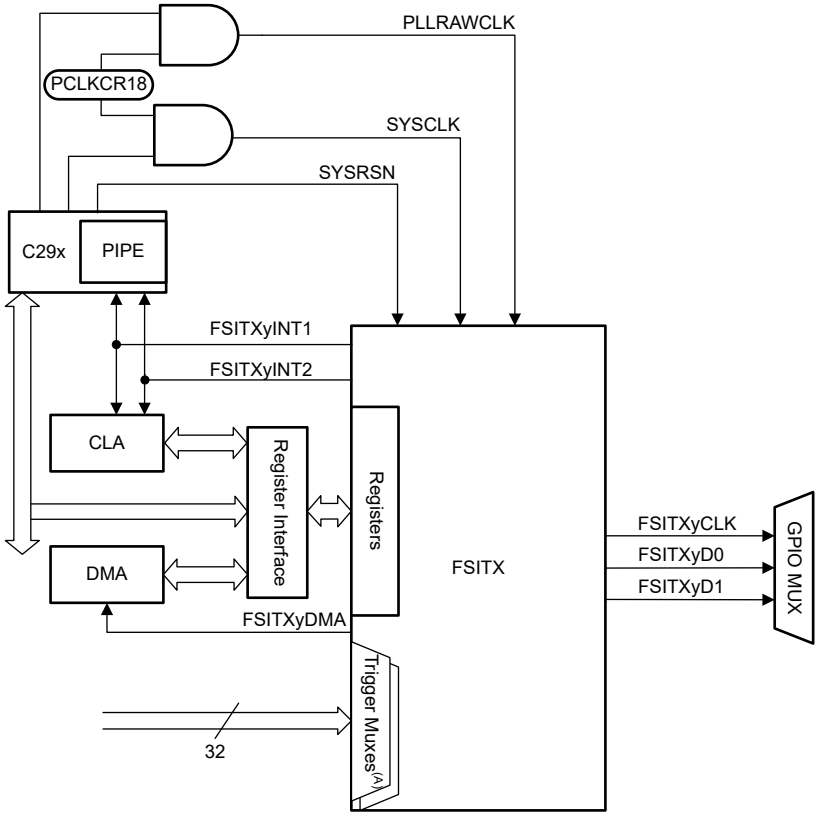
- Independent transmitter and receiver cores
- Source-synchronous transmission
- Double Data Rate (DDR)
- One or two data lines
- Programmable data length
- Skew adjustment block to compensate for board and system delay mismatches
- Frame error detection
- Programmable frame tagging for message filtering
- Hardware ping to detect line breaks during communication (ping watchdog)
- Two interrupts per FSI core
- Externally-triggered frame generation
- Hardware- or software-calculated CRC
- Embedded ECC computation module
- Register write protection
- FSI-SPI compatibility mode (limited features available)
- Tag match notifications

36.2 System-level Integration

This section describes the device-level integration of the FSI module. Some of the features can require additional configuration of modules that are not within the scope of this chapter, the details can be found elsewhere in this TRM.

36.2.1 CPU Interface

The following diagrams show the CPU interface of each FSI module.



A. The signals connected to the trigger muxes are described in Section 36.2.5.

Figure 36-1. FSI Transmitter (FSITX) CPU Interface

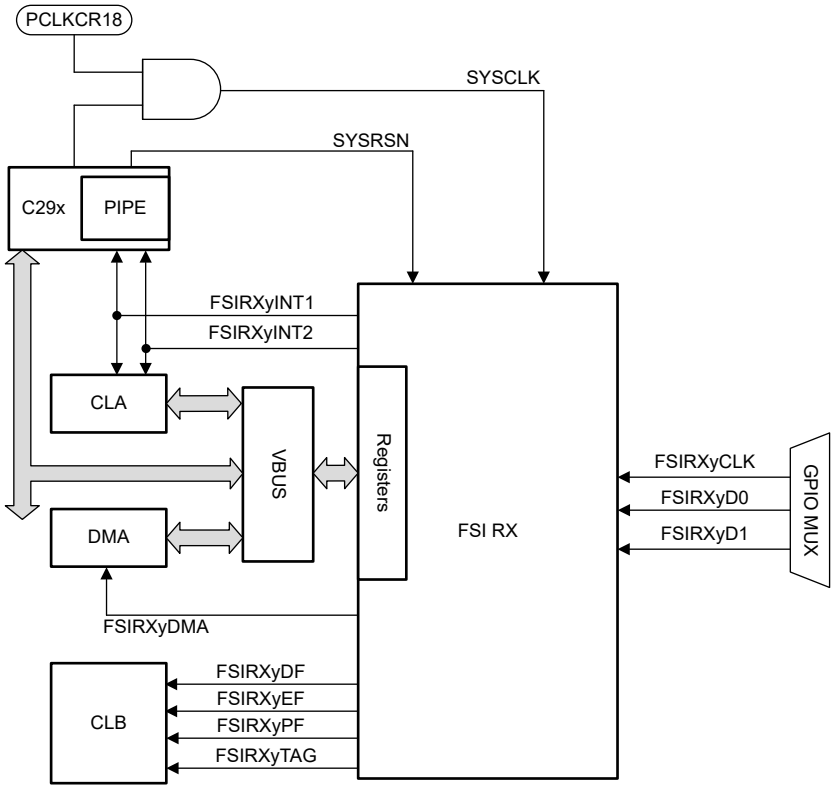


Figure 36-2. FSI Receiver (FSIRX) CPU Interface with CLB

36.2.2 Signal Description

FSI is a point-to-point communication protocol. Hence, an FSI transmitter core communicates directly to a single FSI receiver core. Similarly, an FSI receiver core receives data from a single FSI transmitter core.

Each FSI core has three signals: one clock and two data signals. Data is always transmitted or received with the most-significant bit of each frame field being first. If multilane transmissions are not used, the TXD1 and RXD1 signals can be left unconnected and the GPIOs repurposed for other application needs. Table 36-1 and Table 36-2 describe the various signals that can be selected by the PADCONFIG register to be brought out to device pins.

CAUTION
The maximum RXCLK rate is SYSCLK/2 and must not exceed this limit.

Table 36-1. FSI Receiver Core Signals

Signal Name	Direction	Description	Inactive Level(1)
RXCLK	Input	This is the receive clock input signal for the FSI receive module. This must be connected to TXCLK of the transmitting FSI module.	Logic High
RXD0	Input	This is the primary data input line for reception. This must be connected to the TXD0 of the transmitting FSI module.	Logic High
RXD1	Input	This is an additional data input line for reception. This signal must be connected to the TXD1 of the transmitting FSI module to use multilane transmission.	Logic High

(1) Inactive level refers to the state of the pin while the module is not actively receiving data.

Table 36-2. FSI Transmitter Core Signals

Signal Name	Direction	Description	Inactive Level(1)
TXCLK	Output	This is the transmit clock and is driven by the FSI transmit module. During a transmission, four clock edges are transmitted before the start of frame phase (preamble) and four clock edges follow the last bit of the frame (postamble). Data is transmitted on both edges of the clock. In FSI-SPI compatibility mode, the preamble and the post frame clock edges are not transmitted. Data is transmitted only on one edge of the clock. Data transmits on rising edge and received on falling edge of the clock.	Logic High
TXD0	Output	This is the primary data output line for transmission and is driven by the FSI transmit module. When the FSI is configured for multilane transmission, TXD0 contains all the even numbered bits of the data and CRC bytes. Other frame fields such as frame type, start-of-frame, tag, and end-of-frame are transmitted in full.	Logic High
TXD1	Output	This is an additional data output line for transmission, if the FSI is configured for multilane transmission. This signal is driven by the FSI transmit module. During transmission, the data bits are split between TXD0 and TXD1. TXD1 contains all the odd numbered bits of the data and CRC bytes. This applies only to the data words and the CRC bytes. Other data frame related information like Frame Type, Start-of-Frame, Tag and End-of-frame, the state of this line are identical to TXD0.	Logic High

(1) Inactive level refers to the state of the pin while the module is not actively transmitting, or held in reset.

36.2.2.1 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification must be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 0x3. The internal pullups can be configured in the GPyPUD register. See the *General Purpose Input-Output (GPIO)* chapter for more details on the GPIO mux and settings.

36.2.3 FSI Interrupts

Each FSI module contains multiple interrupt sources that can be assigned to two different interrupt vectors: INT1 and INT2. Each interrupt source has an associated status flag, force, and clear bits in the EVT_STS, EVT_FRC, and the EVT_CLR registers, respectively.

Each interrupt can be assigned to either interrupt vector, INT1 and INT2, to allow for two priority levels. Alternately, the interrupt source can be prevented from generating any interrupt, though the status flag can still be set and monitored by software. The transmitter events are assigned to either interrupt vector in the TX_INT_CTRL register. The receiver events are assigned an interrupt vector using RX_INT1_CTRL and RX_INT2_CTRL registers. If an interrupt is not required, make sure the bit is not set in the respective INT_CTRL register.

36.2.3.1 Transmitter Interrupts

The transmitter can generate the following interrupts:

- **Frame Done (FRAME_DONE):** This event indicates that FSI has completed transmitting a frame.
- **Buffer Underrun (BUF_UNDERRUN):** This event indicates that the transmit buffer has experienced underrun. Buffer underrun occurs when the transmitter tries to read data from a location which has not yet be written to by the CPU, or RTDMA.
- **Buffer Overrun (BUF_OVERRUN):** The buffer overrun interrupt is generated when the buffer has experienced overrun. Buffer overrun can occur if a piece of data is overwritten before the data has been transmitted.
- **Ping Frame Triggered (PING_TRIGGERED):** The ping frame triggered interrupt is generated when the ping frame has been triggered. This bit is set when the ping counter has timed out or an external ping trigger event has occurred.

36.2.3.2 Receiver Interrupts

The receiver core is capable of generating interrupts from many different events:

- **Ping Watchdog Timeout (PING_WD_TO):** This event indicates that the ping watchdog timer has timed out. The receiver has not received a valid frame within the time period specified in the RX_PING_WD_REF register.
- **Frame Watchdog Timeout (FRAME_WD_TO):** This event indicates that the frame watchdog timer has timed out. The conditions of this timeout are set using the RX_FRAME_WD_CTRL register. As soon as the start of frame phase is detected, the frame watchdog counter starts counting from 0. The end of frame phase must complete by the time the watchdog counter reaches the reference value. If this does not happen, the watchdog times out and this event is generated. If this event occurs, the receiver must undergo a soft reset and subsequent resynchronization to resume proper operation.
- **CRC Error (CRC_ERR):** This error indicates that a CRC error has occurred. A CRC error is generated when the received CRC and the computed CRC do not match.
- **Frame Type Error (TYPE_ERR):** This error indicates that an invalid frame type has been received. If this error occurs, the receiver must undergo a soft reset and subsequent resynchronization to resume proper operation.
- **End-of-Frame Error (EOF_ERR):** This error indicates that an invalid end-of-frame bit pattern has been received. If this error occurs, the receiver must undergo a soft reset and subsequent resynchronization to resume proper operation.
- **Receive Buffer Overrun (BUF_OVERRUN):** This event indicates that an overrun condition has occurred in the receive buffer.
- **Receive Buffer Underrun (BUF_UNDERRUN):** This event indicates that an underrun condition has occurred in the receive buffer. This condition occurs when software reads an empty buffer.
- **Frame Done (FRAME_DONE):** This event indicates that a valid frame has been received without error.
- **Error Frame Received (ERR_FRAME):** This event indicates that an error frame has been received.
- **Ping Frame Received (PING_FRAME):** This event indicates that a ping frame has been received.
- **Frame Overrun (FRAME_OVERRUN):** This event indicates that a new frame has been received while the FRAME_DONE flag was still set.
- **Data Frame Received (DATA_FRAME):** This event indicates that a data frame has been received.
- **Ping Tag Matched (PING_TAG_MATCH):** This event indicates that a ping frame with a matching tag has been received.
- **Data Tag Matched (DATA_TAG_MATCH):** This event indicates that a data frame with a matching tag has been received.
- **Error Tag Matched (ERROR_TAG_MATCH):** This event indicates that an error frame with a matching tag has been received.

36.2.3.3 Configuring Interrupts

To configure interrupts on the FSI, the application must select the interrupt vector for each desired event using the TX_INT_CTRL register for the transmitter, and RX_INT1_CTRL and RX_INT2_CTRL registers for the receiver. There is no module-level interrupt enable bit to configure.

Note

If an event is registered for both interrupt vectors, both interrupts fire. There are no hardware checks for overlapping interrupt vector assignments.

36.2.3.4 Handling Interrupts

Inside the interrupt service routine (ISR), the user must clear the event flag using the EVT_CLR register and then acknowledge the CPU interrupt.

If the one event occurs multiple times before the corresponding bit is cleared by software, no new interrupt is generated.

If multiple events occur simultaneously, or very close in time, it is possible to handle multiple conditions within a single interrupt. Each flag is independently set by hardware and must be cleared by application software. If multiple different events occur, the ISR can handle each in whatever order is deemed necessary by the application. It is not advisable to clear the full interrupt status register in every ISR. This can cause the application to miss events that can be detrimental to the application. A sample sequence for handling interrupts on the receiver follows; the transmitter routine is similar.

- On receiving an interrupt, copy the current state of the receive event and error status flag register (RX_EVT_STS) into a local snapshot variable.
- Read all of the bits from the snapshot to determine the events that require action.
- Perform the necessary actions for each of the events seen in the snapshot.
- Write to the receive event and error clear register (RX_EVT_CLR) with the snapshot to clear only those interrupts that were set at the beginning of the ISR.
- Repeat this sequence for every generated ISR.

There is a chance that another event occurred during the just-handled ISR since only the snapshot of events was handled and then cleared; an event flag can still be set at the end of the ISR. As soon as the ISR completes, a new interrupt is generated and this flag is still set and can be handled accordingly.

Software accesses tied to multiple events and handled within the same ISR can cause race conditions that cause the software to not function as desired. For example, it is recommended to use different interrupt lines if the user wants to enable events for both ping and data frames. If both events are handled within the same interrupt line, the software can only respond to one of the events if both events occur close in time.

36.2.4 RTDMA Interface

Both the transmitter and receiver are capable of using the RTDMA for automatic data transfers. The RTDMA trigger is independent from the interrupt signals. RTDMA events are only triggered on the completion of a data frame.

The transmitter RTDMA trigger is enabled by setting TX_DMA_CTRL.DMA_EVT_EN to 1. The transmitter must also set TX_OPER_CTRL_LO.START_MODE to 0x2 to allow either a write to the TX_FRAME_CTRL.START bit or to the TX_FRAME_TAG_UDATA register to start the transmission.

The receiver RTDMA trigger is enabled by setting RX_DMA_CTRL.DMA_EVT_EN to 1.

Refer to Section 36.3.2 and Section 36.3.3 for more RTDMA information specific to each FSI Module.

36.2.5 External Frame Trigger Mux

The FSI has two muxes connected to the transmitter module. These muxes are used to select triggers to start ping frames, and generic frames. These muxes are independently configured for each type of frame. The application can select one trigger source per frame type. Use of these triggers are optional.

The external ping frame trigger is configured by setting TX_PING_CTRL.EXT_TRIG_SEL to the index of the desired trigger. TX_PING_CTRL.EXT_TRIG_EN must also be set to allow the trigger to generate a ping frame.

The generic frame trigger is configured by setting TX_OPER_CTRL_HI.EXT_TRIG_SEL to the index of the desired trigger. TX_OPER_CTRL_LO.START_MODE must be set to 0x1 for a frame to be transmitted by an external trigger.

36.3 FSI Functional Description

36.3.1 Introduction to Operation

The Fast Serial Interface Transmitter and Receiver modules (FSI_TX/FSI_RX) are two completely independent modules on the device. Each module has an independent set of control registers, clocking, and interrupts. The following sections describe the frame format and the various initialization and configuration procedures for both the transmitter and receiver.

36.3.2 FSI Transmitter Module

The FSI transmitter module handles the framing of data, CRC generation, and signal generation of TXCLK, TXD0, and TXD1, as well as interrupt generation. The operation of the transmitter core is controlled and configured through programmable control registers. The transmitter control registers allow the CPU to program, control, and monitor the operation of the FSI receiver. The transmit data buffer is accessible by the CPU and the RTDMA.

The transmitter has the following features:

- Automated ping frame generation
- Externally triggered ping frames
- Externally triggered data frames
- Software-configurable frame lengths
- 16-word data buffer
- Data buffer underrun and overrun detection
- Hardware-generated CRC on data bits
- Software ECC calculation on select data
- RTDMA support

Figure 36-3 shows the high-level block diagram of the FSI transmitter. Figure 36-4 shows the block diagram of the transmitter core submodule.

The following sections describe the various aspects of the FSI transmitter in detail.

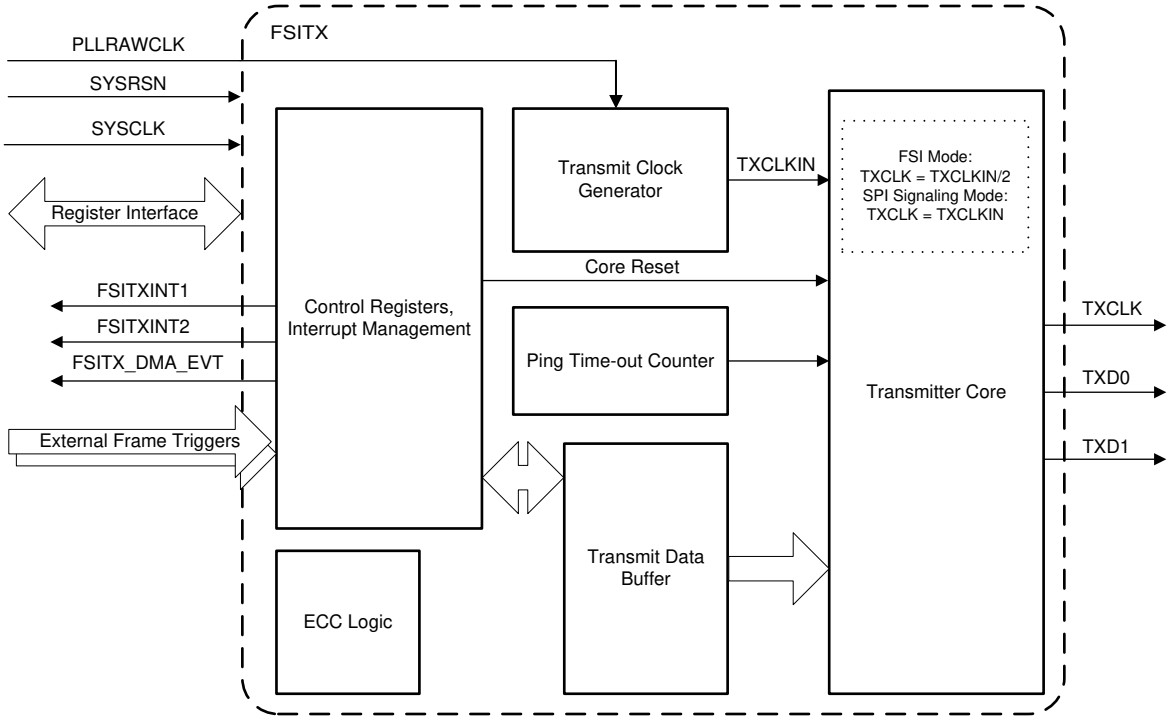

Figure 36-3. FSI Transmitter Block Diagram

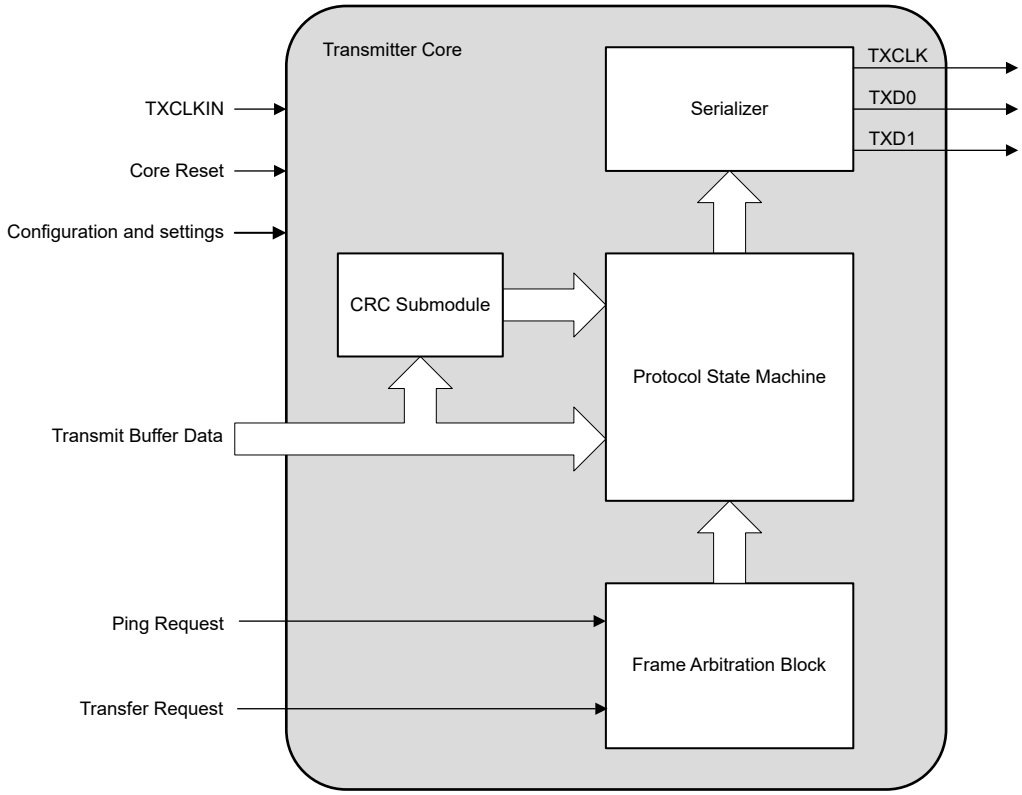

Figure 36-4. FSI Transmitter Core Block Diagram

36.3.2.1 Initialization

On the first initialization or after a module reset due to an underrun condition, the transmitter module executes the following initialization sequence to start or resume transmit operations.

1. Initialize the transmitter clock by setting TX_CLK_CTRL.CLK_RST to 1 and subsequently clearing the bit.
2. Set the clock to the transmitter core to PLLRAWCLK by setting TX_OPER_CTRL_LO.SEL_PLLCLK to 1.
3. Set the clock prescaler value to the desired rate by writing to TX_CLK_CTRL.PRESCALE_VAL.
4. Enable the transmitter clock divider by setting TX_CLK_CTRL.CLK_EN to 1.
5. Assert the transmitter module soft reset by writing 0xA501 to TX_MAIN_CTRL.
6. Wait four TXCLK cycles.
7. Release the transmitter core from reset by writing 0xA500 to TX_MAIN_CTRL.

After initialization and configuration, the transmitter module synchronizes with the receiver module before transmitting. The synchronization sequence is described in Section 36.4.1.

CAUTION

Do not change TX_CLK_CTRL.PRESCALE_VAL while the clock is enabled (TX_CLK_CTRL.CLK_EN = 1). Doing so can cause undefined behavior.

36.3.2.2 FSI_TX Clocking

The transmitter core registers and control logic run off of the device system clock (SYSCLK).

The FSI Transmit Clock (TXCLK) is derived from PLLRAWCLK. PLLRAWCLK is divided down by configuring the clock prescaler value (TX_CLK_CTRL.PRESCALE_VAL) then setting the clock divider enable bit (TX_CLK_CTRL.CLK_EN). The clock prescaler value can be set to divide PLLRAWCLK by 1 (TX_CLK_CTRL.PRESCALE_VAL = 0x0 or 0x1) through 255(TX_CLK_CTRL.PRESCAL_VAL = 0xFF). Though TXCLK and SYSCLK are both derived from PLLRAWCLK, TXCLK is asynchronous with respect to SYSCLK.

CAUTION

TXCLK must never be configured to be faster than SYSCLK/2.

36.3.2.3 Transmitting Frames

On the transmitter, the ping frame is the only frame that can be set up and transmitted without any further software or RTDMA intervention. Ping frames can be transmitted by any (or all) of the three sources: automatic ping timer, software, or external triggers.

Each available frame type can be sent multiple ways. Generically, the following steps must be executed before the frame is sent. These steps can be executed in any order before the start condition is set.

1. Configure the frame type
2. Set the frame tag
3. If the frame to be sent is a data frame:
   - Set the user data
   - Write to the data buffer
   - Set the word length if the frame is a software defined frame length
4. Set the start condition

Note

Transmit Frame Start Restriction:

A new frame transmission can be initiated by one of the methods selected in the TX_OPER_CTRL_LO.START_MODE bits. If there is already a PING frame transmission taking place, due to a hardware initiated PING timer, the new frame transmission begins as soon as the on-going PING transmission is completed.

Once a START of frame has been initiated, the next START of frame is recognized when the first frame has started transmitting the End-of-Frame (EOF) field. If a new START trigger arrives before the current transmission has reached the EOF field, the trigger is lost without a notification.

Note

There is no hardware check implemented to check whether the type field written by software is valid or not. If an invalid type is used and a frame transmission is initiated, the behavior is:

- The transmitted frame structure is exactly like an NWORD data frame. The size of the data frame is determined by the value in the TX_FRAME_CTRL.N_WORDS register.
- The frame type field of the transmitted data frame is transmitted as programmed. If this is received by an FSI receiver, a Type error is generated.

This mechanism can be used for force a Type error in a received frame for testing purposes.

The following sections describe the specific configuration for each frame type and start condition.

36.3.2.3.1 Software Triggered Frames

The most basic way to transmit a data frame is through software. Each step must be handled by the application. To send a data frame using software, the following steps must be executed. Steps 1-6 can be executed in any order before setting TX_FRAME_CTRL.START. Some fields do not need to be reconfigured for every transmission. The frame tag, user data, and frame type are sticky and are retransmitted in the subsequent frame unless modified by software.

1. Write the data to be transmitted to the next location of the transmit data buffer.
2. Set TX_FRAME_CTRL.FRAME_TYPE to the appropriate value for the type of frame to be transmitted.
3. Set TX_FRAME_CTRL.N_WORDS to 1 less than the number of words to be transmitted if TX_FRAME_CTRL.FRAME_TYPE is set to 0011, the frame type of the software-defined length data frame. That is, if 16 words are transmitted, N = 16, set TX_FRAME_CTRL.N_WORDS to 15.
4. When the frame is assembled before transmitting, the FSITX hardware calculates the CRC to be transmitted. If TX_OPER_CTRL_LO.SW_CRC is 1, the application can calculate a custom CRC value and then set TX_USER_CRC to the result.
5. Set TX_FRAME_TAG_UDATA.FRAME_TAG to the desired tag.
6. Set TX_FRAME_TAG_UDATA.USER_DATA to the desired user data.
7. Set TX_FRAME_CTRL.START to 1 to initiate the transmission of the data frame.

Once the frame transmission has started, the TX_FRAME_CTRL.START is cleared by hardware. To monitor if the frame has completed, the software can poll TX_EVT_STS.FRAME_DONE.

36.3.2.3.2 Externally Triggered Frames

The transmitter can transmit frames when triggered by an external source. See Section 36.2.5 for more information on the available external triggers.

To transmit frames using an external trigger, the application must follow the same procedure as described in Section 36.3.2.3.1. The only difference is that in Step 7, the start condition is automatically set when the external trigger condition is met rather than by software.

Note that by externally triggering frames, the frame information to be sent is pulled from the same registers described in the previous section. Because of this, it is possible to send any type of frame from an external trigger including ping, error, and data frames. Also, there is no hardware mechanism by which the FSI can determine if multiple triggers occur. The FSITX takes the data as is, and the application software makes sure that this data has been updated as necessary.

Using TX_EVT_STS fields either by polling or by interrupts, the application can populate or update the frame information to be sent in the next frame

36.3.2.3.3 Ping Frame Generation

Assuming the FSI transmitter has already been properly initialized, the following sequences can be used to configure and send ping frames.

36.3.2.3.3.1 Automatic Ping Frames

To generate periodic ping frames, the following steps must be followed:

1. Initialize the ping counter by writing 1 to TX_PING_CTRL.CNT_RST.
2. Set the desired ping tag to TX_PING_TAG.TAG.
3. Set the ping timer reference value to TX_PING_TO_REF.TO_REF.
4. Enable the ping timer by writing 1 to TX_PING_CTRL.TIMER_EN.

The ping timer is a free-running counter that counts up from 0. The current value of the ping timer counter is found in TX_PING_TO_CNT. When the current value of TX_PING_TO_CNT matches the reference value TX_PING_TO_REF.TO_REF, the TX_EVT_STS.PING_TRIGGERED is set. TX_PING_TO_CNT resets to 0 and resumes counting until the next match has occurred or the ping timer is halted by software (TX_PING_CTRL.TIMER_EN is set to 0).

36.3.2.3.3.2 Software Triggered Ping Frame

Software can also manually generate a ping frame. The process for sending a ping frame with software is very similar to sending the other types of frames. The following steps must be followed:

1. Set TX_FRAME_CTRL.FRAME_TYPE to 0000’b to denote that the frame being sent is a Ping Frame.
2. Set TX_FRAME_TAG_UDATA.FRAME_TAG to the desired value.
3. Write 1 to TX_FRAME_CTRL.START. This starts the transmission.

Once the frame transmission has started, the TX_FRAME_CTRL.START is cleared by hardware. To monitor if the frame has completed, the software can poll TX_EVT_STS.FRAME_DONE.

36.3.2.3.3.3 Externally Triggered Ping Frame

The last source for generating ping frames is an external trigger. One of up to 32 different triggers can be selected. See Section 36.2.5 for the list of input sources.

CAUTION

Ping frames can be triggered by both an external trigger source and the internal ping timer. If TX_PING_CTRL.EXT_TRIG_EN is set to 1, the external trigger source takes precedence and the ping timer is ignored.

36.3.2.3.4 Transmitting Frames with RTDMA

The FSI transmitter can send data that is continuously applied with the RTDMA. A RTDMA trigger is generated every time a data frame transmission is completed. This is concurrent with the FRAME_DONE signal that sets the TX_EVT_STS.FRAME_DONE flag.

To transmit continuous data with the RTDMA, some configurations need to be made on the transmitter:

First, set TX_DMA_CTRL.DMA_EVT_EN to 1. This allows the RTDMA trigger to propagate to the RTDMA module. Next, TX_OPER_CTRL_LO.START_MODE must be set to 0x2. The transmitter is now able to start a transmission using a software write to TX_FRAME_CTRL.START or TX_FRAME_TAG_UDATA..

The RTDMA must also be configured properly for the FSI to send the data. One way of using the RTDMA to continuously feed the transmit buffer is:

- Set up two RTDMA channels to be triggered by the same FSI transmitter and RTDMA trigger.
- Configure one channel to fill the transmit buffer.
- Configure the other channel to set the frame tag and user data fields
- Since the FSI transmit buffer is a 16-word circular buffer, make sure the RTDMA channel servicing the data buffer wraps the after 16 words are copied.

Note

Because the frame tag and user data must be written in to initiate the transmission of the frame, use two consecutive RTDMA channels. This makes sure that the RTDMA channels are always executed in sequence. The RTDMA channel servicing the data buffer must be the lower numbered channel and the tag/user data channel must be the next. For example, configure RTDMA channel 3 to service the data buffer, and configure RTDMA channel 4 to service the tag and user data.

36.3.2.4 Transmit Buffer Management

The FSI transmitter has a 16-word buffer that the FSI transmitter pulls data to transmit. This buffer is implemented as a circular buffer, not a FIFO, so some care must be taken to properly interpret buffer overrun and underrun, as well as the TX_BUF_PTR_STS register. These flags and pointers work under the assumption that the software or RTDMA is using the buffer as a circular buffer. This mode of operation is the only way that the overrun, underrun, and pointer status are meaningful. If data is being sourced by the RTDMA and there is some other periodic trigger mechanism trying to initiate transfers, underrun becomes a critical error. If an underrun happens, a buffer went out of sync. This not only affects the current transfer, but can also affect all future transfers due to the ring buffer. Under such conditions, the underrun needs a soft reset to cleanly recover. Alternately, the software can manually stop the transmitting, reset the buffer pointers, clear the remaining error conditions, and then restart transmission. The software method involves a few steps, while the soft reset is a single action and makes sure of a full reset of the control registers.

Due to the flexibility of the transmit buffer, software can implement a simple ping-pong buffer or randomly load and send from any location of the buffer. If the buffer is used in this manner, error flags and status fields can be ignored without adversely affecting the transmitter capability. Additionally, the CURR_WORD_CNT is also invalid if used in this way. The application can set the buffer pointer manually by writing the 4-bit index to TX_BUF_PTR_LOAD. This forces the transmitter to start picking the data from the indicated location in the buffer.

36.3.2.5 CRC Submodule

The FSI transmitter can supply the CRC to the frame being transmitted through the embedded hardware CRC submodule or by supplying a user-defined value. This is controlled by setting TX_OPER_CTRL_LO.SW_CRC appropriately.

If hardware CRC generation is selected (TX_OPER_CTRL_LO.SW_CRC = 0, the default), the CRC is computed by hardware on the data and user data fields using the CRC polynomial 0x7 ($x^8 + x^2 + x + 1$). The transmitter module automatically computes the CRC on the data fields without user intervention when the frame is transmitted. For more information on how the CRC is generated by the CRC submodule, refer to Section 36.3.7.

If software CRC generation is selected (TX_OPER_CTRL_LO.SW_CRC = 1), the CRC must be computed by software and placed in the TX_USER_CRC register. The next frame to be transmitted uses the value placed in the TX_USER_CRC register in place of the CRC value generated by the hardware.

As the TX_USER_CRC register is software-programmable, the application can use this field as an extra data field for application-specific purposes. If TX_USER_CRC is used in this manner, the CRC detection on the receiver is not valid and must be ignored.

36.3.2.6 Conditions in Which the Transmitter Must Undergo a Soft Reset

Unlike the receiver, there are no detectable errors that require a soft reset. A buffer overrun or underrun interrupt can or cannot require a soft reset to resume proper operation. This determination is up to the application software. Refer to Section 36.3.2.4 for more information on the transmit buffer.

36.3.2.7 Reset

The entire transmitter module and all transmitter registers are reset by SYSRSn. The transmitter core is reset by SYSRSn or by writing a 1 to TX_MAIN_CTRL.CORE_RST.

A module reset causes the registers to be reset to the default state.

36.3.3 FSI Receiver Module

The receiver module interfaces to the FSI clock (RXCLK), and data lines (RXD0 and RXD1) after the data lines pass through an optional programmable delay line. The receiver core handles the data framing, CRC computation, and frame-related error checking. The receiver bit clock and state machine are run by the RXCLK input, which is asynchronous to the device system clock.

The receiver control registers allow the CPU to program, control, and monitor the operation of the FSI receiver. The receive data buffer is accessible by the CPU and the RTDMA.

The receiver core has the following features:

- 16-word data buffer
- Multiple supported frame types
- Ping frame watchdog
- Frame watchdog
- CRC calculation and comparison in hardware
- ECC detection
- Programmable delay line control on incoming signals
- RTDMA support
- FSI-SPI compatibility mode

Figure 36-5 provides a high-level overview of the internal modules present in the FSI receiver. Figure 36-6 shows a view of the FSI receiver core submodule. Not all data paths and internal connections are shown.

The following sections describe the various aspects of the FSI receiver module.

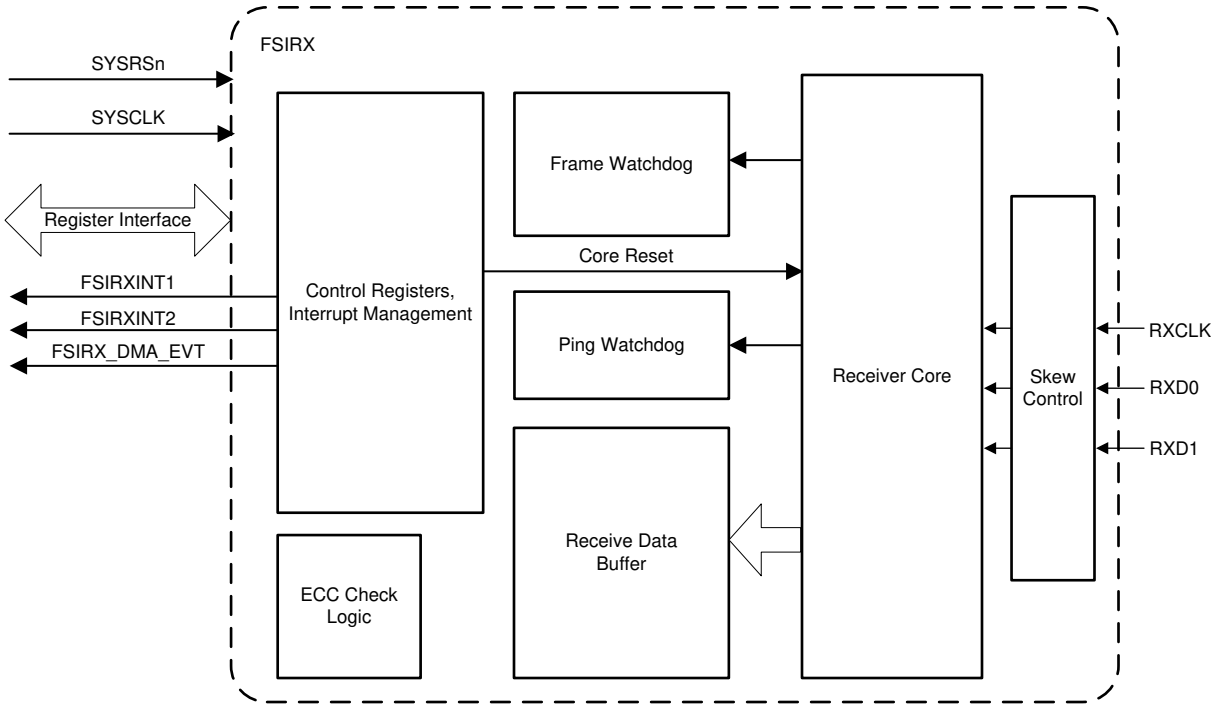

Figure 36-5. FSI Receiver Block Diagram

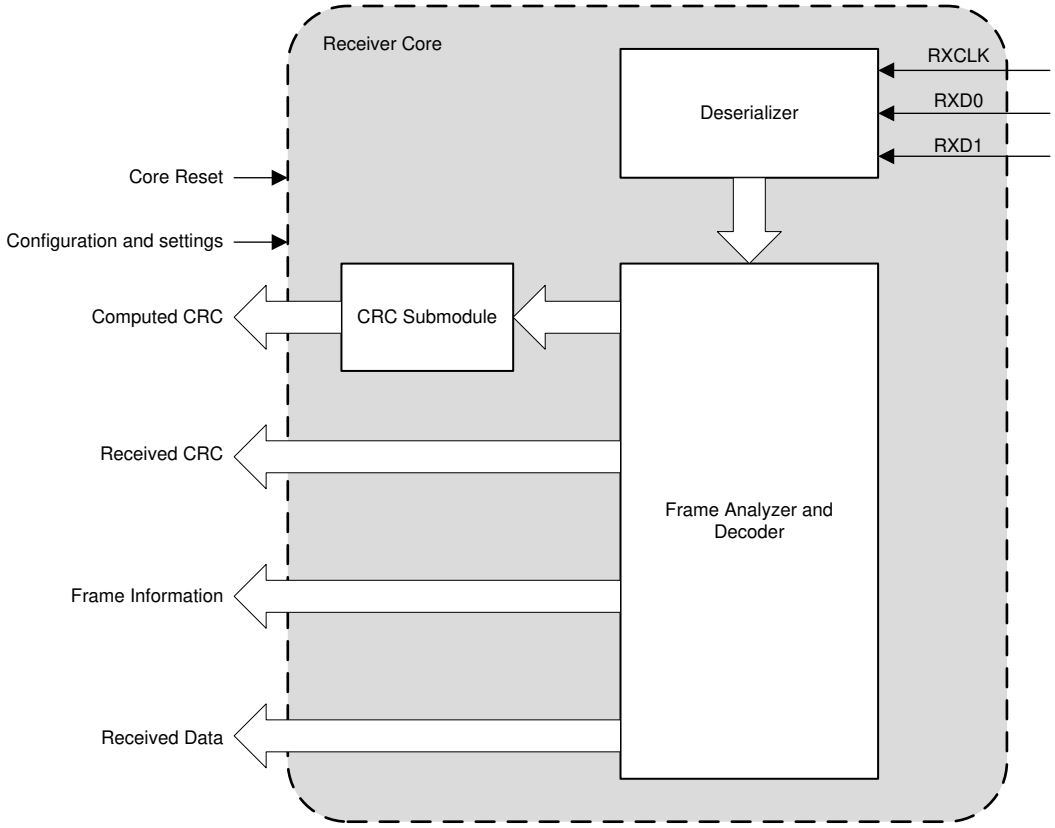

Figure 36-6. FSI Receiver Core Block Diagram

36.3.3.1 Initialization

On the first initialization or after a module reset following any frame error, the receiver module asserts and releases the receiver core reset bit (RX_MAIN_CTRL.CORE_RST) prior to any other initialization. Once the receiver module is initialized, the following steps are executed:

1. If required, assign interrupt sources to the necessary interrupt line.
2. If required, configure the ping watchdog to periodically check for an active link to the transmitter. See Section 36.3.3.4 for configuration details.
3. If required, configure the frame watchdog to make sure that each frame is received within a predetermined window. See Section 36.3.3.5 for configuration details.
4. Initialize the receive buffer pointer by writing to the RX_BUF_PTR_LOAD register. Received data is placed into the buffer starting with the address loaded in this register.
5. Make sure all errors and flags have been cleared from the RX_EVT_STS register.

At this point the receiver is ready to receive any incoming frames. Software can now either poll on the RX_EVT_STS register for various conditions. For example, when the RX_EVT_STS.FRAME_DONE and no other flags are set, the receiver has successfully received a frame without error.

Next, the application configures the various features such as the ping and frame watchdogs, RTDMA, external triggering, and so on. These features are described in subsequent sections. The receiver module is now ready to synchronize with the transmitter then begin reception. The synchronization sequence is described in Section 36.4.1.

36.3.3.2 FSI_RX Clocking

The receiver module registers and control logic are clocked by the device system clock (SYSCLK). The receiver state machine is clocked by the receiver input clock pin (RXCLK).

CAUTION

RXCLK must never be faster than SYSCLK.

36.3.3.3 Receiving Frames

Once the receiver has been properly configured and synchronized, incoming messages are handled as described below. Note that there is no equivalent to a chip-select signal to gate incoming data. Every valid clock edge latches data into the receiver.

The header information of the received frame is placed in the respective register fields.

- RX_FRAME_INFO.FRAME_TYPE contains the received frame type.
- RX_FRAME_TAG_UDATA.FRAME_TAG contains the received frame tag.
- RX_FRAME_TAG_UDATA.USER_DATA contains the received user data.

If any error conditions occur during reception such as a CRC mismatch, frame error, frame timeout, buffer overrun, or ping watchdog timeout, the corresponding flag is set in the RX_EVT_STS register.

Note

If at any point during operation a frame error occurs, the receiver module must be reset and re-synchronized with the transmitter before the next frame can be successfully received. The follow errors are classified as frame errors:

- Type error
- CRC error
- End of frame error

36.3.3.3.1 Receiving Frames with RTDMA

The FSI receiver can continuously receive data and move the data from the receiver buffer with the RTDMA. A RTDMA trigger is generated every time a data frame has been received. This is concurrent with the FRAME_DONE signal that sets the RX_EVT_STS.FRAME_DONE flag. To receive continuous data with the RTDMA, some configurations need to be made on the receiver.

First, set RX_DMA_CTRL.DMA_EVT_EN to 1. This allows the RTDMA trigger to propagate to the RTDMA module. The receiver is now able to trigger a RTDMA event upon the reception of a data frame.

The RTDMA must also be configured properly for the FSI to receive the data. One way for using the receiver to continuously feed the RTDMA is:

- Set up two RTDMA channels to be triggered by the FSI Receiver RTDMA trigger.
- Configure one RTDMA channel to copy data from the receive buffer to a larger data buffer.
- Configure the next RTDMA channel to copy the received frame tag and user data to another data buffer.
- Since the FSI receive buffer is a 16-word circular buffer, make sure the RTDMA channel servicing the data buffer wraps after 16 words are copied.

Unlike the transmitter, there is no requirement to have the RTDMA channel that is handling the data buffer execute before the RTDMA channel handling the received tag and user data.

36.3.3.4 Ping Frame Watchdog

The ping frame watchdog is a hardware-enabled automatic error detection of the connection status to the transmitter. This watchdog monitors the time elapsed between ping frames. If the transmitter has been set up to periodically send out a ping frame, the receiver can be set up to monitor whether this frame has been received within a specified amount of time. If the time between ping frames has exceeded the programmed number of clock cycles, an event is triggered that can generate an interrupt or be monitored by software.

This watchdog has a dedicated counter that is reset and restarted upon the successful reception of a ping frame. The watchdog counter is incremented at the rate of SYSCLK. Optionally, the watchdog can be configured to be reset upon the successful reception of any frame. This option allows the receiver to monitor for any successful frame to indicate that the connection is still alive and the transmitter is still functioning as expected.

To configure the ping frame watchdog for operation:

1. Reset the ping watchdog counter by setting RX_PING_WD_CTRL.PING_WD_RST to 1 and then subsequently clearing the bit to 0.
2. Set RX_OPER_CTRL.PING_WD_RST_MODE to the desired watchdog reset event, set to 0 for ping frames only or set to 1 for any frame.
3. Set RX_PING_WD_REF to the maximum time between frames. Add 10 additional SYSCLK cycles to account for clock synchronization.
4. Enable the ping watchdog by setting RX_PING_WD_CTRL.PING_EN to 1.

The ping watchdog is now enabled and can now monitor for ping frames.

If the RX_PING_WD_CNT value reaches the value programmed in RX_PING_WD_REF, the RX_EVT_STS.PING_WD_TO flag is set. If configured, an interrupt can be generated on this event.

36.3.3.5 Frame Watchdog

The frame watchdog is an additional feature the receiver can use to monitor for any error conditions. This dedicated watchdog monitors the duration for a single frame to be received. The watchdog starts incrementing at the time the receiver detects a proper start of frame condition. If the end of frame condition is not detected within the expected number of SYSCLK cycles, the frame watchdog is triggered that can generate an interrupt or be monitored by software.

This watchdog is automatically started and stopped at the start-of-frame and end-of-frame conditions, respectively. The frame watchdog is connected to SYSCLK.

To configure the frame watchdog for operation:

1. Reset the frame watchdog counter by setting RX_FRAME_WD_CTRL. FRAME_WD_CNT_RST to 1 and then subsequently clearing the bit to 0.
2. Set RX_FRAME_WD_REF.FRAME_WD_REF to the maximum number of SYSCLK cycles expected to be in the longest frame that can be received. Add an additional 10 SYSCLK cycles to account for clock synchronization.
3. Enable the frame watchdog by setting RX_FRAME_WD_CTRL.FRAME_WD_CNT_EN to 1.

The frame watchdog is now enabled and can detect a failed frame.

If the RX_FRAME_WD_CNT reaches the value programmed in RX_FRAME_WD_REF, the RX_EVT_STS.FRAME_WD_TO flag is set. If enabled, an interrupt can be generated on this event.

If the frame watchdog interrupt ever occurs, the receiver core is in an invalid state to receive a new transmission. The only way to recover from a frame watchdog time out is to undergo a soft reset, and subsequently resynchronizing with the transmitter.

36.3.3.6 Delay Line Control

The receiver module has a programmable delay line on each of the external signal inputs: RXCLK, RXD0, and RXD1. The delay elements introduce delays on the respective lines. This is to facilitate adjustment for signal delays introduced by system level components such as signal buffers, ferrite beads, isolators, and so on, or board delays such as uneven trace lengths, long cable length, and so on. The length of the delay is controlled by setting the RX_DLY_LINE_CTRL register values for each line. By default, no delay is introduced by the delay line elements. The delay values must only be adjusted while the FSIRX is held in soft reset, making sure that there are no active transmissions during this process. Figure 36-7 shows a representation of the delay line circuitry for the input signals. The implementation for RXCLK, RXD0, and RXD1 are replicas of this diagram. All circuits behave similarly.

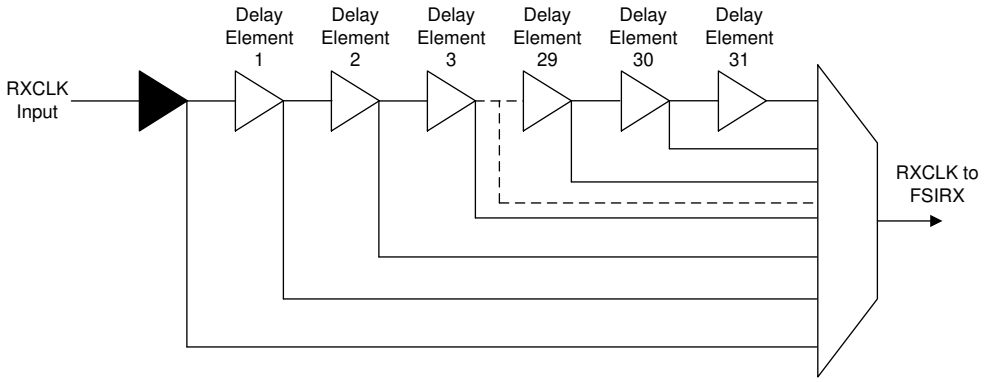

Figure 36-7. Delay Line Control Circuit

For more information on skew compensation, refer to *Fast Serial Interface (FSI) Skew Compensation*.

The FSITX module also has a delay line control circuitry that is placed before the FSITX signals (TXCLK, TXD0, and TXD1) are sent to the TDM signal selection mux (controlled by the SEL_TDM_PATH signal). The TX_DLY_LINE_CTRL register determines the length of the delay for each output line.

36.3.3.7 Buffer Management

The FSI receiver has a 16-word buffer that the data is copied to when the data has been received. This buffer is implemented as a circular buffer, not a FIFO, so some care must be taken to properly interpret buffer overrun and underrun as well as the RX_BUF_PTR_STS register. These flags and pointers work under the assumption that the software or RTDMA is using the buffer as a circular buffer. If the receiver state machine enters into an erroneous state, there is no way for software to cleanly handle this because there is no specified receive clock. For the receiver to detect a clean resynchronization, the state machine needs to be operational and not in the error state. The only way to recover from the error state is to reset the entire receiver module. For overrun and underrun, the receiver can no longer verify that values in the buffer are valid. As such, the best way to recover is to reset the FSI and resynchronize with the transmitter.

Due to the flexibility of the receive buffer, it is possible for software to implement a simple ping-pong buffer, or to randomly receive and read from any location of the buffer. If the buffer is used in this manner, these flags and status fields can be ignored without adversely affecting the receiver capability. Additionally, the CURR_WORD_CNT is also invalid if used in this way. The application can set the buffer pointer manually by writing the 4-bit index to RX_BUF_PTR_LOAD. This forces the receiver to start storing the received data starting at the indicated location in the buffer.

36.3.3.8 CRC Submodule

The receive module automatically calculates the CRC on the incoming data. The received CRC value is placed into RX_CRC_INFO.RX_CRC. The CRC value calculated by hardware on the received data is placed into RX_CRC_INFO.CALC_CRC. These values are compared by hardware and RX_EVT_STS.CRC_ERROR is set if there is a mismatch. The receiver can generate an interrupt based on RX_EVT_STS.CRC_ERROR if enabled.

Since the CRC is only used in data frames, the values found in RX_CRC_INFO.RX_CRC and RX_CRC_INFO.CALC_CRC are undefined during ping and error frames.

For more information on how the CRC is calculated, refer to Section 36.3.7.

If the transmitting module is sending a software-defined CRC value (FSITX.TX_OPER_CTRL_LO.SW_CRC = 1), the receiver module triggers a CRC error event if the received value does not match the hardware-calculated value. As this is an application-level decision, the FSIRX can safely disregard the CRC error event. Application software needs to calculate and verify the incoming CRC using the same custom algorithm used on the transmitter and act appropriately.

The CRC field can also be used as an application-specific value, not a CRC. The application can use the RX_CRC_INFO.RX_CRC as required. All CRC errors and flags can be ignored in this situation.

36.3.3.9 Using the Zero Bits of the Receiver Tag Registers

The receiver tag registers (receiver frame tag and user data (RX_FRAME_TAG_UDATA) register and receiver ping tag (RX_PING_TAG) register)) have the least-significant bit set to 0. The actual received tag is in the bit positions 4:1. The reason for this is to facilitate user software to create a table of functions that can be called depending on the tag value. A function pointer needs a 32-bit storage space and, hence, each successive pointer is offset by 2. If the first pointer is at address x, then the second pointer is at address x + 2, the third at address x + 4, and so on. By keeping the LSB to 0, the five bits of the tag register (bits 4:0) can now be directly used as an index into a table of function pointers.

Note

C29 devices are 8-bit addressable, so each 32-bit pointer requires four addresses. To utilize the frame tag as a pointer on 8-bit addressable devices, the value in the FRAME_TAG field must be multiplied by 2.

36.3.3.10 Conditions in Which the Receiver Must Undergo a Soft Reset

The receiver receives data on every clock edge. While there are specific patterns that determine the a start of a frame, and denote the end of a frame, these patterns are able to occur at any point during normal operation inside of the frame. If there ever is a point at which the receiver fails to detect a successful frame, the module must be reset to make sure that subsequent frames are received properly.

When any of the following errors occur in a received frame, the receiver can be required to be reset and resynchronized with the transmitter:

- Frame type error
- End of frame error
- Ping frame watchdog timeout
- Frame watchdog timeout
- Receiver in an invalid state due to noisy clock

The receiver core status (RX_VIS_1.RX_CORE_STS) can be monitored to determine if the receiver core has entered into an error state requiring a soft reset to resume communication. Incorrect frame type and end of frame errors always cause this bit to become set. A soft reset is required in these cases. A frame watchdog timeout always requires a reset due to the fact that the receiver state machine is still expecting more information when the watchdog timed out. RX_CORE_STS can be used to determine if a noise event was the cause of the failed frame. The ping frame watchdog also does not cause RX_CORE_STS to be set. Similar to the frame watchdog, a corrupt receiver can not be the reason for the ping frame to have timed out. The transmitter can

have gone offline and never sent a ping frame. Alternately, during idle time, a noise event can have occurred, thereby putting the receiver into a corrupt state. As the receiver is able to detect this during the ping frame watchdog timeout interrupt handler, this type of event is not lost and the application can act appropriately.

As the receiver is clocked by RXCLK, not SYSCLK, a noisy clock or data line can cause some internal design constraints to be violated, putting the receiver core logic into undefined states. Make sure that the clock and data lines satisfy the Electrical Characteristics and timing requirements of the FSI module found in the device data sheet. Failure to do so can cause the receiver state machine to go into an unrecoverable error state. The receiver can only be recovered by undergoing a soft reset. To determine the state of the receiver core after an unexpected frame error, the application must check the receiver core status bit.

In addition to the above errors, buffer overrun or underrun can warrant a soft reset to resynchronize with the local application software. Refer to Section 36.3.3.8 for more information on the receive buffers. The requirement of resetting the receiver due to overrun or underrun is up to the application.

After the receiver has been placed into soft reset, the application must notify the other device's transmitter to begin a new synchronization phase. The simplest way to achieve this is through a ping or error frame sent with a designated tag. If the application is not using the FSITX on the device with the detected error, some other method must be established. The other device must stop transmitting and begin a new synchronization phase.

36.3.3.11 FSI_RX Reset

The receiver module and the registers are reset by SYSRSn. The receiver core is reset by SYSRSn or by writing a 1 to RX_MAIN_CTRL.CORE_RST.

A module reset causes the registers to be reset to the default state. After a module reset, the receiver module must be re-initialized and the data link re-established.

36.3.4 Frame Format

The FSI module transmits and receives information in frames. Each frame contains multiple phases where different information can be found. The number of phases as well as the total length of the frame varies depending on the frame type being transmitted. Frames can be as short as 16-bits long for a ping or error frame or 288-bits long for a 16-word data frame.

In normal transmission mode, there are four preamble clock edges before the start of the frame and four post-frame clock edges (postamble). Data is transmitted on both edges of the clock (double data rate). The basic frame structure is shown in Table 36-4. Each phase of the frame (such as start-of-frame, frame type, and so on) is transmitted with the most-significant bit first. Table 36-4 describes the basic frame structure used by the FSI and adapted according to which frame type is transmitted.

Table 36-4. Basic Frame Structure

Idle State	Preamble	Start of Frame	Frame Type	User Data	Data Words	CRC Byte	Frame Tag	End of Frame	Postamble	Idle State
	1111	1001	4 bits	8 bits	1-16 words	8 bits	4 bits	0110	1111	

The FSI also supports a FSI-SPI compatibility mode. The SPI compatible frame structure is similar to a standard FSI frame, but there are differences. Refer to Section 36.3.9 for more information on how to configure and use the FSI-SPI compatibility mode.

Note

One word of the FSI refers to 16 bits.

The terms “frame” and “packet” can be used interchangeably to describe the signaling format of the FSI.

36.3.4.1 FSI Frame Phases

The different phases of the frame structure are described in detail.

- **Idle State:** During the idle state, the clock and data lines are driven high, the inactive state.
- **Preamble:** The preamble phase contains four clock edges (or two complete clock pulses) with the data signals held in the high state. These clock edges serve to flush the receiver logic and prepare the receiver logic for receiving a new frame. This phase is not present in SPI compatibility mode.
- **Start of Frame:** The start of frame phase contains two clock pulses with four bits, 1001, transmitted on the data lines.
- **Frame Type:** The frame type phase contains two clock pulses with the 4-bit frame type code being transmitted on the data lines. The different frame types are described in detail in Section 36.3.4.2. The transmitter must set the TX_FRAME_CTRL.FRAME_TYPE field before transmitting a frame. The received frame type is stored in the RX_FRAME_INFO.FRAME_TYPE.
- **User Data:** The user data phase contains a fully user-configurable data field. There are no restrictions on how this field is used. This phase is only available in data frames. The user data to be transmitted is set by writing to TX_FRAME_TAG_UDATA.USER_DATA. The received user data is stored in RX_FRAME_TAG_UDATA.USER_DATA.
- **Data:** The data phase contains the data that is being transmitted. The data is pulled from the transmit buffer of the transmitter and is placed in the receive buffer of the receiver. Word 0 is transmitted first. This phase is only present in data frames. Depending on the type of frame transmitted, this can contain anywhere between 1 and 16 words depending on the frame type selected. More information on data frames is found in Section 36.3.4.2.3.
- **CRC Byte:** The CRC byte contains the CRC of the transmitted data. The value present in this phase can be sourced from either hardware or software based on the TX_OPER_CTRL_LO.SW_CRC bit. Refer to the module-specific section of the CRC Submodule for more information on the CRC is generated or used, for the transmitter and receiver modules respectively. The CRC byte is only present in data frames.
- **Frame Tag:** The frame tag contains the 4-bit user-defined frame tag. There are no restrictions on how this field is used in an application. The transmitter supplies this tag into the TX_FRAME_TAG_UDATA.FRAME_TAG bits for data frames. Ping frames use the tag defined in TX_PING_TAG.TAG. The receiver can access the received frame tag in RX_FRAME_TAG_UDATA.FRAME_TAG.
- **End of Frame:** The end of frame contains four clock edges with four bits, 0110, transmitted on the data lines.
- **Postamble:** The postamble contains four additional clock edges with the data lines held in the high state. After the postamble, the clock and data lines are driven high (inactive state). This phase is not present in FSI-SPI compatibility mode.

36.3.4.2 Frame Types

The FSI hardware can generate and handle many predefined frame types. The different frame types can be used by the application to signal different types of events or convey different information to the receiver. The different frame types influence which phases and data fields to include in the transmitted frames.

Table 36-5 provides a short overview of the different frame types used by the FSI. Each frame type is described in more detail in the following subsections.

Table 36-5. Frame Types and the 4-bit Codes

Frame Type	4-bit Frame Code	Description
PING	0000	Used typically for checking line integrity. A ping frame can be sent either by software or automatically by hardware.
ERROR	1111	Used typically during error conditions or any condition where one side wants to signal the other side for attention. However, the user software can use an error frame for any purpose.
DATA_1_WORD	0100	1 word data packet (16 bits of data)
DATA_2_WORD	0101	2 word data packet (32 bits of data)
DATA_4_WORD	0110	4 word data packet (64 bits of data)
DATA_6_WORD	0111	6 word data packet (96 bits of data)
DATA_N_WORD	0011	N(1-16) word data packet where software has programmed the number of the data words in a designated register. Both transmitter and receiver modules must have the same value programmed.
Reserved	0001, 0010, and 1000-1110	Reserved

36.3.4.2.1 Ping Frames

Ping frames are one of the most basic frames that can be generated by the FSI. Table 36-6 shows the structure of the ping frames.

Table 36-6. Ping Frame

Idle State	Preamble	SOF	Frame Type	Frame Tag	EOF	Postamble	Idle State
	1111	1001	0000	xxxx	0110	1111	

The ping frame type is always 0000. The frame tag is defined by the application. Separate frame tags exist for timer and software initiated ping frames. No data or CRC is transmitted in a ping frame.

The main purpose of the ping frame is to periodically send a notification to the receiver to make sure an active connection between the transmitter and receiver. The transmitter and receiver cores implement different features to allow the ping frame to operate as a line break detect feature.

On the transmitter, the ping frame is the only frame that can be set up and transmitted without any further software or RTDMA intervention. Ping frames can be transmitted by any (or all) of the three sources: automatic ping timer, software, or external triggers. See Section 36.3.2.3.3 for information on how the transmitter configures and sends the ping frames.

The receiver has a ping watchdog that can detect if a ping frame has not been received in a predetermined window. This allows the receiver to know if the connection between the receiver and the transmitter has been broken. See Section 36.3.3.4 for information on how the receiver handles ping frames.

36.3.4.2.2 Error Frames

Error frames are similar to ping frames in that there are no data fields transmitted. Despite the naming of this frame as an “error frame,” the usage of it is up to the application, as no restrictions are placed on how and when this type of frame is transmitted. Table 36-7 shows the structure of an error frame.

Table 36-7. Error Frame

Idle State	Preamble	SOF	Frame Type	Frame Tag	EOF	Postamble	Idle State
	1111	1001	1111	xxxx	0110	1111	

The structure of the error frame is the same as a ping frame. No data or CRC values are transmitted. The frame type is 1111 for all error frames, and the frame tag is defined by software in the TX_FRAME_TAG_UDATA register.

The receiver can detect if an error frame has been received based on the frame type field. Because of this, the receiver can read the incoming frame tag from the RX_FRAME_TAG_UDATA register and act on up to 16 different conditions.

36.3.4.2.3 Data Frames

Data frames are the most complex frames. As the name indicates, these frames are used to transfer data. Table 36-8 shows the general structure of data frames.

Table 36-8. Data Frame

Idle State	Preamble	SOF	Frame Type	User Data	Data Words	CRC Byte	Frame Tag	EOF	Postamble	Idle State
	1111	1001	0xxx	xxxx xxxx	1-16 words	xxxx xxxx	xxxx	0110	1111	

The frame type field reflects the 4-bit code of the frame type. A list of frame types can be seen in Table 36-5. The number of the data words transmitted is determined by the frame type chosen.

There are four fixed-length data frames supported by the frame type: 1 word, 2 words, 4 words, and 6 words.

Additionally, there is a user-defined data length frame type where the number of data words is fixed by software. Anywhere from 1 to 16 words can be transmitted in this frame type. This length must be configured in the N_WORDS field of the transmitter’s TX_FRAME_CTRL register and receiver’s RX_OPER_CTRL register.

36.3.4.3 Multi-Lane Transmission

The FSI is capable of transmitting and receiving data on two parallel data lines. When enabled, data bits are split between the data lines while the start of frame, frame type, frame tag, and end of frame fields are identical and complete on each line. The user data, data, and CRC fields are split between the data lines. Starting with the most-significant bit, the odd-numbered bits appear on D0 and even-numbered bits appear on D1.

In the following example, assume the following:

8-bit user data: u7u6u5u4u3u2u1u0

16-bit data: d15d14d13d12…d1d0

8-bit CRC: c7c6c5c4c3c2c1c0

Table 36-9. Multi-Lane Frame Format

Idle State	Preamble	SOF	Frame Type	User Data	Data Words	CRC Byte	Frame Tag	EOF	Postamble	Idle State
TXD0	1111	1001	0011	$u^7u^5u^3u^1$	$d^{15}d^{13}…d^1$	$c^7c^5c^3c^1$	xxxx	0110	1111	
TXD1	1111	1001	0011	$u^6u^4u^2u^0$	$d^{14}d^{12}…d^0$	$c^6c^4c^2c^0$	xxxx	0110	1111	

36.3.5 Flush Sequence

Every time there is a soft reset of the receiver, the receiver requires a flush sequence from the transmitter before the receiver can receive and decode frames. The receiver core has an asynchronous reset mechanism that allows the receive module to be reset even in the absence of the receive clocks. However, due to the design, this reset is released synchronous to the receive clock (RXCLK). Thus, the receiver requires five full clock pulses to be able to come out of reset. Sending the flush pattern makes sure that these clock edges are received and any subsequent frames sent to the receiver are correctly interpreted.

The flush sequence consists of a single toggle on both of the data lines as well as five consecutive pulses on the clock line.

If the FSI receiver is receiving data from a standard SPI, a data word of 0xFFFF from the SPI has the same effect as a flush sequence.

Figure 36-8 shows a sample plot of the flush sequence.

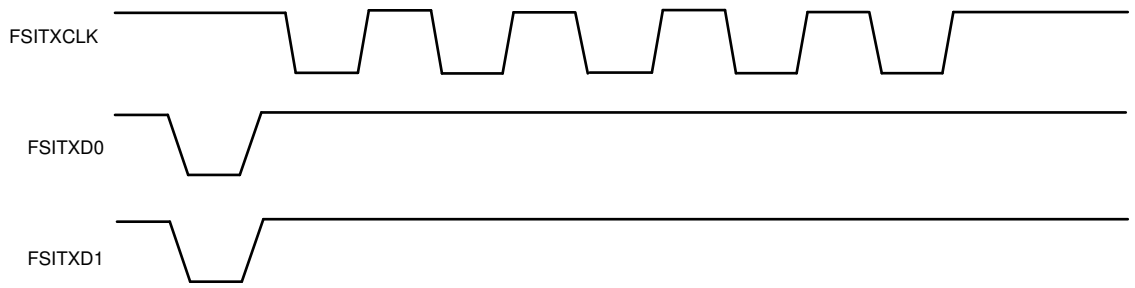

Figure 36-8. Flush Sequence Signals

36.3.6 Internal Loopback

The transmitter and receiver cores can be connected together internally to allow for development and debug. This is achieved by setting RX_MAIN_CTRL.INT_LOOPBACK to 1. Internal loopback routes the signals from the corresponding transmitter to the appropriate receiver pin. No configuration needs to be done in the transmitter. Figure 36-9 shows the signal connections with internal loopback.

In this device, there are four FSI transmitter cores (A, B, C, and D), and four receiver cores (A, B, C, and D). When using loopback mode, each of the FSI transmitter cores can be used in the loopback mode with two FSI receiver cores. Refer to Table 36-10 for specific loopback connections between FSI transmitter and Receiver cores.

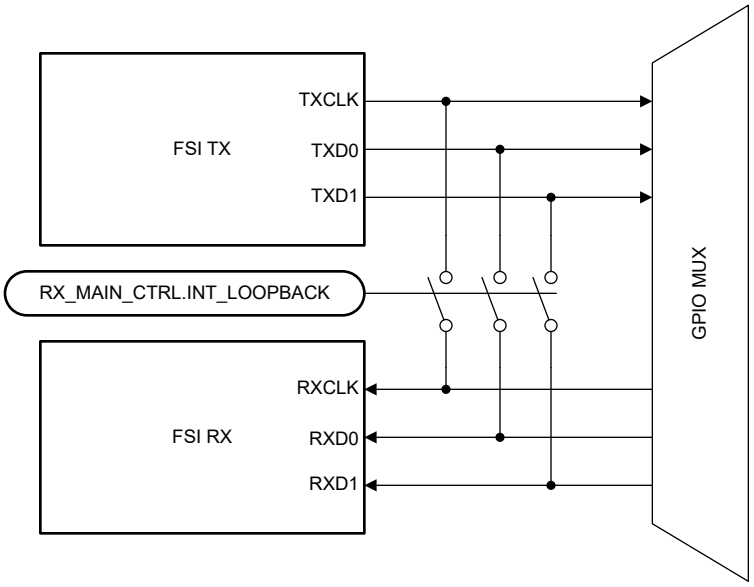

Figure 36-9. FSI with Internal Loopback

Table 36-10. Loopback Connections

TX Module	RX Modules
FSIA TX	FSIA RX, FSIC RX
FSIB TX	FSIB RX, FSID RX
FSIC TX	FSIC RX, FSIA RX
FSID TX	FSID RX, FSIB RX

36.3.7 CRC Generation

The FSI uses CRC-8 with the polynomial 0x07 for the internal hardware CRC generation. This polynomial is also represented as x^8+x^2+x+1.

For example, for a 2-word data packet the following calculation occurs:

Data-1 = 0x4433

Data-0 = 0x2211

User Data = 0xAA

The CRC is computed with the bytes being taken in the following order (first to last):

0xAA – Byte 0, User Data

0x11 – Byte 1, Data-0, Least-significant byte

0x22 – Byte 2, Data-0, Most-significant byte

0x33 – Byte 3, Data-1, Least-significant byte

0x44 – Byte 4, Data-1, Most-significant byte

36.3.8 ECC Module

The FSI module comes with a 16-bit or 32-bit ECC computation module in both the transmitter and receiver. Use of this module is optional.

Note that the ECC is independent and unrelated to the hardware CRC computation module present in both the transmitter and receiver cores.

The following example shows a scenario in which the application requires ECC be calculated and transmitted on a 2-word data frame.

In the FSITX module:

1. Configure the ECC module for 32-bit data by setting TX_OPER_CTRL_HI.ECC_SEL to 1.
2. Write the data to the TX_ECC_DATA register as well as the transmit buffer.
3. Read TX_ECC_VAL Register. This register contains the 8-bit ECC value calculated on the data.
4. Copy the 8-bit data from TX_ECC_VAL to TX_FRAME_TAG_UDATA.USER_DATA.
5. Set the Start Condition to begin the transmission.

The reverse process is followed on the FSIRX module. Once the data frame is received, user software can do the following:

1. Copy the data from the receive buffer to the RX_ECC_DATA register.
2. Copy the received user data that contains the transmitted ECC value from RX_FRAME_TAG_UDATA.USER_DATA to the RX_ECC_VAL register.
3. Read the RX_ECC_LOG register. This contains the result of the ECC computation using the RX_ECC_DATA and RX_ECC_VAL registers.
   a. If no ECC errors were detected, RX_ECC_LOG is 0. The correct data is available in RX_ECC_SEC_DATA.
   b. If a single bit error was detected, RX_ECC_LOG.SBE is 1. The autocorrected data is available in RX_ECC_SEC_DATA.
   c. If multiple bit errors occurred, RX_ECC_LOG.MBE is 1. The data in RX_ECC_SEC_DATA is invalid and must not be used.

Using a 2-word data frame plus using the user data for the ECC is one possible implementation for ECC detection. Another option is to use a larger data frame a allocate one of the data words to be the ECC value.

36.3.9 FSI-SPI Compatibility Mode

The FSI supports a SPI compatibility mode. While the FSI can communicate with a standard SPI module, the FSI supports a limited configuration. The features of this compatibility mode are:

- Data transmits on rising edge and receive on falling edge of the clock.
- Only 16-bit word size is supported.
- TXD1 is driven like an active-low, chip-select signal. The signal is low for the duration for the full frame transmission.
- No receiver chip-select input is required. RXD1 is not used. Data is shifted into the receiver on every active clock edge.
- No preamble or postamble clocks are transmitted. All signals return to the IDLE state after the frame phase is finished.
- It is not possible to transmit in the SPI peripheral configuration because the FSI TXCLK cannot take an external clock source.

Table 36-11 lists the frame structure of the FSI-SPI compatibility mode. Each frame phase is present in this mode. If the FSI is transmitting to a standard SPI module, the SPI must decode the frame structure. Similarly, if the FSI is configured as a SPI peripheral, the standard SPI must encode the transmission to be sent.

Table 36-11. FSI-SPI Compatibility Frame Structure

Idle State	Start of Frame	Frame Type	User Data	Data Words	CRC byte(1)	Frame Tag	End of Frame	Idle State
	1001	4 bits	8 bits	1-16 words	8 bits	4 bits	0110	

(1) The CRC byte is present only in data frames.

Because of the requirement that the standard SPI module encodes the various frame data, this limits the type of modules that can be connected to the FSI in SPI mode. The paired SPI module must have enough functionality to encode and decode the frames.

If the FSI is transmitted to a standard 16-bit SPI, the data is arranged in the following manner. The example provided in Table 36-12 assumes a DATA_2_WORD frame has been sent.

Table 36-12. Contents of Data Received by a Standard SPI

SPI Data	Data Contents
SPI word 0	1001, 0100, 8-bit User Data
SPI word 1	Data word 1
SPI word 2	Data word 2
SPI word 3	8-bit CRC, 4-bit Frame Tag, 0110

36.3.9.1 Available SPI Modes

There are a few wiring schemes available for the FSI to use when communicating with an SPI module.

36.3.9.1.1 FSITX as SPI Controller, Transmit Only

The FSITX can operate as an independent SPI controller module. In this condition, TXCLK is connected to SPICLK, TXD0 is connected to SPIPICO, and TXD1 is connected to $\overline{\text{SPIPTE}}$, the chip select.

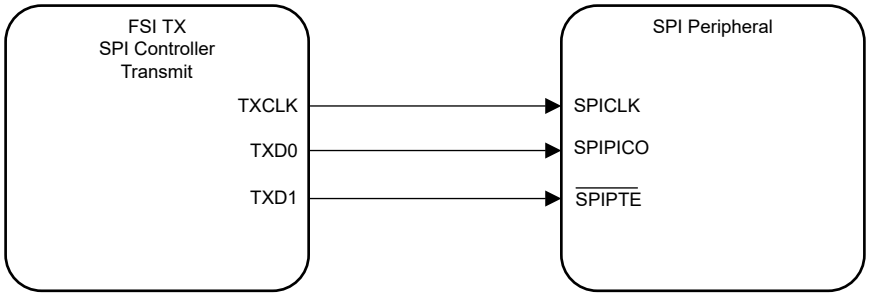

Figure 36-10. FSITX as SPI Controller, Transmit Only

When the FSI is an SPI transmitter, the application has the ability to check for frame errors, line breaks, CRC errors, and ECC checks on data. These are all encoded by hardware in every FSI frame. The SPI receiver requires some software to act upon this information.

Table 36-13. FSI as Controller Transmitter, SPI as Peripheral Receiver

Capability	Availability	Comment
Framing checks on the data frames	Yes	Can be implemented in software on the SPI receiver.
Ability to detect line breaks	Yes	Can be implemented in software on the SPI receiver but requires additional software overhead such as a timer or watchdog.
CRC check	Yes	Can be implemented in software on the SPI receiver. For devices that have VCRC , this is more efficient.
ECC on data	Yes	Can be implemented in software on the SPI receiver
Detection of abruptly terminated frames	No	
Double edge data rate	No	
Recovery from glitches on signal lines between frames	No	
Skew adjustment on signal lines	No	

36.3.9.1.1.1 Initialization

To configure the FSITX module to be an SPI controller for transmit only, proceed through the standard FSITX initialization procedure. Before releasing the FSITX from reset, set TX_OPER_CTRL_LO.SPI_MODE to 1. This enables the SPI clocking scheme and signaling structure.

36.3.9.1.1.2 Operation

The operation of the FSITX module in FSI-SPI Compatibility mode is the same as if the module is in standard FSI mode. The application can utilize the frame timer, ping frames, external frame triggers, and so on. Refer to Section 36.3.2 for more information on each of these features.

36.3.9.1.2 FSIRX as SPI Peripheral, Receive Only

The FSIRX can operate as an independent SPI peripheral module. In this usage, RXCLK is connected to SPICLK and RXD0 is connected to SPIPICO. RXD1 is unused. There is no requirement for a chip select signal to be used when connected to the FSIRX. This is because the FSIRX responds to any incoming clock edge. If there is any noise or unwanted clock transitions, a flush sequence is required to resynchronize the FSIRX module with the controller.

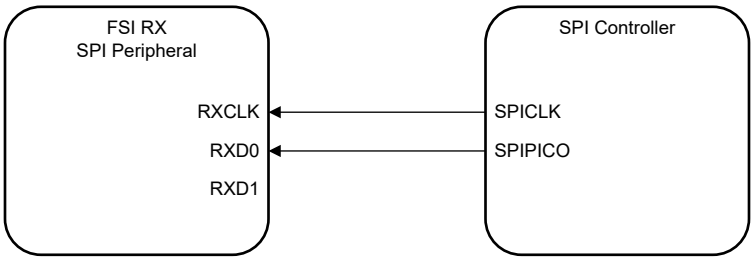

Figure 36-11. FSIRX as SPI Peripheral, Receive Only

When the FSI is an SPI receiver communicating with an SPI transmitter, the application has the ability to detect frame errors, line breaks, CRC errors, ECC checks on data, as well as abruptly terminated frames. Note that the FSI can handle all of this in hardware, but the SPI transmitter must encode the information into the data to be transmitted.

Table 36-14. SPI as Controller Transmitter, FSI as Peripheral Receiver

Capability	Availability	Comment
Framing checks on the data frames	Yes	Standard on FSI
Ability to detect line breaks	Yes	Can be implemented in software on the SPI transmitter but requires the use of a timer or watchdog in the transmitting SPI device.
CRC check	Yes	Can be implemented in software on the SPI transmitter.
ECC on data	Yes	Can be implemented in software on the SPI transmitter.
Detection of abruptly terminated frames	Yes	This is accomplished with the FSI setting up the frame watchdog counter.
Double edge data rate	No	
Recovery from glitches on signal lines between frames	Yes	Whenever glitches occur on either the clock or data lines in between transmissions, the initial flush pattern of a frame discards the effects of these glitches and causes the receiver to resynchronize when the real “start-of-frame” pattern is seen. So, the ability to reject glitches in between frames is very high.
Skew adjustment on signal lines	Yes	The FSI receiver has the ability to add delays to the incoming signal lines.

36.3.9.1.2.1 Initialization

To configure the FSIRX module to be an SPI peripheral for receiving only, proceed through the standard FSIRX initialization procedure. Before releasing the FSIRX from reset, set RX_OPER_CTRL.SPI_MODE to 1. This enables the SPI clocking scheme and signaling structure.

36.3.9.1.2.2 Operation

The operation of the FSIRX module in FSI-SPI compatibility mode is the same as if the module is in standard FSI mode. The application can utilize the Frame and Ping Watchdogs, CRC and ECC checks, and so on. Refer to Section 36.3.3 for more information on each of these features.

36.3.9.1.3 FSITX and FSIRX Emulating a Full Duplex SPI Controller

In this configuration, the FSITX is the controller clock. The FSITX module drives TXCLK (SPICLK), TXD0 (SPIPICO), and TXD1 (SPISTE/chip select) to the SPI peripheral. The SPIPOCI signal is connected back to the RXD0 signal. RXCLK can be applied either using the internal SPI pairing feature or externally wired, depending on the application requirements. Since the FSITX and RX modules are independent, the FSIRX can also be thought of as an additional SPI peripheral. Some software logic is required for the FSI to emulate an SPI controller fully.

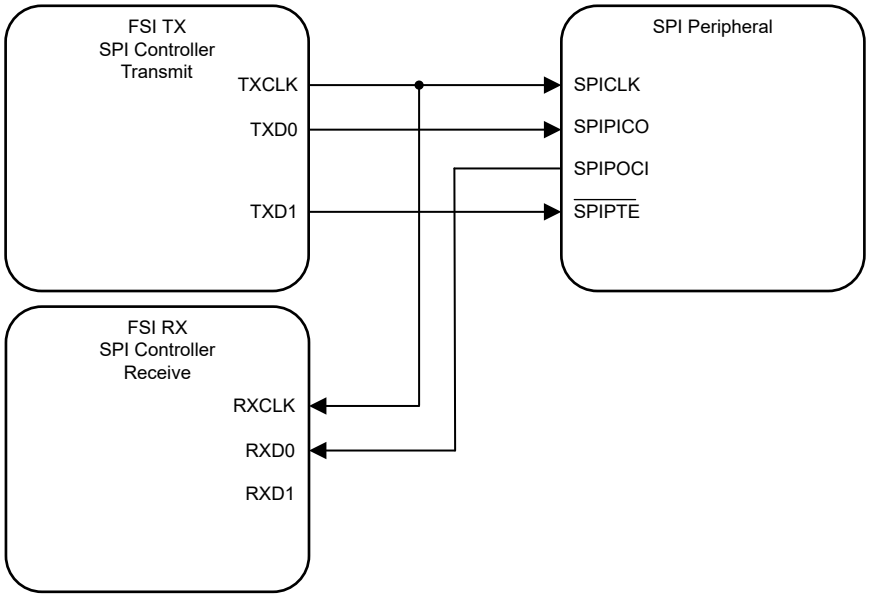

Figure 36-12. FSITX and FSIRX as SPI Controller, Full Duplex

36.3.9.1.3.1 Initialization

To configure both FSITX and RX modules for full duplex SPI controller operation, follow the initialization instructions for each module described in the preceding sections. Both FSITX and RX modules must set the respective SPI_MODE bits. This enables the SPI clocking scheme and signaling structures.

If internal clock loopback is desired, the FSIRX module must also set RX_MAIN_CTRL.SPI_PAIRING to 1. This internally connects TXCLK to RXCLK. If using internal clock loopback, the GPIO used for RXCLK can be reallocated to other application requirements.

If the application requires an external clock loopback, make sure that TXCLK is connected to RXCLK. This is required if the SPI peripheral is across an isolation barrier and there is latency between TXCLK being launched and SPIPOCI data being received on RXD0.

36.3.9.1.3.2 Operation

In this mode of operation, some higher level software must be written to emulate a full SPI controller module. There is no path for the transmit module to determine what the receive module received. Both the TX and RX modules are still able to utilize the various other features available, such as the ping frame timer, ping frame and frame watchdogs, CRC and ECC error checkers, and so on. The procedure for configuring these features is described elsewhere in this document.

36.4 FSI Programing Guide

This section describes various operational sequences and features for the FSI.

36.4.1 Establishing the Communication Link

Once the transmitter and receiver modules have been configured, some synchronization must occur before the modules exchange data. Since the receiver accepts data on any clock transition, the receiver core logic must be flushed to properly interpret the start of a new, valid frame. This is especially true when the FSI modules reside on separate devices and are possibly isolated.

The following example provides a suggested approach for establishing a clean communication link on two separate devices that power up in an arbitrary order. Note that this is only a sample synchronization. Depending on application requirements, a different approach can be followed. The single, most important aspect of synchronization is to make sure that the receiver is properly flushed and ready to receive a complete frame without error. How to achieve this is up to the application.

Figure 36-13 shows the connection of the devices in this example. While there is no true concept of a main device or a remote device node in the FSI protocol, the example uses this nomenclature as a simple way to describe the data flow.

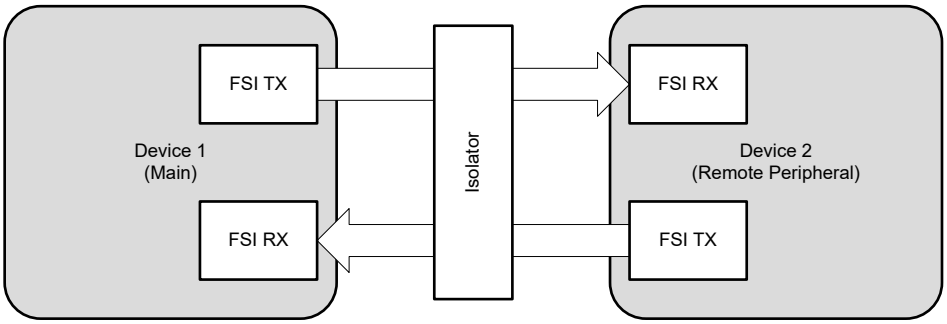

Figure 36-13. Point to Point Connection

Device 1 is the main node; it is the driver of the initialization sequence. Device 2 is the remote node; it responds to the main device commands. In this example, as well as in a real world use-case, neither the main device nor the remote device knows precisely when the other is ready to receive communication.

Sample sequences for both the main device and remote device are provided in the following subsections.

36.4.1.1 Establishing the Communication Link from the Main Device

The following sequence is an example of how the main device node establishes the communication link with the remote device without external signals outside of the standard communication link.

1. Assert the core reset to both the FSITX and FSIRX modules, and then deassert the resets.
2. Configure the transmitter and receiver for desired operation.
3. Set up the receiver interrupts to detect an incoming transmission.
4. Begin the ping loop:
   - Send the flush sequence.
   - Send a ping frame with the frame tag 0000.
   - Wait for some time. (determined by application)
   - If the FSIRX has received a valid ping frame, continue; else, iterate the loop again.
   - If the received ping frame tag was 0001, continue; else, iterate the loop again.
5. Send a ping frame with the frame tag 0001.

At this point, both the main transmit and receive channels have successfully received a frame from the remote counterparts. The link has been established and standard application communication can begin.

36.4.1.2 Establishing the Communication Link from the Remote Device

The following sequence is an example of how the remote device node establishes the communication link with the main device without external signals outside of the standard communication link.

1. Apply the core reset to both the FSITX and FSIRX modules, and then release the reset.
2. Configure the transmitter and receiver for desired operation.
3. Set up the receiver interrupts to detect an incoming transmission.
4. Wait for a receiver interrupt.
5. If the FSIRX has received a valid ping frame, continue; else, return to step 4.
6. If the received frame tag was 0000, continue; else, discard the transmission and return to step 4.
7. Send the flush sequence.
8. Send a ping frame with the frame tag 0001.
9. Wait for a receiver interrupt.
10. If the FSIRX has received a valid ping frame, continue; else, return to step 4.
11. If the received ping frame tag was 0001, continue; else, if the received frame tag was 0000, return to step 9. This can happen if a second ping frame was already in transit before receiving the remote device response in step 8.

At this point, both the transmit and receive modules have successfully received ping frames from the main counterparts. The link has been established and regular communication can now proceed. The application can configure periodic ping frames from the transmitter, initialize the receiver ping and frame watchdogs, and begin the communication required by the application.

36.4.2 Register Protection

Both the FSITX and FSIRX modules contain control registers that have embedded write protection. This is accomplished through EALLOW, register keys, and a main register lock. These protections make sure that no spurious writes or unintentional modifications to these registers are accepted. For the list of registers with write protections available and the register and bit descriptions, refer to the *FSI Registers* section..

EALLOW Protection

EALLOW is a device-level register protection. For those registers with EALLOW protection, the EALLOW bit is set before modifying the register. The application then clears the EALLOW bit to re-enable the write protection when access to EALLOW-protected registers are complete.

Register Key Protection

In addition to EALLOW, some bits in the FSI registers are protected by a key. To write to these bits, the key must be written at the same time. For example, to put the transmitter core into reset, TX_MAIN_CTRL.CORE_RST must be set. To do this, write 0xA501 to TX_MAIN_CTRL, where 0xA500 is the KEY value, and 0x0001 is the CORE_RST value. Refer to the *Registers* section for more information on which registers have write keys added.

Control Register Lock Protection

There also exists a main lock to prevent any modifications to the control registers. There is an independent lock for each FSI module. For the list of registers that are protected by this control register lock, refer to the *Registers* section. The control register lock prevents any writes to the control registers until the lock is released. To set the control register lock, write 0xA501 to RX_LOCK_CTRL and TX_LOCK_CTRL for the receiver and transmitter, respectively.

The control register lock cannot be disabled by the application until a SYSRSn has been asserted. This can occur at the device level, or by writing to the appropriate peripheral soft reset register (DEV_CFG_REGS.SOFTPRESx) for the FSI module. Refer to Section 36.3.2.7 for more information on SYSRSn.

36.4.3 Emulation Mode

There is no specific emulation mode or configuration supported. The FSI cores are always in free running mode. CPU halts do not have any effect on the operation of the FSI. Reads of registers and data buffers by the debugger do not affect any flags or status of the data buffers.

If you want to stop the operation of either FSI module when the debugger halts, the following steps are required:

1. Set the debugger to real-time emulation mode.
2. Mark the FSI interrupt group as a time-critical interrupt. That is, enable the corresponding bit in the DBGIER register.
3. The ISR can check the DSTAT register and to determine if the ISR was called when the debugger was halted.
4. FSI operations can be disabled and the ISR can branch to a debug-specific halt location.

36.5.2 FSI Examples

NOTE: These examples are located in the C29SDK installation from ti.com at the following location: mcu_sdk_DEVICE_GPN/examples/driverlib/CORE_IF_MULTICORE/fsi

Cloud access to these examples is available at the following link: dev.ti.com C29SDK Examples.

36.5.2.1 FSI Loopback:CPU Control - SINGLE_CORE

FILE: fsi_ex1_loopback_cpucontrol.c

Example sets up infinite data frame transfers where trigger happens through *CPU*. Automatic(Hw triggered) Ping frame transmission is also setup along with data.

User can edit some of configuration parameters as per usecase. These are as below. Default values can be referred in code where these globals are defined

- *txUserData* - User data to be sent with Data frame
- *txDataFrameTag* - Frame tag used for Data transfers
- *txPingFrameTag* - Frame tag used for Ping transfers

For any errors during transfers i.e. *error* events such as Frame Overrun, Underrun, Watchdog timeout and CRC/EOF/TYPE errors, execution will stop immediately and status variables can be looked into for more details. Execution will also stop for any mismatch between received data and sent ones and also if transfers takes unusually long time(detected through software counters - txTimeOutCntr and rxTimeOutCntr)

External Connections

- None.

Watch Variables

- *dataFrameCntr* Number of Data frame transfered
- *error* Non zero for transmit/receive data mismatch

36.5.2.2 FSI data transfers upon CPU Timer event - SINGLE_CORE

FILE: fsi_ex2_periodic_frame.c

Example sets up infinite data frame transfers where trigger comes from ISR handling the periodic CPU Timer event. Automatic(Hw triggered) Ping frame transmission is also setup along with data.

CPU Timer0 is chosen for setting up periodic timer events. User can choose any other Timer-1/Timer-2 as well.

Automatic(Hw triggered) Ping frame transmission is also setup along with data.

If there are any comparison failures during transfers or any of error event occurs, execution will stop.

External Connections

- None

Watch Variables

- *dataFrameCntr* Number of Data frame transfered
- *error* Non zero for transmit/receive data mismatch

36.6 FSI Registers

This Section describes the FSI Registers.

36.6.1 FSI Base Address Table

Table 36-16. FSI Base Address Table

Structure	DriverLib Name	Base Address	Frame Applicable	CPU1	CPU2	CPU3	RTDMA1	RTDMA2	HSM	Pipeline Protected
FSI_TX_REGS	FSITXA_BASE	0x7018_0000	YES	YES	YES	YES	YES	YES	-	YES

36.6.2 FSI_TX_REGS Registers

Table 36-17 lists the memory-mapped registers for the FSI_TX_REGS registers. All register offset addresses not listed in Table 36-17 should be considered as reserved locations and the register contents should not be modified.

Table 36-17. FSI_TX_REGS Registers

Offset	Acronym	Register Name	Protection
0h	TX_MAIN_CTRL	Transmit main control register	
4h	TX_CLK_CTRL	Transmit clock control register	and LOCK
8h	TX_OPER_CTRL_LO	Transmit operation control register low	and LOCK
Ah	TX_OPER_CTRL_HI	Transmit operation control register high	and LOCK
Ch	TX_FRAME_CTRL	Transmit frame control register	
Eh	TX_FRAME_TAG_UDATA	Transmit frame tag and user data register	
10h	TX_BUF_PTR_LOAD	Transmit buffer pointer control load register	
12h	TX_BUF_PTR_STS	Transmit buffer pointer control status register	
14h	TX_PING_CTRL	Transmit ping control register	and LOCK
16h	TX_PING_TAG	Transmit ping tag register	
18h	TX_PING_TO_REF	Transmit ping timeout counter reference	and LOCK
1Ch	TX_PING_TO_CNT	Transmit ping timeout current count	
20h	TX_INT_CTRL	Transmit interrupt event control register	and LOCK
22h	TX_DMA_CTRL	Transmit DMA event control register	and LOCK
24h	TX_LOCK_CTRL	Transmit lock control register	and LOCK
28h	TX_EVT_STS	Transmit event and error status flag register	
2Ch	TX_EVT_CLR	Transmit event and error clear register	
2Eh	TX_EVT_FRC	Transmit event and error flag force register	
30h	TX_USER_CRC	Transmit user-defined CRC register	
40h	TX_ECC_DATA	Transmit ECC data register	
44h	TX_ECC_VAL	Transmit ECC value register	
48h	TX_DLYLINE_CTRL	Transmit delay Line control register	and LOCK
80h + formula	TX_BUF_BASE_y	Base address for transmit buffer	

Complex bit access types are encoded to fit into small table cells. Table 36-18 shows the codes that are used for access types in this section.

Table 36-18. FSI_TX_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.

Table 36-18. FSI_TX_REGS Access Type Codes (continued)

Access Type	Code	Description
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

36.6.2.1 TX_MAIN_CTRL Register (Offset = 0h) [Reset = 0000h]

TX_MAIN_CTRL is shown in Figure 36-14 and described in Table 36-19.

Return to the Summary Table.

R-0h						R/W-0h	R/W-0h

Table 36-19. TX_MAIN_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	KEY	W	0h	Write Key In order to write to any bit in this register, 0xA5 must be written to this field at the same time. Otherwise, writes are ignored. The key is cleared immediately after writing, so it must be written again for every change to this register. Reset type: SYSRSn
7-2	RESERVED	R	0h	Reserved
1	FLUSH	R/W	0h	Flush Operation Start bit This bit will cause the transmitter to initiate a flush pattern of a single toggle on the TXD0 and TXD1 followed by five full cycles of TXCLK. This bit should be written only when the CORE_RST bit is 0 and the clock to the Transmitter core is turned on. 0h (R/W) = Clear this bit. 1h (R/W) = Setting this bit will Initiate flush sequence. To properly execute a flush sequence, Set FLUSH to 1, wait for five TXCLK cycles then clear FLUSH to 0. Note: The KEY field must contain 0xA5 for any write to this bit to take effect. The software must keep this bit set to 1 for at least five TXCLK cycles before setting it back to 0. Reset type: SYSRSn
0	CORE_RST	R/W	0h	Transmitter Main Core Reset bit This bit controls the transmitter main core reset. In order to send any frame, this bit must be cleared. 0h (R/W) = Transmitter core is not in reset and can transmit frames. 1h (R/W) = Transmitter core is held in reset. Note: The KEY field must contatin 0xA5 for any write to this bit to take effect. Reset type: SYSRSn

36.6.2.2 TX_CLK_CTRL Register (Offset = 4h) [Reset = 0000h]

TX_CLK_CTRL is shown in Figure 36-15 and described in Table 36-20.

Return to the Summary Table.

Transmit clock control register

Table 36-20. TX_CLK_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-10	RESERVED	R	0h	Reserved
9-2	PRESCALE_VAL	R/W	0h	Clock Divider Prescale Value The input clock is divided by this 8-bit value and fed into the transmitter core. This divided clock is the rate at which TXCLK will operate. 0h (R/W) = Reserved 1h (R/W) = Input clock /1 2h (R/W) = Input clock /2 3h (R/W) = Input clock /3 4h (R/W) = Input clock /4 ... FFh (R/W) = Input clock /255 TXCLKIN = Input clock / PRESCALE_VAL In FSI mode: TXCLK = TXCLKIN / 2 In SPI mode: TXCLK = TXCLKIN Reset type: SYSRSn
1	CLK_EN	R/W	0h	Clock Divider Enable bit This bit will enable and disable the input clock divider and start the clock to the transmitter core. 0h (R/W) = The input clock divider is not enabled and the clock is not connected to the transmitter core. 1h (R/W) = The input clock to the transmitter core is being divided by the PRESCALE_VAL and enabled. Reset type: SYSRSn
0	CLK_RST	R/W	0h	Clock Divider Reset bit This bit will reset the clock counter in the clock divider. 0h (R/W) = The clock divider is set based on the value in PRESCALE_VAL. The input clock will be divided by PRESCALE_VAL if CLK_EN is set. 1h (R/W) = The clock divider will be reset to 0 and will stay reset until software writes a 0 to this bit. Reset type: SYSRSn

36.6.2.3 TX_OPER_CTRL_LO Register (Offset = 8h) [Reset = 0000h]

TX_OPER_CTRL_LO is shown in Figure 36-16 and described in Table 36-21.

Return to the Summary Table.

Transmit operation control register low

Table 36-21. TX_OPER_CTRL_LO Register Field Descriptions

Bit	Field	Type	Reset	Description
15-11	RESERVED	R	0h	Reserved
10	SEL_TDM_IN	R/W	0h	Input TDM port Select bit This bit selects the input port for the transmitter core between the TDM input pins or the RX module. When this bit is '0', the inputs selected for TDM are from the TDM input pins. When this bit is '1', then inputs selected for TDM are from the RX module. Reset type: SYSRSn
9	TDM_ENABLE	R/W	0h	Transmit TDM Mode Enable bit. This bit enables the TDM Mode for multi-remote TDM operation. 0h (R/W) Transmit TDM Mode is not enabled. 1h (R/W) Transmit TDM Mode is enabled. Reset type: SYSRSn
8	SEL_PLLCLK	R/W	0h	Input Clock Select bit This bit selects the input clock source for the transmitter core. 0h (R/W) = SYSCLK is the source of the transmitter clock into the clock prescaler. 1h (R/W) = PLLRAWCLK is the source of the transmitter core clock into the clock prescaler. Reset type: SYSRSn
7	PING_TO_MODE	R/W	0h	Ping Counter Reset Mode Select bit This bit selects when the ping counter will reset. 0h (R/W) = The ping counter will reset and restart only on hardware initiated ping frames, when ping counter has timed out. 1h (R/W) = The ping counter will reset and restart on any software initiated frame as well as a ping counter timeout Reset type: SYSRSn
6	SW_CRC	R/W	0h	CRC Source Select bit This bit selects the source of the CRC value that is transmitted. 0h (R/W) = The transmitted CRC value is computed by hardware. 1h (R/W) = The transmitted CRC value is sourced from the value programmed in the TX_USER_CRC register. Reset type: SYSRSn

Table 36-21. TX_OPER_CTRL_LO Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5-3	START_MODE	R/W	0h	Transmission Start Mode Select bit These bits select the method by which a new frame transmission is started. 0h (R/W) = Only a software write to TX_FRAME_CTRL.START initiate a new transmission. 1h (R/W) = The configured external trigger will initiate a new transmission. 2h (R/W) = Either writing to TX_FRAME_CTRL.START or the TX_FRAME_TAG_UDATA register will initiate a new transmission. All other combinations of bits are illegal and reserved for future use. Reset type: SYSRSn
2	SPI_MODE	R/W	0h	SPI Mode Select bit This bit enables and disables SPI compatibility mode. 0h (R/W) = FSI is in normal mode of operation. 1h (R/W) = FSI is operating in SPI compatibility mode. Reset type: SYSRSn
1-0	DATA_WIDTH	R/W	0h	Transmit Data Width Select bits These bits define the number of data lines used by the transmitter. 0h (R/W) = Data will be transmitted on one data line (TXD0) 1h (R/W) = Data will be transmitted on two data lines (TXD0 and TXD1). The format of the data is described in the preceeding chapter. 2h, 3h (R/W) = Reserved Reset type: SYSRSn

36.6.2.4 TX_OPER_CTRL_HI Register (Offset = Ah) [Reset = 0000h]

TX_OPER_CTRL_HI is shown in Figure 36-17 and described in Table 36-22.

Return to the Summary Table.

Bit	Field	Type	Reset	Description
15-14	RESERVED	R	0h	Reserved
13-7	EXT_TRIG_SEL	R/W	0h	External Trigger Select bit These bits define which of the 128 external inputs will be used as the source for the external input trigger. 00h (R/W) = Trigger 1 is the source. 01h (R/W) = Trigger 2 is the source. 02h (R/W) = Trigger 3 is the source. ... 7Fh (R/W) = Trigger 128 is the source. Reset type: SYSRSn
6	ECC_SEL	R/W	0h	ECC Data Width Select bit This bit selects between 16-bit and 32-bit ECC computation. 0h (R/W) = 32-bit ECC is used. 1h (R/W) = 16-bit ECC is used. Reset type: SYSRSn
5	FORCE_ERR	R/W	0h	Error Frame Force bit This bit will force the the CRC value of the transmitted data frame to 0 whenever there is a buffer overrun or underrun condition. This can be used to force a corrupted CRC as the data is not guaranteed to be reliable. The receiver will treat the data as invalid and can handle this as needed. Note: DO NOT use FORCE_ERR if using the SW CRC mode (FSI Transmit). 0h (R/W) = The CRC will not be forced to 0. 1h (R/W) = The CRC will be forced to 0 in a buffer overrun or underrun condition. Reset type: SYSRSn
4-0	RESERVED	R	0h	Reserved

36.6.2.5 TX_FRAME_CTRL Register (Offset = Ch) [Reset = 0000h]

TX_FRAME_CTRL is shown in Figure 36-18 and described in Table 36-23.

Return to the Summary Table.

Transmit frame control register

Figure 36-18. TX_FRAME_CTRL Register

15	14	13	12	11	10	9	8

Table 36-23. TX_FRAME_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
15	START	R/W	0h	Start Transmission bit This bit will cause the FSI to start transmitting the next frame. 0h (R/W) = Writing a 0 to this bit will have no effect. 1h (R/W) = Start the next transmission. This bit will be cleared by hardware. Reset type: SYSRSn
14-8	RESERVED	R	0h	Reserved
7-4	N_WORDS	R/W	0h	Number of Words to be Transmitted This field defines the number of words which will be transmitted in a DATA_N_WORD frame. This is a user-defined field that must match the corresponding field in the receiver. Set this bitfield to be one less than the number of words to be transmitted. 0h (R/W) = 1 data word frame (16-bit data). 1h (R/W) = 2 data word frame (32-bit data). .. Fh (R/W) = 16 data word frame (256-bit data). Reset type: SYSRSn
3-0	FRAME_TYPE	R/W	0h	Transmit Frame Type This field determines the type of frame that will be transmitted next. 0000b (R/W) = Ping Frame. This frame can be sent either by software or automatically by hardware. 0100b (R/W) = DATA_1_WORD Frame. One word data frame (16-bit data). 0101b (R/W) = DATA_2_WORD Frame. Two word data frame (32-bit data). 0110b (R/W) = DATA_4_WORD Frame. Four word data frame (64-bit data). 0111b (R/W) = DATA_6_WORD Frame. Six word data frame (96-bit data). 0011b (R/W) = DATA_N_WORD Frame. The N_WORDS field will determine the number of words (1 to 16) to be sent. Both the transmitter and receiver must have the same value programmed. 1111b (R/W) = Error Frame. This frame can be used during error conditions or any condition where the transmitter wants to notify the receiver of a high priorty status. However, the user software is at liberty to use this for any purpose. 0001b, 0010b, and 1000b through 1110b are Reserved and should not be used. Reset type: SYSRSn

36.6.2.6 TX_FRAME_TAG_UDATA Register (Offset = Eh) [Reset = 0000h]

TX_FRAME_TAG_UDATA is shown in Figure 36-19 and described in Table 36-24.

Return to the Summary Table.

36.6.3 FSI_RX_REGS Registers

Table 36-42 lists the memory-mapped registers for the FSI_RX_REGS registers. All register offset addresses not listed in Table 36-42 should be considered as reserved locations and the register contents should not be modified.

Table 36-42. FSI_RX_REGS Registers

Offset	Acronym	Register Name	Protection
0h	RX_MAIN_CTRL	Receive main control register	
8h	RX_OPER_CTRL	Receive operation control register	and LOCK
Ch	RX_FRAME_INFO	Receive frame control register	
Eh	RX_FRAME_TAG_UDATA	Receive frame tag and user data register	
10h	RX_DMA_CTRL	Receive DMA event control register	and LOCK
14h	RX_EVT_STS	Receive event and error status flag register	
16h	RX_CRC_INFO	Receive CRC info of received and computed CRC	
18h	RX_EVT_CLR	Receive event and error clear register	
1Ah	RX_EVT_FRC	Receive event and error flag force register	
1Ch	RX_BUF_PTR_LOAD	Receive buffer pointer load register	
1Eh	RX_BUF_PTR_STS	Receive buffer pointer status register	
20h	RX_FRAME_WD_CTRL	Receive frame watchdog control register	and LOCK
24h	RX_FRAME_WD_REF	Receive frame watchdog counter reference	and LOCK
28h	RX_FRAME_WD_CNT	Receive frame watchdog current count	
2Ch	RX_PING_WD_CTRL	Receive ping watchdog control register	and LOCK
2Eh	RX_PING_TAG	Receive ping tag register	
30h	RX_PING_WD_REF	Receive ping watchdog counter reference	and LOCK
34h	RX_PING_WD_CNT	Receive pingwatchdog current count	
38h	RX_INT1_CTRL	Receive interrupt control register for RX_INT1	and LOCK
3Ah	RX_INT2_CTRL	Receive interrupt control register for RX_INT2	and LOCK
3Ch	RX_LOCK_CTRL	Receive lock control register	and LOCK
40h	RX_ECC_DATA	Receive ECC data register	
44h	RX_ECC_VAL	Receive ECC value register	
48h	RX_ECC_SEC_DATA	Receive ECC corrected data register	
4Ch	RX_ECC_LOG	Receive ECC log and status register	
50h	RX_FRAME_TAG_CMP	Receive frame tag compare register	and LOCK
52h	RX_PING_TAG_CMP	Receive ping tag compare register	and LOCK
58h	RX_TRIG_CTRL_0	Receive Trigger Control register 0	and LOCK
5Ch	RX_TRIG_WIDTH_0	Receive Trigger Wdith register 0	and LOCK
60h	RX_DLYLINE_CTRL	Receive delay line control register	and LOCK
64h	RX_TRIG_CTRL_1	Receive Trigger Control register 1	and LOCK
68h	RX_TRIG_CTRL_2	Receive Trigger Control register 2	and LOCK
6Ch	RX_TRIG_CTRL_3	Receive Trigger Control register 3	and LOCK
70h	RX_VIS_1	Receive debug visibility register 1	
74h	RX_UDATA_FILTER	Receive User Data Filter Control register	and LOCK
80h + formula	RX_BUF_BASE_y	Base address for receive data buffer	

Complex bit access types are encoded to fit into small table cells. Table 36-43 shows the codes that are used for access types in this section.

Table 36-43. FSI_RX_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

36.6.3.1 RX_MAIN_CTRL Register (Offset = 0h) [Reset = 0000h]

RX_MAIN_CTRL is shown in Figure 36-37 and described in Table 36-44.

Return to the Summary Table.

Receive main control register

Figure 36-37. RX_MAIN_CTRL Register

15	14	13	12	11	10	9	8

Table 36-44. RX_MAIN_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	KEY	W	0h	Write Key. In order to write to this register, 0xA5 must be written to this field at the same time. Otherwise, writes are ignored. The key is cleared immediately after writing, so it must be written again for every change to this register. Reset type: SYSRSn
7-5	RESERVED	R	0h	Reserved
4	DATA_FILTER_EN	R/W	0h	Data Filter Enable Bit. 0h (R/W) = Data filtering is disabled. 1h (R/W) = Data filtering is enabled. Reset type: SYSRSn
3	INPUT_ISOLATE	R/W	0h	When set to 1, the FSI RX inputs (RXCLK, RXD0 and RXD1) will be isolated from what is driven from the device pins and will be held at inactive level of '1'.This isolation facilitates the user to switch the RX inputs to a different set of device pins and hence any potential glitch that could occur during the process of switching will not affect the RX module itself. Reset type: SYSRSn
2	SPI_PAIRING	R/W	0h	Clock Pairing for SPI-like Behavior Enable bit This bit enables the internal clock pairing with the FSI TX module. This feature internally connects the TXCLK to RXCLK allowing the FSI TX module, acting as a SPI controller, to clock data into the receiver and out of the transmitter like a standard SPI module. This configuration is valid when the Module is in SPI mode only (RX_OPER_CTRL.SPI_MODE = 1) 0h (R/W) = SPI clock pairing is not enabled. 1h (R/W) = SPI clock pairing is enabled. The RXCLK will be internally connected to the TXCLK of the corresponding FSI module. Note: The KEY field must contatin 0xA5 for any write to this bit to take effect. Reset type: SYSRSn

Table 36-44. RX_MAIN_CTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	INT_LOOPBACK	R/W	0h	Internal Loopback Enable bit This bit enables the internal loopback functionality of the FSI receiver. By enabling this bit, a mux will select the signals coming directly from the corresponding FSI transmitter module rather than from the pins. 0h (R/W) = Internal loopback is disabled. The FSI RX module will receive signals coming from the pins. 1h (R/W) = Internal loopback is enabled. The FSI RX module will receive signals from the directly from FSI TX module rather than the pins. Note: The KEY field must contatin 0xA5 for any write to this bit to take effect. Reset type: SYSRSn
0	CORE_RST	R/W	0h	Receiver Main Core Reset bit This bit controls the receiver main core reset. In order to receive any frame, this bit must be cleared. Note: For reset to take affect, the FSI RX module must be held in reset for at least 4 SYSCLK cycles. 0h (R/W) = Receiver core is not in reset and can receive frames. 1h (R/W) = Receiver core is held in reset. Note: The KEY field must contatin 0xA5 for any write to this bit to take effect. Reset type: SYSRSn

36.6.3.2 RX_OPER_CTRL Register (Offset = 8h) [Reset = 0000h]

RX_OPER_CTRL is shown in Figure 36-38 and described in Table 36-45.

Return to the Summary Table.

15-9	RESERVED	R	0h	Reserved
8	PING_WD_RST_MODE	R/W	0h	Ping Watchdog Timeout Mode Select bit This bit selects the mode by which the ping watchdog counter is reset. The watchdog counter can be reset and restarted only by ping frames or by any received frame. 0h (R/W) = The ping watchdog counter will reset and restart only by ping frames. 1h (R/W) = The ping watchdog counter will reset and restart by any received frame. Reset type: SYSRSn
7	ECC_SEL	R/W	0h	ECC Data Width Select bit This bit selects between whether the ECC computation is done on 16-bit or 32-bit words. 0h (R/W) = 32-bit ECC is used. 1h (R/W) = 16-bit ECC is used. Reset type: SYSRSn
6-3	N_WORDS	R/W	0h	Number of Words to Receive This field defines the number of words which will be received in a DATA_N_WORD frame. This is a user-defined field that must match the corresponding field in the transmitter. Set this bitfield to be one less than the number of words to be received. This value is only applicable when the frame type received is DATA_N_WORD. 0h (R/W) = 1 data word frame (16-bit data). 1h (R/W) = 2 data word frame (32-bit data). .. Fh (R/W) = 16 data word frame (256-bit data). Reset type: SYSRSn
2	SPI_MODE	R/W	0h	SPI Mode Enable bit This bit enables and disables the SPI compatibility mode of the FSI RX. The received data must be formatted as an FSI frame in order for the data to properly be received. SPI compatibility mode will allow FSI RX to receive data that is sent using SPI signal format. Refer to the applicable section in the FSI TRM chapter for more information. 0h (R/W) = FSI is in normal mode of operation. 1h (R/W) = FSI is operating in SPI compatibility mode. Reset type: SYSRSn

Table 36-45. RX_OPER_CTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1-0	DATA_WIDTH	R/W	0h	Receive Data Width Select bit These bits decide the number of data lines used for receiving data. 0h (R/W) = Data will be received on one data line, RXD0. 1h (R/W) = Data will be received on two data lines, RXD0 and RXD1. 2h, 3h (R/W) = Reserved Reset type: SYSRSn

36.6.3.3 RX_FRAME_INFO Register (Offset = Ch) [Reset = 0000h]

RX_FRAME_INFO is shown in Figure 36-39 and described in Table 36-46.

Return to the Summary Table.

Bit	Field	Type	Reset	Description
15-4	RESERVED	R	0h	Reserved
3-0	FRAME_TYPE	R	0h	Received Frame Type This field indicates the type of non-ping frame that was successfully received last. Note: Ping frame reception does not update this field, we want to retain the last successful non-ping frame FRAME_TYPE and PING_FRAME_RCVD flag already conveys PING info to the user. 0100b (R/W) = A DATA_1_WORD frame was received (16-bit data). 0101b (R/W) = A DATA_2_WORD frame was received (32-bit data). 0110b (R/W) = A DATA_4_WORD frame was received (64-bit data). 0111b (R/W) = A DATA_6_WORD frame was received (96-bit data). 0011b (R/W) = A DATA_N_WORD frame was received. The N_WORD field will determine the number of words (1 to 16) to be sent. The number of words received must equal the value programmed in RX_OPER_CTRL.N_WORDS. 1111b (R/W) = An error frame was received. This frame can be used during error conditions or any condition where the transmitter wants to signal the receiver for attention. However, the user software is at liberty to use this for any purpose. 0001b, 0010b, and 1000b through 1110b are Reserved and should not be used. Reset type: SYSRSn

36.6.3.4 RX_FRAME_TAG_UDATA Register (Offset = Eh) [Reset = 0000h]

RX_FRAME_TAG_UDATA is shown in Figure 36-40 and described in Table 36-47.

Return to the Summary Table.

14	ERROR_TAG_MATCH	R	0h	Error Tag Match Flag This bit indicates that an error frame was received with a tag comparison matching the masked tag reference. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = No tag-matched error frame received. 1h (R) = A tag-matched error frame has been received. To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn
13	DATA_TAG_MATCH	R	0h	Data Tag Match Flag This bit indicates that a dataframe was received with a tag comparison matching the masked tag reference. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = No tag-matched data frame received. 1h (R) = A tag-matched data frame has been received. To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn
12	PING_TAG_MATCH	R	0h	Ping Tag Match Flag This bit indicates that a ping frame was received with a tag comparison matching the masked tag reference. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = No tag-matched ping frame received. 1h (R) = A tag-matched ping frame has been received. To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn
11	DATA_FRAME	R	0h	Data Frame Received Flag This bit indicates that an data frame has been received. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = No data frame has been received. 1h (R) = A data frame has been received. To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn

Table 36-49. RX_EVT_STS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
10	FRAME_OVERRUN	R	0h	Frame Overrun Flag This bit indicates that a frame overrun condition has occured. This bit gets set to 1 when a new DATA/ERROR frame is received and the corresponding DATA_FRAME_RCVD/ERROR_FRAME_RCVD flag is still set to 1. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = Frame overrun has not ocurred. 1h (R) = Frame overrun has ocurred. To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn
9	PING_FRAME	R	0h	Ping Frame Received Flag This bit indicates that an ping frame has been received. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = No ping frame has been received. 1h (R) = A ping frame has been received. To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn
8	ERR_FRAME	R	0h	Error Frame Received Flag This bit indicates that an error frame has been received. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = No error frame has been received. 1h (R) = An error frame has been received. To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn
7	BUF_UNDERRUN	R	0h	Receive Buffer Underrun Flag This bit indicates that a buffer underrun condition has occured in the receive buffer. This will happen when software reads the buffer which is empty and has no valid data. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = Receive Buffer Underrun has not ocurred. 1h (R) = Receive Buffer Underrun has ocurred. To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn
6	FRAME_DONE	R	0h	Frame Done Flag This bit indicates that a frame has been successfully received without error. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = No frame has been successfully received. 1h (R) = A frame has been successfully received. To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn
5	BUF_OVERRUN	R	0h	Receive Buffer Overrun Flag This bit indicates that a buffer overrun condition has occured in the receive buffer. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = Receive buffer overrun has not ocurred. 1h (R) = Receive buffer overrun has ocurred. To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn

Table 36-49. RX_EVT_STS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4	EOF_ERR	R	0h	End-of-Frame Error Flag This bit indicates that an invalid end-of-frame bit pattern has been received. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = Invalid end-of-frame has not been received. 1h (R) = Invalid end-of-frame has been received To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn
3	TYPE_ERR	R	0h	Frame Type Error Flag This bit inditcates that an invalid frame type has been received. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = Invalid frame type has not been received. 1h (R) = Invalid frame type has been received To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn
2	CRC_ERR	R	0h	CRC Error Flag This bit indicates that a CRC error has occured. A CRC error will be generated on a data frame where the received CRC and the computed CRC do not match. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = CRC error has not occured. 1h (R) = CRC error has occured. To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn
1	FRAME_WD_TO	R	0h	Frame Watchdog Timeout Flag This bit indicates that the frame watchdog timer has timed out. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = Frame watchdog timeout has not occured. 1h (R) = Frame watchdog timeout has occured. To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn
0	PING_WD_TO	R	0h	Ping Watchdog Timeout Flag This bit indicates that the ping watchdog timer has timed out. Software can also force this bit to get set by writing to the RX_EVT_FRC register. 0h (R) = Ping watchdog timeout has not occured. 1h (R) = Ping watchdog timeout has occured. To clear this bit, write to the corresponding bit in the RX_EVT_CLR register. Reset type: SYSRSn

36.6.3.7 RX_CRC_INFO Register (Offset = 16h) [Reset = 0000h]

RX_CRC_INFO is shown in Figure 36-43 and described in Table 36-50.

Return to the Summary Table.

Table 36-53. RX_BUF_PTR_LOAD Register Field Descriptions

Bit	Field	Type	Reset	Description
15-4	RESERVED	R	0h	Reserved
3-0	BUF_PTR_LOAD	R/W	0h	Buffer Pointer Load. This is the value to be loaded into the receive word pointer when written. This is to allow software to force the receiver to start storing the received data starting at a specific location in the buffer. NOTE: The value of the CURR_BUF_PTR in the RX_BUF_PTR_STS will not get reflected immediately. This will take effect only when there is a valid receive operation with incoming clocks after (3 RXCLK + 3 SYCLK) cycles. Reset type: SYSRSn

36.6.3.11 RX_BUF_PTR_STS Register (Offset = 1Eh) [Reset = 0000h]

RX_BUF_PTR_STS is shown in Figure 36-47 and described in Table 36-54.

Return to the Summary Table.

Chapter 37

Inter-Integrated Circuit Module (I2C)

This chapter describes the features and operation of the inter-integrated circuit (I2C) module. The I2C module provides an interface between one of these devices and devices compliant with the NXP Semiconductors Inter-IC bus (I2C bus) specification version 2.1, and connected by way of an I2C bus. External components attached to this 2-wire serial bus can transmit/receive 1- to 8-bit data to/from the device through the I2C module. This chapter assumes the reader is familiar with the I2C bus specification.

Note

A unit of data transmitted or received by the I2C module can have fewer than 8 bits; however, for convenience, a unit of data is called a data byte throughout this chapter. The number of bits in a data byte is selectable by way of the BC bits of the mode register, I2CMDR.

37.1 Introduction

The I2C module supports any target or controller I2C-compatible device. Figure 37-1 shows an example of multiple I2C modules connected for a two-way transfer from one device to other devices.

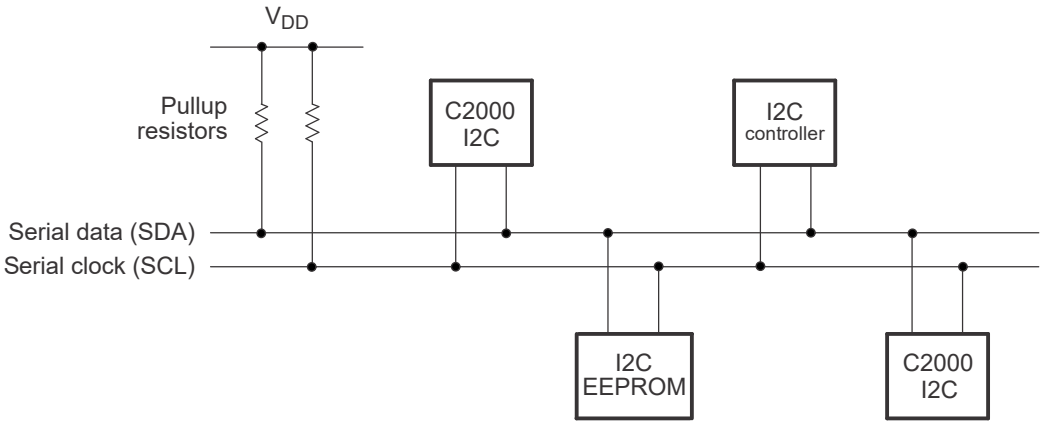

Figure 37-1. Multiple I2C Modules Connected

37.1.2 Features

The I2C module has the following features:

- Compliance with the NXP Semiconductors I2C bus specification (version 2.1):
  - Support for 8-bit format transfers
  - 7-bit and 10-bit addressing modes
  - General call
  - START byte mode
  - Support for multiple controller-transmitters and target-receivers
  - Support for multiple target-transmitters and controller-receivers
  - Combined controller transmit/receive and receive/transmit mode
  - Data transfer rate from 10kbps up to 400kbps (Fast-mode)
- Extended Automatic Clock Stretching and Manual Clock Stretching modes
- Receive FIFO and Transmitter FIFO (16-deep x 8-bit FIFO)
- Supports two Interrupt Controller interrupts:
- – I2Cx Interrupt – Any of the following events can be configured to generate an I2Cx interrupt:
    - Transmit-data ready
    - Receive-data ready
    - Register-access ready
    - No-acknowledgment received
    - Arbitration lost
    - Stop condition detected
    - Addressed as target
    - Extended Automatic Clock Stretch
  - I2Cx_FIFO interrupts:
    - Transmit FIFO interrupt
    - Receive FIFO interrupt
- Module enable and disable capability
- Free data format mode

37.1.3 Features Not Supported

The I2C module does not support:

- High-speed mode (Hs-mode)
- CBUS-compatibility mode

37.1.4 Functional Overview

Each device connected to an I2C bus is recognized by a unique address. Each device can operate as either a transmitter or a receiver, depending on the function of the device. A device connected to the I2C bus can also be considered as the controller or the target when performing data transfers. A controller device is the device that initiates a data transfer on the bus and generates the clock signals to permit that transfer. During this transfer, any device addressed by this controller is considered a target. The I2C module supports the multi-controller mode, in which one or more devices capable of controlling an I2C bus can be connected to the same I2C bus.

For data communication, the I2C module has a serial data pin (SDA) and a serial clock pin (SCL), as shown in Figure 37-2. These two pins carry information between the C28x device and other devices connected to the I2C bus. The SDA and SCL pins are both bidirectional and each must be connected to a positive supply voltage using a pull-up resistor. When the bus is free, both pins are high. The driver of these two pins has an open-drain configuration to perform the required wired-AND function.

There are two major transfer techniques:

- Standard Mode: Send exactly n data values, where n is a value you program in an I2C module register. See the I2CCNT register in the *I2C Registers* section for more information.
- Repeat Mode: Keep sending data values until you use software to initiate a STOP condition or a new START condition. See the I2CMDR register in the *I2C Registers* section for RM bit information.

The I2C module consists of the following primary blocks:

- A serial interface: one data pin (SDA) and one clock pin (SCL)
- Data registers and FIFOs to temporarily hold receive data and transmit data traveling between the SDA pin and the CPU
- Control and status registers
- A peripheral bus interface to enable the CPU to access the I2C module registers and FIFOs.
- A clock synchronizer to synchronize the I2C input clock (from the device clock generator) and the clock on the SCL pin, and to synchronize data transfers with controllers of different clock speeds
- A prescaler to divide down the input clock that is driven to the I2C module
- A noise filter on each of the two pins, SDA and SCL
- An arbitrator to handle arbitration between the I2C module (when the I2C module is a controller) and another controller
- Interrupt generation logic, so that an interrupt can be sent to the CPU
- FIFO interrupt generation logic, so that FIFO access can be synchronized to data reception and data transmission in the I2C module

Figure 37-2 shows the four registers used for transmission and reception in non-FIFO mode. The CPU writes data for transmission to I2CDXR and reads received data from I2CDRR. When the I2C module is configured as a transmitter, data written to I2CDXR is copied to I2CXSR and shifted out on the SDA pin one bit at a time. When the I2C module is configured as a receiver, received data is shifted into I2CRSR and then copied to I2CDRR.

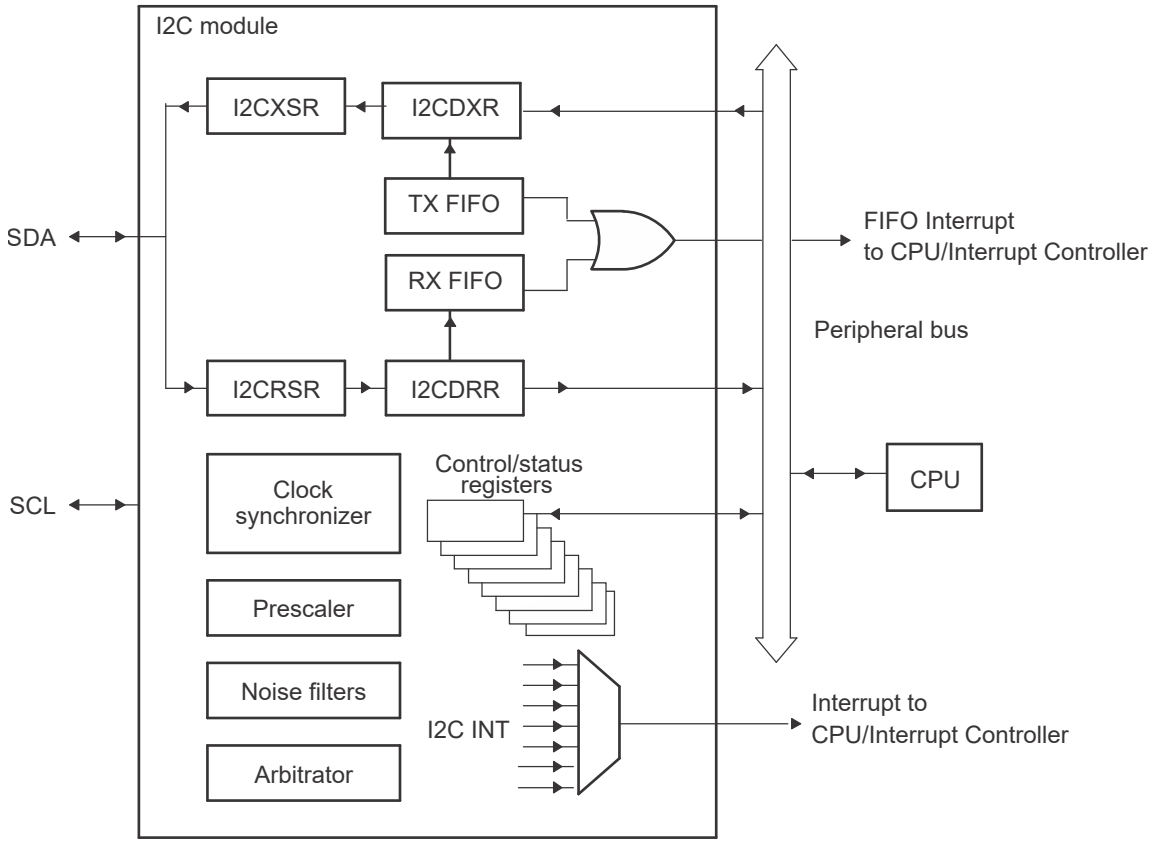

Figure 37-2. I2C Module Conceptual Block Diagram

37.1.5 Clock Generation

The I2C module clock determines the frequency at which the I2C module operates. A programmable prescaler in the I2C module divides down the SYSCLK to produce the I2C module clock and this I2C module clock is divided further to produce the I2C controller clock on the SCL pin. Figure 37-3 shows the clock generation diagram for I2C module.

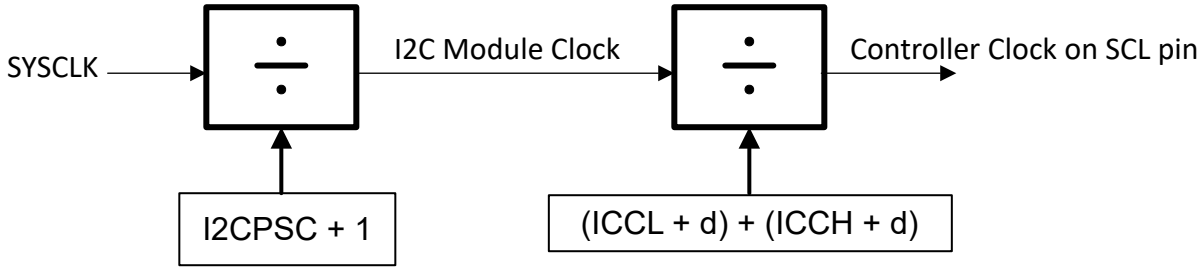

Figure 37-3. Clocking Diagram for the I2C Module

Note

To meet all of the I2C protocol timing specifications, the I2C module clock must be between 7 to 12MHz.

To specify the divide-down value, initialize the IPSC field of the prescaler register, I2CPSC. The resulting frequency is:

$$\text{I2C Module Clock (Fmod)} = \frac{\text{SYSCLK}}{(\text{I2CPSC} + 1)} \quad (35)$$

The prescaler must be initialized only while the I2C module is in the reset state (IRS = 0 in I2CMDR). The prescaled frequency takes effect only when IRS is changed to 1. Changing the IPSC value while IRS = 1 has no effect.

The controller clock appears on the SCL pin when the I2C module is configured to be a controller on the I2C bus. This clock controls the timing of communication between the I2C module and a target. As shown in Figure 37-3, a second clock divider in the I2C module divides down the module clock to produce the controller clock. The clock divider uses the ICCL value of I2CCLKL to divide down the low portion of the module clock signal and uses the ICCH value of I2CCLKH to divide down the high portion of the module clock signal. See Section 37.1.6 for the controller clock frequency equation.

37.1.6 I2C Clock Divider Registers (I2CCLKL and I2CCLKH)

As explained in Section 37.1.5, when the I2C module is a controller, the I2C module clock is divided down further to use as the controller clock on the SCL pin. As shown in Figure 37-4, the shape of the controller clock depends on two divide-down values:

- ICCL in I2CCLKL. For each controller clock cycle, ICCL determines the amount of time the signal is low.
- ICCH in I2CCKLH. For each controller clock cycle, ICCH determines the amount of time the signal is high.

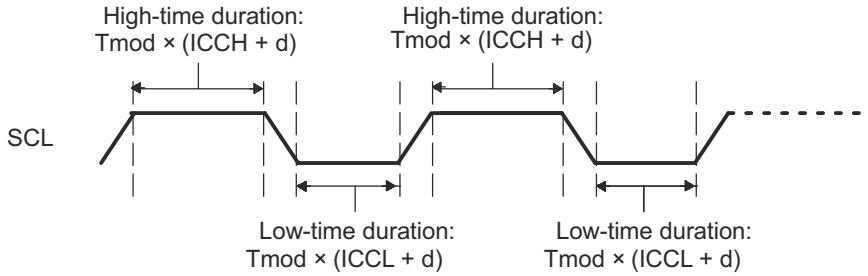

Figure 37-4. Roles of the Clock Divide-Down Values (ICCL and ICCH)

37.1.6.1 Formula for the Controller Clock Period

The controller clock period (Tmst) is a multiple of the period of the I2C Module Clock (Tmod):

$$\text{Controller Clock period (Tmst)} = \frac{[\,(\text{ICCH} + \text{d}) + (\text{ICCL} + \text{d})\,]}{\text{I2C Module Clock (Fmod)}} \quad (36)$$

where d depends on the divide-down value IPSC, as shown in Table 37-1. IPSC is described in the I2CPSC register.

Table 37-1. Dependency of Delay d on the Divide-Down Value IPSC

IPSC	d
0	7

Greater than 1	5

37.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification must be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups can be configured in the GPyPUD register.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

Note

To support a wider range of I2C IO levels, certain GPIOs have configurable fail-safe systems, V_{IH} minimum thresholds, and configurable sinking capabilities.

37.3 I2C Module Operational Details

This section provides an overview of the I2C bus protocol and how it is implemented.

37.3.1 Input and Output Voltage Levels

One clock pulse is generated by the controller device for each data bit transferred. Due to a variety of different technology devices that can be connected to the I2C bus, the levels of logic 0 (low) and logic 1 (high) are not fixed and depend on the associated level of V_{DD}. For details, see the device data sheet.

37.3.2 Selecting Pullup Resistors

The chosen pullup resistor must meet the I2C standard timings. In most circumstances, 2.2kΩ of total bus resistance to VDDIO is sufficient. The value of the pullup resistance used on both the SCL and SDA pins be matched is also recommended. For evaluating pullup resistor values for a particular design, see the *I2C Bus Pullup Resistor Calculation Application Report*.

37.3.3 Data Validity

The data on SDA must be stable during the high period of the clock (see Figure 37-5). The high or low state of the data line, SDA, must change only when the clock signal on SCL is low.

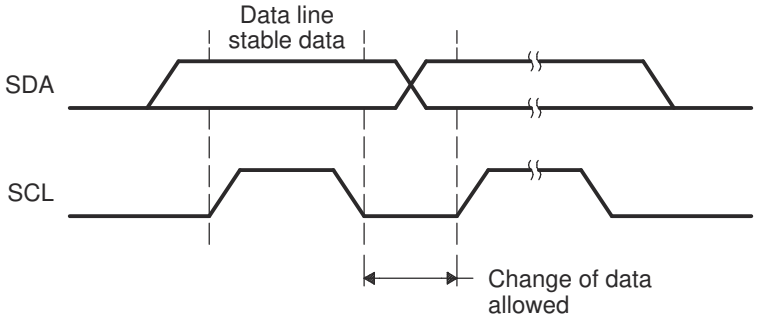

Figure 37-5. Bit Transfer on the I2C bus

37.3.4 Operating Modes

The I2C module has four basic operating modes to support data transfers as a controller and as a target. See Table 37-2 for the names and descriptions of the modes.

If the I2C module is a controller, the I2C module begins as a controller-transmitter and typically transmits an address for a particular target. When giving data to the target, the I2C module must remain a controller-transmitter. To receive data from a target, the I2C module must be changed to the controller-receiver mode.

If the I2C module is a target, the I2C module begins as a target-receiver and typically sends acknowledgment when the I2C module recognizes the target address from a controller. If the controller is sending data to the I2C module, the module must remain a target-receiver. If the controller has requested data from the I2C module, the module must be changed to the target-transmitter mode.

Table 37-2. Operating Modes of the I2C Module

Operating Mode	Description
Target-receiver mode	The I2C module is a target and receives data from a controller. All targets begin in this mode. In this mode, serial data bits received on SDA are shifted in with the clock pulses that are generated by the controller. As a target, the I2C module does not generate the clock signal, but can hold SCL low while the intervention of the device is required (RSFULL = 1 in I2CSTR) after a byte has been received. See Section 37.3.8 for more details.
Target-transmitter mode	The I2C module is a target and transmits data to a controller. This mode can be entered only from the target-receiver mode; the I2C module must first receive a command from the controller. When using any of the 7-bit/10-bit addressing formats, the I2C module enters the target-transmitter mode if the target address byte is the same as the address (in I2COAR) and the controller has transmitted R/ $\overline{W}$ = 1. As a target-transmitter, the I2C module then shifts the serial data out on SDA with the clock pulses that are generated by the controller. While a target, the I2C module does not generate the clock signal, but it can hold SCL low while the intervention of the device is required (XSMT = 0 in I2CSTR) after a byte has been transmitted. See Section 37.3.8 for more details.
Controller-receiver mode	The I2C module is a controller and receives data from a target. This mode can be entered only from the controller-transmitter mode; the I2C module must first transmit a command to the target. When using any of the 7-bit/10-bit addressing formats, the I2C module enters the controller-receiver mode after transmitting the target address byte and R/ $\overline{W}$ = 1. Serial data bits on SDA are shifted into the I2C module with the clock pulses generated by the I2C module on SCL. The clock pulses are inhibited and SCL is held low when the intervention of the device is required (RSFULL = 1 in I2CSTR) after a byte has been received.
Controller-transmitter mode	The I2C module is a controller and transmits control information and data to a target. All controllers begin in this mode. In this mode, data assembled in any of the 7-bit/10-bit addressing formats is shifted out on SDA. The bit shifting is synchronized with the clock pulses generated by the I2C module on SCL. The clock pulses are inhibited and SCL is held low when the intervention of the device is required (XSMT = 0 in I2CSTR) after a byte has been transmitted.

To summarize, SCL is held low in the following conditions:

- When an overrun condition is detected (RSFULL = 1), in Target-receiver mode.
- When an underflow condition is detected (XSMT = 0), in Target-transmitter mode.

I2C target nodes accept and provide data when the I2C controller node requests data.

- To release SCL in target-receiver mode, read data from I2CDRR.
- To release SCL in target-transmitter mode, write data to I2CDXR.
- To force a release without handling the data, reset the module using the I2CMDR.IRS bit.

Table 37-3. Controller-Transmitter/Receiver Bus Activity Defined by the RM, STT, and STP Bits of I2CMDR

RM	STT	STP	Bus Activity(1)	Description
0	0	0	None	No activity
0	0	1	P	STOP condition
0	1	0	S-A-D..(n)..D.	START condition, target address, n data bytes (n = value in I2CCNT)
0	1	1	S-A-D..(n)..D-P	START condition, target address, n data bytes, STOP condition (n = value in I2CCNT)
1	0	0	None	No activity
1	0	1	P	STOP condition
1	1	0	S-A-D-D-D.	Repeat mode transfer: START condition, target address, continuous data transfers until STOP condition or next START condition
1	1	1	None	Reserved bit combination (No activity)

(1) S = START condition; A = Address; D = Data byte; P = STOP condition;

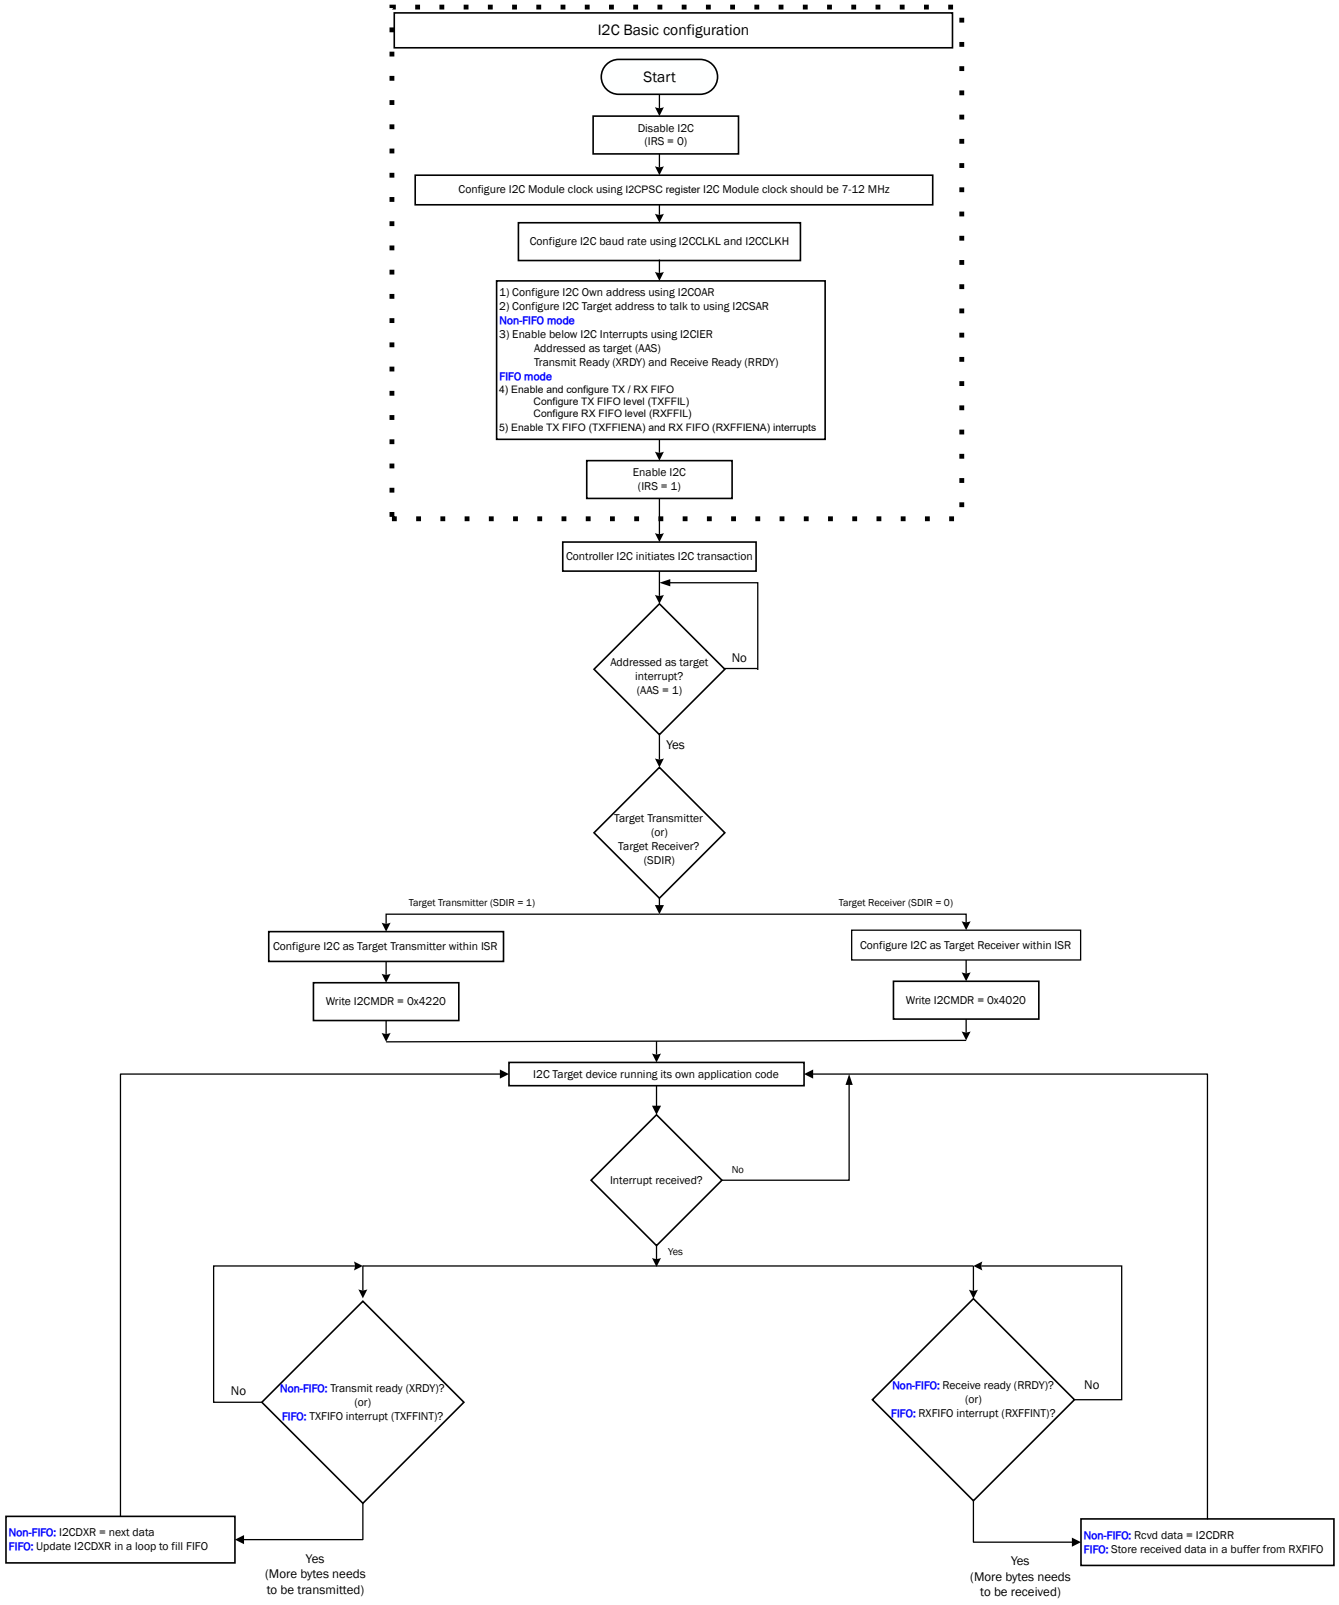

Figure 37-6. I2C Target TX / RX Flowchart

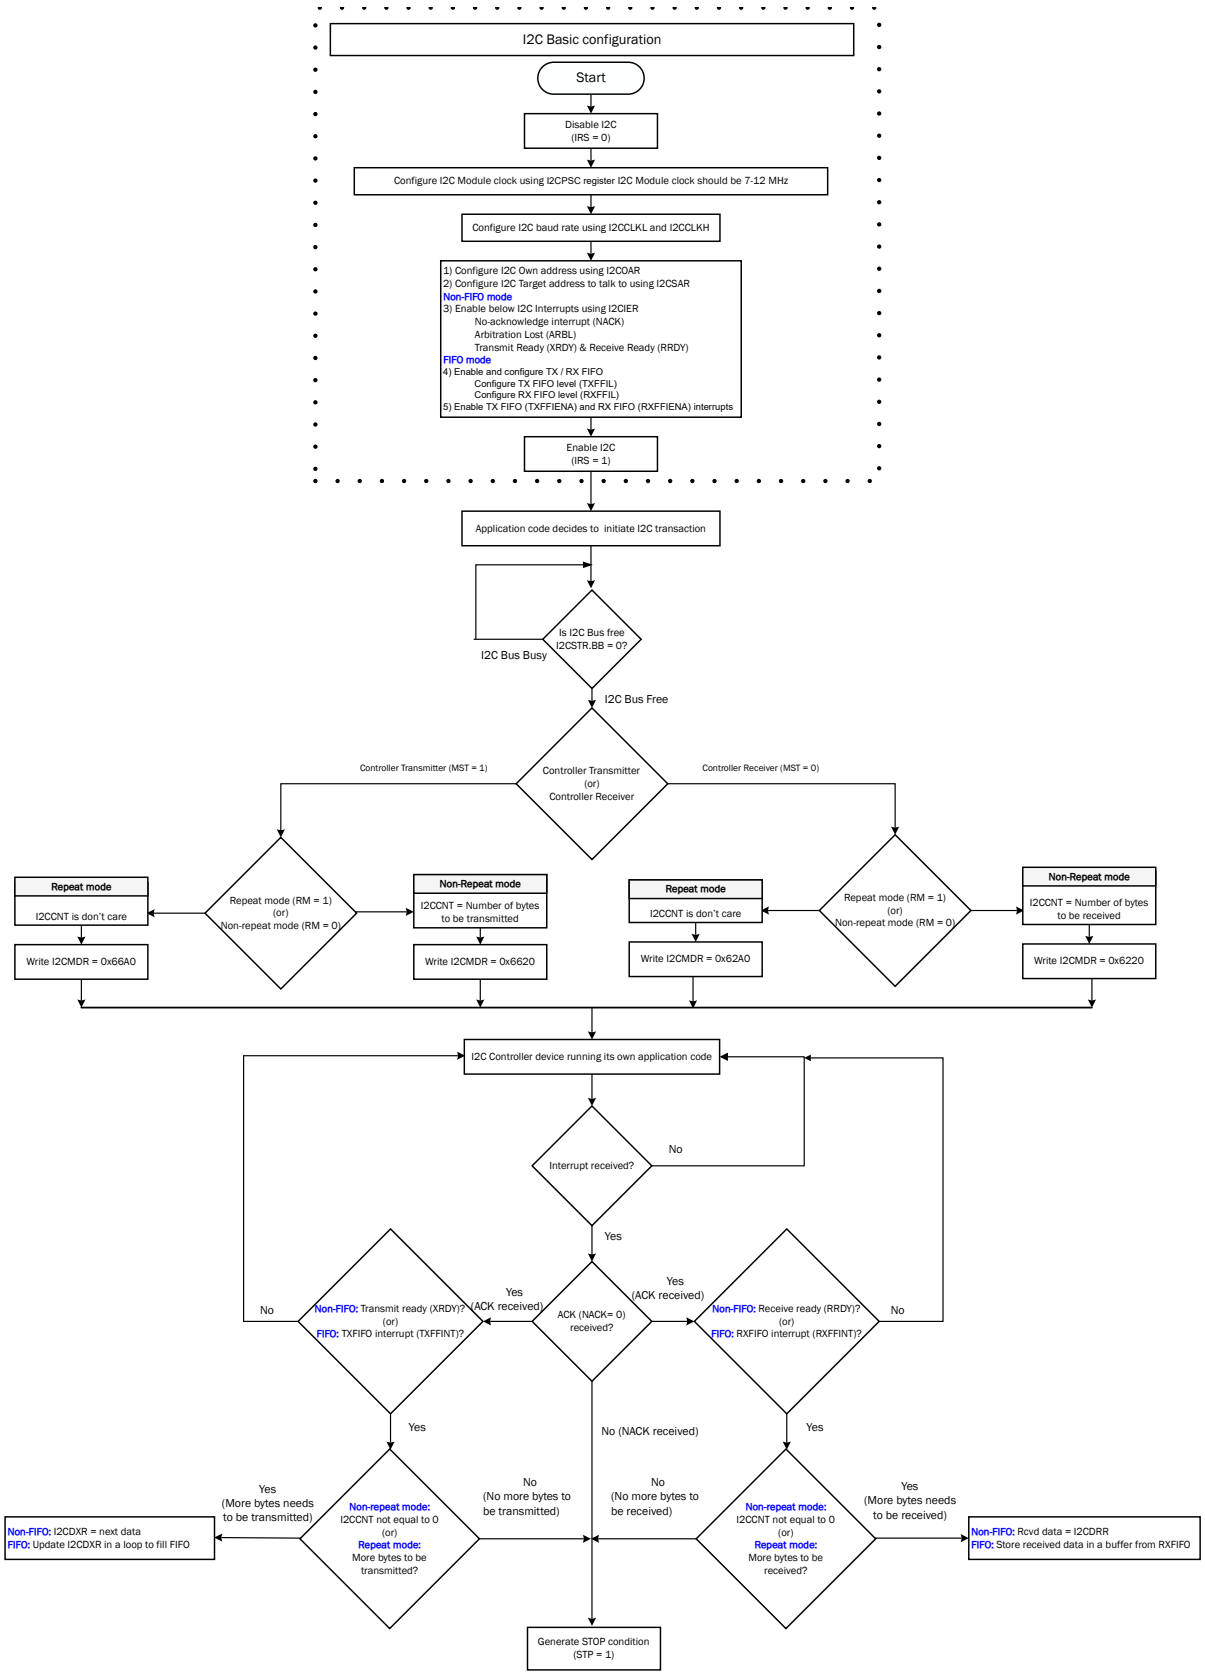

Figure 37-7. I2C Controller TX / RX Flowchart

37.3.5 I2C Module START and STOP Conditions

START and STOP conditions can be generated by the I2C module when the module is configured to be a controller on the I2C bus. As shown in Figure 37-8:

- The START condition is defined as a high-to-low transition on the SDA line while SCL is high. A controller drives this condition to indicate the start of a data transfer.
- The STOP condition is defined as a low-to-high transition on the SDA line while SCL is high. A controller drives this condition to indicate the end of a data transfer.

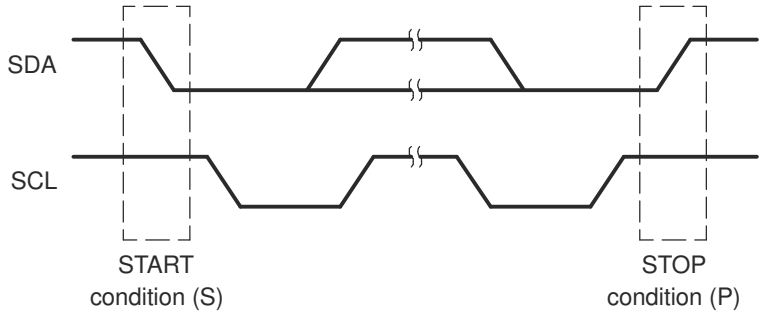

Figure 37-8. I2C Module START and STOP Conditions

After a START condition and before a subsequent STOP condition, the I2C bus is considered busy, and the bus busy (BB) bit of I2CSTR is 1. Between a STOP condition and the next START condition, the bus is considered free, and BB is 0.

For the I2C module to start a data transfer with a START condition, the controller mode bit (MST) and the START condition bit (STT) in I2CMDR must both be 1. For the I2C module to end a data transfer with a STOP condition, the STOP condition bit (STP) must be set to 1. When the BB bit is set to 1 and the STT bit is set to 1, a repeated START condition is generated. For a description of I2CMDR and the bits (including MST, STT, and STP), see Section 37.7.

The I2C peripheral cannot detect a START or STOP condition while in reset (IRS = 0). The BB bit remains in the cleared state (BB = 0) while the I2C peripheral is in reset (IRS = 0). When the I2C peripheral is taken out of reset (IRS set to 1), the BB bit does not correctly reflect the I2C bus status until a START or STOP condition is detected.

Follow these steps before initiating the first data transfer with I2C:

1. After taking the I2C peripheral out of reset by setting the IRS bit to 1, wait a period larger than the total time taken for the longest data transfer in the application. By waiting for a period of time after I2C comes out of reset, make sure that at least one START or STOP condition has occurred on the I2C bus and has been captured by the BB bit. After this period, the BB bit correctly reflects the state of the I2C bus.
2. Check the BB bit and verify that BB = 0 (bus not busy) before proceeding.
3. Begin data transfers.

Not resetting the I2C peripheral in between transfers makes sure that the BB bit reflects the actual bus status. If users must reset the I2C peripheral in between transfers, repeat steps 1 through 3 every time the I2C peripheral is taken out of reset.

37.3.6 Non-repeat Mode versus Repeat Mode

Non-repeat mode:

- When I2CMDR.RM = 0, I2C module is configured in non-repeat mode.
- I2CCNT register determines the number of bytes to be transmitted or received.
- If STP = 0 in I2CMDR, the ARDY bit is set when the internal data counter counts down to 0.
- If STP = 1, ARDY bit does not get set and I2C module generates a STOP condition when the internal data counter counts down to 0.

Note

In non-repeat mode (RM = 0), if I2CCNT is set to 0, I2C state machine expects to transmit or receive 65536 bytes and not 0 bytes.

Repeat mode:

- When I2CMDR.RM = 1, I2C module is configured in repeat mode.
- I2CCNT register contents do not determine the number of bytes to be transmitted or received.
- Number of bytes to be transmitted or received can be controlled by software.
- ARDY bit gets set at end of transmission and reception of each byte.

Note

Once you start I2C transaction in non-repeat mode or repeat mode, you cannot switch into another mode until the I2C transaction is completed with a STOP condition.

37.3.7 Serial Data Formats

Figure 37-9 shows an example of a data transfer on the I2C bus. The I2C module supports 1 to 8-bit data values. In Figure 37-9, 8-bit data is transferred. Each bit put on the SDA line equates to 1 pulse on the SCL line, and the values are always transferred with the most significant bit (MSB) first. The number of data values that can be transmitted or received is unrestricted. The serial data format used in Figure 37-9 is the 7-bit addressing format. The I2C module supports the formats shown in Figure 37-10 through Figure 37-12 and described in the paragraphs that follow the figures.

Note

In Figure 37-9 through Figure 37-12, n = the number of data bits (from 1 to 8) specified by the bit count (BC) field of I2CMDR.

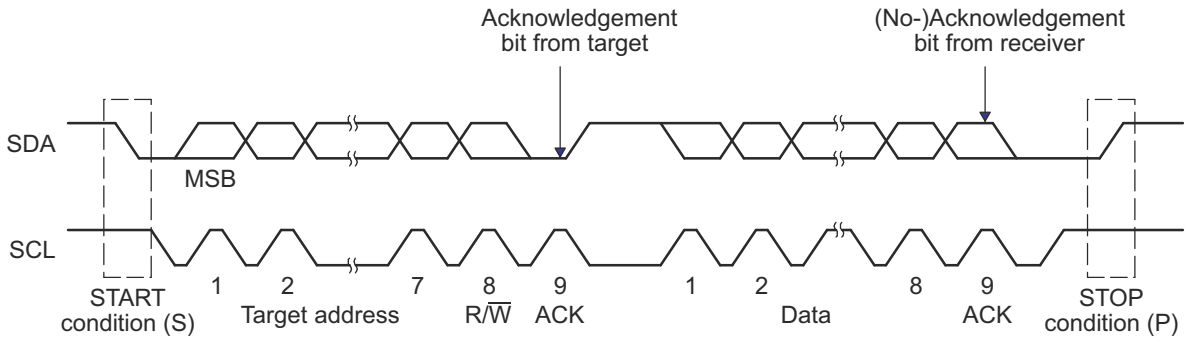

Figure 37-9. I2C Module Data Transfer (7-Bit Addressing with 8-bit Data Configuration Shown)

37.3.7.1 7-Bit Addressing Format

The 7-bit addressing format is the default format after reset. Disabling expanded address (I2CMDR.XA = 0) and free data format (I2CMDR.FDF = 0) enables 7-bit addressing format.

In this format (see Figure 37-10), the first byte after a START condition (S) consists of a 7-bit target address followed by a R/$\overline{W}$ bit. R/$\overline{W}$ determines the direction of the data:

- R/$\overline{W}$ = 0: The I2C controller writes (transmits) data to the addressed target. This can be achieved by setting I2CMDR.TRX = 1 (Transmitter mode)
- R/$\overline{W}$ = 1: The I2C controller reads (receives) data from the target. This can be achieved by setting I2CMDR.TRX = 0 (Receiver mode)

An extra clock cycle dedicated for acknowledgment (ACK) is inserted after each byte. If the ACK bit is inserted by the target after the first byte from the controller, it is followed by n bits of data from the transmitter (controller or target, depending on the R/$\overline{W}$ bit). n is a number from 1 to 8 determined by the bit count (BC) field of I2CMDR. After the data bits have been transferred, the receiver inserts an ACK bit.

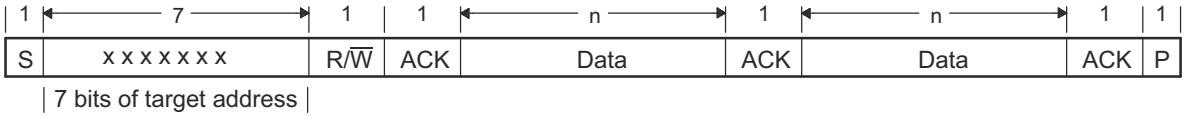

Figure 37-10. I2C Module 7-Bit Addressing Format (FDF = 0, XA = 0 in I2CMDR)

37.3.7.2 10-Bit Addressing Format

The 10-bit addressing format can be enabled by setting expanded address (I2CMDR.XA = 1) and disabling free data format (I2CMDR.FDF = 0).

The 10-bit addressing format (see Figure 37-11) is similar to the 7-bit addressing format, but the controller sends the target address in two separate byte transfers. The first byte consists of 11110b, the two MSBs of the 10-bit target address, and R/$\overline{W}$. The second byte is the remaining 8 bits of the 10-bit target address. The target must send acknowledgment after each of the two byte transfers. Once the controller has written the second byte to the target, the controller can either write data or use a repeated START condition to change the data direction. For more details about using 10-bit addressing, see the NXP Semiconductors I2C bus specification.

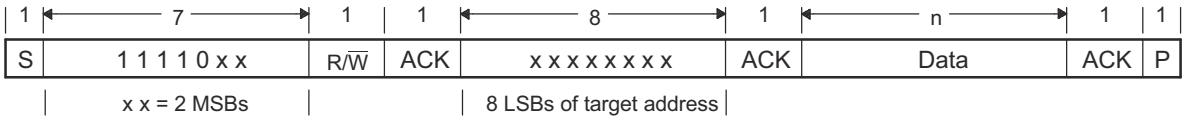

Figure 37-11. I2C Module 10-Bit Addressing Format (FDF = 0, XA = 1 in I2CMDR)

37.3.7.3 Free Data Format

The free data format can be enabled by setting I2CMDR. FDF = 1.

In this format (see Figure 37-12), the first byte after a START condition (S) is a data byte. An ACK bit is inserted after each data byte, which can be from 1 to 8 bits, depending on the BC field of I2CMDR. No address or data-direction bit is sent. Therefore, the transmitter and the receiver must both support the free data format, and the direction of the data must be constant throughout the transfer.

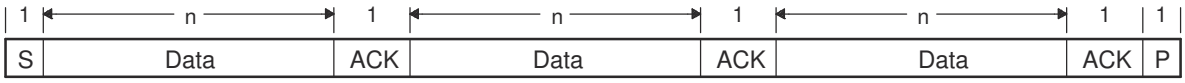

Figure 37-12. I2C Module Free Data Format (FDF = 1 in I2CMDR)

Note

The free data format is not supported in the digital loopback mode (I2CMDR.DLB = 1).

Table 37-4. How the MST and FDF Bits of I2CMDR Affect the Role of the TRX Bit of I2CMDR

MST	FDF	I2C Module State	Function of TRX
0	0	In target mode but not free data format mode	TRX is a don't care. Depending on the command from the controller, the I2C module responds as a receiver or a transmitter.
0	1	In target mode and free data format mode	The free data format mode requires that the I2C module remains the transmitter or the receiver throughout the transfer. TRX identifies the role of the I2C module: TRX = 1: The I2C module is a transmitter. TRX = 0: The I2C module is a receiver.
1	0	In controller mode but not free data format mode	TRX = 1: The I2C module is a transmitter. TRX = 0: The I2C module is a receiver.
1	1	In controller mode and free data format mode	TRX = 0: The I2C module is a receiver. TRX = 1: The I2C module is a transmitter.

37.3.7.4 Using a Repeated START Condition

I2C controller can communicate with multiple target addresses without having to give up control of the I2C bus by driving a STOP condition. This can be achieved by driving another START condition at the end of each data type. The repeated START condition can be used with the 7-bit addressing and 10-bit addressing. Figure 37-13 shows a repeated START condition in the 7-bit addressing format.

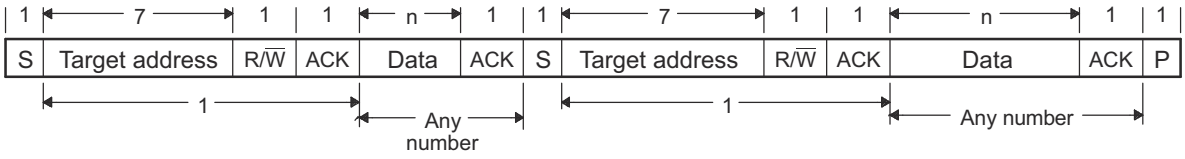

Figure 37-13. Repeated START Condition (in This Case, 7-Bit Addressing Format)

Note

In Figure 37-13, n = the number of data bits (from 1 to 8) specified by the bit count (BC) field of I2CMDR.

37.3.8 Clock Synchronization

Under normal conditions, only one controller device generates the clock signal, SCL. During the arbitration procedure, however, there are two or more controllers and the clock must be synchronized so that the data output can be compared. Figure 37-14 illustrates the clock synchronization. The wired-AND property of SCL means that a device that first generates a low period on SCL overrules the other devices. At this high-to-low transition, the clock generators of the other devices are forced to start a low period. The SCL is held low by the device with the longest low period. The other devices that finish the low periods must wait for SCL to be released, before starting the high periods. A synchronized signal on SCL is obtained, where the slowest device determines the length of the low period and the fastest device determines the length of the high period.

If a device pulls down the clock line for a longer time, the result is that all clock generators must enter the wait state. In this way, a target slows down a fast controller and the slow device creates enough time to store a received byte or to prepare a byte to be transmitted.

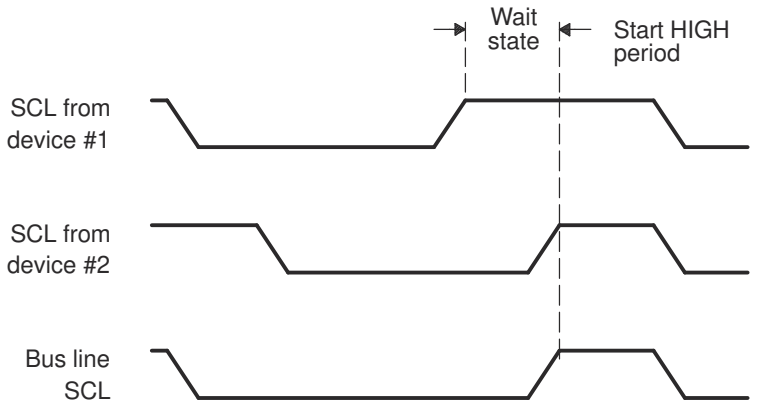

Figure 37-14. Synchronization of Two I2C Clock Generators During Arbitration

37.3.9 Clock Stretching

An I2C target device pulls the SCL line low to push the I2C controller device into the wait state preventing the I2C controller from transmitting data. This concept is called Clock Stretching.

The I2C supports three different types of clock stretching:

- **Automatic Clock Stretching:** Figure 37-15 shows the timing diagram for automatic clock stretching.
  - Target Receiver mode:
    - Non-FIFO mode: I2C clock stretches after receiving 2 bytes from the controller.
    - FIFO mode: I2C clock stretches after receiving 17 bytes from the controller.
  - Target Transmitter mode: I2C clock stretches, if I2C transmit buffer is empty

Note

Automatic Clock Stretching is enabled by default and cannot be disabled.

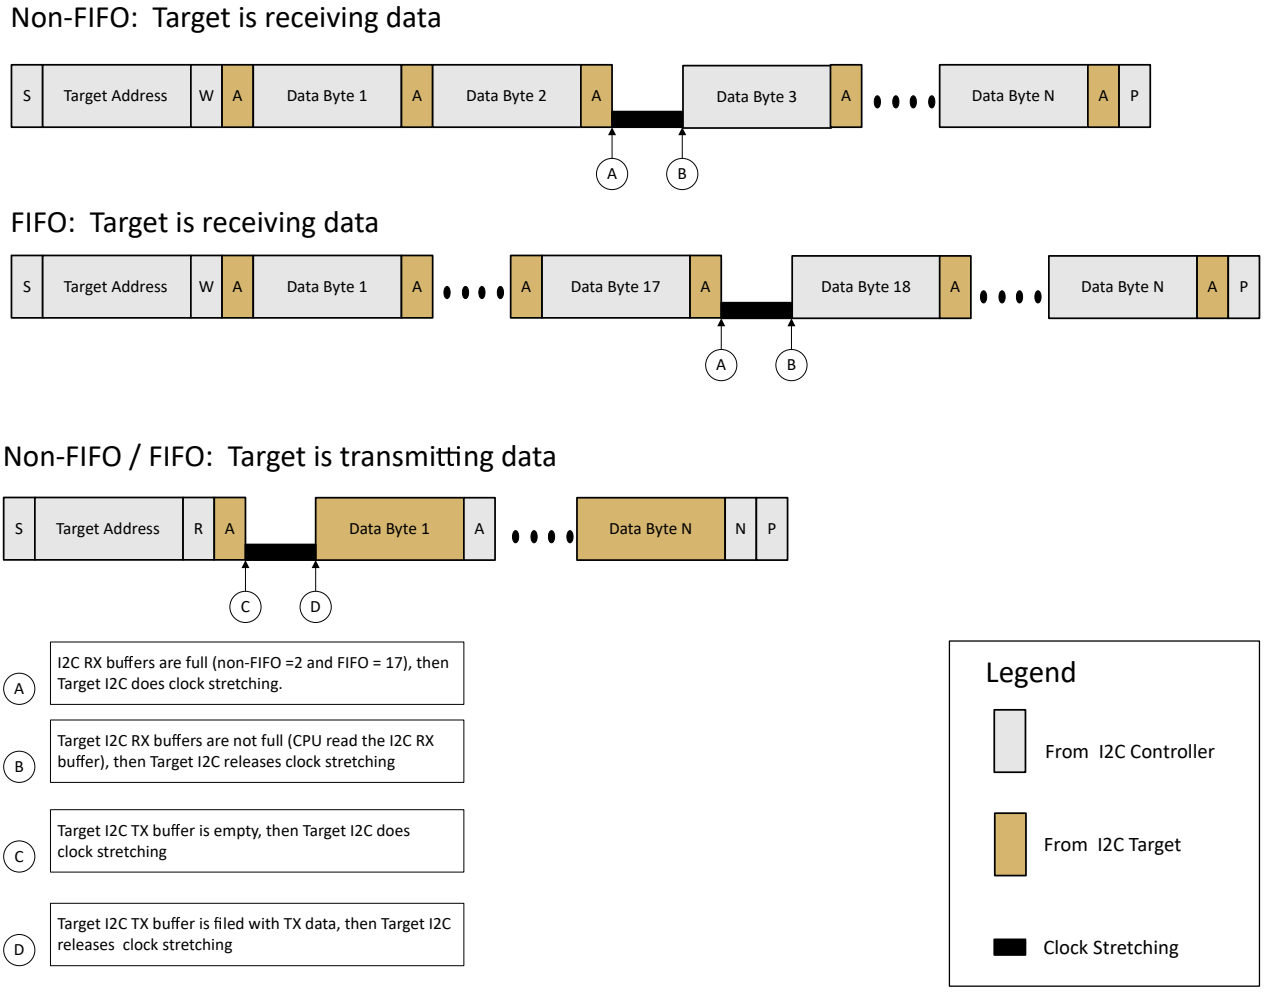

Figure 37-15. Automatic Clock Stretching

- **Extended Automatic Clock Stretching:** Figure 37-16 shows the timing diagram for extended automatic clock stretching.

  Extended Automatic Clock Stretching can be enabled by setting I2CEMDR. ECS = 1. Once this feature is enabled, I2C hardware automatically does clock stretching by pulling the SCL line low after every ACK/NACK cycle and generates an I2C interrupt. Inside the I2C ISR, I2CSTR.SCL_ECS is set to 1 to release the I2C from clock stretching.

Note

Extended Automatic Clock Stretching is disabled by default and can be enabled by setting I2CEMDR.ECS = 1.

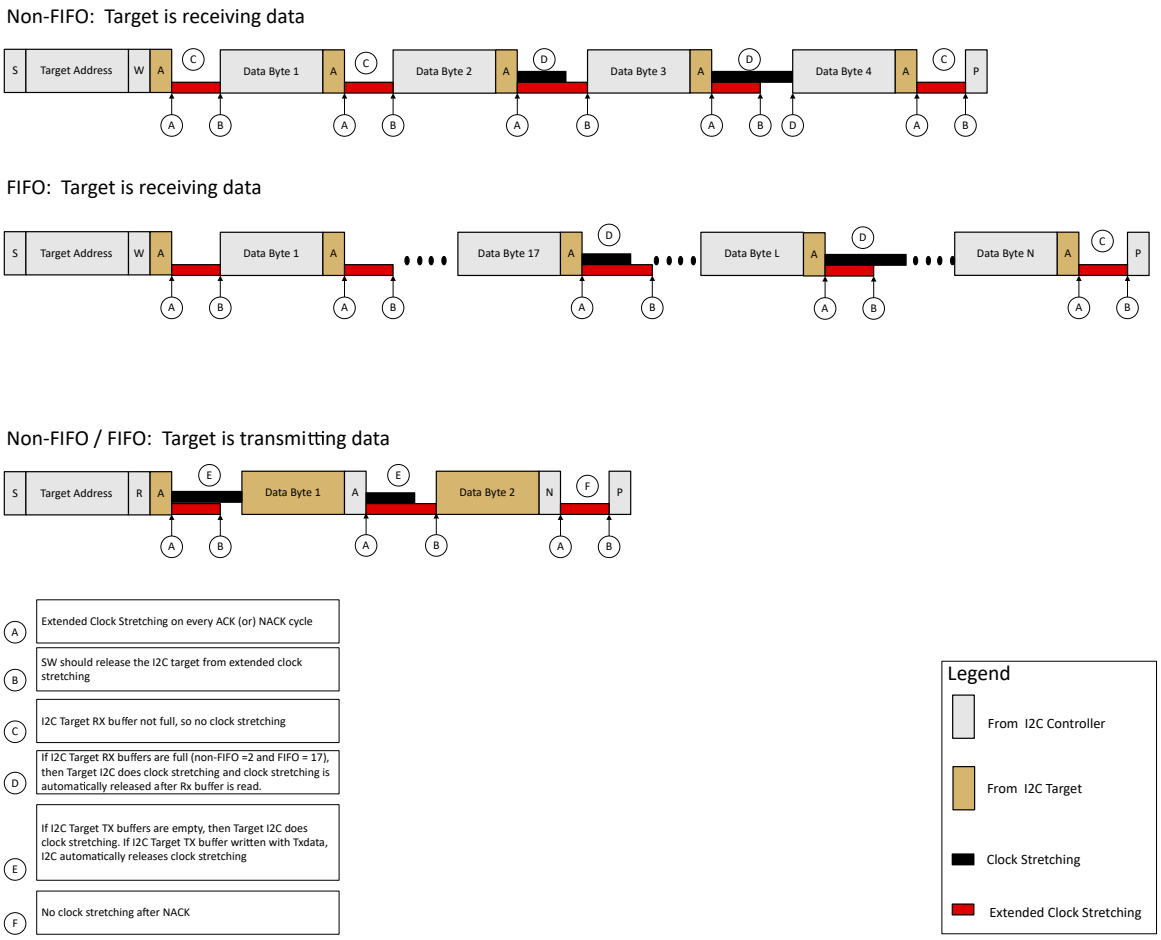

Figure 37-16. Extended Automatic Clock Stretching

- **Manual Clock Stretching:** Manual Clock Stretching can be enabled by setting I2CEMDR.MCS = 1 within an ISR routine. Once this feature is enabled, I2C hardware can be configured to manually do clock stretching by pulling the SCL line low after specific ACK/NACK cycles. I2C module then performs housekeeping and executes normal ISR sequence steps before disabling MCS by setting I2CEMDR.MCS = 0.

Note

Manual Clock Stretching is disabled by default and can be enabled by setting I2CEMDR.MCS = 1. Timing requirements for this type of clock stretching are not provided due to dependency on user configuration and application.

37.3.10 Arbitration

If two or more controller-transmitters attempt to start a transmission on the same bus at approximately the same time, an arbitration procedure is invoked. The arbitration procedure uses the data presented on the serial data bus (SDA) by the competing transmitters. Figure 37-17 illustrates the arbitration procedure between two devices. The first controller-transmitter that releases the SDA line high is overruled by another controller-transmitter that drives the SDA low. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. If two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

If the I2C module is the losing controller, the I2c module switches to the target-receiver mode, sets the arbitration lost (ARBL) flag, and generates the arbitration-lost interrupt request.

If during a serial transfer the arbitration procedure is still in progress when a repeated START condition or a STOP condition is transmitted to SDA, the controller-transmitters involved must send the repeated START condition or the STOP condition at the same position in the format frame. Arbitration is not allowed between:

- A repeated START condition and a data bit
- A STOP condition and a data bit
- A repeated START condition and a STOP condition

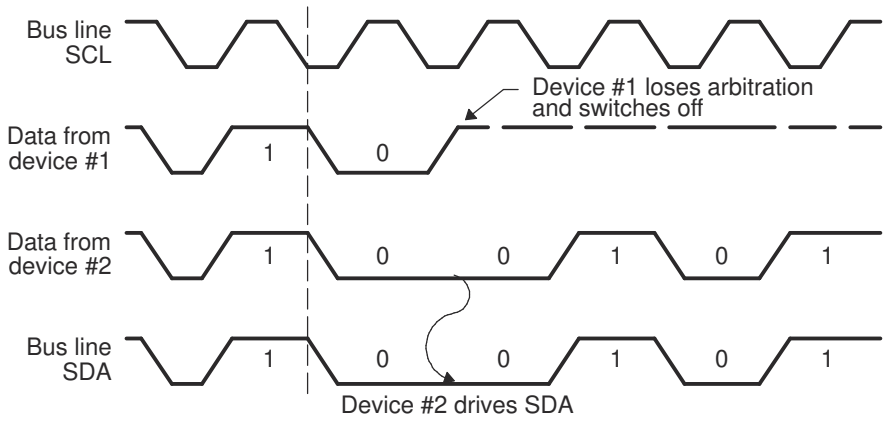

Figure 37-17. Arbitration Procedure Between Two Controller-Transmitters

37.3.11 Digital Loopback Mode

The I2C module support a self-test mode called digital loopback, which is enabled by setting the DLB bit in the I2CMDR register. In this mode, data transmitted out of the I2CDXR register is received in the I2CDRR register. The data follows an internal path, and takes n cycles to reach I2CDRR, where:

n = 8 * (SYSCLK) / (I2C module clock (Fmod))

The transmit clock and the receive clock are the same. The address seen on the external SDA pin is the address in the I2COAR register. Figure 37-18 shows the signal routing in digital loopback mode.

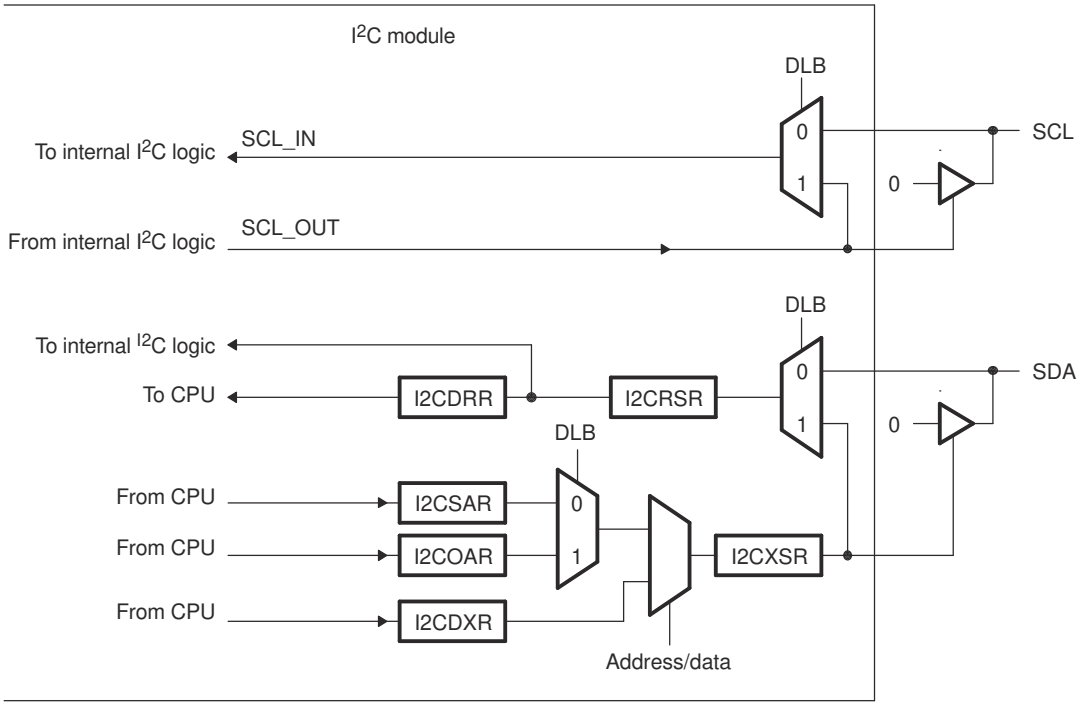

Figure 37-18. Pin Diagram Showing the Effects of the Digital Loopback Mode (DLB) Bit

Note

The free data format (I2CMDR.FDF = 1) is not supported in digital loopback mode.

37.3.12 NACK Bit Generation

When the I2C module is a receiver (controller or target), the I2C module can acknowledge or ignore bits sent by the transmitter. To ignore any new bits, the I2C module must send a no-acknowledge (NACK) bit during the acknowledge cycle on the bus. Table 37-5 summarizes the various ways you can allow the I2C module to send a NACK bit.

Note

When a NACK is sent, the following occurs:

1. The STP in I2CMDR is cleared
2. SCL is held low
3. The NACK in I2CSTR is set

Table 37-5. Ways to Generate a NACK Bit

I2C Module Condition	NACK Bit Generation Options
Target-receiver modes	Allow an overrun condition (RSFULL = 1 in I2CSTR) Reset the module (IRS = 0 in I2CMDR) Set the NACKMOD bit of I2CMDR before the rising edge of the last data bit you intend to receive
Controller-receiver mode AND Repeat mode (RM = 1 in I2CMDR)	Generate a STOP condition (STP = 1 in I2CMDR) Reset the module (IRS = 0 in I2CMDR) Set the NACKMOD bit of I2CMDR before the rising edge of the last data bit you intend to receive
Controller-receiver mode AND Nonrepeat mode (RM = 0 in I2CMDR)	If STP = 1 in I2CMDR, allow the internal data counter to count down to 0 and thus force a STOP condition If STP = 0, make STP = 1 to generate a STOP condition Reset the module (IRS = 0 in I2CMDR) Set STP = 1 to generate a STOP condition Set the NACKMOD bit of I2CMDR before the rising edge of the last data bit you intend to receive

37.4 Interrupt Requests Generated by the I2C Module

Each I2C module can generate two CPU interrupts.

1. Basic I2C interrupt: Possible basic I2C interrupt sources that can trigger this interrupt are described in Section 37.4.1.
2. I2C FIFO interrupt: Possible I2C FIFO interrupt sources that can trigger this interrupt are described in Section 37.4.2

37.4.1 Basic I2C Interrupt Requests

The I2C module generates the interrupt requests described in Table 37-6. As shown in Figure 37-19, all requests are multiplexed through an arbiter to a single I2C interrupt request to the CPU. Each interrupt request has a flag bit in the status register (I2CSTR) and an enable bit in the interrupt enable register (I2CIER). When one of the specified events occurs, the flag bit is set. If the corresponding enable bit is 0, the interrupt request is blocked. If the enable bit is 1, the request is forwarded to the CPU as an I2C interrupt.

The I2C interrupt is one of the maskable interrupts of the CPU. As with any maskable interrupt request, if the request is properly enabled in the CPU, the CPU executes the corresponding interrupt service routine (I2CINT1A_ISR). The I2CINT1A_ISR for the I2C interrupt can determine the interrupt source by reading the interrupt source register, I2CISRC. Then the I2CINT1A_ISR can branch to the appropriate subroutine.

After the CPU reads I2CISRC, the following events occur:

1. The flag for the source interrupt is cleared in I2CSTR. Exception: The ARDY, RRDY, and XRDY bits in I2CSTR are not cleared when I2CISRC is read. To clear one of these bits, write a 1 to the bit.
2. The arbiter determines which of the remaining interrupt requests has the highest priority, writes the code for that interrupt to I2CISRC, and forwards the interrupt request to the CPU.

Table 37-6. Descriptions of the Basic I2C Interrupt Requests

I2C Interrupt Request	Interrupt Source
XRDYINT	Transmit ready condition: The data transmit register (I2CDXR) is ready to accept new data because the previous data has been copied from I2CDXR to the transmit shift register (I2CXSR). As an alternative to using XRDYINT, the CPU can poll the XRDY bit of the status register, I2CSTR. XRDYINT must not be used when in FIFO mode. Use the FIFO interrupts instead.
RRDYINT	Receive ready condition: The data receive register (I2CDRR) is ready to be read because data has been copied from the receive shift register (I2CRSR) to I2CDRR. As an alternative to using RRDYINT, the CPU can poll the RRDY bit of I2CSTR. RRDYINT must not be used when in FIFO mode. Use the FIFO interrupts instead.
ARDYINT	Register-access ready condition: The I2C module registers are ready to be accessed because the previously programmed address, data, and command values have been used. The specific events that generate ARDYINT are the same events that set the ARDY bit of I2CSTR. As an alternative to using ARDYINT, the CPU can poll the ARDY bit.
NACKINT	No-acknowledgment condition: The I2C module is configured as a controller-transmitter and did not received acknowledgment from the target-receiver. As an alternative to using NACKINT, the CPU can poll the NACK bit of I2CSTR.
ARBLINT	Arbitration-lost condition: The I2C module has lost an arbitration contest with another controller-transmitter. As an alternative to using ARBLINT, the CPU can poll the ARBL bit of I2CSTR.
SCDINT	Stop condition detected: A STOP condition was detected on the I2C bus. As an alternative to using SCDINT, the CPU can poll the SCD bit of the status register, I2CSTR.
AASINT	Addressed as target condition: The I2C has been addressed as a target device by another controller on the I2C bus. As an alternative to using AASINT, the CPU can poll the AAS bit of the status register, I2CSTR.
SCLECSINT	SCL Extended Automatic Clock Stretching: SCL line is pulled low in extended automatic clock stretching mode. As an alternative to using SCLECSINT, the CPU can poll the SCL_ECS bit of the status register, I2CSTR.

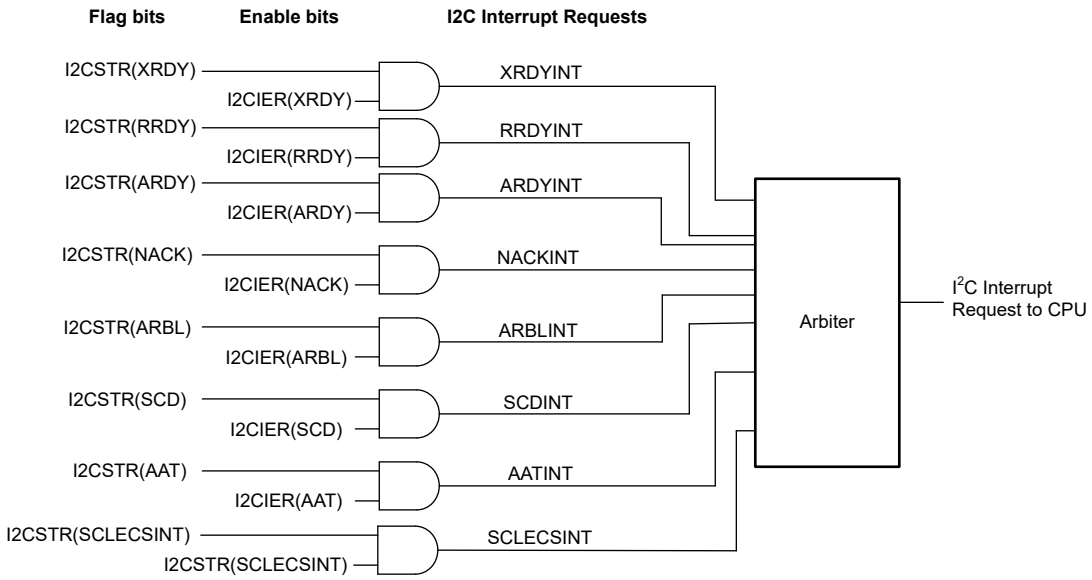

Figure 37-19. Enable Paths of the I2C Interrupt Requests

The priorities of the basic I2C interrupt requests are listed in order of highest priority to lowest priority:

1. ARBLINT
2. NACKINT
3. ARDYINT
4. RRDYINT
5. XRDYINT
6. SCDINT
7. AATINT
8. SCLECSINT

The I2C module has a backwards compatibility bit (BC) in the I2CEMDR register. The timing diagram in demonstrates the effect the backwards compatibility bit has on I2C module registers and interrupts when configured as a target-transmitter.

37.4.2 I2C FIFO Interrupts

In addition to the seven basic I2C interrupts, the transmit and receive FIFOs each contain the ability to generate an interrupt (I2CINT2A). The transmit FIFO can be configured to generate an interrupt after transmitting a defined number of bytes, up to 16. The receive FIFO can be configured to generate an interrupt after receiving a defined number of bytes, up to 16. These two interrupt sources are ORed together into a single maskable CPU interrupt. Figure 37-20 shows the structure of I2C FIFO interrupt. The interrupt service routine can then read the FIFO interrupt status flags to determine from which source the interrupt came. See the I2C transmit FIFO register (I2CFFTX) and the I2C receive FIFO register (I2CFFRX) descriptions.

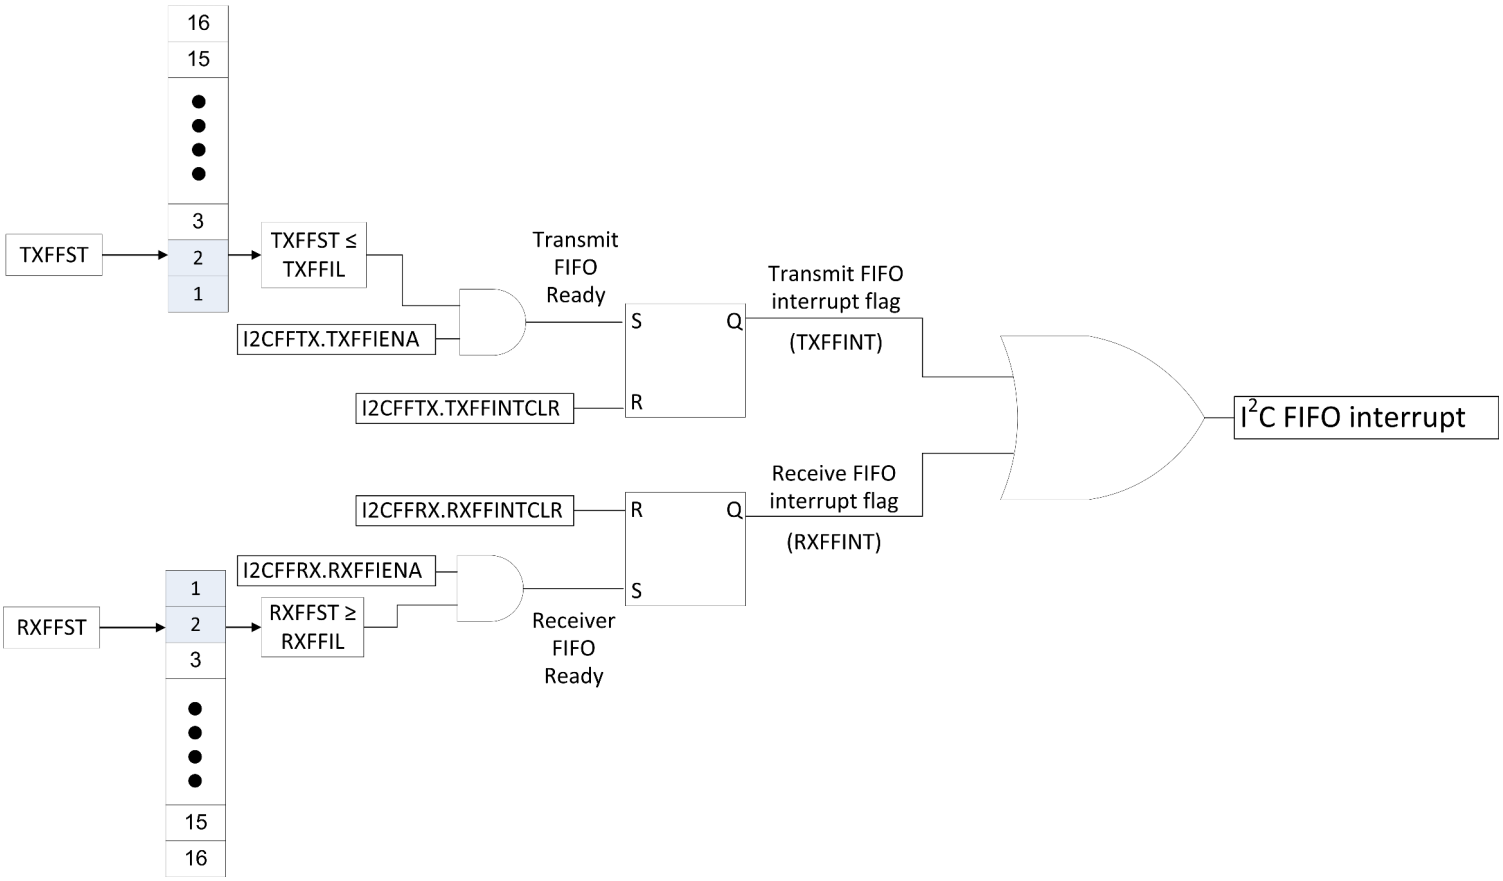

Figure 37-20. I2C FIFO Interrupt

37.5 Resetting or Disabling the I2C Module

You can reset or disable the I2C module in two ways:

- Write 0 to the I2C reset bit (IRS) in the I2C mode register (I2CMDR). All status bits (in I2CSTR) are forced to the default values, and the I2C module remains disabled until IRS is changed to 1. The SDA and SCL pins are in the high-impedance state.
- Initiate a device reset by driving the $\overline{\text{XRS}}$ pin low. The entire device is reset and is held in the reset state until you drive the pin high. When the $\overline{\text{XRS}}$ pin is released, all I2C module registers are reset to the default values. The IRS bit is forced to 0, which resets the I2C module. The I2C module stays in the reset state until you write 1 to IRS.

The IRS must be 0 while you configure or reconfigure the I2C module. Forcing IRS to 0 can be used to save power and to clear error conditions.

37.6.2 I2C Examples

NOTE: These examples are located in the C29SDK installation from ti.com at the following location: mcu_sdk_DEVICE_GPN/examples/driverlib/CORE_IF_MULTICORE/i2c

Cloud access to these examples is available at the following link: dev.ti.com C29SDK Examples.

37.6.2.1 I2C Digital Loopback with FIFO Interrupts - SINGLE_CORE

FILE: i2c_ex1_loopback.c

This program uses the internal loopback test mode of the I2C module. Both the TX and RX I2C FIFOs and their interrupts are used. The pinmux and I2C initialization is done through the sysconfig file.

A stream of data is sent and then compared to the received stream. The sent data looks like this:
0000 0001
0001 0002
0002 0003
....
00FE 00FF
00FF 0000
etc..
This pattern is repeated forever.

External Connections
- None

Watch Variables
- *sData* - Data to send
- *rData* - Received data
- *rDataPoint* - Used to keep track of the last position in the receive stream for error checking

37.6.2.2 I2C EEPROM - SINGLE_CORE

FILE: i2c_ex2_eeprom.c

This program will write 1-14 words to EEPROM and read them back. The data written and the EEPROM address written to are contained in the message structure, i2cMsgOut. The data read back will be contained in the message structure i2cMsgIn.

External Connections
- Connect external I2C EEPROM at address 0x50
- Connect DEVICE_GPIO_PIN_SDAA on to external EEPROM SDA (serial data) pin
- Connect DEVICE_GPIO_PIN_SCLA on to external EEPROM SCL (serial clock) pin

Watch Variables
- *i2cMsgOut* - Message containing data to write to EEPROM
- *i2cMsgIn* - Message containing data read from EEPROM

37.6.2.3 I2C Digital External Loopback with FIFO Interrupts - SINGLE_CORE

FILE: i2c_ex3_external_loopback.c

This program uses the I2CA and I2CB modules for achieving external loopback. The I2CA TX FIFO and the I2CB RX FIFO are used along with their interrupts.

A stream of data is sent on I2CA and then compared to the received stream on I2CB. The sent data looks like this:
0000 0001
0001 0002
0002 0003
....

00FE 00FF
00FF 0000
etc..
This pattern is repeated forever.

External Connections

- Connect SCLA(DEVICE_GPIO_PIN_SCLA) to SCLB (DEVICE_GPIO_PIN_SCLB)
- and SDAA(DEVICE_GPIO_PIN_SDAA) to SDAB (DEVICE_GPIO_PIN_SDAB)
- Connect DEVICE_GPIO_PIN_LED1 to an LED used to depict data transfers.

Watch Variables

- *sData* - Data to send
- *rData* - Received data
- *rDataPoint* - Used to keep track of the last position in the receive stream for error checking

37.6.2.4 I2C Extended Clock Stretching Controller TX - SINGLE_CORE

FILE: i2c_ex7_clock_stretching_controller_tx.c

This program uses the extended clock stretching mode of the I2C module. Both the TX and RX I2C Non-FIFOs and their interrupts are used.

A stream of data is sent and then compared to the received stream.

37.6.2.5 I2C Extended Clock Stretching Target RX - SINGLE_CORE

FILE: i2c_ex7_clock_stretching_target_rx.c

This program uses the extended clock stretching mode of the I2C module. Both the TX and RX I2C Non-FIFOs and their interrupts are used.

A stream of data is sent and then compared to the received stream.

37.7 I2C Registers

This Section describes the I2C Registers.

37.7.1 I2C Base Address Table

Table 37-8. I2C Base Address Table

Structure	DriverLib Name	Base Address	Frame Applicable	CPU1	CPU2	CPU3	RTDMA1	RTDMA2	HSM	Pipeline Protected
I2C_REGS	I2CA_BASE	0x7015_0000	YES	YES	YES	YES	YES	YES	-	YES
I2C_REGS	I2CB_BASE	0x7015_1000	YES	YES	YES	YES	YES	YES	-	YES

37.7.2 I2C_REGS Registers

Table 37-9 lists the memory-mapped registers for the I2C_REGS registers. All register offset addresses not listed in Table 37-9 should be considered as reserved locations and the register contents should not be modified.

Table 37-9. I2C_REGS Registers

Offset	Acronym	Register Name	Protection
0h	I2COAR	I2C Own address	
2h	I2CIER	I2C Interrupt Enable	
4h	I2CSTR	I2C Status	
6h	I2CCLKL	I2C Clock low-time divider	
8h	I2CCLKH	I2C Clock high-time divider	
Ah	I2CCNT	I2C Data count	
Ch	I2CDRR	I2C Data receive	
Eh	I2CTAR	I2C TARGET address	
10h	I2CDXR	I2C Data Transmit	
12h	I2CMDR	I2C Mode	
14h	I2CISRC	I2C Interrupt Source	
16h	I2CEMDR	I2C Extended Mode	
18h	I2CPSC	I2C Prescaler	
40h	I2CFFTX	I2C FIFO Transmit	
42h	I2CFFRX	I2C FIFO Receive	

Complex bit access types are encoded to fit into small table cells. Table 37-10 shows the codes that are used for access types in this section.

Table 37-10. I2C_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

37.7.2.1 I2COAR Register (Offset = 0h) [Reset = 0000h]

I2COAR is shown in Figure 37-21 and described in Table 37-11.

Return to the Summary Table.

The I2C own address register (I2COAR) is a 16-bit register. The I2C module uses this register to specify its own TARGET address, which distinguishes it from other TARGETs connected to the I2C-bus. If the 7-bit addressing mode is selected (XA = 0 in I2CMDR), only bits 6-0 are used
write 0s to bits 9-7.

Figure 37-21. I2COAR Register

Table 37-11. I2COAR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-10	RESERVED	R	0h	Reserved
9-0	OAR	R/W	0h	In 7-bit addressing mode (XA = 0 in I2CMDR): 00h-7Fh Bits 6-0 provide the 7-bit TARGET address of the I2C module. Write 0s to bits 9-7. In 10-bit addressing mode (XA = 1 in I2CMDR): 000h-3FFh Bits 9-0 provide the 10-bit TARGET address of the I2C module. Reset type: SYSRSn

37.7.2.2 I2CIER Register (Offset = 2h) [Reset = 0000h]

I2CIER is shown in Figure 37-22 and described in Table 37-12.

Return to the Summary Table.

I2CIER is used by the CPU to individually enable or disable I2C interrupt requests.

Figure 37-22. I2CIER Register

15	14	13	12	11	10	9	8

14-7	RESERVED	R	0h	Reserved
6	AAT	R/W	0h	Addressed as TARGET interrupt enable Reset type: SYSRSn 0h (R/W) = Interrupt request disabled 1h (R/W) = Interrupt request enabled
5	SCD	R/W	0h	Stop condition detected interrupt enable Reset type: SYSRSn 0h (R/W) = Interrupt request disabled 1h (R/W) = Interrupt request enabled
4	XRDY	R/W	0h	Transmit-data-ready interrupt enable bit. This bit should not be set when using FIFO mode. Reset type: SYSRSn 0h (R/W) = Interrupt request disabled 1h (R/W) = Interrupt request enabled
3	RRDY	R/W	0h	Receive-data-ready interrupt enable bit. This bit should not be set when using FIFO mode. Reset type: SYSRSn 0h (R/W) = Interrupt request disabled 1h (R/W) = Interrupt request enabled
2	ARDY	R/W	0h	Register-access-ready interrupt enable Reset type: SYSRSn 0h (R/W) = Interrupt request disabled 1h (R/W) = Interrupt request enabled
1	NACK	R/W	0h	No-acknowledgment interrupt enable Reset type: SYSRSn 0h (R/W) = Interrupt request disabled 1h (R/W) = Interrupt request enabled
0	ARBL	R/W	0h	Arbitration-lost interrupt enable Reset type: SYSRSn 0h (R/W) = Interrupt request disabled 1h (R/W) = Interrupt request enabled

37.7.2.3 I2CSTR Register (Offset = 4h) [Reset = 0410h]

I2CSTR is shown in Figure 37-23 and described in Table 37-13.

Return to the Summary Table.

The I2C status register (I2CSTR) is a 16-bit register used to determine which interrupt has occurred and to read status information.

Figure 37-23. I2CSTR Register

15	14	13	12	11	10	9	8

Table 37-13. I2CSTR Register Field Descriptions

Bit	Field	Type	Reset	Description
15	SCL_ECS	R/W1C	0h	SCL Status bit in extended automatic clock stretching mode 0: SCL line is pulled high. 1: SCL line is pulled low after ACK (or) NACK phase. Writing '1' to this bit releases SCL. SCL line is pulled high. Note: This bit is applicable only for extended clock stretching mode Reset type: SYSRSn 0h (R/W) = SCL line is not pulled low in extended automatic clock stretching mode. SCL_ECS bit is cleared by one o fthe following events: - It is manually cleared. To clear this bit, write a 1 to it. - The I2C module is reset. 1h (R/W) = SCL line is pulled low in extended automatic clock stretching mode.
14	TDIR	R/W1C	0h	TARGET direction bit Reset type: SYSRSn 0h (R/W) = I2C is not addressed as a TARGET transmitter. TDIR is cleared by one of the following events: - It is manually cleared. To clear this bit, write a 1 to it. - Digital loopback mode is enabled. - A START or STOP condition occurs on the I2C bus. 1h (R/W) = I2C is addressed as a TARGET transmitter.
13	NACKSNT	R/W1C	0h	NACK sent bit. This bit is used when the I2C module is in the receiver mode. One instance in which NACKSNT is affected is when the NACK mode is used (see the description for NACKMOD in Reset type: SYSRSn 0h (R/W) = NACK not sent. NACKSNT bit is cleared by any one of the following events: - It is manually cleared. To clear this bit, write a 1 to it. - The I2C module is reset (either when 0 is written to the IRS bit of I2CMDR or when the whole device is reset). 1h (R/W) = NACK sent: A no-acknowledge bit was sent during the acknowledge cycle on the I2C-bus.

Table 37-13. I2CSTR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
12	BB	R	0h	Bus busy bit. BB indicates whether the I2C-bus is busy or is free for another data transfer. See the paragraph following the table for more information Reset type: SYSRSn 0h (R/W) = Bus free. BB is cleared by any one of the following events: - The I2C module receives or transmits a STOP bit (bus free). - The I2C module is reset. 1h (R/W) = Bus busy: The I2C module has received or transmitted a START bit on the bus.
11	RSFULL	R	0h	Receive shift register full bit. RSFULL indicates an overrun condition during reception. Overrun occurs when new data is received into the shift register (I2CRSR) and the old data has not been read from the receive register (I2CDRR). As new bits arrive from the SDA pin, they overwrite the bits in I2CRSR. The new data will not be copied to ICDRR until the previous data is read. Reset type: SYSRSn 0h (R/W) = No overrun detected. RSFULL is cleared by any one of the following events: - I2CDRR is read by the CPU. Emulator reads of the I2CDRR do not affect this bit. - The I2C module is reset. 1h (R/W) = Overrun detected
10	XSMT	R	1h	Transmit shift register empty bit. XSMT = 0 indicates that the transmitter has experienced underflow. Underflow occurs when the transmit shift register (I2CXSR) is empty but the data transmit register (I2CDXR) has not been loaded since the last I2CDXR-to-I2CXSR transfer. The next I2CDXR-to-I2CXSR transfer will not occur until new data is in I2CDXR. If new data is not transferred in time, the previous data may be re-transmitted on the SDA pin. Reset type: SYSRSn 0h (R/W) = Underflow detected (empty) 1h (R/W) = No underflow detected (not empty). XSMT is set by one of the following events: - Data is written to I2CDXR. - The I2C module is reset
9	AAT	R	0h	Addressed-as-TARGET bit Reset type: SYSRSn 0h (R/W) = In the 7-bit addressing mode, the AAT bit is cleared when receiving a NACK, a STOP condition, or a repeated START condition. In the 10-bit addressing mode, the AAT bit is cleared when receiving a NACK, a STOP condition, or by a TARGET address different from the I2C peripheral's own TARGET address. 1h (R/W) = The I2C module has recognized its own TARGET address or an address of all zeros (general call).
8	AD0	R	0h	Address 0 bits Reset type: SYSRSn 0h (R/W) = AD0 has been cleared by a START or STOP condition. 1h (R/W) = An address of all zeros (general call) is detected.
7	RESERVED	R	0h	Reserved

Table 37-13. I2CSTR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6	BYTESENT	R/W1C	0h	Byte Transmit over indication. BYTESENT is set when the CONTROLLER/TARGET has successfully sent the byte on SCL/SDA lines. This is diagnostic register which needs to be explicitly cleared by Software. In case not cleared the stale status would keep reflecting as no automated clear incorporated to avoid corner conditions. Reset type: SYSRSn 0h (R/W) = The I2C module has not finished transmitting the next data byte. BYTESENT is cleared by any one of the following events: - It is manually cleared. To clear this bit, write a 1 to it. - The I2C module is reset. 1h (R/W) = The I2C module has completed the transmission of a byte.
5	SCD	R/W1C	0h	Stop condition detected bit. SCD is set when the I2C sends or receives a STOP condition. The I2C module delays clearing of the I2CMDR[STP] bit until the SCD bit is set. Reset type: SYSRSn 0h (R/W) = STOP condition not detected since SCD was last cleared. SCD is cleared by any one of the following events: - I2CISRC is read by the CPU when it contains the value 110b (stop condition detected). Emulator reads of the I2CISRC do not affect this bit. - SCD is manually cleared. To clear this bit, write a 1 to it. - The I2C module is reset. 1h (R/W) = A STOP condition has been detected on the I2C bus.
4	XRDY	R	1h	Transmit-data-ready interrupt flag bit. When not in FIFO mode, XRDY indicates that the data transmit register (I2CDXR) is ready to accept new data. FCM=0 : When the previous data has been copied from I2CDXR to the transmit shift register (I2CXSR). The CPU can poll XRDY or use the XRDY interrupt request When in FIFO mode, use TXFFINT instead. FCM=1: XRDY is asserted only when next data is required it gets deasserted with write to I2CDXR. Both Polling and interrupt based data transfers are allowed in the FCM mode. Reset type: SYSRSn 0h (R/W) = I2CDXR not ready. XRDY is cleared when data is written to I2CDXR. 1h (R/W) = I2CDXR ready: Data has been copied from I2CDXR to I2CXSR. XRDY is also forced to 1 when the I2C module is reset.
3	RRDY	R/W1C	0h	Receive-data-ready interrupt flag bit. When not in FIFO mode, RRDY indicates that the data receive register (I2CDRR) is ready to be read because data has been copied from the receive shift register (I2CRSR) to I2CDRR. The CPU can poll RRDY or use the RRDY interrupt request When in FIFO mode, use RXFFINT instead. Reset type: SYSRSn 0h (R/W) = I2CDRR not ready. RRDY is cleared by any one of the following events: - I2CDRR is read by the CPU. Emulator reads of the I2CDRR do not affect this bit. - RRDY is manually cleared. To clear this bit, write a 1 to it. - The I2C module is reset. 1h (R/W) = I2CDRR ready: Data has been copied from I2CRSR to I2CDRR.

Table 37-13. I2CSTR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
2	ARDY	R/W1C	0h	Register-access-ready interrupt flag bit (only Applicable when the I2C module is in the CONTROLLER mode). ARDY indicates that the I2C module registers are ready to be accessed because the previously programmed address, data, and command values have been used. The CPU can poll ARDY or use the ARDY interrupt request Reset type: SYSRSn 0h (R/W) = The registers are not ready to be accessed. ARDY is cleared by any one of the following events: - The I2C module starts using the current register contents. - ARDY is manually cleared. To clear this bit, write a 1 to it. - The I2C module is reset. 1h (R/W) = The registers are ready to be accessed. In the nonrepeat mode (RM = 0 in I2CMDR): If STP = 0 in I2CMDR, the ARDY bit is set when the internal data counter counts down to 0. If STP = 1, ARDY is not affected (instead, the I2C module generates a STOP condition when the counter reaches 0). In the repeat mode (RM = 1): ARDY is set at the end of each byte transmitted from I2CDXR.
1	NACK	R/W1C	0h	No-acknowledgment interrupt flag bit. NACK applies when the I2C module is a CONTROLLER transmitter (or) TARGET transmitter. NACK indicates whether the I2C module has detected an acknowledge bit (ACK) or a noacknowledge bit (NACK). The CPU can poll NACK or use the NACK interrupt request. Reset type: SYSRSn 0h (R/W) = ACK received/NACK not received. This bit is cleared by any one of the following events: - An acknowledge bit (ACK) has been sent by the TARGET receiver. - NACK is manually cleared. To clear this bit, write a 1 to it. - The CPU reads the interrupt source register (I2CISRC) and the register contains the code for a NACK interrupt. Emulator reads of the I2CISRC do not affect this bit. - The I2C module is reset. 1h (R/W) = NACK bit received. The hardware detects that a no-acknowledge (NACK) bit has been received. Note: While the I2C module performs a general call transfer, NACK is 1, even if one or more TARGETs send acknowledgment.
0	ARBL	R/W1C	0h	Arbitration-lost interrupt flag bit (only applicable when the I2C module is a CONTROLLER-transmitter). ARBL primarily indicates when the I2C module has lost an arbitration contest with another CONTROLLERtransmitter. The CPU can poll ARBL or use the ARBL interrupt request. Reset type: SYSRSn 0h (R/W) = Arbitration not lost. AL is cleared by any one of the following events: - AL is manually cleared. To clear this bit, write a 1 to it. - The CPU reads the interrupt source register (I2CISRC) and the register contains the code for an AL interrupt. Emulator reads of the I2CISRC do not affect this bit. - The I2C module is reset. 1h (R/W) = Arbitration lost. AL is set by any one of the following events: - The I2C module senses that it has lost an arbitration with two or more competing transmitters that started a transmission almost simultaneously. - The I2C module attempts to start a transfer while the BB (bus busy) bit is set to 1. When AL becomes 1, the CNT and STP bits of I2CMDR are cleared, and the I2C module becomes a TARGET-receiver.

37.7.2.4 I2CCLKL Register (Offset = 6h) [Reset = 0000h]

I2CCLKL is shown in Figure 37-24 and described in Table 37-14.

To produce the high time duration of the CONTROLLER clock, the period of the module clock is multiplied by (ICCL + d). d is an adjustment factor based on the prescaler. See the Clock Divider Registers section of the Introduction for details. Note: These bits must be set to a non-zero value for proper I2C clock generation. Reset type: SYSRSn

37.7.2.6 I2CCNT Register (Offset = Ah) [Reset = 0000h]

I2CCNT is shown in Figure 37-26 and described in Table 37-16.

Return to the Summary Table.

I2CCNT is a 16-bit register used to indicate how many data bytes to transfer when the I2C module is configured as a transmitter, or to receive when configured as a CONTROLLER receiver. In the repeat mode (RM = 1), I2CCNT is not used.
The value written to I2CCNT is copied to an internal data counter. The internal data counter is decremented by 1 for each byte transferred (I2CCNT remains unchanged). If a STOP condition is requested in the CONTROLLER mode (STP = 1 in I2CMDR), the I2C module terminates the transfer with a STOP condition when the countdown is complete (that is, when the last byte has been transferred).

R/W-0h							

Table 37-16. I2CCNT Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	I2CCNT	R/W	0h	Data count value. I2CCNT indicates the number of data bytes to transfer or receive. If a STOP condition is specified (STP=1) then I2CCNT will decrease after each byte is sent until it reaches zero, which in turn will generate a STOP condition. The value in I2CCNT is a don't care when the RM bit in I2CMDR is set to 1. Reset type: SYSRSn 0h (R/W) = data count value is 65536 1h (R/W) = data count value is 1 2h (R/W) = data count value is 2 FFFFh (R/W) = data count value is 65535

37.7.2.7 I2CDRR Register (Offset = Ch) [Reset = 0000h]

I2CDRR is shown in Figure 37-27 and described in Table 37-17.

Return to the Summary Table.

I2CDRR is a 16-bit register used by the CPU to read received data. The I2C module can receive a data byte with 1 to 8 bits. The number of bits is selected with the bit count (BC) bits in I2CMDR. One bit at a time is shifted in from the SDA pin to the receive shift register (I2CRSR). When a complete data byte has been received, the I2C module copies the data byte from I2CRSR to I2CDRR. The CPU cannot access I2CRSR directly.
If a data byte with fewer than 8 bits is in I2CDRR, the data value is right-justified, and the other bits of I2CDRR(7-0) are undefined. For example, if BC = 011 (3-bit data size), the receive data is in I2CDRR(2-0), and the content of I2CDRR(7-3) is undefined.
When in the receive FIFO mode, the I2CDRR register acts as the receive FIFO buffer.

37.7.2.8 I2CTAR Register (Offset = Eh) [Reset = 03FFh]

I2CTAR is shown in Figure 37-28 and described in Table 37-18.

Return to the Summary Table.

The I2C TARGET address register (I2CSAR) is a 16-bit register for storing the next TARGET address that will be transmitted by the I2C module when it is a CONTROLLER. The SAR field of I2CSAR contains a 7-bit or 10-bit TARGET address. When the I2C module is not using the free data format (FDF = 0 in I2CMDR), it uses this address to initiate data transfers with a TARGET, or TARGETs. When the address is nonzero, the address is for a particular TARGET. When the address is 0, the address is a general call to all TARGETs. If the 7-bit addressing mode is selected (XA = 0 in I2CMDR), only bits 6-0 of I2CSAR are used
write 0s to bits 9-7.

15-10	RESERVED	R	0h	Reserved
9-0	TAR	R/W	3FFh	In 7-bit addressing mode (XA = 0 in I2CMDR): 00h-7Fh Bits 6-0 provide the 7-bit TARGET address that the I2C module transmits when it is in the CONTROLLER-transmitter mode. Write 0s to bits 9-7. In 10-bit addressing mode (XA = 1 in I2CMDR): 000h-3FFh Bits 9-0 provide the 10-bit TARGET address that the I2C module transmits when it is in the CONTROLLER transmitter mode. Reset type: SYSRSn

37.7.2.9 I2CDXR Register (Offset = 10h) [Reset = 0000h]

I2CDXR is shown in Figure 37-29 and described in Table 37-19.

Return to the Summary Table.

The CPU writes transmit data to I2CDXR. This 16-bit register accepts a data byte with 1 to 8 bits. Before writing to I2CDXR, specify how many bits are in a data byte by loading the appropriate value into the bit count (BC) bits of I2CMDR. When writing a data byte with fewer than 8 bits, make sure the value is right-aligned in I2CDXR. After a data byte is written to I2CDXR, the I2C module copies the data byte to the transmit shift register (I2CXSR). The CPU cannot access I2CXSR directly. From I2CXSR, the I2C module shifts the data byte out on the SDA pin, one bit at a time.
When in the transmit FIFO mode, the I2CDXR register acts as the transmit FIFO buffer.

Table 37-20. I2CMDR Register Field Descriptions

Bit	Field	Type	Reset	Description
15	NACKMOD	R/W	0h	NACK mode bit. This bit is only applicable when the I2C module is acting as a receiver. Reset type: SYSRSn 0h (R/W) = In the TARGET-receiver mode: The I2C module sends an acknowledge (ACK) bit to the transmitter during each acknowledge cycle on the bus. The I2C module only sends a no-acknowledge (NACK) bit if you set the NACKMOD bit. In the CONTROLLER-receiver mode: The I2C module sends an ACK bit during each acknowledge cycle until the internal data counter counts down to 0. At that point, the I2C module sends a NACK bit to the transmitter. To have a NACK bit sent earlier, you must set the NACKMOD bit 1h (R/W) = In either TARGET-receiver or CONTROLLER-receiver mode: The I2C module sends a NACK bit to the transmitter during the next acknowledge cycle on the bus. Once the NACK bit has been sent, NACKMOD is cleared. Important: To send a NACK bit in the next acknowledge cycle, you must set NACKMOD before the rising edge of the last data bit.
14	FREE	R/W	0h	This bit controls the action taken by the I2C module when a debugger breakpoint is encountered. Reset type: SYSRSn 0h (R/W) = When I2C module is CONTROLLER: If SCL is low when the breakpoint occurs, the I2C module stops immediately and keeps driving SCL low, whether the I2C module is the transmitter or the receiver. If SCL is high, the I2C module waits until SCL becomes low and then stops. When I2C module is TARGET: A breakpoint forces the I2C module to stop when the current transmission/reception is complete. 1h (R/W) = The I2C module runs free that is, it continues to operate when a breakpoint occurs.
13	STT	R/W	0h	START condition bit (only applicable when the I2C module is a CONTROLLER). The RM, STT, and STP bits determine when the I2C module starts and stops data transmissions (see Table 9-6). Note that the STT and STP bits can be used to terminate the repeat mode, and that this bit is not writable when IRS = 0. Reset type: SYSRSn 0h (R/W) = In the CONTROLLER mode, STT is automatically cleared after the START condition has been generated. 1h (R/W) = In the CONTROLLER mode, setting STT to 1 causes the I2C module to generate a START condition on the I2C-bus
12	RESERVED	R	0h	Reserved

Table 37-20. I2CMDR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11	STP	R/W	0h	STOP condition bit (only applicable when the I2C module is a CONTROLLER). In the CONTROLLER mode, the RM,STT, and STP bits determine when the I2C module starts and stops data transmissions. Note that the STT and STP bits can be used to terminate the repeat mode, and that this bit is not writable when IRS=0. When in non-repeat mode, at least one byte must be transferred before a stop condition can be generated. The I2C module delays clearing of this bit until after the I2CSTR[SCD] bit is set. To avoid disrupting the I2C state machine, the user must wait until this bit is clear before initiating a new message. Reset type: SYSRSn 0h (R/W) = STP is automatically cleared after the STOP condition has been generated 1h (R/W) = STP has been set by the device to generate a STOP condition when the internal data counter of the I2C module counts down to 0.
10	CNT	R/W	0h	CONTROLLER mode bit. CNT determines whether the I2C module is in the TARGET mode or the CONTROLLER mode. CNT is automatically changed from 1 to 0 when the I2C CONTROLLER generates a STOP condition Reset type: SYSRSn 0h (R/W) = TARGET mode. The I2C module is a TARGET and receives the serial clock from the CONTROLLER. 1h (R/W) = CONTROLLER mode. The I2C module is a CONTROLLER and generates the serial clock on the SCL pin.
9	TRX	R/W	0h	Transmitter mode bit. When relevant, TRX selects whether the I2C module is in the transmitter mode or the receiver mode. Reset type: SYSRSn 0h (R/W) = Receiver mode. The I2C module is a receiver and receives data on the SDA pin. 1h (R/W) = Transmitter mode. The I2C module is a transmitter and transmits data on the SDA pin.
8	XA	R/W	0h	Expanded address enable bit. Reset type: SYSRSn 0h (R/W) = 7-bit addressing mode (normal address mode). The I2C module transmits 7-bit TARGET addresses (from bits 6-0 of I2CTAR), and its own TARGET address has 7 bits (bits 6-0 of I2COAR). 1h (R/W) = 10-bit addressing mode (expanded address mode). The I2C module transmits 10-bit TARGET addresses (from bits 9-0 of I2CTAR), and its own TARGET address has 10 bits (bits 9-0 of I2COAR).
7	RM	R/W	0h	Repeat mode bit (only applicable when the I2C module is a CONTROLLER-transmitter or CONTROLLER-receiver). The RM, STT, and STP bits determine when the I2C module starts and stops data transmissions Reset type: SYSRSn 0h (R/W) = Nonrepeat mode. The value in the data count register (I2CCNT) determines how many bytes are received/transmitted by the I2C module. 1h (R/W) = Repeat mode. A data byte is transmitted each time the I2CDXR register is written to (or until the transmit FIFO is empty when in FIFO mode) until the STP bit is manually set. The value of I2CCNT is ignored. The ARDY bit/interrupt can be used to determine when the I2CDXR (or FIFO) is ready for more data, or when the data has all been sent and the CPU is allowed to write to the STP bit.

Table 37-20. I2CMDR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6	DLB	R/W	0h	Digital loopback mode bit. Reset type: SYSRSn 0h (R/W) = Digital loopback mode is disabled. 1h (R/W) = Digital loopback mode is enabled. For proper operation in this mode, the CNT bit must be 1. In the digital loopback mode, data transmitted out of I2CDXR is received in I2CDRR after n device cycles by an internal path, where: n = ((I2C input clock frequency/module clock frequency) x 8) The transmit clock is also the receive clock. The address transmitted on the SDA pin is the address in I2COAR. Note: The free data format (FDF = 1) is not supported in the digital loopback mode.
5	IRS	R/W	0h	I2C module reset bit. Reset type: SYSRSn 0h (R/W) = The I2C module is in reset/disabled. When this bit is cleared to 0, all status bits (in I2CSTR) are set to their default values. 1h (R/W) = The I2C module is enabled. This has the effect of releasing the I2C bus if the I2C peripheral is holding it.
4	STB	R/W	0h	START byte mode bit. This bit is only applicable when the I2C module is a CONTROLLER. As described in version 2.1 of the Philips Semiconductors I2C-bus specification, the START byte can be used to help a TARGET that needs extra time to detect a START condition. When the I2C module is a TARGET, it ignores a START byte from a CONTROLLER, regardless of the value of the STB bit. Reset type: SYSRSn 0h (R/W) = The I2C module is not in the START byte mode. 1h (R/W) = The I2C module is in the START byte mode. When you set the START condition bit (STT), the I2C module begins the transfer with more than just a START condition. Specifically, it generates: 1. A START condition 2. A START byte (0000 0001b) 3. A dummy acknowledge clock pulse 4. A repeated START condition Then, as normal, the I2C module sends the TARGET address that is in I2CTAR.
3	FDF	R/W	0h	Free data format mode bit. Reset type: SYSRSn 0h (R/W) = Free data format mode is disabled. Transfers use the 7-/10-bit addressing format selected by the XA bit. 1h (R/W) = Free data format mode is enabled. Transfers have the free data (no address) format described in Section 9.2.5. The free data format is not supported in the digital loopback mode (DLB=1).

Table 37-20. I2CMDR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
2-0	BC	R/W	0h	Bit count bits. BC defines the number of bits (1 to 8) in the next data byte that is to be received or transmitted by the I2C module. The number of bits selected with BC must match the data size of the other device. Notice that when BC = 000b, a data byte has 8 bits. BC does not affect address bytes, which always have 8 bits. Note: If the bit count is less than 8, receive data is right-justified in I2CDRR(7-0), and the other bits of I2CDRR(7-0) are undefined. Also, transmit data written to I2CDXR must be right-justified Reset type: SYSRSn 0h (R/W) = 8 bits per data byte 1h (R/W) = 1 bit per data byte 2h (R/W) = 2 bits per data byte 3h (R/W) = 3 bits per data byte 4h (R/W) = 4 bits per data byte 5h (R/W) = 5 bits per data byte 6h (R/W) = 6 bits per data byte 7h (R/W) = 7 bits per data byte

37.7.2.11 I2CISRC Register (Offset = 14h) [Reset = 0000h]

I2CISRC is shown in Figure 37-31 and described in Table 37-21.

Return to the Summary Table.

The I2C interrupt source register (I2CISRC) is a 16-bit register used by the CPU to determine which event generated the I2C interrupt.

0	BC	R/W	1h	Backwards compatibility mode. This bit affects the timing of the transmit status bits (XRDY and XSMT) in the I2CSTR register when in TARGET transmitter mode. Reset type: SYSRSn 0h (R/W) = See the 'Backwards Compatibility Mode Bit, TARGET Transmitter' Figure for details. 1h (R/W) = See the 'Backwards Compatibility Mode Bit, TARGET Transmitter' Figure for details.

37.7.2.13 I2CPSC Register (Offset = 18h) [Reset = 0000h]

I2CPSC is shown in Figure 37-33 and described in Table 37-23.

Return to the Summary Table.

The I2C prescaler register (I2CPSC) is a 16-bit register (see Figure 14-21) used for dividing down the I2C input clock to obtain the desired module clock for the operation of the I2C module. See the device-specific data manual for the supported range of values for the module clock frequency.
IPSC must be initialized while the I2C module is in reset (IRS = 0 in I2CMDR). The prescaled frequency takes effect only when IRS is changed to 1. Changing the IPSC value while IRS = 1 has no effect.

Figure 37-33. I2CPSC Register

Bit	Field	Type	Reset	Description
15-8	RESERVED	R	0h	Reserved
7-0	IPSC	R/W	0h	I2C prescaler divide-down value. IPSC determines how much the CPU clock is divided to create the module clock of the I2C module: module clock frequency = I2C input clock frequency/(IPSC + 1) Note: IPSC must be initialized while the I2C module is in reset (IRS = 0 in I2CMDR). Reset type: SYSRSn

37.7.2.14 I2CFFTX Register (Offset = 40h) [Reset = 0000h]

I2CFFTX is shown in Figure 37-34 and described in Table 37-24.

Return to the Summary Table.

The I2C transmit FIFO register (I2CFFTX) is a 16-bit register that contains the I2C FIFO mode enable bit as well as the control and status bits for the transmit FIFO mode of operation on the I2C peripheral.

Figure 37-34. I2CFFTX Register

15	14	13	12	11	10	9	8
RESERVED	I2CFFEN	TXFFRST	TXFFST

R-0h	R-0/W1S-0h	R/W-0h	R/W-0h				

Table 37-24. I2CFFTX Register Field Descriptions

Bit	Field	Type	Reset	Description
15	RESERVED	R	0h	Reserved
14	I2CFFEN	R/W	0h	I2C FIFO mode enable bit. This bit must be enabled for either the transmit or the receive FIFO to operate correctly. Reset type: SYSRSn 0h (R/W) = Disable the I2C FIFO mode. 1h (R/W) = Enable the I2C FIFO mode.
13	TXFFRST	R/W	0h	Transmit FIFO Reset Reset type: SYSRSn 0h (R/W) = Reset the transmit FIFO pointer to 0000 and hold the transmit FIFO in the reset state. 1h (R/W) = Enable the transmit FIFO operation.
12-8	TXFFST	R	0h	Contains the status of the transmit FIFO: xxxxx Transmit FIFO contains xxxxx bytes. 00000 Transmit FIFO is empty. Note: Since these bits are reset to zero, the transmit FIFO interrupt flag will be set when the transmit FIFO operation is enabled and the I2C is taken out of reset. This will generate a transmit FIFO interrupt if enabled. To avoid any detrimental effects from this, write a one to the TXFFINTCLR once the transmit FIFO operation is enabled and the I2C is taken out of reset. Reset type: SYSRSn
7	TXFFINT	R	0h	Transmit FIFO interrupt flag. This bit cleared by a CPU write of a 1 to the TXFFINTCLR bit. If the TXFFIENA bit is set, this bit will generate an interrupt when it is set. Reset type: SYSRSn 0h (R/W) = Transmit FIFO interrupt condition has not occurred. 1h (R/W) = Transmit FIFO interrupt condition has occurred.
6	TXFFINTCLR	R-0/W1S	0h	Transmit FIFO Interrupt Flag Clear Reset type: SYSRSn 0h (R/W) = Writes of zeros have no effect. Reads return a 0. 1h (R/W) = Writing a 1 to this bit clears the TXFFINT flag.
5	TXFFIENA	R/W	0h	Transmit FIFO Interrupt Enable Reset type: SYSRSn 0h (R/W) = Disabled. TXFFINT flag does not generate an interrupt when set. 1h (R/W) = Enabled. TXFFINT flag does generate an interrupt when set.

Table 37-24. I2CFFTX Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4-0	TXFFIL	R/W	0h	Transmit FIFO interrupt level. These bits set the status level that will set the transmit interrupt flag. When the TXFFST4-0 bits reach a value equal to or less than these bits, the TXFFINT flag will be set. This will generate an interrupt if the TXFFIENA bit is set. Because the I2C on this device has a 16-level transmit FIFO, these bits cannot be configured for an interrupt of more than 16 FIFO levels. Reset type: SYSRSn

37.7.2.15 I2CFFRX Register (Offset = 42h) [Reset = 0000h]

I2CFFRX is shown in Figure 37-35 and described in Table 37-25.

Return to the Summary Table.

The I2C receive FIFO register (I2CFFRX) is a 16-bit register that contains the control and status bits for the receive FIFO mode of operation on the I2C peripheral.

Figure 37-35. I2CFFRX Register

15	14	13	12	11	10	9	8
RESERVED		RXFFRST	RXFFST				
R-0h		R/W-0h	R-0h				
7	6	5	4	3	2	1	0
RXFFINT	RXFFINTCLR	RXFFIENA	RXFFIL				
R-0h	R-0/W1S-0h	R/W-0h	R/W-0h				

Table 37-25. I2CFFRX Register Field Descriptions

Bit	Field	Type	Reset	Description
15-14	RESERVED	R	0h	Reserved
13	RXFFRST	R/W	0h	I2C receive FIFO reset bit Reset type: SYSRSn 0h (R/W) = Reset the receive FIFO pointer to 0000 and hold the receive FIFO in the reset state. 1h (R/W) = Enable the receive FIFO operation.
12-8	RXFFST	R	0h	Contains the status of the receive FIFO: xxxxx Receive FIFO contains xxxxx bytes 00000 Receive FIFO is empty. Reset type: SYSRSn
7	RXFFINT	R	0h	Receive FIFO interrupt flag. This bit cleared by a CPU write of a 1 to the RXFFINTCLR bit. If the RXFFIENA bit is set, this bit will generate an interrupt when it is set Reset type: SYSRSn 0h (R/W) = Receive FIFO interrupt condition has not occurred. 1h (R/W) = Receive FIFO interrupt condition has occurred.
6	RXFFINTCLR	R-0/W1S	0h	Receive FIFO interrupt flag clear bit. Reset type: SYSRSn 0h (R/W) = Writes of zeros have no effect. Reads return a zero. 1h (R/W) = Writing a 1 to this bit clears the RXFFINT flag.
5	RXFFIENA	R/W	0h	Receive FIFO interrupt enable bit. Reset type: SYSRSn 0h (R/W) = Disabled. RXFFINT flag does not generate an interrupt when set. 1h (R/W) = Enabled. RXFFINT flag does generate an interrupt when set.
4-0	RXFFIL	R/W	0h	Receive FIFO interrupt level. These bits set the status level that will set the receive interrupt flag. When the RXFFST4-0 bits reach a value equal to or greater than these bits, the RXFFINT flag is set. This will generate an interrupt if the RXFFIENA bit is set. Note: Since these bits are reset to zero, the receive FIFO interrupt flag will be set if the receive FIFO operation is enabled and the I2C is taken out of reset. This will generate a receive FIFO interrupt if enabled. To avoid this, modify these bits on the same instruction as or prior to setting the RXFFRST bit. Because the I2C on this device has a 16-level receive FIFO, these bits cannot be configured for an interrupt of more than 16 FIFO levels. Reset type: SYSRSn

Chapter 38

Power Management Bus Module (PMBus)

This chapter describes the features and operation of the Power Management Bus (PMBus) module.

38.1 Introduction

The PMBus module provides an interface between the microcontroller and devices compliant with the SMI Forum PMBus Specification Part I version 1.0 and Part II version 1.1. The PMBus is based on SMBus, which uses a similar physical layer to the I2C. This chapter assumes you are familiar with the PMBus, SMBus, and I2C bus specifications.

38.1.1 PMBUS Related Collateral

Expert Materials

- 9 things you need to know about PMBus Point-of-Load Power (Video)

38.1.2 Features

The PMBus module has the following features:

- Compliance with the SMI Forum PMBus Specification (Part I v1.0 and Part II v1.1)
- Support for controller and target modes
- Ability to support Zero Hold Time (mentioned in SMBus3.0 specs)
- 5V Fail safe IO and 20mA sink current support. Refer to the device data sheet for more details
- Ability to support VIH = 1.35V. Refer to the device data sheet for more details
- Support for I2C modes
- Support for three speeds:
  - Standard Mode: Up to 100kHz
  - Fast Mode: Up to 400kHz
  - Fast Mode Plus: Up to 1MHz
- Packet error checking
- CONTROL and ALERT signals
- Clock high and low time-outs
- Four-byte transmit and receive buffers
- One maskable interrupt, which can be generated by several conditions:
  - Receive data ready
  - Transmit buffer empty
  - Target address received
  - End of message
  - ALERT input asserted
  - Clock low time-out
  - Clock high time-out
  - Bus free

38.1.3 Block Diagram

Figure 38-1 shows the block diagram for PMBus. The PMBus module handles the lower levels of the PMBus protocol. In addition to controlling signal levels and timing, parsing addresses, and buffering data, the PMBus module also directly supports complex transactions such as Read Word and Process Call.

There are four PMBus signals:

- **SCL** is the bus clock. SCL is normally controlled by the controller, but can be held low by a target to delay a transaction and allow more time for processing.
- **SDA** is the bidirectional data line.
- **CONTROL** is a target input that can trigger an interrupt. CONTROL can be used to shut down a target device.
- **ALERT** is a target output/controller input that allows a target to request attention from the controller.

The SDA and SCL timings produced by the module are derived from SYSCLK. To comply with the PMBus timing specs, the bit clock divider must be set by way of the PMBTIMCLK register to provide a bit clock with respect to the module's configured speed.

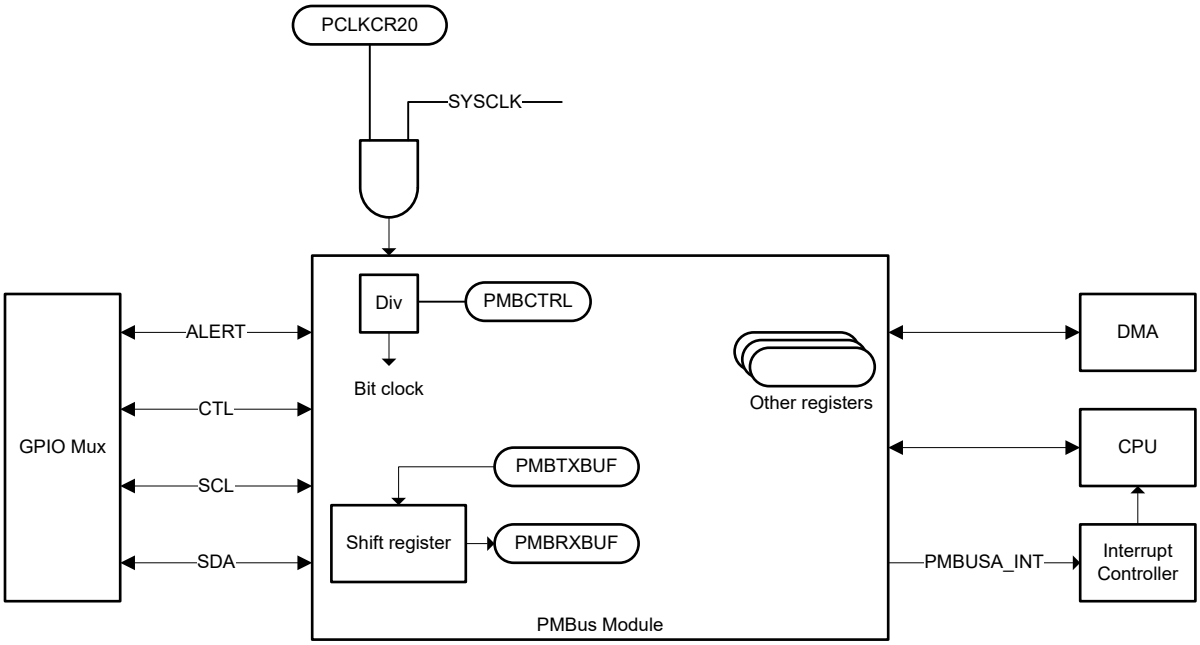

Figure 38-1. PMBus Module Block Diagram

38.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification is set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups are configured in the GPyPUD register.

Note

The GPIO configuration register GPyODR must be set to normal mode when the PMBus is used. The open-drain operation for PMBus is managed by the PMBus module

To support a wider range of PMBus IO levels, certain GPIOs have configurable fail-safe systems, V_{IH} minimum thresholds, and configurable sinking capabilities. ***Specifically, the configurable sink current support is mandated for fast plus mode.***

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

38.3 Target Mode Operation

This section describes the configuration and operation of the PMBus module in target mode.

38.3.1 Configuration

To configure the module, write a clock divider to the PMBCTRL register's CLKDIV field to produce a bit clock frequency with respect to the module's configured speed. To activate target mode, set the TARGET_EN bit in the PMBCTRL register. Next, set up the PMBTCR register. The following options are configurable:

- Target address and mask (TARGET_ADDR and TARGET_MASK): Sets the target address and mask for message acceptance.
- Manual target address acknowledgment (MAN_TARGET_ACK): When enabled, allows software to decide whether to acknowledge (ACK) an address. When disabled, the decision to ACK is made automatically based on the target address and mask.
- PEC enable (PEC_ENA): Set this bit if Packet Error Checking (PEC) is used on the bus.
- Manual command byte acknowledgment (MAN_CMD): Similar to manual target acknowledgment, setting this bit allows software to decide whether to acknowledge (ACK) a command byte.
- Number of bytes to acknowledge automatically (RX_BYTE_ACK_CNT): This is normally set to the maximum value, which allows the entire receive buffer to be used. However, smaller values can be used if the application requires that erroneous messages be detected and not acknowledged (NACKed) as soon as possible.

Manual acknowledgment is done by writing a one to the PMBACK register. Even with automatic acknowledgment, some writes to PMBACK are required. If the message (not including the address) is longer than 4 bytes, each packet of 4 bytes much be acknowledged. The PMBus module stretches the clock (hold the clock low) until an ACK is issued. The module then pulls the data line low and releases the clock, providing the ACK signal to the controller.

If the complete message or the last part of the message is less than 4 bytes (or the RX_BYTE_ACK_CNT limit), do not write to PMBACK.

Writing a zero to the PMBACK bit sends a NACK. This can only be done when the module is waiting for an acknowledgment. If a zero is written at any other time, the NACK is issued during the next message.

38.3.2 Message Handling

This section describes some of the message types for PMBus and how to determine which message type is being received in target mode. This section is oriented toward the most efficient mode of operation – with automatic address and command acknowledgment and is also oriented toward having Packet Error Checking (PEC) enabled.

If automatic address acknowledgment is disabled, all messages start by setting the TARGET_ADDR_READY bit high. Read commands have two instructions one for the read and one for the write. If automatic command acknowledgment is enabled, the DATA READY bit is set high, as well. If the message has no PEC, the number of bytes available is n-1. For example with PEC, a QUICK COMMAND has one byte. With no PEC, a QUICK COMMAND has zero bytes.

Note that the byte count does not increment as bytes arrive. No bits are set in the PMBST register until a stop message is received, the receive buffer is full, or a fault occurs. Then, all appropriate bit values are placed in the register together. All that is necessary to receive a quick command is to ACK the message by writing a one to the PMBACK register.

38.3.2.1 Quick Command

Quick Commands (Figure 38-2) received by the PMBus module in target mode require a simple acknowledgment of the received device address. In automatic address acknowledge mode, the module processes the quick command without firmware interaction. Upon receipt of the end of message, the firmware has the option to read the received address in the PMBHTA register. In manual address acknowledge mode, the address is acknowledged by writing to the PMBACK register.

Figure 38-2. Quick Command Message

38.3.2.2 Send Byte

A Send Byte message (Figure 38-3) consists of the device address, a single data byte, and an optional PEC byte. To process the PEC byte correctly, PEC processing must be enabled in the PMBTCR register. In automatic address acknowledge mode, the data and optional PEC byte are acknowledged without firmware interaction. The module generates an End of Message interrupt, reads the status register and finds the data ready indication bit set. In manual mode, the address is acknowledged by the firmware, while the remaining data and PEC bytes are acknowledged by the module.

The PMBus module stores Data Byte #0 into the PMBRXBUF register. The data byte is stored into bits 7-0. In non-PEC mode, the RX Byte Count in the PMBSTS register indicates one byte received. If PEC processing is enabled, the PEC byte is also stored into the PMBRXBUF register, with the PEC byte residing in bits 15-8. The RX Byte Count in the PMBSTS register indicates two bytes received. The PEC Valid bit in the PMBSTS register indicates the validity of the received PEC byte.

When a Send Byte message is received, the Data Ready bit is set along with the EOM and, assuming that the PEC is valid, the PEC valid bit. The read byte count (RD_BYTE_COUNT) register contains a 2. All that is necessary to receive a send byte command is to ACK the message by writing a 1 to the PMBACK register. Before doing the ACK, read the byte from the lowest byte of the PMBRXBUF register.

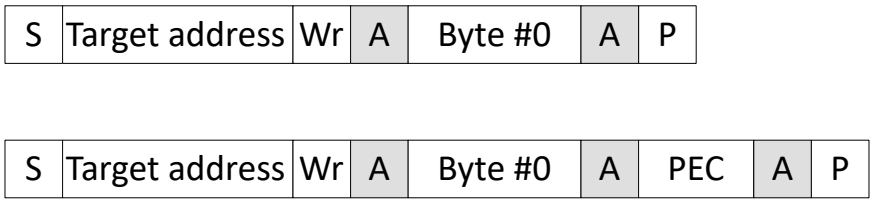

Figure 38-3. Send Byte Message With and Without PEC

38.3.2.3 Receive Byte

A Receive Byte message (Figure 38-4) consists of the device address, a single data byte, and an optional PEC byte. In automatic address acknowledge mode, the firmware receives a data request interrupt following reception of the target address. The data byte to be sent to the controller is stored into bits 7-0 of the PMBTXBUF register and Transmit Byte Count bits within the PMBTCR register are set to a value of 1. If PEC processing is enabled, the Transmit PEC bit (bit 19) within the PMBTCR register is set to 1, along with the Enable PEC bit (bit 15). The module automatically appends the calculated PEC byte at the completion of the message.

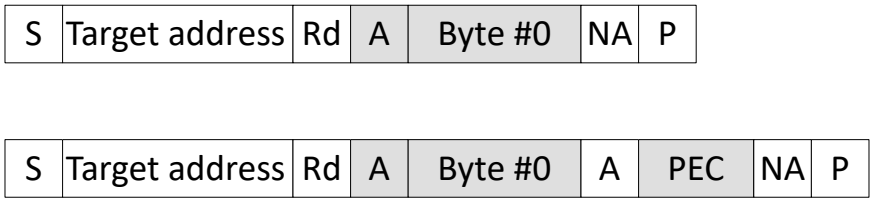

Figure 38-4. Receive Byte Message With and Without PEC

38.3.2.4 Write Byte and Write Word

The Write Byte and Write Word messages (Figure 38-5) consist of a target address, a command word, transmitted data bytes and an optional PEC byte. In automatic address acknowledge mode, the data bytes and optional PEC byte are acknowledged without firmware interaction. The acknowledgment of the command word is configured through the PMBTCR register. The firmware receives an End of Message interrupt in all cases except for Write Word with PEC message, reads the status register and finds the data ready indication bit set.

In the case of a Write Word with PEC byte message, the data ready interrupt is enabled after receiving 4 bytes (command byte, the 2 data bytes and the PEC byte). The firmware reads the data from the PMBRXBUF register and must write the PMBACK register to acknowledge back to the controller. The PMBus module holds SCL low until the firmware responds to the received data.

In all other cases, the EOM interrupt is received and data can be read from the PMBRXBUF register. The firmware is not required to send an acknowledgment back to the controller.

The Write Byte message looks exactly the same as the Send Byte, except the RD_BYTE_COUNT register contains a 3. The Write Word message has a RD_BYTE_COUNT of 4.

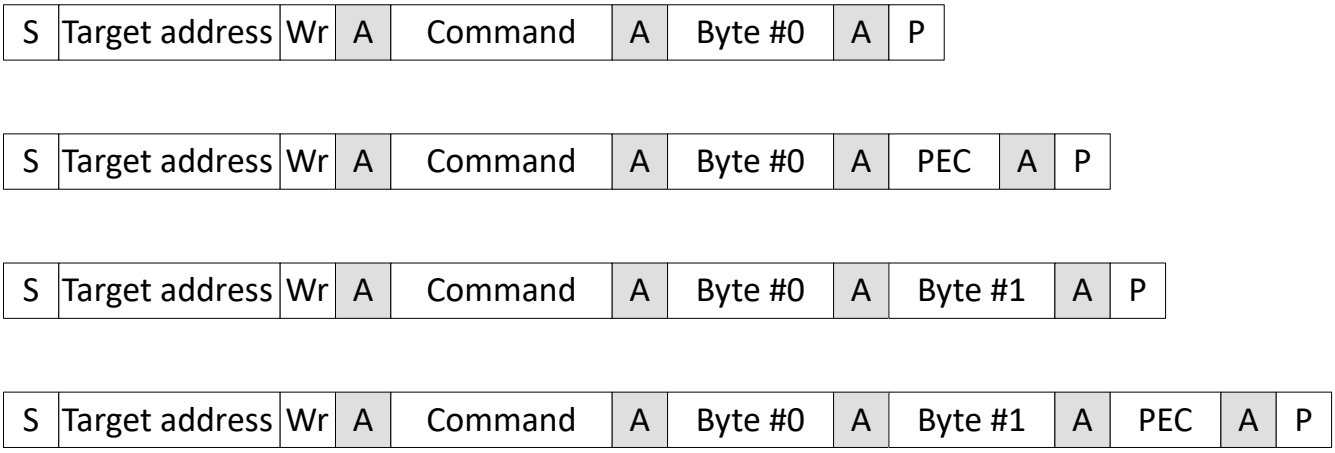

Figure 38-5. Write Byte and Write Word Messages With and Without PEC

38.3.2.5 Read Byte and Read Word

The Read Byte and Read Word messages (Figure 38-6) consist of a target address, a command word, received data bytes from a target, and an optional PEC byte. Address and command acknowledgment is configured through the PMBTCR register. In automatic mode, the PMBus module provides a data ready and data request interrupt following receipt of a repeated start and target address. The received command byte is found in bits 7-0 of the PMBRXBUF register. The firmware responds to the data request by programming the data bytes into the PMBTXBUF register and the TX Byte Count bits in the PMBTCR register. If PEC processing is enabled, the Transmit PEC bit must also be asserted. An EOM interrupt indicates completion of the message to the Controller.

When the repeated start (Sr) signal is received, the Data Ready bit is asserted with a RD_BYTE_COUNT of 1. At this point, the operation cannot be distinguished from a group command Send Byte message. When the same device address is sent out with a read, the Data Request bit is asserted. If data has already been written to the PMTXBUF register before the Device Address is received, the Data Request bit is not asserted. So if group commands are also expected, read the Data Ready with a RD_BYTE_COUNT of 1, and then wait and see whether the next event is an EOM or a Data Request. If the event is an EOM, the command must be processed as a group send byte. If the event is a Data Request, the command must be processed as a read. Depending on the command, the event can be a read byte, word, or block. If the PMBus module is polled, both the Data Ready and the Data Request bits can possibly be set between polling intervals. This must be considered in the design of the firmware.

Once the read command is recognized, you must respond by writing data to the PMBTXBUF register. Make sure that the values in the PMBTCR register are correct. The transmit byte count and PEC bit must be set appropriately. For a read byte, the transmit byte count can be loaded with a 1. If the transmission of a PEC byte is desired, the TX_PEC bit must be set. After this, the data can be written to PMBTXBUF, which starts the transmission. All bytes must be written to PMBTXBUF at the same time. After the controller receives the message, the controller NACKs the last byte to indicate that the correct number of bytes have been received. This causes the EOM bit to be set in the PMBSTS register, indicating to the firmware that the Read Byte message is complete.

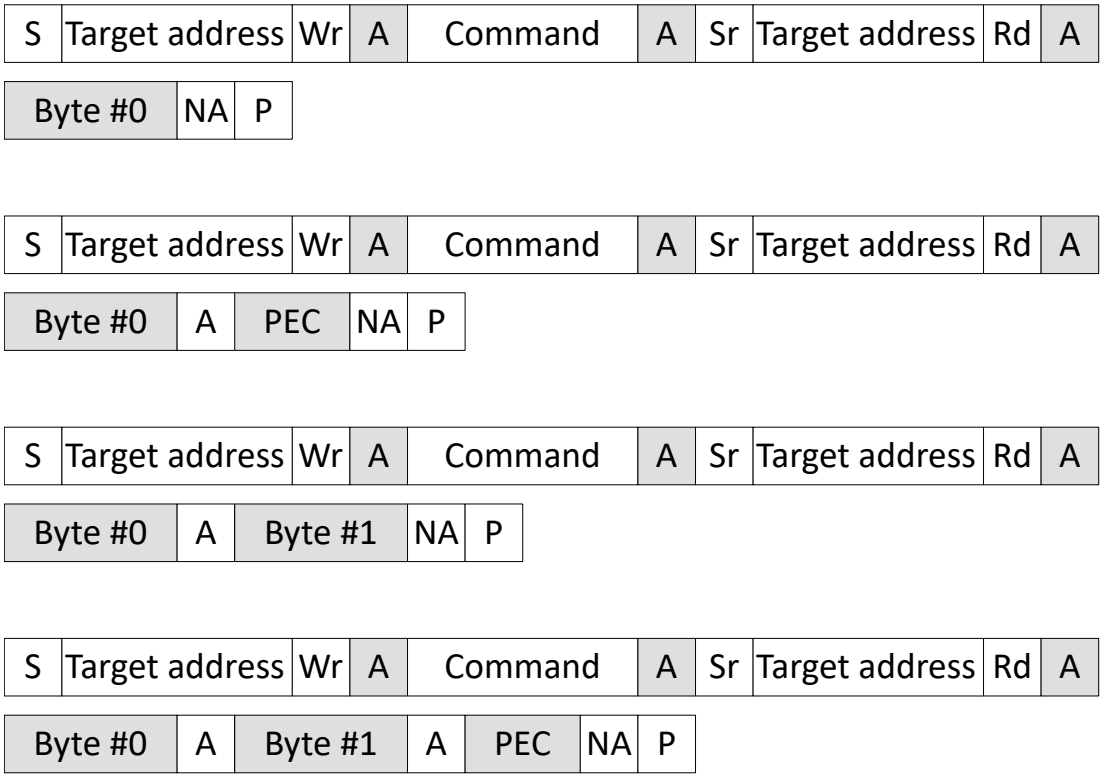

Figure 38-6. Read Byte and Read Word Messages With and Without PEC

38.3.2.6 Process Call

The Process Call (Figure 38-7) protocol consists of a Write Word message, followed by a Read Word message, without a stop condition between the two messages. Address and command acknowledgment is configured through the PMBTCR register. In automatic mode, following receipt of the repeated start and target address, the PMBus module provides a data ready and a data request interrupt. The repeated start bit is set in the PMBSTS register to indicate the receipt of the first part of the Process Call message. The received command byte is found in bits 7-0 of the PMBRXBUF register, while the two data bytes received from the controller can be found in bits 23-8. Upon receipt of the repeated start and a data request from the module, the firmware programs the PMBTXBUF with the 2 data bytes to be sent to the controller. If PEC processing is enabled, the Transmit PEC bit within the PMBTCR register is asserted. The EOM interrupt indicates the read word portion of the Process Call message has been completed by the module.

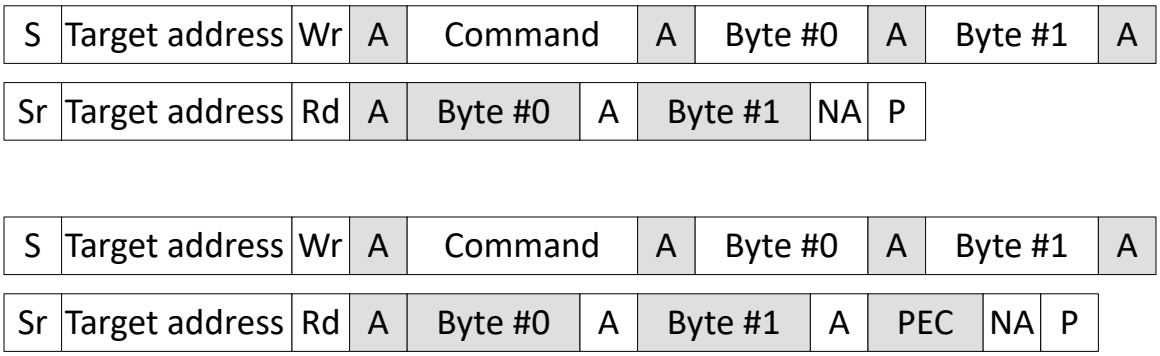

Figure 38-7. Process Call Message With and Without PEC

38.3.2.7 Block Write

The Block Write (Figure 38-8) protocol is similar to Write Word in structure, except that there are more than 2 data bytes in the message. Following the receipt of the command byte, the block length and 2 data bytes, the PMBus module provides a data ready interrupt. The module waits for the firmware to read the received data and program the acknowledge register. While waiting for an ACK from the firmware, the module drives the clock line low, stalling the bus. The data ready interrupts continue for the duration of the message at a frequency of every 4 data bytes. The number of bytes received can be found within the PMBSTS register. At the end of the message, less than 4 bytes can be stored in the PMBRXBUF register. The PEC Valid bit can be checked to determine if the received PEC value is accurate.

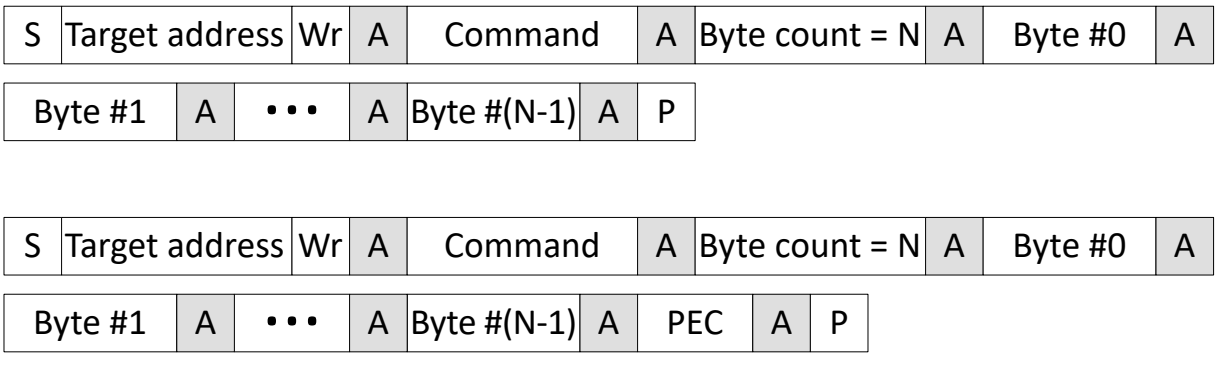

Figure 38-8. Block Write Message With and Without PEC

38.3.2.8 Block Read

The Block Read (Figure 38-9) protocol is similar to a Read Word in structure, except that there are more than 2 data bytes in the message. Following the receipt of the repeated target address, a data ready and data request interrupt is generated by the PMBus module. The command byte received from the controller can be found in bits 7-0 of the PMBRXBUF register. The SCL line is held low until the firmware programs data bytes into the PMBTXBUF register. The firmware is required to load the block length into bits 7-0 of the PMBTXBUF register during the initial programming of the register. After 4 bytes have been transmitted, the module issues a data request interrupt and holds SCL low again until the firmware has programmed additional data into the PMBTXBUF register.

Block read starts the same as Read Word or Read Byte, but TX_COUNT is loaded with a 4 the first time, and TX_PEC is not set. Instead of waiting for an EOM after the first transmission, the firmware instead waits for a Data Request, indicating that the controller is ready for more data. Until the last 4 or less bytes, the firmware simply writes a 4 to TX_COUNT and then writes the 4 bytes to PMBTXBUF. TX_PEC is left cleared. Then when the last 4 or fewer bytes are to be transmitted, the firmware writes out the appropriate byte count, sets the TX_PEC bit, and writes the data to PMBTXBUF. The PMBus module writes out the data, followed by the PEC, and then the EOM bit is set when the controller NACKs the PEC.

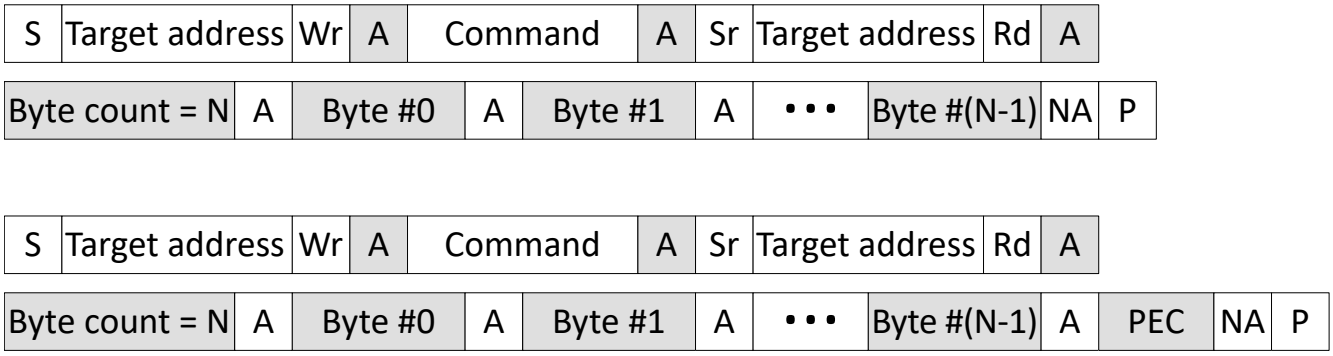

Figure 38-9. Block Read Message With and Without PEC

38.3.2.9 Block Write-Block Read Process Call

The Block Write-Block Read Process Call (Figure 38-10) protocol combines the Block Write and Block Read protocols, removing the stop condition between the two messages. The processing of the Block Read-Block Write Process Call message is similar to the mode of operation for the Process Call message. After acknowledgment of the address and command bytes, the PMBus module generates a data ready interrupt upon detection of 4 data bytes or a repeated start condition. After receiving the repeated start, the firmware is required to load transmit data to send to the controller. Bits 7-0 of the initial programming of the PMBTXBUF register must represent the byte count of the block data sent to the controller.

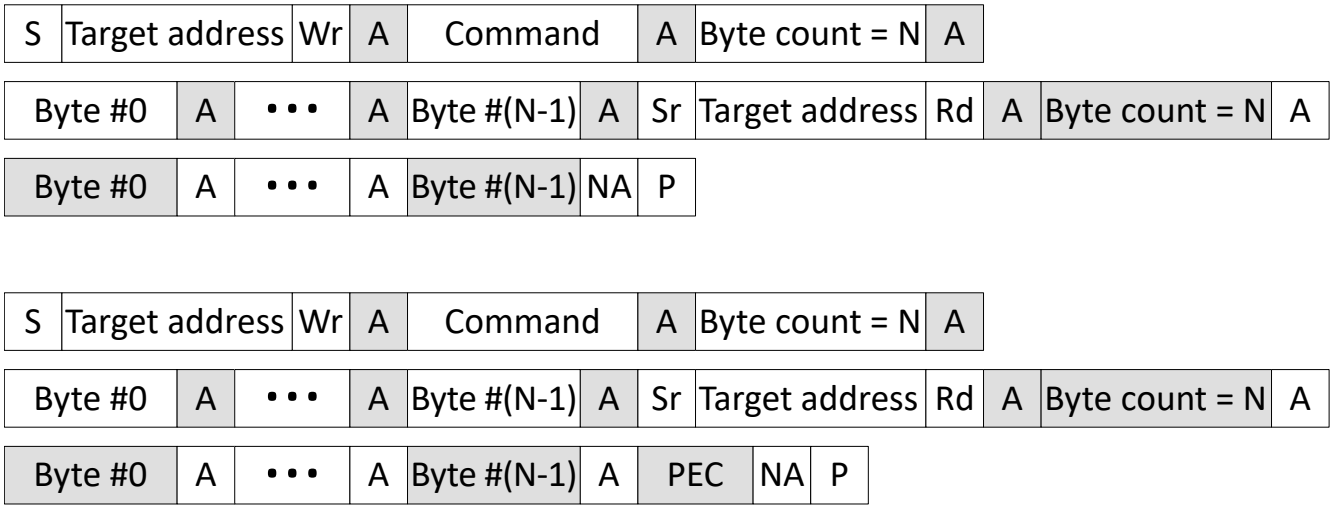

Figure 38-10. Block Write-Block Read Process Call Message With and Without PEC

38.3.2.10 Alert Response

The Alert Response Message (Figure 38-11) is utilized when the controller detects an alert condition from a target on the PMBus. In automatic address acknowledge mode, upon detection of the Alert Response Address, the PMBus module provides an acknowledgment to the controller and sends the programmed target address within the PMBTCR register. The module only responds to the message if the Alert En bit within PMBCTRL register has been previously set. After receiving the Alert Response message, the module clears the alert condition and the enable bit within the PMBCTRL register.

In manual address acknowledge mode, the firmware must read the received address from the PMBRXBUF register and transmit the desired target address back to the controller. The PMBCTRL register must be reprogrammed to disable the Alert En bit used to initiate the Alert Response message from the controller.

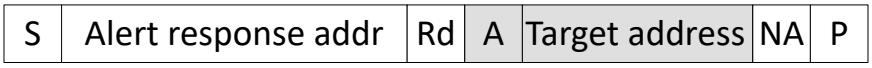

Figure 38-11. Alert Response Message

38.3.2.11 Extended Command

The PMBus module provides support for extended commands that allow for an extra 256 command codes. Both command bytes are stored in the PMBRXBUF register along with the data bytes. In recognizing the extended command messages, the Repeated Start bit and the Rd Byte Count Bits within the PMBSTS register are utilized. For Extended Command Write Byte and Write Word messages (Figure 38-12), the two command bytes are stored in bits 15-0 of the PMBRXBUF register. The initial command byte must hold the command extension code, representing utilization of the extended command protocol. The Repeated Start bit is also set, received after the retransmission of the device address. The Rd Byte Count equals 3 for an Ext Cmd Write Byte message and 4 for an Ext Cmd Write Word message.

For the Extended Command Read Byte and Read Word messages (Figure 38-13), the module generates a data ready and data request interrupt following reception of the repeated device address. The two command bytes are found in bits 15-0 of the PMBRXBUF register, with the initial command byte matching the command extension code. The firmware is required to load transmit data to complete the message back to the controller.

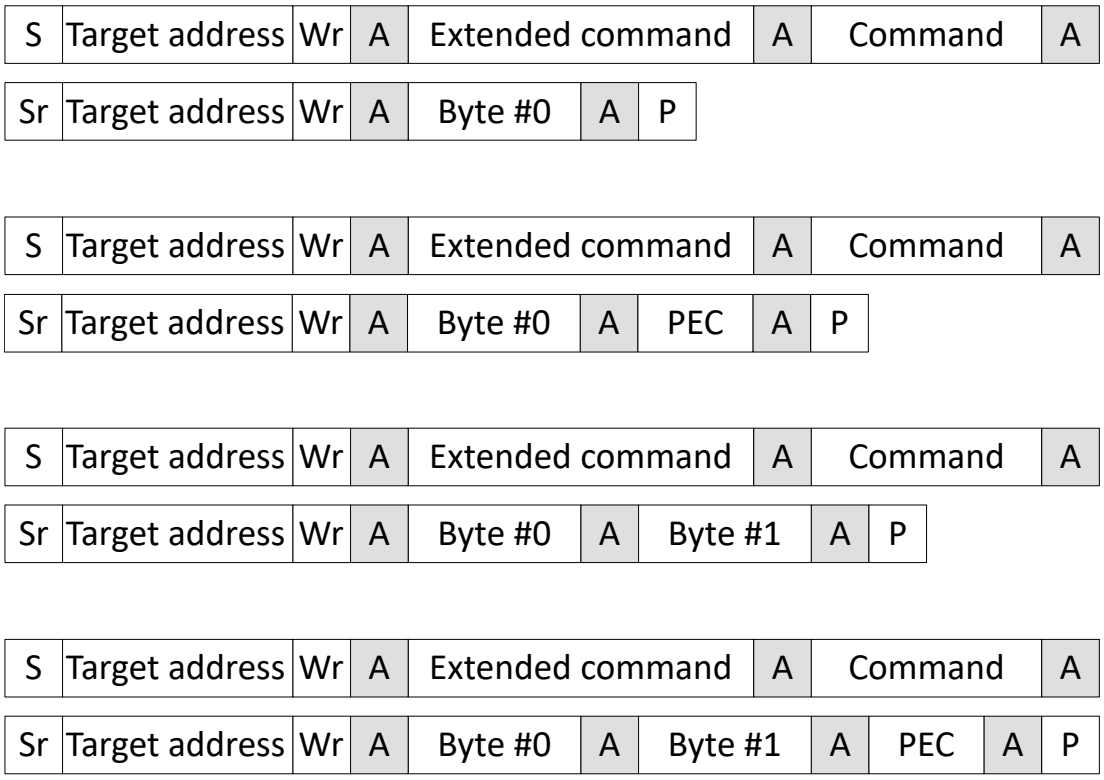

Figure 38-12. Extended Command Write Byte and Write Word Messages With and Without PEC

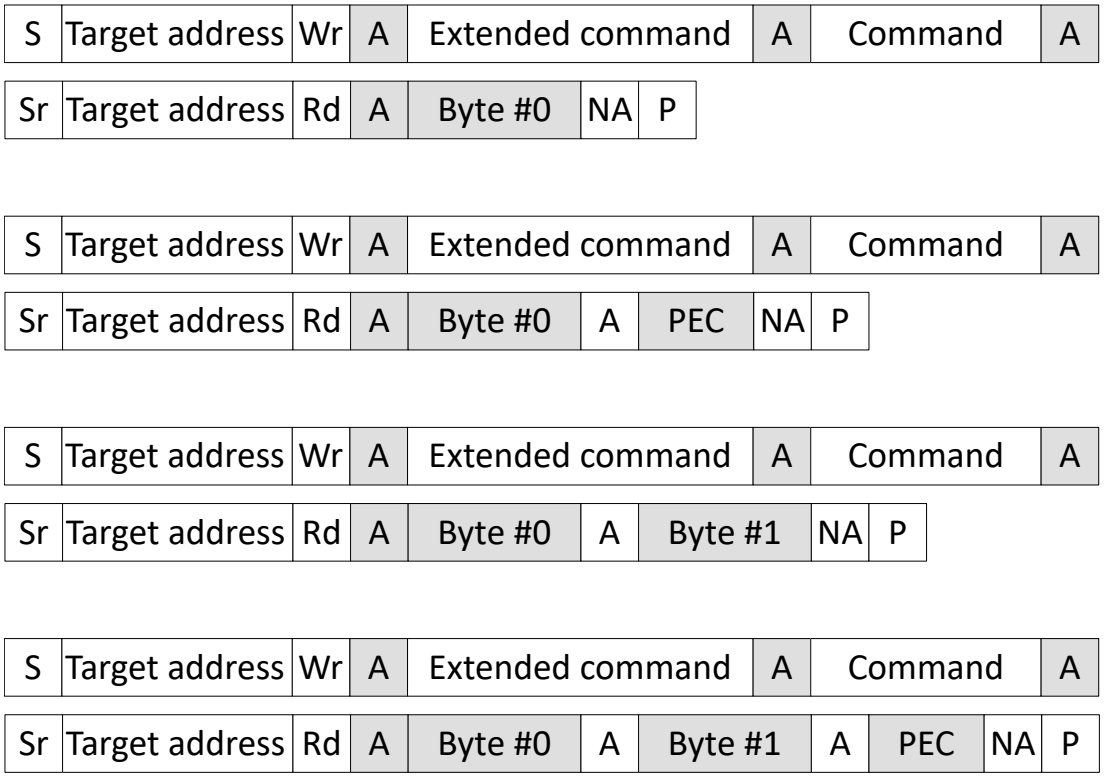

Figure 38-13. Extended Command Read Byte and Read Word Messages With and Without PEC

38.3.2.12 Group Command

The PMBus module supports the Group Command protocol. The Group Command (Figure 38-14) protocol is used to send commands to more than one device within the same message. When devices on the bus detect the stop condition at the conclusion of the Group Command message, the received commands are executed concurrently. Following address and command acknowledgment, the module provides a data ready interrupt upon detection of 4 data bytes or the transmission of a repeated start on the bus. The firmware must wait for the EOM interrupt before processing the received command, as required by the use of the Group Command message.

For Group Commands, the data ready bit is set as soon as the repeated start is received. The data can then be read into memory. But the data must not be acted upon until the EOM bit is set, which occurs when all of the messages have been received. Other than this delayed EOM, there is no difference for the target firmware in receiving a Group Command than any other write message.

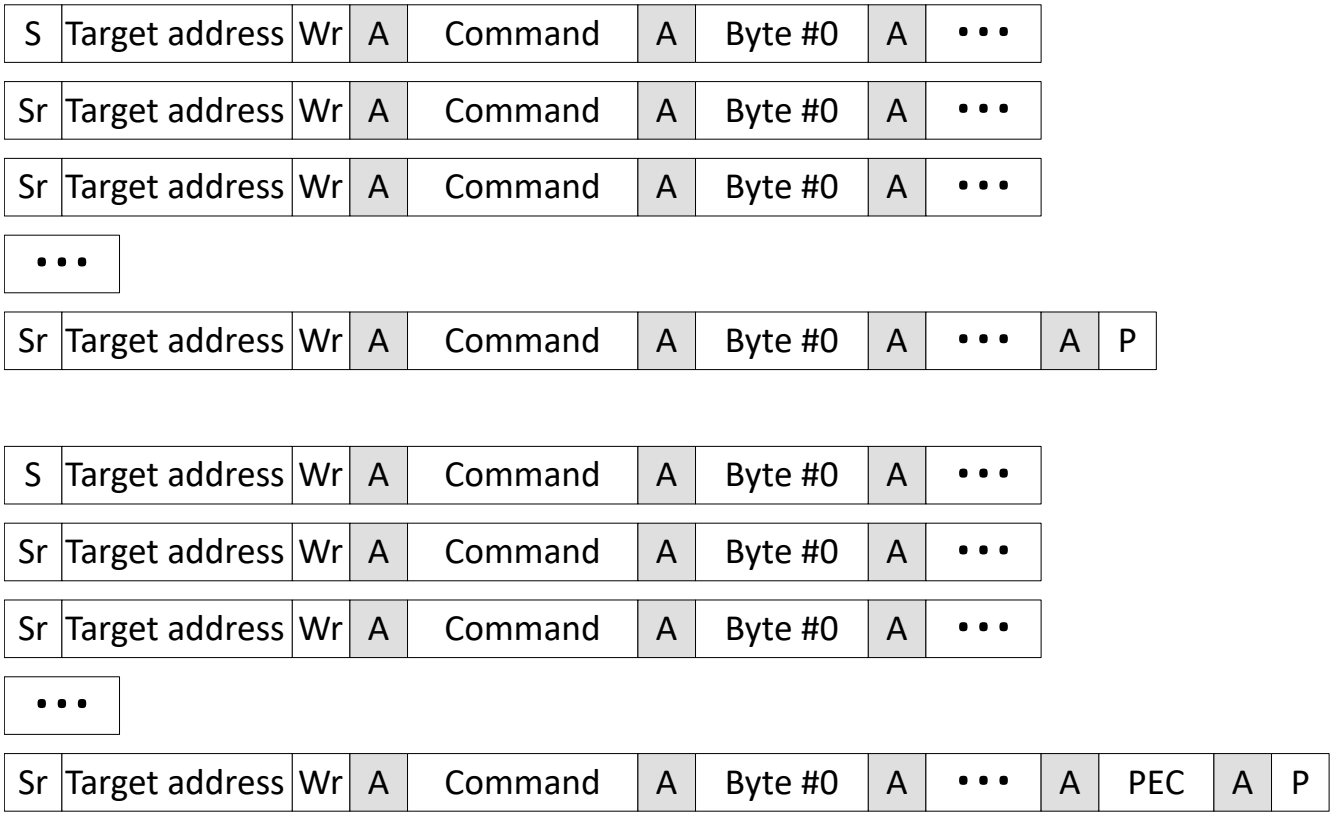

Figure 38-14. Group Command Message With and Without PEC

38.4 Controller Mode Operation

This section describes the configuration and operation of the PMBus module in controller mode.

38.4.1 Configuration

First, write a clock divider to the PMBCTRL register CLKDIV field to produce a bit clock frequency with respect to the module's configured speed. To activate controller mode, set the CONTROLLER_EN bit and clear the TARGET_EN bit in the PMBCTRL register. For each transaction, set up the PMBCCR register. The following options are configurable:

- Target address (TARGET_ADDR): Sets the target address for the next transaction.
- PEC enable (PEC_ENA): If Packet Error Checking (PEC) is used on the bus, set this bit.
- Extended command code enable (EXT_CMD): When set, uses two bytes for commands.
- Command code enable (CMD_ENA): When set, sends a command byte at the start of the transaction.
- Byte count (BYTE_COUNT): Determines the number of data bytes to transfer. This does not include the block length byte, which is generated automatically when needed.
- Special command enables (GRP_CMD and PRC_CALL): Enables special behavior for group commands and process calls.

Writing to the PMBCCR register starts a transfer.

Manual acknowledgment of received data is not needed.

38.4.2 Message Handling

This section describes the behavior and required configuration for each command type.

38.4.2.1 Quick Command

Quick commands (Figure 38-15) are initiated in controller mode by simply programming the desired target device address into the PMBCCR. The byte count within the PMBCCR register is configured to 0 bytes by writing all zeros to bits 15-8. Upon transmission of the device address, the PMBus module monitors the target acknowledgment of the address. If the address is not acknowledged, the NACK bit within the status register is enabled and the PMBus module automatically sends a stop condition on the bus to terminate the message. If the address is acknowledged, a data request is issued to the processor. The firmware writes a zero to the PMBACK to terminate the message, forcing the PMBus modules to write a stop condition onto the bus.

Figure 38-15. Quick Command Message

38.4.2.2 Send Byte

A Send Byte message (Figure 38-16) consists of the device address, a single data byte, and an optional PEC byte. To initiate a Send Byte message, the data byte to be transmitted to the target is loaded into bits 7-0 of the PMBTXBUF register. The PMBCCR register is configured with the device address. To transmit a PEC byte with the message, the PEC_EN bit within the PMBCCR register is asserted high when the address is programmed.

After programming the PMBCCR register, the PMBus module transmits the Send Byte message. The firmware can wait for an End of Message interrupt from the PMBus module. Upon receipt of the EOM interrupt, the PMBSTS register is read to verify the target properly acknowledged the transmitted data.

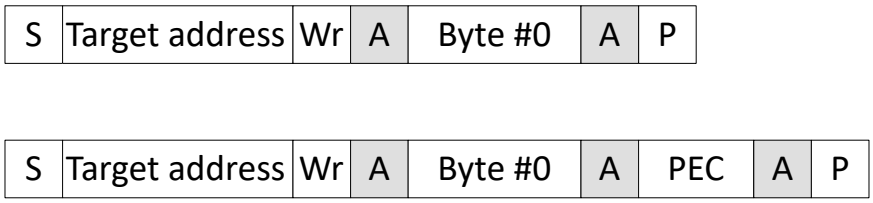

Figure 38-16. Send Byte Message With and Without PEC

38.4.2.3 Receive Byte

A Receive Byte message (Figure 38-17) consists of the device address, a single data byte, and an optional PEC byte. Data is being read from the target in a Receive Byte message. To initiate a Receive Byte message, the firmware programs the device address, the R/W bit and the optional PEC_EN into the PMBCCR register. The R/W bit is enabled high to indicate a read message type (data transmitted from target to controller).

After programming the PMBCCR register, the PMBus module transmits the Receive Byte message. The firmware can wait for an End of Message interrupt from the PMBus module to verify the accuracy of the message transmission. Upon receipt of the EOM interrupt, the PMBSTS register is read to verify proper target acknowledgment of the device address and to determine if any data is available for reading in the PMBRXBUF register. If PEC_EN was asserted in the PMBCCR register, the PEC_VALID bit in the PMBSTS register is also checked to make sure a proper PEC byte was received from the target with the received data.

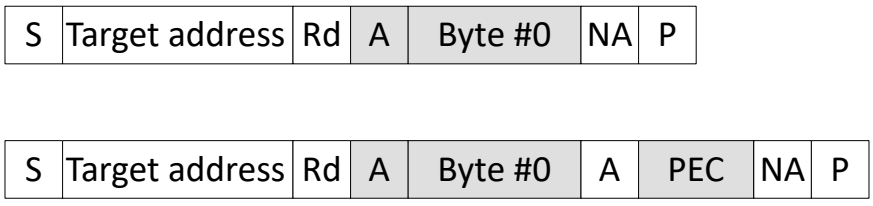

Figure 38-17. Receive Byte Message With and Without PEC

38.4.2.4 Write Byte and Write Word

The Write Byte and Write Word messages (Figure 38-18) consist of a device address, a command byte, transmitted data bytes, and an optional PEC byte. Write Byte messages include a single byte, while the Write Word messages support transmission of 2 bytes to the corresponding target module. Similar to the Send Byte protocol, the PMBCCR register is configured to send 1 or 2 bytes, the CMD_EN bit is set to enable command byte transmission and the optional PEC_EN bit is set.

With the command byte transmission enabled, the format of the PMBTXBUF register differs from the Send Byte protocol. In bits 7-0, the firmware must program the command byte to be sent to the target. The data bytes are programmed into bits 15-8 and bits 23-16.

After programming the PMBCCR register, the PMBus module transmits the Write Byte/Word message. The firmware can wait for an End of Message interrupt from the module to verify the accuracy of the message transmission. The PMBSTS register indicates if the target acknowledged the message properly.

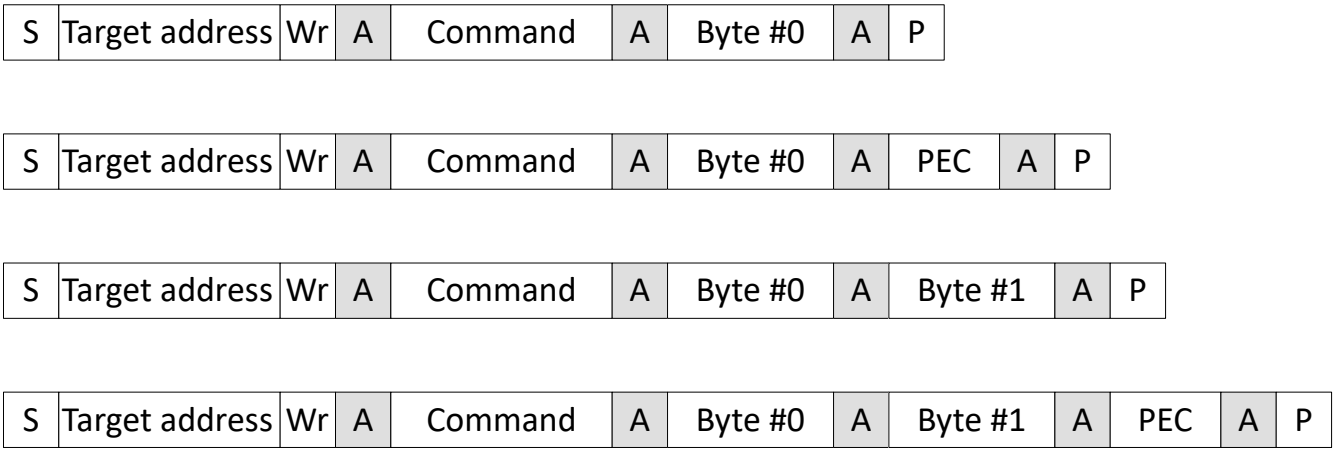

Figure 38-18. Write Byte and Write Word Messages With and Without PEC

38.4.2.5 Read Byte and Read Word

The Read Byte and Read Word messages (Figure 38-19) consist of a device address, a command byte, received data bytes from a target, and an optional PEC byte. Read Byte messages include a single byte, while the Read Word message protocol supports receipt of 2 bytes from the target. Similar to the Receive Byte Protocol, the PMBCCR register is configured to receive 1 or 2 bytes, the CMD_EN bit is set and the PEC_EN is configured to expect or not expect a PEC byte appended to the message. The PMBus module automatically terminates the message after the expected number of bytes is received from the target or if the target does not properly acknowledge any portion of the message.

In addition to programming the PMBCCR register, the firmware is expected to load the command byte into bits 7-0 of the PMBTXBUF register. Any data received from the target is found in the PMBRXBUF register.

Figure 38-19. Read Byte and Read Word Messages With and Without PEC

38.4.2.6 Process Call

The Process Call (Figure 38-20) protocol consists of a Write Word message, followed by a Read Word message, without a stop condition between the two messages. A PEC byte can be appended to the read data from the target as an option to the message protocol. The PMBCCR register includes a PRC_CALL bit, which enables the transmission of a Process Call message onto the PMBus. The PMBus module automatically generates a repeated start condition and initiates the Read Word portion of the message when the process call bit is enabled.

To complete the Write Word portion of the Process Call, the PMBTXBUF register is loaded with the command byte in bits 7-0 and the data bytes are loaded into bits 23-8 of the register.

After programming the PMBCCR register, the PMBus module transmits the Process Call Message. The firmware can wait for an End of Message interrupt from the module to determine the validity of the message. Upon the receipt of the EOM, the PMBSTS register can indicate the receipt of 2 bytes from the Read Word portion of the Process Call message and the status of the target acknowledgment of the transmit data. If PEC processing is enabled, the PEC_VAL bit within the PMBSTS register indicates the accuracy of the PEC byte received from the target during the Read Word part of the message.

The PRC_CALL bit within the PMBCCR register must be disabled for the next non-Process Call message. Note that any write to the PMBCCR register initiates a message, so reconfiguration of the controller is not recommended until the firmware requires a new message to be transmitted.

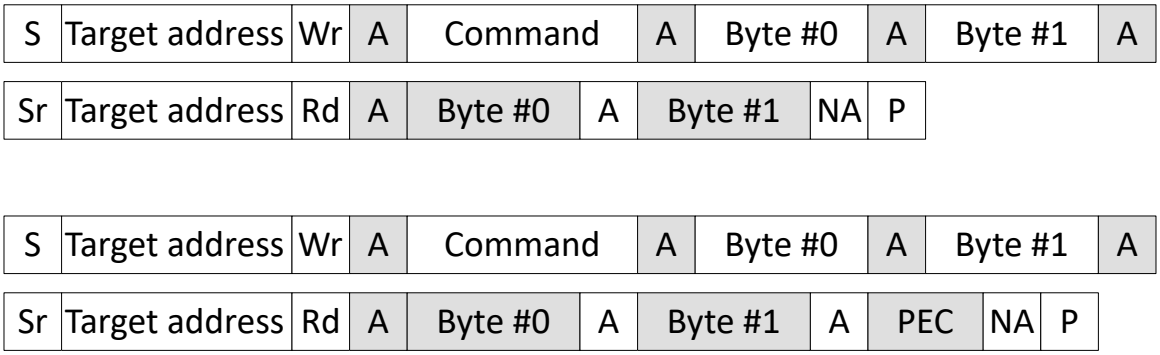

Figure 38-20. Process Call Message With and Without PEC

38.4.2.7 Block Write

The Block Write (Figure 38-21) protocol is similar to a Write Word in structure, with the exception of transmission of more than 2 data bytes in the message. Additionally, the first data byte following the command byte specifies the length of the block of data bytes. As with a majority of the message protocols, the PEC byte can be appended to the end of the write data to the target.

To initiate a Block Write message on the bus, the PMBCCR register is programmed with the block length in the Byte Count bits. The block length is the number of data bytes, excluding the command byte and the first data byte that contains the block length. The PMBus module automatically inserts the block length into the message, if the number of data bytes specified by the firmware exceeds 2. The initial write data is loaded into the PMBTXBUF register. With bits 7-0 representing the command byte, the remaining 3 bytes represent the first 3 data bytes following the block length.

Following programming of the PMBCCR register, the Block Write message is transmitted. If the block length exceeds 3 bytes, the PMBus module provides a data request interrupt, indicating the need for additional data bytes in the PMBTXBUF register. The PMBus module assumes that if more than 4 bytes are needed to complete the message, the firmware utilizes all 4 bytes when programming the PMBTXBUF register. If less than 4 bytes are needed to finish the Block Write message, the firmware only needs to program the appropriate bits of the PMBTXBUF register.

Upon completion of the message, the PMBus module issues an EOM interrupt. The PMBSTS register can be checked to verify the target accepted the block of write data.

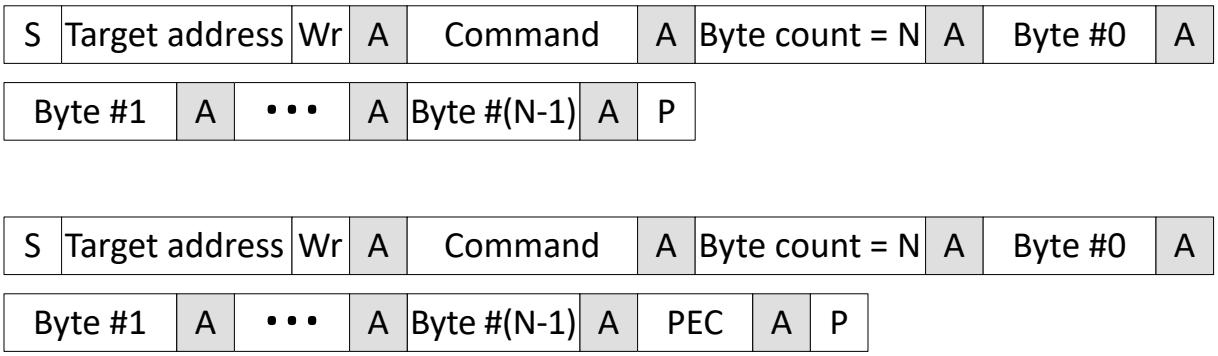

Figure 38-21. Block Write Message With and Without PEC

38.4.2.8 Block Read

The Block Read (Figure 38-22) protocol is similar to a Read Word in structure, with the exception that there are more than 2 data bytes received from the target. The first data byte transmitted by the target represents the block length of the data being written by the target. If PEC processing is enabled, the target appends a PEC byte to the end of the message.

To initiate a Block Read message on the PMBus, the PMBCCR register is programmed with the block length in the Byte Count bits. This count excludes the command byte, any target address and the block length bytes in the message. The command byte to be transmitted to the target is written into bits 7-0 of the PMBTXBUF register prior to the programming of the PMBCCR register.

After configuring the PMBCCR register, the Block Read message is transmitted. The module interrupts the firmware upon receipt of 4 data bytes from the target. If the block length is 3, the EOM interrupt is received concurrently with the data ready interrupt. Otherwise, only a data ready interrupt is asserted, indicating 4 bytes are ready for reading by the firmware. At the end of the message, less than 4 bytes can be stored in the PMBRXBUF register. The RX Byte Count bits in the PMBSTS register indicate the number of bytes available in the final data transfer. The firmware can verify the received PEC upon detection of the End of Message interrupt.

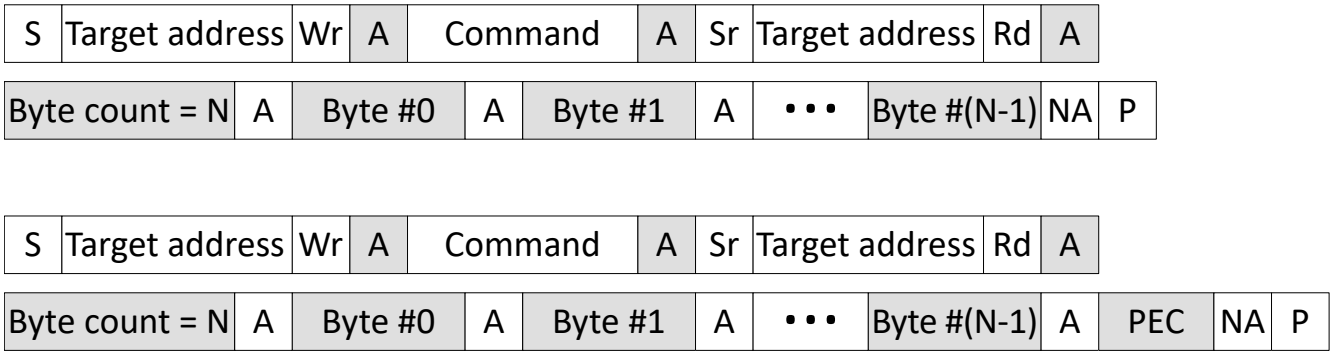

Figure 38-22. Block Read Message With and Without PEC

38.4.2.9 Block Write-Block Read Process Call

The Block Write-Block Read Process Call (Figure 38-23) protocol combines the Block Write and Block Read protocols, removing the stop condition between the two messages. The operation of the controller is similar to a Block Write operation. Loading the block length into the byte count bits of the PMBCCR register provides the length of the Block Write portion of the message. In addition, the PRC_CALL bit within the PMBCCR register must be enabled. Upon completion of the Block Write part of the message, the PMBus module automatically issues a Repeated Start condition on the PMBus and starts transmission of the Block Read portion of the message. Operation of the PMBus module after the Repeated Start condition is the same as a simple Block Read Message.

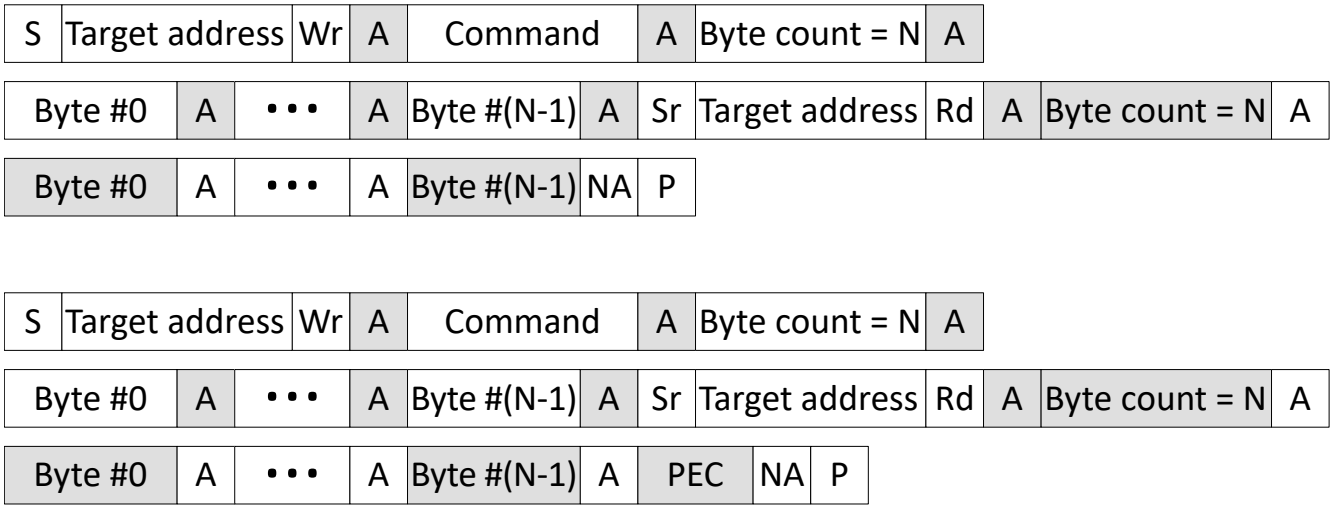

Figure 38-23. Block Write-Block Read Process Call Message With and Without PEC

38.4.2.10 Alert Response

The Alert Response Message (Figure 38-24) is utilized when the controller detects an alert condition from a target. In controller mode, the Alert Response Message is simply a Receive Byte message with PEC disabled and the target address set to 0xC (Alert Response address). The PMBus module detects the alert condition on an input and interrupts the firmware indicating the assertion of an alert condition (target desires to communicate with the controller). Programming the PMBCCR register with the Alert Response address initiates the Alert Response message and provides the device address of the target requesting service. The device address is found in the PMBRXBUF register following receipt of the EOM interrupt.

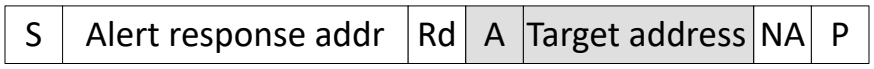

Figure 38-24. Alert Response Message

38.4.2.11 Extended Command

The PMBus module provides support for extended commands which allow for an extra 256 command codes. By asserting the EXT_CMD bit within the PMBCCR register, two command bytes are transmitted on the message protocol. Extended commands can be added to the Write Byte and Write Word (Figure 38-25) and the Read Byte and Read Word (Figure 38-26) protocols. Operation of the PMBus module in extended command mode is similar to these formats. In programming the write data or first part of the read message, the second command byte is loaded into bits 15-8 of the PMBTXBUF register with the remaining data bytes. The remaining operation of the module is identical to the previous protocols, except for the inclusion of a Repeated Start condition and target address in the write messages. No support is required by firmware for these additional bytes in the write messages. The module interprets the EXT_CMD bit and makes the appropriate format changes.

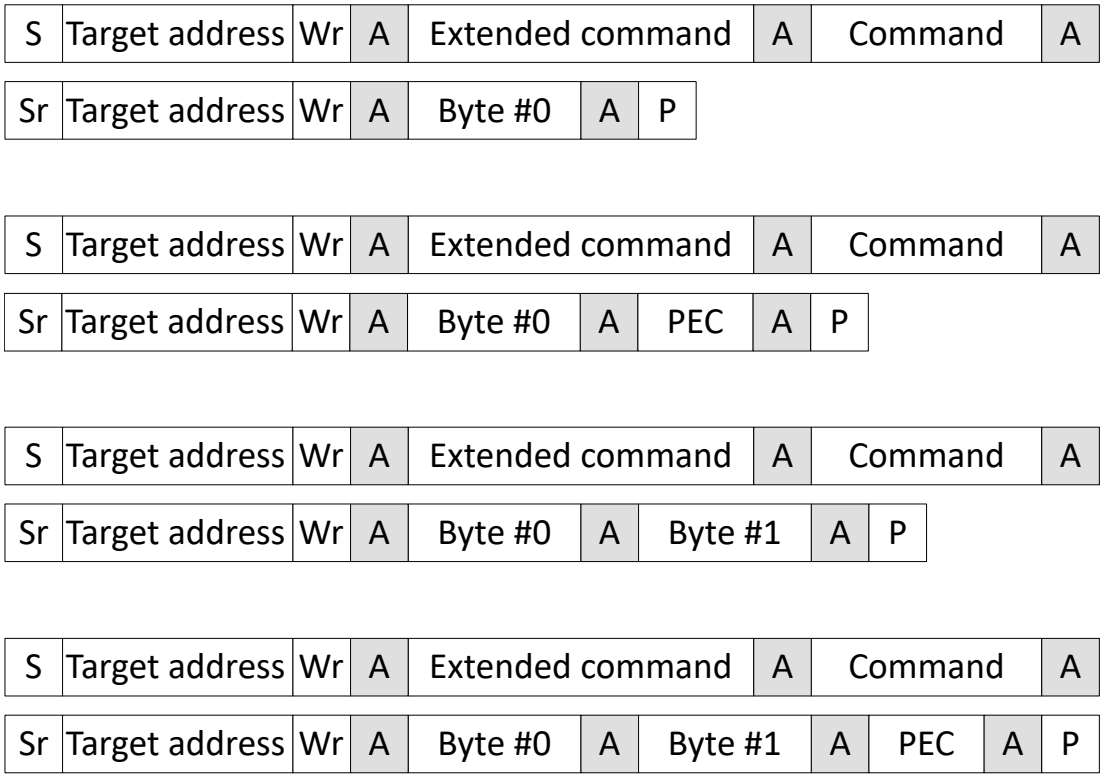

Figure 38-25. Extended Command Write Byte and Write Word Messages With and Without PEC

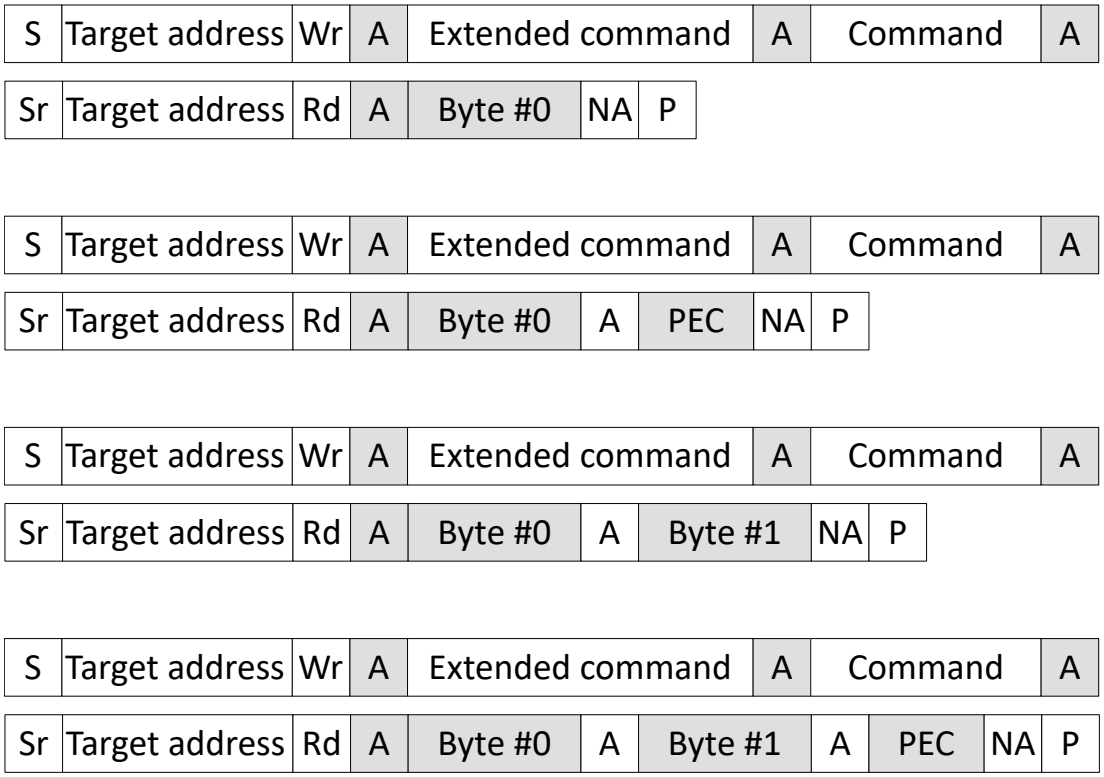

Figure 38-26. Extended Command Read Byte and Read Word Messages With and Without PEC

38.4.2.12 Group Command

The Group Command (Figure 38-27) protocol is used to send commands to more than one device within the same message. When devices on the bus detect the stop condition at the conclusion of the Group Command message, the received commands are executed concurrently. To initiate a Group Command, the GRP_CMD bit within the PMBCCR register must be set when programming the target address for the first device in the message. The rest of the message is processed as a write byte/word message. At the conclusion of the first part of the Group Command message, the firmware programs the next device address in the PMBCCR register. The PMBus module sends a repeated start on the bus and begins the next part of the message. When programming the last device address of the Group Command message, the firmware must disable the GRP_CMD bit when programming the PMBCCR register.

38.6 PMBUS Registers

This Section describes the PMBUS Registers.

38.6.1 PMBUS Base Address Table

Table 38-2. PMBUS Base Address Table

Structure	DriverLib Name	Base Address	Frame Applicable	CPU1	CPU2	CPU3	RTDMA1	RTDMA2	HSM	Pipeline Protected
PMBUS_REGS	PMBUSA_BASE	0x7014_8000	YES	YES	YES	YES	YES	YES	-	YES

38.6.2 PMBUS_REGS Registers

Table 38-3 lists the memory-mapped registers for the PMBUS_REGS registers. All register offset addresses not listed in Table 38-3 should be considered as reserved locations and the register contents should not be modified.

Table 38-3. PMBUS_REGS Registers

Offset	Acronym	Register Name	Protection
0h	PMBCCR	PMBUS CONTROLLER Mode Control Register	
4h	PMBTXBUF	PMBUS Transmit Buffer	
8h	PMBRXBUF	PMBUS Receive buffer	
Ch	PMBACK	PMBUS Acknowledge Register	
10h	PMBSTS	PMBUS Status Register	
14h	PMBINTM	PMBUS Interrupt Mask Register	
18h	PMBTCR	PMBUS TARGET Mode Configuration Register	
1Ch	PMBHTA	PMBUS Hold TARGET Address Register

24h	PMBTIMCTL	PMBUS Timing Control Register	
28h	PMBTIMCLK	PMBUS Clock Timing Register	
2Ch	PMBTIMSTSETUP	PMBUS Start Setup Time Register	
30h	PMBTIMBIDLE	PMBUS Bus Idle Time Register	
34h	PMBTIMLOWTIMOUT	PMBUS Clock Low Timeout Value Register	
38h	PMBTIMHIGHTIMOUT	PMBUS Clock High Timeout Value Register	

Complex bit access types are encoded to fit into small table cells. Table 38-4 shows the codes that are used for access types in this section.

Table 38-4. PMBUS_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
RC	R C	Read to Clear
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

38.6.2.1 PMBCCR Register (Offset = 0h) [Reset = 00000000h]

PMBCCR is shown in Figure 38-28 and described in Table 38-5.

Return to the Summary Table.

Table 38-11. PMBTCR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-23	RESERVED	R	0h	Reserved
22-21	RX_BYTE_ACK_CNT	R/W	3h	Configures number of data bytes to automatically acknowledge when receiving data in TARGET mode. 00 = 1 byte received by TARGET. Firmware is required to manually acknowledge every received byte. 01 = 2 bytes received by TARGET. Hardware automatically acknowledges the first received byte. Firmware is required to manually acknowledge after the second received byte. 10 = 3 bytes received by TARGET. Hardware automatically acknowledges the first 2 received bytes. Firmware is required to manually acknowledge after the third received byte. 11 = 4 bytes received by TARGET. Hardware automatically acknowledges the first 3 received bytes. Firmware is required to manually acknowledge after the fourth received byte Reset type: SYSRSn
20	MAN_CMD	R/W	0h	0 = TARGET automatically acknowledges received command code 1 = Data Request flag generated after receipt of command code, firmware required to issue ACK to continue message Reset type: SYSRSn
19	TX_PEC	R/W	0h	Asserted when the TARGET needs to send a PEC byte at end of message. PMBus Interface will transmit the calculated PEC byte after transmitting the number of data bytes indicated by TX Byte Cnt(Bits 18:16). Reset type: SYSRSn

Table 38-11. PMBTCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
18-16	TX_COUNT	R/W	0h	0 = No bytes valid 1 = One byte valid, Byte #0 (Bits 7:0 of Transmit Data Register) 2 = Two bytes valid, Bytes #0 and #1 (Bits 15:0 of Transmit Data Register) 3 = Three bytes valid, Bytes #0-2 (Bits 23:0 of Transmit Data Register) 4 = Four bytes valid, Bytes #0-3 (Bits 31:0 of Transmit Data Register) Reset type: SYSRSn
15	PEC_ENA	R/W	0h	0 = PEC processing disabled 1 = PEC processing enabled Reset type: SYSRSn
14-8	TARGET_MASK	R/W	7Fh	Used in address detection, the TARGET mask enables acknowledgement of multiple device addresses by the TARGET. Writing a '0' to a bit within the TARGET mask enables the corresponding bit in the TARGET address to be either '1' or '0' and still allow for a match. Writing a '0' to all bits in the mask enables the PMBus Interface to acknowledge any device address. Upon power-up, the TARGET mask defaults to 7Fh, indicating the TARGET will only acknowledge the address programmed into the TARGET Address (Bits 6-0). Reset type: SYSRSn
7	MAN_TARGET_ACK	R/W	0h	0 = TARGET automatically acknowledges device address specified in TARGET_ADDR, Bits 6:0 1 = Enables the Manual TARGET Address Acknowledgement Mode. Firmware is required to read received address and acknowledge on every message Note: When bit 31 (I2C_mode) of PMBCTRL register is set it is recommended to use manual acknowledging of TARGET address only (MAN_TARGET_ACK =1). Reset type: SYSRSn
6-0	TARGET_ADDR	R/W	7Ch	Configures the current device address of the TARGET. Used in automatic TARGET address acknowledge mode (default mode). The PMBus Interface will compare the received device address with the value stored in the TARGET Address bits and the mask configured in the TARGET Mask bits. If matching, the TARGET will acknowledge the device address. Reset type: SYSRSn

38.6.2.8 PMBHTA Register (Offset = 1Ch) [Reset = 00000000h]

PMBHTA is shown in Figure 38-35 and described in Table 38-12.

Chapter 39

Universal Asynchronous Receiver/Transmitter (UART)

This chapter describes the Universal Asynchronous Receivers/Transmitters (UARTs).

39.1 Introduction

The UART module performs the functions of parallel-to-serial and serial-to-parallel conversions.

39.1.1 Features

The Universal Asynchronous Receiver/Transmitter (UART) module in this device contains the following features:

- Programmable baud-rate generator allowing speeds up to 12.5Mbps for regular speed (divide by 16) and 25Mbps for high speed (divide by 8)
- Separate 16-deep and 8-bit wide transmit (TX) and receive (RX) FIFOs to reduce CPU interrupt service loading
- Programmable FIFO length providing conventional double-buffered interface
- FIFO trigger levels of ⅛, ¼, ½, ¾, and ⅞
- Standard asynchronous communication bits for start, stop, and parity
- Line-break generation and detection
- Fully programmable serial interface characteristics
  - 5, 6, 7, or 8 data bits
  - Even, odd, stick, or no parity bit generation and detection
  - 1 or 2 stop bit generation
- IrDA serial-IR (SIR) encoder and decoder providing
  - Programmable use of IrDA SIR or UART input/output
  - Support of IrDA SIR encoder and decoder functions for data rates up to 115.2kbps half-duplex
  - Support of normal 3/16 and low-power (1.41 to 2.23µs) bit durations
  - Programmable internal clock generator enabling division of reference clock by 1 to 256 for low-power mode bit duration
- EIA-485 9-bit support
- Standard FIFO-level and End-of-Transmission (EOT) interrupts
- Efficient transfers using Real-Time Direct Memory Access Controller (RTDMA)
  - Separate channels for transmit and receive
  - Receive single request asserted when data is in the FIFO; burst request asserted at programmed FIFO level
  - Transmit single request asserted when there is space in the FIFO; burst request asserted at programmed FIFO level
- SYSCLK is used to generate the baud clock.

39.1.3 Block Diagram

Figure 39-1 shows the UART block diagram.

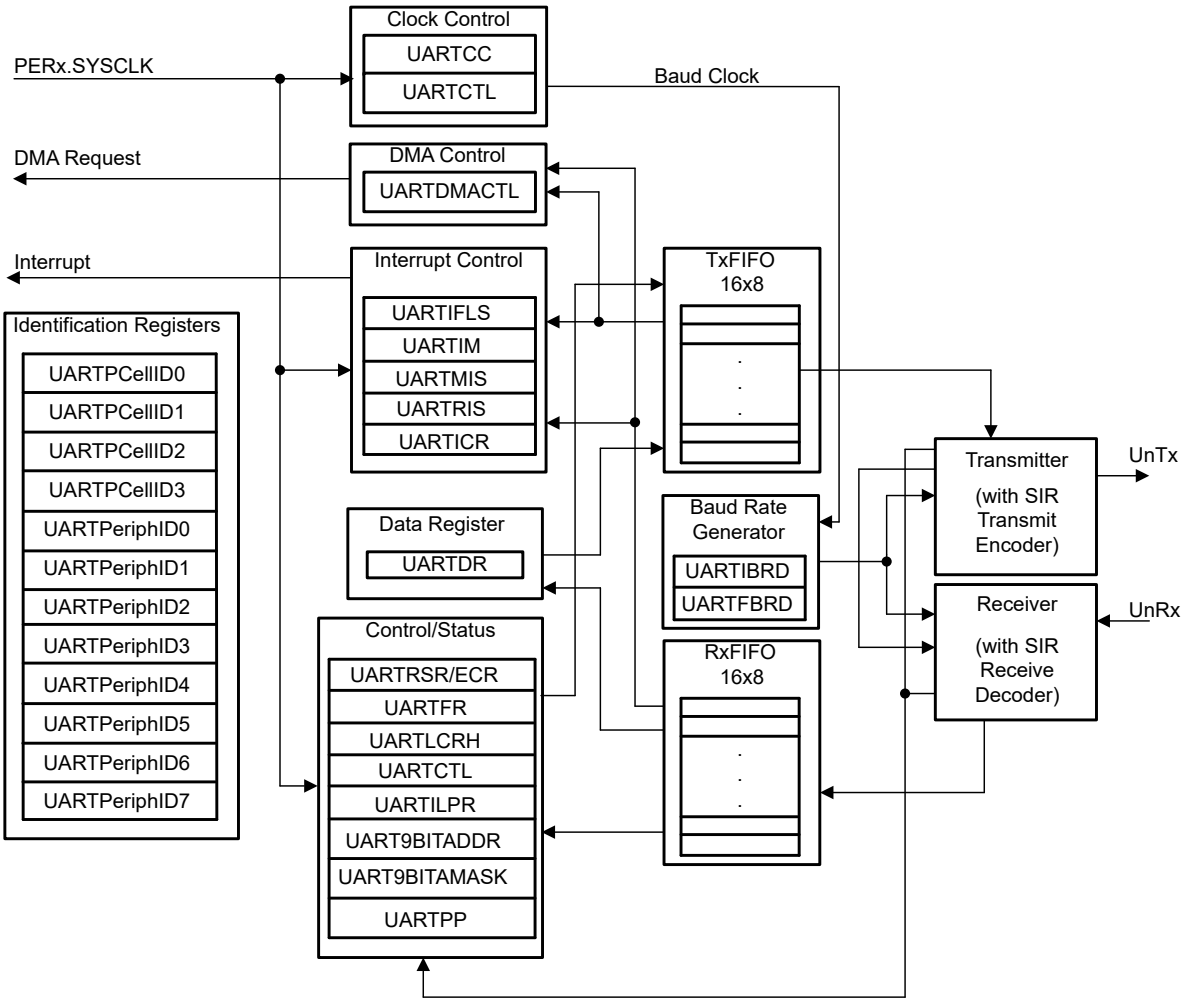

Figure 39-1. UART Module Block Diagram

39.2 Functional Description

The UART module performs the functions of parallel-to-serial and serial-to-parallel conversions. The UART module is similar in functionality to a 16C550 UART, but is not register-compatible.

The UART is configured for transmit or receive through the TXE and RXE bits of the UART Control (UARTCTL) register. Transmit and receive are both enabled out of reset. Before any control registers are programmed, the UART must be disabled by clearing the UARTEN bit in UARTCTL. If the UART is disabled during a TX or RX operation, the current transaction is completed prior to the UART stopping.

The UART module also includes a serial IR (SIR) encoder and decoder block that can be connected to an infrared transceiver to implement an IrDA SIR physical layer. The SIR function is programmed using the UARTCTL register.

39.2.1 Transmit and Receive Logic

The transmit logic performs parallel-to-serial conversion on the data read from the transmit FIFO. The control logic outputs the serial bit stream beginning with a start bit and followed by the data bits (LSB first), parity bit, and the stop bits according to the programmed configuration in the control registers. See Figure 39-2 for details.

The receive logic performs serial-to-parallel conversion on the received bit stream after a valid start pulse has been detected. Overrun, parity, frame error checking, and line-break detection are also performed, and the status accompanies the data that is written to the receive FIFO.

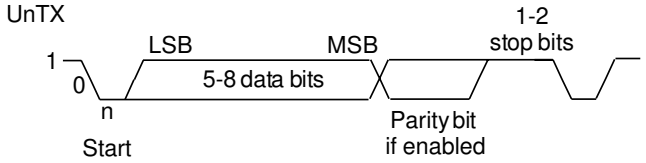

Figure 39-2. UART Character Frame

39.2.2 Baud-Rate Generation

The baud-rate divisor is a 22-bit number consisting of a 16-bit integer and a 6-bit fractional part. The number formed by these two values is used by the baud-rate generator to determine the bit period. Having a fractional baud-rate divisor allows the UART to generate all the standard baud rates.

The 16-bit integer is loaded through the UART Integer Baud-Rate Divisor (UARTIBRD) register and the 6-bit fractional part is loaded with the UART Fractional Baud-Rate Divisor (UARTFBRD) register. The baud-rate divisor (BRD) has the following relationship to the system clock (where BRDI is the integer part of the BRD, and BRDF is the fractional part, separated by a decimal place.)

$$BRD = BRDI + BRDF = UARTSysClk / (ClkDiv \times Baud\ Rate)$$

where

UARTSysClk is the system clock (SYSCLK) connected to the UART, and ClkDiv is either 16 (if HSE in UARTCTL is clear) or 8 (if HSE in UARTCTL is set).

By default, this is the main system clock (SYSCLK).

The 6-bit fractional number (that is to be loaded into the DIVFRAC bit field in the UARTFBRD register) can be calculated by taking the fractional part of the baud-rate divisor, multiplying by 64, and adding 0.5 to account for rounding errors:

$$UARTFBRD[DIVFRAC] = integer(BRDF \times 64 + 0.5)$$

The UART generates an internal baud-rate reference clock at 8× or 16× the baud-rate (referred to as Baud8 and Baud16, depending on the setting of the HSE bit [bit 5] in UARTCTL). This reference clock is divided by 8 or 16 to generate the transmit clock, and is used for error detection during receive operations.

Along with the UART Line Control High Byte (UARTLCRH) register, the UARTIBRD and UARTFBRD registers form an internal 30-bit register. This internal register is only updated when a write operation to UARTLCRH is performed, so any changes to the baud-rate divisor must be followed by a write to the UARTLCRH register for the changes to take effect.

To update the baud-rate registers, there are four possible sequences:

- UARTIBRD write, UARTFBRD write, and UARTLCRH write
- UARTFBRD write, UARTIBRD write, and UARTLCRH write
- UARTIBRD write and UARTLCRH write
- UARTFBRD write and UARTLCRH write

39.2.3 Data Transmission

Data received or transmitted is stored in two 16-byte FIFOs, though the receive FIFO has an extra four bits per character for status information. For transmission, data is written into the transmit FIFO. If the UART is enabled, the UART causes a data frame to start transmitting with the parameters indicated in the UARTLCRH register. Data continues to be transmitted until there is no data left in the transmit FIFO. The BUSY bit in the UART Flag (UARTFR) register is asserted as soon as data is written to the transmit FIFO (that is, if the FIFO is non-empty) and remains asserted while data is being transmitted. The BUSY bit is negated only when the transmit FIFO is empty, and the last character has been transmitted from the shift register, including the stop bits. The UART can indicate that the UART is busy even though the UART is no longer enabled.

When the receiver is idle (the UnRx signal is continuously 1), and the data input goes Low (a start bit has been received), the receive counter begins running and data is sampled on the eighth cycle of Baud16 or fourth cycle of Baud8 depending on the setting of the HSE bit (bit 5) in UARTCTL (described in Section 39.2.1).

The start bit is valid and recognized if the UnRx signal is still low on the eighth cycle of Baud16 (HSE clear) or the fourth cycle of Baud8 (HSE set), otherwise the start bit is ignored. After a valid start bit is detected, successive data bits are sampled on every 16th cycle of Baud16 or eighth cycle of Baud8 (that is, one bit period later) according to the programmed length of the data characters and value of the HSE bit in UARTCTL. The parity bit is then checked if parity mode is enabled. Data length and parity are defined in the UARTLCRH register.

Lastly, a valid stop bit is confirmed if the UnRx signal is High, otherwise a framing error has occurred. When a full word is received, the data is stored in the receive FIFO along with any error bits associated with that word.

39.2.4 Serial IR (SIR)

The UART peripheral includes an IrDA SIR encoder and decoder block. The IrDA SIR block provides functionality that converts between an asynchronous UART data stream and a half-duplex serial SIR interface. No analog processing is performed on-chip. The role of the SIR block is to provide a digital encoded output and decoded input to the UART. When enabled, the SIR block uses the UnTx and UnRx pins for the SIR protocol. These signals must be connected to an infrared transceiver to implement an IrDA SIR physical layer link. The SIR block can receive and transmit, but the SIR block is only half-duplex so the SIR block cannot do both at the same time. Transmission must be stopped before data can be received. The IrDA SIR physical layer specifies a minimum 10ms delay between transmission and reception. The SIR block has two modes of operation:

- In normal IrDA mode, a zero logic level is transmitted as a high pulse of 3/16th duration of the selected baud rate bit period on the output pin, while logic one levels are transmitted as a static low signal. These levels control the driver of an infrared transmitter, sending a pulse of light for each zero. On the reception side, the incoming light pulses energize the photo transistor base of the receiver, pulling the output low and driving the UART input pin low.
- In low-power IrDA mode, the width of the transmitted infrared pulse is set to three times the period of the internally generated IrLPBaud16 signal (1.63µs, assuming a nominal 1.8432MHz frequency) by changing the appropriate bit in the UARTCTL register.

Whether the device is in normal or low-power IrDA mode, a start bit is deemed valid if the decoder is still low one period of IrLPBaud16 after the low was first detected. This enables a normal-mode UART to receive data from a low-power mode UART that can transmit pulses as small as 1.41µs. Thus, for both low-power and normal mode operation, the ILPDVSR field in the UARTILPR register must be programmed such that 1.42MHz < $f_{IrLPBaud16}$< 2.12MHz, resulting in a low-power pulse duration of 1.41 to 2.11µs (three times the period of IrLPBaud16). The minimum frequency of IrLPBaud16 make sure that pulses less than one period of IrLPBaud16 are rejected, but pulses greater than 1.4µs are accepted as valid pulses.

Figure 39-3 shows the UART transmit and receive signals, with and without IrDA modulation.

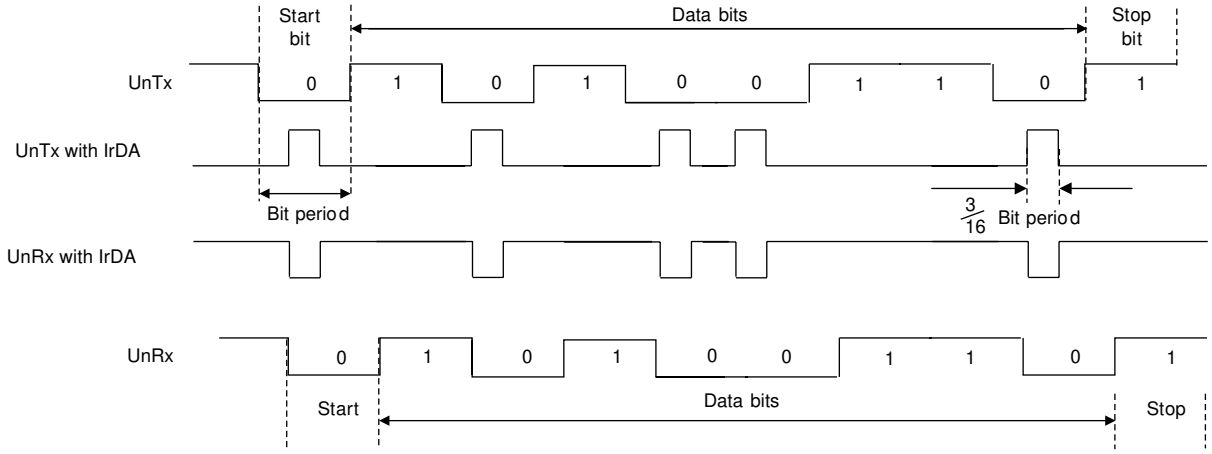

Figure 39-3. IrDA Data Modulation

In both normal and low-power IrDA modes:

- During transmission, the UART data bit is used as the base for encoding
- During reception, the decoded bits are transferred to the UART receive logic

The IrDA SIR physical layer specifies a half-duplex communication link, with a minimum 10ms delay between transmission and reception. This delay must be generated by software because the delay is not automatically supported by the UART. The delay is required because the infrared receiver electronics can become biased or even saturated from the optical power coupled from the adjacent transmitter LED. This delay is known as latency or receiver setup time.

39.2.5 9-Bit UART Mode

The UART provides a 9-bit mode that is enabled with the 9BITEN bit in the UART9BITADDR register. This feature is useful in a multi-drop configuration of the UART, where a single transmitter connected to multiple receivers can communicate with a particular receiver through the address or set of addresses along with a qualifier for an address byte. All the receivers check for the address qualifier in the place of the parity bit and, if set, then compare the byte received with the preprogrammed address. If the address matches, then the receiver receives or sends further data. If the address does not match, the receiver drops the address byte and any subsequent data bytes. If the UART is in 9-bit mode, then the receiver operates with no parity mode. The address can be predefined to match with the received byte and the address can be configured with the UART9BITADDR register. The matching can be extended to a set of addresses using the address mask in the UART9BITAMASK register. By default, the UART9BITAMASK is 0xFF, meaning that only the specified address is matched.

When not finding a match, the rest of the data bytes with the ninth bit cleared are dropped. If a match is found, then an interrupt is generated to the NVIC for further action. The subsequent data bytes with the cleared ninth bit are stored in the FIFO. Software can mask this interrupt in case RTDMA or FIFO operations are enabled for this instance and processor intervention is not required. All the send transactions with 9-bit mode are data bytes and the ninth bit is cleared. Software can override the ninth bit to be set (to indicate address) by overriding the parity settings to sticky parity with odd parity enabled for a particular byte. To match the transmission time with correct parity settings, the address byte can be transmitted as a single then a burst transfer. The transmit FIFO does not hold the address/data bit; hence, software can enable the address bit appropriately.

39.2.6 FIFO Operation

The UART has two 16-deep 8-bit wide FIFOs; one for transmit and one for receive. Both FIFOs are accessed by way of the UART Data (UARTDR) register. Read operations of the UARTDR register return a 12-bit value consisting of eight data bits and four error flags while write operations place 8-bit data in the transmit FIFO.

Out of reset, both FIFOs are disabled and act as 1 byte-deep holding registers. The FIFOs are enabled by setting the FEN bit in the UARTLCRH register.

FIFO status can be monitored through the UART Flag (UARTFR) register and the UART Receive Status (UARTRSR) register. Hardware monitors empty, full, and overrun conditions. The UARTFR register contains empty and full flags (TXFE, TXFF, RXFE, and RXFF bits), and the UARTRSR register shows overrun status with the OE bit. If the FIFOs are disabled, the empty and full flags are set according to the status of the 1 byte-deep holding registers.

The trigger points, at which the FIFOs generate interrupts, is controlled by way of the UART Interrupt FIFO Level Select (UARTIFLS) register. Both FIFOs can be individually configured to trigger interrupts at different levels. Available configurations include ⅛, ¼, ½, ¾, and ⅞ in the TXIFSEL and RXIFSEL fields of the UARTIFLS register.

For example, if the ¼ option is selected for the receive FIFO, the UART generates a receive interrupt after four data bytes are received. If the ¼ option is selected for the transmit FIFO, the UART generates a transmit interrupt after four data bytes can be transmitted, meaning there are at least four empty spaces in the transmit FIFO. Out of reset, both FIFOs are configured to trigger an interrupt at the ½ mark.

39.2.7 Interrupts

The UART can generate interrupts when the following conditions are observed:

- Overrun error
- Break error
- Parity error
- Framing error
- Receive time-out
- Transmit (when condition defined in the TXIFLSEL bit in the UARTIFLS register is met, or if the EOT bit in UARTCTL is set, when the last bit of all transmitted data leaves the serializer)
- Receive (when condition defined in the RXIFLSEL bit in the UARTIFLS register is met)

All of the interrupt events are ORed together before being sent to the interrupt controller, so the UART can only generate a single interrupt request to the controller at any given time. Software can service multiple interrupt events in a single interrupt service routine by reading the UART Masked Interrupt Status (UARTMIS) register.

The interrupt events that can trigger a controller-level interrupt are defined in the UART Interrupt Mask (UARTIM) register by setting the corresponding IM bits. If interrupts are not used, the raw interrupt status is visible by way of the UART Raw Interrupt Status (UARTRIS) register.

Note

For receive time-out, the RTIM bit in the UARTIM register must be set to see the RTMIS and RTRIS status in the UARTMIS and UARTRIS registers.

Interrupts are always cleared (for the UARTMIS and UARTRIS registers) by writing a 1 to the corresponding bit in the UART Interrupt Clear (UARTICR) register. Additionally, write a 1 to the INT_FLG_CLR field of the UART_GLB_INT_CLR register to clear the global interrupt flag and receive further UART interrupts.

The receive time-out interrupt is asserted when the receive FIFO is not empty, and no further data is received over a 32-bit period when the HSE bit is clear or over a 64-bit period when the HSE bit is set. The receive time-out interrupt is cleared either when the FIFO becomes empty through reading all the data (or by reading the holding register), or when a 1 is written to the corresponding bit in the UARTICR register.

The receive interrupt changes state when one of the following events occurs:

- If the FIFOs are enabled and the receive FIFO reaches the programmed trigger level, the RXRIS bit is set. The receive interrupt is cleared by reading data from the receive FIFO until the receive FIFO becomes less than the trigger level, or by clearing the interrupt by writing a 1 to the RXIC bit.
- If the FIFOs are disabled (have a depth of one location) and data is received thereby filling the location, the RXRIS bit is set. The receive interrupt is cleared by performing a single read of the receive FIFO, or by clearing the interrupt by writing a 1 to the RXIC bit.

The transmit interrupt changes state when one of the following events occurs:

- If the FIFOs are enabled and the transmit FIFO progresses through the programmed trigger level, the TXRIS bit is set. The transmit interrupt is based on a transition through level, therefore the FIFO must be written past the programmed trigger level otherwise no further transmit interrupts are generated. The transmit interrupt is cleared by writing data to the transmit FIFO until the transmit FIFO becomes greater than the trigger level, or by clearing the interrupt by writing a 1 to the TXIC bit.
- If the FIFOs are disabled (have a depth of one location) and there is no data present in the transmitters single location, the TXRIS bit is set. The transmit interrupt is cleared by performing a single write to the transmit FIFO, or by clearing the interrupt by writing a 1 to the TXIC bit.

39.2.8 Loopback Operation

The UART can be placed into an internal loopback mode for diagnostic or debug work by setting the LBE bit in the UARTCTL register. In loopback mode, data transmitted on the UnTx output is received on the UnRx input. Note that the LBE bit must be set before the UART is enabled.

39.2.9 RTDMA Operation

The UART provides an interface to the RTDMA controller with separate channels for transmit and receive. The RTDMA operation of the UART is enabled through the UART RTDMA Control (UARTDMACTL) register. When RTDMA operation is enabled, the UART asserts a RTDMA request on the receive or transmit channel when the associated FIFO can transfer data. To trigger the RTDMA with the UART trigger sources, the UART FIFOs on the corresponding channel must be enabled. RTDMA operation does not work in non-FIFO mode.

For the receive channel, a burst request is asserted whenever the amount of data in the receive FIFO is at or above the FIFO trigger level configured in the UARTIFLS register. For the transmit channel, a burst request is asserted whenever the transmit FIFO contains equal or fewer characters than the FIFO trigger level. The burst RTDMA transfer requests are handled automatically by the RTDMA controller depending on how the RTDMA channel is configured. When using the RTDMA to transfer 16-bit or 32-bit data to UARTDR for a transmit, only the 8 least-significant bits are transmitted.

To enable RTDMA operation for the receive channel, set the RXDMAE bit of the RTDMA Control (UARTDMACTL) register. To enable RTDMA operation for the transmit channel, set the TXDMAE bit of the UARTDMACTL register. The UART can also be configured to stop using RTDMA for the receive channel if a receive error occurs. If the DMAERR bit of the UARTDMACR register is set and a receive error occurs, the RTDMA receive requests are automatically disabled. This error condition can be cleared by clearing the appropriate UART error interrupt.

When the RTDMA controller is finished transferring data to the TX FIFO or from the RX FIFO, a dma_done signal is sent to the UART to indicate completion. The dma_done status is indicated through the DMATXRIS and DMARXIS bits of the UARTRIS register. An interrupt can be generated from these status bits by setting the DMATXIM and DMARXIM bits in the UARTIM register.

Note

The DMATXRIS bit can be used to indicate the completion of data transfer from the RTDMA controller to the TX FIFO. To indicate transfer completion from the serializer of the UART, the EOT bit can be enabled in the UARTCTL register.

See the *Real-Time Direct Memory Access (RTDMA)* chapter for more details about programming the RTDMA controller.

39.2.9.1 Receiving Data Using UART with RTDMA

When using the RTDMA with the RX FIFO, the RTDMA Burst Size [DMA_BURST_SIZE] must equal the number of bytes used to trigger the FIFO level interrupt defined by RXIFLSEL in UARTIFLS. For example, a level of 1/8 is triggered by 2 bytes or more present in the FIFO, so DMA_BURST_SIZE = 2. To make sure that the RTDMA correctly receives all data from the RX FIFO, the RTDMA Burst Size also must be an integer divisor of the total number of UART receives. For complete data reception, follow these steps:

1. Decide the total number of words to be received. [BUFFER_SIZE]
2. Decide the necessary FIFO level [UART_BUFFER_SIZE] and set RXIFSEL accordingly.
3. Calculate the number of RTDMA transfers. [DMA_TRANSFER_SIZE = BUFFER_SIZE / UART_BUFFER_SIZE]
4. Set the RTDMA Burst Size. [DMA_BURST_SIZE] equal to the UART_BUFFER_SIZE.
5. Configure RTDMA using the calculated values and use the UART peripheral trigger as the trigger source.

To receive 120 words from the UART using the RTDMA:

BUFFER_SIZE = 120

UART_BUFFER_SIZE = 12

RXIFSEL: UART_BUFFER_SIZE / 16 = 3/4

DMA_TRANSFER_SIZE: BUFFER_SIZE / UART_BUFFER-SIZE = 120/12 = 10

DMA_BURST_SIZE: UART_BUFFER_SIZE = 12

(1 burst = 12 words, 1 transfer = 10 bursts, 120 words received with each transfer)

39.2.9.2 Transmitting Data Using UART with RTDMA

When using the RTDMA with the TX FIFO, the RTDMA Burst Size [DMA_BURST_SIZE] must equal 16 - the number of bytes used to trigger the FIFO level interrupt defined by TXIFSEL in UARTIFLS. For example, a level of 1/8 is triggered by having 14 bytes or less present in the FIFO, so DMA_BURST_SIZE = 16 - 14 = 2. To make sure that the RTDMA writes all data correctly to the TX FIFO, the RTDMA Burst Size must also be an integer divisor of the total number of UART transmissions. For complete data transmission, follow these steps:

1. Decide the total number or words to be transmitted. [BUFFER_SIZE]
2. Decide the necessary FIFO level [UART_BUFFER_SIZE] and set TXIFSEL accordingly.
3. Calculate the number of RTDMA transfers. [DMA_TRANSFER_SIZE = BUFFER_SIZE / UART_BUFFER_SIZE]
4. Calculate the RTDMA Burst Size. [DMA_BURST_SIZE] to equal 16 - UART_BUFFER_SIZE.
5. Configure the RTDMA using the calculated values and use UART peripheral trigger as the trigger source.

Note

For a BUFFER_SIZE less than or equal to 16, a software trigger can alternatively be used.

To transmit 120 words from the UART using the RTDMA:

BUFFER_SIZE = 120

UART_BUFFER_SIZE = 12

TXIFSEL: 1 - (UART_BUFFER_SIZE / 16) = 1 - 3/4 = 1/4

DMA_TRANSFER_SIZE: (BUFFER_SIZE / UART_BUFFER-SIZE) = (120/12) = 10

DMA_BURST_SIZE: UART_BUFFER_SIZE = 12

(1 burst = 12 words, 1 transfer = 10 bursts, 120 words transmitted with each transfer)

39.3 Initialization and Configuration

To enable and initialize the UART, perform the following steps:

1. Disable the UART by clearing the UARTEN bit in the UARTCTL register.
2. Write the integer portion of the BRD to the UARTIBRD register.
3. Write the fractional portion of the BRD to the UARTFBRD register.
4. Write the desired serial parameters to the UARTLCRH register.
5. Optionally, configure the RTDMA channel (see the *Real-Time Direct Memory Access (RTDMA)* chapter and enable the RTDMA options in the UARTDMACTL register.
6. Enable the UART by setting the UARTEN bit in the UARTCTL register.

39.4.2 UART Examples

NOTE: These examples are located in the C29SDK installation from ti.com at the following location:
mcu_sdk_DEVICE_GPN/examples/driverlib/CORE_IF_MULTICORE/uart

Cloud access to these examples is available at the following link: dev.ti.com C29SDK Examples.

39.4.2.1 UART Loopback - SINGLE_CORE

FILE: uart_ex1_loopback.c

Simple UART internal loopback example

The sent data looks like this:
00 01 02 03 .... FE FF 00

This pattern is repeated forever.

External Connections

- None

Watch Variables

- *sData* - Data to send
- *rData* - Received data

Note: Avoid keeping the memory browser open while the execution is in progress.

39.4.2.2 UART Loopback with Interrupt - SINGLE_CORE

FILE: uart_ex2_loopback_fifo_interrupts.c

UART internal loopback w/ interrupt example Receive interrupt with FIFO is used.

A stream of data is sent and then compared to the received stream. The sent data looks like this:
00 01
01 02
02 03
....
FE FF
FF 00
etc..
The pattern is repeated forever.

External Connections
- None

Watch Variables
- *sData* - Data to send
- *rData* - Received data

Note: Avoid keeping the memory browser open while the execution is in progress.

39.4.2.3 UART Loopback with DMA - SINGLE_CORE

FILE: uart_ex3_loopback_dma.c

This program uses the internal loopback test mode of the UART module. Both DMA interrupts and UART FIFOs are used. When the UART transmit FIFO has enough space (as indicated by its FIFO level interrupt signal), the DMA will transfer data from global variable sData into the FIFO. This will be transmitted to the receive FIFO via the internal loopback.

When enough data has been placed in the receive FIFO (as indicated by its FIFO level interrupt signal), the DMA will transfer the data from the FIFO into global variable rData.

When all data has been placed into rData, a check of the validity of the data will be performed in one of the DMA channels' ISRs.

External Connections
- None

Watch Variables
- *sData* - Data to send
- *rData* - Received data

39.4.2.4 UART Echoback - SINGLE_CORE

FILE: uart_ex4_echoback.c

This test receives and echo-backs data through the UART A port.

A terminal such as 'putty' can be used to view the data from the UART and to send information to the UART. Characters received by the UART port are sent back to the host.

Running the Application Open a COM port with the following settings using a terminal:
- Find correct COM port
- Bits per second = 115200
- Data Bits = 8

- Parity = None
- Stop Bits = 1
- Hardware Control = None

The program will print out a greeting and then ask you to enter a character which it will echo back to the terminal.

Watch Variables

- None

External Connections

Connect the UARTA port to a PC via a transceiver and cable.

- GPIO43 is UARTA RX
- GPIO42 is UARTA TX

Note: Avoid keeping the memory browser open while the execution is in progress.

39.5 UART Registers

This Section describes the UART Registers.

39.5.1 UART Base Address Table

Table 39-2. UART Base Address Table

Structure	DriverLib Name	Base Address	Frame Applicable	CPU1	CPU2	CPU3	RTDMA1	RTDMA2	HSM	Pipeline Protected
UART_REGS , UART_REGS_WRITE	UARTA_BASE, UARTA_WRITE_BASE	0x6007_0000	YES	YES	YES	YES	YES	YES	-	YES

Complex bit access types are encoded to fit into small table cells. Table 39-4 shows the codes that are used for access types in this section.

Table 39-4. UART_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		

Table 39-4. UART_REGS Access Type Codes (continued)

Access Type	Code	Description
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

39.5.2.1 UARTDR Register (Offset = 0h) [Reset = 00000000h]

UARTDR is shown in Figure 39-4 and described in Table 39-5.

Return to the Summary Table.

IMPORTANT: This register is read sensitive. This register is the data register (the interface to the FIFOs). For transmitted data, if the FIFO is enabled, data written to this location is pushed onto the transmit FIFO. If the FIFO is disabled, data is stored in the transmitter holding register (the bottom word of the transmit FIFO). A write to this register initiates a transmission from the UART.
For received data, if the FIFO is enabled, the data byte and the 4-bit status (break, frame, parity, and overrun) is pushed onto the 12-bit wide receive FIFO. If the FIFO is disabled, the data byte and status are stored in the receiving holding register (the bottom word of the receive FIFO). The received data can be retrieved by reading this register.

Figure 39-4. UARTDR Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

RESERVED				OE	BE	PE	FE	DATA							
R-0h				R-0h	R-0h	R-0h	R-0h	R/W-0h							

Table 39-5. UARTDR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-12	RESERVED	R	0h	Reserved
11	OE	R	0h	UART Overrun Error 0 No data has been lost due to a FIFO overrun. 1 New data was received when the FIFO was full, resulting in data loss. Reset type: PER.RESET
10	BE	R	0h	UART Break Error 0 No break condition has occurred 1 A break condition has been detected, indicating that the receive data input was held Low for longer than a full-word transmission time (defined as start, data, parity, and stop bits). In FIFO mode, this error is associated with the character at the top of the FIFO. When a break occurs, only one 0 character is loaded into the FIFO. The next character is only enabled after the received data input goes to a 1 (marking state), and the next valid start bit is received. Reset type: PER.RESET
9	PE	R	0h	UART Parity Error 0 No parity error has occurred 1 The parity of the received data character does not match the parity defined by bits 2 and 7 of the UARTLCRH register. In FIFO mode, this error is associated with the character at the top of the FIFO. Reset type: PER.RESET
8	FE	R	0h	UART Framing Error 0 No framing error has occurred 1 The received character does not have a valid stop bit (a valid stop bit is 1). Reset type: PER.RESET

Table 39-5. UARTDR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
7-0	DATA	R/W	0h	Data Transmitted or Received Data that is to be transmitted via the UART is written to this field. When read, this field contains the data that was received by the UART. For transmitted data, if the FIFO is enabled, data written to this location is pushed onto the transmit FIFO. If the FIFO is disabled, data is stored in the transmitter holding register (the bottom word of the transmit FIFO). A write to this register initiates a transmission from the UART. For received data, if the FIFO is enabled, the data byte and the 4-bit status (break, frame, parity, and overrun) is pushed onto the 12-bit wide receive FIFO. If the FIFO is disabled, the data byte and status are stored in the receiving holding register (the bottom word of the receive FIFO). The received data can be retrieved by reading this register. Reset type: PER.RESET

39.5.2.2 UARTRSR Register (Offset = 4h) [Reset = 00000000h]

UARTRSR is shown in Figure 39-5 and described in Table 39-6.

Return to the Summary Table.

The UARTRSR/UARTECR register is the receive status register/error clear register.
In addition to the UARTDR register, receive status can also be read from the UARTRSR register.
If the status is read from this register, then the status information corresponds to the entry read from UARTDR prior to reading UARTRSR. The status information for overrun is set immediately when an overrun condition occurs.
The UARTRSR register cannot be written.
A write of any value to the UARTECR register clears the framing, parity, break, and overrun errors.
All the bits are cleared on reset.

Table 39-6. UARTRSR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-4	RESERVED	R	0h	Reserved
3	OE	R	0h	UART Overrun Error 0 No data has been lost due to a FIFO overrun. 1 New data was received when the FIFO was full, resulting in data loss. This bit is cleared by a write to UARTECR.The FIFO contents remain valid because no further data is written when the FIFO is full, only the contents of the shift register are overwritten. The CPU must read the data in order to empty the FIFO. Reset type: PER.RESET
2	BE	R	0h	UART Break Error 0 No break condition has occurred 1 A break condition has been detected, indicating that the receive data input was held Low for longer than a full-word transmission time (defined as start, data, parity, and stop bits). This bit is cleared to 0 by a write to UARTECR. In FIFO mode, this error is associated with the character at the top of the FIFO. When a break occurs, only one 0 character is loaded into the FIFO. The next character is only enabled after the receive data input goes to a 1 (marking state) and the next valid start bit is received. Reset type: PER.RESET
1	PE	R	0h	UART Parity Error 0 No parity error has occurred 1 The parity of the received data character does not match the parity defined by bits 2 and 7 of the UARTLCRH register. This bit is cleared to 0 by a write to UARTECR. Reset type: PER.RESET

Table 39-6. UARTRSR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	FE	R	0h	UART Framing Error 0 No framing error has occurred 1 The received character does not have a valid stop bit (a valid stop bit is 1). This bit is cleared to 0 by a write to UARTECR. In FIFO mode, this error is associated with the character at the top of the FIFO. Reset type: PER.RESET

39.5.2.3 UARTFR Register (Offset = 18h) [Reset = 00000090h]

UARTFR is shown in Figure 39-6 and described in Table 39-7.

Return to the Summary Table.

The UARTFR register is the flag register. After reset, the TXFF, RXFF, and BUSY bits are 0, and TXFE and RXFE bits are 1.

39.5.2.4 UARTILPR Register (Offset = 20h) [Reset = 00000000h]

UARTILPR is shown in Figure 39-7 and described in Table 39-8.

Return to the Summary Table.

The UARTILPR register stores the 8-bit low-power counter divisor value used to derive the low-power SIR pulse width clock.

Figure 39-7. UARTILPR Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	Reserved
7-0	ILPDVSR	R/W	0h	IrDA Low-Power Divisor This field contains the 8-bit low-power divisor value. The UARTILPR register stores the 8-bit low-power counter divisor value used to derive the low-power SIR pulse width clock by dividing down the system clock (SysClk). All the bits are cleared when reset. The internal IrLPBaud16 clock is generated by dividing down SysClk according to the low-power divisor value written to UARTILPR. The duration of SIR pulses generated when low-power mode is enabled is three times the period of the IrLPBaud16 clock. The low-power divisor value is calculated as follows: ILPDVSR = SysClk / FIrLPBaud16 where FIrLPBaud16 is nominally 1.8432 MHz. Because the IrLPBaud16 clock is used to sample transmitted data irrespective of mode, the ILPDVSR field must be programmed in both low power and normal mode,such that FIrLPBaud16 is between 1.42 and 2.12 MHz, resulting in a low-power pulse duration of 1.41-2.11 us (three times the period of IrLPBaud16). The minimum frequency of IrLPBaud16 ensures that pulses less than one period of IrLPBaud16 are rejected, but pulses greater than 1.4 us are accepted as valid pulses. Note: Zero is an illegal value. Programming a zero value results in no IrLPBaud16 pulses being generated Reset type: PER.RESET

39.5.2.5 UARTIBRD Register (Offset = 24h) [Reset = 00000000h]

UARTIBRD is shown in Figure 39-8 and described in Table 39-9.

Return to the Summary Table.

The UARTIBRD register is the integer part of the baud-rate divisor value. All the bits are cleared on reset. The minimum possible divide ratio is 1 (when UARTIBRD=0), in which case the UARTFBRD register is ignored. When changing the UARTIBRD register, the new value does not take effect until transmission/reception of the current character is complete. Any changes to the baud-rate divisor must be followed by a write to the UARTLCRH register.

When changing the UARTIBRD register, the new value does not take effect until transmission/reception of the current character is complete. Any changes to the baud-rate divisor must be followed by a write to the UARTLCRH register. Reset type: PER.RESET

39.5.2.6 UARTFBRD Register (Offset = 28h) [Reset = 00000000h]

UARTFBRD is shown in Figure 39-9 and described in Table 39-10.

Return to the Summary Table.

The UARTFBRD register is the fractional part of the baud-rate divisor value. All the bits are cleared on reset. When changing the UARTFBRD register, the new value does not take effect until transmission/reception of the current character is complete. Any changes to the baud-rate divisor must be followed by a write to the UARTLCRH register. See 'Baud-Rate Generation' on page 1165 for configuration details.

When changing the UARTFBRD register, the new value does not take effect until transmission/reception of the current character is complete. Any changes to the baud-rate divisor must be followed by a write to the UARTLCRH register. Reset type: PER.RESET

39.5.2.7 UARTLCRH Register (Offset = 2Ch) [Reset = 00000000h]

UARTLCRH is shown in Figure 39-10 and described in Table 39-11.

Return to the Summary Table.

The UARTLCRH register is the line control register. Serial parameters such as data length, parity, and stop bit selection are implemented in this register.
When updating the baud-rate divisor (UARTIBRD and/or UARTIFRD), the UARTLCRH register must also be written. The write strobe for the baud-rate divisor registers is tied to the UARTLCRH register.

Bit	Field	Type	Reset	Description
2	EPS	R/W	0h	UART Even Parity Select 0 Odd parity is performed, which checks for an odd number of 1s. 1 Even parity generation and checking is performed during transmission and reception, which checks for an even number of 1s in data and parity bits. This bit has no effect when parity is disabled by the PEN bit. Reset type: PER.RESET
1	PEN	R/W	0h	UART Parity Enable 0 Parity is disabled and no parity bit is added to the data frame. 1 Parity checking and generation is enabled. Reset type: PER.RESET
0	BRK	R/W	0h	UART Send Break 0 Normal use. 1 A Low level is continually output on the UnTx signal, after completing transmission of the current character. For the proper execution of the break command, software must set this bit for at least two frames (character periods). Reset type: PER.RESET

39.5.2.8 UARTCTL Register (Offset = 30h) [Reset = 00000300h]

UARTCTL is shown in Figure 39-11 and described in Table 39-12.

Return to the Summary Table.

The UARTCTL register is the control register. All the bits are cleared on reset except for the Transmit Enable (TXE) and Receive Enable (RXE) bits, which are set.
To enable the UART module, the UARTEN bit must be set. If software requires a configuration change in the module, the UARTEN bit must be cleared before the configuration changes are written. If the UART is disabled during a transmit or receive operation, the current transaction is completed prior to the UART stopping.

39.5.2.9 UARTIFLS Register (Offset = 34h) [Reset = 00000012h]

UARTIFLS is shown in Figure 39-12 and described in Table 39-13.

Return to the Summary Table.

The UARTIFLS register is the interrupt FIFO level select register. You can use this register to define the FIFO level at which the TXRIS and RXRIS bits in the UARTRIS register are triggered.
The interrupts are generated based on a transition through a level rather than being based on the level. That is, the interrupts are generated when the fill level progresses through the trigger level.
For example, if the receive trigger level is set to the half-way mark, the interrupt is triggered as the module is receiving the 9th character.
Therefore, changing the trigger level does not trigger an interrupt using the new level until another character is received.
Out of reset, the TXIFLSEL and RXIFLSEL bits are configured so that the FIFOs trigger an interrupt at the half-way mark.

2-0	TXIFLSEL	R/W	2h	Value Description 0x0 TX FIFO less than or equal to 1/8 full - at least 14 empty spots 0x1 TX FIFO less than or equal to 1/4 full - at least 12 empty spots 0x2 TX FIFO less than or equal to 1/2 full - at least 8 empty spots (default) 0x3 TX FIFO less than or equal to 3/4 full - at least 4 empty spots 0x4 TX FIFO less than or equal to 7/8 full - at least 2 empty spots 0x5-0x7 Reserved Note: If the EOT bit in UARTCTL is set, the transmit interrupt is generated once the FIFO is completely empty and all data including stop bits have left the transmit serializer. In this case, the setting of TXIFLSEL is ignored. Reset type: PER.RESET

39.5.2.10 UARTIM Register (Offset = 38h) [Reset = 00000000h]

UARTIM is shown in Figure 39-13 and described in Table 39-14.

Return to the Summary Table.

The UARTIM register is the interrupt mask set/clear register.
On a read, this register gives the current value of the mask on the relevant interrupt. Setting a bit allows the corresponding raw interrupt signal to be routed to the interrupt controller. Clearing a bit prevents the raw interrupt signal from being sent to the interrupt controller.

39.5.2.12 UARTMIS Register (Offset = 40h) [Reset = 00000000h]

UARTMIS is shown in Figure 39-15 and described in Table 39-16.

Return to the Summary Table.

The UARTMIS register is the masked interrupt status register. On a read, this register gives the current masked status value of the corresponding interrupt. A write has no effect.

39.5.3 UART_REGS_WRITE Registers

Table 39-37 lists the memory-mapped registers for the UART_REGS_WRITE registers. All register offset addresses not listed in Table 39-37 should be considered as reserved locations and the register contents should not be modified.

Table 39-37. UART_REGS_WRITE Registers

Offset	Acronym	Register Name	Protection
4h	UARTECR	UART Error Clear	

Complex bit access types are encoded to fit into small table cells. Table 39-38 shows the codes that are used for access types in this section.

Table 39-38. UART_REGS_WRITE Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

39.5.3.1 UARTECR Register (Offset = 4h) [Reset = 00000000h]

UARTECR is shown in Figure 39-36 and described in Table 39-39.

Return to the Summary Table.

The UARTECR register is the error clear register.
In addition to the UARTDR register, receive status can also be read from the UARTRSR register. If the status is read from this register, then the status information corresponds to the entry read from UARTDR prior to reading UARTRSR. The status information for overrun is set immediately when an overrun condition occurs.
The UARTRSR register cannot be written.
A write of any value to the UARTECR register clears the framing, parity, break, and overrun errors.
All the bits are cleared on reset.

Chapter 40

Local Interconnect Network (LIN)

This chapter describes the local interconnect network (LIN) module. This module can also operate as a serial communications interface (SCI) port when configured in SCI/UART mode. However, since the LIN module uses a different register/bit structure, code written for this module cannot be directly ported to the standalone SCI module or vice versa.

40.1 LIN Overview

The LIN module is compliant to the LIN2.1 standard in the *LIN Specification Package*. This standard is based on the UART serial protocol. The protocol involves a single commander and one or moreresponder nodes with a message identification for multicast transmission between any network nodes.

Section 40.2 explains how the LIN module operates in SCI mode, while Section 40.3 explains how the LIN module operates in LIN mode. The register descriptions specify which register fields are applicable for each mode.

40.1.1 LIN Mode Features

When operating in LIN mode, the LIN module includes the following features:

- Compatibility with LIN 1.3 , 2.0, and 2.1 protocols
- Configurable baud rate up to 20kbps
- Two external pins: LINRX and LINTX.
- Multibuffered receive and transmit units
- Identification masks for message filtering
- Automatic commander header generation
  - Programmable synchronization break field
  - Synchronization field
  - Identifier field
- Responder Automatic Synchronization
  - Synchronization break detection
  - Optional baud rate update
  - Synchronization validation
- 2^{31} programmable transmission rates with 7 fractional bits
- Wakeup on LINRX active level from transceiver
- Automatic wake-up support
  - LINTX wake-up signal generation
  - Wake-up signal timeout
- Automatic idle bus detection
- Error detection
  - Bit error
  - Bus error
  - No-response error
  - Checksum error
  - Synchronization field error
  - Parity error
- Capability to use real-Time Direct Memory Access (RTDMA) to transmit and receive data.
- 2 interrupt lines (INT0 and INT1) with user-configurable interrupt sources:
  - Receive
  - Transmit
  - ID, error, and status
- Support for LIN 2.0 checksum
- Enhanced synchronizer finite state machine (FSM) support for frame processing
- Enhanced handling of extended frames
- Enhanced baud rate generator

40.1.2 SCI Mode Features

When operating in SCI mode, the LIN module includes the following features:

- Standard universal asynchronous receiver-transmitter (UART) communication
- Supports full-duplex or half-duplex operation
- Standard non-return-to-zero (NRZ) format
- Double-buffered receive and transmit functions
- Supports two individually enabled interrupt lines: level 0 and level 1
- Configurable frame format of three to thirteen bits per character based on the following:
  - One start bit
  - Data word length programmable from one to eight bits
  - Additional address bit in address-bit mode
  - Parity programmable for zero or one parity bit, odd or even parity
  - Stop programmable for one or two stop bits
- Asynchronous communication mode
- Two multiprocessor communication formats allow communication between more than two devices
- Sleep and wake-up functions for multiprocessor communication
- Programmable divider to support up to 2^{24} different baud rates
- Capability to use Real-Time Direct Memory Access (RTDMA) to transmit and receive data
- Error and status flags to provide detailed information about SCI events
- Multibuffer mode for receive and transmit

Note

In SCI mode, the LIN module is functionally compatible with the C2000™ SCI module, but not software compatible due to different register definitions.

The LIN module does not support UART hardware flow control. This feature can be implemented in software using a general-purpose I/O pin.

The LIN module does not support isosynchronous mode as there is no SCICLK pin.

40.1.3 Block Diagram

The LIN module is based on the SCI module with added sub-blocks to support LIN protocol.

The three major components of the SCI block are:

- **Transmitter** (TX) contains two major registers to perform the double-buffering:
  - The transmitter data buffer register (SCITD) contains data loaded by the CPU to be transferred to the shift register for transmission.
  - The transmitter shift register (SCITXSHF) loads data from the data buffer (SCITD) and shifts data onto the LINTX pin, one bit at a time.
- **Baud Clock Generator**
  - A programmable baud generator produces a baud clock scaled from the input clock VCLK
  - LIN VCLK is based on the SYSCLK frequency. VCLK input from SYSCLK and can be divided by 1, 2, or 4 using the CLK_CFG_REGS PERCLKDIVSEL.LINxCLKDIV field for each LIN module individually. By default, VCLK input is SYSCLK divided by 2
- **Receiver** (RX) contains two major registers to perform the double-buffering:
  - The receiver shift register (SCIRXSHF) shifts data in from the LINRX pin one bit at a time and transfers completed data into the receive data buffer.
  - The receiver data buffer register (SCIRD) contains received data transferred from the receiver shift register

There are separate enable and interrupt bits for the LIN receiver and transmitter. The receiver and transmitter can each be operated independently (half-duplex) or simultaneously (full duplex).

To maintain data integrity, the LIN checks the received data for breaks, parity, overrun, and framing errors. The baud rate (bits per second) is programmable to over 16 million different rates through a 24-bit baud-select register. Figure 40-1 shows the detailed diagram of the SCI block.

The LIN module is based on the SCI module with the addition of an error detector (parity calculator, checksum calculator, and bit monitor), a mask filter, a synchronizer, and a multibuffered receiver and transmitter. The SCI interface, the RTDMA control sub-blocks and the baud generator are modified for compatibility with the LIN standard. Figure 40-2 shows the LIN block diagram.

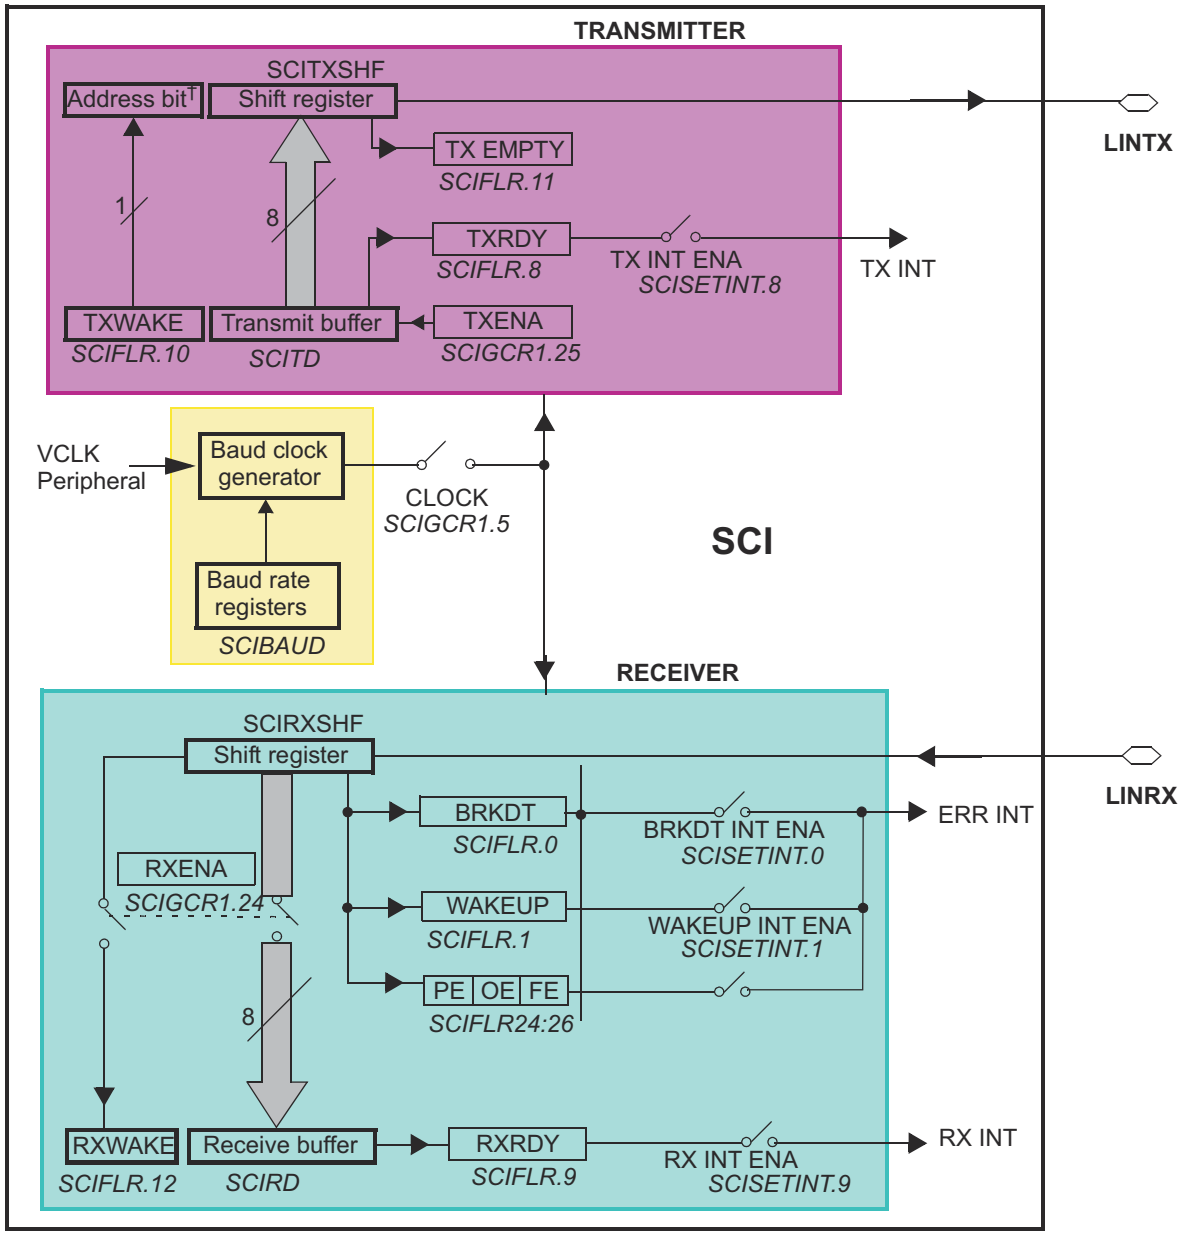

Figure 40-1. SCI Block

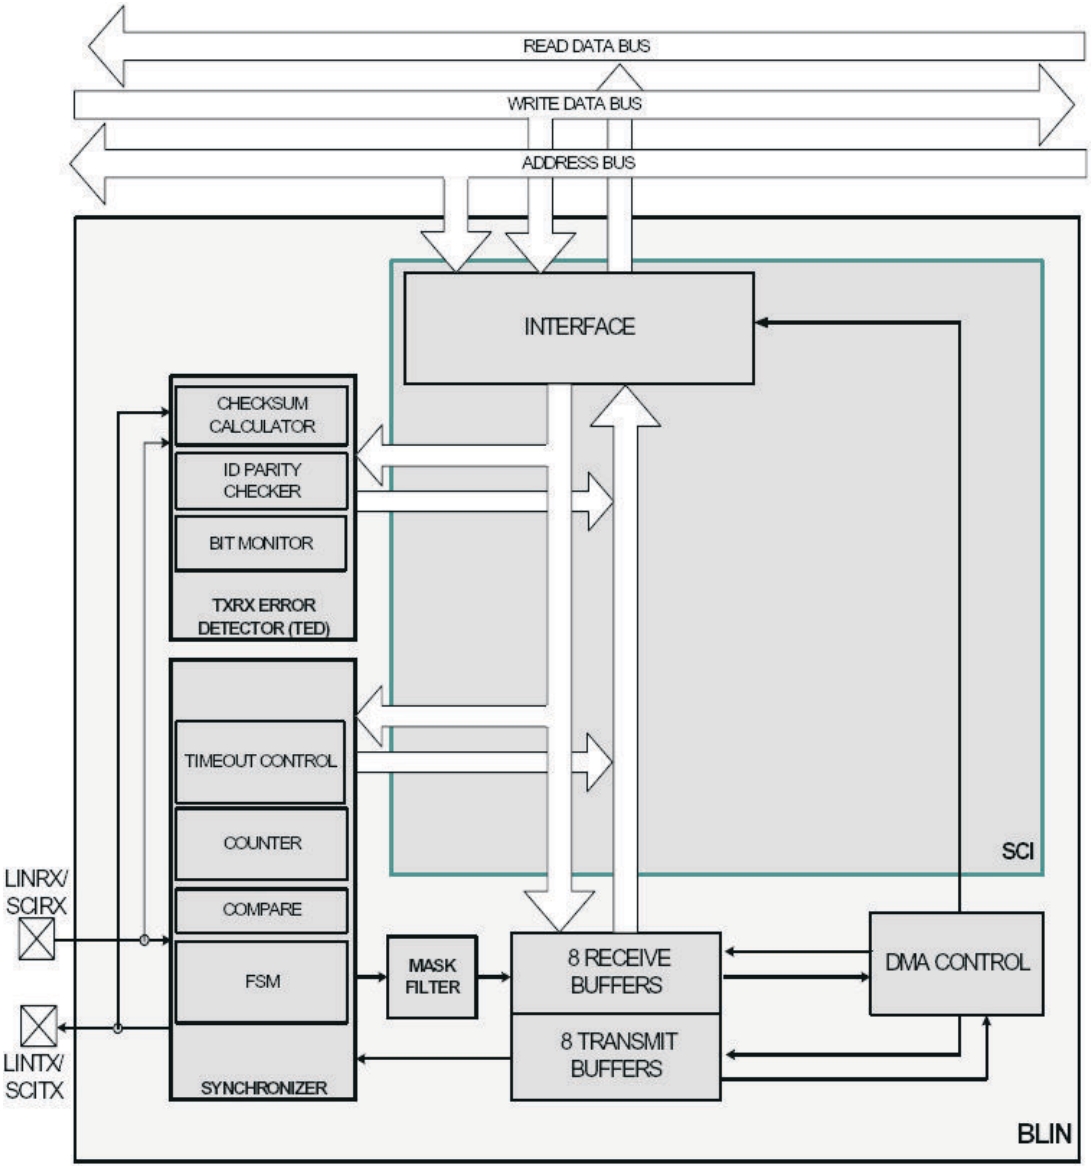

Figure 40-2. LIN Block Diagram

40.2 Serial Communications Interface Module

40.2.1 SCI Communication Formats

The SCI module can be configured to meet the requirements of many applications. Because communication formats vary depending on the specific application, many attributes of the SCI/LIN are user configurable. The configuration options are:

- SCI Frame format
- SCI Timing modes
- SCI Baud rate
- SCI Multiprocessor modes

40.2.1.1 SCI Frame Formats

The SCI uses a programmable frame format. All frames consist of the following:

- One start bit
- One to eight data bits
- Zero or one address bit
- Zero or one parity bit
- One or two stop bits

The frame format for both the transmitter and receiver is programmable through the bits in the SCIGCR1 register. Both receive and transmit data is in nonreturn to zero (NRZ) format, which means that the transmit and receive lines are at logic high when idle. Each frame transmission begins with a start bit, in which the transmitter pulls the SCI line low (logic low). Following the start bit, the frame data is sent and received least significant bit first (LSB).

An address bit is present in each frame if the SCI is configured to be in address-bit mode but is not present in any frame if the SCI is configured for idle-line mode. The format of frames with and without the address bit is illustrated in Figure 40-3.

A parity bit is present in every frame when the PARITY ENA bit is set. The value of the parity bit depends on the number of one bits in the frame and whether odd or even parity has been selected using the PARITY ENA bit. Both examples in Figure 40-3 have parity enabled.

All frames include one stop bit, which is always a high level. This high level at the end of each frame is used to indicate the end of a frame to make sure synchronization between communicating devices. Two stop bits are transmitted, if the STOP bit in SCIGCR1 register is set. The examples shown in Figure 40-3 use one stop bit per frame.

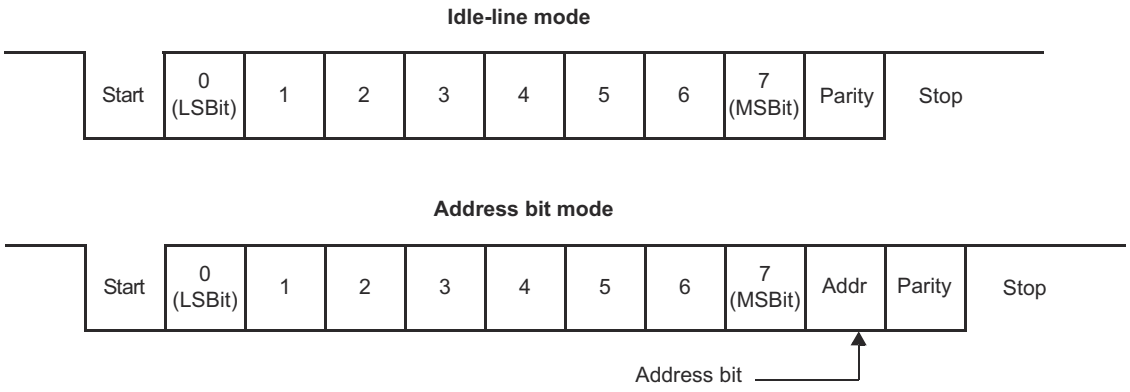

Figure 40-3. Typical SCI Data Frame Formats

40.2.1.2 SCI Asynchronous Timing Mode

The SCI can be configured to use the asynchronous timing mode using TIMING MODE bit in SCIGCR1 register.

The asynchronous timing mode uses only the receive and transmit data lines to interface with devices using the standard universal asynchronous receiver- transmitter (UART) protocol.

In the asynchronous timing mode, each bit in a frame has a duration of 16 SCI baud clock periods. Each bit therefore consists of 16 samples (one for each clock period). When the SCI is using asynchronous mode, the baud rates of all communicating devices must match as closely as possible. Receive errors result from devices communicating at different baud rates.

With the receiver in the asynchronous timing mode, the SCI detects a valid start bit if the first four samples after a falling edge on the LINRX pin are of logic level 0. As soon as a falling edge is detected on LINRX, the SCI assumes that a frame is being received and synchronizes to the bus.

To prevent interpreting noise as Start bit SCI expects LINRX line to be low for at least four contiguous SCI baud clock periods to detect a valid start bit. The bus is considered idle if this condition is not met. When a valid start bit is detected, the SCI determines the value of each bit by sampling the LINRX line value during the seventh, eighth, and ninth SCI baud clock periods. A majority vote of these three samples is used to determine the value stored in the SCI receiver shift register. By sampling in the middle of the bit, the SCI reduces errors caused by propagation delays and rise and fall times and data line noises. Figure 40-4 illustrates how the receiver samples a start bit and a data bit in asynchronous timing mode.

The transmitter transmits each bit for a duration of 16 SCI baud clock periods. During the first clock period for a bit, the transmitter shifts the value of that bit onto the LINTX pin. The transmitter then holds the current bit value on LINTX for 16 SCI baud clock periods.

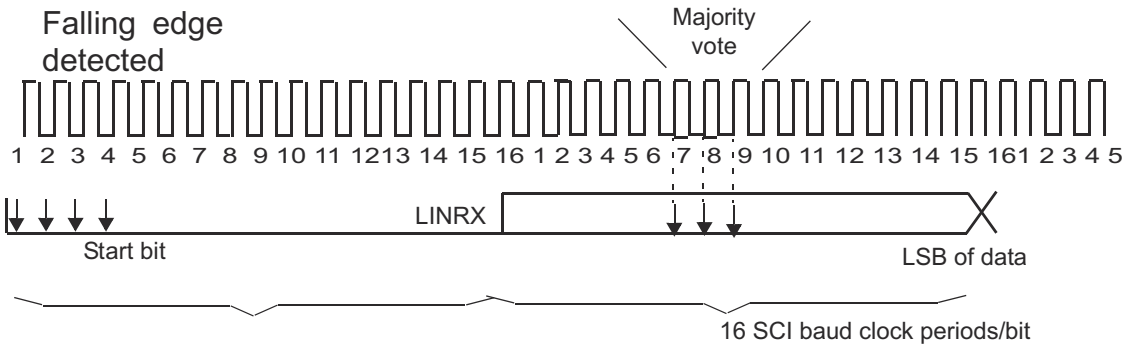

Figure 40-4. Asynchronous Communication Bit Timing

40.2.1.3 SCI Baud Rate

The SCI/LIN has an internally generated serial clock determined by the peripheral VCLK and the prescalers P and M in this register. The SCI uses the 24-bit integer prescaler P value in the BRS register to select the required baud rates. The additional 4-bit fractional divider M refines the baud rate selection.

In asynchronous timing mode, the SCI generates a baud clock according to the following formula:

$$SCICLK\ Frequency = \frac{VCLK\ Frequency}{P + 1 + \frac{M}{16}}$$

$$Asynchronous\ baud\ value = \frac{SCICLK\ Frequency}{16}$$

For P = 0,

$$Asynchronous\ baud\ value = \frac{VCLK\ Frequency}{32}$$

40.2.1.3.1 Superfractional Divider, SCI Asynchronous Mode

The superfractional divider is available in SCI asynchronous mode (idle-line and address-bit mode). Building on the 4-bit fractional divider M (BRS[27:24]), the superfractional divider uses an additional 3-bit modulating value (see Table 40-2). The bits with a 1 in the table have an additional VCLK period added to the T_{bit}. If the character length is more than 10, then the modulation table is a rolled-over version of the original table (Table 40-1), as shown in Table 40-2.

The baud rate varies over a data field to average according to the BRS[30:28] value by a "**d**" fraction of the peripheral internal clock: **0<d<1.** See Figure 40-5 for a simple Average "d' calculation based on "U" value (BRS[30:28]).

The instantaneous bit time is expressed in terms of T_{VCLK} as follows:

For all P other than 0, and all M and d (0 or 1),

$$T^{i}bit = \left[16\left(P + 1 + \frac{M}{16}\right) + d\right]T_{VCLK}$$

For P = 0, $T_{bit} = 32T_{VCLK}$

The averaged bit time is expressed in terms of T_{VCLK} as follows:

For all P other than 0, and all M and d (0<d<1),

$$T^{a}bit = \left[16\left(P + 1 + \frac{M}{16}\right) + d\right]T_{VCLK}$$

For P = 0, $T_{bit} = 32T_{VCLK}$

Table 40-1. Superfractional Bit Modulation for SCI Mode (Normal Configuration)

Normal Configuration = Start Bit + 8 Data Bits + Stop Bit

40.2.1.4 SCI Multiprocessor Communication Modes

In some applications, the SCI can be connected to more than one serial communication device. In such a multiprocessor configuration, several frames of data can be sent to all connected devices or to an individual device. In the case of data sent to an individual device, the receiving devices must determine when the devices are being addressed. When a message is not intended for them, the devices can ignore the following data. When only two devices make up the SCI network, addressing is not needed, so multiprocessor communication schemes are not required.

SCI supports two multiprocessor communication modes which can be selected using COMM MODE bit:

- Idle-Line Mode
- Address Bit Mode

When the SCI is not used in a multiprocessor environment, software can consider all frames as data frames. In this case, the only distinction between the idle-line and address-bit modes is the presence of an extra bit (the address bit) in each frame sent with the address-bit protocol.

The SCI allows full-duplex communication where data can be sent and received using the transmit and receive pins simultaneously. However, the protocol used by the SCI assumes that only one device transmits data on the same bus line at any one time. No arbitration is done by the SCI.

40.2.1.4.1 Idle-Line Multiprocessor Modes

In idle-line multiprocessor mode, a frame that is preceded by an idle period (10 or more idle bits) is an address frame. A frame that is preceded by fewer than 10 idle bits is a data frame. Figure 40-6 illustrates the format of several blocks and frames with idle-line mode.

There are two ways to transmit an address frame using idle-line mode:

Method 1: In software, deliberately leave an idle period between the transmission of the last data frame of the previous block and the address frame of the new block.

Method 2: Configure the SCI to automatically send an idle period between the last data frame of the previous block and the address frame of the new block.

Although Method 1 is only accomplished by a delay loop in software, Method 2 can be implemented by using the transmit buffer and the TXWAKE bit in the following manner:

Step 1: Write a 1 to the TXWAKE bit.

Step 2: Write a dummy data value to the SCITD register. This triggers the SCI to begin the idle period as soon as the transmitter shift register is empty.

Step 3: Wait for the SCI to clear the TXWAKE flag.

Step 4: Write the address value to SCITD.

As indicated by Step 3, software can wait for the SCI to clear the TXWAKE bit. However, the SCI clears the TXWAKE bit at the same time the SCI sets TXRDY (that is, transfers data from SCITD into SCITXSHF). Therefore, if the TX INT ENA bit is set, the transfer of data from SCITD to SCITXSHF causes an interrupt to be generated at the same time that the SCI clears the TXWAKE bit. If this interrupt method is used, software is not required to poll the TXWAKE bit waiting for the SCI to clear the bit.

When idle-line multiprocessor communications are used, software must make sure that the idle time exceeds 10 bit periods before addresses (using one of the methods mentioned above), and software must also make sure that data frames are written to the transmitter quickly enough to be sent without a delay of 10 bit periods between frames. Failure to comply with these conditions results in data interpretation errors by other devices receiving the transmission.

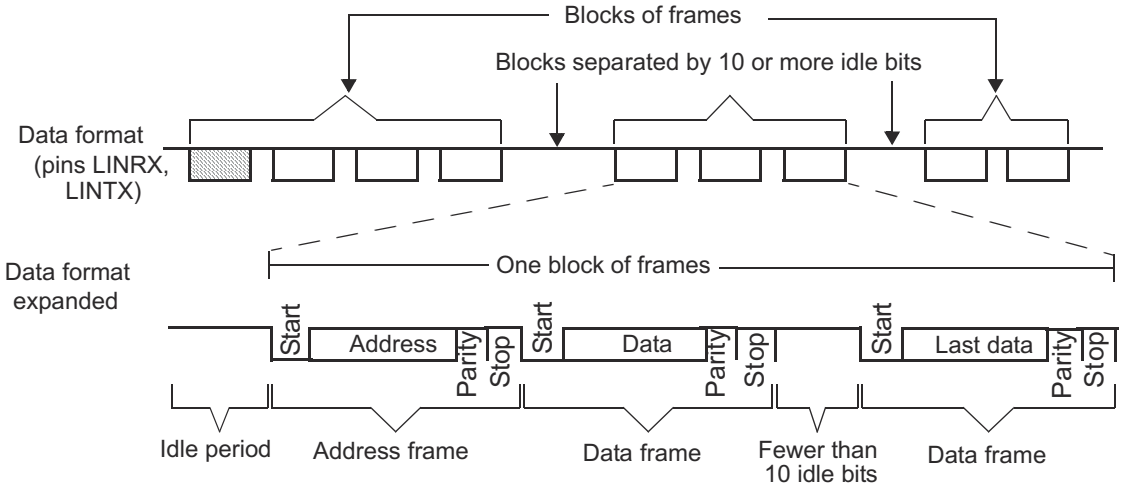

Figure 40-6. Idle-Line Multiprocessor Communication Format

40.2.1.4.2 Address-Bit Multiprocessor Mode

In the address-bit protocol, each frame has an extra bit immediately following the data field called an address bit. A frame with the address bit set to 1 is an address frame; a frame with the address bit set to 0 is a data frame. The idle period timing is irrelevant in this mode. Figure 40-7 illustrates the format of several blocks and frames with the address-bit mode.

When address-bit mode is used, the value of the TXWAKE bit is the value sent as the address bit. To send an address frame, software must set the TXWAKE bit. This bit is cleared as the contents of the SCITD are shifted from the TXWAKE register so that all frames sent are data except when the TXWAKE bit is written as a 1.

No dummy write to SCITD is required before an address frame is sent in address-bit mode. The first byte written to SCITD after the TXWAKE bit is written to 1 is transmitted with the address bit set when address-bit mode is used.

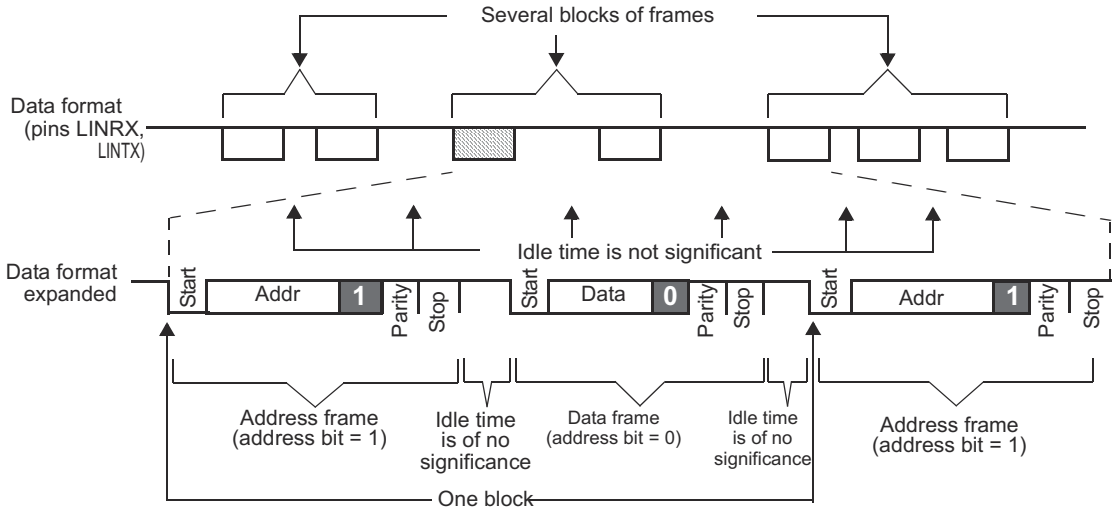

Figure 40-7. Address-Bit Multiprocessor Communication Format

40.2.1.5 SCI Multibuffered Mode

To reduce CPU load when receiving or transmitting data in interrupt mode or RTDMA mode, the SCI/LIN module has eight separate receive and transmit buffers. Multibuffered mode is enabled by setting the MBUF MODE bit.

The multibuffer 3-bit counter counts the data bytes transferred from the SCIRXSHF register to the RDy receive buffers and TDy transmit buffers register to SCITXSHF register. The 3-bit compare register contains the number of data bytes expected to be received or transmitted. the LENGTH value in SCIFORMAT register indicates the expected length and is used to load the 3-bit compare register.

A receive interrupt (RX interrupt; see the SCIINTVECT0 and SCIINTVECT1 registers), and a receive ready RXRDY flag set in SCIFLR register, as well as a RTDMA request (RXDMA) can occur after receiving a response if there are no response receive errors for the frame (such as, there is, frame error, and overrun error).

A transmit interrupt (TX interrupt), and a transmit ready flag (TXRDY flag in SCIFLR register), and a RTDMA request (TXDMA) can occur after transmitting a response.

Figure 40-8 and Figure 40-9 show the receive and transmit multibuffer functional block diagram, respectively.

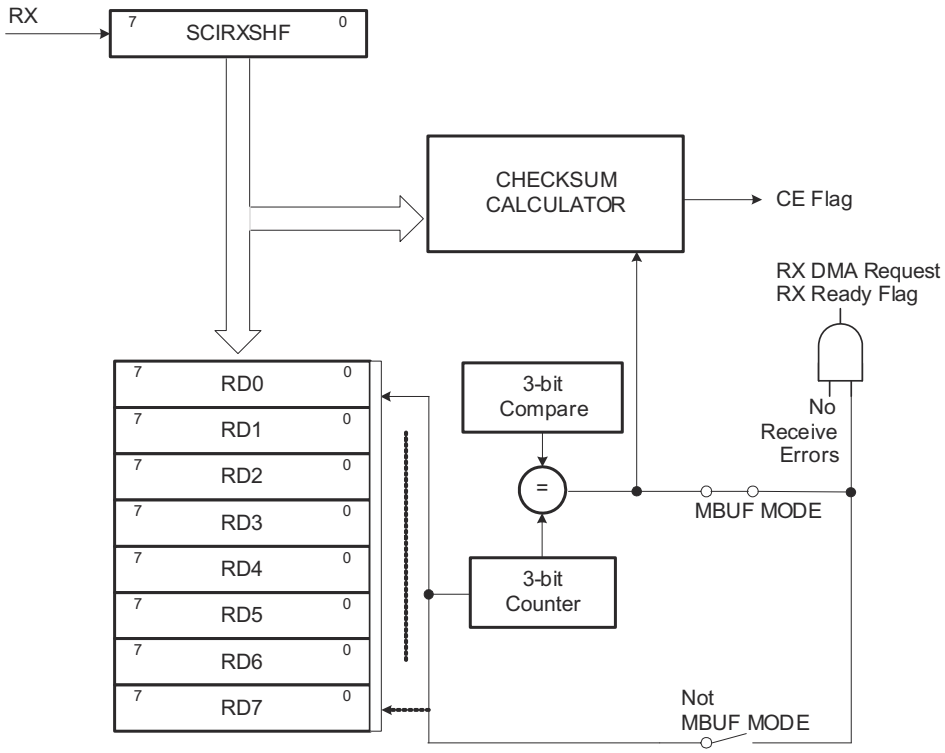

Figure 40-8. Receive Buffers

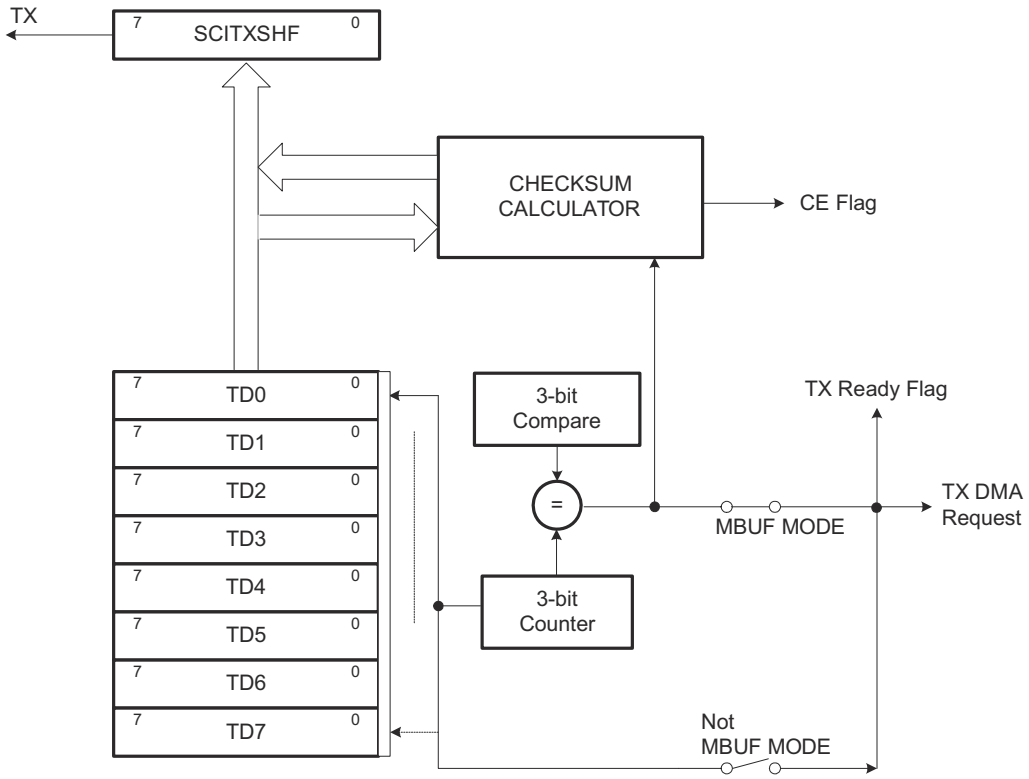

Figure 40-9. Transmit Buffers

40.2.2 SCI Interrupts

The SCI/LIN module has two interrupt lines, level 0 and level 1, to the vectored interrupt manager (VIM) module (see Figure 40-10). Two offset registers SCIINTVECT0 and SCIINTVECT1 determine which flag triggered the interrupt according to the respective priority encoders. Each interrupt condition has a bit to enable/disable the interrupt in the SCISETINT and SCICLRINT registers, respectively.

Each interrupt also has a bit that can be set as interrupt level 0(INT0) or as interrupt level 1(INT1). By default, interrupts are in interrupt level 0. SCISETINTLVL sets a given interrupt to level1. SCICLEARINTLVL resets a given interrupt level to the default level 0.

The interrupt vector registers SCIINTVECT0 and SCIINTVECT1 return the vector of the pending interrupt line INT0 or INT1. If more than one interrupt is pending, the interrupt vector register holds the highest priority interrupt.

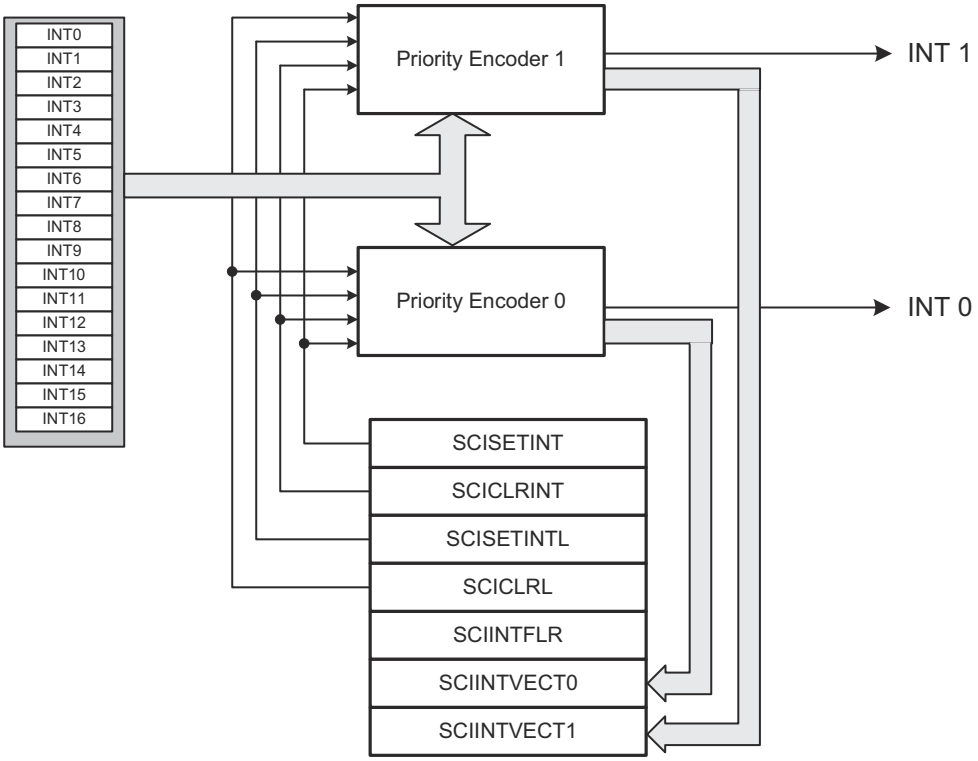

Figure 40-10. General Interrupt Scheme

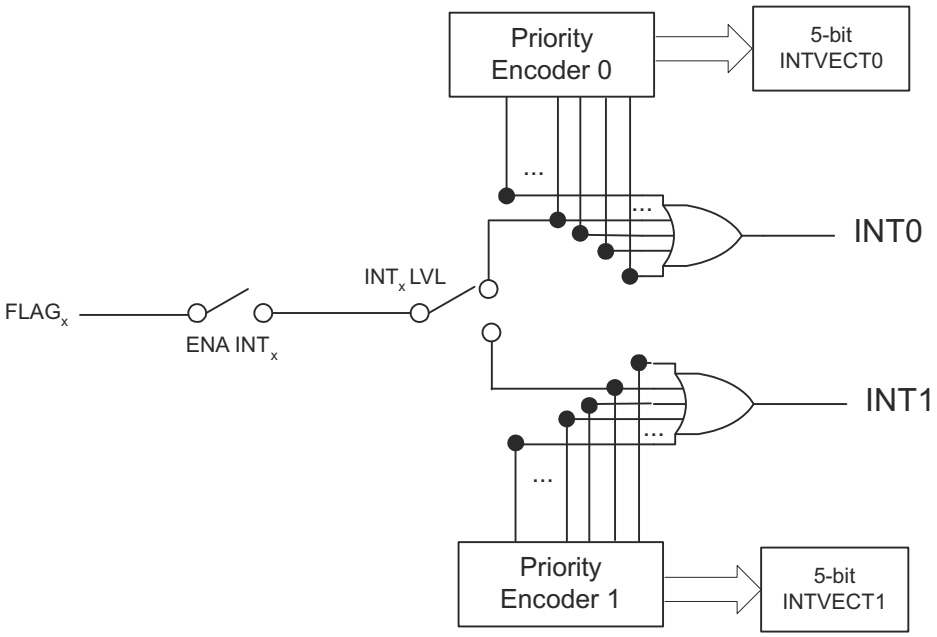

Figure 40-11. Interrupt Generation for Given Flags

40.2.2.1 Transmit Interrupt

To use transmit interrupt functionality, SETTXINT bit must be enabled and SET_TX_DMA bit must be cleared in the SCISETINT register. The transmit ready (TXRDY) flag is set when the SCI transfers the contents of SCITD/TDy to the shift register, SCITXSHF. The TXRDY flag indicates that SCITD/TDy is ready to be loaded with more data. In addition, the SCI sets the TX EMPTY bit if both the SCITD/TDy and SCITXSHF registers are empty. If the SETTXINT bit is set, then a transmit interrupt is generated when the TXRDY flag goes high. The transmit interrupt is not generated immediately after setting the SETTXINT bit unlike the transmit RTDMA request. The transmit interrupt is generated only after the first transfer from SCITD/TDy to SCITXSHF, that is first data has to be written to SCITD/TDy before any interrupt gets generated. To transmit further data, data can be written to SCITD/TDy in the transmit interrupt service routine.

Writing data to the SCITD/TDy register clears the TXRDY bit. When this data has been moved to the SCITXSHF register, the TXRDY bit is set again. The interrupt request can be suspended by setting the CLRTXINT bit in the SCICLEARINT register; however, when the SETTXINT bit is again set to 1, the TXRDY interrupt is asserted again. The transmit interrupt request can be eliminated until the next series of values is written to SCITD/TDy, by disabling the transmitter using the TXENA bit, by a software reset SWnRST, or by a device hardware reset.

40.2.2.2 Receive Interrupt

The receive ready (RXRDY) flag is set when the SCI transfers newly received data from SCIRXSHF to SCIRD/RDy. The RXRDY flag therefore indicates that the SCI has new data to be read. Receive interrupts are enabled by the SETRXINT bit in the SCISETINT register. If the SETRXINT is set when the SCI sets the RXRDY flag, then a receive interrupt is generated. The received data can be read in the Interrupt Service routine.

On a device with a RTDMA controller, the SET_RX_DMA bit in the SCISETINT register must be cleared to select interrupt functionality.

40.2.2.3 WakeUp Interrupt

SCI sets the WAKEUP flag if bus activity on the RX line either prevents power-down mode from being entered, or RX line activity causes an exit from power-down mode. If enabled (SCISETINT.SETWAKEUPINT is set), the wakeup interrupt is triggered once the WAKEUP flag in the SCIFLR register is set.

40.2.2.4 Error Interrupts

The following error detections are supported with an interrupt by the SCI module:

- Parity errors (PE)
- Frame errors (FE)
- Break Detect errors (BRKDT)
- Overrun errors (OE)
- Bit errors (BE)

There are 16 interrupt sources in the SCI/LIN module. In SCI mode, 8 interrupts are supported, as listed in Table 40-4.

If all of these errors (PE, FE, BRKDT, OE, BE) are flagged, an interrupt for the flagged errors is generated if enabled. A message is valid for both the transmitter and the receiver, if there is no error detected until the end of the frame. Each of these flags is located in the receiver status (SCIFLR) register (Table 40-5 and Table 40-6).

Table 40-4. SCI/LIN Interrupts

Offset(1)	Interrupt	Applicable to SCI	Applicable to LIN
0	No interrupt	-	-
1	Wakeup	Yes	Yes
2	Inconsistent-sync-field error (ISFE)	No	Yes
3	Parity error (PE)	Yes	Yes
4	ID	No	Yes
5	Physical bus error (PBE)	No	Yes
6	Frame error (FE)	Yes	Yes
7	Break detect (BRKDT)	Yes	No
8	Checksum error (CE)	No	Yes
9	Overrun error (OE)	Yes	Yes
10	Bit error (BE)	Yes	Yes
11	Receive	Yes	Yes
12	Transmit	Yes	Yes
13	No-response error (NRE)	No	Yes
14	Timeout after wakeup signal (150ms)	No	Yes
15	Timeout after three wakeup signals (1.5s)	No	Yes
16	Timeout (Bus Idle, 4s)	No	Yes

(1) Offset 1 is the highest priority. Offset 16 is the lowest priority.

Table 40-5. SCI Receiver Status Flags

SCI Flag	Register	Bit	Value After Reset(1)
CE	SCIFLR	29	0
ISFE	SCIFLR	28	0
NRE	SCIFLR	27	0
FE	SCIFLR	26	0
OE	SCIFLR	25	0
PE	SCIFLR	24	0
RXWAKE	SCIFLR	12	0
RXRDY	SCIFLR	9	0
BUSY	SCIFLR	3	0
IDLE	SCIFLR	2	1
WAKEUP	SCIFLR	1	0
BRKDT	SCIFLR	0	0

(1) The flags are frozen with the reset value while SWnRST = 0.

Table 40-6. SCI Transmitter Status Flags

SCI Flag	Register	Bit	Value After Reset(1)
BE	SCIFLR	31	0
PBE	SCIFLR	30	0
TXWAKE	SCIFLR	10	0
TXEMPTY	SCIFLR	11	1
TXRDY	SCIFLR	8	1

(1) The flags are frozen with the reset value while SWnRST = 0.

40.2.3 SCI RTDMA Interface

RTDMA requests for receive (RXDMA request) and transmit (TXDMA request) are available for the SCI/LIN module. The RTDMA must be configured to transfer to/from the SCITD/SCIRD register if multibuffer mode is disabled (MBUFMODE in the SCIGCR1 register is cleared), and to/from the TDy/RDy registers if multibuffer mode is enabled (MBUFMODE in the SCIGCR1 register is set.)

40.2.3.1 Receive RTDMA Requests

This RTDMA functionality is enabled/disabled by the CPU using the SETRXDMA/CLRRXDMA bits, respectively.

In multibuffered SCI mode with RTDMA enabled, the receiver loads the RDy buffers for each received character. RXDMA request is triggered once the last character of the programmed number of characters (LENGTH) are received and copied to the corresponding RDy buffer successfully.

If the multibuffer option is disabled, then RTDMA requests are generated on a byte-per-byte basis.

In multiprocessor mode, the SCI can generate receiver interrupts for address frames and RTDMA requests for data frames or RTDMA requests for both. This is controlled by the SET_RX_DMA_ALL bit.

In multiprocessor mode with the SLEEP bit set, no RTDMA request is generated for received data frames. The software must clear the SLEEP bit before data frames can be received.

40.2.3.2 Transmit RTDMA Requests

RTDMA functionality is enabled/disabled by the CPU with SET_TX_DMA/CLR_TX_DMA bits, respectively.

In multibuffered SCI mode once TXRDY bit is set or after a transmission of programmed number of characters (LENGTH) (up to eight data bytes stored in the transmit buffers (TDy) in the LINTD0 and LINTD1 registers), a RTDMA request is generated to reload the transmit buffer for the next transmission. If the multibuffer option is disabled, then RTDMA requests are generated on a byte-per-byte basis.

40.2.4 SCI Configurations

Before the SCI sends or receives data, the SCI registers can be properly configured. Upon power-up or a system-level reset, each bit in the SCI registers is set to a default state. The registers are writable only after the RESET bit in the SCIGCR0 register is set to 1. Of particular importance is the SWnRST bit in the SCIGCR1 register. The SWnRST is an active-low bit initialized to 0 and keeps the SCI in a reset state until the bit is programmed to 1. Therefore, all SCI configuration can be completed before a 1 is written to the SWnRST bit.

The following list details the configuration steps that software can perform prior to the transmission or reception of data. As long as the SWnRST bit is cleared to 0 the entire time that the SCI is being configured, the order in which the registers are programmed is not important.

- Enable SCI by setting the RESET bit to 1.
- Clear the SWnRST bit to 0 before SCI is configured.
- Select the desired frame format by programming the SCIGCR1 register.
- Set both the RX FUNC and TX FUNC bits in SCIPIO0 to 1 to configure the LINRX and LINTX pins for SCI functionality.
- Select the baud rate to be used for communication by programming the BRS register.
- Set the CLOCK bit in SCIGCR1 to 1 to select the internal clock.
- Set the CONT bit in SCIGCR1 to 1 to make SCI not halt for an emulation breakpoint until the current reception or transmission is complete (this bit is used only in an emulation environment).
- Set the LOOP BACK bit in SCIGCR1 to 1 to connect the transmitter to the receiver internally (this feature is used to perform a self-test).
- Set the RXENA bit in SCIGCR1 to 1, if data is to be received.
- Set the TXENA bit in SCIGCR1 to 1, if data is to be transmitted.
- Set the SWnRST bit to 1 after SCI is configured.
- Perform receiving or transmitting data (see Section 40.2.4.1 or Section 40.2.4.2).

40.2.4.1 Receiving Data

The SCI receiver is enabled to receive messages, if both the RX FUNC bit and the RXENA bit are set to 1. If the RX FUNC bit is not set, the LINRX pin functions as a general-purpose I/O pin rather than as an SCI function pin.

SCI module can receive data in one of the following modes:

- Single-Buffer (Normal) Mode
- Multibuffer Mode

After a valid idle period is detected, data is automatically received as the data arrives on the LINRX pin.

40.2.4.1.1 Receiving Data in Single-Buffer Mode

Single-buffer mode is selected when the MBUFMODE bit in SCIGCR1 is cleared to 0. In this mode, SCI sets the RXRDY bit when the SCI transfers newly received data from SCIRXSHF to SCIRD. The RXRDY bit is cleared after the new data in SCIRD has been read. Also, as data is transferred from SCIRXSHF to SCIRD, the FE, OE, or PE flags are set if any of these error conditions were detected in the received data. These error conditions are supported with configurable interrupt capability. The wakeup and break-detect status bits are also set if one of these errors occurs, but the bits do not necessarily occur at the same time that new data is being loaded into SCIRD.

You can receive data by:

1. Polling the Receive Ready Flag
2. Receive Interrupt
3. RTDMA

In polling method, software can poll for the RXRDY bit and read the data from the SCIRD register once the RXRDY bit is set high. The CPU is unnecessarily overloaded by selecting the polling method. To avoid this, you can use either the interrupt or RTDMA method. To use the interrupt method, set the SETRXINT bit. To use the RTDMA method, set the SET_RX_DMA bit. Either an interrupt or a RTDMA request is generated the moment the RXRDY bit is set.

40.2.4.1.2 Receiving Data in Multibuffer Mode

Multibuffer mode is selected when the MBUFMODE bit in SCIGCR1 is set to 1. In this mode, SCI sets the RXRDY bit after receiving the programmed number of data in the receive buffer, the complete frame. The error condition detection logic is similar to the single-buffer mode, except that this logic monitors for the complete frame. Like single-buffer mode, use the polling, RTDMA, or interrupt method to read the data. The RXRDY bit is automatically cleared after the new data in SCIRD has been read.

40.2.4.2 Transmitting Data

The SCI transmitter is enabled if both the TXFUNC bit and the TXENA bit are set to 1. If the TXFUNC bit is not set, the LINTX pin functions as a general-purpose I/O pin rather than as an SCI function pin. Any value written to the SCITD/TDy before TXENA is set to 1 is not transmitted. Both of these control bits allow for the SCI transmitter to be held inactive independently of the receiver.

The SCI module can transmit data in one of the following modes:

- Single-Buffer (Normal) Mode
- Multibuffered or Buffered SCI Mode

40.2.4.2.1 Transmitting Data in Single-Buffer Mode

Single-buffer mode is selected when the MBUFMODE bit in SCIGCR1 is cleared to 0. In this mode, the SCI waits for data to be written to SCITD, transfers the data to SCITXSHF, and transmits the data. The TXRDY and TXEMPTY bits indicate the status of the transmit buffers. That is, when the transmitter is ready for data to be written to SCITD, the TXRDY bit is set. Additionally, if both SCITD and SCITXSHF are empty, then the TXEMPTY bit is also set.

You can transmit data by:

1. Polling the Transmit Ready Flag
2. Transmit Interrupt
3. RTDMA

With the polling method, software can poll for the TXRDY bit to go high before writing the data to the SCITD register. The CPU is unnecessarily overloaded by selecting the polling method. To avoid this, you can use the interrupt or RTDMA method. To use the interrupt method, the SETTXINT bit is set. To use the RTDMA method, the SET_TX_DMA bit is set. Either an interrupt or a RTDMA request is generated the moment the TXRDY bit is set. When the SCI has completed transmission of all pending frames, the SCITXSHF register and SCITD are empty, the TXRDY bit is set, and an interrupt/RTDMA request is generated, if enabled. Because all data has been transmitted, the interrupt/RTDMA request must be halted. This can either be done by disabling the transmit interrupt (CLRTXINT)/RTDMA request (CLRTXDMA bit), or by disabling the transmitter (clear TXENA bit).

Note

The TXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0 or SCIINTVECT1 register.

40.2.4.2.2 Transmitting Data in Multibuffer Mode

Multibuffer mode is selected when the MBUFMODE bit in SCIGCR1 is set to 1. Like single-buffer mode, you can use the polling, RTDMA, or interrupt method to write the data to be transmitted. The transmitted data has to be written to the SCITD registers. The SCI waits for data to be written to the SCITD register and then transfers the programmed number of bytes to SCITXSHF to transmit one by one automatically.

40.2.5 SCI Low-Power Mode

The SCI/LIN can be put in either local or global low-power mode. Global low-power mode is asserted by the system and is not controlled by the SCI/LIN. During global low-power mode, all clocks to the SCI/LIN are turned off so the module is completely inactive.

Local low-power mode is asserted by setting the POWERDOWN bit; setting this bit stops the clocks to the SCI/LIN internal logic and the module registers. Setting the POWERDOWN bit causes the SCI to enter local low-power mode and clearing the POWERDOWN bit causes SCI/LIN to exit from local low-power mode. All the registers are accessible during local power-down mode as any register access enables the clock to SCI for that particular access alone.

The wakeup interrupt is used to allow the SCI to exit low-power mode automatically when a low level is detected on the LINRX pin and also this clears the POWERDOWN bit. If wakeup interrupt is disabled, then the SCI/LIN immediately enters low-power mode whenever it is requested and also any activity on the LINRX pin does not cause the SCI to exit low-power mode.

Note

Enabling Local Low-Power Mode During Receive and Transmit

If the wakeup interrupt is enabled and low-power mode is requested while the receiver is receiving data, then the SCI immediately generates a wakeup interrupt to clear the powerdown bit and prevents the SCI from entering low-power mode and thus completes the current reception. Otherwise, if the wakeup interrupt is disabled, then the SCI completes the current reception and then enters the low-power mode.

40.2.5.1 Sleep Mode for Multiprocessor Communication

When the SCI receives data and transfers that data from SCIRXSHF to SCIRD, the RXRDY bit is set and if SETRXINT is set, the SCI also generates an interrupt. The interrupt triggers the CPU to read the newly received frame before another one is received. In multiprocessor communication modes, this default behavior can be enhanced to provide selective indication of new data. When the SCI receives an address frame that does not match the address, the device can ignore the data following this non-matching address until the next address frame by using sleep mode. Sleep mode can be used with both idle-line and address-bit multiprocessor modes.

If sleep mode is enabled by the SLEEP bit, then the SCI transfers data from SCIRXSHF to SCIRD only for address frames. Therefore, in sleep mode, all data frames are assembled in the SCIRXSHF register without being shifted into the SCIRD and without initiating a receive interrupt or RTDMA request. Upon reception of an address frame, the contents of the SCIRXSHF are moved into SCIRD, and the software must read SCIRD and determine if the SCI is being addressed by comparing the received address against the address previously set in the software and stored somewhere in memory (the SCI does not have hardware available for address comparison). If the SCI is being addressed, the software must clear the SLEEP bit so that the SCI loads SCIRD with the data of the data frames that follow the address frame.

When the SCI has been addressed and sleep mode has been disabled (in software) to allow the receipt of data, the SCI can check the RXWAKE bit (SCIFLR.12) to determine when the next address has been received. The bit is set to 1, if the current value in SCIRD is an address; the bit is set to 0, if SCIRD contains data. If the RXWAKE bit is set, then software can check the address in SCIRD against the address. If SCIRD is still being addressed, then sleep mode can remain disabled; otherwise, the SLEEP bit can be set again.

Following is a sequence of events typical of sleep mode operation:

- The SCI is configured and both sleep mode and receive actions are enabled.
- An address frame is received and a receive interrupt is generated.
- Software compares the received address frame against that set by software and determines that the SCI is not being addressed, so the value of the SLEEP bit is not changed.
- Several data frames are shifted into SCIRXSHF, but no data is moved to SCIRD and no receive interrupts are generated.
- A new address frame is received and a receive interrupt is generated.
- Software compares the received address frame against that set by software and determines that the SCI is being addressed and clears the SLEEP bit.
- Data shifted into SCIRXSHF is transferred to SCIRD, and a receive interrupt is generated after each data frame is received.
- In each interrupt routine, software checks RXWAKE to determine if the current frame is an address frame.
- Another address frame is received, RXWAKE is set, software determines that the SCI is not being addressed and sets the SLEEP bit back to 1. No receive interrupts are generated for the data frames following this address frame.

By ignoring data frames that are not intended for the device, fewer interrupts are generated. Otherwise, these interrupts require CPU intervention to read data that is of no significance to this specific device. Using sleep mode can help free some CPU resources.

Except for the RXRDY flag, the SCI continues to update the receiver status flags (see Table 40-5) while sleep mode is active. In this way, if an error occurs on the receive line, an application can immediately respond to the error and take the appropriate corrective action.

Because the RXRDY bit is not updated for data frames when sleep mode is enabled, the SCI can enable sleep mode and use a polling algorithm if desired. In this case, when RXRDY is set, software knows that a new address has been received. If the SCI is not being addressed, then the software can not change the value of the SLEEP bit and can continue to poll RXRDY.

40.3 Local Interconnect Network Module

40.3.1 LIN Communication Formats

The SCI/LIN module can be used in LIN mode or SCI mode. The enhancements for baud generation, RTDMA controls, and additional receive/transmit buffers necessary for LIN mode operation are also part of the enhanced buffered SCI module. LIN mode is selected by enabling the LINMODE bit in SCIGCR1 register.

Note

The SCI/LIN is built around the SCI platform and uses a similar sampling scheme: 16 samples for each bit with majority vote on samples 8, 9, and 10. For the START bit, the first three samples are used.

The SCI/LIN control registers are located at the SCI/LIN base address. For a detailed description of each register, see Section 40.7.

40.3.1.1 LIN Standards

For compatibility with LIN2.0 standard the following additional features are implemented over LIN1.3:

1. Support for LIN 2.0 checksum
2. Enhanced synchronizer FSM support for frame processing
3. Enhanced handling of extended frames
4. Enhanced baud rate generator
5. Update wakeup/go to sleep

The LIN module covers the CPU performance-consuming features, defined in the *LIN Specification Package* Revision 1.3 and 2.0 by hardware. The Commander Mode of LIN module is compatible with LIN 2.1 standard.

40.3.1.2 Message Frame

The LIN protocol defines a message frame format, shown in Figure 40-12. Each frame includes one commander header, one response, one in-frame response space, and inter-byte spaces. In-frame-response and inter-byte spaces can be 0.

There is no arbitration in the definition of the LIN protocol; therefore, multiple responder nodes responding to a header can be detected as an error.

The LIN bus is a single-channel wired-AND bus. The bus has a binary level: either dominant for a value of 0 or recessive for a value of 1.

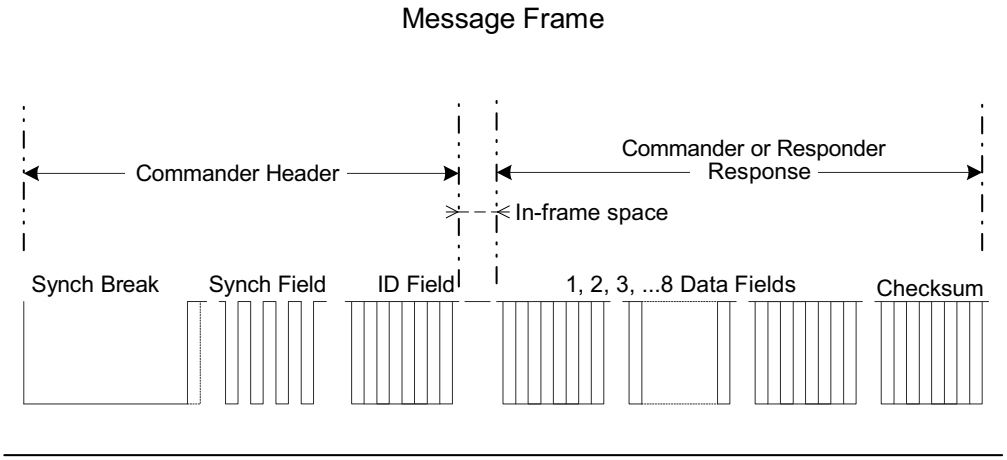

Figure 40-12. LIN Protocol Message Frame Format: Commander Header and Responder Peripheral Response

40.3.1.2.1 Message Header

The header of a message is initiated by a commander (see Figure 40-13) and consists of a three field-sequence:

- The synchronization break field signaling the beginning of a message
- The synchronization field conveying bit rate information of the LIN bus
- The identification field denoting the content of a message

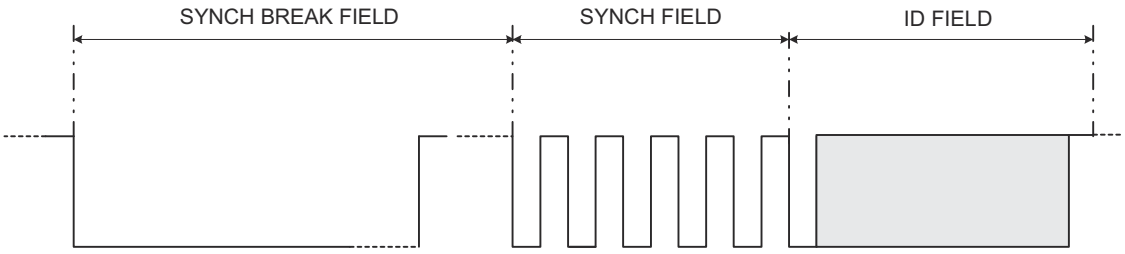

Figure 40-13. Header 3 Fields: Synch Break, Synch, and ID

40.3.1.2.2 Response

The format of the response is as illustrated in Figure 40-14. There are two types of fields in a response: data and checksum. The data field consists of exactly one data byte, one start bit, and one stop bit, for a total of 10 bits. The LSB is transmitted first. The checksum field consists of one checksum byte, one start bit and one stop bit. The checksum byte is the inverted modulo-256 sum over all data bytes in the data fields of the response.

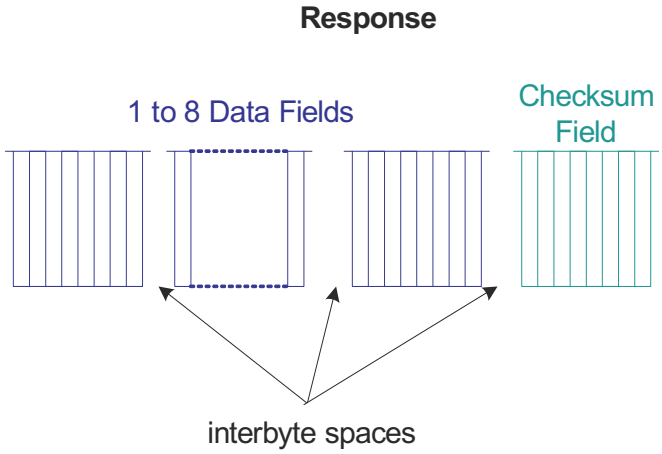

Figure 40-14. Response Format of LIN Message Frame

The format of the response is a stream of N data fields and one checksum field. Typically N is from 1 to 8, with the exception of the extended command frames (Section 40.3.1.6). The length N of the response is indicated either with the optional length control bits of the ID Field (this is used in standards earlier than LIN 1.x); see Table 40-7, or by LENGTH value in SCIFORMAT[18:16] register; see Table 40-8. The SCI/LIN module supports response lengths from 1 to 8 bytes in compliance with LIN 2.0.

Table 40-7. Response Length Info Using IDBYTE Field Bits [5:4] for LIN Standards Earlier than v1.3

ID5	ID4	Number of Data Bytes
0	0	2
0	1	2
1	0	4
1	1	8

Table 40-8. Response Length with SCIFORMAT[18:16] Programming

SCIFORMAT[18:16]	Number of Bytes
000	1
001	2
010	3
011	4
100	5
101	6
110	7
111	8

40.3.1.3 Synchronizer

The synchronizer has three major functions in the messaging between commander and responder nodes. The synchronizer generates the commander header data stream, the synchronizer synchronizes to the LIN bus for responding, and the synchronizer locally detects timeouts. A bit rate is programmed using the prescalers in the BRSR register to match the indicated LIN_speed value in the LIN description file.

The LIN synchronizer performs the following functions: commander header signal generation, responder detection and synchronization to message header with optional baud rate adjustment, response transmission timing and timeout control.

The LIN synchronizer is capable of detecting an incoming break and initializing communication at all times.

40.3.1.4 Baud Rate

The transmission baud rate of any node is configured by the CPU at the beginning; this defines the bit time T_{bit}. The bit time is derived from the fields P and M in the baud rate selection register (BRSR). There is an additional 3-bit fractional divider value, field U in the BRSR register, which further fine-tunes the data-field baud rate.

The ranges for the prescaler values in the BRSR register are:

P = 0, 1, 2, 3, . . . , 2^{24} - 1

M = 0, 1, 2, . . . , 15

U = 0, 1, 2, 3, 4, 5, 6, 7

The P, M, and U values in the BRSR register are user programmable. The P and M dividers can be used for both SCI mode and LIN mode to select a baud rate. The U value is an additional 3-bit value determining that "**a** T_{VCLK} " (with **a** = 0, 1) is added to each T_{bit} as explained in Section 40.3.1.4.2. If the ADAPT bit is set and the LIN peripheral is in adaptive baud rate mode, then all these divider values are automatically obtained during header reception when the synchronization field is measured.

The LIN protocol defines baud rate boundaries as:

$1kHz \le F_{LINCLK} \le 20kHz$

All transmitted bits are shifted in and out at T_{bit} periods.

40.3.1.4.1 Fractional Divider

The M field of the BRSR register modifies the integer prescaler P for fine tuning of the baud rate. The M value adds in increments of 1/16 of the P value.

The bit time, T_{bit} is expressed in terms of the VCLK period T_{VCLK} as follows:

For all P other than 0, and all M,

$$T_{bit} = 16\left(P + 1 + \frac{M}{16}\right)T_{VCLK}$$

For P = 0 : $T_{bit} = 32T_{VCLK}$

Therefore, the LINCLK frequency is given by:

$$F_{LINCLK} = \frac{F_{VCLK}}{16(P + 1 + \frac{M}{16})} \quad \text{For all P other than zero}$$

$$F_{LINCLK} = \frac{F_{VCLK}}{32} \quad \text{For P = 0}$$

40.3.1.4.2 Superfractional Divider

The superfractional divider scheme applies to the following modes:

- LIN commander mode (sync field + identifier field + response field + checksum field)
- LIN responder mode (response field + checksum field)

40.3.1.4.2.1 Superfractional Divider In LIN Mode

Building on the 4-bit fractional divider M (BRSR[27:24], the superfractional divider uses an additional 3-bit modulating value, illustrated in Table 40-9. The sync field (0x55), the identifier field, and the response field can all be seen as 8-bit data bytes flanked by a start bit and a stop bit. The bits with a 1 in the table have an additional VCLK period added to the T_{bit}. In LIN commander mode, bit modulation applies to sync field + identifier field + response field. In LIN responder mode, bit modulation applies to identifier field + response field.

Table 40-9. Superfractional Bit Modulation for LIN Commander Mode and Responder Mode

BRSR[30:28]	Start Bit	D[0]	D[1]	D[2]	D[3]	D[4]	D[5]	D[6]	D[7]	Stop Bit
0h	0	0	0	0	0	0	0	0	0	0
1h	1	0	0	0	0	0	0	0	1	0
2h	1	0	0	0	1	0	0	0	1	0
3h	1	0	1	0	1	0	0	0	1	0
4h	1	0	1	0	1	0	1	0	1	0
5h	1	1	1	0	1	0	1	0	1	1
6h	1	1	1	0	1	1	1	0	1	1
7h	1	1	1	1	1	1	1	0	1	1

The baud rate varies over a LIN data field to average according to the BRSR[30:28] value by a *d* fraction of the peripheral internal clock: 0<d<1.

The instantaneous bit time is expressed in terms of T_{VCLK} as follows:

For all P other than 0, and all M and d (0 or 1),

$$T^{i}bit = \left[16\left(P + 1 + \frac{M}{16}\right) + d\right]T_{VCLK}$$

For P = 0, $T_{bit} = 32T_{VCLK}$

The averaged bit time is expressed in terms of T_{VCLK} as follows:

For all P other than 0, and all M and d (0 < d <1),

$$T^{a}bit = \left[16\left(P + 1 + \frac{M}{16}\right) + d\right]T_{VCLK}$$

For P = 0, $T_{bit} = 32T_{VCLK}$

40.3.1.5 Header Generation

Automatic generation of the LIN protocol header data stream is supported without CPU interaction. The CPU or the RTDMA triggers the LIN state machine to generate a message header. A commander node initiates header generation on the CPU or RTDMA writes to the IDBYTE in the LINID register. The header is always sent by the commander to initiate a LIN communication and consists of three fields: synchronization break field, synchronization field, and identification field, as seen in Figure 40-15.

Note

The LIN protocol uses the parity bits in the identifier. The control length bits are optional to the LIN protocol.

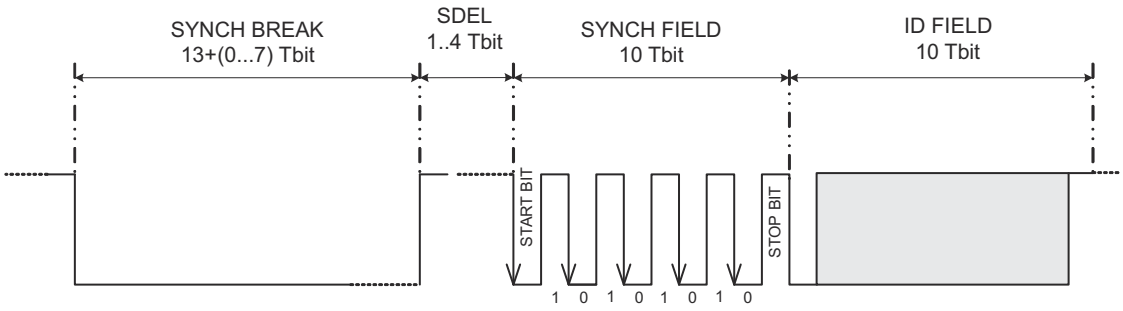

Figure 40-15. Message Header in Terms of T_{bit}

- The break field consists of two components:
  - The synchronization break (SYNCH BREAK) consists of a minimum of 13 (dominant) low bits to a maximum of 20 dominant bits. The sync break length can be extended from the minimum with the 3-bit SBREAK value in the LINCOMP register.
  - The synchronization break delimiter (SDEL) consists of a minimum of 1 (recessive) high bit to a maximum of 4 recessive bits. The delimiter marks the end of the synchronization break field. The sync break delimiter length depends on the 2-bit SDEL value in the LINCOMP register.
- The synchronization field (SYNCH FIELD) consists of one start bit, byte 0x55, and a stop bit. SYNCH FIELD is used to convey T_{bit} information and resynchronize LIN bus nodes.
- The identifier field ID byte can use 6 bits as an identifier, with optional length control and two optional bits as parity of the identifier. The identifier parity is used and checked if the PARITYENA bit is set. If length control bits are not used, then there can be a total of 64 identifiers plus parity. If neither length control or parity are used there can be up to 256 identifiers. See Figure 40-16 for an illustration of the ID field.

Note

Optional Control Length Bits

The control length bits only apply to LIN standards prior to LIN 1.3. IDBYTE field conveys response length information if compliant to standards earlier than LIN1.3. The SCIFORMAT register stores the length of the response for later versions of the LIN protocol.

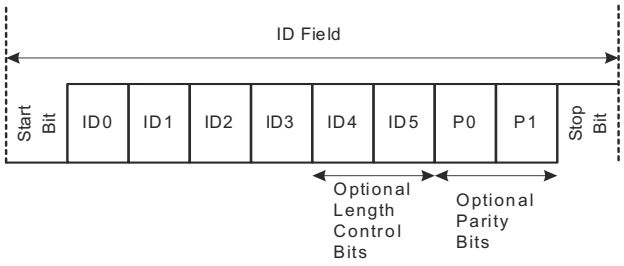

Figure 40-16. ID Field

Note

If the LIN module, configured as a responder in multibuffer mode, is in the process of transmitting data while a new header comes in, the module can end up responding with the data from the previous interrupted response (not the data corresponding to the new ID). To avoid this scenario, the following procedure can be used:

1. Check for the Bit Error (BE) during the response transmission. If the BE flag is set, this indicates that a collision has happened on the LIN bus (here because of the new Synch Break).
2. In the Bit Error ISR, configure the TD0 and TD1 registers with the next set of data to be transmitted on a TX Match for the incoming ID. Before writing to TD0/TD1 make sure that there was not already an update because of a Bit Error; otherwise, TD0/TD1 can be written twice for one ID.
3. Once the complete ID is received, based on the match, the newly configured data is transmitted by the node.

40.3.1.5.1 Event Triggered Frame Handling

The LIN 2.0 protocol uses event-triggered frames that can occasionally cause collisions. Event-triggered frames are handled in software.

If no responder answers to an event triggered frame header, the commander node sets the NRE flag, and a NRE interrupt occurs if enabled. If a collision occurs, a frame error and checksum error can arise before the NRE error. Those errors are flagged and the appropriate interrupts occur, if enabled.

Frame errors and checksum errors depend on the behavior and synchronization of the responding responders. If the responders are totally synchronized and stop transmission once the collision occurred, it is possible that only the NRE error is flagged despite the occurrence of a collision. To detect if there has been a reception of one byte before the NRE error is flagged, the BUS BUSY flag can be used as an indicator.

The BUS BUSY flag is set on the reception of the first bit of the header and remains set until the header reception is complete, and again is set on the reception of the first bit of the response. In the case of a collision, the flag is cleared in the same cycle as the NRE flag is set.

Software can implement the following sequence:

- Once the reception of the header is done (poll for RXID flag), wait for the BUS BUSY flag to get set or the NRE flag to get set.
- If the BUS BUSY flag is not set before the NRE flag, then a true no response is the case (no data has been transmitted onto the bus).
- If the BUS BUSY flag gets set, then wait for the NRE flag to get set or for successful reception. If the NRE flag is set, then a collision has occurred on the bus.

Even in the case of a collision, the received (corrupted) data is accessible in the RX buffers; registers LINRD0 and LINRD1.

40.3.1.5.2 Header Reception and Adaptive Baud Rate

A responder node baud rate can optionally be adjusted to the detected bit rate as an option to the LIN module. The adaptive baud rate option is enabled by setting the ADAPT bit. During header reception, a responder measures the baud rate during detection of the synch field. If ADAPT bit is set, then the measured baud rate is compared to the responder node programmed baud rate and adjusted to the LIN bus baud rate if necessary.

The responder node adjusts to any measured baud rate that is within ±10% of the programmed baud rate. For example, if the expected baud rate is programmed at 20kbps, the responder node detects any baud rate between 18kbps and 22kbps and adjusts accordingly. The MBRSR register prescaler is determined by the following formula:

$$\text{MBR} = \frac{\text{F}_{\text{VCLK}}}{1.1 \times \text{F}_{\text{LINCLK}}}$$

The LIN synchronizer determines two measurements: BRK_count and BAUD_count (Figure 40-17). These values are always calculated during the Header reception for synch field validation (Figure 40-18).

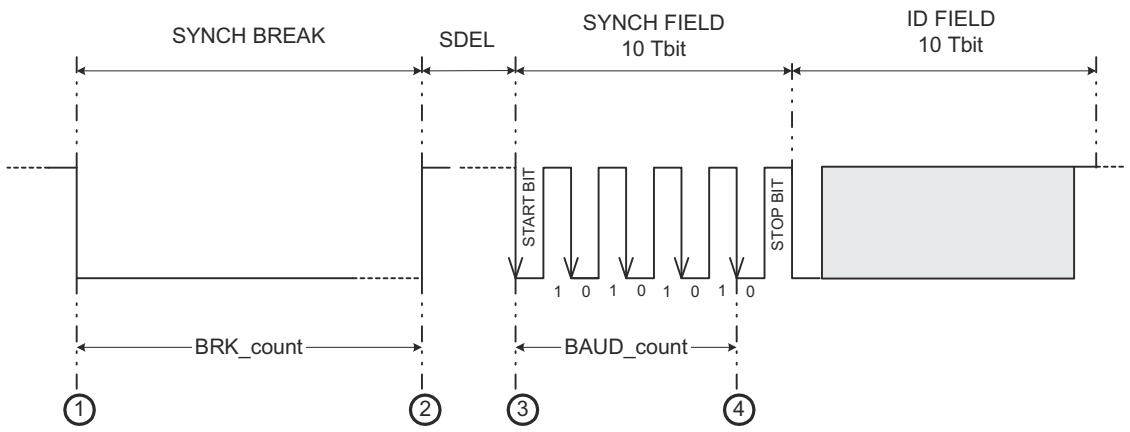

Figure 40-17. Measurements for Synchronization

By measuring the values BRK_count and BAUD_count, a valid sync break sequence can be detected as described in Figure 40-18. The four numbered events in Figure 40-17 signal the start/stop of the synchronizer counter. The synchronizer counter uses VCLK as the time base.

The synchronizer counter is used to measure the sync break relative to the detecting node T_{bit}. For a responder node receiving the sync break, a threshold of 11 T_{bit} is used as required by the LIN protocol. For detection of the dominant data stream of the sync break, the synchronizer counter is started on a falling edge and stopped on a rising edge of the LINRX. On detection of the sync break delimiter, the synchronizer counter value is saved and then reset.

On detection of five consecutive falling edges, the BAUD_count is measured. Bit timing calculation and consistency to required accuracy is implemented following the recommendations of LIN revision 2.0. A responder node can calculate a single T_{bit} time by division of BAUD_count by 8. In addition, for consistency between the detected edges the following is evaluated:

BAUD_count + BAUD_count » 2 + BAUD_count » 3 ≤ BRK_count

The BAUD_count value is shifted 3 times to the right and rounded using the first insignificant bit to obtain a T_{bit} unit. If the ADAPT bit is set, then the detected baud rate is compared to the programmed baud rate.

During the header reception processing as illustrated in Figure 40-18, if the measured BRK_count value is less than 11 T_{bit}, the sync break is not valid according to the protocol for a fixed rate. If the ADAPT bit is set, then the MBRS register is used for measuring BRK_count and BAUD_count values and automatically adjusts to any allowed LIN bus rate (refer to *LIN Specification Package 2.0*).

Note

In adaptive mode, the MBRS divider can be set to allow a maximum baud rate that is not more than 10% above the expected operating baud rate in the LIN network. Otherwise, a 0x00 data byte can mistakenly be detected as a sync break.

The break-threshold relative to the responder node is 11 T_{bit}. The break is 13 T_{bit} as specified in LIN v1.3.

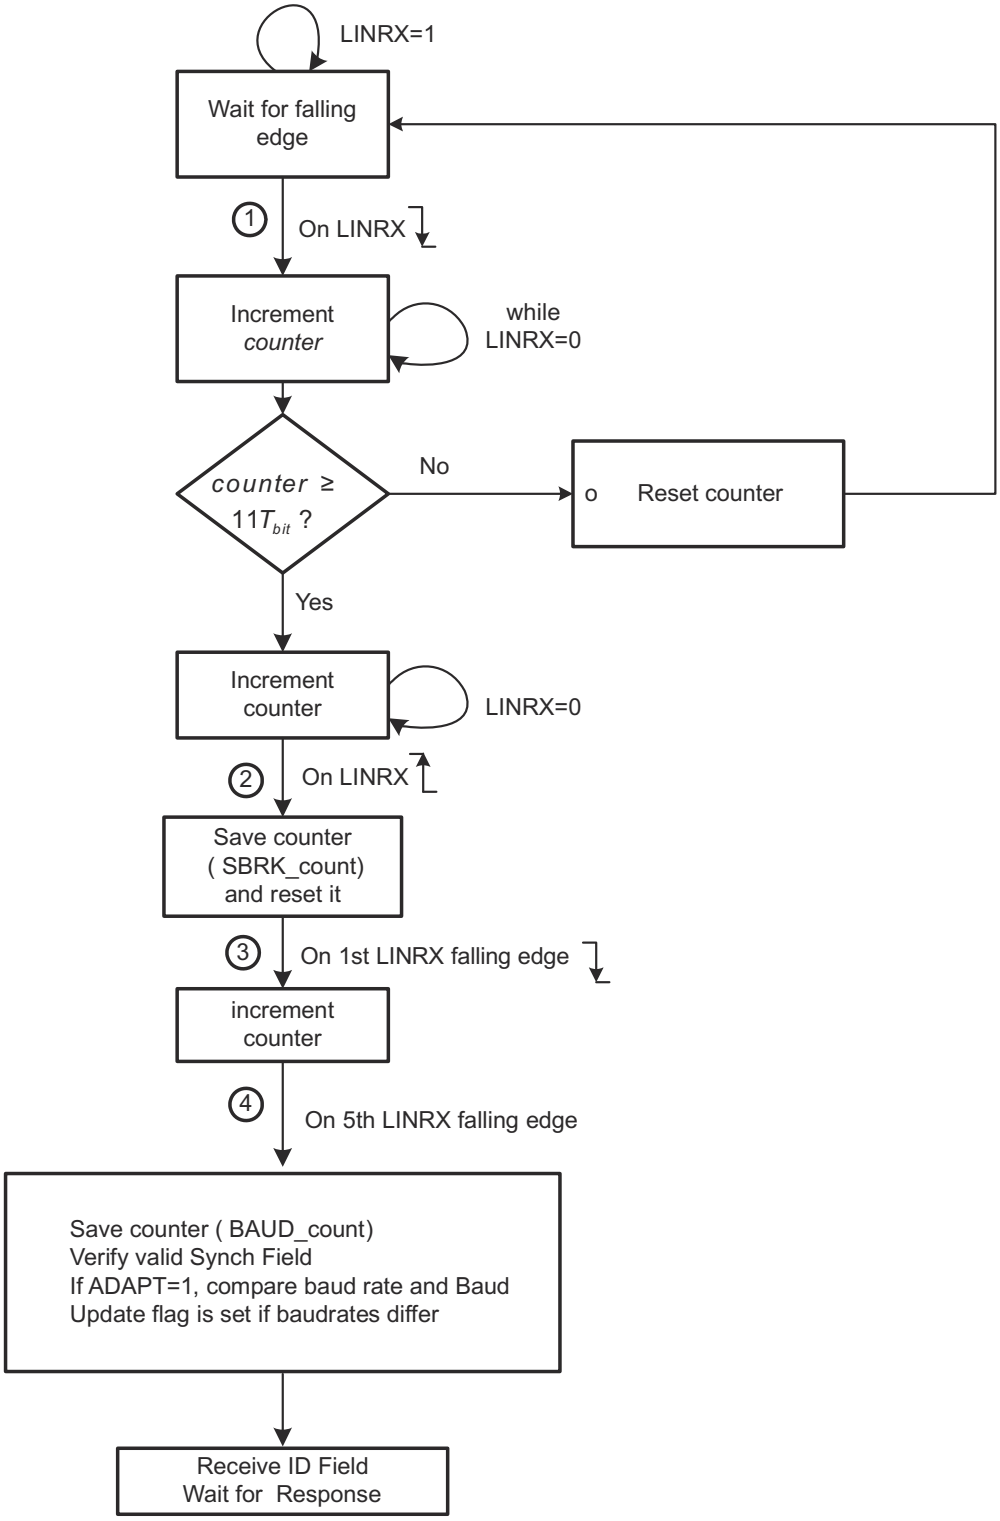

Figure 40-18. Synchronization Validation Process and Baud Rate Adjustment

If the synch field is not detected within the given tolerances, the inconsistent-sync-field-error (ISFE) flag is set. An ISFE interrupt is generated, if enabled by the respective bit in the SCISETINT register. The ID byte can be received after the synch field validation was successful. Any time a valid break (larger than 11 T_{bit}) is detected, the receiver state machine can reset to reception of this new frame. This reset condition is only valid during response state, not if an additional synch break occurs during header reception.

Note

When an inconsistent synch field (ISFE) error occurs, suggested action for the application is to reset the SWnRST bit and set the SWnRST bit to make sure that the internal state machines are back to the normal states.

40.3.1.6 Extended Frames Handling

The LIN protocol 2.0 and prior includes two extended frames with identifiers 62 (user-defined) and 63 (reserved extended). The response data length of the user-defined frame (ID 62, or 0x3E) is unlimited. The length for this identifier is set at network configuration time to be shared with the LIN bus nodes.

Extended frame communication is triggered on reception of a header with identifier 0x3E; see Figure 40-19. Once the extended frame communication is triggered, unlike normal frames, this communication needs to be stopped before issuing another header. To stop the extended frame communication the STOP EXT FRAME bit must be set.

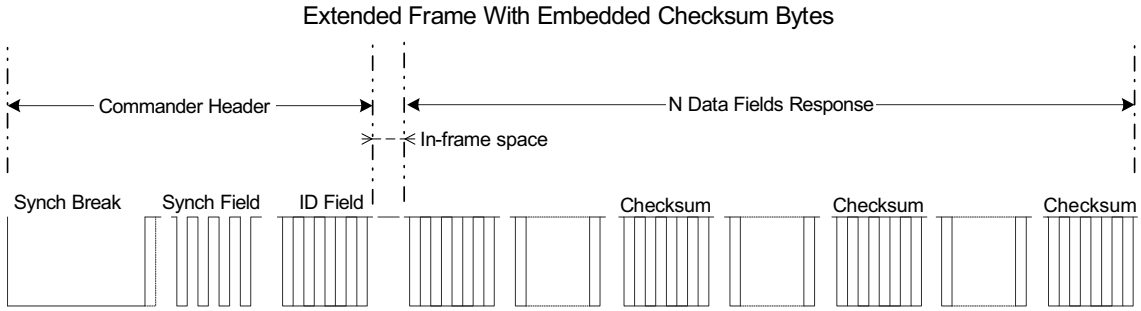

Figure 40-19. Optional Embedded Checksum in Response for Extended Frames

An ID interrupt is generated (if enabled and there is a match) on reception of ID 62 (0x3E). This interrupt allows the CPU using a software counter to keep track of the bytes that are being sent out and decides when to calculate and insert a checksum byte (recommended at periodic rates). To handle this procedure, SC bit is used. A write to the send checksum bit SC initiates an automatic send of the checksum byte. The last data field can always be a checksum in compliance with the LIN protocol.

The periodicity of the checksum insertion, defined at network configuration time, is used by the receiving node to evaluate the checksum of the ongoing message, and has the benefit of enhanced reliability.

For the sending node, the checksum is automatically embedded each time the send checksum bit SC is set. For the receiving node, the checksum is compared each time the compare checksum bit CC is set; see Figure 40-20.

Note

The LIN 2.0 enhanced checksum does not apply to the reserved identifiers. The reserved identifiers always use the classic checksum.

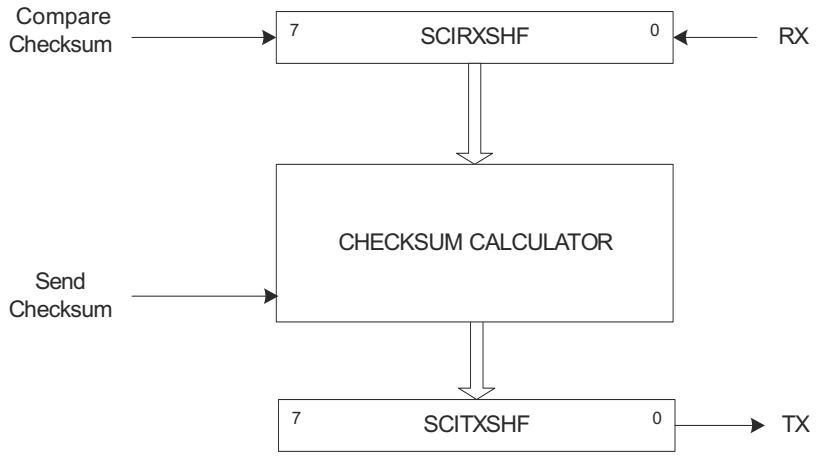

Figure 40-20. Checksum Compare and Send for Extended Frames

40.3.1.7 Timeout Control

Any LIN node listening to the bus and expecting a response initiated from a commander node can flag a no-response error timeout event. The LIN protocol defines four types of timeout events, which are all handled by the hardware of the LIN module. The four LIN protocol events are:

- No-response timeout error
- Bus idle detection
- Timeout after wakeup signal
- Timeout after three wakeup signals

40.3.1.7.1 No-Response Error (NRE)

The no-response error occurs when any node expecting a response waits for T_{FRAME_MAX} time and the message frame is not fully completed within the maximum length allowed, T_{FRAME_MAX}. After this time, a no-response error (NRE) is flagged in the NRE bit of the SCIFLR register. An interrupt is triggered, if enabled.

As specified in the LIN 1.3 standard, the minimum time to transmit a frame is:

$$T_{FRAME\_MIN} = T_{HEADER\_MIN} + T_{DATA\_FIELD} + T_{CHECKSUM\_FIELD} = 44 + 10N$$

where N = number of data fields.

And the maximum time frame is given by:

$$T_{FRAME\_MAX} = T_{FRAME\_MIN} * 1.4 = (44 + 10N) * 1.4$$

The timeout value T_{FRAME_MAX} is derived from the *N* number of data fields value, see Table 40-10. The *N* value is either embedded in the header ID field for messages or is part of the description file. In the latter case, the 3-bit CHAR value in SCIFORMAT register indicates the value for *N*.

Note

The length coding of the ID field does not apply to two extended frame identifiers, ID fields of 0x3E (62) and 0x3F (63). In these cases, the ID field can be followed by an arbitrary number of data byte fields. Also, the LIN 2.0 protocol specification mentions that ID field 0x3F (63) cannot be used. For these two cases, the NRE is not handled by the LIN hardware.

Table 40-10. Timeout Values in T_{bit} Units

N	T_{DATA_FIELD}	T_{FRAME_MIN}	T_{FRAME_MAX}
1	10	54	76
2	20	64	90
3	30	74	104
4	40	84	118
5	50	94	132
6	60	104	146
7	70	114	160
8	80	124	174

40.3.1.7.2 Bus Idle Detection

The second type of timeout can occur when a node detects an inactive LIN bus: no transitions between recessive and dominant values are detected on the bus. This happens after a minimum of 4 seconds (this is 80,000 F_{LINCLK} cycles with the fastest bus rate of 20kbps). If a node detects no activity in the bus as the TIMEOUT bit is set, assume that the LIN bus is in sleep mode. Application software can use the Timeout flag to determine when the LIN bus is inactive and put the LIN into sleep mode by writing the POWERDOWN bit.

Note

After the timeout was flagged, a SWnRESET must be asserted before entering Low-Power Mode. This is required to reset the receiver in case that an incomplete frame is on the bus before the idle period.

40.3.1.7.3 Timeout After Wakeup Signal and Timeout After Three Wakeup Signals

The third and fourth types of timeout are related to the wakeup signal. A node initiating a wakeup must expect a header from the commander within a defined amount of time: timeout after wakeup signal. See Section 40.4.3 for more details.

40.3.1.8 TXRX Error Detector (TED)

The following sources of error are detected by the TXRX error detector logic (TED). The TED logic consists of a bit monitor, an ID parity checker, and a checksum error. The following errors are detected:

- Bit errors (BE)
- Physical bus errors (PBE)
- Identifier parity errors (PE)
- Checksum errors (CE)

All of these errors (BE, PBE, PE, CE) are flagged. An interrupt for the flagged errors is generated if enabled. A message is valid for both the transmitter and the receiver if there is no error detected until the end of the frame.

40.3.1.8.1 Bit Errors

A bit error (BE) is detected at the bit time when the bit value that is monitored is different from the bit value that is sent. A bit error is indicated by the BE flag in SCIFLR. After signaling a BE, the transmission is aborted no later than the next byte. The bit monitor makes sure that the transmitted bit in LINTX is the correct value on the LIN bus by reading back on the LINRX pin as shown in Figure 40-21.

Note

If a bit occurs due to receiving a header during a responder response, NRE/TIMEOUT flag is not set for the new frame.

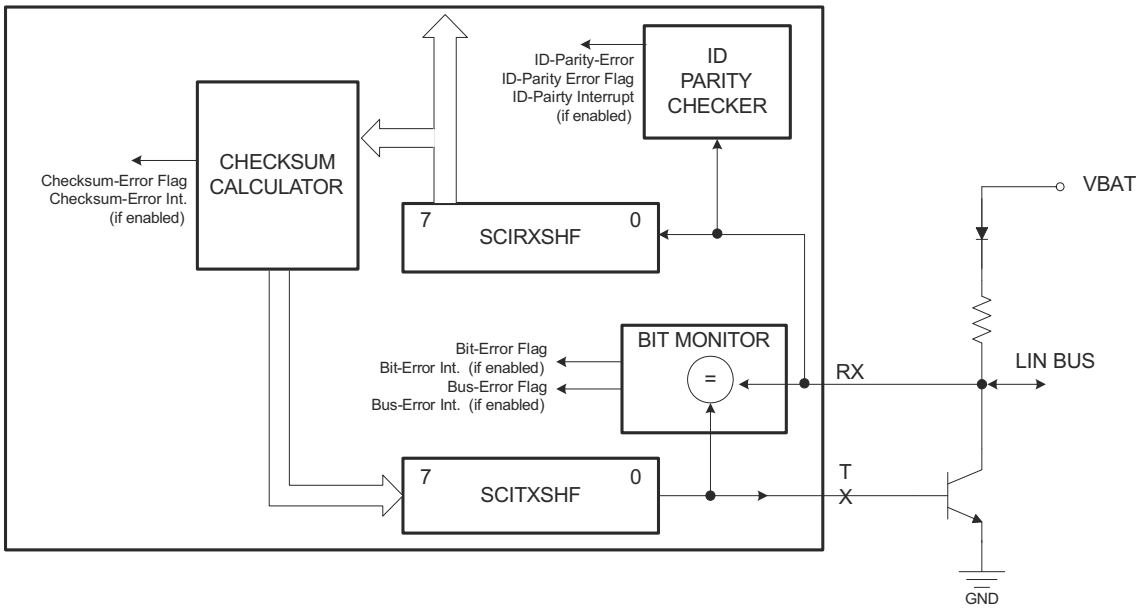

Figure 40-21. TXRX Error Detector

40.3.1.8.2 Physical Bus Errors

A Physical Bus Error (PBE) has to be detected by a commander, if no valid message can be generated on the bus (bus shorted to GND or VBAT). The bit monitor detects a PBE during the header transmission, if no Synch Break can be generated (for example, because of a bus shortage to VBAT) or if no Synch Break delimiter can be generated (for example, because of a bus shortage to GND). Once the Sync Break Delimiter was validated, all other deviations between the monitored and the sent bit value are flagged as Bit Errors (BE) for this frame.

40.3.1.8.3 ID Parity Errors

If parity is enabled, an ID parity error (PE) is detected if any of the two parity bits of the sent ID byte are not equal to the calculated parity on the receiver node. The two parity bits are generated using the following mixed parity algorithm:

$$P0 = ID0 \oplus ID1 \oplus ID2 \oplus ID4 \ (even\ Parity)$$
$$P1 = ID1 \oplus ID3 \oplus ID4 \oplus ID5 \ (odd\ Parity)$$

If an ID-parity error is detected, the ID-parity error is flagged, and the received ID is not valid. See Section 40.3.1.9 for details.

40.3.1.8.4 Checksum Errors

A checksum error (CE) is detected and flagged at the receiving end, if the calculated modulo-256 sum over all received data bytes (including the ID byte if the enhanced checksum type) plus the checksum byte does not result in 0xFF. The modulo-256 sum is calculated over each byte by adding with carry, where the carry bit of each addition is added to the LSB of the resulting sum.

For the transmitting node, the checksum byte sent at the end of a message is the inverted sum of all the data bytes (see Figure 40-22) for classic checksum implementation. The checksum byte is the inverted sum of the identifier byte and all the data bytes (see Figure 40-23) for the LIN 2.0 compliant enhanced checksum implementation. The classic checksum implementation can always be used for reserved identifiers 60 to 63; therefore, the CTYPE bit is overridden in this case. For signal-carrying-frame identifiers (0 to 59) the type of checksum used depends on the CTYPE bit.

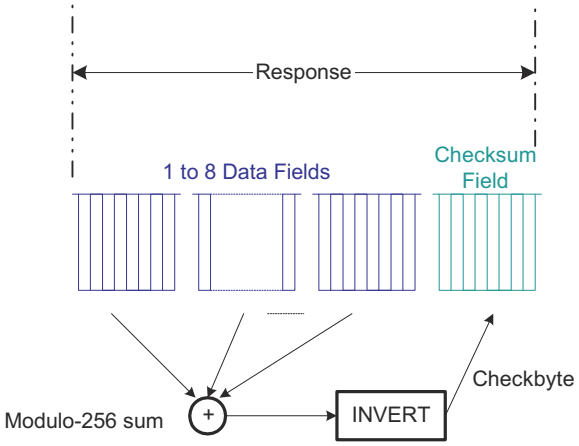

Figure 40-22. Classic Checksum Generation at Transmitting Node

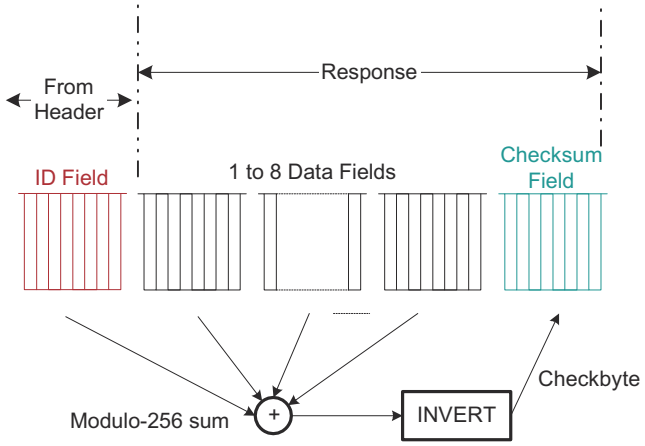

Figure 40-23. LIN 2.0-Compliant Checksum Generation at Transmitting Node

40.3.1.9 Message Filtering and Validation

Message filtering uses the entire identifier to determine which nodes participate in a response, either receiving or transmitting a response. Therefore, two acceptance masks are used as shown in Figure 40-24. During header reception, all nodes filter the ID-Field (ID-Field is the part of the header explained in Figure 40-16) to determine whether the nodes transmit a response or receive a response for the current message. There are two masks for message ID filtering: one to accept a response reception, the other to initiate a response transmission. See Figure 40-24. All nodes compare the received ID to the identifier stored in the ID-Responder Task BYTE of the LINID register and use the RX ID MASK and the TX ID MASK fields in the LINMASK register to filter the bits of the identifier that can not be compared.

If there is an RX match with no parity error and the RXENA bit is set, there is an ID RX flag and an interrupt is triggered if enabled. If there is a TX match with no parity error and the TXENA bit is set, there is an ID TX flag and an interrupt is triggered if enabled in the SCISETINT register.

The masked bits become "don't cares" for the comparison. To build a mask for a set of identifiers, an XOR function can be used.

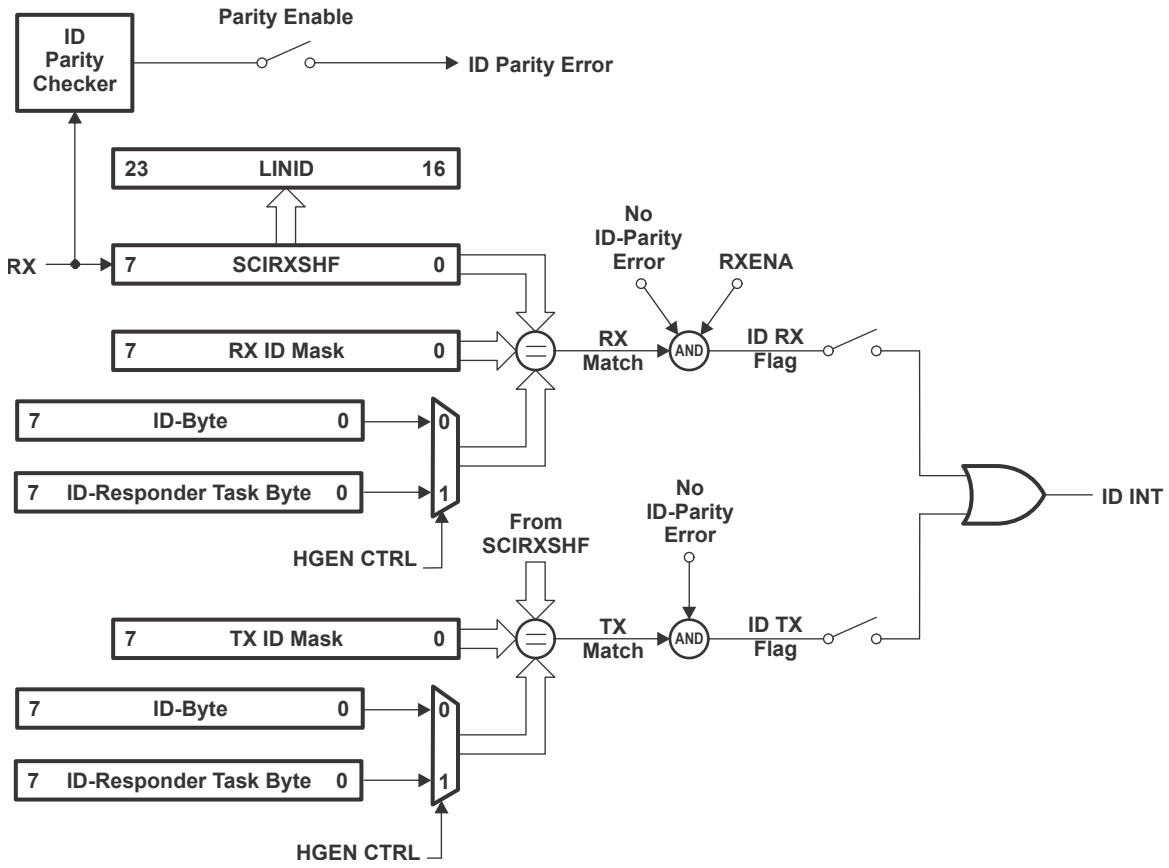

Figure 40-24. ID Reception, Filtering, and Validation

For example, to build a mask to accept IDs 0x26 and 0x25 using LINID[7:0] = 0x20; that is, compare 5 most-significant bits (MSBs) and filter 3 least-significant bits (LSBs), the acceptance mask can be:

$$(0x26 + 0x25) \oplus 0x20 = 0x07$$

A mask of all zeros compares all bits of the received identifier in the shift register with the ID-BYTE in LINID[7:0]. If HGEN CTRL is set to 1, a mask of 0xFF always causes a match. A mask of all 1s filters all bits of the received identifier, and thus there is an ID match regardless of the content of the ID-Responder Task BYTE field in the LINID register.

Note

When the HGEN CTRL bit = 0, the LIN nodes compare the received ID to the ID-BYTE field in the LINID register, and use the RX ID MASK and the TX ID MASK in the LINMASK register to filter the bits of the identifier that can not be compared.

If there is an RX match with no parity error and the RXENA bit is set, there is an ID RX flag and an interrupt is triggered if enabled. A mask of all 0s compares all bits of the received identifier in the shift register with the ID-BYTE field in LINID[7:0]. A mask of all 1s filters all bits of the received identifier and there is no match.

If HGEN CTLR = 1:

- Received ID is compared with the ID-Responder Task byte, using the RXID mask and the TXID mask.
- A mask of all 1s always result in a match.
- A mask of all 0s means all the bits must be the same to result in a match.
- If a mask has some bits that are 1s, then those bits are not used for the filtering criterion.

If HGEN CTRL = 0:

- Received ID is compared with the ID byte, using the RXID mask and the TXID mask.
- A mask of all 1s results in no match.
- A mask of all 0s means all the bits must be the same to result in a match.
- If a mask has some bits that are 1s, then those bits are not used for the filtering criterion.

During header reception, the received identifier is copied to the Received ID field LINID[23:16]. If there is no parity error and there is either a TX match or an RX match, then the corresponding TX or RX ID flag is set. If the ID interrupt is enabled, then an ID interrupt is generated.

After the ID interrupt is generated, the CPU can read the Received ID field LINID[23:16] and determine what response to load into the transmit buffers.

Note

When byte 0 is written to TD0 (LINTD0[31:24]), the response transmission is automatically generated.

In multibuffer mode, the TXRDY flag is set when all the response data bytes and checksum byte are copied to the shift register SCITXSHF. In non-multibuffer mode, the TXRDY flag is set each time a byte is copied to the SCITXSHF register, and also for the last byte of the frame after the checksum byte is copied to the SCITXSHF register.

In multibuffer mode, the TXEMPTY flag is set when both the transmit buffers TDy and the SCITXSHF shift register are emptied and the checksum has been sent. In non-multibuffer mode, TXEMPTY is set each time TD0 and SCITXSHF are emptied, except for the last byte of the frame where the checksum byte must also be transmitted.

If parity is enabled, all responder receiving nodes validate the identifier using all eight bits of the received ID byte. The SCI/LIN flags a corrupted identifier if an ID-parity error is detected.

40.3.1.10 Receive Buffers

To reduce CPU load when receiving a LIN N-byte (with N = 1–8) response in interrupt mode or RTDMA mode, the SCI/LIN module has eight receive buffers. These buffers can store an entire LIN response in the RDy receive buffers. Figure 40-8 illustrates the receive buffers.

The checksum byte following the data bytes is validated by the internal checksum calculator. The checksum error (CE) flag indicates a checksum error and a CE interrupt is generated if enabled in the SCISETINT register.

The multibuffer 3-bit counter counts the data bytes transferred from the SCIRXSHF register to the RDy receive buffers if multibuffer mode is enabled, or to RD0 if multibuffer mode is disabled. The 3-bit compare register contains the number of data bytes expected to be received. In cases where the IDBYTE field does not convey message length (see *Note: Optional Control Length Bits* in Section 40.3.1.5), the LENGTH value, indicates the expected length and is used to load the 3-bit compare register. Whether the length control field or the LENGTH value is used is selectable with the COMMMODE bit.

A receive interrupt, and a receive ready RXRDY flag , and a RTDMA request (RXDMA) can occur after receiving a response, if there are no response receive errors for the frame (such as, there is no checksum error, frame error, and overrun error). The checksum byte is compared before acknowledging a reception. A RTDMA request can be generated for each received byte or for the entire response depending on whether the multibuffer mode is enabled or not (MBUFMODE bit).

Note

In multibuffer mode following are the scenarios associated with clearing the RXRDY flag bit:

1. The RXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0/1 register.
2. For LENGTH less than or equal to 4, Read to RD0 register clears the RXRDY flag.
3. For LENGTH greater than 4, Read to RD1 register clears the RXRDY flag.

40.3.1.11 Transmit Buffers

To reduce the CPU load when transmitting a LIN N-byte (with N = 1–8) response in interrupt modeor RTDMA mode, the SCI/LIN module has 8 transmit buffers, TD0–TD7 in LINTD0 and LINTD1. With these transmit buffers, an entire LIN response field can be preloaded in the TDy transmit buffers. Optionally, a RTDMA transfer can be done on a byte-per-byte basis when multibuffer mode is not enabled (MBUFMODE bit). Figure 40-9 illustrates the transmit buffers.

The multibuffer 3-bit counter counts the data bytes transferred from the TDy transmit buffers register if multibuffer mode is enabled, or from TD0 to SCITXSHF if multibuffer mode is disabled. The 3-bit compare register contains the number of data bytes expected to be transmitted. If the ID field is not used to convey message length (see *Note: Optional Control Length Bits* in Section 40.3.1.5), the LENGTH value indicates the expected length and is used instead to load the 3-bit compare register. Whether the length control field or the LENGTH value is used is selectable with the COMMMODE bit.

A transmit interrupt (TX interrupt) and a transmit ready flag (TXRDY flag), as well as a RTDMA request (TXDMA) can occur after transmitting a response.A RTDMA request can be generated for each transmitted byte or for the entire response depending on whether multibuffer mode is enabled or not (MBUFMODE bit).

The checksum byte is automatically generated by the checksum calculator and sent after the data-fields transmission is finished. The multibuffer 3-bit counter counts the data bytes transferred from the TDy buffers into the SCITXSHF register.

Note

The transmit interrupt request can be eliminated until the next series of data is written into the transmit buffers LINTD0 and LINTD1, by disabling the corresponding interrupt using the SCICLRINT register or by disabling the transmitter using the TXENA bit.

40.3.2 LIN Interrupts

LIN and SCI modes have a common interrupt block, as explained in Section 40.2.2. There are 16 interrupt sources in the SCI/LIN module, with 8 of them being LIN mode only, as seen in Table 40-4.

A LIN message frame indicating the timing and sequence of the LIN interrupts that can occur is shown in Figure 40-25.

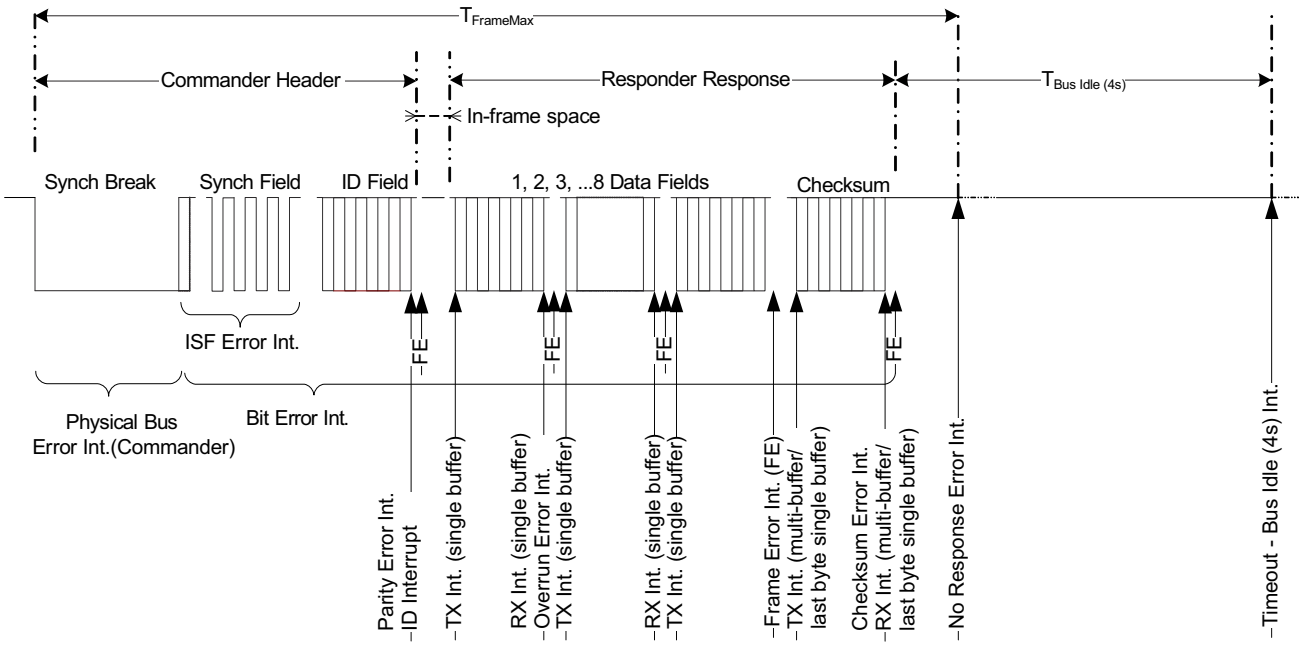

Figure 40-25. LIN Message Frame Showing LIN Interrupt Timing and Sequence

40.3.3 Servicing LIN Interrupts

When servicing an interrupt, clear the corresponding flag in the flag register (SCIFLR) before clearing the global interrupt (LIN_GLB_INT_CLR). The ISR can follow the guidelines below. This prevents any spurious or duplicate interrupt from occurring.

- Clear the LIN interrupt flag in the SCIFLR register.
- Read the LIN interrupt status register to make sure the flag is cleared.
- Clear the global interrupt flag bit in LIN_GLB_INT_CLR.

Note

The transmit interrupt is generated before the LIN transmitter is ready to accept new data. Inside of the LIN transmit ISR, the software can wait until the buffer is completely empty before loading the next data. This can be done by polling for the Bus Busy Flag (SCIFLR.BUSY) to be 0.

40.3.4 LIN RTDMA Interface

The LIN RTDMA interface uses the SCI RTDMA interface logic. RTDMA requests for receive (RXDMA request) and transmit (TXDMA request) are available for the SCI/LIN module. There are two modes for RTDMA transfers depending on whether multibuffer mode is enabled or not using the multibuffer enable control bit (MBUFMODE).

Note

Do not use the RTDMA to transmit data to multiple peripheral IDs. Writing to the LINID register initiates a new transmission. The RTDMA writes to the LINID register before the LIN state machine is ready to accept the new ID. Doing so causes the LIN to miss this transmission.

40.3.4.1 LIN Receive RTDMA Requests

In LIN mode, when the multibuffer option is enabled, if a received response (up to eight data bytes) is transferred to the receive buffers (RDy), then a RTDMA request is generated. If the multibuffer option is disabled, then RTDMA requests are generated on a byte-per-byte basis until all the expected response data fields are received. This RTDMA functionality is enabled and disabled using the SET_RX_DMA and CLRRXDMA bits, respectively.

40.3.4.2 LIN Transmit RTDMA Requests

In LIN mode with the multibuffer option enabled, after a transmission (up to eight data bytes stored in the transmit buffers (TDy) in the LINTD0 and LINTD1 registers), a RTDMA request is generated to reload the transmit buffer for the next transmission. If the multibuffer option is disabled, then RTDMA requests are generated on a byte-per-byte basis until all bytes are transferred. This RTDMA functionality is enabled and disabled using the SET_TX_DMA and CLRTXDMA bits, respectively.

40.3.5 LIN Configurations

The following list details the configuration steps that software can perform prior to the transmission or reception of data in LIN mode. As long as the SWnRST bit in the SCIGCR1 register is cleared to 0 the entire time that the LIN is being configured, the order in which the registers are programmed is not important.

- Enable LIN by setting RESET bit (SCIGCR0.0).
- Clear SWnRST to 0 before configuring the LIN (SCIGCR1.7).
- Enable the LINRX and LINTX pins by setting the RXFUNC and TXFUNC bits.
- Select LIN mode by programming the LINMODE bit (SCIGCR1.6).
- Select commander or responder mode by programming the CLOCK bit.
- Select the desired frame format (checksum, parity, length control) by programming SCIGCR1.
- Select multibuffer mode by programming MBUFMODE bit (SCIGCR1.10).
- Select the baud rate to be used for communication by programming BRSR.
- Set the maximum baud rate to be used for communication by programming MBRSR.
- Set the CONT bit to make LIN not halt for an emulation breakpoint until the LIN current reception or transmission is complete (this bit is used only in an emulation environment).
- Set LOOPBACK bit (SCIGCR1.16) to connect the transmitter to the receiver internally if needed (this feature is used to perform a self-test).
- Select the receiver enable RXENA bit (SCIGCR1.24), if data is to be received.
- Select the transmit enable TXENA bit (SCIGCR1.25), if data is to be transmitted.
- Select the RXIDMASK and the TXIDMASK fields in the LINMASK register.
- Set SWnRST (SCIGCR1.7) to 1 after the LIN is configured.
- Receive or Transmit data (see Section 40.3.1.9, Section 40.3.5.1, and Section 40.3.5.2).

Note

If TXENA is set and the SWnRST is released, the LIN immediately generates a new RTDMA request but not a new transmit interrupt request. If using interrupts, the first transmission must be started with software by writing data to the transmit buffer, followed by writing the chosen ID to the LINID register to initiate the transmission.

40.3.5.1 Receiving Data

The LIN receiver is enabled to receive messages if both the RXFUNC bit and the RXENA bit are set to 1. If the RXFUNC bit is not set, the LINRX pin functions as a general-purpose I/O pin rather than as a LIN function pin.

The IDRXFLAG in the SCIFLR register is set after a valid LINID is received with an RX Match. An ID interrupt is then generated, if enabled.

40.3.5.1.1 Receiving Data in Single-Buffer Mode

Single-buffer mode is selected when the MBUFMODE bit is cleared to 0. In this mode, LIN sets the RXRDY bit when the LIN transfers newly received data from SCIRXSHF to RD0. The SCI clears the RXRDY bit after the new data in RD0 has been read. Also, as data is transferred from SCIRXSHF to RD0, the LIN sets the FE, OE, or PE flags if any of these error conditions were detected in the received data. These error conditions are supported with configurable interrupt capability.

You can receive data by:

1. Polling Receive Ready Flag
2. Receive Interrupt
3. RTDMA

In polling method, software can poll for the RXRDY bit and read the data from RD0 byte of the LINRD0 register once the RXRDY bit is set high. The CPU is unnecessarily overloaded by selecting the polling method. To avoid this, you can use the interrupt or RTDMA method. To use the interrupt method, the SETRXINT bit is set. To use the RTDMA method, the SET_RX_DMA bit must be set. Either an interrupt or a RTDMA request is generated the moment the RXRDY bit is set. If the checksum scheme is enabled by setting the Compare Checksum (CC) bit to 1, the checksum is compared on the byte that is currently being received, which is expected to be the checksum byte. The CC bit is cleared once the checksum is received. A CE is immediately flagged, if there is a checksum error.

40.3.5.1.2 Receiving Data in Multibuffer Mode

Multibuffer mode is selected when the MBUFMODE bit is set to 1. In this mode, LIN sets the RXRDY bit after receiving the programmed number of data in the receive buffer and the checksum field, the complete frame. The error condition detection logic is similar to the single-buffer mode, except that this logic monitors for the complete frame. Like single-buffer mode, you can use the polling, RTDMA, or interrupt method to read the data. The received data has to be read from the LINRD0 and LINRD1 registers, based on the number of bytes. For a LENGTH less than or equal to 4, a read from the LINRD0 register clears the RXRDY flag. For a LENGTH greater than 4, a read from the LINRD1 register clears the RXRDY flag. If the checksum scheme is enabled by setting the Compare Checksum (CC) bit to 1 during the reception of the data, then the byte that is received after the reception of the programmed number of data bytes indicated by the LENGTH field is treated as a checksum byte. The CC bit is cleared once the checksum is received and compared.

40.3.5.2 Transmitting Data

The LIN transmitter is enabled if both the TXFUNC bit and the TXENA bit are set to 1. If the TXFUNC bit is not set, the LINTX pin functions as a general-purpose I/O pin rather than as a LIN function pin. Any value written to the TD0 before the TXENA bit is set to 1 is not transmitted. Both of these control bits allow for the LIN transmitter to be held inactive independently of the receiver.

The IDTXFLAG bit in the SCIFLR register is set after a valid LIN ID is received with a TX Match. An ID interrupt is then generated, if enabled.

40.3.5.2.1 Transmitting Data in Single-Buffer Mode

Single-buffer mode is selected when the MBUFMODE bit is cleared to 0. In this mode, LIN waits for data to be written to TD0, transfers the data to SCITXSHF, and transmits the data. The TXRDY and TXEMPTY bits indicate the status of the transmit buffers. That is, when the transmitter is ready for data to be written to TD0, the TXRDY bit is set. Additionally, if both TD0 and SCITXSHF are empty, then the TXEMPTY bit is also set.

You can transmit data by:

1. Polling Transmit Ready Flag
2. Transmit Interrupt
3. RTDMA

In polling method, software can poll for the TXRDY bit to go high before writing the data to the TD0. The CPU is unnecessarily overloaded by selecting the polling method. To avoid this, you can use the interrupt or RTDMA method. To use the interrupt method, the SETXINT bit is set. To use the RTDMA method, the SET_TX_DMA bit is set. Either an interrupt or a RTDMA request is generated the moment the TXRDY bit is set. When the LIN has completed transmission of all pending frames, the SCITXSHF register and the TD0 are empty, the TXRDY bit is set, and an interrupt/RTDMA request is generated, if enabled. Because all data has been transmitted, the interrupt/RTDMA request can be halted. This can either be done by disabling the transmit interrupt (CLRTXINT)/ RTDMA request (CLRTXDMA bit) or by disabling the transmitter (clear TXENA bit). If the checksum scheme is enabled by setting the Send Checksum (SC) bit to 1, the checksum byte is sent after the current byte transmission. The SC bit is cleared after the checksum byte has been transmitted.

Note

The TXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0 or SCIINTVECT1 register.

40.3.5.2.2 Transmitting Data in Multibuffer Mode

Multibuffer mode is selected when the MBUFMODE bit is set to 1. Like single-buffer mode, you can use the polling, RTDMA, or interrupt method to write the data to be transmitted. The transmitted data has to be written to the LINTD0 and LINTD1 registers, based on the number of bytes. LIN waits for data to be written to Byte 0 (TD0) of the LINTD0 register and transfers the programmed number of bytes to SCITXSHF to transmit one by one automatically. If the checksum scheme is enabled by setting the Send Checksum (SC) bit to 1, the checksum is sent after transmission of the last byte of the programmed number of data bytes, indicated by the LENGTH field. The SC bit is cleared after the checksum byte has been transmitted.

40.4 Low-Power Mode

The SCI/LIN module can be put in either local or global low-power mode. Global low-power mode is asserted by the system and is not controlled by the SCI/LIN module. During global low-power mode, all clocks to the SCI/LIN are turned off so the module is completely inactive. If global low-power mode is requested while the receiver is receiving data, then the SCI/LIN completes the current reception and then enters the low-power mode, that is, module enters low-power mode only when Busy bit (SCIFLR.3) is cleared.

The LIN module can enter low-power mode either when there was no activity on the LINRX pin for more than 4 seconds (this can be either a constant recessive or dominant level) or when a Sleep Command frame was received. Once the Timeout flag (SCIFLR.4) was set or once a Sleep Command was received, the POWERDOWN bit (SCIGCR2.0) must be set by the application software to make the module enter local low-power mode. A wakeup signal terminates the sleep mode of the LIN bus.

Note

Enabling Local Low-Power Mode During Receive and Transmit

If the wakeup interrupt is enabled and low-power mode is requested while the receiver is receiving data, then the SCI/LIN immediately generates a wakeup interrupt to clear the power-down bit. Thus, the SCI/LIN is prevented from entering low-power mode and completes the current reception. Otherwise, if the wakeup interrupt is disabled, the SCI/LIN completes the current reception and then enters the low-power mode.

40.4.1 Entering Sleep Mode

In LIN protocol, a sleep command is used to broadcast the sleep mode to all nodes. The sleep command consists of a diagnostic commander request frame with identifier 0x3C (60), with the first data field as 0x00. There must be no activity in the bus once all nodes receive the sleep command: the bus is in sleep mode.

Local low-power mode is asserted by setting the POWERDOWN bit; setting this bit stops the clocks to the SCI/LIN internal logic and registers. Clearing the POWERDOWN bit causes SCI/LIN to exit from local low-power mode. All the registers are accessible during local power-down mode. If a register is accessed in low-power mode, this access results in enabling the clock to the module for that particular access alone.

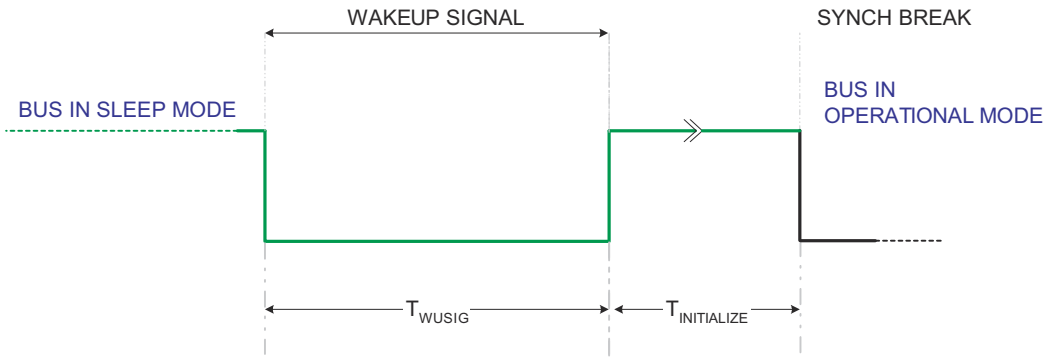
40.4.2 Wakeup

The wakeup interrupt is used to allow the SCI/LIN module to automatically exit a low-power mode. A SCI/LIN wakeup is triggered when a low level is detected on the receive RX pin, and this clears the POWERDOWN bit.

Note

If the wakeup interrupt is disabled, then the SCI/LIN enters low-power mode whenever the SCI/LIN is requested to do so, but a low level on the receive RX pin does not cause the SCI/LIN to exit low-power mode.

In LIN mode, any node can terminate sleep mode by sending a wakeup signal, see Figure 40-26. A responder node that detects the bus in sleep mode, and with a wakeup request pending, sends a wakeup signal. The wakeup signal is a dominant value on the LIN bus for T_{WUSIG}; this is at least 5 T_{bits} for the LIN bus baud rates. The wakeup signal is generated by sending a 0xF0 byte containing 5 dominant T_{bits} and 5 recessive T_{bits}.



0.25ms ≤ T_{WUSIG} ≤ 5ms

Figure 40-26. Wakeup Signal Generation

Assuming a bus with no noise or loading effects, a write of 0xF0 to TD0 loads the transmitter to meet the wakeup signal timing requirement for T_{WUSIG}. Then, setting the GENWU bit transmits the preloaded value in TD0 for a wakeup signal transmission.

Note

The GENWU bit can be set/reset only when SWnRST is set to 1 and the node is in power-down mode. The bit is cleared on a valid synch break detection. A commander sending a wakeup request, exits power-down mode upon reception of the wakeup pulse. The bit is cleared on a SWnRST. This can be used to stop a commander from sending further wakeup requests.

The TI TPIC1021 LIN transceiver, upon receiving a wakeup signal, translates it to the microcontroller for wakeup with a dominant level on the RX pin, or a signal to the voltage regulator. While the POWERDOWN bit is set, if the LIN module detects a recessive-to-dominant edge (falling edge) on the RX pin, the LIN module generates a wakeup interrupt if enabled in the SCISETINT register.

According to LIN protocol 2.0, the TI TPIC1021 LIN transceiver detecting a dominant level on the bus longer than 150ms detects it as a wakeup request. The LIN responder is ready to listen to the bus in less than 100ms ($T_{INITIALIZE}$<100ms) after a dominant-to-recessive edge (end-of-wakeup signal).

40.4.3 Wakeup Timeouts

The LIN protocol defines the following timeouts for a wakeup sequence. After a wakeup signal has been sent to the bus, all nodes wait for the commander to send a header. If no synch field is detected before 150ms (3,000 cycles at 20kHz) after a wakeup signal is transmitted, a new wakeup is sent by the same node that requested the first wakeup. This sequence is not repeated more than two times. After three attempts to wake up the LIN bus, wakeup signal generation is suspended for a 1.5s (30,000 cycles at 20kHz) period after three breaks.

Note

To achieve compatibility to LIN1.3 timeout conditions, the MBRS register must be set to make sure that the LIN 2.0 (real-time-based) timings meet the LIN 1.3 bit time base. A node triggering the wakeup can set the MBRS register accordingly to meet the targeted time as 128 Tbits × programmed prescaler.

The LIN handles the wakeup expiration times defined by the LIN protocol with a hardware implementation.

40.5 Emulation Mode

In emulation mode, the CONT bit determines how the SCI/LIN operates when the program is suspended. The SCI/LIN counters are affected by this bit during debug mode. when set, the counters are not stopped and when cleared, the counters are stopped debug mode.

Any reads in emulation mode to a SCI/LIN register do not have any effect on the flags in the SCIFLR register.

Note

When emulation mode is entered during the Frame transmission or reception of the frame and CONT bit is not set, Communication is not expected to be successful. The suggested usage is to set CONT bit during emulation mode for successful communication.

40.6.2 LIN Examples

NOTE: These examples are located in the C29SDK installation from ti.com at the following location: mcu_sdk_DEVICE_GPN/examples/driverlib/CORE_IF_MULTICORE/lin

Cloud access to these examples is available at the following link: dev.ti.com C29SDK Examples.

40.6.2.1 LIN Internal Loopback with Interrupts - SINGLE_CORE

FILE: lin_ex1_loopback_interrupt.c

This example configures the LIN module in commander mode for internal loopback with interrupts. The module is setup to perform 8 data transmissions with different transmit IDs and varying transmit data. Upon reception of an ID header, an interrupt is triggered on line 0 and an interrupt service routine (ISR) is called. The received data is then checked for accuracy.

External Connections

- None.

Watch Variables

- txData - An array with the data being sent
- rxData - An array with the data that was received
- result - The example completion status (PASS = 0xABCD, FAIL = 0xFFFF)

- level0Count - The number of line 0 interrupts
- level1Count - The number of line 1 interrupts

40.6.2.2 LIN SCI Mode Internal Loopback with Interrupts - SINGLE_CORE

FILE: lin_ex2_sci_loopback.c

This example configures the LIN module in SCI mode for internal loopback with interrupts. The LIN module performs as a SCI with a set character and frame length in a non-multi-buffer mode. The module is setup to continuously transmit a character, wait to receive that character, and repeat.

External Connections

- None.

Watch Variables

- rxCount - The number of RX interrupts
- transmitChar - The character being transmitted
- receivedChar - The character received

40.6.2.3 LIN SCI MODE Internal Loopback with DMA - SINGLE_CORE

FILE: lin_ex3_sci_dma.c

This example configures the LIN module in SCI mode for internal loopback with the use of the DMA. The LIN module performs as SCI with a set character and frame length in multi-buffer mode. When the transmit buffers in the LINTD0 and LINTD1 registers have enough space, the DMA will transfer data from global variable sData into those transmit registers. Once the received buffers in the LINRD0 and LINRD1 registers contain data,the DMA will transfer the data into the global variable rdata.

When all data has been placed into rData, a check of the validity of the data will be performed in one of the DMA channels' ISRs.

External Connections

- None

Watch Variables

- *sData* - Data to send
- *rData* - Received data

40.6.2.4 LIN Internal Loopback without interrupts (polled mode) - SINGLE_CORE

FILE: lin_ex4_loopback_polling.c

This example configures the LIN module in commander mode for internal loopback without interrupts. The module is setup to perform 8 data transmissions with different transmit IDs and varying transmit data. Waits for reception of an ID header. The received data is then checked for accuracy.

External Connections

- None.

Watch Variables

- txData - An array with the data being sent
- rxData - An array with the data that was received
- result - The example completion status (PASS = 0xABCD, FAIL = 0xFFFF)

40.6.2.5 LIN SCI MODE (Single Buffer) Internal Loopback with DMA - SINGLE_CORE

FILE: lin_ex5_sci_dma_single_buffer.c

This example configures the LIN module in SCI mode for internal loopback with the use of the DMA. The LIN module performs as SCI with a set character and frame length in single-buffer compatibility mode. When the transmit buffer i.e. the SCITD register is free, the DMA will transfer data from global variable sData into this

register. Once the received buffer, i.e. the SCIRD register contains data, the DMA will transfer the data into the global variable rdata.

When all data has been placed into rData, a check of the validity of the data will be performed in one of the DMA channels' ISRs.

External Connections

- None

Watch Variables

- *sData* - Data to send
- *rData* - Received data

40.7 LIN Registers

This Section describes the LIN Registers.

40.7.1 LIN Base Address Table

Table 40-12. LIN Base Address Table

Structure	DriverLib Name	Base Address	Frame Applicable	CPU1	CPU2	CPU3	RTDMA1	RTDMA2	HSM	Pipeline Protected
LIN_REGS	LINA_BASE	0x6006_0000	YES	YES	YES	YES	YES	YES	-	YES
LIN_REGS	LINB_BASE	0x6006_1000	YES	YES	YES	YES	YES	YES	-	YES

40.7.2 LIN_REGS Registers

Table 40-13 lists the memory-mapped registers for the LIN_REGS registers. All register offset addresses not listed in Table 40-13 should be considered as reserved locations and the register contents should not be modified.

Table 40-13. LIN_REGS Registers

Offset	Acronym	Register Name	Protection
0h	SCIGCR0	Global Control Register 0	
4h	SCIGCR1	Global Control Register 1	
8h	SCIGCR2	Global Control Register 2	
Ch	SCISETINT	Interrupt Enable Register	
10h	SCICLEARINT	Interrupt Disable Register	
14h	SCISETINTLVL	Set Interrupt Level Register	
18h	SCICLEARINTLVL	Clear Interrupt Level Register	
1Ch	SCIFLR	Flag Register	
20h	SCIINTVECT0	Interrupt Vector Offset Register 0	
24h	SCIINTVECT1	Interrupt Vector Offset Register 1	
28h	SCIFORMAT	Length Control Register	
2Ch	BRSR	Baud Rate Selection Register	
30h	SCIED	Emulation buffer Register	
34h	SCIRD	Receiver data buffer Register	
38h	SCITD	Transmit data buffer Register	
3Ch	SCIPIO0	Pin control Register 0	
44h	SCIPIO2	Pin control Register 2	
60h	LINCOMP	Compare register	
64h	LINRD0	Receive data register 0	
68h	LINRD1	Receive data register 1	
6Ch	LINMASK	Acceptance mask register	
70h	LINID	LIN ID Register	
74h	LINTD0	Transmit Data Register 0	
78h	LINTD1	Transmit Data Register 1	
7Ch	MBRSR	Maximum Baud Rate Selection Register	
90h	IODFTCTRL	IODFT for LIN	
E0h	LIN_GLB_INT_EN	LIN Global Interrupt Enable Register	
E4h	LIN_GLB_INT_FLG	LIN Global Interrupt Flag Register	
E8h	LIN_GLB_INT_CLR	LIN Global Interrupt Clear Register	

Complex bit access types are encoded to fit into small table cells. Table 40-14 shows the codes that are used for access types in this section.

Table 40-14. LIN_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear

Table 40-14. LIN_REGS Access Type Codes (continued)

Access Type	Code	Description
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

40.7.2.1 SCIGCR0 Register (Offset = 0h) [Reset = 00000000h]

SCIGCR0 is shown in Figure 40-27 and described in Table 40-15.

Return to the Summary Table.

The SCIGCR0 register defines the module reset.

31-16	RESERVED	R	0h	Reserved
15-1	RESERVED	R	0h	Reserved
0	RESET	R/W	0h	This bit resets the SCI/LIN module. This bit is effective in LIN or SCI-compatible mode.. This bit affects the reset state of the SCI/LIN module. Reset type: SYSRSn 0h (R/W) = SCI/LIN module is in held in reset. 1h (R/W) = SCI/LIN module is out of reset.

40.7.2.2 SCIGCR1 Register (Offset = 4h) [Reset = 00000000h]

SCIGCR1 is shown in Figure 40-28 and described in Table 40-16.

Return to the Summary Table.

The SCIGCR1 register defines the frame format, protocol, and communication mode used by the SCI.

Figure 40-28. SCIGCR1 Register

Table 40-16. SCIGCR1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-26	RESERVED	R	0h	Reserved
25	TXENA	R/W	0h	Transmit enable. This bit is effective in LIN and SCI modes. Data is transferred from SCITD or the TDy (with y=0, 1,...7) buffers in LIN mode to the SCITXSHF shift out register only when the TXENA bit is set. Note: Data written to SCITD or the transmit multi-buffer before TXENA is set is not transmitted. If TXENA is cleared while transmission is ongoing, the data previously written to SCITD is sent (including the checksum byte in LIN mode). Reset type: SYSRSn 0h (R/W) = Disable transfers from SCITD or TDy to SCITXSHF 1h (R/W) = Enable transfers of data from SCITD or TDy to SCITXSHF

Table 40-16. SCIGCR1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
24	RXENA	R/W	0h	Receive enable. This bit is effective in LIN or SCI-compatible mode. RXENA allows or prevents the transfer of data from SCIRXSHF to SCIRD or the receive multibuffers. Note: Clearing RXENA stops received characters from being transferred into the receive buffer or multi-buffers, prevents the RX status flags (see Table 7) from being updated by receive data, and inhibits both receive and error interrupts. However, the shift register continues to assemble data regardless of the state of RXENA. Note: If RXENA is cleared before the time the reception of a frame is complete, the data from the frame is not transferred into the receive buffer. Note: If RXENA is set before the time the reception of a frame is complete, the data from the frame is transferred into the receive buffer. If RXENA is set while SCIRXSHF is in the process of assembling a frame, the status flags are not guaranteed to be accurate for that frame. To ensure that the status flags correctly reflect what was detected on the bus during a particular frame, RXENA should be set before the detection of that frame Reset type: SYSRSn 0h (R/W) = Prevents the receiver from transferring data from the shift buffer to the receive buffer or multi-buffers 1h (R/W) = Allows the receiver to transfer data from the shift buffer to the receive buffer or multi-buffers
23-18	RESERVED	R	0h	Reserved
17	CONT	R/W	0h	Continue on suspend. This bit has an effect only when a program is being debugged with an emulator, and it determines how the SCI/LIN operates when the program is suspended. This bit affects the LIN counters. When this bit is set, the counters are not stopped during debug. When this bit is cleared, the counters are stopped during debug. Reset type: SYSRSn 0h (R/W) = When debug mode is entered, the SCI/LIN state machine is frozen. Transmissions and LIN counters are halted and resume when debug mode is exited. 1h (R/W) = When debug mode is entered, the SCI/LIN continues to operate until the current transmit and receive functions are complete.
16	LOOPBACK	R/W	0h	Loopback bit. This bit is effective in LIN or SCI-compatible mode. The self-checking option for the SCI/LIN can be selected with this bit. If the LINTX and LINRX pins are configured with SCI/LIN functionality, then the LINTX pin is internally connected to the LINRX pin. Externally, during loop back operation, the LINTX pin outputs a high value and the LINRX pin is in a high-impedance state. If this bit value is changed while the SCI/LIN is transmitting or receiving data, errors may result. Reset type: SYSRSn 0h (R/W) = Loopback mode is disabled. 1h (R/W) = Loopback mode is enabled.
15-14	RESERVED	R	0h	Reserved
13	STOPEXTFRAME	R/W	0h	Stop extended frame communication. This bit is effective in LIN mode only. This bit can be written only during extended frame communication. When the extended frame communication is stopped, this bit is cleared automatically. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Extended frame communication will be stopped, once current frame transmission/reception is completed.

Table 40-16. SCIGCR1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
12	HGENCTRL	R/W	0h	HGEN control bit. This bit is effective in LIN mode only. This bit controls the type of mask filtering comparison. Reset type: SYSRSn 0h (R/W) = ID filtering using ID-Byte. RECEIVEDID and IDBYTE fields in the LINID register are used for detecting a match (using TX/RXMASK values). Mask of 0xFF in LINMASK register will result in NO match. 1h (R/W) = ID filtering using ID-RESPONDERTask byte (Recommended). RECEIVEDID and IDRESPONDERTASKBYTE fields in the LINID register are used for detecting a match (using TX/RXMASK values). Mask of 0xFF in LINMASK register will result in ALWAYS match
11	CTYPE	R/W	0h	Checksum type. This bit is effective in LIN mode only. This bit controls the type of checksum to be used: classic or enhanced. Reset type: SYSRSn 0h (R/W) = Classic checksum is used. This checksum is compatible with LIN 1.3 Responder nodes. The classic checksum contains the modulo-256 sum with carry over all data bytes. Frames sent with Identifier 60 (0x3C) to 63 (0x3F) must allways use the classic checksum. 1h (R/W) = Enhanced checksum is used. The enhanced checksum is compatible with LIN 2.0 and newer Responder nodes. The enhanced checksum contains the modulo-256 sum with carry over all data bytes AND the protected Identifier.
10	MBUFMODE	R/W	0h	Multibuffer mode. This bit is effective in LIN or SCI-compatible mode. This bit controls receive/transmit buffer usage, that is, whether the RX/TX multibuffers are used or a single register, RD0/TD0, is used. Reset type: SYSRSn 0h (R/W) = The multi-buffer mode is disabled. 1h (R/W) = The multi-buffer mode is enabled.
9	ADAPT	R/W	0h	Adapt mode enable. This mode is effective in LIN mode only. This bit has an effect during the detection of the Sync Field. There are two LIN protocol bit rate modes that could be enabled with this bit according to the Node capability file definition: automatic or select. Software and network configuration will decide which of the previous two modes. When this bit is cleared, the LIN 2.0 protocol fixed bit rate should be used. If the ADAPT bit is set, a LIN Responder node detecting the baudrate will compare it to the prescalers in BRSR register and update it if they are different. The BRSR register will be updated with the new value. If this bit is not set there will be no adjustment to the BRSR register. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Automatic baudrate adjustment is disabled. 1h (R/W) = Automatic baudrate adjustment is enabled.

Table 40-16. SCIGCR1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
8	SLEEP	R/W	0h	SCI sleep. SCI compatibility mode only. In a multiprocessor configuration, this bit controls the receive sleep function. Clearing this bit brings the SCI out of sleep mode. The receiver still operates when the SLEEP bit is set however, RXRDY is updated and SCIRD is loaded with new data only when an address frame is detected. The remaining receiver status flags are updated and an error interrupt is requested if the corresponding interrupt enable bit is set, regardless of the value of the SLEEP bit. In this way, if an error is detected on the receive data line while the SCI is asleep, software can promptly deal with the error condition. The SLEEP bit is not automatically cleared when an address byte is detected. This field is writable in SCI mode only. Reset type: SYSRSn 0h (R/W) = Sleep mode is disabled. 1h (R/W) = Sleep mode is enabled.
7	SWnRST	R/W	0h	Software reset (active low). This bit is effective in LIN or SCI-compatible mode. The SCI/LIN should only be configured while SWnRST = 0. Only the following configuration bits can be changed in runtime (i.e., while SWnRESET = 1): - STOP EXT Frame (SCIGCR1[13]) - CC bit (SCIGCR2[17]) - SC bit (SCIGCR2[16]) Reset type: SYSRSn 0h (R/W) = The SCI/LIN is in its reset state no data will be transmitted or received. Writing a 0 to this bit intializes the SCI/LIN state machines and operating flags. All affected logic is held in the reset state until a 1 is written to this bit. 1h (R/W) = The SCI/LIN is in its ready state transmission and reception can occur. After this bit is set to 1, the configuration of the module should not change.
6	LINMODE	R/W	0h	LIN mode This bit controls the mode of operation of the module. Reset type: SYSRSn 0h (R/W) = LIN mode is disabled SCI compatibility mode is enabled. 1h (R/W) = LIN mode is enabled SCI compatibility mode is disabled.
5	CLK_COMMANDER	R/W	0h	SCI internal clock enable or LIN Commander/Responder configuration. In the SCI mode, this bit enables the clock to the SCI module. In LIN mode, this bit determines whether a LIN node is a Responder or Commander. Reset type: SYSRSn 0h (R/W) = SCI-compatible mode: Reserved. LIN mode: The module is in Responder mode. 1h (R/W) = SCI-compatible mode: Enable clock to the SCI module. LIN mode: The node is in Commander mode.
4	STOP	R/W	0h	SCI number of stop bits. This bit is effective in SCI-compatible mode only. Note: The receiver checks for only one stop bit. However in idle-line mode, the receiver waits until the end of the second stop bit (if STOP = 1) to begin checking for an idle period. This field is writable in SCI mode only. Reset type: SYSRSn 0h (R/W) = One stop bit is used. 1h (R/W) = Two stop bits are used.

Table 40-16. SCIGCR1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	PARITY	R/W	0h	SCI parity odd/even selection. This bit is effective in SCI-compatible mode only. If the PARITY ENA bit (SCIGCR1.2) is set, PARITY designates odd or even parity. The parity bit is calculated based on the data bits in each frame and the address bit (in address-bit mode). The start and stop fields in the frame are not included in the parity calculation. This field is writable in SCI mode only. Reset type: SYSRSn 0h (R/W) = Odd parity is used. The SCI transmits and expects to receive a value in the parity bit that makes odd the total number of bits in the frame with the value of 1. 1h (R/W) = Even parity is used. The SCI transmits and expects to receive a value in the parity bit that makes even the total number of bits in the frame with the value of 1.
2	PARITYENA	R/W	0h	Parity enable. Enables or disables the parity function. Reset type: SYSRSn 0h (R/W) = SCI-compatible mode: Parity disabled no parity bit is generated during transmission or is expected during reception. LIN mode: ID-parity verification is disabled. 1h (R/W) = SCI compatible mode: Parity enabled. A parity bit is generated during transmission and is expected during reception. LIN mode: ID-parity verification is enabled.
1	TIMINGMODE	R/W	0h	SCI timing mode bit. This bit is effective in SCI-compatible mode only. It must be set to 1 when the SCI mode is used. This bit configures the SCI for asynchronous operation. Reset type: SYSRSn 0h (R/W) = Reserved. 1h (R/W) = Must be set to 1 when module is configured for SCI operation
0	COMMMODE	R/W	0h	SCI/LIN communication mode bit. In compatibility mode, it selects the SCI communication mode. In LIN mode it selects length control option for ID-field bits ID4 and ID5. Reset type: SYSRSn 0h (R/W) = SCI-compatible mode: Idle-line mode is used. LIN mode: ID4 and ID5 are not used for length control. 1h (R/W) = SCI-compatible mode: Address-bit mode is used. LIN mode: ID4 and ID5 are used for length control.

40.7.2.3 SCIGCR2 Register (Offset = 8h) [Reset = 00000000h]

SCIGCR2 is shown in Figure 40-29 and described in Table 40-17.

Return to the Summary Table.

The SCIGCR2 register is used to send or compare a checksum byte during extended frames, to generate a wakeup and for low-power mode control of the LIN module.

Table 40-17. SCIGCR2 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-18	RESERVED	R	0h	Reserved
17	CC	R/W	0h	Compare Checksum. This mode is effective in LIN mode only. This bit is used by the receiver for extended frames to trigger a checksum compare. The user will initiate this transaction by writing a one to this bit. In non multibuffer mode, once the CC bit is set, the checksum will be compared on the byte that is currently being received, expected to be the checkbyte. During Multi-buffer mode, following are the scenarios associated with the CC bit : - If CC bit is set during the reception of the data, then the byte that is received after the reception of the programmed no. of data bytes indicated by SCIFORMAT[18:16], is treated as a checksum byte. - If CC bit is set during the IDLE period (i.e. during inter-frame space), then the next immediate byte will be treated as a checksum byte. A CE will immediatly be flagged if there is a checksum error. This bit is automatically cleared once the checksum is successfully compared. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Compare checksum on expected checkbyte

Table 40-17. SCIGCR2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
16	SC	R/W	0h	Send Checksum This mode is effective in LIN mode only. This bit is used by the transmitter with extended frames to send a checkbyte. In non multibuffer mode the checkbyte will be sent after the current byte transmission. In multibuffer mode the checkbyte will be sent after the last byte count, indicated by the SCIFORMAT[18:16]). This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = No checkbyte will be sent. 1h (R/W) = A checkbyte will be sent. This bit will automatically get cleared after the checkbyte is transmitted. The checksum will not be sent if this bit is set before transmitting the very first byte, that is, during interframe space.
15-9	RESERVED	R	0h	Reserved
8	GENWU	R/W	0h	Generate wakeup signal. This bit controls the generation of a wakeup signal, by transmitting the TDO buffer value. This bit is cleared on reception of a valid sync break. Reset type: SYSRSn 0h (R/W) = No effect 1h (R/W) = Transmit TDO for wakeup. This bit will be cleared on a SWnRST (SCIGCR1.7)
7-1	RESERVED	R	0h	Reserved
0	POWERDOWN	R/W	0h	Power down. This bit is effective in LIN or SCI-compatible mode. When the powerdown bit is set, the SCI/LIN module attempts to enter local low-power mode. If the POWERDOWN bit is set while the receiver is actively receiving data and the wakeup interrupt is disabled, then the SCI/LIN will delay low-power mode from being entered until completion of reception. In LIN mode the user may set the POWERDOWN bit on Sleep Command reception or on idle bus detection (more than 4 seconds, i.e. 80,000 cycles at 20kHz) Reset type: SYSRSn 0h (R/W) = Normal operation 1h (R/W) = Request local low-power mode

40.7.2.4 SCISETINT Register (Offset = Ch) [Reset = 00000000h]

SCISETINT is shown in Figure 40-30 and described in Table 40-18.

Return to the Summary Table.

The SCISETINT register is used to enable the various interrupts available in the LIN module.

Table 40-18. SCISETINT Register Field Descriptions

Bit	Field	Type	Reset	Description
31	SETBEINT	R/W1S	0h	Set bit error interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN module to generate an interrupt when there is a bit error. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
30	SETPBEINT	R/W1S	0h	Set physical bus error interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN module to generate an interrupt when a physical bus error occurs. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
29	SETCEINT	R/W1S	0h	Set checksum-error Interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN module to generate an interrupt when there is a checksum error. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
28	SETISFEINT	R/W1S	0h	Set inconsistent-sync-field-error interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN module to generate an interrupt when there is an inconsistent sync field error. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.

Table 40-18. SCISETINT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
27	SETNREINT	R/W1S	0h	Set no-response-error interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN module to generate an interrupt when a no-response error occurs. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
26	SETFEINT	R/W1S	0h	Set framing-error interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit enables the SCI/LIN module to generate an interrupt when a framing error occurs. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
25	SETOEINT	R/W1S	0h	Set overrun-error interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit enables the SCI/LIN module to generate an interrupt when an overrun error occurs. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
24	SETPEINT	R/W1S	0h	Set parity interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit enables the SCI/LIN module to generate an interrupt when a parity error occurs. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
23-19	RESERVED	R	0h	Reserved
18	SET_RX_DMA_ALL	R/W1S	0h	Set receiver DMA for Address & Data frames. This bit is effective in LIN or SCI-compatible mode for devices with a DMA module. To enable RX DMA request for address and data frames this bit must be set. If it is cleared, RX interrupt request is generated for address frames and DMA requests are generated for data frames. Reset type: SYSRSn 0h (R/W) = Receiver DMA request is disabled for address frames (RX interrupt request is enabled for address frames). Writing a 0 to this bit has no effect. 1h (R/W) = Receiver DMA request is enabled for address and data frames
17	SET_RX_DMA	R/W1S	0h	Set receiver DMA. This bit is effective in LIN or SCI-compatible mode for devices with a DMA module. To enable DMA requests for the receiver this bit must be set. If it is cleared, interrupt requests are generated depending on SETRXINT. Reset type: SYSRSn 0h (R/W) = Receiver DMA request is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Receiver DMA request is enabled.
16	SET_TX_DMA	R/W1S	0h	Set transmit DMA. This bit is effective in LIN or SCI-compatible mode for devices with a DMA module. To enable DMA requests for the transmitter, this bit must be set. If it is cleared, interrupt requests are generated depending on SETTXINT. Reset type: SYSRSn 0h (R/W) = Transmit DMA request is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Transmit DMA request is enabled

Table 40-18. SCISETINT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
15-14	RESERVED	R	0h	Reserved
13	SETIDINT	R/W1S	0h	Set Identification interrupt. This bit is effective in LIN mode only. This bit is set to enable interrupt once a valid matching identifier is received. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
12-10	RESERVED	R	0h	Reserved
9	SETRXINT	R/W1S	0h	Set Receiver interrupt. Setting this bit enables the SCI/LIN to generate a receive interrupt after a frame has been completely received and the data is being transferred from SCIRXSHF to SCIRD. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
8	SETTXINT	R/W1S	0h	Set Transmitter interrupt. Setting this bit enables the SCI/LIN to generate a transmit interrupt as data is being transferred from SCITD to SCITXSHF and the TXRDY bit is being set. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
7	SETTOA3WUSINT	R/W1S	0h	Set Timeout After 3 Wakeup Signals interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN to generate an interrupt when there is a timeout after 3 wakeup signals have been sent. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
6	SETTOAWUSINT	R/W1S	0h	Set Timeout After Wakeup Signal interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN to generate an interrupt when there is a timeout after one wakeup signal has been sent. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
5	RESERVED	R	0h	Reserved
4	SETTIMEOUTINT	R/W1S	0h	Set timeout interrupt. This bit is effective in LIN mode only. Setting this bit enables the SCI/LIN to generate an interrupt when no LIN bus activity (bus idle) occurs for at least 4 seconds. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
3-2	RESERVED	R	0h	Reserved

Table 40-18. SCISETINT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	SETWAKEUPINT	R/W1S	0h	Set wake-up interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit enables the SCI/LIN to generate a wake-up interrupt and thereby exit low-power mode. The wake-up interrupt is asserted on falling edge of the wake-up pulse. If enabled, the wake-up interrupt is asserted when local low-power mode is requested while the receiver is busy or if a low level is detected on the SCIRX pin during low-power mode. Wake-up interrupt is not asserted upon a wakeup pulse if the module is not in power down mode. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.
0	SETBRKDTINT	R/W1S	0h	Set break-detect interrupt. This bit is effective in SCI-compatible mode only. Setting this bit enables the SCI/LIN to generate an interrupt if a break condition is detected on the LINRX pin. This field is writable in SCI mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled.

40.7.2.5 SCICLEARINT Register (Offset = 10h) [Reset = 00000000h]

SCICLEARINT is shown in Figure 40-31 and described in Table 40-19.

Return to the Summary Table.

The SCICLEARINT register is used to disable the enabled interrupts without accessing the SCISETINT register.

Bit	Field	Type	Reset	Description
31	CLRBEINT	R/W1C	0h	Clear Bit Error Interrupt. This bit is effective in LIN mode only. Setting this bit disables the bit error interrupt. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.
30	CLRPBEINT	R/W1C	0h	Clear Physical Bus Error Interrupt. This bit is effective in LIN mode only. Setting this bit disables the physical-bus error interrupt. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.
29	CLRCEINT	R/W1C	0h	Clear checksum-error Interrupt. This bit is effective in LIN mode only. Setting this bit disables the checksum-error interrupt. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.
28	CLRISFEINT	R/W1C	0h	Clear Inconsistent-Sync-Field-Error Interrupt. This bit is effective in LIN mode only. Setting this bit disables the ISFE interrupt. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.

Table 40-19. SCICLEARINT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
27	CLRNREINT	R/W1C	0h	Clear No-Reponse-Error Interrupt. This bit is effective in LIN mode only. Setting this bit disables the no-response error interrupt. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.
26	CLRFEINT	R/W1C	0h	Clear Framing-Error Interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit disables framing-error interrupt. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.
25	CLROEINT	R/W1C	0h	Clear Overrun-Error Interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit disables the overrun interrupt. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.
24	CLRPEINT	R/W1C	0h	Clear Parity Interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit disables the parity error interrupt. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.
23-19	RESERVED	R	0h	Reserved
18	RESERVED	R	0h	Reserved
17	CLRRXDMA	R/W1C	0h	Clear receiver DMA. This bit is effective in LIN or SCI-compatible mode. Setting this bit disables the receive DMA request. Reset type: SYSRSn 0h (R/W) = Receiver DMA request is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Receiver DMA request is enabled. Writing a 1 to this bit will disable the DMA request and clear this bit.
16	CLRTXDMA	R/W1C	0h	Clear transmit DMA. This bit is effective in LIN or SCI-compatible mode. Setting this bit disables the transmit DMA request. Reset type: SYSRSn 0h (R/W) = Transmit DMA request is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Transmit DMA request is enabled. Writing a 1 to this bit will disable the DMA request and clear this bit.
15-14	RESERVED	R	0h	Reserved
13	CLRIDINT	R/W1C	0h	Clear Identifier interrupt. This bit is effective in LIN mode only. Setting this bit disables the ID interrupt. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.
12-10	RESERVED	R	0h	Reserved

Table 40-19. SCICLEARINT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
9	CLRRXINT	R/W1C	0h	Clear Receiver interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit disables the receiver interrupt. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.
8	CLRTXINT	R/W1C	0h	Clear Transmitter interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit disables the transmitter interrupt. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.
7	CLRTOA3WUSINT	R/W1C	0h	Clear Timeout After 3 Wakeup Signals interrupt. This bit is effective in LIN mode only. Setting this bit disables the timeout after 3 wakeup signals interrupt. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.
6	CLRTOAWUSINT	R/W1C	0h	Clear Timeout After Wakeup Signal interrupt. This bit is effective in LIN mode only. Setting this bit disables the timeout after one wakeup signal interrupt. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.
5	RESERVED	R	0h	Reserved
4	CLRTIMEOUTINT	R/W1C	0h	Clear Timeout interrupt. This bit is effective in LIN mode only. Setting this bit disables the timeout (LIN bus idle) interrupt. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.
3-2	RESERVED	R	0h	Reserved
1	CLRWAKEUPINT	R/W1C	0h	Clear Wake-up interrupt. This bit is effective in LIN or SCI-compatible mode. Setting this bit disables the wake-up interrupt. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.
0	CLRBRKDTINT	R/W1C	0h	Clear Break-detect interrupt. This bit is effective in SCI-compatible mode only. Setting this bit disables the Break-detect interrupt. This field is writable in SCI mode only. Reset type: SYSRSn 0h (R/W) = Interrupt is disabled. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt is enabled. Writing a 1 to this bit will disable the interrupt and clear this bit.

40.7.2.6 SCISETINTLVL Register (Offset = 14h) [Reset = 00000000h]

SCISETINTLVL is shown in Figure 40-32 and described in Table 40-20.

Return to the Summary Table.

The SCISETINTLVL register is used to map individual interrupt sources to the INT1 interrupt line.

Table 40-20. SCISETINTLVL Register Field Descriptions

Bit	Field	Type	Reset	Description
31	SETBEINTLVL	R/W1S	0h	Set Bit Error interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the Bit Error interrupt level to the INT1 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.
30	SETPBEINTLVL	R/W1S	0h	Set Physical Bus Error interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the Physical Bus Error interrupt level to the INT1 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.
29	SETCEINTLVL	R/W1S	0h	Set Checksum-error interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the Checksum-error interrupt level to the INT1 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.
28	SETISFEINTLVL	R/W1S	0h	Set Inconsistent-Sync-Field-Error interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the Inconsistent-Sync-Field-Error interrupt level to the INT1 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.

Table 40-20. SCISETINTLVL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
27	SETNREINTLVL	R/W1S	0h	Set No-Reponse-Error interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the No-Response-Error interrupt level to the INT1 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.
26	SETFEINTLVL	R/W1S	0h	Set Framing-Error interrupt level. This bit is effective in LIN or SCI-compatible mode. Writing to this bit maps the Framing-Error interrupt level to the INT1 line. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.
25	SETOEINTLVL	R/W1S	0h	Set Overrun-Error Interrupt Level. This bit is effective in LIN or SCI-compatible mode. Writing to this bit maps the Overrun-Error interrupt level to the INT1 line. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.
24	SETPEINTLVL	R/W1S	0h	Set Parity Error interrupt level. This bit is effective in LIN or SCI-compatible mode. Writing to this bit maps the Parity error interrupt level to the INT1 line. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.
23-19	RESERVED	R	0h	Reserved
18	RESERVED	R	0h	Reserved

13	SETIDINTLVL	R/W1S	0h	Set ID interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the ID interrupt level to the INT1 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.
12-10	RESERVED	R	0h	Reserved
9	SETRXINTOVO	R/W1S	0h	Set Receiver interrupt level. This bit is effective in LIN or SCI-compatible mode. Writing to this bit maps the receiver interrupt level to the INT1 line. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.
8	SETTXINTLVL	R/W1S	0h	Set Transmitter interrupt level. This bit is effective in LIN or SCI-compatible mode. Writing to this bit maps the transmitter interrupt level to the INT1 line. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.
7	SETTOA3WUSINTLVL	R/W1S	0h	Set Timeout After 3 Wakeup Signals interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the timeout after 3 wakeup signals interrupt level to the INT1 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.

Table 40-20. SCISETINTLVL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6	SETTOAWUSINTLVL	R/W1S	0h	Set Timeout After Wakeup Signal interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the the timeout after wakeup interrupt level to the INT1 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.
5	RESERVED	R	0h	Reserved
4	SETTIMEOUTINTLVL	R/W1S	0h	Set Timeout interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the timeout interrupt level to the INT1 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.
3-2	RESERVED	R	0h	Reserved
1	SETWAKEUPINTLVL	R/W1S	0h	Set Wake-up interrupt level. This bit is effective in LIN or SCI-compatible mode. Writing to this bit maps the Wake-up interrupt level to the INT1 line. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.
0	SETBRKDTINTLVL	R/W1S	0h	Set Break-detect interrupt level. This bit is effective in SCI-compatible mode only. Writing to this bit maps the Break-detect interrupt level to the INT1 line. This field is writable in SCI mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line.

40.7.2.7 SCICLEARINTLVL Register (Offset = 18h) [Reset = 00000000h]

SCICLEARINTLVL is shown in Figure 40-33 and described in Table 40-21.

Return to the Summary Table.

The SCICLEARINTLVL register is used to map individual interrupt sources to the INT0 line.

Table 40-21. SCICLEARINTLVL Register Field Descriptions

Bit	Field	Type	Reset	Description
31	CLRBEINTLVL	R/W1C	0h	Clear Bit Error interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the Bit Error interrupt level to the INT0 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.
30	CLRPBEINTLVL	R/W1C	0h	Clear Physical Bus Error interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the Physical Bus Error interrupt level to the INT0 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.
29	CLRCEINTLVL	R/W1C	0h	Clear Checksum-error interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the Checksum-error interrupt level to the INT0 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.
28	CLRISFEINTLVL	R/W1C	0h	Clear Inconsistent-Sync-Field-Error interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the Inconsistent-Sync-Field-Error interrupt level to the INT0 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.

Table 40-21. SCICLEARINTLVL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
27	CLRNREINTLVL	R/W1C	0h	Clear No-Reponse-Error interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the No-Response-Error interrupt level to the INT0 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.
26	CLRFEINTLVL	R/W1C	0h	Clear Framing-Error interrupt level. This bit is effective in LIN or SCI-compatible mode. Writing to this bit maps the Framing-Error interrupt level to the INT0 line. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.
25	CLROEINTLVL	R/W1C	0h	Clear Overrun-Error Interrupt Level. This bit is effective in LIN or SCI-compatible mode. Writing to this bit maps the Overrun-Error interrupt level to the INT0 line. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.
24	CLRPEINTLVL	R/W1C	0h	Clear Parity Error interrupt level. This bit is effective in LIN or SCI-compatible mode. Writing to this bit maps the Parity Error interrupt level to the INT0 line. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.

17-16	RESERVED	R	0h	Reserved
15-14	RESERVED	R	0h	Reserved
13	CLRIDINTLVL	R/W1C	0h	Clear ID interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the ID interrupt level to the INT0 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.
12-10	RESERVED	R	0h	Reserved
9	CLRRXINTLVL	R/W1C	0h	Clear Receiver interrupt level. This bit is effective in LIN or SCI-compatible mode. Writing to this bit maps the receiver interrupt level to the INT0 line. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.
8	CLRTXINTLVL	R/W1C	0h	Clear Transmitter interrupt level. This bit is effective in LIN or SCI-compatible mode. Writing to this bit maps the transmitter interrupt level to the INT0 line. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.

Table 40-21. SCICLEARINTLVL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
7	CLRTOA3WUSINTLVL	R/W1C	0h	Clear Timeout After 3 Wakeup Signals interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the timeout after 3 wakeup signals interrupt level to the INT0 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.
6	CLRTOAWUSINTLVL	R/W1C	0h	Clear Timeout After Wakeup Signal interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the the timeout after wakeup interrupt level to the INT0 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.
5	RESERVED	R	0h	Reserved
4	CLRTIMEOUTINTLVL	R/W1C	0h	Clear Timeout interrupt level. This bit is effective in LIN mode only. Writing to this bit maps the timeout interrupt level to the INT0 line. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.
3-2	RESERVED	R	0h	Reserved
1	CLRWAKEUPINTLVL	R/W1C	0h	Clear Wake-up interrupt level. This bit is effective in LIN or SCI-compatible mode. Writing to this bit maps the Wake-up interrupt level to the INT0 line. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. Writing a 0 to this bit has no effect. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.
0	CLRBRKDTINTLVL	R/W1C	0h	Clear Break-detect interrupt level. This bit is effective in SCI-compatible mode only. Writing to this bit maps the Break-detect interrupt level to the INT0 line. This field is writable in SCI mode only. Reset type: SYSRSn 0h (R/W) = Interrupt level mapped to INT0 line. 1h (R/W) = Interrupt level mapped to INT1 line. Writing a 1 to this bit will map the interrupt to INT0 and clear this bit.

40.7.2.8 SCIFLR Register (Offset = 1Ch) [Reset = 00000904h]

SCIFLR is shown in Figure 40-34 and described in Table 40-22.

Return to the Summary Table.

The SCIFLR register indicates the current status of the various interrupt sources of the LIN module.

Figure 40-34. SCIFLR Register

Table 40-22. SCIFLR Register Field Descriptions

Bit	Field	Type	Reset	Description
31	BE	R/W1C	0h	Bit Error Flag. This bit is effective in LIN mode only. This bit is set when there has been a bit error. This is detected by the bit monitor in the internal bit monitor. This bit is cleared by: - Reading the corresponding interrupt offset in the SCIINTVECT0/1 register - Setting the SWnRESET bit (SCIGCR1.7) - RESET bit (SCIGCR0.0) - System reset - Writing a 1 to this bit - Reception of a new sync break This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = No bit error detected. 1h (R/W) = Bit error detected.
30	PBE	R/W1C	0h	Physical Bus Error Flag. This bit is effective in LIN mode only. This bit is set when there has been a physical bus error. This is detected by the bit monitor in TED. This bit is cleared by: - Reading the corresponding interrupt offset in the SCIINTVECT0/1 register - Setting the SWnRESET bit (SCIGCR1.7) - RESET bit (SCIGCR0.0) - System reset - Writing a 1 to this bit - Reception of a new sync break Note: thie PBE will ony be flagged if no sync break can be generated. (because of a bus shortage to VBAT) or if no sync break delimeter can be generated (because of a bus shortage to GND). This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = No physiscal bus error detected. 1h (R/W) = Physical bus error detected.

Table 40-22. SCIFLR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
29	CE	R/W1C	0h	Checksum Error Flag. This bit is effective in LIN mode only. This bit is set when there is checksum error detected by a receiving node. The type of checksum to be used depends on the SCIGCR1.CTYPE bit. This bit is cleared by: - Reading the corresponding interrupt offset in the SCIINTVECT0/1 register - Setting the SWnRESET bit (SCIGCR1.7) - RESET bit (SCIGCR0.0) - System reset - Writing a 1 to this bit - Reception of a new sync break This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = No Checksum error detected. 1h (R/W) = Checksum error detected.
28	ISFE	R/W1C	0h	Inconsistent Sync Field Error Flag. This bit is effective in LIN mode only. This bit is set when there has been an inconsistent Sync Field error detected by the synchronizer during header reception. See the 'Header Reception and Adaptive Baudrate' section for more information. This bit is cleared by: - Reading the corresponding interrupt offset in the SCIINTVECT0/1 register - Setting the SWnRESET bit (SCIGCR1.7) - RESET bit (SCIGCR0.0) - System reset - Writing a 1 to this bit - Reception of a new sync break This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = No Inconsistent Sync Field error detected. 1h (R/W) = Inconsistent Sync Field error detected.
27	NRE	R/W1C	0h	No-Response Error Flag. This bit is effective in LIN mode only. This bit is set when there is no response to a Commander's header completed within TFRAME_MAX. This timeout period is applied for message frames of unknown length (identifiers 0 to 61). This error is detected by the synchronizer of the module. This bit is cleared by: - Reading the corresponding interrupt offset in the SCIINTVECT0/1 register - Setting the SWnRESET bit (SCIGCR1.7) - RESET bit (SCIGCR0.0) - System reset - Writing a 1 to this bit - Reception of a new sync break This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = No No-Response error detected. 1h (R/W) = No-Response error detected.

Table 40-22. SCIFLR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
26	FE	R/W1C	0h	Framing error flag. This bit is effective in LIN or SCI-compatible mode. This bit is set when an expected stop bit is not found. In SCI compatible mode, only the first stop bit is checked. The missing stop bit indicates that synchronization with the start bit has been lost and that the character is incorrectly framed. Detection of a framing error causes the SCI to generate an error interrupt if the RXERR INT ENA bit is set. This bit is cleared by: - Reading the corresponding interrupt offset in the SCIINTVECT0/1 register - Setting the SWnRESET bit (SCIGCR1.7) - RESET bit (SCIGCR0.0) - System reset - Writing a 1 to this bit - Reception of a new character (SCI-compatible mode), or frame (LIN mode) In multibuffer mode the frame is defined in the SCIFORMAT register. Reset type: SYSRSn 0h (R/W) = No framing error detected. 1h (R/W) = Framing error detected.
25	OE	R/W1C	0h	Overrun error flag. This bit is effective in LIN or SCI-compatible mode. This bit is set when the transfer of data from SCIRXSHF to SCIRD overwrites unread data already in SCIRD or the RDy buffers. Detection of an overrun error causes the LIN to generate an error interrupt if the SET OE INT bit is one. This bit is cleared by: - Reading the corresponding interrupt offset in the SCIINTVECT0/1 register - Setting the SWnRESET bit (SCIGCR1.7) - RESET bit (SCIGCR0.0) - System reset - Writing a 1 to this bit Reset type: SYSRSn 0h (R/W) = No overrun error detected. 1h (R/W) = Overrun error detected.
24	PE	R/W1C	0h	Parity error flag. This bit is effective in LIN or SCI-compatible mode. This bit is set when a parity error is detected in the received data. In SCI address-bit mode, the parity is calculated on the data and address bit fields of the received frame. In idle-line mode, only the data is used to calculate parity. An error is generated when a character is received with a mismatch between the number of 1s and its parity bit. For more information on parity checking, see the 'SCI Global Control Register (SCIGCR1)' description. If the parity function is disabled (that is, SCIGCR1.2 = 0), the PE flag is disabled and read as 0. Detection of a parity error causes the LIN to generate an error interrupt if the SET PE INT bit = 1. This bit is cleared by: - Reading the corresponding interrupt offset in the SCIINTVECT0/1 register - Setting the SWnRESET bit (SCIGCR1.7) - RESET bit (SCIGCR0.0) - System reset - Reception of a new charcter (SCI-compatible mode) or frame (LIN mode) - Writing a 1 to this bit Reset type: SYSRSn 0h (R/W) = No parity error or parity disabled. 1h (R/W) = Parity error detected.
23-16	RESERVED	R	0h	Reserved
15	RESERVED	R	0h	Reserved

Table 40-22. SCIFLR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
14	IDRXFLAG	R/W1C	0h	Identifier On Receive Flag. This bit is effective in LIN mode only. This flag is set once an identifier is received with an RX match and no ID-parity error. See the 'Message Filtering and Validation' section for more details. When this flag is set it indicates that a new valid identifier has been received on an RX match. This bit is cleared by: - Reading the corresponding interrupt offset in the SCIINTVECT0/1 register - Setting the SWnRESET bit (SCIGCR1.7) - RESET bit (SCIGCR0.0) - System reset - Reading the LINID register - Writing a 1 to this bit This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = No valid ID received. 1h (R/W) = Valid ID RX received in LINID[23:16] on RX match.
13	IDTXFLAG	R/W1C	0h	Identifier On Transmit Flag. This bit is effective in LIN mode only. This flag is set once an identifier is received with a TX match and no ID-parity error. See the 'Message Filtering and Validation' section for more details. When this flag is set it indicates that a new valid identifier has been received on a TX match. This bit is cleared by: - Reading the corresponding interrupt offset in the SCIINTVECT0/1 register - RESET bit (SCIGCR0.0) - Setting SWnRESET - System reset - Reading the LINID register - Writing a 1 to this bit This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = No valid ID received. 1h (R/W) = Valid ID received in LINID[23:16] on TX match.
12	RXWAKE	R	0h	Receiver wakeup detect flag. This bit is effective in SCI-compatible mode only. The SCI sets this bit to indicate that the data currently in SCIRD is an address. This bit is cleared by: - RESET bit - Setting the SWnRESET bit (SCIGCR1.7) - System reset - Receipt of a data frame This bit is writable in SCI mode only. Reset type: SYSRSn 0h (R/W) = The data in SCIRD is not an address. 1h (R/W) = The data in SCIRD is an address. See [1] Section 3.4.4, Sleep Mode for Multiprocessor Communication, on page 16 for more information on using the RXWAKE bit with sleep mode.

Table 40-22. SCIFLR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11	TXEMPTY	R	1h	Transmitter Empty flag. The value of this flag indicates the contents of the transmitter's buffer register(s) (SCITD/TDy) and shift register (SCITXSHF). In multibuffer mode, this flag indicates the value of the TDx registers and shift register (SCITXSHF). In non multibuffer mode, this flag indicates the value of LINTD0 (byte) and shift register (SCITXSHF). This bit is set by: - RESET bit (SCIGCR0.0) - Setting the SWnRESET bit (SCIGCR1.7) - System reset. Note: This bit does not cause an interrupt request. Reset type: SYSRSn 0h (R/W) = Compatible mode or LIN with no multibuffer: Transmitter buffer or shift register (or both) are loaded with data. In LIN mode using multibuffer mode: Multibuffer or shift register (or all) are loaded with data. 1h (R/W) = Compatible mode or LIN with no multibuffer: Transmitter buffer and shift registers are both empty. In LIN mode using multibuffer mode: Multibuffer and shift registers are all empty.
10	TXWAKE	R/W	0h	SCI transmitter wakeup method select. This bit is effective in SCI-compatible mode only. The TXWAKE bit controls whether the data in SCITD should be sent as an address or data frame using multiprocessor communication format. This bit is set to 1 or 0 by software before a byte is written to SCITD and is cleared by the SCI when data is transferred from SCITD to SCITXSHF or by a system reset. TXWAKE is not cleared by the SWnRESET bit (SCIGCR1.7). Reset type: SYSRSn 0h (R/W) = Address-bit mode: Frame to be transmitted will be data (address bit = 0). Idle-line mode: Frame to be transmitted will be data. 1h (R/W) = Address-bit mode: Frame to be transmitted will be an address (address bit=1). Idle-line mode: Following frame to be transmitted will be an address (writing a 1 to this bit followed by writing dummy data to the SCITD will result in a idle period of 11 bit periods before the next frame is transmitted).
9	RXRDY	R/W1C	0h	Receiver ready flag. In SCI compatibility mode, the receiver sets this bit to indicate that the SCIRD contains new data and is ready to be read by the CPU. In LIN mode, RXRDY is set once a valid frame is received in multibuffer mode, a valid frame being a message frame received with no errors. In non multibuffer mode RXRDY is set for each received byte and will be set for the last byte of the frame if there are no errors. The SCI/LIN generates a receive interrupt when RXRDY flag bit is set if the interrupt-enable bit is set (SCISETINT.9). RXRDY is cleared by: - RESET bit (SCIGCR0.0) - Setting the SWnRESET - System reset - Writing a 1 to this bit - Reading SCIRD in while in SCI compatibility mode - Reading last data byte RDy of the response in LIN mode Note: The RXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0/1 register. Reset type: SYSRSn 0h (R/W) = No new data in SCIRD/RDy. 1h (R/W) = New data ready to be read from SCIRD.

Table 40-22. SCIFLR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
8	TXRDY	R	1h	Transmitter buffer register ready flag. When set, this bit indicates that the transmit buffer(s) register (SCITD in compatibility mode and LINTD0, LINTD1 in MBUF mode) is/are ready to get another character from a CPU write. In SCI compatibility mode, writing data to SCITD automatically clears this bit. In LIN mode, this bit is cleared once byte 0 (TD0) is written to LINTD0. This bit is set after the data of the TX buffer are shifted into the SCITXSHF register. For devices with a DMA module, this event can trigger a transmit DMA event if the DMA enable bit is set. This bit is set to 1 by: - RESET bit (SCIGCR0.0) - Setting the SWnRESET (SCIGCR1.7) - System reset Note: The TXRDY flag cannot be cleared by reading the corresponding interrupt offset in the SCIINTVECT0/1 register. Note: The transmit interrupt request can be eliminated until the next series of data is written into the transmit buffers LINTD0 and LINTD1, by disabling the corresponding interrupt via the SCICLEARINT register or by disabling the transmitter via the TXENA bit (SCIGCR1.25=0). Reset type: SYSRSn 0h (R/W) = Compatible mode: SCITD is full. LIN mode: The multibuffers are full. 1h (R/W) = Compatible mode: SCITD is ready to receive the next character. LIN mode: The multibuffers are ready to receive the next character(s).
7	TOA3WUS	R/W1C	0h	Timeout After 3 Wakeup Signals flag. This bit is effective in LIN mode only. This flag is set if there is no Sync Break received after 3 wakeup signals and a period of 1.5 seconds have passed. Such expiration time is used before issuing another round of wakeup signals. This bit is cleared by: - Reading the corresponding interrupt offset in the SCIINTVECT0/1 register - Setting the SWnRESET bit (SCIGCR1.7) - RESET bit (SCIGCR0.0) - System reset - Writing a 1 to this bit This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = No timeout after 3 wakeup signals. 1h (R/W) = Timeout after 3 wakeup signals and 1.5s time.
6	TOAWUS	R/W1C	0h	Timeout After Wakeup Signal flag. This bit is effective in LIN mode only. This bit is set if there is no Sync Break received after a wakeup signal has been sent. A minimum of 150 ms expiration time is used before issuing another wakeup signal. This bit is cleared by: - Reading the corresponding interrupt offset in the SCIINTVECT0/1 register - Setting the SWnRESET bit (SCIGCR1.7) - RESET bit (SCIGCR0.0) - System reset - Writing a 1 to this bit This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = No timeout after one wakeup signal (150 ms). 1h (R/W) = Timeout after one wakeup signal.
5	RESERVED	R	0h	Reserved

Table 40-22. SCIFLR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4	TIMEOUT	R/W1C	0h	LIN Bus IDLE timeout flag. This bit is effective in LIN mode only. This bit is set if there is no LIN bus activity for at least 4 seconds. LIN bus activity being a transition from recessive to dominant. This bit is cleared by: - Reading the corresponding interrupt offset in the SCIINTVECT0/1 register - Setting the SWnRESET bit (SCIGCR1.7) - RESET bit (SCIGCR0.0) - System reset - Writing a 1 to this bit This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = No bus idle detected. 1h (R/W) = LIN bus idle detected.
3	BUSY	R	0h	Bus BUSY flag. This bit is effective in LIN mode and SCI-compatible mode. This bit indicates whether the receiver is in the process of receiving a frame. As soon as the receiver detects the beginning of a start bit, the BUSY bit is set to 1. When the reception of a frame is complete, the BUSY bit is cleared. If SET WAKEUP INT is set and power down is requested while this bit is set, the SCI/LIN automatically prevents low-power mode from being entered and generates wakeup interrupt. The BUSY bit is controlled directly by the SCI receiver but can be cleared by: - Setting the SWnRESET bit (SCIGCR1.7) - RESET bit (SCIGCR0.0) - System reset. Reset type: SYSRSn 0h (R/W) = Receiver is not currently receiving a frame. 1h (R/W) = Receiver is currently receiving a frame.
2	IDLE	R	1h	SCI receiver in idle state. This bit is effective in SCI-compatible mode only. While this bit is set, the SCI looks for an idle period to resynchronize itself with the bit stream. The receiver does not receive any data while the bit is set. The bus must be idle for 11 bit periods to clear this bit. The SCI enters this state: - After a system reset - Setting the SWnRESET bit (SCIGCR1.7) - After coming out of power down This bit is writable in SCI mode only. Reset type: SYSRSn 0h (R/W) = Idle period detected, the SCI is ready to receive. 1h (R/W) = Idle period not detected, the SCI will not receive any data.
1	WAKEUP	R/W1C	0h	Wake-up flag. This bit is effective in LIN mode only. This bit is set by the SCI/LIN when receiver or transmitter activity has taken the module out of power-down mode. An interrupt is generated if the SET WAKEUP INT bit (SCISETINT.1) is set. This bit is cleared by: - Reading the corresponding interrupt offset in the SCIINTVECT0/1 register. - Setting the SWnRESET bit (SCIGCR1.7) - RESET bit (SCIGCR0.0) - System reset - Writing a 1 to this bit. This field is writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = Do not wake up from power-down mode. 1h (R/W) = Wake up from power-down mode.

Table 40-22. SCIFLR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	BRKDT	R/W1C	0h	SCI break-detect flag. This bit is effective in SCI-compatible mode only. This bit is set when the SCI detects a break condition on the LINRX pin. A break condition occurs when the LINRX pin remains continuously low for at least 10 bits after a missing first stop bit, that is, after a framing error. Detection of a break condition causes the SCI to generate an error interrupt if the BRKDT INT ENA bit is set. The BRKDT bit is cleared by the following: - Reading the corresponding interrupt offset in the SCIINTVECT0/1 register. - Setting the SWnRESET bit (SCIGCR1.7) - RESET bit (SCIGCR0.0) - System reset - By writing a 1 to this bit. This bit is writable in SCI mode only. Reset type: SYSRSn 0h (R/W) = No break condition detected. 1h (R/W) = Break condition detected.

40.7.2.9 SCIINTVECT0 Register (Offset = 20h) [Reset = 00000000h]

SCIINTVECT0 is shown in Figure 40-35 and described in Table 40-23.

Return to the Summary Table.

The SCIINTVECT0 register indicates the offset for the INT0 interrupt line.

Figure 40-35. SCIINTVECT0 Register

15-5	RESERVED	R	0h	Reserved
4-0	INTVECT0	R	0h	Interrupt vector offset for INT0. This register indicates the offset for interrupt line INT0. A read to this register updates its value to the next highest priority pending interrupt in SCIFLR and clears the flag corresponding to the offset that was read. Note: The flags for the receive (SCIFLR.9) and the transmit (SCIFLR.8) interrupts cannot be cleared by reading the corresponding offset vector in this register (see detailed description in SCIFLR register). Reset type: SYSRSn

40.7.2.10 SCIINTVECT1 Register (Offset = 24h) [Reset = 00000000h]

SCIINTVECT1 is shown in Figure 40-36 and described in Table 40-24.

Return to the Summary Table.

The SCIINTVECT1 register indicates the offset for the INT1 interrupt line.

Figure 40-36. SCIINTVECT1 Register

15-5	RESERVED	R	0h	Reserved
4-0	INTVECT1	R	0h	Interrupt vector offset for INT1. This register indicates the offset for interrupt line INT1. A read to this register updates its value to the next highest priority pending interrupt in SCIFLR and clears the flag corresponding to the offset that was read. Note: The flags for the receive (SCIFLR.9) and the transmit (SCIFLR.8) interrupts cannot be cleared by reading the corresponding offset vector in this register (see detailed description in SCIFLR register). Reset type: SYSRSn

40.7.2.11 SCIFORMAT Register (Offset = 28h) [Reset = 00000000h]

SCIFORMAT is shown in Figure 40-37 and described in Table 40-25.

Return to the Summary Table.

The SCIFORMAT register is used to set up the character and frame lengths.

Figure 40-37. SCIFORMAT Register

Table 40-25. SCIFORMAT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-19	RESERVED	R	0h	Reserved
18-16	LENGTH	R/W	0h	Frame length control bits. In LIN mode, these bits indicate the number of bytes in the response field from 1 to 8 bytes. In buffered SCI mode, these bits indicate the number of characters. When these bits are used to indicate LIN response length (SCIGCR1[0] = 1), then when there is an ID RX match, this value should be updated with the expected length of the response. In buffered SCI mode, these bits indicate the number of characters with SCIFORMAT[2:0] bits per character. i.e. these bits indicate the transmitter/receiver format for the number of characters: 1 to 8. There can be up to eight characters with eight bits each. Reset type: SYSRSn 0h (R/W) = The response field has 1 bytes/characters. 1h (R/W) = The response field has 2 bytes/characters. 2h (R/W) = The response field has 3 bytes/characters. 3h (R/W) = The response field has 4 bytes/characters. 4h (R/W) = The response field has 5 bytes/characters. 5h (R/W) = The response field has 6 bytes/characters. 6h (R/W) = The response field has 7 bytes/characters. 7h (R/W) = The response field has 8 bytes/characters.
15-3	RESERVED	R	0h	Reserved
2-0	CHAR	R/W	0h	Character length control bits. These bits are effective in SCI compatible mode only. These bits set the SCI character length from 1 to 8 bits. Note: In compatibility mode or buffered SCI mode, when data of fewer than eight bits in length is received, it is left justified in SCIRD/RDy and padded with trailing zeros. Data read from the SCIRD should be shifted by software to make the received data right justified. Note: Data written to the SCITD should be right justified but does not need to be padded with leading zeros. These bits are witable in SCI mode only. Reset type: SYSRSn 0h (R/W) = The character is 1 bits long. 1h (R/W) = The character is 2 bits long. 2h (R/W) = The character is 3 bits long. 3h (R/W) = The character is 4 bits long. 4h (R/W) = The character is 5 bits long. 5h (R/W) = The character is 6 bits long. 6h (R/W) = The character is 7 bits long. 7h (R/W) = The character is 8 bits long.

40.7.2.12 BRSR Register (Offset = 2Ch) [Reset = 00000000h]

BRSR is shown in Figure 40-38 and described in Table 40-26.

Return to the Summary Table.

The BRSR register is used to configure the baud rate of the LIN module.

Figure 40-38. BRSR Register

30-28	U	R/W	0h	Superfractional Divider Selection. (U) These bits are an additional fractional part for the baudrate specification. These bits allow a super fine tuning of the fractional baudrate with 7 more intermediate values for each of the M fractional divider values. See the Superfractional Divider section for more details. Reset type: SYSRSn
27-24	M	R/W	0h	SCI/LIN 4-bit Fractional Divider Selection. (M) These bits are effective in LIN or SCI asynchronous mode. These bits are used to select a baud rate for the SCI/LIN module, and they are a fractional part for the baud rate specification. The M divider allows fine-tuning of the baud rate over the P prescaler with 15 additional intermediate values for each of the P integer values. Reset type: SYSRSn
23-16	SCI_LIN_PSH	R/W	0h	PRESCALER P (High Bits). SCI/LIN 24-bit Integer Prescaler Selection. These bits are used to select a baudrate for the SCI/LIN module. These bits are effective in LIN mode and SCI compatible mode. The SCI/LIN has an internally generated serial clock determined by the LIN module input clock and the prescalers P and M in this register. The SCI/LIN uses the 24-bit integer prescaler P value to select 1 of over 16,700,000 available baud rates. The additional 4-bit fractional prescaler M refines the baudate selection. Reset type: SYSRSn

Table 40-26. BRSR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
15-0	SCI_LIN_PSL	R/W	0h	PRESCALER P (Low Bits). SCI/LIN 24-bit Integer Prescaler Selection. These bits are used to select a baudrate for the SCI/LIN module. These bits are effective in LIN mode and SCI compatible mode. The SCI/LIN has an internally generated serial clock determined by the LIN module input clock and the prescalers P and M in this register. The SCI/LIN uses the 24-bit integer prescaler P value to select 1 of over 16,700,000 available baud rates. The additional 4-bit fractional prescaler M refines the baudate selection. Reset type: SYSRSn

40.7.2.13 SCIED Register (Offset = 30h) [Reset = 00000000h]

SCIED is shown in Figure 40-39 and described in Table 40-27.

Return to the Summary Table.

The SCIED register is a duplicate copy of SCIRD register that has no affect on the RXRDY flag for use with an emulator.

Figure 40-39. SCIED Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 40-28. SCIRD Register Field Descriptions

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	Reserved
7-0	RD	R	0h	Received Data. This bit is effective in SCI-compatible mode only. When a frame has been completely received, the data in the frame is transferred from the receiver shift register SCIRXSHF to this register. As this transfer occurs, the RXRDY flag is set and a receive interrupt is generated if RX INT ENA (SCISETINT0.9) is set. When the data is read from SCIRD, the RXRDY flag is automatically cleared. When the SCI receives data that is fewer than eight bits in length, it loads the data into this register in a left justified format padded with trailing zeros. Therefore, your software should perform a logical shift on the data by the correct number of positions to make it right justified. Reset type: SYSRSn

40.7.2.15 SCITD Register (Offset = 38h) [Reset = 00000000h]

SCITD is shown in Figure 40-41 and described in Table 40-29.

Return to the Summary Table.

The SCITD register is where data to be transmitted is written to by application software.

Figure 40-41. SCITD Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

31-16	RESERVED	R	0h	Reserved
15-10	RESERVED	R	0h	Reserved
9-8	SDEL	R/W	0h	2-bit Sync Delimiter compare. These bits are effective in LIN mode only. These bits are used to configure the number of Tbit for the sync delimiter in the sync field. The time delay calculation for the synchronization delimiter is: TSDEL = (SDEL + 1)Tbit These bits are writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = The sync delimiter has 1 Tbit. 1h (R/W) = The sync delimiter has 2 Tbit. 2h (R/W) = The sync delimiter has 3 Tbit. 3h (R/W) = The sync delimiter has 4 Tbit.
7-3	RESERVED	R	0h	Reserved
2-0	SBREAK	R/W	0h	3-bit Sync Break extend. LIN mode only. These bits are used to configure the number of Tbits for the sync break to extend the minimum 13 Tbit in the Sync Field to a maximum of 20 Tbit. The time delay calculation for the sync break is: TSYNBRK = 13Tbit + SBREAK x Tbit These bits are writable in LIN mode only. Reset type: SYSRSn 0h (R/W) = The sync break has no additional Tbit. 1h (R/W) = The sync break has 1 additional Tbit. 2h (R/W) = The sync break has 2 additional Tbit. 3h (R/W) = The sync break has 3 additional Tbit. 4h (R/W) = The sync break has 4 additional Tbit. 5h (R/W) = The sync break has 5 additional Tbit. 6h (R/W) = The sync break has 6 additional Tbit. 7h (R/W) = The sync break has 7 additional Tbit.

40.7.2.19 LINRD0 Register (Offset = 64h) [Reset = 00000000h]

LINRD0 is shown in Figure 40-45 and described in Table 40-33.

Return to the Summary Table.

The LINRD0 register contains the lower 4 bytes of the received LIN frame data.

Figure 40-45. LINRD0 Register

Table 40-35. LINMASK Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	RESERVED	R	0h	Reserved
23-16	RXIDMASK	R/W	0h	Receive ID mask. This field is effective in LIN mode only.This 8-bit mask is used for filtering an incoming ID message and compare it to the ID-byte. A compare match of the received ID with the RX ID mask will set the ID RX flag and trigger and ID interrupt if enabled. A 0 bit in the mask indicates that bit is compared to the ID-byte. A 1 bit in the mask indicates that that bit is filtered and therefore not used in the compare. When HGENCTRL is set to 1, this field must be set to 0xFF if the complete ID must be compared. Reset type: SYSRSn
15-8	RESERVED	R	0h	Reserved
7-0	TXIDMASK	R/W	0h	Transmit ID mask. This field is effective in LIN mode only. This 8-bit mask is used for filtering an incoming ID message and comparing it to the ID-byte. A compare match of the received ID with the TX ID Mask will set the ID TX flag and trigger an ID interrupt if enabled. A 0 bit in the mask indicates that bit is compared to the ID-byte. A 1 bit in the mask indicates that bit is filtered and therefore not used for the compare. When HGENCTRL is set to 1, this field must be set to 0xFF if the complete ID must be compared. Reset type: SYSRSn

40.7.2.22 LINID Register (Offset = 70h) [Reset = 00000000h]

LINID is shown in Figure 40-48 and described in Table 40-36.

Return to the Summary Table.

The LINID register contains the identification fields for LIN communication.
NOTE: For software compatibility with future LIN modules, the HGEN CTRL bit must be set to 1, the RX ID MASK field must be set to FFh, and the TX ID MASK field must be set to FFh.

Figure 40-48. LINID Register

Table 40-36. LINID Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	RESERVED	R	0h	Reserved
23-16	RECEIVEDID	R	0h	Received ID. This bit is effective in LIN mode only. This byte contains the current message identifier. During header reception the received ID is copied from the SCIRXSHF register to this byte if there is no ID-parity error and there has been an RX/TX match. Note: If a framing error (FE) is detected during ID reception, the received ID will also not be copied to the LINID register. Reset type: SYSRSn
15-8	IDRESPONDERTASKBYTE	R/W	0h	ID Responder Task byte. This field is effective in LIN mode only. This byte contains the identifier to which the received ID of an incoming header will be compared in order to decide whether a RX response, a TX response, or no action needs to be done by the LIN node. These bits are writable in LIN mode only. Reset type: SYSRSn
7-0	IDBYTE	R/W	0h	ID byte. This field is effective in LIN mode only. This byte is the LIN mode message ID. On a Commander node, a write to this register by the CPU initiates a header transmission. For a Responder task, this byte is used for message filtering when HGENCTRL (SCIGCR1.12) is '0'. These bits are writable in LIN mode only. Reset type: SYSRSn

40.7.2.23 LINTD0 Register (Offset = 74h) [Reset = 00000000h]

LINTD0 is shown in Figure 40-49 and described in Table 40-37.

Return to the Summary Table.

The LINTD0 register contains the lower 4 bytes of the data to be transmitted.
NOTE: TD<x-1> is equivalent to Data byte <x> of the LIN frame.

Figure 40-49. LINTD0 Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

7-0	TD7	R/W	0h	8-bit Transmit Buffer 7. Byte 7 to be transmitted is written into this register and then copied to SCITXSHF for transmission. Reset type: SYSRSn

40.7.2.25 MBRSR Register (Offset = 7Ch) [Reset = 00000DACh]

MBRSR is shown in Figure 40-51 and described in Table 40-39.

Return to the Summary Table.

The MBRSR register is used to configure the expected maximum baud rate of the LIN network.

Figure 40-51. MBRSR Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																			MBR												
R-0h																			R/W-DACh											

Table 40-39. MBRSR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-13	RESERVED	R	0h	Reserved
12-0	MBR	R/W	DACh	Maximum Baud Rate Prescaler. This field is effective in LIN mode only. This 13-bit prescaler is used during the synchronization phase (see the 'Header Reception and Adaptive Baudrate' section) of a responder module if the ADAPT bit is set. In this way, a SCI/LIN responder using automatic or select bit rate modes detects any LIN bus legal rate automatically if the measured baud rate is within ±10% of the programmed baud rate. The MBR value should be programmed to allow a maximum baud rate that is not more than 10% above the expected operating baud rate in the LIN network. Otherwise a s 0x00 data byte could mistakenly be detected as sync break. The default value is for a 70MHz VCLK and ~18kbps expected baud rate. (0xDAC). This MBR prescaler is used by the wake-up and idle time counters for a constant expiration time relative to a 20kHz rate. MBR = VCLK Frequency / (1.1*Expected Baud Rate Frequency) Note: The MBR field must be written with a 13-bit value. If the calculated MBR exceeds 2^{13} = 8192, either the baud rate or the VCLK frequency must be adjusted for valid operation. Reset type: SYSRSn

40.7.2.26 IODFTCTRL Register (Offset = 90h) [Reset = 00000500h]

IODFTCTRL is shown in Figure 40-52 and described in Table 40-40.

Return to the Summary Table.

The IODFTCTRL register is used to emulate various error and test conditions.

Figure 40-52. IODFTCTRL Register

Table 40-40. IODFTCTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31	BERRENA	R/W	0h	Bit Errror Enable bit. This bit is effective in LIN mode only. This bit is used to create a Bit error. When this bit is set, the bit received is ORed with 1 and passed to the Bit monitor circuitry. Reset type: SYSRSn
30	PBERRENA	R/W	0h	Physical Bus Error Enable bit. This bit is effective in LIN mode only. This bit is used to create a Physical Bus Error. When this bit is set, the bit received during Sync Break field transmission is ORed with 1 and passed to the Bit monitor circuitry Reset type: SYSRSn
29	CERRENA	R/W	0h	Checksum Error Enable bit. This bit is effective in LIN mode only. This bit is used to create a checksum error. When this bit is set, the polarity of the CTYPE (checksum type) in the receive checksum calculator is changed so that a checksum error is generated. Reset type: SYSRSn
28	ISFERRENA	R/W	0h	Inconsistent Sync Field Error Enable bit. This bit is effective in LIN mode only. This bit is used to create an ISF error. When this bit is set, the bit widths in the sync field are varied so that the ISF check fails and the error flag is set. Reset type: SYSRSn
27	RESERVED	R	0h	Reserved
26	FERRENA	R/W	0h	This bit is used to create a Frame Error. This bit is effective in SCI-compatible mode only. When this bit is set, the stop bit received is ANDed with '0' and passed to the stop bit check circuitry. Reset type: SYSRSn

Table 40-40. IODFTCTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
25	PERRENA	R/W	0h	Compatible Mode only This bit is effective in SCI-compatible mode only. This bit is used to create a Parity Error. When this bit is set, in compatible mode, the parity bit received is toggled so that a parity error occurs. Reset type: SYSRSn
24	BRKDTERRENA	R/W	0h	Compatible Mode only This bit is effective in SCI-compatible mode only. This bit is used to create BRKDT error (SCI mode only). When this bit is set, the stop bit of the frame is ANDed with '0' and passed to the RSM so that a frame error occurs. Then the RX Pin is forced to continuous low for 10 Tbits so that a BRKDT error occurs. Reset type: SYSRSn
23-21	RESERVED	R/W	0h	Reserved
20-19	PINSAMPLEMASK	R/W	0h	Pin sample mask. These bits define the sample number at which the TX Pin value that is being transmitted will be inverted to verify the receive pin samples correctly with the majority detection circuitry. Note: During IODFT mode testing for the pin sample mask, the prescalar P must be programmed to be greater than 2. Reset type: SYSRSn 0h (R/W) = No Mask 1h (R/W) = Invert the TX Pin value at TBIT_CENTER 2h (R/W) = Invert the TX Pin value at TBIT_CENTER + SCLK 3h (R/W) = Invert the TX Pin value at TBIT_CENTER + 2 SCLK
18-16	TXSHIFT	R/W	0h	Transmit shift. These bits define the delay by which the value on LINTX is delayed so that the value on LINRX is asynchronous. (Not applicable to Start Bit) Reset type: SYSRSn 0h (R/W) = No Delay 1h (R/W) = Delay by 1 SCLK 2h (R/W) = Delay by 2 SCLK 3h (R/W) = Delay by 3 SCLK 4h (R/W) = Delay by 4 SCLK 5h (R/W) = Delay by 5 SCLK 6h (R/W) = Delay by 6 SCLK 7h (R/W) = Delay by 7 SCLK
15-12	RESERVED	R	0h	Reserved

Chapter 41

Serial Peripheral Interface (SPI)

This chapter describes the serial peripheral interface (SPI) which is a high-speed synchronous serial input and output (I/O) port that allows a serial bit stream of programmed length (one to 16 bits) to be shifted into and out of the device at a programmed bit-transfer rate. The SPI is normally used for communications between the MCU controller and external peripherals or another controller. Typical applications include external I/O or peripheral expansion using devices such as shift registers, display drivers, and analog-to-digital converters (ADCs). Multi-device communications are supported by the controller or peripheral operation of the SPI. The port supports a 16-level, receive and transmit FIFO for reducing CPU servicing overhead.

41.1 Introduction

41.1.1 Features

The SPI module features include:

- SPIPOCI: SPI peripheral-output/controller-input pin
- SPIPICO: SPI peripheral-input/controller-output pin
- $\overline{\text{SPIPTE}}$: SPI peripheral transmit-enable pin
- SPICLK: SPI serial-clock pin

Note

All four pins can be used as GPIO if the SPI module is not used.

- Two operational modes: Controller and Peripheral
- Baud rate: 125 different programmable rates. The maximum baud rate that can be employed is limited by the maximum speed of the I/O buffers used on the SPI pins. See the device data sheet for more details.
- Data word length: 1 to 16 data bits
- Four clocking schemes (controlled by clock polarity and clock phase bits) include:
  - Falling edge without phase delay: SPICLK active-high. SPI transmits data on the falling edge of the SPICLK signal and receives data on the rising edge of the SPICLK signal.
  - Falling edge with phase delay: SPICLK active-high. SPI transmits data one half-cycle ahead of the falling edge of the SPICLK signal and receives data on the falling edge of the SPICLK signal.
  - Rising edge without phase delay: SPICLK inactive-low. SPI transmits data on the rising edge of the SPICLK signal and receives data on the falling edge of the SPICLK signal.
  - Rising edge with phase delay: SPICLK inactive-low. SPI transmits data one half-cycle ahead of the rising edge of the SPICLK signal and receives data on the rising edge of the SPICLK signal.
- Simultaneous receive and transmit operation (transmit function can be disabled in software)
- Transmitter and receiver operations are accomplished through either interrupt- driven or polled algorithm
- Delayed transmit control
- 16-level transmit/receive FIFO
- RTDMA support
- High-speed mode
- 3-wire SPI mode
- $\overline{\text{SPIPTE}}$ inversion for digital audio interface receive mode on devices with two SPI modules

41.1.2 Block Diagram

Figure 41-1 shows the SPI CPU interfaces.

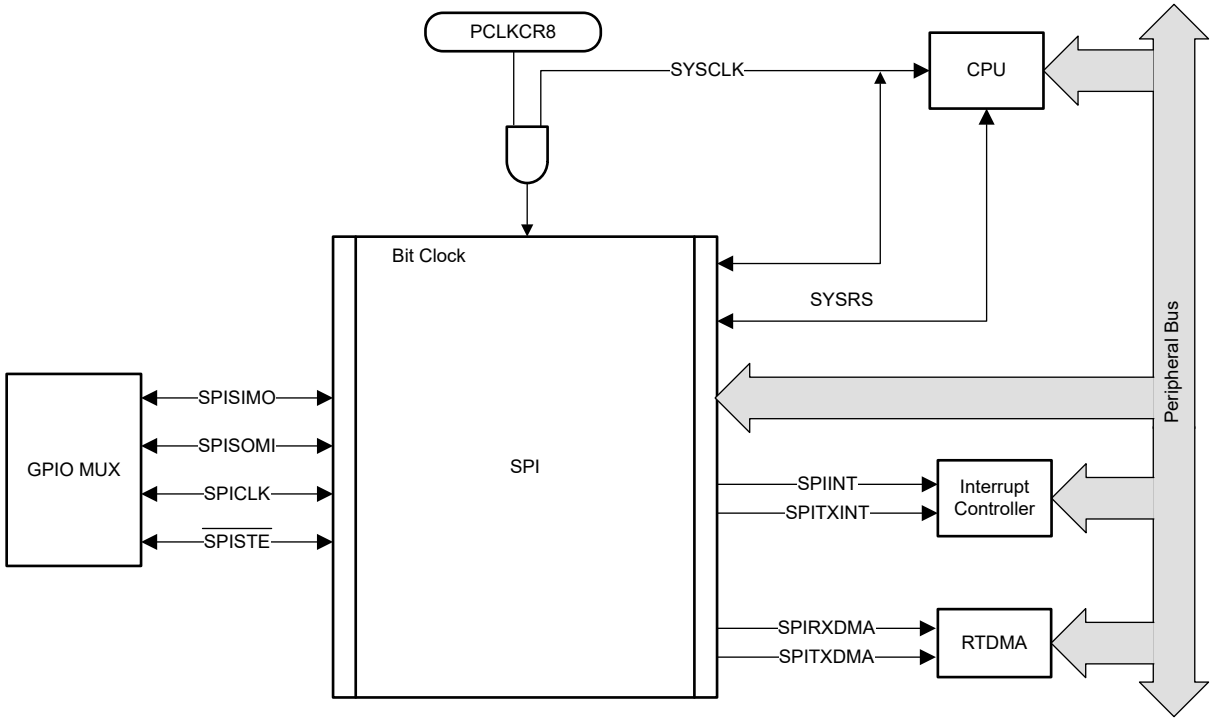

Figure 41-1. SPI CPU Interface

41.2 System-Level Integration

This section describes the various functionality that is applicable to the device integration. These features require configuration of other modules in the device that are not within the scope of this chapter.

41.2.1 SPI Module Signals

Table 41-1 classifies and provides a summary of the SPI module signals.

Table 41-1. SPI Module Signal Summary

Signal Name	Description
External Signals	
SPICLK	SPI clock
SPIPICO	SPI peripheral in, controller out
SPIPOCI	SPI peripheral out, controller in
$\overline{\text{SPIPTE}}$	SPI peripheral transmit enable
Control	
SPI Clock Rate	SYSCLK
Interrupt Signals	
SPIINT/SPIRXINT	Transmit interrupt/ Receive Interrupt in non FIFO mode (referred to as SPIINT)
	Receive interrupt in FIFO mode
SPITXINT	Transmit interrupt in FIFO mode
RTDMA Triggers	
SPITXDMA	Transmit request to RTDMA
SPIRXDMA	Receive request to RTDMA

Special Considerations

The $\overline{\text{SPIPTE}}$ signal provides the ability to gate any spurious clock and data pulses when the SPI is in peripheral mode. A HIGH logic signal on $\overline{\text{SPIPTE}}$ does not allow the peripheral to receive data. This prevents the SPI peripheral from losing synchronization with the controller. TI does not recommend that the $\overline{\text{SPIPTE}}$ always be tied to the active state.

If the SPI peripheral does ever lose synchronization with the controller, toggling SPISWRESET resets the internal bit counter as well as the various status flags in the module. By resetting the bit counter, the SPI interprets the next clock transition as the first bit of a new transmission. The register bit fields that are reset by SPISWRESET are found in .

Configuring a GPIO to Emulate $\overline{\text{SPIPTE}}$

In many systems, a SPI controller can be connected to multiple SPI peripherals using multiple instances of $\overline{\text{SPIPTE}}$. Though this SPI module does not natively support multiple $\overline{\text{SPIPTE}}$ signals, it is possible to emulate this behavior in software using GPIOs. In this configuration, the SPI must be configured as the controller. Rather than using the GPIO Mux to select $\overline{\text{SPIPTE}}$, the application can configure pins to be GPIO outputs, one GPIO per SPI peripheral. Before transmitting any data, the application can drive the desired GPIO to the active state. Immediately after the transmission has been completed, the GPIO chip select can be driven to the inactive state. This process can be repeated for many peripherals that share the SPICLK, SPIPICO, and SPIPOCI lines.

41.2.2 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification must be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups can be configured in the GPyPUD register.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

41.2.2.1 GPIOs Required for High-Speed Mode

To enable the high-speed enhancements, set SPICCR.HS_MODE to 1. Make sure that the capacitive loading on the pin does not exceed the value stated in the device data sheet.

When not operating in high-speed mode or if the capacitive loading on the pins exceed the value stated in the device data sheet, SPICCR.HS_MODE can be set to 0.

41.2.3 SPI Interrupts

This section includes information on the available interrupts present in the SPI module. The SPI module contains two interrupt lines: SPIINT/SPIRXINT and SPITXINT. When the SPI is operating in non-FIFO mode, all available interrupts are routed together to generate the single SPIINT interrupt. When FIFO mode is used, both SPIRXINT and SPITXINT can be generated.

SPIINT/SPIRXINT

When the SPI is operating in non-FIFO mode, the interrupt generated is called SPIINT. If FIFO enhancements are enabled, the interrupt is called SPIRXINT. These interrupts share the same interrupt vector in the Interrupt Controller block.

In non-FIFO mode, two conditions can trigger an interrupt: a transmission is complete (INT_FLAG), or there is overrun in the receiver (OVERRUN_FLAG). Both of these conditions share the same interrupt vector: SPIINT.

The transmission complete flag (INT_FLAG) indicates that the SPI has completed sending or receiving the last bit and is ready to be serviced. At the same time this bit is set, the received character is placed in the receiver buffer (SPIRXBUF). The INT_FLAG generates an interrupt on the SPIINT vector if the SPIINTENA bit is set.

The receiver overrun flag (OVERRUN_FLAG) indicates that a transmit or receive operation has completed before the previous character has been read from the buffer. The OVERRUN_FLAG generates an interrupt on the SPIINT vector if the OVERRUNINTENA bit is set and OVERRUN_FLAG was previously cleared.

In FIFO mode, the SPI can interrupt the CPU upon a match condition between the current receive FIFO status (RXFFST) and the receive FIFO interrupt level (RXFFIL). If RXFFST is greater than or equal to RXFFIL, the receive FIFO interrupt flag (RXFFINT) is set. SPIRXINT is triggered in the Interrupt Controller block, if RXFFINT is set and the receive FIFO interrupt is enabled (RXFFIENA = 1).

SPITXINT

The SPITXINT interrupt is not available when the SPI is operating in non-FIFO mode.

In FIFO mode, the SPITXINT behavior is similar to the SPIRXINT. SPITXINT is generated upon a match condition between the current transmit FIFO status (TXFFST) and the transmit FIFO interrupt level (TXFFIL). If TXFFST is less than or equal to TXFFIL, the transmit FIFO interrupt flag (TXFFINT) is set. SPITXINT is triggered in the Interrupt Controller block, if TXFFINT is set and the transmit FIFO interrupt is enabled in the SPI module (TXFFIENA = 1).

Figure 41-2 and Table 41-2 show how these control bits influence the SPI interrupt generation.

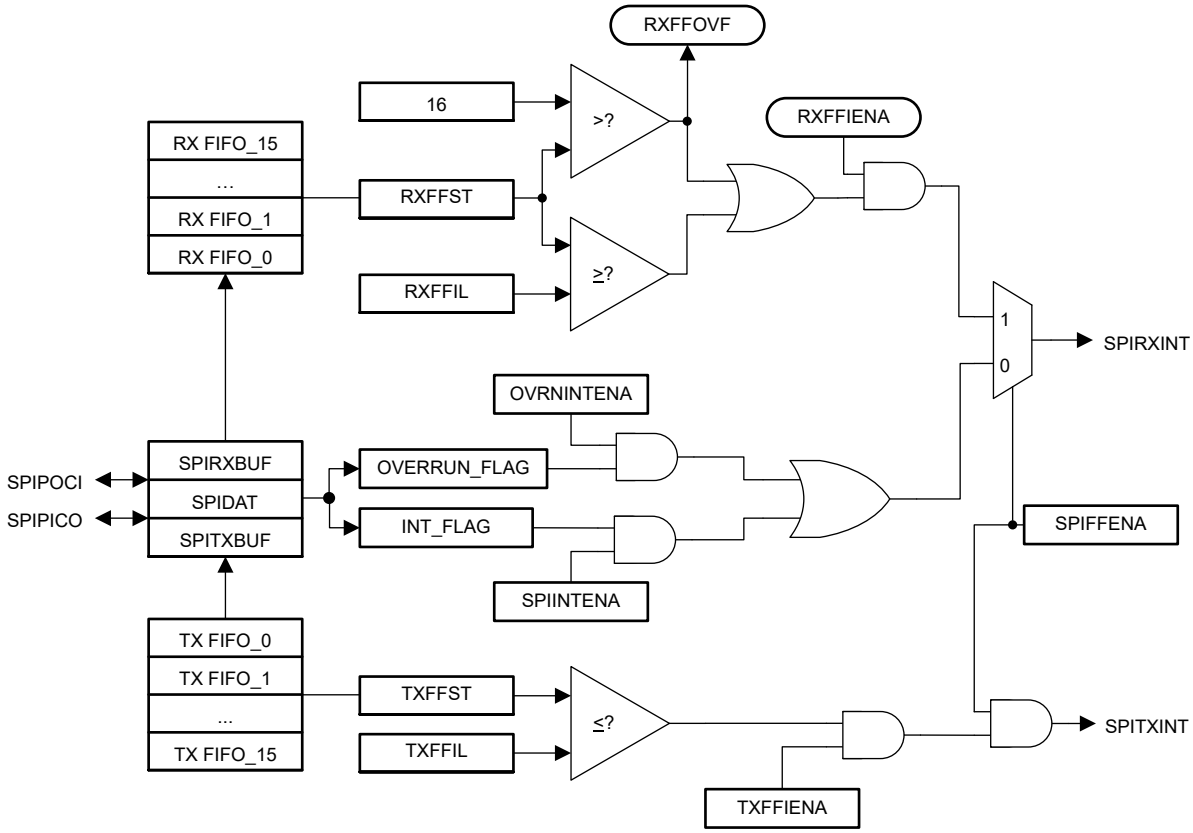

Figure 41-2. SPI Interrupt Flags and Enable Logic Generation

Table 41-2. SPI Interrupt Flag Modes

FIFO Options	SPI Interrupt Source	Interrupt Flags	Interrupt Enables	FIFO Enable (SPIFFENA)	Interrupt Line (1)
SPI without FIFO	Receive overrun	RXOVRN	OVRNINTENA	0	SPIRXINT
	Data receive	SPIINT	SPIINTENA	0	SPIRXINT
	Transmit empty	SPIINT	SPIINTENA	0	SPIRXINT
SPI FIFO mode	FIFO receive	RXFFIL	RXFFIENA	1	SPIRXINT
	Transmit empty	TXFFIL	TXFFIENA	1	SPITXINT

(1) In non-FIFO mode, SPIRXINT is the same name as the SPIINT interrupt in C29x devices.

41.2.4 RTDMA Support

Both the CPU and RTDMA have access to the SPI data registers using the internal peripheral bus. This access is limited to 16-bit register reads and writes. Each SPI module can generate two RTDMA events, SPITXDMA and SPIRXDMA. The RTDMA events are controlled by configuring the SPIFFTX.TXFFIL and SPIFFRX.RXFFIL appropriately. SPITXDMA activates when TXFFST is less than the interrupt level (TXFFIL). SPIRXDMA activates when RXFFST is greater than or equal to the interrupt level (RXFFIL).

The SPI must have FIFO enhancements enabled for the RTDMA triggers to be generated.

For more information on configuring the SPI for RTDMA transfers, refer to Section 41.3.8.

Figure 41-3 is a block diagram showing the RTDMA trigger generation from the SPI module.

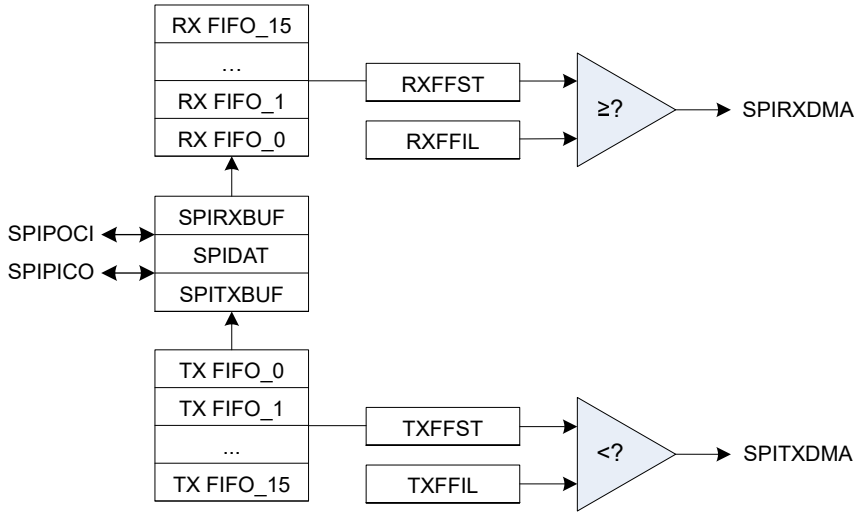

Figure 41-3. SPI RTDMA Trigger Diagram

41.3 SPI Operation

This section describes the various modes of operation of the SPI. Included are explanations of the operational modes, interrupts, data format, clock sources, and initialization. Typical timing diagrams for data transfers are given.

41.3.1 Introduction to Operation

Figure 41-4 shows typical connections of the SPI for communications between two controllers: a controller and a peripheral.

The controller transfers data by sending the SPICLK signal. For both the peripheral and the controller, data is shifted out of the shift registers on one edge of the SPICLK and latched into the shift register on the opposite SPICLK clock edge. If the CLK_PHASE bit is high, data is transmitted and received a half-cycle before the SPICLK transition. As a result, both controllers send and receive data simultaneously. The application software determines whether the data is meaningful or dummy data. There are three possible methods for data transmission:

- Controller sends data; peripheral sends dummy data.
- Controller sends data; peripheral sends data.
- Controller sends dummy data; peripheral sends data.

The controller can initiate data transfer at any time because the controller controls the SPICLK signal. The software, however, determines how the controller detects when the peripheral is ready to broadcast data.

The SPI operates in controller or peripheral mode. The CONTROLLER_PERIPHERAL bit selects the operating mode and the source of the SPICLK signal.

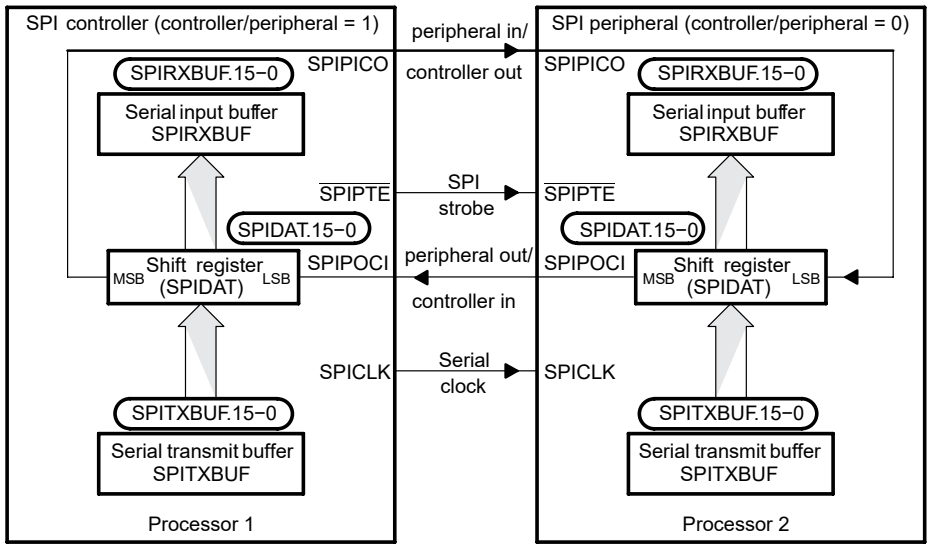

Figure 41-4. SPI Controller/Peripheral Connection

41.3.2 Controller Mode

In controller mode (CONTROLLER_PERIPHERAL = 1), the SPI provides the serial clock on the SPICLK pin for the entire serial communications network. Data is output on the SPIPICO pin and latched from the SPIPOCI pin.

The SPIBRR register determines both the transmit and receive bit transfer rate for the network. SPIBRR can select 125 different data transfer rates.

Data written to SPIDAT or SPITXBUF initiates data transmission on the SPIPICO pin, MSB (most-significant bit) first. Simultaneously, received data is shifted through the SPIPOCI pin into the LSB (least- significant bit) of SPIDAT. When the selected number of bits has been transmitted, the received data is transferred to the SPIRXBUF (buffered receiver) for the CPU to read. Data is stored right-justified in SPIRXBUF.

When the specified number of data bits has been shifted through SPIDAT, the following events occur:

- SPIDAT contents are transferred to SPIRXBUF.
- INT_FLAG bit is set to 1.
- If there is valid data in the transmit buffer SPITXBUF, as indicated by the transmit buffer full flag (BUFFULL_FLAG), this data is transferred to SPIDAT and is transmitted; otherwise, SPICLK stops after all bits have been shifted out of SPIDAT.
- If the SPIINTENA bit is set to 1, an interrupt is asserted.

In a typical application, the $\overline{\text{SPIPTE}}$ pin serves as a chip-enable pin for a SPI peripheral device. This pin is driven low by the controller before transmitting data to the peripheral and is taken high after the transmission is complete.

Figure 41-5 is a block diagram of the SPI in controller mode. The block diagram shows the basic control blocks available in SPI controller mode.

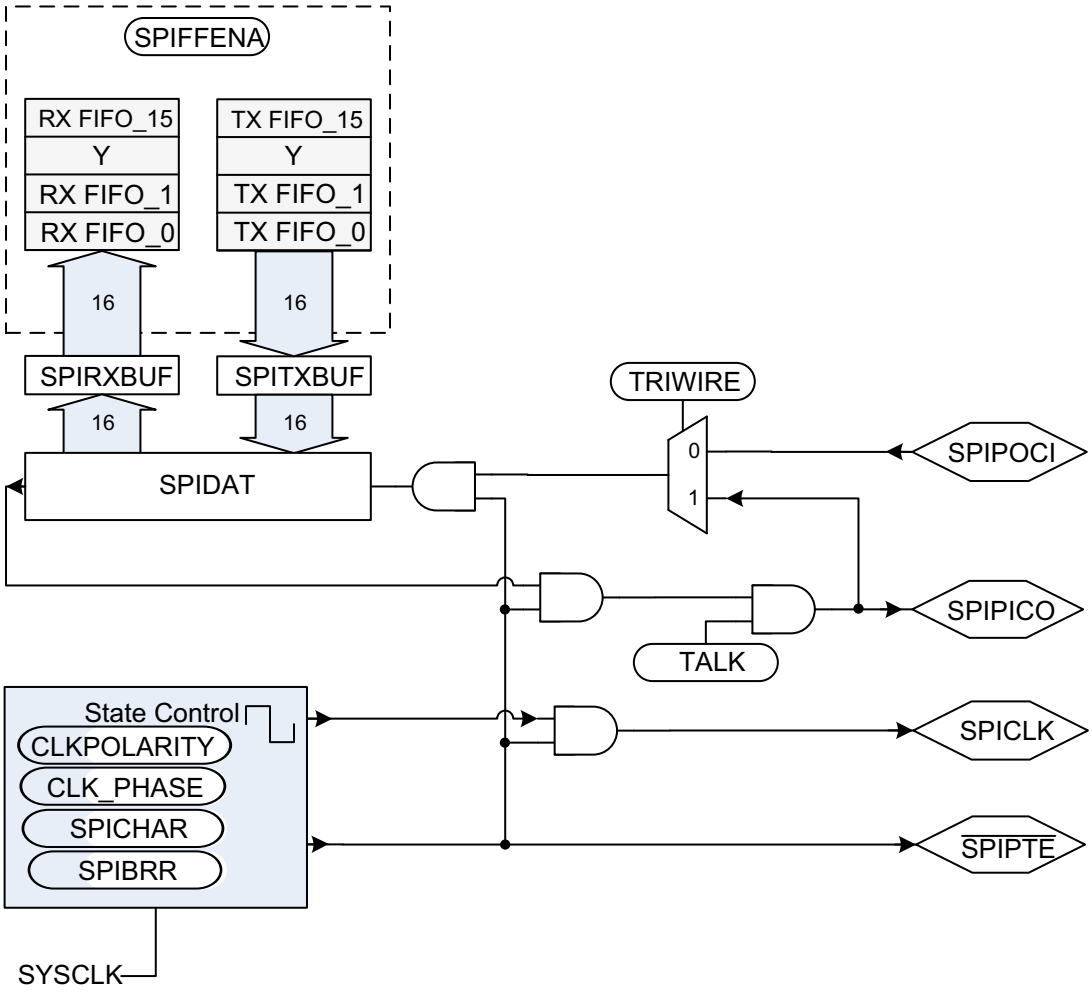

Figure 41-5. SPI Module Controller Configuration

41.3.3 Peripheral Mode

In peripheral mode (CONTROLLER_PERIPHERAL = 0), data shifts out on the SPIPOCI pin and in on the SPIPICO pin. The SPICLK pin is used as the input for the serial shift clock, which is supplied from the external network controller. The transfer rate is defined by this clock. The SPICLK input frequency can be no greater than the SYSCLK frequency divided by 4.

Data written to SPIDAT or SPITXBUF is transmitted to the network when appropriate edges of the SPICLK signal are received from the network controller. A character written to the SPITXBUF register is copied to the SPIDAT register when all bits of the current character in SPIDAT have been shifted out. If no character was previously copied to SPIDAT, then any character written to SPITXBUF is immediately copied to SPIDAT. If a character was previously copied to SPIDAT, any data written to SPITXBUF is not copied to SPIDAT until the current character in SPIDAT has been shifted out. To receive data, the SPI waits for the network controller to send the SPICLK signal and then shifts the data on the SPIPICO pin into SPIDAT. If data is to be transmitted by the peripheral simultaneously, and SPIDAT has not been previously loaded, the character must be written to SPITXBUF before the beginning of the SPICLK signal.

When the TALK bit is cleared, data transmission is disabled, and the output line (SPIPOCI) is put into the high-impedance state. If this occurs while a transmission is active, the current character is completely transmitted even though SPIPOCI is forced into the high-impedance state. This makes sure that the SPI is still able to

receive incoming data correctly. This TALK bit allows many peripheral devices to be tied together on the network, but only one peripheral at a time is allowed to drive the SPIPOCI line.

The $\overline{\text{SPIPTE}}$ pin operates as the peripheral-select pin. An active-low signal on the $\overline{\text{SPIPTE}}$ pin allows the peripheral SPI to transfer data to the serial data line; an inactive-high signal causes the peripheral SPI serial shift register to stop and the serial output pin to be put into the high-impedance state. This allows many peripheral devices to be tied together on the network, although only one peripheral device is selected at a time.

Figure 41-6 is a block diagram of the SPI in peripheral mode. The block diagram shows the basic control blocks available in SPI peripheral mode.

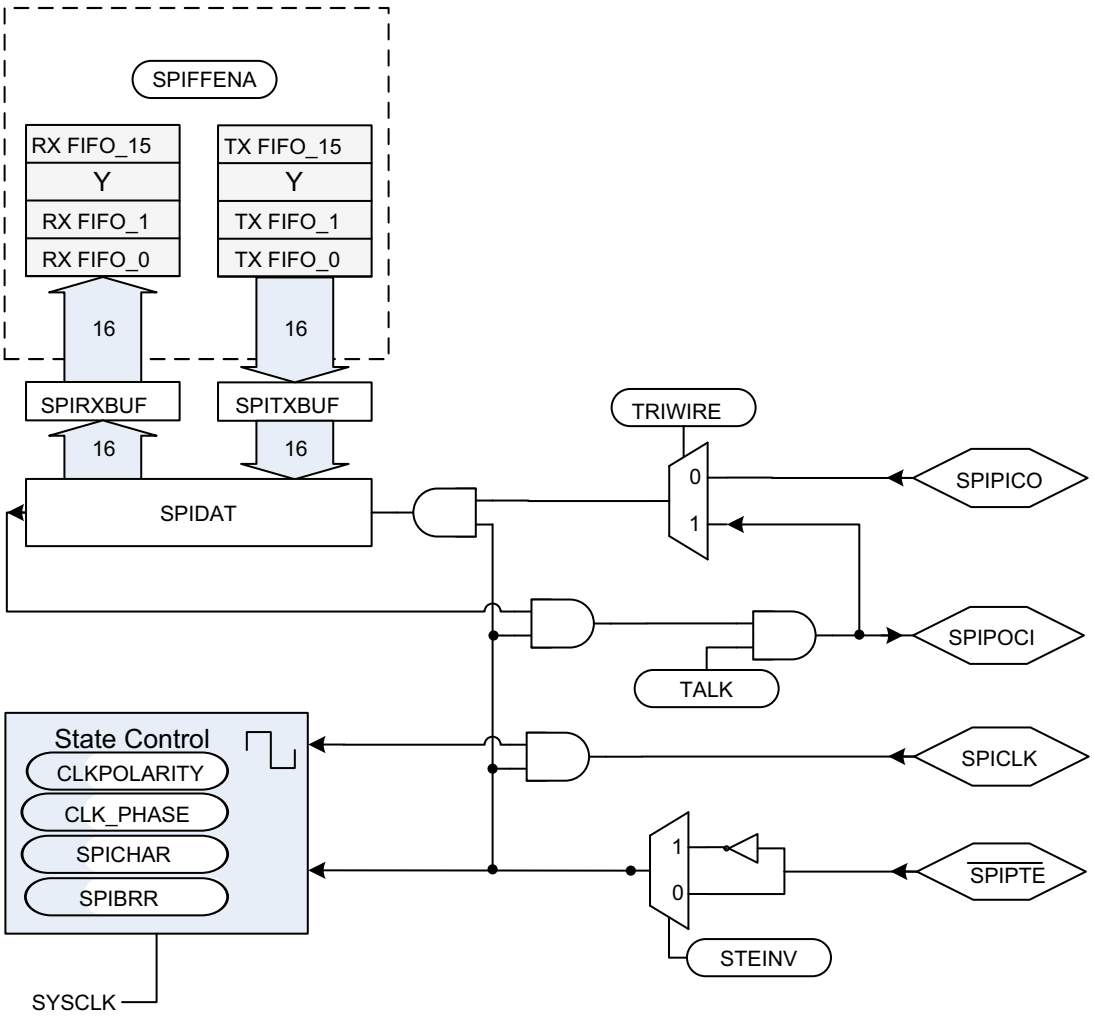

Figure 41-6. SPI Module Peripheral Configuration

41.3.4 Data Format

The 4-bit SPICHAR register field specifies the number of bits in the data character (1 to 16). This information directs the state control logic to count the number of bits received or transmitted to determine when a complete character has been processed.

The following statements apply to characters with fewer than 16 bits:

- Data must be left-justified when written to SPIDAT and SPITXBUF.
- Data read back from SPIRXBUF is right-justified.
- SPIRXBUF contains the most recently received character, right-justified, plus any bits that remain from previous transmissions that have been shifted to the left (shown in Example 41-1).

Example 41-1. Transmission of Bit from SPIRXBUF

Conditions:

1. Transmission character length = 1 bit (specified in SPICHAR bits)
2. The current value of SPIDAT = 737Bh

SPIDAT (before transmission)																	
	0	1	1	1	0	0	1	1	0	1	1	1	1	0	1	1	
SPIDAT (after transmission)																	
(TXed) 0 ←	1	1	1	0	0	1	1	0	1	1	1	1	0	1	1	x(1)	← (RXed)
SPIRXBUF (after transmission)																	
	1	1	1	0	0	1	1	0	1	1	1	1	0	1	1	x(1)	

(1) x = 1, if SPIPOCI data is high; x = 0, if SPIPOCI data is low; controller mode is assumed.

41.3.5 Baud Rate Selection

The SPI module supports 125 different baud rates and four different clock schemes. Depending on whether the SPI clock is in peripheral or controller mode, the SPICLK pin can receive an external SPI clock signal or provide the SPI clock signal, respectively.

- In the peripheral mode, the SPI clock is received on the SPICLK pin from the external source and can be no greater than the SYSCLK frequency divided by 4.
- In the controller mode, the SPI clock is generated by the SPI and is output on the SPICLK pin and can be no greater than the SYSCLK frequency divided by 4.

Note

The baud rate must be configured to not exceed the maximum rated GPIO toggle frequency. Refer to the device data sheet for the maximum GPIO toggle frequency.

Example 41-2 shows how to determine the SPI baud rates.

Example 41-3 shows how to calculate the baud rate of the SPI module in standard SPI mode (HS_MODE = 0).

Example 41-2. Baud Rate Determination

For SPIBRR = 3 to 127:

$$\text{SPI Baud Rate} = \frac{\text{SYSCLK}}{(\text{SPIBRR} + 1)}$$

For SPIBRR = 0, 1, or 2:

$$\text{SPI Baud Rate} = \frac{\text{SYSCLK}}{4}$$

where:

SYSCLK = System clock of the device

SPIBRR = Contents of the SPIBRR in the controller SPI device

To determine what value to load into SPIBRR, you must know the device system clock (SYSCLK) frequency (that is device-specific) and the baud rate at which you are operating.

Example 41-3. Baud Rate Calculation in Non-High Speed Mode (HS_MODE = 0)

$$SPI\ Baud\ Rate = \frac{SYSCLK}{SPIBRR + 1'} \quad SYSCLK = 50\ MHz$$
$$= \frac{50 \times 10^6}{3 + 1}$$
$$= 12.5\ Mbps$$

Example 41-4. Baud Rate Calculation

$$\text{Maximum SPI Baud Rate} = \frac{\text{SYSCLK}}{4}$$
$$= \frac{40 \times 10^6}{4}$$
$$= 10 \times 10^6 \text{ bps}$$

41.3.6 SPI Clocking Schemes

The clock polarity select bit (CLKPOLARITY) and the clock phase select bit (CLK_PHASE) control four different clocking schemes on the SPICLK pin. CLKPOLARITY selects the active edge, either rising or falling, of the clock. CLK_PHASE selects a half-cycle delay of the clock. The four different clocking schemes are:

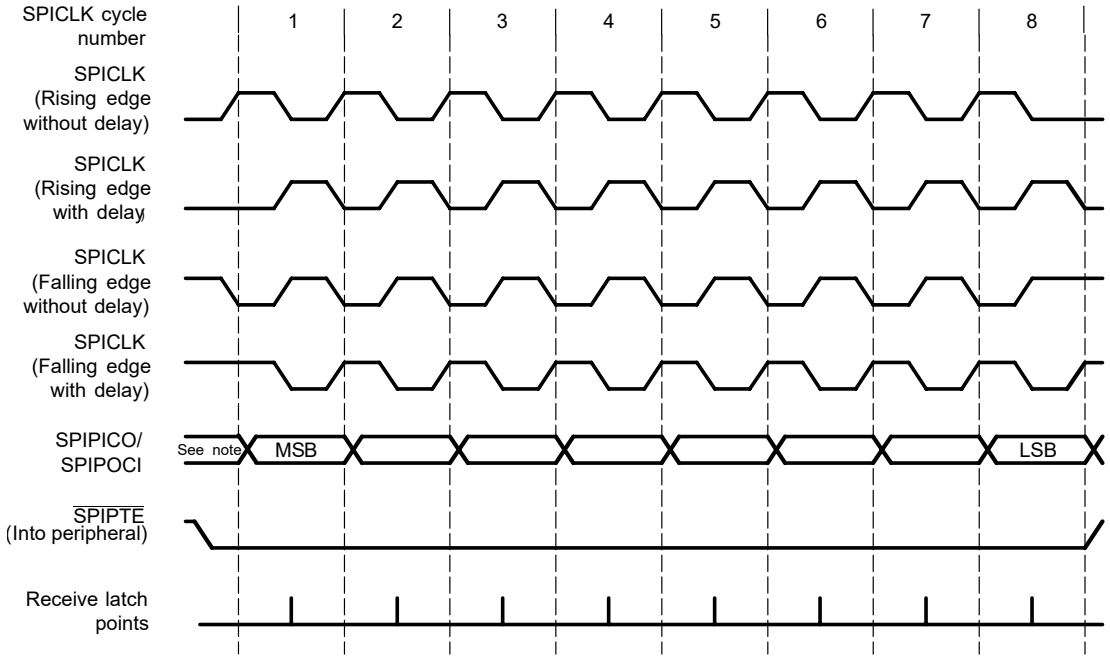
- Falling Edge Without Delay. The SPI transmits data on the falling edge of the SPICLK and receives data on the rising edge of the SPICLK.
- Falling Edge With Delay. The SPI transmits data one half-cycle ahead of the falling edge of the SPICLK signal and receives data on the falling edge of the SPICLK signal.
- Rising Edge Without Delay. The SPI transmits data on the rising edge of the SPICLK signal and receives data on the falling edge of the SPICLK signal.
- Rising Edge With Delay. The SPI transmits data one half-cycle ahead of the rising edge of the SPICLK signal and receives data on the rising edge of the SPICLK signal.

The selection procedure for the SPI clocking scheme is shown in Table 41-3. Examples of these four clocking schemes relative to transmitted and received data are shown in Figure 41-7.

Table 41-3. SPI Clocking Scheme Selection Guide

SPICLK Scheme	CLKPOLARITY(1)	CLK_PHASE(1)
Rising edge without delay	0	0
Rising edge with delay	0	1
Falling edge without delay	1	0
Falling edge with delay	1	1

(1) The description of CLK_PHASE and CLKPOLARITY differs between manufacturers. For proper operation, select the desired waveform to determine the clock phase and clock polarity settings.



Note: Previous data bit

Figure 41-7. SPICLK Signal Options

SPICLK symmetry is retained only when the result of (SPIBRR + 1) is an even value. When (SPIBRR + 1) is an odd value and SPIBRR is greater than 3, SPICLK becomes asymmetrical. The low pulse of SPICLK is one SYSCLK cycle longer than the high pulse when CLKPOLARITY bit is clear (0). When CLKPOLARITY bit is set to 1, the high pulse of the SPICLK is one SYSCLK cycle longer than the low pulse, as shown in Figure 41-8.

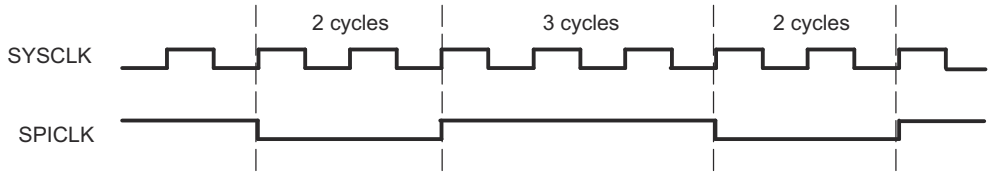


Figure 41-8. SPI: SPICLK-SYSCLK Characteristic when (BRR + 1) is Odd, BRR > 3, and CLKPOLARITY = 1

41.3.7 SPI FIFO Description

The following steps explain the FIFO features and help with programming the SPI FIFOs:

1. **Reset.** At reset the SPI powers up in standard SPI mode and the FIFO function is disabled. The FIFO registers SPIFFTX, SPIFFRX and SPIFFCT remain inactive.
2. **Standard SPI.** The standard 28x SPI mode works with SPIINT/SPIRXINT as the interrupt source.
3. **Mode change.** FIFO mode is enabled by setting the SPIFFENA bit to 1 in the SPIFFTX register. SPIRST can reset the FIFO mode at any stage of the operation.
4. **Active registers.** All the SPI registers and SPI FIFO registers SPIFFTX, SPIFFRX, and SPIFFCT are active.
5. **Interrupts.** FIFO mode has two interrupts: one for the transmit FIFO, SPITXINT; one for the receive FIFO, SPIRXINT. SPIRXINT is the common interrupt for SPI FIFO receive, receive error and receive FIFO overflow conditions. The single SPIINT for both transmit and receive sections of the standard SPI are disabled and this interrupt is serviced as SPI receive FIFO interrupt. For more information, refer to Section 41.2.3.
6. **Buffers.** Transmit and receive buffers are each supplemented with a 16-word FIFO. The one-word transmit buffer (SPITXBUF) of the standard SPI functions as a transition buffer between the transmit FIFO and shift register. The one-word transmit buffer is loaded from transmit FIFO only after the last bit of the shift register is shifted out.
7. **Delayed transfer.** The rate at which transmit words in the FIFO are transferred to transmit shift register is programmable. The SPIFFCT register bits (7−0) FFTXDLY7−FFTXDLY0 define the delay between the word transfer. The delay is defined in number SPI serial clock cycles. The 8-bit register can define a minimum delay of 0 SPICLK cycles and a maximum of 255 SPICLK cycles. With zero delay, the SPI module can transmit data in continuous mode with the FIFO words shifting out back to back. With the 255 clock delay, the SPI module can transmit data in a maximum delayed mode with the FIFO words shifting out with a delay of 255 SPICLK cycles between each words. The programmable delay facilitates glueless interface to various slow SPI peripherals, such as EEPROMs, ADC, DAC, and so on.
8. **FIFO status bits.** Both transmit and receive FIFOs have status bits TXFFST or RXFFST that define the number of words available in the FIFOs at any time. The transmit FIFO reset bit (TXFIFO) and receive reset bit (RXFIFO) reset the FIFO pointers to zero when these bits are set to 1. The FIFOs resume operation from start once these bits are cleared to zero.
9. **Programmable interrupt levels.** Both transmit and receive FIFOs can generate CPU interrupts and RTDMA triggers. The transmit interrupt (SPITXINT) is generated whenever the transmit FIFO status bits (TXFFST) match (less than or equal to) the interrupt trigger level bits (TXFFIL). The receive interrupt (SPIRXINT) is generated whenever the receive FIFO status bits (RXFFST) match (greater than or equal to) the interrupt trigger level RXFFIL. This provides a programmable interrupt trigger for transmit and receive sections of the SPI. The default value for these trigger level bits is 0x11111 for receive FIFO and 0x00000 for transmit FIFO, respectively.

41.3.8 SPI RTDMA Transfers

41.3.8.1 Transmitting Data Using SPI with RTDMA

When using the RTDMA with the TX FIFO, the RTDMA Burst Size (DMA_BURST_SIZE) must be no greater than 16 - TXFFIL, to prevent the RTDMA from writing to an already full FIFO. This leads to data loss and is not recommended.

For complete data transmission, follow these steps:

1. Calculate the total number of 8-bit words to be transmitted. [NUM_WORDS]
2. Decide the transmit FIFO level. [TXFFIL]
3. Calculate the total number of RTDMA transfers. [DMA_TRANSFER_SIZE]
4. Calculate the size of the RTDMA Burst. [DMA_BURST_SIZE]
5. Configure RTDMA using calculated values.
6. Configure SPI with FIFO using the calculated values.

To transfer 128 words to SPI using the RTDMA:

NUM_WORDS: 128

TXFFIL: 8

DMA_TRANSFER_SIZE: (NUM_WORDS /(16 - TXFFIL)) - 1 = (128/8) - 1 = 15 (16 transfers)

DMA_BURST_SIZE: 2(16 - TXFFIL) - 1 = 2(16 - 8) - 1 = 15 (16 words per burst)

Note

Avoid setting TXFFIL to 0h or 10h to make sure of proper RTDMA configuration.

41.3.8.2 Receiving Data Using SPI with RTDMA

When using the RTDMA with the RX FIFO, the RTDMA Burst Size (BURST_SIZE) must be no greater than RXFFIL to prevent the RTDMA from reading from an empty FIFO. To make sure that the RTDMA correctly receives all data from the RX FIFO, the RTDMA Burst Size can equal RXFFIL and also be an integer divisor of the total number of SPI transmissions.

For complete data reception, follow these steps:

1. Calculate the total number of 8-bit words to be received. [NUM_WORDS]
2. Calculate the necessary FIFO level [RXFFIL]
3. Calculate the total number of RTDMA transfers. [DMA_TRANSFER_SIZE]
4. Calculate the size of the RTDMA Burst. [DMA_BURST_SIZE]
5. Configure RTDMA using the calculated values.
6. Configure SPI with FIFO using the calculated values.

To receive 200 words from SPI using the RTDMA:

NUM_WORDS = 200

RXFFIL: 4

DMA_TRANSFER_SIZE: (NUM_WORDS /RXFFIL) - 1 = (200/4) - 1 = 49 (50 transfers)

DMA_BURST_SIZE: 2(RXFFIL) - 1 = 2(4) - 1 = 7 (8 words per burst)

Note

Avoid setting RXFFIL to 0h to make sure proper RTDMA configuration.

41.3.9 SPI High-Speed Mode

The SPI module is capable of reaching full-duplex communication speeds up to SYSCLK/4. For the maximum rated speed, refer to the device data sheet.

To achieve the maximum full-duplex speeds, the following restrictions are placed on the design:

- Single controller to single peripheral configuration is supported.
- Loading on the pins must not exceed the value stated in the device data sheet.

When configuring the GPIOs to support high-speed mode, refer to Section 41.2.2.1 for more information.

41.3.10 SPI 3-Wire Mode Description

SPI 3-wire mode allows for SPI communication over three pins instead of the normal four pins.

In controller mode, if the TRIWIRE bit is set, enabling 3-wire SPI mode, SPIPICOx becomes the bi-directional SPICOCIx (SPI controller out, controller in) pin, and SPIPOCIx is no longer used by the SPI. In peripheral mode, if the TRIWIRE bit is set, SPIPOCIx becomes the bi-directional SPIPIPOx (SPI peripheral in, peripheral out) pin, and SPIPICOx is no longer used by the SPI.

Table 41-4 indicates the pin function differences between 3-wire and 4-wire SPI mode for a controller and peripheral SPI.

Table 41-4. 4-wire versus 3-wire SPI Pin Functions

4-wire SPI	3-wire SPI (Controller)	3-wire SPI (Peripheral)
SPICLKx	SPICLKx	SPICLKx
SPISTEx	SPISTEx	SPISTEx
SPIPICOx	SPICOCIx	Free
SPIPOCIx	Free	SPIPIPOx

Because in 3-wire mode, the receive and transmit paths within the SPI are connected, any data transmitted by the SPI module is also received. The application software must take care to perform a dummy read to clear the SPI data register of the additional received data.

The TALK bit plays an important role in 3-wire SPI mode. The bit must be set to transmit data and cleared prior to reading data. In controller mode, to initiate a read, the application software must write dummy data to the SPI data register (SPIDAT or SPIRXBUF) while the TALK bit is cleared (no data is transmitted out the SPICOCI pin) before reading from the data register.

Figure 41-9 and Figure 41-10 illustrate 3-wire controller and peripheral mode.

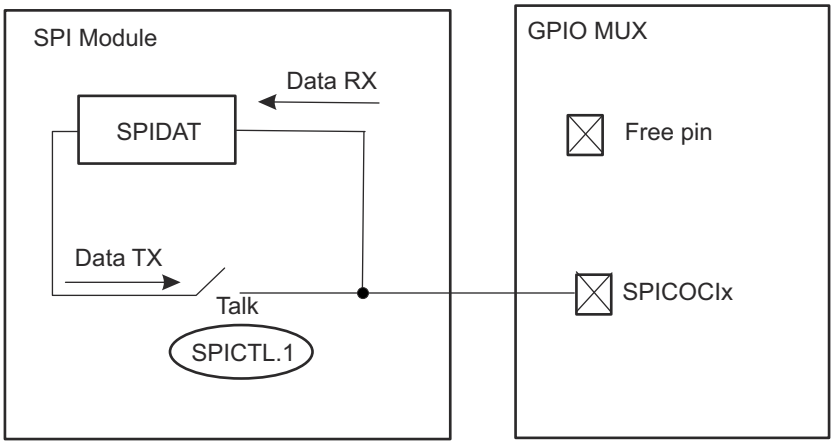

Figure 41-9. SPI 3-wire Controller Mode

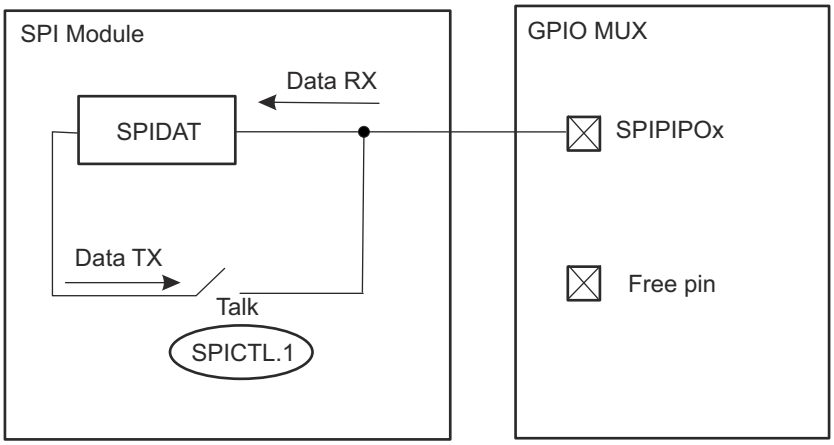

Figure 41-10. SPI 3-wire Peripheral Mode

Table 41-5 indicates how data is received or transmitted in the various SPI modes while the TALK bit is set or cleared.

Table 41-5. 3-Wire SPI Pin Configuration

Pin Mode	SPIPRI[TRIWIRE]	SPICTL[TALK]	SPIPICO	SPIPOCI
		Controller Mode		
4-wire	0	X	TX	RX
3-pin mode	1	0	RX	Disconnect from SPI
		1	TX/RX	
		Peripheral Mode		
4-wire	0	X	RX	TX
3-pin mode	1	0	Disconnect from SPI	RX
		1		TX/RX

41.4 Programming Procedure

This section describes the procedure for configuring the SPI for the various modes of operation.

41.4.1 Initialization Upon Reset

A system reset forces the SPI peripheral into the following default configuration:

- Unit is configured as a peripheral module (CONTROLLER_PERIPHERAL = 0)
- Transmit capability is disabled (TALK = 0)
- Data is latched at the input on the falling edge of the SPICLK signal
- Character length is assumed to be one bit
- SPI interrupts are disabled
- Data in SPIDAT is reset to 0000h

41.4.2 Configuring the SPI

This section describes the procedure in which to configure the SPI module for operation. To prevent unwanted and unforeseen events from occurring during or as a result of initialization changes, clear the SPISWRESET bit before making initialization changes, and then set this bit after initialization is complete. While the SPI is held in reset (SPISWRESET = 0), configuration can be changed in any order. The following list shows the SPI configuration procedure in a logical order. However, the SPI registers can be written with single 16-bit writes, so the order is not required with the exception of SPISWRESET.

Note

Do not change the SPI configuration when communication is in progress.

To change the SPI configuration:

1. Clear the SPI Software Reset bit (SPISWRESET) to 0 to force the SPI to the reset state.
2. Configure the SPI as desired:
   - Select either controller or peripheral mode (CONTROLLER_PERIPHERAL).
   - Choose SPICLK polarity and phase (CLKPOLARITY and CLK_PHASE).
   - Set the desired baud rate (SPIBRR).
   - Set the SPI character length (SPICHAR).
   - Clear the SPI Flags (OVERRUN_FLAG, INT_FLAG).
   - Enable $\overline{\text{SPIPTE}}$ inversion (STEINV), if needed.
   - Enable 3-wire mode (TRIWIRE), if needed.
   - If using FIFO enhancements:
     - Enable the FIFO enhancements (SPIFFENA).
     - Clear the FIFO Flags (TXFFINTCLR, RXFFOVFCLR, and RXFFINTCLR).
     - Release transmit and receive FIFO resets (TXFIFO and RXFIFORESET).
     - Release SPI FIFO channels from reset (SPIRST).
3. If interrupts are used:
   - In non-FIFO mode, enable the receiver overrun and/or SPI interrupts (OVERRUNINTENA and SPIINTENA).
   - In FIFO mode, set the transmit and receive interrupt levels (TXFFIL and RXFFIL) then enable the interrupts (TXFFIENA and RXFFIENA).
4. Set SPISWRESET to 1 to release the SPI from the reset state.

41.4.3 Configuring the SPI for High-Speed Mode

To achieve the maximum rated speeds, the following settings must be made. This example assumes that the device is operating at 100MHz.

Select the appropriate Pin Mux options in GPIO_CTRL_REGS.

During the SPI configuration procedure:

Set HS_MODE to 1.

```
SpiaRegs.SPICCR.bit.HS_MODE = 0x1;
```

Set SPIBRR to 3. SPICLK = SYSCLK/(SPIBRR+1) = 25MHz

```
SpiaRegs.SPIBRR = 0x3;
```

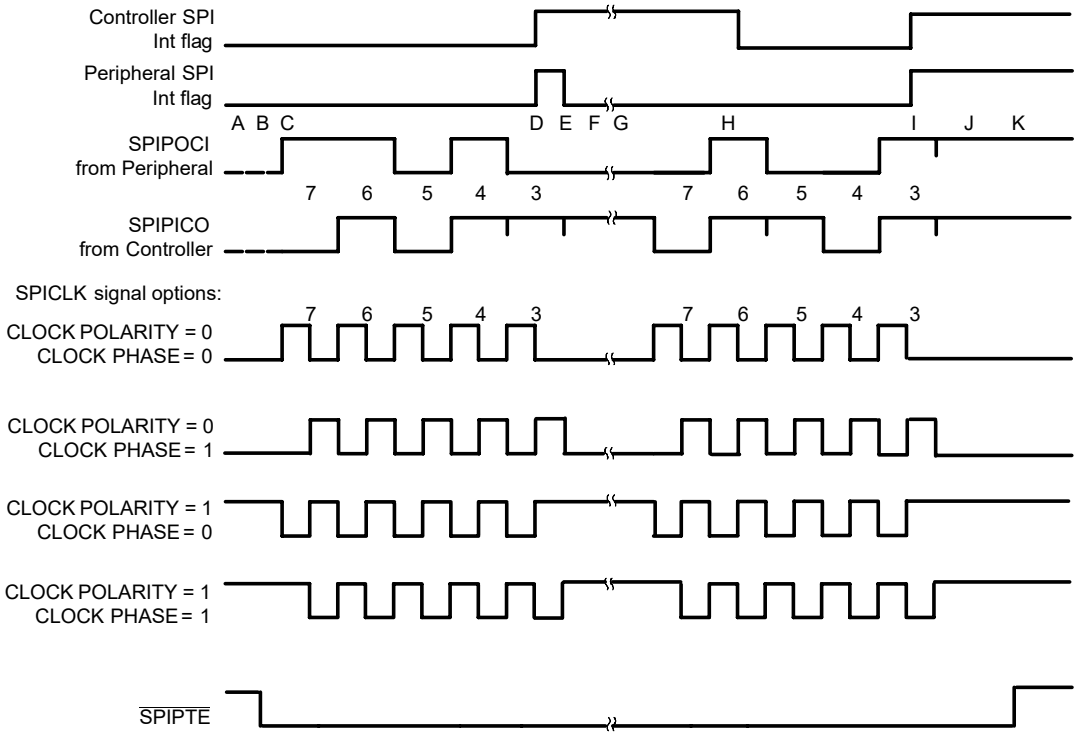
There are no other differences in the configuration from normal SPI operation. Sending and receiving data, RTDMA operation, and interrupts operates without change.

41.4.4 Data Transfer Example

The timing diagram shown in Figure 41-11 shows an SPI data transfer between two devices using a character length of five bits with the SPICLK being symmetrical.

The timing diagram with SPICLK asymmetrical (Figure 41-8) shares similar characterizations with Figure 41-11 except that the data transfer is one SYSCLK cycle longer per bit during the low pulse (CLKPOLARITY = 0) or during the high pulse (CLKPOLARITY = 1) of the SPICLK.

Figure 41-11 is applicable for 8-bit SPI only and is not for C28x devices that are capable of working with 16-bit data. The figure is shown for illustrative purposes only.



A. Peripheral writes 0D0h to SPIDAT and waits for the controller to shift out the data.
B. Controller sets the peripheral $\overline{\text{SPIPTE}}$ signal low (active).
C. Controller writes 058h to SPIDAT, which starts the transmission procedure.
D. First byte is finished and sets the interrupt flags.
E. Peripheral reads 0Bh from the SPIRXBUF (right-justified).
F. Peripheral writes 04Ch to SPIDAT and waits for the controller to shift out the data.
G. Controller writes 06Ch to SPIDAT, which starts the transmission procedure.
H. Controller reads 01Ah from the SPIRXBUF (right-justified).
I. Second byte is finished and sets the interrupt flags.
J. Controller reads 89h and the peripheral reads 8Dh from the respective SPIRXBUF. After the user software masks off the unused bits, the controller receives 09h and the peripheral receives 0Dh.
K. Controller clears the peripheral $\overline{\text{SPIPTE}}$ signal high (inactive).

Figure 41-11. Five Bits per Character

41.4.5 SPI 3-Wire Mode Code Examples

In addition to the normal SPI initialization, to configure the SPI module for 3-wire mode, the TRIWIRE bit (SPIPRI.0) must be set to 1. After initialization, there are several considerations to take into account when transmitting and receiving data in 3-wire controller and peripheral mode. The following examples demonstrate these considerations.

In 3-wire controller mode, SPICLKx, $\overline{\text{SPIPTE}}$x, and SPIPICOx pins must be configured as SPI pins (SPIPOCIx pin can be configured as non-SPI pin). When the controller transmits, the controller receives the data the controller transmits (because SPIPICOx and SPIPOCIx are connected internally in 3-wire mode). Therefore, the junk data received must be cleared from the receive buffer every time data is transmitted.

Example 41-5. 3-Wire Controller Mode Transmit

```
Uint16 data;
Uint16 dummy;
     SpiaRegs.SPICTL.bit.TALK = 1;              // Enable Transmit path
     SpiaRegs.SPITXBUF = data; // Controller transmits data
     while(SpiaRegs.SPISTS.bit.INT_FLAG !=1) {} // Waits until data rx'd
     dummy = SpiaRegs.SPIRXBUF;                 // Clears junk data because
                                                // rx'd same data as tx'd
```

To receive data in 3-wire controller mode, the controller must clear the TALK (SPICTL.1) bit to 0 to close the transmit path and then transmit dummy data to initiate the transfer from the peripheral. Because the TALK bit is 0, unlike in transmit mode, the controller dummy data does not appear on the SPIPICOx pin, and the controller does not receive the dummy data. Instead, the data from the peripheral is received by the controller.

Example 41-6. 3-Wire Controller Mode Receive

```
Uint16 rdata;
Uint16 dummy;
     SpiaRegs.SPICTL.bit.TALK = 0;              // Disable Transmit path
     SpiaRegs.SPITXBUF = dummy;                 // Send dummy to start tx
     // NOTE: because TALK = 0, data does not tx onto SPIPICOA pin
     while(SpiaRegs.SPISTS.bit.INT_FLAG !=1) {} // Wait until data received
     rdata = SpiaRegs.SPIRXBUF;                 // Controller reads data
```

In 3-wire peripheral mode, SPICLKx, SPISTEx, and SPIPOCIx pins must be configured as SPI pins (SPIPICOx pin can be configured as non-SPI pin). Like in controller mode, when transmitting, the peripheral receives the data transmitted and must clear this junk data from the receive buffer.

Example 41-7. 3-Wire Peripheral Mode Transmit

```
Uint16 data;
Uint16 dummy;
     SpiaRegs.SPICTL.bit.TALK = 1;              // Enable Transmit path
     SpiaRegs.SPITXBUF = data;                  // Peripheral transmits data
     while(SpiaRegs.SPISTS.bit.INT_FLAG !=1) {} // Wait until data rx'd
     dummy = SpiaRegs.SPIRXBUF;                 // Clears junk data
```

As in 3-wire controller mode, the TALK bit must be cleared to 0. Otherwise, the peripheral receives data normally.

Example 41-8. 3-Wire Peripheral Mode Receive

```
Uint16 rdata;
    SpiaRegs.SPICTL.bit.TALK = 0;              // Disable Transmit path
    while(SpiaRegs.SPISTS.bit.INT_FLAG !=1) {} // Waits until data rx'd
    rdata = SpiaRegs.SPIRXBUF;                 // Peripheral reads data
```

41.4.6 SPI STEINV Bit in Digital Audio Transfers

On those devices with two SPI modules, enabling the STEINV bit on one of the SPI modules allows the pair of SPIs to receive both left and right-channel digital audio data in peripheral mode. The SPI module that receives a normal active-low $\overline{\text{SPIPTE}}$ signal stores right-channel data, and the SPI module that receives an inverted active-high $\overline{\text{SPIPTE}}$ signal stores left-channel data from the controller. To receive digital audio data from a digital audio interface receiver, the SPI modules can be connected as shown in Figure 41-12.

Note

This configuration is only applicable to peripheral mode (CONTROLLER_PERIPHERAL = 0). When the SPI is configured as controller (CONTROLLER_PERIPHERAL = 1), the STEINV bit has no effect on the $\overline{\text{SPIPTE}}$ pin.

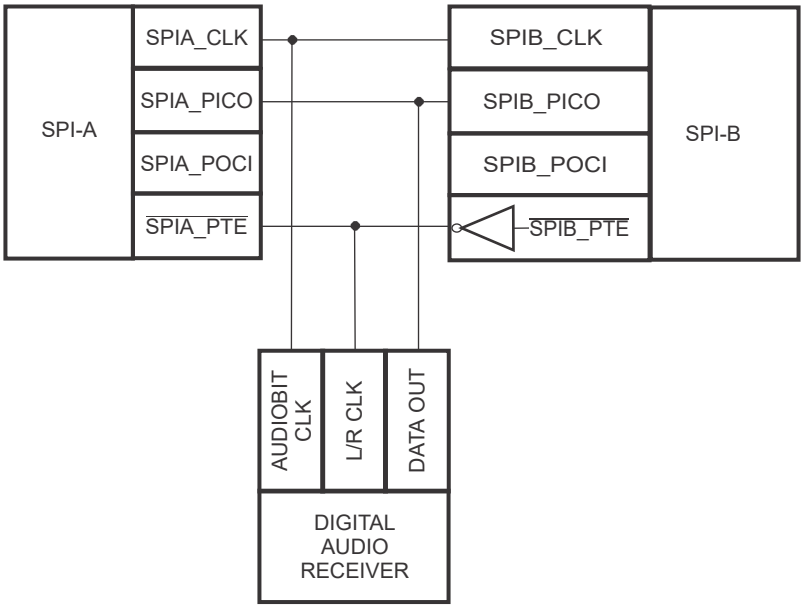


Figure 41-12. SPI Digital Audio Receiver Configuration Using Two SPIs

Standard C29x SPI timing requirements limit the number of digital audio interface formats supported using the 2-SPI configuration with the STEINV bit. See the device data sheet electrical specifications for SPI timing requirements. With the SPI clock phase configured such that the CLKPOLARITY bit is 0 and the CLK_PHASE bit is 1 (data latched on rising edge of clock), standard right-justified digital audio interface data format is supported as shown in Figure 41-13.

41.5.2 SPI Examples

NOTE: These examples are located in the C29SDK installation from ti.com at the following location: mcu_sdk_DEVICE_GPN/examples/driverlib/CORE_IF_MULTICORE/spi

Cloud access to these examples is available at the following link: dev.ti.com C29SDK Examples.

41.5.2.1 SPI Digital Loopback - SINGLE_CORE

FILE: spi_ex1_loopback.c

This program uses the internal loopback test mode of the SPI module. This is a very basic loopback that does not use the FIFOs or interrupts. A stream of data is sent and then compared to the received stream. The pinmux and SPI modules are configured through the sysconfig file.

The sent data looks like this:
0000 0001 0002 0003 0004 0005 0006 0007 .... FFFE FFFF 0000

This pattern is repeated forever.

External Connections

- None

Watch Variables

- *sData* - Data to send
- *rData* - Received data

41.5.2.2 SPI Digital Loopback with FIFO Interrupts - SINGLE_CORE

FILE: spi_ex2_loopback_fifo_interrupts.c

This program uses the internal loopback test mode of the SPI module. Both the SPI FIFOs are used, and SPI RX interrupt is used.

A stream of data is sent and then compared to the received stream. The sent data looks like this:
0000 0001
0001 0002
0002 0003
....
FFFE FFFF
FFFF 0000
etc..
This pattern is repeated forever.

Note : The SPI peripheral generates level interrupts, which should be cleared in ISR to avoid generating false pending interrupt on clear edge, followed by some wait cycles

External Connections

- None

Watch Variables

- *sData* - Data to send
- *rData* - Received data
- *rDataPoint* - Used to keep track of the last position in the receive stream for error checking

41.5.2.3 SPI Digital External Loopback without FIFO Interrupts - SINGLE_CORE

FILE: spi_ex3_external_loopback.c

This program uses the external loopback between two SPI modules. Both the SPI FIFOs and interrupts are not used in this example. SPIA is configured as a peripheral and SPI B is configured as controller. This example demonstrates full duplex communication where both controller and peripheral transmits and receives data simultaneously.

External Connections
-GPIO16 and GPIO63 - SPIPICO -GPIO17 and GPIO25 - SPIPOCI -GPIO34 and GPIO26 - SPICLK -GPIO61 and GPIO27 - SPISTE

Watch Variables

- *TxData_SPIA* - Data send from SPIA (peripheral)
- *TxData_SPIB* - Data send from SPIB (controller)
- *RxData_SPIA* - Data received by SPIA (peripheral)
- *RxData_SPIB* - Data received by SPIB (controller)

41.5.2.4 SPI Digital External Loopback with FIFO Interrupts - SINGLE_CORE

FILE: spi_ex4_external_loopback_fifo_interrupts.c

This program uses the external loopback between two SPI modules. Both the SPI FIFOs are used. SPI-A is configured as a peripheral and receives data from SPI-B which is configured as a controller. SPI-A RX interrupt is used.

A stream of data is sent and then compared to the received stream. The sent data looks like this:
0000 0001
0001 0002

0002 0003
....
FFFE FFFF
FFFF 0000
etc..
This pattern is repeated forever.

Note : The SPI peripheral generates level interrupts, which should be cleared in ISR to avoid generating false pending interrupt on clear edge, followed by some wait cycles

External Connections
-GPIO16 and GPIO63 - SPIPICO -GPIO17 and GPIO25 - SPIPOCI -GPIO34 and GPIO26 - SPICLK -GPIO61 and GPIO27 - SPISTE

Watch Variables
- *sData* - Data to send
- *rData* - Received data
- *rDataPoint* - Used to keep track of the last position in the receive stream for error checking

41.5.2.5 SPI Digital Loopback with DMA - SINGLE_CORE

FILE: spi_ex5_loopback_dma.c

This program uses the internal loopback test mode of the SPI module. Both DMA interrupts and the SPI FIFOs are used. When the SPI transmit FIFO has enough space (as indicated by its FIFO level interrupt signal), the DMA will transfer data from global variable sData into the FIFO. This will be transmitted to the receive FIFO via the internal loopback.

When enough data has been placed in the receive FIFO (as indicated by its FIFO level interrupt signal), the DMA will transfer the data from the FIFO into global variable rData.

When all data has been placed into rData, a check of the validity of the data will be performed in one of the DMA channels' ISRs.

External Connections
- None

Watch Variables
- *sData* - Data to send
- *rData* - Received data

41.6 SPI Registers

This Section describes the SPI Registers.

41.6.1 SPI Base Address Table

Table 41-7. SPI Base Address Table

Structure	DriverLib Name	Base Address	Frame Applicable	CPU1	CPU2	CPU3	RTDMA1	RTDMA2	HSM	Pipeline Protected
SPI_REGS	SPIA_BASE	0x7015_8000	YES	YES	YES	YES	YES	YES	-	YES
SPI_REGS	SPIB_BASE	0x7015_9000	YES	YES	YES	YES	YES	YES	-	YES
SPI_REGS	SPIC_BASE	0x7015_A000	YES	YES	YES	YES	YES	YES	-	YES
SPI_REGS	SPID_BASE	0x7015_B000	YES	YES	YES	YES	YES	YES	-	YES
SPI_REGS	SPIE_BASE	0x7015_C000	YES	YES	YES	YES	YES	YES	-	YES

41.6.2 SPI_REGS Registers

Table 41-8 lists the memory-mapped registers for the SPI_REGS registers. All register offset addresses not listed in Table 41-8 should be considered as reserved locations and the register contents should not be modified.

Table 41-8. SPI_REGS Registers

Offset	Acronym	Register Name	Protection
0h	SPICCR	SPI Configuration Control Register	
2h	SPICTL	SPI Operation Control Register	
4h	SPISTS	SPI Status Register	
8h	SPIBRR	SPI Baud Rate Register	
Ch	SPIRXEMU	SPI Emulation Buffer Register	
Eh	SPIRXBUF	SPI Serial Input Buffer Register	
10h	SPITXBUF	SPI Serial Output Buffer Register	
12h	SPIDAT	SPI Serial Data Register	
14h	SPIFFTX	SPI FIFO Transmit Register	
16h	SPIFFRX	SPI FIFO Receive Register	
18h	SPIFFCT	SPI FIFO Control Register	
1Eh	SPIPRI	SPI Priority Control Register	

Complex bit access types are encoded to fit into small table cells. Table 41-9 shows the codes that are used for access types in this section.

Table 41-9. SPI_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
RC	R C	Read to Clear
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
Reset or Default Value		
-n		Value after reset or the default value

41.6.2.1 SPICCR Register (Offset = 0h) [Reset = 0000h]

SPICCR is shown in Figure 41-14 and described in Table 41-10.

Return to the Summary Table.

SPICCR controls the setup of the SPI for operation.

Figure 41-14. SPICCR Register

15	14	13	12	11	10	9	8
RESERVED							
R-0h							
7	6	5	4	3	2	1	0
SPISWRESET	CLKPOLARITY	HS_MODE	SPILBK	SPICHAR			
R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h			

Table 41-10. SPICCR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	RESERVED	R	0h	Reserved
7	SPISWRESET	R/W	0h	SPI Software Reset When changing configuration, you should clear this bit before the changes and set this bit before resuming operation. Reset type: SYSRSn 0h (R/W) = Initializes the SPI operating flags to the reset condition. Specifically, the RECEIVER OVERRUN Flag bit (SPISTS.7), the SPI INT FLAG bit (SPISTS.6), and the TXBUF FULL Flag bit (SPISTS.5) are cleared. SPIPTE will become inactive. SPICLK will be immediately driven to 0 regardless of the clock polarity. The SPI configuration remains unchanged. 1h (R/W) = SPI is ready to transmit or receive the next character. When the SPI SW RESET bit is a 0, a character written to the transmitter will not be shifted out when this bit is set. A new character must be written to the serial data register. SPICLK will be returned to its inactive state one SPICLK cycle after this bit is set.
6	CLKPOLARITY	R/W	0h	Shift Clock Polarity This bit controls the polarity of the SPICLK signal. CLOCK POLARITY and POLARITY CLOCK PHASE (SPICTL.3) control four clocking schemes on the SPICLK pin. Reset type: SYSRSn 0h (R/W) = Data is output on rising edge and input on falling edge. When no SPI data is sent, SPICLK is at low level. The data input and output edges depend on the value of the CLOCK PHASE bit (SPICTL.3) as follows: - CLOCK PHASE = 0: Data is output on the rising edge of the SPICLK signal. Input data is latched on the falling edge of the SPICLK signal. - CLOCK PHASE = 1: Data is output one half-cycle before the first rising edge of the SPICLK signal and on subsequent falling edges of the SPICLK signal. Input data is latched on the rising edge of the SPICLK signal. 1h (R/W) = Data is output on falling edge and input on rising edge. When no SPI data is sent, SPICLK is at high level. The data input and output edges depend on the value of the CLOCK PHASE bit (SPICTL.3) as follows: - CLOCK PHASE = 0: Data is output on the falling edge of the SPICLK signal. Input data is latched on the rising edge of the SPICLK signal. - CLOCK PHASE = 1: Data is output one half-cycle before the first falling edge of the SPICLK signal and on subsequent rising edges of the SPICLK signal. Input data is latched on the falling edge of the SPICLK signal.

Table 41-10. SPICCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	HS_MODE	R/W	0h	High Speed Mode Enable Bits This bit determines if the High Speed mode is enabled. The correct GPIOs should be selected in the GPxGMUX/GPxMUX registers. Reset type: SYSRSn 0h (R/W) = SPI High Speed mode disabled. This is the default value after reset. 1h (R/W) = SPI High Speed mode enabled,
4	SPILBK	R/W	0h	SPI Loopback Mode Select Loopback mode allows module validation during device testing. This mode is valid only in CONTROLLER mode of the SPI. Reset type: SYSRSn 0h (R/W) = SPI loopback mode disabled. This is the default value after reset. 1h (R/W) = SPI loopback mode enabled, PICO/POCI lines are connected internally. Used for module self-tests.
3-0	SPICHAR	R/W	0h	Character Length Control Bits These four bits determine the number of bits to be shifted in or SPI CHAR0 out as a single character during one shift sequence. SPICHAR = Word length - 1 Reset type: SYSRSn 0h (R/W) = 1-bit word 1h (R/W) = 2-bit word 7h (R/W) = 8-bit word Fh (R/W) = 16-bit word

41.6.2.2 SPICTL Register (Offset = 2h) [Reset = 0000h]

SPICTL is shown in Figure 41-15 and described in Table 41-11.

Return to the Summary Table.

SPICTL controls data transmission, the SPI's ability to generate interrupts, the SPICLK phase, and the operational mode (PERIPHERAL or CONTROLLER).

Figure 41-15. SPICTL Register

15	14	13	12	11	10	9	8
RESERVED							
R-0h							
7	6	5	4	3	2	1	0
RESERVED			OVERRUNINTENA	CLK_PHASE	CONTROLLER_PERIPHERAL	TALK	SPIINTENA
R-0h			R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

Table 41-11. SPICTL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-5	RESERVED	R	0h	Reserved
4	OVERRUNINTENA	R/W	0h	Overrun Interrupt Enable Overrun Interrupt Enable. Setting this bit causes an interrupt to be generated when the RECEIVER OVERRUN Flag bit (SPISTS.7) is set by hardware. Interrupts generated by the RECEIVER OVERRUN Flag bit and the SPI INT FLAG bit (SPISTS.6) share the same interrupt vector. Reset type: SYSRSn 0h (R/W) = Disable RECEIVER OVERRUN interrupts. 1h (R/W) = Enable RECEIVER_OVERRUN interrupts.
3	CLK_PHASE	R/W	0h	SPI Clock Phase Select This bit controls the phase of the SPICLK signal. CLOCK PHASE and CLOCK POLARITY (SPICCR.6) make four different clocking schemes possible (see clocking figures in SPI chapter). When operating with CLOCK PHASE high, the SPI (CONTROLLER or PERIPHERAL) makes the first bit of data available after SPIDAT is written and before the first edge of the SPICLK signal, regardless of which SPI mode is being used. Reset type: SYSRSn 0h (R/W) = Normal SPI clocking scheme, depending on the CLOCK POLARITY bit (SPICCR.6). 1h (R/W) = SPICLK signal delayed by one half-cycle. Polarity determined by the CLOCK POLARITY bit.
2	CONTROLLER_PERIPHERAL	R/W	0h	SPI Network Mode Control This bit determines whether the SPI is a network CONTROLLER or PERIPHERAL. After SPI reset, SPI is automatically configured as a PERIPHERAL Reset type: SYSRSn 0h (R/W) = SPI is configured as a PERIPHERAL. 1h (R/W) = SPI is configured as a CONTROLLER.

Table 41-11. SPICTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	TALK	R/W	0h	Transmit Enable The TALK bit can disable data transmission (CONTROLLER or PERIPHERAL) by placing the serial data output in the high-impedance state. If this bit is disabled during a transmission, the transmit shift register continues to operate until the previous character is shifted out. When the TALK bit is disabled, the SPI is still able to receive characters and update the status flags. TALK is cleared (disabled) by a system reset. Reset type: SYSRSn 0h (R/W) = Disables transmission: - PERIPHERAL mode operation: If not previously configured as a general-purpose I/O pin, the SPIPOCI pin will be put in the high-impedance state. - CONTROLLER mode operation: If not previously configured as a general-purpose I/O pin, the SPIPICO pin will be put in the high-impedance state. 1h (R/W) = Enables transmission For the 4-pin option, ensure to enable the receiver's SPIPTEn input pin.
0	SPIINTENA	R/W	0h	SPI Interrupt Enable This bit controls the SPI's ability to generate a transmit/receive interrupt. The SPI INT FLAG bit (SPISTS.6) is unaffected by this bit. Reset type: SYSRSn 0h (R/W) = Disables the interrupt. 1h (R/W) = Enables the interrupt.

41.6.2.3 SPISTS Register (Offset = 4h) [Reset = 0000h]

SPISTS is shown in Figure 41-16 and described in Table 41-12.

Return to the Summary Table.

SPISTS contrains interrupt and status bits.

Figure 41-16. SPISTS Register

15	14	13	12	11	10	9	8
RESERVED							
R-0h							
7	6	5	4	3	2	1	0
OVERRUN_FLAG	INT_FLAG	BUFFULL_FLAG	RESERVED				
W1C-0h	RC-0h	R-0h	R-0h				

Table 41-12. SPISTS Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	RESERVED	R	0h	Reserved
7	OVERRUN_FLAG	W1C	0h	SPI Receiver Overrun Flag This bit is a read/clear-only flag. The SPI hardware sets this bit when a receive or transmit operation completes before the previous character has been read from the buffer. The bit is cleared in one of three ways: - Writing a 1 to this bit - Writing a 0 to SPI SW RESET (SPICCR.7) - Resetting the system If the OVERRUN INT ENA bit (SPICTL.4) is set, the SPI requests only one interrupt upon the first occurrence of setting the RECEIVER OVERRUN Flag bit. Subsequent overruns will not request additional interrupts if this flag bit is already set. This means that in order to allow new overrun interrupt requests the user must clear this flag bit by writing a 1 to SPISTS.7 each time an overrun condition occurs. In other words, if the RECEIVER OVERRUN Flag bit is left set (not cleared) by the interrupt service routine, another overrun interrupt will not be immediately re-entered when the interrupt service routine is exited. Reset type: SYSRSn 0h (R/W) = A receive overrun condition has not occurred. 1h (R/W) = The last received character has been overwritten and therefore lost (when the SPIRXBUF was overwritten by the SPI module before the previous character was read by the user application). Writing a '1' will clear this bit. The RECEIVER OVERRUN Flag bit should be cleared during the interrupt service routine because the RECEIVER OVERRUN Flag bit and SPI INT FLAG bit (SPISTS.6) share the same interrupt vector. This will alleviate any possible doubt as to the source of the interrupt when the next byte is received.

Table 41-12. SPISTS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6	INT_FLAG	RC	0h	SPI Interrupt Flag SPI INT FLAG is a read-only flag. Hardware sets this bit to indicate that the SPI has completed sending or receiving the last bit and is ready to be serviced. This flag causes an interrupt to be requested if the SPI INT ENA bit (SPICTL.0) is set. The received character is placed in the receiver buffer at the same time this bit is set. This bit is cleared in one of three ways: - Reading SPIRXBUF - Writing a 0 to SPI SW RESET (SPICCR.7) - Resetting the system Note: This bit should not be used if FIFO mode is enabled. The internal process of copying the received word from SPIRXBUF to the Receive FIFO will clear this bit. Use the FIFO status, or FIFO interrupt bits for similar functionality. Reset type: SYSRSn 0h (R/W) = No full words have been received or transmitted. 1h (R/W) = Indicates that the SPI has completed sending or receiving the last bit and is ready to be serviced.
5	BUFFULL_FLAG	R	0h	SPI Transmit Buffer Full Flag This read-only bit gets set to 1 when a character is written to the SPI Transmit buffer SPITXBUF. It is cleared when the character is automatically loaded into SPIDAT when the shifting out of a previous character is complete. Reset type: SYSRSn 0h (R/W) = Transmit buffer is not full. 1h (R/W) = Transmit buffer is full.
4-0	RESERVED	R	0h	Reserved

41.6.2.4 SPIBRR Register (Offset = 8h) [Reset = 0000h]

SPIBRR is shown in Figure 41-17 and described in Table 41-13.

Return to the Summary Table.

SPIBRR contains the bits used for baud-rate selection.

Figure 41-17. SPIBRR Register

Table 41-13. SPIBRR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-7	RESERVED	R	0h	Reserved
6-0	SPI_BIT_RATE	R/W	0h	SPI Baud Rate Control These bits determine the bit transfer rate if the SPI is the network SPI BIT RATE 0 CONTROLLER. There are 125 data-transfer rates (each a function of the CPU clock, SYSCLK) that can be selected. One data bit is shifted per SPICLK cycle. (SPICLK is the baud rate clock output on the SPICLK pin.) If the SPI is a network PERIPHERAL, the module receives a clock on the SPICLK pin from the network CONTROLLER. Therefore, these bits have no effect on the SPICLK signal. The frequency of the input clock from the CONTROLLER should not exceed the PERIPHERAL SPI's SYSCLK signal divided by 4. In CONTROLLER mode, the SPI clock is generated by the SPI and is output on the SPICLK pin. The SPI baud rates are determined by the following formula: For SPIBRR = 3 to 127: SPI Baud Rate = SYSCLK / (SPIBRR + 1) For SPIBRR = 0, 1, or 2: SPI Baud Rate = SYSCLK / 4 Reset type: SYSRSn 3h (R/W) = SPI Baud Rate = SYSCLK/4 4h (R/W) = SPI Baud Rate = SYSCLK/5 7Eh (R/W) = SPI Baud Rate = SYSCLK/127 7Fh (R/W) = SPI Baud Rate = SYSCLK/128

41.6.2.5 SPIRXEMU Register (Offset = Ch) [Reset = 0000h]

SPIRXEMU is shown in Figure 41-18 and described in Table 41-14.

Return to the Summary Table.

SPIRXEMU contains the received data. Reading SPIRXEMU does not clear the SPI INT FLAG bit of SPISTS. This is not a real register but a dummy address from which the contents of SPIRXBUF can be read by the emulator without clearing the SPI INT FLAG.

Figure 41-18. SPIRXEMU Register

Table 41-14. SPIRXEMU Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	ERXBn	R	0h	Emulation Buffer Received Data SPIRXEMU functions almost identically to SPIRXBUF, except that reading SPIRXEMU does not clear the SPI INT FLAG bit (SPISTS.6). Once the SPIDAT has received the complete character, the character is transferred to SPIRXEMU and SPIRXBUF, where it can be read. At the same time, SPI INT FLAG is set. This mirror register was created to support emulation. Reading SPIRXBUF clears the SPI INT FLAG bit (SPISTS.6). In the normal operation of the emulator, the control registers are read to continually update the contents of these registers on the display screen. SPIRXEMU was created so that the emulator can read this register and properly update the contents on the display screen. Reading SPIRXEMU does not clear the SPI INT FLAG bit, but reading SPIRXBUF clears this flag. In other words, SPIRXEMU enables the emulator to emulate the true operation of the SPI more accurately. It is recommended that you view SPIRXEMU in the normal emulator run mode. Reset type: SYSRSn

41.6.2.6 SPIRXBUF Register (Offset = Eh) [Reset = 0000h]

SPIRXBUF is shown in Figure 41-19 and described in Table 41-15.

Return to the Summary Table.

SPIRXBUF contains the received data. Reading SPIRXBUF clears the SPI INT FLAG bit in SPISTS. If FIFO mode is enabled, reading this register will also decrement the RXFFST counter in SPIFFRX.

Table 41-15. SPIRXBUF Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	RXBn	R	0h	Received Data Once SPIDAT has received the complete character, the character is transferred to SPIRXBUF, where it can be read. At the same time, the SPI INT FLAG bit (SPISTS.6) is set. Since data is shifted into the SPI's most significant bit first, it is stored right-justified in this register. Reset type: SYSRSn

41.6.2.7 SPITXBUF Register (Offset = 10h) [Reset = 0000h]

SPITXBUF is shown in Figure 41-20 and described in Table 41-16.

Return to the Summary Table.

SPITXBUF stores the next character to be tranmitted. Writing to this register sets the TX BUF FULL Flag bit in SPISTS. When the transmission of the current character is complete, the contents of this register are automatically loaded in SPIDAT and the TX BUF FULL Flag is cleared. If no tranmission is currently active, data written to this register falls through into the SPIDAT register and the TX BUF FULL Flag is not set.
In CONTROLLER mode, if no tranmission is currently active, writing to this register initiates a transmission in the same manner that writing to SPIDAT does.

Bit	Field	Type	Reset	Description
15-0	TXBn	R/W	0h	Transmit Data Buffer This is where the next character to be transmitted is stored. When the transmission of the current character has completed, if the TX BUF FULL Flag bit is set, the contents of this register is automatically transferred to SPIDAT, and the TX BUF FULL Flag is cleared. Writes to SPITXBUF must be left-justified. Reset type: SYSRSn

41.6.2.8 SPIDAT Register (Offset = 12h) [Reset = 0000h]

SPIDAT is shown in Figure 41-21 and described in Table 41-17.

Return to the Summary Table.

SPIDAT is the transmit and receive shift register. Data written to SPIDAT is shifted out (MSB) on subsequent SPICLK cycles. For every bit (MSB) shifted out of the SPI, a bit is shifted into the LSB end of the shift register.

Figure 41-21. SPIDAT Register

Table 41-20. SPIFFCT Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	RESERVED	R	0h	Reserved
7-0	TXDLY	R/W	0h	FIFO Transmit Delay Bits These bits define the delay between every transfer from FIFO transmit buffer to transmit shift register. The delay is defined in number SPI serial clock cycles. The 8-bit register could define a minimum delay of 0 serial clock cycles and a maximum of 255 serial clock cycles. In FIFO mode, the buffer (TXBUF) between the shift register and the FIFO should be filled only after the shift register has completed shifting of the last bit. This is required to pass on the delay between transfers to the data stream. In the FIFO mode TXBUF should not be treated as one additional level of buffer. Reset type: SYSRSn 0h (R/W) = The next word in the TX FIFO buffer is transferred to SPITXBUF immediately upon completion of transmission of the previous word. 1h (R/W) = The next word in the TX FIFO buffer is transferred to SPITXBUF1 serial clock cycle after completion of transmission of the previous word. 2h (R/W) = The next word in the TX FIFO buffer is transferred to SPITXBUF 2 serial clock cycles after completion of transmission of the previous word. FFh (R/W) = The next word in the TX FIFO buffer is transferred to SPITXBUF 255 serial clock cycles after completion of transmission of the previous word.

41.6.2.12 SPIPRI Register (Offset = 1Eh) [Reset = 0000h]

SPIPRI is shown in Figure 41-25 and described in Table 41-21.

Return to the Summary Table.

SPIPRI controls auxillary functions for the SPI including emulation control, SPIPTE inversion, and 3-wire control.

Figure 41-25. SPIPRI Register

15	14	13	12	11	10	9	8
RESERVED							
R-0h							
7	6	5	4	3	2	1	0
RESERVED	RESERVED	SOFT	FREE	RESERVED		PTEINV	TRIWIRE
R-0h	R/W-0h	R/W-0h	R/W-0h	R-0h		R/W-0h	R/W-0h

Table 41-21. SPIPRI Register Field Descriptions

Bit	Field	Type	Reset	Description
15-7	RESERVED	R	0h	Reserved
6	RESERVED	R/W	0h	Reserved
5	SOFT	R/W	0h	Emulation Soft Run This bit only has an effect when the FREE bit is 0. Reset type: SYSRSn 0h (R/W) = Transmission stops midway in the bit stream while TSUSPEND is asserted. Once TSUSPEND is deasserted without a system reset, the remainder of the bits pending in the DATBUF are shifted. Example: If SPIDAT has shifted 3 out of 8 bits, the communication freezes right there. However, if TSUSPEND is later deasserted without resetting the SPI, SPI starts transmitting from where it had stopped (fourth bit in this case) and will transmit 8 bits from that point. 1h (R/W) = If the emulation suspend occurs before the start of a transmission, (that is, before the first SPICLK pulse) then the transmission will not occur. If the emulation suspend occurs after the start of a transmission, then the data will be shifted out to completion. When the start of transmission occurs is dependent on the baud rate used. Standard SPI mode: Stop after transmitting the words in the shift register and buffer. That is, after TXBUF and SPIDAT are empty. In FIFO mode: Stop after transmitting the words in the shift register and buffer. That is, after TX FIFO and SPIDAT are empty.
4	FREE	R/W	0h	Emulation Free Run These bits determine what occurs when an emulation suspend occurs (for example, when the debugger hits a breakpoint). The peripheral can continue whatever it is doing (free-run mode) or, if in stop mode, it can either stop immediately or stop when the current operation (the current receive/transmit sequence) is complete. Reset type: SYSRSn 0h (R/W) = Emulation mode is selected by the SOFT bit 1h (R/W) = Free run, continue SPI operation regardless of suspend or when the suspend occurred.
3-2	RESERVED	R	0h	Reserved

Table 41-21. SPIPRI Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	PTEINV	R/W	0h	SPIPTEn Inversion Bit On devices with 2 or more SPI modules, inverting the SPIPTE signal on one of the modules allows the device to receive left and right-channel digital audio data. This bit is only applicable to PERIPHERAL mode. Writing to this bit while configured as CONTROLLER (CONTROLLER_PERIPHERAL = 1) has no effect Reset type: SYSRSn 0h (R/W) = SPIPTEn is active low (normal) 1h (R/W) = SPIPTE is active high (inverted)
0	TRIWIRE	R/W	0h	SPI 3-wire Mode Enable Reset type: SYSRSn 0h (R/W) = Normal 4-wire SPI mode. 1h (R/W) = 3-wire SPI mode enabled. The unused pin becomes a GPIO pin. In CONTROLLER mode, the SPIPICO pin becomes the SPICOCI (CONTROLLER receive and transmit) pin and SPIPOCI is free for non-SPI use. In PERIPHERAL mode, the SPIPOCI pin becomes the SPIPIPO (PERIPHERAL receive and transmit) pin and SPIPICO is free for non-SPI use.

Chapter 42

Single Edge Nibble Transmission (SENT)

This chapter describes the features and operation of the Single Edge Nibble Transmission Extended Receiver Features module (SENT). The SENT protocol is unidirectional and uses single wire between two or more points to transmit signals from one or more sensors to a controller. SENT uses the open standard released by the Society of Automotive Engineers (SAE) and supports J2716 January 2010 and J2716 April 2016, and is mainly used for automotive applications. This protocol can transmit high resolution data at a low cost to the system. The SENT module utilizes a Master Trigger Pulse Generator to control and receive data from one or more sensors, using a configurable pulse signal. The received data can be stored directly into memory or a FIFO and read by the CPU or RTDMA.

42.1 Introduction

The SENT module is based on the open standard SAE J2716 with additional enhancements such as additional sensor format support.

Note

The term 'channel' within this chapter and 'sensor' in the register descriptions are equivalent.

42.1.1 Features

The SENT module includes the following features:

- Based on SAE J2716 (J2716 January 2010 and J2716 April 2016)
- Supports 2007 and 2010 CRC checksum calculation
- Fast channel receiver
- Slow channel receiver
  - Short serial message (8-bit data and 4-bit message ID)
  - Enhanced serial 12-bit message (12-bit data and 8-bit message ID)
  - Enhanced serial 12-bit message (12-bit data and 8-bit message ID)
- Configurable memory depth
- Master Trigger Pulse Generator (MTPG) enables multiple sensors for the same SENT bus
- 5 SENT channels that can each be set to be triggered by one of 63 trigger sources
- Nibble sorting to minimize CPU intervention
- Timeout feature in SENT channel can be re-purposed for watchdog (only usable in continuous receive mode)
- RXD_I_R bit in the CSENT_RXD register is used for debugging 1 bit of the SENT receive at a time
- Time stamp captures for received data frames
  - Uses 32-bit free running counter
  - Can use external counter for one or all SENT modules
- Receiver and Interrupt Features
  - Programmable glitch filter on input (bypass mode available)
  - Automatic detection of CRC error and framing error on Fast and Slow Channel Data
  - Option to save data received with error
  - Configurable number of data nibbles to receive (1-8)
  - FIFO and direct map support for received data frames
  - RTDMA and interrupts can be used to send data depending on how full the FIFO is
  - Error Detection Supported:
    - Timeout
    - Calibration
    - FIFO Overflow/Underflow
    - Frequency Drift
    - Overflow Trigger Request

42.1.2 SENT Related Collateral

Foundational Materials

- C29x Academy - Single Edge Nibble Transmission (SENT)

42.2 Advanced Topologies: MTPG

The Master Trigger Pulse Generator (MTPG) generates pulses for synchronous mode sensors that sends data only after receiving a specific trigger pulse.

42.2.1 MTPG Features

- Supports variety of sensors which support synchronous access
- Supports up to four sensors on the same bus
- Broadcast Channel can configure the sensors (no response expected from sensor)
- Up to five sensor trigger channels (Broadcast, Channel 1-4), each of which has:
  - MTPG enable
  - Software trigger
  - Period value for indicating drive time for the specific waveform sequence
  - Timeout counter that triggers an interrupt when response is not received in the configured time limit
  - Nine compare registers for toggle specification and one receiver enable compare register
  - Trigger select
- 58 external triggers and 5 internal triggers
- Arbiter for selecting one of the five trigger pulse sources (round-robin priority)
- Wait time for MTPG to start after previous response

Note

The standard SENT configuration only uses a single channel (channel 1). Enabling the MTPG with the MTP_MODE bit in the RCFG2 register enables support for using multiple channels.

42.2.2 MTPG Description

The MTPG triggers can be used to configure sensors or request data from synchronous mode sensors, since the MTPG can create desired pulse patterns that are recognized by the sensors. For sensors with synchronous transmit, the sensor sends data when the MTPG has sent a pulse that matches with the sensor's pulse size requirement.

The MTPG enables the operational modes laid out in Table 42-1.

Table 42-1. MTPG Operational Modes

Mode	Maximum Number of Sensors Supported	Description
Synchronous Transmit	1	Sensor sends data only after receiving trigger pulse
Multiple Sensors on Bus	4	Each sensor has a specific address which the MTPG triggers in a predefined sequence. There can be a predefined broadcast sequence to configure the sensors
Change Mode of Operation	1	MTPG can change the mode of sensor operation

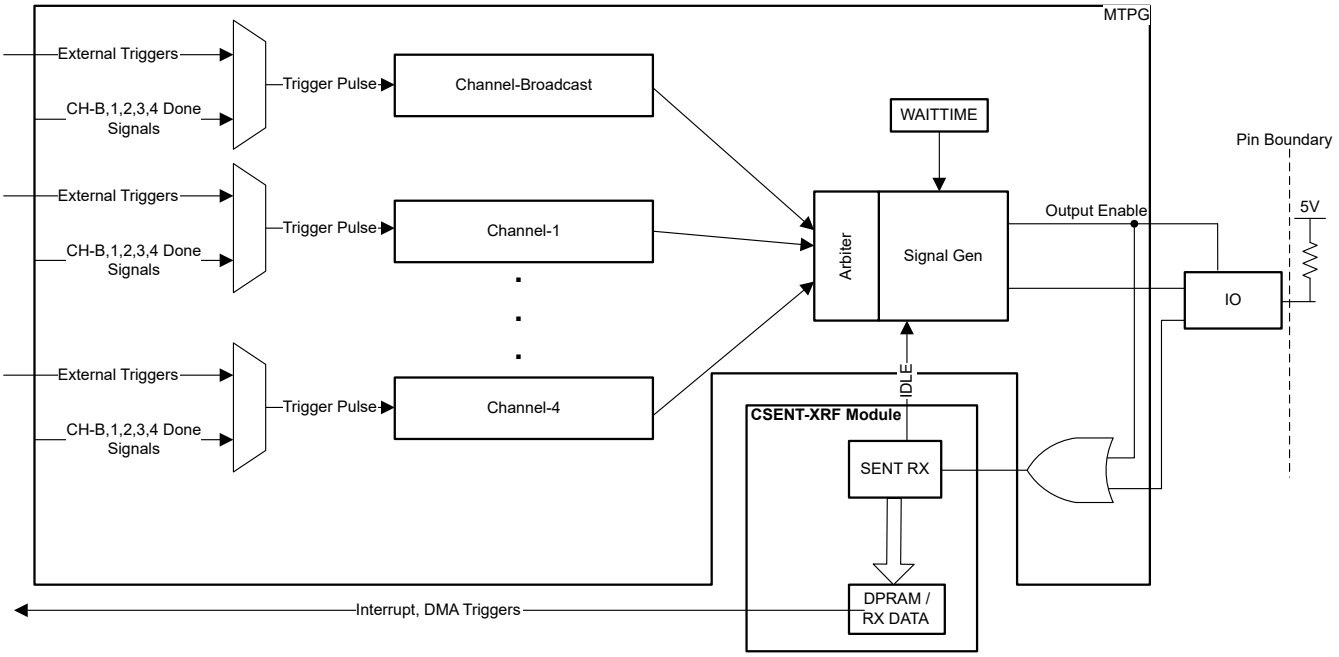

Figure 42-1. SENT Block Diagram

Figure 42-1 shows that the MTPG consists of one signal generator and five trigger channels (Broadcast and Channels 1-4). Each channel has a set of configurations that control the signal generation, and the signal generator uses one set of configurations to generate the pulse.

On the Broadcast channel the MTPG generates a pulse and the SENT receiver does not expect data in return. There can be a predefined broadcast of sequences to configure the sensors or to change the mode of the operation. In normal mode, the SENT receiver expects data in response to a pulse, and a timeout counter acts as a check to trigger an interrupt if there is no received sync pulse within a specified time limit. The SENT channel's period register defines the length of the pulse produced by the MTPG.

The channel has ten compare registers, which toggle the signal generator output when the channel counter matches any of the compare values. The maximum number of toggles that can be created is limited by the number of compare registers.

The CMP10 compare register is unique in that this compare register controls when the receiver is enabled to sample the RX line. The SENT peripheral can only drive the output when the period of the SENT channel's counter is non-zero.

Figure 42-2 shows the interaction between the output control, RX line, and the compare registers. To generate one trigger pulse, two compare registers must be non-zero. This is because the compare registers are triggered in sequence, so for example the CMP9 register must be larger than CMP8, which must be larger than CMP7, and so on. The purpose of this is to reduce the logic and length of the critical path. The respective Sn_MTP_CMP10RE register (where n is 1 through 4) is only used if the receiver input gating needs to occur earlier than the period time. The MTPG counter uses clock tick units.

Note

There is no BC_MTP_CMP10RE register since the broadcast channel does not expect a response.

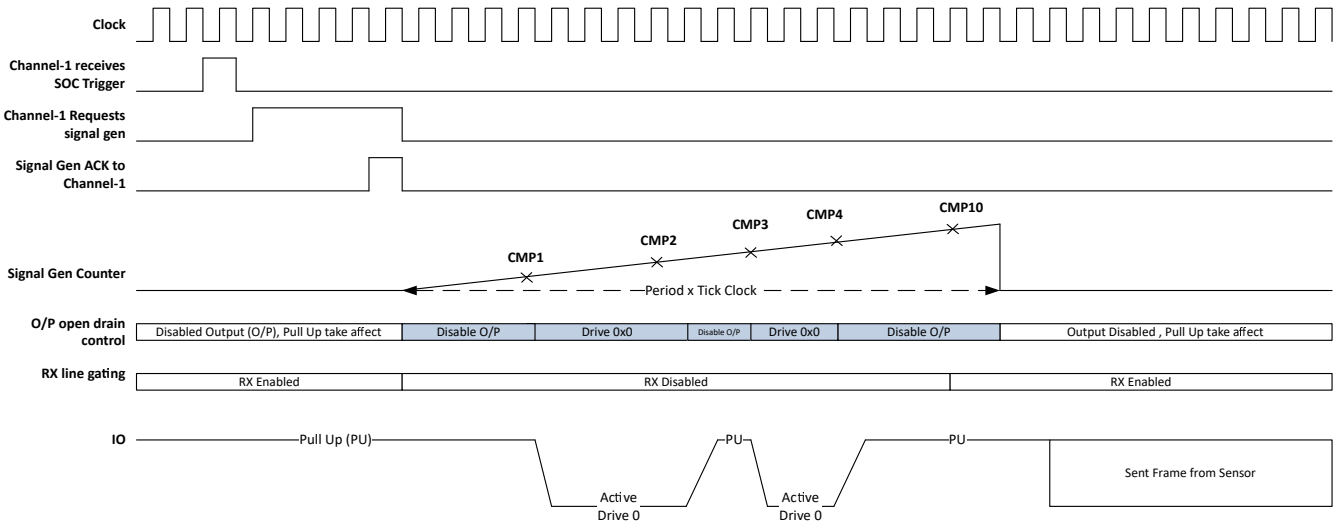

Figure 42-2. SENT Output Control

The signal generator initializes a counter to 0x0 after receiving a request from a channel to start the pulse sequence, and counts to the value stored in the channel's respective period register.

Note

The SENT pin must be configured for open-drain. This can be set using the GPIO open-drain register.

42.2.3 Channel Triggers

A channel is triggered by software, a trigger external to the SENT peripheral, or by another channel. See External Triggers for more details on the trigger sources for the SENT channels. The channel's done signal can be used to self-trigger, which allows continuous sampling of data. The use of another channel's done signal simplifies sequentially sampling sensors. When the SENT bus is idle and the trigger is received, the start of the pulse trigger is generated by the selected source from the TRIGSEL bitfield in the respective BC_TRIGSEL or Sn_TRIGSEL register (where n is 1 through 4). The trigger source from a channel is only valid when the channel's MTP_EN bit is set.

Note that because of the way the trigger connection is structured, all channels can be triggered by a single trigger, in which case the channels are serviced in a round-robin fashion. Valid trigger requests go through a round-robin to determine which channel trigger request is serviced, following this order of priority:

1. Broadcast Channel
2. Channel 1
3. Channel 2
4. Channel 3
5. Channel 4

After choosing the channel to be serviced, the valid trigger source for each channel can be checked using the TRIG_REQ bits in the TPGENSTAT register. If there is a trigger received before a pulse-sensor-response sequence completes, an overflow error occurs on the channel.

Once the arbiter chooses the channel to be serviced, the channel's configuration data is loaded and the trigger pulse is generated if the SENT peripheral is in idle or disabled. There is no wait time for the first trigger pulse serviced because there is no flag for the last received frame. After the first trigger pulse, the counter starts counting until reaching a configured wait time value in the WAITTIME register. This is a global register which controls the idle time between the last rising edge of the RX frame to the start of the MTPG pulse. This register can be a value from 0 to 511 and is in terms of SENT ticks.

Note

When SENT is disabled by RX_ENB, this indicates that the MTPG is used to enable the receiver after the pulse is sent. For this reason, a trigger pulse can be generated if the SENT peripheral is disabled.

The trigger changes the direction of the pin to be an output until the pulse sequence completes. The SENT receiver is gated when the pulse is generated so the pulse is not treated as a SENT frame.

42.2.4 Timeout

The timeout count down timer is an independent timer that can be used for the MTPG timeout and SENT timeout. The MTPG has the respective register Sn_MTP_TO where n is 1 through 4, for configuring the timeout value. The SENT peripheral has the CSENT_TO register for setting the timeout value.

Note

There is no BC_MTP_TO register since the broadcast channel does not expect a response.

For the MTPG, once the pulse is sent out, the timeout value of a non-broadcast channel is set. At the end of the period of the current trigger pulses, the timeout value is loaded to the counter to start counting down. If the RX line does not receive a low pulse within the timeout value, a timeout error occurs and creates an interrupt. This timeout can be configured for when there is no response from a sensor in a specified length of time, or on a per channel basis.

For the SENT peripheral, the timeout error occurs when SENT is idle for too long or the time between frames is longer than the timeout time. The value is set using the CSENT_TO register, and is loaded after the sensor frame is received.

Once the low pulse of the synchronization pulse is detected or the timeout expires, the countdown counter is disabled. The default timeout registers are set to 0, meaning the timeout countdown timer is disabled.

42.3 Protocol Description

SENT messages are encoded and decoded based on the time between falling or rising edges, depending on the idle polarity. For this section, the high idle polarity is described as an example. The same information applies for low idle polarity, given the edge direction of the clock is swapped. The messages are timed using clock tick time, or TT, which is calculated during the calibration/synchronization pulse.

A slow frame is composed of multiple fast frames, and transmits longer streams of data. The slow frame also utilizes multiple fast frames to transmit additional information through the status and communication nibble, such as the message ID, slow data, and CRC.

The frame format for SENT is as follows:

1. Calibration or synchronization pulse with a fixed period (56 clock ticks)
   a. This is used by the receiver as a reference to measure the TT. The pulse starts with a falling edge for high idle polarity and rising edge for low idle polarity and the counter for the synchronization period starts counting. For a high idle polarity, the period between the first falling edge and the second falling edge is divided into 56 to determine the TT. The TT is used to sample the nibbles' values. If more than one synchronization pulse is detected, the first one is ignored under the assumption the pulse is a pause pulse.
2. One status and serial communication nibble pulse (12 to 27 clock ticks)
   a. The status nibble transmits miscellaneous information such as part numbers, mode of operation, and error code information in slow channel mode (1-bit per frame serial message). This nibble is not included for the frame's CRC calculation if the RX_CRC_WITH_STATUS bit is not set.

Table 42-3. Status Nibble Description

Bit	Functionality
0	Channel 2 error indicator (1 = error)
1	Channel 1 error indicator (1 = error)
2	Serial data message bit (CRC, message ID, and data)
3	Short Serial Message Pattern: Start with 1 and the rest of the 15 messages are 0 Enhanced Serial Message Pattern: Unique pattern [0]1111110, message 13 and 18 are 0; the [0] is a zero pre-condition before the start of serial message 1

   i. The status nibble for the FAST channel without a slow serial message is 0, with an option for using bit 0 and/or bit 1 as an error flag for certain sensors. If the sensor is in error, bit 0 or 1 of the status nibble is set to 1.
   ii. A Short or Enhanced Serial Message is ignored on the status and communication nibble until the appropriate pattern of the message is received. Note that if the status nibble is used in a way not defined by the J2716 standard, then mask the serial errors appropriately.
3. Sequence of one to eight data nibble pulses (12 to 27 clock ticks for each nibble pulse)
   a. For high idle polarity, the pulse starts with a falling edge and remains low for a few clock ticks. Then each nibble's value is determined between falling edges, with the minimum pulse period being 12 clock ticks and the maximum being 27 clock ticks. The incoming serial nibble value is sampled at a clock tick length of TT / 2. The sampling occurs at the middle of the nibble pulse. For high idle polarity, the SENT TT counter counts the number of TT between two falling edges of the nibble pause and offsets the value with 12.

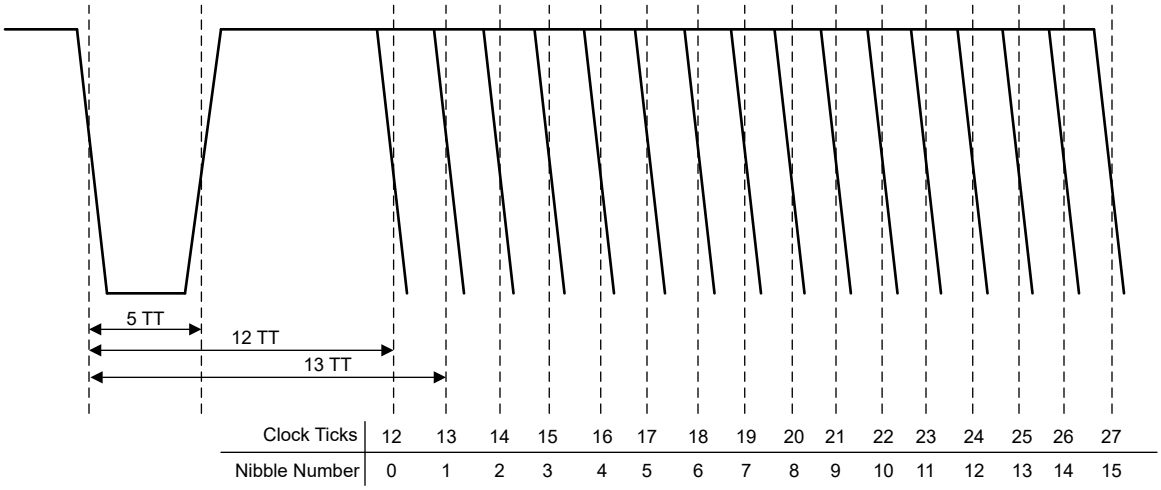

Figure 42-3. Nibble Pulse

   b. If the number of TT between the two falling edges is less than 11 or greater than 27, the value is invalid and the frame error is set.
4. One CRC nibble pulse (12 to 27 clock ticks)
   a. See Section 42.3.2.
5. Pause pulse (optional)
   a. This is an optional part of the SENT message format. For a fixed-length frame, the pause pulse fills up the message after the checksum nibble. This is the portion between 12 clock ticks and 768 clock ticks. If the RX_PPENB is enabled in the RCFG register the receiver expects the next pulse to be a pause pulse after the CRC nibble. When no pause pulse is enabled, the receiver expects that a packet received is immediately followed by another packet calibration/synchronization pulse. This does not apply for MTP_MODE, where an end pulse is expected at the end of the final CRC field.
6. End pulse for synchronous mode SENT that requires MTPG (12 ticks)
   a. For sensors synchronously responding to the MTPG, a 12-clock tick end pulse terminates the frame transmission after the CRC nibble and idly waits for the next trigger pulse. The SENT peripheral does not require a complete end pulse, and acknowledges the received packet when the CRC is verified.

42.3.1 Nibble Frame Format

A sensor's frame can contain one or two sensor data channels. The SENT receives data nibbles according to the format sent by the connected sensor. The DATA0_MAP and DATA1_MAP registers configure the nibble sorting and determine whether the received nibble is part of data 0 or data 1 memory map, as well as where the data nibble, status nibble, or CRC nibble are stored in the corresponding FIFO or direct memory location in SENT_MEM.

Figure 42-4 shows the format for a fast SENT message. For the Short Serial Message Format or Enhanced Serial Message Format, this is a single frame of the entire message.

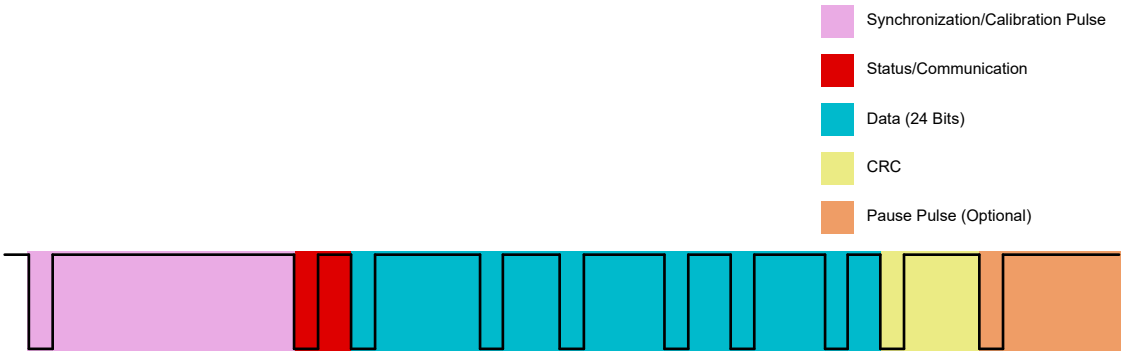

Figure 42-4. Fast Message

Table 42-4. SENT Data Frame Format Examples

Frame Format	Data Nibbles	Data 1	Data 2	Data 3	Data 4	Data 5	Data 6
Two 12-bit fast channels	6	Ch1 Most-Significant Nibble	Ch1 Middle-Significant Nibble	Ch1 Least-Significant Nibble	Ch2 Most-Significant Nibble	Ch2 Middle-Significant Nibble	Ch2 Least-Significant Nibble
One 12-bit fast channel	3	Ch1 Most-Significant Nibble	Ch1 Middle-Significant Nibble	Ch1 Least-Significant Nibble	N/A	N/A	N/A
High-speed with one 12-bit fast channel	4	Bits [11..9]	Bits [8..6]	Bits [5..3]	Bits [2..0]	N/A	N/A
Secure sensor with 12-bit fast channel 1 and secure sensor information on fast channel 2	6	Ch1 Most-Significant Nibble	Ch1 Middle-Significant Nibble	Ch1 Least-Significant Nibble	Counter Most-Significant Nibble	Counter Least-Significant Nibble	Inverted Copy of Ch1 Most-Significant Nibble
Single sensor with 12-bit fast channel 1 and no value on fast channel 2	6	Ch1 Most-Significant Nibble	Ch1 Middle-Significant Nibble	Ch1 Least-Significant Nibble	0	0	0
14-bit fast channel 1 and 10-bit fast channel 2	6	Ch1 Most-Significant Nibble	Ch1 Middle Most-Significant Nibble	Ch1 Middle Least-Significant Nibble	Ch1/Ch2 Least-Significant Nibble	Ch2 Middle-Significant Nibble	Ch2 Least-Significant Nibble
16-bit fast channel 1 and 8-bit fast channel 2	6	Ch1 Most-Significant Nibble	Ch1 Middle Most-Significant Nibble	Ch1 Middle Least-Significant Nibble	Ch2 Least-Significant Nibble	Ch2 Least-Significant Nibble	Ch2 Most-Significant Nibble

An example of the data mapping for two 12-bit fast channels frame format is shown in Table 42-5. This table uses an address offset, which is relevant to the corresponding base address for the SENT peripheral used.

Table 42-5. Data Mapping for Two 12-Bit Fast Channels

Address Offset	Byte 3	Byte 2	Byte 1	Byte 0	Word
0x0	Timestamp[31..24]	Timestamp[23..16]	Timestamp[15..8]	Timestamp[7..0]	Timestamp
0x4	0x00	0x00	0x0, Data Nibble 1	Data Nibble 2, Data Nibble 3	Data 0
0x8	0x00	0x00	0x0, Data Nibble 6	Data Nibble 5, Data Nibble 4	Data 1

42.3.2 CRC

The Cyclic Redundancy Check, or CRC, is a method of detecting errors in transmitted data. The CRC checksum is used when the RX_CRCENB bit in the RCFG register is enabled. CRC4, CRC6, and CRC8 are used for the receiver to check against the received data. The corresponding CRC check outputs a 4-bit, 6-bit, or 8-bit CRC respectively.

1. CRC4
   a. The CRC4 value is used to verify the validity of data nibbles in the Fast Channel frame, the message ID, and the 8-bit data in the Slow Channel Short Serial Message. CRC4 uses polynomial G(x) = x^4 + x^3 + x^2 + 1 with a seed value of 0101. The status and communication nibbles are included in this CRC calculation if the RX_CRC_WITH_STATUS parameter or programmable bit is enabled. The checksum is implemented as a bit-wise XOR with a 16-element array lookup. The checksum is determined by using all data nibbles in sequence and check-summing the result with an extra zero value. A 4-bit zero nibble is added after the data nibbles to protect for common errors in the last data nibble and checksum.
2. CRC6
   a. The CRC6 value is used to verify the validity of the 24-bit Slow Channel Enhanced Serial Message using the polynomial G(x) = x^6 + x^4 + x^3 + 1 with a seed value of 010101. CRC6 is also used to verify the 24-bit Fast Channel Frame format data using a different polynomial, G(x) = x^6 + x + 1 with a seed value of 010101. The checksum is implemented using a bit-wise XOR with a 64-array lookup. The checksum is determined by reading in 6-bit groups of the 24-bit message data in order and check-summing the result with an extra zero value, as mentioned in Section 42.3.5. The 6-bit zero nibble is added after the data nibbles to protect for common errors in the last data nibble and checksum.
3. CRC8
   a. The CRC8 value is used to verify the validity of the 28-bit Fast Channel Frame format data, which contains 7 data nibbles and 2x2 Rolling counter data. This checksum uses the polynomial G(x) = x^8 + x^5 + x^3 + x^2 + x + 1 with a seed value of 01010101.

42.3.3 Short Serial Message Format

The short serial message format uses multiple fast SENT data frames to transmit slow data. While the fast data is transmitted through each single SENT frame, the slow data is transmitted using bit 2 of the status and communication nibble pulse, with the most-significant bit first. The serial data is communicated in a 16-bit sequence. This means that after 16 SENT frames are received correctly, there is a 4-bit message ID, an 8-bit slow data, and a 4-bit CRC. The start bit of the serial message is indicated by a 1 in bit 3 of the status and communication nibble pulse, and the subsequent 15 frames must have a status bit 3 which is 0.

Note

To receive serial data correctly, all 16 frames must have no errors relating to the calibration pulse, CRC, frame, or other error types. This is verified using the RSLOW_DV flag.

The 16-bit message contains a 4-bit message ID nibble, 2 nibbles of data, and a CRC nibble. The CRC checksum is derived from the message ID and 2 data nibbles.

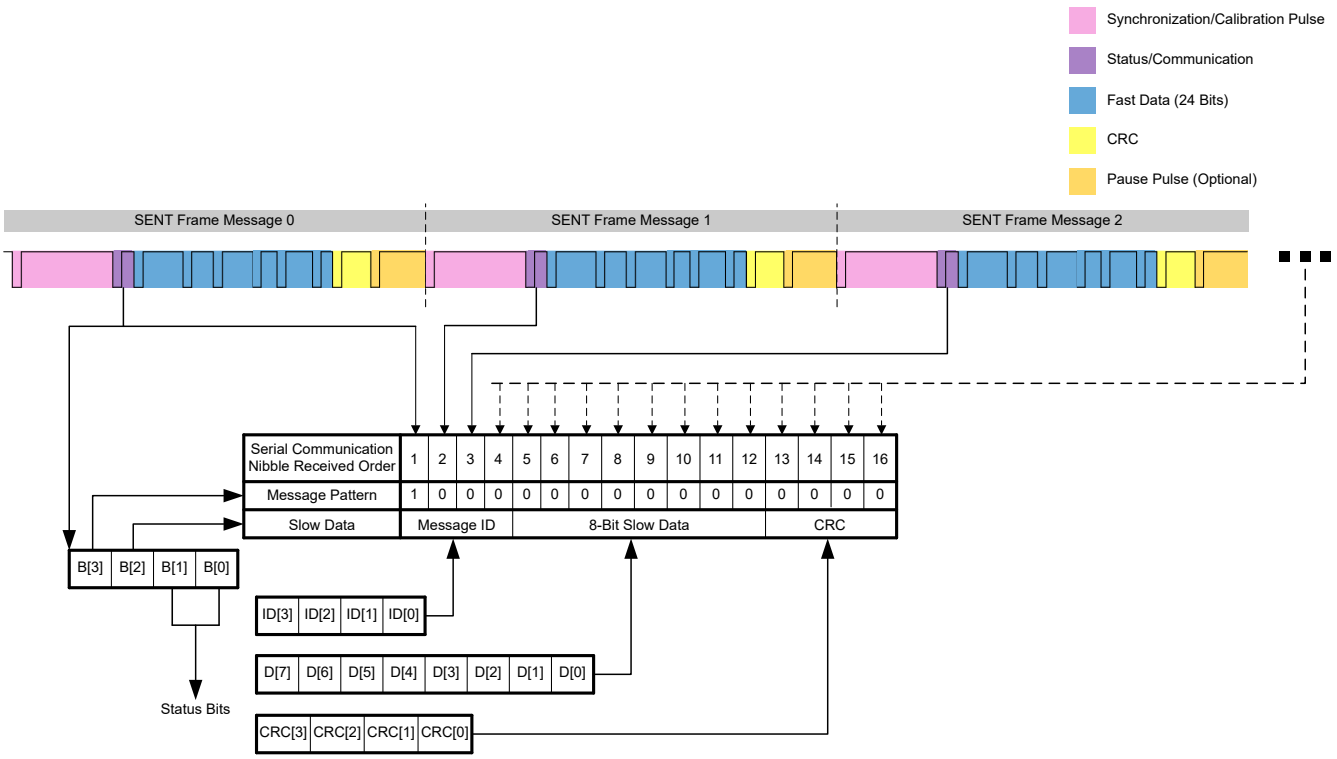

Figure 42-5. Short Serial Message

The message ID indicates the type of data in the data byte, which is ordered most-significant bit first.

Table 42-6. Message IDs

Message ID	Sensed Value for Data Field
0000	High Byte of Air Temperature
0001	Low Byte of Air Temperature
0010	High Byte of Humidity
0011	Low Byte of Humidity
0100	High Byte of Barometric Pressure Data
0101	Low Byte of Barometric Pressure Data
0110-1110	Reserved
1111	Error Codes

42.3.4 Enhanced Serial Message Format

The Enhanced Serial Message Format has a larger data field and set of message IDs available than the Short Serial Message Format. The serial message frame consists of a configuration bit and configurable 20-bit payload. The Enhanced Serial Message Format allows for this 20-bit payload to be configurable as an 8-bit message ID with 12-bit slow data or a 4-bit message ID with 16-bit slow data. The serial data is transmitted in bit 2 and 3 of the status and communication nibble from 18 consecutive data frames, similar to the Short Serial Message Format. The serial message is interleaved in 18 frames, so SENT keeps track and extracts the status and communication bits from every frame. Thus, by the 18th frame the complete message is received, given there are no errors.

Note

To receive serial data correctly, all 18 frames must have no errors, such as calibration error, CRC error, frame error, format error, or a zero before the start. The slow message counter and the FSM is reset when the message does not have zero before the start, "111110" after the start, or message 13 or 18 does not have 0 in bit 3 of the status and communication nibble.

The start of a serial message frame is indicated by "01111110" in bit 3 of the status and communication nibble. The first 1 in the sequence indicates the first nibble in the serial message frame. Bit 3 of the status and communication nibble must be 0 for message 7, 13, and 18. Bit 3 of the status and communication nibble of frame 8 is the C bit, which chooses the configuration.

1. C = 0 indicates 12-bit data and 8-bit message ID
2. C = 1 indicates 16-bit data and 4-bit message ID

The advantage to using the Enhanced Serial Message Format is that either a larger selection of message IDs can be used or more slow data can be transmitted using bit 3 of the status and communication nibble pulse, but in both cases there is more slow data received than the Short Serial Message Format.

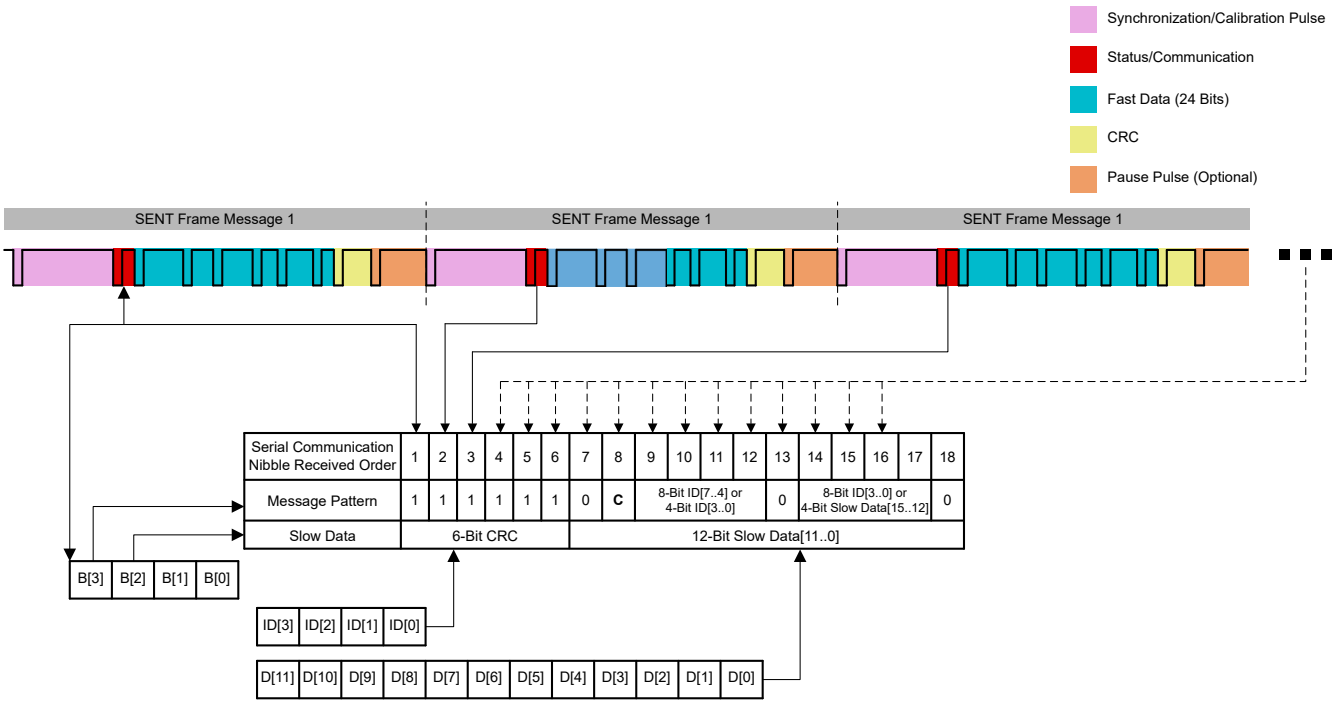

Figure 42-6. Enhanced Serial Message

42.3.5 Enhanced Serial Message Format CRC

The 6-bit CRC value is the result of the CRC calculation of the serial data message bit 2 and bit 3 in message frame 7 through 18. The polynomial G(x) = x^6 + x^4 + x^3 + 1 with a seed value 010101 is used. Six zeros are added to the message for CRC generation: Mcrc = [m0, m1, m2, … m23, 0, 0, 0, 0, 0, 0].

Serial Communication Nibble Received Order	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18
Start Bit (bit 3)	1	1	1	1	1	1	0	C	ID7	ID6	ID5	ID4	0	ID3	ID2	ID1	ID0	0
Serial Data (bit 2)	6-Bit CRC						D11	D10	D9	D8	D7	D6	D5	D4	D3	D2	D1	D0

24-Bit Data for CRC Generation

Message CRC Bit	m0	m1	m2	m3	m4	m5	m6	m7	m8	m9	m10	m11	m12	m13	m14	m15	m16	m17	m18	m19	m20	m21	m22	m23

First Data Bit

Figure 42-7. Enhanced Serial Message Data Order for CRC Generation

42.3.6 Receive Modes

The SENT peripheral decodes serial data and performs a CRC check before the data is stored in the receive buffer. The decoding includes arranging the module before writing the data to the buffer, such as when a Fast Channel frame is received. The SENT frame format varies among different types of sensors, with the greatest number of nibbles being 11 (two CRC nibbles, eight data nibbles, and one status nibble).

The receive buffer for the SENT peripheral can be configured as a FIFO or a direct map. The received data is stored in the SENT_MEM location, with the offset depending on the receive frame and the mode chosen.

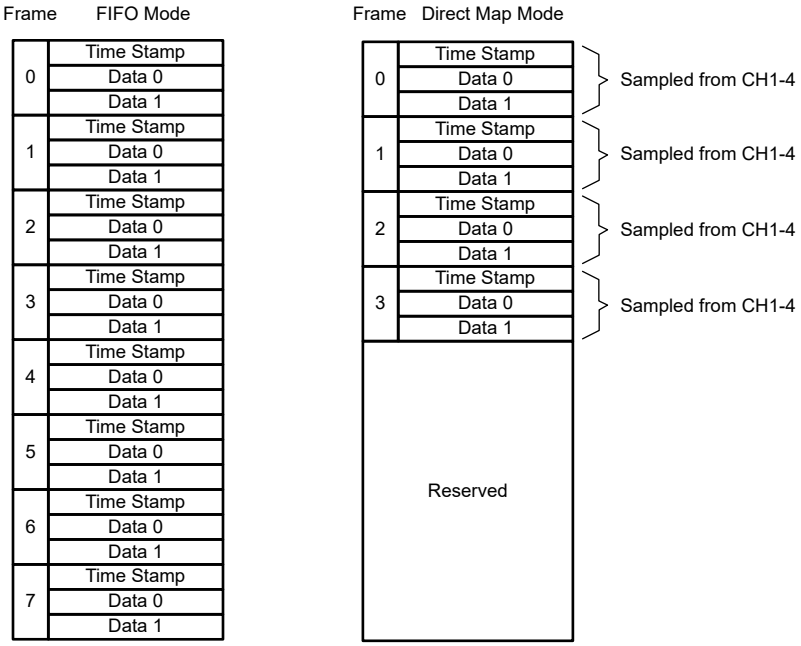

Figure 42-8. FIFO vs Direct Map Receive Modes

The FIFO mode is enabled by the FIFO_MODE bit in the RCFG2 register. In FIFO mode, the FIFO supports a depth of 24 values. This mode allows the host to be slow without causing data loss. Each sensor can store up to two data per frame, in addition to the time stamp. This allows 8 individual frames of data to be store using FIFO mode. The FIFO level is an indication of the number of 32-bit words available in the buffer, where each frame consists of three 32-bit words (timestamp, data 0, and data 1). This FIFO level can be used to generate an interrupt, if the level meets or exceeds the user configured threshold in RFIFO_TRIGLEV. See Section 42.5 for more details.

If the receiver FIFO receives a valid frame while the FIFO is full, the RFIFO_OVFERR bit in the RINTFLAG register is set and causes a receiver error interrupt. If the CPU or RTDMA try to read the FIFO when the FIFO is empty, the RFIFO_UNDFERR bit in the RINTFLAG register is set and causes a receiver error interrupt.

If the FIFO mode is disabled, the received data is directly mapped to a buffer at a specific address (see Section 42.8 for more details). In the direct map configuration, target devices can be triggered in any order. Upon a receive interrupt, the data is grabbed by the CPU from the specific memory location.

42.4 RTDMA Trigger

The SENT RTDMA trigger creates a transfer request to the RTDMA. The DMA_ENB bit must be enabled and the FIFO level must be greater than or equal to the user-configured threshold in RFIFO_TRIGLEV to trigger this RTDMA request. Disabling the RTDMA trigger resets the trigger logic. Figure 42-9 shows an example of implementing a RTDMA trigger for the SENT peripheral.

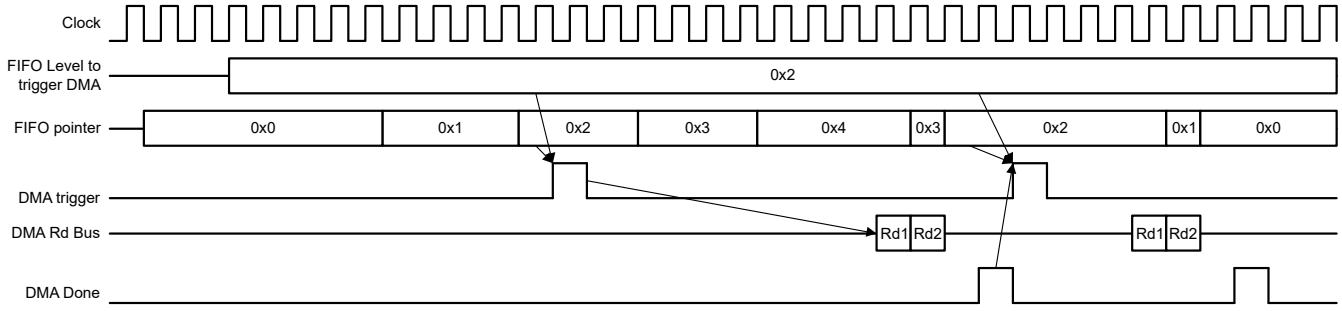

Figure 42-9. RTDMA Trigger Example

42.5 Interrupts Configuration

The SENT peripheral has interrupts for receive errors and FIFO thresholds. The RINTFLAG register is updated when there are errors in the received data, and the RSTAT register is updated with the relevant status information is made available.

An interrupt can be created based on the FIFO level of the SENT peripheral when the interrupt is enabled and the FIFO level is greater than or equal to the user-configured threshold in RFIFO_TRIGLEV. Figure 42-10 shows an example of implementing an interrupt trigger for the SENT peripheral with a FIFO threshold.

When a receive error occurs the entire packet or frame is not considered valid, depending on the NOWR_ERRDATA in the RCFG2 register. Frame data with errors are still saved to the receive buffer if NOWR_ERRDATA is 0. Receive error flags can occur simultaneously, with the RINTFLAG register showing the cause of the flags raised. The following errors activate the error interrupt flags:

- Fast CRC Error: The receiver CRC calculation does not match the CRC nibble received of the fast channel; enabled by RX_CRCENB in the RCFG register
- Fast Frame Error: The received status or data nibble of the fast channel is less than 12 TT or greater than 27 TT
- Slow CRC Error: The received slow channel message ID and data CRC calculation does not match the received slow channel CRC; enabled by RX_CRCENB in the RCFG register
- Slow Format Error: The received slow channel message contains an incorrect format than what is expected. In this case, the state machine for detecting the correct sequence for a slow frame restarts each time there is an error (this way the state machine gets properly synchronized again with the calibration pulse after enough restarts)

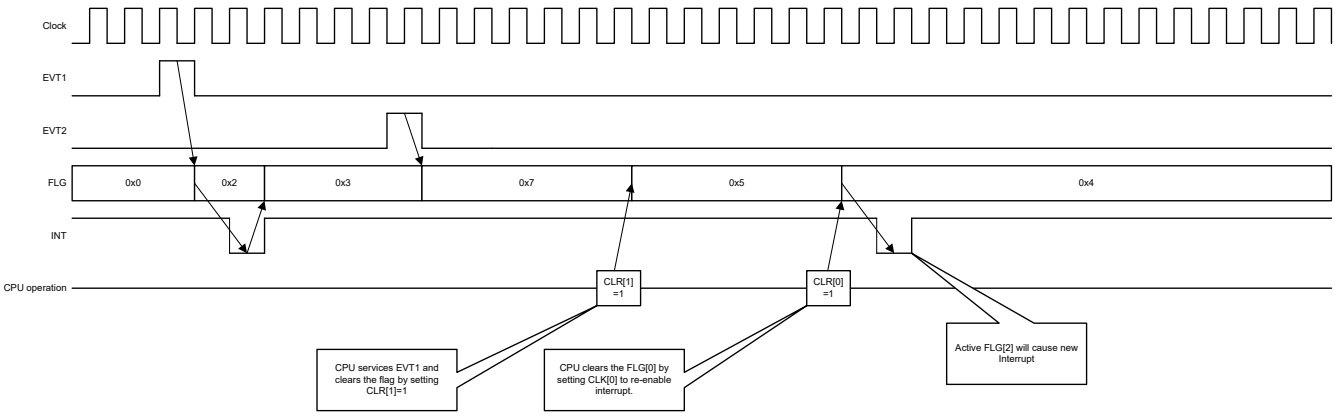

Figure 42-10. Interrupt Trigger Example

The following list shows additional conditions which, when detected, can generate an error or interrupt:

1. Calibration errors (two types)
   a. Type 1: Receiver is programmed with initial tick-time clock cycle according to the TTCLK bits in the RCFG register, which is derived from the calibration pulse of a frame. If the newly determined calibration TT differs by more than 25% from the initially programmed time, the RFAST_SYNCERR25 flag is raised. The receiver assumes the newly derived TT going forward unless the TTCLK is re-programmed.
   b. Type 2: Synchronization pulse conversion with the previous frame differs by more than 1.5625%, then the RFAST_SYNCERR flag is raised.
2. Too many/few nibbles between calibration pulses
   a. A RFAST_SnFRME error can occur (where n can be 1 through 4) when there are too few nibbles between calibration pulses, or when the received nibble is <12 ticks or >27 ticks; a RFAST_SnCRCE error can occur if there are too many nibbles and the RX_CRCENB is enabled. This can happen because the next nibble beyond the expected and configured value gets interpreted as a CRC. There is no frame error because the receiver is expecting a valid calibration pulse after the extra nibble
3. Frequency drift
   a. If two successive frames vary in length by more than 1.5625%, the FREQDRIFT_ERR flag is raised. This is determined by a ratio of the calibration pulses to the message length. This condition occurs if this ratio varies by more than $\frac{1}{64}$ or less than $-\frac{1}{64}$. This interrupt must be masked unless you are confident there are fixed length frames, which can be created by included a pause pulse. This check is active if the pause pulse RX_PPENB is expected and enabled.

The interrupt architecture for the SENT peripheral is shown in Figure 42-11.

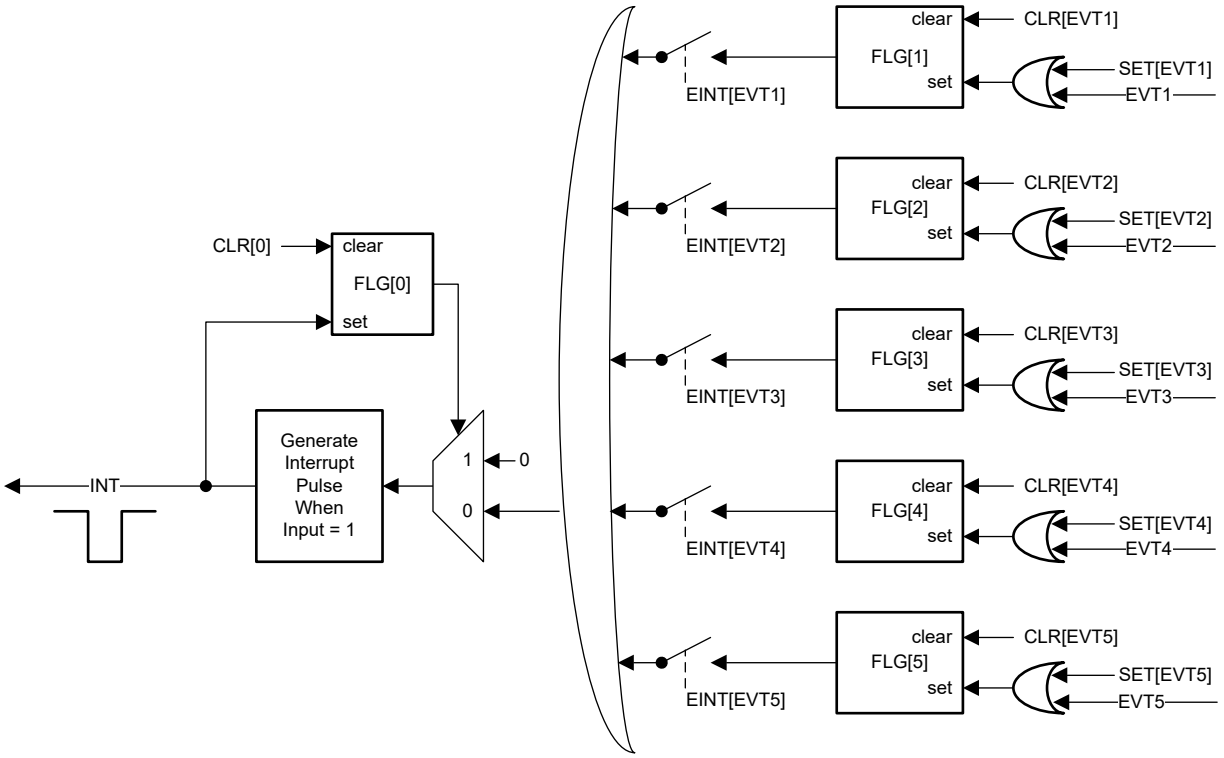

Figure 42-11. Interrupt Block Diagram

Table 42-7. Interrupt Types

Type	Flag	Event[1] [2]	Condition	Clear Interrupt
Valid Receives	GLBL	GLBL_flag0	This flag generates a low pulse interrupt flag	RCLRINT[0]
	RFAST_S1DV	rs1valid_evt	Active when SENT is in multi sensor mode and receives the corresponding channel's fast channel frame or standard SENT[3] frame data without any errors	RCLRINT[1]
	RFAST_S2DV	rs2valid_evt		RCLRINT[2]
	RFAST_S3DV	rs3valid_evt		RCLRINT[3]
	RFAST_S4DV	rs4valid_evt		RCLRINT[4]
	RSLOW_DV	rslow_valid_evt	Set when SENT receives slow channel data (16 or 18 consecutive fast channel data) without any errors	RCLRINT[5]

Table 42-7. Interrupt Types (continued)

Type	Flag	Event[1] [2]	Condition	Clear Interrupt
Receive Errors	RSLOW_CRCERR	rslow_crcerr_evt	The RSLOW_CRCERR is set when the received slow channel message ID and data CRC calculation does not match the received slow channel CRC; RX_CRCENB in the RCFG register must be enabled	RCLRINT[6]
	RSLOW_FORMATERR	rslow_formaterr_evt	The RSLOW_FORMATERR is set when the received Slow Channel message contains wrong format	RCLRINT[7]
	RFAST_S1CRCE	rfast_crcerr_evt	The RFAST_CRCERR is set when the Receiver CRC calculation (RX_CRCENB must be enabled) does not match the CRC nibble received on the corresponding channel or standard SENT[3] fast channel	RCLRINT[8]
	RFAST_S2CRCE	rfast_crcerr_evt		RCLRINT[9]
	RFAST_S3CRCE	rfast_crcerr_evt		RCLRINT[10]
	RFAST_S4CRCE	rfast_crcerr_evt		RCLRINT[11]
	RFAST_S1FRME	rfast_frmerr_evt	The RFAST_FRMERR is set when the received status or data nibble of the Sensor1 or standard SENT[3] fast channel is less than 12 TT or greater than 27 TT, which is invalid	RCLRINT[12]
	RFAST_S2FRME	rfast_frmerr_evt		RCLRINT[13]
	RFAST_S3FRME	rfast_frmerr_evt		RCLRINT[14]
	RFAST_S4FRME	rfast_frmerr_evt		RCLRINT[15]
	RTIMEOUT_ERR[0]	rtimeout_err_evt[0]	The RTIMEOUT_ERR[0] is set when there is no response, since the MTPG is sent out to the channel, or there is an unexpectedly long idle time between frames for standard SENT mode[3]	RCLRINT[16]
	RTIMEOUT_ERR[1]	rtimeout_err_evt[1]		RCLRINT[17]
	RTIMEOUT_ERR[2]	rtimeout_err_evt[2]		RCLRINT[18]
	RTIMEOUT_ERR[3]	rtimeout_err_evt[3]		RCLRINT[19]
	RFAST_SYNCERR25	rfast_syncerr25_evt	The RFAST_SYNCERR is set when the received Calibration or Synchronization pulse is more than +/-25% from the nominal 56 ticks	RCLRINT[20]
	RFAST_SYNCERR	rfast_syncerr_evt	The RFAST_SYNCERR is set when the received Calibration or Synchronization pulse is more than +/-25% from the nominal 56 ticks or the successive calibration pulse differ by more than 1.5625%	RCLRINT[21]
	FREQDRIFT_ERR	freqdrift_err_evt	The FREQDRIFT_ERR is set when the frequency drift on the fixed length frames (the ratio of the calibration pulse to the message length varies by more than 1/64 or less than -1/64 from one message to another)	RCLRINT[22]
	RFIFO_TRIGGER	rfifo_trig_evt	The RFIFO_TRIGGER is set when the Receiver FIFO's pointer is greater than or equal to the programmed trigger level	RCLRINT[23]
	RFIFO_OVFERR	rfifo_ovferr_evt	The RFIFO_OVFERR is set when the Receiver FIFO is overflow	RCLRINT[24]
	RFIFO_UNDFERR	rfifo_undferr_evt	The RFIFO_UNDFERR is set when the Receiver FIFO is underflow	RCLRINT[25]
MTPG Errors	OVFTRIG_ERR[0]	ovftrig_err_evt[0]	The OVFTRIG_ERR is set when the Broadcast Channel of the MTPG has Overflow trigger requests	RCLRINT[26]
	OVFTRIG_ERR[1]	ovftrig_err_evt[1]	The OVFTRIG_ERR is set when the corresponding channel of the MTPG has Overflow trigger requests	RCLRINT[27]
	OVFTRIG_ERR[2]	ovftrig_err_evt[2]		RCLRINT[28]
	OVFTRIG_ERR[3]	ovftrig_err_evt[3]		RCLRINT[29]
	OVFTRIG_ERR[4]	ovftrig_err_evt[4]		RCLRINT[30]

(1) The appropriate REINT bit must be set for the event to occur
(2) The RSETINT bit corresponding to the RINTFLAG bit can be set to trigger the event/flag manually, and the same applies to the RCLRINT to clear the event/flag manually

(3) Standard SENT mode in the table refers to using SENT without the MTPG to trigger a pulse

42.6 Glitch Filter

The GFILT field in the RCFG2 register contains the number of SYSCLKS that the received serial data input is filtered by. The glitch filter can cause a delay up to GFILT SYSCLKS, but this is usually negligible in terms of TT resolution.

In Figure 42-12, the GFILT is programmed to be 5. For every change on the receive input that is less than or equal to this value, the change is filtered out. The number of clock cycles per tick period is normally much larger than GFILT.

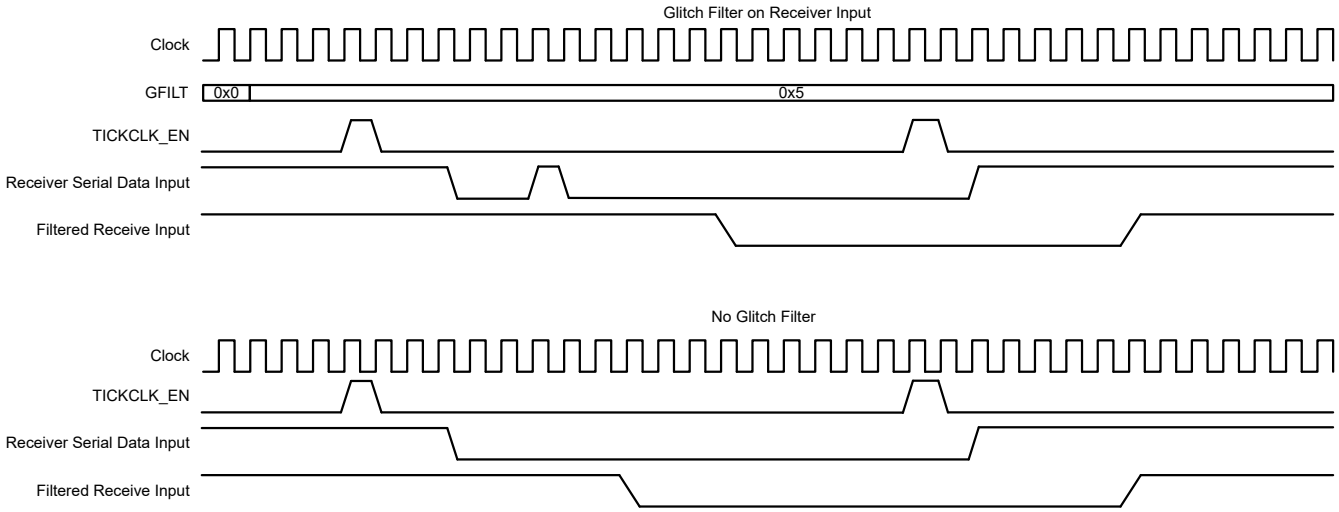

Figure 42-12. Glitch Filter Examples

42.7.2 SENT Examples

NOTE: These examples are located in the C29SDK installation from ti.com at the following location: mcu_sdk_DEVICE_GPN/examples/driverlib/CORE_IF_MULTICORE/sent

Cloud access to these examples is available at the following link: dev.ti.com C29SDK Examples.

42.7.2.1 SENT Single Sensor - SINGLE_CORE

FILE: sent_ex1_single_sensor.c

This program will receive sensor data from a magnetic angle sensor using the SENT communication protocol. This data can be further utilized to convert and get the sensed information.

The sensor sends out a signal that is made up of a string of pulses with data encoded as falling to falling edge periods. It happens independently of any receiver module activity, which occurs without the receiver module sending a sync signal. The modulated signal with a constant amplitude voltage and an evaluation of the time interval between two falling edges (a single edge) is delivered in units of 4 bits (1 nibble), which can represent values ranging from 0 to 15.

This example configures SENT module to receive 6 Data-nibble per frame for fast channel.

External Connections

- Connect GPIO58 to sensor's SENT channel 1 pin

Watch Variables

- *SENT_Frame*[] - Frame received from the Sensor
- *timestamp*[] - Time stamp of the data nibble received

42.8 SENT Registers

This section describes the SENT Registers.

42.8.1 SENT Base Address Table

Table 42-9. SENT Base Address Table

42.8.2 SENT_CFG Registers

Table 42-10 lists the memory-mapped registers for the SENT_CFG registers. All register offset addresses not listed in Table 42-10 should be considered as reserved locations and the register contents should not be modified.

Table 42-10. SENT_CFG Registers

Offset	Acronym	Register Name
20h	RCFG	Receiver Configuration Register
24h	RFDATA	FIFO's read data
28h	RSDATA	Receiver slow channel Data Register
2Ch	RSTAT	Receiver Status Register
34h	RCFG2	Receiver Configuration 2 Register
40h	RINTFLAG	Receiver Interrupt Status Register
44h	REINT	Receiver Interrupt Enable Register
48h	RSETINT	Receiver Set Interrupt Register
4Ch	RCLRINT	Receiver Clear Interrupt Register
50h	CSENT_SWR	CSENT Software Reset register
54h	DATA0_MAP	Receiver Data0 Sorting format
58h	DATA1_MAP	Receiver Data1 Sorting format register
5Ch	CSENT_TO	CSENT's Timeout register
60h	CSENT_RXD	CSENT Receiver Serial Data input register
64h	RXVAL_CNT	CSENT Rx Valid Frames Counter
68h	RXDEDGE_CNT	CSENT Receiver Serial Data Input Falling-edge Counter
6Ch	SWR_RXVAL_CNT	Valid CSENT frames counter Sofware Reset
70h	SWR_RXDEDGE_CNT	CSENT Receiver Serial Data input Falling-edge Counter Software Reset
7Ch	CSENT_VERSION	CSENT_XRF Version Number register

Complex bit access types are encoded to fit into small table cells. Table 42-11 shows the codes that are used for access types in this section.

Table 42-11. SENT_CFG Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value

42.8.2.1 RCFG Register (Offset = 20h) [Reset = 012C0000h]

RCFG is shown in Figure 42-13 and described in Table 42-12.

Return to the Summary Table.

Receiver Configuration Register

Figure 42-13. RCFG Register

15	14	13	12	11	10	9	8
RSVD				RX_CRCTYPE	RX_CRC_WITH_STATUS	CRC_WIDTH	
R-0h				R/W-0h	R/W-0h	R/W-0h	
7	6	5	4	3	2	1	0
RX_DNIB				RX_PPENB	RSVD_0	RX_CRCENB	RX_ENB
R/W-0h				R/W-0h	R-0h	R/W-0h	R/W-0h

Table 42-12. RCFG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	TTCLK	R/W	12Ch	The TTCLK determines the number of clock cycles per Tick when generating the internal tick clock. This tick clock is used for the initial calculation of calibration Sync errors (25% differential). The default is 300 (12Ch), which is typically 3 us ticks for 100 Mhz clock.
15-12	RSVD	R	0h	Reserved bits
11	RX_CRCTYPE	R/W	0h	0h: The recommended CRC (J2716 2010 or newer spec) checksum calculation is used. 1h: The original Legacy CRC (J2716 2007 spec) checksum calculation is used.
10	RX_CRC_WITH_STATUS	R/W	0h	0h: The CRC checksum calculation for the data nibbles only. 1h: The CRC checksum calculation include the status nibble and data nibble.
9-8	CRC_WIDTH	R/W	0h	CRC_WIDTH indicates the expected number of CRC bits for fast channel. The default is 0h, which is a 4-bit CRC. 0h: 4-bit CRC 1h: 6-bit CRC 2h: 8-bit CRC 3h: Reserved
7-4	RX_DNIB	R/W	0h	RX_DNIB indicates the number of data nibbles should be expected (1 to 6) for standard SENT. Some of the enhanced sensors support 7 and 8 nibbles. RX_DNIB[3:0] 0h: Reserved 1h: 1 data nibble per-frame 2h: 2 data nibbles per-frame 3h: 3 data nibbles per-frame 4h: 4 data nibbles per-frame 5h: 5 data nibbles per-frame 6h: 6 data nibbles per-frame 7h: 7 data nibbles per-frame 8h: 8 data nibbles per-frame 9h-Fh: Reserved

Table 42-12. RCFG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	RX_PPENB	R/W	0h	0h: The sensor is continuously supplying SENT data that the calibration pulse follows immediately after the CRC. 1h: Indicates that Pause Pulse will be expected after the CRC if this is enabled. The RX_PPENB must be enabled for frequency drift's detection on the fixed length frames.
2	RSVD_0	R	0h	Reserve bit
1	RX_CRCENB	R/W	0h	0h: The CRC calculation and check is disabled 1h: The CRC for fast channel and slow channel is enabled to calculate and check.
0	RX_ENB	R/W	0h	0h: CSENT Receiver is disabled 1h: The receiver is enabled to monitor the SENT bus. When using a master trigger pulse to trigger a sensor, the RX_ENB must be set to 0 and the CSENT receiver is controlled by MTPG module.

42.8.2.2 RFDATA Register (Offset = 24h) [Reset = 00000000h]

RFDATA is shown in Figure 42-14 and described in Table 42-13.

Return to the Summary Table.

FIFO's read data

Figure 42-14. RFDATA Register

RSVD			PP	RXNIB			
R-0h			R-0h	R-0h			

Table 42-15. RSTAT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	RX_TTCLK	R	0h	RX_TTCLK contains the most recent synchronization tick time calculation in clocks. The user can read this value and compare it to the previous frame to determine if the tick clock time has changed significantly.
15	RX_SYNC	R	0h	0h: Indicates that the Receiver is receiving data 1h: Indicates that the Receiver is waiting for a synchronization period
14	RXSLOW_DN	R	0h	0h: No slow channel serial message has been received 1h: Indicates that the receiving of the slow channel serial message is done. This bit will be cleared after the received RSDATA is read
13	RXSLOW_ACT	R	0h	0h: Indicates that the slow channel is not active 1h: Indicates that the receiving of the slow channel serial message is active
12-8	RXSLOW_ST	R	0h	RXSLOW_ST contains the receiving status of the slow channel data (Message ID or Data or CRC) during receiving Status and Communication nibble.
7-5	RSVD	R	0h	Reserved bits
4	PP	R	0h	0h: No pause pulse 1h: Indicates that it is currently receiving the pause pulse (only if the RX_PPENB in RCFG register is set to 1)
3-0	RXNIB	R	0h	RXNIB indicates Received data nibble's status. RXNIB[3:0] 0h: Invalid 1h: Receiving Data Nibble 1 2h: Receiving Data Nibble 2 3h: Receiving Data Nibble 3 4h: Receiving Data Nibble 4 5h: Receiving Data Nibble 5 6h: Receiving Data Nibble 6 7h: Receiving Data Nibble 7 8h: Receiving Data Nibble 8 9h-Fh: Invalid

42.8.2.5 RCFG2 Register (Offset = 34h) [Reset = 00000050h]

RCFG2 is shown in Figure 42-17 and described in Table 42-16.

Return to the Summary Table.

Receiver Configuration 2 Register

Figure 42-17. RCFG2 Register

31	30	29	28	27	26	25	24
RSVD_0

RSVD			MTP_MODE	GFILT			
R-0h			R/W-0h	R/W-5h			
7	6	5	4	3	2	1	0
GFILT				NOWR_ERRDATA	TSTAMP_DIS	DMA_ENB	FIFO_MODE
R/W-5h				R/W-0h	R/W-0h	R/W-0h	R/W-0h

Table 42-16. RCFG2 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-20	RSVD_0	R	0h	Reserved bits
19-16	RFIFO_TRIGLEV	R/W	0h	This field indicates the trigger level for the receiver FIFO trigger interrupt and the DMA trigger. The level can be from 1 up to the maximum level of the FIFOs depth (16). This field is used only when the FIFO_MODE is 1. Receiver FIFO trigger interrupt will be disabled if RFIFO_TRIGLEV is set to 0 (default value).
15-13	RSVD	R	0h	Reserved bits
12	MTP_MODE	R/W	0h	0h: MTP_MODE is disabled 1h: This mode indicates that the Receiver will send the master trigger pulse(s) and then expects Sensor's data response
11-4	GFILT	R/W	5h	GFILT indicates the number of clock cycle pulse on the Receiver Serial Data input that will be filtered out. A range from 0 (bypass) to 255 can be specified. The default is 5.
3	NOWR_ERRDATA	R/W	0h	0h: Default value, indicates always write to the memory although the data contains errors 1h: The received message with errors will not be written to the FIFO or memory
2	TSTAMP_DIS	R/W	0h	0h: Default value that indicates the timestamp will be written to the memory. The Timestamp will be recorded at the start of the incoming frame 1h: Disable the timestamp. The timestamp of the frame received will not be written into the memory
1	DMA_ENB	R/W	0h	0h: Disable DMA trigger 1h: Enable DMA trigger. The receiver FIFO DMA trigger is generated when the FIFO level is >= trigger level (RFIFO_TRIGLEV)

Table 42-16. RCFG2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	FIFO_MODE	R/W	0h	0h: The Timestamp, data0 and data1 data will be mapped directly to a memory. For Multiple Sensor mode, the timestamp and data for each sensor will be written into the same FIFO/memory. The default is 0 for direct mapping 1h: The Receivers memory is in FIFO mode. It contains Timestamp, data0, and data1. The FIFO width is 32-bit and its depth is configurable

42.8.2.6 RINTFLAG Register (Offset = 40h) [Reset = 00000000h]

RINTFLAG is shown in Figure 42-18 and described in Table 42-17.

Return to the Summary Table.

Receiver Interrupt Status Register

Table 42-17. RINTFLAG Register Field Descriptions

Bit	Field	Type	Reset	Description
31	RSVD	R	0h	Reserved bit
30-26	OVFTRIG_ERR	R	0h	OVFTRIG_ERR: when one of the bit is set, it indicates that there is an overflow trigger on that channel. This error appears only when the MTP_MODE is enabled. It happens when the same channel trigger pulse generator receives trigger request while it is busy. OVFTRIG_ERR[4:0] 00h: No Overflow Trigger 01h: Overflow Trigger on the Broadcast channel 02h: Overflow Trigger on the Sensor 1 channel 04h: Overflow Trigger on the Sensor 2 channel 08h: Overflow Trigger on the Sensor 3 channel 10h: Overflow Trigger on the Sensor 4 channel
25	RFIFO_UNDFERR	R	0h	0h: No underflow error on the receiver FIFO 1h: The receiver FIFO is underflow. The CPU reads the receiver FIFO when it is empty
24	RFIFO_OVFERR	R	0h	0h: No overflow error on the receiver FIFO 1h: The Receiver FIFO is overflow, a write to the receiver FIFO while it is full
23	RFIFO_TRIGGER	R	0h	0h: No FIFO Trigger 1h: The number of data in the Receivers FIFO is >= the programmed trigger
22	FREQDRIFT_ERR	R	0h	0h: No frequency drift error 1h: There is a frequency drifts error on the fixed length frames. The ratio of the calibration pulse to the message length varies by > 1/64 or < -1/64 from one message to another . The RX_PPENB in RCFG register is required to be enabled for the fixed frames length
21	RFAST_SYNCERR	R	0h	0h: No synchronization error 1h: Synchronization error, the successive calibration pulses differ by >+1.5625% or < -1.5625%

Table 42-17. RINTFLAG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
20	RFAST_SYNCERR25	R	0h	0h: No Calibration/Synchonization error 1h: Indicates that the Calibration/Synchronization pulse varies by more than 25% from the expected 56 clock ticks
19-16	RTIMEOUT_ERR	R	0h	RTIMEOUT_ERR is used for the Synchronous mode Sensor, which needs master trigger pulse (MTP_MODE is enabled) or standard CSENT (MTP_MODE is disabled). For the MTP_MODE, this flag is set when the receiver does receive the low Synchronous pulse in reponse to a trigger pulse before the timeout specified. RTIMEOUT_ERR[3:0] 0h: No Timeout 1h: No response from Sensor 1 in timeout specified 2h: No response from Sensor 2 in timeout specified 4h: No response from Sensor 3 in timeout specified 8h: No response from Sensor 4 in timeout specified For standard CSENT (MTP_MODE is disabled) timeout, RTIMEOUT_ERR[0] is set when the receiver does not receive the next frame's low synchronous pulse after a frame is received (long idle time) before the timeout specified.
15	RFAST_S4FRME	R	0h	0h: No Frame error in the Sensor 4 fast channel data 1h: For multi-sensor mode, it indicates that there is a Frame Error (invalid nibble) in the Sensor 4 fast channel data
14	RFAST_S3FRME	R	0h	0h: No Frame error in the Sensor 3 fast channel data 1h: For multi-sensor mode, it indicates that there is a Frame Error (invalid nibble) in the Sensor 3 fast channel data
13	RFAST_S2FRME	R	0h	0h: No Frame error in the Sensor 2 fast channel data 1h: For multi-sensor mode, it indicates that there is a Frame Error (invalid nibble) in the Sensor 2 fast channel data
12	RFAST_S1FRME	R	0h	0h: No Frame error in the Sensor 1 fast channel data 1h: For non MTP_MODE sensor (standard CSENT), it indicates that there is a Frame Error (invalid nibble) in the fast channel data. In the multi-sensor mode, it indicates that there is a Frame error in the Sensor 1 fast channel data
11	RFAST_S4CRCE	R	0h	0h: No CRC Error in the Sensor 4 fast channel data 1h: For multi-sensor mode, it indicates that there is a CRC Error in the Sensor 4 fast channel data.
10	RFAST_S3CRCE	R	0h	0h: No CRC Error in the Sensor 3 fast channel data 1h: For multi-sensor mode, it indicates that there is a CRC Error in the Sensor 3 fast channel data
9	RFAST_S2CRCE	R	0h	0h: No CRC Error in the Sensor 2 fast channel data 1h: For multi-sensor mode, it indicates that there is a CRC Error in the Sensor 2 fast channel data
8	RFAST_S1CRCE	R	0h	0h: No Sensor 1 fast channel CRC error 1h: For non MTP_MODE sensor (standard CSENT), this flag will be set when there is a CRC error (mismatched CRC calculation result with received CRC data) in the received fast channel data. In multi-sensor mode, this will only be set when Sensor 1 fast channel data has CRC error
7	RSLOW_FORMATERR	R	0h	0h: No slow channel Format Error 1h: There is Format Error in the slow channel data
6	RSLOW_CRCERR	R	0h	0h: No slow channel CRC Error 1h: There is CRC Error in the slow channel data
5	RSLOW_DV	R	0h	0h: No valid slow channel data 1h: A valid slow channel data is received from single sensor
4	RFAST_S4DV	R	0h	0h: No valid Sensor 4 data is received 1h: In multi-sensor mode, it indicates Sensor 4 fast channel data is received
3	RFAST_S3DV	R	0h	0h: No valid Sensor 3 data is received 1h: In multi-sensor mode, it indicates Sensor 3 fast channel data is received

Table 42-17. RINTFLAG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
2	RFAST_S2DV	R	0h	0h: No valid Sensor 2 data is received 1h: In multi-sensor mode, it indicates Sensor 2 fast channel data is received
1	RFAST_S1DV	R	0h	0h: No valid Sensor 1 data is received 1h: For non MTP_MODE sensor (standard CSENT) mode, it indicates a valid fast frame is received. In multi-sensor mode, it indicates Sensor 1 fast channel data is received
0	GLBL	R	0h	This GLBL flag will be set whenever an interrupt occurs (that is not masked)

42.8.2.7 REINT Register (Offset = 44h) [Reset = 00000000h]

REINT is shown in Figure 42-19 and described in Table 42-18.

Return to the Summary Table.

42.8.2.13 CSENT_TO Register (Offset = 5Ch) [Reset = 00000000h]

CSENT_TO is shown in Figure 42-25 and described in Table 42-24.

Return to the Summary Table.

CSENT's Timeout register

Figure 42-25. CSENT_TO Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TO_VAL																															
R/W-0h																															

Table 42-24. CSENT_TO Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	TO_VAL	R/W	0h	TO_VAL is used to specify the timeout setting to indicate that no synchronization pulse has been received within the timeout time specified. This can be used for functional safety and a timeout interrupt will occur when this time as expired. The Timeout functionality is enabled only after receiving a synchronization pulse. The value is specified in clock tick units, and it can be disabled by setting the value to 0, which is the default value.

42.8.2.14 CSENT_RXD Register (Offset = 60h) [Reset = 00000001h]

CSENT_RXD is shown in Figure 42-26 and described in Table 42-25.

Return to the Summary Table.

VERSION																															
R-01000001h																															

Table 42-30. CSENT_VERSION Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	VERSION	R	01000001h	VERSION can programmatically provide the version number of the CSENT_XRF IP core.

42.8.3 SENT_MEM Registers

Table 42-31 lists the memory-mapped registers for the SENT_MEM registers. All register offset addresses not listed in Table 42-31 should be considered as reserved locations and the register contents should not be modified.

Table 42-31. SENT_MEM Registers

Offset	Acronym	Register Name
400h + formula	MDATA_y	Data word 'N' in TPRAM memory. The SENT TPRAM contains fast channel SENT frames whether in FIFO or Direct Map mode. In Direct Map mode, the user must read the SENT frame data out from this memory (refer to the section regarding Receive Modes for more details)

Complex bit access types are encoded to fit into small table cells. Table 42-32 shows the codes that are used for access types in this section.

Table 42-32. SENT_MEM Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

42.8.3.1 MDATA_y Register (Offset = 400h + formula) [Reset = 00000000h]

MDATA_y is shown in Figure 42-32 and described in Table 42-33.

Return to the Summary Table.

32-bit data word 'N' in TPRAM memory. The SENT TPRAM contains fast channel SENT frames whether in FIFO or Direct Map mode. In Direct Map mode, the user must read the SENT frame data out from this memory (refer to the section regarding Receive Modes for more details)

Offset = 400h + (y * 4h); where y = 0h to Fh

C30h	S4_MTP_TO	Sensor 4 Channel MTP TimeOut Register
C34h	S4_TRIGSEL	Sensor 4 Channel MTP Trigger Select Register
C38h	S4_MTP_SWTR	Sensor 4 Channel MTP Software Trigger Register
F00h	WAITTIME	Global Waittime Register
F04h	TPGENSTAT	Master Trigger Pulse Global Status Register
F30h	MTP_VERSION	MTPG IP Core Version Number Register
F3Ch	MTP_SWR	MTPG Global Software Reset Register. Writing 1 to this register will cause Software Reset

Complex bit access types are encoded to fit into small table cells. Table 42-35 shows the codes that are used for access types in this section.

Table 42-35. SENT_MTPG Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read

Table 42-35. SENT_MTPG Access Type Codes (continued)

Access Type	Code	Description
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

42.8.4.1 BC_MTP_EN Register (Offset = 800h) [Reset = 00000000h]

BC_MTP_EN is shown in Figure 42-33 and described in Table 42-36.

Return to the Summary Table.

Broadcast Channel MTP Enable Register

Table 42-59. S1_MTP_CMP10RE Register Field Descriptions

Bit	Field	Type	Reset	Description
31-11	RSVD	R	0h	Reserved bits
10-0	TOGGLETIME	R/W	0h	TOGGLETIME of the S1_MTP_CMP10RE defines when to enable the CSENT Receiver while the Sensor 1's trigger pulses are generated. This TOGGLETIME will be compared independently, since it might be higher or lower than other Sensor 1's compare register value. The value is specified in clock tick units.

42.8.4.25 S1_MTP_PERIOD Register (Offset = 92Ch) [Reset = 00000000h]

S1_MTP_PERIOD is shown in Figure 42-57 and described in Table 42-60.

Return to the Summary Table.

Sensor 1 Channel MTP Period Register

Figure 42-57. S1_MTP_PERIOD Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSVD																					PERIOD										
R-0h																					R/W-0h										

Table 42-60. S1_MTP_PERIOD Register Field Descriptions

Bit	Field	Type	Reset	Description
31-11	RSVD	R	0h	Reserved bits
10-0	PERIOD	R/W	0h	PERIOD of the S1_MTP_PERIOD register indicates the total time that the master trigger pulse output waveform is active. The PERIOD must be larger than all Sensor 1 Channel Compares' TOGGLETIME value. The value is specified in clock tick units.

42.8.4.26 S1_MTP_TO Register (Offset = 930h) [Reset = 00000000h]

S1_MTP_TO is shown in Figure 42-58 and described in Table 42-61.

Return to the Summary Table.

Sensor 1 Channel MTP TimeOut Register

Figure 42-58. S1_MTP_TO Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TIMEOUT																															
R/W-0h																															

Table 42-61. S1_MTP_TO Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	TIMEOUT	R/W	0h	The TIMEOUT of the S1_MTP_TO register indicates a time to initiate an interrupt if the CSENT Receiver has not received response (low pulse of calibration/synchronization) from Sensor 1 within timeout time after the Master trigger pulse is generated. The value is specified in clock tick units.

42.8.4.27 S1_TRIGSEL Register (Offset = 934h) [Reset = 00000000h]

S1_TRIGSEL is shown in Figure 42-59 and described in Table 42-62.

Return to the Summary Table.

Sensor 1 Channel MTP Trigger Select Register

Figure 42-59. S1_TRIGSEL Register

RSVD																					PERIOD										
R-0h																					R/W-0h										

Table 42-90. S3_MTP_PERIOD Register Field Descriptions

Bit	Field	Type	Reset	Description
31-11	RSVD	R	0h	Reserved bits
10-0	PERIOD	R/W	0h	PERIOD of the S3_MTP_PERIOD register indicates the total time that the master trigger pulse output waveform is active. The PERIOD must be larger than all Sensor 3 Channel Compares' TOGGLETIME value. The value is specified in clock tick units.

42.8.4.56 S3_MTP_TO Register (Offset = B30h) [Reset = 00000000h]

S3_MTP_TO is shown in Figure 42-88 and described in Table 42-91.

Return to the Summary Table.

Sensor 3 Channel MTP TimeOut Register

Figure 42-88. S3_MTP_TO Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TIMEOUT																															
R/W-0h																															

Table 42-91. S3_MTP_TO Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	TIMEOUT	R/W	0h	The TIMEOUT of the S3_MTP_TO register indicates a time to initiate an interrupt if the CSENT Receiver has not received response (low pulse of calibration/synchronization) from Sensor 3 within timeout time after master trigger pulse is generated. The value is specified in clock tick units.

42.8.4.57 S3_TRIGSEL Register (Offset = B34h) [Reset = 00000000h]

S3_TRIGSEL is shown in Figure 42-89 and described in Table 42-92.

Return to the Summary Table.

Sensor 3 Channel MTP Trigger Select Register

Figure 42-89. S3_TRIGSEL Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSVD																									TRIGSEL						
R-0h																									R/W-0h						

Table 42-92. S3_TRIGSEL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-7	RSVD	R	0h	Reserved bits
6-0	TRIGSEL	R/W	0h	Specifies which hardware trigger source enables the Sensor 3 Channel Master Trigger Pulse Generator. The possible internal triggers are: 0h: Disable (no hardware triggers) 1h: Broadcast Trigger done 2h: Sensor 1 Trigger done 3h: Sensor 2 Trigger done 4h: Sensor 3 Trigger done 5h: Sensor 4 Trigger done External triggers are also available and are described by the 'Channel Triggers' section.

42.8.4.58 S3_MTP_SWTR Register (Offset = B38h) [Reset = 00000000h]

S3_MTP_SWTR is shown in Figure 42-90 and described in Table 42-93.

Return to the Summary Table.

TIMEOUT																															
R/W-0h																															

Table 42-106. S4_MTP_TO Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	TIMEOUT	R/W	0h	The TIMEOUT of the S4_MTP_TO register indicates a time to initiate an interrupt if the CSENT Receiver has not received response (low pulse of calibration/synchronization) from Sensor 4 within timeout time after master trigger pulse is generated. The value is specified in clock tick units.

42.8.4.72 S4_TRIGSEL Register (Offset = C34h) [Reset = 00000000h]

S4_TRIGSEL is shown in Figure 42-104 and described in Table 42-107.

Return to the Summary Table.

Sensor 4 Channel MTP Trigger Select Register

Figure 42-104. S4_TRIGSEL Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSVD																									TRIGSEL						
R-0h																									R/W-0h						

Table 42-107. S4_TRIGSEL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-7	RSVD	R	0h	Reserved bits
6-0	TRIGSEL	R/W	0h	Specifies which hardware trigger source enables the Sensor 4 Channel Master Trigger Pulse Generator. The possible internal triggers are: 0h: Disable (no hardware triggers) 1h: Broadcast Trigger done 2h: Sensor 1 Trigger done 3h: Sensor 2 Trigger done 4h: Sensor 3 Trigger done 5h: Sensor 4 Trigger done External triggers are also available and are described by the 'Channel Triggers' section.

42.8.4.73 S4_MTP_SWTR Register (Offset = C38h) [Reset = 00000000h]

S4_MTP_SWTR is shown in Figure 42-105 and described in Table 42-108.

Return to the Summary Table.

0	SWR	W	0h	0h: No MTPG software reset 1h: It will cause MTPG software reset and all registers will have their default value

Chapter 43

► SECURITY PERIPHERALS

The following chapters describe the Security peripherals.

Technical Reference Manual Overview

The block diagram is shown in Figure 43-1. This Technical Reference Manual is organized into five major sections:

- C29x SYSTEM RESOURCES

  These chapters describe the C29x CPU subsystem, C29x Boot ROM, device configuration, and other system peripherals.

- ANALOG PERIPHERALS

  These chapters describe the general analog subsystem configuration, Analog-to-Digital Converter (ADC), Buffered Digital-to-Analog Converter (DAC), and Comparator Subsystem (CMPSS).

- CONTROL PERIPHERALS

  These chapters describe the Enhanced Capture (eCAP), High-Resolution Capture (HRCAP), Enhanced Pulse-Width Modulator (ePWM) with High-Resolution Pulse-Width Modulator (HRPWM), Enhanced Quadrature Encoder Pulse (eQEP), and Sigma Delta Filter Module (SDFM) peripherals.

- COMMUNICATION PERIPHERALS

  These chapters describe the communication peripherals available to the C29x subsystem such as the EtherCAT, FSI, I2C, PMBUS, UART, LIN, SPI, and SENT.

- SECURITY PERIPHERALS

  This chapter describes the safety peripherals available to the C29x subsystem such as the Hardware Security Module (HSM) and Cryptographic Accelerator.

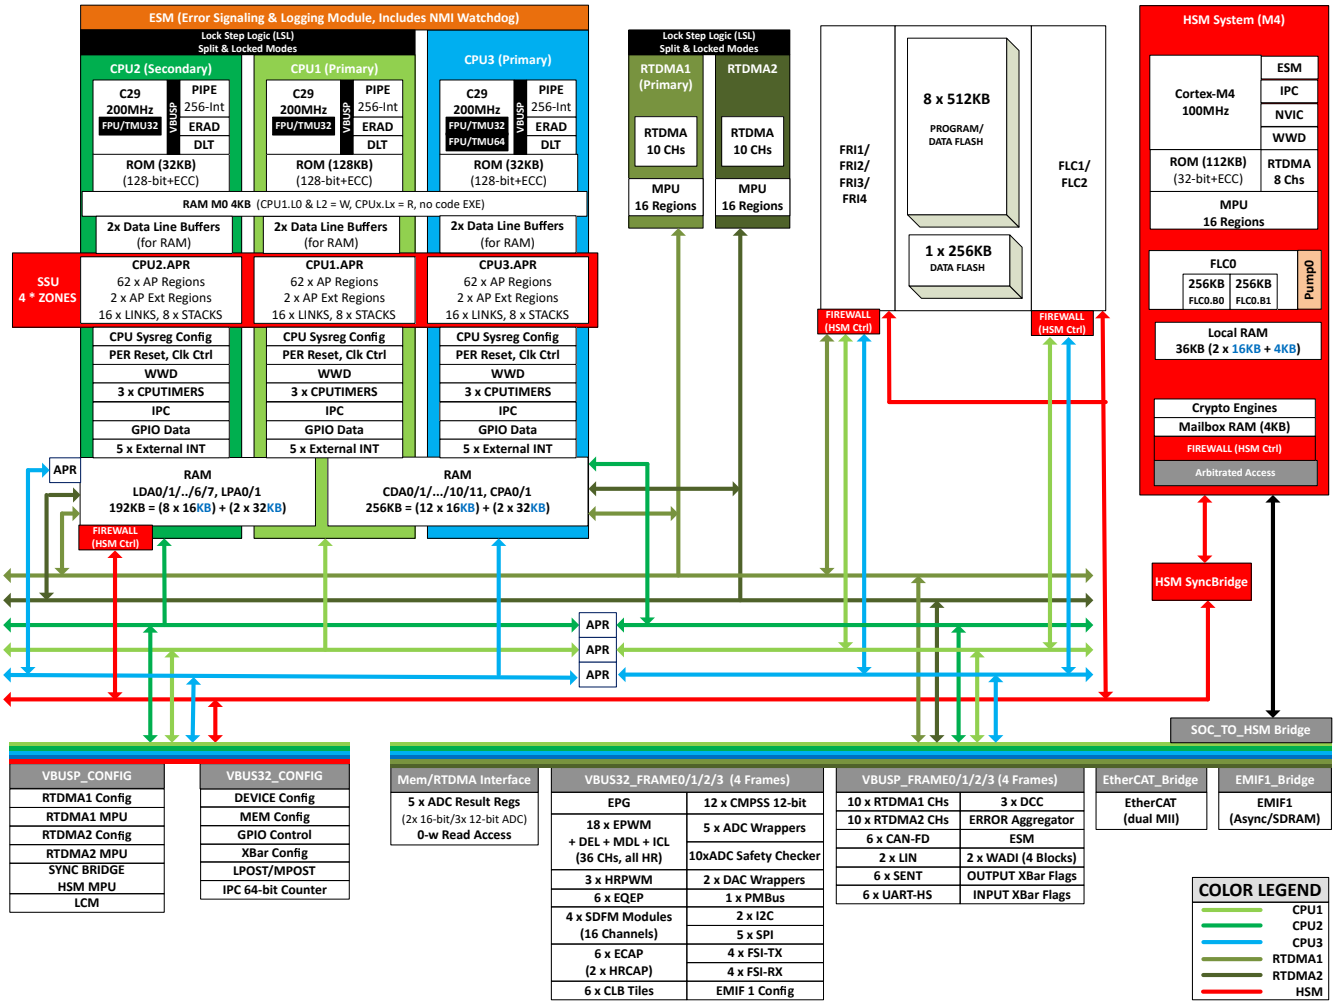

Figure 43-1. Block Diagram

Chapter 44

Security Modules

This chapter explains security modules for the C29x cores found on this MCU.

44.1 Hardware Security Module (HSM)

The Hardware Security Module (HSM) is a self-contained subsystem within the device that provides security and cryptographic functions. The host C29x subsystem interfaces with the HSM subsystem to perform the cryptographic operations required for code authentication, secure boot, secure firmware upgrades and encrypted run-time communications. A high-level view of the various subsystems in this device, with the HSM subsystem highlighted, is shown in Figure 44-1.

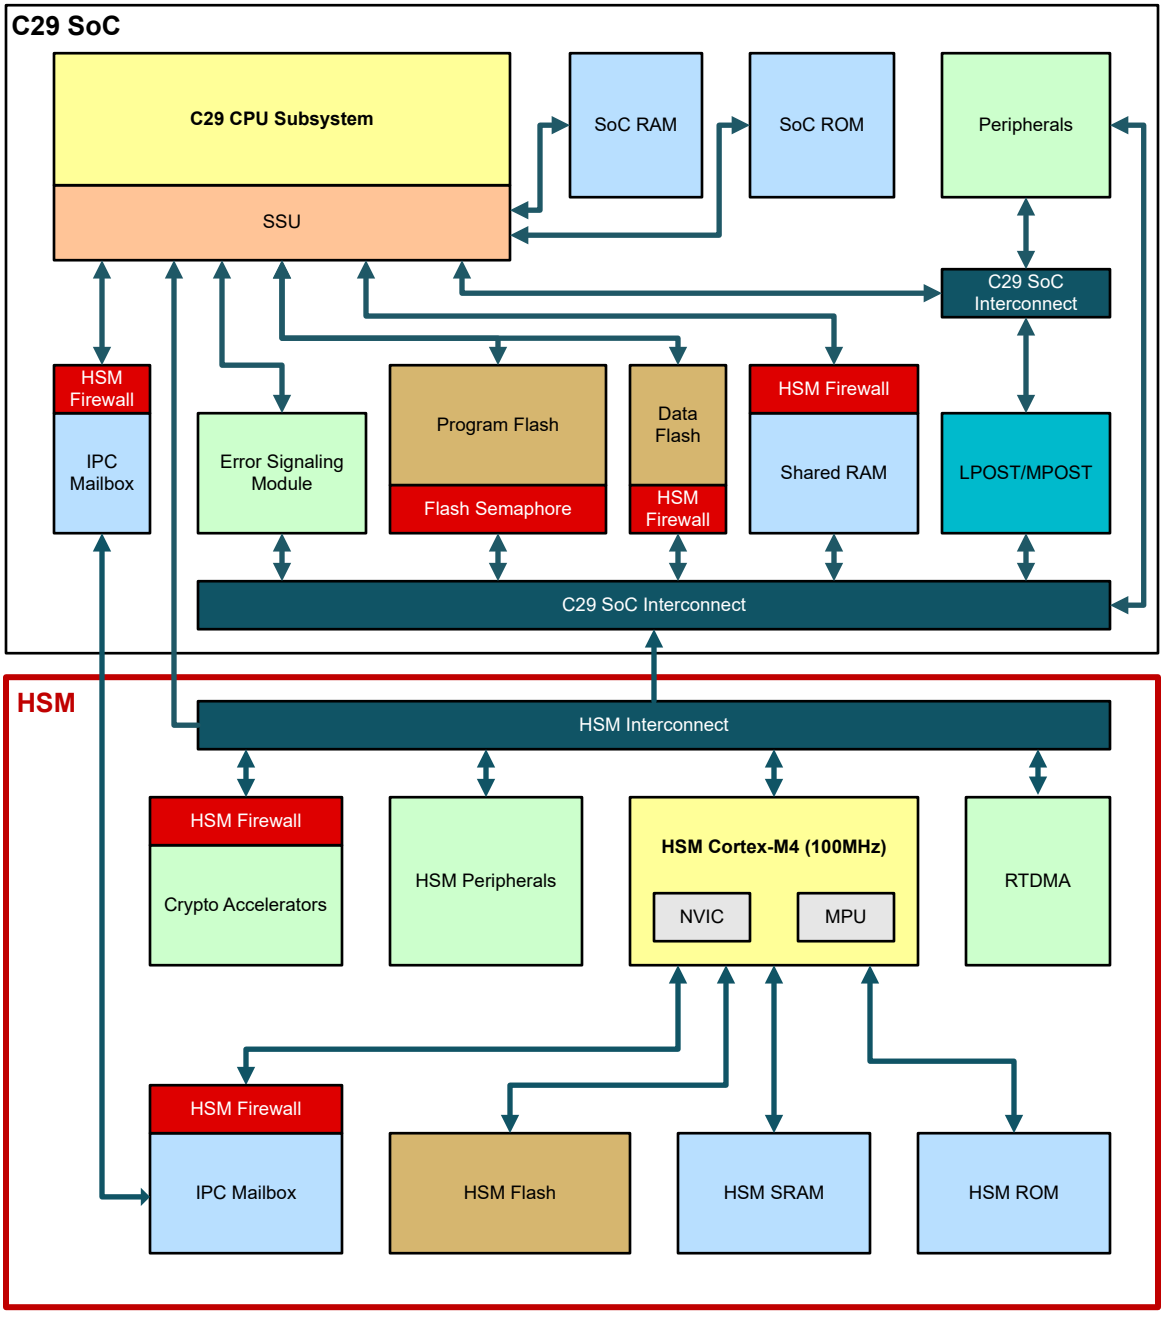

Figure 44-1. Device High-Level Block Diagram

At the center of the HSM is an ARM® Cortex®-M4 CPU running at 100MHz, with embedded SRAM, ROM, and up to 512KB of Flash memory. The Real-Time DMA (RTDMA) module enables fast data transfers between the HSM CPU and SRAM, HSM and application Flash memory banks, secure mailbox, and cryptographic engines.

The Security Manager module hosts the root-of-trust keys, defines the secure access mechanisms, controls the debug firewalls, and performs the security override sequences to establish protection of security assets if debug or failure-analysis operation is required.

The HSM includes a set of accelerator engines for executing cryptographic algorithms. These engines enable fast execution of symmetric encryption algorithms, hash functions, asymmetric encryption algorithms for public key infrastructure, and a true random number generator (TRNG). The Data Transform and Hashing Engine (DTHE) interfaces between the CPU and the cryptographic accelerators, providing interrupt and RTDMA trigger management and essential functions such as CRC and checksum computation.

In addition, the HSM provides peripheral modules to aid various security functions: timers, a real-time counter, a watchdog, DCC for clock monitoring, and ESM for error handling.

Communication between the HSM and the host application cores happens over a secure mailbox interface. The HSM controls various secure firewalls in the device, including the secure mailbox, cryptographic engines, shared RAM, and device Flash memory.

44.1.1 HSM Related Collateral

Foundational Materials

- C29x Academy - Hardware Security Module (HSM)

44.2 Cryptographic Accelerators

The Hardware Security Manager (HSM) includes several hardware accelerators to enable fast execution of key cryptographic algorithms. These engines are described in Table 44-1.

Table 44-1. List of Cryptographic Accelerator Engines

Engine	Algorithms Supported
AES (Advanced Encryption Standard)	Symmetric Algorithms: AES-128, AES-192, AES-256 Cipher modes: ECB, CTR, CBC, CFB, OFB, CCM, GCM Authentication: CBC-MAC
SM4	Symmetric Algorithms: SM4
PKE (Public Key Engine)	High-performance PKE for large-vector math/modulus operation Ciphers: RSA-2048, RSA-3092, RSA-4096, ECC (Curve25519, X25519, SecP256r1, secP256k1, secP384r1, secP384k1, Brain Pool, and more), SM2 Supports cryptographic operations: ECDSA, EdDSA, ECDH, EdDH, SM2DSA Side-channel protection (DPA, FIA)
SHA	Hash Algorithms: SHA-256, SHA-384, SHA-512 Keyed hashing: HMAC-SHA256, HMAC-SHA512
SM3	Hash Algorithms: SM3 (256 bits, 384 bits, 512 bits)
TRNG	True random number generator Deterministic random bit generator (DRBG)
