About This Manual

This Technical Reference Manual (TRM) details the integration, the environment, the functional description, and the programming models for each peripheral and subsystem in the device.

The TRM should not be considered a substitute for the data sheet, rather a companion guide that can be used alongside the device-specific data sheet to understand the details to program the device. The primary purpose of the TRM is to abstract the programming details of the device from the data sheet. This allows the data sheet to outline the high-level features of the device without unnecessary information about register descriptions or programming models.

Note

Texas Instruments is transitioning to use more inclusive terminology. Some language may be different than what you would expect to see for certain technology areas.

Notational Conventions

This document uses the following conventions.

- Hexadecimal numbers can be shown with the suffix h or the prefix 0x. For example, the following number is 40 hexadecimal (decimal 64): 40h or 0x40.
- Registers in this document are shown in figures and described in tables.
  - Each register figure shows a rectangle divided into fields that represent the fields of the register. Each field is labeled with its bit name, its beginning and ending bit numbers above, and its read/write properties with default reset value below. A legend explains the notation used for the properties.
  - Reserved bits in a register figure can have one of multiple meanings:
    - Not implemented on the device
    - Reserved for future device expansion
    - Reserved for TI testing
    - Reserved configurations of the device that are not supported
  - Writing nondefault values to the Reserved bits could cause unexpected behavior and should be avoided.

Glossary

TI Glossary	This glossary lists and explains terms, acronyms, and definitions.

Related Documentation From Texas Instruments

For a complete listing of related documentation and development-support tools for these devices, visit the Texas Instruments website at www.ti.com.

Additionally, the *F29x CPU Reference Guide* must be used in conjunction with this TRM.

Support Resources

TI E2E™ support forums are an engineer's go-to source for fast, verified answers and design help — straight from the experts. Search existing answers or ask your own question to get the quick design help you need.

Linked content is provided "AS IS" by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's Terms of Use.

Chapter 1

► C29x SYSTEM RESOURCES

The following chapters describe the C29x Configuration and System Resources.

Technical Reference Manual Overview

The block diagram is shown in Figure 1-1. This Technical Reference Manual is organized into five major sections:

- C29x SYSTEM RESOURCES

  These chapters describe the C29x CPU subsystem, C29x Boot ROM, device configuration, and other system peripherals.

- ANALOG PERIPHERALS

  These chapters describe the general analog subsystem configuration, Analog-to-Digital Converter (ADC), Buffered Digital-to-Analog Converter (DAC), and Comparator Subsystem (CMPSS).

- CONTROL PERIPHERALS

  These chapters describe the Enhanced Capture (eCAP), High-Resolution Capture (HRCAP), Enhanced Pulse-Width Modulator (ePWM) with High-Resolution Pulse-Width Modulator (HRPWM), Enhanced Quadrature Encoder Pulse (eQEP), and Sigma Delta Filter Module (SDFM) peripherals.

- COMMUNICATION PERIPHERALS

  These chapters describe the communication peripherals available to the C29x subsystem such as the EtherCAT, FSI, I2C, PMBUS, UART, LIN, SPI, and SENT.

- SECURITY PERIPHERALS

  This chapter describes the safety peripherals available to the C29x subsystem such as the Hardware Security Module (HSM) and Cryptographic Accelerator.

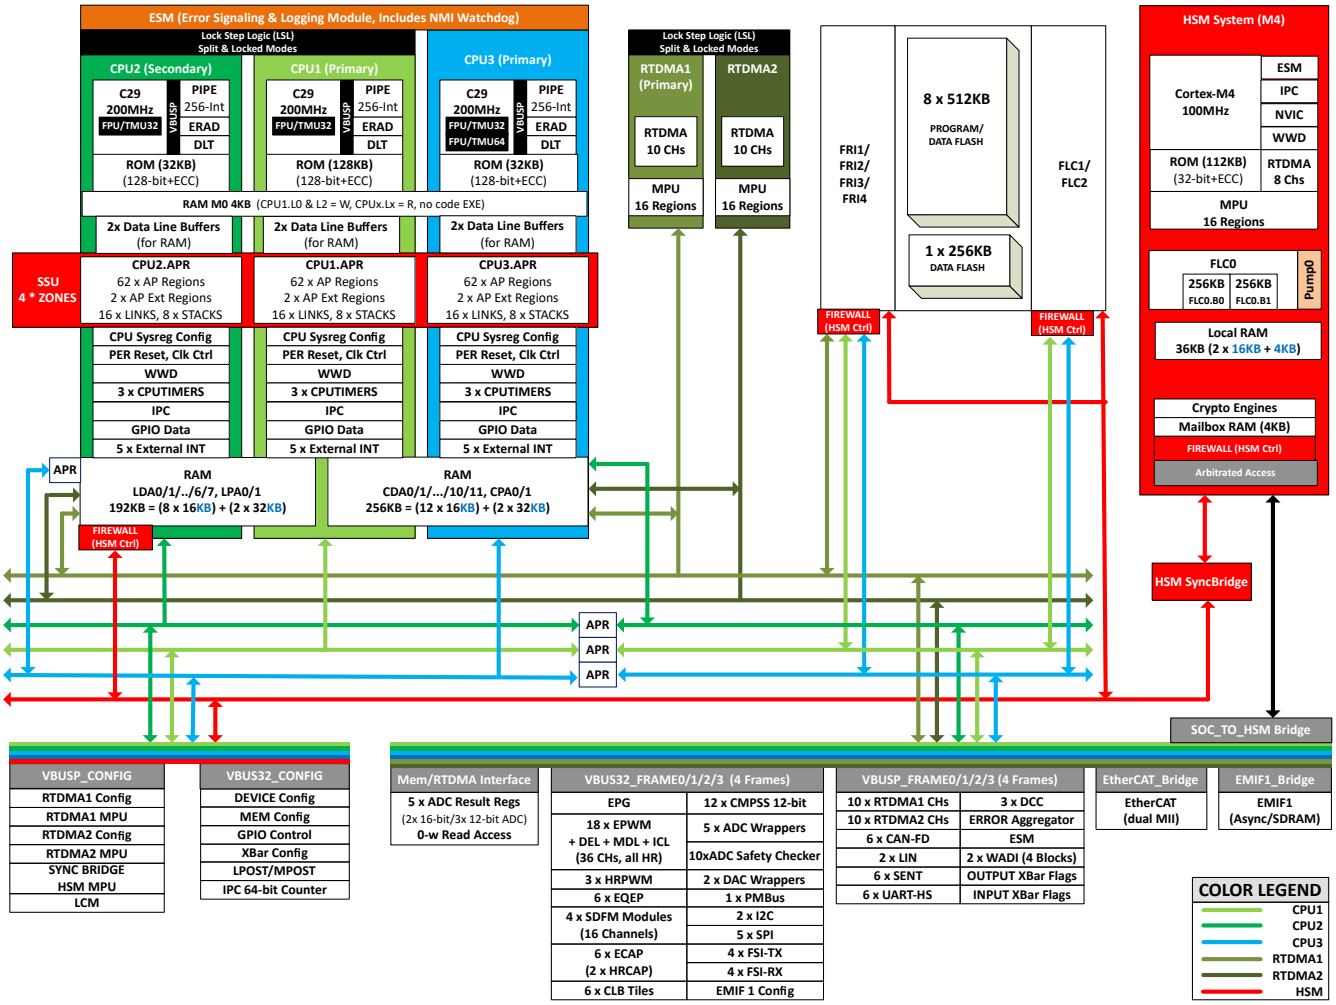

Figure 1-1. Block Diagram

Chapter 2

F29x Processor

This chapter contains a short description of the F29x processor.

Further information can be found in the following documents:

- *F29x CPU Reference Guide*
- *Accelerators: Enhancing the Capabilities of the C2000 MCU Family Technical Brief*

2.1 CPU Architecture

The CPU is a VLIW (Very-Long Instruction Word) architecture with a fully protected pipeline. The CPU supports multiple instruction sizes (16/32/48 bits). The CPU also supports variable instruction packet size, with each packet able to contain up to eight instructions that execute in parallel. For example, the CPU architecture can execute up to eight 16-bit instructions in parallel. This is enabled by multiple functional units inside the CPU which can execute concurrently. A total of 64 working registers, broken into three different categories (Ax, Dx, and Mx Register banks) support the parallel operations in the CPU. In addition to the working registers, the CPU contains multiple status registers (DSTS, ESTS, and ISTS) that maintain execution-related and interrupt-context-related information.

Following are the list of CPU major features:

- **Ease of use:**
  - Byte addressable CPU.
  - Linear and unified memory map with 4GB address range.
  - Fully Protected Pipeline: 9 stage pipeline that prevents writes and reads from same location from occurring out of order.
  - Deterministic execution and maximum performance without cached memories.
- **Improved parallelism:**
  - Execute from 1 to 8 instructions in parallel.
  - Execute fixed-point, floating-point, and addressing operations in parallel.
  - Multiple parallel functional units.
  - Specialized operations to minimize discontinuities and accelerate decision making code (for example, if-then-else statements and switch statements).
  - Specialized operations targeting real-time control (for example, trigonometric operations and multiphase vector translation operations).
- **Improved bus throughput:**
  - Capable of fetching up to 128-bit instruction packet every cycle.
  - Capable of performing 8/16/32/64-bit dual reads and single writes per cycle.
  - Improved addressing modes reduce overhead in accessing memory and peripheral resources.
  - Improved pipeline allows for additional 0-wait memory to be accessible to CPU for max performance.
- **Code efficiency:**
  - Supports variable length instruction set (16-bit, 32-bit, and 48-bit instructions).
  - Rich instruction set optimizes the most common operations in smallest instructions.
- **ASIL-D safety capability with code isolation in hardware:**
  - Lock step core capable of independent execution in split-lock mode (acting as a separate core) or lock step execution (for redundancy).
  - Integrated ECC logic
  - Integrated memory management (MPU) and protection mechanisms in hardware to maximize MIPS.
  - Separate code threads are fully isolated and protected (including software stacks).
- **Multizone security in hardware:**
  - Run time content protection and IP protection of code.
  - Individual passwords for each zone to control access.
- **Enhanced debug and trace capabilities:**
  - Specialized data logging and code flow trace instructions.
  - Trace data capable of being logged in on-chip RAM or exported through serial communication peripherals.

Figure 2-1 shows a block diagram.

2.2 Lock and Commit Registers

Lock and Commit mechanism is provided for C29 registers to prevent unintentional or spurious writes to the critical registers.

TI highly recommends that users lock the SECCALL and RTINT stack memory mapped registers using the C29_REGS_LOCK register for fault avoidance from safety aspect and also commit the lock registers using the C29_REGS_COMMIT register for additional security so that registers are not altered during runtime. This can be done at initialization.

2.3 C29x CPU Registers

This section describes the C29x CPU Registers.

2.3.1 C29CPU Base Address Table

Table 2-1. C29CPU Base Address Table

Structure	DriverLib Name	Base Address	Frame Applicable	CPU1	CPU2	CPU3	RTDMA1	RTDMA2	HSM	Pipeline Protected
C29_RTINT_STACK	C29CPURTINTSTACK_BASE	0x3000_8000	-	YES	YES	YES	-	-	-	YES
C29_SECCALL_STACK	C29CPUSECCALLSTACK_BASE	0x3000_C000	-	YES	YES	YES	-	-	-	YES
C29_SECURE_REGS	C29CPUSECURE_BASE	0x3000_D000	-	YES	YES	YES	-	-	-	YES
C29_DIAG_REGS	C29CPUDIAG_BASE	0x3000_E000	-	YES	YES	YES	-	-	-	YES
C29_SELFTEST_REGS	C29CPUSELFTEST_BASE	0x3000_F000	-	YES	YES	YES	-	-	-	YES

2.3.2 C29_RTINT_STACK Registers

Table 2-2 lists the memory-mapped registers for the C29_RTINT_STACK registers. All register offset addresses not listed in Table 2-2 should be considered as reserved locations and the register contents should not be modified.

Table 2-2. C29_RTINT_STACK Registers

Offset	Acronym	Register Name	Protection
0h + formula	RTINT_STACK_DATA0_j	RTINT stack Data0	
4h + formula	RTINT_STACK_DATA1_j	RTINT stack Data1	
8h + formula	RTINT_STACK_DATA2_j	RTINT stack Data2	
Ch + formula	RTINT_STACK_DATA3_j	RTINT stack Data3	
10h + formula	RTINT_STACK_DATA4_j	RTINT stack Data4	
14h + formula	RTINT_STACK_DATA5_j	RTINT stack Data5	
18h + formula	RTINT_STACK_DATA6_j	RTINT stack Data6	
1Ch + formula	RTINT_STACK_DATA7_j	RTINT stack Data7	
20h + formula	RTINT_STACK_DATA8_j	RTINT stack Data8	
24h + formula	RTINT_STACK_ECC0_j	RTINT stack ECC0	
28h + formula	RTINT_STACK_ECC1_j	RTINT stack ECC1	
2Ch + formula	RTINT_STACK_ECC2_j	RTINT stack ECC2	
30h + formula	RTINT_STACK_ECC3_j	RTINT stack ECC3	

Complex bit access types are encoded to fit into small table cells. Table 2-3 shows the codes that are used for access types in this section.

Table 2-3. C29_RTINT_STACK Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-*n*		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

2.3.2.1 RTINT_STACK_DATA0_j Register (Offset = 0h + formula) [Reset = 00000000h]

RTINT_STACK_DATA0_j is shown in Figure 2-2 and described in Table 2-4.

Return to the Summary Table.

RTINT stack Data0

Offset = 0h + (j * 40h); where j = 0h to 7Fh

2.3.4 C29_SECURE_REGS Registers

Table 2-22 lists the memory-mapped registers for the C29_SECURE_REGS registers. All register offset addresses not listed in Table 2-22 should be considered as reserved locations and the register contents should not be modified.

Table 2-22. C29_SECURE_REGS Registers

Offset	Acronym	Register Name	Protection
0h	SECSP0	Secure Stackpointer 0	
4h	SECSP1	Secure Stackpointer 1	
8h	SECSP2	Secure Stackpointer 2	
Ch	SECSP3	Secure Stackpointer 3	
10h	SECSP4	Secure Stackpointer 4	
14h	SECSP5	Secure Stackpointer 5	
18h	SECSP6	Secure Stackpointer 6	
1Ch	SECSP7	Secure Stackpointer 7	
80h	PSP	Protected call stack pointer	
84h	WARNPSP	Warning level register for protected call stack pointer	
88h	MAXPSP	Maximum levels of protected calls supported by the HW	
8Ch	REVISION	IP revision id register	
90h	C29_REGS_LOCK	Lock register	
94h	C29_REGS_COMMIT	Commit register	

Complex bit access types are encoded to fit into small table cells. Table 2-23 shows the codes that are used for access types in this section.

Table 2-23. C29_SECURE_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

2.3.4.1 SECSP0 Register (Offset = 0h) [Reset = 00000000h]

SECSP0 is shown in Figure 2-18 and described in Table 2-24.

Return to the Summary Table.

2.3.6 C29_SELFTEST_REGS Registers

Table 2-45 lists the memory-mapped registers for the C29_SELFTEST_REGS registers. All register offset addresses not listed in Table 2-45 should be considered as reserved locations and the register contents should not be modified.

Table 2-45. C29_SELFTEST_REGS Registers

Offset	Acronym	Register Name	Protection
0h	SELFTEST_DIAG_DATA0	Diagnostics data register 0	
4h	SELFTEST_DIAG_DATA1	Diagnostics data register 1	
8h	SELFTEST_DIAG_DATA2	Diagnostics data register 2	
20h	SELFTEST_DIAG_ECC	Diagnostics ECC	
28h	SELFTEST_DIAG_CONTROL	Diagnostic test enable	
2Ch	SELFTEST_DIAG_STATUS	Diagnostic status register	
30h	SELFTEST_DIAG_STATUS_CLR	Diagnostic status clear register	

Complex bit access types are encoded to fit into small table cells. Table 2-46 shows the codes that are used for access types in this section.

Table 2-46. C29_SELFTEST_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

2.3.6.1 SELFTEST_DIAG_DATA0 Register (Offset = 0h) [Reset = 00000000h]

Chapter 3

System Control and Interrupts

This chapter explains system control and interrupts for the C29x cores found on this MCU. The system control module configures and manages the overall operation of the device, and provides information about the device status. The details relating to system control include various sections like reset control, bus architecture, power control, clock control, low-power modes and memory controller subsystem.

3.1 C29x System Control Introduction

On this device, the CPU1 subsystem acts as a controller, and by default (upon reset), the CPU1 subsystem owns all the configuration and control. Through software running on CPU1, peripherals and I/Os can be configured to be accessible by the other CPU subsystems and the chosen configurations can be locked.

The PLL clock configuration is also owned by the CPU1 subsystem by default and HSM subsystem can also access clock configuration if permissions are enabled (by default enabled).

Each CPU can be independently configured to accept interrupts from different peripherals. The interrupt path is divided into three stages – the peripheral (in some cases ESM also), the PIPE, and the CPU. All stages must be configured and enabled for an interrupt to propagate to the CPU.

Each CPU has their own NMI module to handle different exceptions during run time. If the NMI was on CPU1, any NMI exception that is not handled before the NMI Watchdog (ESM NMIWD) timer expiration resets the entire device using XRSn. If the NMI was on any other CPU subsystem, then the specific CPU subsystem is reset (or the entire device is reset depending on the configuration) and all other CPU subsystems can be informed using ESM that the CPU subsystem was reset because of NMIWD timer expiration.

Each CPU subsystem has their own watchdog timer module for software to use. Watchdog timer expiration on CPU1 resets the entire device and Watchdog timer expiration on other CPU resets that specific CPU subsystem alone when configured to generate a reset.

The register space of the device system control module can be found in Section 3.13.

This chapter explains the system control module on all the CPU subsystems.

3.2 System Control Functional Description

The system control module provides the following capabilities:

- Device identification and configuration registers
- Reset control
- Exceptions and Interrupt control (Refer to PIPE Chapter)
- Safety and error handling features of the device
- Power control
- Clock control
- Low Power modes
- Bus Architecture
- Memory Controller Subsystem

3.2.1 Device Identification

Device identification registers provide information on device class, device family, revision, part number, pin count, and device qualification status.

All of the device information is part of the DEV_CFG_REGS space and is accessible only by the software running on the CPU1 subsystem.

The F29x device identification registers are: PARTIDL, PARTIDH, and REVID.

The Unique ID (UID) is available in SOCID information stored at M0 RAM location 0x2000_0980.

3.2.2 Device Configuration Registers

Several registers provide users with configuration information for the C29x subsystems for debug and identification purposes. This information includes the features of the peripherals and how much RAM and Flash memory is available on this part.

These registers are part of DEV_CFG_REGS space and are accessible only by the software running on the CPU1 subsystem.

- MCUCNFx: MCU Configuration registers have been implemented to enable customers to emulate a sub-set device on a super-set device. The following function is provided to configure the device accordingly.
  - `SysCtl_emulateDevice( SysCtl_DevicePartNumber partNumber )`
- CPUID: CPU identification register. This register is available for software to identify on which CPU the register is executing.

3.3 Resets

This section explains the types and effects of the different resets on this device.

3.3.1 Reset Sources

Table 3-1 summarizes the various reset signals and the effect on the device.

Table 3-1. Reset Signals

Reset Source	LPOST	HSM Reset	CPU1 Subsystem Reset	CPU2 Subsystem Reset	CPU3 Subsystem Reset	JTAG / Debug Logic Reset	IOs	XRSn Output
PORESETn_RAW	Yes	Yes	Yes	Yes	Yes	Yes	Hi-Z	Yes
PORESETn	-	Yes	Yes	Yes	Yes	Yes	Hi-Z	Yes
XRSn Pin	-	Yes	Yes	Yes	Yes	-	Hi-Z	-
CPU1.SIMRESET.XRSn	-	Yes	Yes	Yes	Yes	-	Hi-Z	Yes
CPU1.WDRSn	-	Yes	Yes	Yes	Yes	-	Hi-Z	Yes
ESM CPU1.NMIWDRSn(1)	-	Yes	Yes	Yes	Yes	-	Hi-Z	Yes
CPU1.SYSRSn (Debugger Reset)	-	-	Yes	Yes	Yes	-	Hi-Z	-
CPU2.WDRSn	-	-	-	Yes	-	-	-	-
ESM CPU2.NMIWDRSn(1)	-	Yes	Yes	Yes	Yes	-	Hi-Z	Yes
CPU2.SYSRSn (Debugger Reset)	-	-	-	Yes	-	-	-	-
CPU3.WDRSn	-	-	-	-	Yes	-	-	-
ESM CPU3.NMIWDRSn(1)	-	Yes	Yes	Yes	Yes	-	Hi-Z	Yes
CPU3.SYSRSn (Debugger Reset)	-	-	-	-	Yes	-	-	-
ECAT_RESET_OUT	-	Yes	Yes	Yes	Yes	-	Hi-Z	Yes

(1) Applicable only if ESM CPU instances are programmed in ESMXRSNCTL register to trigger XRSn. Refer to Chapter 7 for more details.

Note

After a reset, the reset cause register (RESC) is updated with the reset cause. The bits in this register maintain the state across multiple resets. These can only be cleared by a power-on reset (POR) or by writing 1 to the corresponding bit in RESCCLR register (status can be cleared by also writing a 1 to the RESC register bits). Each CPU has an RESC register, referred to as CPU1.RESC, CPU2.RESC and CPU3.RESC.

The resets can be divided into a few groups:

- Chip-level resets (XRSn, PORESETn, CPU1.WDRSn, ESM CPU1.NMIWDRSn (if enabled to trigger XRSn), ESM CPU2.NMIWDRSn (if enabled to trigger XRSn), ESM CPU3.NMIWDRSn (if enabled to trigger XRSn), SIMRESET.XRSn and ECAT_RESET_OUT (if enabled)), which reset all or almost all of the device.
- System resets (CPU1.$\overline{\text{SYSRS}}$), which reset a large subset of the device but maintain some system-level configuration.
- CPU2 subsystem resets (CPU2. SYSRSn, CPU2. WDRSn, ESM CPU2. NMIWDRSn (if configured to trigger CPU3.RSn)), which reset only CPU2 and the peripherals.
- CPU3 subsystem resets (CPU3. SYSRSn, CPU3. WDRSn, ESM CPU3. NMIWDRSn (if configured to trigger CPU3.RSn)), which reset only CPU3 and the peripherals.

Whenever the CPU1 subsystem is reset, CPU2 and CPU3 also gets reset if configured in SSU CPU2 and CPU3 Reset Control (CPU_RST_CTRL) registers and held in reset until CPU1 brings CPU2 and CPU3 out of reset by writing to the CPU_RST_CTRL register or as determined by HSM input. This is done by user application code on CPU1.

Many peripheral modules have individual resets accessible through the system control registers. For information about a module reset state, refer to the appropriate chapter for that module.

Note

After a POR, the boot ROMs clear all of the system and message RAMs on all CPUs.

Figure 3-1 captures the overall device level reset connectivity and propagation.

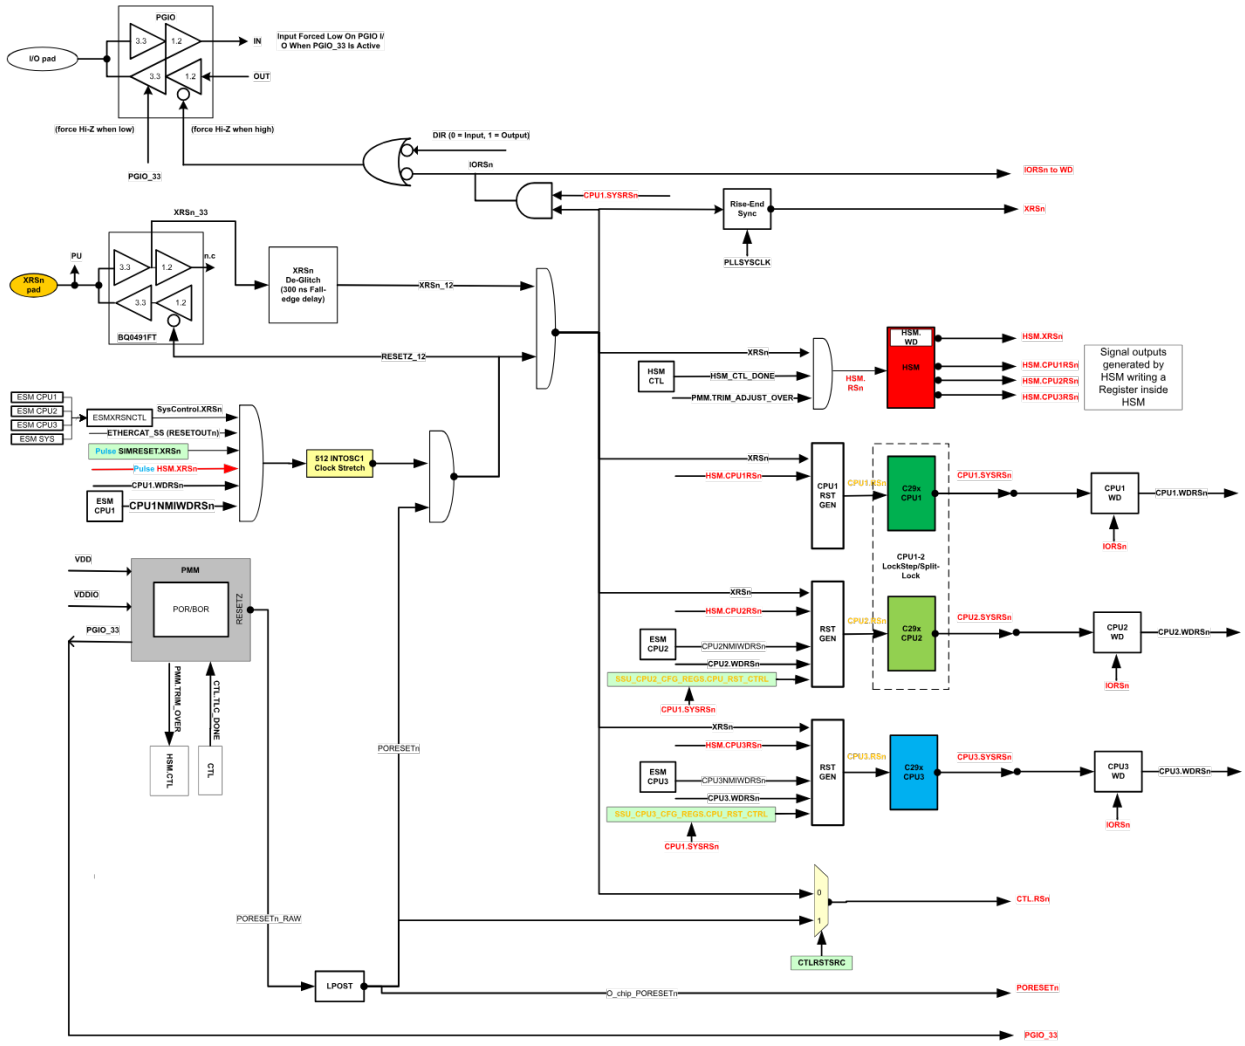

Figure 3-1. Device Reset Diagram

3.3.2 External Reset ($\overline{XRS}$)

The external reset ($\overline{XRS}$) is the main chip-level reset for the device. $\overline{XRS}$ resets all C29x CPUs, HSM , all peripherals and I/O pin configurations, and most of the system control registers. $\overline{XRS}$ also holds CPU2, CPU3 and HSM in reset. There is a dedicated open-drain pin for $\overline{XRS}$. This pin can be used to drive reset pins for other ICs in the application, and can be driven by an external source. The $\overline{XRS}$ is driven internally during watchdog, NMI, and power-on resets.

The XRSn bit in the RESC register is set whenever $\overline{XRS}$ is driven low for any reason. This bit is then cleared by the boot ROM.

3.3.3 Simulate External Reset

The user can simulate an external reset ($\overline{XRS}$) by setting the XRSn bit to 1 in the SIMRESET register using CPU1 software. This toggles the $\overline{XRS}$ pin; hence, resetting the full device (just like an external reset).

After this reset, the SIMRESET_XRSn bit in the RESC register is set. Software can read this bit to know the cause of the reset and clear the status by writing a 1 into the corresponding bit in the RESCCLR register.

3.3.4 Power-On Reset (POR)

The power-on reset (POR) circuit creates a clean reset throughout the device during power-up, suppressing glitches on the GPIOs. The $\overline{\text{XRS}}$ pin is held low for the duration of the POR. In most applications, $\overline{\text{XRS}}$ is held low long enough to reset other system ICs, but some applications can require a longer pulse. In these cases, $\overline{\text{XRS}}$ can be driven low externally to provide the correct reset duration. A POR resets everything that $\overline{\text{XRS}}$ does, along with the register – the reset cause register (RESC).

After a POR, the POR and XRSn bits in RESC are set. These bits are then cleared by the boot ROM.

3.3.5 Debugger Reset ($\overline{\text{SYSRS}}$)

During development, it is sometimes necessary to reset the CPU and the peripherals without disconnecting the debugger or disrupting the system-level configuration. To facilitate this, each CPU has a subsystem reset, which can be triggered by a debugger using Code Composer Studio IDE. CPU2 subsystem reset (CPU2.$\overline{\text{SYSRS}}$) resets only CPU2, the peripherals, and the clock gating and LPM configuration. It does not hold CPU2 in reset. CPU3 subsystem reset (CPU3.$\overline{\text{SYSRS}}$) resets only CPU3, the peripherals, and the clock gating and LPM configuration. CPU1 subsystem reset (CPU1.$\overline{\text{SYSRS}}$) resets CPU1, the peripherals, many system control registers (including the clock gating and LPM configuration and the peripheral CPU ownership), and all I/O pin configurations. CPU1.$\overline{\text{SYSRS}}$ also produces a CPU2.$\overline{\text{SYSRS}}$ and CPU3.$\overline{\text{SYSRS}}$ (CCS Gel file may have code to release CPU2 and CPU3 out of reset on CPU1 debug reset).

Figure 3-2 explains how the all CPU $\overline{\text{SYSRS}}$ and Software Reset signals are connected to cause particular peripheral to reset in the device.

Neither $\overline{\text{SYSRS}}$ resets the debug module, the device capability registers, the clock source and PLL configurations, the missing clock detection state, the PIPE vector fetch error handler address, the NMI flags, the analog trims, or anything reset only by a POR (see Section 3.3.4).

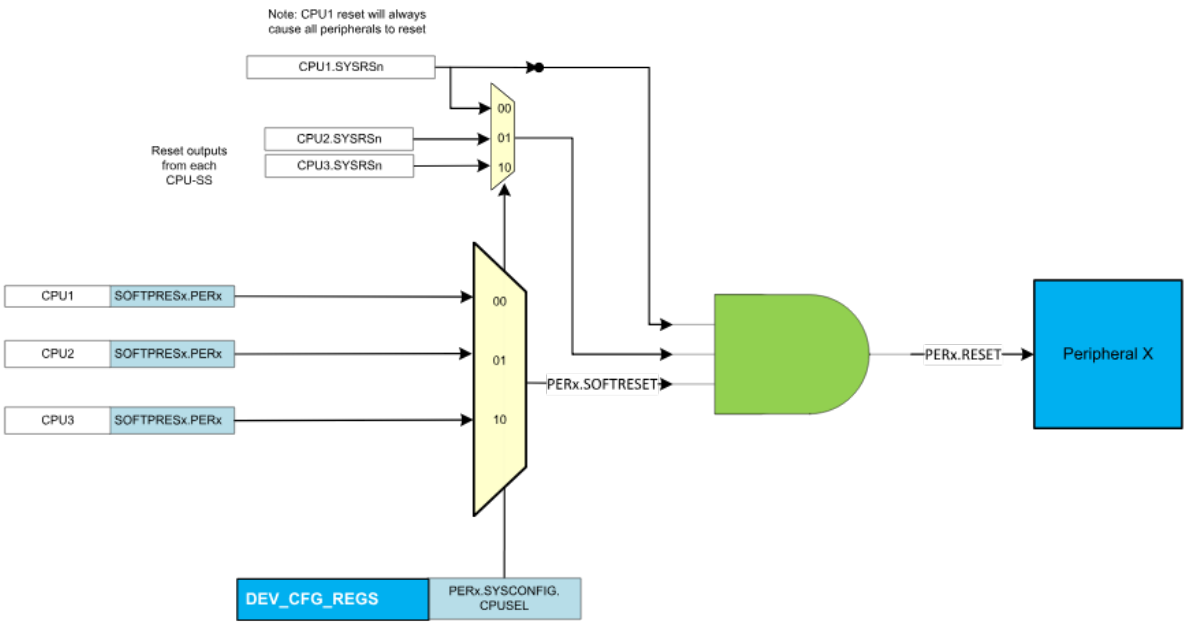

Figure 3-2. Software and SYSRSn Connectivity Diagram for Peripheral Reset

Note

Since the reset signals are active low any input to the AND gate when active (low) outputs the peripheral reset signal to be active (low).

3.3.6 Watchdog Reset ($\overline{\text{WDRS}}$)

Each CPU has a watchdog timer that can optionally trigger a reset that lasts for 512 INTOSC1 cycles. CPU1 watchdog reset (CPU1.$\overline{\text{WDRS}}$) produces an $\overline{\text{XRS}}$. CPU2 watchdog reset (CPU2.$\overline{\text{WDRS}}$) produces a CPU2.$\overline{\text{SYSRS}}$ and similarly CPU3 watchdog reset (CPU3.$\overline{\text{WDRS}}$) produces a CPU3.$\overline{\text{SYSRS}}$.

After a watchdog reset, the WDRSn bit in the RESC register is set. Software can read this bit to know the cause of reset and clear the status by writing a 1 into the corresponding bit in the RESCCLR register.

3.3.7 ESM NMI Watchdog Reset ($\overline{\text{NMIWDRS}}$)

Each ESM CPU module in ESM Subsystem (ESM-SS) has a watchdog timer that triggers a reset if the CPU does not respond to an error within a user-specified amount of time. ESM CPU1 NMI watchdog reset (ESM CPU1.$\overline{\text{NMIWDRS}}$) produces an $\overline{\text{XRS}}$. ESM CPU2 NMI watchdog reset (CPU2.$\overline{\text{NMIWDRS}}$) produces a CPU2.$\overline{\text{SYSRS}}$ and ESM CPU3 NMI watchdog reset (CPU3.$\overline{\text{NMIWDRS}}$) produces a CPU3.$\overline{\text{SYSRS}}$.

After an NMI watchdog reset, the NMIWDRSn bit in the RESC register is set.

3.3.8 EtherCAT Slave Controller (ESC) Module Reset Output

You can configure the EtherCAT Slave Controller (ESC) module to drive the $\overline{\text{XRS}}$ pin low whenever the ESC module receives a reset. This is done by setting the DEVICE_RESET_EN bit to 1 in the ESCSS_RESET_DEST_CONFIG register of the ESC module (EtherCAT subsystem). By default, this is not enabled. Since this toggles the $\overline{\text{XRS}}$ pin, all effects of an external $\overline{\text{XRS}}$ reset take effect.

After an ECAT_RESET_OUT reset, the ECAT_RESET_OUT bit in the RESC register is set. Software can read this bit to know the cause of reset and clear the status by writing a 1 into the corresponding bit in the RESCCLR register.

3.4 Safety Features

This section gives details on features that monitor device operation during run-time to detect any error in operation.

3.4.1 Write Protection on Registers

3.4.1.1 LOCK Protection on System Configuration Registers

Several system configuration registers are protected from spurious CPU writes by “LOCK” registers. Once these associated LOCK register bits are set, the respective locked registers can no longer be modified by software. See the register descriptions for details.

3.4.1.2 EALLOW Protection

EALLOW protection mechanism is not applicable for this device.

3.4.2 PIPE Vector Address Validity Check

PIPE Vector tables are protected by ECC safety mechanism.

3.4.3 NMIWDs

Each ESM CPU instance has user-programmable NMIWD period registers, in which users can set a limit on how much time to allocate for the device to acknowledge the NMI. If the NMI is not acknowledged, the NMI causes a device reset.

3.4.4 System Control Registers Parity Protection

Critical System Control Register are parity protected. The registers that are covered by parity protection have "PARITY" mentioned in the respective "Protection" column in register descriptions table. There is also a provision to test the parity protection feature by enabling parity test using the DEV_CFG_REGS.PARITY_TEST, CPU_PER_CFG_REGS.PARITY_TEST_ALT1 and CPU_SYS_REGS.PARITY_TEST_ALT2 register.

If parity error is detected, ESM is notified and appropriate action is taken based on user configurations. Refer to ESM Chapter for more details.

3.4.5 ECC Enabled RAMs, Shared RAMs Protection

Each CPU subsystem has different RAM blocks. All the RAM blocks are ECC-enabled. All errors go to ESM and all single-bit ECC RAM errors are auto-corrected by ECC logic inside CPU. Also, an interrupt is generated to the corresponding CPU using ErrorAggregator and ESM. Single-bit errors are not corrected inside the RAM blocks; hence, RAM blocks still have the incorrect data (single-bit error). User software needs to write back the correct data.

All uncorrectable double-bit errors end up triggering an NMI to the corresponding CPUs using ErrorAggregator and ESM.

3.4.6 ECC Enabled Flash Memory

Flash single-bit errors are corrected automatically by ECC logic inside CPU, but the Flash single-bit errors are not corrected in Flash memory. Flash memory still contains wrong data until another erase/program operation happens to correct the Flash contents. Irrespective of whether the error interrupt is enabled or disabled, single-bit errors are always corrected. When the interrupt is disabled, users can check the single-bit error flag for any single-bit error occurrences.

Flash uncorrectable errors end up triggering an NMI to the respective CPU using ErrorAggregator and ESM.

3.4.7 ERRORSTS Pin

ERRORSTS signal is driven from Error Signaling Module (ESM). The ERRORSTS signal is ‘always output’ on a selected GPIO pin and remains high until an error is detected inside the chip. On an error, the ERRORSTS pin goes low (default polarity) until the corresponding internal error status flag for that error source is cleared.

The ERRORSTS pin is tri-stated until the chip power rails ramp up to the lower operational limit. As the ERRORSTS pin is an active-low pin (default polarity), users who care about the state of this pin during power-up can connect an external pull-down on this pin. Polarity of ERRORSTS pin is configurable (default setting is active-low polarity).

3.5 Clocking

This section explains the clock sources and clock domains on this device, and how to configure them for application use. Figure 3-3 provides an overview of the device clocking system.

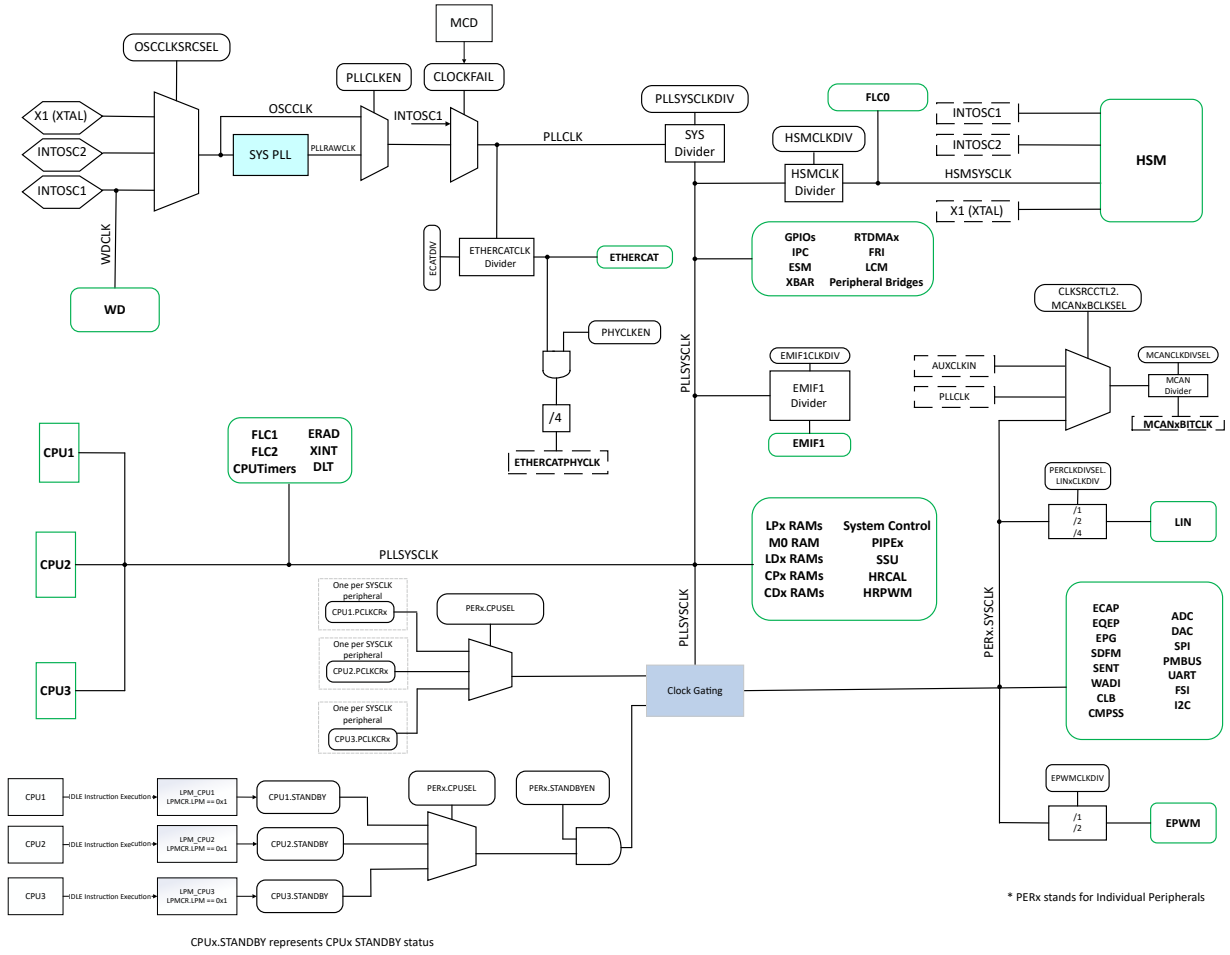

Figure 3-3. Clocking System

3.5.1 Clock Sources

The needs of the application are what ultimately determine the clock configuration. Specific concerns such as application performance, power consumption, total system cost, and EMC are beyond the scope of this document, but consider the following questions:

1. What is the desired CPU frequency?
2. Are there any additional communication protocols or peripherals required ?
3. What types of external oscillators or clock sources are available?

If required an external clock source with a precise frequency must be used as a reference clock. Otherwise, it may be possible to use only INTOSC2 and avoid the need for more external components.

All of the clocks in the device are derived from one of four clock sources.

3.5.1.1 Primary Internal Oscillator (INTOSC2)

At power-up, the device is clocked from an on-chip 10MHz oscillator (INTOSC2). INTOSC2 is the primary internal clock source and is the default system clock at reset. INTOSC2 is used to run the boot ROM and can be used as the system clock source for the application.

Note

INTOSC2 frequency tolerance is too loose to meet the timing requirements for some communication peripherals, so an external clock must be used to support those features.

3.5.1.2 Backup Internal Oscillator (INTOSC1)

The device also includes a redundant on-chip 10 MHz oscillator (INTOSC1). INTOSC1 is a backup clock source that normally only clocks the watchdog timers and missing clock detection circuit (MCD). If MCD is enabled and a missing system clock is detected, the system PLL is bypassed and all system clocks are connected to INTOSC1 automatically. INTOSC1 may also be manually selected as the system and auxiliary clock source for debug purposes.

3.5.1.3 External Oscillator (XTAL)

The dedicated X1 and X2 pins support an external clock source (XTAL), which can be used as the main system. Frequency limits and timing requirements can be found in the device data sheet. Three types of external clock sources are supported:

- A single-ended 3.3V external clock. The clock signal must be connected to X1 while X2 is left unconnected, as shown in Figure 3-4.

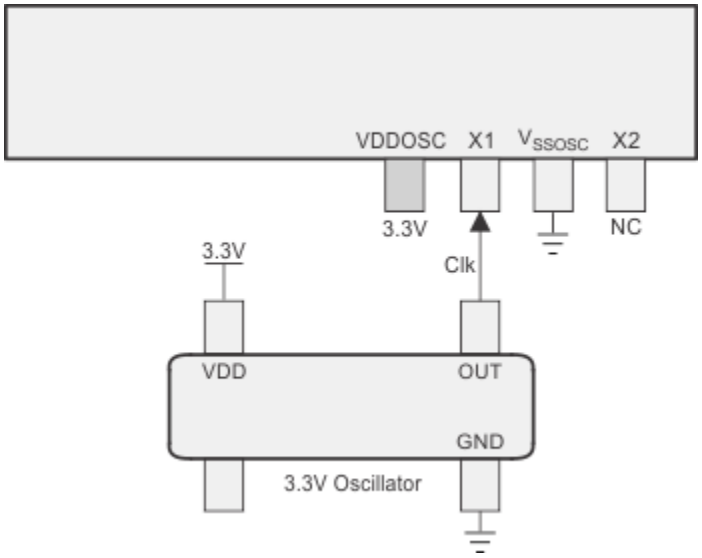

Figure 3-4. Single-ended 3.3V External Clock

- An external crystal. The crystal must be connected across X1 and X2 with the load capacitors connected to VSSOSC as shown in Figure 3-5.

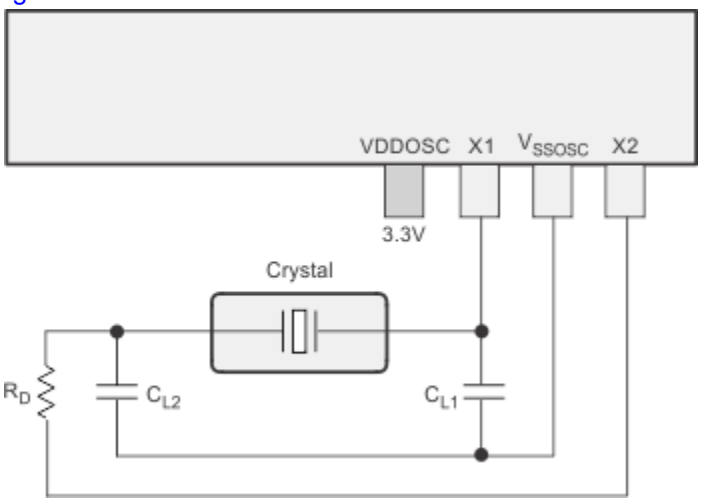

Figure 3-5. External Crystal

- An external resonator. The resonator must be connected across X1 and X2 with the ground connected to VSSOSC as shown in Figure 3-6.

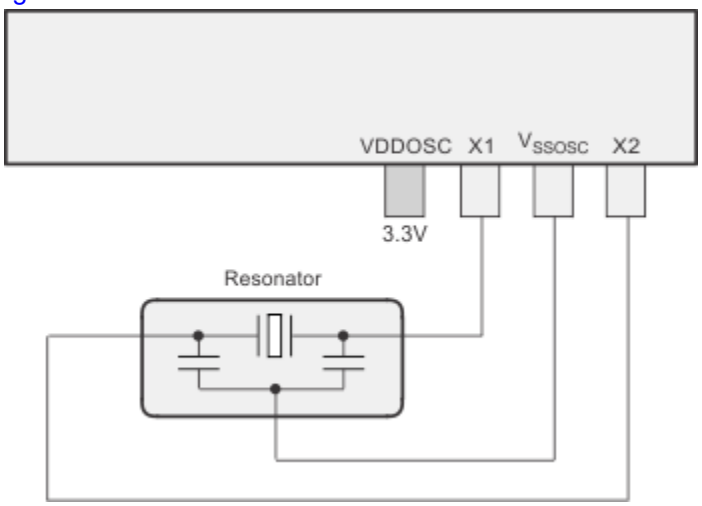

Figure 3-6. External Resonator

3.5.1.4 Auxiliary Clock Input (AUXCLKIN)

An additional external clock source is supported on GPIO133 (AUXCLKIN). This must be a single-ended 3.3V external clock that can be used as the clock source for MCAN bit clock. Frequency limits and timing requirements can be found in the device data sheet. The external clock must be connected directly to the GPIO133 pin, as shown in Figure 3-7.

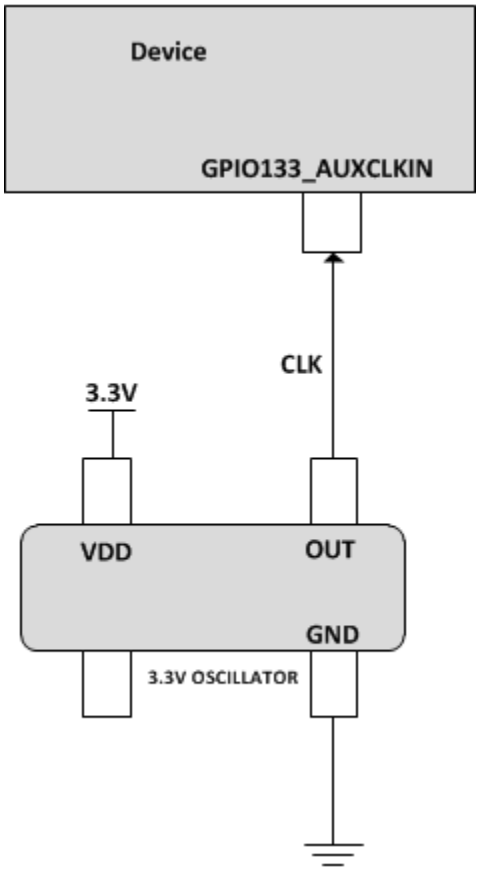

Figure 3-7. Auxiliary Clock Input (AUXCLKIN)

3.5.2 Derived Clocks

The clock sources discussed in the previous section can be multiplied (using PLL) and divided down to produce the desired clock frequencies for the application. This process produces a set of derived clocks, which are described in this section.

3.5.2.1 Oscillator Clock (OSCCLK)

One of INTOSC2, XTAL, or INTOSC1 must be chosen to be the controller reference clock (OSCCLK) for the CPU and most of the peripherals. OSCCLK can be used directly or applied through the system PLL to reach a higher frequency. At reset, OSCCLK is the default system clock and is connected to INTOSC2.

3.5.2.2 System PLL Output Clock (PLLRAWCLK)

The system PLL allows the device to run at the maximum rated operating frequency, and in most applications generates the main system clock. This PLL uses OSCCLK as a reference, and features a fractional multiplier and slip detection. For configuration instructions, see Section 3.5.7.

3.5.3 Device Clock Domains

The device clock domains feed the clock inputs of the various modules in the device. They are connected to the derived clocks, either directly or through an additional divider.

3.5.3.1 System Clock (PLLSYSCLK)

The system control registers, RAMs, IPC module, GPIO qualification, SSU, LCM, Flash read interfaces, FLC1/2 , all SRAMs, XBAR, ESM, Peripheral Bridges, RTDMA1/2 and PIPE modules have a clock domain (PLLSYSCLK). Despite the name, PLLSYSCLK can be connected to the system PLL (PLLRAWCLK) or to OSCCLK. The chosen clock source is run through a frequency divider, which is configured using the SYSCLKDIVSEL register.

3.5.3.2 CPU Clock (CPUCLK)

Each CPU has its own clock (CPU1.CPUCLK,CPU2.CPUCLK and CPU3.CPUCLK) which is used to clock the CPU, and its coprocessor's. This clock is identical to PLLSYSCLK, but is gated when the CPU enters STANDBY mode. CPUCLK provides clock to individual CPU timers (CPUTIMERx) and DLT.

3.5.3.3 Peripheral Clock (PERx.SYSCLK)

This clock is identical to PLLSYSCLK, but is gated when the CPU selected by CPUSEL enters STANDBY mode based on individual STANDBYEN bit in respective peripheral system configuration register (PERxSYSCONFIG).

Each peripheral has a CPU selection logic to select either CPU1, CPU2, or CPU3 which is done by using the CPUSEL register. The CPU selection logic is only for clock gating purposes since there is no CPU to peripheral allocation and any CPU can access and configure any peripheral provided the respective CPU has access to it. Each peripheral clock also has an independent clock gating that is controlled by the CPU PCLKCRx and STANDBYEN registers.

By default, the ePWM, EMIF, and LIN clocks each have an additional /2 divider, which is required to support CPU frequencies over 100MHz. At slower CPU frequencies, these dividers can be disabled using the PERCLKDIVSEL register.

Note

The application needs to wait for 5 SYSCLK cycles after enabling the clock to the peripherals, when using PCLKCRx.

3.5.3.4 MCAN Bit Clock

The required frequency tolerance for the MCAN bit clock depends on the bit timing setup and network configuration, and can be as tight as 0.1%. Since the main system clock (in the form of PERx.SYSCLK) can not be precise enough, the bit clock can also be connected to PLLCLK or AUXCLKIN using the CLKSRCCTL2 register. There is an independent selection for each MCAN bit clock source.

3.5.3.5 CPU Timer2 Clock (TIMER2CLK)

CPU timers 0 and 1 are connected to PLLSYSCLK. Timer 2 is connected to PLLSYSCLK by default, but can also be connected to INTOSC1, INTOSC2, XTAL, FLC1/2 PUMPOSC or CRUDEOSC using the TMR2CLKCTL register. This register also provides a separate prescale divider for timer 2. If a source other than PLLSYSCLK is used, the frequency must be at least twice the source frequency to make sure of correct sampling. Each CPU has independent CPU timers and TMR2CLKCTL register.

The main reason to use a non-SYSCLK source is for internal frequency measurement. In most applications, timer 2 runs off of the SYSCLK.

3.5.4 External Clock Output (XCLKOUT)

To observe a clock directly for debug and testing purposes, the external clock output (XCLKOUT) supports this by connecting a clock to external pins, GPIO73 and GPIO224. The available clock sources are PLLSYSCLK, PLLRAWCLK, PLLCLK, CPUx.CLOCK, XTAL, INTOSC1, and INTOSC2.

To use XCLKOUT, first select the clock source using the CLKSRCCTL3 register. Next, select the desired output divider using the XCLKOUTDIVSEL register. Finally, connect either GPIO73 or GPIO219 to mux channel 3 using the GPIO configuration registers.

3.5.5 Clock Connectivity

Table 3-2 provides details on the clock connections of every module present in the device.

Table 3-2. Clock Connections Sorted by Clock Domain

Clock Domain	CPU1 Subsystem	CPU2 Subsystem	CPU3 Subsystem	Shared Modules
CPUx.CPUCLK	CPU1	CPU2	CPU3	
PLLSYSCLK				PIPEx GPIO Input Sync and Qual IPC XBARs EMIF1 AnalogSubsys SSU System Control Registers HRCAL RTDMAx ESM Peripheral Bridges LCM FRIx, FLC1/2 All SRAMs ERADx XINT HRPWM DLT CPUTimers
PERx.SYSCLK				ADC CMPSS DAC ePWM eCAP eQEP I2C SDFM FSI PMBUS CLB SPI LIN UART SENT WADI EPG

Table 3-2. Clock Connections Sorted by Clock Domain (continued)

Clock Domain	CPU1 Subsystem	CPU2 Subsystem	CPU3 Subsystem	Shared Modules
MCAN Bit Clock				MCAN (CAN-FD)
WDCLK (INTOSC1)	CPU1.Watchdog	CPU2.Watchdog	CPU3.Watchdog	

3.5.6 Using an External Crystal or Resonator

The X1 and X2 pins double as GPIO221 and GPIO220. At power-up, these pins are in GPIO mode and the on-chip crystal oscillator is powered off. The following procedure can be used to switch the pins to X1 and X2 mode and enable the oscillator:

1. Clear the XTALCR.OSCOFF bit.
2. Wait for the crystal to power up. The typical wait time is 1ms, but this depends on the crystal that is being used.
3. Clear the X1 counter by writing a 1 to X1CNT.CLR and keep clearing until the X1 counter value in the X1CNT register is no longer saturated 2047 (0x7FF).
4. Wait for the X1 counter value in the X1CNT register to reach 2047 (0x7FF).
5. Repeat steps 3-4 three additional times.
6. Select XTAL as the OSCCLK source by writing a 1 to CLKSRCCTL1.OSCCLKSRCSEL.
7. Check the MCLKSTS bit in the MCDCR register. If the bit is set, the oscillator has not finished powering up, and more time is required:
   a. Clear the missing clock status by writing a 1 to MCDCR.MCLKCLR.
   b. Repeat steps 2-7. Do not reset the device. Doing so powers down the oscillator, which requires the procedure to be restarted from step 1.
   c. If the oscillator has not finished powering up in 10 milliseconds, there is a real clock failure.
8. If MCDCR.MCLKSTS is clear, the oscillator startup is a success. The system clock is now derived from XTAL.

3.5.6.1 X1/X2 Precondition Circuit

The GPIO220/221 alternate functionality on X1/X2 can be used to speed up the start-up time of the crystal by as much as 30% if needed. This functionality is achieved by preconditioning the load capacitors CL1 and CL2 to a known state before the XTAL is turned on.

The steps below outline the procedure to precondition X1/X2 before turning on the XTAL:

1. DevCfgRegs.XTALCR2.bit.XIF = 1; // Precondition X1 to High
2. DevCfgRegs.XTALCR2.bit.XOF = 1; // Precondition X2 to High
3. DevCfgRegs.XTALCR2.bit.FEN = 1; // Enable X1/X2 Precondition
4. DEVICE_DELAY_US(1);
5. DevCfgRegs.XTALCR.bit.OSCOFF = 0; // Removes Precondition and Turns on the XTAL
6. DevCfgRegs.XTALCR2.bit.FEN = 0; // Disables X1/X2 Precondition

3.5.7 PLL

The PLL is responsible for synthesizing an output frequency from the input clock (from the oscillator). Figure 3-8 shows a simple block diagram of the PLL. The PLL divides the reference input for a lower frequency input into the PLL by (REFDIV + 1). Then multiplies this internal frequency by IMULT to get the VCO output clock. The PLL output is divided by (ODIV + 1) to generate PLLRAWCLK that is further divided by SYSCLKDIVSEL.PLLSYSCLKDIV to generate PLLSYSCLK.

There is PLL also called as SYSPLL and the equations shown in Figure 3-8 can be used to configure the respective PLL.

- IMULT is the integer value of the multiplier
- REFDIV is the reference divider for the OSCCLK
- ODIV is the output divider of the PLLRAWCLK
- PLLSYSCLKDIV is the system clock divider

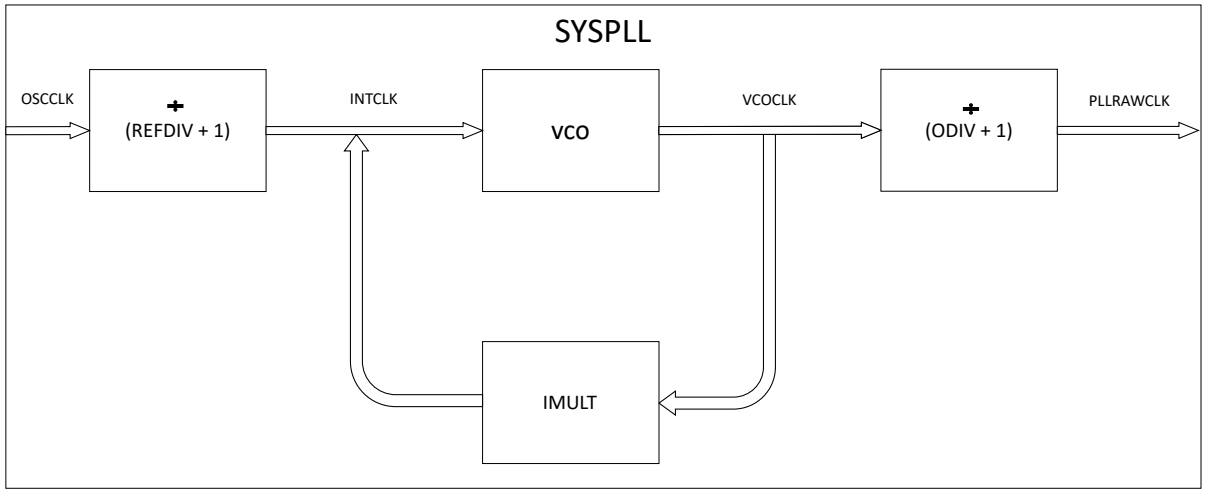
For the permissible values of the multipliers and dividers, see the documentation for their respective registers.

Many combinations of multiplier and divider can produce the same output frequency. However, the product of the reference clock frequency and the multiplier (known as the VCO frequency) must be in the range specified in the data sheet.

Note

The system clock frequency (PLLSYSCLK) cannot exceed the limit specified in the data sheet. This limit does not allow for oscillator tolerance.

The clock source and PLL configuration can only be done by CPU1 and can be read by other CPUs.



$$f_{PLLRAWCLK} = \frac{f\,OSCCLK}{(REFDIV+1)} \times \frac{IMULT}{(ODIV+1)}$$

Figure 3-8. PLL

3.5.7.1 System Clock Setup

Once the application requirements are understood, a specific clock configuration can be determined. The default configuration is for INTOSC2 to be used as the system clock (PLLSYSCLK) with a divider of 1. The following procedure can be used to set up the desired application configuration:

Refer to your device SysCtl_setClock() function inside C2000Ware installation for an example.

Recommended sequence to set up the system PLL:

1. Bypass the PLL by clearing SYSPLLCTL1[PLLCLKEN] and wait for at least 120 CPU clock cycles by adding 120 NOP instructions.
2. Power down the PLL by writing to SYSPLLCTL1.PLLEN = 0 and wait for at least 60 CPU clock cycles by adding 60 NOP instructions.
3. Select the reference clock source (OSCCLK) by writing to CLKSRCCTL1.OSCCLKSRCSEL and wait for at least 300 CPU clock cycles by adding 300 NOP instructions.
4. Set the system clock divider to /1 to make sure of the fastest PLL configuration by clearing SYSCLKDIVSEL[PLLSYSCLKDIV].
5. Set the IMULT, REFDIV, and ODIV simultaneously by writing 32-bit value in SYSPLLMULT at once. This automatically enables the PLL. Be sure the settings for multiplier and dividers do not violate the frequency specifications as defined in the data sheet.
6. Wait for PLL to lock by polling for lock status bit to go high, that is, SYSPLLSTS.LOCKS = 1
7. Configure DCC with reference clock as OSCCLK and clock under measurement as PLLRAWCLK, and verify the frequency of the PLL. If the frequency is out of range, do not enable PLLRAWCLK as SYSCLK, stop here and troubleshoot. Refer to Dual Clock Comparator (DCC) chapter for more information on the configuration and usage.
8. If the PLLRAWCLK is within the valid range, then set the system clock divider one setting higher than the final desired value. For example DEV_CFG_REGS.SYSCLKDIVSEL.bit.PLLSYSCLKDIV = divsel + 1. This limits the current increase when switching to the PLL.
9. Switch to the PLL as the system clock by setting SYSPLLCTL1[PLLCLKEN] and wait for 200 PLLSYSCLK cycles for current to stabilize by adding 200 NOP instructions.
10. Change the system clock divider (PLLSYSCLKDIV) to the appropriate value.

Note

1. SYSPLL must be bypassed and powered down manually before changing the OSCCLK source.
2. At least 120 CPU clock cycles delay is needed after bypassing PLL, that is, SYSPLLCTL1.PLLCLKEN=0.
3. At least 60 CPU clock cycles delay is needed after PLL is powered down, that is, SYSPLLCTL1.PLLEN=0.
4. At least 300 CPU clock cycles delay is needed after OSSCLK source is changed.
5. PLL SLIP bit is not supported. DCC can be used to check the validity of the PLL clock. This feature is included as part of SysCtl_setClock() function inside C2000Ware.

3.5.7.2 SYS PLL Bypass

If the application requires the PLL clock to be bypassed from the system, then the application needs to configure SYSPLLCTL1.PLLCLKEN = 0. It takes up to 120 CPU clock cycles before the bypass is effective. In the meantime, if PLLSYSCLKDIV is reduced to a lower value (for example, from /2 to /1 or /4 to /2), the device can be clocked above the maximum rated frequency and can lead to unpredictable device behavior. Hence, a delay of 120 CPU clock cycles is required after bypassing the PLL from the enable state, that is, going from PLLCLKEN = 1 to PLLCLKEN = 0.

3.5.8 Clock (OSCCLK) Failure Detection

To achieve safety diagnostic, Missing Clock Detection (MCD) can be used. Table 3-3 lists the details.

Table 3-3. Clock Source (OSCCLK) Failure Detection

Clock Failure Detection Circuitry	Clocks Detected	Time for Detection (in Cycles)	Limitations
Missing Clock Detection (MCD)	INTOSC2, XTAL/X1	8192 INTOSC1 cycles	Cannot detect INTOSC1 clock failure.
Dual Clock Comparator (DCC)	INTOSC1, INTOSC2, XTAL/X1	Depends on the frequency of reference and monitored clocks	Software configuration is required for clock monitoring

3.5.8.1 Missing Clock Detection Logic

The missing clock detect (MCD) logic detects OSCCLK failure, using INTOSC1 as the reference clock source. This circuit only detects complete loss of OSCCLK and does not do any detection of frequency drift on the OSCCLK.

This circuit monitors the OSCLK (primary clock) using the 10MHz clock provided by the INTOSC1 (secondary clock) as a backup clock. This circuit functions as:

1. The primary clock (OSCCLK) clock keeps ticking a 7-bit counter (named as MCDPCNT). This counter is asynchronously reset with XRSn.
2. The secondary clock (INTOSC1) clock keeps ticking a 13-bit counter (named as MCDSCNT). This counter is asynchronously reset with XRSn.
3. Each time MCDPCNT overflows, the MCDSCNT counter is reset. Thus, if OSCCLK is present or not slower than INTOSC1 by a factor of 64, MCDSCNT never overflows.
4. If OSCCLK stops for some reason or is slower than INTOSC1 by at least a factor of 64, the MCDSCNT overflows and a missing clock condition is detected on OSCCLK.
5. The above check is continuously active, unless the MCD is disabled using MCDCR register (by making the MCLKOFF bit 1).
6. If the circuit ever detects a missing OSCCLK, the following occurs:
   - The MCDSTS flag is set.
   - The MCDSCNT counter is frozen to prevent further missing clock detection.
   - The CLOCKFAIL signal goes high, which generates TRIP events to PWM modules and can be configured to trigger NMI in Error Signaling Module (ESM)
   - PLL is forcefully bypassed and OSCCLK source is switched to INTOSC1 (System Clock Frequency = INTOSC1 Frequency (10MHz)/SYSDIV). PLLMULT is zeroed out automatically in this case.
   - While the MCDSTS bit is set, the OSCCLKSRCSEL bits have no effect and OSCCLK is forcefully connected to INTOSC1.
   - PLLRAWCLK going to the system is switched to INTOSC1 automatically.
7. If the MCLKCLR bit is written (this is a W = 1 bit), MCDSTS bit is cleared and OSCCLK source is decided by the OSCCLKSRCSEL bits. Writing to MCLKCLR also clears the MCDPCNT and MCDSCNT counters to allow the circuit re-evaluate missing clock detection. If the user wants to lock the PLL after missing clock detection, switch the clock source to INTOSC1 (using OSCCLKSRCSEL register), do a MCLKCLR, and relock the PLL.
8. The MCD is enabled at power up.

Figure 3-9 shows the missing clock logic functional flow.

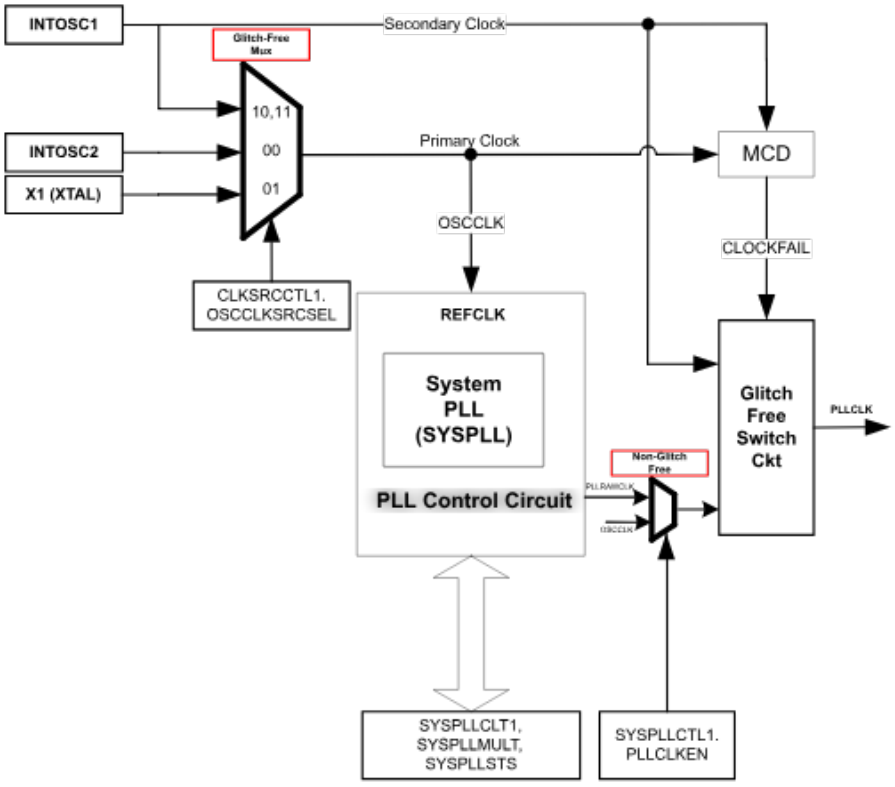


Figure 3-9. Missing Clock Detection Logic

Note

On a complete clock failure when OSCCLK is dead, the operation can take a maximum time of 8192 INTOSC1 cycles (that is, 0.8192ms) before the CLOCKFAIL signal goes high, after which:

- NMI is generated by enabling the CLOCKFAIL signal event configurations in ESM
- OSCCLK is switched to INTOSC1
- PWM Trip happens

3.5.8.2 Dual Clock Comparator (DCC)

DCC can be used for clock quality check as well as clock loss detection. Depending upon the counter settings in DCC, the desired goal can be achieved. In systems where DCC error is indicative of critical failure needing CPU intervention or reset, the DCC error is routed to NMI using ESM. Refer to Chapter 12 for more details on the configuration.

3.6 Bus Architecture

This section covers the details about bus architecture.

3.6.1 Safe Interconnect

Safe interconnect mechanism detects any faults that occur in bus interconnect of C29x CPU and external memory or peripherals. Bus interconnect includes C29x CPU buses (control and data), address decodes, memory controllers and peripheral bridges.

Any data corruption in memory is detected and this is achieved by storing ECC along with data in memory.

To achieve safe interconnect there are checks that are done in the CPU and certain checks are implemented outside CPU. Forward path (CPU to Endpoint) checks are done at endpoint controller. Return path (Endpoint to CPU) checks are done by CPU. This provides end to end safing for the interconnect between initiators (CPU, RTDMA) to memory and peripherals.

In addition to the ECC checks every access placed on the bus has following checks associated :

1. Acknowledge (ACK) : Every access placed on the bus receives ACK from the endpoint (memory controller (in case of memory) or peripheral bridge (in case of peripherals)). This detects any address decode faults that is blocking the access propagation to endpoint.
2. Ready Timeout : Ready timeout checks if for any reason ready is indefinitely pulled low by endpoint due to a fault, timeout logic generates abort request to endpoint. Timeout value is user configurable in SICCONFIG register.

3.6.1.1 Safe Interconnect for Read Operation

CPU generates the ECC for the address and control information needed for the read access to endpoint. This ECC is propagated to memory controller and peripheral bridges along with address and control information.

ECC is for error detection only when the fault is detected the error is sent to ESM via Error Aggregator and CPU goes to fault state. ESM needs to configured to generate NMI and read from address that was captured in error aggregator and user needs to write back the corrected data to fix correctable error at endpoint.

Safe Interconnect mechanisms for read operations :

1. Base Address Check at the Endpoint - Checks for address decode faults
2. ECC Check at the Endpoint - On forward path (CPU to Endpoint) ECC check is performed on address and control information integrity. CPU performs ECC calculation on address and control information locally and send the same to endpoint for cross checking with the ECC calculated at endpoint locally
3. ECC Check at CPU - On return path (Endpoint to CPU) ECC along with Data is fed back to CPU. CPU performs ECC Check

Coverage of the below possible causes of errors are covered by the safe interconnect mechanisms employed above :

1. Address decode fault, for example if the request is routed to the wrong memory due to fault in address decode interconnect logic
2. Address decode execution is correct but on the way to the endpoint if the address bits get flipped resulting in wrong address information sent to endpoint

3.6.1.2 Safe Interconnect for Write Operation

Checks performed are similar to read operation. In addition to address and control the write data is also checked for errors at endpoint in forward path. Write Data ECC generated on combination of address and data is also written along with data to endpoint without any modification if size of access is same as ECC granularity.

In case of endpoints like peripherals that do not support storing of ECC, the ECC is generated at the peripheral bridge so that transactions to and from peripheral bridge are covered.

3.6.2 Peripheral Access Configuration using FRAMESEL

The peripheral access from any initiators (CPUx and RTDMAx) is managed from FRAMES. All peripherals are mapped across 4 FRAME's such that every peripheral instance is accessed at one of the four memory map addresses as shown in Table 3-4 and Table 3-5. The frame selection configuration mechanism allows non-conflicting Initiator to target accesses complete faster and without arbitration stalls. For example, EPWM1 peripheral instance configurations can be accessed from FRAME0 by CPU1 while EPWM2 peripheral instance configurations be accessed from FRAME1 by CPU3. SSU-APR configuration controls the access from CPU to each FRAME region.

Note

Not all peripherals access is managed from FRAMESEL so check the respective Chapter Base Address tables to see if the Structure is Frame Applicable or not.

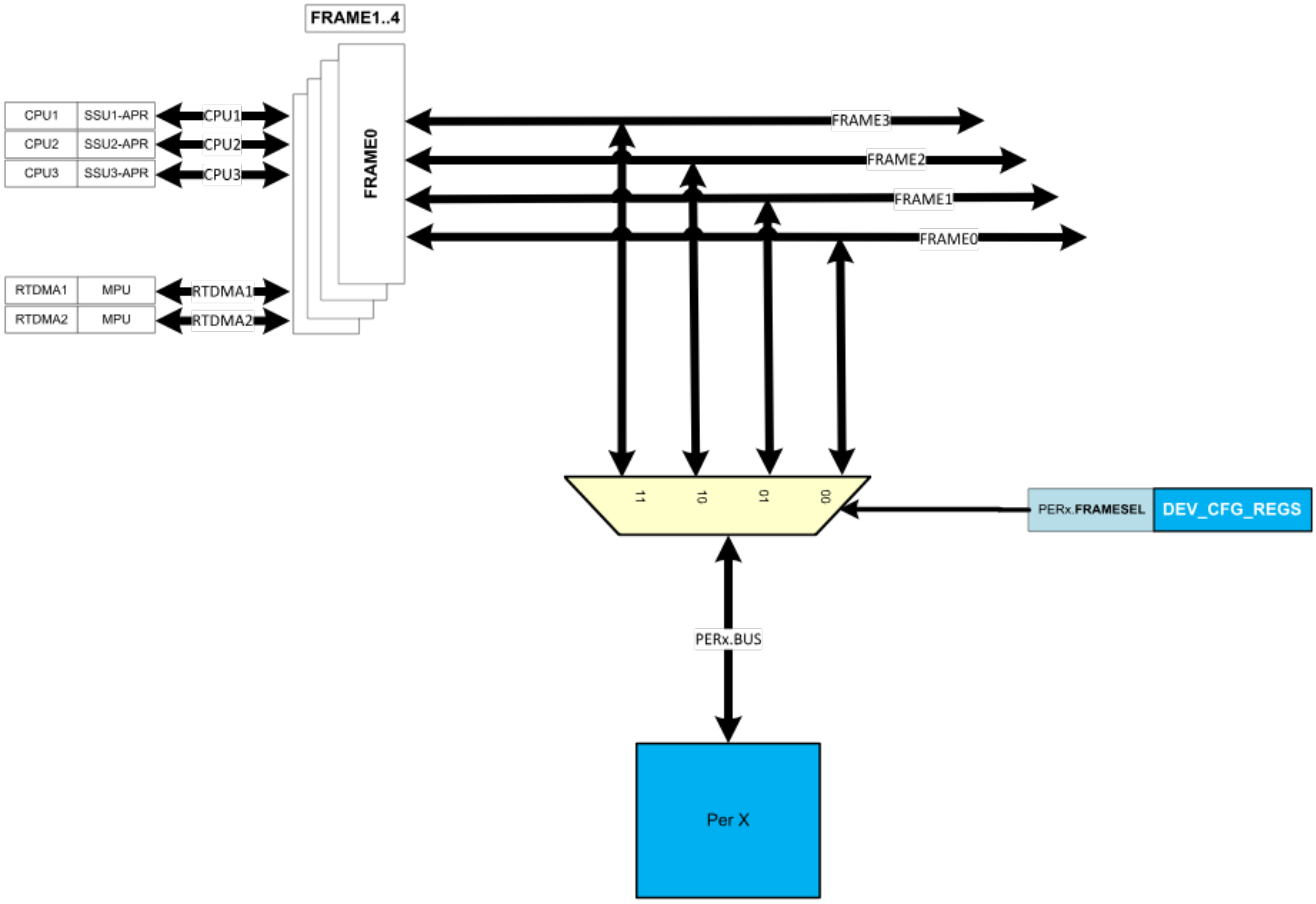

Figure 3-10. Peripheral Access Configuration

Table 3-4. VBUS32 Frame Base Addresses

Peripheral Frame	Base Address
Peripheral Frame 0	7000_0000
Peripheral Frame 1	7040_0000
Peripheral Frame 2	7080_0000
Peripheral Frame 3	70C0_0000

Note

VBUS32 Frame Peripherals do not support x8 access. Any x8 Access to these peripherals gives a Bridge ACK error using Error Aggregator and ESM.

Table 3-5. VBUSP Frame Base Addresses

Peripheral Frame	Base Address
Peripheral Frame 0	6000_0000
Peripheral Frame 1	6040_0000
Peripheral Frame 2	6080_0000
Peripheral Frame 3	60C0_0000

Note

Check data sheet Peripheral Registers Memory Map to see what peripherals are mapped to VBUS32 and VBUSP. All base address tables shown here are FRAME0 addresses. To find the respective FRAME addresses, add the FRAME0 offset to the respective FRAME base addresses.

3.6.3 Bus Arbitration

Access to same peripheral from multiple initiators is handled using the round-robin arbitration. Within round-robin arbitration the priority is given as below :

1. CPU1 Program access
2. CPU2 Program access
3. CPU1 Data accesses
4. CPU2 Data accesses
5. RTDMA1
6. RTDMA2
7. EtherCAT
8. HSM

The arbitration scheme makes sure that no initiator is stalled forever except when intentionally required by user during ATOMIC and burst operations. Back to back access or multiple simultaneous access from same initiator does not block other initiator from getting grant.

Access originating from same initiator is arbitrated using fixed priority as described below in case of CPU :

1. Write
2. Read Bus 1
3. Read Bus 2
4. Program Access

3.7 32-Bit CPU Timers 0/1/2

This section describes the three 32-bit CPU-Timers (TIMER0/1/2) shown in Figure 3-11.

CPU-Timer2 is reserved for real-time operating system uses (for example, TI-RTOS), but if CPU-Timer2 is not used by real-time operating systems then, CPU-Timer2 can also be used for other applications. The CPU-Timer0 and CPU-Timer1 run off of PLLSYSCLK. The CPU-Timer2 normally runs off of PLLSYSCLK, but can also use INTOSC1, INTOSC2 or XTAL. The CPU-Timer interrupt signals (TINT0, TINT1, TINT2) are connected to PIPE Module. Please refer to PIPE Channel mapping table for more details.

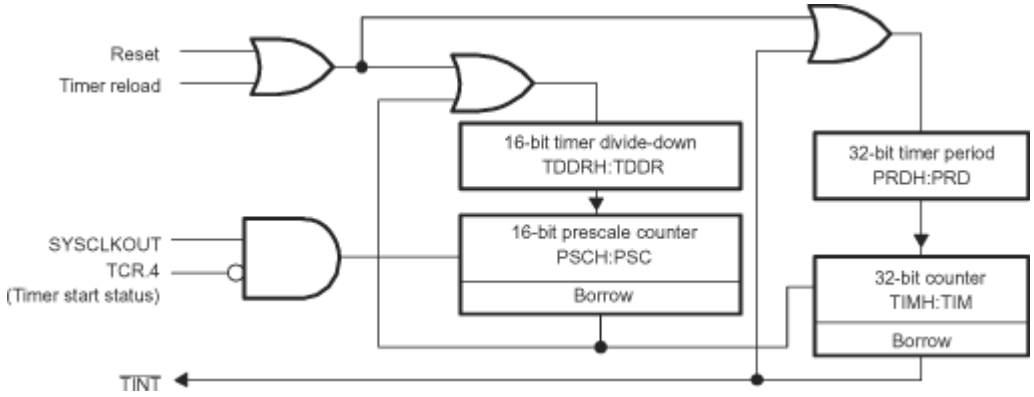

Figure 3-11. CPU Timers

The timer registers are connected to the memory bus of the C29x processor.
The CPU Timers are synchronized to SYSCLKOUT.

The general operation of the CPU-Timer is as follows:

- The 32-bit counter register, TIMH:TIM, is loaded with the value in the period register PRDH:PRD.
- The counter decrements once every (TPR[TDDRH:TDDR]+1) SYSCLKOUT cycles, where TDDRH:TDDR is the timer divider.
- When the counter reaches 0, a timer interrupt output signal generates an interrupt pulse.

The registers listed in Section 3.13 are used to configure the timers.

3.8 Watchdog Timers

The watchdog module generates an output pulse 512 watchdog-clocks (WDCLKs) wide whenever the 8-bit watchdog up counter has reached the maximum value. The watchdog clock source is INTOSC1. Software must periodically write a 0x55 + 0xAA sequence into the watchdog key register to reset the watchdog counter. The counter can also be disabled. Figure 3-12 shows the various functional blocks within the watchdog module.

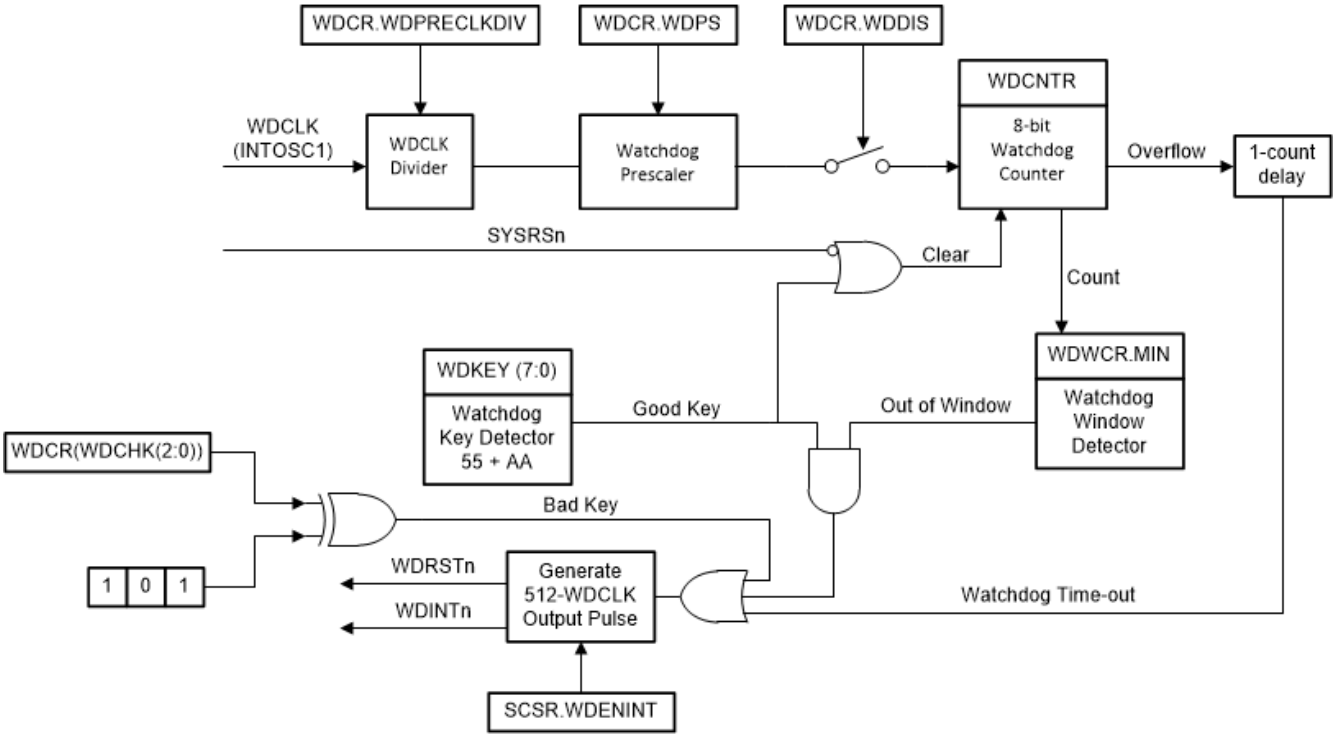

Figure 3-12. CPU Watchdog Timer Module

3.8.1 Servicing the Watchdog Timer

The watchdog counter (WDCNTR) is reset when the proper sequence is written to the WDKEY register before the 8-bit watchdog counter overflows. The WDCNTR is reset-enabled when a value of 0x55 is written to the WDKEY. When the next value written to the WDKEY register is 0xAA, then the WDCNTR is reset. Any value written to the WDKEY other than 0x55 or 0xAA causes no action. Any sequence of 0x55 and 0xAA values can be written to the WDKEY without causing a system reset; only a write of 0x55 followed by a write of 0xAA to the WDKEY resets the WDCNTR.

Table 3-6. Example Watchdog Key Sequences

Step	Value Written to WDKEY	Result
1	0xAA	No action
2	0xAA	No action
3	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
4	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
5	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
6	0xAA	WDCNTR is reset.
7	0xAA	No action
8	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
9	0xAA	WDCNTR is reset.
10	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
11	0x32	Improper value written to WDKEY. No action, WDCNTR no longer enabled to be reset by next 0xAA.
12	0xAA	No action due to previous invalid value.
13	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
14	0xAA	WDCNTR is reset.

Step 3 in Table 3-6 is the first action that enables the WDCNTR to be reset. The WDCNTR is not actually reset until step 6. Step 8 again re-enables the WDCNTR to be reset and step 9 resets the WDCNTR. Step 10 again re-enables the WDCNTR to be reset. Writing the wrong key value to the WDKEY in step 11 causes no action, however the WDCNTR is no longer enabled to be reset and the 0xAA in step 12 now has no effect.

If the watchdog is configured to reset the device, then a WDCNTR overflow or writing the incorrect value to the WDCR[WDCHK] bits resets the device and sets the watchdog flag (WDRSn) in the reset cause register (RESC). After a reset, the program can read the state of this flag to determine whether the reset was caused by the watchdog. After doing this, the program must clear WDRSn to allow subsequent watchdog resets to be detected. Watchdog resets are not prevented when the flag is set.

3.8.2 Minimum Window Check

To complement the timeout mechanism, the watchdog also contains an optional "windowing" feature that requires a minimum delay between counter resets. This can help protect against error conditions that bypass large parts of the normal program flow but still include watchdog handling.

To set the window minimum, write the desired minimum watchdog count to the WDWCR register. This value takes effect after the next WDKEY sequence. From then on, any attempt to service the watchdog when WDCNTR is less than WDWCR triggers a watchdog interrupt or reset. When WDCNTR is greater than or equal to WDWCR, the watchdog can be serviced normally.

At reset, the window minimum is zero, which disables the windowing feature.

3.8.3 Watchdog Reset or Watchdog Interrupt Mode

The watchdog can be configured in the SCSR register to either reset the device ($\overline{\text{WDRST}}$) or assert an interrupt ($\overline{\text{WDINT}}$), if the watchdog counter reaches the maximum value. The behavior of each condition is:

- **Reset mode:** If the watchdog is configured to reset the device, then the $\overline{\text{WDRST}}$ signal pulls the device reset ($\overline{\text{XRS}}$) pin low for 512 INTOSC1 cycles when the watchdog counter reaches the maximum value.
- **Interrupt mode:** When the watchdog counter expires, the watchdog asserts an interrupt by driving the $\overline{\text{WDINT}}$ signal low for 512 INTOSC1 cycles. $\overline{\text{WDINT}}$ is mapped to the PIPE module to assert appropriate CPU interrupt line as configured.

  An error event input is also generated to ESM (for more details refer to ESM Inputs section in ESM Chapter) which can be configured to take actions as deemed necessary by system integrator.

  To avoid unexpected behavior, software must not change the configuration of the watchdog while $\overline{\text{WDINT}}$ is active. For example, changing from interrupt mode to reset mode while $\overline{\text{WDINT}}$ is active immediately resets the device. Disabling the watchdog while $\overline{\text{WDINT}}$ is active causes a duplicate interrupt, if the watchdog is later re-enabled. If a debug reset is issued while $\overline{\text{WDINT}}$ is active, the reset cause register (RESC) shows a watchdog reset. The WDINTS bit in the SCSR register can be read to determine the current state of $\overline{\text{WDINT}}$.

3.8.4 Watchdog Operation in Low-Power Modes

In IDLE mode, the watchdog interrupt ($\overline{\text{WDINT}}$) signal can generate an interrupt to the CPU to take the CPU out of IDLE mode. User software must determine which peripheral caused the interrupt.

In STANDBY mode, clocks to the peripherals are turned off based on LPMCR, PCLKCRx and STANDBYEN registers. The CPU clock is gated when entering STANDBY mode based on LPMCR.LPM configuration but the watchdog remains functional since the module runs off the internal oscillator clock (INTOSC1). The $\overline{\text{WDINT}}$signal is applied to the Low Power Modes (LPM) block, so that the LPM block can be used to wake the CPU from STANDBY low-power mode. This feature is enabled by setting LPMCR.WDINTE = 1. See Section 3.9 for details. CPU can be brought out of IDLE or STANDBY mode using any of the enabled INT, RINT or NMI.

Note

If the watchdog interrupt is used to wake-up from an IDLE or STANDBY low-power mode condition, software must make sure that the $\overline{\text{WDINT}}$ signal goes back high before attempting to reenter the IDLE or STANDBY mode. The $\overline{\text{WDINT}}$ signal is held low for 512 INTOSC1 cycles when the watchdog interrupt is generated. The current state of $\overline{\text{WDINT}}$ can be determined by reading the watchdog interrupt status (WDINTS) bit in the SCSR register. WDINTS follows the state of $\overline{\text{WDINT}}$ by two SYSCLKOUT cycles.

3.8.5 Emulation Considerations

The watchdog module behaves as follows under various debug conditions:

CPU Suspended:	When the CPU is suspended, the watchdog clock (WDCLK) is suspended
Run-Free Mode:	When the CPU is placed in run-free mode, then the watchdog module resumes operation as normal.
Real-Time Single-Step Mode:	When the CPU is in real-time single-step mode, the watchdog clock (WDCLK) is suspended. The watchdog remains suspended even within real-time interrupts.
Real-Time Run-Free Mode:	When the CPU is in real-time run-free mode, the watchdog operates as normal.

3.9 Low-Power Modes

This device has two clock-gating, low-power modes. All low-power modes are entered by setting the LPMCR register and executing the IDLE instruction. More information about this instruction can be found in the *F29x CPU Reference Guide*.

Low-power modes cannot be entered into while a Flash program or erase is ongoing. The application can verify the following before entering STANDBY:

1. Check the value of the GPIODAT register of the pin selected for STANDBY (GPIOLPMSEL0/1) prior to entering the low-power mode to make sure that the wake event has not already been asserted.
2. The LPMCR.QUALSTDBY register can be set to a value greater than the ratio of INTOSC1/PLLSYSCLK to make sure proper wake up.

3.9.1 IDLE

IDLE is a standard feature of the CPU. In this mode, the CPU is turned off while CPUx.CLOCK and all peripheral clocks are left running. IDLE can thus be used to conserve power while a CPU is waiting for peripheral events. When one CPU is in IDLE, there is no effect on the other CPU subsystem.

Any enabled interrupt wakes up the CPU from IDLE mode.

To enter IDLE mode, set LPMCR.LPM to 0x0 and execute the IDLE instruction.

3.9.2 STANDBY

STANDBY is a more aggressive low-power mode that gates both the CPU clock and any peripheral clocks derived from PLLSYSCLK (based on STANDBYEN setting). The watchdog however, is left active. Like IDLE, this mode affects only one CPU subsystem. The other CPU subsystem and all of the peripherals are unaffected. STANDBY is good for an application where the wake-up signal comes from an external system (or CPU subsystem) rather than a peripheral input.

An NMI (or optionally) any interrupt or a configured GPIO can wake the CPU from STANDBY mode. Each GPIO from GPIO0-63 can be configured to wake the CPU when the GPIO are driven active low. Additionally a CMPSS based wake up can be used for coming out of standby mode by configuring CMPSSLPMSEL register.

IPC interrupt 1 (flag 0), an NMI fired to the other CPU, or (optionally) any interrupt, wakes the CPU subsystem up from STANDBY mode. Any of GPIO0-63 can also be configured to wake up the subsystem when the GPIO is driven active low.

To enter STANDBY mode:

1. Set LPMCR.LPM to 0x1.
2. Enable the required interrupt in the PIPE
3. For watchdog interrupt wakeup, set LPMCR.WDINTE to 1 and configure the watchdog to generate interrupts.
4. For GPIO wakeup, set GPIOLPMSEL0 and GPIOLPMSEL1 to connect the chosen GPIOs to the LPM module, and set LPMCR.QUALSTDBY to select the number of OSCCLK cycles for input qualification.
5. Execute the IDLE instruction to enter STANDBY.

To wake up from Standby mode:

1. Configure the desired GPIO to trigger the wakeup.
2. Drive the selected GPIO signal low; the signal must remain low for the number of OSCCLK cycles specified in the QUALSTDBY bits in the LPMCR register. If the signal is sampled high during this period, the count restarts.

At the end of the qualification period, the PLL enables the CLKIN to the CPU and the associated wake up interrupt is latched in the PIPE module.

The CPU is now out of STANDBY mode and can resume normal execution.

3.10 Memory Subsystem (MEMSS)

This section discusses the memory subsystem of the device and how the buses, arbitration, and memory controllers are configured.

3.10.1 Introduction

The MEMSS, or Memory Subsystem, covers the memory architecture (RAM and ROM) used on the C29x platform. There are multiple initiators accessing the memories on the device like C29 CPU's, RTDMA's, HSM and EtherCAT.

Each CPU has a 128-bit program bus, two 64-bit read buses, and a 64-bit write bus. Hence, there are separate 128-bit and 64-bit memory controllers that are optimized based on program or data access from specific CPU pairs.

Certain memories are optimized for zero wait state access from specific CPU pair (CPU1/2 or CPU1/3) and type of access (program or data) as described in Table 3-7. Access from other initiators like RTDMA is pipelined but burst mechanism is added between RTDMA and MEMSS to improve throughput.

The MEMSS registers can be found in Section 3.13.

Table 3-7. Naming Conventions

Name	Read Word Access	Zero Wait State Optimization
LPAx RAM	128-bit word	Program Access for CPU1 and CPU2
LDAx RAM	64-bit word	Data Access for CPU1 and CPU2
CPAx RAM	128-bit word	Program Access for CPU1 and CPU3
CDAx RAM	64-bit word	Data Access for CPU1 and CPU3

3.10.2 Features

The MEMSS implements the following features for memory:

- RAM:
  - RTDMA throughput optimization with local lookahead address generation
  - Common dataline buffer for each CPU (2x64-bit words)
  - Common program bridge for each CPU
  - ECC support with 32-bit granularity
  - Read-modify-write for write access smaller than ECC granularity
  - Posted write to minimize stalls on read-modify-write operation
  - Test mode to read/write ECC bits and error injection
- ROM:
  - ECC support with 64-bit granularity to reduce ECC bits overhead
  - One wait state program and data access
  - Prefetch with 256-bit wide memory
  - Dedicated local line buffer of 256 bits
- To reduce ECC bit overhead, there are no separate address ECC bits; ECC is generated by combining data and address

3.10.3 Configuration Bits

Each memory block has the following configuration bits:

- Test mode to read ECC bits and error injection (TESTMODE)
- Memory initialization trigger bit (MEMINIT)

These bits can be configured by CPU1 LINK0, LINK1, or LINK2. Debug accesses are only allowed if Zone 0 or Zone 1 are enabled for full-debug by all CPUs.

3.10.3.1 Memory Initialization

Memory initialization is initiated by writing to a software-programmable bit. Each memory has independent memory initialization control. Accesses are stalled for the memory being initialized until the initialization is complete. MEMINIT can be set only from CPU1 LINK0, LINK1, or LINK2.

3.10.4 RAM

This section details the architecture and configuration of the MEMSS for RAM.

3.10.4.1 MEMSS Architecture

Table 3-8 shows the different wait states for accessing different memory sections, depending on the initiator that is accessing the memory.

Note

In Table 3-8, nWS indicates a wait state of n cycles.

Table 3-8. Memory Configuration

RAM Section	Interleaved	CPU1	CPU2	CPU3	HSM	RTDMA1	RTDMA2
LPAx RAM	Yes	0WS program 1WS data	0WS program 1WS data	3WS data		1WS	1WS
LDAx RAM	Yes	1WS program 0WS data	1WS program 0WS data	3WS data	2WS	1WS	1WS
M0 RAM	Yes	0WS data	0WS data (read-only)	3WS data (read-only)			
CPAx RAM	Yes	0WS program 1WS data	3WS data	0WS program 1WS data		1WS	1WS
CDAx RAM	Yes	1WS program 0WS data	3WS data	1WS program 0WS data		1WS	1WS
CPU1 ROM	Yes	1WS program 1WS data					
CPU2 ROM	Yes		1WS program 1WS data				
CPU3 ROM	Yes			1WS program 1WS data			

Figure 3-13 shows the integration view of all the RAM and the respective accesses.

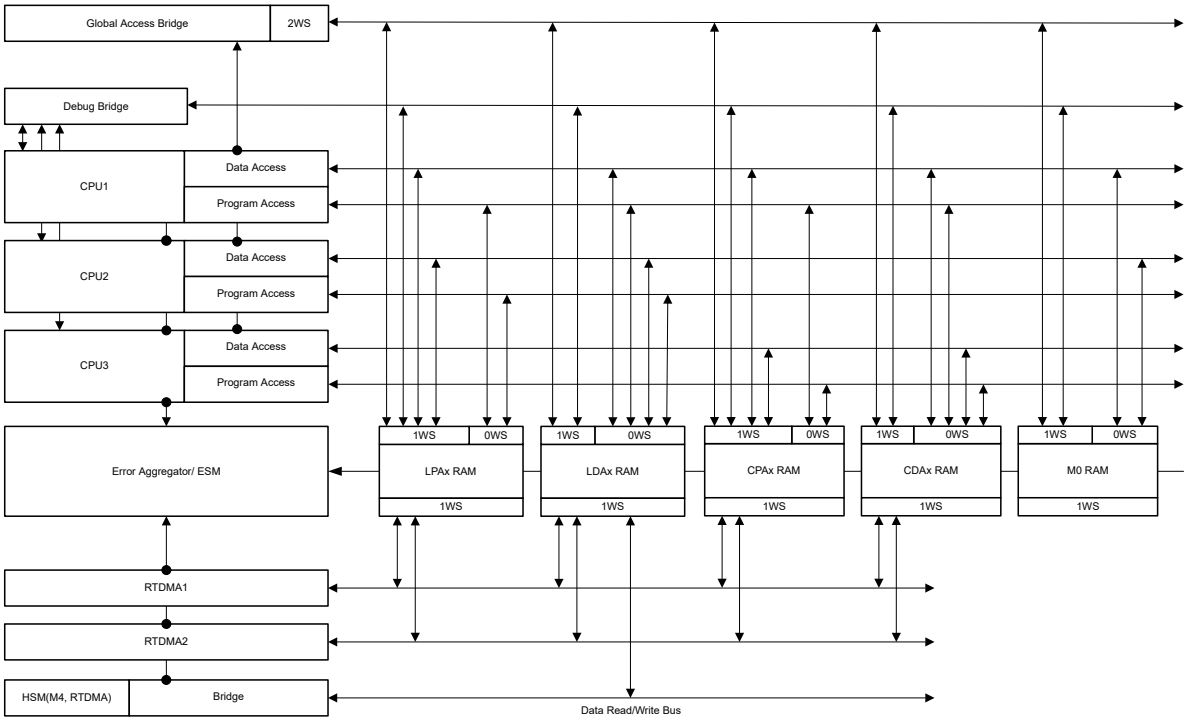

Figure 3-13. Integration View of All RAMs

3.10.4.2 RAM Memory Controller Overview

Each CPU has a dataline buffer in common for all RAMs. This buffer is only used for RAM accesses, and accesses to other regions of the memory map are not be buffered or served from the dataline buffer. The Flash read interface and ROM controllers have dedicated line buffers local to the controller and are 256-bit wide memories.

Each CPU has a program bridge to interface 64-bit memories. This bridge is common for all 64-bit RAMs connected to a CPU and bridges the 128-bit bus of the CPU and the 64-bit buses of the LDx and CDx memory controller. Global bridge access allows data access to any RAM from any CPU which does not already have direct access, with a tradeoff of being three wait states to access the memory.

Memory controllers have a fast access port and slow access port. Fast access ports are zero wait state and limited, while slow access ports are one wait state and can have improved throughput if the initiator supports burst mode. Each CPU also has a debug access port, which are arbitrated externally. Only one port is routed to the memory controller. Debug accesses are connected to slow access ports.

Safe interconnect checks are done in initiators and memory controllers. Any errors resulting from HSM accesses are aggregated in the HSM-ESM, whiles others are aggregated in the ESM.

ECC granularity for RAM data is 32 bits. Write accesses of 8 or 16 bits require a read-modify-write operation. M0 memory is the similar to LDAx memory, and access permissions are determined by the SSU.

The LDAx memories are accessible from the CPU and HSM and can be used as shared memories or dedicated memories. Freedom from interference is provided so the CPU does not get access to secure HSM data. The LDAx memories have a multi-layer protection:

- HSM controls shared memory access using independent USURP control for each LDAx memory block (enables/blocks access completely)
- CPU enables the access to LDAx memories using MPU present in HSM bridge. Only access to selected portion is allowed
- Two additional levels of protection that can be enabled with the SSU and other MPUs in the system

Read and write to the LDAx memories is only allowed if both systems allow the access type, otherwise an access violation error is generated to the respective system.

3.10.4.3 Memory Controllers

3.10.4.3.1 128-Bit LPx and CPx Memory Controller

The 128-bit memory controller enables zero wait states on program accesses. This also allows data accesses, providing the ability to copy code, download code, and insert software breakpoints. Data accesses can be one or more wait states. Each logical block of the 128-bit memory has four memory banks. The data width of these RAMs is 39 bits (32-bit data and 7-bit ECC). The four banks are grouped together and the addresses are interleaved to form a 128-bit word. All data reads are treated as 64-bit reads, and 64-bit data is returned because the dataline buffer is 64-bit wide.

The 128-bit memory controllers have accesses from the following initiators:

- CPU1,2,3
- RTDMA1-2
- Debug

Figure 3-14 shows a view of the 128-bit memory.

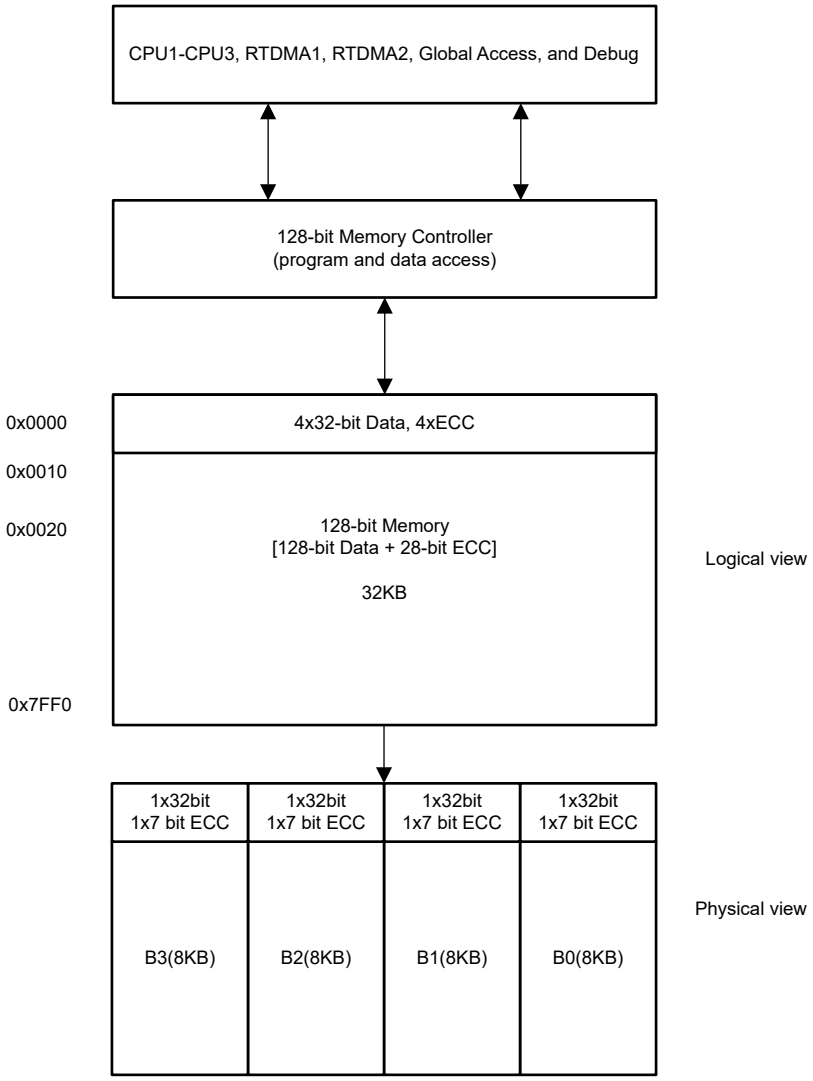

Figure 3-14. 128-Bit Memory

Figure 3-15 shows the 128-bit memory controller. This controller implements LPx and CPx memories. Each instance of the controller is optimized for zero wait states from two specific CPUs (CPUa and CPUb). For example, LPAx is optimized for CPU1 and CPU2 program access while CPAx is optimized for CPU1 and CPU3 program access. For these configurations, the controller is the same but the CPUs that get connected as CPUa and CPUb are different.

Note

Program accesses from CPUs other than CPUa and CPUb are not supported. For example, LPAx does not have CPU3 program access.

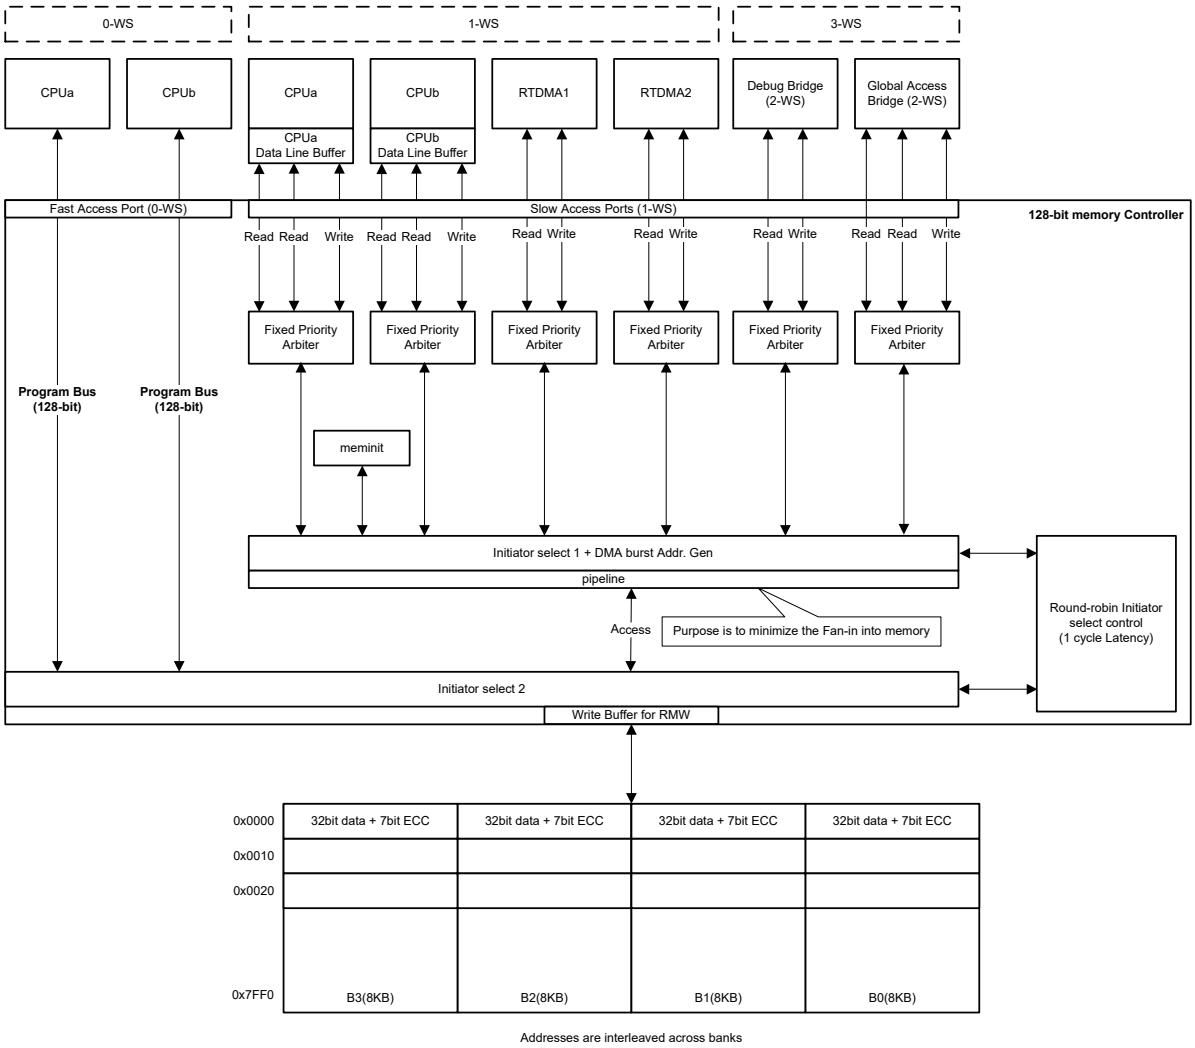

Figure 3-15. 128-Bit Memory Controller

The 128-bit controller has fast and slow access ports. Fast access ports have zero wait state program access from CPUa and CPUb. Slow access ports are intended for non-critical data access and have one wait state due to pipelining. Lookahead reads using the RTDMA burst signaling is supported on slow access ports.

Note

CPUa and CPUb use the respective clock domain when accessing memory.

The read-modify write operation happens in the background without stalling the CPU, using the write buffer close to the memory.

Data accesses from CPUs other than CPUa and CPUb are routed through global access bridge. Debug access is routed through debug access bridge. The latency of these accesses is three wait states. Two wait states are introduced by the global access bridge for data access and debug access bridge for debug access with additional one wait state introduced by the slow access port of 128-bit memory controller.

Note

There is no restriction on using a portion of the program RAM as data memory, so long as the SSU setting allows for this. However, this is not recommended as arbitration affects CPU performance.

The following is the round-robin priority order:

1. CPUa Program Access
2. CPUb Program Access
3. CPUa Data Access
4. CPUb Data Access
5. RTDMA1
6. RTDMA2
7. Debug Access Bridge
8. Global Access Bridge

3.10.4.3.2 64-Bit LDx and CDx Memory Controller

The 64-bit LDx and CDx memory controller is similar to the 128-bit LPx and CPx memory controller, but differs in a few ways. The 64-bit memory controller has zero wait states on data access and one wait state on program access. Each block of 64-bit memory has two memory banks. The data width of these RAMs is 39 bits (32-bit data and 7-bit ECC). The two banks are grouped together and the addresses are interleaved to form a 64-bit word.

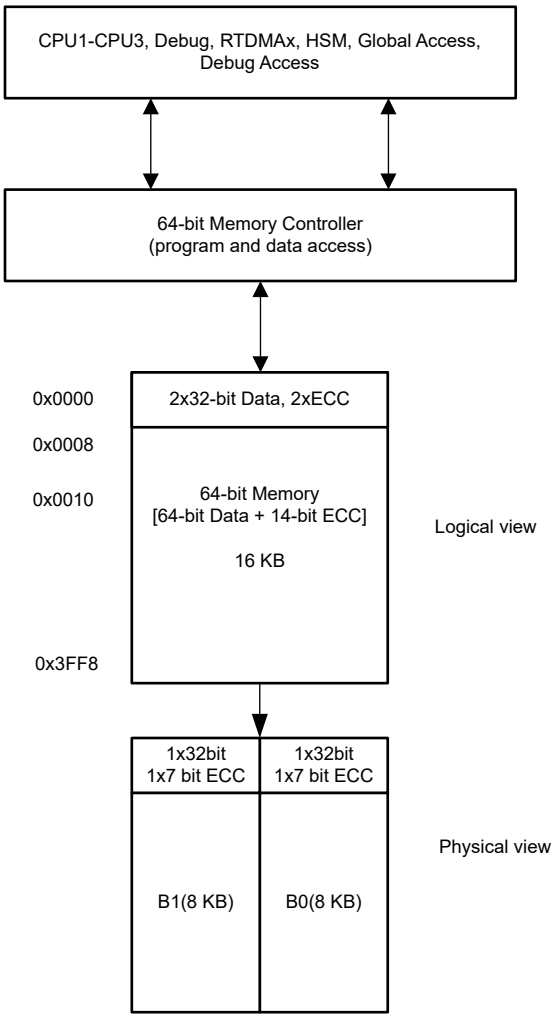

Figure 3-16. 64-Bit Memory

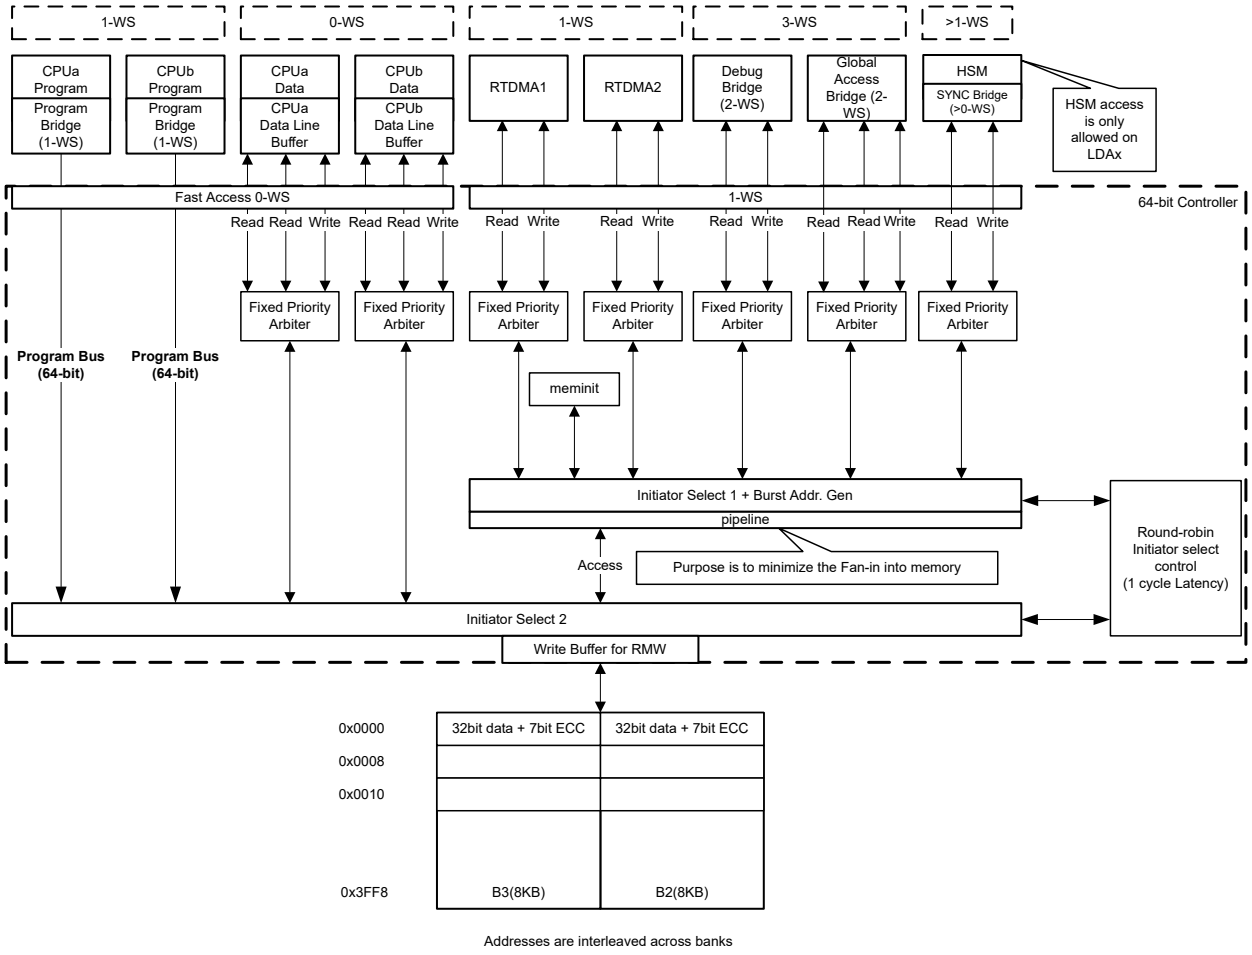

Figure 3-17. 64-Bit Memory Controller

Fast access ports have zero wait states for program and data access from CPUa and CPUb. For example, LDAx RAM has fast access port access for CPU1 and CPU2 program and data access while CDAx RAM has fast port access for CPU1 and CPU3 program and data access.

Program access from other CPUs is not supported. For example, CPU3 does not have program access for LDAx RAM. Fast access ports support 64-bit program access, and the program access bridge connects the 64-bit memory interface to the 128-bit memory bus of the CPU. The accesses between the program access bridge and the 64-bit memory controller are zero wait states, but the bridge initiates two accesses to form a 128-bit word. This is effectively one wait state for a 128-bit word with respect to CPU. The CPUa and CPUb data write access ports have one level of buffering, and the write buffer also handles read-modify-write operations.

The following is the round-robin priority order:

1. CPUa Program Access
2. CPUb Program Access
3. CPUa Data Access
4. CPUb Data Access
5. RTDMA1
6. RTDMA2

7. HSM
8. Debug Access Bridge
9. Global Access Bridge

Other details regarding the 64-bit memory controller are the same as the 128-bit memory controller, with the only difference being the width of the memory controller. Refer to Section 3.10.4.3.1 for more information.

3.10.4.3.3 M0 Memory Controller

M0 memory is similar to LDAx memory, but M0 only has accesses from the CPUs. Below are some restrictions on M0. Refer to SSU Chapter for more details.

- No RTDMA access
- Only CPU1 has permission read/write
- Only read is supported from CPU2 and CPU3
- Fetch is not allowed

3.10.4.4 RTDMA Burst Support

RTDMA is connected through a slow access port as shown in Figure 3-18, so all accesses are minimum one wait state. To improve throughput, RTDMA supports local address generation within the MEMSS memory controller. This enables performance close to zero wait states.

Local address generation within a burst is enabled by the following signals:

- First access of burst sequence (FIRST)
- Last access of burst sequence (LAST)
- Address Increment for next address (XCNT)
  - Next Address = Current Address + XCNT; this is for lookahead access generation

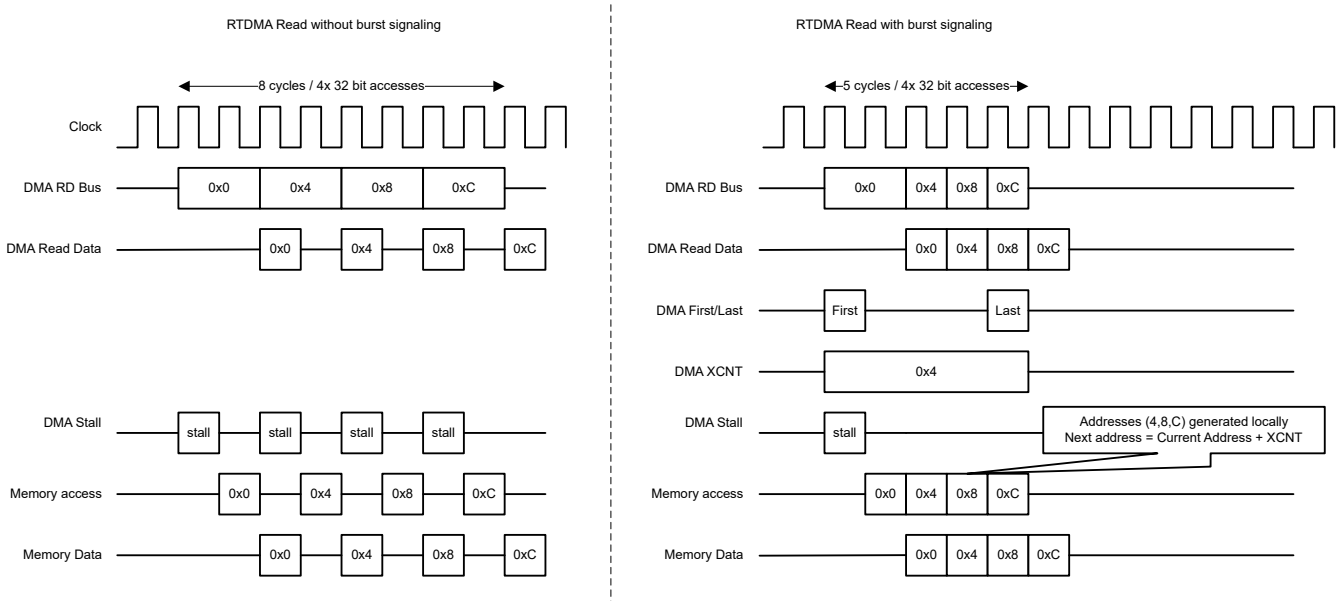

Figure 3-18. RTDMA Read

Without burst signaling, the address is latched first and then presented to memory. With burst, this happens only once for the first access, since the MEMSS memory controller does not use addresses generated by the RTDMA for subsequent accesses, as addresses is generated locally.

The LAST signal is an indication to stop the lookahead read. If the LAST signal is not generated, the RTDMA request going inactive is treated as a burst termination.

The RTDMA arbitration is locked when the FIRST access of a burst is granted, and the arbitration is released on the LAST access. Accesses with the FIRST and LAST signals asserted are treated as non-burst, and a lookahead read is not initiated nor is the arbitration locked. The arbitration lock is removed if the RTDMA channel is halted due to a CPU halt.

3.10.4.5 Atomic Memory Operations

The ATOMIC.M, or atomic, operation executes a protected sequence of memory operations while preventing other memory initiators from interrupting. This sequence can involve reading and updating shared variables in memory, where there is a need to protect these variables from updates by other initiators. The CPU atomic operation feature is typically used to implement a mutex or semaphore operation on shared data.

For true atomic CPU operations, the atomic operation must extend to memory accesses. The arbitration is locked to the CPU doing the atomic operations as soon as access is granted to the CPU. This can be a read or write operation. The lock is released when both signals transition low. From this point, other initiators can access the memory. This is visualized in Figure 3-19.

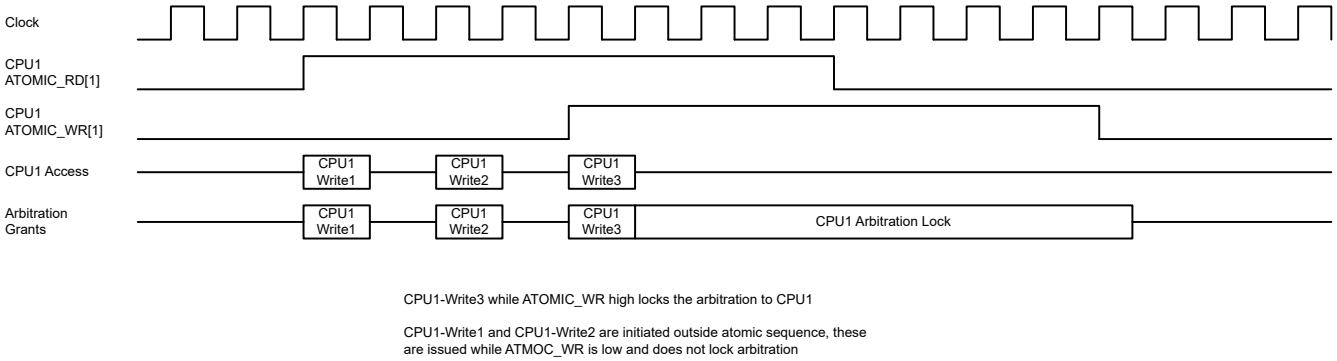

Figure 3-19. Atomic Operations in the MEMSS

The CPU atomic operation extends to a maximum of 256 instruction packets. For atomic operations, reads are always directed to the memory controller to fetch the latest data from memory to make sure the latest data is being returned.

The arbitration lock is removed if the corresponding CPU enters a halt state. This prevents other initiators from being stalled forever and causing the CPU timeout checkers to generate a fault in the case where a CPU is halted. For this reason, atomic operations among initiators is not specified under debug scenarios. To maintain an atomic sequence during debug the DBGM control must be used to mark the atomic sequence as non-haltable.

Read-modify-write and memory-to-memory data move CPU instruction types are treated as regular reads and writes by the MEMSS. To have these operations treated as a protected sequence, the instructions need to be explicitly included in an atomic section of the code.

More than one memory controller can be locked to a CPU if the atomic block of code accesses more than one memory block. The lock is released simultaneously for MEMSS memory controllers at the end of an atomic sequence. If there are back-to-back atomic blocks being executed on a CPU, the MEMSS memory controller can be locked to that CPU through all blocks of code.

If a CPU has both an atomic read and atomic write, the access arbitration follows the fixed priority scheme. If two or more CPUs have atomic accesses, the arbitration is locked to one CPU and moves round-robin among the other CPUs. When some CPUs have non-atomic accesses, the accesses are serviced in between each access in the round-robin scheme. For example, if CPU1 has an atomic access, CPU2 has a non-atomic access, and CPU3 has an atomic access, and CPU1 is currently being serviced with an atomic lock, then one access for CPU2 is serviced followed by an atomic lock for CPU3.

3.10.4.6 RAM ECC

All RAMs have ECC protection with a 32-bit granularity. This means that every 32 bits has 7 bits of ECC. ECC for write data is generated in the CPU and written to memory directly. The read-modify-write operation is performed within the MEMSS memory controller for accesses that are less than 32 bits, and the ECC is generated locally for these write accesses.

Note

There is no separate address ECC. The ECC code generated is a combination of the address and data.

3.10.4.7 Read-Modify-Write Operations

Memory initiators are byte addressable and can generate write accesses that are 8/16/32/64 bits. A read-modify-write operation is performed locally in the MEMSS memory controller for 8 and 16-bit write accesses.

3.10.4.8 Dataline Buffer

Figure 3-20 shows a high level view of the dataline buffer scheme. LB1 and LB2 are two data Line Buffers. The buffer is reset by the respective CPUx.SYSRSn reset.

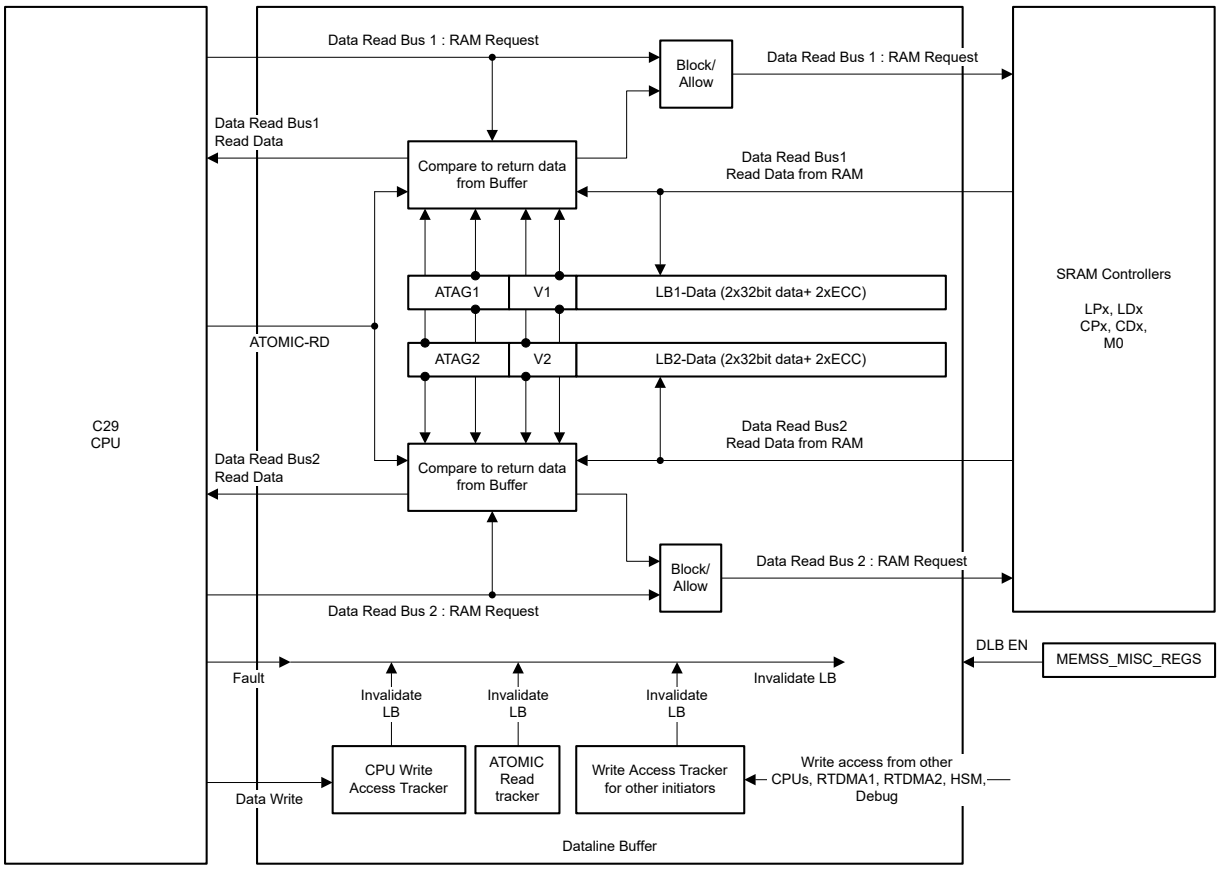

Figure 3-20. Dataline Buffer

LB1 is loaded with data returned on data read bus 1, while LB2 is loaded with data from data read bus 2. The width of line buffer is 64 bits and has an associated valid bit (Vx) and address tag (ATAGx). ATAGx is a 64-bit aligned address of the data being held in the dataline buffer. The memory controller returns 64 bits of data regardless of the read access size. On every read access, the read address is compared with the ATAGx of LB1 and LB2. When the tag matches, data is returned from the corresponding dataline buffer. Read access to the memory controller is blocked at that time.

Initiators other than the CPU have access to RAM on the device. The dataline buffer is updated on CPU reads only, and the data in the buffer does not hold the latest data if another initiator updated the same address already. Write accesses from other initiators are tracked local to the dataline buffer, as shown by the "Write Access Tracker from Other Initiators" in Figure 3-20. The dataline buffer is marked as invalid upon write access completion from another initiator if the address tag matched the write address. The CPU reads the old data until the time at which the buffer is marked as invalid using the Vx bit.

The CPU can issue a read and write to the same address simultaneously, in which case the dataline buffer detects this and invalidates the dataline buffer when there is an address tag match. An address tag match to a write address does not update the dataline buffer locally. For this, the write is performed to memory first then a read is initiated to fetch the latest data. This is shown by "CPU Write Access Tracker" in Figure 3-20.

The ECC check is done within the CPU. When there is an uncorrectable ECC error detected, the CPU enters a fault state. Dataline buffers of a CPU are invalidated upon any CPU fault.

Dataline buffer needs to be disabled using MEM_DLB_CONFIG register before memory initialization or running test mode to invalidate last buffered data.

3.10.4.9 HSM Sync Bridge

HSM Subsystem has two initiators, M4 core and HSM-RTDMA. HSM Sync bridge connects the C29 peripherals and memories to HSM subsystem.

Figure 3-21 consists of MPU (Memory Protection Unit), Data line buffer and Safe interconnect.

MPU configuration can only be done by CPU1 Link0/1/2 using the SYNCBRIDGEMPU Registers.

Read access going into C29 system memories must be 64 bit reads with reads buffered in dataline buffer improving throughput as compared to two 32-bit reads. Although read access to C29 system peripherals are 32-bit reads and is not buffered into dataline buffer.

Write access from other initiators are tracked and dataline buffer is invalidated if the address of the write matches address tag of line buffer similar to C29CPU dataline buffer.

ECC Checks are also performed in the sync bridge as part of the safe interconnect and errors are sent to HSM-ESM (Error Signaling Module).

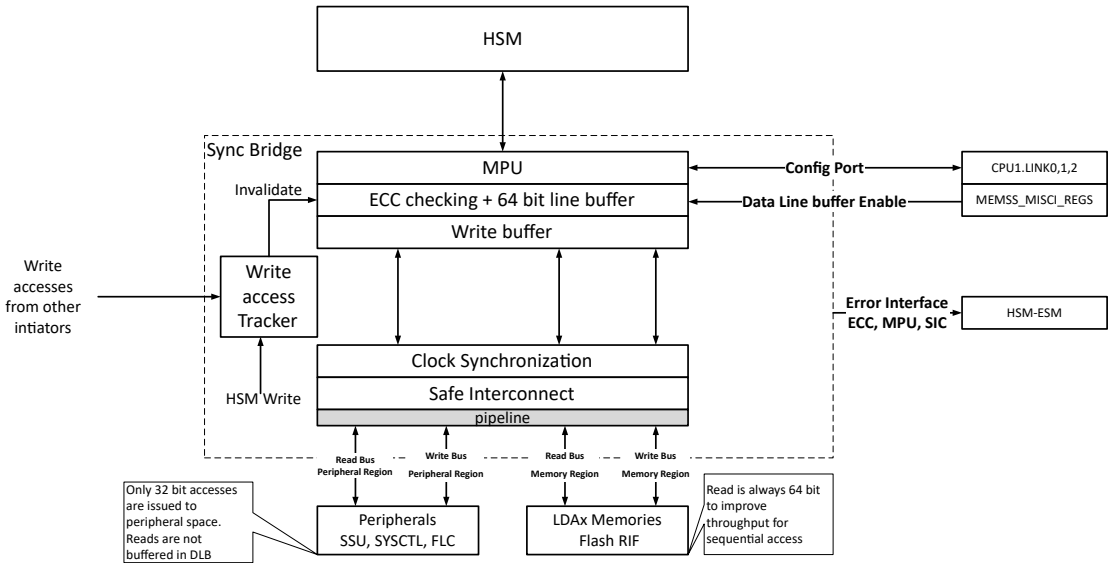

Figure 3-21. HSM Sync Bridge Block Diagram

3.10.4.10 Access Bridges

3.10.4.10.1 Debug Access Bridge

The debug access bridge arbitrates and connects one set of read and write ports from a CPU to the MEMSS memory controller using static select arbitration as described in Section 3.10.6. This is common to the entire system. Arbitration and security access filtering can take up to two cycles, and debug accesses through this bridge are a two wait state minimum.

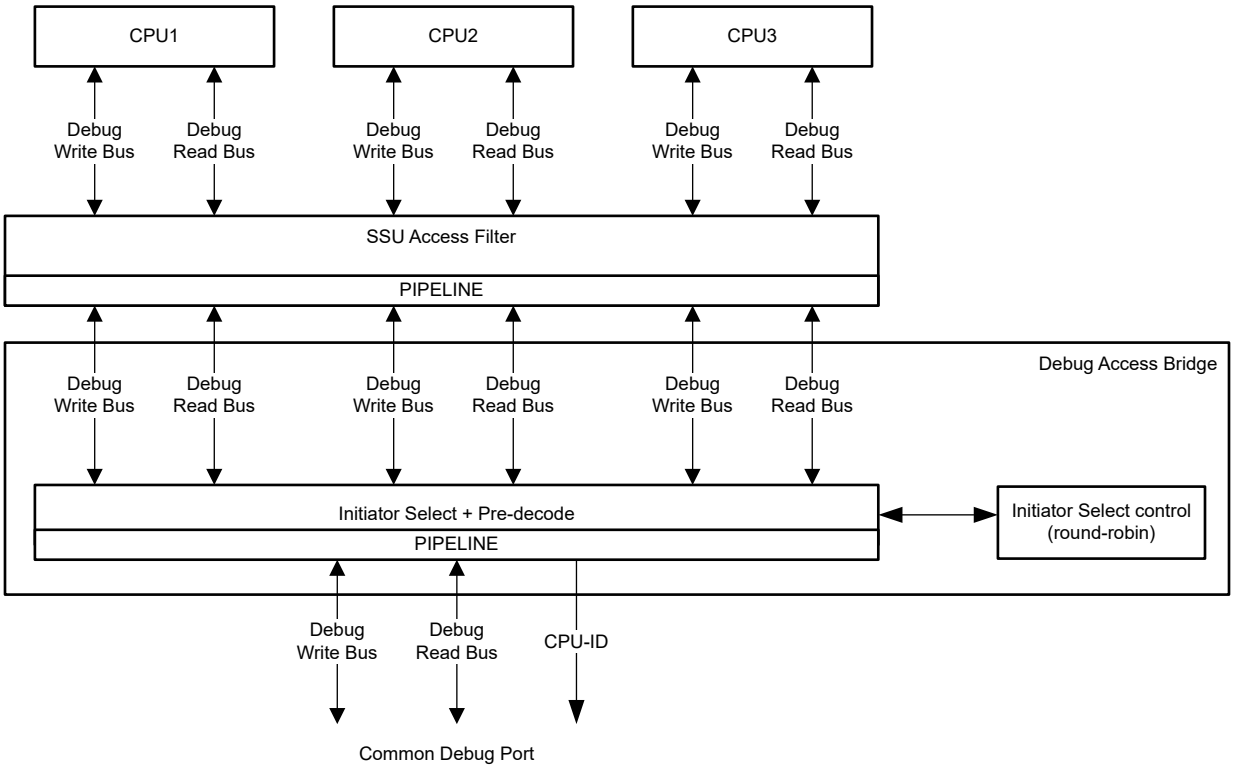

Figure 3-22. Debug Access Bridge

The initiator select connects one of the CPU buses to a common debug port, so the output buses cannot have accesses from more than one initiator at a given time. Debug read and write accesses identified as illegal are blocked in the debug access bridge.

Common debug access ports have a CPU-ID to indicate the origin of the current access. This ID can be used to implement access filtering, if needed. Following are the CPU-ID assignments:

- CPU1: 0001
- CPU2: 0010
- CPU3: 0011

The two types of memory regions have access filter handling :

1. Peripheral and uniquely memory-mapped memories
   a. The SSU handles access filtering.
2. Tightly-coupled CPU peripherals (that is, PIPE, ERAD, and the CPU). These are mapped at some address respective to the CPU memory-map, and only the respective CPU has access to that memory (access checked using CPU-ID).
   a. The SSU access filter always allows access to the ERAD region.

3.10.4.10.2 Global Access Bridge

The global access bridge arbitrates accesses in a round-robin priority. Data access to RAM is accessible from all CPUs, with 9 CPU ports on the RAM controller (two data read ports and one data write port for each CPU). Data accesses are optimized for two CPUs, connected to the MEMSS memory controller directly. Accesses from the remaining CPUs are arbitrated and merged into a generic CPU port with two data read and one data write port. These ports are connected to only one CPU at any given point in time. Figure 3-23 depicts how the LDAn memories are optimized for zero wait states by connecting CPU1 and CPU2 to the direct access port and CPU3 to the global bridge.

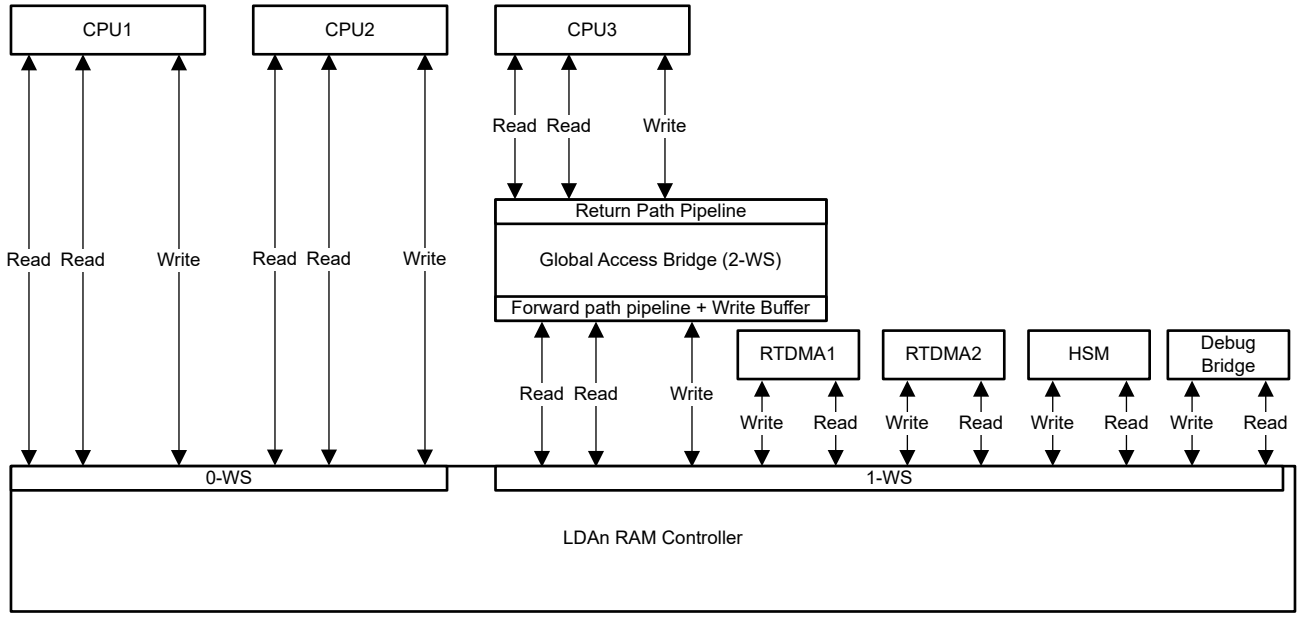

Figure 3-23. Global Access Bridge for LDAn RAMs

At any given time, accesses from one CPU are routed to the other side of the bridge. This global access bridge has only one set of output ports; hence, two different CPUs from bridge cannot access two memory instances concurrently. When a specific CPU is granted access, all active accesses from that CPU are placed into memory simultaneously, helping to support the throughput as shown in Figure 3-24.

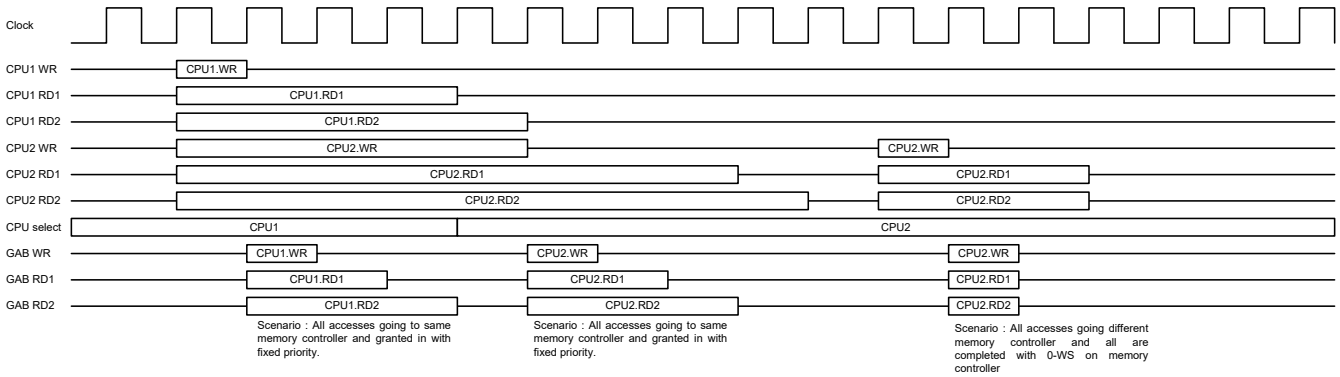

Figure 3-24. Global Access Bridge Arbitration

The global access bridges available to each RAM are shown by Figure 3-13. The global access bridges support atomic operations and posted write with the write buffer. The posted write support is common for all CPUs.

3.10.4.10.3 Program Access Bridge

Figure 3-25 shows the program access bridge, which bridges the 128-bit bus of the CPU and the 64-bit bus of the LDx and CDx memories. The program access bridge is only active when the program access is issued to LDx and CDx memories. The bridge issues two 64-bit accesses in place of one 128-bit access from the CPU. Data is then locally buffered to accumulate 128-bits before returning to the CPU.

Program accesses to LPx and CPx memories bypass the program bridge and are transparent. If the address falls on the second half of the 128-bit word only one access is issued, with the lower 64 bits of the data word ignored by the CPU.

Note

Prefetch access is not supported for M0 RAM from any CPU.

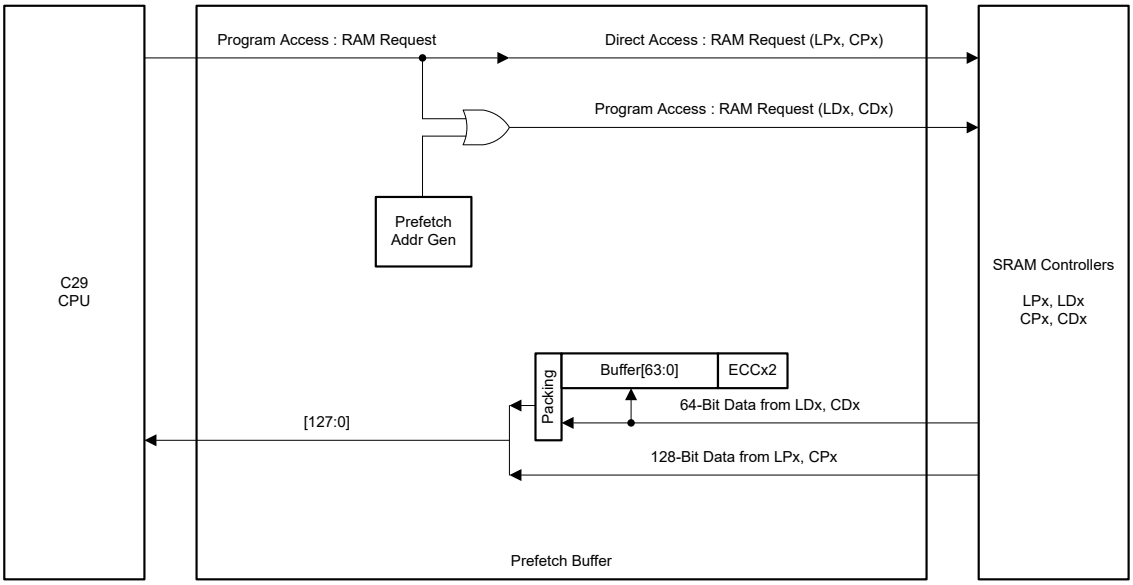

Figure 3-25. Program Access Bridge

3.10.5 ROM

This section details the architecture and configuration of the MEMSS for ROM. Each CPU has dedicated ROM. Program and data accesses are supported and are one wait state. Multiple ROM banks are interleaved to form 256-bit words. ECC is implemented with a 64-bit granularity, which is the same as Flash. A prefetch buffer compensates for the one wait state latency. There is a local 256-bit dataline buffer that holds the last data read from ROM.

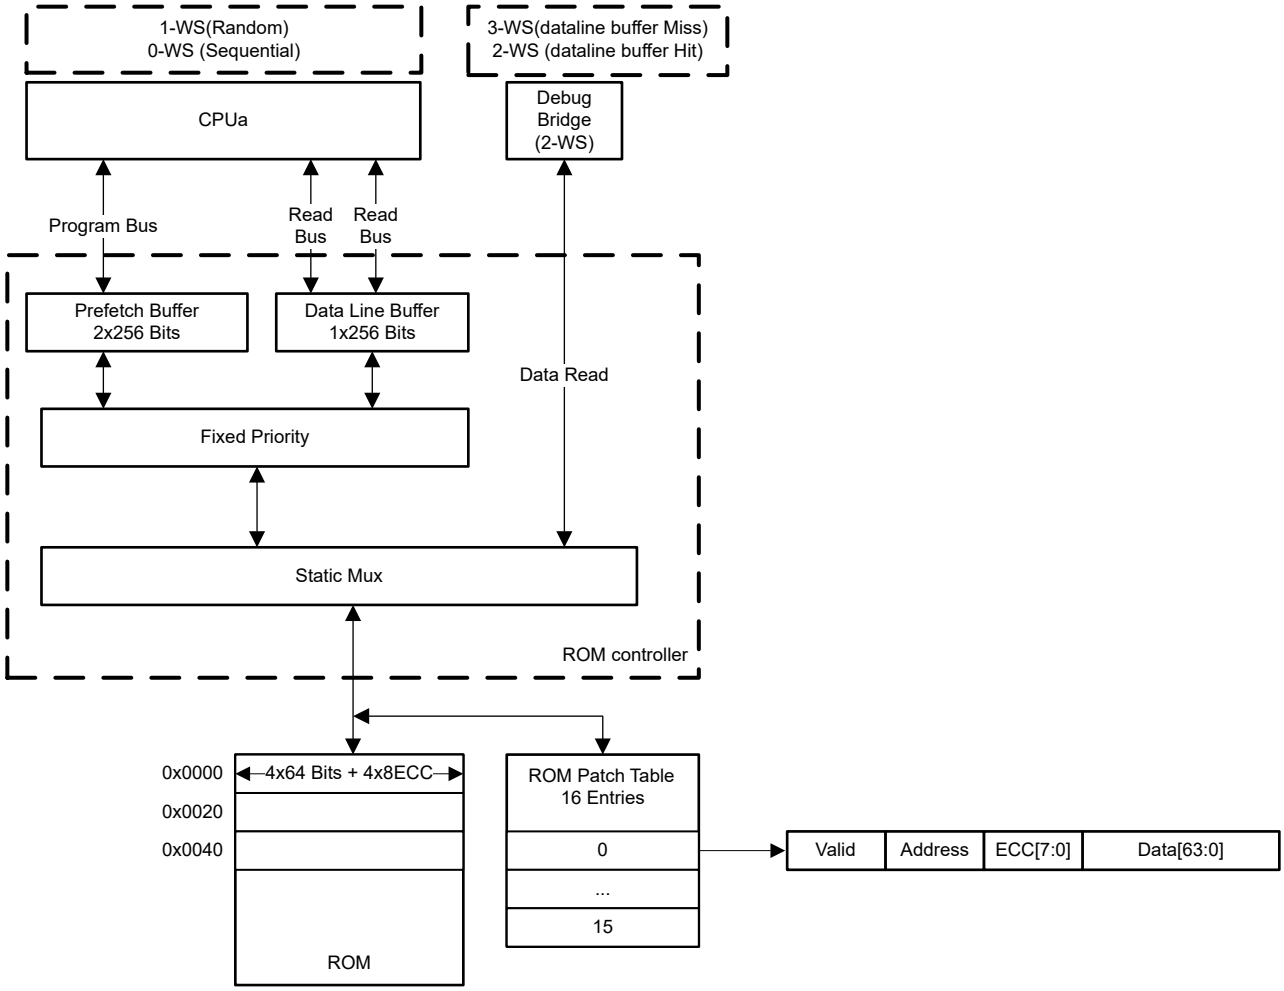

Figure 3-26. ROM Controller

The following is the round-robin priority order:

1. CPUa Access
2. Debug Access

3.10.5.1 ROM Dataline Buffer

The ROM memory controller has a 256-bit dataline buffer. The latest CPU data access from ROM is stored in the dataline buffer. ECC bits are stored with data. Program accesses from the CPU do not affect the dataline buffer. During a simultaneous data read access from bus 1 and bus 2, if the address of the accesses is within the 256-bit aligned address then only one access is issued to ROM. The second access is served from the same data. Debug read access is not buffered in the dataline buffer.

The dataline buffer is flushed when the CPU enters a fault state. The test mode does not affect the dataline buffer operation since ROM is read-only. Depending on the test mode setting, either data or ECC bits are returned.

3.10.5.2 ROM Prefetch

Upon the first program access, data is fetched from memory and presented to the CPU. On every access to ROM, 256 bits are fetched from the address that is aligned to the 256-bit boundary. The prefetch buffer can store up to two 256-bit words and stores both ECC and data. The ROM memory controller prefetches data from the next sequential 256-bit boundary-aligned address as long as there is an empty slot in the prefetch buffer. This is known as a prefetch access. Prefetch and program accesses are lower priority than data accesses as shown in Arbitration section.

This process does not start until ROM receives the first program access. After reset, the prefetch logic is idle until a program access with a discontinuity is received. This discontinuity is indicated by the CPU.

The prefetch buffer is flushed whenever a CPU program access with a discontinuity anywhere on the memory map occurs, not just when ROM is accessed.

3.10.6 Arbitration

The MEMSS uses a three-level arbitration scheme. The first level of arbitration is the fixed priority arbiter, which arbitrates accesses originating from within the same initiator. The following is the priority for the CPU accesses:

1. Write
2. Read Bus 1
3. Read Bus 2
4. Program Access (applies to ROM)
5. Prefetch Access (generated locally and applies to ROM)

Initiators other than the CPU have only one read and one write bus, arbitrated with the following priority:

1. Write
2. Read Bus

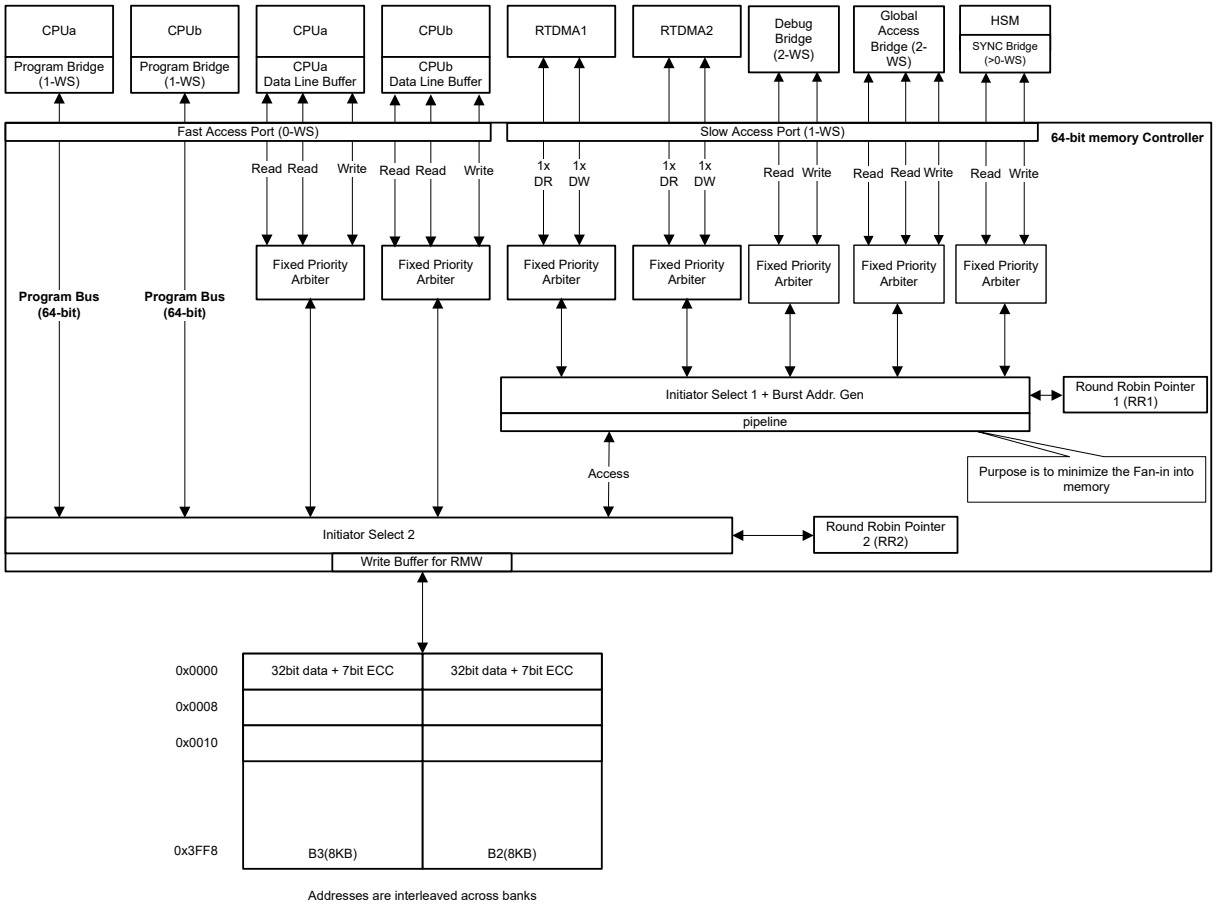

Figure 3-27. Three-Level Arbitration Scheme

The second and third level of arbitration controls the initiator selects. Initiator select 1 and 2 are controlled by independent round-robin pointers RR1 and RR2 respectively. RR1 arbitrates accesses connected to slow access ports. When access is granted by RR1, the access is pipelined and then passes to initiator select 2. Next, RR2 arbitrates accesses from initiator select 1 and fast access ports.

The following tables help to illustrate the round-robin arbitration using 64-bit memory controller as an example and same applies to 128-bit memory controller.

Table 3-9. Example 1

Cycle	CPUa	RTDMA1	RTDMA2	Round-Robin Pointer 2	Round-Robin Pointer 1	Access Granted at Initiator Select 1	Memory Access
1	CPUa Read Access 1	RTDMA1 Read Access 1	RTDMA2 Read Access 1	CPUa	RTDMA1		CPUa Read Access 1
2	CPUa Read Access 2	RTDMA1 Read Access 1	RTDMA2 Read Access 1	CPUa	RTDMA1	RTDMA1 Read Access 1	CPUa Read Access 2
3		RTDMA1 Read Access 1	RTDMA2 Read Access 1	Initiator Select 1	RTDMA1	RTDMA1 Read Access 1	RTDMA1 Read Access1
4			RTDMA2 Read Access 1	Initiator Select 1	RTDMA2		
5			RTDMA2 Read Access 1	Initiator Select 1	RTDMA2	RTDMA2 Read Access 1	RTDMA2 Read Access1

Table 3-9. Example 1 (continued)

Cycle	CPUa	RTDMA1	RTDMA2	Round-Robin Pointer 2	Round-Robin Pointer 1	Access Granted at Initiator Select 1	Memory Access
6				Initiator Select 1	RTDMA2		
7	CPUa Read Access 3			Initiator Select 1	RTDMA2		
8	CPUa Read Access 3			CPUa	RTDMA2		CPUa Read Access 3
9				CPUa	RTDMA2		

Table 3-10. Example 2

Cycle	CPUa	RTDMA1	RTDMA2	Round-Robin Pointer 2	Round-Robin Pointer 1	Access Granted at Initiator Select 1	Memory Access
1	CPUa Read Access 1	RTDMA1 Read Access 1	RTDMA2 Read Access 1	CPUa	RTDMA1		CPUa Read Access 1
2	CPUa Read Access 2	RTDMA1 Read Access 1	RTDMA2 Read Access 1	CPUa	RTDMA1	RTDMA1 Read Access 1	CPUa Read Access 2
3	CPUa Read Access 3	RTDMA1 Read Access 1	RTDMA2 Read Access 1	Initiator Select 1	RTDMA1	RTDMA1 Read Access 1	RTDMA1 Read Access 1
4	CPUa Read Access 3		RTDMA2 Read Access 1	CPUa	RTDMA2		CPUa Read Access 3
5	CPUa Read Access 4		RTDMA2 Read Access 1	CPUa	RTDMA2	RTDMA2 Read Access 1	CPUa Read Access 4
6			RTDMA2 Read Access 1	Initiator Select 1	RTDMA2		RTDMA2 Read Access 1
7				Initiator Select 1	RTDMA2		
8				Initiator Select 1	RTDMA2		
9				Initiator Select 1	RTDMA2		

The default initiator selects at reset is set such that the primary CPU has access to the memory (that is, the primary CPU has access to LPx, LDx, CDx, CPx, and M0 by default).

The round-robin pointer is changed when triggered by a pending request from an initiator other than the one currently granted access. The pointer is changed to the next initiator with priority, which takes 1 cycle. This occurs for each round-robin pointer, with greater weight given to initiators coming from fast access ports.

This two-level arbitration scheme makes sure that no initiator is stalled forever except for atomic and burst operations. Back-to-back accesses or multiple simultaneous accesses from an initiator does not block the other initiator from getting granted access. Essentially, when the round-robin pointer is set to an initiator, a pending request from any other initiator forces the round-robin pointer to switch, so there is fair arbitration without blocking an initiator.

For example, if CPUa and CPUb are initiating back-to-back read accesses the round-robin pointer switches between CPUa and CPUb every cycle so accesses from CPUa and CPUb are served alternatively one after the other.

Another example is if CPUa initiates four possible accesses (program read, data read 1, data read 2, and data write) and the RTDMA is initiating back-to-back read accesses at the same time. If the current pointer is set to CPUa, only the CPUa data write access gets granted before the pointer is switched to RTDMA to serve the read request. The pointer is then switched back to service CPUa program read, and at this time both the new RTDMA request as well as the CPUa data read 1 and 2 are pending. The pointer is switched back to CPUa to serve the data read 1 access and then CPUa data read 2 access.

3.10.7 Test Modes

Test modes can be used for implementing diagnostics tests on memory controllers. These modes enable error injection in data and ECC. The memory controller supports three modes of operation:

- Mode 0: Normal mode of operation
- Mode 1: Write to memory does not update the ECC, only data bits are updated (reading the ECC check is disabled)
- Mode 2: Reading an address returns ECC bits of the data at that address. Writing updates the ECC bits, while the data bits remain unchanged (reading the ECC check is disabled)

In mode 2, only 32-bit reads are supported. The ECC bits appear in byte 0 position of the read data.

The following is an example sequence to inject faults into RAM to implement diagnostics tests:

1. Write data to an address in mode 0 (both data and ECC get written to memory)
2. To induce errors on the data, set the mode to 1; to induce errors on ECC, set the mode to 2
3. Set the mode back to 0
4. Read the same address, with handling available if there is an error

ECC checks are performed in the CPU. CPU has built-in self-test controller and fault emulation to implement diagnostics. The MEMSS test mode is to implement diagnostic tests on ECC logic used for read-modify-write operations local to the memory controller.

Note

Test mode is not a global setting. Each memory controller has a separate TESTMODE control.

The test mode can be enabled by CPU1 code running from LINK0, LINK1, and LINK2. RAM test mode takes effect only for CPU1 accesses. Accesses from other initiators are serviced in the normal mode of operation, irrespective of the RAM test mode setting. Implementing ECC diagnostics for read-modify-write from CPU1 is sufficient since ECC checking logic is common for all initiators. A software handshake can be implemented in case RAM diagnostics are run on shared memory addresses.

Note

The dataline buffer is recommended to be disabled when using test modes to avoid RAM test data from getting buffered.

Real-time interrupts can still be enabled during diagnostics. In this scenario, an atomic sequence can be used to make sure the real-time interrupt is taken only after the dataline buffer is enabled and RAM is configured to mode 0.

3.10.8 Emulation Mode

Safe interconnect checks are disabled for debug accesses. Debug accesses that are less than 32 bits cause a read-modify-write operation. Any errors during this operation do not trigger an NMI, so as to avoid an NMIWD timeout while the CPU is halted. A status is set in the debug controller for CCS to read. An arbitration lock to a CPU is released if that CPU is halted. The RTDMA completes the burst if enabled before being halted.

Debug accesses are tracked as part of the dataline buffer and the buffer is flushed during debug writes.

3.11 System Control Register Configuration Restrictions

Memory-mapped registers in System Control operate on INTOSC1 clock domain, hence any CPU writes to these registers requires delay in between subsequent writes otherwise second write can be lost. The application needs to take this into consideration and check the **SYNCBUSY** and **SYNCBUSYWD** status registers after every write to the registers that are mentioned in Table 3-11.

3.12.8 SYSCTL Examples

NOTE: These examples are located in the C29SDK installation from ti.com at the following location: mcu_sdk_DEVICE_GPN/examples/driverlib/CORE_IF_MULTICORE/sysctl

Cloud access to these examples is available at the following link: dev.ti.com C29SDK Examples.

3.12.8.1 Missing clock detection (MCD) - SINGLE_CORE

FILE: sysctl_ex1_missing_clock_detection.c

This example demonstrates the missing clock detection functionality and the way to handle it. Once the MCD is simulated by disconnecting the OSCCLK to the MCD module an NMI would be generated. This NMI determines that an MCD was generated due to a clock failure which is handled in the ISR.

Before an MCD the clock frequency would be as per device initialization (200Mhz). Post MCD the frequency would move to 10Mhz or INTOSC1.

The example also shows how we can lock the PLL after missing clock, detection, by first explicitly switching the clock source to INTOSC1, resetting the missing clock detect circuit and then re-locking the PLL. Post a re-lock the clock frequency would be 200Mhz but using the INTOSC1 as clock source.

External Connections

- None.

Watch Variables

- *fail* - Indicates that a missing clock was either not detected or was not handled correctly.
- *mcd_clkfail_isr* - Indicates that the missing clock failure caused an NMI to be triggered and called an the ISR to handle it.
- *mcd_detect* - Indicates that a missing clock was detected.
- *result* - Status of a successful handling of missing clock detection

3.12.8.2 XCLKOUT (External Clock Output) Configuration - SINGLE_CORE

FILE: sysctl_ex2_xclkout.c

This example demonstrates how to configure the XCLKOUT pin for observing internal clocks through an external pin, for debugging and testing purposes.

In this example, we are using INTOSC1 as the XCLKOUT clock source and configuring the divider as 8. Expected frequency of XCLKOUT = (INTOSC1 freq)/8 = 10/8 = 1.25MHz

View the XCLKOUT on GPIO73 using an oscilloscope.

3.12.9 TIMER Examples

NOTE: These examples are located in the C29SDK installation from ti.com at the following location: mcu_sdk_DEVICE_GPN/examples/driverlib/CORE_IF_MULTICORE/timer

Cloud access to these examples is available at the following link: dev.ti.com C29SDK Examples.

3.12.9.1 Timer Academy Lab - SINGLE_CORE

FILE: timer_academy_lab.c

This example demonstrates how to use a CPU Timer to blink two LEDs. The timer and the LED GPIOs are each configured wthin the SysConfig file. The LED GPIO pins are toggled in the CPU Timer interrupt service routine. A global variable is incremented at the end of each timer interrupt.

External Connections

- None.

Watch Variables

- *cpuTimer0IntCount* - CPU Timer interrupt counts.

3.12.9.2 CPU Timers - SINGLE_CORE

FILE: timer_ex1_cputimers.c

This example configures CPU Timer0, 1, and 2 and increments a counter each time the timer asserts an interrupt.

External Connections

- None

Watch Variables

- cpuTimer0IntCount
- cpuTimer1IntCount
- cpuTimer2IntCount

3.12.9.3 CPU Timers - SINGLE_CORE

FILE: timer_ex2_cputimers_syscfg.c

This example configures CPU Timer0, 1, and 2 and increments a counter each time the timer asserts an interrupt.

The interrupt priorities are configured as follows :
- RTINT Threshold = 15
- Timer 0 Interrupt priority = 10 -> RTINT
- Timer 1 Interrupt priority = 20 -> INT
- Timer 2 Interrupt priority = 30 -> INT

Sysconfig inserts the required attributes to the ISR functions to inform the compiler that the function is an interrupt / realtime interrupt.

External Connections
- None

Watch Variables
- cpuTimer0IntCount
- cpuTimer1IntCount
- cpuTimer2IntCount

3.12.10 WATCHDOG Examples

NOTE: These examples are located in the C29SDK installation from ti.com at the following location: mcu_sdk_DEVICE_GPN/examples/driverlib/CORE_IF_MULTICORE/watchdog

Cloud access to these examples is available at the following link: dev.ti.com C29SDK Examples.

3.12.10.1 Watchdog - SINGLE_CORE

FILE: watchdog_ex1_service.c

This example shows how to service the watchdog or generate a watchdog interrupt using the watchdog. By default the example will generate a watchdog interrupt. To service the watchdog and not generate the interrupt, uncomment the SysCtl_serviceWatchdog() line in the main for loop.

External Connections
- None.

Watch Variables
- ISRCount - The number of times entered into the watchdog ISR
- loopCount - The number of loops performed while not in ISR

3.12.11 LPM Examples

NOTE: These examples are located in the C29SDK installation from ti.com at the following location: mcu_sdk_DEVICE_GPN/examples/driverlib/CORE_IF_MULTICORE/lpm

Cloud access to these examples is available at the following link: dev.ti.com C29SDK Examples.

3.12.11.1 Low Power Modes: Device Idle Mode and Wakeup using GPIO - SINGLE_CORE

FILE: lpm_ex1_idlewake_gpio.c

This example puts the device into IDLE mode and then wakes up the device from IDLE using XINT1 which triggers on a falling edge of GPIO0.

The GPIO0 pin must be pulled from high to low by an external agent for wakeup. GPIO0 is configured as an XINT1 pin to trigger an XINT1 interrupt upon detection of a falling edge.

Initially, pull GPIO0 high externally. To wake device from IDLE mode by triggering an XINT1 interrupt, pull GPIO0 low (falling edge). The wakeup process begins as soon as GPIO0 is held low for the time indicated in the device datasheet.

GPIO1 is pulled high before entering the IDLE mode and is pulled low when in the external interrupt ISR.

External Connections

- GPIO0 needs to be pulled low to wake up the device.
- On device wakeup, the GPIO1 will be low and LED1 will start blinking

3.12.11.2 Low Power Modes: Device Idle Mode and Wakeup using Watchdog - SINGLE_CORE

FILE: lpm_ex2_idlewake_watchdog.c

This example puts the device into IDLE mode and then wakes up the device from IDLE using watchdog timer.

The device wakes up from the IDLE mode when the watchdog timer overflows, triggering an interrupt. A pre scalar is set for the watchdog timer to change the counter overflow time.

GPIO1 is pulled high before entering the IDLE mode and is pulled low when in the wakeup ISR.

External Connections

- On device wakeup, the GPIO1 will be low and LED1 will start blinking

3.12.11.3 Low Power Modes: Device Standby Mode and Wakeup using GPIO - SINGLE_CORE

FILE: lpm_ex3_standbywake_gpio.c

This example puts the device into STANDBY mode. If the lowest possible current consumption in STANDBY mode is desired, the JTAG connector must be removed from the device board while the device is in STANDBY mode.

This example puts the device into STANDBY mode and then wakes up the device from STANDBY using an LPM wakeup pin.

The pin GPIO0 is configured as the LPM wakeup pin to trigger a WAKEINT interrupt upon detection of a low pulse. Initially, pull GPIO0 high externally. To wake device from STANDBY mode, pull GPIO0 low for at least (2+QUALSTDBY), OSCLKS, then pull it high again.

The example then wakes up the device from STANDBY using GPIO0. GPIO0 wakes the device from STANDBY mode when a low pulse (signal goes high->low->high)is detected on the pin. This pin must be pulsed by an external agent for wakeup.

GPIO1 is pulled high before entering the STANDBY mode and is pulled low when in the wakeup ISR.

External Connections

- GPIO0 needs to be pulled low to wake up the device.
- On device wakeup, the GPIO1 will be low and LED1 will start blinking

3.12.11.4 Low Power Modes: Device Standby Mode and Wakeup using Watchdog - SINGLE_CORE

FILE: lpm_ex4_standbywake_watchdog.c

This example puts the device into STANDBY mode. If the lowest possible current consumption in STANDBY mode is desired, the JTAG connector must be removed from the device board while the device is in STANDBY mode.

This example puts the device into STANDBY mode then wakes up the device from STANDBY using watchdog timer.

The device wakes up from the STANDBY mode when the watchdog timer overflows triggering an interrupt. In the ISR, the GPIO1 is pulled low. the GPIO1 is toggled to indicate the device is out of STANDBY mode. A pre scalar is set for the watchdog timer to change the counter overflow time.

GPIO1 is pulled high before entering the STANDBY mode and is pulled low when in the wakeup ISR.

External Connections

- On device wakeup, the GPIO1 will be low and LED1 will start blinking

3.13 SYSCTRL Registers

This Section describes the SYSCTRL Registers.

3.13.1 SYSCTRL Base Address Table

Table 3-19. SYSCTRL Base Address Table

Structure	DriverLib Name	Base Address	Frame Applicable	CPU1	CPU2	CPU3	RTDMA1	RTDMA2	HSM	Pipeline Protected

(1) Registers writeable by CPU1.LINK0, CPU1.LINK1, CPU1.LINK2 only. All CPUs can read all registers in all LINKs. Debug write access only allowed if Zone0 or Zone1 are enabled for full debug by all CPUs. Debug reads always allowed. Register Read/Write access by HSM.

3.13.2 DEV_CFG_REGS Registers

Table 3-20 lists the memory-mapped registers for the DEV_CFG_REGS registers. All register offset addresses not listed in Table 3-20 should be considered as reserved locations and the register contents should not be modified.

Table 3-20. DEV_CFG_REGS Registers

Offset	Acronym	Register Name	Protection

Complex bit access types are encoded to fit into small table cells. Table 3-21 shows the codes that are used for access types in this section.

Table 3-21. DEV_CFG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
WOnce	W Once	Write Write once
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.13.2.1 DEVCFGLOCK1 Register (Offset = 0h) [Reset = 00000000h]

DEVCFGLOCK1 is shown in Figure 3-28 and described in Table 3-22.

Return to the Summary Table.

Lock bit for CPUSELx registers
The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed
Note:
Any SOnce bit in this register, once set can only be cleared through a CPU1.SYSRSn. Write of 0 to any bit of this register has no effect

3.13.2.2 DEVCFGLOCK2 Register (Offset = 4h) [Reset = 00000000h]

DEVCFGLOCK2 is shown in Figure 3-29 and described in Table 3-23.

Return to the Summary Table.

Lock bit for DEVCFG registers
Note:
[1] The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed
[2] Any SOnce bit in this register, once set can only be cleared through a CPU1.SYSRSn. Write of 0 to any bit of this register has no effect

Table 3-57. SICCONFIG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	TIMEOUT	R/W	FFFFh	Safety Interconnect (SIC) READY TIMEOUT value, in terms of number of clock cycles. This is a 16-bit value common across multiple CPU, DMA or any other initiator on the inyterconnect. This value controls the input to the C29 CPU/SIC to detect bus-hang condition. Due to a fault, if ready is pulled low by the endpoint longer than number of clock cycles programmed in this register, then timeout logic inside SIC will generate abort access to endpoint and aborts the ongoing access on bus, communicates as error on the error interface bus. Reset type: XRSn
15-1	RESERVED	R-0	0h	Reserved
0	Enable	R/W	0h	Safety Interconnect (SIC) Enable Reset type: XRSn

3.13.2.66 CLKSRCCTL1 Register (Offset = 530h) [Reset = 00000000h]

CLKSRCCTL1 is shown in Figure 3-93 and described in Table 3-87.

Return to the Summary Table.

Clock Source Control register-1
This memory mapped register requires a delay of 69 SYSCLK cycles between subsequent writes to the register, otherwise a second write can be lost. This delay can be realized by adding 69 NOP instructions.

Table 3-87. CLKSRCCTL1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1-0	OSCCLKSRCSEL	R/W	0h	Oscillator Clock Source Select Bit: This bit selects the source for OSCCLK. 00 = INTOSC2 (default on reset) 01 = External Oscillator (XTAL) 10 = INTOSC1 11 = reserved (default to INTOSC1) At power-up or after an XRSn, INTOSC2 is selected by default. Whenever the user changes the clock source using these bits, the SYSPLLMULT[13:0] register will be forced to zero and the PLL will be bypassed and powered down. This prevents potential PLL overshoot. The user will then have to write to the SYSPLLMULT register to configure the appropriate multiplier. The user must wait 10 OSCCLK cycles before writing to SYSPLLMULT or disabling the previous clock source to allow the change to complete.. Notes: [1] INTOSC1 is recommended to be used only after missing clock detection. If user wants to re-lock the PLL with INTOSC1 (the back-up clock source) after missing clock is detected, he can do a MCLKCLR and lock the PLL. Reset type: XRSn

3.13.2.67 CLKSRCCTL2 Register (Offset = 534h) [Reset = 00000000h]

CLKSRCCTL2 is shown in Figure 3-94 and described in Table 3-88.

Return to the Summary Table.

Clock Source Control register-2
This memory mapped register requires a delay of 69 SYSCLK cycles between subsequent writes to the register, otherwise a second write can be lost. This delay can be realized by adding 69 NOP instructions.

Bit	Field	Type	Reset	Description
31-17	RESERVED	R-0	0h	Reserved
16	CLR	R-0/W1C	0h	X1 Counter clear: A write of '1' to this bit field clears the X1CNT and makes it count from 0x0 again (provided X1 clock is ticking). Writes of '0' are ignore to this bit field Reset type: XRSn
15-11	RESERVED	R-0	0h	Reserved
10-0	X1CNT	R	0h	X1 Counter: - This counter increments on every X1 CLOCKs positive-edge. - Once it reaches the values of 0x7ff, it freezes - Before switching from INTOSC2 to X1, application must check this counter and make sure that it has saturated. This will ensure that the Crystal connected to X1/X2 is oscillating. Reset type: XRSn

3.13.2.80 XTALCR Register (Offset = 58Ch) [Reset = 00000001h]

XTALCR is shown in Figure 3-107 and described in Table 3-101.

Return to the Summary Table.

XTAL Control Register
This memory mapped register requires a delay of 69 SYSCLK cycles between subsequent writes to the register, otherwise a second write can be lost. This delay can be realized by adding 69 NOP instructions.

Table 3-233. PARITY_TEST Register Field Descriptions

Bit	Field	Type	Reset	Description
31-4	RESERVED	R	0h	Reserved
3-0	TESTEN	R/W	0h	1010: Parity test feature is enabled All other values: Parity test feature is disabled Note: (1) When the parity test feature is enabled, actual registers are not accessible in the memory map. Instead, the parity values (final XOR output indicating the parity error) are accessible. Parity is computed for every byte and the corresponding parity error value is available at the bit-0 of every byte. Value of '1' written to the parity bit after enabling the parity test feature can be used to inject the error by inverting the stored parity value. (2) It is recommended to leave the field as 0101 or 0000 after completing the parity test. Reset type: SYSRSn

3.13.3 MEMSS_L_CONFIG_REGS Registers

Table 3-234 lists the memory-mapped registers for the MEMSS_L_CONFIG_REGS registers. All register offset addresses not listed in Table 3-234 should be considered as reserved locations and the register contents should not be modified.

Table 3-234. MEMSS_L_CONFIG_REGS Registers

Offset	Acronym	Register Name	Protection
0h	LPA0_MEM_CONFIG	LPA0 Memory Configuration Register	PARITY
4h	LPA0_MEM_CONFIG_LOCK	Temporary Lock for LPA0 Memory Configuration Register	PARITY

Complex bit access types are encoded to fit into small table cells. Table 3-267 shows the codes that are used for access types in this section.

Table 3-267. MEMSS_C_CONFIG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value

3.13.4.1 CPA0_MEM_CONFIG Register (Offset = 0h) [Reset = 00000000h]

CPA0_MEM_CONFIG is shown in Figure 3-270 and described in Table 3-268.

Return to the Summary Table.

3.13.5 MEMSS_M_CONFIG_REGS Registers

Table 3-310 lists the memory-mapped registers for the MEMSS_M_CONFIG_REGS registers. All register offset addresses not listed in Table 3-310 should be considered as reserved locations and the register contents should not be modified.

Table 3-310. MEMSS_M_CONFIG_REGS Registers

Offset	Acronym	Register Name	Protection
0h	M0_MEM_CONFIG	M0 Memory Configuration Register	PARITY
4h	M0_MEM_CONFIG_LOCK	Temporary Lock for M0 Memory Configuration Register	PARITY
8h	M0_MEM_CONFIG_COMMIT	Permament Lock for M0 Memory Configuration Register	PARITY

Complex bit access types are encoded to fit into small table cells. Table 3-311 shows the codes that are used for access types in this section.

Table 3-311. MEMSS_M_CONFIG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value

3.13.5.1 M0_MEM_CONFIG Register (Offset = 0h) [Reset = 00000000h]

M0_MEM_CONFIG is shown in Figure 3-312 and described in Table 3-312.

Return to the Summary Table.

0	M0_MEM_CONFIG_LOCK	WSonce	0h	When set, locks the M0_MEM_CONFIG_LOCK register. This bit cannot be cleared, except by reset. 0 : M0_MEM_CONFIG is modifiable 1 : M0_MEM_CONFIG is committed permanently Reset type: CPU1.SYSRSn

3.13.6 MEMSS_MISCI_REGS Registers

Table 3-315 lists the memory-mapped registers for the MEMSS_MISCI_REGS registers. All register offset addresses not listed in Table 3-315 should be considered as reserved locations and the register contents should not be modified.

Table 3-315. MEMSS_MISCI_REGS Registers

Offset	Acronym	Register Name	Protection
0h	MEM_DLB_CONFIG	Dataline buffer enable	PARITY
4h	MEM_DLB_CONFIG_LOCK	Temporary Lock for DLB Configuration Register	PARITY
8h	MEM_DLB_CONFIG_COMMIT	Permament Lock for DLB Configuration Register	PARITY
10h	PERI_MEM_TEST_LOCK	Peripheral Memory Test Lock Register	PARITY
14h	PERI_MEM_TEST_CONTROL	Peripheral Memory Test control Register	PARITY
1FCh	PARITY_TEST	Enabling the parity test feature	

Complex bit access types are encoded to fit into small table cells. Table 3-316 shows the codes that are used for access types in this section.

Table 3-316. MEMSS_MISCI_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.13.6.1 MEM_DLB_CONFIG Register (Offset = 0h) [Reset = 0000007Fh]

MEM_DLB_CONFIG is shown in Figure 3-315 and described in Table 3-317.

Return to the Summary Table.

Table 3-322. PARITY_TEST Register Field Descriptions

Bit	Field	Type	Reset	Description
31-4	RESERVED	R	0h	Reserved
3-0	TESTEN	R/W	0h	1010: Parity test feature is enabled All other values: Parity test feature is disabled Note: (1) When the parity test feature is enabled, acutal registers are not accessible in the memory map. Instead, the parity values (final XOR output indicating the parity error) are accessible. Parity is computed for every byte and the correponding parity error value is available at the bit-0 of every byte. Value of '1' written to the parity bit after enabling the parity test feature can be used to inject the error by inverting the stored parity value. (2) It is recommended to leave the field as 0101 or 0000 after completing the parity test. Reset type: CPU1.SYSRSn

3.13.7 CPU_SYS_REGS Registers

Table 3-323 lists the memory-mapped registers for the CPU_SYS_REGS registers. All register offset addresses not listed in Table 3-323 should be considered as reserved locations and the register contents should not be modified.

Table 3-323. CPU_SYS_REGS Registers

Offset	Acronym	Register Name	Protection
0h	CPUSYSLOCK1	Lock bit for CPUSYS registers	PARITY
Ch	CPUID	Indicates CPU1, CPU2.. CPU6	PARITY
28h	LPMCR	LPM Control Register	PARITY
2Ch	CMPSSLPMSEL	CMPSS LPM Wakeup select registers	PARITY
30h	GPIOLPMSEL0	GPIO LPM Wakeup select registers	PARITY
34h	GPIOLPMSEL1	GPIO LPM Wakeup select registers	PARITY
38h	TMR2CLKCTL	Timer2 Clock Measurement functionality control register	PARITY
3Ch	RESCCLR	Reset Cause Clear Register	
40h	RESC	Reset Cause register	PARITY
70h	MCANWAKESTATUS	MCAN Wake Status Register	
74h	MCANWAKESTATUSCLR	MCAN Wake Status Clear Register	
78h	CLKSTOPREQ	Peripheral Clock Stop Request Register	PARITY
7Ch	CLKSTOPACK	Peripheral Clock Stop Ackonwledge Register	
80h	USER_REG1_SYSRSn	Software Configurable registers reset by SYSRSn	PARITY

8Ch	USER_REG2_XRSn	Software Configurable registers reset by XRSn	PARITY
90h	USER_REG1_PORESETn	Software Configurable registers reset by PORESETn	PARITY
94h	USER_REG2_PORESETn	Software Configurable registers reset by PORESETn	PARITY
98h	USER_REG3_PORESETn	Software Configurable registers reset by PORESETn	PARITY
9Ch	USER_REG4_PORESETn	Software Configurable registers reset by PORESETn	PARITY
A0h	JTAG_MMR_REG	Readback of JTAG registers for test purpose	
A4h	SIMRESET	Simulated Reset Register	PARITY
A8h	PARITY_TEST_ALT2	Enables parity test	

Complex bit access types are encoded to fit into small table cells. Table 3-324 shows the codes that are used for access types in this section.

Table 3-324. CPU_SYS_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
WSonce	W Sonce	Write Set once
Reset or Default Value		

Table 3-324. CPU_SYS_REGS Access Type Codes (continued)

Access Type	Code	Description
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.13.7.1 CPUSYSLOCK1 Register (Offset = 0h) [Reset = 00000000h]

CPUSYSLOCK1 is shown in Figure 3-321 and described in Table 3-325.

Return to the Summary Table.

Lock bit for CPUSYS registers
Notes:
[1] Any bit in this register, once set can only be cleared through a CPU1.SYSRSn. Write of 0 to any bit of this register has no effect
[2] The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed

Table 3-347. SIMRESET Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	KEY	R-0/W	0h	Write to this register succeeds only if this field is written with a value of 0xa5a5 Note: [1] Due to this KEY, only 32-bit writes will succeed (provided the KEY matches). 16-bit writes to the upper or lower half of this register will be ignored Reset type: XRSn
15-2	RESERVED	R-0	0h	Reserved
1	XRSn	R-0/W1S	0h	Writing a 1 to this field generates a XRSn like reset. Writing a 0 has no effect. Note: Writing to this pin will pull the XRSn pin low for 512 INTOSC1 clock cycles. This bit is implemented only for SIMRESET copy of CPU1. For CPU2,3,4,5,6 this is a reserved bit. No effect on writes, and Read=0 Reset type: XRSn
0	RESERVED	R-0/W1S	0h	Reserved

3.13.7.24 PARITY_TEST_ALT2 Register (Offset = A8h) [Reset = 00000000h]

PARITY_TEST_ALT2 is shown in Figure 3-344 and described in Table 3-348.

Return to the Summary Table.

Enables parity test

Figure 3-344. PARITY_TEST_ALT2 Register

Table 3-348. PARITY_TEST_ALT2 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-4	RESERVED	R	0h	Reserved
3-0	TESTEN	R/W	0h	1010: Parity test feature is enabled All other values: Parity test feature is disabled Note: (1) When the parity test feature is enabled, actual registers are not accessible in the memory map. Instead, the parity values (final XOR output indicating the parity error) are accessible. Parity is computed for every byte and the corresponding parity error value is available at the bit-0 of every byte. Value of '1' written to the parity bit after enabling the parity test feature can be used to inject the error by inverting the stored parity value. (2) It is recommended to leave the field as 0101 or 0000 after completing the parity test. Reset type: SYSRSn

3.13.8 CPU_PER_CFG_REGS Registers

Table 3-349 lists the memory-mapped registers for the CPU_PER_CFG_REGS registers. All register offset addresses not listed in Table 3-349 should be considered as reserved locations and the register contents should not be modified.

Table 3-349. CPU_PER_CFG_REGS Registers

Complex bit access types are encoded to fit into small table cells. Table 3-350 shows the codes that are used for access types in this section.

Table 3-350. CPU_PER_CFG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.13.8.1 CPUPERCFGLOCK1 Register (Offset = 0h) [Reset = 00000000h]

CPUPERCFGLOCK1 is shown in Figure 3-345 and described in Table 3-351.

Return to the Summary Table.

Lock bit for CPUx_PER_CFG registers
Notes:
[1] Any bit in this register, once set can only be cleared through a CPUx.SYSRSn. Write of 0 to any bit of this register has no effect
[2] The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed

Table 3-401. PARITY_TEST_ALT1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-4	RESERVED	R	0h	Reserved
3-0	TESTEN	R/W	0h	1010: Parity test feature is enabled All other values: Parity test feature is disabled Note: (1) When the parity test feature is enabled, actual registers are not accessible in the memory map. Instead, the parity values (final XOR output indicating the parity error) are accessible. Parity is computed for every byte and the corresponding parity error value is available at the bit-0 of every byte. Value of '1' written to the parity bit after enabling the parity test feature can be used to inject the error by inverting the stored parity value. (2) It is recommended to leave the field as 0101 or 0000 after completing the parity test. Reset type: SYSRSn

3.13.9 WD_REGS Registers

Table 3-402 lists the memory-mapped registers for the WD_REGS registers. All register offset addresses not listed in Table 3-402 should be considered as reserved locations and the register contents should not be modified.

Table 3-402. WD_REGS Registers

Offset	Acronym	Register Name	Protection
44h	SCSR	System Control & Status Register	
46h	WDCNTR	Watchdog Counter Register	
4Ah	WDKEY	Watchdog Reset Key Register	
50h	SYNCBUSYWD	SYNCBUSY status for Watchdog Register	
52h	WDCR	Watchdog Control Register	
54h	WDWCR	Watchdog Windowed Control Register	

Complex bit access types are encoded to fit into small table cells. Table 3-403 shows the codes that are used for access types in this section.

Table 3-403. WD_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.13.9.1 SCSR Register (Offset = 44h) [Reset = 0005h]

SCSR is shown in Figure 3-396 and described in Table 3-404.

Return to the Summary Table.

System Control & Status Register

R-0-0h					R-1h	R/W-0h	R/W1S-1h

Table 3-404. SCSR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-3	RESERVED	R-0	0h	Reserved
2	WDINTS	R	1h	Watchdog Interrupt Status This bit indicates the state of the active-low watchdog interrupt signal (synchronized to SYSCLK). If the watchdog interrupt is used to wake the system from a low-power mode, then that mode should only be entered while this bit is high. Likewise, this bit must go high before the watchdog can be safely disabled and re-enabled. 0h = The watchdog interrupt signal is active. 1h = The watchdog interrupt signal is inactive. Reset type: SYSRSn
1	WDENINT	R/W	0h	Watchdog Interrupt Enable/Reset Disable This bit determines whether the watchdog triggers an interrupt (WAKE/WDOG) or a reset (WDRS) when the counter expires. The error event is also generated to ESM on counter expiration 0h = Counter expiration triggers a reset. This is the default state on power-up and after any system reset. 1h = Counter expiration triggers an interrupt. Reset type: SYSRSn
0	WDOVERRIDE	R/W1S	1h	Watchdog Enable Lock Writing a 1 to this bit clears it and locks the WDDIS bit in the WDCR register. The bit will remain in this state until the next system reset. Reads of this bit return its current value. Writing a 0 to this bit has no effect. Reset type: SYSRSn

3.13.9.2 WDCNTR Register (Offset = 46h) [Reset = 0000h]

WDCNTR is shown in Figure 3-397 and described in Table 3-405.

Return to the Summary Table.

Watchdog Counter Register

WDCNTR							
R-0h							

Table 3-405. WDCNTR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	RESERVED	R-0	0h	Reserved
7-0	WDCNTR	R	0h	Watchdog Counter These bits contain the current value of the watchdog counter. This counter increments with each WDCLK (INTOSC1) cycle. If the counter overflows, either an interrupt or a reset is generated based on the value of the WDINTEN bit in the SCSR register. If the correct value is written to the WDKEY register, this counter is reset to zero. Note : Reads to this register before watchdog is enabled will return unpredictable value Reset type: IORSn

3.13.9.3 WDKEY Register (Offset = 4Ah) [Reset = 0000h]

WDKEY is shown in Figure 3-398 and described in Table 3-406.

Return to the Summary Table.

Table 3-408. WDCR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-12	RESERVED	R-0	0h	Reserved
11-8	WDPRECLKDIV	R/W	0h	Watchdog Clock Pre-divider These bits determine the watchdog clock pre-divider, which is the first of the two dividers between INTOSC1 and the watchdog counter clock (WDCLK). The frequency of WDCLK is given by the formulas: PREDIVCLK = INTOSC1 / Pre-divider WDCLK = PREDIVCLK / Prescaler The watchdog reset or interrupt pulse is 512 INTOSC1 cycles long, so the counter period must be longer. To guarantee this, the product of the prescaler and pre-divider must be greater than or equal to four. The default pre-divider value is 512. Reset type: IORSn
7	RESERVED	R/W1S	0h	Reserved
6	WDDIS	R/W	0h	Watchdog Disable Setting this bit disables the watchdog module. Clearing this bit enables the watchdog module. This bit can be locked by the WDOVERRIDE bit in the SCSR register. The watchdog is enabled on reset. Reset type: IORSn
5-3	WDCHK	R-0/W	0h	Watchdog Check Bits During any write to this register, these bits must be written with the value 101 (binary). Writing any other value will immediately trigger the watchdog reset or interrupt. Reset type: IORSn
2-0	WDPS	R/W	0h	Watchdog Clock Prescaler These bits determine the watchdog clock prescaler, which is the second of the two dividers between INTOSC1 and the watchdog counter clock (WDCLK). The frequency of WDCLK is given by the formulas: PREDIVCLK = INTOSC1 / Pre-divider WDCLK = PREDIVCLK / Prescaler The watchdog reset or interrupt pulse is 512 INTOSC1 cycles long, so the counter period must be longer. To guarantee this, the product of the prescaler and pre-divider must be greater than or equal to four. The default prescaler value is 1. Reset type: IORSn

3.13.9.6 WDWCR Register (Offset = 54h) [Reset = 0000h]

WDWCR is shown in Figure 3-401 and described in Table 3-409.

Return to the Summary Table.

Table 3-409. WDWCR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-9	RESERVED	R-0	0h	Reserved
8	RESERVED	R	0h	Reserved
7-0	MIN	R/W	0h	Watchdog Window Threshold These bits specify the lower limit of the watchdog counter reset window. If the counter is reset via the WDKEY register before the counter value reaches the value in this register, the watchdog immediately triggers a reset or interrupt. Reset type: IORSn

3.13.10 CPUTIMER_REGS Registers

Table 3-410 lists the memory-mapped registers for the CPUTIMER_REGS registers. All register offset addresses not listed in Table 3-410 should be considered as reserved locations and the register contents should not be modified.

Table 3-410. CPUTIMER_REGS Registers

Offset	Acronym	Register Name	Protection
0h	TIM	CPU-Timer, Counter Register	
4h	PRD	CPU-Timer, Period Register	
8h	TCR	CPU-Timer, Control Register	
Ch	TPR	CPU-Timer, Prescale Register	
Eh	TPRH	CPU-Timer, Prescale Register High	

Complex bit access types are encoded to fit into small table cells. Table 3-411 shows the codes that are used for access types in this section.

Table 3-411. CPUTIMER_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
Reset or Default Value		
-n		Value after reset or the default value

3.13.10.1 TIM Register (Offset = 0h) [Reset = 0000FFFFh]

TIM is shown in Figure 3-402 and described in Table 3-412.

Return to the Summary Table.

CPU-Timer, Counter Register

Figure 3-402. TIM Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R/W-0h																R/W-FFFFh															

Table 3-412. TIM Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	MSW	R/W	0h	CPU-Timer Counter Registers The TIMH register holds the high 16 bits of the current 32-bit count of the timer. The TIMH:TIM decrements by one every (TDDRH:TDDR+1) clock cycles, where TDDRH:TDDR is the timer prescale dividedown value. When the TIMH:TIM decrements to zero, the TIMH:TIM register is reloaded with the period value contained in the PRDH:PRD registers. The timer interrupt (TINT) signal is generated. Reset type: SYSRSn
15-0	LSW	R/W	FFFFh	CPU-Timer Counter Registers The TIM register holds the low 16 bits of the current 32-bit count of the timer. The TIMH:TIM decrements by one every (TDDRH:TDDR+1) clock cycles, where TDDRH:TDDR is the timer prescale dividedown value. When the TIMH:TIM decrements to zero, the TIMH:TIM register is reloaded with the period value contained in the PRDH:PRD registers. The timer interrupt (TINT) signal is generated. Reset type: SYSRSn

3.13.10.2 PRD Register (Offset = 4h) [Reset = 0000FFFFh]

PRD is shown in Figure 3-403 and described in Table 3-413.

Return to the Summary Table.

CPU-Timer, Period Register

Figure 3-403. PRD Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MSW																LSW															
R/W-0h																R/W-FFFFh															

Table 3-413. PRD Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	MSW	R/W	0h	CPU-Timer Period Registers The PRDH register holds the high 16 bits of the 32-bit period. When the TIMH:TIM decrements to zero, the TIMH:TIM register is reloaded with the period value contained in the PRDH:PRD registers, at the start of the next timer input clock cycle (the output of the prescaler). The PRDH:PRD contents are also loaded into the TIMH:TIM when you set the timer reload bit (TRB) in the Timer Control Register (TCR). Reset type: SYSRSn
15-0	LSW	R/W	FFFFh	CPU-Timer Period Registers The PRD register holds the low 16 bits of the 32-bit period. When the TIMH:TIM decrements to zero, the TIMH:TIM register is reloaded with the period value contained in the PRDH:PRD registers, at the start of the next timer input clock cycle (the output of the prescaler). The PRDH:PRD contents are also loaded into the TIMH:TIM when you set the timer reload bit (TRB) in the Timer Control Register (TCR). Reset type: SYSRSn

3.13.10.3 TCR Register (Offset = 8h) [Reset = 0001h]

TCR is shown in Figure 3-404 and described in Table 3-414.

Return to the Summary Table.

CPU-Timer, Control Register

Figure 3-404. TCR Register

15	14	13	12	11	10	9	8
TIF	TIE	RESERVED		FREE	SOFT	RESERVED	
R/W1C-0h	R/W-0h	R-0h		R/W-0h	R/W-0h	R-0h	
7	**6**	**5**	**4**	**3**	**2**	**1**	**0**
RESERVED		TRB	TSS	RESERVED			
R-0h		R/W-0h	R/W-0h	R-1h			

Table 3-414. TCR Register Field Descriptions

Bit	Field	Type	Reset	Description
15	TIF	R/W1C	0h	CPU-Timer Overflow Flag. TIF indicates whether a timer overflow has happened since TIF was last cleared. TIF is not cleared automatically and does not need to be cleared to enable the next timer interrupt. Reset type: SYSRSn 0h (R/W) = The CPU-Timer has not decremented to zero. Writes of 0 are ignored. 1h (R/W) = This flag gets set when the CPU-timer decrements to zero. Writing a 1 to this bit clears the flag.
14	TIE	R/W	0h	CPU-Timer Interrupt Enable. Reset type: SYSRSn 0h (R/W) = The CPU-Timer interrupt is disabled. 1h (R/W) = The CPU-Timer interrupt is enabled. If the timer decrements to zero, and TIE is set, the timer asserts its interrupt request.
13-12	RESERVED	R	0h	Reserved
11	FREE	R/W	0h	If the FREE bit is set to 1, then, upon a software breakpoint, the timer continues to run. If FREE is 0, then the SOFT bit controls the emulation behavior. Reset type: SYSRSn 0h (R/W) = Stop after the next decrement of the TIMH:TIM (hard stop) (SOFT bit controls the emulation behavior) 1h (R/W) = Free Run (SOFT bit is don't care, counter is free running)
10	SOFT	R/W	0h	If the FREE bit is set to 1, then, upon a software breakpoint, the timer continues to run (that is, free runs). In this case, SOFT is a don't care. But if FREE is 0, then SOFT takes effect. Reset type: SYSRSn 0h (R/W) = Stop after the next decrement of the TIMH:TIM (hard stop). (ONLY if FREE=0, if FREE=1 this bit is don't care) 1h (R/W) = Stop after the TIMH:TIM decrements to 0 (soft stop) In the SOFT STOP mode, the timer generates an interrupt before shutting down (since reaching 0 is the interrupt causing condition). (ONLY if FREE=0, if FREE=1 this bit is don't care)
9-6	RESERVED	R	0h	Reserved

Table 3-414. TCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	TRB	R/W	0h	Timer reload Reset type: SYSRSn 0h (R/W) = The TRB bit is always read as zero. Writes of 0 are ignored. 1h (R/W) = When you write a 1 to TRB, the TIMH:TIM is loaded with the value in the PRDH:PRD, and the prescaler counter (PSCH:PSC) is loaded with the value in the timer dividedown register (TDDRH:TDDR).
4	TSS	R/W	0h	CPU-Timer stop status bit. TSS is a 1-bit flag that stops or starts the CPU-timer. Reset type: SYSRSn 0h (R/W) = Reads of 0 indicate the CPU-timer is running. To start or restart the CPU-timer, set TSS to 0. At reset, TSS is cleared to 0 and the CPU-timer immediately starts. 1h (R/W) = Reads of 1 indicate that the CPU-timer is stopped. To stop the CPU-timer, set TSS to 1.
3-0	RESERVED	R	1h	Reserved

3.13.10.4 TPR Register (Offset = Ch) [Reset = 0000h]

TPR is shown in Figure 3-405 and described in Table 3-415.

Return to the Summary Table.

7	6	5	4	3	2	1	0
TDDR							
R/W-0h							

Table 3-415. TPR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	PSC	R	0h	CPU-Timer Prescale Counter. These bits hold the current prescale count for the timer. For every timer clock source cycle that the PSCH:PSC value is greater than 0, the PSCH:PSC decrements by one. One timer clock (output of the timer prescaler) cycle after the PSCH:PSC reaches 0, the PSCH:PSC is loaded with the contents of the TDDRH:TDDR, and the timer counter register (TIMH:TIM) decrements by one. The PSCH:PSC is also reloaded whenever the timer reload bit (TRB) is set by software. The PSCH:PSC can be checked by reading the register, but it cannot be set directly. It must get its value from the timer divide-down register (TDDRH:TDDR). At reset, the PSCH:PSC is set to 0. Reset type: SYSRSn
7-0	TDDR	R/W	0h	CPU-Timer Divide-Down. Every (TDDRH:TDDR + 1) timer clock source cycles, the timer counter register (TIMH:TIM) decrements by one. At reset, the TDDRH:TDDR bits are cleared to 0. To increase the overall timer count by an integer factor, write this factor minus one to the TDDRH:TDDR bits. When the prescaler counter (PSCH:PSC) value is 0, one timer clock source cycle later, the contents of the TDDRH:TDDR reload the PSCH:PSC, and the TIMH:TIM decrements by one. TDDRH:TDDR also reloads the PSCH:PSC whenever the timer reload bit (TRB) is set by software. Reset type: SYSRSn

3.13.10.5 TPRH Register (Offset = Eh) [Reset = 0000h]

TPRH is shown in Figure 3-406 and described in Table 3-416.

3.13.11 XINT_REGS Registers

Table 3-417 lists the memory-mapped registers for the XINT_REGS registers. All register offset addresses not listed in Table 3-417 should be considered as reserved locations and the register contents should not be modified.

Table 3-417. XINT_REGS Registers

Offset	Acronym	Register Name	Protection
0h	XINT1CR	XINT1 configuration register	
2h	XINT2CR	XINT2 configuration register	
4h	XINT3CR	XINT3 configuration register	
6h	XINT4CR	XINT4 configuration register	
8h	XINT5CR	XINT5 configuration register	
10h	XINT1CTR	XINT1 counter register	
12h	XINT2CTR	XINT2 counter register	
14h	XINT3CTR	XINT3 counter register	

Complex bit access types are encoded to fit into small table cells. Table 3-418 shows the codes that are used for access types in this section.

Table 3-418. XINT_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

3.13.11.1 XINT1CR Register (Offset = 0h) [Reset = 0000h]

XINT1CR is shown in Figure 3-407 and described in Table 3-419.

Return to the Summary Table.

Chapter 4

ROM Code and Peripheral Booting

This chapter explains the boot procedure, the available boot modes, and the various details of the ROM code including memory maps, initializations, reset handling, and status information.

4.1 Introduction

The purpose of this chapter is to explain the boot read-only memory (ROM) code functionality for the C29x CPU core's, including the boot procedure. This chapter also discusses the functions and features of the boot ROM code, and provides details about the ROM memory-map contents. On every reset, the device executes a boot sequence in the ROM depending on the reset type and boot configuration. This sequence initializes the device to run the application code. For the CPU, the boot ROM also contains peripheral bootloaders that can be used to load an application into RAM. These bootloaders can be disabled for safety or security purposes.

See Table 4-1 for details on available boot features for the C29x CPU. Additionally, Table 4-2 shows the sizes of the various ROMs on the device.

Various tables are provided in ROM for use in software library, refer to Section 4.7.5 for more details.

Table 4-1. Boot System Overview

Boot Feature	CPU
Initial boot process	Device reset
Boot mode selection	GPIOs
Boot modes supported	Flash boot RAM boot Wait boot Parallel IO CAN CAN-FD I2C SPI UART

Table 4-2. ROM Memory

ROM	Size
CPU1 boot ROM	128KB
CPU2 boot ROM	32KB
CPU3 boot ROM	32KB

CPU2 and CPU3 doesn't have any BootROM code and just contains default NMI handler. During initialization application needs to re-assign the handler to override the default handler. CPU2/3 default NMI handlers points to infinite while loop. This section further explains in detail on the CPU1 Boot ROM flow.

4.1.1 ROM Related Collateral

Foundational Materials

- Bootloading 101 (Video)

Expert Materials

- *C2000 Software Controlled Firmware Update Process Application Report*

4.2 Device Boot Sequence

Table 4-3 describes the general boot ROM procedure each time the CPU1 core is reset.

During boot, boot ROM code updates a boot status location in RAM that details the actions taken during this process. Refer to Section 4.7.9 for more details.

Table 4-3. CPU1 Boot ROM Sequence

Step	CPU1 Action
1	Flash Read Interface (FRI) wait state configuration
2	Enable Watchdog
3	Zone0 full debug password configured from OTP into SSU registers
4	UID (Unique ID) is configured from OTP into SSU registers
5	On PORESETn only, All CPU RAMs (LPAx,LDAx, CPAx and CDAx) are initialized
6	Critical Trims (APLL, PMM, OSC, Flash) are loaded from OTP and device configuration registers are programmed
7	ESM configurations are performed for Group0 events
8	SIC (Safe Interconnect) is enabled
9	UPP (User Protection Policy) revision from User-OTP is configured into SSU register
10	Error status pin configuration input from User-OTP is configured
11	External crystal power-up if enabled in User-OTP
12	Reading the Device Configurations from OTP into DCx Registers
13	Load non-critical (ADC, DAC) trims
14	SSU configurations based on User-OTP inputs which include : 1. SSU register self-test 2. SSU register configurations
15	Lock DCx (Device Configuration), PARTID, MCUCNF26 and PERxSYSCONFIG (Peripheral System Configuration) registers
16	Wait for RAM initializaion, done only on PORESETn
17	Clear PORRESETn and XRSn reset cause on PORESETn and only clear XRSn reset cause on XRSn
18	Pull-ups are enabled on unbonded IOs
19	The boot mode GPIO pins are polled to determine the boot mode to run. Boot loader is executed based on boot mode/configurations. Refer to Section 4.5.2 for a flow chart of the boot sequences.
20	RAMOPEN for LINK1 which includes: LPA0 and LDA0-7
21	Lock and Commit LINK1 RAMPOPEN by writing to SSU registers based on User-OTP inputs
22	APR's (Access Protection Regions) are set from User-OTP configurations
23	Disable watchdog for Link1 bootloaders execution
24	Bootloader process under Link1 execution
25	Clear Link1 RAMOPEN
26	Jump to C29 Application Link2

4.3 Device Boot Modes

This section explains the default boot modes, as well as all the available custom boot modes supported on this device. The boot ROM uses the boot mode select, general purpose input/output (GPIO) pins to determine the boot mode configuration.

4.3.1 Default Boot Modes

Table 4-4 shows the boot mode options available for selection by the default boot mode select pins. Users have the option to program the device to customize the boot modes selectable in the boot-up table as well as the boot mode select pin GPIOs used. Default BMSP (Boot Mode Select Pin) used are GPIO72 (BMSP1) and GPIO84 (BMSP0).

Table 4-4. Device Default Boot Modes

Boot Mode	GPIO72 (Default boot mode select pin 1)	GPIO84 (Default boot mode select pin 0)
Parallel IO	0	0
UART	0	1
CAN	1	0
Flash	1	1

Refer to Section 4.4 for details of boot configurations.

Refer to Section 4.7.6.2 for details of the boot modes that use a peripheral boot loader.

Refer to Section 4.7.7 for GPIOs used for selecting the boot modes.

Note

All the peripheral boot modes that are supported use the first instance of the peripheral module (SPIA, I2CA, CANA, and so forth). Whenever these boot modes are referred to in this chapter, such as SPI boot, the mode is actually referring to the first module instance, which means the SPI boot on the SPIA port. The same applies to the other peripheral boot modes.

4.3.2 Custom Boot Modes

Once the user programs a custom boot table in user OTP, an entry in the custom table is used for booting. Users can customize the boot mode select pins in the end system design by programming the BOOTPIN_CONFIG location in user OTP. This allows customers to use 0, 1, 2, or 3 boot mode select pins as needed. You can also customize the boot definition table and indicate which location to boot from by programming the boot mode definition table in the BOOTDEF location of user OTP. Table 4-5 show the options for various boot modes.

Note

All peripheral boot modes supported in Table 4-5 use the first instance of the peripheral modules (that is SPIA, I2CA, and so on).

Table 4-5. CPU1 Boot Modes

Boot Mode Number	Boot Modes
0	Parallel
1	UART
2	CAN
3	Flash
4	Wait
5	RAM
6	SPI
7	I2C
8	CAN-FD

4.4 Device Boot Configurations

This section details what boot configurations are available and how to configure them. This device supports from zero boot mode select pins up to three boot mode select pins and from one configured boot mode up to eight configured boot modes.

To change and configure the device from the default settings to custom settings for your application, use the following process:

1. Determine all the various ways you want application to be able to boot. (For example: Primary boot option of Flash boot for your main application, secondary boot option of CAN boot for firmware updates, tertiary boot option of SPI boot for debugging, and so on.)
2. Based on the number of boot modes needed, determine how many boot mode select pins (BMSPs) are required to select between your selected boot modes. (For example: Two BMSPs are required to select between three boot mode options.)
3. Assign the required BMSPs to a physical GPIO pin. (For example, BMSP0 to GPIO10, BMSP1 to GPIO51, and BMSP2 left as default that is disabled.). Refer to Section 4.4.1 for all the details on performing these configurations.
4. Assign the determined boot mode definitions to indexes in your custom boot table that correlate to the decoded value of the BMSPs. For example, BOOTDEF0 = Boot to Flash, BOOTDEF1 = CAN Boot, BOOTDEF2 = SPI Boot; all other BOOTDEFx remain as default/nothing). Refer to Section 4.4.2 for all the details on setting up and configuring the custom boot mode table.

Additionally, Section 4.4.3 provides some example use cases on how to configure the boot mode select pins and custom boot tables.

4.4.1 Configuring Boot Mode Pins

This section explains how the boot mode select pins are customized by the user, by programming the BOOTPIN_CONFIG location (refer to Table 4-6), in the user-configurable OTP. The location in the OTP is BOOTPIN-CONFIG. When debugging, EMU_BOOTPIN_CONFIG register in SSU_GEN_REGS is the emulation equivalent of BOOTPIN_CONFIG, and can be programmed to experiment with different boot modes without writing to OTP. The device can be programmed to use **zero**, **one**, **two**, or **three** boot mode select pins as needed.

BMSP configuration and boot definition table is either read from User-OTP or SSU registers based on debugger connection status as explained below :

- If debugger is connected then emulation boot flow is followed, where following SSU registers are used to determine GPIO to be used :
  - EMU_BOOTPIN_CONFIG
  - EMU_BOOTDEF_LOW
  - EMU_BOOTDEF_HIGH
- If debugger is not connected then following User-OTP locations are used to determine the bootmodes :
  - BOOTPIN_CONFIG
  - BOOTDEF_LOW
  - BOOTDEF_HIGH

Table 4-6. BOOTPIN-CONFIG Bit Fields

Bit	Name	Description
31:24	Key	Write 0x5A to these 8-bits to tell the boot ROM code that the bits in this register are valid.
23:16	Boot Mode Select Pin 2 (BMSP2)	Refer to BMSP0 description.
15:8	Boot Mode Select Pin 1 (BMSP1)	Refer to BMSP0 description.
7:0	Boot Mode Select Pin 0 (BMSP0)	Set to the GPIO pin to be used during boot (GPIO0 up to GPIO254). 0x0 = GPIO0 0x01 = GPIO1, and so on. Writing 0xFF disables this BMSP and this pin is no longer used to select the boot mode.

Note

GPIO that can be either digital and analog type pins, digital type inputs are possible on these pins provided the software writes to the GPIOHAMSEL register bits.

The following GPIOs that are not available on any package cannot be used as a boot mode select pin. If selected for a particular BMSP, the boot ROM automatically selects the factory default GPIOs for BMSP0 and BMSP1. Factory default for BMSP2 is 0xFF, which disables the BMSP.

Table 4-7. Standalone Boot Mode Select Pin Decoding

BOOTPIN_CONFIG Key	BMSP0	BMSP1	BMSP2	Realized Boot Mode
!= 0x5A	Don't Care	Don't Care	Don't Care	Boot as defined by the factory default BMSPs.
= 0x5A	0xFF	0xFF	0xFF	Boot as defined in the boot table for boot mode 0 (All BMSPs disabled).
	Valid GPIO	0xFF	0xFF	Boot as defined by the value of BMSP0 (BMSP1 and BMSP2 disabled).
	0xFF	Valid GPIO	0xFF	Boot as defined by the value of BMSP1 (BMSP0 and BMSP2 disabled).
	0xFF	0xFF	Valid GPIO	Boot as defined by the value of BMSP2 (BMSP0 and BMSP1 disabled)
	Valid GPIO	Valid GPIO	0xFF	Boot as defined by the values of BMSP0 and BMSP1 (BMSP2 disabled).
	Valid GPIO	0xFF	Valid GPIO	Boot as defined by the values of BMSP0 and BMSP2 (BMSP1 disabled).
	0xFF	Valid GPIO	Valid GPIO	Boot as defined by the values of BMSP1 and BMSP2 (BMSP0 disabled).
	Valid GPIO	Valid GPIO	Valid GPIO	Boot as defined by the values of BMSP0, BMSP1, and BMSP2.
	Invalid GPIO	Valid GPIO	Valid GPIO	BMSP0 is reset to the factory default BMSP0 GPIO. Boot as defined by the values of BMSP0, BMSP1, and BMSP2.
	Valid GPIO	Invalid GPIO	Valid GPIO	BMSP1 is reset to the factory default BMSP1 GPIO. Boot as defined by the values of BMSP0, BMSP1, and BMSP2.
	Valid GPIO	Valid GPIO	Invalid GPIO	BMSP2 is reset to the factory default state, which is disabled. Boot as defined by the values of BMSP0 and BMSP1.

Note

When decoding the boot mode, BMSP0 is the least-significant bit and BMSP2 is the most-significant bit of the boot table index value. It is recommended when disabling BMSPs to start with disabling BMSP2. For example, in an instance when only using BMSP2 (BMSP1 and BMSP0 are disabled), then only the boot table indexes of 0 and 4 are selectable. In the instance when using only BMSP0, then the selectable boot table indexes are 0 and 1.

4.4.2 Configuring Boot Mode Table Options

This section explains how to configure the boot definition table, BOOTDEF, for the device and the associated boot options (refer to Table 4-8). The 64-bit location is located in user-configurable OTP in the BOOTDEF_LOW and BOOTDEF_HIGH locations. When debugging, EMU_BOOTDEF_LOW and EMU_BOOTDEF_HIGH are the emulation equivalents of BOOTDEF_LOW and BOOTDEF_HIGH, and can be programmed to experiment with different boot mode options without writing to OTP.

The range of customization to the boot definition table depends on how many boot mode select pins (BMSP) are being used. For example, 0 BMSPs equals to 1 table entry, 1 BMSP equals to 2 table entries, 2 BMSPs equals to 4 table entries, and 3 BMSPs equals to 8 table entries. Refer to Section 4.4.3 for examples on how to setup the BOOTPIN_CONFIG and BOOTDEF values.

Table 4-8. BOOTDEF Bit Fields

BOOTDEF Name	Byte Position	Name	Description
BOOT_DEF0	7:0	[3:0] BOOT_DEF0 Mode	Set the boot mode number from Section 4.3.2. Any unsupported boot mode causes the device to either go to wait boot (debugger connected) or boot to Flash (standalone).
		[7:4] BOOT_DEF0 Options	Set alternate/additional boot options. This can include changing the GPIOs for a particular boot peripheral or specifying a different Flash entry point. Refer to Section 4.7.7 for valid BOOTDEF values to set in the table.
BOOT_DEF1	15:8	BOOT_DEF1 Mode/Options	Refer to BOOT_DEF0 description.
BOOT_DEF2	23:16	BOOT_DEF2 Mode/Options	
BOOT_DEF3	31:24	BOOT_DEF3 Mode/Options	
BOOT_DEF4	39:32	BOOT_DEF4 Mode/Options	
BOOT_DEF5	47:40	BOOT_DEF5 Mode/Options	
BOOT_DEF6	55:48	BOOT_DEF6 Mode/Options	
BOOT_DEF7	63:56	BOOT_DEF7 Mode/Options	

4.4.3 Boot Mode Example Use Cases

This section demonstrates some use cases for configuring the boot mode select pins and boot modes.

4.4.3.1 Zero Boot Mode Select Pins

This use-case demonstrates a scenario for an application that does not use any boot mode select pins and always has the device boot to Flash.

1. Program the BOOTPIN_CONFIG location in OTP as follows:
   - Set BOOTPIN_CONFIG.BMSP0 to 0xFF
   - Set BOOTPIN_CONFIG.BMSP1 to 0xFF
   - Set BOOTPIN_CONFIG.BMSP2 to 0xFF
   - Set BOOTPIN_CONFIG.KEY to 0x5A for boot ROM to treat these register bits as valid and use the custom boot table.
2. Program the BOOTDEF location options for the device. This essentially sets up a device-specific boot mode table. Refer to Section 4.7.7 for valid BOOTDEF values to set in the table.
   - Set BOOTDEF.BOOTDEF0 to 0x03 for booting to Flash (entry address option 0). This sets Flash boot to boot table index 0.
   - Refer to Section 4.7.2 for the available Flash entry points.

Table 4-9. Zero Boot Pin Boot Table Result

Boot Mode Table Number	Boot Mode
0	Flash Boot (0x03)

4.4.3.2 One Boot Mode Select Pin

This use-case demonstrates a scenario for an application using one boot mode select pin to select between booting to Flash or using CAN boot.

1. Program the BOOTPIN_CONFIG location in OTP as follows:
   - Set BOOTPIN_CONFIG.BMSP0 to a user specified GPIO, such as 0x0 for GPIO0
   - Set BOOTPIN_CONFIG.BMSP1 to 0xFF
   - Set BOOTPIN_CONFIG.BMSP2 to 0xFF
   - Set BOOTPIN_CONFIG.KEY to 0x5A for boot ROM to treat these register bits as valid and use the custom boot table.
2. Program the BOOTDEF location options for the device. This essentially sets up a device-specific boot mode table. Refer to Section 4.7.7 for valid BOOTDEF values to set in the table.
   - Set BOOTDEF.BOOTDEF0 to 0x02 for CAN booting. This sets CAN boot to boot table index 0.
   - Set BOOTDEF.BOOTDEF1 to 0x03 for booting to Flash (entry address option 0). This sets Flash boot to boot table index 1.

Table 4-10. One Boot Pin Boot Table Result

Boot Mode Table Number	Boot Mode
0	CAN Boot (0x02)
1	Flash Boot (0x03)

4.4.3.3 Three Boot Mode Select Pins

This use-case demonstrates a scenario for an application using three boot mode select pins to select between various boot modes in the custom boot table.

1. Program the BOOTPIN_CONFIG location in OTP as follows:
   - Set BOOTPIN_CONFIG.BMSP0 to a user specified GPIO, such as 0x0 for GPIO0
   - Set BOOTPIN_CONFIG.BMSP1 to a user specified GPIO, such as 0x1 for GPIO1
   - Set BOOTPIN_CONFIG.BMSP2 to a user specified GPIO, such as 0x2 for GPIO2
   - Set BOOTPIN_CONFIG.KEY to 0x5A for boot ROM to treat these register bits as valid and use the custom boot table.
2. Program the BOOTDEF location options for the device. This essentially sets up a device-specific boot mode table. Refer to Section 4.7.7 for valid BOOTDEF values to set in the table.
   - Set BOOTDEF.BOOTDEF0 to 0x02 for CAN booting. This sets CAN boot to boot table index 0.
   - Set BOOTDEF.BOOTDEF1 to 0x03 for booting to Flash. This sets Flash boot to boot table index 1.
   - Set BOOTDEF.BOOTDEF2 to 0x01 for booting to UART booting. This sets UART boot to boot table index 2.
   - Set BOOTDEF.BOOTDEF3 to 0x66 for SPI booting (alternate GPIO option 3). This sets SPI boot to boot table index 3.
   - Set BOOTDEF.BOOTDEF4 to 0x05 for booting to RAM. This sets RAM boot to boot table index 4.

Table 4-11. Three Boot Pins Boot Table Result

Boot Mode Table Number	Boot Mode
0	CAN Boot (0x02)
1	Flash Boot (0x03)
2	UART Boot (0x01)
3	SPI - Alt3 (0x66)
4	RAM Boot (0x05)
5, 6, 7	Not used in this example

4.5 Device Boot Flow Diagrams

This section details the C29 CPU boot flow diagrams for standalone and emulation boot flows.

4.5.1 Device Boot Flow

The following flow diagrams describe how the device boots up after PORESETn. HSM starts up first and then releases reset to CPU1. Detailed CPU1 boot flow is explained in later sections and for detailed HSM boot flow, refer to the *F29x Hardware Security Manager (HSM) User's Guide*.

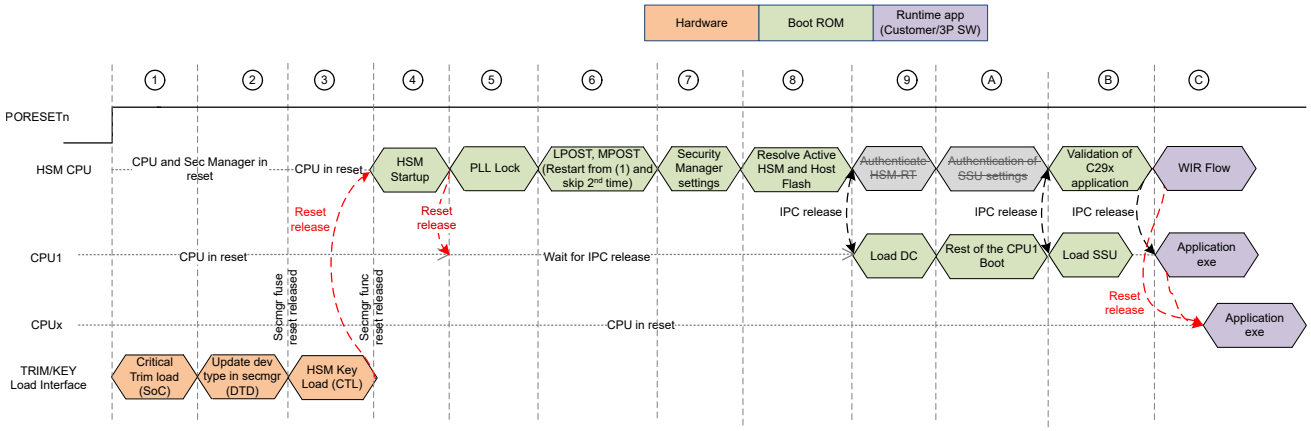

Figure 4-1. HS-FS Device Boot Flow Diagram

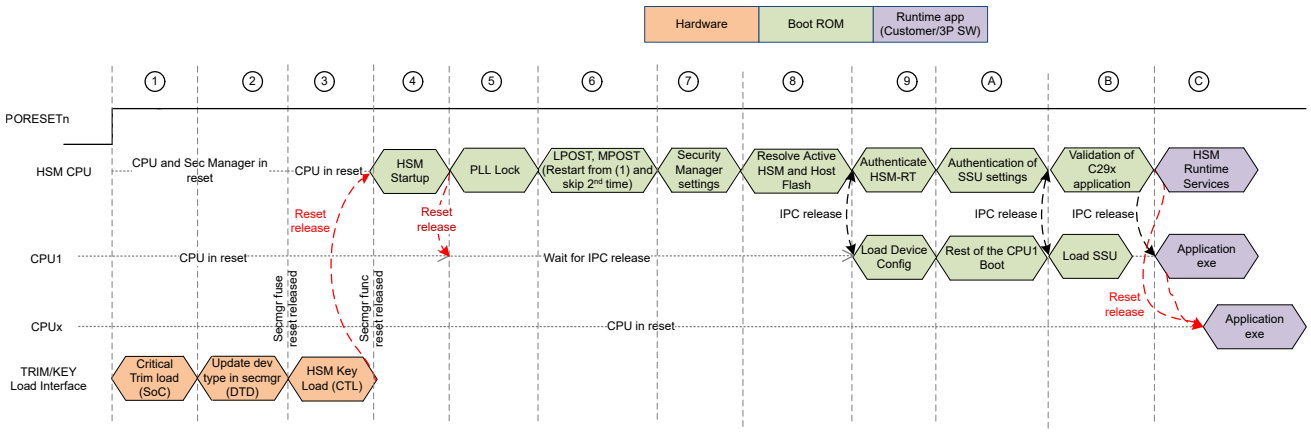

Figure 4-2. HS-SE Secure Boot Flow Diagram

4.5.2 CPU1 Boot Flow

Upon reset, CPU1 follows the boot flow shown in Figure 4-3. Depending on whether a JTAG debugger is connected to the device, the CPU1 either continues booting following the emulation boot flow or the standalone boot flow.

Note

Boot on reset (BOR) follows same flow as power on reset (POR).

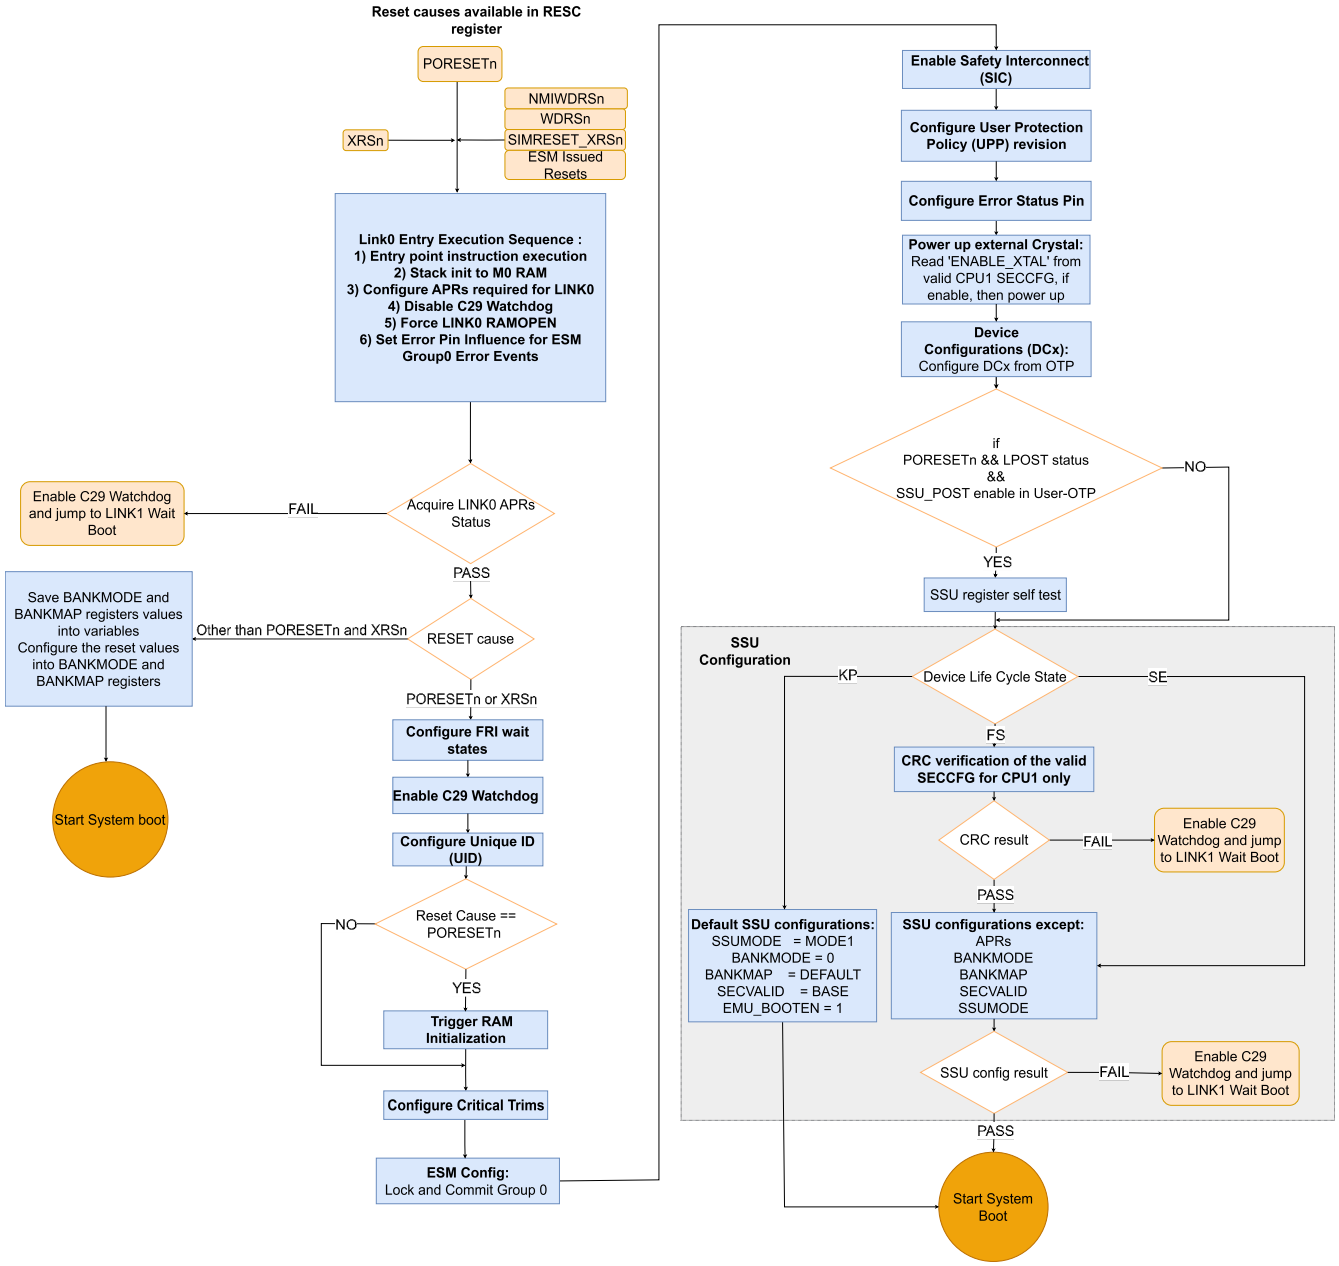

Figure 4-3. Device Boot Flow from Reset to System Boot

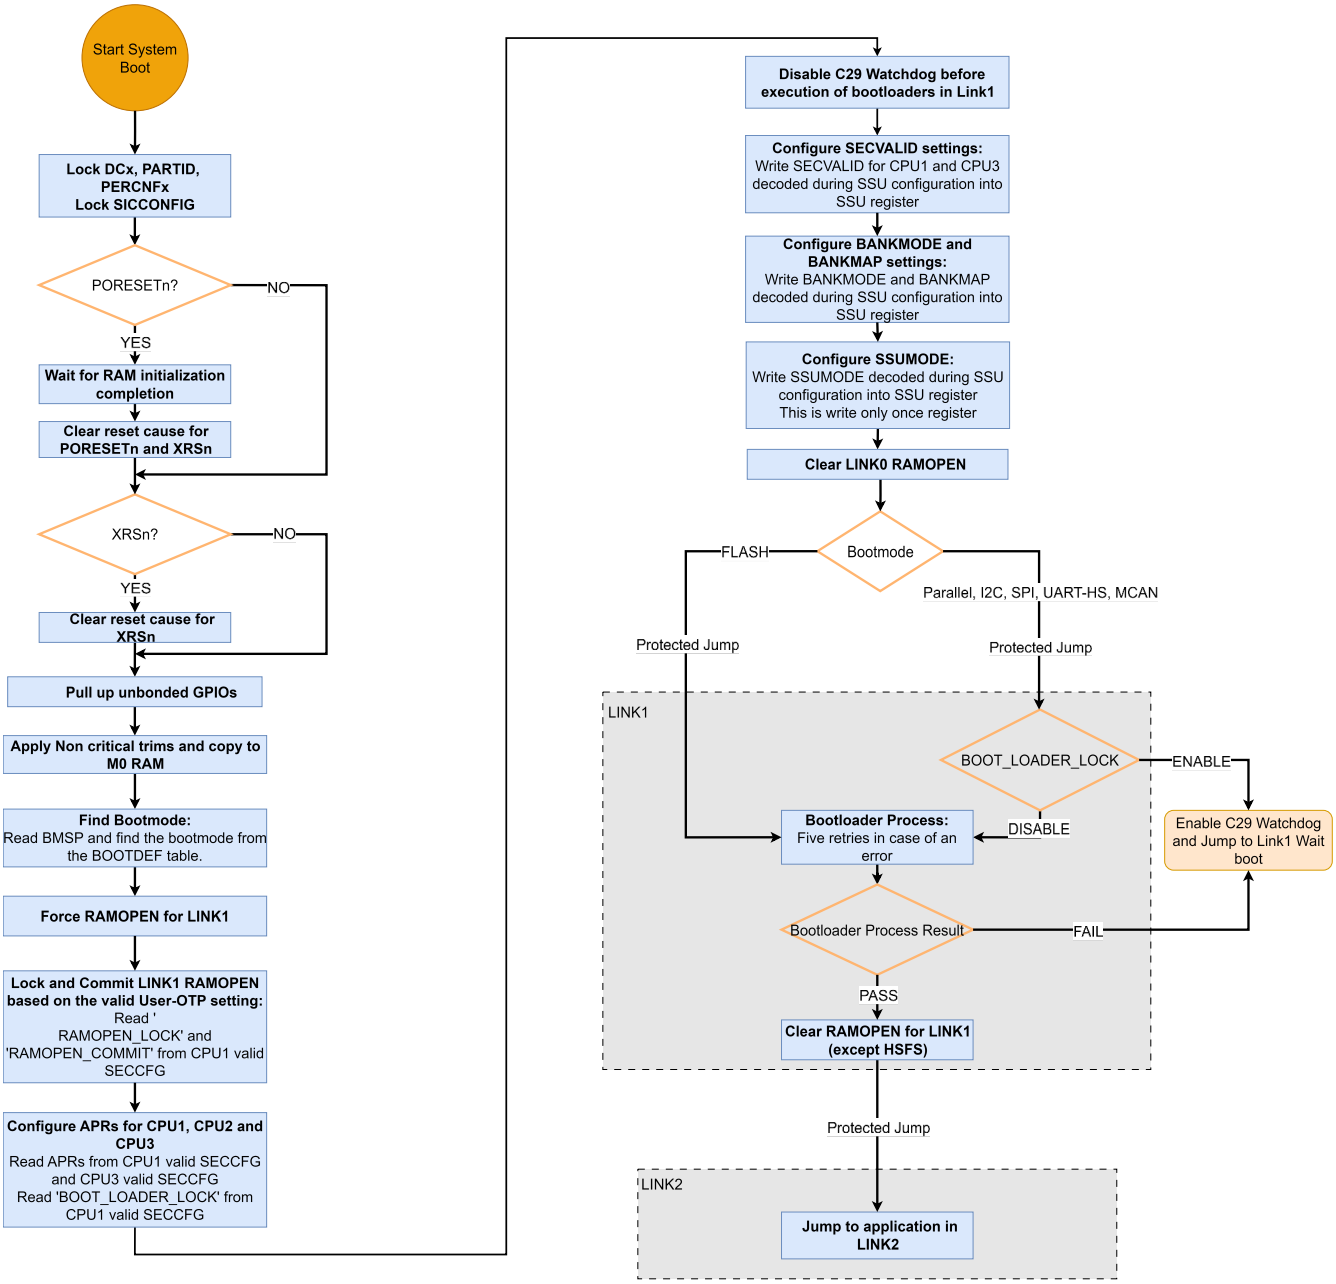

Figure 4-4. System Boot Flow to Application Code

4.5.3 Emulation Boot Flow

Figure 4-5 shows the emulation boot flow when JTAG debugger is connected and emulation boot is enabled in SECCFG User OTP.

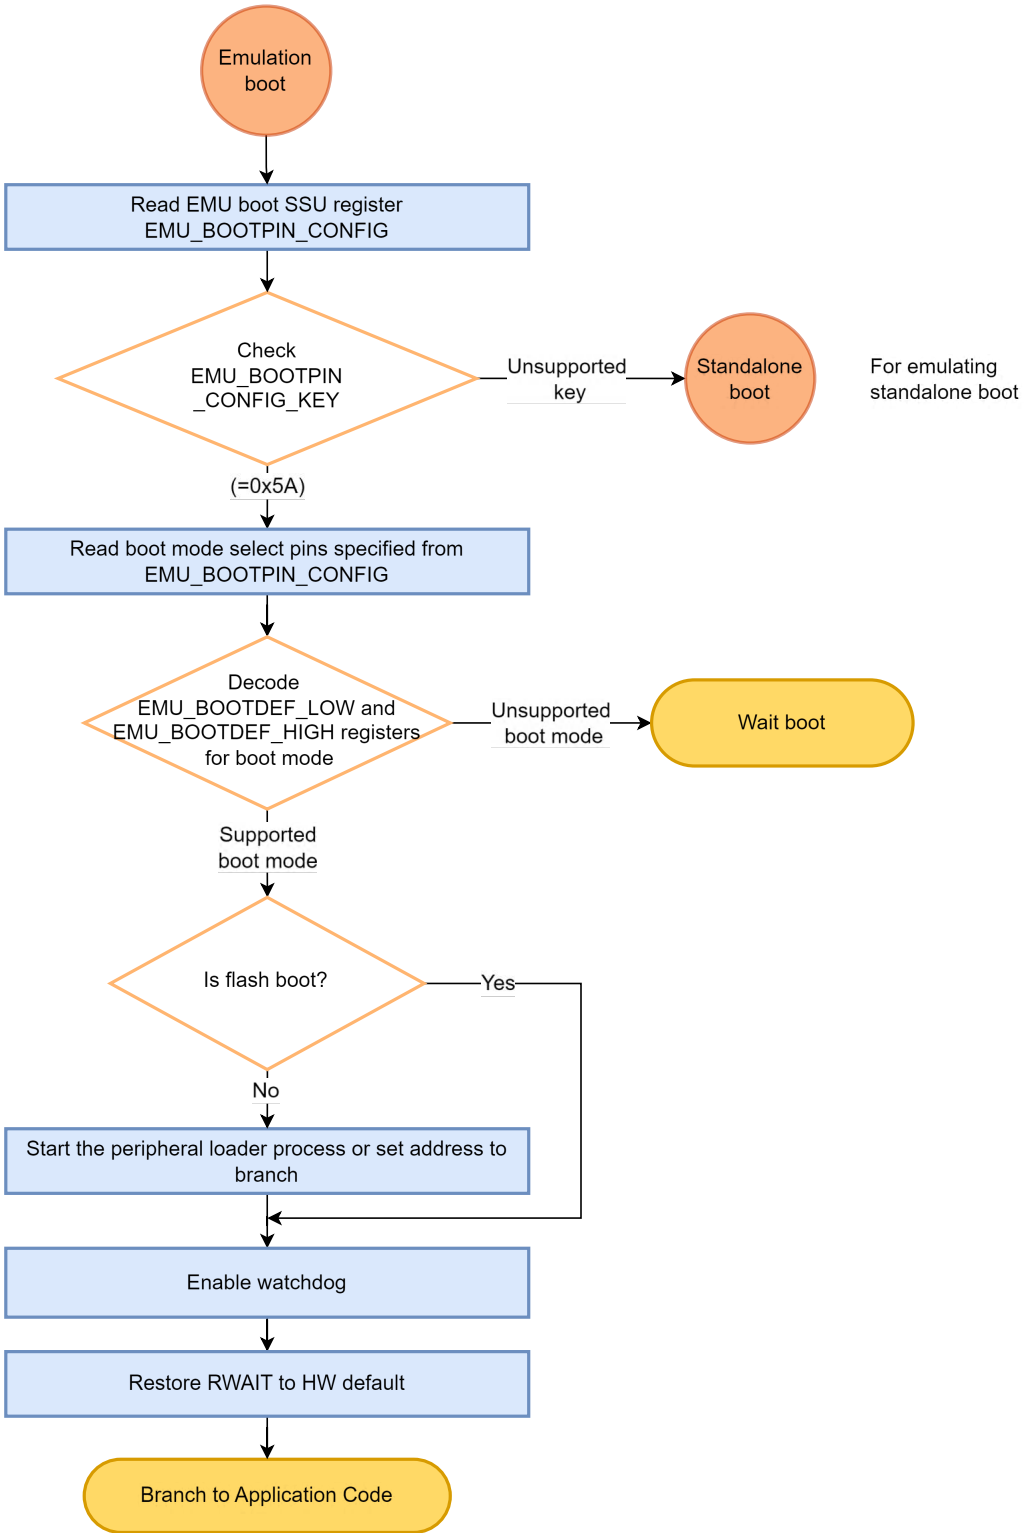

Figure 4-5. Emulation Boot Flow

4.5.4 Standalone Boot Flow

Section 4.5.4 shows the standalone boot flow for CPU1 when no JTAG debugger is connected to the device.

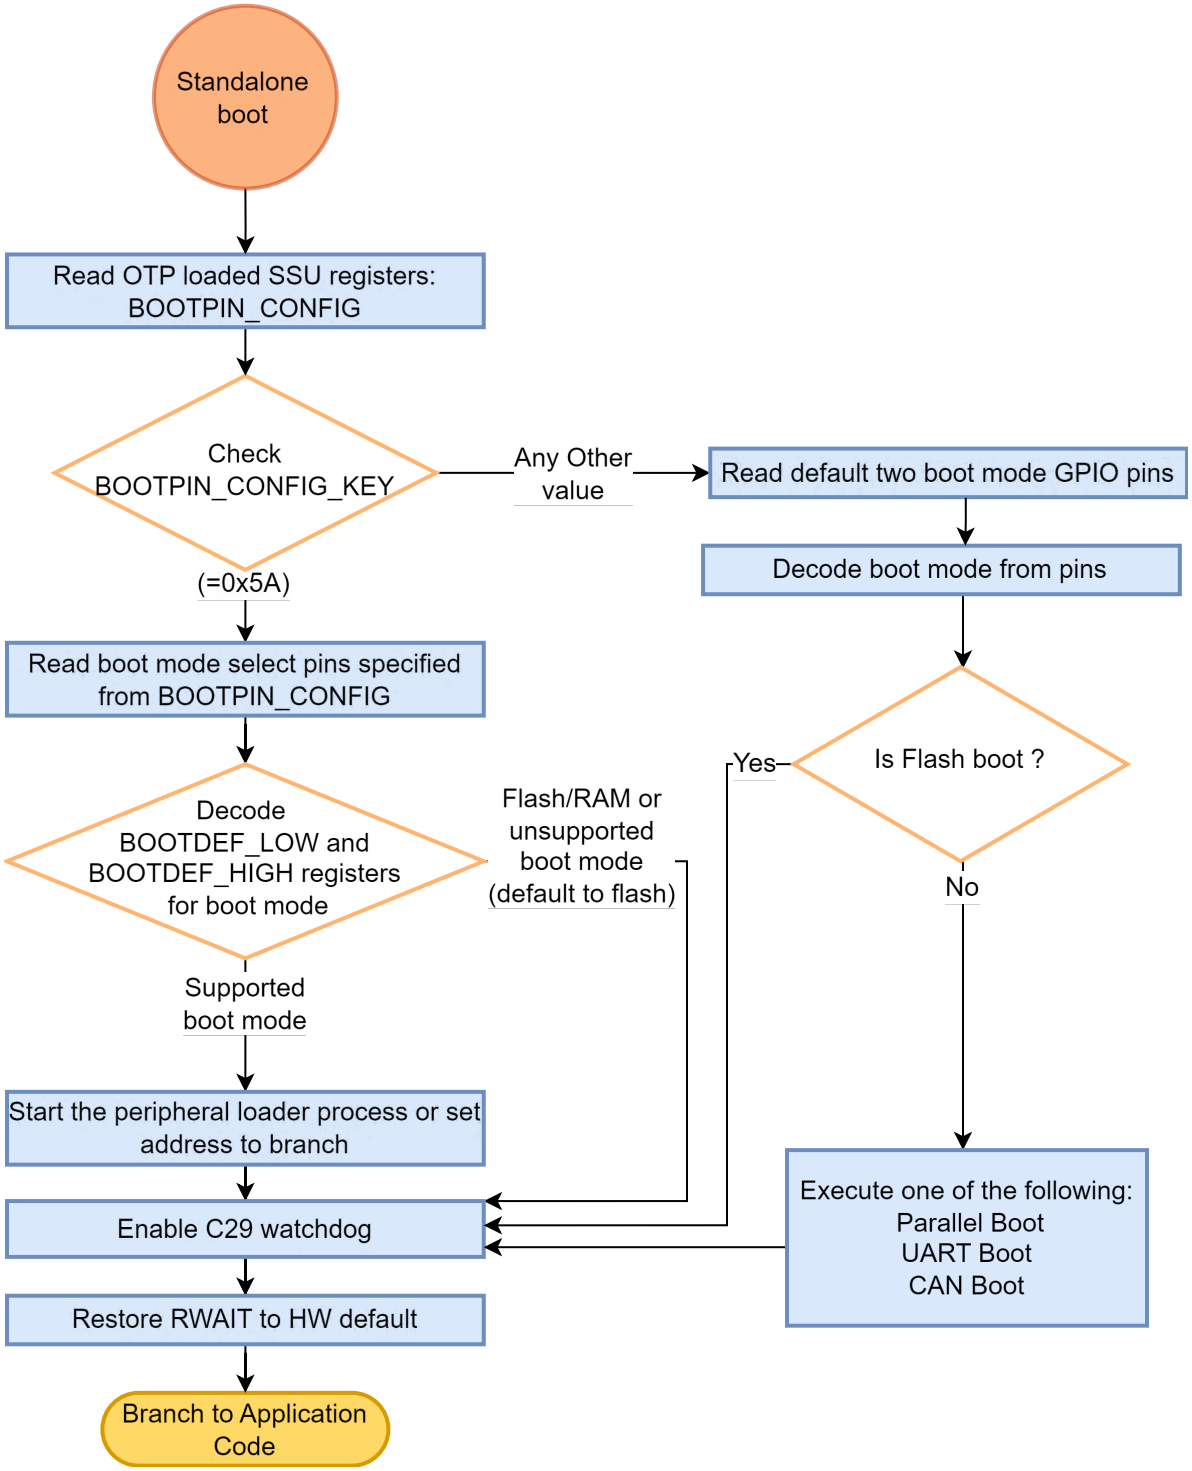

Figure 4-6. Standalone Boot Flow

4.6 Device Reset and Exception Handling

4.6.1 Reset Causes and Handling

Table 4-12 explains the actions each boot ROM performs upon reset for a specific reset cause. The boot ROM flow only explicitly checks for POR and XRS reset cause flags.

Table 4-12. Boot ROM Reset Causes and Actions

Reset Source	CPU1 Boot ROM Action
Power on Reset (POR)	1. Default boot flow 2. RAM initialization
External Reset (XRS) Includes: • CPU1 Watchdog Reset • NMI Watchdog Reset (Issued by ESM) • SIMRESET XRSn • ESM Critical Priority Output (ESMCPUxCRITICAL,ESMRESET) • ECAT RESET	1. Default boot flow
Debugger Reset	1. No change to RAM 2. Save default BANKMAP and BANKMODE

4.6.2 Exceptions and Interrupts Handling

Table 4-13 explains the actions that the boot ROM performs, if any exceptions occur during boot. The philosophy of boot ROM is to try and start the application and log the error.

The boot ROM sets up the default NMI handlers and enables NMI on every reset type. When NMI is triggered on any of the Group0 error event input to CPU1 ESM, the error status pin is driven LOW. The interval for which the error pin remains LOW is determined by the count programmed into SYSTEM ESM instance PIN_CNTR_PRE register. The error status pin GPIO number is read from the SECCFG and configured as error status pin

Table 4-13. Boot ROM Exceptions and Actions

Link	Exception Event Source	CPU1 Boot ROM Action	Event Logged
LINK0 and LINK1	NMI - Uncorrectable ECC Errors	Reset the device	Yes
LINK0 and LINK1	NMI - Other than Uncorrectable ECC Errors	Enable C29 Watchdog and Jump to Link1 and wait in while(1) loop	Yes
LINK0	Critical Trim Loading	Reset the device	Yes
LINK0	LINK0 SSU APR - Failure to acquire APR's for LINK0 execution	Enable C29 Watchdog and Jump to Link1 and wait in while(1) loop	Yes
LINK0	CPU1 valid SECCFG CRC check mismatch	Enable C29 Watchdog and Jump to Link1 and wait in while(1) loop	Yes
LINK0	Error during SSU configuration, SSU self test or SSU APR configurations	Enable C29 Watchdog and Jump to Link1 and wait in while(1) loop	Yes
LINK1	Error during Certificate parsing	Enter Wait Boot	Yes
LINK1	HSM authentication result is "RETRY"	Enter Wait Boot	Yes

4.7 Boot ROM Description

This section explains the details regarding the device boot ROMs.

4.7.1 Boot ROM Configuration Registers

The boot ROM code involves several memory addresses and registers used during execution. There are two sets of configurations; one for emulation and one for standalone boot flow. The emulation locations located in SSU registers - SSU_GEN_REGS, SSU_CPU1_CFG_REGS, SSU_CPU2_CFG_REGS and SSU_CPU3_CFG_REGS emulate the OTP configurations and can be written to as many times as needed. The user configurable SECCFG OTP locations used in the standalone boot flow program the device OTP and hence can only be written once. Table 4-14 details these locations. For bit field configuration details of BOOTPIN_CONFIG and BOOTDEF, see Section 4.4.1 and Section 4.4.2, respectively.

Table 4-14. Boot ROM Registers

Boot Flow	SSU Register Name	OTP SECCFG Name	Register Address	User OTP Address
Emulation	EMU_BOOTPIN_CONFIG		0x3008_0030	-
	EMU_BOOTDEF_LOW		0x3008_1028	-
	EMU_BOOTDEF_HIGH		0x3008_102C	-
Standalone		BOOTPIN_CONFIG	-	0x10D8_17A8
		BOOTDEF_LOW	-	0x10D8_17C8
		BOOTDEF_HIGH	-	0x10D8_17CC

4.7.1.1 MPOST and LPOST Configurations

Using Sysconfig-System Security tab, the users can load the appropriate settings for MPOST and LPOST executions as needed.

4.7.2 Entry Points

This sections gives details about the entry point addresses for various boot modes. These entry points direct the boot ROM what address to branch to at the end of booting as per the selected boot mode.

Table 4-15 give details about the entry point addresses for the Flash boot mode and RAM boot mode.

Table 4-15. Entry Point Addresses for CPU1

Boot Mode	Option	BOOTDEFx Value	Flash Read Port	Address	Packages Supported
Flash	0	0x03	FRI1 RP0	0x1000_1000	All
RAM	0	0x05	N/A	0x2010_0000 (LPA0 SRAM)	All
RAM	1	0x25	N/A	0x2011_0000 (CPA0 SRAM)	All

4.7.3 Wait Points

The wait mode puts the CPU in a loop in the boot ROM code and does not branch to the user application code. The device can enter the wait boot mode either through manually being set or because of some issue during boot up. Using the wait boot mode is recommended when using a debugger to avoid any JTAG issues. There is an infinite for loop when entered in wait boot so user can easily halt CPU and load code when connected using debugger.

Table 4-16. Wait Boot Options

Option	BOOTDEFx Value	Watchdog Status	Package Supported
0 (default)	0x04	Disabled	All

During boot ROM execution, there are situations where the CPU can enter a wait loop in the code. This state can occur for a variety of reasons.

Table 4-17 details the address ranges that the CPU PC register value reaches to if the CPU has entered one of these instances.

Following are the actions for entering wait boot mode:

- Wait boot is set by the user as the boot mode.
- Boot mode is unrecognizable and a debugger is connected to the device.
- An error occurs during emulation boot and the boot mode pins are decoded with a value not recognized as a valid boot mode.

Table 4-17. Wait Point Addresses

Program Counter Address Range	Description
0x1535C	In Wait Boot mode
0x14EB0	In Wait Boot mode

4.7.4 Memory Maps

4.7.4.1 Boot ROM Memory-Maps

Table 4-18 details the ROM memory-map including Link0 and Link1 ROM.

Table 4-18. Boot ROM Memory-Map

Memory	Start Address	Length
Reset Vector	0x0000_0000	0x0040
NMI Vector	0x0000_0040	0x0040
Default Handlers	0x0000_0080	0x0F80
User Data Tables	0x0000_1000	0x7000
Link0 Boot code	0x0000_8000	0x8000
Link1 Boot code	0x0001_0000	0xFFFF

4.7.4.2 Reserved RAM Memory-Maps

Table 4-19 details memory usage in RAM that is reserved for boot ROM to use. These memory sections can be reserved in the user application.

Table 4-19. Reserved RAM Memory-Map

Memory	Description	Origin Address	Length
M0 RAM	Link0 Stack	0x2000_0000	0x800
M0 RAM	Boot ROM Status	0x2000_0800	0x170
M0 RAM	Link0 Data Sections	0x2000_0970	0x5C0
M0 RAM	Non Critical TRIM's	0x2000_0F30	0xCF

4.7.5 ROM Structure and Status Information

This section details the boot ROM structure that can be integrated into an application to use the available ROM code status information and tables.

Table 4-20. ROM Symbol Tables

ROM Structure	Library Name	Location
ROM Code Status Information	driverlib	Under *source/driverlib/bootrom.c and bootrom.h* in MCU_SDK_F29H85x
Twiddle Tables	driverlib	

4.7.6 Boot Modes and Loaders

The available boot modes and bootloaders supported on this device are detailed in this section.

4.7.6.1 Boot Modes

This section details the available boot modes that do not involve a peripheral boot loader. Table 4-21 details the available boot modes that do not involve a peripheral boot loader.

Table 4-21. Boot Mode Availability

Boot Mode	CPU Support
Flash Boot	C29x CPU
RAM Boot	C29x CPU
Wait Boot	C29x CPU

4.7.6.1.1 Flash Boot

Flash boot mode branches to the configured memory address in Flash. Refer to Section 4.7.2 for all the available Flash address options.

4.7.6.1.2 RAM Boot

RAM boot mode branches to the configured memory address in RAM. Refer to Section 4.7.2 for all the available RAM address options.

4.7.6.1.3 Wait Boot

Wait boot mode branches to the memory address as mentioned in Section 4.7.3.

4.7.6.2 Bootloaders

This section details the available boot modes that use a peripheral boot loader.

4.7.6.2.1 SPI Boot Mode

The SPI loader expects an SPI-compatible 16-bit or 24-bit addressable serial EEPROM or serial Flash device to be present on the SPI-A pins as shown in Figure 4-7. The SPI bootloader supports an 8-bit data stream and does not support a 16-bit data stream.

Figure 4-7. Overview of SPI Bootloader Operation

The SPI boot ROM loader initializes the SPI module to interface to a serial SPI EEPROM or Flash. Devices of this type include, but are not limited to, the Xicor X25320 (4Kx8) and Xicor X25256 (32Kx8) SPI serial SPI EEPROMs and the Atmel AT25F1024A serial Flash.

The SPI boot ROM loader initializes the SPI with the following settings: FIFO enabled, 8-bit character length, internal SPICLK controller mode and talk mode, transfer protocol : Mode 1 - rising edge with phase delay, clock phase = 1, polarity = 0 and using 2 Mbps baud rate.

If the download is to be performed from an SPI port on another device, then that device must be set up to operate in the peripheral mode and mimic a serial SPI EEPROM. Immediately after entering the SPI_Boot function, the pin functions for the SPI pins are set to primary and the SPI is initialized.

4.7.6.2.2 I2C Boot Mode

The I2C bootloader expects an 8-bit wide I2C-compatible EEPROM device to be present at address 0x50 on the I2C-A bus as shown in Figure 4-8. The EEPROM must adhere to conventional I2C EEPROM protocol, as described in this section, with a 16-bit base address architecture.

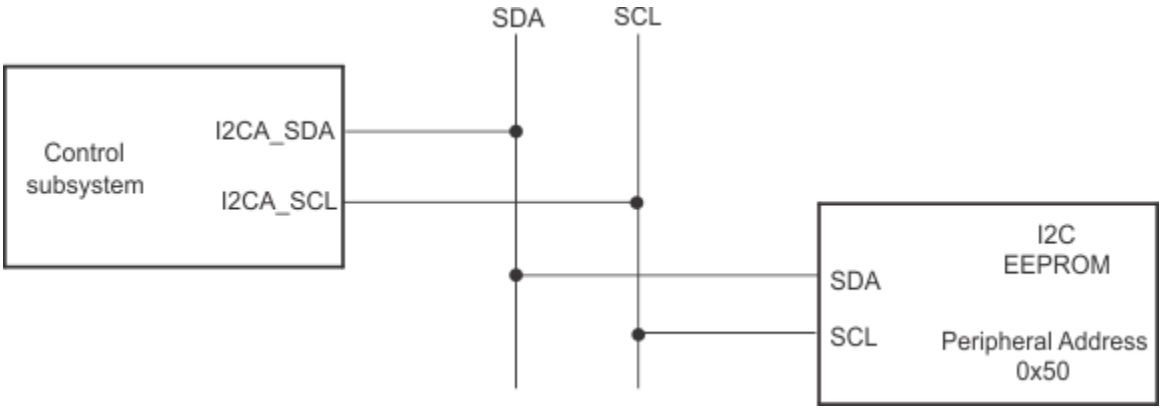

Figure 4-8. EEPROM Device at Address 0x50

If the download is to be performed from a device other than an EEPROM, then that device must be set up to operate in the target mode and mimic the I2C EEPROM. Immediately after entering the I2C boot function, the GPIO pins are configured for I2C-A operation and the I2C is initialized. The following requirements must be met when booting from the I2C module:

- The input frequency to the device must be in the appropriate range.
- The EEPROM must be at target address 0x50.

The bit-period prescalers (I2CCLKH and I2CCLKL) are configured by the bootloader to run the I2C at a 50 percent duty cycle at 100kHz bit rate (standard I2C mode) when the system clock is 10MHz.

Arbitration, bus busy, and target signals are not checked. Therefore, no other controller is allowed to control the bus during this initialization phase. If the application requires another controller during I2C boot mode, that controller must be configured to hold off sending any I2C messages until the application software signals that the software is past the bootloader portion of initialization.

The non-acknowledgment bit is checked only during the first message sent to initialize the EEPROM base address. This is to make sure that an EEPROM is present at address 0x50 before continuing. If an EEPROM is not present, the non-acknowledgment bit is not checked during the address phase of the data read messages. If a non-acknowledgment is received during the data read messages, the I2C bus hangs.

4.7.6.2.3 Parallel Boot Mode

The parallel general-purpose I/O (GPIO) boot mode asynchronously transfers code from the host to C29x internal memory. Each value is 8-bits long and follows the same data flow as outlined in Figure 4-9.

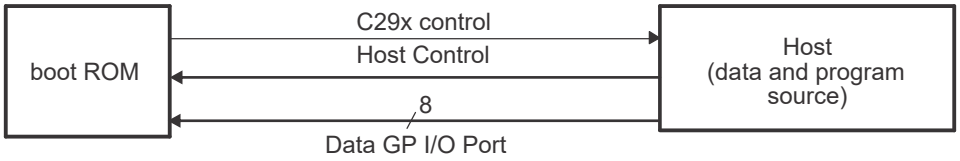

Figure 4-9. Overview of Parallel GPIO Bootloader Operation

The control subsystem communicates with the external host device by polling/driving the Host Control and C29x control lines. The handshake protocol shown in Figure 4-10 must be used to successfully transfer each word using GPIO [D0:D7]. This protocol is very robust and allows for a slower or faster host to communicate with the controller subsystem.

Two consecutive 8-bit words are read to form a single 16-bit word. The least-significant byte (LSB) is read first followed by the most-significant byte (MSB). In this case, data is read from GPIO[D0:D7].

The device first signals the host that the device is ready to begin data transfer by pulling the C29x control pin low. The host load then initiates the data transfer by pulling the DSP control pin low. The complete handshake protocol is shown in Figure 4-10.

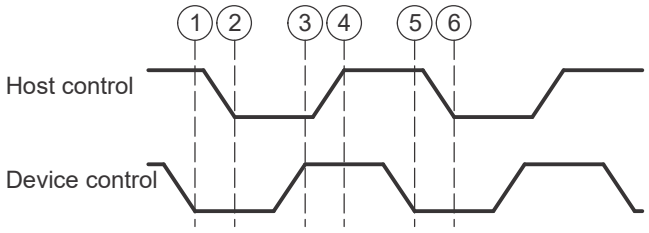

Figure 4-10. Parallel GPIO Bootloader Handshake Protocol

1. The device indicates the device is ready to start receiving data by pulling the C29x control pin low.
2. The bootloader waits until the host puts data on GPIO [D0:D7]. The host signals to the device that data is ready by pulling the host control pin low.
3. The device reads the data and signals the host that the read is complete by pulling the C29x control pin high.
4. The bootloader waits until the host acknowledges the device by pulling the host control pin high.
5. The device again indicates the device is ready for more data by pulling the C29x control pin low.

This process is repeated for each data value to be sent.

Figure 4-11 shows the transfer flow from the host side. The operating speed of the CPU and host are not critical in this mode as the host waits for the device and the device in turn waits for the host. In this manner, the protocol works with both a host running faster and a host running slower than the device.

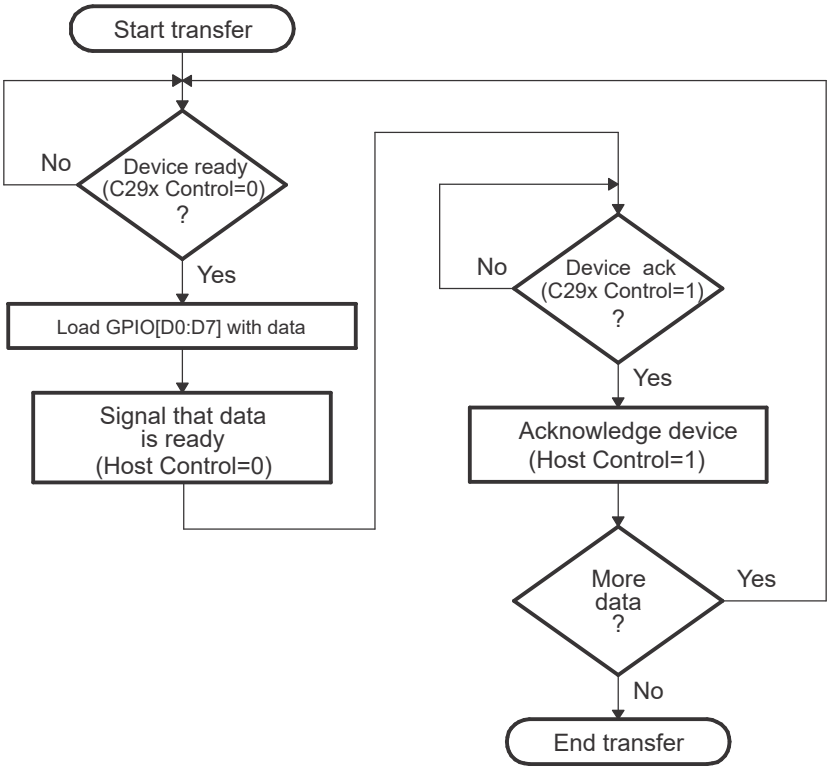

Figure 4-11. Parallel GPIO Mode - Host Transfer Flow

4.7.6.2.4 CAN Boot Mode

The CAN bootloader asynchronously transfers code from CAN-A to internal memory as shown in Figure 4-12. The host can be any CAN node. The communication is first done with 11-bit standard identifiers (with a MSGID of 0x1) using two bytes per data frame.

Note

MCAN and CAN boot can be used with an external oscillator with a 25MHz and 20MHz frequency.

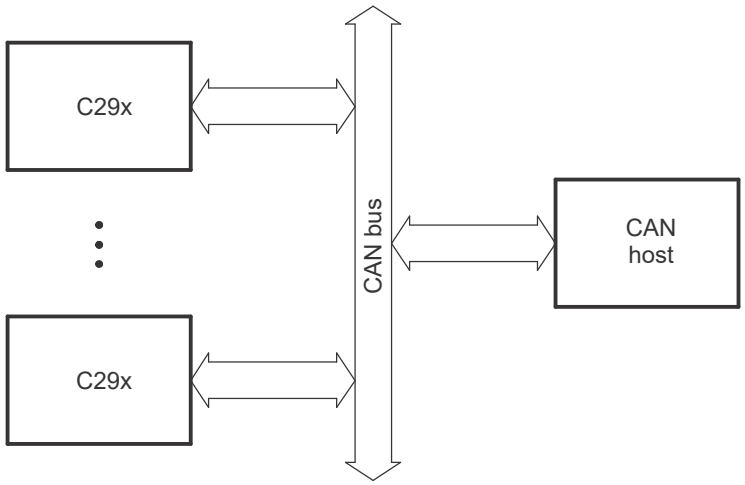

Figure 4-12. Overview of CAN-A Bootloader Operation

The bit timing registers are programmed in such a way that a 100kbps bit rate is achieved with a 20MHz external oscillator, as shown in Table 4-22.

Table 4-22. Bit-Rate Value for External Oscillators

OSCCLK	SYSCLK	Bit Rate
20MHz	200MHz	100kbps
25MHz	200MHz	100kbps

The bootROM configures and locks PLL at 200MHz and also configures CAN bit clock at 20MHz using XTAL oscillator as clock source if detected; otherwise, defaults to INTOSC2.

Note

The CAN boot loader uses XTAL as the bit clock source and INTOSC2 as the system clock source.

Mailbox 1 is programmed with a standard MSGID of 0x1 for bootloader communication. The CAN host transmits only two bytes at a time, LSB first and MSB next. For example, to transmit the word 0x08AA to the device, transmit AA first, followed by 08.

4.7.6.2.5 CAN-FD Boot Mode

The CAN-FD bootloader asynchronously transfers code from CAN-FD to internal memory and follows same bootloader execution flow as Section 4.7.6.2.4. The host can be any CAN-FD node. The communication is first done with 11-bit standard identifiers (with a MSGID of 0x1) using two bytes per data frame. The CAN-FD bootloader uses a fixed 64-byte payload size and default bit rate of 1Mbps for nominal phase and 2Mbps for data phase.

Mailbox 1 is programmed with a standard MSGID of 0x1 for boot-loader communication. The CAN-FD host transmits only two bytes at a time, LSB first and MSB next. For example, to transmit the word 0x08AA to the device, transmit AA first, followed by 08. The program flow of the CAN-FD bootloader is identical to the CAN bootloader.

4.7.6.2.6 UART Boot Mode

The UART bootloader is a peripheral bootloader that receives data and program over the UARTA RX line.

After power-on, when the host is connected and the device is set in UART boot mode, the controller (MCU) sends the SOCID on the UART TX line. Host can start sending the actual image data once the SOCID is received. After each data transfer, the bootloader echo's back the 8-bit character received to the host. This allows the host to check that each character was received by the bootloader.

The SOCID is sent out to the host on every cold/warm reset. The SOCID is also copied to M0 RAM (at address 0x2000 0980), which is transmitted over the UART to the host.

The UART bootloader supports 1 stop bit, no parity and 8-bit character transfers at baud rate of 115200bps.

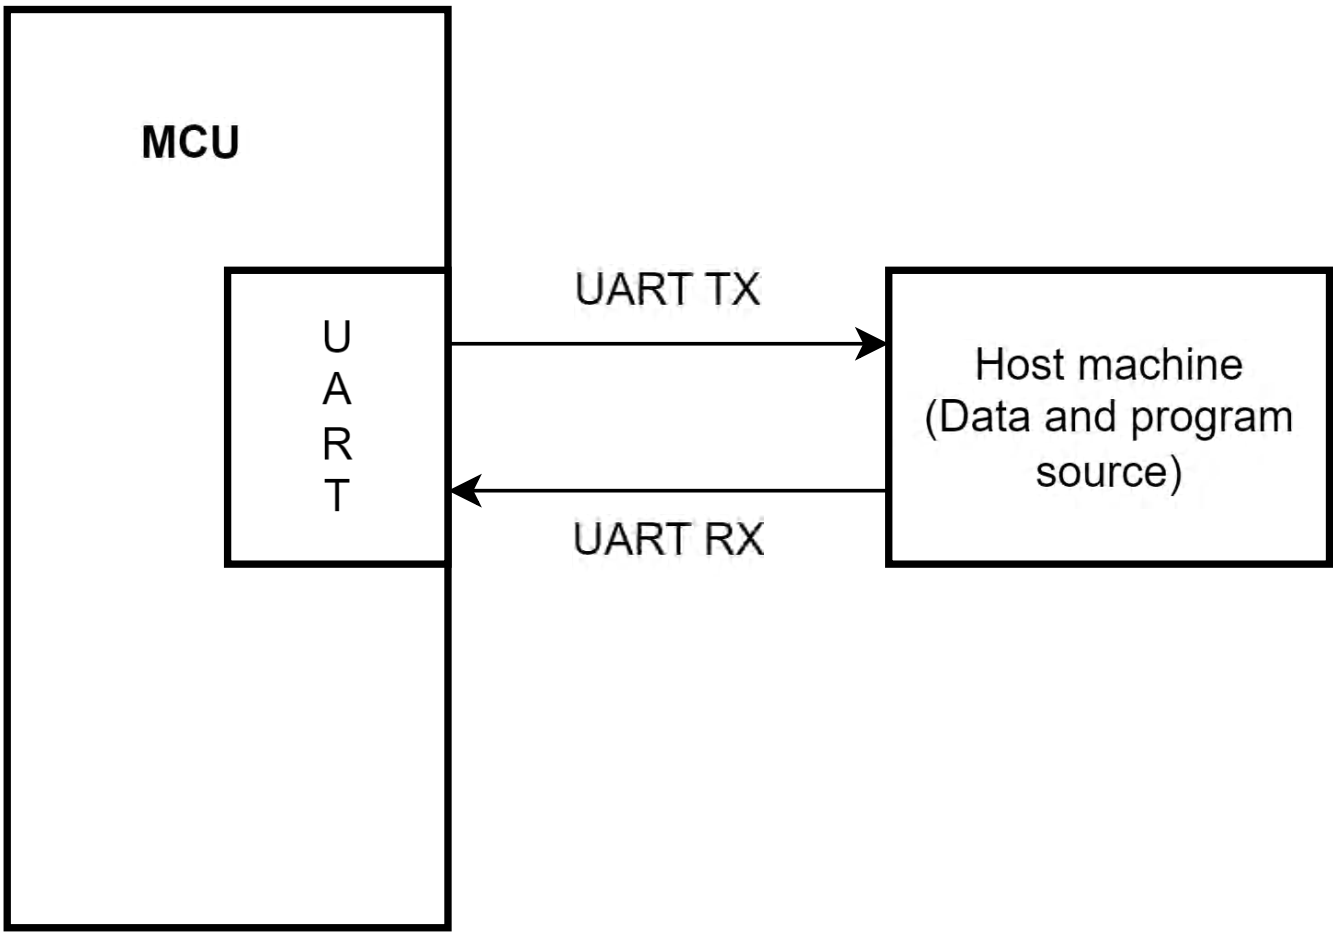

Figure 4-13. UART Boot Mode

4.7.7 GPIO Assignments

This section details the GPIOs and boot option values used for boot mode set in the BOOT_DEF memory location located at BOOTDEF_LOW and BOOTDEF_HIGH. Refer to Section 4.4.2 on how to configure BOOT_DEFx. When selecting a boot mode option, make sure to verify that the necessary pins are available in the pin mux options for the specific device package being used.

Default boot mode GPIO pins:

- Boot mode pin 0 - GPIO84
- Boot mode pin 1 - GPIO72

Guidelines on boot pin selection:

- Avoid pins that have PWM functionality.
- Cannot be analog or USB pins.
- Boot mode select pins and default boot peripheral pins can be available on all packages.
- Avoid JTAG emulation pins and crystal pins.
- Boot mode select pins can be inputs.
- Pins cannot have PHY bootstrap functionality.

4.7.8 HSM and C29 ROM Task Ownership and Interactions

HSM (M4) has the primary ownership of the device at boot up and does the following tasks:

1. PLL Initialization and Lock
2. Run MPOST based on input from SECCFG settings input by user
3. Run LPOST based on input from SECCFG settings input by user
4. IPC Initialization and C29 CPU1 reset release
5. C29 Application Image authentication
6. C29 SBL validation and integrity check
7. HSMRT validation and integrity check

C29 SBL (Secondary Bootloader) authentication process:

1. Initialize Boot Peripheral to receive the image
2. Copies image from host and loads into LDA RAM
3. After copying, C29 sends IPC message to HSM
4. HSM starts certificate validation and image integrity checks
5. HSM sends ACK back to C29 CPU1 and copies image from LDA to LPA RAM in case image authentication succeeds
6. If the image authentication fails, then HSM retries the process again for a maximum of 5 times

HSMRT (HSM Realtime App) authentication process:

1. SBL downloads HSMRT from the peripheral bootloader chosen by user
2. SBL copies HSMRT image at LDA RAM
3. C29CPU sends IPC message to HSM after copying image
4. HSM protects LDA memory and starts certificate and image validation
5. HSM branches to LDA and releases protection in case of successful validation
6. In case of failure, send NACK message to C29 CPU1

4.7.8.1 Application Authentication by HSM

The application image either present on Flash or downloaded to RAM by peripheral bootloader is authenticated by HSM.

In case of peripheral bootloader, the following procedure is followed:

1. The certificate is downloaded to LDA7 RAM (0x200E_0000)
2. The image is downloaded at an offset of maximum size of certificate (4KB) at 0x200E_1000
3. HSM reads the certificate and image and authenticates the image
4. If the image authentication succeeds, then the image is copied to LPA0 RAM (0x20100000)
5. Then LINK1 makes protected jump to LPA0 address and starts executing the image

The HSM and C29 CPU image authentication process is also summarized in Figure 4-14.

Table 4-29. Authentication Process Error Handling

Error	Handling
Authentication Failure	Retry for 5 times and if error still persists then enter wait boot

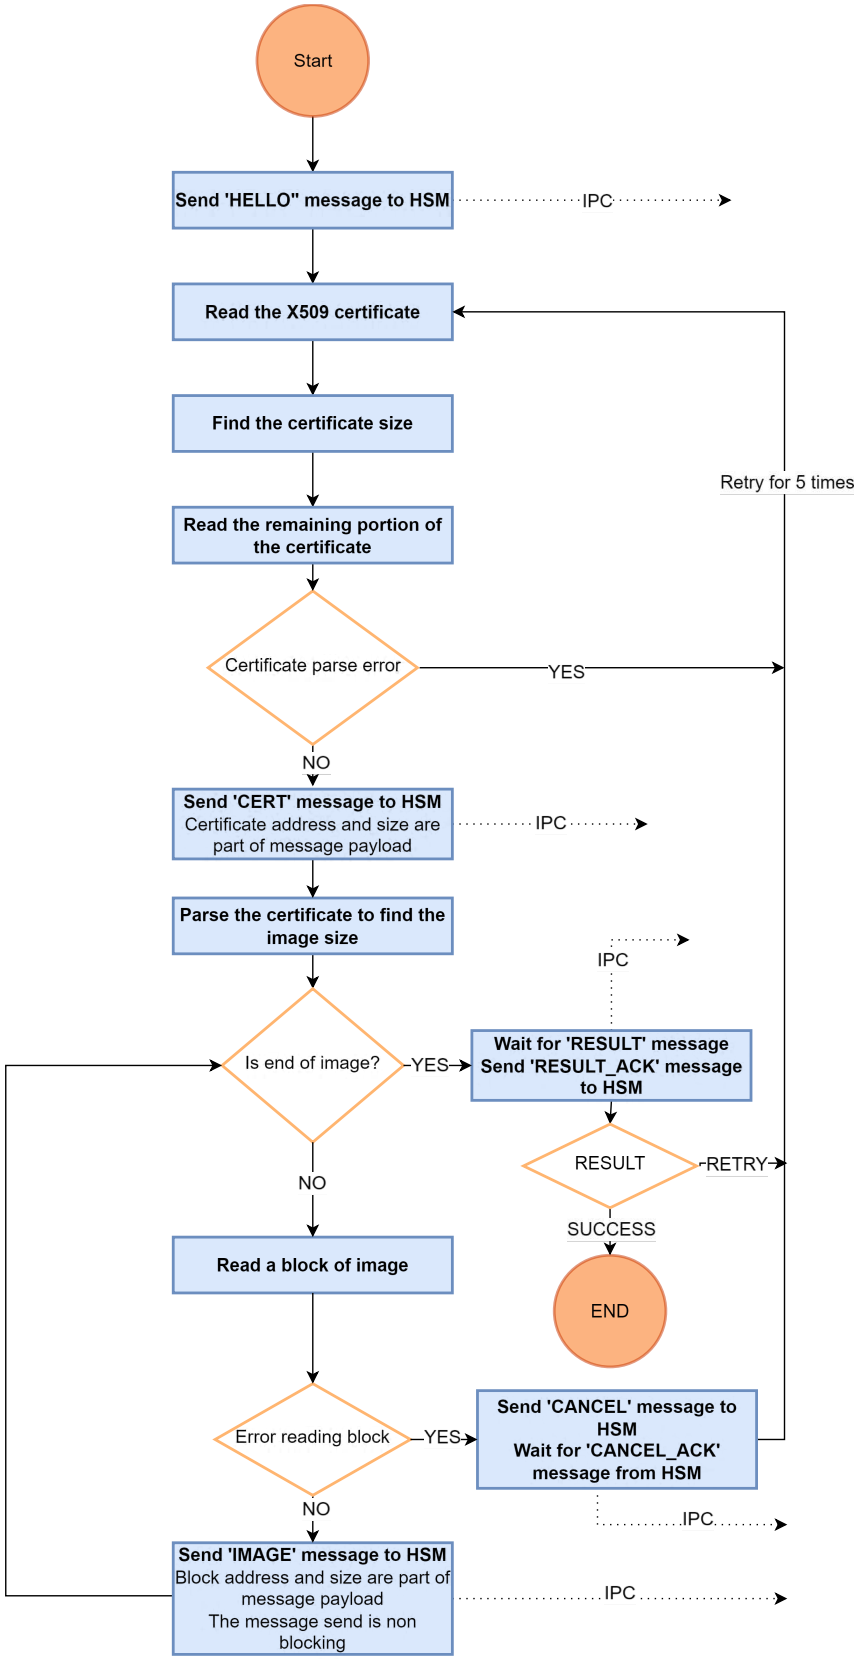

Figure 4-14. Image Authentication by HSM

4.7.9 Boot Status Information

Boot ROM keeps a record of the various actions and events that occur during boot ROM execution. The reason for this is because NMI and other exceptions are enabled by default in the device and must be handled accordingly. Boot ROM stores the boot status information in a RAM location so that the user application can read this boot status and take the necessary actions per application's needs to handle these events.

4.7.9.1 Booting Status

Boot ROM health and booting status for CPU1 is written to a 32-bit address in the respective M0 RAM. This status is cleared on a POR or XRS reset. The previous status is retained on any other reset. For example, clear the status before performing a debugger device reset to view the latest boot ROM actions reflected in the status.

Table 4-30. Boot Information Parameters Address

Parameter	Address	Description

4.8.1 BOOT Examples

NOTE: These examples are located in the C2000Ware installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/boot

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

Chapter 5

Lockstep Compare Module (LCM)

This chapter describes the Lockstep Compare Module (LCM).

5.1 Introduction

Hardware module integrity during run-time is a critical functional safety requirement. Hardware Redundancy implemented by the lockstep CPU architecture (two CPUs executing the same function and the output of the CPUs are continuously compared) is a proven method for achieving high diagnostic coverage for both permanent and transient faults. The Lockstep Comparator Module (LCM) is implemented to compare output from the CPU to detect permanent and transient faults.

5.1.1 Features

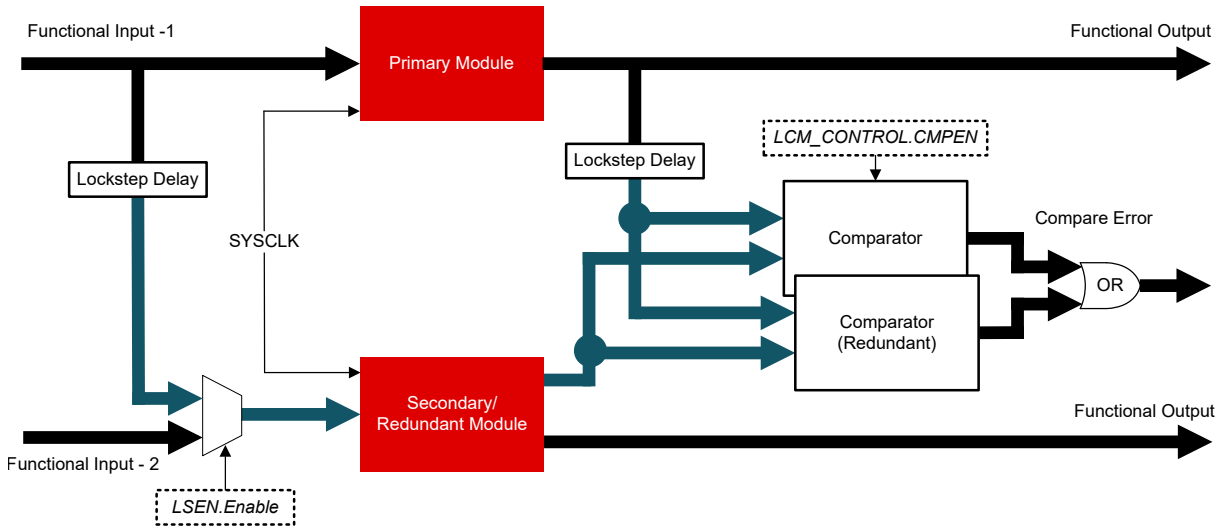
The LCM implements the following features:

- Pipelined architecture
- Redundant comparison
- Self-test capability
  - Match and mismatch test
  - Error forcing capability
- Temporal redundancy: The operation of the two modules is skewed by two cycles to address the issue of common cause failures like failure of clock, power, and so on. This makes sure of temporal redundancy.
- Spatial redundancy: In the lockstep architecture, module instances are redundantly instantiated and the outputs are compared. Redundant instantiation provides spatial redundancy.
- Non-delayed functional output path to provide non-delayed CPU execution for the system (while still having temporal redundancy).
- Register protection of critical memory mapped registers of the module, using a parity scheme.

5.1.2 Block Diagram

Figure 5-1 shows the LCM block diagram.

Figure 5-1. LCM Block Diagram



Note

The *Module* described in this block diagram can be either a CPU (for example, CPU1) or a peripheral (for example, RTDMA) depending on availability for the device.

5.1.3 Lockstep Compare Modules

Following modules are supported with Lockstep comparison feature in this device :

1. CPU1 in lockstep with CPU2
2. CPU1 PIPE in lockstep with CPU2 PIPE
3. RTDMA1 in lockstep with RTDMA2
4. CPU1 Timers (0, 1, and 2) in lockstep with CPU2 Timers (0, 1, and 2)
5. CPU1 ERAD and DLT in lockstep with CPU2 ERAD and DLT, respectively

DEV_CFG_REGS[LSEN] register controls lockstep enable/disable for all the modules that are mentioned above, which means either all of them operate as lockstep or split-lock (operating as independent modules).

Table 5-1. Lockstep versus Split-Lock Configurations

Configuration Type	DEV_CFG_REGS[LSEN] Default : 1	LCM_CONTROL_REGS[CMPEN] Default : 0
Lock-Step	1	1
Split-Lock (Modules operating independently)	0	Not Applicable

5.2 Enabling LCM Comparators

Note

The redundant module is automatically enabled at boot.

To enable the LCM comparators upon device startup or after reset, perform the following steps at the beginning of the user application code:

1. Lock the LSEN configuration using the following bit:
   - DEV_CFG_REGS[DEVCFGLOCK2.LSEN = 1]
2. Enable the comparator for the desired modules using the following bit:
   - LCM_REGS[LCM_CONTROL.CMPEN = 1]
   - Lockstep compare begins the immediate next cycle.

   Note: The lockstep comparison is enabled by this write and cannot be disabled again without a reset.

5.3 LCM Redundant Module Configuration

In systems that do not require the redundant module output for comparison in functional safety requirements, the LCM redundant module can be used for functional output. To change the LCM comparators configuration upon device startup or after reset, the following steps must be taken at the beginning of the user application code:

1. Disable the redundant module using the following bit:
   - DEV_CFG_REGS[LSEN.Enable = 0]

   Note: The redundant lockstep module is supplied with a functional input and the comparison must also be disabled at this time. The configuration cannot be altered without a reset.
2. (Optional) Lock the LSEN configuration using the following bit:
   - DEV_CFG_REGS[DEVCFGLOCK2.LSEN = 1]

5.4 LCM Error Handling

Upon an error generated by the LCM module, an error event input is sent to the error signaling module (ESM). The ESM can be configured to take appropriate action that includes error status pin indication, generation of an interrupt or NMI to the CPU. The LCM error can be triggered by any of the following:

- Functional failure: LCM detecting an error (functional failure between the two modules).
- Self-test failure: LCM self-test failure detected (functional failure on one or both of the modules).
- Force Compare Error Request: Running LCM_CONTROL.CMPx_ERR_FORCE to force a compare error.

To determine the specific cause of the LCM error-induced NMI, the LCM_STATUS register bits can be read. Particularly:

- CMP_FAIL
- STPASS
- CMPx_ERR_FORCE_PASS
- CMPx_ERR_FORCE_DONE

For details on system-level NMIs vector locations and interrupt-handling, see Chapter 6.

5.5 Debug Mode with LCM

Lockstep comparison is disabled automatically during debug/emulation mode of the device. However, some items are still available when a debugger is connected:

- Code can continue to be debugged even though lockstep compare is disabled with a debugger connection.
- Self-test logic (match test and mismatch test) is still accessible with debugger connected.
- Clock and inputs to the secondary module are not impacted, and continue to get delayed clock and delayed inputs.

The status of the debugger connection is readable from the status register, specifically the LCM_REGS[LCM_STATUS.DBGCON] bit.

To re-initialize the lockstep compare module (after debugger is disconnected), a reset is required. This reset is called using a system reset requested from the debugger which in turn generates an XRSn in the device.

5.6 Register Parity Error Protection

The following critical LCM registers are protected by a parity scheme:

- LCM_CONTROL
- LCM_STATUS
- LCM_LOCK
- LCM_COMMIT

The parity scheme provides one parity bit per byte of data in the corresponding registers. Updates to any of the constantly-monitored registers causes an update to the parity bit. A single bit fault can therefore immediately flag an error. If the parity check determines a parity error has occurred, a dedicated error output line from the LCM module flags an error to the system.

All register parity errors (from the LCM) are sent as error inputs to the ESM module, refer to Chapter 7 for more details.

Upon a parity error detection, SYSRSN must be asserted and the LCM_REGS[LCM_STATUS_CLEAR] register must then be cleared using the a write of 1 to all appropriate bits in the register.

Details on the self-test capability of the register parity error test are explained in Section 5.7.3.

5.7 Functional Logic

This section describes the various logical blocks within the LCM that contribute to the goal of improved diagnostic coverage.

5.7.1 Comparator Logic

To implement lockstep scheme, a comparator block is needed. The comparator block compares the delayed version of relevant outputs of the primary module and the equivalent outputs of the secondary (redundant) module. This provides immunity towards the common cause failures like loss of power, clock failures, etc.

The LCM has two instantiations of the comparator block to provide redundancy of the comparator block. This enables availability of one comparator block during self-test of the other comparator block and also provides additional failure protection capability for the comparator logic.

Although the lockstep secondary (redundant) module is enabled upon startup, lockstep comparison must be enabled in software.

Once lockstep compare is enabled in software, the comparison is performed continuously every cycle, from the immediate next cycle. Any difference between the primary and secondary modules generates an error signal from the LCM to the SoC. The corresponding register bit is also set (LCM_STATUS.CMP_FAIL).

CPU reset (or any higher-level resets) disables the lockstep comparators, requiring re-enabling of the comparator in software.

5.7.2 Self-Test Logic

The self-test of the comparator has two different modes:

- Match Test
- Mismatch Test

These two tests are run together. Self-test is initiated by setting the appropriate register bit (LCM_CONTROL.STEN). When the self-test is initiated, the two different modes are executed on the two comparators one after the other. A self-test error also triggers error to ESM which can be configured to generate an NMI.

Redundant instantiation of the comparator block allows for one instantiation to be conducting a self-test while the other instantiation is active and performing the comparison check.

Self-test can also be performed before the comparator block is enabled in software.

Execution of the self-test is stopped immediately on failure. If either comparator fails the self-test, a status bit (LCM_STATUS.STPASS) is 0 instead of being set to 1.

During self-test, the LCM_STATUS.STACTIVE bit has a value of 1. Another self-test or compare error force must not be started until completion of the self-test, as indicated by LCM_STATUS.STDONE = 1.

The following subsections describe functionality of each of the individual test modes, Mismatch Test and Match Test.

5.7.2.1 Match Test Mode

The match test mode checks to make sure identical inputs on each comparator provide passing outputs. This makes sure that the comparator inputs and comparators themselves are working correctly and that a fault is successfully propagated to the module output.

This test is executed using two different patterns fed to the two inputs of each comparator (bit) in the comparator block: {0,0} and {1,1}. Both inputs can provide a passing output to the comparator since both patterns are providing identical inputs to both inputs of the comparator. This tests output-stuck-at-one, input-stuck-at-one, and input-stuck-at-zero issues. Table 5-2 shows the test execution sequence for a single comparator in the comparator block.

Table 5-2. Match Test Simplified Example

Clock Cycle	A Input (Primary Module) of Comparator	B Input (Secondary Module) of Comparator	Output
0	0	0	0
1	1	1	0

5.7.2.2 Mismatch Test Mode

The mismatch test mode creates an error output of 1 on each individual comparator (bit) within the comparator block, one at a time. This makes sure that all comparators in the block are working correctly and that a fault is successfully propagated to the module output.

This test is executed using a walking 1s pattern to test for output-stuck-at-zero issues. The walking 1s pattern is where all comparators in the comparator block are zero except for one of the comparators.

For example, the primary module has a 1 at the spot that the secondary module has a 0. This can force an intentional error.

This is repeated for every comparator in the block, with the 1 being set on both modules. The passing scenario for this is that all comparators see a mismatch, flagging a mismatch each iteration. See Figure 5-2 for a simplified illustration of how this is implemented for a comparator block with 8 comparators (not the number used in the actual design).

	Secondary Module Signal								Primary Module Signal								
Cycle #	7 (n)	6	5	4	3	2	1	0	7 (n)	6	5	4	3	2	1	0	Output
0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1
1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1

15 (2n)	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Figure 5-2. Mismatch Test Simplified Example

5.7.3 Error Injection Tests

There are two error injection tests available for the LCM:

- Comparator Error Force Test
- Register Parity Error Injection Test

Each error injection test is run individually, as described in the following subsections.

5.7.3.1 Comparator Error Force Test

The LCM has the capability to force a fault to check the error signaling path between the LCM and ESM at the device level (for example, generate NMI, indicate error on ERRORSTS pin or trigger reset.) This test is executed separately from the self-test, and is executed on the primary and redundant comparators individually through separate calls.

Note

- The lockstep comparator must be enabled to execute this test.
- Once this self-test is triggered, another self-test or compare error force request must not be triggered again until the current test is completed, as indicated by LCM_STATUS.STDONE == 1.

Execution of this self-test is started by setting the appropriate bit: LCM_CONTROL.CMPx_ERR_FORCE, where x is the number designator of the redundant comparator to be tested.

Upon execution of this one-cycle-long test, the LCM asserts a lockstep comparison error signal to the device. The normal functional compare fail flag (LCM_STATUS.CMP_FAIL) is not set by this test mode.

The following bits are set by the test:

- LCM_STATUS register:
  - CMPx_ERR_FORCE_DONE bit - 1 when the test is completed.
    - This bit must be cleared before running the test again for comparator "x".
  - CMPx_ERR_FORCE_PASS bit - 1 when the test passes.
    - This bit must be cleared before running the test again for comparator "x".

Because the test can trigger an NMI if configured in ESM on a test pass, the "DONE" flag allows the cause to be determined by either a functional fail or an error forcing test fail.

5.7.3.2 Register Parity Error Test

An error can be injected into the register parity error protection that exists for critical LCM registers, to test for latent faults. This error is inserted by forcing a particular byte to output a failing parity state to the system.

The test can be executed by running setting the LCM_REGS[PARITY_TEST.TESTEN] bits to the appropriate value.

Once the TESTEN register bits are set, the actual registers are no longer accessible in the memory map. Instead, the one bit parity error status values are accessible for every byte in the registers. Parity is computed for every byte, and the corresponding parity pass/fail value is available at the bit 0 location of every byte, in-place. A 0 in the bit 0 location corresponds to a pass; a 1 in the bit 0 location corresponds to a fail.

To actually inject an error, the value 1 can then be written to the bit 0 location of any byte. This inverts the stored parity value, and therefore inject an error into the parity test mechanism. Note that this propagates like an actual parity error in ESM and handled accordingly.

This section describes the LCM Registers.

5.9.1 LCM Base Address Table

Table 5-4. LCM Base Address Table

Structure	DriverLib Name	Base Address	Frame Applicable	CPU1	CPU2	CPU3	RTDMA1	RTDMA2	HSM	Pipeline Protected
LCM_REGS [1]	LCM_CPU_BASE	0x3003_2000	-	YES	-	-	-	-	-	YES
LCM_REGS [1]	LCM_DMA_BASE	0x301F_4000	-	YES	YES	YES	-	-	YES	YES

(1) Registers writeable by CPU1.LINK0, CPU1.LINK1, CPU1.LINK2 only. All CPUs can read all registers in all LINKs. Debug write access only allowed if Zone0 or Zone1 are enabled for full debug by all CPUs. Debug reads always allowed. Register Read/Write access by HSM.

5.9.2 LCM_REGS Registers

Table 5-5 lists the memory-mapped registers for the LCM_REGS registers. All register offset addresses not listed in Table 5-5 should be considered as reserved locations and the register contents should not be modified.

Table 5-5. LCM_REGS Registers

Offset	Acronym	Register Name	Protection
0h	REVISION	IP Revision tie-off value	
8h	LCM_CONTROL	LCM Control configuration	PARITY
20h	LCM_STATUS	LCM status register	PARITY
28h	LCM_STATUS_CLEAR	LCM Status clear register	
68h	PARITY_TEST	Enabling the parity test feature	
70h	LCM_LOCK	LCM lock configuration	PARITY
78h	LCM_COMMIT	LCM commit configuration	PARITY

Complex bit access types are encoded to fit into small table cells. Table 5-6 shows the codes that are used for access types in this section.

Table 5-6. LCM_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

5.9.2.1 REVISION Register (Offset = 0h) [Reset = 40000000h]

REVISION is shown in Figure 5-3 and described in Table 5-7.

Return to the Summary Table.

Chapter 6

Peripheral Interrupt Priority and Expansion (PIPE)

This chapter describes the peripheral interrupt priority and expansion (PIPE) module. The PIPE module controls peripheral interrupt handling on the device.

6.1 Introduction

Each PIPE module instance arbitrates peripheral interrupts for the respective CPU. All asserted interrupts are arbitrated each clock cycle, with the highest priority interrupt asserted to the corresponding CPU interrupt line (NMI, RTINT, or INT). The PIPE module is responsible for providing vector addresses to the CPU for NMI, RTINT, INT and RESET. The PIPE is capable of custom ordering of interrupts, prioritization, and nesting.

6.1.1 Features

The PIPE module has the following features:

- Hardware support for interrupt prioritization, arbitration, grouping, software hand-shake, and nesting.
- Dynamic arbitration of interrupts in hardware on every clock.
- Selectable priority level to choose interrupts as either RTINT and INT.
- Interrupt grouping of adjacent-prioritized interrupts to block nesting within groups.
- Default index-based priority order for interrupts used in arbitration.
- Vector fetch support for RESET, NMI, RTINT, and INT.
- User access to the stack configured for INT.
- Contexts used by a software task manager system or operating system.
- Link-based protection verifies only legal code from the assigned interrupt owner services the interrupt.
- Device level protection validates only legal code source updates interrupt configuration and vector tables.
- Automatic context save and restore for RTINT and NMI.
- RTINT stack overflow protection always provides NMI a block of reserved stack space for execution.
- ECC protection for interrupt vector table.
- Parity protection for configuration registers.
- Optional locking capability of interrupt configurations.

6.1.2 Interrupt Concepts

An interrupt is a signal that causes the CPU to pause the currently running process and branch to a different piece of code known as an interrupt service routine (ISR). This is a useful mechanism for handling peripheral events, and involves less CPU overhead and program complexity than register polling. However, because interrupts are asynchronous to the program flow, care must be taken to avoid conflicts over resources that are accessed both in interrupts and in the main program code.

Interrupts propagate to the CPU through a series of flag and enable registers. The flag registers store the interrupt until the interrupt is processed. The enable registers allow or block the propagation of the interrupt. When an interrupt signal reaches the CPU, the CPU fetches the appropriate ISR address from the vector table.

6.1.3 PIPE Related Collateral

Foundational Materials

- C29x Academy - Interrupts

6.2 Interrupt Architecture

The PIPE module has three primary functional blocks:

1. Dynamic Priority Arbitration Circuit
2. Post Processing Block
3. Memory-Mapped Registers (includes vector table and bus interface)

These three blocks are explained in detail in the following subsections.

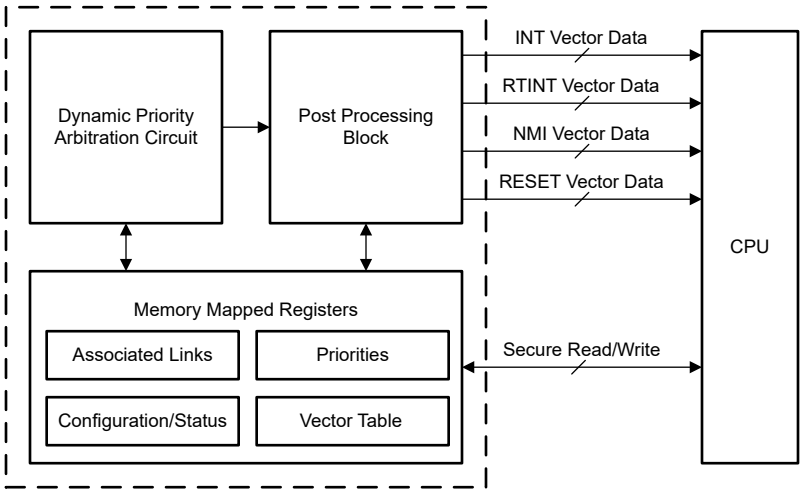

Figure 6-1. PIPE Architecture

6.2.1 Dynamic Priority Arbitration Block

The dynamic priority arbitration block provides the CPU with the highest priority interrupt vector that is available every clock cycle. The CPU processes the highest priority interrupt at the provided vector address.

6.2.2 Post Processing Block

The post processing block takes the highest priority interrupt that won the arbitration process and selects which interrupt line (INT or RTINT) to forward the interrupt to. The post processing block also automatically checks which link is accessing an interrupt line and whether a secure link is accessing protected registers.

Note

The NMI line provided to the CPU is an independent line that overrides any other interrupt (INT or RTINT) ready for assertion.

6.2.3 Memory-Mapped Registers

The memory-mapped registers (MMR) contain the interrupt configuration registers. Below are the type of registers available in the memory-mapped registers:

- Link associated with each interrupt.
- Priority configured for each interrupt.
- Interrupt configurations.
- Interrupt status.
- Vector table.

Accesses are controlled by the same security rules that apply to all registers.

6.3 Interrupt Propagation

Interrupts propagate to the CPU through several steps. Peripheral interrupts set the corresponding FLAG bit in the INT_CTL_REG_L_y register of a given interrupt. If the EN bit of the interrupt's INT_CTL_REG_L_y register is set, the interrupt propagates to the dynamic priority arbitration circuit. Next, the dynamic priority arbitration block and post processing block arbitrate the highest priority interrupt and assert this to the CPU on one of the two interrupt lines (RTINT or INT). Finally, the CPU chooses the highest priority interrupt line that is asserted (amongst NMI, RTINT, and INT) and begins execution of that interrupt.

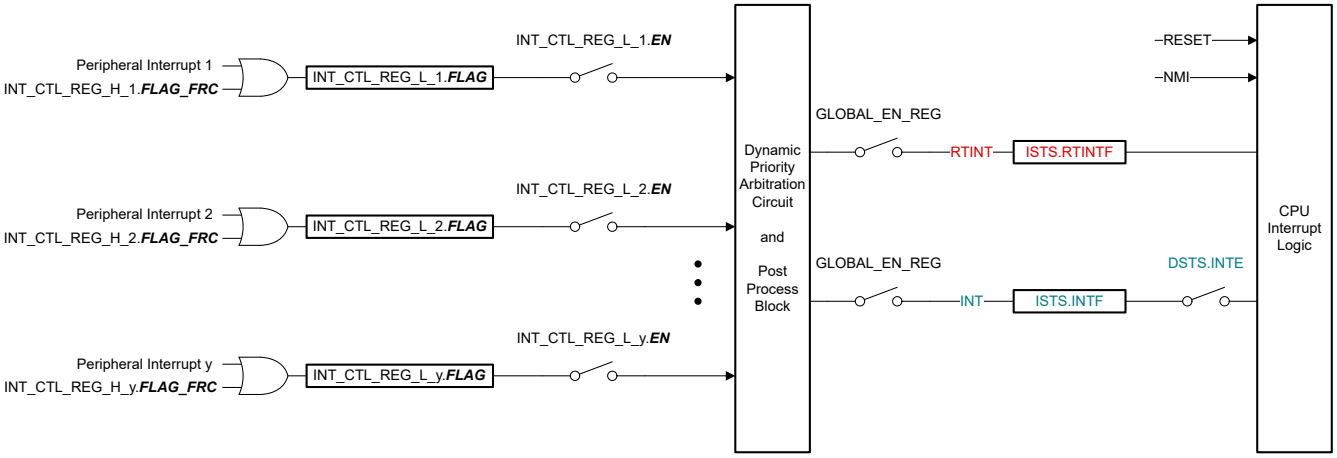

Figure 6-2. Interrupt Propagation

Note

NMI is an independent line that overrides any other interrupts ready for assertion. An NMI event asserted to PIPE is forwarded to the CPU, including NMI in service. CPU can select a new NMI at any time, but the PIPE module does not forward the new NMI until the in-service NMI interrupt service routine is complete.

The same rule is applicable to RESET. Once the CPU receives the RESET, there are no conditions to meet before reset assertion to CPU.

6.4 Configuring Interrupts

At power-up, all interrupts return to the default reset conditions:

- All interrupts are disabled.
- All interrupts are set to the default priority (INT_CONFIG.PRI_LEVEL).
- All interrupts are set to the default context (INT_CONFIG.CONTEXT_ID).
- All interrupts are assigned as INT by default (RTINT_THRESHOLD.INT_RTINT_THRESHOLD).
- All interrupt vectors point to the default NMI vector (INT_VECT_ADDR.*).
- Stack pointer warning levels are reset to default values (RTINT_SP_H.*).
- All interrupt owner and API links are set to a default link (INT_LINK_OWNER.*). The user needs to update the link to SROOT_LINK (LINK2) to be able to configure the PIPE even when SSU is in Mode 1.

Interrupts are configured as follows:

1. **Disable INT and RTINT:** Disable INT and RTINT using the GLOBAL_EN.ENABLE/KEY fields.
2. **Prioritization:** Set the interrupt priority as required.
3. **Nesting:** Set the group as required.
4. **Context:** Set the context ID as required.
5. **Stack protection:** Set stack pointer warning levels (RTINT_SP_H.*) as required.
6. **Enabling interrupts:** Enable required interrupts using INT_CTL_L_y.EN bit for each interrupt.
7. **Enabling INT and RTINT:** Enable INT and RTINT using the GLOBAL_EN.ENABLE/KEY bits.

Note

Enables/disables must be done within an ATOMIC block for predictable CPU behavior

Interrupts can be re-configured while GLOBAL_EN is enabled. However, interrupts that have already been forwarded from the PIPE to the CPU and have reached the CPU, being serviced, or are nested-in are not affected by any re-configuration changes. These settings do not apply until the next interrupt is forwarded from the PIPE to the CPU.

6.4.1 Enabling and Disabling Interrupts

Individual interrupts can be enabled first, using the INT_CTL_L.EN register bit. Once the desired interrupts are enabled at the peripheral level coming into PIPE, the user can then enable the PIPE module to begin forwarding interrupts to the CPU.

To enable the PIPE to forward INT and RTINT interrupts to the CPU, GLOBAL_EN.ENABLE/KEY bits must be set properly. See the register description for GLOBAL_EN register for values required for enabling the PIPE forwarding.

When disabling interrupts, caution must be taken to avoid unexpected interrupts from occurring. The steps below must be taken when disabling one or more interrupts.

1. Global disable PIPE interrupts (GLOBAL_EN.ENABLE).
2. Disable the individual interrupts desired (INT_CTL_L.EN).
3. Wait 6 cycles for any ongoing arbitration to complete.
4. Global enable PIPE interrupts (GLOBAL_EN disable).

Note

In this chapter, references to the global enable are referring to the GLOBAL_EN within the PIPE module which is different than the DSTS.INTE within the CPU that is needed to propagate INTs to the CPU.

6.4.2 Prioritization

The PIPE arbitrates incoming interrupts based on interrupt priority, with the lowest value being the highest priority. Priority is determined for each interrupt using two different values:

1. User-configured interrupt priority.
2. Index-based fixed interrupt priority.

6.4.2.1 User-Configured Interrupt Priority

User-configured interrupt priority is configured in software through the INT_CONFIG.PRI_LEVEL field that exists for every interrupt. The lower the PRI_LEVEL, the higher the priority of the interrupt. For example, an interrupt with PRI_LEVEL = 0 is serviced before an interrupt with PRI_LEVEL = 1 if both arrive at the same time.

When multiple interrupts are configured to the same PRI_LEVEL, the interrupts with the same PRI_LEVEL use the index-based fixed interrupt priority to determine the highest priority interrupt.

Note

By default every interrupt is configured to the highest PRI_LEVEL value (lowest priority). Therefore, all interrupts use index-based fixed interrupt priority by default.

6.4.2.2 Index-Based Fixed Interrupt Priority

The input number at which a particular interrupt is connected to the PIPE is called the "interrupt index". This is the index-based fixed interrupt priority that is fixed per device. This is also the indexing used to configure the interrupts in the PIPE.

For example, the INT_CONFIG register is repeated for every interrupt, and is indexed as INT_CONFIG_y (where y is the index of each interrupt).

Table 6-1 shows the "interrupt index" for all peripheral interrupt channels on this device.

This recommended interrupt handling process can be followed for level interrupts to avoid unnecessary interrupts getting triggered:

1. Enter ISR.
2. Perform ISR functions.
3. Clear interrupt status within peripheral.
4. Wait for peripheral interrupt status to get cleared using NOPs or poll for interrupt flag status to get cleared.
5. Write to INT_{#}_CTL_REG_H.FLAG_CLR to clear the INT_{#}_CTL_REG_L.FLAG in software.
6. Wait for the PIPE flag to get cleared by writing 7 NOPs.
7. Exit ISR.
8. Clear interrupt within peripheral.

6.4.3 Nesting and Priority Grouping

Interrupt Nesting

By default, nesting is supported at the hardware level in the C29x CPU. The PIPE module allows for interrupt types RTINT and INT to nest within one another. A higher priority interrupt nests within a lower priority interrupt. Nesting for INTs within the PIPE module is enabled within a Interrupt Service Routine (ISR) by setting the CPU level DSTS.INTE bit active because this bit is disabled while entering the ISR.

Grouping Interrupts Based on Priority Levels

The PIPE also allows for interrupts to prevent nesting within other interrupts using "groups". Interrupts in a given group do not preempt or nest within other interrupts in the group.

To form a group, the least significant bits of the priority (INT_CONFIG.PRI_LEVEL) are used to choose which interrupts are in the same group. The number of least significant bits of the INT_CONFIG.PRI_LEVEL that is used for grouping interrupts is also configurable (masked using the INT_GRP_MASK register) in binary multiples (ex: 2, 4, 8, 16). Groups are made up of interrupts that are near one another in configured priority levels.

Note

The RTINT_THRESHOLD needs to be aligned with the configured group mask to maintain proper RTINT behavior. The PIPE module first groups the interrupts and then processes them to be RTINT or INT. In other words, grouping takes priority over RTINT resolution based on the threshold value.

For example when this above note is not followed, some group includes both priority levels INT_7 and INT_29 and the RTINT_THRESHOLD is set to 10. If the CPU was servicing INT_29 (INT) and INT_7 comes (RTINT), irrespective of the RTINT threshold, INT_7 is not forwarded on RTINT/INT lines.

The group mask combinations possible are outlined in Table 6-2. Any other group mask chosen for INT_GRP_MASK that is not listed in Table 6-2 results in using the default group mask of 0xFF where all interrupts can nest.

Table 6-2. Group Mask Combinations

Group Mask	Group Size	Number of Groups	Priority Assignment Distance	Comment
0xFF/Other	1	256	1	0xFF: All interrupts can nest in one another. All interrupt levels are in individual groups, so 256 configurable priorities are available with 1 interrupt level in each. All other values: If any other value is used, the mask value defaults to 0xFF that correlates to no group mask.
0xFE	2	128	2	128 priority groups with 2 interrupt levels in each; hence, the number of priorities reduce to 128 for preemption.
0xFC	4	64	4	64 priority groups with 4 interrupt levels in each; hence, the number of priorities reduce to 64 for preemption.
0xF8	8	32	8	32 priority groups with 8 interrupt levels in each; hence, the number of priorities reduce to 32 for preemption.
0xF0	16	16	16	16 priority groups with 16 interrupt levels in each; hence, the number of priorities reduce to 16 for preemption.
0xE0	32	8	32	8 priority groups with 32 interrupt levels in each; hence, the number of priorities reduce to 8 for preemption.
0xC0	64	4	64	4 priority groups with 64 interrupt levels in each; hence, the number of priorities reduce to 4 for preemption.
0x80	128	2	128	2 priority groups with 128 interrupt levels in each; hence, the number of priorities reduce to 2 for preemption.

Table 6-2. Group Mask Combinations (continued)

Group Mask	Group Size	Number of Groups	Priority Assignment Distance	Comment
0x00	256	1	256	No interrupts can nest in one another. All interrupts are in one group, so configurable priorities are used for the highest priority interrupt. There is no nesting of interrupt priority levels regardless of INT or RTINT status.

For example, in the case of an interrupt with priority level 13, this interrupt can belong to different groups depending on the group mask: 0xFF: Group 14, 0xFC: Group 11, 0xFC: Group 4, and so on.

Figure 6-3 illustrates one example of how grouping allows interrupts to nest, and is shown with PRI_LEVEL 0 to 7 set and group sizes selected as shown. In this example, no two interrupts have the same interrupt priority level configurations.

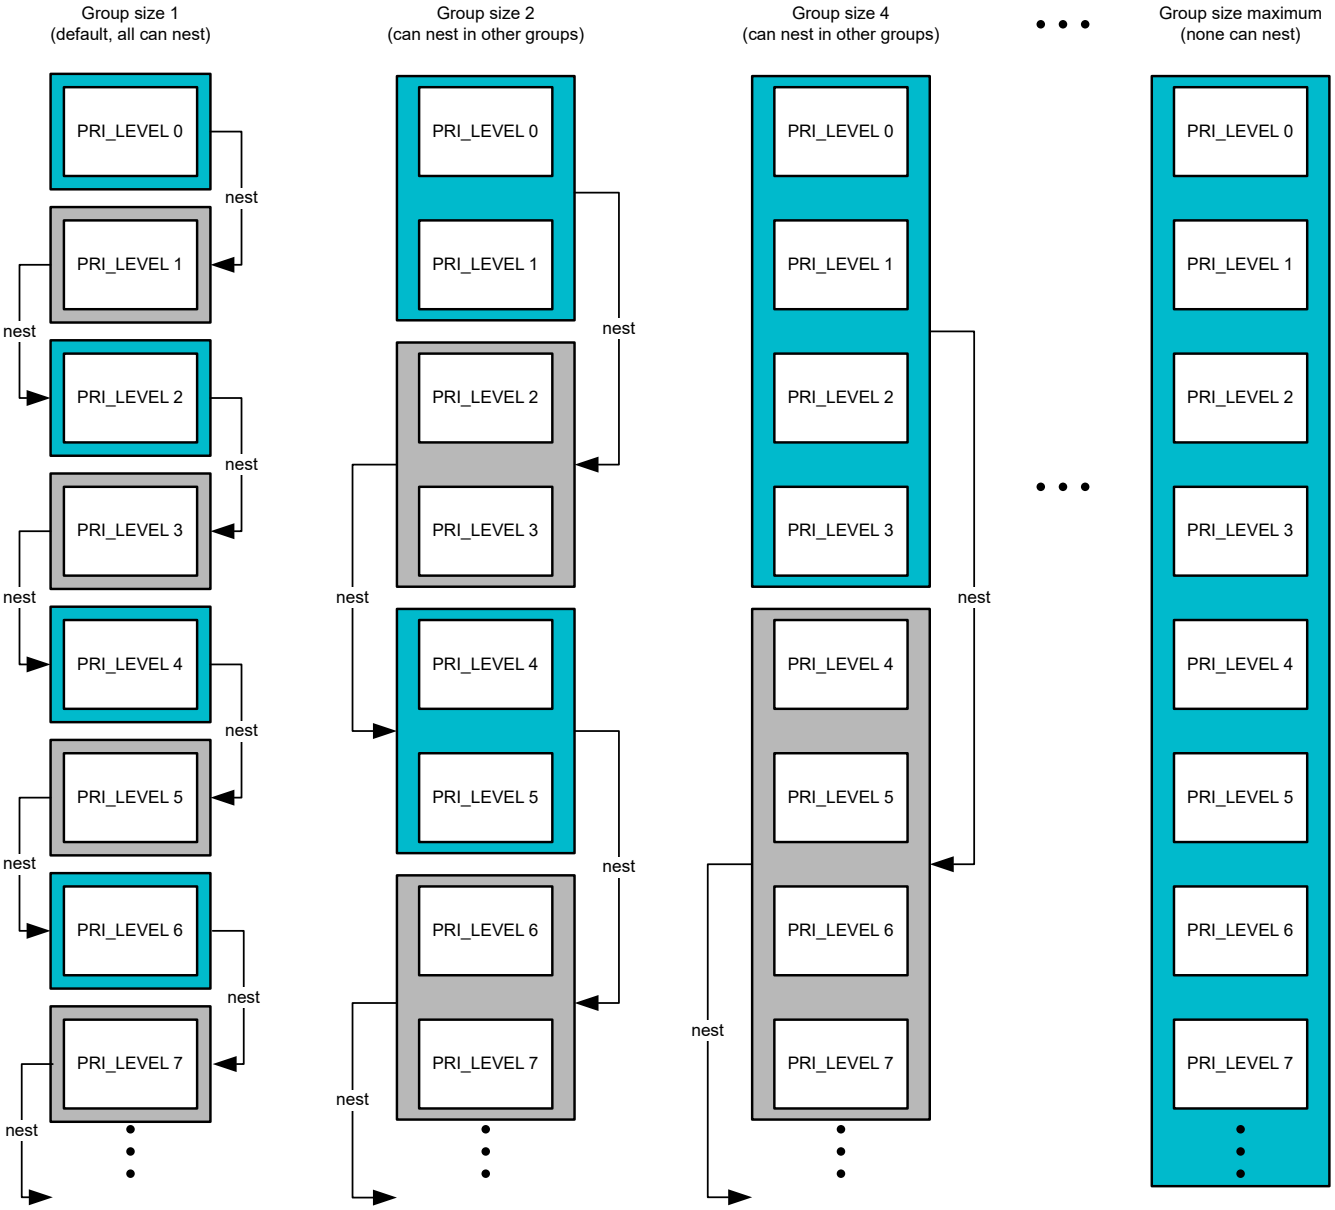

Figure 6-3. Interrupt Grouping

6.4.4 Stack Protection

INT uses the software stack that is configured in the INTSP register. The INT stack has no hardware stack overflow protection. Software can be used to implement a software stack overflow protection scheme for the INT stack as required.

RTINT and NMI use the RTINT stack which is a dedicated hardware stack used for RTINT and NMI context save and restore.

Context save for RTINT and NMI executes the following in hardware automatically upon ISR entry:

- Increment RTISP (interrupt stack pointer for RTINT stack).
- Transfer all CPU registers to RTINT stack.
- Clear CPU registers before ISR start.

Context restore for RTINT and NMI executes the following in hardware automatically upon ISR exit:

- Copy all CPU registers back from RTINT stack.
- Decrement RTISP.

To avoid excessive nesting of the RTINT stack leading to stack overflow, the CPU tracks the level of nesting on RTINT and outputs this information to the PIPE.

WARNRTISP

The first line of defense against stack overflow is the user-configurable RTINT_SP_H.WARNRTISP register field. The number of stack blocks used by the RTINT stack (counted by RTISP) is compared to the level configured in RTINT_SP_H.WARNRTISP. If RTISP is greater than or equal to RTINT_SP_H.WARNRTISP, the PIPE changes which interrupts are allowed to be asserted: only interrupts with a priority level higher than the user-configured RTINT_SP_H.WARNRTISP_PRIO_LEVEL are allowed. This can be summarized using the pseudo-code below.

```
if(RTISP >= RTINT_SP_H.WARNRTISP){
    Only allow RTINT with INT_CONFIG.PRI_LEVEL < RTINT_SP_H.WARNRTISP_PRIO_LEVEL
}
else{
    Allow all RTINT.
}
```

The status of whether or not RTISP level has reached the user-configured WARNRTISP level is located in the RTISP_STS.WARNRTISP_STS field.

Note

WARNRTISP must not be configured as 0 to avoid immediately firing an error on a register write.

WARNRTISP must not be configured as 1 to avoid firing an error to the ESM on the first RTINT occurrence. However, there is no impact if the user is not utilizing and/or expecting any RTINT.

MAXRTISP

When RTISP = MAXRTISP, all RTINT stack space has been exhausted except for one stack slot which is used by a NMI to alert the CPU of the overflow. When this condition is true, the PIPE does the following:

- Stops asserting any and all new RTINTs to the CPU.
- Raises a fault to the Error Signaling Module (ESM).
- Sets this max breach status in RTISP_STS.MAXRTISP_STS.

The MAXRTISP puts the CPU in a fault state, and the ESM responds to the PIPE fault assertion by raising an NMI back to the PIPE. However, PIPE does not allow any other NMIs to nest within this NMI. PIPE only allows further RTINTs to execute once the second-to-last stack slot is available again in the RTINT stack. A system reset is required to recover the device from fault.

6.4.5 Context

PIPE allows interrupts to be grouped into "contexts". These contexts can be used by a software task manager system or operating system to switch between multiple execution contexts.

Each interrupt is configured with a CONTEXT_ID (INT_CONFIG.CONTEXT_ID) that determines which context the interrupt is in. By default, all interrupts are assigned the same CONTEXT_ID.

The PIPE can then be configured to only arbitrate interrupts whose context matches the "active context". Active context is selected by setting the TASK_CTRL.ACTIVE_CONTEXT_ID field.

Any updates to INT_CONFIG.CONTEXT_ID and TASK_CTRL.ACTIVE_CONTEXT_ID take place on the next arbitration cycle.

Changing the active context or context ID does not stop accumulation of interrupt events that are out of context. This only disables interrupt participation in arbitration.

Note

GLOBAL_EN.ENABLE must be disabled before changing TASK_CTRL.ACTIVE_CONTEXT_ID. This is done to avoid disrupting the priority arbitration as some interrupts can become disabled and out of arbitration and others can be enabled and join arbitration.

Once TASK_CTRL.ACTIVE_CONTEXT_ID is modified, software must wait at least 6 system clock cycles for arbitration to complete before re-enabling GLOBAL_EN.ENABLE.

6.5 Safety and Security

The PIPE has protection mechanisms to provide safety and security for the interrupt architecture.

6.5.1 Access Control

Access privileges for vector table and registers are explained in Table 6-3.

Table 6-3. Access Privileges

Access Privilege	Accessing Link	Reason	Check if PIPE matches CPU settings
OWNER_LINK	Owner link of interrupt line	Only the OWNER_LINK of the particular interrupt line is allowed to update or read the operational registers such as flag RD/SET/CLR, status RD, and so on.	CURRLINK=OWNER_LINK
API_LINK	API link of interrupt line when called by OWNER_LINK.	Common-code link access is allowed when API_LINK is enabled. This is needed as often times, the codes to update the PIPE in ISR are based on common-code link used across different interrupts.	CURRLINK=API_LINK && API_LINK_EN='1' && CLINK=OWNER_LINK
SROOT_LINK	Secure Root Link (LINK2)	SROOT_LINK is the most trusted secure code with access to all the PIPE registers to configure interrupts and handle exceptions beyond the regular ISR.	CURRLINK=SROOT_LINK
BOOT_LINK	Boot link (LINK1) access for interrupt handling during boot and boot loading.	BOOT_LINK needs access to configure PIPE and handle peripheral interrupts during boot process. As user code has not started yet, this access is for a short period. Access is granted as long the BOOT_LINK_LOCK is not set. Once the boot process is over, either the BOOT_LINK or SROOT_LINK shall update the BOOT_LINK_LOCK, disabling access.	CURRLINK=BOOT_LINK && BOOT_LINK_LOCK = '0'

6.5.2 PIPE Errors

The PIPE module is directly connected to the Error Aggregator which aggregates errors occurred during interrupt related errors such as interrupt service routines (ISRs). PIPE outputs the error, error type, and error address to the Error Aggregator. The errors from the CPUx and associated PIPE instance are combined as CPUx INT.

The errors are propagated to the ESM, PIPE, and CPU to take the appropriate action, typically a NMI. The following table summarizes various types of errors that can occur with INT, RTINT, NMI, and overall PIPE module.

Table 6-4. CPUx INT Error Aggregator Errors

CPUx INT Interface Errors	Priority	Description
MAIN/INT/RTINT/NMI ISR ENTRY ERROR	HIGH	Error in entering an interrupt service routine for a specific interrupt type.
MAIN/INT/RTINT/NMI CORRECTABLE VECTOR ERROR	LOW	Reading interrupt vector and/or link register related to a specific interrupt type that result in a single-bit ECC error.
MAIN/INT/RTINT/NMI UNCORRECTABLE VECTOR ERROR	HIGH	Reading interrupt vector address related to a specific interrupt type that result in a double-bit ECC error.
MAIN/INT/RTINT/NMI INTERRUPT RETURN ERROR	HIGH	Error in exiting an interrupt service routine for a specific interrupt type.
RTINT/NMI CONTEXT RESTORE CORRECTABLE VECTOR ERROR	LOW	CPU performs an ECC check on the vector address related to a specific interrupt type that result in a single-bit ECC error.
RTINT/NMI CONTEXT RESTORE UNCORRECTABLE VECTOR ERROR	HIGH	CPU performs an ECC check on the vector address related to a specific interrupt type that result in a double-bit ECC error.

Table 6-4. CPUx INT Error Aggregator Errors (continued)

CPUx INT Interface Errors	Priority	Description
NMI MAXISP ERROR	HIGH	CPU current interrupt stack pointer reaches the maximum allotted RTINT stack space (Ex. 15 for F29H85x).
PIPE SCRUBBING / VECTOR INIT CORRECTABLE ERROR	LOW	PIPE reads interrupt vector address that results in a single-bit ECC error.
PIPE SCRUBBING / VECTOR INIT UNCORRECTABLE ERROR	HIGH	PIPE reads interrupt vector and/or link register that results in a double-bit ECC error.
PIPE WARNISP	LOW	CPU current interrupt stack reaches or exceeds the value of the WARNISP Threshold. NOTE: This error is only automatically cleared when the interrupt stack pointer value falls below this threshold.
PIPE MAXISP	HIGH	CPU current interrupt stack pointer reaches the maximum allotted RTINT stack space (Ex. 15 for F29H85x).
PIPE SECURITY VIOLATION	HIGH	Unsecure access is made by illegitimate code during a PIPE register read and/or write.
PIPE REG PARITY ERROR	HIGH	Parity mismatch in a PIPE register and the respective stored parity value.
PIPE REGISTER PARITY DIAG ERROR	LOW	To determine if the parity checkers in the diagnostics registers are working correctly, user injects an error intentionally into this parity checker to see if an error is being generated as expected.
PIPE LOCK_KEY ERROR	LOW	Locked register is written to or a wrong key is used for a keyed register.

Note

Refer to Chapter 8and Chapter 7 for the complete list of error sources and information on how to read and use these errors for debugging purposes.

6.5.3 Register Data Integrity and Safety

The PIPE vector table and critical configuration registers have ECC protection. All other PIPE configuration registers have parity protection. The registers with parity-protection are mentioned in the registers section of this chapter.

6.5.4 Self-Test and Diagnostics

For diagnostics of safety mechanisms, ECC logic needs to be checked periodically. However, running test-of-diagnostics in software to check ECC logic is time consuming as many patterns have to be run to get to the required coverage. To enable seamless diagnostics, self-test logic is added.

The self-test controller generates test sequences to detect faults in ECC logic. Any errors found as part of the test sequences is logged into self-test configuration registers that are part of the PIPE module. Different data patterns can be required to get additional coverage. The input data and ECC values to the ECC logic is programmable through self-test registers.

If at any point the software reads the INT_VECT_ADDR registers to perform ECC checks on the read vector address value, any enabled self-test sequences are paused. Software is required to continually poll for the completion status of the self-test sequences to account for such pauses.

The self-test controller can run the following test sequences, see Figure 6-4, to detect an error in ECC logic:

1. Positive check: Input pattern (Data, Address, ECC bits) that is written does not result in ECC errors. No errors are generated by the ECC logic when none are expected.
2. 1-bit error check: Single bit errors are induced sequentially and then checked for the expected correctable error.
3. 2-bit error check: Double bit errors are induced sequentially and then checked for the expected uncorrectable error.

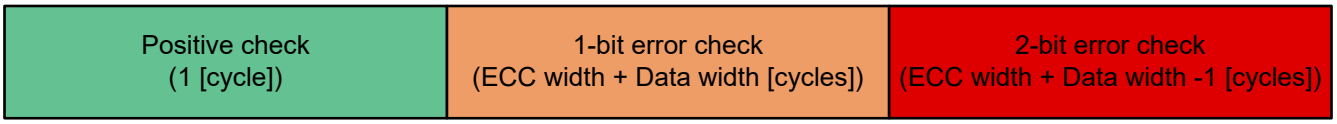

Figure 6-4. ECC Self-Test Sequence

If any of these checks fails, then self-test execution is aborted. The SELFTEST_DIAG_STATUS register can be read to check for these errors.

Programming sequence for self-test controller:

1. Enable self-test controller (SELFTEST_DIAG_CONTROL. DIAG_TEST_EN = 0x11).
2. Write the input data pattern to be used for self-test
   a. Write input pattern to SELFTEST_DIAG_DATAx registers with a data width of 52 bits.
3. Write the ECC pattern to SELFTEST_DIAG_ECC.
4. Execute ECCSELFTEST instruction.
5. Check for errors. If errors are found, take corrective action:
   a. SELFTEST_DIAG_STATUS.DIAG_FAIL_CHECK_TYPE can be read to determine the sequence that was failed (Positive check, Correctable error check, or Uncorrectable error check).
   b. SELFTEST_DIAG_STATUS. DIAG_FAIL_BIT_INDEX can be read to determine the data bit that was failed with error injection.
6. Clear the self-test status by writing to SELFTEST_DIAG_STATUS_CLR.

Refer to PIPE Self-Test registers for additional details.

6.6.2 INTERRUPT Examples

NOTE: These examples are located in the C29SDK installation from ti.com at the following location: mcu_sdk_DEVICE_GPN/examples/driverlib/CORE_IF_MULTICORE/interrupt

Cloud access to these examples is available at the following link: dev.ti.com C29SDK Examples.

6.6.2.1 RTINT vs INT Latency example - SINGLE_CORE

FILE: interrupt_ex1_int_rtint_latency.c

This example demonstrates the interrupt latencies of INT and RTINT. This configures 2 CPU timer interrupts with following priorities.

- RTINT Threshold = 15
- Timer 0 Interrupt priority = 10 -> RTINT
- Timer 1 Interrupt priority = 20 -> INT

User can set the macro ENABLE_FUNCTION_CALL_IN_ISR to 1 to configure both the ISRs to invoke a function call, hence multiple core registers needs to be saved and restored. If the macro is set to 0, both ISRs just updates a counter variable, hence requires only 1 register to be saved and restored. In case of RTINT, register saves and restores are done by the hardware. In case of INT, register saves and restores are done by the software.

The ERAD module is configured to measure the cycles taken between the timer interrupt event to the first instruction in the ISR.

Note : Run the example for some duration to get the min and max values. The watch variables are arrays with min and max values [Min, Max]

External Connections

- None

Watch Variables

- timer0_intEvent_to_isr : Min and Max cycles count between the timer event to the ISR entry
- timer0_isr_to_data : Min and Max cycle count between the ISR entry to the first C instruction (data access to cpuTimer0IntCount variable)
- timer1_intEvent_to_isr : Min and Max cycles count between the timer event to the ISR entry
- timer1_isr_to_data : Min and Max cycle count between the ISR entry to the first C instruction (data access to cpuTimer1IntCount variable)

Expected results : (With opt level = 1)

| RTINT | RTINT | INT | INT |

| w/o func | with func | w/o func | with func |

intEvent_to_isr | 21-27 | 21-27 | 19-25 | 19-25 |

isr_to_data | 1 | 1 | 2 | 25-26 |

6.6.2.2 INT and RTINT Nesting Example - SINGLE_CORE

FILE: interrupt_ex2_int_rtint_nesting.c

This example showcases nesting of INTs and RTINTs in groups using software interrupts and increments every time the software asserts an interrupt. The watch variables and print statements can be used to determine entry and exit points of ISR.

The interrupt priorities / group mask are configured as follows :

- RTINT Threshold = 20
- Group Mask = 0xFE
- INT 1 Interrupt priority = 50 -> INT (Group 24)
- INT 2 Interrupt priority = 51 -> INT (Group 24)
- INT 3 Interrupt priority = 49 -> INT (Group 23)
- RTINT 1 Interrupt priority = 10 -> RTINT (Group 4)
- RTINT 2 Interrupt priority = 11 -> RTINT (Group 4)
- RTINT 3 Interrupt priority = 9 -> RTINT (Group 3)

Order of Interrupt Triggers: INT1 -> INT2 -> INT3 -> RTINT1 -> RTINT2 -> RTINT3

Order of Interrupt Execution: INT1 -> INT3 -> RTINT1 -> RTINT3 -> RTINT1 -> RTINT2 -> INT3 -> INT1 -> INT2

Sysconfig inserts the required attributes to the ISR functions to inform the compiler that the function is an interrupt / realtime interrupt.

External Connections

- None

Watch Variables

- *SWINT1Count* - INT1 count
- *SWINT2Count* - INT2 count
- *SWINT3Count* - INT3 count
- *SWINT4Count* - RTINT1 count
- *SWINT5Count* - RTINT2 count
- *SWINT6Count* - RTINT3 count

6.7 PIPE Registers

This section describes the PIPE Registers.

6.7.1 PIPE Base Address Table

Table 6-6. PIPE Base Address Table

Structure	DriverLib Name	Base Address	Frame Applicable	CPU1	CPU2	CPU3	RTDMA1	RTDMA2	HSM	Pipeline Protected
PIPE_REGS	PIPE_BASE	0x3002_0000	-	YES	YES	YES	-	-	-	YES

6.7.2 PIPE_REGS Registers

Table 6-7 lists the memory-mapped registers for the PIPE_REGS registers. All register offset addresses not listed in Table 6-7 should be considered as reserved locations and the register contents should not be modified.

Table 6-7. PIPE_REGS Registers

Offset	Acronym	Register Name	Protection
0h	RTINT_THRESHOLD	Interrupt threshold register	SROOT_LINK_RW, BOOT_LINK_RW: BOOT_LINK_CTRL. BOOT_LINK_LOCK, LOCK: LOCK.GLOBAL_LOCK,, PARITY

Complex bit access types are encoded to fit into small table cells. Table 6-8 shows the codes that are used for access types in this section.

Table 6-8. PIPE_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

6.7.2.1 RTINT_THRESHOLD Register (Offset = 0h) [Reset = 00000000h]

RTINT_THRESHOLD is shown in Figure 6-5 and described in Table 6-9.

Return to the Summary Table.

Interrupt threshold register

Figure 6-5. RTINT_THRESHOLD Register

Chapter 7

Error Signaling Module (ESM_C29)

This chapter describes the features and operation of the error signaling module (ESM_C29) module.

7.1 Introduction

The Error Signaling Module (ESM) provides systematic consolidation of responses to error events throughout the device into one location. The Module can signal programmable priority interrupts to the processor to deal with an event and/or manipulate an I/O error pin to signal an external hardware that an error has occurred. Therefore, an external controller is able to reset the device or keep the system in a safe, known state.

7.1.1 Features

The following points highlights the main features of the Error Signaling Module Subsystem :

- ESM Subsystem consists of three ESM CPU Instances (one for each CPU), a single System ESM (SYS ESM) for Error Pin Output and Monitoring, and an additional Safety Aggregator (ESM Register Parity Error Aggregator) Instance for Register Parity Error Aggregation for all ESM instances (ESM CPU and System ESM).
- Supports up to 256 error event inputs: Error events from Error Aggregator and System level fault event sources are mapped to ESM subsystem and applied to all ESM instances (Refer to Section 7.3.1 for more details)
  - Divided in groups of 32 error events (Total 8 Groups)
- Selectable Low and High Priority Interrupt prioritization of each error event for each ESM CPU instance
- Critical Priority and High Priority Watchdog Interrupt outputs for each ESM CPU instance
  - Pulse type output only
- System ESM Instance to signal severe device failure produces an Error Pin Output in addition to set of interrupt outputs
  - Supports of level or PWM modes for error pin output
  - Error Pin Monitoring
- Configurable timebase for error pin signal output
- Error forcing capability
- Parity Detection and Commit/Lock for MMRs

7.1.2 ESM Related Collateral

Foundational Materials

- C29x Academy - Error Handling

7.2 ESM Subsystem

The Error Signaling Module Subsystem (ESM-SS) groups error signaling module (ESM) instances as shown in Figure 7-1. ESMSS supports a number of ESM instances that is triggered from common set of error event inputs. Each ESM instance is used to drive interrupts to individual CPU and resets to individual CPU or System. The subsystem combines the ESM instances and output pulse interrupt from each ESM instances are exported at the subsystem boundary for integration at the device level.

ESM subsystem is comprised of the following instances :

- ESM CPU instances one for each CPU
  - **Input's**: The error inputs listed in Section 7.3.1, common to all ESM Subsystem instances
  - **Output's**:
    - Low Priority Interrupt
    - High Priority Interrupt
    - High Priority WD Event (Event triggered by watchdog timeout on High Priority Interrupt hence also referred to as High Priority Watchdog Interrupt in the later part of the document): Similar functionality as NMIWD on C28x devices
    - Critical Priority Interrupt

- Additional System ESM instance for Error Pin output and monitoring.
  - **Input's**: The error inputs listed in Section 7.3.1, common to all ESM Subsystem instances
  - **Output's**:
    - Low Priority Interrupt
    - Critical Priority Interrupt
    - Error Pin Output
    - Error Pin Monitor Event : Error pin monitoring and error detection output
- Register Parity Error Aggregator Instance (Safety Aggregator)
  - **Input's**:
    - Input from EDC (Error Detection and Correction) Control Interfaces of all ESM Instances (ESM CPU and SYS ESM)
  - **Output**:
    - Parity Error Interrupt : Interrupt generated by parity error detected on ESM register configurations

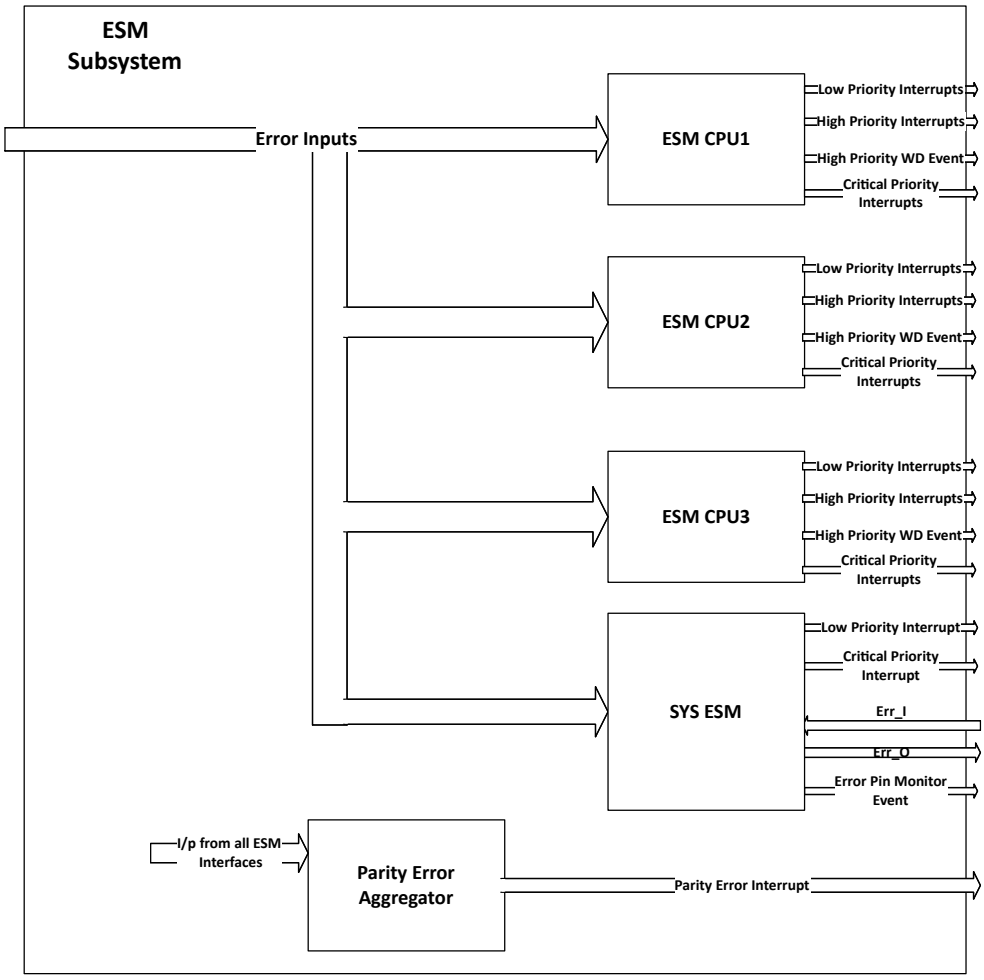

Figure 7-1. ESM-SS Block Diagram

7.2.1 System ESM

Error Pin inputs and outputs are controlled by System ESM instance. The System ESM produces an configurable error pin output (err_o/ERRORSTS) in addition to the set of interrupt outputs. The System ESM generates a critical priority interrupt (ESMRESET) output that causes system reset request (XRSn) by default, if not disabled by the ESMXRSNCTL register. The System ESM additionally has the Error Pin Monitor feature and associated Error Pin Monitor event that is exported at subsystem as a pulse interrupt. Error Pin Monitor event is also applied back to ESM-SS as an error event input so that the ESM can take appropriate action on the mismatch event.

The low-priority interrupt output of System ESM is mapped to the XBARs as an ESMGENEVT signal.

7.2.1.1 Error Pin Monitor Event

The error pin monitor event indicates that the err_i and err_o pins (input and output to the ESM, respectively) have differed for eight or more consecutive cycles. This detects if the error pin connectivity external to the ESM is malfunctioning.

ERR_I is stored, in case previous values of ERR_I are either all 0's or 1's, the previous 8 values of ERR_O is checked for atleast one match. If there is no match between previous 8 values of ERR_I and ERR_O, this indicates that the external connection from ERR_O back to ERR_I is malfunctioning. Error Pin Monitor event/ interrupt is triggered only if all values of ERR_I being equal (all zeroes or ones) and stored ERR_O values being the logical inverse (all zeroes or ones). The above mechanism provides immunity against glitches or pin transitions triggering spurious pin monitor interrupt outputs. PWM low and high counters values need to be greater than 8 cycles when using pwm mode for error pin monitor to detect a malfunctioning ERR_I.

When an error pin monitor interrupt occurs, a processor handling this interrupt logs or alerts the external system associated with error pin monitoring. This interrupt can be enabled/disabled via the Error Pin Monitor Config Register and set or cleared via Error Pin Monitor Interrupt Status/Set Register and Error Pin Monitor Interrupt Status/Clear Register respectively.

A software write of the EOI vector to the EOI Interrupt Register also results in a re-evaluation of the error pin monitor interrupt/event.

7.2.2 Safety Aggregator

Safety Aggregator module is used within the ESM subsystem to aggregate all the error detection and correction (EDC) interfaces from each ESM instance. The ESM instances (including the System ESM instance) each has an EDC Controller to control parity detection logic and injection of errors for testing purposes.

7.2.2.1 EDC Controller Interface Description

Each ESM Instance has a EDC (Error detection and Correction) control interface which works with Safety aggregator for parity detection. Control interface receives command from Safety Aggregator though a serial vbus connection, the error status information can be accessed through the registers described in Section 7.2.2.1.1.

7.2.2.1.1 EDC_REGS Registers

Table 7-1 lists the memory-mapped registers for the EDC_REGS registers. All register offset addresses not listed in Table 7-1 should be considered as reserved locations and the register contents should not be modified.

Table 7-1. EDC_REGS Registers

Offset	Acronym	Register Name	Protection
10h	REVISION	Revision Register	
14h	CONTROL	Control Register	
18h	ERROR1	Error 1 Register	
1Ch	ERROR2	Error 2 Register	
20h	ERRORSTATUS1	Error Status 1 Register	
24h	ERRORSTATUS2	Error Status 2 Register	

Complex bit access types are encoded to fit into small table cells. Table 7-2 shows the codes that are used for access types in this section.

Table 7-2. EDC_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value

7.2.2.1.1.1 REVISION Register (Offset = 10h) [Reset = 4F404900h]

REVISION is shown in Figure 7-2 and described in Table 7-3.

Return to the Summary Table.

15-0	ERR_BIT	R	0h	Bit information that casued the error Reset type: SYSRSn

7.2.2.2 Read Operation on EDC Controller

User needs to follow the outlined steps for read transaction on serial VBUS :

1. Write Vector register with the appropriate vector field ID, address of EDC Controller register to rd_svbus_address, and set rd_svbus to a 1 to trigger a read on the serial VBUS.
2. Poll Vector register till rd_svbus_done (bit 24) is 1
3. Once rd_svbus_done = 1 do a normal read of the reserved_svbus_y register in the safety aggregator address space, this returns the read value

7.2.2.3 Write Operation on EDC Controller

User needs to follow the outlined steps for write transaction on serial VBUS :

1. Write the Vector register with the appropriate vector ID (bits 10-0), make sure rd_svbus = 0. Read address is a don't care
2. Do a regular write operation to the address that user wants to write to.

7.2.2.4 Safety Aggregator Error Injection

User needs to follow the outlined steps for parity error injection using serial VBUS :

1. Write the Vector register (offset - 0x8) with the index of the EDC controller to vector ID (bits 10-0), make sure rd_svbus = 0
2. Write to Error 1 register (offset - 0x18) of the EDC controller to program following :
   a. The GRP (group of checker to inject)
   b. The bit location thats is to be flipped
3. Write to the Control register (offset - 0x14) of the EDC controller to start the injection with the following :
   a. Make sure CHECK field (bit 1) is enabled
   b. Set force_se (bit 3) for single bit error to trigger parity error
4. When an interrupt from the safety aggregator is detected (assuming interrupts are enabled), software can read the raw interrupt status registers DED_STATUS_REG0 and check which ESM EDC controller has parity error.
5. To further find out information about the checker that detects the error, follow this sequence:
   a. Do a read operation from the ESM EDC Controller to read ERROR STATUS 1 register (offset - 0x20)
   b. From Error Status 1 register - user can check which specific checker reported the error and how many injected and non-injected errors are pending.
6. User can then do a Write operation to Error Status 1 register to clear injected error while exiting the parity error interrupt ISR and write the EOI register to acknowledge future error interrupts.

7.2.3 ESM Subsystem Integration View

The subsystem interacts with multiple blocks at the device level. The key ones being sources of errors, CPU's, Interrupt modules, System Control modules, and I/O pin interfaces. User can configure the controls and access various states of errors and actions. Subsystem consolidates various error sources and captures them to determine the right action based on user configurations. Figure 7-8 describes how the subsystem integrates at the device level in detail.

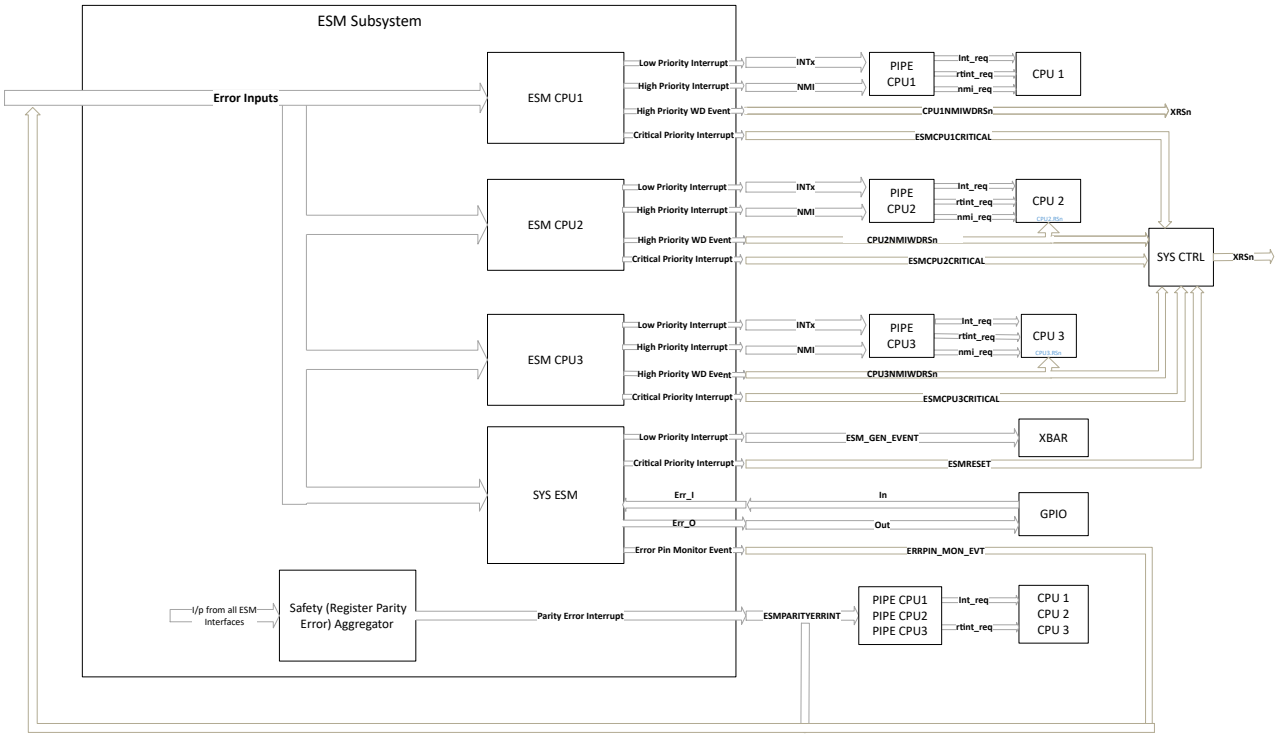

Figure 7-8. ESM Subsystem Integration View

7.3 ESM Functional Description

Figure 7-9 and Figure 7-10 illustrates the module features and functionality. The Error Signaling Module (ESM) centralizes fault reports and provides mechanisms to classify errors by severity and to provide programmable error response. The error classification in the ESM is determined by programmed configuration for each individual error input. For each individual error input the configuration can be set to assert an output error pin, or generate an interrupt to a CPU, or both. When an individual error input is configured to generate an interrupt, the configuration also selects whether the interrupt that is generated is high priority or low priority.

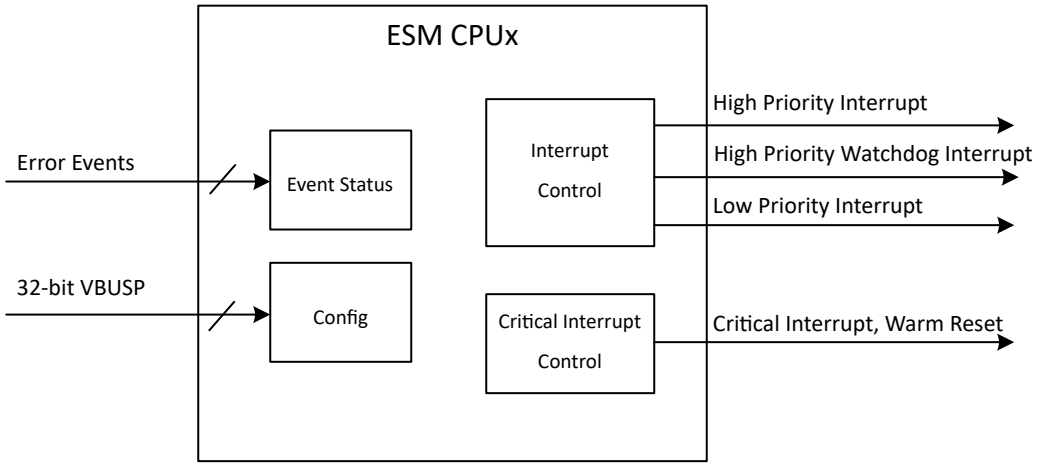

Figure 7-9. ESM CPU Block Diagram

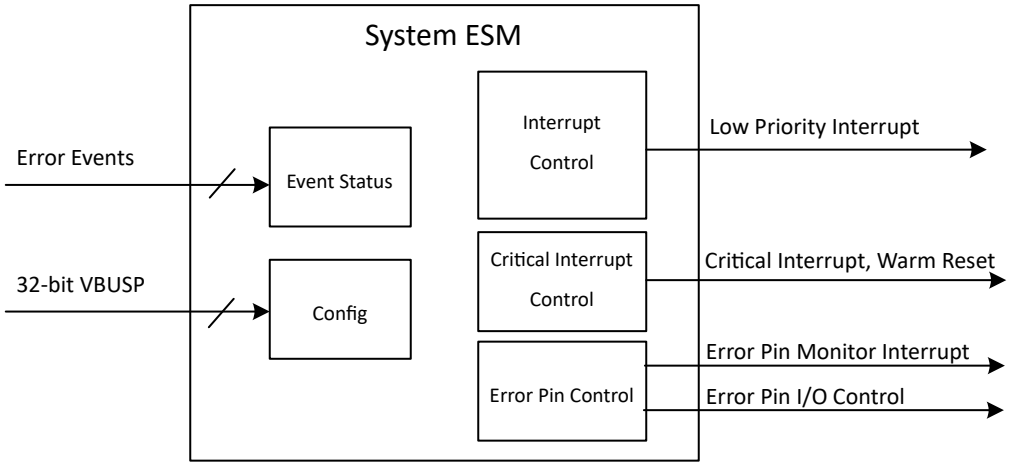

Figure 7-10. System ESM Block Diagram

By reporting the faults in a central location, the system can determine what caused the fault and what action can be taken. In general the faults can be split into two categories:

- Corrected faults
- Non-corrected faults

The ESM reports errors in two ways:

- An interrupt to a processor in the device. This allows the device to analyze and try to recover from an error.
- An external ERROR pin for System ESM module. This allows the system outside of the device to monitor for potentially fatal errors (errors that the device cannot self-recover from). Moreover, the external I/O (ERROR pin) can operate in level or PWM modes. In level mode, the output remains asserted (active low) for a minimum period of time. After that period of time, if the error has been cleared by an internal processor, the pin goes inactive (high). If signal does not go inactive in that time, then an external agent must intervene, as

an unrecoverable error can occur. In PWM mode, the error causes the output pin to maintain the value for a minimum period of time. After that period of time, if the error has been cleared by an internal processor, the pin continues the PWM pattern. If the signal does not go inactive in that time, then an external agent must intervene, as an unrecoverable error can occur.

Both mechanisms can be used at the same time for the same fault, signaling both an interrupt and the external ERROR pin. This allows the device to attempt to recover, but if recovery fails, then the external system is still alerted. If recovery succeeds, then the ERROR pin assertion can be removed so that the external system knows that a potentially unsafe condition was avoided.

Lastly, the ESM does not specify any methods of intervention, only the process of alerting internal CPUs and external monitors of an existing error event.

7.3.1 Error Event Inputs

Single ESM module supports up to 256 error event inputs, configurable by groups of 32. Error event inputs type can be either level or pulse. *N* (0-31) is the total number of groups, and *X* is the number of groups that are pulse. For this device, *N=X* means there are only pulse events and no level events. All events are relative to 0; hence, Event Group 0 Event 0 is global event 0 and sequentially Event Group1 Event 0 is global event 32.

Global event 0 to 31 are part of *Group0* similarly global event 32 to 63 belong to *Group1* and so on.

The pulse error event has a dedicated rising-edge detection circuit for each input.

Input Error Event Mapping to ESM is captured in Table 7-9.

Note

All Error Events that cause CPU to go into fault state must be configured to generate NMI (High Priority Interrupt) only. Group 0 events (Event Number 0 to 31) are mapped to High Priority Interrupt by default. CPUx_TMUROM_PAR_ERR also must to configured to generate NMI (high priority interrupt) in ESM configurations at device initialization.

All error event inputs are Pulse type only for this device.

7.3.2 Error Interrupt Outputs

Each module generates Interrupt Output so that the processor in the device is signalled to intervene when an Error Event occurs. Each error event input is to be enabled to cause an Error Interrupt to occur (via Error Group *N* Interrupt Enabled Set Register). Additionally, each error event input is configured to be programmed to influence either the Low Priority (default) interrupt or the High Priority interrupt (via Error Group *N* Interrupt Priority Register). The Low Priority interrupt is intended for events that are of interest, but does not require immediate intervention. For example, an indication that there was a single bit error that was corrected can be configured to signal a low priority interrupt, so that information can be collected for statistical purposes. A High Priority interrupt is intended for events that need immediate attention. For example, an indication that there was an uncorrected two-bit error can be configured to signal a high priority interrupt.

7.3.2.1 High Priority Watchdog

A High Priority Watchdog can be enabled to monitor if the process associated with servicing the High Priority Interrupt has failed to do so. Count down starts from a Pre-Load value and triggers the High Priority Watchdog

Interrupt when the time has expired. As long as at least one enabled error associated with the High Priority Interrupt is outstanding, the Watchdog continues to count down.

The Watchdog only triggers the High Priority Watchdog Interrupt a single time until and unless the Interrupt is cleared. The High Priority Interrupt can be cleared with the High Priority Watchdog Interrupt Status/Clear Register or by writing the EOI vector to the EOI Interrupt Register.

If the Watchdog value is non-zero and all High Priority errors are cleared, the Watchdog timer resets to the Pre-Load value and waits until the next High Priority error to begin counting down again.

An MMR write to the Pre-Load value overwrites the Watchdog counter value if the Watchdog is inactive. If the Watchdog is counting down, a write to the Pre-Load value does not have any effect until the Watchdog is once again inactive.

If the Pre-Load value is zero, a High Priority Watchdog Interrupt is triggered when an error associated with the High Priority Interrupt occurs.

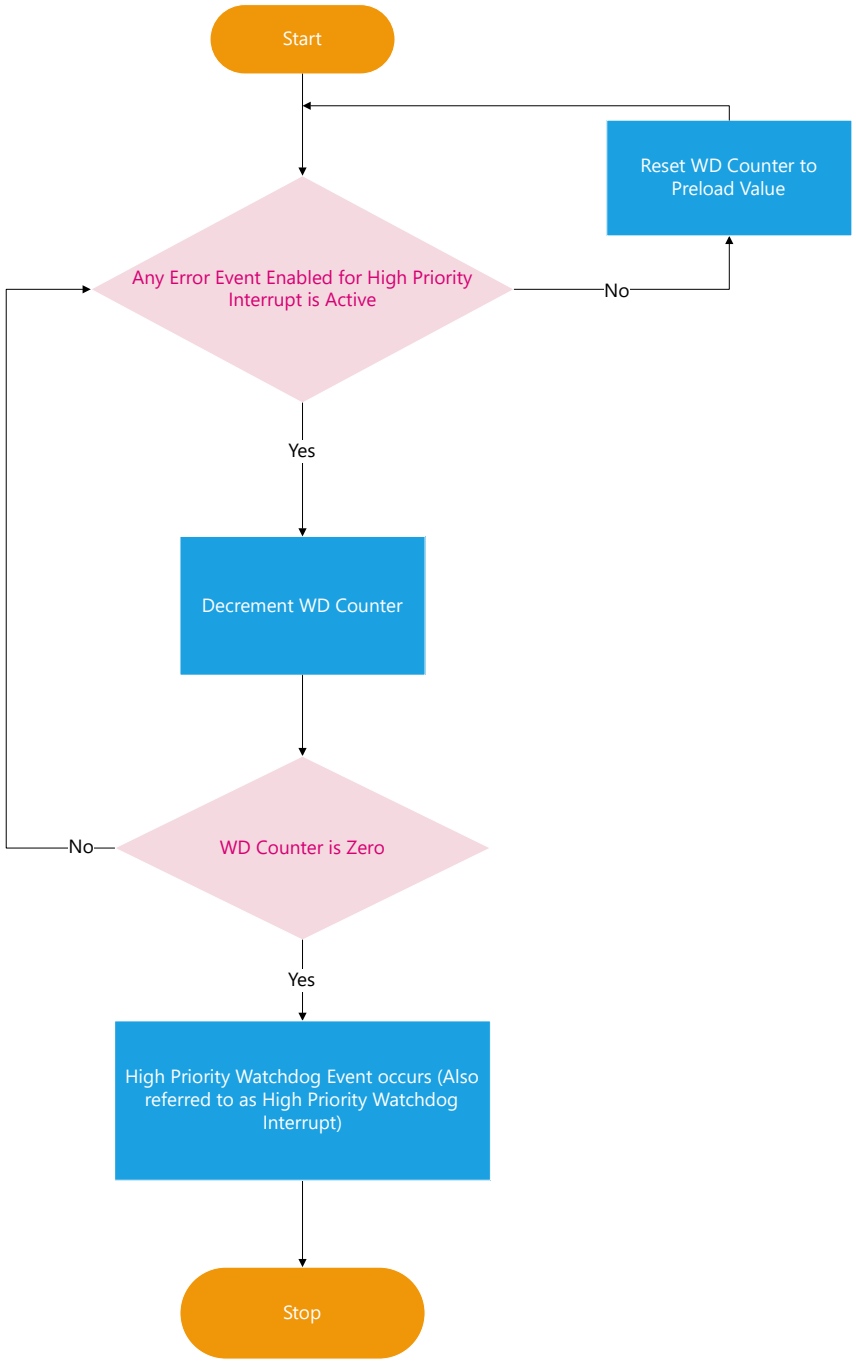

Figure 7-11. High Priority Watchdog Event Flowchart

7.3.2.2 Critical Priority Interrupt Output

The ESM supports a third interrupt output for events which are deemed even more critical than high priority events. For example, an error whose desired end result is a warm reset of a domain or the entire device. Unlike Low/High Priority Error Events, Critical Priority Error Events don't require enabling via the Error Group *N* Interrupt Enabled Set Register . Instead each Critical Priority Error Event Input is configured individually to influence the Critical Priority Interrupt Output via Error Group *N* Critical Priority Interrupt Influence Set Register .

The critical priority interrupt output is sensitive to the ESM's warm reset input as well as the Global Soft Reset MMR. The ESM's warm reset input is used synchronously and assertion of the ESM Warm Reset Input disables the ESM Global Enable MMR. When the critical priority interrupt output triggers, the occurrence is logged in the Info Register. The logging status is only reset via POR and the Global Soft Reset MMR.

7.3.3 Error Pin Output (ERR_O/ERRORSTS)

The error pin output (ERR_O/ERRORSTS) is used to signal an external agent to intervene because of an error. Each error event input can be programmed, via software, to influence the error pin output (using the Error Group *N* Error Pin Influence Set Register). The error pin output is active low or PWM based on the Error Pin Control Register[7-4] PWM_EN field. This bit field can only be modified when the ESM is disabled, based on the Global Enable register.

During Power-On Reset (POR), the error pin is active (asserted low) and the device drives this using a weak internal pull-down. The I/O is under the control of the device. When POR is removed from the ESM, error pin is driven by internal pull-down so the device can hand over control to the ESM. The user can also add an external pull-down that is only active when the device is in reset.

During a warm reset the state of the error pin is unchanged, that is the error pin logic is only reset by a POR. The device leaves the I/O active during a warm reset.

Figure 7-12 describes the behavior of the Error Pin. Not shown is that a reset (Power-On-Reset only) immediately transitions the Error pin to the ESM_RESET state and a Global Soft Reset immediately transitions the Error pin to the ESM_IDLE state. A Pending Error Event is any error event with the raw state set and the Error Pin Influence enabled. There are two types of "clear" events associated with servicing the Error Pin. The first is to clear the status of the pending event (see Section 7.5 for how to clear level and pulse pending events). The second is the CLEAR event meant to de-assert the Error Pin.

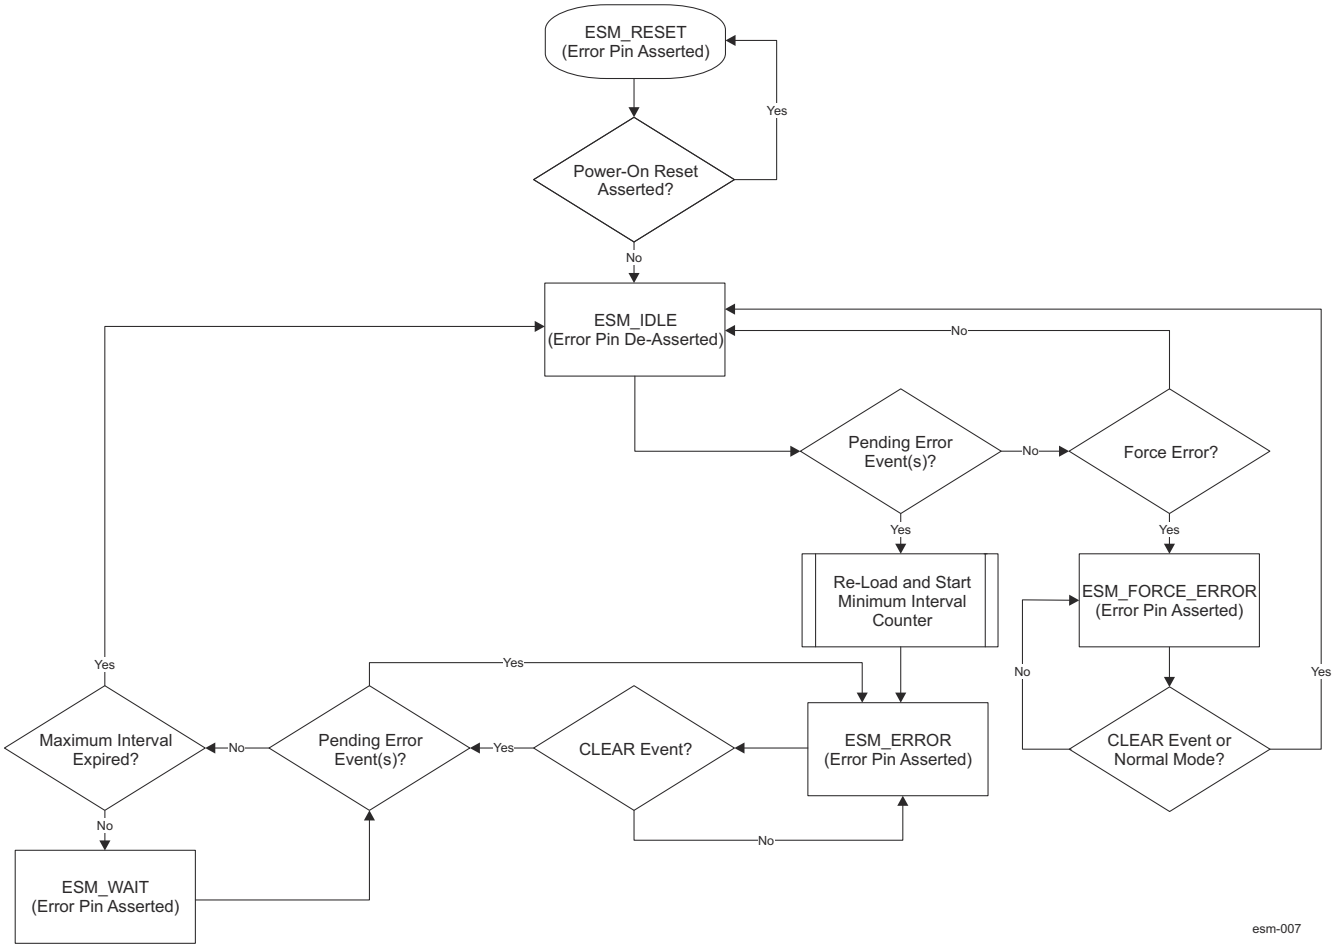

Figure 7-12. Error Pin State Flowchart

If an error event happens that has been programmed to influence the Error Pin, the Error Pin asserts (active low) for a minimum time as programmed (using the Error Pin Counter Pre-Load Register). For the Error Pin to de-assert, the following 3 things must happen : 1. The Minimum Time Interval must expire 2. The event that caused the Error Pin to assert must be cleared (see section for Interrupt Handling) 3. A CLEAR must be written to the Error Pin Control Register. Note that step 3 can only happen after step 2, but either (or both) of those steps can occur before or after step 1.

Figure 7-13 shows a typical error pin assertion.

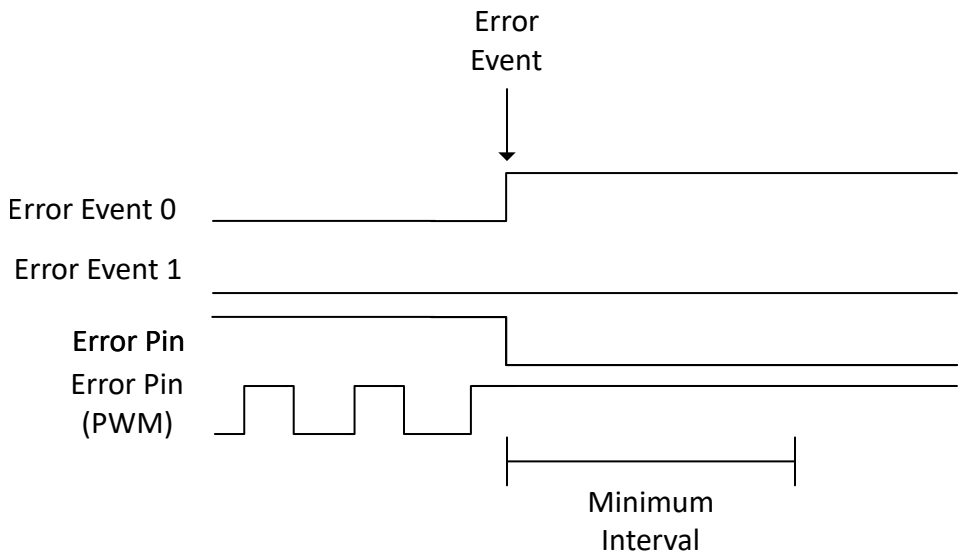

Figure 7-13. ESM Error Pin Assertion

If, during the minimum time, CLEAR is written to the error key, then the error pin de-asserts after the minimum time interval, as shown in Figure 7-14.

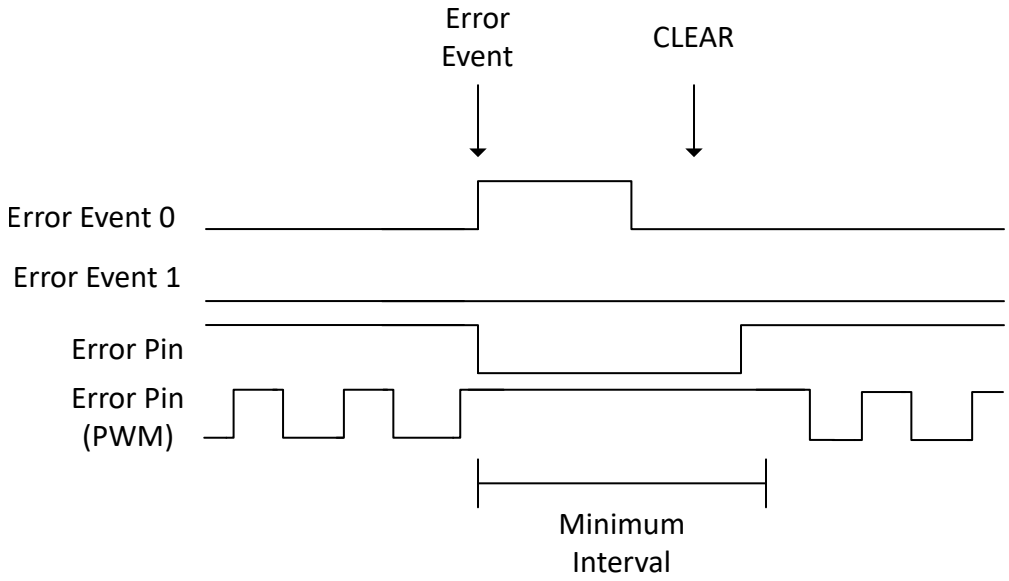

Figure 7-14. ESM Error Pin Assertion with CLEAR During Minimum Interval

If CLEAR is not written until after the Minimum Interval, the Error Pin de-asserts when CLEAR is written. This is regardless of whether the Error Event is removed before or after the Minimum Interval (as shown by the dotted line in Figure 7-15).

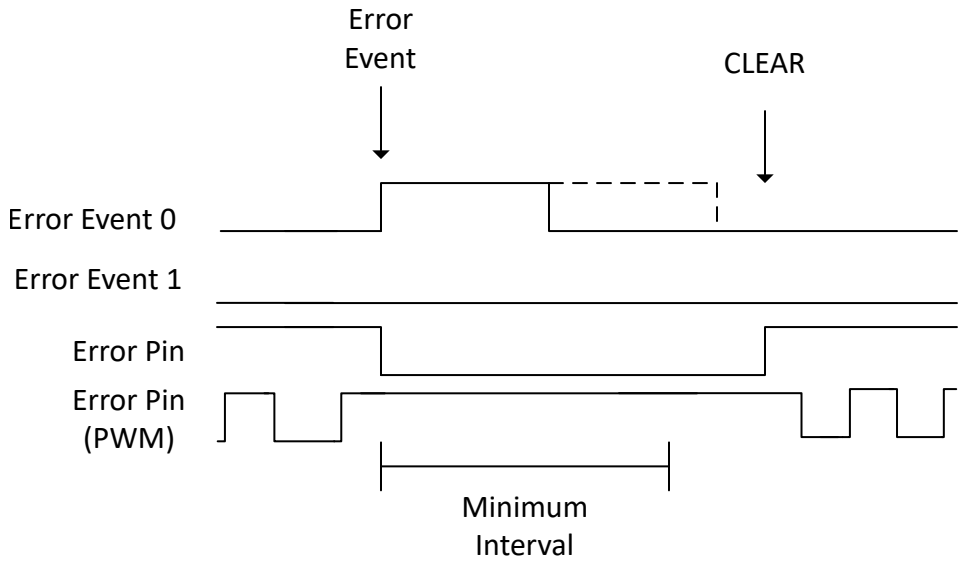

Figure 7-15. Error Pin Asserting with CLEAR after Minimum Interval

When in the ESM_ERROR state and a CLEAR event happens, if there are still pending Error Events, the ESM stays in the ESM_ERROR state with the Error Pin asserted. Multiple Error Events when in the ESM_ERROR state do not reset the Minimum Interval counter.

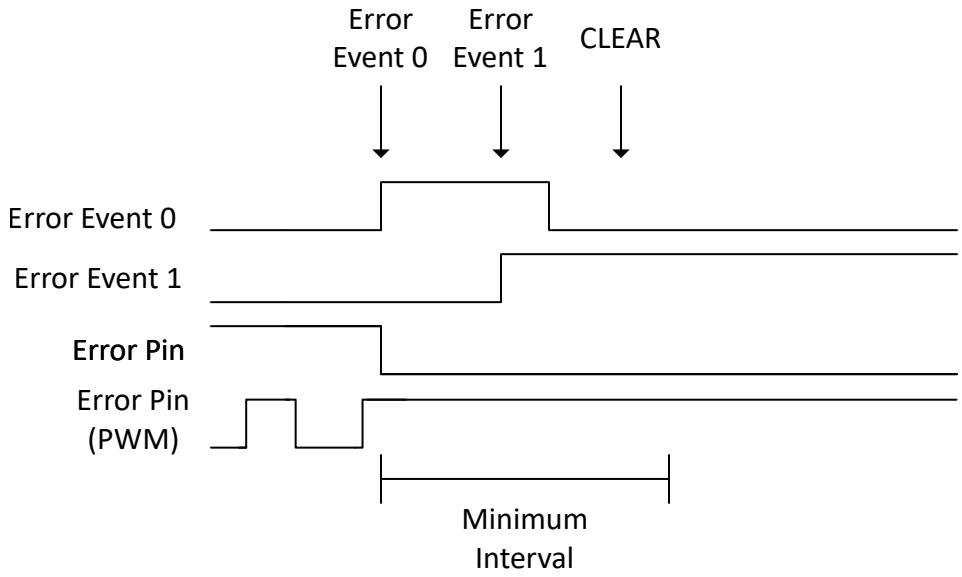

Figure 7-16. Error Pin Asserting with Interval Reset by Additional Error Event

A CLEAR event causes a re-evaluation of whether there are any pending Error Events. As such, a single CLEAR can be used to clear the Error Pin after multiple Error Events. Multiple CLEAR events can occur (such as the one with the dotted arrow in Figure 7-17), but are not necessary. No matter how many Error Events occur nor when (or how many) CLEAR events occur, the Error Pin is always asserted for at least the Minimum Interval.

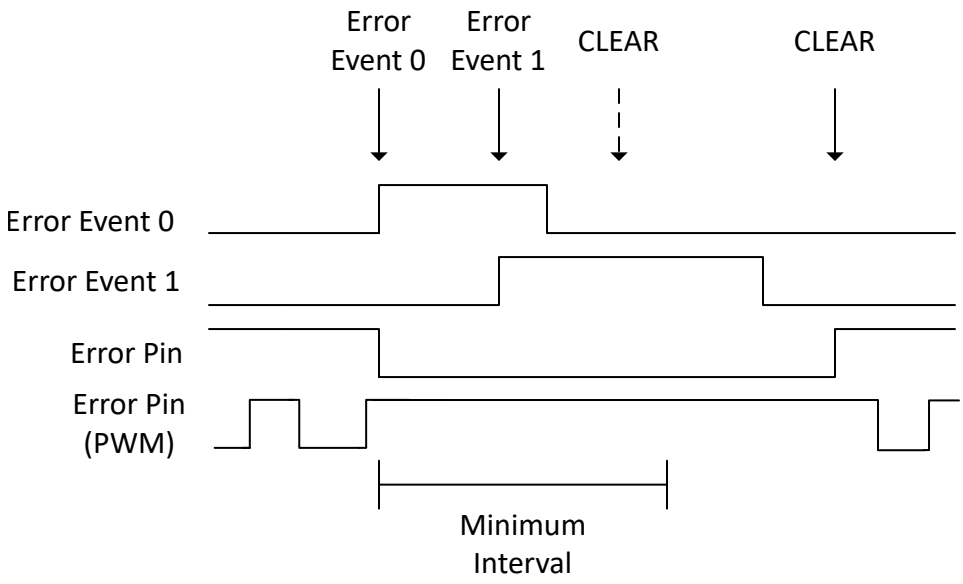

Figure 7-17. Error Pin Asserting with Single CLEAR for Multiple Events

If all Error Events are cleared and the ESM is in the ESM_WAIT state, waiting for the Minimum Interval to expire, and a new Error Event occurs, the ESM goes back to the ESM_ERROR state. The Minimum Interval does not reset, but a new CLEAR event is required.

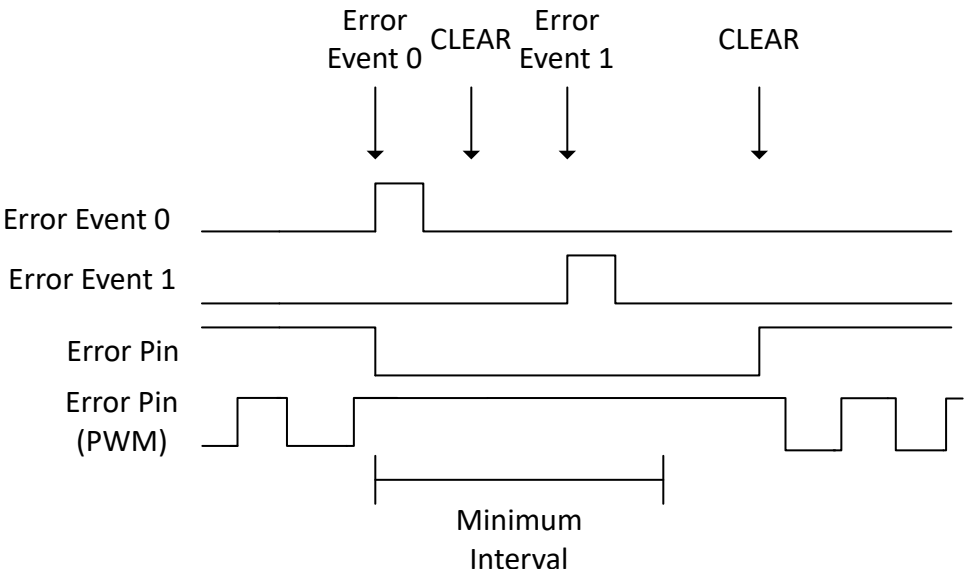

Figure 7-18. Error Pin Asserting with New Error During Minimum Time Interval

Table 7-10 shows some common scenarios of how the error pin as well as the two associated registers (Error Pin Control Register and Error Pin Status Register) are set.

Table 7-10. ESM Error Pin Scenarios

Scenario	Error Pin State Value	KEY	Error Pin Register Status	Additional Notes
POR Asserted	0	N/A	N/A	Registers are inaccessible. Device disables the I/O and pulls down internally.
After de-assertion of POR	1	0x0 (Normal Mode)	0x1	-
After de-assertion of Warm Reset (error was not asserted when reset asserted)	1	0x0 (Normal Mode)	0x1	-
After de-assertion of Warm Reset (error was asserted when reset asserted)	0	0x0 (Normal Mode)	0x0	-
Force error pin	0	0xA (Force Error Mode)	0x0	Forcing error on the pin using software.

7.3.3.1 Minimum Time Interval

The Minimum Time Interval is the minimum amount of time that the Error Pin remains asserted (active low) when an enabled Error Event occurs. This value is system dependent, but time interval must be high enough so that the external monitoring agent can always detect the Error Pin asserted, but short enough so that if all of the Error Events are cleared, then the Error Pin can be de-asserted before the external agent decides to intervene. This is highly dependent on the application and the Fault Tolerant Time Interval.

The Minimum Time Interval counter is clock cycle based, therefore the time of the interval is a combination of the value in the Error Pin Counter Pre-Load Register and the clock frequency of the ESM. For Software configuration the value must be calculated accordingly. The Minimum Time Interval default value is set to 0xFF FFFF (for both modes: level and pwm (high and low minimum time interval values)), although this value can be changed according to the needs of the application after start-up.

7.3.3.2 PWM Mode

If the error output pin is in PWM mode and when no error is detected pin toggles according to programmable MMR widths for high and low periods. When an error occurs, the error pin stops toggling and remains constant until the error is cleared. An external Power Management Integrated Circuits (PMIC) that is detecting the PWM toggles can identify the error if the pin stops toggling. The periods must be programmed considering the expectation of the external PMIC.

7.3.4 Reset Type Information for ESM Registers

Table 7-11. Reset Type Information

Register	Reset Domains		
	Module Reset	SFT_RST (Global Soft Reset)	PORESETn
INFO Register Bit 31			Yes
INFO Register Bit 30		Yes	Yes
EN (Global Enable)	Yes	Yes	Yes
LOW_PRI, HI_PRI, LOW, HI	Yes	Yes	Yes
HI_PRI_WD_CFG, HI_PRI_WD_CNTR, HI_PRI_WD_CNTR_PRE, HI_PRI_WD_INTR_SET, HI_PRI_WD_INTR_CLR	Yes	Yes	Yes

RAW_j , STS_j , INTR_EN_SET_j, INTR_EN_CLR_j, INT_PRIO_j, CRIT_EN_SET_j, CRIT_EN_CLR_j		Yes	Yes

Table 7-11. Reset Type Information (continued)

Register	Reset Domains		
	Module Reset	SFT_RST (Global Soft Reset)	PORESETn
PIN_CTRL, PIN_STS, PIN_CNTR, PIN_CNTR_PRE, PWMH_PIN_CNTR, PWMH_PIN_CNTR_PRE, PWML_PIN_CNTR, PWML_PIN_CNTR_PRE, ERRPIN_MON_CFG, ERRPIN_MON_INTR_SET, ERRPIN_MON_INTR_CLR		Yes	Yes
PIN_EN_SET_j, PIN_EN_CLR_j		Yes	Yes

Table 7-12. Module Reset Domain Information

ESM Subsystem Instance	Module Reset
ESM CPU1	CPU1SYSRSn
ESM CPU2	CPU2SYSRSn
ESM CPU3	CPU3SYSRSn
SYS ESM	XRSn

ESMCPU2 and ESMCPU3 instance only available after the respective CPU2 and CPU3 reset is released. If CPU2 is held in reset ESMCPU2 is not functional and same applies to ESMCPU3. Even when CPU2 is in lockstep with CPU1, ESMCPU2 instance is not available. If user wants to operate CPU2 as standalone core, lockstep needs to be disabled and then CPU2 reset needs to be released for ESMCPU2 instance to be functional. Table 7-12 helps to explain the above.

SYS ESM and Safety Aggregator instances is always available for functional use case irrespective of CPU2 or CPU3 being held in reset.

7.3.5 Clock Stop

The ESM can only be put in to clock stop if all of the internal state machines are idle and the global_enable is cleared (using the Global Enable register).

7.3.6 Commit/Lock for MMRs

Lock/Commit feature allows the configured Enable bits for given errors to be locked to prevent further changes. To prevent changes, the Lock must be written, then the Commit. The Commit prevents the Lock from changing. Both Commit and Lock MMRs are reset by the warm reset (module reset) and by global soft reset.

When Lock is set to 1, the associated MMR values can not be changed. When Commit is set to 1, the Lock value can not be changed. Additionally, once set to 1, the Commit value can not be changed. Both Commit and Lock are reset by the warm reset (mod_g_rst_n) and by global soft reset.

All of the writeable MMRs have Commit/Lock bits except for the following:

- EOI Interrupt Register
- All of Status/Clear Registers
  - Error Group *N* Event Raw Status/Set Register
  - Error Group *N* Event Enabled Status/Clear Register

7.3.7 Safety Protection for MMRs

The configuration MMRs are backed by parity checker, with one bit of parity per 8 bits of MMR data.

The parity detection logic is controlled by an EDC Controller instance, which can also be used to inject errors for testing purposes. The EDC Controller from each ESM module works with Safety Aggregator instance as described in Section 7.2.2.1.

7.3.8 Register Configuration Tieoffs

ESM Modules have MMR tieoffs namely Group 0 High priority Tieoffs and High Priority Watchdog Enable Tieoff set for the ESM Subsystem. Hence Group 0 events are mapped to High Priority Interrupt Outputs and High Priority Watchdog Counter is enabled by default.

7.3.8.1 Group0 High Priority Tieoff

All group 0 events are pre-set to be both enabled and high priority. This is the equivalent of a write to both the Error Group 0 Interrupt Enabled Set Register and Error Group 0 Interrupt Priority Register.

This setting defaults all Group 0 events to drive the high priority interrupt by default after POR or global soft reset. Group 0 events can still be configured. User can lock and commit by writing bit 0 of the Group *N* Interrupt Lock Register and Group *N* Interrupt Commit Register.

Additionally, pre-setting the error events for Group 0 in this way results in Group 0 by passing global enable. This means that a high priority interrupt can be triggered before software has written any configuration to the ESM.

7.3.8.2 High Priority Watchdog Enable Tieoff

The high priority watchdog enable is set which is equivalent to a write of 0xA to the High Priority Watchdog Config Register.

This defaults the High Priority Watchdog to be enabled by default after POR or global soft reset although user can still disabled by software. Additionally user can lock and commit the watchdog settings by writing to the watchdog lock/commit (bit 0) of the MMR Config Lock Register and MMR Config Commit Register. Pre-setting the High Priority Watchdog Enable in this way results in the High Priority Watchdog Interrupt bypassing global enable. This means that a high priority watchdog interrupt can be triggered before software has written any configuration to the ESM.

Note

As both High Priority Watchdog Enable Tieoff and the Group0 High Priority Enable Tieoff are enabled by default, care is taken that the high priority watchdog counter preload default value (0x0000 FFFF) is sufficiently large such that a Group 0 event that occurs during boot does not trigger a High Priority Watchdog Interrupt before a CPU can service the Group 0 event; as when the High Priority Watchdog triggers a CPU reset, this can result in a reset loop if the High Priority Watchdog triggers before a CPU is awake to handle a Group 0 event. User can change the preload counter value as required later.

7.4 ESM Configuration Guide

The following steps are to be performed by user depending on the error handling and condition control :

1. Configure the error event to affect either low priority or high priority interrupt for respective ESM instance. Error events that cause CPU to go into fault state must be configured to high priority interrupt to trigger NMI to respective CPU. For System ESM instance, high priority interrupt priority is not applicable.
2. Enable Interrupt generation for respective error event using Interrupt Enable Set Register. Based on Step1, the enabled interrupt event when active triggers selected priority error event.
3. Configure Global Enable to enable all interrupts, this is interrupt mask for all error events.
4. If the error event needs to affect the critical priority interrupt, set the respective event in the Critical Priority Interrupt Influence Set Register.
5. In Step1 if the interrupt priority is set to trigger high priority interrupt, watchdog on high priority interrupt is enabled at start-up with tie-off unless user wants to disable.
6. Optionally Lock and Commit the configurations.
7. For System ESM only : If error needs to be enabled to influence error pin, enable the event using Error Pin Influence Set Register. Error Pin configurations are only applicable to System ESM instance.
8. For System ESM only : After Step 7, Enable the Error Pin Monitor using Error Pin Monitor Config Register and enable Error Pin Monitor Interrupt using the Error Pin Monitor Interrupt Status/Set Register.

7.5 Interrupt Condition Control and Handling

This section describes in detail about each Interrupt type condition control and handling.

7.5.1 ESM Low Priority Error Interrupt

Any error event can be mapped to the low priority error interrupt. A low priority error interrupt is generated when an event is enabled to cause an interrupt (via the Error Group *N* Interrupt Enable Set Register) and mapped to the low priority error interrupt (via Error Group *N* Interrupt Priority Register) and the raw status is set (via the Error Group *N* Event Raw Status/Set Register).

When a Low Priority Error Interrupt is received, the acting processor is recommended to follow the outlined steps:

1. Read the Low Priority Prioritized Register
   - If both [31-16] PLS (low_pulse_prio) or [15-0] LVL (low_level_prio) bit fields are equal to 0xFFFF, then Interrupt is no longer asserted/pending.
   - If either [31-16] PLS (low_pulse_prio) or [15-0] LVL (low_level_prio) bit fields are not equal to 0xFFFF, software has two options for determining what event to service:
     – First Option: Record the value in low_pulse_prio and/or low_level_prio. Determine which is higher priority. This is the Global Event Number of the highest priority in Low Priority Error Event.
     – Second Option:
       - Read the Low Priority Interrupt Status Register to determine which Event Groups have pending Low Priority Interrupts.
       - Read the desired Error Group *N* Interrupt Enabled Status/Clear Register.
       - Identify which Low Priority Interrupt to service.
2. Based on the global event map for the device find the error event source.
3. Service the error event based on the individual peripheral specification:
   a. The system takes several actions including (but not limited to):
      i. Fixing the error
      ii. Resetting the errored peripheral
      iii. Resetting the device
      iv. Communicating outside the device via the error pin for outside intervention

Rest of the steps assume the error handling is complete and system wants to clear the error event. Clearing of error event is as described below :

Pulse Events

When a low priority error pulse event has to be cleared, the acting processor must perform the following steps in order:

1. Write 0x1 to the appropriate bit in the Error Group *N* Interrupt Enabled Status/Clear Register. This step clears the raw status and deassert the level interrupt.
2. Write the end of interrupt vector to the EOI Interrupt Register. In case there are enabled error events pending then a new pulse is generated and level interrupt remains asserted else no new pulse is generated.
3. Clear the Error Event at the source. The source generates a new pulse which shows up as a new error event at the ESM.
4. Write a CLEAR(0x5) to the Error Pin Control Register. This step is optional if the event is not enabled to influence the error pin (via the Error Pin Influence Set Register), but recommended to be done regardless as an extra CLEAR is not harmful.

7.5.2 ESM High Priority Error Interrupt

Any error event can be mapped to the high priority error interrupt. A high priority error interrupt is generated when an event is enabled to cause an interrupt (via the Error Group *N* Interrupt Enable Set Register) and mapped to the high priority error interrupt (via Error Group *N* Interrupt Priority Register) and the raw status is set (via the Error Group *N* Event Raw Status/Set Register).

When a high Priority Error Interrupt is received, the acting processor is recommended to follow the outlined steps:

1. Read the High Priority Prioritized Register
   - If both [31-16] PLS (high_pulse_prio) or [15-0] LVL (high_level_prio) bit fields are equal to 0xFFFF, then Interrupt is no longer asserted/pending.
   - If either [31-16] PLS (high_pulse_prio) or [15-0] LVL (high_level_prio) bit fields are not equal to 0xFFFF, software has two options for determining what event to service:
     – First Option: Record the value in high_pulse_prio and/or high_level_prio. Determine which is higher priority. This is the Global Event Number of the highest priority in high Priority Error Event.
     – Second Option:
       - Read the High Priority Interrupt Status Register to determine which Event Groups have pending high Priority Interrupts.
       - Read the desired Error Group *N* Interrupt Enabled Status/Clear Register.
       - Identify which high Priority Interrupt to service.
2. Determine, based on the global event map for the device find the error event source.
3. Service the error event based on the peripherals specification:
   a. The system takes several actions including (but not limited to):
      i. Fixing the error
      ii. Resetting the errored peripheral
      iii. Resetting the device
      iv. Communicating outside the device via the error pin for outside intervention

Rest of the steps assume the error handling is complete and system wants to clear the error event. Clearing of error event is as described below :

Pulse Events

When a high priority error pulse event has to be cleared, the acting processor must perform the following steps in order:

1. Write 0x1 to the appropriate bit in the Error Group *N* Interrupt Enabled Status/Clear Register. This step clears the raw status and deassert the level interrupt.
2. Write the end of interrupt vector to the EOI Interrupt Register. In case there are enabled error events pending then a new pulse is generated and level interrupt remains asserted else no new pulse is generated.
3. Clear the Error Event at the source. The source generates a new pulse which shows up as a new error event at the ESM.
4. Write a CLEAR(0x5) to the Error Pin Control Register. This step is optional if the event is not enabled to influence the error pin (via the Error Pin Influence Set Register), but recommended to be done regardless as an extra CLEAR is not harmful.

7.5.3 Critical Priority Error Interrupt

Any error event can be mapped to the critical priority interrupt. A high priority error interrupt is generated when an event is enabled to cause an interrupt (via the Error Group *N* Critical Priority Interrupt Influence Set Register) and the raw status is set (via the Error Group *N* Event Raw Status/Set Register).

When a critical priority error interrupt occurs following steps must be performed by acting processor :

1. Read the Info Register to confirm that the critical priority error output triggered.
2. Read Error Group *N* Critical Priority Interrupt Influence Set Register and the raw status in Error Group *N* Event Raw Status/Set Register to determine the input error events which triggered the critical priority error interrupt.
3. Perform Global Soft Reset to clear the Info Register (Base Address + 0x04) critical priority error interrupt status bit as well as all raw interrupt status
4. If the critical priority error interrupt resulted in an ESM Warm Reset, re-enable the Global Enable Register.

7.5.4 High Priority Watchdog Interrupt

The High Priority Watchdog Interrupt occurs when the process tasked with servicing the High Priority Interrupt has failed to do so for an amount of time set by the pre-loaded timeout value. The device can use the High Priority Watchdog Interrupt as a reset request.

Following actions must be taken by acting processor for Interrupt handling :

- If the High Priority Watchdog Interrupt triggers an ESM Warm Reset, Global Enable Register is reenabled after servicing all outstanding errors that triggered the High Priority Watchdog Interrupt and servicing the High Priority Interrupt.
- Write EOI vector to the EOI Interrupt Register or the Interrupt Clear results in a re-evaluation of the High Priority Watchdog Interrupt.

7.5.5 Safety Aggregator Interrupt Control and Handling

The safety aggregator generates the non-correctable error interrupt where hardware cannot correct the error in case of parity checker error.

The following is the sequence for servicing interrupts:

- Software enables the interrupts for a each edc_ctrl interface by writing 0x1 to the corresponding bit of the interrupt enable register (DED_ENABLE_SET_REG0).
- On receiving an interrupt, software checks which edc_ctrl interface has caused the error by reading the interrupt status (using DED_STATUS_SET_REG0).
- Software writes the edc_ctrl interface ID in the ECC vector field bits 10:0 along with the read message that includes setting bit 15 to trigger the serial VBUS read and writing the address to bits 23:16. The address corresponds to the register to read from the EDC controller component. Refer to the EDC Controller Register for more details.
- Software polls the read done bit (bit 24) in the ECC vector register.
- To clear the interrupt software does a write operation to Error Status 1 register to clear injected error and writes 0x1 to the end of interrupt register to clear the interrupt (using DED_EOI_REG).

7.6.4 ESM Examples

NOTE: These examples are located in the C29SDK installation from ti.com at the following location: mcu_sdk_DEVICE_GPN/examples/driverlib/CORE_IF_MULTICORE/esm

Cloud access to these examples is available at the following link: dev.ti.com C29SDK Examples.

7.6.4.1 ESM Multicore Example (CPU1,CPU3) - MULTI_CORE

FILE: esm_cpu1_cpu3_multi_c29x1.c

This example demonstrates how to handle fault conditions using ESM and Error Aggregator in a muli-core example (ESM_cpu1_cpu3_multi_c29x1.c).

When using CCS for debugging this Multi-core example, after launching the debug session,

- Connect to CPU1 and load only the c29x1.out.
- After the program is loaded, run CPU1.
- Once c29x1 configures and releases CPU3 out of reset, the program stops.
- Connect to CPU3 target now. c29x3.out would have started execution as soon as it is released from reset.
- In case of RAM configuration, restart the CPU3 target and load the symbols.

For FLASH configuration, this example is run in FLASH BANKMODE2, where CPU3 has access to FLASH (FRI-2). Refer to the Flash Plugin documentation to know about changing FLASH BANKMODEs and more. Additionally, the CPAx and CDAx RAMs are used for allocating various RAM sections. *External Connections*

- None.

Watch Variables

- None.

7.6.4.2 ESM Multicore Example (CPU1,CPU3) - MULTI_CORE

FILE: esm_cpu1_cpu3_multi_c29x3.c

This example demonstrates how to handle fault conditions using ESM and Error Aggregator in a muli-core example (ESM_cpu1_cpu3_multi_c29x3.c).

When using CCS for debugging this Multi-core example, after launching the debug session,

- Connect to CPU1 and first load the c29x3.out. (When loaded to FLASH, this might not halt at main due to an error, since CPU1 cannot execute from CPU3 FLASH memory (FRI-2)).
- c29x1.out can be loaded next.
- After the program is loaded, run CPU1.
- Once c29x1 configures and releases CPU3 out of reset, the program stops.
- Connect to CPU3 target now. c29x3.out would have started execution as soon as it is released from reset.
- In case of RAM configuration, restart the CPU3 target and load the symbols.
- In case of FLASH, do a Power-on-Reset, connect to CPU1/ CPU3 and load the respective symbols.

For FLASH configuration, this example is run in FLASH BANKMODE2, where CPU3 has access to FLASH (FRI-2). Refer to the Flash Plugin documentation to know about changing FLASH BANKMODEs and more. Additionally, the CPAx and CDAx RAMs are used for allocating various RAM sections. *External Connections*

- None.

Watch Variables

- CPU3nmigen
- Globalerroreventnumber

7.6.4.3 ESM - SINGLE_CORE

FILE: esm_ex1_tmuromparity_test.c

Example shows how to generate and check the error response configuration during development phase of software. It highlights the capability to self test the error propogation path providing test for diagnostic (TMU ROM Parity logic) Note - TMU ROM parity error puts CPU in fault state and only NMI can take CPU out of the fault state.

External Connections

- None.

Watch Variables

- error_generated - check if the proper error is generated

7.6.4.4 ESM - SINGLE_CORE

FILE: esm_ex2_safetyaggregator.c

This example shows how to do parity error injection for safety aggregator and generate parity error interrupt using the safety aggregator. For parity error generation, the example injects a single bit error and waits for the code execution to jump to parity error ISR in for loop. The parity error ISR clears the DED_STATUS_REG and sets EOI to acknowledge future Parity interrupts.

External Connections

- None.

Watch Variables

- ISRCount - The number of times entered into the ESM Parity Error ISR
- loopCount - The number of loops performed while not in ISR

7.7 ESM Registers

This Section describes the ESM Registers.

7.7.1 ESM Base Address Table

Table 7-16. ESM Base Address Table

Structure	DriverLib Name	Base Address	Frame Applicable	CPU1	CPU2	CPU3	RTDMA1	RTDMA2	HSM	Pipeline Protected
ESM_CPU_REGS	ESMCPU1_BASE	0x6009_0000	YES	YES	YES	YES	YES	YES	-	YES
ESM_CPU_REGS	ESMCPU2_BASE	0x6009_1000	YES	YES	YES	YES	YES	YES	-	YES
ESM_CPU_REGS	ESMCPU3_BASE	0x6009_2000	YES	YES	YES	YES	YES	YES	-	YES
ESM_SYSTEM_REGS	ESMSYSTEM_BASE	0x6009_F000	YES	YES	YES	YES	YES	YES	-	YES
ESM_SAFETYAGG_REGS	ESMSAFETYAGG_BASE	0x600A_0000	YES	YES	YES	YES	YES	YES	-	YES

7.7.2 ESM_CPU_REGS Registers

Table 7-17 lists the memory-mapped registers for the ESM_CPU_REGS registers. All register offset addresses not listed in Table 7-17 should be considered as reserved locations and the register contents should not be modified.

Table 7-17. ESM_CPU_REGS Registers

Offset	Acronym	Register Name
0h	PID	Revision Register
4h	INFO	Info Register
8h	EN	Global Enable Register
Ch	SFT_RST	Global Soft Reset Register
20h	LOW_PRI	Low Priority Prioritized Register
24h	HI_PRI	High Priority Prioritized Register
28h	LOW	Low Priority Interrupt Status Register
2Ch	HI	High Priority Interrupt Status Register
30h	EOI	EOI Interrupt Register
80h	HI_PRI_WD_CFG	High Priority Watchdog Config Register
84h	HI_PRI_WD_CNTR	High Priority Watchdog Counter Value Register
88h	HI_PRI_WD_CNTR_PRE	High Priority Watchdog Pre-Load Register
8Ch	HI_PRI_WD_INTR_SET	High Priority Watchdog Interrupt Status/Set Register
90h	HI_PRI_WD_INTR_CLR	High Priority Watchdog Interrupt Status/Clear Register
100h	GROUP_N_LOCK	Group N Interrupt Lock Register
104h	GROUP_N_COMMIT	Group N Interrupt Commit Register
118h	CRI_PRI_INFLUENCE_LOCK	Critical Prioirty Interrupt Influence Lock Register
11Ch	CRI_PRI_INFLUENCE_COMMIT	Critical Priority Interrupt Influence Lock Register
120h	MMR_CONFIG_LOCK	MMR Config Lock Register
124h	MMR_CONFIG_COMMIT	MMR Config Commit Register
400h + formula	RAW_j	Error Group N Event Raw Status/Set Register
404h + formula	STS_j	Error Group N Interrupt Enable Status/Clear Register
408h + formula	INTR_EN_SET_j	Error Group N Interrupt Enable Set Register
40Ch + formula	INTR_EN_CLR_j	Error Group N Interrupt Enabled Clear Register
410h + formula	INT_PRIO_j	Error Group N Interrupt Priority Register
800h + formula	CRIT_EN_SET_j	Error Group N Critical Priority Interrupt Influence Set Register
804h + formula	CRIT_EN_CLR_j	Error Group N Critical Priority Interrupt Influence Clear Register

Complex bit access types are encoded to fit into small table cells. Table 7-18 shows the codes that are used for access types in this section.

Table 7-18. ESM_CPU_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		

Table 7-18. ESM_CPU_REGS Access Type Codes (continued)

Access Type	Code	Description
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

7.7.2.1 PID Register (Offset = 0h) [Reset = 6FE03101h]

PID is shown in Figure 7-19 and described in Table 7-19.

Return to the Summary Table.

The Revision Register contains the major and minor revisions for the module.

Figure 7-19. PID Register

31-30	scheme	R	1h	PID register scheme
29-28	bu	R	2h	Business Unit: 10 = Processors
27-16	func	R	FE0h	Module ID
15-11	rtl	R	6h	RTL revision. Will vary depending on release.
10-8	major	R	1h	Major revision
7-6	custom	R	0h	Custom
5-0	minor	R	1h	Minor revision

7.7.2.2 INFO Register (Offset = 4h) [Reset = XXXX0808h]

INFO is shown in Figure 7-20 and described in Table 7-20.

Return to the Summary Table.

The Info Register gives the configuration Inforrmation of this ESM.

Figure 7-20. INFO Register

31	30	29	28	27	26	25	24

7-4	RESERVED	R/W	Xh	
3-0	wd_en	R/W	Ah	Enable field for the High Priority Watchdog. 0xA Enables the watchdog. All other values disable the watchdog

7.7.2.11 HI_PRI_WD_CNTR Register (Offset = 84h) [Reset = 0000FFFFh]

HI_PRI_WD_CNTR is shown in Figure 7-29 and described in Table 7-29.

Return to the Summary Table.

The High Priority Watchdog Counter Register reflects the current value of the High Priority Watchdog Counter. When enabled, this counter will start decrementing (from the High Priority Pre-Load value) as soon as any of the enabled Errors associated with the High Priority Interrupt is active. This counter is reset by the warm reset.

Figure 7-29. HI_PRI_WD_CNTR Register

7.7.2.13 HI_PRI_WD_INTR_SET Register (Offset = 8Ch) [Reset = 00000000h]

HI_PRI_WD_INTR_SET is shown in Figure 7-31 and described in Table 7-31.

Return to the Summary Table.

The High Priority Watchdog Status/Set Register indicates the status of the High Priority Watchdog Interrupt. This register is reset by the Power On Reset. A write to this register may allow software to set the interrupt output.

Figure 7-31. HI_PRI_WD_INTR_SET Register

7.7.2.14 HI_PRI_WD_INTR_CLR Register (Offset = 90h) [Reset = 00000000h]

HI_PRI_WD_INTR_CLR is shown in Figure 7-32 and described in Table 7-32.

Return to the Summary Table.

The High Priority Watchdog Status/Clear Register indicates the status of the High Priority Watchdog Interrupt. This register is reset by the Power On Reset. A write to this register may allow software to temporarily clear the interrupt.

Figure 7-32. HI_PRI_WD_INTR_CLR Register

7.7.2.15 GROUP_N_LOCK Register (Offset = 100h) [Reset = 00000000h]

GROUP_N_LOCK is shown in Figure 7-33 and described in Table 7-33.

Return to the Summary Table.

The fields of the Group N Interrupt Lock Register lock the configuration for the associated Error Group N Interrupt Enable Set/Clear Registers and the Error Group N Interrupt Priority Register. This locks the associated enable and priority bits for each Group for Low and High Priority Interrupts. Locks may be written until the associated Commit MMR fields are set to 1. Once Lock is 1 and Commit is 1, the associated configuration may not be changed until reset.

Figure 7-33. GROUP_N_LOCK Register

7.7.2.16 GROUP_N_COMMIT Register (Offset = 104h) [Reset = 00000000h]

GROUP_N_COMMIT is shown in Figure 7-34 and described in Table 7-34.

Return to the Summary Table.

The fields of the Group N Interrupt Commit Register commit the lock configuration for the associated Group N Interrupt Lock Register. This prevents the Locks in the Group N Interrupt Lock Register from changing. Once Commit is 1, the associated Lock and Commit may not be changed until reset.

Figure 7-34. GROUP_N_COMMIT Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

7.7.2.17 CRI_PRI_INFLUENCE_LOCK Register (Offset = 118h) [Reset = 00000000h]

CRI_PRI_INFLUENCE_LOCK is shown in Figure 7-35 and described in Table 7-35.

Return to the Summary Table.

The fields of the Critical Priority Interrupt Influence Lock Register lock the Critical Priority Interrupt Influence configuration for the associated Error Groups. Locks may be written until the associated Commit MMR fields are set to 1. Once Lock is 1 and Commit is 1, the associated configuration may not be changed until reset.

Figure 7-35. CRI_PRI_INFLUENCE_LOCK Register

7.7.2.18 CRI_PRI_INFLUENCE_COMMIT Register (Offset = 11Ch) [Reset = 00000000h]

CRI_PRI_INFLUENCE_COMMIT is shown in Figure 7-36 and described in Table 7-36.

Return to the Summary Table.

The fields of the Critical Priority Interrupt Influence Commit Register commit the lock configuration for the associated Error Groups. This prevents the Locks in the Critical Priority Interrupt Influence Lock Register from changing. Once Commit is 1, the associated Lock and Commit may not be changed until reset.

Figure 7-36. CRI_PRI_INFLUENCE_COMMIT Register

7.7.2.19 MMR_CONFIG_LOCK Register (Offset = 120h) [Reset = 000000XXh]

MMR_CONFIG_LOCK is shown in Figure 7-37 and described in Table 7-37.

Return to the Summary Table.

The fields of the MMR Config Lock Register lock the configuration for the associated MMRs. This prevents changes once the lock configuration is committed with the MMR Config Commit Register. Locks may be written until the associated Commit MMR fields are set to 1. Once Lock is 1 and Commit is 1, the associated configuration may not be changed until reset.

7.7.2.20 MMR_CONFIG_COMMIT Register (Offset = 124h) [Reset = 000000XXh]

MMR_CONFIG_COMMIT is shown in Figure 7-38 and described in Table 7-38.

Return to the Summary Table.

The fields of the MMR Config Commit Register commit the lock configuration for the associated MMR Config Lock MMR bits. This prevents the Locks in the MMR Config Lock Register from changing. Once Commit is 1, the associated Lock and Commit may not be changed until reset.

Complex bit access types are encoded to fit into small table cells. Table 7-47 shows the codes that are used for access types in this section.

Table 7-47. ESM_SYSTEM_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

7.7.3.1 PID Register (Offset = 0h) [Reset = 6FE03101h]

PID is shown in Figure 7-46 and described in Table 7-48.

Return to the Summary Table.

The Revision Register contains the major and minor revisions for the module.

Table 7-55. PIN_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-12	RESERVED	R/W	0h	
11-8	polarity	R/W	0h	Level mode polarity. When the error output pin is a level, by default it is active low, driving the error pin low to indicate an error. When 4'F is written to this field, the polarity will be active high instead. Software should not write values other than 4'h0 and 4'hF Any other values will default to active low behavior.
7-4	pwm_en	R/W	0h	PWM enable 0h = Error output pin is a level Fh = Error output pin is a PWM signal
3-0	key	R/W	0h	Pin Control Key 0h = Normal Mode. Error Pin will activate when an enabled Error Event occurs 5h = Clear Event. Generates a Clear event to the ESM state machine. Will return to Normal Mode on the next cycle. Ah = Force Error Mode. Forces the Error Pin active. To clear, write this field back to Normal Mode. You may only write to Force Error Mode while in IDLE. Attempting Force Error while in another state will have no effect.

7.7.3.9 PIN_STS Register (Offset = 44h) [Reset = 00000000h]

PIN_STS is shown in Figure 7-54 and described in Table 7-56.

Return to the Summary Table.

This register reflects the status of the error_pin_n output

0	val	R/W1C	0h	Read the current interrupt status. Write 1 to clear the interrupt output. The interrupt will reassert if the conditions that triggered it persist

7.7.3.19 GROUP_N_LOCK Register (Offset = 100h) [Reset = 00000000h]

GROUP_N_LOCK is shown in Figure 7-64 and described in Table 7-66.

Return to the Summary Table.

The fields of the Group N Interrupt Lock Register lock the configuration for the associated Error Group N Interrupt Enable Set/Clear Registers and the Error Group N Interrupt Priority Register. This locks the associated enable and priority bits for each Group for Low and High Priority Interrupts. Locks may be written until the associated Commit MMR fields are set to 1. Once Lock is 1 and Commit is 1, the associated configuration may not be changed until reset.

Figure 7-64. GROUP_N_LOCK Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

7.7.3.25 MMR_CONFIG_LOCK Register (Offset = 120h) [Reset = 000000XXh]

MMR_CONFIG_LOCK is shown in Figure 7-70 and described in Table 7-72.

Return to the Summary Table.

The fields of the MMR Config Lock Register lock the configuration for the associated MMRs. This prevents changes once the lock configuration is committed with the MMR Config Commit Register. Locks may be written until the associated Commit MMR fields are set to 1. Once Lock is 1 and Commit is 1, the associated configuration may not be changed until reset.

Each bit corresponds to event Q where Q=N*32+Bit, e.g. bit 0 is event N*32+0, bit 1 is N*32+1, etc. If the corresponding bit and the global_enable are set, then the interrupt is unmasked. This field is only reset by a Power-On-Reset, not warm reset. A global soft reset will set this field to 0. Read 0 is Disabled. Read 1 is Enabled. Write 0 has no effect. Write 1 clears the Enable. The corresponding event will no longer count as a pending event towards generating a critical priority interrupt.

7.7.4 ESM_SAFETYAGG_REGS Registers

Table 7-83 lists the memory-mapped registers for the ESM_SAFETYAGG_REGS registers. All register offset addresses not listed in Table 7-83 should be considered as reserved locations and the register contents should not be modified.

Table 7-83. ESM_SAFETYAGG_REGS Registers

Offset	Acronym	Register Name
0h	rev	Aggregator Revision Register
8h	vector	ECC Vector Register
Ch	stat	Misc Status
10h + formula	reserved_svbus_y	Reserved Area for Serial VBUS Registers
13Ch	ded_eoi_reg	EOI Register
140h	ded_status_reg0	Interrupt Status Register 0
180h	ded_enable_set_reg0	Interrupt Enable Set Register 0
1C0h	ded_enable_clr_reg0	Interrupt Enable Clear Register 0
200h	aggr_enable_set	AGGR interrupt enable set Register
204h	aggr_enable_clr	AGGR interrupt enable clear Register
208h	aggr_status_set	AGGR interrupt status set Register
20Ch	aggr_status_clr	AGGR interrupt status clear Register

Complex bit access types are encoded to fit into small table cells. Table 7-84 shows the codes that are used for access types in this section.

Table 7-84. ESM_SAFETYAGG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Wdecr	W decr	Write
Wincr	W incr	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

7.7.4.1 rev Register (Offset = 0h) [Reset = 66A03A01h]

rev is shown in Figure 7-81 and described in Table 7-85.

Return to the Summary Table.

Chapter 8

Error Aggregator

This chapter describes the features and operation of the error aggregator module. The error aggregator is an interface module that aggregates and stores error information needed for critical errors in the device. The aggregated error output is passed on to ESM (Error Signalling Module) to take appropriate/configurable action on the error occurrence.

8.1 Introduction

Error aggregator is an interface module between peripherals that generate various errors like C29x, RTDMA, Memory controllers, Peripheral bridges, Read Interfaces, and ESM (Error Signaling Module). The main purpose of the Error Aggregator is to accumulate various errors from various sources and provide aggregated error output to ESM module. The module also logs the error status, error address, and error type information while segregating high-priority errors and low-priority errors for ESM to generate appropriate action to alert the CPU.

8.2 Error Aggregator Modules

Each Error Source provides the following information for all Error Aggregator Modules:

- Error - Pulse signal is generated on the occurrence of any error sent to ESM for further action.
- Error Address - System Address at which the error occurred used to detect and debug the error origin.
- Error Type - Multibit signal that indicates the type of error used to classify the error into predefined categories outlined later in the chapter.

All CPU Error Aggregator Modules additionally provide a Program Counter (PC) log for first high-priority error occurrence.

Figure 8-1 illustrates the module working and implementation. Each Aggregator module aggregates an error from various sources. Upon error occurrence, the corresponding error address and type are logged into the error address and error type registers, respectively.

The errors are classified as high or low priority based on the list in Section 8.6.

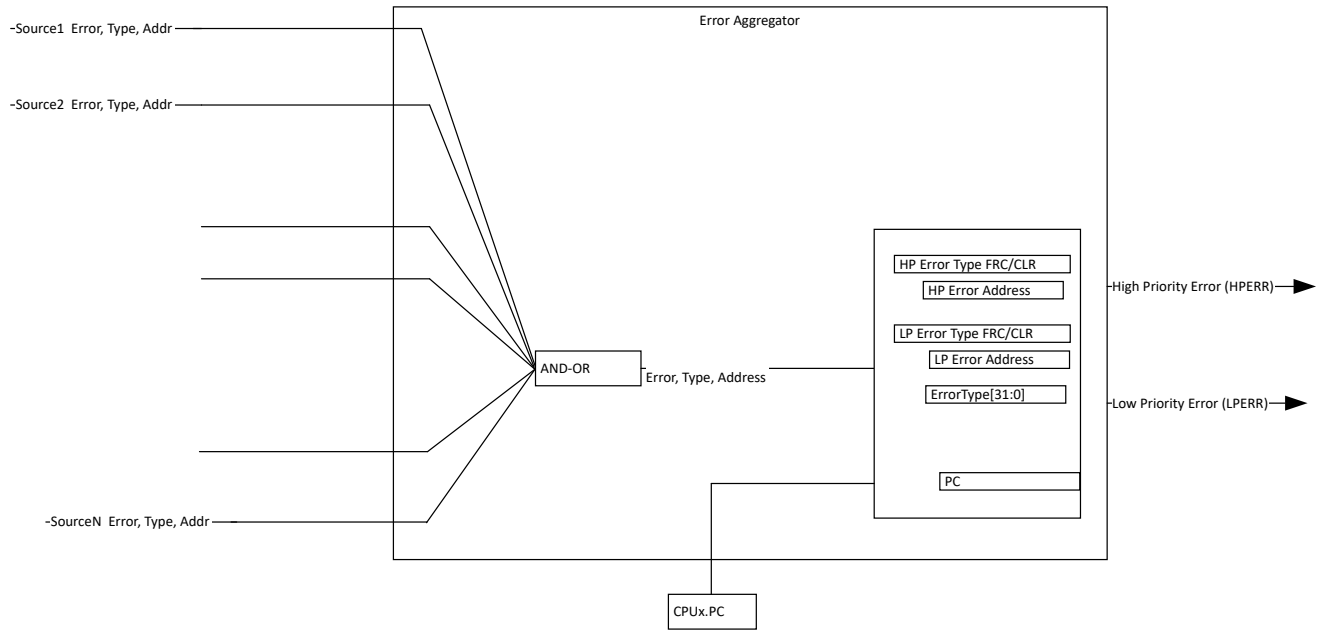

Figure 8-1. Error Aggregator Block Diagram

Error Aggregator modules implemented in the device are:

1. CPUx PR Error Aggregator - Aggregates errors occurred during CPUx program fetch access
2. CPUx DR1 Error Aggregator - Aggregates errors occurred during CPUx Data Read access on DR1 port
3. CPUx DR2 Error Aggregator - Aggregates errors occurred during CPUx Data Read access on DR2 port
4. CPUx DW Error Aggregator - Aggregates errors occurred during CPUx data write access
5. CPUx INT Error Aggregator - Aggregates interrupt related errors from CPUx and associated PIPE module
6. RTDMAx DR Error Aggregator - Aggregates errors occurred during RTDMAx data read access
7. RTDMAx DW Error Aggregator - Aggregates errors occurred during RTDMAx data write access
8. SSU Error Aggregator - Aggregates errors sent out by SSU module

9. EtherCAT Error Aggregator - Aggregates errors occurred during EtherCAT memory access
10. HSM Error Aggregator - Aggregates errors sent out by HSM subsystem

Note

x indicates that each error aggregator is repeated per initiator instance. EtherCAT only provides error and error address information so error type is tied off to uncorrectable error (0x40).

8.3 Error Propagation Path from Source to CPU

The Section 8.3 shown below describes the device level error handling and propagation from source to CPU. Error events from Error aggregator combined with other device level error events are provided to ESM (Error Signalling Module). Please refer to ESM error event map table for the complete list of error sources. ESM consolidates the responses to the error events and combined with other device level interrupt sources are sent to PIPE. For complete list of interrupts sent to PIPE refer to the PIPE channel mapping table. Optionally the error events can be configured to signal error pin output, trigger reset to device or respective CPU depending on the application through ESM. Refer to ESM chapter for more details.

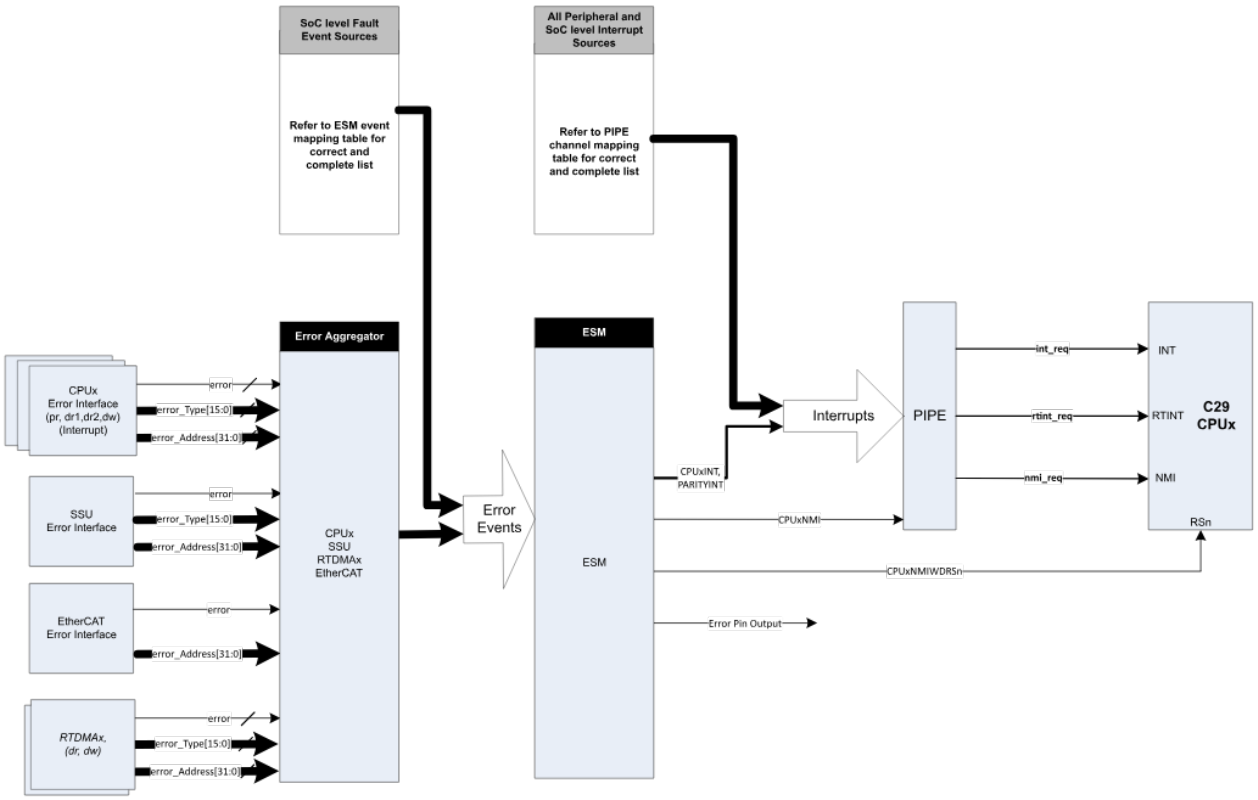

Figure 8-2. Error Propagation from Source to CPU

8.4 Error Aggregator Interface

This section provides details on how error information is handled and interfaced to the Error Signaling Module (ESM). The error outputs from multiple error aggregators are ORed and applied as single source to ESM. These includes:

- Low-Priority Errors from CPUx PR, CPUx DR1, CPUx DR2, CPUx DW are combined as CPUx LPERR

- High-Priority Errors from CPUx PR, CPUx DR1, CPUx DR2, CPUx DW are combined as CPUx HPERR
- Low-Priority Errors from RTDMAx DR + RTDMAx DW are combined as RTDMAx LPERR
- High-Priority Errors from RTDMAx DR + RTDMAx DW are combined as RTDMAx HPERR

Figure 8-3 shows a conceptual block diagram of the module functionality and how the output flag from each aggregator is combined as described in points above. The block diagram does not show all error aggregator modules available in the system, refer to the detailed list of supported error aggregators.

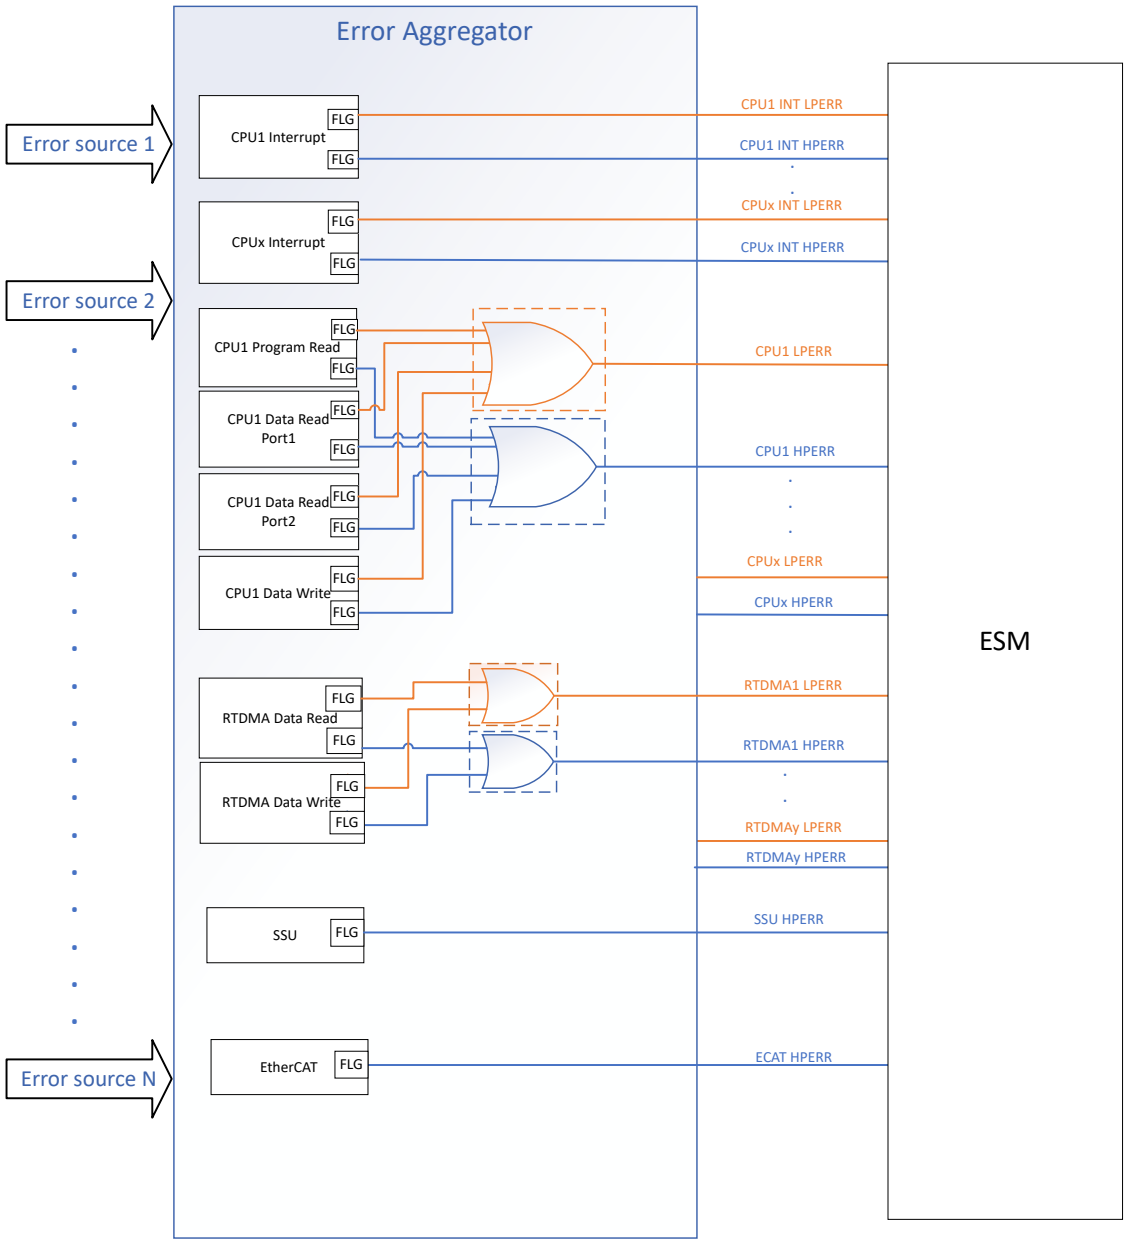

Figure 8-3. Error Aggregator Interface

8.4.1 Functional Description

The address at which the first error occurred and the corresponding error type are logged into the error address and error type registers, respectively. The errors are categorized into high- and low-priority errors.

Following actions are taken by the Error Aggregator on the occurrence of any high-priority error:

- Error type bit corresponding to the error occurred is set.
- High-Priority Error output pulse is generated.
- Address at which the first high-priority error occurred is latched to the High-Priority Error Address register. This register is not updated on further error occurrence until the high-priority errors in the error type register are cleared.
- On further occurrence of high-priority errors, the error type register continues to accumulate new errors but the error address register is not updated and no further high-priority error output pulses are generated until all the high-priority errors in the error type register are cleared.
- Additionally the user can also emulate or force an error condition by writing to the corresponding error_type in the ERROR_TYPE_FRC register.

Following actions are taken by the Error Aggregator on the occurrence of any low-priority error:

- Error type bit corresponding to the error occurred is set.
- Low-Priority Error output pulse is generated.
- Address at which the first low-priority error occurred is latched to the Low-Priority Error Address register. This register is not updated on further error occurrence until the low-priority errors in the error type register are cleared.
- On further occurrence of low-priority errors, the error type register continues to accumulate new errors but the error address register is not updated and no further low-priority error output pulses are generated until all the low-priority errors in the error type register are cleared.
- Additionally the user can also emulate or force an error condition by writing to the corresponding error_type in the ERROR_TYPE_FRC register.

  The error type register is cleared by writing to the ERROR_TYPE_CLR register.

  In addition to the above error aggregator logs, the program counter value at the time of occurrence of the first high-priority error is applicable to all CPUx (PR, DR1, DR2, DW, and INT) Error Aggregators only.

Note

The program counter value logged is not always a precise value. In some cases, the error address value is more precise than the program counter value.

8.5 Error Condition Handling User Guide

User's configure the NMI ISR which are output from ESM to do the following checks for errors passed on from Error Aggregator to the ESM:

1. Check the ESM Raw Status Register - Error Group N Event Raw Status/Set Register to check which events caused the error interrupt to trigger from ESM using the ESM Event Map.
2. If the error trigger is caused due to an error aggregator event mapped to ESM (Group 0 Events), then check the corresponding error aggregator Instance Type register.
   a. For example: If the Error Event 0 (ErrorAggregator_CPU1_HPERR) is detected from ESM in Step 1, user configures ISR to check error aggregator registers - CPU1_PR_ERROR_TYPE, CPU1_DR1_ERROR_TYPE, CPU1_DR2_ERROR_TYPE and CPU1_DW_ERROR_TYPE to determine what type of error was detected and in which instance of the error aggregator.
3. From Step 2, when user knows the error type, to narrow down the location of error user reads the corresponding error address register and program counter register.
   a. For example: If user finds out that the ILLEGAL_INSTRUCTION (Bit 10) in CPU1_PR_ERROR_TYPE is set, then user reads the corresponding CPU1_PR_HIGHPRIO_ERROR_ADDRESS register to find out the address at which the first high-priority error occurred on CPU1_PR access.

b. Also user reads CPU1_PR_PC register that contains the program counter value at the first high-priority error event.

4. While exiting the ISR, if user wants to clear the error when the source of the error is cleared - From Step 2, user stores the value of the error type register then copies the value to the error type clear register. If the source of the error still persists after the error clear, then the error aggregator generates another error pulse trigger to ESM.
   a. For example: From Step 3, user stores the value from the CPU1_PR_ERROR_TYPE register and copies the same value to the CPU1_PR_ERROR_TYPE_CLR register to clear the CPU1_PR_ERROR_TYPE register.

Note

If user does not do step 4, the error aggregator does not generate another error event input to ESM until corresponding priority error type register is cleared.

When the application is not able to clear the error before a NMIWD (High Priority Watchdog) timeout, then a reset is triggered from ESMCPU1 instance (refer to Figure 7-8). In this case, BootROM clears errors to avoid a back-to-back NMIWD rest loop and stores the error information and status to M0 RAM (refer to Table 4-35) for further debug.

In above case, BootROM clears the following status:
1. ESM Group0 RAW Status for ESMCPU1 and SYSESM instances of ESM-Subsystem
2. All CPUx error aggregator type registers

Also saves the following in M0 RAM for user to debug the source of error:
1. ESM RAW Status for Group0 only
2. Error Aggregator CPU1 - PR, DR1/2, DW, and INT instances error information including high-priority error address, low-priority error address, error type, and program counter registers

8.6 Error Type Information

This section lists the error type information and associated priority for all error aggregators.

Table 8-1. Errors on CPUx PR Interfaces

Error Type	CPUx PR Error	RAM, ROM, FRI – PR Error	Priority
0x01	Instruction fetch security violation. Instruction packet crossed LINK, STACK, ZONE boundary. Linear code crossed LINK, STACK, ZONE boundary. Regular Branch and Calls crossed STACK, ZONE boundary.	Reserved	High
0x02	Secure entry error	Reserved	High
0x04	Secure exit error	Reserved	High
0x08	MAX PSP error	Reserved	High
0x10	Access timeout error	Reserved	High
0x20	Access ACK error	Access ACK error	High
0x40	Uncorrectable error	Uncorrectable error	High
0x80	Correctable error	Reserved	Low
0x100	WARN PSP error	Reserved	Low
0x200	Software breakpoint error	Reserved	High
0x400	Illegal instruction error	Reserved	High
0x800	Instruction timeout error	Reserved	High

8.9 ERRORAGGREGATOR Registers

This Section describes the ERRORAGGREGATOR Registers.

8.9.1 ERRORAGGREGATOR Base Address Table

Table 8-16. ERRORAGGREGATOR Base Address Table

Structure	DriverLib Name	Base Address	Frame Applicable	CPU1	CPU2	CPU3	RTDMA1	RTDMA2	HSM	Pipeline Protected
HSM_ERROR_AGGREGATOR_CONFIG_REGS	HSMERRORAGGREGATOR_BASE	0x3012_0000	-	-	-	-	-	-	YES	YES
ERROR_AGGREGATOR_CONFIG_REGS	ERRORAGGREGATOR_BASE	0x6008_C000	YES	YES	YES	YES	YES	YES	-	YES

8.9.2 HSM_ERROR_AGGREGATOR_CONFIG_REGS Registers

Table 8-17 lists the memory-mapped registers for the HSM_ERROR_AGGREGATOR_CONFIG_REGS registers. All register offset addresses not listed in Table 8-17 should be considered as reserved locations and the register contents should not be modified.

Table 8-17. HSM_ERROR_AGGREGATOR_CONFIG_REGS Registers

Offset	Acronym	Register Name	Protection
0h	HSM_HIGHPRIO_ERROR_ADDRESS	High Priority Error address register	
4h	HSM_LOWPRIO_ERROR_ADDRESS	Low Priority Error address register	
8h	HSM_ERROR_TYPE	Error Type Register	
Ch	HSM_ERROR_TYPE_FRC	Error Type Force Register	
10h	HSM_ERROR_TYPE_CLR	Error Type Clear Register	

Complex bit access types are encoded to fit into small table cells. Table 8-18 shows the codes that are used for access types in this section.

Table 8-18. HSM_ERROR_AGGREGATOR_CONFIG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

8.9.2.1 HSM_HIGHPRIO_ERROR_ADDRESS Register (Offset = 0h) [Reset = 00000000h]

HSM_HIGHPRIO_ERROR_ADDRESS is shown in Figure 8-4 and described in Table 8-19.

Return to the Summary Table.

High Priority Error address register

Complex bit access types are encoded to fit into small table cells. Table 8-25 shows the codes that are used for access types in this section.

Table 8-25. ERROR_AGGREGATOR_CONFIG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		

Table 8-25. ERROR_AGGREGATOR_CONFIG_REGS Access Type Codes (continued)

Access Type	Code	Description
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

8.9.3.1 CPU1_PR_HIGHPRIO_ERROR_ADDRESS Register (Offset = 0h) [Reset = 00000000h]

CPU1_PR_HIGHPRIO_ERROR_ADDRESS is shown in Figure 8-9 and described in Table 8-26.

Return to the Summary Table.

Chapter 9

Flash Module

This chapter describes the architecture and operation of the C29x Flash subsystem.

9.1 Introduction to Flash Memory

Flash is a type of electrically erasable and programmable non-volatile memory. In C2000™ real-time microcontrollers, Flash memory is primarily used to store application code, which executes directly from the internally embedded Flash memory banks. Additionally, Flash can be used to store static data that needs to be preserved between power cycles or device resets.

This chapter describes the structure of Flash memory modules in the device, the proper sequence to initialize and configure Flash, how to improve Flash performance by enabling prefetch and cache mechanisms, and mechanisms for management of firmware updates.

9.1.1 FLASH Related Collateral

Foundational Materials

- C29x Academy - Flash Memory
- Embedded Flash Memory (Video)

Getting Started Materials

- *Serial Flash Programming of C2000 Microcontrollers Application Report*
- [FAQ] FAQ for Flash ECC usage in C2000 devices - Includes ECC test mode, Linker ECC options:
- [FAQ] FAQ on Flash API usage for C2000 devices
- [FAQ] Flash - How to modify an application from RAM configuration to Flash configuration?
- [FAQ] How can we improve the Flash tool performance?
- [FAQ] TI C2000 Device Programming Tools and Services

9.1.2 Features

The features of Flash memory include:

- Up to 8 Flash program code banks, 4 of which can optionally be allocated to CPU3 (if available) at boot time for instruction fetches (For the number and size of Flash banks, refer to the device data manual);
- Up to two Flash controller modules, with up to four program banks per module;
- One dedicated data Flash bank housed in Flash Controller 1 (FLC1), optimized for data bus read accesses;
- Enhanced Flash Read Interface module (FRI), with interleaving of program bank pairs for high performance during 128 bit-wide instruction word fetches;
- Each Flash Controller can program or erase a Flash bank or bank pair while simultaneously reading from the other pair of Flash banks;
- Tight integration with the Safety and Security Unit (SSU) for security management and access control for Flash program, erase and read operations;
- 128-bit-wide Flash programming, with configurable programming options;
- Multiple sectors, with the ability to erase individual/specific sectors while leaving others programmed;
- Dedicated SECCFG Flash regions for storing user security policy settings and boot mode options that are loaded at device start-up;
- BANKMGMT sectors for management of Flash firmware updates using FOTA or Live Firmware Update mechanisms, with anti-rollback protection capability;
- Code prefetch, block cache and data cache mechanisms for enhanced read performance for program code and data;
- Configurable wait states to achieve the best performance at a given clock frequency;
- Safety Features:
  - ECC error detection in address bits, with reporting to the Error Signaling Module (ESM);
  - Supports ECC bits for single error correction and double error detection (SECDED);
- Integrated Flash program and erase state machines in the Flash Controller modules:
  - Simple Flash API algorithms;
  - Fast erase and program times (refer to the device data manual for details);
- Automatic arbitration of data accesses between multiple initiators (C29x CPUs, HSM, RTDMA and debugger accesses).

9.1.3 Flash Tools

Texas Instruments provides the following tools for Flash:

- Code Composer Studio™ (CCS) IDE - the development environment with integrated Flash plugin. TI recommends performing a debug reset and restart after programming the code into Flash using CCS.
- Flash API Library - a set of software peripheral functions to erase/program Flash
- UniFlash - standalone tool to erase/program/verify the Flash content through JTAG. No CCS is required.
- Users must check and install available updates for CCS On-Chip Flash Plugin and UniFlash tools.

9.1.4 Block Diagram

A top-level block diagram of the C29x Flash subsystem is shown in Figure 9-1.

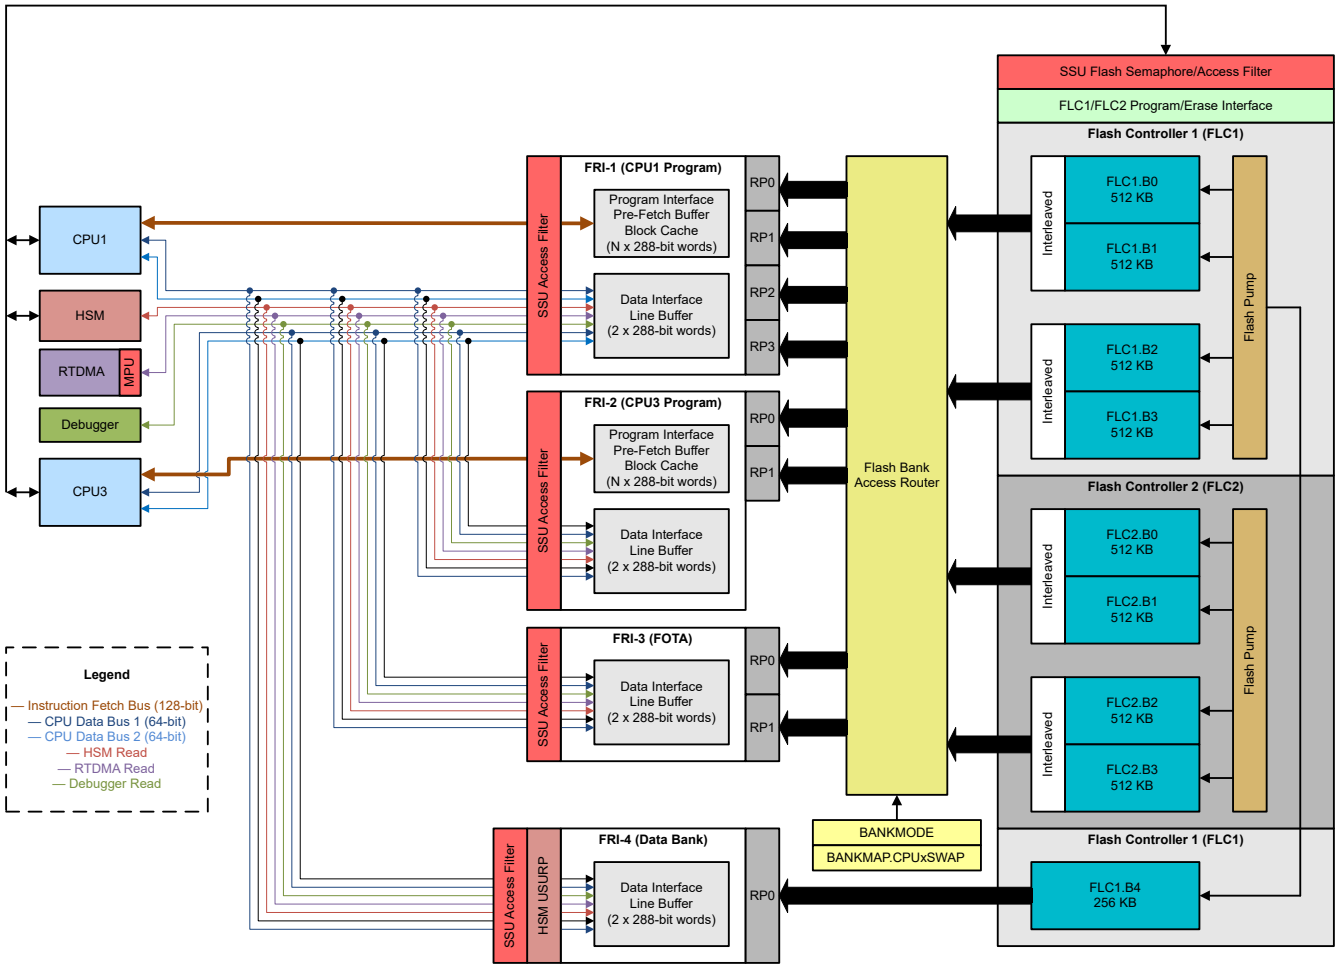

Figure 9-1. Flash Subsystem Block Diagram

9.2 Flash Subsystem Overview

At the heart of the C29x Flash subsystem are one or more Flash Controllers (FLCn), which interface directly with the Flash banks and charge pump. Each Flash controller performs the following primary functions:

- Provides a simple interface for software to program or erase the Flash memory.
- Interfaces with the Flash Bank Access Router (FBAR) for reads of program code and data.
- Provides the capability to block unwanted bank program or erase operations.

Additionally, there are four Flash Read Interfaces (FRI-n), which provide an interface for various initiators in the device to read from Flash memory. The Flash Read Interfaces provide memory address regions for Flash read, and include buffer and cache mechanisms to maximize read performance. The Flash Bank Access Router (FBAR) connects each Flash read port to the associated Flash bank or bank pair, depending on MODE and SWAP configuration. These modules are explained in detail in the following sections. Accesses from all initiators to the Flash Read Interface or Flash Controller registers are filtered through the SSU access permission logic and HSM usurp controls.

9.3 Flash Banks and Pumps

This device includes up to 8 Flash application code banks, and one application data bank. Each Flash bank stores code or data as 128-bit Flash words, plus 16 bits of ECC per Flash word. To meet the performance requirements of the C29 CPU, each group of two code banks is interleaved to form a bank pair, enabling 256-bit instruction fetches. The data bank is a single bank, and does not require interleaving since C29 data buses are 64-bits wide. The F29x Flash API automatically handles the addressing and interleaving of code banks, enabling user code to perform program and erase operations on interleaved bank pairs with a single command.

For naming purposes, each bank or bank pair is referred to by the Flash controller name and bank numbers. Banks are numbered starting with 0. For example, FLC2.B0/B1 refers to the first interleaved bank pair in Flash Controller 2, and FLC1.B4 refers to the 5th non-interleaved bank in FLC1, which is a data bank.

Each bank is divided into the following regions:

1. **MAIN**: This region is the primary storage region for the Flash bank, and is used to store application code and data.
2. **SECCFG**: This region contains security policy settings (also known as the User Protection Policy (UPP)), and other device configuration parameters. Security policy settings are loaded by the boot ROM into the Safety and Security Unit (SSU). For more information and content mapping for the SECCFG region, see Section 10.8.2.
3. **BANKMGMT**: This region is used to manage firmware updates using Firmware-Over-The-Air (FOTA) or Live Firmware Update (LFU) processes. The BANKMGMT sector also contains code version information for rollback protection. For more information on the BANKMGMT region, see Section 10.8.

Each Flash controller also contains a charge pump. The charge pump generates the special voltages and currents required for Flash program, erase and read operations.

9.4 Flash Read Interfaces

The C29x Flash subsystem includes up to four Flash Read Interface modules (FRI-n). The Flash read interface modules provide a means for the various initiators on the system to perform read operations on Flash memory. These initiators include:

- **C29x CPUs**: Each CPU has one 128-bit instruction fetch bus, and two 64-bit data buses. In the C29x architecture, only primary CPUs (odd-numbered) have access to Flash memory for code fetch and data. Secondary CPUs (even-numbered) do not have access to Flash. Code that runs on an independent secondary CPU must first be copied to RAM and then executed from there.
- **RTDMA1**: The primary Real-Time DMA module can perform 64-bit data reads of Flash memory.
- **HSM**: If present, the Hardware Security Module can perform 32-bit data reads of Flash memory through the HSM_TO_SOC bus.
- **Debug Interface**: A debugger connected to either the C29x or HSM CPUs can perform data read accesses to C29x Flash memory locations.

Each Flash read interface is addressable through one or more Flash read ports. Because of bank interleaving, multiple CPU support, and support for bank swapping during firmware updates, Flash code banks do not have a fixed mapping to CPU address space. Rather, each read port has a fixed address range, but can map to a different Flash region depending on the current system configuration. The Flash bank access router performs the background translation, routing read access requests to the intended bank or banks as directed by the Safety and Security Unit (SSU). The are two types of Flash read operations that can be performed: program instruction fetches for CPU execution, and data accesses.

Each of the Flash read interfaces is described in the following sections.

FRI-1: CPU1 Program

FRI-1 interfaces with the instruction fetch bus of the first C29x CPU (CPU1), and is primarily used for executing program code on CPU1. Additionally, FRI-1 is connected to all data read initiators in the system. This read interface has four read ports, numbered RP0 to RP3. These read ports are mapped to code banks depending on the configuration of BANKMODE and BANKMAP.CPU1SWAP registers in the SSU. These settings are described in subsequent sections.

FRI-2: CPU3 Program

On 3- or 4-CPU systems, FRI-2 interfaces with the instruction fetch bus of the third C29x CPU (CPU3). When program Flash memory is allocated to CPU3 by configuring BANKMODE, FRI-2 can be used to execute program code on CPU3, and additionally can be used as a data read interface by all initiators in the system. This read interface has two read ports, numbered RP0 to RP1. These read ports are mapped to code banks depending on the configuration of BANKMODE and BANKMAP.CPU3SWAP. On single-CPU systems, FRI-2 is not present.

FRI-3: Firmware Update Region

FRI-3 provides an address range to be used for programming and verifying an updated firmware image into the second half of Flash memory, while the current application continues to execute from the first half through FRI-1 and FRI-2 (if present). When the firmware update is complete, the Flash memory ranges can then be swapped using BANKMAP.CPUxSWAP, and the newly programmed firmware now executes from FRI-1 and FRI-2 (if present). This supports Firmware-Over-The-Air (FOTA) and Live Firmware Update (LFU) firmware upgrade mechanisms. FRI-3 does not have an instruction fetch interface—only data reads are possible from all system initiators. FRI-3 has two read ports, numbered RP0 to RP1, which are mapped to available Flash code memory.

FRI-4: Data Bank

FRI-4 is exclusively used for the data bank (FLC1.B4), and does not have an instruction fetch interface. Thus, application code cannot be executed from the data bank; only read accesses are possible from all system initiators. FRI-4 has one read port (RP0) which has a fixed mapping to the data Flash bank, and does not change based on the BANKMODE or BANKMAP.CPUxSWAP settings.

9.4.1 Bank Modes and Swapping

The BANKMODE register in the SSU_GEN_REGS register range configures the system Flash bank mode setting. These modes determine the allocation of Flash memory to primary C29 CPUs in the system, and whether the swapping feature is enabled for firmware updates. The BANKMODE register is loaded from the BANKMGMT sector of the active code bank pair in FLC1 during device boot. The active BANKMGMT sector is determined based on the values of the BANK_STATUS and BANK_UPDATE fields; afterward, the winning BANKMGMT sector is used to configure the system BANKMODE.

The available bank mode options are described in Table 9-1.

Table 9-1. C29 Bank Modes

BANKMODE	Flash Mapping	Swap Enabled	1-CPU Devices
0	All program Flash mapped to CPU1	No	Available
1		Yes	Available
2	Program Flash memory is split between CPU1 and CPU3	No	N/A
3		Yes	N/A

The BANKMAP register in SSU_GEN_REGS is used to determine the current active A/B swap setting for firmware updates using FOTA or LFU. This register contains a swap enable bit for each primary CPU (CPUxSWAP).

For specific mappings of Flash address ranges to read port addresses based on BANKMODE and CPUxSWAP settings, refer to the device data sheet.

9.4.2 Flash Wait States

When a CPU performs a read access to a Flash memory address, data is returned after (RWAIT + 1) SYSCLK cycles.

For an access to the SECCFG or BANKMGMT Flash regions, data is returned after 10 SYSCLK cycles.

RWAIT defines the number of random access wait states, and is configured using the RWAIT field in the FRDCNTL register. At reset, RWAIT defaults to a value of 2. RWAIT can be reconfigured to a lower value when the CPU clock frequency is low enough to accommodate the Flash access time. For a table of supported RWAIT values versus CPU clock frequency ranges, refer to the device data sheet.

For a given system clock frequency, configure RWAIT using the following formula:

$$\mathrm{RWAIT} = \mathrm{ceiling}\left(\frac{\mathrm{SYSCLK}}{\mathrm{FCLK}} - 1\right)$$

where SYSCLK is the system operating frequency, and where FCLK is the Flash clock frequency.

FCLK must be ≤ $\mathrm{FCLK}_{\mathrm{max}}$, the allowed maximum Flash clock frequency.

If RWAIT results in a fractional value when calculated using the above formula, round up RWAIT to the nearest integer.

Note

The minimum value that RWAIT can be configured to on this device is 1. Zero wait state reads are not supported.

9.4.3 Buffer and Cache Mechanisms

Each Flash read interface includes mechanisms designed to maximize performance for read operations. These mechanisms include:

- An instruction prefetch buffer,
- A program code block cache, and
- A line buffer for data read operations.

These mechanisms are disabled by default at device boot, and must be configured to enable them before application execution commences.

9.4.3.1 Prefetch Mechanism and Block Cache

Flash memory is typically used to store application code. During code execution, instructions are fetched from contiguous memory addresses, except when a discontinuity occurs. Usually, the portion of code that resides in contiguous address locations makes up the majority of the application code, and is referred to as linear code. To improve the performance of linear code execution, the Flash read interface includes a code prefetch mechanism and block cache. The prefetch mechanism and block cache are available on FRI-1 (and FRI-2, if present). Figure 9-2 shows a functional block diagram of the Flash prefetch mechanism and block cache.

The prefetch mechanism does a look-ahead prefetch on linear address increments, starting from the address of the last instruction fetch. The Flash prefetch mechanism is disabled by default. To enable prefetch mode, set the PREFETCH_EN bit in the FRIx_INTF_CTRL register to 1, or call the Flash_enablePrefetch() driverlib function.

Each instruction fetch from Flash memory reads out 256 bits total—128 bits from each half of an interleaved pair (not counting ECC bits). The starting address of the access from Flash is automatically aligned to a 256-bit boundary, such that the instruction location is within the 256 bits to be fetched. When the prefetch mechanism is enabled, the 256 bits read from the instruction fetch are stored in a 128-bit wide by 4-level deep instruction prefetch buffer. The contents of this prefetch buffer are then sent to the CPU for processing as required.

The C29 CPU receives instruction packets up to 128 bits wide, over a 128-bit program read bus. Each instruction packet can contain a combination of 16-bit, 32-bit or 48-bit instructions. While the instructions are processing through the CPU, the Flash prefetch mechanism automatically initiates another access to the Flash bank to prefetch the next 256 bits. In this manner, the Flash prefetch mechanism works in the background to keep the instruction prefetch buffer as full as possible. Using this technique, the overall efficiency of sequential code execution from Flash is significantly improved.

In addition to the prefetch buffer, the Flash read interface includes a block cache mechanism, consisting of two 256-bit-wide by 16-deep blocks. The block cache sits between the prefetch buffer and the Flash banks, and is loaded with 256-bit data simultaneously with the prefetch buffer. Whenever there is a discontinuity in execution (such as a branch instruction), the mechanism checks if the requested data is already in the block cache. If so, the instruction data is read from the block cache and fed into the prefetch buffer, which then sends the data to the CPU on the next cycle. This improves the latency for discontinuity instructions to just one wait state, boosting code performance in short-branch loops and other minor discontinuities. To enable the block cache, set the CODE_CACHE_EN bit in the FRIx_INTF_CTRL register to 1, or call the Flash_enableCodeCache() driverlib function.

Note

The block cache is designed such that execution loops of 512 bytes or less run with minimum latency once loaded into the cache. Loops that are larger than 512 bytes exceed the size of one cache block, and in these cases, the performance benefit can be reduced.

Because the block cache interfaces between the prefetch buffer and the Flash banks, the prefetch mechanism must be enabled for the block cache to function. If the block cache is enabled without the prefetch buffer, neither mechanism ever gets loaded, and Flash performance is equivalent to both mechanisms being turned off. Always enable the prefetch buffer when enabling the block cache.

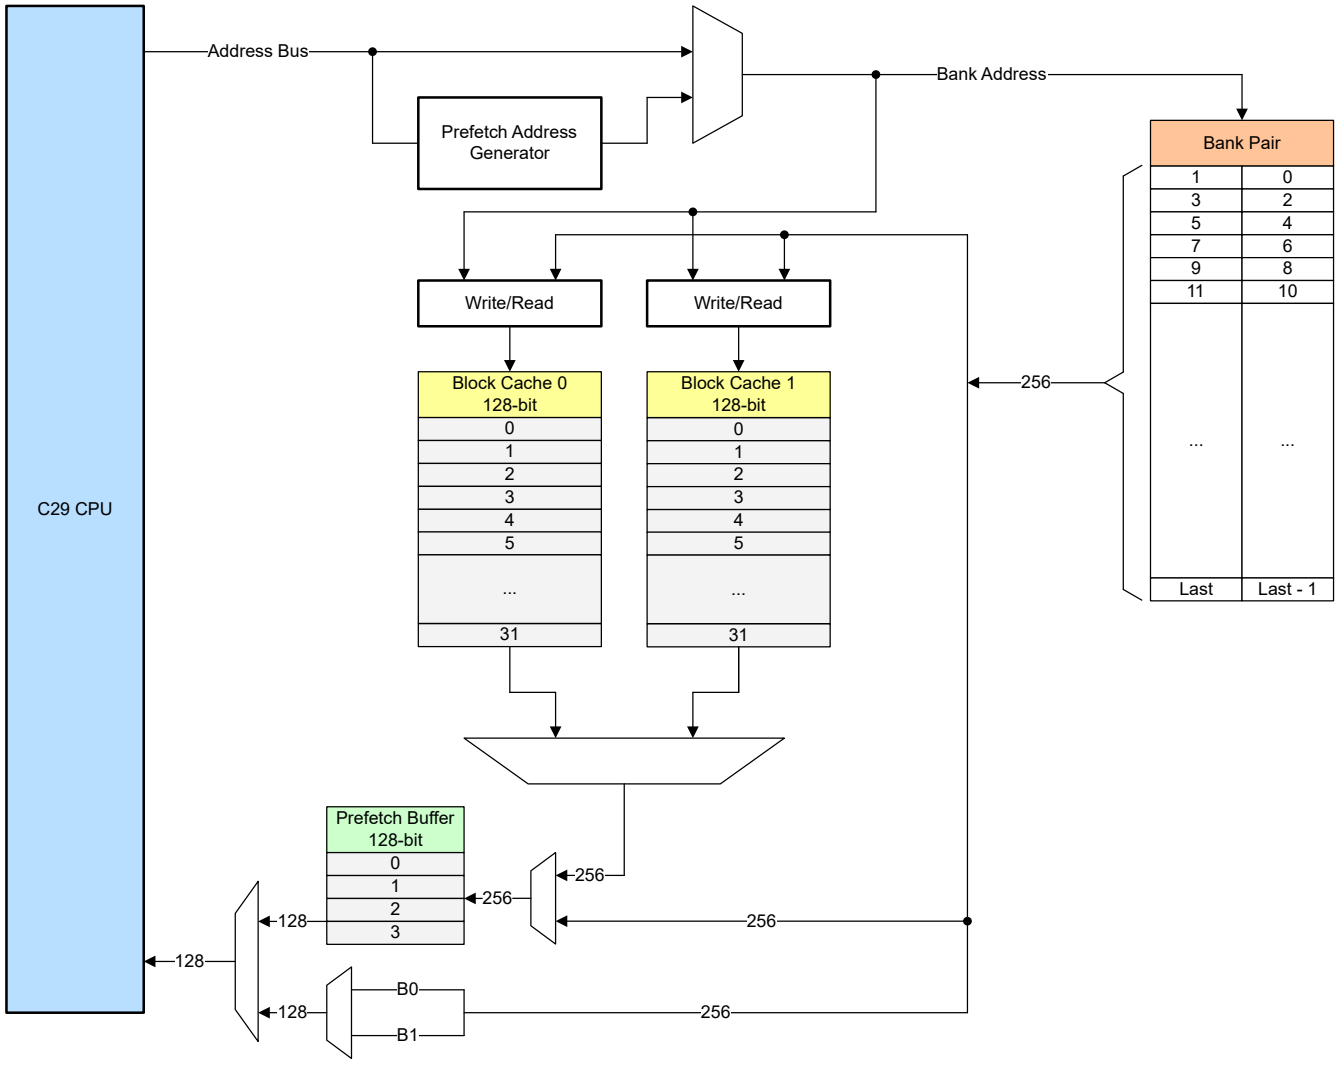

Figure 9-2. Flash Prefetch Mechanism and Block Cache

9.4.3.2 Data Line Buffer

To improve the performance of data reads, the Flash read interface includes a data line buffer. The size of the data line buffer is 288 bits for an interleaved bank pair (including 32 ECC bits), and 144 bits for a non-interleaved data bank (including 16 ECC bits). To activate the Flash data line buffer, write 1 to the DATA_CACHE_EN bit of the FRIx_INTF_CTRL register for the target Flash read interface.

When a read request is received from one or more initiators in the system, the upper portion of the address is compared to the buffer tag to determine if the requested data is in the line buffer. If a match is found, and the valid bit (V) is set, then the Flash read interface returns data directly from the line buffer to the initiator, without making a new access to the Flash bank. The address of the data is also returned to the CPU for ECC checking.

There is a dedicated compare unit for each read initiator (for example, CPU1, RTDMA, debugger), so multiple initiators can read from the data line buffer simultaneously without added wait states. Figure 9-3 shows a functional block diagram of the data line buffer for interleaved bank pairs. Figure 9-4 shows a functional block diagram of the data line buffer for non-interleaved banks.

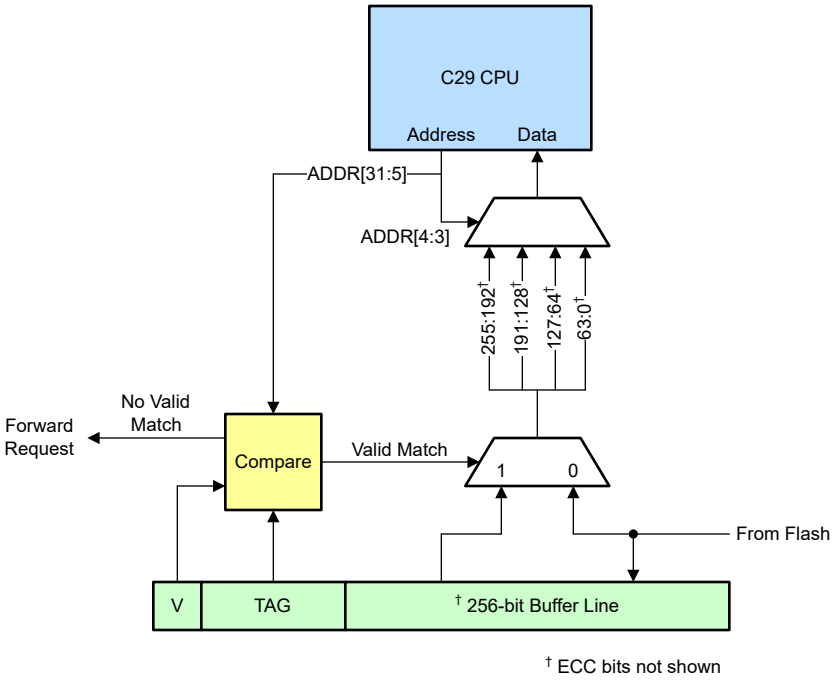

Figure 9-3. Flash Data Line Buffer for Interleaved Banks

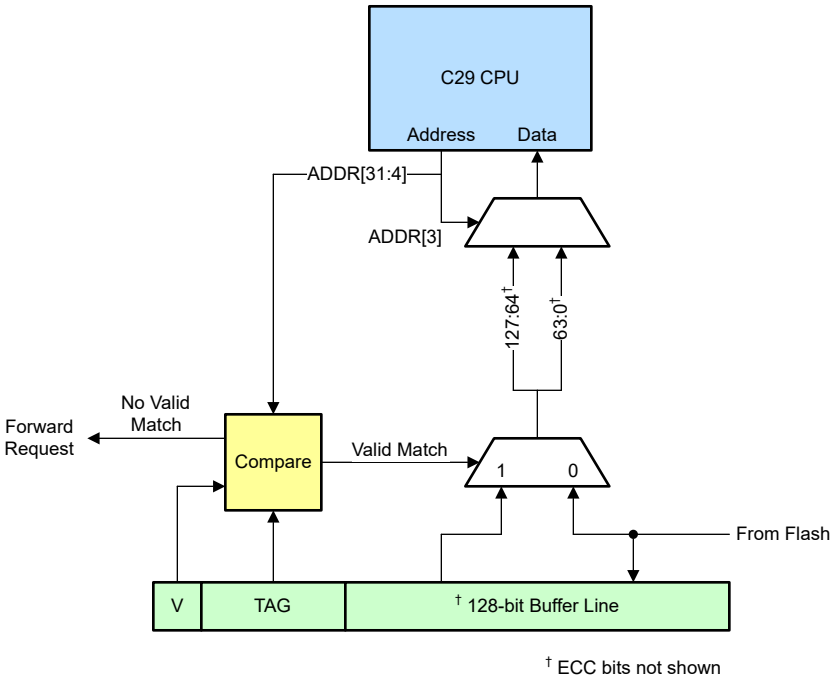

Figure 9-4. Flash Data Line Buffer for Single Bank

If a query does not match the line buffer tag, then a read operation is performed on the associated Flash bank or bank pair. When the data is returned from the Flash, the Flash read interface sends the requested data portion to the CPU, updates the data line buffer, and sets the valid bit. For non-interleaved banks, the line buffer is always 128-bit aligned. For interleaved bank pairs, the line buffer contents are always 256-bit aligned, such that the lower 128 bits come from the first bank and the upper 128 bits come from the second bank. Figure 9-5 illustrates the mapping of interleaved bank pairs to data line buffer bits.

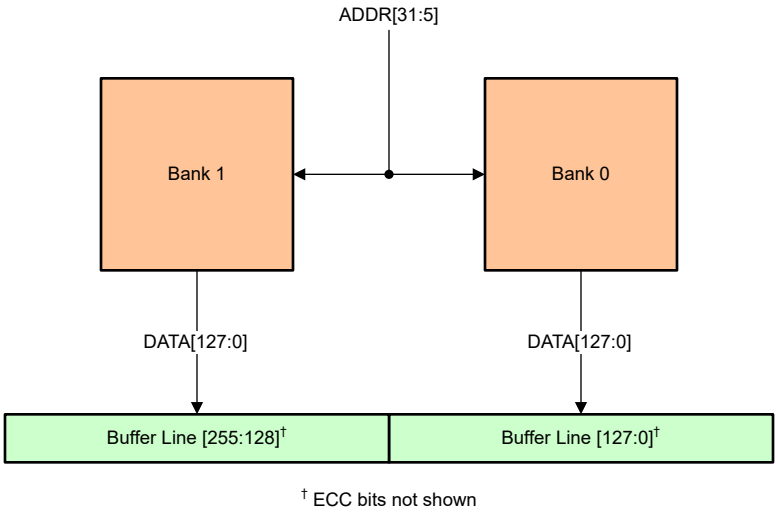

Figure 9-5. Interleaved Bank to Buffer Mapping

Note

Since each Flash Read Interface contains only one buffer, attempts to concurrently read data at different Flash addresses by multiple initiators through the same FRI can potentially lead to a bottleneck. In this situation, the line buffer contents are replaced by each concurrent request without being used. To prevent a slowdown in performance, avoid or limit simultaneous reads by multiple CPUs to the same Flash Read Interface.

The data line buffer valid bit is only cleared automatically on a reset. Always flush the buffer manually after programming or erasing Flash memory, or whenever a CPU fault is detected. To clear the valid bit and flush the buffer, write 1 to the DATA_CACHE_CLR bit of the corresponding FRIx_INTF_CLR register.

Note

The Flash read interface registers can only be written to by CPU1. When programming or erasing Flash memory from another CPU (e.g. CPU3), the application must request CPU1 to flush the data line buffer via IPC.

9.4.3.3 Sequential Data Pre-read Mode

Each Flash read interface provides a user-configurable sequential data pre-read mode. In this mode, the data line automatically pre-reads the Flash and refills the line buffer with the next sequential set of addresses after a previous read is completed. When sequential pre-read mode is active and an initiator reads the last 64-bit word in the line buffer (bits [255:192] for interleaved banks, [127:64] for single banks), the pre-read logic reads the next sequential Flash bank address, and replaces the buffer contents with the data read. The line buffer is then ready for the initiator at the next Flash read request. If an initiator requests a part of the data while the Flash read access is in progress, then the data is returned to the initiator as soon as the Flash read operation is complete.

Flash sequential data pre-read mode is turned off by default, and must be explicitly activated by the user. This mode is intended to be used only during sequential data reads for maximum performance. To enable

sequential data pre-read mode, write 1 to the DATA_PREREAD_EN bit of the FRIx_INTF_CTRL for the target read interface. When the sequential read operation is complete, write 0 to the DATA_PREREAD_EN bit to turn off the pre-read mechanism.

Note

The sequential data pre-read logic is part of the data line buffer, and cannot function if the line buffer is turned off. Always enable the line buffer when using sequential pre-read mode.

9.4.4 Flash Read Arbitration

Each Flash read interface contains multiple levels of arbitration to determine in which order concurrent read requests from multiple initiators are serviced.

1. The first level of arbitration is a fixed priority arbiter between C29 CPU buses. Data Read Bus 1 (DRB1) always gets a higher priority than Data Read Bus 2 (DRB2). This arbitration level enables zero-wait-state switching between the two data buses belonging to the same CPU. The actual data read bus used for a specific read request is automatically generated by the compiler.
2. The second level of arbitration is the L1 data read pipeline. This level arbitrates between data read requests generated by multiple initiators in the system. The initiators are selected using a round-robin pointer. The round-robin selection order for FRI-1, FRI-3, and FRI-4 is as follows:
   a. CPU1
   b. CPU2 (if present)
   c. CPU3 (if present)
   d. CPU4 (if present)
   e. RTDMA
   f. HSM (if present)
   g. Data Pre-read
   h. Debugger

   The round-robin selection order for FRI-2, if present, is as follows:
   a. CPU3
   b. CPU4 (if present)
   c. CPU1
   d. CPU2 (if present)
   e. RTDMA
   f. HSM (if present)
   g. Data Pre-read
   h. Debugger

   Switching between initiators incurs a one-cycle pipeline delay, to allow for the round-robin pointer change.
3. For FRI-1 (and FRI-2, when present), there is a third level of arbitration between fetch and data requests (L2). This arbiter is also a round-robin arbiter like the second level, selecting using the following order:
   a. Instruction fetch (CPU1 for FRI-1, CPU3 for FRI-2)
   b. L1 data read pipeline output

   Changes to the L2 round-robin pointer incur a one-cycle pipeline delay, similar to the L1 arbiter.

9.4.5 Error Correction Code (ECC) Protection

F29x platform devices feature an end-to-end safety architecture, with ECC logic built into the C29 CPU. When a Flash data read or instruction fetch operation is performed, ECC check bits are sent along with the data bits onto the CPU program or data buses. The CPU automatically checks incoming instructions and data using the ECC bits, correcting single-bit data errors, and generating a fault for double-bit (uncorrectable) errors. These errors generate events to the Error Signaling Module (ESM), which in turn can generate a regular interrupt for a single-bit error, or a non-masking interrupt (NMI) for a double-bit error.

Each 8-bit ECC code is computed based on the requested data address and 64 bits of data. For each 128-bit Flash word, there are two ECC codes (upper 64 bits and lower 64 bits), for a total of 16 ECC bits. ECC bits can be independently read through separate FRI read port memory regions as described in the device data sheet.

For more information on ECC protections, see Chapter 3.

Note

Because the ECC logic is built into the C29 CPU, read accesses from other initiators such as the debugger, RTDMA or HSM CPU do not have ECC protection. Flash reads from these initiators do not have error detection and correction enabled.

9.4.6 Procedure to Change Flash Read Interface Registers

While configuring a Flash Read Interface (FRI), no accesses to any Flash memory that is covered by the Flash Read Interface can be in progress. This includes instructions still in the CPU pipeline, data reads, and instruction prefetch operations. To be sure that no access takes place during the configuration change, follow the procedure shown below for any code that modifies the Flash Read Interface registers.

Note

Flash Read Interface registers can only be modified by code running as CPU1.LINK2, CPU1.LINK1, or the HSM CPU. All other LINKs have read-only access to these registers.

1. Start executing the application code from RAM or Flash.
2. Branch to or call the Flash configuration code (that writes the FRI registers) in RAM. This is required to properly flush the CPU pipeline before the configuration change. Any function that changes the FRI configuration must reside in RAM, and cannot execute from Flash memory using the same FRI.
3. Execute the Flash configuration code to configure the FRI registers (FRDCNTL, FLCLKCTL, FRIx_INTF_CTRL, and so on).
4. At the end of the Flash configuration code execution, wait nine cycles to allow the write instructions to propagate through the CPU pipeline. This must be done before the return-from-function call is made.
5. Return to the calling function residing in Flash or RAM, and continue execution.

Note

Flash read interfaces that do not include instruction fetch capability, such as FRI-3 and FRI-4, can be configured by code executing directly from Flash, provided that no data access to the covered Flash banks is being made. In such cases, verify that no current data access to the target Flash banks is being performed by placing the FRI configuration code in a separate function. Be sure to wait nine cycles to flush the CPU pipeline before branching back to regular application execution.

9.5 Flash Erase and Program

Flash memory can be programmed either by using the CCS Flash plug-in or by using the UniFlash application. If these methods are not feasible in an application, the Flash API can be used. The Flash memory can be programmed, erased, and verified only by using the Flash API library. These functions are written, compiled and validated by Texas Instruments. The Flash module contains a Flash state machine (FSM) to perform program and erase operations.

The recommended flow for programming Flash is:
Erase → Program → Verify

9.5.1 Flash Semaphore and Update Protection

Before program and erase operations can be performed, the currently running application must grab the Flash semaphore. The Flash semaphore is managed by the Safety and Security Unit, and can be grabbed by writing to the FLSEMREQ SSU register. For more information on how to use the Flash semaphore, see Section 10.9.

The device security architecture also provides mechanisms to protect Flash banks and sectors from program and erase operations for safety and security. For more on these protection mechanisms, see Section 10.9.1.

9.5.2 Erase

An erase operation causes all bits in the target Flash memory region to read as 1. A previously programmed Flash word (128 bits) must first be erased before new data can be programmed into the Flash word. The minimum memory size that can be erased in one operation is a Flash sector; single bits or words cannot be erased individually.

Erase operations are performed by the Flash State Machine (FSM) inside the Flash controller. All bits in each target sector are erased together, including data and ECC bits. Erase operations must be initiated using the F29x Flash API, or a GUI front-end such as the Code Composer Studio Flash plug-in or UniFlash. The Flash API always erases sectors from both banks of an interleaved pair when an erase command is issued. When using the Flash API, erase is a non-blocking operation, so the application can perform other tasks while waiting for an erase command to complete.

Bank erase operations are also supported on this device. When performing bank erase, special sectors such as SECCFG and BANKMGMT are not included in the erase operation and must be erased separately.

Note

Because of the physical nature of Flash erase operations, the amount of time taken to complete an erase command gradually increases over time as more write-erase cycles are performed. There is also a lifetime limit on the number of write-erase cycles that are possible for each Flash Controller on a single device. For details on erase timing and write-erase cycle limits, see the device data sheet.

9.5.3 Program

A program operation modifies individual bits in a Flash word to read as 0 instead of 1. A program operation can only be performed on a previously erased bit. Flash programming must be aligned to 64-bit address boundaries, and each 64-bit word can only be programmed once per write/erase cycle.

The Flash State Machine provides a command to program the available user Flash regions: main Flash, SECCFG, and BANKMGMT. This command is also used to program the Error Correction Code (ECC) check bits. Program operations must be initiated using the F29x Flash API, or a GUI front-end such as the Code Composer Studio Flash plug-in or UniFlash. The API provides the ability to automatically generate and program ECC check bits together with the data being programmed. Programming is a non-blocking operation, so the application can perform other tasks while waiting for programming to complete.

After programming, the user must perform a verify operation on the programmed Flash region using the API function Fapi_doVerify(), or using one of the Flash API GUI front-ends. This function verifies the Flash contents against the supplied data.

On this device, any of the primary application CPUs (CPU1, CPU3) or the HSM CPU can program any of the Flash banks on the device after grabbing the Flash semaphore. Secondary CPUs such as CPU2 do not have access to Flash memory. For security, programming access can be restricted to authorized code only by configuring the Flash update owner LINK and CPU in the SSU. Additionally, specific sectors can be completely blocked from program and erase using write/erase protection bits (WEPROT). For more information on these protection mechanisms, see Section 10.9.1.

9.6 Migrating an Application from RAM to Flash

To migrate an existing application that is configured to run from RAM to a Flash-based linker configuration, follow these steps:

1. Replace the RAM linker command file with a Flash linker command file. For examples of Flash-based linker command files, see the `device_support\<device>\common\cmd` directory.
2. When modifying the Flash-based linker command file, be sure to map any initialized sections to Flash memory regions.
3. Make sure the boot mode pins are configured for Flash boot. This tells the boot ROM to redirect execution to the application programmed into Flash memory after boot code execution is complete. For more information on boot mode configuration, see *Detailed Description* > *Device Boot Modes* in the device data sheet.
4. When the device is configured for Flash boot, the boot ROM redirects execution to the Flash entry point location (defined as `BEGIN` in TI-provided Flash linker command files) at the end of boot code execution. Make sure there is a branch instruction at the Flash entry point to your code initialization (for example, `_c_int00`) function. In the C2000Ware examples, the entry point code is specified in the `codestartbranch.asm` file.
5. To achieve best performance for Flash execution, configure the Flash wait states as per the device operating clock frequency, as specified in the device data sheet. In addition, enable prefetch mode and data cache mode. Calling the `Flash_initModule()` driverlib function achieves these steps. Note that code that initializes the Flash module must execute from a RAM location. This is accomplished by assigning the Flash initialization function to the `.TI.ramfunc` section. In the linker command file, map this section to Flash for load, and RAM for execution. The example cmd files provided in C2000Ware show how to do this correctly.
6. For any functions that require 0- or 1-wait state performance, be sure to map to RAM for execution in the linker command file, similar to the Flash initialization function. The `.TI.ramfunc` section in the TI-provided Flash linker command files accomplishes this purpose.
7. Align all code and data sections to 128-bit address boundaries when mapping to Flash memory, using the `ALIGN` directive in the linker command file.
8. For EABI executable formats, define all uninitialized sections mapped to RAM as NOINIT sections (using the directive "`type=NOINIT`") in the linker command file.
9. Be sure to program ECC bits correctly for the Flash application image. Keep the AutoEccGeneration option enabled in the Code Composer Studio Flash Plugin or UniFlash GUI.

9.7 Flash Registers

This section describes the Flash Module Registers.

9.7.1 FLASH Base Address Table

Table 9-2. FLASH Base Address Table

Structure	DriverLib Name	Base Address	Frame Applicable	CPU1	CPU2	CPU3	RTDMA1	RTDMA2	HSM	Pipeline Protected
FLASH_CMD_REGS_FLC1	FLASHCONTROLLER1_BASE	0x3010_0000	-	YES	-	YES	-	-	YES	YES
FLASH_CMD_REGS_FLC2	FLASHCONTROLLER2_BASE	0x3011_0000	-	YES	-	YES	-	-	YES	YES
FRI_CTRL_REGS [1]	FRI1_BASE	0x301D_0000	-	YES	YES	YES	-	-	YES	YES

(1) Registers writeable by CPU1.LINK0, CPU1.LINK1, CPU1.LINK2 only. All CPUs can read all registers in all LINKs. Debug write access only allowed if Zone0 or Zone1 are enabled for full debug by all CPUs. Debug reads always allowed. Register Read/Write access by HSM.

9.7.2 FLASH_CMD_REGS_FLC1 Registers

Table 9-3 lists the memory-mapped registers for the FLASH_CMD_REGS_FLC1 registers. All register offset addresses not listed in Table 9-3 should be considered as reserved locations and the register contents should not be modified.

Table 9-3. FLASH_CMD_REGS_FLC1 Registers

Offset	Acronym	Register Name
1D0h	CMDWEPROTA	Command Write Erase Protect A Register
1D4h	CMDWEPROTB	Command Write Erase Protect B Register
210h	CMDWEPROTNM	Command Write Erase Protect Non-Main Register
3D0h	STATCMD	Command Status Register

Complex bit access types are encoded to fit into small table cells. Table 9-4 shows the codes that are used for access types in this section.

Table 9-4. FLASH_CMD_REGS_FLC1 Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value

9.7.2.1 CMDWEPROTA Register (Offset = 1D0h) [Reset = 00000000h]

CMDWEPROTA is shown in Figure 9-6 and described in Table 9-5.

Return to the Summary Table.

Command WriteErase Protect A Register
This register allows the first 32 sectors of the main region to be protected from program or erase, with 1 bit protecting each sector. If the main region size is smaller than 32 sectors, then this register provides protection for the whole region.
This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.
In addition, this register is used to aggregate masking for sectors that do not require additional erase pulses during bank erase operations, and will be written to all 1 after the completion of all flash wrapper commands.

Figure 9-6. CMDWEPROTA Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 9-5. CMDWEPROTA Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	VAL	R/W	FFFFFFFFh	Each bit protects 1 sector. bit [0]: When 1, sector 0 of the flash memory will be protected from program and erase. bit [1]: When 1, sector 1 of the flash memory will be protected from program and erase. : : bit [31]: When 1, sector 31 of the flash memory will be protected from program and erase. 0h = Minimum value of [VAL] FFFFFFFFh = Maximum value of [VAL]

9.7.2.2 CMDWEPROTB Register (Offset = 1D4h) [Reset = 00000000h]

CMDWEPROTB is shown in Figure 9-7 and described in Table 9-6.

Return to the Summary Table.

Command WriteErase Protect B Register
This register allows main region sectors to be protected from program and erase. Each bit corresponds to a group of 8 sectors.
There are 3 cases for how these protect bits are applied:
1. Single-bank system:
In the case where only a single flash bank is present, the first 32 sectors are protected via the CMDWEPROTA register. Thus, the protection give by the bits in CMDWEPROTB begin with sector 32.
2. Multi-bank system, Bank 0:
When multiple flash banks are present, the first 32 sectors of bank 0 are protected via the CMDWEPROTA register. Thus, only bits 4 and above of CMDWEPROTB would be applicable to bank 0. The protection of bit 4 and above would begin at sector 32. Bits 3:0 of WEPROTB are ignored for bank 0.
3. Multi-bank system, Banks 1-N:
For banks other than bank 0 in a multi-bank system, CMDWEPROTA has no effect, so the bits in CMDWEPROTB will protect these banks starting from sector 0.
This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.
In addition, this register is used to aggregate masking for sectors that do not require additional erase pulses during bank erase operations, and will be written to all 1 after the completion of all flash wrapper commands.

Figure 9-7. CMDWEPROTB Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit	Field	Type	Reset	Description
31-0	VAL	R/W	FFFFFFFFh	Each bit protects a group of 8 sectors. When a bit is 1, the associated 8 sectors in the flash will be protected from program and erase. A maximum of 256 sectors can be protected with this register. 0h = Minimum value of [VAL] FFFFFFFFh = Maximum value of [VAL]

9.7.2.3 CMDWEPROTNM Register (Offset = 210h) [Reset = 00000000h]

CMDWEPROTNM is shown in Figure 9-8 and described in Table 9-7.

Return to the Summary Table.

Command WriteErase Protect Non-Main
Register
This register allows non-main region region sectors to be protected from program and erase. Each bit corresponds to 1 sector.
This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.
In addition, this register is used to aggregate masking for sectors that do not require additional erase pulses during bank erase operations, and will be written to all 1 after the completion of all flash wrapper commands.

210h	CMDWEPROTNM	Command Write Erase Protect Non-Main Register
3D0h	STATCMD	Command Status Register

Complex bit access types are encoded to fit into small table cells. Table 9-10 shows the codes that are used for access types in this section.

Table 9-10. FLASH_CMD_REGS_FLC2 Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value

9.7.3.1 CMDWEPROTA Register (Offset = 1D0h) [Reset = 00000000h]

CMDWEPROTA is shown in Figure 9-10 and described in Table 9-11.

Return to the Summary Table.

Command WriteErase Protect A Register
This register allows the first 32 sectors of the main region to be protected from program or erase, with 1 bit protecting each sector. If the main region size is smaller than 32 sectors, then this register provides protection for the whole region.
This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.
In addition, this register is used to aggregate masking for sectors that do not require additional erase pulses during bank erase operations, and will be written to all 1 after the completion of all flash wrapper commands.

Bit	Field	Type	Reset	Description
31-0	VAL	R/W	FFFFFFFFh	Each bit protects 1 sector. bit [0]: When 1, sector 0 of the flash memory will be protected from program and erase. bit [1]: When 1, sector 1 of the flash memory will be protected from program and erase. : : bit [31]: When 1, sector 31 of the flash memory will be protected from program and erase. 0h = Minimum value of [VAL] FFFFFFFFh = Maximum value of [VAL]

9.7.3.2 CMDWEPROTB Register (Offset = 1D4h) [Reset = 00000000h]

CMDWEPROTB is shown in Figure 9-11 and described in Table 9-12.

Return to the Summary Table.

Command WriteErase Protect B Register
This register allows main region sectors to be protected from program and erase. Each bit corresponds to a group of 8 sectors.
There are 3 cases for how these protect bits are applied:
1. Single-bank system:
In the case where only a single flash bank is present, the first 32 sectors are protected via the CMDWEPROTA register. Thus, the protection give by the bits in CMDWEPROTB begin with sector 32.
2. Multi-bank system, Bank 0:
When multiple flash banks are present, the first 32 sectors of bank 0 are protected via the CMDWEPROTA register. Thus, only bits 4 and above of CMDWEPROTB would be applicable to bank 0. The protection of bit 4 and above would begin at sector 32. Bits 3:0 of WEPROTB are ignored for bank 0.
3. Multi-bank system, Banks 1-N:
For banks other than bank 0 in a multi-bank system, CMDWEPROTA has no effect, so the bits in CMDWEPROTB will protect these banks starting from sector 0.
This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.
In addition, this register is used to aggregate masking for sectors that do not require additional erase pulses during bank erase operations, and will be written to all 1 after the completion of all flash wrapper commands.

Bit	Field	Type	Reset	Description
31-0	VAL	R/W	FFFFFFFFh	Each bit protects a group of 8 sectors. When a bit is 1, the associated 8 sectors in the flash will be protected from program and erase. A maximum of 256 sectors can be protected with this register. 0h = Minimum value of [VAL] FFFFFFFFh = Maximum value of [VAL]

9.7.3.3 CMDWEPROTNM Register (Offset = 210h) [Reset = 00000000h]

CMDWEPROTNM is shown in Figure 9-12 and described in Table 9-13.

Return to the Summary Table.

Command WriteErase Protect Non-Main
Register
This register allows non-main region region sectors to be protected from program and erase. Each bit corresponds to 1 sector.
This register is blocked for writes after a 1 is written to the CMDEXEC register and prior to STATCMD.DONE being set by the flash wrapper hardware.
In addition, this register is used to aggregate masking for sectors that do not require additional erase pulses during bank erase operations, and will be written to all 1 after the completion of all flash wrapper commands.

Complex bit access types are encoded to fit into small table cells. Table 9-16 shows the codes that are used for access types in this section.

Table 9-16. FRI_CTRL_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

9.7.4.1 REVISION Register (Offset = 0h) [Reset = 00000000h]

REVISION is shown in Figure 9-14 and described in Table 9-17.

Return to the Summary Table.

Chapter 10

Safety and Security Unit (SSU)

This chapter describes the features and operation of the Safety and Security Unit (SSU). The SSU is the central element of the C29x security architecture. The SSU provides run-time safety and security for the application CPU subsystems, and governs debug access to various resources on the chip. The SSU also provides hardware infrastructure for managing Flash firmware update operations, using the Firmware-Over-The-Air (FOTA) or Live Firmware Update (LFU) processes.

10.1 Introduction

At the heart of the architecture is the Safety and Security Unit (SSU). The SSU acts as a firewall between the C29x CPUs and the memory and peripherals. The primary role of the SSU is to enforce user access protection policy every time the C29x CPU performs accesses to peripherals and memory on the chip. In addition, the SSU governs debug access and Flash Controller operations in the C29x application subsystem (note: the SSU has no control over the HSM Flash, or any other HSM resources). While the Hardware Security Module (HSM) provides cryptographic services and governs authentication, secure boot and secure key/code provisioning, the SSU is responsible for run-time safety and security protections in application CPU subsystems. Both the HSM and SSU govern debug access authorization; both must enable access to a specific resource for debug to be authorized. For more information on debug access authorization, see Section 10.11.

10.1.2 Block Diagram

A simplified view of the F29x Real-Time Security architecture in this device is shown in Figure 10-1.

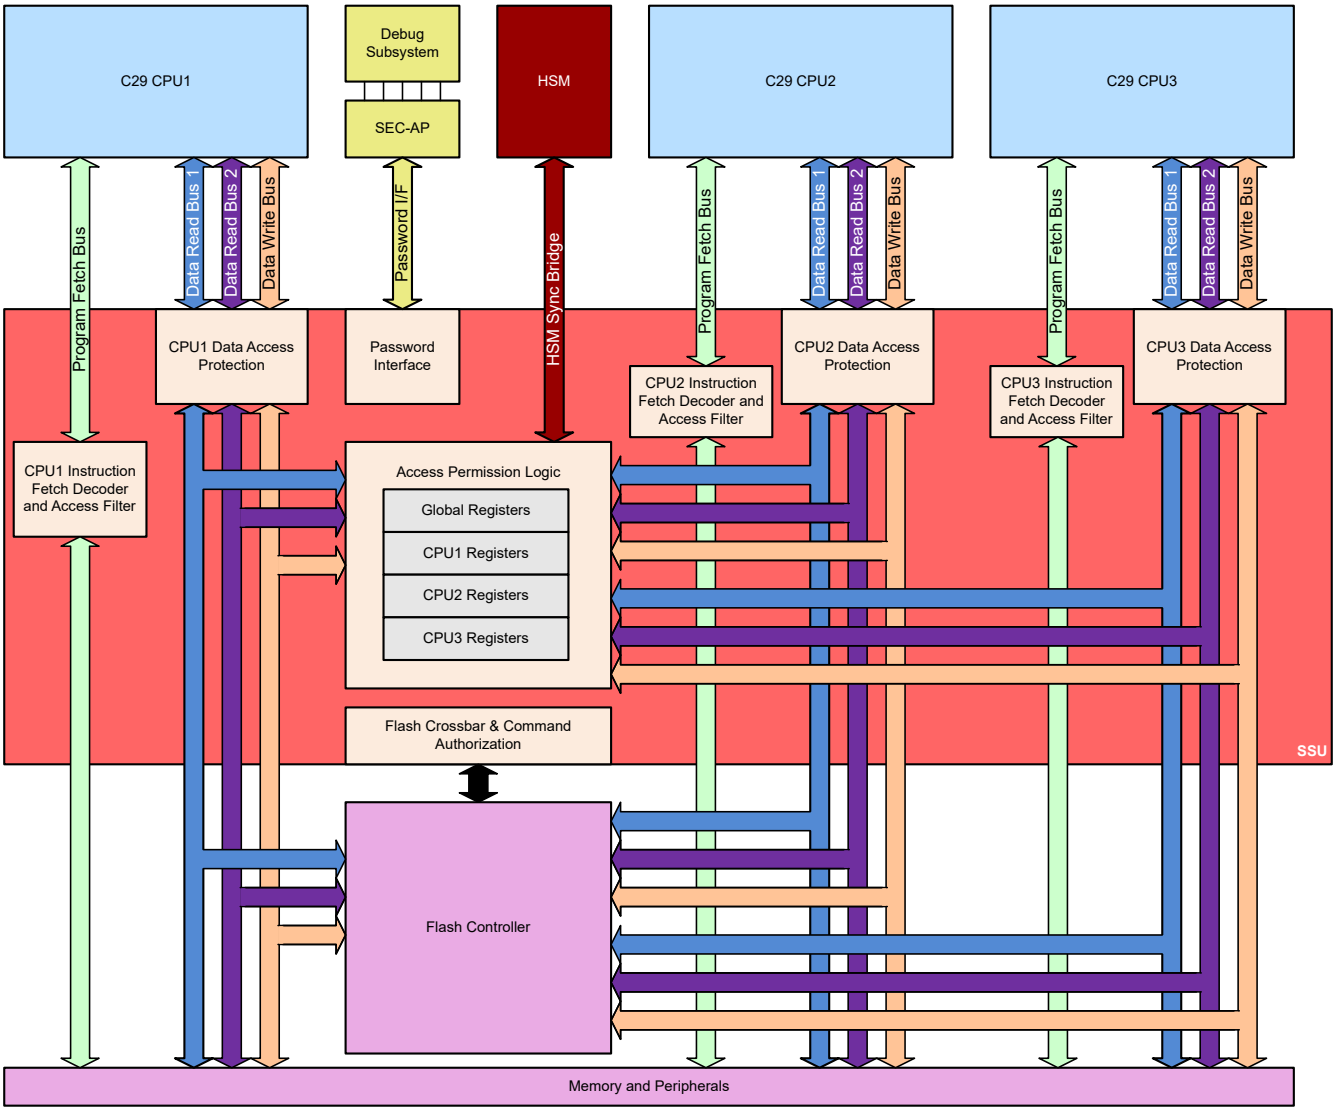

Figure 10-1. C29x Real-Time Security Architectural Block Diagram

10.1.3 System SSU Configuration Example

The SSU is tightly coupled to the C29x CPUs and the C29x Flash Controllers. Each C29x CPU is designed to support hardware function isolation and protections using memory protection identifiers (LINKs), safety and security isolation contexts (STACKs), and debug access ZONEs. An example of a system SSU configuration, showing the relationship between access protection ranges, LINKs, STACKs and ZONEs is shown in Figure 10-2. When the CPU requests an instruction fetch, the SSU first decodes the instruction address to a LINK, STACK, and ZONE, and then passes that information back to the CPU along with the fetched data. The CPU retains this security context information together with the instruction throughout the execution pipeline, and passes the context along to the SSU when making a data memory read or write access.

Each LINK consists of one or more regions of executable code, defined by the memory ranges in which the code resides, and is typically associated with a specific task or software module. The Access Protection Ranges, or APRs, are the basic unit of memory protection. Each APR has a start address and an end address, and can be associated with executable code (associating that code with a specific LINK), or can cover data or peripheral memory. Each APR then defines read and write access permissions for every LINK available on the CPU, enabling dynamic memory access permissions that automatically change based on which code is accessing the memory region. Each LINK is associated with one STACK. Each STACK is associated with a physically distinct and separate stack pointer in the CPU for secure code isolation. Finally, every STACK is associated with one device-level ZONE that governs debug and firmware update security.

These concepts are explained in detail in the following sections.

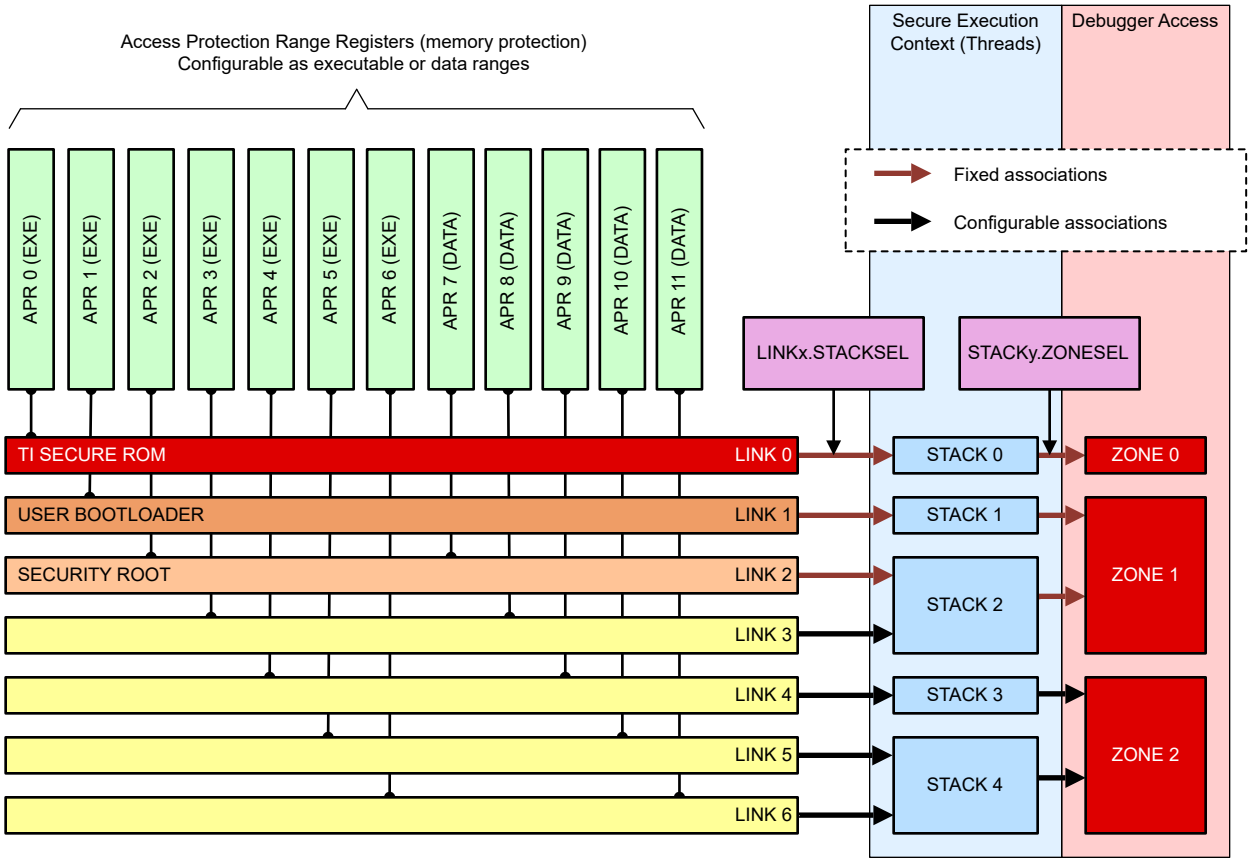

Figure 10-2. System SSU Configuration Example

10.2 Access Protection Ranges

The SSU defines memory protections using Access Protection Ranges (APRs), governing CPU access to on-chip memories, peripherals, and external memories. There are a total of 64 APRs available per CPU. Each APR specifies the following:

- Starting address
- Ending address
- Associated code execution LINK
- Code execution permissions
- Read and write permissions per LINK
- Inherited permissions
- Lock and commit settings

Access protection ranges are defined using the APx registers. The access protection registers are loaded at boot time, but can be modified afterward by code running with security root privileges. Before performing a CPU access to any memory location, the user must make sure to define an access protection range that includes that location. In addition, access protection range definitions must not overlap each other. If a CPU access is performed to a memory location that is covered by zero or more than one access protection range, the SSU generates a fault signal to the CPU, which then forwards the error to the Error Aggregator module.

Each standard AP range has a start address, defined in the APx_START register, and an end address, defined in the APx_END register. Every AP range is aligned to a 4KB memory boundary, so the lower 12 bits of each APx_START register are hardcoded to 0, and the lower 12 bits of each APx_END register are hardcoded to 0xFFF. The regular AP ranges can address the first 2GB of the device address space, covering on-chip memories or peripheral memory-mapped registers. Each AP range has a maximum size of 16MB. The MEMTYPE field in the start address indicates what type of memory is covered by the AP range. Note that the MEMTYPE bits are the same as the CPU address bits per the device memory-map; there is no special handling of these bits in the SSU. Simply writing the range's start address to APx_START is sufficient.

Access permissions for an AP range are configured using the APx_ACCESS register. This register defines, for each LINK, whether to grant no access permission, read-only permission, or read/write permission.

AP ranges also include the following configuration options:

- Access Protection Disable, by writing to the APx_CFG.APD bit.
- Execute Enable/Disable, by writing to the APx_CFG.XE bit. This setting defines the AP region as a code/program memory region, and any code instruction that is fetched from the memory range is associated with the LINK defined in the APx_CFG.LINKID field.

The first two AP ranges (AP0 and AP1) are extended AP ranges. These special ranges have address ranges spanning the full 4GB address space available, and as such can cover extended memory ranges such as external memories connected using the EMIF interface. The start and end addresses of these extended AP ranges are defined in the APx_START_EXT and APx_END_EXT registers. Like standard AP ranges, the extended AP ranges must also be aligned to 4KB address boundaries.

Note

Not all memory regions can be configured for protection by an AP range. Certain peripherals, memory regions and bridges are governed by system-level hardcoded protections. For a detailed memory map showing which memory regions can be APR-protected, see the device data sheet.

10.2.1 Access Protection Inheritance

An AP range can be configured to inherit protection settings from a specific LINK's caller. The APx_CFG.APILINK register field specifies the LINKID which inherits permissions for access to Access Protection Range APx. The C29x CPU sets DSTS.CLINK to the current LINK's caller LINKID whenever a protected call is performed. Whenever code belonging to the LINKn specified in APx_CFG.APILINK performs an access to memory within APx, the access permissions granted to LINKn match the access permissions for LINKn's caller (as identified by CLINK on the data access request). The access protection inheritance feature is enabled by setting APx_CFG.APILINKE to 1.

Access protection inheritance is useful for maintaining memory protection when using common or utility functions such as *memcpy*. Without inheritance, an unauthorized LINK can access data memory covered by APx by simply calling a shared memory function with direct read or write access to APx. However, when APx_CFG.APILINKE is set to 1 and APx_CFG.APILINK is defined to be the LINK associated with the common code functions, then the shared function is imputed the same permissions as the LINK that called the shared function. An illustration of how access protection inheritance enables the sharing of common code functions between different LINKs is shown in Figure 10-3.

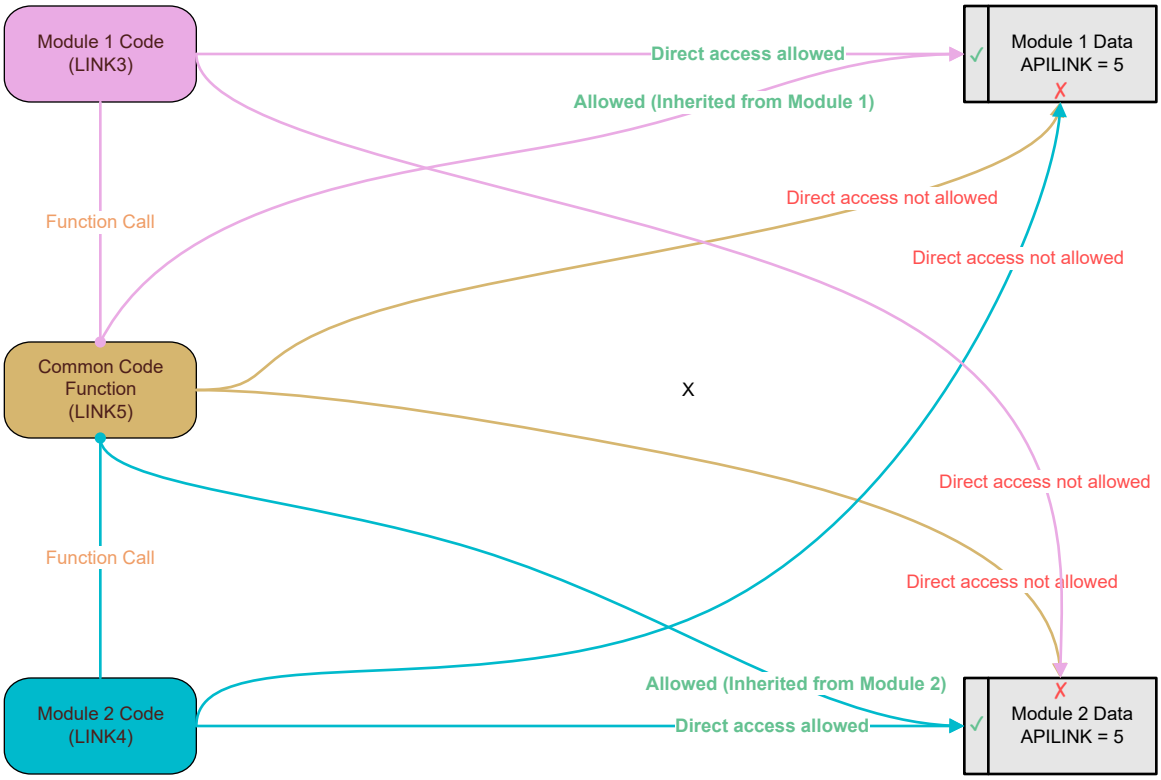

Figure 10-3. Access Protection Inheritance Example

Note

In the C29x CPU, DSTS.CLINK is only updated by a protected function call, and is not updated during a regular function call or branch. For LINKs within the same STACK, branches and function calls must be executed using protected call instructions for the access protection inheritance feature to work correctly.

10.3 LINKs

LINKs form the basis for context-sensitive memory protection. Each LINK represents one or more regions of executable code, and determines what data memory ranges (APRs) can be accessed by that code. Every code instruction that executes on the CPU has an associated LINK ID, which is assigned based on the memory region the instruction was fetched from. Thus, memory protections across the entire SoC can be automatically configured for each instruction at execution time, eliminating the need for software-based MPU reconfiguration.

The APx_CFG.LINKID register defines the execution LINK for all code that the CPU fetches from the APx memory address range. In addition, to enable code execution from an AP range, the user must configure the APx_CFG.XE (execution enable) bit. For data-only LINKs, make sure to set the XE bit to zero to preserve code safety. The SSU inputs the LINKID to the CPU when an instruction is fetched, and the CPU outputs the LINKID to the SSU whenever the CPU performs a data access to a memory location. The SSU compares the requesting LINKID to the access permissions for the APR containing the target memory address by examining the corresponding APx_ACCESS.LINKy register. If the permissions defined in the APx_ACCESS.LINKy do not authorize the requesting LINKID, then the SSU generates a fault to the CPU. If the memory region containing the address is governed by hardcoded protections (e.g. writable by LINK0, LINK1 or LINK2 only), the SSU checks the requested operation against the hardcoded protection, and generates a fault to the CPU if unauthorized. See Figure 10-4 for an illustration of how the SSU filters data access requests from the CPU using associated LINKIDs.

There are 16 LINKs per CPU. The SSU predefines and reserves the following special roles for the first three links:

- LINK0 is reserved for internal use and cannot be configured by the user.
- LINK1 is primarily used for TI and user boot loaders, but can also be used for user run-time code.
- LINK2 is the primary user LINK. CPU1.LINK2 is the Security Root LINK (SROOT).

All other LINKs are secondary user LINKs, and can be defined by the user application as required. LINK0, LINK1 and LINK2 have special hard-coded permissions. For more info, see Section 10.12.

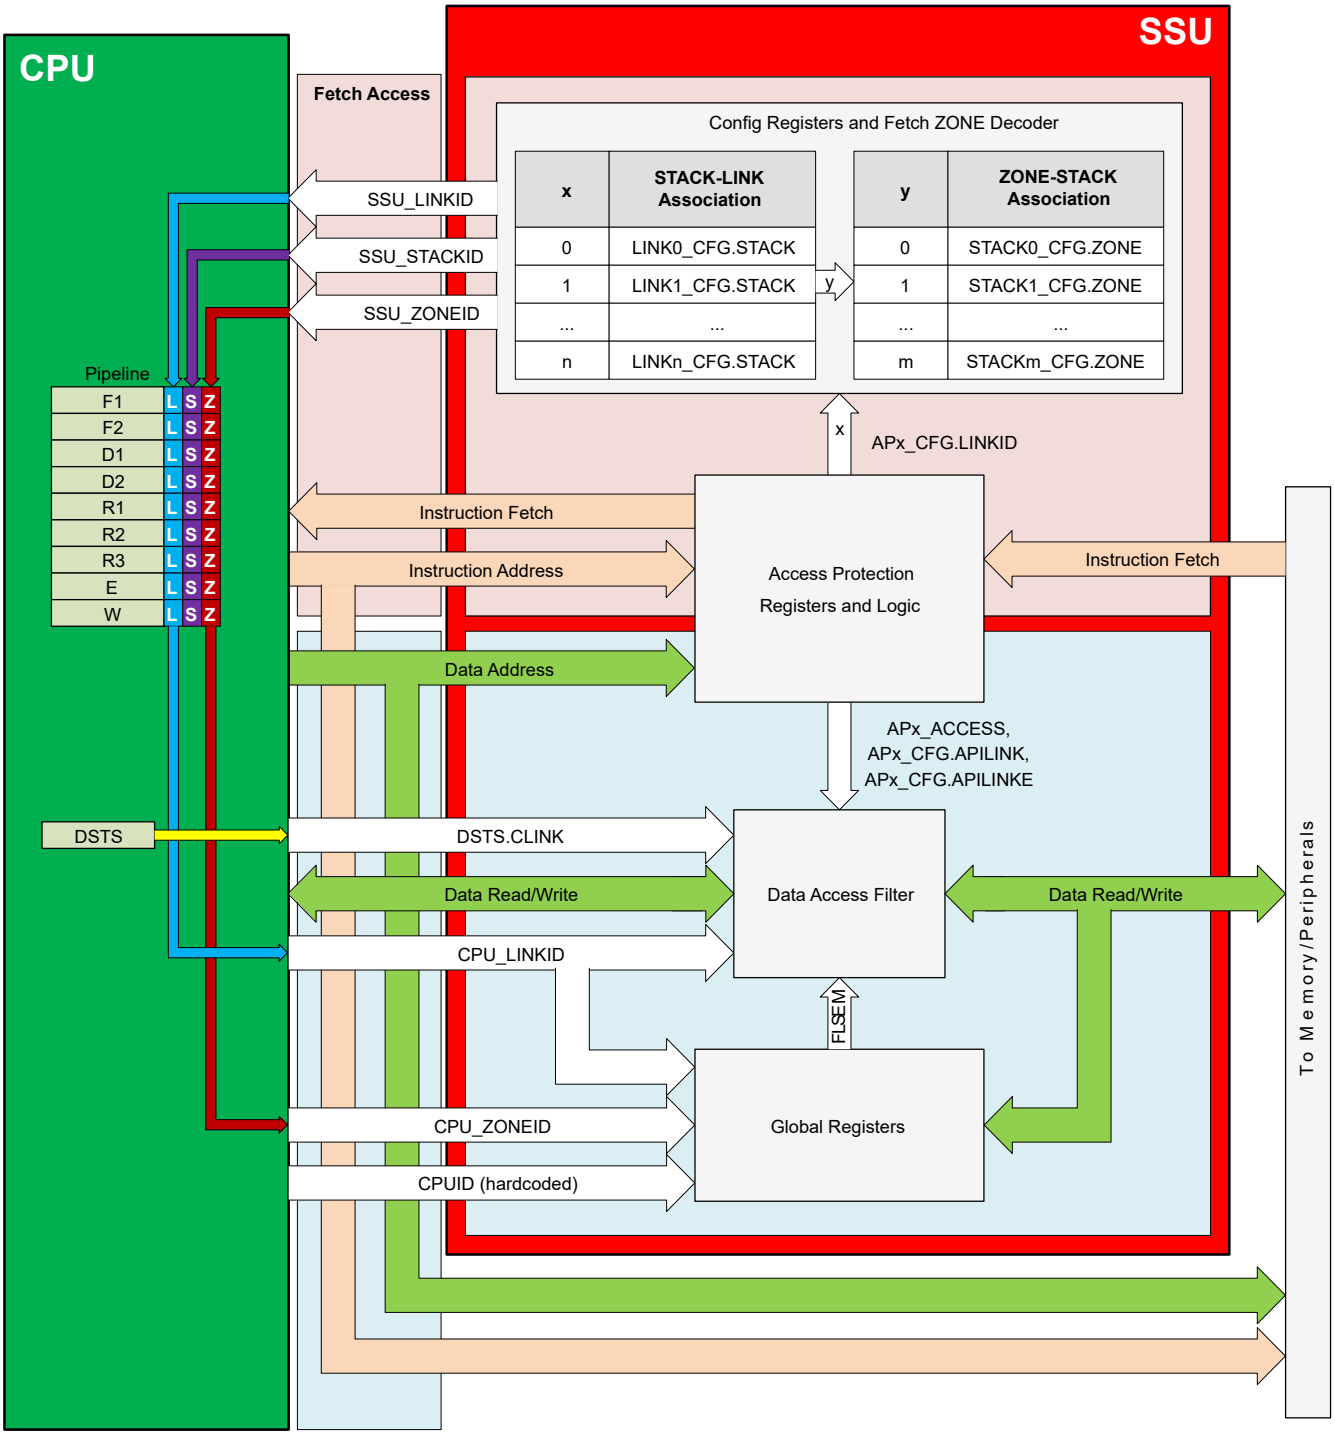

Figure 10-4. SSU-CPU Tightly Coupled Interface

10.4 STACKs

STACKs isolate code execution contexts from each other. Each STACK has a dedicated stack pointer in the CPU, and a dedicated set of CPU registers, and provides hardware safety and security isolation of code from other STACKs. Every LINK belongs to one and only one STACK, but a STACK can contain multiple LINKs. For CPU execution to cross from a LINK associated with one STACK to a LINK associated with another STACK, the code must execute special instructions that preserve data safety during context switching.

To specify which STACK a LINK belongs to, configure the LINKx_CFG field/register in the SSU configuration.

Like LINKs, the SSU passes the STACKID to the CPU during instruction fetch, and the CPU outputs the instruction STACKID to the SSU when performing data accesses.

Each CPU has a total of 8 STACKs. The SSU predefines and reserves the first three stacks as follows:

- STACK0 is reserved for internal use, and is always associated with LINK0 only.
- STACK1 is primarily used for boot loaders, but can also be used for user application code. STACK1 is always associated with LINK1 only.
- STACK2 is the primary user stack. STACK2 is associated with LINK2, and can be associated with other secondary user LINKs depending on the configured user protection policy.

STACK3 and above are secondary user STACKs, and can be defined by the user application as required.

10.5 ZONEs

Each ZONE governs debugger access to the system, and as well as firmware update permissions. ZONEs determine what permissions an external user or programmer has to download or program code, perform firmware updates, and debug the system. While AP ranges, LINKs and STACKs are independently defined per CPU, ZONEs span the entire device, excluding the HSM (which is not governed by the SSU).

Each device has a total of 4 available ZONEs. ZONE0 is reserved for TI internal use, and is always associated with STACK0/LINK0. The primary user ZONE is ZONE1. ZONE1 is always associated with STACK1 and STACK2, but can include other STACKs depending on user configuration. ZONE2 and ZONE3 are secondary user ZONEs, and can be associated with STACK3 and other secondary user STACKs.

To configure which ZONE a STACK is associated with, write to the STACKx_CFG field/register in the SECCFG sector.

Each user ZONE has three possible operating permission levels:

- **Debug not allowed**
- **Partial debug allowed:** This mode permits the user to debug CPU execution (halt, resume, view registers), but prevents read/write access to memories.
- **Full debug allowed:** This mode enables full debug capability.

In partial debug mode, the SSU blocks debugger access to various registers, as described in Section 10.13. For information on how to enable debug for user ZONEs, see Section 10.11. The SSU_GEN_REGS.DEBUG_STAT register indicates the current active debug permission level for each user ZONE.

A debug ZONE inherits memory access permissions from the sum total of all LINKs that are associated with the ZONE. This means that if a ZONE is enabled for full debug, then the debugger's ability to read or write any memory address depends on whether the access protection range covering that address gives permission to any LINK belonging to the ZONE.

Note

If an AP range has the APx_CFG.XE bit set (that is, defined as a code region), and the LINKID of the AP region belongs to a ZONE that is enabled for full debug, then the debugger is given read and write access to the AP range—even if no associated LINKs have read/write access to the AP range.

10.6 SSU-CPU Interface

The SSU is tightly coupled with each CPU during different phases of execution. When the CPU requests an instruction fetch, the SSU first decodes the instruction address to a LINK, STACK, and ZONE, and passes that information back to the CPU along with the fetched data. The CPU retains this security context information together with the instruction throughout the execution pipeline, and passes the context along to the SSU when making a data memory read or write access. Within the SSU, the data access filter logic uses the LINKID and CLINK associated with the instruction to qualify each memory access request and determine whether to permit the access.

The SSU provides a CPUID register, can be read by the application to determine which CPU the application is executing on. Additionally, the decoder logic can be used to determine which LINK, STACK and ZONE a particular code instruction belongs to, by writing the instruction's address to the DECODER_ADDR_IN register and reading the DECODER_OUT register.

Figure 10-4 illustrates the tightly-coupled interface between the SSU and the C29x CPU.

10.6.1 SSU Operation in Lockstep Mode

When lockstep mode is enabled on a CPU pair (for example, CPU1 and CPU2), the SSU enforces protections based on the security policy for CPU1. Security sideband signals for LINK, STACK, ZONE and protection fault status are forwarded to both CPUs in lockstep. For a description of functional safety requirement compliance in this mode, see the device safety manual.

Note

Flash programming and erase operations cannot be performed in lockstep. To implement a functional safety strategy for Flash programming, incorporate verify reads of the programmed Flash content after programming. For more information, see the device safety manual.

10.7 SSU Operation Modes

The SSU has three modes of operation: SSUMODE1, SSUMODE2, and SSUMODE3. Devices ship from the TI factory in SSUMODE1 mode. Once safety and security has been integrated into the development project, configure the SSU to SSUMODE2 to enable safety/code isolation features, and then configure to SSUMODE3 when development is finalized for production programming to enable full security. If safety and security features are not desired in the target application, the device can be left in SSUMODE1; and if safety features are desired but not security, the device can be left in SSUMODE2.

In SSUMODE3:

1. All safety and security features of the SSU are active and enforced.
2. All user ZONEs (ZONE1, ZONE2, and ZONE3) are disabled for debug by default. Each ZONE must be authorized as configured to enable partial or full debug access.
3. JTAG and debug access are governed by debug authorization settings.
4. Debugger accesses to LINK1 RAM and LINK1 Flash are only permitted when ZONE1 is enabled for full debug.

In SSUMODE2:

1. JTAG is enabled;
2. All user ZONEs (ZONE1, ZONE2, and ZONE3) are enabled for full debug;
3. CPU1.LINK1 and/or any C29x CPU debug access is allowed to:
   a. Write to the RAMOPENFRC and RAMOPENCLR registers
   b. Write to the SSU APx registers
   c. Update all Flash SECCFG sectors
   d. Update all Flash MAIN sectors

In SSUMODE1:

1. All characteristics of SSUMODE2 are present;
2. User access protection (AP) regions are disabled for all CPUs;
3. The entire memory map of the device, excluding ROM, RAMOPENed RAM and hard-coded RAM and Flash memory regions, is mapped to run as LINK2;
4. The entire memory map of the device, excluding ROM, RAMOPENed RAM and hardcoded RAM and Flash memory regions, is accessible by all LINKs.

Both SSUMODE1 and SSUMODE2 permit generic programmers to program Flash memory. However, in SSUMODE3, the user must explicitly give LINK1 Flash memory write permissions to enable any kind of bootloader/Flash kernel to program the Flash.

SSUMODE must be configured by programming SSU_MODE location in Section 10.8.2. The value of SSUMODE is loaded from SECCFG into the SSUMODE register during boot. The value of SSUMODE cannot be changed during run time.

Note

SSUMODE is a 32-bit register. All 32 bits must be programmed into the SECCFG field, including leading zeroes, for the device to boot successfully.

Although all user ZONEs are enabled for full debug in SSUMODE2, this does not automatically give the debugger full access to device memory. Every debug ZONE inherits permissions from the LINKs belonging to that ZONE, and these permissions are configured in the AP ranges. If there is no AP range covering a memory address, debugger accesses to that memory address are blocked in SSUMODE2. To enable debugger access to a memory region in SSUMODE2, make sure to configure an AP range covering the region, and grant at least one LINK the access level required for the debugger to access the memory region.

10.8 Security Configuration and Flash Management

Each Flash bank in the C29x application subsystem has two regions that contain information which configures the SSU: SECCFG and BANKMGMT. These regions are separate from the main Flash sectors, and do not count against the stated available Flash memory for application use. SECCFG is used for storing the SSU configuration, also known as the User Protection Policy (UPP). BANKMGMT is used for managing Flash updates using the Firmware-Over-The-Air (FOTA) or Live Firmware Update (LFU) mechanisms.

The configuration settings stored in these Flash regions are loaded into the SSU registers at device startup. Most UPP settings cannot be modified by the application during run time. To modify the UPP, the application or connected debugger must erase and re-program SECCFG with the desired settings. See Section 10.9 for details on protection mechanisms to prevent unauthorized updates to these sectors. Section 10.13 contains details on run-time access permissions for individual SSU registers.

Texas Instruments recommends using the SysConfig tool, included as part of the device MCU-SDK, to configure the SSU and generate user security settings. This tool provides an easy-to-use graphical user interface to create application security partitions and protection definitions, and automatically generates linker command files, a SECCFG image, and header files to be included in the user application.

Note

An accurate SECCFG CRC value is required for the device to boot successfully. To avoid device boot problems due to inaccurate CRC computation, use the SysConfig tool to build the SECCFG image and auto-compute the associated CRC.

10.8.1 BANKMGMT Sectors

The BANKMGMT region of each bank pair contains three fields that are used to manage bank status and firmware updates:

1. **BANK_STATUS[63:0]** (Offset 0x00): This field specifies whether the bank contents are currently valid or invalid. A valid bank pair has a status value of 0x55555555_55555555. If both banks are inactive, the device is unable to execute Flash code and can fail to boot. If both banks have valid active statuses, then the current active bank is determined by BANK_UPDATE_CTR.
2. **BANK_UPDATE_CTR[63:0]** (Offset 0x08): This is a 64-bit *decrementing* counter value that is used to determine the most recent firmware revision. The counter has a value of 0xFFFFFFFF_FFFFFFFF when shipped from the TI factory. When both bank pairs have valid status values, the BANK_UPDATE_CTR for each bank pair is compared against the other to determine the most recent firmware revision. The bank pair with the lower counter value is determined to be the most recent revision.
3. **BANKMODE[63:0]** (Offset 0x10): This field only exists in FLC1 BANKMGMT regions (for CPU1). The BANKMODE field configures the device bankmode and is loaded into the SSU_GEN_REGS.BANKMODE register at device boot. After BANKMODE is configured, the boot ROM then reads the value of each bank pair's BANK_UPDATE_CTR to determine whether CPUxSWAP is enabled.

The BANKMGMT region is best programmed and configured using the Flash API and TI Flash tools, such as the CCS Flash Plugin or UniFlash. To avoid misconfiguration resulting in an unbootable device, do not allocate data directly into the BANKMGMT region in the application image/.out file.

The following security restrictions apply to updates of the BANKMGMT region:

- In SSUMODE1, all code running from any LINK has permission to update the BANKMGMT sectors, since ZONE1 is enabled for full debug. This enables ease of code development.
- In SSUMODE2, all code running from any LINK has permission to update the BANKMGMT sectors, since ZONE1 is enabled for full debug.
- In SSUMODE3, only the SECCFG update owner defined in SECCFG_UPDATE_CFG has permission to update BANKMGMT sectors. In addition, SECCFG_UPDATE_CFG.UPDATE_EN must be set to 0xC to enable updates to BANKMGMT when operating in SSUMODE3.

10.8.2 SECCFG Sectors

SECCFG sectors are a portion of Flash memory designated for storing the SSU user configuration, or User Protection Policy (UPP). The following rules apply to SECCFG sectors:

- Each SECCFG sector is 2KB in size.
- Each CPU pair (for example, CPU1/CPU2) has an associated active SECCFG sector, and a reserve SECCFG sector.
- All code banks are interleaved in pairs to enable 256-bit instruction fetches. As a result, the effective SECCFG sector size is 4KB, due to the interleaving of the two banks. However, the SECCFG image size is 2KB; the remaining half is unused.

Table 10-1 shows the mapping of SECCFG sectors to CPU addresses. Each CPU has an active SECCFG start address, and an alternate (reserve) SECCFG start address. Reserve SECCFG sectors are used for Flash updates, and are swapped with the active sector (together with all other bank sectors) when the firmware update process is complete. The locations of these addresses in the CPU memory map depend on the active settings in the BANKMODE and BANKMAP registers. The SECVALID register, in combination with the BANKMODE register, defines which address holds the valid SECCFG information for a CPU pair. The CPUxSWAP fields in the BANKMAP register specify which bank contains this information; however, the address range does not change even if CPUxSWAP changes.

The values of BANKMODE and BANKMAP in the Flash BANKMGMT sectors are automatically loaded into the SSU registers at boot time. After determining the active SECCFG sector, the device then loads the User Protection Policy from the active SECCFG sector into the SSU registers.

Table 10-2 shows a map of the SECCFG sector contents as mapped to SSU registers.

10.8.3 SECCFG Sector Address Mapping

Table 10-1 shows the mapping of physical bank SECCFG sectors to CPU addresses, depending on the Flash bank mode and swap configuration.

Table 10-1. SECCFG Address Mapping

Bank Mode	CPUxSWAP	Region	CPU1/CPU2 Bank	CPU1 Address	CPU2 Address	CPU3 Bank	CPU3 Address
MODE 0		Active	FLC1.B0/B1	0x10D8 1000	0x10D8 1800	FLC2.B0/B1	0x10D8 9000
		Update	FLC1.B2/B3	0x10D8 5000	0x10D8 5800	FLC2.B2/B3	0x10D8 D000
MODE 1	SWAP = 0	Active	FLC1.B0/B1	0x10D8 1000	0x10D8 1800	FLC2.B0/B1	0x10D8 5000
		Update	FLC1.B2/B3	0x10D9 9000	0x10D9 9800	FLC2.B2/B3	0x10D9 D000
	SWAP = 1	Active	FLC1.B2/B3	0x10D8 1000	0x10D8 1800	FLC2.B2/B3	0x10D8 5000
		Update	FLC1.B0/B1	0x10D9 9000	0x10D9 9800	FLC2.B0/B1	0x10D9 D000

10.8.5 SECCFG CRC

As an added security measure, the device boot ROM verifies the contents of the active CPU1 SECCFG sector using a CRC32 algorithm before loading the settings stored in the SECCFG sector into SSU registers. If the CRC check fails, the boot process is aborted. The SECCFG CRC is computed using the following parameters:

- **CRC Polynomial:** 0x04C1 1DB7 (CRC-32/ISO-HDLC)
- **Initial Value:** 0xFFFF FFFF
- **Final XOR Value:** 0xFFFF FFFF
- **Address Ranges:**
  1. 0x000 to 0x6BF
  2. 0x7A0 to 0x7F3
  3. 0x7F8 to 0x7FF

10.9 Flash Write/Erase Access Control

In addition to LINK, STACK and ZONE IDs, the SSU includes a Flash semaphore (FLSEM) to grant exclusive access to the Flash controller for programming, program verify, erase, and erase verify operations by a given initiator at any point in time. The Flash semaphore locks all data accesses to the Flash controller registers to a specific CPU and LINK. Upon receiving a command, the Flash Controller sends a permission request out through the Flash Crossbar port (FXB) to the SSU. The SSU then determines, based on the current security context and the FLSEM owner, whether to grant permission to execute the Flash command. Flash Controller operations are not permitted when the FLSEM has no owner.

The LINK, ZONE and CPU fields in the FLSEMSTAT register specify the current owner of the Flash semaphore. In addition, code running from any LINK can confirm ownership of the semaphore by reading the FLSEMSTAT.MATCH bit. This bit returns 1 only if the LINKID and CPUID of the code performing the read match the current owner of the Flash semaphore. The FLSEMSTAT.ASSIGNED bit indicates whether the Flash semaphore is currently owned.

To grab the Flash semaphore:
1. Write 1 to the FLSEMREQ register.
2. Confirm ownership of the Flash semaphore by checking that FLSEMSTAT.MATCH = 1.

To release the Flash semaphore:
1. Write 1 to the FLSEMCLR register.
2. Confirm the Flash semaphore has been released by checking that FLSEMSTAT.MATCH = 0.

Note

With the Flash semaphore mechanism, configuring an access protection range to cover the Flash Controller registers is not necessary. Once the Flash semaphore has been assigned to a specific CPU ID and LINK ID, all accesses to the Flash Controller registers are restricted to that LINK, until the semaphore owner LINK releases the FLSEM by writing 1 to the FLSEMCLR register. In this way, the designated LINK can lock the Flash controller for exclusive self use, enabling code security and preventing access by other LINKs.

10.9.1 Permanent Flash Lock (Write/Erase Protection)

The SSU provides a mechanism to globally block program and erase operations to any Flash bank. To block all program and erase operations on code Flash banks throughout the device, write 1 to the WEPROT_CODE_BANKS.PROT register. To block program and erase operations to data Flash banks, write 1 to the WEPROT_DATA_BANKS.PROT register.

These protections can be hardened for safety or security purposes with the SSU's LOCK/COMMIT scheme using the following registers: WEPROT_CODE_BANKS_LOCK, WEPROT_CODE_BANKS_COMMIT, WEPROT_DATA_BANKS_LOCK, and WEPROT_DATA_BANKS_COMMIT.

Additionally, individual Flash sectors can be protected from write and erase operations using the WEPROT_FLC*x*_B*y*_* registers. For each bank, there are three registers. The first, WEPROT_FLC*x*_B*y*_A, contains individual protection bits for the first 32 sectors in bank *y* of Flash Controller *x*. The other two, WEPROT_FLC*x*_B*y*_B and WEPROT_FLC*x*_B*y*_C, define protections for the remaining Flash sectors in the bank, in groups of 8 contiguous sectors. These registers also have LOCK and COMMIT mechanisms, similar to WEPROT_CODE_BANKS and WEPROT_DATA_BANKS.

All the Flash protection registers are mapped to the SECCFG sector, so that Flash protections defined in SECCFG are automatically loaded by the boot ROM at device start-up. Using this mechanism, Flash bank or sector protections can be locked and committed before the application starts, and critical Flash contents remain unmodifiable throughout the current power-on cycle.

10.9.2 Updating Flash MAIN Sectors

For each ZONE, the user can configure a firmware update owner CPU and LINK using the FWU_CPU and FWU_LINK fields in the ZONEx_CFG register. The following restrictions apply when updating code in the Flash MAIN sectors:

- When in SSUMODE3, the firmware update owner CPU and LINK defined in the ZONEx_CFG register is the only LINK allowed to program and erase the Flash MAIN sectors. In addition, ZONEx_CFG.UPDATE_EN must be set to 0xC to enable updates.
- In SSUMODE1 and SSUMODE2, Flash write/erase protections are inactive as all ZONES are enabled for full debug. In these modes, Flash memory can always be programmed or erased. This enables easy code development.

10.9.3 Firmware-Over-The-Air Updates (FOTA)

This device supports Firmware-Over-The-Air (FOTA) updates using a Flash bank-swapping mechanism. The FOTA process is managed and controlled using the Flash Controller BANKMAP register and the BANKMGMT sector in each bank. Figure 10-5 shows an example of how banks are swapped.

When bank swap is active, all sectors of a Flash bank are swapped, including the SECCFG and BANKMGMT sectors.

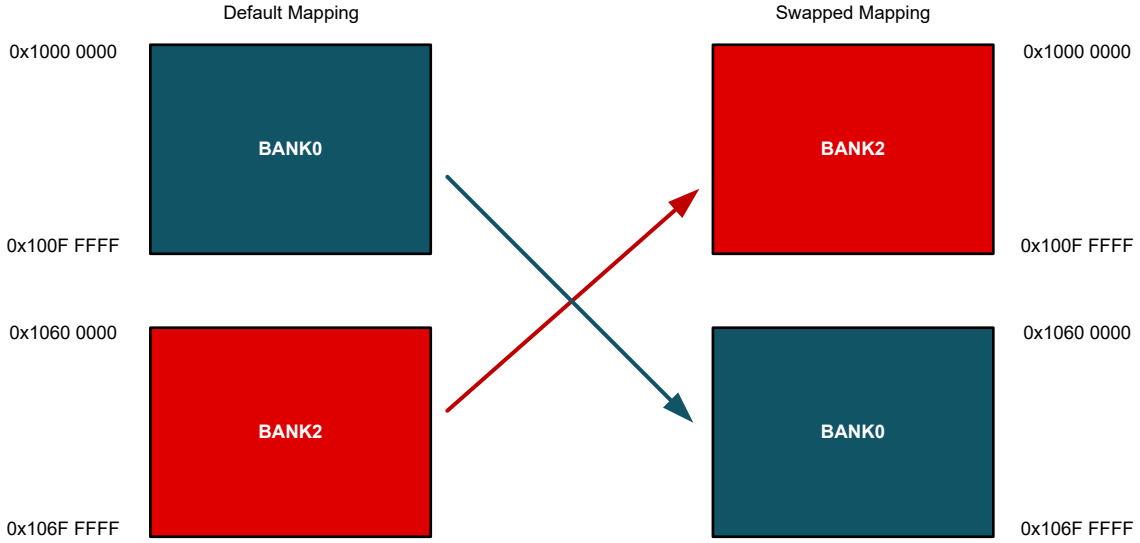

Figure 10-5. Bank Swap Mapping Example

The FOTA concept is designed to enable programming of inactive Flash banks while the application continues to run from the active banks without interruption. The update process is comprised of the following steps:

1. **Image Creation and Deployment:** The user creates an application update image. This image can be transferred into the device using a Flash kernel, over a communications interface such as CAN or UART. The update image is typically delivered in chunks, since the RAM available is not large enough to hold an entire Flash image. For security, the update image can be authenticated using cryptographic methods such as a digital signature algorithm.
2. **Installation Phase:** The Flash kernel downloads Flash chunks, authenticates them, and programs them into the Flash update region (FRI-3). This phase consists of three steps:
   a. Erase the inactive banks by addressing the update region with a Flash erase command.
   b. Download, authenticate/decrypt and program updated firmware into the Flash update region.
   c. Issue Flash API command to update BANKMGMT sector of inactive banks to be active and newer than the currently active banks. The Flash API commands are executed in the following order:
      i. (CPU1 only) Program inactive bank's BANKMODE to the expected/new BANKMODE value. Note that changing the BANKMODE during a firmware update is possible.
      ii. Program the inactive bank's BANK_UPDATE_CTR to be one less than the active bank's BANK_UPDATE_CTR.
      iii. Program the inactive bank's BANK_STATUS to 0x55555555_55555555.
3. **Activation Phase:** The update manager waits for the application to reach a safe state (or brings the application to a safe state), then issues a full device reset (XRSn). A reset can be issued by software running in LINK2 by writing to the DEV_CFG_REGS.SIMRESET register. During device startup, the boot ROM reevaluates the BANKMGMT sectors, and configures BANKMAP to reflect the new update. After a timeout period, the FOTA manager requests the active firmware revision from the device. If the expected new version is not returned, the FOTA manager re-issues the update command, since the update has not completed successfully.

4. (Optional) **Rollback:** If desired, the user can return to the most recent (currently inactive) application firmware version. The rollback service erases and reprograms the current inactive BANKMGMT sector to be active and have a newer update counter value than the current active sector. This allows a rollback to the previous firmware version without having to re-download from an external interface. The rollback steps are executed in the following order:
   a. Authenticate the code in the inactive bank to confirm the code's validity and integrity.
   b. Erase the inactive bank's BANKMGMT sector.
   c. (CPU1 only) Program inactive bank's BANKMODE to the correct BANKMODE value.
   d. Program the inactive bank's BANK_UPDATE_CTR to one less than the active bank's BANK_UPDATE_CTR.
   e. Program the inactive bank's BANK_STATUS to 0x55555555_55555555.
   f. After bringing the application to a safe state, issue a device XRSn reset to activate the old firmware image.
5. (Optional) **Anti-Rollback:** To prevent any possibility of a rollback to the previous firmware version, invalidate the old firmware image completely by erasing the inactive bank's MAIN sectors.

10.9.4 Updating Flash SECCFG Sectors

The following security restrictions apply to updates of the SECCFG sectors:

- In SSUMODE1, all code running from any LINK has permission to update the SECCFG sectors, since ZONE1 is enabled for full debug. This enables ease of code development.
- In SSUMODE2, all code running from any LINK has permission to update SECCFG sectors, since ZONE1 is enabled for full debug.
- In SSUMODE3, only the SECCFG update owner defined in SECCFG_UPDATE_CFG has permission to update SECCFG sectors. In addition, SECCFG_UPDATE_CFG.UPDATE_EN must be set to 0xC to enable updates to SECCFG when operating in SSUMODE3.

Each CPU has two SECCFG sectors for storing User Protection Policy (UPP). One sector holds the active policy, while the other is available for updating. The SECVALID register specifies which of the two SECCFG sectors is active for each CPU subsystem.

When updating the SSU configuration, always program the SECCFG image to the reserve (B2/B3) SECCFG sector address, regardless of which sector is currently active. The SSU automatically routes the reserve address to the current inactive sector when a Flash program or erase command is performed. The SECCFG image base addresses are defined in Table 10-3. However, CPU read operations must be addressed to the correct Flash read port address, as defined in Section 10.8.3.

Table 10-3. CPU1 SECCFG Update Address Table

	CPU1/CPU2	CPU3/CPU4	CPU1/CPU2 (FOTA/LFU)	CPU3/CPU4 (FOTA/LFU)
Erase/Program	0x10D8 5000	0x10D9 5000	0x10D9 9000	0x10D9 D000
Read	Refer to Section 10.8.3			

10.9.5 Reading Flash SECCFG Sectors

As a countermeasure against overclocking attacks, all reads to Flash SECCFG sectors are hard-coded to 10 cycles (9 wait states), regardless of the current Flash wait state configuration.

10.10 RAMOPEN Feature

The RAMOPEN mode provides a means for bootloader applications to exclusively access RAM for the purpose of storing code or data downloaded from an external source. RAMOPEN can only be initiated by two sources:

1. Direct JTAG writes to the RAMOPENFRC register. This gives the debugger the ability to open RAM access for writing before downloading code to the RAM. Debugger writes to LINK1 RAM are only allowed in SSUMODE1, in SSUMODE2, or when ZONE1 is enabled for full debug.
2. Boot loader code running in LINK1.

RAMOPEN cannot be initiated by code running from any of the user LINKs (2 and above).

When RAMOPEN is opened, the following sequence occurs:

1. The hardware erases the RAMs using RAMINIT.
2. Any write to RAM that was initiated prior to or during RAMINIT is aborted. Write accesses can only update RAM after RAMINIT completes and RAMOPEN status becomes active.
3. LINK1 gains read, write and execute permissions for RAMOPENed memories. All other LINKs have no access to any of the RAMs.
4. The SSU sets RAMOPENSTAT.LINK1_RAMOPENS to 1 to indicate RAMOPEN is now active.

After the intended use for RAMOPEN completes, return the RAM back to the user application by writing 1 to the RAMOPENCLR.CLEAR_LINK1 register. Once the bit has been written, if the RAMOPENFRC.WIPE_ON_LINK1_CLR bit was set, the device erases the RAM content for all RAMOPENed memories using the RAMINIT feature, and then clears the RAMOPENSTAT.LINK1_RAMOPENS bit. If the RAMOPENFRC.WIPE_ON_LINK1_CLR bit was not set, then the RAM contents are preserved when RAM is returned to the user application. This feature gives user bootloaders (for example, firmware updaters) the ability to automatically wipe sensitive data or code from the RAM after the bootloader operation completes.

The following sequence occurs when RAMOPENCLR.CLEAR_LINK1 is written:

1. If RAMOPENFRC.WIPE_ON_LINK1_CLR is set, then the RAMs are erased using RAMINIT.
2. Any write to RAM that was initiated prior to or during RAMINIT is aborted. Only writes initiated after RAMINIT completes and RAMOPEN status is set to inactive update the RAM.
3. RAM access permissions are allocated according to the configured user protection policy (UPP).
4. The SSU sets RAMOPENSTAT.LINK1_RAMOPENS to 0 to indicate RAMOPEN is now inactive.

Note

In RAMOPEN mode, unauthorized code can be loaded into memory as LINK1 code. Any ZONEs that permit firmware updates from the LINK1 can be updated without user code control. The most secure way to perform a firmware update is to lock boot loaders down and use a secure firmware update algorithm.

10.11 Debug Authorization

There are two levels of debug authorization provided by the SSU:

- Global JTAG authorization (C29DBGEN)
- ZONE debug authorization

Debug access control features are active in SSUMODE3. In SSUMODE1 and SSUMODE2, JTAG is automatically enabled, and all user ZONEs are enabled for full debug.

10.11.1 Global CPU Debug Enable

The global debug enable control gates debug access to all C29x CPU test access ports (TAPs). When C29DBGEN is inactive (set to 0), none of the CPU cores are accessible directly using JTAG; only communication with the device Security Access Port (SEC-AP) handler is permitted.

When present, the HSM can also control debug access to the C29x CPUs by writing to the C29DBGEN or ZONE_DBGEN registers in the SSU.

Note

C29DBGEN only controls debug access to the C29x CPUs, and has no effect on HSM debug access. C29DBGEN is different from the HSM global JTAG disable control (JTAG_DIS) which blocks access to all device debug ports, including both HSM and C29x CPU subsystems.

10.11.2 ZONE Debug

In addition to the global C29x debug enable control, each ZONE has a separate enable setting, for more granular debug access control. ZONEs can span one or more CPUs, and are orthogonal to individual CPU TAP enables. ZONEs can be used to separate debug authorization across different parts of the device between different users, with different authentication credentials established for each user. When a user performs a debug access to a memory region, the SSU checks to see if at least one LINK with the requested access to the region belongs a ZONE that has been enabled for full debug. If no LINKs match this condition, then the SSU blocks the debug access, and notifies the C29x SEC-AP handler that a debug read or write error occurred, depending on the type of access attempted.

10.11.3 Authentication for Debug Access

The DEBUG_CFG register controls the authentication method used to control debug access at the C29DBGEN level and each of the user ZONE debug levels. For each debug access control, there are three valid configuration options:

- Password-based authentication
- CPU-based authentication
- Debug disabled

The DEBUG_CFG register has LOCK/COMMIT protections to prevent unintended or unauthorized changes to the debug authentication scheme. To lock or commit these settings, write to the DEBUG_CFG_LOCK and DEBUG_CFG_COMMIT registers as required.

The current debug status for C29DBGEN and each of the user debug ZONEs can be determined by connecting to the SEC-AP and reading the DEBUG_ENABLE_STATUS register. For more details, see the Debug Controller chapter.

Devices shipped from the TI factory have password-based authentication active at boot-up by default. To change the startup debug authentication mode, update the DEBUG_CFG field in the SECCFG sector accordingly.

10.11.3.1 Password-based Authentication

When password-based authorization is enabled for C29DBGEN or a user ZONE, the associated register bit field (C29DBGEN.ENA, ZONE_DBG.ZONEx) is ignored by the SSU. Instead, the user scans a 128-bit password into the appropriate internal key register using the SEC-AP, and the SSU hardware compares the scanned-in password to a predefined password that is preloaded from the SECCFG sector during device boot. If the password matches, then the SSU opens debug access to the requested resource.

There are two levels of ZONE debug authorization that can be enabled by password authentication: full debug, and partial debug. These are controlled using the full debug password and partial debug password respectively. When a user scans in a password for debug authorization, the SSU performs the following sequence:

1. Compare scanned-in password to full debug password. If matching, then open the ZONE for full debug.
2. If the previous compare resulted in a mismatch, then compare the scanned-in password to the partial debug password. If matching, then open the ZONE for partial debug.
3. If the previous compare resulted in a mismatch, then the ZONE remains closed.

To enable C29DBGEN or open debug access to a zone when using password-based authentication, scan the appropriate command as defined in Table 10-4 into the SEC-AP PASSWORD_ID register, and then scan in the 128-bit password into the SEC-AP password registers (PASSWORD1, PASSWORD2, PASSWORD3, PASSWORD4). Note that there is a single password scan required for both full and partial ZONE debug. The SSU first compares the scanned in password to the full debug password. If there is a match, then full debug is enabled for the ZONE. If there is a mismatch, then the SSU compares the scanned in password to the partial debug password to determine whether to enable partial debug for the ZONE.

Table 10-4. Password Scan Commands

Value	Command
0x0	Reserved for internal use
0x1	ZONE1 Debug Password Scan
0x2	ZONE2 Debug Password Scan
0x3	ZONE3 Debug Password Scan
0x4	C29DBGEN Unlock Password Scan
Others	Reserved for future use

For C29DBGEN, there is only one password that controls debug access. When the user scans in a password matching the C29DBGEN password, the SSU unlocks the Test Access Ports (TAPs) for all application CPUs in the device. The HSM also has control over the application CPU TAPs. When the HSM is present, both C29DBGEN and the corresponding HSM debug enable control must be active for debug access to the C29x CPU TAP to be opened. If either C29DBGEN or the HSM denies access, then the C29x CPU TAP remains closed.

Note

The SSU has no control over HSM resources. C29DBGEN only controls debug access to C29x CPUs. For information on how to enable debug access to the HSM, see the *F29x Security Hardware User Guide*.

C29DBGEN does not override ZONE debug authorization. Even with C29DBGEN active, a password-protection ZONE must still be unlocked for the debugger to access any memory-mapped resources in that ZONE. C29DBGEN only controls access to the CPU TAPs.

10.11.3.2 CPU-based Authentication

CPU-based debug authentication enables users to write customized code for debug authorization, instead of a simple password scan and compare. In this mode, the application can execute challenge-response authentication schemes using cryptographic algorithms, including schemes involving public/private key encryption pairs. Challenge-response authentication provides stronger security by eliminating the need to store a common password across all devices which, if stolen, potentially compromises security for existing deployed devices.

When CPU-based authentication is selected in DEBUG_CFG for a particular ZONE or for C29DBGEN, the corresponding register bit fields (ZONE_DBGEN.ZONEx, C29DBGEN.ENA) become valid, and the password comparison is ignored. The ZONE_DBGEN and C29DBGEN registers are only accessible by CPU1.LINK2 and the HSM. The application authorization code, running on CPU1.LINK2 or on the HSM, can read values scanned into the SEC-AP through the debugger, and through the interactive challenge-response process determine if and when to enable debug by writing to the C29DBGEN or ZONE_DBGEN registers.

10.12 Hardcoded Protections

The user has the ability to configure all LINKs, STACKs and ZONEs that are owned by the user. However, certain system resources have protections that are fixed in hardware and cannot be altered:

- LINK0 belongs to STACK0, and STACK0 belongs to ZONE0. These are TI internal resources and cannot be accessed by user code. User code cannot assign any user LINKs to STACK0, or user STACKs to ZONE0.
- LINK1 for each CPU always belongs to STACK1.
- STACK1 for each CPU always belongs to ZONE1.
- LINK2 for each CPU always belongs to STACK2.
- STACK2 for each CPU always belongs to ZONE1.
- In SSUMODE3, the Flash SECCFG sector can only be read by:
  - The SECCFG update owner defined in SECCFG_UPDATE_CFG, or
  - The HSM, if present and enabled.
- Code instruction fetches to M0 memory always generate a fault.
- Data reads of M0 RAM are allowed for all CPUs and all LINKs.
- Data writes to M0 RAM are only allowed for CPU1.LINK2.
- Certain memory and peripheral regions are restricted to one or more of the special-purpose LINKs (LINK0, LINK1 and LINK2). For details on these non-APR-based memory protections, refer to the memory-map in the device data sheet.

10.13 SSU Register Access Permissions

SSU register permissions vary depending on category and function. CPU1 is the primary owner of all SSU registers, including those for all other CPUs. Most registers are automatically loaded at device startup; however, some are designated for run-time operation, for example, FLSEM. The tables in this section describe the access permissions for each register, organized by register groups. For register access permission tables that do not include a column for the HSM, there is no HSM access permitted to these registers.

Accesses to SSU registers that are denied generate a fault to the ESM.

Note

When lockstep mode is enabled, the register access permissions for the secondary CPU are always identical to the access permissions for the primary CPU. For instance, if CPU2 is present and in lockstep with CPU1, then CPU2's access permissions are the same as CPU1's. The CPU2 permission tables do not apply. For more information on SSU operation in lockstep mode, see Section 10.6.1.

In SSUMODE1, CPU register read access is granted if any LINK is enabled for hardcoded read permissions. Similarly, in SSUMODE1 CPU register write access is granted if any LINK is enabled for hardcoded write permissions. This rule does not supersede Flash semaphore ownership rules.

10.13.1 Permissions for SSU General Control Registers

Table 10-5 describes access permissions for the SSU_GEN_REGS group of registers.

Table 10-5. Access Permissions for SSU General Control Registers

Register	Register Load Method	Boot	CPU1				CPU2+			HSM
			CPU1 LINK1	CPU1 LINK2	CPU1 LINK3+	CPU1 Debug	CPU2+ LINK0,1, and 3+	CPU2+ LINK2	CPU2+ Debug	
REVISION	None	R-only	R-only	R-only	R-only	R-only(1)	R-only	R-only	R-only(1)	No
UPP_ REVISION	Boot	R/W	R-only	R-only	R-only	R-only(1)	No	No	No	No

WEPROT_FLC1_*	None	R/W	R/W	R/W	R-only	R-only(1)	R-only	R-only	R-only(1)	R/W
WEPROT_FLC2_*	None	R/W	R/W	R/W	R-only	R-only(1)	R-only	R-only	R-only(1)	R/W

(1) If any ZONE is enabled for partial or full debug (note that this occurs automatically when SSUMODE = 1 or 2); otherwise, no access.
(2) If ZONE1 is enabled for full debug (note that this occurs automatically when SSUMODE = 1 or 2); otherwise, R-only (with note 1 applied).
(3) Only writable if FLSEMSTAT.ASSIGNED is set and FLSEMSTAT.CPU and FLSEMSTAT.LINK match the transaction's CPUID/LINKID sideband signals.
(4) BANKMAP registers are R/W by CPU1.LINK2 when HSM is in HS-FS state. This allows C29x FW to control updates on non-HSM (or not-secured-yet HSM devices).
(5) FLSEMCLR is only writable if FLSEMSTAT.ASSIGNED is set and FLSEMSTAT.CPU and FLSEMSTAT.LINK match the transaction's CPUID/LINKID, or if the transaction's CPUID.LINKID is CPU1.LINK2.

10.13.2 Permissions for SSU CPU1 Configuration Registers

Table 10-6 describes access permissions to the SSU_CPU1_CFG_REGS register group. This group of registers is not accessible by the HSM.

Table 10-6. Access Permissions for SSU CPU1 Configuration Registers

Register	Register Load Method	Boot	CPU1				CPU2+	
			CPU1 LINK1	CPU1 LINK2	CPU1 LINK3+	CPU1 Debug	CPU2+ LINK0+	CPU2+ Debug
EMU_BOOTDEF_LOW	None	R-only	R-only	R-only	R-only	R/W(1)	No	No
EMU_BOOTDEF_HIGH	None	R-only	R-only	R-only	R-only	R/W(1)	No	No
LINKx_CFG	Boot	R/W	R-only	R-only	R-only	R-only(1)	No	No
STACKy_CFG	Boot	R/W	R-only	R-only	R-only	R-only(1)	No	No
RAMOPENSTAT	None	R-only	R-only	R-only	R-only	R-only(1)	No	No
RAMOPENFRC	Boot	R/W	R/W	R-only	R-only	R/W(1)	No	No
RAMOPENCLR	Boot	R/W	R/W	R-only	R-only	R/W(1)	No	No
DECODER_ADDR_IN	None	R/W	No	R/W	No	No	No	No
DECODER_OUT	None	R-only	No	R-only	No	No	No	No
EMU_DECODER_ADDR_IN	None	No	No	No	No	R/W(1)	No	No
EMU_DECODER_OUT	None	No	No	No	No	R-only(1)	No	No

(1) If ZONE1 is enabled for full debug (note that this occurs automatically when SSUMODE=1 or 2); otherwise, no access.

10.13.3 Permissions for SSU CPU2+ Configuration Registers

Table 10-7 describes the access permissions for the SSU_CPUx_CFG_REGS register groups. This register group exists for each additional CPU present in the device, beginning with CPU2.

Table 10-7. Access Permissions for SSU CPU2/CPU3 Configuration Registers

Register	Boot Load Method	Boot	CPU1			CPUn					Other CPUs
			CPU1 LINK1	CPU1 LINK2+	CPU1 Debug	CPUn LINK0	CPUn LINK1	CPUn LINK2	CPUn LINK3+	CPUn Debug	
RST_VECT	Boot	R/W	R-only	R-only	R-only(1)	R-only	R-only	R-only	R-only	R-only(1)	No
RST_LINK	Boot	R/W	R-only	R-only	R-only(1)	R-only	R-only	R-only	R-only	R-only(1)	No
CPU_RST_CTRL	None	R-only	R-only	R/W	R-only(1)	R-only	R-only	R-only	R-only	R-only(1)	No(3)
DEF_NMI_VECT	Boot	R/W	R-only	R-only	R-only(1)	R-only	R-only	R-only	R-only	R-only(1)	No
DEF_NMI_LINK	Boot	R/W	R-only	R-only	R-only(1)	R-only	R-only	R-only	R-only	R-only(1)	No
EMU_BOOTDEF_LOW	None	R-only	R-only	R-only	R/W(2)	R-only	R-only	R-only	R-only	R/W(2)	No
EMU_BOOTDEF_HIGH	None	R-only	R-only	R-only	R/W(2)	R-only	R-only	R-only	R-only	R/W(2)	No
LINKx_CFG	Boot	R/W	R-only	R-only	R-only(2)	R-only	R-only	R-only	R-only	R-only(2)	No
STACKy_CFG	Boot	R/W	R-only	R-only	R-only(2)	R-only	R-only	R-only	R-only	R-only(2)	No
RAMOPENSTAT	None	R-only	R-only	R-only	R-only(2)	R-only	R-only	R-only	R-only	R-only(2)	No
RAMOPENFRC	Boot	R/W	R/W	R-only	R/W(2)	R/W	R/W	R-only	R-only	R/W(2)	No
RAMOPENCLR	Boot	R/W	R/W	R-only	R/W(2)	R/W	R/W	R-only	R-only	R/W(2)	No
DECODER_ADDR_IN	None	No	No	No	No	R/W	No	R/W	No	No	No
DECODER_OUT	None	No	No	No	No	R-only	No	R-only	No	No	No
EMU_DECODER_ADDR_IN	None	No	No	No	No	No	No	No	No	R/W(2)	No
EMU_DECODER_OUT	None	No	No	No	No	No	No	No	No	R-only(2)	No

(1) If any ZONE is enabled for partial or full debug (note that this occurs automatically when SSUMODE=1 or 2); otherwise, no access.
(2) f ZONE1 is enabled for full debug (note that this occurs automatically when SSUMODE=1 or 2); otherwise, no access.
(3) With exception: the primary CPU's LINK2 has access to modify (R/W) the secondary CPU's CPU_RST_CTRL register. For instance, CPU3.LINK2 has R/W access to CPU_RST_CTRL for CPU4, if present.

10.13.4 Permissions for CPU1 Access Protection Registers

Table 10-8 describes access permissions for the SSU_CPU1_AP_REGS register group. The HSM has no access to these registers.

Table 10-8. Access Permissions for CPU1 Access Protection Registers

Register	Boot Load Method	Boot	CPU1				CPU2+	
			CPU1 LINK1	CPU1 LINK2	CPU1 LINK3+	CPU1 Debug	CPU2+ LINK0+	CPU2+ Debug
APn_CFG	Boot	R/W	R/W(1)	R/W	R-only	R/W(2)	No	No
APn_START[_EXT]	Boot	R/W	R/W(1)	R/W	R-only	R/W(2)	No	No
APn_END[_EXT]	Boot	R/W	R/W(1)	R/W	R-only	R/W(2)	No	No
APn_LOCK	Boot	R/W	R/W(1)	R/W	R-only	R/W(2)	No	No
APn_COMMIT	Boot	R/W	R/W(1)	R/W	R-only	R/W(2)	No	No
APn_ACCESS	Boot	R/W	R/W(1)	R/W	R-only	R/W(2)	No	No

(1) If in SSUMODE1 or SSUMODE2; otherwise, no access.
(2) f ZONE1 is enabled for full debug (note that this occurs automatically when SSUMODE=1 or 2); otherwise, no access.

10.13.5 Permissions for CPU2+ Access Protection Registers

Table 10-9 describes access permissions for the SSU_CPUn_AP_REGS register group or groups, starting with CPU2, for each additional CPU present in a multicore device. The HSM does not have access to these registers.

Table 10-9. Access Permissions for CPU2+ Access Protection Registers

Register	Boot Load Method	Boot	CPU1				CPUn				Other CPUs
			CPU1 LINK1	CPU1 LINK2	CPU1 LINK3+	CPU1 Debug	CPUn LINK0/1	CPUn LINK2	CPUn LINKs	CPUn Debug	
APn_CFG	Boot	R/W	R/W(1)	R/W	No	R/W(2)	R-only	R/W	R-only	R/W(2)	No
APn_START [_EXT]	Boot	R/W	R/W(1)	R/W	No	R/W(2)	R-only	R/W	R-only	R/W(2)	No
APn_END [_EXT]	Boot	R/W	R/W(1)	R/W	No	R/W(2)	R-only	R/W	R-only	R/W(2)	No
APn_LOCK	Boot	R/W	R/W(1)	R/W	No	R/W(2)	R-only	R/W	R-only	R/W(2)	No
APn_ COMMIT	Boot	R/W	R/W(1)	R/W	No	R/W(2)	R-only	R/W	R-only	R/W(2)	No
APn_ ACCESS	Boot	R/W	R/W(1)	R/W	No	R/W(2)	R-only	R/W	R-only	R/W(2)	No

(1) If in SSUMODE1 or SSUMODE2; otherwise, no access.
(2) If ZONE1 is enabled for full debug (note that this occurs automatically when SSUMODE=1 or 2); otherwise, no access.

10.14 SSU Fault Signals

The Safety and Security Unit can generate faults to two different interfaces: the C29x CPU interface, and the Error Aggregator interface that forwards error signals to the Error Signaling Module (ESM). In general, errors that occur as a result of an unauthorized CPU access to a protected memory region generate a fault signal to the CPU, while other types of errors generate a fault signal to the Error Aggregator. The following tables describe the various faults that are generated by the SSU to the CPU and Error Aggregator interfaces. Because the SSU interfaces between the CPU and Flash Controllers for performing program and erase operations, the SSU also reports errors generated by the Flash Controllers to the Error Aggregator. These errors are described in Table 10-11 and Table 10-12.

Table 10-10. SSU to C29x CPU Fault Signals

Security Fault	Error Type	Bus	Error Description
CPUx_PR_HIGHPRIO_ERROR	0x01	Program Bus	This error is generated when a program read occurs, and the address is not covered by a hardcoded protection or a currently active RAMOPEN region, and one of the following is true: • Zero or more than one AP regions respond, or • The responding AP region's XE bit is set to 0, or • The responding AP region's LINKID field is set to 0, or • The responding AP region's LINKID decodes to STACK0 or ZONE0
CPUx_DR1_HIGHPRIO_ERROR	0x01	Data Read Bus 1	This error is generated when a CPU data read occurs on DRB1, and zero or more than one AP region responds with valid read access permissions for the instruction's LINK.
CPUx_DR2_HIGHPRIO_ERROR	0x01	Data Read Bus 2	This error is generated when a CPU data read occurs on DRB2, and zero or more than one AP region responds with valid read access permissions for the instruction's LINK.
CPUx_DW_HIGHPRIOR_ERROR	0x01	Data Write Bus	This error is generated when a CPU data write occurs, and zero or more than one AP region responds with valid write access permissions for the instruction's LINK.

Table 10-11. SSU to Error Aggregator Fault Signals

Error Signal	Description	Error Address	Priority
SSU_ERROR_TYPE[0]	HSM SSU Register Access Error	SSU register address	High
SSU_ERROR_TYPE[1]	CPU1 SSU Register Access Error	SSU register address	High
SSU_ERROR_TYPE[2]	CPU2 SSU Register Access Error	SSU register address	High
SSU_ERROR_TYPE[3]	CPU3 SSU Register Access Error	SSU register address	High
SSU_ERROR_TYPE[4]	CPU4 SSU Register Access Error	SSU register address	High
SSU_ERROR_TYPE[6:5]	Reserved	-	-
SSU_ERROR_TYPE[7]	Invalid BANKMAP, SECVALID, BANKMODE or SSUMODE	N/A	High
SSU_ERROR_TYPE[8]	Error on Flash Controller 1	See Table 10-12	High
SSU_ERROR_TYPE[11:9]	FLC1 Error Type		High
SSU_ERROR_TYPE[12]	FLC1 Register Access Error	FLC1 register address	High
SSU_ERROR_TYPE[13]	Error on Flash Controller 2	See Table 10-12	High
SSU_ERROR_TYPE[16:14]	FLC2 Error Type		High
SSU_ERROR_TYPE[17]	FLC2 Register Access Error	FLC2 register address	High

Table 10-12. Flash Controller Error Codes

Error Code	Error Name	Description	Error Address
0x0	ILLADDR	Controller reported an out of range/illegal Flash address, or a security violation.	Flash address
0x1	ILLPROG	An error occurred while trying to execute a programming command.	
0x2	ILLERASE	An error occurred while trying to execute an erase command.	
0x3	ILLRDVER	The Flash Controller failed to completely program or erase all target bits in the Flash within the maximum number of pulses.	
0x4	ILLMODECH	An attempt was made to execute a program or erase command while the Flash was not in READ mode. The erase/program command was aborted.	
0x5	ILLCMD	An illegal command was issued to the Flash Controller.	Command type
0x6	ILLSIZE	An illegal size value was provided for the Flash Controller command.	Command size
0x7	ILLBANKERASE	An error occurred while trying to execute a bank erase command.	Flash address

10.16 SSU Registers

This section describes the SSU Registers.

10.16.1 SSU Base Address Table

Table 10-14. SSU Base Address Table

Structure	DriverLib Name	Base Address	Frame Applicable	CPU1	CPU2	CPU3	RTDMA1	RTDMA2	HSM	Pipeline Protected
SSU_GEN_REGS	SSUGEN_BASE	0x3008_0000	-	YES	YES	YES	-	-	YES	YES
SSU_CPU1_CFG_REGS	SSUCPU1CFG_BASE	0x3008_1000	-	YES	-	-	-	-	-	YES
SSU_CPU2_CFG_REGS	SSUCPU2CFG_BASE	0x3008_2000	-	YES	YES	-	-	-	-	YES
SSU_CPU3_CFG_REGS	SSUCPU3CFG_BASE	0x3008_3000	-	YES	-	YES	-	-	-	YES
SSU_CPU1_AP_REGS	SSUCPU1AP_BASE	0x3008_7000	-	YES	-	-	-	-	-	YES
SSU_CPU2_AP_REGS	SSUCPU2AP_BASE	0x3008_8000	-	YES	YES	-	-	-	-	YES
SSU_CPU3_AP_REGS	SSUCPU3AP_BASE	0x3008_9000	-	YES	-	YES	-	-	-	YES

10.16.2 SSU_GEN_REGS Registers

Table 10-15 lists the memory-mapped registers for the SSU_GEN_REGS registers. All register offset addresses not listed in Table 10-15 should be considered as reserved locations and the register contents should not be modified.

Table 10-15. SSU_GEN_REGS Registers

Offset	Acronym	Register Name	Protection
0h	REVISION	Module Revision Register	
4h	UPP_REVISION	User Protection Policy Revision	
8h	SSUMODE	Safety and Security Operational Mode	
Ch	LINK2_AP_OVERRIDE	LINK2 Access Protection Override Register	
2Ch	BOOTMODE_STAT	User Boot Mode Status Register	
30h	EMU_BOOTPIN_CONFIG	User Emulation Boot Pin Configuration	
34h	EMU_BOOT_DIAG	User Emulation Boot Options	
38h	EMU_BOOT_CLKCFG	User Emulation Boot Clock Configuration Register	
3Ch	EMU_BOOTEN	User Emulation Boot Enable	
40h	RAMOPEN_LOCK	RAMOPEN Feature Lock Register	
44h	RAMOPEN_COMMIT	RAMOPEN Feature Commit Register	
4Ch	CPUID	CPUID Register	
50h	BANKMAP	Valid Banks	
54h	BANKMAP_LOCK	Bank Map Lock Register	
58h	BANKMAP_COMMIT	Bank Map Commit Register	
5Ch	BANKMODE	Bank Mode Configuration Register	
60h	BANKMODE_LOCK	Bank Mode Lock Register	
64h	BANKMODE_COMMIT	Bank Mode Commit Register	
68h	SECCFG_UPDATE_CFG	SECCFG Flash Update Configuration Register	
70h	PROG_BANKMODE	Programming BANKMODE Register	
74h	SECVALID	Valid SECCFG Sector

340h	WEPROT_FLC1_B2_A	Flash Controller 1 B2 Write Erase Protection A	
344h	WEPROT_FLC1_B2_B	Flash Controller 1 B2 Write Erase Protection B	
350h	WEPROT_FLC1_B2_LOCK	Flash Controller 1 B2 WEPROTA Lock	
354h	WEPROT_FLC1_B2_COMMIT	Flash Controller 1 B2 WEPROTA Commit	
3A0h	WEPROT_FLC2_B0_A	Flash Controller 2 B0 Write Erase Protection A	
3A4h	WEPROT_FLC2_B0_B	Flash Controller 2 B0 Write Erase Protection B	
3B0h	WEPROT_FLC2_B0_LOCK	Flash Controller 2 B0 WEPROTA Lock	
3B4h	WEPROT_FLC2_B0_COMMIT	Flash Controller 2 B0 WEPROTA Commit	
3E0h	WEPROT_FLC2_B2_A	Flash Controller 2 B2 Write Erase Protection A	
3E4h	WEPROT_FLC2_B2_B	Flash Controller 2 B2 Write Erase Protection B	
3F0h	WEPROT_FLC2_B2_LOCK	Flash Controller 2 B2 WEPROTA Lock	
3F4h	WEPROT_FLC2_B2_COMMIT	Flash Controller 2 B2 WEPROTA Commit	

Complex bit access types are encoded to fit into small table cells. Table 10-16 shows the codes that are used for access types in this section.

Table 10-16. SSU_GEN_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
WOnce	W Once	Write Write once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.

Table 10-16. SSU_GEN_REGS Access Type Codes (continued)

Access Type	Code	Description
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

10.16.2.1 REVISION Register (Offset = 0h) [Reset = 00000000h]

REVISION is shown in Figure 10-6 and described in Table 10-17.

Return to the Summary Table.

Module Revision Register

RESERVED				LINK			
R-0h				R-0h			

Table 10-53. FLSEMSTAT Register Field Descriptions

Bit	Field	Type	Reset	Description
31	ASSIGNED	R	0h	CPU and LINK fields are valid when this bit is set. 0 : CPU and LINK are unassigned and flash controller is not accessible 1 : CPU and LINK values are valid and the flash controller is currently assigned to them Reset type: XRSn
30	MATCH	R	0h	On a read, this bit will reflect whether the reader's CPUID and LINKID matches the ownership of the flash controller (LINKID matches LINK, CPUID matches CPU, and ASSIGNED equals '1'). 0 : Code performing read does not own the flash controller semaphore 1 : Code performing read owns the flash controller semphore. This avoids code from being required to know which CPU and LINK it belongs to when reading the status of the semaphore. Reset type: XRSn
29-16	RESERVED	R	0h	Reserved
15	RESERVED	R	0h	Reserved
14-12	CPU	R	0h	Defines the current CPU owner of the flash controller. 0x0 : CPU-HSM (if available) 0x1 : CPU1 0x2 : CPU2 (if available) ... 0x7 : CPU7 (if available) Reset type: XRSn
11-10	RESERVED	R	0h	Reserved
9-8	ZONE	R	0h	Defines the current ZONE owner of the flash controller. 0x0 : ZONE0 0x1 : ZONE1 0x2 : ZONE2 0x3 : ZONE3 Reset type: XRSn
7-4	RESERVED	R	0h	Reserved

Table 10-53. FLSEMSTAT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3-0	LINK	R	0h	Defines the current LINK owner of the flash controller. 0x0 : LINK0 0x1 : LINK1 0x2 : LINK2 ... 0xF : LINK15 Reset type: XRSn

10.16.2.38 FLSEMREQ Register (Offset = 224h) [Reset = 00000000h]

FLSEMREQ is shown in Figure 10-43 and described in Table 10-54.

Return to the Summary Table.

Flash Controller Semaphore Request Register

Figure 10-43. FLSEMREQ Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RESERVED

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED															REQ
R-0h															R-0/W1S-0h

Table 10-54. FLSEMREQ Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	Reserved
15-1	RESERVED	R	0h	Reserved
0	REQ	R-0/W1S	0h	If the FLSEMSTAT.ASSIGNED bit is cleared, writing a '1' to this bit causes the SSU logic to: 1) Load the LINKID of the code performing the write into the FLSEMSTAT.LINK bit field, and 2) Load the ZONEID of the code performing the write into the FLSEMSTAT.ZONE bit field, and 3) Load the CPUID of the code performing the write into the FLSEMSTAT.CPU bit field, and 4) Set the FLSEMSTAT.ASSIGNED bit. If the FLSEMSTAT.ASSIGNED is already set when a write to this bit occurs, the write will be ignored. Code should check the contents of FLSEMSTAT.MATCH after writing to this bit to determine if it was successfully granted ownership. If the above conditions are not met during the write, the write will be ignored with no error indicator. It is advised that the writing code perform a read of the FLSEMSTAT register to ensure it was set after writing to this bit. Note that if the HSM (if present) performs the write, the CPUID, LINKID, and ZONEID values that are captured are all zeros. Reset type: XRSn

10.16.2.39 FLSEMCLR Register (Offset = 228h) [Reset = 00000000h]

FLSEMCLR is shown in Figure 10-44 and described in Table 10-55.

Return to the Summary Table.

Flash Controller Semaphore Clear Register

80h	STACK4_CFG	STACK4 Configuration	
84h	STACK5_CFG	STACK5 Configuration	
88h	STACK6_CFG	STACK6 Configuration	
8Ch	STACK7_CFG	STACK7 Configuration	
90h	RAMOPENSTAT	RAMOPEN Feature Status Register	
94h	RAMOPENFRC	RAMOPEN Feature Force Register	
98h	RAMOPENCLR	RAMOPEN Feature Clear Register	
A0h	DECODER_ADDR_IN	SW ZONE Decoder Address Input	
A4h	DECODER_OUT	SW ZONE Decoder Output	
A8h	EMU_DECODER_ADDR_IN	SW ZONE Decoder Address Input	
ACh	EMU_DECODER_OUT	SW ZONE Decoder Output	

Complex bit access types are encoded to fit into small table cells. Table 10-79 shows the codes that are used for access types in this section.

Table 10-79. SSU_CPU1_CFG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		

Table 10-79. SSU_CPU1_CFG_REGS Access Type Codes (continued)

Access Type	Code	Description
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

10.16.3.1 EMU_BOOTDEF_LOW Register (Offset = 28h) [Reset = 00000000h]

EMU_BOOTDEF_LOW is shown in Figure 10-67 and described in Table 10-80.

Return to the Summary Table.

User Emulation Boot Definition Low Register

Figure 10-67. EMU_BOOTDEF_LOW Register

Complex bit access types are encoded to fit into small table cells. Table 10-108 shows the codes that are used for access types in this section.

Table 10-108. SSU_CPU2_CFG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s

Table 10-108. SSU_CPU2_CFG_REGS Access Type Codes (continued)

Access Type	Code	Description
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

10.16.4.1 RST_VECT Register (Offset = 0h) [Reset = 00000000h]

RST_VECT is shown in Figure 10-94 and described in Table 10-109.

Return to the Summary Table.

Complex bit access types are encoded to fit into small table cells. Table 10-142 shows the codes that are used for access types in this section.

Table 10-142. SSU_CPU3_CFG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s

Table 10-142. SSU_CPU3_CFG_REGS Access Type Codes (continued)

Access Type	Code	Description
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

10.16.5.1 RST_VECT Register (Offset = 0h) [Reset = 00000000h]

RST_VECT is shown in Figure 10-126 and described in Table 10-143.

Return to the Summary Table.

Table 10-173. EMU_DECODER_ADDR_IN Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	ADDR_H	R/W	0h	See ADDR_L. Reset type: XRSn
15-12	ADDR_L	R/W	0h	The 4KB address written to this register is evaluated against the user AP regions to determine the LINK, STACK, and ZONE of the address. The output is provided in DECODER_OUT. The Access Protection region number responding to the request is also provided. Debugger accesses should use this register and its corresponding output register and reserve the DECODER_ADDR_IN/OUT registers for runtime use. Reset type: XRSn
11-0	RESERVED	R	0h	Reserved

10.16.5.32 EMU_DECODER_OUT Register (Offset = ACh) [Reset = 80000000h]

EMU_DECODER_OUT is shown in Figure 10-157 and described in Table 10-174.

Return to the Summary Table.

SW ZONE Decoder Output

Table 10-174. EMU_DECODER_OUT Register Field Descriptions

Bit	Field	Type	Reset	Description
31	INVALID	R	1h	If either no AP region or multiple AP regions respond to the address query requested in EMU_DECODER_ADDR_IN, this bit will be set. If set, the contents in this register are not valid. Reset type: XRSn
30-23	RESERVED	R-0	0h	Reserved
22-16	APR	R	0h	See LINK. In SSUMODE1, this field will always read as a zero. Reset type: XRSn
15-10	RESERVED	R-0	0h	Reserved
9-8	ZONE	R	0h	See LINK. Reset type: XRSn
7	RESERVED	R-0	0h	Reserved
6-4	STACK	R	0h	See LINK. Reset type: XRSn
3-0	LINK	R	0h	The output from EMU_DECODER_ADDR_IN. Reset type: XRSn

10.16.6 SSU_CPU1_AP_REGS Registers

Table 10-175 lists the memory-mapped registers for the SSU_CPU1_AP_REGS registers. All register offset addresses not listed in Table 10-175 should be considered as reserved locations and the register contents should not be modified.

Table 10-175. SSU_CPU1_AP_REGS Registers

Offset	Acronym	Register Name	Protection
0h + formula	AP_CFG_j	Access Protection Configuration	
4h + formula	AP_START_EXT_j	Access Protection Start Address	
8h + formula	AP_END_EXT_j	Access Protection End Address	
Ch + formula	AP_LOCK_j	Access Protection Temporary Lock	
10h + formula	AP_COMMIT_j	Access Protection Permanent Commit	
14h + formula	AP_ACCESS_j	Access Protection R/W Access Permissions	
40h + formula	AP_CFG_j	Access Protection Configuration	
44h + formula	AP_START_j	Access Protection Start Address	
48h + formula	AP_END_j	Access Protection End Address	
4Ch + formula	AP_LOCK_j	Access Protection Temporary Lock	
50h + formula	AP_COMMIT_j	Access Protection Permanent Commit	
54h + formula	AP_ACCESS_j	Access Protection R/W Access Permissions	

Complex bit access types are encoded to fit into small table cells. Table 10-176 shows the codes that are used for access types in this section.

Table 10-176. SSU_CPU1_AP_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-*n*		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

10.16.6.1 AP_CFG_j Register (Offset = 0h + formula) [Reset = 00008242h]

AP_CFG_j is shown in Figure 10-158 and described in Table 10-177.

Return to the Summary Table.

Access Protection Configuration

Offset = 0h + (j * 20h); where j = 0h to 1h

3-2	LINK1	R/W	0h	Enables code running with the LINKID of 1 to access this Access Protection's range. 00 : No access 01 : Read Access 10 : Reserved 11 : Read/Write Access Reset type: XRSn
1-0	LINK0	R/W	0h	Enables code running with the LINKID of 0 to access this Access Protection's range. 00 : No access 01 : Read Access 10 : Reserved 11 : Read/Write Access Reset type: XRSn

10.16.7 SSU_CPU2_AP_REGS Registers

Table 10-189 lists the memory-mapped registers for the SSU_CPU2_AP_REGS registers. All register offset addresses not listed in Table 10-189 should be considered as reserved locations and the register contents should not be modified.

Table 10-189. SSU_CPU2_AP_REGS Registers

Offset	Acronym	Register Name	Protection
0h + formula	AP_CFG_j	Access Protection Configuration	
4h + formula	AP_START_EXT_j	Access Protection Start Address	
8h + formula	AP_END_EXT_j	Access Protection End Address	
Ch + formula	AP_LOCK_j	Access Protection Temporary Lock	
10h + formula	AP_COMMIT_j	Access Protection Permanent Commit	
14h + formula	AP_ACCESS_j	Access Protection R/W Access Permissions	
40h + formula	AP_CFG_j	Access Protection Configuration	
44h + formula	AP_START_j	Access Protection Start Address	
48h + formula	AP_END_j	Access Protection End Address	
4Ch + formula	AP_LOCK_j	Access Protection Temporary Lock	
50h + formula	AP_COMMIT_j	Access Protection Permanent Commit	
54h + formula	AP_ACCESS_j	Access Protection R/W Access Permissions	

Complex bit access types are encoded to fit into small table cells. Table 10-190 shows the codes that are used for access types in this section.

Table 10-190. SSU_CPU2_AP_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-*n*		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

10.16.7.1 AP_CFG_j Register (Offset = 0h + formula) [Reset = 00008242h]

AP_CFG_j is shown in Figure 10-170 and described in Table 10-191.

Return to the Summary Table.

Access Protection Configuration

Offset = 0h + (j * 20h); where j = 0h to 1h

1-0	LINK0	R/W	0h	Enables code running with the LINKID of 0 to access this Access Protection's range. 00 : No access 01 : Read Access 10 : Reserved 11 : Read/Write Access Reset type: XRSn

10.16.8 SSU_CPU3_AP_REGS Registers

Table 10-203 lists the memory-mapped registers for the SSU_CPU3_AP_REGS registers. All register offset addresses not listed in Table 10-203 should be considered as reserved locations and the register contents should not be modified.

Table 10-203. SSU_CPU3_AP_REGS Registers

Offset	Acronym	Register Name	Protection
0h + formula	AP_CFG_j	Access Protection Configuration	
4h + formula	AP_START_EXT_j	Access Protection Start Address	
8h + formula	AP_END_EXT_j	Access Protection End Address	
Ch + formula	AP_LOCK_j	Access Protection Temporary Lock	
10h + formula	AP_COMMIT_j	Access Protection Permanent Commit	
14h + formula	AP_ACCESS_j	Access Protection R/W Access Permissions	
40h + formula	AP_CFG_j	Access Protection Configuration	
44h + formula	AP_START_j	Access Protection Start Address	
48h + formula	AP_END_j	Access Protection End Address	
4Ch + formula	AP_LOCK_j	Access Protection Temporary Lock	
50h + formula	AP_COMMIT_j	Access Protection Permanent Commit	
54h + formula	AP_ACCESS_j	Access Protection R/W Access Permissions	

Complex bit access types are encoded to fit into small table cells. Table 10-204 shows the codes that are used for access types in this section.

Table 10-204. SSU_CPU3_AP_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-*n*		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

10.16.8.1 AP_CFG_j Register (Offset = 0h + formula) [Reset = 00008242h]

AP_CFG_j is shown in Figure 10-182 and described in Table 10-205.

Return to the Summary Table.

Access Protection Configuration

Offset = 0h + (j * 20h); where j = 0h to 1h

Chapter 11

Configurable Logic Block (CLB)

This chapter describes the features and operation of the configurable logic block (CLB) that is a collection of configurable blocks that can be inter-connected using software to implement custom digital logic functions.

11.1 Introduction

The configurable logic block (CLB) is a collection of configurable blocks that can be inter-connected using software to implement custom digital logic functions. The CLB is able to enhance existing peripherals through a set of crossbar interconnections, which provide a high level of connectivity to existing control peripherals such as enhanced pulse width modulators (ePWM), enhanced capture modules (eCAP), and enhanced quadrature encoder pulse modules (eQEP). The crossbars also allow the CLB to be connected to external GPIO pins. In this way, the CLB can be configured to interact with device peripherals to perform small logical functions such as simple PWM generators, or to implement custom serial data exchange protocols.

The CLB peripheral is configured through the CLB tool. For more information on the CLB tool, available examples, application reports, and user's guide, refer to the following location in your C2000WARE package (C2000Ware_2_00_00_03 and higher): C2000WARE_INSTALL_LOCATION\utilities\clb_tool\clb_syscfg\doc

11.2 Description

The CLB subsystem contains a number of identical tiles. There are four such tiles in the CLB subsystem; other devices can contain more or fewer tiles. Tiles are numbered 1 to N, where N is the total tile count on the device. Each tile contains combinational and sequential logic blocks, as well as other dedicated hardware to be described later in this document. Figure 11-1 shows the structure of the CLB subsystem in the device.

The tile contains the core logic, providing the logic reconfiguration capability. Each CLB tile is associated with a separate CPU interface, which contains the registers needed to control and configure the logic in the tile. The CPU interface also contains data transfer buffers that can be used as part of the configurable logic to exchange data with the rest of the device. Figure 11-2 shows the connections between the tile, the CPU interface, and the device.

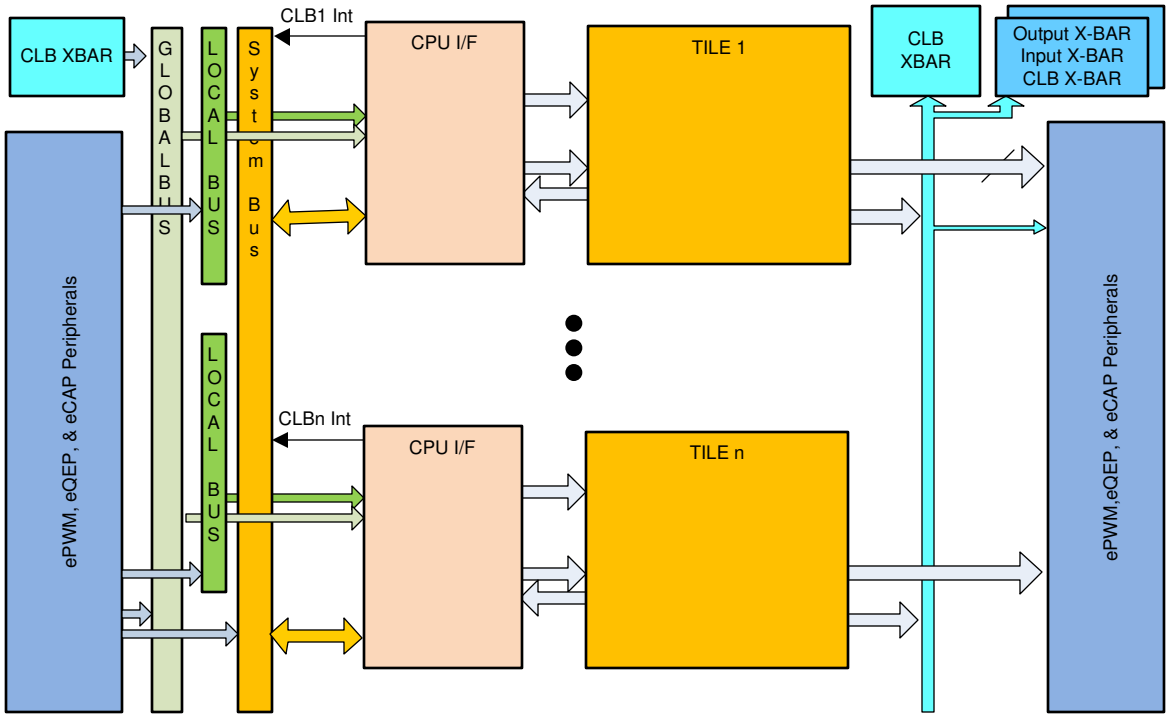

Figure 11-1. Block Diagram of the CLB Subsystem in the Device

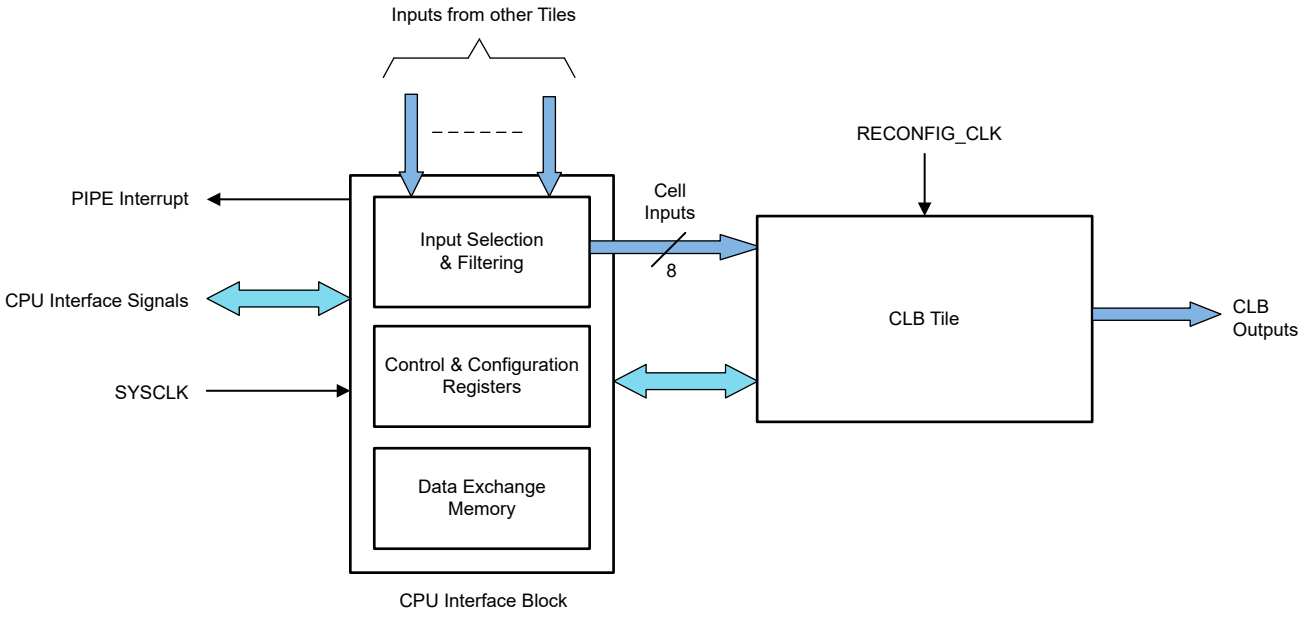

Figure 11-2. Block Diagram of a CLB Tile and CPU Interface

11.2.1 CLB Clock

In this device, the CLB clock is called CLBx clock that can be enabled or disabled by SYSCTL_PERIPH_CLK_CLBx through the SysCtl_enablePeripheral function. The maximum frequency is 150MHz and the clock can be enabled and configured by modifying the CLBx clock. Refer to the device data sheet for specifications on frequencies for the CLB. The *Clocking System* figure in the *System Control and Interrupts* chapter shows how the CLB is clocked.

Note

When clock frequencies are above 100MHz (for example, 150MHz), PIPELINE mode must be enabled.

The CLB TILE clock and CLB register clock can be in ASYNC/SYNC mode with the SYSCLK. An example CLB clock configuration is shown in Table 11-1. Check the device data sheet for details on clocking specifications.

Table 11-1. Example CLB Clocking Configuration

Clock	SYNC Mode (CLKMODECLBx = 0)	ASYNC Mode (CLKMODECLBx = 1)	
		TILECLKDIV = 1	TILECLKDIV = 0
CLB Register Clock	SYSCLK	SYSCLK	SYSCLK
CLB TILE Clock	SYSCLK	SYSCLK / 2	SYSCLK

Starting with CLB Type 2, a clock prescalar module is available. The prescalar module can generate a prescaled version of the CLB clock signal that can be used as an input to the CLB TILE's counter.

Note

The prescalar logic does not change the actual clocking speed of the CLB. The prescalar generates a strobe (that can toggle at the defined prescaled rate) that is made available as another input signal to the CLB logic and the strobe is only used when required.

The prescalar module is shown in Figure 11-3.

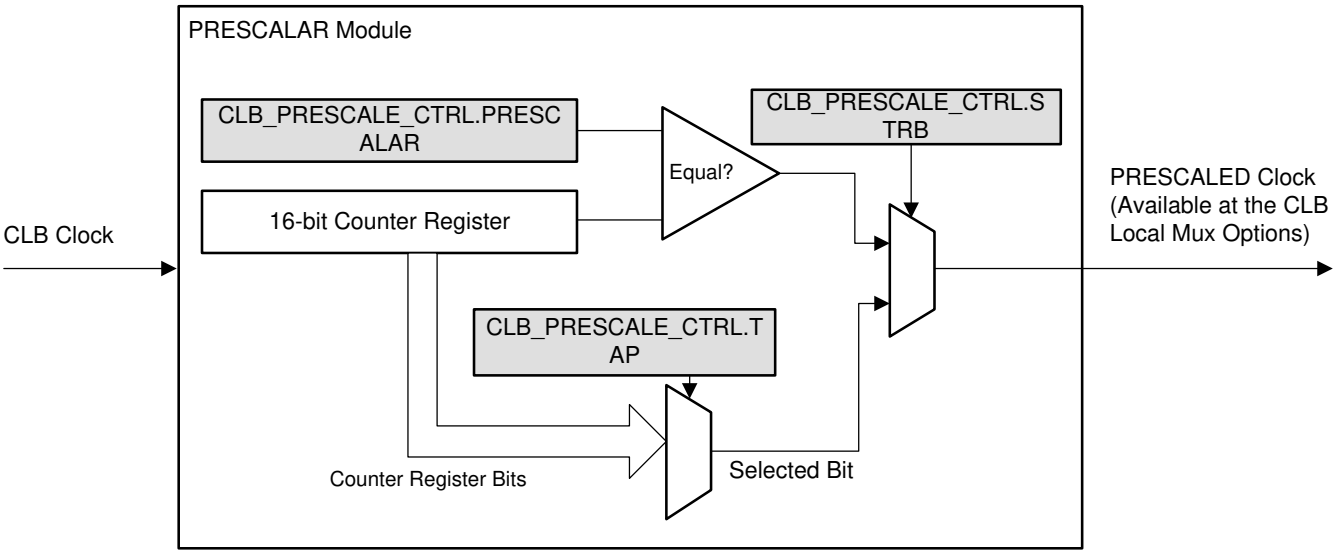

Figure 11-3. CLB Clock Prescalar

11.3 CLB Input/Output Connection

11.3.1 Overview

There are four instances of the CLB module in the device. Each CLB instance has a common set of input signals referred to as global input signals. Additionally, each CLB instance has a specific set of input signals that are unique to each instance, and are referred to as local input signals. Each of the eight inputs of a CLB can be chosen from any of the global input signals or the local input signals.

Note

Signals routed into the CLB using the XBAR must be synchronized within the CLB.

11.3.2 CLB Input Selection

Each CLB module has eight inputs that are applied to the reconfigurable logic cell. Each of these inputs can be selectively driven by a predefined set of signals. A two-level mux structure allows each input of each CLB instance to select a signal.

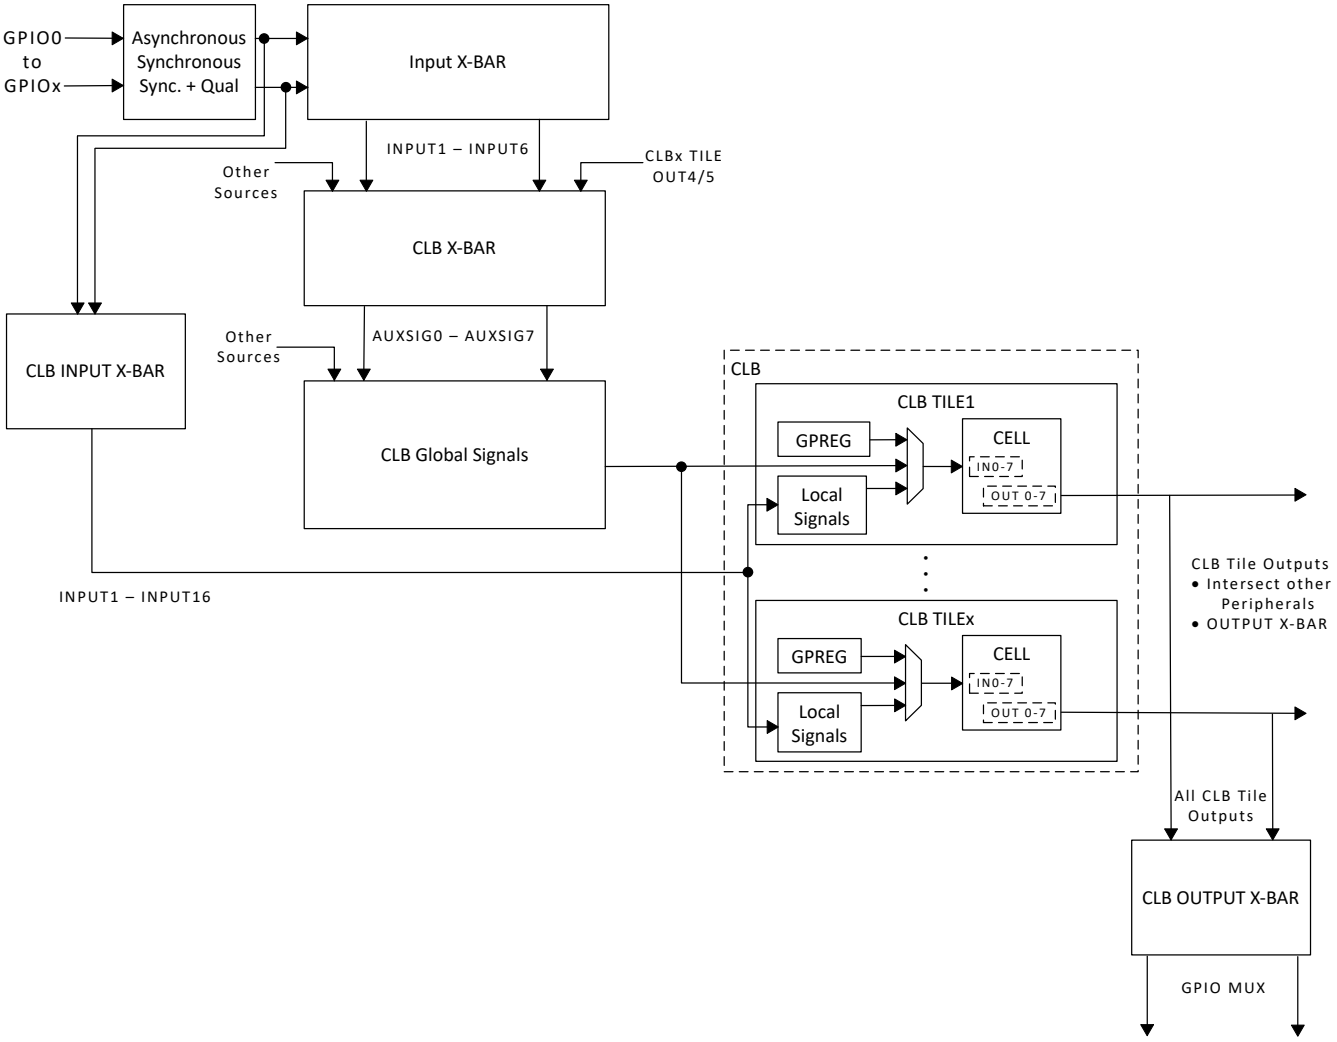

Figure 11-4. GPIO to CLB Tile Connections

A set of signals is common to all the CLB instances. These are referred to as global inputs in Figure 11-5. A separate set of signals is unique to each instance of the CLB. These are referred to as local inputs in Figure 11-5.

Registers CLB_LCL_MUX_SEL_1 and CLB_LCL_MUX_SEL_2 control the local mux selection for each of the eight inputs. The mux control registers CLB_GLBL_MUX_SEL_1 and CLB_GLBL_MUX_SEL_2 control the global mux selection for each of the eight inputs.

The local mux select value of 0 causes the selected global mux input signal to be connected to the corresponding CLB Input. For example, setting CLB_LCL_MUX_SEL_IN_0 = 0 and CLB_GLBL_MUX_SEL_IN_0 = 8 causes the global mux input number 8 to be connected to CLB Input 0. The input filter feature can be used to enable edge detection on the CLB inputs. The input filter feature can also synchronize the input with the CLB clock.

The global mux settings are shown in Table 11-2 and Table 11-3 . The local input mux settings are shown in Table 11-4 and Table 11-5 .

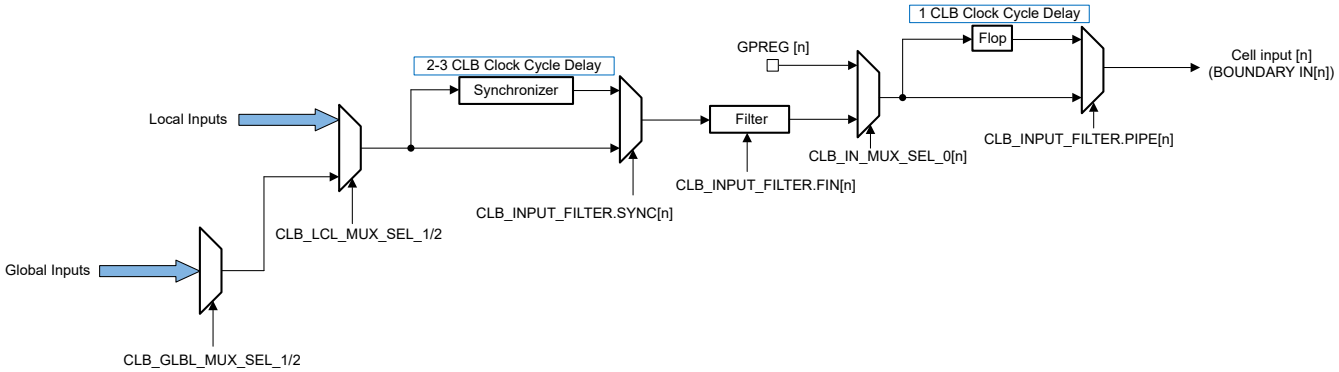

Figure 11-5. CLB Input Mux and Filter

Figure 11-6 shows an example of how to use synchronization for an asynchronous signal, in this case the ePWM signal. Figure 11-7 shows an instance of using input pipelining for a synchronous signal, which here is the ePWM TBCLK signal. Note that these two input configurations are not used simultaneously, and each have a cycle delay that adds to the input path.

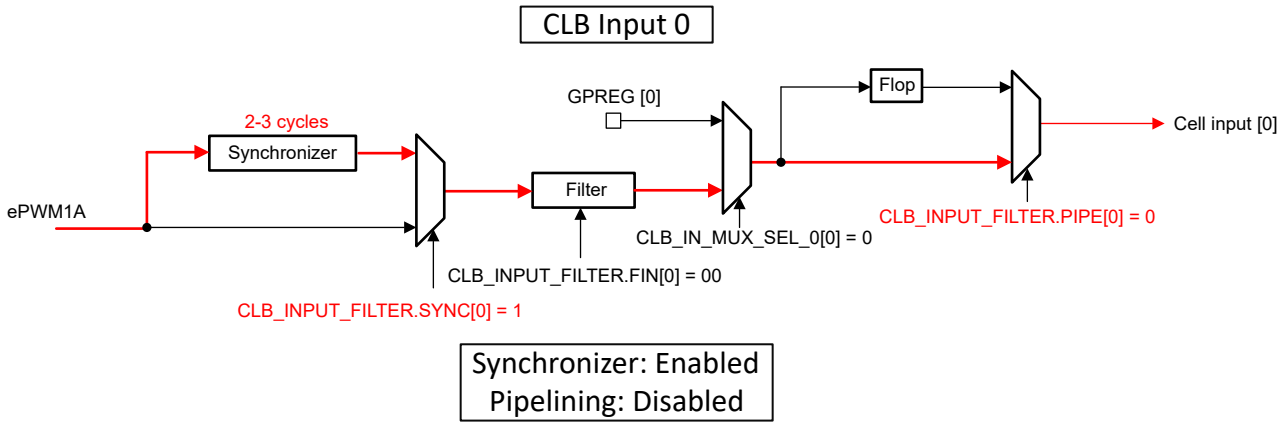

Figure 11-6. CLB Input Synchronization Example

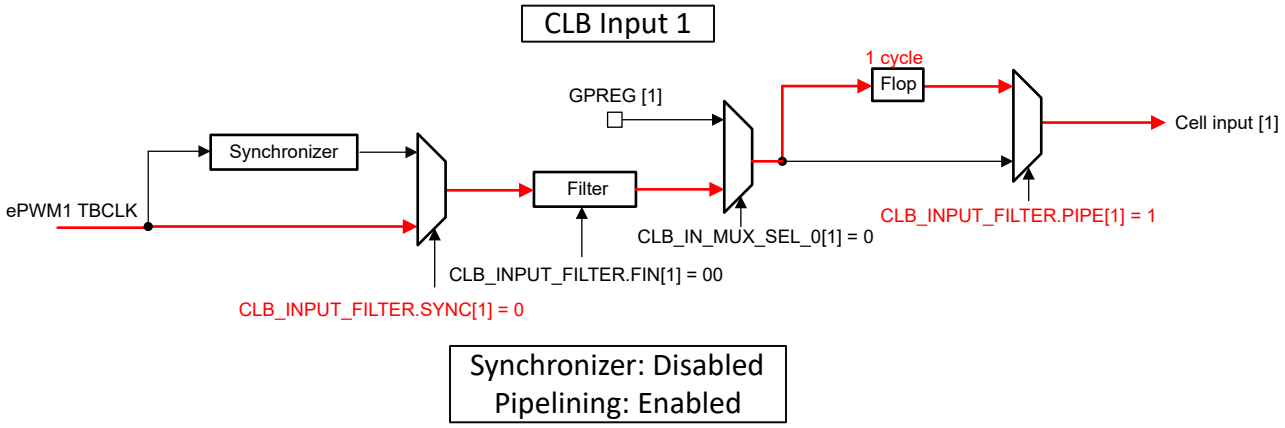

Figure 11-7. CLB Input Pipelining Example

Note

If a signal in the following table indicates that synchronization is required, then the CLB input synchronizer must be enabled using the appropriate SYNC bit in the CLB_INPUT_FILTER register. This synchronization adds a 2-3 CLB clock cycle delay to the input. This delay is either 2 or 3 cycles and is not predictable. There is a potential for a metastability hazard, if the indicated signals are not first synchronized before going into the CLB tile. This metastability can cause errors dependent on voltage, temperature, and wafer fab process. Note that this requirement is in addition to and separate from GPIO input synchronization.

If a signal in the following table indicates that synchronization is not required, as the signal is already synchronous, then pipelining is required and must be enabled using the PIPE bit in the CLB_INPUT_FILTER register. This pipelining adds a 1 CLB clock cycle delay to the input. This is not to be mistaken with the PIPELINE_EN bit in the CLB_LOAD_EN register, which controls pipelining of the CLB operations in the HLC and counter blocks. This PIPELINE_EN bit is also used when the device is run above 100MHz. Having synchronization and pipelining both enabled or both disabled is not recommended. Enabling both synchronization and pipelining introduces a delay of more than 2-3 CLB clock cycles on the signal path. Disabling both allows the completely asynchronous signal to be routed as an input.

Note

EPWMxA_OE and EPWMxB_OE refer to trip outputs from the respective EPWM module.

EPWMxA_AQ and EPWMxB_AQ refer to the output of the AQ submodule in the respective EPWM module.

EPWMxA_DB and EPWMBx_DB refer to the output of the DB submodule in the respective EPWM module.

Note

If a signal in the following table indicates that synchronization is required, then the CLB input synchronizer must be enabled using the appropriate SYNC bit in the CLB_INPUT_FILTER register. This synchronization adds a 2-3 CLB clock cycle delay to the input. This delay is either 2 or 3 cycles and is not predictable. There is a potential for a metastability hazard, if the indicated signals are not first synchronized before going into the CLB tile. This metastability can cause errors dependent on voltage, temperature, and wafer fab process. Note that this requirement is in addition to and separate from GPIO input synchronization.

If a signal in the following table indicates that synchronization is not required, as the signal is already synchronous, then pipelining is required and must be enabled using the PIPE bit in the CLB_INPUT_FILTER register. This pipelining adds a 1 CLB clock cycle delay to the input. This is not to be mistaken with the PIPELINE_EN bit in the CLB_LOAD_EN register, which controls pipelining of the CLB operations in the HLC and counter blocks. Having synchronization and pipelining both enabled or both disabled is not recommended. Enabling both synchronization and pipelining introduces a delay of more than 2-3 CLB clock cycles on the signal path. Disabling both allows the completely asynchronous signal to be routed as an input.

The GPREG is accessible by the CPU and the bits of this register can be used as BOUNDARY INPUTs for the CLB Tiles. For example, CLB1s GPREG[0] can be used as BOUNDARY IN0 (Cell Input 0) for the corresponding CLB Tile.

To connect multiple tiles to each other, you can use the CLBx OUT4/5 and connect to CLBy BOUNDARY INz through the CLB X-BAR and the Global Signals Mux.

Another option is to connect the CLBx OUT0-7 to a GPIO and then use the INPUT X-BAR to bring the signal back in to the device and connect to the CLBy BOUNDARY INz through the CLB X-BAR and the Global Signals Mux.

To use GPIOs as inputs to the CLB, you must utilize the Input X-BAR and the CLB X-BAR. Figure 11-4 shows how GPIOs can be used as inputs to the CLB tiles.

11.3.3 CLB Output Selection

The eight outputs of the CLB are replicated to create 32 output signals. Each of these outputs has a separate enable bit defined in the CLB output enable register, CLB_OUT_EN. The CLB outputs go to the ePWM, eCAP, eQEP and the crossbar module in the device. This allows the user to enhance the functionality of these modules with the CLB. Figure 11-8 shows the CLB outputs.

The user has the capability to disable updated to the CLB_OUT_EN register by blocking access to the register through setting the CLB_MISC_ACCESS_CTRL.BLKEN bit. The eight outputs are replicated to generate a total of 32 outputs (shown in Figure 11-8). Some of these new outputs can be used for TILE to TILE connection through the CLB Global Mux inputs.

Note

The output from OUTLUT0 is connected to OUT0, OUT8, OUT16, and OUT24. While the signal is the same, each OUTy has access to a different peripheral as shown in Section 11.3.4. Likewise, OUTLUT1 is connected to OUT1, OUT9, OUT17, and OUT25, and are the same signal.

CLBx_OUT12 through CLBx_OUT15 are unregistered and asynchronous to the CLB clock.

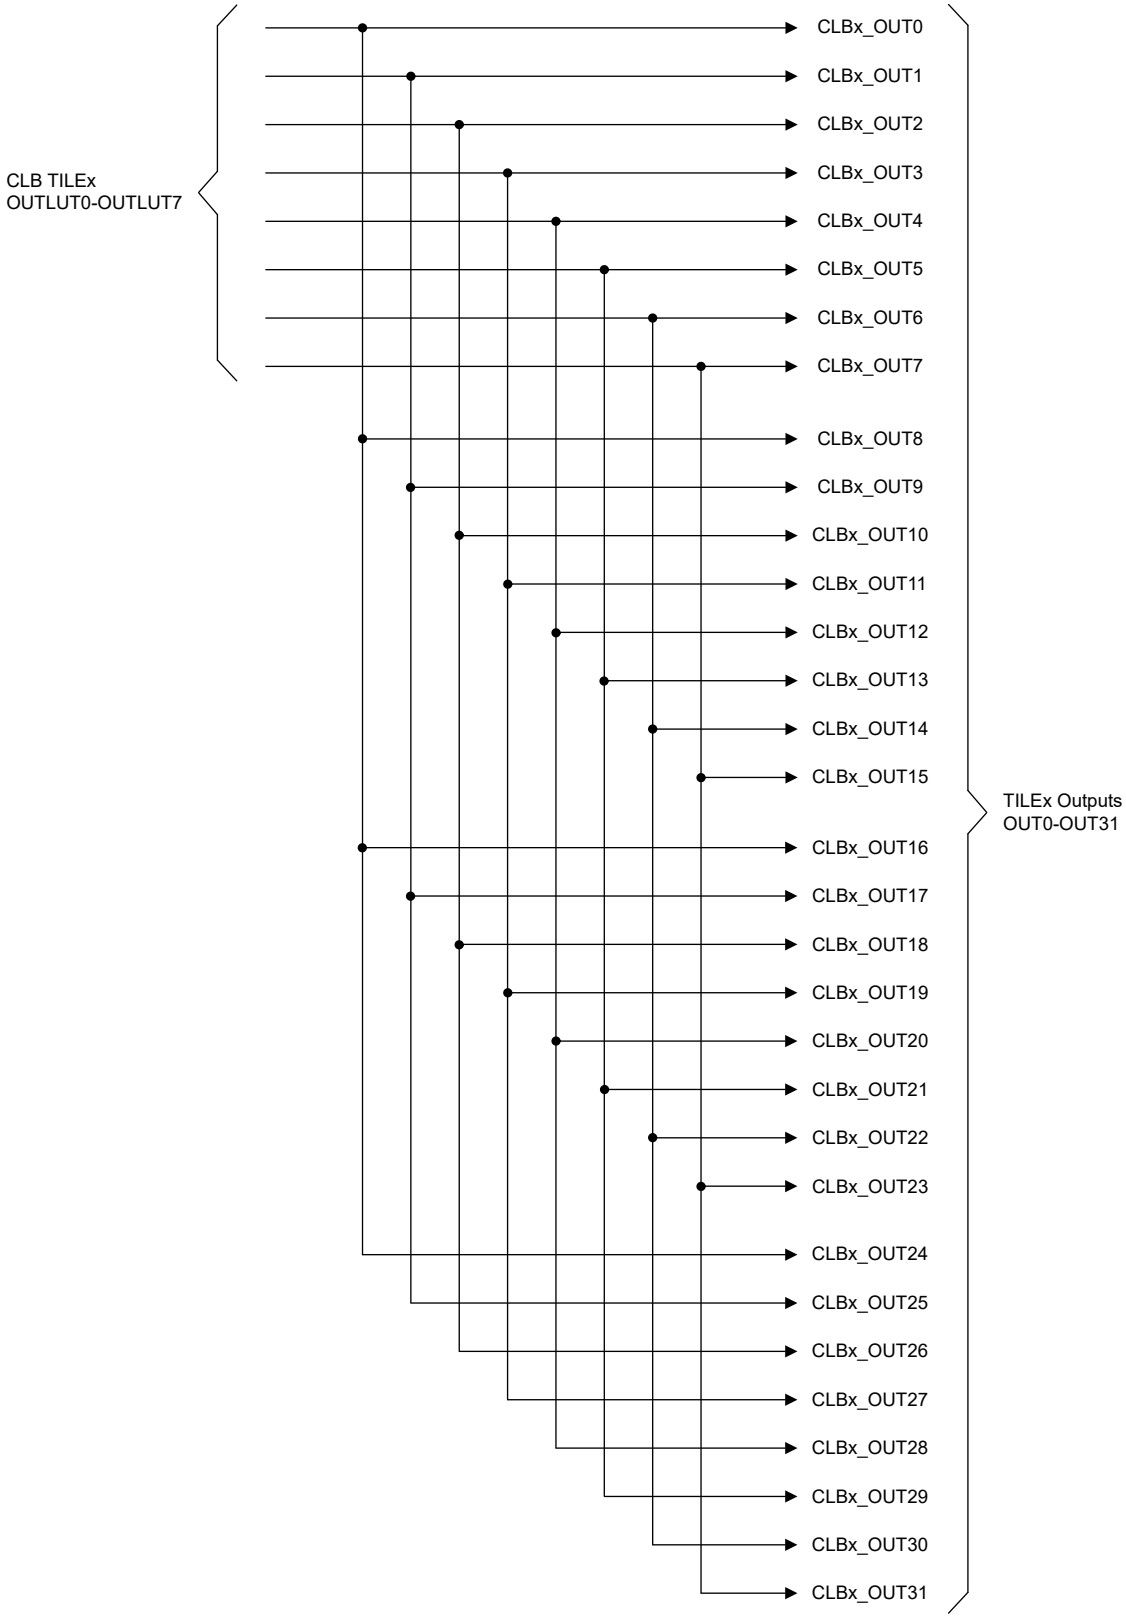

Figure 11-8. CLB Outputs

11.3.4 CLB Output Signal Multiplexer

Each CLB output signal passes through an external multiplexer that intersects a specific peripheral signal, see Figure 11-9. The output of the multiplexer is connected to the destination of the original peripheral signal and the default multiplexer setting is that the peripheral signal is passed through. The multiplexer is controlled by bit[n] in the CLB output enable register CLB_OUT_EN.

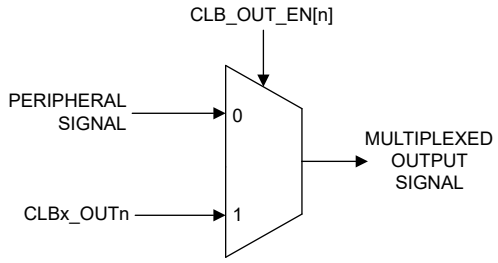

Figure 11-9. CLB Output Signal Multiplexer

For example, if the CLB1 OUT0 must override the EPWM1A signal, the OUPTUT ENABLE bit for OUT0 must be set to 1.

Table 11-6 and Table 11-7 shows the allocation of peripheral signals and the CLB outputs.

When not explicitly specified in the table above, refer to corresponding IP chapters for exact CLB Output destinations (that is, FSI, ECAP, XBAR connections).

11.4 CLB Tile

The purpose of the CLB tile is to provide the logic reconfiguration capability of the CLB. The CLB tile contains the following submodules:

- **Counter:** The counter submodule can be configured as an adder, a counter, or a shifter. When functioning as an adder, the counter submodule can either add or subtract. When functioning as a counter, the counter submodule can count up or count down. When functioning as a shifter, the counter submodule can shift left or shift right. The counter event inputs, as well as the reset input, can be freely connected to any of the other submodules in the same tile. Starting with CLB Type 2, the counter module can also operate as a serializer or linear feedback shift register. There are three counters in each tile.
- **LUT4:** The LUT4 submodule has a 4-input look-up table functionality and is capable of realizing any combinatorial Boolean equation of up to four inputs. There are three LUT4 submodules in each CLB tile.
- **FSM:** The Finite State Machine (FSM) submodule can be configured either as a single four-state finite state machine, or as two independent two-state finite state machines. The FSM accepts two external inputs, and generates two state outputs and one combination output. When not used as a state machine, the FSM submodule can accept two external inputs and function as a 4-input LUT. There are three FSM submodules in each CLB tile.
- **Output LUT:** The output LUT is a 3-input lookup table submodule capable of realizing any combinatorial Boolean equation of up to three inputs. There are eight such blocks in a CLB tile, each associated with one of the tile outputs.
- **Asynchronous Output Conditioning Block:** The primary purpose of the Asynchronous Output Conditioning (AOC) block is to provide asynchronous conditioning capabilities on the TILE outputs or directly on the inputs of the TILE.
- **High Level Controller:** The High Level Controller (HLC) submodule is an event-driven block that can handle up to four concurrent events. The event can be an activity on any of the other block outputs. A predefined set of operations is executed when each event occurs. The HLC also provides a data exchange and interrupt mechanism to the CPU subsystem. There are four working registers (R0, R1, R2, and R3) that can be used for basic operations, and to modify or set up values for the three counter blocks. Unlike the other submodules, there is only one HLC in each CLB tile.
- **Static Switch Block:** The static switch block provides dynamic connectivity between all of the blocks listed above. Submodules can be connected by the user, with the only restriction that the submodules must not form a combinational loop within the tile.

A CLB tile consists of three sets each of the counter block, FSM, and LUT4, one high-level controller, and eight output LUT blocks. The submodule numbering is shown in Figure 11-10.

The functionality of the LUT submodules is configured using a register field containing the binary pattern of the output of the desired look-up table. For example, a 4-input LUT has 16 possible input permutations, each of which corresponds to a desired binary 0 or 1 at the output. The register field can, therefore, be 16-bits in length, with each bit representing the desired result of a binary pattern. Input pattern sequences start at 0000 and continue sequentially to 1111. A similar method is used to encode the 16-bit state equations in the FSM submodule.

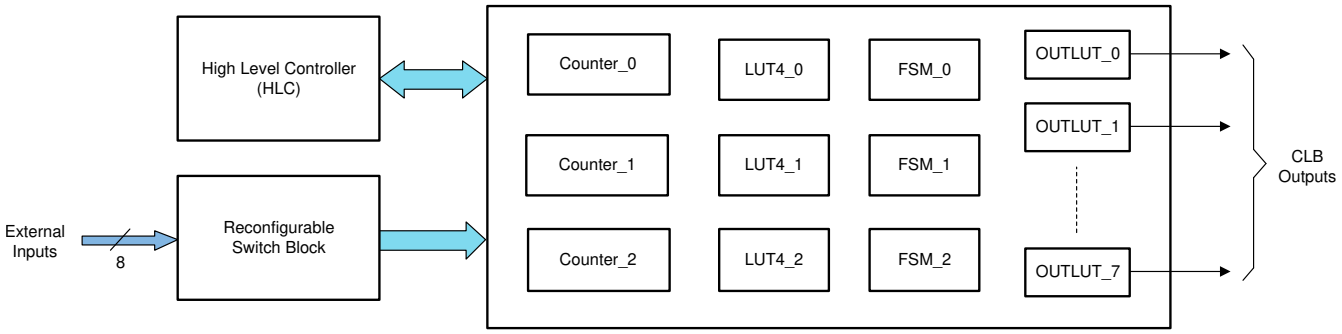

Figure 11-10. CLB Tile Submodules

11.4.1 Static Switch Block

The Static Switch Block provides the configurable connectivity between the submodules in the CLB tile. The outputs of all the submodules and the eight external inputs are connected to a common internal bus inside the tile. Every input port has a 32-to-1 multiplexer and an associated 5-bit selection value that allows the user to select one of the inputs on the bus. The only restrictions are certain signals (described below) that are tied off in the design to prevent creation of accidental combinatorial loops.

Table 11-8. Output Table

Bit Position	Signal Connection	Comment
0	Always 0	This select value is used to tie an input to 0.
1	COUNTER_0 MATCH2	
2	COUNTER_0 ZERO	
3	COUNTER_0 MATCH1	
4	FSM_0 STATE_BIT_0	
5	FSM_0 STATE_BIT_1	
6	FSM_0 LUT output	
7	LUT4_0 output	
8	Always 1	This select value is used to tie an input to 1.
9	COUNTER_1 MATCH2	
10	COUNTER_1 ZERO	
11	COUNTER_1 MATCH1	
12	FSM_1 STATE_BIT_0	
13	FSM_1 STATE_BIT_1	
14	FSM_1 LUT output	
15	LUT4_1 output	
16	Always ‘0’	
17	COUNTER_2 MATCH2	
18	COUNTER_2 ZERO	
19	COUNTER_2 MATCH1	
20	FSM_2 STATE_BIT_0	
21	FSM_2 STATE_BIT_1	
22	FSM_2 LUT output	
23	LUT4_2 output	
24	External Input 0	
25	External Input 1	
26	External Input 2	
27	External Input 3	
28	External Input 4	
29	External Input 5	
30	External Input 6	
31	External Input 7	

Table 11-9. Input Table

Module Name	Port Name	Description
Counter Block	RESET	Acts as an active high reset when used as a counter
	MODE_0	Acts as an enable when used as a counter. The counter counts only when this input is 1.
	MODE_1	Acts as a direction control when used as a counter. If this input is 1, then the counter counts up; else, the counter counts down.
LUT	IN0	Input 0 of the 4-input LUT.
	IN1	Input 1 of the 4-input LUT.
	IN2	Input 2 of the 4-input LUT.
	IN3	Input 3 of the 4-input LUT.
FSM	EXT_IN0	Input 0 of the FSM block.
	EXT_IN1	Input 1 of the FSM block.
	EXTRA_EXT_IN0	Extra external input 0 of the FSM block. This input matters only if configured in the LUT mode.
	EXTRA_EXT_IN1	Extra external input 1 of the FSM block. This input matters only if configured in the LUT mode.

The static switch block allows the user to define the input connection of any submodule to come from any of the outputs in Table 11-8. It is therefore easy to create a combinatorial loop. To prevent this, certain paths are broken in the input path of each submodule. These port positions are tied to 0, as shown in Table 11-10.

Table 11-10. Ports Tied Off to Prevent Combinatorial Loops

Module Name	Ports of Input MUX Tied Off to 0 to Prevent Combinational Loops
LUT_0	LUT_0 , LUT_1, and LUT_2 output, FSM_0, FSM_1, and FSM_2 output.
FSM_0	LUT_1 and LUT_2 output, FSM_0, FSM_1, and FSM_2 output.
LUT_1	LUT_1 and LUT_2 output, FSM_1 and FSM_2 output.
FSM_1	LUT_2 output, FSM_1 and FSM_2 output.
LUT_2	LUT_2 output, FSM_2 output.
FSM_2	FSM_2 output.

11.4.2 Counter Block

11.4.2.1 Counter Description

The counter block is a complex functional submodule that can be configured either as a counter, an adder, or a shifter. Apart from the normal operational control, this block has a dedicated EVENT input, which can trigger an addition, subtraction or shift operation, or load data into the counter register. The inputs to the counter submodule are shown in Figure 11-11.

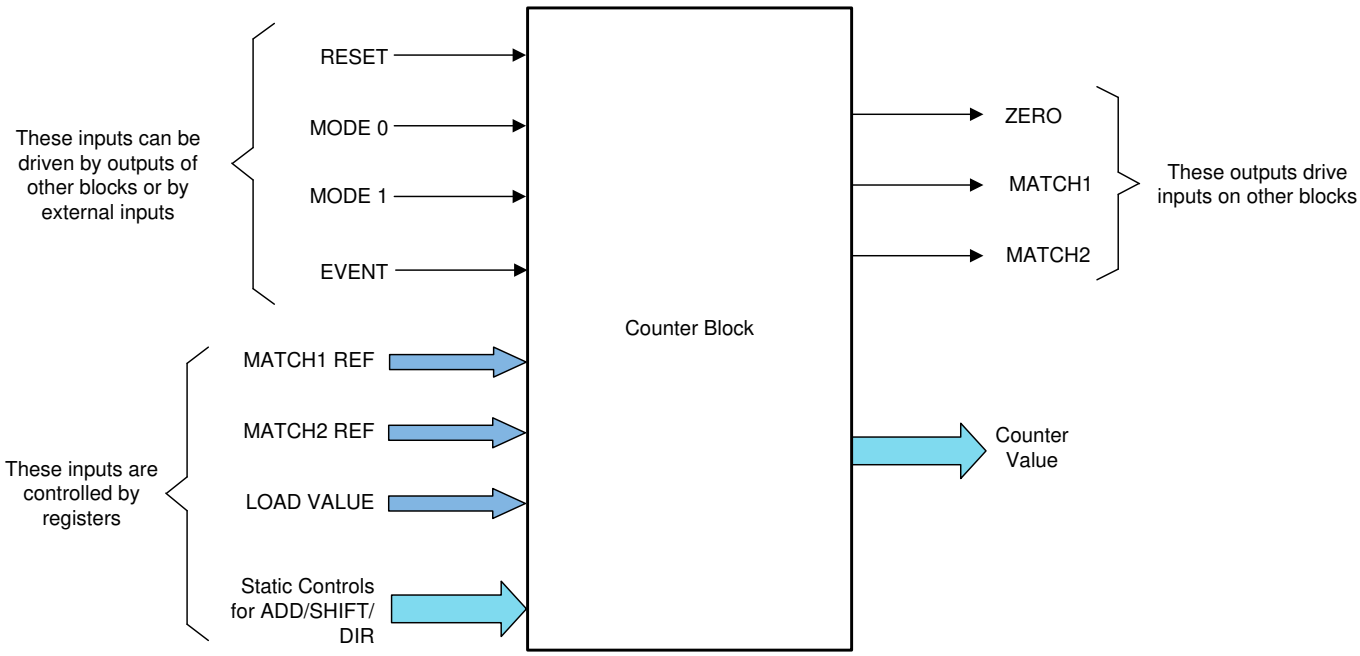

Figure 11-11. Counter Block

11.4.2.2 Counter Operation

At the heart of the counter block is a 32-bit count register. This register can either be loaded statically before counting commences, or dynamically at run time. The operation of the counter submodule is determined by the inputs described below. Note that each of the inputs can be connected to the outputs of any of the other blocks in the CLB tile. These connections are made by configuring the static switch block.

The counter inputs are:

- **RESET:** This is the highest priority input and takes precedence over all other inputs. The input is level sensitive and as long as the input remains high, the counter resets to 0 on the next clock cycle.
- **MODE_0:** This input is an enable for the counter. The counter begins counting (up or down depending on the MODE_1 setting) only when this input is high. If this input is low, then no counting takes place.
- **MODE_1:** This input is the direction control for the counter. If this input is high, then the counter increments on every clock cycle where MODE_0 is high. If this input is low, then the counter decrements on every clock cycle where MODE_0 is high. The counter wraps around to 0x0000 0000 after 0xFFFF FFFF when counting up. The counter wraps around to 0xFFFF FFFF after 0x0000 0000 when counting down. The only exception to this is when an EVENT occurs at exactly the same time, causing a different value to be loaded into the counter.
- **EVENT:** This input is defined for the purpose of triggering actions in the counter based on certain events. The event can be any of the outputs of the other blocks or an external input to the tile. The counter's static control inputs define the behavior of the counter on an active event. An active event is defined as a rising edge on the EVENT input. The counter can be configured to perform one of the following actions:
  - Load a predefined 32-bit value from the LOAD VALUE register into the count register
  - Shift the contents of the counter register left or right by a predefined amount between 0 and 31
  - Add or subtract a predefined 32-bit value. Addition and subtraction are treated as 32-bit unsigned operations and there is no saturation.

  Note that the effect of a rising edge on the EVENT input only lasts for one cycle. On the next cycle, the counter operation continues based on the MODE_0, MODE_1, and RESET inputs.

MATCH1 REF and MATCH2 REF are 32-bit reference values that are used to generate the MATCH1 and MATCH2 outputs. The MATCH1 output becomes active high whenever the counter register value matches the 32-bit MATCH1 REF value. MATCH2 behaves in a similar manner in relation to the MATCH2 REF register. The reference values for MATCH1 and MATCH2 can either be setup once before the start of operation, or can be modified dynamically. The High Level Controller can load desired values into the MATCH1 REF and MATCH2 REF registers.

Note that the counter load and match registers are not memory-mapped. For more information, see Section 11.5.2.

The three logic outputs of the counter block are:

- **ZERO:** This output goes high whenever the counter register is 0.
- **MATCH1:** This output goes high whenever the counter register is equal to the MATCH1 REF input register.
- **MATCH2:** This output goes high whenever the counter register is equal to the MATCH2 REF input register.

The operation of the counter block is controlled by the CFG_MISC_CTRL register. The following three bits of this register are relevant for each counter. The "x" below refers to the counter instance; 0, 1, or 2. For more information, see the CLB_MISC_CONTROL register description located in Section 11.10.

- COUNT_EVENT_CTRL_x: This bit defines whether the counter performs an addition or a shift on an event. A value of 0 means that on an event, the counter loads the static value; 1 means an add/shift operation is performed. This bit must be 0 for indirect loads and HLC loads of the counter to take effect.
- COUNT_ADD_SHIFT_x. 1 means add, 0 means shift.
- COUNT_DIR_x. 1 means left shift or add. 0 means right shift or subtract.

Table 11-11 shows the logical operation of the counter block in terms of the inputs and control register bits. Count up and down modes are the normal operation with EVENT = 0. The operations on the CNTVAL register are:

Load: CNTVAL = EVENT_LOAD_VAL

Shift right: CNTVAL = CNTVAL >> EVENT_LOAD_VAL

Shift left: CNTVAL = CNTVAL << EVENT_LOAD_VAL

Subtract: CNTVAL = CNTVAL - EVENT_LOAD_VAL

Add: CNTVAL = CNTVAL + EVENT_LOAD_VAL

Table 11-11. Counter Block Operating Modes

EVENT	MODE_0	MODE_1	COUNT_EVENT_CTRL_x	COUNT_ADD_SHIFT_x	COUNT_DIR_x	Action on CNTVAL
0	0	0	X	X	X	None
0	0	1	X	X	X	None
0	1	0	X	X	X	Count down
0	1	1	X	X	X	Count up
1	X	X	0	X	X	Load
1	X	X	1	0	0	Shift right
1	X	X	1	0	1	Shift left
1	X	X	1	1	0	Subtract
1	X	X	1	1	1	Add

11.4.2.3 Serializer Mode

Starting with CLB Type 2, the Counter module can operate as a serializer. In this mode of operation, this module acts as a shift register (also referred to as a serializer). In serializer mode of operation, the EVENT input is used to shift one bit of data into the serializer. Either of MATCH1 and MATCH2 can be configured to send out the shift register data.Using the MATCH1/2_TAP_SEL bit of CLB_COUNT_MATCH_TAP_SEL, any bit position of the counter can be brought out on the MATCH1/MATCH2 outputs. The shifting and direction of the counter in this mode is controlled by MODE_0 (enable) and MODE_1 (direction).

To enable the Serializer mode, CLB_MISC_CONTROL.COUNT_SERIALIZER_0 (for Counter 0) must be set.

11.4.2.4 Linear Feedback Shift Register (LFSR) Mode

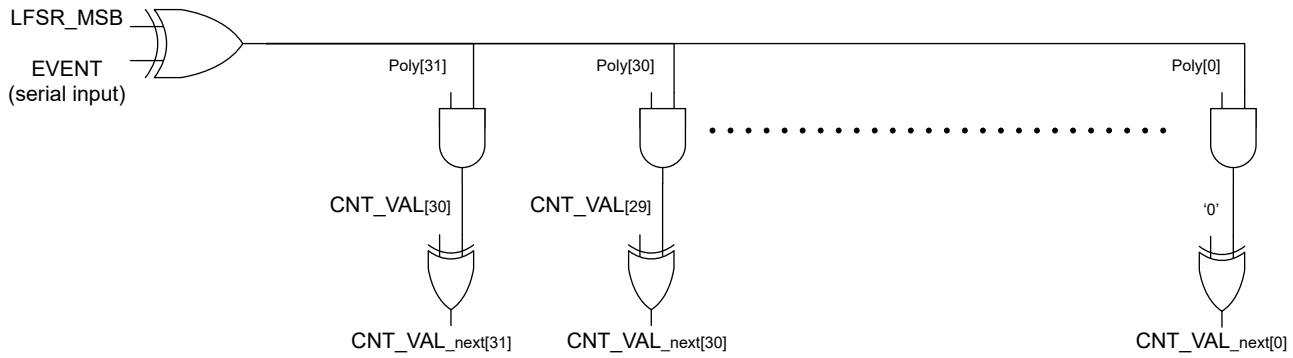
Starting with CLB Type 2, the Counter module operates as a linear feedback shift register. By configuring the characteristics of the LFSR, the counter module is used to compute the CRC on a serial bit stream. The polynomial for LFSR is in the MATCH2 reference register. The feedback bit position is in the MATCH1 reference register.

To enable the LFSR mode, CLB_MISC_CONTROL.COUNT_SERIALIZER_0 (for Counter 0) must be set along with COUNT0_LFSR_EN.

There are two types of LSFR that can be selected by changing the MODE1 value (0 or 1), as shown in Figure 11-12.

Structure for LFSR Type 1 (MODE_1 = 0)

CNT_VAL is the 32-bit counter's active register
CNT_VAL_next is the 32-bit value to be written into CNT_VAL on the next active cycle (clock edge when MODE_0 == 1)
LFSR_MSB = CNT_VAL[MATCH1_REF[4:0]]
Poly[31:0] is MATCH2_REF which acts as the CRC polynomial



Structure for LFSR Type 2 (MODE_1 = 1)

CNT_VAL is the 32-bit counter register
CNT_VAL_next is the 32-bit value to be written into CNT_VAL on the next active cycle (clock edge when MODE_0 == 1)
LFSR_MSB = CNT_VAL[MATCH1_REF[4:0]]
Poly[31:0] is MATCH2_REF which acts as the CRC polynomial

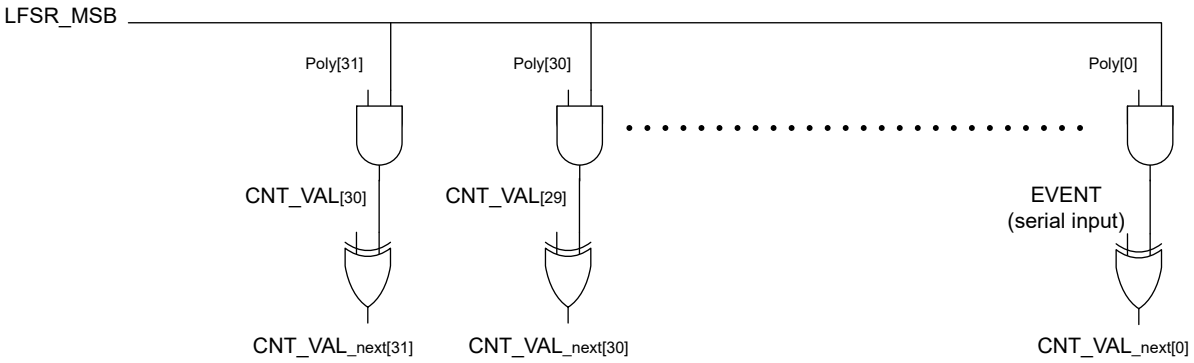


Figure 11-12. LFSR Modes

11.4.3 FSM Block

The Finite State Machine (FSM) block provides the ability to build programmable finite state machines with up to four states. The FSM block has two register bits and two external inputs, and can be programmed either as two 2-state machines or as a single 4-state machine. For additional flexibility, there are two auxiliary inputs (EXTRA_EXT_IN0 and EXTRA_EXT_IN1) that can be used to create larger combinational functions by giving up a state functionality. The structure of the FSM is shown in Figure 11-13.

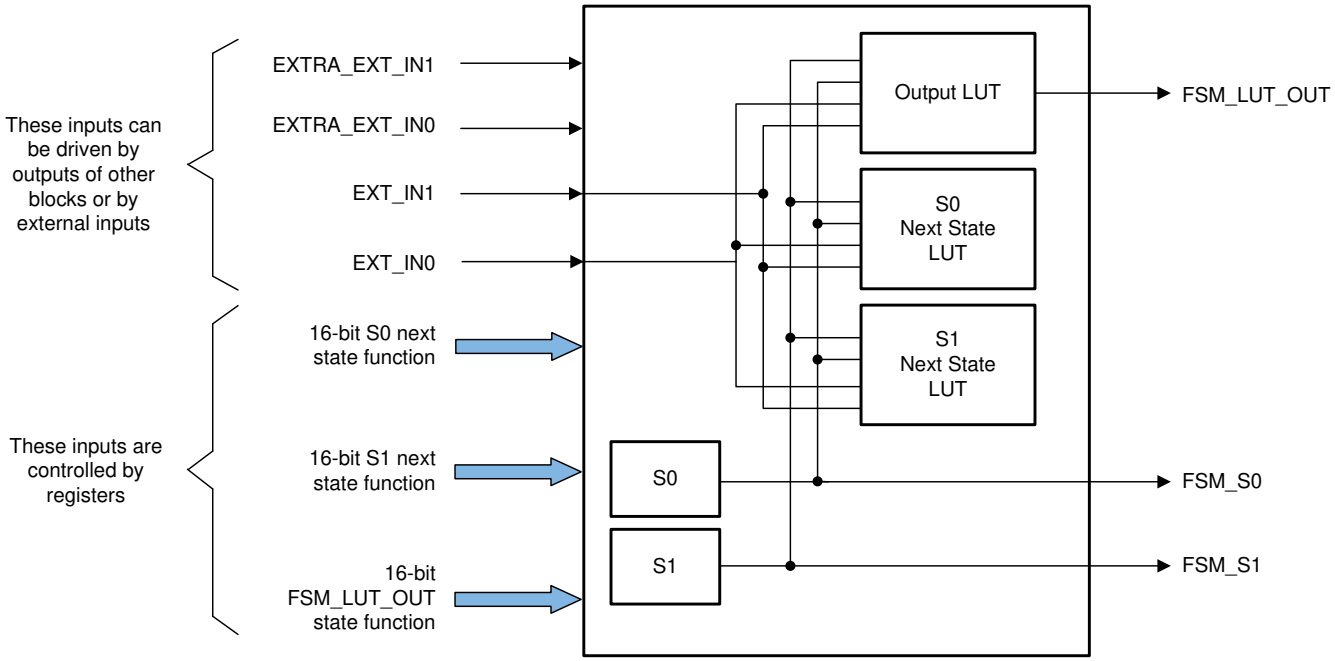

Figure 11-13. FSM Block

The signals and functionality of the FSM block are:

- **EXT_IN0 and EXT_IN1:** These are the two external inputs that can be used to control the output FSM_LUT_OUT or either of the states S0 and S1.
- **S0** and **S1** are two state bits that have independent state control equations.
- **16-bit S0 equation** defines a function (EXT_IN1, EXT_IN0, S1, S0). The four bits in the order defined are used as an index into the 16-bit register to decide the next state of S0.
- **16-bit S1 equation** defines a function (EXT_IN1, EXT_IN0, S1, S0). The four bits in the order defined are used as an index into the 16-bit register to decide the next state of S1.
- **16-bit output equation** defines a function (EXT_IN1, EXT_IN0, S1, S0). The four bits in the order defined are used as an index into the 16-bit register to decide the output value of FSM_LUT_OUT. An additional level of configurability is provided such that FSM_LUT_OUT can use extra inputs in case the states S0 and S1 are unused.

  One extra bit is used to select EXTRA_EXT_IN0 instead of S0. One extra bit is used to select EXTRA_EXT_IN1 instead of S1. Using these, one can effectively build 3-input or a 4-input LUT for the FSM_LUT_OUT by giving up one or two state bits, respectively.

The CFG_MISC_CTRL register controls the operation of the FSM block. Two bits in this register are used for each FSM Block to determine whether the FSM output LUT function uses the state variable S0/S1, or the corresponding extra external input signal FSM_EXTRA_EXT_INx. A 0 means use the state bit, and a 1 means use the FSM_EXTRA_EXT_IN0 / FSM_EXTRA_EXT_IN1 signal.

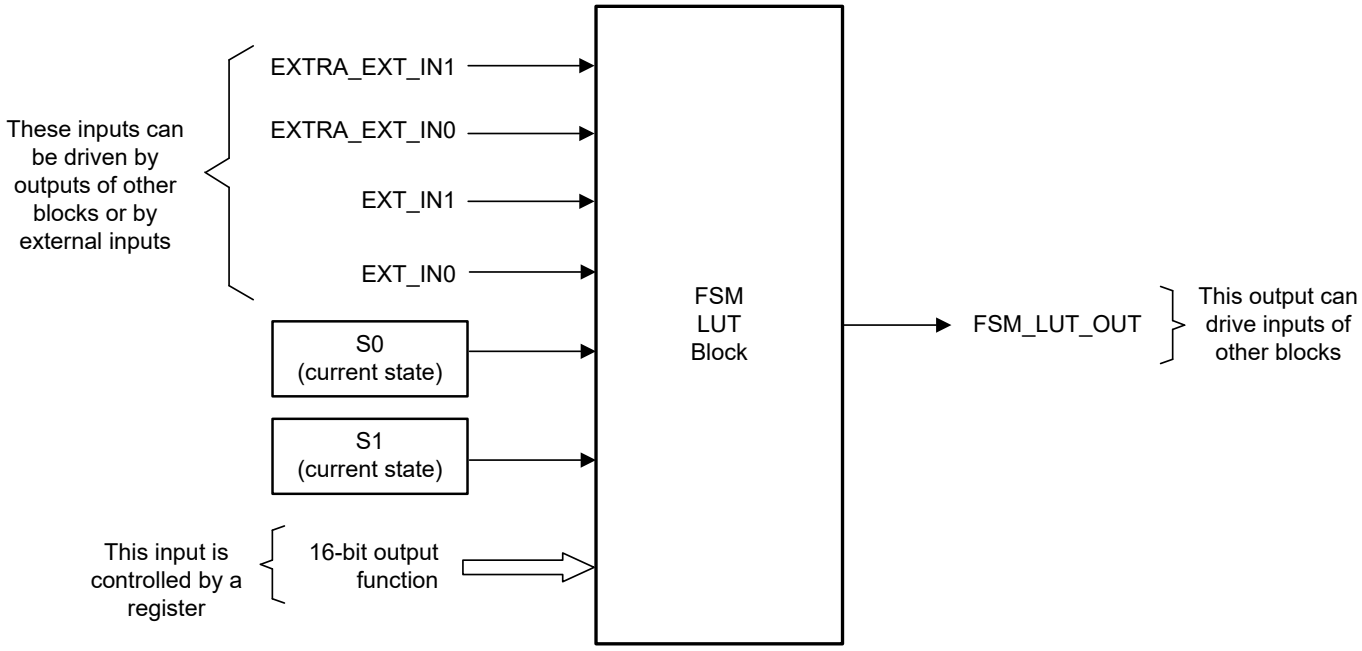

Figure 11-14. FSM LUT Block

11.4.4 LUT4 Block

This is a simple four input Look-Up table (LUT) block with inputs IN0, IN1, IN2, and IN3 (see Figure 11-15). Any combinatorial Boolean equation using the four inputs can be realized by programming the 16-bit control register associated with each LUT4 block. For more information, see the LUT4 register descriptions located in Section 11.10.

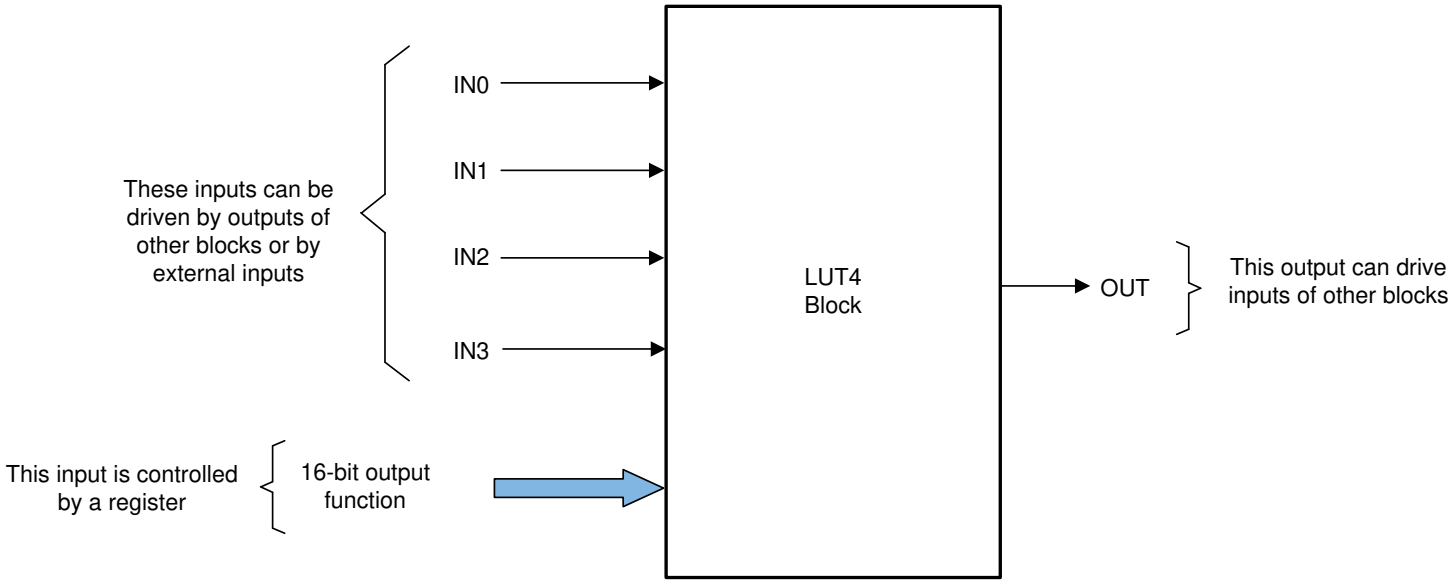

Figure 11-15. LUT4 Block

11.4.5 Output LUT Block

The output LUT block (Figure 11-16) is very similar in functionality to the LUT4 block, except that the output LUT block has three inputs. Unlike the other sub blocks, the outputs of these blocks are meant to go out of the tile and hence cannot be used by any other block within the tile. Any combinatorial function of the three inputs can be realized by the output LUT block. For more information, see the output LUT register descriptions located in Section 11.10.

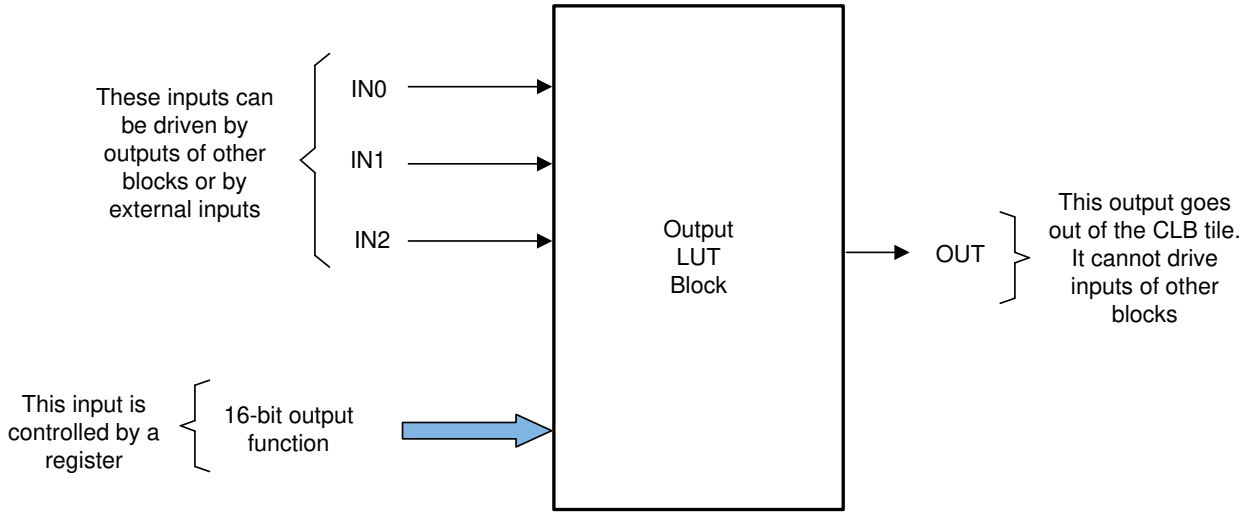

Figure 11-16. Output LUT Block

11.4.6 Asynchronous Output Conditioning (AOC) Block

The logic in the AOC block is organized into three stages with the inputs passing through different types of logic modification at each stage before proceeding to the next level. This is shown in Figure 11-17.

There are 8 inputs to this block. Each of these 8 inputs can pick the corresponding BOUNDARY input to the CLB or the CLB TILE output (for example, the INPUT 0 of the AOC block can choose between CLB BOUNDARY INPUT0 and CLB TILE OUTPUT 0). If the CLB TILE OUTPUT 0 is selected, the CLB TILE OUTPUT 0 is always registered before being sent to the subsequent asynchronous signal conditioning stages. In each of the three stages, there is always an option to do nothing and just send the signal as is to the next stage (bypass).

Stage 1: The input signal can be inverted before sending the signal to the next stage.

Stage 2: The signal coming from Stage 1 can be GATED with a gating control signal. The gating control signal can either be from a software register or can be any of the CLB TILE outputs. The GATING function can be a logical AND, OR, or XOR.

Stage 3: The input signal can be used to either set or clear the output on the rising edge of the signal. This is a purely asynchronous set/clear that occurs without needing any clocks. The release control signal, when high, restores the output to the default state (HIGH if asynchronous clear is selected and LOW if asynchronous set is selected). The release control signal can be either from a software register or can be any of the CLB TILE outputs. Optionally, instead of any of the asynchronous set and clear operations, the input signal can just be delayed by a clock cycle.

The interaction of the CLB TILE and the AOC block is shown in Figure 11-18.

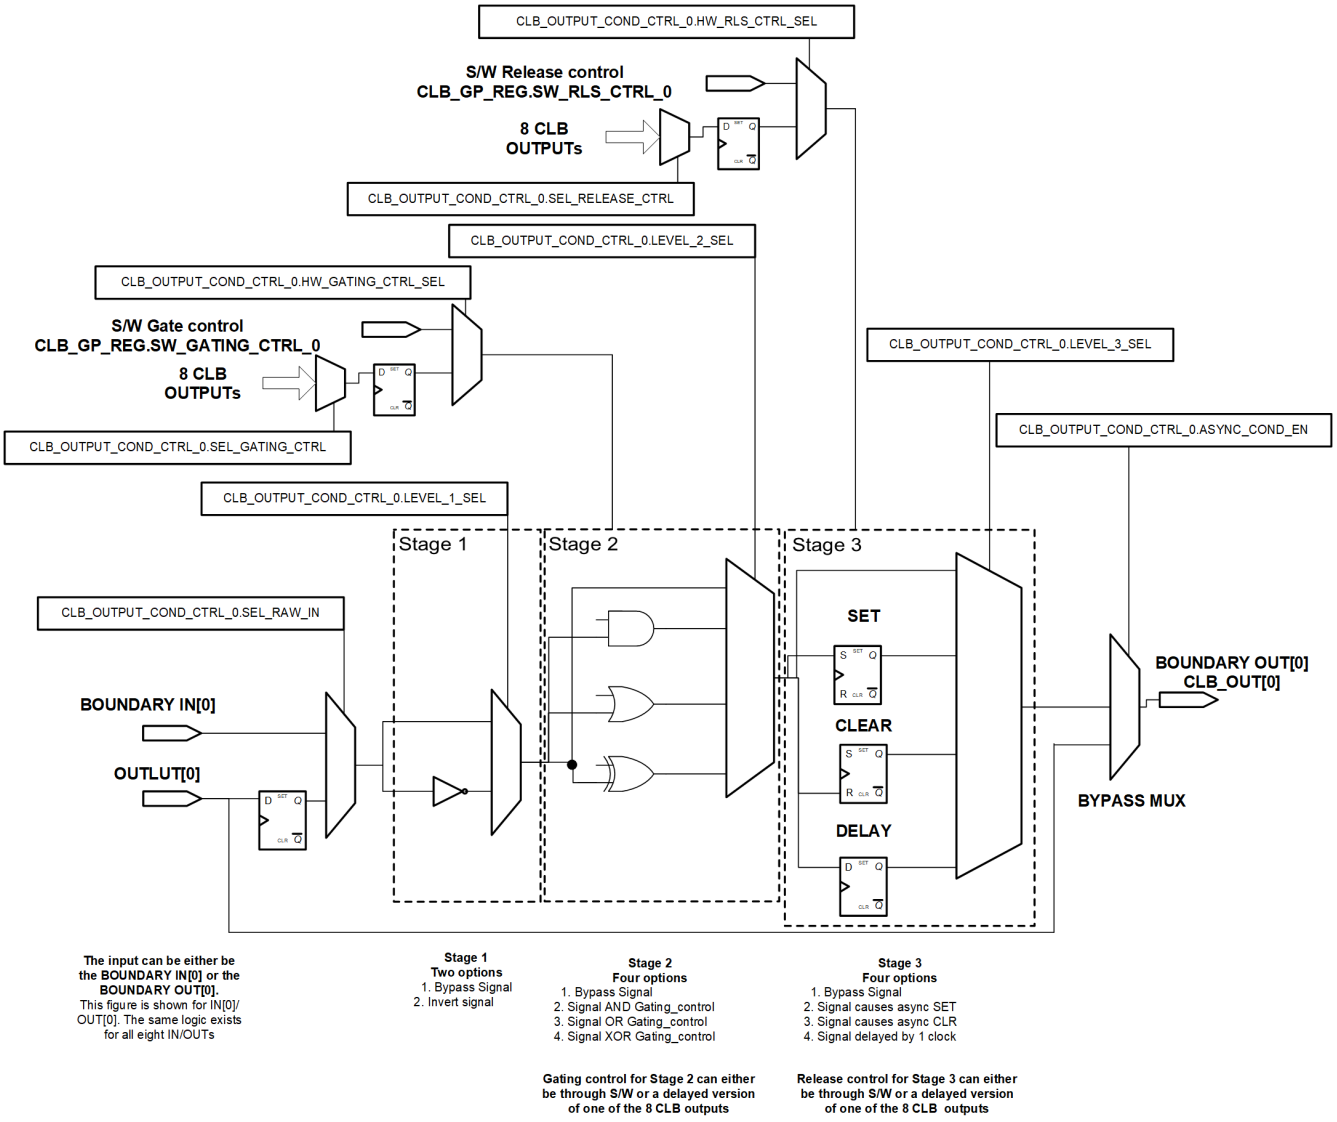

Figure 11-17. AOC Block

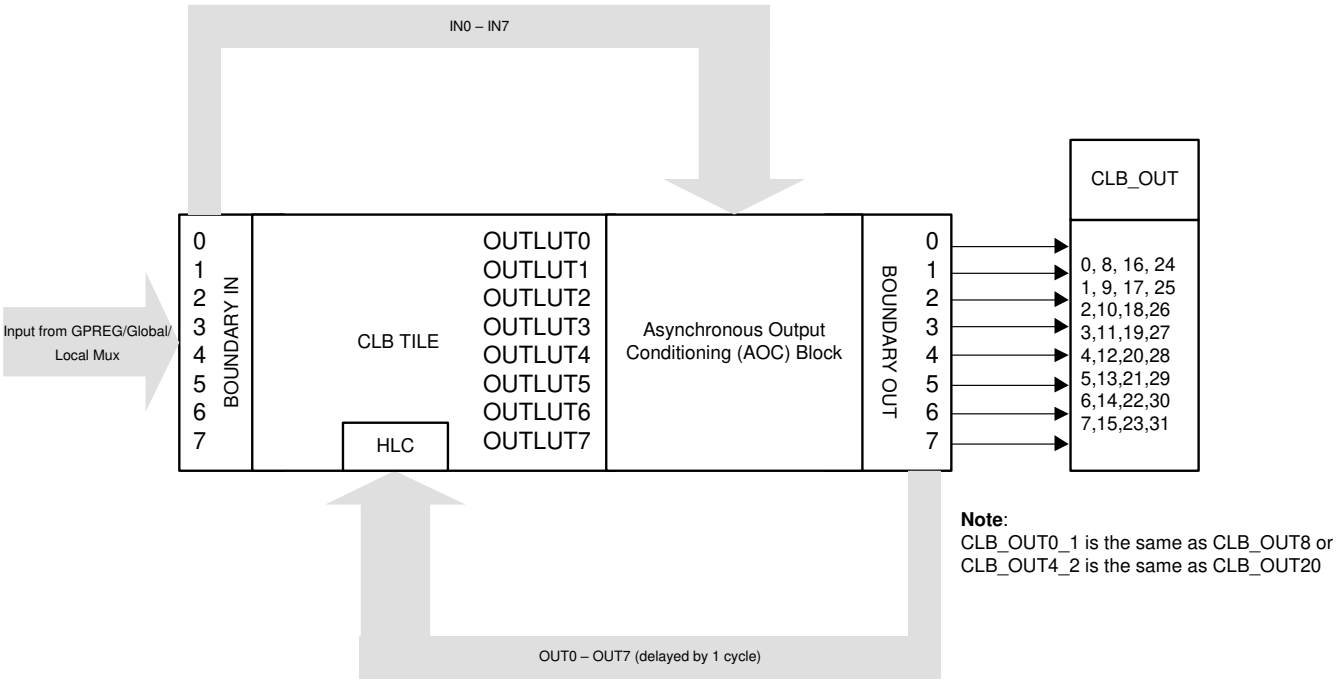

Figure 11-18. AOC Block and The CLB TILE

Note

Only CLB_OUT12 to CLB_OUT15 can be used as ASYNC outputs. This is the same as CLB_OUT4_1 to CLB_OUT7_1. GPIO Output XBAR can be used to route the OUT4_1 and OUT5_1 ASYNC outputs to GPIOs.

11.4.7 High Level Controller (HLC)

The High Level Controller (HLC) is significantly more complex than the other blocks in the CLB tile. The HLC performs two main functions:

- Provides a means of communication and data exchange with the rest of the device. This is done through two methods: a global access path to four general purpose HLC registers (R0 through R3) and PUSH and PULL FIFOs between the CPU and the HLC. The general-purpose HLC registers are designed to only be written to during device configuration time. To avoid unexpected behavior, the HLC registers must not be written to during run-time operation. The PUSH and PULL FIFOs are the primary avenues of data exchange during run-time, refer to Section 11.4.7.4 for more information.
- Provides a programmable, event-based action system, which performs computation, manipulation of logic functionality, and data movement. In other words, events can be configured to trigger a predefined set of actions in the CLB tile, or to initiate data exchange with the rest of the device.

The architecture of the HLC is shown in Figure 11-19. The HLC is an event-based system capable of handling up to four simultaneous events that can be selected from any outputs of the other blocks within the tile or from an external input.

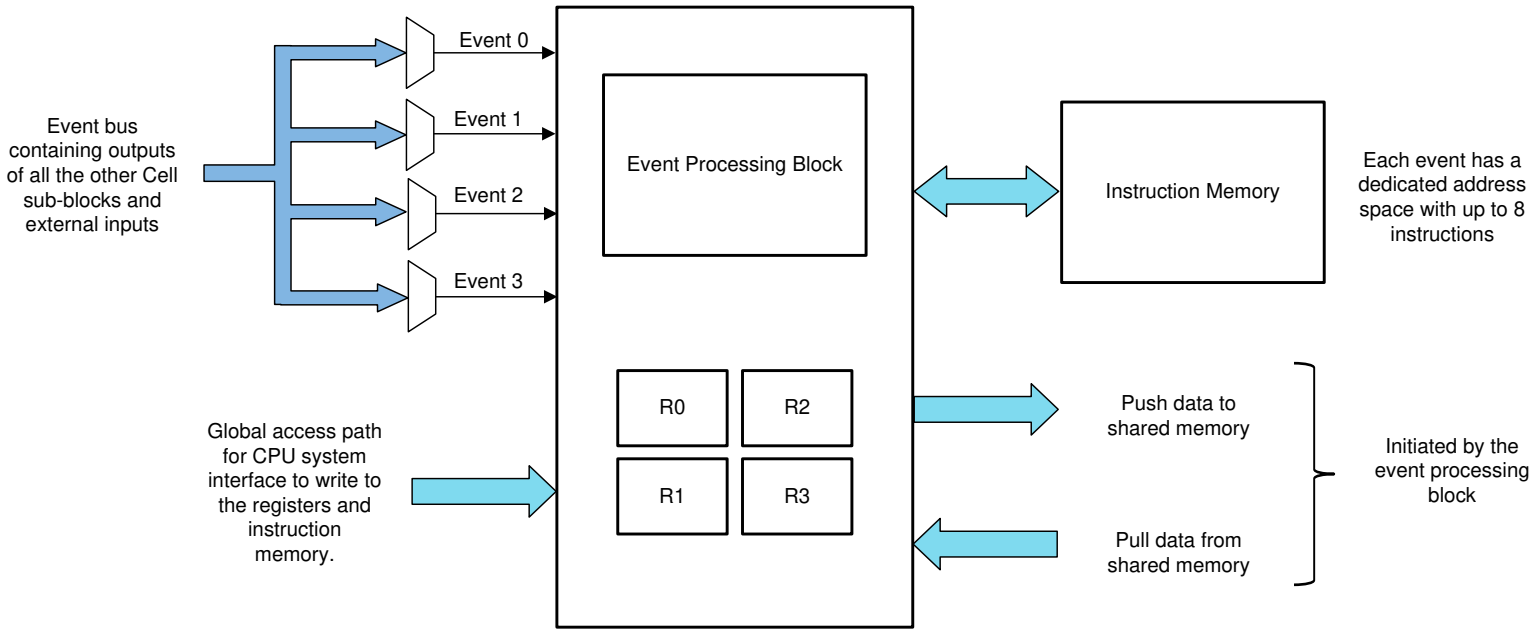

Figure 11-19. High Level Controller Block

11.4.7.1 High Level Controller Events

Each of the four HLC events has a dedicated address from which instructions are executed. Events are selected from the set of signals listed in Table 11-12. The lowest numbered event (Event 0) has the highest priority, and the highest numbered event (Event 3) has the lowest priority.

Table 11-12. HLC Event List

Index	HLC Event Mux
0	Always 0
1	COUNTER_0 MATCH2
2	COUNTER_0 ZERO
3	COUNTER_0 MATCH1
4	FSM_0 STATE_BIT_0
5	FSM_0 STATE_BIT_1
6	FSM_0 LUT output

30	CLB_ASYNC_OUT_6.INVERTED
31	CLB_ASYNC_OUT_7.INVERTED

11.4.7.2 High Level Controller Instructions

The instruction memory supports up to eight instructions per event. Each instruction sequence gets triggered on the rising edge of the corresponding event. Starting with CLB Type 2, the option to trigger the execution of instructions using both falling edge and rising edge is available.

The HLC memory supports up to eight instructions per event, starting at the beginning of the fixed address range shown in Table 11-14. An instruction sequence is triggered on the rising edge of the corresponding event. If two or more events occur simultaneously, the associated instruction sequences each are executed sequentially in priority order.

Table 11-14. HLC Instruction Address Ranges

Address	Instructions for
00000 to 00111	Event 0
01000 to 01111	Event 1
10000 to 10111	Event 2
11000 to 11111	Event 3

The HLC instruction format is shown in Table 11-15.

Table 11-15. HLC Instruction Format

Last Instruction Bit	5-Bit Opcode	3-Bit Source	3-Bit Destination
This bit when set to 1 stops execution after the current instruction.	MOV 00000 MOV_T1 00001 MOV_T2 00010 PUSH 00011 PULL 00100 ADD 00101 SUB 00110 INTR 00111	Source can be R0, R1, R2, R3, C0, C1, C2.	Destination can be R0, R1, R2, R3, C0, C1, C2. Note that for ADD/SUB instructions, only R0, R1, R2, or R3 can be the destination.

R0, R1, R2, and R3 are four 32-bit general-purpose registers in the HLC. C0, C1, and C2 are three counter registers present in the CLB tile. <Src> is used to indicate the source and <Dest> is used to indicate the destination. Table 11-16 describes the HLC instructions.

Table 11-16. HLC Instruction Description

Instruction	Description
ADD <Src>, <Dest>	This instruction performs an unsigned 32-bit addition. <Dest> = <Dest> + <Src>. The <Src> can be R0, R1, R2, R3, C0, C1, or C2. The <Dest> can only be R0, R1, R2, or R3.
INTR <6-bit constant>	This instruction flags an interrupt through the CPU interface. The 6-bit constant is stored in the interrupt flag register CLB_INTR_TAG_REG. If multiple INTR instructions are called consecutively, only the first one has an effect. When multiple INTR calls are needed, each can be separated by other HLC instructions to make sure the interrupt calls take effect. **Note** Starting with CLB Type 2, NMI can be generated by the CLB. This feature is DISABLED by default and must be enabled (**CLB_LOAD_EN.NMI_EN**).
MOV <Src>, <Dest>	This instruction moves <Src> to <Dest>. Both <Src> and <Dest> can be any of R0, R1, R2, R3, C0, C1, or C2. The COUNT_EVENT_CTRL_x bit must be configured to load (that is, 0) for indirect loads and HLC loads of the counter to take effect.

Table 11-16. HLC Instruction Description (continued)

Instruction	Description
MOV_T1 <Src>, <Dest>	This instruction moves <Src> to the Match1 register of the <Dest> counter. <Src> can be any of the registers R0, R1, R2, R3, or the counter values associated with C0, C1, or C2. <Dest> is the Match1 register of any of the counters C0, C1, or C2. Examples are: • This instruction moves the count value in C1 into register R0: MOV_T1 C1 R0 • This instruction moves the value in R2 into the Match1 register of counter C0: MOV_T1 R2 C0
MOV_T2 <Src>, <Dest>	This instruction is similar to MOV_T1. The instruction moves <Src> to the Match2 register of the <Dest> counter. <Src> can be any of the registers R0, R1, R2, R3, or the counter values associated with C0, C1, or C2. <Dest> is the Match2 register of any of the counters C0, C1, or C2.
PULL <Dest>	This instruction transfers data from the data exchange pull memory buffer in the CPU interface to the <Dest> register. <Dest> can be any of R0, R1, R2, or R3. The PULL instruction is used as seen from the High Level Controller and a PULL operation reads (pulls) data from an internal 4-word FIFO.
PUSH <Src>	This instruction transfers data from <Src> to the data exchange push memory buffer in the CPU interface. <Src> can be any of R0, R1, R2, R3, C0, C1, or C2. The PUSH instruction is used as seen from the High Level Controller and pushes data into an internal 4 word FIFO.
SUB <Src>, <Dest>	This instruction performs an unsigned 32-bit subtraction. <Dest> = <Dest> - <Src>. The <Src> can be R0, R1, R2, R3, C0, C1, or C2. The <Dest> can only be R0, R1, R2, or R3.

MOV, MOV_T1, MOV_T2, ADD, SUB, and INTR instructions take one cycle to execute. PUSH and PULL require two cycles to execute. Note that the PUSH and PULL instructions are pipeline protected, meaning that a register can be used immediately after a PUSH/PULL to that register.

For multiple events triggered simultaneously, if the last instruction in the higher priority event is a PUSH or a PULL, there is an additional cycle delay between the end of the higher priority event and the start of the next event. If the last instruction is not a PUSH or PULL, then there is no cycle delay between the events.

11.4.7.3 <Src> and <Dest>

Three bits are used to encode the <Src> and <Dest> registers as shown in Table 11-17.

Table 11-17. HLC Register Encoding

Bits	Register
000	R0
001	R1
010	R2
011	R3
100	C0
101	C1
110	C2

11.4.7.4 Operation of the PUSH and PULL Instructions (Overflow and Underflow Detection)

The PUSH and PULL operations of the HLC are intended for data exchange with the host system. There are separate FIFO buffers for PUSH and PULL operations. For example, a series of PUSH operations write to successive locations in a linearly mapped-memory buffer. The PUSH buffer and the PULL buffer are mapped at address offsets shown in the *Registers* section.

The CPU can read from and write to the PUSH and PULL buffers, respectively, to exchange data with the HLC. Data pushed by the HLC is read by the CPU from the PUSH buffers. Data sent from the CPU to the HLC is written by the CPU to the PULL buffer and is read by the HLC using the PULL instruction.

Refer to *clb_ex13_push_pull* for guidance on properly using the PUSH and PULL buffers. To make use of one of the CLB inputs as a GPREG, have this input indicate when data is written to the FIFO by the CPU.

There are separate PUSH and PULL address pointers that increment each time the HLC performs a PUSH or PULL operation. These address pointers are also memory-mapped so that the CPU can determine the value. These address pointers are also writable and can be reset by the CPU at any time.

Overflow and underflow detection is done by simply reading the values of the PUSH and PULL address pointers.

In the CLB module of the device, the depth of the PUSH and PULL FIFOs is four 32-bit words each. If the CPU starts a fresh data transfer to the PULL buffers and sees the address pointer greater than four, then an underflow has occurred since the HLC has pulled more data than the number of words written by the CPU into the buffer.

11.5 CPU Interface

11.5.1 Register Description

There are three classes of registers that are used to control and configure the CLB tile. This specification only describes the offset addresses of the registers. The absolute register addresses are different for each CLB tile. The three instances of the various blocks (LUT4, FSM, and Counter Block) are numbered 0, 1, and 2.

- **Logic configuration registers (0x000–0x0FF):** These registers control the core reconfiguration logic for the tile. All registers in this group are EALLOW protected and also protected by the LOCK register.
- **Top level control registers (0x100–0x1FF):** These registers are used for top level and device related control of the CLB. These registers typically control mux selects for inputs, global enables, and so forth, and are accessible by normal memory mapped access. Some of these registers have EALLOW and LOCK protection.
- **Data exchange registers (0x200–0x3FF):** These registers are used to exchange data between the CLB and the rest of the device. The registers are accessible by normal memory-mapped access and no EALLOW or LOCK protection exists.

Note

EALLOW protection means that the write access to the register is enabled only when the EALLOW instruction has been executed prior to the write access. The complementary EDIS instruction disables access to all registers protected in this way. For more information, see Section 11.10.

11.5.2 Non-Memory Mapped Registers

The memory-mapped CLB registers are described later in this chapter; however, many of the CLB resources including counters, the instruction memory of the High Level Controller, and the HLC general-purpose registers (R0 through R3) are only indirectly accessible through a local interface bus and are not memory-mapped. These registers are accessible through the two memory-mapped registers CLB_LOAD_DATA and CLB_LOAD_ADDR. Note that the general-purpose registers R0 through R3 must only be written to during configuration-time and are not intended to be written to during run-time. Writes during run-time can lead to unexpected behavior. If run-time data exchange is desired, refer to Section 11.4.7.4.

Load the data to be written into the CLB_LOAD_DATA register, then load the appropriate address into CLB_LOAD_ADDR to determine where this data is written. Writing a 1 to bit position 0 in the CLB_LOAD_EN register then causes an internal write operation to be triggered. The address allocation for the CLB_LOAD_ADDR register is shown in Table 11-18.

Note

The COUNT_EVENT_CTRL_x bit must be configured to load (that is, 0) for indirect loads and for HLC loads of the counter to take effect.

Table 11-18. Non-Memory Mapped Register Addresses

Address (Binary)	Resource
000000 to 000010	Counter 0 to 2 Load value
000100 to 000110	Counter 0 to 2 Match1 value
001000 to 001010	Counter 0 to 2 Match2 value
001100 to 001111	R0 to R3 of High Level Controller
100000 to 100111	Instructions for Event 0
101000 to 101111	Instructions for Event 1
110000 to 110111	Instructions for Event 2
111000 to 111111	Instructions for Event 3

Use the following steps to load the value 0x11223344 into the general purpose R0 register:

1. Write 0x11223344 to CLB_LOAD_DATA.
2. Write 0xc to CLB_LOAD_ADDR.
3. Write 0x1 to CLB_LOAD_EN.

Note

Even though HLC registers are accessible by the CPU, your application code needs to make sure that no other CLB internal logics are updating the same HLC register at the same time, causing a race condition.

11.6 RTDMA Access

The RTDMA does not have access to the CLB memory-mapped registers, including the PUSH and PULL FIFO registers. For more information, refer to Section 11.10.

11.7 CLB Data Export Through SPI RX Buffer

For a continuous export of data from the CLB peripherals, SPI RX buffers can be used. CLB data can be exported through the SPI RX buffers without CPU/CLA interventions.

CLB1 to CLB5 have access to SPIA to SPIE, respectively, as shown in Table 11-19.

Table 11-19. CLB to SPI RX Access

CLB Instance	SPI Instance
CLB1	SPIA
CLB2	SPIB
CLB3	SPIC
CLB4	SPID
CLB5	SPIE

When the CLB to SPI data exporting is enabled, 16-bit data can be exported from CLB to SPI RX buffers. The 32-bit HLC R0 register is the data that is exported to the SPI RX buffers. The user can select which 16-bit range of the HLC R0 is exported by configuring the CLB_SPI_DATA_CTRL_HI.SHIFT. The CLB also controls when HLC R0 data must be transferred to the SPI RX buffer through CLB_SPI_DATA_CTRL_HI.STRB that selects one of the HLC event signals from the static switch block.

When CLB to SPI data exporting is required, note:

- The selected SPI transmit functionality is not affected.
- Even though the data is being pushed into the SPI RX buffers by the CLB, the SPI RX interrupt and the RTDMA trigger for SPI RX in the respective peripherals must be configured.
- The SPI can resume normal operation when the CLB to SPI data exporting is disabled.

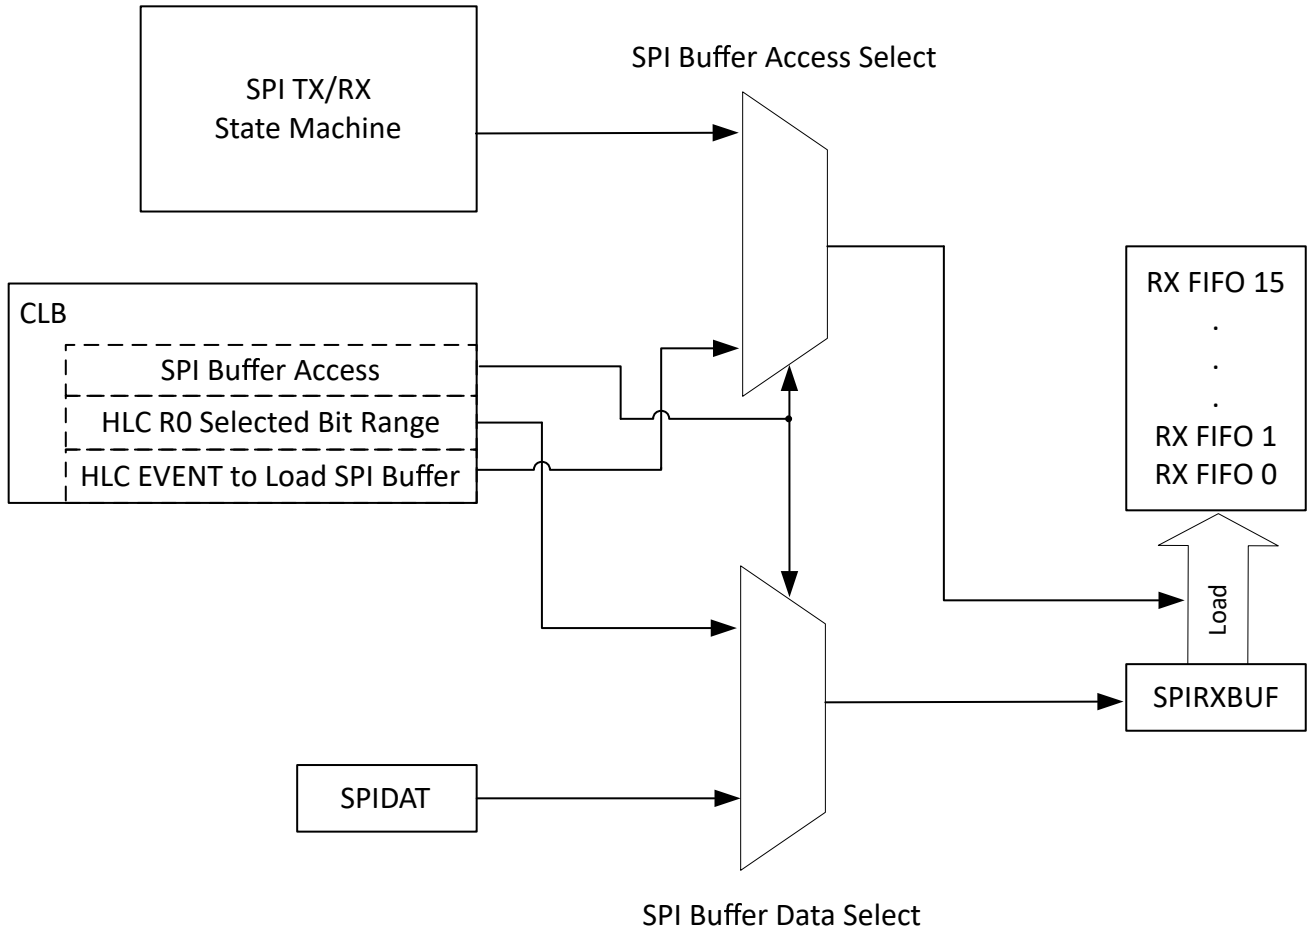

Figure 11-20. CLB Control of SPI RX Buffer

11.8 CLB Pipeline Mode

When operating the CLB TILE at frequencies higher than 100MHz, the Pipeline mode MUST be enabled. When CLB Pipeline mode is enabled, the operations of the HLC and COUNTER modules are changed.

- When operating at higher frequencies that require Pipeline mode to be enabled, the pipelined versions of the the CLB CELL OUTPUTs are brought into the HLC. The Pipeline mode causes the CELL outputs delayed by 1 clock cycle to be used as the source of the HLC event triggers.
- In Pipeline mode, the COUNTER module's add/sub/shift operations, which are triggered by an event, use the value of the counter in the previous clock cycle (pipelined).

To enable the CLB Pipeline mode, set the CLB_LOAD_EN.PIPELINE_EN.

11.10.2 CLB_LOGIC_CONFIG_REGS Registers

Table 11-22 lists the memory-mapped registers for the CLB_LOGIC_CONFIG_REGS registers. All register offset addresses not listed in Table 11-22 should be considered as reserved locations and the register contents should not be modified.

Table 11-22. CLB_LOGIC_CONFIG_REGS Registers

Offset	Acronym	Register Name	Protection
4h	CLB_COUNT_RESET	Counter Block RESET	LOCK
8h	CLB_COUNT_MODE_1	Counter Block MODE_1	LOCK
Ch	CLB_COUNT_MODE_0	Counter Block MODE_0	LOCK
10h	CLB_COUNT_EVENT	Counter Block EVENT	LOCK
14h	CLB_FSM_EXTRA_IN0	FSM Extra EXT_IN0	LOCK
18h	CLB_FSM_EXTERNAL_IN0	FSM EXT_IN0	LOCK
1Ch	CLB_FSM_EXTERNAL_IN1	FSM_EXT_IN1	LOCK
20h	CLB_FSM_EXTRA_IN1	FSM Extra_EXT_IN1	LOCK
24h	CLB_LUT4_IN0	LUT4_0/1/2 IN0 input source	LOCK
28h	CLB_LUT4_IN1	LUT4_0/1/2 IN1 input source	LOCK
2Ch	CLB_LUT4_IN2	LUT4_0/1/2 IN2 input source	LOCK
30h	CLB_LUT4_IN3	LUT4_0/1/2 IN3 input source	LOCK
38h	CLB_FSM_LUT_FN1_0	LUT function for FSM Unit 1 and Unit 0	LOCK
3Ch	CLB_FSM_LUT_FN2	LUT function for FSM Unit 2	LOCK
40h	CLB_LUT4_FN1_0	LUT function for LUT4 block of Unit 1 and 0	LOCK
44h	CLB_LUT4_FN2	LUT function for LUT4 block of Unit 2	LOCK
48h	CLB_FSM_NEXT_STATE_0	FSM Next state equations for Unit 0	LOCK
4Ch	CLB_FSM_NEXT_STATE_1	FSM Next state equations for Unit 1	LOCK
50h	CLB_FSM_NEXT_STATE_2	FSM Next state equations for Unit 2	LOCK
54h	CLB_MISC_CONTROL	Static controls for Ctr,FSM	LOCK
58h	CLB_OUTPUT_LUT_0	Inp Sel, LUT fns for Out0	LOCK
5Ch	CLB_OUTPUT_LUT_1	Inp Sel, LUT fns for Out1	LOCK
60h	CLB_OUTPUT_LUT_2	Inp Sel, LUT fns for Out2	LOCK
64h	CLB_OUTPUT_LUT_3	Inp Sel, LUT fns for Out3	LOCK
68h	CLB_OUTPUT_LUT_4	Inp Sel, LUT fns for Out4	LOCK
6Ch	CLB_OUTPUT_LUT_5	Inp Sel, LUT fns for Out5	LOCK
70h	CLB_OUTPUT_LUT_6	Inp Sel, LUT fns for Out6	LOCK
74h	CLB_OUTPUT_LUT_7	Inp Sel, LUT fns for Out7	LOCK
78h	CLB_HLC_EVENT_SEL	Event Selector register for the High Level controller	LOCK
7Ch	CLB_COUNT_MATCH_TAP_SEL	Counter tap values for match1 and match2 outputs	LOCK
80h	CLB_OUTPUT_COND_CTRL_0	Output conditioning control for output 0	LOCK
84h	CLB_OUTPUT_COND_CTRL_1	Output conditioning control for output 1	LOCK
88h	CLB_OUTPUT_COND_CTRL_2	Output conditioning control for output 2	LOCK
8Ch	CLB_OUTPUT_COND_CTRL_3	Output conditioning control for output 3	LOCK
90h	CLB_OUTPUT_COND_CTRL_4	Output conditioning control for output 4	LOCK
94h	CLB_OUTPUT_COND_CTRL_5	Output conditioning control for output 5	LOCK
98h	CLB_OUTPUT_COND_CTRL_6	Output conditioning control for output 6	LOCK
9Ch	CLB_OUTPUT_COND_CTRL_7	Output conditioning control for output 7	LOCK
A0h	CLB_MISC_ACCESS_CTRL	Miscellaneous Access and enable control	LOCK
A2h	CLB_SPI_DATA_CTRL_HI	CLB to SPI buffer control High	LOCK

Complex bit access types are encoded to fit into small table cells. Table 11-23 shows the codes that are used for access types in this section.

Table 11-23. CLB_LOGIC_CONFIG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

11.10.2.1 CLB_COUNT_RESET Register (Offset = 4h) [Reset = 00000000h]

CLB_COUNT_RESET is shown in Figure 11-21 and described in Table 11-24.

Return to the Summary Table.

Counter Block RESET

Bit	Field	Type	Reset	Description
15-13	RESERVED	R/W1C	0h	Reserved
12-8	SHIFT	R/W1C	0h	This is a 5 bit value which denotes the first bit position of register R0 from which the Least Significant Bit of the output data should start. 00000 Output data is R0[15:0] 00001 Output data is R0[16:1] 00010 Output data is R0[17:2] 00011 Output data is R0[18:3] ... ... 10000 Output data is R0[31:16] Reset type: SYSRSn
7	STRB_DEL	R/W1C	0h	0 Selected strobe event goes directly to SPI module 1 Selected strobe event is delayed by 4 CLB clock cycles to SPI module (This is done to facilitate use of STROBE as the same event to initiate a HLC task that can get the required data on to R0 for SPI data transfer before Strobe becomes valid at SPI block) Reset type: SYSRSn
6-5	RESERVED	R/W1C	0h	Reserved
4-0	STRB	R/W1C	0h	This is a 5 bit value which selects one of the HLC_EVENT inputs to be treated as the data_valid strobe Reset type: SYSRSn

11.10.3 CLB_LOGIC_CONTROL_REGS Registers

Table 11-64 lists the memory-mapped registers for the CLB_LOGIC_CONTROL_REGS registers. All register offset addresses not listed in Table 11-64 should be considered as reserved locations and the register contents should not be modified.

Table 11-64. CLB_LOGIC_CONTROL_REGS Registers

Offset	Acronym	Register Name	Protection
0h	CLB_LOAD_EN	Global enable & indirect load enable control, only Global Enable Bit is LOCK protected	LOCK
4h	CLB_LOAD_ADDR	Indirect address	
8h	CLB_LOAD_DATA	Data for indirect loads	
Ch	CLB_INPUT_FILTER	Input filter selection for both edge detection and synchronizers	LOCK
10h	CLB_IN_MUX_SEL_0	Input selection to decide between Signals and GP register	LOCK
14h	CLB_LCL_MUX_SEL_1	Input Mux selection for local mux	LOCK
18h	CLB_LCL_MUX_SEL_2	Input Mux selection for local mux	LOCK
1Ch	CLB_BUF_PTR	PUSH and PULL pointers	
20h	CLB_GP_REG	General purpose register for CELL inputs	
24h	CLB_OUT_EN	CELL output enable register	
28h	CLB_GLBL_MUX_SEL_1	Global Mux select for CELL inputs	LOCK
2Ch	CLB_GLBL_MUX_SEL_2	Global Mux select for CELL inputs	LOCK
30h	CLB_PRESCALE_CTRL	Prescaler register control	LOCK
40h	CLB_INTR_TAG_REG	Interrupt Tag register	
44h	CLB_LOCK	Lock control register	
48h	CLB_HLC_INSTR_READ_PTR	HLC instruction read pointer	
4Ch	CLB_HLC_INSTR_VALUE	HLC instruction read value	
5Ch	CLB_DBG_OUT_2	Visibility for CLB inputs and final asynchronous outputs	
60h	CLB_DBG_R0	R0 of High level Controller	
64h	CLB_DBG_R1	R1 of High level Controller	
68h	CLB_DBG_R2	R2 of High level Controller	
6Ch	CLB_DBG_R3	R3 of High level Controller	
70h	CLB_DBG_C0	Count of Unit 0	
74h	CLB_DBG_C1	Count of Unit 1	
78h	CLB_DBG_C2	Count of Unit 2	
7Ch	CLB_DBG_OUT	Outputs of various units in the Cell	

Complex bit access types are encoded to fit into small table cells. Table 11-65 shows the codes that are used for access types in this section.

Table 11-65. CLB_LOGIC_CONTROL_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
R-1	R -1	Read Returns 1s
Write Type		
W	W	Write

Table 11-65. CLB_LOGIC_CONTROL_REGS Access Type Codes (continued)

Access Type	Code	Description
W1C	W 1C	Write 1 to clear
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

11.10.3.1 CLB_LOAD_EN Register (Offset = 0h) [Reset = 0000h]

CLB_LOAD_EN is shown in Figure 11-61 and described in Table 11-66.

Return to the Summary Table.

Global enable & indirect load enable control, only Global Enable Bit is LOCK protected

R-0-0h			R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

Table 11-66. CLB_LOAD_EN Register Field Descriptions

Bit	Field	Type	Reset	Description
15-5	RESERVED	R-0	0h	Reserved
4	PIPELINE_EN	R/W	0h	This bit controls pipelining of all the CLB operations in HLC and Counter blocks. Pipelined operation is enabled when this bit is set to 1. Reset type: SYSRSn
3	NMI_EN	R/W	0h	This bit controls the generation of NMI along with the interrupt whenever a INTR operation is executed by the HLC. NMI generation is disabled by default. It will be enabled when this bit is set to 1. Reset type: SYSRSn
2	STOP	R/W	0h	This bit defines the behaviour of the sequential elements in the CELL during debug HALTs of the CPU. If this bit is set to 0, the debug HALT condition is ignored. Reset type: SYSRSn
1	GLOBAL_EN	R/W	0h	This bit is a global enable signal for the logic in the CELL. This also acts as a soft reset for the CELL logic. CLB outputs (including LUTs and OUTLUTs) will be gated when this bit is cleared from 1 to 0, i.e., the CLB outputs will be low when GLOBAL_EN is low. Additionally, the FSM and AOC blocks will also be reset. Note that when this bit goes low, the COUNTER blocks and HLC are simply halted, but they will NOT be reset internally. This allows the ability to preload these submodules when GLOBAL_EN is 0. This bit is normally set after all the other configuration settings are completed. This bit is LOCK protected. Reset type: SYSRSn
0	LOAD_EN	R/W	0h	A write with this bit set to 1 will pulse the Load Enable signal for the indirect register loads in the CELL. Reset type: SYSRSn

11.10.3.2 CLB_LOAD_ADDR Register (Offset = 4h) [Reset = 00000000h]

CLB_LOAD_ADDR is shown in Figure 11-62 and described in Table 11-67.

Return to the Summary Table.

R-0-0h			R/W-0h			R/W-0h	R/W-0h

Table 11-78. CLB_PRESCALE_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	PRESCALE	R/W	0h	16-bit Value of prescaler to be used for the counter as reference to reset when reaching this value. The counter is a simple incrementing counter which will count up to the reference value and reset to 0 and this cycle will continue as long as the counter is enabled. This 16-bit register value is used as a reference for the 16-bit counter to reset to zero whenever count reaches this value. Reset type: SYSRSn
15-6	RESERVED	R-0	0h	Reserved
5-2	TAP	R/W	0h	TAP Select value. These 4 bits will be used as a select to tap one of the 16 register bit position of the counter as the output. 0000 selects Counter Bit position 0 0001 selects Counter Bit position 1 .... 1111 selects Counter Bit position 15 Reset type: SYSRSn
1	STRB	R/W	0h	When set to 0, a strobe output will be sent out whenever the counter value matches the PRESCALE_VALUE. When set to 1, the output of the counter register bit position as selected by TAP_SELECT_VALUE will be sent out. Reset type: SYSRSn
0	CLKEN	R/W	0h	Enable the prescale clock/strobe generator. A 16-bit counter is used to either generate a strobe or send out a selected counter bit position to the CLB CELL. This is meant to be a general purpose strobe/prescaled clock which can be used by the CELL logic if needed. This will be sent to the CELL through one of the LCL_IN MUX ports. Reset type: SYSRSn

11.10.3.14 CLB_INTR_TAG_REG Register (Offset = 40h) [Reset = 0000h]

CLB_INTR_TAG_REG is shown in Figure 11-74 and described in Table 11-79.

Return to the Summary Table.

Chapter 12

Dual-Clock Comparator (DCC)

This chapter describes the Dual-Clock Comparator (DCC) module.

12.1 Introduction

The dual-clock comparator module is used for evaluating and monitoring the clock input based on a second clock, which can be a more accurate and reliable version. This instrumentation is used to detect faults in clock source or clock structures, thereby enhancing the system's safety metrics.

12.1.1 Features

The main features of each of the DCC modules are:

- Allows the application to make sure that a fixed ratio is maintained between frequencies of two clock signals.
- Supports the definition of a programmable tolerance window in terms of the number of reference clock cycles.
- Supports continuous monitoring without requiring application intervention.
- Supports a single-sequence mode for spot measurements.
- Allows the selection of a clock source for each of the counters, resulting in several specific use cases.

12.1.2 Block Diagram

Figure 12-1 shows how the DCC connects to the rest of the system. Figure 12-2 shows the main concept of the DCC module.

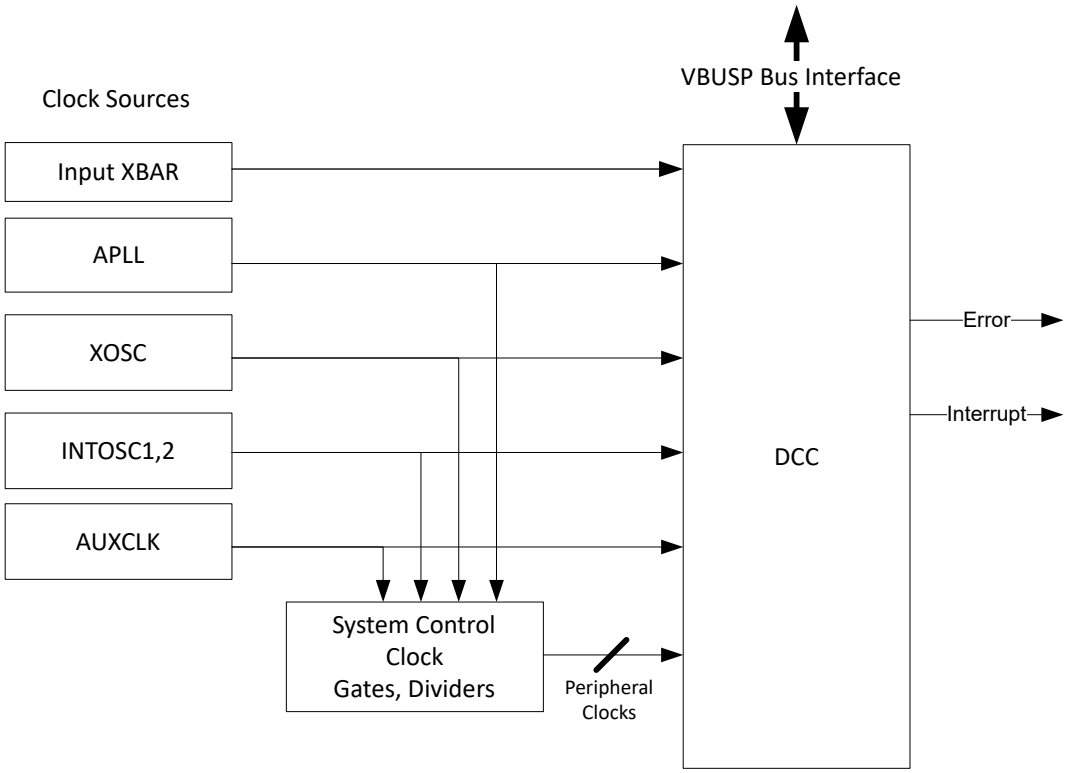

Figure 12-1. DCC Module Overview

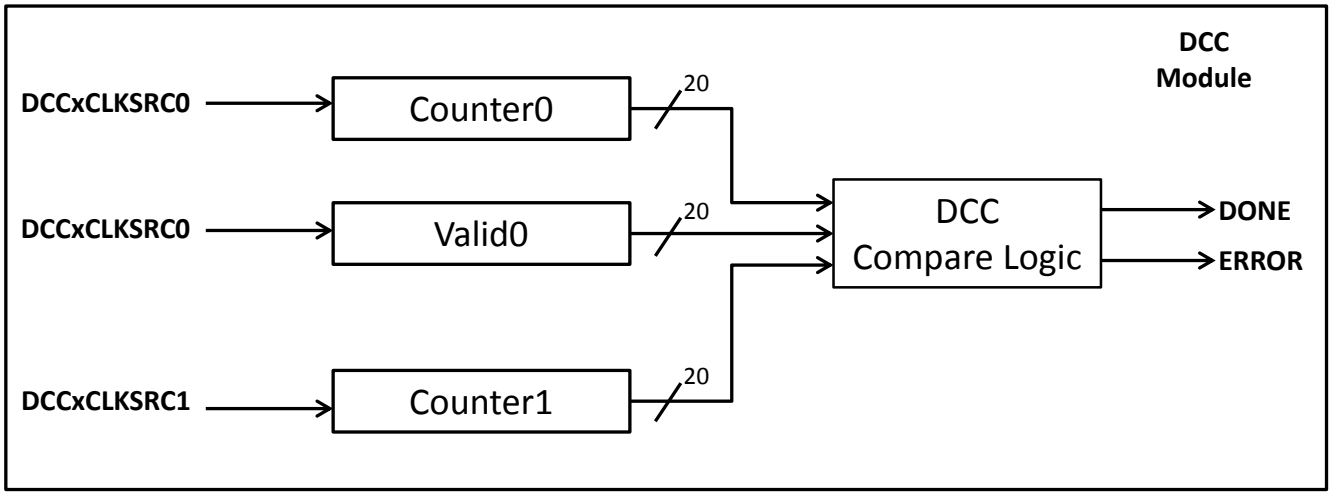

Figure 12-2. DCC Operation

12.2 Module Operation

As shown in Figure 12-2, DCC contains three counters – Counter0, Valid0 and Counter1. Initially, all counters are loaded with the user-defined, pre-load value. Counter0 and Counter1 start decrementing once the DCC is enabled at rates determined by the frequencies of Clock0 and Clock1, respectively. When Counter0 equals 0 (expires), the Valid0 counter decrements at a rate determined by Clock0. If Counter1 decrements to 0 in the valid window, then no error is generated and Clock1 is considered to be good within allowable tolerance as configured by the user.

12.2.1 Configuring DCC Counters

Counter0 and Counter1 are configured based on the ratio between the frequencies of Clock0 and Clock1 (Fclk1 × Counter0 = Fclk0×Counter1). The Valid0 counter provides tolerance and is configured based on the error in DCC. Since Clock0 and Clock1 are asynchronous, the start and stop of the counters do not occur synchronously. Hence, while configuring the counters, two different sources of errors must be accounted for:

- DCC Errors due to the asynchronous timing of Clock0 and Clock1: this depends on the frequency of Clock0 and Clock1:
  - If Fclk1 > Fclk0, then Async. Error (in Clock0 cycles) = 2 + 2 × (Fsysclk/Fclk0)
  - If Fclk1 < Fclk0, then Async. Error (in Clock0 cycles) = 2 × (Fclk0/Fclk1) + 2 × (Fsysclk/Fclk0)
  - If Fclk1 is unknown, then Async. Error (in Clock0 cycles) = 2 + 2 × (Fsysclk/Fclk0)
- Digitization Error = 8 Clock0 cycles

DCC Error (in Clock0 Cycles) = Async. Error + Digitization Error

DCC error shows up as a frequency error for clock under measurement. This error is DCC induced and does not represent error in frequency of clock under measurement. The application needs to take this into consideration while configuring the counters, and determine a desirable tolerance for DCC error that defines the window of measurement. To illustrate:

Window (in Clock0 Cycles) = (DCC Error)/(0.01 × Tolerance)

For example, if DCC Error is 10 and the tolerance desired is ±0.1%, then:

Window (in Clock0 Cycles) = 10/(0.01 × 0.1) = 10000

Based on above formula for Window, if the desired tolerance is low, then the counter values are large and increase the window of measurement. This means that counter values for a tolerance of 0.1% are larger than that of 0.2%. So, based on the application defined tolerance, define the window of measurement in terms of Clock0 cycles.

The clock under measurement can have an allowed frequency error. If this error is expected, then the error can also be accounted while configuring counters. For example, if measuring INTOSC1/2 frequency using an external crystal as a reference clock, the allowable tolerance of INTOSC1/2 (for example, ±1%) can be accounted for and factored into the counter configuration. The formula is:

Frequency Error Allowed (in Clock0 Cycles) = Window × (Allowable Frequency Tolerance (in %) / 100)

Total Error (in Clock0 Cycles) = DCC Error + Frequency Error Allowed

The following equations are used to configure counter values:

Counter0 (DCCCNTSEED0) = Window - Total Error

Valid0 (DCCVALIDSEED0) = 2 × Total Error

Counter1 (DCCCNTSEED1) = Window × (Fclk1/Fclk0)

Note

Counter1 is a 20-bit counter, so the maximum possible value cannot exceed 1048575. If the value does exceed, then increase the desired Tolerance for DCC error, so that Window of measurement is lowered. The following formula can be used to compute minimum tolerance possible:

Tolerance (%) = (100 × DCC Error × (Fclk1/Fclk0)) / 1048575

12.2.2 Single-Shot Measurement Mode

The DCC module can be programmed to count down one time by enabling the single-shot mode. In this mode, the DCC stops operating when the down counter0 and the valid counter0 reach 0.

At the end of one sequence of counting down in this single-shot mode, the DCC gets disabled automatically, which prevents further counting. This mode is typically used for spot-checking the frequency of a signal.

Example-1: Validating PLLRAWCLK frequency

A practical example of the usage is to validate the PLL output clock frequency using the XTAL as the reference clock. Assume XTAL is 10MHz, PLL output frequency is 100MHz, SYSCLK is 100MHz, allowable Frequency Tolerance is 0.1%, and DCC Tolerance required is 0.1%. The measurement sequence proceeds as follows:

- Set Clock0 source for Counter0 and Valid0 as XTAL, and Clock1 source for Counter1 as PLL output clock.
- Based on the equations defined in Section 12.2.1, calculated seed values for Counters can be Counter0 = 29940; Valid0 = 120; Counter1 = 300000
- Once the DCC is enabled, the counters Counter0 and Counter1 both start counting down from the seed values.
- When Counter0 reaches zero, Counter0 automatically triggers the Valid0 counter.
- When Valid0 reaches zero and Counter1 is not zero, an ERROR status flag is set and a "DCC error" is sent to the Interrupt Controller. Counter1 is frozen so that the counter stops counting down any further. The application can enable an interrupt to be generated from the Interrupt Controller whenever this DCC error is indicated.
- The application then needs to clear the ERROR status flag and restart the DCC module so that the module is ready for the next spot measurement.

If there is no error generated at the end of the sequence, then the DONE status flag is set and a DONE interrupt is generated. The application must clear the DONE flag before restarting the DCC.

Error Conditions:

An error condition is generated by any one of the following:

1. Counter1 counts down to 0 before Counter0 reaches 0. This means that Clock1 is faster than expected, or Clock0 is slower than expected. This error includes the case when Clock0 is stuck at 1 or 0.
2. Counter1 does not reach 0 even when Counter0 and Valid0 have both reached 0. This means that Clock1 is slower than expected. This error includes the case when Clock1 is stuck at 1 or 0.

Any error freezes the counters from counting. An application can then read out the counter values to help determine what caused the error.

Example-2: Measuring AUXCLKIN frequency

Another example of single-shot mode is to measure the frequency of AUXCLKIN (unknown frequency) using INTOSC1 (10MHz) as the reference clock and SYSCLK is 10MHz. The measurement sequence proceeds as follows:

- Set Clock0 source for Counter0 and Valid0 as INTOSC1 (10MHz), and Clock1 source for Counter1 as AUXCLKIN.
- Now configure counter values using equations in Section 12.2.1. For tolerance = ±0.1%, Total Error = 10 clock0 cycles; Window = 10000 clock0 cycles; Counter0 = 9990; Valid0 = 20. Since Clock1 frequency (Fclk1) is unknown, the Counter1 value can be set to the maximum value, 1048575 (0xFFFFF).
- Once the DCC is enabled, the counters Counter0 and Counter1 both start counting down from the seed values.
- Since Counter1 is set to the maximum value, 1048575, the counter does not expire when Counter0 and Valid0 have expired. This generates an error that is expected and the application ignores this error and uses Counter1 values to compute the frequency of Clock1 (Fclk1).
- Knowing the frequency of Clock0 (INTOSC1), Fclk0 = 10MHz, and using Equation 1, the frequency of AUXCLKIN, Fclk1, can be measured:

$$Fclk1 = \frac{Fclk0 \times (1048575 - Meas.Counter1)}{(Counter0 + Valid0)} = \frac{10 \times (1048575 - Meas.Counter1)}{(9990 + 20)} \quad (1)$$

12.2.3 Continuous Monitoring Mode

In this mode, the DCC is used by the application to make sure that two clock signals maintain the correct frequency ratio. Suppose the application wants to make sure that the PLL output signal always maintains a fixed frequency relationship with the XTAL:

- In this case, the application can use the XTAL as the Clock0 signal (for Counter0 and Valid0) and the PLL output as the Clock1 (for Counter1).
- The seed values of Counter0, Valid0 and Counter1 are selected based on the equations defined in Section 12.2.1 such that if the actual frequencies of Clock0 and Clock1 are equal to the expected frequencies, then the Counter1 reaches zero during the count down of the Valid0 counter.
- If the Counter1 reaches zero during the count down of the Valid0 counter, then all the counters (Counter0, Valid0, Counter1) are reloaded with the initial seed values.
- This sequence of counting down and checking then continues as long as there is no error, or until the DCC module is disabled.
- The counters must get reloaded if the application resets and restarts the DCC module.

Error Conditions:

An error condition is generated by one of the following:

1. Counter1 counts down to 0 before Counter0 reaches 0. This means that Clock1 is faster than expected or Clock0 is slower than expected. This condition includes the case when Clock0 is stuck at 1 or 0.
2. Counter1 does not reach 0 even when Counter0 and Valid0 have both reached 0. This means that Clock1 is slower than expected. This condition includes the case when Clock1 is stuck at 1 or 0.

Any error freezes the counters from counting. An application can then read out the counter values to help determine what caused the error.

12.2.4 Error Conditions

While operating in continuous mode, the counters get reloaded with the seed values and continue counting down under the following conditions:

- The module is reset or restarted by the application, OR
- Counter0, Valid 0, and Counter1 all reach 0 without any error.

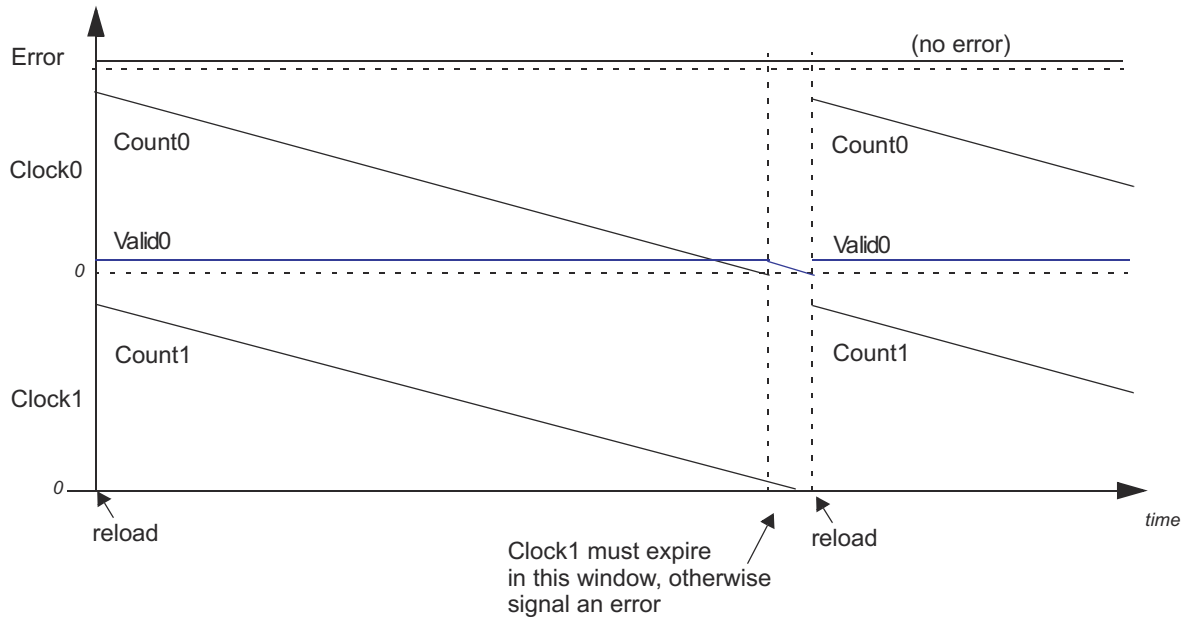

Figure 12-3. Counter Relationship

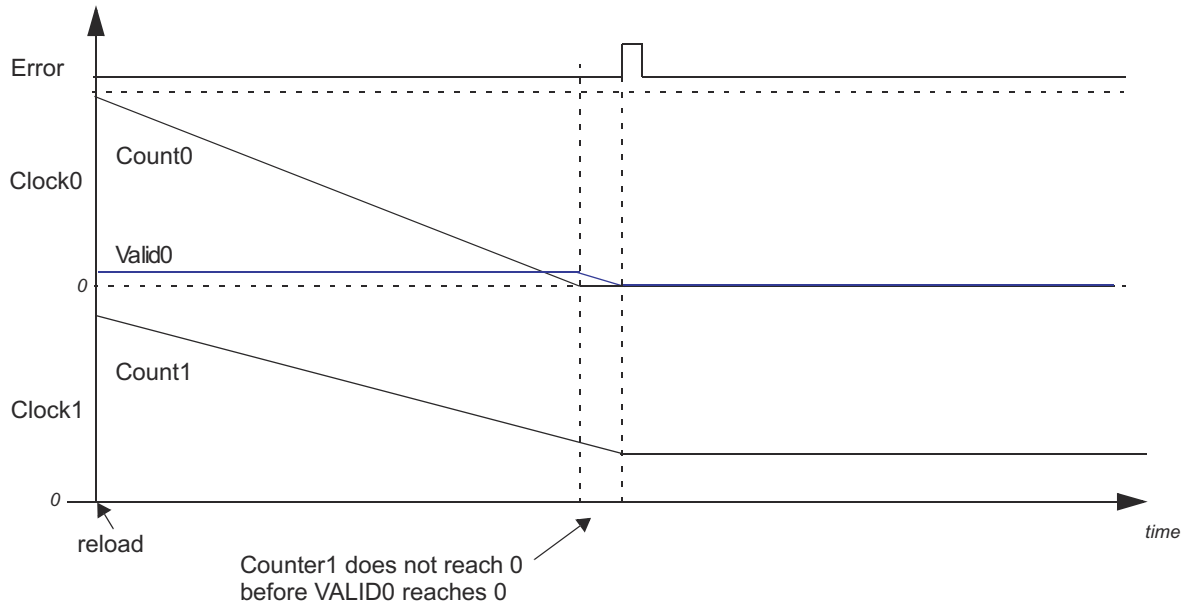

Figure 12-4. Clock1 Slower Than Clock0 - Results in an Error and Stops Counting

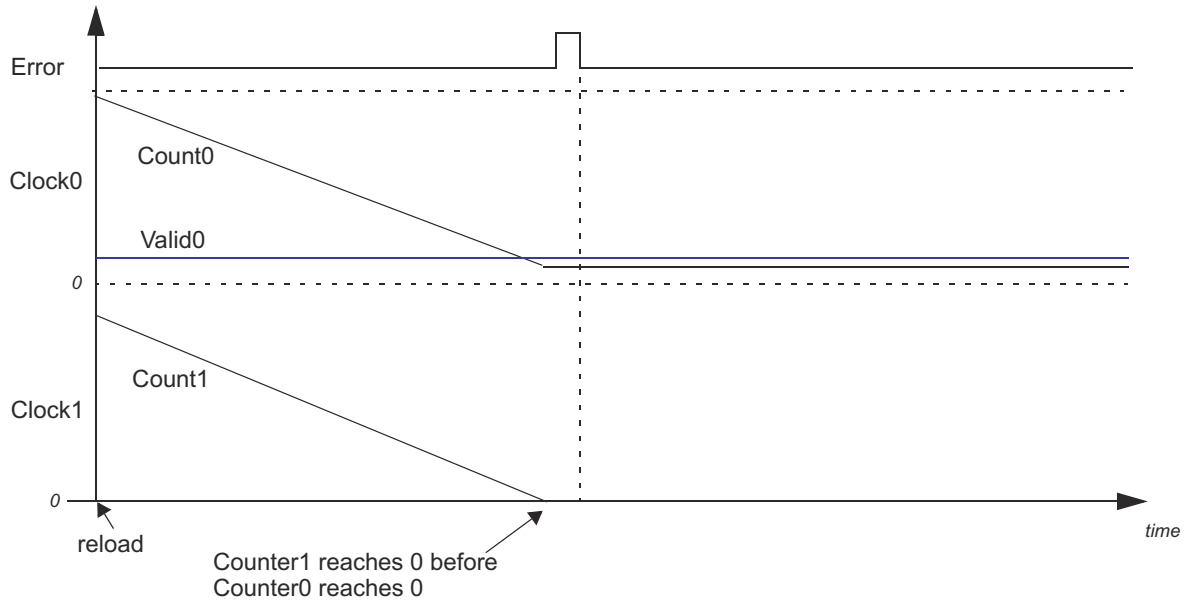

Figure 12-5. Clock1 Faster Than Clock0 - Results in an Error and Stops Counting

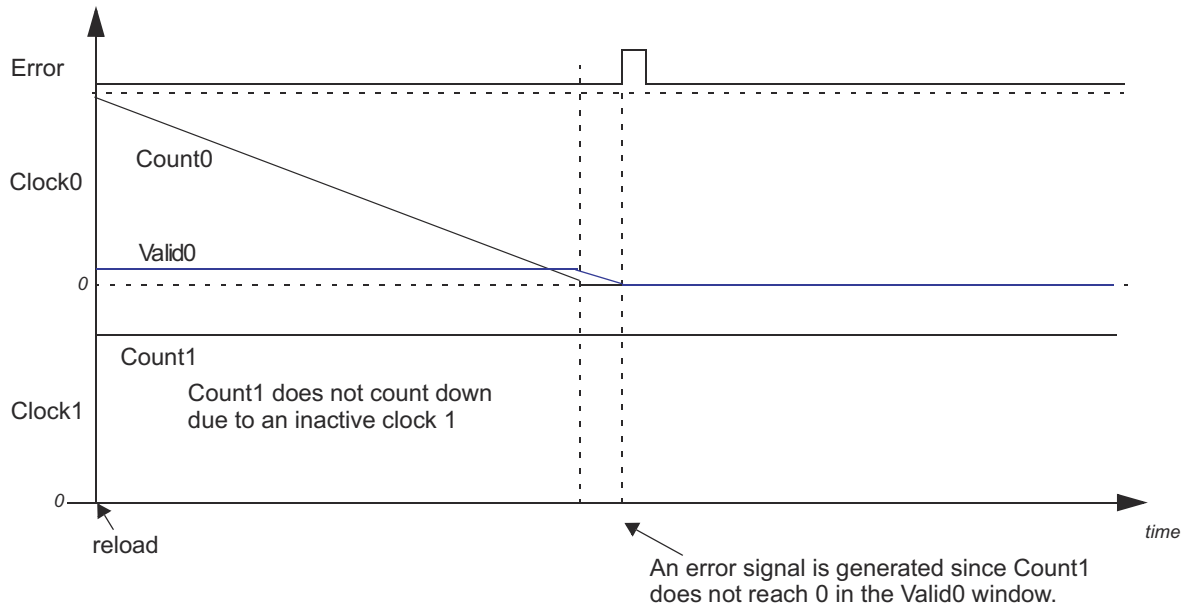

Figure 12-6. Clock1 Not Present - Results in an Error and Stops Counting

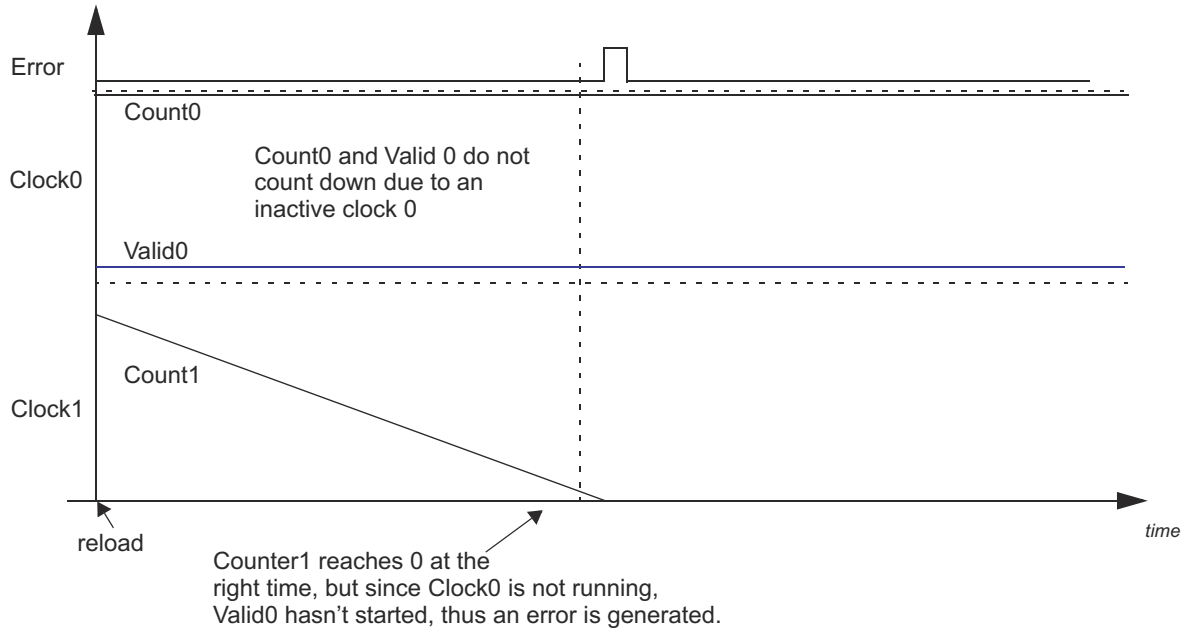

Figure 12-7. Clock0 Not Present - Results in an Error and Stops Counting

12.3 Interrupts

DCC generates an interrupt on either of two events:

- DCC finishes counting and all the counters expire within a defined window indicating DONE operation, provided DCCGCTRL.DONENA = 1.
- DCC finishes counting with error where counters do not expire in a defined window. This indicates an ERROR event, and sets an interrupt provided DCCGCTRL.ERRENA = 1.

Interrupts generated by DONE or ERROR events are ORed and flagged as a DCCn_DONE or DCCn_ERROR interrupt, respectively. Refer to PIPE Channel Mapping table in the *System Control and Interrupts* chapter determine the interrupt channel mapping. The application interrupt service routine needs to check the status flag inside the DCCSTATUS register to determine whether the interrupt is due to ERROR or DONE.

12.4.2 DCC Examples

NOTE: These examples are located in the C29SDK installation from ti.com at the following location: mcu_sdk_DEVICE_GPN/examples/driverlib/CORE_IF_MULTICORE/dcc

Cloud access to these examples is available at the following link: dev.ti.com C29SDK Examples.

12.4.2.1 DCC Single shot Clock verification - SINGLE_CORE

FILE: dcc_ex1_single_shot_verification.c

This program uses the XTAL oscillator as a reference clock to verify the frequency of the PLL.

The Dual-Clock Comparator Module 1 is used for the clock verification. The clocksource0 is the reference clock (Fclk0 = 25Mhz) and the clocksource1 is the clock that needs to be verified (Fclk1 = 200Mhz). Seed is the value that gets loaded into the Counter.

Please refer to the TRM for details on counter seed values to be set.

External Connections

- None

Watch Variables

- *result* - Status of the clock verification

12.4.2.2 DCC Single shot Clock measurement - SINGLE_CORE

FILE: dcc_ex2_single_shot_measurement.c

This program demonstrates Single Shot measurement of the INTOSC1 clock post trim using XTAL as the reference clock.

The Dual-Clock Comparator Module 1 is used for the clock measurement. The clocksource0 is the reference clock (Fclk0 = 25Mhz) and the clocksource1 is the clock that needs to be measured (Fclk1 = 10Mhz). Since the frequency of clock1 needs to be measured, an initial seed is set to the max value of the counter.

Please refer to the TRM for details on counter seed values to be set.

External Connections

- None

Watch Variables

- *result* - Status if the INTOSC1 clock measurement completed successfully.
- *meas_freq1* - measured clock frequency, in this case for INTOSC1.

12.4.2.3 DCC Continuous clock monitoring - SINGLE_CORE

FILE: dcc_ex3_continuous_monitoring_of_clock.c

This program demonstrates continuous monitoring of PLL Clock in the system using INTOSC1 as the reference clock. This would trigger an error signal on any error, causing the decrement/ reload of counters to stop. The Dual-Clock Comparator Module 1 is used for the clock monitoring. The clocksource0 is the reference clock (Fclk0 = 10Mhz) and the clocksource1 is the clock that needs to be monitored (Fclk1 = 200Mhz). The clock0 and clock1 seed are set automatically by the error tolerances defined in the sysconfig file included in this project. For the sake of demo an un-realistic tolerance is assumed to generate an error on continuous monitoring.

Please refer to the TRM for details on counter seed values to be set. Note : When running in flash configuration it is good to do a reset & restart after loading the example to remove any stale flags/states.

External Connections

- None

Watch Variables

- *result* - Status of the PLLRAW clock monitoring
- *cnt0* - Counter0 Value measure when error is generated
- *cnt1* - Counter1 Value measure when error is generated
- *valid* - Valid0 Value measure when error is generated
- *esm0IntCount* - Indication that ESM Low Priority Int ISR is entered
- *highestIntr* - ESM Global event number of the highest priority outstanding low priority interrupt that is pending - corresponds to DCCx_ERR for this example

12.5 DCC Registers

This section describes the DCC Registers.

12.5.1 DCC Base Address Table

Table 12-2. DCC Base Address Table

Structure	DriverLib Name	Base Address	Frame Applicable	CPU1	CPU2	CPU3	RTDMA1	RTDMA2	HSM	Pipeline Protected
DCC_REGS	DCC1_BASE	0x6008_0000	YES	YES	YES	YES	YES	YES	-	YES
DCC_REGS	DCC2_BASE	0x6008_1000	YES	YES	YES	YES	YES	YES	-	YES
DCC_REGS	DCC3_BASE	0x6008_2000	YES	YES	YES	YES	YES	YES	-	YES

12.5.2 DCC_REGS Registers

Table 12-3 lists the memory-mapped registers for the DCC_REGS registers. All register offset addresses not listed in Table 12-3 should be considered as reserved locations and the register contents should not be modified.

Table 12-3. DCC_REGS Registers

Offset	Acronym	Register Name	Protection
0h	DCCGCTRL	Starts / stops the counters. Clears the error signal.	
8h	DCCCNTSEED0	Seed value for the counter attached to Clock Source 0.	
Ch	DCCVALIDSEED0	Seed value for the timeout counter attached to Clock Source 0.	
10h	DCCCNTSEED1	Seed value for the counter attached to Clock Source 1.	
14h	DCCSTATUS	Specifies the status of the DCC Module.	
18h	DCCCNT0	Value of the counter attached to Clock Source 0.	
1Ch	DCCVALID0	Value of the valid counter attached to Clock Source 0.	
20h	DCCCNT1	Value of the counter attached to Clock Source 1.	
24h	DCCCLKSRC1	Selects the clock source for Counter 1.	
28h	DCCCLKSRC0	Selects the clock source for Counter 0.	

Complex bit access types are encoded to fit into small table cells. Table 12-4 shows the codes that are used for access types in this section.

Table 12-4. DCC_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
R-1	R -1	Read Returns 1s
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value

12.5.2.1 DCCGCTRL Register (Offset = 0h) [Reset = 00005555h]

DCCGCTRL is shown in Figure 12-8 and described in Table 12-5.

Return to the Summary Table.

Starts / stops the counters. Clears the error signal.

Chapter 13

Real-Time Direct Memory Access (RTDMA)

The Real-Time Direct Memory Access (RTDMA) module provides a hardware method of transferring data between peripherals and memory without intervention from the CPU; thereby, freeing up bandwidth for other system functions. Additionally, the RTDMA has the capability to orthogonally rearrange the data as the data is transferred as well as “ping-pong” data between buffers. These features are useful for structuring data into blocks for CPU processing.

13.1 Introduction

The strength of a controller is not measured purely in processor speed, but in total system capabilities. As a part of the equation, any time the CPU bandwidth for a given function can be reduced, the greater the system capabilities. Many times applications spend a significant amount of their bandwidth moving data, whether moving data from off-chip memory to on-chip memory, from a peripheral such as an analog-to-digital converter (ADC) to RAM, or from one peripheral to another. Furthermore, many times this data comes in a format that is not conducive to the optimal processing powers of the CPU. The RTDMA module described in this chapter has the ability to free up CPU bandwidth and rearrange the data into a pattern for more streamlined processing in real time.

The RTDMA module is an event-based machine, meaning the RTDMA module requires a peripheral, channel, or software trigger to start a RTDMA transfer. The RTDMA module can be made into a periodic time-driven machine by configuring a timer as the RTDMA trigger source as well as utilizing the channels within the module itself to start memory transfers periodically. The RTDMA module has ten independent RTDMA channels that can be configured separately, and each channel contains their own independent Interrupt Controller interrupt to let the CPU know when a RTDMA transfer has either started or completed. All ten channels can be configured at one of four priority levels with one selected channel at a higher priority than the others. At the heart of the RTDMA is a state machine and tightly coupled address control logic. This address control logic allows for rearrangement of the block of data during the transfer as well as the process of ping-ponging data between buffers. Each of these features is discussed in detail in this chapter.

13.1.1 Features

RTDMA features include:

- 10 RTDMA channels with software configurable priority levels and independent Interrupt Controller interrupts
- Up to 256 hardware trigger sources to initiate RTDMA transfers
- Internal trigger generation for data transfers and trigger sources for channels
- Independent Read and Write buses
- Word Size: 8-bit, 16-bit, 32-bit, and 64-bit transfers
- Throughput: 1 cycle/word after the initial read-write access with 0 cycle read/write stall
- FIFO implemented within hardware to optimize data transfers
- Linear and circular addressing modes
- Support for multiple data transformation functions as data is transferred from source to destination
  - Ability to reverse words, half words, and so on.
- Burst Mode Support (for transfers with EMIF)
- Access protection through the Memory Protection Unit (MPU)

13.3 RTDMA Bus

The RTDMA bus architecture consists of a 32-bit address bus, a 64-bit data read bus, and a 64-bit data write bus. Memories and register locations connected to the RTDMA bus by way of interfaces that sometimes share resources with the CPU memory or peripheral bus.

Note

RTDMA allows RD and WR ports to have different size configurations. DATASIZE (of the RD port) must always be configured as an integral multiple of WR_DATASIZE configuration. It is still recommended to keep the RD and WR ports to have the same size configurations.

- EX: If DATASIZE_64, WR_DATASIZE can be configured as WR_DATASIZE_64, WR_DATASIZE_32, WR_DATASIZE_16, or WR_DATASIZE_8.

Refer to the device memory map for the complete list of allowed peripheral and memory accesses with the RTDMA.

13.4 Address Pointer and Transfer Control

The RTDMA state machine is, at the most basic level, two nested loops.

Burst (Inner) Loop:

The burst (inner) loop transfers a programmable number of bytes set by (BURST_SIZE + 1) register when a RTDMA channel trigger (Peripheral or Software trigger) is received. The BURST_SIZE register allows a maximum of 256 bytes to be transferred in one burst. Each RTDMA channel supports 8-bit, 16-bit, 32-bit, or 64-bit bursts that can be controlled by MODE.DATASIZE bit field. Each RTDMA channel contains a shadowed address pointer for the source (SRC_ADDR_SHADOW) and the destination (DST_ADDR_SHADOW) address. At the beginning of each transfer, the shadowed version of each pointer is copied into the respective active (SRC_ADDR_ACTIVE or DST_ADDR_ACTIVE) register. During the burst loop, after each byte is transferred, the signed value contained in the appropriate source or destination BURST_STEP register is added to the active register:

SRC_ADDR_ACTIVE = SRC_ADDR_ACTIVE + SRC_BURST_STEP

DST_ADDR_ACTIVE = DST_ADDR_ACTIVE + DST_BURST_STEP

The burst (inner) loop transfers a burst of data when a RTDMA Channel Trigger (Peripheral or Software trigger) is received.

Transfer (Outer) Loop:

The Transfer (outer) loop transfers a programmable number of bursts set by (TRANSFER_SIZE + 1) register for each channel. Since TRANSFER_SIZE is a 32-bit register, the total size of a transfer allowed is well beyond any practical requirement. During the transfer loop, after each burst is complete, there are two methods that can be used to modify the active address pointer.

Method 1 (Default): When address wrapping is disabled (SRC_WRAP_SIZE or DST_WRAP_SIZE is greater than TRANSFER_SIZE), active address pointer is updated as shown below

SRC_ADDR_ACTIVE = SRC_ADDR_ACTIVE + SRC_TRANSFER_STEP

DST_ADDR_ACTIVE = DST_ADDR_ACTIVE + DST_TRANSFER_STEP

Method 2: Address wrapping gets enabled when SRC_WRAP_SIZE or DST_WRAP_SIZE is less than TRANSFER_SIZE. This allows the channel to wrap multiple times within a single transfer. When the number of bursts is equal to (SRC/DST_WRAP_SIZE + 1) register, the state machine modifies the active address pointers as:

SRC_BEG_ADDR_ACTIVE = SRC_BEG_ADDR_ACTIVE + SRC_WRAP_STEP

DST_BEG_ADDR_ACTIVE = DST_BEG_ADDR_ACTIVE + DST_WRAP_STEP

SRC_ADDR_ACTIVE = SRC_BEG_ADDR_ACTIVE

DST_ADDR_ACTIVE = DST_BEG_ADDR_ACTIVE

At the end of RTDMA transfer, RTDMA can have transferred (BURST_SIZE + 1) x (TRANSFER_SIZE + 1) words.

Note

The RD and WR ports can be configured with different data sizes, make sure reads and writes are happening properly.

OneShot Mode:

Note

The OneShot mode can create a condition where one trigger uses up the majority of the RTDMA bandwidth and causes long CPU stalls. It is recommended to configure a CPU timer (or similar) and disable ONESHOT to avoid this situation.

The OneShot mode must not be used with channels configured with a priority of 0.

OneShot mode is disabled by default.

When OneShot mode is disabled (MODE.CHx[ONESHOT] = 0), RTDMA transfers one burst [(BURST_SIZE + 1) bytes] of data each time a RTDMA Channel Trigger is received until (TRANSFER_COUNT = 0). After the burst is completed, the state machine moves on to the next pending channel in the priority scheme, even if another trigger for the channel just completed is pending. This feature keeps any single channel from monopolizing the RTDMA bus.

When OneShot mode is enabled (MODE.CHx[ONESHOT] = 1), RTDMA transfers all the bursts [(BURST_SIZE + 1) x (TRANSFER_SIZE + 1) words] on a single RTDMA channel trigger until (TRANSFER_COUNT = 0).

Continuous Mode:

Continuous mode is disabled by default.

When Continuous mode is disabled (MODE.CHx[CONTINUOUS] = 0), RTDMA state machine disables channel after all bursts in a transfer loop (TRANSFER_COUNT = 0) are complete. The channel stops and the RUNSTS bit is cleared. The channel must be re-enabled by setting the RUN bit in the CONTROL register before another transfer can be started on that channel.

When Continuous mode is enabled (MODE.CHx[CONTINUOUS] = 1), RTDMA state machine keep channel active even after all bursts in a transfer loop (TRANSFER_COUNT = 0) are complete.

Each RTDMA channel can trigger an Interrupt Controller interrupt for each RTDMA transfer either at start of RTDMA transfer or end of RTDMA transfer using MODE.CHx[CHINTMODE] bit.

When an RTDMA channel receives a peripheral event trigger, the PERINTFLG bit in the CONTROL register is set, pending enabling of the channel to the RTDMA state machine. To initiate an RTDMA event using software, setting the PERINTFRC bit forces an event.

Source/Destination Address Pointers (SRC/DST_ADDR)

The value written into the shadow register is the start address of the first location where data is read or written to.

At the beginning of a transfer the shadow register (SRC/DST_ADDR_SHADOW) is copied into the active register (SRC/DST_ADDR_ACTIVE). The active register performs as the current address pointer.

Source/Destination Begin Address Pointers (SRC/DST_BEG_ADDR)

This is the wrap pointer.

The value written into the shadow register (SRC/DST_BEG_ADDR_SHADOW) is loaded into the active register (SRC/DST_BEG_ADDR_ACTIVE) at the start of a transfer. On a wrap condition, the active register (SRC/DST_BEG_ADDR_ACTIVE) is incremented by the signed value in the appropriate SRC/DST_WRAP_STEP register prior to being loaded into the active register ((SRC/DST_ADDR_ACTIVE).

For each channel, the transfer process can be controlled with the following size values:

Source and Destination Burst Size (BURST_SIZE)

This specifies the number of bytes to be transferred in a burst.

This value is loaded into the BURST_COUNT register at the beginning of each burst. The BURST_COUNT decrements each byte that is transferred and when the register reaches a zero value, the burst is complete, indicating that the next channel can be serviced. The behavior of the current channel is defined by the ONE_SHOT bit in the MODE register. The maximum size of the burst is dictated by the type of peripheral. For the ADC, the burst size can be all 32 registers (if all 32 registers are used). For RAM, the burst size can be up to the maximum allowed by the BURST_SIZE register, which is 256. See Table 13-2 to understand how BURST_SIZE register affects the number of bytes transferred with respect to DATASIZE.

Table 13-2. BURSTSIZE versus DATASIZE Behavior

<table>
<tr><th rowspan="2">BURSTSIZE</th><th colspan="4">Number of Bytes Transferred in</th></tr>

<tr><td>254</td><td>255</td><td rowspan="2">256</td><td rowspan="2">256</td></tr>
<tr><td>255</td><td>256</td></tr>
</table>

In other words, BURSTSIZE has to be configured as a multiple of DATASIZE. The following configurations are the only allowed options:

	DATASIZE = 8-bit n = 1	DATASIZE = 16-bit n = 2	DATASIZE = 32-bit n = 4	DATASIZE = 64-bit n = 8
BURSTSIZE	n - 1	2n - 1	4n - 1	8n - 1

Source and Destination Transfer Size (TRANSFER_SIZE)

This specifies the number of bursts to be transferred per CPU interrupt (if enabled).

Whether this interrupt is generated at the beginning or the end of the transfer is defined in the CHINTMODE bit in the MODE register. Whether the channel remains enabled or not after the transfer is completed is defined by the CONTINUOUS bit in the MODE register. The TRANSFER_SIZE register is loaded into the TRANSFER_COUNT register at the beginning of each transfer. The TRANSFER_COUNT register keeps track of how many bursts of data the channel has transferred and when the register reaches zero, the RTDMA transfer is complete.

Source/Destination Wrap Size (SRC/DST_WRAP_SIZE)

This specifies the number of bursts to be transferred before the current address pointer wraps around to the beginning.

This feature is used to implement a circular addressing type function. This value is loaded into the appropriate SRC/DST_WRAP_COUNT register at the beginning of each transfer. The SRC/DST_WRAP_COUNT registers keep track of how many bursts of data the channel has transferred and when the registers reach zero, the wrap procedure is performed on the appropriate source or destination address pointer. A separate size and count register is allocated for source and destination pointers. To *disable* the wrap function, assign the value of these registers to be larger than the TRANSFER_SIZE.

Note

The values written to the BURST_SIZE and TRANSFER_SIZE registers are one less than the intended size. To transfer three 8-bit words in one transfer, the value 2 can be placed in the BURST_SIZE and the value 0 can be placed in the TRANSFER_SIZE registers. To transfer three 16-bit words in one transfer, the value 5 can be placed in the BURST_SIZE and the value 0 can be placed in the TRANSFER_SIZE registers.

Regardless of the state of the DATASIZE bit, the value specified in the STEP registers are for 8-bit addresses. So, to transfer one 32-bit word, a value 4 can be placed in these registers.

For each source/destination pointer, the address changes can be controlled with the following step values:

Source/Destination Burst Step (SRC/DST_BURST_STEP)

Within each burst transfer, the address source and destination step sizes are specified by these registers.

This value is a signed 2s compliment number so that the address pointer can be incremented or decremented as required. If no increment is desired, such as when accessing the data receive or transmit registers in a communication peripheral, the value of these registers can be set to zero.

Source/Destination Transfer Step (SRC/DST_TRANSFER_STEP)

This specifies the address offset to start the next burst transfer after completing the current burst transfer.

This is used in cases where registers or data memory locations are spaced at constant intervals. This value is a signed 2s compliment number so that the address pointer can be incremented or decremented as required.

Source/Destination Wrap Step (SRC/DST_WRAP_STEP)

When the wrap counter reaches zero, this value specifies the number of words to add/subtract from the SRC/DST_BEG_ADDR pointer and hence sets the new start address.

This implements a circular type of addressing mode, useful in many applications. This value is a signed 2s compliment number so that the address pointer can be incremented or decremented as required.

Note

Regardless of the state of the DATASIZE bit, the value specified in the STEP registers are for 16-bit addresses. So, to increment one 32-bit address, a value of 4 can be placed in these registers.

Channel Interrupt Mode (CHINTMODE)

This mode bit selects whether the RTDMA interrupt from the respective channel is generated at the beginning of a new transfer or at the end of the transfer.

If implementing a ping-pong buffer scheme with continuous mode of operation, then the interrupt can be generated at the beginning, just after the working registers are copied to the shadow set. If the RTDMA does not operate in continuous mode, then the interrupt is typically generated at the end when the transfer is complete.

All of the previous features and modes are shown in Figure 13-2. The following items are in reference to Figure 13-2.

- The *HALT* points represent where the channel halts operation when interrupted by a high priority channel trigger, or when the HALT command is set, or when an emulation halt is issued and the FREE bit is cleared to 0.
- The SRC/DST_ADDR_ACTIVE registers are not affected by SRC/DST_BEG_ADDR_ACTIVE at the start of a transfer. SRC/DST_BEG_ADDR_ACTIVE only affects the SRC/DST_ADDR_ACTIVE registers on a wrap. Following is what happens when a transfer first starts:
  - SRC/DST_BEG_ADDR_SHADOW remains unchanged.
  - SRC/DST_ADDR_SHADOW remains unchanged.
  - SRC/DST_BEG_ADDR_ACTIVE = SRC/DST_BEG_ADDR_SHADOW
  - SRC/DST_ADDR_ACTIVE = SRC/DST_ADDR_SHADOW
- The active registers get updated when a wrap occurs. The shadow registers remain unchanged. Specifically:
  - SRC/DST_BEG_ADDR_SHADOW remains unchanged.
  - SRC/DST_ADDR_SHADOW remains unchanged.
  - SRC/DST_BEG_ADDR_ACTIVE += SRC/DST_WRAP_STEP
  - SRC/DST_ADDR_ACTIVE = SRC/DST_BEG_ADDR_ACTIVE
- The best way to remember this is:
  - The shadow registers never change except by software.
  - The active registers never change except by hardware, and a shadow register is only copied into the active register, never an active register by another name.

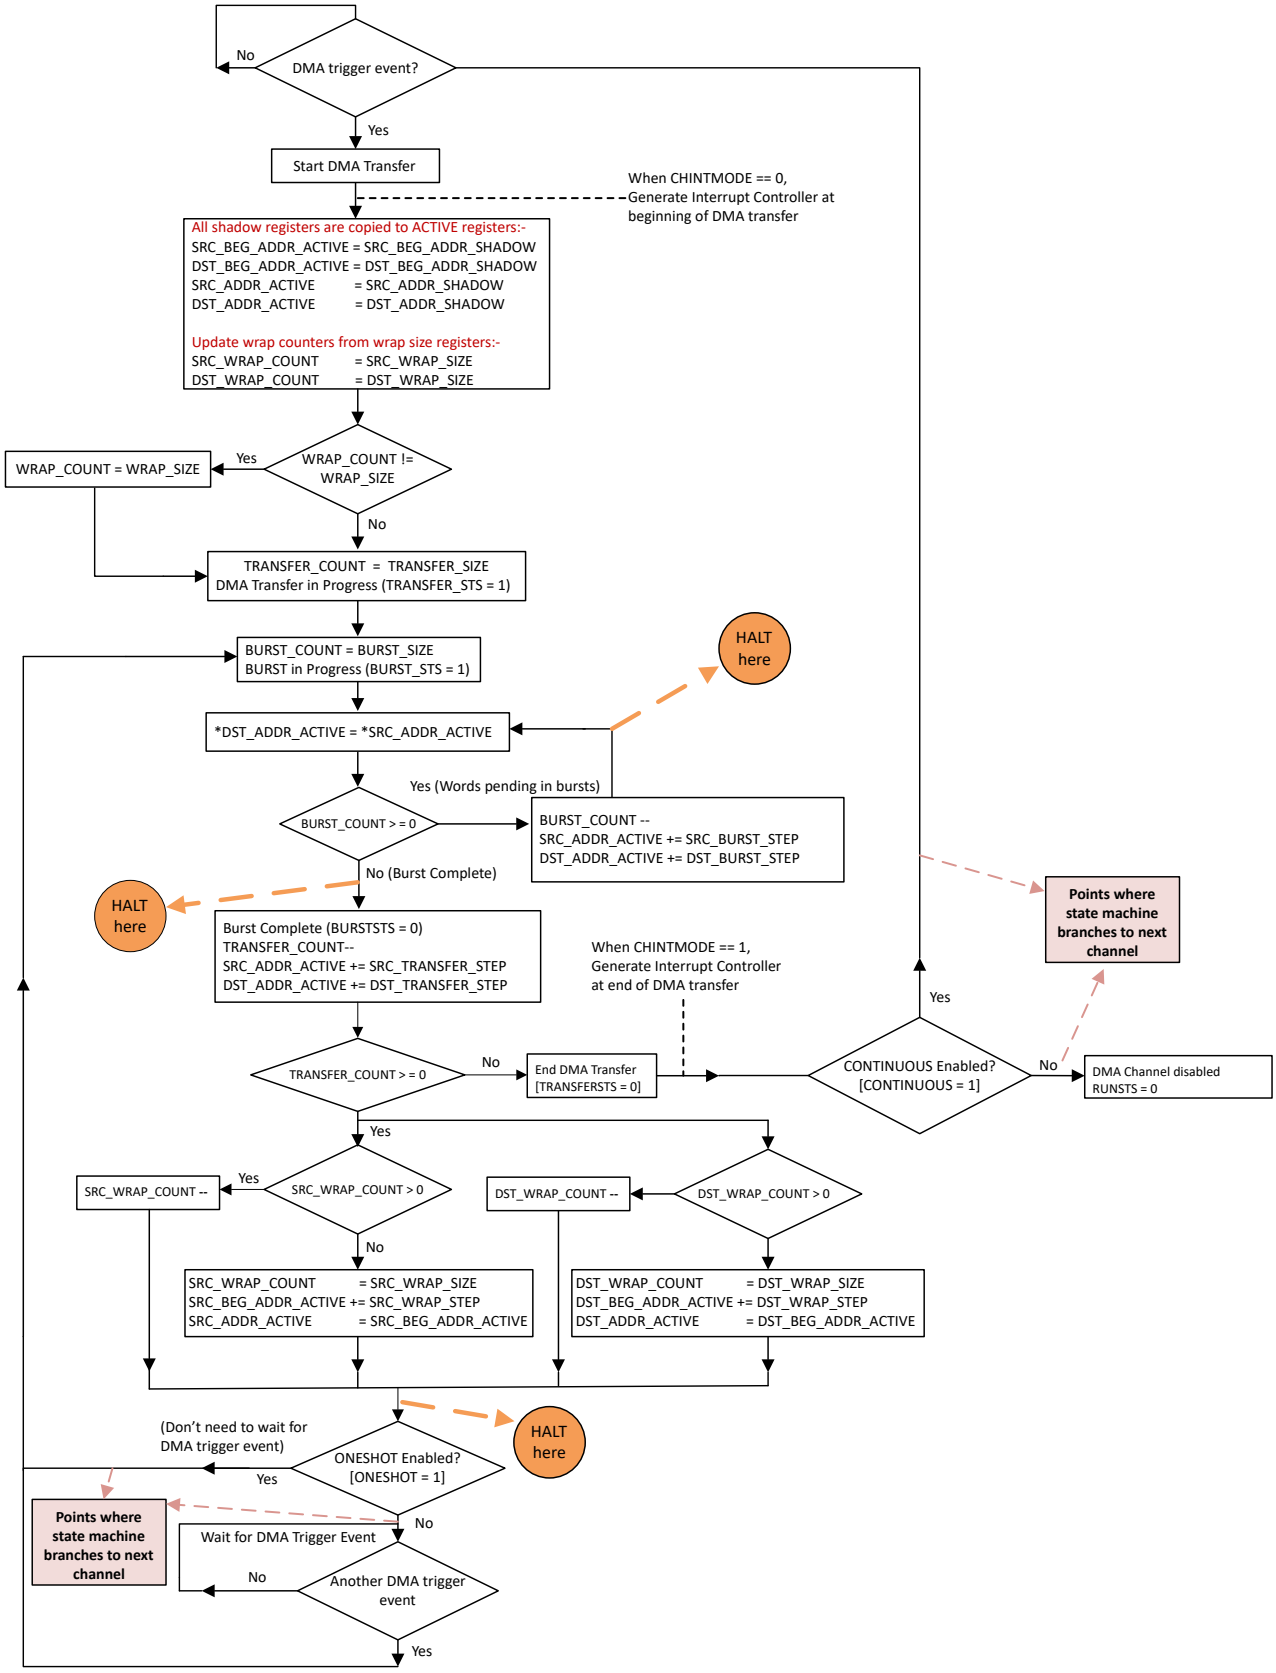

Figure 13-2. RTDMA State Diagram

13.5 Pipeline Timing and Throughput

In addition to the pipeline there are a few other behaviors of the RTDMA that affect the total throughput:

- A 1-cycle delay is added between bursts of different channels.
- A 1-cycle delay is added when a burst is interrupted by a channel with priority equal to 0.
- A 1-cycle delay is added when a burst is interrupted by a CPU suspend or the HALT bit.
- The last cycle does not require an extra cycle delay.
- 32-bit transfers run at double the speed of a 16-bit transfer (takes the same amount of time to transfer a 32-bit word as to transfer a 16-bit word).

For example, to transfer 128 16-bit words from LDA0 RAM to LDA3 RAM, a channel can be configured to transfer 8 bursts of 16 words/burst. The transfer can take:

1 burst × 4 cycles/word + 7 bursts × [(16 cycles/word × 1 words/burst + 1 cycles/word × 1 words/burst) + 1] = 139 cycles

If instead the channel were configured to transfer the same amount of data 32 bits at a time (the word size is configured to 32 bits), the transfer can take:

1 burst × 4 cycles/word + 7 bursts × [(8 cycles/word × 1 words/burst + 1 cycles/word × 1 words/burst) + 1] = 139 cycles

The RTDMA module consists of a 3-stage pipeline as shown in Figure 13-3, Figure 13-4, Figure 13-5, and Figure 13-6.

Note

These diagrams refer to peripherals that are edge triggered. For peripherals that are level triggered, the next arbitration happens only after the last write of the previous burst is complete.

13.6 Channel Priority

The priority of the RTDMA channels is configurable in two modes:

13.6.1 Round-Robin Mode

In this mode, all channels have *equal* priority and each enabled channel is serviced in round-robin fashion as follows:

CH1 → CH2 → CH3 → CH4 → CH5 → ... → CH10 → CH1 → CH2 → …

In the case above, after each channel has transferred a burst of bytes, the next channel is serviced. The user can specify the size of the burst for each channel. Once CH10 (or the last enabled channel) has been serviced, and no other channels are pending, the round-robin state machine remains in the current state. The round-robin state machine enters an idle state only when there a priority, hard, or system reset is executed.

From the idle state, channel 1 (if enabled) is always serviced first. However, if the RTDMA is currently processing another channel x, all other pending channels between x and the end of the round are serviced before CH1. All the channels are of *equal* priority. For instance, take an example where CH1, CH4, and CH5 are enabled in round-robin mode and CH4 is currently being processed. Then CH1 and CH5 both receive an interrupt trigger from their respective peripherals before CH4 completes. CH1 and CH5 are now both pending. When CH4 completes the burst, CH5 is serviced next. Only after CH5 completes is CH1 serviced. Upon completion of CH1, if there are no more channels pending, the round-robin state machine enters an idle state.

A more complicated example is:

- Assume all channels are enabled, and the RTDMA is in an idle state,
- Initially a trigger occurs on CH1, CH3, and CH5 on the same cycle,
- When the CH1 burst transfer starts, requests from CH3 and CH5 are pending,
- Before completion of the CH1 burst, the RTDMA receives a request from CH2. Now the pending requests are from CH2, CH3, and CH5,
- After completing the CH1 burst, CH2 is serviced since this channel is next in the round-robin scheme after CH1.
- After the burst from CH2 is finished, the CH3 burst is serviced, followed by CH5 burst.
- Now while the CH5 burst is being serviced, the RTDMA receives a request from CH1, CH3, and CH6.
- The burst from CH6 starts after the completion of the CH5 burst, since this channel is the next channel after CH5 in the round-robin scheme.
- This is followed by the CH1 burst and then the CH3 burst
- After the CH3 burst finishes, assuming no more triggers have occurred, the round-robin state machine enters an idle state.

The round-robin state machine can be reset to the idle state using the DMACTRL[PRIORITYRESET] bit.

Note

It is recommended to only modify the PRIORITYRESET bit in a reset sequence.

13.6.2 Software Configurable Priority of Channels

In this mode, each of the 10 channels can be set to a software configurable priority of 0 to 3 using the registers SWPRI1 (for channels 1-8) and SWPRI2 (for channels 9-10). The channels can be assigned priority orthogonally, that is, any channel can be set to any priority. The lowest priority number implies highest priority during arbitration. When the same priority number is assigned to multiple channels, during the arbitration, the channel with lowest channel number assigned wins the arbitration. All the channels are set to a default priority of 1.

A channel with PRI = 0 is considered as a special case. In this mode, if a channel with PRI = 0 event occurs, the current word transfer (read then write) on any other channel is completed (not the complete burst) and execution is halted. The channel with PRI = 0 is then serviced for the complete BURST count. When this channel with PRI = 0 burst is complete, execution returns to the channel that was active when the channel with PRI = 0 event occurred. The configuration listed below is one use case of how priority levels can be used to enhance RTDMA operation.

Higher priority:	CH5 (PRI = 0)
Lower priority:	CH3 (PRI = 1) → CH12(PRI = 2) → CH1(PRI = 3 → CH15(PRI = 4) → CH6(PRI = 5) → CH2(PRI = 6) → …

Multiple channels can be configured to be PRI = 0. Another example is when CH1, CH4, and CH5 are enabled in Channel 1 high-priority mode and CH4 is currently being processed. CH1 and CH5 both receive an interrupt trigger from the respective peripherals before CH4 completes. CH1 and CH5 are now both pending. When the current CH4 word transfer is completed, regardless of whether the RTDMA has completed the entire CH4 burst, CH4 execution is suspended and CH1 is serviced. After the CH1 burst completes, CH4 resumes execution.

13.7 Overrun Detection Feature

The RTDMA contains overrun detection logic. When the burst for a channel is started, the PERINTFLG is cleared. If however, between the time that the PERINTFLG bit is set by an event trigger and cleared by the start of the burst, an additional event trigger arrives, and the second trigger is lost. This condition sets the OVRFLG bit in the CONTROL register as in Figure 13-7. If the overrun interrupt is enabled, the channel interrupt is generated to the Interrupt Controller module.

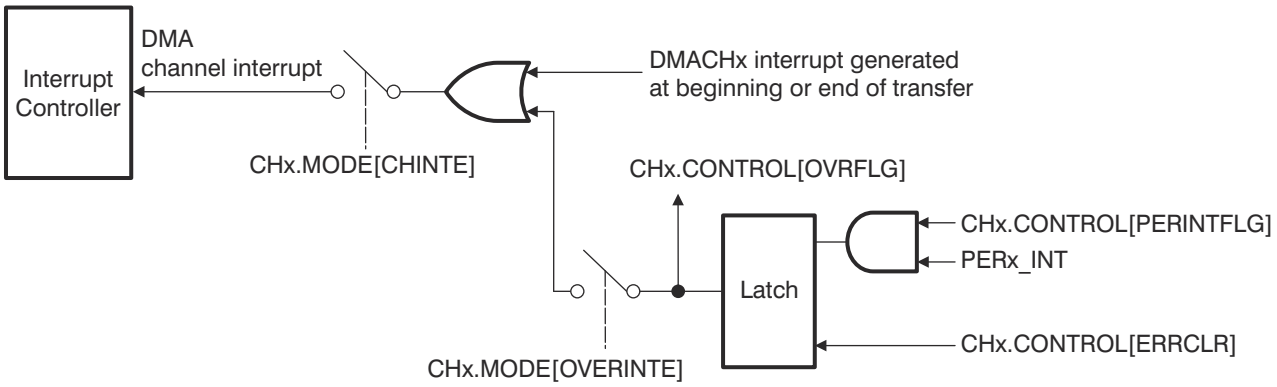

Figure 13-7. Overrun Detection Logic

13.8 Burst Mode

The Real-Time DMA when used with EMIF supports Burst Mode. In this mode, sideband signals are directly connected to the RTDMA RD / WR ports with the bus. These signals identify the bus size and location of the EMIF for which the RTDMA is configured to perform burst writes. By setting this bit as active, the RTDMA is optimized for better performance.

When RTDMA is configured to perform burst writes to the EMIF interface, the transfer size needs to be at least 32-bits. In cases where data size has to be 16-bits in a BURST, the user can first copy the 16-bit data from the source (ex: ADC result) to an SRAM block using a 16-bit access and further move data from the SRAM block to EMIF using 32-bit access . The same concept is applicable where the data size is 8 bits, so the minimum is the transfer size = 4 * DATASIZE.

Note

For best throughput, BURSTSIZE can be configured as a multiple of 4. Burst accesses when BURSTSIZE<4 are treated as normal accesses and not an uninterrupted burst access. Similarly, during an ongoing BURST transaction when BURSTCOUNT reaches < 4 entries, the last transaction is be treated as a normal (non-burst) mode.

Example: If the BURSTSIZE = 10 and DATASIZE = 8 bits, there are 2 burst accesses and the last access with 3 bytes are non-burst access.

Two modes are supported during burst mode operation using the BURST_INTF_CTRL register:

- **Mode 0 (Burst signaling disabled):** Burst Mode is disabled and the RTDMA accesses data as normal.
- **Mode 1 (Reserved)**
- **Mode 2 (Burst signaling enabled):** Burst mode is enabled and cannot be interrupted.

13.9 Safety and Security

The RTDMA has protection mechanisms to provide safety and security for the RTDMA sub-system.

13.9.1 Safety

13.9.1.1 Lockstep Mode

Multiple RTDMA instances can operate in Lockstep to detect faults required to meet safety standards. On a device that supports this configuration, the RTDMA instances are in lockstep by default. In this mode, RTDMA1 individually or RTDMA1/2 in lockstep can be used.CPU3 can configure and service RTDMA independent of CPU1's LPM status (IDLE, STANDBY).

The application can clock gate RTDMA, whether or not the RTDMA is actually operating in lockstep to save power while the CPUx is in lock step configuration and the RTDMA is controlled by the clock enable control (PCLKCR0).

Note

When disabling the default lockstep mode of the device, make sure that the secondary RTDMA instance is in soft reset.

Refer to Chapter 3 and Chapter 5 for information about lockstep settings as well as the device data sheet to see which devices support lockstep.

13.9.1.2 Memory Protection Unit (MPU)

RTDMA has a dedicated, integrated Memory Protection Unit (MPU) which provides memory protection support and prevents illegal accesses. Only the privileged software executing from SROOT (CPU1 LINK2) and CPU1 LINK0/1 can access and define the RTDMA-MPU registers.

The primary function of the MPU is to prevent the RTDMA from accessing regions that are not allocated to the corresponding channels/regions. Key features of the MPU are:

- Associate RTDMA channels to MPU regions.
- Demarcate Read / Write ranges across FLASH, RAM, ROM, and other peripheral memories.
- Detect errors, block access, and trigger an interrupt on any violations.

MPU consists of (16) 4KB regions with individual user-configurable registers to define:

- Start and end addresses
- Read / Write permissions
- Channel Configurations
- Lock / Commit configurations

The region of addresses is set to SROOT only access by the SSU at boot, and these settings cannot be modified by the user afterwards. The start and end addresses (MPUn_RD/WR_START and MPUn_RD/WR_END) are user configurable to any range covering FLASH, RAM, ROM, and the peripherals. MPUn_CHMASK register is used to set association of channels to MPU regions. Each channel can be enabled in one or more MPU regions and each MPU region can be enabled in multiple channels.

Note

MPU_LOCK and MPU_COMMIT are global to all MPU regions and modify access of the MPU_CTRL register. MPUR_LOCK and MPUR_COMMIT are specific to the configured MPU region and modify access of region configuration registers.

In Figure 13-8, the following configuration is depicted for peripheral-to-memory transfer:

- SROOT sets up RTDMA MPU regions to
  - Region 2: Start, End addresses encompass ADCA, ADCB, ADCC - MPU region enabled for Channel 1, Read
  - Region 3: Start, End addresses encompass ADCD, ADCE - MPU region enabled for Channel 2, Read
  - Region 4: Start, End addresses encompass CPU1 Local RAM - MPU region enabled for Channel 1, Write
  - Region 5: Start, End addresses encompass Global RAM - MPU region enabled for Channel 2, Write
- Channel SSU settings
  - RTDMA1 Channel 1: CPU1.APR6 LINK3 Read / Write
  - RTDMA1 Channel 2: CPU2.APR4 LINK1 Read / Write

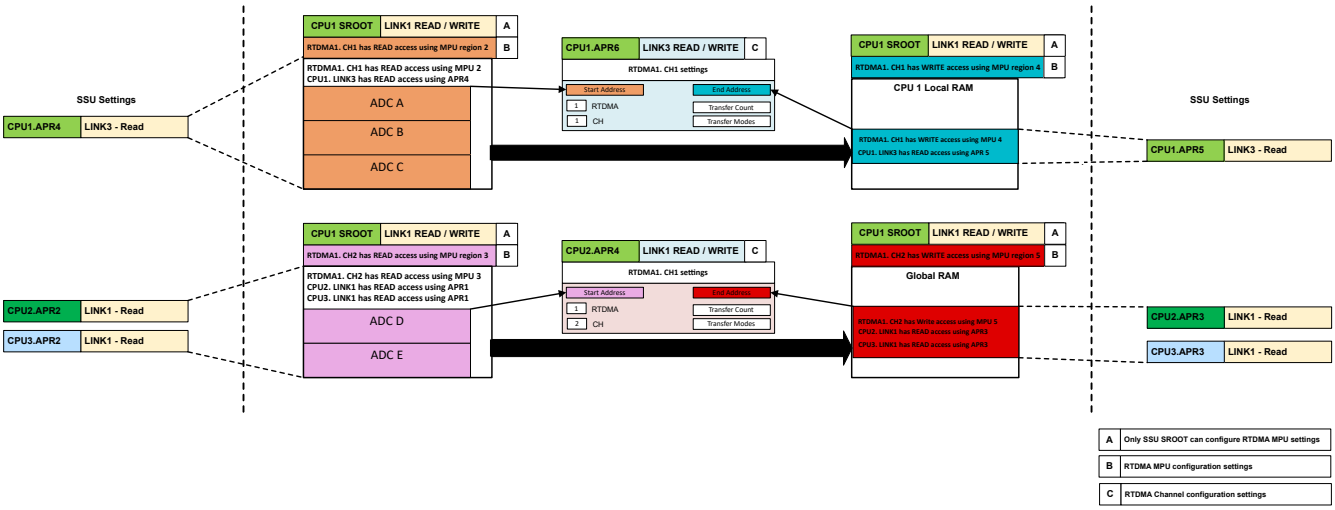

Figure 13-8. Peripheral-to-Memory Transfer Example

In Figure 13-9, the following configuration is depicted for memory-to-memory transfer:

RTDMA1:

- SROOT sets up RTDMA MPU regions to
  - Region 2: Start, End addresses encompass a section of CPU1 Local RAM - MPU region Enabled for RTDMA1.Channel 1 / Channel 4 - Read
  - Region 3: Start, End addresses encompass a section of CPU2 Local RAM - MPU region Enabled for RTDMA1.Channel 1 / Channel 4 - Write
- Channel SSU settings
  - RTDMA1 Channel1: CPU1.APR6.LINK3 - READ / WRITE
  - RTDMA1 Channel4: CPU1.APR6.LINK3 - READ / WRITE

RTDMA2:

- SROOT sets up RTDMA MPU regions to
  - Region 4: Start, End addresses encompass a section of CPU1 Local RAM - MPU region Enabled for RTDMA2.Channel 3 - Write
  - Region 5: Start, End addresses encompass a section of CPU2 Local RAM - MPU region Enabled for RTDMA2.Channel 3 - Read
- Channel SSU settings
  - RTDMA2 Channel3: CPU2.APR4.LINK1 - READ / WRITE

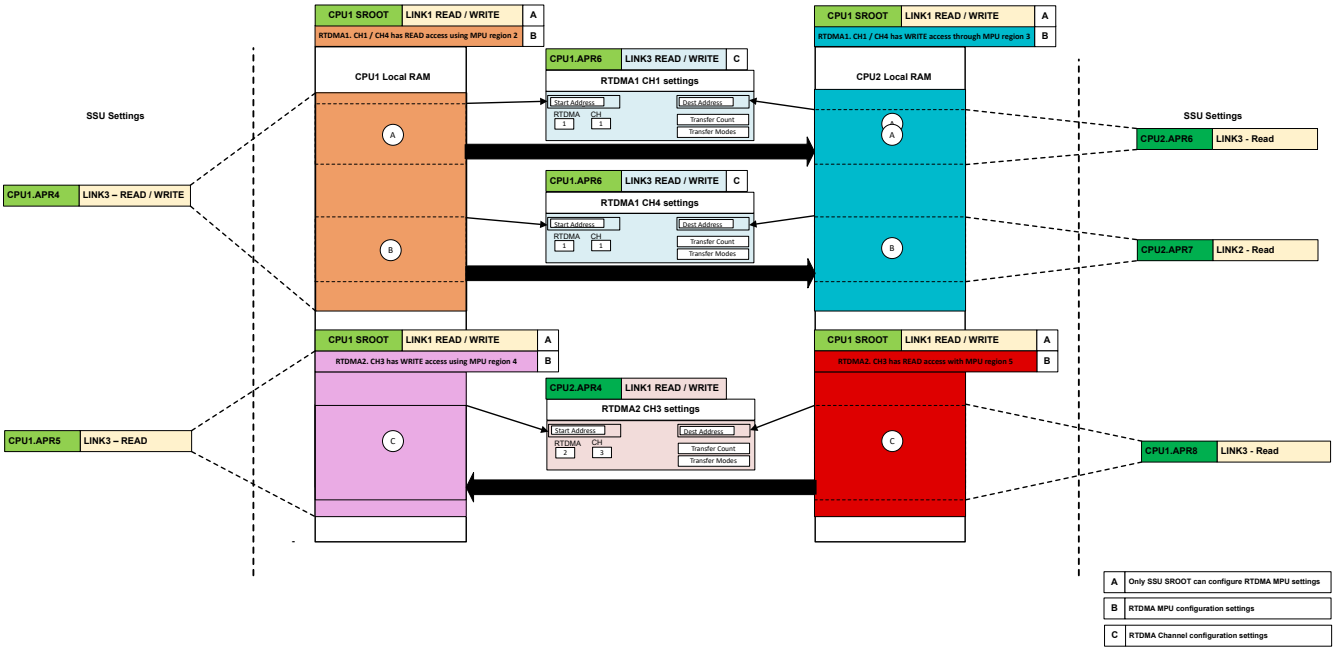

Figure 13-9. Memory-to-Memory Transfer Example

13.9.1.2.1 MPU Errors

MPU monitors all the read and write accesses happening on the bus continuously. Any faults in the interface are communicated to the ESM module where the errors are latched and RTDMA access permissions is determined accordingly.

Errors can be of the following types:

- Address Checks:
  - If an address does not belong to any region, a fault is generated and triggered to the ESM. In this case, access is blocked.
  - More than one MPU regions responded to a data write or read access
    - Multiple regions respond and allow the access – no fault is generated and access goes through.
    - Multiple regions respond and one of the regions blocks the access – fault is generated and triggered to the ESM and access is blocked.
- Access Permission Checks:
  - If an access to a range defined by MPU region does not have the necessary access permissions, a fault is generated and triggered to the ESM and access is blocked.

Note

When SIC and MPU error happens on the same cycle – MPU error address is reported to the ESM. Refer to Section 7.2.3 for more details about how all errors are registered within the ESM.

The MPU is enabled by default. If memory protection support is not needed, disable the MPU during RTDMA initialization.

13.9.2 Security

In addition to MPU specific configurations, the SSU can be used to add another level of security to the RTDMA system, optionally.

RTDMA MPU versus SSU

RTDMA is an independent bus initiator that is not directly governed by SSU access filters. RTDMA receives sideband signals from the SSU that determines LINK ownership of channel configurations. The MPU is used to actually protect data transfers initiated by a DMA channel.

How RTDMA utilizes the SSU

Only the privileged software executing from SROOT (CPU1 LINK2) and CPU1 LINK0/1 can read / write and define the RTDMA MPU registers. Safety and Security Unit (SSU) related checks are placed in a hardcoded region outside of the RTDMA to verify appropriate permissions. User can assign each channel to an AP region inside the SSU to define the channel ownership to a certain link / zone and prevent illegal accesses to channel specific registers from other sources.

Note

MPU register definition and channel association is similar to the SSU architecture.

13.9.3 RTDMA Errors

The RTDMA interfaces are directly connected to the Error Aggregator which aggregates errors occurred during RTDMA data write accesses and RTDMA data read accesses. RTDMA outputs the error, error type, and error address to the Error Aggregator. The high-priority errors from the RD / WR interfaces are combined as RTDMAx HPERR, and the low-priority errors from the RD / WR interfaces are combined as RTDMAx LPERR.

The errors are propagated to the ESM, PIPE, and CPU to take the appropriate further action.

Table 13-3. RTDMAx Error Aggregator Errors

RTDMAx DW Interface Errors	Priority/Description	RTDMAx DR Interface Errors	Priority/Description
Security Violation Error	High Priority - Illegal write to memory or peripherals, Write to an illegal location	Security Violation Error	High Priority - Illegal read of memory or peripherals, Read of an illegal location
Access Timeout Error	High Priority - Mechanism to check for timeout	Access Timeout Error	High Priority - Mechanism to check for timeout
Access ACK Error	High Priority - Any access that does not receive an ACK from the memory controller or peripheral bridge	Access ACK Error	High Priority - Any access that does not receive an ACK from the memory controller or peripheral bridge
		Uncorrectable Error	High Priority - Read accesses that result in a double-bit ECC error.
		Correctable Error	Low Priority - Read accesses that result in a single-bit ECC error.

Note

Refer to Chapter 8 and Chapter 7 for the complete list of error sources and information on how to read and use these errors for debugging purposes.

13.9.4 Self-Test and Diagnostics

RTDMA contains safety diagnostics registers reflecting the architecture of the C29x self-test and diagnostic registers. Parity and ECC logic is implemented for the bus and registers to help achieve overall safety goals.

Self-test logic is used to cover faults local to the ECC module. Once a self-test controller is configured and the CPU initiates diagnostics on the program bus, the controller detects faults in ECC logic and stores these values in the appropriate registers.

Fault emulation logic is used to induce errors and check that the error signal generation is working as expected as a part of diagnostics tests (example, NMI servicing after CPU fault).

Note

Refer to the RTDMA Diagnostics and Self-Test Registers for more information on fault emulation and ECC checker diagnostics capabilities of the RTDMA.

13.10 Software

13.10.1 RTDMA Registers to Driverlib Functions

Table 13-4. RTDMA Registers to Driverlib Functions

File	Driverlib Function
