13.10.2 RTDMA Examples

NOTE: These examples are located in the C29SDK installation from ti.com at the following location: mcu_sdk_DEVICE_GPN/examples/driverlib/CORE_IF_MULTICORE/rtdma

Cloud access to these examples is available at the following link: dev.ti.com C29SDK Examples.

13.10.2.1 RTDMA Academy Lab - SINGLE_CORE

FILE: rtdma_academy_lab.c

This example demonstrates how to use the RTDMA to service the ADC in a real-time processing application. The ePWM and ADC modules generate and sample a PWM waveform. The DMA is used to store the ADC samples in a ping pong buffer, so sample groups can be simultaneously processed by the CPU in an ISR.

External Connections

- ADCINA0 (AIO160) to EPWM1_A (GPIO0)

Watch Variables

- *PingPongState* - Ping-pong buffer state.
- *LedCtr* - Counter to slow LED toggling.
- *TaskDelayUs* - Delay to simulate data processing task.
- *OverCnt* - Counter to store DMA overwrites.
- *TimDiff* - To measure the DMA ISR time.
- *AdcBufRaw* - Ping-pong buffer.

13.10.2.2 RTDMA Transfer - SINGLE_CORE

FILE: rtdma_ex1_mem_transfer.c

This example uses one RTDMA channel to transfer data from a buffer to another buffer in RAM. The example triggers the DMA channel repeatedly until the transfer of 16 bursts (where each burst is 4 8-bit words) has been completed. When the whole transfer is complete it will trigger the DMA interrupt. The RTDMA1 MPU is disabled in this example.

Watch Variables

- *TxData* - Data to send
- *RxData* - Received data
- *done* - Transfer successful

13.10.2.3 RTDMA Transfer with MPU - SINGLE_CORE

FILE: rtdma_ex2_mem_transfer_mpu.c

This example uses one RTDMA channel to transfer data from a buffer to another buffer in RAM. The example triggers the DMA channel repeatedly until the transfer of 16 bursts (where each burst is 4 8-bit words) has been completed. When the whole transfer is complete it will trigger the DMA interrupt.

The RTDMA1 MPU is enabled in this example to configure a predefined region that dictates read and write access to the transmit buffer and receive buffer. When a DMA channel attempts to access data at an illegal address, MPU outputs a security violation. Any faults in the interface are communicated to the Error Aggregator module which are sent to the Error Signaling Module (ESM) where the errors are latched and RTDMA access is blocked.

Configured Address Ranges: MPU Region Start Address - 0x200E0000 MPU Region End Address - 0x200E0FFF TxData Start Address - 0x200E0100 TxData End Address - 0x200E013F
RxData Start Address - 0x200E0FDC RxData End Address - 0x200E101B

13.11 RTDMA Registers

This section describes the RTDMA registers.

13.11.1 RTDMA Base Address Table

Table 13-5. RTDMA Base Address Table

Structure	DriverLib Name	Base Address	Frame Applicable	CPU1	CPU2	CPU3	RTDMA1	RTDMA2	HSM	Pipeline Protected

RTDMA_CH_REGS	RTDMA2CH8_BASE	0x6001_7000	YES	YES	YES	YES	YES	YES	-	YES

Table 13-5. RTDMA Base Address Table (continued)

Structure	DriverLib Name	Base Address	Frame Applicable	CPU1	CPU2	CPU3	RTDMA1	RTDMA2	HSM	Pipeline Protected
RTDMA_CH_REGS	RTDMA2CH9_BASE	0x6001_8000	YES	YES	YES	YES	YES	YES	-	YES
RTDMA_CH_REGS	RTDMA2CH10_BASE	0x6001_9000	YES	YES	YES	YES	YES	YES	-	YES

(1) Registers writeable by CPU1.LINK0, CPU1.LINK1, CPU1.LINK2 only. All CPUs can read all registers in all LINKs. Debug write access only allowed if Zone0 or Zone1 are enabled for full debug by all CPUs. Debug reads always allowed. Register Read/Write access by HSM.

13.11.2 RTDMA_REGS Registers

Table 13-6 lists the memory-mapped registers for the RTDMA_REGS registers. All register offset addresses not listed in Table 13-6 should be considered as reserved locations and the register contents should not be modified.

Table 13-6. RTDMA_REGS Registers

Offset	Acronym	Register Name	Protection
0h	DMACTRL	DMA Control Register	LOCK: DMACFG_LOCK.LOCK
4h	DEBUGCTRL	Debug Control Register	LOCK: DMACFG_LOCK.LOCK
8h	REVISION	RTDMA Revision Control Register	
14h	SWPRI1	Software Priority Configuration Register 1	LOCK: DMACFG_LOCK.LOCK
18h	SWPRI2	Software Priority Configuration Register 2	LOCK: DMACFG_LOCK.LOCK
1Ch	PRIORITYSTAT	Priority Status Register	
40h	DMACFG_LOCK	Channel Configuration Temporary Lock	COMMIT: DMACFG_COMMIT.COMMIT
44h	DMACFG_COMMIT	Channel Configuration Permanent Commit	

Complex bit access types are encoded to fit into small table cells. Table 13-7 shows the codes that are used for access types in this section.

Table 13-7. RTDMA_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

13.11.2.1 DMACTRL Register (Offset = 0h) [Reset = 00000000h]

DMACTRL is shown in Figure 13-10 and described in Table 13-8.

Return to the Summary Table.

Table 13-8. DMACTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-17	RESERVED	R	0h	Reserved
16	PRIORITYSEL	R/W	0h	The priority select bit: 0: the round-robin priority scheme. 1: Software configurable priority for channels, Priority of the channels is set in the SWPRI reg Reset type: SYSRSn
15-2	RESERVED	R	0h	Reserved
1	PRIORITYRESET	R-0/W1S	0h	If PRIORITYSEL==0: The priority reset bit resets the round-robin state machine when a 1 is written. Service starts from the first enabled channel. Writes of 0 are ignored and this bit always reads back a 0. If PRIORITYSEL==1: The SWPRI register is reset to it's reset value when a 1 is written. All channels will be of priority '1'. Writes of 0 are ignored and this bit always reads back a 0. Reset type: SYSRSn
0	HARDRESET	R-0/W1S	0h	Writing a 1 to the hard reset bit resets the whole DMA and aborts any current access (similar to applying a device reset). Writes of 0 are ignored and this bit always reads back a 0. For a soft reset, a bit is provided for each channel to perform a gentler reset. Refer to the channel control registers. When writing to this bit, there is a one cycle delay before it takes effect. Hence, a one-cycle delay (such as a NOP instruction) is required in software before attempting to access any other DMA register. Reset type: SYSRSn

13.11.2.2 DEBUGCTRL Register (Offset = 4h) [Reset = 00000000h]

DEBUGCTRL is shown in Figure 13-11 and described in Table 13-9.

Return to the Summary Table.

31-1	RESERVED	R	0h	Reserved
0	COMMIT	R/W1S	0h	When set, locks the DMACFG_LOCK register. This bit cannot be cleared, except by reset. 0 : DMACFG_LOCK is modifiable 1 : DMACFG_LOCK is committed permanently Reset type: SYSRSn

13.11.3 RTDMA_DIAG_REGS Registers

Table 13-16 lists the memory-mapped registers for the RTDMA_DIAG_REGS registers. All register offset addresses not listed in Table 13-16 should be considered as reserved locations and the register contents should not be modified.

Table 13-16. RTDMA_DIAG_REGS Registers

Offset	Acronym	Register Name	Protection
0h	FLTEMU_CONFIG	Fault emulation configuration registerr	KEY:KEY=0xa5
4h	FLTEMU_ACCGRPSEL	Fault emulation access information group selection register	
8h	FLTEMU_BITSEL	Fault emulation bitsel	
Ch	FLTEMU_ADDR	Fault emulation access address register	

Complex bit access types are encoded to fit into small table cells. Table 13-17 shows the codes that are used for access types in this section.

Table 13-17. RTDMA_DIAG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

13.11.3.1 FLTEMU_CONFIG Register (Offset = 0h) [Reset = 00000000h]

FLTEMU_CONFIG is shown in Figure 13-18 and described in Table 13-18.

Return to the Summary Table.

100h	CHCFG_LOCK	Channel Configuration Temporary Lock	COMMIT: CHCFG_COMMIT.COMMIT
104h	CHCFG_COMMIT	Channel Configuration Permanent Commit	

Complex bit access types are encoded to fit into small table cells. Table 13-43 shows the codes that are used for access types in this section.

Table 13-43. RTDMA_CH_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

13.11.6.1 MODE Register (Offset = 0h) [Reset = 00000000h]

MODE is shown in Figure 13-38 and described in Table 13-44.

Return to the Summary Table.

Table 13-44. MODE Register Field Descriptions

Bit	Field	Type	Reset	Description
31-22	RESERVED	R	0h	Reserved
21-20	WRT_DATASIZE	R/W	0h	Write Data Size Mode Bit This bit determines whether the DMA channel transfers on the Data Write port are 8 bits, 16 bits, 32 bits or 64 of data per read/write operation. Regardless of this setting, all data lengths and offsets in other DMA registers refer to 8- bit words(Bytes). The pointer step increments must be configured to accommodate 8, 16, 32, 64-bit words. 00: DATASIZE_8 01: DATASIZE_16 10: DATASIZE_32 11: DATASIZE_64 DATASIZE >= WR_DATASIZE. i.e. DST size to be integral multiple of SRC. If DATASIZE_64 then, WR_DATASIZE should be configured to WR_DATASIZE_64 or WR_DATASIZE_32 or WR_DATASIZE_16 or WR_DATASIZE_8 If DATASIZE_32 then, WR_DATASIZE should be configured to WR_DATASIZE_32 or WR_DATASIZE_16 or WR_DATASIZE_8 if DATA_SIZE_16 then, WR_DATASIZE should be configured to WR_DATASIZE_16 or WR_DATASIZE_8 If DATA_SIZE_8 then WR_DATASIZE should be configured to WR_DATASIZE_8 Reset type: SYSRSn
19	CHINTE	R/W	0h	Channel Interrupt Enable Bit This bit enables the DMA channel's CPU interrupt. Reset type: SYSRSn 0h (R/W) = Interrupt disabled 1h (R/W) = Interrupt enabled

Table 13-44. MODE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
18-17	DATASIZE	R/W	0h	Data Size Mode Bit This bit determines whether the DMA channel transfers 8 bits, 16 bits, 32 bits or 64 of data per read/write operation. Regardless of this setting, all data lengths and offsets in other DMA registers refer to 8-bit words (Bytes). The pointer step increments must be configured to accommodate 8, 16, 32, 64-bit words. 00: DATASIZE_8 01: DATASIZE_16 10: DATASIZE_32 11: DATASIZE_64 Reset type: SYSRSn
16	RESERVED	R/W	0h	Reserved
15	RESERVED	R/W	0h	Reserved
14	CONTINUOUS	R/W	0h	Continuous Mode Bit If this bit is set to 1, then the channel re-initializes when TRANSFER_COUNT is zero and waits for the next event trigger. Otherwise, the DMA stops and clears the RUNSTS bit. Reset type: SYSRSn
13	ONESHOT	R/W	0h	One Shot Mode If this bit is set to 1, each peripheral event trigger causes the channel to perform an entire transfer. Otherwise, the channel only performs one burst per trigger. Reset type: SYSRSn
12	CHINTMODE	R/W	0h	Channel Interrupt Generation Mode This bit specifies when the DMA channel generates a CPU interrupt for a transfer. Reset type: SYSRSn 0h (R/W) = Generate interrupt at beginning of new transfer 1h (R/W) = Generate interrupt at end of transfer.
11	PERINTE	R/W	0h	Peripheral Event Trigger Enable This bit enables peripheral event triggers on the DMA channel. Reset type: SYSRSn 0h (R/W) = Peripheral event trigger disabled. Neither the selected peripheral nor software can start a DMA burst. 1h (R/W) = Peripheral event trigger enabled.
10	OVRINTE	R/W	0h	Overflow Interrupt Enable The bit determines whether the DMA module generates a CPU interrupt when it detects an overflow event. Reset type: SYSRSn 0h (R/W) = Overflow interrupt disabled 1h (R/W) = Overflow interrupt enabled
9-8	RESERVED	R	0h	Reserved
7-0	PERINTSEL	R/W	0h	Peripheral Event Trigger Source Select Selects the Trigger and Sync Source of the DMA Channel 0: No Peripheral Connection 1..239: Details in DMA trigger select mux of the device 240: CH1 Interrupt (Reserved for CH1) 241: CH2 Interrupt (Reserved for CH2) 242: CH3 Interrupt (Reserved for CH3) ... ... 249: CH10 Interrupt (Reserved for CH10) 250: Reserved ... ... 255: Reserved Reset type: SYSRSn

13.11.6.2 CONTROL Register (Offset = 4h) [Reset = 00000000h]

CONTROL is shown in Figure 13-39 and described in Table 13-45.

Return to the Summary Table.

Table 13-45. CONTROL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-15	RESERVED	R	0h	Reserved
14	OVRFLG	R	0h	Overflow Flag This bit indicates that a peripheral event trigger was received while PERINTFLG was already set. It can be cleared by writing to the ERRCLR bit. Reset type: SYSRSn 0h (R/W) = No overflow detected 1h (R/W) = Overflow detected
13	RUNSTS	R	0h	Run Status Flag This bit indicates that the DMA channel is ready to respond to peripheral event triggers. This bit is set when a 1 is written to the RUN bit. It is cleared when a transfer completes (TRANSFER_COUNT = 0) and corresponding Write access is complete and continuous mode is disabled, or when the HARDRESET, SOFTRESET, or HALT bit is set. Reset type: SYSRSn 0h (R/W) = The channel is disabled 1h (R/W) = The channel is enabled
12	BURSTSTS	R	0h	Burst Status Flag This bit is set when a DMA burst begins. The BURST_COUNT is set to the BURST_SIZE. This bit is cleared when BURST_COUNT reaches zero and corresponding Write access is complete, or when the HARDRESET or SOFTRESET bit is set. Reset type: SYSRSn 0h (R/W) = No burst activity 1h (R/W) = The DMA is currently servicing or suspending a burst transfer from this channel

Table 13-45. CONTROL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11	TRANSFERSTS	R	0h	Transfer Status Flag This bit is set when a DMA transfer begins. The address registers are copied to the shadow set and the TRANSFER_COUNT is set to the TRANSFER_SIZE. This bit is cleared when TRANSFER_COUNT reaches zero and corresponding Write access is complete, or when the HARDRESET or SOFTRESET bit is set. Reset type: SYSRSn 0h (R/W) = No transfer activity 1h (R/W) = The channel is currently in the middle of a transfer regardless of whether a burst of data is actively being transferred or not
10	RESERVED	R	0h	Reserved
9	RESERVED	R	0h	Reserved
8	PERINTFLG	R	0h	Peripheral Event Trigger Flag This bit indicates whether a peripheral event trigger has arrived. This bit is automatically cleared when the first burst transfer begins. Reset type: SYSRSn 0h (R/W) = Waiting for event trigger 1h (R/W) = Event trigger pending
7	ERRCLR	R-0/W1S	0h	Clear Error Writing a 1 to this bit will clear the OVRFLG bit. This is normally done when initializing the DMA module or if an overflow condition is detected. If an overflow event occurs at the same time this bit is set, the overrun has priority and the OVRFLG bit is set. [Note] When Overflow and perintflg are set for a channel and at the same time trigger is asserted for the same channel and when its ERRCLR bit is also set to 1, the overflow flag will be de-asserted. Reset type: SYSRSn
6	RESERVED	R-0/W1S	0h	Reserved
5	RESERVED	R-0/W1S	0h	Reserved
4	PERINTCLR	R-0/W1S	0h	Clear Peripheral Event Trigger Writing a 1 to this bit clears PERINTFLG, which cancels a pending event trigger. This is normally done when initializing the DMA module. If an event trigger arrives at the same time this bit is set, the trigger has priority and PERINTFLG is set. Reset type: SYSRSn
3	PERINTFRC	R-0/W1S	0h	Force Peripheral Event Trigger If the PERINTE bit of the MODE register is set, writing a 1 to this bit sets PERINTFLG, which triggers a DMA burst. This bit can be used to start a DMA transfer in software. Reset type: SYSRSn
2	SOFTRESET	R-0/W1S	0h	Channel Soft Reset Writing a 1 to this bit places the channel into its default state after the current read/write access has completed: RUNSTS = 0 TRANSFERSTS = 0 BURSTSTS = 0 BURST_COUNT = 0 TRANSFER_COUNT = 0 SRC_WRAP_COUNT = 0 DST_WRAP_COUNT = 0 When writing to this bit, there is a one cycle delay before it takes effect. Hence, a one-cycle delay (such as a NOP instruction) is required in software before attempting to access any other DMA register. Reset type: SYSRSn

Table 13-45. CONTROL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	HALT	R-0/W1S	0h	Halt Channel Writing a 1 to this bit halts the DMA channel in its current state after any ongoing read/write access has completed. Reset type: SYSRSn
0	RUN	R-0/W1S	0h	Run Channel Writing a 1 to this bit enables the DMA channel and sets the RUNSTS bit to 1. This bit is also used to resume after a channel halt. The RUN bit is typically used to start the DMA channel after configuration. The channel will then wait for the first peripheral event trigger (PERINTFLG == 1) to start a burst. Reset type: SYSRSn

13.11.6.3 BURST_SIZE Register (Offset = 8h) [Reset = 00000000h]

BURST_SIZE is shown in Figure 13-40 and described in Table 13-46.

Return to the Summary Table.

Chapter 14

External Memory Interface (EMIF)

This chapter describes the external memory interface (EMIF).

Further information can be found in the following documents:

Accessing External SDRAM on the TMS320F2837x/2807x Microcontrollers Using C/C++ Application Report

Design and Usage Guidelines for the C2000™ External Memory Interface (EMIF) Application Report

14.1 Introduction

This device supports one EMIF module — EMIF1, as shown in Figure 14-1.

Table 14-1 gives the configuration for the EMIF module.

The EMIF module is accessible from all CPUs, but fast access ports are limited to the primary CPU. Other initiators use the slow access ports. Code execution from the EMIF is not supported.

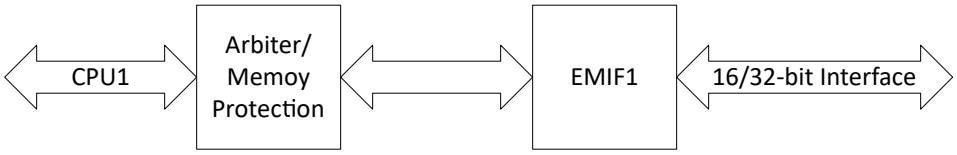

Figure 14-1. EMIF Module Overview

Table 14-1. Configuration for the EMIF1 Module

	EMIF1
Maximum Data Width	32
Maximum Address Width	22 (Some of EMIF1 pins are muxed with each other. Refer to Section 14.2.11 for usage)
SDRAM CSx Support	1 (CS0)
ASRAM CSx Support	3 (CS2/CS3/CS4)

Note

Subsequent sections in this chapter provide the details on the generic EMIF module. Unless otherwise specified, pin names are used from EMIF1 to define the functionality.

14.1.1 Purpose of the Peripheral

This EMIF memory controller is compliant with the JESD21-C SDR SDRAM memories utilizing a 32-bit/16-bit data bus. The purpose of this EMIF is to provide a means for the CPU to connect to a variety of external devices including:

- Single data rate (SDR) SDRAM
- Asynchronous devices including NOR Flash and SRAM

A common use for the EMIF is to interface with both a Flash device and an SDRAM device simultaneously. Section 14.4 contains an example of operating the EMIF in this configuration.

14.1.2 Features

The EMIF controller includes many features to enhance the ease and flexibility of connecting to the external SDR SDRAM and asynchronous devices.

- Accessible by all CPUs, RTDMA1, and RTDMA2
  - Fast port access from primary CPU, slow port access from other CPUs and RTDMA
- RTDMA burst support
- Separate buffer module for each CPU with a write FIFO that contains up to 4 entries
- EMIF splits accesses based on data size
  - 64-bit access causes two 32-bit accesses
- Arbitration for same and different initiators
- Supports single chip select for SDRAM, three chip selects for ASRAM, and an additional range for EMIF register accesses

14.1.2.1 Asynchronous Memory Support

The EMIF controller supports asynchronous:

- SRAM memories
- NOR Flash memories

There is an external wait input that allows slower asynchronous memories to extend the memory access. The EMIF module supports more than one chip select (enable). Each chip select has the following individually programmable attributes:

- Data bus width
- Read cycle timings: setup, hold, strobe
- Write cycle timings: setup, hold, strobe
- Bus turnaround time
- Extended wait option with programmable timeout
- Select strobe option

14.1.2.2 Synchronous DRAM Memory Support

The EMIF module supports 16-bit/32-bit SDRAM in addition to the asynchronous memories listed in Section 14.1.2.1. The EMIF module has a single SDRAM chip select. SDRAM configurations that are supported are:

- One, two and four bank SDRAM devices
- Devices with eight, nine, ten, and eleven column address
- CAS latency of two or three clock cycles
- 16-bit/32-bit data bus width
- 3.3V LVCMOS interface

Additionally, the EMIF supports placing the SDRAM in self-refresh and power-down modes. The self-refresh mode allows the SDRAM to be put in a low-power state while still retaining memory contents, since the SDRAM continues to refresh itself even without clocks from the microcontroller. The power-down mode achieves even lower power, except the microcontroller must periodically wake up and issue refreshes if data retention is required.

Note that the EMIF module does not support mobile SDRAM devices.

14.1.3 Functional Block Diagram

Figure 14-2 shows the connections between the EMIF and the internal requesters, along with the external EMIF pins. Section 14.2.2 contains a description of the entities internal to the MCU that can send requests to the EMIF, along with their prioritization. Section 14.2.3 describes the EMIF external pins and summarizes their purpose when interfacing with the SDRAM and asynchronous devices.

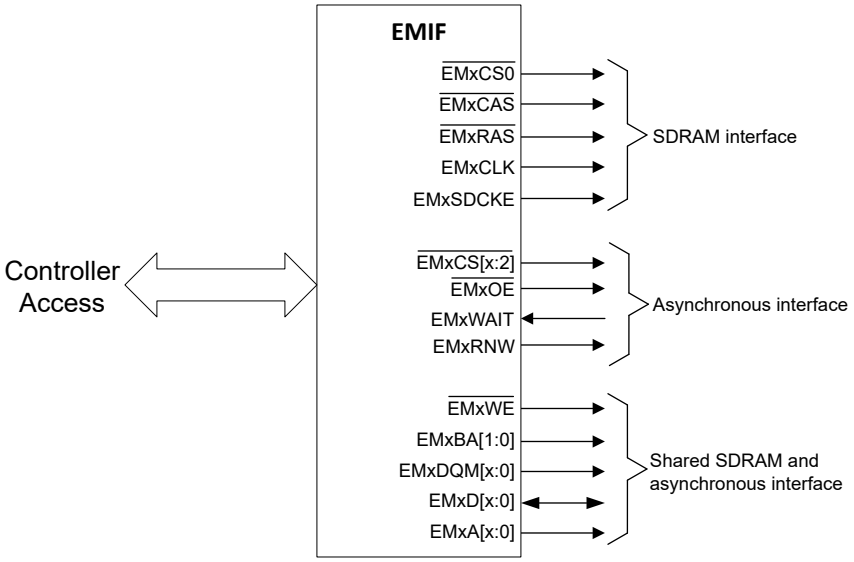

Figure 14-2. EMIF Functional Block Diagram

14.1.4 Configuring Device Pins

The GPIO mux registers must be configured to connect this peripheral to the device pins. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

Some IO functionality is defined by GPIO register settings independent of this peripheral. For input signals, the GPIO input qualification must be set to asynchronous mode by setting the appropriate GPxQSELn register bits to 11b. The internal pullups can be configured in the GPyPUD register.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux and settings.

14.2 EMIF Module Architecture

This section provides details about the architecture and operation of the EMIF. Both the SDRAM and asynchronous interface are covered, along with other system-related configurations such as clock control.

14.2.1 EMIF Clock Control

The EMIF clock is output on the pin and must be used when interfacing to external SDRAM devices. The EMIF module gets the PLLSYSCLK clock domain as the input. The user can choose to run the EMIF at PLLSYSCLK/1 or PLLSYSCLK/2 clock frequency by configuring the field in the PERCLKDIVSEL register in the *Clock Control* module.

14.2.2 EMIF Requests

Different sources within the MCU can make requests to the EMIF. These requests consist of accesses to the SDRAM memory, the asynchronous memory, and the EMIF registers. The EMIF can process only one request at a time. Therefore, a high performance controller arbitration block exists within the MCU to provide prioritized requests from the different sources to the EMIF. The sources are:

- CPU1
- CPU2
- CPU3
- RTDMA

If a request is submitted from two or more sources simultaneously, the crossbar switch forwards the highest priority request to the EMIF first. Upon completion of a request, the controller arbitration block again evaluates the pending requests and forwards the highest priority pending request to the EMIF.

The controller arbitration block always allows RD access from any of the controller. But for WR access (or execute access), the controller arbitration block arbitrates between the accesses controller from multiple resources (CPU1/2/3 and RTDMA) controller using a round robin priority scheme.

When the EMIF receives a request, it is possible that the request is not immediately processed. In some cases, the EMIF performs one or more auto-refresh cycles before processing the request. For details on the EMIF internal arbitration between performing requests and performing auto-refresh cycles, see Section 14.2.13.

14.2.3 EMIF Signal Descriptions

This section describes the function of each of the EMIF signals.

Table 14-2. EMIF Pins Used to Access Both SDRAM and Asynchronous Memories

Pins	I/O	Description
EM1D[x:0]	I/O	**EMIF data bus.**
EM1A[x:0]	O	**EMIF address bus.** When interfacing to an SDRAM device, these pins are primarily used to provide the row and column address to the SDRAM. The mapping from the internal program address to the external values placed on these pins is found in Table 14-14. EM1A[10] is also used during the PRE command to select which banks to deactivate. When interfacing to an asynchronous device, these pins are used in conjunction with the EM1BA pins to form the address that is sent to the device. The mapping from the internal program address to the external values placed on these pins is found in Section 14.2.6.1.
EM1BA[1:0]	O	**EMIF bank address.** When interfacing to an SDRAM device, these pins are used to provide the bank address inputs to the SDRAM. The mapping from the internal program address to the external values placed on these pins is found in Table 14-14. When interfacing to an asynchronous device, these pins are used in conjunction with the EM1A pins to form the address that is sent to the device. The mapping from the internal program address to the external values placed on these pins is found in Section 14.2.6.1.
EM1DQM[x:0]	O	**Active-low byte enables.** When interfacing to SDRAM, these pins are connected to the DQM pins of the SDRAM to individually enable/disable each of the bytes in a data access. When interfacing to an asynchronous device, these pins are connected to byte enables. See Section 14.2.6 for details.
$\overline{\text{EM1WE}}$	O	**Active-low write enable.** When interfacing to SDRAM, this pin is connected to the nWE pin of the SDRAM and is used to send commands to the device. When interfacing to an asynchronous device, this pin provides a signal which is active-low during the strobe period of an asynchronous write access cycle.

Table 14-3. EMIF Pins Specific to SDRAM

Pins	I/O	Description
$\overline{\text{EM1CS0}}$	O	**Active-low chip enable pin for SDRAM devices.** This pin is connected to the chip-select pin of the attached SDRAM device and is used for enabling/disabling commands. By default, EMIF keeps this SDRAM chip select active, even if EMIF is not interfaced with an SDRAM device. This pin is deactivated when accessing the asynchronous memory bank and is reactivated on completion of the asynchronous access.
EM1RAS	O	**Active-low row address strobe pin.** This pin is connected to the nRAS pin of the attached SDRAM device and is used for sending commands to the device.
EM1CAS	O	**Active-low column address strobe pin.** This pin is connected to the nCAS pin of the attached SDRAM device and is used for sending commands to the device.
EM1SDCKE	O	**Clock enable pin.** This pin is connected to the CKE pin of the attached SDRAM device and is used for issuing the SELF REFRESH command which places the device in self-refresh mode. See Section 14.2.5.7 for details.
EM1CLK	O	**SDRAM clock pin.** This pin is connected to the CLK pin of the attached SDRAM device. See Section 14.2.1 for details on the clock signal.

Table 14-4. EMIF Pins Specific to Asynchronous Memory

Pins	I/O	Description
$\overline{\text{EM1CS}}$[4:2]	O	**Active-low chip enable pins for asynchronous devices.** These pins are meant to be connected to the chip-select pins of the attached asynchronous device. These pins are active only during accesses to the asynchronous memory.
EM1WAIT	I	**Wait input with programmable polarity.** A connected asynchronous device can extend the strobe period of an access cycle by asserting the EM1WAIT input to EMIF as described in Section 14.2.6.6. To enable this functionality, the EW bit in the asynchronous 1 configuration register (ASYNC_CS2_CFG) must be set to 1. In addition, the WP0 bit in ASYNC_CS2_CFG must be configured to define the polarity of the EM1WAIT pin.
$\overline{\text{EM1OE}}$	O	**Active-low pin enable for asynchronous devices.** This pin provides a signal which is active-low during the strobe period of an asynchronous read access cycle.
EM1RNW	O	**EMIF asynchronous read/write control.** This pin stays high during reads and stays low during writes (same duration as CS).

14.2.4 EMIF Signal Multiplexing Control

Several EMIF signals are multiplexed with other functions on this microcontroller. Refer to the multiplexing section of the *General-Purpose Input/Output (GPIO)* chapter for more information on how to enable the output of these EMIF signals.

14.2.5 SDRAM Controller and Interface

The EMIF controller provides a glueless interface to most standard SDR SDRAM devices and supports features like self-refresh mode and prioritized refresh. In addition, the EMIF controller provides flexibility through programmable parameters such as the refresh rate, CAS latency, and many SDRAM timing parameters. The following sections include details on how to Interface and properly configure the EMIF to perform read and write operations to externally connected SDR SDRAM devices. Also, Section 14.4 provides a detailed example of interfacing the EMIF to a common SDRAM device.

14.2.5.1 SDRAM Commands

The EMIF controller supports the SDRAM commands described in Table 14-5. Table 14-6 shows the truth table for the SDRAM commands, and an example timing waveform of the PRE command is shown in Figure 14-3. EM1A[10] is pulled low in this example to deactivate only the bank specified by the EM1BA pins.

Table 14-5. EMIF SDRAM Commands

Command	Function
PRE	**Precharge.** Depending on the value of EM1A[10], the PRE command either deactivates the open row in all banks (EM1A[10] = 1) or only the bank specified by the EM1BA[1:0] pins (EM1A[10] = 0).
ACTV	**Activate**. The ACTV command activates the selected row in a particular bank for the current access.
READ	**Read.** The READ command outputs the starting column address and signals the SDRAM to begin the burst read operation. Address EM1A[10] is always pulled low to avoid auto precharge. This allows for better bank interleaving performance.
WRT	**Write.** The WRT command outputs the starting column address and signals the SDRAM to begin the burst write operation. Address EM1A[10] is always pulled low to avoid auto precharge. This allows for better bank interleaving performance.
BT	**Burst terminate**. The BT command is used to truncate the current read or write burst request. On this device, all the SDRAM accesses are single access except when EMIF controller splits a single access into multiple access (for example, a 32-bit access from CPU is split into two 16-bit accesses if external SDRAM device is 16 bit (NM =1).
LMR	**Load mode register**. The LMR command sets the mode register of the attached SDRAM devices and is only issued during the SDRAM initialization sequence described in Section 14.2.5.4.
REFR	**Auto refresh**. The REFR command signals the SDRAM to perform an auto refresh according to the internal address.
SLFR	**Self refresh**. The self-refresh command places the SDRAM into self-refresh mode, during which the SDRAM provides a clock signal and auto refresh cycles.
NOP	**No operation**. The NOP command is issued during all cycles in which one of the above commands is not issued.

Table 14-6. Truth Table for SDRAM Commands

SDRAM Pins:	CKE	nCS	nRAS	nCAS	nWE	BA[1:0]	A[12:11]	A[10]	A[9:0]
EMIF Pins:	EM1SDCKE	$\overline{\text{EM1CS}}$[0]	EM1RAS	EM1CAS	$\overline{\text{EM1WE}}$	EM1BA[1:0]	EM1A[12:11]	EM1A[10]	EM1A[9:0]

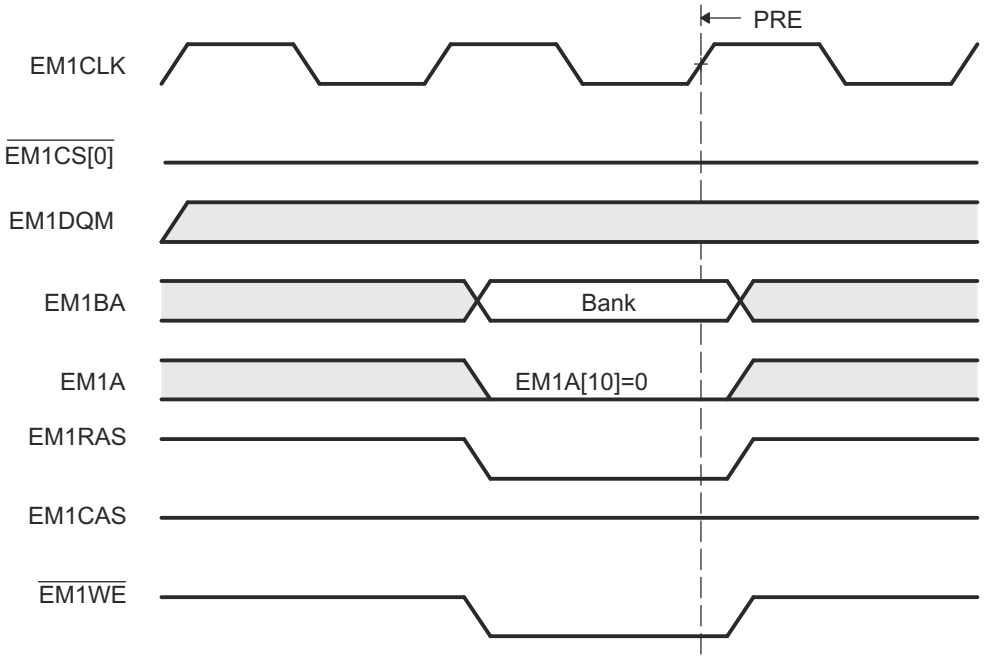

Figure 14-3. Timing Waveform of SDRAM PRE Command

14.2.5.2 Interfacing to SDRAM

The EMIF supports a glueless interface to SDRAM devices with the following characteristics:

- Pre-charge bit is A[10]
- The number of column address bits is 8, 9, 10, or 11.
- The number of row address bits is 13, 14, 15, or 16.
- The number of internal banks is 1, 2, or 4.

Figure 14-4 shows an interface between the EMIF and a 2M × 16 × 4 bank SDRAM device, and Figure 14-5 shows an interface between the EMIF and a 512K × 16 × 2 bank SDRAM device. For devices supporting 16-bit interface, refer to Table 14-7 for list of commonly-supported SDRAM devices and the required connections for the address pins.

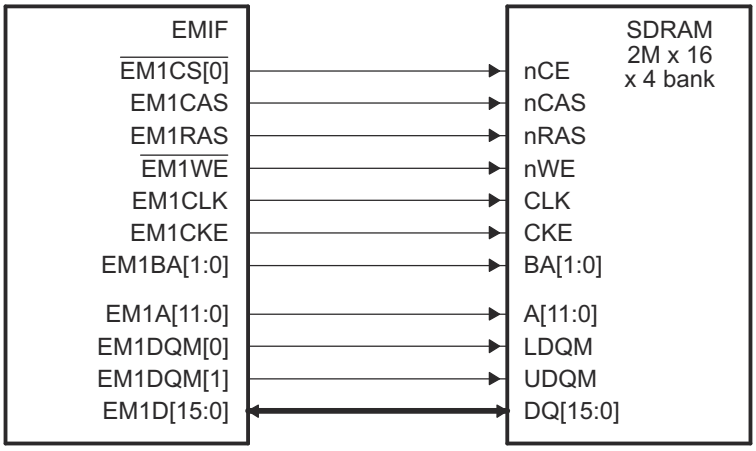

Figure 14-4. EMIF to 2M × 16 × 4 Bank SDRAM Interface

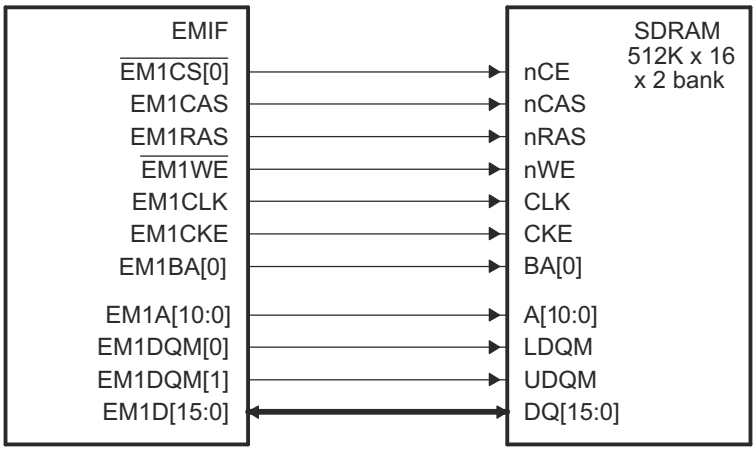

Figure 14-5. EMIF to 512K × 16 × 2 Bank SDRAM Interface

Table 14-7. 16-bit EMIF Address Pin Connections

SDRAM Size	Width	Banks	Device	Address Pins
16M bits	×16	2	SDRAM	A[10:0]
			EMIF	EM1A[10:0]
64M bits	×16	4	SDRAM	A[11:0]
			EMIF	EM1A[11:0]
128M bits	×16	4	SDRAM	A[11:0]
			EMIF	EM1A[11:0]
256M bits	x16	4	SDRAM	A[12:0]
			EMIF	EM1A[12:0]
512M bits	x16	4	SDRAM	A[12:0]
			EMIF	EM1A[12:0]

14.2.5.3 SDRAM Configuration Registers

The operation of the EMIF SDRAM interface is controlled by programming the appropriate configuration registers. This section describes the purpose and function of each configuration register, but Section 14.6 can be referred to for a more detailed description of each register, including the default registers values and bit-field positions. The following tables list the four such configuration registers, along with a description of each of their programmable fields.

Note

Writing to any of the fields: NM, CL, IBANK, and PAGESIZE in the SDRAM configuration register (SDRAM_CR) causes the EMIF to abandon whatever the EMIF is currently doing and trigger the SDRAM initialization procedure described in Section 14.2.5.4.

Table 14-8. Description of the SDRAM Configuration Register (SDRAM_CR)

Parameter	Description
SR	This bit controls entering and exiting of the self-refresh mode
PD	This bit controls entering and exiting of the power-down mode. If both SR and PD bits are set, the EMIF goes into self-refresh mode.
PDWR	Perform refreshes during power down. Writing a 1 to this bit causes the EMIF to exit the power-down state and issue an AUTO REFRESH command every time Refresh May level is set. This bit must be set along with PD when entering power-down mode.
NM	**Narrow Mode.** This bit defines the width of the data bus between the EMIF and the attached SDRAM device. When set to 1, the data bus is set to 16-bits. When set to 0, the data bus is set to 32-bits.
CL	**CAS latency.** This field defines the number of clock cycles between when an SDRAM issues a READ command and when the first piece of data appears on the bus. The value in this field is sent to the attached SDRAM device using the LOAD MODE REGISTER command during the SDRAM initialization procedure as described in Section 14.2.5.4. Only, values of 2h (CAS latency = 2) and 3h (CAS latency = 3) are supported and must be written to this field. While updating the CL field, BIT11_9LOCK bit field must be set to 1 simultaneously.
IBANK	**Number of Internal SDRAM Banks.** This field defines the number of banks inside the attached SDRAM devices in the following way: • When IBANK = 0, 1 internal bank is used • When IBANK = 1h, 2 internal banks are used • When IBANK = 2h, 4 internal banks are used This field value affects the mapping of logical addresses to the SDRAM row, column, and bank addresses. See Section 14.2.5.11 for details.
PAGESIZE	**Page Size.** This field defines the internal page size of the attached SDRAM devices in the following way: • When PAGESIZE = 0, 256-word pages are used • When PAGESIZE = 1h, 512-word pages are used • When PAGESIZE = 2h, 1024-word pages are used • When PAGESIZE = 3h, 2048-word pages are used This field value affects the mapping of logical addresses to the SDRAM row, column, and bank addresses. See Section 14.2.5.11 for details.

Table 14-9. Description of the SDRAM Refresh Control Register (SDRAM_RCR)

Parameter	Description
RR	**Refresh Rate**. This field controls the rate at which attached SDRAM devices are refreshed. The following equation can be used to determine the required value of RR for an SDRAM device: • RR = f_{EM1CLK} / (Required SDRAM Refresh Rate) More information about the operation of the SDRAM refresh controller is found in Section 14.2.5.6.

Table 14-10. Description of the SDRAM Timing Register (SDRAM_TR)

Parameter	Description
T_RFC T_RP T_RCD T_WR T_RAS T_RC T_RRD	**SDRAM Timing Parameters.** These fields configure the EMIF to comply with the AC timing requirements of the attached SDRAM devices. This allows the EMIF to avoid violating SDRAM timing constraints and to more efficiently schedule operations. More details about each of these parameters can be found in the SDRAM_TR register description. These parameters must be set to satisfy the corresponding timing requirements found in the SDRAM data sheet.

Table 14-11. Description of the SDRAM Self Refresh Exit Timing Register (SDR_EXT_TMNG)

Parameter	Description
T_XS	**Self Refresh Exit Parameter.** The T_XS field of this register informs the EMIF about the minimum number of EM1CLK cycles required between exiting self-refresh and issuing any command. This parameter must be set to satisfy the t_{XSR} value for the attached SDRAM device.

14.2.5.4 SDRAM Auto-Initialization Sequence

The EMIF automatically performs an SDRAM initialization sequence, regardless of whether the EMIF is interfaced to an SDRAM device, when either of the following two events occur:

- The EMIF comes out of reset. No memory accesses to the SDRAM and asynchronous interfaces are performed until this auto-initialization is complete.
- A write is performed to any of the three least-significant bytes of the SDRAM configuration register (SDRAM_CR)

An SDRAM initialization sequence consists of the following steps:

1. If the initialization sequence is activated by a write to SDRAM_CR, and if any of the SDRAM banks are open, the EMIF issues a PRE command with EM1A[10] held high to indicate all banks. This is done so that the maximum ACTV to PRE timing for an SDRAM is not violated.
2. The EMIF drives EM1SDCKE high and begins continuously issuing NOP commands until eight SDRAM refresh intervals have elapsed. An SDRAM refresh interval is equal to the value of the RR field of the SDRAM refresh control register (SDRAM_RCR), divided by the frequency of EM1CLK (RR/f_{EM1CLK}). This step is used to avoid violating the power-up constraint of most SDRAM devices that requires 200µs (sometimes 100µs) between receiving stable Vdd and CLK and the issuing of a PRE command. Depending on the frequency of EM1CLK, this step can be insufficient to avoid violating the SDRAM constraint. See Section 14.2.5.5 for more information.
3. After the refresh intervals have elapsed, the EMIF issues a PRE command with EM1A[10] held high to indicate all banks.
4. The EMIF issues eight AUTO REFRESH commands.
5. The EMIF issues the LMR command with the EM1A[9:0] pins set as described in Table 14-12.
6. Finally, the EMIF performs a refresh cycle, which consists of the following steps:
   a. Issuing a PRE command with EM1A[10] held high if any banks are open
   b. Issuing an REF command

Table 14-12. SDRAM LOAD MODE REGISTER Command

EM1A[9:7]	EM1A[6:4]	EM1A[3]	EM1A[2:0]
0 (Write bursts are of the programmed burst length in EM1A[2:0])	These bits control the CAS latency of the SDRAM and are set according to CL field in the SDRAM configuration register (SDRAM_CR) as follows: • If CL = 2, EM1A[6:4] = 2h (CAS latency = 2) • If CL = 3, EM1A[6:4] = 3h (CAS latency = 3)	0 (Sequential Burst Type. Interleaved Burst Type not supported)	These bits control the burst length of the SDRAM and are set according to the NM field in the SDRAM configuration register (SDRAM_CR) as follows: • If NM = 0, EM1A[2:0] = 2h (Burst Length = 4) • If NM = 1, EM1A[2:0] = 3h (Burst Length = 8)

14.2.5.5 SDRAM Configuration Procedure

There are two different SDRAM configuration procedures. Although the EMIF automatically performs the SDRAM initialization sequence described in Section 14.2.5.4 when coming out of reset, follow one of the procedures before performing any EMIF memory requests.

Procedure A must be followed if the SDRAM power-up constraint was not violated during the SDRAM auto-initialization sequence detailed in Section 14.2.5.4 on coming out of Reset. The SDRAM power-up constraint specifies that 200µs (sometimes 100µs) must exist between receiving stable Vdd and CLK and the issuing of a PRE command.

Procedure B must be followed if the SDRAM power-up constraint was violated. The 200µs (100µs) SDRAM power-up constraint is violated, if the frequency of EM1CLK is greater than 50MHz (100MHz for 100µs SDRAM power-up constraint) during SDRAM Auto-Initialization Sequence. Procedure B must be followed if there is any doubt that the power-up constraint was not met.

Procedure A — Following is the procedure to be followed if the SDRAM power-up constraint was not violated:

1. Place the SDRAM into self-refresh mode by setting the SR bit of SDRAM_CR to 1. The SDRAM can be placed into self-refresh mode when changing the frequency of the EM1CLK to avoid incurring the 200µs power-up constraint again.
2. Configure the desired EMIF1 clock (EM1CLK) frequency. The frequency of the memory clock must meet the timing requirements in the SDRAM manufacturer's documentation and the timing limitations shown in the electrical specifications of the device data sheet.
3. Remove the SDRAM from self-refresh mode by clearing the SR bit of the SDRAM_CR to 0.
4. Program SDRAM_TR and SDR_EXT_TMNG to satisfy the timing requirements for the attached SDRAM device. The timing parameters must be taken from the SDRAM data sheet.
5. Program the RR field of SDRAM_RCR to match that of the attached device's refresh interval. See Section 14.2.5.6.1 details on determining the appropriate value.
6. Program the SDRAM_CR to match the characteristics of the attached SDRAM device. This causes the auto-initialization sequence in Section 14.2.5.4 to be re-run. This second initialization generally takes much less time due to the increased frequency of EM1CLK.

Procedure B — Following is the procedure to be followed if the SDRAM power-up constraint was violated:

1. Configure the desired EM1CLK clock frequency. The frequency of the memory clock must meet the timing requirements in the SDRAM manufacturer's documentation and the timing limitations shown in the electrical specifications of the device data sheet.
2. Program SDRAM_TR and SDR_EXT_TMNG to satisfy the timing requirements for the attached SDRAM device. The timing parameters must be taken from the SDRAM data sheet.
3. Program the RR field of the SDRAM_RCR such that the following equation is satisfied: $(RR \times 8)/(f_{EM1CLK}) > 200\mu s$ (sometimes 100µs). For example, an EM1CLK frequency of 100MHz requires setting RR to 2501 (9C5h) or higher to meet a 200µs constraint.
4. Program the SDRAM_CR to match the characteristics of the attached SDRAM device. This causes the auto-initialization sequence in Section 14.2.5.4 to be re-run with the new value of RR.
5. Perform a read from the SDRAM to make sure that step 5 of this procedure occurs after the initialization process has completed. Alternatively, wait for 200µs instead of performing a read.
6. Finally, program the RR field to match that of the attached device's refresh interval. See Section 14.2.5.6.1 details on determining the appropriate value.

After following the above procedure, the EMIF is ready to perform accesses to the attached SDRAM device.

14.2.5.6 EMIF Refresh Controller

An SDRAM device requires that each of the rows be refreshed at a minimum required rate. The EMIF can meet this constraint by performing auto refresh cycles at or above this required rate. An auto-refresh cycle consists of issuing a PRE command to all banks of the SDRAM device followed by issuing a REFR command. To inform the EMIF of the required rate for performing auto refresh cycles, the RR field of the SDRAM refresh control register (SDRAM_RCR) must be programmed. The EMIF uses this value along with two internal counters to automatically perform auto refresh cycles at the required rate. The auto-refresh cycles cannot be disabled, even if the EMIF is not interfaced with an SDRAM. The remainder of this section details the EMIF's refresh scheme and provides an example for determining the appropriate value to place in the RR field of the SDRAM_RCR.

The two counters used to perform auto-refresh cycles are a 13-bit refresh interval counter and a 4-bit refresh backlog counter. At reset and upon writing to the RR field, the refresh interval counter is loaded with the value from RR field and begins decrementing, by one, each EMIF clock cycle. When the refresh interval counter reaches zero, the following actions occur:

- The refresh interval counter is reloaded with the value from the RR field and restarts decrementing.
- The 4-bit refresh backlog counter increments unless the counter has already reached the maximum value.

The refresh backlog counter records the number of auto refresh cycles that the EMIF currently has outstanding. This counter is decremented by one each time an auto refresh cycle is performed and incremented by one each time the refresh interval counter expires. The refresh backlog counter saturates at the values of 0000b and 1111b. The EMIF uses the refresh backlog counter to determine the urgency with which an auto refresh cycle must be performed. The four levels of urgency are described in Table 14-13. This refresh scheme allows the required refreshes to be performed with minimal impact on access requests.

Table 14-13. Refresh Urgency Levels

Urgency Level	Refresh Backlog Counter Range	Action Taken
Refresh May	1-3	An auto-refresh cycle is performed only if the EMIF has no requests pending and none of the SDRAM banks are open.
Refresh Release	4-7	An auto-refresh cycle is performed if the EMIF has no requests pending, regardless of whether any SDRAM banks are open.
Refresh Need	8-11	An auto-refresh cycle is performed at the completion of the current access unless there are read requests pending.
Refresh Must	12-15	Multiple auto-refresh cycles are performed at the completion of the current access until the Refresh Release urgency level is reached. At that point, the EMIF can begin servicing any new read or write requests.

14.2.5.6.1 Determining the Appropriate Value for the RR Field

The value that must be programmed into the RR field of the SDRAM_RCR must can be calculated by using the frequency of the EM1CLK signal (f_{EM1CLK}) and the required refresh rate of the SDRAM ($f_{Refresh}$). The following formula can be used:

$RR = f_{EM1CLK} / f_{Refresh}$

The SDRAM data sheet often communicates the required SDRAM Refresh Rate in terms of the number of REFR commands required in a given time interval. The required SDRAM Refresh Rate in the formula above can therefore be calculated by dividing the number of required cycles per time interval (n_{cycles}) by the time interval given in the data sheet ($t_{Refresh\ Period}$) :

$f_{Refresh} = n_{cycles} / t_{Refresh\ Period}$

Combining these formulas, the value that must be programmed into the RR field can be computed as:

$RR = f_{EM1CLK} \times t_{Refresh\ Period} / n_{cycles}$

The following example illustrates calculating the value of RR. Given that:

- f_{EM1CLK} = 100MHz (frequency of EMIF clock)
- $t_{Refresh\ Period}$ = 64ms (required refresh interval of the SDRAM)
- n_{cycles} = 8192 (number of cycles in a refresh interval for the SDRAM)

RR can be calculated as:

RR = 100MHz × 64ms/8192

RR = 781.25

RR = 782 cycles = 30Eh cycles

14.2.5.7 Self-Refresh Mode

The EMIF can be programmed to enter the self-refresh state by setting the SR bit of SDRAM_CR to 1. This causes the EMIF to issue the SLFR command after completing any outstanding SDRAM access requests and clearing the refresh backlog counter by performing one or more auto refresh cycles. This places the attached SDRAM device into self-refresh mode in which the EMIF consumes a minimal amount of power while performing the refresh cycles.

While in the self-refresh state, the EMIF continues to service asynchronous bank requests and register accesses as normal, with one caveat. The EMIF does not park the data bus following a read to asynchronous memory while in the self-refresh state. Instead, the EMIF tri-states the data bus. Therefore, it is not recommended to perform asynchronous read operations while the EMIF is in the self-refresh state to prevent floating inputs on the data bus. More information about data bus parking can be found in Section 14.2.7.

The EMIF exits from the self-refresh state, if either of the following events occur:

- The SR bit of SDRAM_CR is cleared to 0.
- An SDRAM accesses is requested.

The EMIF exits from the self-refresh state by driving EM1SDCKE high and performing an auto refresh cycle.

The attached SDRAM device must also be placed into self-refresh mode when changing the frequency of EM1CLK. If the frequency of EM1CLK changes while the SDRAM is not in self-refresh mode, Procedure B in Section 14.2.5.5 must be followed to reinitialize the device.

14.2.5.8 Power-Down Mode

To support low-power modes, the EMIF can be requested to issue a POWER DOWN command to the SDRAM by setting the PD bit in the SDRAM configuration register (SDRAM_CR). When this bit is set, the EMIF continues normal operation until all outstanding memory access requests have been serviced and the SDRAM refresh backlog (if there is one) has been cleared. At this point, the EMIF enters the power-down state. Upon entering this state, the EMIF issues a POWER DOWN command (same as a NOP command but driving the EM1SDCKE low on the same cycle). The EMIF then maintains the EM1SDCKE low until the EMIF exits the power-down state.

Since the EMIF services the refresh backlog before the EMIF enters the power-down state, all internal banks of the SDRAM are closed (precharged) prior to issuing the POWER DOWN command. Therefore, the EMIF only supports precharge power-down. The EMIF does not support active power-down, where internal banks of the SDRAM are open (active) before the POWER DOWN command is issued.

During the power-down state, the EMIF services the SDRAM, asynchronous memory, and register accesses as normal, returning to the power-down state upon completion.

The PDWR bit in the SDRAM_CR indicates whether the EMIF must perform refreshes in power-down state. If the PDWR bit is set, the EMIF exits the power-down state every time the Refresh Must level is set, performs AUTO REFRESH commands to the SDRAM, and returns back to the power-down state. This evenly distributes the refreshes to the SDRAM in power-down state. If the PDWR bit is not set, the EMIF does not perform any refreshes to the SDRAM. Therefore, the data integrity of the SDRAM is not maintained upon power-down exit, if the PDWR bit is not set.

If the PD bit is cleared while in the power-down state, the EMIF comes out of the power-down state. The EMIF:

- Drives EM1SDCKE high
- Enters the idle state

14.2.5.9 SDRAM Read Operation

When the EMIF receives a read request to the SDRAM from one of the requesters listed in Section 14.2.2, the EMIF performs one or more read access cycles. A read access cycle begins with the issuing of the ACTV command to select the desired bank and row of the SDRAM device. After the row has been opened, the EMIF proceeds to issue a READ command while specifying the desired bank and column address. EM1A[10] is held low during the READ command to avoid auto-precharging. The READ command signals the SDRAM device to output data from the specified address while EMIF issues NOP commands. Following a READ command, the CL field of the SDRAM configuration register (SDRAM_CR) defines how many delay cycles are present before the read data appears on the data bus. This is referred to as the CAS latency.

Figure 14-6 shows the signal waveforms for a basic SDRAM read operation in which multiple data is read from a single page. On this device, burst accesses are not supported; hence, the EMIF issues a READ command for each data access. Only when the EMIF SDRAM interface is configured to 16-bit by setting the NM bit of the SDRAM configuration register (SDRAM_CR) to 1 and CPU (or any other controller) does a 32-bit READ access, a burst access is issued with a size of two.

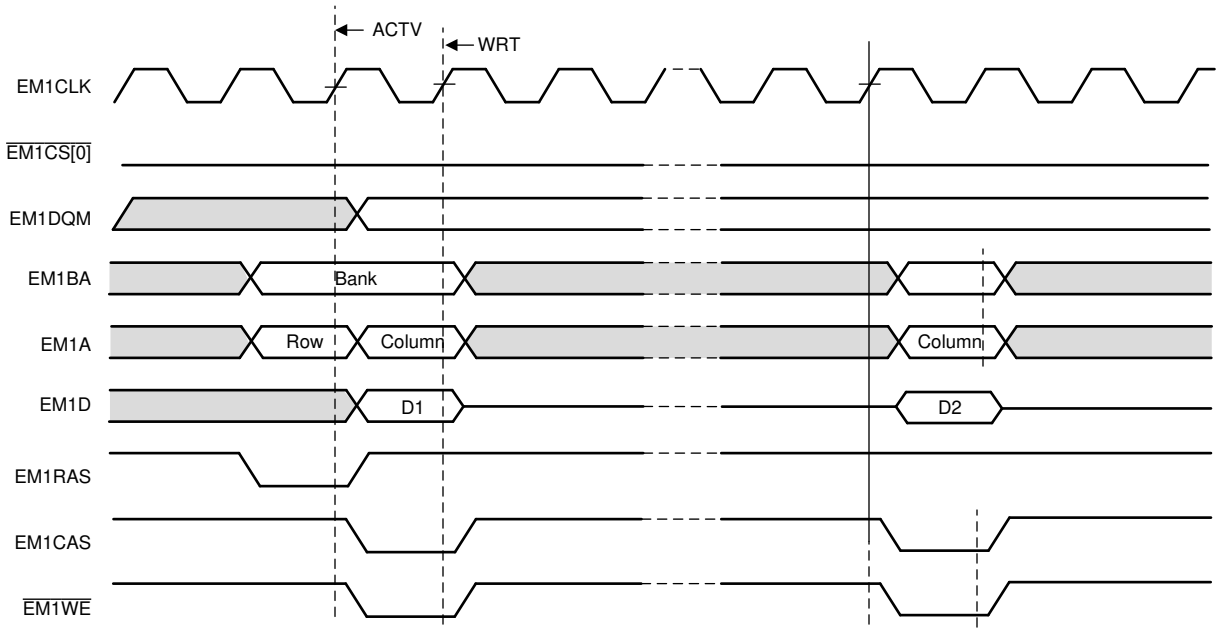

Figure 14-6. Timing Waveform for Basic SDRAM Read Operation

Several other pins are also active during a read access. The EM1DQM[x:0] pins are driven low during the READ commands and are kept low during the NOP commands that correspond to the burst request. The state of the other EMIF pins during each command can be found in Table 14-6.

The EMIF schedules the commands based on the timing information that is provided to the EMIF in the SDRAM timing register (SDRAM_TR). The values for the timing parameters in this register must be chosen to satisfy the timing requirements listed in the SDRAM data manual. The EMIF uses this timing information to avoid violating any timing constraints related to issuing commands. This is commonly accomplished by inserting NOP commands between various commands during an access. Refer to the register description of SDRAM_TR in the SDTIMER register for more details on the various timing parameters.

14.2.5.10 SDRAM Write Operations

When the EMIF receives a write request to SDRAM from one of the requesters listed in Section 14.2.2, the EMIF performs one or more write-access cycles. A write-access cycle begins with the issuing of the ACTV command to select the desired bank and row of the SDRAM device. After the row has been opened, the EMIF proceeds to issue a WRT command while specifying the desired bank and column address. EM1A[10] is held low during the WRT command to avoid auto-precharging. The WRT command signals the SDRAM device to start writing the given data to the specified address while the EMIF issues NOP commands. On this device, burst accesses are not supported; hence, the EMIF issues a WRITE command for each data access. Only when the EMIF SDRAM interface is configured to 16-bit by setting the NM bit of the SDRAM configuration register (SDRAM_CR) to 1 and CPU (or any other controller) does a 32bit WRITE access, a burst access is issued with size of two.

Figure 14-7 shows the signal waveforms for a basic SDRAM write operation.

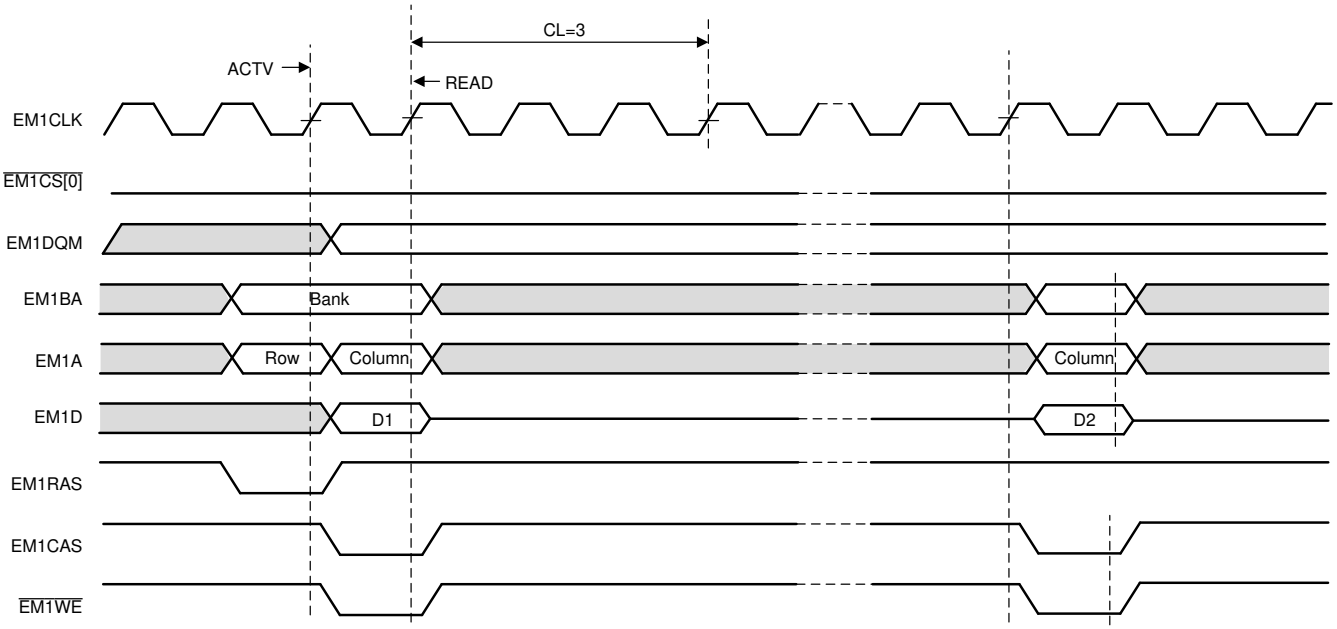

Figure 14-7. Timing Waveform for Basic SDRAM Write Operation

The EMIF truncates a series of bursting data if the remaining addresses of the burst are not part of the write request. The EMIF can truncate the burst in three ways:

- By issuing another WRT to the same page
- By issuing a PRE command to prepare for accessing a different page of the same bank
- By issuing a BT command to prepare for accessing a page in a different bank

Several other pins are also active during a write access. The EM1DQM[x:0] pins are driven to select which bytes of the data word are written to the SDRAM device. The pins are also used to mask out entire undesired data words during a burst access. The state of the other EMIF pins during each command can be found in Table 14-6.

The EMIF schedules the commands based on the timing information that is provided to the EMIF in the SDRAM timing register (SDRAM_TR). The values for the timing parameters in this register must be chosen to satisfy the timing requirements listed in the SDRAM data sheet. The EMIF uses this timing information to avoid violating any timing constraints related to issuing commands. This is commonly accomplished by inserting NOP commands during various cycles of an access. Refer to the register description of SDRAM_TR in the SDTIMR register for more details on the various timing parameters.

14.2.5.11 Mapping from Logical Address to EMIF Pins

When the EMIF receives an SDRAM access request, the EMIF must convert the address of the access into the appropriate signals to send to the SDRAM device. The details of this address mapping are shown in Table 14-14 for 32-bit operation and in Table 14-15 for 16-bit operation. Using the settings of the IBANK and PAGESIZE fields of the SDRAM configuration register (SDRAM_CR), the EMIF determines which bits of the logical address are mapped to the SDRAM row, column, and bank addresses.

As the logical address is incremented by one halfword (16-bit operation), the column address is likewise incremented by one until a page boundary is reached. When the logical address increments across a page boundary, the EMIF moves into the same page in the next bank of the attached device by incrementing the bank address EM1BA and resetting the column address. The page in the previous bank is left open until necessary to close the page. This method of traversal through the SDRAM banks helps maximize the number of open banks inside of the SDRAM and results in an efficient use of the device. There is no limitation on the number of banks that can be open at one time, but only one page within a bank can be open at a time.

The EMIF uses the EM1DQM[3:0] pins during a WRT command to mask out selected bytes or entire words. The EM1DQM[3:0] pins are always low during a READ command.

Table 14-14. Mapping from Logical Address to EMIF Pins for 32-bit SDRAM

IBANK	PAGESIZE	Logical Address													
		31:27	26	25	24	23	22	21:14	13	12	11	10	9	8:1	0
0	0	-						Row Address						Col Address	EM1DQM[2]/EM1DQM[3]
1	0	-						Row Address					EM1BA[0]	Col Address	EM1DQM[2]/EM1DQM[3]
2	0	-						Row Address				EM1BA[1:0]		Col Address	EM1DQM[2]/EM1DQM[3]
0	1	-						Row Address					Column Address		EM1DQM[2]/EM1DQM[3]
1	1	-						Row Address				EM1BA[0]	Column Address		EM1DQM[2]/EM1DQM[3]
2	1	-						Row Address			EM1BA[1:0]		Column Address		EM1DQM[2]/EM1DQM[3]
0	2	-						Row Address				Column Address			EM1DQM[2]/EM1DQM[3]
1	2	-						Row Address			EM1BA[0]	Column Address			EM1DQM[2]/EM1DQM[3]
2	2	-						Row Address		EM1BA[1:0]		Column Address			EM1DQM[2]/EM1DQM[3]
0	3	-						Row Address			Column Address				EM1DQM[2]/EM1DQM[3]
1	3	-						Row Address		EM1BA[0]	Column Address				EM1DQM[2]/EM1DQM[3]
2	3	-						Row Address		EM1BA[1:0]	Column Address				EM1DQM[2]/EM1DQM[3]

Table 14-15. Mapping from Logical Address to EMIF Pins for 16-bit SDRAM

IBANK	PAGESIZE	Logical Address												
		31:26	25	24	23	22	21	20:13	12	11	10	9	8	7:0
0	0	-						Row Address						Col Address
1	0	-						Row Address					EM1BA[0]	Col Address
2	0	-						Row Address				EM1BA[1:0]		Col Address
0	1	-						Row Address					Column Address	
1	1	-						Row Address				EM1BA[0]	Column Address	
2	1	-						Row Address			EM1BA[1:0]		Column Address	
0	2	-						Row Address				Column Address		
1	2	-						Row Address			EM1BA[0]	Column Address		
2	2	-						Row Address		EM1BA[1:0]		Column Address		
0	3	-						Row Address			Column Address			
1	3	-						Row Address		EM1BA[0]	Column Address			
2	3	-						Row Address		EM1BA[1:0]	Column Address			

Note

The upper bit of the row address is used only when addressing 256-Mbit and 512-Mbit SDRAM memories.

14.2.6 Asynchronous Controller and Interface

The EMIF easily interfaces to a variety of asynchronous devices including NOR Flash and SRAM. The EMIF can be operated in two major modes (see Table 14-16):

- Normal Mode
- Select Strobe Mode

Table 14-16. Normal Mode vs. Select Strobe Mode

Mode	Function of EM1DQM pins	Operation of $\overline{\text{EM1CS}}$[4:2]
Normal Mode	Byte enables	Active during the entire asynchronous access cycle
Select Strobe Mode	Byte enables	Active only during the strobe period of an access cycle

The first mode of operation is normal mode, in which the EM1DQM pins of the EMIF function as byte enables. In this mode, the $\overline{\text{EM1CS}}$[4:2] pins behave as typical chip select signals, remaining active for the duration of the asynchronous access. See Section 14.2.6.1 for an example interface with multiple 8-bit devices.

The second mode of operation is select strobe mode, in which the $\overline{\text{EM1CS}}$[4:2] pins act as a strobe, active only during the strobe period of an access. In this mode, the EM1DQM pins of the EMIF function as standard byte enables for reads and writes. A summary of the differences between the two modes of operation are shown in Table 14-16. Refer to Section 14.2.6.4 for the details of asynchronous operations in normal mode, and to Section 14.2.6.5 for the details of asynchronous operations in select strobe mode. The EMIF hardware defaults to normal mode, but can be manually switched to select strobe mode by setting the SS bit in the asynchronous *m* (m = 1, 2, 3, or 4) configuration register (CE*n*CFG) (*n* = 2, 3, or 4). Throughout the chapter, *m* can hold the values 1, 2, 3 or 4; and *n* can hold the values 2, 3, or 4.

The EMIF also provides configurable cycle timing parameters and an extended wait mode that allows the connected device to extend the strobe period of an access cycle. The following sections describe the features related to interfacing with external asynchronous devices.

14.2.6.1 Interfacing to Asynchronous Memory

Figure 14-8 shows the EMIF's external pins used in interfacing with an asynchronous device. In $\overline{\text{EM1CS}}$[n], n = 2, 3, or 4.

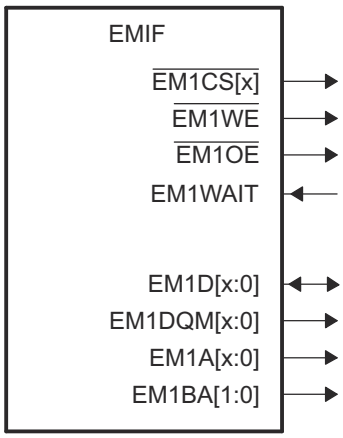

Figure 14-8. EMIF Asynchronous Interface

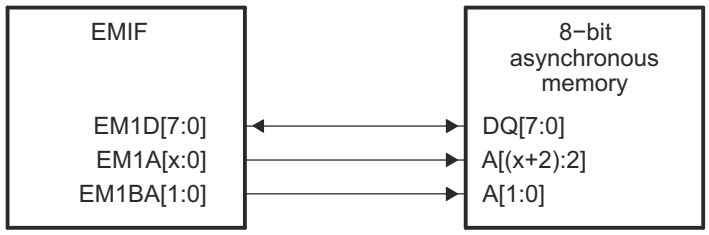
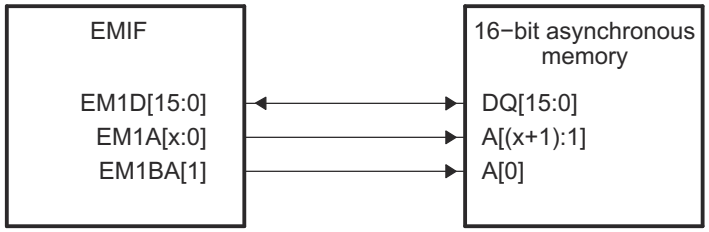
Of special note is the connection between the EMIF and the external device's address bus. The EMIF address pin EM1A[0] always provides the least-significant bit of a 32-bit word address. Therefore, when interfacing to a 16-bit or 8-bit asynchronous device, the EM1BA[1] and EM1BA[0] pins provide the least-significant bits of the halfword or byte address, respectively. Figure 14-9 and Figure 14-10 show the mapping between the EMIF and the connected device's data and address pins for various programmed data bus widths. The data bus width can be configured in the asynchronous *n* configuration register (ASYNC_CS*n*_CR).

Figure 14-10 shows an interface between the EMIF and an external memory with byte enables. The EMIF must be operated in either normal mode or select strobe mode when using this interface, so that the EM1DQM signals operate as byte enables.



a) EMIF to 8-bit memory interface



b) EMIF to 16-bit memory interface

Figure 14-9. EMIF to 8-bit/16-bit Memory Interface

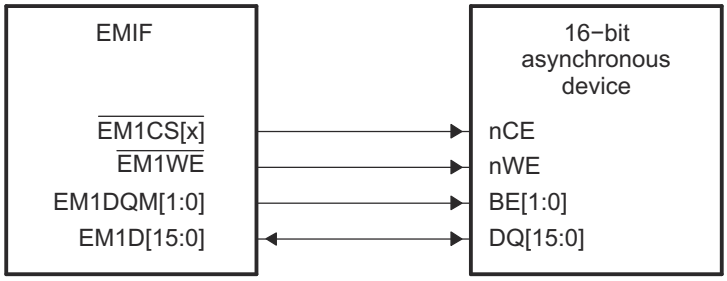


Figure 14-10. Common Asynchronous Interface

14.2.6.2 Accessing Larger Asynchronous Memories

If a device such as a large asynchronous Flash needs to be attached to the EMIF, then GPIO pins can be used to control the Flash device upper address lines.

14.2.6.3 Configuring EMIF for Asynchronous Accesses

The operation of the EMIF's asynchronous interface can be configured by programming the appropriate register fields. The reset value and bit position for each register field can be found in Section 14.6. The following tables list the register fields that can be programmed and describe the purpose of each field. These registers can be programmed prior to accessing the external memory, and the transfer following a write to these registers uses the new configuration.

Table 14-17. Description of the Asynchronous *m* Configuration Register (ASYNC_CSn_CR)

Parameter	Description
SS	**Select Strobe mode.** This bit selects the EMIF's mode of operation in the following way: • SS = 0 selects Normal Mode – EM1DQM pins function as byte enables – $\overline{\text{EM1CS}}$[4:2] active for duration of access • SS = 1 selects Select Strobe Mode – EM1DQM pins function as byte enables – $\overline{\text{EM1CS}}$[4:2] acts as a strobe.
EW	**Extended Wait Mode enable.** • EW = 0 disables extended wait mode • EW = 1 enables extended wait mode When set to 1, the EMIF enables the extended wait mode in which the strobe width of an access cycle can be extended in response to the assertion of the EM1WAIT pin. The WP*n* bit in the asynchronous wait cycle configuration register (ASYNC_WCCR) controls the polarity of the EM1WAIT pin. See Section 14.2.6.6 for more details on this mode of operation.
W_SETUP/R_SETUP	**Read/Write setup widths.** These fields define the number of EMIF clock cycles of setup time for the address pins (EM1A), byte enables (EM1DQM), and asynchronous chip enable ($\overline{\text{EM1CS}}$[4:2]) before the read strobe pin (EM103) or write strobe pin ($\overline{\text{EM1WE}}$) falls, minus one cycle. For writes, the W_SETUP field also defines the setup time for the data pins (EM1D). Refer to the asynchronous device 's data sheet to determine the appropriate setting for this field.
W_STROBE/R_STROBE	**Read/Write strobe widths.** These fields define the number of EMIF clock cycles between the falling and rising of the read strobe pin (EM103) or write strobe pin (EM1WEn), minus one cycle. If Extended Wait Mode is enabled by setting the EW field in the asynchronous *n* configuration register (ASYNC_CS*n*_CR), these fields must be set to a value greater than zero. Refer to the data manual of the external asynchronous device to determine the appropriate setting for this field.
W_HOLD/R_HOLD	**Read/Write hold widths.** These fields define the number of EMIF clock cycles of hold time for the address pins (EM1A and EM1BA), byte enables (EM1DQM), and asynchronous chip enable ($\overline{\text{EM1CS}}$[4:2]) after the read strobe pin (EM103) or write strobe pin ($\overline{\text{EM1WE}}$) rises, minus one cycle. For writes, the W_HOLD field also defines the hold time for the data pins (EM1D). Refer to the data manual of the external asynchronous device to determine the appropriate setting for this field.
TA	**Minimum turnaround time.** This field defines the minimum number of EMIF clock cycles between asynchronous reads and writes, minus one cycle. The purpose of this feature is to avoid contention on the bus. The value written to this field also determines the number of cycles that are inserted between asynchronous accesses and SDRAM accesses. Refer to the data manual of the external asynchronous device to determine the appropriate setting for this field.

Table 14-17. Description of the Asynchronous *m* Configuration Register (ASYNC_CSn_CR) (continued)

Parameter	Description
ASIZE	**Asynchronous Device Bus Width.** This field determines the data bus width of the asynchronous interface in the following way: • ASIZE = 0 selects an 8-bit bus • ASIZE = 1 selects a 16-bit bus • ASIZE = 2 selects a 32-bit bus The configuration of ASIZE determines the function of the EM1A and EM1BA pins as described in Section 14.2.6.1. This field also determines the number of external accesses required to fulfill a request generated by one of the sources mentioned in Section 14.2.2. For example, a request for a 32-bit word requires four external access when ASIZE = 0. Refer to the data manual of the external asynchronous device to determine the appropriate setting for this field.

Table 14-18. Description of the Asynchronous Wait Cycle Configuration Register (ASYNC_WCCR)

Parameter	Description
WP*n*	**EM_WAIT Polarity.** • WP*n* = 0 selects active-low polarity • WP*n* = 1 selects active-high polarity When set to 1, the EMIF waits if the EM1WAIT pin is high. When cleared to 0, the EMIF waits if the EM1WAIT pin is low. The EMIF must have the Extended Wait Mode enabled for the EM1WAIT pin to affect the width of the strobe period.
MAX_EXT_WAIT	**Maximum Extended Wait Cycles.** This field configures the number of EMIF clock cycles the EMIF waits for the EM1WAIT pin to be deactivated during the strobe period of an access cycle. The maximum number of EMIF clock cycles the EMIF waits is determined by the following formula: Maximum Extended Wait Cycles = (MAX_EXT_WAIT + 1) × 16 If the EM1WAIT pin is not deactivated within the time specified by this field, the EMIF resumes the access cycle, registering whatever data is on the bus and proceeding to the hold period of the access cycle. This situation is referred to as an Asynchronous Timeout. An Asynchronous Timeout generates an interrupt, if the interrupt has been enabled in the EMIF interrupt mask set register (INT_MSK_SET). Refer to Section 14.2.9.1 for more information about EMIF interrupts.

Table 14-19. Description of EMIF Interrupt Mask Set Register (INT_MSK_SET)

Parameter	Description
WR_MASK_SET	**Wait Rise Mask Set.** Writing a 1 enables an interrupt to be generated when a rising edge on EM1WAIT occurs.
AT_MASK_SET	**Asynchronous Timeout Mask Set.** Writing a 1 to this bit enables an interrupt to be generated when an Asynchronous Timeout occurs.

Table 14-20. Description of EMIF Interrupt Mast Clear Register (INT_MSK_CLR)

Parameter	Description
WR_MASK_CLR	**Wait Rise Mask Clear.** Writing a 1 to this bit disables the interrupt, clearing the WR_MASK_SET bit in EMIF interrupt mask set register (INT_MSK_SET).
AT_MASK_CLR	**Asynchronous Timeout Mask Clear.** Writing a 1 to this bit prevents an interrupt from being generated when an Asynchronous Timeout occurs.

Note

The EMIF performs SDRAM refreshes even if the SDRAM interface is not used. If using only the ASRAM interface, then SDRAM refreshes impact the ASRAM performance. To avoid this, set PD = 1 in the SDRAM_CR register (Emif1Regs.SDRAM_CR.PD = 1). This bit can be updated only if there are no pending EMIF accesses.

14.2.6.4 Read and Write Operations in Normal Mode

Normal mode is the asynchronous interface default mode of operation. Normal mode is selected when the SS bit in the asynchronous *n* configuration register (ASYNC_CS*n*_CR) is cleared to 0. In this mode, the EM1DQM pins operate as byte enables. Section 14.2.6.4.1 and Section 14.2.6.4.2 explain the details of read and write operations while in normal mode.

14.2.6.4.1 Asynchronous Read Operations (Normal Mode)

Note

During an entire asynchronous read operation, the $\overline{\text{EM1WE}}$ pin is driven high.

An asynchronous read is performed when any of the requesters mentioned in Section 14.2.2 request a read from the attached asynchronous memory. After the request is received, a read operation is initiated once the request becomes the EMIF's highest priority task, according to the priority scheme detailed in Section 14.2.13. In the event that the read request cannot be serviced by a single access cycle to the external device, multiple access cycles are performed by EMIF until the entire request is fulfilled. The details of an asynchronous read operation in normal mode are described in Table 14-21. Also, Figure 14-11 shows an example timing diagram of a basic read operation.

Table 14-21. Asynchronous Read Operation in Normal Mode

Time Interval	Pin Activity in Normal Mode
Turnaround period	Once the read operation becomes the highest priority task for EMIF, the EMIF waits for the programmed number of turn-around cycles before proceeding to the setup period of the operation. The number of wait cycles is taken directly from the TA field of the asynchronous *n* configuration register (ASYNC_CS*n*_CR). Between each access (write or read), the EMIF inserts two cycles of delay even though TA field is programmed as 0. After the EMIF has waited for the turnaround cycles to complete, the EMIF again checks to make sure that the read operation is still the highest priority task. If so, the EMIF proceeds to the setup period of the operation. If the read operation is no longer the highest priority task, the EMIF terminates the operation.
Start of the setup period	The following actions occur at the start of the setup period: • The setup, strobe, and hold values are set according to the R_SETUP, R_STROBE, and R_HOLD values in ASYNC_CS*n*_CR. • The address pins EM1A and EM1BA become valid and carry the values described in Section 14.2.6.1. • $\overline{\text{EM1CS}}$[4:2] falls to enable the external device (if not already low from a previous operation)

Table 14-21. Asynchronous Read Operation in Normal Mode (continued)

Time Interval	Pin Activity in Normal Mode
Strobe period	The following actions occur during the strobe period of a read operation: 1. $\overline{\text{EM1OE}}$ falls at the start of the strobe period 2. On the rising edge of the clock that is concurrent with the end of the strobe period: • $\overline{\text{EM1OE}}$ rises • The data on the EM1Dx bus is sampled by EMIF. In Figure 14-11, EM1WAIT is inactive. If EM1WAIT is instead activated, the strobe period can be extended by the external device to give it more time to provide the data. Section 14.2.6.6 contains more details on using the EM1WAIT pin.
End of the hold period	At the end of the hold period: • The address pins EM1A and EM1BA become invalid • $\overline{\text{EM1CS}}$[4:2] rises (if no more operations are required to complete the current request) The EMIF can be required to issue additional read operations to a device with a small data bus width to complete an entire word access. In this case, the EMIF immediately re-enters the setup period to begin another operation without incurring the turn-round cycle delay. The setup, strobe, and hold values are not updated in this case. If the entire word access has been completed, the EMIF returns to the previous state unless another asynchronous request has been submitted and is currently the highest priority task. If this is the case, EMIF instead enters directly into the turnaround period for the pending read or write operation.

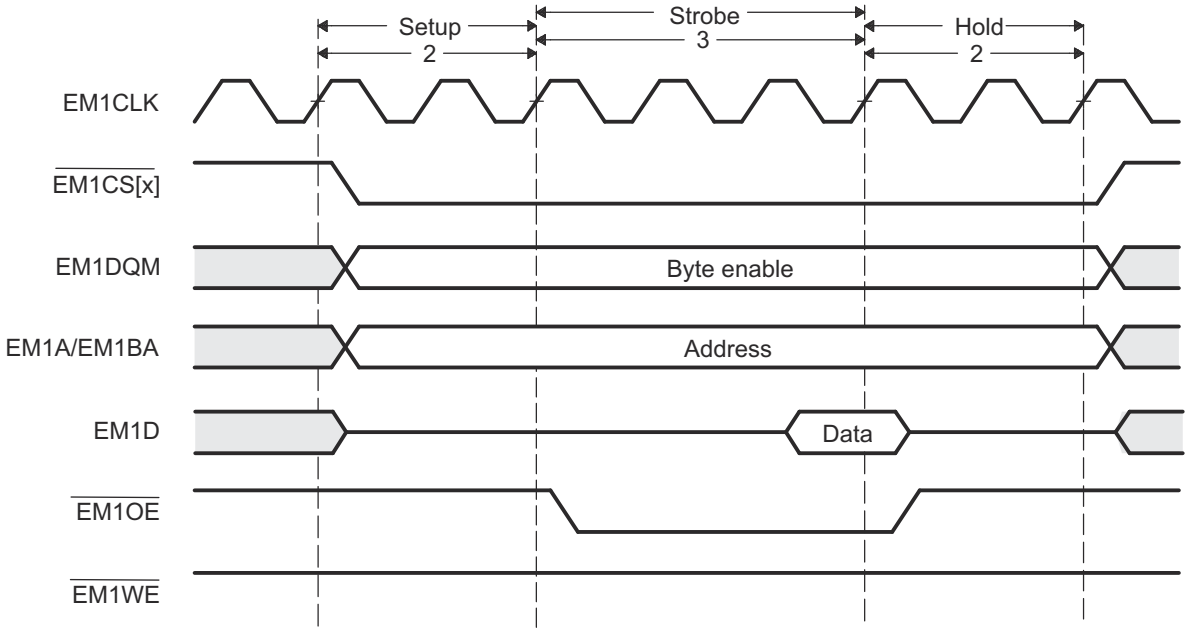

Figure 14-11. Timing Waveform of an Asynchronous Read Cycle in Normal Mode

14.2.6.4.2 Asynchronous Write Operations (Normal Mode)

Note

During an entire asynchronous write operation, the $\overline{\text{EM1OE}}$ pin is driven high.

An asynchronous write is performed when any of the requesters mentioned in Section 14.2.2 request a write to memory in the asynchronous bank of EMIF. After the request is received, a write operation is initiated once the request becomes the EMIF's highest priority task, according to the priority scheme detailed in Section 14.2.13. In the event that the write request cannot be serviced by a single access cycle to the external device, multiple access cycles are performed by the EMIF until the entire request is fulfilled. The details of an asynchronous write operation in normal mode are described in Table 14-22. Also, Figure 14-12 shows an example timing diagram of a basic write operation.

Table 14-22. Asynchronous Write Operation in Normal Mode

Time Interval	Pin Activity in Normal Mode
Turnaround period	Once the write operation becomes the highest priority task for the EMIF, the EMIF waits for the programmed number of turn-around cycles before proceeding to the setup period of the operation. The number of wait cycles is taken directly from the TA field of the asynchronous *n* configuration register (ASYNC_CS*n*_CR). Between each access (write or read) EMIF inserts two cycles of delay even though TA field is programmed as 0. After the EMIF has waited for the turn-around cycles to complete, the EMIF again checks to make sure that the write operation is still the highest priority task. If so, the EMIF proceeds to the setup period of the operation. If the write operation is no longer the highest priority task, EMIF terminates the operation.
Start of the setup period	The following actions occur at the start of the setup period: • The setup, strobe, and hold values are set according to the W_SETUP, W_STROBE, and W_HOLD values in ASYNC_CS*n*_CR. • The address pins EM1A and EM1BA and the data pins EM1Dx become valid. The EM1A and EM1BA pins carry the values described in Section 14.2.6.1. • $\overline{\text{EM1CS}}$[4:2] falls to enable the external device (if not already low from a previous operation).
Strobe period	The following actions occur at the start of the strobe period of a write operation: 1. $\overline{\text{EM1WE}}$ falls 2. The EM1DQM pins become valid as byte enables. The following actions occur on the rising edge of the clock that is concurrent with the end of the strobe period: 1. $\overline{\text{EM1WE}}$ rises 2. The EM1DQM pins deactivate In Figure 14-12, EM1WAIT is inactive. If EM1WAIT is instead activated, the strobe period can be extended by the external device to give it more time to accept the data. Section 14.2.6.6 contains more details on using the EM1WAIT pin.
End of the hold period	At the end of the hold period: • The address pins EM1Ax and EM1BAx become invalid • The data pins become invalid • $\overline{\text{EM1CS}}$[n] (n = 2, 3, or 4) rises (if no more operations are required to complete the current request) The EMIF can be required to issue additional write operations to a device with a small data bus width to complete an entire word access. In this case, the EMIF immediately re-enters the setup period to begin another operation without incurring the turnaround cycle delay. The setup, strobe, and hold values are not updated in this case. If the entire word access has been completed, the EMIF returns to the previous state unless another asynchronous request has been submitted and is currently the highest priority task. If this is the case, the EMIF instead enters directly into the turnaround period for the pending read or write operation.

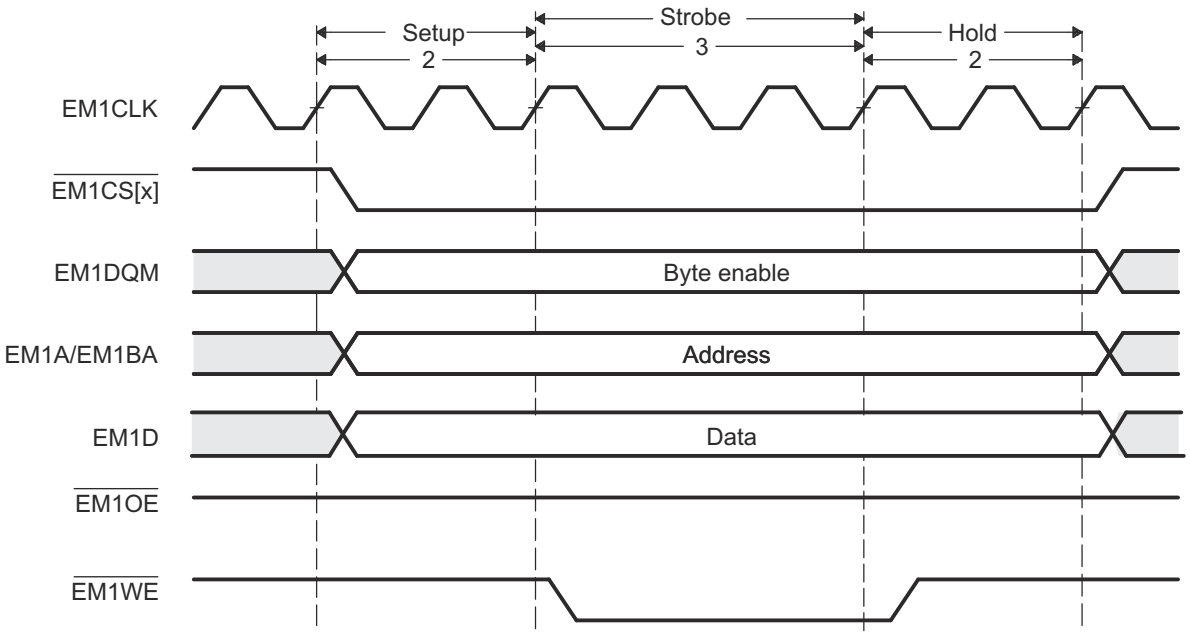

Figure 14-12. Timing Waveform of an Asynchronous Write Cycle in Normal Mode

14.2.6.5 Read and Write Operation in Select Strobe Mode

Select Strobe mode is the EMIF's second mode of operation. Select Strobe mode is selected when the SS bit of the asynchronous *n* configuration register (ASYNC_CSn_CR) is set to 1. In this mode, the EM1DQM pins operate as byte enables and the $\overline{\text{EM1CS}}$[n] (n = 2, 3, or 4) pin is only active during the strobe period of an access cycle. Section 14.2.6.4.1 and Section 14.2.6.4.2 explain the details of read and write operations while in select strobe mode.

14.2.6.5.1 Asynchronous Read Operations (Select Strobe Mode)

Note

During the entirety of an asynchronous read operation, the EM1WEn pin is driven high.

An asynchronous read is performed when any of the requesters mentioned in Section 14.2.2 request a read from the attached asynchronous memory. After the request is received, a read operation is initiated once the request becomes the EMIF's highest priority task, according to the priority scheme detailed in Section 14.2.13. In the event that the read request cannot be serviced by a single access cycle to the external device, multiple access cycles are performed by the EMIF until the entire request is fulfilled. The details of an asynchronous read operation in select strobe mode are described in Table 14-23. Also, Figure 14-13 shows an example timing diagram of a basic read operation.

Table 14-23. Asynchronous Read Operation in Select Strobe Mode

Time Interval	Pin Activity in Select Strobe Mode
Turnaround period	Once the read operation becomes the highest priority task for the EMIF, the EMIF waits for the programmed number of turnaround cycles before proceeding to the setup period of the operation. The number of wait cycles is taken directly from the TA field of the asynchronous *n* configuration register (ASYNC_CSn_CR). Between each access (Write or Read) EMIF inserts two cycles of delay even though TA field is programmed as 0. After the EMIF has waited for the turn-around cycles to complete, the EMIF again checks to make sure that the read operation is still the highest priority task. If so, the EMIF proceeds to the setup period of the operation. If the read operation is no longer the highest priority task, the EMIF terminates the operation.
Start of the setup period	The following actions occur at the start of the setup period: • The setup, strobe, and hold values are set according to the R_SETUP, R_STROBE, and R_HOLD values in ASYNC_CS*n*_CR. • The address pins EM1A and EM1BA become valid and carry the values described in Section 14.2.6.1. • The EM1DQM pins become valid as byte enables.

Strobe period	The following actions occur during the strobe period of a read operation:
	1. $\overline{\text{EM1CS}}$[n] (n = 2, 3, or 4) and $\overline{\text{EM1OE}}$ fall at the start of the strobe period
	2. On the rising edge of the clock that is concurrent with the end of the strobe period:
	  • $\overline{\text{EM1CS}}$[n] (n = 2, 3, or 4) and $\overline{\text{EM10E}}$ rise
	  • The data on the EM1D bus is sampled by EMIF.
	In Figure 14-13, EM1WAIT is inactive. If EM1WAIT is instead activated, the strobe period can be extended by the external device to give more time to provide the data. Section 14.2.6.6 contains more details on using the EM1WAIT pin.

End of the hold period	At the end of the hold period: • The address pins EM1A and EM1BA become invalid • The EM1DQM pins become invalid The EMIF can be required to issue additional read operations to a device with a small data bus width to complete an entire word access. In this case, the EMIF immediately re-enters the setup period to begin another operation without incurring the turnaround cycle delay. The setup, strobe, and hold values are not updated in this case. If the entire word access has been completed, the EMIF returns to the previous state unless another asynchronous request has been submitted and is currently the highest priority task. If this is the case, the EMIF instead enters directly into the turnaround period for the pending read or write operation.

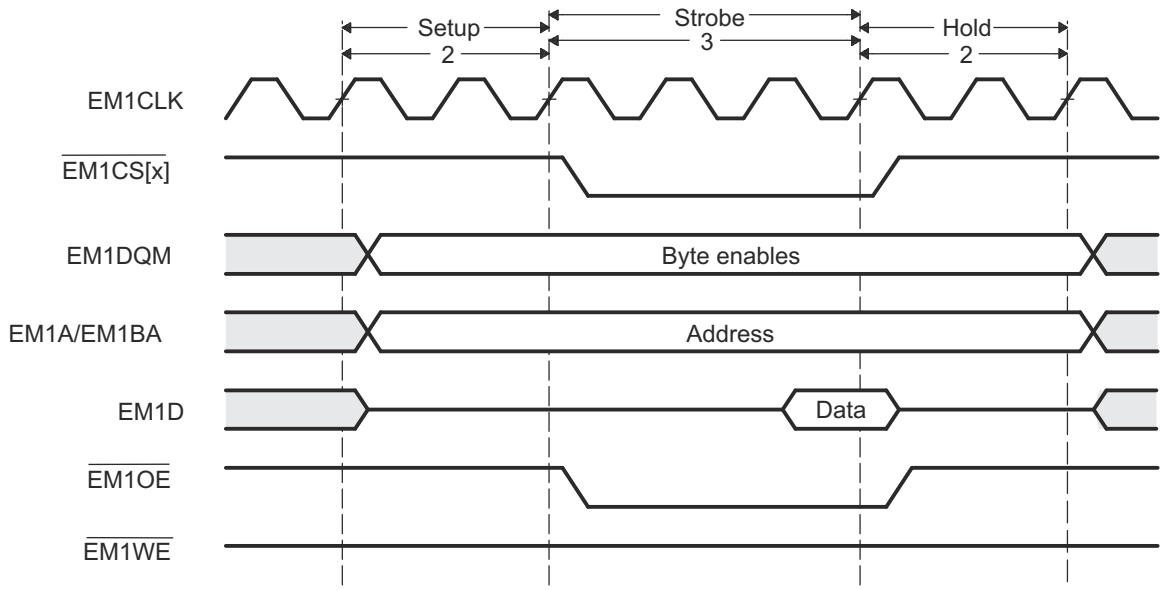

Figure 14-13. Timing Waveform of an Asynchronous Read Cycle in Select Strobe Mode

14.2.6.5.2 Asynchronous Write Operations (Select Strobe Mode)

Note

During the entirety of an asynchronous write operation, the $\overline{\text{EM1OE}}$ pin is driven high.

An asynchronous write is performed when any of the requesters mentioned in Section 14.2.2 request a write to memory in the asynchronous bank of EMIF. After the request is received, a write operation is initiated once the request becomes the EMIF's highest priority task, according to the priority scheme detailed in Section 14.2.13. In the event that the write request cannot be serviced by a single access cycle to the external device, multiple access cycles are performed by the EMIF until the entire request is fulfilled. The details of an asynchronous write operation in select strobe mode are described in Table 14-24. Also, Figure 14-14 shows an example timing diagram of a basic write operation.

Table 14-24. Asynchronous Write Operation in Select Strobe Mode

Time Interval	Pin Activity in Select Strobe Mode
Turnaround period	Once the write operation becomes the highest priority task for the EMIF, the EMIF waits for the programmed number of turnaround cycles before proceeding to the setup period of the operation. The number of wait cycles is taken directly from the TA field of the asynchronous *n* configuration register (ASYNC_CSn_CR). Between each access (Write or Read) EMIF inserts two cycles of delay even though TA field is programmed as 0. After the EMIF has waited for the turnaround cycles to complete, the EMIF again checks to make sure that the write operation is still the highest priority task. If so, the EMIF proceeds to the setup period of the operation. If the write operation is no longer the highest priority task, the EMIF terminates the operation.
Start of the setup period	The following actions occur at the start of the setup period: • The setup, strobe, and hold values are set according to the W_SETUP, W_STROBE, and W_HOLD values in ASYNC_CSn_CR. • The address pins EM1A and EM1BA and the data pins EM1D become valid. The EM1A and EM1BA pins carry the values described in Section 14.2.6.1. • The EM1DQM pins become active as byte enables.
Strobe period	The following actions occur at the start of the strobe period of a write operation: • $\overline{\text{EM1CS}}$[n] (n = 2, 3, or 4) and $\overline{\text{EM1WE}}$ fall The following actions occur on the rising edge of the clock which is concurrent with the end of the strobe period: • $\overline{\text{EM1CS}}$[n] (n = 2, 3, or 4) and $\overline{\text{EM1WE}}$ rise In Figure 14-14, EM1WAIT is inactive. If EM1WAIT is instead activated, the strobe period can be extended by the external device to give more time to accept the data. Section 14.2.6.6 contains more details on using the EM1WAIT pin.
End of the hold period	At the end of the hold period: • The address pins EM1A and EM1BA become invalid • The data pins become invalid • The EM1DQM pins become invalid The EMIF can be required to issue additional write operations to a device with a small data bus width to complete an entire word access. In this case, the EMIF immediately re-enters the setup period to begin another operation without incurring the turnaround cycle delay. The setup, strobe, and hold values are not updated in this case. If the entire word access has been completed, the EMIF returns to the previous state unless another asynchronous request has been submitted and is currently the highest priority task. If this is the case, the EMIF instead enters directly into the turnaround period for the pending read or write operation.

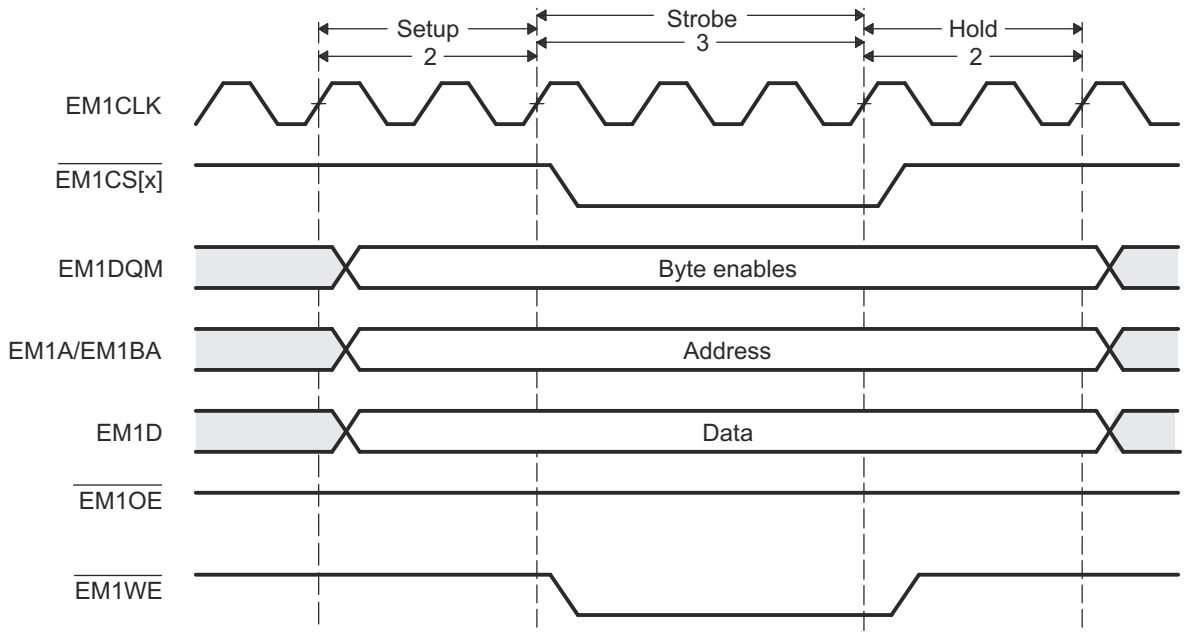

Figure 14-14. Timing Waveform of an Asynchronous Write Cycle in Select Strobe Mode

14.2.6.6 Extended Wait Mode and the EM1WAIT Pin

The EMIF supports the extended wait mode. This is a mode that the external asynchronous device can assert control over the length of the strobe period. The extended wait mode can be entered by setting the EW bit in the asynchronous *n* configuration register (ASYNC_CS*n*_CR (*n* = 2, 3, or 4). When this bit is set, the EMIF monitors the EM1WAIT pin to determine if the attached device wishes to extend the strobe period of the current access cycle beyond the programmed number of clock cycles.

When the EMIF detects that the EM1WAIT pin has been asserted, the EMIF begins inserting extra strobe cycles into the operation until the EM1WAIT pin is deactivated by the external device. The EMIF then returns to the last cycle of the programmed strobe period and the operation proceeds as usual from this point. Refer to the device data sheet for details on the timing requirements of the EM1WAIT signal.

The EM1WAIT pin cannot be used to extend the strobe period indefinitely. The programmable MAX_EXT_WAIT field in the asynchronous wait cycle configuration register (AWCC) determines the maximum number of EM1CLK cycles the strobe period can be extended beyond the programmed length. When the counter expires, the EMIF proceeds to the hold period of the operation regardless of the state of the EM1WAIT pin. The EMIF can also generate an interrupt upon expiration of this counter. See Section 14.2.9.1 for details on enabling this interrupt.

For the EMIF to function properly in the extended wait mode, the WP*n* bit of AWCC must be programmed to match the polarity of the EM1WAIT pin. In the reset state of 1, the EMIF inserts wait cycles when the EM1WAIT pin is sampled high. When set to 0, the EMIF inserts wait cycles only when EM1WAIT is sampled low. This programmability allows for a glueless connection to larger variety of asynchronous devices.

Finally, a restriction is placed on the strobe period timing parameters when operating in extended wait mode. Specifically, the sum of the W_SETUP and W_STROBE fields must be greater than four, and the sum of the R_SETUP and R_STROBE fields must be greater than four for the EMIF to recognize the EM1WAIT pin has been asserted. The W_SETUP, W_STROBE, R_SETUP, and R_STROBE fields are in ASYNC_CS*n*_CR.

14.2.7 Data Bus Parking

The EMIF always drives the data bus to the previous write data value when the EMIF is idle. This feature is called data bus parking. Only when the EMIF issues a read command to the external memory does the EMIF stop driving the data bus. After the EMIF latches the last read data, the EMIF immediately parks the data bus again.

The one exception to this behavior occurs after performing an asynchronous read operation while the EMIF is in the self-refresh state. In this situation, the read operation is not followed by the EMIF parking the data bus. Instead, the EMIF tri-states the data bus. Therefore, it is not recommended to perform asynchronous read operations while the EMIF is in the self-refresh state, to prevent floating inputs on the data bus. External pull-ups, such as 10-kohm resistors, must be placed on the 16 EMIF data bus pins (that do not have internal pull-ups) if required to perform reads in this situation. The precise resistor value must be chosen so that the worst case combined off-state leakage currents do not cause the voltage levels on the associated pins to drop below the high-level input voltage requirement.

For information about the self-refresh state, see Section 14.2.5.7.

14.2.8 Reset and Initialization Considerations

The EMIF memory controller has two active-low reset signals, CHIP_RST_n and MOD_G_RST_n. Both these reset signals are driven by the device system reset signal. This device does not offer the flexibility to reset just the EMIF state machine without also resetting the EMIF controller's memory-mapped registers. As soon as the device system reset is released (driven high), the EMIF memory controller immediately begins its initialization sequence. Command and data stored in the EMIF memory controller FIFOs are lost. Refer to Section 14.2 for more information on conditions that can cause a device system reset to be asserted.

When system reset is released, the EMIF automatically begins running the SDRAM initialization sequence described in Section 14.2.5.4. Even though the initialization procedure is automatic, a special procedure, found in Section 14.2.5.5 must still be followed.

14.2.9 Interrupt Support

The EMIF supports a single interrupt to the CPU. Section 14.2.9.1 details the generation and internal masking of EMIF interrupts.

14.2.9.1 Interrupt Events

There are three conditions that can cause the EMIF to generate an interrupt to the CPU. These conditions are:

- A rising edge on the EM1WAIT signal (wait rise interrupt)
- An asynchronous time out
- Usage of unsupported addressing mode (line trap interrupt)

The wait rise interrupt occurs when a rising edge is detected on EM1WAIT signal. This interrupt generation is not affected by the WP*n* bit in the asynchronous wait cycle configuration register (ASYNC_WCCR). The asynchronous time out interrupt condition occurs when the attached asynchronous device fails to deassert the EM1WAIT pin within the number of cycles defined by the MAX_EXT_WAIT bit in AWCC (this happens only in extended wait mode). The EMIF supports only linear incrementing and cache line wrap addressing modes . If an access request for an unsupported addressing mode is received, the EMIF sets the LT bit in the EMIF interrupt raw register (INT_RAW) and treats the request as a linear incrementing request.

Only when the interrupt is enabled by setting the appropriate bit (WR_MASK_SET/AT_MASK_SET/ LT_MASK_SET) in the EMIF interrupt mask set register (INT_MSK_SET) to 1, is the interrupt sent to the CPU. Once enabled, the interrupt can be disabled by writing a 1 to the corresponding bit in the EMIF interrupt mask clear register (INT_MSK_CLR). The bit fields in both the INT_MSK_SET and INT_MSK_CLR can be used to indicate whether the interrupt is enabled. When the interrupt is enabled, the corresponding bit field in both the INT_MSK_SET and INT_MSK_CLR have a value of 1; when the interrupt is disabled, the corresponding bit field has a value of 0.

The EMIF interrupt raw register (INT_RAW) and the IF interrupt mask register (INT_MSK) indicate the status of each interrupt. The appropriate bit (WR/AT/LT) in INT_RAW is set when the interrupt condition occurs, whether or not the interrupt has been enabled. However, the appropriate bit (WR_MASKED/AT_MASKED/LT_MASKED) in INT_MSK is set only when the interrupt condition occurs and the interrupt is enabled. Writing a 1 to the bit in INT_RAW clears the INT_RAW bit as well as the corresponding bit in INT_MSK. Table 14-25 contains a brief summary of the interrupt status and control bit fields. See Section 14.6 for complete details on the register fields.

Table 14-25. Interrupt Monitor and Control Bit Fields

Register Name	Bit Name	Description
EMIF interrupt raw register (INT_RAW)	WR	This bit is set when an rising edge on the EM1WAIT signal occurs. Writing a 1 clears the WR bit as well as the WR_MASKED bit in INT_MSK.
	AT	This bit is set when an asynchronous timeout occurs. Writing a 1 clears the AT bit as well as the AT_MASKED bit in INT_MSK.
	LT	This bit is set when an unsupported addressing mode is used. Writing a 1 clears LT bit as well as the LT_MASKED bit in INT_MSK.
EMIF interrupt mask register (INT_MSK)	WR_MASKED	This bit is set only when a rising edge on the EM1WAIT signal occurs and the interrupt has been enabled by writing a 1 to the WR_MASK_SET bit in INT_MSK_SET.
	AT_MASKED	This bit is set only when an asynchronous timeout occurs and the interrupt has been enabled by writing a 1 to the AT_MASK_SET bit in INT_MSK_SET.
	LT_MASKED	This bit is set only when line trap interrupt occurs and the interrupt has been enabled by writing a 1 to the LT_MASK_SET bit in INT_MSK_SET.
EMIF interrupt mask set register (INT_MSK_SET)	WR_MASK_SET	Writing a 1 to this bit enables the wait rise interrupt.
	AT_MASK_SET	Writing a 1 to this bit enables the asynchronous timeout interrupt.
	LT_MASK_SET	Writing a 1 to this bit enables the line trap interrupt.
EMIF interrupt mask clear register (INT_MSK_CLR)	WR_MASK_CLR	Writing a 1 to this bit disables the wait rise interrupt.
	AT_MASK_CLR	Writing a 1 to this bit disables the asynchronous timeout interrupt.
	LT_MASK_CLR	Writing a 1 to this bit disables the line trap interrupt.

14.2.10 RTDMA Event Support

The EMIF memory controller is a RTDMA target peripheral and therefore does not generate RTDMA events. Data read and write requests can be made directly, by controllers and the RTDMA.

14.2.11 EMIF Signal Multiplexing

For details on the EMIF signal multiplexing, see the *GPIO* chapter, I/O Multiplexing Module section, of this technical reference manual.

14.2.12 Memory Map

For information describing the device memory-map, see the data sheet.

14.2.13 Priority and Arbitration

Section 14.2.2 describes the external prioritization and arbitration among requests from different sources within the microcontroller. The result of this external arbitration is that only one request is presented to the EMIF at a time. Once the EMIF completes a request, the external arbiter then provides the EMIF with the next pending request.

Internally, the EMIF undertakes memory device transactions according to a strict priority scheme. The highest priority events are:

- A device reset.
- A write to any of the three least significant bytes of the SDRAM configuration register (SDRAM_CR).

Either of these events causes the EMIF to immediately commence the initialization sequence as described in Section 14.2.5.4.

Once the EMIF has completed its initialization sequence, the EMIF performs memory transactions according to the following priority scheme (highest priority listed first):

1. If the EMIF's backlog refresh counter is at the Refresh Must urgency level, the EMIF performs multiple SDRAM auto-refresh cycles until the Refresh Release urgency level is reached.
2. If an SDRAM or asynchronous read has been requested, the EMIF performs a read operation.
3. If the EMIF's backlog refresh counter is at the Refresh Need urgency level, the EMIF performs an SDRAM auto-refresh cycle.
4. If an SDRAM or asynchronous write has been requested, the EMIF performs a write operation.
5. If the EMIF's backlog refresh counter is at the Refresh May or Refresh Release urgency level, the EMIF performs an SDRAM auto-refresh cycle.
6. If the value of the SR bit in SDRAM_CR has been set to 1, the EMIF enters the self-refresh state as described in Section 14.2.5.7.

After taking one of the actions listed above, the EMIF then returns to the top of the priority list to determine the next action.

Because the EMIF does not issue auto-refresh cycles when in the self-refresh state, the above priority scheme does not apply when in this state. See Section 14.2.5.7 for details on the operation of the EMIF when in the self-refresh state.

14.2.14 System Considerations

This section describes various system considerations to keep in mind when operating the EMIF.

14.2.14.1 Asynchronous Request Times

In a system that interfaces to both SDRAM and asynchronous memory, the asynchronous requests must not take longer than the smaller of the following two values:

- t_{RAS} (typically 120µs) - to avoid violating the maximum time allowed between issuing an ACTV and PRE command to the SDRAM.
- $t_{Refresh\ Rate}$ × 11 (typically 15.7µs × 11 = 172.7µs) - to avoid refresh violations on the SDRAM.

The length of an asynchronous request is controlled by multiple factors, the primary factor being the number of access cycles required to complete the request. For example, an asynchronous request for 4 bytes requires four access cycles using an 8-bit data bus and only two access cycle using a 16-bit data bus. The maximum request size that the EMIF can be sent is 16 words; therefore, the maximum number of access cycles per memory request is 64 when the EMIF is configured with an 8-bit data bus. The length of the individual access cycles that make up the asynchronous request is determined by the programmed setup, strobe, hold, and turnaround values, but can also be extended with the assertion of the EM1WAIT input signal up to a programmed maximum limit. The user must make sure that an entire asynchronous request does not exceed the timing values listed above when also interfacing to an SDRAM device. This can be done by limiting the asynchronous timing parameters.

14.2.15 Power Management

Power dissipation from the EMIF memory controller can be managed by following methods:

- Self-refresh mode
- Power-down mode
- Gating input clocks to the module off

Gating input clocks off to the EMIF memory controller achieves higher power savings when compared to the power savings of self-refresh or power down mode. The input clock to EMIF can be turned off through the use of the Global Clock Module (GCM). Before gating clocks off, the EMIF memory controller must place the SDR SDRAM memory in self-refresh mode. If the external memory requires a continuous clock, the VCLK3 clock domain must not be turned off because this can result in data corruption. See the following subsections for the proper procedures to follow when stopping EMIF memory controller clocks.

14.2.15.1 Power Management Using Self-Refresh Mode

The EMIF memory controller can be placed into a self-refresh state in order to place the attached SDRAM devices into self-refresh mode, which consumes less power for most SDRAM devices. In this state, the attached SDRAM device uses an internal clock to perform its own auto refresh cycles. This maintains the validity of the data in the SDRAM without the need for any external commands. Refer to Section 14.2.5.7 for more details on placing the EMIF into the self-refresh state.

14.2.15.2 Power Management Using Power Down Mode

In the power down mode, the EMIF drives EM1SDCKE low to lower the power consumption. EM1SDCKE goes high when there is a need to send refresh (REFR) commands, after which EM1SDCKE is again driven low. EM1SDCKE remains low until any request arrives. Refer to Section 14.2.5.8 for more details on placing the EMIF in power-down mode.

14.2.16 Emulation Considerations

The EMIF remains fully functional during emulation halts in order to allow emulation access to external memory.

14.3 EMIF Subsystem (EMIFSS)

This section details the configuration of the EMIF subsystem, which is used by memory access initiators to support access to the EMIF peripheral.

Figure 14-15 shows that different initiators are connected to the fast and slow access ports. Fast access ports are limited to the primary CPU. Slow access ports take an additional cycle for accesses, but have mechanisms to improve throughput for certain scenarios like RTDMA accesses. Debug accesses are connected to slow access ports and are arbitrated externally from the EMIFSS. The round-robin arbitration scheme is used among all fast and slow access ports as follows:

1. CPU1 (default)
2. CPU2
3. CPU3
4. RTDMA1
5. RTDMA2
6. Debug Bridge

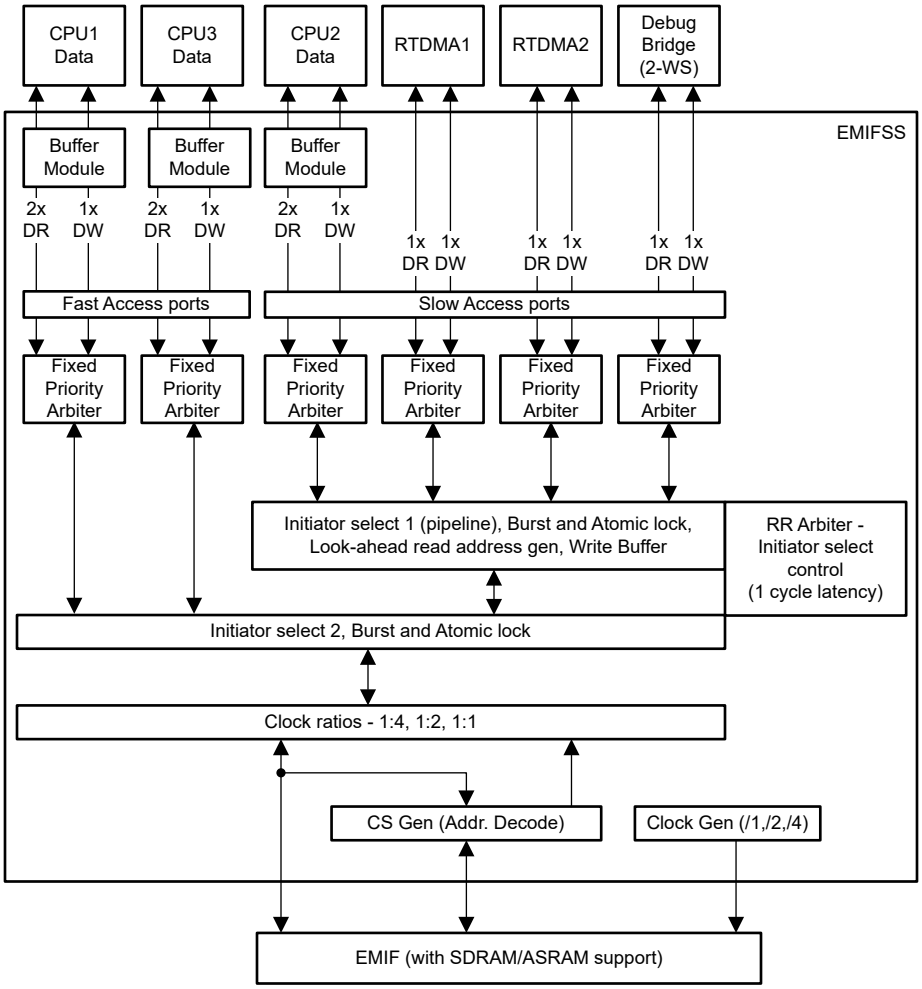

Figure 14-15. EMIFSS Block Diagram

14.3.1 Burst Support

The RTDMA is connected through a slow access port, so all accesses take an extra cycle as opposed to the fast access port. For this reason, the RTDMA is enhanced to support local address generation within the EMIFSS arbiter initiator select 1 component. This enables read burst performance close to that of the fast access port, thereby improving throughput. For more information, refer to the *Real-Time Direct Memory Access (RTDMA)* chapter.

14.3.2 EMIFSS Performance Improvement

The C29x EMIFSS enables devices to improve access performance using the inherent burst support and dataline buffer for each CPU. The following tables show the improvement increase for different accesses.

Table 14-26. SDRAM Sequential Bulk Transfer

Access Type[1]	Access Time on C28x (Cycles)	Access Time on C29x (Cycles)	C28x:C29x Improvement	Access Time with DMA (Cycles)	Access Time with RTDMA (Cycles)	DMA:RTDMA Improvement
SDRAM to SRAM 16-bit Access	8196	2821[2]	2.9X	9267	Not Available[3]	-
SDRAM to SRAM 32-bit Access	5125	2564[2]	2.0X	4633	1125	4.1X
SDRAM to SRAM 64-bit Access	Not Available	2559	-	Not Available	1125	-

Table 14-26. SDRAM Sequential Bulk Transfer (continued)

Access Type[1]	Access Time on C28x (Cycles)	Access Time on C29x (Cycles)	C28x:C29x Improvement	Access Time with DMA (Cycles)	Access Time with RTDMA (Cycles)	DMA:RTDMA Improvement
SRAM to SRDAM 16-bit Access	4097	4100[2]	1.0X	5172	Not Available[3]	-

64-Bit Write	13	25

14.3.3 Buffer Module

The buffer module is implemented for each CPU and consists of the following:

- A dataline buffer that services the data read 1/2 accesses (DR1/DR2)
- A write FIFO that services the data write accesses (DW)
- Associated logic to conditionally bypass the dataline buffer

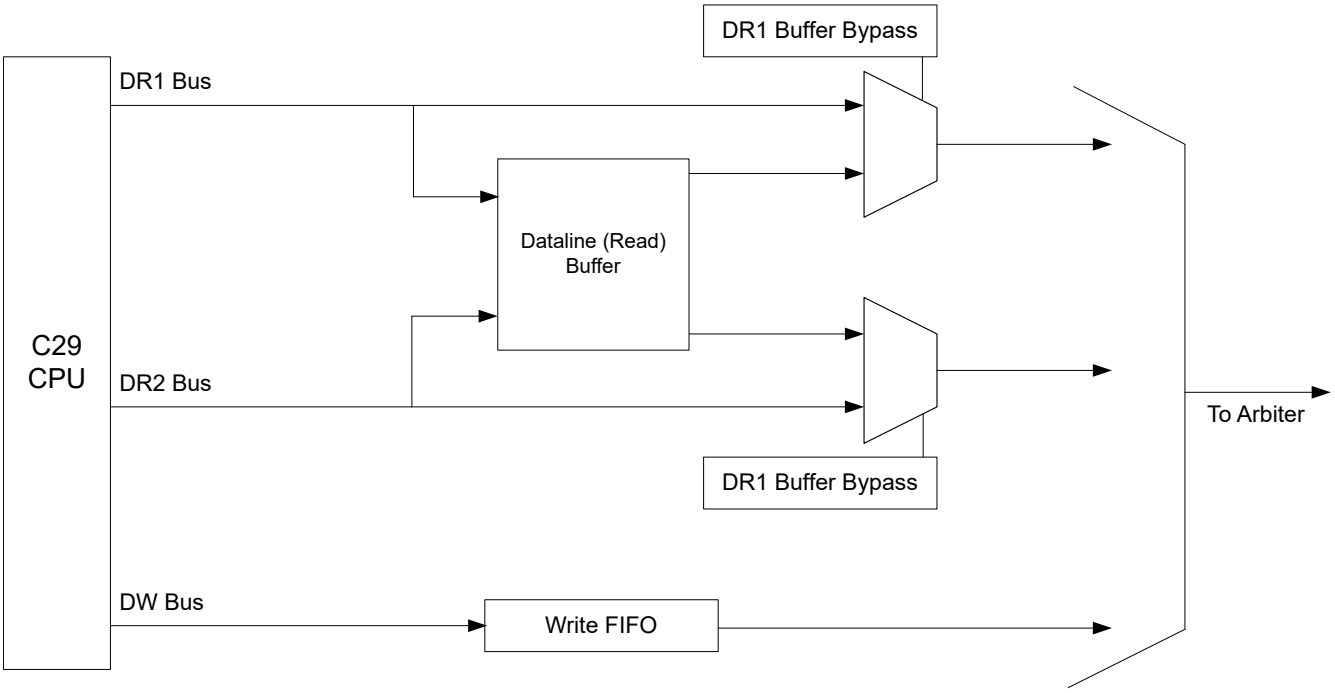

Figure 14-16. Buffer Module Block Diagram

Any 16-bit or 32-bit read which misses the dataline buffer initiates a 64-bit access to the EMIF and stalls the CPU until the four 16-bit access completes and refills the buffer (on a 16-bit SDRAM or ASRAM). This means that sequential accesses have better performance.

If the accesses are not sequential memory locations, dual-mapped regions are provided for the software to chosse between the following:

- The Primary Memory Map - This uses the dataline buffer for reads and is optimized for sequential accesses
- The Secondary Memory Map - This bypasses the dataline buffer for reads and is optimized for random accesses

For DR1 and DR2 accesses, the EMIF SDRAM and ASRAM memory regions for each of the CSx are dual-mapped. The EMIF register regions are not dual-mapped and always bypass the buffer. DW accesses to either of the dual memory maps behave identically and always go through the write FIFO.

Table 14-31 is an example of the memory map for EMIF. For actual address range information, see the device data sheet memory map.

Table 14-31. Dual Memory Map Example

Address Range	EMIF Region
A	EMIF SDRAM CS0 (Primary Map)
B	EMIF ASRAM CS2 (Primary Map)
C	EMIF ASRAM CS3 (Primary Map)
E	EMIF ASRAM CS4 (Primary Map)
E	EMIF Configuration Registers
F	EMIF SDRAM CS0 (Secondary Map)
G	EMIF ASRAM CS2 (Secondary Map)
I	EMIF ASRAM CS3 (Secondary Map)
J	EMIF ASRAM CS4 (Secondary Map)

The EMIF module is accessible by initiators other than the CPU. The CPU dataline buffer is updated on CPU reads only, and does not hold the latest data if another initiator updated the same address. For this reason, write accesses from other initiators are tracked locally to the dataline buffer. The dataline buffer is invalidated on the completion of a write access from another initiator if the tag matches the write address. In such a case, the arbitration scheme makes sure the write is performed to memory first to maintain data coherency. The corresponding dataline buffer of a CPU is also invalidated if the CPU enters a fault state. The CPU reads the old data until the time at which the buffer is invalidated.

14.3.3.1 CPU Write FIFO

The CPU write FIFO has entries for the access's Address[31:3], data, size/position of access (which bytes are valid), and whether the operation is part of an atomic access. This information is necessary to reconstruct the write access. The FIFO stalls the data write signal for subsequent CPU write accesses. The push logic routes incoming accesses to the arbiter if there is no outstanding write request. Otherwise, the entry is put onto the FIFO and outstanding accesses complete before popping the first-in entry onto the arbiter interface.

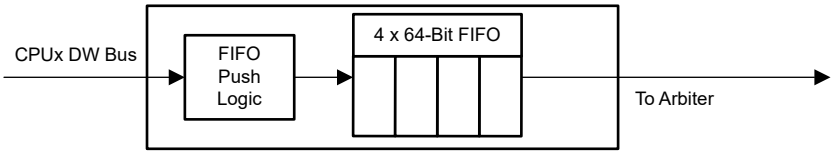

Figure 14-17. Write FIFO

14.3.4 Emulation Mode

Emulation mode is covered in the Debug Subsystem and the *Safety and Security Unit (SSU)* chapter.

14.4 Example Configuration

This section presents an example of interfacing the EMIF1 to both an SDR SDRAM device and an asynchronous Flash device.

14.4.1 Hardware Interface

Figure 14-18 shows the hardware interface between the EMIF, a Samsung K4S641632H-TC(L)70 64Mb SDRAM device, and a SHARP LH28F800BJE-PTTL90 8Mb Flash memory. The connection between EMIF and the SDRAM is straightforward, but the connection between the EMIF and the Flash deserves a detailed look.

The address inputs for the Flash are provided by three sources. The A[18:0] address inputs are provided by a combination of the EM1A and EM1BA pins according to Section 14.2.6.1, and a set of GPIO pins. The RD/nBY signal from Flash is connected to EM1WAIT pin of the EMIF.

Finally, this example configuration connects the $\overline{\text{EM1WE}}$ pin to the nWE input of the Flash and operates the EMIF in select strobe mode.

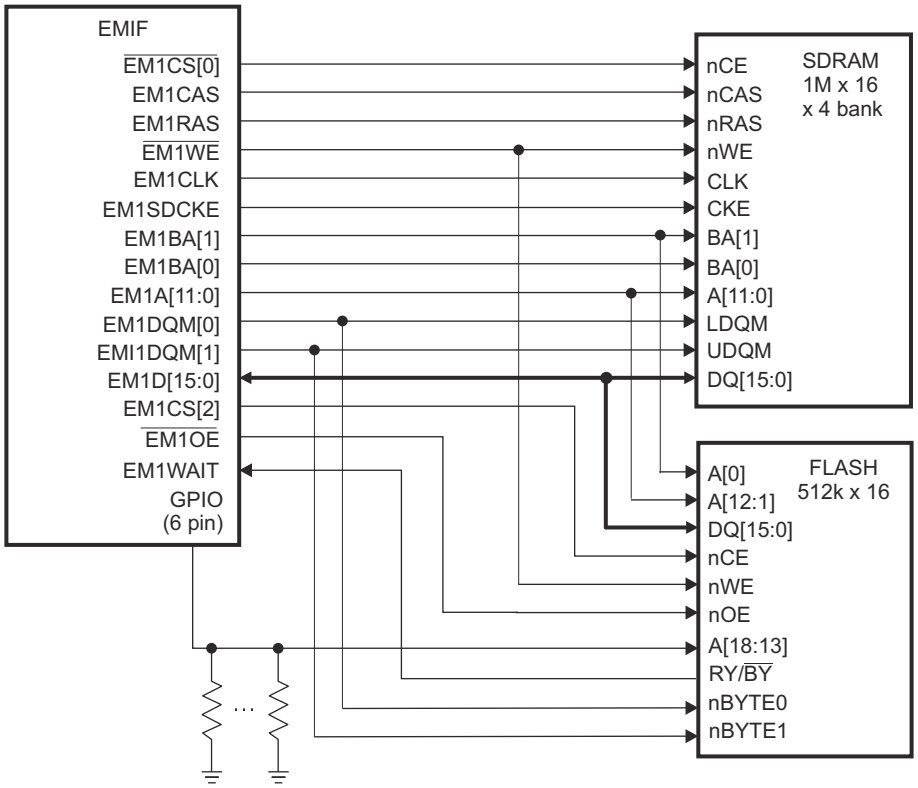

Figure 14-18. Example Configuration Interface

14.4.2 Software Configuration

The following sections describe how to configure the EMIF registers and bit fields to interface the EMIF with the Samsung K4S641632H-TC(L)70 SDRAM and the SHARP LH28F800BJE-PTTL90 8Mb Flash memory.

14.4.2.1 Configuring the SDRAM Interface

This section describes how to configure the EMIF to interface with the Samsung K4S641632H-TC(L)70 SDRAM with a clock frequency of f_{EM1CLK} = 100MHz. Procedure A described in Section 14.2.5.5 is followed that assumes that the SDRAM power-up timing constraints were met during the SDRAM auto-initialization sequence after reset.

14.4.2.1.1 PLL Programming for EMIF to K4S641632H-TC(L)70 Interface

If the system PLL is programmed to provide a SYSCLK frequency > 100MHz, then configure the EMIF1CLKDIV field in the PERSYSCLKDIVSEL register to make EM1CLK = SYSCLK/2 (default configuration). Before doing this, the SDRAM must be placed in self-refresh mode by setting the SR bit in the SDRAM configuration register. Once the EM1CLK frequency has been configured, remove the SDRAM from self-refresh by clearing the SR bit in SDRAM_CR.

Table 14-32. SR Field Value For EMIF to K4S641632H-TC(L)70 Interface

Field	Value	Purpose
SR	1 then 0	To place the EMIF into the self-refresh state

14.4.2.1.2 SDRAM Timing Register (SDRAM_TR) Settings for EMIF to K4S641632H-TC(L)70 Interface

The fields of the SDRAM timing register (SDRAM_TR) must be programmed first as described in Table 14-33 to satisfy the required timing parameters for the K4S641632H-TC(L)70. Based on these calculations, a value of 6111 4610h must be written to the SDRAM_TR. Figure 14-19 shows a graphical description of how the SDRAM_TR must be programmed.

Table 14-33. SDRAM_TR Field Calculations for EMIF to K4S641632H-TC(L)70 Interface

Field Name	Formula	Value from K4S641632H-TC(L)70 Data Sheet	Value Calculated for Field
T_RFC	T_RFC >= (t_{RFC} × f_{EM1CLK}) - 1	t_{RC} = 68ns (minimum)(1)	6
T_RP	T_RP >= (t_{RP} × f_{EM1CLK}) - 1	t_{RP} = 20ns (minimum)	1
T_RCD	T_RCD >= (t_{RCD} × f_{EM1CLK}) - 1	t_{RCD} = 20ns (minimum)	1
T_WR	T_WR >= (t_{WR} × f_{EM1CLK}) - 1	t_{RDL} = 2 CLK = 20ns (minimum)(2)	1
T_RAS	T_RAS >= (t_{RAS} × f_{EM1CLK}) - 1	t_{RAS} = 49ns (minimum)	4
T_RC	T_RC >= (t_{RC} × f_{EM1CLK}) - 1	t_{RC} = 68ns (minimum)	6
T_RRD	T_RRD >= (t_{RRD} × f_{EM1CLK}) - 1	t_{RRD} = 14ns (minimum)	1

(1) The Samsung data sheet does not specify a t_{RFC} value. Instead, Samsung specifies t_{RC} as the minimum auto refresh period.
(2) The Samsung data sheet does not specify a t_{WR} value. Instead, Samsung specifies t_{RDL} as last data in to row precharge minimum delay.

Figure 14-19. SDRAM Timing Register (SDRAM_TR)

31	30	29	28	27	26	24	23	22	21	20	19	18	17	16

14.4.2.1.3 SDRAM Self Refresh Exit Timing Register (SDR_EXT_TMNG) Settings for EMIF to K4S641632H-TC(L)70 Interface

The SDRAM self-refresh exit timing register (SDSRETR) must be programmed second to satisfy the t_{XSR} timing requirement from the K4S641632H-TC(L)70 data sheet. Table 14-34 shows the calculation of the proper value to program into the T_XS field of this register. Based on this calculation, a value of 6h must be written to the SDSRETR. Figure 14-20 shows how the SDSRETR must be programmed.

Table 14-34. RR Calculation for EMIF to K4S641632H-TC(L)70 Interface

Field Name	Formula	Value from K4S641632H-TC(L)70 Data Sheet	Value Calculated for Field
T_XS	T_XS >= (t_{XSR} × f_{EM1CLK}) - 1	t_{RC} = 68ns (minimum)(1)	6

(1) The Samsung data sheet does not specify a t_{XSR} value. Instead, Samsung specifies t_{RC} as the minimum required time after CKE going high to complete self-refresh exit.

Figure 14-20. SDRAM Self Refresh Exit Timing Register (SDR_EXT_TMNG)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reserved											T_XS				

14.4.2.1.4 SDRAM Refresh Control Register (SDRAM_RCR) Settings for EMIF to K4S641632H-TC(L)70 Interface

The SDRAM refresh control register (SDRAM_RCR) can next be programmed to satisfy the required refresh rate of the K4S641632H-TC(L)70. Table 14-35 shows the calculation of the proper value to program into the RR field of this register. Based on this calculation, a value of 61Ah must be written to the SDRAM_RCR. Figure 14-21 shows how the SDRAM_RCR must be programmed.

Table 14-35. RR Calculation for EMIF to K4S641632H-TC(L)70 Interface

Field Name	Formula	Values	Value Calculated for Field
RR	RR ≤ f_{EM1CLK} × $t_{Refresh\ Period}$ / n_{cycles}	From SDRAM data sheet: $t_{Refresh\ Period}$ = 64ms; n_{cycles} = 4096 EMIF clock rate: f_{EM1CLK} = 100MHz	RR = 1562 cycles = 61Ah cycles

Figure 14-21. SDRAM Refresh Control Register (SDRAM_RCR)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
000			0 0110 0001 1010 (61Ah)												
Reserved			RR												

14.4.2.1.5 SDRAM Configuration Register (SDRAM_CR) Settings for EMIF to K4S641632H-TC(L)70 Interface

Finally, the fields of the SDRAM configuration register (SDRAM_CR) must be programmed as described in Table 14-36 to properly interface with the K4S641632H-TC(L)70 device. Based on these settings, a value of 4720h must be written to the SDRAM_CR. Figure 14-22 shows how the SDRAM_CR must be programmed. The EMIF is now ready to perform read and write accesses to the SDRAM.

Table 14-36. SDRAM_CR Field Values For EMIF to K4S641632H-TC(L)70 Interface

Field	Value	Purpose
SR	0	To avoid placing the EMIF into the self-refresh state
NM	1	To configure the EMIF for a 16-bit data bus
CL	011b	To select a CAS latency of 3
BIT11_9LOCK	1	To allow the CL field to be written
IBANK	010b	To select 4 internal SDRAM banks
PAGESIZE	0	To select a page size of 256 words

Figure 14-22. SDRAM Configuration Register (SDRAM_CR)

14.4.2.2 Configuring the Flash Interface

This section describes how to configure the EMIF to interface with the SHARP LH28F800BJE-PTTL90 8Mb Flash memory with a clock frequency of f_{EM1CLK} = 100MHz.

14.4.2.2.1 Asynchronous 1 Configuration Register (ASYNC_CS2_CFG) Settings for EMIF to LH28F800BJE-PTTL90 Interface

The asynchronous 1 configuration register (ASYNC_CS2_CFG) is the only register that is necessary to program for this asynchronous interface. The SS bit must be set to 1 to enable select strobe command and the ASIZE field can be set to 1 to select a 16-bit interface. The other fields in this register control the shaping of the EMIF signals, and the proper values can be determined by referring to the AC Characteristics in the Flash data sheet and the device data sheet. Table 14-37 and Table 14-38 show the pertinent AC Characteristics for reads and writes to the Flash device, and Figure 14-23 and Figure 14-24 show the associated timing waveforms. Finally, Figure 14-25 shows programming the ASYNC_CS2_CFG with the calculated values.

Table 14-37. AC Characteristics for a Read Access

AC Characteristic	Device	Definition	Minimum	Maximum	Unit
t_{SU}	EMIF	Setup time, read EM1D before EM1OE high	15		ns
t_{H}	EMIF	Data hold time, read EM1D after EM1OE high	0		ns
t_{ELQV}	Flash	nCE to Output Delay		90	ns
t_{EHQZ}	Flash	nCE High to Output in High Impedance		55	ns

Table 14-38. AC Characteristics for a Write Access

AC Characteristic	Device	Definition	Minimum	Maximum	Unit
t_{AVAV}	Flash	Write Cycle Time	90		ns
t_{ELEH}	Flash	nCE Pulse Width Low	50		ns
t_{EHEL}	Flash	nCE Pulse Width High (not shown in Figure 14-24)	30		ns

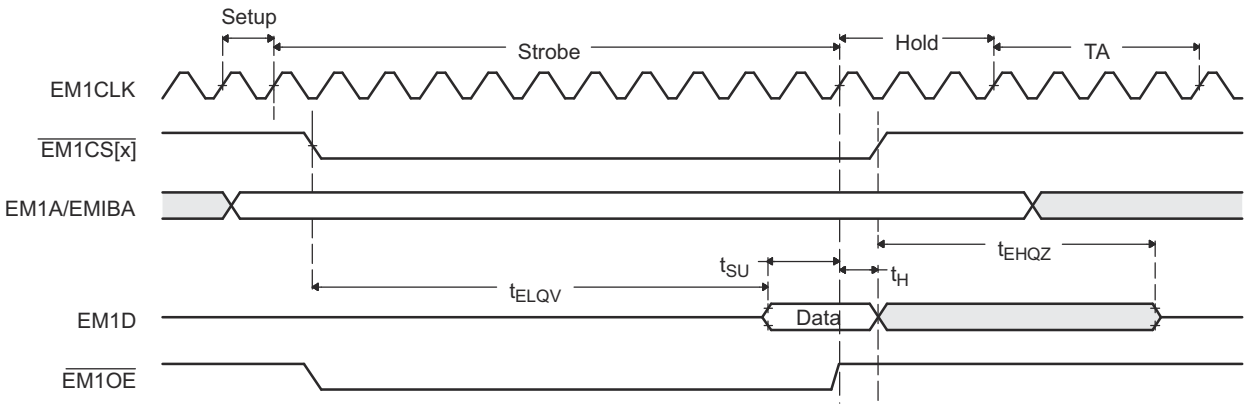

Figure 14-23. LH28F800BJE-PTTL90 to EMIF Read Timing Waveforms

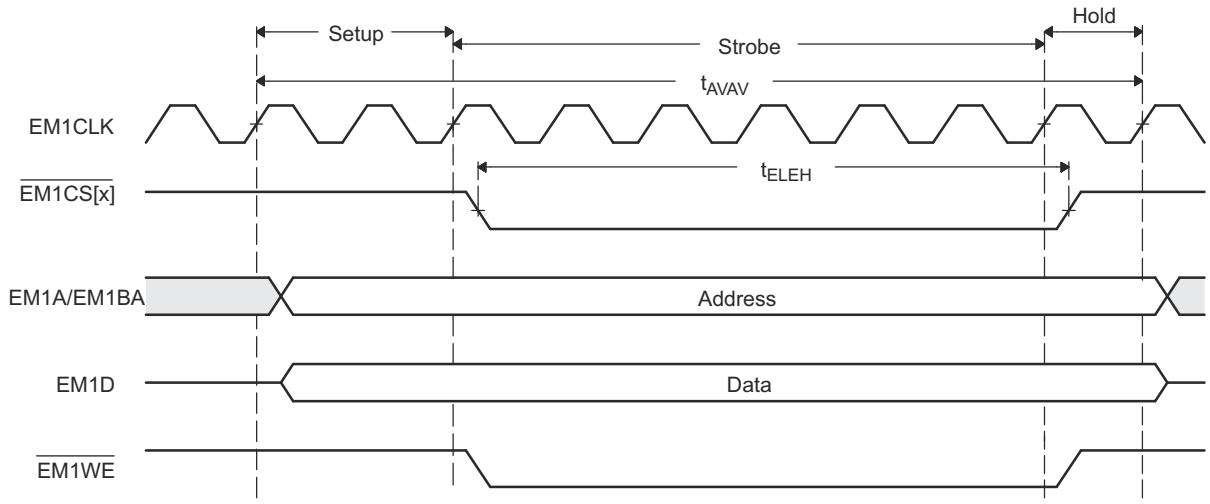

Figure 14-24. LH28F800BJE-PTTL90 to EMIF Write Timing Waveforms

The R_STROBE field must be set to meet the following equation:

$R\_STROBE >= (t_{ELQV} + t_{SU}) \times f_{EM1CLK} - 1$

R_STROBE >= (90ns + 15ns) × 200MHz - 1

R_STROBE >= 20

R_STROBE = 20

The R_HOLD field must be large enough to satisfy EMIF Data hold time, t_H:

$R\_HOLD > = t_H \times f_{EM1CLK} - 1$

R_HOLD >= 0ns × 200MHz - 1

R_HOLD >= -1

The R_HOLD field must also combine with the TA field to satisfy the Flash nCE High to Output in High Impedance time, t_{EHQZ}:

$R\_HOLD + TA >= t_{EHQZ} \times f_{EM1CLK} - 2$

R_HOLD + TA >= 55ns × 200MHz - 2

R_HOLD + TA >= 9

The largest value that can be programmed into the TA field is 3h, therefore the following values must be used:

R_HOLD = 6

TA = 3

For Writes, the W_STROBE field must be set to satisfy the Flash nCE Pulse Width constraint, t_{ELEH}:

$W\_STROBE >= t_{ELEH} \times f_{EM1CLK} - 1$

W_STROBE >= 50ns × 200MHz - 1

W_STROBE >= 9

The W_SETUP and W_HOLD fields must combine to satisfy the Flash nCE Pulse Width High constraint, t_{EHEL}:

W_SETUP + W_HOLD > = t_{EHEL} × f_{EM1CLK} - 2

W_SETUP + W_HOLD > = 30ns × 200MHz - 2

W_SETUP + W_HOLD > = 4

In addition, the entire Write access length must satisfy the Flash minimum Write Cycle Time, t_{AVAV}:

W_SETUP + W_STROBE + W_HOLD >= t_{AVAV} × f_{EM1CLK} - 3

W_SETUP + W_STROBE + W_HOLD >= 90ns × 200MHz - 3

W_SETUP + W_STROBE + W_HOLD >= 15

Solving the above equations for the Write fields results in the following:

W_SETUP = 4

W_STROBE = 10

W_HOLD = 1

Adding a 5ns (1 cycle) margin to each of the periods (excluding TA that is already at the maximum) in this example produces the following recommended values:

W_SETUP = 5h

W_STROBE = Bh

W_HOLD = 2h

R_SETUP = 1h

R_STROBE = 15h

R_HOLD = 7h

TA = 3h

14.5.2 EMIF Examples

NOTE: These examples are located in the C2000Ware installation at the following location: C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/emif

Cloud access to these examples is available at the following link: dev.ti.com C2000Ware Examples.

14.6 EMIF Registers

This section describes the EMIF Registers.

14.6.1 EMIF Base Address Table

Table 14-40. EMIF Base Address Table

Structure	DriverLib Name	Base Address	Frame Applicable	CPU1	CPU2	CPU3	RTDMA1	RTDMA2	HSM	Pipeline Protected
EMIF_REGS	EMIF1_BASE	0x3080_0000	-	YES	YES	YES	-	-	-	YES

14.6.2 EMIF_REGS Registers

Table 14-41 lists the memory-mapped registers for the EMIF_REGS registers. All register offset addresses not listed in Table 14-41 should be considered as reserved locations and the register contents should not be modified.

Table 14-41. EMIF_REGS Registers

Offset	Acronym	Register Name	Protection
0h	RCSR	Revision Code and Status Register	
4h	ASYNC_WCCR	Async Wait Cycle Config Register	
8h	SDRAM_CR	SDRAM (EMxCS0n) Config Register	
Ch	SDRAM_RCR	SDRAM Refresh Control Register	
10h	ASYNC_CS2_CR	Async 1 (EMxCS2n) Config Register	
14h	ASYNC_CS3_CR	Async 2 (EMxCS3n) Config Register	
18h	ASYNC_CS4_CR	Async 3 (EMxCS4n) Config Register	
20h	SDRAM_TR	SDRAM Timing Register	
30h	TOTAL_SDRAM_AR	Total SDRAM Accesses Register	
34h	TOTAL_SDRAM_ACTR	Total SDRAM Activate Register	
3Ch	SDR_EXT_TMNG	SDRAM SR/PD Exit Timing Register	
40h	INT_RAW	Interrupt Raw Register	
44h	INT_MSK	Interrupt Masked Register	
48h	INT_MSK_SET	Interrupt Mask Set Register	
4Ch	INT_MSK_CLR	Interrupt Mask Clear Register	

Complex bit access types are encoded to fit into small table cells. Table 14-42 shows the codes that are used for access types in this section.

Table 14-42. EMIF_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

14.6.2.1 RCSR Register (Offset = 0h) [Reset = 40000205h]

RCSR is shown in Figure 14-26 and described in Table 14-43.

Return to the Summary Table.

Table 14-45. SDRAM_CR Register Field Descriptions

Bit	Field	Type	Reset	Description
31	SR	R/W	0h	Self Refresh. Writing a 1 to this bit will cause connected SDRAM devices to be placed into Self Refresh mode and the EMIF to enter the self refresh state. In this state the EMIF will service all asynchronous memory accesses immediately but any SDRAM access will take at least t_ras + 1 cycles due to the time required for the SDRAM devices to out of Self Refresh mode. If an SDRAM access immediately follows the setting of the sr bit, the access will take t_ras + t_xs + 2 cycles. If both sr and pd bits are set, the EMIF will go into Self Refresh. Reset type: SYSRSn
30	PD	R/W	0h	Power Down. Writing a 1 to this bit will cause connected SDRAM devices to be placed into Power Down mode. If both sr and pd bits are set, the EMIF will go into Self Refresh. Reset type: SYSRSn
29	PDWR	R/W	0h	Perform refreshes during Power Down. Writing a 1 to this bit will cause the EMIF to exit the power down state and issue an AUTO REFRESH command every time Refresh May level is set. Reset type: SYSRSn

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	Reserved
15-6	RESERVED	R	0h	Reserved
5-2	WR_MASKED	R/W1S	0h	Masked Wait Rise. Set to 1 by hardware to indicate rising edge on the corresponding EMxWAIT has been detected, only if the wr_mask_set bit in the Interrupt Mask Set register is set to 1. The WPx bits in the Async Wait Cycle Config register has no effect on these bits. Writing a 1 will clear these bits as well as the wr bits in the Interrupt Raw register. Writing a 0 has no effect. Reset type: SYSRSn
1	LT_MASKED	R/W1S	0h	Masked Line Trap. Set to 1 by hardware to indicate illegal memory access type or invalid cache line size, only if the lt_mask_set bit in the Interrupt Mask Set register is set to 1. Writing a 1 will clear this bit as well as the lt bit in the Interrupt Raw register. Writing a 0 has no effect. Reset type: SYSRSn
0	AT_MASKED	R/W1S	0h	Masked Asynchronous Timeout. Set to 1 by hardware to indicate that during an extended asynchronous memory access cycle, the EMxWAIT signal did not go inactive within the number of cycles defined by the max_ext_wait field in Async Wait Cycle Config register, only if the at_mask_set bit in the Interrupt Mask Set register is set to 1. Writing a 1 will clear this bit as well as the at bit in the Interrupt Raw register. Writing a 0 has no effect. Reset type: SYSRSn

14.6.2.14 INT_MSK_SET Register (Offset = 48h) [Reset = 00000000h]

INT_MSK_SET is shown in Figure 14-39 and described in Table 14-56.

Chapter 15

General-Purpose Input/Output (GPIO)

The GPIO module controls the device's digital multiplexing, which uses shared pins to maximize application flexibility. The pins are named by the general-purpose I/O name (for example, GPIO0, GPIO25, GPIO58). These pins can be individually selected to operate as digital I/O (also called GPIO mode), or connected to one of several peripheral I/O signals. The input signals can be qualified to remove unwanted noise.

15.1 Introduction

Up to twelve independent peripheral signals are multiplexed on a single GPIO-enabled pin in addition to the CPU-controlled I/O capability. Each pin output can be controlled by either a peripheral or one of the CPU controllers.

There are up to 8 possible I/O ports:

- Port A consists of GPIO0-GPIO31
- Port B consists of GPIO32-GPIO63
- Port C consists of GPIO64-GPIO95
- Port D consists of GPIO96-GPIO127
- Port E consists of GPIO128-GPIO159
- Port F consists of GPIO160-GPIO191
- Port G consists of GPIO192-GPIO223
- Port H consists of GPIO224-GPIO255

Note

Some GPIO and I/O ports can be unavailable on particular devices. See the *GPIO Registers* section for available GPIO and I/O ports.

The analog signals on this device are multiplexed with digital inputs and outputs. Some of these analog IO (AIO) pins do not have digital output capability. Others of these pins are analog pins capable of full digital input and output capability (AGPIO). Analog pins with AIO (digital input only) capability contain "AIO" signals in the Pin Attributes table of the device data sheet. Analog pins with full input and output capability (AGPIO pins) contain "GPIO" signals in the Pin Attributes table of the device data sheet. AGPIO pins also have pin names with both analog signals and GPIO in the name.

Figure 15-1 shows the GPIO logic for a single pin.

There are two key features to note in Figure 15-1. The first is that the input and output paths are entirely separate, connecting only at the pin. The second is that peripheral muxing takes place far from the pin. As a result, for the CPU to read the physical state of the pin independent of peripheral muxing is possible. Likewise, external interrupts can be generated from peripheral activity. All pin options such as input qualification and open-drain output are valid for all controllers and peripherals.

Note

In open-drain mode, the GPIO does not drive the pin high, the GPIO can only pull the pin low. Instead, use an external pull-up to the bus voltage to drive the high level. When open-drain mode is enabled, the value in the GPyDAT register still controls the pin state. Writing a value of 1 turns off the driver to allow the external pull-up to control the pin; writing a value of 0 pulls the pin to ground. The open-drain configuration is automatically used by peripherals such as I2C and PMBus (no need to enable open-drain mode locally). This mode can also be set manually by writing to the GPyODR register and can be used when there are multiple nodes on the same net to avoid the pin contention that a push-pull driver can cause.

15.2 Configuration Overview

I/O pin configuration consists of several steps:

1. **Plan the device pin-out:** Make a list of all required peripherals for the application. Using the peripheral mux information in the device data sheet, choose which GPIOs to use for the peripheral signals. Decide which of the remaining GPIOs to use as inputs and outputs for each CPU.

   Once the peripheral muxing has been chosen, implement the mux by writing the appropriate values to the GPyMUX1/2 and GPyGMUX1/2 registers. When changing the GPyGMUX value for a pin, always set the corresponding GPyMUX bits to zero first to avoid glitching in the muxes. By default, all pins are general-purpose I/Os, not peripheral signals, with the exception of GPIO35 and GPIO37.
2. **(Optional) Enable internal pullup resistors:** To enable or disable the pullup resistors, write to the appropriate bits in the GPIO pullup disable registers (GPyPUD). All pullups are disabled by default. Pullups can be used to keep input pins in a known state when there is no external signal driving them.
3. **Select input qualification:** If the pin is used as an input, specify the required input qualification, if any. The input qualification sampling period is selected in the GPyCTRL registers, while the type of qualification is selected in the GPyQSEL1 and GPyQSEL2 registers. By default, all qualification is synchronous with a sampling period equal to PLLSYSCLK, with the exception of GPIO35 and GPIO37. For an explanation of input qualification, see Section 15.6.
4. **Select the direction of any general-purpose I/O pins:** For each pin configured as a GPIO, specify the direction of the pin as either input or output using the GPyDIR registers. By default, all GPIO pins are inputs. Before changing a pin to an output, load the output latch with the value to be driven by writing that value to the GPySET, GPyCLEAR, or GPyDAT registers. Once the latch is loaded, write to GPyDIR to change the pin direction. By default, all output latches are zero.

   The GPyDAT_R register can be used to read what value was written to the GPyDAT register.
5. **Select low-power mode wake-up sources:** GPIOs 0-63 can be used to wake the system up from low power modes. To select one or more GPIOs for wake-up, write to the appropriate bits in the GPIOLPMSEL0 and GPIOLPMSEL1 registers. These registers are part of the CPU system register space. For more information on low-power modes and GPIO wake-up, see the Low-Power Modes section in the *System Control and Interrupts* chapter.
6. **Select external interrupt sources:** Configuring external interrupts is a two-step process. First, the interrupts themselves must be enabled and the polarity must be configured using the XINTnCR registers. Second, the XINT1-5 GPIO pins must be set by selecting the sources for Input X-BAR signals 4, 5, 6, 13, and 14, respectively. For more information on the Input X-BAR architecture, see the *Crossbar (X-BAR)* chapter.

15.3 Digital Inputs on ADC Pins (AIOs)

Some GPIOs are multiplexed with analog pins and only have digital input functionality. These are also referred to as AIOs. Pins with only an AIO option on this port can only function in input mode. See the device data sheet for list of AIO signals. By default, these pins function as analog pins and the GPIOs are in a high-impedance state. The GPyAMSEL register is used to configure these pins for digital or analog operation.

Note

If digital signals with sharp edges (high dv/dt) are connected to the AIOs, cross-talk can occur with adjacent analog signals. Therefore, limit the edge rate of signals connected to AIOs if adjacent channels are being used for analog functions.

15.4 Digital Inputs and Outputs on ADC Pins (AGPIOs)

Some GPIOs are multiplexed with analog pins and have digital input and output functionality. These are also referred to as AGPIOs. Unlike AIOs, AGPIOs have full input and output capability. By default, the AGPIOs are not connected and must be configured. Table 15-1 shows how to configure the AGPIOs. To enable the analog functionality, set the register AGPIOCTRLx from analog subsystem. To enable the digital functionality, set the register GPxAMSEL from the *General-Purpose Input/Output (GPIO)* chapter.

Table 15-1. AGPIO Configuration

AGPIOCTRLx.GPIOy (Default = 0)	GPxAMSEL.GPIOy (Default = 1)	Pin Connected To:	
		ADC	GPIOy
0	0	-	Yes
0	**1**	**-** (1)	**-** (1)
1	0	-	Yes
1	1	Yes	-

(1) By default there are no signals connected to AGPIO pins. One of the other rows in the table must be chosen for pin functionality.

Note

If digital signals with sharp edges (high dv/dt) are connected to the AGPIOs, cross-talk can occur with adjacent analog signals. The user must therefore limit the edge rate of signals connected to AGPIOs, if adjacent channels are being used for analog functions.

15.5 Digital General-Purpose I/O Control

The values on the pins that are configured as GPIO can be changed by using the following registers.

- **GPyDAT Registers**

  Each I/O port has one data register. Each bit in the data register corresponds to one GPIO pin. No matter how the pin is configured (GPIO or peripheral function), the corresponding bit in the data register reflects the current state of the pin after qualification. Writing to the GPyDAT register clears or sets the corresponding output latch and if the pin is enabled as a general-purpose output (GPIO output), the pin is also driven either low or high. If the pin is not configured as a GPIO output, then the value is latched but the pin is not driven. Only if the pin is later configured as a GPIO output is the latched value driven onto the pin.

  When using the GPyDAT register to change the level of an output pin, be cautious to not accidentally change the level of another pin. For example, to change the output latch level of GPIOA0 by writing to the GPADAT register bit 0 using a read-modify-write instruction, a problem can occur if another I/O port A signal changes level between the read and the write stage of the instruction. Following is an analysis of why this happens:

  The GPyDAT registers reflect the state of the pin, not the latch. This means the register reflects the actual pin value. However, there is a lag between when the register is written to when the new pin value is reflected back in the register. This can pose a problem when this register is used in subsequent program statements to alter the state of GPIO pins. An example is shown below where two program statements attempt to drive two different GPIO pins that are currently low to a high state.

  If Read-Modify-Write operations are used on the GPyDAT registers, because of the delay between the output and the input of the first instruction (I1), the second instruction (I2) reads the old value and writes the value back.

```
GpioDataRegs.GPADAT.bit.GPIO1 = 1;  //I1 performs read-modify-write of GPADAT
GpioDataRegs.GPADAT.bit.GPIO2 = 1;  //I2 also a read-modify-write of GPADAT
                                    //GPADAT gets the old value of GPIO1 due to the delay
```

  The second instruction waits for the first to finish the write due to the write-followed-by-read protection on this peripheral frame. There is some lag, however, between the write of (I1) and the GPyDAT bit reflecting the new value (1) on the pin. During this lag, the second instruction reads the old value of GPIO1 (0) and writes the value back along with the new value of GPIO2 (1). Therefore, GPIO1 pin stays low.

  One answer is to put some NOPs between instructions. A better answer is to use the GPySET/GPyCLEAR/GPyTOGGLE registers instead of the GPyDAT registers. These registers always read back a 0 and writes of 0 have no effect. Only bits that need to be changed can be specified without disturbing any other bits that are currently in the process of changing.

- **GPyDAT_R Registers**

  The GPyDAT_R registers are read only registers that return the value written to the GPyDAT registers instead of pin status. Writes to these registers have no effect.

- **GPySET Registers**

  The set registers are used to drive specified GPIO pins high without disturbing other pins. Each I/O port has one set register and each bit corresponds to one GPIO pin. The set registers always read back 0. If the corresponding pin is configured as an output, then writing a 1 to that bit in the set register sets the output latch high and the corresponding pin is driven high. If the pin is not configured as a GPIO output, then the value is latched but the pin is not driven. Only if the pin is later configured as a GPIO output is the latched value driven onto the pin. Writing a 0 to any bit in the set registers has no effect.

- **GPyCLEAR Registers**

  The clear registers are used to drive specified GPIO pins low without disturbing other pins. Each I/O port has one clear register. The clear registers always read back 0. If the corresponding pin is configured as a general-purpose output, then writing a 1 to the corresponding bit in the clear register clears the output latch and the pin is driven low. If the pin is not configured as a GPIO output, then the value is latched but the pin is not driven. Only if the pin is later configured as a GPIO output is the latched value driven onto the pin. Writing a 0 to any bit in the clear registers has no effect.

- **GPyTOGGLE Registers**

  The toggle registers are used to drive specified GPIO pins to the opposite level without disturbing other pins. Each I/O port has one toggle register. The toggle registers always read back 0. If the corresponding pin is configured as an output, then writing a 1 to that bit in the toggle register flips the output latch and pulls the corresponding pin in the opposite direction. That is, if the output pin is driven low, then writing a 1 to the corresponding bit in the toggle register pulls the pin high. Likewise, if the output pin is high, then writing a 1 to the corresponding bit in the toggle register pulls the pin low. If the pin is not configured as a GPIO output, then the value is latched but the pin is not driven. Only if the pin is later configured as a GPIO output is the latched value driven onto the pin. Writing a 0 to any bit in the toggle registers has no effect.

15.6 Input Qualification

The input qualification scheme has been designed to be very flexible. Select the type of input qualification for each GPIO pin by configuring the GPyQSEL1 and GPyQSEL2 registers. In the case of a GPIO input pin, the qualification can be specified as only synchronized to SYSCLKOUT or qualification by a sampling window. For pins that are configured as peripheral inputs, the input can also be asynchronous in addition to synchronized to SYSCLKOUT or qualified by a sampling window. The remainder of this section describes the options available.

15.6.1 No Synchronization (Asynchronous Input)

This mode is used for peripherals where input synchronization is not required or the peripheral performs the synchronization. Examples include communication ports McBSP, SCI, SPI, and I^2C. In addition, the ePWM trip zone ($\overline{TZn}$) signals can function independent of the presence of SYSCLKOUT.

Note

Using input synchronization when the peripheral performs the synchronization can cause unexpected results. The user must make sure that the GPIO pin is configured for asynchronous in this case.

15.6.2 Synchronization to SYSCLKOUT Only

This is the default qualification mode of all the pins at reset. In this mode, the input signal is only synchronized to the system clock (SYSCLKOUT). Because the incoming signal is asynchronous, a SYSCLKOUT period of delay is needed for the input to the device to be changed. No further qualification is performed on the signal.

15.6.3 Qualification Using a Sampling Window

In this mode, the signal is first synchronized to the system clock (SYSCLKOUT) and then qualified by a specified number of cycles before the input is allowed to change. Figure 15-2 and Figure 15-3 show how the input qualification is performed to eliminate unwanted noise. Two parameters are specified by the user for this type of qualification: 1) the sampling period, or how often the signal is sampled, and 2) the number of samples to be taken.

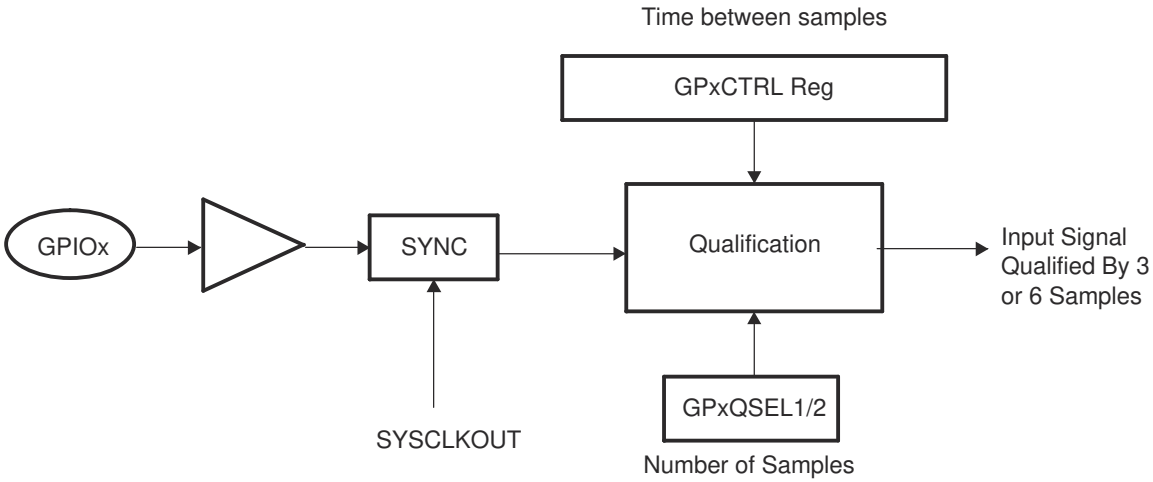

Figure 15-2. Input Qualification Using a Sampling Window

Time between samples (sampling period):

To qualify the signal, the input signal is sampled at a regular period. The sampling period is specified by the user and determines the time duration between samples, or how often the signal is sampled, relative to the CPU clock (SYSCLKOUT).

The sampling period is specified by the qualification period (QUALPRDn) bits in the GPxCTRL register . The sampling period is configurable in groups of 8 input signals. For example, GPIO0 to GPIO7 use GPACTRL[QUALPRD0] setting and GPIO8 to GPIO15 use GPACTRL[QUALPRD1]. Table 15-2 and Table 15-3 show the relationship between the sampling period or sampling frequency and the GPxCTRL[QUALPRDn] setting.

Table 15-2. Sampling Period

	Sampling Period
If GPxCTRL[QUALPRDn] = 0	1 × $T_{SYSCLKOUT}$
If GPxCTRL[QUALPRDn] ≠ 0	2 × GPxCTRL[QUALPRDn] × $T_{SYSCLKOUT}$
	Where $T_{SYSCLKOUT}$ is the period in time of SYSCLKOUT

Table 15-3. Sampling Frequency

	Sampling Frequency
If GPxCTRL[QUALPRDn] = 0	$f_{SYSCLKOUT}$
If GPxCTRL[QUALPRDn] ≠ 0	$f_{SYSCLKOUT}$ × 1 ÷ (2 × GPxCTRL[QUALPRDn])
	Where $f_{SYSCLKOUT}$ is the frequency of SYSCLKOUT

From these equations, the minimum and maximum time between samples can be calculated for a given SYSCLKOUT frequency:

Example: Maximum Sampling Frequency:

If GPxCTRL[QUALPRDn] = 0

then the sampling frequency is $f_{SYSCLKOUT}$

If, for example, $f_{SYSCLKOUT}$ = 60MHz

then the signal is sampled at 60MHz or one sample every 16.67ns.

Example: Minimum Sampling Frequency:

If GPxCTRL[QUALPRDn] = 0xFF (255)

then the sampling frequency is $f_{SYSCLKOUT} \times 1 \div (2 \times$ GPxCTRL[QUALPRDn])

If, for example, $f_{SYSCLKOUT}$ = 60MHz

then the signal is sampled at 60MHz × 1 ÷ (2 × 255) (117.647kHz) or one sample every 8.5µs.

Number of samples:

The number of times the signal is sampled is either three samples or six samples as specified in the qualification selection (GPyQSEL1, GPyQSEL2) registers. When three or six consecutive cycles are the same, then the input change is passed through to the device.

Total Sampling-Window Width:

The sampling window is the time during which the input signal is sampled as shown in Figure 15-3. By using the equation for the sampling period, along with the number of samples to be taken, the total width of the window can be determined.

For the input qualifier to detect a change in the input, the level of the signal must be stable for the duration of the sampling-window width or longer.

The number of sampling periods within the window is always one less than the number of samples taken. For a three-sample window, the sampling-window width is two sampling-periods wide where the sampling period is defined in Table 15-2. Likewise, for a six-sample window, the sampling-window width is five sampling-periods wide. Table 15-4 and Table 15-5 show the calculations used to determine the total sampling-window width based on GPxCTRL[QUALPRDn] and the number of samples taken.

Table 15-4. Case 1: Three-Sample Sampling-Window Width

	Total Sampling-Window Width
If GPxCTRL[QUALPRDn] = 0	2 × $T_{SYSCLKOUT}$
If GPxCTRL[QUALPRDn] ≠ 0	2 × 2 × GPxCTRL[QUALPRDn] × $T_{SYSCLKOUT}$
	Where $T_{SYSCLKOUT}$ is the period in time of SYSCLKOUT

Table 15-5. Case 2: Six-Sample Sampling-Window Width

	Total Sampling-Window Width
If GPxCTRL[QUALPRDn] = 0	5 × $T_{SYSCLKOUT}$
If GPxCTRL[QUALPRDn] ≠ 0	5 × 2 × GPxCTRL[QUALPRDn] × $T_{SYSCLKOUT}$
	Where $T_{SYSCLKOUT}$ is the period in time of SYSCLKOUT

Note

The external signal change is asynchronous with respect to both the sampling period and SYSCLKOUT. Due to the asynchronous nature of the external signal, the input must be held stable for a time greater than the sampling-window width to make sure the logic detects a change in the signal. The extra time required can be up to an additional sampling period + $T_{SYSCLKOUT}$.

The required duration for an input signal to be stable for the qualification logic to detect a change is described in the data sheet.

Example Qualification Window:

For the example shown in Figure 15-3, the input qualification has been configured as follows:

- GPxQSEL1/2 = 1,0. This indicates a six-sample qualification.
- GPxCTRL[QUALPRDn] = 1. The sampling period is $t_w(SP) = 2 \times$ GPxCTRL[QUALPRDn] $\times T_{SYSCLKOUT} = 2 \times T_{SYSCLKOUT}$.

This configuration results in the following:

- The width of the sampling window is:

  $t_w(IQSW) = 5 \times t_w(SP) = 5 \times 2 \times$ GPxCTRL[QUALPRDn] $\times T_{SYSCLKOUT} = 5 \times 2 \times T_{SYSCLKOUT}$

- If, for example, $T_{SYSCLKOUT}$ = 16.67ns, then the duration of the sampling window is:

  Sampling period, $t_w(SP) = 2 \times T_{SYSCLKOUT} = 2 \times 16.67ns = 33.3ns$

  Sampling window, $t_w(IQSW) = 5 \times t_w(SP) = 5 \times 33.3ns = 166.7ns$

- To account for the asynchronous nature of the input relative to the sampling period and SYSCLKOUT, up to a single additional sampling period and SYSCLK period is required to detect a change in the input signal. For this example:

  $t_w(IQSW) + t_w(SP) + T_{SYSCLKOUT} = 166.7ns + 33.3ns + 16.67ns = 216.7ns$

- In Figure 15-3, the glitch (A) is shorter then the qualification window and is ignored by the input qualifier.

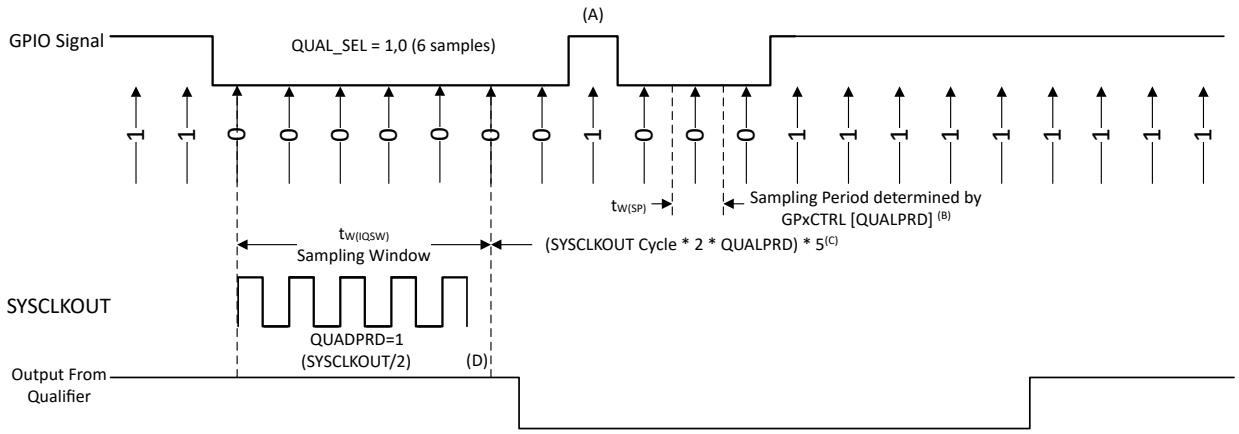

Figure 15-3. Input Qualifier Clock Cycles

- **A.** This glitch will be ignored by the input qualifier. The QUALPRD bit field specifies the qualification sampling period. It can vary from 0x00 to 0xFF. If QUALPRD = 00, then the sampling period is 1 SYSCLKOUT cycle. For any other value 'n', the qualificiation sampling period is 2n SYSCLKOUT cycles (i.e. at every 2n SYSCLKOUT cycles, the GPIO pin will be sampled).
- **B.** The qualification period selected via the GPxCTRL register applies to groups of 8 GPIO pins.

- **C.** the qualification block can take either 3 or 6 samples. The QUAL_SEL Register selects which samples mode is used.
- **D.** In the example shown, for the qualifier to detect the change, the input should be stable for 10 SYSCLKOUT cycles. That would ensure 5 sampling periods for detection to occur. Since external signals are driven asynchronously, a 13-SYSCLKOUT-wide pulse ensures reliable recognition.

15.7 PMBUS and I2C Signals

To support a wider range of PMBUS and I2C IO levels, certain GPIOs on this device have configurable V_{IH} minimum thresholds and configurable current sinking capabilities.

- PMBUS_IO_MODESEL register configures the V_{IH} threshold of the GPIO
- PMBUS_IO_DRVSEL register configures the current sinking capability of the GPIO

Note

The PMBUS_IO_MODESEL and PMBUS_IO_DRVSEL registers apply to the entire GPIO, not just the PMBUS module. Any peripheral or module in the given GPIO's mux is able to utilize the customizable V_{IH} threshold and current sinking capability.

The list of GPIOs that have these capabilities, and the configurable levels for these GPIOs are available in the PMBUS_IO_MODESEL and PMBUS_IO_DRVSEL registers.

15.8.2 Peripheral Muxing

For example, multiplexing for the GPIO6 pin is controlled by writing to GPAGMUX[13:12] and GPAMUX[13:12]. By writing to these bits, GPIO6 is configured as either a general-purpose digital I/O or one of several different peripheral functions. An example of GPyGMUX and GPyMUX selection and options for a single GPIO are shown in Table 15-7.

Note

The following table is for example only. Refer to the device data sheet to check the availability of GPIO6 on this device. If GPIO6 is available, the functions mentioned in the table may not match the actual functions available. See Section 15.8.1 for correct list of GPIOs and corresponding mux options for this device.

Table 15-7. GPIO and Peripheral Muxing

GPAGMUX1[13:12]	GPAMUX1[13:12]	Pin Functionality
00	00	GPIO6
00	01	Peripheral 1
00	10	Peripheral 2
00	11	Peripheral 3
01	00	GPIO6
01	01	Peripheral 4
01	10	Peripheral 5
01	11	
10	00	GPIO6
10	01	
10	10	Peripheral 6
10	11	Peripheral 7
11	00	GPIO6
11	01	Peripheral 8
11	10	Peripheral 9
11	11	Peripheral 10

The devices have different multiplexing schemes. If a peripheral is not available on a particular device, that mux selection is reserved on that device and must not be used.

CAUTION

If a reserved GPIO mux configuration that is not mapped to either a peripheral or GPIO mode is selected, the state of the pin is undefined and the pin is driven. Unimplemented configurations are for future expansion and must not be selected. In the device mux table (see the data sheet), these options are indicated as Reserved or left blank.

Some peripherals can be assigned to more than one pin by way of the mux registers. For example, OUTPUTXBAR1 can be assigned to GPIOs p, q, or r (where p, q, and r are example GPIO numbers), depending on individual system requirements. An example of this is shown in Table 15-8.

Note

The following table is for example only. Bit ranges cannot correspond to OUTPUTXBAR1 on this device. See Section 15.8.1 for correct list of GPIOs and corresponding mux options for this device.

If none or more then one of the GPIO pins is configured as peripheral input pins, then that GPIO is set to a hard-wired default value.

Table 15-8. Peripheral Muxing (Multiple Pins Assigned)

GMUX Configuration	MUX Configuration	
Choice 1: GPIOp	GPyGMUX1[5:4] = 01	GPyMUX1[5:4] = 01
or Choice 2: GPIOq	GPyGMUX2[17:16] = 00	GPyMUX2[17:16] = 01
or Choice 3: GPIOr	GPyGMUX1[7:6] = 01	GPyMUX1[7:6] = 01

15.9 Internal Pullup Configuration Requirements

On reset, GPIOs are in input mode and have the internal pullups disabled. An un-driven input can float to a mid-rail voltage and cause wasted shoot-through current on the input buffer. The user must always put each GPIO in one of these configurations:

- Input mode and driven on the board by another component to a level above V_{ih} or below V_{il}
- Input mode with GPIO internal pullup enabled
- Output mode

On devices with lesser pin count packages, pull-ups on unbonded GPIOs are by default enabled to prevent floating inputs. The user must take care to avoid disabling these pullups in the application code.

On devices with larger pin count packages, the pullups for any internally unbonded GPIO must be enabled to prevent floating inputs. TI has provided functions in controlSUITE/C2000Ware that users can call to enable the pullup on any unbonded GPIO for the package in use. This function, GPIO_EnabledUnbondedIOPullups(), resides in the (Device)_Sysctrl.c file and is called by default from InitSysCtrl(). The user must take care to avoid disabling these pullups in the application code.

15.10.2 GPIO Examples

NOTE: These examples are located in the C29SDK installation from ti.com at the following location: mcu_sdk_DEVICE_GPN/examples/driverlib/CORE_IF_MULTICORE/gpio

Cloud access to these examples is available at the following link: dev.ti.com C29SDK Examples.

15.10.2.1 Device GPIO Toggle - SINGLE_CORE

FILE: gpio_ex1_toggle.c

Configures the device GPIO through the sysconfig file. The GPIO pin is toggled in the infinite loop.

15.10.2.2 XINT/XBAR example - SINGLE_CORE

FILE: gpio_ex2_interrupt.c

This example demonstrates the XINT feature in SysConfig by using it in conjunction with the input and output XBARs. The GPIO is toggled and connected to the input XBAR, while simultaneously triggering an external interrupt. The interrupt increments a counter which can be observed in the watch window. In addition to triggering an interrupt, the input signal is routed from the input XBAR to the output XBAR so that the output can be observed via oscilloscope or logic analyzer on a separate pin.

Watch Variables

- *counter* - Number of interrupts generated

15.10.3 LED Examples

NOTE: These examples are located in the C29SDK installation from ti.com at the following location: mcu_sdk_DEVICE_GPN/examples/driverlib/CORE_IF_MULTICORE/led

Cloud access to these examples is available at the following link: dev.ti.com C29SDK Examples.

15.10.3.1 LED Blinky Example - MULTI_CORE

FILE: led_ex1_blinky_cpu1_cpu3_multi_c29x1.c

This example demonstrates how to blink a LED using CPU1 and blink another LED using CPU3 (led_ex1_blinky_cpu1_cpu3_multi_c29x3.c).

When using CCS for debugging this Multi-core example, after launching the debug session,

- Connect to CPU1 and load only the c29x1.out.
- After the program is loaded, run CPU1.
- Once c29x1 configures and releases CPU3 out of reset, the program stops.
- Connect to CPU3 target now. c29x3.out would have started execution as soon as it is released from reset.
- In case of RAM configuration, restart the CPU3 target and load the symbols.

For FLASH configuration, this example is run in FLASH BANKMODE2, where CPU3 has access to FLASH (FRI-2). Refer to the Flash Plugin documentation to know about changing FLASH BANKMODEs and more. Additionally, the CPAx and CDAx RAMs are used for allocating various RAM sections. *External Connections*

- None.

Watch Variables

- None.

15.10.3.2 LED Blinky Example (CPU1,CPU3) - MULTI_CORE

FILE: led_ex1_blinky_cpu1_cpu3_multi_c29x3.c

This example demonstrates how to blink a LED using CPU1 and blink another LED using CPU3 (led_ex1_blinky_cpu1_cpu3_multi_c29x3.c).

When using CCS for debugging this Multi-core example, after launching the debug session,

- Connect to CPU1 and first load the c29x3.out. (When loaded to FLASH, this might not halt at main due to an error, since CPU1 cannot execute from CPU3 FLASH memory (FRI-2)).
- c29x1.out can be loaded next.
- After the program is loaded, run CPU1.
- Once c29x1 configures and releases CPU3 out of reset, the program stops.
- Connect to CPU3 target now. c29x3.out would have started execution as soon as it is released from reset.
- In case of RAM configuration, restart the CPU3 target and load the symbols.
- In case of FLASH, do a Power-on-Reset, connect to CPU1/ CPU3 and load the respective symbols.

For FLASH configuration, this example is run in FLASH BANKMODE2, where CPU3 has access to FLASH (FRI-2). Refer to the Flash Plugin documentation to know about changing FLASH BANKMODEs and more. Additionally, the CPAx and CDAx RAMs are used for allocating various RAM sections. *External Connections*

- None.

Watch Variables

- None.

15.10.3.3 LED Blinky example - SINGLE_CORE

FILE: led_ex1_blinky.c

This example demonstrates how to blink an LED. The device GPIO is configured through the sysconfig file. The GPIO pin is toggled in an infinite loop.

15.10.3.4 LED Blinky Example (CPU1|CPU2|CPU3) - MULTI_CORE

FILE: led_ex2_blinky_cpu1_cpu2_cpu3_multi_c29x1.c

This example demonstrates how to configure LEDs using CPU1 and blink two LEDs using CPU2 (led_ex2_blinky_cpu1_cpu2_cpu3_multi_c29x2.c) and CPU3 (led_ex2_blinky_cpu1_cpu2_cpu3_multi_c29x3.c).

When using CCS for debugging this Multi-core example, after launching the debug session,

- Connect to CPU1 and load only the c29x1.out.
- After the program is loaded, run CPU1.
- Once c29x1 disables lockstep, configures and releases CPU2 & CPU3 out of reset, the program stops.
- Connect to the CPU2 target now. c29x2.out would have started execution as soon as it is released from reset.

- Connect to the CPU3 target now. c29x3.out would have started execution as soon as it is released from reset.
- In case of RAM configuration, restart CPU2, CPU3 targets and load the symbols.

Note: Since CPU2 does not have FLASH access, the CPU2 application code is loaded to CPU1's FLASH, which is copied to CPU2 RAM by the CPU1 application. The CPU3 application code is loaded to its Flash (FRI-2) in FLASH BANKMODE2.

External Connections

- None.

Watch Variables

- None.

15.10.3.5 LED Blinky Example (CPU2) - MULTI_CORE

FILE: led_ex2_blinky_cpu1_cpu2_cpu3_multi_c29x2.c

This example demonstrates how to configure LEDs using CPU1 and blink two LEDs using CPU2 (led_ex2_blinky_cpu1_cpu2_cpu3_multi_c29x2.c) and CPU3 (led_ex2_blinky_cpu1_cpu2_cpu3_multi_c29x3.c).

When using CCS for debugging this Multi-core example, after launching the debug session,

- Connect to CPU1 and first load the c29x3.out, c29x2.out.
- When loaded to FLASH, these might not halt at main due to an error.
- c29x1.out can be loaded next.
- After the program is loaded, run CPU1.
- Once c29x1 disables lockstep, configures and releases CPU2 & CPU3 out of reset, the program stops.
- Connect to the CPU2 target now. c29x2.out would have started execution as soon as it is released from reset.
- Connect to the CPU3 target now. c29x3.out would have started execution as soon as it is released from reset.
- In case of RAM configuration, restart CPU2, CPU3 targets and load the symbols.
- In case of FLASH, do a Power-on-Reset, connect to CPU1, CPU2, CPU3 and load the respective symbols.

Note: Since CPU2 does not have FLASH access, the CPU2 application code is loaded to CPU1's FLASH, which is copied to CPU2 RAM by the CPU1 application. The CPU3 application code is loaded to its Flash (FRI-2) in FLASH BANKMODE2.

External Connections

- None.

Watch Variables

- None.

15.10.3.6 LED Blinky Example (CPU3) - MULTI_CORE

FILE: led_ex2_blinky_cpu1_cpu2_cpu3_multi_c29x3.c

This example demonstrates how to configure LEDs using CPU1 and blink two LEDs using CPU2 (led_ex2_blinky_cpu1_cpu2_cpu3_multi_c29x2.c) and CPU3 (led_ex2_blinky_cpu1_cpu2_cpu3_multi_c29x3.c).

When using CCS for debugging this Multi-core example, after launching the debug session,

- Connect to CPU1 and first load the c29x3.out, c29x2.out.
- When loaded to FLASH, these might not halt at main due to an error.
- c29x1.out can be loaded next.
- After the program is loaded, run CPU1.
- Once c29x1 disables lockstep, configures and releases CPU2 & CPU3 out of reset, the program stops.
- Connect to the CPU2 target now. c29x2.out would have started execution as soon as it is released from reset.

- Connect to the CPU3 target now. c29x3.out would have started execution as soon as it is released from reset.
- In case of RAM configuration, restart CPU2, CPU3 targets and load the symbols.
- In case of FLASH, do a Power-on-Reset, connect to CPU1, CPU2, CPU3 and load the respective symbols.

Note: Since CPU2 does not have FLASH access, the CPU2 application code is loaded to CPU1's FLASH, which is copied to CPU2 RAM by the CPU1 application. The CPU3 application code is loaded to its Flash (FRI-2) in FLASH BANKMODE2.

External Connections

15.11 GPIO Registers

This section describes the GPIO Registers.

15.11.1 GPIO Base Address Table

Table 15-10. GPIO Base Address Table

Structure	DriverLib Name	Base Address	Frame Applicable	CPU1	CPU2	CPU3	RTDMA1	RTDMA2	HSM	Pipeline Protected
GPIO_CTRL_REGS [1]	GPIOCTRL_BASE	0x3019_0000	-	YES	YES	YES	-	-	YES	YES
GPIO_DATA_REGS	GPIODATA_BASE	0x3026_8000	-	YES	YES	YES	-	-	-	YES
GPIO_DATA_READ_REGS	GPIODATAREAD_BASE	0x3026_9000	-	YES	YES	YES	-	-	-	YES

(1) Registers writeable by CPU1.LINK0, CPU1.LINK1, CPU1.LINK2 only. All CPUs can read all registers in all LINKs. Debug write access only allowed if Zone0 or Zone1 are enabled for full debug by all CPUs. Debug reads always allowed. Register Read/Write access by HSM.

15.11.2 GPIO_CTRL_REGS Registers

Table 15-11 lists the memory-mapped registers for the GPIO_CTRL_REGS registers. All register offset addresses not listed in Table 15-11 should be considered as reserved locations and the register contents should not be modified.

Table 15-11. GPIO_CTRL_REGS Registers

Offset	Acronym	Register Name	Protection
0h	GPACTRL	GPIO A Qualification Sampling Period Control (GPIO0 to 31)	
4h	GPAQSEL1	GPIO A Qualifier Select 1 Register (GPIO0 to 15)	
8h	GPAQSEL2	GPIO A Qualifier Select 2 Register (GPIO16 to 31)	
Ch	GPAMUX1	GPIO A Mux 1 Register (GPIO0 to 15)	
10h	GPAMUX2	GPIO A Mux 2 Register (GPIO16 to 31)	
18h	GPAPUD	GPIO A Pull Up Disable Register (GPIO0 to 31)	
20h	GPAINV	GPIO A Input Polarity Invert Registers (GPIO0 to 31)	
24h	GPAODR	GPIO A Open Drain Output Register (GPIO0 to GPIO31)	
40h	GPAGMUX1	GPIO A Peripheral Group Mux (GPIO0 to 15)	
44h	GPAGMUX2	GPIO A Peripheral Group Mux (GPIO16 to 31)	
50h	GPACSEL1	GPIO A Core Select Register (GPIO0 to 7)	
54h	GPACSEL2	GPIO A Core Select Register (GPIO8 to 15)	
58h	GPACSEL3	GPIO A Core Select Register (GPIO16 to 23)	
5Ch	GPACSEL4	GPIO A Core Select Register (GPIO24 to 31)	
78h	GPALOCK	GPIO A Lock Configuration Register (GPIO0 to 31)	
7Ch	GPACR	GPIO A Lock Commit Register (GPIO0 to 31)	
80h	GPBCTRL	GPIO B Qualification Sampling Period Control (GPIO32 to 63)	
84h	GPBQSEL1	GPIO B Qualifier Select 1 Register (GPIO32 to 47)	
88h	GPBQSEL2	GPIO B Qualifier Select 2 Register (GPIO48 to 63)	
8Ch	GPBMUX1	GPIO B Mux 1 Register (GPIO32 to 47)	
90h	GPBMUX2	GPIO B Mux 2 Register (GPIO48 to 63)	
98h	GPBPUD	GPIO B Pull Up Disable Register (GPIO32 to 63)	
A0h	GPBINV	GPIO B Input Polarity Invert Registers (GPIO32 to 63)	
A4h	GPBODR	GPIO B Open Drain Output Register (GPIO32 to GPIO63)	
C0h	GPBGMUX1	GPIO B Peripheral Group Mux (GPIO32 to 47)	
C4h	GPBGMUX2	GPIO B Peripheral Group Mux (GPIO48 to 63)	
D0h	GPBCSEL1	GPIO B Core Select Register (GPIO32 to 39)	
D4h	GPBCSEL2	GPIO B Core Select Register (GPIO40 to 47)	
D8h	GPBCSEL3	GPIO B Core Select Register (GPIO48 to 55)	
DCh	GPBCSEL4	GPIO B Core Select Register (GPIO56 to 63)	
F8h	GPBLOCK	GPIO B Lock Configuration Register (GPIO32 to 63)	
FCh	GPBCR	GPIO B Lock Commit Register (GPIO32 to 63)	
100h	GPCCTRL	GPIO C Qualification Sampling Period Control (GPIO64 to 95)	
104h	GPCQSEL1	GPIO C Qualifier Select 1 Register (GPIO64 to 79)	
108h	GPCQSEL2	GPIO C Qualifier Select 2 Register (GPIO80 to 95)	
10Ch	GPCMUX1	GPIO C Mux 1 Register (GPIO64 to 79)

Complex bit access types are encoded to fit into small table cells. Table 15-12 shows the codes that are used for access types in this section.

Table 15-12. GPIO_CTRL_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		

Table 15-12. GPIO_CTRL_REGS Access Type Codes (continued)

Access Type	Code	Description
W	W	Write
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

15.11.2.1 GPACTRL Register (Offset = 0h) [Reset = 00000000h]

GPACTRL is shown in Figure 15-4 and described in Table 15-13.

Return to the Summary Table.

GPIO A Qualification Sampling Period Control (GPIO0 to 31)

Bit	Field	Type	Reset	Description
1-0	GPIO16	R/W	0h	Select input qualification type for GPIO16: 0,0,Sync 0,1,Qualification (3 samples) 1,0,Qualification (6 samples) 1,1,Async (no Sync or Qualification) Reset type: SYSRSn

15.11.2.4 GPAMUX1 Register (Offset = Ch) [Reset = 00000000h]

GPAMUX1 is shown in Figure 15-7 and described in Table 15-16.

Return to the Summary Table.

GPIO A Mux 1 Register (GPIO0 to 15)
Defines pin-muxing selection for GPIO.
Notes:
The respective GPyGMUXn.GPIOz must be configured prior to this register to avoid intermediate peripheral selects being mapped to the GPIO. Refer to GPIO chapter for more details.

Figure 15-7. GPAMUX1 Register

15.11.2.6 GPAPUD Register (Offset = 18h) [Reset = FFFFFFFFh]

GPAPUD is shown in Figure 15-9 and described in Table 15-18.

Return to the Summary Table.

GPIO A Pull Up Disable Register (GPIO0 to 31)
Disables the Pull-Up on GPIO.
0: Enables the Pull-Up.
1: Disables the Pull-Up.
Reading the register returns the current value of the register setting.
Note:
[1] The Pull-Ups on the GPIO pins are disabled asynchronously when IORSn signal is low.

15.11.2.7 GPAINV Register (Offset = 20h) [Reset = 00000000h]

GPAINV is shown in Figure 15-10 and described in Table 15-19.

Return to the Summary Table.

GPIO A Input Polarity Invert Registers (GPIO0 to 31)
Selects between non-inverted and inverted GPIO input to the device.
0: selects non-inverted GPIO input
1: selects inverted GPIO input
Reading the register returns the current value of the register setting.

15.11.2.8 GPAODR Register (Offset = 24h) [Reset = 00000000h]

GPAODR is shown in Figure 15-11 and described in Table 15-20.

Return to the Summary Table.

GPIO A Open Drain Output Register (GPIO0 to GPIO31)
Selects between normal and open-drain output for the GPIO pin.
0: Normal Output
1: Open Drain Output
Reading the register returns the current value of the register setting.
Note:
[1] In the Open Drain output mode, if the buffer is configured for output mode, a 0 value to be driven out comes out on the on the PAD while a 1 value to be driven out tri-states the buffer.

15.11.2.19 GPBQSEL2 Register (Offset = 88h) [Reset = 00000000h]

GPBQSEL2 is shown in Figure 15-22 and described in Table 15-31.

Return to the Summary Table.

GPIO B Qualifier Select 2 Register (GPIO48 to 63)
Input qualification type:
0,0 Sync
0,1 Qualification (3 samples)
1,0 Qualification (6 samples)
1,1 Async (no Sync or Qualification)

15.11.2.20 GPBMUX1 Register (Offset = 8Ch) [Reset = 00000000h]

GPBMUX1 is shown in Figure 15-23 and described in Table 15-32.

Return to the Summary Table.

GPIO B Mux 1 Register (GPIO32 to 47)
Defines pin-muxing selection for GPIO.
Notes:
The respective GPyGMUXn.GPIOz must be configured prior to this register to avoid intermediate peripheral selects being mapped to the GPIO. Refer to GPIO chapter for more details.

Figure 15-23. GPBMUX1 Register

15.11.2.22 GPBPUD Register (Offset = 98h) [Reset = FFFFFFFFh]

GPBPUD is shown in Figure 15-25 and described in Table 15-34.

Return to the Summary Table.

GPIO B Pull Up Disable Register (GPIO32 to 63)
Disables the Pull-Up on GPIO.
0: Enables the Pull-Up.
1: Disables the Pull-Up.
Reading the register returns the current value of the register setting.
Note:
[1] The Pull-Ups on the GPIO pins are disabled asynchronously when IORSn signal is low.

15.11.2.23 GPBINV Register (Offset = A0h) [Reset = 00000000h]

GPBINV is shown in Figure 15-26 and described in Table 15-35.

Return to the Summary Table.

GPIO B Input Polarity Invert Registers (GPIO32 to 63)
Selects between non-inverted and inverted GPIO input to the device.
0: selects non-inverted GPIO input
1: selects inverted GPIO input
Reading the register returns the current value of the register setting.

15.11.2.24 GPBODR Register (Offset = A4h) [Reset = 00000000h]

GPBODR is shown in Figure 15-27 and described in Table 15-36.

Return to the Summary Table.

GPIO B Open Drain Output Register (GPIO32 to GPIO63)
Selects between normal and open-drain output for the GPIO pin.
0: Normal Output
1: Open Drain Output
Reading the register returns the current value of the register setting.
Note:
[1] In the Open Drain output mode, if the buffer is configured for output mode, a 0 value to be driven out comes out on the on the PAD while a 1 value to be driven out tri-states the buffer.

15.11.2.25 GPBGMUX1 Register (Offset = C0h) [Reset = 00000000h]

GPBGMUX1 is shown in Figure 15-28 and described in Table 15-37.

Return to the Summary Table.

GPIO B Peripheral Group Mux (GPIO32 to 47)
Defines pin-muxing selection for GPIO.
Notes:
[1]For complete pin-mux selection on GPIOx, GPAMUXy.GPIOx configuration is also required.

15.11.2.36 GPCMUX1 Register (Offset = 10Ch) [Reset = 00000000h]

GPCMUX1 is shown in Figure 15-39 and described in Table 15-48.

Return to the Summary Table.

GPIO C Mux 1 Register (GPIO64 to 79)
Defines pin-muxing selection for GPIO.
Notes:
The respective GPyGMUXn.GPIOz must be configured prior to this register to avoid intermediate peripheral selects being mapped to the GPIO. Refer to GPIO chapter for more details.

Figure 15-39. GPCMUX1 Register

15.11.2.38 GPCPUD Register (Offset = 118h) [Reset = FFFFFFFFh]

GPCPUD is shown in Figure 15-41 and described in Table 15-50.

Return to the Summary Table.

GPIO C Pull Up Disable Register (GPIO64 to 95)
Disables the Pull-Up on GPIO.
0: Enables the Pull-Up.
1: Disables the Pull-Up.
Reading the register returns the current value of the register setting.
Note:
[1] The Pull-Ups on the GPIO pins are disabled asynchronously when IORSn signal is low.

15.11.2.39 GPCINV Register (Offset = 120h) [Reset = 00000000h]

GPCINV is shown in Figure 15-42 and described in Table 15-51.

Return to the Summary Table.

GPIO C Input Polarity Invert Registers (GPIO64 to 95)
Selects between non-inverted and inverted GPIO input to the device.
0: selects non-inverted GPIO input
1: selects inverted GPIO input
Reading the register returns the current value of the register setting.

15.11.2.40 GPCODR Register (Offset = 124h) [Reset = 00000000h]

GPCODR is shown in Figure 15-43 and described in Table 15-52.

Return to the Summary Table.

GPIO C Open Drain Output Register (GPIO64 to GPIO95)
Selects between normal and open-drain output for the GPIO pin.
0: Normal Output
1: Open Drain Output
Reading the register returns the current value of the register setting.
Note:
[1] In the Open Drain output mode, if the buffer is configured for output mode, a 0 value to be driven out comes out on the on the PAD while a 1 value to be driven out tri-states the buffer.

15.11.2.47 GPCLOCK Register (Offset = 178h) [Reset = 00000000h]

GPCLOCK is shown in Figure 15-50 and described in Table 15-59.

Return to the Summary Table.

GPIO C Lock Configuration Register (GPIO64 to 95)
GPIO Configuration Lock for GPIO.
0: Bits in GPyMUX1, GPyMUX2, GPyINV, GPyODR, GPyAMSEL, GPyGMUX1, GPyGMUX2 and GPyCSELx register which control the same pin can be changed
1: Locks changes to the bits in GPyMUX1, GPyMUX2, GPyINV, GPyODR, GPyAMSEL, GPyGMUX1, GPyGMUX2 and GPyCSELx registers which control the same pin

15.11.2.54 GPDPUD Register (Offset = 198h) [Reset = FFFFFFFFh]

GPDPUD is shown in Figure 15-57 and described in Table 15-66.

Return to the Summary Table.

GPIO D Pull Up Disable Register (GPIO96 to 127)
Disables the Pull-Up on GPIO.
0: Enables the Pull-Up.
1: Disables the Pull-Up.
Reading the register returns the current value of the register setting.
Note:
[1] The Pull-Ups on the GPIO pins are disabled asynchronously when IORSn signal is low.

15.11.2.55 GPDINV Register (Offset = 1A0h) [Reset = 00000000h]

GPDINV is shown in Figure 15-58 and described in Table 15-67.

Return to the Summary Table.

GPIO D Input Polarity Invert Registers (GPIO96 to 127)
Selects between non-inverted and inverted GPIO input to the device.
0: selects non-inverted GPIO input
1: selects inverted GPIO input
Reading the register returns the current value of the register setting.

15.11.2.56 GPDODR Register (Offset = 1A4h) [Reset = 00000000h]

GPDODR is shown in Figure 15-59 and described in Table 15-68.

Return to the Summary Table.

GPIO D Open Drain Output Register (GPIO96 to GPIO127)
Selects between normal and open-drain output for the GPIO pin.
0: Normal Output
1: Open Drain Output
Reading the register returns the current value of the register setting.
Note:
[1] In the Open Drain output mode, if the buffer is configured for output mode, a 0 value to be driven out comes out on the on the PAD while a 1 value to be driven out tri-states the buffer.

15.11.2.63 GPDLOCK Register (Offset = 1F8h) [Reset = 00000000h]

GPDLOCK is shown in Figure 15-66 and described in Table 15-75.

Return to the Summary Table.

GPIO D Lock Configuration Register (GPIO96 to 127)
GPIO Configuration Lock for GPIO.
0: Bits in GPyMUX1, GPyMUX2, GPyINV, GPyODR, GPyAMSEL, GPyGMUX1, GPyGMUX2 and GPyCSELx register which control the same pin can be changed
1: Locks changes to the bits in GPyMUX1, GPyMUX2, GPyINV, GPyODR, GPyAMSEL, GPyGMUX1, GPyGMUX2 and GPyCSELx registers which control the same pin

15.11.2.68 GPFMUX1 Register (Offset = 28Ch) [Reset = 00000000h]

GPFMUX1 is shown in Figure 15-71 and described in Table 15-80.

Return to the Summary Table.

GPIO F Mux 1 Register (GPIO160 to 175)
Defines pin-muxing selection for GPIO.
Notes:
The respective GPyGMUXn.GPIOz must be configured prior to this register to avoid intermediate peripheral selects being mapped to the GPIO. Refer to GPIO chapter for more details.

15.11.2.69 GPFMUX2 Register (Offset = 290h) [Reset = 00000000h]

GPFMUX2 is shown in Figure 15-72 and described in Table 15-81.

Return to the Summary Table.

GPIO F Mux 2 Register (GPIO176 to 191)
Defines pin-muxing selection for GPIO.
Notes:
The respective GPyGMUXn.GPIOz must be configured prior to this register to avoid intermediate peripheral selects being mapped to the GPIO. Refer to GPIO chapter for more details.

15.11.2.70 GPFPUD Register (Offset = 298h) [Reset = FFFFFFFFh]

GPFPUD is shown in Figure 15-73 and described in Table 15-82.

Return to the Summary Table.

GPIO F Pull Up Disable Register (GPIO160 to 191)
Disables the Pull-Up on GPIO.
0: Enables the Pull-Up.
1: Disables the Pull-Up.
Reading the register returns the current value of the register setting.
Note:
[1] The Pull-Ups on the GPIO pins are disabled asynchronously when IORSn signal is low.

15.11.2.71 GPFINV Register (Offset = 2A0h) [Reset = 00000000h]

GPFINV is shown in Figure 15-74 and described in Table 15-83.

Return to the Summary Table.

GPIO F Input Polarity Invert Registers (GPIO160 to 191)
Selects between non-inverted and inverted GPIO input to the device.
0: selects non-inverted GPIO input
1: selects inverted GPIO input
Reading the register returns the current value of the register setting.

15.11.2.72 GPFAMSEL Register (Offset = 2A8h) [Reset = FFFFFFFFh]

GPFAMSEL is shown in Figure 15-75 and described in Table 15-84.

Return to the Summary Table.

GPIO F Analog Mode Select register (GPIO160 to GPIO 191)
Selects between digital and analog functionality for GPIO pins.
0: The analog function of the pin is disabled and the pin is capable of digital functions as specified by the other GPIO configuration registers
1: The analog function of the pin is enabled and the pin is capable of analog functions
Reading the register returns the current value of the register setting.
Note:
[1] This register and bits are only valid for GPIO signals that share analog function through a unified I/O pad. For all the IOs, t

15.11.2.79 GPFLOCK Register (Offset = 2F8h) [Reset = 00000000h]

GPFLOCK is shown in Figure 15-82 and described in Table 15-91.

Return to the Summary Table.

GPIO F Lock Configuration Register (GPIO160 to 191)
GPIO Configuration Lock for GPIO.
0: Bits in GPyMUX1, GPyMUX2, GPyINV, GPyODR, GPyAMSEL, GPyGMUX1, GPyGMUX2 and GPyCSELx register which control the same pin can be changed
1: Locks changes to the bits in GPyMUX1, GPyMUX2, GPyINV, GPyODR, GPyAMSEL, GPyGMUX1, GPyGMUX2 and GPyCSELx registers which control the same pin

15.11.2.84 GPGMUX1 Register (Offset = 30Ch) [Reset = 00000000h]

GPGMUX1 is shown in Figure 15-87 and described in Table 15-96.

Return to the Summary Table.

GPIO G Mux 1 Register (GPIO192 to 207)
Defines pin-muxing selection for GPIO.
Notes:
The respective GPyGMUXn.GPIOz must be configured prior to this register to avoid intermediate peripheral selects being mapped to the GPIO. Refer to GPIO chapter for more details.

15.11.2.86 GPGPUD Register (Offset = 318h) [Reset = FFFFFFFFh]

GPGPUD is shown in Figure 15-89 and described in Table 15-98.

Return to the Summary Table.

GPIO G Pull Up Disable Register (GPIO192 to 223)
Disables the Pull-Up on GPIO.
0: Enables the Pull-Up.
1: Disables the Pull-Up.
Reading the register returns the current value of the register setting.
Note:
[1] The Pull-Ups on the GPIO pins are disabled asynchronously when IORSn signal is low.

15.11.2.87 GPGINV Register (Offset = 320h) [Reset = 00000000h]

GPGINV is shown in Figure 15-90 and described in Table 15-99.

Return to the Summary Table.

GPIO G Input Polarity Invert Registers (GPIO192 to 223)
Selects between non-inverted and inverted GPIO input to the device.
0: selects non-inverted GPIO input
1: selects inverted GPIO input
Reading the register returns the current value of the register setting.

15.11.2.88 GPGODR Register (Offset = 324h) [Reset = 00000000h]

GPGODR is shown in Figure 15-91 and described in Table 15-100.

Return to the Summary Table.

GPIO G Open Drain Output Register (GPIO92 to 223)
Selects between normal and open-drain output for the GPIO pin.
0: Normal Output
1: Open Drain Output
Reading the register returns the current value of the register setting.
Note:
[1] In the Open Drain output mode, if the buffer is configured for output mode, a 0 value to be driven out comes out on the on the PAD while a 1 value to be driven out tri-states the buffer.

15.11.2.89 GPGAMSEL Register (Offset = 328h) [Reset = 003FFFFFh]

GPGAMSEL is shown in Figure 15-92 and described in Table 15-101.

Return to the Summary Table.

GPIO G Analog Mode Select register (GPIO192 to 223)
Selects between digital and analog functionality for GPIO pins.
0: The analog function of the pin is disabled and the pin is capable of digital functions as specified by the other GPIO configuration registers
1: The analog function of the pin is enabled and the pin is capable of analog functions
Reading the register returns the current value of the register setting.
Note:
[1] This register and bits are only valid for GPIO signals that share analog function through a unified I/O pad. For all the IOs, t

15.11.2.97 GPGCR Register (Offset = 37Ch) [Reset = 00000000h]

GPGCR is shown in Figure 15-100 and described in Table 15-109.

Return to the Summary Table.

GPIO G Lock Commit Register (GPIO192 to 223)
GPIO Configuration Lock Commit for GPIO:
1: Locks changes to the bit in GPyLOCK register which controls the same pin
0: Bit in the GPyLOCK register which controls the same pin can be changed

15.11.2.101 GPHMUX1 Register (Offset = 38Ch) [Reset = 00000000h]

GPHMUX1 is shown in Figure 15-104 and described in Table 15-113.

Return to the Summary Table.

GPIO H Mux 1 Register (GPIO224 to 239)
Defines pin-muxing selection for GPIO.
Notes:
The respective GPyGMUXn.GPIOz must be configured prior to this register to avoid intermediate peripheral selects being mapped to the GPIO. Refer to GPIO chapter for more details.

15.11.2.103 GPHPUD Register (Offset = 398h) [Reset = FFFFFFFFh]

GPHPUD is shown in Figure 15-106 and described in Table 15-115.

Return to the Summary Table.

GPIO H Pull Up Disable Register (GPIO224 to 255)
Disables the Pull-Up on GPIO.
0: Enables the Pull-Up.
1: Disables the Pull-Up.
Reading the register returns the current value of the register setting.
Note:
[1] The Pull-Ups on the GPIO pins are disabled asynchronously when IORSn signal is low.

15.11.2.105 GPHODR Register (Offset = 3A4h) [Reset = 00000000h]

GPHODR is shown in Figure 15-108 and described in Table 15-117.

Return to the Summary Table.

GPIO H Open Drain Output Register (GPIO224 to GPIO255)
Selects between normal and open-drain output for the GPIO pin.
0: Normal Output
1: Open Drain Output
Reading the register returns the current value of the register setting.
Note:
[1] In the Open Drain output mode, if the buffer is configured for output mode, a 0 value to be driven out comes out on the on the PAD while a 1 value to be driven out tri-states the buffer.

15.11.2.106 GPHAMSEL Register (Offset = 3A8h) [Reset = 03FFFFFFh]

GPHAMSEL is shown in Figure 15-109 and described in Table 15-118.

Return to the Summary Table.

GPIO H Analog Mode Select register (GPIO224 to GPIO255)
Selects between digital and analog functionality for GPIO pins.
0: The analog function of the pin is disabled and the pin is capable of digital functions as specified by the other GPIO configuration registers
1: The analog function of the pin is enabled and the pin is capable of analog functions
Reading the register returns the current value of the register setting.
Note:
[1] This register and bits are only valid for GPIO signals that share analog function through a unified I/O pad. For all the IOs, t

15.11.3 GPIO_DATA_REGS Registers

Table 15-127 lists the memory-mapped registers for the GPIO_DATA_REGS registers. All register offset addresses not listed in Table 15-127 should be considered as reserved locations and the register contents should not be modified.

Table 15-127. GPIO_DATA_REGS Registers

Offset	Acronym	Register Name	Protection
0h	GPADAT	GPIO A Data Register (GPIO0 to 31)	
4h	GPASET	GPIO A Data Set Register (GPIO0 to 31)	
8h	GPACLEAR	GPIO A Data Clear Register (GPIO0 to 31)	
Ch	GPATOGGLE	GPIO A Data Toggle Register (GPIO0 to 31)	
10h	GPADIR	GPIO A Direction Register (GPIO0 to 31)	
14h	GPBDAT	GPIO B Data Register (GPIO32 to 63)	
18h	GPBSET	GPIO B Data Set Register (GPIO32 to 63)	
1Ch	GPBCLEAR	GPIO B Data Clear Register (GPIO32 to 63)	
20h	GPBTOGGLE	GPIO B Data Toggle Register (GPIO32 to 63)	
24h	GPBDIR	GPIO B Direction Register (GPIO0 to 31)	
28h	GPCDAT	GPIO C Data Register (GPIO64 to 95)	
2Ch	GPCSET	GPIO C Data Set Register (GPIO64 to 95)	
30h	GPCCLEAR	GPIO C Data Clear Register (GPIO64 to 95)	
34h	GPCTOGGLE	GPIO C Data Toggle Register (GPIO64 to 95)	
38h	GPCDIR	GPIO C Direction Register (GPIO0 to 31)	
3Ch	GPDDAT	GPIO D Data Register (GPIO96 to 127)	
40h	GPDSET	GPIO D Data Set Register (GPIO96 to 127)	
44h	GPDCLEAR	GPIO D Data Clear Register (GPIO96 to 127)	
48h	GPDTOGGLE	GPIO D Data Toggle Register (GPIO96 to 127)	
4Ch	GPDDIR	GPIO D Direction Register (GPIO0 to 31)	
64h	GPFDAT	GPIO F Data Register (GPIO160 to 191)	
78h	GPGDAT	GPIO G Data Register (GPIO192 to 223)	
7Ch	GPGSET	GPIO G Data Set Register (GPIO192 to 223)	
80h	GPGCLEAR	GPIO G Data Clear Register (GPIO192 to 223)	
84h	GPGTOGGLE	GPIO G Data Toggle Register (GPIO192 to 223)	
88h	GPGDIR	GPIO G Direction Register (GPIO0 to 31)	
8Ch	GPHDAT	GPIO H Data Register (GPIO224 to 255)	
90h	GPHSET	GPIO H Data Set Register (GPIO224 to 255)	
94h	GPHCLEAR	GPIO H Data Clear Register (GPIO224 to 255)	
98h	GPHTOGGLE	GPIO H Data Toggle Register (GPIO224 to 255)	
9Ch	GPHDIR	GPIO H Direction Register (GPIO0 to 31)	

Complex bit access types are encoded to fit into small table cells. Table 15-128 shows the codes that are used for access types in this section.

Table 15-128. GPIO_DATA_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		

Table 15-128. GPIO_DATA_REGS Access Type Codes (continued)

Access Type	Code	Description
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

15.11.3.1 GPADAT Register (Offset = 0h) [Reset = 00000000h]

GPADAT is shown in Figure 15-118 and described in Table 15-129.

Return to the Summary Table.

GPIO A Data Register (GPIO0 to 31)
Reading this register indicates the current status of the GPIO pin, irrespective of which mode the pin is in. Writing to this register will set the GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero.
DESIGNER NOTE:
[1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the GPIODAT register.

15.11.3.2 GPASET Register (Offset = 4h) [Reset = 00000000h]

GPASET is shown in Figure 15-119 and described in Table 15-130.

Return to the Summary Table.

GPIO A Data Set Register (GPIO0 to 31)
Writing a 1 will force GPIO output data latch to 1.
Writes of 0 are ignored.
Always reads back a 0.

15.11.3.3 GPACLEAR Register (Offset = 8h) [Reset = 00000000h]

GPACLEAR is shown in Figure 15-120 and described in Table 15-131.

Return to the Summary Table.

GPIO A Data Clear Register (GPIO0 to 31)
Writing a 1 will force GPIO0 output data latch to 0.
Writes of 0 are ignored.
Always reads back a 0.

15.11.3.5 GPADIR Register (Offset = 10h) [Reset = 00000000h]

GPADIR is shown in Figure 15-122 and described in Table 15-133.

Return to the Summary Table.

GPIO A Direction Register (GPIO0 to 31)
Controls direction of GPIO pins when the specified pin is configured in GPIO mode.
0: Configures pin as input.
1: Configures pin as output.
Reading the register returns the current value of the register setting.

Figure 15-122. GPADIR Register

0	GPIO0	R/W	0h	Defines direction for this pin in GPIO mode Reset type: CPUx.SYSRSn

15.11.3.6 GPBDAT Register (Offset = 14h) [Reset = 00000000h]

GPBDAT is shown in Figure 15-123 and described in Table 15-134.

Return to the Summary Table.

GPIO B Data Register (GPIO32 to 63)
Reading this register indicates the current status of the GPIO pin, irrespective of which mode the pin is in. Writing to this register will set the GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero.
DESIGNER NOTE:
[1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the GPIODAT register.

15.11.3.7 GPBSET Register (Offset = 18h) [Reset = 00000000h]

GPBSET is shown in Figure 15-124 and described in Table 15-135.

Return to the Summary Table.

GPIO B Data Set Register (GPIO32 to 63)
Writing a 1 will force GPIO output data latch to 1.
Writes of 0 are ignored.
Always reads back a 0.

15.11.3.10 GPBDIR Register (Offset = 24h) [Reset = 00000000h]

GPBDIR is shown in Figure 15-127 and described in Table 15-138.

Return to the Summary Table.

GPIO A Direction Register (GPIO0 to 31)
Controls direction of GPIO pins when the specified pin is configured in GPIO mode.
0: Configures pin as input.
1: Configures pin as output.
Reading the register returns the current value of the register setting.

Figure 15-127. GPBDIR Register

15.11.3.11 GPCDAT Register (Offset = 28h) [Reset = 00000000h]

GPCDAT is shown in Figure 15-128 and described in Table 15-139.

Return to the Summary Table.

GPIO C Data Register (GPIO64 to 95)
Reading this register indicates the current status of the GPIO pin, irrespective of which mode the pin is in. Writing to this register will set the GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero.
DESIGNER NOTE:
[1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the

15.11.3.12 GPCSET Register (Offset = 2Ch) [Reset = 00000000h]

GPCSET is shown in Figure 15-129 and described in Table 15-140.

Return to the Summary Table.

GPIO C Data Set Register (GPIO64 to 95)
Writing a 1 will force GPIO output data latch to 1.
Writes of 0 are ignored.
Always reads back a 0.

15.11.3.14 GPCTOGGLE Register (Offset = 34h) [Reset = 00000000h]

GPCTOGGLE is shown in Figure 15-131 and described in Table 15-142.

Return to the Summary Table.

GPIO C Data Toggle Register (GPIO64 to 95)
Writing a 1 will toggle GPIO0 output data latch 1 to 0 or 0 to 1.
Writes of 0 are ignored.
Always reads back a 0.

15.11.3.15 GPCDIR Register (Offset = 38h) [Reset = 00000000h]

GPCDIR is shown in Figure 15-132 and described in Table 15-143.

Return to the Summary Table.

GPIO A Direction Register (GPIO0 to 31)
Controls direction of GPIO pins when the specified pin is configured in GPIO mode.
0: Configures pin as input.
1: Configures pin as output.
Reading the register returns the current value of the register setting.

15.11.3.16 GPDDAT Register (Offset = 3Ch) [Reset = 00000000h]

GPDDAT is shown in Figure 15-133 and described in Table 15-144.

Return to the Summary Table.

GPIO D Data Register (GPIO96 to 127)
Reading this register indicates the current status of the GPIO pin, irrespective of which mode the pin is in. Writing to this register will set the GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero.
DESIGNER NOTE:
[1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the GPIODAT register.

15.11.3.20 GPDDIR Register (Offset = 4Ch) [Reset = 00000000h]

GPDDIR is shown in Figure 15-137 and described in Table 15-148.

Return to the Summary Table.

GPIO A Direction Register (GPIO0 to 31)
Controls direction of GPIO pins when the specified pin is configured in GPIO mode.
0: Configures pin as input.
1: Configures pin as output.
Reading the register returns the current value of the register setting.

15.11.3.21 GPFDAT Register (Offset = 64h) [Reset = 00000000h]

GPFDAT is shown in Figure 15-138 and described in Table 15-149.

Return to the Summary Table.

GPIO F Data Register (GPIO160 to 191)
Reading this register indicates the current status of the GPIO pin, irrespective of which mode the pin is in. Writing to this register will set the GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero.
DESIGNER NOTE:
[1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the

15.11.3.22 GPGDAT Register (Offset = 78h) [Reset = 00000000h]

GPGDAT is shown in Figure 15-139 and described in Table 15-150.

Return to the Summary Table.

GPIO G Data Register (GPIO192 to 223)
Reading this register indicates the current status of the GPIO pin, irrespective of which mode the pin is in. Writing to this register will set the GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero.
DESIGNER NOTE:
[1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the

GPGDIR is shown in Figure 15-143 and described in Table 15-154.

Return to the Summary Table.

GPIO A Direction Register (GPIO0 to 31)
Controls direction of GPIO pins when the specified pin is configured in GPIO mode.
0: Configures pin as input.
1: Configures pin as output.
Reading the register returns the current value of the register setting.

15.11.3.27 GPHDAT Register (Offset = 8Ch) [Reset = 00000000h]

GPHDAT is shown in Figure 15-144 and described in Table 15-155.

Return to the Summary Table.

GPIO H Data Register (GPIO224 to 255)
Reading this register indicates the current status of the GPIO pin, irrespective of which mode the pin is in. Writing to this register will set the GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero.
DESIGNER NOTE:
[1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the

25	GPIO249	R/W	0h	Reading this register indicates the current status of this GPIO pin, irrespective of which mode the pin is in. Writing to this register will set this GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero. DESIGNER NOTE: [1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the GPIODAT register. Reset type: SYSRSn

Table 15-155. GPHDAT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
24	GPIO248	R/W	0h	Reading this register indicates the current status of this GPIO pin, irrespective of which mode the pin is in. Writing to this register will set this GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero. DESIGNER NOTE: [1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the GPIODAT register. Reset type: SYSRSn
23	GPIO247	R/W	0h	Reading this register indicates the current status of this GPIO pin, irrespective of which mode the pin is in. Writing to this register will set this GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero. DESIGNER NOTE: [1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the GPIODAT register. Reset type: SYSRSn
22	GPIO246	R/W	0h	Reading this register indicates the current status of this GPIO pin, irrespective of which mode the pin is in. Writing to this register will set this GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero. DESIGNER NOTE: [1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the GPIODAT register. Reset type: SYSRSn
21	GPIO245	R/W	0h	Reading this register indicates the current status of this GPIO pin, irrespective of which mode the pin is in. Writing to this register will set this GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero. DESIGNER NOTE: [1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the GPIODAT register. Reset type: SYSRSn
20	GPIO244	R/W	0h	Reading this register indicates the current status of this GPIO pin, irrespective of which mode the pin is in. Writing to this register will set this GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero. DESIGNER NOTE: [1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the GPIODAT register. Reset type: SYSRSn

Table 15-155. GPHDAT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19	GPIO243	R/W	0h	Reading this register indicates the current status of this GPIO pin, irrespective of which mode the pin is in. Writing to this register will set this GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero. DESIGNER NOTE: [1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the GPIODAT register. Reset type: SYSRSn
18	GPIO242	R/W	0h	Reading this register indicates the current status of this GPIO pin, irrespective of which mode the pin is in. Writing to this register will set this GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero. DESIGNER NOTE: [1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the GPIODAT register. Reset type: SYSRSn
17	GPIO241	R/W	0h	Reading this register indicates the current status of this GPIO pin, irrespective of which mode the pin is in. Writing to this register will set this GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero. DESIGNER NOTE: [1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the GPIODAT register. Reset type: SYSRSn
16	GPIO240	R/W	0h	Reading this register indicates the current status of this GPIO pin, irrespective of which mode the pin is in. Writing to this register will set this GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero. DESIGNER NOTE: [1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the GPIODAT register. Reset type: SYSRSn
15	GPIO239	R/W	0h	Reading this register indicates the current status of this GPIO pin, irrespective of which mode the pin is in. Writing to this register will set this GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero. DESIGNER NOTE: [1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the GPIODAT register. Reset type: SYSRSn

Table 15-155. GPHDAT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
14	GPIO238	R/W	0h	Reading this register indicates the current status of this GPIO pin, irrespective of which mode the pin is in. Writing to this register will set this GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero. DESIGNER NOTE: [1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the GPIODAT register. Reset type: SYSRSn
13	GPIO237	R/W	0h	Reading this register indicates the current status of this GPIO pin, irrespective of which mode the pin is in. Writing to this register will set this GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero. DESIGNER NOTE: [1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the GPIODAT register. Reset type: SYSRSn
12	GPIO236	R/W	0h	Reading this register indicates the current status of this GPIO pin, irrespective of which mode the pin is in. Writing to this register will set this GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero. DESIGNER NOTE: [1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the GPIODAT register. Reset type: SYSRSn
11	GPIO235	R/W	0h	Reading this register indicates the current status of this GPIO pin, irrespective of which mode the pin is in. Writing to this register will set this GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero. DESIGNER NOTE: [1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the GPIODAT register. Reset type: SYSRSn
10	GPIO234	R/W	0h	Reading this register indicates the current status of this GPIO pin, irrespective of which mode the pin is in. Writing to this register will set this GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero. DESIGNER NOTE: [1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the GPIODAT register. Reset type: SYSRSn

Table 15-155. GPHDAT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
9	GPIO233	R/W	0h	Reading this register indicates the current status of this GPIO pin, irrespective of which mode the pin is in. Writing to this register will set this GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero. DESIGNER NOTE: [1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the GPIODAT register. Reset type: SYSRSn
8	GPIO232	R/W	0h	Reading this register indicates the current status of this GPIO pin, irrespective of which mode the pin is in. Writing to this register will set this GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero. DESIGNER NOTE: [1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the GPIODAT register. Reset type: SYSRSn
7	GPIO231	R/W	0h	Reading this register indicates the current status of this GPIO pin, irrespective of which mode the pin is in. Writing to this register will set this GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero. DESIGNER NOTE: [1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the GPIODAT register. Reset type: SYSRSn
6	GPIO230	R/W	0h	Reading this register indicates the current status of this GPIO pin, irrespective of which mode the pin is in. Writing to this register will set this GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero. DESIGNER NOTE: [1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the GPIODAT register. Reset type: SYSRSn
5	GPIO229	R/W	0h	Reading this register indicates the current status of this GPIO pin, irrespective of which mode the pin is in. Writing to this register will set this GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero. DESIGNER NOTE: [1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the GPIODAT register. Reset type: SYSRSn

Table 15-155. GPHDAT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4	GPIO228	R/W	0h	Reading this register indicates the current status of this GPIO pin, irrespective of which mode the pin is in. Writing to this register will set this GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero. DESIGNER NOTE: [1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the GPIODAT register. Reset type: SYSRSn
3	GPIO227	R/W	0h	Reading this register indicates the current status of this GPIO pin, irrespective of which mode the pin is in. Writing to this register will set this GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero. DESIGNER NOTE: [1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the GPIODAT register. Reset type: SYSRSn
2	GPIO226	R/W	0h	Reading this register indicates the current status of this GPIO pin, irrespective of which mode the pin is in. Writing to this register will set this GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero. DESIGNER NOTE: [1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the GPIODAT register. Reset type: SYSRSn
1	GPIO225	R/W	0h	Reading this register indicates the current status of this GPIO pin, irrespective of which mode the pin is in. Writing to this register will set this GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero. DESIGNER NOTE: [1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the GPIODAT register. Reset type: SYSRSn
0	GPIO224	R/W	0h	Reading this register indicates the current status of this GPIO pin, irrespective of which mode the pin is in. Writing to this register will set this GPIO pin high or low if the pin is enabled for GPIO output mode, otherwise the value written is latched but ignored. The state of the output register latch will remain in its current state until the next write operation. A system reset will clear all bits and latched values to zero. DESIGNER NOTE: [1] Reading the GPIODAT register should reflect the state of the PIN (after qualification), not the state of the output latch of the GPIODAT register. Reset type: SYSRSn

15.11.3.28 GPHSET Register (Offset = 90h) [Reset = 00000000h]

GPHSET is shown in Figure 15-145 and described in Table 15-156.

Return to the Summary Table.

GPIO H Data Set Register (GPIO224 to 255)
Writing a 1 will force GPIO output data latch to 1.
Writes of 0 are ignored.
Always reads back a 0.

15.11.3.30 GPHTOGGLE Register (Offset = 98h) [Reset = 00000000h]

GPHTOGGLE is shown in Figure 15-147 and described in Table 15-158.

Return to the Summary Table.

GPIO H Data Toggle Register (GPIO224 to 255)
Writing a 1 will toggle GPIO0 output data latch 1 to 0 or 0 to 1.
Writes of 0 are ignored.
Always reads back a 0.

15.11.3.31 GPHDIR Register (Offset = 9Ch) [Reset = 00000000h]

GPHDIR is shown in Figure 15-148 and described in Table 15-159.

Return to the Summary Table.

GPIO A Direction Register (GPIO0 to 31)
Controls direction of GPIO pins when the specified pin is configured in GPIO mode.
0: Configures pin as input.
1: Configures pin as output.
Reading the register returns the current value of the register setting.

15.11.4 GPIO_DATA_READ_REGS Registers

Table 15-160 lists the memory-mapped registers for the GPIO_DATA_READ_REGS registers. All register offset addresses not listed in Table 15-160 should be considered as reserved locations and the register contents should not be modified.

Table 15-160. GPIO_DATA_READ_REGS Registers

Offset	Acronym	Register Name	Protection
0h	GPADAT_R	GPIO A Data Read Register	
4h	GPBDAT_R	GPIO B Data Read Register	
8h	GPCDAT_R	GPIO C Data Read Register	
Ch	GPDDAT_R	GPIO D Data Read Register	
14h	GPFDAT_R	GPIO F Data Read Register	
18h	GPGDAT_R	GPIO G Data Read Register	
1Ch	GPHDAT_R	GPIO H Data Read Register	

Complex bit access types are encoded to fit into small table cells. Table 15-161 shows the codes that are used for access types in this section.

Table 15-161. GPIO_DATA_READ_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

15.11.4.1 GPADAT_R Register (Offset = 0h) [Reset = 00000000h]

GPADAT_R is shown in Figure 15-149 and described in Table 15-162.

Return to the Summary Table.

GPIO A Data Read Register.
Returns the contents of GPADAT register on a read, write to this register has no effect

Figure 15-149. GPADAT_R Register

Chapter 16

Interprocessor Communication (IPC)

The Interprocessor Communications (IPC) module allows communication between the two CPU subsystems.

16.1 Introduction

This section details the IPC features that each CPU can use to request and share information. The IPC features are:

- IPC flags and interrupts
- IPC command registers
- Free-running counter

All IPC features are independent of each other, and most do not require any specific data format.

IPC Module Architecture shows the design structure of the IPC module. The functionality is the same between any two CPUs.

There is no message RAM for devices with C29x processors, since it is possible to designate any memory as readable or writable by the various CPUs.

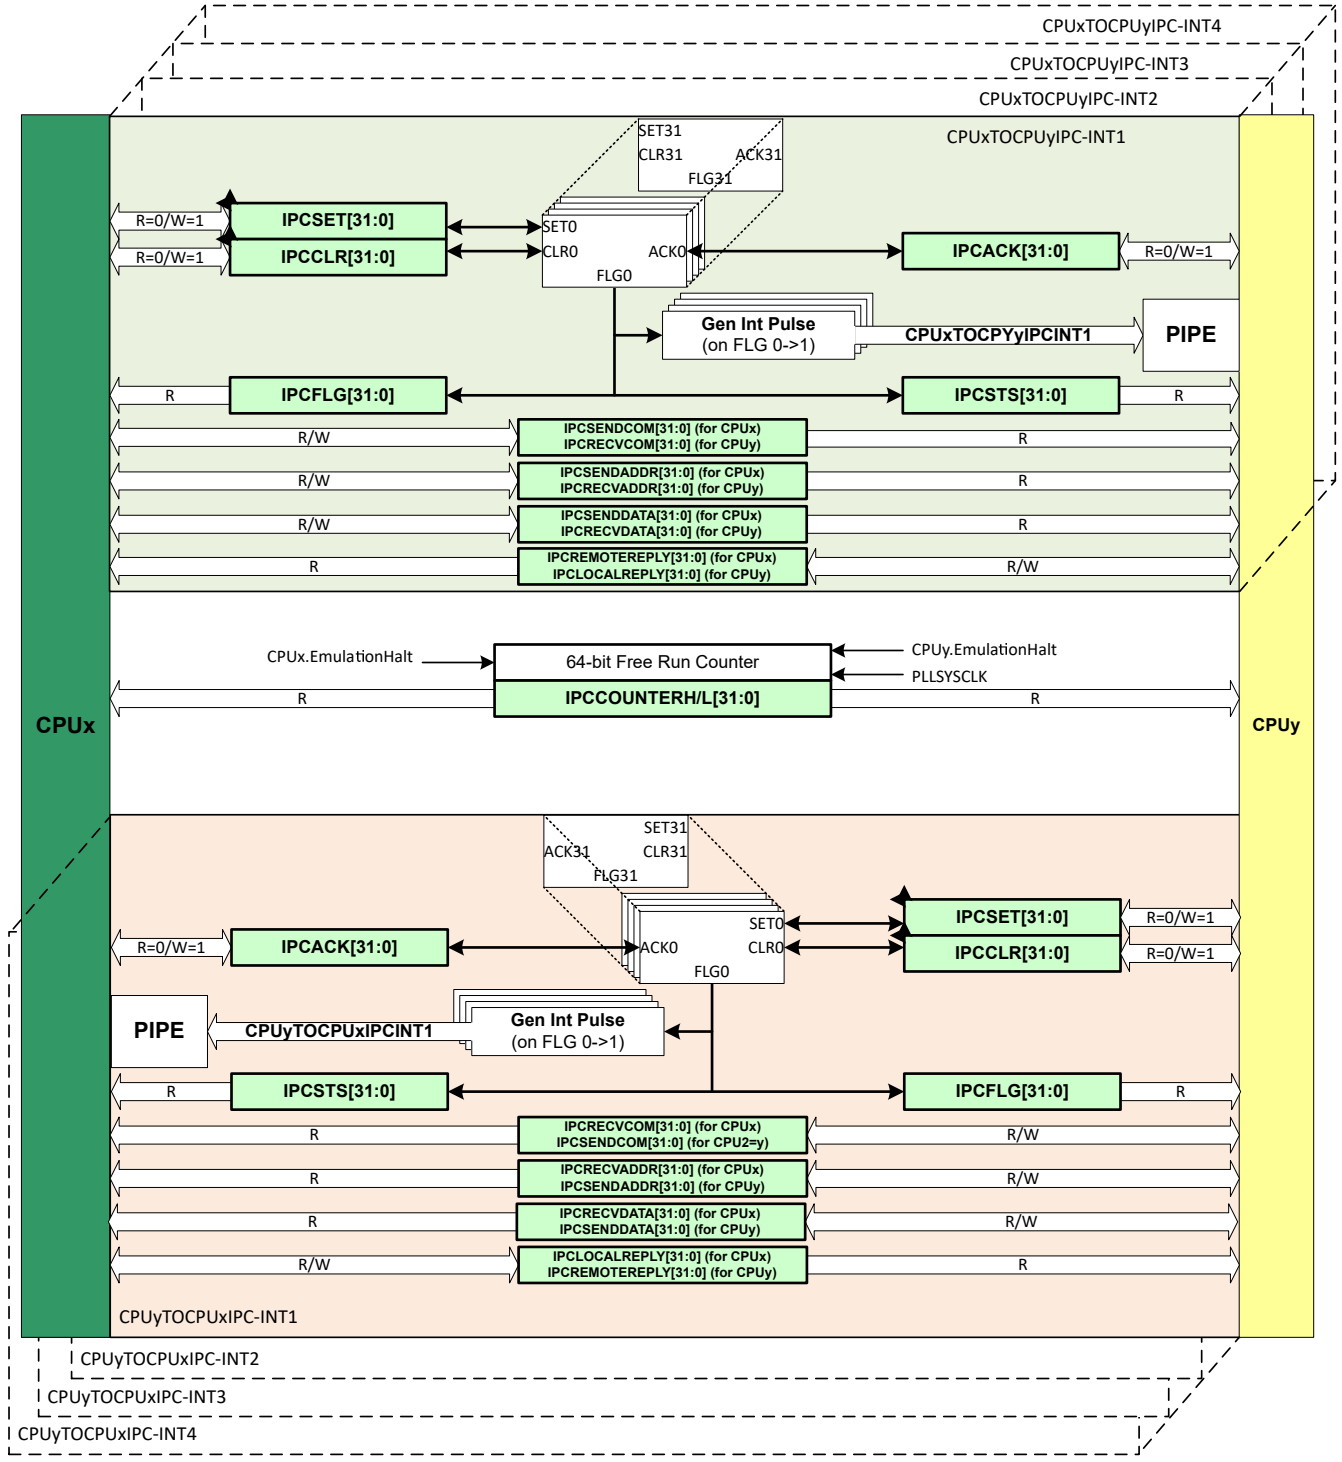

Figure 16-1. IPC Module Architecture

16.2 IPC Flags and Interrupts

There are 32 IPC event signals in each direction between the CPU pairs. These signals can be used for flag-based event polling. Between any two C29x cores, each of the four blocks of IPC registers has one IPC interrupt to go in each direction. This IPC interrupt can only be triggered by IPC flag 0.

16.3 IPC Command Registers

The IPC command registers provide a simple and flexible way for the CPUs to exchange more complex messages. Each CPU has eight dedicated registers; four for sending messages and four for receiving messages. The register names were chosen to support a simple command/response protocol, but can be used for any purpose. Only the read/write permissions are determined by hardware; the data format is entirely software-defined.

For sending messages, each CPU has three writable registers and one read-only register. Those same registers are accessible on the remote CPU as three read-only registers and one writable register. Table 16-1 shows the command registers.

Table 16-1. IPC Command Registers

Local Register Name	Local CPU	Remote CPU	Remote Register Name
IPCSENDCOM	R/W	R	IPCRECVCOM
IPCSENDADDR	R/W	R	IPCRECVADDR
IPCSENDDATA	R/W	R	IPCRECVDATA
IPCREMOTEREPLY	R	R/W	IPCLOCALREPLY

16.4 Free-Running Counter

A 64-bit free-running counter is present in the device and can be used to timestamp IPC events between processors. The counter is clocked by PLLSYSCLK and reset by XRSn. The counter is implemented as two 32-bit registers, IPCCOUNTERH and IPCCOUNTERL. When IPCCOUNTERL is read, the value of IPCCOUNTERH is saved. A subsequent read to IPCCOUNTERH returns this saved value. Therefore, the user must always read IPCCOUNTERL first then read IPCCOUNTERH next. This design prevents race conditions due to IPCCOUNTERL overflowing between reads of the two registers.

The free-running counter stops only when emulation is suspended (when debugger hits a breakpoint) on all CPUs. If any core is executing, the counter runs.

16.5 IPC Communication Protocol

This section describes the hardware support options for IPC communication between the two CPUs. These options can be used independently or in combination. All flag definitions and data formats are entirely user-defined.

- The flag system supports event-based communication via interrupts and register polling.
  - CPUx can raise an IPC event by writing to any of the 32 bits of the IPCSET register. This sets the corresponding bits in the CPUx IPCFLG register and CPUy IPCSTS register.
  - CPUy can signal the response to the event by setting the appropriate bit in the IPCACK register. This clears the corresponding bits in the CPUx IPCFLG register and the CPUy IPCSTS register.
  - If CPUx needs to cancel an event, CPUx can set the appropriate bit in the IPCCLR register. This has the same effect as CPUy writing to IPCACK.
  - Flag 0 (set using IPCSET[0]) fires an interrupt to the remote CPU. The remote CPU must configure the PIPE module properly to receive an IPC interrupt. Flags 1–31 (set using IPCSET[31:1]) do not produce interrupts. Multiple flags can be set, acknowledged, and cleared simultaneously.
- The command registers support sending several distinct pieces of information and are named COM, ADDR, DATA, and REPLY for convenience only and can hold whatever data the application needs.
  - CPUx can write data to the IPCSENDCOM, IPCSENDADDR, and IPCSENDDATA registers. CPUy receives these in the IPCRECVCOM, IPCRECVADDR, and IPCRECVDATA registers.
  - CPUy can respond by writing to the IPCLOCALREPLY register. CPUx receives this data in the IPCREMOTEREPLY register.

16.6.2 IPC Examples

NOTE: These examples are located in the C29SDK installation from ti.com at the following location: mcu_sdk_DEVICE_GPN/examples/driverlib/CORE_IF_MULTICORE/ipc

Cloud access to these examples is available at the following link: dev.ti.com C29SDK Examples.

16.6.2.1 IPC basic message passing example with interrupt - MULTI_CORE

FILE: ipc_ex1_basic_cpu1_cpu2_multi_c29x1.c

This example demonstrates how to configure IPC and pass information from C29x1 to C29x2 core without message queues.

When using CCS for debugging this Multi-core example, after launching the debug session,
- Connect to CPU1 and load only the c29x1.out.
- After the program is loaded, run CPU1.
- Once c29x1 disables lock-step and releases CPU2 out of reset, the program stops.
- Connect to CPU2 target now. c29x2.out would have started execution as soon as it is released from reset.
- In case of RAM configuration, restart the CPU2 target and load the symbols.

In FLASH configuration, the CPU2 application code is loaded to CPU1 FLASH. At runtime, CPU1 copies it to RAM for CPU2 to execute. *External Connections*
- None.

Watch Variables
- pass

16.6.2.2 IPC basic message passing example with interrupt - MULTI_CORE

FILE: ipc_ex1_basic_cpu1_cpu2_multi_c29x2.c

This example demonstrates how to configure IPC and pass information from C29x1 to C29x2 core without message queues.

When using CCS for debugging this Multi-core example, after launching the debug session,
- Connect to CPU1 and load the c29x2.out first. (In case of FLASH configuration, this might not halt at main, ignore this)
- Load c29x1.out next.
- After the program is loaded, run CPU1.
- Once c29x1 disables lock-step and releases CPU2 out of reset, the program stops.
- Connect to CPU2 target now. c29x2.out would have started execution as soon as it is released from reset.
- In case of RAM configuration, restart the CPU2 target and load the symbols.
- In case of FLASH, do a Power-on-Reset, connect to CPU1/ CPU2 and load the respective symbols.

In FLASH configuration, the CPU2 application code is loaded to CPU1 FLASH. At runtime, CPU1 copies it to RAM for CPU2 to execute. *External Connections*
- None.

Watch Variables
- None.

16.6.2.3 IPC basic message passing example with interrupt - MULTI_CORE

FILE: ipc_ex2_basic_cpu1_cpu3_multi_c29x1.c

This example demonstrates how to configure IPC and pass information from C29x1 to C29x3 core without message queues.

When using CCS for debugging this Multi-core example, after launching the debug session,
- Connect to CPU1 and load only the c29x1.out.
- After the program is loaded, run CPU1.
- Once c29x1 configures and releases CPU3 out of reset, the program stops.
- Connect to CPU3 target now. c29x3.out would have started execution as soon as it is released from reset.
- In case of RAM configuration, restart the CPU3 target and load the symbols.

For FLASH configuration, this example is run in FLASH BANKMODE2, where CPU3 has access to FLASH (FRI-2). Refer to the Flash Plugin documentation to know about changing FLASH BANKMODEs and more. Additionally, the CPAx and CDAx RAMs are used for allocating various RAM sections. *External Connections*
- None.

Watch Variables
- pass

16.6.2.4 IPC basic message passing example with interrupt - MULTI_CORE

FILE: ipc_ex2_basic_cpu1_cpu3_multi_c29x3.c

This example demonstrates how to configure IPC and pass information from C29x1 to C29x3 core without message queues.

When using CCS for debugging this Multi-core example, after launching the debug session,
- Connect to CPU1 and first load the c29x3.out. (When loaded to FLASH, this might not halt at main due to an error, since CPU1 cannot execute from CPU3 FLASH memory (FRI-2)).
- c29x1.out can be loaded next.
- After the program is loaded, run CPU1.
- Once c29x1 configures and releases CPU3 out of reset, the program stops.
- Connect to CPU3 target now. c29x3.out would have started execution as soon as it is released from reset.
- In case of RAM configuration, restart the CPU3 target and load the symbols.
- In case of FLASH, do a Power-on-Reset, connect to CPU1/ CPU3 and load the respective symbols.

For FLASH configuration, this example is run in FLASH BANKMODE2, where CPU3 has access to FLASH (FRI-2). Refer to the Flash Plugin documentation to know about changing FLASH BANKMODEs and more. Additionally, the CPAx and CDAx RAMs are used for allocating various RAM sections. *External Connections*
- None.

Watch Variables
- None.

16.7 IPC Registers

This section describes the IPC Registers.

16.7.1 IPC Base Address Table

Table 16-3. IPC Base Address Table

Structure	DriverLib Name	Base Address	Frame Applicable	CPU1	CPU2	CPU3	RTDMA1	RTDMA2	HSM	Pipeline Protected
IPC_COUNTER_REGS [1]	IPCCOUNTER_BASE	0x301B_0000	-	YES	YES	YES	-	-	YES	YES
CPU1_IPC_SEND_REGS	CPU1IPCSEND_BASE	0x3022_0000	-	YES	YES	YES	-	-	-	YES
CPU2_IPC_SEND_REGS	CPU2IPCSEND_BASE	0x3022_8000	-	YES	YES	YES	-	-	-	YES
CPU3_IPC_SEND_REGS	CPU3IPCSEND_BASE	0x3023_0000	-	YES	YES	YES	-	-	-	YES
CPU1_IPC_RCV_REGS	CPU1IPCRCV_BASE	0x3024_0000	-	YES	YES	YES	-	-	-	YES
CPU2_IPC_RCV_REGS	CPU2IPCRCV_BASE	0x3024_8000	-	YES	YES	YES	-	-	-	YES
CPU3_IPC_RCV_REGS	CPU3IPCRCV_BASE	0x3025_0000	-	YES	YES	YES	-	-	-	YES

(1) Registers writeable by CPU1.LINK0, CPU1.LINK1, CPU1.LINK2 only. All CPUs can read all registers in all LINKs. Debug write access only allowed if Zone0 or Zone1 are enabled for full debug by all CPUs. Debug reads always allowed. Register Read/Write access by HSM.

16.7.2 IPC_COUNTER_REGS Registers

Table 16-4 lists the memory-mapped registers for the IPC_COUNTER_REGS registers. All register offset addresses not listed in Table 16-4 should be considered as reserved locations and the register contents should not be modified.

Table 16-4. IPC_COUNTER_REGS Registers

Offset	Acronym	Register Name	Protection
0h	IPCCOUNTERL	IPCCOUNTERL Register	
4h	IPCCOUNTERH	IPCCOUNTERH Register	

Complex bit access types are encoded to fit into small table cells. Table 16-5 shows the codes that are used for access types in this section.

Table 16-5. IPC_COUNTER_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Reset or Default Value		
-*n*		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

16.7.2.1 IPCCOUNTERL Register (Offset = 0h) [Reset = 00000000h]

IPCCOUNTERL is shown in Figure 16-2 and described in Table 16-6.

Return to the Summary Table.

IPC Counter High Register

Figure 16-2. IPCCOUNTERL Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
COUNT																															
R-0h																															

Table 16-6. IPCCOUNTERL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	COUNT	R	0h	This is the lower 32-bits of free running 64 bit timestamp counter clocked by the PLLSYSCLK. Reset type: XRSn

16.7.2.2 IPCCOUNTERH Register (Offset = 4h) [Reset = 00000000h]

IPCCOUNTERH is shown in Figure 16-3 and described in Table 16-7.

Return to the Summary Table.

IPC Counter Low Register

Figure 16-3. IPCCOUNTERH Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
COUNT																															
R-0h																															

Table 16-7. IPCCOUNTERH Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	COUNT	R	0h	This is the upper 32-bits of free running 64 bit timestamp counter clocked by the PLLSYSCLK. Reset type: XRSn

16.7.3 CPU1_IPC_SEND_REGS Registers

Table 16-8 lists the memory-mapped registers for the CPU1_IPC_SEND_REGS registers. All register offset addresses not listed in Table 16-8 should be considered as reserved locations and the register contents should not be modified.

Table 16-8. CPU1_IPC_SEND_REGS Registers

Offset	Acronym	Register Name	Protection
0h + formula	CPU1TOCPU2INTIPCSET_j	CPU1TOCPU2INTIPCSET Register	
4h + formula	CPU1TOCPU2INTIPCCLR_j	CPU1TOCPU2INTIPCCLR Register	
8h + formula	CPU1TOCPU2INTIPCFLG_j	CPU1TOCPU2INTIPCFLG Register	
10h + formula	CPU1TOCPU2INTIPCSENDCOM_j	CPU1TOCPU2INTIPCSENDCOM Register	
14h + formula	CPU1TOCPU2INTIPCSENDADDR_j	CPU1TOCPU2INTIPCSENDADDR Register	
18h + formula	CPU1TOCPU2INTIPCSENDDATA_j	CPU1TOCPU2INTIPCSENDDATA Register	
1Ch + formula	CPU2TOCPU1INTREMOTEREPLY_j	CPU2TOCPU1INTREMOTEREPLY Register	
2000h + formula	CPU1TOCPU3INTIPCSET_j	CPU1TOCPU3INTIPCSET Register	
2004h + formula	CPU1TOCPU3INTIPCCLR_j	CPU1TOCPU3INTIPCCLR Register	
2008h + formula	CPU1TOCPU3INTIPCFLG_j	CPU1TOCPU3INTIPCFLG Register	
2010h + formula	CPU1TOCPU3INTIPCSENDCOM_j	CPU1TOCPU3INTIPCSENDCOM Register	
2014h + formula	CPU1TOCPU3INTIPCSENDADDR_j	CPU1TOCPU3INTIPCSENDADDR Register	
2018h + formula	CPU1TOCPU3INTIPCSENDDATA_j	CPU1TOCPU3INTIPCSENDDATA Register	
201Ch + formula	CPU3TOCPU1INTREMOTEREPLY_j	CPU3TOCPU1INTREMOTEREPLY Register	
6000h + formula	CPU1TOHSMINTIPCSET_j	CPU1TOHSMINTIPCSET Register	
6004h + formula	CPU1TOHSMINTIPCCLR_j	CPU1TOHSMINTIPCCLR Register	
6008h + formula	CPU1TOHSMINTIPCFLG_j	CPU1TOHSMINTIPCFLG Register	

Complex bit access types are encoded to fit into small table cells. Table 16-9 shows the codes that are used for access types in this section.

Table 16-9. CPU1_IPC_SEND_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		

Table 16-9. CPU1_IPC_SEND_REGS Access Type Codes (continued)

Access Type	Code	Description
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

16.7.3.1 CPU1TOCPU2INTIPCSET_j Register (Offset = 0h + formula) [Reset = 00000000h]

CPU1TOCPU2INTIPCSET_j is shown in Figure 16-4 and described in Table 16-10.

Return to the Summary Table.

Set CPU2TOCPU1IPCFLG register

Offset = 0h + (j * 800h); where j = 0h to 3h

Table 16-10. CPU1TOCPU2INTIPCSET_j Register Field Descriptions

Bit	Field	Type	Reset	Description
31	IPC31	R-0/W1S	0h	Writing 1 to this bit sets the IPC31 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU1.SYSRSn
30	IPC30	R-0/W1S	0h	Writing 1 to this bit sets the IPC30 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU1.SYSRSn
29	IPC29	R-0/W1S	0h	Writing 1 to this bit sets the IPC29 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU1.SYSRSn
28	IPC28	R-0/W1S	0h	Writing 1 to this bit sets the IPC28 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU1.SYSRSn
27	IPC27	R-0/W1S	0h	Writing 1 to this bit sets the IPC27 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU1.SYSRSn
26	IPC26	R-0/W1S	0h	Writing 1 to this bit sets the IPC26 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU1.SYSRSn
25	IPC25	R-0/W1S	0h	Writing 1 to this bit sets the IPC25 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU1.SYSRSn
24	IPC24	R-0/W1S	0h	Writing 1 to this bit sets the IPC24 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU1.SYSRSn
23	IPC23	R-0/W1S	0h	Writing 1 to this bit sets the IPC23 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU1.SYSRSn

Table 16-10. CPU1TOCPU2INTIPCSET_j Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
22	IPC22	R-0/W1S	0h	Writing 1 to this bit sets the IPC22 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU1.SYSRSn
21	IPC21	R-0/W1S	0h	Writing 1 to this bit sets the IPC21 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU1.SYSRSn
20	IPC20	R-0/W1S	0h	Writing 1 to this bit sets the IPC20 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU1.SYSRSn
19	IPC19	R-0/W1S	0h	Writing 1 to this bit sets the IPC19 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU1.SYSRSn
18	IPC18	R-0/W1S	0h	Writing 1 to this bit sets the IPC18 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU1.SYSRSn
17	IPC17	R-0/W1S	0h	Writing 1 to this bit sets the IPC17 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU1.SYSRSn
16	IPC16	R-0/W1S	0h	Writing 1 to this bit sets the IPC16 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU1.SYSRSn
15	IPC15	R-0/W1S	0h	Writing 1 to this bit sets the IPC15 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU1.SYSRSn
14	IPC14	R-0/W1S	0h	Writing 1 to this bit sets the IPC14 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU1.SYSRSn
13	IPC13	R-0/W1S	0h	Writing 1 to this bit sets the IPC13 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU1.SYSRSn
12	IPC12	R-0/W1S	0h	Writing 1 to this bit sets the IPC12 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU1.SYSRSn
11	IPC11	R-0/W1S	0h	Writing 1 to this bit sets the IPC11 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU1.SYSRSn
10	IPC10	R-0/W1S	0h	Writing 1 to this bit sets the IPC10 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU1.SYSRSn
9	IPC9	R-0/W1S	0h	Writing 1 to this bit sets the IPC9 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU1.SYSRSn
8	IPC8	R-0/W1S	0h	Writing 1 to this bit sets the IPC8 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU1.SYSRSn
7	IPC7	R-0/W1S	0h	Writing 1 to this bit sets the IPC7 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU1.SYSRSn
6	IPC6	R-0/W1S	0h	Writing 1 to this bit sets the IPC6 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU1.SYSRSn

Table 16-10. CPU1TOCPU2INTIPCSET_j Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	IPC5	R-0/W1S	0h	Writing 1 to this bit sets the IPC5 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU1.SYSRSn
4	IPC4	R-0/W1S	0h	Writing 1 to this bit sets the IPC4 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU1.SYSRSn
3	IPC3	R-0/W1S	0h	Writing 1 to this bit sets the IPC3 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU1.SYSRSn
2	IPC2	R-0/W1S	0h	Writing 1 to this bit sets the IPC2 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU1.SYSRSn
1	IPC1	R-0/W1S	0h	Writing 1 to this bit sets the IPC1 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU1.SYSRSn
0	IPC0	R-0/W1S	0h	Writing 1 to this bit sets the IPC0 event flag for the remote CPU. Writing 0 has no effect. Notes: [1] IPC event flags 0 will trigger interrupts in the receiving CPU via the PIPE. Reset type: CPU1.SYSRSn

16.7.3.2 CPU1TOCPU2INTIPCCLR_j Register (Offset = 4h + formula) [Reset = 00000000h]

CPU1TOCPU2INTIPCCLR_j is shown in Figure 16-5 and described in Table 16-11.

Return to the Summary Table.

16.7.4 CPU2_IPC_SEND_REGS Registers

Table 16-27 lists the memory-mapped registers for the CPU2_IPC_SEND_REGS registers. All register offset addresses not listed in Table 16-27 should be considered as reserved locations and the register contents should not be modified.

Table 16-27. CPU2_IPC_SEND_REGS Registers

Offset	Acronym	Register Name	Protection
0h + formula	CPU2TOCPU1INTIPCSET_j	CPU2TOCPU1INTIPCSET Register	
4h + formula	CPU2TOCPU1INTIPCCLR_j	CPU2TOCPU1INTIPCCLR Register	
8h + formula	CPU2TOCPU1INTIPCFLG_j	CPU2TOCPU1INTIPCFLG Register	
10h + formula	CPU2TOCPU1INTIPCSENDCOM_j	CPU2TOCPU1INTIPCSENDCOM Register	
14h + formula	CPU2TOCPU1INTIPCSENDADDR_j	CPU2TOCPU1INTIPCSENDADDR Register	
18h + formula	CPU2TOCPU1INTIPCSENDDATA_j	CPU2TOCPU1INTIPCSENDDATA Register	
1Ch + formula	CPU1TOCPU2INTREMOTEREPLY_j	CPU1TOCPU2INTREMOTEREPLY Register	
2000h + formula	CPU2TOCPU3INTIPCSET_j	CPU2TOCPU3INTIPCSET Register	
2004h + formula	CPU2TOCPU3INTIPCCLR_j	CPU2TOCPU3INTIPCCLR Register	
2008h + formula	CPU2TOCPU3INTIPCFLG_j	CPU2TOCPU3INTIPCFLG Register	
2010h + formula	CPU2TOCPU3INTIPCSENDCOM_j	CPU2TOCPU3INTIPCSENDCOM Register	
2014h + formula	CPU2TOCPU3INTIPCSENDADDR_j	CPU2TOCPU3INTIPCSENDADDR Register	
2018h + formula	CPU2TOCPU3INTIPCSENDDATA_j	CPU2TOCPU3INTIPCSENDDATA Register	
201Ch + formula	CPU3TOCPU2INTREMOTEREPLY_j	CPU3TOCPU2INTREMOTEREPLY Register	
6000h + formula	CPU2TOHSMINTIPCSET_j	CPU2TOHSMINTIPCSET Register	
6004h + formula	CPU2TOHSMINTIPCCLR_j	CPU2TOHSMINTIPCCLR Register	
6008h + formula	CPU2TOHSMINTIPCFLG_j	CPU2TOHSMINTIPCFLG Register	

Complex bit access types are encoded to fit into small table cells. Table 16-28 shows the codes that are used for access types in this section.

Table 16-28. CPU2_IPC_SEND_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		

Table 16-28. CPU2_IPC_SEND_REGS Access Type Codes (continued)

Access Type	Code	Description
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

16.7.4.1 CPU2TOCPU1INTIPCSET_j Register (Offset = 0h + formula) [Reset = 00000000h]

CPU2TOCPU1INTIPCSET_j is shown in Figure 16-21 and described in Table 16-29.

Return to the Summary Table.

Set CPU1TOCPU2IPCFLG register

Offset = 0h + (j * 800h); where j = 0h to 3h

31	IPC31	R-0/W1S	0h	Writing 1 to this bit sets the IPC31 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU2.SYSRSn
30	IPC30	R-0/W1S	0h	Writing 1 to this bit sets the IPC30 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU2.SYSRSn
29	IPC29	R-0/W1S	0h	Writing 1 to this bit sets the IPC29 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU2.SYSRSn
28	IPC28	R-0/W1S	0h	Writing 1 to this bit sets the IPC28 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU2.SYSRSn
27	IPC27	R-0/W1S	0h	Writing 1 to this bit sets the IPC27 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU2.SYSRSn
26	IPC26	R-0/W1S	0h	Writing 1 to this bit sets the IPC26 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU2.SYSRSn
25	IPC25	R-0/W1S	0h	Writing 1 to this bit sets the IPC25 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU2.SYSRSn
24	IPC24	R-0/W1S	0h	Writing 1 to this bit sets the IPC24 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU2.SYSRSn
23	IPC23	R-0/W1S	0h	Writing 1 to this bit sets the IPC23 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU2.SYSRSn

Table 16-43. CPU2TOHSMINTIPCSET_j Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
22	IPC22	R-0/W1S	0h	Writing 1 to this bit sets the IPC22 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU2.SYSRSn
21	IPC21	R-0/W1S	0h	Writing 1 to this bit sets the IPC21 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU2.SYSRSn
20	IPC20	R-0/W1S	0h	Writing 1 to this bit sets the IPC20 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU2.SYSRSn
19	IPC19	R-0/W1S	0h	Writing 1 to this bit sets the IPC19 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU2.SYSRSn
18	IPC18	R-0/W1S	0h	Writing 1 to this bit sets the IPC18 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU2.SYSRSn
17	IPC17	R-0/W1S	0h	Writing 1 to this bit sets the IPC17 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU2.SYSRSn
16	IPC16	R-0/W1S	0h	Writing 1 to this bit sets the IPC16 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU2.SYSRSn
15	IPC15	R-0/W1S	0h	Writing 1 to this bit sets the IPC15 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU2.SYSRSn
14	IPC14	R-0/W1S	0h	Writing 1 to this bit sets the IPC14 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU2.SYSRSn
13	IPC13	R-0/W1S	0h	Writing 1 to this bit sets the IPC13 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU2.SYSRSn
12	IPC12	R-0/W1S	0h	Writing 1 to this bit sets the IPC12 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU2.SYSRSn
11	IPC11	R-0/W1S	0h	Writing 1 to this bit sets the IPC11 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU2.SYSRSn
10	IPC10	R-0/W1S	0h	Writing 1 to this bit sets the IPC10 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU2.SYSRSn
9	IPC9	R-0/W1S	0h	Writing 1 to this bit sets the IPC9 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU2.SYSRSn
8	IPC8	R-0/W1S	0h	Writing 1 to this bit sets the IPC8 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU2.SYSRSn
7	IPC7	R-0/W1S	0h	Writing 1 to this bit sets the IPC7 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU2.SYSRSn
6	IPC6	R-0/W1S	0h	Writing 1 to this bit sets the IPC6 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU2.SYSRSn

Table 16-43. CPU2TOHSMINTIPCSET_j Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	IPC5	R-0/W1S	0h	Writing 1 to this bit sets the IPC5 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU2.SYSRSn
4	IPC4	R-0/W1S	0h	Writing 1 to this bit sets the IPC4 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU2.SYSRSn
3	IPC3	R-0/W1S	0h	Writing 1 to this bit sets the IPC3 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU2.SYSRSn
2	IPC2	R-0/W1S	0h	Writing 1 to this bit sets the IPC2 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU2.SYSRSn
1	IPC1	R-0/W1S	0h	Writing 1 to this bit sets the IPC1 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPU2.SYSRSn
0	IPC0	R-0/W1S	0h	Writing 1 to this bit sets the IPC0 event flag for the remote CPU. Writing 0 has no effect. Notes: [1] IPC event flags 0 will trigger interrupts in the receiving CPU via the PIPE. Reset type: CPU2.SYSRSn

16.7.4.16 CPU2TOHSMINTIPCCLR_j Register (Offset = 6004h + formula) [Reset = 00000000h]

CPU2TOHSMINTIPCCLR_j is shown in Figure 16-36 and described in Table 16-44.

Return to the Summary Table.

Clear CPU2TOHSMIPCFLG register

Offset = 6004h + (j * 1000h); where j = 0h to 1h

16.7.5 CPU3_IPC_SEND_REGS Registers

Table 16-46 lists the memory-mapped registers for the CPU3_IPC_SEND_REGS registers. All register offset addresses not listed in Table 16-46 should be considered as reserved locations and the register contents should not be modified.

Table 16-46. CPU3_IPC_SEND_REGS Registers

Offset	Acronym	Register Name	Protection
0h + formula	CPU3TOCPU1INTIPCSET_j	CPU3TOCPU1INTIPCSET Register	
4h + formula	CPU3TOCPU1INTIPCCLR_j	CPU3TOCPU1INTIPCCLR Register	
8h + formula	CPU3TOCPU1INTIPCFLG_j	CPU3TOCPU1INTIPCFLG Register	
10h + formula	CPU3TOCPU1INTIPCSENDCOM_j	CPU3TOCPU1INTIPCSENDCOM Register	
14h + formula	CPU3TOCPU1INTIPCSENDADDR_j	CPU3TOCPU1INTIPCSENDADDR Register	
18h + formula	CPU3TOCPU1INTIPCSENDDATA_j	CPU3TOCPU1INTIPCSENDDATA Register	
1Ch + formula	CPU1TOCPU3INTREMOTEREPLY_j	CPU1TOCPU3INTREMOTEREPLY Register	
2000h + formula	CPU3TOCPU2INTIPCSET_j	CPU3TOCPU2INTIPCSET Register	
2004h + formula	CPU3TOCPU2INTIPCCLR_j	CPU3TOCPU2INTIPCCLR Register	
2008h + formula	CPU3TOCPU2INTIPCFLG_j	CPU3TOCPU2INTIPCFLG Register	
2010h + formula	CPU3TOCPU2INTIPCSENDCOM_j	CPU3TOCPU2INTIPCSENDCOM Register	
2014h + formula	CPU3TOCPU2INTIPCSENDADDR_j	CPU3TOCPU2INTIPCSENDADDR Register	
2018h + formula	CPU3TOCPU2INTIPCSENDDATA_j	CPU3TOCPU2INTIPCSENDDATA Register	
201Ch + formula	CPU2TOCPU3INTREMOTEREPLY_j	CPU2TOCPU3INTREMOTEREPLY Register	
6000h + formula	CPU3TOHSMINTIPCSET_j	CPU3TOHSMINTIPCSET Register	
6004h + formula	CPU3TOHSMINTIPCCLR_j	CPU3TOHSMINTIPCCLR Register	
6008h + formula	CPU3TOHSMINTIPCFLG_j	CPU3TOHSMINTIPCFLG Register	

Complex bit access types are encoded to fit into small table cells. Table 16-47 shows the codes that are used for access types in this section.

Table 16-47. CPU3_IPC_SEND_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		

Table 16-47. CPU3_IPC_SEND_REGS Access Type Codes (continued)

Access Type	Code	Description
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

16.7.5.1 CPU3TOCPU1INTIPCSET_j Register (Offset = 0h + formula) [Reset = 00000000h]

CPU3TOCPU1INTIPCSET_j is shown in Figure 16-38 and described in Table 16-48.

Return to the Summary Table.

Set CPU1TOCPU3IPCFLG register

Offset = 0h + (j * 800h); where j = 0h to 3h

Table 16-48. CPU3TOCPU1INTIPCSET_j Register Field Descriptions

Bit	Field	Type	Reset	Description
31	IPC31	R-0/W1S	0h	Writing 1 to this bit sets the IPC31 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPUx.SYSRSn
30	IPC30	R-0/W1S	0h	Writing 1 to this bit sets the IPC30 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPUx.SYSRSn
29	IPC29	R-0/W1S	0h	Writing 1 to this bit sets the IPC29 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPUx.SYSRSn
28	IPC28	R-0/W1S	0h	Writing 1 to this bit sets the IPC28 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPUx.SYSRSn
27	IPC27	R-0/W1S	0h	Writing 1 to this bit sets the IPC27 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPUx.SYSRSn
26	IPC26	R-0/W1S	0h	Writing 1 to this bit sets the IPC26 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPUx.SYSRSn
25	IPC25	R-0/W1S	0h	Writing 1 to this bit sets the IPC25 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPUx.SYSRSn
24	IPC24	R-0/W1S	0h	Writing 1 to this bit sets the IPC24 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPUx.SYSRSn
23	IPC23	R-0/W1S	0h	Writing 1 to this bit sets the IPC23 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPUx.SYSRSn

Table 16-48. CPU3TOCPU1INTIPCSET_j Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
22	IPC22	R-0/W1S	0h	Writing 1 to this bit sets the IPC22 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPUx.SYSRSn
21	IPC21	R-0/W1S	0h	Writing 1 to this bit sets the IPC21 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPUx.SYSRSn
20	IPC20	R-0/W1S	0h	Writing 1 to this bit sets the IPC20 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPUx.SYSRSn
19	IPC19	R-0/W1S	0h	Writing 1 to this bit sets the IPC19 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPUx.SYSRSn
18	IPC18	R-0/W1S	0h	Writing 1 to this bit sets the IPC18 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPUx.SYSRSn
17	IPC17	R-0/W1S	0h	Writing 1 to this bit sets the IPC17 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPUx.SYSRSn
16	IPC16	R-0/W1S	0h	Writing 1 to this bit sets the IPC16 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPUx.SYSRSn
15	IPC15	R-0/W1S	0h	Writing 1 to this bit sets the IPC15 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPUx.SYSRSn
14	IPC14	R-0/W1S	0h	Writing 1 to this bit sets the IPC14 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPUx.SYSRSn
13	IPC13	R-0/W1S	0h	Writing 1 to this bit sets the IPC13 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPUx.SYSRSn
12	IPC12	R-0/W1S	0h	Writing 1 to this bit sets the IPC12 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPUx.SYSRSn
11	IPC11	R-0/W1S	0h	Writing 1 to this bit sets the IPC11 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPUx.SYSRSn
10	IPC10	R-0/W1S	0h	Writing 1 to this bit sets the IPC10 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPUx.SYSRSn
9	IPC9	R-0/W1S	0h	Writing 1 to this bit sets the IPC9 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPUx.SYSRSn
8	IPC8	R-0/W1S	0h	Writing 1 to this bit sets the IPC8 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPUx.SYSRSn
7	IPC7	R-0/W1S	0h	Writing 1 to this bit sets the IPC7 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPUx.SYSRSn
6	IPC6	R-0/W1S	0h	Writing 1 to this bit sets the IPC6 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPUx.SYSRSn

Table 16-48. CPU3TOCPU1INTIPCSET_j Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	IPC5	R-0/W1S	0h	Writing 1 to this bit sets the IPC5 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPUx.SYSRSn
4	IPC4	R-0/W1S	0h	Writing 1 to this bit sets the IPC4 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPUx.SYSRSn
3	IPC3	R-0/W1S	0h	Writing 1 to this bit sets the IPC3 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPUx.SYSRSn
2	IPC2	R-0/W1S	0h	Writing 1 to this bit sets the IPC2 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPUx.SYSRSn
1	IPC1	R-0/W1S	0h	Writing 1 to this bit sets the IPC1 event flag for the remote CPU. Writing 0 has no effect. Reset type: CPUx.SYSRSn
0	IPC0	R-0/W1S	0h	Writing 1 to this bit sets the IPC0 event flag for the remote CPU. Writing 0 has no effect. Notes: [1] IPC event flags 0 will trigger interrupts in the receiving CPU via the PIPE. Reset type: CPUx.SYSRSn

16.7.5.2 CPU3TOCPU1INTIPCCLR_j Register (Offset = 4h + formula) [Reset = 00000000h]

CPU3TOCPU1INTIPCCLR_j is shown in Figure 16-39 and described in Table 16-49.

Return to the Summary Table.

Clear CPU3TOCPU1IPCFLG register

Offset = 4h + (j * 800h); where j = 0h to 3h

Table 16-64. CPU3TOHSMINTIPCFLG_j Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	IPC5	R	0h	0: No IPC5 event request to CPU3 1: IPC5 event request to CPU3 Reset type: CPUx.SYSRSn
4	IPC4	R	0h	0: No IPC4 event request to CPU3 1: IPC4 event request to CPU3 Reset type: CPUx.SYSRSn
3	IPC3	R	0h	0: No IPC3 event request to CPU3 1: IPC3 event request to CPU3 Reset type: CPUx.SYSRSn
2	IPC2	R	0h	0: No IPC2 event request to CPU3 1: IPC2 event request to CPU3 Reset type: CPUx.SYSRSn
1	IPC1	R	0h	0: No IPC1 event request to CPU3 1: IPC1 event request to CPU3 Reset type: CPUx.SYSRSn
0	IPC0	R	0h	0: No IPC0 event request to CPU3 1: IPC0 event request to CPU3 Reset type: CPUx.SYSRSn

16.7.6 CPU1_IPC_RCV_REGS Registers

Table 16-65 lists the memory-mapped registers for the CPU1_IPC_RCV_REGS registers. All register offset addresses not listed in Table 16-65 should be considered as reserved locations and the register contents should not be modified.

Table 16-65. CPU1_IPC_RCV_REGS Registers

Offset	Acronym	Register Name	Protection
0h + formula	CPU2TOCPU1INTIPCSTS_j	CPU2TOCPU1INTIPCSTS Register	
4h + formula	CPU1TOCPU2INTIPCACK_j	CPU1TOCPU2INTIPCACK Register	
10h + formula	CPU2TOCPU1INTIPCRECVCOM_j	CPU2TOCPU1INTIPCRECVCOM Register	
14h + formula	CPU2TOCPU1INTIPCRECVADDR_j	CPU2TOCPU1INTIPCRECVADDR Register	
18h + formula	CPU2TOCPU1INTIPCRECVDATA_j	CPU2TOCPU1INTIPCRECVDATA Register	
1Ch + formula	CPU1TOCPU2INTLOCALREPLY_j	CPU1TOCPU2INTLOCALREPLY Register	
2000h + formula	CPU3TOCPU1INTIPCSTS_j	CPU3TOCPU1INTIPCSTS Register	
2004h + formula	CPU1TOCPU3INTIPCACK_j	CPU1TOCPU3INTIPCACK Register	
2010h + formula	CPU3TOCPU1INTIPCRECVCOM_j	CPU3TOCPU1INTIPCRECVCOM Register	
2014h + formula	CPU3TOCPU1INTIPCRECVADDR_j	CPU3TOCPU1INTIPCRECVADDR Register	
2018h + formula	CPU3TOCPU1INTIPCRECVDATA_j	CPU3TOCPU1INTIPCRECVDATA Register	
201Ch + formula	CPU1TOCPU3INTLOCALREPLY_j	CPU1TOCPU3INTLOCALREPLY Register	

Complex bit access types are encoded to fit into small table cells. Table 16-66 shows the codes that are used for access types in this section.

Table 16-66. CPU1_IPC_RCV_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.

Table 16-66. CPU1_IPC_RCV_REGS Access Type Codes (continued)

Access Type	Code	Description
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

16.7.6.1 CPU2TOCPU1INTIPCSTS_j Register (Offset = 0h + formula) [Reset = 00000000h]

CPU2TOCPU1INTIPCSTS_j is shown in Figure 16-55 and described in Table 16-67.

Return to the Summary Table.

Status of CPU1TOCPU2IPCFLG register

Offset = 0h + (j * 800h); where j = 0h to 3h

Table 16-67. CPU2TOCPU1INTIPCSTS_j Register Field Descriptions

Bit	Field	Type	Reset	Description
31	IPC31	R	0h	Indicates to the local CPU if the IPC31 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
30	IPC30	R	0h	Indicates to the local CPU if the IPC30 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
29	IPC29	R	0h	Indicates to the local CPU if the IPC29 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
28	IPC28	R	0h	Indicates to the local CPU if the IPC28 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
27	IPC27	R	0h	Indicates to the local CPU if the IPC27 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
26	IPC26	R	0h	Indicates to the local CPU if the IPC26 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn

Table 16-67. CPU2TOCPU1INTIPCSTS_j Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
25	IPC25	R	0h	Indicates to the local CPU if the IPC25 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
24	IPC24	R	0h	Indicates to the local CPU if the IPC24 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
23	IPC23	R	0h	Indicates to the local CPU if the IPC23 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
22	IPC22	R	0h	Indicates to the local CPU if the IPC22 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
21	IPC21	R	0h	Indicates to the local CPU if the IPC21 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
20	IPC20	R	0h	Indicates to the local CPU if the IPC20 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
19	IPC19	R	0h	Indicates to the local CPU if the IPC19 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
18	IPC18	R	0h	Indicates to the local CPU if the IPC18 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
17	IPC17	R	0h	Indicates to the local CPU if the IPC17 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
16	IPC16	R	0h	Indicates to the local CPU if the IPC16 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
15	IPC15	R	0h	Indicates to the local CPU if the IPC15 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn

Table 16-67. CPU2TOCPU1INTIPCSTS_j Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
14	IPC14	R	0h	Indicates to the local CPU if the IPC14 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
13	IPC13	R	0h	Indicates to the local CPU if the IPC13 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
12	IPC12	R	0h	Indicates to the local CPU if the IPC12 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
11	IPC11	R	0h	Indicates to the local CPU if the IPC11 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
10	IPC10	R	0h	Indicates to the local CPU if the IPC10 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
9	IPC9	R	0h	Indicates to the local CPU if the IPC9 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
8	IPC8	R	0h	Indicates to the local CPU if the IPC8 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
7	IPC7	R	0h	Indicates to the local CPU if the IPC7 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
6	IPC6	R	0h	Indicates to the local CPU if the IPC6 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
5	IPC5	R	0h	Indicates to the local CPU if the IPC5 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
4	IPC4	R	0h	Indicates to the local CPU if the IPC4 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn

Table 16-67. CPU2TOCPU1INTIPCSTS_j Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	IPC3	R	0h	Indicates to the local CPU if the IPC3 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
2	IPC2	R	0h	Indicates to the local CPU if the IPC2 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
1	IPC1	R	0h	Indicates to the local CPU if the IPC1 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
0	IPC0	R	0h	Indicates to the local CPU if the IPC0 event flag was set by the remote CPU. 0: No IPC0 event was set by the remote CPU 1: An IPC0 event was set by the remote CPU Notes [1] IPC event flags 0 will trigger interrupts in the receiving CPU via the PIPE. Reset type: CPU2.SYSRSn

16.7.6.2 CPU1TOCPU2INTIPCACK_j Register (Offset = 4h + formula) [Reset = 00000000h]

CPU1TOCPU2INTIPCACK_j is shown in Figure 16-56 and described in Table 16-68.

Return to the Summary Table.

Table 16-73. CPU3TOCPU1INTIPCSTS_j Register Field Descriptions

Bit	Field	Type	Reset	Description
31	IPC31	R	0h	Indicates to the local CPU if the IPC31 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
30	IPC30	R	0h	Indicates to the local CPU if the IPC30 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
29	IPC29	R	0h	Indicates to the local CPU if the IPC29 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
28	IPC28	R	0h	Indicates to the local CPU if the IPC28 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
27	IPC27	R	0h	Indicates to the local CPU if the IPC27 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
26	IPC26	R	0h	Indicates to the local CPU if the IPC26 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn

Table 16-73. CPU3TOCPU1INTIPCSTS_j Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
25	IPC25	R	0h	Indicates to the local CPU if the IPC25 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
24	IPC24	R	0h	Indicates to the local CPU if the IPC24 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
23	IPC23	R	0h	Indicates to the local CPU if the IPC23 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
22	IPC22	R	0h	Indicates to the local CPU if the IPC22 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
21	IPC21	R	0h	Indicates to the local CPU if the IPC21 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
20	IPC20	R	0h	Indicates to the local CPU if the IPC20 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
19	IPC19	R	0h	Indicates to the local CPU if the IPC19 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
18	IPC18	R	0h	Indicates to the local CPU if the IPC18 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
17	IPC17	R	0h	Indicates to the local CPU if the IPC17 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
16	IPC16	R	0h	Indicates to the local CPU if the IPC16 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
15	IPC15	R	0h	Indicates to the local CPU if the IPC15 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn

Table 16-73. CPU3TOCPU1INTIPCSTS_j Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
14	IPC14	R	0h	Indicates to the local CPU if the IPC14 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
13	IPC13	R	0h	Indicates to the local CPU if the IPC13 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
12	IPC12	R	0h	Indicates to the local CPU if the IPC12 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
11	IPC11	R	0h	Indicates to the local CPU if the IPC11 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
10	IPC10	R	0h	Indicates to the local CPU if the IPC10 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
9	IPC9	R	0h	Indicates to the local CPU if the IPC9 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
8	IPC8	R	0h	Indicates to the local CPU if the IPC8 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
7	IPC7	R	0h	Indicates to the local CPU if the IPC7 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
6	IPC6	R	0h	Indicates to the local CPU if the IPC6 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
5	IPC5	R	0h	Indicates to the local CPU if the IPC5 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
4	IPC4	R	0h	Indicates to the local CPU if the IPC4 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn

Table 16-73. CPU3TOCPU1INTIPCSTS_j Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	IPC3	R	0h	Indicates to the local CPU if the IPC3 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
2	IPC2	R	0h	Indicates to the local CPU if the IPC2 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
1	IPC1	R	0h	Indicates to the local CPU if the IPC1 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
0	IPC0	R	0h	Indicates to the local CPU if the IPC0 event flag was set by the remote CPU. 0: No IPC0 event was set by the remote CPU 1: An IPC0 event was set by the remote CPU Notes [1] IPC event flags 0 will trigger interrupts in the receiving CPU via the PIPE. Reset type: CPUx.SYSRSn

16.7.6.8 CPU1TOCPU3INTIPCACK_j Register (Offset = 2004h + formula) [Reset = 00000000h]

CPU1TOCPU3INTIPCACK_j is shown in Figure 16-62 and described in Table 16-74.

Return to the Summary Table.

CPU1TOCPU3INTIPCACK Register

Offset = 2004h + (j * 800h); where j = 0h to 3h

2000h + formula	CPU3TOCPU2INTIPCSTS_j	CPU3TOCPU2INTIPCSTS Register	
2004h + formula	CPU2TOCPU3INTIPCACK_j	CPU2TOCPU3INTIPCACK Register	
2010h + formula	CPU3TOCPU2INTIPCRECVCOM_j	CPU3TOCPU2INTIPCRECVCOM Register	
2014h + formula	CPU3TOCPU2INTIPCRECVADDR_j	CPU3TOCPU2INTIPCRECVADDR Register	
2018h + formula	CPU3TOCPU2INTIPCRECVDATA_j	CPU3TOCPU2INTIPCRECVDATA Register	
201Ch + formula	CPU2TOCPU3INTLOCALREPLY_j	CPU2TOCPU3INTLOCALREPLY Register	

Complex bit access types are encoded to fit into small table cells. Table 16-80 shows the codes that are used for access types in this section.

Table 16-80. CPU2_IPC_RCV_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.

Table 16-80. CPU2_IPC_RCV_REGS Access Type Codes (continued)

Access Type	Code	Description
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

16.7.7.1 CPU1TOCPU2INTIPCSTS_j Register (Offset = 0h + formula) [Reset = 00000000h]

CPU1TOCPU2INTIPCSTS_j is shown in Figure 16-67 and described in Table 16-81.

Return to the Summary Table.

Status of CPU2TOCPU1IPCFLG register

27	IPC27	R	0h	Indicates to the local CPU if the IPC27 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
26	IPC26	R	0h	Indicates to the local CPU if the IPC26 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn

Table 16-81. CPU1TOCPU2INTIPCSTS_j Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
25	IPC25	R	0h	Indicates to the local CPU if the IPC25 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
24	IPC24	R	0h	Indicates to the local CPU if the IPC24 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
23	IPC23	R	0h	Indicates to the local CPU if the IPC23 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
22	IPC22	R	0h	Indicates to the local CPU if the IPC22 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
21	IPC21	R	0h	Indicates to the local CPU if the IPC21 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
20	IPC20	R	0h	Indicates to the local CPU if the IPC20 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
19	IPC19	R	0h	Indicates to the local CPU if the IPC19 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
18	IPC18	R	0h	Indicates to the local CPU if the IPC18 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
17	IPC17	R	0h	Indicates to the local CPU if the IPC17 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
16	IPC16	R	0h	Indicates to the local CPU if the IPC16 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
15	IPC15	R	0h	Indicates to the local CPU if the IPC15 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn

Table 16-81. CPU1TOCPU2INTIPCSTS_j Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
14	IPC14	R	0h	Indicates to the local CPU if the IPC14 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
13	IPC13	R	0h	Indicates to the local CPU if the IPC13 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
12	IPC12	R	0h	Indicates to the local CPU if the IPC12 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
11	IPC11	R	0h	Indicates to the local CPU if the IPC11 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
10	IPC10	R	0h	Indicates to the local CPU if the IPC10 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
9	IPC9	R	0h	Indicates to the local CPU if the IPC9 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
8	IPC8	R	0h	Indicates to the local CPU if the IPC8 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
7	IPC7	R	0h	Indicates to the local CPU if the IPC7 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
6	IPC6	R	0h	Indicates to the local CPU if the IPC6 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
5	IPC5	R	0h	Indicates to the local CPU if the IPC5 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
4	IPC4	R	0h	Indicates to the local CPU if the IPC4 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn

Table 16-81. CPU1TOCPU2INTIPCSTS_j Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	IPC3	R	0h	Indicates to the local CPU if the IPC3 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
2	IPC2	R	0h	Indicates to the local CPU if the IPC2 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
1	IPC1	R	0h	Indicates to the local CPU if the IPC1 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
0	IPC0	R	0h	Indicates to the local CPU if the IPC0 event flag was set by the remote CPU. 0: No IPC0 event was set by the remote CPU 1: An IPC0 event was set by the remote CPU Notes [1] IPC event flags 0 will trigger interrupts in the receiving CPU via the PIPE. Reset type: CPU1.SYSRSn

16.7.7.2 CPU2TOCPU1INTIPCACK_j Register (Offset = 4h + formula) [Reset = 00000000h]

CPU2TOCPU1INTIPCACK_j is shown in Figure 16-68 and described in Table 16-82.

Return to the Summary Table.

CPU2TOCPU1INTIPCACK Register

Offset = 4h + (j * 800h); where j = 0h to 3h

Table 16-82. CPU2TOCPU1INTIPCACK_j Register Field Descriptions

Bit	Field	Type	Reset	Description
31	IPC31	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC31 bit. Reset type: CPU1.SYSRSn
30	IPC30	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC30 bit. Reset type: CPU1.SYSRSn
29	IPC29	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC29 bit. Reset type: CPU1.SYSRSn
28	IPC28	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC28 bit. Reset type: CPU1.SYSRSn
27	IPC27	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC27 bit. Reset type: CPU1.SYSRSn
26	IPC26	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC26 bit. Reset type: CPU1.SYSRSn
25	IPC25	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC25 bit. Reset type: CPU1.SYSRSn
24	IPC24	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC24 bit. Reset type: CPU1.SYSRSn
23	IPC23	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC23 bit. Reset type: CPU1.SYSRSn
22	IPC22	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC22 bit. Reset type: CPU1.SYSRSn
21	IPC21	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC21 bit. Reset type: CPU1.SYSRSn
20	IPC20	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC20 bit. Reset type: CPU1.SYSRSn
19	IPC19	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC19 bit. Reset type: CPU1.SYSRSn

Table 16-82. CPU2TOCPU1INTIPCACK_j Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
18	IPC18	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC18 bit. Reset type: CPU1.SYSRSn
17	IPC17	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC17 bit. Reset type: CPU1.SYSRSn
16	IPC16	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC16 bit. Reset type: CPU1.SYSRSn
15	IPC15	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC15 bit. Reset type: CPU1.SYSRSn
14	IPC14	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC14 bit. Reset type: CPU1.SYSRSn
13	IPC13	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC13 bit. Reset type: CPU1.SYSRSn
12	IPC12	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC12 bit. Reset type: CPU1.SYSRSn
11	IPC11	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC11 bit. Reset type: CPU1.SYSRSn
10	IPC10	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC10 bit. Reset type: CPU1.SYSRSn
9	IPC9	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC9 bit. Reset type: CPU1.SYSRSn
8	IPC8	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC8 bit. Reset type: CPU1.SYSRSn
7	IPC7	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC7 bit. Reset type: CPU1.SYSRSn
6	IPC6	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC6 bit. Reset type: CPU1.SYSRSn
5	IPC5	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC5 bit. Reset type: CPU1.SYSRSn
4	IPC4	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC4 bit. Reset type: CPU1.SYSRSn
3	IPC3	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC3 bit. Reset type: CPU1.SYSRSn
2	IPC2	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC2 bit. Reset type: CPU1.SYSRSn
1	IPC1	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC1 bit. Reset type: CPU1.SYSRSn
0	IPC0	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU2IPCFLG.IPC0 bit. Reset type: CPU1.SYSRSn

16.7.7.3 CPU1TOCPU2INTIPCRECVCOM_j Register (Offset = 10h + formula) [Reset = 00000000h]

CPU1TOCPU2INTIPCRECVCOM_j is shown in Figure 16-69 and described in Table 16-83.

Return to the Summary Table.

Refelects the value in CPU1TOCPU2IPCSENDCOM Register

Offset = 10h + (j * 800h); where j = 0h to 3h

Figure 16-69. CPU1TOCPU2INTIPCRECVCOM_j Register

Table 16-87. CPU3TOCPU2INTIPCSTS_j Register Field Descriptions

Bit	Field	Type	Reset	Description
31	IPC31	R	0h	Indicates to the local CPU if the IPC31 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
30	IPC30	R	0h	Indicates to the local CPU if the IPC30 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
29	IPC29	R	0h	Indicates to the local CPU if the IPC29 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
28	IPC28	R	0h	Indicates to the local CPU if the IPC28 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
27	IPC27	R	0h	Indicates to the local CPU if the IPC27 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
26	IPC26	R	0h	Indicates to the local CPU if the IPC26 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn

Table 16-87. CPU3TOCPU2INTIPCSTS_j Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
25	IPC25	R	0h	Indicates to the local CPU if the IPC25 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
24	IPC24	R	0h	Indicates to the local CPU if the IPC24 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
23	IPC23	R	0h	Indicates to the local CPU if the IPC23 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
22	IPC22	R	0h	Indicates to the local CPU if the IPC22 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
21	IPC21	R	0h	Indicates to the local CPU if the IPC21 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
20	IPC20	R	0h	Indicates to the local CPU if the IPC20 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
19	IPC19	R	0h	Indicates to the local CPU if the IPC19 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
18	IPC18	R	0h	Indicates to the local CPU if the IPC18 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
17	IPC17	R	0h	Indicates to the local CPU if the IPC17 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
16	IPC16	R	0h	Indicates to the local CPU if the IPC16 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
15	IPC15	R	0h	Indicates to the local CPU if the IPC15 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn

Table 16-87. CPU3TOCPU2INTIPCSTS_j Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
14	IPC14	R	0h	Indicates to the local CPU if the IPC14 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
13	IPC13	R	0h	Indicates to the local CPU if the IPC13 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
12	IPC12	R	0h	Indicates to the local CPU if the IPC12 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
11	IPC11	R	0h	Indicates to the local CPU if the IPC11 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
10	IPC10	R	0h	Indicates to the local CPU if the IPC10 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
9	IPC9	R	0h	Indicates to the local CPU if the IPC9 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
8	IPC8	R	0h	Indicates to the local CPU if the IPC8 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
7	IPC7	R	0h	Indicates to the local CPU if the IPC7 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
6	IPC6	R	0h	Indicates to the local CPU if the IPC6 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
5	IPC5	R	0h	Indicates to the local CPU if the IPC5 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
4	IPC4	R	0h	Indicates to the local CPU if the IPC4 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn

Table 16-87. CPU3TOCPU2INTIPCSTS_j Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	IPC3	R	0h	Indicates to the local CPU if the IPC3 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
2	IPC2	R	0h	Indicates to the local CPU if the IPC2 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
1	IPC1	R	0h	Indicates to the local CPU if the IPC1 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPUx.SYSRSn
0	IPC0	R	0h	Indicates to the local CPU if the IPC0 event flag was set by the remote CPU. 0: No IPC0 event was set by the remote CPU 1: An IPC0 event was set by the remote CPU Notes [1] IPC event flags 0 will trigger interrupts in the receiving CPU via the PIPE. Reset type: CPUx.SYSRSn

16.7.7.8 CPU2TOCPU3INTIPCACK_j Register (Offset = 2004h + formula) [Reset = 00000000h]

CPU2TOCPU3INTIPCACK_j is shown in Figure 16-74 and described in Table 16-88.

Return to the Summary Table.

CPU2TOCPU3INTIPCACK Register

Offset = 2004h + (j * 800h); where j = 0h to 3h

16.7.8 CPU3_IPC_RCV_REGS Registers

Table 16-93 lists the memory-mapped registers for the CPU3_IPC_RCV_REGS registers. All register offset addresses not listed in Table 16-93 should be considered as reserved locations and the register contents should not be modified.

Table 16-93. CPU3_IPC_RCV_REGS Registers

Offset	Acronym	Register Name	Protection
0h + formula	CPU1TOCPU3INTIPCSTS_j	CPU1TOCPU3INTIPCSTS Register	
4h + formula	CPU3TOCPU1INTIPCACK_j	CPU3TOCPU1INTIPCACK Register	
10h + formula	CPU1TOCPU3INTIPCRECVCOM_j	CPU1TOCPU3INTIPCRECVCOM Register	
14h + formula	CPU1TOCPU3INTIPCRECVADDR_j	CPU1TOCPU3INTIPCRECVADDR Register	
18h + formula	CPU1TOCPU3INTIPCRECVDATA_j	CPU1TOCPU3INTIPCRECVDATA Register	
1Ch + formula	CPU3TOCPU1INTLOCALREPLY_j	CPU3TOCPU1INTLOCALREPLY Register	
2000h + formula	CPU2TOCPU3INTIPCSTS_j	CPU2TOCPU3INTIPCSTS Register	
2004h + formula	CPU3TOCPU2INTIPCACK_j	CPU3TOCPU2INTIPCACK Register	
2010h + formula	CPU2TOCPU3INTIPCRECVCOM_j	CPU2TOCPU3INTIPCRECVCOM Register	
2014h + formula	CPU2TOCPU3INTIPCRECVADDR_j	CPU2TOCPU3INTIPCRECVADDR Register	
2018h + formula	CPU2TOCPU3INTIPCRECVDATA_j	CPU2TOCPU3INTIPCRECVDATA Register	
201Ch + formula	CPU3TOCPU2INTLOCALREPLY_j	CPU3TOCPU2INTLOCALREPLY Register	

Complex bit access types are encoded to fit into small table cells. Table 16-94 shows the codes that are used for access types in this section.

Table 16-94. CPU3_IPC_RCV_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.

Table 16-94. CPU3_IPC_RCV_REGS Access Type Codes (continued)

Access Type	Code	Description
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

16.7.8.1 CPU1TOCPU3INTIPCSTS_j Register (Offset = 0h + formula) [Reset = 00000000h]

CPU1TOCPU3INTIPCSTS_j is shown in Figure 16-79 and described in Table 16-95.

Return to the Summary Table.

Bit	Field	Type	Reset	Description
25	IPC25	R	0h	Indicates to the local CPU if the IPC25 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
24	IPC24	R	0h	Indicates to the local CPU if the IPC24 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
23	IPC23	R	0h	Indicates to the local CPU if the IPC23 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
22	IPC22	R	0h	Indicates to the local CPU if the IPC22 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
21	IPC21	R	0h	Indicates to the local CPU if the IPC21 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
20	IPC20	R	0h	Indicates to the local CPU if the IPC20 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
19	IPC19	R	0h	Indicates to the local CPU if the IPC19 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
18	IPC18	R	0h	Indicates to the local CPU if the IPC18 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
17	IPC17	R	0h	Indicates to the local CPU if the IPC17 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
16	IPC16	R	0h	Indicates to the local CPU if the IPC16 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
15	IPC15	R	0h	Indicates to the local CPU if the IPC15 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn

Table 16-95. CPU1TOCPU3INTIPCSTS_j Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
14	IPC14	R	0h	Indicates to the local CPU if the IPC14 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
13	IPC13	R	0h	Indicates to the local CPU if the IPC13 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
12	IPC12	R	0h	Indicates to the local CPU if the IPC12 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
11	IPC11	R	0h	Indicates to the local CPU if the IPC11 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
10	IPC10	R	0h	Indicates to the local CPU if the IPC10 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
9	IPC9	R	0h	Indicates to the local CPU if the IPC9 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
8	IPC8	R	0h	Indicates to the local CPU if the IPC8 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
7	IPC7	R	0h	Indicates to the local CPU if the IPC7 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
6	IPC6	R	0h	Indicates to the local CPU if the IPC6 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
5	IPC5	R	0h	Indicates to the local CPU if the IPC5 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
4	IPC4	R	0h	Indicates to the local CPU if the IPC4 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn

Table 16-95. CPU1TOCPU3INTIPCSTS_j Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	IPC3	R	0h	Indicates to the local CPU if the IPC3 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
2	IPC2	R	0h	Indicates to the local CPU if the IPC2 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
1	IPC1	R	0h	Indicates to the local CPU if the IPC1 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU1.SYSRSn
0	IPC0	R	0h	Indicates to the local CPU if the IPC0 event flag was set by the remote CPU. 0: No IPC0 event was set by the remote CPU 1: An IPC0 event was set by the remote CPU Notes [1] IPC event flags 0 will trigger interrupts in the receiving CPU via the PIPE. Reset type: CPU1.SYSRSn

16.7.8.2 CPU3TOCPU1INTIPCACK_j Register (Offset = 4h + formula) [Reset = 00000000h]

CPU3TOCPU1INTIPCACK_j is shown in Figure 16-80 and described in Table 16-96.

Return to the Summary Table.

CPU3TOCPU1INTIPCACK Register

Offset = 4h + (j * 800h); where j = 0h to 3h

Table 16-96. CPU3TOCPU1INTIPCACK_j Register Field Descriptions

Bit	Field	Type	Reset	Description
31	IPC31	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU3IPCFLG.IPC31 bit. Reset type: CPU1.SYSRSn
30	IPC30	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU3IPCFLG.IPC30 bit. Reset type: CPU1.SYSRSn
29	IPC29	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU3IPCFLG.IPC29 bit. Reset type: CPU1.SYSRSn
28	IPC28	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU3IPCFLG.IPC28 bit. Reset type: CPU1.SYSRSn
27	IPC27	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU3IPCFLG.IPC27 bit. Reset type: CPU1.SYSRSn
26	IPC26	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU3IPCFLG.IPC26 bit. Reset type: CPU1.SYSRSn
25	IPC25	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU3IPCFLG.IPC25 bit. Reset type: CPU1.SYSRSn
24	IPC24	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU3IPCFLG.IPC24 bit. Reset type: CPU1.SYSRSn
23	IPC23	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU3IPCFLG.IPC23 bit. Reset type: CPU1.SYSRSn
22	IPC22	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU3IPCFLG.IPC22 bit. Reset type: CPU1.SYSRSn
21	IPC21	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU3IPCFLG.IPC21 bit. Reset type: CPU1.SYSRSn
20	IPC20	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU3IPCFLG.IPC20 bit. Reset type: CPU1.SYSRSn
19	IPC19	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU3IPCFLG.IPC19 bit. Reset type: CPU1.SYSRSn

Table 16-96. CPU3TOCPU1INTIPCACK_j Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
18	IPC18	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU3IPCFLG.IPC18 bit. Reset type: CPU1.SYSRSn
17	IPC17	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU3IPCFLG.IPC17 bit. Reset type: CPU1.SYSRSn
16	IPC16	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU3IPCFLG.IPC16 bit. Reset type: CPU1.SYSRSn
15	IPC15	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU3IPCFLG.IPC15 bit. Reset type: CPU1.SYSRSn
14	IPC14	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU3IPCFLG.IPC14 bit. Reset type: CPU1.SYSRSn
13	IPC13	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU3IPCFLG.IPC13 bit. Reset type: CPU1.SYSRSn
12	IPC12	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU3IPCFLG.IPC12 bit. Reset type: CPU1.SYSRSn
11	IPC11	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU3IPCFLG.IPC11 bit. Reset type: CPU1.SYSRSn
10	IPC10	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU3IPCFLG.IPC10 bit. Reset type: CPU1.SYSRSn
9	IPC9	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU3IPCFLG.IPC9 bit. Reset type: CPU1.SYSRSn
8	IPC8	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU3IPCFLG.IPC8 bit. Reset type: CPU1.SYSRSn
7	IPC7	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU3IPCFLG.IPC7 bit. Reset type: CPU1.SYSRSn
6	IPC6	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU3IPCFLG.IPC6 bit. Reset type: CPU1.SYSRSn
5	IPC5	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU3IPCFLG.IPC5 bit. Reset type: CPU1.SYSRSn
4	IPC4	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU3IPCFLG.IPC4 bit. Reset type: CPU1.SYSRSn
3	IPC3	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU3IPCFLG.IPC3 bit. Reset type: CPU1.SYSRSn
2	IPC2	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU3IPCFLG.IPC2 bit. Reset type: CPU1.SYSRSn
1	IPC1	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU3IPCFLG.IPC1 bit. Reset type: CPU1.SYSRSn
0	IPC0	R-0/W1S	0h	Writing 1 to this bit, will clear CPU1TOCPU3IPCFLG.IPC0 bit. Reset type: CPU1.SYSRSn

16.7.8.3 CPU1TOCPU3INTIPCRECVCOM_j Register (Offset = 10h + formula) [Reset = 00000000h]

CPU1TOCPU3INTIPCRECVCOM_j is shown in Figure 16-81 and described in Table 16-97.

Return to the Summary Table.

Refelects the value in CPU1TOCPU3IPCSENDCOM Register

Offset = 10h + (j * 800h); where j = 0h to 3h

Figure 16-81. CPU1TOCPU3INTIPCRECVCOM_j Register

Table 16-101. CPU2TOCPU3INTIPCSTS_j Register Field Descriptions

Bit	Field	Type	Reset	Description
31	IPC31	R	0h	Indicates to the local CPU if the IPC31 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
30	IPC30	R	0h	Indicates to the local CPU if the IPC30 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
29	IPC29	R	0h	Indicates to the local CPU if the IPC29 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
28	IPC28	R	0h	Indicates to the local CPU if the IPC28 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
27	IPC27	R	0h	Indicates to the local CPU if the IPC27 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
26	IPC26	R	0h	Indicates to the local CPU if the IPC26 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn

Table 16-101. CPU2TOCPU3INTIPCSTS_j Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
25	IPC25	R	0h	Indicates to the local CPU if the IPC25 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
24	IPC24	R	0h	Indicates to the local CPU if the IPC24 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
23	IPC23	R	0h	Indicates to the local CPU if the IPC23 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
22	IPC22	R	0h	Indicates to the local CPU if the IPC22 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
21	IPC21	R	0h	Indicates to the local CPU if the IPC21 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
20	IPC20	R	0h	Indicates to the local CPU if the IPC20 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
19	IPC19	R	0h	Indicates to the local CPU if the IPC19 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
18	IPC18	R	0h	Indicates to the local CPU if the IPC18 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
17	IPC17	R	0h	Indicates to the local CPU if the IPC17 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
16	IPC16	R	0h	Indicates to the local CPU if the IPC16 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
15	IPC15	R	0h	Indicates to the local CPU if the IPC15 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn

Table 16-101. CPU2TOCPU3INTIPCSTS_j Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
14	IPC14	R	0h	Indicates to the local CPU if the IPC14 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
13	IPC13	R	0h	Indicates to the local CPU if the IPC13 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
12	IPC12	R	0h	Indicates to the local CPU if the IPC12 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
11	IPC11	R	0h	Indicates to the local CPU if the IPC11 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
10	IPC10	R	0h	Indicates to the local CPU if the IPC10 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
9	IPC9	R	0h	Indicates to the local CPU if the IPC9 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
8	IPC8	R	0h	Indicates to the local CPU if the IPC8 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
7	IPC7	R	0h	Indicates to the local CPU if the IPC7 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
6	IPC6	R	0h	Indicates to the local CPU if the IPC6 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
5	IPC5	R	0h	Indicates to the local CPU if the IPC5 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
4	IPC4	R	0h	Indicates to the local CPU if the IPC4 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn

Table 16-101. CPU2TOCPU3INTIPCSTS_j Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	IPC3	R	0h	Indicates to the local CPU if the IPC3 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
2	IPC2	R	0h	Indicates to the local CPU if the IPC2 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
1	IPC1	R	0h	Indicates to the local CPU if the IPC1 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Reset type: CPU2.SYSRSn
0	IPC0	R	0h	Indicates to the local CPU if the IPC0 event flag was set by the remote CPU. 0: No IPC0 event was set by the remote CPU 1: An IPC0 event was set by the remote CPU Notes [1] IPC event flags 0 will trigger interrupts in the receiving CPU via the PIPE. Reset type: CPU2.SYSRSn

16.7.8.8 CPU3TOCPU2INTIPCACK_j Register (Offset = 2004h + formula) [Reset = 00000000h]

CPU3TOCPU2INTIPCACK_j is shown in Figure 16-86 and described in Table 16-102.

Return to the Summary Table.

Chapter 17

Embedded Real-time Analysis and Diagnostic (ERAD)

This chapter describes the features and operation of the embedded real-time analysis and diagnostic (ERAD) module. The ERAD module enhances the debug and system analysis capabilities of the device. The debug and system analysis enhancements provided by the ERAD module are implemented external to the CPU. The ERAD module consists of the enhanced bus comparator (EBC) units, and the system event counter (SEC) units. The EBC units are used to generate hardware breakpoints, hardware watch points, and other output events. The SEC units are used to analyze and profile the system. The ERAD module is accessible both by the debugger and the application software, which significantly increases the debug capabilities of many real-time systems, especially in situations where the debugger is not connected.

17.1 Introduction

The ERAD module is shown in Figure 17-1.

The ERAD enhances the debug and system analysis capabilities of the device external to the CPU. The ERAD module further expands this capability to provide additional hardware breakpoints, hardware watch points, and counters for profiling, as well as other advanced features. The ERAD module can be utilized by the debugger, and also by the application software. For many real-time systems, it is not always possible to connect a debugger and perform an intrusive debug. Under these situations, the user's code has the ability to set up and control the ERAD module to debug and profile the system without disturbing the end application.

Refer to the data sheet for the number of enhanced bus comparator (EBC) units and system event counter (SEC) units. The EBC units monitor buses and generate output events. The SEC units can be used with EBC units to profile and analyze the system. These units are described in detail in the following sections.

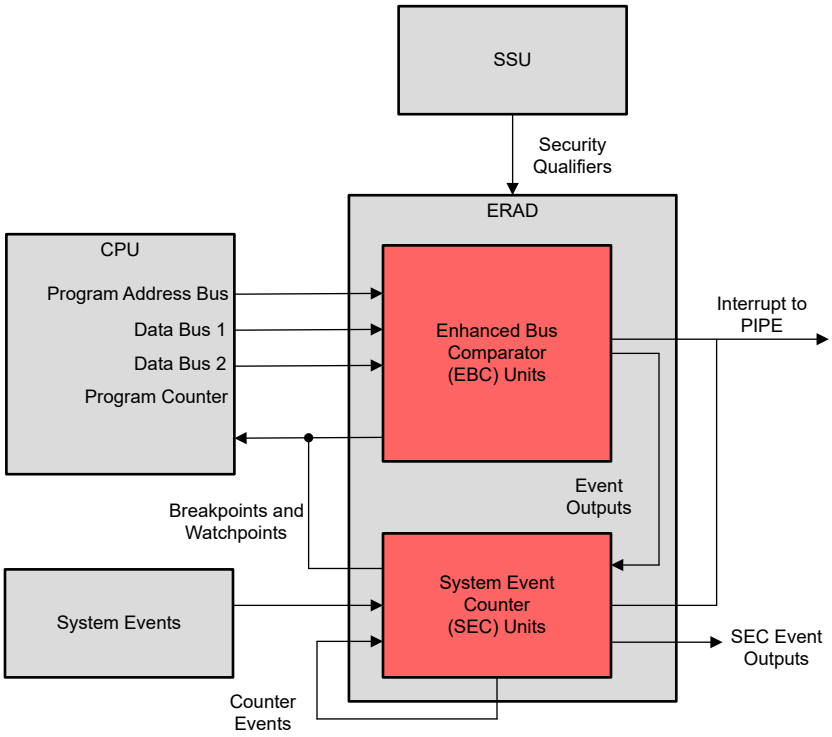

Figure 17-1. ERAD Overview

17.2 Enhanced Bus Comparator Unit

The Enhanced Bus Comparator (EBC) units connect to the CPU using a direct memory interface. This includes the program address and data buses, the data address, write and read data buses, debug qualifiers for memory access, and the ability to set breakpoints, watch points, and trace points on the CPU. Typically, the EBC is owned and controlled by the debugger application (for example, Code Composer Studio™ IDE). A user application running on the CPU can also configure and use the EBC units to generate events and interrupts for real-time diagnostic purposes. Note that ownership is exclusive—the debugger and application software cannot simultaneously control an EBC unit. For more information on EBC unit ownership, see Section 17.5.

The EBC units have the following capabilities:

- Generate hardware breakpoints
- Generate hardware watch points
- Generate trace tags for instruction fetch matches
- Monitor data address and read and write buses
- Generate event outputs that can be used by other modules.
- Generate interrupts and non-maskable interrupts
- Monitor program counter for currently executing instruction

The following features are not supported by the EBC units:

- Chained breakpoints
- Ability to monitor RTDMA transfers

Each EBC unit has the capability to monitor a range of addresses by defining masks and generating outputs based on greater than, less than, or equal events.

The EBC units can also be used with the System Event Counter (SEC) units for system or code profiling and analysis purposes.

17.2.1 Enhanced Bus Comparator Unit Operations

The following operations are supported by each EBC unit:

- Hardware Breakpoints: The EBC unit generates a break point tag when the specified instruction address is accessed on the program address bus. When the instruction reaches the DECODE-2 (D2) stage of the pipeline, the CPU is halted.
- Watch Points: A watch point detects a read or write to specified locations in data memory, and halts the CPU. Unlike hardware breakpoints, watch points do not have precise timing for halting the CPU—this is entirely dependent on the current state of the CPU pipeline. The CPU halts at the next interruptible boundary.
- Program Trace: Program traces are very similar to hardware breakpoints. The difference here is that instead of halting the CPU, a program trace generates an interrupt when the instruction reaches the D2 stage of the pipeline. If the instruction is discarded in the fetch buffer due to discontinuity, no interrupt is generated.
- Data Trace: A data trace is similar to a watch point, except that a data trace generates an interrupt instead of halting the CPU on an access to the specified data memory.

Note that hardware breakpoints only halt the CPU if a debugger is connected. If EBC or SEC is owned by application, no breakpoint or watch point can cause a halt on the CPU, even if EBC_CNTL.HALT is programmed to '1'.

17.2.2 Stack Qualification

Within the EBC, there is direct access to the stack pointer which can detect stack overflow scenarios. To configure the stack overflow detection:

1. Set register EBC_CNTL.STACK_QUAL = 1
2. Set register EBC_CNTL.BUS_SEL = 0x1
3. Set register EBC_CNTL.COMP_MODE = 0x4

17.2.3 Event Masking and Exporting

The events generated by different EBC units can be combined using OR and AND logic to generate new events as required, see Figure 17-2. There are AND and OR combinations that can be exported using masks to suppress undesired events. These events can be configured to generate an interrupt. The AND and OR events are also available as inputs to the system event counter unit for event counting and system profiling.

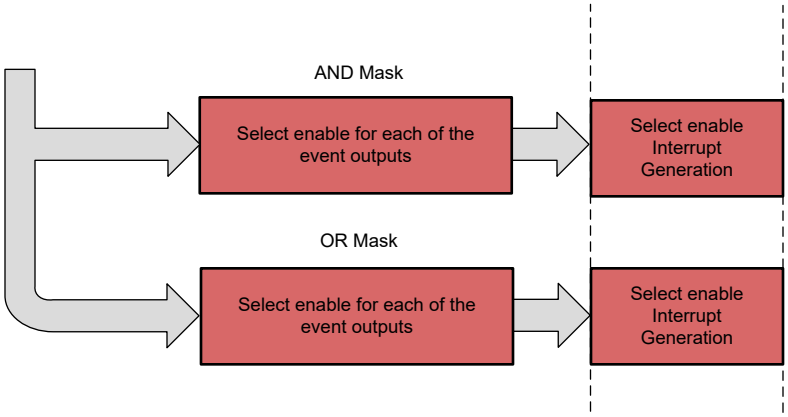

Figure 17-2. EBC Units Event Masking

To use the AND and OR masks:

1. Configure the EVENT_AND_MASK and OR_EVENT_MASK registers to select the desired EBC unit outputs for any of the available four masks.
2. To enable an interrupt for the configured mask, write 1 to the corresponding bit in the AND_MASK_CTL or OR_MASK_CTL register.
3. To use the mask output as an input to the system event counter unit, configure the SEC_INPUT_SEL1 register with the mux value for the desired mask. The input mux values are listed in Section 17.3.1.4.

For example, to generate a real-time interrupt on MASK1 when EBC units 2, 3, AND 6 events are triggered, write 0x26 to EVENT_AND_MASK, and then write 0x1 to AND_MASK_CTL[INTERRUPT].

17.3 System Event Counter Unit

The SEC units provide system profiling, analysis, and debug capability. The SEC units contain counters that can enhance the debug and profiling process in various types of system scenarios such as:

- Profiling code segments
- Counting duration between specified memory reads and writes
- Counting system events (such as interrupts)
- Counting duration between system events
- System timer
- Measuring the number of wait states in code segments
- Measuring the maximum amount of time spent in between a pair of events, measured over multiple iterations
- Chaining counters to link events or create larger counters

Furthermore, the SEC unit has the capability to:

- Function as a counter capable of counting:
  - Any of the match events generated by the EBC units.
  - Events generated by the EBC units. These events can be used to start and stop the counting.
  - System events including the interrupts to the interrupt controller, and timer interrupts. These system events can be used to start and stop the counting.
  - More information on the input sources for the SEC units can be found in Section 17.3.1.4.
- Generate an interrupt or a watch point if the count reaches a reference value.
- Perform counter operation in one of the following two modes:
  - Duration mode: The counter counts the CPU cycles as long as the event is active.
  - Event mode: The counter counts only the positive edge of the event signal. This is effectively counting the number of times the event transitions from inactive to active.

17.3.1 System Event Counter Modes

The following are the operating modes of the SEC unit. The counters are initialized to zero when the SEC module receives a reset input signal, and always count up.

- Continuous Count: In this mode, the counter continues to count as specified by the input selector. The counter can count the CPU cycles without any events selected. In this mode, the module can be used as a software-controlled SYSCLK counter. Continuous mode is active when SEC_CNTL.START_STOP_MODE and SEC_REF are both set to 0.
- Timer Mode Count: In this mode, the counter counts up to a set reference value, defined in the SEC_REF register. Upon reaching the reference value, the counter generates an event that can send an interrupt to the CPU or generate a watch point. The RST_ON_MATCH bit in the SEC_CNTL register configures the counter to either continue incrementing or reset when a match event occurs.
- Start-Stop Count: In this mode, two events are configured to act as start and stop indicators to the counter. The counter commences counting only when the defined start event occurs. The counter then continues to count up until the stop event occurs. Once the first start event has occurred, further start events are ignored until the stop event occurs.

In any of the counter modes of operation, there is a possibility that the 32-bit counter value overflows. If an overflow occurs, the counter value resets to zero and continues to count up, and the OVERFLOW bit in the SEC_STATUS register is set high. The OVERFLOW bit remains high until either the counter is reset, or the application writes 1 to the OVERFLOW bit of the SEC_STATUSCLEAR register.

17.3.1.1 Counting Active Levels Versus Edges

The SEC units can be configured to either count active levels or edges of the selected inputs.

Each SEC unit has eight inputs from the EBC units and many inputs from other events in the device. Each SEC unit can be configured to count any of the input events or just count up on every cycle. For example, if an input event occurs and is active for 25 cycles, the SEC unit counter increments only by 1 in event mode; whereas in the duration mode, the counter increments by 25.

17.3.1.2 Max and Min Mode

Max and min mode is also supported by the SEC units. This mode allows the user to detect the maximum and minimum count that has occurred during various count iterations in start-stop mode. For example, a user can set up the counter in the start-stop count mode to count the duration of a critical code loop. Every time the stop event occurs and the counter stops, the counter value is checked against the current MAX_COUNT and MIN_COUNT present in the register. If the new value is greater, then the MAX_COUNT register is updated. Similarly, if the current count is lesser than the MIN_COUNT, then the new value is loaded on to the MIN_COUNT register. The counter always resets to zero at the stop event and is ready to start counting on the next start event. Therefore, the MAX_COUNT contains the maximum number of cycles that occurred between the start and stop condition over many iterations. The MIN_COUNT register would show the minimum number of cycles.

17.3.1.3 Cumulative Mode

The SEC units can be used to yield the cumulative count over several start and stop events. In this mode the, unlike Max and Min mode, the counter does not reset due to a stop event. Instead it stops counting and resumes counting when a start event occurs. in cumulative count mode, the MAX_COUNT and MIN_COUNT is not valid.

17.3.1.4 Input Signal Selection

The SEC inputs can be selected from various signals from in the system to enable debug and system analysis. Figure 17-3 shows the SEC inputs. Each event selector MUX can select from various signals on in the system. These signals are shown in Table 17-1.

17.3.2 Reset on Event

Resetting the counters on external events is also possible. Additionally all the counter event outputs are applied back to each of counter input MUX, which selects the event that can be used as a reset input. When enabled, an active high on the reset input causes the counter to reset. This gives a powerful feature that allows setting up threshold monitors. This can be used to flag an interrupt or a watch point, if the distance between two events crosses a certain threshold.

17.3.3 Operation Conditions

The SEC units count accurately only when the CPU is operating in normal conditions. If the counters are running and capturing the CPU cycles while the CPU is controlled through the debugger to single-step through the code, then the result can differ from when the CPU was executing the code in normal conditions.

17.4 Program Counter Trace

The Program Counter (PC) Trace module can be used to keep track of PC discontinuities or jumps, as a means to trace an entire program execution sequence over a period of time. When trace is completed or stopped, trace data can be read out using a debugger and analyzed to reconstruct the code execution sequence. The PC Trace module provides multiple modes and controls to govern when to trace and when not to trace. The trace module is tightly coupled with the Enhanced Bus Comparator, the System Event Counter Unit, and certain critical system level event signals.

Trace data is stored in an addressable memory buffer that can be read by software or a debugger. The trace data stored in this buffer includes additional status information on trace validity that can be used to correctly reconstruct the code execution system. For each discontinuity, two PC values are stored: the source of the discontinuity, and the destination. Figure 17-4 illustrates the operation of the PC trace module. The trace buffer is a circular buffer with overflow: when the buffer becomes full, new trace data is written starting from the top of the buffer, and an overflow status bit is set.

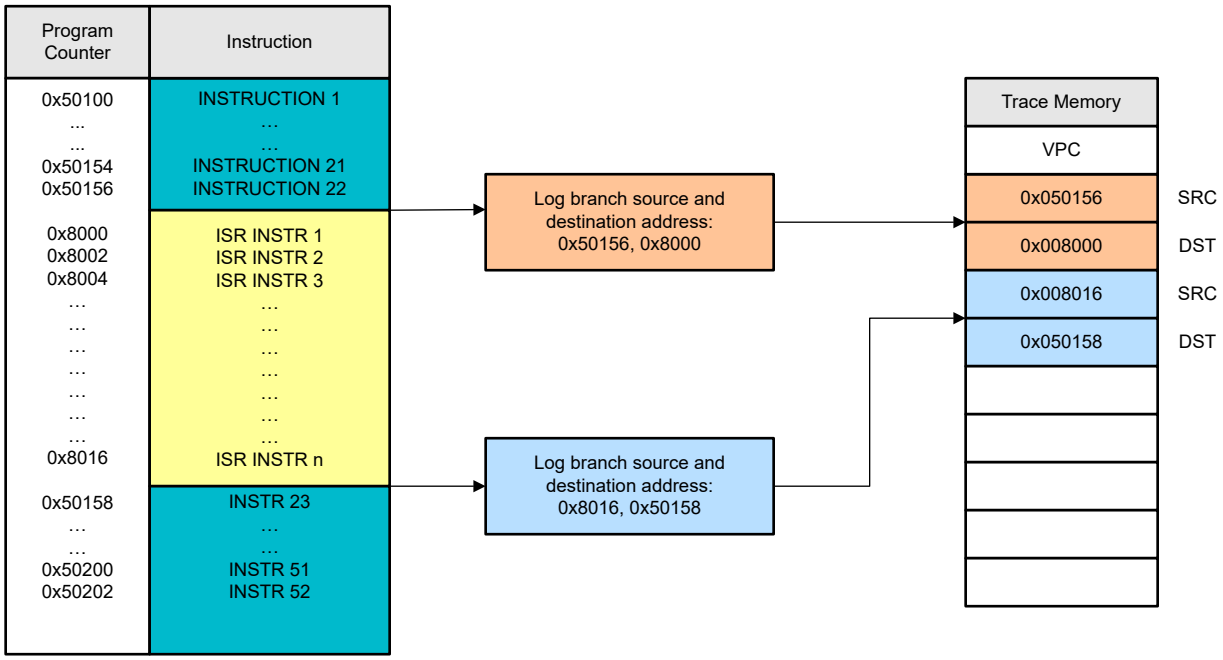

Figure 17-4. PC Trace Operation

17.4.1 Functional Block Diagram

Figure 17-5 describes the device PC trace architecture. The trace module is tightly coupled with the CPU, and receives the current program counter (VPC), program address (PAB), and various qualifying signals from the CPU interface. The Trace core captures these values whenever a PC discontinuity (for example, branch operation) is detected. The PC Trace module interfaces with the SSU. The SSU provides security sideband data needed to prevent unauthorized trace information from being exposed in trace memory. The PC Trace module interfaces with the Enhanced Bus Comparator Unit and System Event Counter Unit, providing the ability to select events from these units as triggers to start a trace, stop a trace, or determine the bounding conditions for a windowed trace operation.

The Trace Core qualifies trace source and destination addresses, and stores these addresses sequentially in the trace memory buffer. Additionally, the Trace Core can generate hit events every time a new trace is stored in the memory buffer; this event signal is connected to the ERAD counter block so that the number of entries in the buffer can be tracked. This counter value can in turn be used to create a STOP event at a predefined threshold.

Note

The Trace Core generates a trace hit event for a discontinuity arising from a speculative instruction fetch, even if the fetched instruction does not reach the execution phase in the CPU pipeline. As a result, the BUFFER_FULL signal can be set prematurely due to a speculative prefetch. The user can always safely discard the oldest discontinuity pair present in the memory buffer when a full buffer is detected, to mitigate this scenario.

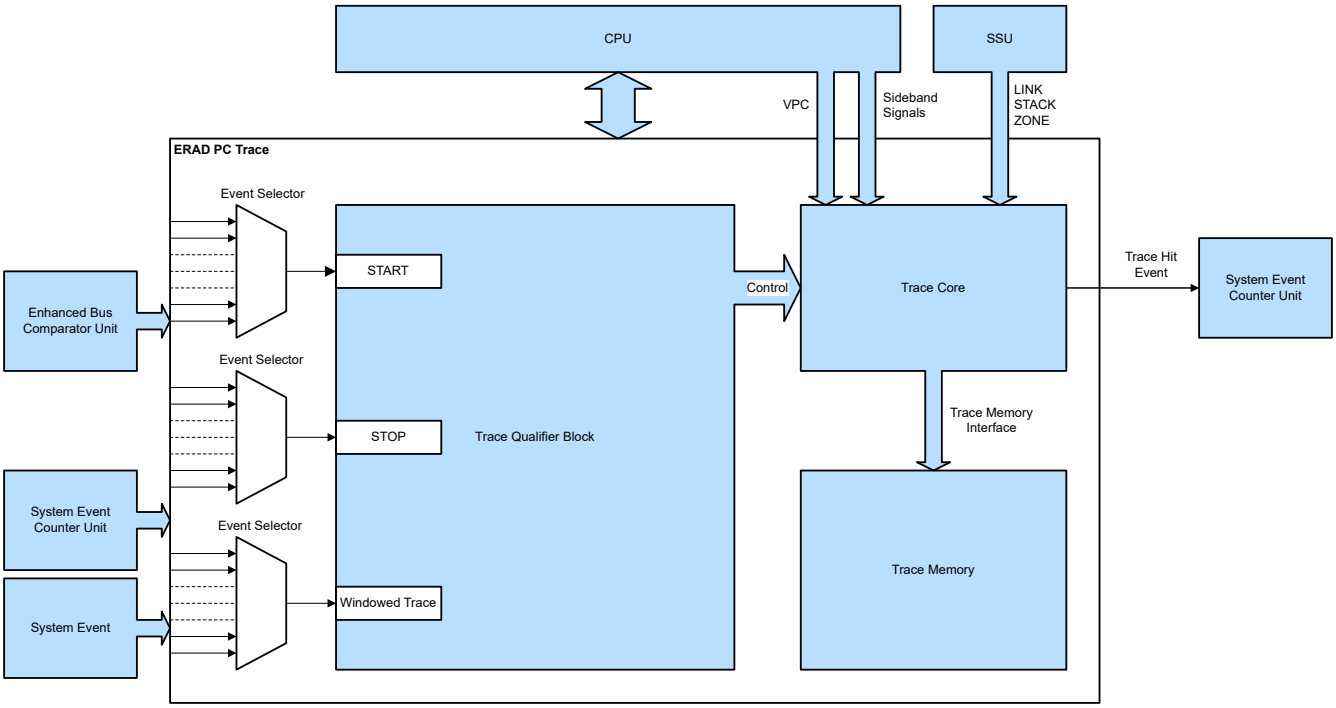

Figure 17-5. PC Trace Block Diagram

17.4.2 Trace Qualification Modes

There are three modes of trace qualification available:

1. Normal mode: In this mode, trace is enabled without any qualifiers. Trace control happens purely through software writing to the PCTRACE_GLOBAL register. When operating PC Trace in normal mode, The PCTRACE_LOGPC_SOFTENABLE captures the program counter value at the point when PCTRACE_GLOBAL.EN is set to 1, and the PCTRACE_LOGPC_SOFTDISABLE register captures the program counter value at the point PCTRACE_GLOBAL.EN is set to 0.
2. Windowed Trace mode: In windowed mode, PC Trace can be activated or stopped based on the value of a signal coming from the Event Bus Comparator, System Event Counter, or other system events. The WINDOWED_INP_SEL field in the PCTRACE_QUAL1 register specifies the input signal used to qualify PC Trace operation in windowed mode. By default trace is active when the input signal is high and inactive when the input signal is low; this behavior can be reversed by setting the PCTRACE_QUAL1.WINDOWED_INP_INV bit high.
3. Start-Stop mode: In this mode, one input signal starts the PC trace operation, and a different input signal stops the trace operation. Event Bus Comparator signals, System Event Counter signals and other system event signals can be used as inputs to start or stop the PC Trace. The START_INP_SEL and STOP_INP_SEL fields in the PCTRACE_QUAL2 register specify the input signals used to qualify PC Trace operation in start-stop mode. Once a start event arrives and PC trace operation begins, the PC Trace module ignores all further start events until a stop event is received. Trace start and stop operations are triggered on the rising edge of the input event; this behavior can be reversed by setting the START_INP_INV and STOP_INP_INV bits in the PCTRACE_QUAL1 register.

To set the PC Trace operation mode, write to the TRACE_MODE bit in the PCTRACE_QUAL1 register.

17.4.2.1 Trace Input Signal Conditioning

The PC Trace module provides input conditioning options for signals that are used to qualify operation in Start-Stop or Windowed modes. For each of these (START, STOP, WINDOWED), there is a two-stage synchronizer for asynchronous input signals, and an inverter. The PC Trace input conditioning options are controllable using the PCTRACE_QUAL1 register with the following bits:

- WINDOWED_INP_INV: This bit inverts the input signal for Windowed trace mode selected in WINDOWED_INP_SEL. When set to 1, the trace operation starts on the falling edge of the input, and stops the rising edge of the input. When this bit is set to 0, the trace operation starts on the rising edge of the input, and stops on the falling edge of the input.
- START_INP_INV: This bit inverts the input signal for trace START operation selected in PCTRACE_QUAL2.START_INP_SEL. When set to 1, the trace operation starts on the falling edge of the input. When this bit is set to 0, the trace operation starts on the rising edge of the input.
- STOP_INP_INV: This bit inverts the input signal for trace STOP operation selected in PCTRACE_QUAL2.STOP_INP_SEL. When set to 1, the trace operation stops on the falling edge of the input. When this bit is set to 0, the trace operation stops on the rising edge of the input.

Figure 17-6 describes the signal conditioning circuit available for each input qualifier signal.

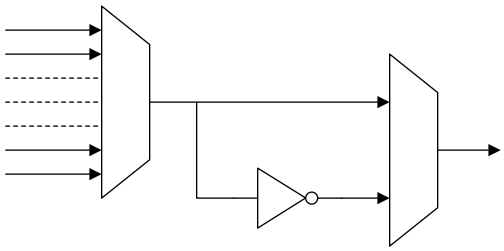

Figure 17-6. Trace Qualifier Input Conditioning Circuit

17.4.3 Trace Memory

PC Trace memory is a 32-bit-wide read-only memory buffer that holds each 31-bit PC value, together with a security BLOCKED status bit. The memory-map section of the device data sheet specifies the size of the PC Trace memory buffer. Trace memory entries are stored in pairs: the discontinuity source and destination addresses. Table 17-2 describes the bit field structure of each trace memory entry.

Table 17-2. Trace Memory Entry Bit Fields

Bits	Field Name	Description
31:1	PROGRAM_COUNTER	Program counter source or destination address value where discontinuity occurred
0	BLOCKED	1 = PROGRAM_COUNTER[31:1] is invalid due to security permissions 0 = PROGRAM_COUNTER[31:1] is valid

Note

For addresses that are blocked due to security zone restrictions, the PROGRAM_COUNTER value is set to 0.

Trace memory is intended solely for debug purposes and does not have parity or Error Correction Code (ECC) support.

17.4.4 PC Trace Software Operation

An example software sequence to perform PC Trace operation is as follows:

1. Initialize the PC Trace module by writing 1 to PCTRACE_GLOBAL.INIT. The trace initialize operation resets the buffer pointer and overflow flags, and clears the values of the PCTRACE_LOGPC_SOFTENABLE and PCTRACE_LOGPC_SOFTDISABLE registers.
2. Start the PC Trace operation by writing 1 to PCTRACE|_GLOBAL.EN.
3. Execute the desired code sequence to be profiled.
4. Stop the PC Trace operation by writing 0 to PCTRACE_GLOBAL.EN. This step is optional, as the PC Trace buffer can be read while trace operation is active.
5. To determine if there are valid entries in the trace buffer and how many:
   a. Examine the buffer pointer by reading PCTRACE_BUFFER.PTR. If the pointer value is 0, then no discontinuities have been detected since PC Trace was initialized. A non-zero value indicates the number of locations in the buffer that contain valid entries. For instance, PTR = 4 indicates that locations 0, 1, 2, and 3 contain valid entries (SRC, DST, SRC, DST).
   b. Examine the BUFFER_FULL bit in the PCTRACE_BUFFER register. If BUFFER_FULL = 1, then the following possibilities apply:
      - If PTR = 0, then the buffer is simply full and contains the maximum number of entries possible.
      - If PTR > 0, then a buffer overflow has occurred. The value of PTR indicates by how many entries the buffer has overflowed: this is a circular buffer.
6. Read PCTRACE_LOGPC_SOFTENABLE (and optionally PCTRACE_LOGPC_SOFTDISABLE) if needed to determine the bounding addresses of the trace operation, in case the code sequence being traced does not begin or end at a discontinuity boundary (for example, partial function trace).
7. Trace discontinuities are recorded in the trace buffer in pairs (SRC, DST). Use this data to reconstruct the code execution sequence. While reading the trace buffer, be sure to examine the BLOCKED status bit to confirm the validity of each trace entry.

17.4.5 Trace Operation in Debug Mode

PC Trace is designed to capture data while the CPU is executing code. Debugger operations such as halt, step, and manual PC modification can compromise the reliability of PC trace data collection. Only use or interpret PC Trace data in the context of a continuous CPU run without debugger interruption or intervention.

CPU execution does not preclude debugger operation of the PC trace module if the debugger owns the PCTRACE module. While the CPU is running and executing code, the debugger can read and write PC Trace registers, read the trace buffer, and enable or disable PC trace operation. Debugger can update the PC Trace registers if debugger owns PCTRACE module. The PCTRACE_LOGPC_SOFTENABLE and PCTRACE_LOGPC_SOFTDISABLE registers record the start and stop PC addresses to provide accurate trace window information during manual trace starts or stops triggered by writing to the PCTRACE_GLOBAL.EN bit.

17.5 ERAD Ownership, Initialization, and Reset

Although the features of the ERAD module are typically used by the debugger, user applications can also take advantage of the capabilities to monitor buses and generate interrupts and events. ERAD's features such as the EBC, SEC, ANDOR, and PCTRACE have a dedicated ownership scheme and register set for every instance. There are three possible ownership scenarios:

1. The user elects to completely hand over the ownership of the ERAD features to the application software or the debugger.
2. Only the current owner of the module (application code or debugger) is allowed to use the module at a given time. Either the debugger or application own a particular EBC/SEC block to ensure no conflicts arising.
3. There is no ERAD features. In this mode, both application code and debugger can access the module at any given time. It is critical for the software, both on the application side and the debugger side, to resolve any potential conflicts. An example scenario in this mode can be for the debugger to use some of the EBC and SEC units, while the application software uses the remaining units.

The ERAD module initializes the internal states and all registers to the initial/reset states under the following conditions:

- At power-on-reset (POR)
- With DCON and SYSRSN
  - Debug logic disconnected when the debugger owns the module
  - Functional reset when application owns the module

17.5.1 Feature Level Ownership

For each feature such as the EBC, SEC, Masks, and PCTrace an ownership scheme is implemented by specifying if the debugger or application owns the feature. By default the Owner register belongs to no owner and ZONE register is set to ZONE0.

Scenario 1 Basic use: Debugger Ownership

1. Write to OWNER register of 0x01 is permitted since existing value was 0x00
   - Writes to OWNER register is successful and ZONE register remains at 0
2. Read back and check if OWNER register is 0x01
3. Debugger can configure and start using the block
   - If application accidentally writes to OWNER register, accesses are blocked during this time
4. Debugger completes work and a write to the OWNER register of 0x00 releases this block
   - Writes are successful and OWNER register is 0x00
   - ZONE register is 0x0000

Scenario 2: Application Ownership

1. Write to OWNER register of 0x2 is permitted since existing value was 0x00
   - Writes to OWNER register is successful and ZONE register is loaded with ZONE ID from CPU
   - Write to this register emerged from ZONE2, so ZONE register gets loaded with 0x2
2. Read back and check if OWNER register is 0x2
3. Application code from ZONE2 can configure and start using the block
   - If application code from another ZONE tries to write to OWNER register, the write is blocked
   - If debugger tries to write to OWNER register, the write is blocked
   - Application code from ZONE2 completes work and writes OWNER register to 0x00
4. Writes are successful and OWNER register becomes 0x00

These two scenarios are the flow of the feature level ownership. For application code to identify whether the application has ownership a simple read to the Semaphore register can indicate the status. Debugger has no notion of ZONES, only CPU does.

17.5.2 Feature Access Security Mechanism

Ownership	Registers Writable?	Registers Readable?
No Owner	No	Ownership register alone is always readable by debugger and the application
Debugger	Writes are allowed by debugger. Writes are blocked by application.	Reads are allowed by debugger. Application reads are blocked, returns all zero data.
Application	Writes are blocked by debugger. Writes are allowed by application if access and owner come from same ZONE. In addition if CPU1.LINK2 owns the block and access originated from CPU1.LINK2. Writes are blocked if access and owner from different ZONE or if SROOT owns block but access originated from non CPU1.LINK2 location.	Reads are allowed by debugger only if corresponding owner ZONE is enabled for debug. Application reads are allowed if access and owner come from same ZONE. In addition if CPU1.LINK2 owns block and access originated from CPU1.LINK2. Reads are blocked by application if access and owner come from different ZONEs or if CPU1.LINK2 owns block but access originated from non CPU1.LINK2 location.

Note

ERAD security is based on the granularity of ZONEs only (Not LINKs). Only exception is the CPU1.LINK2 (security root LINK). If an ERAD feature is owned by CPU1.LINK2, then there is no security check performed and all the valid accesses generate triggers irrespective of which zone performed that access (Any matching access from ZONE0, ZONE1, ZONE2 or ZONE3 can generate a trigger if that particular feature is owned by CPU1.LINK2).

Table 17-3. EBC Specific Function and Security Mechanism

Ownership	All EBC Event Except Hardware Breakpoints(1)
Application (CPU1.LINK2 not configured)	• EBC events are generated when the EBC is owned by a given ZONE and CPU is executing code from the same ZONE • EBC events are NOT generated when the EBC is owned by a given ZONE and CPU is executing code from a different ZONE, irrespective of that ZONE being enabled for debug or not.
Application (CPU1.LINK2)	• EBC events are ALWAYS generated when the EBC is owned by CPU1.LINK2 • CPU code execution ZONE is ignored • ZONE debug enables are also ignored
Debug	• EBC events are generated when CPU is executing code from a ZONE that is enabled for debug • If an environment to debug everything like the CPU1.LINK2 equivalent in Debug mode is needed, enable all the zones for debug

(1) Hardware breakpoints tags are generated always irrespective of ownership/security. CPU takes care of handling the breakpoints accordingly.

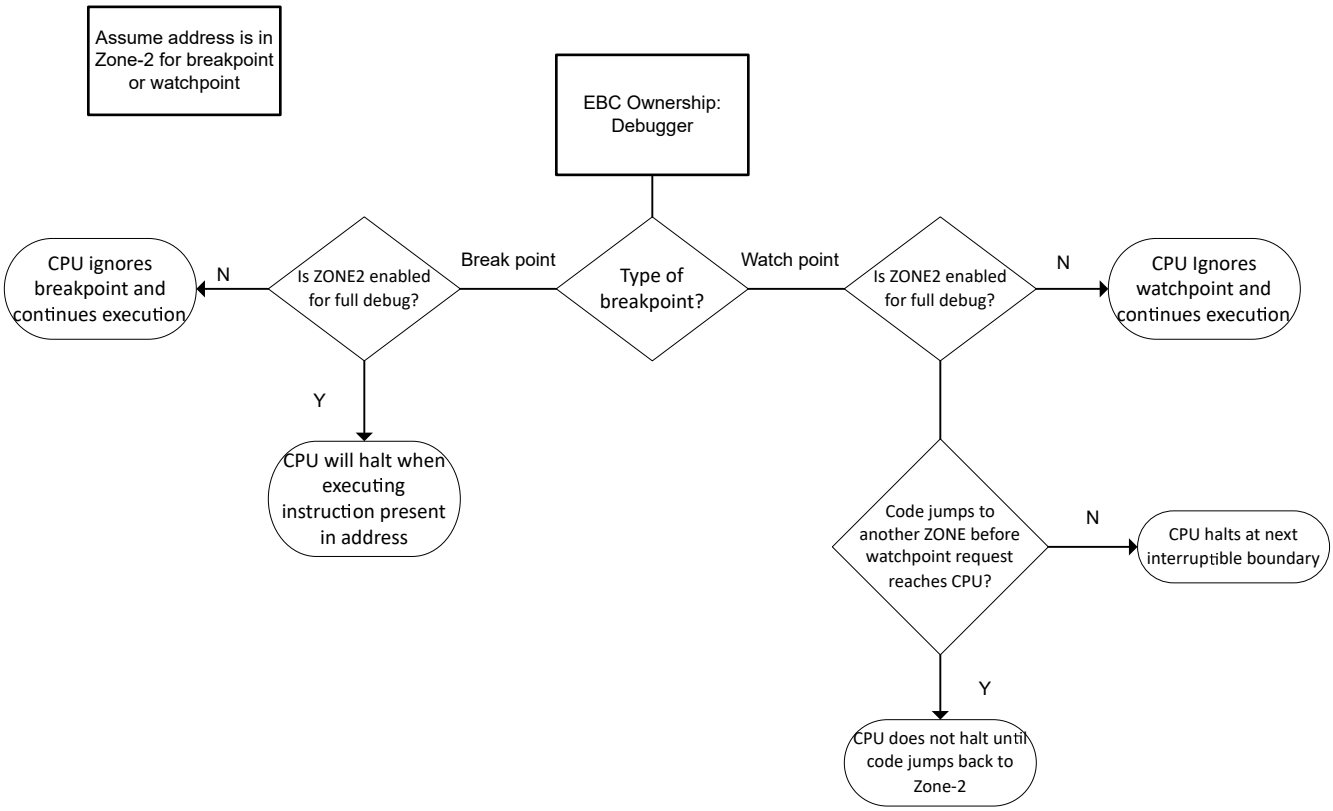

Figure 17-7. EBC Owned by Debugger

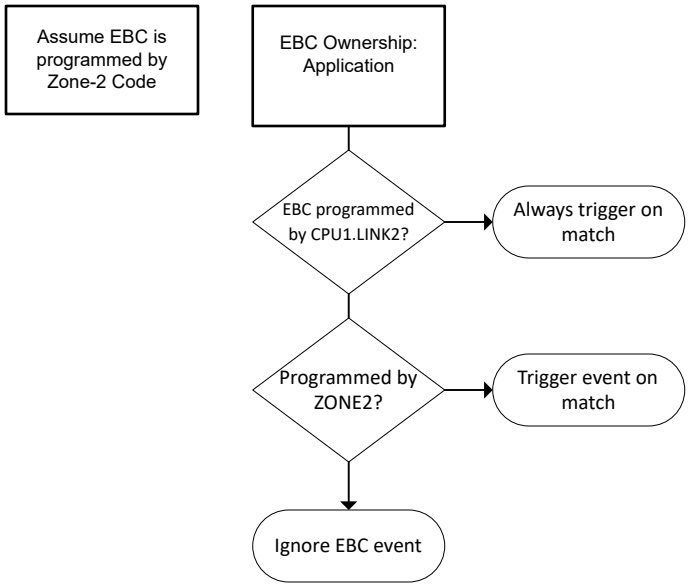

Figure 17-8. EBC Owned by Application

17.5.3 PC Trace Access Security Mechanism

Irrespective of which zone is executing code, trace values are always dumped when there is discontinuity. Only when memory is read back security restrictions apply. In a nutshell if application code is reading the trace memory, only the discontinuities stored for the zone from where code is executing is sent out and other are blocked. If the ZONE for which the discontinuity is stored is enabled for debug, then the trace memory is readable.

For example, if reads are initiated to the trace RAM by code originating from SROOT LINK, then all the entries present in the trace RAM are accessible, irrespective of which zone that discontinuity belonged to. Otherwise based on security permissions, either the discontinuity address is read if allowed or is zeroed out with the blocked status bit set.

17.6 ERAD Programming Sequence

The ERAD module can be used to set hardware breakpoints and hardware watch points. The programming sequences to set hardware breakpoints, hardware watch points, or to use the timers to profile and analyze the system are described in this section. The same sequences can be used by both the debugger software and user application code.

Refer to the Driverlib example projects in C2000Ware for JavaScript files to configure the ERAD module. Example projects are also available to showcase the usage of these script files. These examples can be found in the driverlib\\examples\erad directory under the C2000Ware installation directory.

17.6.1 Hardware Breakpoint and Hardware Watch Point Programming Sequence

The programming sequence is identical when using the EBC units, regardless of whether the debug software or the application is programing the units. A typical programming sequence for a unit is:

- Read and make sure the ownership is set as expected; if not, acquire the ownership before proceeding further if required.
- Make sure the unit is in IDLE mode.
- Set up the address reference, mask, bus select and stop bits.
- Enable the corresponding module bit in the global enable register.
- Once the usage is completed, write 1 to clear the EVENT_FIRED sticky bit. This takes the module back to the enabled state.

The example programming sequences for hardware breakpoints and hardware watch points are:

Set a hardware breakpoint on address 0x201000:

- Read OWNER to confirm ownership.
- Read EBC_STATUS to confirm the module is in IDLE state.
- Write 0x0 to EBC_MASKH/MASKL.
- Write 0x201000 to EBC_REFH/REFL.
- Enable the corresponding module bit in the EBC enable register.

Set a hardware watch point on read of addresses from 0x121010 to 0x12101F:

- Read OWNER to confirm ownership.
- Read EBC_STATUS to confirm the module is in IDLE state.
- Write 0xF to EBC_MASKH/MASKL.
- Write 0x121010 to EBC_REFH/REFL.
- Enable the corresponding module bit in the global enable register.

Set a hardware watch point on write to address 0xFF10101A:

- Read OWNER to confirm ownership
- Read EBC_STATUS to confirm the module is in IDLE state
- Write 0x0 to EBC_MASKH/MASKL
- Write 0xFF10101A to EBC_REFH/REFL
- Enable the corresponding module bit in the global enable register.

17.6.2 Timer and Counter Programming Sequence

The programming sequence is identical when using the SEC units, regardless of whether the debug software or the application is programing the units. Typical programming sequence for a unit is:

- Read and make sure the ownership is set as expected. If not, acquire the ownership before proceeding further if required.
- Make sure the unit is in IDLE mode.
- Set up the counter reference, counter registers (clear/reset if a clean start is required).
- Enable the corresponding module bit in the enable register.
- Once the usage is completed, write 1 to clear the EVENT_FIRED sticky bit. This takes the module back to the enabled state.

Set up a free running counter:

- Read and make sure the ownership is set as expected. If not, acquire the ownership before proceeding further, if required.
- Read SEC_STATUS to confirm that the module is in IDLE state.
- Write 0x0 to CNT_INP_SEL_EN.
- Write 0x0 to SEC_CNTL.
- Enable the module in the SEC_CNTL.EN register.

Set up the counter to count the duration spent between addresses 0x1000 and 0x1210:

- Read and make sure the ownership is set as expected. If not, acquire the ownership before proceeding further, if required.
- Read SEC_STATUS to confirm that the module is in IDLE state.
- Set up the EBC unit 1 to generate an event for VPC = 0x1000.
- Set up the EBC unit 2 to generate an event for VPC = 0x1210.
- Enable the module in the SEC_CNTL.EN register.

Set up the counter to count the number of times a function at address 0x2010 is called and fire an interrupt if this count reaches 0x300:

- Read and make sure the ownership is set as expected. If not, acquire the ownership before proceeding further, if required.
- Read SEC_STATUS to confirm that the module is in IDLE state.
- Set up the EBC unit 1 to generate an event for VPC = 0x2010.
- Write 0x300 SEC_REF.
- Enable the counter in the EDGE_LEVEL, and also allow the counter to generate an interrupt when the count matches the reference. This is achieved by writing 0x42 to SEC_CNTL.
- Enable the module in the SEC_CNTL.EN register.

Complex bit access types are encoded to fit into small table cells. Table 17-7 shows the codes that are used for access types in this section.

Table 17-7. ERAD_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

17.8.1.1.1 GLBL_ERAD_ID Register (Offset = 0h) [Reset = 62090000h]

GLBL_ERAD_ID is shown in Figure 17-9 and described in Table 17-8.

Return to the Summary Table.

Table 17-20. SEC_CNTL_j Register Field Descriptions

Bit	Field	Type	Reset	Description
31-11	RESERVED	R	0h	Reserved
10	FREE_RUN	R/W	0h	0 = CPU halt is ignored by the SEC counter all times 1 = CPU halt with stop the counter until CPU is halted. i.e. If counter gets enabled by SEC to count and CPU is halted then the counter stops counting until CPU is in halt state. Once the CPU resumes execution out of halt mode, then Counter will be active again. Reset type: ERAD_RESET
9	RST_INP_SEL_EN	R/W	0h	This bit decides if the reset input is enabled or not. Setting this to 1 will cause the counter to reset to zero whenever the selected reset input goes active high. No event will be generated when the counter is reset. Setting this bit to 0 will cause the counter to ignore the reset inputs. Reset type: ERAD_RESET
8	CNT_INP_SEL_EN	R/W	0h	0 = Disable using the input_select register for the count input. The counter will always count CPU cycles. 1 = Enable using the input_select register for the count input. The counter will count the event selected by the count input register. Reset type: ERAD_RESET
7	NMI_EN	R/W	0h	0 = Will assert ERAD interrupt 1 = Will assert NMI Reset type: ERAD_RESET

Table 17-20. SEC_CNTL_j Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6	INTERRUPT	R/W	0h	This bit decides whether the counter module will generate interrupt when count value matches the reference. Note that the event outputs will always be generated regardless of the state of this bit. 0 SEC unit will not cause any action towards the CPU. 1 SEC unit will assert NMI/ERAD interrupt based on NMI_EN bit when the counter value matches the reference value. Reset type: ERAD_RESET
5	HALT	R/W	0h	This bit decides whether the counter module will generate a watchpoint to the CPU when the count value matches the reference. Note that the event outputs will always be generated regardless of the state of this bit. 0 SEC unit will not cause any action towards halting the CPU. 1 SEC unit will assert Halt request rest of the matching accesses(Watchpoint). These can cause the CPU to HALT Reset type: ERAD_RESET
4	RST_ON_MATCH	R/W	0h	This bit is used to decide whether the counter will reset to zero once it reaches the reference value. 0 Counter will stay at the reference value and the counter will go to COMPLETED state and further counting will be stopped. 1 The counter will reset to zero once it reaches the match value and will stay enabled. Reset type: ERAD_RESET
3	START_STOP_CUMULATIVE	R/W	0h	This bit decides whether the counter counts to give the cumulative cycle count for 'n' number of successive start stop events or clears the counter on very stop event to record the MAX_COUNT across successive start stop sequences. 0 When in START_STOP mode counter gets cleared on every stop event and MAX_COUNT records the max value 1 When in START_STOP mode counter keeps counting between successive start stop events to generate a cumulative count w/o clearing the counter on any stop events. MAX_COUNT register is invalid when this bit is set. Reset type: ERAD_RESET
2	START_STOP_MODE	R/W	0h	This bit is used to decide whether the counter will count in the START_STOP mode or not. 0 Normal count mode. The counter will not depend on the START and STOP events 1 This is the START-STOP mode of the counter. The counter will start counting only after the START input has been asserted. It will continue to count the selected event till the STOP event is seen. Reset type: ERAD_RESET
1	EDGE_LEVEL	R/W	0h	This bit is used to decide whether the counter will count the level of the event or the edge of the event. 0 Counter will increment the count as long as the count input is active high. 1 The counter will count only on the rising edge of the count input. Note: If the selected counter input signal was already high when SEC{#}_INPUT_SEL1.CNT_INP_SEL gets configured, the counter will increment by 1 when enabled, even if edge counting mode is selected Reset type: ERAD_RESET
0	EN	R/W	0h	0 = SEC Disabled 1 = SEC Enabled Reset type: ERAD_RESET

17.8.1.1.14 SEC_STATUS_j Register (Offset = 448h + formula) [Reset = 00000000h]

SEC_STATUS_j is shown in Figure 17-22 and described in Table 17-21.

Return to the Summary Table.

9-8	STATUS	R	0h	SEC unit status 00 Idle 10 Enabled 11 Completed Reset type: ERAD_RESET
7-2	RESERVED	R	0h	Reserved
1	OVERFLOW	R	0h	This is a sticky bit which gets set every time the counter overflows and wraps around after reaching 0xffffffff. This bit will get cleared by writing a '1' to OVERFLOW of SEC_STATUSCLEAR register. Note : If hardware is trying to set OVERFLOW bit at the same cycle software is trying to clear, then the clear will be ignored and status will remain set Reset type: ERAD_RESET
0	EVENT_FIRED	R	0h	This is a sticky bit which gets set every time the SEC unit generates a match event. This will be used by software to figure out whether this SEC module fired an event or not. This bit will get cleared by writing a '1' to EVENT of SEC_STATUSCLEAR register. Note : If hardware is trying to set EVENT_FIRED bit at the same cycle software is trying to clear, then the clear will be ignored and status will remain set Reset type: ERAD_RESET

17.8.1.1.15 SEC_STATUSCLEAR_j Register (Offset = 44Ch + formula) [Reset = 00000000h]

SEC_STATUSCLEAR_j is shown in Figure 17-23 and described in Table 17-22.

Return to the Summary Table.

Chapter 18

Data Logger and Trace (DLT)

This chapter describes the features and operation of the data logger and trace (DLT) module. The DLT module enhances real-time non-intrusive data-logging and system analysis capabilities of the device. Filtering out what is data-logged, using generated ERAD start commands to initiate data-logging and stop commands, using DLT start and stop commands for data-logging, and time stamping when or where in the program code data is being logged are the main features of the DLT. The DLT is accessible by the RTDMA and CPU.

18.1 Introduction

For critical CPU run-time content the data logger and trace (DLT) module has the ability to control what data gets logged, when to start data-logging, and the size of the data to capture. Critical run-time content can include any information that needs to be monitored as the content is computed. When data-logging the DLT is non-intrusive meaning there is no impact to run-time or CPU core behavior. The ability to view intermediate values of computation in a critical task, such as a control loop, can help users fine-tune the loop. The DLT module can generate interrupts to the interrupt controller, issue RTDMA transfer requests, and interact with ERAD event triggers.

The DLT can collect, time-stamp, prefilter, export, and do real-time and post analysis of data.

18.1.1 Features

The DLT has the following capabilities:

- Logging critical run-time content referred to as data logging
- Analyze program execution sequence using tags referred to as trace
- Logging is non-intrusive to run-time/CPU core behavior
- Flexible logging capability for extended period of time by transferring data to external memory or short period of time to on-chip memory
- Logging of registers can be up to 32-bit size, depending on the size on the variable to be logged
- Each CPU has DLT support
- Time stamping records time difference from last logged variable and can time stamp the IPC timer's count
- RTDMA triggering
- Global, FIFO and timer interrupt generation

18.1.2 DLT Related Collateral

Foundational Materials

- C29x Academy - Data Log and Trace (DLT)

18.1.3 Interfaces

The DLT has the following interfaces:

- System Clock
- System Reset
- CPU
- ERAD
- IPC Timer
- Peripheral data bus
- RTDMA
- CPU interrupt flags

18.1.3.1 Block Diagram

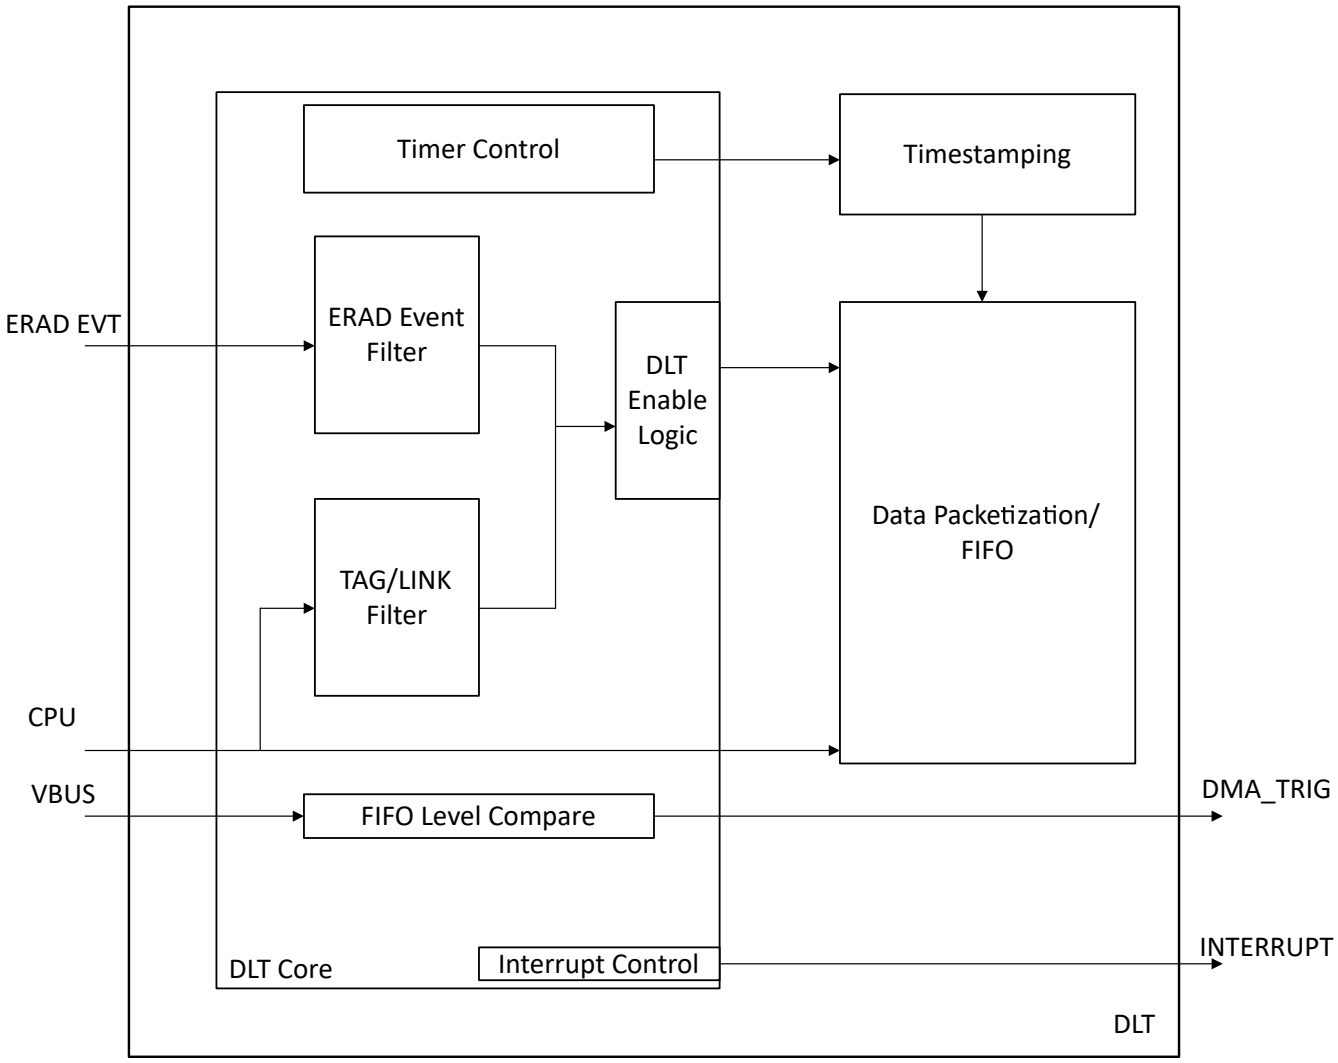

Figure 18-1. DLT Block Diagram

18.2 Functional Overview

The DLT operates mainly between the CPU and RTDMA. The DLT monitors data logging information coming from the CPU, applies filters on what data to log and stores the data in the local FIFO. When enough data is collected, the DLT requests a CPU Interrupt and a RTDMA transfer request, either of which must take contents out of the FIFO and store the contents on on-chip RAM/External RAM or export the contents out using the FSI for example. The user can choose to enable either the RTDMA or CPU Interrupt to perform this task.

18.2.1 DLT Configuration

DLT module can be configured with the steps as followed:

1. What capture mode to configure the DLT?
   a. With a TAG or DLREG entry, the mode can be configured to capture the program counter or time of the event.
2. When did an entry occur? (Only when capture mode is set to track time of event)
   a. Time-stamping provides the CPU the time when data logging started and when the DLREG has stored value.
3. Where to start and end data logging? (TAG Filter)
   a. TAG filters help with indicating to the CPU where to start and end data logging.
   b. In addition to TAG filters, ERAD start/end filters can also be used.
4. How to export the data log? (FIFO construction)
   a. Internal on-chip memory
   b. External memory
5. What code region is enabled for data log? (LINK Filter)

The filtering unit provides security configurations to specify what links can be available for data-logging before production and during development. The filtering unit can regulate throughput from DLT FIFO buffer by attaching a tag to a variable or register to capture the value for data logging.

The DLT_EN configuration acts as a global enable for DLT, whereby all components of the DLT module can be completely disabled. All configurations of DLT discussed in upcoming sections are part of DLT_CORE_REGS and are only configurable from CPUx.LINK2.

The data bus is used to access registers and FIFO memory in DLT. DLT configurations are located under DLT_CORE_REGS. The internal FIFO is available in both FIFO mode (FIFO_REGS), and memory mode (FIFO_MEM) for debug.

If there is an incorrect access by CPU, error is generated, and access is dropped. In case of incorrect debugger access, no error is generated but access is dropped. The below table describes the access protections and permissions for the registers belonging to DLT.

Table 18-1. DLT Data Bus Apertures

Register Map	CPU Access Protection	Debugger Access Permissions	DMA Access Permission
DLT_CORE_REGS	Only LINK2 of corresponding CPU can write/read	Zone corresponding to LINK2, if enabled for debug can write/read	No Access
FIFO_REGS	LINKs of corresponding CPU can write/read	ZONE corresponding to LINK enabled by SSU, is enabled for debug read No write access	LINKs enabled by DMA can read. No write accesss
FIFO_MEM	Not writable	ZONE corresponding to LINK enabled by SSU, is enabled for debug read. No write access	LINKs enabled by DMA can read. No write access

Note

Access protections/permissions implemented inside SSU. DMA access configurations implemented in DMA.

18.2.1.1 LINK Filter

The purpose of this filter is security. To prevent data being logged by one user, that is, one LINK, from being visible to another, a LINK qualifier is sent with each CPI (Co-processor interface) access from the CPU. DLT has a bit to enable/disable each LINK'ss DLT entries from being captured into the internal FIFO in the LINK_EN register. This helps control visibility of sensitive data.

For example, if data logging all sections of code belonging to a CPU is required then enabling all LINKs for the CPU would be the correct configuration.

This is also a feature that allows different data logging controls during development time versus production, as data logging is useful during both. Application code may want to disable data logging of certain regions before production.

In both cases, DLT code remains the same and the DLT instructions stay embedded in the user code.

18.2.1.2 TAG Filter

The purpose of this filter is to regulate throughput via the DLT FIFO, and to divide Data Logging within a LINK into multiple sections.

Each Data Log set is preceded by a TAG identifier. This TAG can be masked with a reference and used to enable/disable entries into the internal FIFO. This also helps in preventing overflow of Data Logging FIFO, by prioritizing the different Data Logging sections. This feature must be enabled using TAG_FILTER_EN, which is a static configuration.

If TAG_FILTER_EN && ((TAG & TAG_FILTER_START_MASK) = TAG_FILTER_START_REFERENCE), data logging is started.

If TAG_FILTER_EN && ((TAG & TAG_FILTER_END_MASK) = TAG_FILTER_END_REFERENCE), data logging is stopped.

18.2.1.3 ERAD Event Trigger

The purpose of this filter is to regulate throughput via the DLT FIFO, via Hardware events. ERAD generates SEC and EBC events, derived from processing system events.

DLT has a bit for each ERAD input to DLT, separately for START and STOP, and a bit to enable the ERAD filtering logic, ERAD_FILTER_EN. By default, if LINK and TAG filters are enabled, Data is Logged. When ERAD_FILTER_EN is high, if ERAD stop event is triggered, Data Logging is paused until the next ERAD start event.

Table 18-2. ERAD START and END MASK Lower 32 Events

4-31	Reserved

18.2.1.4 Concurrent FILTERING modes

LINK FILTER is a necessary condition for data logging in FIFO. If a LINK is masked, data logging is disabled irrespective of other filters. However, in case of any overlap between TAG FILTER and ERAD FILTER, or if both TAG/ERAD START/STOP events are triggered at the same time, the START command takes precedence and data logging is allowed.

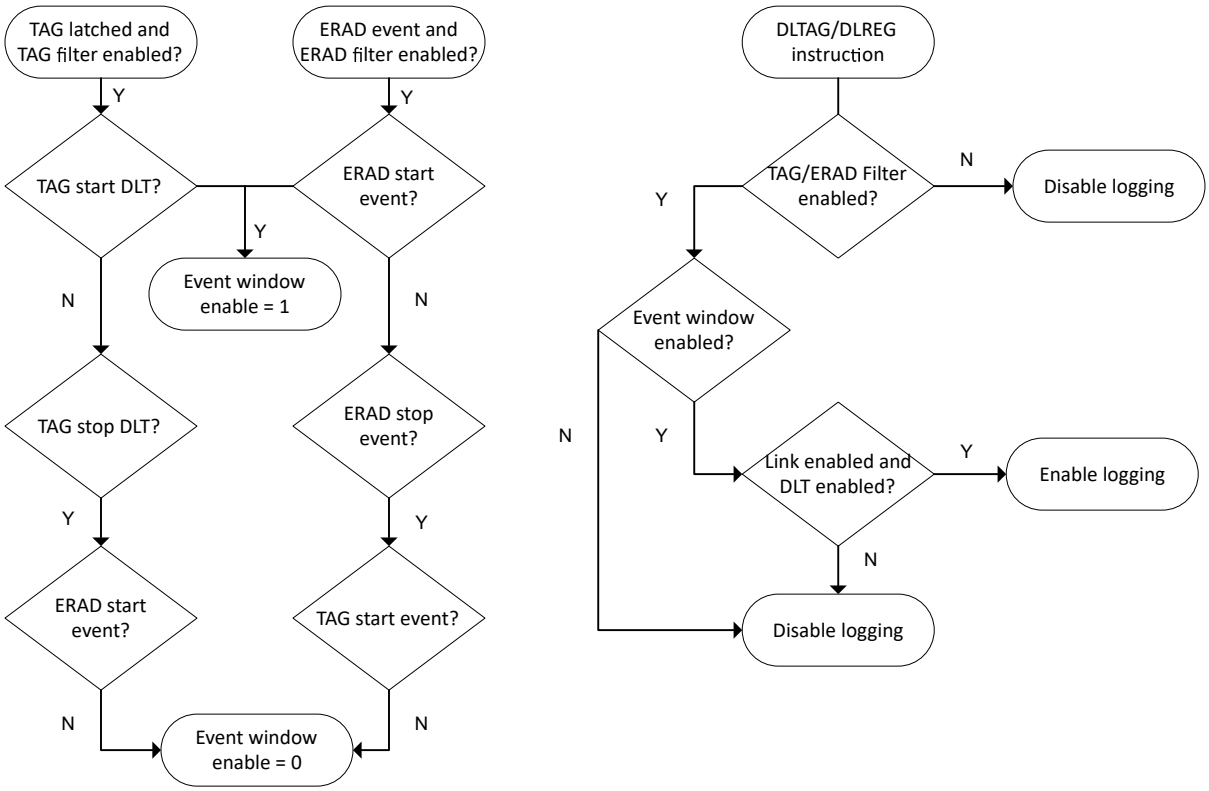

Figure 18-2. Data Log Decision Chart

If a START event from either TAG or ERAD is received, a windowed signal is set and cleared when a STOP event occurs from either TAG or ERAD. When repeated START events without a STOP event occur, the repeated start events have no meaning.

Filter enables are not expected to change dynamically in the middle of data logging, and take effect after a few cycles. The user must give sufficient time before inserting DLT instructions, while re-configuring.

Note

It is recommended to use a non zero reference TAG. In the case where TAG is a 0 and TAG reference is 0, and TAG filter is enabled, the DLT will have a false start condition.

18.2.2 Time-stamping

As part of DLT, time-stamping is done internally for every entry in the FIFO. This is a simple scheme of continuously running counters, and not clock time. Since the structure of DLT code is such that every data set comes with TAG identifier, two counters are used, one for TAGs and the other for REGs. The time-stamping structure has been split to give higher granularity to the TAG inputs.

TIMER1 is exported with TAGS and is a 45 bit timer. TIMER1's value is derived from the 64-bit IPC timer outside DLT.

The TIMER2 is exported with REGS. This indicates the time-difference from the last reported TAG value. TIMER2 is an internal counter.

Also, from a use case perspective, the relative time-stamp of data (REGs) with respect to TAGs gives a clear indication of the code performance for the section. To compare across different sections of code, the absolute values from TAGs can be compared.

TIMER 2 has reset controls that stop the timer and resets the timer to 0. In addition, whenever a new TAG is received and passes through the filters, the TIMER1 overflow, TIMER2 overflow and TIMER2 counter are also reset, so that the relative value is now computed from the newly received TAG.

In case there is a data logging section that is interrupted and a new TAG is received, the relative time and TAG filtering of the subsequent entries is calculated based on Interrupt TAG. It is recommended to use TAG filtering at the start of every ISR or function call, followed by the registers to be data logged.

18.2.3 FIFO Construction

All DLT entries, both TAG and REG, that have passed the FILTERs are recorded in the FIFO. The FIFO is constructed as 64 bit rows, with the REG/TAG, TIMESTAMP/PC source and Overflow Indicators.

Each packet received is entered on a new row. The C29x CPU and DLT both support TAG of size 8 bits and 16 bits. Always allocate 16 bits for the TAG in the FIFO irrespective of the incoming TAG size. The maximum size of REG supported in the C29x CPU is 64 bits, but only up-to 32 bits are supported in DLT. The 64-bit REG is not supported.

DLT Capture mode static configuration decides whether to capture TIMER/PC value. A packet does not differentiate between them and must be analyzed by the user based on the configuration set. The following tables depict how the raw data stored in the FIFO must be interpreted. The LSB represents whether the data log is a TAG or REG, where TAG = 1 and REG = 0.

Table 18-4. FIFO 16-bit TAG Structure

Higher 32 Bits (FIFO_BUF_H)		Lower 32 Bits (FIFO_BUF_L)			
TIMER1's MSBs	**16-bit TAG Entry (MSBs Padded with Zeros if 8-bit TAG)**	**TIMER1's LSBs**	**TIMER1's Overflow**	**FIFO Overflow**	**TAG**
16 bits [31:16]	16 bits [15:0]	29 bits [31:3]	1 bit [2]	1 bit [1]	1

Table 18-5. FIFO 16-bit PC TAG Structure

Higher 32 Bits (FIFO_BUF_H)		Lower 32 Bits (FIFO_BUF_L)		
Reserved	**TAG Entry**	**Program Counter**	**FIFO Overflow**	**TAG**
16 bits [31:16]	16 bits [15:0]	30 bits [31:2]	1 bit [1]	1

Table 18-6. FIFO 32-bit REG Structure

Higher 32 Bits (FIFO_BUF_H)	Lower 32 Bits (FIFO_BUF_L)			
REG Content	**TIMER2's Count**	**TIMER2's Overflow**	**FIFO Overflow**	**REG**
32 bits [63:32]	29 bits [31:3]	1 bit [2]	1 bit [1]	0

Table 18-7. FIFO 32-bit PC REG Structure

Higher 32 Bits (FIFO_BUF_H)	Lower 32 Bits (FIFO_BUF_L)		
REG Content	**Program Counter**	**FIFO Overflow**	**REG**
32 bits [63:32]	30 bits [31:2]	1 bit [1]	0

In C29x CPU, the minimum instruction is 16-bit size. Hence, the PC always points to a 16-bit word size, and the 0th bit of the PC is irrelevant. The EMIF space in the first device is in the upper 2GB, and is not covered, but you cannot execute code from EMIF space anyway. Hence, using PC[30:1] as a Trace source is used. Also note that in PC mode, there is no Time entry in FIFO. Hence, no TIMER overflow is indicated. To read the PC value properly, left shift by 1 yields the correct PC capture.

TAG/REG indication has been kept at bit[0] of the FIFO for ease of software processing. In assembly, the LSB can be ANDed with 1 and an if-else discontinuity can be executed. Moving it elsewhere requires code to an add right-shift operation that you want to avoid. Similarly, TAGs are also preferred to be aligned to 32-bit boundary for ease of software processing, since TAGs are decision making points. To enable this, DLTIME has been split up into lower and higher words, when Capture mode is TIMER.

18.2.3.1 FIFO Interrupt

The FIFO is implemented as a memory and the depth of FIFO is 256. Three interrupts are generated from the FIFO:

- When the FIFO is full and a write is attempted (overflow).
- When a read is attempted with no data in the FIFO (underflow).
- When the number of writes in the FIFO reaches the configured trigger level. This also initiates a RTDMA request, if enabled.

Reading a 1 from the global interrupt status within INT_FLG [INT] indicates that an interrupt was generated from the events.

The FIFO read pointer is incremented on a 32-bit read to FIFO_H register by any of the peripherals.

Cases where FIFO pointers are not incremented, and statuses are not modified:

- If only FIFO_L register is read
- If FIFO_H register is read using lesser than 32-bit access size
- If FIFO is read through FIFO_MEM aperture
- If FIFO is read using Debug Access

18.3.2 DLT Examples

NOTE: These examples are located in the C29SDK installation from ti.com at the following location: mcu_sdk_DEVICE_GPN/examples/driverlib/CORE_IF_MULTICORE/dlt

Cloud access to these examples is available at the following link: dev.ti.com C29SDK Examples.

18.3.2.1 DLT TAG filter example - SINGLE_CORE

FILE: dlt_ex1_datalog_tag.c

This example configures DLT and datalogs four variables MultVar, Current, Speed, Voltage throughout code execution. The DLT contents are read from the DLTFIFO via CPU and transferred to internal memory.

- DLT configured for Time capture mode, tag filter enabled
- In order to use the tag filter, compiler intrinsics are used:
- __builtin_c29_datalog_tag for tag
- __builtin_c29_datalog_write for reg

18.3.2.2 DLT TAG filter example - SINGLE_CORE

FILE: dlt_ex2_dma_fsi_export.c

This example, configures the DLT to data log a single variable within a CPU Timer ISR and export out the DLT contents via FSI. The DMA is used to transfer the contents. When the FIFO reaches a level of 4, the DMA is triggered to transfer contents to FSI TX buffer.

DLT is setup using TAG filter and REGs in order to data log.

- DLT configured for Time capture mode, tag filter enabled
- In order to use the tag filter, compiler intrinsics are used:
- __builtin_c29_datalog_tag for tag

- __builtin_c29_datalog_write for reg

18.3.2.3 DLT ERAD filter example - SINGLE_CORE

FILE: dlt_ex3_datalog_erad.c

This example configures DLT and datalogs four variables MultVar, Current, Speed, Voltage throughout code execution. The DLT contents are read from the DLTFIFO via CPU and transferred to internal memory.

- DLT configured for Time capture mode, ERAD filter enabled
- In order to use the ERAD filter, ERAD is configured in SysCfg:

18.4 DLT Registers

This Section describes the DLT Registers.

18.4.1 DLT Base Address Table

Table 18-9. DLT Base Address Table

Structure	DriverLib Name	Base Address	Frame Applicable	CPU1	CPU2	CPU3	RTDMA1	RTDMA2	HSM	Pipeline Protected
DLT_CORE_REGS	CPUDLT_BASE	0x3001_0000	-	YES	YES	YES	-	-	-	YES
DLT_FIFO_REGS	CPU1DLTFIFO_BASE	0x600F_8000	YES	YES	YES	YES	YES	YES	-	YES
DLT_FIFO_REGS	CPU2DLTFIFO_BASE	0x600F_A000	YES	YES	YES	YES	YES	YES	-	YES
DLT_FIFO_REGS	CPU3DLTFIFO_BASE	0x600F_C000	YES	YES	YES	YES	YES	YES	-	YES

18.4.2 DLT_CORE_REGS Registers

Table 18-10 lists the memory-mapped registers for the DLT_CORE_REGS registers. All register offset addresses not listed in Table 18-10 should be considered as reserved locations and the register contents should not be modified.

Table 18-10. DLT_CORE_REGS Registers

Offset	Acronym	Register Name	Protection
0h	ERAD_START_MASK_L	ERAD Start Mask for Lower 32 lines	
4h	ERAD_START_MASK_H	ERAD Start Mask for Higher 32 lines	
8h	ERAD_END_MASK_L	ERAD End Mask for Lower 32 lines	
Ch	ERAD_END_MASK_H	ERAD End Mask for Higher 32 lines	
10h	TAG_FILTER_START_REF	Tag Filer Start Reference	
14h	TAG_FILTER_START_MASK	Tag Filer Start Mask	
18h	TAG_FILTER_END_REF	Tag Filer End Reference	
1Ch	TAG_FILTER_END_MASK	Tag Filer End Mask	
20h	LINK_EN	Link Enable	
24h	DLT_CONTROL	DLT Control Register	KEY:KEY=0x5a5a
28h	FIFO_CONTROL	FIFO Control Register	
2Ch	TIMER_CONTROL	Timer Control Register	
30h	FIFO_STS	Number of entries in FIFO	
34h	FIFO_PTR	Pointer locations in FIFO	
38h	TIMER2_COUNT	Timer2 Status	
3Ch	INT_FLG	Interrupt Flag	
40h	INT_EN	Interrupt Enable	
44h	INT_FRC	Interrupt Force	
48h	INT_CLR	Interrupt Clear	

Complex bit access types are encoded to fit into small table cells. Table 18-11 shows the codes that are used for access types in this section.

Table 18-11. DLT_CORE_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.

Table 18-11. DLT_CORE_REGS Access Type Codes (continued)

Access Type	Code	Description
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

18.4.2.1 ERAD_START_MASK_L Register (Offset = 0h) [Reset = 00000000h]

ERAD_START_MASK_L is shown in Figure 18-3 and described in Table 18-12.

Return to the Summary Table.

ERAD Start Mask for Lower 32 lines

Figure 18-3. ERAD_START_MASK_L Register

Chapter 19

Waveform Analyzer Diagnostic (WADI)

This chapter discusses the features and functions of the waveform analyzer diagnostic (WADI).

19.1 WADI Overview

The waveform analyzer and diagnostic (WADI) peripheral consists of many useful built in signal analysis support and provides a safety mechanism for the signals. WADI is primarily useful for safety applications where driving switches or capturing signals require an action or a linking of actions to occur if the signal analysis reports any misbehavior.

19.1.1 Features

- Ability to select an input signal from multiple sources (CMPSS, ePWM, Input-XBAR, CLB, ADC) to WADI block and configure trigger to start analysis and perform safety diagnostics on the signals
- Ability to perform different checks as configured:
  - Pulse width measurement
  - Frequency measurement
  - Phase Overlap measurement
  - Dead-band measurement
- Ability to perform checks on individual signal or perform checks between two signals
- Ability to override outputs to a certain state or define a link of output combination based on analysis of signals
- Registers with parity support
- Support for RTDMA trigger and RTDMA acknowledgment

19.1.2 WADI Related Collateral

Foundational Materials

- C29x Academy - Waveform Analyzer Diagnostic (WADI)

19.1.3 Block Diagram

Figure 19-1 shows a block diagram of the WADI.

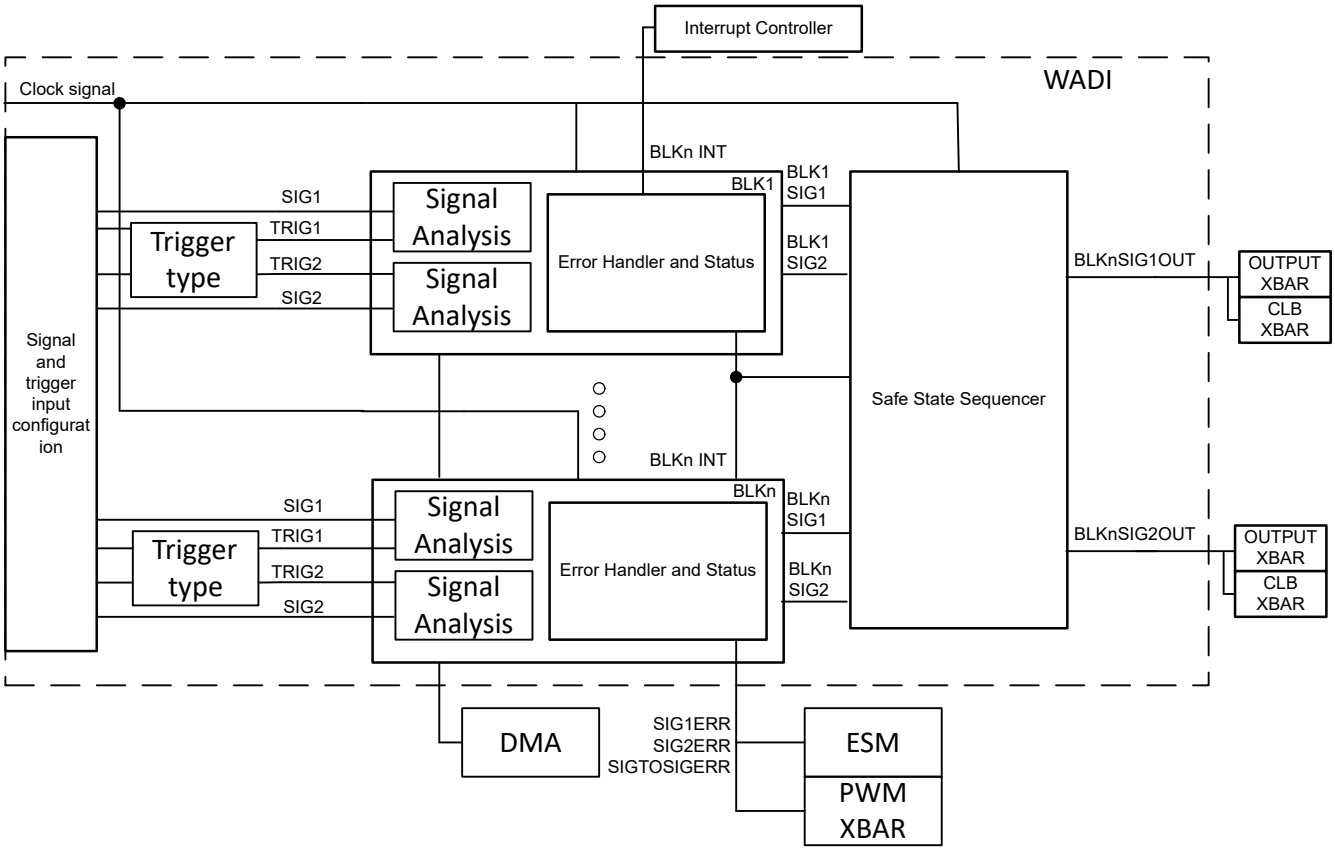

Figure 19-1. WADI Block Diagram

19.1.4 Description

The waveform analyzer diagnostic (WADI) determines the correctness and quality of the underlying real time control system by performing measurements, aggregation and comparison on the input signals. Each input signal is characterized for certain attributes of pulse width, frequency, phase, dead-band and so on. WADI validates the measurements for each signal against a compare value with some error of margin that the signal can still be considered valid. WADI allows comparison of individual signals or signal to signal analysis within a WADI block. There are four WADI blocks for each WADI instance. Each WADI block can monitor up to two signals and perform signal analysis on each.

19.2 Signal and Trigger Input Configuration

The WADI block is flexible in choosing signals to analyze. INPUTXBAR and PWMXBAR are routed to the WADI block (see Figure 19-2). There are two signals (SIG1, SIG2) that can be analyzed and two signals (TRIG1, TRIG2) that are used to start the capture of these signals. Each WADI block has two input signals and two trigger signals. Configuration for SIG1, SIG2, TRIG1, and TRIG2 are done through the BLKCFG register. TRIG1 triggers SIG1 analysis, and TRIG2 triggers SIG2 analysis.

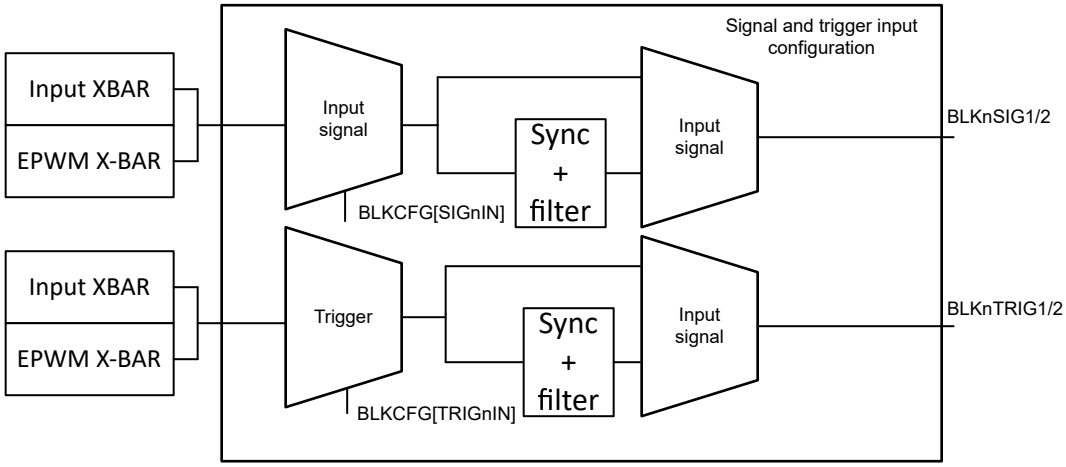

Figure 19-2. WADI Signal Input and Trigger Configuration

19.2.1 SIG1 and SIG2 Configuration

Cross-bar is used to provide flexibility to compare different input signals from various peripherals or external signals. Each WADI block can have access to INPUTXBAR and PWMXBAR for SIG1 and SIG2 respectively which can be configured in the BLKCFG[SIG1IN] and BLKCFG[SIG2IN] register.

SIG1 and SIG2 are the input signals for the WADI blocks. Table 19-1 shows the input sources for SIG1 and SIG2.

- SIG1 and SIG2 are configured independently of each other. Each WADI block has SIG1 and SIG2. For 4 WADI blocks, there are configurations for the 8 inputs (2 input signals per block).
- SIG1 and SIG2 can be configured to be synced and filtered before going to the signal analysis block. There is an added delay of up to 3-4 clock cycles when syncing and using the glitch filter.

Table 19-1. WADI Input Signals

19.2.2 Trigger 1 and Trigger 2

Trigger 1 and trigger 2 are used to apply the start condition for the signal analysis. The triggers have flexibility to use either of the two triggers for a specific WADI block. Table 19-2 shows the trigger selections for TRIG1 and TRIG2, respectively. This allows two entirely different sets of trigger inputs providing flexibility for triggering each SIGx. The trigger for SIG1 and SIG2 can be configured in BLKCFG[TRIG1IN] and BLKCFG[TRIG2IN] registers, respectively.

Table 19-2. WADI Trigger 1 Input Signals

15	INPUTXBAR40	INPUTXBAR56

To start the analysis based on trigger, the configurations need to be complete before the WADI block is enabled.

The start of the signal analysis can be enabled for each of the signal measurement using triggers or if no triggers are configured the start of the first event detection right after the clock is enabled begins the signal analysis. SIG1 and SIG2 have individual configuration of the trigger which are no trigger, hardware trigger, software trigger, or synchronized trigger. Once the event triggers the measurements, the comparisons are continuous until the next trigger. If there is subsequent trigger then the measurement count restarts. If there are pending errors from previous counts, those are not reset, the application code must address the errors. Triggers selectable are categorized in Table 19-4.

Table 19-4. Trigger Types and Trigger Selection per WADI Block Signal

Selection	Trigger Type	Description
0x0	No Trigger (Default)	In this mode right after configuration for check is done on first event of configured type the measurement starts.
0x1	Hardware Trigger	This uses the hardware input from the WADI peripheral to start the measurement of signal.
0x2	Software Trigger	Each WADI block signal has an independent software bit control that the application can use to start the measurement.
0x3	Either Trigger	Whenever either hardware or software event is present the measurement is reset and started again.
0x4	Synchronized Trigger	This is special case when this is configured for signal then the triggers configured for other signal in WADI block is used for starting the measurement, this is useful for the signal to signal comparisons as well as having common trigger for related signals.
0x5-0x7	Reserved	All other configurations are reserved and those default to No trigger condition.

No Trigger condition is used when external trigger is not expected but continuous signal characterization is required. In this case once after WADI clock is enabled the event detection and measurement started. The WADI configurations must be configured before enabling clock. Similarly, if there is need to change the WADI block configuration then the clock must first be disabled followed by configuration change and enable of clock again. In case “No trigger” is set then clock enable acts as trigger, in all other cases detection and measurement waits for trigger.

On revision of settings, if there are stale measurements in WADI block then those are cleared and fresh measurements started for both SIG1 and SIG2. Rewriting the same setting again does not change the status or ongoing waveform measurement.

19.3 WADI Block

19.3.1 Overview

WADI block has multiple modes and types of checks to analyze the input signals. There are dedicated counters to aggregate the number of measurements, counters for pulse width, edges, dead-band and phase overlap. To verify the signals there are comparisons and measurement error events. For cases where simultaneous modes are needed but the modes are exclusive then another WADI block must be used to analyze the signals. For example, pulse width measurement and edge count analysis cannot be used together in the same block. Below descriptions give overview of some of the common hardware components of WADI block

19.3.2 Counters

Each input signal into the WADI Block (SIG1 and SIG2) have independent counters to perform signal analysis for either pulse width measurement or edge count measurement along with signal to signal analysis.

1. Width of the time between two configured edges.
2. Number of signal edges within the fixed time interval to determine the signal frequency.

The counter can start based on the trigger configured in the trigger settings. If there are no triggers configured, and the WADI block is still enabled, the counter begins upon first programmed edge of SIGx.

The counter restarts for next iteration once the pulse width or frequency measurement is completed. Triggers can be programmed such that SIGx within WADI block or multiple signals across WADI blocks can be synchronized together to start the operation using hardware or software triggers. Thus all the SIGx counters in WADI IP can be used as standalone counters and measurements or be synchronized to common event.

In case there is assertion of configured trigger while the measurement is on-going then the respective block restarts the measurement and aggregation. Any errors which are detected in previous cycles are not cleared and those need to be explicitly cleared by the software.

Note

Pulse width and Frequency are mutually exclusive modes hence common counter is used to measure either based on the configuration of width or edge count and corresponding edge/time window details.

Counter for aggregating number of measurements

Each of the SIGx of WADI block has capability to accumulate pulse width and frequency readings. This accumulation is used in multiple ways :

- For Pulse width accumulation the aggregation depicts the total assertion of signal with particular polarity configured within the SIGxCFG[SIGPOL] register. Such a sum is indicative of total energy transferred over number of accumulated readings. The number of readings to accumulate are configurable in the SIGxCFG[NUMAGGR] register. Same accumulator used for frequency reading accumulation.
- This accumulator output and margin can be directly compared to a compare value defined in the register SIGxCMPA/B, SIGxPKCFG, and SIGxAVGCFG. Comparison also provides flexible margin(+/-) to allow for variation between two different types of systems.
- Secondly the average of the accumulated value at the end of the accumulation can also be compared. Given the power of 2 units accumulation the average is based on right shift of the accumulator value in hardware (no complex division is expected in hardware). An independent counter that tracks the number of measurements done on each signal.

Counter for dead band and phase overlap

In addition to individual signal analysis, dead band and phase overlap between two signals can also be done. The WADI block handles the logic to compute the signal to signal differences to perform signal to signal analysis. The dead band and phase overlap checks directly count the time difference between edges of two input waveforms on WADI block, hence separate counter is used for each of these modes. Both of these modes are mutually exclusive and based on check selected.

1. Dead-band: Based on edge type programmed, the distance between SIG1 to SIG2 edge is measured. Only EDGE_TYPE is applicable for this check, EDGE_SPAN is not. Whether to check configured EDGE_TYPE pairs from SIG1 and SIG2 or also check the opposite pairs is configured by DBAND_CHK_TYPE.
2. Phase Overlap: Uses the configuration of EDGE_TYPE similar to Dead-band. The end state of the configured edge is considered as level under review. For example, if SIG1 is configured as rise edge and SIG2 is configured with fall edge then the high “level” assertion of SIG1 simultaneous with low “level” assertion is counted. Normal expectation is that signal that asserted first can also be de-asserted prior to other signal de-assertion, but hardware only considers simultaneous configured level assertions of both signals.

19.3.3 Pulse Width

There are 3 types of measurements associated with pulse width:

1. Pulse width single measurement
2. Pulse width aggregation
3. Pulse width average and peak

19.3.3.1 Pulse Width Single Measurement

- Single pulse width measurement means to validate a single waveform for time width between two programmed edges. The time between two edges of given waveform is measured in terms of input clock to the block. Measurement is based on the configuration of the edge type and edge numbers.
- The pulse width single measurement and pulse width aggregation are mutually exclusive, one can do individual edge-to-edge width check or does sum check. The software configured values come from the same compare registers; hence, only either the individual readings or accumulated readings are compared.
- The WADI block measures the pulse width of the signal waveform. On which edge the counters start is defined in the SIGxCFG[SIG_POL] that can be on rising, falling, or either edge. The SIGxCFG[EDGESPAN] defines how many edges to span to measure the width.
- Figure 19-3 shows a few examples of how to measure a given pulse width. For example, if SIGxCFG[EDGESPAN] = 0x1, the pulse width being measured is from 1 to 2. If SIGx_CONFIG[EDGE_SPAN] = 0x2, the pulse width being measured is from 1 to 3.
- Configuration to span across more than the third edge is possible and provides flexibility for multiphase or multilevel waveforms.

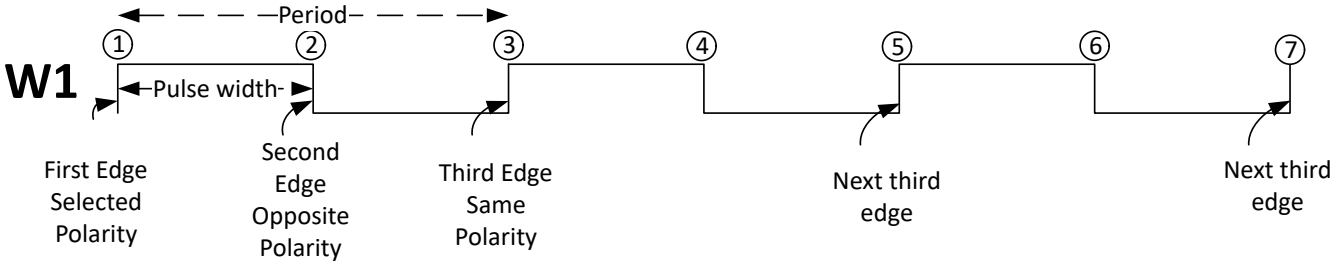

Figure 19-3. Pulse Width Diagram

19.3.3.2 Pulse Width Aggregation

Pulse width aggregation is the accumulated width measurement for configured number of units. For example, pulse width aggregation for every 2nd edge for 32 times. Pulse width aggregation readings are distinct and after one accumulation cycle is over the next one is started without any history of accumulation. However if there is an error in the previous cycle the aggregation results stay until software clears the error.

- SIGxCFG[NUMAGGR] is the register to configure the number of measurements configurable only in terms of power of 2 – 2,4,8,16,32,64.
- If aggregation is enabled, single measurement pulse width can aggregate instead of being independently compared.

19.3.3.3 Pulse Width Average and Peak

WADI block signal analysis can determine both the peak (highest value) and the averaging of the pulse width aggregation (Average of units as power of 2 hence simpler division)

- SIGxCFG[AGGRMODE] register selects the type of check to be enabled whether only aggregate(sum), peak or average or combinations of the same.

19.3.4 Edge Count

To characterize the frequency of a single waveform, WADI counts the number of edges in the prefixed time window set by the SIGxEDGECFG register. To use the edge counter, the SIGxEDGECFG[CNTEN] bit must be set.

- The time window within which the edges are counted is defined with the SIGxEDGECFG[TIMEWNDOW]. The window size is in terms of SYSCLK in which the edges are counted. The time window starts upon event of the configured trigger (start of edge counting) and ends upon lapse of configured window length (edge counting is stopped). The count begins on the edge defined by SIGxCFG[SIGPOL].
- The SIGxCFG[SIGPOL] is useful to start counting specific edge. While SIGxCFG[EDGE_SPAN] allows skipping intermediate edges. For frequency or edge count measurement, the recommended configuration for SIGxCFG[EDGE_SPAN] is 0x2. This captures the second edge from the previous edge detected, which counts the same edge type (that is, rise edge to next rise edge) and measures the frequency of the waveform in the time window. If the SIGxCFG[EDGE_SPAN] is configured greater than 2, then edges counted accordingly skipping intermediate edges.

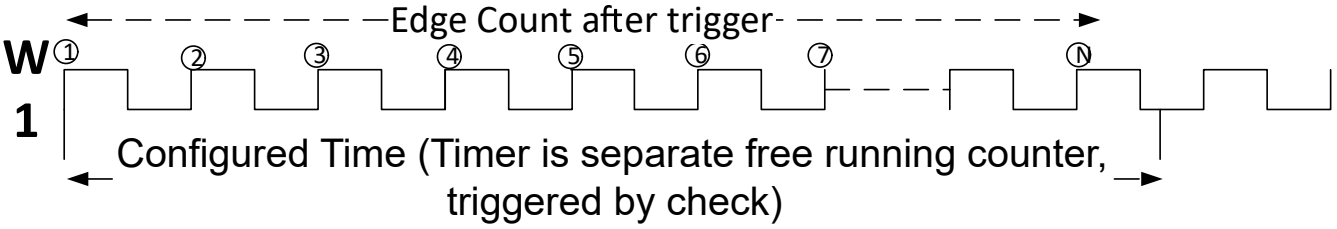

Figure 19-4. Edge Count Diagram

19.3.4.1 Edge Count with Fixed Window

Frequency uses the SIGxCMPA values, margin, edge type to count, average, peak, comparison settings.

The register to configure a fixed time window to analyze the edge counts is defined in SIGxEDGECFG[TIMEWNDOW].

19.3.4.2 Edge Count with Moving Window

This comparison counts edges in moving time window. Moving time window is the same time window but with overlap start within existing window. This allows better granularity to check that edge counts are uniform in the window and if those are changing the transition is smooth.

For example:

1. If the moving timing window (MVWTIME) is configured to 2000 time-base counts and number of readings (MVWCNT) is configured to be 3 (0x3).
2. Then after trigger signal edges are counted for every 2000 time-base count. Readings of multiple (2 or 3), in this case (MVW_CNT) 3, moving windows are accumulated to make one fixed window.
3. Thus the size of the fixed window is 6000. After first fixed window measurement is over, the measurement is compared against SIGxCMPA/B and the corresponding margin to verify the measurement is within the minimum-maximum range.
4. Further upon next moving window reading accumulation, it is added to fixed window measurement and the earliest reading is retired (subtracted) from the signal edge count of the fixed window. Thus the reading to be compared is always maintained for one fixed window. For example, Windows intervals successively progress for time base counts of 0-6000, 2000-8000, 4000-10000, 6000-12000, so on.

- The given size of the moving window is configured in the SIGxEDGEMVWCFG[MVWTIME] and the number of moving windows SIGxEDGEMVWCFG[MVWCNT] is to be accumulated.
- Moving window count MVWCNT is limited to 1, 2, 3, or 4 of which a count of 1 means that there is no moving window. Either bisect or trisect the fixed window with as many readings (3 readings for bisect and 4 for trisect) to manipulate.
- As depicted multiple accumulator snapshots can be taken for the measurement count at the interval of MVWTIME and readings are computed to find the number of edges within MVWTIME * MVWCNT period. Check of readings after every snapshot gives granular movement of window.

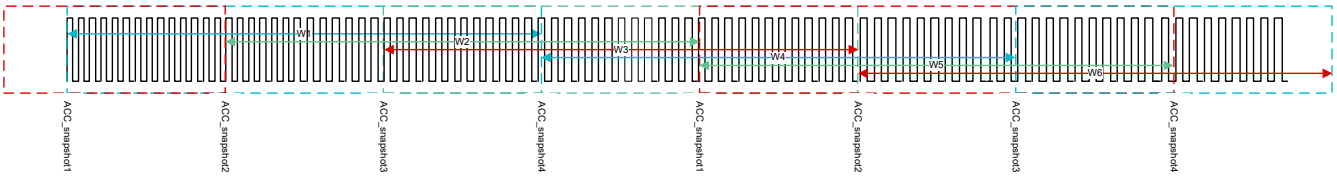

Figure 19-5. Edge Counting of Signals for Moving Window

19.3.5 Signal1 to Signal2 Comparison

To use signal to signal comparison for pulse width, edge count, phase, deadband the BLKTRIGCFG register must be configured such that SIG1 and SIG2 have a common trigger input. This can be done by configuring the BLKTRIGCFG[SIGx_TRIG_TYPE] to set either SIG1 or SIG2 to be set to synchronized trigger.

Pulse Width SIG1 to SIG2 Comparison

- Signal to signal comparison is enabled by the SIGTOSIGCFG[SIGTOSIG_CMPEN] register. The common configuration to start signal comparison is to have a hardware trigger on one SIGx, and configure a synchronized trigger for the other signal. This starts counting from a common trigger point for both signals. This trigger mechanism of synchronized use is common for all the SIGTOSIG operations including width, edge-count, dead-band, and phase overlap.
- In case the SIGTOSIG compare enabled and synchronized trigger is not configured to either SIG, then hardware forces SIG1 trigger to be used for both SIG1 and SIG2.
- A valid signal to signal comparison is when there are pulses occurring on both SIG1 and SIG2. An example of an invalid signal to signal comparison is when comparing the widths of two signals and there is no pulse on the second signal. If the next pulse is started on the first signal, and second signal does not have a pulse then the earlier reading of the signal is discarded and no comparison is reported.
- In such case, the error reported within the BLKERRSTS[SIGTOSIG_ERR] register can be raised to indicate that after trigger there was imbalance in compare points of two waveforms. The BLKERRINFO[ERRCNT] register reflects the measurement count and the type of error to log in this register is defined in the BLKERRINFO[ERRTYPE] register. Like any other event that is triggering interrupt or RTDMA request, BLKERRSTS[SIGTOSIG_ERR] also causes an interrupt or RTDMA request.
- The expected compare value and margin for the difference between width of two signals can be defined in the SIGTOSIGCFG[CMP] and SIGTOSIGCFG[CMPMARGIN] registers.

Pulse width Aggregation signal to signal comparison

- Signal to signal aggregation comparison: This comparison is exclusive of single pulse width measurement and compares the difference of aggregated measurements of two signal values. The width of signals is measured as per edge configuration and such N successive measurements accumulated. Where N is the configured aggregation count. The difference is taken when both readings are available and comparison is performed. Compare values are programmed by user through SIGTOSIGCFG[CMP] and SIGTOSIGCFG[CMPMARGIN]. These are same registers used for single pulse width comparisons.

Pulse width average, Pulse width peak signal to signal comparison

- Pulse width peak comparison is detected for both signals and then the difference of peak values is compared to the programmed threshold with margin.
- Pulse width average signal to signal comparison is taken the average of accumulated value of N measurements of both signals and finding the difference of average compared to the programmed threshold with margin.
- Both peak and average have separate compare values available hence these both checks can be simultaneous and can also be concurrent with each other.

Edge count comparison

Edge count signal to signal comparison can be done in two ways:

1. Fixed window comparison
2. Moving window comparison

While comparing the edge count, in a given interval if there are zero edges from another signal, then the compare is not a valid comparison point.

- Comparing edge counts of two signals on moving window basis. This compares the fixed window accumulation for every moving window completion between SIG1 and SIG2. Given that clock is common for WADI block and same between SIG1 and SIG2, the same settings of moving time window are used for both SIG1 and SIG2. This needs to be made sure by software. Any mismatch leads to erroneous results that do not help in comparison. Note the check can be simultaneous with MVW mode of individual signal characterization; hence, no hardware restrictions are imposed.

Comparing the number of edges between each interval such that there are no glitches or excursion within small windows and at the same time the check of time-window having certain frequency range is covered. The check works in similar manner as basic window comparison except that for basic moving window check the differences between the counts is compared against SIG_TO_SIG_CONFIG[DIFF_CMPARE_CNTRE] and with SIG_TO_SIG_CONFIG[DIFF_CMPARE_MARGIN] margin.

Note

Pulse width and pulse width aggregation versus frequency fixed time window and frequency with moving window are mutually exclusive. The WADI block for accumulating measurement, and calculating the difference between measurements must be for either pulse width or frequency measurement.

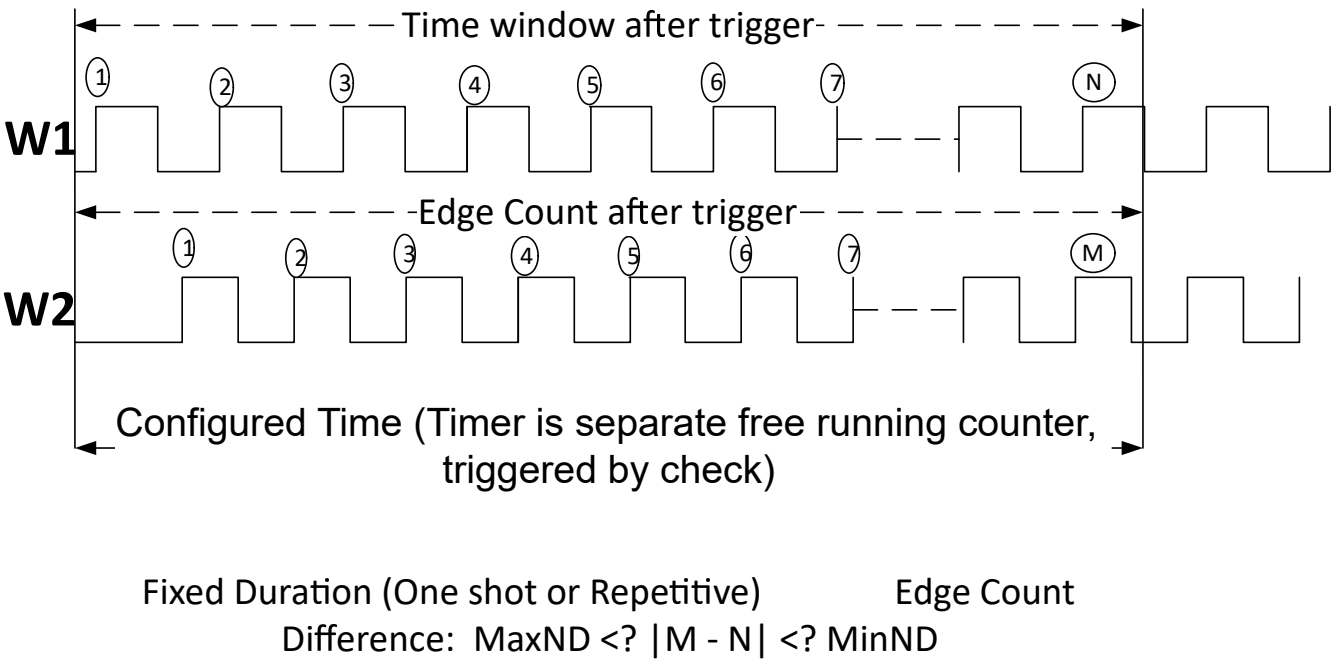

Figure 19-6. Signal to Signal Edge Count Comparison

19.3.6 Dead Band and Phase

Dead Band

Dead band and phase overlap checks are based on specific edges hence whether specific edges as configured in SIGPOL or ones opposite to the SIG or both to be compared is critical to the configuration.

Note

EDGESPAN configuration is not used for dead-band check as edges of two signals of the configured type are compared on continuous basis for any violation on the minimum width. Check starts after trigger to search for configured edge type for each signal.

This configuration of singular or both edges of dead band check is done in SIGTOSIGCFG[SIGTOSIG_DBCMPEN]. The order of edges can be either SIG1 or SIG2, rise or fall but only edges which are configured need to be measured. Dead band looks only for distance between edges if less than compare value defined in SIGTOSIG_DBOLAPA/B[DBCMPA/B].

- When SIGTOSIGCFG[SIGTOSIG_DBCMPEN] bit is enabled and SIGTOSIGCFG[DBCMPTYPE] = 0x0, this configuration compares the distance between configured edges of the respective signal. For example, if SIG1-rise and SIG2-fall is to be compared, then after trigger on SIG1-rise occurs then distance to SIG2-fall can be compared to the compare value.
- When SIGTOSIGCFG[DBCMPTYPE] = 0x1 with SIGTOSIGCFG[SIGTOSIG_DBCMPEN] enabled, this configuration allows either comparing configured or the compared and complementary edges for dead-band. Complementary check can be specifically enabled. For example, if configured edges are SIG1-fall and SIG2-rise, then upon enabling both SIG1-fall to SIG2-rise and SIG1-rise to SIG2-fall is checked.
- The edge to edge distance is measured as per configuration continuously edge after edge. If SIG1 edge of programmed type (for example, Rise) is received then counter starts counting till SIG2 edge of configured type (for example, Fall) occurs.

Note

For the dead-band check the EDGE_SPAN configuration is ignored and the comparison is performed for every two associated or associated + complementary edges.

1. Same is applicable if the order of signals reverses and SIG2 (for example, Fall) occurs ahead of SIG1 (for example, Rise).
2. In case dead-band check is enabled for either edge (DBAND_CHK_TYPE=0x1) then upon detecting edge on either signal say SIG1 (for example, Rise) in this case, corresponding configured edge on SIG2 (for example, Fall) is detected and the interim period is checked for meeting at least required threshold compare.
3. Further for case in 2. The opposite edge of either signal configured in EDGE_TYPE (for example, SIG2.Rise) is detected and the distance to corresponding opposite edge of other signal (for example, SIG1.Fall) is validated. Thus both edges of signals are validated against the corresponding edges of paired signal.
4. In case after detection of specific edge (for example, SIG1.Rise), if corresponding edge (for example, SIG2.Fall) for paired signal does not occur before the opposite edge (for example, SIG1.Fall) of the same signal then the count is reset and check is started for the recent edge.

Phase Overlap

Phase measurement also takes settings similar to dead-band, except that the level after configured edge is measured for overlap. Order of signal occurrence is not concern as overlap is measured.

- Signal to Signal phase overlap : Checks particular signal levels (say SIG1-high and SIG2-low) are simultaneously asserted with time overlap within range of minimum to maximum. Measurement starts when both signals at configured level. Whereas upon exit of either signal from the level sought, the measurement is stopped and compared against SIGTOSIG_DBOLAPA/B[DBCMPA/B] with margin of +/- OLAPCMPA/BMARGIN
- In this mode of operation, expected the waveforms provided for comparison do not have individual pulse widths such as one signal has pulse more than 2^x wider than other. If for some reason while one of the signals remains asserted and the second signal gets reasserted, then a second time the measurement is triggered flushing the previous measurement. However, if there are errors raised in earlier comparisons then those are not deasserted until cleared by software.
- SIGTOSIGCFG[OLAPCMPTYPE]: Enables and selects the type of overlap comparison. The following table indicates the configuration and the effect on the checks. The example is for the configuration of rise edge of the SIG1 and Fall edge of the SIG2.
- For the phase-overlap check the EDGESPAN configuration is ignored and the comparison is performed for every two configured or configured complementary edges.

Control	Value	Check	Check for Example
OLAPCMPTYPE	0x0	0x0 - Overlap of levels per configuration (edge configuration extended to derive level).	Overlap of SIG1-level-High and SIG2-level-Low
OLAPCMPTYPE	0x1	0x1 - Overlap of levels per configuration and complementary levels as well.	Overlap of SIG1-level-High and SIG2-level-Low and Overlap of SIG1-level-Low and SIG2-level-High

19.3.7 Simultaneous Measurement

WADI block can measure the pulse width, frequency, dead band, and phase overlap. WADI block can be configured for single measurements or be configured to instead calculate an aggregated measurement and take the average or find the peak value of the measurements.

Each WADI block can be configured to measure either pulse width of a signal or the frequency (edge counts) of a signal. Configuration for measuring both pulse width and frequency on one signal cannot be done. However configuration to measure frequency on one signal, and pulse width on another signal is allowed.

Single signal measurements can be done with out any signal to signal comparison. There is flexibility to perform signal to signal measurements on top of single signal measurements.

For example, you can measure the pulse width in addition with a signal to signal measurement of dead band and phase overlap. The following scenarios show the possible simultaneous measurements that can be done depending on what is needed to be measured.

For simultaneous measurements, here are the three configuration scenarios that are feasible with each WADI block. Dead band and phase overlap measurements are possible in all scenarios since an internal independent counter is used for them. The following scenarios go through what can be measured on SIG1 and SIG2 independently, and what can be done when performing a SIG1 to SIG2 comparison.

Scenario 1 (Pulse width and frequency measurement):

One WADI block can be used to measure SIG1's pulse width and measure SIG2's frequency independently. In this scenario you cannot use any of the signal to signal comparisons since one is measuring pulse width and another measuring frequency and the measurements are not be related to each other. You can measure the individual signals for the single measurement or if you enable measuring the signal's sum, average, and peak.

Scenario 2 (Pulse width only):

One WADI block can be used to measure pulse width of SIG1 and SIG2. During the scenario, you can measure the independent pulse widths and do signal to signal comparison. Signal to signal comparison can be done since both counters have pulse width measurements related to each other. If the WADI block is measuring a single pulse width (SIG1/2CFG.NUMAGGR = 0x0) then sum, average, and peak comparisons as well the signal to signal for sum, average and peak can not be used for comparison. If SIG1/2CFG.NUMAGGR is non-zero, then the sum, average, and peak comparisons can be used and can be enabled using SIG1/2CFG.AGGRMODE. In this scenario frequency comparison can not be available since we are measuring pulse width.

Scenario 3 (Frequency only):

To enable measurement of frequency or edge count, SIG1/2EDGECFG.CNTEN must be set. One WADI block can be used to measure frequency or edge count of SIG1 and SIG2. During the scenario, you can measure the edge count, or measure a moving window of edge counts. In addition you can do signal to signal comparison only for comparing the single edge count measurement or the moving window measurement. Signal to signal comparison can be done since both counters have edge count measurements related to each other. Sum, average, and peak comparisons as well the signal to signal for sum, average and peak can not be used when in edge count mode for comparison. In this scenario pulse width comparison or pulse width measurement can not be available since we are measuring edge count.

19.4 Safe State Sequencer (SSS)

- WADI can analyze the input waveforms and has the flexibility to override the input waveform to a desired event of outputs required to meet safety or efficiency requirements. The corrections to input waveform can be set to a fixed state after certain events or chain the output of events in a specific manner or do nothing.

The outputs of the WADI blocks are routed to the Safe State Sequencer(SSS). The SSS provides a safe state handling method for processing the signal upon a fault or error during signal analysis. Once an error is detected or a pattern of error events are detected, the SSS can generate a define pattern of outputs.

The SSS has a number of event triggers and safe state event outputs that is used to drive the outputs to a known state. In order to enable SSS, a minimum of 4 events and 4 event outputs are needed. The maximum are 8 events and 8 event outputs can be used. Key functions/blocks and their relation is depicted in figure below.

19.4.1 SSS Configuration

The WADI's signal analysis block (see Figure 19-7) generates error events related to SIG1 and SIG2 that can be used to start the SSS block. The SSS block essentially provides a waveform pattern generation based off the WADI block signal analysis events. The SSS has custom configurations for how long to hold a signal low or high. The trigger or multiple trigger configuration block is how the SSS is enabled. The output event + output event trigger + duration + link configuration block are flexible settings that can be used to control the outputs, control which events triggers the outputs, control how long to hold the outputs in a high or low state, and allows cyclic signal generation. For example, if an error event occurs from the WADI block's signal analysis the SSS can output a pattern of high and low signals in a cyclic manner or perform the pattern of outputs once.

Each WADI's block signal analysis events can be used to start the SSS block. There are a total of eight configurable events (SSS_EVTnCFG[EVTn]) that can be used to compare against the trigger event (SSS_EVTTRIG) for SSS to start. Each configurable event holds the settings for all WADI blocks 1 to n. The trigger event triggers the start of the SSS if the trigger event matches one of the configured SSS events (SSS_EVTnCFG[EVTn]). Once the trigger event is met with the SSS event, the signal SIGn is overwritten with the configurations defined in the SSS output event configuration (SSS_BLKSOUTEVTnCFG[OUTEVTn]). The

SSS output event can either set the output high or low. After defining the output event configurations, the SSS maps the output event to the WADI block's signal output.

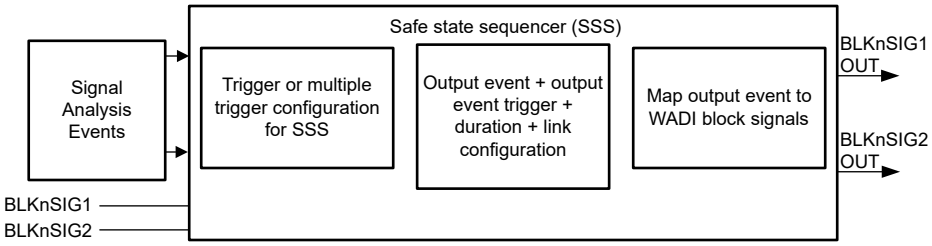

Figure 19-7. SSS High-Level Block Diagram

Steps for output event configuration (see Figure 19-8) for WADI block 1 and 2 example:

1. Configure what action to occur for output event 1-8 using SSS_BLKSOUTEVTnCFG[OUTEVTn]
2. Configure which output events can control which block signals using SSS_BLK1_2OUTSEL[BLK1SIG1], SSS_BLK1_2OUTSEL[BLK1SIG2], SSS_BLK1_2OUTSEL[BLK2SIG1], SSS_BLK1_2OUTSEL[BLK2SIG2]

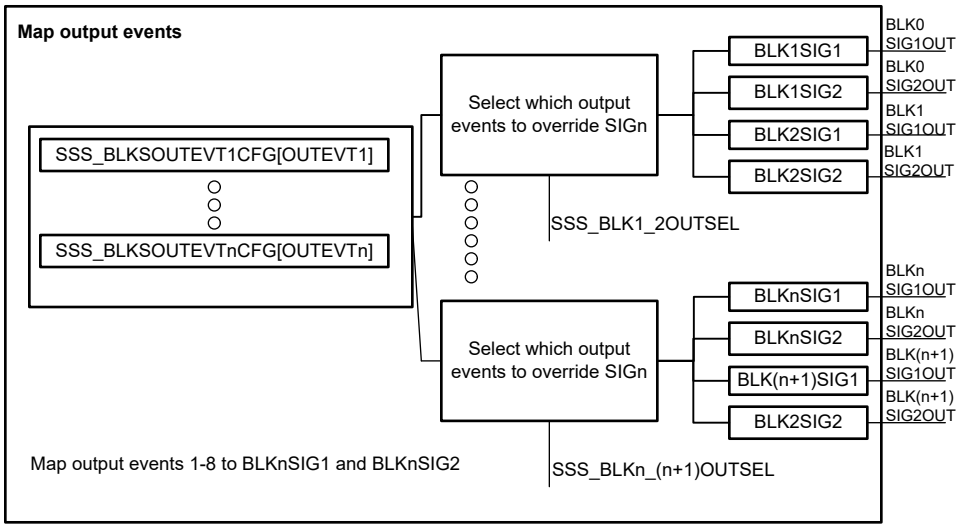

Figure 19-8. Map Output Events to BLKnSIGn

There are four common ways to configure the SSS.

1. Single trigger with single pattern output events: Used for single trigger based enabling of SSS
2. Single trigger with cyclic pattern output events
3. Multiple trigger with single pattern output events: Used for chaining event triggers before enabling SSS
4. Multiple trigger with cyclic pattern output events

Figure 19-9 is a general diagram of configuring the SSS for single trigger with a single pattern of output events. Each output event can be configured to trigger on different events. For example, OUTEVT1 can be triggered on EVT1, EVT2, EVT3, and so on, using SSS_OUTEVTnTRIGCFG. To configure the duration of the output event, that is done through the SSS_OUTEVTnDUR.

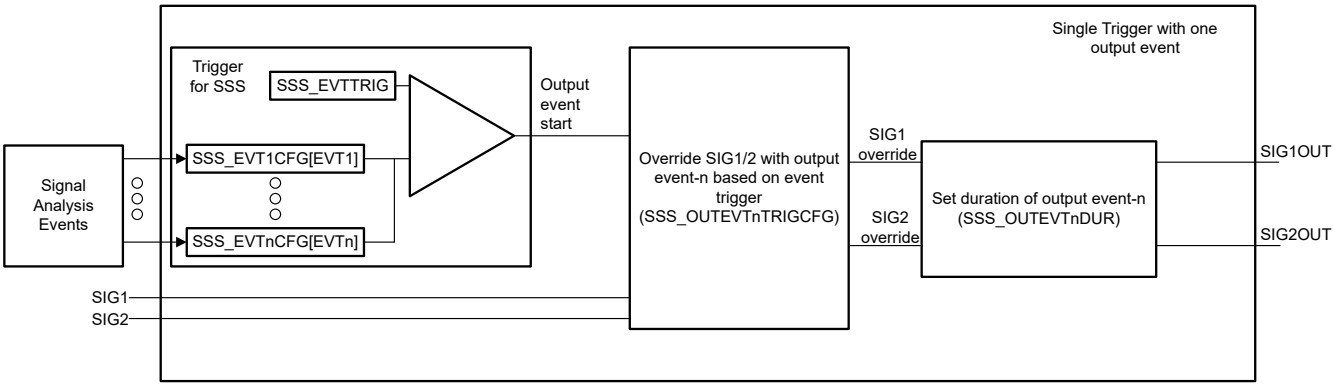

Figure 19-9. Single Trigger with Single Pattern Output Event

Each output event has a fixed time of activation unless the output event is configured to be always high or low. This time is configured using the SSS_OUTEVTnDUR count that is configured by user and starts down-counting once trigger to activate the output event is met. Once the counter reaches 0, the output event is removed and delay word is reloaded for next activation. User can configure the count to 0xFF_FFFF, which is the maximum count and that is used to keep the output event continuously active. This is a special setting used for driving fixed value safe state output.

In case the subsequent sequence word is configured to be linked and shares the outputs, then make sure that before configuring the fixed overrides to 0xFF_FFFF (to delay count), the configuration either changes the output sharing or link condition of subsequent sequence word to avoid an unpredictable condition.

By hardware design, the delay condition overrides and the subsequent sequence word steps are ignored if delay count is configured to be 0xFF_FFFF.

If the second trigger to occur while sequence word is active then count is re-initialized to configured count and down-count is restarted again. Thus extending the sequence word application to related outputs.

Sequence delay setting is an independent word for each sequence word, SSS_SEQUENCE_DELAYx. The setting is a 24-bit setting that allows a delay of up to 40ms (400MHz input clock - without division) that is sufficient to drive the intermediate state of switch activations in present topologies.

Figure 19-10 shows multiple trigger with single pattern output events.

For configuring multiple triggers, in Figure 19-10, EVT1 must occur before moving onto the second event trigger. Once that event has occurred, then EVT2 must happen for the SSS to start.

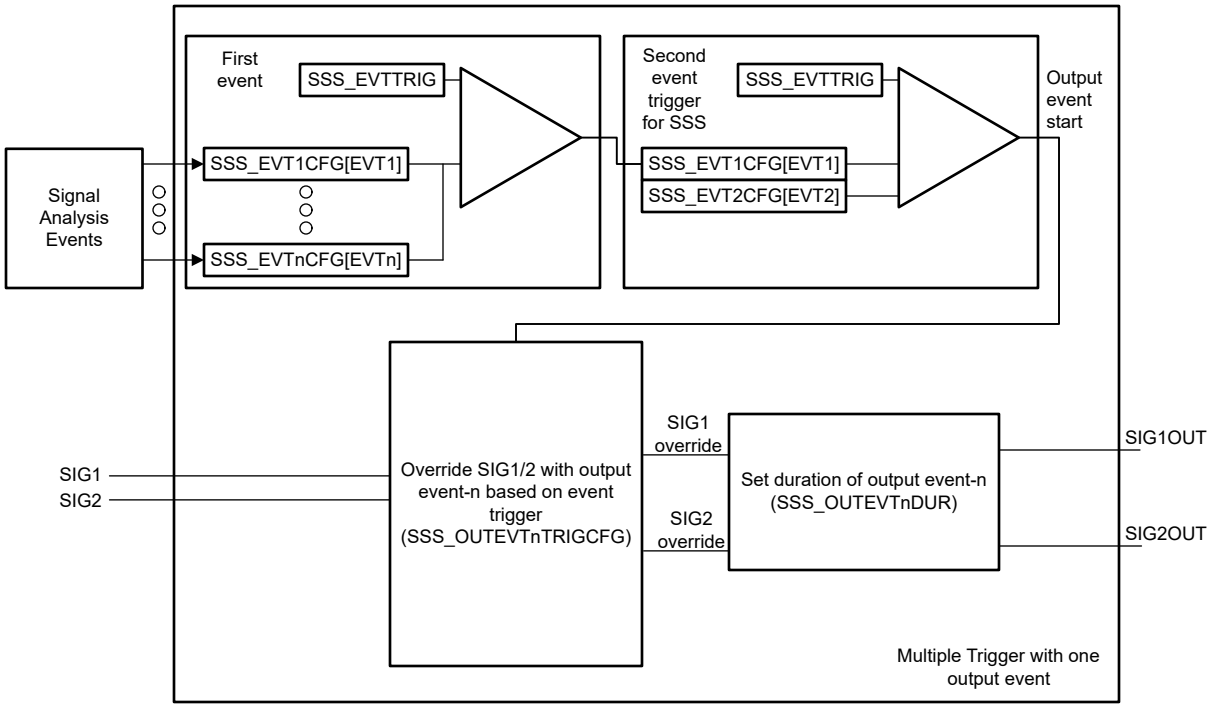

Figure 19-10. Multiple Trigger with Single Pattern Output Events

Figure 19-11 shows a multiple trigger configuration before the start of the SSS and linking output events to each other to generate a single pattern of output events. For example, if the desired output is four output events high, low, high, low, the SSS can do this with linking output events to one another. The linking can be done through the SSS_OUTPUTEVTnLINKCFG.

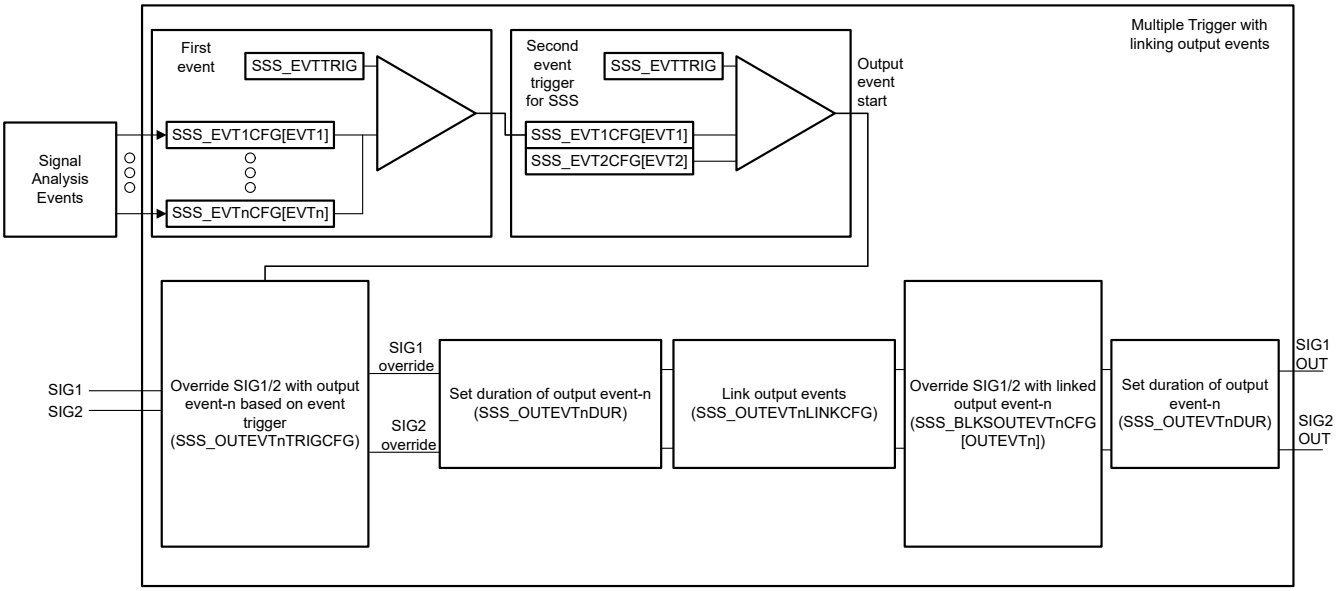

Figure 19-11. Linking Output Events for Generating Pattern Output Events

To generate a cyclic pattern of output events, Figure 19-12, you can do so by linking the output events in a circular fashion. For example if the waveform generation pattern requires a continuous cyclic pattern of high, low, high, low. The output events 1, 2, 3, 4 can be used. Then linking output events 1 → 2 , 2 → 3, 3 → 4, then configure output event 1's link to be output event's 4. This creates the cycle of the pattern generation to continuously output this linking of output events.

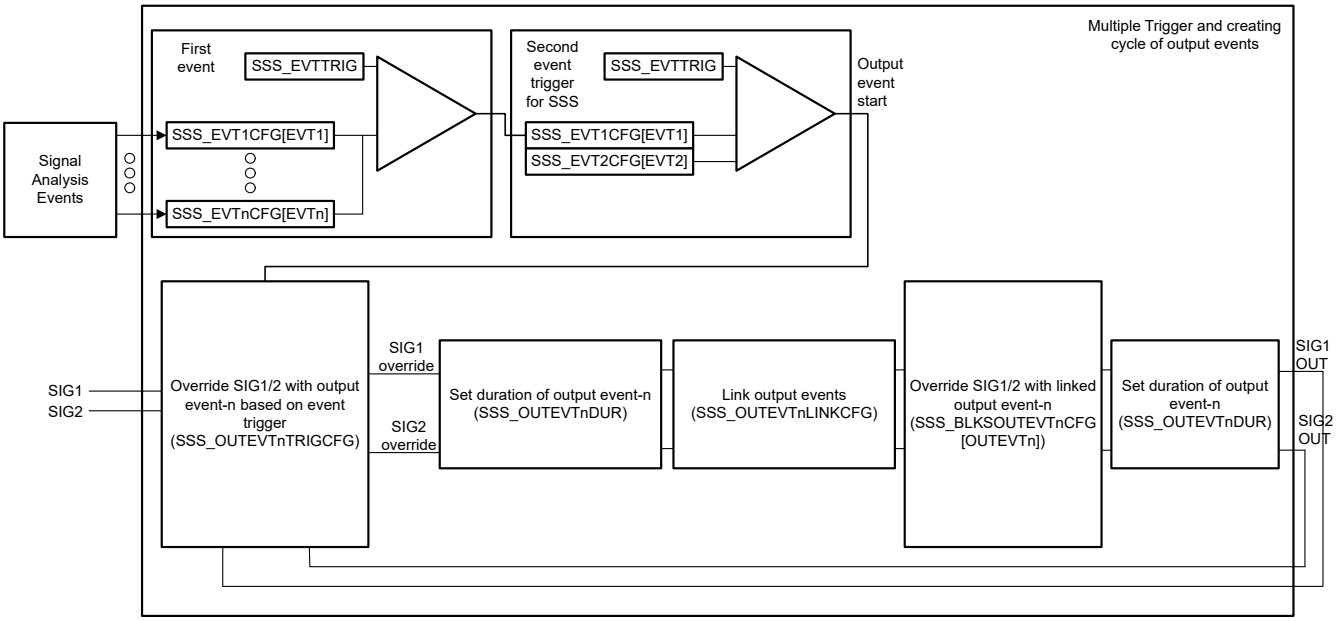

Figure 19-12. Multiple Trigger with Cyclic Pattern Output Events

Configuration of multiple triggers

In intricate switch topologies, a single event can not reflect the full condition to trigger the SSS. The topology can need two or more states to fully detect the failure condition before starting the safe state sequences. In such cases, the SSS allows linking multiple trigger events together. The register to configure multiple triggers is SSS_TRIGEVT1_4CFG and SSS_TRIGEVT5_8CFG.

Note

To configure SSS_TRIGEVT1_4CFG or SSS_TRIGEVT5_8CFG, the user must write the compliment before the actual value. For example, if four trigger events are needed before SSS is enabled writing 0x1999 does not work. Instead writing 0xE1_69_69_69 is required to configure SSS_TRIGEVT1_4CFG.

Table 19-5. Multiple Trigger Configuration

Event Word Select Combination				Words Combination for Sequences	Trigger Numbering	Action for Event Word Compare
Event 4	Event 3	Event 2	Event 1		Trig# (EVT#, next EVT#,...)	
0	0	0	0	0	NA	None of the event words are used and safe-sequencer is not used.
1	1	1	1	1+1+1+1	T4(EVT4), T3(EVT3), T2(EVT2), T1(EVT1)	Each event trigger is independently configured and has individual sequence.
0	1	1	1	1+1+1	T3(EVT3), T2(EVT2), T1(EVT1)	Three triggers based on event as shown, fourth word is not used.
0	0	1	1	1+1	T2(EVT2), T1(EVT1)	Two triggers based on trigger event as shown.
0	0	0	1	1	T1(EVT1)	One trigger is used based on Event 1.
1	1	1	9	1+1+2	T3(EVT4), T2(EVT3), T1(EVT1, EVT2)	Two of the events are used together and other two triggers are independent triggers. Create up-to 3 possible event triggers.
0	1	1	9	1+2	T2(EVT3), T1(EVT1, EVT2)	Two triggers. One independent trigger and the other on event 1 and event 2 occurring.
0	0	1	9	2	T1(EVT1, EVT2)	Single trigger based on event 1 followed by event 2.
1	9	1	9	2+2	T2(EVT3, EVT4), T1(EVT1, EVT2)	Two pairs of events independently checked as two o/p sequences are correspondingly triggered independently. Event order applicable only between consecutive numbers 1 and 2.
1	1	9	9	1+3	T2(EVT4), T1(EVT1, EVT2, EVT3)	Three trigger events are linked and can be checked in order 1, 2, then 3. The fourth event word is independent. Thus two possible triggers.
0	1	9	9	3	T1(EVT1, EVT2, EVT3)	3 trigger events
1	9	9	9	4	T1 (EVT1, EVT2, EVT3, EVT4)	All 4 events are indicated in consecutive increasing order. Events are checked in order.
Any other combination				Sequence as per configuration	Events linked is 0x9	In case 0x1, the trigger word can cause the trigger. In case 0x9, the trigger word can relay the event to next event in order.

Note

Multiword triggers always look for specific order of events and event words hence strictly the same order needs to be followed. Same sets of events occurring but not in the given order does not cause the trigger.

The SSS does not have to be used, and output can be driven by WADI block instead. However both settings are not to be used simultaneously.

19.5 Lock and Commit Registers

To protect the configuration registers of the WADI and SSS from rouge/run-away code the lock and commit registers are defined. Each of these registers allow range of configuration registers to be protected from writing. Read does not have a restriction. Table 19-6 lists the registers.

Table 19-6. Lock and Commit Registers

Register Name	Protected Address Range	Protected Registers	Comment
CFGREGLOCK	WADI_CONFIG_REGS: 0x000-0xFFF	All registers except Status registers like BLKERRSTS	When set, locks the writes to these registers. Can be unlocked before writes, if commit is not set to 1.
CFGREGCOMMIT	WADI_CONFIG_REGS: 0x000-0xFFF	All registers except Status registers like BLKERRSTS	Once set, does not allow to clear the CONFIG_REG_LOCK set value to 1.
OPERREGLOCK	WADI_OPER_SSS_REGS: 0x100-0x2FF	All registers in this range.	When set, locks the writes to these registers. Can be unlocked before writes, if commit is not set to 1.
OPERREGCOMMIT	WADI_OPER_SSS_REGS: 0x100-0x2FF	All registers in this range.	Once set, does not allow to clear the OPER_REG_LOCK set value to 1.

19.6 Interrupt and Error Handling

Interrupt Generation

Interrupts are generated based in the masked interrupt status of the WADI. Upon the error event, WADI generates an active-low pulse of 3 clock cycles to be triggered to CPU as an interrupt. Any overlapping events during this 3 clock assertion are not separately asserted. If the event gets created at the end of third clock, then next assertion is done from clock 6 covering any other event occurrence until that point

Error Status Handling

Often the signals to be characterized do not have the format or have lag that can affect the measurement counter, for example if measuring pulse width and signal gets stuck at that polarity after first or first few toggles. Or while averaging/accumulating number of counts do not complete and signal gets stuck in active pulse state hence overrunning measurements. Such situations can trigger an event that can assert an interrupt to CPU.BLKERRSTS[SIG_ERR] tracks this and corresponding interrupt registers can be used by CPU to service interrupt.

Once an event is detected, the event is reported to the system either through interrupt event, RTDMA event, and WADI outputs to trigger an event, error status for software debug, or the event gets connected to event trigger for safe state sequencer.

Upon interrupted, the CPU knows which WADI block caused an error and what was the error. The masked interrupt status provides the WADI blocks that triggered error. For each WADI block there is a register that provides the status of which type of event triggered the interrupt. This is stored within BLKERRINFO that can further lead to the exact event type that triggered the error.

The BLKERRINFO register contains information about the first recorded failed count of the signal analysis (BLKERRINFO[ERRNT]) and the type of error (BLKERRINFO[ERRTYPE]).

Note

BLKERRSTS is writable to allow debug and emulation of events during software development. Hence, writes to these registers can trigger events downwards to be an interrupt or RTDMA or SSS.

BLKERRCFG[OVERIDESIGn] are settings used for WADI instances that do not incorporate the SSS. In case the number of event words and sequence words are 0, then OVERIDESIGn give limited flexibility to build the fixed safe states. In cases where SSS components are instantiated, these fields are treated as reserved.

19.7 RTDMA Interfaces

WADI raises RTDMA request based on the events occurring in the WADI block or SSS. WADI has a RTDMA mechanism that has only one RTDMA request and corresponding RTDMA ACK. Hence, it is expected that software configuring RTDMA action knows the range it needs to configure and change WADI settings or operational registers. To make it easier for software to affect only configurations that are affected, the feature for filtered writes is enabled. When writes are filtered, WADI instance tracks the WADI block, events, output events that has an error event and selectively allows change in that WADI block alone. Filtered writes are to the WADI blocks, event words and output events those are enabled for filtered writes.

If the filtered write is not enabled then all writes are allowed to WADI block. When Filtered write is enabled, then any writes within a window of a RTDMA request to RTDMA acknowledgment go through only if there is occurrence of the event within WADI block or event is triggered or output event was active and corresponding event was enabled for RTDMA trigger through DMATRIGEN.

Note

Filtered access rule is applicable only for the window when RTDMA request of WADI is active. At all other times accesses to registered are allowed as long as those are not locked.

For filtered writes within each WADI block there are three types of events and there are dedicated registers enabled for filtered writes. Thus the filtered access are granular based on events internal to the WADI. While the common filtered_en signal and RTDMA trigger enable, RTDMA update status, and RTDMA trigger status is applicable to entire WADI block.

In case the block needs an update regardless of any event, then the block must be left disabled for filtered writes.

If the event occurs after the RTDMA request and RTDMA write is not passed the corresponding address region yet then incoming filtered writes are exercised on the region though originally corresponding RTDMA request did not trigger the writes. Upon assertion of RTDMA acknowledgment the status of the filtered regions which are written is updated to the DMASTSUPDATE. Note DMASTSUPDATE is reserved for filtered writes hence regions unfiltered if written do not reflect here as software has way to deduce the same based on the DMAFILTWRCFG. Upon RTDMA acknowledgment the blocks which were written successfully deassert the RTDMA trigger (DMATRIGSTS).

The following describes the specific WADI registers having DMA filtered writes enabled

- WADI Block registers related DMA filtered writes
  - SIGTOSIGCFG
  - SIGTOSIG_PKCFG
  - SIGTOSIG_AVGCFG
  - SIGTOSIG_DBOLAPA
  - SIGTOSIG_DBOLAPB
  - SIG1/2CMPA
  - SIG1/2CMPB
  - SIG1/2PKCFG
  - SIG1/2AVGCFG
- WADI SSS registers related DMA filtered writes
  - SSS_EVT[1..8]CFG
  - SSS_TRIGEVT1_4CFG
  - SSS_TRIGEVT5_8CFG
  - SSS_BLKSOUTEVT[1..8]CFG
  - SSS_BLK1_2OUTSEL → SSS_BLK7_8OUTSEL
  - SSS_BLKSOUTEVT[1..8]CFG
  - SSS_OUTEVT[1..8]TRIGCFG
  - SSS_OUTEVT[1..8]DUR

19.7.1 RTDMA Trigger

RTDMA Trigger Enable

DMATRIGEN register is used to enable a specific block event or the SSS trigger event or the output events to cause the RTDMA activation. This allows the RTDMA request be selectively raised. DMATRIGEN is the enable for triggering RTDMA, if the event happens hence updates DMATRIGSTS only when corresponding DMATRIGEN.

RTDMA Trigger Status

DMATRIGSTS is a status register that reflects the event that drives the RTDMA request. The status shall remain asserted.

- Either until RTDMA request is serviced and RTDMA ACK for the corresponding event has been updated.
- User clears the status bits with specific 0x0 write to the bit. The hardware update has priority over software writes to avoid loosing the event/ RTDMA action.

RTDMA Update Status

WADI RTDMA can work to update all the configured MMRs without filter or with specific filtered updates to WADI blocks or event words or output events that have triggered the event. Further once the MMR for specific filtered WADI block, event or sequencer is updated the status of the same is recorded in the RTDMA update status register. This status can be cleared by the user writing 0x0 to clear specific bit. Note RTDMA update status is for filtered writes within RTDMA request assertion and RTDMA acknowledgment assertion. DMASTSUPDATE is thus dependent on RTDMA filtered write or occurrence of event.

RTDMA Filtered Write Enable Control

DMAFILTWRCFG register controls settings of filtered writes to be enabled by the RTDMA. When this setting is not enabled the writes to WADI configurations go through without filter. The Read from RTDMA access have no restrictions.

WADI has no means to track whether access is from RTDMA or CPU; hence, any access after RTDMA request assertion and before RTDMA acknowledgment is filtered to WADI block for which it is enabled.

19.8.2 WADI Examples

NOTE: These examples are located in the C29SDK installation from ti.com at the following location: mcu_sdk_DEVICE_GPN/examples/driverlib/CORE_IF_MULTICORE/wadi

Cloud access to these examples is available at the following link: dev.ti.com C29SDK Examples.

19.8.2.1 WADI Duty and Frequency check - SINGLE_CORE

FILE: wadi_ex1_duty_freq_capture.c

This example configures WADI1 Block 1 and Block 2 as follows

- WADI1 Block 1 has an input from the PWM using INPUTXBAR
- Pulse width checking is enabled with defined margin of error
- WADI1 Block 2 has an input from the PWM using INPUTXBAR
- Frequency checking is enabled with defined margin of error

The WADI block has error status register that can be used to monitor if any erroneous signals occur. (BLKERRSTS)

This example also makes use of the Input X-BAR. GPIO0 (ePWM1A output) is routed to the input X-BAR, from which it is routed to WADI SIG1 input.

19.9 WADI Registers

This Section describes the WADI Registers.

19.9.1 WADI Base Address Table

Table 19-8. WADI Base Address Table

Structure	DriverLib Name	Base Address	Frame Applicable	CPU1	CPU2	CPU3	RTDMA1	RTDMA2	HSM	Pipeline Protected
WADI_CONFIG_REGS	WADI1BLK1CONFIG_BASE	0x600B_0000	YES	YES	YES	YES	YES	YES	-	YES
WADI_CONFIG_REGS	WADI1BLK2CONFIG_BASE	0x600B_0100	YES	YES	YES	YES	YES	YES	-	YES

19.9.2 WADI_CONFIG_REGS Registers

Table 19-9 lists the memory-mapped registers for the WADI_CONFIG_REGS registers. All register offset addresses not listed in Table 19-9 should be considered as reserved locations and the register contents should not be modified.

Table 19-9. WADI_CONFIG_REGS Registers

Offset	Acronym	Register Name	Protection
0h	BLKCFG	WADI Block Clock Divider	PARITY_PROTECTED
4h	SIGTOSIGCFG	Configuration for SIG1 to SIG2 comparison for WADI Block	PARITY_PROTECTED
8h	SIGTOSIG_PKCFG	Signal1 to Signal2 peak comparison value and margin for WADI Block	PARITY_PROTECTED
Ch	SIGTOSIG_AVGCFG	Signal1 to Signal2 average comparison value and margin for WADI Block	PARITY_PROTECTED
10h	SIGTOSIG_DBOLAPA	Signal1 to Signal2 dead-band comparison difference and margin for WADI Block	PARITY_PROTECTED
14h	SIGTOSIG_DBOLAPB	Signal1 to Signal2 dead-band and Overlap compare values for WADI Block	PARITY_PROTECTED
18h	BLKTRIGCFG	The trigger configuration for SIG1 and SIG2 of the WADI Block	PARITY_PROTECTED
40h	SIG1CFG	Measurement configuration for SIG1 of WADI Block	PARITY_PROTECTED
44h	SIG1CMPA	Envelope-1 compare value and margin for SIG1 for WADI Block	PARITY_PROTECTED
48h	SIG1CMPB	Envelope-2 compare value and margin for SIG1 for WADI Block	PARITY_PROTECTED
4Ch	SIG1PKCFG	Peak of the aggregation compare configuration for SIG1 of WADI Block	PARITY_PROTECTED
50h	SIG1AVGCFG	Average of the aggregation comparison configuration for SIG1 of WADI Block	PARITY_PROTECTED
54h	SIG1EDGECFG	Frequency measurement configuration for SIG1 of WADI Block	PARITY_PROTECTED
58h	SIG1EDGEMVWCFG	Moving Window Configuration for SIG1 of WADI Block	PARITY_PROTECTED
80h	SIG2CFG	Measurement configuration for SIG2 of WADI Block	PARITY_PROTECTED
84h	SIG2CMPA	Compare value A and +/- margin for SIG2 for WADI Block	PARITY_PROTECTED
88h	SIG2CMPB	Compare value B and +/- margin for SIG2 for WADI Block	PARITY_PROTECTED
8Ch	SIG2PKCFG	Peak of the aggregation compare configuration for SIG2 of WADI Block	PARITY_PROTECTED
90h	SIG2AVGCFG	Average of the aggregation comparison configuration for SIG2 of WADI Block	PARITY_PROTECTED
94h	SIG2EDGECFG	Frequency measurement configuration for SIG2 of WADI Block	PARITY_PROTECTED
98h	SIG2EDGEMVWCFG	Moving Window Configuration for SIG2 of WADI Block	PARITY_PROTECTED
C0h	BLKERRSTS	Block status register	
C4h	BLKERRINFO	Block count value of failed register	
C8h	BLKERRCFG	Block Debug additional info.	PARITY_PROTECTED
CCh	SSS_EVTMASK	Mask to combine Block errors for trigger of SSS in event word Output by WADI block	PARITY_PROTECTED

Table 19-9. WADI_CONFIG_REGS Registers (continued)

Offset	Acronym	Register Name	Protection
E8h	PARTEST	Enables parity test	

Complex bit access types are encoded to fit into small table cells. Table 19-10 shows the codes that are used for access types in this section.

Table 19-10. WADI_CONFIG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

19.9.2.1 BLKCFG Register (Offset = 0h) [Reset = 00000000h]

BLKCFG is shown in Figure 19-13 and described in Table 19-11.

Return to the Summary Table.

Table 19-12. SIGTOSIGCFG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	RESERVED	R	0h	Reserved
29	OLAPCMPTYPE	R/W	0h	When configured selects type of OLAP check as below. Default is configured edge 0: Overlap of levels per configuration 1: Overlap of levels per configuration and complementary levels as well Ex: 0: Overalap of SIG1-level-High and SIG2-level-Low 1: Overalap of SIG1-level-High and SIG2-level-Low and Overalap of SIG1-level-Low and SIG2-level-High Reset type: SYSRSn
28	DBCMPTYPE	R/W	0h	When configured selects type of comparison for deadband as below. Default is configured edge 0: Deadband of configured edge comparison 1: Deadband of configured and opposite edge pairs comparison Ex: SIG1CFG[SIGPOL] for rise to SIG2CFG[SIGPOL] for fall 0: Deadband between asswertion of SIG1 rise and SIG2 fall 1: Deadband between assertion of SIG1 rise and SIG2 fall, and assertion of SIG1 fall and SIG2 rise Reset type: SYSRSn
27	SIGTOSIG_OLAPCMPEN	R/W	0h	When set enables the overlap comparison For overlap signal edge polarity is considered for measuring level post edge assertion. e.g. rise edge-high level Reset type: SYSRSn
26	SIGTOSIG_DBCMPEN	R/W	0h	When set enables the deadband comparison The distance between configured edges of both signals is compared. Reset type: SYSRSn
25	RESERVED	R	0h	Reserved

Table 19-12. SIGTOSIGCFG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
24	SIGTOSIG_CMPEN	R/W	0h	This bit when set enables the SIG1 to SIG2 comparison of measurements either widths or edge counts based on block configuration Default '0' , hence no SIGTOSIG compare Reset type: SYSRSn
23-20	RESERVED	R	0h	Reserved
19-16	CMPMARGIN	R/W	0h	This margin (+/-) against SIGTOSIGCFG[CMP] allows the variation of comparison to be in range for difference of measurements of two signals Reset type: SYSRSn
15-0	CMP	R/W	0h	This is the compare value for difference of SIG1 and SIG2 measurement either width or edge count depending upon the mode set for SIG1 The difference is compared against the base of this value with +/- margin as in CMPMARGIN Reset type: SYSRSn

19.9.2.3 SIGTOSIG_PKCFG Register (Offset = 8h) [Reset = 00000000h]

SIGTOSIG_PKCFG is shown in Figure 19-15 and described in Table 19-13.

Return to the Summary Table.

Signal to Signal peak compare difference and threshold

Table 19-17. BLKTRIGCFG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-25	RESERVED	R	0h	Reserved
24	TRIG2SWEN	R-0/W1S	0h	When this signal is set the measurement for SIG2 is started. It is also used in 'Either-0x3' trigger condition 'TRIG2TYPE' for SIG2. Reset type: SYSRSn
23-19	RESERVED	R	0h	Reserved
18-16	TRIG2TYPE	R/W	0h	Selects the type of trigger that shall be used for the SIG2 signal. 0x0: No Trigger - In this mode the signal will be measured right after configuration is done 0x1: Hardware Trigger , based on the assertion of the trigger the measurement begins 0x2: Software Trigger, after software trigger assertion measurement begins 0x3: Either trigger, the measurement begins when either of the software or hardware trigger is asserted. 0x4: Synchronized Trigger, When Set no trigger setting from SIG2 is used but SIG1 setting is used. If both are set to Synchronized then either SIG1 or SIG2 hardware triggers will start measurement 0x5-0x7: Reserved and defaults to NO trigger condition Reset type: SYSRSn
15-9	RESERVED	R	0h	Reserved
8	TRIG1SWEN	R-0/W1S	0h	When this signal is set the measurement for SIG1 is started. It is also used in 'Either-0x3' trigger condition 'TRIG1TYPE' for SIG1. Reset type: SYSRSn
7-3	RESERVED	R	0h	Reserved

Table 19-17. BLKTRIGCFG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
2-0	TRIG1TYPE	R/W	0h	Selects the type of trigger that shall be used for the SIG1 signal. 0x0: No Trigger - In this mode the signal will be measured right after configuration is done 0x1: Hardware Trigger , based on the assertion of the trigger the measurement begins 0x2: Software Trigger, after software trigger assertion measurement begins 0x3: Either trigger, the measurement begins when either of the software or hardware trigger is asserted. 0x4: Synchronized Trigger, When Set no trigger setting from SIG1 is used but SIG2 setting is used. If both are set to Synchronized then either SIG1 or SIG2 hardware triggers will start measurement 0x5-0x7: Reserved and defaults to NO trigger condition Reset type: SYSRSn

19.9.2.8 SIG1CFG Register (Offset = 40h) [Reset = 00000000h]

SIG1CFG is shown in Figure 19-20 and described in Table 19-18.

Return to the Summary Table.

Edge, width measurement configuration to characterize the SIG1 of WADI block

Figure 19-20. SIG1CFG Register

MVWTIME							
R/W-0h							

Table 19-24. SIG1EDGEMVWCFG Register Field Descriptions

Bit	Field	Type	Reset	Description
31	MVWEN	R/W	0h	This bit when set enables the moving time window feature. Reset type: SYSRSn
30	RESERVED	R	0h	Reserved
29-28	MVWCNT	R/W	0h	Number of moving time window Snapshots taken. Multiple snapshots complete one Window of frequency measurement. 0x0 : Only one snapshot for window count. No moving window measurements 0x1 : Two snapshots in one window. The reading is for fixed window, despite size difference there is no moving operation. 0x2 : Three snapshots in one window it means Window is bisected. 0x3 : Four snapshots in one window it means Fixed window has three moving window portions. Reset type: SYSRSn
27-26	RESERVED	R	0h	Reserved
25-0	MVWTIME	R/W	0h	Moving window time provides the smaller unit such that multiple MVW can be counted for completing one reading. And advancement of each such count gives full window reading at smaller than a window increments. This time is directly used to count the portion of window. With MVWCNT iterations of MVWTIME measurements one can get the full window reading. Every MVWTIME measurement is recorded and readings of multiple part used to get reading of full window, hence at every MVWTIME interval, the earliest reading of equivalent period is retired and recent reading for equivalent period is added. Thus giving moving window measurement check. Reset type: SYSRSn

19.9.2.15 SIG2CFG Register (Offset = 80h) [Reset = 00000000h]

SIG2CFG is shown in Figure 19-27 and described in Table 19-25.

Return to the Summary Table.

Table 19-36. PARTEST Register Field Descriptions

Bit	Field	Type	Reset	Description
31-4	RESERVED	R	0h	Reserved
3-0	TESTEN	R/W	0h	1010: Parity test feature is enabled All other values: Parity test feature is disabled Note: (1) When the parity test feature is enabled, actual registers are not accessible in the memory map. Instead, the parity values (final XOR output indicating the parity error) are accessible Parity is computed for every byte and the corresponding parity error value is available at the bit-0 of every byte. Value of '1' written to the parity bit after enabling the parity test feature can be used to inject the error by inverting the stored parity value (2) It is recommended to leave the field as 0101 or 0000 after completing the parity test Reset type: SYSRSn

19.9.3 WADI_OPER_SSS_REGS Registers

Table 19-37 lists the memory-mapped registers for the WADI_OPER_SSS_REGS registers. All register offset addresses not listed in Table 19-37 should be considered as reserved locations and the register contents should not be modified.

Table 19-37. WADI_OPER_SSS_REGS Registers

Offset	Acronym	Register Name	Protection
0h	BASETIMERLOW	Read only value for lower word of the base timer.	PARITY_PROTECTED
4h	BASETIMERHIGH	Upper word of the base timer and trigger to start the timer.	
8h	INTSTS	Gives the block wise aggregated raw error status that shall trigger the interrupt.	
Ch	INTSTSMASK	Provides mask for application to suppress or allow a particular block related errors to cause interrupt or not	
10h	BLKSMASKSTS	This is AND combination of active high indication of block-wise status asserting an interrupt.	
14h	INTSTSCLR	Provides way for application to clear the interrupt status.	
18h	INTSTSFRC	Allows emulation of the RIS to raise interrupt in software	
1Ch	SIGSYNCFILTCFG	Each input SIG to be connected through synchroniser or not	PARITY_PROTECTED
20h	TRIGSYNCFILTCFG	Each trigger to be connected through synchroniser or not	
3Ch	REVISION	IP Revision	
40h	DMATRIGSTS	Status of the DMA triggers active	
44h	DMATRIGEN	Mask to enable individual trigger cause	PARITY_PROTECTED
48h	DMASTSUPDATE	Indicates the register set updated post DMA write	
4Ch	DMAFILTWRCFG	DMA writes Filter enable for each of WADI & SSS blocks	PARITY_PROTECTED
A4h	CFGREGLOCK	Configuration Register Lock

2C8h	PARTEST	Enables parity test	

Complex bit access types are encoded to fit into small table cells. Table 19-38 shows the codes that are used for access types in this section.

Table 19-38. WADI_OPER_SSS_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W0C	W 0C	Write 0 to clear
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

19.9.3.1 BASETIMERLOW Register (Offset = 0h) [Reset = 00000000h]

BASETIMERLOW is shown in Figure 19-39 and described in Table 19-39.

Return to the Summary Table.

Reflects the latest read value of common time base lower word.

Figure 19-39. BASETIMERLOW Register

19.9.3.2 BASETIMERHIGH Register (Offset = 4h) [Reset = 00000000h]

BASETIMERHIGH is shown in Figure 19-40 and described in Table 19-40.

Return to the Summary Table.

Has latest read value of the common time base of the upper word. Also has time-base start control. This is write once after reset, configured by application after clocks and resets are stable.

15-0	BLKSMASK	R/W	0h	Each register bit is representative of the block and can enable or mask the corresponding error to trigger an interrupt or not to the CPU '0': corresponding interrupt is not asserted to the CPU '1': related interrupt is allowed to cause an interrupt to CPU Reset type: SYSRSn

19.9.3.5 BLKSMASKSTS Register (Offset = 10h) [Reset = 00000000h]

BLKSMASKSTS is shown in Figure 19-43 and described in Table 19-43.

Return to the Summary Table.

This is masked interrupt status for the WADI IP that triggered the interrupt to CPU. ISR can directly read this to check which WADI block(s) caused an interrupt.

Bit	Field	Type	Reset	Description
31	SIGTOSIGBLKS	R	0h	This register gives the bit wise status of activated and asserted error bits block-wise Hence interrupt service routine can readily reach to the detailed status of respective block Reset type: SYSRSn
30	SIGBLKS	R	0h	This register gives the bit wise status of activated and asserted error bits block-wise Hence interrupt service routine can readily reach to the detailed status of respective block Reset type: SYSRSn
29-16	RESERVED	R	0h	Reserved
15-0	BLKSMASK	R	0h	This register gives the bit wise status of activated and asserted error bits block-wise Hence interrupt service routine can readily reach to the detailed status of respective block Reset type: SYSRSn

19.9.3.6 INTSTSCLR Register (Offset = 14h) [Reset = 00000000h]

INTSTSCLR is shown in Figure 19-44 and described in Table 19-44.

Return to the Summary Table.

This is for interrupt service routines to clear the aggregated status of the block error as in RAW_INT_STATUS.

Bit	Field	Type	Reset	Description
31-28	SSS_OUTEVT5_8DMA	R/W	0h	Application needs to enable respective bits to ensure the DMA request is raised based on the event. 0x1 configuration enables DMA request assertion, 0x0 is disable for the event and does not cause the DMA request. Each bit is indicative of the SSS output events as below. [28] :DMA Request Enable for event of OUTEVT5 [29] :DMA Request Enable for event of OUTEVT6 [30] :DMA Request Enable for event of OUTEVT7 [31] :DMA Request Enable for event of OUTEVT8 Reset type: SYSRSn
27-24	SSS_OUTEVT1_4DMA	R/W	0h	Application needs to enable respective bits to ensure the DMA request is raised based on the event. 0x1 configuration enables DMA request assertion, 0x0 is disable for the event and does not cause the DMA request. Each bit is indicative of the SSS output events as below. [24] :DMA Request Enable for event of OUTEVT1 [25] :DMA Request Enable for event of OUTEVT2 [26] :DMA Request Enable for event of OUTEVT3 [27] :DMA Request Enable for event of OUTEVT4 Reset type: SYSRSn
23-20	SSS_EVT5_8DMA	R/W	0h	Application needs to enable respective bits to ensure the DMA request is raised based on the event. 0x1 configuration enables DMA request assertion, 0x0 is disable for the event and does not cause the DMA request. Each bit is indicative of the SSS Event word as below. [20] :DMA Request Enable for event of SSS_EVT5 [21] :DMA Request Enable for event of SSS_EVT6 [22] :DMA Request Enable for event of SSS_EVT7 [23] :DMA Request Enable for event of SSS_EVT8 Reset type: SYSRSn

Table 19-50. DMATRIGEN Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19-16	SSS_EVT1_4DMA	R/W	0h	Application needs to enable respective bits to ensure the DMA request is raised based on the event. 0x1 configuration enables DMA request assertion, 0x0 is disable for the event and does not cause the DMA request. Each bit is indicative of the SSS Event word as below. [16] :DMA Request Enable for event of SSS_EVT1 [17] :DMA Request Enable for event of SSS_EVT2 [18] :DMA Request Enable for event of SSS_EVT3 [19] :DMA Request Enable for event of SSS_EVT4 Reset type: SYSRSn
15-0	BLKSDMAEVT	R/W	0h	Application needs to enable respective bits to ensure the DMA request is raised based on the event. 0x1 configuration enables DMA request assertion, 0x0 is disable for the event and does not cause the DMA request. Each bit is indicative of the WADI Block event as below. [0] :DMA Request Enable for event of block1 [1] :DMA Request Enable for event of block2 [2] :DMA Request Enable for event of block3 [3] :DMA Request Enable for event of block4 [4:15] : Reserved Reset type: SYSRSn

19.9.3.13 DMASTSUPDATE Register (Offset = 48h) [Reset = 00000000h]

DMASTSUPDATE is shown in Figure 19-51 and described in Table 19-51.

Return to the Summary Table.

Status register indicating which register thresholds got updated after the DMA write

Table 19-103. PARTEST Register Field Descriptions

Bit	Field	Type	Reset	Description
31-4	RESERVED	R	0h	Reserved
3-0	TESTEN	R/W	0h	1010: Parity test feature is enabled All other values: Parity test feature is disabled Note: (1) When the parity test feature is enabled, actual registers are not accessible in the memory map. Instead, the parity values (final XOR output indicating the parity error) are accessible Parity is computed for every byte and the corresponding parity error value is available at the bit-0 of every byte. Value of '1' written to the parity bit after enabling the parity test feature can be used to inject the error by inverting the stored parity value (2) It is recommended to leave the field as 0101 or 0000 after completing the parity test Reset type: SYSRSn

Chapter 20

Crossbar (X-BAR)

The crossbars (referred to as X-BAR throughout this chapter) provide flexibility to connect device inputs, outputs, and internal resources in a variety of configurations.

The device contains a total of six X-BARs:

- Input X-BAR
- Output X-BAR
- CLB X-BAR
- ePWM X-BAR
- MINDB X-BAR
- ICL X-BAR

Each of the X-BARs is named according to where the X-BAR takes signals. For example, the Input X-BAR brings external signals “in” to the device. The Output X-BAR takes internal signals “out” of the device to a GPIO. The ePWM X-BAR takes signals to the ePWM modules.

20.1 X-BAR Related Collateral

Foundational Materials

- C29x Academy - Crossbars (X-BAR)

20.2 Input X-BAR, ICL XBAR, MINDB XBAR,

On this device, the Input X-BAR is used to route signals from a GPIO to many different IP blocks such as the ADC, eCAP, ePWM, and external interrupts. The input of each Input X-BAR instance (INPUTx) can be any GPIO, while the output of each instance connects to various IP blocks in the device. The digital input of AIOs are also available as inputs to the Input X-BAR. This flexibility relieves some of the constraints on peripheral muxing by allowing the user to connect any GPIO to the specified outputs of each Input X-BAR instance. Note that the GPIO selected by the Input X-BAR can be configured as either an input or an output. The Input X-BAR simply connects the signal on the input buffer to the output of the selected Input X-BAR instance. Therefore, you can do things such as route the output of an ePWM to the eCAP module for a frequency test).

The Input X-BAR is configured by way of the INPUTxSELECT registers. The destinations for each INPUTx are shown in Figure 20-1 and Table 20-1. For additional details on how each Input X-BAR connects to other IP blocks throughout the device, look for references to Input X-BAR in the chapter associated with that IP. Note that the destinations of each INPUTx are fixed and are not user-configurable. For more information on configuring the Input X-BAR, see the INPUT_XBAR_REGS register definitions in the *XBAR Registers* section.

Note

All input sources to the generic XBAR can be active high.

The minimum input pulse width required for ePWM, CLB XBAR (CLB Clocks required) and SYSCLK for Output XBAR is 3 ticks of the respective clocks.

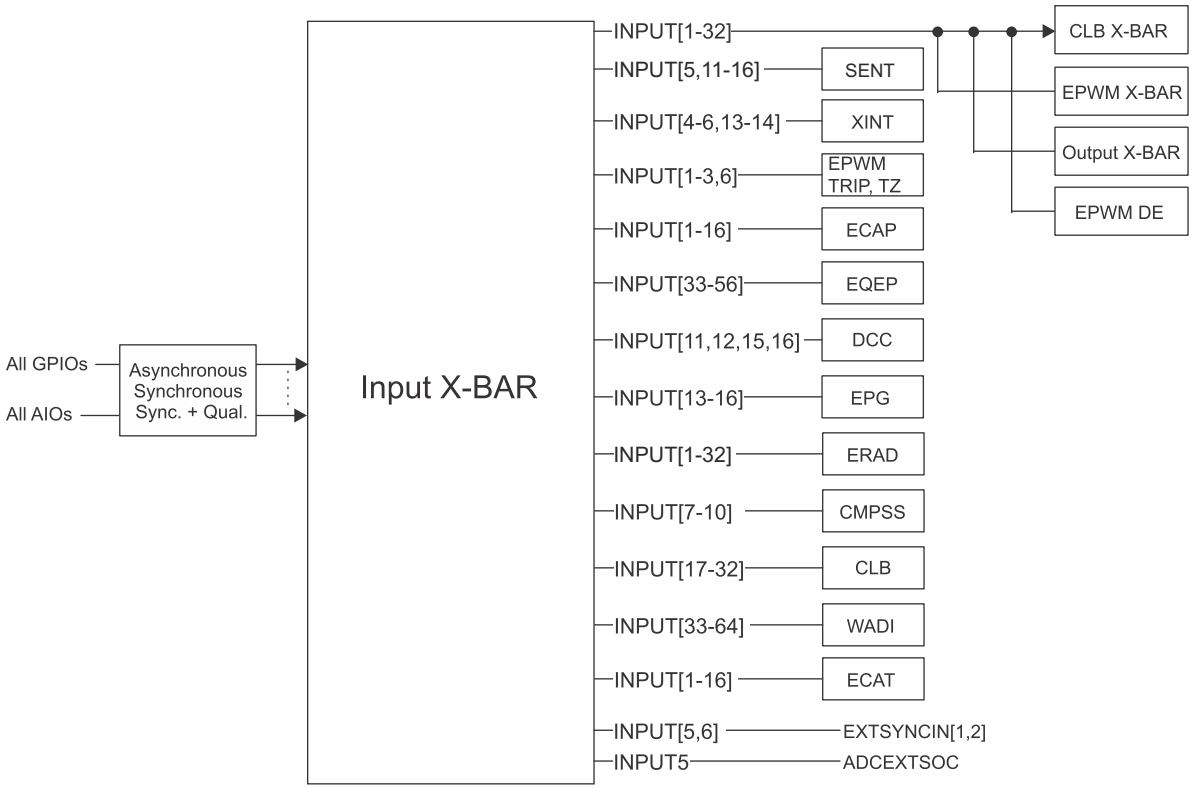

Figure 20-1. Input X-BAR

Note

INPUTXBARx, INPUTXBAR_INPUTx, and INPUTx (when referenced in the context of Input X-BAR) are equivalent in all C2000 software and documentation.

20.2.1 ICL and MINDB X-BAR

The Illegal Combo Logic (ICL) X-BAR and Minimum Dead-band (MINDB) X-BAR are used to route various EPWM signals and CLB outputs to the Minimum Dead-band and Illegal Combination Logic sub-module of the EPWM.The MINDB and ICL XBARs are architecturally equivalent to the CLB X-BAR and EPWM X-BAR. The inputs for each ICL X-BAR are listed in Table 20-2. The inputs for each MINDB X-BAR are listed in Table 20-3.

20.3 ePWM , CLB, and GPIO Output X-BAR

This section describes the ePWM , CLB, and GPIO Output X-BAR. Remember that the minimum input pulse width required for ePWM, CLB XBAR (CLB Clocks required), SYSCLK for Output XBAR is 3 ticks of the respective clocks.

20.3.1 ePWM X-BAR

The ePWM X-BAR brings signals to the ePWM modules. Specifically, the ePWM X-BAR is connected to the Digital Compare (DC) submodule of each ePWM module for actions such as tripzones and syncing. Refer to the *Enhanced Pulse Width Modulator (ePWM)* chapter for more information on additional ways the DC submodule can be used. Figure 20-3 shows the architecture of the ePWM X-BAR. Note that the architecture of the ePWM X-BAR is identical to the architecture of the GPIO Output X-BAR (with the exception of the output latch).

20.3.1.1 ePWM X-BAR Architecture

The ePWM X-BAR has eight outputs that are routed to each ePWM module. There are two instances of ePWM X-BAR (ePWM X-BAR A and ePWM X-BAR B), resulting in 16 outputs total. Figure 20-3 represents the architecture of a single output, but this output is identical to the architecture of all of the other outputs.

First, determine the signals that can be passed to the ePWM by referencing Table 20-4. Select up to one signal for each TRIPx output. Select the inputs to ePWM X-BAR using the PWMXBARGxSEL registers. To pass any signal through to the ePWM, enable the signal using the INPUTx bit in the PWMXBARGxSEL register. All signals that are enabled are logically ORed before being passed on to the respective TRIPx signal on the ePWM. To optionally invert the signal, use the PWMXBAROutInvert register.

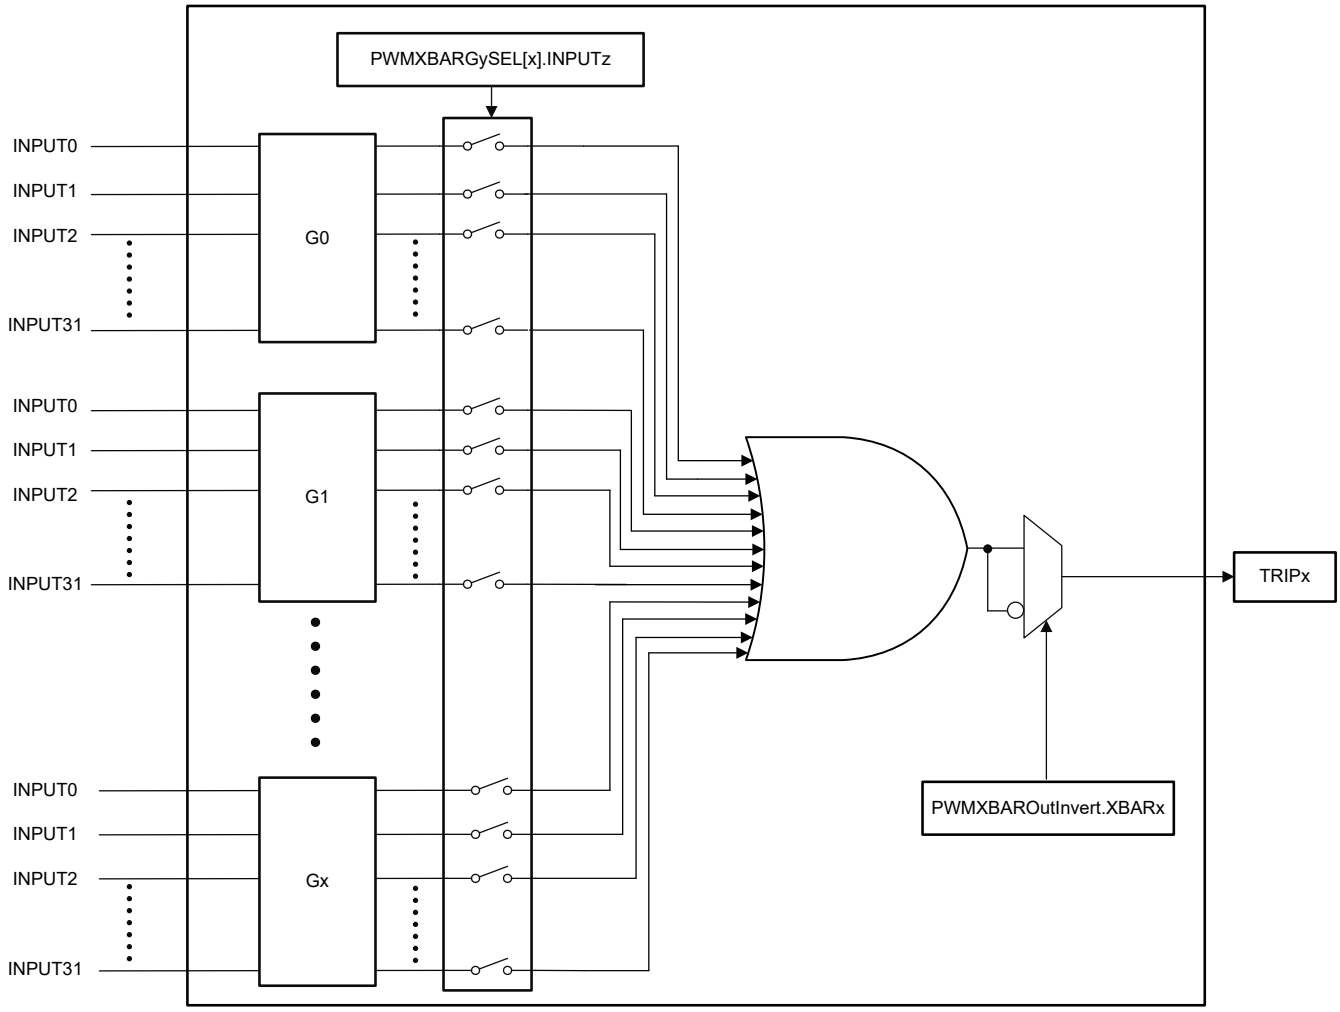

Figure 20-3. ePWM X-BAR Architecture - Single Output

Note

Do not use "Reserved" signals in your application.

There are two instances of the ePWM X-BAR (ePWM X-BAR A and ePWM X-BAR B). Table 20-4 describes the inputs to the ePWM X-BARs, which are identical for both instances. Each instance has 8 outputs. The outputs of ePWM X-BAR A are connected to trips 1-8 of each ePWM instance, while outputs 1-4 and output 6-7 of ePWM X-BAR B are connected to trips 9-12 and trips 14-15 of each ePWM instance, respectively. Note that outputs 5 and 8 of ePWM X-BAR B are not connected to any ePWM trip source.

20.3.2 CLB X-BAR

The CLB X-BAR brings signals to the CLB modules. Figure 20-4 shows the architecture of the CLB X-BAR.

20.3.2.1 CLB X-BAR Architecture

The CLB X-BAR has eight outputs that are routed to each CLB module. Figure 20-4 represents the architecture of a single output, but the output is identical to the architecture of all of the other outputs.

First, determine the signals that can be passed to the CLB by referencing Table 20-5. Each of these signals are enabled or disabled using the CLBXBARxGySEL registers before being passed through an OR gate. Additionally, there is an option to invert the output of the OR gate before the signal is passed to one of the auxiliary inputs (AUXSIG) of the CLB. There is one instance of CLB-XBAR per AUXSIG input. This architecture is identical to the ePWM X-BAR, ICL and MINDB X-BARs.

20.3.3 GPIO Output X-BAR

The GPIO Output X-BAR takes signals from inside the device and brings them out to a GPIO. Figure 20-6 shows the architecture of the GPIO Output X-BAR. The X-BAR contains sixteen outputs and each contains at least one position on the GPIO mux, denoted as OUTPUTXBARx. The X-BAR allows the selection of a single input or a logical-OR of many inputs.

20.3.3.1 GPIO Output X-BAR Architecture

The GPIO Output X-BAR has sixteen outputs that are routed to the GPIO module. Figure 20-6 represents the architecture of a single output, but this output is identical to the architecture of all of the other outputs.

First, determine the signals that can be passed to the GPIO by referencing Table 20-6. Each of these signals are enabled or disabled via the OUTPUTBARGxSEL registers before being passed through an OR gate. In contrast to the other XBAR modules, there are also features for output stretching, latching the output, and inverting the output either at the flag or final output stage. The diagram below shows these features in depth. The final output is only recognized on the GPIO if the proper OUTPUTx muxing options are selected using the GPIO registers.

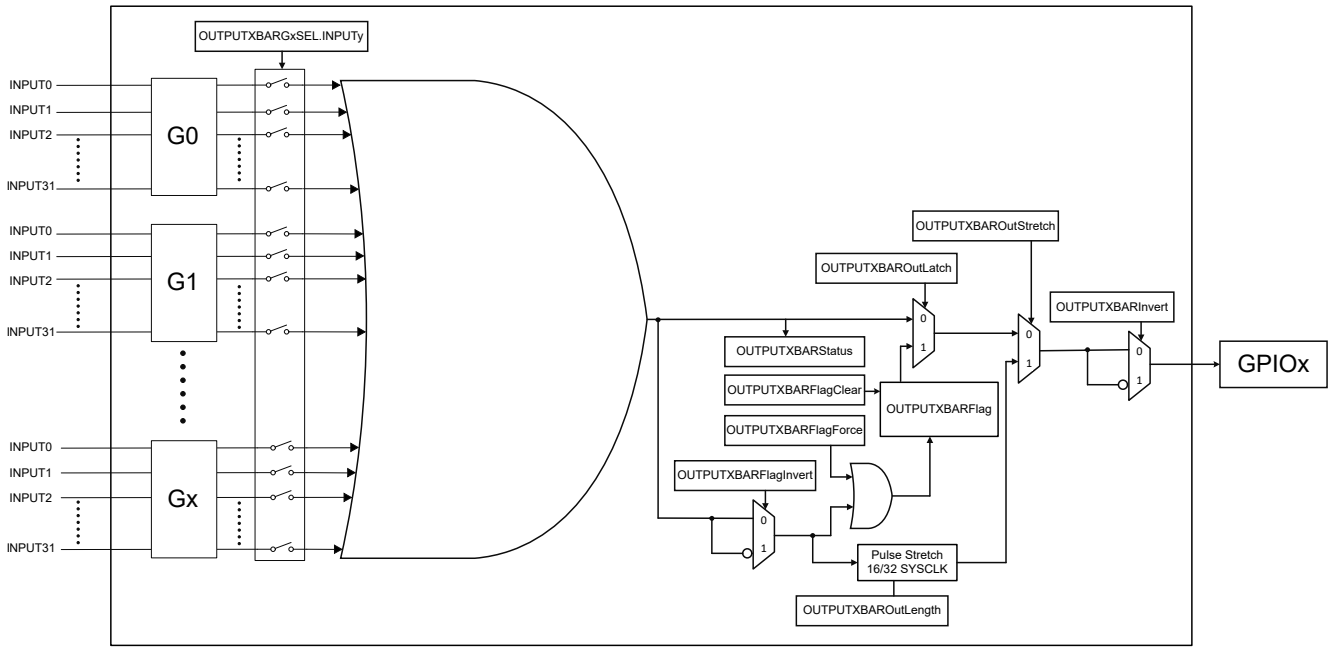

Figure 20-6. GPIO Output X-BAR Architecture

Note

Do not use "Reserved" signals in your application.

20.3.4 X-BAR Flags

With the exception of the CMPSS signals, the ePWM X-BAR and the Output X-BAR have all of the same input signals. Due to the inputs being similar between the ePWM X-BAR, CLB X-BAR, and Output X-BAR, all X-BAR modules leverage a single set of input flags to indicate which input signals have been triggered. This allows software to check the input flags when an event occurs. See Figure 20-7 for more information. There is a bit allocated for each input signal in one of the XBARFLGx registers. The flag remains set until cleared through the appropriate XBARCLRx register.

Note

Not all input sources are routed to all X-BAR modules. Refer to the X-BAR specific configuration tables for exact connections.

20.4.8 XBAR Examples

NOTE: These examples are located in the C29SDK installation from ti.com at the following location: mcu_sdk_DEVICE_GPN/examples/driverlib/CORE_IF_MULTICORE/xbar

Cloud access to these examples is available at the following link: dev.ti.com C29SDK Examples.

20.4.8.1 Input XBAR to Output XBAR Connection - SINGLE_CORE

FILE: xbar_ex1_input_output.c

Utilizes the Input XBAR and Output XBAR modules to connect one GPIO to another without the use of external jumpers.

External Connections

- GPIO0 is an input. Connect an external signal to this GPIO
- GPIO1 is an output. Probe this GPIO with an oscilloscope

The state of GPIO1 should always match the state of GPIO0 trigger) is routed to the input X-BAR, from which it is routed to TZ1.

20.4.8.2 Output XBAR Pulse Stretch - SINGLE_CORE

FILE: xbar_ex2_output_pulse_stretch.c

Reads an EPWM with a short duty cycle via an Input XBAR and connects it to the Output XBAR module. Enables pulse stretching in the Output XBAR to create a minimum duty cycle of 16 SYSCLKs.

External Connections

- GPIO0 and GPIO1 are EPWM outputs.
- GPIO2 is the pulse-stretched Output XBAR output.

20.5 XBAR Registers

This Section describes the XBAR Registers.

20.5.1 XBAR Base Address Table

Table 20-14. XBAR Base Address Table

XBAR_REGS	XBAR_BASE	0x600E_0000	YES	YES	YES	YES	YES	YES	-	YES

(1) Registers writeable by CPU1.LINK0, CPU1.LINK1, CPU1.LINK2 only. All CPUs can read all registers in all LINKs. Debug write access only allowed if Zone0 or Zone1 are enabled for full debug by all CPUs. Debug reads always allowed. Register Read/Write access by HSM.

20.5.2 INPUT_XBAR_REGS Registers

Table 20-15 lists the memory-mapped registers for the INPUT_XBAR_REGS registers. All register offset addresses not listed in Table 20-15 should be considered as reserved locations and the register contents should not be modified.

Table 20-15. INPUT_XBAR_REGS Registers

Offset	Acronym	Register Name	Protection
0h + formula	INPUTSELECT_y	Input Select Register (GPIO0 to x)	
400h	INPUTSELECTLOCK1	Input Select Lock Register 1	
404h	INPUTSELECTLOCK2	Input Select Lock Register 2	

Complex bit access types are encoded to fit into small table cells. Table 20-16 shows the codes that are used for access types in this section.

Table 20-16. INPUT_XBAR_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

20.5.2.1 INPUTSELECT_y Register (Offset = 0h + formula) [Reset = 0000FFFEh]

INPUTSELECT_y is shown in Figure 20-8 and described in Table 20-17.

Return to the Summary Table.

Input Select Register (GPIO0 to x)

Offset = 0h + (y * 4h); where y = 0h to 3Fh

Figure 20-8. INPUTSELECT_y Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																SELECT															
R-0-0h																R/W-FFFEh															

Table 20-17. INPUTSELECT_y Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	RESERVED	R-0	0h	Reserved
15-0	SELECT	R/W	FFFEh	Select GPIO for INPUT{#} signal: 0x0 : Select GPIO0 0x1 : Select GPIO1 0x2 : Select GPIO2 ... 0xFFFD: '1' will be driven to the destination 0xFFFE: '1' will be driven to the destination 0xFFFF: '0' will be driven to the destination NOTE: SELECT value greater than the available number of GPIO pins on a device (except 0xFFFF) will cause the destination to be driven '1'. Reset type: XRSn

20.5.2.2 INPUTSELECTLOCK1 Register (Offset = 400h) [Reset = 00000000h]

INPUTSELECTLOCK1 is shown in Figure 20-9 and described in Table 20-18.

Return to the Summary Table.

Input Select Lock Register.
Any bit in this register, once set can only be cleared through SYSRSn. Write of 0 to any bit of this register has no effect. Reads to the registers which have LOCK protection are always allowed.

20.5.2.3 INPUTSELECTLOCK2 Register (Offset = 404h) [Reset = 00000000h]

INPUTSELECTLOCK2 is shown in Figure 20-10 and described in Table 20-19.

Return to the Summary Table.

Input Select Lock Register.
Any bit in this register, once set can only be cleared through SYSRSn. Write of 0 to any bit of this register has no effect. Reads to the registers which have LOCK protection are always allowed.

20.5.3 EPWM_XBAR_REGS Registers

Table 20-20 lists the memory-mapped registers for the EPWM_XBAR_REGS registers. All register offset addresses not listed in Table 20-20 should be considered as reserved locations and the register contents should not be modified.

Table 20-20. EPWM_XBAR_REGS Registers

Offset	Acronym	Register Name	Protection
30h	PWMXBAROutInvert	Output Signal Invert Select	
80h	PWMXBARLock	Configuration Lock register	
100h + formula	PWMXBARG0SEL_j	PWMXBAR G0 Input Select	
104h + formula	PWMXBARG1SEL_j	PWMXBAR G1 Input Select	
108h + formula	PWMXBARG2SEL_j	PWMXBAR G2 Input Select	
10Ch + formula	PWMXBARG3SEL_j	PWMXBAR G3 Input Select	
110h + formula	PWMXBARG4SEL_j	PWMXBAR G4 Input Select	
114h + formula	PWMXBARG5SEL_j	PWMXBAR G5 Input Select	
118h + formula	PWMXBARG6SEL_j	PWMXBAR G6 Input Select	
11Ch + formula	PWMXBARG7SEL_j	PWMXBAR G7 Input Select	
120h + formula	PWMXBARG8SEL_j	PWMXBAR G8 Input Select	
124h + formula	PWMXBARG9SEL_j	PWMXBAR G9 Input Select	

Complex bit access types are encoded to fit into small table cells. Table 20-21 shows the codes that are used for access types in this section.

Table 20-21. EPWM_XBAR_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.

Table 20-21. EPWM_XBAR_REGS Access Type Codes (continued)

Access Type	Code	Description
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

20.5.3.1 PWMXBAROutInvert Register (Offset = 30h) [Reset = 00000000h]

PWMXBAROutInvert is shown in Figure 20-11 and described in Table 20-22.

Return to the Summary Table.

20.5.4 CLB_XBAR_REGS Registers

Table 20-34 lists the memory-mapped registers for the CLB_XBAR_REGS registers. All register offset addresses not listed in Table 20-34 should be considered as reserved locations and the register contents should not be modified.

Table 20-34. CLB_XBAR_REGS Registers

Offset	Acronym	Register Name	Protection
30h	CLBXBAROutInvert	Output Signal Invert Select	
80h	CLBXBARLock	Configuration Lock register	
100h + formula	CLBXBARG0SEL_j	CLBXBAR G0 Input Select	
104h + formula	CLBXBARG1SEL_j	CLBXBAR G1 Input Select	
108h + formula	CLBXBARG2SEL_j	CLBXBAR G2 Input Select	
10Ch + formula	CLBXBARG3SEL_j	CLBXBAR G3 Input Select	
110h + formula	CLBXBARG4SEL_j	CLBXBAR G4 Input Select	
114h + formula	CLBXBARG5SEL_j	CLBXBAR G5 Input Select	
118h + formula	CLBXBARG6SEL_j	CLBXBAR G6 Input Select	
11Ch + formula	CLBXBARG7SEL_j	CLBXBAR G7 Input Select	

Complex bit access types are encoded to fit into small table cells. Table 20-35 shows the codes that are used for access types in this section.

Table 20-35. CLB_XBAR_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

20.5.4.1 CLBXBAROutInvert Register (Offset = 30h) [Reset = 00000000h]

CLBXBAROutInvert is shown in Figure 20-23 and described in Table 20-36.

Return to the Summary Table.

20.5.5 OUTPUTXBAR_REGS Registers

Table 20-46 lists the memory-mapped registers for the OUTPUTXBAR_REGS registers. All register offset addresses not listed in Table 20-46 should be considered as reserved locations and the register contents should not be modified.

Table 20-46. OUTPUTXBAR_REGS Registers

Offset	Acronym	Register Name	Protection
14h	OUTPUTXBARFlagInvert	Output Signal inversion register	
24h	OUTPUTXBAROutLatch	Output Signal Select Latch	
28h	OUTPUTXBAROutStretch	Output Signal Stretched Pulse Version Select	
2Ch	OUTPUTXBAROutLength	Output Signal Stretched Pulse Length Select	
30h	OUTPUTXBAROutInvert	Output Signal Invert Select	
80h	OUTPUTXBARLock	Configuration Lock register	
100h + formula	OUTPUTXBARG0SEL_j	OUTPUTXBAR G0 Input Select	
104h + formula	OUTPUTXBARG1SEL_j	OUTPUTXBAR G1 Input Select	
108h + formula	OUTPUTXBARG2SEL_j	OUTPUTXBAR G2 Input Select	
10Ch + formula	OUTPUTXBARG3SEL_j	OUTPUTXBAR G3 Input Select	
110h + formula	OUTPUTXBARG4SEL_j	OUTPUTXBAR G4 Input Select	
114h + formula	OUTPUTXBARG5SEL_j	OUTPUTXBAR G5 Input Select	
118h + formula	OUTPUTXBARG6SEL_j	OUTPUTXBAR G6 Input Select	
11Ch + formula	OUTPUTXBARG7SEL_j	OUTPUTXBAR G7 Input Select	
120h + formula	OUTPUTXBARG8SEL_j	OUTPUTXBAR G8 Input Select	
124h + formula	OUTPUTXBARG9SEL_j	OUTPUTXBAR G9 Input Select	

Complex bit access types are encoded to fit into small table cells. Table 20-47 shows the codes that are used for access types in this section.

Table 20-47. OUTPUTXBAR_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		

Table 20-47. OUTPUTXBAR_REGS Access Type Codes (continued)

Access Type	Code	Description
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

20.5.5.1 OUTPUTXBARFlagInvert Register (Offset = 14h) [Reset = 00000000h]

OUTPUTXBARFlagInvert is shown in Figure 20-33 and described in Table 20-48.

Return to the Summary Table.

20.5.6 MDL_XBAR_REGS Registers

Table 20-64 lists the memory-mapped registers for the MDL_XBAR_REGS registers. All register offset addresses not listed in Table 20-64 should be considered as reserved locations and the register contents should not be modified.

Table 20-64. MDL_XBAR_REGS Registers

Offset	Acronym	Register Name	Protection
30h	MDLXBAROutInvert	Output Signal Invert Select	
80h	MDLXBARLock	Configuration Lock register	
100h + formula	MDLXBARG0SEL_j	MDLXBAR G0 Input Select	
104h + formula	MDLXBARG1SEL_j	MDLXBAR G1 Input Select	
108h + formula	MDLXBARG2SEL_j	MDLXBAR G2 Input Select	

Complex bit access types are encoded to fit into small table cells. Table 20-65 shows the codes that are used for access types in this section.

Table 20-65. MDL_XBAR_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

20.5.6.1 MDLXBAROutInvert Register (Offset = 30h) [Reset = 00000000h]

MDLXBAROutInvert is shown in Figure 20-49 and described in Table 20-66.

Return to the Summary Table.

20.5.7 ICL_XBAR_REGS Registers

Table 20-71 lists the memory-mapped registers for the ICL_XBAR_REGS registers. All register offset addresses not listed in Table 20-71 should be considered as reserved locations and the register contents should not be modified.

Table 20-71. ICL_XBAR_REGS Registers

Offset	Acronym	Register Name	Protection
30h	ICLXBAROutInvert	Output Signal Invert Select	
80h	ICLXBARLock	Configuration Lock register	
100h + formula	ICLXBARG0SEL_j	ICLXBAR G0 Input Select	
104h + formula	ICLXBARG1SEL_j	ICLXBAR G1 Input Select	
108h + formula	ICLXBARG2SEL_j	ICLXBAR G2 Input Select	

Complex bit access types are encoded to fit into small table cells. Table 20-72 shows the codes that are used for access types in this section.

Table 20-72. ICL_XBAR_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

20.5.7.1 ICLXBAROutInvert Register (Offset = 30h) [Reset = 00000000h]

ICLXBAROutInvert is shown in Figure 20-54 and described in Table 20-73.

Return to the Summary Table.

20.5.8 OUTPUTXBAR_FLAG_REGS Registers

Table 20-78 lists the memory-mapped registers for the OUTPUTXBAR_FLAG_REGS registers. All register offset addresses not listed in Table 20-78 should be considered as reserved locations and the register contents should not be modified.

Table 20-78. OUTPUTXBAR_FLAG_REGS Registers

Offset	Acronym	Register Name	Protection
10h	OUTPUTXBARStatus	Output Signal Status register	
18h	OUTPUTXBARFlag	Output latched flag register	
1Ch	OUTPUTXBARFlagClear	Output latched flag clear register	
20h	OUTPUTXBARFlagForce	Output latched flag Force register	

Complex bit access types are encoded to fit into small table cells. Table 20-79 shows the codes that are used for access types in this section.

Table 20-79. OUTPUTXBAR_FLAG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

20.5.8.1 OUTPUTXBARStatus Register (Offset = 10h) [Reset = 00000000h]

OUTPUTXBARStatus is shown in Figure 20-59 and described in Table 20-80.

Return to the Summary Table.

-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

20.5.9.1 XBARFLG1 Register (Offset = 0h) [Reset = 00000000h]

XBARFLG1 is shown in Figure 20-63 and described in Table 20-86.

Return to the Summary Table.

This register is used to flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered.
1: Corresponding Input was triggered
0: Corresponding Input was not triggered

23	SD3FLT4_COMPL	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: SD3FLT4_COMPL input was triggered 0: SD3FLT4_COMPL Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
22	SD3FLT4_COMPH	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: SD3FLT4_COMPH input was triggered 0: SD3FLT4_COMPH Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
21	SD3FLT3_COMPL	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: SD3FLT3_COMPL input was triggered 0: SD3FLT3_COMPL Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn

Table 20-88. XBARFLG3 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
20	SD3FLT3_COMPH	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: SD3FLT3_COMPH input was triggered 0: SD3FLT3_COMPH Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
19	SD3FLT2_COMPL	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: SD3FLT2_COMPL input was triggered 0: SD3FLT2_COMPL Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
18	SD3FLT2_COMPH	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: SD3FLT2_COMPH input was triggered 0: SD3FLT2_COMPH Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
17	SD3FLT1_COMPL	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: SD3FLT1_COMPL input was triggered 0: SD3FLT1_COMPL Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
16	SD3FLT1_COMPH	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: SD3FLT1_COMPH input was triggered 0: SD3FLT1_COMPH Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
15	SD2FLT4_COMPH	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: SD2FLT4_COMPH input was triggered 0: SD2FLT4_COMPH Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
14	SD2FLT4_COMPL	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: SD2FLT4_COMPL input was triggered 0: SD2FLT4_COMPL Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
13	SD2FLT3_COMPH	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: SD2FLT3_COMPH input was triggered 0: SD2FLT3_COMPH Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn

Table 20-88. XBARFLG3 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
12	SD2FLT3_COMPL	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: SD2FLT3_COMPL input was triggered 0: SD2FLT3_COMPL Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
11	SD2FLT2_COMPH	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: SD2FLT2_COMPH input was triggered 0: SD2FLT2_COMPH Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
10	SD2FLT2_COMPL	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: SD2FLT2_COMPL input was triggered 0: SD2FLT2_COMPL Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
9	SD2FLT1_COMPH	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: SD2FLT1_COMPH input was triggered 0: SD2FLT1_COMPH Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
8	SD2FLT1_COMPL	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: SD2FLT1_COMPL input was triggered 0: SD2FLT1_COMPL Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
7	SD1FLT4_COMPH	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: SD1FLT4_COMPH input was triggered 0: SD1FLT4_COMPH Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
6	SD1FLT4_COMPL	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: SD1FLT4_COMPL input was triggered 0: SD1FLT4_COMPL Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
5	SD1FLT3_COMPH	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: SD1FLT3_COMPH input was triggered 0: SD1FLT3_COMPH Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn

Table 20-88. XBARFLG3 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4	SD1FLT3_COMPL	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: SD1FLT3_COMPL input was triggered 0: SD1FLT3_COMPL Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
3	SD1FLT2_COMPH	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: SD1FLT2_COMPH input was triggered 0: SD1FLT2_COMPH Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
2	SD1FLT2_COMPL	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: SD1FLT2_COMPL input was triggered 0: SD1FLT2_COMPL Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
1	SD1FLT1_COMPH	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: SD1FLT1_COMPH input was triggered 0: SD1FLT1_COMPH Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
0	SD1FLT1_COMPL	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: SD1FLT1_COMPL input was triggered 0: SD1FLT1_COMPL Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn

20.5.9.4 XBARFLG4 Register (Offset = Ch) [Reset = 00000000h]

XBARFLG4 is shown in Figure 20-66 and described in Table 20-89.

Return to the Summary Table.

This register is used to flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered.
1: Corresponding Input was triggered
0: Corresponding Input was not triggered

Table 20-89. XBARFLG4 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	INPUT32	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT32 input was triggered 0: INPUT32 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
30	INPUT31	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT31 input was triggered 0: INPUT31 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
29	INPUT30	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT30 input was triggered 0: INPUT30 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
28	INPUT29	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT29 input was triggered 0: INPUT29 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn

Table 20-89. XBARFLG4 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
27	INPUT28	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT28 input was triggered 0: INPUT28 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
26	INPUT27	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT27 input was triggered 0: INPUT27 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
25	INPUT26	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT26 input was triggered 0: INPUT26 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
24	INPUT25	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT25 input was triggered 0: INPUT25 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
23	INPUT24	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT24 input was triggered 0: INPUT24 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
22	INPUT23	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT23 input was triggered 0: INPUT23 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
21	INPUT22	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT22 input was triggered 0: INPUT22 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
20	INPUT21	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT21 input was triggered 0: INPUT21 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn

Table 20-89. XBARFLG4 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19	INPUT20	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT20 input was triggered 0: INPUT20 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
18	INPUT19	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT19 input was triggered 0: INPUT19 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
17	INPUT18	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT18 input was triggered 0: INPUT18 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
16	INPUT17	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT17 input was triggered 0: INPUT17 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
15	INPUT16	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT16 input was triggered 0: INPUT16 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
14	INPUT15	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT15 input was triggered 0: INPUT15 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
13	INPUT14	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT14 input was triggered 0: INPUT14 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
12	INPUT13	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT13 input was triggered 0: INPUT13 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn

Table 20-89. XBARFLG4 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11	INPUT12	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT12 input was triggered 0: INPUT12 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
10	INPUT11	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT11 input was triggered 0: INPUT11 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
9	INPUT10	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT10 input was triggered 0: INPUT10 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
8	INPUT9	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT9 input was triggered 0: INPUT9 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
7	INPUT8	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT8 input was triggered 0: INPUT8 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
6	INPUT7	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT7 input was triggered 0: INPUT7 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
5	INPUT6	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT6 input was triggered 0: INPUT6 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
4	INPUT5	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT5 input was triggered 0: INPUT5 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn

Table 20-89. XBARFLG4 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	INPUT4	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT4 input was triggered 0: INPUT4 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
2	INPUT3	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT3 input was triggered 0: INPUT3 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
1	INPUT2	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT2 input was triggered 0: INPUT2 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
0	INPUT1	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: INPUT1 input was triggered 0: INPUT1 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn

20.5.9.5 XBARFLG5 Register (Offset = 10h) [Reset = 00000000h]

XBARFLG5 is shown in Figure 20-67 and described in Table 20-90.

Return to the Summary Table.

This register is used to flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered.
1: Corresponding Input was triggered
0: Corresponding Input was not triggered

Bit	Field	Type	Reset	Description
27	CPU2_ADCCHECKEVT4	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CPU2_ADCCHECKEVT4 input was triggered 0: CPU2_ADCCHECKEVT4 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
26	CPU2_ADCCHECKEVT3	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CPU2_ADCCHECKEVT3 input was triggered 0: CPU2_ADCCHECKEVT3 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
25	CPU2_ADCCHECKEVT2	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CPU2_ADCCHECKEVT2 input was triggered 0: CPU2_ADCCHECKEVT2 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
24	CPU2_ADCCHECKEVT1	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CPU2_ADCCHECKEVT1 input was triggered 0: CPU2_ADCCHECKEVT1 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
23	CPU1_ADCCHECKEVT4	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CPU1_ADCCHECKEVT4 input was triggered 0: CPU1_ADCCHECKEVT4 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
22	CPU1_ADCCHECKEVT3	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CPU1_ADCCHECKEVT3 input was triggered 0: CPU1_ADCCHECKEVT3 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
21	CPU1_ADCCHECKEVT2	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CPU1_ADCCHECKEVT2 input was triggered 0: CPU1_ADCCHECKEVT2 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
20	CPU1_ADCCHECKEVT1	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CPU1_ADCCHECKEVT1 input was triggered 0: CPU1_ADCCHECKEVT1 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn

Table 20-90. XBARFLG5 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19	ADCEEVT4	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: ADCEEVT4 input was triggered 0: ADCEEVT4 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
18	ADCEEVT3	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: ADCEEVT3 input was triggered 0: ADCEEVT3 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
17	ADCEEVT2	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: ADCEEVT2 input was triggered 0: ADCEEVT2 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
16	ADCEEVT1	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: ADCEEVT1 input was triggered 0: ADCEEVT1 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
15	ADCDEVT4	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: ADCDEVT4 input was triggered 0: ADCDEVT4 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
14	ADCDEVT3	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: ADCDEVT3 input was triggered 0: ADCDEVT3 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
13	ADCDEVT2	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: ADCDEVT2 input was triggered 0: ADCDEVT2 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
12	ADCDEVT1	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: ADCDEVT1 input was triggered 0: ADCDEVT1 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn

Table 20-90. XBARFLG5 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11	ADCCEVT4	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: ADCCEVT4 input was triggered 0: ADCCEVT4 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
10	ADCCEVT3	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: ADCCEVT3 input was triggered 0: ADCCEVT3 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
9	ADCCEVT2	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: ADCCEVT2 input was triggered 0: ADCCEVT2 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
8	ADCCEVT1	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: ADCCEVT1 input was triggered 0: ADCCEVT1 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
7	ADCBEVT4	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: ADCBEVT4 input was triggered 0: ADCBEVT4 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
6	ADCBEVT3	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: ADCBEVT3 input was triggered 0: ADCBEVT3 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
5	ADCBEVT2	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: ADCBEVT2 input was triggered 0: ADCBEVT2 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
4	ADCBEVT1	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: ADCBEVT1 input was triggered 0: ADCBEVT1 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn

29	EPWM15_B0_sclk	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: EPWM15_B0_sclk input was triggered 0: EPWM15_B0_sclk Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn

Table 20-96. XBARFLG11 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
28	EPWM15_A0_sclk	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: EPWM15_A0_sclk input was triggered 0: EPWM15_A0_sclk Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
27	EPWM14_B0_sclk	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: EPWM14_B0_sclk input was triggered 0: EPWM14_B0_sclk Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
26	EPWM14_A0_sclk	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: EPWM14_A0_sclk input was triggered 0: EPWM14_A0_sclk Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
25	EPWM13_B0_sclk	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: EPWM13_B0_sclk input was triggered 0: EPWM13_B0_sclk Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
24	EPWM13_A0_sclk	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: EPWM13_A0_sclk input was triggered 0: EPWM13_A0_sclk Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
23	EPWM12_B0_sclk	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: EPWM12_B0_sclk input was triggered 0: EPWM12_B0_sclk Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
22	EPWM12_A0_sclk	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: EPWM12_A0_sclk input was triggered 0: EPWM12_A0_sclk Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
21	EPWM11_B0_sclk	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: EPWM11_B0_sclk input was triggered 0: EPWM11_B0_sclk Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn

Table 20-96. XBARFLG11 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
20	EPWM11_A0_sclk	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: EPWM11_A0_sclk input was triggered 0: EPWM11_A0_sclk Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
19	EPWM10_B0_sclk	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: EPWM10_B0_sclk input was triggered 0: EPWM10_B0_sclk Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
18	EPWM10_A0_sclk	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: EPWM10_A0_sclk input was triggered 0: EPWM10_A0_sclk Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
17	EPWM9_B0_sclk	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: EPWM9_B0_sclk input was triggered 0: EPWM9_B0_sclk Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
16	EPWM9_A0_sclk	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: EPWM9_A0_sclk input was triggered 0: EPWM9_A0_sclk Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
15	EPWM8_B0_sclk	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: EPWM8_B0_sclk input was triggered 0: EPWM8_B0_sclk Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
14	EPWM8_A0_sclk	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: EPWM8_A0_sclk input was triggered 0: EPWM8_A0_sclk Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
13	EPWM7_B0_sclk	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: EPWM7_B0_sclk input was triggered 0: EPWM7_B0_sclk Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn

Table 20-96. XBARFLG11 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
12	EPWM7_A0_sclk	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: EPWM7_A0_sclk input was triggered 0: EPWM7_A0_sclk Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
11	EPWM6_B0_sclk	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: EPWM6_B0_sclk input was triggered 0: EPWM6_B0_sclk Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
10	EPWM6_A0_sclk	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: EPWM6_A0_sclk input was triggered 0: EPWM6_A0_sclk Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
9	EPWM5_B0_sclk	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: EPWM5_B0_sclk input was triggered 0: EPWM5_B0_sclk Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
8	EPWM5_A0_sclk	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: EPWM5_A0_sclk input was triggered 0: EPWM5_A0_sclk Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
7	EPWM4_B0_sclk	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: EPWM4_B0_sclk input was triggered 0: EPWM4_B0_sclk Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
6	EPWM4_A0_sclk	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: EPWM4_A0_sclk input was triggered 0: EPWM4_A0_sclk Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
5	EPWM3_B0_sclk	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: EPWM3_B0_sclk input was triggered 0: EPWM3_B0_sclk Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn

Table 20-96. XBARFLG11 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4	EPWM3_A0_sclk	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: EPWM3_A0_sclk input was triggered 0: EPWM3_A0_sclk Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
3	EPWM2_B0_sclk	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: EPWM2_B0_sclk input was triggered 0: EPWM2_B0_sclk Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
2	EPWM2_A0_sclk	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: EPWM2_A0_sclk input was triggered 0: EPWM2_A0_sclk Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
1	EPWM1_B0_sclk	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: EPWM1_B0_sclk input was triggered 0: EPWM1_B0_sclk Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
0	EPWM1_A0_sclk	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: EPWM1_A0_sclk input was triggered 0: EPWM1_A0_sclk Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn

20.5.9.12 XBARFLG12 Register (Offset = 2Ch) [Reset = 00000000h]

XBARFLG12 is shown in Figure 20-74 and described in Table 20-97.

Return to the Summary Table.

This register is used to flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered.
1: Corresponding Input was triggered
0: Corresponding Input was not triggered

Table 20-98. XBARFLG13 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
27	MDL14_OUTB	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: MDL14_OUTB input was triggered 0: MDL14_OUTB Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
26	MDL14_OUTA	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: MDL14_OUTA input was triggered 0: MDL14_OUTA Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
25	MDL13_OUTB	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: MDL13_OUTB input was triggered 0: MDL13_OUTB Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
24	MDL13_OUTA	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: MDL13_OUTA input was triggered 0: MDL13_OUTA Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
23	MDL12_OUTB	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: MDL12_OUTB input was triggered 0: MDL12_OUTB Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
22	MDL12_OUTA	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: MDL12_OUTA input was triggered 0: MDL12_OUTA Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
21	MDL11_OUTB	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: MDL11_OUTB input was triggered 0: MDL11_OUTB Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
20	MDL11_OUTA	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: MDL11_OUTA input was triggered 0: MDL11_OUTA Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn

Table 20-98. XBARFLG13 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19	MDL10_OUTB	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: MDL10_OUTB input was triggered 0: MDL10_OUTB Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
18	MDL10_OUTA	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: MDL10_OUTA input was triggered 0: MDL10_OUTA Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
17	MDL9_OUTB	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: MDL9_OUTB input was triggered 0: MDL9_OUTB Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
16	MDL9_OUTA	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: MDL9_OUTA input was triggered 0: MDL9_OUTA Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
15	MDL8_OUTB	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: MDL8_OUTB input was triggered 0: MDL8_OUTB Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
14	MDL8_OUTA	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: MDL8_OUTA input was triggered 0: MDL8_OUTA Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
13	MDL7_OUTB	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: MDL7_OUTB input was triggered 0: MDL7_OUTB Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
12	MDL7_OUTA	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: MDL7_OUTA input was triggered 0: MDL7_OUTA Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn

Table 20-98. XBARFLG13 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11	MDL6_OUTB	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: MDL6_OUTB input was triggered 0: MDL6_OUTB Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
10	MDL6_OUTA	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: MDL6_OUTA input was triggered 0: MDL6_OUTA Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
9	MDL5_OUTB	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: MDL5_OUTB input was triggered 0: MDL5_OUTB Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
8	MDL5_OUTA	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: MDL5_OUTA input was triggered 0: MDL5_OUTA Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
7	MDL4_OUTB	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: MDL4_OUTB input was triggered 0: MDL4_OUTB Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
6	MDL4_OUTA	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: MDL4_OUTA input was triggered 0: MDL4_OUTA Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
5	MDL3_OUTB	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: MDL3_OUTB input was triggered 0: MDL3_OUTB Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
4	MDL3_OUTA	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: MDL3_OUTA input was triggered 0: MDL3_OUTA Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn

Table 20-98. XBARFLG13 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	MDL2_OUTB	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: MDL2_OUTB input was triggered 0: MDL2_OUTB Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
2	MDL2_OUTA	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: MDL2_OUTA input was triggered 0: MDL2_OUTA Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
1	MDL1_OUTB	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: MDL1_OUTB input was triggered 0: MDL1_OUTB Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
0	MDL1_OUTA	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: MDL1_OUTA input was triggered 0: MDL1_OUTA Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn

20.5.9.14 XBARFLG14 Register (Offset = 34h) [Reset = 00000000h]

XBARFLG14 is shown in Figure 20-76 and described in Table 20-99.

Return to the Summary Table.

This register is used to flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered.
1: Corresponding Input was triggered
0: Corresponding Input was not triggered

Bit	Field	Type	Reset	Description
27	CLB5_OUT3	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CLB5_OUT3 input was triggered 0: CLB5_OUT3 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
26	CLB5_OUT2	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CLB5_OUT2 input was triggered 0: CLB5_OUT2 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
25	CLB5_OUT1	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CLB5_OUT1 input was triggered 0: CLB5_OUT1 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
24	CLB5_OUT0	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CLB5_OUT0 input was triggered 0: CLB5_OUT0 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
23	CLB4_OUT7	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CLB4_OUT7 input was triggered 0: CLB4_OUT7 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
22	CLB4_OUT6	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CLB4_OUT6 input was triggered 0: CLB4_OUT6 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
21	CLB4_OUT3	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CLB4_OUT3 input was triggered 0: CLB4_OUT3 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
20	CLB4_OUT2	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CLB4_OUT2 input was triggered 0: CLB4_OUT2 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn

Table 20-100. XBARFLG15 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19	CLB4_OUT1	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CLB4_OUT1 input was triggered 0: CLB4_OUT1 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
18	CLB4_OUT0	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CLB4_OUT0 input was triggered 0: CLB4_OUT0 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
17	CLB3_OUT7	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CLB3_OUT7 input was triggered 0: CLB3_OUT7 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
16	CLB3_OUT6	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CLB3_OUT6 input was triggered 0: CLB3_OUT6 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
15	CLB3_OUT3	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CLB3_OUT3 input was triggered 0: CLB3_OUT3 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
14	CLB3_OUT2	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CLB3_OUT2 input was triggered 0: CLB3_OUT2 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
13	CLB3_OUT1	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CLB3_OUT1 input was triggered 0: CLB3_OUT1 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
12	CLB3_OUT0	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CLB3_OUT0 input was triggered 0: CLB3_OUT0 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn

Table 20-100. XBARFLG15 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11	CLB2_OUT7	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CLB2_OUT7 input was triggered 0: CLB2_OUT7 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
10	CLB2_OUT6	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CLB2_OUT6 input was triggered 0: CLB2_OUT6 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
9	CLB2_OUT3	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CLB2_OUT3 input was triggered 0: CLB2_OUT3 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
8	CLB2_OUT2	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CLB2_OUT2 input was triggered 0: CLB2_OUT2 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
7	CLB2_OUT1	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CLB2_OUT1 input was triggered 0: CLB2_OUT1 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
6	CLB2_OUT0	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CLB2_OUT0 input was triggered 0: CLB2_OUT0 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
5	CLB1_OUT7	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CLB1_OUT7 input was triggered 0: CLB1_OUT7 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
4	CLB1_OUT6	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CLB1_OUT6 input was triggered 0: CLB1_OUT6 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn

Table 20-100. XBARFLG15 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	CLB1_OUT3	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CLB1_OUT3 input was triggered 0: CLB1_OUT3 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
2	CLB1_OUT2	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CLB1_OUT2 input was triggered 0: CLB1_OUT2 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
1	CLB1_OUT1	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CLB1_OUT1 input was triggered 0: CLB1_OUT1 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn
0	CLB1_OUT0	R	0h	This register is used to Flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered. 1: CLB1_OUT0 input was triggered 0: CLB1_OUT0 Input was not triggered Note: [1] setting of this bit has priority over clear by software Reset type: CPU1.SYSRSn

20.5.9.16 XBARFLG16 Register (Offset = 3Ch) [Reset = 00000000h]

XBARFLG16 is shown in Figure 20-78 and described in Table 20-101.

Return to the Summary Table.

This register is used to flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered.
1: Corresponding Input was triggered
0: Corresponding Input was not triggered

2	CMPSS2_CTRIPL	R-0/W1S	0h	Writing 1 to this bit clears the CMPSS2_CTRIPL bit in the XBARFLG1 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
1	CMPSS1_CTRIPH	R-0/W1S	0h	Writing 1 to this bit clears the CMPSS1_CTRIPH bit in the XBARFLG1 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
0	CMPSS1_CTRIPL	R-0/W1S	0h	Writing 1 to this bit clears the CMPSS1_CTRIPL bit in the XBARFLG1 register. Writing 0 has no effect Reset type: CPU1.SYSRSn

20.5.9.20 XBARCLR2 Register (Offset = 104h) [Reset = 00000000h]

XBARCLR2 is shown in Figure 20-82 and described in Table 20-105.

Return to the Summary Table.

This register is used to clear the flag(s) in the XBARFLG register.
1: Clears the corresponding bit in the XBARFLG register.
0: Writing 0 has no effect

Bit	Field	Type	Reset	Description
5	INPUT6	R-0/W1S	0h	Writing 1 to this bit clears the INPUT6 bit in the XBARFLG4 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
4	INPUT5	R-0/W1S	0h	Writing 1 to this bit clears the INPUT5 bit in the XBARFLG4 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
3	INPUT4	R-0/W1S	0h	Writing 1 to this bit clears the INPUT4 bit in the XBARFLG4 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
2	INPUT3	R-0/W1S	0h	Writing 1 to this bit clears the INPUT3 bit in the XBARFLG4 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
1	INPUT2	R-0/W1S	0h	Writing 1 to this bit clears the INPUT2 bit in the XBARFLG4 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
0	INPUT1	R-0/W1S	0h	Writing 1 to this bit clears the INPUT1 bit in the XBARFLG4 register. Writing 0 has no effect Reset type: CPU1.SYSRSn

20.5.9.23 XBARCLR5 Register (Offset = 110h) [Reset = 00000000h]

XBARCLR5 is shown in Figure 20-85 and described in Table 20-108.

Return to the Summary Table.

This register is used to clear the flag(s) in the XBARFLG register.
1: Clears the corresponding bit in the XBARFLG register.
0: Writing 0 has no effect

1	ECAP2_OUT	R-0/W1S	0h	Writing 1 to this bit clears the ECAP2_OUT bit in the XBARFLG7 register. Writing 0 has no effect Reset type: CPU1.SYSRSn
0	ECAP1_OUT	R-0/W1S	0h	Writing 1 to this bit clears the ECAP1_OUT bit in the XBARFLG7 register. Writing 0 has no effect Reset type: CPU1.SYSRSn

20.5.9.26 XBARCLR8 Register (Offset = 11Ch) [Reset = 00000000h]

XBARCLR8 is shown in Figure 20-88 and described in Table 20-111.

Return to the Summary Table.

This register is used to clear the flag(s) in the XBARFLG register.
1: Clears the corresponding bit in the XBARFLG register.
0: Writing 0 has no effect

18	CLB4_OUT0	R-0/W1S	0h	Writing 1 to this bit clears the CLB4_OUT0 bit in this register. Writing 0 has no effect Reset type: CPU1.SYSRSn
17	CLB3_OUT7	R-0/W1S	0h	Writing 1 to this bit clears the CLB3_OUT7 bit in this register. Writing 0 has no effect Reset type: CPU1.SYSRSn
16	CLB3_OUT6	R-0/W1S	0h	Writing 1 to this bit clears the CLB3_OUT6 bit in this register. Writing 0 has no effect Reset type: CPU1.SYSRSn
15	CLB3_OUT3	R-0/W1S	0h	Writing 1 to this bit clears the CLB3_OUT3 bit in this register. Writing 0 has no effect Reset type: CPU1.SYSRSn
14	CLB3_OUT2	R-0/W1S	0h	Writing 1 to this bit clears the CLB3_OUT2 bit in this register. Writing 0 has no effect Reset type: CPU1.SYSRSn
13	CLB3_OUT1	R-0/W1S	0h	Writing 1 to this bit clears the CLB3_OUT1 bit in this register. Writing 0 has no effect Reset type: CPU1.SYSRSn
12	CLB3_OUT0	R-0/W1S	0h	Writing 1 to this bit clears the CLB3_OUT0 bit in this register. Writing 0 has no effect Reset type: CPU1.SYSRSn
11	CLB2_OUT7	R-0/W1S	0h	Writing 1 to this bit clears the CLB2_OUT7 bit in this register. Writing 0 has no effect Reset type: CPU1.SYSRSn
10	CLB2_OUT6	R-0/W1S	0h	Writing 1 to this bit clears the CLB2_OUT6 bit in this register. Writing 0 has no effect Reset type: CPU1.SYSRSn
9	CLB2_OUT3	R-0/W1S	0h	Writing 1 to this bit clears the CLB2_OUT3 bit in this register. Writing 0 has no effect Reset type: CPU1.SYSRSn
8	CLB2_OUT2	R-0/W1S	0h	Writing 1 to this bit clears the CLB2_OUT2 bit in this register. Writing 0 has no effect Reset type: CPU1.SYSRSn
7	CLB2_OUT1	R-0/W1S	0h	Writing 1 to this bit clears the CLB2_OUT1 bit in this register. Writing 0 has no effect Reset type: CPU1.SYSRSn
6	CLB2_OUT0	R-0/W1S	0h	Writing 1 to this bit clears the CLB2_OUT0 bit in this register. Writing 0 has no effect Reset type: CPU1.SYSRSn

Table 20-118. XBARCLR15 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	CLB1_OUT7	R-0/W1S	0h	Writing 1 to this bit clears the CLB1_OUT7 bit in this register. Writing 0 has no effect Reset type: CPU1.SYSRSn
4	CLB1_OUT6	R-0/W1S	0h	Writing 1 to this bit clears the CLB1_OUT6 bit in this register. Writing 0 has no effect Reset type: CPU1.SYSRSn
3	CLB1_OUT3	R-0/W1S	0h	Writing 1 to this bit clears the CLB1_OUT3 bit in this register. Writing 0 has no effect Reset type: CPU1.SYSRSn
2	CLB1_OUT2	R-0/W1S	0h	Writing 1 to this bit clears the CLB1_OUT2 bit in this register. Writing 0 has no effect Reset type: CPU1.SYSRSn
1	CLB1_OUT1	R-0/W1S	0h	Writing 1 to this bit clears the CLB1_OUT1 bit in this register. Writing 0 has no effect Reset type: CPU1.SYSRSn
0	CLB1_OUT0	R-0/W1S	0h	Writing 1 to this bit clears the CLB1_OUT0 bit in this register. Writing 0 has no effect Reset type: CPU1.SYSRSn

20.5.9.34 XBARCLR16 Register (Offset = 13Ch) [Reset = 00000000h]

XBARCLR16 is shown in Figure 20-96 and described in Table 20-119.

Return to the Summary Table.

This register is used to clear the flag(s) in the XBARFLG register.
1: Clears the corresponding bit in the XBARFLG register.
0: Writing 0 has no effect

Chapter 21

Embedded Pattern Generator (EPG)

This chapter describes the Embedded Pattern Generator (EPG) module.

21.1 Introduction

The Embedded Pattern Generator (EPG) module is a customizable pattern and clock generator that can serve many test and application scenarios that require a simple pattern generator or a periodic clock generator. The EPG module can also be used to capture an incoming serial stream of data.

21.1.1 Features

Features of the EPG module are:

- Clock generation:
  - Independent clock generation and clock division
  - Synchronous clock generation with programmable offsets
  - Can generate clocks to act as source for external modulator and internal demodulator for the SDFM
- Pattern generation:
  - Independent serial data stream generation
  - Serial data stream and the associated clock generation
  - Ability to skew clock with respect to serial data
  - Synchronous data stream with programmable offset with respect to one another
  - Can generate waveforms for loopback test of communication peripherals
  - Useful as diagnostics test if not already built-in

The EPG output signals are connected to GPIOs or other peripherals inside the device. The EPG inputs act as shift register inputs to capture incoming serial data streams. This allows the EPG to be configured as a custom serial module. The EPG is also capable of generating interrupts that are used to supply the pattern generators with new data or signal the completion of a generated pattern.

21.1.2 EPG Block Diagram

Figure 21-1 shows the EPG overview block diagram.

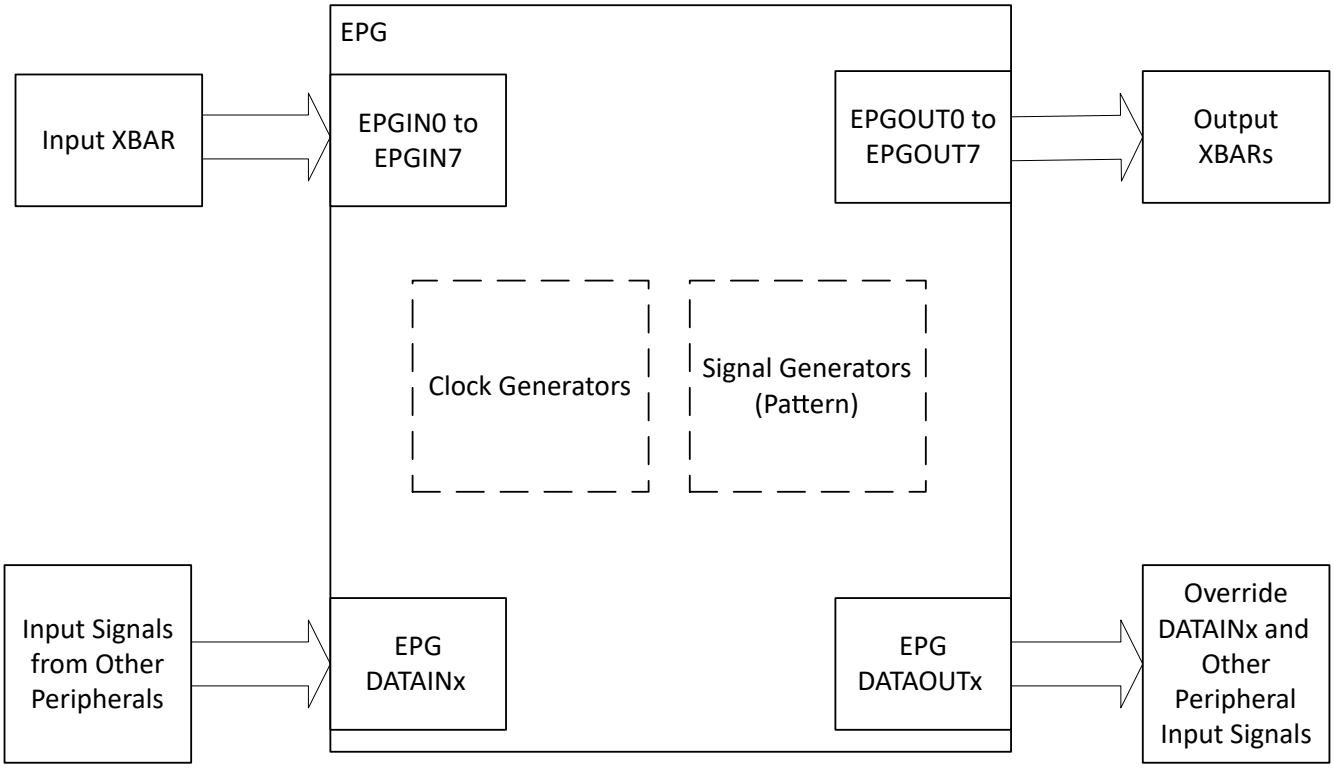

Figure 21-1. EPG Overview Block Diagram

Figure 21-2 shows the EPG block diagram.

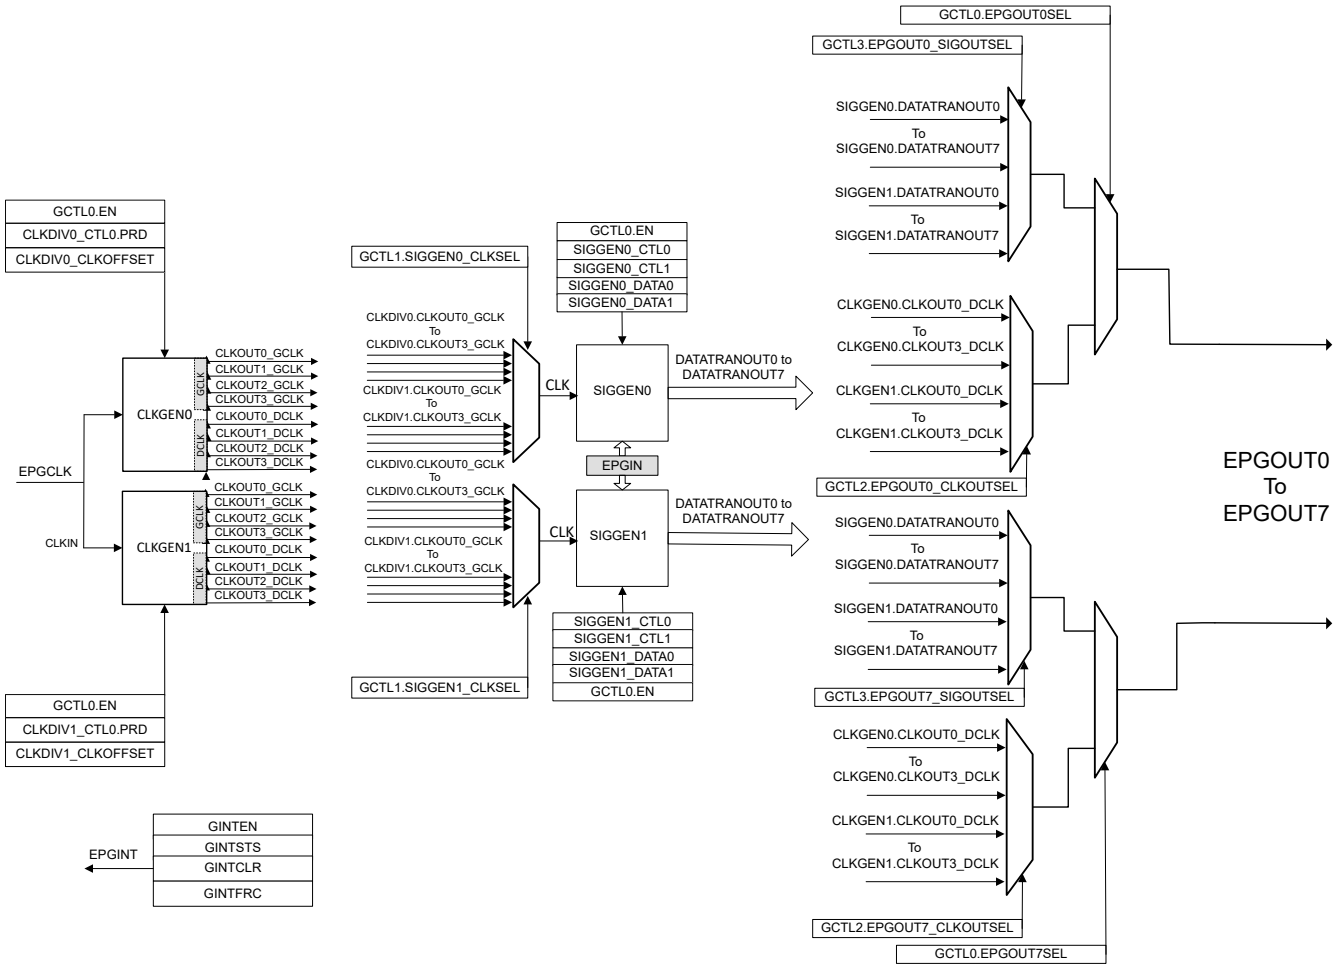

Figure 21-2. EPG Detailed Block Diagram

Note

The number of available EPGx SIGGEN modules for each device can be different. This diagram shows an EPG with 2 SIGGEN modules (SIGGEN0 and SIGGEN1). Refer to the EPG_REGS register description to see how many SIGGEN modules are available for a specific device.

The EPG input clock (EPGCLK) is sourced from PERx.SYSCLK.

21.2 Clock Generator Modules

The clock generator modules use the EPG input clock and generate four output clocks, see Figure 21-3. Each of the four output clocks (CLKOUT0 to CLKOUT3) has a DCLK and a GCLK version. The EPG clock division results in a gated, GCLK, version of the EPG input clock which are named CLKOUT0_GCLK to CLKOUT3_GCLK. The other version, DCLK (CLKOUT0_DCLK to CLKOUT3_DCLK), have the same period but with an approximately 50% duty cycle. The clock generation takes place using the divider settings CLKDIVx_CTL0.PRD, and clock offset settings CLKDIVx_CLK.CLKyOFFSET. The RUNCLOCK signal generated by the clock stop logic determines when the clock generation is started and stopped.

The clock divider counter is a simple up counter, which has a period determined by CLKDIVx_CTL0.PRD. This divider counter begins counting when RUNCLOCK is set. The CLKOUT0 to CLKOUT4 GCLKs are gated versions of the CLKIN (EPG input clock). The clock gates are enabled when the counter value matches the corresponding clock offsets. In the case where RUNCLOCK is cleared, the clock gates are disabled and the counter is set to zero.

Note

The CLKDIVx_CTL0.PRD register can only be written when GCTL0.EN is 0.

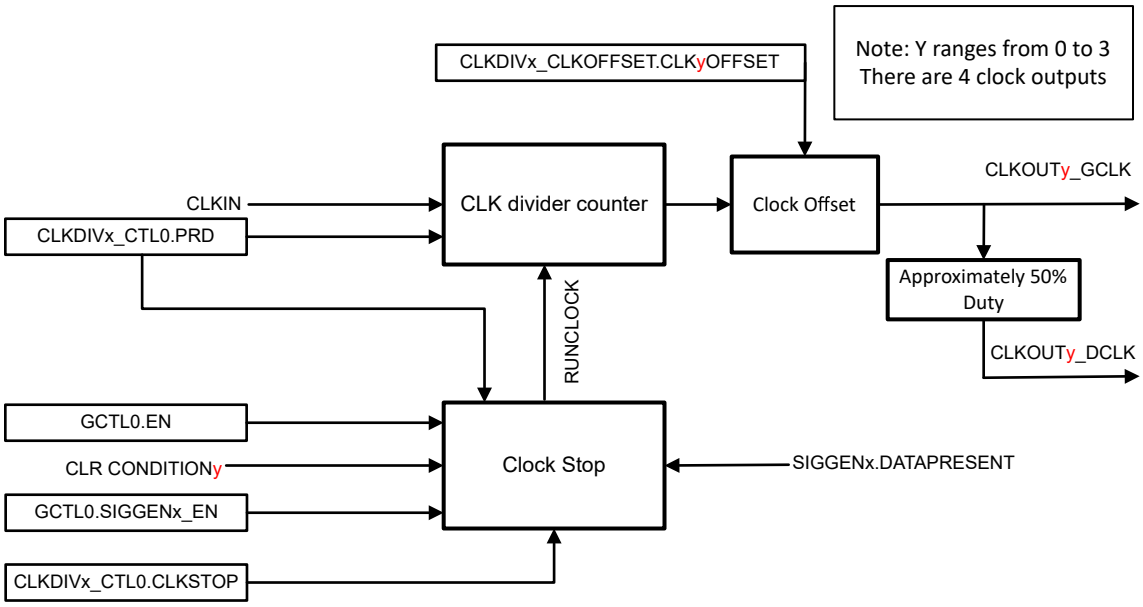

Figure 21-3. EPG Clock Generator

21.2.1 DCLK (50% duty cycle clock)

The CLKOUTy_DCLK is generated by setting the clock output for half the clock divider period. When CLKDIVx_CTL0.PRD is set to zero, CLKOUTy_DCLK is the same as the input clock.

21.2.2 Clock Stop

Figure 21-4 shows how the Clock Stop module sets and clears the RUNCLOCK signal.

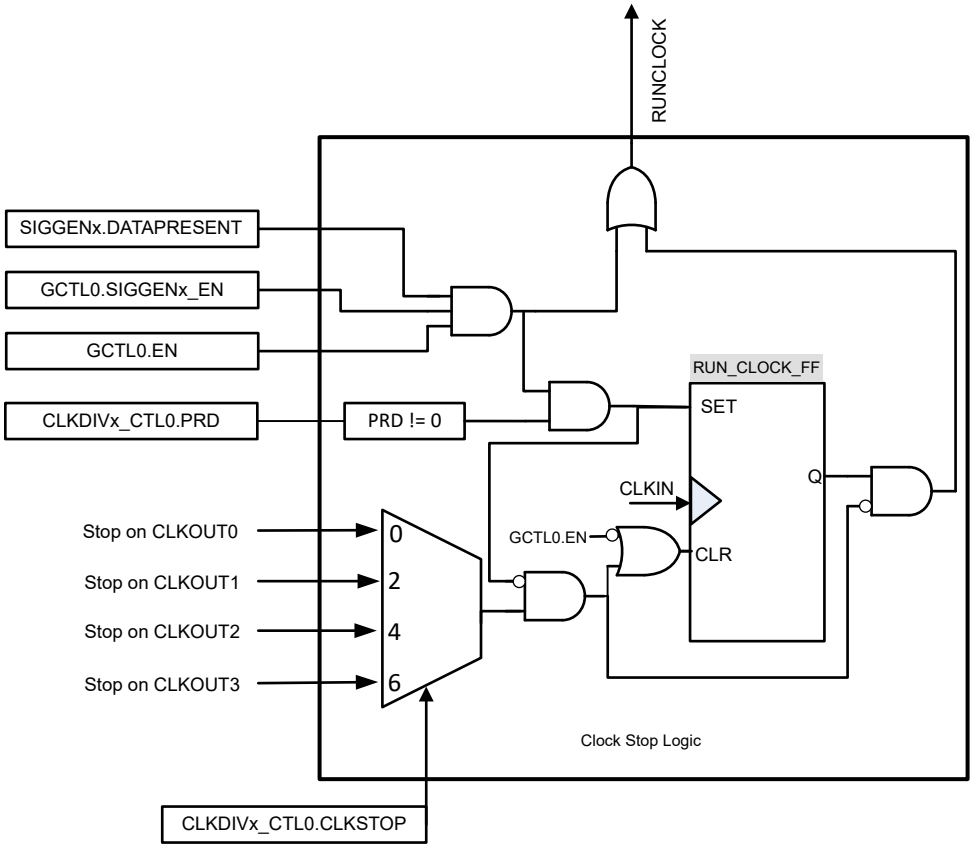

Figure 21-4. EPG Clock Stop

In signal generator modes, GCTL0.SIGGENx_EN bit is cleared when BIT_LENGTH shifts (or rotates) is completed. This makes sure that data is not shifted out. In addition, clock generation (generation of CLKOUT0 to CLKOUT3) also is stopped to make sure that sampling of input data does not continue after BIT_LENGTH shifts when GCTL0.SIGGENx_EN is cleared to 0.

The RUNCLOCK signal has to be high for the clock generation circuitry to be active. When GCTL0.SIGGENx_EN is cleared, the clock generation can be selected to stop on the falling edge of CLKOUT0 to CLKOUT3.

The clock stop module operates as follow:

- RUNCLOCK is asserted as soon as both GCTL0.SIGGENx_EN and GCTL0.EN are set.
- RUN_CLOCK_FF is set when both GCTL0.SIGGENx_EN and GCTL0.EN are set and CLKDIVx_CTL0.PRD is not zero.
- When GCTL0.SIGGENx_EN is cleared, RUN_CLOCK_FF is not cleared immediately. This makes sure that RUNCLOCK remains set and the clock generation circuitry remains enabled.
- When SIGGENx.DATA0 and SIGGENx.DATA1 are not filled with data before the next shift sequence (repeat shift modes) and signal generator is waiting for data to be written, clocks are stopped.
- The RUN_CLOCK_FF can be cleared on the falling edge of CLKOUT0 to CLKOUT3 based on the configuration of CLKSTOP field.
- Clearing GCTL0.EN clears RUN_CLOCK_FF unconditionally.

21.3 Signal Generator Module

The signal generator module is the main component of the EPG and generates the data stream that follows custom patterns. Figure 21-5 shows the main components. This module has 8 output ports DATATRANOUT0 to DATATRANOUT7. The two registers SIGGENx_DATA1 and SIGGENx_DATA0 constitute a 64-bit bus named DATA[63:0]. DATATRANIN[63:0], which is used for all the data transform operations, can be DATA[63:0] or bit reversed DATA (when SIGGENx_CTL0.BRIN bit is set). The DATATRANOUT0 to DATATRANOUT7 are connected to DATATRANIN0 to DATATRANIN7 when the signal generator is not in BIT_BANG mode. In BIT_BANG mode, DATATRANOUT0 to DATATRANOUT7 are connected to DATATRANIN0, DATATRANIN8, and DATATRANIN16 to DATATRANIN56.

In addition to generating data outputs, one of the 8 EPGIN inputs can act as data input to SIGGENx_DATAy registers. In Figure 21-5, the EPGIN_MUX block illustrates the mechanism used to capture the input data stream. This enables one to capture a data input stream using EPG module.

Data transformation is done on the DATATRANIN bus, and is determined by the configured mode (SIGGENx_CTL0.MODE), provided GCTL0.EN and GCTL0.SIGGENx_EN are both set. If either of these enable bits are 0, then the data output of the transform block is the same as the input. The transformed output is bit reversed when SIGGENx_CTL0.BROUT bit is set. Conditions under which the DATA active register (SIGGENx_DATA0_ACTIVE and SIGGENx_DATA1_ACTIVE) are:

- Loaded from SIGGENx_DATA1 and SIGGENx_DATA0
- Directly updated on a memory mapped write to SIGGENx_DATA1 and SIGGENx_DATA0
- Holds the current data

Table 21-1. SIGGENx Active Register Loading

Condition	SIGGENx_DATA1_ACTIVE DATA ACTIVE Register [63:32]	SIGGENx_DATA0_ACTIVE DATA ACTIVE Register [31:0]
Memory mapped write to SIGGENx_DATA0 register and GCTL0.SIGGENx_EN is 0	No updates	Updated with the value written to SIGGENx_DATA0 register
Memory mapped write to SIGGENx_DATA1 register and GCTL0.SIGGENx_EN is 0.	Updated with the value written to SIGGENx_DATA1 register	No updates
“BITLENGTH” number of shifts are done, and Mode is SHIFT_RIGHT_REPEAT or SHIFT_LEFT_REPEAT, and BITLENGTH <= 32, and Either SIGGENx_DATA0 or SIGGENx_DATA1 has been updated	Copy SIGGENx_DATA1 register content	Copy SIGGENx_DATA0 register content
“BITLENGTH” number of shifts are done, and Mode is SHIFT_RIGHT_REPEAT or SHIFT_LEFT_REPEAT, and BITLENGTH >= 32, and Both SIGGENx_DATA0 and SIGGENx_DATA1 have been updated	Copy SIGGENx_DATA1 register contents	Copy SIGGENx_DATA0 register contents
“BITLENGTH” number of shifts are done, and Mode is SHIFT_RIGHT_REPEAT or SHIFT_LEFT_REPEAT, and BITLENGTH <= 32, and Neither SIGGENx_DATA0, nor SIGGENx_DATA1 has been updated	Hold the current value, no shifts	Hold the current value, no shifts
“BITLENGTH” number of shifts are done, and Mode is SHIFT_RIGHT_REPEAT or SHIFT_LEFT_REPEAT, and BITLENGTH >= 32, and Neither SIGGENx_DATA0, nor SIGGENx_DATA1 has not been updated	Hold the current value, no shifts	Hold the current value, no shifts
All other conditions	Updates based on current mode of operation	Updates based on current mode of operation

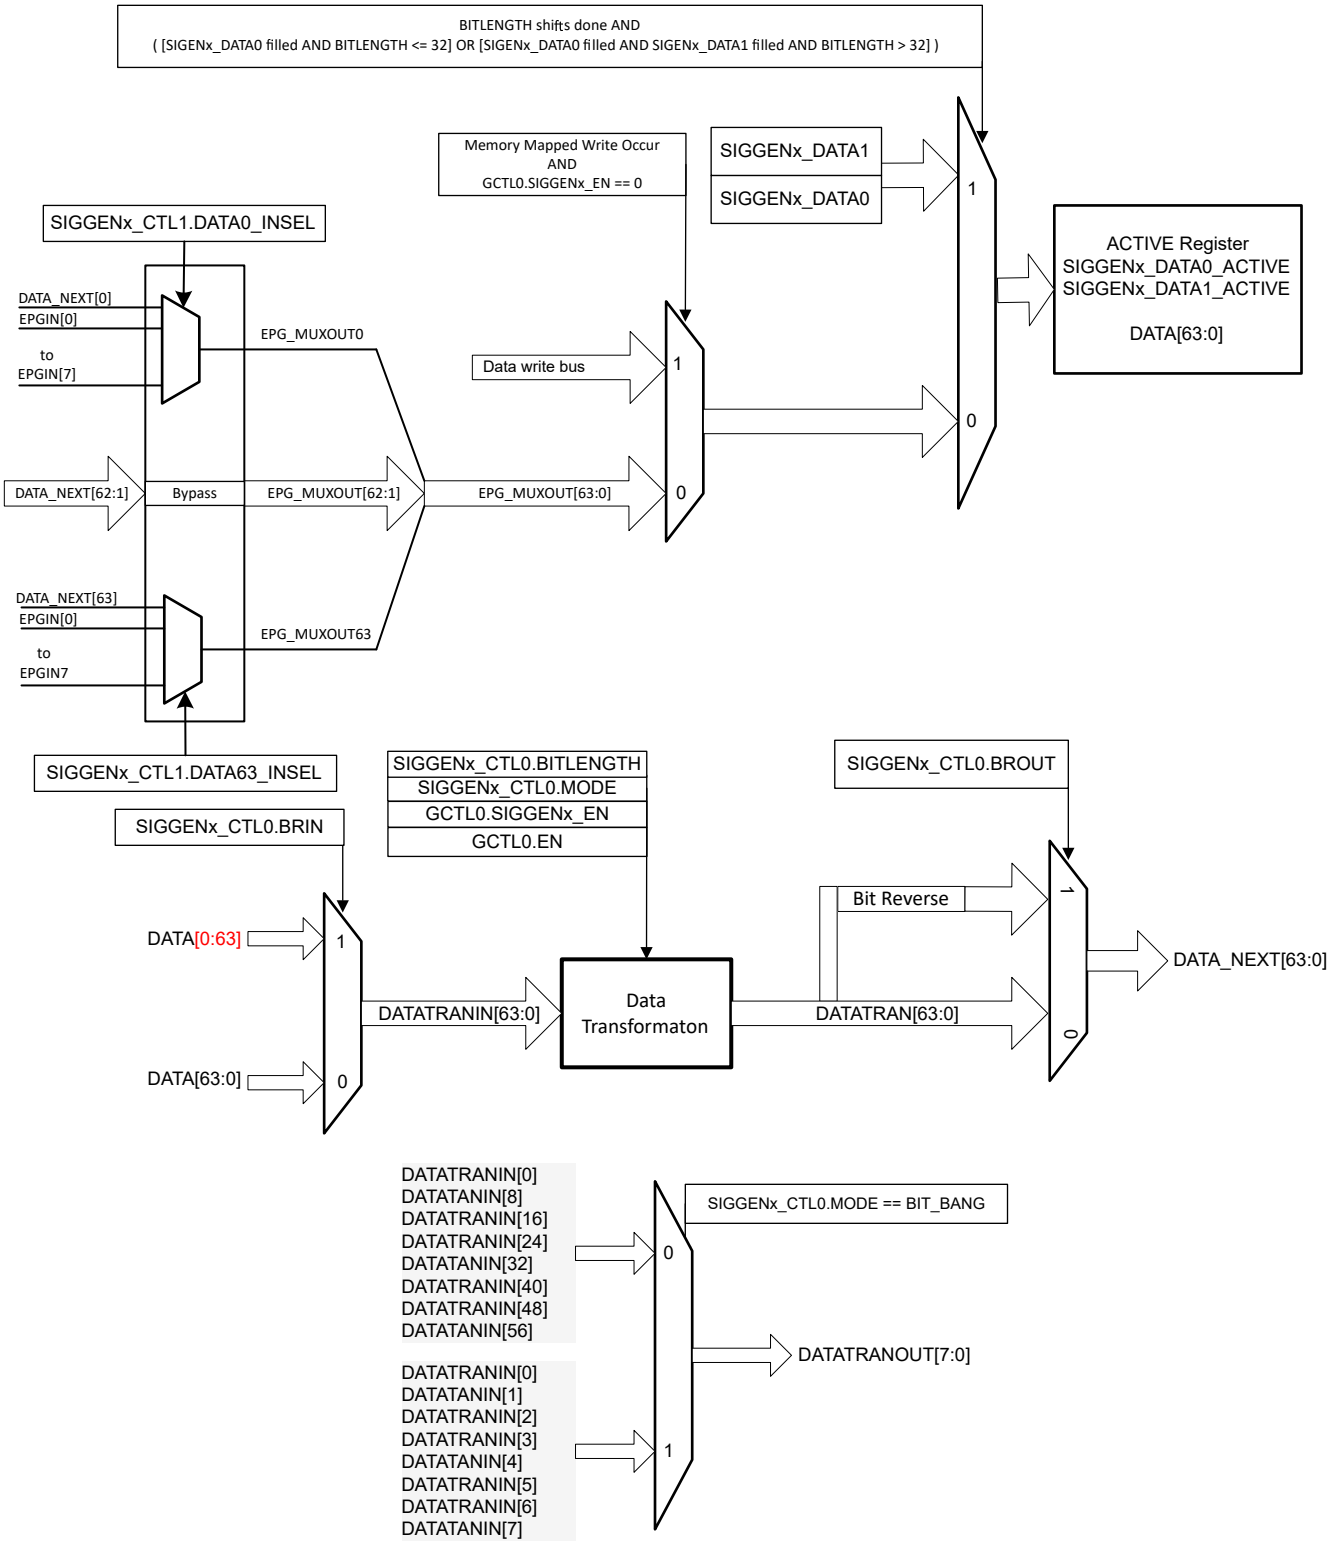

Figure 21-5. EPG Signal Generator Detailed Overview

Following are the possible data transformations:

Bit-bang mode: In this mode, DATATRAN[63:0] is the same as DATATRANIN[63:0].

Shift right once mode: In this mode, DATATRAN[63:0] = {0,DATATRANIN[63:1]}. After SIGENx_CTL0.BITLENGTH shifts, SIGENx_CTL0.EN is cleared.

Shift right repeat mode: In this mode, DATATRAN[63:0] = {0,DATATRANIN[63:1]}. After SIGENx_CTL0.BITLENGTH shifts, load the data as per Table 21-1.

Rotate right once mode: In this mode, DATATRAN[63:0] = {DATATRANIN[0],DATATRANIN[63:1]}. After SIGENx_CTL0.BITLENGTH shifts, active register is loaded from the {DATA1,DATA0} register, and SIGENx_CTL0.EN is cleared.

Rotate right repeat: This mode is same as rotate right once, except that SIGENx_CTL0.EN is not cleared upon SIGENx_CTL0.BITLENGTH rotates.

Shift left once mode: In this mode, DATATRAN[63:0] = {DATATRANIN[62:1],0}. After SIGENx_CTL0.BITLENGTH shifts, SIGENx_CTL0.EN is cleared.

Shift left repeat mode: In this mode, DATATRAN[63:0] = {DATATRANIN[62:1],0}. After SIGENx_CTL0.BITLENGTH shifts, load the data as per Table 21-1.

Rotate left once mode: In this mode, DATATRAN[63:0] = {DATATRANIN[62:1],DATATRANIN[63]}. After SIGENx_CTL0.BITLENGTH shifts, active register is loaded from the {DATA1,DATA0} register, and SIGENx_CTL0.EN is cleared.

Rotate left repeat: This mode is same as rotate left once, except that SIGENx_CTL0.EN is not cleared upon SIGENx_CTL0.BITLENGTH rotates.

Note

SIGGENx_CTL0.MODE and SIGGENx_CTL.BITWIDTH must only be updated when GCTL0.SIGGENx_EN is 0.

21.4 EPG Peripheral Signal Mux Selection

EPG DATAINx signals are connected to input signal sources from other peripherals. The EPG DATAINx signal sources are listed in Table 21-2.

EPGOUT0 to EPGOUT7 can override peripheral input signals connected to DATAINx. For example, the peripheral CAN RX input signal can be overwritten by EPGOUTx. DATAINx can be passed to DATAOUTx untouched, if EPG is not required, or the DATAINx can be replaced with EPGOUTy (y = x%8). The EPGMXSEL0 and EPGMXSEL1 registers must be configured to select the source of the DATAOUTx signals. Also, EPGOUTx signals can be connected to GPIOs through the Output XBARs and CLB Output XBARs, while EPGINx signals can be connected to the Input XBARs.

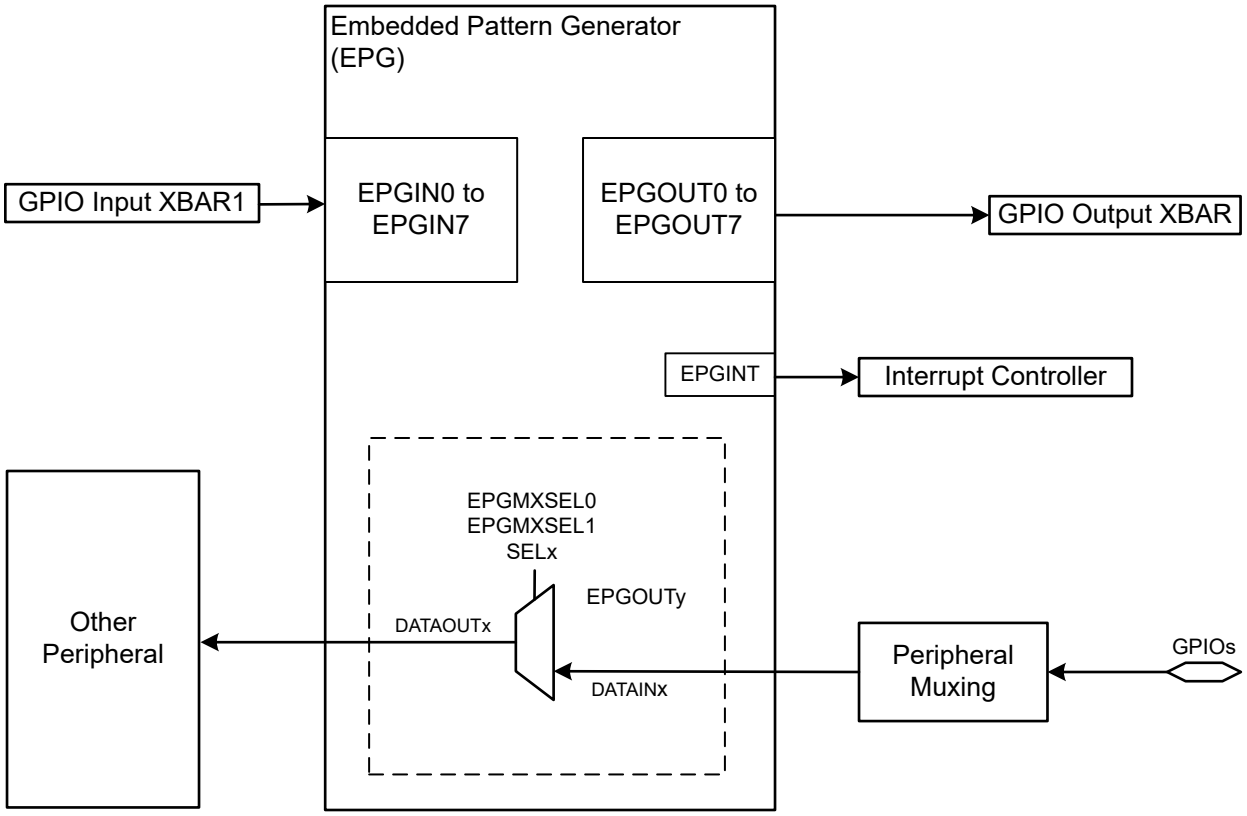

Figure 21-6. EPG Peripheral Signal Muxing

4-7	Reserved

21.5 Application Software Notes

The following points are important considerations when utilizing the EPG:

- SIGGENx_CTL0.MODE and SIGGENx_CTL0.BITLENGTH can only be written to when SIGGENx_CTL0.EN is 0
- CLKDIVx_CTL0.PRD register can be written, when GCTL0.EN is 0
- GCTL0.EN can be enabled before GCTL0.SIGGENx_EN

21.6 EPG Example Use Cases

This section provides example register configurations for different EPG use cases.

Note

Some examples can require more than one SIGGEN module. Check the device registers or data sheet for the number of available SIGGEN modules.

21.6.1 EPG Example: Synchronous Clocks with Offset

Example 21-1 register configuration generates 4 clocks, all synchronous to one another with edges offset by 2 clock cycles. In Example 21-1, a clock divide value of 12 is used.

Example 21-1. Synchronous Clocks with Offset Register Configuration

Register	Value	Selected Mode
Epg1MuxRegs		
EPGMXSEL0.SEL0	0x1	Select EPGOUT0 to drive DATAOUT[0]
EPGMXSEL0.SEL1	0x1	Select EPGOUT1 to drive DATAOUT[1]
EPGMXSEL0.SEL2	0x1	Select EPGOUT2 to drive DATAOUT[2]
EPGMXSEL0.SEL3	0x1	Select EPGOUT3 to drive DATAOUT[3]
Epg1Regs		
Global Settings		
GCTL0.EPGOUT0SEL	0x0	Selects signal mux output on EPGOUT0
GCTL0.EPGOUT1SEL	0x0	Selects signal mux output on EPGOUT1
GCTL0.EPGOUT2SEL	0x0	Selects signal mux output on EPGOUT2
GCTL0.EPGOUT3SEL	0x0	Selects signal mux output on EPGOUT3
GCTL3.EPGOUT0_SIGOUTSEL	0x0	Select SIGGEN0.OUT[0] on EPGOUT0
GCTL3.EPGOUT1_SIGOUTSEL	0x1	Select SIGGEN0.OUT[1] on EPGOUT1
GCTL3.EPGOUT2_SIGOUTSEL	0x2	Select SIGGEN0.OUT[2] on EPGOUT2
GCTL3.EPGOUT3_SIGOUTSEL	0x3	Select SIGGEN0.OUT[3] on EPGOUT3
GCTL1.SIGGEN0_CLKSEL	0x0	Select CLKOUT0 of CLKGEN0 as the clock source of SIGGEN0
CLKGEN0 Setting		
CLKDIV0_CTL0.PRD	0x0	Divide by 1
CLKDIV0_CLKOFFSET.CLK0OFFSET	0x0	No offset
SIGGEN0 Mode and Bit Length Configuration		
SIGGEN0_CTL0.BITLENGTH	0xC	Configure bit length to 12 to get a divide-by-12 clock.
SIGGEN0_CTL0.MODE	0x3	Configure the mode to rotate right repeat mode to generate a periodic waveform.
SIGGEN0_DATA0[11:0]	0000 0111 1110	Initialize the 12 bits to 6 ones and 6 zeroes, which makes sure of a 50% duty cycle clock.
SIGGEN0_DATA0[27:16]	0001 1111 1000	Create a 2-cycle offset with respect to first clock.
SIGGEN0_DATA1[11:0]	0111 1110 0000	Create a 4-cycle offset with respect to first clock.
SIGGEN0_DATA1[27:16]	1111 1000 0001	Create a 6-cycle offset with respect to first clock.

21.6.2 EPG Example: Serial Data Bit Stream (LSB first)

Example 21-2 register configuration shifts out a data word, the data rate is set to divide by 8 and the LSB is shifted out first. After 32 shifts are completed, an interrupt is generated for further sequencing.

Example 21-2. Serial Data Bit Stream (LSB first) Register Configuration

Register	Value	Selected Mode
Epg1MuxRegs		
EPGMXSEL0.SEL0	0x1	Select EPGOUT0 to drive DATAOUT[0]
Epg1Regs		
Global Settings		
GCTL1.SIGGEN0_CLKSEL	0x0	Select CLKOUT0 of CLKGEN0 as the clock source of SIGGEN0
CLKGEN0 Setting		
CLKDIV0_CTL0.PRD	0x7	Divide by 8
CLKDIV0_CLKOFFSET.CLK0OFFSET	0x0	No offset
SIGGEN0 Mode and Bit Length Configuration		
SIGGEN0_CTL0.BITLENGTH	0x20	Do 32 shifts.
SIGGEN0_CTL0.MODE	0x1	Configure the mode to shift right once mode. Generates an interrupt after 32 shifts.
SIGGEN0_DATA0[15:0]	0xAA55	Data to be shifted out
SIGGEN0_DATA0[31:16]	0xCCCC	Data to be shifted out
SIGGEN0_DATA1[15:0]	0xAA55	Data to be shifted out
SIGGEN0_DATA1[31:16]	0x55AA	Data to be shifted out

21.6.3 EPG Example: Serial Data Bit Stream (MSB first)

Example 21-3 register configuration shifts out a data word, the data rate is set to divide by 8 and MSB is shifted out first. After 32 shifts are complete, an interrupt is generated for further sequencing.

Example 21-3. Serial Data Bit Stream (MSB first) Register Configuration

Register	Value	Selected Mode
Epg1MuxRegs		
EPGMXSEL0.SEL0	0x1	Select EPGOUT0 to drive DATAOUT[0]
Epg1Regs		
Global Settings		
GCTL0.EPGOUT0SEL	0x0	Selects signal mux output on EPGOUT0
GCTL3.EPGOUT0_SIGOUTSEL	0x4	Select SIGGEN0.OUT[4] on EPGOUT0, on 64-bit reversal, 31 bit appears on 32 bit (hence, configuring to 4).
GCTL1.SIGGEN0_CLKSEL	0x0	Select CLKOUT0 of CLKGEN0 as the clock source of SIGGEN0
CLKGEN0 Setting		
CLKDIV0_CTL0.PRD	0x7	Divide by 8
CLKDIV0_CLKOFFSET.CLK0OFFSET	0x0	No offset
SIGGEN0 Mode and Bit Length Configuration		
SIGGEN0_CTL0.BITLENGTH	0x20	Do 32 shifts.
SIGGEN0_CTL0.MODE	0x1	Configure the mode to shift right once mode. Generates an interrupt after 32 shifts.
SIGGEN0_CTL0.BRIN	0x1	Reverse the bits to the data transform block to make sure that the MSB is transmitted first.
SIGGEN0_CTL0.BROUT	0x1	Reverse the data back and store in the register
SIGGEN0_DATA0[15:0]	0xAA55	Data to be shifted out
SIGGEN0_DATA0[31:16]	0xCCCC	Data to be shifted out
SIGGEN0_DATA1[15:0]	0xAA55	Data to be shifted out
SIGGEN0_DATA1[31:16]	0x55AA	Data to be shifted out

21.6.4 EPG Example: Clock and Data Pair

Example 21-4 register configuration shifts out a data word, also an associated clock is generated to latch the data (EPGOUT1), the data rate is set to divide by 8 and MSB is shifted out first. After 32 shifts are complete, an interrupt is generated for further sequencing.

Example 21-4. Clock and Data Pair Register Configuration

Register	Value	Selected Mode
Epg1MuxRegs		
EPGMXSEL0.SEL0	0x1	Select EPGOUT0 to drive DATAOUT[0]
EPGMXSEL0.SEL1	0x1	Select EPGOUT1 to drive DATAOUT[1]
Epg1Regs		
Global Settings		
GCTL0.EPGOUT0SEL	0x0	Selects signal mux output on EPGOUT0
GCTL3.EPGOUT0_SIGOUTSEL	0x4	Select SIGGEN0.OUT[4] on EPGOUT0, on 64-bit reversal, 31 bit appears on 32 bit (hence, configuring to 4).
GCTL0.EPGOUT1SEL	0x0	Selects signal mux output on EPGOUT1
GCTL3.EPGOUT1_SIGOUTSEL	0x8	Select SIGGEN1.OUT[0] on EPGOUT1.
GCTL1.SIGGEN0_CLKSEL	0x0	Select CLKOUT0 of CLKGEN0 as the clock source of SIGGEN0
GCTL1.SIGGEN1_CLKSEL	0x4	Select CLKOUT0 of CLKGEN1 as the clock source of SIGGEN1
CLKGEN0 Setting		
CLKDIV0_CTL0.PRD	0x7	Divide by 8
CLKDIV0_CLKOFFSET.CLK0OFFSET	0x0	No offset
CLKDIV1_CTL0.PRD	0x3	Divide by 4
SIGGEN0 Mode and Bit Length Configuration		
SIGGEN0_CTL0.BITLENGTH	0x20	Do 32 shifts.
SIGGEN0_CTL0.MODE	0x1	Configure the mode to shift right once mode. Generates an interrupt after 32 shifts.
SIGGEN0_CTL0.BRIN	0x1	Reverse the bits to the data transform block to make sure that the MSB is transmitted first.
SIGGEN0_CTL0.BROUT	0x1	Reverse the data back and store in the register
SIGGEN0_DATA0[15:0]	0xAA55	Data to be shifted out
SIGGEN0_DATA0[31:16]	0xCCCC	Data to be shifted out
SIGGEN0_DATA1[15:0]	0xAA55	Data to be shifted out
SIGGEN0_DATA1[31:16]	0x55AA	Data to be shifted out
SIGGEN1 Mode and Bit Length Configuration		
SIGGEN1_CTL0.BITLENGTH	0x2	Set bit length to 2 to generate a 50% duty clock.
SIGGEN1_CTL0.MODE	0x3	Configure the mode to rotate right repeat mode. Generates a 50% duty cycle clock.
SIGGEN1_DATA0[15:0]	0x2	Data to be shifted out

21.6.5 EPG Example: Clock and Skewed Data Pair

Example 21-5 register configuration shows the data shifted out is skewed by few a EPG input clock cycles.

Example 21-5. Clock and Skewed Data Pair Register Configuration

Register	Value	Selected Mode
Epg1MuxRegs		
EPGMXSEL0.SEL0	0x1	Select EPGOUT0 to drive DATAOUT[0]
EPGMXSEL0.SEL1	0x1	Select EPGOUT1 to drive DATAOUT[1]
Epg1Regs		
Global Settings		
GCTL0.EPGOUT0SEL	0x0	Selects signal mux output on EPGOUT0
GCTL3.EPGOUT0_SIGOUTSEL	0x4	Select SIGGEN0.OUT[4] on EPGOUT0, on 64-bit reversal, 31 bit appears on 32 bit (hence, configuring to 4).
GCTL0.EPGOUT1SEL	0x0	Selects signal mux output on EPGOUT1
GCTL3.EPGOUT1_SIGOUTSEL	0x8	Select SIGGEN1.OUT[0] on EPGOUT1.
GCTL1.SIGGEN0_CLKSEL	0x0	Select CLKOUT0 of CLKGEN0 as the clock source of SIGGEN0
GCTL1.SIGGEN1_CLKSEL	0x4	Select CLKOUT0 of CLKGEN1 as the clock source of SIGGEN1
CLKGEN0 Setting		
CLKDIV0_CTL0.PRD	0x7	Divide by 8
CLKDIV0_CLKOFFSET.CLK0OFFSET	0x2	Offset of 2 cycles.
CLKDIV1_CTL0.PRD	0x3	Divide by 4
SIGGEN0 Mode and Bit Length Configuration		
SIGGEN0_CTL0.BITLENGTH	0x20	Do 32 shifts.
SIGGEN0_CTL0.MODE	0x1	Configure the mode to shift right once mode. Generates an interrupt after 32 shifts.
SIGGEN0_CTL0.BRIN	0x1	Reverse the bits to the data transform block to make sure that the MSB is transmitted first.
SIGGEN0_CTL0.BROUT	0x1	Reverse the data back and store in the register
SIGGEN0_DATA0[15:0]	0xAA55	Data to be shifted out
SIGGEN0_DATA0[31:16]	0xCCCC	Data to be shifted out
SIGGEN0_DATA1[15:0]	0xAA55	Data to be shifted out
SIGGEN0_DATA1[31:16]	0x55AA	Data to be shifted out
SIGGEN1 Mode and Bit Length Configuration		
SIGGEN1_DATA0[15:0]	0x2	Data to be shifted out
SIGGEN1_CTL0.BITLENGTH	0x2	Set bit length to 2 to generate a 50% duty clock.
SIGGEN1_CTL0.MODE	0x3	Configure the mode to rotate right repeat mode. Generates a 50% duty cycle clock.

21.6.6 EPG Example: Capturing Serial Data with a Known Baud Rate

Example 21-6 register configuration captures a 32-bit data stream. The data is generated from SIGGEN0 and captured in SIGGEN1 (EPGOUT0 looped back as EPGIN0). The clock to SIGEN1 is offset by a few cycles to reliably capture the data.

Example 21-6. Capturing Serial Data with a Known Baud Rate Register Configuration

Register	Value	Selected Mode
Epg1MuxRegs		
EPGMXSEL0.SEL0	0x1	Select EPGOUT0 to drive DATAOUT[0]
EPGMXSEL0.SEL1	0x1	Select EPGOUT1 to drive DATAOUT[1]
Epg1Regs		
Global Settings		
GCTL0.EPGOUT0SEL	0x0	Selects signal mux output on EPGOUT0
GCTL3.EPGOUT0_SIGOUTSEL	0x4	Select SIGGEN0.OUT[4] on EPGOUT0, on 64-bit reversal, 31 bit appears on 32 bit (hence, configuring to 4).
GCTL0.EPGOUT1SEL	0x0	Selects signal mux output on EPGOUT1
GCTL3.EPGOUT1_SIGOUTSEL	0x8	Select SIGGEN1.OUT[0] on EPGOUT1.
GCTL1.SIGGEN0_CLKSEL	0x0	Select CLKOUT0 of CLKGEN0 as the clock source of SIGGEN0
GCTL1.SIGGEN1_CLKSEL	0x4	Select CLKOUT0 of CLKGEN1 as the clock source of SIGGEN1
CLKGEN0 Setting		
CLKDIV0_CTL0.PRD	0x7	Divide by 8
CLKDIV0_CLKOFFSET.CLK0OFFSET	0x0	No offset
CLKDIV1_CTL0.PRD	0x7	Divide by 8
CLKDIV1_CLKOFFSET.CLK0OFFSET	0x2	Offset the capture clock by a few cycles to capture the data reliably.
SIGGEN0 Mode and Bit Length Configuration		
SIGGEN0_CTL0.BITLENGTH	0x20	Do 32 shifts, data out looped back to EPGIN[0] to demonstrate the data capture function.
SIGGEN0_CTL0.MODE	0x1	Configure the mode to shift right once mode. Generates an interrupt after 32 shifts.
SIGGEN0_CTL0.BRIN	0x0	Reverse the bits to the data transform block to make sure that the MSB is transmitted first.
SIGGEN0_CTL0.BROUT	0x0	Reverse the data back and store in the register
SIGGEN_DATA0[15:0]	0xAA55	Data to be shifted out
SIGGEN_DATA0[31:16]	0xCCCC	Data to be shifted out
SIGGEN_DATA1[15:0]	0xAA55	Data to be shifted out
SIGGEN_DATA1[31:16]	0x55AA	Data to be shifted out
SIGGEN1 Mode and Bit Length Configuration		
SIGGEN1_CTL0.BITLENGTH	0x32	Set bit length to 2 to generate a 50% duty clock.
SIGGEN1_CTL0.MODE	0x4	Configure the mode to shift left once mode. To capture the data pattern on EPGIN[0].
SIGGEN1_CTL1.DATA0_INSEL	0x1	Select EPGIN[0] as the data input of bit 0.
SIGGEN1_DATA0	0x0	Clear the data contents. Holds 0xAA55 3333 at the end of 32 shifts.

21.7 EPG Interrupt

EPG interrupt can be generated on “BIT_LENGTH" shifts or rotates, or “BIT_LENGTH/2” shifts or rotates. Interrupts can be generated in any of the signal generator modes.

The GINTSTS, GINTEN, GINTCLR, and GINTFRC registers are used to configure the EPG interrupt, as shown in Figure 21-7.

21.8.2 EPG Examples

NOTE: These examples are located in the C29SDK installation from ti.com at the following location: mcu_sdk_DEVICE_GPN/examples/driverlib/CORE_IF_MULTICORE/epg

Cloud access to these examples is available at the following link: dev.ti.com C29SDK Examples.

21.8.2.1 EPG Generating Synchronous Clocks - SINGLE_CORE

FILE: epg_ex1_generate_clocks.c

This example shows how to generate 2 synchronous clocks with edges being offset by 2 clock cycles. It configures Signal Generator to shift a periodic data. Generated Clock has period EPG CLOCK/6.

External Connections

- None. Signal is generated on GPIO 34, 3. Can be visualized through oscilloscope.

Watch Variables

- sigGenActiveData - Active Data of signal generator transform output

21.8.2.2 EPG Generating Two Offset Clocks - SINGLE_CORE

FILE: epg_ex2_generate_two_offset_clocks.c

This example generates two offset clocks using the CLKGEN (CLKDIV) modules. For more information on this example, visit: *Designing With the C2000 Embedded Pattern Generator (EPG)*

External Connections

- None. Signal is generated on GPIO 34, 3. Can be visualized through oscilloscope.

21.8.2.3 EPG Generating Two Offset Clocks With SIGGEN - SINGLE_CORE

FILE: epg_ex3_generate_two_offset_clocks_with_siggen.c

This example generates two offset clocks using the SIGGEN module. For more information on this example, visit: *Designing With the C2000 Embedded Pattern Generator (EPG)*

External Connections

- None. Signal is generated on GPIO 34, 3. Can be visualized through oscilloscope.

21.8.2.4 EPG Generate Serial Data - SINGLE_CORE

FILE: epg_ex4_generate_serial_data.c

This example generates SPICLK and SPI DATA signals using the SIGGEN module. For more information on this example, visit: *Designing With the C2000 Embedded Pattern Generator (EPG)*

External Connections

- None. Signal is generated on GPIO 34, 3. Can be visualized through oscilloscope.

21.8.2.5 EPG Generate Serial Data Shift Mode - SINGLE_CORE

FILE: epg_ex5_generate_serial_data_shift_mode.c

This example generates SPICLK and SPI DATA signals using the SIGGEN module in SHIFT mode. For more information on this example, visit: *Designing With the C2000 Embedded Pattern Generator (EPG)*

External Connections

- None. Signal is generated on GPIO 34, 3. Can be visualized through oscilloscope.

21.9 EPG Registers

This Section describes the EPG Registers.

21.9.1 EPG Base Address Table

Table 21-6. EPG Base Address Table

Structure	DriverLib Name	Base Address	Frame Applicable	CPU1	CPU2	CPU3	RTDMA1	RTDMA2	HSM	Pipeline Protected
EPG_REGS	EPG_BASE	0x701C_0000	YES	YES	YES	YES	YES	YES	-	YES
EPG_MUX_REGS	EPGMUX_BASE	0x701C_0200	YES	YES	YES	YES	YES	YES	-	YES

21.9.2 EPG_REGS Registers

Table 21-7 lists the memory-mapped registers for the EPG_REGS registers. All register offset addresses not listed in Table 21-7 should be considered as reserved locations and the register contents should not be modified.

Table 21-7. EPG_REGS Registers

Offset	Acronym	Register Name	Protection
0h	GCTL0	EPG Global control register 0	
4h	GCTL1	EPG Global control register 1	
8h	GCTL2	EPG Global control register 2	
Ch	GCTL3	EPG Global control register 3	
10h	EPGLOCK	EPG LOCK Register	
14h	EPGCOMMIT	EPG COMMIT register	
18h	GINTSTS	EPG Global interrupt status register.	
1Ch	GINTEN	EPG Global interrupt enable register.	
20h	GINTCLR	EPG Global interrupt clear register.	
24h	GINTFRC	EPG Global interrupt force register.	
30h	CLKDIV0_CTL0	Clock divider 0's control register 0	
3Ch	CLKDIV0_CLKOFFSET	Clock divider 0's clock offset value	
48h	CLKDIV1_CTL0	Clock divider 1's control register 0	
54h	CLKDIV1_CLKOFFSET	Clock divider 1's clock offset value	
60h	SIGGEN0_CTL0	Signal generator 0's control register 0	
64h	SIGGEN0_CTL1	Signal generator 0's control register 1	
70h	SIGGEN0_DATA0	Signal generator 0's data register 0	
74h	SIGGEN0_DATA1	Signal generator 0's data register 1	
78h	SIGGEN0_DATA0_ACTIVE	Signal generator 0's data active register 0	
7Ch	SIGGEN0_DATA1_ACTIVE	Signal generator 0's data active register 1	
A0h	REVISION	IP Revision tie-off value	

Complex bit access types are encoded to fit into small table cells. Table 21-8 shows the codes that are used for access types in this section.

Table 21-8. EPG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1C	W 1C	Write 1 to clear
W1S	W 1S	Write 1 to set
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		

Table 21-8. EPG_REGS Access Type Codes (continued)

Access Type	Code	Description
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

21.9.2.1 GCTL0 Register (Offset = 0h) [Reset = 00000000h]

GCTL0 is shown in Figure 21-8 and described in Table 21-9.

Return to the Summary Table.

Table 21-23. SIGGEN0_CTL0 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3-0	MODE	R/W	0h	0 : BIT_BANG mode, The value written into DATA0 and DATA1 registers appear on the signal generator outputs as is. 1 : SHIFT_RIGHT_ONCE mode, The data value written into (DATA1,DATA0) registers are shifted right by 1 on every clock. Shifting operations stops when BITLENGTH shifts are done and SIGGEN0_CTL0.EN bit is cleared. 2 : ROTATE_RIGHT_ONCE, The data value written into (DATA1,DATA0) registers are rotated right by 1 on every clock. Rotation happens within (DATA1,DATA0)[BITLENGTH-1:0] Rotate operations stops when BITLENGTH shifts are done and SIGGEN0_CTL0.EN bit is cleared. 3 : ROTATE_RIGHT_REPEAT, The data value written into (DATA1,DATA0) registers are rotated right by 1 on every clock. Rotation happens within (DATA1,DATA0)[BITLENGTH-1:0] Rotate operations continue until SIGGEN0_CTL0.EN bit is cleared. 4 : SHIFT_LEFT_ONCE mode, The data value written into (DATA1,DATA0) registers are shifted left by 1 on every clock. Shifting operations stops when BITLENGTH shifts are done and SIGGEN0_CTL0.EN bit is cleared. 5 : ROTATE_LEFT_ONCE, The data value written into (DATA1,DATA0) registers are rotated left by 1 on every clock. Rotation happens within (DATA1,DATA0)[BITLENGTH-1:0] Rotate operations stops when BITLENGTH shifts are done and SIGGEN0_CTL0.EN bit is cleared. 6 : ROTATE_LEFT_REPEAT, The data value written into (DATA1,DATA0) registers are rotated left by 1 on every clock. Rotation happens within (DATA1,DATA0)[BITLENGTH-1:0] Rotate operations continue until SIGGEN0_CTL0.EN bit is cleared. 7 : SHIFT_RIGHT_REPEAT mode, The data value written into (DATA1,DATA0) registers are shifted right by 1 on every clock. Shifting operations stops when SIGGEN0_CTL0.EN bit is cleared. 8 : SHIFT_LEFT_REPEAT mode, The data value written into (DATA1,DATA0) registers are shifted left by 1 on every clock. Shifting operations stops when SIGGEN0_CTL0.EN bit is cleared. Reset type: SYSRSn

21.9.2.16 SIGGEN0_CTL1 Register (Offset = 64h) [Reset = 00000000h]

SIGGEN0_CTL1 is shown in Figure 21-23 and described in Table 21-24.

Return to the Summary Table.

Chapter 22

► ANALOG PERIPHERALS

The following chapters describe the analog peripherals.

Technical Reference Manual Overview

The block diagram is shown in Figure 22-1. This Technical Reference Manual is organized into five major sections:

- C29x SYSTEM RESOURCES

  These chapters describe the C29x CPU subsystem, C29x Boot ROM, device configuration, and other system peripherals.

- ANALOG PERIPHERALS

  These chapters describe the general analog subsystem configuration, Analog-to-Digital Converter (ADC), Buffered Digital-to-Analog Converter (DAC), and Comparator Subsystem (CMPSS).

- CONTROL PERIPHERALS

  These chapters describe the Enhanced Capture (eCAP), High-Resolution Capture (HRCAP), Enhanced Pulse-Width Modulator (ePWM) with High-Resolution Pulse-Width Modulator (HRPWM), Enhanced Quadrature Encoder Pulse (eQEP), and Sigma Delta Filter Module (SDFM) peripherals.

- COMMUNICATION PERIPHERALS

  These chapters describe the communication peripherals available to the C29x subsystem such as the EtherCAT, FSI, I2C, PMBUS, UART, LIN, SPI, and SENT.

- SECURITY PERIPHERALS

  This chapter describes the safety peripherals available to the C29x subsystem such as the Hardware Security Module (HSM) and Cryptographic Accelerator.

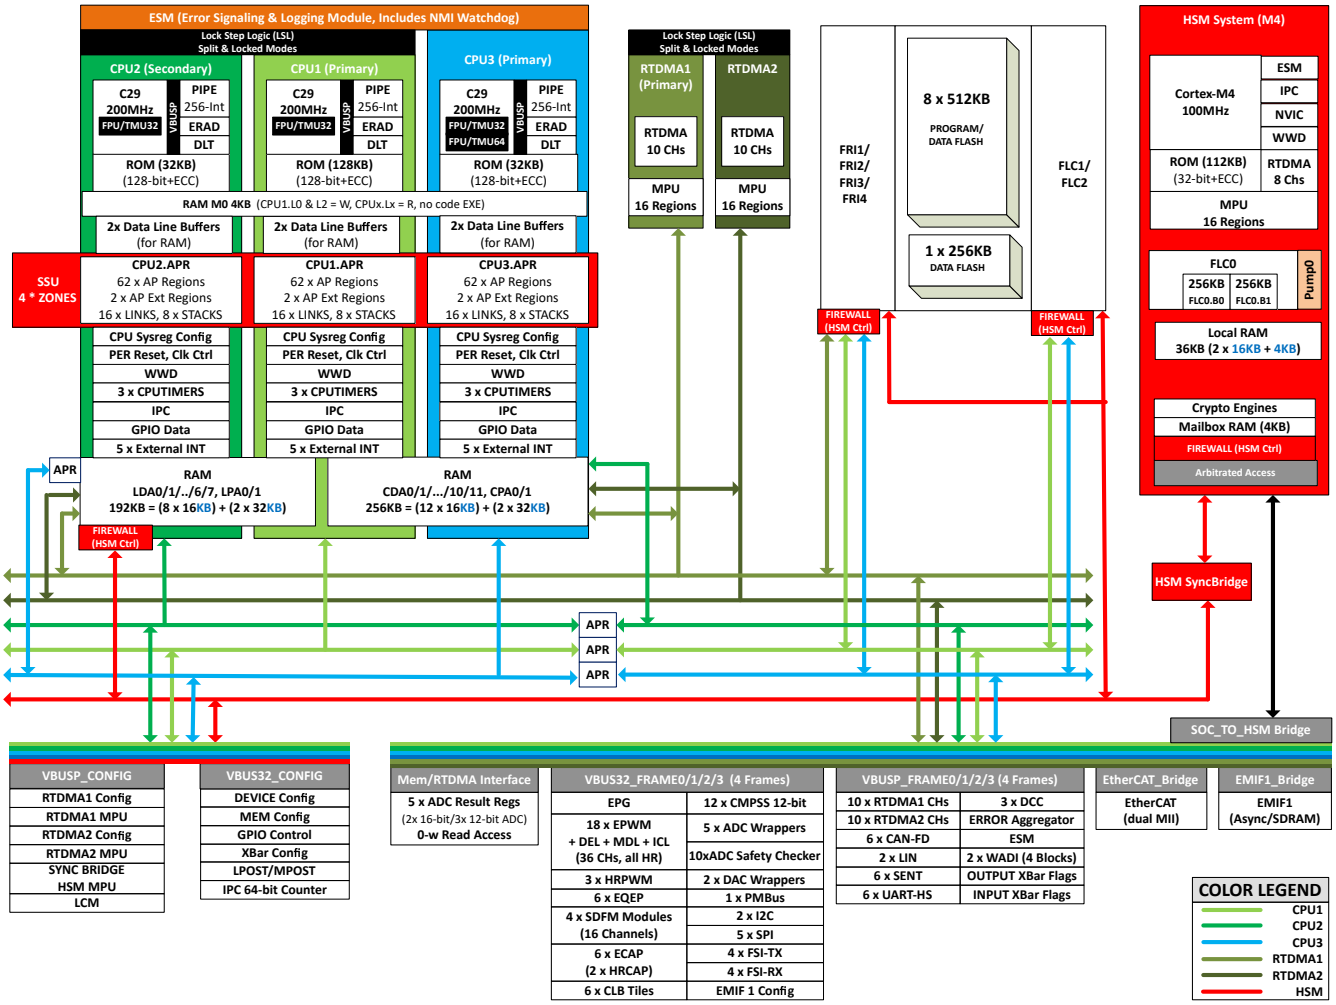

Figure 22-1. Block Diagram

Chapter 23

Analog Subsystem

The analog subsystem module is described in this chapter.

23.1 Introduction

23.1.1 Features

The analog subsystem has the following features:

- Flexible voltage references:
  - The ADCs are referenced to VREFHIx and VREFLOx pins.
    - VREFHIAB and VREFHICDE pin voltages can be driven in externally or can be generated by an internal bandgap voltage reference.
    - The internal voltage reference range can be selected to be 0V to 2.5V for ADC A and ADC B when operated in 16-bit mode; however, the internal voltage reference range can be selected to be 0V to 3.3V or 0V to 2.5V for ADC A and ADC B when operated in 12-bit mode.
    - The internal voltage reference range can be selected to be 0V to 3.3V or 0V to 2.5V for ADC C, ADC D, and ADC E.
  - The buffered DACs are referenced to VREFHIx and VSSA
    - Alternately, these DACs can be referenced to the VDAC pin and VSSA
  - The comparator DACs are referenced to VDDA and VSSA
    - Alternately, these DACs can be referenced to the VDAC pin and VSSA
- Flexible pin usage
  - Buffered DAC outputs, comparator subsystem inputs, and digital inputs (AIOs)/outputs (AGPIOs) are multiplexed with ADC inputs
  - Internal connection to V_{REFLO} for offset self-calibration

23.1.2 Block Diagram

The following analog subsystem block diagrams show the connections between the different integrated analog modules to the device pins. These pins fall into two categories: analog module inputs/outputs and reference pins.

There are two reference pair pins, VREFHIAB /VREFLOAB and VREFHICDE/VREFLOCDE. VREFHIAB and VREFLOAB supply the reference for ADC A and ADC B modules which support both 16-bit and 12-bit mode. VREFHICDE and VREFLOCDE supply ADC C, ADC D and ADC E modules which only support 12-bit mode. VREFHIAB can also be used to supply DAC A, and VREFHICDE can also be used to supply DAC B

The VDAC reference pin can be used to set an alternate range for DAC A and DAC B, and for the DACs inside the CMPSS modules (the CMPSS DACs are referenced to VDDA and VSSA by default). Using this pin as a reference prevents the channel from being used as an ADC input (but the ADC can be used to sample the VDAC voltage, if desired). The choice of reference is configurable per module for each CMPSS or buffered DAC; the selection is made using the module's configuration registers.

Some analog pins support digital functionality through muxed AIOs and AGPIOs. AIOs only support digital input functionality, while AGPIOs support full digital input and output functionality.

The following notes apply to all packages:

- Not all analog pins are available on all devices. See the device data sheet to determine which pins are available.
- See the device data sheet to determine the allowable voltage range for VREFHI and VREFLO.
- An external capacitor is required on the VREFHI pins. See the device data sheet for the specific value required.
- For buffered DAC modules, VSSA is the low reference whether VREFHIx or VDAC is selected as the high reference.
- For CMPSS modules, VSSA is the low reference whether VDAC or VDDA is selected as the high reference.

The following figures show how each analog group is structured. Table 23-3 lists the analog pins and internal connections.

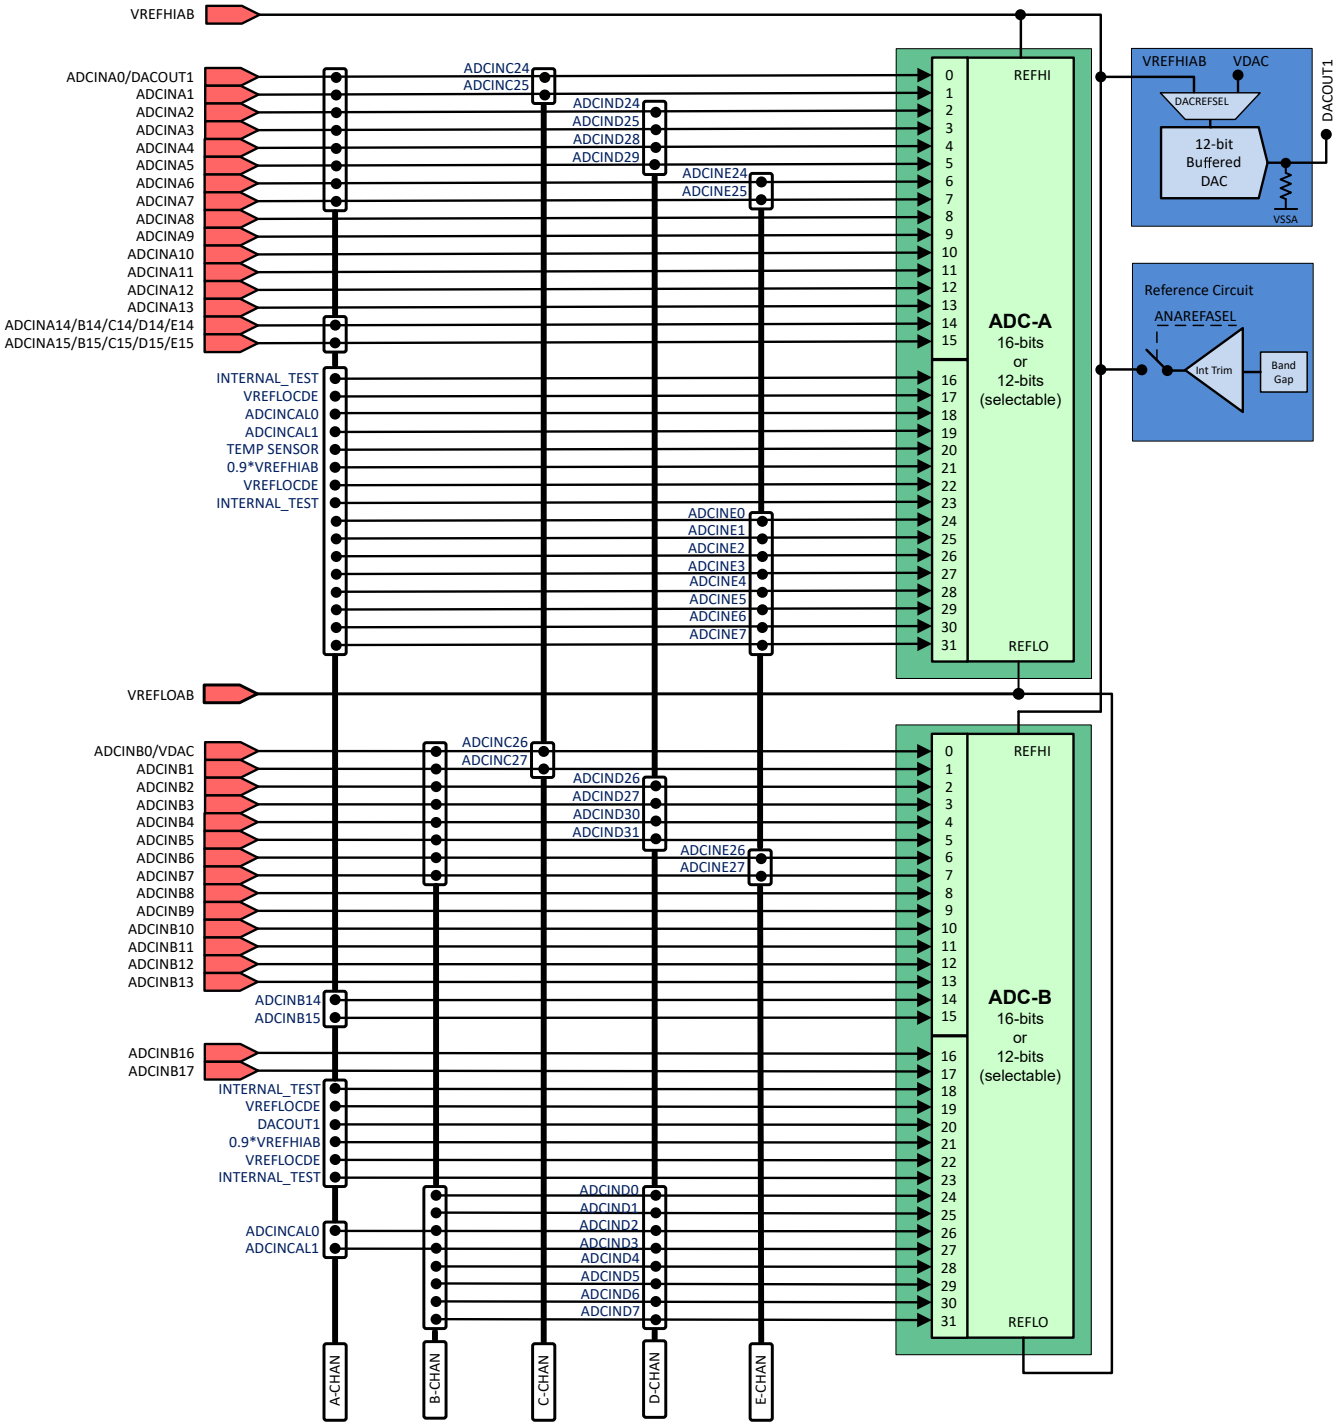

Figure 23-1. Analog Subsystem Block Diagram (ADC A and ADC B)

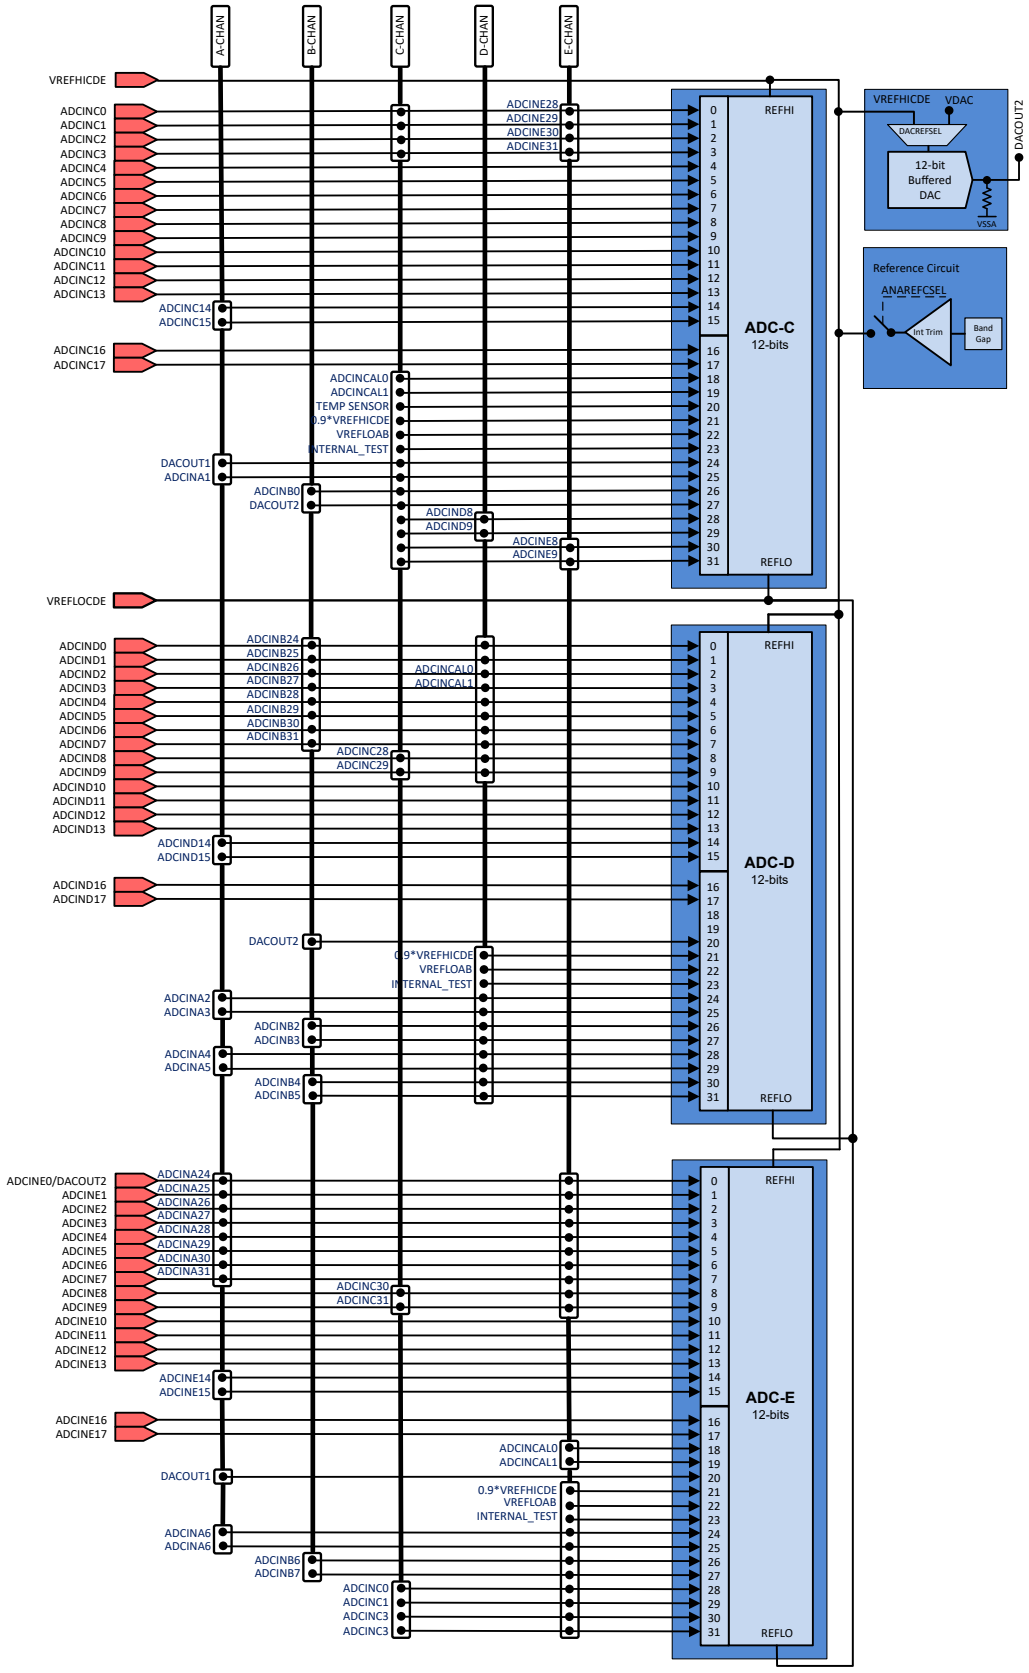

Figure 23-2. Analog Subsystem Block Diagram (ADC C, ADC D, and ADC E)

Input connections to the CMPSS modules are selectable through a programmable input mux. Figure 23-3 shows the CMPSS input connections. Table 23-1 shows the mapping of ADC input signals to CMPSS mux inputs.

- To configure the CMPH_POSIN input mux for CMPSSx, write to the CMPxHPMXSEL field in the CMPHPMXSEL or CMPHPMXSEL1 analog subsystem register.
- To configure the CMPH_NEGIN input mux for CMPSSx, write to the CMPxHNMXSEL field in the CMPHNMXSEL analog subsystem register.
- To configure the CMPL_POSIN input mux for CMPSSx, write to the CMPxLPMXSEL field in the CMPLPMXSEL or CMPLPMXSEL1 analog subsystem register.
- To configure the CMPL_NEGIN input mux for CMPSSx, write to the CMPxLNMXSEL field in the CMPLNMXSEL analog subsystem register.

23.2 Optimizing Power-Up Time

The analog-to-digital converters (ADC) and buffered digital-to-analog converters (DAC) share a common reference circuit. If needed, an application using one or more of these modules can optimize power-up time by taking advantage of the shared reference. Once one of the modules using the shared reference has been initialized in internal reference mode, the power-up time for subsequent modules can be optimized by subtracting the reference power-up time from the minimum power-up time requirement.

For instance, if ADCA requires $t_{ADCPUINT}$ to power up in internal reference mode, and $t_{ADCPUEXT}$ to power up in external reference mode, the application does not need to wait $t_{ADCPUINT}$ to power up a second ADC instance such as ADCC in internal reference mode. In this case, the application can simply wait for $t_{ADCPUEXT}$ after powering up ADCC, even though both ADCs are used in internal reference mode. In the same scenario, if the application wished to use DACA in internal reference mode, the required wait time after power-up is $t_{DACPUEXT}$, not the longer $t_{DACPUINT}$.

There is also a wait time associated with power-up in internal reference mode when switching between 2.5V and 3.3V range. See the device data sheet for wait time values.

23.3 Digital Inputs on ADC Pins (AIOs)

Some GPIOs are multiplexed with analog pins and only have digital input functionality. These are also referred to as AIOs. Pins with only an AIO option on this port can only function in input mode. See the device data sheet for list of AIO signals. By default, these pins function as analog pins and the GPIOs are in a high-impedance state. The GPyAMSEL register is used to configure these pins for digital or analog operation.

Note

If digital signals with sharp edges (high dv/dt) are connected to the AIOs, cross-talk can occur with adjacent analog signals. Therefore, limit the edge rate of signals connected to AIOs if adjacent channels are being used for analog functions.

23.4 Digital Inputs and Outputs on ADC Pins (AGPIOs)

Some GPIOs are multiplexed with analog pins and have digital input and output functionality. These are also referred to as AGPIOs. Unlike AIOs, AGPIOs have full input and output capability. By default, the AGPIOs are not connected and must be configured. Table 23-2 shows how to configure the AGPIOs. To enable the analog functionality, set the register AGPIOCTRLx from analog subsystem. To enable the digital functionality, set the register GPxAMSEL from the *General-Purpose Input/Output (GPIO)* chapter.

Table 23-2. AGPIO Configuration

AGPIOCTRLx.GPIOy (Default = 0)	GPxAMSEL.GPIOy (Default = 1)	Pin Connected To:	
		ADC	GPIOy
0	0	-	Yes
0	**1**	**-** (1)	**-** (1)
1	0	-	Yes
1	1	Yes	-

(1) By default there are no signals connected to AGPIO pins. One of the other rows in the table must be chosen for pin functionality.

Note

If digital signals with sharp edges (high dv/dt) are connected to the AGPIOs, cross-talk can occur with adjacent analog signals. The user must therefore limit the edge rate of signals connected to AGPIOs, if adjacent channels are being used for analog functions.

23.5 Analog Pins and Internal Connections

Table 23-3. Analog Pin Connections

Pin Name	Pins/Package				ADC					DAC	Comparator Subsystem (Mux)				AIO Input/ GPIO

Table 23-4. Analog Signal Descriptions

Signal Name	Description
ADCINAx, Ax	ADC A Input
ADCINBx, Bx	ADC B Input
ADCINCx, Cx	ADC C Input
ADCINDx, Dx	ADC D Input
ADCINEx, Ex	ADC E Input
CMPx_HNy	Comparator subsystem high comparator negative input
CMPx_HPy	Comparator subsystem high comparator positive input
CMPx_LNy	Comparator subsystem low comparator negative input
CMPx_LPy	Comparator subsystem low comparator positive input
DACOUTx	Buffered DAC Output
TEMP SENSOR, TS	Internal temperature sensor
VDAC	Optional external reference voltage for on-chip DACs. There is a 100pF capacitor to VSSA on this pin whether used for ADC input or DAC reference that cannot be disabled. If this pin is being used as a reference for the on-chip DACs, place at least a 1µF capacitor on this pin.

Table 23-5. Reference Summary

Module	Reference Option	Configured Where?	Register	Driverlib Function	Notes
ADC	External or Internal	Analog Subsystem	AnalogSubsysRegs.ANAREFACTL.bit.ANAREFxSEL AnalogSubsysRegs.ANAREFCCTL.bit.ANAREFxSEL	ASysCtl_setAnalogReferenceInternal, ASysCtl_setAnalogReferenceExternal	Internal reference for ADCA/B and ADCC/D/E.
	Internal Reference 2.5V or 3.3V	Analog Subsystem	AnalogSubsysRegs.ANAREFxCTL.bit.ANAREFx2P5SEL	ASysCtl_setAnalogReference2P5, ASysCtl_setAnalogReference1P65

23.7 Lock Registers

Setting one of the bits in the lock registers prevents further writes to the associated analog subsystem configuration register. This lock can only be cleared by a device reset.

23.8 ASBSYS Registers

This Section describes the ASBSYS Registers.

23.8.1 ASBSYS Base Address Table

Table 23-7. ASBSYS Base Address Table

Structure	DriverLib Name	Base Address	Frame Applicable	CPU1	CPU2	CPU3	RTDMA1	RTDMA2	HSM	Pipeline Protected
ANALOG_SUBSYS_REGS [1]	ANALOGSUBSYS_BASE	0x3018_2000	-	YES	YES	YES	-	-	YES	YES

(1) Registers writeable by CPU1.LINK0, CPU1.LINK1, CPU1.LINK2 only. All CPUs can read all registers in all LINKs. Debug write access only allowed if Zone0 or Zone1 are enabled for full debug by all CPUs. Debug reads always allowed. Register Read/Write access by HSM.

23.8.2 ANALOG_SUBSYS_REGS Registers

Table 23-8 lists the memory-mapped registers for the ANALOG_SUBSYS_REGS registers. All register offset addresses not listed in Table 23-8 should be considered as reserved locations and the register contents should not be modified.

Table 23-8. ANALOG_SUBSYS_REGS Registers

Offset	Acronym	Register Name	Protection
44h	PMMVREGTRIM	Power Management Module VREG Trim Register	PARITY
70h	CTLTRIMSTS	HWCTL TRIM Error Status register

Complex bit access types are encoded to fit into small table cells. Table 23-9 shows the codes that are used for access types in this section.

Table 23-9. ANALOG_SUBSYS_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R -0	Read Returns 0s
Write Type		
W	W	Write
W1S	W 1S	Write 1 to set
WOnce	W Once	Write Write once

Table 23-9. ANALOG_SUBSYS_REGS Access Type Codes (continued)

Access Type	Code	Description
WSonce	W Sonce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

23.8.2.1 PMMVREGTRIM Register (Offset = 44h) [Reset = 00000000h]

PMMVREGTRIM is shown in Figure 23-4 and described in Table 23-10.

Return to the Summary Table.

Table 23-19. CMPHPMXSEL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	RESERVED	R-0	0h	Reserved
29-27	CMP10HPMXSEL	R/W	0h	CMP10HPMXSEL bits, Refer to analog grouping connection in the Analog Chapter of TRM Note: Only values 0 to 4 are valid, rest are reserved Reset type: XRSn
26-24	CMP9HPMXSEL	R/W	0h	CMP9HPMXSEL bits, Refer to analog grouping connection in the Analog Chapter of TRM Note: Only values 0 to 4 are valid, rest are reserved Reset type: XRSn
23-21	CMP8HPMXSEL	R/W	0h	CMP8HPMXSEL bits, Refer to analog grouping connection in the Analog Chapter of TRM Note: Only values 0 to 4 are valid, rest are reserved Reset type: XRSn
20-18	CMP7HPMXSEL	R/W	0h	CMP7HPMXSEL bits, Refer to analog grouping connection in the Analog Chapter of TRM Note: Only values 0 to 4 are valid, rest are reserved Reset type: XRSn
17-15	CMP6HPMXSEL	R/W	0h	CMP6HPMXSEL bits, Refer to analog grouping connection in the Analog Chapter of TRM Note: Only values 0 to 4 are valid, rest are reserved Reset type: XRSn
14-12	CMP5HPMXSEL	R/W	0h	CMP5HPMXSEL bits, Refer to analog grouping connection in the Analog Chapter of TRM Note: Only values 0 to 4 are valid, rest are reserved Reset type: XRSn
11-9	CMP4HPMXSEL	R/W	0h	CMP4HPMXSEL bits, Refer to analog grouping connection in the Analog Chapter of TRM Note: Only values 0 to 4 are valid, rest are reserved Reset type: XRSn

Table 23-19. CMPHPMXSEL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
8-6	CMP3HPMXSEL	R/W	0h	CMP3HPMXSEL bits, Refer to analog grouping connection in the Analog Chapter of TRM Note: Only values 0 to 4 are valid, rest are reserved Reset type: XRSn
5-3	CMP2HPMXSEL	R/W	0h	CMP2HPMXSEL bits, Refer to analog grouping connection in the Analog Chapter of TRM Note: Only values 0 to 4 are valid, rest are reserved Reset type: XRSn
2-0	CMP1HPMXSEL	R/W	0h	CMP1HPMXSEL bits, Refer to analog grouping connection in the Analog Chapter of TRM Note: Only values 0 to 4 are valid, rest are reserved Reset type: XRSn

23.8.2.11 CMPHPMXSEL1 Register (Offset = 270h) [Reset = 00000000h]

CMPHPMXSEL1 is shown in Figure 23-14 and described in Table 23-20.

Return to the Summary Table.

Bits to select one of the many sources on CopmHP inputs. Refer to Pimux diagram for details.

23.8.2.12 CMPLPMXSEL Register (Offset = 274h) [Reset = 00000000h]

CMPLPMXSEL is shown in Figure 23-15 and described in Table 23-21.

Return to the Summary Table.

Bits to select one of the many sources on CopmLP inputs. Refer to Pimux diagram for details.
