11.5 On-Chip Memory (OCM) Subsystem

11.5.1 OCM Subsystem Overview

The OCM subsystem consists of one OCM Controller (OCMC) that is associated with the on-chip RAM. This is the OCMC_RAM with 512 KiB of dedicated memory space. The OCM controller is also introduced in [Section 11.1.4, OCM Overview](#) of [Section 11.1, Memory Subsystem Overview](#).

[Figure 11-65](#) shows the OCMC_RAM controller.

Figure 11-65. OCMC_RAM Overview

11.5.2 OCM Subsystem Integration

[Figure 11-66](#) shows the integration of the OCMC_RAM in the device.

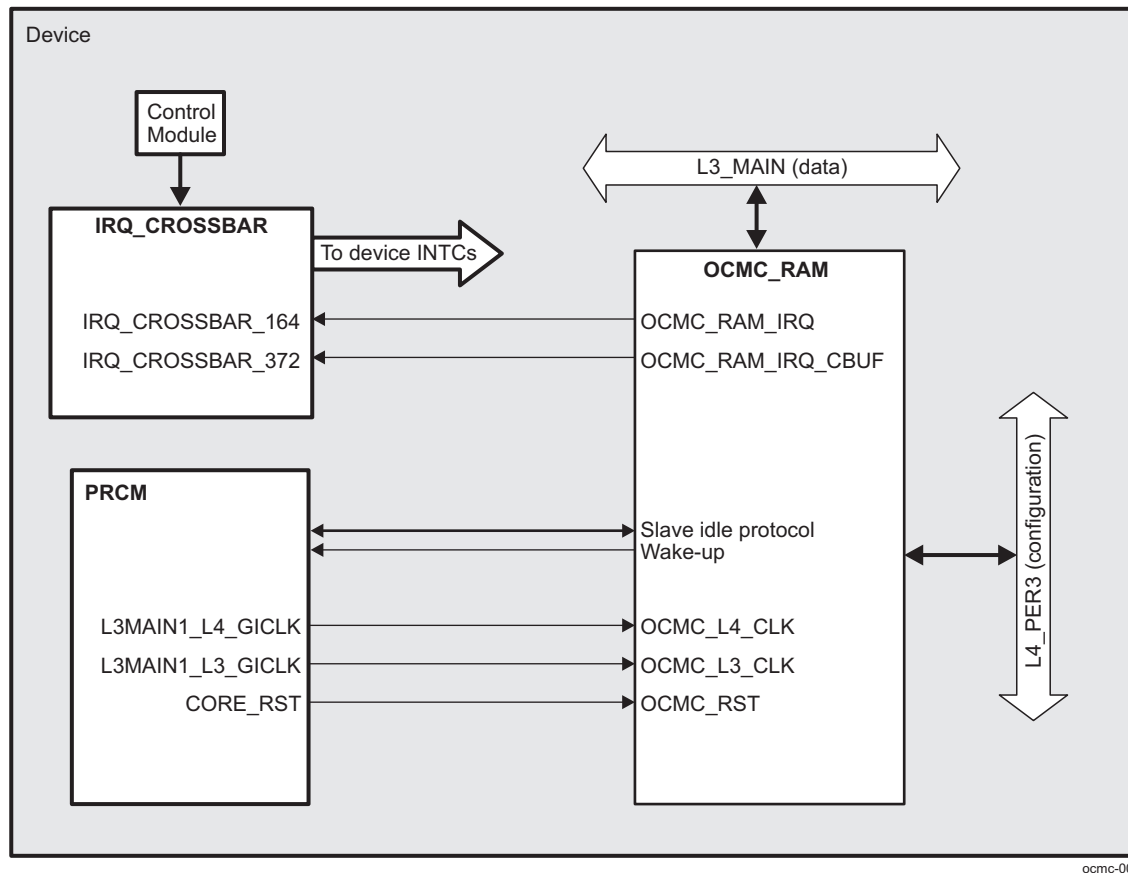

Figure 11-66. OCMC_RAM Integration

Table 11-564 through Table 11-566 summarize the integration of the OCMC_RAM in the device.

Table 11-564. OCMC_RAM Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
OCMC_RAM	PD_COREAON	Yes	L3_MAIN L4_PER3

Table 11-565. OCMC_RAM Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
OCMC_RAM	OCMC_L3_CLK	L3MAIN1_L3_GICLK	PRCM	Clock used to drive and receive data over the L3 data bus. This is also the processing clock of the OCM Controller and the SRAM. With this clock all internal data transfers are clocked.
	OCMC_L4_CLK	L3MAIN1_L4_GICLK	PRCM	Clock used to drive and receive data over the L4_PER3 configuration bus. This clock should run at half the OCMC_L3_CLK clock rate.
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
OCMC_RAM	OCMC_RST	CORE_RST	PRCM	Reset signal for the OCMC_RAM

Table 11-566. OCMC_RAM Hardware Requests

Module Instance	Source Signal Name	Interrupt Requests		Description
		Destination IRQ_CROSSBAR Input	Default Mapping	
OCMC_RAM	OCMC_RAM_IRQ	IRQ_CROSSBAR_164	-	First OCMC_RAM interrupt request. This IRQ source signal is not mapped by default to any device INTC.
	OCMC_RAM_IRQ_CBUF	IRQ_CROSSBAR_372	-	Second OCMC_RAM interrupt request. This IRQ source signal is not mapped by default to any device INTC.

NOTE: The “Default Mapping” column in [Table 11-566 OCMC_RAM Hardware Requests](#) shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR module.

For more information about the IRQ_CROSSBAR module, see [Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#). For more information about the device interrupt controllers, see [Chapter 13, Interrupt Controllers](#).

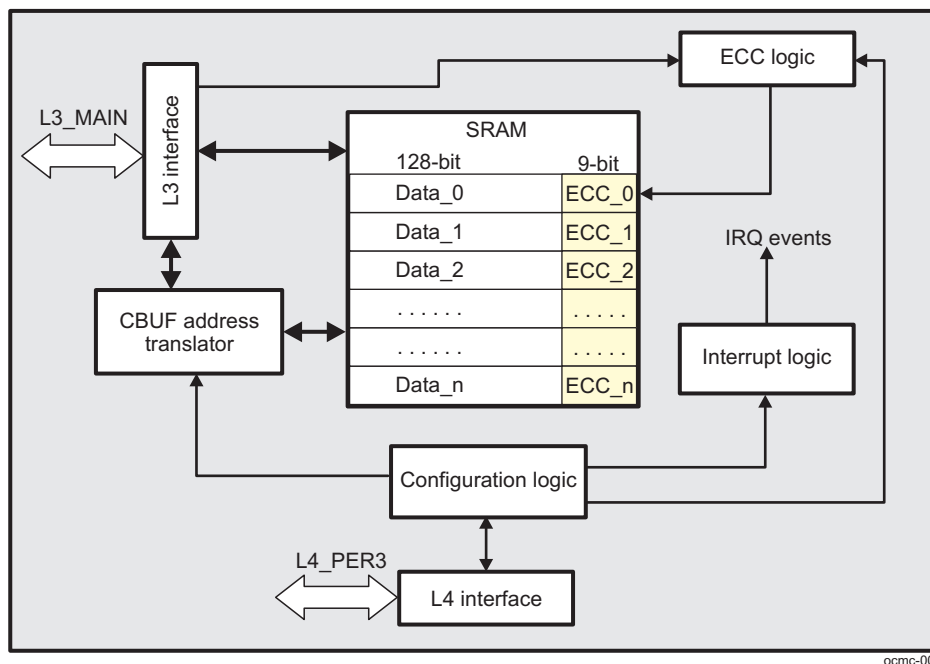

NOTE: For description of the interrupt sources, see [Section 11.5.3.4, Interrupt Requests](#).

11.5.3 OCM Subsystem Functional Description

11.5.3.1 Block Diagram

[Figure 11-67](#) shows the OCMC block diagram.

Figure 11-67. OCMC Block Diagram

The module is composed by the following main blocks:

- L3 interface used for data transactions
- L4 interface used for configuration
- CBUF address translator which converts the L3_MAIN VBUF addresses into SRAM addresses
- ECC logic to support single error correction and double error detection
- SRAM used for storing data and the corresponding for each 128-bit word ECC
- Interrupt logic used for generating interrupt requests
- Configuration logic in which reside the registers used for configuring the OCM controller operation modes

11.5.3.2 Resets

The OCMC_RST is the reset signal for the OCM controller which asynchronously resets the whole internal logic of the controller, including all configuration registers. It does not reset the SRAM. In addition, the [OCMC_SYSCONFIG_RST\[0\]](#) SW_RST bit provides a software way to reset the OCM controller. In this case all of its internal logic is reset except the configuration registers accessible through the L4_PER3.

11.5.3.3 Clock Management

The OCM controller complies with the PRCM slave idle protocol. The OCMC_L3_CLK and OCMC_L4_CLK clocks are gated based on the values loaded in the [OCMC_SYSCONFIG_PM\[3:2\]](#) IDLEMODE bit field.

11.5.3.4 Interrupt Requests

The OCM controller generates two interrupt requests, OCMC_RAM_IRQ and OCMC_RAM_IRQ_CBUF.

The OCMC_RAM_IRQ line is associated with the following registers:

- [INTR0_STATUS_RAW_SET](#) - interrupt raw status register
- [INTR0_STATUS_ENABLED_CLEAR](#) - interrupt status register
- [INTR0_ENABLE_SET](#) - interrupt enable register
- [INTR0_ENABLE_CLEAR](#) - interrupt disable register

The OCMC_RAM_IRQ_CBUF line is associated with the following registers:

- [INTR1_STATUS_RAW_SET](#) - interrupt raw status register
- [INTR1_STATUS_ENABLED_CLEAR](#) - interrupt status register
- [INTR1_ENABLE_SET](#) - interrupt enable (event unmask) register
- [INTR1_ENABLE_CLEAR](#) - interrupt disable (event mask) register

Both the register groups previously described have identical bits. When for example, only one event occurs one or the two IRQ lines will be asserted depending on the masks applied to the [INTR0_ENABLE_SET](#) and [INTR1_ENABLE_SET](#) registers. When for example, a short frame detection event occurs and if both the [INTR0_ENABLE_SET\[14\]](#) CBUF_SHORT_FRAME_DETECT_FOUND and [INTR1_ENABLE_SET\[14\]](#) CBUF_SHORT_FRAME_DETECT_FOUND bits are set to 0x1, then both the OCMC_RAM_IRQ and OCMC_RAM_IRQ_CBUF lines are asserted. If only the [INTR0_ENABLE_SET\[14\]](#) CBUF_SHORT_FRAME_DETECT_FOUND bit is set to 0x1, then only the OCMC_RAM_IRQ line is asserted and the OCMC_RAM_IRQ_CBUF line remains inactive (deasserted). Thus depending on the mask applied one IRQ line of the OCM controller can be associated only with CBUF events for example, and the other one IRQ line can be associated with ECC events. In other words, two unique interrupts can be provided.

[Table 11-567](#) lists the interrupt events which can assert the two interrupt lines of the OCM controller.

The OCM controller asserts each of its interrupt lines only if the interrupts are enabled by setting to 0x1 the corresponding bits in the [INTR0_ENABLE_SET/INTR1_ENABLE_SET](#) register. These interrupts can be disabled by setting to 0x1 the corresponding bits in the [INTR0_ENABLE_CLEAR/INTR1_ENABLE_CLEAR](#) register. After the interrupt has been serviced the corresponding status flag must be cleared by software. This is done by setting to 0x1 the corresponding bit in the [INTR0_STATUS_ENABLED_CLEAR/INTR1_STATUS_ENABLED_CLEAR](#) register which also

clears the corresponding bit in the [INTR0_STATUS_RAW_SET/INTR1_STATUS_RAW_SET](#) register. The status flags in the [INTR0_STATUS_RAW_SET/INTR1_STATUS_RAW_SET](#) register are set even if the corresponding interrupt is disabled as opposed to those in the [INTR0_STATUS_ENABLED_CLEAR/INTR1_STATUS_ENABLED_CLEAR](#) register, which are set only if the corresponding interrupt is enabled. An interrupt is also generated by the OCM controller, if certain bit in the [INTR0_STATUS_RAW_SET/INTR1_STATUS_RAW_SET](#) register is set to 0x1 and the corresponding interrupt is enabled through the [INTR0_ENABLE_SET/INTR1_ENABLE_SET](#) register. This is useful when user software debugging is performed. Additionally, even if interrupts are not enabled, certain status bit in the [INTR0_STATUS_RAW_SET/INTR1_STATUS_RAW_SET](#) register can be cleared by setting to 0x1 the corresponding bit in the [INTR0_STATUS_ENABLED_CLEAR/INTR1_STATUS_ENABLED_CLEAR](#) register.

For additional details regarding the CBUF related events, see [Section 11.5.3.11, CBUF Mode Error Handling](#).

Table 11-567. OCMC_RAM Events

Event Flag	Event Mask	Description
INTR0_STATUS_RAW_SET [14] CBUF_SHORT_FRAME_DETECT_FOUND/ INTR1_STATUS_RAW_SET [14] CBUF_SHORT_FRAME_DETECT_FOUND and	INTR0_ENABLE_SET [14] CBUF_SHORT_FRAME_DETECT_FOUND/ INTR1_ENABLE_SET [14] CBUF_SHORT_FRAME_DETECT_FOUND and	This bit indicates a short frame detection. It is set if at least one of the bits in the STATUS_CBUF_SHORT_FRAME_DETECT register is set to 0x1.
INTR0_STATUS_ENABLED_CLEAR [14] CBUF_SHORT_FRAME_DETECT_FOUND/ INTR1_STATUS_ENABLED_CLEAR [14] CBUF_SHORT_FRAME_DETECT_FOUND	INTR0_ENABLE_CLEAR [14] CBUF_SHORT_FRAME_DETECT_FOUND/ INTR1_ENABLE_CLEAR [14] CBUF_SHORT_FRAME_DETECT_FOUND

⁽²⁾ The `LAST_ILLEGAL_OCMC_ADDR` register stores the last illegal L3_MAIN address caused the assertion of this event.

Table 11-567. OCMC_RAM Events (continued)

Event Flag	Event Mask	Description
INTRO_STATUS_RAW_SET [3] OUT_OF_RANGE_ERR_FOUND/INTR1_STAT US_RAW_SET [3] OUT_OF_RANGE_ERR_FOUND and INTRO_STATUS_ENABLED_CLEAR [3] OUT_OF_RANGE_ERR_FOUND/INTR1_STAT US_ENABLED_CLEAR [3] OUT_OF_RANGE_ERR_FOUND	INTRO_ENABLE_SET [3] OUT_OF_RANGE_ERR_FOUND/INTR1_ENAB LE_SET [3] OUT_OF_RANGE_ERR_FOUND and INTRO_ENABLE_CLEAR [3] OUT_OF_RANGE_ERR_FOUND/INTR1_ENAB LE_CLEAR [3] OUT_OF_RANGE_ERR_FOUND	General interrupt for an access made with illegal VBUF address ⁽²⁾ .
INTRO_STATUS_RAW_SET [2] ADDR_ERR_FOUND/INTR1_STATUS_RAW_S ET [2] ADDR_ERR_FOUND and INTRO_STATUS_ENABLED_CLEAR [2] ADDR_ERR_FOUND/INTR1_STATUS_ENABL ED_CLEAR [2] ADDR_ERR_FOUND	INTRO_ENABLE_SET [2] ADDR_ERR_FOUND/INTR1_ENABLE_SET [2] ADDR_ERR_FOUND and INTRO_ENABLE_CLEAR [2] ADDR_ERR_FOUND/INTR1_ENABLE_CLEAR [2] ADDR_ERR_FOUND	This status flag is set when the value of the STATUS_ERROR_CNT [23:20] ADDR_ERROR_CNT bit field reaches the threshold counter value configured through the CFG_OCMC_ECC_ERROR [23:20] CFG_ADDR_ERR_CNT_MAX bit field. The status remains asserted until the counter is not cleared. This is done by setting to 0x1 the CFG_OCMC_ECC_CLEAR_HIST [2] CLEAR_ADDR_ERR_CNT bit. If the counter is not cleared another interrupt is re-issued.
INTRO_STATUS_RAW_SET [1] DED_ERR_FOUND/INTR1_STATUS_RAW_SE T [1] DED_ERR_FOUND and INTRO_STATUS_ENABLED_CLEAR [1] DED_ERR_FOUND/INTR1_STATUS_ENABL D_CLEAR [1] DED_ERR_FOUND	INTRO_ENABLE_SET [1] DED_ERR_FOUND/INTR1_ENABLE_SET [1] DED_ERR_FOUND and INTRO_ENABLE_CLEAR [1] DED_ERR_FOUND/INTR1_ENABLE_CLEAR [1] DED_ERR_FOUND	This status flag is set when the value of the STATUS_ERROR_CNT [19:16] DED_ERROR_CNT bit field reaches the threshold counter value configured through the CFG_OCMC_ECC_ERROR [19:16] CFG_DED_CNT_MAX bit field. The status remains asserted until the counter is not cleared. This is done by setting to 0x1 the CFG_OCMC_ECC_CLEAR_HIST [1] CLEAR_DED_ERR_CNT bit. If the counter is not cleared another interrupt is re-issued.
INTRO_STATUS_RAW_SET [0] SEC_ERR_FOUND/INTR1_STATUS_RAW_SE T [0] SEC_ERR_FOUND and INTRO_STATUS_ENABLED_CLEAR [0] SEC_ERR_FOUND/INTR1_STATUS_ENABLED _CLEAR [0] SEC_ERR_FOUND	INTRO_ENABLE_SET [0] SEC_ERR_FOUND/INTR1_ENABLE_SET [0] SEC_ERR_FOUND and INTRO_ENABLE_CLEAR [0] SEC_ERR_FOUND/INTR1_ENABLE_CLEAR [0] SEC_ERR_FOUND	This status flag is set when the value of the STATUS_ERROR_CNT [15:0] SEC_ERROR_CNT bit field reaches the threshold counter value configured through the CFG_OCMC_ECC_ERROR [15:0] CFG_SEC_CNT_MAX bit field. The status remains asserted until the counter is not cleared. This is done by setting to 0x1 the CFG_OCMC_ECC_CLEAR_HIST [0] CLEAR_SEC_ERR_CNT bit. If the counter is not cleared another interrupt is re-issued.

11.5.3.5 OCM Subsystem Memory Regions

The SRAM associated with the OCMC_RAM is accessible through the L3_MAIN interconnect. The start address is 0x4030 0000 and the end address is 0x4037 FFFF. That is address space of 512KiB. The configuration registers of the OCMC_RAM are accessible through the L4_PER3 starting at address 0x4880 4000.

11.5.3.6 OCM Controller Modes Of Operation

The OCM controller supports four modes of operation. Each of these modes is selected through the [CFG_OCMC_ECC\[2:0\]](#) CFG_OCMC_MODE bit field. The four supported modes are the following:

- Non-ECC mode (Data Access) - Accesses to the SRAM are non-ECC-enabled and an ECC is not calculated.
- Non-ECC mode (Code Access) - The L3_MAIN address is mapped to the SRAM memory space where the ECC code is stored. This mode allows read and write access to the 9-bit ECC word associated with each 128-bit data word. This mode is used for test purposes.
- Full-ECC mode - Accesses to the SRAM are ECC-enabled and a 9-bit ECC is calculated for each 128 bits of data.
- Block-ECC mode - A 9-bit ECC is calculated only for a 128KiB block of the SRAM. Accesses outside the 128KiB ECC-enabled block are non-ECC data accesses. In other words, a 9-bit ECC will be calculated not for each 128-bit data word of the whole SRAM space, but for each 128-bit data word within the boundaries of this 128KiB block of the SRAM. The selection of a 128KiB ECC-enabled block is done using bits[19:0] of the [CFG_OCMC_ECC_MEM_BLK](#) register. Each bit specifies which 128KiB block of the SRAM is ECC-enabled. 0x1 is the active value for each bit. In addition, more than one 128KiB ECC-enabled block can be selected.

The default mode of operation for the OCM controller is the non-ECC data access mode.

11.5.3.7 ECC Associated FIFOs

There are three FIFOs used when ECC mode is enabled. Each FIFO is four level deep. The FIFOs are the following:

- Address FIFO for single errors also referred to as SEC FIFO
- Address FIFO for double errors also referred to as DED FIFO
- Address FIFO for address errors also referred to as ADDRERR FIFO

The SEC FIFO stores the SRAM addresses at which a single error is detected. The FIFO is able to store up to four unique addresses of the single errors occurred. If there are more than four single errors associated with unique addresses, then only the first four addresses are stored in the FIFO. In case of occurrence of multiple correctable errors, the addresses are stored in the order the errors occurred. The SEC FIFO can be optionally configured to store all addresses of the single errors occurred including also the repeated addresses. This is done by setting to 0x0 the [CFG_OCMC_ECC_ERROR\[24\]](#) CFG_DISCARD_DUP_ADDR bit. The SEC FIFO can be cleared by setting to 0x1 the [CFG_OCMC_ECC_CLEAR_HIST\[0\]](#) CLEAR_SEC_ERR_CNT bit or by reading FIFO's content one by one through the [STATUS_SEC_ERROR_TRACE\[17:0\]](#) ADDRESS_128BIT bit field which points to the SEC FIFO. In addition, the [STATUS_SEC_ERROR_TRACE\[18\]](#) VALID bit shows whether the FIFO is empty or not. A value of 0x1 means that the SEC FIFO is not empty and valid address can be read.

The DED FIFO stores the SRAM addresses when a double error is detected. The FIFO is able to store up to four unique addresses, but it can also be configured to store the repeated addresses by setting to 0x0 the [CFG_OCMC_ECC_ERROR\[24\]](#) CFG_DISCARD_DUP_ADDR bit. The [STATUS_DED_ERROR_TRACE\[17:0\]](#) ADDRESS_128BIT bit field points to the DED FIFO. The [STATUS_DED_ERROR_TRACE\[18\]](#) VALID bit shows whether the FIFO is empty or not. The DED FIFO can be cleared by setting to 0x1 the [CFG_OCMC_ECC_CLEAR_HIST\[1\]](#) CLEAR_DED_ERR_CNT bit or by reading its content one by one through the [STATUS_DED_ERROR_TRACE\[17:0\]](#) ADDRESS_128BIT.

The ADDRERR FIFO stores the SRAM addresses where the single error occurred is an address error. The [STATUS_ADDR_TRANSLATION_ERROR_TRACE\[17:0\]](#) ADDRESS_128BIT bit field points to the ADDRERR FIFO. The [STATUS_ADDR_TRANSLATION_ERROR_TRACE\[18\]](#) VALID bit shows whether the FIFO is empty or not. The ADDRERR FIFO can be cleared by setting to 0x1 the [CFG_OCMC_ECC_CLEAR_HIST\[2\]](#) CLEAR_ADDR_ERR_CNT bit or by reading its content one by one through the [STATUS_ADDR_TRANSLATION_ERROR_TRACE\[17:0\]](#) ADDRESS_128BIT pointer. The ADDRERR FIFO is also able to store up to four unique addresses and can also be configured to store repeated addresses by setting to 0x0 the [CFG_OCMC_ECC_ERROR\[24\]](#) CFG_DISCARD_DUP_ADDR bit.

11.5.3.8 ECC Counters And Corrected Bit Distribution Register

There are three counters which are used to count different types of errors occurred when the ECC mode is enabled. The counters are the following:

- SEC Counter - [STATUS_ERROR_CNT\[15:0\]](#) SEC_ERROR_CNT. This is the counter for the single errors occurred. It keeps track of all single errors. That is, even for those with error addresses that have already been logged.
- DED Counter - [STATUS_ERROR_CNT\[19:16\]](#) DED_ERROR_CNT. This is the counter for the double error detections.
- ADDRERR Counter - [STATUS_ERROR_CNT\[23:20\]](#) ADDR_ERROR_CNT. This is the counter for the address errors found when a single error occurs. That is, when the single error is an address error.

When a single error in the 128-bit data word occurs and this error is corrected, the OCM controller indicates for the corrected bit of this 128-bit word by setting to 0x1 a corresponding bit in the corrected bit distribution register. This is a 128-bit register composed by the following registers:

- [STATUS_SEC_ERROR_DISTR_0\[31:0\]](#) SEC_BIT_ERROR_FOUND - Bits [31:0] of the corrected 128-bit data word.
- [STATUS_SEC_ERROR_DISTR_1\[31:0\]](#) SEC_BIT_ERROR_FOUND - Bits [63:32] of the corrected 128-bit data word.
- [STATUS_SEC_ERROR_DISTR_2\[31:0\]](#) SEC_BIT_ERROR_FOUND - Bits [95:64] of the corrected 128-bit data word.
- [STATUS_SEC_ERROR_DISTR_3\[31:0\]](#) SEC_BIT_ERROR_FOUND - Bits [127:96] of the corrected 128-bit data word.

When a single error in the ECC itself occurs, the OCM controller indicates for this error by setting to 0x1 a corresponding bit in the [STATUS_SEC_ERROR_DISTR_4\[7:0\]](#) SEC_ECC_CODE_ERROR_FOUND bit field. The parity bit is not associated with this bit field.

11.5.3.9 ECC Support

The ECC mode is enabled through the [CFG_OCMC_ECC\[2:0\]](#) CFG_OCMC_MODE bit field. When enabled a 9-bit Hamming ECC is calculated and stored for each consecutive 128-bit block of the SRAM. The ECC is calculated based on a codeword constructed by concatenating the 128 bits of data with the address bits A21 through A4 of the L3_MAIN. The ECC generated is Hamming(155,146) code and has a Hamming distance of 4. The OCM controller uses this code to validate the content of the SRAM, to correct a single bit error that occurs within the 128-bit boundary or to determine if a non-correctable error has occurred within the 128-bit boundary.

During write transactions and when ECC is enabled, for every 128-bit data word, the ECC is calculated and stored in a 9-bit field of the SRAM associated only with the address where that 128-bit data word is written. If an initiator performs a write transaction which is less than 128 bits or it is non-128-bit aligned transaction, then the content of all 128 bits is read, the new sub-quanta of data is inserted and the ECC is calculated based on all 128 bits.

During read transactions and when ECC is enabled, the ECC is calculated based on the memory address (bits A21 through A4) and the 128-bit data word read from the SRAM. This ECC is then compared to the ECC stored at the address when the data was written to the SRAM. If the two ECCs are matching then the data is transferred to the requesting initiator without further exceptions. If the two ECCs are not matching then a check is made to determine if the error is correctable or not. If the error is not correctable, that is a double error, then the address of the erroneous word is stored in the DED FIFO, the

STATUS_ERROR_CNT[19:16] DED_ERROR_CNT counter is incremented by 1 and the double error flag is asserted. The double error flag is indicated by the **INTR0_STATUS_RAW_SET**[1] DED_ERR_FOUND/INTR1_STATUS_RAW_SET[1] DED_ERR_FOUND bits, but its assertion depends on the threshold configured through the **CFG_OCMC_ECC_ERROR**[19:16] CFG_DED_CNT_MAX bit field. For more information see, [Table 11-567, OCMC_RAM Events](#).

In case of a single error, the OCM controller first determines whether the erroneous bit is in the data, address or the ECC itself. In this case the following applies:

- If the single error is located in the data read, then the erroneous bit is corrected and the data is passed to the requesting initiator. The erroneous bit is corrected also in the SRAM location by the auto re-write feature of the OCM controller if this feature is enabled by setting to 0x1 the **CFG_OCMC_ECC**[3] CFG_ECC_SEC_AUTO_CORRECT bit field. In addition, the address of the corrected data word is pushed to the SEC FIFO and the **STATUS_ERROR_CNT**[15:0] SEC_ERROR_CNT counter is incremented by 1. The single error flag is asserted too, but only if the value of the **STATUS_ERROR_CNT**[15:0] SEC_ERROR_CNT counter reaches the threshold configured by the **CFG_OCMC_ECC_ERROR**[15:0] CFG_SEC_CNT_MAX bit field. The single error flag is indicated by the **INTR0_STATUS_RAW_SET**[0] SEC_ERR_FOUND/INTR1_STATUS_RAW_SET[0] SEC_ERR_FOUND bits. For more information see, [Table 11-567, OCMC_RAM Events](#).
- If the single error is located in the address portion of the quanta, then the data is passed to the requesting initiator unchanged and the **STATUS_ERROR_CNT**[23:20] ADDR_ERROR_CNT and **STATUS_ERROR_CNT**[15:0] SEC_ERROR_CNT counters are incremented by 1. The address associated with this error is stored in the ADDRERR FIFO and the address error flag is asserted. This flag is indicated by the **INTR0_STATUS_RAW_SET**[2] ADDR_ERR_FOUND/INTR1_STATUS_RAW_SET[2] ADDR_ERR_FOUND bits, but its assertion depends on the threshold configured through the **CFG_OCMC_ECC_ERROR**[23:20] CFG_ADDR_ERR_CNT_MAX bit field. For more information see, [Table 11-567, OCMC_RAM Events](#).
- If the single error is located in the ECC itself, then the data is passed to the initiator unchanged but the **STATUS_ERROR_CNT**[15:0] SEC_ERROR_CNT counter is incremented by 1 and the address associated with this error is stored in the SEC FIFO.

[Table 11-568](#) summarizes the actions taken by the OCM controller for the different error types.

Table 11-568. OCMC Error Handling In Case Of Different Error Types

Error Type	Data Returned	SRAM Data/ECC Update	SEC Counter	SEC FIFO	DED Counter	DED FIFO	ADDRERR Counter	ADDRERR FIFO	Error Bit Distribution
Single data error	Corrected	Data corrected/ECC re-generated	Incremented by 1	Address written	-	-	-	-	The content of the corrected bit distribution register is updated
Single address error	Unchanged	ECC re-generated	Incremented by 1	-	-	-	Incremented by 1	Address written	-
Single ECC error	Unchanged	ECC re-generated	Incremented by 1	Address written	-	-	-	-	The content of the STATUS_SEC_ERROR_DISTR_4 [7:0] SEC_ECC_CODE_ERROR_FOUND bit field is updated
Double error	Unchanged	-	-	-	Incremented by 1	Address written	-	-	-

If ECC has to be used, before performing SRAM read/write operations the following steps should be performed:

- Configuring the ECC registers
- Enabling the ECC
- Initializing the SRAM with data
- Clearing the status flags

[Table 11-569](#) describes in detail the steps to be performed.

Table 11-569. OCMC ECC Configuration

Step	Associated Register/ Bit Field	Value
(Optional) Enable the error response on L3_MAIN for a non-correctable error	CFG_OCMC_ECC [4] CFG_ECC_ERR_SRESP_EN	0x1
(Optional) Enable data auto correction in case of a single error	CFG_OCMC_ECC [3] CFG_ECC_SEC_AUTO_CORRECT	0x1
Enable the memory blocks to be ECC protected, if ECC block mode is used	CFG_OCMC_ECC_MEM_BLK [19:0] CFG_ECC_ENABLED_128K_BLK	0x-
(Optional) Configure the address errors count needed for triggering an interrupt	CFG_OCMC_ECC_ERROR [23:20] CFG_ADDR_ERR_CNT_MAX	0x-
(Optional) Configure the DED count needed for triggering an interrupt	CFG_OCMC_ECC_ERROR [19:16] CFG_DED_CNT_MAX	0x-
(Optional) Configure the SEC count needed for triggering an interrupt	CFG_OCMC_ECC_ERROR [15:0] CFG_SEC_CNT_MAX	0x-
Enable ECC	CFG_OCMC_ECC [2:0] CFG_OCMC_MODE	0x2 for full ECC or 0x3 for block ECC mode
Initialize the memory with data		
Clear the error counters in the STATUS_ERROR_CNT register	CFG_OCMC_ECC_CLEAR_HIST [2:0]	0x7
Clear the SEC bit distribution history from the following registers:	CFG_OCMC_ECC_CLEAR_HIST [3] CLEAR_SEC_BIT_DISTR	0x1
• STATUS_SEC_ERROR_DISTR_0		
• STATUS_SEC_ERROR_DISTR_1		
• STATUS_SEC_ERROR_DISTR_2		
• STATUS_SEC_ERROR_DISTR_3		
• STATUS_SEC_ERROR_DISTR_4		

11.5.3.10 Circular Buffer (CBUF) Support

The OCM controller provides up to 12 programmable circular buffers that are mapped to virtual video frames to support sliced based on-the-fly video frame processing. Each circular buffer must be programmed with the following:

- Unique virtual frame start address - configured through [CBUF_i_VBUF_START_ADDR](#)[31:4] ADDR.
- Unique virtual frame end address - configured through [CBUF_i_VBUF_END_ADDR](#)[31:4] ADDR.
- SRAM start address - configured through [CBUF_i_OCMC_START_ADDR](#)[31:4] ADDR.
- SRAM size allocated for that circular buffer - configured through [CBUF_i_OCMC_BUF_SIZE](#)[19:4] BUF_SIZE.

The circular buffer mode is enabled when the [CFG_OCMC_CBUF_EN](#)[0] CBUF_MODE_EN bit is set to 0x1. In addition, to enable certain circular buffer the corresponding bit in the [CFG_OCMC_CBUF_EN](#)[27:16] bit field must be set to 0x1. For example, to enable CBUF_0 both the [CFG_OCMC_CBUF_EN](#)[0] CBUF_MODE_EN and [CFG_OCMC_CBUF_EN](#)[16] CBUF_EN_0 bits must be set to 0x1.

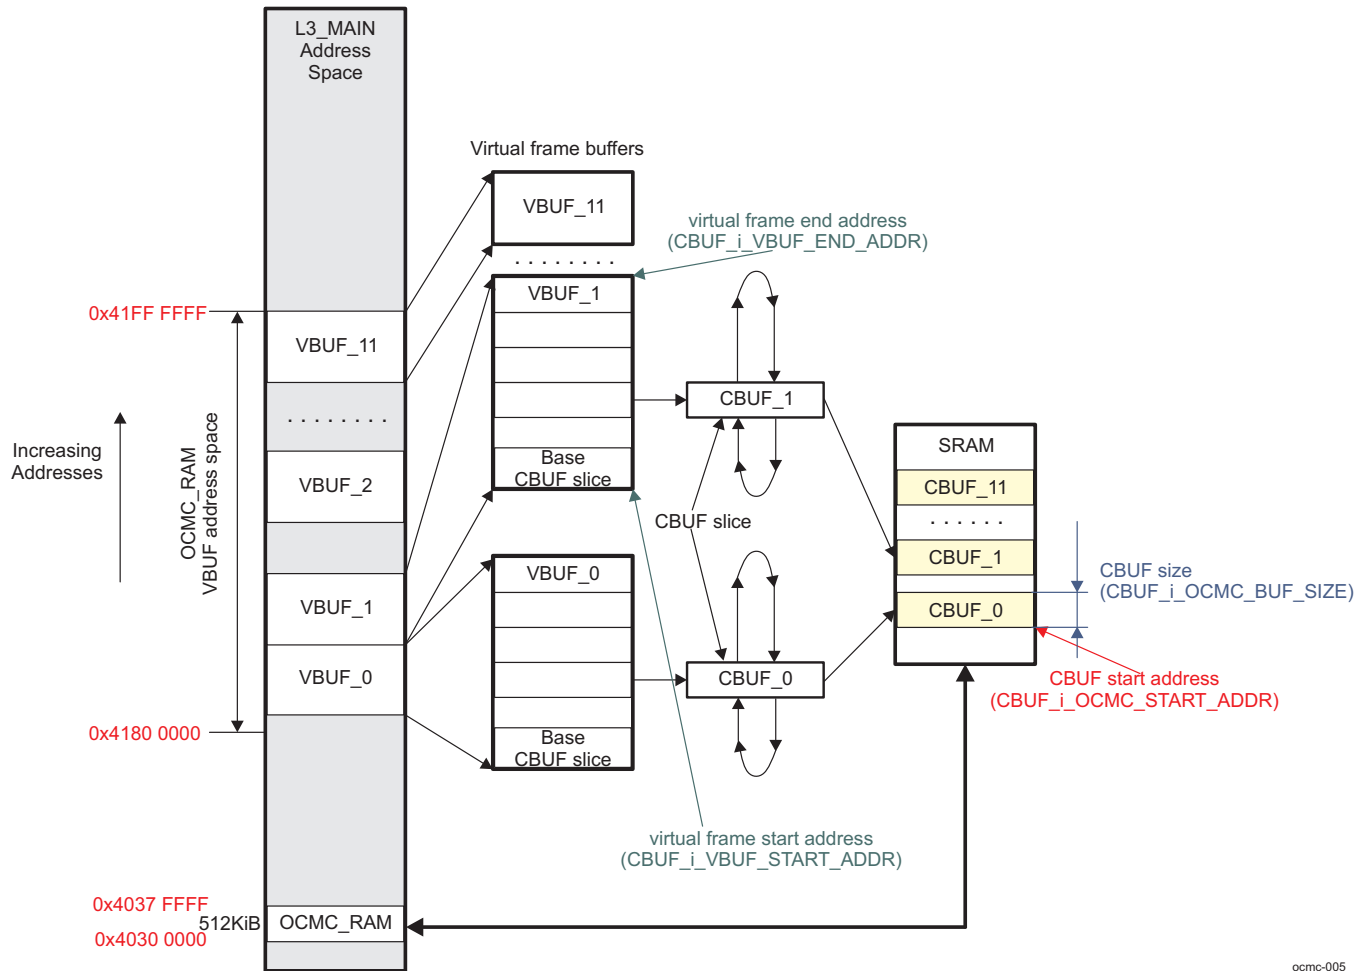

The data transfers are made to the virtual frame addresses. The OCM controller translates these virtual addresses to SRAM addresses allocated for the CBUF. The address translation is done on-the-fly without leading to any additional latency and therefore has no performance impact on the overall operation of the OCM controller.

The L3_MAIN address range associated with the virtual frame addresses is the following:

- For OCMC_RAM the start address is 0x4180 0000 and the end address is 0x41FF FFFF.

When an initiator performs an access to these L3_MAIN addresses, these virtual frame addresses will be translated automatically by the OCM controller into SRAM addresses. [Figure 11-68](#) shows the address mapping of the virtual frame addresses to CBUF addresses.

Figure 11-68. VBUF to CBUF Address Mapping

It must be taken into account that the start address of a virtual frame always begins at the start of the CBUF. Since the virtual frame buffer size is not necessarily to be a multiple of the CBUF size, the last VBUF write location may not be the last line of the CBUF. As the CBUF read and write pointers are independently managed the initiators that are writing to and reading from the CBUF should be coordinated in order to avoid overflow and underflow conditions.

11.5.3.11 CBUF Mode Error Handling

For each L3_MAIN write or read access associated with the virtual frame buffer, the OCM controller performs various address error checks to prevent illegal CBUF accesses from causing false overflow and underflow conditions. Once the L3_MAIN VBUF address is determined as valid, the OCM controller further checks for overflow and underflow conditions to properly handle the access to the CBUF during each one of these conditions and to notify for error condition an external host.

For more information regarding all CBUF events see, [Table 11-567, OCMC_RAM Events](#).

11.5.3.11.1 VBUF Address Not Mapped to a CBUF Memory Space

The L3_MAIN VBUF address should be mapped to a valid CBUF region. If this address is mapped to none of the configured CBUF regions, then the OCM controller generates a virtual address error or out of range CBUF address error event. It is possible both virtual address error and out of range CBUF address error to be generated. The L3_MAIN VBUF address caused these two events can be read through the [LAST_ILLEGAL_OCMC_ADDR\[31:0\] ADDR](#) bit field.

Virtual address error is generated when the L3_MAIN VBUF address is lower than the virtual frame start address. This is indicated by asserting the [INTR0_STATUS_RAW_SET\[4\]](#) [CBUF_VIRTUAL_ADDR_ERR_FOUND/INTR1_STATUS_RAW_SET\[4\]](#) [CBUF_VIRTUAL_ADDR_ERR_FOUND](#) bit.

The out of range CBUF address error is generated when the L3_MAIN VBUF address is greater than the virtual frame end address. This error is an indication of an unexpected change in the frame size or a long frame and should be handled immediately to prevent further memory corruption. The out of range CBUF address error can be caused when performing write or read access. The out of range CBUF write address error is indicated by the [STATUS_CBUF_WR_OUT_OF_RANGE_ERR\[11:0\]](#) CBUF_ERR bit field. The out of range CBUF read address error is indicated by the [STATUS_CBUF_RD_OUT_OF_RANGE_ERROR\[11:0\]](#) CBUF_ERR bit field. Each bit in these registers is associated only with one CBUF. Bit 0 corresponds to CBUF_0, bit 1 corresponds to CBUF_1 and so on. A value of 0x1 for each bit means that there is an error (CBUF address is out of CBUF range) for the corresponding CBUF. Writing 0x1 for each bit clears the status.

The [INTR0_STATUS_RAW_SET\[5\]](#) [CBUF_WR_OUT_OF_RANGE_ERR_FOUND/INTR1_STATUS_RAW_SET\[5\]](#) [CBUF_WR_OUT_OF_RANGE_ERR_FOUND](#) bit is asserted if at least one of the bits in the [STATUS_CBUF_WR_OUT_OF_RANGE_ERR\[11:0\]](#) CBUF_ERR bit field is set to 0x1.

The [INTR0_STATUS_RAW_SET\[8\]](#) [CBUF_READ_OUT_OF_RANGE_ERR_FOUND/INTR1_STATUS_RAW_SET\[8\]](#) [CBUF_READ_OUT_OF_RANGE_ERR_FOUND](#) bit is asserted if at least one of the bits in the [STATUS_CBUF_RD_OUT_OF_RANGE_ERROR\[11:0\]](#) CBUF_ERR bit field is set to 0x1.

11.5.3.11.2 VBUF Access Not Starting At The Base Address

After (hardware or software) reset or on a new frame start condition, a frame write or read access for any VBUF must start from its virtual frame start address ([CBUF_i_VBUF_START_ADDR\[31:4\]](#) ADDR). If this is not met the OCM controller ignores all accesses which don't start at address [CBUF_i_VBUF_START_ADDR\[31:4\]](#) ADDR and also generates an interrupt. The [STATUS_CBUF_WR_VBUF_START_ERR\[11:0\]](#) CBUF_ERR register contains the status bits of this interrupt which are associated with frame write access. The [STATUS_CBUF_VBUF_RD_START_ERROR\[11:0\]](#) CBUF_ERR register contains the status bits associated with frame read access. Each bit in these two registers is associated only with one CBUF. A value of 0x1 for each bit means that the read/write access does not start at the VBUF start address.

While this error condition exists, no updates to the CBUF channel status registers are made. An exception to this constraint is when the last read/write access is still within the base CBUF slice. The enforcing of a frame starting at VBUF starting address is not done in this case to allow random access within the same CBUF. However, this will be flagged and handled as a short frame occurrence.

The [INTR0_STATUS_RAW_SET\[6\]](#) [CBUF_VBUF_WRITE_START_ERR_FOUND/INTR1_STATUS_RAW_SET\[6\]](#) [CBUF_VBUF_WRITE_START_ERR_FOUND](#) bit is asserted if at least one of the bits in the [STATUS_CBUF_WR_VBUF_START_ERR\[11:0\]](#) CBUF_ERR bit field is set to 0x1.

The [INTR0_STATUS_RAW_SET\[9\]](#) [CBUF_VBUF_READ_START_ERR_FOUND/INTR1_STATUS_RAW_SET\[9\]](#) [CBUF_VBUF_READ_START_ERR_FOUND](#) bit is asserted if at least one of the bits in the [STATUS_CBUF_VBUF_RD_START_ERROR\[11:0\]](#) CBUF_ERR bit field is set to 0x1.

11.5.3.11.3 Illegal Address Change Between Two Same Type Accesses

The OCM controller requires both read and write accesses to a virtual frame buffer to be performed in the positive raster scan order, that is, successive write or read accesses should be to a higher address except on a new frame start for which the address jumps back down to the beginning of the virtual frame buffer. The OCM controller checks to make sure that a virtual address meets one of the following conditions:

- It is within the same CBUF slice as the last access of the same type (read or write)
- It is within the next CBUF slice of the last access of the same type (read or write)
- The virtual address is to the VBUF frame start address

Based on these constraints, the OCM controller generates an write/read address sequence error interrupt and invalidates the access, that is, writes are disabled and reads return unknown data, if the following two conditions are met:

- The current access address is not to a current or next CBUF slice space
- The current access address is not to the base of the virtual frame buffer (the first CBUF slice)

The random accesses within the current CBUF slice are permitted to allow some variations in the line width of the captured video which often happens with weak video signal conditions.

To avoid illegal CBUF slice backward switching, the modules capturing the input video and sending it to the CBUF of the OCM controller should limit the maximum width of a line width to be less than the stride size (in pixels). This guarantees that a start of a new line does not point back to the previous CBUF slice.

If a write or read address sequence error event is detected on an access, the OCM controller will simply invalidate the accesses and will not update the CBUF status registers.

The bits in the [STATUS_CBUF_WR_ADDR_SEQ_ERROR](#)[11:0] CBUF_ERR bit field indicate write address sequence error event.

The bits in the [STATUS_CBUF_RD_ADDR_SEQ_ERROR](#)[11:0] CBUF_ERR bit field indicate read address sequence error event.

In both the registers each bit is associated only with one CBUF.

The [INTR0_STATUS_RAW_SET](#)[7]

[CBUF_WRITE_SEQUENCE_ERR_FOUND](#)/[INTR1_STATUS_RAW_SET](#)[7]

[CBUF_WRITE_SEQUENCE_ERR_FOUND](#) bit is asserted if at least one of the bits in the [STATUS_CBUF_WR_ADDR_SEQ_ERROR](#)[11:0] CBUF_ERR bit field is set to 0x1.

The [INTR0_STATUS_RAW_SET](#)[10]

[CBUF_READ_SEQUENCE_ERR_FOUND](#)/[INTR1_STATUS_RAW_SET](#)[10]

[CBUF_READ_SEQUENCE_ERR_FOUND](#) bit is asserted if at least one of the bits in the [STATUS_CBUF_RD_ADDR_SEQ_ERROR](#)[11:0] CBUF_ERR bit field is set to 0x1.

11.5.3.11.4 Illegal Frame Size (Short Frame Detection)

If a frame write access for any VBUF begins from its virtual frame start address without a CBUF software reset and the last write address is not the virtual frame end address or is in the last CBUF slice, then the previous frame is considered to be short. This includes the case where a new frame write happens twice without a new frame read in between, which is an indication of an extremely short frame. When a short frame event is detected, the OCM controller generates a short frame detection interrupt and temporarily disables overflow checking on the write access, including also the current access, until a frame read happens in order to avoid false overflow indication on a suspended read side following the short frame detection.

If the last write address is in the last CBUF slice the short frame detection can be ignored if the [CFG_OCMC_CBUF_ERR_HANDLER](#)[1] [SHORT_FRAME_PREV_EOF_SEL](#) bit is set to 0x1.

The [STATUS_CBUF_SHORT_FRAME_DETECT](#)[11:0] CBUF_ERR bit field has status flags to indicate a short frame detection for each CBUF. When a short frame condition occurs the corresponding bit is set to 0x1.

The [INTR0_STATUS_RAW_SET](#)[14]

[CBUF_SHORT_FRAME_DETECT_FOUND](#)/[INTR1_STATUS_RAW_SET](#)[14]

[CBUF_SHORT_FRAME_DETECT_FOUND](#) bit is asserted if at least one of the bits in the [STATUS_CBUF_SHORT_FRAME_DETECT](#)[11:0] CBUF_ERR bit field is set to 0x1.

In addition, the short frame detection enabling/disabling is controlled by the [CFG_OCMC_CBUF_ERR_HANDLER](#)[0] [SHORT_FRAME_DETECT_CHECK_EN](#) bit.

11.5.3.11.5 CBUF Overflow

For each valid CBUF write access, the write address is compared to the last read address for an overflow condition. If an overflow is detected, the corresponding CBUF overflow status bit in the [STATUS_CBUF_OVERFLOW_MID](#) or [STATUS_CBUF_OVERFLOW_WRAP](#) registers is set to 0x1 and an interrupt is generated. This interrupt condition exists until the corresponding overflow status bit is cleared.

There are two types of overflow conditions referred to as `Cbuf_overflow_wrap` and `Cbuf_overflow_mid`.

`Cbuf_overflow_wrap` occurs in case at least one of the following two:

- VBUF write address – VBUF frame start address < CBUF size
- VBUF write address – VBUF frame start address > VBUF last read address – Current VBUF start address

`Cbuf_overflow_mid` occurs in case at least one of the following two:

- VBUF write address – VBUF frame start address > CBUF size
- VBUF write address – VBUF last read address > CBUF size

If an overflow condition is detected on a CBUF write access, the OCM controller generates a CBUF overflow (`Cbuf_overflow_wrap` or `Cbuf_overflow_mid`) interrupt and enter an overflow error handling state. In this state, the OCM controller do the following in the default error handling configuration:

- When a `Cbuf_Overflow_Wrap` condition occurs (write buffer wraparound with read from previous frame still remaining), writes are disabled but reads are serviced normally. This mechanism preserves the back end of the previous frame and discards the new frame which is already showing signs of overflowing. Writes will be re-enabled automatically on write to the virtual frame start address which indicates the next frame after the overflowed frame has begun. The overflow (and underflow) check for this CBUF will be disabled until detection of write to/read from the virtual frame start address. The module which reads should not start reading the next frame (which is being discarded) or stop reading the frame if the read of this new frame has already started. This mechanism allows both write and read sides to re-synchronize on the next frame after one-frame drop.
- When a `Cbuf_Overflow_Mid` condition occurs, writes and reads are serviced normally allowing the read side to catch up to the write side. The overflow (and underflow) check will be disabled until first a write to the virtual frame start address and then a read from the virtual frame start address is detected. This mechanism allows the frame with a “momentary” overflow condition to be saved. The reader side has an option to stop reading and discarding the data by just resetting its CBUF read pointer at the next frame start, if the read side is too far back.

These steps are taken to minimize the frame loss due to an overflow condition. To support the previously described behavior but to allow software to override the default error handling behavior the following controls are available:

- [CFG_OCMC_CBUF_ERR_HANDLER\[7:6\]](#) OVERFLOW_CHECK_REENABLE_SEL
- [CFG_OCMC_CBUF_ERR_HANDLER\[5:4\]](#) OVERFLOW_WRITE_HANDLER_SEL

In addition, the overflow check can be enabled or disabled through the [CFG_OCMC_CBUF_ERR_HANDLER\[2\]](#) OVERFLOW_ERR_CHECK_EN bit.

11.5.3.11.6 CBUF Underflow

According to the CBUF operation a read request can only be made when there are enough number of video lines written to the CBUF. Therefore, there should not be any underflow conditions due to normal processing speed variations. An underflow condition occurs when the VBUF read address is greater than the last VBUF write address. To detect an abnormal failure in the read/write mechanism which could cause an underflow condition, each valid CBUF read access is checked for an underflow condition and if detected, an underflow interrupt is generated for the selected CBUF. The [STATUS_CBUF_UNDERFLOW\[11:0\]](#) CBUF_ERR bit field has status flags indicating when underflow occurs. This interrupt condition exists until the corresponding underflow status bit in the [STATUS_CBUF_UNDERFLOW](#) register is cleared.

If an underflow is detected on a CBUF read access, the OCM controller generates an underflow interrupt and continues to perform reads and writes normally, but the return data will not be correct while the underflow condition exists.

To avoid a false underflow detection at the end of a frame (due to external decoders sending short last line or due to interlaced input video having different number of lines in even/odd fields), the [CFG_OCMC_CBUF_ERR_HANDLER\[8\]](#) UNDERFLOW_LAST_CBUF_SLICE_DISABLE bit can be set to 0x1 which disables the underflow checking in the last CBUF slice.

The [INTR0_STATUS_RAW_SET\[13\]](#) CBUF_UNDERFLOW_ERR_FOUND/[INTR1_STATUS_RAW_SET\[13\]](#) CBUF_UNDERFLOW_ERR_FOUND bit is asserted if at least one of the bits in the [STATUS_CBUF_UNDERFLOW\[11:0\]](#) CBUF_ERR bit field is set to 0x1.

In addition, the underflow check can be enabled or disabled through the [CFG_OCMC_CBUF_ERR_HANDLER\[3\]](#) UNDERFLOW_ERR_CHECK_EN bit.

11.5.3.12 Status Reporting

The OCM controller keeps a history of last valid write and read addresses for each CBUF. The [CBUF_k_LAST_WR_ADDR](#) register stores the address for the last valid write and the [CBUF_k_LAST_RD_ADDR](#) register stores the address for the last valid read access.

The OCMC_ECC generates also a general VBUF mode error event for an access made with illegal VBUF address. The [INTR0_STATUS_RAW_SET\[3\]](#) OUT_OF_RANGE_ERR_FOUND/[INTR1_STATUS_RAW_SET\[3\]](#) OUT_OF_RANGE_ERR_FOUND bit indicates for this event.

Enhanced DMA

This chapter describes the Enhanced Direct Memory Access (EDMA) controller.

Topic	Page
12.1 EDMA Module Overview	4294
12.2 EDMA Controller Environment.....	4298
12.3 EDMA Controller Integration	4299
12.4 EDMA Controller Functional Description	4311
12.5 EDMA Transfer Examples	4360
12.6 EDMA Debug Checklist and Programming Tips	4381
12.7 EDMA Register Manual	4383

12.1 EDMA Module Overview

The enhanced direct memory access module, also called EDMA, performs high-performance data transfers between two slave points, memories and peripheral devices without microprocessor unit (MPU) or digital signal processor (DSP) support during transfer. EDMA transfer is programmed through a logical EDMA channel, which allows the transfer to be optimally tailored to the requirements of the application.

The EDMA can also perform transfers between external memories and between device subsystems internal memories, with some performance loss caused by resource sharing between the read and write ports.

EDMA controller is based on two major principal blocks:

- EDMA third-party channel controller (EDMA_TPCC)
- EDMA third-party transfer controller (EDMA_TPTC)

The **TPCC** is a high flexible Channel Controller. It serves as an user interface and an event interface for the EDMA controller. The EDMA_TPCC serves to prioritize incoming software requests or events from peripherals and submits transfer requests (TRs) to the transfer controller.

The **TPTC** performs read and write transfers by EDMA ports to the slave peripherals as programmed in the "Active" and "Pending" set of the registers. The transfer controllers are responsible for data movement and issue read/write commands to the source and destination addresses that are programmed for a given transfer in the EDMA_TPCC.

The SoC integrates the following EDMA instances:

- One system-level EDMA
- One DSP internal EDMA (per DSP)
- One EVE internal EDMA (per EVE)

Each of these EDMA modules consists of:

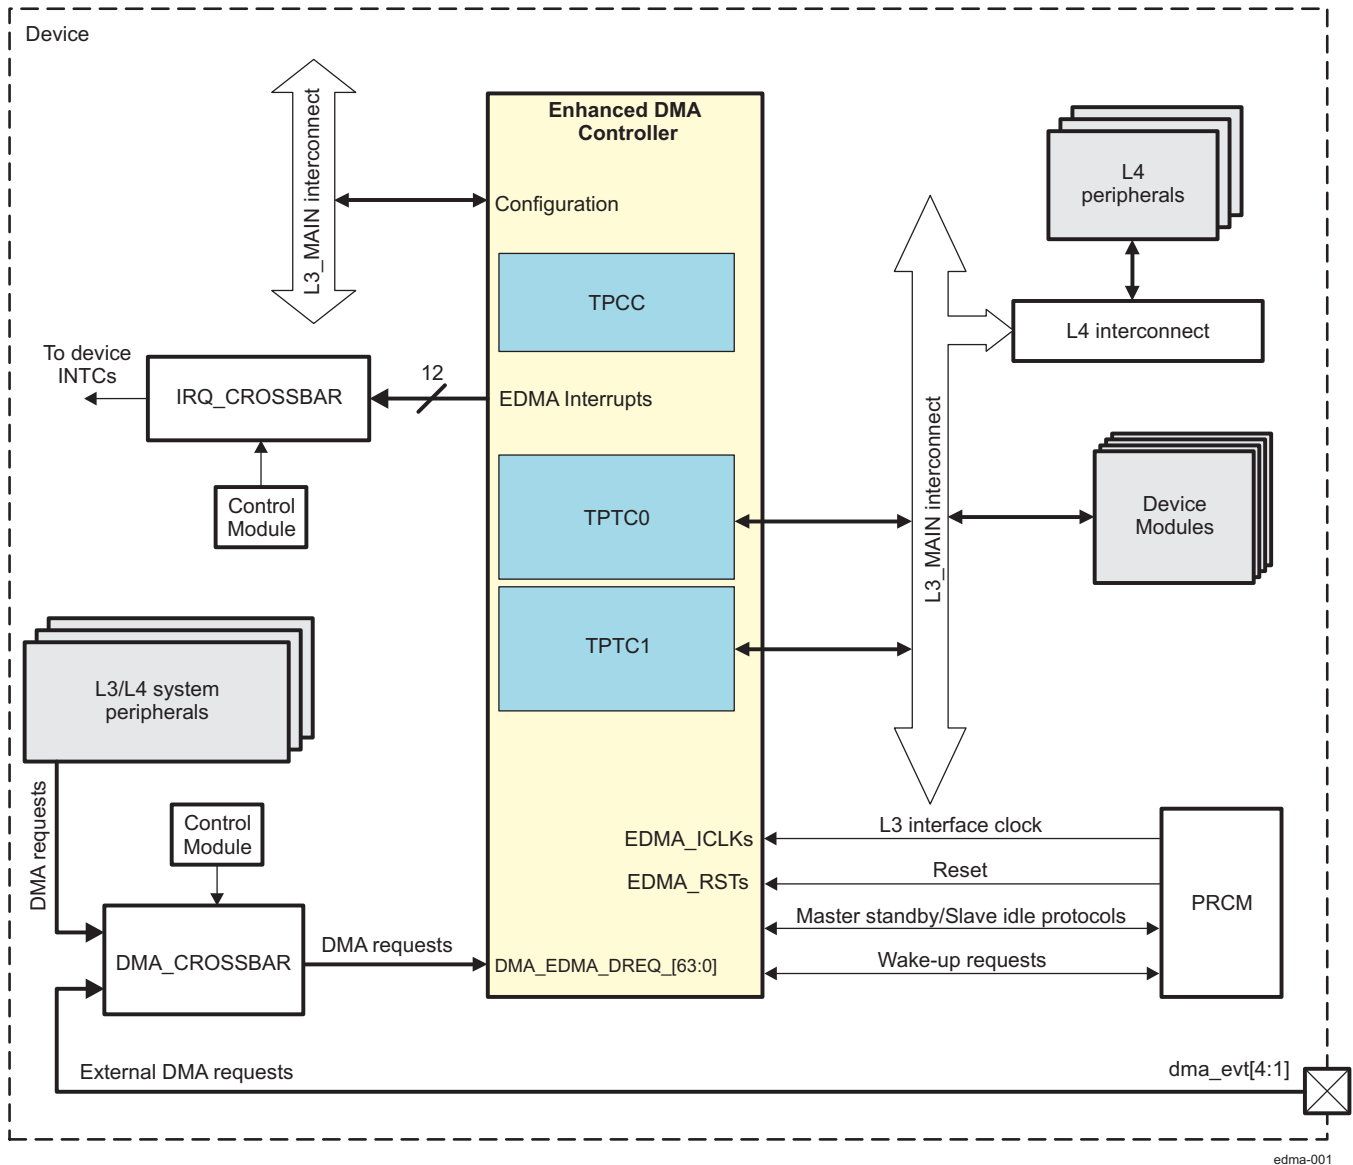

- One TPCC instance
- Two TPTC instances

NOTE: All EDMA modules in the SoC are functionally identical. Note that some of the configuration parameters may be different for the various EDMA instances (see [Section 12.1.2, EDMA Controllers Configuration](#)).

This chapter is mostly focused on describing the system-level EDMA module (in terms of configuration and integration in the SoC). For details on DSPx_EDMA / EVEEx_EDMA integration, see their respective chapters.

[Figure 12-1](#) shows an overview of the EDMA module.

Figure 12-1. EDMA Module Overview

The device CPUs can configure the EDMA controller blocks through the L3_MAIN interconnect.

12.1.1 EDMA Features

The **EDMA_TPCC** channel controller has following features:

- Fully orthogonal transfer description:
 - Three transfer dimensions.
 - A-synchronized transfers: one-dimension serviced per event.
 - AB-synchronized transfers: two-dimensions serviced per event.
 - Independent indexes on source and destination.
 - Chaining feature allows a 3-D transfer based on a single event.
- Flexible transfer definition:
 - Increment or FIFO transfer addressing modes.
 - Linking mechanism allows automatic PaRAM set update.

- Chaining allows multiple transfers to execute with one event.
- Interrupt generation for the following:
 - Transfer completion.
 - Error conditions.
- Debug visibility:
 - Queue water marking/threshold.
 - Error and status recording to facilitate debug.
- 64 DMA request channels:
 - Event synchronization.
 - Manual synchronization (CPU(s) write to event set registers [EDMA_TPCC_ESR](#) and [EDMA_TPCC_ESRH](#)).
 - Chain synchronization (completion of one transfer triggers another transfer).
- Eight QDMA channels:
 - QDMA channels trigger automatically upon writing to a parameter RAM (PaRAM) set entry.
 - Support for programmable QDMA channel to PaRAM mapping.
- 512 PaRAM sets:
 - Each PaRAM set can be used for a DMA channel, QDMA channel, or link set.
- Two transfer controllers/event queues.
- 16 event entries per event queue.
- Memory protection support:
 - Proxy memory protection for TR submission.
 - Active memory protection for accesses to PaRAM and registers.

The **EDMA_TPTC** transfer controller has the following features:

- Two transfer controllers (TC).
- 128-bit wide read and write ports per TC.
- Up to four in-flight transfer requests (TRs).
- Programmable priority level.
- Supports two-dimensional transfers with independent indexes on source and destination (EDMA_TPCC manages the 3rd dimension).
- Support for increment or constant addressing mode transfers.
- Interrupt and error support.
- Memory-Mapped Register (MMR) bit fields are fixed position in 32-bit MMR regardless of endianness.

EDMA controller uses the shared MMU1 module for transferring to and from DSP module. This provides several benefits including:

- Protection of Host CPU memory regions from accidental corruption by EDMA TPTCs.
- Direct allocation of buffers in user space without the need for translation between CPU and DSP applications utilizing EDMA TPTCs.

Accesses by the EDMA TPTCs (both TPTC0 and TPTC1) may optionally be routed through the MMU1.

The TPTC0 and TPTC1 routing allows EDMA transfer controller to be used to perform transfers using only the virtual addresses of the associated buffers.

For more information about MMU1 module refer to [Chapter 16 Memory Management Units](#).

NOTE: The device DSP integrated EDMA controller instances (DSP_EDMA_TPCC, DSP_EDMA_TPTC0 and DSP_EDMA_TPTC1) are functionally identical with the device EDMA controller instances (EDMA_TPCC, EDMA_TPTC0 and EDMA_TPTC1). The only difference is that the DSP_EDMA instances are located at different physical addresses.

For detail information about DSPSS refer to [Chapter 4 DSP Subsystem](#).

12.1.2 EDMA Controllers Configuration

[Table 12-1](#) summarizes the configuration for each of the EDMA channel controllers present on the SoC.

Table 12-1. EDMA Channel Controllers Configuration

Parameter	SYS_EDMA CC Configuration	DSPx_EDMA CC Configuration	EVE _x _EDMA CC Configuration
Number of DMA channels (NUM_DMACH)	64	64	16
Number of QDMA channels (NUM_QDMACH)	8	8	8
Number of interrupt channels (NUM_INTCH)	64	64	16
Number of PaRAM set entries (NUM_PARAMENTRY)	512	128	128
Number of event queues (NUM_EVQUE)	2	2	2
Number of transfer controllers (NUM_TC)	2	2	2
Memory protection existence (MPEXIST)	Yes	Yes	Yes
Number of memory protection and shadow regions (NUM_REGIONS)	8	8	8
Channel mapping existence (CHMAPEXIST)	Yes	Yes	Yes

[Table 12-2](#) summarizes the configuration of each of the EDMA transfer controllers present on the SoC.

Table 12-2. EDMA Transfer Controllers Configuration

Parameter	SYS_EDMA TC0 / TC1 Configuration	DSPx_EDMA TC0 / TC1 Configuration	EVE _x _EDMA TC0 / TC1 Configuration
Data FIFO size (FIFOSIZE)	1024 bytes	2048 bytes	2048 bytes
Bus width (BUSBYTE)	16 bytes	16 bytes	16 bytes
Number of destination FIFO register sets (DSTREGDEPTH)	4 entries	4 entries	4 entries
Default burst size (DBS)	Defined by CTRL_CORE_CONTROL_ IO_1 register	Defined by DSP_SYS_BUS_CONFIG register	Defined by EVE_BUS_CONFIG register

12.2 EDMA Controller Environment

The EDMA controller supports external DMA requests through the dma_evt[4:1] pins (see [Table 12-3](#)). A logical channel can be configured to respond to an external synchronization request.

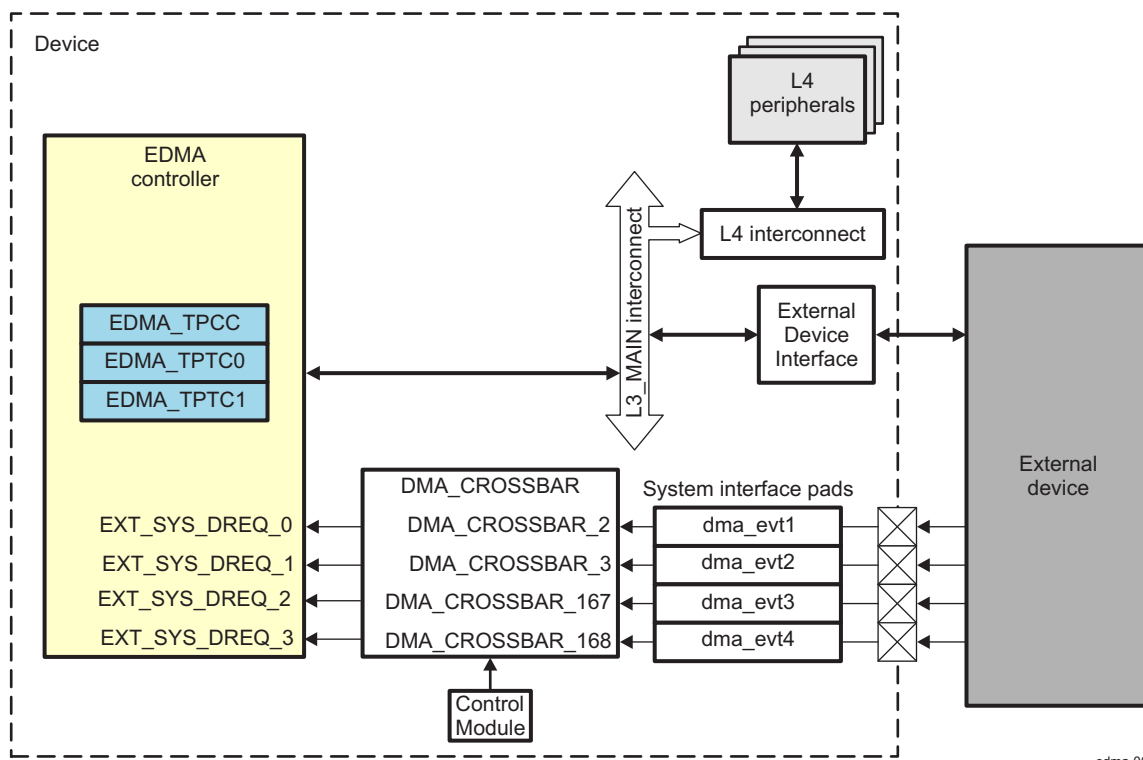

Table 12-3. External EDMA Request Signals

Pin Name	DMA_CROSSBAR Input	Signal Name	I/O ⁽¹⁾	Description	Module Reset Value
dma_evt1	DMA_CROSSBAR_2	EXT_SYS_DREQ_0	I	External DMA request 0 (system expansion)	Z
dma_evt2	DMA_CROSSBAR_3	EXT_SYS_DREQ_1	I	External DMA request 1 (system expansion)	Z
dma_evt3	DMA_CROSSBAR_167	EXT_SYS_DREQ_2	I	External DMA request 2 (system expansion)	Z
dma_evt4	DMA_CROSSBAR_168	EXT_SYS_DREQ_3	I	External DMA request 3 (system expansion)	Z

⁽¹⁾ I = Input, O = Output

[Figure 12-2](#) shows an example of how to use the external hardware DMA request pins in the EDMA environment.

Figure 12-2. Example of External DMA Requests Use

edma-005

An external device can use the external DMA request pins to start a logical channel transfer. The transfer can be a memory-to-memory transfer in which the source memory is in the external device.

By default, the external DMA request signals are not available on external pins after a cold reset. For more information about multiplexing out the two signal lines to pins, refer to [Chapter 14, Control Module](#).

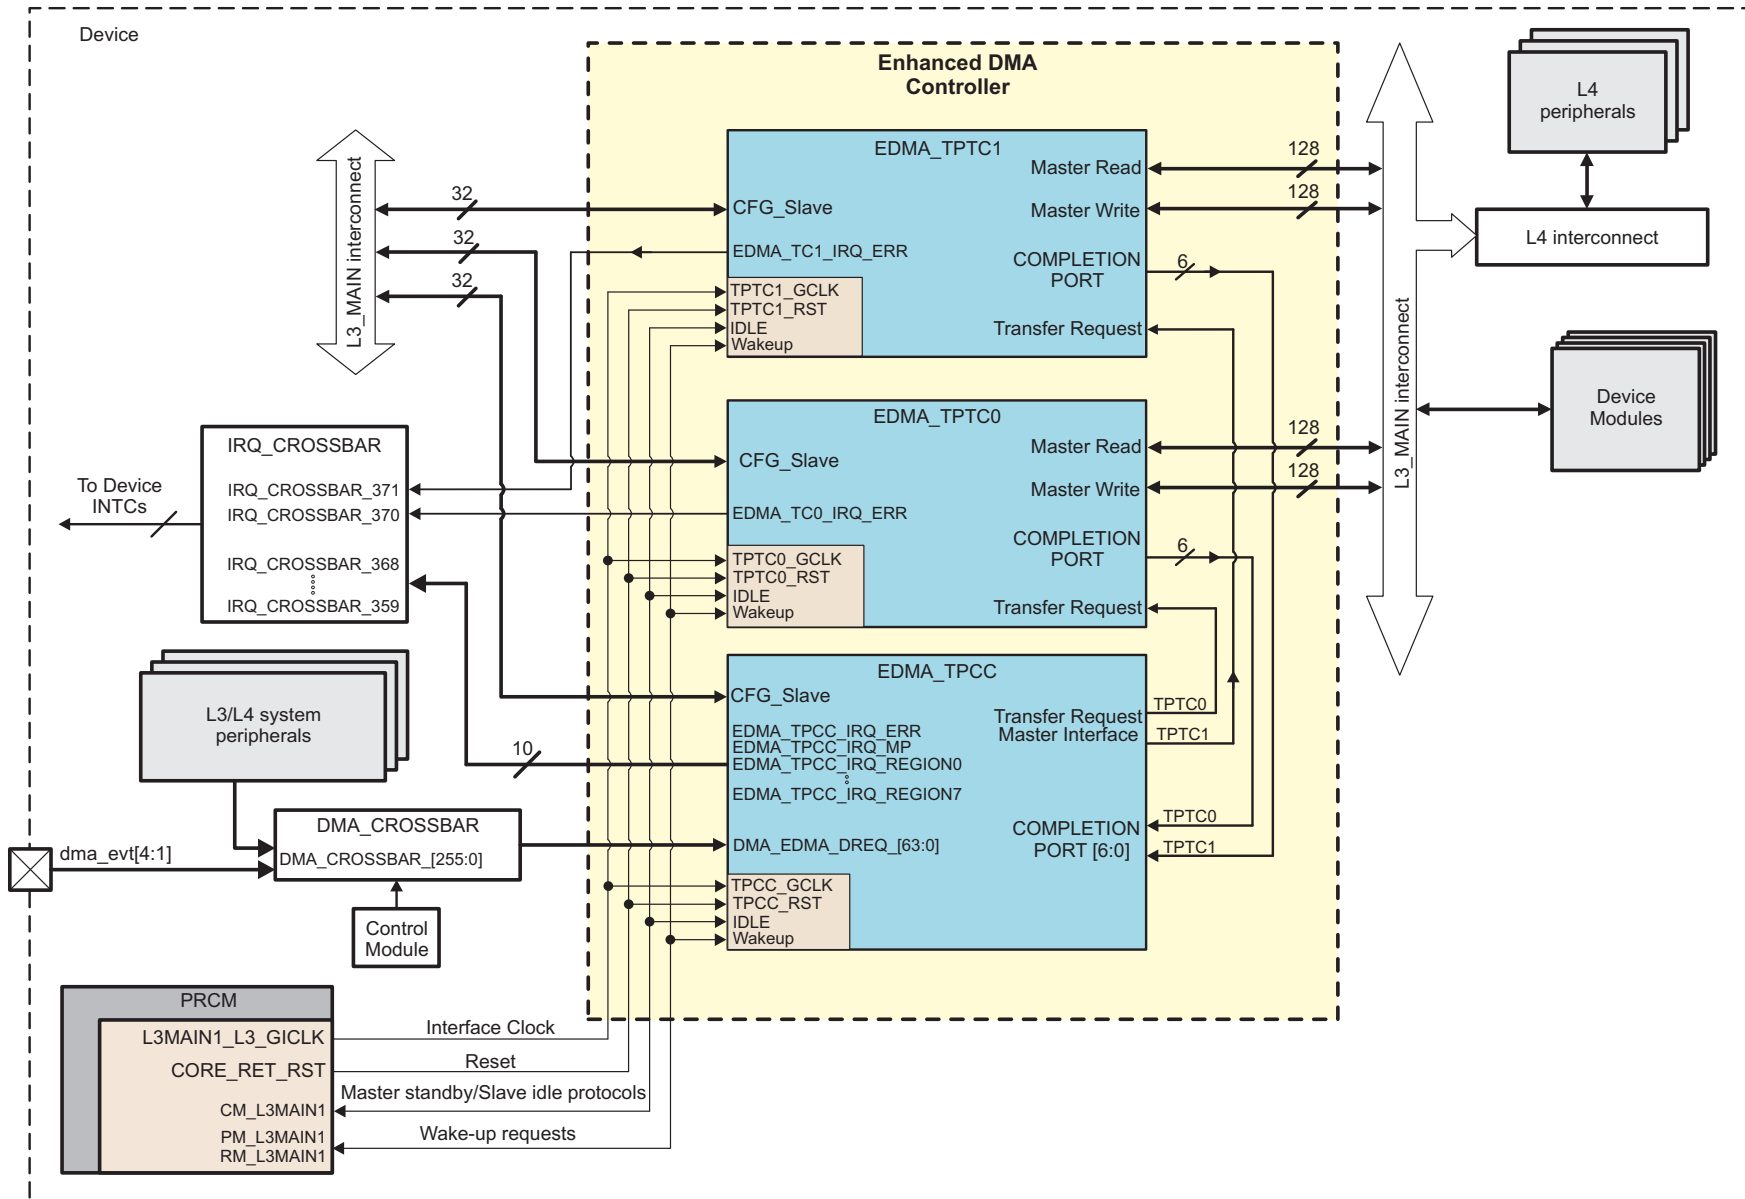

All 64 DMA request lines are transition sensitive.

12.3 EDMA Controller Integration

This section describes the integration of the module in the device, including information about clocks, resets, and hardware requests.

[Figure 12-3](#) shows the EDMA controller integration.

Figure 12-3. EDMA Controller Integration

edma-002

Table 12-4 through Table 12-6 summarize the integration of the module in the device.

Table 12-4. EDMA Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
EDMA_TPCC	PD_COREAON	L3_MAIN
EDMA_TPTC0		
EDMA_TPTC1		

Table 12-5. EDMA Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
EDMA_TPCC	EDMA_TPCC_GCLK	L3MAIN1_L3_GICKL	PRCM	Interface clock. It supports the configuration port. For information about PRCM clock gating and management, see Chapter 3, Power, Reset, and Clock Management .
EDMA_TPTC0	EDMA_TPTC0_GCLK			
EDMA_TPTC1	EDMA_TPTC1_GCLK			
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
EDMA_TPCC	EDMA_TPCC_RST	CORE_RET_RST	PRCM	Hardware retention reset. It initializes all internal logic of the EDMA controller modules, all global registers, and some of the per-channel registers, implemented in flip-flops. However, all remaining per-channel registers are memory-based, and, therefore, are not reset (have undefined values). Thus, when programming a channel for the first time, all bits that have undefined reset values must be configured before enabling the channel. For information about PRCM reset sources and distribution, see Chapter 3, Power, Reset, and Clock Management .
EDMA_TPTC0	EDMA_TPTC0_RST			
EDMA_TPTC1	EDMA_TPTC1_RST			

Table 12-6. EDMA Hardware Requests

Interrupt Requests				
Module Instance	Source Signal Name	Destination IRQ_CROSSBAR INPUT	Default mapping	Description
EDMA_TPCC	EDMA_TPCC_IRQ_ERR	IRQ_CROSSBAR_359	-	TPCC error interrupt. This IRQ source signal is not mapped by default to any device INTC.
	EDMA_TPCC_IRQ_MP	IRQ_CROSSBAR_360	-	TPCC memory protection interrupt. This IRQ source signal is not mapped by default to any device INTC.
	EDMA_TPCC_IRQ_REGION0	IRQ_CROSSBAR_361	-	TPCC Region 0 interrupt. This IRQ source signal is not mapped by default to any device INTC.

Table 12-6. EDMA Hardware Requests (continued)

EDMA_TPCC_IRQ_REGION1	IRQ_CROSSBAR_362	-	TPCC Region 1 interrupt. This IRQ source signal is not mapped by default to any device INTC.	
EDMA_TPCC_IRQ_REGION2	IRQ_CROSSBAR_363	-	TPCC Region 2 interrupt. This IRQ source signal is not mapped by default to any device INTC.	
EDMA_TPCC_IRQ_REGION3	IRQ_CROSSBAR_364	-	TPCC Region 3 interrupt. This IRQ source signal is not mapped by default to any device INTC.	
EDMA_TPCC_IRQ_REGION4	IRQ_CROSSBAR_365	-	TPCC Region 4 interrupt. This IRQ source signal is not mapped by default to any device INTC.	
EDMA_TPCC_IRQ_REGION5	IRQ_CROSSBAR_366	-	TPCC Region 5 interrupt. This IRQ source signal is not mapped by default to any device INTC.	
EDMA_TPCC_IRQ_REGION6	IRQ_CROSSBAR_367	-	TPCC Region 6 interrupt. This IRQ source signal is not mapped by default to any device INTC.	
EDMA_TPCC_IRQ_REGION7	IRQ_CROSSBAR_368	-	TPCC Region 7 interrupt. This IRQ source signal is not mapped by default to any device INTC.	
EDMA_TPTC0	EDMA_TC0_IRQ_ERR	IRQ_CROSSBAR_370	-	TPTC0 error interrupt. This IRQ source signal is not mapped by default to any device INTC.
EDMA_TPTC1	EDMA_TC1_IRQ_ERR	IRQ_CROSSBAR_371	-	TPTC1 error interrupt. This IRQ source signal is not mapped by default to any device INTC.

NOTE: The “**Default Mapping**” column in [Table 12-6 EDMA Hardware Requests](#) shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR or DMA_CROSSBAR modules. For more information about the IRQ_CROSSBAR and DMA_CROSSBAR modules, see sections: [Section 14.4.6.4 IRQ_CROSSBAR Module Functional Description](#) and [Section 14.4.6.5 DMA_CROSSBAR Module Functional Description](#), in [Chapter 14 Control Module](#). For more information about the device interrupt controllers, see [Chapter 13 Interrupt Controllers](#).

NOTE: For a description of the interrupt source, see [Section 12.4.9, EDMA interrupts](#).

12.3.1 DMA Requests to the EDMA Controller

[Table 12-7](#) lists the default DMA sources for the EDMA controller. In addition, the EDMA inputs (DMA_EDMA_DREQ_[63:0]) can alternatively be sourced through the associated DMA_CROSSBAR from one of the 256 multiplexed device DMA sources listed in [Table 12-8](#). The CTRL_CORE_DMA_EDMA_DREQ_y_z registers (where y and z are indexes of EDMA input lines) in the Control Module are used to select between the default DMA sources and the multiplexed DMA sources.

Table 12-7. EDMA Default Request Mapping

DMA Request Line	DMA_CROSSBAR Instance Number	DMA_CROSSBAR Configuration Register	DMA_CROSSBAR Default Input Index	Default DMA Source Name	Default DMA Source Description
DMA_EDMA_DREQ_0	1	CTRL_CORE_DMA_EDMA_DREQ_0_1 [7:0]	1	Reserved	Reserved
DMA_EDMA_DREQ_1	2	CTRL_CORE_DMA_EDMA_DREQ_0_1 [23:16]	2	EXT_SYS_DREQ_0	External DMA request 0 (system expansion)
DMA_EDMA_DREQ_2	3	CTRL_CORE_DMA_EDMA_DREQ_2_3 [7:0]	3	EXT_SYS_DREQ_1	External DMA request 1 (system expansion)
DMA_EDMA_DREQ_3	4	CTRL_CORE_DMA_EDMA_DREQ_2_3 [23:16]	4	GPMC_DREQ	GPMC data transmit request from prefetch engine
DMA_EDMA_DREQ_4	5	CTRL_CORE_DMA_EDMA_DREQ_4_5 [7:0]	5	Reserved	Reserved
DMA_EDMA_DREQ_5	6	CTRL_CORE_DMA_EDMA_DREQ_4_5 [23:16]	6	DISPC_DREQ	Frame update request
DMA_EDMA_DREQ_6	7	CTRL_CORE_DMA_EDMA_DREQ_6_7 [7:0]	7	CT_TBR_DREQ	DEBUG subsystem CT_TBR request
DMA_EDMA_DREQ_7	8	CTRL_CORE_DMA_EDMA_DREQ_6_7 [23:16]	8	Reserved	Reserved
DMA_EDMA_DREQ_8	9	CTRL_CORE_DMA_EDMA_DREQ_8_9 [7:0]	9	ISS_DREQ_1	ISS DMA request 1
DMA_EDMA_DREQ_9	10	CTRL_CORE_DMA_EDMA_DREQ_8_9 [23:16]	10	ISS_DREQ_2	ISS DMA request 2
DMA_EDMA_DREQ_10	11	CTRL_CORE_DMA_EDMA_DREQ_10_11 [7:0]	11	Reserved	Reserved
DMA_EDMA_DREQ_11	12	CTRL_CORE_DMA_EDMA_DREQ_10_11 [23:16]	12	ISS_DREQ_3	ISS DMA request 3
DMA_EDMA_DREQ_12	13	CTRL_CORE_DMA_EDMA_DREQ_12_13 [7:0]	13	ISS_DREQ_4	ISS DMA request 4
DMA_EDMA_DREQ_13	14	CTRL_CORE_DMA_EDMA_DREQ_12_13 [23:16]	14	Reserved	Reserved
DMA_EDMA_DREQ_14	15	CTRL_CORE_DMA_EDMA_DREQ_14_15 [7:0]	15	MCSPi3_DREQ_TX0	McSPi3 transmit request channel 0
DMA_EDMA_DREQ_15	16	CTRL_CORE_DMA_EDMA_DREQ_14_15 [23:16]	16	MCSPi3_DREQ_RX0	McSPi3 receive request channel 0
DMA_EDMA_DREQ_16	17	CTRL_CORE_DMA_EDMA_DREQ_16_17 [7:0]	17	Reserved	Reserved
DMA_EDMA_DREQ_17	18	CTRL_CORE_DMA_EDMA_DREQ_16_17 [23:16]	18	Reserved	Reserved
DMA_EDMA_DREQ_18	19	CTRL_CORE_DMA_EDMA_DREQ_18_19 [7:0]	19	Reserved	Reserved
DMA_EDMA_DREQ_19	20	CTRL_CORE_DMA_EDMA_DREQ_18_19 [23:16]	20	Reserved	Reserved
DMA_EDMA_DREQ_20	21	CTRL_CORE_DMA_EDMA_DREQ_20_21 [7:0]	21	Reserved	Reserved
DMA_EDMA_DREQ_21	22	CTRL_CORE_DMA_EDMA_DREQ_20_21 [23:16]	22	Reserved	Reserved
DMA_EDMA_DREQ_22	23	CTRL_CORE_DMA_EDMA_DREQ_22_23 [7:0]	23	MCSPi3_DREQ_TX1	McSPi3 transmit request channel 1
DMA_EDMA_DREQ_23	24	CTRL_CORE_DMA_EDMA_DREQ_22_23 [23:16]	24	MCSPi3_DREQ_RX1	McSPi3 receive request channel 1
DMA_EDMA_DREQ_24	25	CTRL_CORE_DMA_EDMA_DREQ_24_25 [7:0]	25	Reserved	Reserved
DMA_EDMA_DREQ_25	26	CTRL_CORE_DMA_EDMA_DREQ_24_25 [23:16]	26	Reserved	Reserved
DMA_EDMA_DREQ_26	27	CTRL_CORE_DMA_EDMA_DREQ_26_27 [7:0]	27	I2C1_DREQ_TX	I2C1 transmit request
DMA_EDMA_DREQ_27	28	CTRL_CORE_DMA_EDMA_DREQ_26_27 [23:16]	28	I2C1_DREQ_RX	I2C1 receive request
DMA_EDMA_DREQ_28	29	CTRL_CORE_DMA_EDMA_DREQ_28_29 [7:0]	29	I2C2_DREQ_TX	I2C2 transmit request
DMA_EDMA_DREQ_29	30	CTRL_CORE_DMA_EDMA_DREQ_28_29 [23:16]	30	I2C2_DREQ_RX	I2C2 receive request
DMA_EDMA_DREQ_30	31	CTRL_CORE_DMA_EDMA_DREQ_30_31 [7:0]	31	Reserved	Reserved

Table 12-7. EDMA Default Request Mapping (continued)

DMA Request Line	DMA_CROSSBAR Instance Number	DMA_CROSSBAR Configuration Register	DMA_CROSSBAR Default Input Index	Default DMA Source Name	Default DMA Source Description
DMA_EDMA_DREQ_31	32	CTRL_CORE_DMA_EDMA_DREQ_30_31 [23:16]	32	Reserved	Reserved
DMA_EDMA_DREQ_32	33	CTRL_CORE_DMA_EDMA_DREQ_32_33 [7:0]	33	Reserved	Reserved

DMA_EDMA_DREQ_61	62	CTRL_CORE_DMA_EDMA_DREQ_60_61 [23:16]	62	MMC_DREQ_RX	MMC receive request
DMA_EDMA_DREQ_62	63	CTRL_CORE_DMA_EDMA_DREQ_62_63 [7:0]	63	UART5_DREQ_TX	UART5 transmit request

Table 12-7. EDMA Default Request Mapping (continued)

DMA Request Line	DMA_CROSSBAR Instance Number	DMA_CROSSBAR Configuration Register	DMA_CROSSBAR Default Input Index	Default DMA Source Name	Default DMA Source Description
DMA_EDMA_DREQ_63	64	CTRL_CORE_DMA_EDMA_DREQ_62_63 [23:16]	64	UART5_DREQ_RX	UART5 receive request

12.3.2 Mapping of DMA Requests to DMA_CROSSBAR Inputs

NOTE: The information about the DMA_CROSSBAR module, see in the [Section 14.4.6.5 DMA_CROSSBAR Module Functional Description](#) from the *Control Module* in the device TRM.

[Table 12-8](#) lists the DMA_CROSSBAR inputs request mapping.

NOTE: All DREQs from column “Device Module DREQs” can also be mapped to an input of the device ESM using dedicated DMA_CROSSBAR register. For more information, see *IRQ_CROSSBAR Registers Associated With The Device ESM* in *Control Module*

NOTE: **ESM is not supported on the DM50x family of devices.**

Table 12-8. Connection of The Device DREQs to The DMA_CROSSBAR Inputs

DMA_CROSSBAR Input	Device Module DREQs	Description
DMA_CROSSBAR_0	Reserved	Reserved
DMA_CROSSBAR_1	Reserved	Reserved
DMA_CROSSBAR_2	EXT_SYS_DREQ_0	External DMA request 0 (system expansion) - coming from SOC IOs. Level sensitive only
DMA_CROSSBAR_3	EXT_SYS_DREQ_1	External DMA request 1 (system expansion) - coming from SOC IOs. Level sensitive only
DMA_CROSSBAR_4	GPMC_DREQ	GPMC request from prefetch engine
DMA_CROSSBAR_5	Reserved	Reserved
DMA_CROSSBAR_6	DISPC_DREQ	The line trigger signal to synchronize a memory to memory logical channel in the DMA is generated by the Display Controller IP.
DMA_CROSSBAR_7	CT_TBR_DREQ	DMA request coming from CT_TBR in DEBUGSS (used to be External DMA request 2 - coming from SOC IOs)
DMA_CROSSBAR_8	Reserved	Reserved
DMA_CROSSBAR_9	ISS_DREQ_1	ISS DMA request 1 ⁽¹⁾
DMA_CROSSBAR_10	ISS_DREQ_2	ISS DMA request 2 ⁽¹⁾
DMA_CROSSBAR_11	Reserved	Reserved
DMA_CROSSBAR_12	ISS_DREQ_3	ISS DMA request 3 ⁽¹⁾
DMA_CROSSBAR_13	ISS_DREQ_4	ISS DMA request 4 ⁽¹⁾
DMA_CROSSBAR_14	Reserved	Reserved
DMA_CROSSBAR_15	MCSPI3_DREQ_TX0	McSPI module 3 - transmit request channel 0
DMA_CROSSBAR_16	MCSPI3_DREQ_RX0	McSPI module 3 - receive request channel 0
DMA_CROSSBAR_17 to DMA_CROSSBAR_22	Reserved	Reserved
DMA_CROSSBAR_23	MCSPI3_DREQ_TX1	McSPI module 3 - transmit request channel 1
DMA_CROSSBAR_24	MCSPI3_DREQ_RX1	McSPI module 3 - receive request channel 1
DMA_CROSSBAR_25	Reserved	Reserved
DMA_CROSSBAR_26	Reserved	Reserved
DMA_CROSSBAR_27	I2C1_DREQ_TX	I2C module 1 - transmit request
DMA_CROSSBAR_28	I2C1_DREQ_RX	I2C module 1 - receive request
DMA_CROSSBAR_29	I2C2_DREQ_TX	I2C module 2 - transmit request
DMA_CROSSBAR_30	I2C2_DREQ_RX	I2C module 2 - receive request
DMA_CROSSBAR_31 to DMA_CROSSBAR_34	Reserved	Reserved
DMA_CROSSBAR_35	MCSPI1_DREQ_TX0	McSPI module 1 - transmit request channel 0
DMA_CROSSBAR_36	MCSPI1_DREQ_RX0	McSPI module 1 - receive request channel 0
DMA_CROSSBAR_37	MCSPI1_DREQ_TX1	McSPI module 1 - transmit request channel 1
DMA_CROSSBAR_38	MCSPI1_DREQ_RX1	McSPI module 1 - receive request channel 1
DMA_CROSSBAR_39	MCSPI1_DREQ_TX2	McSPI module 1 - transmit request channel 2
DMA_CROSSBAR_40	MCSPI1_DREQ_RX2	McSPI module 1 - receive request channel 2
DMA_CROSSBAR_41	MCSPI1_DREQ_TX3	McSPI module 1 - transmit request channel 3
DMA_CROSSBAR_42	MCSPI1_DREQ_RX3	McSPI module 1 - receive request channel 3
DMA_CROSSBAR_43	MCSPI2_DREQ_TX0	McSPI module 2 - transmit request channel 0
DMA_CROSSBAR_44	MCSPI2_DREQ_RX0	McSPI module 2 - receive request channel 0
DMA_CROSSBAR_45	MCSPI2_DREQ_TX1	McSPI module 2 - transmit request channel 1
DMA_CROSSBAR_46	MCSPI2_DREQ_RX1	McSPI module 2 - receive request channel 1
DMA_CROSSBAR_47 to DMA_CROSSBAR_48	Reserved	Reserved
DMA_CROSSBAR_49	UART1_DREQ_TX	UART module 1 - transmit request

⁽¹⁾ CRC are not supported on the DM50x family of devices.

Table 12-8. Connection of The Device DREQs to The DMA_CROSSBAR Inputs (continued)

DMA_CROSSBAR Input	Device Module DREQs	Description
DMA_CROSSBAR_50	UART1_DREQ_RX	UART module 1 - receive request
DMA_CROSSBAR_51	UART2_DREQ_TX	UART module 2 - transmit request
DMA_CROSSBAR_52	UART2_DREQ_RX	UART module 2 - receive request
DMA_CROSSBAR_53	UART3_DREQ_TX	UART module 3 - transmit request
DMA_CROSSBAR_54	UART3_DREQ_RX	UART module 3 - receive request
DMA_CROSSBAR_55 to DMA_CROSSBAR_60	Reserved	Reserved
DMA_CROSSBAR_61	MMC_DREQ_TX	MMC/SD1 transmit request
DMA_CROSSBAR_62	MMC_DREQ_RX	MMC/SD1 receive request
DMA_CROSSBAR_63 to DMA_CROSSBAR_69	Reserved	Reserved
DMA_CROSSBAR_70	MCSPi4_DREQ_TX0	McSPI module 4 - transmit request channel 0
DMA_CROSSBAR_71	MCSPi4_DREQ_RX0	McSPI module 4 - receive request channel 0
DMA_CROSSBAR_72 to DMA_CROSSBAR_127	Reserved	Reserved
DMA_CROSSBAR_128	McASP1_DREQ_RX	McASP1 receive event
DMA_CROSSBAR_129	McASP1_DREQ_TX	McASP1 transmit event
DMA_CROSSBAR_130 to DMA_CROSSBAR_157	Reserved	Reserved
DMA_CROSSBAR_158	DCAN_DREQ_IF1	DCAN IF1 Event
DMA_CROSSBAR_159	DCAN_DREQ_IF2	DCAN IF2 Event
DMA_CROSSBAR_160	DCAN_DREQ_IF3	DCAN IF3 Event
DMA_CROSSBAR_161	MCAN_DREQ_TX	MCAN TX DMA Event
DMA_CROSSBAR_162	MCAN_DREQ_RX_FE1	MCAN RX Filter Event 1
DMA_CROSSBAR_163	MCAN_DREQ_RX_FE2	MCAN RX Filter Event 2
DMA_CROSSBAR_164 to DMA_CROSSBAR_166	Reserved	Reserved
DMA_CROSSBAR_167	EXT_SYS_DREQ_2	External DMA request 2 (system expansion) - coming from SOC IOs. Level sensitive only
DMA_CROSSBAR_168	EXT_SYS_DREQ_3	External DMA request 3 (system expansion) - coming from SOC IOs. Level sensitive only
DMA_CROSSBAR_169	MCSPi2_DREQ_TX2	McSPI module 2 - transmit request channel 2
DMA_CROSSBAR_170	MCSPi2_DREQ_RX2	McSPI module 2 - receive request channel 2
DMA_CROSSBAR_171	MCSPi2_DREQ_TX3	McSPI module 2 - transmit request channel 3
DMA_CROSSBAR_172	MCSPi2_DREQ_RX3	McSPI module 2 - receive request channel 3
DMA_CROSSBAR_173	MCSPi3_DREQ_TX2	McSPI module 3 - transmit request channel 2
DMA_CROSSBAR_174	MCSPi3_DREQ_RX2	McSPI module 3 - receive request channel 2
DMA_CROSSBAR_175	MCSPi3_DREQ_TX3	McSPI module 3 - transmit request channel 3
DMA_CROSSBAR_176	MCSPi3_DREQ_RX3	McSPI module 3 - receive request channel 3
DMA_CROSSBAR_177	MCSPi4_DREQ_TX1	McSPI module 4 - transmit request channel 1
DMA_CROSSBAR_178	MCSPi4_DREQ_RX1	McSPI module 4 - receive request channel 1
DMA_CROSSBAR_179	MCSPi4_DREQ_TX2	McSPI module 4 - transmit request channel 2
DMA_CROSSBAR_180	MCSPi4_DREQ_RX2	McSPI module 4 - receive request channel 2
DMA_CROSSBAR_181	MCSPi4_DREQ_TX3	McSPI module 4 - transmit request channel 3
DMA_CROSSBAR_182	MCSPi4_DREQ_RX3	McSPI module 4 - receive request channel 3
DMA_CROSSBAR_183 to DMA_CROSSBAR_186	Reserved	Reserved
DMA_CROSSBAR_187	GPIO1_DREQ_EVT	GPIO module 1 - event/interrupt 1
DMA_CROSSBAR_188	GPIO2_DREQ_EVT	GPIO module 2 - event/interrupt 1
DMA_CROSSBAR_189	GPIO3_DREQ_EVT	GPIO module 3 - event/interrupt 1

Table 12-8. Connection of The Device DREQs to The DMA_CROSSBAR Inputs (continued)

DMA_CROSSBAR Input	Device Module DREQs	Description
DMA_CROSSBAR_190	GPIO4_DREQ_EVT	GPIO module 4 - event/interrupt 1
DMA_CROSSBAR_191 to DMA_CROSSBAR_194	Reserved	Reserved
DMA_CROSSBAR_195	PWMSS_DREQ_ePWM0_EVT	eHRPWM0 event/interrupt
DMA_CROSSBAR_196 to DMA_CROSSBAR_197	Reserved	Reserved
DMA_CROSSBAR_198	PWMSS_DREQ_eQEP0_EVT	eQEP0 event/interrupt
DMA_CROSSBAR_199 to DMA_CROSSBAR_200	Reserved	Reserved
DMA_CROSSBAR_201	PWMSS_DREQ_eCAP0_EVT	eCAP0 event/interrupt
DMA_CROSSBAR_202 to DMA_CROSSBAR_203	Reserved	Reserved
DMA_CROSSBAR_204	CRC_DREQ_EVT0	CRC DMA event 0 ⁽²⁾
DMA_CROSSBAR_205	TSC_ADC_DREQ_FIFO0	ADC FIFO0 DMA request
DMA_CROSSBAR_206	TSC_ADC_DREQ_FIFO1	ADC FIFO1 DMA request
DMA_CROSSBAR_207	CRC_DREQ_EVT1	CRC DMA event 1 ⁽²⁾
DMA_CROSSBAR_208	CRC_DREQ_EVT2	CRC DMA event 2 ⁽²⁾
DMA_CROSSBAR_209	CRC_DREQ_EVT3	CRC DMA event 3 ⁽²⁾

12.4 EDMA Controller Functional Description

This chapter discusses the architecture of the EDMA controller.

12.4.1 Block Diagram

Figure 12-4 shows the functional block diagram of the EDMA controller.

Figure 12-4. EDMA Controller Block Diagram

12.4.1.1 Third-Party Channel Controller

The TPCC is the EDMA transfer scheduler responsible for scheduling, arbitrating, and issuing user programmed transfers to the two TPTCs.

Figure 12-5 shows a functional block diagram of the EDMA channel controller (EDMA_TPCC).

The main blocks of the EDMA_TPCC are as follows:

- **Parameter RAM (PaRAM):** The PaRAM maintains parameter sets for channel and reload parameter sets. The PaRAM must be written with the transfer context for the desired channels and link parameter sets. EDMA_TPCC processes and sets based on a trigger event and submits a transfer request (TR) to the transfer controllers.
- **EDMA event and interrupt processing registers:** Allows mapping of events to parameter sets, enable/disable events, enable/disable interrupt conditions, and clearing interrupts.
- **Completion detection:** The completion detect block detects completion of transfers by the EDMA_TPTCs or slave peripherals. The completion of transfers can be used optionally to chain trigger new transfers or to assert interrupts.
- **Event queues:** Event queues form the interface between the event detection logic and the transfer request submission logic.
- **Memory protection registers:** Memory protection registers define the accesses (privilege level and requestor(s)) that are allowed to access the DMA channel shadow region view(s) and regions of PaRAM.

Other functions include the following:

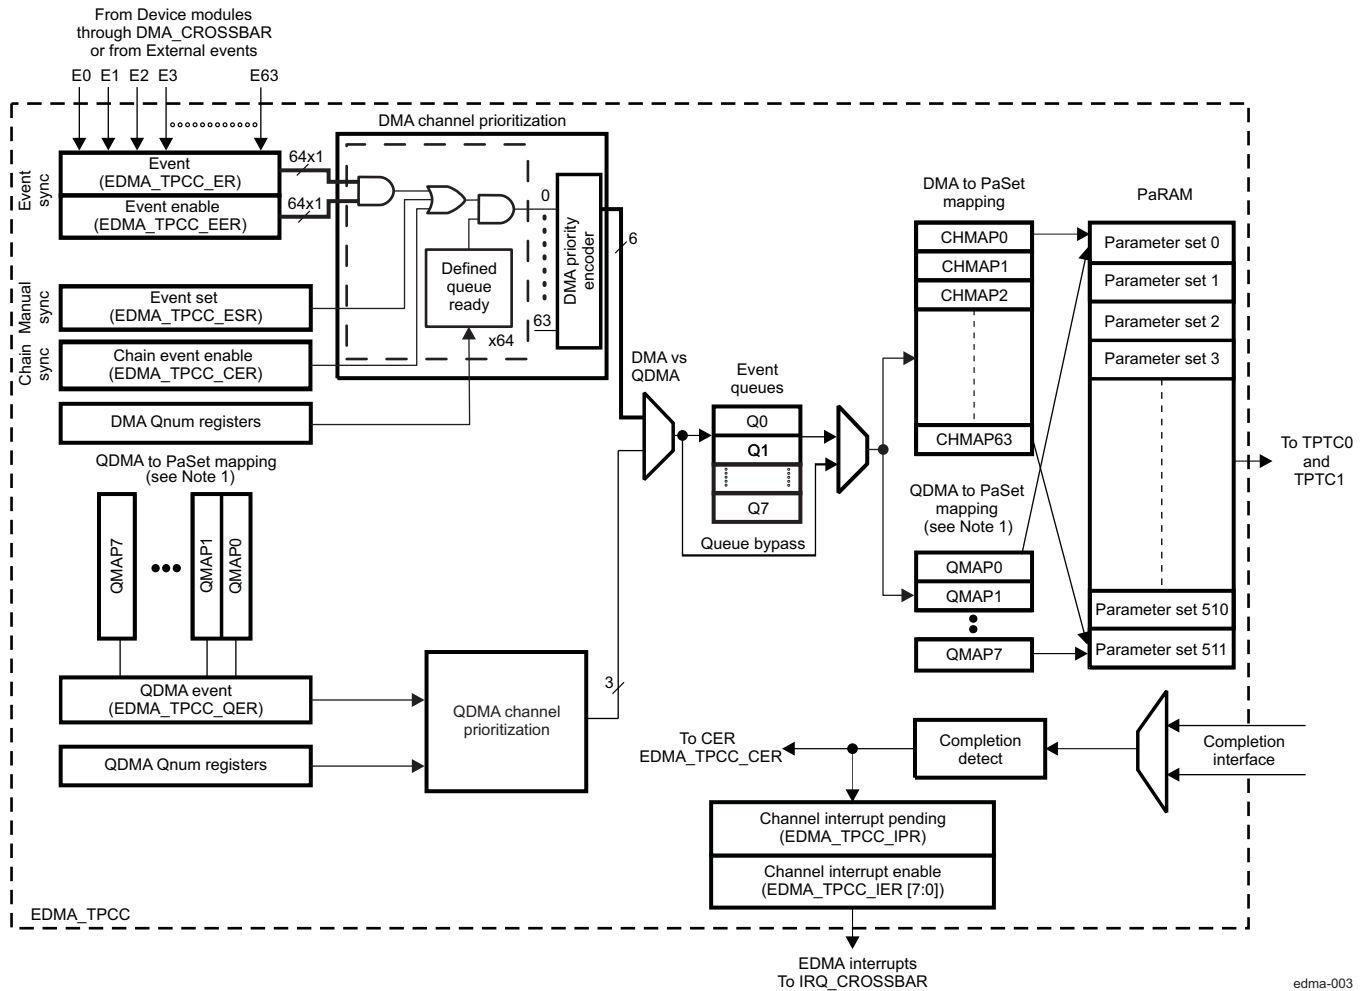

- **Region registers:** Region registers allow DMA resources (DMA channels and interrupts) to be assigned to unique regions that different EDMA programmers own (for example, DSPs).
- **Debug registers:** Debug registers allow debug visibility by providing registers to read the queue status, controller status, and missed event status.

The EDMA_TPCC includes two channel types: DMA channels (64 channels) and QDMA channels (8 channels).

Each channel is associated with a given event queue/transfer controller and with a given PaPARAM set. The main difference between a DMA channel and a QDMA channel is the method that the system uses to trigger transfers.

Figure 12-5 is a block diagram of the EDMA_TPCC.

Figure 12-5. EDMA Channel Controller Block Diagram

(1) Although it is depicted twice in Figure 12-5, there is only one physical register set for the QDMA to PaRAM set mapping block.

The EDMA_TPCC supports up to 64 DMA channels and up to 8 QDMA channels. These channels are identical, except for how they are triggered:

- DMA channels are triggered by external events (such as McSPI modules TX event and McSPI modules RX event) by the event set registers [EDMA_TPCC_ESR](#) and [EDMA_TPCC_ESRH](#), or through chaining register [EDMA_TPCC_CER](#).
- QDMA channels are triggered automatically (auto-triggered) by the CPU. QDMAs allow a minimum number of linear writes to be issued to the TPCC to force a series of transfers to occur.

The TPCC arbitrates among pending DMA and QDMA events with a fixed [64:1] and [8:1] priority encoder for these events, respectively (a low channel number corresponds to a high priority).

DMA events are always higher priority than QDMA events. The higher-priority event is placed in the event queue to await submission to the transfer controllers, which occurs at the earliest opportunity. Each event queue is serviced in FIFO order, with a maximum of 16 queued events per event queue. If more than one TPTC is ready to be programmed with a transmission request (TR), the event queues are serviced with fixed priority: Q0 is higher than Q1. When an event is ready to be queued and the event queue and the TC channel are empty, the event bypasses the event queue and goes directly to the PaRAM processing logic for submission to the appropriate TC. If the transfer request TR bus or PaPARAM processing are busy, the bypass path is not used. The bypass is not used to dequeue for a higher-priority event.

Events are extracted from the event queue when the EDMA_TPTC is available for a new TR to be programmed into the EDMA_TPTC (signaled with the empty signal, indicating an empty program register set). As an event is extracted from the event queue, the associated PaPARAM entry is processed and submitted to the TPTC as a TR. The TPCC updates the appropriate counts and addresses in the PaPARAM entry in anticipation of the next trigger event for that PaPARAM entry.

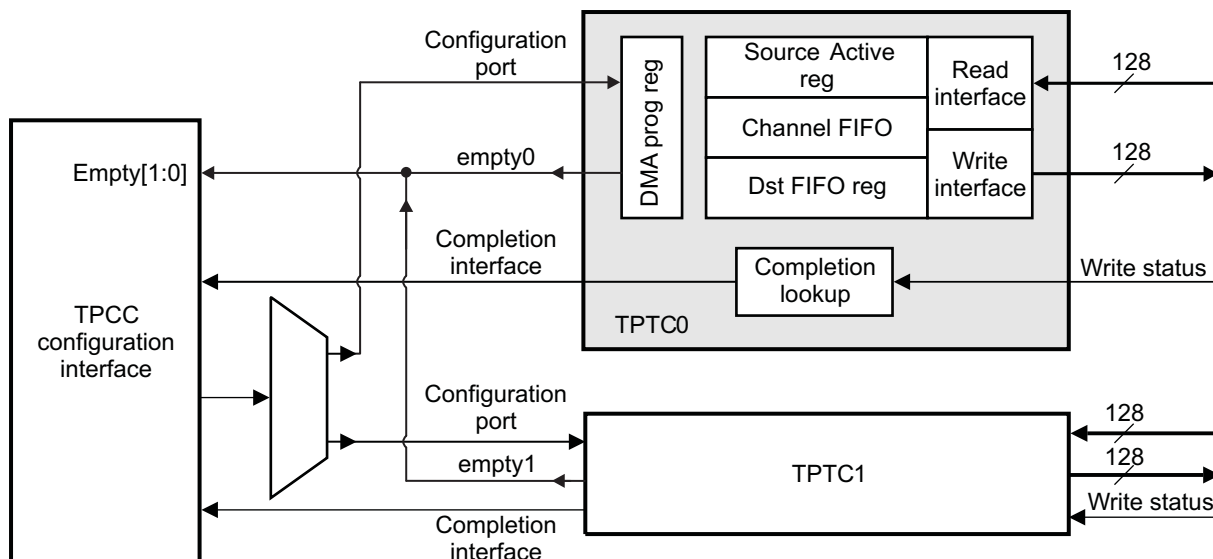

The EDMA_TPCC also has an error detection logic that causes an error interrupt generation on various error conditions (for example: missed events [EDMA_TPCC_EMR](#) and [EDMA_TPCC_EMRH](#) registers, exceeding event queue thresholds in [EDMA_TPCC_CCERR](#) register, etc.).

12.4.1.2 Third-Party Transfer Controller

The TPTC module is the EDMA transfer engine that generates transfers as programmed in dedicated working registers, using two dedicated master ports: a read-only port and a write-only port.

Figure 12-6 shows a functional block diagram and of the EDMA transfer controller (EDMA_TPTC) and its connection to the EDMA_TPCC.

Figure 12-6. TPTC Block Diagram

NOTE: The port data bus width of the instances of the TPTC is fixed at 128 bits.

Two instances of the EDMA_TPTC generate concurrent traffic on the L3_MAIN interconnect. Each TC controller consists of the following components:

- **DMA Program Register Set:** Stores the context for the DMA transfer that is loaded into the active register set when the current active register set completes. The CPU or TPCC programs the Program Register Set, not the active register set. For typical standalone operation, the CPU programs the Program Register while the TC services the Active register set. The Program Register set includes ownership control such that CPU software and the EDMA stay synchronized relative to one another.
- **Source Active Register Set :** Stores the context (src/dst/cnt/etc) for the DMA Transfer Request (TR) in

progress in the Read Controller. The Active register set is split into independent Source and Destination, because the source interconnect controller and the distant interconnect controller operate independently of one another.

- Destination FIFO Register Set: Stores the context (src/dst/cnt/etc) for the DMA Transfer Request (TR) in progress, or pending, in the Write Controller. The pending register must allow the source controller to begin processing a new TR while the distant register set processes the previous TR.
- Channel FIFO: Temporary holding buffer for in-flight data. The read return data of the source peripheral is stored in the Data FIFO, and then is written to the destination peripheral by the write command/data bus.
- Read Controller/Interconnect Read Interface: The Interconnect read interface issues optimally sized read commands to the source peripheral, based on a burst size of 128 bytes and available landing space in the channel FIFO.
- Write controller/Interconnect Write interface: The local interconnect write interface issues optimally sized write commands to the destination peripheral, based on a burst size of 128 bytes and available data in the channel FIFO.
- Completion interface: sends completion codes to the EDMA_TPCC when a transfer completes and generates interrupts and chained events in the TPCC module.
- Configuration port: Slave interface that provides read/write access to program registers and read access to all memory-mapped TPTC registers.

When one EDMA_TPTC module is idle and receive its first TR, DMA program register set receives the TR, where it transitions to the DMA source active set and the destination FIFO register set immediately. The second TR (if pending from EDMA_TPCC) is loaded into the DMA program set, ensuring it can start as soon as possible when the active transfer completes. As soon as the current active set is exhausted, the TR is loaded from the DMA program register set into the DMA source active register set as well as to the appropriate entry in the destination FIFO register set.

The read controller issues read commands controlled by the rules of command fragmentation and optimization. These are issued only when the data FIFO has space available for the data read. When sufficient data is in the data FIFO, the write controller starts issuing a write command again following the rules for command fragmentation and optimization.

Depending on the number of entries, the read controller can process up to two or four transfer requests ahead of the destination subject to the amount of free data FIFO.

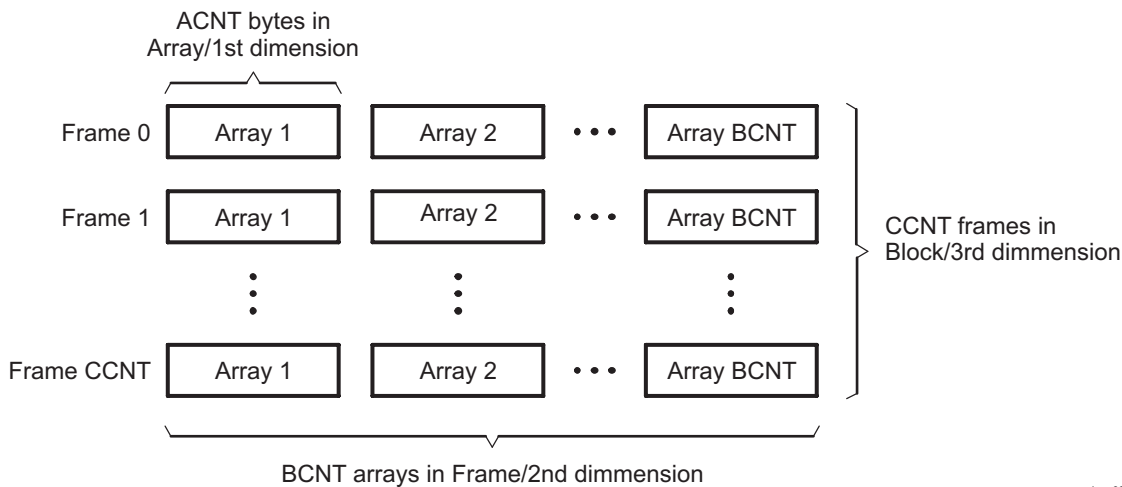

12.4.2 Types of EDMA controller Transfers

An EDMA transfer is always defined in terms of three dimensions. Figure 12-7 shows the three dimensions used by EDMA controller transfers. These three dimensions are defined as:

- 1st Dimension or Array (A): The 1st dimension in a transfer consists of EDMA_TPCC_ABCNT_n[15:0] ACNT contiguous bytes.
- 2nd Dimension or Frame (B): The 2nd dimension in a transfer consists of EDMA_TPCC_ABCNT_n[31:16] BCNT arrays of ACNT bytes. Each array transfer in the 2nd dimension is separated from each other by an index programmed using bit-fields EDMA_TPCC_BIDX_n[15:0] SBIDX or EDMA_TPCC_BIDX_n[31:16] DBIDX.
- 3rd Dimension or Block (C): The 3rd dimension in a transfer consists of CCNT frames of BCNT arrays of ACNT bytes. The Count for 3rd Dimension is defined in register EDMA_TPCC_CCNT_n[15:0] CCNT. Each transfer in the 3rd dimension is separated from the previous by an index programmed using EDMA_TPCC_CIDX_n[15:0] SCIDX or EDMA_TPCC_CIDX_n[31:16] DCIDX.

NOTE: The reference point for the index depends on the synchronization type. The amount of data transferred upon receipt of a trigger/synchronization event is controlled by the synchronization types (EDMA_TPCC_OPT_n[2] SYNCDIM bit). For these three dimensions, only two synchronization types are supported: A-synchronized transfers and AB-synchronized transfers.

Figure 12-7. Definition of ACNT, BCNT, and CCNT

edma-007

12.4.2.1 A-Synchronized Transfers

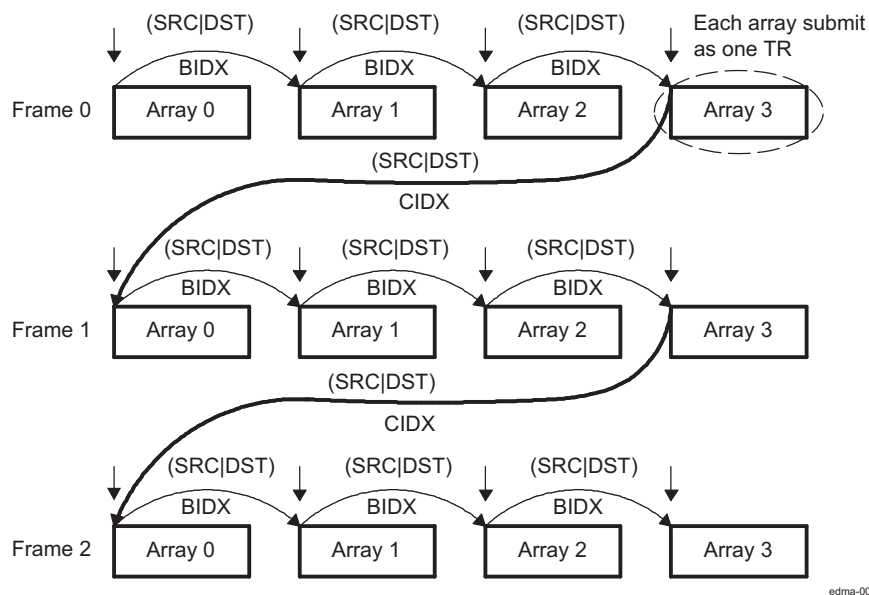

In an A-synchronized transfer, each EDMA sync event initiates the transfer of the 1st dimension of `EDMA_TPCC_ABCNT_n[15:0]` ACNT bytes, or one array of ACNT bytes. Each event/TR packet conveys the transfer information for one array only. Thus, $BCNT \times CCNT$ events are needed to completely service a PaRAM set.

Arrays are always separated by `EDMA_TPCC_BIDX_n[15:0]` SBIDX and `EDMA_TPCC_BIDX_n[31:16]` DBIDX, as shown in Figure 12-8, where the start address of Array N is equal to the start address of Array N – 1 plus source (SRC) or destination (DST) in `EDMA_TPCC_BIDX_n` register.

Frames are always separated by `EDMA_TPCC_CIDX_n[15:0]` SCIDX and `EDMA_TPCC_CIDX_n[31:16]` DCIDX. For A-synchronized transfers, after the frame is exhausted, the address is updated by adding `SRCCIDX/DSTCIDX` to the beginning address of the last array in the frame. As in Figure 12-8, `SRCCIDX/DSTCIDX` is the difference between the start of Frame 0 Array 3 to the start of Frame 1 Array 0.

Figure 12-8 shows an A-synchronized transfer of 3 (CCNT) frames of 4 (BCNT) arrays of n (ACNT) bytes. In this example, a total of 12 sync events ($BCNT \times CCNT$) exhaust a PaRAM set. See Figure 12-8 for details on parameter set updates.

Figure 12-8. A-Synchronized Transfers (ACNT = n, BCNT = 4, CCNT = 3)

edma-008

12.4.2.2 AB-Synchronized Transfers

In a AB-synchronized transfer, each EDMA sync event initiates the transfer of 2 dimensions or one frame. Each event/TR packet conveys information for one entire frame of BCNT_n arrays of ACNT_n bytes. Thus, [EDMA_TPCC_CCNT_n](#) events are needed to completely service a PaRAM set.

Arrays are always separated by [EDMA_TPCC_BIDX_n\[15:0\]](#) SBIDX and [EDMA_TPCC_BIDX_n\[31:16\]](#) DBIDX as shown in [Figure 12-9](#). Frames are always separated by SRCCIDX and DSTCIDX.

Note that for AB-synchronized transfers, after a TR for the frame is submitted, the address update is to add [EDMA_TPCC_CIDX_n\[15:0\]](#) SCIDX / [EDMA_TPCC_CIDX_n\[31:16\]](#) DCIDX to the beginning address of the beginning array in the frame. This is different from A-synchronized transfers where the address is updated by adding SRCCIDX/DSTCIDX to the start address of the last array in the frame. See [Section 12.4.3.6 Parameter Set Updates](#) for details on parameter set updates.

[Figure 12-9](#) shows an AB-synchronized transfer of 3 (CCNT) frames of 4 (BCNT) arrays of *n* (ACNT) bytes. In this example, a total of 3 sync events (CCNT) exhaust a PaRAM set; that is, a total of 3 transfers of 4 arrays each completes the transfer.

Figure 12-9. AB-Synchronized Transfers (ACNT = n, BCNT = 4, CCNT = 3)

NOTE: ABC-synchronized transfers are not directly supported. It can be logically achieved by chaining between multiple AB-synchronized transfers.

12.4.3 Parameter RAM (PaRAM)

The EDMA controller is a RAM-based architecture. The transfer context (source/destination addresses, count, indexes, etc.) for DMA or QDMA channels is programmed in a parameter RAM table in EDMA_TPCC. The PaRAM table is segmented into multiple PaRAM sets. Each PaRAM set includes eight four-byte PaRAM set entries (32-bytes total per PaRAM set), which includes typical DMA transfer parameters such as source address, destination address, transfer counts, indexes, options, etc.

The PaRAM structure supports flexible ping-pong, circular buffering, channel chaining, and auto-reloading (linking).

The contents of the PaRAM include the following:

- 512 PaRAM sets
- 64 channels that are direct mapped and can be used as link or QDMA sets if not used for DMA channels

- 64 channels remain for link or QDMA sets

By default, all channels map to PaRAM set to 0, they should be remapped before use by [EDMA_TPCC_DCHMAPN_m](#) and [EDMA_TPCC_QCHMAPN_j](#) registers.

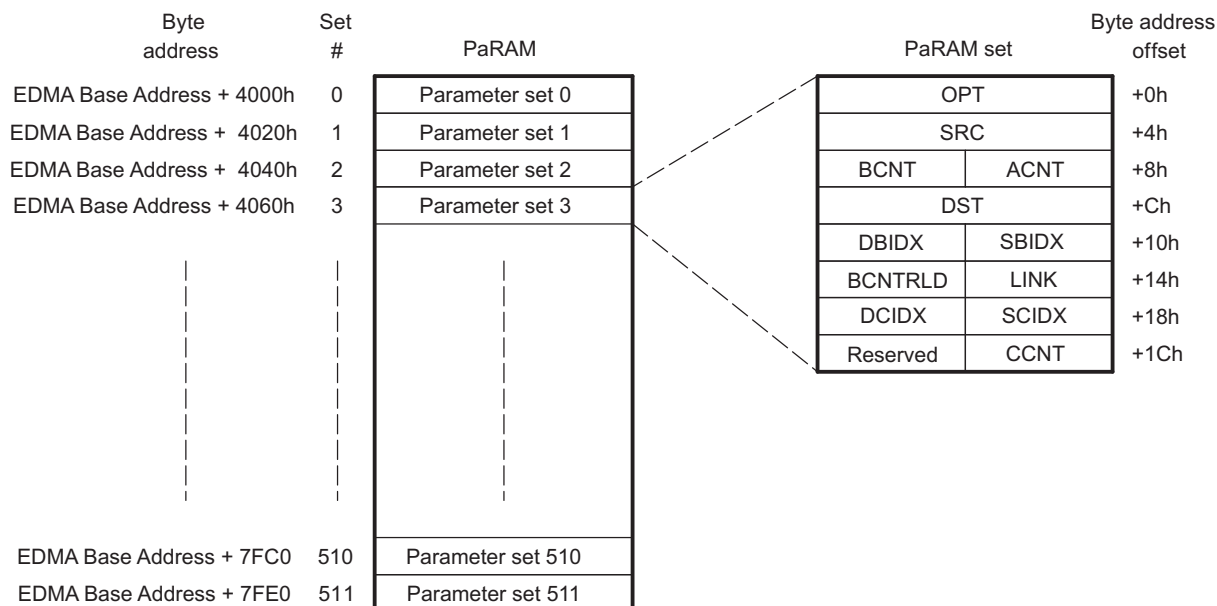

Table 12-9. EDMA Parameter RAM Contents

PaRAM Set Number	Base Address	Parameters ⁽¹⁾
0	EDMA Base Address + 4000h to EDMA Base Address + 401Fh	PaRAM set 0
1	EDMA Base Address + 4020h to EDMA Base Address + 403Fh	PaRAM set 1
2	EDMA Base Address + 4040h to EDMA Base Address + 405Fh	PaRAM set 2
3	EDMA Base Address + 4060h to EDMA Base Address + 407Fh	PaRAM set 3
4	EDMA Base Address + 4080h to EDMA Base Address + 409Fh	PaRAM set 4
5	EDMA Base Address + 40A0h to EDMA Base Address + 40BFh	PaRAM set 5
6	EDMA Base Address + 40C0h to EDMA Base Address + 40DFh	PaRAM set 6
7	EDMA Base Address + 40E0h to EDMA Base Address + 40FFh	PaRAM set 7
8	EDMA Base Address + 4100h to EDMA Base Address + 411Fh	PaRAM set 8
9	EDMA Base Address + 4120h to EDMA Base Address + 413Fh	PaRAM set 9
...
63	EDMA Base Address + 47E0h to EDMA Base Address + 47FFh	PaRAM set 63
64	EDMA Base Address + 4800h to EDMA Base Address + 481Fh	PaRAM set 64
65	EDMA Base Address + 4820h to EDMA Base Address + 483Fh	PaRAM set 65
...
510	EDMA Base Address + 7FC0h to EDMA Base Address + 7FDFh	PaRAM set 510
511	EDMA Base Address + 7FE0h to EDMA Base Address + 7FFFh	PaRAM set 511

⁽¹⁾ The device has 8 QDMA channels that can be mapped to any parameter set number from 0 to 511.

12.4.3.1 PaRAM

Each parameter set of PaRAM is organized into eight 32-bit words or 32 bytes, as shown in [Figure 12-10](#) and described in [Table 12-10](#). Each PaRAM set consists of 16-bit and 32-bit parameters.

Figure 12-10. PaRAM Set

edma-010

Table 12-10. EDMA Channel Parameter Description

Offset Address (bytes)	Acronym	Parameter	Description
0h	OPT	Channel Options EDMA_TPCC_OPT_n register	Transfer configuration options
4h	SRC	Channel Source Address EDMA_TPCC_SRC_n register	The byte address from which data is transferred
8h ⁽¹⁾	ACNT	Count for 1st Dimension EDMA_TPCC_ABCNT_n [15:0] ACNT bit-field.	Unsigned value specifying the number of contiguous bytes within an array (first dimension of the transfer). Valid values range from 1 to 65 535.
	BCNT	Count for 2nd Dimension EDMA_TPCC_ABCNT_n [31:16] BCNT bit-field.	Unsigned value specifying the number of arrays in a frame, where an array is ACNT bytes. Valid values range from 1 to 65 535.
Ch	DST	Channel Destination Address EDMA_TPCC_DST_n register	The byte address to which data is transferred
10h ⁽¹⁾	SBIDX	Source BCNT Index EDMA_TPCC_BIDX_n [15:0] SBIDX bit-field.	Signed value specifying the byte address offset between source arrays within a frame (2nd dimension). Valid values range from –32 768 and 32 767.
	DBIDX	Destination BCNT Index EDMA_TPCC_BIDX_n [31:16] DBIDX bit-field.	Signed value specifying the byte address offset between destination arrays within a frame (2nd dimension). Valid values range from –32 768 and 32 767.
14h ⁽¹⁾	LINK	Link Address EDMA_TPCC_LNK_n [15:0] LINK bit-field	The PaRAM address containing the PaRAM set to be linked (copied from) when the current PaRAM set is exhausted. A value of FFFFh specifies a null link.
	BCNTRL	BCNT Reload EDMA_TPCC_LNK_n [31:16] BCNTRL bit-field	The count value used to reload BCNT when BCNT decrements to 0 (TR is submitted for the last array in 2nd dimension). Only relevant in A-synchronized transfers.
18h ⁽¹⁾	SCIDX	Source CCNT index. EDMA_TPCC_CIDX_n [15:0] SCIDX bit-field.	Signed value specifying the byte address offset between frames within a block (3rd dimension). Valid values range from –32 768 and 32 767. A-synchronized transfers: The byte address offset from the beginning of the last source array in a frame to the beginning of the first source array in the next frame. AB-synchronized transfers: The byte address offset from the beginning of the first source array in a frame to the beginning of the first source array in the next frame.
	DCIDX	Destination CCNT index. EDMA_TPCC_CIDX_n [31:16] DCIDX bit-field.	Signed value specifying the byte address offset between frames within a block (3rd dimension). Valid values range from –32 768 and 32 767. A-synchronized transfers: The byte address offset from the beginning of the last destination array in a frame to the beginning of the first destination array in the next frame. AB-synchronized transfers: The byte address offset from the beginning of the first destination array in a frame to the beginning of the first destination array in the next frame.
1Ch	CCNT	Count for 3rd Dimension. EDMA_TPCC_CCNT_n [15:0] CCNT bit-field.	Unsigned value specifying the number of frames in a block, where a frame is BCNT arrays of ACNT bytes. Valid values range from 1 to 65 535.
	Reserved	Reserved	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.

⁽¹⁾ If OPT, SRC, or DST is the trigger word for a QDMA transfer then it is required to do a 32-bit access to that field. Furthermore, it is recommended to perform only 32-bit accesses on the parameter RAM for best code compatibility. For example, switching the endianness of the processor will swap addresses of the 16-bit fields, but 32-bit accesses avoid the issue entirely.

12.4.3.2 EDMA Channel PaRAM Set Entry Fields

12.4.3.2.1 Channel Options Parameter (OPT)

For detailed information about the channel options parameter, see the [EDMA_TPCC_OPT_n](#) register description in [Section 12.7.2.2.1, EDMA_TPCC Register Description](#).

12.4.3.2.2 Channel Source Address (SRC)

The 32-bit source address parameter specifies the starting byte address of the source. For SAM in increment mode, there are no alignment restrictions imposed by EDMA. For SAM in constant addressing mode, it must program the source address to be aligned to a 256-bit aligned address (5 LSBs of address must be 0). If this rule is not observed, the EDMA_TPTC returns an error. Refer to [Section 12.4.12.3 Error Generation](#) for additional details.

12.4.3.2.3 Channel Destination Address (DST)

The 32-bit destination address parameter specifies the starting byte address of the destination. For DAM in increment mode, there are no alignment restrictions imposed by EDMA. For DAM in constant addressing mode, it must program the destination address to be aligned to a 256-bit aligned address (5 LSBs of address must be 0). If this rule is not observed, the EDMA_TPTC returns an error. Refer to [Section 12.4.12.3 Error Generation](#) for additional details.

12.4.3.2.4 Count for 1st Dimension (ACNT)

[EDMA_TPCC_ABCNT_n\[15:0\]](#) ACNT represents the number of bytes within the 1st dimension of a transfer. ACNT is a 16-bit unsigned value with valid values between 0 and 65 535. Therefore, the maximum number of bytes in an array is 65 535 bytes (64K – 1 bytes). ACNT must be greater than or equal to 1 for a TR to be submitted to EDMA_TPTC. A transfer with ACNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in [EDMA_TPCC_OPT_n](#).

Refer to [Section 12.4.3.5 Dummy Versus Null Transfer Comparison](#) and [Section 12.4.5.3 Dummy or Null Completion](#) for details on dummy/null completion conditions.

12.4.3.2.5 Count for 2nd Dimension (BCNT)

[EDMA_TPCC_ABCNT_n\[15:0\]](#) BCNT is a 16-bit unsigned value that specifies the number of arrays of length ACNT. For normal operation, valid values for BCNT are between 1 and 65 535. Therefore, the maximum number of arrays in a frame is 65 535 (64K – 1 arrays). A transfer with BCNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in [EDMA_TPCC_OPT_n](#).

Refer to [Section 12.4.3.5 Dummy Versus Null Transfer Comparison](#) and [Section 12.4.5.3 Dummy or Null Completion](#) for details on dummy/null completion conditions.

12.4.3.2.6 Count for 3rd Dimension (CCNT)

[EDMA_TPCC_CCNT_n\[15:0\]](#) CCNT is a 16-bit unsigned value that specifies the number of frames in a block. Valid values for CCNT are between 1 and 65 535. Therefore, the maximum number of frames in a block is 65 535 (64K – 1 frames). A transfer with CCNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in [EDMA_TPCC_OPT_n](#).

A CCNT value of 0 is considered either a null or dummy transfer.

Refer to [Section 12.4.3.5 Dummy Versus Null Transfer Comparison](#) and [Section 12.4.5.3 Dummy or Null Completion](#) for details on dummy/null completion conditions.

12.4.3.2.7 BCNT Reload (BCNTRLD)

[EDMA_TPCC_LNK_n\[31:16\]](#) BCNTRLD is a 16-bit unsigned value used to reload the [EDMA_TPCC_ABCNT_n\[15:0\]](#) BCNT field once the last array in the 2nd dimension is transferred. This field is only used for A-synchronized transfers. In this case, the EDMA_TPCC decrements the BCNT value by 1 on each TR submission. When BCNT reaches 0, the EDMA_TPCC decrements CCNT and uses the BCNTRLD value to reinitialize the BCNT value.

For AB-synchronized transfers, the EDMA_TPCC submits the BCNT in the TR and the EDMA_TPTC decrements BCNT appropriately. For AB-synchronized transfers, BCNTRLD is not used.

12.4.3.2.8 Source B Index (SBIDX)

[EDMA_TPCC_BIDX_n\[15:0\]](#) SBIDX is a 16-bit signed value (2s complement) used for source address modification between each array in the 2nd dimension. Valid values for [EDMA_TPCC_BIDX_n\[15:0\]](#) SBIDX are between $-32\,768$ and $32\,767$. It provides a byte address offset from the beginning of the source array to the beginning of the next source array. It applies to both A-synchronized and AB-synchronized transfers. Some examples:

- [EDMA_TPCC_BIDX_n\[15:0\]](#) SBIDX = 0000h (0): no address offset from the beginning of an array to the beginning of the next array. All arrays are fixed to the same beginning address.
- [EDMA_TPCC_BIDX_n\[15:0\]](#) SBIDX = 0003h (+3): the address offset from the beginning of an array to the beginning of the next array in a frame is 3 bytes. For example, if the current array begins at address 1000h, the next array begins at 1003h.
- [EDMA_TPCC_BIDX_n\[15:0\]](#) SBIDX = FFFFh (−1): the address offset from the beginning of an array to the beginning of the next array in a frame is −1 byte. For example, if the current array begins at address 5054h, the next array begins at 5053h.

12.4.3.2.9 Destination B Index (DBIDX)

[EDMA_TPCC_BIDX_n\[31:16\]](#) DBIDX is a 16-bit signed value (2s complement) used for destination address modification between each array in the 2nd dimension. Valid values for [EDMA_TPCC_BIDX_n\[31:16\]](#) DBIDX are between $-32\,768$ and $32\,767$. It provides a byte address offset from the beginning of the destination array to the beginning of the next destination array within the current frame. It applies to both A-synchronized and AB-synchronized transfers. Refer to [Section 12.4.3.2.8 Source B Index \(SBIDX\)](#) for examples.

12.4.3.2.10 Source C Index (SCIDX)

[EDMA_TPCC_CIDX_n\[15:0\]](#) SCIDX is a 16-bit signed value (2s complement) used for source address modification in the 3rd dimension. Valid values for [EDMA_TPCC_CIDX_n\[15:0\]](#) SCIDX are between $-32\,768$ and $32\,767$. It provides a byte address offset from the beginning of the current array (pointed to by SRC address) to the beginning of the first source array in the next frame. It applies to both A-synchronized and AB-synchronized transfers.

NOTE: When SCIDX is applied, the current array in an A-synchronized transfer is the last array in the frame ([Figure 12-8](#)), while the current array in an AB-synchronized transfer is the first array in the frame ([Figure 12-9](#)).

12.4.3.2.11 Destination C Index (DCIDX)

[EDMA_TPCC_CIDX_n\[31:16\]](#) DCIDX is a 16-bit signed value (2s complement) used for destination address modification in the 3rd dimension. Valid values are between $-32\,768$ and $32\,767$. It provides a byte address offset from the beginning of the current array (pointed to by DST address) to the beginning of the first destination array TR in the next frame. It applies to both A-synchronized and AB-synchronized transfers.

NOTE: When DCIDX is applied, the current array in an A-synchronized transfer is the last array in the frame (Figure 12-8), while the current array in an AB-synchronized transfer is the first array in the frame (Figure 12-9).

12.4.3.2.12 Link Address (LINK)

The EDMA_TPCC provides a mechanism, called linking, to reload the current PaRAM set upon its natural termination (that is, after the count fields are decremented to 0) with a new PaRAM set. The 16-bit parameter `EDMA_TPCC_LNK_n[15:0]` LINK specifies the byte address offset in the PaRAM from which the EDMA_TPCC loads/reloads the next PaRAM set during linking.

It must program the link address to point to a valid aligned 32-byte PaRAM set. The 5 LSBs of the LINK field should be cleared to 0.

The EDMA_TPCC ignores the upper 2 bits of the LINK entry, allowing the flexibility of programming the link address as either an absolute/literal byte address or use the PaRAM-base-relative offset address. Therefore, if it use the literal address with a range from 4000h to 7FFFh, it will be treated as a PaRAM-base-relative value of 0000h to 3FFFh.

It should check that the programmed value in the `EDMA_TPCC_LNK_n[15:0]` LINK field is correctly, so that link update is requested from a PaRAM address that falls in the range of the available PaRAM addresses on the device.

Value of FFFFh in `EDMA_TPCC_LNK_n[15:0]` LINK bit-field is referred to as a NULL link that should cause the EDMA_TPCC to perform an internal write of 0 to all entries of the current PaRAM set, except for the `EDMA_TPCC_LNK_n[15:0]` LINK field is set to FFFFh. Also, see Section 12.4.5 *Completion of a DMA Transfer* for details on terminating a transfer.

12.4.3.3 Null PaRAM Set

A null PaRAM set is defined as a PaRAM set where all count fields (`EDMA_TPCC_ABCNT_n[15:0]` ACNT, `EDMA_TPCC_ABCNT_n[31:16]` BCNT, and `EDMA_TPCC_CCNT_n[15:0]` CCNT) are cleared to 0. If a PaRAM set associated with a channel is a NULL set, then when serviced by the EDMA_TPCC, the bit corresponding to the channel is set in the associated event missed register (`EDMA_TPCC_EMR`, `EDMA_TPCC_EMRH`, or `EDMA_TPCC_QEMR`). This bit remains set in the associated secondary event register (`EDMA_TPCC_SER`, `EDMA_TPCC_SERH`, or `EDMA_TPCC_QSER`).

This implies that any future events on the same channel are ignored by the EDMA_TPCC and it is required to clear the bit in `EDMA_TPCC_SER`, `EDMA_TPCC_SERH`, or `EDMA_TPCC_QSER` for the channel. This is considered an error condition, since events are not expected on a channel that is configured as a null transfer.

12.4.3.4 Dummy PaRAM Set

A dummy PaRAM set is defined as a PaRAM set where at least one of the count fields (`EDMA_TPCC_ABCNT_n[15:0]` ACNT, `EDMA_TPCC_ABCNT_n[31:16]` BCNT, or `EDMA_TPCC_CCNT_n[15:0]` CCNT) is cleared to 0 and at least one of the count fields is nonzero.

If a PaRAM set associated with a channel is a dummy set, then when serviced by the EDMA_TPCC, it will not set the bit corresponding to the channel (DMA/QDMA) in the event missed register (`EDMA_TPCC_EMR`, `EDMA_TPCC_EMRH`, or `EDMA_TPCC_QEMR`) and the secondary event register (`EDMA_TPCC_SER`, `EDMA_TPCC_SERH`, or `EDMA_TPCC_QSER`) bit gets cleared similar to a normal transfer. Future events on that channel are serviced. A dummy transfer is a legal transfer of 0 bytes.

12.4.3.5 Dummy Versus Null Transfer Comparison

There are some differences in the way the EDMA_TPCC logic treats a dummy versus a null transfer request. A null transfer request is an error condition, but a dummy transfer is a legal transfer of 0 bytes. A null transfer causes an error bit (E_n) in `EDMA_TPCC_EMR` to get set and the E_n bit in `EDMA_TPCC_SER` remains set, essentially preventing any further transfers on that channel without clearing the associated error registers.

Table 12-11 summarizes the conditions and effects of null and dummy transfer requests.

Table 12-11. Dummy and Null Transfer Request

Feature	Null TR	Dummy TR
EDMA_TPCC_EMR / EDMA_TPCC_EMRH / EDMA_TPCC_QEMR is set	Yes	No
EDMA_TPCC_SER / EDMA_TPCC_SERH / EDMA_TPCC_QSER remains set	Yes	No
Link update (STATIC = 0 in EDMA_TPCC_OPT_n)	Yes	Yes
EDMA_TPCC_QER is set	Yes	Yes
EDMA_TPCC_IPR / EDMA_TPCC_IPRH , EDMA_TPCC_CER / EDMA_TPCC_CERH is set using early completion	Yes	Yes

12.4.3.6 Parameter Set Updates

When a TR is submitted for a given DMA/QDMA channel and its corresponding PaRAM set, the EDMA_TPCC is responsible for updating the PaRAM set in anticipation of the next trigger event. For events that are not final, this includes address and count updates; for final events, this includes the link update.

The specific PaRAM set entries that are updated depend on the channel's synchronization type (A-synchronized or B-synchronized) and the current state of the PaRAM set. A B-update refers to the decrementing of [EDMA_TPCC_ABCNT_n\[31:16\]](#) BCNT in the case of A-synchronized transfers after the submission of successive TRs. A C-update refers to the decrementing of CCNT in the case of A-synchronized transfers after BCNT TRs for [EDMA_TPCC_ABCNT_n\[15:0\]](#) ACNT byte transfers have submitted. For AB-synchronized transfers, a C-update refers to the decrementing of [EDMA_TPCC_CCNT_n\[15:0\]](#) CCNT after submission of every transfer request.

Refer to [Table 12-12](#) for details and conditions on the parameter updates. A link update occurs when the PaRAM set is exhausted, as described in [Section 12.4.3.7 Linking Transfers](#).

After the TR is read from the PaRAM (and is in process of being submitted to EDMA_TPTC), the following fields are updated if needed:

- A-synchronized: BCNT, CCNT, SRC, DST.
- AB-synchronized: CCNT, SRC, DST.

The following fields are not updated (except for during linking, where all fields are overwritten by the link PaRAM set):

- A-synchronized: [EDMA_TPCC_ABCNT_n\[15:0\]](#) ACNT, [EDMA_TPCC_LNK_n\[31:16\]](#) BCNTRLD, [EDMA_TPCC_BIDX_n\[15:0\]](#) SBIDX, [EDMA_TPCC_BIDX_n\[31:16\]](#) DBIDX, [EDMA_TPCC_CIDX_n\[15:0\]](#) SCIDX, [EDMA_TPCC_CIDX_n\[31:16\]](#) DCIDX, [EDMA_TPCC_OPT_n](#), [EDMA_TPCC_LNK_n\[15:0\]](#)LINK.
- AB-synchronized: [EDMA_TPCC_ABCNT_n\[15:0\]](#) ACNT, [EDMA_TPCC_ABCNT_n\[31:16\]](#) BCNT, [EDMA_TPCC_LNK_n\[31:16\]](#) BCNTRLD, [EDMA_TPCC_BIDX_n\[15:0\]](#) SBIDX, [EDMA_TPCC_BIDX_n\[31:16\]](#) DBIDX, [EDMA_TPCC_CIDX_n\[15:0\]](#) SCIDX, [EDMA_TPCC_CIDX_n\[31:16\]](#) DCIDX, [EDMA_TPCC_OPT_n](#), [EDMA_TPCC_LNK_n\[15:0\]](#)LINK.

NOTE: PaRAM updates only pertain to the information that is needed to properly submit the next transfer request to the EDMA_TPTC. Updates that occur while data is moved within a transfer request are tracked within the transfer controller, and is detailed in [Section 12.4.12 EDMA Transfer Controller \(EDMA_TPTC\)](#). For A-synchronized transfers, the EDMA_TPCC always submits a TRP for [EDMA_TPCC_ABCNT_n\[15:0\]](#) ACNT bytes ([EDMA_TPCC_ABCNT_n\[31:16\]](#) BCNT = 1 and [EDMA_TPCC_CCNT_n\[15:0\]](#) CCNT = 1). For AB-synchronized transfers, the EDMA_TPCC always submits a TRP for [EDMA_TPCC_ABCNT_n\[15:0\]](#) ACNT bytes of BCNT arrays ([EDMA_TPCC_CCNT_n\[15:0\]](#) CCNT = 1). The EDMA_TPTC is responsible for updating source and destination addresses within the array based on [EDMA_TPCC_ABCNT_n\[15:0\]](#) ACNT and [EDMA_TPCC_OPT_n\[10:8\]](#) FWID. For AB-synchronized transfers, the EDMA_TPTC is also responsible to update source and destination addresses between arrays based on [EDMA_TPCC_BIDX_n\[15:0\]](#) SBIDX and [EDMA_TPCC_BIDX_n\[31:16\]](#) DBIDX.

Table 12-12 shows the details of parameter updates that occur within EDMA_TPCC for A-synchronized and AB-synchronized transfers.

Table 12-12. Parameter Updates in EDMA_TPCC (for Non-Null, Non-Dummy PaRAM Set)

	A-Synchronized Transfer			AB-Synchronized Transfer		
	B-Update	C-Update	Link Update	B-Update	C-Update	Link Update
Condition:	BCNT > 1	BCNT == 1 && CCNT > 1	BCNT == 1 && CCNT == 1	N/A	EDMA_TPCC_C CNT_n[15:0] CCNT > 1	EDMA_TPCC_CCNT_n[15:0] CCNT == 1
SRC	+= SBIDX	+= SCIDX	= Link.EDMA_TPCC_SRC_n	in EDMA_TP TC	+= SCIDX	= Link.EDMA_TPCC_SRC_n
DST	+= DBIDX	+= DCIDX	= Link.EDMA_TPCC_DST_n	in EDMA_TP TC	+= DCIDX	= Link.EDMA_TPCC_DST_n
ACNT	None	None	= Link.EDMA_TPCC_ABCNT_n[15:0] ACNT	None	None	= Link.EDMA_TPCC_ABCNT_n[15:0] ACNT
BCNT	-- 1	= BCNTRLD	= Link.EDMA_TPCC_ABCNT_n[31:16] BCNT	in EDMA_TP TC	N/A	= Link.EDMA_TPCC_ABCNT_n[31:16] BCNT
CCNT	None	-- 1	= Link.EDMA_TPCC_CCNT_n[15:0] CCNT	in EDMA_TP TC	--1	= Link.EDMA_TPCC_CCNT_n[15:0] CCNT
SBIDX	None	None	= Link.EDMA_TPCC_BIDX_n[15:0] SBIDX	in EDMA_TP TC	None	= Link.EDMA_TPCC_BIDX_n[15:0] SBIDX
DBIDX	None	None	= Link.EDMA_TPCC_BIDX_n[31:16] DBIDX	None	None	= Link.EDMA_TPCC_BIDX_n[31:16] DBIDX
SCIDX	None	None	= Link.EDMA_TPCC_BIDX_n[15:0] SBIDX	in EDMA_TP TC	None	= Link.EDMA_TPCC_BIDX_n[15:0] SBIDX
DCIDX	None	None	= Link.EDMA_TPCC_BIDX_n[31:16] DBIDX	None	None	= Link.EDMA_TPCC_BIDX_n[31:16] DBIDX
LINK	None	None	= Link.EDMA_TPCC_LNK_n[15:0] LINK	None	None	= Link.EDMA_TPCC_LNK_n[15:0] LINK
BCNTRLD	None	None	= Link.EDMA_TPCC_LNK_n[31:16] BCNTRLD	None	None	= Link.EDMA_TPCC_LNK_n[31:16] BCNTRLD
OPT ⁽¹⁾	None	None	= LINK.EDMA_TPCC_OPT_n	None	None	= LINK.EDMA_TPCC_OPT_n

⁽¹⁾ In all cases, no updates occur if EDMA_TPCC_OPT_n[3] STATIC == 1 for the current PaRAM set.

NOTE: The EDMA_TPCC includes no special hardware to detect when an indexed address update calculation overflows/underflows. The address update will wrap across boundaries as programmed by the user. It should ensure that no transfer is allowed to cross internal port boundaries between peripherals. A single TR must target a single source/destination slave endpoint.

12.4.3.7 Linking Transfers

The EDMA_TPCC provides a mechanism known as linking, which allows the entire PaRAM set to be reloaded from a location within the PaRAM memory map (for both DMA and QDMA channels). Linking is especially useful for maintaining ping-pong buffers, circular buffering, and repetitive/continuous transfers with no CPU intervention. Upon completion of a transfer, the current transfer parameters are reloaded with the parameter set pointed to by the 16-bit link address field of the current parameter set. Linking only occurs when the [EDMA_TPCC_OPT_n\[3\]](#) STATIC bit is cleared.

NOTE: It should always link a transfer (EDMA or QDMA) to another useful transfer. If it must terminate a transfer, then link the transfer to a NULL parameter set. Refer to [Section 12.4.3.3 Null PaRAM Set](#).

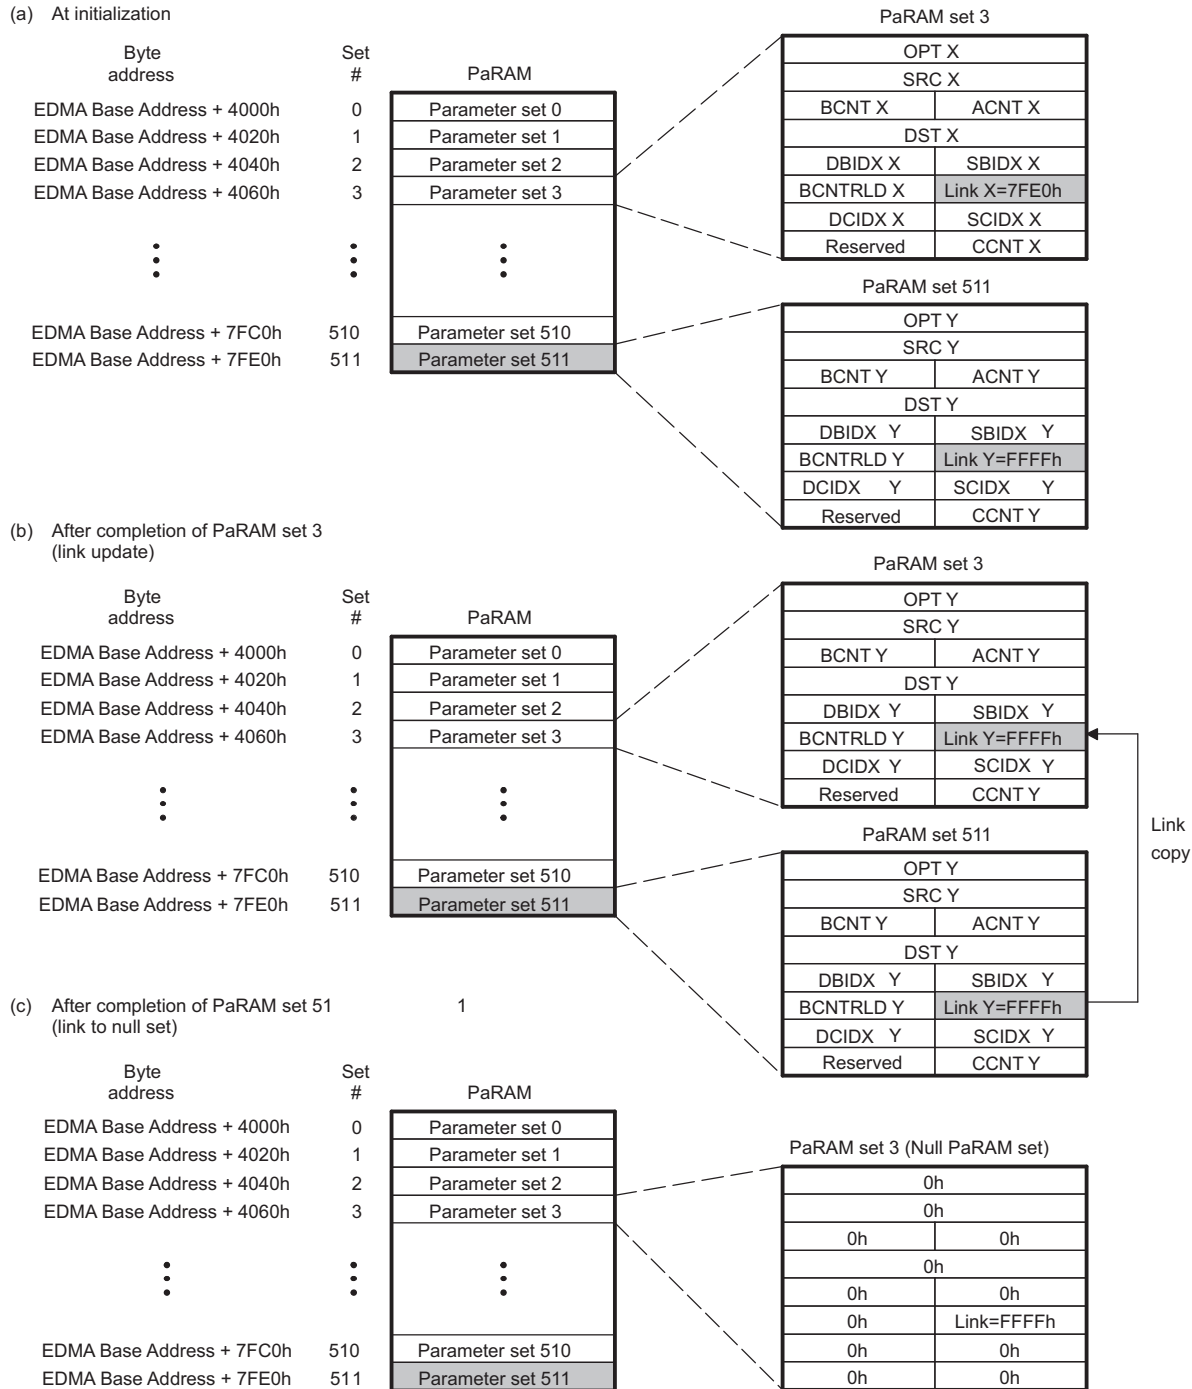

The link update occurs after the current PaRAM set event parameters have been exhausted. An event's parameters are exhausted when the EDMA channel controller has submitted all of the transfers that are associated with the PaRAM set.

A link update occurs for null and dummy transfers depending on the state of the [EDMA_TPCC_OPT_n\[3\]](#) STATIC bit and the [EDMA_TPCC_LNK_n\[15:0\]](#) LINK field. In both cases (null or dummy), if the value of [EDMA_TPCC_LNK_n\[15:0\]](#) LINK is FFFFh, then a null PaRAM set (with all 0s and [EDMA_TPCC_LNK_n\[15:0\]](#) LINK set to FFFFh) is written to the current PaRAM set.

Similarly, if [EDMA_TPCC_LNK_n\[15:0\]](#) LINK is set to a value other than FFFFh, then the appropriate PaRAM location that [EDMA_TPCC_LNK_n\[15:0\]](#) LINK points to is copied to the current PaRAM set.

Once the channel completion conditions are met for an event, the transfer parameters that are located at the link address are loaded into the current DMA or QDMA channel's associated parameter set. This indicates that the EDMA_TPCC reads the entire set (eight words) from the PaRAM set specified by [EDMA_TPCC_LNK_n\[15:0\]](#) LINK and writes all eight words to the PaRAM set that is associated with the current channel. [Figure 12-11](#) shows an example of a linked transfer.

Figure 12-11. Linked Transfer

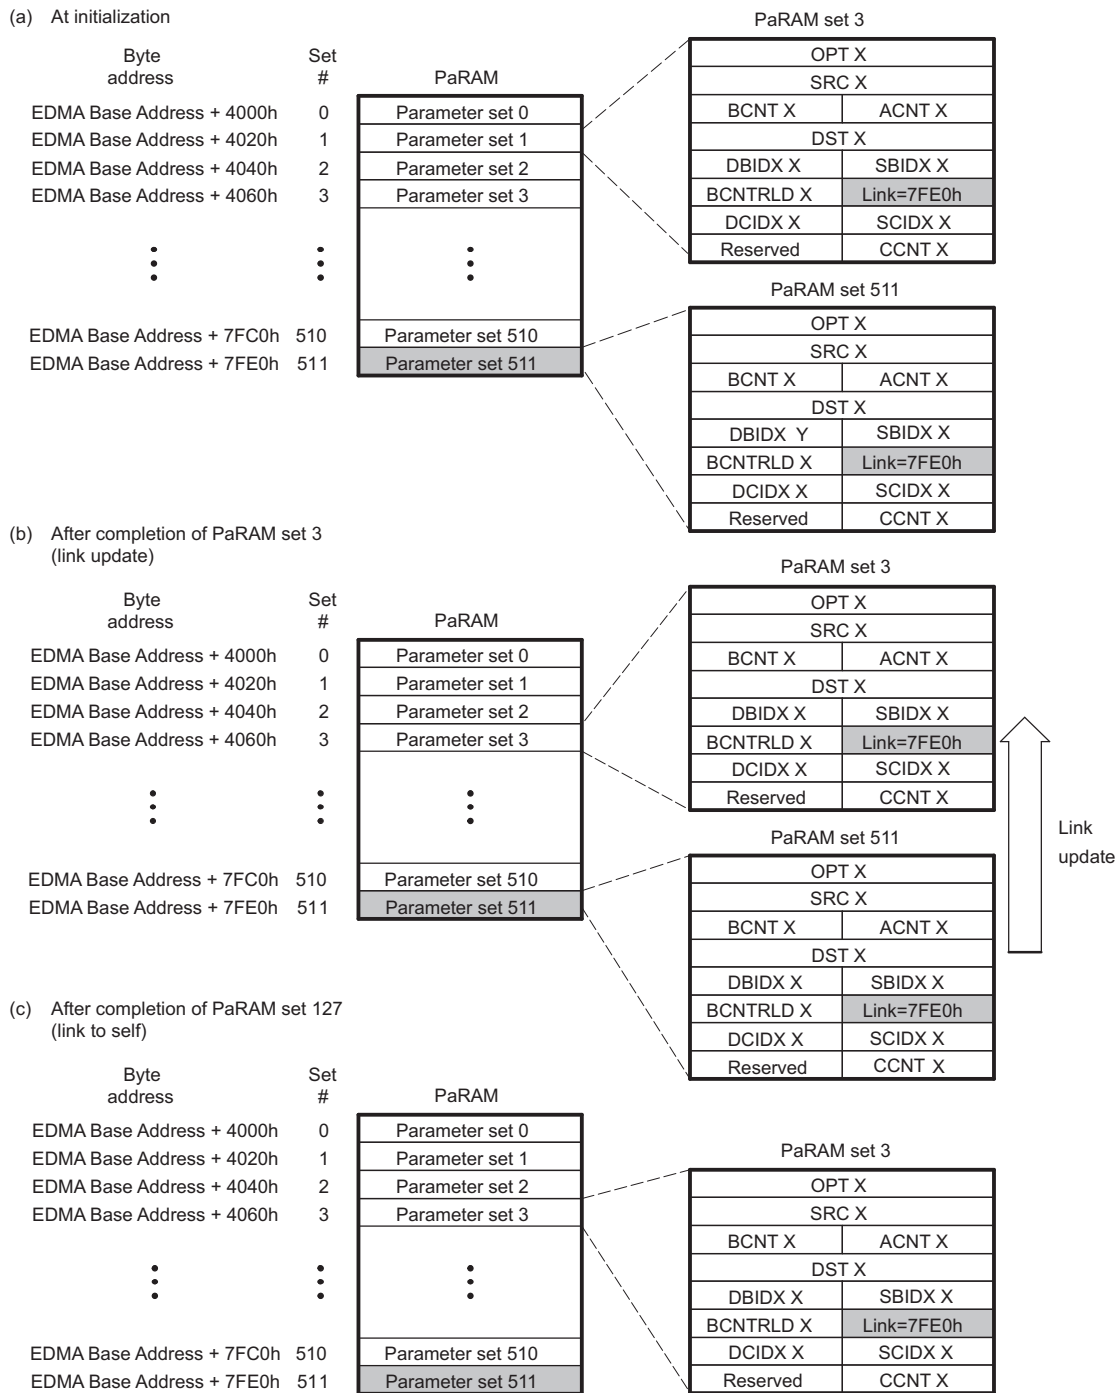

Any PaRAM set in the PaRAM can be used as a link/reload parameter set. The PaRAM sets associated with peripheral synchronization events (refer to [Section 12.4.6 Event, Channel, and PaRAM Mapping](#)) only use for linking if the corresponding events are disabled.

If a PaRAM set location is defined as a QDMA channel PaRAM set (by [EDMA_TPCC_QCHMAPN_j](#) register), then copying the link PaRAM set into the current QDMA channel PaRAM set is recognized as a trigger event. It is latched in [EDMA_TPCC_QER](#) because a write to the trigger word was performed. This feature is used to create a linked list of transfers using a single QDMA channel and multiple PaRAM sets. Refer to [Section 12.4.4.2 QDMA Channels](#).

Linking to itself replicates the behavior of auto-initialization, thus facilitating the use of circular buffering and repetitive transfers. After an EDMA channel exhausts its current PaRAM set, it reloads all of the parameter set entries from another PaRAM set, which is initialized with values that are identical to the original PaRAM set. Figure 12-12 shows an example of a linked to self transfer. Here, the PaRAM set 511 has the link field pointing to the address of parameter set 511 (linked to self).

Figure 12-12. Link-to-Self Transfer

NOTE: If the in `EDMA_TPCC_OPT_n[3]` STATIC bit is set for a PaRAM set, then link updates are not performed.

12.4.3.8 Constant Addressing Mode Transfers/Alignment Issues

If either `EDMA_TPCC_OPT_n[0]` SAM or `EDMA_TPCC_OPT_n[1]` DAM is set (constant addressing mode), then the source or destination address must be aligned to a 256-bit aligned address, respectively, and the corresponding `EDMA_TPCC_BIDX_n` is an even multiple of 32 bytes (256 bits). The EDMA_TPCC does not recognize errors here, but the EDMA_TPTC asserts an error if this is not true. Refer to [Section 12.4.12.3 Error Generation](#).

NOTE: The constant addressing (CONST) mode has limited applicability. The EDMA is configured for the constant addressing mode (`EDMA_TPCC_OPT_n[0]` SAM / `EDMA_TPCC_OPT_n[1]` DAM = 1) only if the transfer source or destination (on-chip memory, off-chip memory controllers, slave peripherals) support the constant addressing mode. If the constant addressing mode is not supported, the similar logical transfer can be achieved using the increment (INCR) mode (`EDMA_TPCC_OPT_n[0]` SAM / `EDMA_TPCC_OPT_n[1]` DAM = 0) by appropriately programming the count and indices values.

12.4.3.9 Element Size

The EDMA controller does not use element-size and element-indexing. Instead, all transfers are defined in terms of all three dimensions: `EDMA_TPCC_ABCNT_n[15:0]` ACNT, `EDMA_TPCC_ABCNT_n[31:16]` BCNT, and `EDMA_TPCC_CCNT_n[15:0]` CCNT. An element-indexed transfer is logically achieved by programming `EDMA_TPCC_ABCNT_n[15:0]` ACNT to the size of the element and `EDMA_TPCC_ABCNT_n[31:16]` BCNT to the number of elements that need to be transferred. For example: If there are 16-bit audio data and 256 audio samples that must be transferred to a serial port, therefore the `EDMA_TPCC_ABCNT_n[15:0]` ACNT = 2 (2 bytes) and `EDMA_TPCC_ABCNT_n[31:16]` BCNT = 256.

12.4.4 Initiating a DMA Transfer

There are multiple ways to initiate a programmed data transfer using the EDMA_TPCC channel controller. Transfers on DMA channels are initiated by three sources.

They are listed as follows:

- **Event-triggered transfer request** (this is the typical usage of EDMA controller): A peripheral, system, or externally-generated event triggers a transfer request.
- **Manually-triggered transfer request:** The CPU manually triggers a transfer by writing a 1 to the corresponding bit in the event set registers (`EDMA_TPCC_ESR` / `EDMA_TPCC_ESRH`).
- **Chain-triggered transfer request:** A transfer is triggered on the completion of another transfer or sub-transfer.

Transfers on QDMA channels are initiated by two sources. They are as follows:

- **Auto-triggered transfer request:** Writing to the programmed trigger word triggers a transfer.
- **Link-triggered transfer requests:** Writing to the trigger word triggers the transfer when linking occurs.

12.4.4.1 DMA Channels

12.4.4.1.1 Event-Triggered Transfer Request

When an event is asserted from a peripheral or device pins, it gets latched in the corresponding bit of the event register (`EDMA_TPCC_ER[31:0]` $E_n = 1$). For more information about peripheral events to EDMA events mapping, refer to *the device data manual*.

If the corresponding event in the event enable register (`EDMA_TPCC_EER`) is enabled (`EDMA_TPCC_EER[31:0]` $E_n = 1$), then the EDMA_TPCC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

If the PaRAM set is valid (not a NULL set), then a transfer request packet (TRP) is submitted to the EDMA_TPTC and the `EDMA_TPCC_ER[31:0]` E_n bit is cleared. At this point, a new event can be safely received by the EDMA_TPCC.

If the PaRAM set associated with the channel is a NULL set (see [Section 12.4.3.3 Null PaRAM Set](#)), then no transfer request (TR) is submitted and the corresponding `EDMA_TPCC_ER[31:0] En` bit is cleared and simultaneously the corresponding channel bit is set in the event miss register (`EDMA_TPCC_EMR[31:0] En = 1`) to indicate that the event was discarded due to a null TR being serviced. Good programming practices should include cleaning the event missed error before re-triggering the DMA channel.

When an event is received, the corresponding event bit in the event register is set (`EDMA_TPCC_ER[31:0] En = 1`), regardless of the state of `EDMA_TPCC_EER[31:0] En`. If the event is disabled when an external event is received (`EDMA_TPCC_ER[31:0] En = 1` and `EDMA_TPCC_EER[31:0] En = 0`), the `EDMA_TPCC_ER[31:0] En` bit remains set. If the event is subsequently enabled (`EDMA_TPCC_EER[31:0] En = 1`), then the pending event is processed by the EDMA_TPCC and the TR is processed/submitted, after which the `EDMA_TPCC_ER[31:0] En` bit is cleared.

If an event is being processed (prioritized or is in the event queue) and another sync event is received for the same channel prior to the original being cleared (`EDMA_TPCC_ER[31:0] En != 0`), then the second event is registered as a missed event in the corresponding bit of the event missed register (`EDMA_TPCC_EMR[31:0] En = 1`).

12.4.4.1.2 Manually-Triggered Transfer Request

The CPU or any peripheral device module initiates a DMA transfer by writing to the event set register `EDMA_TPCC_ESR`. Writing a 1 to an event bit in the `EDMA_TPCC_ESR` results in the event being prioritized/queued in the appropriate event queue, regardless of the state of the `EDMA_TPCC_EER[31:0] En` bit. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA_TPTC and the channel can be triggered again.

If the PaRAM set associated with the channel is a NULL set (see [Section 12.4.3.3 Null PaRAM Set](#)), then no transfer request (TR) is submitted and the corresponding `EDMA_TPCC_ER[31:0] En` bit is cleared and simultaneously the corresponding channel bit is set in the event miss register `EDMA_TPCC_EMR[31:0] En = 1` to indicate that the event was discarded due to a null TR being serviced. Good programming practices should include clearing the event missed error before re-triggering the DMA channel.

If an event is being processed (prioritized or is in the event queue) and the same channel is manually set by a write to the corresponding channel bit of the event set register `EDMA_TPCC_ESR[31:0] En = 1` prior to the original being cleared `EDMA_TPCC_ESR[31:0] En = 0`, then the second event is registered as a missed event in the corresponding bit of the event missed register `EDMA_TPCC_EMR[31:0] En = 1`.

12.4.4.1.3 Chain-Triggered Transfer Request

Chaining is a mechanism by which the completion of one transfer automatically sets the event for another channel. When a chained completion code is detected, the value of which is dictated by the transfer completion code `EDMA_TPCC_OPT_n[17:12] TCC` of the PaRAM set associated with the channel, it results in the corresponding bit in the chained event register `EDMA_TPCC_CER` to be set (`EDMA_TPCC_CER[31:0] E[TCC] = 1`).

Once a bit is set in `EDMA_TPCC_CER`, the EDMA_TPCC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA_TPTC and the channel can be triggered again.

If the PaRAM set associated with the channel is a NULL set (see [Section 12.4.3.3 Null PaRAM Set](#)), then no transfer request (TR) is submitted and the corresponding `EDMA_TPCC_CER[31:0] En` bit is cleared and simultaneously the corresponding channel bit is set in the event miss register `EDMA_TPCC_EMR[31:0] En = 1` to indicate that the event was discarded due to a null TR being serviced. In this case, the error condition must be cleared before the DMA channel can be re-triggered. Good programming practices might include clearing the event missed error before re-triggering the DMA channel.

If a chaining event is being processed (prioritized or queued) and another chained event is received for the same channel prior to the original being cleared (`EDMA_TPCC_CER[31:0] En != 0`), then the second chained event is registered as a missed event in the corresponding channel bit of the event missed register `EDMA_TPCC_EMR[31:0] En = 1`.

NOTE: Chained event registers `EDMA_TPCC_CER`, event registers `EDMA_TPCC_ER`, and event set registers `EDMA_TPCC_ESR` operate independently. An event E_n can be triggered by any of the trigger sources (event-triggered, manually-triggered, or chain-triggered).

12.4.4.2 QDMA Channels

12.4.4.2.1 Auto-triggered and Link-Triggered Transfer Request

QDMA-based transfer requests are issued when a QDMA event gets latched in the QDMA event register `EDMA_TPCC_QER[31:0] En = 1`. A bit corresponding to a QDMA channel is set in the QDMA event register `EDMA_TPCC_QER` when the following occurs:

- A CPU (or any device module) write occurs to a PaRAM address that is defined as a QDMA channel trigger word (programmed in the QDMA channel mapping register `EDMA_TPCC_QCHMAPN_j` for the particular QDMA channel and the QDMA channel is enabled via the QDMA event enable register `EDMA_TPCC_QEER[31:0] En = 1`.
- EDMA_TPCC performs a link update on a PaRAM set address that is configured as a QDMA channel matches `EDMA_TPCC_QCHMAPN_j` settings and the corresponding channel is enabled via the QDMA event enable register `EDMA_TPCC_QEER[31:0] En = 1`.

Once a bit is set in `EDMA_TPCC_QER`, the EDMA_TPCC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA_TPTC and the channel can be triggered again.

If a bit is already set in `EDMA_TPCC_QER[31:0] En = 1` and a second QDMA event for the same QDMA channel occurs prior to the original being cleared, the second QDMA event gets captured in the QDMA event miss register `EDMA_TPCC_QEMR[7:0] En = 1`.

12.4.4.3 Comparison Between DMA and QDMA Channels

The primary difference between DMA and QDMA channels is the event/channel synchronization.

QDMA events are either auto-triggered or link triggered. Auto-triggering allows QDMA channels to be triggered by CPU(s) with a minimum number of linear writes to PaRAM. Link triggering allows a linked list of transfers to be executed, using a single QDMA PaRAM set and multiple link PaRAM sets.

A QDMA transfer is triggered when a CPU (or other device modules) writes to the trigger word of the QDMA channel parameter set (auto-triggered) or when the EDMA_TPCC performs a link update on a PaRAM set that has been mapped to a QDMA channel (link triggered).

NOTE: The CPUs triggered (manually triggered) DMA channels, in addition to writing to the PaRAM set, it is required to write to the event set register `EDMA_TPCC_ESR` to kick-off the transfer.

QDMA channels are typically for cases where a single event accomplishes a complete transfer since the CPU (or other device modules) must reprogram some portion of the QDMA PaRAM set in order to re-trigger the channel. QDMA transfers are programmed with `EDMA_TPCC_ABCNT_n[31:0] BCNT = 1` and `EDMA_TPCC_CCNT_n[15:0] CCNT = 1` for A-synchronized transfers, and `EDMA_TPCC_CCNT_n[15:0] CCNT = 1` for AB-synchronized transfers.

Additionally, since linking is also supported (if `EDMA_TPCC_OPT_n[3] STATIC = 0`) for QDMA transfers, it allows to initiate a linked list of QDMAs, so when EDMA_TPCC copies over a link PaRAM set (including the write to the trigger word), the current PaRAM set mapped to the QDMA channel automatically recognizes as a valid QDMA event and initiate another set of transfers as specified by the linked set.

12.4.5 Completion of a DMA Transfer

A parameter set for a given channel is complete when the required number of transfer requests is submitted (based on receiving the number of synchronization events). The expected number of TRs for a non-null/non-dummy transfer is shown in [Table 12-13](#) for both synchronization types along with state of the PaRAM set prior to the final TR being submitted. When the counts ([EDMA_TPCC_ABCNT_n\[31:0\]](#) BCNT and/or [EDMA_TPCC_CCNT_n\[15:0\]](#) CCNT) are this value, the next TR results in:

- Final chaining or interrupt codes sent by the transfer controllers (instead of intermediate).
- Link updates (linking to either null or another valid link set).

Table 12-13. Expected Number of Transfers for Non-Null Transfer

Sync Mode	Counts at time 0	Total # Transfers	Counts prior to final TR
A-synchronized	ACNT BCNT CCNT	(BCNT × CCNT) TRs of ACNT bytes each	EDMA_TPCC_ABCNT_n[31:0] BCNT == 1 && EDMA_TPCC_CCNT_n[15:0] CCNT == 1
AB-synchronized	ACNT BCNT CCNT	CCNT TRs for ACNT × BCNT bytes each	EDMA_TPCC_CCNT_n[15:0] CCNT == 1

The PaRAM OPT field must program with a specific transfer completion code TCC or [EDMA_TPCC_OPT_n\[17:12\]](#) TCC along with the other [EDMA_TPCC_OPT_n](#) fields ([22] TCCHEN, [20] TCINTEN, [23] ITCCHEN, and [21] ITCINTEN bits) to indicate whether the completion code is to be used for generating a chained event or/and for generating an interrupt upon completion of a transfer.

The specific [EDMA_TPCC_OPT_n\[17:12\]](#) TCC value (6-bit binary value) programmed dictates which of the 64-bits in the chain event register [EDMA_TPCC_CER](#) [TCC] and/or interrupt pending register [EDMA_TPCC_IPR](#) [TCC] is set.

It can selectively program whether the transfer controller sends back completion codes on completion of the final transfer request (TR) of a parameter set [EDMA_TPCC_OPT_n\[22\]](#) TCCHEN or [EDMA_TPCC_OPT_n\[20\]](#) TCINTEN, for all but the final transfer request (TR) of a parameter set [EDMA_TPCC_OPT_n\[23\]](#) ITCCHEN or [EDMA_TPCC_OPT_n\[21\]](#) ITCINTEN), or for all TRs of a parameter set (both). Refer to [Section 12.4.8 Chaining EDMA Channels](#) for details on chaining (intermediate/final chaining) and [Section 12.4.9 EDMA Interrupts](#) for details on intermediate/final interrupt completion.

A completion detection interface exists between the EDMA channel controller and transfer controller(s). This interface sends back information from the transfer controller to the channel controller to indicate that a specific transfer is completed. Completion of a transfer is used for generating chained events and/or generating interrupts to the CPU(s).

All DMA/QDMA PaRAM sets must also specify a link address value. For repetitive transfers such as ping-pong buffers, the link address value must point to another predefined PaRAM set. Alternatively, a non-repetitive transfer must set the link address value to the null link value. The null link value is defined as FFFFh. Refer to [Section 12.4.3.7 Linking Transfers](#) for more details.

NOTE: Any incoming events that are mapped to a null PaRAM set results in an error condition. The error condition must clear before the corresponding channel is used again. Refer to [Section 12.4.3.5 Dummy Versus Null Transfer Comparison](#).

There are three ways the EDMA_TPCC gets updated/informed about a transfer completion: normal completion, early completion, and dummy/null completion. This applies to both chained events and completion interrupt generation.

12.4.5.1 Normal Completion

In normal completion mode [EDMA_TPCC_OPT_n\[11\]](#) TCCMODE = 0, the transfer or sub-transfer is considered to be complete when the EDMA channel controller receives the completion codes from the EDMA transfer controller. In this mode, the completion code to the channel controller is posted by the transfer controller after it receives a signal from the destination peripheral. Normal completion is typically used to generate an interrupt to inform the CPU that a set of data is ready for processing.

12.4.5.2 Early Completion

In early completion mode [EDMA_TPCC_OPT_n\[11\]](#) TCCMODE = 1, the transfer is considered to be complete when the EDMA channel controller submits the transfer request (TR) to the EDMA transfer controller. In this mode, the channel controller generates the completion code internally. Early completion is typically useful for chaining, as it allows subsequent transfers to be chained-triggered while the previous transfer is still in progress within the transfer controller, maximizing the overall throughput of the set of the transfers.

12.4.5.3 Dummy or Null Completion

This is a variation of early completion. Dummy or null completion is associated with a dummy set [Section 12.4.3.4](#) or null set [Section 12.4.3.3](#). In both cases, the EDMA channel controller does not submit the associated transfer request to the EDMA transfer controller(s). However, if the set (dummy/null) has the OPT field programmed to return completion code (intermediate/final interrupt/chaining completion), then it sets the appropriate bits in the interrupt pending registers [EDMA_TPCC_IPR](#) and [EDMA_TPCC_IPRH](#) or chained event register [EDMA_TPCC_CER](#) and [EDMA_TPCC_CERH](#). The internal early completion path is used by the channel controller to return the completion codes internally (that is, EDMA_TPCC generates the completion code).

12.4.6 Event, Channel, and PaRAM Mapping

Several of the 64 DMA channels are tied to a specific hardware event, thus allowing events from device peripherals or external hardware (via the `dma_evt[4:1]` pins) to trigger transfers. A DMA channel typically requests a data transfer when it receives its event (apart from manually-triggered, chain-triggered, and other transfers). The amount of data transferred per synchronization event depends on the channel's configuration ([EDMA_TPCC_ABCNT_n\[15:0\]](#) ACNT, [EDMA_TPCC_ABCNT_n\[31:16\]](#) BCNT, [EDMA_TPCC_CCNT_n\[15:0\]](#) CCNT, etc.) and the synchronization type (A-synchronized or AB-synchronized).

The association of an event to a channel is fixed within the EDMA Channel Controller, that is, each DMA channel has one specific event associated with it. The EDMA event crossbar can be used to select which level events (of which there are more than 64) are mapped to the 64 input events to the EDMA Channel Controller. The default mapping and event crossbar mapping are defined in [Section 12.3.1, EDMA Requests to the EDMA Controller](#). The event crossbar mapping is controlled by the device Control Modules registers refer to [Section 14.4.6.4 IRQ_CROSSBAR Module Functional Description](#), in [Chapter 14 Control Module](#).

In an application, if a channel does not use the associated synchronization event or if it does not have an associated synchronization event (unused), that channel can be used for manually-triggered or chained-triggered transfers, for linking/reloading, or as a QDMA channel.

12.4.6.1 DMA Channel to PaRAM Mapping

The mapping between the DMA channel numbers and the PaRAM sets is programmable (see [Table 12-9](#)). The DMA channel mapping registers [EDMA_TPCC_DCHMAPN_m](#) in the EDMA_TPCC provide programmability that allows the DMA channels to be mapped to any of the PaRAM sets in the PaRAM memory map. [Figure 12-13](#) illustrates the use of [EDMA_TPCC_DCHMAPN_m](#). There is one [EDMA_TPCC_DCHMAPN_m](#) register per channel.

Figure 12-13. DMA Channel and QDMA Channel to PaRAM Mapping

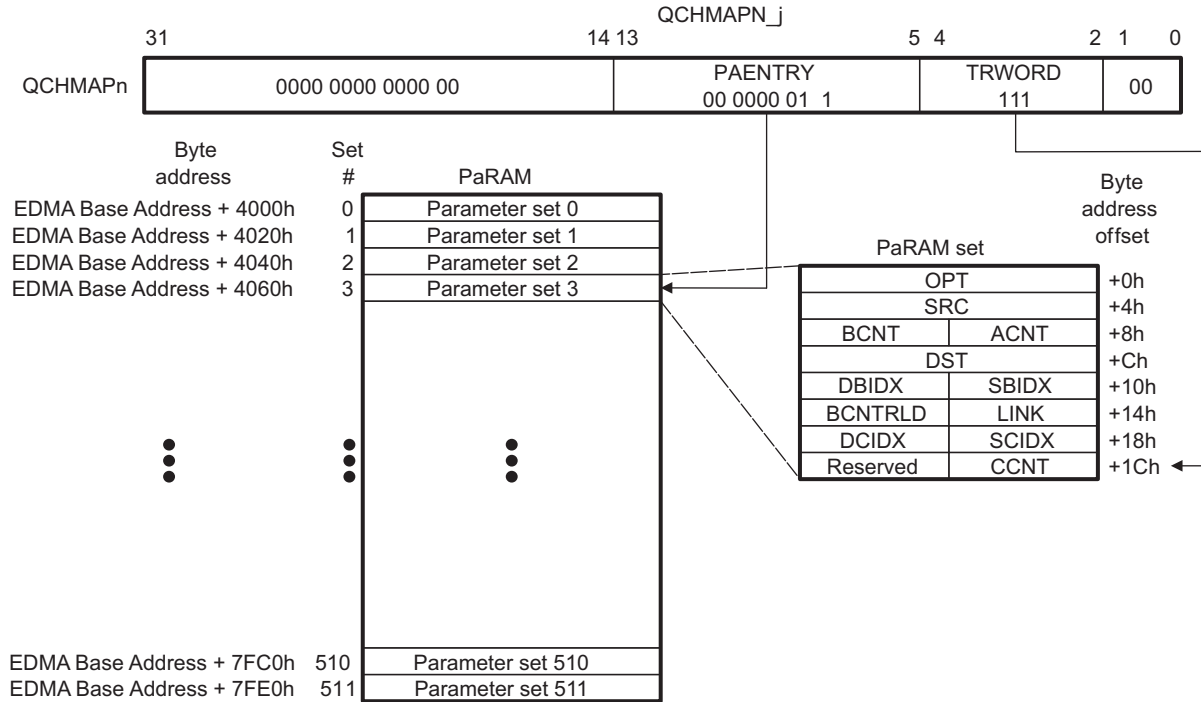

edma-013

12.4.6.2 QDMA Channel to PaRAM Mapping

The mapping between the QDMA channels and the PaRAM sets is programmable. The QDMA channel mapping register [EDMA_TPCC_QCHMAPN_j](#) in the EDMA_TPCC allows to map the QDMA channels to any of the PaRAM sets in the PaRAM memory map. [Figure 12-14](#) illustrates the use of [EDMA_TPCC_QCHMAPN_j](#).

[EDMA_TPCC_QCHMAPN_j\[4:2\]](#) TRWORD bit-field allows to program the trigger word in the PaRAM set for the QDMA channel. A trigger word is one of the eight words in the PaRAM set. For a QDMA transfer to occur, a valid TR synchronization event for EDMA_TPCC is a write to the trigger word in the PaRAM set pointed to by [EDMA_TPCC_QCHMAPN_j](#) for a particular QDMA channel. By default, QDMA channels are mapped to PaRAM set 0.

It must appropriately re-map PaRAM set 0 before use.

Figure 12-14. QDMA Channel to PaRAM Mapping

edma-014

12.4.7 EDMA Channel Controller Regions

The EDMA channel controller divides its address space into eight regions. Individual channel resources are assigned to a specific region, where each region is typically assigned to a specific device module uses the EDMA controller.

Application software can use regions or to ignore them altogether. It can be used active memory protection in conjunction with regions so that only a specific device module which uses the EDMA (for example, privilege identification) or privilege level (for example, user vs. supervisor) is allowed access to a given region, and thus to a given DMA or QDMA channel. This allows robust system-level DMA code where each EDMA initiator only modifies the state of the assigned resources. Memory protection is described in [Section 12.4.10 Memory Protection](#).

12.4.7.1 Region Overview

The EDMA channel controller memory-mapped registers are divided in three main categories:

1. Global registers
2. Global region channel registers
3. Shadow region channel registers

The global registers are located at a single/fixed location in the EDMA_TPCC memory map. These registers control EDMA resource mapping and provide debug visibility and error tracking information.

The channel registers (including DMA, QDMA, and interrupt registers) are accessible via the global channel region address range, or in the shadow n channel region address range(s). For example, the event enable register [EDMA_TPCC_EER](#) is visible at the global address of EDMA Base Address + 1020h or region addresses of EDMA Base Address + 2020h for region 0, EDMA Base Address + 2220h for region 1, ... EDMA Base Address + 2E20h for region 7.

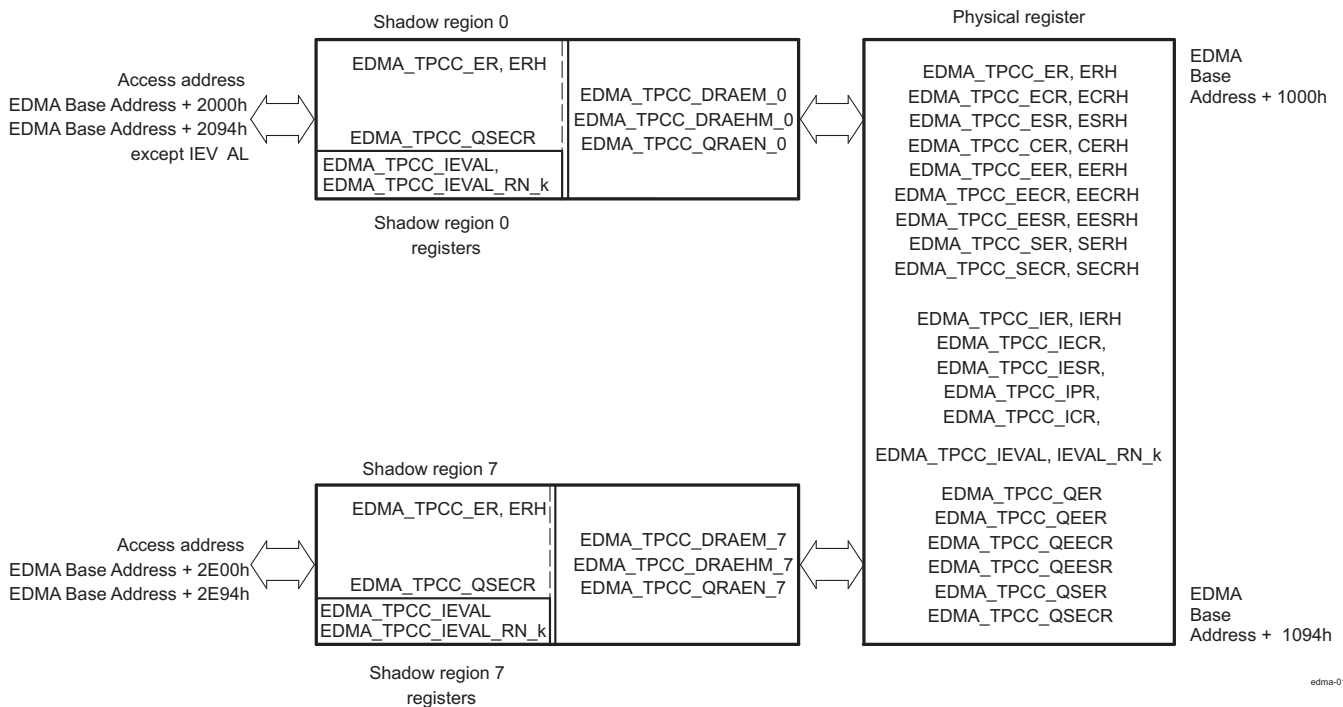

The DMA region access enable registers [EDMA_TPCC_DRAEM_k](#) and the QDMA region access enable registers [EDMA_TPCC_QRAEN_k](#) control the underlying control register bits that are accessible via the shadow region address space (except for [EDMA_TPCC_IEVAL](#) and [EDMA_TPCC_IEVAL_RN_k](#) registers). [Table 12-14](#) lists the registers in the shadow region memory map. Refer to [Table 12-30](#) *EDMA_TPCC register mapping summary* for the complete global and shadow region memory maps.

Table 12-14. Shadow Region Registers

Figure 12-15. Shadow Region Registers

edma-015

12.4.7.2 Channel Controller Regions

There are eight EDMA shadow regions (and associated memory maps). Associated with each shadow region are a set of registers defining which channels and interrupt completion codes belong to that region. These registers are user-programmed per region to assign ownership of the DMA/QDMA channels to a region.

- [EDMA_TPCC_DRAEM_k](#) and [EDMA_TPCC_DRAEHM_k](#): One register pair exists for each of the shadow regions. The number of bits in each register pair matches the number of DMA channels (64 DMA channels). These registers need to be programmed to assign ownership of DMA channels and interrupt (or [EDMA_TPCC_OPT_n\[17:12\]](#) TCC codes) to the respective region. Accesses to DMA and interrupt registers via the shadow region address view are filtered through the DRAEM/DRAEHM pair. A value of 1 in the corresponding [EDMA_TPCC_DRAEM_k\[31:0\]](#) / [EDMA_TPCC_DRAEHM_k\[31:0\]](#) bit implies that the corresponding DMA interrupt channel is accessible; a value of 0 in the corresponding [EDMA_TPCC_DRAEM_k\[31:0\]](#) / [EDMA_TPCC_DRAEHM_k\[31:0\]](#) bit forces writes to be discarded and returns a value of 0 for reads.
- [EDMA_TPCC_QRAEN_k](#): One register exists for every region. The number of bits in each register matches the number of QDMA channels (4 QDMA channels). These registers must be programmed to assign ownership of QDMA channels to the respective region. To enable a channel in a shadow region using shadow region 0 [EDMA_TPCC_QEER](#), the corresponding bits in QRAE must be set or writing into [EDMA_TPCC_QEESR](#) there will be no the desired effect.
- [EDMA_TPCC_MPPAN_k](#) and [EDMA_TPCC_MPPAG](#): One register exists for every region. This register defines the privilege level, requestor, and types of accesses allowed to a region's memory-mapped registers.

It is typical for an application to have a unique assignment of QDMA/DMA channels (and, therefore, a given bit position) to a given region.

The use of shadow regions allows restricted access to EDMA resources (DMA channels, QDMA channels, TCC, interrupts) by tasks in a system by setting or clearing bits in the [EDMA_TPCC_DRAEM_k](#) / [EDMA_TPCC_QRAEN_k](#) registers.

If exclusive access to any given channel / TCC code is required for a region, then only that region's [EDMA_TPCC_DRAEM_k](#) / [EDMA_TPCC_QRAEN_k](#) have the associated bit set.

Example 12-1. Resource Pool Division Across Two Regions

This example illustrates a resource pool division across two regions, assuming region 0 must be allocated 16 DMA channels (0-15) and 1 QDMA channel (0) and 32 TCC codes (0-15 and 48-63).

Region 1 needs to be allocated 16 DMA channels (16-32) and the remaining 7 QDMA channels (1-7) and TCC codes (16-47).

[EDMA_TPCC_DRAEM_k](#) should be equal to the OR of the bits that are required for the DMA channels and the TCC codes:

```
Region 0: DRAEHM, DRAEM = 0xFFFF0000, 0x0000FFFF QRAEN = 0x0000001
Region 1: DRAEHM, DRAEM = 0x0000FFFF, 0xFFFF0000 QRAEN = 0x00000FE
```

12.4.7.3 Region Interrupts

In addition to the EDMA_TPCC global completion interrupt, there is an additional completion interrupt line that is associated with every shadow region. Along with the interrupt enable register [EDMA_TPCC_IER](#), DRAEM acts as a secondary interrupt enable for the respective shadow region interrupts. Refer to [Table 12-6 Hardware Request](#) for more information about EDMA Interrupts.

12.4.8 Chaining EDMA Channels

The channel chaining capability for the EDMA allows the completion of an EDMA channel transfer to trigger another EDMA channel transfer. The purpose is to allow the ability to chain several events through one event occurrence.

Chaining is different from linking ([Section 12.4.3.7 Linking Transfers](#)). The EDMA link feature reloads the current channel parameter set with the linked parameter set. The EDMA chaining feature does not modify or update any channel parameter set. It provides a synchronization event to the chained channel (see [Section 12.4.4.1.3 Chain-Triggered Transfer Request](#)).

Chaining is achieved at either final transfer completion or intermediate transfer completion, or both, of the current channel. Consider a channel m (DMA/QDMA) required to chain to channel n . Channel number n (0-63) needs to be programmed into the `EDMA_TPCC_OPT_n[17:12]` TCC bit-field of channel m channel options parameter (OPT) set.

- If final transfer completion chaining `EDMA_TPCC_OPT_n[22] TCCHEN = 1` is enabled, the chain-triggered event occurs after the submission of the last transfer request of channel m is either submitted or completed (depending on early or normal completion).

- If intermediate transfer completion chaining `EDMA_TPCC_OPT_n[23] ITCCHEN = 1` is enabled, the chain-triggered event occurs after every transfer request, except the last of channel *m* is either submitted or completed (depending on early or normal completion).
- If both final and intermediate transfer completion chaining (`EDMA_TPCC_OPT_n[22] TCCHEN = 1` and `EDMA_TPCC_OPT_n[23] ITCCHEN = 1`) are enabled, then the chain-trigger event occurs after every transfer request is submitted or completed (depending on early or normal completion).

Table 12-15 illustrates the number of chain event triggers occurring in different synchronized scenarios. Consider channel 31 programmed with `EDMA_TPCC_ABCNT_n[15:0] ACNT = 3`, `EDMA_TPCC_ABCNT_n[31:16] BCNT = 4`, `EDMA_TPCC_CCNT_n[15:0] CCNT = 5`, and `EDMA_TPCC_OPT_n[17:12] TCC = 30`.

Table 12-15. Chain Event Triggers

Options	(Number of chained event triggers on channel 30)	
	A-Synchronized	AB-Synchronized
<code>EDMA_TPCC_OPT_n[22] TCCHEN = 1</code> , <code>EDMA_TPCC_OPT_n[23] ITCCHEN = 0</code>	1 (Owing to the last TR)	1 (Owing to the last TR)
<code>EDMA_TPCC_OPT_n[22] TCCHEN = 0</code> , <code>EDMA_TPCC_OPT_n[23] ITCCHEN = 1</code>	19 (Owing to all but the last TR)	4 (Owing to all but the last TR)
<code>EDMA_TPCC_OPT_n[22] TCCHEN = 1</code> , <code>EDMA_TPCC_OPT_n[23] ITCCHEN = 1</code>	20 (Owing to a total of 20 TRs)	5 (Owing to a total of 5 TRs)

12.4.9 EDMA Interrupts

The EDMA interrupts are divided into 2 categories: transfer completion interrupts and error interrupts.

There are nine region interrupts, eight shadow regions and one global region. The transfer completion interrupts are listed in Table 12-16. The transfer completion interrupts and the error interrupts from the transfer controllers are all routed to the device interrupt controllers INTCs through the inputs of the IRQ_CROSSBAR module.

Table 12-16. EDMA Transfer Completion Interrupts

Name	Description
<code>EDMA_TPCC_INT0</code>	EDMA_TPCC Transfer Completion Interrupt Shadow Region 0
<code>EDMA_TPCC_INT1</code>	EDMA_TPCC Transfer Completion Interrupt Shadow Region 1
<code>EDMA_TPCC_INT2</code>	EDMA_TPCC Transfer Completion Interrupt Shadow Region 2
<code>EDMA_TPCC_INT3</code>	EDMA_TPCC Transfer Completion Interrupt Shadow Region 3
<code>EDMA_TPCC_INT4</code>	EDMA_TPCC Transfer Completion Interrupt Shadow Region 4
<code>EDMA_TPCC_INT5</code>	EDMA_TPCC Transfer Completion Interrupt Shadow Region 5
<code>EDMA_TPCC_INT6</code>	EDMA_TPCC Transfer Completion Interrupt Shadow Region 6
<code>EDMA_TPCC_INT7</code>	EDMA_TPCC Transfer Completion Interrupt Shadow Region 7

Table 12-17. EDMA Error Interrupts

Name	Description
<code>EDMA_TPCC_ERRINT</code>	EDMA_TPCC Error Interrupt
<code>EDMA_TPCC_MPINT</code>	EDMA_TPCC Memory Protection Interrupt
<code>EDMA_TC0_ERRINT</code>	TC0 Error Interrupt
<code>EDMA_TC1_ERRINT</code>	TC1 Error Interrupt

12.4.9.1 Transfer Completion Interrupts

The EDMA_TPCC is responsible for generating transfer completion interrupts to the CPU(s) (and other EDMA masters). The EDMA generates a single completion interrupt per shadow region, as well as one for the global region on behalf of all 64 channels. The various control registers and bit fields facilitate EDMA interrupt generation.

The software architecture must either use the global interrupt or the shadow interrupts, but not both.

The transfer completion code [EDMA_TPCC_OPT_n\[17:12\]](#) TCC value is directly mapped to the bits of the interrupt pending register [EDMA_TPCC_IPR](#) / [EDMA_TPCC_IPRH](#).

For example, if [EDMA_TPCC_OPT_n\[17:12\]](#) TCC = 10 0001b, [EDMA_TPCC_IPRH\[1\]](#) is set after transfer completion, and results in interrupt generation to the CPU(s) if the completion interrupt is enabled for the CPU. See [Section 12.4.9.1.1 Enabling Transfer Completion Interrupts](#) for details about enabling EDMA transfer completion interrupts.

When a completion code is returned (as a result of early or normal completions), the corresponding bit in [EDMA_TPCC_IPR](#) / [EDMA_TPCC_IPRH](#) registers is set if transfer completion interrupt (final/intermediate) is enabled in the channel options parameter (OPT) for a PaRAM set associated with the transfer.

Table 12-18. Transfer Complete Code (TCC) to EDMA_TPCC Interrupt Mapping

TCC values in EDMA_TPCC_OPT_n[17:12] TCC (EDMA_TPCC_OPT_n[20] TCINTEN / EDMA_TPCC_OPT_n[21] ITCINTEN = 1)		EDMA_TPCC_IPR Bit Set	TCC values in EDMA_TPCC_OPT_n[17:12] TCC (EDMA_TPCC_OPT_n[20] TCINTEN / EDMA_TPCC_OPT_n[21] ITCINTEN = 1)		EDMA_TPCC_IPRH Bit Set ⁽¹⁾
0		EDMA_TPCC_IPR[0]	20h		EDMA_TPCC_IPR[32] / EDMA_TPCC_IPRH[0]
1		EDMA_TPCC_IPR[1]	21h		EDMA_TPCC_IPR[33] / EDMA_TPCC_IPRH[1]
2h		EDMA_TPCC_IPR[2]	22h		EDMA_TPCC_IPR[34] / EDMA_TPCC_IPRH[2]
3h		EDMA_TPCC_IPR[3]	23h		EDMA_TPCC_IPR[35] / EDMA_TPCC_IPRH[3]
4h		EDMA_TPCC_IPR[4]	24h		EDMA_TPCC_IPR[36] / EDMA_TPCC_IPRH[4]
...	
1Eh		EDMA_TPCC_IPR[30]	3Eh		EDMA_TPCC_IPR[62] / EDMA_TPCC_IPRH[30]
1Fh		EDMA_TPCC_IPR[31]	3Fh		EDMA_TPCC_IPR[63] / EDMA_TPCC_IPRH[31]

⁽¹⁾ Bit fields [EDMA_TPCC_IPR](#) [32-63] correspond to bits 0 to 31 in [EDMA_TPCC_IPRH](#), respectively.

The transfer completion code (TCC) can program to any value for a DMA/QDMA channel. A direct relation between the channel number and the transfer completion code value does not need to exist. This allows multiple channels having the same transfer completion code value to cause a CPU to execute the same interrupt service routine (ISR) for different channels.

If the channel is used in the context of a shadow region and it intends for the shadow region interrupt to be asserted, then ensure that the bit corresponding to the TCC code is enabled in [EDMA_TPCC_IER](#) / [EDMA_TPCC_IERH](#) and in the corresponding shadow region's DMA region access registers ([EDMA_TPCC_DRAEM_k](#) / [EDMA_TPCC_DRAEHM_k](#)).

Interrupt generation can be enabled at either final transfer completion or intermediate transfer completion, or both. Consider channel *m* as an example.

- If the final transfer interrupt ([EDMA_TPCC_OPT_n\[20\]](#) TCINTEN = 1) is enabled, the interrupt occurs after the last transfer request of channel *m* is either submitted or completed (depending on early or normal completion).

- If the intermediate transfer interrupt ([EDMA_TPCC_OPT_n\[21\]](#) ITCINTEN = 1) is enabled, the interrupt occurs after every transfer request, except the last TR of channel *m* is either submitted or completed (depending on early or normal completion).
- If both final and intermediate transfer completion interrupts ([EDMA_TPCC_OPT_n\[20\]](#) TCINTEN = 1, and [EDMA_TPCC_OPT_n\[21\]](#) ITCINTEN = 1) are enabled, then the interrupt occurs after every transfer request is submitted or completed (depending on early or normal completion).

[Table 12-19](#) shows the number of interrupts that occur in different synchronized scenarios. Consider channel 31, programmed with [ABCNT_n\[15:0\]](#) ACNT = 3, [EDMA_TPCC_ABCNT_n\[31:16\]](#) BCNT = 4, [EDMA_TPCC_CCNT_n\[15:0\]](#) CCNT = 5, and [EDMA_TPCC_OPT_n\[17:12\]](#) TCC = 30.

Table 12-19. Number of Interrupts

Options	A-Synchronized	AB-Synchronized
EDMA_TPCC_OPT_n[20] TCINTEN = 1, EDMA_TPCC_OPT_n[21] ITCINTEN = 0	1 (Last TR)	1 (Last TR)
EDMA_TPCC_OPT_n[20] TCINTEN = 0, EDMA_TPCC_OPT_n[21] ITCINTEN = 1	19 (All but the last TR)	4 (All but the last TR)
EDMA_TPCC_OPT_n[20] TCINTEN = 1, EDMA_TPCC_OPT_n[21] ITCINTEN = 1	20 (All TRs)	5 (All TRs)

12.4.9.1.1 Enabling Transfer Completion Interrupts

For the EDMA channel controller to assert a transfer completion to the external environment, the interrupts must be enabled in the EDMA_TPCC. This is in addition to setting up the [EDMA_TPCC_OPT_n\[20\]](#) TCINTEN and [EDMA_TPCC_OPT_n\[21\]](#) ITCINTEN bits of the associated PaRAM set.

The EDMA channel controller has interrupt enable registers [EDMA_TPCC_IER](#) / [EDMA_TPCC_IERH](#) and each bit location in [EDMA_TPCC_IER](#) / [EDMA_TPCC_IERH](#) serves as a primary enable for the corresponding interrupt pending registers [EDMA_TPCC_IPR](#) / [EDMA_TPCC_IPRH](#).

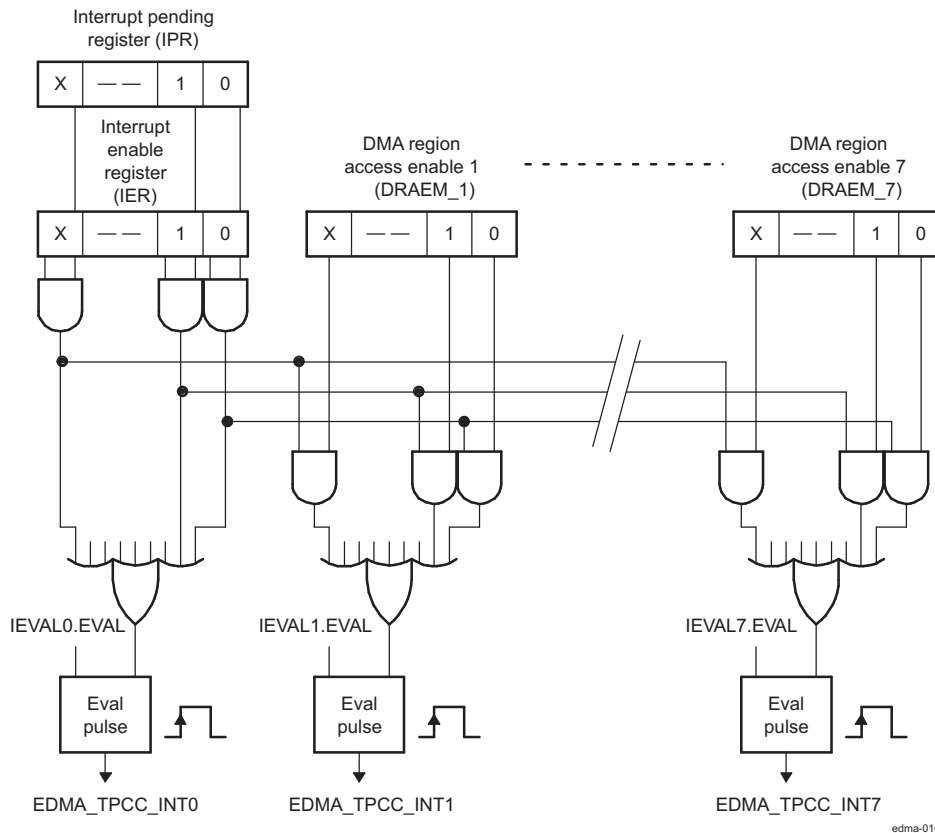

All of the interrupt registers ([EDMA_TPCC_IER](#), [EDMA_TPCC_IESR](#), [EDMA_TPCC_IECR](#), and [EDMA_TPCC_IPR](#)) are either manipulated from the global DMA channel region, or by the DMA channel shadow regions. The shadow regions provide a view to the same set of physical registers that are in the global region.

The EDMA channel controller has a hierarchical completion interrupt scheme that uses a single set of interrupt pending registers [EDMA_TPCC_IPR](#) / [EDMA_TPCC_IPRH](#) and single set of interrupt enable registers [EDMA_TPCC_IER](#) / [EDMA_TPCC_IERH](#). The programmable DMA region access enable registers [EDMA_TPCC_DRAEM_k](#) / [EDMA_TPCC_DRAEHM_k](#) provides a second level of interrupt masking. The global region interrupt output is gated based on the enable mask that is provided by [EDMA_TPCC_IER](#) / [EDMA_TPCC_IERH](#), see [Figure 12-16](#)

The region interrupt outputs are gated by [EDMA_TPCC_IER](#) and the specific [EDMA_TPCC_DRAEM_k](#) / [EDMA_TPCC_DRAEHM_k](#) associated with the region.

[Figure 12-16](#) shows the Interrupt diagram of the EDMA controller.

Figure 12-16. Interrupt Diagram

edma-016

The EDMA_TPCC generates the transfer completion interrupts that are associated with each shadow region, the following conditions must be true:

- EDMA_TPCC_INT0: (EDMA_TPCC_IPR[0] E0 & EDMA_TPCC_IER[0] E0 & EDMA_TPCC_DRAEM_k.DRAEM_0[0] E0) | (EDMA_TPCC_IPR[1] E1 & EDMA_TPCC_IER[1] E1 & EDMA_TPCC_DRAEM_k.DRAEM_0[1] E1) | ...|(EDMA_TPCC_IPRH[31] E63 & EDMA_TPCC_IERH[31] E63 & EDMA_TPCC_DRAEHM_k.DRAEHM_0[31] E63)
- EDMA_TPCC_INT1: (EDMA_TPCC_IPR[0] E0 & EDMA_TPCC_IER[0] E0 & EDMA_TPCC_DRAEM_k.DRAEM_1[0] E0) | (EDMA_TPCC_IPR[1] E1 & EDMA_TPCC_IER[1] E1 & EDMA_TPCC_DRAEM_k.DRAEM_1[1] E1) | ...|(EDMA_TPCC_IPRH[31] E63 & EDMA_TPCC_IERH[31] E63 & EDMA_TPCC_DRAEHM_k.DRAEHM_1[31] E63)
- EDMA_TPCC_INT2: (EDMA_TPCC_IPR[0] E0 & EDMA_TPCC_IER[0] E0 & EDMA_TPCC_DRAEM_k.DRAEM_2[0] E0) | (EDMA_TPCC_IPR[1] E1 & EDMA_TPCC_IER[1] E1 & EDMA_TPCC_DRAEM_k.DRAEM_2[1] E1) | ...|(EDMA_TPCC_IPRH[31] E63 & EDMA_TPCC_IERH[31] E63 & EDMA_TPCC_DRAEHM_k.DRAEHM_2[31] E63)....
- Up to EDMA_TPCC_INT7: (EDMA_TPCC_IPR[0] E0 & EDMA_TPCC_IER[0] E0 & EDMA_TPCC_DRAEM_k.DRAEM_7[0] E0) | (EDMA_TPCC_IPR[1] E1 & EDMA_TPCC_IER[1] E1 & EDMA_TPCC_DRAEM_k.DRAEM_7[1] E1) | ...|(EDMA_TPCC_IPRH[31] E63 & EDMA_TPCC_IERH[31] E63 & EDMA_TPCC_DRAEHM_k.DRAEHM_7[31] E63)

NOTE: The [EDMA_TPCC_DRAEM_k](#) / [EDMA_TPCC_DRAEHM_k](#) for all regions are expected to be set up at system initialization and to remain static for an extended period of time. The interrupt enable registers are used for dynamic enable/disable of individual interrupts.

Because there is no relation between the [EDMA_TPCC_OPT_n\[17:12\]](#) TCC value and the DMA/QDMA channel, it is possible, the DMA channel 0 to have the [EDMA_TPCC_OPT_n\[17:12\]](#) TCC = 63 in its associated PaRAM set. This mean that if a transfer completion interrupt is enabled ([EDMA_TPCC_OPT_n\[20\]](#) TCINTEN or [EDMA_TPCC_OPT_n\[21\]](#) ITCINTEN is set), then based on the TCC value, [EDMA_TPCC_IPRH\[31\]](#) E63 is set up on completion. For proper channel operations and interrupt generation using the shadow region map - program the [EDMA_TPCC_DRAEM_k](#) / [EDMA_TPCC_DRAEHM_k](#) that is associated with the shadow region to have read/write access to both bit 0 (corresponding to channel 0) and bit 63 (corresponding to [EDMA_TPCC_IPRH](#) bit that is set upon completion).

12.4.9.1.2 Clearing Transfer Completion Interrupts

Transfer completion interrupts that are latched to the interrupt pending registers ([EDMA_TPCC_IPR](#) / [EDMA_TPCC_IPRH](#)) are cleared by writing a 1 to the corresponding bit in the interrupt pending clear register ([EDMA_TPCC_ICR](#) / [EDMA_TPCC_ICRH](#)). For example, a write of 1 to [EDMA_TPCC_ICR\[0\]](#) E0 clears a pending interrupt in [EDMA_TPCC_IPR\[0\]](#) E0.

If an incoming transfer completion code TCC ([EDMA_TPCC_OPT_n\[17:12\]](#) TCC) gets latched to a bit in [EDMA_TPCC_IPR](#) / [EDMA_TPCC_IPRH](#), then additional bits that get set due to a subsequent transfer completion does not result in asserting the EDMA_TPCC completion interrupt. In order for the completion interrupt to be pulsed, the required transition is from a state where no enabled interrupts are set to a state where at least one enabled interrupt is set.

12.4.9.2 EDMA Interrupt Servicing

Upon completion of a transfer (early or normal completion), the EDMA channel controller sets the appropriate bit in the interrupt pending registers ([EDMA_TPCC_IPR](#) / [EDMA_TPCC_IPRH](#)), as the transfer completion codes specify. If the completion interrupts are appropriately enabled, then the CPU enters the interrupt service routine (ISR) when the completion interrupt is asserted.

After servicing the interrupt, the ISR should clear the corresponding bit in [EDMA_TPCC_IPR/EDMA_TPCC_IPRH](#), thereby enabling recognition of future interrupts. The EDMA_TPCC only asserts additional completion interrupts when all [EDMA_TPCC_IPR](#) / [EDMA_TPCC_IPRH](#) bits clear.

When one interrupt is serviced many other transfer completions may result in additional bits being set in [EDMA_TPCC_IPR](#) / [EDMA_TPCC_IPRH](#), thereby resulting in additional interrupts. Each of the bits in [EDMA_TPCC_IPR](#) / [EDMA_TPCC_IPRH](#) may need different types of service therefore, the ISR must check all pending interrupts and continue until all of the posted interrupts are serviced appropriately.

Examples of pseudo code for a CPU interrupt service routine for an EDMA_TPCC completion interrupt are shown in [Example 12-2](#) and [Example 12-3](#).

The ISR routine in [Example 12-2](#) is more exhaustive and incurs a higher latency.

Example 12-2. Interrupt Servicing

The pseudo code:

1. Reads the interrupt pending register [EDMA_TPCC_IPR](#) / [EDMA_TPCC_IPRH](#).
2. Performs the operations needed.
3. Writes to the interrupt pending clear register [EDMA_TPCC_ICR](#) / [EDMA_TPCC_ICRH](#) to clear the corresponding [EDMA_TPCC_IPR](#) / [EDMA_TPCC_IPRH](#) bit(s).
4. Reads [EDMA_TPCC_IPR](#) / [EDMA_TPCC_IPRH](#) again:
 - a. If [EDMA_TPCC_IPR](#) / [EDMA_TPCC_IPRH](#) is not equal to 0, repeat from step 2 (implies occurrence of new event between step 2 to step 4).

Example 12-2. Interrupt Servicing (continued)

- b. If `EDMA_TPCC_IPR` / `EDMA_TPCC_IPRH` is equal to 0, assure that all of the enabled interrupts are inactive.

NOTE: An event may occur during step 4 while the `EDMA_TPCC_IPR` / `EDMA_TPCC_IPRH` bits are read as 0 and the application is still in the interrupt service routine. If this happens, a new interrupt is recorded in the device interrupt controller and a new interrupt generates as soon as the application exits in the interrupt service routine.

[Example 12-3](#) is less rigorous, with less burden on the software in polling for set interrupt bits, but can occasionally cause a race condition as mentioned above.

Example 12-3. Interrupt Servicing

If any enabled and pending (possibly lower priority) interrupts are left, force the interrupt logic to reassert the interrupt pulse by setting the `EDMA_TPCC_IEVAL[0]` EVAL bit in the interrupt evaluation register.

The pseudo code is as follows:

1. Enters ISR.
2. Reads `EDMA_TPCC_IPR` / `EDMA_TPCC_IPRH`.
3. For the condition that is set in `EDMA_TPCC_IPR` / `EDMA_TPCC_IPRH`:
 - a. Service interrupt as the application requires.
 - b. Clear the bit for serviced conditions (others may still be set, and other transfers may have resulted in returning the TCC to `EDMA_TPCC` after step 2).
4. Reads `EDMA_TPCC_IPR` / `EDMA_TPCC_IPRH` prior to exiting the ISR:
 - a. If `EDMA_TPCC_IPR` / `EDMA_TPCC_IPRH` is equal to 0, then exit the ISR.
 - b. If `EDMA_TPCC_IPR` / `EDMA_TPCC_IPRH` is not equal to 0, then set `EDMA_TPCC_IEVAL` so that upon exit of ISR, a new interrupt triggers if any enabled interrupts are still pending.

12.4.9.3 Interrupt Evaluation Operations

The `EDMA_TPCC` has interrupt evaluate registers `EDMA_TPCC_IEVAL` that exist in the global region and in each shadow region. The registers in the shadow region are the only registers in the DMA channel shadow region memory map that are not affected by the settings for the DMA region access enable registers `EDMA_TPCC_DRAEM_k` / `EDMA_TPCC_DRAEHM_k`. Writing a 1 to the `EDMA_TPCC_IEVAL[0]` EVAL bit in the registers that are associated with a particular shadow region results in pulsing the associated region interrupt (global or shadow), if any enabled interrupt (via `EDMA_TPCC_IER` / `EDMA_TPCC_IERH`) is still pending `EDMA_TPCC_IPR` / `EDMA_TPCC_IPRH`. This register assures that the CPU does not miss the interrupts (or the EDMA master associated with the shadow region) if the software architecture chooses not to use all interrupts. Refer to [Example 12-3](#) about the use of `EDMA_TPCC_IEVAL` in the EDMA interrupt service routine (ISR).

Similarly an error evaluation register `EDMA_TPCC_EEVAL` exists in the global region. Writing a 1 to the `EDMA_TPCC_EEVAL[0]` EVAL bit causes the pulsing of the error interrupt if any pending errors are in `EDMA_TPCC_EMR` / `EDMA_TPCC_EMRH`, `EDMA_TPCC_QEMR`, or `EDMA_TPCC_CCERR`. See [Section 12.4.9.4 Error Interrupts](#) for additional information regarding error interrupts.

NOTE: While using `EDMA_TPCC_IEVAL` for shadow region completion interrupts, check that the `EDMA_TPCC_IEVAL` operated upon is from that particular shadow region memory map.

12.4.9.4 Error Interrupts

The EDMA_TPCC error registers provide the capability to differentiate error conditions (event missed, threshold exceed, etc.). Additionally, setting the error bits in these registers results in asserting the EDMA_TPCC error interrupt. If the EDMA_TPCC error interrupt is enabled in the device interrupt controller(s), then it allows the CPU(s) to handle the error conditions.

The EDMA_TPCC has a single error interrupt (EDMA_TPCC_ERRINT) that is asserted for all EDMA_TPCC error conditions. There are four conditions that cause the error interrupt:

- DMA missed events: for all 64 DMA channels. DMA missed events are latched in the event missed registers [EDMA_TPCC_EMR](#) / [EDMA_TPCC_EMRH](#).
- QDMA missed events: for all 8 QDMA channels. QDMA missed events are latched in the QDMA event missed register [EDMA_TPCC_QEMR](#).
- Threshold exceed: for all event queues. These are latched in EDMA_TPCC error register [EDMA_TPCC_CCERR](#).
- TCC error: for outstanding transfer requests that are expected to return completion code [EDMA_TPCC_OPT_n\[22\]](#) TCCHEN or [EDMA_TPCC_OPT_n\[23\]](#) TCINTEN bit is set to 1, exceeding the maximum limit of 63. This is also latched in the EDMA_TPCC error register [EDMA_TPCC_CCERR](#).

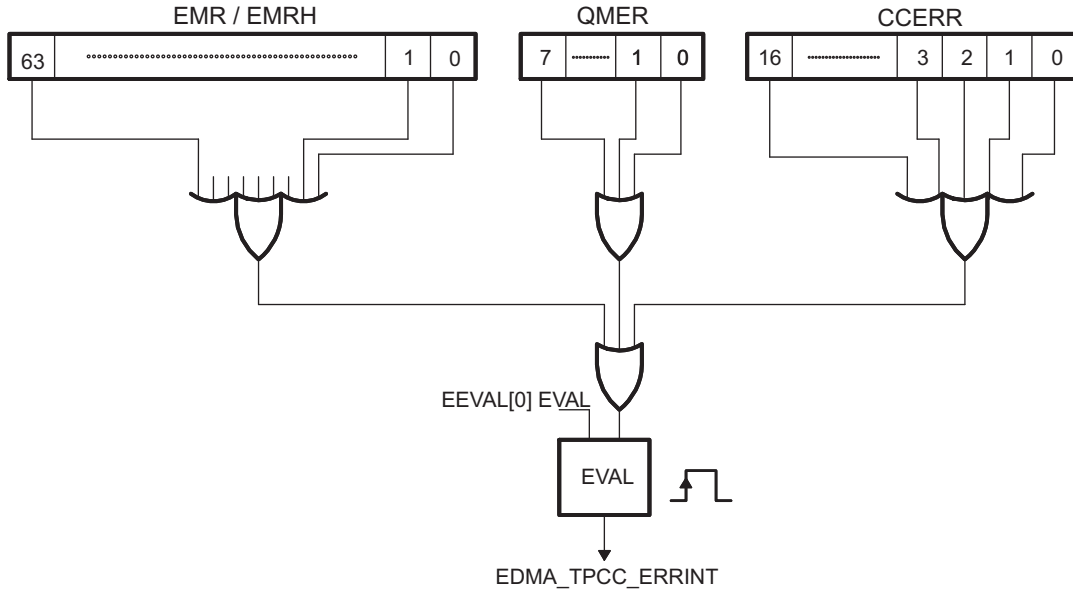

[Figure 12-17](#) illustrates the EDMA_TPCC error interrupt generation operation.

If any of the bits are set in the error registers due to any error condition, the EDMA_TPCC_ERRINT is always asserted, as there are no enables for masking these error events. Similar to transfer completion interrupts (EDMA_TPCC_INT), the error interrupt also only pulses when the error interrupt condition transitions from no errors being set to at least one error being set. If additional error events are latched prior to the original error bits clearing, the EDMA_TPCC does not generate additional interrupt.

To reduce the burden on the software, there is an error evaluate register [EDMA_TPCC_EEVAL](#) that allows re-evaluation of pending set error events/bits, similar to the interrupt evaluate register [EDMA_TPCC_IEVAL](#). Unlike the [EDMA_TPCC_IEVAL](#) functionality, the [EDMA_TPCC_EEVAL](#) register must be written with '1' after any error interrupts are serviced (even when all pending errors are cleared) in order for subsequent errors to trigger a new interrupt.

NOTE: It is good practice to enable the error interrupt in the device interrupt controller and to associate an interrupt service routine with it to address the various error conditions appropriately. Doing so puts less burden on the software (polling for error status), it provides a good debug mechanism for unexpected error conditions.

12.4.10 Memory Protection

The EDMA channel controller supports two kinds of memory protection: active and proxy.

12.4.10.1 Active Memory Protection

Active memory protection is a feature that allows or prevents read and write accesses to the EDMA_TPCC registers. Active memory protection is achieved by a set of memory protection permissions attribute [EDMA_TPCC_MPPAN_k](#) registers.

The EDMA_TPCC register map is divided into three categories:

- a global region.
- a global channel region.
- eight shadow regions.

Each shadow region consists of the respective shadow region registers and the associated PaRAM. For more detailed information regarding the contents of a shadow region, refer to [Table 12-30 EDMA_TPCC Registers Mapping Summary](#).

Each of the eight shadow regions has an associated [EDMA_TPCC_MPPAN_k](#) registers that defines the specific requestor(s) and types of requests that are allowed to the regions resources.

The global channel region is also protected with a memory-mapped register [EDMA_TPCC_MPPAG](#). The [EDMA_TPCC_MPPAG](#) applies to the global region and to the global channel region, except the other [EDMA_TPCC_MPPAN_k](#) registers themselves.

[Table 12-20](#) shows the accesses that are allowed or not allowed to the [EDMA_TPCC_MPPAG](#) and [EDMA_TPCC_MPPAN_k](#). The active memory protection uses the [EDMA_TPCC_OPT_n\[31\]](#) PRIV and [EDMA_TPCC_OPT_n\[27:24\]](#) PRIVID attributes of the EDMA peripheral modules. The [EDMA_TPCC_OPT_n\[31\]](#) PRIV is the privilege level (i.e., user vs. supervisor).

The [EDMA_TPCC_OPT_n\[27:24\]](#) PRIVID refers to a privilege ID with a number that is associated with an EDMA peripheral modules.

Table 12-20. Allowed Accesses

Access	Supervisor	User
Read	Yes	Yes
Write	Yes	No

[Table 12-21](#) describes the [EDMA_TPCC_MPPAN_k](#) register mapping for the shadow regions (which includes shadow region registers and PaRAM addresses).

The region-based [EDMA_TPCC_MPPAN_k](#) registers are used to protect accesses to the DMA shadow regions and the associated region PaRAM. Because there are eight regions, there are eight [EDMA_TPCC_MPPAN_k](#) region registers (MPPAN[0-7]).

Table 12-21. MPPA Registers to Region Assignment

Register	Registers Protect	Address Range	PaRAM Protect ⁽¹⁾	Address Range
EDMA_TPCC_MPPAG	Global Range	0000h-1FFCh	N/A	N/A
EDMA_TPCC_MPPAN_k . MPPAN_0	DMA Shadow 0	2000h-21FCh	1st octant	4000h-47FCh
MPPAN_1	DMA Shadow 1	2200h-23FCh	2nd octant	4800h-4FFCh
MPPAN_2	DMA Shadow 2	2400h-25FCh	3rd octant	5000h-57FCh
MPPAN_3	DMA Shadow 3	2600h-27FCh	4th octant	5800h-5FFCh
MPPAN_4	DMA Shadow 4	2800h-29FCh	5th octant	6000h-67FCh
MPPAN_5	DMA Shadow 5	2A00h-2BFCh	6th octant	6800h-6FFCh
MPPAN_6	DMA Shadow 6	2C00h-2DFCh	7th octant	7000h-77FCh
MPPAN_7	DMA Shadow 7	2E00h-2FFCh	8th octant	7800h-7FFCh

⁽¹⁾ The PARAM region is divided into 8 regions referred to as an octant.

Example Access denied.

Write access to shadow region 7's event enable set register [EDMA_TPCC_EESR](#):

1. The original value of the event enable register [EDMA_TPCC_EER](#) at address offset 0x1020 is 0x0.
2. The [EDMA_TPCC_MPPAN_k](#). [EDMA_TPCC_MPPAN_7\[7\]](#) NS is set to prevent user level accesses ([EDMA_TPCC_MPPAN_k](#). [EDMA_TPCC_MPPAN_7\[1\]](#) UW = 0, [EDMA_TPCC_MPPAN_k](#). [EDMA_TPCC_MPPAN_7\[2\]](#) UR = 0), but it allows supervisor level accesses ([EDMA_TPCC_MPPAN_k](#). [EDMA_TPCC_MPPAN_7\[4\]](#) SW = 1, [EDMA_TPCC_MPPAN_k](#). [EDMA_TPCC_MPPAN_7\[5\]](#) SR = 1) with a privilege ID of 0. ([EDMA_TPCC_MPPAN_k](#). [EDMA_TPCC_MPPAN_7\[10\]](#) AID0 = 1).
3. EDMA peripheral modules with a privilege ID of 0 attempts to perform a user-level write of a value of 0xFF00FF00 to shadow region 7's event enable set register [EDMA_TPCC_EESR](#) at address offset 0x2E30.

NOTE: The [EDMA_TPCC_EER](#) is a read-only register and the only way that write to it is by writing to the [EDMA_TPCC_EESR](#). There is only one physical register for [EDMA_TPCC_EER](#), [EDMA_TPCC_EESR](#), etc. and that the shadow regions only provide to the same physical set.

4. Since the [EDMA_TPCC_MPPAN_k](#). [EDMA_TPCC_MPPAN_7\[1\]](#) UW = 0, though the privilege ID of the write access is set to 0, the access is not allowed and the [EDMA_TPCC_EER](#) is not written too.

Table 12-22. Example Access Denied

Register	Value	Description
EDMA_TPCC_EER (offset 0x1020)	0x0000 0000	Value in EDMA_TPCC_EER to begin with.
EDMA_TPCC_EESR (offset 0x2E30)	0xFF00 FF00 ↓	Value attempted to be written to shadow region 7's EDMA_TPCC_EESR . This is done by an EDMA connected device module with a privilege level of User and Privilege ID of 0.
EDMA_TPCC_MPPAN_k (offset 0x082C)	0x0000 04B0 X	Memory Protection Filter EDMA_TPCC_MPPAN_k[10] AID0 = 1, EDMA_TPCC_MPPAN_k[1] UW = 0, EDMA_TPCC_MPPAN_k[2] UR = 0, EDMA_TPCC_MPPAN_k[4] SW = 1, EDMA_TPCC_MPPAN_k[5] SR = 1. Access Denied
EDMA_TPCC_EER (offset 0x1020)	0x0000 0000	Final value of EDMA_TPCC_EER

Example Access Allowed

Write access to shadow region 7's event enable set register [EDMA_TPCC_EESR](#):

1. The original value of the event enable register [EDMA_TPCC_EER](#) at address offset 0x1020 is 0x0.
2. The [EDMA_TPCC_MPPAN_k](#). [EDMA_TPCC_MPPAN_7](#) is set to allow user-level accesses ([EDMA_TPCC_MPPAN_k](#). [EDMA_TPCC_MPPAN_7\[1\]](#) UW = 1, [EDMA_TPCC_MPPAN_k](#). [EDMA_TPCC_MPPAN_7\[2\]](#) UR = 1) and supervisor-level accesses ([EDMA_TPCC_MPPAN_k](#). [EDMA_TPCC_MPPAN_7\[4\]](#) SW = 1, [EDMA_TPCC_MPPAN_k](#). [EDMA_TPCC_MPPAN_7\[5\]](#) SR = 1) with a privilege ID of 0. ([EDMA_TPCC_MPPAN_k](#). [EDMA_TPCC_MPPAN_7\[10\]](#) AID0 = 1).
3. EDMA peripheral modules with a privilege ID of 0, attempts to perform a user-level write of a value of 0xABCD0123 to shadow region 7's event enable set register [EDMA_TPCC_EESR](#) at address offset 0x2E30.

NOTE: The [EDMA_TPCC_EER](#) is a read-only register and the only way that write to it is by writing to the [EDMA_TPCC_EESR](#). There is only one physical register for [EDMA_TPCC_EER](#), [EDMA_TPCC_EESR](#), etc. and that the shadow regions only provide to the same physical set.

4. Since the [EDMA_TPCC_MPPAN_k](#). [EDMA_TPCC_MPPAN_7\[1\]](#) UW = 1 and [EDMA_TPCC_MPPAN_k](#). [MPPAN_7\[10\]](#) AID0 = 1, the user-level write access is allowed.
5. The accesse to shadow region registers are masked by their respective [EDMA_TPCC_DRAEM_k](#)

register. In this example, the [EDMA_TPCC_DRAEM_k](#). [EDMA_TPCC_DRAEM_7](#) is set of 0x9FF00FC2.

6. The value finally written to [EDMA_TPCC_EER](#) is 0x8BC00102.

Table 12-23. Example Access Allowed

Register	Value	Description
EDMA_TPCC_EER (offset 0x1020)	0x0000 0000	Value in EER to begin with.
EDMA_TPCC_EESR (offset 0x2E30)	0xFF00 FF00	Value attempted to be written to shadow region 7's EESR. This is done by an EDMA peripheral module with a privilege level of User and Privilege ID of 0.
EDMA_TPCC_MPPAN_k , EDMA_TPCC_MPPAN_7 (offset 0x082C)	0x0000 04B3	Memory Protection Filter EDMA_TPCC_MPPAN_k [10] AID = 1, EDMA_TPCC_MPPAN_k . EDMA_TPCC_MPPAN_7 [1] UW = 1, EDMA_TPCC_MPPAN_k . EDMA_TPCC_MPPAN_7 [2] UR = 1, EDMA_TPCC_MPPAN_k . EDMA_TPCC_MPPAN_7 [4] SW = 1, EDMA_TPCC_MPPAN_k . EDMA_TPCC_MPPAN_7 [5] SR = 1.
	√ ↓	Access allowed.
EDMA_TPCC_DRAEM_k , EDMA_TPCC_DRAEM_7 (offset 0x0378)	0x9FF0 0FC2 ↓	DMA Region Access Enable Filter
EDMA_TPCC_EESR (offset 0x2E30)	0x8BC0 0102 ↓	Value written to shadow region 7's EESR. This is done by an EDMA peripheral module with a privilege level of User and a Privilege ID of 0.
EDMA_TPCC_EER (offset 0x1020)	↓ 0xBC0 0102	Final value of EER.

12.4.10.2 Proxy Memory Protection

Proxy memory protection allows an EDMA transfer programmed by a given peripheral module connected to EDMA, to have its permissions travel with the transfer through the EDMA_TPTC. The permissions travel along with the read transactions to the source and the write transactions to the destination endpoints. The [EDMA_TPCC_OPT_n](#)[31] PRIV bit and [EDMA_TPCC_OPT_n](#)[27:24] PRIVID bit is set with the peripheral module's PRIV value and PRIVID values, respectively, when any part of the PaRAM set is written.

The [EDMA_TPCC_OPT_n](#)[31] PRIV is the privilege level (i.e., user vs. supervisor). The [EDMA_TPCC_OPT_n](#)[27:24] PRIVID refers to a privilege ID with a number that is associated with an peripheral module connected to EDMA.

These options are part of the TR that are submitted to the transfer controller. The transfer controller uses the above values on their respective read and write command bus so that the target endpoints can perform memory protection checks based on these values.

Consider a parameter set that is programmed by a CPU in user privilege level for a simple transfer with the source buffer on an L2 page and the destination buffer on an L1D page. The [EDMA_TPCC_OPT_n](#)[31] PRIV is 0 for user-level and the CPU has a [EDMA_TPCC_OPT_n](#)[27:24] PRIVID to 0.

The PaRAM set is shown in [Figure 12-18](#).

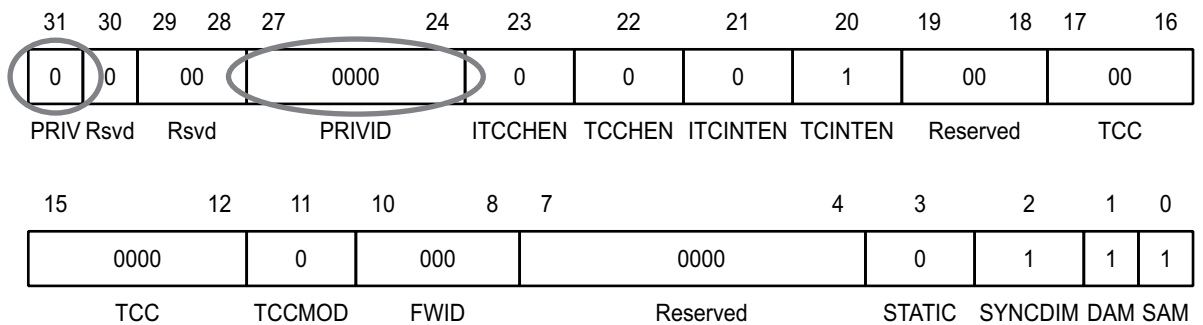

Figure 12-18. PaRAM Set Content for Proxy Memory Protection Example

(a) EDMA Parameters

Parameter Contents		Parameter	
0010 0007h		Channel Options Parameter (OPT)	
009F 0000h		Channel Source Address (SRC)	
0001h	0004h	Count for 2nd Dimension (BCNT)	Count for 1st Dimension (ACNT)
00F0 7800h		Channel Destination Address (DST)	
0001h	0001h	Destination BCNT Index (DBIDX)	Source BCNT Index (SBIDX)
0000h	FFFFh	BCNT Reload (BCNTRLD)	Link Address (LINK)
0001h	1000h	Destination CCNT Index (DCIDX)	Source CCNT Index (SCIDX)
0000h	0001h	Reserved	Count for 3rd Dimension (CCNT)

Figure 12-19. Channel Options Parameter (OPT) Example

(b) Channel Options Parameter (OPT_n) Content

edma-018

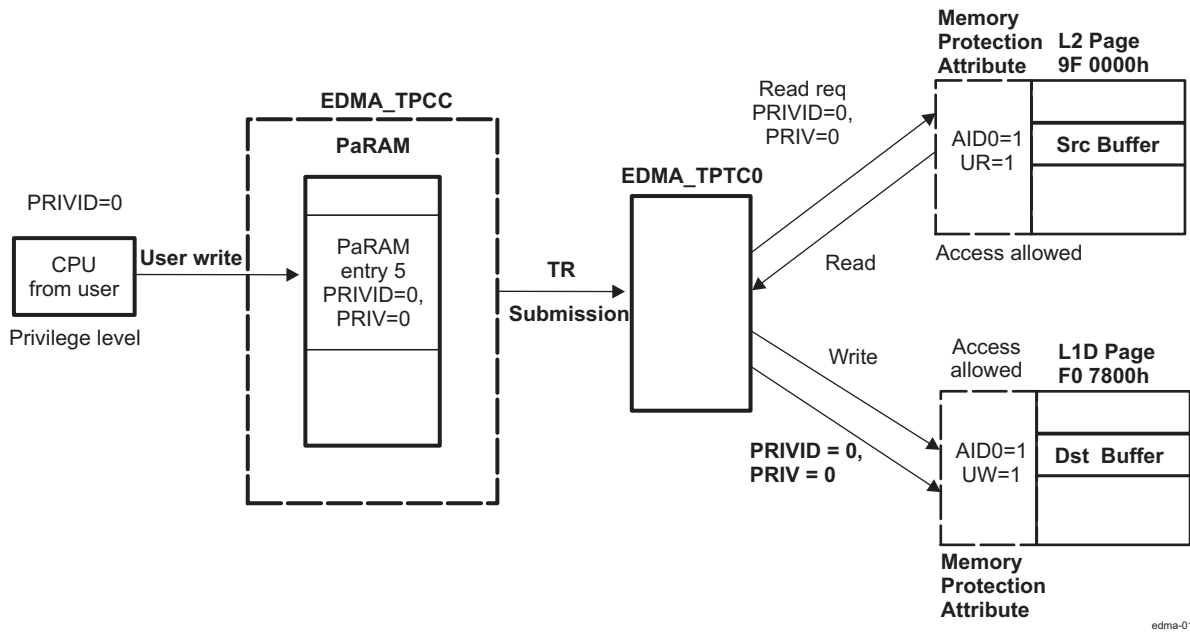

The [EDMA_TPCC_OPT_n\[31\]](#) PRIV and [EDMA_TPCC_OPT_n\[27:24\]](#) PRIVID information travels along with the read and write requests that are issued to the source and destination memories.

For example, if the access attributes that are associated with the L2 page with the source buffer only allow supervisor read, write accesses [EDMA_TPCC_MPPAN_k\[4\]](#) SW and [EDMA_TPCC_MPPAN_k\[5\]](#) SR, the user-level read request above is refused. Similarly, if the access attributes that are associated with the L1D page with the destination buffer only allow supervisor read and write accesses ([EDMA_TPCC_MPPAN_k\[4\]](#) SW, [EDMA_TPCC_MPPAN_k\[5\]](#) SR), the user-level write request above is refused. For the transfer to succeed, the source and destination pages must have user-read and user-write permissions, respectively, along with allowing accesses from a PRIVID = 0.

Because the privilege level and privilege identification travel with the read and write requests, EDMA acts as a proxy.

[Figure 12-20](#) illustrates the propagation of [EDMA_TPCC_OPT_n\[31\]](#) PRIV and [EDMA_TPCC_OPT_n\[27:24\]](#) PRIVID at the boundaries of all the interacting entities (CPU, EDMA_TPCC, EDMA_TPTCs, and slave memories).

Figure 12-20. Proxy Memory Protection Example

12.4.11 Event Queue(s)

Event queues are a part of the EDMA channel controller. Event queues form the interface between the event detection logic in the EDMA_TPCC and the transfer request (TR) submission logic of the EDMA_TPCC. Each queue is 16 entries deep. Each event queue can queue a maximum of 16 events. If there are more than 16 events, then the events that cannot find a place in the event queue remain set in the associated event register and the CPU does not stall.

There are two event queues for the device: Queue0, Queue1. Events in Queue0 result in submission of its associated transfer requests (TRs) to TC0. The transfer requests that are associated with events in Queue1 are submitted to TC1.

An event that wins prioritization against other DMA and/or QDMA pending events is placed at the tail of the appropriate event queue. Each event queue is serviced in FIFO order. Once the event reaches the head of its queue and the corresponding transfer controller is ready to receive another TR, the event is de-queued and the PaRAM set corresponding to the de-queued event is processed and submitted as a transfer request packet (TRP) to the associated EDMA transfer controller.

Queue0 has highest priority and Queue1 has the lowest priority, if Queue0 and Queue1 both have at least one event entry and if both TC0 and TC1 can accept transfer requests, then the event in Queue0 is de-queued first and its associated PaRAM set is processed and submitted as a transfer request (TR) to TC0.

Refer to [Section 12.4.11.4](#) for system-level performance considerations. All of the event entries in all of the event queues are software readable (not writeable) by accessing the event entry registers [EDMA_TPCC_Q0E_p](#) and [EDMA_TPCC_Q1E_p](#). Each event entry register characterizes the queued event in terms of the type of event (manual, event, chained or auto-triggered) and the event number. Refer to [Section 12.7.2.2.1 EDMA_TPCC Register Description](#) for [EDMA_TPCC_Q0E_p](#) / [EDMA_TPCC_Q1E_p](#) descriptions of the bit fields.

12.4.11.1 DMA/QDMA Channel to Event Queue Mapping

Each of the 64 DMA channels and eight QDMA channels are programmed independently to map to a specific queue, using the DMA queue number register [EDMA_TPCC_DMAQNUMN_k](#) and the QDMA queue number register [EDMA_TPCC_QDMAQNUM](#). The mapping of DMA/QDMA channels is critical to achieving the desired performance level for the EDMA and most importantly, in meeting real-time deadlines. Refer to [Section 12.4.11.4 System-level Performance Considerations](#).

NOTE: If an event is ready to be queued and both the event queue and the EDMA transfer controller that is associated to the event queue are empty, then the event bypasses the event queue, and moves the PaRAM processing logic, and eventually to the transfer request submission logic for submission to the EDMA_TPTC. In this case, the event is not logged in the event queue status registers.

12.4.11.2 Queue RAM Debug Visibility

There are two event queues and each queue has 16 entries. These 16 entries are managed in a circular FIFO. There is a queue status register [EDMA_TPCC_QSTATN_i](#) associated with each queue. These along with all of the 16 entries per queue can be read via registers [EDMA_TPCC_QSTATN_i](#) and [Q0E_p / Q1E_p](#), respectively.

These registers provide user visibility.

The event queue entry register ([QxEy Q0E_p / Q1E_p](#)) uniquely identifies the specific event type (event-triggered, manually-triggered, chain-triggered, and QDMA events) along with the event number (for all DMA/QDMA event channels) that are in the queue or have been de-queued (passed through the queue).

Each of the 16 entries in the event queue are read using the EDMA_TPCC memory-mapped register. To see the history of the last 16 TRs that have been processed by the EDMA on a given queue, read the event queue registers. This provides user/software visibility and is helpful for debugging real-time issues (typically post-mortem), involving multiple events and event sources.

The queue status register ([QSTATn EDMA_TPCC_QSTATN_i](#)) includes fields for the start pointer [EDMA_TPCC_QSTATN_i\[3:0\] STRTPTR](#) which provides the offset to the head entry of an event. It also includes a field called [EDMA_TPCC_QSTATN_i\[12:8\] NUMVAL](#) that provides the total number of valid entries residing in the event queue at a given instance of time. The [EDMA_TPCC_QSTATN_i\[3:0\] STRTPTR](#) is used to index appropriately into the 16 event entries. [EDMA_TPCC_QSTATN_i\[12:8\] NUMVAL](#) number of entries starting from STRTPTR are indicative of events still queued in the respective queue. The remaining entry must be read to determine what's already de-queued and submitted to the associated transfer controller.

12.4.11.3 Queue Resource Tracking

The EDMA_TPCC event queue includes watermarking/threshold logic that allows to keep track of maximum usage of all event queues. This is useful for debugging real-time deadline violations that may result from head-of-line blocking on a given EDMA event queue.

The maximum number of events are programmed that the queue up in an event queue by programming the threshold value (between 0 to 15) in the queue watermark threshold A register [EDMA_TPCC_QWMTHRA](#). The maximum queue usage is recorded actively in the watermark [EDMA_TPCC_QSTATN_i\[20:16\] WM](#) field of the queue status register, that keeps getting updated based on a comparison of number of valid entries, which is also visible in the [EDMA_TPCC_QSTATN_i\[12:8\] NUMVAL](#) bit and the maximum number of entries.

If the queue usage is exceeded, this status is visible in the EDMA_TPCC registers: the [QTHRXCdn](#) bits in the channel controller error register [EDMA_TPCC_CCERR\[7:0\]](#) and the [EDMA_TPCC_QSTATN_i\[24\] THRXCD](#) bit, where *n* stands for the event queue number. Any bits that are set in [EDMA_TPCC_CCERR](#) also generate an EDMA_TPCC error interrupt.

12.4.11.4 Performance Considerations

The main system bus infrastructure (L3) arbitrates bus requests from all of the masters (TCs, CPU(S), and other bus masters) to the shared slave resources (peripherals and memories).

The priorities of transfer requests (read and write commands) from the EDMA transfer controllers with respect to other masters within the device [IRQ_CROSSBAR](#) are programmed using the Control Module registers. The [EDMA_TPCC_QUEPRI](#) register has no affect.

Therefore, the priority of unloading queues has a secondary affect compared to the priority of the transfers as they are executed by the EDMA_TPTC (dictated by the priority set using the Control Module registers, refer to [Section 14.5 Control Module Register Manual](#) in [Chapter 14 Control Module](#) chapter).

12.4.12 EDMA Transfer Controller (EDMA_TPTC)

The EDMA channel controller is the user-interface of the EDMA and the EDMA transfer controller (EDMA_TPTC) is the data movement engine of the EDMA controller. The EDMA_TPCC submits transfer requests (TR) to the EDMA_TPTC and the EDMA_TPTC performs the data transfers dictated by the TR, so the EDMA_TPTC is a slave to the EDMA_TPCC.

12.4.12.1 Architecture Details

12.4.12.1.1 Command Fragmentation

The TC read and write controllers in conjunction with the source and destination register sets are responsible for issuing optimally-sized reads and writes to the slave endpoints. An optimally-sized command is defined by the transfer controller default burst size (DBS), which is defined in [Section 12.4.12.5 EDMA_TPTC Configuration](#).

The EDMA_TPTC attempts to issue the largest possible command size as limited by the DBS value or the [EDMA_TPCC_ABCNT_n\[15:0\]](#) ACNT and [EDMA_TPCC_ABCNT_n\[31:16\]](#) BCNT value of the TR. EDMA_TPTC obeys the following rules:

- The read/write controllers always issue commands less than or equal to the DBS value.
- The first command of a 1D transfer command always aligns the address of subsequent commands to the DBS value.

[Table 12-24](#) lists the TR segmentation rules that are followed by the EDMA_TPTC. In summary, if the [EDMA_TPCC_ABCNT_n\[15:0\]](#) ACNT value is larger than the DBS value, then the EDMA_TPTC breaks the [EDMA_TPCC_ABCNT_n\[15:0\]](#) ACNT array into DBS-sized commands to the source/destination addresses. Each [EDMA_TPCC_ABCNT_n\[31:16\]](#) BCNT number of arrays are then serviced in succession.

For BCNT arrays of ACNT bytes (that is, a 2D transfer), if the [EDMA_TPCC_ABCNT_n\[15:0\]](#) ACNT value is less than or equal to the DBS value, then the TR may be optimized into a 1D-transfer in order to maximize efficiency. The optimization takes place if the EDMA_TPTC recognizes that the 2D-transfer is organized as a single dimension ([EDMA_TPCC_ABCNT_n\[15:0\]](#) ACNT == [EDMA_TPCC_BIDX_n](#)) and the ACNT value is a power of 2.

[Table 12-24](#) lists conditions in which the optimizations are performed.

Table 12-24. Read/Write Command Optimization Rules

ACNT ≤ DBS	ACNT is power of 2	BIDX = ACNT	BCNT ≤ 1023	SAM/DAM = Increment	Description
Yes	Yes	Yes	Yes	Yes	Optimized
No	x	x	x	x	Not Optimized
x	No	x	x	x	Not Optimized
x	x	No	x	x	Not Optimized
x	x	x	No	x	Not Optimized
x	x	x	x	No	Not Optimized

12.4.12.1.2 TR Pipelining

TR pipelining refers to the ability of the source active set to proceed ahead of the destination active set. Essentially, the reads for a given TR may already be in progress while the writes of a previous TR may not have completed.

The number of outstanding TRs is limited by the number of destination FIFO register entries.

TR pipelining is useful for maintaining throughput on back-to-back small TRs. It minimizes the startup overhead because reads start in the background of a previous TR writes.

Example 12-4. Command Fragmentation (DBS = 64)

The pseudo code:

1. [EDMA_TPTCn_PCNT\[15:0\]](#) ACNT = 8, [EDMA_TPTCn_PCNT\[31:16\]](#) BCNT = 8, [EDMA_TPTCn_PBDX\[15:0\]](#) SBIDX = 8, [EDMA_TPTCn_PBDX\[31:16\]](#) DBIDX = 10, [EDMA_TPTCn_PSRC\[31:0\]](#) SADDR = 64, [EDMA_TPTCn_SADST\[31:0\]](#) DADDR = 191

Read Controller: This is optimized from a 2D-transfer to a 1D-transfer such that the read side is equivalent to [EDMA_TPTCn_PCNT\[15:0\]](#) ACNT = 64, [EDMA_TPTCn_PCNT\[31:16\]](#) BCNT = 1.

Cmd0 = 64 byte

Write Controller: Because DBIDX != ACNT, it is not optimized.

Cmd0 = 8 byte, Cmd1 = 8 byte, Cmd2 = 8 byte, Cmd3 = 8 byte, Cmd4 = 8 byte, Cmd5 = 8 byte, Cmd6 = 8 byte, Cmd7 = 8 byte.

2. [EDMA_TPTCn_PCNT\[15:0\]](#) ACNT=128, [EDMA_TPTCn_PCNT\[31:16\]](#) BCNT = 1, [EDMA_TPTCn_PSRC\[31:0\]](#) SADDR = 63, [EDMA_TPTCn_SADST\[31:0\]](#) DADDR = 513

Read Controller: Read address is not aligned.

Cmd0 = 1 byte, (now the SADDR is aligned to 64 for the next command)

Cmd1 = 64 bytes

Cmd2 = 63 bytes

Write Controller: The write address is also not aligned.

Cmd0 = 63 bytes, (now the DADDR is aligned to 64 for the next command)

Cmd1 = 64 bytes

Cmd2 = 1 byte

12.4.12.1.3 Performance Tuning

By default, reads are as issued as fast as possible. In some cases, the reads issued by the EDMA_TPTC could fill the available command buffering for a slave, delaying other (potentially higher priority) masters from successfully submitting commands to that slave. The rate at which read commands are issued by the EDMA_TPTC is controlled by the [EDMA_TPTCn_RDRATE](#) register. The [EDMA_TPTCn_RDRATE](#) register defines the number of cycles that the EDMA_TPTC read controller waits before issuing subsequent commands for a given TR, thus minimizing the chance of the EDMA_TPTC consuming all available slave resources. The [EDMA_TPTCn_RDRATE\[2:0\]](#) RDRATE value must be set to a relatively small value if the transfer controller is targeted for high priority transfers and to a higher value if the transfer controller is targeted for low priority transfers.

In contrast, the Write Interface does not have any performance turning knobs because writes always have an interval between commands as write commands are submitted along with the associated write data.

12.4.12.2 Memory Protection

The transfer controller plays an important role in handling proxy memory protection. There are two access properties associated with a transfer: for instance, the privilege id (system-wide identification assigned to a master) of the master initiating the transfer, and the privilege level (user versus supervisor) used to program the transfer. This information is maintained in the PaRAM set when it is programmed in the channel controller. When a TR is submitted to the transfer controller, this information is made available to the EDMA_TPTC and used by the EDMA_TPTC while issuing read and write commands. The read or write commands have the same privilege identification, and privilege level as that programmed in the EDMA transfer in the channel controller.

12.4.12.3 Error Generation

Errors are generated if enabled under three conditions:

- EDMA_TPTC detection of an error signaled by the source or destination address.
- Attempt to read or write to an invalid address in the configuration memory map.

- Detection of a constant addressing mode TR violating the constant addressing mode transfer rules (the source/destination addresses and source/destination indexes must be aligned to 32 bytes).

Either or all error types may be disabled. If an error bit is set and enabled, the error interrupt for the concerned transfer controller is generated.

12.4.12.4 Debug Features

The DMA program register set, DMA source active register set, and the destination FIFO register set are used to derive a brief history of TRs serviced through the transfer controller.

Additionally, the EDMA_TPTC status register [EDMA_TPTCn_TCSTAT](#) has dedicated bit fields to indicate the ongoing activity within different parts of the transfer controller:

- The [EDMA_TPTCn_TCSTAT\[1\]](#) SRCACTV bit indicates whether the source active set is active.
- The [EDMA_TPTCn_TCSTAT\[6:4\]](#) DSTACTV bit indicates the number of TRs resident in the destination register active set at a given instance.
- The [EDMA_TPTCn_TCSTAT\[0\]](#) PROGBUSY bit indicates whether a valid TR is present in the DMA program set.

NOTE: If the TRs are in progression, it must realize that there is a chance that the values read from the EDMA_TPTC status registers will be inconsistent since the EDMA_TPTC changes the values of these registers due to ongoing activities.

It is recommended that to ensure no additional submission of TRs to the EDMA_TPTC in order to facilitate ease of debug.

12.4.12.4.1 Destination FIFO Register Pointer

The destination FIFO register pointer is implemented as a circular buffer with the start pointer being [EDMA_TPTCn_TCSTAT\[12:11\]](#) DFSTRTPTR and a buffer depth of usually 2 or 4. The EDMA_TPTC maintains two important status details in [EDMA_TPTCn_TCSTAT](#) that are used during advanced debugging, if necessary. The [EDMA_TPTCn_TCSTAT\[12:11\]](#) DFSTRTPTR is a start pointer, the index to the head of the destination FIFO register. The [EDMA_TPTCn_TCSTAT\[6:4\]](#) DSTACTV is a counter for the number of valid (occupied) entries. These registers are used to get a brief history of transfers.

Examples of some register field values and their interpretation:

- [EDMA_TPTCn_TCSTAT\[12:11\]](#) DFSTRTPTR = 0x0 and [EDMA_TPTCn_TCSTAT\[6:4\]](#) DSTACTV = 0x0 implies that no TRs are stored in the destination FIFO register.
- [EDMA_TPTCn_TCSTAT\[12:11\]](#) DFSTRTPTR = 0x1 and [EDMA_TPTCn_TCSTAT\[6:4\]](#) DSTACTV = 0x2 implies that two TRs are present. The first pending TR is read from the destination FIFO register entry 1 and the second pending TR is read from the destination FIFO register entry 2.
- [EDMA_TPTCn_TCSTAT\[12:11\]](#) DFSTRTPTR = 0x3 and [EDMA_TPTCn_TCSTAT\[6:4\]](#) DSTACTV = 0x2 implies that two TRs are present. The first pending TR is read from the destination FIFO register entry 3 and the second pending TR is read from the destination FIFO register entry 0.

12.4.12.5 EDMA_TPTC Configuration

[Table 12-25](#) provides the configuration of the individual EDMA transfer controllers present on the device. The DBS for each transfer controller is defined by Control Module register ([CTRL_CORE_CONTROL_IO_1](#)) settings.

Table 12-25. EDMA Transfer Controller Configurations

Name	TC0	TC1
EDMA_TPTCn_TCCFG[2:0] FIFOSIZE	1024 bytes	1024 bytes
EDMA_TPTCn_TCCFG[5:4] BUSWIDTH	16 bytes	16 bytes
EDMA_TPTCn_TCCFG[9:8] DSTREGDEPTH	4 entries	4 entries

Table 12-25. EDMA Transfer Controller Configurations (continued)

Name	TC0	TC1
DBS	Defined by CTRL_CORE_CONTROL_IO_1[9:8] TC0_DEFAULT_BURST_SIZE	Defined by CTRL_CORE_CONTROL_IO_1[13:12] TC1_DEFAULT_BURST_SIZE

12.4.13 Event Dataflow

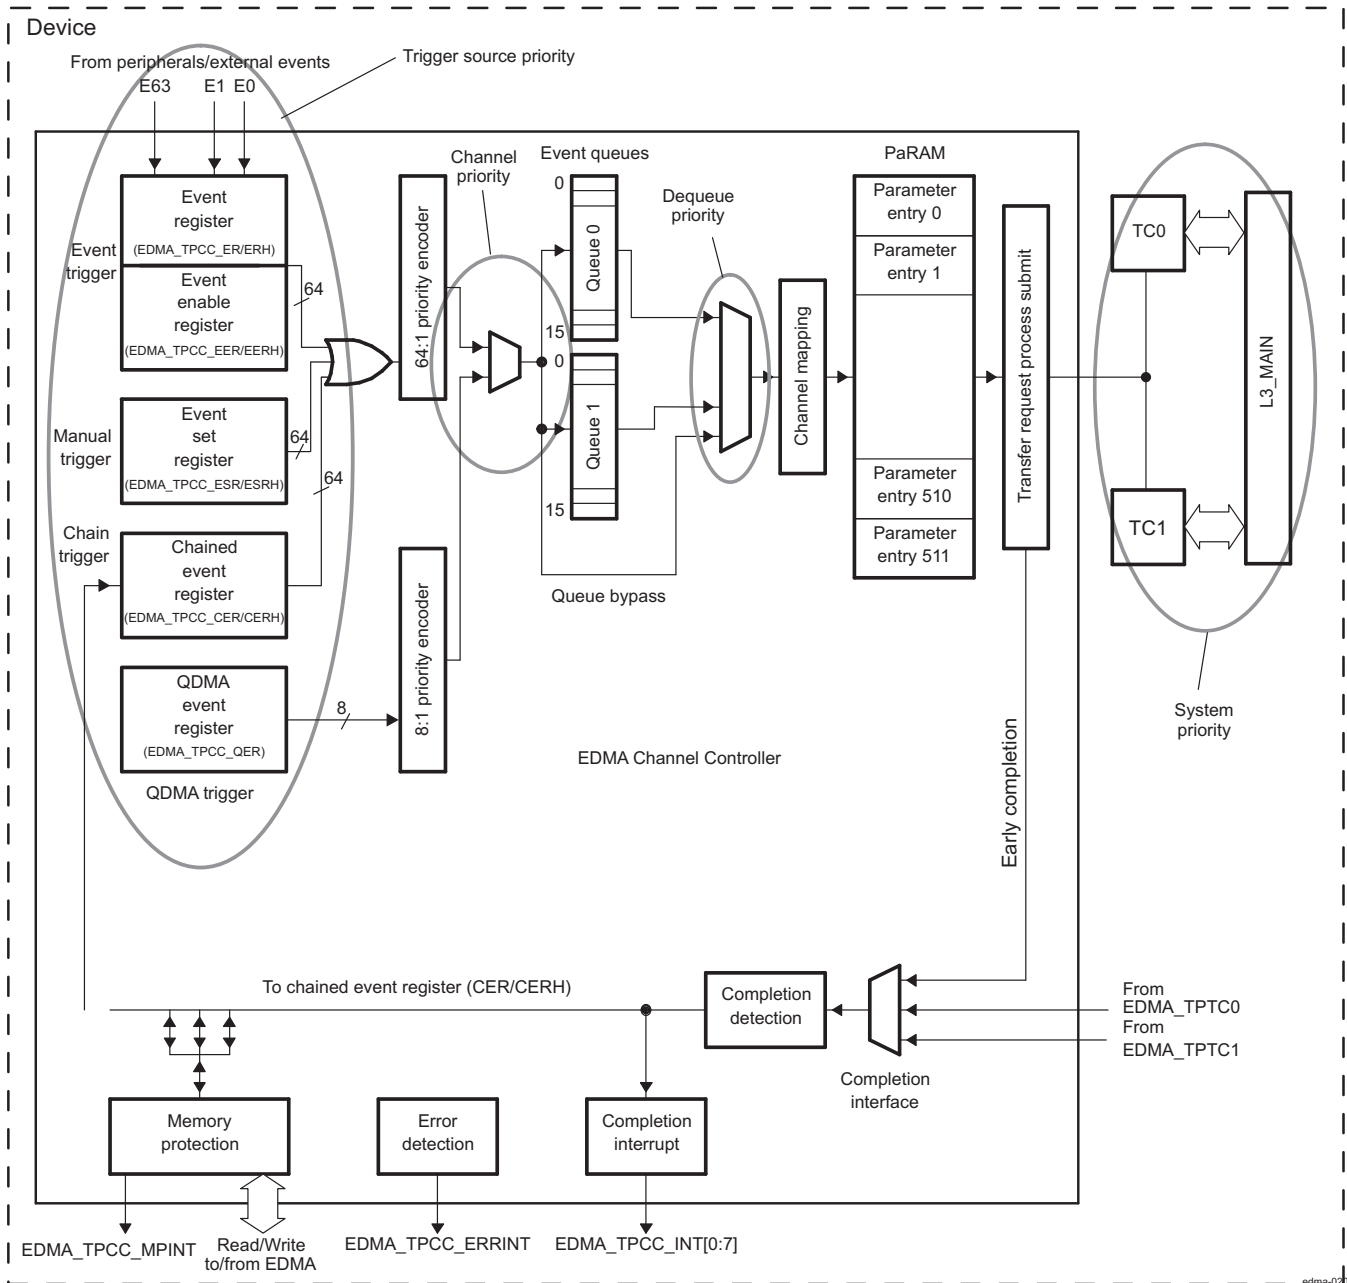

This section summarizes the data flow of a single event, from the time the event is latched to the channel controller to the time the transfer completion code is returned. The following steps list the sequence of EDMA_TPCC activity:

1. Event is asserted from an external source (peripheral or external interrupt). This also is similar for a manually-triggered, chained-triggered, or QDMA-triggered event. The event is latched into the [EDMA_TPCC_ER\[31:0\]En](#) / [EDMA_TPCC_ERH\[31:0\] En](#) (or [EDMA_TPCC_CER\[31:0\] En](#) / [EDMA_TPCC_CERH\[31:0\] En](#), [EDMA_TPCC_ESR\[31:0\] En](#) / [EDMA_TPCC_ESRH\[31:0\] En](#), [EDMA_TPCC_QER\[7:0\] En](#)) bit.
2. Once an event is prioritized and queued into the appropriate event queue, the [EDMA_TPCC_SER\[31:0\] En](#) \ [EDMA_TPCC_SERH\[31:0\] En](#) (or [EDMA_TPCC_QSER\[7:0\] En](#)) bit is set to inform the event prioritization / processing logic to disregard this event since it is already in the queue. Alternatively, if the transfer controller and the event queue are empty, then the event bypasses the queue.
3. The EDMA_TPCC processing and the submission logic evaluates the appropriate PaRAM set and determines whether it is a non-null and non-dummy transfer request (TR).
4. The EDMA_TPCC clears the [EDMA_TPCC_ER\[31:0\] En](#) / [EDMA_TPCC_ERH\[31:0\] En](#) (or [EDMA_TPCC_CER\[31:0\] En](#) / [EDMA_TPCC_CERH\[31:0\] En](#), [EDMA_TPCC_ESR\[31:0\]En](#) / [EDMA_TPCC_ESRH\[31:0\] En](#), [EDMA_TPCC_QER\[31:0\] En](#)) bit and the [EDMA_TPCC_SER\[31:0\] En](#) / [EDMA_TPCC_SERH\[31:0\] En](#) bit as soon as it determines the TR is non-null. In the case of a null set, the [EDMA_TPCC_SER\[31:0\] En](#) / [EDMA_TPCC_SERH\[31:0\] En](#) bit remains set. It submits the non-null/non-dummy TR to the associated transfer controller. If the TR was programmed for early completion, the EDMA_TPCC immediately sets the interrupt pending register ([EDMA_TPCC_IPR\[31:0\] I\[TCC\]](#) / [EDMA_TPCC_IPRH\[31:0\] I\[TCC\]](#) - 32).
5. If the TR was programmed for normal completion, the EDMA_TPCC sets the interrupt pending register ([EDMA_TPCC_IPR\[31:0\] I\[TCC\]](#) / [EDMA_TPCC_IPRH\[31:0\] I\[TCC\]](#)) when the EDMA_TPTC informs the EDMA_TPCC about completion of the transfer (returns transfer completion codes).
6. The EDMA_TPCC programs the associated EDMA_TPTC's Program Register Set with the TR.
7. The TR is then passed to the Source Active set and the DST FIFO Register Set, if both the register sets are available.
8. The Read Controller processes the TR by issuing read commands to the source slave endpoint. The Read Data lands in the Data FIFO of the EDMA_TPTC_n.
9. As soon as sufficient data is available, the Write Controller begins processing the TR by issuing write commands to the destination slave endpoint.
10. This continues until the TR completes and the EDMA_TPTC_n then signals completion status to the EDMA_TPCC.

12.4.14 EDMA controller Prioritization

The EDMA controller has many implementation rules to deal with concurrent events/channels, transfers, etc. The following subsections detail various arbitration details whenever there might be occurrence of concurrent activity. [Figure 12-21](#) shows the different places EDMA priorities come into play.

Figure 12-21. EDMA Prioritization

12.4.14.1 Channel Priority

The EDMA event registers `EDMA_TPCC_ER` and `EDMA_TPCC_ERH` capture up to 64 events, the QDMA event register `EDMA_TPCC_QER` captures QDMA events for all QDMA channels therefore, it is possible for events to occur simultaneously on the DMA/QDMA event inputs. For events arriving simultaneously, the event associated with the lowest channel number is prioritized for submission to the event queues (for DMA events, channel 0 has the highest priority and channel 63 has the lowest priority, for QDMA events, channel 0 has the highest priority and channel 7 has the lowest priority). This mechanism only sorts simultaneous events for submission to the event queues.

If a DMA and QDMA event occurs simultaneously, the DMA event always has prioritization against the QDMA event for submission to the event queues.

12.4.14.2 Trigger Source Priority

If a EDMA channel is associated with more than one trigger source (event trigger, manual trigger, and chain trigger), and if multiple events are set simultaneously for the same channel ($EDMA_TPCC_ER[31:0] E_n = 1$, $EDMA_TPCC_ESR[31:0] E_n = 1$, $EDMA_TPCC_CER[31:0] E_n = 1$), then the EDMA_TPCC always services these events in the following priority order: event trigger (via $EDMA_TPCC_ER$) is higher priority than chain trigger (via $EDMA_TPCC_CER$) and chain trigger is higher priority than manual trigger (via $EDMA_TPCC_ESR$).

This implies that if for channel 0, both $EDMA_TPCC_ER[0] E_0 = 1$ and $EDMA_TPCC_CER[0] E_0 = 1$ at the same time, then the $EDMA_TPCC_ER[0] E_0$ event is always queued before the $EDMA_TPCC_CER[0] E_0$ event.

12.4.14.3 Dequeue Priority

The priority of the associated transfer request (TR) is further mitigated by which event queue is being used for event submission (dictated by $EDMA_TPCC_DMAQNUMN_k$ and $EDMA_TPCC_QDMAQNUM$). For submission of a TR to the transfer request, events need to be de-queued from the event queues. Queue 0 has the highest dequeue priority and queue 1 the lowest.

12.4.15 EDMA Power, Reset and Clock Management

12.4.15.1 Clock and Power Management

The EDMA channel controller and transfer controller are clocked from L3MIAN1_L3_GICLK interface clock. The EDMA system runs at the L3 clock frequency.

The Auto clock gating for the EDMA_TPCC module is controlled by the $EDMA_TPCC_CLKGDIS[0]$ CLKGDIS bit at the module level.

The L3MIAN1_L3_GICLK interface clock to EDMA controller's modules are controlled by the following registers in the PRCM module:

- PRCM.CM_L3MAIN1_TPCC_CLKCTRL - manages EDMA_TPCC module clock.
- PRCM.CM_L3MAIN1_TPTC1_CLKCTRL - manages EDMA_TPTC0 module clock.
- PRCM.CM_L3MAIN1_TPTC2_CLKCTRL - manages EDMA_TPTC1 module clock.

EDMA_TPCC and EDMA_TPTC0 and EDMA_TPTC1 modules have wakeup dependances to several device modules. The wakeup dependency based on EDMA modules service requests are controlled by registers in PRCM module:

- PRCM.PM_L3MAIN1_TPCC_WKDEP - controls wakeup dependency based on TPCC service requests.
- PRCM.PM_L3MAIN1_TPTC1_WKDEP - controls wakeup dependency based on TPTC0 service requests.
- PRCM.PM_L3MAIN1_TPTC2_WKDEP - controls wakeup dependency based on TPTC1 service requests.

The EDMA_TPCC, EDMA_TPTC0 and EDMA_TPTC1 can be placed in reduced-power modes to conserve power during periods of low activity. The power management of the peripheral is controlled by the PRCM module. The PRCM acts as a master controller for power management for all peripherals on the device.

The EDMA controller can be idled on receiving a clock stop request from the PRCM. The requests to EDMA_TPCC and EDMA_TPTC0 and EDMA_TPTC1 are separate. In general, it should be verified that there are no pending activities in the EDMA controller

NOTE: When EDMA controller modules no longer require the interface clock, software can disable it at the PRCM level by configuring the MODULEMODE bit field (PRCM.CM_L3MAIN1_TPCC_CLKCTRL[1:0], PRCM.CM_L3MAIN1_TPTC1_CLKCTRL[1:0], PRCM.CM_L3MAIN1_TPTC2_CLKCTRL[1:0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it.

At the PRCM level, when all the conditions to shut off the L3MIAN1_L3_GICLK clock are met the PRCM module automatically launches a hardware handshake protocol to ensure EDMA modules are ready to have this clock switched off. Namely, the PRCM module asserts an IDLE request to the EDMA modules. For more information, refer to [Chapter 3, Power, Reset, and Clock Management](#).

12.4.15.2 Reset Considerations

A hardware resets the EDMA (EDMA_TPCC, EDMA_TPTC0 and EDMA_TPTC1) and the EDMA configuration registers. The PaRAM memory contents are undefined after device reset and it should not rely on parameters to be reset to a known state. The PaRAM entry must be initialized to a desired value before it is used. The EDMA modules are reset by CORE_RET_RST reset signal from PRCM.

12.4.16 Emulation Considerations

During debug when using the emulator, the CPU(s) may be halted on an execute packet boundary for single-stepping, benchmarking, profiling, or other debug purposes. During an emulation halt, the EDMA channel controller and transfer controller operations continue. Events continue to be latched and processed and transfer requests continue to be submitted and serviced.

Since EDMA is involved in servicing multiple master and slave peripherals, it is not feasible to have an independent behavior of the EDMA for emulation halts. EDMA functionality would be coupled with the peripherals it is servicing, which might have different behavior during emulation halts.

12.5 EDMA Transfer Examples

The EDMA channel controller performs a variety of transfers depending on the parameter configuration. The following sections provide a description and PaRAM configuration for some typical use case scenarios.

12.5.1 Block Move Example

The most basic transfer performed by the EDMA is a block move. During device operation it is often necessary to transfer a block of data from one location to another, usually between on-chip and off-chip memory.

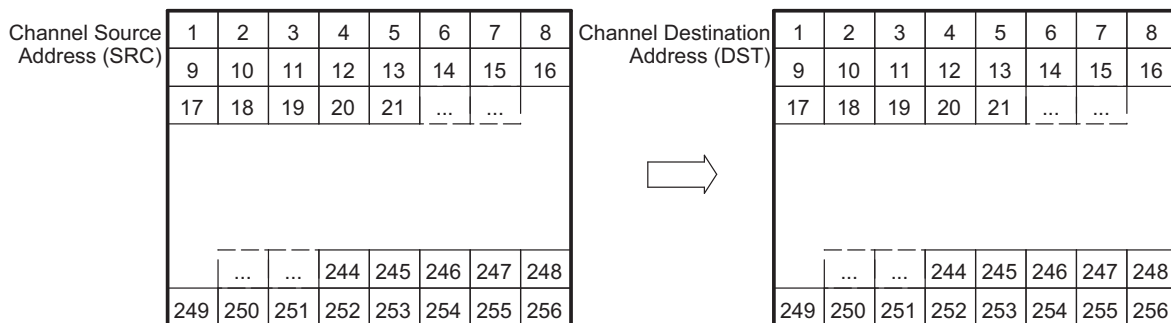

In this example, a section of data is to be copied from external memory to internal L2 SRAM as shown in [Figure 12-22](#).

The source address for the transfer is set to the start of the data block in external memory, and the destination address is set to the start of the data block in L2. If the data block is less than 64K bytes, the PaRAM configuration shown in [Figure 12-23](#) holds true with the synchronization type set to A-synchronized and indexes cleared to 0. If the amount of data is greater than 64K bytes, `EDMA_TPCC_ABCNT_n[31:16]` BCNT and the B-indexes need to be set appropriately with the synchronization type set to AB-synchronized. The `EDMA_TPCC_OPT_n[3]` STATIC bit is set to prevent linking.

This transfer example may also be set up using QDMA. For successive transfer submissions, of a similar nature, the number of cycles used to submit the transfer are fewer depending on the number of changing transfer parameters. The QDMA trigger word must be programmed to be the highest numbered offset in the PaRAM set that undergoes change.

[Figure 12-23](#) shows the parameters Block Move transfer.

12.5.2 Subframe Extraction Example

The EDMA can efficiently extract a small frame of data from a larger frame of data. By performing a 2D-to-1D transfer, the EDMA retrieves a portion of data for the CPU to process. In this example, a 640 x 480-pixel frame of video data is stored in external memory. Each pixel is represented by a 16-bit halfword. The CPU extracts a 16 x 12-pixel subframe of the image for processing. To facilitate more efficient processing time by the CPU, the EDMA places the subframe in internal L2 SRAM. Figure 12-24 shows the transfer of a subframe from external memory to L2.

The same PaRAM entry options are used for QDMA channels, as well as DMA channels. The EDMA_TPCC_OPT_n[3] STATIC bit is set to prevent linking. For successive transfers, only changed parameters need to be programmed before triggering the channel.

Figure 12-25 shows the parameters for Subframe Extraction transfer.

12.5.3 Data Sorting Example

Many applications require the use of multiple data arrays, it is often desirable to have the arrays arranged such that the first elements of each array are adjacent, the second elements are adjacent, and so on. Often this is not how the data is presented to the device. Either data is transferred via a peripheral with the data arrays arriving one after the other or the arrays are located in memory with each array occupying a portion of contiguous memory spaces. For these instances, the EDMA can reorganize the data into the desired format.

To determine the parameter set values, the following need to be considered:

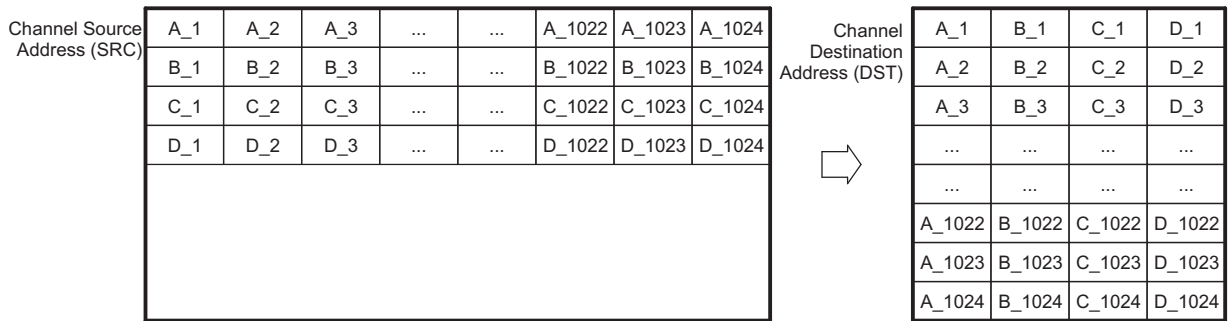

- ACNT - Program this to be the size in bytes of an element.
- BCNT - Program this to be the number of elements in a frame.
- CCNT - Program this to be the number of frames.
- SBIDX - Program this to be the size of the element or ACNT.
- DBIDX - CCNT x ACNT
- SCIDX - ACNT x BCNT
- DCIDX - ACNT

The synchronization type needs to be AB-synchronized and the `EDMA_TPCC_OPT_n[3]` STATIC bit is 0 to allow updates to the parameter set. It is advised to use normal EDMA channels for sorting.

It is not possible to sort this with a single trigger event. Instead, the channel can be programmed to be chained to itself. After BCNT elements get sorted, intermediate chaining could be used to trigger the channel again causing the transfer of the next BCNT elements and so on. [Figure 12-27](#) shows the parameter set programming for this transfer, assuming channel 0 and an element size of 4 bytes.

[Figure 12-26](#) shows the Data Sorting transfer

12.5.4 Peripheral Servicing Example

The EDMA channel controller also services peripherals in the background of CPU operation, without requiring any CPU intervention. Through proper initialization of the EDMA channels, they can be configured to continuously service on-chip and off-chip peripherals throughout the device operation. Each event available to the EDMA has its own dedicated channel, and all channels operate simultaneously. The only requirements are to use the proper channel for a particular transfer and to enable the channel event in the event enable register `EDMA_TPCC_EER`. When programming an EDMA channel to service a peripheral, it is necessary to know how data is to be presented to the processor. Data is always provided with some kind of synchronization event as either one element per event (non-bursting) or multiple elements per event (bursting).

12.5.4.1 Non-bursting Peripherals

Non-bursting peripherals include the on-chip multichannel audio serial port (McASP) and many external devices, such as codecs. Regardless of the peripheral, the EDMA channel configuration is the same.

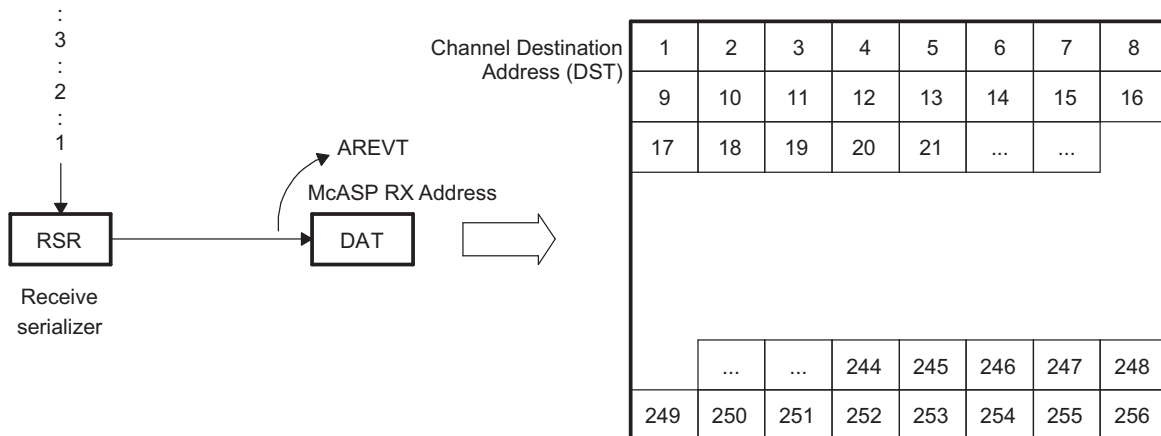

The McASP transmit and receive data streams are treated independently by the EDMA. The transmit and receive data streams can have completely different counts, data sizes, and formats.

To transfer the incoming data stream to its proper location in DDR memory, the EDMA channel must be set up for a 1D-to-1D transfer with A-synchronization. Because an event (AREVT) is generated for every word as it arrives, it is necessary to have the EDMA issue the transfer request for each element individually. Figure 12-29 shows the parameters for this transfer. The source address of the EDMA channel is set to the data port address (DAT) for McASP, and the destination address is set to the start of the data block in DDR. Because the address of serializer buffer is fixed, the source B index is cleared to 0 (no modification) and the destination B index is set to 0x2 (increment).

Based on the premise that serial data is typically a high priority, the EDMA channel should be programmed to be on queue 0.

Figure 12-28 shows servicing incoming McASP data.

12.5.4.2 Bursting Peripherals

Higher bandwidth applications require that multiple data elements be presented to the processor core for every synchronization event. This frame of data can either be from multiple sources that are working simultaneously or from a single high-throughput peripheral that streams data to/from the processor.

In this example, a port is receiving a video frame from a camera and presenting it to the DSP one array at a time. The video image is 640 × 480 pixels, with each pixel represented by a 16-bit element. The image is to be stored in external memory.

To transfer data from an external peripheral to an external buffer one array at a time based on EVT_n , channel n must be configured. Due to the nature of the data (a video frame made up of arrays of pixels) the destination is essentially a 2D entity. Figure 12-31 shows the parameters to service the incoming data with a 1D-to-2D transfer using AB-synchronization. The source address is set to the location of the video framer peripheral, and the destination address is set to the start of the data buffer. Because the input address is static, the $BDIX_n[15:0]$ SBIDX is 0 (no modification to the source address). The destination is made up of arrays of contiguous, linear elements; therefore, the $EDMA_TPCC_BIDX_n[31:16]$ DBIDX is set to pixel size, 2 bytes. $EDMA_TPCC_ABCNT_n[15:0]$ ANCT is equal to the pixel size, 2 bytes. $EDMA_TPCC_ABCNT_n[31:16]$ BCNT is set to the number of pixels in an array, 640. $EDMA_TPCC_CCNT_n[15:0]$ CCNT is equal to the total number of arrays in the block, 480. $EDMA_TPCC_CIDX_n[15:0]$ SCIDX is 0 because the source address undergoes no increment. The $EDMA_TPCC_CIDX_n[31:16]$ DCIDX is equal to the difference between the starting addresses of each array. Because one pixel is 16 bits (2 bytes), $EDMA_TPCC_CIDX_n[31:16]$ DCIDX is equal to 640×2 .

Figure 12-30 shows Bursting Peripherals Transfer.

12.5.4.3 Continuous Operation

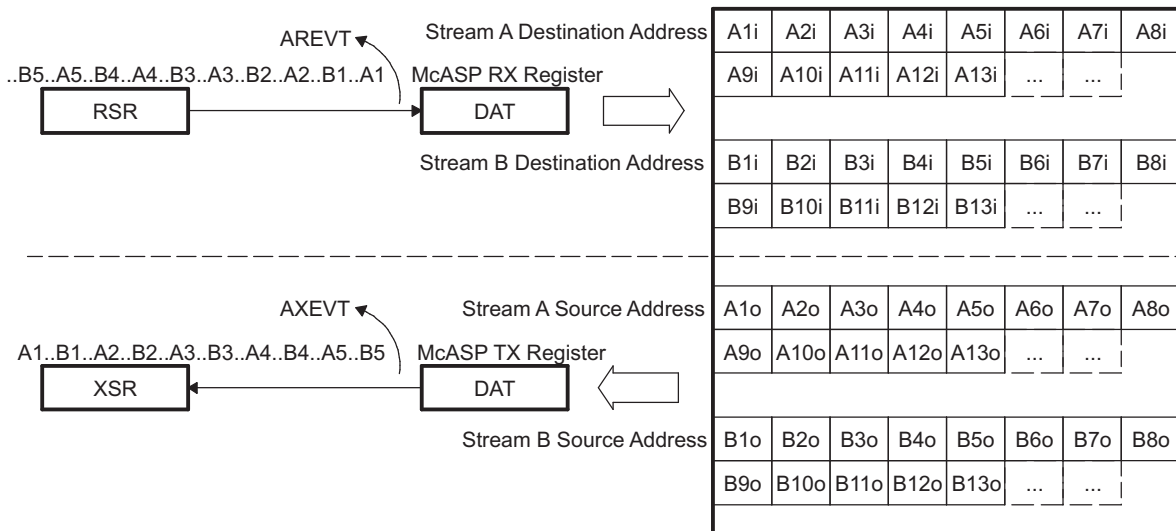

Configuring an EDMA channel to receive a single frame of data is useful, and is applicable to some systems. A majority of the time, however, data is going to be continuously transmitted and received throughout the entire operation of the processor. In this case, it is necessary to implement some form of linking such that the EDMA channels continuously reload the necessary parameter sets. In this example, McASP is configured to transmit and receive data on a T1 array. To simplify the example, only two channels are active for both transmit and receive data streams. Each channel receives packets of 128 elements. The packets are transferred from the serial port to internal memory and from internal memory to the serial port, as shown in Figure 12-32.

The McASP generates AREVT for every element received and generates AXEVT for every element transmitted. To service the data streams, the DMA channels associated with the McASP must be setup for 1D-to-1D transfers with A-synchronization.

Figure 12-33 shows the parameter entries for the channel for these transfers. To service the McASP continuously throughout DSP operation, the channels must be linked to a duplicate PaRAM set in the PaRAM. After all frames have been transferred, the EDMA channels reload and continue.

Figure 12-34 shows the reload parameters for the channel.

Figure 12-32. Servicing Continuous McASP Data Example

edma-026

12.5.4.3.1 Receive Channel

EDMA channel 15 services the incoming data stream of McASP. The source address is set to that of the receive serializer buffer, and the destination address is set to the first element of the data block. Because there are two data channels being serviced, A and B, they are to be located separately within the L2 SRAM.

To facilitate continuous operation, a copy of the PaRAM set for the channel is placed in PaRAM set 64. The LINK option is set and the link address is provided in the PaRAM set. Upon exhausting the channel 15 parameter set, the parameters located at the link address are loaded into the channel 15 parameter set and operation continues. This function continues throughout device operation until halted by the CPU.

12.5.4.3.2 Transmit Channel

EDMA channel 12 services the outgoing data stream of McASP. In this case the destination address needs no update, hence, the parameter set changes accordingly. Linking is also used to allow continuous operation by the EDMA channel, with duplicate PaRAM set entries at PaRAM set 65.

12.5.4.4 Ping-Pong Buffering

Although the previous configuration allows the EDMA to service a peripheral continuously, it presents a number of restrictions to the CPU. Because the input and output buffers are continuously being filled/emptied, the CPU must match the pace of the EDMA very closely to process the data. The EDMA receive data must always be placed in memory before the CPU accesses it, and the CPU must provide the output data before the EDMA transfers it. Though not impossible, this is an unnecessary challenge. It is particularly difficult in a 2-level cache scheme.

Ping-pong buffering is a simple technique that allows the CPU activity to be distanced from the EDMA activity. This means that there are multiple (usually two) sets of data buffers for all incoming and outgoing data streams. While the EDMA transfers the data into and out of the ping buffers, the CPU manipulates the data in the pong buffers. When both CPU and EDMA activity completes, they switch. The EDMA then writes over the old input data and transfers the new output data. Figure 12-35 shows the ping-pong scheme for this example.

To change the continuous operation example, such that a ping-pong buffering scheme is used, the EDMA channels need only a moderate change. Instead of one parameter set, there are two; one for transferring data to/from the ping buffers and one for transferring data to/from the pong buffers. As soon as one transfer completes, the channel loads the PaPARAM set for the other and the data transfers continue. Figure 12-36 shows the EDMA channel configuration required.

Each channel has two parameter sets, ping and pong. The EDMA channel is initially loaded with the ping parameters (Figure 12-37). The link address for the ping set is set to the PaPARAM offset of the pong parameter set (Figure 12-37). The link address for the pong set is set to the PaPARAM offset of the ping parameter set (Figure 12-38). The channel options, count values, and index values are all identical between the ping and pong parameters for each channel. The only differences are the link address provided and the address of the data buffer.

Figure 12-35. Ping-Pong Buffering for McASP Data Example

edma-027

12.5.4.4.1 Synchronization with the CPU

To utilize the ping-pong buffering technique, the system must signal the CPU when to begin to access the new data set. After the CPU finishes processing an input buffer (ping), it waits for the EDMA to complete before switching to the alternate (pong) buffer. In this example, both channels provide their channel numbers as their report word and set the EDMA_TPCC_OPT_n[20] TCINTEN bit to generate an interrupt after completion. When channel 15 fills an input buffer, the E15 bit in the interrupt pending register

[EDMA_TPCC_IPR](#) is set; when channel 12 empties an output buffer, the E12 bit in [EDMA_TPCC_IPR](#) is set. The CPU must manually clear these bits. With the channel parameters set, the CPU polls [EDMA_TPCC_IPR](#) to determine when to switch. The EDMA and CPU could alternatively be configured such that the channel completion interrupts the CPU. By doing this, the CPU could service a background task while waiting for the EDMA to complete.

12.5.4.5 Transfer Chaining Examples

The following examples explain the intermediate transfer complete chaining function.

12.5.4.5.1 Servicing Input/Output FIFOs with a Single Event

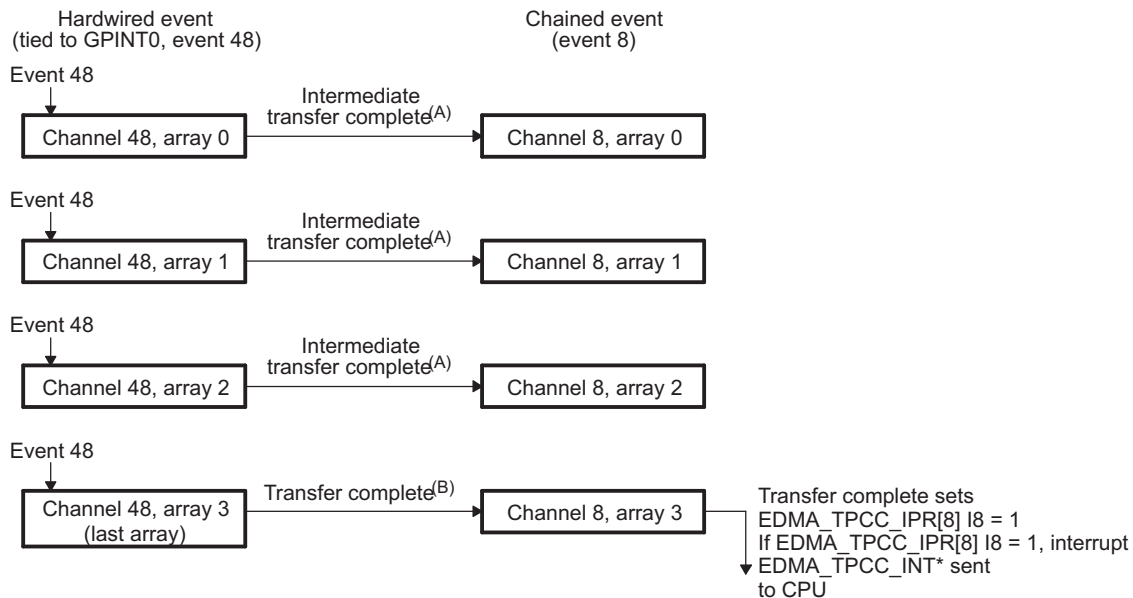

Many systems require the use of a pair of external FIFOs that must be serviced at the same rate. One FIFO buffers data input, and the other buffers data output. The EDMA channels that service these FIFOs can be set up for AB-synchronized transfers. While each FIFO is serviced with a different set of parameters, both can be signaled from a single event.

For example, an external interrupt pin can be tied to the status flags of one of the FIFOs. When this event arrives, the EDMA needs to perform servicing for both the input and output streams. Without the intermediate transfer complete chaining feature this would require two events, and thus two external interrupt pins. The intermediate transfer complete chaining feature allows the use of a single external event (for example, a GPIO event). [Figure 12-39](#) shows the EDMA setup and illustration for this example.

A GPIO event (in this case, GPINT0) triggers an array transfer. Upon completion of each intermediate array transfer of channel 48, intermediate transfer complete chaining sets the E8 bit (specified by TCC of 8) in the chained event register [EDMA_TPCC_CER](#) and provides a synchronization event to channel 8. Upon completion of the last array transfer of channel 48, transfer complete chaining—not intermediate transfer complete chaining—sets the E8 bit in [EDMA_TPCC_CER](#) (specified by [EDMA_TPCC_OPT_n\[11\]](#) TCCMODE: TCC) and provides a synchronization event to channel 8. The completion of channel 8 sets the I8 bit (specified by [EDMA_TPCC_OPT_n\[11\]](#) TCCMODE: TCC) in the interrupt pending register [EDMA_TPCC_IPR](#), which can generate an interrupt to the CPU, if the I8 bit in the interrupt enable register [EDMA_TPCC_IER](#) is set.

[Figure 12-39](#) shows the Intermediate Transfer Completion Chaining Example.

Figure 12-39. Intermediate Transfer Completion Chaining Example

Notes: (A) Intermediate transfer complete chaining synchronizes event 8
EDMA_TPCC_OPT_n[23] ITCCHEN = 1, TCC = 01000b, and sets EDMA_TPCC_CER[8] E8 = 1
(B) Transfer complete chaining synchronizes event 8
EDMA_TPCC_OPT_n[22] TCCHEN = 1, EDMA_TPCC_OPT_n[17:12] TCC = 01000b and sets EDMA_TPCC_CER[8] E8 = 1

Setup

Channel 48 parameters for chaining

- Enable transfer complete chaining:
EDMA_TPCC_OPT_n[22] TCCHEN = 1
EDMA_TPCC_OPT_n[17:12] TCC = 01000b
- Enable intermediate transfer complete chaining:
EDMA_TPCC_OPT_n[23] ITCCHEN = 1
EDMA_TPCC_OPT_n[17:12] TCC = 01000b

Channel 8 parameters for chaining

- Enable transfer complete chaining:
EDMA_TPCC_OPT_n[20] TCINTEN = 1
EDMA_TPCC_OPT_n[17:12] TCC = 01000b
- Disable intermediate transfer complete chaining:
EDMA_TPCC_OPT_n[23] ITCCHEN = 0

Event enable register (EDMA_TPCC_EER)

- Enable channel 48
EDMA_TPCC_EERH[16] E48 = 1

edma-028

12.5.4.5.2 Breaking Up Large Transfers with Intermediate Chaining

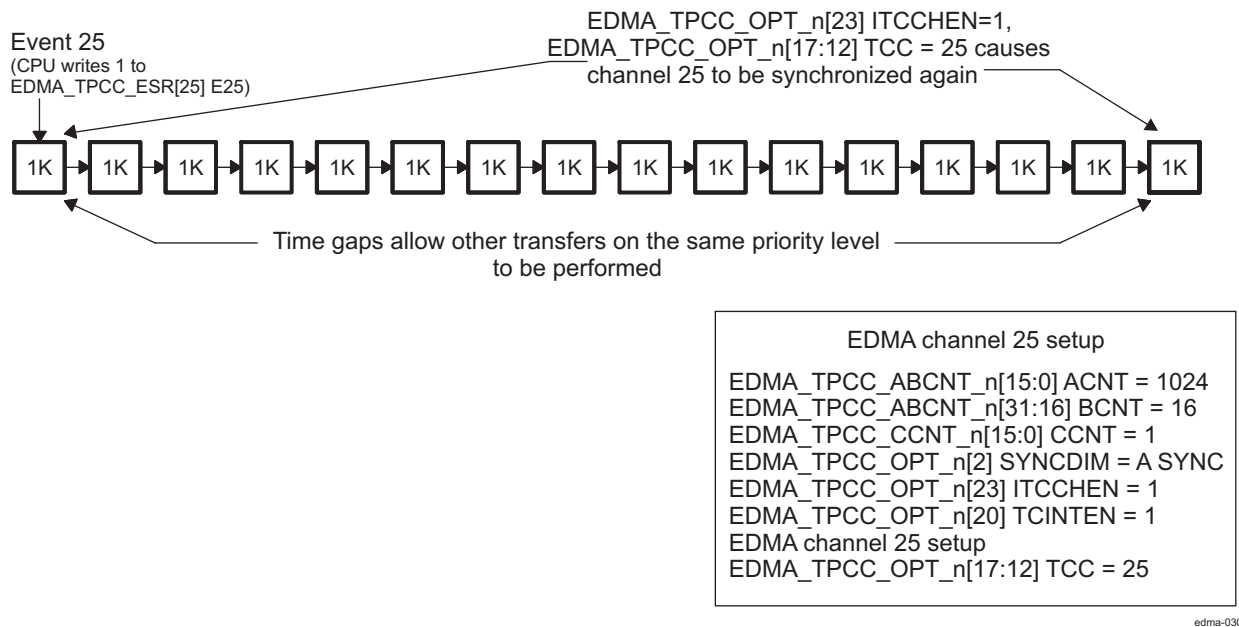

Another feature of intermediate transfer chaining EDMA_TPCC_OPT_n[23] ITCCHEN is for breaking up large transfers. A large transfer may lock out other transfers of the same priority level for the duration of the transfer. For example, a large transfer on queue 0 from the internal memory to the external memory using the EMIF may starve other EDMA transfers on the same queue. In addition, this large high-priority transfer may prevent the EMIF for a long duration to service other lower priority transfers. When a large transfer is considered to be high priority, it should be split into multiple smaller transfers. Figure 12-40 shows the EDMA setup and illustration of an example single large block transfer.

Figure 12-40. Single Large Block Transfer Example

The intermediate transfer chaining enable `EDMA_TPCC_OPT_n[23] ITCCHEN` provides a method to break up a large transfer into smaller transfers. For example, to move a single large block of memory (16K bytes), the EDMA performs an A-synchronized transfer. The element count is set to a reasonable value, where reasonable derives from the amount of time it would take to move this smaller amount of data. Assume 1 Kbyte is a reasonable small transfer in this example. The EDMA is set up to transfer 16 arrays of 1 Kbyte elements, for a total of 16K byte elements. The `EDMA_TPCC_OPT_n[17:12] TCC` field in the channel options parameter (OPT) is set to the same value as the channel number and `EDMA_TPCC_OPT_n[23] ITCCHEN` are set. In this example, EDMA channel 25 is used and `EDMA_TPCC_OPT_n[17:12] TCC` is also set to 25. The `EDMA_TPCC_OPT_n[20] TCINTEN` may also be set to trigger interrupt 25 when the last 1 Kbyte array is transferred. The CPU starts the EDMA transfer by writing to the appropriate bit of the event set register `EDMA_TPCC_ESR[25] E25`. The EDMA transfers the first 1 Kbyte array. Upon completion of the first array, intermediate transfer complete code chaining generates a synchronization event to channel 25, a value specified by the `EDMA_TPCC_OPT_n[17:12] TCC` field. This intermediate transfer completion chaining event causes EDMA channel 25 to transfer the next 1 Kbyte array. This process continues until the transfer parameters are exhausted, at which point the EDMA has completed the 16K byte transfer. This method breaks up a large transfer into smaller packets, thus providing natural time slices in the transfer such that other events may be processed. Figure 12-41 shows the EDMA setup and illustration of the broken up smaller packet transfers.

Figure 12-41. Smaller Packet Data Transfers Example

12.5.5 Setting Up an EDMA Transfer

The following list provides a quick guide for the typical steps involved in setting up a transfer.

Step 1. Initiating a DMA/QDMA channel

1. Determine the type of channel (QDMA or DMA) to be used.
2. Channel mapping
 - i. If using a QDMA channel, program the [EDMA_TPCC_QCHMAPN_j](#) with the parameter set number to which the channel maps and the trigger word.
 - ii. If using a DMA channel, program the [EDMA_TPCC_DCHMAPN_m](#) with the parameter set number to which the channel maps.
3. If the channel is being used in the context of a shadow region, ensure the [EDMA_TPCC_DRAEM_k](#) / [EDMA_TPCC_DRAEHM_k](#) for the region is properly set up to allow read write accesses to bits in the event registers and interrupt registers in the Shadow region memory map. The subsequent steps in this process should be done using the respective shadow region registers. (Shadow region descriptions and usage are provided in [Section 12.4.7.1.](#))
4. Determine the type of triggering used.
 - i. If external events are used for triggering (DMA channels), enable the respective event in [EDMA_TPCC_EER](#) / [EDMA_TPCC_EERH](#) by writing into [EDMA_TPCC_EESR](#) / [EDMA_TPCC_EESRH](#).
 - ii. If QDMA Channel is used, enable the channel in [EDMA_TPCC_QEER](#) by writing into [EDMA_TPCC_QEESR](#).
5. Queue setup
 - i. If a QDMA channel is used, set up the [EDMA_TPCC_QDMAQNUM](#) to map the channel to the respective event queue.
 - ii. If a DMA channel is used, set up the [EDMA_TPCC_DMAQNUMN_k](#) to map the event to the respective event queue.

Step 2. Parameter set setup

1. Program the PaRAM set number associated with the channel. Note that

NOTE: If it is a QDMA channel, the PaPARAM entry that is configured as trigger word is written to last. Alternatively, enable the QDMA channel (step 1-b-ii above) just before the write to the trigger word.

Step 3. Interrupt setup

1. Enable the interrupt in the [EDMA_TPCC_IER](#) / [EDMA_TPCC_IERH](#) by writing into [EDMA_TPCC_IESR](#) / [EDMA_TPCC_IESRH](#).
2. Ensure that the EDMA_TPCC completion interrupt (either the global or the shadow region interrupt) is enabled properly in the device interrupt controller.
3. Ensure the EDMA_TPCC completion interrupt (this refers to either the Global interrupt or the shadow region interrupt) is enabled properly in the Device Interrupt controller.
4. Set up the interrupt controller properly to receive the expected EDMA interrupt.

Step 4. Initiate transfer

1. This step is highly dependent on the event trigger source:
 - i. If the source is an external event coming from a peripheral, the peripheral will be enabled to start generating relevant EDMA events that can be latched to the [EDMA_TPCC_ER](#) transfer.
 - ii. For QDMA events, writes to the trigger word (step 2-a above) will initiate the transfer.
 - iii. Manually triggered transfers will be initiated by writes to the Event Set Registers [EDMA_TPCC_ESR](#) / [EDMA_TPCC_ESRH](#).
 - iv. Chained-trigger events initiate when a previous transfer returns a transfer completion code equal to the chained channel number.

Step 5. Wait for completion

1. If the interrupts are enabled as mentioned in step 3 above, then the EDMA_TPCC will generate a completion interrupt to the CPU whenever transfer completion results in setting the corresponding bits in the interrupt pending register [EDMA_TPCC_IPR](#) / [EDMA_TPCC_IPRH](#). The set bits must be cleared in the [EDMA_TPCC_IPR](#) / [EDMA_TPCC_IPRH](#) by writing to corresponding bit in [EDMA_TPCC_ICR](#) / [EDMA_TPCC_ICRH](#).
2. If polling for completion (interrupts not enabled in the device controller), then the application code can wait on the expected bits to be set in the [EDMA_TPCC_IPR](#) / [EDMA_TPCC_IPRH](#). Again, the set bits in the [EDMA_TPCC_IPR](#) / [EDMA_TPCC_IPRH](#) must be manually cleared via [EDMA_TPCC_ICR](#) / [EDMA_TPCC_ICRH](#) before the next set of transfers is performed for the same transfer completion code values.

12.6 EDMA Debug Checklist and Programming Tips

This section lists some tips to keep in mind while debugging applications using the EDMA controller.

12.6.1 EDMA Debug Checklist

Table 12-26 provides some common issues and their probable causes and resolutions.

Table 12-26. Debug Checklist

Issue	Description/Solution
<p>The transfer associated with the channel does not happen. The channel does not get serviced.</p>	<p>The EDMA_TPCC may not service a transfer request, even though the associated PaRAM set is programmed appropriately. Check for the following:</p> <ol style="list-style-type: none"> 1) Verify that events are enabled, i.e., if an external/peripheral event is latched in Event Registers EDMA_TPCC_ER / EDMA_TPCC_ERH, check that the event is enabled in the Event Enable Registers EDMA_TPCC_EER / EDMA_TPCC_EERH. Similarly, for QDMA channels, check that QDMA events are appropriately enabled in the QDMA Event Enable Register EDMA_TPCC_QEER. 2) Verify that the DMA or QDMA Secondary Event Register EDMA_TPCC_SER / EDMA_TPCC_SERH / EDMA_TPCC_QSER bits corresponding to the particular event or channel are not set.
<p>The Secondary Event Registers bits are set, not allowing additional transfers to occur on a channel.</p>	<p>It is possible that a trigger event was received when the parameter set associated with the channel/event was a NULL set for a previous transfer on the channel. This is typical in two cases:</p> <ol style="list-style-type: none"> 1) QDMA channels: Typically if the parameter set is non-static and expected to be terminated by a NULL set (i.e., EDMA_TPCC_OPT_n[3] STATIC = 0x0, EDMA_TPCC_LNK_n[15:0] LINK = 0xFFFF), the parameter set is updated with a NULL set after submission of the last TR. Because QDMA channels are auto-triggerred, this update caused the generation of an event. An event generated for a NULL set causes an error condition and results in setting the bits corresponding to the QDMA channel in the EDMA_TPCC_QEMR and EDMA_TPCC_QSER. This will disable further prioritization of the channel. 2) DMA channels used in a continuous mode: The peripheral may be set up to continuously generate infinite events (for instance, in case of McASP, every time the data shifts out from the DXR register, it generates an XEVT). The parameter set may be programmed to expect only a finite number of events and to be terminated by a NULL link. After the expected number of events, the parameter set is reloaded with a NULL parameter set. Because the peripheral will generate additional events, an error condition is set in the EDMA_TPCC_SER[31:0] En and EDMA_TPCC_EMR[31:0] En set, preventing further event prioritization. <p>Check the number of events received is limited to the expected number of events for which the parameter set is programmed, or check the bits corresponding to particular channel or event are not set in the Secondary event registers (EDMA_TPCC_SER / EDMA_TPCC_SERH / EDMA_TPCC_QSER) and Event Missed Registers (EDMA_TPCC_EMR / EDMA_TPCC_EMRH / EDMA_TPCC_QEMR) before trying to perform subsequent transfers for the event/channel.</p>
<p>Completion interrupts are not asserted, or no further interrupts are received after the first completion interrupt.</p>	<p>Check the following:</p> <ol style="list-style-type: none"> 1) The interrupt generation is enabled in the EDMA_TPCC_OPT_n of the associated PaRAM set (EDMA_TPCC_OPT_n[20] TCINTEN = 0x1 and/or EDMA_TPCC_OPT_n[20] ITCINTEN = 0x1). 2) The interrupts are enabled in the EDMA Channel Controller, via the Interrupt Enable Registers (EDMA_TPCC_IER / EDMA_TPCC_IERH). 3) The corresponding interrupts are enabled in the device interrupt controller. 4) The set interrupts are cleared in the interrupt pending registers (EDMA_TPCC_IPR / EDMA_TPCC_IPRH) before exiting the transfer completion interrupt service routine (ISR). See Section 12.4.9.1.2 Clearing Transfer Completion Interrupts for details on writing EDMA ISRs. 5) If working with shadow region interrupts, make sure that the DMA Region Access registers (EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k) are set up properly, because the EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k registers act as secondary enables for shadow region completion interrupts, along with the EDMA_TPCC_IER / EDMA_TPCC_IERH registers. <p>If working with shadow region interrupts, make sure that the bits corresponding to the transfer completion code EDMA_TPCC_OPT_n[17:12] TCC value are also enabled in the EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k registers. For instance, if the PaRAM set associated with Channel 0 returns a completion code of 63 EDMA_TPCC_OPT_n[17:12] TCC = 63, ensure that EDMA_TPCC_DRAEHM_k[31] E63 is also set for a shadow region completion interrupt because the interrupt pending register bit set will be EDMA_TPCC_IPRH[31] I63 (not EDMA_TPCC_IPR[0] I0).</p>

12.6.2 EDMA Programming Tips

1. For several registers, the setting and clearing of bits needs to be done via separate dedicated registers.
 For example, the Event Register ([EDMA_TPCC_ER](#) / [EDMA_TPCC_ERH](#)) can only be cleared by writing a 1 to the corresponding bits in the Event Clear Registers ([EDMA_TPCC_ECR](#) / [EDMA_TPCC_ECRH](#)). Similarly, the Event Enable Register ([EDMA_TPCC_EER](#) / [EDMA_TPCC_EERH](#)) bits can only be set with writing of 0x1 to the Event Enable Set Registers ([EDMA_TPCC_EESR](#) / [EDMA_TPCC_EESRH](#)) and cleared with writing of 0x1 to the corresponding bits in the Event Enable Clear Register ([EDMA_TPCC_EECR](#) / [EDMA_TPCC_EECRH](#)).
2. Writes to the shadow region memory maps are governed by region access registers ([EDMA_TPCC_DRAE](#) / [EDMA_TPCC_DRAEHM_k](#) / [EDMA_TPCC_QRAEN_k](#)). If the appropriate channels are not enabled in these registers, read/write access to the shadow region memory map is not enabled.
3. When working with shadow region completion interrupts, ensure that the DMA Region Access Registers ([EDMA_TPCC_DRAEM_k](#) / [EDMA_TPCC_DRAEHM_k](#)) for every region are set in a mutually exclusive way (unless it is a requirement for an application). If there is an overlap in the allocated channels and transfer completion codes (setting of Interrupt Pending Register bits) in the region resource allocation, it results in multiple shadow region completion interrupts.
 For example, if [EDMA_TPCC_DRAEM_k.DRAEM_0\[0\]](#) E0 and [EDMA_TPCC_DRAEM_k.DRAEM_1\[0\]](#) E0 are both set, then on completion of a transfer that returns a TCC = 0x0, they will generate both shadow region 0 and 1 completion interrupts.
4. While programming a non-dummy parameter set, ensure the [EDMA_TPCC_CCNT_n\[15:0\]](#) CCNT is not left to zero.
5. Enable the EDMA_TPCC error interrupt in the device controller and attach an interrupt service routine (ISR) to ensure that error conditions are not missed in an application and are appropriately addressed with the ISR.
6. Depending on the application, it can want to break large transfers into smaller transfers and use self-chaining to prevent starvation of other events in an event queue.
7. In applications where a large transfer is broken into sets of small transfers using chaining or other methods, it chooses to use the early chaining option to reduce the time between the sets of transfers and increase the throughput.
 However, keep in mind that with early completion, all data might have not been received at the end point when completion is reported because the EDMA_TPCC internally signals completion when the TR is submitted to the EDMA_TPTC, potentially before any data has been transferred.
8. The event queue entries can be observed to determine the last few events if there is a system failure (provided the entries were not bypassed).

7	QTHRCD7	Queue Threshold Error for Q7 0x0: Watermark/threshold has not been exceeded. 0x1: Watermark/threshold has been exceeded. QTHRCD7 can be cleared by writing a '1' to corresponding bit in EDMA_TPCC_CCERRCLR register. If any bit in the EDMA_TPCC_CCERR register is set (and all errors (including EDMA_TPCC_EMR/EDMA_TPCC_QEMR) were previously clear), then an error will be signaled with the TPCC error interrupt.	R	0x0
6	QTHRCD6	Queue Threshold Error for Q6 0x0 : Watermark/threshold has not been exceeded. 0x1 : Watermark/threshold has been exceeded. QTHRCD6 can be cleared by writing a '1' to corresponding bit in EDMA_TPCC_CCERRCLR register. If any bit in the EDMA_TPCC_CCERR register is set (and all errors (including EDMA_TPCC_EMR/EDMA_TPCC_QEMR) were previously clear), then an error will be signaled with the TPCC error interrupt.	R	0x0
5	QTHRCD5	Queue Threshold Error for Q5 0x0 : Watermark/threshold has not been exceeded. 0x1 : Watermark/threshold has been exceeded. QTHRCD5 can be cleared by writing a '1' to corresponding bit in EDMA_TPCC_CCERRCLR register. If any bit in the EDMA_TPCC_CCERR register is set (and all errors (including EDMA_TPCC_EMR/EDMA_TPCC_QEMR) were previously clear), then an error will be signaled with the TPCC error interrupt.	R	0x0

Bits	Field Name	Description	Type	Reset
4	QTHRXCD4	Queue Threshold Error for Q4 0x0: Watermark/threshold has not been exceeded. 0x1: Watermark/threshold has been exceeded. QTHRXCD4 can be cleared by writing a '1' to corresponding bit in EDMA_TPCC_CCERRCLR register. If any bit in the EDMA_TPCC_CCERR register is set (and all errors (including EDMA_TPCC_EMR/EDMA_TPCC_QEMR) were previously clear), then an error will be signaled with the TPCC error interrupt.	R	0x0
3	QTHRXCD3	Queue Threshold Error for Q3 0x0: Watermark/threshold has not been exceeded. 0x1 : Watermark/threshold has been exceeded. QTHRXCD3 can be cleared by writing a '1' to corresponding bit in EDMA_TPCC_CCERRCLR register. If any bit in the EDMA_TPCC_CCERR register is set (and all errors (including EDMA_TPCC_EMR/EDMA_TPCC_QEMR) were previously clear), then an error will be signaled with the TPCC error interrupt.	R	0x0
2	QTHRXCD2	Queue Threshold Error for Q2 0x0: Watermark/threshold has not been exceeded. 0x1: Watermark/threshold has been exceeded. QTHRXCD2 can be cleared by writing a '1' to corresponding bit in EDMA_TPCC_CCERRCLR register. If any bit in the EDMA_TPCC_CCERR register is set (and all errors (including EDMA_TPCC_EMR/EDMA_TPCC_QEMR) were previously clear), then an error will be signaled with the TPCC error interrupt.	R	0x0
1	QTHRXCD1	Queue Threshold Error for Q1 0x0: Watermark/threshold has not been exceeded. 0x1: Watermark/threshold has been exceeded. QTHRXCD1 can be cleared by writing a '1' to corresponding bit in EDMA_TPCC_CCERRCLR register. If any bit in the EDMA_TPCC_CCERR register is set (and all errors (including EDMA_TPCC_EMR/EDMA_TPCC_QEMR) were previously clear), then an error will be signaled with the TPCC error interrupt.	R	0x0
0	QTHRXCD0	Queue Threshold Error for Q0: 0x0: Watermark/threshold has not been exceeded. 0x1: Watermark/threshold has been exceeded. QTHRXCD0 can be cleared by writing a '1' to corresponding bit in EDMA_TPCC_CCERRCLR register. If any bit in the EDMA_TPCC_CCERR register is set (and all errors (including EDMA_TPCC_EMR/EDMA_TPCC_QEMR) were previously clear), then an error will be signaled with the TPCC error interrupt.	R	0x0

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																ETYPE	ENUM														

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Reserved	R	0x0
7:6	ETYPE	Event Type: Specifies the specific Event Type for the given entry in the Event Queue.	R	0x0
5:0	ENUM	Event Number: Specifies the specific Event Number for the given entry in the Event Queue. For DMA Channel events (EDMA_TPCC_ER / EDMA_TPCC_ESR / EDMA_TPCC_CER), ENUM will range between 0 and NUM_DMACH (up to 63). For QDMA Channel events (EDMA_TPCC_QER), ENUM will range between 0 and NUM_QDMACH (up to 7).	R	0x0

RESERVED								THRXCD	RESERVED				WM				RESERVED				NUMVAL				RESERVED				STRTPTR			

Bits	Field Name	Description	Type	Reset
31:25	RESERVED	Reserved	R Returns 0's	0x0
24	THRXCD	Threshold Exceeded 0x0 : Threshold specified by QWMTHR(A B).Qn has not been exceeded. 0x1 : Threshold specified by QWMTHR(A B).Qn has been exceeded. THRXCD is cleared via EDMA_TPCC_CCERR . WMCLRn bit.	R	0x0
23:21	RESERVED	Reserved	R Returns 0's	0x0
20:16	WM	Watermark for Maximum Queue Usage: Watermark tracks the most entries that have been in QueueN since reset or since the last time that the watermark (WM) was cleared. QSTATn. WM is cleared via EDMA_TPCC_CCERR .WMCLRn bit. Legal values: 0x0: empty 0x10: full	R	0x0
15:13	RESERVED	Reserved	Returns 0's	0x0
12:8	NUMVAL	Number of Valid Entries in QueueN: Represents the total number of entries residing in the Queue Manager FIFO at a given instant. Always enabled. Legal values: = 0x0 (empty) to 0x10 (full) 0x0: empty 0x10: full	R	0x0
7:4	RESERVED	Reserved	Returns 0's	0x0
3:0	STRTPTR	Start Pointer: Represents the offset to the head entry of QueueN, in units of *entries*. Always enabled. Legal values: 0x0: 0th entry 0xF: 15th entry	R	0x0

Table 12-110. EDMA_TPCC_ER (continued)

Description	<p>Event Register: If EDMA_TPCC_ER.En bit is set and the EDMA_TPCC_EER.En bit is also set, then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. EDMA_TPCC_ER.En bit is set when the input event #n transitions from inactive (low) to active (high), regardless of the state of EDMA_TPCC_EER.En bit. EDMA_TPCC_ER.En bit is cleared when the corresponding event is prioritized and serviced. If the EDMA_TPCC_ER.En bit is already set and a new inactive to active transition is detected on the input event #n input AND the corresponding bit in the EDMA_TPCC_EER register is set, then the corresponding bit in the Event Missed Register is set. Event N can be cleared via sw by writing a '1' to the EDMA_TPCC_ECR pseudo-register.</p>

Table 12-126. EDMA_TPCC_EER

Address Offset	0x0000 1020	Instance	SYS_EDMA_TPCC
Physical Address	0x4330 1020 0x40D1 1020 0x4151 1020 0x01D1 1020 0x420A 1020		DSP1_EDMA_TPCC DSP2_EDMA_TPCC DSP_EDMA_TPCC EVE_EDMA_TPCC
Description	Event Enable Register: Enables DMA transfers for EDMA_TPCC_ER.En pending events. EDMA_TPCC_ER.En is set based on externally asserted events (via tpcc_eventN_pi). This register has no effect on Chained Event Register (EDMA_TPCC_CER) or Event Set Register (EDMA_TPCC_ESR). Note that if a bit is set in EDMA_TPCC_ER.En while EDMA_TPCC_EER.En is disabled, no action is taken. If EDMA_TPCC_EER.En is enabled at a later point (and EDMA_TPCC_ER.En has not been cleared via SW) then the event will be recognized as a valid 'TR Sync'. EDMA_TPCC_EER.En is not directly writeable. Events can be enabled via writes to EDMA_TPCC_EESR and can be disabled via writes to EDMA_TPCC_EECR register. EDMA_TPCC_EER.En = 0: EDMA_TPCC_ER.En is not enabled to trigger DMA transfers. EDMA_TPCC_EER.En = 1: EDMA_TPCC_ER.En is enabled to trigger DMA transfers.

Description	Secondary Event Clear Register (High Part) The secondary event clear register is used to clear the status of the EDMA_TPCC_SERH registers. CPU write of '1' to the EDMA_TPCC_SECRH .En bit clears the EDMA_TPCC_SERH register. CPU write of '0' has no effect.

Table 12-168. EDMA_TPCC_QER

Address Offset	0x0000 1080	Instance	SYS_EDMA_TPCC DSP1_EDMA_TPCC DSP2_EDMA_TPCC DSP_EDMA_TPCC EVE_EDMA_TPCC
Physical Address	0x4330 1080 0x40D1 1080 0x4151 1080 0x01D1 1080 0x420A 1080		
Description	QDMA Event Register: If EDMA_TPCC_QER.En bit is set, then the corresponding QDMA channel is prioritized vs. other qdma events for submission to the TC. EDMA_TPCC_QER.En bit is set when a vbus write byte matches the address defined in the QCHMAPn register. EDMA_TPCC_QER.En bit is cleared when the corresponding event is prioritized and serviced. EDMA_TPCC_QER.En is also cleared when user writes a '1' to the EDMA_TPCC_QSECR.En bit. If the EDMA_TPCC_QER.En bit is already set and a new QDMA event is detected due to user write to QDMA trigger location and EDMA_TPCC_QEER register is set, then the corresponding bit in the QDMA Event Missed Register is set.

Address Offset	0x0000 1084		
Physical Address	0x4330 1084 0x40D1 1084 0x4151 1084 0x01D1 1084 0x420A 1084	Instance	SYS_EDMA_TPCC DSP1_EDMA_TPCC DSP2_EDMA_TPCC DSP_EDMA_TPCC EVE_EDMA_TPCC
Description	QDMA Event Enable Register Enabled/disabled QDMA address comparator for QDMA Channel N. EDMA_TPCC_QEER .En is not directly writeable. QDMA channels can be enabled via writes to EDMA_TPCC_QEESR and can be disabled via writes to EDMA_TPCC_QEECR register. EDMA_TPCC_QEER .En = 1, The corresponding QDMA channel comparator is enabled and Events will be recognized and latched in EDMA_TPCC_QER .En. EDMA_TPCC_QEER .En = 0, The corresponding QDMA channel comparator is disabled. Events will not be recognized/latched in EDMA_TPCC_QER .En.

Description	Event Register If EDMA_TPCC_ER .En bit is set and the EDMA_TPCC_EER .En bit is also set, then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. EDMA_TPCC_ER .En bit is set when the input event #n transitions from inactive (low) to active (high), regardless of the state of EDMA_TPCC_EER .En bit. EDMA_TPCC_ER .En bit is cleared when the corresponding event is prioritized and serviced. If the EDMA_TPCC_ER .En bit is already set and a new inactive to active transition is detected on the input event #n input AND the corresponding bit in the EDMA_TPCC_EER register is set, then the corresponding bit in the Event Missed Register is set. Event N can be cleared via sw by writing a '1' to the EDMA_TPCC_ECR pseudo-register.

Table 12-192. EDMA_TPCC_CER_RN_k

Address Offset	0x0000 2018 + (0x200 * k)		
Physical Address	0x4330 2018 + (0x200 * k) 0x40D1 2018 + (0x200 * k) 0x4151 2018 + (0x200 * k) 0x01D1 2018 + (0x200 * k) 0x420A 2018 + (0x200 * k)	Instance	SYS_EDMA_TPCC DSP1_EDMA_TPCC DSP2_EDMA_TPCC DSP_EDMA_TPCC EVE_EDMA_TPCC
Description	Chained Event Register If EDMA_TPCC_CER.En bit is set (regardless of state of EDMA_TPCC_EER.En), then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. EDMA_TPCC_CER.En bit is set when a chaining completion code is returned from one of the 3PTCs via the completion interface, or is generated internally via Early Completion path. EDMA_TPCC_CER.En bit is cleared when the corresponding event is prioritized and serviced. If the EDMA_TPCC_CER.En bit is already set and the corresponding chaining completion code is returned from the TC, then the corresponding bit in the Event Missed Register is set. EDMA_TPCC_CER.En cannot be set or cleared via software.

Description	Secondary Event Clear Register (High Part) The secondary event clear register is used to clear the status of the EDMA_TPCC_SERH registers. CPU write of '0' has no effect. CPU write of '1' to the EDMA_TPCC_SECRH .En bit clears the EDMA_TPCC_SERH register.

Table 12-238. EDMA_TPCC_QER_RN_k

Address Offset	0x0000 2080 + (0x200 * k)		
Physical Address	0x4330 2080 + (0x200 * k) 0x40D1 2080 + (0x200 * k) 0x4151 2080 + (0x200 * k) 0x01D1 2080 + (0x200 * k) 0x420A 2080 + (0x200 * k)	Instance	SYS_EDMA_TPCC DSP1_EDMA_TPCC DSP2_EDMA_TPCC DSP_EDMA_TPCC EVE_EDMA_TPCC
Description	QDMA Event Register If EDMA_TPCC_QER.En bit is set, then the corresponding QDMA channel is prioritized vs. other qdma events for submission to the TC. EDMA_TPCC_QER.En bit is set when a vbus write byte matches the address defined in the QCHMAPn register. EDMA_TPCC_QER.En bit is cleared when the corresponding event is prioritized and serviced. EDMA_TPCC_QER.En is also cleared when user writes a '1' to the EDMA_TPCC_QSECR.En bit. If the EDMA_TPCC_QER.En bit is already set and a new QDMA event is detected due to user write to QDMA trigger location and EDMA_TPCC_QEER register is set, then the corresponding bit in the QDMA Event Missed Register is set.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BCNT																ACNT															

Bits	Field Name	Description	Type	Reset
31:16	BCNT	BCNT: Count for 2nd Dimension: BCNT is a 16-bit unsigned value that specifies the number of arrays of length ACNT. For normal operation, valid values for BCNT can be anywhere between 1 and 65535. Therefore, the maximum number of arrays in a frame is 65535 (64K-1 arrays). BCNT=1 means 1 array in the frame, and BCNT=0 means 0 arrays in the frame. In normal mode, a BCNT of '0' is considered as either a Null or Dummy transfer. A Dummy or Null transfer will generate a Completion code depending on the settings of the completion bit fields of the OPT field. If the EDMA_TPCC_OPT_n.WIMODE bit is set, then the programmed BCNT value will be incremented by '1' before submission to TC. I.e., 0 means 1, 1 means 2, 2 means 3, ..., 0xFFFFE means 0xFFFF. A value of 0xFFFF is an illegal value that will be treated as a Null TR.	RW	0x0

Bits	Field Name	Description	Type	Reset
15:0	ACNT	<p>ACNT: number of bytes in 1st dimension: ACNT represents the number of bytes within the first dimension of a transfer. ACNT is a 16-bit unsigned value with valid values between 0 and 65535. Therefore, the maximum number of bytes in an array is 65535 bytes (64K-1 bytes). ACNT must be greater than or equal to '1' for a TR to be submitted to TC. An ACNT of '0' is considered as either a null or dummy transfer. A Dummy or Null transfer will generate a Completion code depending on the settings of the completion bit fields of the OPT field. If the EDMA_TPCC_OPT_n.WIMODE bit is set then the ACNT field represents a word count. The CC must internally multiply by 4 to translate the word count to a byte count prior to submission to the TC. The 2 MSBs of the 16-bit ACNT are reserved and should always be written as 'b00' by the user. If user writes a value other than 0, it will still be treated as 0 since the multiply-by-4 operation (to translate between a word count and a byte count) will drop the 2 msbits. For dummy and null transfer definition, the ACNT definition will disregard the 2 msbits. I.e., a programmed ACNT value of 0x8000 in WI-mode will be treated as 0 byte transfer, resulting in null or dummy operation dependent on the state of BCNT and CCNT.</p>	RW	0x0

Description	Link and Reload parameters		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BCNTRLD																LINK															

Bits	Field Name	Description	Type	Reset
31:16	BCNTRLD	BCNT Reload: BCNTRLD is a 16-bit unsigned value used to reload the BCNT field once the last array in the 2nd dimension is transferred. This field is only used for A-Sync'ed transfers. In this case, the CC decrements the BCNT value by one on each TR submission. When BCNT (conceptually) reaches zero, then the CC decrements CCNT and uses the BCNTRLD value to reinitialize the BCNT value. For AB-synchronized transfers, the CC submits the BCNT in the TR and therefore the TC is responsible to keep track of BCNT, not thus BCNTRLD is a don't care field.	RW	0x0

Bits	Field Name	Description	Type	Reset
15:0	LINK	<p>Link Address:</p> <p>The CC provides a mechanism to reload the current PaRAM Entry upon its natural termination (i.e., after count fields are decremented to '0') with a new PaRAM Entry. This is called 'linking'. The 16-bit parameter LINK specifies the byte address offset in the PaRAM from which the CC loads/reloads the next PaRAM entry in the link. The CC should disregard the value in the upper 2 bits of the LINK field as well as the lower 5-bits of the LINK field. The upper two bits are ignored such that the user can program either the 'literal' byte address of the LINK parameter or the 'PaRAM base-relative' address of the link field. Therefore, if the user uses the literal address with a range from 0x4000 to 0x7FFF, it will be treated as a PaRAM-base-relative value of 0x0000 to 0x3FFF. The lower-5 bits are ignored and treated as 'b00000, thereby guaranteeing that all Link pointers point to a 32-byte aligned PaRAM entry. In the latter case (5-lsbs), behavior is undefined for the user (i.e., don't have to test it). In the former case (2 msbs), user should be able to take advantage of this feature (i.e., do have to test it). If a Link Update is requested to a PaRAM address that is beyond the actual range of implemented PaRAM, then the Link will be treated as a Null Link and all 0s plus 0xFFFF will be written to the current entry location. A LINK value of 0xFFFF is referred to as a NULL link which should cause the CC to write 0x0 to all entries of the current PaRAM Entry except for the LINK field which is set to 0xFFFF. The Priv/Privid state is overwritten to 0x0 when linking. MSBs and LSBS should not be masked when comparing against the 0xFFFF value. I.e., a value of 0x3FFE is a non-NUL PaRAM link field.</p>	RW	0x0

DCIDX																SCIDX															

Bits	Field Name	Description	Type	Reset
31:16	DCIDX	Destination Frame Index: DCIDX is a 16-bit signed value (2's complement) used for destination address modification for the 3rd dimension. It is a signed value between -32768 and 32767. It provides a byte address offset from the beginning of the current array (pointed to by DST address) to the beginning of the first destination array in the next frame. It applies to both A-sync and AB-sync transfers. Note that when DCIDX is applied, the current array in an A-sync transfer is the last array in the frame, while the current array in a ABsync transfer is the first array in the frame.	RW	0x0
15:0	SCIDX	Source Frame Index: SCIDX is a 16-bit signed value (2's complement) used for source address modification for the 3rd dimension. It is a signed value between -32768 and 32767. It provides a byte address offset from the beginning of the current array (pointed to by SRC address) to the beginning of the first source array in the next frame. It applies to both A-sync and AB-sync transfers. Note that when SCIDX is applied, the current array in an A-sync transfer is the last array in the frame, while the current array in a AB-sync transfer is the first array in the frame.	RW	0x0

RESERVED																CCNT															

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Reserved	RW	0x0
15:0	CCNT	CCNT: Count for 3rd Dimension: CCNT is a 16-bit unsigned value that specifies the number of frames in a block. Valid values for CCNT can be anywhere between 1 and 65535. Therefore, the maximum number of frames in a block is 65535 (64K-1 frames). CCNT of '1' means '1' frame in the block, and CCNT of '0' means '0' frames in the block. A CCNT value of '0' is considered as either a null or dummy transfer. A Dummy or Null transfer will generate a Completion code depending on the settings of the completion bit fields of the OPT field. WIMODE has no affect on CCNT operation.	RW	0x0

RESERVED														TCCHEN	TCINTEN	RESERVED	TCC				RESERVED				STAT						

Bits	Field Name	Description	Type	Reset
31:18	RESERVED	Reserved	R Return 0's	0x0
17	TCCHEN	Contains the EDMA_TPCC_OPT_n[17] TCCHEN value programmed by the user for the Read or Write transaction that resulted in an error.	R	0x0
16	TCINTEN	Contains the EDMA_TPCC_OPT_n[16] TCINTEN value programmed by the user for the Read or Write transaction that resulted in an error.	R	0x0
15:14	RESERVED	Reserved	R Return 0's	0x0
13:8	TCC	Transfer Complete Code: Contains the EDMA_TPCC_OPT_n[13:8] TCC value programmed by the user for the Read or Write transaction that resulted in an error.	R	0x0
7:4	RESERVED	Reserved	R Return 0's	0x0
3:0	STAT	Transaction Status: Stores the non-zero status/error code that was detected on the read status or write status bus. MS-bit effectively serves as the read vs. write error code. If read status and write status are returned on the same cycle, then the TC chooses non-zero version. If both are non-zero then write status is treated as higher priority. Encoding of errors matches the CBA spec and is summarized here: 0xF =	R	0x0

Interrupt Controllers

This chapter describes the interrupt controllers (INTCs) in the device.

Topic	Page
13.1 Interrupt Controllers Overview	4553
13.2 Interrupt Controllers Environment	4555
13.3 Interrupt Controllers Integration	4556
13.4 Interrupt Controllers Functional Description	4582

13.1 Interrupt Controllers Overview

The device has a large number of interrupts to service the needs of its many peripherals and subsystems. The DSP (x2), IPU, and EVE subsystems are capable of servicing these interrupts via their integrated interrupt controllers. In addition, each processor's interrupt controller is preceded by an Interrupt Controller Crossbar (IRQ_CROSSBAR) that provides flexibility in mapping the device interrupts to processor interrupt inputs. For more information about IRQ crossbar, see [Chapter 14, Control Module](#).

C66x DSP Subsystem Interrupt Controller (DSPx_INTC, where x = 1, 2)

There are two Digital Signal Processing (DSP) subsystems in the device - DSP1, and DSP2. Each DSP subsystem integrates an interrupt controller - DSPx_INTC, which interfaces the system events to the C66x core interrupt and exceptions inputs. It combines up to 128 interrupts into 12 prioritized interrupts presented to the C66x CPU.

For detailed information about this module, see [Chapter 4, DSP Subsystem](#).

Dual Cortex-M4 IPU Subsystem Interrupt Controller (IPU_Cx_INTC, where x = 1, 2)

There is one Image Processing Unit (IPU) subsystem in the device. The IPU subsystem integrates two ARM® Cortex-M4 cores.

A Nested Vectored Interrupt Controller (NVIC) is integrated within each Cortex-M4. The interrupt mapping is the same for the two cores to facilitate parallel processing. The NVIC supports:

- 96 external interrupts (in addition to 16 Cortex-M4 internal interrupts), which are dynamically prioritized with 16 levels of priority defined for each core
- Low-latency exception and interrupt handling
- Prioritization and handling of exceptions
- Control of the local power management
- Debug accesses to the processor core

For detailed information about this module, refer to *ARM Cortex-M4 Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).

EVE Subsystem Interrupt Controller (EVE_INTC)

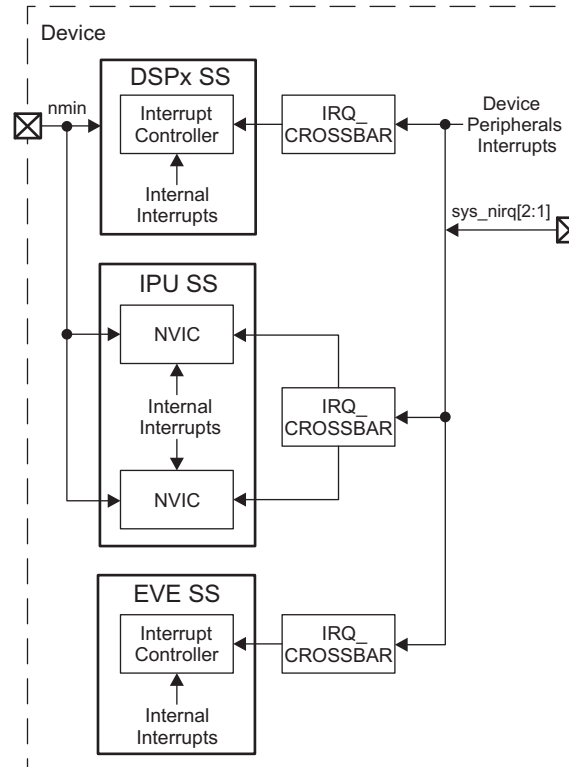

There is one Embedded Video Engine (EVE) subsystems in the device. The EVE subsystem integrates an interrupt controller - EVE_INTC, which handles incoming interrupts, merging them with internal interrupt sources to drive ARP32's interrupt inputs. It also allows ARP32 to generate outgoing interrupts or events to synchronize with other system processors and EDMA.

The EVE_INTC supports up to 32 active-high level interrupt inputs. Its architecture allows both hardware and software prioritization.

For detailed information about this module, see [Section 6.1, Embedded Vision Engine](#).

[Figure 13-1](#) shows the top-level block diagram of the interrupt controllers in this device.

Figure 13-1. Interrupt Controllers in the Device

13.2 Interrupt Controllers Environment

Figure 13-2 shows the relationship between the device INTCs and external interrupts.

Figure 13-2. Interrupts From External Devices

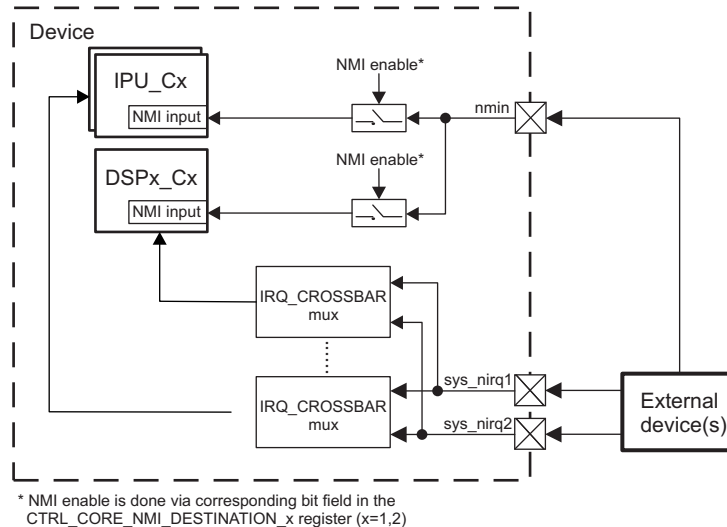

Table 13-1 describes the signals that can be used by external devices to generate interrupts to the device INTCs.

Table 13-1. Interrupts From External Devices

Device Pin	I/O ⁽¹⁾	Description
sys_nirq1	I	External devices can use these pins to generate a system wake-up interrupt event to any device INTC. The user must take care to configure the corresponding IRQ_CROSSBAR properly (via Control Module).
sys_nirq2	I	
nmin	I	External device can use this pin to generate a non-maskable interrupt (NMI) event to the following device processors: - IPU_C0, IPU_C1. Upon enable (via Control Module), the NMI is routed directly to the NMI input of Cortex M4 core. Note that NMI can be enabled separately for IPU_C0 and IPU_C1. - DSP1, DSP2. Upon enable (via Control Module), the NMI is routed directly to the NMI input of C66x CPU.
		The Control Module registers CTRL_CORE_NMI_DESTINATION_1 and CTRL_CORE_NMI_DESTINATION_2 are used to route the NMI signal to the corresponding device processor subsystems as follows: <ul style="list-style-type: none"> • Writing 0x1 to CTRL_CORE_NMI_DESTINATION_1[7:0] IPU_C1 enables NMI mapping to IPU_C1; • Writing 0x1 to CTRL_CORE_NMI_DESTINATION_2[31:24] IPU_C0 enables NMI mapping to IPU_C0; • Writing 0x1 to CTRL_CORE_NMI_DESTINATION_2[23:16] DSP2 enables NMI mapping to DSP2; • Writing 0x1 to CTRL_CORE_NMI_DESTINATION_2[15:8] DSP1 enables NMI mapping to DSP1; For more information about CTRL_CORE_NMI_DESTINATION_1 and CTRL_CORE_NMI_DESTINATION_2 registers, see Chapter 14, Control Module.

⁽¹⁾ I = Input, O = Output

NOTE: External devices can also use the GPIO modules to generate an interrupt to the device INTCs. For more information, see Chapter 21, General-Purpose Interface.

13.3 Interrupt Controllers Integration

Table 13-2 through Table 13-5 present the default interrupt mapping of the device INTCs. The mapping of device interrupts to IRQ_CROSSBAR inputs is presented in Table 13-6.

NOTE: All device interrupts (external to the DSP [x2], IPU, and EVE subsystems) are active-high, level-sensitive.

CAUTION

A single interrupt source can be physically mapped to multiple INTCs. With multiple-mapped interrupts, it is strongly recommended to unmask each interrupt source in only one INTC at a time.

13.3.1 Interrupt Requests to DSP1_INTC

Table 13-2 lists the default interrupt sources for the DSP1_INTC. In addition, interrupts DSP1_IRQ_32 through DSP1_IRQ_95 can alternatively be sourced through the DSP1's IRQ_CROSSBAR from one of the 460 multiplexed device interrupts listed in Table 13-6. The CTRL_CORE_DSP1_IRQ_y_z registers in the Control Module are used to select between the default interrupts and the multiplexed interrupts.

Table 13-2. DSP1_INTC Default Interrupt Mapping

IRQ Input Line	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
DSP1_IRQ_0	N/A	N/A	N/A	CGEM_IRQ_0	CGEM Internal Interrupt

Table 13-2. DSP1_INTC Default Interrupt Mapping (continued)

IRQ Input Line	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
DSP1_IRQ_78	47	CTRL_CORE_DSP1_IRQ_78_79 [8:0]	47	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP1_IRQ_79	48	CTRL_CORE_DSP1_IRQ_78_79 [24:16]	48	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP1_IRQ_80	49	CTRL_CORE_DSP1_IRQ_80_81 [8:0]	49	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP1_IRQ_81	50	CTRL_CORE_DSP1_IRQ_80_81 [24:16]	50	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP1_IRQ_82	51	CTRL_CORE_DSP1_IRQ_82_83 [8:0]	51	I2C1_IRQ	I2C1 interrupt
DSP1_IRQ_83	52	CTRL_CORE_DSP1_IRQ_82_83 [24:16]	52	I2C2_IRQ	I2C2 interrupt
DSP1_IRQ_84	53	CTRL_CORE_DSP1_IRQ_84_85 [8:0]	53	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP1_IRQ_85	54	CTRL_CORE_DSP1_IRQ_84_85 [24:16]	54	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP1_IRQ_86	55	CTRL_CORE_DSP1_IRQ_86_87 [8:0]	55	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP1_IRQ_87	56	CTRL_CORE_DSP1_IRQ_86_87 [24:16]	56	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP1_IRQ_88	57	CTRL_CORE_DSP1_IRQ_88_89 [8:0]	57	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP1_IRQ_89	58	CTRL_CORE_DSP1_IRQ_88_89 [24:16]	58	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP1_IRQ_90	59	CTRL_CORE_DSP1_IRQ_90_91 [8:0]	59	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP1_IRQ_91	60	CTRL_CORE_DSP1_IRQ_90_91 [24:16]	60	MCSP11_IRQ	McSPI1 interrupt
DSP1_IRQ_92	61	CTRL_CORE_DSP1_IRQ_92_93 [8:0]	61	MCSP12_IRQ	McSPI2 interrupt
DSP1_IRQ_93	62	CTRL_CORE_DSP1_IRQ_92_93 [24:16]	62	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP1_IRQ_94	63	CTRL_CORE_DSP1_IRQ_94_95 [8:0]	63	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP1_IRQ_95	64	CTRL_CORE_DSP1_IRQ_94_95 [24:16]	64	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP1_IRQ_96	N/A	N/A	N/A	CGEM_IRQ_16	CGEM Internal Interrupt
DSP1_IRQ_97	N/A	N/A	N/A	CGEM_IRQ_17	CGEM Internal Interrupt
DSP1_IRQ_98	N/A	N/A	N/A	CGEM_IRQ_18	CGEM Internal Interrupt
DSP1_IRQ_99	NA	N/A	N/A	CGEM_IRQ_19	CGEM Internal Interrupt

Table 13-2. DSP1_INTC Default Interrupt Mapping (continued)

IRQ Input Line	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
DSP1_IRQ_100	N/A	N/A	N/A	CGEM_IRQ_20	CGEM Internal Interrupt
DSP1_IRQ_101	N/A	N/A	N/A	CGEM_IRQ_21	CGEM Internal Interrupt
DSP1_IRQ_102	N/A	N/A	N/A	CGEM_IRQ_22	CGEM Internal Interrupt
DSP1_IRQ_103	N/A	N/A	N/A	CGEM_IRQ_23	CGEM Internal Interrupt
DSP1_IRQ_104	N/A	N/A	N/A	CGEM_IRQ_24	CGEM Internal Interrupt
DSP1_IRQ_105	NA	N/A	N/A	CGEM_IRQ_25	CGEM Internal Interrupt
DSP1_IRQ_106	N/A	N/A	N/A	CGEM_IRQ_26	CGEM Internal Interrupt
DSP1_IRQ_107	N/A	N/A	N/A	CGEM_IRQ_27	CGEM Internal Interrupt
DSP1_IRQ_108	N/A	N/A	N/A	CGEM_IRQ_28	CGEM Internal Interrupt
DSP1_IRQ_109	N/A	N/A	N/A	CGEM_IRQ_29	CGEM Internal Interrupt
DSP1_IRQ_110	N/A	N/A	N/A	CGEM_IRQ_30	CGEM Internal Interrupt
DSP1_IRQ_111	N/A	N/A	N/A	CGEM_IRQ_31	CGEM Internal Interrupt
DSP1_IRQ_112	N/A	N/A	N/A	CGEM_IRQ_32	CGEM Internal Interrupt
DSP1_IRQ_113	N/A	N/A	N/A	CGEM_IRQ_33	CGEM Internal Interrupt
DSP1_IRQ_114	N/A	N/A	N/A	CGEM_IRQ_34	CGEM Internal Interrupt
DSP1_IRQ_115	N/A	N/A	N/A	CGEM_IRQ_35	CGEM Internal Interrupt
DSP1_IRQ_116	N/A	N/A	N/A	CGEM_IRQ_36	CGEM Internal Interrupt
DSP1_IRQ_117	N/A	N/A	N/A	CGEM_IRQ_37	CGEM Internal Interrupt
DSP1_IRQ_118	N/A	N/A	N/A	CGEM_IRQ_38	CGEM Internal Interrupt
DSP1_IRQ_119	NA	N/A	N/A	CGEM_IRQ_39	CGEM Internal Interrupt
DSP1_IRQ_120	N/A	N/A	N/A	CGEM_IRQ_40	CGEM Internal Interrupt
DSP1_IRQ_121	N/A	N/A	N/A	CGEM_IRQ_41	CGEM Internal Interrupt
DSP1_IRQ_122	N/A	N/A	N/A	CGEM_IRQ_42	CGEM Internal Interrupt
DSP1_IRQ_123	N/A	N/A	N/A	CGEM_IRQ_43	CGEM Internal Interrupt
DSP1_IRQ_124	N/A	N/A	N/A	CGEM_IRQ_44	CGEM Internal Interrupt
DSP1_IRQ_125	N/A	N/A	N/A	CGEM_IRQ_45	CGEM Internal Interrupt
DSP1_IRQ_126	N/A	N/A	N/A	CGEM_IRQ_46	CGEM Internal Interrupt
DSP1_IRQ_127	N/A		N/A	CGEM_IRQ_47	CGEM Internal Interrupt

NOTE: The "IRQ_CROSSBAR Default Input Index" column of [Table 13-2](#) shows which input of the corresponding IRQ_CROSSBAR instance is mapped to its output (and then routed to the corresponding DSP1_INTC input) by default. In other words, this column specifies the default (reset) values (in decimal) of the CTRL_CORE_DSP1_IRQ_y_z register bit fields that are used to control the mapping of device interrupts to DSP1_INTC inputs. For example, the DSP1_IRQ_32_33[8:0] bit field is used to configure which device interrupt would be mapped to the DSP1_IRQ_32 line. The reset value of this bit field is 0x1, meaning that ELM_IRQ would be mapped to DSP1_IRQ_32 by default because it is connected to the IRQ_CROSSBAR_1 input.

'N/A' in this column means that the corresponding interrupt is internal to the DSP1 subsystem. There is no IRQ_CROSSBAR dedicated to the associated DSP1_INTC input line and therefore, the user cannot change its default mapping.

13.3.2 Interrupt Requests to DSP2_INTC

[Table 13-3](#) lists the default interrupt sources for the DSP2_INTC. In addition, interrupts DSP2_IRQ_32 through DSP2_IRQ_95 can alternatively be sourced through the DSP2's IRQ_CROSSBAR from one of the 460 multiplexed device interrupts listed in [Table 13-6](#). The DSP2_IRQ_y_z registers in the Control Module are used to select between the default interrupts and the multiplexed interrupts.

Table 13-3. DSP2_INTC Default Interrupt Mapping

IRQ Input Line	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
DSP2_IRQ_0	N/A	N/A	N/A	CGEM_IRQ_0	CGEM Internal Interrupt
DSP2_IRQ_1	N/A	N/A	N/A	CGEM_IRQ_1	CGEM Internal Interrupt
DSP2_IRQ_2	N/A	N/A	N/A	CGEM_IRQ_2	CGEM Internal Interrupt
DSP2_IRQ_3	N/A	N/A	N/A	CGEM_IRQ_3	CGEM Internal Interrupt
DSP2_IRQ_4	N/A	N/A	N/A	CGEM_IRQ_4	CGEM Internal Interrupt
DSP2_IRQ_5	N/A	N/A	N/A	CGEM_IRQ_5	CGEM Internal Interrupt
DSP2_IRQ_6	N/A	N/A	N/A	CGEM_IRQ_6	CGEM Internal Interrupt
DSP2_IRQ_7	N/A	N/A	N/A	CGEM_IRQ_7	CGEM Internal Interrupt
DSP2_IRQ_8	N/A	N/A	N/A	CGEM_IRQ_8	CGEM Internal Interrupt
DSP2_IRQ_9	N/A	N/A	N/A	CGEM_IRQ_9	CGEM Internal Interrupt
DSP2_IRQ_10	N/A	N/A	N/A	CGEM_IRQ_10	CGEM Internal Interrupt
DSP2_IRQ_11	N/A	N/A	N/A	CGEM_IRQ_11	CGEM Internal Interrupt
DSP2_IRQ_12	N/A	N/A	N/A	CGEM_IRQ_12	CGEM Internal Interrupt
DSP2_IRQ_13	N/A	N/A	N/A	CGEM_IRQ_13	CGEM Internal Interrupt
DSP2_IRQ_14	N/A	N/A	N/A	CGEM_IRQ_14	CGEM Internal Interrupt
DSP2_IRQ_15	N/A	N/A	N/A	CGEM_IRQ_15	CGEM Internal Interrupt
DSP2_IRQ_16	N/A	N/A	N/A	TPCC_INTG	EDMA CC global interrupt

Table 13-3. DSP2_INTC Default Interrupt Mapping (continued)

IRQ Input Line	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
DSP2_IRQ_17	N/A	N/A	N/A	TPCC_INT0	EDMA CC region0 interrupt
DSP2_IRQ_18	N/A	N/A	N/A	TPCC_INT1	EDMA CC region1 interrupt
DSP2_IRQ_19	N/A	N/A	N/A	TPCC_INT2	EDMA CC region2 interrupt
DSP2_IRQ_20	N/A	N/A	N/A	TPCC_INT3	EDMA CC region3 interrupt
DSP2_IRQ_21	N/A	N/A	N/A	FW0_FUNC_ERROR	Firewall0 func access error
DSP2_IRQ_22	N/A	N/A	N/A	FW0_DEBUG_ERROR	Firewall0 debug access error
DSP2_IRQ_23	N/A	N/A	N/A	FW1_FUNC_ERROR	Firewall1 func access error
DSP2_IRQ_24	N/A	N/A	N/A	FW1_DEBUG_ERROR	Firewall1 debug access error
DSP2_IRQ_25	N/A	N/A	N/A	MMU0_INT	DSP MMU0 Interrupt
DSP2_IRQ_26	N/A	N/A	N/A	MMU1_INT	DSP MMU1 Interrupt
DSP2_IRQ_27	N/A	N/A	N/A	TPCC_ERRINT	EDMA CC error interrupt
DSP2_IRQ_28	N/A	N/A	N/A	TPTC_ERRINT0	EDMA TC0 error interrupt
DSP2_IRQ_29	N/A	N/A	N/A	TPTC_ERRINT1	EDMA TC1 error interrupt
DSP2_IRQ_30	N/A	N/A	N/A	NOC_ERRINT	Interconnect error interrupt
DSP2_IRQ_31	NA	N/A	N/A	EDMA_WAKE_INT	EDMA wakeup interrupt
DSP2_IRQ_32	1	CTRL_CORE_DSP2_IRQ_32_33[8:0]	1	ELM_IRQ	Error location process completion interrupt
DSP2_IRQ_33	2	CTRL_CORE_DSP2_IRQ_32_33[24:16]	2	EXT_SYS_IRQ_1	External interrupt (active low) via sys_nirq1 pin
DSP2_IRQ_34	3	CTRL_CORE_DSP2_IRQ_34_35[8:0]	3	CTRL_MODULE_CORE_IRQ_SE C_EVTS	Combined firewall error interrupt. For more information, see Section 14.4.6.13.2 .
DSP2_IRQ_35	4	CTRL_CORE_DSP2_IRQ_34_35[24:16]	4	L3_MAIN_IRQ_DBG_ERR	L3_MAIN debug error
DSP2_IRQ_36	5	CTRL_CORE_DSP2_IRQ_36_37[8:0]	5	L3_MAIN_IRQ_APP_ERR	L3_MAIN application or non-attributable error
DSP2_IRQ_37	6	CTRL_CORE_DSP2_IRQ_36_37[24:16]	6	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP2_IRQ_38	7	CTRL_CORE_DSP2_IRQ_38_39[8:0]	7	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP2_IRQ_39	8	CTRL_CORE_DSP2_IRQ_38_39[24:16]	8	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP2_IRQ_40	9	CTRL_CORE_DSP2_IRQ_40_41[8:0]	9	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP2_IRQ_41	10	CTRL_CORE_DSP2_IRQ_40_41[24:16]	10	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP2_IRQ_42	11	CTRL_CORE_DSP2_IRQ_42_43[8:0]	11	L3_MAIN_IRQ_STAT_ALARM	L3_MAIN statistic collector alarm interrupt
DSP2_IRQ_43	12	CTRL_CORE_DSP2_IRQ_42_43[24:16]	12	Reserved	Reserved by default but can be remapped to a valid interrupt source

Table 13-3. DSP2_INTC Default Interrupt Mapping (continued)

IRQ Input Line	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
DSP2_IRQ_44	13	CTRL_CORE_DSP2_IRQ_44_45[8:0]	13	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP2_IRQ_45	14	CTRL_CORE_DSP2_IRQ_44_45[24:16]	14	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP2_IRQ_46	15	CTRL_CORE_DSP2_IRQ_46_47[8:0]	15	GPMC_IRQ	GPMC interrupt
DSP2_IRQ_47	16	CTRL_CORE_DSP2_IRQ_46_47[24:16]	16	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP2_IRQ_48	17	CTRL_CORE_DSP2_IRQ_48_49[8:0]	17	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP2_IRQ_49	18	CTRL_CORE_DSP2_IRQ_48_49[24:16]	18	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP2_IRQ_50	19	CTRL_CORE_DSP2_IRQ_50_51[8:0]	19	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP2_IRQ_51	20	CTRL_CORE_DSP2_IRQ_50_51[24:16]	20	DISPC_IRQ	Display controller interrupt
DSP2_IRQ_52	21	CTRL_CORE_DSP2_IRQ_52_53[8:0]	21	MAILBOX1_IRQ_USER0	Mailbox 1 user 0 interrupt
DSP2_IRQ_53	22	CTRL_CORE_DSP2_IRQ_52_53[24:16]	22	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP2_IRQ_54	23	CTRL_CORE_DSP2_IRQ_54_55[8:0]	23	DSP2_IRQ_MMU0	DSP2 MMU0 interrupt
DSP2_IRQ_55	24	CTRL_CORE_DSP2_IRQ_54_55[24:16]	24	GPIO1_IRQ_1	GPIO1 interrupt 1
DSP2_IRQ_56	25	CTRL_CORE_DSP2_IRQ_56_57[8:0]	25	GPIO2_IRQ_1	GPIO2 interrupt 1
DSP2_IRQ_57	26	CTRL_CORE_DSP2_IRQ_56_57[24:16]	26	GPIO3_IRQ_1	GPIO3 interrupt 1
DSP2_IRQ_58	27	CTRL_CORE_DSP2_IRQ_58_59[8:0]	27	GPIO4_IRQ_1	GPIO4 interrupt 1
DSP2_IRQ_59	28	CTRL_CORE_DSP2_IRQ_58_59[24:16]	28	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP2_IRQ_60	29	CTRL_CORE_DSP2_IRQ_60_61[8:0]	29	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP2_IRQ_61	30	CTRL_CORE_DSP2_IRQ_60_61[24:16]	30	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP2_IRQ_62	31	CTRL_CORE_DSP2_IRQ_62_63[8:0]	31	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP2_IRQ_63	32	CTRL_CORE_DSP2_IRQ_62_63[24:16]	32	TIMER1_IRQ	TIMER1 interrupt
DSP2_IRQ_64	33	CTRL_CORE_DSP2_IRQ_64_65[8:0]	33	TIMER2_IRQ	TIMER2 interrupt
DSP2_IRQ_65	34	CTRL_CORE_DSP2_IRQ_64_65[24:16]	34	TIMER3_IRQ	TIMER3 interrupt
DSP2_IRQ_66	35	CTRL_CORE_DSP2_IRQ_66_67[8:0]	35	TIMER4_IRQ	TIMER4 interrupt
DSP2_IRQ_67	36	CTRL_CORE_DSP2_IRQ_66_67[24:16]	36	TIMER5_IRQ	TIMER5 interrupt

Table 13-3. DSP2_INTC Default Interrupt Mapping (continued)

IRQ Input Line	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
DSP2_IRQ_68	37	CTRL_CORE_DSP2_IRQ_68_69[8:0]	37	TIMER6_IRQ	TIMER6 interrupt
DSP2_IRQ_69	38	CTRL_CORE_DSP2_IRQ_68_69[24:16]	38	TIMER7_IRQ	TIMER7 interrupt
DSP2_IRQ_70	39	CTRL_CORE_DSP2_IRQ_70_71[8:0]	39	TIMER8_IRQ	TIMER8 interrupt
DSP2_IRQ_71	40	CTRL_CORE_DSP2_IRQ_70_71[24:16]	40	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP2_IRQ_72	41	CTRL_CORE_DSP2_IRQ_72_73[8:0]	41	Reserved	Reserved by default but can be remapped to a valid interrupt source
DSP2_IRQ_73	42	CTRL_CORE_DSP2_IRQ_72_73[24:16]	42	Reserved	Reserved by default but can be remapped to a valid interrupt source

DSP2_IRQ_123	N/A	N/A	N/A	CGEM_IRQ_43	CGEM Internal Interrupt
DSP2_IRQ_124	N/A	N/A	N/A	CGEM_IRQ_44	CGEM Internal Interrupt
DSP2_IRQ_125	N/A	N/A	N/A	CGEM_IRQ_45	CGEM Internal Interrupt
DSP2_IRQ_126	N/A	N/A	N/A	CGEM_IRQ_46	CGEM Internal Interrupt
DSP2_IRQ_127	N/A	N/A	N/A	CGEM_IRQ_47	CGEM Internal Interrupt

NOTE: The "IRQ_CROSSBAR Default Input Index" column of [Table 13-3](#) shows which input of the corresponding IRQ_CROSSBAR instance is mapped to its output (and then routed to the corresponding DSP2_INTC input) by default. In other words, this column specifies the default (reset) values (in decimal) of the CTRL_CORE_DSP2_IRQ_y_z register bit fields that are used to control the mapping of device interrupts to DSP2_INTC inputs. For example, the DSP2_IRQ_32_33[8:0] bit field is used to configure which device interrupt would be mapped to the DSP2_IRQ_32 line. The reset value of this bit field is 0x1, meaning that ELM_IRQ would be mapped to DSP2_IRQ_32 by default because it is connected to the IRQ_CROSSBAR_1 input.

'N/A' in this column means that the corresponding interrupt is internal to the DSP2 subsystem. There is no IRQ_CROSSBAR dedicated to the associated DSP2_INTC input line and therefore, the user cannot change its default mapping.

13.3.3 Interrupt Requests to IPU_Cx_INTC

[Table 13-4](#) lists the default interrupt sources for the IPU_Cx_INTC. In addition, device interrupts IPU_IRQ_23 through IPU_IRQ_79 can alternatively be sourced through the IPU's IRQ_CROSSBAR from one of the 460 multiplexed device interrupts listed in [Table 13-6](#). The CTRL_CORE_IPU_IRQ_y_z registers in the Control Module are used to select between the default interrupts and the multiplexed interrupts.

Table 13-4. IPU_Cx_INTC Default Interrupt Mapping

IRQ Input Line ⁽¹⁾	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
IPU_IRQ_0	N/A	N/A	N/A	Reserved	MSP initial value in exception vector table

⁽¹⁾ This column shows the number of the corresponding exception type.

Table 13-4. IPU_Cx_INTC Default Interrupt Mapping (continued)

IRQ Input Line ⁽¹⁾	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
IPU_IRQ_1	N/A	N/A	N/A	RESET_IRQ	Reset
IPU_IRQ_2	N/A	N/A	N/A	NMI_IRQ	External NMI input (interrupt from nmin device pad)
IPU_IRQ_3	N/A	N/A	N/A	HARD_FAULT_IRQ	All fault conditions, if the fault handle is not enabled
IPU_IRQ_4	N/A	N/A	N/A	MEM_MANAGE_FAULT_IRQ	Memory management fault; access to illegal locations
IPU_IRQ_5	N/A	N/A	N/A	BUS_FAULT_IRQ	Bus error (on AHB intf)
IPU_IRQ_6	N/A	N/A	N/A	USAGE_FAULT_IRQ	Program error

IPU_IRQ_78	56	CTRL_CORE_IPU_IRQ_77_78[24:16]	62	Reserved	Reserved by default but can be remapped to a valid interrupt source
IPU_IRQ_79	57	CTRL_CORE_IPU_IRQ_79_80[8:0]	63	Reserved	Reserved by default but can be remapped to a valid interrupt source
IPU_IRQ_80	N/A	N/A	N/A	L1TAG_ECC_SEC_IRQ	SEC interrupt for L1-Tag
IPU_IRQ_81	N/A	N/A	N/A	L1TAG_ECC_DED_IRQ	DED interrupt for L1-Tag
IPU_IRQ_82	N/A	N/A	N/A	L1DATA_ECC_SEC_IRQ	SEC interrupt for L1-Data
IPU_IRQ_83	N/A	N/A	N/A	L1DATA_ECC_DED_IRQ	DED interrupt for L1-Data
IPU_IRQ_84	N/A	N/A	N/A	L2_RAM_ECC_SEC_IRQ	SEC interrupt for L2-RAM
IPU_IRQ_85	N/A	N/A	N/A	L2_RAM_ECC_DED_IRQ	DED interrupt for L2-RAM

NOTE: Exceptions/interrupts IPU_IRQ_[15:0] are all internal to the Cortex-M4 core.

Exceptions/interrupts IPU_IRQ_[79:16] are all external to the Cortex-M4 core – that is, the first Cortex-M4 external interrupt is mapped to IPU_IRQ_16 (exception #16), and the last (sixty-fourth) Cortex-M4 external interrupt is mapped to IPU_IRQ_79 (exception #79).

For more information about Cortex-M4 exception types, refer to ARM *Cortex™-M4 Devices Generic User Guide* (available at <http://infocenter.arm.com/help/index.jsp>).

NOTE: The "IRQ_CROSSBAR Default Input Index" column of [Table 13-4](#) shows which input of the corresponding IRQ_CROSSBAR instance is mapped to its output (and then routed to the corresponding IPU1_Cx_INTC input) by default. In other words, this column specifies the default (reset) values (in decimal) of the CTRL_CORE_IPU1_IRQ_y_z register bit fields that are used to control the mapping of device interrupts to IPU1_Cx_INTC inputs. For example, the IPU1_IRQ_23_24[8:0] bit field is used to configure which device interrupt would be mapped to the IPU1_IRQ_23 line. The reset value of this bit field is 0x14, meaning that DISPC_IRQ would be mapped to IPU1_IRQ_23 by default because it is connected to the IRQ_CROSSBAR_20 input.

'N/A' in this column means that the corresponding interrupt is internal to the IPU1 subsystem. There is no IRQ_CROSSBAR dedicated to the associated IPU1_Cx_INTC input line and therefore, the user cannot change its default mapping.

The CTRL_CORE_IPU1_IRQ_y_z registers control the IRQ_CROSSBAR settings for both NVICs in the IPU1 subsystem. That is, it is not possible to map different interrupts to the same interrupt input of the NVICs in IPU1.

13.3.4 Interrupt Requests to EVE_INTC1

[Table 13-5](#) lists the default interrupt sources for the EVE_INTC1. In addition, device interrupts EVE_IRQ_0 through EVE_IRQ_7 can alternatively be sourced through the EVE's IRQ_CROSSBAR from one of the 460 multiplexed device interrupts listed in [Table 13-6](#). The CTRL_CORE_EVE_IRQ_y_z registers in the Control Module are used to select between the default interrupts and the multiplexed interrupts.

Table 13-5. EVE_INTC1 Default Interrupt Mapping

IRQ Input Line	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
EVE_IRQ_0	1	CTRL_CORE_EVE_IRQ_0_1 [8:0]	1	ELM_IRQ	Error location process completion interrupt
EVE_IRQ_1	2	CTRL_CORE_EVE_IRQ_0_1 [24:16]	2	EXT_SYS_IRQ_1	External interrupt (active low) via sys_nirq1 pin
EVE_IRQ_2	3	CTRL_CORE_EVE_IRQ_2_3 [8:0]	3	CTRL_MODULE_CORE_IRQ_SEC_EVTS	Combined firewall error interrupt. For more information, see Section 14.4.6.13.2 .
EVE_IRQ_3	4	CTRL_CORE_EVE_IRQ_2_3 [24:16]	4	L3_MAIN_IRQ_DBG_ERR	L3_MAIN debug error
EVE_IRQ_4	5	CTRL_CORE_EVE_IRQ_4_5 [8:0]	5	L3_MAIN_IRQ_APP_ERR	L3_MAIN application or non-attributable error
EVE_IRQ_5	6	CTRL_CORE_EVE_IRQ_4_5 [24:16]	6	Reserved	Reserved by default but can be remapped to a valid interrupt source
EVE_IRQ_6	7	CTRL_CORE_EVE_IRQ_6_7 [8:0]	7	Reserved	Reserved by default but can be remapped to a valid interrupt source
EVE_IRQ_7	8	CTRL_CORE_EVE_IRQ_6_7 [24:16]	8	Reserved	Reserved by default but can be remapped to a valid interrupt source
EVE_IRQ_8	N/A	N/A	N/A	Reserved	Reserved
EVE_IRQ_9	N/A	N/A	N/A	Reserved	Reserved
EVE_IRQ_10	N/A	N/A	N/A	Reserved	Reserved
EVE_IRQ_11	N/A	N/A	N/A	Reserved	Reserved
EVE_IRQ_12	N/A	N/A	N/A	Reserved	Reserved
EVE_IRQ_13	N/A	N/A	N/A	Reserved	Reserved
EVE_IRQ_14	N/A	N/A	N/A	Reserved	Reserved

Table 13-5. EVE_INTC1 Default Interrupt Mapping (continued)

IRQ Input Line	IRQ_CROSSBAR Instance Number	IRQ_CROSSBAR Configuration Register	IRQ_CROSSBAR Default Input Index	Default Interrupt Name	Default Interrupt Source Description
EVE_IRQ_15	N/A	N/A	N/A	Reserved	Reserved
EVE_IRQ_16	N/A	N/A	N/A	Reserved	Reserved
EVE_IRQ_17	N/A	N/A	N/A	Reserved	Reserved

EVE_IRQ_27	N/A	N/A	N/A	Reserved	Reserved
EVE_IRQ_28	N/A	N/A	N/A	EVE_MBX2_INT0	EVE Mailbox 2 Interrupt 0
EVE_IRQ_29	N/A	N/A	N/A	Reserved	Reserved
EVE_IRQ_30	N/A	N/A	N/A	Reserved	Reserved
EVE_IRQ_31	N/A	N/A	N/A	Reserved	Reserved

NOTE: The "IRQ_CROSSBAR Default Input Index" column of [Table 13-5](#) shows which input of the corresponding IRQ_CROSSBAR instance is mapped to its output (and then routed to the corresponding EVE_INTC1 input) by default. In other words, this column specifies the default (reset) values (in decimal) of the CTRL_CORE_EVE1_IRQ_y_z register bit fields that are used to control the mapping of device interrupts to EVE_INTC1 inputs. For example, the EVE1_IRQ_0_1[8:0] bit field is used to configure which device interrupt would be mapped to the EVE1_IRQ_0 line. The reset value of this bit field is 0x1, meaning that ELM_IRQ would be mapped to EVE1_IRQ_0 by default because it is connected to the IRQ_CROSSBAR_1 input.

'N/A' in this column means that the corresponding interrupt is internal to the EVE1 subsystem. There is no IRQ_CROSSBAR dedicated to the associated EVE_INTC1 input line and therefore, the user cannot change its default mapping.

13.3.5 Mapping of Device Interrupts to IRQ_CROSSBAR Inputs

[Table 13-6](#) shows the individual connection between all module IRQs and all IRQ_CROSSBAR inputs.

Table 13-6. Connection of Device IRQs to IRQ_CROSSBAR Inputs

IRQ_CROSSBAR Input	Interrupt Name	Interrupt Source	Description
IRQ_CROSSBAR_0	Reserved	Reserved	Reserved
IRQ_CROSSBAR_1	ELM_IRQ	ELM	Error location process completion interrupt
IRQ_CROSSBAR_2	EXT_SYS_IRQ_1	External system	External interrupt (active low) via sys_nirq1 pin
IRQ_CROSSBAR_3	CTRL_MODULE_CORE_IRQ_SEC_EVTS	CTRL_MODULE_CORE	Combined firewall error interrupt. For more information, see Section 14.4.6.13.2
IRQ_CROSSBAR_4	L3_MAIN_IRQ_DBG_ERR	L3_MAIN	L3_MAIN debug error
IRQ_CROSSBAR_5	L3_MAIN_IRQ_APP_ERR	L3_MAIN	L3_MAIN application or non-attributable error
IRQ_CROSSBAR_6	Reserved	Reserved	Reserved

13.4 Interrupt Controllers Functional Description

For detailed information about each device INTC (including functional description and registers descriptions), see the TRM chapters and ARM documents referenced in [Section 13.1](#), *Interrupt Controllers Overview*.

Control Module

This chapter describes the system control module for the device.

Topic	Page
14.1 Control Module Overview	4584
14.2 Control Module Environment.....	4586
14.3 Control Module Integration	4587
14.4 Control Module Functional Description	4589
14.5 Control Module Register Manual.....	4617

14.1 Control Module Overview

The control module is composed of two submodules, the CTRL_MODULE_CORE submodule and the CTRL_MODULE_WKUP submodule. These two submodules represent a set of registers which are used to control the device I/O ports and also various kinds of settings related to the different modules available in this device.

The CTRL_MODULE_CORE submodule has registers for the following features:

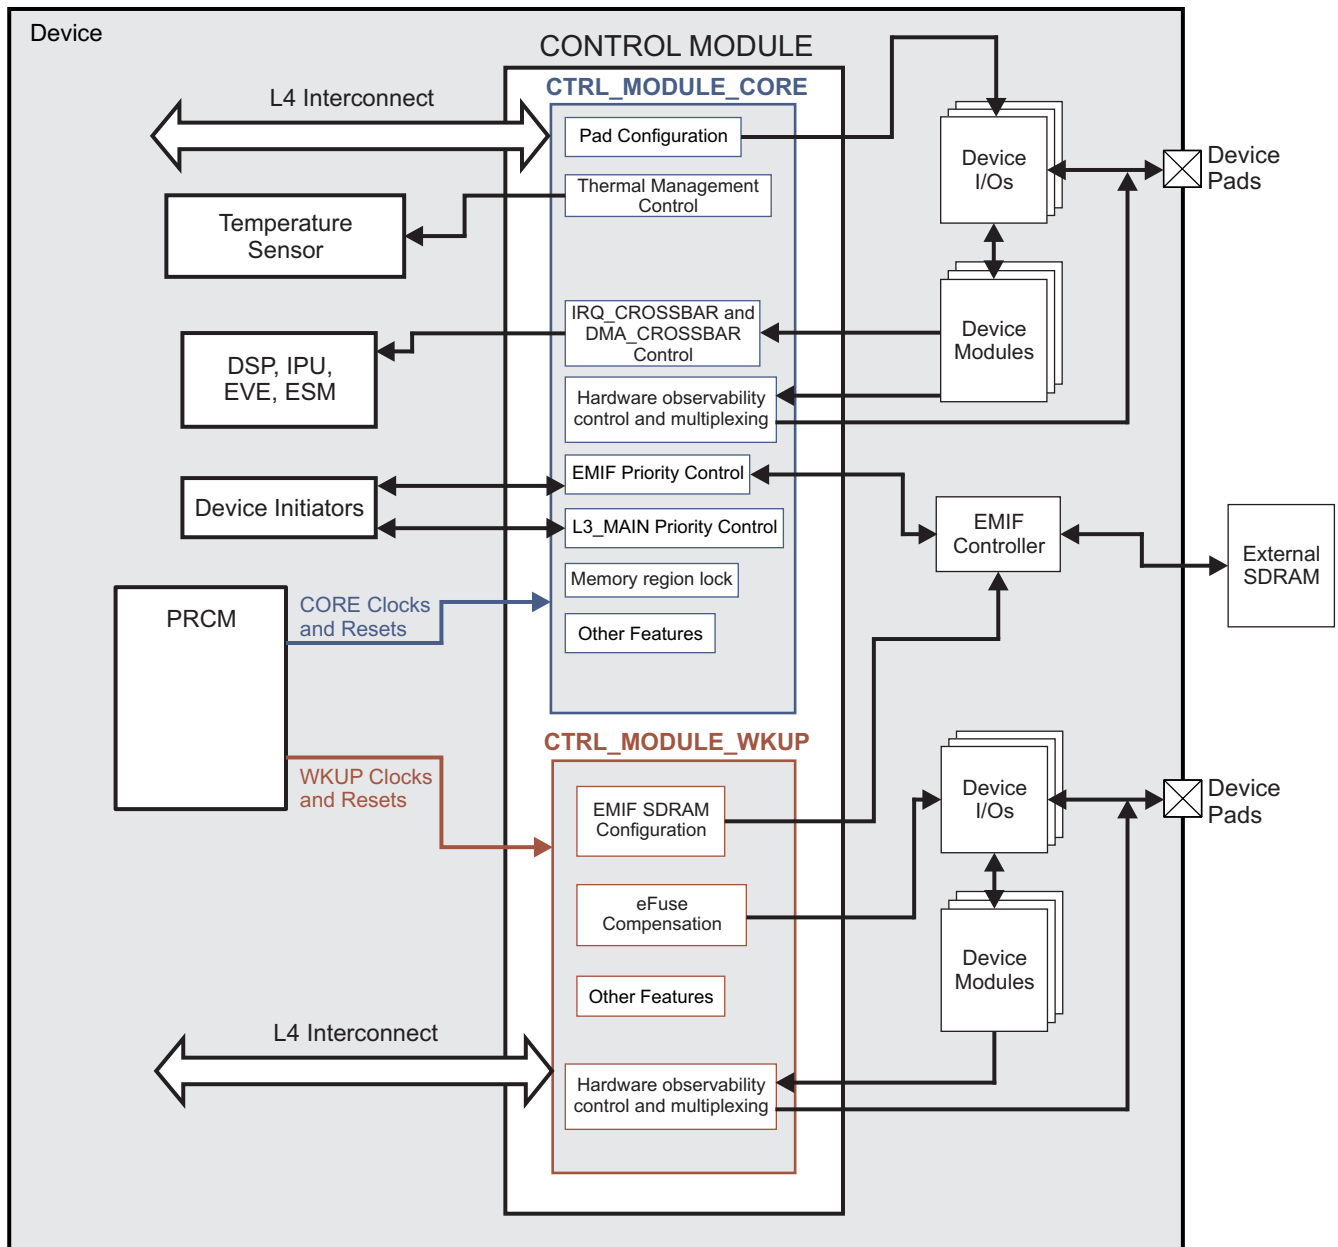

- Pad configuration with following controls:
 - Pad I/O multiplexing
 - Pad pull-up and pull-down configuration
 - Pad input buffer enabling
 - Pad slew rate control
- Device thermal management control and status registers
- IRQ_CROSSBAR and DMA_CROSSBAR control
- Control the priority of initiator accesses to the external SDRAM
- Control the priority of initiators connected to L3_MAIN interconnect
- Memory region lock registers
- Mapping of the device non-maskable interrupt (NMI) to respective cores
- Controls for the LPDDR2/DDR2/DDR3 I/O Cells
- Controls for the LPDDR2/DDR2/DDR3 associated vref-generation cells
- AVS Class 0 associated registers
- Status of the system boot settings
- Firewalls error status
- Settings related to different peripheral modules
- Hardware observability control and multiplexing
- Registers related to PRCM and PLL control
- Registers related to the boot ROM
- Other functions

The CTRL_MODULE_WKUP submodule has registers for the following features:

- Basic EMIF configuration settings
- XTAL Oscillator control
- Efuse I/O compensation
- Hardware observability control and multiplexing
- Other functions

[Figure 14-1](#) represents an overview block diagram of the control module.

14.3 Control Module Integration

Figure 14-3 shows the integration of the control module in the device.

Figure 14-3. Control Module Integration

ctrlmod-003

Table 14-2 through Table 14-4 summarize the integration of the Control Module in the device.

Table 14-2. Control Module Integration Attributes

Submodule	Attributes	
	Power Domain	Interconnect
CTRL_MODULE_CORE	PD_COREAON	L4_CFG
CTRL_MODULE_WKUP	PD_WKUPAON	L4_WKUP

Table 14-3. Control Module Clocks and Resets

Clocks				
Submodule	Destination Signal Name	Source Signal Name	Source	Description

Table 14-3. Control Module Clocks and Resets (continued)

CTRL_MODULE_CORE	L4CFG_L4_GICKL	L4CFG_L4_GICKL	PRCM	Interface clock to the CTRL_MODULE_CORE submodule
	L3INSTR_TS_GCLK	L3INSTR_TS_GCLK	PRCM	Functional clock for the thermal FSM instantiated in the CTRL_MODULE_CORE submodule
CTRL_MODULE_WKUP	WKUPAON_GICKL	WKUPAON_GICKL	PRCM	Interface clock to the CTRL_MODULE_WKUP submodule
Resets				
CTRL_MODULE_CORE	CORE_PWRON_RST	CORE_PWRON_RST	PRCM	Internal power-on reset (POR) affecting the CTRL_MODULE_CORE submodule
CTRL_MODULE_WKUP	WKUPAON_PWRON_RST	WKUPAON_PWRON_RST	PRCM	Internal POR affecting the CTRL_MODULE_WKUP submodule

Table 14-4. Control Module Hardware Requests

Submodule	Source Signal Name	Interrupt Requests		Description
		Destination IRQ_CROSSBAR Input	Default Mapping	
CTRL_MODULE_CORE	CTRL_MODULE_CORE_IRQ_THERMAL_ALERT	IRQ_CROSSBAR_121	-	Thermal alert interrupt signal generated when the thermal sensor goes over the temperature threshold value. This IRQ source signal is not mapped by default to any device INTC.

NOTE: The “Default Mapping” column in [Table 14-4 Control Module Hardware Requests](#) shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR module.
 For more information about the IRQ_CROSSBAR module, see [Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description](#).
 For more information about the device interrupt controllers, see [Chapter 13, Interrupt Controllers](#).

The integration of the control module is the following:

- No wake-up request generation
- No DMA request generation
- No master standby protocol with the PRCM
- Slave idle protocol, between the CTRL_MODULE_CORE submodule and the PRCM, related only to the L3INSTR_TS_GCLK
- One interrupt request to the IRQ_CROSSBAR module
- One (thermal shutdown) TSHUT signal used as PRCM warm reset source
- Two clocks and one reset signal to the CTRL_MODULE_CORE submodule
- One clock and one reset signal to the CTRL_MODULE_WKUP submodule

14.4 Control Module Functional Description

14.4.1 Control Module Clock Configuration

There is no software control over the L4CFG_L4_GICLK and WKUPAON_GICLK clocks neither in the control module nor in the PRCM module. The L4CFG_L4_GICLK clock is automatically gated when there is no access to the CTRL_MODULE_CORE registers and the WKUPAON_GICLK is automatically gated when there is no access to the CTRL_MODULE_WKUP registers. There are clock activity status bits for these two clocks in the PRCM module.

The L3INSTR_TS_GCLK is controlled by the [CTRL_CORE_BANDGAP_MASK_1](#)[31:30] SIDLEMODE bit field. For more information, see [Section 14.4.6.3.5](#).

The L3INSTR_TS_GCLK has also the following software controls located in the PRCM module:

- Status: see [Chapter 3, Power, Reset, and Clock Management](#)
- Divider ratio: see [Chapter 3, Power, Reset, and Clock Management](#)

14.4.2 Control Module Resets

The control module is not sensitive to software reset. It does not respond to global warm reset too. The control module can be reset only by the internal POR (global cold reset).

Despite the previously stated that control module is not sensitive to global warm reset the following registers are exception of this rule and are sensitive to global warm reset:

- All CTRL_CORE_PAD_x registers
- [CTRL_CORE_IPU_WAKEUP](#)
- [CTRL_CORE_TESOC_LAST_RESET_INDICATOR](#)
- [CTRL_CORE_ROM_AUXBOOT0](#)
- [CTRL_CORE_ROM_AUXBOOT1](#)

All other control module registers are sensitive only to global cold reset.

The PRCM provides the CORE_PWRON_RET_RST POR signal to the CTRL_MODULE_CORE and the WKUPAON_PWRON_RST POR signal to the CTRL_MODULE_WKUP. For more information, see [Section 3.5.5, Reset Domains](#), in [Chapter 3, Power, Reset, and Clock Management](#).

14.4.3 Control Module Power Management

14.4.3.1 Power Management Protocols

The control module, which is slave on the L4 interconnect, does not support master standby or slave idle protocols for handshaking with the PRCM. Only the thermal FSM supports slave idle protocol used to control its functional clock, that is the L3INSTR_TS_GCLK clock.

14.4.4 Hardware Requests

The control module does not generate DMA and wake-up requests. The CTRL_MODULE_CORE submodule generates only one IRQ to the IRQ_CROSSBAR module. This is the CTRL_MODULE_CORE_IRQ_THERMAL_ALERT interrupt. For more information, see [Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description](#).

14.4.5 Control Module Initialization

The control module responds to the internal POR. During device initialization, only modules used at boot time are associated with the pads. Other module inputs are internally tied and output buffers are turned off. After POR, software must set the pad configuration registers to appropriate values according to the desired device configuration.

The [CTRL_CORE_BOOTSTRAP](#)[15:0] bit field reflects the state of the sysboot[15:0] pads captured at POR in the PRCM module.

14.4.6 Functional Description Of The Various Register Types In CTRL_MODULE_CORE Submodule

The following sections describe the purpose of the various kinds of registers and register groups which reside in the CTRL_MODULE_CORE submodule.

14.4.6.1 Pad Configuration Registers

The pad configuration registers are used to configure most of the device pads. Each pad configuration register is associated only with one pad. The name of each register is formed by the corresponding pad name and the prefix "CTRL_CORE_PAD_". Almost all pad configuration registers have same bits. In some of these registers certain bits cannot be present. Figure 14-4 shows the general case in which all the pad configuration register bits are present. Table 14-5 describes these bits.

After POR, software must set the pad configuration registers to appropriate values depending on the desired device configuration.

Figure 14-4. Pad Configuration Register Bits

ctrlmod-005

Table 14-5. Description Of The Pad Configuration Register Bits

Bit/Bit Field	Bit Meaning		Description
	0b0	0b1	
SLEWCONTROL	Fast slew is selected	Slow slew is selected	Selects the slew rate for a given pad. The slew rate should be set to the value specified in the device Data Manual for a given mode of operation.
INPUTENABLE	Receive mode is disabled. The pad is configured in output mode only.	Receive mode is enabled. The pad is configured in bidirectional mode.	Enables the input buffer of a given I/O
PULLTYPESELECT	Weak pull-down resistor is selected	Weak pull-up resistor is selected	Weak pull-up or weak pull-down resistor selection for a given pad
PULLUDENABLE	Weak pull-up/pull-down resistor is enabled	Weak pull-up/pull-down resistor is disabled	Enables weak pull-up/pull-down feature of a given pad
MUXMODE	This bit field selects one of maximum sixteen possible functions to be available on the corresponding pad. Mostly, only several functions are available.		

When MUXMODE is set to 0x0 the function mapped to the pad corresponds to the name of the pad. In other words, pad names are signal names available when MUXMODE = 0x0.

By default the MUXMODE bit field of most device pads is set to 0xF, which means that there are no signals routed to these pads and the pads are in Hi-Z. The only exception are the sysboot signals available on several pads when MUXMODE = 0xF.

Only MUXMODE values which correspond to defined functions should be used.

NOTE: The default SLEWCONTROL settings in each pad configuration register must be used to guarantee timings, unless specific instructions otherwise are given in the individual timing sub-sections of the device Data Manual. The only exception is when the MUXMODE is configured to select a vout*_ * signal. In this case the corresponding SLEWCONTROL bit must be configured to slow slew instead of the default fast slew.

NOTE: When an external pull resistor is desired, the internal pull resistors must be disabled by software because they are enabled by default.

NOTE: For information about the signals available on each pad, see the *Multiplexing Characteristics* table in the device Data Manual.

The following signals require CTRL_CORE_PAD_x to be programmed with INPUTENABLE=1 for retiming purposes:

- mmc_clk
- gpmc_clk
- i2cj_scl where j=1-2
- spim_sclk where m=1-4
- mcasp1_aclkx, mcasp1_ahclkx, and mcasp1_aclkr
- mcasp2_aclkx, mcasp2_ahclkx, mcasp2_aclkr, mcasp3_aclkx, mcasp3_ahclkx, and mcasp3_aclkr

Except the maximum 16 possible combinations through the MUXMODE bit fields using the bits within CTRL_CORE_SMA_SW_14 and CTRL_CORE_SMA_SW_15 registers an additional signal can be mapped to several device pads. In other words, for these pads there are up to 17 possible signal combinations although not all of them are really implemented. These registers control McASP2 and McASP3 signal multiplexing. If a bit is set to 0x1, function 17 is selected for the corresponding pad. In that case the MUXMODE field of the corresponding CTRL_CORE_PAD_x register must be set to 0xF. If a bit is set to 0x0, function 17 is not selected.

14.4.6.2 Pull Selection

There is no automatic gating control to ensure that internal weak pull-up or pull-down resistors on a pad are disconnected whenever pad is configured as output. If a pad is always configured in output mode, it is recommended for user software to disable any internal pull resistor tied to it to avoid unnecessary consumption.

Table 14-6 describes the software controls available for pad internal pull-up and pull-down resistors in the control module pad configuration registers.

Table 14-6. Pull Selection

PULL		Pad Behavior
PULLTYPESELECT	PULLUDENABLE	
0	1	Pull-down selected but not activated
0	0	Pull-down selected and activated
1	1	Pull-up selected but not activated
1	0	Pull-up selected and activated

14.4.6.3 Thermal Management Related Registers

There is one temperature sensor on the device die. It is part of a VBGAPTS cell. This cell has a 10-bit ADC. The ADC converts the temperature values into digital output values proportional to the temperature measured. The VBGAPTS cell is controlled by a dedicated FSM referred to as thermal FSM. The registers associated with this FSM reside in the CTRL_MODULE_CORE submodule. The FSM is clocked by the L3INSTR_TS_GCLK clock. The PRCM module controls this clock through the slave idle protocol.

The device thermal management related registers can be split into the following classes:

- Temperature sensor control registers
- Registers for the thermal alert comparator block
- Temperature timestamp registers
- Other registers used for:

- controlling the FIFO
- controlling the clock provided to the thermal FSM

Figure 14-5 shows the block diagram of the device thermal management.

Figure 14-5. Thermal Management Functional Block Diagram

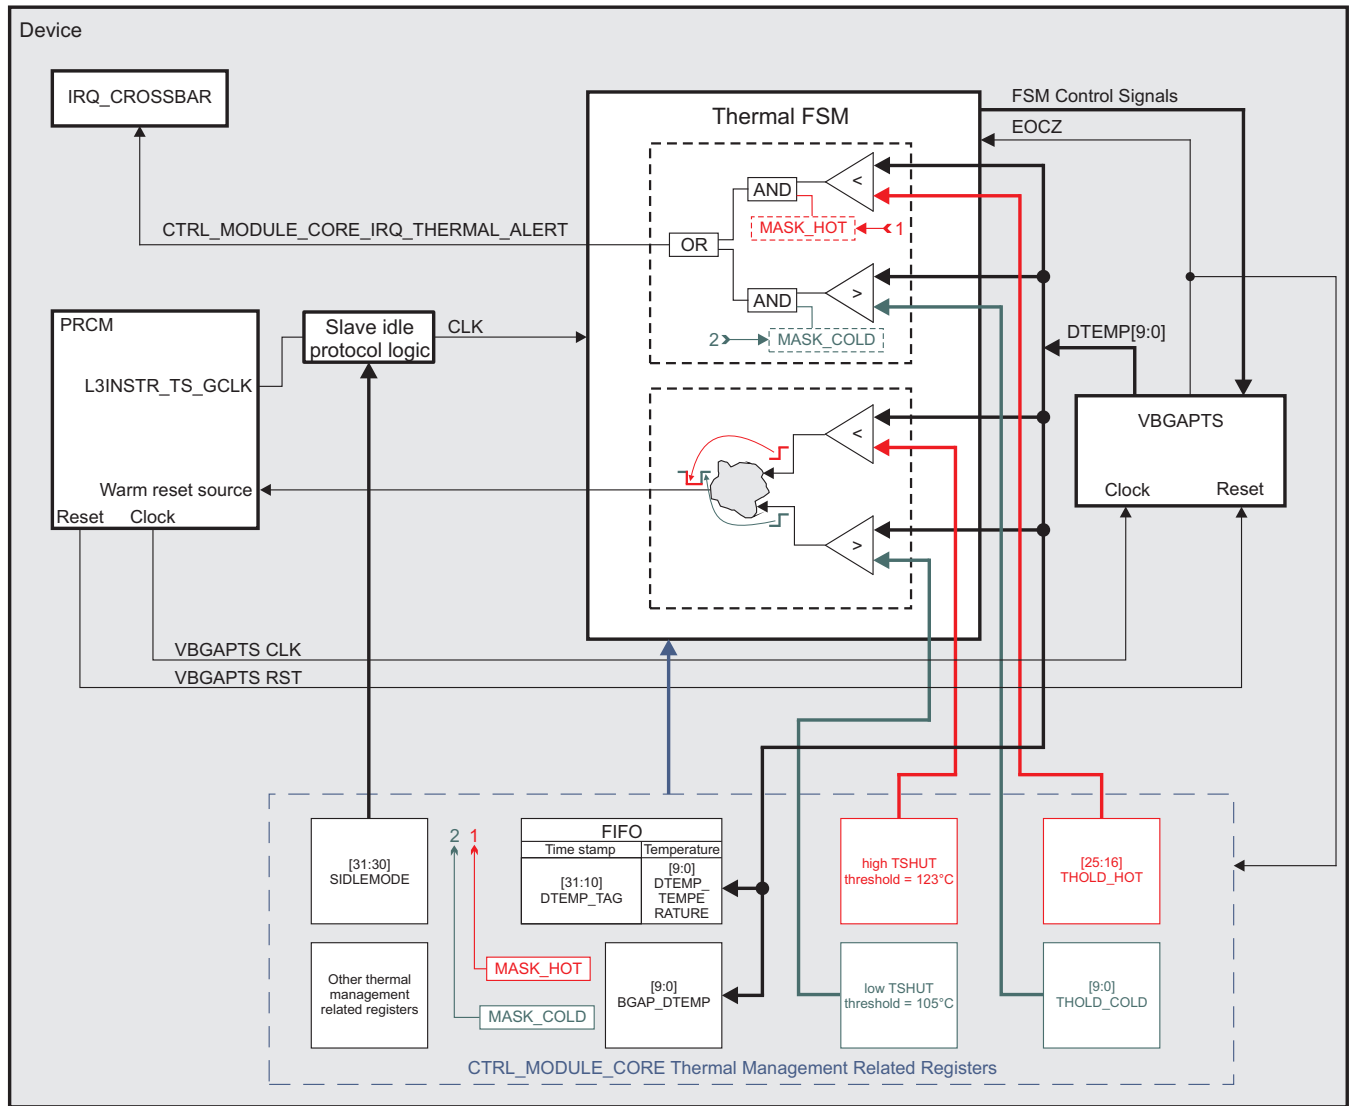

Table 14-7 describes the signals related to the device thermal management logic.

Table 14-7. Thermal Management Signals Description

Signal	I/O ⁽¹⁾	Description
EOCZ	O	End of conversion signal. When low, this signal indicates that the value of DTEMP[9:0] is valid.
DTEMP[9:0]	O	Temperature data from the temperature sensor. This value is valid when EOCZ is low.
VBGAPTS CLK	I	Functional clock from the WKUPAON power domain used by the temperature sensor during temperature conversion.
THERMAL ALERT	O	This is an output signal from the thermal FSM mapped as an interrupt request to the IRQ_CROSSBAR module. Software uses this interrupt to implement the device thermal management policy.

(1) I = Input; O = Output

Table 14-7. Thermal Management Signals Description (continued)

Signal	I/O ⁽¹⁾	Description
TSHUT	O	This is an output signal from the thermal FSM mapped to the PRCM and is used as a warm reset signal. This overheat protection signal is high during normal operation and go low during thermal shutdown event.

The ADC values which correspond to the current temperature are listed in [Table 14-10](#).

14.4.6.3.1 Temperature Sensor Control Registers

The VBGAPTS cell works in continuous conversion mode controlled by the thermal FSM. This means that the temperature is measured at regular time intervals. The start of temperature measurement is initiated automatically by the thermal FSM after it goes out of reset state. To control the main delay between two measurements the [CTRL_CORE_BANDGAP_MASK_1\[29:27\]](#) COUNTER_DELAY bit field is used. After this delay expires the FSM automatically starts a temperature conversion.

The conversion is complete when the [CTRL_CORE_TEMP_SENSOR_CORE\[10\]](#) BGAP_EOCZ_CORE status bits is set to 0x0. After this the valid temperature is written automatically in the [CTRL_CORE_TEMP_SENSOR_CORE\[9:0\]](#) BGAP_DTEMP_CORE bit field, and then software is able to read it. After writing the valid temperature value the FSM waits one clock cycle and start another conversion cycle.

14.4.6.3.2 Registers For The Thermal Alert Comparator Block

There is a comparator block responsible for the thermal alert function of the CTRL_MODULE_CORE thermal management logic. This comparator block is composed of two comparators. One dedicated to low temperature threshold and the other one to high temperature threshold. Software can configure the low temperature threshold through the [CTRL_CORE_BANDGAP_THRESHOLD_CORE\[9:0\]](#) THOLD_COLD_CORE bit field and high temperature threshold through the [CTRL_CORE_BANDGAP_THRESHOLD_CORE\[25:16\]](#) THOLD_HOT_CORE bit field. The values which have to be loaded in these bit fields are the same as those listed in [Table 14-10](#). For example, to set the high temperature threshold value to 120°C, the THOLD_HOT_CORE filed must be loaded with value of 931 (0x3A3).

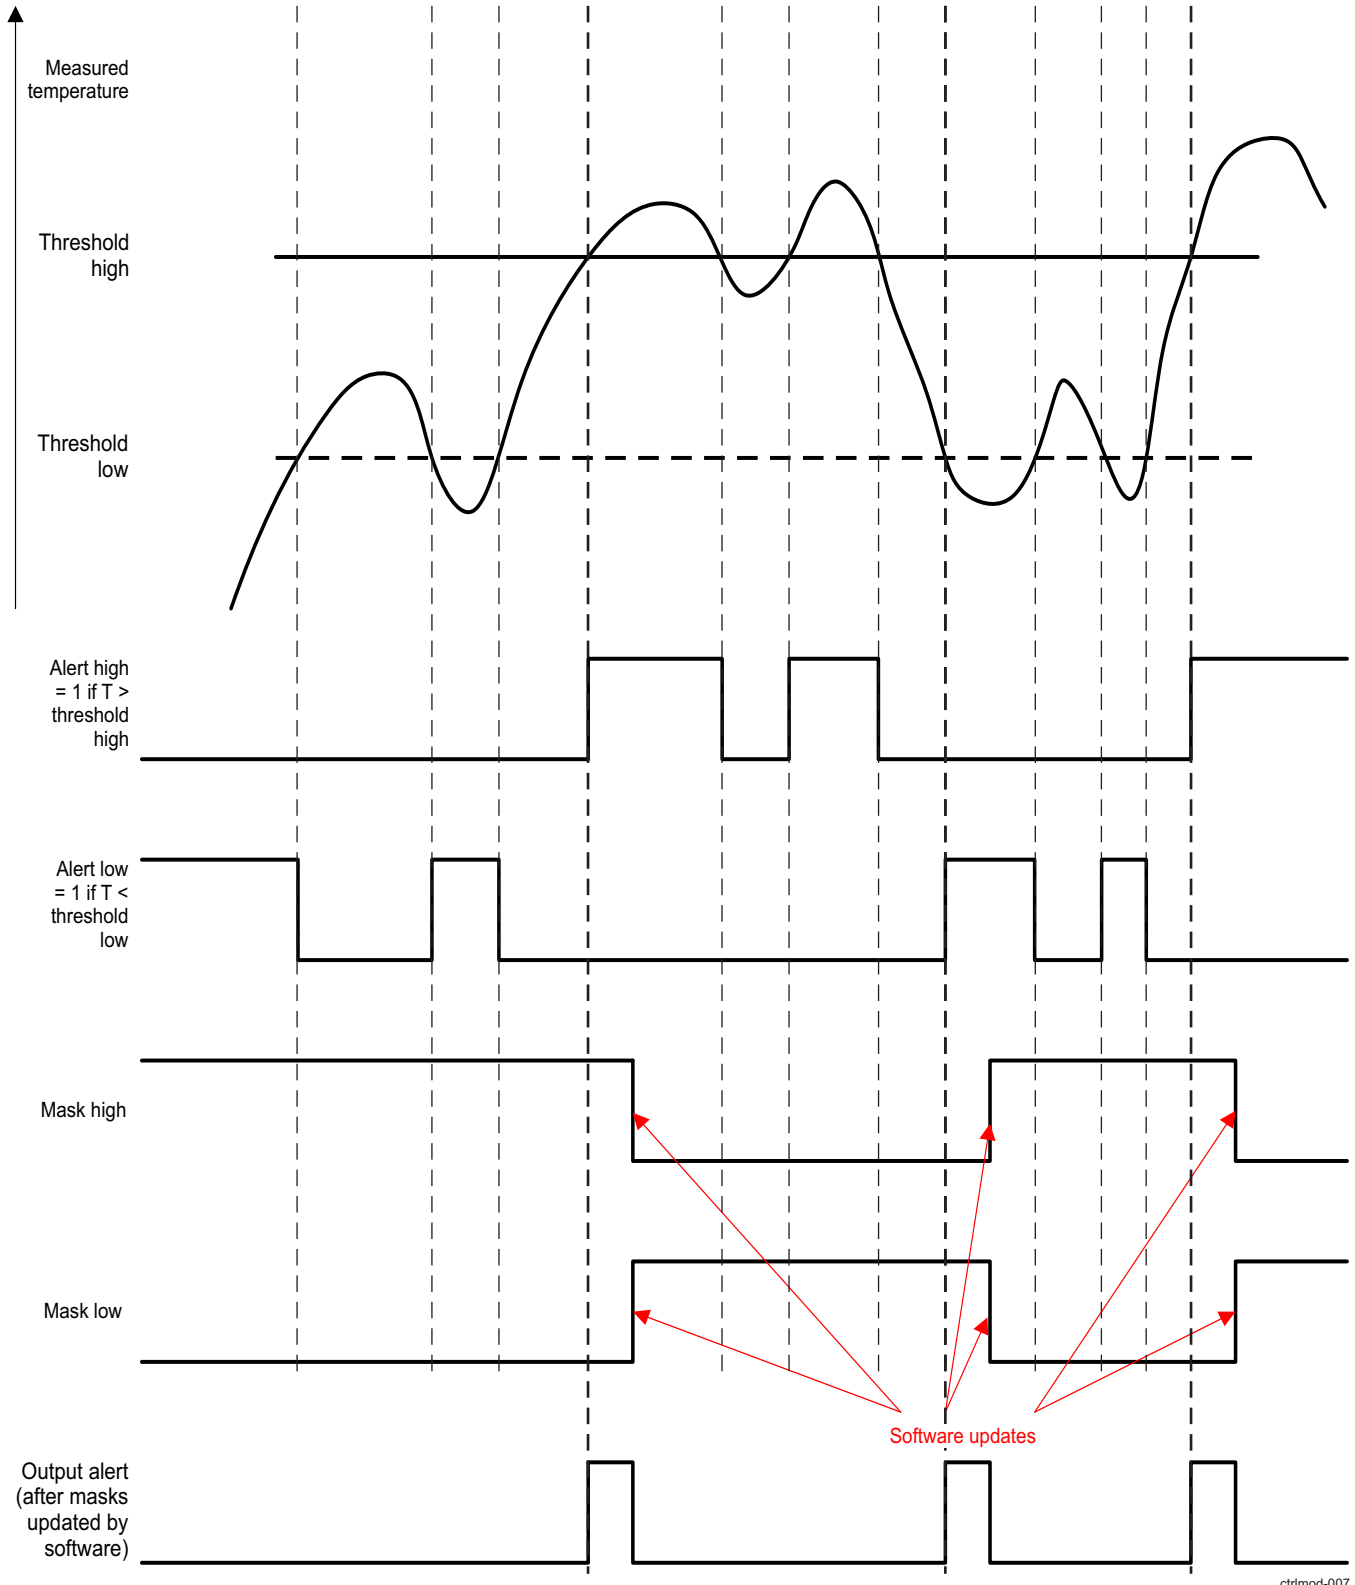

The thermal alert logic provides also a capability to mask the outputs of the comparators associated with low and high temperature thresholds. The low temperature threshold comparator output can be masked by setting to 0x0 the [CTRL_CORE_BANDGAP_MASK_1\[4\]](#) MASK_COLD_CORE bit. The high temperature threshold comparator output can be masked by setting to 0x0 the [CTRL_CORE_BANDGAP_MASK_1\[5\]](#) MASK_HOT_CORE bit.

The masked low and high temperature threshold outputs are ORed (see [Figure 14-5](#)) in the CTRL_MODULE_CORE_IRQ_THERMAL_ALERT signal, which delivers an interrupt to the IRQ_CROSSBAR_121 input line of the IRQ_CROSSBAR module. Software can use this interrupt to implement the device thermal management policy. The CTRL_MODULE_CORE_IRQ_THERMAL_ALERT signal is also routed to the [CTRL_CORE_BANDGAP_STATUS_1\[31\]](#) ALERT bit. Value of 0x1 indicates that the CTRL_MODULE_CORE_IRQ_THERMAL_ALERT signal is asserted.

The [CTRL_CORE_BANDGAP_STATUS_1\[4\]](#) COLD_CORE bit indicates the non masked (raw) comparator output for the low temperature threshold. The [CTRL_CORE_BANDGAP_STATUS_1\[5\]](#) HOT_CORE bit indicates the non masked (raw) comparator output for the high temperature threshold.

[Figure 14-6](#) shows the behavior of the thermal alert logic.

Figure 14-6. Behavior Of The Thermal Alert Logic

ctrlmod-007

14.4.6.3.3 Thermal Shutdown Comparator Block

There is also a comparator block responsible for the thermal shutdown (TSHUT) function of the CTRL_MODULE_CORE thermal management logic. This comparator block is also composed of two comparators. One dedicated to low TSHUT threshold and the other one to high TSHUT threshold. The comparator outputs for the low and high TSHUT thresholds are connected to a logic which then generates a single TSHUT signal tied to the PRCM and used as warm reset source. For details, see [Figure 14-5](#).

The values of the low and high TSHUT thresholds are fixed and can be neither overridden nor read by software. The value for the high TSHUT threshold is 123°C (assuming +/-2C temperature sensor accuracy) and for the low TSHUT threshold it is 105°C.

When the high TSHUT threshold is reached, the TSHUT output is activated. To deactivate the TSHUT output, the temperature must go below the value of the low TSHUT threshold.

The TSHUT signal is used as an overheat protection. [Figure 14-7](#) shows the behavior of the TSHUT logic.

Figure 14-7. Behavior Of The Thermal Shutdown Logic

ctrlmod-008

14.4.6.3.4 Temperature Timestamp Registers

Each time when the CTRL_CORE_TEMP_SENSOR_CORE[9:0] BGAP_DTEMP_CORE bit field is updated with new temperature value, this value is also automatically stored into a 5-level deep FIFO and a timestamp is registered too. This FIFO is used to store a brief history for the last few temperature measurements and is also dedicated to temperature timestamping. The FIFO has two fields. The first one is 10 bits wide, 5 levels deep, and is intended to store the temperature values for the last five measurements. The second field is 22 bits wide, 5 levels deep, and acts like a counter for the number of temperature measurements. The FIFO is composed of the following registers:

- [CTRL_CORE_DTEMP_CORE_0](#)
- [CTRL_CORE_DTEMP_CORE_1](#)
- [CTRL_CORE_DTEMP_CORE_2](#)
- [CTRL_CORE_DTEMP_CORE_3](#)

- [CTRL_CORE_DTEMP_CORE_4](#)

Table 14-8 describes the FIFO.

Table 14-8. FIFO Description

FIFO Levels	Second FIFO Field (22 Bits) – Timestamp Bits [31:10]	Description	First FIFO field (10 Bits) – Temperature Bits [9:0]	Description
Level 1	DTEMP_TAG_CORE_0	Indicates the number of temperature measurements	DTEMP_TEMPERATURE_CORE_0	Indicates the last measured temperature value (the most recent sample)
Level 2	DTEMP_TAG_CORE_1	Indicates the number of temperature measurements minus one (DTEMP_TEMPERATURE_CORE_0 – 1)	DTEMP_TEMPERATURE_CORE_1	Indicates the penultimate measured temperature value
Level 3	DTEMP_TAG_CORE_2	Indicates the number of temperature measurements minus two (DTEMP_TEMPERATURE_CORE_0 – 2)	DTEMP_TEMPERATURE_CORE_2	Indicates temperature value measured before DTEMP_TEMPERATURE_CORE_1
Level 4	DTEMP_TAG_CORE_3	Indicates the number of temperature measurements minus three (DTEMP_TEMPERATURE_CORE_0 – 3)	DTEMP_TEMPERATURE_CORE_3	Indicates temperature value measured before DTEMP_TEMPERATURE_CORE_2
Level 5	DTEMP_TAG_CORE_4	Indicates the number of temperature measurements minus four (DTEMP_TEMPERATURE_CORE_0 – 4)	DTEMP_TEMPERATURE_CORE_4	Indicates temperature value measured before DTEMP_TEMPERATURE_CORE_3 (the oldest sample)

NOTE: DTEMP_TAG_CORE_4 increments its value with one after each fifth temperature measurement.

DTEMP_TAG_CORE_3 increments its value with one after each fourth temperature measurement.

DTEMP_TAG_CORE_2 increments its value with one after each third temperature measurement.

DTEMP_TAG_CORE_1 increments its value with one after each second temperature measurement.

DTEMP_TAG_CORE_0 increments its value with one after each temperature measurement.

14.4.6.3.5 Other Thermal Management Related Registers

- **Controlling the FIFO:**

Software can stop the FIFO to update with new temperature and timestamp values when setting to 0x1 the [CTRL_CORE_BANDGAP_MASK_1\[23\]](#) FREEZE_CORE bit. This bit is automatically cleared by hardware after the FIFO has been cleared.

The FIFO is cleared by setting to 0x1 the [CTRL_CORE_BANDGAP_MASK_1\[20\]](#) CLEAR_CORE bit. This bit is automatically set by hardware to 0x0 after the FIFO clearing procedure completes.

- **Controlling the clock provided to the thermal FSM:**

The thermal FSM complies with the PRCM slave idle protocol. Its functional clock (L3INSTR_TS_GCLK) is automatically gated by PRCM depending on the value of the [CTRL_CORE_BANDGAP_MASK_1\[31:30\]](#) SIDLEMODE bit field. L3INSTR_TS_GCLK clock is also enabled automatically by the PRCM module.

14.4.6.3.6 Summary Of The Thermal Management Related Registers

Table 14-9 summarizes all the thermal management related registers.

Table 14-9. Summary Of The Thermal Management Related Registers

Register Name	Description	Access
CTRL_CORE_TEMP_SENSOR_CORE	Temperature sensor control register	RW
CTRL_CORE_BANDGAP_THRESHOLD_CORE	Register for the thermal alert comparator	RW
CTRL_CORE_BANDGAP_TSHUT_CORE	Register for the thermal shutdown comparator	RW
CTRL_CORE_DTEMP_CORE_0	Temperature timestamp registers	RO
CTRL_CORE_DTEMP_CORE_1		
CTRL_CORE_DTEMP_CORE_2		
CTRL_CORE_DTEMP_CORE_3		
CTRL_CORE_DTEMP_CORE_4		
CTRL_CORE_BANDGAP_STATUS_1	Register with status bits for the non masked comparator outputs and the thermal alert signal.	RO
CTRL_CORE_BANDGAP_MASK_1	Register used to mask the comparator outputs for the low and high thermal alert thresholds. This register is also used to control the FIFO and the clock provided to the thermal FSM.	RW

14.4.6.3.7 ADC Values Versus Temperature

Table 14-10 provides all valid ADC values corresponding to the measured temperature which should be read from the [CTRL_CORE_TEMP_SENSOR_CORE\[9:0\]](#) BGAP_DTEMP_CORE bit field. Table 14-10 also provides the values for the low and high temperature thresholds which are configurable through the [CTRL_CORE_BANDGAP_THRESHOLD_CORE\[9:0\]](#) THOLD_COLD_CORE and [CTRL_CORE_BANDGAP_THRESHOLD_CORE\[25:16\]](#) THOLD_HOT_CORE bit fields.

Table 14-10. ADC Values Versus Temperature

ADC Code	Temperature		ADC Code	Temperature		ADC Code	Temperature		ADC Code	Temperature	
	From	To		From	To		From	To		From	To
0-539	Outside region of operation		641	0.8	1.2	743	43.4	44	845	85.2	85.6

14.4.6.4 IRQ_CROSSBAR Module Functional Description

There is an IRQ_CROSSBAR module in the device, which is controlled by registers in the CTRL_MODULE_CORE submodule. The IRQ_CROSSBAR is able to map any of its input signals to any of its outputs. This module is associated with the device interrupt sources. The IRQs from all the device modules are connected to the IRQ_CROSSBAR inputs. Each module IRQ is connected only to one crossbar input. Each output of the IRQ_CROSSBAR module is connected only to one interrupt line of certain interrupt controller (INTC). Thus, the device IRQs are mapped to the device INTCs through the

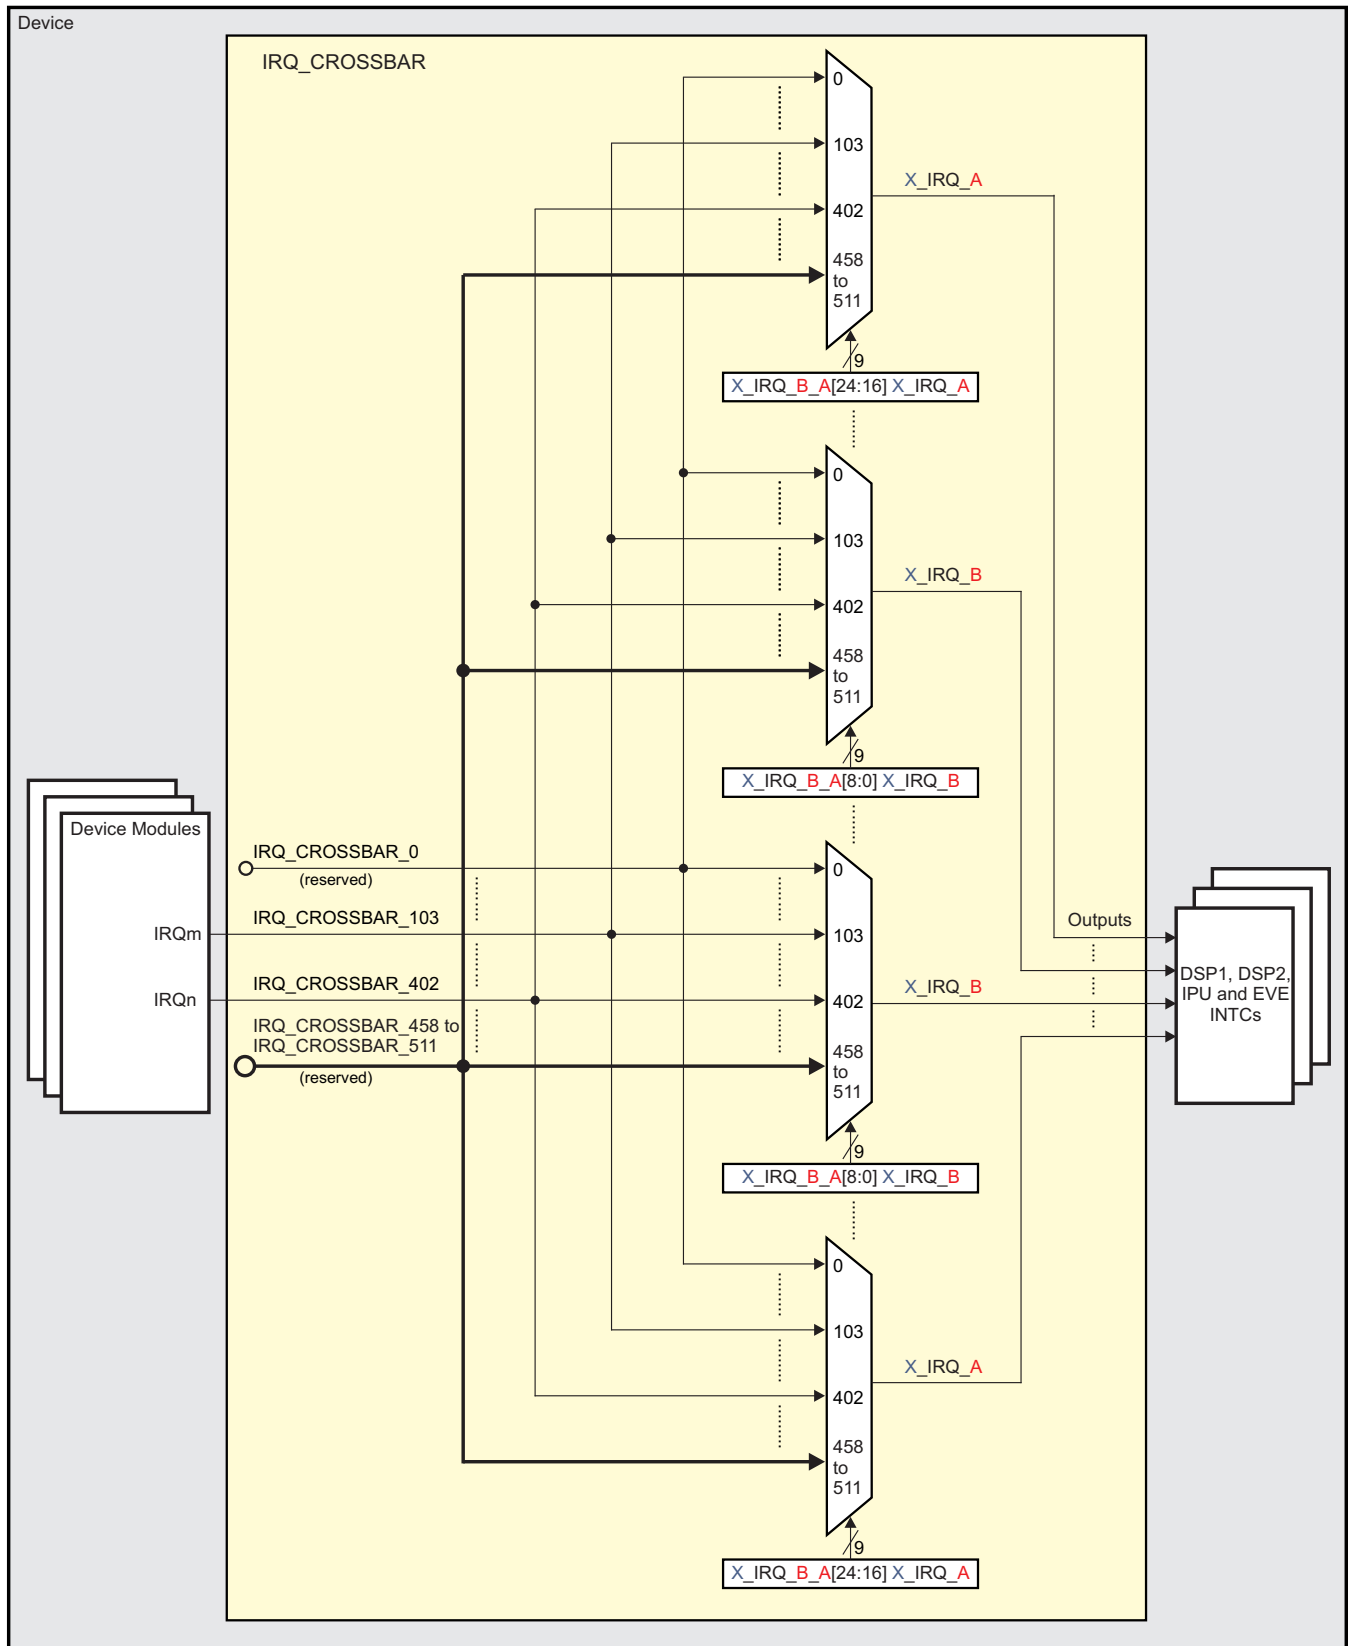

IRQ_CROSSBAR. Some of these IRQs are mapped by default to certain interrupt lines of one of the device INTCs, but there are IRQs which are not mapped by default to any interrupt line of any device INTC. All IRQs, connected to the IRQ_CROSSBAR inputs, can be remapped to other interrupt lines of the different device INTCs through the CTRL_CORE_X_IRQ_B_A registers. Each of these registers has a structure described in [Table 14-11](#).

Table 14-11. Generic Description of the CTRL_CORE_X_IRQ_B_A IRQ_CROSSBAR Control Registers

Bits	Field Name	Description	Type	Note
31:25	RESERVED		R	
24:16	X_IRQ_A	Selects an interrupt source signal for the X_IRQ_A INTC line 0x0: Reserved 0x1: Maps IRQ_CROSSBAR input 1 to X_IRQ_A INTC line 0x2: Maps IRQ_CROSSBAR input 2 to X_IRQ_A INTC line 0x-: 0x67: Maps IRQ_CROSSBAR input 103 to X_IRQ_A INTC line 0x-: 0x1C5 to 0x1FF: Reserved	RW	X is summarization. It is equal to: <ul style="list-style-type: none"> • DSP1 • DSP2 • IPU • EVE X shows the module name to which interrupt controller all inputs of the IRQ_CROSSBAR module can be mapped to. A is also summarization. It shows the number of the line for the corresponding INTC. A is equal to 0, 1, 2, ..., and so on, depending on the count of the INTC lines controlled by the IRQ_CROSSBAR module. For more details, see Table 14-12 .
15:9	RESERVED		R	
8:0	X_IRQ_B	Selects an interrupt source signal for the X_IRQ_B INTC line 0x0: Reserved 0x1: Maps IRQ_CROSSBAR input 1 to X_IRQ_B INTC line 0x2: Maps IRQ_CROSSBAR input 2 to X_IRQ_B INTC line 0x-: 0x67: Maps IRQ_CROSSBAR input 103 to X_IRQ_B INTC line 0x-: 0x1C5 to 0x1FF: Reserved	RW	B is summarization. It shows the number of the line for the corresponding INTC. B is equal to 0, 1, 2, ..., and so on, depending on the count of the INTC lines controlled by the IRQ_CROSSBAR module.

Figure 14-8 represents the way in which the IRQ_CROSSBAR module works. It shows the device modules and their IRQs connected to the IRQ_CROSSBAR inputs, the structure of the cross-bar and its outputs connected to the device INTCs.

Figure 14-8. IRQ_CROSSBAR Module Functional Diagram

ctrlmod-010

Each IRQ_CROSSBAR control register has two 9-bit fields. Each 9-bit field is associated only with one interrupt line. Through this 9-bit field any of the IRQs connected to the IRQ_CROSSBAR inputs can be mapped to the INTC line associated with this 9-bit field. For example, the register [CTRL_CORE_DSP1_IRQ_56_57](#) is associated with DSP1_IRQ_56 and DSP1_IRQ_57. The 9-bit field [CTRL_CORE_DSP1_IRQ_56_57\[24:16\]](#) DSP1_IRQ_57 is associated only with DSP1_IRQ_57 interrupt line of the DSP1 INTC. Setting this bit field to any other value different than its reset value will map another module IRQ to the DSP1_IRQ_57 interrupt line. The default (reset) value of this bit field is 0x1A which corresponds to IRQ_CROSSBAR_26 input. The GPIO3_IRQ_1 is connected to this cross-bar input. Setting another register to 0x1A will cause the GPIO3_IRQ_1 to be mapped to another INTC line. For example, if the [CTRL_CORE_DSP1_IRQ_40_41\[8:0\]](#) DSP1_IRQ_40 is set to 0x1A the GPIO3_IRQ_1 will be mapped to the DSP1_IRQ_40 interrupt line. The same logic also applies to the other interrupt lines of the device INTCs.

In addition, not all of the interrupt lines of a given INTC are controlled by the IRQ_CROSSBAR registers. This means, that there are interrupt lines which are not connected to any IRQ_CROSSBAR output and thus only one IRQ is connected to these interrupt lines. In the most common case these lines are used by interrupt sources internal or specific for the corresponding module, which has an INTC.

[Table 14-12](#) shows which lines of each INTC are associated with the IRQ_CROSSBAR control registers. The rest of the INTC lines (not listed in the table) cannot be controlled by the cross-bar registers.

Table 14-12. Interrupt Lines Associated With The IRQ_CROSSBAR Control Registers

DSP INTC Lines	IPU INTC Lines	EVE INTC Lines
DSP1_IRQ_32 to DSP1_IRQ_95, DSP2_IRQ_32 to DSP2_IRQ_95	IPU_IRQ_23 to IPU_IRQ_80	EVE_IRQ_0 to EVE_IRQ_7

The individual connection between all module IRQs and all IRQ_CROSSBAR inputs is shown in [Section 13.3.5, Mapping of Device Interrupts to IRQ_CROSSBAR Inputs](#) of [Chapter 13, Interrupt Controllers](#).

In addition, there are three IRQ_CROSSBAR registers associated with three channels of the device ESM. The registers are the following:

- [CTRL_CORE_ESM_GROUP1_0](#)
- [CTRL_CORE_ESM_GROUP1_1](#)
- [CTRL_CORE_ESM_GROUP1_2](#)

These three registers follow the same logic as previously described. For example, using the [CTRL_CORE_ESM_GROUP1_0\[8:0\]](#) ESM_GROUP1_0_IRQ_0 bit field any of the device interrupts connected to an IRQ_CROSSBAR input can be mapped to channel ESM_GROUP1_0.

NOTE: [ESM is not supported on the DM50x family of devices.](#)

14.4.6.5 DMA_CROSSBAR Module Functional Description

There is a DMA_CROSSBAR module in the device, which is controlled by registers in the CTRL_MODULE_CORE submodule. The DMA_CROSSBAR is able to map any of its input signals to any of its outputs. This module is associated with the device DMA request (DREQ) source signals. The DREQs from all the device modules are connected to the DMA_CROSSBAR inputs. Each DREQ signal is connected only to one DMA cross-bar input. Each output of the DMA_CROSSBAR module is connected only to one input line of the device DMA modules. The DMAs associated with the DMA_CROSSBAR are the following:

- DMA_EDMA
- DMA_DSP1_EDMA
- DMA_DSP2_EDMA

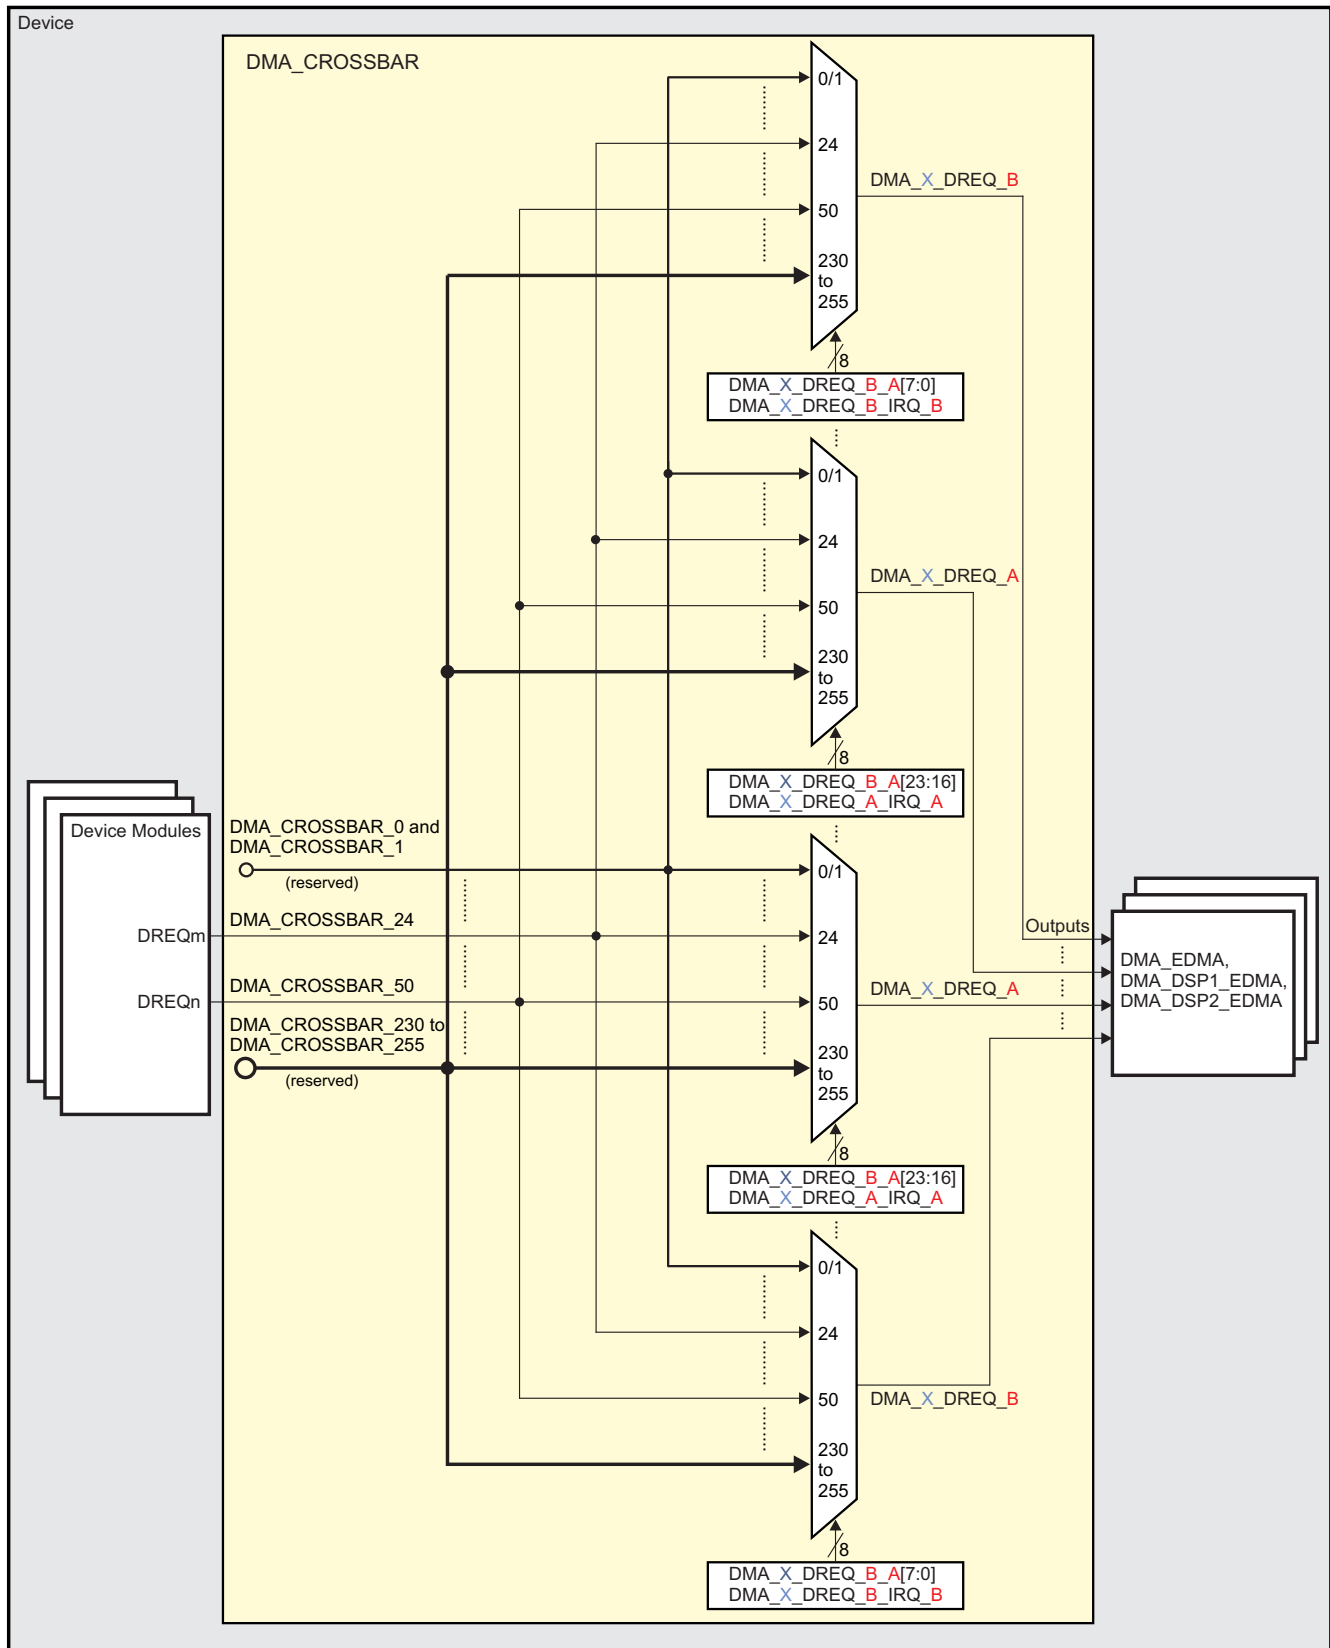

All DREQs, connected to the DMA_CROSSBAR inputs, can be remapped to other lines of the these DMA modules through the CTRL_CORE_DMA_X_DREQ_B_A registers. Each of these registers has a structure described in [Table 14-13](#).

Table 14-13. Generic Description of the CTRL_CORE_DMA_X_DREQ_B_A DMA_CROSSBAR Control Registers

Bits	Field Name	Description	Type	Note
31:24	RESERVED		R	
23:16	DMA_X_DREQ_A_IRQ_A	Selects a DMA request source signal for the DMA_X_DREQ_A_IRQ_A DMA line 0x0: Reserved 0x1: Reserved 0x2: Maps DMA_CROSSBAR input 2 to DMA_X_DREQ_A_IRQ_A DMA line 0x3: Maps DMA_CROSSBAR input 3 to DMA_X_DREQ_A_IRQ_A DMA line 0x-: 0x32: Maps DMA_CROSSBAR input 50 to DMA_X_DREQ_A_IRQ_A DMA line 0x-: 0xE6 to 0xFF: Reserved	RW	X is summarization. It is equal to: <ul style="list-style-type: none"> • EDMA • DSP1_EDMA • DSP2_EDMA X shows to which DMA all inputs of the DMA_CROSSBAR module can be mapped to. A is also summarization. It shows the number of the DREQ line for the corresponding DMA module. A is equal to 0, 1, 2, ..., and so on, depending on the count of the DMA lines controlled by the DMA_CROSSBAR module. For more details, see Table 14-14 .
15:8	RESERVED		R	
7:0	DMA_X_DREQ_B_IRQ_B	Selects a DMA request source signal for the DMA_X_DREQ_B_IRQ_B DMA line 0x0: Reserved 0x1: Reserved 0x2: Maps DMA_CROSSBAR input 2 to DMA_X_DREQ_B_IRQ_B DMA line 0x3: Maps DMA_CROSSBAR input 3 to DMA_X_DREQ_B_IRQ_B DMA line 0x-: 0x32: Maps DMA_CROSSBAR input 50 to DMA_X_DREQ_B_IRQ_B DMA line 0x-: 0xE6 to 0xFF: Reserved	RW	B is also summarization. It shows the number of the DREQ line for the corresponding DMA module. B is equal to 0, 1, 2, ..., and so on, depending on the count of the DMA lines controlled by the DMA_CROSSBAR module. For more details, see Table 14-14 .

Figure 14-9 represents the way in which the DMA_CROSSBAR module works. It shows the device modules and their DREQs connected to the DMA_CROSSBAR inputs, the structure of the cross-bar and its outputs connected to the device DMA modules.

Figure 14-9. DMA_CROSSBAR Module Functional Diagram

ctrlmod-011

Each DMA_CROSSBAR control register has two 8-bit fields. Each 8-bit field is associated only with one line of certain DMA module. Through this 8-bit field any of the DREQs connected to the DMA_CROSSBAR inputs can be mapped to the DMA line associated with this 8-bit field. For example, the register [CTRL_CORE_DMA_EDMA_DREQ_48_49](#) is associated with DMA_EDMA_DREQ_48 and DMA_EDMA_DREQ_49 lines. The 8-bit field [CTRL_CORE_DMA_EDMA_DREQ_48_49\[7:0\]](#) DMA_EDMA_DREQ_48_IRQ_48 is associated only with DMA_EDMA_DREQ_48 line of the DMA_EDMA module. Setting this bit field to any other value different than its reset value will map another DREQ from the device modules to the DMA_EDMA_DREQ_48 line. The default (reset) value of this bit field is 0x31 which corresponds to the DMA_CROSSBAR_49 input. The UART1_DREQ_TX is connected to this crossbar input. Setting another register to 0x31 will cause the UART1_DREQ_TX to be mapped to another DMA line. For example, if the [CTRL_CORE_DMA_EDMA_DREQ_40_41\[23:16\]](#) DMA_EDMA_DREQ_41_IRQ_41 is set to 0x31 the UART1_DREQ_TX will be mapped to the DMA_EDMA_DREQ_41 line. The same logic also applies to the other lines of the device DMAs.

[Table 14-14](#) shows which lines of each DMA are associated with the DMA_CROSSBAR control registers. The rest of the lines (not listed in the table) cannot be controlled by the cross-bar registers.

Table 14-14. DREQ Lines Associated With The DMA_CROSSBAR Control Registers

DMA_EDMA DREQ Lines	DMA_DSP1_EDMA DREQ Lines	DMA_DSP2_EDMA DREQ Lines
DMA_EDMA_DREQ_0 to DMA_EDMA_DREQ_63	DMA_DSP1_DREQ_0 to DMA_DSP1_DREQ_19	DMA_DSP2_DREQ_0 to DMA_DSP2_DREQ_19

The individual connection between all module DREQs and all DMA_CROSSBAR inputs is shown in , *Mapping of DMA Requests to DMA_CROSSBAR Inputs* of [Chapter 12, Enhanced DMA Controllers](#).

In addition, the [CTRL_CORE_ESM_GROUP1_3](#) register can be used to map any of the device DREQs connected to a DMA_CROSSBAR input to channel ESM_GROUP1_3 of the device ESM. The same logic as previously described applies when configuring this register.

NOTE: ESM is not supported on the DM50x family of devices.

14.4.6.6 SDRAM Initiator Priority Registers

The [CTRL_CORE_EMIF_INITIATOR_PRIORITY_1](#) to [CTRL_CORE_EMIF_INITIATOR_PRIORITY_8](#) registers are intended to control the priority of each initiator accessing the EMIF controller. Each 3-bit field in these registers is associated only with one initiator. Setting this bit field to 0x0 means that the corresponding initiator has a highest priority over the others and setting it to 0x7 is for lowest priority. This is useful in case of concurrent access to the external SDRAM from several initiators.

14.4.6.7 L3_MAIN Initiator Priority Registers

The [CTRL_CORE_L3_INITIATOR_PRESSURE_1](#) register is used for controlling the priority of certain initiators on the L3_MAIN. Each 2-bit field in this register is associated only with one initiator. Setting this bit field to 0x3 means that the traffic of this initiator has highest priority over the other traffics. A value of 0x0 is for lowest priority. This register provides a dynamic priority escalation for the following L3_MAIN initiators:

- DSP1
- DSP2

14.4.6.8 Memory Region Lock Registers

There are five registers used to lock different memory regions of CTRL_MODULE_CORE memory mapped space. A memory region is locked, means that all write accesses to this region are ignored. Writing a value unique for each register will lock certain memory region and writing another unique value results in unlocking of the same region. These five registers can lock the entire memory space of the CTRL_MODULE_CORE submodule. [Table 14-15](#) gives more details.

Table 14-15. Memory Region Lock Registers

Register	Memory Space to Lock	Groups of Registers Associated With This Memory Region	Lock/Unlock (register reset value)
CTRL_CORE_MMR_LOCK_1	Region from 0x0000 0100 to 0x0000 079F and from 0x0000 1A00 to 0x0000 1FFF	Thermal management related registers, EMIF initiator priority, L3_MAIN initiator pressure (priority) and other registers	locked
CTRL_CORE_MMR_LOCK_2	Region from 0x0000 07A0 to 0x0000 0D9F	IRQ_CROSSBAR and DMA_CROSSBAR registers	locked
CTRL_CORE_MMR_LOCK_3	Region from 0x0000 0DA0 to 0x0000 0FFF	A few registers associated with device I/Os	locked
CTRL_CORE_MMR_LOCK_4	Region from 0x0000 1000 to 0x0000 13FF	Hardware observability related registers	locked
CTRL_CORE_MMR_LOCK_5	Region from 0x0000 1400 to 0x0000 19FF	Pad configuration registers	locked

NOTE: By default the entire CTRL_MODULE_CORE memory space is locked but the ROM code unlocks it by writing corresponding unlock values to all CTRL_CORE_MMR_LOCK_x registers.

14.4.6.9 NMI Mapping To Respective Cores

Two registers [CTRL_CORE_NMI_DESTINATION_1](#) and [CTRL_CORE_NMI_DESTINATION_2](#) are intended to map the external non-maskable interrupt (NMI) to certain of the device host processors. Writing 0x1 into a bit field of these registers enables the NMI to be mapped to the corresponding processor associated with this bit field. Writing 0x0 disables the NMI mapping to this processor.

14.4.6.10 Software Controls for the LPDDR2/DDR2/DDR3 I/O Cells

There are two types of I/O cells associated with the LPDDR2/DDR2/DDR3 interface. These are single-ended and differential I/O cells.

These I/O cells have the following software controls which reside in registers of the CTRL_MODULE_CORE:

- Output impedance controls - I[2:0]
- Slew rate controls - SR[2:0]
- Weak driver controls - WD[1:0]

The I and SR controls apply when the I/Os operate as outputs. The WD controls apply when the I/Os operate as both inputs or outputs.

The bits I[2:0] are used for programming the desired impedance value of the output buffer. [Table 14-16](#) describes the I[2:0] controls which are valid for pull-up and pull-down outputs.

Table 14-16. Output Impedance Controls - I[2:0]

I[2]	I[1]	I[0]	Drive Setting Name	Output Impedance
0	0	0	Imp80	80 Ohms
0	0	1	Imp60	60 Ohms
0	1	0	Imp48	48 Ohms
0	1	1	Imp40	40 Ohms
1	0	0	Imp34	34 Ohms
1	0	1	Reserved	Reserved
1	1	0	Reserved	Reserved
1	1	1	Reserved	Reserved

To achieve optimal noise/slew trade-off the slew rate of the output signal can also be programmed using the slew rate control bits SR[2:0] shown in [Table 14-17](#). These SR settings do not affect the DC drive strength of the output buffer. They only control its turn-on time.

Table 14-17. Slew Rate Controls - SR[2:0]

SR[2]	SR[1]	SR[0]	Turn-On Time Level	Note
0	0	0	fastest	All 8 values are valid.
...		
...		
1	1	1	slowest	

Weak pull-up, pull-down or keeper option for device LPDDR2/DDR2/DDR3 pads is enabled through the WD[1:0] bits. The weak pull-up or pull-down option is used to define the pad state (high or low) when no signal is driving the pad. The weak keeper option is used to maintain the previous output value when nothing is driving the pad. [Table 14-18](#) describes the WD controls. They are used for avoiding floating pads on the LPDDR2/DDR2/DDR3 interface.

Table 14-18. Weak Driver Controls - WD[1:0]

WD[1]	WD[0]	Single-Ended Operation	Differential Pair Operation	
			padp	padn
0	0	Pull logic disabled	Pull logic disabled	Pull logic disabled
0	1	Weak pullup enabled	Weak pullup enabled	Weak pulldown enabled
1	0	Weak pulldown enabled	Weak pulldown enabled	Weak pullup enabled
1	1	Weak keeper enabled	Weak keeper enabled	Weak keeper enabled

NOTE: To avoid unnecessary power consumption, software must overwrite the Weak Driver (WD) reset values by setting them to 0x0.

It must be taken into account that the I, SR and WD software controls apply for several pads combined in groups, and not for a single pad. For example, writing 0x1 to the [CTRL_CORE_CONTROL_DDR3CH1_0\[17:16\]](#) DDR3CH1_PART5A_WD bit field enables the weak pull-up resistors for all pads in the PART5A group. These are the ddr1_a[15:0] pads. [Table 14-19](#) shows the I, SR and WD controls for the different LPDDR2/DDR2/DDR3 pad groups.

Table 14-19. Software Group Controls for the LPDDR2/DDR2/DDR3 Pads

LPDDR2/DDR2/DDR3 Interface I/O Group Controls	Group Name	EMIF Pads in a Group
CTRL_CORE_CONTROL_DDR3CH1_0[31:29] DDR3CH1_PART0_I	PART0	ddr1_casn, ddr1_rasn, ddr1_rst, ddr1_wen, ddr1_csn[0], ddr1_cke, ddr1_odt[0]

14.4.6.11 Reference Voltage for the Device LPDDR2/DDR2/DDR3 Receivers

The device LPDDR2/DDR2/DDR3 input buffers work in so-called Vref-based receiver mode. In this mode, the buffers act like differential comparators with positive terminal connected to a device pad which receives signals from LPDDR2/DDR2/DDR3 memory and negative terminal connected to a source of reference voltage.

To work properly, a reference voltage must be provided to the device LPDDR2/DDR2/DDR3 input buffers. There are two Vref-generation cells in the device intended to supply this internal reference voltage.

[Figure 14-10](#) shows the Vref-generation cells in the device.

Figure 14-10. Vref-Generation Cells and Their Controls

ctrlmod-004

The control bits for the Vref-generation cells reside in the [CTRL_CORE_CONTROL_DDRIO_0](#) register. There are VREF_x_TAP[1:0] control bits which set the output drive capability of the Vref cells. [Table 14-20](#) lists the possible options for selection of load current sourced from the output of each Vref-generation cell.

Table 14-20. Vref Cell Load Current Selection

VREF_x_TAP1	VREF_x_TAP0	Description
0	0	2- μ A load current
0	1	4- μ A load current
1	0	8- μ A load current
1	1	32- μ A load current

According to the noise environment, the user can choose to filter the supplied reference voltage. Two coupling capacitors internal to each Vref-generation cell are available and configurable through the VREF_x_CCAP[1:0] control bits in the [CTRL_CORE_CONTROL_DDRIO_0](#) register as specified in [Table 14-21](#).

Table 14-21. Vref Cell Coupling Capacitor Selection

VREF_x_CCAP1	VREF_x_CCAP0	Capacitor
0	0	No capacitor connected.
0	1	One capacitor connected between Vbias and ground. ⁽¹⁾
1	0	One capacitor connected between Vbias and Vdds. ⁽²⁾
1	1	One capacitor connected between Vbias and ground and one capacitor connected between Vbias and Vdds.

⁽¹⁾ Vbias is the output of the Vref-generation cell which provides the reference voltage.

⁽²⁾ Vdds is the power supply voltage of the Vref-generation cell.

The Vref-generation cells can be enabled by setting to 0x1 the VREF_x_EN bits in the [CTRL_CORE_CONTROL_DDRIO_0](#) register. These cells can be disabled (for leakage improvement and when not in use) by clearing the same VREF_x_EN bits.

[Table 14-22](#) shows the Vref-generation cells control bits and the LPDDR2/DDR2/DDR3 pads used as receivers to which the corresponding Vref cell supplies reference voltage.

Table 14-22. Controls for the Vref-Generation Cells Versus LPDDR2/DDR2/DDR3 Receiver Pads

Vref-generation Cell Control Bits	LPDDR2/DDR2/DDR3 Vref Cell Associated Pads Used as Receivers
CTRL_CORE_CONTROL_DDRIO_0 [19] DDRCH1_VREF_DQ0_INT_CCAP0	ddr1_d[7:0], ddr1_d[15:8]

CTRL_CORE_CONTROL_DDRIO_0 [13] DDRCH1_VREF_DQ1_INT_CCAP1	
CTRL_CORE_CONTROL_DDRIO_0 [12] DDRCH1_VREF_DQ1_INT_TAP0	
CTRL_CORE_CONTROL_DDRIO_0 [11] DDRCH1_VREF_DQ1_INT_TAP1	
CTRL_CORE_CONTROL_DDRIO_0 [10] DDRCH1_VREF_DQ1_INT_EN	

14.4.6.12 AVS Class 0 Associated Registers

AVS Class 0 attempts to normalize the power consumption across all devices by lowering the operating voltage of certain voltage rails. This procedure of lowering the voltage should be performed in the boot loader after ROM code. The new voltage to be set for each AVS Class 0 supported voltage rail should be read from the eFuse using dedicated registers. Then the power supply output voltage is adjusted to this new voltage value.

The following voltage rails support AVS Class 0:

- vdd_dspeve
- vdd

NOTE: For descriptions of the voltage rails previously listed see the "Power Supply Signal Descriptions" table in the device Data Manual.

[Table 14-23](#) shows all registers associated with AVS Class 0. The corresponding AVS Class 0 voltage value can be read from the 12 LSbits of each of the listed registers. They contain the voltage value in hex format. To find the actual value in mV a conversion from hex to decimal value is needed. For example, if the value read from [CTRL_CORE_STD_FUSE_OPP_VMIN_CORE_2](#)[11:0] [STD_FUSE_OPP_VMIN_CORE_2](#) is 0x041F, then this corresponds to 1055 mV.

Table 14-23. Registers Associated With AVS Class 0 Voltage

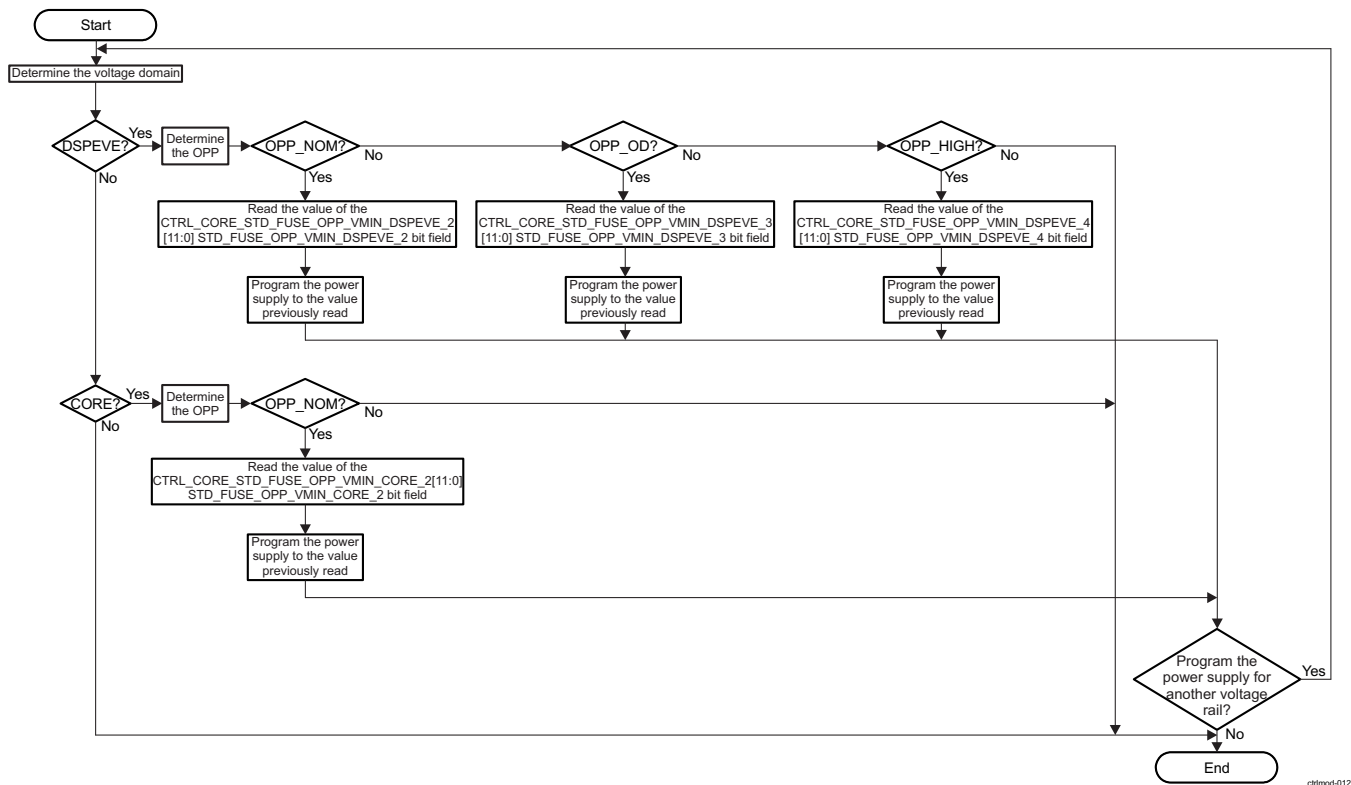

Physical Address	Bit Field Containing the AVS Class 0 Voltage Value	Voltage Rail	Supported OPP
0x4A00 25E0	CTRL_CORE_STD_FUSE_OPP_VMIN_DSPEVE_2 [11:0] STD_FUSE_OPP_VMIN_DSPEVE_2	vdd_dspeve	OPP_NOM
0x4A00 25E4	CTRL_CORE_STD_FUSE_OPP_VMIN_DSPEVE_3 [11:0] STD_FUSE_OPP_VMIN_DSPEVE_3		OPP_OD
0x4A00 25E8	CTRL_CORE_STD_FUSE_OPP_VMIN_DSPEVE_4 [11:0] STD_FUSE_OPP_VMIN_DSPEVE_4		OPP_HIGH
0x4A00 25F4	CTRL_CORE_STD_FUSE_OPP_VMIN_CORE_2 [11:0] STD_FUSE_OPP_VMIN_CORE_2	vdd	OPP_NOM

NOTE: For more information about the supported OPPs, see the "Operating Performance Points" section of the device Data Manual.

In some cases, the AVS Class 0 voltage that is read from the CTRL_CORE_STD_FUSE_OPP_VMIN_xxx_y registers has a value between two incremental voltage steps of the power supply. If such a case occurs, the higher voltage value should be selected.

Figure 14-11 shows a general example of how AVS Class 0 should be performed.

Figure 14-11. AVS Class 0 Procedure

14.4.6.13 Registers For Other Miscellaneous Functions

14.4.6.13.1 System Boot Status Settings

The CTRL_CORE_BOOTSTRAP register is a status register which indicates the state of the sysboot0 through sysboot15 input signals. Their purpose is to select the boot interface, the device source clock configuration and also other boot related settings.

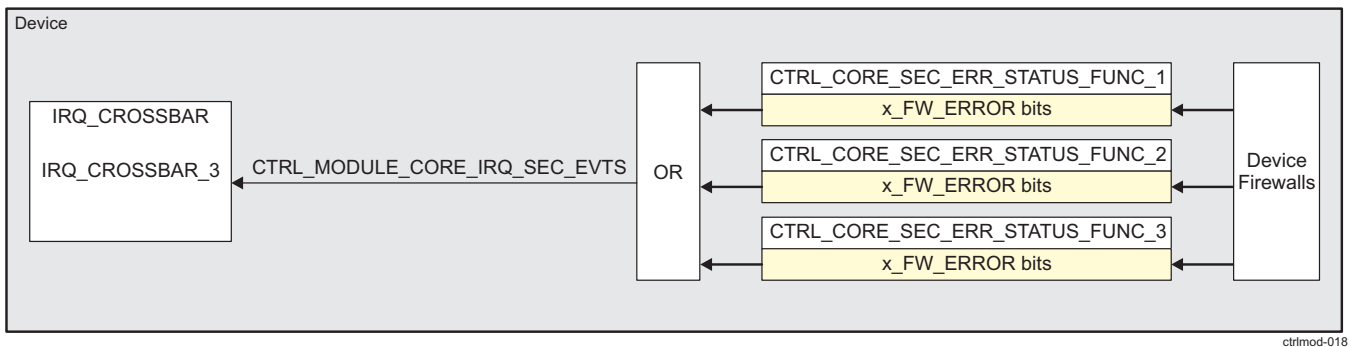

NOTE: For proper device operation, sysboot15 must be tied to vdd and sysboot14 must be tied to vss.

14.4.6.13.2 Firewall Error Status Registers

There are several status registers which show when there is a firewall error. The [CTRL_CORE_SEC_ERR_STATUS_FUNC_1](#), [CTRL_CORE_SEC_ERR_STATUS_FUNC_2](#) and [CTRL_CORE_SEC_ERR_STATUS_FUNC_3](#) registers are used in device normal operation mode. The x_FW_ERROR bits from these three registers are combined into a single interrupt signal sent to the IRQ_CROSSBAR module as shown in [Figure 14-12](#). The [CTRL_CORE_SEC_ERR_STATUS_DEBUG_1](#), [CTRL_CORE_SEC_ERR_STATUS_DEBUG_2](#) and [CTRL_CORE_SEC_ERR_STATUS_DEBUG_3](#) registers are used when the device is in debug mode. These registers have same bits as in the [CTRL_CORE_SEC_ERR_STATUS_FUNC_1](#), [CTRL_CORE_SEC_ERR_STATUS_FUNC_2](#) and [CTRL_CORE_SEC_ERR_STATUS_FUNC_3](#) registers.

All bits in these registers are cleared when the [ERROR_LOG_k](#) and [L4_IA_ERROR_LOG_L](#) registers are cleared.

Figure 14-12. Combined Firewall Error Interrupt

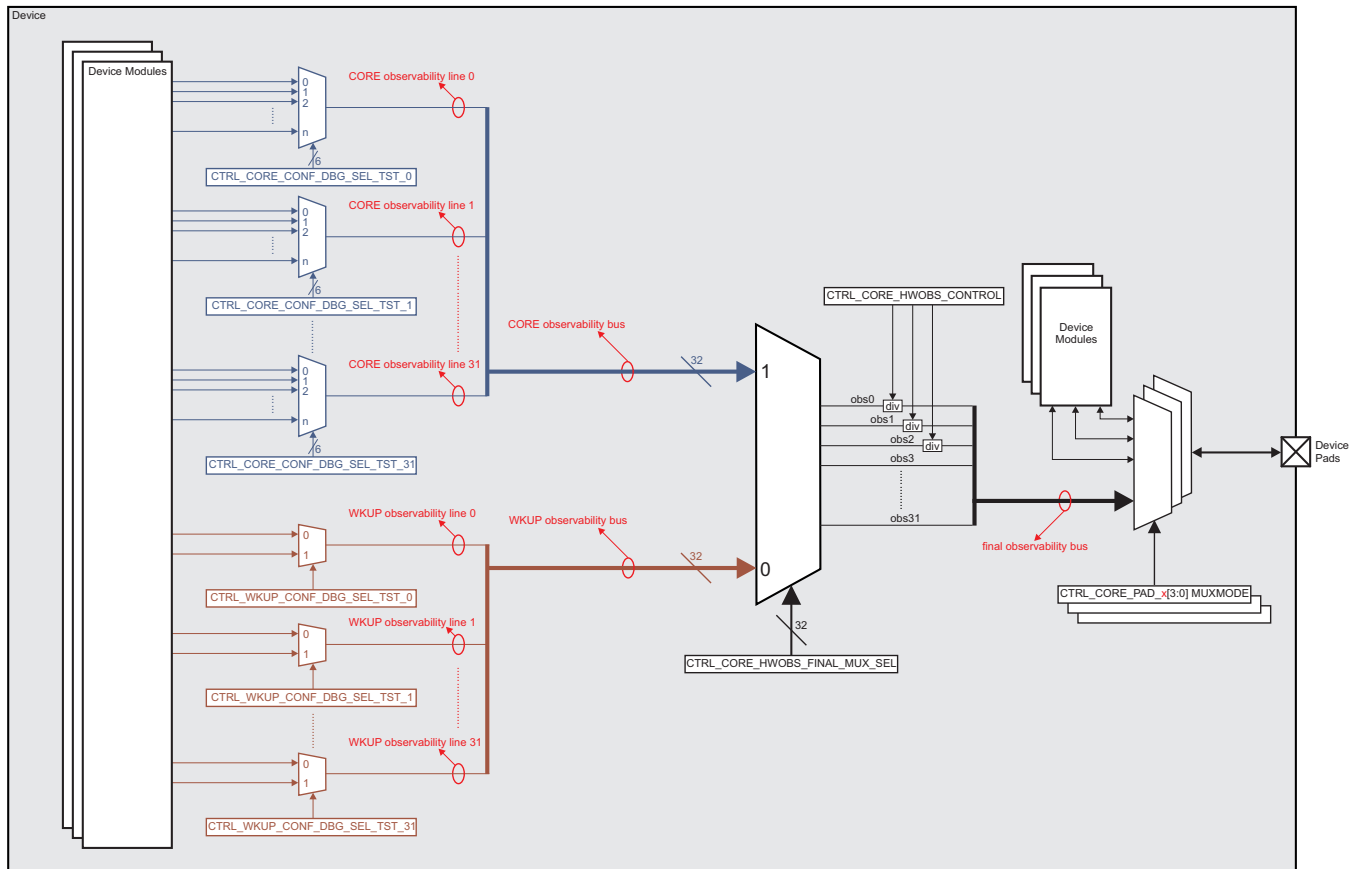

14.4.6.13.3 Settings Related To Different Peripheral Modules

The [CTRL_CORE_CONTROL_IO_1](#) and [CTRL_CORE_CONTROL_IO_2](#) registers have controls for specific settings of several device peripheral modules. For more information, see the bit field descriptions.

14.4.6.14 Hardware Observability Related Registers

There is a set of registers which are associated with the device observability logic. Using these registers a desired module signal can be mapped to dedicated-for-observation pad and then this signal can be observed. [Figure 14-13](#) shows the device observability logic.

Figure 14-13. Hardware Observability Logic

As can be seen on [Figure 14-13](#) there are two 32-bit wide observability buses. One associated with signals in CORE and one with signals in WKUP power domain. The multiplexing of the CORE observable signals is controlled by [CTRL_CORE_CONF_DEBUG_SEL_TST_0](#) through [CTRL_CORE_CONF_DEBUG_SEL_TST_31](#) registers. The multiplexing of the WKUP observable signals is controlled by [CTRL_WKUP_CONF_DEBUG_SEL_TST_0](#) through [CTRL_WKUP_CONF_DEBUG_SEL_TST_31](#) registers. Each of these registers is associated with one observability line. For example, the [CTRL_CORE_CONF_DEBUG_SEL_TST_0](#) register selects one of N observability signals to be mapped to CORE observability line 0.

The [CTRL_CORE_HWOBS_FINAL_MUX_SEL](#) register is used to control the final multiplexer which selects CORE or WKUP observable signals to be mapped to the final observability bus. This bus is composed of obs0 through obs31 lines. Each bit in the [CTRL_CORE_HWOBS_FINAL_MUX_SEL](#) register is associated with one of these lines. A value of 0x0 selects a WKUP observable signal and 0x1 select CORE observable signal.

Optionally, the frequency of obs0, obs1 and obs2 lines can be divided through the bit fields HWOBS_CLKDIV_SEL, HWOBS_CLKDIV_SEL_1 and HWOBS_CLKDIV_SEL_2 from register [CTRL_CORE_HWOBS_CONTROL](#). This register provides also an option to force all 32 signals (obs0 through obs31) of the observability bus to 0 or to 1 setting to 0x1 bit HWOBS_ALL_ZERO_MODE or bit HWOBS_ALL_ONE_MODE, respectively.

14.4.7 Functional Description Of The Various Register Types In CTRL_MODULE_WKUP Submodule

The following sections describe the purpose of the registers which reside in the CTRL_MODULE_WKUP submodule.

14.4.7.1 Registers For Basic EMIF configuration

The [CTRL_WKUP_SECURE_EMIF1_SDRAM_CONFIG](#) register has bits which determine the basic settings of the EMIF controller. These are, for example, settings like CAS write latency, SDRAM drive strength, SDRAM termination resistor values, SDRAM type and others. The [CTRL_WKUP_SECURE_EMIF1_SDRAM_CONFIG](#) bit field values are exported upon POR to the EMIF.EMIF_SDRAM_CONFIG register.

The [CTRL_WKUP_EMIF1_SDRAM_CONFIG_EXT](#) register is associated with DDR PHY controls, ODT values for device DDR I/Os, some leveling related parameters and others.

Table 14-80. CTRL_CORE_HWOBS_CONTROL

Address Offset	0x0000 0360	
Physical Address	0x4A00 2360	Instance CTRL_MODULE_CORE
Description	HW observability control. This register enables or disables HW observability outputs (to save power primarily)	
Type	RW	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								HWOBS_CLKDIV_SEL_2				HWOBS_CLKDIV_SEL_1				RESERVED	HWOBS_CLKDIV_SEL			HWOBS_ALL_ZERO_MODE	HWOBS_ALL_ONE_MODE	HWOBS_MACRO_ENABLE									

Bits	Field Name	Description	Type	Reset
31:19	RESERVED		R	0x0
18:14	HWOBS_CLKDIV_SEL_2	Clock divider selection for obs2 line. 0x1 = output is not divided 0x2 = output is divided by 2 0x4 = output is divided by 4 0x8 = output is divided by 8 0x10 = output is divided by 16	RW	0x0

Bits	Field Name	Description	Type	Reset
13:9	HWOBS_CLKDIV_SEL_1	Clock divider selection for obs1 line. 0x1 = output is not divided 0x2 = output is divided by 2 0x4 = output is divided by 4 0x8 = output is divided by 8 0x10 = output is divided by 16	RW	0x0
8	RESERVED		R	0x0
7:3	HWOBS_CLKDIV_SEL	Clock divider selection for obs0 line. 0x1 = output is not divided 0x2 = output is divided by 2 0x4 = output is divided by 4 0x8 = output is divided by 8 0x10 = output is divided by 16	RW	0x0
2	HWOBS_ALL_ZERO_MODE	Used to gate observable signals. When set all outputs are set to zero (can be used to check the path from HW observability to external pads). 0x0 = hw observability ports are not gated 0x1 = hw observability ports are all set to 0	RW	0x0
1	HWOBS_ALL_ONE_MODE	Used to gate observable signals. When set all outputs are set to one (can be used to check the path from HW observability to external pads). 0x0 = hw observability ports are not gated 0x1 = hw observability ports are all set to 1	RW	0x0
0	HWOBS_MACRO_ENABLE	Used to gate observable signals coming from macros using the 32-bit HWOBS bus definition. When deasserted all outputs of the HWOBS busdef are set to zero. 0x0 = hw observability ports from macros are gated and set to zero 0x1 = hw observability ports from macros are not gated	RW	0x0

Table 14-936. CTRL_CORE_SMA_SW_17

Address Offset	0x0000 1C9C	Instance	CTRL_MODULE_CORE
Physical Address	0x4A00 3C9C		
Description	This register holds some controls and status bits for H14 HS divider of DPLL_GMAC_DSP which is the source of MCAN functional clock (MCAN_CLK).		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
SMA_SW_17																MCAN_CLK_HSDIV_CHANGE_ACK	MCAN_CLK_HSDIV_EN_ACK	MCAN_CLK_TENABLEDIV_SEL	RESERVED	MCAN_CLK_HSDIV_EN	MCAN_CLK_HSDIV_LATCH_EN	MCAN_CLK_HSDIV										

Bits	Field Name	Description	Type	Reset
31:12	SMA_SW_17	OCP Spare Bits	RW	0x0
11	MCAN_CLK_HSDIV_CHANGE_ACK	Acknowledge flag which indicates that the on-the-fly change of H14 divider of DPLL_GMAC_DSP is done. This bit changes its state (0 to 1 or 1 to 0) on each on-the-fly change of H14.	R	0x1
10	MCAN_CLK_HSDIV_EN_ACK	Indicates whether CLKOUTX2_H14 of DPLL_GMAC_DSP is enabled or not. 0x0: CLKOUTX2_H14 is disabled 0x1: CLKOUTX2_H14 is enabled	R	0x0
9	MCAN_CLK_TENABLEDIV_SEL	TENABLEDIV control select for H14 of DPLL_GMAC_DSP 0x0: Control from PRCM 0x1: Control from Control Module (bit CTRL_CORE_SMA_SW_17 [6] MCAN_CLK_HSDIV_LATCH_EN)	RW	0x0
8	RESERVED	Reserved	RW	0x0
7	MCAN_CLK_HSDIV_EN	Output clock (CLKOUTX2_H14) enable for H14 of DPLL_GMAC_DSP 0x0: Output clock disabled 0x1: Output clock enabled	RW	0x0
6	MCAN_CLK_HSDIV_LATCH_EN	To be toggled (LO->HI->LO) to latch MCAN_CLK_HSDIV value in H14 of DPLL_GMAC_DSP. This bit takes effect only when bit CTRL_CORE_SMA_SW_17 [9] MCAN_CLK_TENABLEDIV_SEL is set to 0x1.	RW	0x0
5:0	MCAN_CLK_HSDIV	This field programs the H14 divider of DPLL_GMAC_DSP. The actual division is equal to this register value+1. 0x0: H14 = /1 0x1: H14 = /2 ... 0x3F: H14 = /64	RW	0x18

Table 14-977. CTRL_WKUP_EMIF1_SDRAM_CONFIG_EXT

Address Offset	0x0000 0144	Instance	CTRL_MODULE_WKUP
Physical Address	0x4AE0 C144		
Description	SLICE register for emif1 and emif2		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0														
RESERVED																EMIF1_NARROW_ONLY		EMIF1_EN_ECC		EMIF1_REG_PHY_NUM_OF_SAMPLES				EMIF1_REG_PHY_SEL_LOGIC		EMIF1_REG_PHY_ALL_DQ_MPR_RD_RESP		EMIF1_REG_PHY_OUTPUT_STATUS_SELECT		RESERVED		EMIF1_SDRAM_DISABLE_RESET		EMIF1_PHY_RD_LOCAL_ODT		RESERVED		EMIF1_DFI_CLOCK_PHASE_CTRL		EMIF1_EN_SLICE_2		EMIF1_EN_SLICE_1		EMIF1_EN_SLICE_0	

Bits	Field Name	Description	Type	Reset
31:18	RESERVED		R	0x0
17	EMIF1_NARROW_ONLY	EMIF1 operates in narrow mode, to allow for data macros to be powered down to save power 0x0 = narrow mode disabled 0x1 = narrow mode enabled	RW	0x0
16	EMIF1_EN_ECC	EMIF1 ECC enable 0x0 = ECC is disabled 0x1 = ECC is enabled	RW	0x0
15:14	EMIF1_REG_PHY_NUM_OF_SAMPLES	Controls the number of DQ samples required for read leveling. The recommended setting for full leveling is 0x3 (128 samples) and for incremental leveling is 0x0 (4 samples). 0x0 = 4 samples 0x1 = 8 samples. 0x2 = 16 samples 0x3 = 128 samples	RW	0x0
13	EMIF1_REG_PHY_SEL_LOGIC	Selects an algorithm for read leveling. The use of algorithm 1 (set by default) is recommended. 0x0 = Algorithm 1 is used 0x1 = Algorithm 2 is used	RW	0x0
12	EMIF1_REG_PHY_ALL_DQ_MPR_RD_RESP	Analysis method of DQ bits during read leveling. 0x0: if the DRAM provides a read response on only one DQ bit (this can be any bit, since in this mode all 8 DQ bits are OR-ed together). This is the default setting and works with all memory types (memories send responses on all DQ bits or on a single DQ bit). 0x1: if the DRAM provides a read response on all DQ bits.	RW	0x0
11:9	EMIF1_REG_PHY_OUTPUT_STATUS_SELECT	Selects the status to be observed on the outputs of the DDR PHYs through CTRL_WKUP_EMIF1_SDRAM_CONFIG_EXT_1 register. 0x0 = selects phy_reg_rdlvl_start_ratio[7:0] 0x1 = selects phy_reg_rdlvl_start_ratio[15:8] 0x2 = selects phy_reg_rdlvl_end_ratio[7:0] 0x3 = selects phy_reg_rdlvl_end_ratio[15:8]	RW	0x0

Bits	Field Name	Description	Type	Reset
8	RESERVED		R	0x1
7	EMIF1_SDRAM_DISABLE_RESET	DDR3 SDRAM reset disable. 0x0 = DDR3 SDRAM reset signal is enabled. It can be asserted by EMIF 0x1 = DDR3 SDRAM reset signal is disabled. It is forbidden to EMIF to assert it.	RW	0x0
6:5	EMIF1_PHY_RD_LOCAL_ODT	Control of ODT (on – die termination) settings for the device DDR I/Os. ODT is enabled only during read operations when termination is required. 0x0 = ODT disabled 0x1= 60 Ohms 0x2 = 80 Ohms 0x3 =120 Ohms	RW	0x0
4	RESERVED		RW	0x0
3	EMIF1_DFI_CLOCK_PHASE_CTRL	EMIF_FICLK clock phase control (shifting by 180°). For normal operation this bit must always be set to 0x0 (disabled).	RW	0x0
2	EMIF1_EN_SLICE_2	Enable command PHY 2. When using DDR3 this bit can be set to 0x0 or 0x1. For lower power consumption 0x0 is used.	RW	0x1
1	EMIF1_EN_SLICE_1	Enable command PHY 1. 0x1 is the mandatory setting if DDR3 is used. EMIF1_EN_SLICE_0 and EMIF1_EN_SLICE_1 have to be programmed with the same value.	RW	0x1
0	EMIF1_EN_SLICE_0	Enable command PHY 0. 0x1 is the mandatory setting if DDR3 is used. EMIF1_EN_SLICE_0 and EMIF1_EN_SLICE_1 have to be programmed with the same value.	RW	0x1

Mailbox

This chapter describes the mailbox module in the device.

Topic	Page
15.1 Mailbox Overview.....	4997
15.2 Mailbox Integration	4997
15.3 Mailbox Functional Description	5001
15.4 Mailbox Programming Guide	5007
15.5 Mailbox Register Manual.....	5010

15.1 Mailbox Overview

Communication between the on-chip processors of the device uses a queued mailbox-interrupt mechanism.

The queued mailbox-interrupt mechanism allows the software to establish a communication channel between two processors through a set of registers and associated interrupt signals by sending and receiving messages (mailboxes).

The device implements the following mailbox types:

- System mailbox:
 - Number of instances: 2
 - Used for communication between: DSP1, DSP2, and IPU subsystems
 - Reference names: MAILBOX1, MAILBOX2
- EVE mailbox:
 - Number of instances: 2
 - Used for communication between: EVE local user (ARP32) and three external users (DSP1, DSP2, and IPU) – EVE_MBOX0 and EVE_MBOX1 are dedicated for this communication
 - Reference names: EVE_MBOX0, EVE_MBOX1

Each mailbox module supports the following features:

- Parameters configurable at design time (see [Table 15-1](#)):
 - Number of users
 - Number of mailbox message queues
 - Number of messages (FIFO depth) for each message queue
- 32-bit message width
- Message reception and queue-not-full notification using interrupts
- Support of 16-/32-bit addressing scheme
- Power management support

[Table 15-1](#) shows the configuration of the mailbox modules in the device.

Table 15-1. Mailbox Configuration in the Device

Module Parameters	Mailbox Type		
	System Mailbox		EVE Mailbox (0, 1)
	MAILBOX1	MAILBOX2	
Number of users	3	4	4
Number of mailbox message queues	8	12	16
Number of messages (FIFO depth) for each message queue	4		4

15.2 Mailbox Integration

This section describes the mailbox integration in the device, including information about clocks, resets, and hardware requests.

15.2.1 System MAILBOX Integration

[Figure 15-1](#) and [Figure 15-2](#) show the MAILBOX1 and MAILBOX2 integration, respectively.

Figure 15-1. MAILBOX1 Integration

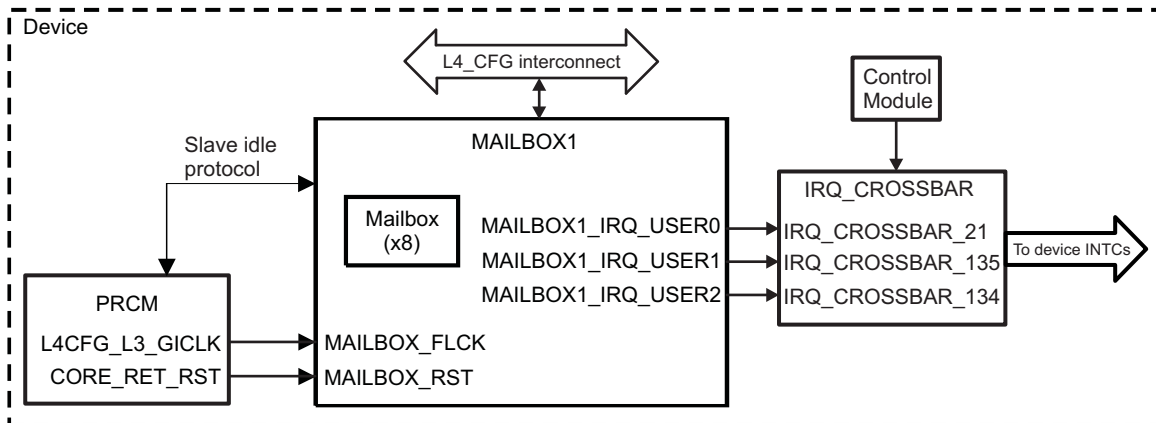

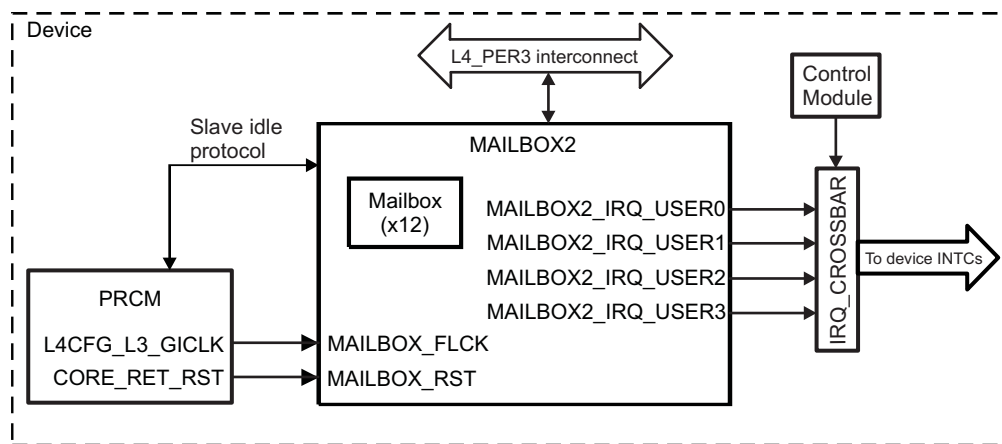

Figure 15-2. MAILBOX2 Integration

NOTE: For more information about the Slave idle protocol, see [Section 3.1.1.1.2, Module-Level Clock Management](#) in [Chapter 3, Power, Reset, and Clock Management](#).

Table 15-2 through Table 15-4 summarize the MAILBOX1/2 integration in the device.

Table 15-2. MAILBOX Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
MAILBOX1	PD_COREAON	N/A	L4_CFG
MAILBOX2	PD_COREAON	N/A	L4_PER3

Table 15-3. MAILBOX Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
MAILBOX	MAILBOX_FCLK	L4CFG_L3_GICLK	PRCM	MAILBOX interface clock. This clock is used for all interface and functional operations.
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description

Table 15-3. MAILBOX Clocks and Resets (continued)

MAILBOX	MAILBOX_RST	CORE_RET_RST	PRCM	MAILBOX hardware reset. This reset is asynchronously applied to the MAILBOX registers.
---------	-------------	--------------	------	--

Table 15-4. MAILBOX Hardware Requests

Module Instance	Interrupt Name (Source)	IRQ_CROSSBAR Input (Destination)	Interrupt Requests		
			Default Mapping	Description	
MAILBOX1	MAILBOX1_IRQ_USER0	IRQ_CROSSBAR_21	DSP1_IRQ_52; DSP2_IRQ_52;	MAILBOX1 request.	user 0 interrupt
	MAILBOX1_IRQ_USER1	IRQ_CROSSBAR_135	–	MAILBOX1 request.	user 1 interrupt
	MAILBOX1_IRQ_USER2	IRQ_CROSSBAR_134	IPU_IRQ_50;	MAILBOX1 request.	user 2 interrupt
MAILBOX2	MAILBOX2_IRQ_USER0	IRQ_CROSSBAR_237	–	MAILBOX2 request.	user 0 interrupt
	MAILBOX2_IRQ_USER1	IRQ_CROSSBAR_238	–	MAILBOX2 request.	user 1 interrupt
	MAILBOX2_IRQ_USER2	IRQ_CROSSBAR_239	–	MAILBOX2 request.	user 2 interrupt
	MAILBOX2_IRQ_USER3	IRQ_CROSSBAR_240	–	MAILBOX2 request.	user 3 interrupt

No DMA Requests

NOTE: The “Default Mapping” column in [Table 15-4](#) and [Table 15-7](#) shows the default mapping of module interrupts. These interrupts can also be mapped to other input lines of each device interrupt controller through the IRQ_CROSSBAR module.

For more information about the IRQ_CROSSBAR module, see [Chapter 14, Control Module](#).

For more information about the device interrupt controllers, see [Chapter 13, Interrupt Controllers](#).

NOTE: For information about interrupt source description, see [Section 15.3.4, Mailbox Interrupt Requests](#).

15.2.2 EVE Mailbox Integration

[Figure 15-3](#) shows the EVE_MBOX integration.

Figure 15-3. EVE_MBOX Integration

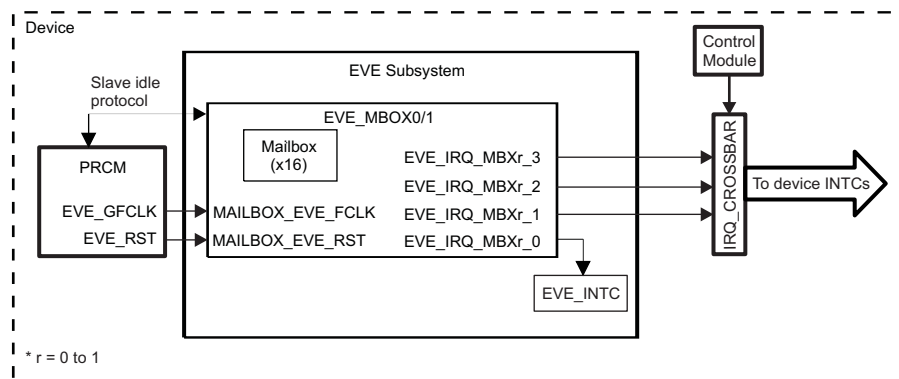

Table 15-5 through Table 15-7 summarize the EVE_MBOX integration in the device.

Table 15-5. EVE_MBOX Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
EVE_MBOX	PD_EVE	N/A	EVE local interconnect

Table 15-6. EVE_MBOX Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
EVE_MBOX	MAILBOX_EVE_FCLK	EVE_GCLK	PRCM	EVE_MBOX interface clock. This clock is used for all interface and functional operations.
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
EVE_MBOX	MAILBOX_EVE_RST	EVE_RST	PRCM	EVE_MBOX hardware reset. This reset is asynchronously applied to the EVE_MBOX registers.

Table 15-7. EVE_MBOX Hardware Requests

Interrupt Requests				
Module Instance	Interrupt Name (Source)	IRQ_CROSSBAR Input (Destination)	Default Mapping	Description
EVE_MBOX0	EVE1_IRQ_MBX0_USER0	TBD	–	EVE_MBOX0 user 0 interrupt request.
	EVE1_IRQ_MBX0_USER1	IRQ_CROSSBAR_284	–	EVE_MBOX0 user 1 interrupt request.
	EVE1_IRQ_MBX0_USER2	IRQ_CROSSBAR_285	–	EVE_MBOX0 user 2 interrupt request.
	EVE1_IRQ_MBX0_USER3	IRQ_CROSSBAR_286	–	EVE_MBOX0 user 3 interrupt request.
EVE_MBOX1	EVE1_IRQ_MBX1_USER0	TBD	–	EVE_MBOX1 user 0 interrupt request.
	EVE1_IRQ_MBX1_USER1	IRQ_CROSSBAR_287	–	EVE_MBOX1 user 1 interrupt request.
	EVE1_IRQ_MBX1_USER2	IRQ_CROSSBAR_288	–	EVE_MBOX1 user 2 interrupt request.
	EVE1_IRQ_MBX1_USER3	IRQ_CROSSBAR_289	–	EVE_MBOX1 user 3 interrupt request.

No DMA Requests

15.3 Mailbox Functional Description

NOTE: The functionality of all mailbox instances in the device is the same and is described in this section.

NOTE: In this chapter, u is the user number and m is the mailbox number as follows:

- For MAILBOX1: $u = 0$ to 2 and $m = 0$ to 7;
- For MAILBOX2: $u = 0$ to 3 and $m = 0$ to 11;
- For EVE_MBOX: $u = 0$ to 3 and $m = 0$ to 15;

The mailbox module provides a means of communication through message queues among the users. The individual mailbox modules, or FIFOs, can associate (or de-associate) with any of the processors using the [MAILBOX_IRQENABLE_SET_u](#) (or [MAILBOX_IRQENABLE_CLR_u](#)) register.

[Table 15-8](#) shows the potential users of the mailbox modules in the device.

Table 15-8. Mailbox Users in the Device

Mailbox Type		Users			
		User 0	User 1	User 2	User 3
System Mailbox	MAILBOX1	Any of: DSP1, DSP2, and IPU ⁽¹⁾			–
	MAILBOX2	Any of: DSP1, DSP2, and IPU ⁽¹⁾			
EVE Mailbox	EVE_MBOX0, EVE_MBOX1	TBD	Any of: DSP1, DSP2, and IPU ⁽¹⁾		

⁽¹⁾ It is software responsibility to select a user by mapping (via `IRQ_CROSSBAR`) the corresponding mailbox interrupt to the interrupt controller of the appropriate processor subsystem.

Each user has a dedicated interrupt signal from the corresponding mailbox module instance and dedicated interrupt enabling and status registers.

Each [MAILBOX_IRQSTATUS_RAW_u](#)/[MAILBOX_IRQSTATUS_CLR_u](#) interrupt status register corresponds to a particular user.

15.3.1 Mailbox Block Diagram

Figure 15-4 shows the mailbox block diagram.

Figure 15-4. Mailbox Block Diagram

15.3.2 Mailbox Software Reset

The mailbox module supports a software reset through the `MAILBOX_SYSCONFIG[0]` SOFTRESET bit. Setting this bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. Reading the `MAILBOX_SYSCONFIG[0]` SOFTRESET bit gives the status of the software reset:

- Read 1: the software reset is on-going.
- Read 0: the software reset is complete.

The software must ensure that the software reset completes before doing mailbox operations.

15.3.3 Mailbox Power Management

Table 15-9 describes power-management features available for the mailbox module.

Table 15-9. Local Power Management Features

Feature	Registers	Description
Clock autogating	N/A	Feature not available
Slave idle modes	<code>MAILBOX_SYSCONFIG[3:2]</code> SIDLEMODE bit field	Force-idle, no-idle and smart-idle modes are available
Clock activity	N/A	Feature not available
Master standby modes	N/A	Feature not available
Global wake-up enable	N/A	Feature not available
Wake-up sources enable	N/A	Feature not available

The mailbox module can be configured using the [MAILBOX_SYSCONFIG\[3:2\]](#) SIDLEMODE bit field to one of the following acknowledgment modes:

- Force-idle mode (SIDLEMODE = 0x0): The mailbox module immediately enters the idle state on receiving a low-power-mode request from the PRCM module. In this mode, the software must ensure that there are no asserted output interrupts before requesting this mode to go into the idle state.
- No-idle mode (SIDLEMODE = 0x1): The mailbox module never enters the idle state.
- Smart-idle mode (SIDLEMODE = 0x2): After receiving a low-power-mode request from the PRCM module, the mailbox module enters the idle state only after all asserted output interrupts are acknowledged.

15.3.4 Mailbox Interrupt Requests

An interrupt request allows the user of the mailbox to be notified when a message is received or when the message queue is not full. There is one interrupt per user.

[Table 15-10](#) lists the event flags, and their mask, that can cause module interrupts.

Table 15-10. Interrupt Events

Non-Maskable Event Flag ⁽¹⁾	Maskable Event Flag	Event Mask Bit	Event Unmask Bit	Description
MAILBOX_IRQSTATUS_RAW_u[0+m*2] NEWMSGSTATUSUUM Bm	MAILBOX_IRQSTATUS_CLR_u[0+m*2] NEWMSGSTATUSUUM Bm	MAILBOX_IRQENABLE_CLR_u[0+m*2] NEWMSGSTATUSUUM Bm	MAILBOX_IRQENABLE_SET_u[0+m*2] NEWMSGSTATUSUUM Bm	Mailbox <i>m</i> receives a new message.
MAILBOX_IRQSTATUS_RAW_u[1+m*2] NOTFULLSTATUSUUM Bm	MAILBOX_IRQSTATUS_CLR_u[1+m*2] NOTFULLSTATUSUUM Bm	MAILBOX_IRQENABLE_CLR_u[1+m*2] NOTFULLSTATUSUUM Bm	MAILBOX_IRQENABLE_SET_u[1+m*2] NOTFULLSTATUSUUM Bm	Mailbox <i>m</i> message queue is not full.

⁽¹⁾ [MAILBOX_IRQSTATUS_RAW_u](#) register is mostly used for debug purposes.

CAUTION

Once an event generating the interrupt request has been processed by the software, it must be cleared by writing a logical 1 in the corresponding bit of the [MAILBOX_IRQSTATUS_CLR_u](#) register.

Writing a logical 1 in a bit of the [MAILBOX_IRQSTATUS_CLR_u](#) register will also clear to 0 the corresponding bit in the appropriate [MAILBOX_IRQSTATUS_RAW_u](#) register.

An event can generate an interrupt request when a logical 1 is written to the corresponding unmask bit in the [MAILBOX_IRQENABLE_SET_u](#) register. Events are reported in the appropriate [MAILBOX_IRQSTATUS_CLR_u](#) and [MAILBOX_IRQSTATUS_RAW_u](#) registers.

An event stops generating interrupt requests when a logical 1 is written to the corresponding mask bit in the [MAILBOX_IRQENABLE_CLR_u](#) register. Events are only reported in the appropriate [MAILBOX_IRQSTATUS_RAW_u](#) register.

In case of the [MAILBOX_IRQSTATUS_RAW_u](#) register, the event is reported in the corresponding bit even if the interrupt request generation is disabled for this event.

15.3.5 Mailbox Assignment

15.3.5.1 Description

To assign a receiver to a mailbox, set the new message interrupt enable bit corresponding to the desired mailbox in the [MAILBOX_IRQENABLE_SET_u](#) register. The receiver reads the [MAILBOX_MESSAGE_m](#) register to retrieve a message from the mailbox.

An alternate method for the receiver that does not use the interrupts is to poll the [MAILBOX_FIFOSTATUS_m](#) and/or [MAILBOX_MSGSTATUS_m](#) registers to know when to send or retrieve a message to or from the mailbox. This method does not require assigning a receiver to a mailbox. Because this method does not include the explicit assignment of the mailbox, the software must avoid having multiple receivers use the same mailbox, which can result in incoherency.

To assign a sender to a mailbox, set the queue-not-full interrupt enable bit of the desired mailbox in the [MAILBOX_IRQENABLE_SET_u](#) register, where *u* is the number of the sending user. However, direct allocation of a mailbox to a sender is not recommended because it can cause the sending processor to be constantly interrupted.

It is recommended that register polling be used to:

- Check the status of either the [MAILBOX_FIFOSTATUS_m](#) or [MAILBOX_MSGSTATUS_m](#) registers
- Write the message to the corresponding [MAILBOX_MESSAGE_m](#) register, if space is available.

The sender might use the queue-not-full interrupt when the initial mailbox status check indicates the mailbox is full. In this case, the sender can enable the queue-not-full interrupt for its mailbox in the appropriate [MAILBOX_IRQENABLE_SET_u](#) register. This allows the sender to be notified by interrupt only when a FIFO queue has at least one available entry.

Reading the [MAILBOX_IRQSTATUS_CLR_u](#) register determines the status of the new message and the queue-not-full interrupts for a particular user. Writing 1 to the corresponding bit in the [MAILBOX_IRQSTATUS_CLR_u](#) register acknowledges, and subsequently clears, an interrupt.

CAUTION

Assigning multiple senders or multiple receivers to the same mailbox is not recommended.

15.3.6 Sending and Receiving Messages

15.3.6.1 Description

When a 32-bit message is written to the [MAILBOX_MESSAGE_m](#) register, the message is appended into the FIFO queue. This queue holds four messages. If the queue is full, the message is discarded.

Queue overflow can be avoided by first reading the [MAILBOX_FIFOSTATUS_m](#) register to check that the mailbox message queue is not full before writing a new message to it.

Reading the [MAILBOX_MESSAGE_m](#) register returns the message at the beginning of the FIFO queue and removes it from the queue. If the FIFO queue is empty when the [MAILBOX_MESSAGE_m](#) register is read, the value 0 is returned.

The new message interrupt is asserted when at least one message is in the mailbox message FIFO queue. To determine the number of messages in the mailbox message FIFO queue, read the [MAILBOX_MSGSTATUS_m](#) register.

15.3.7 16-Bit Register Access

15.3.7.1 Description

So that 16-bit processors can access the mailbox module, the module allows 16-bit register read and write access, with restrictions for the [MAILBOX_MESSAGE_m](#) registers. The 16-bit half-words are organized in little endian fashion; that is, the least-significant 16 bits are at the low address and the most-significant 16 bits are at the high address (low address + 0x02).

All mailbox module registers can be read or written to directly using individual 16-bit accesses with no restriction on interleaving, except the [MAILBOX_MESSAGE_m](#) registers, which must always be accessed by either single 32-bit accesses or two consecutive 16-bit accesses.

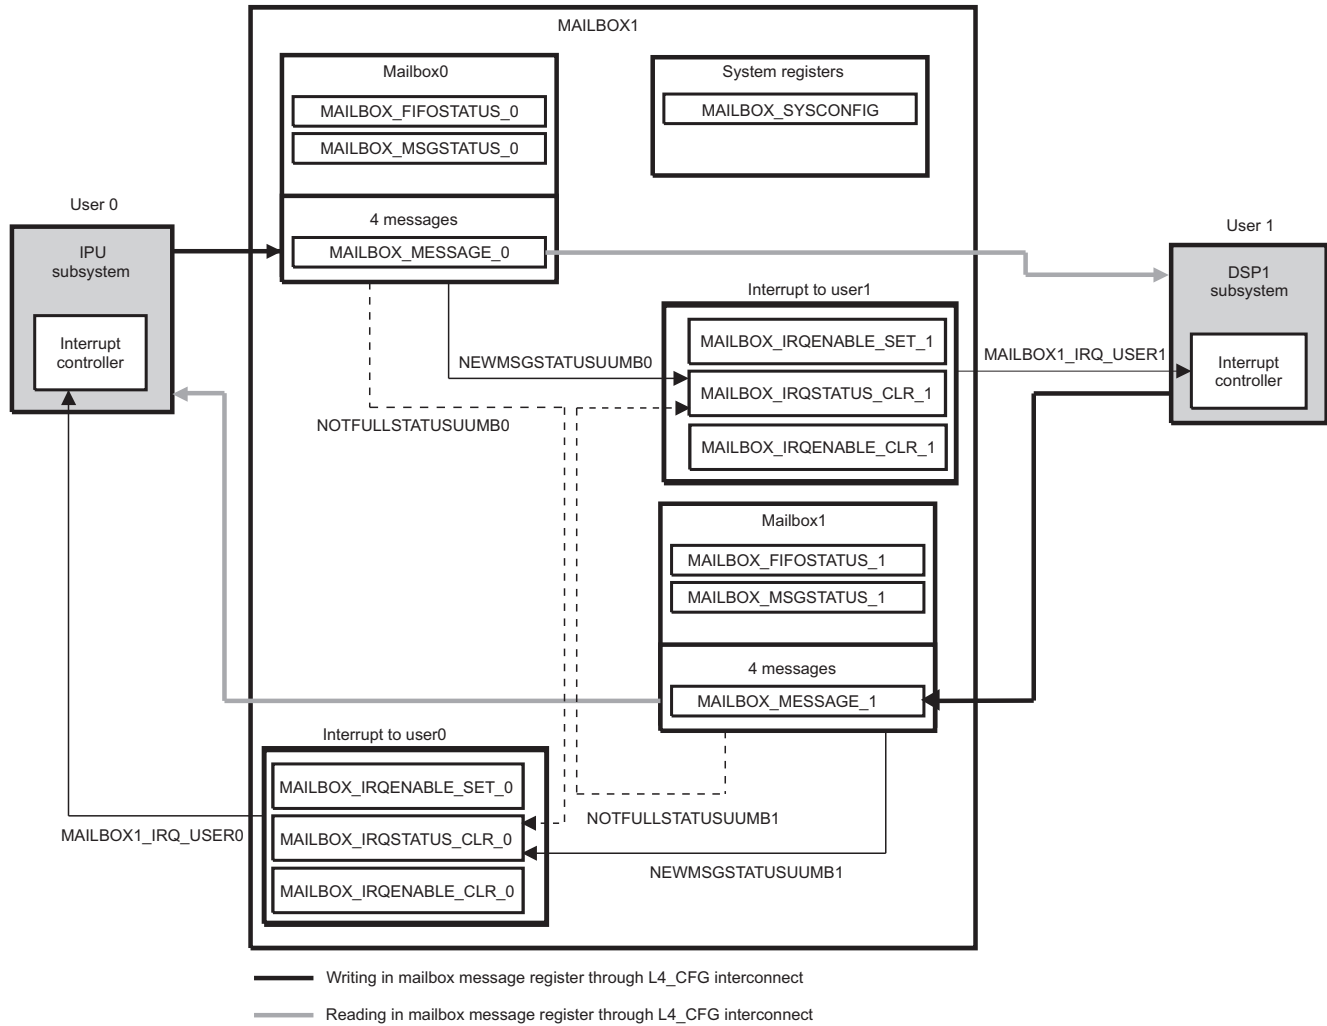

CAUTION

When using 16-bit accesses to the [MAILBOX_MESSAGE_m](#) registers, the order of access must be the least-significant half-word first (low address) and the most-significant half-word last (high address). This requirement is because of the update operation by the message FIFO of the [MAILBOX_MSGSTATUS_m](#) registers. The update of the FIFO queue contents and the associated status registers and possible interrupt generation occurs only when the most-significant 16 bits of a [MAILBOX_MESSAGE_m](#) are accessed.

15.3.8 Example of Communication

Figure 15-5 shows an example of communication between IPU and DSP1 subsystems.

Figure 15-5. Example of Communication

15.4 Mailbox Programming Guide

15.4.1 Mailbox Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the mailbox module.

15.4.1.1 Global Initialization

15.4.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the mailbox module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the mailbox.

See [Section 15.2, Mailbox Integration](#), for further information.

Table 15-11. Global Initialization of Surrounding Modules for MAILBOX

Surrounding Modules	Comments
PRCM	MAILBOX functional/interface clock must be enabled.
Interrupt Controllers	IPU, or DSP1, or DSP2 interrupt controller must be configured to enable the interrupt request generation to the corresponding subsystem.
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description , in Chapter 14, Control Module .

Table 15-12. Global Initialization of Surrounding Modules for EVE_MBOX

Surrounding Modules	Comments
PRCM	EVE_MBOX functional/interface clock must be enabled.
Interrupt Controllers	IPU, or DSP1, or DSP2, or EVE interrupt controller must be configured to enable the interrupt request generation to the corresponding subsystem.
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description , in Chapter 14, Control Module .

15.4.1.1.2 Mailbox Global Initialization

15.4.1.1.2.1 Main Sequence - Mailbox Global Initialization

This procedure initializes the mailbox module after a power-on or software reset.

Table 15-13. Mailbox Global Initialization

Step	Register/ Bit Field / Programming Model	Value
Perform a software reset	MAILBOX_SYSCONFIG[0] SOFTRESET	0x1
Wait until reset is complete	MAILBOX_SYSCONFIG[0] SOFTRESET	= 0x0
Set idle mode configuration	MAILBOX_SYSCONFIG[3:2] SIDLEMODE	0x-

15.4.1.2 Mailbox Operational Modes Configuration

15.4.1.2.1 Mailbox Processing modes

15.4.1.2.1.1 Main Sequence - Sending a Message (Polling Method)

Table 15-14. Sending a Message (Polling Method)

Step	Register/ Bit Field / Programming Model	Value
IF : Is FIFO full ?	MAILBOX_FIFOSTATUS_m[0] FIFOFULLMB	= 0x1
Wait until at least one message slot is available	MAILBOX_FIFOSTATUS_m[0] FIFOFULLMB	= 0x0
ELSE		
Write message	MAILBOX_MESSAGE_m[31:0] MESSAGEVALUEMBM	0x----
ENDIF		

15.4.1.2.1.2 Main Sequence - Sending a Message (Interrupt Method)

Table 15-15. Sending a Message (Interrupt Method)

Step	Register/ Bit Field / Programming Model	Value
IF : Is FIFO full ?	MAILBOX_FIFOSTATUS_m[0] FIFOFULLMB	= 0x1
Enable interrupt event	MAILBOX_IRQENABLE_SET_u[1+ m*2]	0x1
User (processor) can perform another task until interrupt occurs See Section 15.4.1.3.1 for interrupt handling in sending mode		
ELSE		
Write message	MAILBOX_MESSAGE_m[31:0] MESSAGEVALUEMBM	0x----
ENDIF		

15.4.1.2.1.3 Main Sequence - Receiving a Message (Polling Method)

Table 15-16. Receiving a Message (Polling Method)

Step	Register/ Bit Field / Programming Model	Value
IF : Number of messages is not equal to 0	MAILBOX_MSGSTATUS_m[2:0] NBOFMSGMB	!= 0x0
Read message	MAILBOX_MESSAGE_m[31:0] MESSAGEVALUEMBM	0x----
ENDIF		

15.4.1.2.1.4 Main Sequence - Receiving a Message (Interrupt Method)

Table 15-17. Receiving a Message (Interrupt Method)

Step	Register/ Bit Field / Programming Model	Value
Enable interrupt event	MAILBOX_IRQENABLE_SET_u[0 + m*2]	0x1
User (processor) can perform another task until interrupt occurs See Section 15.4.1.3.2 for interrupt handling in receiving mode		

15.4.1.3 Mailbox Events Servicing

15.4.1.3.1 Events Servicing in Sending Mode

[Table 15-18](#) describes the events servicing in sending mode.

Table 15-18. Events Servicing in Sending Mode

Step	Register/ Bit Field / Programming Model	Value
Read interrupt status bit	MAILBOX_IRQSTATUS_CLR_u[1 + m*2]	0x1
Write message	MAILBOX_MESSAGE_m[31:0] MESSAGEVALUEMBM	0x----
Write 1 to acknowledge interrupt	MAILBOX_IRQSTATUS_CLR_u[1 + m*2]	0x1

15.4.1.3.2 Events Servicing in Receiving Mode

Table 15-19 describes the events servicing in receiving mode.

Table 15-19. Events Servicing in Receiving Mode

Step	Register/ Bit Field / Programming Model	Value
Read interrupt status bit	MAILBOX_IRQSTATUS_CLR_u[0 + m*2]	0x1
IF : Number of messages is not equal to 0 ?	MAILBOX_MSGSTATUS_m[2:0] NBOFMSGMB	!= 0x0
Read message	MAILBOX_MESSAGE_m[31:0] MESSAGEVALUEMBM	0x----
ELSE		
Write 1 to acknowledge interrupt	MAILBOX_IRQSTATUS_CLR_u[0 + m*2]	0x1
ENDIF

Memory Management Units

This chapter describes the memory management units (MMUs) in the device.

Topic	Page
16.1 MMU Overview.....	5034
16.2 MMU Integration	5036
16.3 MMU Functional Description	5038
16.4 MMU Low-level Programming Models.....	5050
16.5 MMU Register Manual.....	5054

16.1 MMU Overview

A memory management unit (MMU) is a hardware component responsible for handling accesses to memory requested by a processing unit, DMA controller, or other bus requestor. MMU functions include:

- Translation of initiator internal (virtual) addresses to physical addresses (that is, virtual memory management)
- Preventing an initiator from making accesses to unmapped pages of the system memory

This device includes the following MMUs:

- One top-level (system) MMU, dedicated to EDMA Transfer Controller 0 (TC0), and EDMA Transfer Controller 1 (TC1):
- Two MMUs inside each of the DSP1, and DSP2 subsystems:
 - DSP1 subsystem: DSP1_MMU0, and DSP1_MMU1
 - DSP2 subsystem: DSP2_MMU0, and DSP2_MMU1
- Two MMUs inside the EVE subsystem: EVE_MMU0, and EVE_MMU1
- Two MMUs inside the IPU subsystem:
 - L1 unicache MMU – IPU_UNICACHE_MMU
 - L2 MMU – IPU_MMU

NOTE: This chapter provides a detailed description of the following MMUs:

- System MMU
- DSP MMUs
- EVE MMUs
- IPU L2 MMU

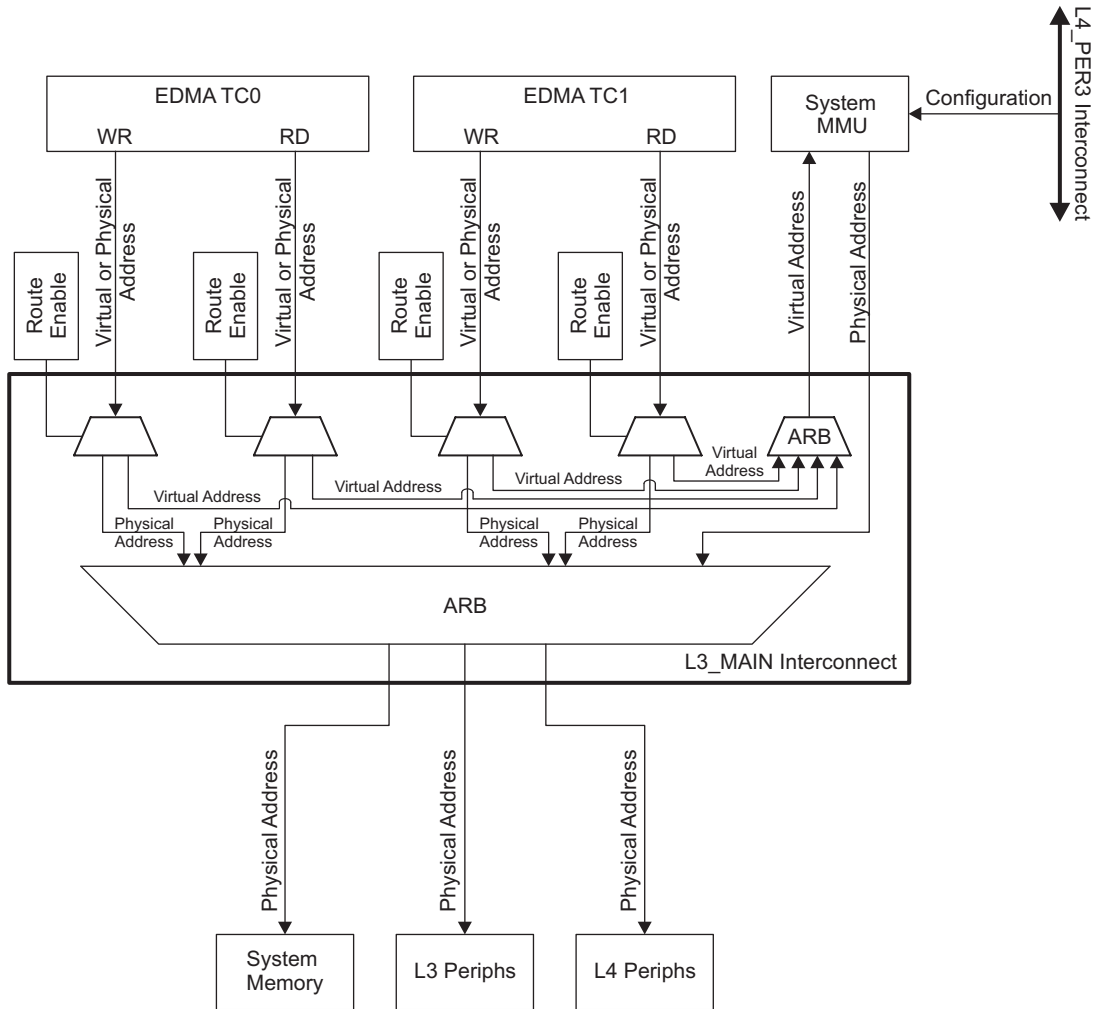

System MMUs, DSP MMUs and EVE MMUs are fully identical from functional perspective. IPU L2 MMU is different in that it does not support “bypass” functionality.

For more information about IPU unicache MMU, see [Chapter 5, Dual Cortex-M4 IPU Subsystem](#).

[Figure 16-1](#) shows an overview of system MMU. In summary, requests initiated by a given requestor (EDMA TC0 or TC1 [both read and write ports]) can optionally be routed through the system MMU. Each requestor’s use (or not) of the MMU is independently controllable via the Control Module CTRL_CORE_SMA_SW_7 register bitfields. It is recommended that this register is set during system initialization and remain static.

If the MMU loopback path is enabled for a given requestor, requests will be routed via the L3_MAIN interconnect to the MMU and will again go through the L3_MAIN interconnect to the requested physical address. If the MMU loopback path is disabled for a given requestor, those bus requests go directly through the L3_MAIN interconnect to the requested physical address, thus minimizing bus request latency.

Figure 16-1. System MMU1 Overview

16.2 MMU Integration

This section describes the system MMUs integration in the device, including information about clocks, resets, and hardware requests. For more information about DSP, EVE, and IPU MMUs integration, refer to their respective chapters.

Figure 16-2 shows system MMU integration.

Figure 16-2. System MMU1 Integration

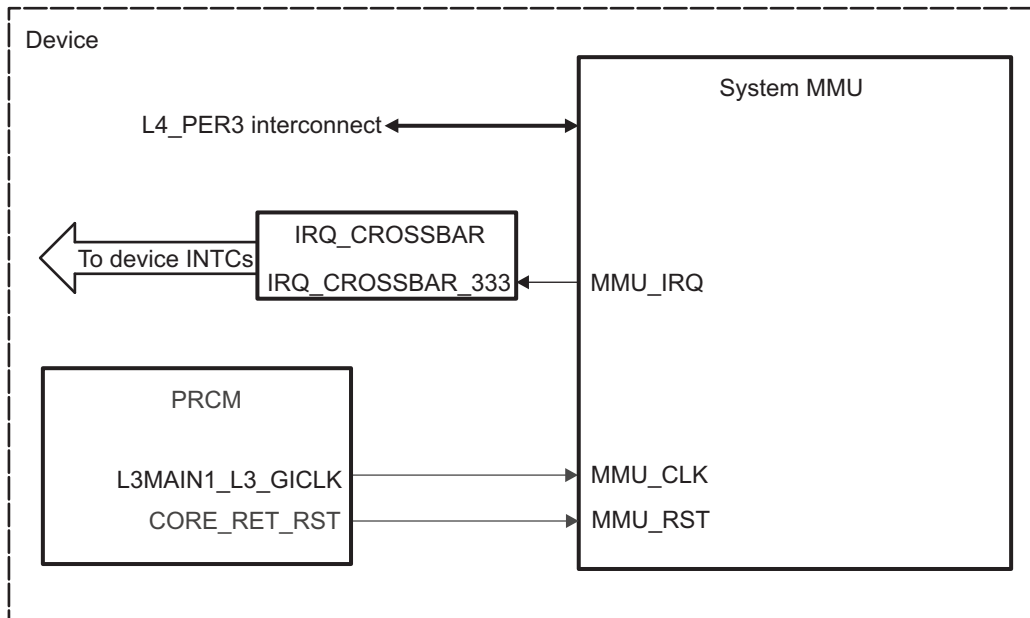

Table 16-1 through Table 16-3 summarize the system MMU integration.

Table 16-1. MMU Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
System MMU	PD_COREAON	L4_PER3

Table 16-2. MMU Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
System MMU	MMU_CLK	L3MAIN1_L3_GICKL	PRCM	System MMU interface/functional clock. This clock is used for all interface and functional operations.
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
System MMU	MMU_RST	CORE_RET_RST	PRCM	System MMU hardware reset. This reset is asynchronously applied to the MMU internal registers.

Table 16-3. MMU Hardware Requests

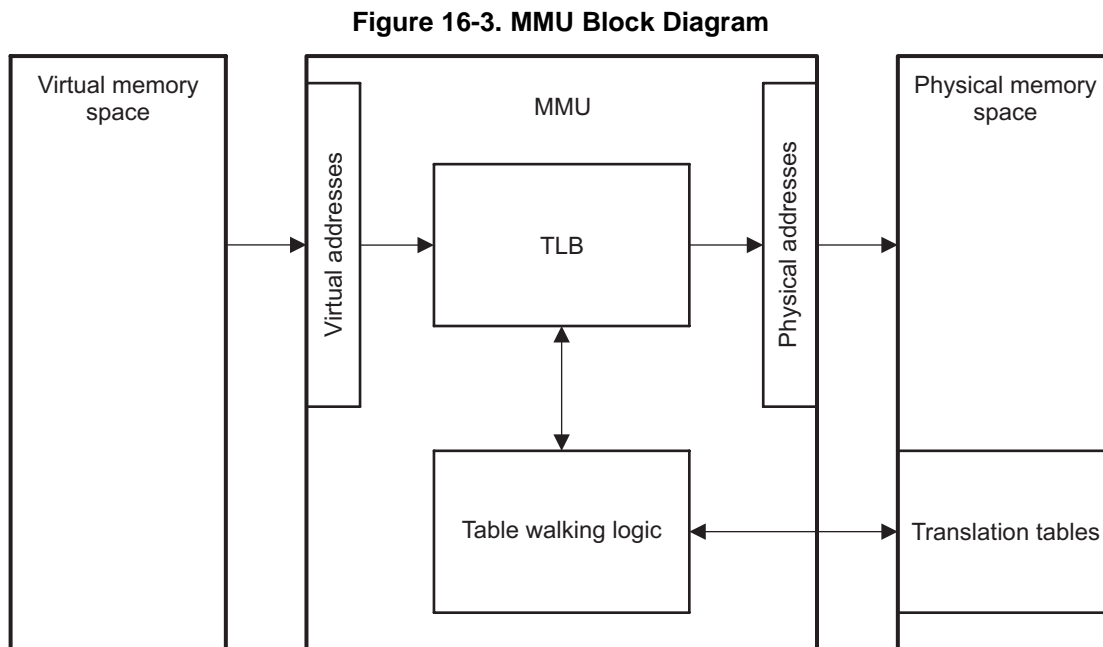

Interrupt Requests				
Module Instance	Interrupt Name (Source)	IRQ_CROSSBAR Input (Destination)	Default Mapping	Description
System MMU	MMU_IRQ	IRQ_CROSSBAR_333	–	System MMU interrupt.
No DMA Requests				

NOTE: For a description of the interrupt sources, see [Section 16.3.4, MMU Interrupt Requests](#).

16.3 MMU Functional Description

16.3.1 MMU Block Diagram

The MMU manages the virtual to physical address translation for external addresses. [Figure 16-3](#) shows the MMU block diagram.

Each table entry describes the translation of one contiguous memory region. For a description of the structure of these tables, see [Section 16.3.1.2, Translation Tables](#).

Two major functional units exist in the MMU to provide address translation automatically based on the table entries:

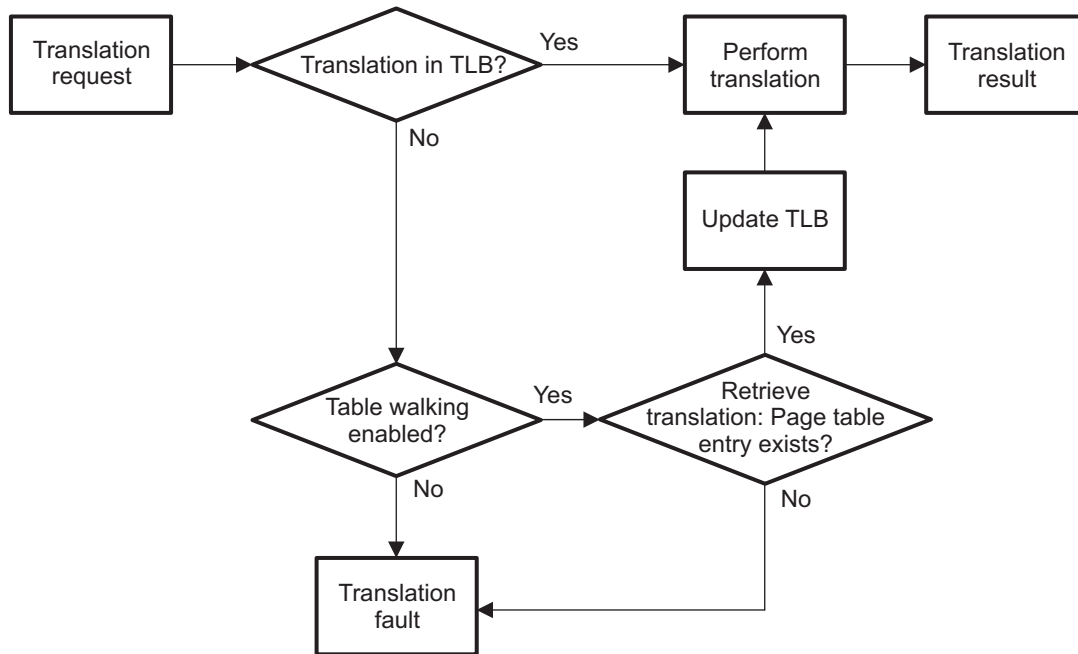

- The table walker automatically retrieves the correct translation table entry for a requested translation. If two-level translation is used (for the translation of small memory pages), the table walker also automatically reads the required second-level translation table entry. The two-level translation is described later in the chapter.
- The translation look-aside buffer (TLB) stores recently used translation entries, acting like a cache of the translation table.

16.3.1.1 MMU Address Translation Process

Whenever an address translation is requested (that is, for every access with the MMU enabled), the MMU first checks whether the translation is contained in the TLB, which acts like a cache storing recent translations. The TLB can also be programmed manually to ensure that time-critical data can be translated without delay.

If the requested translation is not in the TLB, the table-walking logic retrieves this translation from the translation table(s), and then updates the TLB. The address translation is then performed. [Figure 16-4](#) summarizes the process.

Figure 16-4. Translation Process

16.3.1.2 Translation Tables

The translation of virtual to physical addresses is based on entries in translation tables that define the following properties:

- Address translation, that is, the correspondence between virtual and physical addresses
- Size of the memory region the entry translates

The virtual addresses index the translation tables. Each virtual address corresponds to exactly one entry in the translation table.

16.3.1.2.1 Translation Table Hierarchy

When developing a table-based address translation scheme, one of the most important design parameters is the memory page size described by each translation table entry. MMU instances support 4-KiB and 64-KiB pages, a 1-MiB section, and a 16-MiB supersection. Using bigger page sizes means a smaller translation table.

Using a smaller page size greatly increases the efficiency of dynamic memory allocation and defragmentation. That is why many operating systems (OSs) can operate on memory blocks as small as 4 KiB; however, the smaller size implies a more complex table structure.

A quick calculation shows that using 4 KiB memory pages with one translation table would require one million entries to span the entire 4-GiB address range. The table itself would be 32 MiB, a size that is not feasible.

However, using bigger pages reduces the flexibility of typical OS memory management. Implementing a two-level hierarchy reconciles these two requirements. Within this hierarchy, one first-level translation table describes the translation properties based on 1 MiB memory regions.

Each of the entries in this first-level translation table can specify the following:

- The translation properties for a big memory section. This memory section can be either 1 MiB (section) or 16 MiB (supersection). In this case, all translation parameters are specified in the first-level translation table entry.
- A pointer to a second-level translation table that specifies individual translation properties based on smaller pages within the 1-MiB page of memory. These pages can be either 64 KiB (large page) or 4

KiB (small page). In this case, the actual translation parameters are specified in the second-level translation table entry. The first-level translation table entry specifies only the base address of the second-level translation table.

This hierarchical approach means that additional translation information for smaller pages must be provided only when the pages are actually used. [Figure 16-5](#) shows the hierarchy.

Figure 16-5. Translation Hierarchy

The structure of the first and second-level translation tables and their entries are described in more detail in [Section 16.3.1.2.2, First-Level Translation Table](#), and [Section 16.3.1.2.3, Two-Level Translation](#).

16.3.1.2.2 First-Level Translation Table

The first-level translation table describes the translation properties for 1-MiB sections. To describe a 4-GiB address range requires 4096 32-bit entries (so-called first-level descriptors).

The first-level translation table start address must be aligned on a multiple of the table size with a 128-byte minimum. Consequently, an alignment of at least 16K bytes is required for a complete 4096-entry table; that is, at least the last fourteen address bits must be zero.

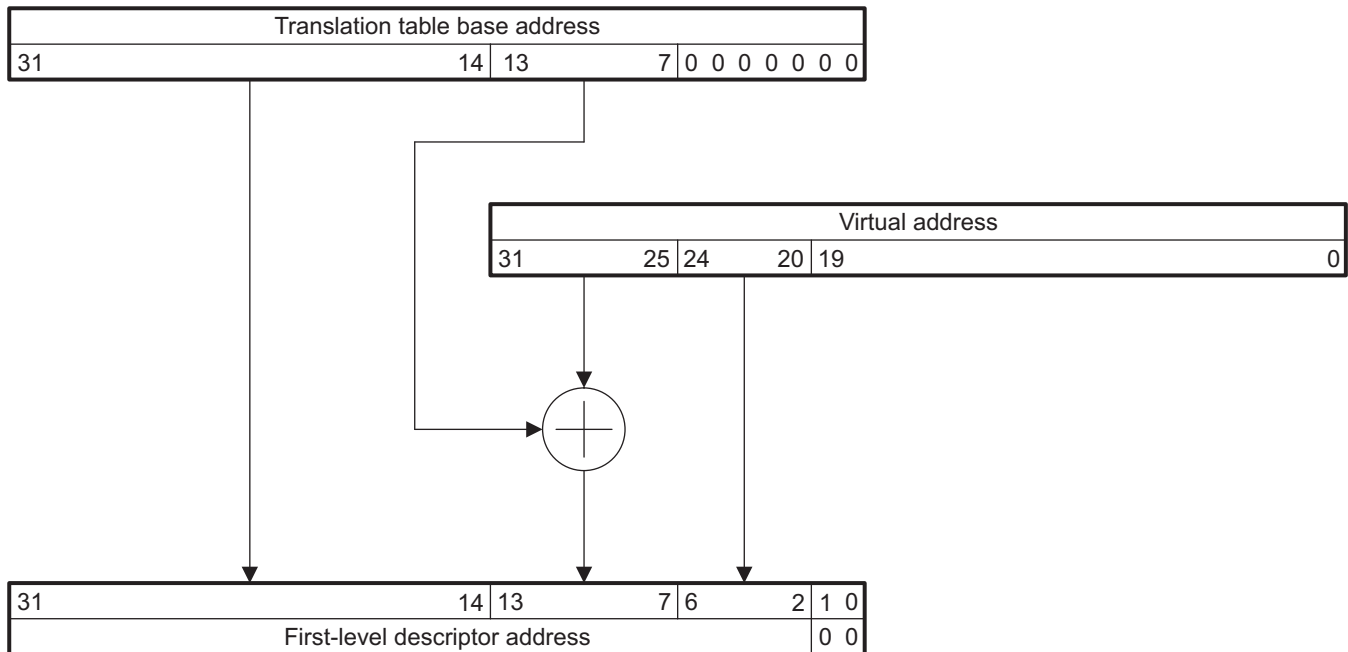

The start address of the first-level translation table is specified by the so-called translation table base. The table is indexed by the upper 12-bits of the virtual address. [Figure 16-6](#) shows this mechanism.

Figure 16-6. First-level Descriptor Address Calculation

To summarize, the translation table base and the translation table index together define the first-level descriptor address. [Figure 16-7](#) outlines the precise mechanism used to calculate this address.

Figure 16-7. Detailed First-Level Descriptor Address Calculation

As an example of this mechanism, consider a translation table base address of 0x8000:0000 and a virtual address of 0x1234:5678. In this case, the first-level descriptor address is $0x8000:0000 + (0x123 \ll 2) = 0x8000:048C$.

16.3.1.2.2.1 First-Level Descriptor Format

Each first-level descriptor provides either the complete address translation for 1-MiB or 16-MiB sections or provides a pointer to a second-level translation table for 4 KiB or 64 KiB pages. Table 16-4 shows the first-level descriptor format.

Table 16-4. First-Level Descriptor Format

First-Level Descriptor Format									
31:24	23:20	19	18	17:10	9:2	1	0		
X							0	0	Fault
Second-Level Translation Table Base Address					X	0	1	Page	
Section Base Address		X	0	X		1	0	Section	
Supersection Base Address		X		1	X		1	0	Supersection
X							1	1	Fault

X = Don't care. Set to 0 for future compatibility.

16.3.1.2.2.2 First-Level Page Descriptor Format

If a translation granularity smaller than 1 MiB is required, a two-level translation process is used. In this case, the first-level block descriptor specifies only the start address of a second-level translation table. The second-level translation table entries specify the actual translation properties.

16.3.1.2.2.3 First-Level Section Descriptor Format

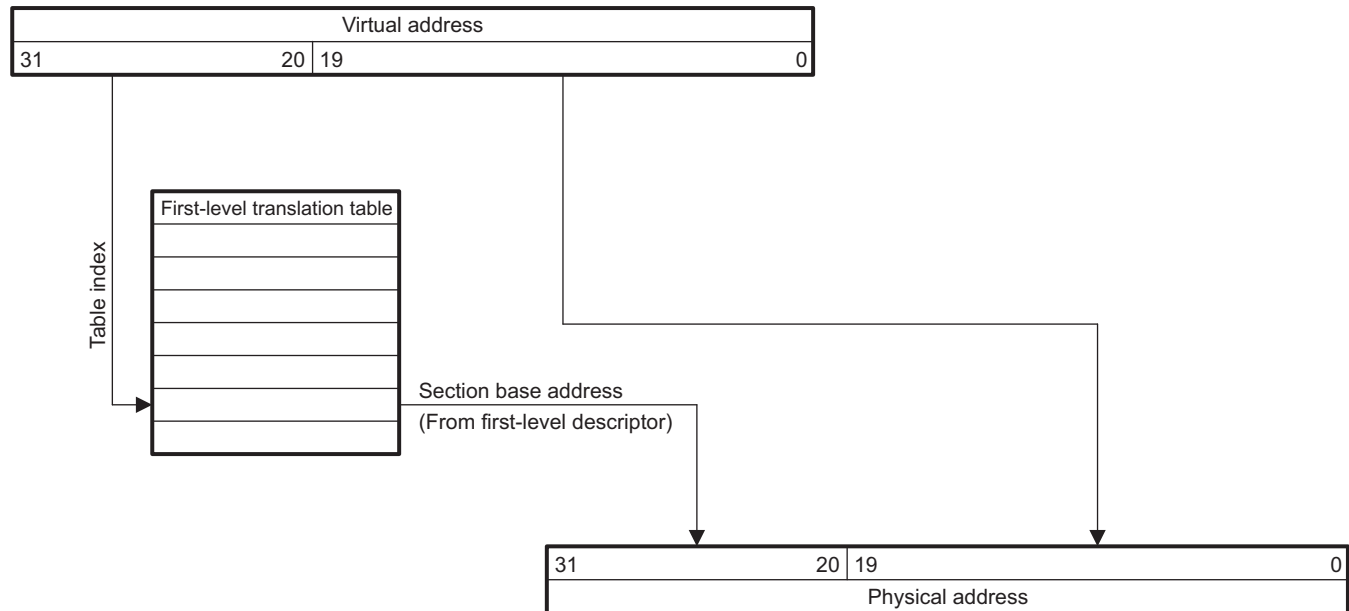

Each section descriptor in the first-level translation table specifies the complete translation properties for a 1-MiB section or a 16-MiB supersection.

NOTE: Supersection descriptors must be repeated 16 times, because each descriptor in the first-level translation table describes 1 MiB of memory. If an access points to a descriptor that is not initialized, the MMU will behave in an unpredictable way.

16.3.1.2.2.4 Section Translation Summary

Sections and supersections can be translated based solely on the information in the first-level translation table. Figure 16-8 summarizes the address translation process for a section.

Figure 16-8. Section Translation Summary

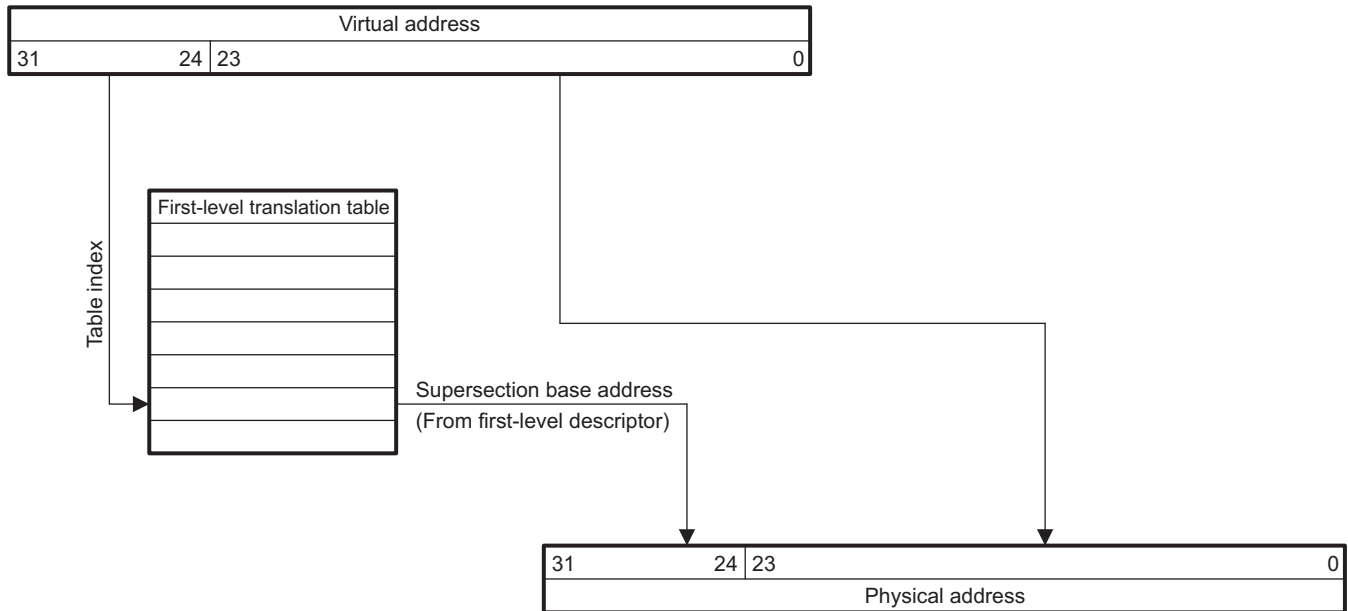

16.3.1.2.2.5 Supersection Translation Summary

The translation of a supersection is similar to the translation of a section. The difference is that for a supersection only bits 31 to 24 index into the first-level translation table. The last four bits of the table index are implicitly assumed to be zero as there are 16 identical consecutive entries for a supersection.

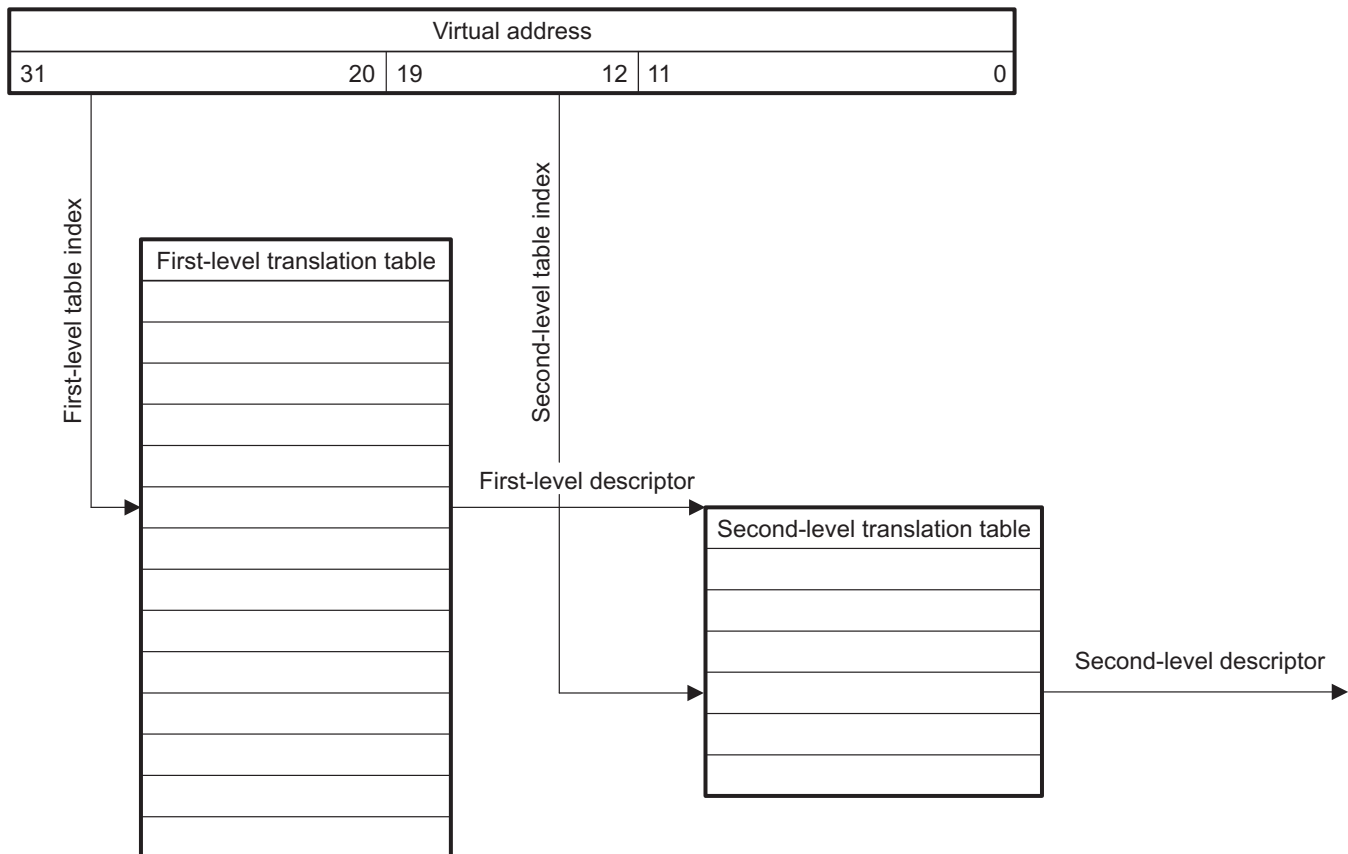

Figure 16-9 shows the translation mechanism for a supersection.

Figure 16-9. Supersection Translation Summary

16.3.1.2.3 Two-Level Translation

Two-level translation is used when fine-grain granularity is required, that is, when memory sections smaller than 1 MiB are needed. In this case, the first-level descriptor provides a pointer to the base address of a second-level translation table. This second-level table is indexed by bits 19 to 12 of the virtual address. [Figure 16-10](#) shows this indexing mechanism.

Figure 16-10. Two-Level Translation

Each second-level translation table describes the translation of 1 MiB of address space in pages of 64 KiB (large page) or 4 KiB (small page). It consists of 256 second-level descriptors describing 4 KiB each.

NOTE: In the case of a large page, the same descriptor must be repeated 16 times. If an access points to a descriptor that is not initialized, the MMU will behave in an unpredictable way.

16.3.1.2.3.1 Second-Level Descriptor Format

Similar to first-level section descriptors, second-level descriptors provide all of the necessary information for the translation of a large or small page. [Table 16-5](#) shows the format of second-level descriptors.

Table 16-5. Second-Level Descriptor Format

Second-Level Descriptor Format					
31:16	15:12	11:2	1	0	
X				0	0
Large Page Base Address				0	1
Small Page Base Address				1	X
					Fault
					Large Page
					Small Page

X = Don't care. Set to 0 for future compatibility.

16.3.1.2.3.2 Small Page Translation Summary

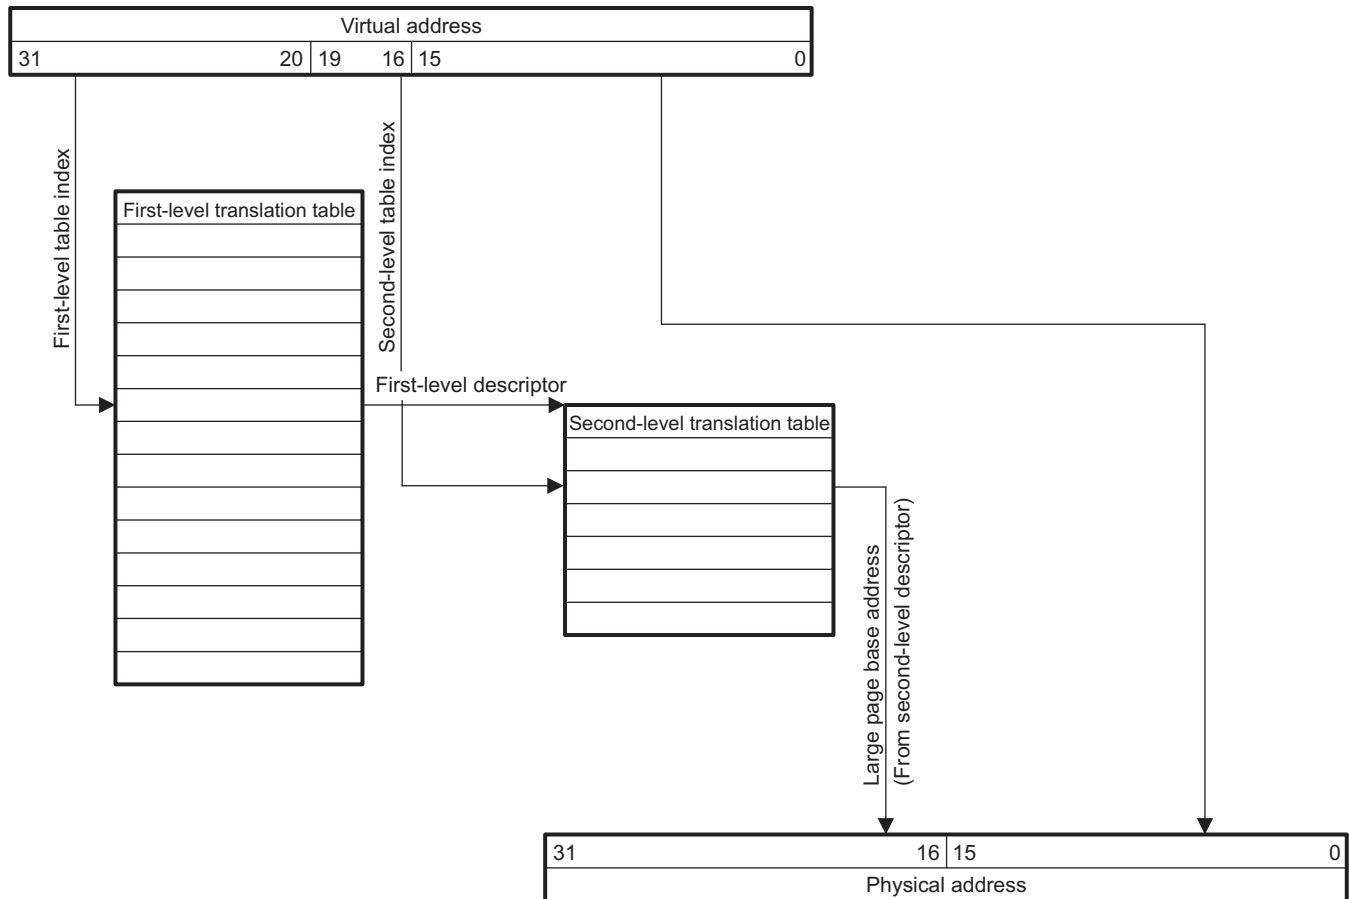

Figure 16-11 summarizes the translation process for small pages.

Figure 16-11. Small Page Translation Summary

16.3.1.2.3.3 Large Page Translation Summary

The translation of a large page is similar to the translation of a small page. The difference is that, for a large page, only bits 19 to 16 index into the second-level translation table. The last four bits of the table index are implicitly assumed to be zero as there are 16 identical consecutive entries for a large page. This is shown in Figure 16-12.

Figure 16-12. Large Page Translation Summary

16.3.1.3 Translation Lookaside Buffer

Translating virtual addresses to physical addresses is required for each memory access in systems using an MMU. To accelerate this translation process, a cache, or TLB, holds the result of recent translations.

For every translation, the MMU internal logic first checks whether the requested translation is already cached in the TLB. If the translation is cached, this translation is used; otherwise the translation is retrieved from the translation tables and the TLB is updated. If the TLB is full, one of its entries must be replaced. This entry is selected on a random basis.

The first n TLB entries, where $n < \text{Total Number } N \text{ of TLB Entries}$, can be protected (locked) against being overwritten by setting the TLB base pointer to n . When this mechanism is used, only unprotected entries can be overwritten. The victim pointer indicates the next TLB entry to be written. Figure 16-13 shows an example of the TLB with N TLB entries (ranging from 0 to $N-1$). The base pointer contains the value "3" protecting Entry 0, Entry 1, and Entry 2 and the victim pointer points to the next TLB entry to be updated.

NOTE: The last TLB entry (Entry $N-1$) always remains unprotected.

Figure 16-13. TLB Entry Lock Mechanism

The table walking logic automatically writes the TLB entries. The entries can also be manually written, which is done typically to ensure that the translation of time-critical data accesses is already present in the TLB so that they execute as fast as possible. The entries must be locked to prevent them from being overwritten.

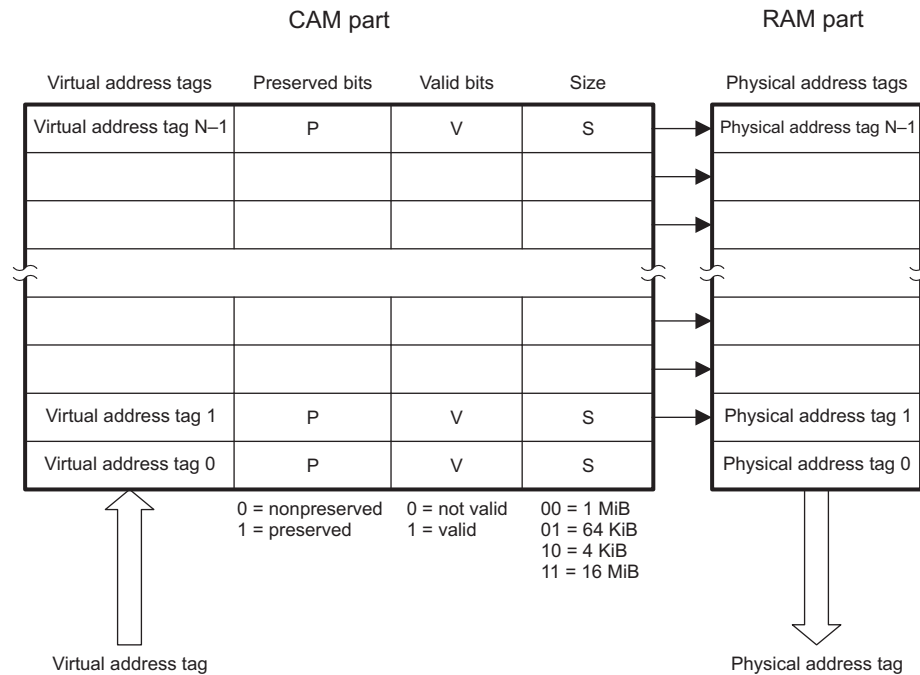

16.3.1.3.1 TLB Entry Format

TLB entries consist of two parts:

- The Content Addressable Memory (CAM) part contains the virtual address tag used to determine if a virtual address translation is in the TLB. The TLB acts like a fully associative cache addressed by the virtual address tag. The CAM part also contains the section/page size, as well as the preserved and the valid parameters. See the [MMU_CAM](#) register table for more details.
- The Random Addressable Memory (RAM) part contains the address translation that belongs to the virtual address tag. See the [MMU_RAM](#) register table for more details.

The valid parameter specifies whether an entry is valid or not. The preserved parameter determines the behavior of an entry in the event of a TLB flush. If an entry is set as preserved, it is not deleted when a TLB is flushed, that is, when [MMU_GFLUSH\[0\]](#) GLOBALFLUSH is set to 1. Preserved entries must be deleted manually. [Section 16.3.1.2.2, First-Level Translation Table](#) describes the procedure to delete TLB entries.

[Figure 16-15](#) shows the TLB entry structure.

Figure 16-14. TLB Entry Structure

16.3.1.4 No Translation (Bypass) Regions

The MMU provides support for up to four user programmable regions where there is no address translation. Any access to a region specified by the MMU_BYPASS_REGIONx_ADDR and MMU_BYPASS_REGIONx_SIZE registers (where x = 1 to 4) will have no virtual to physical address translation.

16.3.2 MMU Software Reset

To perform a software reset, write 1 in the MMU_SYSCONFIG[1] SOFTRESET bit. The MMU_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. When the software reset completes, the MMU_SYSCONFIG[1] SOFTRESET bit is automatically reset. The software must ensure that the software reset completes before doing MMU operations. When an MMU instance is released from reset, its TLB is empty and the MMU is disabled.

16.3.3 MMU Power Management

Table 16-6 describes the power-management features available for the MMU modules.

Table 16-6. MMU Local Power Management Features

Feature	Register
Idle modes	MMU_SYSCONFIG[4:3] IDLEMODE
Clock activity	MMU_SYSCONFIG[9:8] CLOCKACTIVITY
Clock autogating	MMU_SYSCONFIG[0] AUTOIDLE

NOTE: The MMU_SYSCONFIG[9:8] CLOCKACTIVITY bit field is read only.

16.3.4 MMU Interrupt Requests

Table 16-7. MMU Events

Event Flag	Event Mask	Description
MMU_IRQSTATUS[4] MULTIHITFAULT	MMU_IRQENABLE[4] MULTIHITFAULT	Error due to multiple matches in the TLB
MMU_IRQSTATUS[3] TABLEWALKFAULT	MMU_IRQENABLE[3] TABLEWALKFAULT	Error due to error response received during a Table Walk
MMU_IRQSTATUS[2] EMUMISS	MMU_IRQENABLE[2] EMUMISS	Error due to unrecoverable TLB miss during debug (hardware TWL disabled)
MMU_IRQSTATUS[1] TRANSLATIONFAULT	MMU_IRQENABLE[1] TRANSLATIONFAULT	Error due to invalid descriptor in the translation tables (translation fault)
MMU_IRQSTATUS[0] TLBMISS	MMU_IRQENABLE[0] TLBMISS	Error due to unrecoverable TLB miss (hardware TWL disabled)

16.3.5 MMU Error Handling

Table 16-8 summarizes the intended operation for real and potential error conditions.

Table 16-8. Error Handling

Item	Condition	Action
1	Table-walk read has an error response.	Treat generally the same as a translation fault, but set the TableWalkFault interrupt status bit to aid in diagnosis
2	MMU is disabled during table-walk.	Not permitted; can result in loss of the current transaction but must not deadlock the MMU. Avoid this condition by first disabling the table-walk logic and then polling the TWLRunning bit to ensure that no table walk is pending
3	MMU is disabled during an address translation.	Not permitted; can result in access to an unintended location, but must not deadlock MMU. This condition should be avoided by ensuring that no accesses are pending.
4	TLB is accessed during an address translation or a table walk.	Reading permitted; write should be done with care to ensure that the TLB is self-consistent at all times that a translation can occur.
5	TLB is flushed during address translation or a table walk.	Permitted; the flush is processed first, followed by the TWL update.
6	MMU is disabled while an interrupt is pending.	Not permitted; all pending interrupts should be processed before disabling the MMU.
7	Interrupt is not enabled and a fault/miss happens during translation.	If MMU_GPR[0] FAULT_INTR_DIS = 1 : Error response is sent back. If MMU_GPR[0] FAULT_INTR_DIS = 0 : <ul style="list-style-type: none"> Mreqdebug = 1 (debug access) : Error response is sent back Mreqdebug = 0 (application access) : Error response is not sent. MMU is waiting for TLB to be updated through config port. But since the interrupt is not asserted, system does not know there was a fault. This results in deadlock. Software must take care of this by enabling interrupts.

16.4 MMU Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the module.

16.4.1 Global Initialization

16.4.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the MMU module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the MMU. For more information, see [Section 16.2, MMU Module Integration](#).

Table 16-9. Global Initialization of Surrounding Modules

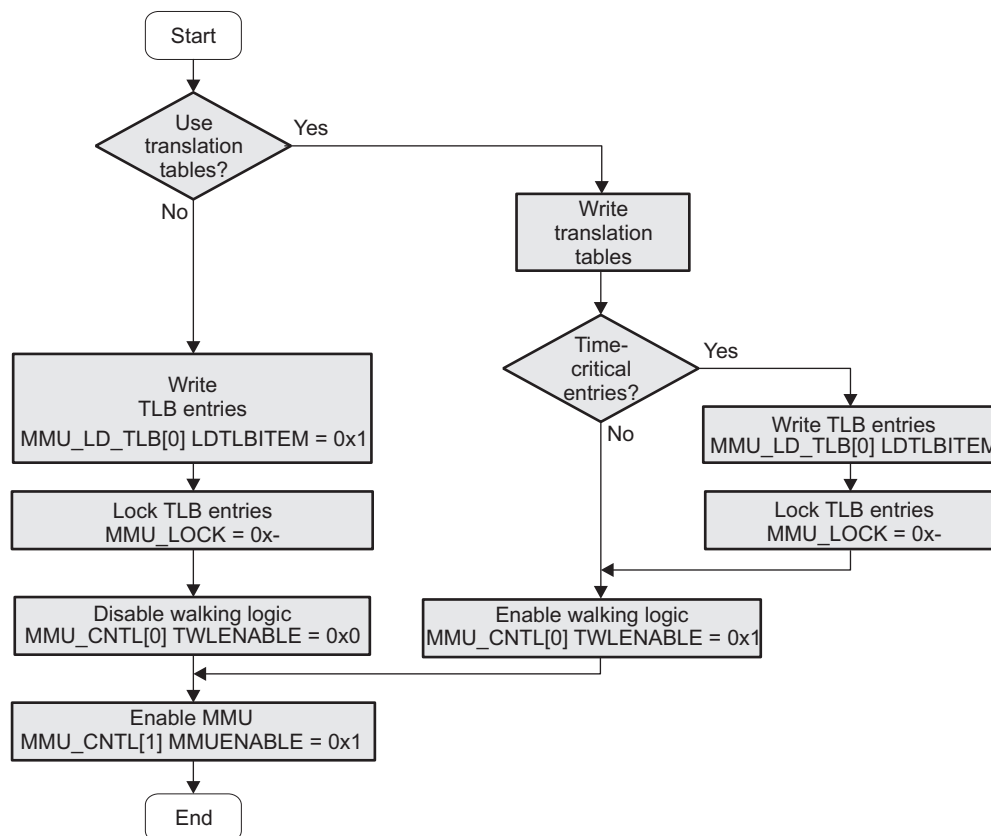

Surrounding Modules	Comments
PRCM	Enable MMU interface/functional clock.
(optional) Interrupt controller(s)	Configure device interrupt controller(s) to enable the interrupts from MMU.
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description , in Chapter 14, Control Module .

16.4.1.2 MMU Global Initialization

16.4.1.2.1 Main Sequence - MMU Global Initialization

[Figure 16-15](#) shows the procedure to initialize the MMU after a power-on or software reset.

Figure 16-15. MMU Global Initialization

16.4.1.2.2 Subsequence - Configure a TLB entry
Table 16-10. Configure a TLB Entry

Step	Register / Bit Field / Programming Model	Value
Load the Virtual Address Tag	MMU_CAM[31:12] VATAG	0x-
Protect the TLB entry against flush	MMU_CAM[3] P	0x1
Validate the TLB entry	MMU_CAM[2] V	0x1
Define the page size	MMU_CAM[1:0] PAGESIZE	0x-

16.4.1.3 Operational Modes Configuration

16.4.1.3.1 Main Sequence - Writing TLB Entries Statically

Writing TLB entries statically avoids the need to write translation tables in memory and is commonly used for relatively small address spaces. This method ensures that the translation of time-critical data accesses execute as fast as possible with entries already present in the TLB. These entries must be locked to prevent them from being overwritten.

Table 16-11. MMU Writing TLB Entries Statically

Step	Register/ Bit Field / Programming Model	Value
Execute software reset	MMU_SYSCONFIG[1] SOFTRESET	0x1
Wait for reset to complete	MMU_SYSSTATUS[0] RESETDONE	=0x1
Enable power saving via automatic interface clock gating	MMU_SYSCONFIG[0] AUTOIDLE	0x1
Configure TLB entries	See Table 16-10	
Load the physical Address of the page	MMU_RAM[31:12] PHYSICALADDRESS	0x-
Specify the TLB entry you want to write	MMU_LOCK[8:4] CURRENTVICTIM	0x-
Load the specified entry in the TLB	MMU_LD_TLB[0] LDTLBITEM	0x1
Enable multihit fault and TLB miss	MMU_IRQENABLE[4] MULTIHITFAULT	0x1
	MMU_IRQENABLE[0] TLBMISS	0x1
Enable memory translations	MMU_CNTL[1] MMUENABLE	0x1

16.4.1.3.2 Main Sequence - Protecting TLB Entries

The first n TLB entries (with $n <$ total number of TLB entries) can be protected from being overwritten with new translations. This is useful to ensure that certain commonly used or time-critical translations are always in the TLB and do not require retrieval using the table walking process.

Table 16-12. Protecting TLB Entries

Step	Register/Bit Field/Programming Model	Value
Locks the TLB entries	MMU_LOCK[14:10] BASEVALUE	0x-

16.4.1.3.3 Main Sequence - Deleting TLB Entries

Two mechanisms exist to delete TLB entries. All unpreserved TLB entries, that is, TLB entries written with the preserved bit set to zero, can be deleted by invoking a TLB flush. The preserved bit should only be used on protected TLB entries, as it does not prevent replacement by the table walking logic.

Table 16-13. Deleting TLB Entries

Step	Register / Bit Field / Programming Model	Value
Flush all nonprotected TLB entries	MMU_GFLUSH[0] GLOBALFLUSH	0x1
Flush all TLB entries specified by the CAM register	MMU_FLUSH_ENTRY[0] FLUSHENTRY	0x1

16.4.1.3.4 Main Sequence - Read TLB Entries

TLB entries can be read by the programmer to determine the TLB content at runtime.

Table 16-14. Read TLB Entries

Step	Register / Bit Field / Programming Model	Value
Set the current victim pointer	MMU_LOCK[8:4] CURRENTVICTIM	0x-
Read RAM parts of the TLB entry	MMU_READ_RAM	

Table 16-14. Read TLB Entries (continued)

Step	Register / Bit Field / Programming Model	Value
Read CAM parts of the TLB entry	MMU_READ_CAM	

16.5 MMU Register Manual

16.5.1 MMU Instance Summary

Table 16-15. MMU Instance Summary

Module Name	Base Address (L3/L4 Access)	Base Address (CPU Private Access)	Size
System MMU	0x4881 C000	–	176 Bytes

Table 16-23. MMU_SYSCONFIG

Address Offset	0x0000 0010	Instance	See Table 16-15
Physical Address	See Section 16.5.2.1		
Description	This register controls the various parameters of the OCP interface		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																CLOCKACTIVITY		RESERVED		IDLEMODE		RESERVED	SOFTRESET	AUTOIDLE							

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Write 0's for future compatibility. Reads return 0	R	0x000000
9:8	CLOCKACTIVITY	Clock activity during wake-up mode 0x0: Functional and OCP clocks can be switched off	R	0x0
7:5	RESERVED	Write 0's for future compatibility Reads returns 0	R	0x0
4:3	IDLEMODE	Idle mode 0x0: Force-idle. An idle request is acknowledged unconditionally 0x1: No-idle. An idle request is never acknowledged 0x2: Smart-idle. Acknowledgement to an idle request is given based on the internal activity of the module 0x3: Reserved. Do not use	RW	0x0
2	RESERVED	Write 0's for future compatibility Reads returns 0	R	0x0
1	SOFTRESET	Software reset. This bit is automatically reset by the hardware. During reads, it always return 0 Write 0x0: No functional effect Write 0x1: The module is reset	W	0x0
0	AUTOIDLE	Internal OCP clock gating strategy 0x0: OCP clock is free-running 0x1: Automatic interconnect clock gating strategy is applied, based on the interconnect interface activity	RW	0x0

Table 16-27. MMU_IRQSTATUS

Address Offset	0x0000 0018
Physical Address	See Section 16.5.2.1
Instance	See Table 16-15
Description	This interrupt status register regroups all the status of the module internal events that can generate an interrupt.
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																MULTIHITFAULT	TABLEWALKFAULT	EMUMISS	TRANSLATIONFAULT	TLBMISS											

Bits	Field Name	Description	Type	Reset
31:5	RESERVED	Write 0's for future compatibility. Read returns 0	R	0x00000000
4	MULTIHITFAULT	Error due to multiple matches in the TLB Read 0x0: MultiHitFault false Write 0x0: MultiHitFault status bit unchanged Write 0x1: MultiHitFault status bit is reset Read 0x1: MultiHitFault is true ('pending')	RW (W1toClr)	0x0

Bits	Field Name	Description	Type	Reset
3	TABLEWALKFAULT	Error response received during a Table Walk Read 0x0: TableWalkFault false Write 0x0: TableWalkFault status bit unchanged Write 0x1: TableWalkFault status bit is reset Read 0x1: TableWalkFault is true ('pending')	RW (W1toClr)	0x0
2	EMUMISS	Unrecoverable TLB miss during debug (hardware TWL disabled) Read 0x0: EMUMiss false Write 0x0: EMUMiss status bit unchanged Write 0x1: EMUMiss status bit is reset Read 0x1: EMUMiss is true ('pending')	RW (W1toClr)	0x0
1	TRANSLATIONFAULT	Invalid descriptor in translation tables (translation fault) Read 0x0: TranslationFault false Write 0x0: TranslationFault status bit unchanged Write 0x1: TranslationFault status bit is reset Read 0x1: TranslationFault is true ('pending')	RW (W1toClr)	0x0
0	TLBMISS	Unrecoverable TLB miss (hardware TWL disabled) Read 0x0: TLBMiss false Write 0x0: TLBMiss status bit unchanged Write 0x1: TLBMiss status bit is reset Read 0x1: TLBMiss is true ('pending')	RW (W1toClr)	0x0

Spinlock

This chapter describes the Spinlock module of the device.

Topic	Page
17.1 Spinlock Overview	5077
17.2 Spinlock Integration	5078
17.3 Spinlock Functional Description	5079
17.4 Spinlock Programming Guide.....	5081
17.5 Spinlock Register Manual	5084

17.1 Spinlock Overview

The Spinlock module provides hardware assistance for synchronizing the processes running on multiple processors in the device:

- Digital signal processor (DSP) subsystems – DSP1 and DSP2
- Dual Cortex-M4 image processing unit (IPU) subsystem – IPU

The Spinlock module implements 256 spinlocks (or hardware semaphores), which provide an efficient way to perform a lock operation of a device resource using a single read-access, avoiding the need of a read-modify-write bus transfer that the programmable cores are not capable of.

Figure 17-1 shows an overview of the Spinlock module.

Figure 17-1. Spinlock Overview

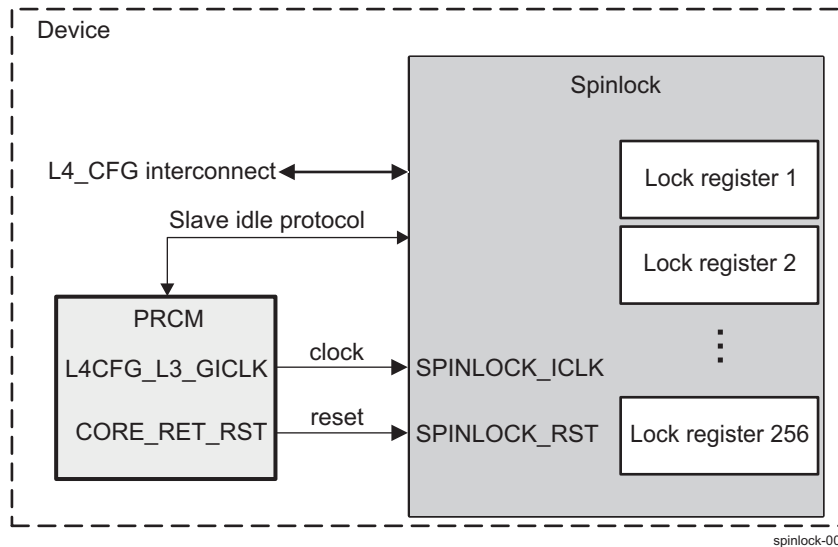

17.2 Spinlock Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 17-2 shows the Spinlock integration.

Figure 17-2. Spinlock Integration

NOTE: For more information about the Slave idle protocol and the wake-up request, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

[Table 17-1](#) and [Table 17-2](#) summarize the integration of the module in the device.

Table 17-1. Spinlock Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
SPINLOCK	PD_COREAON	L4_CFG

Table 17-2. Spinlock Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
SPINLOCK	SPINLOCK_ICLK	L4CFG_L3_GICLK	PRCM	Spinlock interface/functional clock. This clock is used for all interface and functional operations.
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
SPINLOCK	SPINLOCK_RST	CORE_RET_RST	PRCM	Spinlock hardware reset. This reset is asynchronously applied to the Spinlock internal registers.

NOTE: The Spinlock module does not support any interrupt and DMA requests.

17.3 Spinlock Functional Description

17.3.1 Spinlock Software Reset

The Spinlock module can be reset by software through the `SPINLOCK_SYSCONFIG[1]` `SOFTRESET` bit. Setting this bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. The `SPINLOCK_SYSTATUS[0]` `RESETDONE` bit can be polled to check the reset status (reading 1 indicates that reset sequence is done; reading 0 indicates that reset sequence is in progress). The software must ensure that the software reset completes before doing Spinlock operations.

17.3.2 Spinlock Power Management

Table 17-3 describes power-management features available to the Spinlock module.

Table 17-3. Spinlock Local Power Management Features

Feature	Registers	Description
Clock auto gating	<code>SPINLOCK_SYSCONFIG[0]</code> <code>AUTOGATING</code> bit	This bit indicates that the Spinlock module uses an automatic internal interface clock gating strategy, based on interface activity.
Global wake-up enable	<code>SPINLOCK_SYSCONFIG[2]</code> <code>ENAWAKEUP</code> bit	This bit indicates that the wake-up generation feature (at Spinlock module level) is disabled.
Slave idle modes	<code>SPINLOCK_SYSCONFIG[4:3]</code> <code>SIDLEMODE</code> bit field	This bit field indicates that the Spinlock module uses smart-idle mode.

NOTE: All Spinlock local power management features are non-configurable – that is, their respective bit fields are read-only and only show the actual hardware implementation.

For information about source clock gating and sleep/wake-up transitions description, see [Section 3.1.1.1.4, Clock Domain-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#). For descriptions of `EnaWakeUp`, and `IdleMode` features, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

The Spinlock module is normally idle, except when processing a request from its slave interface port. The smart-idle mode acknowledges idle requests from the PRCM only when the module is prepared to go idle. The Spinlock module is always ready to go idle if it does not have any request that it is processing.

17.3.3 About Spinlocks

Spinlocks are present to solve the need for synchronization and mutual exclusion between heterogeneous processors and those not operating under a single, shared operating system. There is no alternative mechanism to accomplish these operations between processors in separate subsystems.

Spinlocks are not the best way to synchronize between tasks or threads on one CPU. Instead, spinlocks are for use in synchronization between different subsystems in the device that don't have any other means of hardware-based synchronization.

Spinlocks do not solve all system synchronization issues. They have limited applicability and should be used with care to implement higher level synchronization protocols.

A spinlock is appropriate for mutual exclusion for access to a shared data structure. It should be used only when:

1. The time to hold the lock is predictable and small (for example, a maximum hold time of less than 200 CPU cycles may be acceptable).
2. The locking task cannot be preempted, suspended, or interrupted while holding the lock (this would make the hold time large and unpredictable).
3. The lock is lightly contended, that is the chance of any other process (or processor) trying to acquire the lock while it is held is small.

If these conditions are met, then the locking code can retry a failed attempt to acquire the lock until success.

If the conditions are not met, then a spinlock is not a good candidate. One alternative is to use a spinlock for critical section control (engineered to meet the conditions) to implement a higher level semaphore that can support preemption, notification, timeout or other higher level properties.

17.3.4 Spinlock Functional Operation

The Spinlock module supports 256 spinlocks. It accepts only a single command at a time and processes the command fully before accepting the next command. A lock is requested by reading the `SPINLOCK_LOCK_REG_i[0]` TAKEN bit. There are two states: Taken (`SPINLOCK_LOCK_REG_i[0]` TAKEN = 1) or Not Taken (`SPINLOCK_LOCK_REG_i[0]` TAKEN = 0).

When the status of lock i (where $i = 0$ to 255) is Not Taken (free), a read from the `SPINLOCK_LOCK_REG_i` register returns 0 and sets the lock to Taken (locked). When the status of lock i is Taken, a read returns 1 and does not change the state of the lock.

A write to the `SPINLOCK_LOCK_REG_i` register does not change the state of lock, unless when writing 0 when the lock is in Taken state. By doing this, the requester frees the lock.

CAUTION

Only 32-bit reads and writes are supported.

Figure 17-3 shows the `SPINLOCK_LOCK_REG_i` register state diagram.

Figure 17-3. Lock Register State Diagram

NOTE:

- There is no support to ensure that a lock register is locked and unlocked by the same process. This must be ensured in software.
- There is no support to check that the same initiator that acquired the lock is the one that is freeing the lock.

17.4 Spinlock Programming Guide

17.4.1 Spinlock Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the module.

17.4.1.1 Surrounding Modules Global Initialization

This procedure initializes the surrounding modules when the Spinlock module is used for the first time after a device reset.

Table 17-4. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Spinlock interface clock must be enabled. For more information, see Section 3.6.4.11, CD_L4_CFG Clock Domain , in Chapter 3, Power, Reset, and Clock Management .
Interconnect	For more information about the L4_CFG interconnect configuration, see Section 10.3, L4 Interconnects .

17.4.1.2 Basic Spinlock Operations

The main spinlock operations are:

- Clear all the Taken spinlocks (only after a system bug recovery)
- Take a spinlock
- Release spinlock

17.4.1.2.1 Spinlocks Clearing After a System Bug Recovery

Module initialization (after reset) is not needed, except after system bug recovery. The following table presents the Spinlock initialization after a system bug recovery. Software should store 0 into each of the [SPINLOCK_LOCK_REG_i](#) registers at system startup to insure that all locks are initialized to Not Taken.

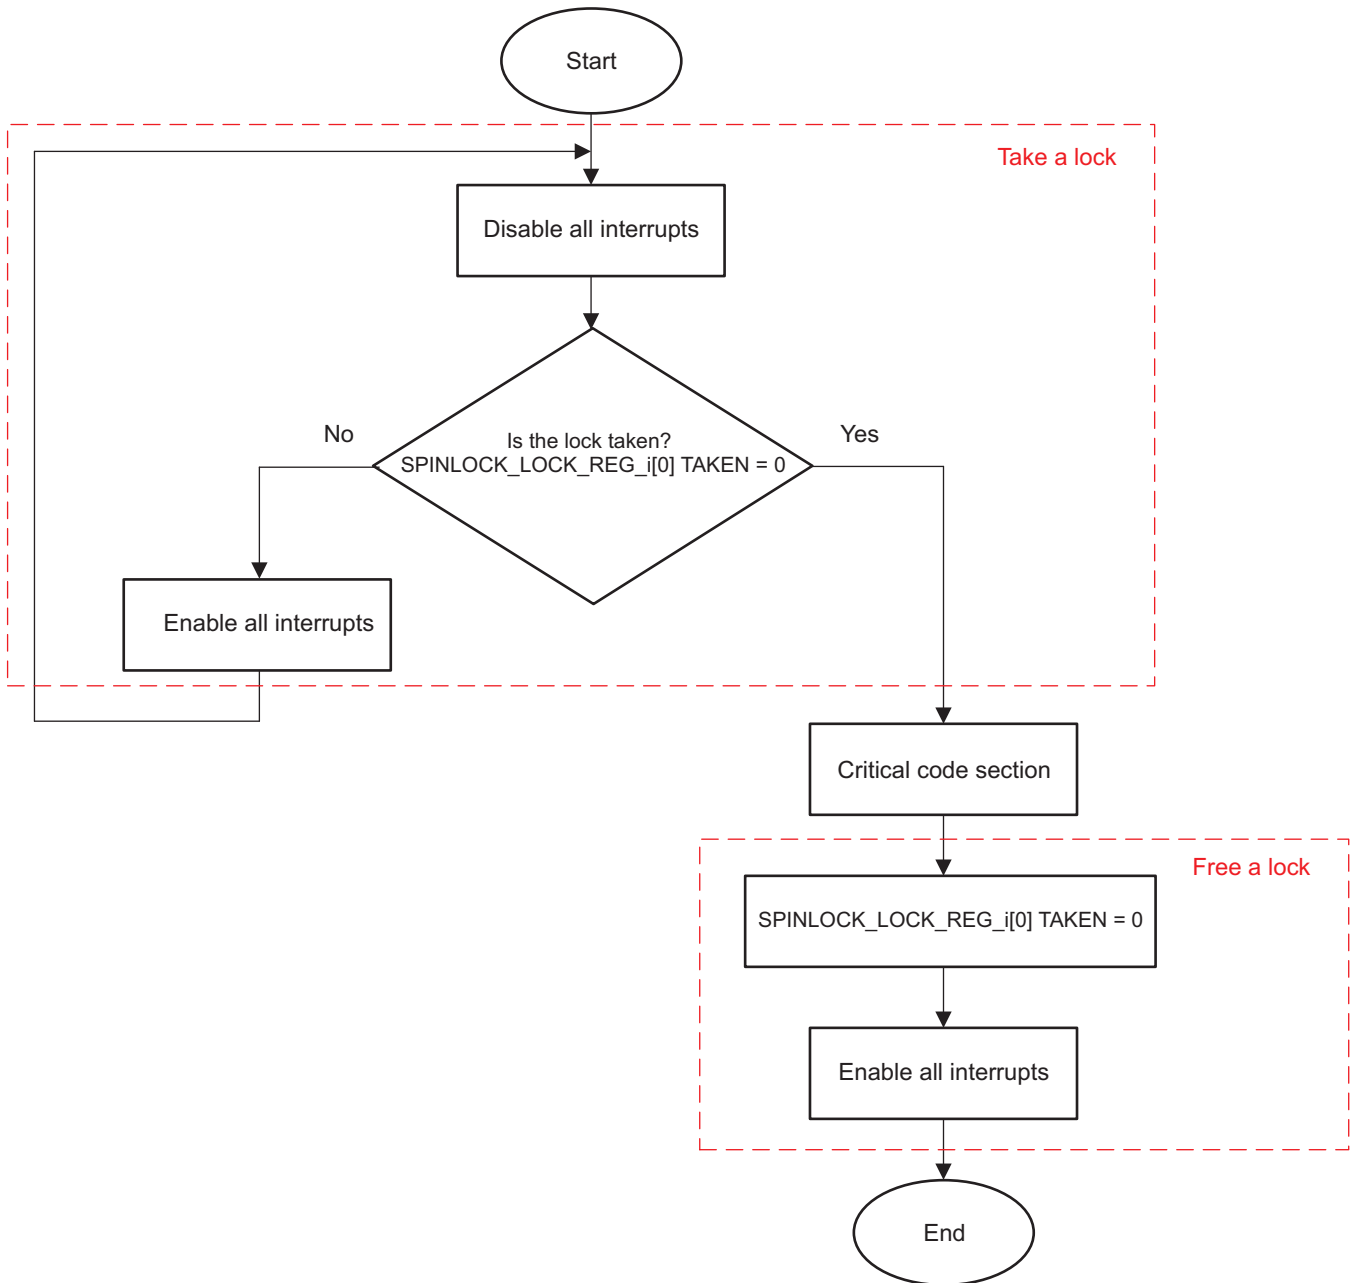

Table 17-5. Spinlock System Bug Recovery

Step	Register	Value
IF: SPINLOCK_SYSTATUS[0] IU0 == 1?	SPINLOCK_SYSTATUS[0] IU0	
Free the 256 locks	SPINLOCK_LOCK_REG_i[0] TAKEN (i = 0 to 255)	0x0
END		

17.4.1.2.2 Take and Release Spinlock

This procedure configures the take and release (free) operations for the Spinlock module. A spinlock should only be held with interrupts disabled. So, before attempting to obtain the spinlock, software should disable interrupts. Then it should read the [SPINLOCK_LOCK_REG_i\[0\]](#) TAKEN bit to attempt to obtain the lock. If it succeeds, it should proceed directly through the critical section then unlock and re-enable interrupts. If the acquisition attempt fails, the acquisition should be reattempted. To prevent unknown interrupt disabled time, interrupts should be re-enabled and then disabled before reattempting to acquire the lock. [Figure 17-4](#) shows the described above procedure.

Timers

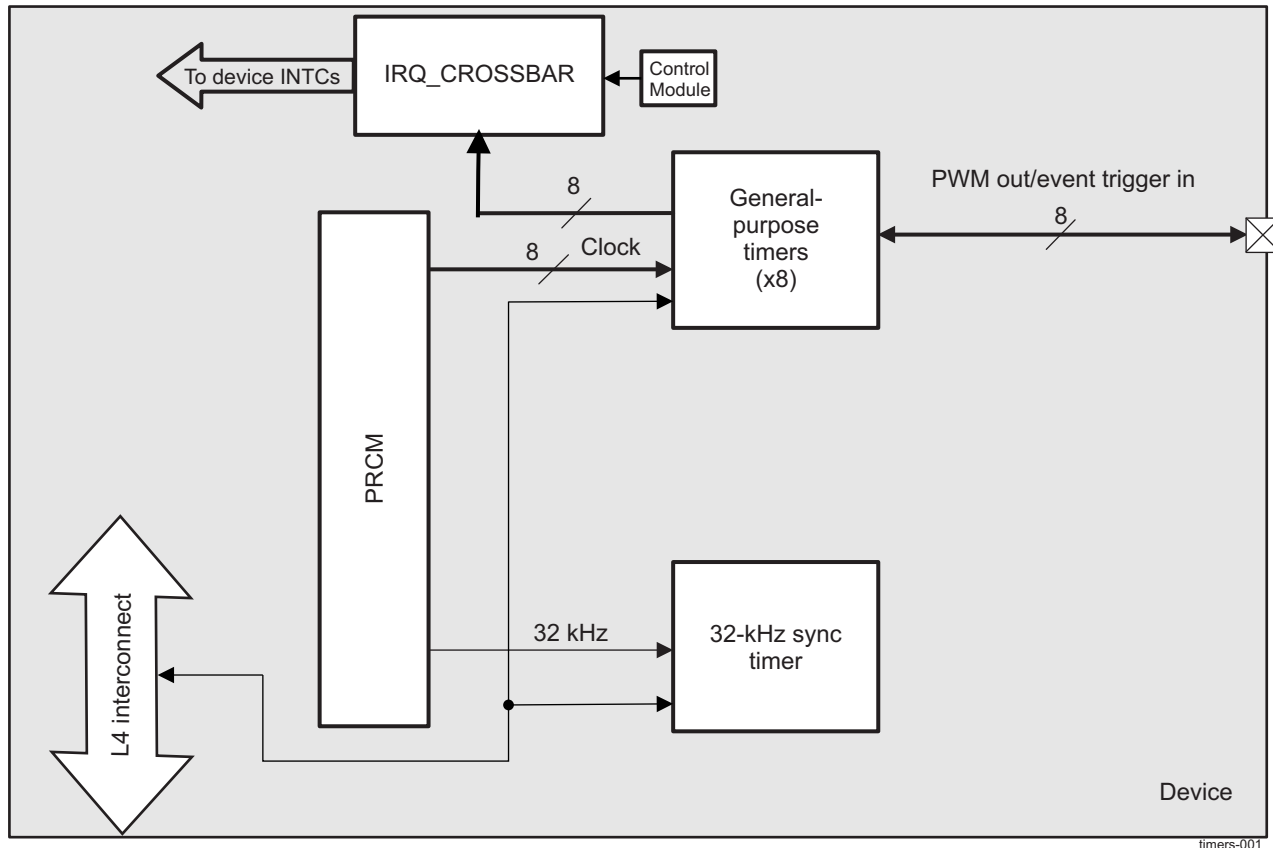

This chapter describes the timer modules for the device.

Topic	Page
18.1 Timers Overview	5089
18.2 General-Purpose Timers	5090
18.3 32-kHz Synchronized Timer (COUNTER_32K)	5136

18.1 Timers Overview

The device includes several types of timers used by the system software, including eight general-purpose (GP) timers, and a 32-kHz synchronized timer (COUNTER_32K). Figure 18-1 shows a high-level block diagram of the device timers.

Figure 18-1. Timers Overview

timers-001

The 32-kHz sync timer, which is reset only at power up, provides the operating system (OS) with a stable timing source that stores the relative time since the last power cycle of the product. The eight GP timers, which are useful as basic timers, are included to generate time-stamp-based interrupts to the system software or to use as a source of pulse-width modulation (PWM) signals.

18.2 General-Purpose Timers

18.2.1 General-Purpose Timers Overview

The device has eight GP timers: TIMER1 through TIMER8.

- TIMER1 (1-ms tick) includes a specific function to generate accurate tick interrupts to the operating system and it belongs to the PD_WKUPAON domain.
- TIMER2 through TIMER8 belong to the PD_COREAON module.

Each timer can be clocked from the system clock (19.2, 20, or 27 MHz) or the 32-kHz clock. Select the clock source at the power, reset, and clock management (PRCM) module level.

Each timer provides an interrupt through the device IRQ_CROSSBAR.

Each timer is connected to an external pin by their PWM output or their event capture input pin (for external timer triggering). Figure 18-2 shows an overview of the GP timers.

Figure 18-2. GP Timers Overview

18.2.1.1 GP Timer Features

The following are the main features of the GP timer controllers:

- Level 4 (L4) slave interface support:
 - 32-bit data bus width

- 32- or 16-bit access supported
- 8-bit access not supported
- 10-bit address bus width
- Burst mode not supported
- Write nonposted transaction mode supported
- Interrupts generated on overflow, compare, and capture
- Free-running 32-bit upward counter
- Compare and capture modes
- Autoreload mode
- Start and stop mode
- Programmable divider clock source (2^n , where $n = [0:8]$)
- Dedicated input trigger for capture mode and dedicated output trigger/PWM signal
- Dedicated GP output signal for using the `TIMERi_GPO_CFG` signal
- On-the-fly read/write register (while counting)
- 1-ms tick with 32.768-Hz functional clock generated (only TIMER1)

18.2.2 GP Timer Environment

18.2.2.1 GP Timer External System Interface

Each timer can send or receive stimulus to and from the external (off-chip) system. In the device all timers are configured to output a PWM pulse or receive an external event signal used as a trigger to capture the current timer count.

Figure 18-3 shows the external system interface for the GP timers, and Table 18-1 describes the GP timer inputs and outputs.

NOTE: Software control must ensure that MUX mode is configured to select the timer_i (where i = 1 to 8) signal on only one pad. Other pads on which the same signal is multiplexed must be configured in safe mode or non-dmtimer mode to avoid two different pads driving the same signal.

For more information about the configuration of the timer_i I/O pads, see Section 14.4.6.1, Pad Configuration Registers.

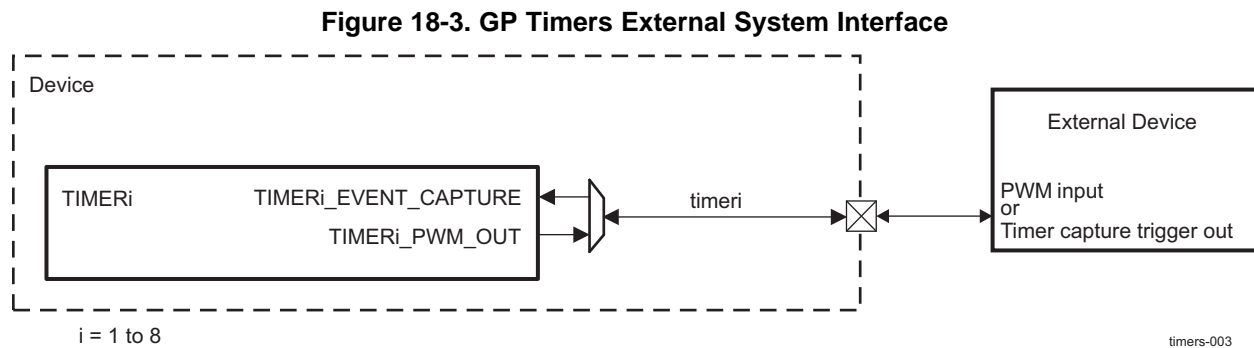

Table 18-1. Input/Output Description

Pin Name	Type ⁽¹⁾	Reset Value	Signal Name	Description
timer1	I/O	0	TIMER1_PI_EVENT_CAPTURE TIMER1_PWM_OUT	TIMER1 trigger input/ PWM output
timer2	I/O	0	TIMER2_PI_EVENT_CAPTURE TIMER2_PWM_OUT	TIMER2 trigger input/ PWM output
timer3	I/O	0	TIMER3_PI_EVENT_CAPTURE TIMER3_PWM_OUT	TIMER3 trigger input/ PWM output
timer4	I/O	0	TIMER4_PI_EVENT_CAPTURE TIMER4_PWM_OUT	TIMER4 trigger input/ PWM output
timer5	I/O	0	TIMER5_PI_EVENT_CAPTURE TIMER5_PWM_OUT	TIMER5 trigger input/ PWM output
timer6	I/O	0	TIMER6_PI_EVENT_CAPTURE TIMER6_PWM_OUT	TIMER6 trigger input/ PWM output
timer7	I/O	0	TIMER7_PI_EVENT_CAPTURE TIMER7_PWM_OUT	TIMER7 trigger input/ PWM output
timer8	I/O	0	TIMER8_PI_EVENT_CAPTURE TIMER8_PWM_OUT	TIMER8 trigger input/ PWM output

⁽¹⁾ When configured for that function; I = Input, O = Output

NOTE: Each TIMER_i_PO_GPOCFG signal is used to as an output enable to control the function of the TIMER_i pin (where i = 1 to 8) as the PWM output (PO_GPOCFG = 0) or capture input (PO_GPOCFG = 1).

18.2.3 GP Timer Integration

Figure 18-4 shows the integration of the GP timer in the device.

Figure 18-4. GP Timer Integration

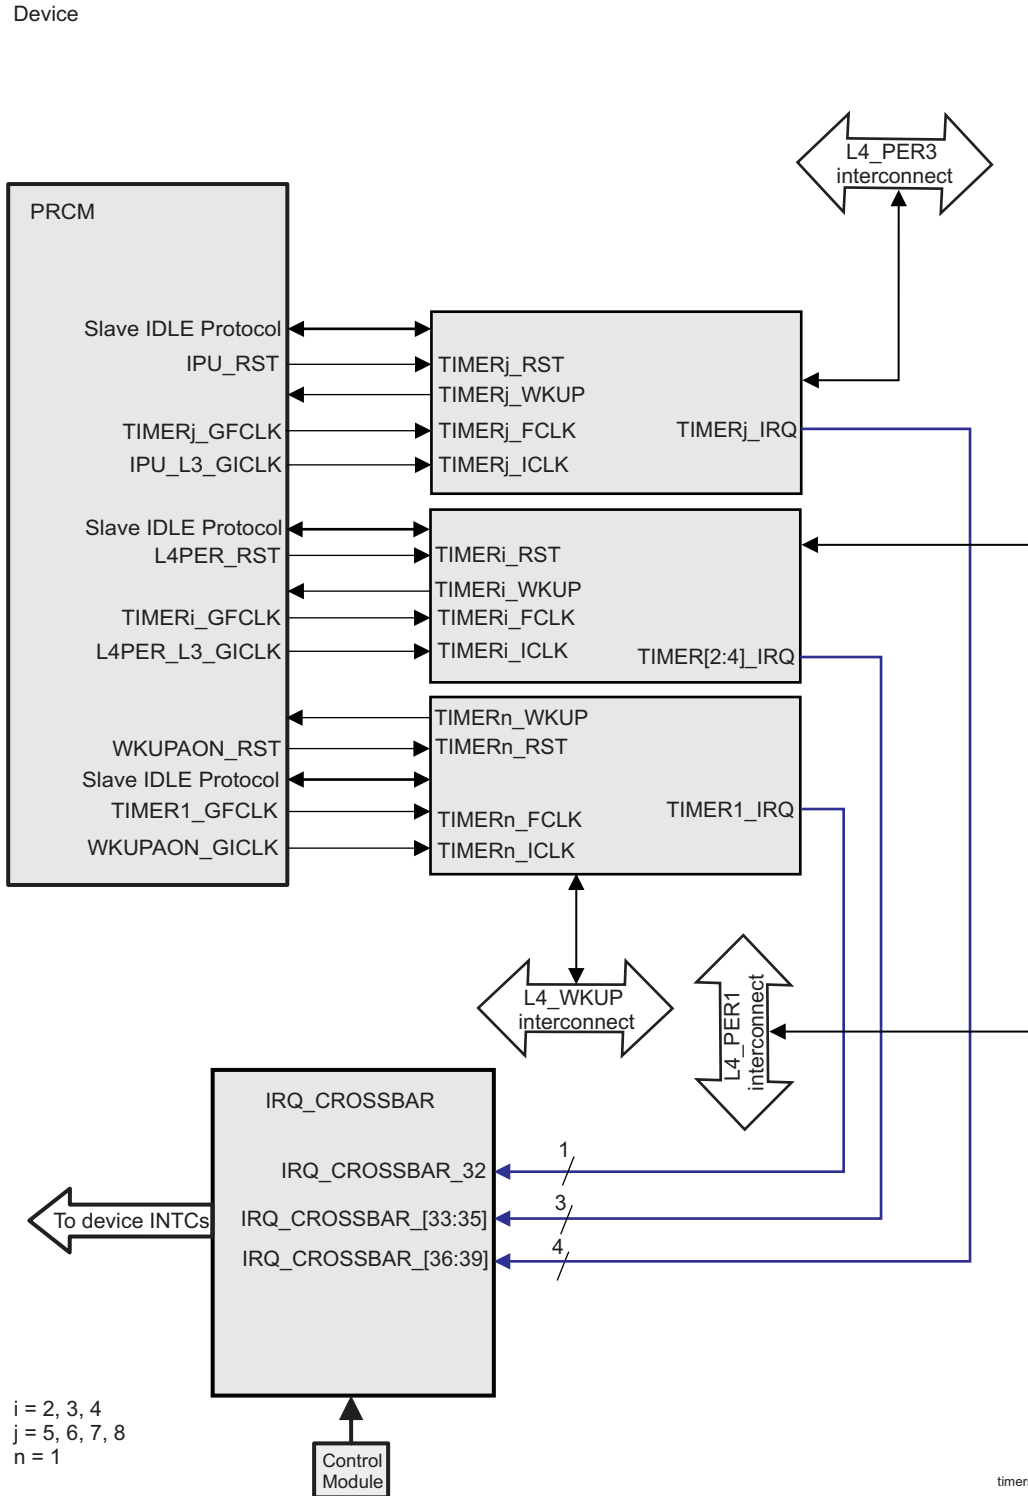

Table 18-2 through Table 18-4 summarize the integration of the module in the device.

Table 18-2. Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
TIMER1	PD_WKUPAON	Yes	L4_WKUP
TIMER2	PD_COREAON	Yes	L4_PER1
TIMER3	PD_COREAON	Yes	L4_PER1
TIMER4	PD_COREAON	Yes	L4_PER1
TIMER5	PD_COREAON	Yes	L4_PER3

No DMA Requests				

NOTE: The Default Mapping column in [Table 18-4](#) shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device interrupt controller through the IRQ_CROSSBAR module. For more information about the IRQ_CROSSBAR module, see [Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#). For more information about the device interrupt controllers, see [Chapter 13, Interrupt Controllers](#).

NOTE: For the description of the interrupt source, see [Section 18.2.4.5, GP Timer Interrupt](#).

18.2.4 GP Timer Functional Description

Each GP timer contains a free-running upward counter with autoreload capability on overflow. The timer counter can be read and written on-the-fly (while counting). Each GP timer includes compare logic to allow an interrupt event on a programmable counter matching value. A dedicated output signal can be pulsed or toggled on either an overflow or a match event. This offers time-stamp trigger signaling or PWM signal sources. A dedicated input signal can be used to trigger an automatic timer counter capture or an interrupt event on a programmable input signal transition. A programmable clock divider (prescaler) allows reduction of the timer input clock frequency. All internal timer interrupt sources are merged into one module interrupt line and one wake-up line.

Each internal interrupt source can be independently enabled and disabled by a dedicated bit in the [IRQSTATUS_SET](#) and [IRQSTATUS_CLR](#) registers for the interrupt features, and a dedicated bit of the [IRQWAKEEN](#) register for the wake-up of TIMER1. In addition, a mechanism implemented in these timers generate an accurate tick interrupt.

For all other internal interrupts, the source can be independently enabled and disabled through the [IRQENABLE_SET](#) and [IRQENABLE_CLR](#) registers.

For each GP timer implemented in the device, there are two possible clock sources:

- 32-kHz clock
- System clock

The input clock source is selected in the registers in the PRCM configuration (see [Section 18.2.1, GP Timer Overview](#)).

Each GP timer supports three functional modes:

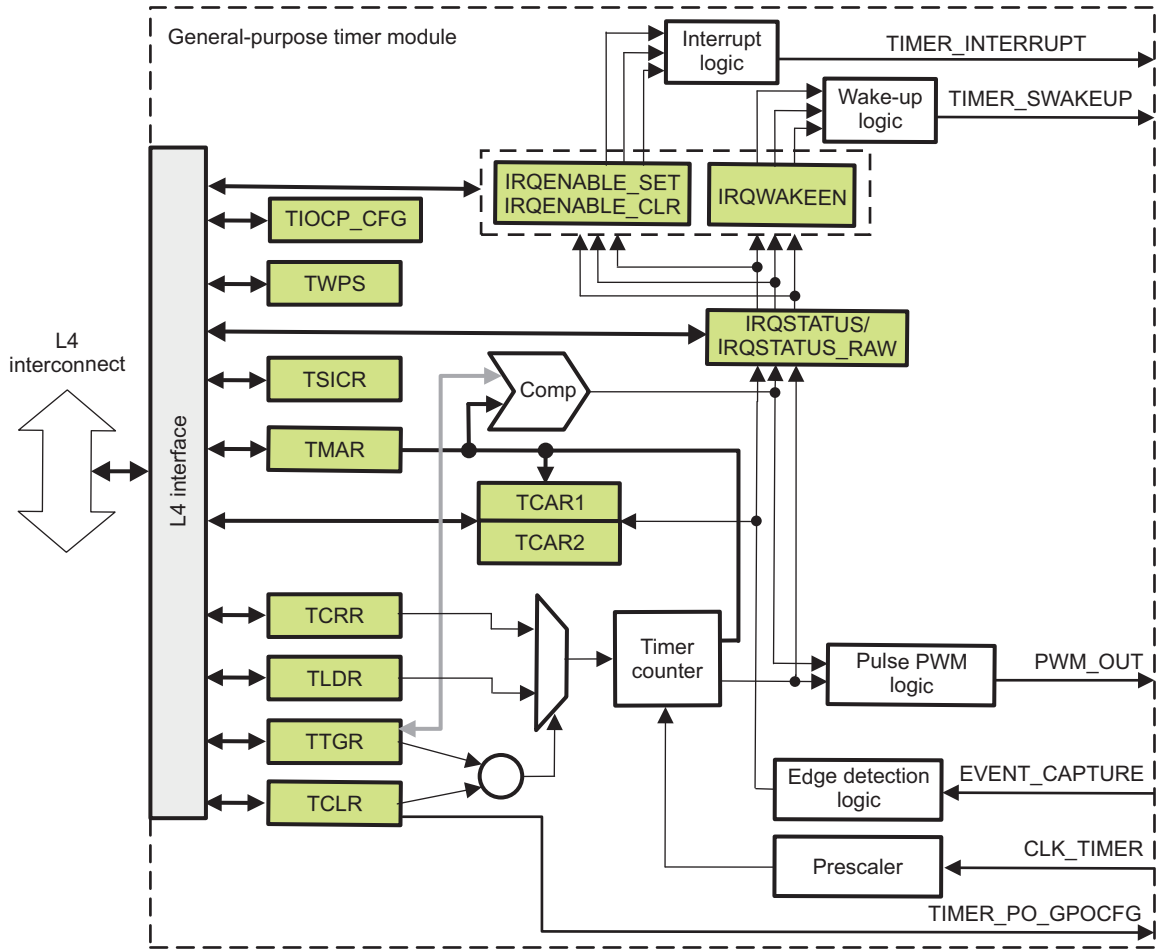

- Timer mode
- Capture mode
- Compare mode

The capture and compare modes are disabled by default after core reset.

18.2.4.1 GP Timer Block Diagram

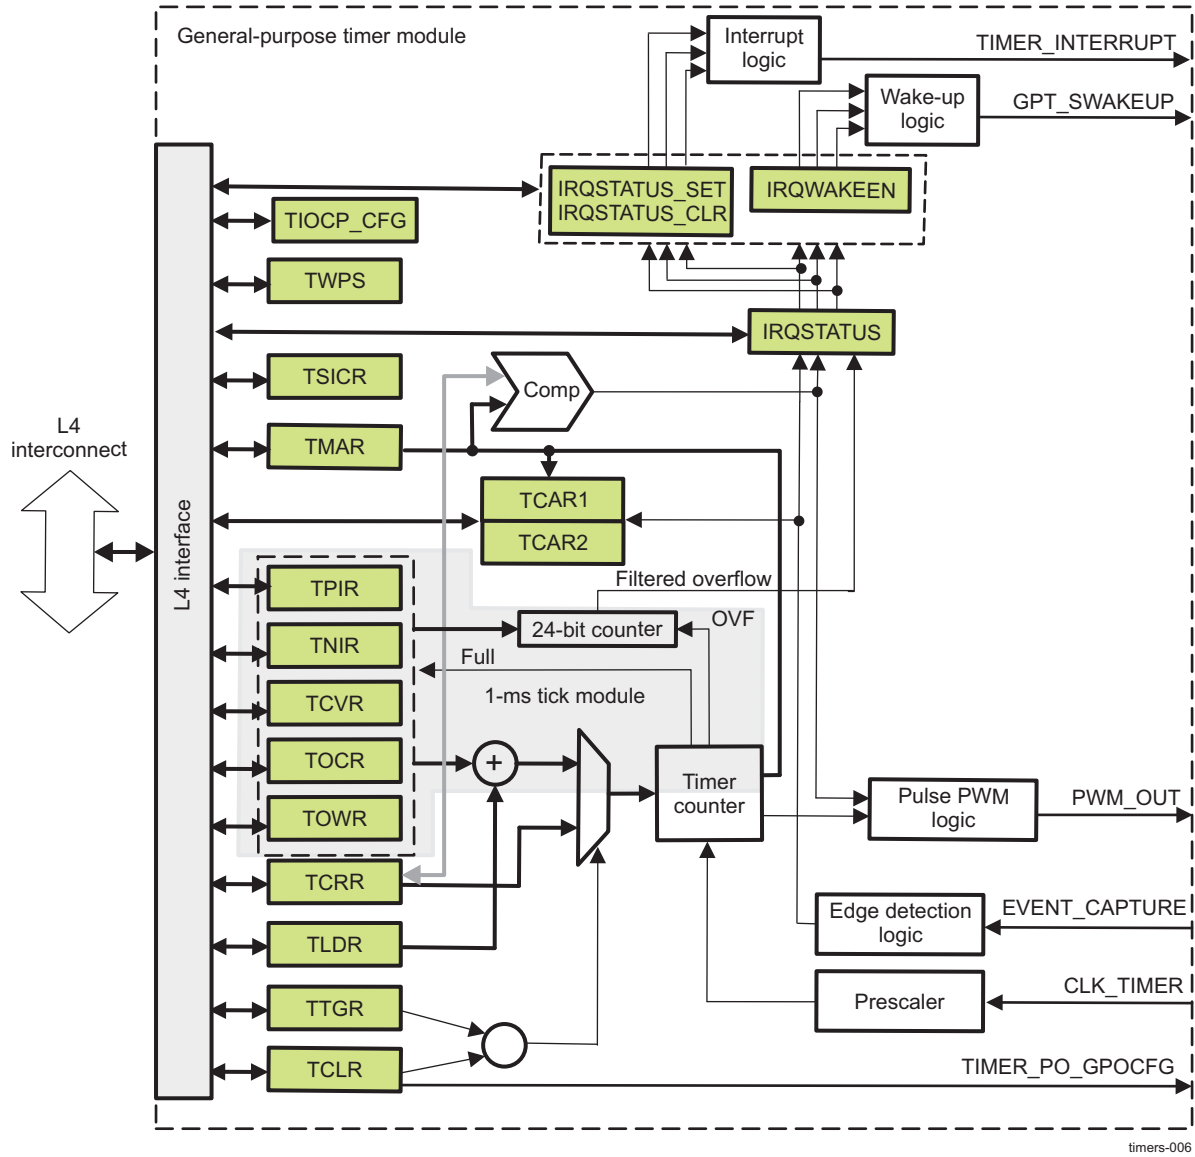

[Figure 18-5](#) is a block diagram of the common GP timers, and [Figure 18-6](#) is a block diagram of the GP timers with a 1-ms tick generation module.

timers-006

18.2.4.2 TIMER1 Power Management

At the PRCM module level, when all conditions to shut off the functional or interface output clocks in the PRCM module are met (see [Section 3.1.1.1.4, Clock Domain-Level Clock Management](#)), the PRCM module automatically launches a hardware handshake protocol to ensure the GP timer is ready to have its clocks switched off. Namely, the PRCM module asserts an IDLE request to the GP timer.

Although this handshake is a hardware function and is out of software control, the way the GP timer acknowledges the PRCM IDLE request is configurable through the `TIOCP_CFG[3:2]` IDLEMODE bit field.

[Table 18-5](#) lists the IDLEMODE settings and the related acknowledgment modes.

Table 18-5. IDLEMODE Settings

IDLEMODE Value	Selected Mode	Description
00	Force-idle	The GP timer unconditionally acknowledges the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully, because it does not prevent the loss of data when the clock is switched off.
01	No-idle	The GP timer never acknowledges an IDLE request from the PRCM module. This mode is safe from a module point of view, because it ensures that the clocks remain active. No-idle mode is not efficient from a power-saving perspective, because it does not allow the PRCM output clock to be shut off, and thus the power domain to be set to a lower power state.
10	Smart-idle	The GP timer acknowledges the IDLE request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and IRQ requests are treated. This is the best approach to efficient system power management.
11	Smart-idleWakeup	The module behaves like in smart-idle mode, with the exception, that it can issue a wake-up request in sleep mode, if the functional clock is not cut off.

18.2.4.2.1 Wake-Up Capability

If the `TIOCP_CFG[3:2]` IDLEMODE bit field sets the smart-idle mode or smart-idle with wakeup mode, the timer evaluates its internal capability to have the interface clock switched off. When there is no further internal activity (no pending interrupt sources: match, overflow, or timer capture events), the idle acknowledge signal is asserted and the timer enters sleep mode, ready to issue a wake-up request if is configured in smart-idle with wakeup mode.

[Figure 18-7](#) shows the wake-up request generation. For more information about the GP timer clock control, see [Section 3.6, Clock Management Functional Description](#), in [Chapter 3, Power, Reset and Clock Management](#).

Figure 18-7. Wake-Up Request Generation

timers-007

For TIMER1 the timer wake-up-enable register allows masking of the expected source of the wake-up event that generates a wake-up request. The register is synchronously programmed with the interface clock before the PRCM module sends an idle mode request. The expected source of the wake-up event is an overflow (TCRR), a timer match (the compare result of TCRR and TMAR matches the counter value), and a timer capture (detection of an external pulse transition of the correct polarity on the TIMER_EVENT_CAPTURE).

When the wake-up event is issued, the associated interrupt status bit is set in the timer status register (IRQSTATUS). The pending wake-up event is reset when the set status bit is overwritten with 1.

NOTE: The status bit must be reset to re-enter idle mode.

18.2.4.3 Power Management of Other GP Timers

At the PRCM module level, when all conditions to shut off the functional or interface output clocks of the PRCM module are met (see Section 3.1.1.1.4, *Clock Domain-Level Clock Management*), the PRCM module automatically launches a hardware handshake protocol to ensure the GP timer is ready to have its clocks switched off. Namely, the PRCM module asserts an IDLE request to the GP timer.

Although this handshake is a hardware function and is out of software control, the way the GP timer acknowledges the PRCM IDLE request is configurable through the TIOCP_CFG[3:2] IDLEMODE bit field.

Table 18-6 lists the IDLEMODE settings and the related acknowledgment modes.

Table 18-6. IDLEMODE Settings

IDLEMODE Value	Selected Mode	Description
00	Force-idle	The GP timer unconditionally acknowledges the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully, because it does not prevent the loss of data when the clock is switched off.
01	No-idle	The GP timer never acknowledges an IDLE request from the PRCM module. This mode is safe from a module point of view, because it ensures that the clocks remain active. INo-idle mode is not efficient from a power-saving perspective, however, because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.

Table 18-6. IDLEMODE Settings (continued)

IDLEMODE Value	Selected Mode	Description
10	Smart-idle	The GP timer acknowledges the IDLE request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and IRQ requests are treated. This is the best approach to efficient system power management.
11	Smart-idleWakeup	The module behaves like in Smart-idle mode, with the exception, that it can issue a wake-up request in sleep mode, if the functional clock is not cut off.

18.2.4.3.1 Wake-Up Capability

If the `TIOCP_CFG[3:2]` IDLEMODE bit field sets the smart-idle mode or smart-idle with wakeup mode, the timer evaluates its internal capability to have the interface clock switched off. When there is no further internal activity (no pending interrupt sources: match, overflow, or timer capture events), the idle acknowledge signal is asserted and the timer enters sleep mode, ready to issue a wake-up request if is configured in smart-idle with wakeup mode. This wake-up request is sent only if the `IRQWAKEEN[2:0]` bit field enables the timer wake-up capability.

Figure 18-8 shows the wake-up request generation. For more information about the GP timer clock control, see Section 3.6, *Clock Management Functional Description*, in Chapter 3, *Power, Reset, and Clock Management*.

Figure 18-8. Wake-Up Request Generation

timers-008

When the wake-up event is issued, the associated interrupt status bit is set in the timer status register (`IRQSTATUS`). The pending wake-up event is reset when the set status bit is overwritten with 1.

NOTE: The status bit must be reset to re-enter idle mode.

18.2.4.4 Software Reset

Two bits can generate a software reset of the GP timer:

- `TIOCP_CFG[0]` SOFTRESET
- `TSICR[1]` SFT

For both bits, all read accesses return 0.

The `TIOCP_CFG[0]` SOFTRESET bit allows resetting of the functional and interface domains. The `TSICR[1]` SFT bit allows resetting the functional part of the GP timer.

Before accessing or using the GP timer, the local host must ensure that both internal resets are released by reading the `TIOCP_CFG[0]` SOFTRESET bit. This bit monitors the internal reset status.

18.2.4.5 GP Timer Interrupts

The timer can issue an overflow interrupt, a timer match interrupt, and a timer capture interrupt. Each internal interrupt source can be independently enabled and disabled in the interrupt-enable register (`IRQSTATUS_SET` for `TIMER1` and `IRQENABLE_SET` for other timers) and disabled in the interrupt-disable register (`IRQSTATUS_CLR` for `TIMER1` and `IRQENABLE_CLR` for other timers). When the interrupt event is issued, the associated interrupt status bit is set in the timer status register (`IRQSTATUS`).

18.2.4.6 Timer Mode Functionality

The timer is an upward counter that can be started and stopped at any time through the timer control register (the `TCLR[0]` ST bit). The timer counter register (`TCRR`) can be loaded when stopped or on-the-fly (while counting). `TCRR` can be loaded directly by a `TCRR` write access with a new timer value. `TCRR` can also be loaded with the value held in the timer load register (`TLDR`) by a trigger register (`TTGR`) write access. The loading of `TCRR` is done regardless of the written value of `TTGR`. The value of `TCRR` can be read when stopped or captured on-the-fly by a `TCRR` read access. The timer is stopped and the counter value is set to 0 when the module reset is asserted. The timer is maintained at stop after the reset is released.

In one-shot mode (the `TCLR[1]` AR bit is set to 0), the counter is stopped after counting overflow occurs (the counter value remains at 0).

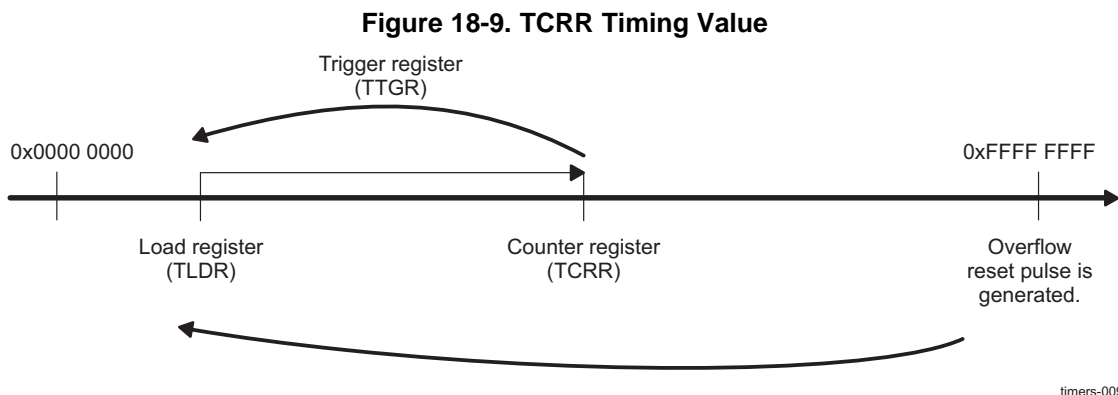

When the autoreload mode is enabled (the `TCLR[1]` AR bit is set to 1), `TCRR` is reloaded with the value of `TLDR` after a counting overflow occurs.

CAUTION

Do not put the overflow value (0xFFFF FFFF) in the `TLDR` register because it can lead to undesirable results.

An interrupt can be issued on overflow if the overflow interrupt-enable bit is set in the timer interrupt-enable register (the `IRQSTATUS_SET[1]` OVF_EN_FLAG bit is set to 1 for `TIMER1/2/10` and the `IRQENABLE_SET[1]` OVF_EN_FLAG bit is set to 1 for other timers). A dedicated output pin (timer PWM) can be programmed in the `TCLR[12]` PT bit through the `TCLR[11:10]` (PT and TRG bits) to generate one positive pulse (prescaler duration) or to invert the current value (toggle mode) when an overflow occurs. The `TCLR[12]` PT bit selects pulse/toggle modulation (the `TCLR[11:10]` TRG bit field selects trigger mode).

Figure 18-9 shows the `TCRR` timing value.

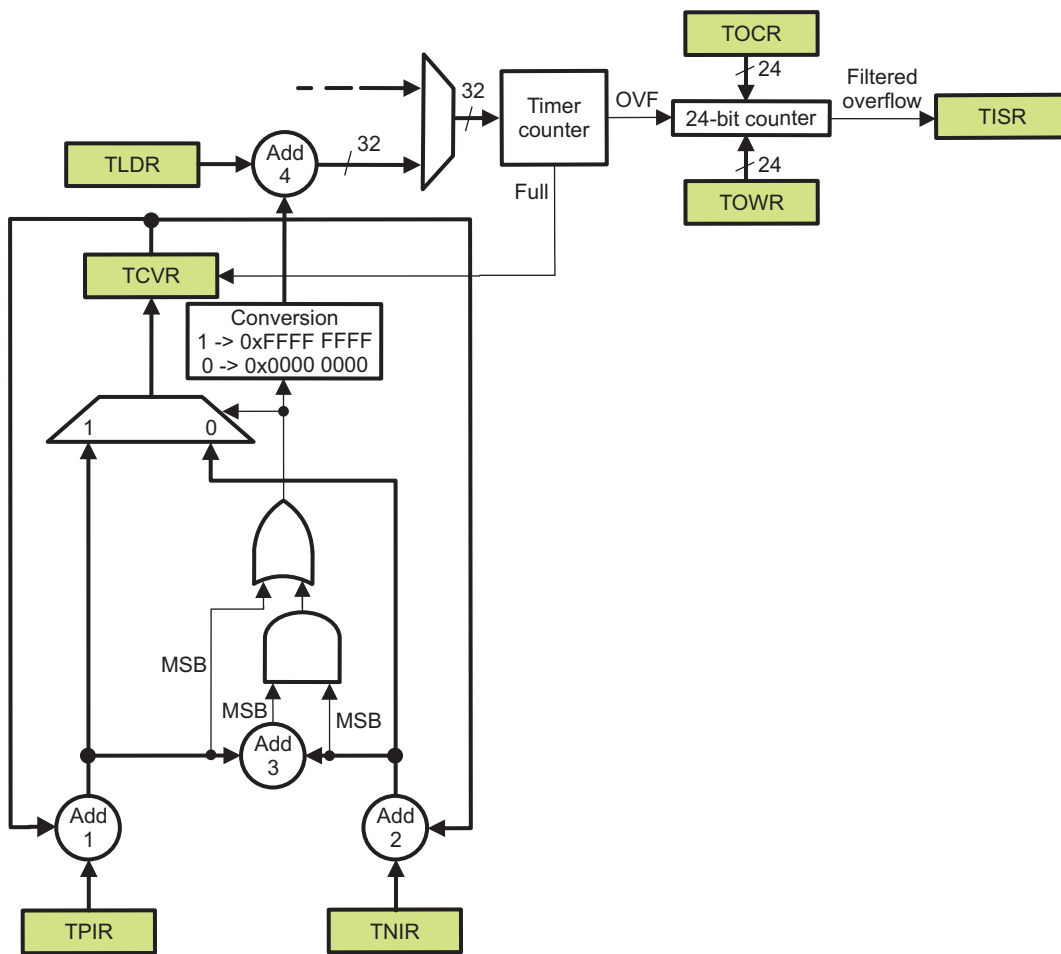

18.2.4.6.1 1-ms Tick Generation (Only TIMER1)

The interrupt period is not exactly 1 ms, because the timer input clock is 32.768 Hz. If the clock counts up to 32, it obtains a 0.977-ms period; if it counts up to 33, it obtains a 1.007-ms period. For large granularity, the error is cumulative and can generate important deviations from the standard value.

To minimize the error between a true 1-ms tick and the tick generated by the 32.768-Hz timer, the sequencing of periods less than 1 ms and periods greater than 1 ms must be shuffled. An additional 1-ms block is used to correct this error. See Figure 18-10.

In this implementation, the increment sequencing is automatically managed by the timer to minimize the error. The user must define only the value of the timer positive increment register (the **TPIR**[31:0] POSITIVE_INC_VALUE bit field) and the timer negative increment register (the **TNIR**[31:0] NEGATIVE_INC_VALUE bit field). An automatic adaptation mechanism is used to simplify the programming model.

Figure 18-10. Block Diagram of the 1-ms Tick Module

timers-010

The **TPIR**, **TNIR**, and **TCVR** registers and adders Add1, Add2, and Add3 are used to define whether the next value loaded in the timer counter register (the **TCRR**[31:0] TIMER_COUNTER bit field) is the value of the **TLDR**[31:0] LOAD_VALUE bit field (period less than 1 ms) or the value of **TLDR**[31:0] LOAD_VALUE -1 (period greater than 1 ms).

Table 18-7 lists the value loaded in the **TCRR** according to the sign of the result of Add1, Add2, and Add3.

MSB = 0: Positive value; MSB = 1: Negative value

Table 18-7. Value Loaded in TCRR to Generate 1-ms Tick

Add1 MSB	Add2 MSB	Add3 MSB	Value of TCRR Register
0	0	0	TLDR[31:0] LOAD_VALUE bit field
0	0	1	TLDR[31:0] LOAD_VALUE bit field
0	1	0	TLDR[31:0] LOAD_VALUE bit field
0	1	1	TLDR[31:0] LOAD_VALUE -1
1	0	0	N/A
1	0	1	N/A
1	1	0	TLDR[31:0] LOAD_VALUE -1
1	1	1	TLDR[31:0] LOAD_VALUE -1

The values of the **TPIR** and **TNIR** registers are calculated using the following formulas:

- Positive increment value = $((\text{INTEGER}[F_{\text{clk}} \times T_{\text{tick}}] + 1) \times 1\text{e}6) - (F_{\text{clk}} \times T_{\text{tick}} \times 1\text{e}6)$
- Negative increment value = $(\text{INTEGER}[F_{\text{clk}} \times T_{\text{tick}}] \times 1\text{e}6) - (F_{\text{clk}} \times T_{\text{tick}} \times 1\text{e}6)$

NOTE: F_{clk} clock frequency (kHz)

T_{tick} tick period (ms)

The timer overflow counter register (**TOCR**) and the timer overflow wrapping register (**TOWR**) are used to filter interrupts. When the timer overflows, it increments the 24-bit **TOCR**. When the values in the 24-bit **TOCR** match the values in the 24-bit **TOWR** and the timer overflow is asserted, the **TOCR** is reset and an interrupt is generated to the **IRQSTATUS** register.

NOTE: **TOWR** must to be set to requested value. For example, if no interrupt needs to be masked, **TOWR** must be set to 0; if one interrupt must be masked, **TOWR** must be set to 1; if two interrupts must be masked **TOWR** must be set to 2, and so on.

It is important to remember that it is not possible to mask the FFFFFFF interrupt.

With the conversion block in reset state (the positive increment register, negative increment register, and counter value register are zeroed), the programming model and the behavior of **TIMER1** remain unchanged.

For 1-ms tick with a 32.768-Hz clock:

- **TPIR**[31:0] **POSITIVE_INC_VALUE** = 232,000
- **TNIR**[31:0] **NEGATIVE_INC_VALUE** = -768,000
- **TLDR**[31:0] **LOAD_VALUE** = 0xFFFF FFE0

NOTE: Any value of the tick period can be generated with the appropriate value of the **TPIR**, **TNIR**, and **TLDR** registers.

By default, the **TPIR**, **TNIR**, **TCVR**, **TOCR**, and **TOWR** registers and the associated logic are in reset mode (all 0s) and have no effect on the programming model.

18.2.4.7 Capture Mode Functionality

When a transition is detected on the module input pin (**EVENT_CAPTURE**), the timer value in the **TCRR** can be captured and saved in the **TCAR1** or **TCAR2** register function of the mode selected in the **TCLR**[13] **CAPT_MODE** bit. The edge detection circuitry monitors transitions on the input pin (**EVENT_CAPTURE**).

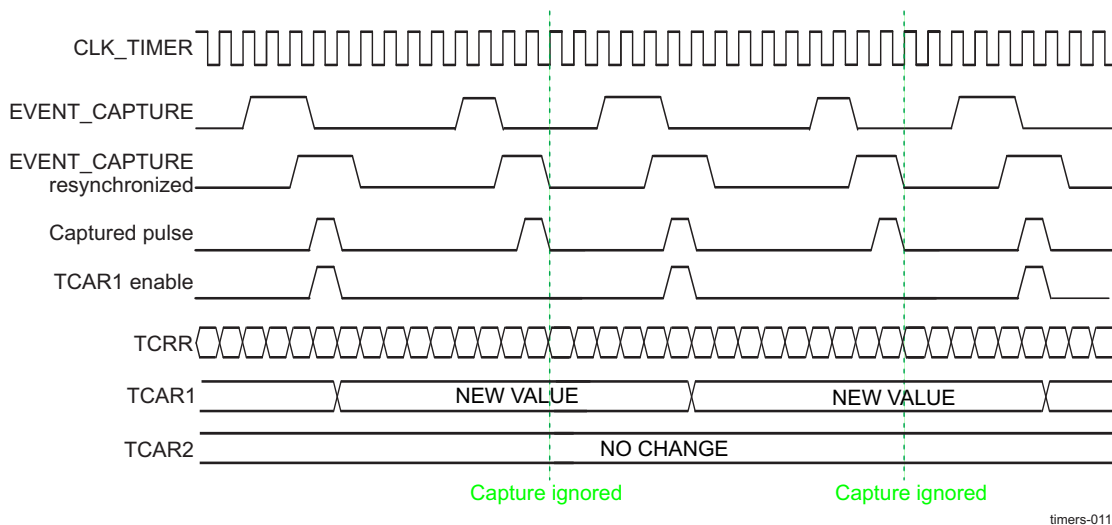

The rising edge, falling edge, or both, can be selected in the **TCLR**[9:8] **TCM** bit field to trigger the timer counter capture. The module sets the **IRQSTATUS**[2] **TCAR_IT_FLAG** bit when an active edge is detected, and at the same time, the counter value **TCRR** is stored in timer capture register **TCAR1** or **TCAR2**, as follows:

- If the **TCLR[13] CAPT_MODE** bit is 0, on the first enabled capture event, the value of the counter register is saved in the **TCAR1** register, and the next events are ignored (no update on the **TCAR1** register and no interrupt triggering) until the detection logic is reset or the **IRQSTATUS[2] TCAR_IT_FLAG** is cleared by writing 1 to it.
- If the **TCLR[13] CAPT_MODE** bit is 1, on the first enabled capture event, the value of the counter register is saved in the **TCAR1** register, and on the second enabled capture event, the value of the counter register is saved in the **TCAR2** register. If a capture interrupt is enabled, the interrupt triggers on the second event capture. All other events are ignored (no update on **TCAR1/TCAR2** and no interrupt triggering) until the detection logic is reset or the **IRQSTATUS[2] TCAR_IT_FLAG** bit is cleared by writing 1 to it. This mechanism is useful for period calculation of a clock, if that clock is connected to the **EVENT_CAPTURE** input pin.

The edge detection logic is reset (a new capture is enabled) when the active capture interrupt is served. The **IRQSTATUS[2] TCAR_IT_FLAG** bit is cleared by writing 1 to it or when the edge detection mode bits (the **TCLR[9:8] TCM** bit field) are changed from no-capture mode detection to any other mode. The timer functional clock (input to prescaler) is used to sample the input pin (**EVENT_CAPTURE**). A negative or positive pulse input can be detected when the pulse time is greater than the functional clock period. An interrupt is issued on edge detection if the capture interrupt-enable bit is set in the **IRQSTATUS_SET[2] TCAR_EN_FLAG** bit (for **TIMER1**) or in the **IRQENABLE_SET[2] TCAR_EN_FLAG** bit (for other timers). See the examples in **Figure 18-11** and **Figure 18-12**.

In **Figure 18-11**, the value of the **TCLR[9:8] TCM** bit field is 0b01, and the **TCLR[13] CAPT_MODE** bit is 0. Only the rising edge of **EVENT_CAPTURE** triggers a capture in the **TCAR1** and **TCAR2** registers, and only the **TCAR1** register updates.

Figure 18-11. Capture Wave Example for **TCLR[13] CAPT_MODE = 0**

In **Figure 18-12**, the value of the **TCLR[9:8] TCM** bit field is 0b01, and the **TCLR[13] CAPT_MODE** bit is 1. Only the rising edge of **EVENT_CAPTURE** triggers a capture in the **TCAR1** register on the first enabled event, and the **TCAR2** register updates on the second enabled event.

Figure 18-12. Capture Wave Example for TCLR[13] CAPT_MODE = 1

18.2.4.8 Compare Mode Functionality

When the [TCLR\[6\]](#) CE bit of the compare-enable register is set to 1, the timer value (the [TCRR\[31:0\]](#) TIMER_COUNTER bit field) is continuously compared to the value held in the timer match register ([TMAR](#)). The value of the [TMAR\[31:0\]](#) COMPARE_VALUE bit field can be loaded at any time (timer counting or stopped). When the values of the [TCRR](#) and the [TMAR](#) registers match, an interrupt is issued, if the [IRQSTATUS_SET\[0\]](#) MAT_EN_FLAG bit (for TIMER1), or the [IRQENABLE_SET\[0\]](#) MAT_EN_FLAG bit (for other timers) is set.

To prevent any unwanted interrupts due to reset value matching effect, write a compare value to the [TMAR](#) before setting the [TCLR\[6\]](#) CE bit.

The dedicated output pin (timer PWM) can be programmed in the [TCLR\[12\]](#) PT bit through the [TCLR\[11:10\]](#) TRG bit field to generate one positive pulse (timer clock duration) or to invert the current value (toggle mode) when an overflow or a match occurs.

18.2.4.9 Prescaler Functionality

A prescaler can be used to divide the timer counter input clock frequency. The prescaler is enabled when the [TCLR\[5\]](#) PRE bit is set. The [TCLR\[4:2\]](#) PTV bit field sets the 2ⁿ division ratio (the prescaler value is 2^(PTV + 1)). The prescaler counter is reset when the timer counter is stopped or reloaded on-the-fly.

[Table 18-8](#) lists the prescaler/timer reload values versus contexts.

Table 18-8. Prescaler/Timer Reload Values Versus Contexts

Context	Prescaler	Timer Counter
Overflow (when autoreload is on)	Reset	TLDR[31:0]
TCRR write	Reset	TCRR[31:0]
TTGR write	Reset	TLDR[31:0]
Stop	Reset	Frozen

18.2.4.10 Pulse-Width Modulation

The timer can be configured to provide a programmable PWM output. The timer PWM output pin can be configured to toggle on an event. The **TCLR**[11:10] TRG bit field determines on which register value the PWM pin toggles. Either overflow or both overflow and match can be selected to toggle the timer PWM pin when a compare condition occurs.

NOTE: In toggle mode, when **TCLR**[11:10] TRG = 0x2 (overflow and match), the first event that toggles the PWM line is an overflow event. If a match event occurs first, it does not toggle the PWM line (see [Figure 18-14](#)).

The **TCLR**[7] SCPWM bit can be programmed to set or clear the timer PWM output signal only while the counter is stopped or the trigger is off. This allows setting the output pin to a known state before modulation starts. Modulation synchronously stops when the **TCLR**[11:10] TRG bit field is cleared and overflow occurs. This allows fixing a deterministic state of the output pin when modulation stops.

In [Figure 18-13](#), the internal overflow pulse is set each time the (0xFFFF FFFF – **TLDR**[31:0] LOAD_VALUE + 1) value is reached, and the internal match pulse is set when the counter reaches the value of **TMAR**. Depending on the value of the **TCLR**[12] PT bit and **TCLR**[11:10] TRG bit field, the timer provides pulse or PWM event on the output pin (timer PWM).

The **TLDR** and **TMAR** must keep values below the overflow value (0xFFFF FFFF) by at least two units. If the PWM trigger events are both overflow and match, the difference between the values kept in the **TMAR** and the value in the **TLDR** must be at least two units. When match event is used, the compare mode **TCLR**[6] CE bit must be set.

In [Figure 18-13](#), the **TCLR**[7] SCPWM bit is set to 0. In [Figure 18-14](#), the **TCLR**[7] SCPWM bit is set to 1. To obtain the desired wave form, start the counter at 0xFFFF FFFE value (to ensure an overflow first) or adjust the line polarity (**TCLR**[7] SCPWM bit).

Figure 18-13. Timing Diagram of PWM With **TCLR[7] SCPWM Bit = 0**

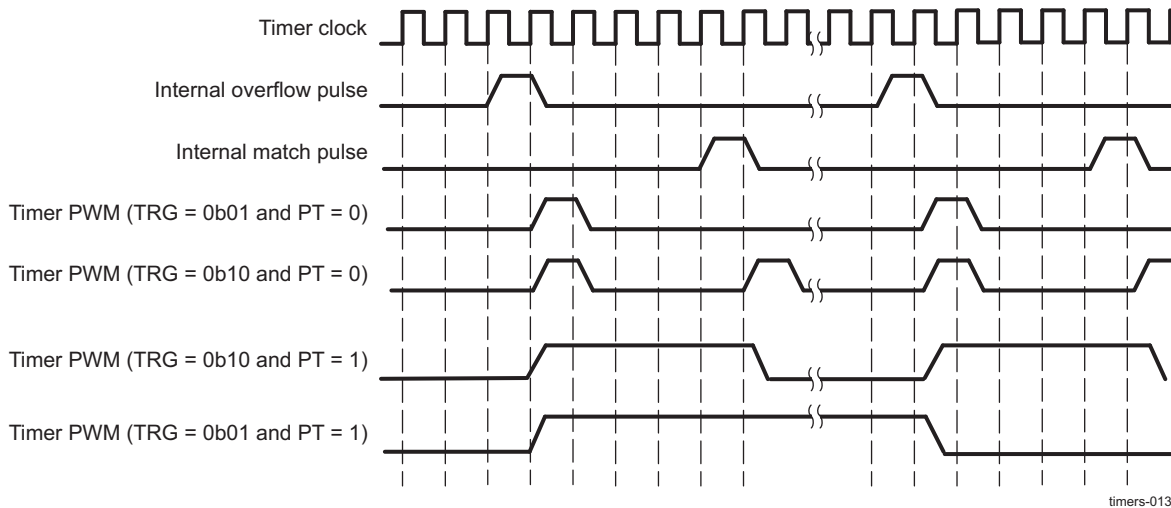

Figure 18-14. Timing Diagram of PWM With TCLR[7] SCPWM Bit = 1

18.2.4.11 Timer Counting Rate

The timer rate is defined by the following values:

- Value of the prescaler fields (the [TCLR\[5\]](#) PRE bit and the [TCLR\[4:2\]](#) PTV bit field)
- Value loaded into the [TLDR](#)

[Table 18-9](#) lists the prescaler clock ratio values.

Table 18-9. Prescaler Clock Ratio Values

TCLR[5] PRE	TCLR[4:2] PTV	Divisor (PS)
0	X	1
1	0	2
1	1	4
1	2	8
1	3	16
1	4	32
1	5	64
1	6	128
1	7	256

Thus, the timer overflow rate is expressed as:

$$\text{OVF_Rate} = (0\text{x}\text{FFFF FFFF} - \text{TLDR} + 1) \times (\text{timer-functional clock period}) \times \text{PS}$$

With (timer-functional clock period) = $1/(\text{timer-functional clock frequency})$ and $\text{PS} = 2^{(\text{PTV} + 1)}$ if prescaler is enabled, or $\text{PS} = 1$ if prescaler is disabled.

NOTE: Internal resynchronization causes any write to the [TCLR\[1\]](#) ST bit to have some latency before the register is updated:

2.5 × functional clock cycles write_TIMER_TCLR_latency 3.5 × functional clock cycles

Remember to consider this latency whenever the timer must be started or stopped by a software change to the [TCLR\[1\]](#) ST bit.

NOTE:

- In non-PWM mode, **TLDR** must be maintained at less than or equal to 0xFFFF FFFE.
- In PWM mode, **TLDR** must be maintained at less than or equal to 0xFFFF FFFD.

For example, with a timer clock input of 32 kHz and the **TCLR**[5] PRE bit set to 0, the timer output period is as listed in [Table 18-10](#).

Table 18-10. Value and Corresponding Interrupt Period

TLDR [31:0] LOAD_VALUE	Interrupt Period
0x0000 0000	37 h
0xFFFF 0000	2 s
0xFFFF FFF0	500 μ s
0xFFFF FFFE	62.5 μ s

18.2.4.12 Timer Under Emulation

During emulation mode, the timer continues to run according to the value of the **TIOCP_CFG**[1] **EMUFREE** bit.

If the **TIOCP_CFG**[1] **EMUFREE** bit is set to 1, timer execution is not stopped in emulation mode and the interrupt is still generated when overflow or match is reached.

If the **TIOCP_CFG**[1] **EMUFREE** bit is set to 0, the prescaler and timer are frozen and both resume on exit from emulation mode. The asynchronous external input pin (timerx_pwm_evt, where x = [8:11]) is internally synchronized on two timer-clock rising edges.

18.2.4.13 Accessing GP Timer Registers

All accesses are nonposted until software reconfiguration. All registers are 32 bits wide, accessible through the OCP interface with 16- or 32-bit access (read/write).

Any 16-bit write access must be least significant bit (LSB) first, and the second write access must be most significant bit (MSB) first. Write operations to the following GP timer registers can skip the MSB access if it is not necessary to update the 16 MSBs of the register:

- **TIDR** (all GP timers)
- **TIOCP_CFG** (all GP timers)
- **IRQSTATUS_SET** (GP timer 1)
- **IRQSTATUS_RAW** (all GP timers)
- **IRQSTATUS** (all GP timers)
- **IRQENABLE_SET** (all GP timers except 1)
- **IRQENABLE_CLR** (all GP timers except 1)
- **IRQSTATUS_SET** (GP timer 1)
- **IRQSTATUS_CLR** (GP timer 1)
- **IRQWAKEEN** (all GP timers)
- **TSICR** (all GP timers)

Write operations to the following functional registers must be complete (the MSB must be written even if the MSB data is not used):

- **TCLR** (all GP timers)
- **TCRR** (all GP timers)
- **TLDR** (all GP timers)
- **TTGR** (all GP timers)
- **TMAR** (all GP timers)

- [TPIR](#) (GP timer 1)
- [TNIR](#) (GP timer 1)
- [TCVR](#) (GP timer 1)
- [TOCR](#) (GP timer 1)
- [TOWR](#) (GP timer 1)

The following L4 synchronous registers are not affected by the posted/nonposted mode selection; the write/read operation is effective and acknowledged (command accepted) after one L4 clock cycle from command assertion:

- [TIDR](#)
- [TIOCP_CFG](#)
- [IRQSTATUS](#)
- [IRQSTATUS_RAW](#)
- [IRQENABLE_SET](#)
- [IRQENABLE_CLR](#)
- [IRQSTATUS_SET](#)
- [IRQSTATUS_CLR](#)
- [IRQWAKEEN](#)
- [TWPS](#)
- [TSICR](#)

18.2.4.13.1 Writing to Timer Registers

The host uses the OCP interface to write to the following registers synchronously with the timer interface clock:

- [TLDR](#)
- [TCRR](#)
- [TCLR](#)
- [TIOCP_CFG](#)
- [IRQSTATUS](#)
- [IRQENABLE_SET](#)
- [IRQENABLE_CLR](#)
- [IRQWAKEEN](#)
- [TTGR](#)
- [TSICR](#)
- [TMAR](#)

TIMER1 also has the following registers:

- [IRQSTATUS_SET](#)
- [IRQSTATUS_CLR](#)
- [TPIR](#)
- [TNIR](#)
- [TCVR](#)
- [TOCR](#)
- [TOWR](#)

In 16-bit access mode, the 16 LSBs must be written before writing to the 16 MSBs.

18.2.4.13.1.1 Write Posting Synchronization Mode

This mode is used if the [TSICR\[2\]](#) POSTED bit is set to 1.

This mode uses a posted write scheme to update any internal register (**TCLR**, **TCRR**, **TLDR**, **TTGR**, **TMAR**, and **TPIR**, **TNIR**, **TCVR**, **TOCR**, and **TOWR** for **TIMER1**). Therefore, the write transaction is immediately acknowledged on the open-core protocol (OCP) interface, although the effective write operation occurs later because of a resynchronization in the timer clock domain. The advantage is that neither the interconnect nor the device that requested the write transaction is stalled.

For each register, the timer write-posted status (**TWPS**) register provides a status bit. In this mode, software must check this status bit before any write access. If a write is attempted to a register with a previous access pending, the previous access is discarded without notice.

The timer module updates the value of the timer counter register synchronously with the OCP clock. Consequently, any read access to **TCRR** does not add any resynchronization latency; the current value is always available.

NOTE: Because the overflow IRQ is generated when the value of **TCRR** reaches 0xFFFF FFFF, and not when it changes its value to the value after overflow, it is necessary to wait a delay of $(1 \times PS \times \text{timer-functional clock period})$ before any read access to **TCRR** to ensure a correct reading of its content.

NOTE: If the **TTGR** register is written during posted write to **TCRR**, the value written to **TCRR** will be discarded.

If a posted write to **TCVR** is started, the user must not write to **TPIR** or **TNIR** before the **TCVR** write is finished, because the value of **TCVR** is re-evaluated, so both the value to be written, and the recalculated value will be discarded.

If a write access is pending for a register, reading from this register does not yield a correct result. Software synchronization must be used to avoid incorrect results.

Functional frequency range: $\text{freq}(\text{timer clock}) < \text{freq}(\text{OCP interface clock}) / 4$.

18.2.4.13.1.2 Write Nonposting Synchronization Mode

This mode is used if the **TSICR**[2] **POSTED** bit is set to 0. It uses a nonposted write scheme to update any internal register. Therefore, the write transaction is not acknowledged on the L4 interface until the effective write operation occurs after the resynchronization in the timer functional clock domain. The drawback is that the interconnect and the device that requested the write transaction are stalled during this period.

The same full resynchronization scheme is used for a read transaction, and the same stall period applies. A register read following a write to the same register is always coherent.

This mode is functional regardless of the ratio between the OCP interface frequency and the timer clock frequency.

18.2.4.13.2 Reading From Timer Counter Registers

In 16-bit access mode, reading the 16 LSBs from the timer counter registers (**TCRR**, **TCAR1**, and **TCAR2**) captures the current timer counter value. This must be followed by reading the 16 MSBs. The synchronization schemes for read posted and read non-posted transactions are the same as the corresponded write transactions described before.

NOTE: LSB/MSB accesses cannot be interleaved (that is, the sequence LSB register 1, LSB register 2, MSB register 1, MSB register 2 is not supported).

The **TCRR** is a 32-bit “atomic datum” and its 16-bit capture is done on the 16-bit LSB first to allow atomic **LSB16 + MSB16** capture. This capture scheme is also performed for the **TCAR1** and **TCAR2** registers as they can be changed due to internal processes too. DSP 16 bit accesses can be interleaved with MCU 32 bit accesses.

NOTE: The counter value of GPTimer5/6/7/8 should be read with a delay of 10 L4_PER clock cycles when the functional clock source is 32kHz and the IPU CD is in the hardware Auto state.

NOTE: The counter value of GPTimer5/6/7/8 can be read without any delay when the functional clock source is 32kHz and the IPU CD is in software Wakeup mode.

18.2.4.13.2.1 Read Posted

This mode is functional whatever the ratio between the OCP interface frequency and the functional clock frequency are. The recommended functional frequency range is $\text{freq}(\text{timer}) < \text{freq}(\text{OCP}) / 4$.

Read posted mode is used if **TSICR**[2] POSTED = 0x1 or **TSICR**[3] READ_MODE is set to 0. This mode uses a posted-read scheme for reading any internal timer register. The read transaction is immediately acknowledged on the OCP interface, and the value to be read has been resynchronized. With this method, neither the interconnect nor the device that requested the read transaction are stalled.

Read posted mode applies to TCRR, TCAR1, TCAR2, TCVR, and TOWR, which need resynchronization from functional to OCP clock domains.

18.2.4.13.2.2 Read Non-Posted

This mode is functional regardless of the ratio between the OCP interface frequency and the functional clock frequency. Recommended functional frequency range is $\text{freq}(\text{timer}) \geq \text{freq}(\text{OCP}) / 4$.

Read non-posted mode is used if **TSICR**[2] POSTED = 0x0 and **TSICR**[3] READ_MODE = 0x1. This mode uses a non-posted read scheme for reading internal timer registers. The read transaction is not acknowledged on the OCP interface until the effective read operation occurs, after the resynchronization in the timer clock domain. The result is that both the interconnect and the device that requested the read transaction are stalled during this period.

This mode applies to TCRR, TCAR1, TCAR2, TCVR, and TOWR, which need resynchronization from functional to OCP clock domains.

18.2.4.14 Posted Mode Selection

A choice between two synchronization modes is made taking into account the frequency ratio and the stall periods that can be supported by the system, without impacting the global performance.

The posted mode selection applies only to registers that require synchronization on or from the timer clock domain. For write operation, the registers affected by posted and non-posted selection are TCLR, TLDR, TCRR, TTGR, TMAR, TPIR, TNIR, TCVR, TOCR, and TOWR. For read operation, the registers affected by this selection are: TCRR, TCAR1, TCAR2, TCVR, and TOWR.

The OCP clock domain synchronous registers TIDR, TIOCP_CFG, IRQSTATUS, IRQSTATUS_SET, IRQWAKEEN, TWPS, and TSICR are not affected by posted and non-posted mode selection. The operation (read or write) is effective and acknowledged after one OCP clock cycle from the command assertion.

The configuration of posted or non-posted mode can be changed (overwritten) by software by writing in **TSICR**[2] POSTED bit. The **TSICR**[3] READ_MODE defines how the read operation is performed when the module is configured in non-posted mode (see **TSICR**). The following cases are possible:

- **TSICR**[2] POSTED = 0x1 and **TSICR**[3] READ_MODE = x (don't care): read and write operations are expected in posted mode.
- **TSICR**[2] POSTED = 0x0 and **TSICR**[3] READ_MODE = 0x0: the write operation is executed in non-posted mode and read is executed in posted mode.
- **TSICR**[2] POSTED = 0x0 and **TSICR**[3] READ_MODE = 0x1: write is executed in non-posted mode and read is executed in non-posted mode.

18.2.5 GP Timer Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the module.

18.2.5.1 Global Initialization

18.2.5.1.1 Global Initialization of Surrounding Modules

This section identifies the requirements for initializing the surrounding modules when the GP timer module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the GP timer. For more information, see [Section 18.2.3, GP Timers Integration](#), and [Section 18.2.2, GP Timers Environment](#). [Table 18-11](#) summarizes the surrounding modules.

Table 18-11. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	The module interface and functional clocks must be enabled. For more information about the module configuration, see Section 3.1.1.1.2, Module-Level Clock Management , in Chapter 3, Power, Reset, and Clock Management .
Control module	The module-specific pad muxing must be set in the control module. For more information about the module configuration, see Section 14.4.6.1 Pad Configuration Registers , in Chapter 14, Control Module .
IRQ_CROSSBAR	The IRQ_CROSSBAR configuration must be done to enable the interrupts from the GP timer module. See Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description .

18.2.5.1.2 GP Timer Module Global Initialization

18.2.5.1.2.1 Main Sequence – GP Timer Module Global Initialization

[Table 18-12](#) identifies the main steps for initializing the GP timer module when the module is to be used for the first time.

Table 18-12. GP Timer Module Global Initialization

Step	Register/Bit Field/Programming Model	Value
Execute software reset.	TIOCP_CFG[0] SOFTRESET	0x1
Wait until reset release?	TIOCP_CFG[0] SOFTRESET	0x0
Configure idle mode.	TIOCP_CFG[3:2] IDLEMODE	0x-
Enable wake-up interrupt events.	IRQWAKEEN[2:0]	0x-
Select posted mode.	TSICR[2] POSTED	0x-

18.2.5.2 Operational Mode Configuration

18.2.5.2.1 GP Timer Mode

18.2.5.2.1.1 Main Sequence – GP Timer Mode Configuration

[Table 18-13](#) lists the steps in the GP timer mode configuration.

Table 18-13. GP Timer Mode Configuration

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	TCLR[1] AR	0x-
Set prescale timer value.	TCLR[4:2] PTV	0x-
Enable prescaler.	TCLR[5] PRE	0x1

Table 18-13. GP Timer Mode Configuration (continued)

Step	Register/Bit Field/Programming Model	Value
Enable overflow interrupt.	IRQSTATUS_SET[1] OVF_EN_FLAG ⁽¹⁾ or IRQENABLE_SET[1] OVF_EN_FLAG ⁽²⁾	0x1
Load timer counter value.	TCRR	0x-
Load timer load value.	TLDR	0x-
Start the timer.	TCLR[0] ST	0x1

⁽¹⁾ Applies only to TIMER1

⁽²⁾ Applies to TIMER3 through TIMER8

18.2.5.2.2 GP Timer Compare Mode

18.2.5.2.2.1 Main Sequence – GP Timer Compare Mode Configuration

Table 18-14 lists the steps in the GP timer compare mode configuration.

Table 18-14. GP Timer Compare Mode Configuration

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	TCLR[1] AR	0x-
Set prescale timer value.	TCLR[4:2] PTV	0x-
Enable prescaler.	TCLR[5] PRE	0x1
Enable match interrupt.	IRQSTATUS_SET[0] MAT_EN_FLAG ⁽¹⁾ or IRQENABLE_SET[0] MAT_EN_FLAG ⁽²⁾	0x1
Load timer counter value.	TCRR	0x-
Load timer compare value.	TMAR	0x-
Enable compare mode.	TCLR[6] CE	0x1
Start the timer.	TCLR[0] ST	0x1

⁽¹⁾ Applies only to TIMER1

⁽²⁾ Applies to TIMER3 through TIMER8

18.2.5.2.3 GP Timer Capture Mode

18.2.5.2.3.1 Main Sequence – GP Timer Capture Mode Configuration

Table 18-15 lists the steps in the GP timer capture mode configuration.

Table 18-15. GP Timer Capture Mode Configuration

Step	Register/Bit Field/Programming Model	Value
Initialize capture mode.	See Section 18.2.5.2.3.2.	
Enable capture interrupt.	IRQENABLE_SET[2] TCAR_EN_FLAG ⁽¹⁾ or IRQSTATUS_SET[2] TCAR_EN_FLAG ⁽²⁾	0x1
Start the timer.	TCLR[0] ST	0x1
Detect event.	See Section 18.2.5.2.3.3.	

⁽¹⁾ Applies only to TIMER3 through TIMER8

⁽²⁾ Applies only to TIMER1

18.2.5.2.3.2 Subsequence – Initialize Capture Mode

Table 18-16 lists the steps to initialize capture mode.

Table 18-16. Initialize Capture Mode

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	TCLR[1] AR	0x-
Set prescale timer value.	TCLR[4:2] PTV	0x-
Enable prescaler.	TCLR[5] PRE	0x1
Select TIMER _i (where i = 2 to 8). Capture input at device pin timer _i .	TCLR[14] GPO_CFG	0x1
Select single or second event capture.	TCLR[13] CAPT_MODE	0x-
Select transition capture mode.	TCLR[9:8] TCM	0x-

18.2.5.2.3.3 Subsequence – Detect Event

Table 18-17 lists the steps in detecting an event.

Table 18-17. Detect Event

Step	Register/Bit Field/Programming Model	Value
Wait until event detected?	IRQSTATUS[2] TCAR_IT_FLAG	= 0x1
Read timer capture value.	TCAR1 and/or TCAR2	
Clear capture interrupt request.	IRQSTATUS[2] TCAR_IT_FLAG	0x1

18.2.5.2.4 GP Timer PWM Mode

18.2.5.2.4.1 Main Sequence – GP Timer PWM Mode Configuration

Table 18-18 lists the steps in the GP timer PWM mode configuration.

Table 18-18. GP Timer PWM Mode Configuration

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	TCLR[1] AR	0x-
Set prescale timer value.	TCLR[4:2] PTV	0x-
Enable prescaler.	TCLR[5] PRE	0x1
Select trigger output mode.	TCLR[11:10] TRG	0x-
Select pulse or toggle modulation PWM mode.	TCLR[12] PT	0x-
Select TIMER _i (where i = 2 to 11 and 13 to 16) PWM output at device pin timer _i .	TCLR[14] GPO_CFG	0x0
Configure PWM output pin default value.	TCLR[7] SCPWM	0x-
Load timer load value.	TLDR	0x-
Load timer compare value.	TMAR	0x-
Enable compare.	TCLR[6] CE	0x1
Start the timer.	TCLR[0] ST	0x1

18.2.6 GP Timer Register Manual

18.2.6.1 GP Timer Instance Summary

Table 18-19 lists the base address and block size for the GP timer module instances.

Table 18-19. GP Timer Instance Summary

Module Name	Base Address L4_PER1 Interconnect	Base Address L4_PER3 Interconnect	Base Address L4_WKUP Interconnect	Size
TIMER2	0x4803 2000	–	–	92 Bytes
TIMER3	0x4803 4000	–	–	92 Bytes
TIMER4	0x4803 6000	–	–	92 Bytes
TIMER5	–	0x4882 0000	--	92 Bytes

18.2.6.2 GP Timer Registers

18.2.6.2.1 GP Timer Register Summary

CAUTION

The GP timer registers are limited to 32- and 16-bit data accesses; 8-bit access is not allowed and can corrupt the register content.

Table 18-20 through Table 18-22 provide the register summary and associated offset addresses for the 8 GP timer internal registers.

Table 18-20. TIMER1 Register Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	TIMER1 Physical Address L4_WKUP Interconnect

18.2.6.2.2 GP Timer Register Description

Table 18-23 through Table 18-69 describe the individual GP timer registers.

Table 18-23. TIDR

Address Offset	0x0000 0000		
Physical Address	See Table 18-20 Table 18-21 Table 18-22	Instance	See Table 18-19
Description	This read-only register contains the revision number of the module. A write to this register has no effect. This register is used by software to track features, bugs, and compatibility.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REVISION																															

Bits	Field Name	Description	Type	Reset
31: 0	REVISION	IP Revision	R	0x- ⁽¹⁾

Table 18-25. TIOCP_CFG

Address Offset	0x0000 0010		
Physical Address	See Table 18-20 Table 18-21 Table 18-22	Instance	See Table 18-19
Description	This register controls the various parameters of the L4 interface.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																IDLEMODE		EMUFREE		SOFTRESET											

Bits	Field Name	Description	Type	Reset
31:4	RESERVED	Reserved	R	0x00000000
3:2	IDLEMODE	Power management, req/ack control 0x0: Force-idle mode: local target idle state follows (acknowledges) the system idle requests unconditionally, that is, regardless of the IP module internal requirements. Back-up mode, for debug only. 0x1: No-idle mode: local target never enters idle state. Back-up mode, for debug only. 0x2: Smart-idle mode: local target idle state eventually follows (acknowledges) the system idle requests, depending on the IP module internal requirements. IP module should not generate (IRQ- or DMA-request-related) wake-up events. 0x3: Smart-idle wake-up-capable mode: local target idle state eventually follows (acknowledges) the system idle requests, depending on the IP module internal requirements. IP module may generate (IRQ- or DMA-request-related) wake-up events when in IDLE state. Mode is relevant only if the appropriate IP module <i>swake-up</i> output(s) is (are) implemented.	RW	0x0
1	EMUFREE	Emulation mode 0x0: The timer is frozen in emulation mode (PINSUSPENDN signal active). 0x1: The timer runs free, regardless of PINSUSPENDN value.	RW	0
0	SOFTRESET	Software reset 0x0: Read 0: reset done, no pending action Write 0: No action 0x1: Read 1: initiate software reset Write 1: Reset ongoing	RW	0

Table 18-27. IRQ_EOI

Address Offset	0x0000 0020
Physical Address	See Table 18-20 Table 18-21 Table 18-22 Instance See Table 18-19
Description	Software End-Of-Interrupt: Allows the generation of further pulses on the interrupt line, if a new interrupt event is pending, when using the pulsed output. Unused when using the level interrupt line (depending on module integration).
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																	LINE_NUMBER														

Bits	Field Name	Description	Type	Reset
31:1	RESERVED		R	0x0
0	LINE_NUMBER	Write the number of the interrupt line to apply a SW EOI to it. Note that there is only a single line (i.e. number 0). Read : Read always returns 0 Write 0 : SW EOI on interrupt line Write 1 : No action	RW	0x0

Table 18-39. TCLR

Address Offset	0x0000 0038		
Physical Address	See Table 18-20 Table 18-21 Table 18-22	Instance	See Table 18-19
Description	This register controls optional features specific to the timer functionality.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
RESERVED																GPO_CFG	CAPT_MODE	PT	TRG	TCM	SCPWM	CE	PRE	PTV	AR	ST						

Bits	Field Name	Description	Type	Reset
31:15	RESERVED	Reserved	R	0x00000
14	GPO_CFG	General-purpose output - this register directly drives the PO_GPOCFG output. For specific use of the GPO_CFG bit, see Section 18.2.2.1 , <i>GP Timer External System Interface</i> . 0x0: PO_GPOCFG drives 0. 0x1: PO_GPOCFG drives 1.	RW	0
13	CAPT_MODE	Capture mode select bit (first/second) 0x0: Single capture: Capture the first enabled capture event in TCAR1 . 0x1: Capture on second event: Capture the second enabled capture event in TCAR1 and the second enabled capture event in TCAR2 .	RW	0
12	PT	Pulse or toggle mode on TIMERi_PWM_out output pin 0x0: Pulse modulation 0x1: Toggle modulation	RW	0
11:10	TRG	Trigger output mode on TIMERi_PWM_out output pin 0x0: No trigger 0x1: Trigger on overflow. 0x2: Trigger on overflow and match. 0x3: Reserved	RW	0x0
9:8	TCM	Transition capture mode on TIMERi_EVENT_CAPTURE input pin (When the TCM field passed from (00) to any other combination, the TCAR_IT_FLAG and the edge detection logic are cleared.) 0x0: No capture 0x1: Capture on rising edges of TIMERi_EVENT_CAPTURE pin 0x2: Capture on falling edges of TIMERi_EVENT_CAPTURE pin 0x3: Capture on both edges of TIMERi_EVENT_CAPTURE pin	RW	0x0
7	SCPWM	Pulse width modulation output pin default setting This bit must be set or clear while the timer is stopped or the trigger is off. 0x0: Clear the TIMERi_PWM_out output pin and select positive pulse for pulse mode. 0x1: Set the TIMERi_PWM_out output pin and select negative pulse for pulse mode.	RW	0

Bits	Field Name	Description	Type	Reset
6	CE	Compare enable 0x0: Compare mode is disable. 0x1: Compare mode is enable.	RW	0
5	PRE	Prescaler enable 0x0: The TIMER clock input pin clocks the counter. 0x1: The divided input pin clocks the counter.	RW	0
4:2	PTV	Prescale clock timer value The timer counter is prescaled with the value $2^{(PTV+1)}$. Example: PTV = 3, counter increases value (if started) after 16 functional clock periods.	RW	0x0
1	AR	Autoreload mode 0x0: One shot timer 0x1: Autoreload timer	RW	0
0	ST	Start/stop timer control 0x0: Stop timer: Only the counter is frozen. If one-shot mode selected (AR =0), this bit is automatically reset by internal logic when the counter is overflowed. 0x1: Start timer	RW	0

18.3 32-kHz Synchronized Timer (COUNTER_32K)

18.3.1 32-kHz Synchronized Timer Overview

The 32-kHz synchronized timer (COUNTER_32K) is a 32-bit counter clocked by the falling edge of the 32-kHz system clock.

Figure 18-15 is the block diagram of the 32-kHz synchronized timer.

Figure 18-15. 32-kHz Synchronized Timer Block Diagram

18.3.1.1 32-kHz Synchronized Timer Features

The main features of the 32-kHz synchronized timer controller are:

- L4 slave interface (OCP) support:
 - 32-bit data bus width
 - 32-/16-bit access supported
 - 8-bit access not supported
 - 16-bit address bus width
 - Burst mode not supported
 - Write nonposted transaction mode not supported
- Only read operations are supported on the module registers; no write operation is supported (no error/no action on write).
- Free-running 32-bit upward counter
- Start and keep counting after power-on reset
- Automatic roll over to 0; highest value reached: 0xFFFF FFFF
- On-the-fly read (while counting)

18.3.2 32-kHz Synchronized Timer Integration

The synchronized timer is accessible only through the L4_WKUP interface.

Table 18-71 through Table 18-73 summarize the integration of the module in the device.

Table 18-71. Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
COUNTER_32K	PD_WKUPAON	No	L4_WKUP

Table 18-72. Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
COUNTER_32K	COUNTER_32K_FCLK	FUNC_32K_CLK	PRCM	COUNTER_32K functional 32KHz clock
COUNTER_32K	COUNTER_32K_ICLK	WKUPAON_GICLK	PRCM	COUNTER_32K interface clock
Resets				
COUNTER_32K	COUNTER_32K_NRESPWRON	WKUPAON_SYS_PWRON_RST	PRM	Reset to COUNTER_32K. Reset all internal logic, running on COUNTER_32K_FCLK
COUNTER_32K	COUNTER_32K_OCPRESETN	WKUPAON_RST	PRM	Reset to COUNTER_32K. Reset all L4 interface logic, running on COUNTER_32K_ICLK.

Table 18-73. Hardware Requests

No Interrupt Requests
No DMA Requests

18.3.3 32-kHz Synchronized Timer Functional Description

The synchronized timer is a counter that starts on the rising edge of an external asynchronous signal (COUNTER_32K_NRESPWRON). When COUNTER_32K_NRESPWRON is released (on the rising edge of COUNTER_32K_FCLK), the counter starts counting up from the reset value of the counter register on the falling edge of the 32-kHz COUNTER_32K_FCLK clock after three inverted 32-kHz clock periods. After reaching its highest value, the counter wraps back to 0 and starts counting again with no additional delay.

Figure 18-16 shows the reset synchronization timing diagram.

Figure 18-16. Reset Resynchronization Timing Diagram

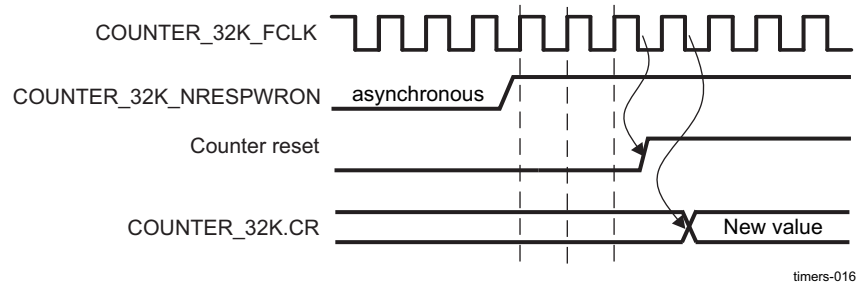

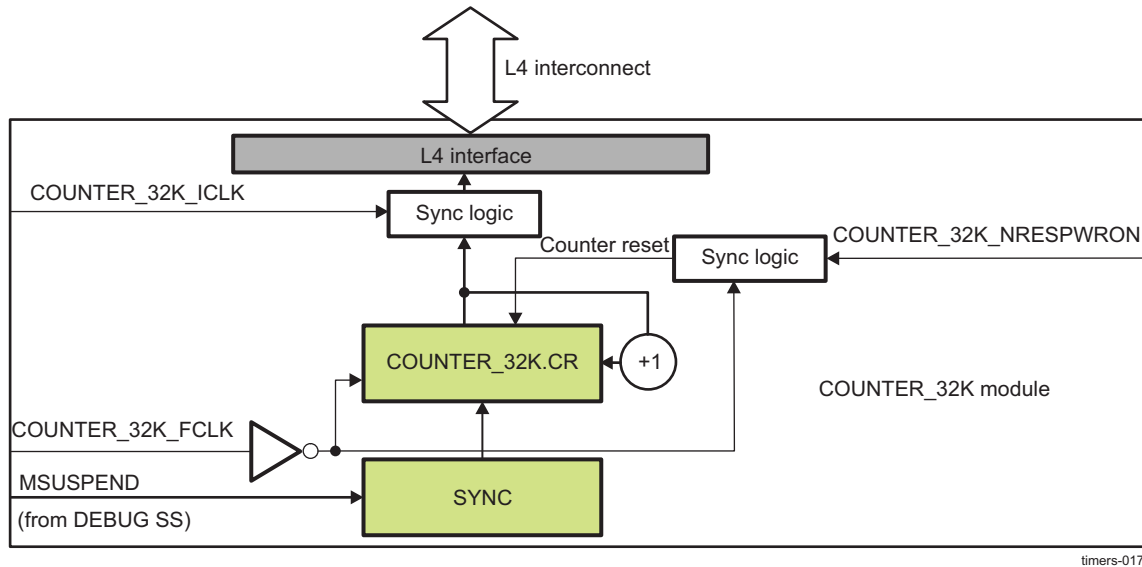

Figure 18-17 is the block diagram of the synchronized timer.

Figure 18-17. COUNTER_32K Block Diagram

The sync logic ensures the correctness of the read transaction by synchronizing the counter register read access on COUNTER_32K_ICLK, because the COUNTER_32K_ICLK clock signal is completely asynchronous with COUNTER_32K_FCLK. The COUNTER_32K_NRESPWRON input resets the counter register (CR). The inverted COUNTER_32K_FCLK clocks the counter register CR.

The counting is temporally stopped when MSUSPEND control signal (coming from DEBUG SS) is asserted.

18.3.3.1 Reading the 32-kHz Synchronized Timer

The counter register (CR) is 32 bits wide. For correct count capture, it must be accessed as 16-bit LSB access first and 16-bit MSB access next. The value of the counter is read through the L4 interconnect slave interface. Internal synchronization logic allows the reading of the counter value with COUNTER_32K_ICLK while the counter is running. The time latency to read the synchronized counter register is one COUNTER_32K_ICLK clock period.

The user can select between two synchronization schemes by setting SYSCONFIG[0]SYNCSMODE bit.

- **SYSCONFIG[0]SYNCSMODE = 0x0** - default. In this mode COUNTER_32K timer uses Gray encode/decode scheme. When the L4 interface sends a LSB16 read request command, the 32 bit coded value is registered directly to the interface domain. Due to the characteristics of this encoding if a read command arrives during a count up event either the old or the new value of CR is captured, not a transient value. The captured value will be decoded and send on the SDATA bus. The MSB16 read command reads upper 16 bits of the 32 bit value of counter register captured during the last LSB16 read access.
- **SYSCONFIG[0]SYNCSMODE = 0x1** - legacy synchronization scheme. In this mode the value of the CR is synchronized to the OCP domain at every count up event. This synchronization is possible because the COUNTER_32K_ICLK is much faster that the 32KHz clock (COUNTER_32K_FCLK). The drawback of this method is that if the interface clock is switched back after wake up from idle mode, the synchronized value will be updated only at the next count up event , until then it will be incorrect.

18.3.4 COUNTER_32K Timer Register Manual

Table 18-74 lists the base address and block size for the 32-kHz synchronized timer. It is memory-mapped to the L4 peripheral bus memory space.

Table 18-74. COUNTER_32KTimer Instance Summary

Module Name	Module Base Address	Size
L4_WKUP_COUNTER_32K	0x4AE0 4000	52 Bytes

18.3.4.1 COUNTER_32K Timer Register Mapping Summary

CAUTION

The 32-kHz synchronized timer registers are limited to 32- and 16-bit data accesses; 8-bit access is not allowed and can corrupt the register content.

Table 18-75 lists the 32-kHz synchronized timer registers. Table 18-76 through Table 18-80 describe the register bits.

19.8 Gigabit Ethernet Switch (GMAC_SW)	5723

19.1 Multimaster I²C Controller

This section describes the two inter-integrated circuit (I²C) controller modules in the device.

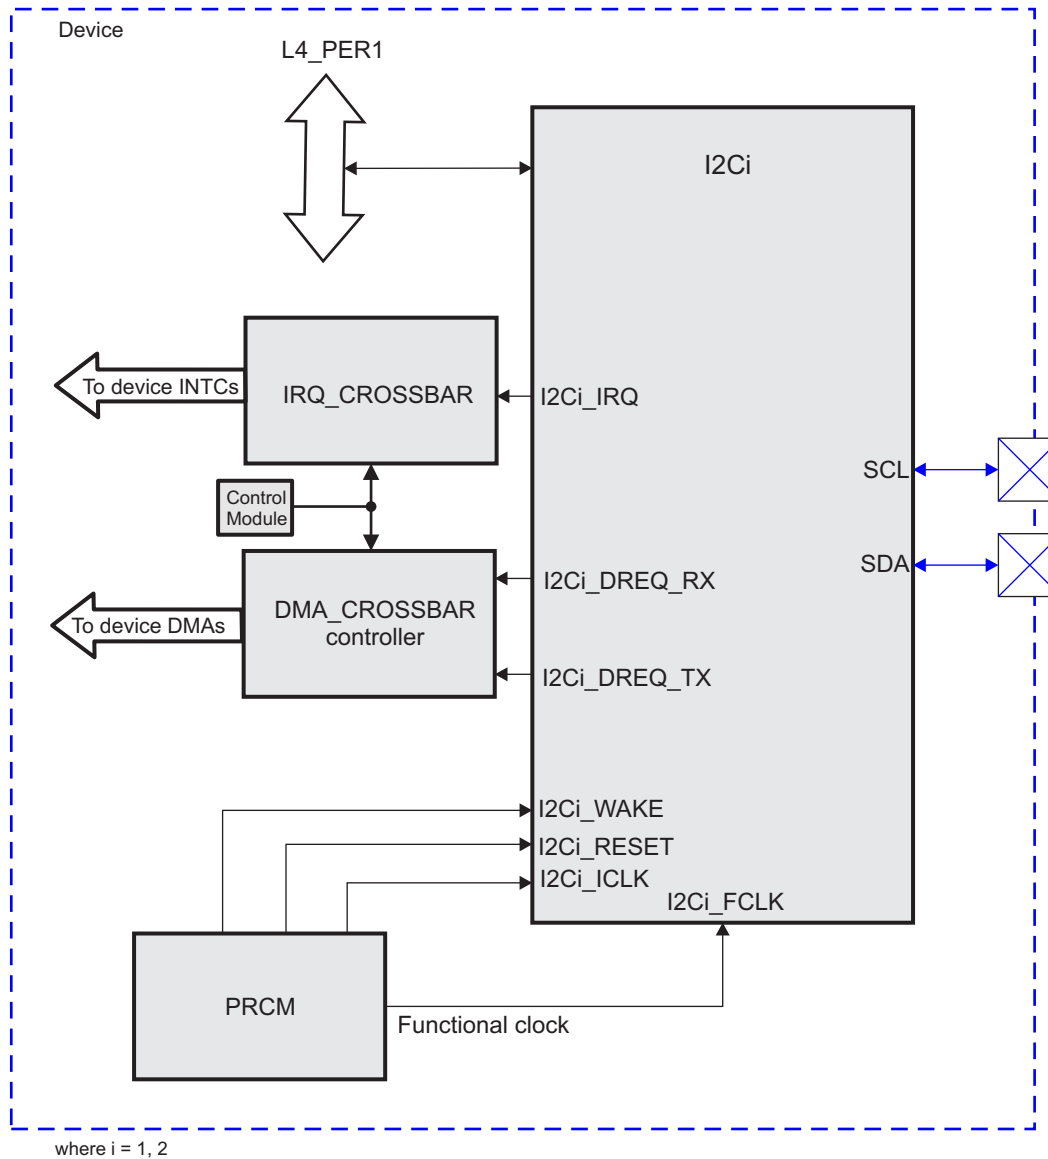

NOTE: The device I²C controllers do not support high-speed (HS) mode. See the Device Data Manual for details.

19.1.1 I²C Overview

The device contains two multimaster inter-integrated circuit (I²C) controllers (I²C_{*i*} modules, where *i* = 1, 2) each of which provides an interface between a local host (LH), such as a digital signal processor (DSP), and any I²C-bus-compatible device that connects through the I²C serial bus. External components attached to the I²C bus can serially transmit and receive up to 8 bits of data to and from the LH device through the 2-wire I²C interface.

Each multimaster I²C controller can be configured to act like a slave or master I²C-compatible device.

[Figure 19-1](#) shows the I²C.

Figure 19-1. I²C Controllers

I2C-001

The multimaster I²C controllers have the following features:

- Compliant with Philips I²C specification version 2.1
- Supports a standard mode (up to 100 kbps) and fast mode (up to 400 kbps)
- 7-bit and 10-bit device addressing modes
- General call
- Start/Restart/Stop
- Multimaster transmitter/slave receiver mode
- Multimaster receiver/slave transmitter mode
- Combined master transmit/receive and receive/transmit mode
- Built-in configurable FIFOs (8, 16, 32, 64 bytes) for buffered read or write
- Module enable/disable capability
- Programmable multislave channel (responds to four separate addresses)
- Programmable clock generation

- 8-bit-wide data access
- Designed for low power consumption
- Implement Auto Idle mechanism
- Implement Idle Request/Idle Acknowledge handshake mechanism
- Support for asynchronous wakeup mechanism
- Two direct memory access (DMA) channels
- Wide interrupt capability

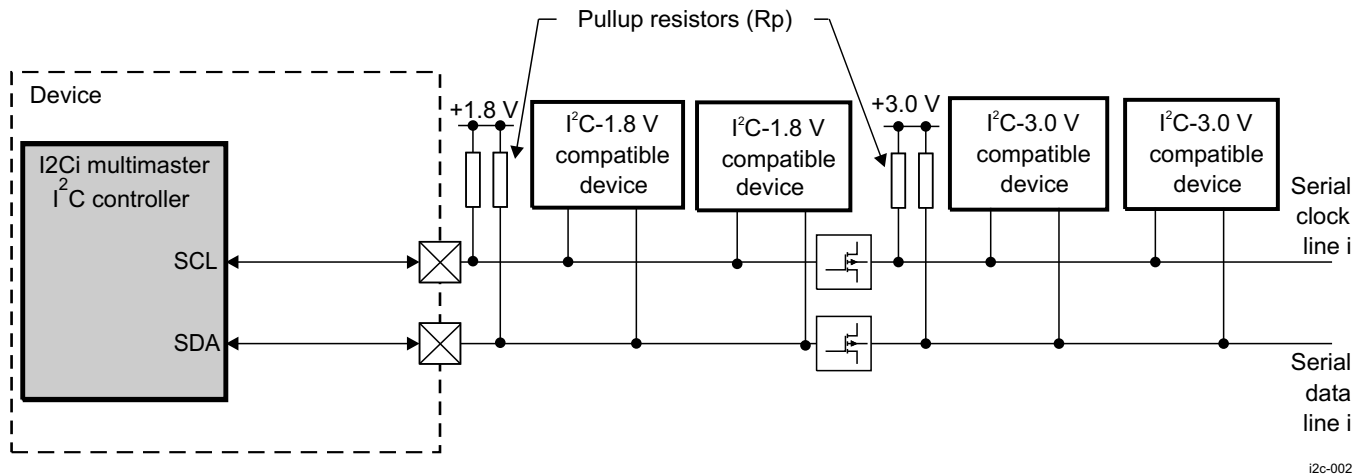

19.1.2 I²C Environment

This section describes the I²C application fields from an environment point of view (external connections). It describes I²C connectivity options, lists all possible interfaces, and describes the protocol and data format used in each case.

19.1.2.1 I²C Typical Application

Figure 19-2 shows the multimaster I²C controllers and their related connections with I²C-compliant devices.

Figure 19-2. I²C and Typical Connections to I²C Devices

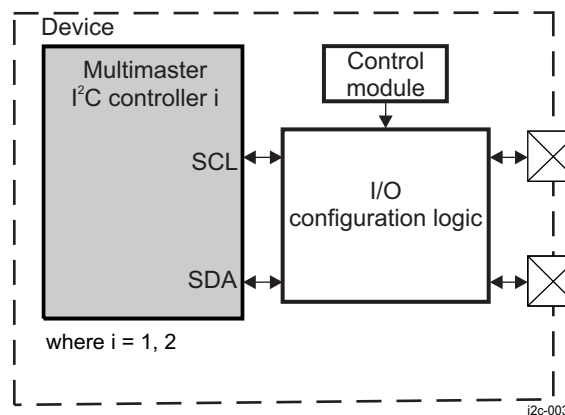

i2c-002

19.1.2.1.1 I²C Pins for Typical Connections in I²C Mode

Figure 19-3 shows the multimaster I²C controller pins used for typical connections with I²C devices.

Figure 19-3. I²C Interface Signals

i2c-003

19.1.2.1.2 I²C Interface Typical Connections

Table 19-1 lists the pins associated with the I²C interface.

Table 19-1. I²C Input/Output

Signal	Device Level Signal	I/O ⁽¹⁾	Description	Reset Value
SCL	i2cj_scl ⁽²⁾	I/O	I ² C serial clock line.	1

⁽¹⁾ I = Input; O = Output

⁽²⁾ j = 1 and 2

Table 19-1. I²C Input/Output (continued)

Signal	Device Level Signal	I/O ⁽¹⁾	Description	Reset Value
SDA	i2cj_sda ⁽²⁾	I/O	I ² C serial data line.	1

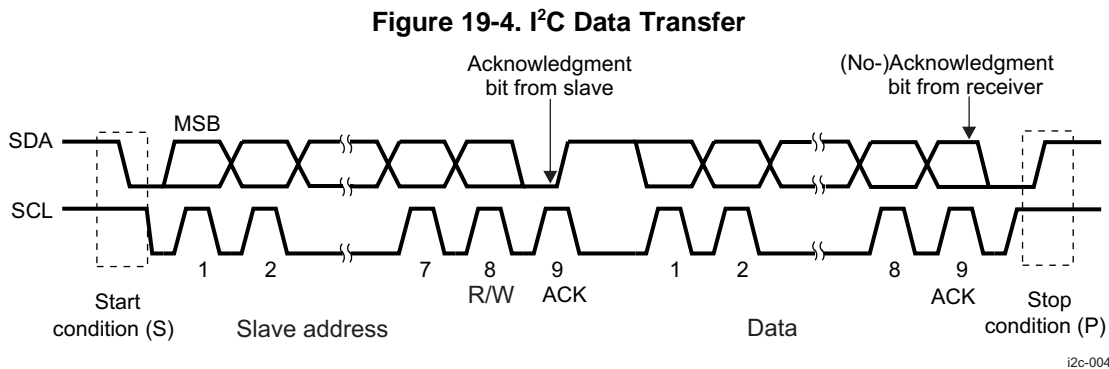

NOTE: For the i2cj_scl and i2ci_scl signals to work properly, the INPUTENABLE bit of the appropriate CTRL_CORE_PAD_x registers should be set to 0x1 because of retiming purposes.

NOTE: The path from a module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the Control Module registers. Refer to the sections [Section 14.4.6.1 Pad Functional Multiplexing](#) of the chapter *Control Module*, for more information.

19.1.2.2 I²C Typical Connection Protocol and Data Format

19.1.2.2.1 I²C Serial Data Format

The I²C controller operates in 8-bit word data format (byte write access supported for the last access). Each byte transmitted or received on the serial data line is 8 bits long. The number of bytes that can be transmitted or received is not restricted. The data is transferred with the most-significant bit (MSB) first. In receiver mode, each byte is followed by an acknowledge bit from the I²C. [Figure 19-4](#) shows a typical I²C communication format.

19.1.2.2.2 I²C Data Validity

The data on the serial data line (SDA) must be stable during the high period of the serial clock line. The high and low states of the data line can change only when the clock signal on the serial clock line (SCL) is low.

[Figure 19-5](#) is an example of data validity requirements.

Figure 19-5. I²C Bit Transfer on the I²C Bus

i2c-005

19.1.2.2.3 I²C Start and Stop Conditions

The I²C module generates start (S) and stop (P) conditions when it is configured as a master.

- An S condition is a high-to-low transition on the serial data line while serial clock line is high.
- A P condition is a low-to-high transition on the serial data line while serial clock line is high.

The bus is considered busy after the S condition (the I2Ci. [12] BB bit is 1 to indicate that the bus is busy) and free after the P condition (the I2Ci.I2C_IRQSTATUS_RAW [12] BB bit is 0 to indicate that the bus is free).

Figure 19-6 shows the waveforms that occur during an S and a P condition.

Figure 19-6. I²C S and P Condition Events

i2c-006

NOTE: I²C controller does not support messages non-compliant with I2C standard. Void messages are non-standard I²C messages and will lockup the controller. A void message is a START condition followed by a STOP condition, in other words, while the bus is free the SDA line is pulled low (START) and then released (STOP). This would result in a timeout (software) of the next master transfer which would never complete. A soft reset of the controller is recommended for recovery.

19.1.2.2.4 I²C Addressing

The I²C module supports two data formats in fast/standard (F/S) modes:

- 7-bit/10-bit addressing format
- 7-bit/10-bit addressing format with repeated start (Sr) condition

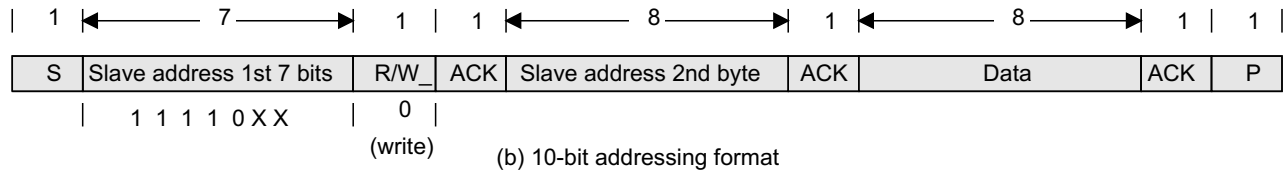

19.1.2.2.4.1 Data Transfer Formats in F/S Mode

Figure 19-7 shows the I²C data transfer formats in F/S mode.

Figure 19-7. I²C Data Transfer Formats in F/S Mode

(a) 7-bit addressing format

(b) 10-bit addressing format

(c) Addressing format with repeated start condition

i2c-007

The first word after an S condition consists of 8 bits. In acknowledge mode, an extra dedicated acknowledgment bit is inserted after each byte.

In addressing formats with 7-bit addresses, the first byte is composed of 7 MSB slave address bits and 1 least-significant bit (LSB) R/W_ bit.

The LSB R/W_ bit of the address byte indicates the transmission direction of the data bytes that follow it. If R/W_ is 0, the master writes data to the selected slave; if it is 1, the master reads data from the slave.

In addressing formats with 10-bit addresses, the structure of the first byte is 11110XXY, where XX is the two MSBs of the 10-bit addresses, and Y is the R/W_ bit. If the R/W_ bit is 0, the next byte contains the last 8 bits of the slave address. If the R/W_ bit is 1, the next byte contains data transmitted from the slave to the master.

19.1.2.2.5 I²C Master Transmitter

In master transmitter mode, data assembled in one of the previously described data formats is shifted out on the serial data line SDA in sync with the self-generated clock pulses on the serial clock line SCL. The clock pulses are inhibited and SCL is held low when the intervention of the processor is required (XUDF) after a byte is transmitted.

19.1.2.2.6 I²C Master Receiver

Master receiver mode can be entered only from master transmitter mode. With any of the address formats (a), (b), or (c) (see Figure 19-7), if R/W_ is high, the module enters master receiver mode after the slave address byte and bit R/W_ are transmitted. Serial data bits received on bus line SDA are shifted in synchronization with the self-generated clock pulses on SCL.

19.1.2.2.7 I²C Slave Transmitter

Slave transmitter mode can be entered only from slave receiver mode. With any of the address formats (a), (b), or (c) (see Figure 19-7), the slave transmitter is entered if the slave address byte is the same as its own address and bit R/W_ is transmitted, if R/W_ is high. The slave transmitter shifts the serial data out on the data line SDA in sync with the clock pulses that are generated by the master device. It does not generate the clock but it can hold clock line SCL low while intervention of the LH is required (XUDF).

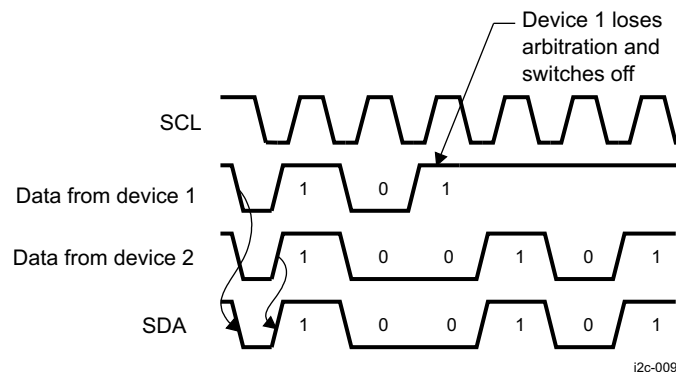

19.1.2.2.8 I²C Slave Receiver

In this mode, serial data bits received on the bus line SDA are shifted-in in sync with the clock pulses on SCL that are generated by the master device. It does not generate the clock but it can hold clock line SCL low while intervention of the LH is required (ROVR) after a byte is received.

19.1.2.2.9 I²C Bus Arbitration

If two or more master transmitters start a transmission on the same bus almost simultaneously, an arbitration procedure is invoked. The arbitration procedure uses the data presented on the serial bus by the competing transmitters. When a transmitter senses that a high signal it has presented on the bus has been overruled by a low signal, it switches to the slave receiver mode, sets the arbitration lost (AL) flag, and generates the arbitration lost interrupt. [Figure 19-8](#) shows the arbitration procedure between two devices. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. If two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

Figure 19-8. I²C Arbitration Between Master Transmitters

19.1.2.2.10 I²C Clock Generation and Synchronization

Under normal conditions, only one master device generates the clock signal, SCL. However, there are two or more master devices during the arbitration procedure, and the clock must be synchronized so that the data output can be compared. The wired-AND property of the clock line means that a device that first generates a low period of the clock line overrules the other devices. At this high/low transition, the clock generators of the other devices are forced to start generation of their own low period. The clock line is then held low by the device with the longest low period, while the other devices that finish their low periods must wait for the clock line to be released before starting their high periods. A synchronized signal on the clock line is thus obtained, where the slowest device determines the length of the low period and the fastest device determines the length of the high period. If a device pulls down the clock line for a longer time, the result is that all clock generators must enter the WAIT-state. In this way a slave can slow down a fast master and the slow device can create enough time to store a received byte or prepare a byte to be transmitted (clock stretching).

NOTE: In case the SCL or SDA lines are stuck low, a bus clearing operation is supported:

- If the clock line (SCL) is stuck low, the preferential procedure is to reset the bus using the hardware reset signal if your I²C devices have hardware reset inputs. If the I²C devices do not have hardware reset inputs, cycle power to the devices to activate the mandatory internal power-on reset (POR) circuit.
 - If the data line (SDA) is stuck low, the master should send nine clock pulses. The device that held the bus low should release it sometime within those nine clocks. If not, then use the hardware reset or cycle power to clear the bus.
-

[Figure 19-9](#) shows clock synchronization.

Figure 19-9. I²C Clock Generators Synchronization

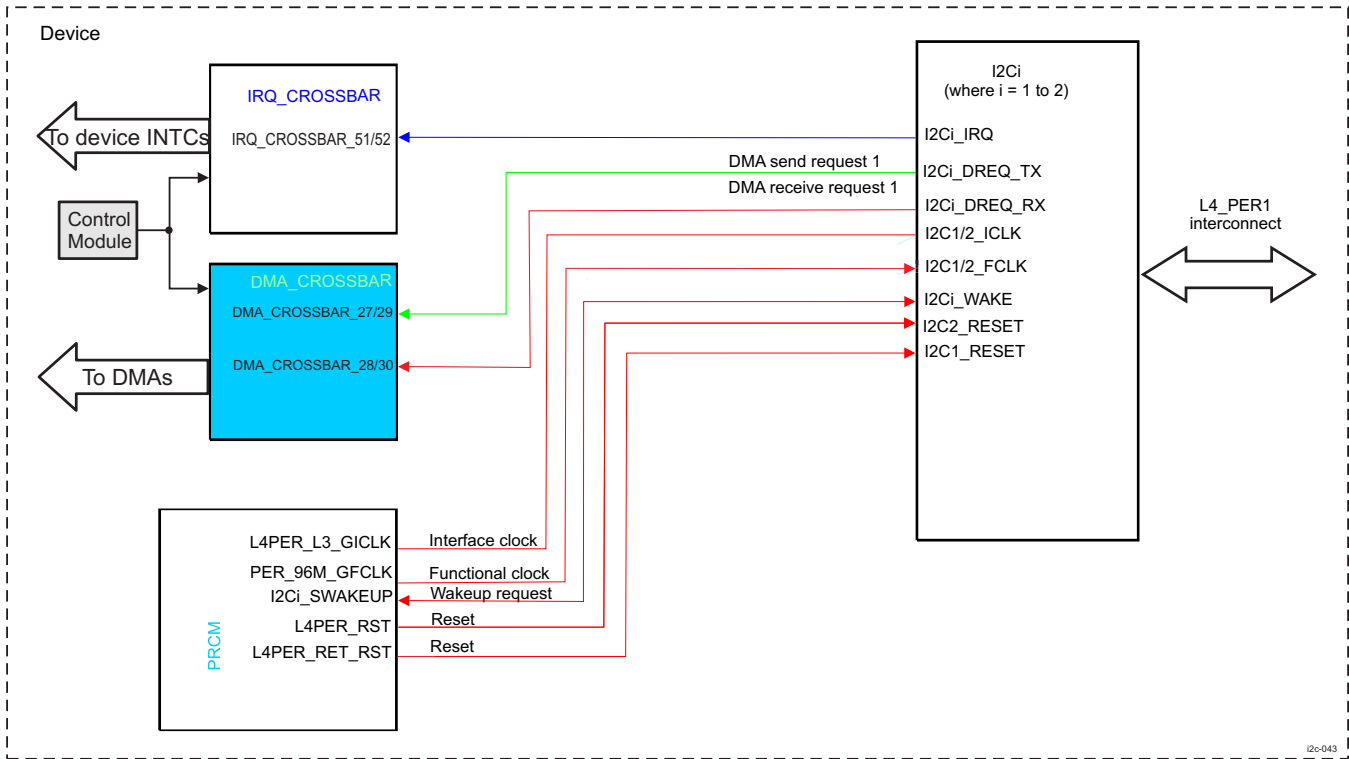

19.1.3 I²C Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 19-10 shows the integration of the two I²C controllers in the device.

Figure 19-10. I²C Integration

NOTE: For more information about the slave idle protocol and the wake-up request, see [Section 3.7, Power Management Functional Description](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 19-2 through Table 19-4 summarize the integration of the module in the device.

Table 19-2. I²C Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
I2C1	PD_COREAON	L4_PER1

Module Instance	Source Signal Name	Destination DMA_CROSSBAR Input	Default Mapping	Description
I2C1	I2C1_DREQ_TX	DMA_CROSSBAR_27	DMA_EDMA_DREQ_26	I2C1 DMA transmit request
	I2C1_DREQ_RX	DMA_CROSSBAR_28	DMA_EDMA_DREQ_27	I2C1 DMA receive request
I2C2	I2C2_DREQ_TX	DMA_CROSSBAR_29	DMA_EDMA_DREQ_28	I2C2 DMA transmit request
	I2C2_DREQ_RX	DMA_CROSSBAR_30	DMA_EDMA_DREQ_29	I2C2 DMA receive request

NOTE: The “Default Mapping” column in [Table 19-4 I²C Hardware Requests](#) shows the default mapping of module IRQ and DREQ source signals. These module IRQ and DREQ source signals can also be mapped to other lines of each device Interrupt or DMA controller through the IRQ_CROSSBAR and DMA_CROSSBAR modules, respectively.

For more information about the IRQ_CROSSBAR module, see [Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#).

For more information about the DMA_CROSSBAR module, see [Section 14.4.6.5, DMA_CROSSBAR Module Functional Description](#), in [Section 14.4.6.5 Chapter 14, Control Module](#).

For more information about the device interrupt controllers, see [Chapter 13, Interrupt Controllers](#).

For more information about the device EDMA module, see [Chapter 12, Enhanced DMA](#).

NOTE:

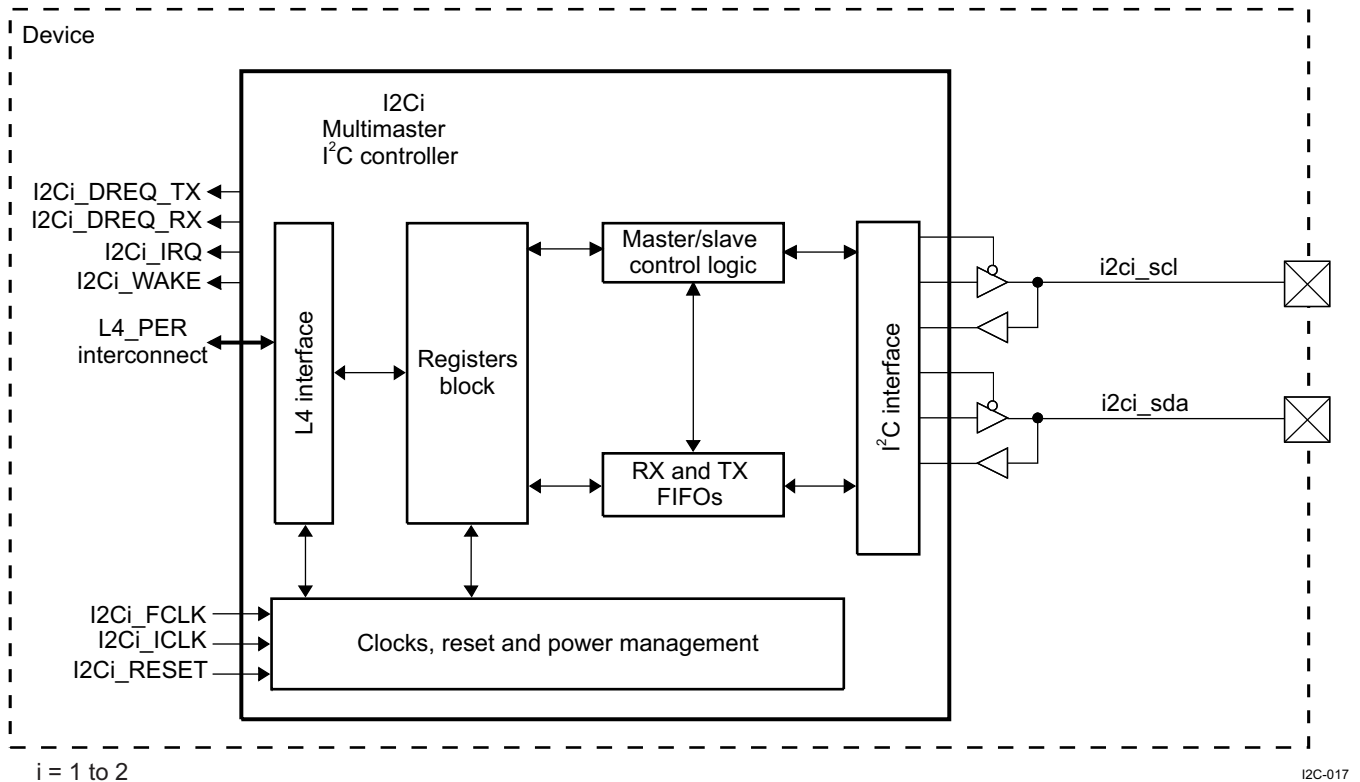

- For a description of interrupt source, see [Table 19-10](#).
- For a description of DMA source, see [Table 19-11](#).

19.1.4 I²C Functional Description

19.1.4.1 I²C Block Diagram

Figure 19-11 is the multimaster I²C controller block diagram.

Figure 19-11. I²C Block Diagram

The two multimaster I²C controllers can be configured in F/S I²C mode . The operation mode is selected by configuring the I2Ci.I2C_CON[13:12] OPMODE bit field. Table 19-5 lists the available operation modes.

Table 19-5. I²C Operation Mode Selection

Operation Mode	Value of I2Ci.I2C_CON[13:12] OPMODE Bit Field
F/S I ² C	0x0
Reserved	0x1
Reserved	0x2
Reserved (not used)	0x3

19.1.4.2 I²C Clocks

19.1.4.2.1 I²C Clocking

Each multimaster I²C controller uses the I2Ci_FCLK functional clock in the PRCM module. The internal sampling clock I2Ci_INTERNAL_CLK is generated by dividing the functional clock by the I2Ci.I2C_PSC[7:0] PSC bit field value + 1 in F/S mode.

The low time of the I2Ci_SCLL signal is determined by the I2Ci.I2C_SCLL[7:0] SCLL bit field in F/S mode.

The high time of the I2Ci_SCLL signal is determined by the I2Ci.I2C_SCLH[7:0] SCLH bit field in F/S mode.

Table 19-6 lists the t_{LOW} and t_{HIGH} values in master mode only (in slave mode, the I²C controller does not generate the I²C clock).

Table 19-6. I²C t_{LOW} and t_{HIGH} Values of the I²C Clock

Mode	I2C/ Clock	t_{LOW}	t_{HIGH}
F/S first phase	$I2Ci_INTERNAL_CLK = I2Ci_FCLK / (I2Ci.I2C_PSC[7:0] \text{ PSC bit field} + 1)$	$(I2Ci.I2C_SCLL[7:0] \text{ SCLL bit field value} + 7) \times I2Ci_INTERNAL_CLK \text{ period}$	$(I2Ci.I2C_SCLH[7:0] \text{ SCLH bit field value} + 5) \times I2Ci_INTERNAL_CLK \text{ period}$

NOTE: The equations in Table 19-6 give the SCLL timing values for SCLL/SCLH/HSSCLL/HSSCLH at I²C controller outputs. Actual low and high periods may vary depending on the board (the load capacitance on the SCLL signal). If necessary, any adjustments to the SCLL/SCLH/HSSCLL/HSSCLH values must be determined by measurements of actual SCL signal on the board.

CAUTION

During active mode (the I2Ci.I2C_CON[15] I2C_EN bit is set to 1), make no changes to the I2Ci.I2C_SCLL and I2Ci.I2C_SCLH registers. Changes may result in unpredictable behavior.

Table 19-7 lists the register values for obtaining the maximum I²C bit rates and the maximum period of the filtered spikes in F/S modes.

Table 19-7. I²C Register Values for Maximum I²C Bit Rates in I²C F/S Modes⁽¹⁾

	I ² C Mode for I2Ci,		Description
	Standard Mode	Fast Mode	
I2Ci_FCLK frequency (MHz)	96		
I2C i .I2C_PSC[7:0] PSC bit field value	23	9	Prescaler value for F/S modes
I2Ci_INTERNAL_CLK frequency (MHz)	4	9.6	
I2C i .I2C_SCLL[7:0] SCLL bit field value	13	7	Value for F/S mode
I2C i .I2C_SCLH[7:0] SCLH bit field value	15	5	Value for F/S mode
Maximum bit rate (Mbps)	0.1	0.4	F/S mode maximum bit rate
Maximum filter period (ns)	250	104.2	
Maximum filter period (ns)			

⁽¹⁾ Programmable fields are in bold.

NOTE: This table presents informative values only for the configuration parameters and the I²C bus performance obtained according to these values. The delays added by the analog pads are not considered in these figures.

NOTE: For I2Ci (where i=1, 2)

$$I2Ci_INTERNAL_CLK \text{ freq} = I2Ci_FCLK / (PSC + 1)$$

$$F/S \text{ filter period} = 1 / I2Ci_INTERNAL_CLK$$

$$FS \text{ bit rate} = I2Ci_INTERNAL_CLK / (SCLL + 7 + SCLH + 5)$$

19.1.4.2.2 I²C Automatic Blocking of the I²C Clock Feature

This feature offers the possibility for the LH to command the blocking of the I²C clock after the slave addressing phase, when the I²C controller is addressed by an external master device using a certain Own Address.

The release of the I²C clock can be performed independently for each Own Address (I2Ci.I2C_OA, and I2Ci.I2C_OAx registers, where $i = 1$ to 2, $x = 1, 2, 3$) by deasserting the corresponding bit in the I2Ci.I2C_SBLOCK register.

19.1.4.3 I²C Software Reset

Each multimaster I²C controller supports the software reset by accessing the I2Ci.I2C_SYSC[1] SRST bit (1: reset; 0: normal mode).

The software reset status can be checked by accessing the I2Ci.I2C_SYSS[0] RDONE bit (1: reset is done; 0: reset is ongoing).

To do a software reset, the following steps must be done:

1. Ensure that the module is disabled (clear the I2Ci.I2C_CON[15] I2C_EN bit to 0).
2. Set the I2Ci.I2C_SYSC[1] SRST bit to 1.
3. Enable the module by setting I2Ci.I2C_CON[15] I2C_EN bit to 1.
4. Check the I2Ci.I2C_SYSS[0] RDONE bit until it is set to 1 to indicate the software reset is complete.

NOTE: The I2Ci.I2C_CON[15] I2C_EN bit can hold the functional clock domain of the multimaster I²C controller in reset after the device reset has been released. When the system bus reset is removed, this bit remains cleared. The functional part of the I²C controller is held in reset state while this bit is 0, and all configuration registers can be accessed.

The I2Ci.I2C_CON[15] I2C_EN bit must be set to 1 to enable the functional part of the I²C controller.

The I2Ci.I2C_SYSS[0] RDONE bit is asserted only after the module is enabled by setting the I2Ci.I2C_CON[15] I2C_EN bit to 1.

19.1.4.4 I²C Power Management

Table 19-8 describes power-management features available for the multimaster I²C controllers.

NOTE:

- For information about source clock gating and sleep/wake-up transitions description, see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.
 - For descriptions of EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.
-

Table 19-8. I²C Local Power-Management Features

Feature	Registers	Description
Clock auto gating	I2Ci.I2C_SYSC[0] AUTOIDLE	This bit allows a local power optimization inside the module.
Slave idle modes	I2Ci.I2C_SYSC[4:3] IDLEMODE	Force-idle, no-idle, smart-idle, and smart-idle wakeup-capable modes are available.
Clock activity	I2Ci.I2C_SYSC[9:8] CLOCKACTIVITY	For configuration details, see Table 19-9.
Global wake-up enable	I2Ci.I2C_SYSC[2] ENAWAKEUP	This bit enables the wake-up feature at module level.

NOTE: The voltage controllers, in which the I²C controller is implemented, have no idle request/acknowledge mechanism. The idle modes for the voltage controllers are directly managed by the PRCM module.

Table 19-9. I²C Clock Activity Settings

I2C <i>i</i> .I2C_SYSC[9:8] CLOCKACTIVITY	Clock State When Module is in IDLE State		Features Available/Unavailable When Module is in IDLE State
	I2C <i>i</i> _ICLK	I2C <i>i</i> _FCLK	
00	OFF	OFF	Both clocks are disabled.
10	OFF	ON	Interface clock is disabled; functional clock is enabled
01	ON	OFF	Functional clock is disabled; interface clock is enabled
11	ON	ON	Both clocks are enabled.

CAUTION

The PRCM module has no hardware means of reading the settings of CLOCKACTIVITY. Thus, software must ensure consistent programming between the I²C CLOCKACTIVITY and I²C clock PRCM control bits. For a description of the ClockActivity feature, see [Section 3.1.1.1.2, Module-Level Clock Management](#) in [Chapter 3, Power, Reset, and Clock Management](#).

19.1.4.5 I²C Interrupt Requests

[Table 19-10](#) lists the event flags, and their mask, that can cause module interrupts.

Table 19-10. I²C Events

Event Flag	Event Unmask	Event Mask	Map to	Description
I2C <i>i</i> .I2C_IRQSTATUS[0] AL	I2C <i>i</i> .I2C_IRQENABLE_SET[0] AL_IE	I2C <i>i</i> .I2C_IRQENABLE_C LR[0] AL_IE	I2C <i>i</i> _IRQ	Arbitration lost IRQ enabled status. This bit is automatically set by the hardware when it loses the Arbitration in master transmit mode, an interrupt is signaled to the IRQ_Crossbar. During reads, it always returns 0.
I2C <i>i</i> .I2C_IRQSTATUS[1] NACK	I2C <i>i</i> .I2C_IRQENABLE_SET[1] NACK_IE	I2C <i>i</i> .I2C_IRQENABLE_C LR[1] NACK_IE	I2C <i>i</i> _IRQ	No acknowledgement IRQ enabled status. Bit is set when No Acknowledge is received, an interrupt is signaled to the IRQ_Crossbar. Write 1 to clear this bit.

I2Ci.I2C_IRQSTATUS[11] ROVR	I2Ci.I2C_IRQENABLE_SET [11] ROVR_IE	I2Ci.I2C_IRQENABLE_C LR[11] ROVR_IE	I2Ci_IRQ	Receive overrun enabled status. Writing into this bit has no effect.
I2Ci.I2C_IRQSTATUS[12] BB	Reserved	Reserved	I2Ci_IRQ	Bus busy enabled status. Writing into this bit has no effect.
I2Ci.I2C_IRQSTATUS[13] RDR	I2Ci.I2C_IRQENABLE_SET [13] RDR_IE	I2Ci.I2C_IRQENABLE_C LR[13] RDR_IE	I2Ci_IRQ	Receive draining IRQ enabled status.
I2Ci.I2C_IRQSTATUS[14] XDR	I2Ci.I2C_IRQENABLE_SET [14] XDR_IE	I2Ci.I2C_IRQENABLE_C LR[14] XDR_IE	I2Ci_IRQ	Transmit draining IRQ enabled status.

19.1.4.6 I²C DMA Requests

Each multimaster I²C controller can generate two DMA requests to the device DMA controllers through the DMA_CROSSBAR module. [Table 19-11](#) lists the DMA requests. For information about DMA generation, see [Section 19.1.4.8.3, I²C FIFO DMA Mode \(I²C Mode Only\)](#).

Table 19-11. I²C DMA Requests

Name	Source	Description
I2C1_DREQ_TX	I2C1	I2C1 DMA write request to inform the DMAs to write new data in the I2C1.I2C_DATA[7:0] DATA bit field
I2C1_DREQ_RX	I2C1	I2C1 DMA read request to inform the DMAs to read the data in the I2C1.I2C_DATA[7:0] DATA bit field
I2C2_DREQ_TX	I2C2	I2C2 DMA write request to inform the DMAs to write new data in the I2C2.I2C_DATA[7:0] DATA bit field
I2C2_DREQ_RX	I2C2	I2C2 DMA read request to inform the DMAs to read the data in the I2C2.I2C_DATA[7:0] DATA bit field

NOTE: For more information about I2Ci_DREQ_TX and I2Ci_DREQ_RX (where $i = 1$ to 2) signals mapping to DMA_CROSSBAR, see [Section 12.3.2, Mapping of DMA Requests to DMA_CROSSBAR Inputs](#), in [Table 19-4, I²C Hardware Requests](#).

19.1.4.7 I²C Programmable Multislave Channel Feature

This feature allows each multimaster I²C controller to be addressed using four separate Own Addresses configured in the I2Ci.I2C_OA and I2Ci.I2C_OAx registers (where = 1 to 2 , x = 1, 2, 3). An additional register (I2Ci.I2C_ACTOA) is used to indicate to the LH which address is used by the external master to communicate with the I²C controller.

Each Own Address can be independently configured in 7-bit or 10-bit mode by setting the corresponding bit (I2Ci.I2C_CON[7] XOA0, I2Ci.I2C_CON[6] XOA1, I2Ci.I2C_CON[5] XOA2, or I2Ci.I2C_CON[4] XOA3).

19.1.4.8 I²C FIFO Management

Each multimaster I²C controller implements two internal 8-bit FIFOs, the RX and TX FIFOs.

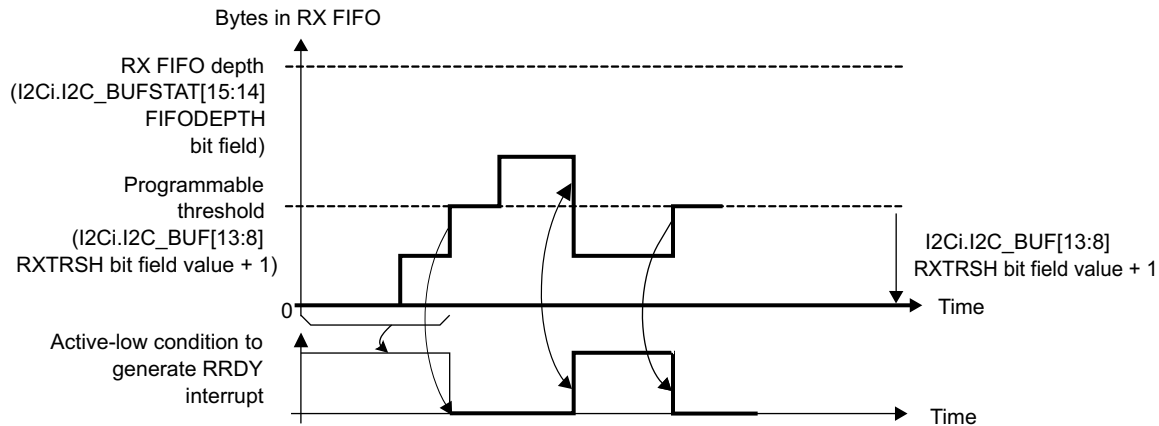

The depth of the RX and TX FIFOs can be checked by reading the I2Ci.I2C_BUFSTAT[15:14] FIFODEPTH bit field (0x0: 8 bytes, 0x1: 16 bytes, 0x2: 32 bytes, and 0x3: 64 bytes).

19.1.4.8.1 I²C FIFO Interrupt Mode

In FIFO interrupt mode (relevant interrupts enabled by the I2Ci.I2C_IRQENABLE_SET register), an interrupt signal informs the processor of the receiver and transmitter status. These interrupts are raised when the RX/TX FIFO thresholds (defined by the I2Ci.I2C_BUF[13:8] RXTRSH bit field value + 1 for the RX FIFO or the I2Ci.I2C_BUF[5:0] TXTRSH bit field value + 1 for the TX FIFO) are reached; the interrupt signals instruct the LH to transfer data to the destination (from the I²C controller in receive mode and/or from any source to the I²C controller FIFO in transmit mode).

and show receive and transmit operations, respectively, from a FIFO management point of view.

Figure 19-12. I²C Receive FIFO Interrupt Request Generation

i = 1 to 2

I2C-019

In , the RRDY interrupt condition shows that the condition for generating an RRDY interrupt is achieved. The interrupt request is generated when this signal is active, and it can be cleared only by the LH by writing 1 in the corresponding bit. If the condition is still present after clearing the previous interrupt, another interrupt request is generated.

In receive mode, an RRDY interrupt is generated as soon as the FIFO reaches its receive threshold (I2Ci.I2C_BUF[13:8] RXTRSH bit field value + 1). The interrupt can be deasserted only when the LH has handled enough bytes to make the number of bytes in the RX FIFO lower than the programmed threshold. For each interrupt, the LH can be configured to read a number of bytes equal to the value of the RX FIFO threshold.

Figure 19-13. I²C Transmit FIFO Interrupt Request Generation

In , the XRDY interrupt condition shows that the condition for generating an XRDY interrupt is achieved. The interrupt request is generated when TX FIFO is empty or when the TX FIFO threshold is not reached, and the LH can clear the XRDY status bit by setting the I2Ci.I2C_IRQENABLE_CLR [4] XRDY_IE bit to 1 after transmitting the configured number of bytes. If the condition is still present after clearing the previous interrupt, another interrupt request is generated.

In interrupt mode, the module offers two options for the LH application to handle the interrupts:

- When detecting an interrupt request (XRDY or RRDY type), the LH can write/read 1 data byte to/from the TX/RX FIFO and then clear the interrupt. The module reasserts the interrupt until the interrupt condition is not met.
- When detecting an interrupt request (XRDY or RRDY type), the LH can be programmed to write/read the amount of data bytes specified by the corresponding FIFO threshold (I2C_BUF[5:0] TXTRSH + 1 or I2C_BUF[5:0] RXTRSH + 1). In this case, the interrupt condition is cleared and the next interrupt is asserted again when the XRDY or RRDY condition is met again.

If the second-interrupt-serving approach is used, an additional mechanism (draining feature) is implemented for cases where the transfer length is not a multiple of the FIFO threshold value (see Section 19.1.4.8.4, *Draining Feature [I²C Mode Only]*).

NOTE: In slave transmit mode (the I2Ci.I2C_CON[10] MST bit is cleared and the I2Ci.I2C_CON[9] TRX bit is set to 1), the draining feature must not be used, because the transfer length is not known at configuration time, and the external master can end the transfer at any point by not acknowledging 1 data byte. If the draining feature is used in slave transmit mode, data can remain in the TX FIFO without being transmitted over the I²C bus. In this case, the TX FIFO must be cleared by setting the I2Ci.I2C_BUF[6] TXFIFO_CLR bit.

19.1.4.8.2 I²C FIFO Polling Mode

In FIFO polling mode (the I2Ci.I2C_IRQENABLE_SET [4] XRDY_IE and I2Ci.I2C_IRQENABLE_SET [3] RRDY_IE bits are disabled), the status of the module (receiver or transmitter) can be checked by polling the I2Ci.I2C_IRQSTATUS_RAW [4] XRDY and the I2Ci.I2C_IRQSTATUS_RAW [3] RRDY bits (the I2Ci.I2C_IRQSTATUS_RAW [13] RDR and I2Ci.I2C_IRQSTATUS_RAW [14] XDR bits can also be polled if the draining feature is enabled). The I2Ci.I2C_IRQSTATUS_RAW [4] XRDY and I2Ci.I2C_IRQSTATUS_RAW [3] RRDY bits accurately reflect the interrupt conditions described in the discussion of FIFO interrupt mode.

19.1.4.8.3 I²C FIFO DMA Mode

In receive mode, a DMA request is generated by the I2Ci_DREQ_RX signal as soon as the RX FIFO exceeds its threshold level (the I2Ci.I2C_BUF[13:8] RXTRSH bit field value + 1). This request is deasserted when the number of bytes defined by the threshold level is read by the DMA controller.

shows the DMA request generation in receive mode.

Figure 19-14. I²C Receive FIFO DMA Request Generation

In transmit mode, a DMA request is automatically asserted by the I2Ci_DREQ_TX signal when the TX FIFO is empty. This request is deasserted when the number of bytes (the I2Ci.I2C_BUF[5:0] TXTRSH bit field value + 1) is written in the FIFO by the DMA controller. If an insufficient number of bytes is written, the DMA request remains active, and show the DMA TX transfers with different values for the I2Ci.I2C_BUF[5:0] TXTRSH bit field.

Figure 19-15. I²C Transmit FIFO Request Generation (High Threshold)

Figure 19-16. I²C Transmit FIFO Request Generation (Low Threshold)

I2C-022

The I2C module provides the possibility to the user to clear the RX or TX FIFO, by setting the I2Ci.I2C_BUF[14]RXFIFO_CLR and I2Ci.I2C_BUF[6]TXFIFO_CLR registers, which act like software reset for the FIFOs. In DMA mode, these bits will also reset the DMA state machines.

The FIFO clearing feature can be used when the following conditions are met:

1. The module is configured as a transmitter
2. The external receiver responds with a NACK in the middle of the transfer
3. There is still data in TX FIFO waiting to be transferred

19.1.4.8.4 I²C Draining Feature

The draining feature is implemented to handle the end of a transfer whose length is not a multiple of the FIFO threshold values (the I2Ci.I2C_BUF[13:8] RXTRSH bit field value + 1 for the RX threshold and the I2Ci.I2C_BUF[5:0] TXTRSH field value + 1 for the TX threshold). It can also transfer the remaining number of bytes (because the threshold is not reached).

This feature prevents the LH or the DMA controller from trying more FIFO accesses than necessary (for example, to generate at the end of a transfer a DMA RX request having fewer bytes in the FIFO than the configured DMA transfer length). Otherwise, an AERR interrupt is generated by the I2Ci.I2C_IRQSTATUS_RAW [7] AERR bit.

The draining mechanism generates an interrupt using the I2Ci.I2C_IRQSTATUS_RAW [13] RDR or I2Ci.I2C_IRQSTATUS_RAW [14] XDR bit at the end of the transfer, informing the LH that it must check the amount of data left to be transferred (the I2Ci.I2C_BUFSTAT[13:8] RXSTAT or I2Ci.I2C_BUFSTAT[5:0] TXSTAT bit fields) and enable the draining feature of the DMA controller by reconfiguring the DMA transfer length according to this value (when the DMA mode is enabled) or perform only the required number of data accesses (when the DMA mode is disabled).

In receive mode (master or slave), if the RX FIFO threshold (the I2Ci.I2C_BUF[13:8] RXTRSH bit field value + 1) is not reached, but the transfer ends on the I²C bus and data remains in the RX FIFO (less than the threshold), the receive draining interrupt (the I2Ci.I2C_IRQSTATUS_RAW [13] RDR bit) is asserted to inform the LH that it can read the amount of data in the RX FIFO (the I2Ci.I2C_BUFSTAT[13:8] RXSTAT bit field). The LH performs a number of data read accesses equal to the I2Ci.I2C_BUFSTAT[13:8] RXSTAT bit field (interrupt or polling mode), or reconfigures the DMA controller with the required value to drain the FIFO.

In master transmit mode, if the TX FIFO threshold (the I2Ci.I2C_BUF[5:0] TXTRSH bit field value + 1) is not reached, but the amount of data remaining to be written in the TX FIFO is less than the threshold, the transmit draining interrupt (the I2Ci.I2C_IRQSTATUS_RAW [14] XDR bit) is asserted to inform the LH that it can read the amount of data remaining to be written in the TX FIFO (the I2Ci.I2C_BUFSTAT[5:0] TXSTAT bit field). The LH must write the required number of data bytes specified by the I2Ci.I2C_BUFSTAT[5:0] TXSTAT bit field value or reconfigure the DMA controller with the value required to transfer the last bytes to the FIFO.

In master mode, the LH can alternately not check the values of the I2Ci.I2C_BUFSTAT[5:0] TXSTAT and I2Ci.I2C_BUFSTAT[13:8] RXSTAT bit fields, because it can obtain this information internally (by computing the I2Ci.I2C_CNT[15:0] DATACOUNT bit field value modulo I2Ci.I2C_BUF[13:8] RXTRSH or I2Ci.I2C_BUF[5:0] TXTRSH).

By default, the draining feature is disabled; it can be enabled using the I2Ci.I2C_IRQENABLE_SET [14] XDR_IE or I2Ci.I2C_IRQENABLE_SET [13] RDR_IE bits (default disabled) only for transfers with lengths not equal to the threshold values (I2Ci.I2C_BUF[5:0] TXTRSH bit field value + 1 for the TX threshold or the I2Ci.I2C_BUF[13:8] RXTRSH bit field value + 1 for the RX threshold).

19.1.4.9 I²C Noise Filter

The noise filter is used to suppress any noise that is 50 ns or less in case of F/S operation modes. The noise filter is always one period of the I2Ci_INTERNAL_CLK clock.

For standard mode (for example, the I2Ci.I2C_PSC[7:0] PSC bit field = 4), the maximum width of suppressed spikes is 46.1 ns.

To ensure correct filtering, the prescaler must be programmed accordingly by the I2Ci.I2C_PSC[7:0] PSC bit field.

19.1.4.10 I²C System Test Mode

A system test mode is available for multimaster I²C controller module testing. This mode is enabled by setting the I2Ci.I2C_SYSTEST[15] ST_EN bit to 1. When this bit is cleared to 0, the I²C controller is configured in normal operation mode.

In system test mode, the I2Ci.I2C_SYSTEST [13:12] TMODE bit field selects the type of test. [Table 19-12](#) lists the tests available for the multimaster I²C controllers.

Table 19-12. I²C List of Tests

I2Ci.I2C_SYSTEST[13:12] TMODE	Test	Description
00	Functional mode	Normal operation mode
01	Reserved (not used)	
10	Test of i2ci_scl serial clock line	The i2ci_scl line is driven with a permanent clock as if mastered with the parameters set in the I2Ci.I2C_PSC, I2Ci.I2C_SCLL, and I2Ci.I2C_SCLH registers.
11	Loop-back mode + i2ci_scl/ i2ci_sda I/O	In master transmit mode only, data transmitted out of the I2Ci.I2C_DATA register (write action) is received in the same I2Ci.I2C_DATA register through an internal path through the FIFO buffers. The DMA and interrupt requests are normally generated if they are enabled. Moreover, the i2ci_scl and i2ci_sda are controlled with the I2Ci.I2C_SYSTEST[3:0] bits.

NOTE: When the I2Ci.I2C_SYSTEST[13:12] TMODE bit field is set to 11, the I²C controller must be configured in I²C F/S (I2Ci.I2C_CON[13:12] OPMODE set to 00).

NOTE: In normal operation mode (the I2Ci.I2C_SYSTEST[15] ST_EN bit cleared to 0), the I2Ci.I2C_SYSTEST[3:0] bits that control the i2ci_scl, i2ci_sda lines in system test mode are read-only bits.

In system test mode (the I2C*i*.I2C_SYSTEST[15] ST_EN bit set to 1), the I2C*i*.I2C_IRQSTATUS_RAW.XRDY, I2C_IRQSTATUS_RAW.RRDY, I2C_IRQSTATUS_RAW.XUDF, I2C_IRQSTATUS_RAW.ROVR, I2C_IRQSTATUS_RAW.ARDY and I2C_IRQSTATUS_RAW.NACK status bits can be set to 1 when the I2C*i*.I2C_SYSTEST[11] SSB bit is set to 1. Clearing the I2C*i*.I2C_SYSTEST[11] SSB bit to 0 does not clear the I2C*i*.I2C_IRQSTATUS_RAW bits to 0. The I2C*i*.I2C_IRQSTATUS_RAW bit field can be cleared to 0 only by writing 1 in the corresponding bits.

19.1.5 I²C Programming Guide

19.1.5.1 I²C Low-Level Programming Models

19.1.5.1.1 I²C Programming Model

This section describes the programming model of the multimaster I²C controllers configured in I²C mode.

19.1.5.1.1.1 Main Program

19.1.5.1.1.1.1 Configure the Module Before Enabling the I²C Controller

Before enabling the I²C controller, perform the following steps:

1. Enable the functional and interface clocks (see [Table 19-3](#)).
2. Program the prescaler to obtain an approximately 12-MHz internal sampling clock by programming the corresponding value in the I2Ci.I2C_PSC[7:0] PSC bit field. This value depends on the frequency of the functional clock (I2Ci_FCLK).
3. Program the I2Ci.I2C_SCLL[7:0] SCLL and I2Ci.I2C_SCLH[7:0] SCLH bit fields to obtain a bit rate of 100 kbps or 400 kbps. These values depend on the internal sampling clock frequency (see [Table 19-6](#)).
4. Configure the Own Address of the I²C controller by storing it in the I2Ci.I2C_OA register. Up to four Own Addresses can be programmed in the I2Ci.I2C_OA and I2Ci.I2C_OAx registers (where x = 1, 2, 3) for each I²C controller.

NOTE: For a 10-bit address, set the corresponding expand Own Address bit in the I2Ci.I2C_CON register.

5. Set the TX threshold (in transmitter mode) and the RX threshold (in receiver mode) by setting the I2Ci.I2C_BUF[5:0] TXTRSH bit field to (TX threshold – 1) and the I2Ci.I2C_BUF[13:8] RXTRSH bit field to (RX threshold – 1), where the TX and RX thresholds are greater than or equal to 1.
6. Take the I²C controller out of reset by setting the I2Ci.I2C_CON[15] I2C_EN bit to 1.

19.1.5.1.1.1.2 Initialize the I²C Controller

To initialize the I²C controller, perform the following steps:

1. Configure the I2Ci.I2C_CON register:
 - For master or slave mode, set the I2Ci.I2C_CON[10] MST bit (0: slave; 1: master).
 - For transmitter or receiver mode, set the I2Ci.I2C_CON[9] TRX bit (0: receiver; 1: transmitter).
2. If using an interrupt to transmit and receive data, set the corresponding bit in the I2Ci.I2C_IRQENABLE_SET register to 1 (the I2Ci.I2C_IRQENABLE_SET [4] XRDY_IE bit for the transmit interrupt, the I2Ci.I2C_IRQENABLE_SET [3] RRDY bit for the receive interrupt).
3. If using DMA to receive and transmit data, set the corresponding bit in the I2Ci.I2C_BUF register to 1 (the I2Ci.I2C_BUF[15] RDMA_EN bit for the receive DMA channel, the I2Ci.I2C_BUF[7] XDMA_EN bit for the transmit DMA channel).

19.1.5.1.1.1.3 Configure Slave Address and the Data Control Register

In master mode, configure the slave address register by programming the I2Ci.I2C_SA[9:0] SA bit field and the number of data bytes (I²C data payload) associated with the transfer by programming the I2Ci.I2C_CNT[15:0] DCOUNT bit field.

NOTE: For a 10-bit address, set the I2Ci.I2C_CON[8] XSA bit to 1.

19.1.5.1.1.1.4 Initiate a Transfer

Poll the I2Ci.I2C_IRQSTATUS_RAW [12] BB bit. If it is cleared to 0 (bus not busy), configure the I2Ci.I2C_CON[0] STT and I2Ci.I2C_CON[1] STP bits. To initiate a transfer, the I2Ci.I2C_CON[0] STT bit must be set to 1, and it is not mandatory to set the I2Ci.I2C_CON[1] STP bit to 1.

19.1.5.1.1.1.5 Receive Data

Poll the I2Ci.I2C_IRQSTATUS_RAW [3] RRDY bit, or use the RRDY interrupt (the I2Ci.I2C_IRQENABLE_SET [3] RRDY_IE bit must be set to 1) or the DMA RX channel (the I2Ci.I2C_BUF[15] RDMA_EN bit must be set to 1 together with I2C_DMARXENABLE_SET) to read the receive data in the I2Ci.I2C_DATA register.

If the transfer length does not equal the RX FIFO threshold (the I2Ci.I2C_BUF[13:8] RTRSH bit field + 1), use the draining feature (enable the RDR interrupt by setting the I2Ci.I2C_IRQENABLE_SET [13] RDR_IE bit to 1).

NOTE: In receive mode only, the I2Ci.I2C_IRQSTATUS_RAW [11] ROVR (receive overrun) bit indicates whether the receiver has experienced overrun. An overrun condition occurs when the shift register and the RX FIFO are full. An overrun condition does not result in data loss; the I²C controller simply holds i2ci_scl to low to prevent other bytes from being received.

The I2Ci.I2C_IRQSTATUS_RAW[7] AERR bit is set to 1 when a read access is performed in the I2Ci.I2C_DATA register while the RX FIFO is empty. The corresponding interrupt can be enabled by setting the I2Ci.I2C_IRQENABLE_SET [7] AERR_IE bit to 1.

19.1.5.1.1.1.6 Transmit Data

Poll the I2Ci.I2C_IRQSTATUS_RAW [4] XRDY bit, or use the XRDY interrupt (the I2Ci.I2C_IRQENABLE_SET [4] XRDY_IE bit must be set to 1) or the DMA TX channel (the I2Ci.I2C_BUF[7] XDMA_EN bit must be set to 1 together with I2C_DMATXENABLE_SET) to write data to the I2Ci.I2C_DATA register.

If the transfer length does not equal the TX FIFO threshold (the I2Ci.I2C_BUF[5:0] TXTRSH bit field + 1), use the draining feature (enable the XDR interrupt by setting the I2Ci.I2C_IRQENABLE_SET [14] XDR_IE bit to 1).

NOTE: In transmit mode only, the I2Ci.I2C_IRQSTATUS_RAW [10] XUDF bit indicates whether the transmitter has experienced underflow.

In master transmit mode, underflow occurs when the shift register and the TX FIFO are empty and there are still some bytes to transmit (the value of the I2Ci.I2C_CNT[15:0] DCOUNT bit field is not 0).

In slave transmit mode, underflow occurs when the shift register and the TX FIFO are empty and the external I²C master device still requests data bytes to be read.

The I2Ci.I2C_IRQSTATUS_RAW [7] AERR bit is set to 1 when a write access is performed in the I2Ci.I2C_DATA register while the TX FIFO is full. The corresponding interrupt can be enabled by setting the I2Ci.I2C_IRQENABLE_SET [7] AERR_IE bit to 1.

19.1.5.1.1.2 Interrupt Subroutine Sequence

1. Test for arbitration lost (the I2Ci.I2C_IRQSTATUS_RAW [0] AL bit) and resolve accordingly.
2. Test for no acknowledgment (the I2Ci.I2C_IRQSTATUS_RAW [1] NACK bit) and resolve accordingly.
3. Test for register access ready (the I2Ci.I2C_IRQSTATUS_RAW [2] ARDY bit) and resolve accordingly.
4. Test for receive data ready (the I2Ci.I2C_IRQSTATUS_RAW [3] RRDY bit) and resolve accordingly.
5. Test for transmit data ready (the I2Ci.I2C_IRQSTATUS_RAW [4] XRDY bit) and resolve accordingly.
6. Test for general call (the I2Ci.I2C_IRQSTATUS_RAW [5] GC bit) and resolve accordingly.
7. Test for start (S) condition (the I2Ci.I2C_IRQSTATUS_RAW [6] STC bit) and resolve accordingly. For this test, the functional clock must be inactive.
8. Test for access error (the I2Ci.I2C_IRQSTATUS_RAW [7] AERR bit) and resolve accordingly.
9. Test for bus free (the I2Ci.I2C_IRQSTATUS_RAW [8] BF bit) and resolve accordingly.

19.1.5.1.1.3 Programming Flow Diagrams

Address Offset	0x0000 0024		
Physical Address	0x4807 0024 0x4807 2024	Instance	I2C1 I2C2
Description	Per-event raw interrupt status vector. The raw status is set even if event is not enabled. Write 1 to set the (raw) status, mostly for debug		
Type	RW		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED	XDR	RDR	BB	ROVR	XUDF	AAS	BF	AERR	STC	GC	XRDY	RRDY	ARDY	NACK	AL

Bits	Field Name	Description	Type	Reset
15	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0
14	XDR	Transmit draining IRQ status. 0x0: Transmit draining inactive. 0x1: Transmit draining enabled.	RW	0
13	RDR	Receive draining IRQ status. 0x0: Receive draining inactive. 0x1: Receive draining enabled.	RW	0
12	BB	Bus busy status. Writing into this bit has no effect. Read 0x1: Bus is occupied. Read 0x0: Bus is free.	R	0

Bits	Field Name	Description	Type	Reset
11	ROVR	Receive overrun status. Writing into this bit has no effect. Read 0x1: Receiver overrun. Read 0x0: Normal operation.	RW	0
10	XUDF	Transmit underflow status. Writing into this bit has no effect. Read 0x1: Transmit underflow. Read 0x0: Normal operation.	RW	0
9	AAS	Address recognized as slave IRQ status. 0x0: No action. 0x1: Address recognized.	RW	0
8	BF	Bus Free IRQ status. 0x0: No action. 0x1: Bus Free.	RW	0
7	AERR	Access Error IRQ status. 0x0: No action. 0x1: Access Error.	RW	0
6	STC	Start Condition IRQ status. 0x0: No action. 0x1: Start Condition detected.	RW	0

Bits	Field Name	Description	Type	Reset
5	GC	General call IRQ status. Set to 1 by core when General call address detected and interrupt signaled to IRQ_Crossbar. ⁽¹⁾ 0x0: No general call detected. 0x1: General call address detected.	RW	0
4	XRDY	Transmit data ready IRQ status. Set to 1 by core when transmitter and when new data is requested. When set to 1 by core, an interrupt is signaled to IRQ_Crossbar. ⁽¹⁾ 0x0: Transmission ongoing. 0x1: Transmit data ready.	RW	0
3	RRDY	Receive data ready IRQ status. Set to 1 by core when receiver mode, a new data is able to be read. When set to 1 by core, an interrupt is signaled to IRQ_Crossbar. ⁽¹⁾ 0x0: No data available. 0x1: Receive data available.	RW	0
2	ARDY	Register access ready IRQ status. When set to 1 it indicates that previous access has been performed and registers are ready to be accessed again. An interrupt is signaled to IRQ_Crossbar. ⁽¹⁾ 0x0: Module busy. 0x1: Access ready.	RW	0
1	NACK	No acknowledgement IRQ status. Bit is set when No Acknowledge has been received, an interrupt is signaled to IRQ_Crossbar. ⁽¹⁾ 0x0: Normal operation. 0x1: Not Acknowledge detected.	RW	0
0	AL	Arbitration lost IRQ status. This bit is automatically set by the hardware when it loses the Arbitration in master transmit mode, an interrupt is signaled to IRQ_Crossbar. During reads, it always returns 0. 0x0: Normal operation. 0x1: Arbitration lost detected.	RW	0

⁽¹⁾ Writing 1 in the bit field will only set the respective field to 1, used mainly for debug.

19.2 UART

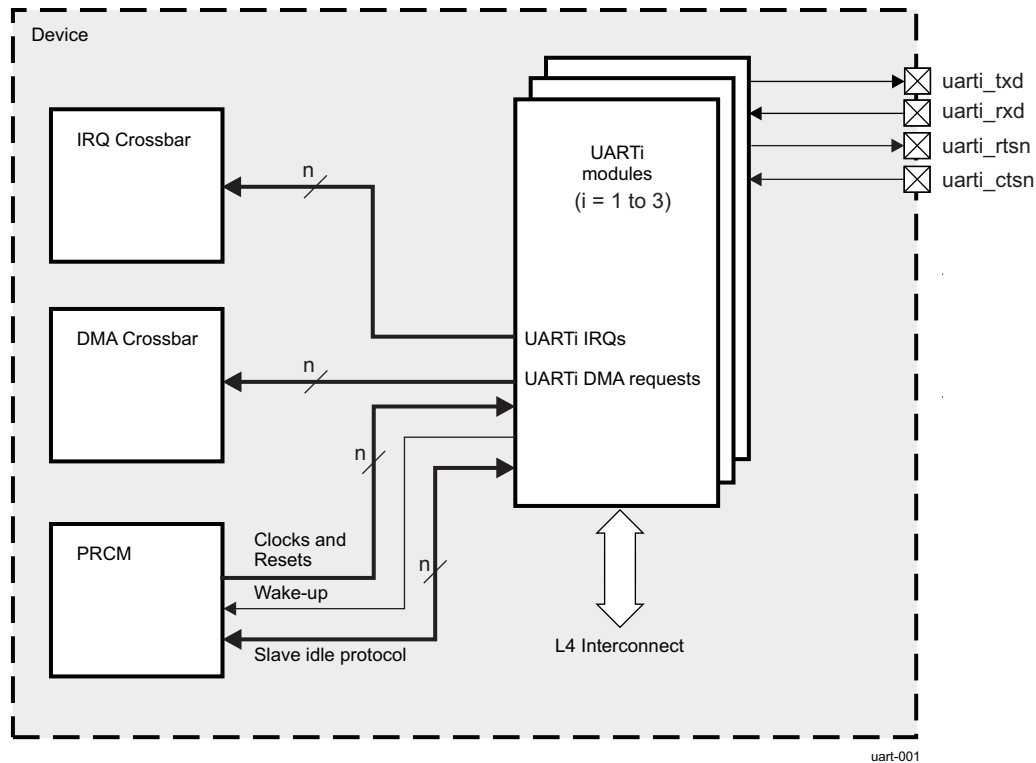

This chapter describes the function, operation, and configuration of the universal asynchronous receiver/transmitter (UART) module in the device.

19.2.1 UART Overview

The UART is a simple L4 slave peripheral that utilizes the EDMA for data transfer or IRQ polling via CPU. There are 3 UART modules in the device. Each UART can be used for configuration and data exchange with a number of external peripheral devices or interprocessor communication between devices.

Figure 19-26 shows the UART module overview.

Figure 19-26. UART Overview

19.2.1.1 UART Features

The UART_i (where $i = 1$ to 3) include the following features:

- 16C750 compatibility
- 64-byte FIFO buffer for receiver and 64-byte FIFO for transmitter
- Programmable interrupt trigger levels for FIFOs
- Baud generation based on programmable divisors N (where $N = 1 \dots 16,384$) operating from a fixed functional clock of 48 MHz or 192 MHz

Oversampling is programmed by software as 16 or 13. Thus, the baud rate computation is one of two options:

- Baud rate = (functional clock / 16) / N
- Baud rate = (functional clock / 13) / N
- This software programming mode enables higher baud rates with the same error amount without changing the clock source
- Break character detection and generation
- Configurable data format:

- Data bit: 5, 6, 7, or 8 bits
- Parity bit: Even, odd, none
- Stop-bit: 1, 1.5, 2 bit(s)
- Flow control: Hardware (RTS/CTS) or software (XON/XOFF)
- The 48 MHz functional clock option allows baud rates up to 3.6Mbps
- The 192 MHz functional clock option allows baud rates up to 12Mbps

19.2.2 UART Environment

This section describes the UART connection with an external device.

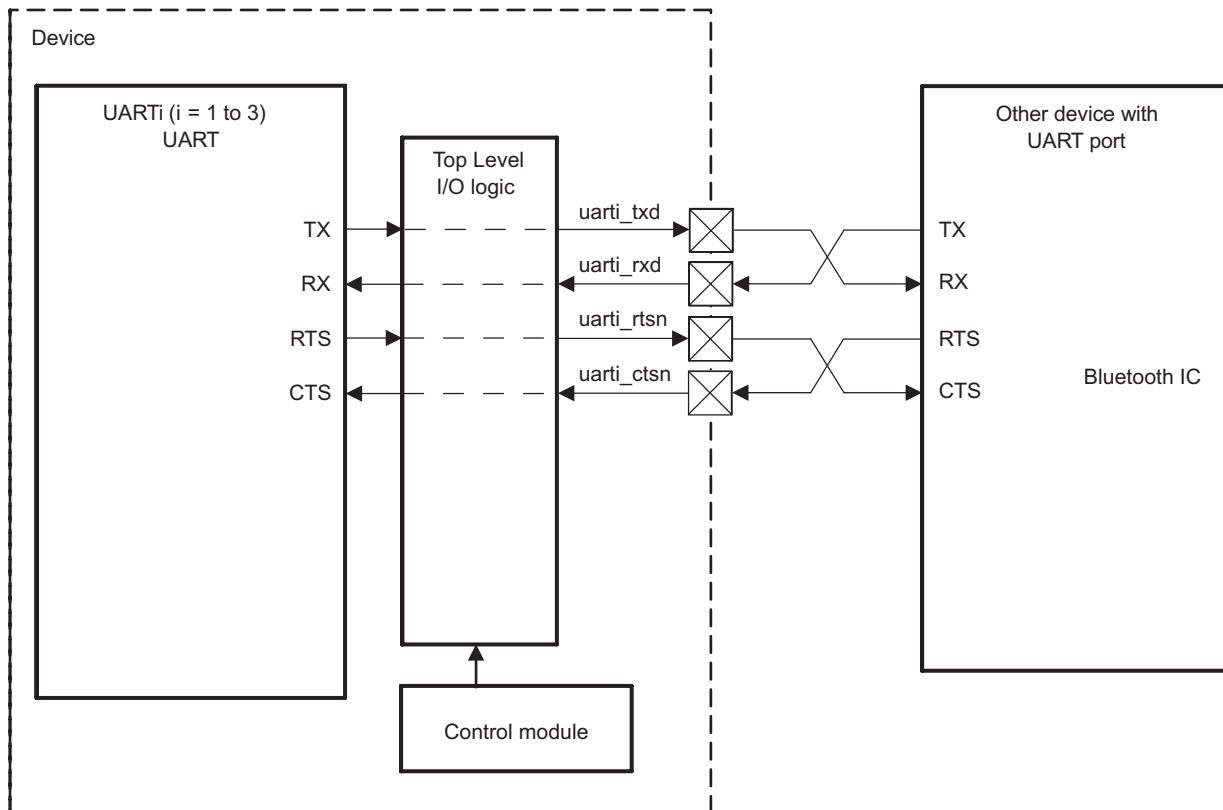

- The UART interface is described in [Section 19.2.2.1](#).

19.2.2.1 UART Interface

19.2.2.1.1 System Using UART Communication With Hardware Handshake

Each UART instance can be easily connected to the UART port of an external IC (see [Figure 19-27](#)).

Figure 19-27. UART Mode Bus System Overview

uart-002

19.2.2.1.2 UART Interface Description

[Table 19-89](#) lists the UART interface input/output (I/O) signals.

Table 19-89. UART Interface Signals

Signal	I/O ⁽¹⁾	Description	Module Level Reset Value
UARTi Interface Signals⁽²⁾			
uarti_rxd	I	Serial data input.	Unknown
uarti_txd	O	Serial data output This pin is set to low on reset (when the UARTi.UART_MDR1[2:0] bit field is set to 0x7) and takes the inactive level when the UARTi.UART_MDR1 register is programmed; that is, the output is 1 (inactive for UART modem modes).	0
uarti_ctsn	I	Clear to send	Unknown

⁽¹⁾ I = Input; O = Output; I/O = Bidirectional

⁽²⁾ i = 1 to 3

Table 19-89. UART Interface Signals (continued)

Signal	I/O ⁽¹⁾	Description	Module Level Reset Value
		Active-low modem status signal. Reading the UARTi.UART_MSR[4] NCTS_STS bit checks the condition of uarti_ctsn. Reading the UARTi.UART_MSR[0] CTS_STS bit checks a change of state of uarti_ctsn since the last read of the modem status register. The auto-CTS mode uses uarti_ctsn to control the transmitter.	
uarti_rtsn	O	Request to send When active (low), the module is ready to receive data. Setting the UARTi.UART_MCR[1] RTS bit activates uarti_rtsn, which becomes inactive as the result of a module reset, loopback mode, or clearing the UARTi.UART_MCR[1] RTS bit. In auto-RTS mode, uarti_rtsn becomes inactive as a result of the receiver threshold logic.	1

NOTE: The path from a module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the Control Module registers. For more information on control module settings, see [Section 14.4.6.1, Pad Configuration Registers](#), in [Chapter 14, Control Module](#).

19.2.2.1.3 UART Protocol and Data Format

The UART device operates in three modes:

- UART 16x (<= 230.4 kbps)
- UART 16x with autobauding (>= 1200 bps and >= 115.2 kbps)
- UART 13x (>= 460.8 kbps)

CAUTION

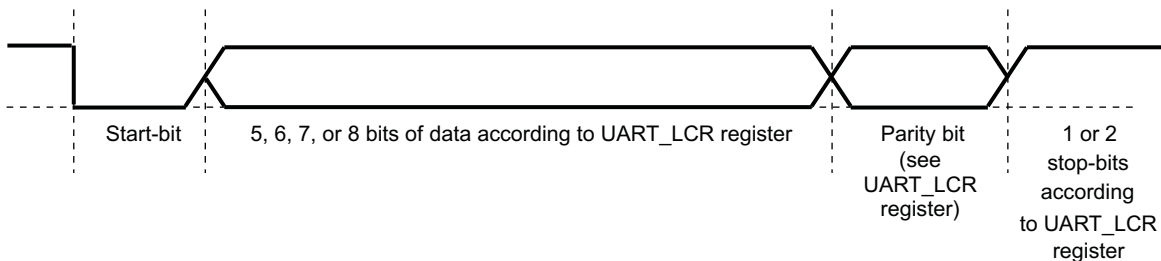

To be used as a UART, the operating mode must be programmed appropriately in the UARTi.UART_MDR1[2:0] MODE_SELECT bit field to select UART.

The UART uses a wired interface for serial communication with a remote device.

The UART is functionally compatible with the TL16C750 UART and earlier designs such as the TL16C550.

[Figure 19-28](#) shows the UART frame data format.

Figure 19-28. UART Frame Data Format

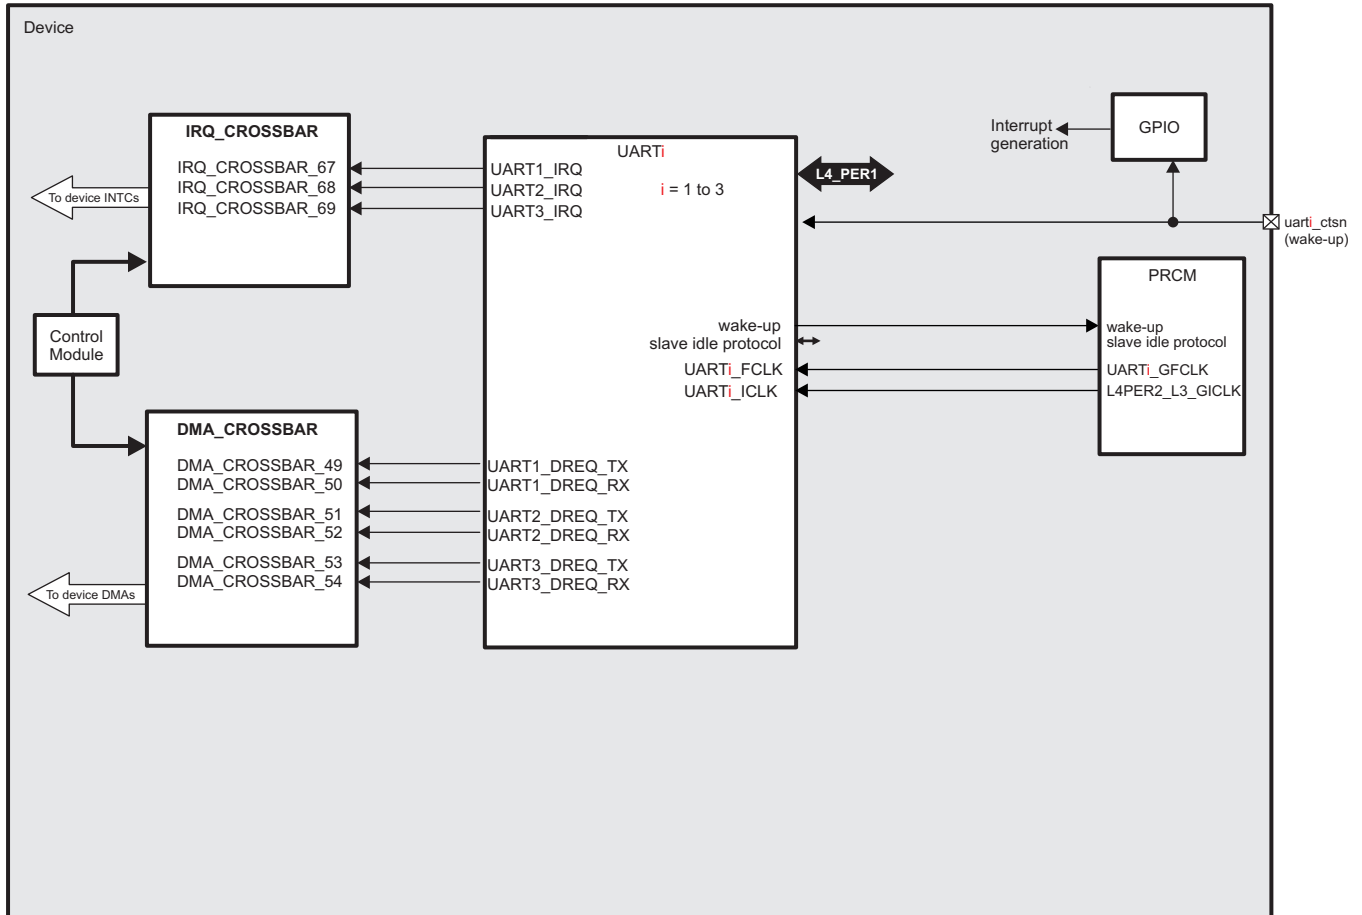

uart-005

19.2.3 UART Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 19-29 shows the device internal connections with related modules for UART functions.

Figure 19-29. UART Integration

uart-021

NOTE: For more information about the slave idle and master standby protocols and the wake-up request, see [Section 3.1.1.1.4, Clock Domain-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#)

Table 19-90 through Table 19-92 summarize the integration of the module in the device.

Table 19-90. UART Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
UART1	PD_COREAON	Yes	L4_PER1
UART2	PD_COREAON	Yes	L4_PER1
UART3	PD_COREAON	Yes	L4_PER1

Table 19-91. UART Clocks and Resets

Clocks				
Module Instance	Destination Signal	Source Signal	Source	Description
UART1	UART1_ICLK	L4PER_L3_GICLK	PRCM	UART1 interface clock
	UART1_FCLK	UART1_GFCLK	PRCM	UART1 functional clock
UART2	UART2_ICLK	L4PER_L3_GICLK	PRCM	UART2 interface clock
	UART2_FCLK	UART2_GFCLK	PRCM	UART2 functional clock
UART3	UART3_ICLK	L4PER_L3_GICLK	PRCM	UART3 interface clock
	UART3_FCLK	UART3_GFCLK	PRCM	UART3 functional clock
Resets				
Module Instance	Destination Signal	Source Signal	Source	Description
UART1	UART1_RST	L4PER_RET_RST	PRCM	UART1 reset
UART2	UART2_RST	L4PER_RET_RST	PRCM	UART2 reset
UART3	UART3_RST	L4PER_RET_RST	PRCM	UART3 reset

Table 19-92. UART Hardware Requests

Interrupt Requests				
Module Instance	Source Signal Name	Destination IRQ_CROSSBAR input	Default Mapping	Description
UART1	UART1_IRQ	IRQ_CROSSBAR_67	-	UART module 1 IRQ line
UART2	UART2_IRQ	IRQ_CROSSBAR_68	-	UART module 2 IRQ line
UART3	UART3_IRQ	IRQ_CROSSBAR_69	IPU_IRQ_45	UART module 3 IRQ line
Direct Memory Access (DMA) Requests				
Module Instance	Source Signal Name	Destination DMA_CROSSBAR input	Default Mapping	Description
UART1	UART1_DREQ_TX	DMA_CROSSBAR_49	DMA_EDMA_DREQ_48	UART module 1 – transmit request
	UART1_DREQ_RX	DMA_CROSSBAR_50	DMA_EDMA_DREQ_49	UART module 1 – receive request
UART2	UART2_DREQ_TX	DMA_CROSSBAR_51	DMA_EDMA_DREQ_50	UART module 2 – transmit request
	UART2_DREQ_RX	DMA_CROSSBAR_52	DMA_EDMA_DREQ_51	UART module 2 – receive request
UART3	UART3_DREQ_TX	DMA_CROSSBAR_53	DMA_EDMA_DREQ_52	UART module 3 – transmit request
	UART3_DREQ_RX	DMA_CROSSBAR_54	DMA_EDMA_DREQ_53	UART module 3 – receive request

NOTE: The “**Default Mapping**” column in [Table 19-92, UART Hardware Requests](#), shows the default mapping of module IRQ and DREQ source signals. These module IRQ and DREQ source signals can also be mapped to other lines of each device Interrupt or DMA controller through the IRQ_CROSSBAR and DMA_CROSSBAR modules, respectively.

For more information about the IRQ_CROSSBAR module, see [Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#).

For more information about the DMA_CROSSBAR module, see [Section 14.4.6.5, DMA_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#).

For more information about the device interrupt controllers, see [Chapter 13, Interrupt Controllers](#).

For more information about the device EDMA module, see [Chapter 12, Enhanced DMA](#).

19.2.4 UART Functional Description

19.2.4.1 Block Diagram

The UART module can be divided into three main blocks:

- FIFO management
- Mode selection
- Protocol formatting

FIFO management is common to all functions and enables the transmission and reception of data from the host processor point of view.

There are two modes:

- Function mode: Routes the data to UART and enables UART function
- Register mode: Enables conditional access to registers

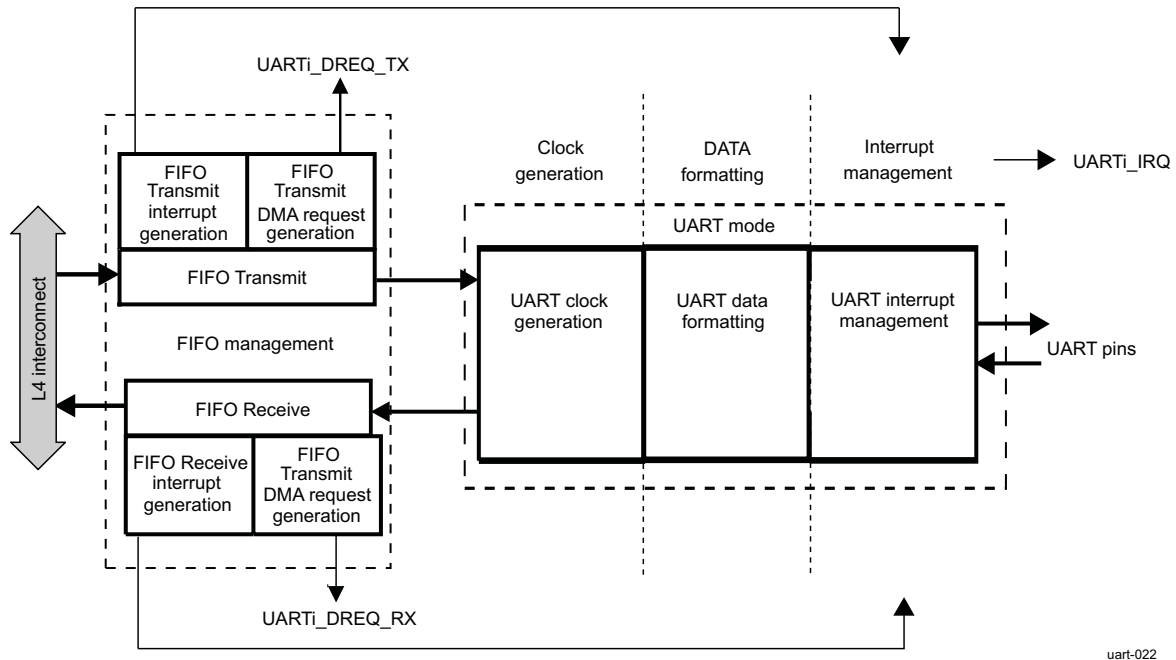

For more information about mode configuration, see [Section 19.2.4.7, Mode Selection](#).

Protocol formatting has three subcategories:

- Clock generation: The 48-MHz input clock generates all necessary clocks.
- Data formatting: Each function uses its own state-machine that is responsible for the transition between FIFO data and frame data associated with it.
- Interrupt management: When an interrupt is generated, the [UART_IIR](#) register indicates the interrupt type.
 - Seven interrupts prioritized in six different levels

In parallel with these functional blocks, a power-saving strategy exists for each function.

[Figure 19-30](#) is the UART block diagram.

Figure 19-30. UART Functional Block Diagram

uart-022

19.2.4.2 Clock Configuration

Each UART uses a 48-MHz functional clock for its logic and to generate external interface signals. Each UART uses an interface clock for register accesses. The PRCM module generates and controls all these clocks (for more information, see [Section 3.1.1.1.4, Clock Domain-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#)).

The idle and wake-up processes use a handshake protocol between the PRCM and the UART (for a description of the protocol, see [Section 3.1.1.1.4, Clock Domain Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#)). The `UARTi.UART_SYSC[4:3] IDLEMODE` bit field controls UART idle mode.

19.2.4.3 Software Reset

The `UARTi.UART_SYSC[1] SOFTRESET` bit controls the software reset; setting this bit to 1 triggers a software reset functionally equivalent to hardware reset.

19.2.4.4 Power Management

19.2.4.4.1 UART Mode Power Management

19.2.4.4.1.1 Module Power Saving

In UART modes, sleep mode is enabled by setting the `UARTi.UART_IER[4] SLEEP_MODE` bit to 1 (when the `UARTi.UART_EFR[4] ENHANCED_EN` bit is set to 1).

Sleep mode is entered when all of the following conditions exist:

- The serial data input line, `uarti_rxd`, is idle.
- The TX FIFO and TX shift register are empty.
- The RX FIFO is empty.
- The only pending interrupts are THR interrupts.

Sleep mode is a good way to lower UART power consumption, but this state can be achieved only when the UART is set to modem mode. Therefore, even if the UART has no key role functionally, it must be initialized in a functional mode to take advantage of sleep mode.

In sleep mode, the module clock and baud rate clock are stopped internally. Because most registers are clocked by these clocks, this greatly reduces power consumption. The module wakes up when a change is detected on the `uarti_rxd` line, when data is written to the TX FIFO, and when there is a change in the state of the modem input pins.

An interrupt can be generated on a wake-up event by setting the `UARTi.UART_SCR[4] RX_CTS_WU_EN` bit to 1. To understand how to manage the interrupt, see [Section 19.2.4.5.1.2, Wake-Up Interrupt](#).

NOTE: There must be no writing to the divisor latches, `UARTi.UART_DLL` and `UARTi.UART_DLH`, to set the baud clock (BCLK) while in sleep mode. It is advisable to disable sleep mode using the `UARTi.UART_IER[4] SLEEP_MODE` bit before writing to the `UARTi.UART_DLL` or `UARTi.UART_DLH` register.

19.2.4.4.1.2 System Power Saving

Sleep and auto-idle modes are embedded power-saving features. Power-reduction techniques can be applied at the system level by shutting down certain internal clock and power domains of the device.

The UART supports an idle req/idle ack handshaking protocol used at the system level to shut down the UART clocks in a clean and controlled manner and to switch the UART from interrupt-generation mode to wake-up generation mode for unmasked events (see the `UARTi.UART_SYSC[2] ENAWAKEUP` bit and the `UARTi.UART_WER` register).

For more information, see [Section 3.1.1.1.2, Module Level Clock Management, Chapter 3, Power, Reset, and Clock Management](#).

19.2.4.4.2 Local Power Management

[Table 19-93](#) describes power-management features available for the UART.

NOTE: For information about source clock gating and the sleep/wake-up transitions description, see [Section 3.1.1.1.2, Module Level Clock Management, Chapter 3, Power, Reset, and Clock Management](#).

Table 19-93. Local Power-Management Features

Feature	Registers	Description
Clock autogating	<code>UART_SYSC[0] AUTOIDLE</code>	This bit allows local power optimization in the module by gating the <code>UARTi_ICLK</code> clock on interface activity or gating the <code>UARTi_FCLK</code> clock on internal activity.
Slave idle modes	<code>UART_SYSC[4:3] IDLEMODE</code>	Force-idle, no-idle, smart-idle, and smart-idle wakeup-capable modes are available.
Clock activity	N/A	Feature not available
Master standby modes	N/A	Feature not available
Global wake-up enable	<code>UART_SYSC[2] ENAWAKEUP</code>	This bit enables the wake-up feature at module level.
Wake-Up sources enable	N/A	Feature not available

19.2.4.5 Interrupt Requests

19.2.4.5.1 UART Interrupt Management

19.2.4.5.1.1 UART Interrupts

UART includes seven possible interrupts prioritized to six levels.

When an interrupt is generated, the interrupt identification register (UARTi.UART_IIR) sets the UARTi.UART_IIR[0] IT_PENDING bit to 0 to indicate that an interrupt is pending, and indicates the type of interrupt through the UARTi.UART_IIR[5:1] bit field. Table 19-94 summarizes the interrupt control functions.

Table 19-94. UART Interrupts

IIR[5:0]	Priority Level	Interrupt Type	Interrupt Source	Interrupt Reset Method
000001	None	None	None	None
000110	1	Receiver line status	OE, FE, PE, or BI errors occur in characters in the RX FIFO.	FE, PE, BI: Read the UART_RHR register. OE: Read the UART_LSR register.
001100	2	RX time-out	Stale data in RX FIFO	Read the UART_RHR register.
000100	2	RHR interrupt	DRDY (data ready) (FIFO disable) RX FIFO above trigger level (FIFO enable)	Read the UART_RHR register until the interrupt condition disappears.
000010	3	THR interrupt	TFE (THR empty) (FIFO disable) TX FIFO below trigger level (FIFO enable)	Write to the UART_THR until the interrupt condition disappears.
000000	4	Modem status	See the UART_MSR register.	Read the MSR register.
010000	5	XOFF interrupt/special character interrupt	Receive XOFF characters/special character	Receive XON character(s), if XOFF interrupt/read of the UART_IIR register, if special character interrupt.
100000	6	CTS, RTS	RTS pin or CTS pin change state from active (low) to inactive (high).	Read the UART_IIR register.

For the receiver-line status interrupt, the RX_FIFO_STS bit (UARTi.UART_LSR[7]) generates the interrupt.

For the XOFF interrupt, if an XOFF flow character detection caused the interrupt, the interrupt is cleared by an XON flow character detection. If special character detection caused the interrupt, the interrupt is cleared by a read of the UARTi.UART_IIR register.

19.2.4.5.1.2 Wake-Up Interrupt

Wake-up interrupt is a special interrupt that works differently from other interrupts. This interrupt is enabled when the UARTi.UART_SCR[4] RX_CTS_WU_EN bit is set to 1. The UARTi.UART_IIR register is not modified when this occurs; the UART3.UART_SSR[1] RX_CTS_WU_STS bit must be checked to detect a wake-up event.

When a wake-up interrupt occurs, it can be cleared only by resetting the UARTi.UART_SCR[4] RX_CTS_WU_EN bit. This bit must be reenabled (set to 1) after the current wake-up interrupt event is processed to detect the next incoming wake-up event.

19.2.4.6 FIFO Management

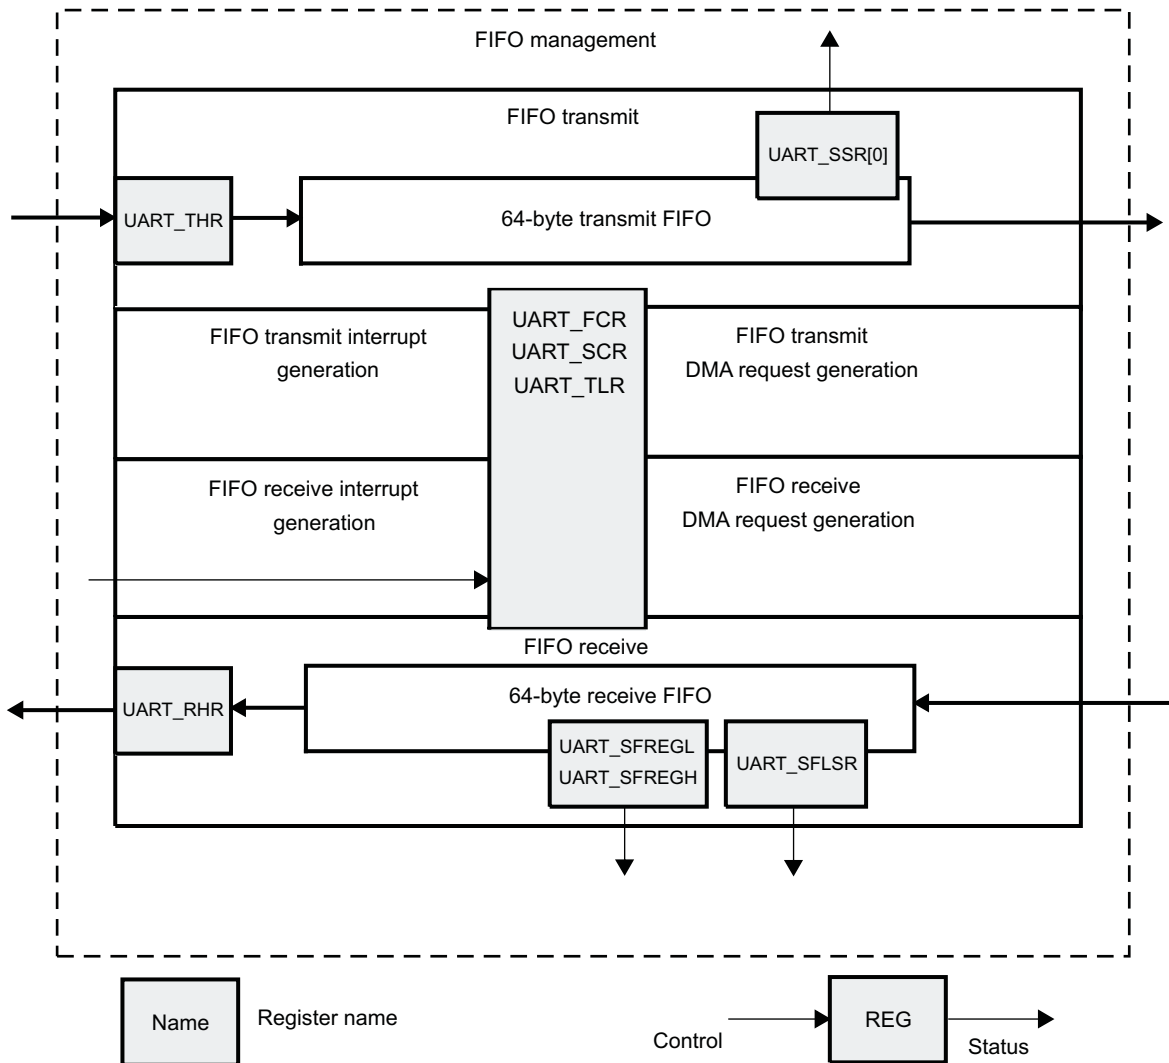

The FIFO is accessed by reading and writing the UARTi.UART_RHR and UARTi.UART_THR registers. Parameters are controlled using the FIFO control register (UARTi.UART_FCR) and supplementary control register (UARTi.UART_SCR). Reading the UARTi.UART_SSR[0] TX_FIFO_FULL bit at 1 means the FIFO is full.

The UARTi.UART_TLR register controls the FIFO trigger level, which enables DMA and interrupt generation. After reset, transmit (TX) and receive (RX) FIFOs are disabled; thus, the trigger level is the default value of 1 byte. Figure 19-31 shows the FIFO management registers.

NOTE: Data in the UARTi.UART_RHR register is not overwritten when an overflow occurs.

NOTE: Bits UARTi.UART_FCR[2] TX_FIFO_CLEAR and UARTi.UART_FCR[1] RX_FIFO_CLEAR are automatically cleared by hardware after 4* UARTi_ICLK + 5* UARTi_FCLK clock cycles. This delay is needed to finish the resetting of the corresponding FIFO and DMA control registers.

Figure 19-31. FIFO Management Registers

uart-023

19.2.4.6.1 FIFO Trigger

19.2.4.6.1.1 Transmit FIFO Trigger

Table 19-95 lists the TX FIFO trigger level settings.

Table 19-95. TX FIFO Trigger Level Setting Summary

SCR[6]	TLR[3:0]	TX FIFO Trigger Level
0	= 0x0	Defined by the UARTi.UART_FCR[5:4] TX_FIFO_TRIG bit field (8,16, 32, or 56 spaces)
0	!= 0x0	Defined by the UARTi.UART_TLR[3:0] TX_FIFO_TRIG_DMA bit field (from 4 to 60 spaces with a granularity of 4 spaces)
1	Value	Defined by the concatenated value of TX_FIFO_TRIG_DMA and TX_FIFO_TRIG (from 1 to 63 spaces with a granularity of 1 space) Note: The combination of TX_FIFO_TRIG_DMA = 0x0 and TX_FIFO_TRIG = 0x0 (all zeros) is not supported (minimum of 1 space required). All zeros result in unpredictable behavior.

19.2.4.6.1.2 Receive FIFO Trigger

Table 19-96 lists the RX FIFO trigger-level settings.

Table 19-96. RX FIFO Trigger-Level Setting Summary

SCR[7]	TLR[7:4]	RX FIFO Trigger Level
0	= 0x0	Defined by the UARTi.UART_FCR[7:6] RX_FIFO_TRIG bit field (8,16, 56, or 60 characters)
0	!= 0x0	Defined by the UARTi.UART_TLR[7:4] RX_FIFO_TRIG_DMA bit field (from 4 to 60 characters with a granularity of 4 characters)
1	Value	Defined by the concatenated value of RX_FIFO_TRIG_DMA and RX_FIFO_TRIG (from 1 to 63 characters with a granularity of 1 character) Note: The combination of RX_FIFO_TRIG_DMA = 0x0 and RX_FIFO_TRIG = 0x0 (all zeros) is not supported (minimum of 1 character required). All zeros result in unpredictable behavior.

The receive threshold is programmed using the UARTi.UART_TCR[7:4] RX_FIFO_TRIG_START and UARTi.UART_TCR[3:0] RX_FIFO_TRIG_HALT bit fields:

- Trigger levels from 0 to 60 bytes are available with a granularity of 4 (trigger level = 4 × [4-bit register value]).
- To ensure correct device operation, ensure that RX_FIFO_TRIG_HALT > RX_FIFO_TRIG when auto-RTS is enabled.

$$\text{Delay} = [4 + 16 \times (1 + \text{CHAR_LENGTH} + \text{Parity} + \text{Stop} - 0.5)] \times \text{Baud_rate} + 4 \times \text{FCLK}$$

NOTE: The RTS signal is deasserted after the UART module receives the data over RX_FIFO_TRIG_HALT. Delay means how long the UART module takes to deassert the RTS signal after reaching RX_FIFO_TRIG_HALT.

- In FIFO interrupt mode with flow control, ensure that the trigger level to HALT transmission is greater than or equal to the RX FIFO trigger level (the UARTi.UART_TCR[7:4] RX_FIFO_TRIG_START bit field or the UARTi.UART_FCR[7:6] RX_FIFO_TRIG bit field); otherwise, FIFO operation stalls. In FIFO DMA mode with flow control, this concept does not exist, because a DMA request is sent when a byte is received.

19.2.4.6.2 FIFO Interrupt Mode

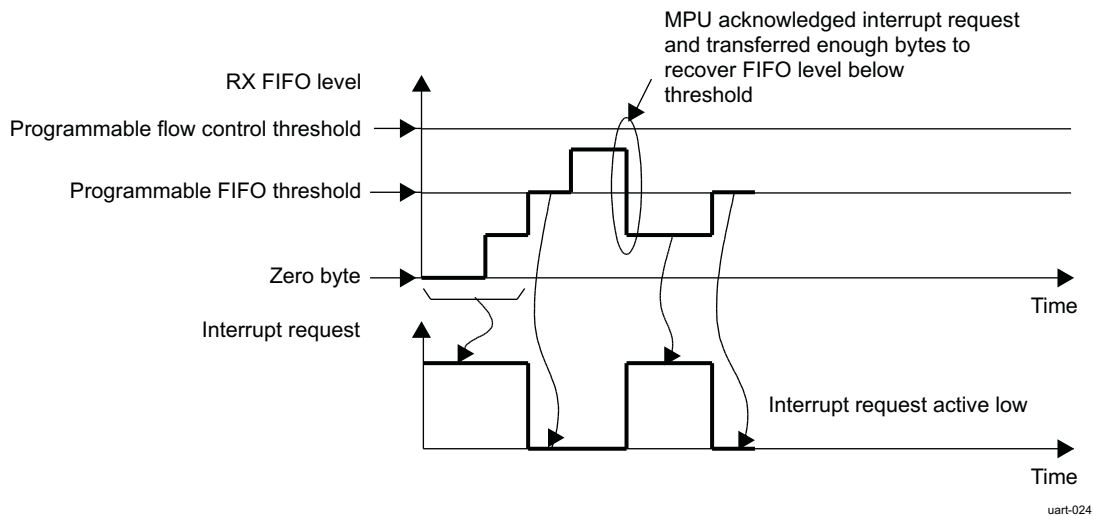

In FIFO interrupt mode (the FIFO control register UARTi.UART_FCR[0] FIFO_EN bit is set to 1 and relevant interrupts are enabled by the UARTi.UART_IER register), an interrupt signal informs the processor of the status of the receiver and transmitter. These interrupts are raised when the RX/TX FIFO threshold (the UARTi.UART_TLR[7:4] RX_FIFO_TRIG_DMA and UARTi.UART_TLR[3:0] TX_FIFO_TRIG_DMA bit fields or the UARTi.UART_FCR[7:6] RX_FIFO_TRIG and UARTi.UART_FCR[5:4] TX_FIFO_TRIG bit fields, respectively) is reached.

The interrupt signals instruct the CPU to transfer data to the destination (from the UART in receive mode and/or from any source to the UART FIFO in transmit mode).

When UART flow control is enabled with interrupt capabilities, the UART flow control FIFO threshold (the UARTi.UART_TCR[3:0] RX_FIFO_TRIG_HALT bit field) must be greater than or equal to the RX FIFO threshold.

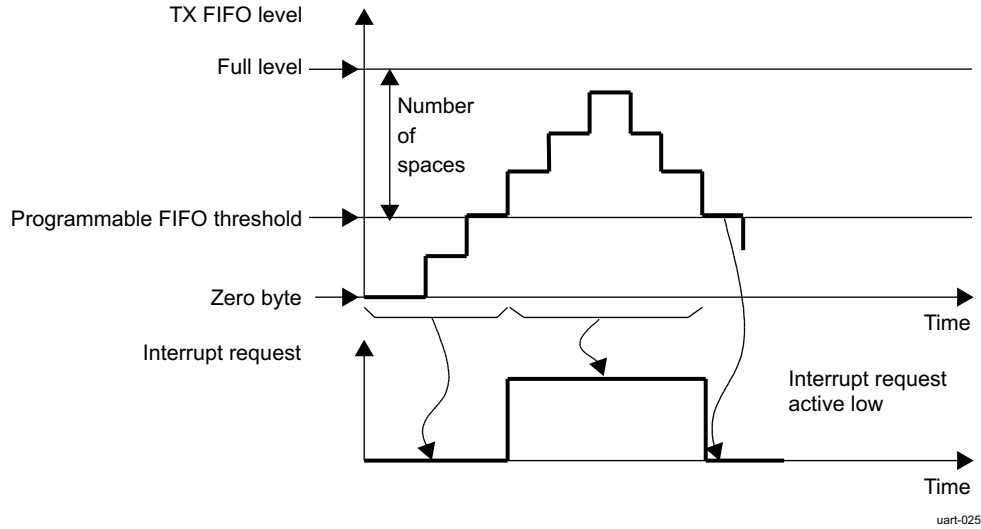

Figure 19-32 shows the generation of the RX FIFO interrupt request.

Figure 19-32. RX FIFO Interrupt Request Generation

In receive mode, no interrupt is generated until the RX FIFO reaches its threshold. Once low, the interrupt can be deasserted only when the CPU has handled enough bytes to put the FIFO level below threshold. The flow control threshold is set at a higher value than the FIFO threshold.

Figure 19-33 shows the generation of the TX FIFO interrupt request.

Figure 19-33. TX FIFO Interrupt Request Generation

In transmit mode, an interrupt request is automatically asserted when the TX FIFO is empty. This request is deasserted when the TX FIFO crosses the threshold level. The interrupt line is deasserted until a sufficient number of elements is transmitted to go below the TX FIFO threshold.

19.2.4.6.3 FIFO Polled Mode Operation

In FIFO polled mode (the `UARTi.UART_FCR[0]` `FIFO_EN` bit is set to 0 and the relevant interrupts are disabled by the `UARTi.UART_IER` register), the status of the receiver and transmitter can be checked by polling the line status register (`UARTi.UART_LSR`).

This mode is an alternative to the FIFO interrupt mode of operation in which the status of the receiver and transmitter is automatically determined by sending interrupts to the CPU.

19.2.4.6.4 FIFO DMA Mode Operation

Although the DMA operation includes four modes (DMA modes 0 through 3), the information in [Table 19-92, Hardware Requests](#), assumes that mode 1 is used. (Mode 2 and mode 3 are legacy modes that use only one DMA request for each module.)

In mode 2, the remaining DMA request is used for RX. In mode 3, the remaining DMA request is used for TX.

DMA requests in mode 2 and mode 3 use the `UARTi_DREQ_TX` signals (where $i = 1$ to 10).

The `UARTi_DREQ_RX` signals are not used by the module in mode 2 and mode 3:

The DMA mode and signals usage can be selected as follows:

- When the `UARTi.UART_SCR[0]` `DMA_MODE_CTL` bit is set to 0, setting the `UARTi.UART_FCR[3]` `DMA_MODE` bit to 0 enables DMA mode 0. Setting the `UARTi.UART_FCR[3]` `DMA_MODE` bit to 1 enables DMA mode 1.
- When the `UARTi.UART_SCR[0]` `DMA_MODE_CTL` bit is set to 1, the `UARTi.UART_SCR[2:1]` `DMA_MODE_2` bit field determines DMA mode 0 to mode 3 based on the supplementary control register (SCR) description.

For example:

- If no DMA operation is desired, set the `UARTi.UART_SCR[0]` `DMA_MODE_CTL` bit to 1 and the `UARTi.UART_SCR[2:1]` `DMA_MODE_2` bit field to 0x0. (The `DMA_MODE` bit is discarded.)
- If DMA mode 1 is desired, set the `UARTi.UART_SCR[0]` `DMA_MODE_CTL` bit to 0 and the `UARTi.UART_FCR[3]` `DMA_MODE` bit to 1, or set the `UARTi.UART_SCR[0]` `DMA_MODE_CTL` bit to 1 and the `SCR[2:1]` `DMA_MODE_2` bit field to 01. (The `UARTi.UART_FCR[3]` `DMA_MODE` bit is discarded.)

If the FIFOs are disabled (the UARTi.UART_FCR[0] FIFO_EN bit is set to 0), the DMA occurs in single-character transfers.

When DMA mode 0 is programmed, the signals associated with DMA operation are not active.

Depending on UARTi.UART_MDR3[2] SET_DMA_TX_THRESHOLD, the threshold can be programmed different ways:

- SET_TX_DMA_THRESHOLD = 1:

The threshold value will be the value of the TX_DMA_THRESHOLD register. If SET_TX_DMA_THRESHOLD + TX trigger spaces 64, then the default method of threshold is used: threshold value = TX FIFO size.

- SET_TX_DMA_THRESHOLD = 0:

The threshold value = TX FIFO size TX trigger space. The TX DMA line is asserted if the TX FIFO level is lower than the threshold. It remains asserted until TX trigger spaces number of bytes are written into the FIFO. The DMA line is then deasserted and the FIFO level is compared with the threshold value.

19.2.4.6.4.1 DMA sequence to disable TX DMA

In order to disable TX DMA if it is not needed anymore (e.g. all transfers are done and UART idle mode is desired), the following sequence must be use

1. DMA mode 1 is set (both TX/RX DMA) by registers UARTi.UART_SCR[0] = 0 and UARTi.UART_FCR[3] = 1:

- A. Set the UARTi.UART_SCR[2:1]DMA_MODE_2 bit fields to 01 (DMA mode 1)
- B. Set the UARTi.UART_SCR[0]DMA_MODE_CTL bit to 1 (this setting of UARTi.UART_SCR[0]DMA_MODE-CTL will ignores UARTi.UART_FCR[3]DMA_MODE_CTL bit)

NOTE: It is strongly suggested to do steps 'a' and 'b' in two separate write in order to avoid malfunction of the device.

- C. Set the UARTi.UART_FCR[3]DMA_MODE bit to 0. It is not necessary but suggested to avoid restore of DMA mode 1 during accidental reset of UARTi.UART_SCR[0]DMA_MODE_CTL bit. Be sure that all data was read out from RX FIFO and if it possible disable the RX side. In UART mode the RTS/CTS or XOFF/XON protocol can be used.

NOTE: There can be RX DATA loss during the next steps if all DATA was not read out or there was an ongoing reception!

- D. Set the UARTi.UART_FCR[2:1]DMA_MODE bit field to 11 (clear TX and RX FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO).
- E. Set the UARTi.UART_SCR[2:1]DMA_MODE_2 bit field to 10 (DMA mode 2, RX only).
- F. Set the UARTi.UART_FCR[2:1]DMA_MODE bit field to 11 (clear TX and RX FIFO and the DMA request again).
- G. Set the UARTi.UART_SCR[2:1] DMA_MODE_2 bit field to 00 (no DMA) or keep 10 if RX DMA is needed.

2. DMA mode 1 is set (both TX/RX DMA) by registers UARTi.UART_FCR[3] = 0 and UARTi.UART_SCR[0] = 1, UARTi.UART_SCR[2:1] = 01. It is almost the same as above, but steps 'a', and 'b' can be skipped:

- A. Set the UARTi.UART_FCR[3]DMA_MODE bit to 0. It is not necessary but suggested to avoid restore of DMA mode 1 during accidental reset of UARTi.UART_SCR[0]DMA_MODE_CTL bit. Be sure that all data was read out from RX FIFO and if it possible disable the RX side. In UART mode the RTS/CTS or XOFF/XON protocol can be used.

NOTE: There can be RX DATA loss during the next steps if all DATA was not read out or there was an ongoing reception!

- B. Set the UARTi.UART_FCR[2:1]DMA_MODE bit field to 11 (clear TX and RX FIFO and resets its

- counter logic to 0. Returns to 0 after clearing FIFO).
 - C. Set the UARTI.UART_SCR[2:1]DMA_MODE_2 bit field to 10 (DMA mode 2, RX only).
 - D. Set the UARTI.UART_FCR[2:1]DMA_MODE bit field to 11 (clear TX and RX FIFO and the DMA request again).
 - E. Set the UARTI.UART_SCR[2:1] DMA_MODE_2 bit field to 00 (no DMA) or keep 10 if RX DMA is needed.
3. DMA mode 3 is set (TX DMA only) by registers UARTI.UART_FCR[3] = 0 and UARTI.UART_SCR[0] = 1, UARTI.UART_SCR[2:1] = 11. It is the same as above:
- A. Set the UARTI.UART_FCR[3]DMA_MODE bit to 0. It is not necessary but suggested to avoid restore of DMA mode 1 during accidental reset of UARTI.UART_SCR[0]DMA_MODE_CTL bit. Be sure that all data was read out from RX FIFO and if it possible disable the RX side. In UART mode the RTS/CTS or XOFF/XON protocol can be used.

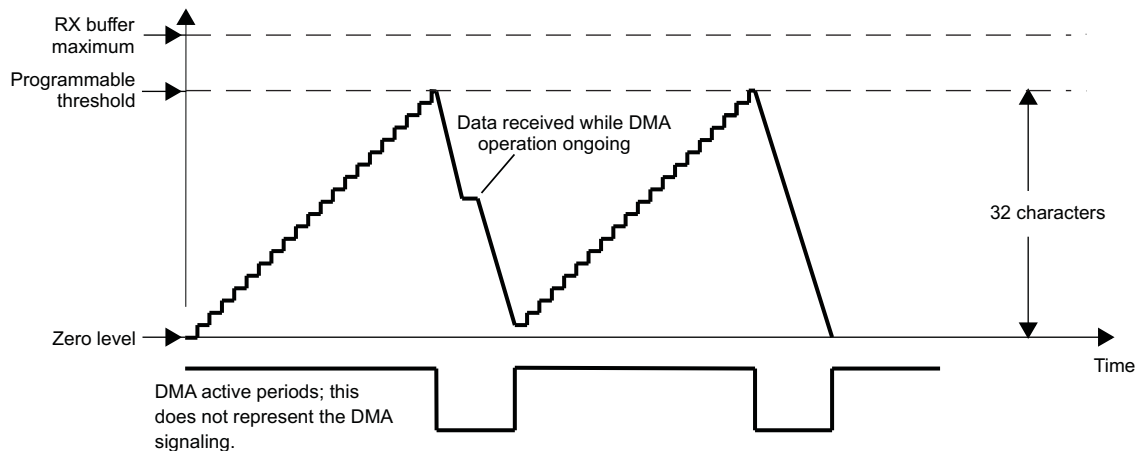

NOTE: There can be RX DATA loss during the next steps if all DATA was not read out or there was an ongoing reception!

- B. Set the UARTI.UART_FCR[2:1]DMA_MODE bit field to 11 (clear TX and RX FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO).
- C. Set the UARTI.UART_SCR[2:1]DMA_MODE_2 bit field to 10 (DMA mode 2, RX only).
- D. Set the UARTI.UART_FCR[2:1]DMA_MODE bit field to 11 (clear TX and RX FIFO and the DMA request again).
- E. Set the UARTI.UART_SCR[2:1] DMA_MODE_2 bit field to 00 (no DMA) or keep 10 if RX DMA is needed.

19.2.4.6.4.2 DMA Transfers (DMA Mode 1, 2, or 3)

Figure 19-34 through Figure 19-37 show the supported DMA operations.

Figure 19-34. Receive FIFO DMA Request Generation (32 Characters)

uart-026

In receive mode, a DMA request is generated when the RX FIFO reaches its threshold level defined in the trigger level register (UARTi.UART_TLR). This request is deasserted when the number of bytes defined by the threshold level is read by the device DMA controllers.

In transmit mode, a DMA request is automatically asserted when the TX FIFO is empty. This request is deasserted when the number of bytes defined by the number of spaces in the UARTi.UART_TLR register is written by the device DMA controllers. If an insufficient number of characters is written, the DMA request stays active.

Figure 19-35. Transmit FIFO DMA Request Generation (56 Spaces)

uart-027

The DMA request is again asserted if the FIFO can receive the number of bytes defined by the UARTi.UART_TLR register.

The threshold can be programmed in a number of ways. Figure 19-35 shows a DMA transfer operating with a space setting of 56 that can arise from using the auto settings in the UARTi.UART_FCR[5:4] TX_FIFO_TRIG bit field or the UARTi.UART_TLR[3:0] TX_FIFO_TRIG_DMA bit field concatenated with the TX_FIFO_TRIG bit field.

The setting of 56 spaces in the UART module must correlate with the settings of the device DMA controllers, so that the buffer does not overflow (program the DMA request size of the LH controller to equal the number of spaces in the UART module).

Figure 19-36 shows an example with eight spaces to show the buffer level crossing the space threshold. The LH DMA controller settings must correspond to those of the UART module.

Figure 19-36. Transmit FIFO DMA Request Generation (8 Spaces)

uart-028

The next example shows the setting of one space that uses the DMA for each transfer of one character to the transmit buffer (see Figure 19-37). The buffer is filled faster than the baud rate at which data is transmitted to the TX pin. Eventually, the buffer is completely full and the DMA operations stop transferring data to the transmit buffer.

On two occasions, the buffer holds the maximum amount of data words; shortly after this, the DMA is disabled to show the slower transmission of the data words to the TX pin. Eventually, the buffer is emptied at the rate specified by the baud rate settings of the UARTi.UART_DLL and UARTi.UART_DLH registers.

The DMA settings must correspond to the system LH DMA controller settings to ensure correct operation of this logic.

Figure 19-37. Transmit FIFO DMA Request Generation (1 Space)

uart-029

The final example illustrates the setting of eight spaces but setting the TX DMA threshold directly by setting `UART_MDR3[1] NONDEFAULT_FREQ` bit and `UART_TX_DMA_THRESHOLD` register (see Figure 19-38). In the example, `UART_TX_DMA_THRESHOLD[5:0] TX_DMA_THRESHOLD = 3` and the trigger level is 8. The buffer is filled at a faster rate than the BAUD rate transmits data to the TX pin. The buffer is filled with 8 bytes and the DMA operations stop transferring data to the transmit buffer. When the buffer is emptied to the threshold level by transmission, the DMA operation activates again to fill the buffer with 8 bytes.

Eventually, the buffer will be emptied at the rate specified by the BAUD Rate settings of the `UART_DLL` and `UART_DLH` registers.

If the selected threshold level + trigger level exceeds max buffer size, then the original TX DMA threshold method is used to prevent TX overrun, regardless of the `UART_MDR3[1] NONDEFAULT_FREQ` value.

The DMA settings should correspond to the system Local Host DMA controller settings in order to ensure the correct operation of this logic.

Figure 19-38. Transmit FIFO DMA Request Generation Using Direct TX DMA Threshold Programming. (Threshold = 3; Spaces = 8)

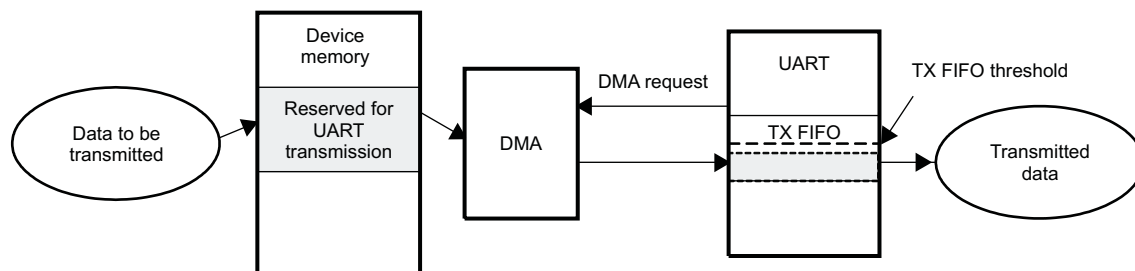

uart-036

19.2.4.6.4.3 DMA Transmission

Figure 19-39 shows DMA transmission.

Figure 19-39. DMA Transmission

uart-030

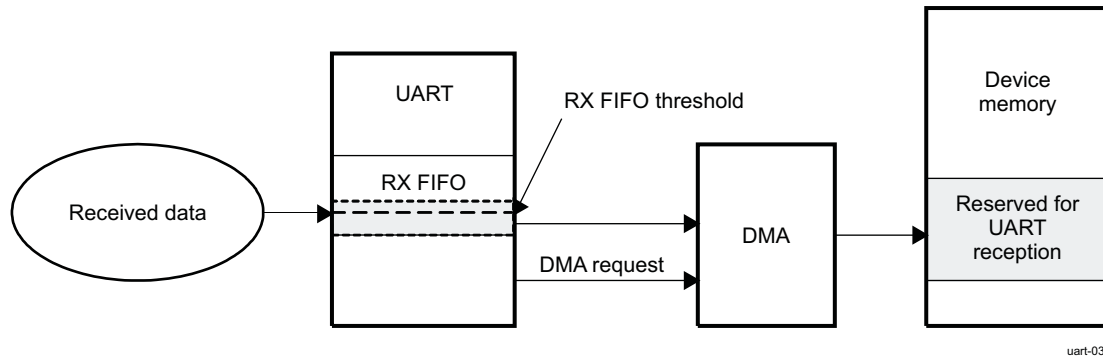

1. Data to be transmitted are put in the device memory reserved for UART transmission by the DMA:

- a. Until the TX FIFO trigger level is not reached, a DMA request is generated
- b. An element (1 byte) is transferred from the SDRAM to the TX FIFO at each DMA request (DMA element synchronization).
2. Data in the TX FIFO are automatically transmitted.
3. The end of the transmission is signaled by the UARTi.UART_THR empty (TX FIFO empty).

19.2.4.6.4.4 DMA Reception

Figure 19-40 shows DMA reception.

Figure 19-40. DMA Reception

1. Enable the reception.
2. Received data are put in the RX FIFO.
3. Data are transferred from the RX FIFO to the device memory by the DMA:
 - a. At each received byte, the RX FIFO trigger level (one character) is reached and a DMA request is generated.
 - b. An element (1 byte) is transferred from the RX FIFO to the SDRAM at each DMA request (DMA element synchronization).
4. The end of the reception is signaled by the EOF interrupt.

19.2.4.7 Mode Selection

19.2.4.7.1 Register Access Modes

19.2.4.7.1.1 Operational Mode and Configuration Modes

Register access depends on the register access mode, although register access modes are not correlated to functional mode selection. Three different modes are available:

- Operational mode
- Configuration mode A
- Configuration mode B

Operational mode is the selected mode when the function is active; serial data transfer can be performed in this mode.

Configuration mode A and configuration mode B are used during module initialization steps. These modes enable access to configuration registers, which are hidden in the operational mode. The modes are used when the module is inactive (no serial data transfer processed) and only for initialization or reconfiguration of the module.

The value of the UARTi.UART_LCR register determines the register access mode (see [Table 19-97](#)).

Table 19-97. UART Register Access Mode Programming (Using UART_LCR)

Mode	Condition
Configuration mode A	UART_LCR[7] = 0x1 and UART_LCR[7:0] != 0xBF
Configuration mode B	UART_LCR[7] = 0x1 and UART_LCR[7:0] = 0xBF
Operational mode	UART_LCR[7] = 0x0

19.2.4.7.1.2 Register Access Submode

In each access register mode (operational mode or configuration mode A/B), some register accesses are conditional on the programming of a submode (MSR_SPR, TCR_TLR, and XOFF). These registers are identified in [Table 19-116](#), *UART Register Manual*.

[Table 19-98](#) through [Table 19-100](#) summarize the register access submodes.

Table 19-98. Subconfiguration Mode A Summary

Mode	Condition
MSR_SPR	(UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0)
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1

Table 19-99. Subconfiguration Mode B Summary

Mode	Condition
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1
XOFF	(UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0)

Table 19-100. Suboperational Mode Summary

Mode	Condition
MSR_SPR	UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1

19.2.4.7.2 UART Mode Selection

To select a mode, set the UARTi.UART_MDR1[2:0] MODE_SELECT bit field (see [Table 19-101](#)).

Table 19-101. UART Mode Selection

Value	Mode
0x0:	UART 16x mode
0x1:	Reserved
0x2:	UART 16x auto-baud
0x3:	UART 13x mode
0x4:	Reserved
0x5:	Reserved
0x6:	Reserved
0x7:	Disable (default state)

MODE_SELECT is effective when the module is in operational mode (see [Section 19.2.4.7.1](#), *Register Access Modes*).

19.2.4.7.2.1 Registers Available for the UART Function

Only the registers listed in [Table 19-102](#) are used for the UART function.

Table 19-102. UART Mode Register Overview

Address Offset	Registers					
	Configuration Mode A		Configuration Mode B		Operational Mode	
	Read	Write	Read	Write	Read	Write

19.2.4.8 Protocol Formatting

19.2.4.8.1 UART Mode

19.2.4.8.1.1 UART Clock Generation: Baud Rate Generation

The UART function contains a programmable baud generator and a set of fixed dividers that divide the 48-MHz clock input down to the expected baud rate.

Figure 19-41 shows the baud rate generator and associated controls.

Figure 19-41. Baud Rate Generation

CAUTION

Before initializing or modifying clock parameter controls (UARTi.UART_DLH, UARTi.UART_DLL), MODE_SELECT = DISABLE (UARTi.UART_MDR1[2:0]) must be set to 0x7. Failure to observe this rule can result in unpredictable module behavior.

19.2.4.8.1.2 Choosing the Appropriate Divisor Value

Two divisor values are:

- UART 16x mode: Divisor value = Operating frequency / (16x baud rate)
- UART 13x mode: Divisor value = Operating frequency / (13x baud rate)

Table 19-103 and Table 19-104 describe the UART baud rate settings.

Table 19-103. UART Baud Rate Settings (48-MHz Clock)

19.2.4.8.1.3 UART Data Formatting

The UART can use hardware flow control to manage transmission and reception. Hardware flow control significantly reduces software overhead and increases system efficiency by automatically controlling serial data flow using the RTS output and CTS input signals.

The UART is enhanced with the autobauding function. In control mode, autobauding lets the speed, the number of bits per character, and the parity selected be set automatically.

19.2.4.8.1.3.1 Frame Formatting

When autobauding is not used, frame format attributes must be defined in the UARTi.UART_LCR register.

Character length is specified using the UARTi.UART_LCR[1:0] CHAR_LENGTH bit field.

The number of stop-bits is specified using the UARTi.UART_LCR[2] NB_STOP bit.

The parity bit is programmed using the UARTi.UART_LCR[5:3] PARITY_EN, PARITY_TYPE_1, and PARITY_TYPE_2 bit fields (see [Table 19-105](#)).

Table 19-105. UART Parity Bit Encoding

PARITY_EN	PARITY_TYPE_1	PARITY_TYPE_2	Parity
0	N/A	N/A	No parity
1	0	0	Odd parity
1	1	0	Even parity
1	0	1	Forced 1
1	1	1	Forced 0

19.2.4.8.1.3.2 Hardware Flow Control

Hardware flow control is composed of auto-CTS and auto-RTS. Auto-CTS and auto-RTS can be enabled and disabled independently by programming the UARTi.UART_EFR[7:6] AUTO_CTS_EN and AUTO_RTS_EN bit fields, respectively.

With auto-CTS, `uarti_ctsn` must be active before the module can transmit data.

Auto-RTS activates the `uarti_rtsn` output only when there is enough room in the RX FIFO to receive data. It deactivates the `uarti_rtsn` output when the RX FIFO is sufficiently full. The HALT and RESTORE trigger levels in the UARTi.UART_TCR register determine the levels at which `uarti_rtsn` is activated and deactivated.

If auto-CTS and auto-RTS are enabled, data transmission does not occur unless the RX FIFO has empty space. Thus, overrun errors are eliminated during hardware flow control. If auto-CTS and auto-RTS are not enabled, overrun errors occur if the transmit data rate exceeds the RX FIFO latency.

- Auto-RTS:

Auto-RTS data flow control originates in the receiver block. The RX FIFO trigger levels used in auto-RTS are stored in the UARTi.UART_TCR register. `uarti_rtsn` is active if the RX FIFO level is below the HALT trigger level in the UARTi.UART_TCR[3:0] RX_FIFO_TRIG_HALT bit field. When the RX FIFO HALT trigger level is reached, `uarti_rtsn` is deasserted. The sending device (for example, another UART) can send an additional byte after the trigger level is reached because it may not recognize the deassertion of RTS until it begins sending the additional byte.

`uarti_rtsn` is automatically reasserted when the RX FIFO reaches the RESUME trigger level programmed by the UARTi.UART_TCR[7:4] RX_FIFO_TRIG_START bit field. This reassertion requests the sending device to resume transmission.

In this case, `uarti_rtsn` is an active-low signal.

- Auto-CTS:

The transmitter circuitry checks `uarti_ctsn` before sending the next data byte. When `uarti_ctsn` is active, the transmitter sends the next byte. To stop the transmitter from sending the next byte, `uarti_ctsn` must be deasserted before the middle of the last stop-bit currently sent.

The auto-CTS function reduces interrupts to the host system. When auto-CTS flow control is enabled, the `uarti_ctsn` state changes do not have to trigger host interrupts because the device automatically controls its own transmitter. Without auto-CTS, the transmitter sends any data present in the transmit FIFO, and a receiver overrun error can result.

In this case, `uarti_ctsn` is an active-low signal.

19.2.4.8.1.3.3 Software Flow Control

Software flow control is enabled through the enhanced feature register (UARTi.UART_EFR) and the modem control register (UARTi.UART_MCR). Different combinations of software flow control can be enabled by setting different combinations of the UARTi.UART_EFR[3:0] bit field (see Table 19-106).

Two other enhanced features relate to software flow control:

- XON-any function (UARTi.UART_MCR[5]): Operation resumes after receiving any character after the XOFF character is recognized. If special character detect is enabled and special character is received after XOFF1, it does not resume transmission. The special character is stored in the RX FIFO.

NOTE: The XON-any character is written into the RX FIFO even if it is a software flow character.

- Special character (UARTi.UART_EFR[5]): Incoming data is compared to XOFF2. When the special character is detected, the XOFF interrupt (UARTi.UART_IIR[4]) is set, but it does not halt transmission. The XOFF interrupt is cleared by a read of UARTi.UART_IIR. The special character is transferred to the RX FIFO. Special character does not work with XON2, XOFF2, or sequential XOFFs.

Table 19-106. UART_EFR[3:0] Software Flow Control Options

Bit 3	Bit 2	Bit 1	Bit 0	TX, RX Software Flow Controls
0	0	X	X	No transmit flow control
1	0	X	X	Transmit XON1, XOFF1
0	1	X	X	Transmit XON2, XOFF2

Table 19-106. UART_EFR[3:0] Software Flow Control Options (continued)

Bit 3	Bit 2	Bit 1	Bit 0	TX, RX Software Flow Controls
1	1	X	X	Transmit XON1, XON2: XOFF1, XOFF2 ⁽¹⁾
X	X	0	0	No receive flow control
X	X	1	0	Receiver compares XON1, XOFF1
X	X	0	1	Receiver compares XON2, XOFF2
X	X	1	1	Receiver compares XON1, XON2: XOFF1, XOFF2 ⁽¹⁾

⁽¹⁾ In these cases, the XON1 and XON2 characters or the XOFF1 and XOFF2 characters must be transmitted/received sequentially with XON1/XOFF1 followed by XON2/XOFF2.
 XON1 is defined in the UARTi.UART_XON1_ADDR1[7:0] XON_WORD1 bit field. XON2 is defined in the UARTi.UART_XON2_ADDR2[7:0] XON_WORD2 bit field.
 XOFF1 is defined in the UARTi.UART_XOFF1[7:0] XOFF_WORD1 bit field. XOFF2 is defined in the UARTi.UART_XOFF2[7:0] XOFF_WORD2 bit field.

19.2.4.8.1.3.3.1 Receive (RX)

When software flow control operation is enabled, the UART compares incoming data with XOFF1/2 programmed characters (in certain cases, XOFF1 and XOFF2 must be received sequentially). When the correct XOFF characters are received, transmission stops after transmission of the current character completes. Detection of XOFF also sets the UARTi.UART_IIR[4] bit (if enabled by UARTi.UART_IER[5]) and causes the interrupt line to go low.

To resume transmission, an XON1/2 character must be received (in certain cases, XON1 and XON2 must be received sequentially). When the correct XON characters are received, the UARTi.UART_IIR[4] bit is cleared and the XOFF interrupt disappears.

NOTE: When a parity, framing, or break error occurs while receiving a software flow control character, this character is treated as normal data and is written to the RX FIFO.

When XON-any and special character detect are disabled and software flow control is enabled, no valid XON or XOFF characters are written to the RX FIFO. For example, when UARTi.UART_EFR[1:0] = 0x2, if XON1 and XOFF1 characters are received, they are not written to the RX FIFO.

When pairs of software flow characters are programmed to be received sequentially (UARTi.UART_EFR[1:0] = 0x3), the software flow characters are not written to the RX FIFO if they are received sequentially. However, received XON1/XOFF1 characters must be written to the RX FIFO if the subsequent character is not XON2/XOFF2.

19.2.4.8.1.3.3.2 Transmit (TX)

Two XOFF1 characters are transmitted when the RX FIFO passes the trigger level programmed by UARTi.UART_TCR[3:0]. As soon as the RX FIFO reaches the trigger level programmed by UARTi.UART_TCR[7:4], two XON1 characters are sent, so the data transfer recovers.

NOTE: If software flow control is disabled after an XOFF character is sent, the module transmits XON characters automatically to enable normal transmission.

The transmission of XOFF(s)/XON(s) follows the same protocol as transmission of an ordinary byte from the TX FIFO. This means that even if the word length is 5, 6, or 7 characters, the 5, 6, or 7 LSBs of XOFF1/2 and XON1/2 are transmitted. The 5, 6, or 7 bits of a character are seldom transmitted, but this function is included to maintain compatibility with earlier designs.

It is assumed that software flow control and hardware flow control are never enabled simultaneously.

19.2.4.8.1.3.4 Autobauding Modes

In autobauding mode, the UART can extract transfer characteristics (speed, length, and parity) from an "at" (AT) command (ASCII code). These characteristics are used to receive data after an AT and to send data.

The following AT commands are valid:

```

AT      DATA  <CR>
at      DATA  <CR>
A/
a/

```

A line break during the acquisition of the sequence AT is not recognized, and an echo function is not implemented in hardware.

A/ and a/ are not used to extract characteristics, but they must be recognized because of their special meaning. A/ or a/ is used to instruct the software to repeat the last received AT command; therefore, an a/ always follows an AT, and transfer characteristics are not expected to change between an AT and an a/.

When a valid AT is received, AT and all subsequent data, including the final <CR> (0x0D), are saved to the RX FIFO. The autobaud state-machine waits for the next valid AT command. If an a/ (A/) is received, the a/ (A/) is saved in the RX FIFO and the state-machine waits for the next valid AT command.

On the first successful detection of the baud rate, the UART activates an interrupt to signify that the AT (upper or lower case) sequence is detected. The UARTi.UART_UASR register reflects the correct settings for the baud rate detected. Interrupt activity can continue in this fashion when a subsequent character is received. Therefore, it is recommended that the software enable the RHR interrupt when using the autobaud mode.

The following settings are detected in autobaud mode with a module clock of 48 MHz:

- Speed:
 - 115.2K baud
 - 57.6K baud
 - 38.4K baud
 - 28.8K baud
 - 19.2K baud
 - 14.4K baud
 - 9.6K baud
 - 4.8K baud
 - 2.4K baud
 - 1.2K baud
- Length: 7 or 8 bits
- Parity: Odd, even, or space

NOTE: The combination of 7-bit character plus space parity is not supported.

Autobauding mode is selected when the UARTi.UART_MDR1[2:0] MODE_SELECT bit field is set to 0x2. In UART autobauding mode, UARTi.UART_DLL, UARTi.UART_DLH, and UARTi.UART_LCR[5:0] bit field settings are not used; instead, UASR is updated with the configuration detected by the autobauding logic.

UASR Autobauding Status Register Use

This register is used to set up transmission according to the characteristics of the previous reception instead of the UARTi.UART_LCR, UARTi.UART_DLL, and UARTi.UART_DLH registers when the UART is in autobauding mode.

To reset the autobauding hardware (to start a new AT detection) or to set the UART in standard mode (no autobaud), the UARTi.UART_MDR1[2:0] MODE_SELECT bit field must be set to reset state (0x7) and then to the UART in autobauding mode (0x2) or to the UART in standard mode (0x0).

Use limitation:

- Only 7- and 8-bit characters (5- and 6-bit not supported)
- 7-bit character with space parity not supported
- Baud rate between 1200 and 115,200 bps (10 possibilities)

19.2.4.8.1.3.5 Error Detection

When the UARTi.UART_LSR register is read, the UARTi.UART_LSR[4:2] bit field reflects the error bits (BI: break condition, FE: framing error, PE: parity error) of the character at the top of the RX FIFO (the next character to be read). Therefore, reading the UARTi.UART_LSR register and then reading the UARTi.UART_RHR register identifies errors in a character.

Reading the UARTi.UART_RHR register updates the BI, FE, and PE bits (see Table 19-94 for the UART mode interrupts).

The UARTi.UART_LSR[7] RX_FIFO_STS bit is set when there is an error in the RX FIFO and is cleared only when no errors remain in the RX FIFO.

NOTE: Reading the UARTi.UART_LSR register does not cause an increment of the RX FIFO read pointer. The RX FIFO read pointer is incremented by reading the UARTi.UART_RHR register.

Reading the UARTi.UART_LSR register clears the OE bit if it is set (see Table 19-94 for the UART mode interrupts).

19.2.4.8.1.3.6 Overrun During Receive

Overrun during receive occurs if the RX state-machine tries to write data into the RX FIFO when it is already full. When overrun occurs, the device interrupts the CPU with the UARTi.UART_IIR[5:1] IT_TYPE bit field set to 0x3 (receiver line status error) and discards the remaining portion of the frame.

Overrun also causes an internal flag to be set, which disables further reception. Before the next frame can be received, the CPU must:

- Reset the RX FIFO.
- Read the UARTi.UART_RESUME register, which clears the internal flag.

19.2.4.8.1.3.7 Time-Out and Break Conditions

19.2.4.8.1.3.7.1 Time-Out Counter

An RX idle condition is detected when the receiver line (uarti_rxd) is high for a time that equals 4x the programmed word length + 12 bits. uarti_rxd is sampled midway through each bit.

For sleep mode, the counter is reset when there is activity on uarti_rxd.

For the time-out interrupt, the counter counts only when there is data in the RX FIFO, and the count is reset when there is activity on uarti_rxd or when the UARTi.UART_RHR register is read.

19.2.4.8.1.3.7.2 Break Condition

When a break condition occurs, uarti_txd is pulled low. A break condition is activated by setting the UARTi.UART_LCR[6] BREAK_EN bit. The break condition is not aligned on word stream (a break condition can occur in the middle of a character). The only way to send a break condition on a full character is:

1. Reset the TX FIFO (if enabled).
2. Wait for the transmit shift register to empty (the UARTi.UART_LSR[6] TX_SR_E bit is set to 1).

3. Take a guard time according to stop-bit definition.
4. Set the BREAK_EN bit to 1.

The break condition is asserted while the BREAK_EN bit is set to 1.

19.2.5 UART Basic Programming Model

This section describes the procedure for operating the UART with FIFO and DMA or interrupts. This three-part procedure ensures the quick start of the UART. It does not cover every UART feature.

The first programming model covers software reset of the UART. The second programming model describes FIFO and DMA configuration. The last programming model describes protocol, baud rate, and interrupt configuration.

NOTE: Each programming model can be used independently of the other two; for instance, reconfiguring the FIFOs and DMA settings only.

Each programming model can be executed starting from any UART register access mode (register modes, submodes, and other register dependencies). However, if the UART register access mode is known before executing the programming model, some steps that enable or restore register access are optional. For more information, see [Section 19.2.4.7.1, Register Access Modes](#).

19.2.5.1 Global Initialization

19.2.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the UART module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the UART.

For more information, see [Section 19.2.3, UART Integration](#).

Table 19-107. Global Initialization of Surrounding Modules for UART

Surrounding Modules	Comments
PRCM	UART functional and interface clocks must be enabled. For more information, see Chapter 3, Power, Reset, and Clock Management .
Control module	Module-specific pad muxing must be set in the control module. For more information, see Chapter 14, Control Module .
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description , in Chapter 14, Control Module
Interrupt controllers	Device INTCs must be configured to enable the interrupt request generation. For information about enabling interrupts, see Chapter 13, Interrupt Controllers .
DMA_CROSSBAR	DMA_CROSSBAR configuration must be done to allow module DREQs to be mapped to certain device DMA line. For more information see Section 14.4.6.4, DMA_CROSSBAR Module Functional Description , in Chapter 14, Control Module .
DMA controllers	DMA controllers configuration must be done to enable the module DMA channel request.
Interconnects	For information about the L4 interconnect configuration, see Chapter 10, Interconnect .

19.2.5.1.2 UART Module Global Initialization

The procedure in [Table 19-108](#) can be used to initialize UART when performing software reset.

Table 19-108. UART Global Initialization

Step	Register/Bit Field/Programming Model	Value
Perform a software reset.	UART_SYSC[1] SOFTRESET	0x1
Wait until reset is finished.	UART_SYSS[0] RESETDONE	= 0x1

19.2.5.2 Mode selection

The [Table 19-109](#) describes how to set different register access mode.

Table 19-109. Configure register access mode

Step	Register/Bit Field/Programming Model	Value
Set the register access mode A	UART_LCR[7]DIV_EN	0x1
	UART_LCR[7:0]	!=0xBF
Set the register access mode B	UART_LCR[7:0]	0xBF
Set the operational mode	UART_LCR[7]DIV_EN	0x1

19.2.5.3 Submode selection

This section describes how to set different register access submode.

Table 19-110. Configure register access submode TCR_TLR

Step	Register/Bit Field/Programming Model	Value
Configure the submode TCR_TLR		
Configure mode B	see Table 19-109	
Enable writing to register bits UART_MCR[7:5]	UART_EFR[4]ENHANCED_EN	0x1
Configure mode A	see Table 19-109	0x1
Set the submode TCR_TLR	UART_MCR[6]TCR_TLR	0x1

Table 19-111. Configure register access submode MSR_SPR

Step	Register/Bit Field/Programming Model	Value
First option configure the submode MSR_SPR		
Configure mode B	see Table 19-109	
Set the submode MSR_SPR	UART_EFR[4]ENHANCED_EN	0x0
Second option configure the submode MSR_SPR		
Configure mode B	see Table 19-109	
Enable writing to register bits UART_MCR[7:5]	UART_EFR[4]ENHANCED_EN	0x1
Set the submode MSR_SPR	UART_MCR[6]TCR_TLR	0x0

Table 19-112. Configure register access submode XOFF

Step	Register/Bit Field/Programming Model	Value
Configuration of the XOFF		
Configure B	see Table 19-109	
Set the submode XOFF	UART_EFR[4] ENHANCED_EN	0x0

19.2.5.4 Load FIFO trigger and DMA mode settings

19.2.5.4.1 DMA mode Settings

To enable and configure the DMA mode, perform the following steps:

Table 19-113. DMA mode settings

Step	Register/Bit Field/Programming Model	Value
Set the option of DMA mode configuration.	UART_SCR[0] DMA_MODE_CTL	0x-
IF Configure DMA mode 0 and 1	UART_SCR[0] DMA_MODE_CTL	0x0
Select the DMA mode, for more information see Section 19.2.4.6.4	UART_FCR[3] DMA_MODE	0x-
IF Configure DMA mode from 0 to 3	UART_SCR[0] DMA_MODE_CTL	0x1
Select the DMA mode, for more information see Section 19.2.4.6.4	UART_SCR[2:1] DMA_MODE_2	0x-

19.2.5.4.2 FIFO Trigger Settings

In this section is described configuration and settings of FIFO trigger level, which enable DMA and interrupt generation.

Table 19-114. Load FIFO triggers defined by the FCR

Step	Register/Bit Field/Programming Model	Value
Configure register submodule TCR_TLR	see Table 19-110	0x-
Set the desire RX FIFO trigger level	UART_FCR[5:4] TX_FIFO_TRIG	0x-
Set the desire TX FIFO trigger level	UART_FCR[7:6] RX_FIFO_TRIG	0x-

Table 19-115. Load FIFO triggers defined by the TLR

Step	Register/Bit Field/Programming Model	Value
Configure register submodule TCR_TLR	see Table 19-110	0x-
Set the desire RX FIFO trigger level	UART_TLR[7:4] RX_FIFO_TRIG_DMA	0x-
Set the desire TX FIFO trigger level	UART_TLR[3:0] TX_FIFO_TRIG_DMA	0x-

Table 19-116. Load FIFO triggers defined by the concatenated value

Step	Register/Bit Field/Programming Model	Value
Configure register submodule TCR_TLR	see Table 19-110	0x-
Set the register bit	UART_SCR[7] RX_TRIG_GRANU1	0x1
Set the desire RX FIFO trigger level	UART_TLR[7:4] RX_FIFO_TRIG_DMA UART_FCR[7:6] RX_FIFO_TRIG	0x-
Set the register bit	UART_SCR[6] TX_TRIG_GRANU1	0x1
Set the desire TX FIFO trigger level	UART_TLR[3:0] TX_FIFO_TRIG_DMA UART_FCR[5:4] TX_FIFO_TRIG	0x-

19.2.5.5 Protocol, Baud rate and interrupt settings

19.2.5.5.1 Baud rate settings

Table 19-117. Baud rate settings

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2:0] MODE_SELECT	0x7
Switch to register configuration mode B	see Table 19-109	
Enable access to UART_IER[7:4]	UART_EFR[4] ENHANCED_EN	0x1
Switch register operational mode	see Table 19-109	
Disable sleep mode	UART_IER[4] SLEEP_MODE	0x0
Switch to register configuration mode A or B	see Table 19-109	
Set the appropriate divisor value	UART_DLL[7:0] CLOCK_LSB UART_DLH[5:0] CLOCK_MSB	0x-

19.2.5.5.2 Interrupt settings

Table 19-118. Interrupt settings

Step	Register/Bit Field/Programming Model	Value
Switch to register configuration mode B	see Table 19-109	0x7
Enable access to UART_IER[7:4]	UART_EFR[4] ENHANCED_EN	
Switch register operational mode	see Table 19-109	
Set the desired interrupt configuration (0: Disable the interrupt; 1: Enable the interrupt)	UART_IER[7] CTS_IT UART_IER[6] RTS_IT UART_IER[5] XOFF_IT UART_IER[4] SLEEP_MODE UART_IER[3] MODEM_STS_IT UART_IER[2] LINE_STS_IT UART_IER[1] THR_IT UART_IER[0] RHR_IT	0x-

19.2.5.5.3 Protocol settings

Load the desired protocol formatting (parity, stop-bit, character length) and switch to register operational mode.

Table 19-119. Protocol settings

Step	Register/Bit Field/Programming Model	Value
Load desired protocol formatting, see Section 19.2.4.8.1.3.1 , <i>Frame Formatting</i>	UART_LCR[5] PARITY_TYPE_2 UART_LCR[4] PARITY_TYPE_1 UART_LCR[3] PARITY_EN UART_LCR[2] NB_STOP UART_LCR[1:0] PARITY_LENGTH	0x-
Switch to register operational mode	UART_LCR[7] DIV_EN UART_LCR[6] BREAK_EN	0x0

19.2.5.5.4 UART Mode Selection

Table 19-120. UART mode selection

Step	Register/Bit Field/Programming Model	Value
Load the desired UART mode, see Section 19.2.4.7.2, UART Mode Selection	UART_MDR1[2:0] MODE_SELECT	0x-

19.2.5.6 Hardware and Software Flow Control Configuration

This section describes the programming steps to enable and configure hardware and software flow control. Hardware and software flow control cannot be used at the same time.

19.2.5.6.1 Hardware Flow Control Configuration

Table 19-121. Hardware Flow Control Configuration

Step	Register/Bit Field/Programming Model	Value
Configure register submode TCR_TLR	see Table 19-110	0x7
Load the start and halt trigger value.	UART_TCR[7:4] AUTO_RTS_START UART_TCR[3:0] AUTO_RTS_HALT	0x-
Enable or disable receive and transmit hardware flow control mode.	UART_EFR[7] AUTO_CTS_EN UART_EFR[6] AUTO_RTS_EN	0x-

19.2.5.6.2 Software Flow Control Configuration

Table 19-122. Software Flow Control Configuration

Step	Register/Bit Field/Programming Model	Value
Set the register access submode XOFF	see Table 19-112	
Load the software control characters	UART_XON1_ADDR1[7:0] XON_WORD1 UART_XON2_ADDR2[7:0] XON_WORD2 UART_XOFF1[7:0] XOFF_WORD1 UART_XOFF2[7:0] XOFF_WORD2	0x-
Set the register access submode TCR_TLR	see Table 19-110	
Enable or disable XON any function (0: Disable; 1: Enable).	UART_MCR[5] XON_EN	0x-
Load start and halt trigger value for software flow control	UART_TCR[7:4] AUTO_RTS_START UART_TCR[3:0] AUTO_RTS_HALT	0x-
Enable or disable special character function(0: Disable; 1: Enable)	UART_EFR[5] SPEC_CHAR	0x-
Set the software flow control mode	UART_EFR[3:0] SW_FLOW_CONTROL	0x-

19.2.6 UART Register Manual

19.2.6.1 UART Instance Summary

Table 19-123. UART Instance Summary

Module Name	Module Base Address	Size
UART1	0x4806 A000	136 Bytes
UART2	0x4806 C000	136 Bytes
UART3	0x4802 0000	136 Bytes

19.2.6.2.2 UART Register Description

Table 19-125. UART_THR

Address Offset	0x0000 0000		
Physical Address	0x4806 A000 0x4806 C000 0x4802 0000	Instance	UART1 UART2 UART3
Description	The transmitter section consists of the transmit holding register (THR) and the transmit shift register. The THR is a 64-byte FIFO. The local host (LH) writes data to the THR. The data is placed in the transmit shift register where it is shifted out serially on the TX output. If the FIFO is disabled, location 0 of the FIFO stores the data.		
Type	W		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																THR															

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Write has no effect.	W	0x000000
7:0	THR	Transmit holding register	W	0x-

Table 19-127. UART_RHR

Address Offset	0x0000 0000		
Physical Address	0x4806 A000 0x4806 C000 0x4802 0000	Instance	UART1 UART2 UART3
Description	The receiver section consists of the receiver holding register (RHR) and the receiver shift register. The RHR is a 64-byte FIFO. The receiver shift register receives serial data from RX input. The data is converted to parallel data and moved to the RHR. If the FIFO is disabled, location 0 of the FIFO stores the single data character. Note: If an overflow occurs, the data in the RHR is not overwritten.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																RHR															

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Read returns 0	R	0x000000
7:0	RHR	Receive holding register	R	0x-

Table 19-137. UART_FCR

Address Offset	0x0000 0008		
Physical Address	0x4806 A008 0x4806 C008 0x4802 0008	Instance	UART1 UART2 UART3
Description	FIFO control register		
	Notes: Bits 4 and 5 can only be written to when UART_EFR[4] = 1. Bits 0 and 3 can be changed only when the baud clock is not running (DLL and DLH set to 0). See Table 19-95 for UART_FCR[5:4] setting restriction when UART_SCR[6] = 1. See Table 19-96 for UART_FCR[7:6] setting restriction when UART_SCR[7] = 1.		
Type	W		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																							RX_FIFO_TRIG	TX_FIFO_TRIG	DMA_MODE	TX_FIFO_CLEAR	RX_FIFO_CLEAR	FIFO_EN			

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Write has no effect.	W	0x000000
7:6	RX_FIFO_TRIG	Sets the trigger level for the RX FIFO: If UART_SCR[7] = 0 and UART_TLR[7:4] = 0000: 00: 8 characters 01: 16 characters 10: 56 characters 11: 60 characters If UART_SCR[7] = 0 and UART_TLR[7:4] != 0000, RX_FIFO_TRIG is not considered. If UART_SCR[7] = 1, RX_FIFO_TRIG is 2 LSBs of the trigger level (1-63 on 6 bits) with the granularity 1.	W	0x0

Bits	Field Name	Description	Type	Reset
5:4	TX_FIFO_TRIG	Sets the trigger level for the TX FIFO: If UART_SCR[6] = 0 and UART_TLR[3:0] = 0000: 00: 8 spaces 01: 16 spaces 10: 32 spaces 11: 56 spaces If UART_SCR[6] = 0 and UART_TLR[3:0] != 0000, TX_FIFO_TRIG is not considered. If UART_SCR[6] = 1, TX_FIFO_TRIG is 2 LSBs of the trigger level (1-63 on 6 bits) with the granularity 1	W	0x0
3	DMA_MODE	This register is considered if UART_SCR[0] = 0. Write 0x0: DMA_MODE 0 (No DMA) Write 0x1: DMA_MODE 1 (UART_nDMA_REQ[0] in TX (UARTi_DREQ_TX), UART_nDMA_REQ[1] in RX (UARTi_DREQ_RX))	W	0
2	TX_FIFO_CLEAR	Write 0x0: No change Write 0x1: Clears the TX FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO.	W	0
1	RX_FIFO_CLEAR	Write 0x0: No change Write 0x1: Clears the RX FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO.	W	0
0	FIFO_EN	Write 0x0: Disables the transmit and RX FIFOs. The transmit and receive holding registers are 1-byte FIFOs. Write 0x1: Enables the transmit and RX FIFOs. The transmit and receive holding registers are 64-byte FIFOs.	W	0

Address Offset	0x0000 0008	Instance	UART1 UART2 UART3
Physical Address	0x4806 A008 0x4806 C008 0x4802 0008		
Description	Enhanced feature register This register enables or disables enhanced features.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																AUTO_CTS_EN		AUTO_RTS_EN		SPECIAL_CHAR_DETECT		ENHANCED_EN		SW_FLOW_CONTROL							

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Read returns 0. Write has no effect.	RW	0x000000
7	AUTO_CTS_EN	Auto-CTS enable bit 0x0: Normal operation 0x1: Auto-CTS flow control is enabled. Transmission is halted when the CTS* pin is high (inactive).	RW	0
6	AUTO_RTS_EN	Auto-RTS enable bit 0x0: Normal operation 0x1: Auto-RTS flow control is enabled. RTS* pin goes high (inactive) when the RX FIFO HALT trigger level, UART_TCR [3:0], is reached, and goes low (active) when the RX FIFO RESTORE transmission trigger level is reached.	RW	0
5	SPECIAL_CHAR_DETECT	0x0: Normal operation 0x1: Special character detect enable. Received data is compared with XOFF2 data. If a match occurs, the received data is transferred to the RX FIFO and the UART_IIR [4] bit is set to 1 to indicate that a special character was detected.	RW	0
4	ENHANCED_EN	Enhanced functions write enable bit 0x0: Disables writing to IER bits 4-7, UART_FCR bits 4-5, and UART_MCR bits 5-7. 0x1: Enables writing to IER bits 4-7, UART_FCR bits 4-5, and UART_MCR bits 5-7.	RW	0
3:0	SW_FLOW_CONTROL	Combinations of software flow control can be selected by programming bit 3 - bit 0. See Table 19-106 .	RW	0x0

Address Offset	0x0000 0018		
Physical Address	0x4806 A018 0x4806 C018 0x4802 0018	Instance	UART1 UART2 UART3
Description	Transmission control register This register stores the RX FIFO threshold levels to start/stop transmission during hardware/software flow control. Notes: Trigger levels from 0 to 60 bytes are available with a granularity of 4. (Trigger level = 4 x [4-bit register value]) The programmer must ensure that <code>UART_TCR[3:0] > UART_TCR[7:4]</code> when auto-RTS or software flow control is enabled to avoid a mis-operation of the device. In FIFO interrupt mode with flow control, the programmer must ensure that the trigger level to halt transmission is greater than or equal to the RX FIFO trigger level (<code>UART_TLR[7:4]</code> or <code>UART_FCR[7:6]</code>); otherwise, FIFO operation stalls. In FIFO DMA mode with flow control, this concept does not exist because a DMA request is sent each time a byte is received.

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Read returns 0.	R	0x000000
7	NCD_STS	This bit is the complement of the DCD* input. In loopback mode, it is equivalent to UART_MCR[3] .	R	-
6	NRI_STS	This bit is the complement of the RI* input. In loopback mode, it is equivalent to UART_MCR[2] .	R	-
5	NDSR_STS	This bit is the complement of the DSR* input. In loopback mode, it is equivalent to UART_MCR[0] .	R	-
4	NCTS_STS	This bit is the complement of the CTS* input. In loopback mode, it is equivalent to UART_MCR[1] .	R	-
3	DCD_STS	Indicates that DCD* input (or UART_MCR[3] in loopback) changed. Cleared on a read.	R	0
2	RI_STS	Indicates that RI* input (or UART_MCR[2] in loopback) changed state from low to high. Cleared on a read.	R	0
1	DSR_STS	Read 0x1: Indicates that DSR* input (or UART_MCR[0] in loopback) changed state. Cleared on a read.	R	0
0	CTS_STS	Read 0x1: Indicates that CTS* input (or UART_MCR[1] in loopback) changed state. Cleared on a read.	R	0

Table 19-163. UART_MDR1

Address Offset	0x0000 0020		
Physical Address	0x4806 A020 0x4806 C020 0x4802 0020	Instance	UART1 UART2 UART3
Description	Mode definition register 1 The mode of operation can be programmed by writing to MDR1[2:0] and therefore the MDR1 must be programmed on startup after configuration of the configuration registers (UART_DLL , UART_DLH , and UART_LCR). The value of MDR1[2:0] must not be changed again during normal operation. Note: If the module is disabled by setting the MODE_SELECT field to 111, interrupt requests can still be generated unless disabled through the interrupt enable register (UART_IER). In this case, UART mode interrupts are visible. Reading the interrupt identification register (UART_IIR) shows UART mode interrupt flags.

Address Offset	0x0000 0038	Instance	UART1 UART2 UART3
Physical Address	0x4806 A038 0x4806 C038 0x4802 0038		
Description	UART autobauding status register This status register returns the speed, the number of bits by characters, and the type of the parity in UART autobauding mode. In autobauding mode, the input frequency of the UART modem must be fixed to 48 MHz. Any other module clock frequency results in incorrect baud rate recognition. Note: When the UART is in autobauding mode, this register, instead of the UART_LCR , UART_DLL , and UART_DLH registers, is used to set up transmission according to the characteristics of the previous reception. To reset the autobauding hardware (to start a new AT detection), set UART_MDR1[2:0] to 111 (reset value), then set UART_MDR1[2:1] to 010 (UART in autobaud mode). To set the UART to standard mode (no autobaud), set UART_MDR1[2:1] to 000.

19.3 Multichannel Serial Peripheral Interface

This section describes the four Multichannel Serial Peripheral Interface (McSPI) modules for the device.

19.3.1 McSPI Overview

The SPI is a master/slave synchronous serial bus. There are four separate McSPI modules (McSPI1, McSPI2, McSPI3, and McSPI4) in the device (see Figure 19-42). All these four modules are able to work as both master and slave and support the following chip selects:

- McSPI1: spi1_cs[0], spi1_cs[1], spi1_cs[2], spi1_cs[3]
- McSPI2: spi2_cs[0], spi2_cs[1]
- McSPI3: spi3_cs[0], spi3_cs[1]
- McSPI4: spi4_cs[0]

Figure 19-42. Multichannel SPI Modules

mcspi-001

The McSPI modules include the following main features:

- Serial clock with programmable frequency, polarity, and phase for each channel
- Wide selection of SPI word lengths, ranging from 4 to 32 bits
- Up to four master channels, or single channel in slave mode
- Master multichannel mode:
 - Full duplex/half duplex
 - Transmit-only/receive-only/transmit-and-receive modes
 - Flexible input/output (I/O) port controls per channel
 - Programmable clock granularity
 - SPI configuration per channel. This means, clock definition, polarity enabling and word width
- Single interrupt line for multiple interrupt source events
- Power management through wake-up capabilities
- Enable the addition of a programmable start-bit for SPI transfer per channel (start-bit mode)
- Supports start-bit write command
- Supports start-bit pause and break sequence
- Programmable timing control between chip select and external clock generation
- Built-in FIFO available for a single channel

19.3.2 McSPI Environment

19.3.2.1 Basic McSPI Pins for Master Mode

Figure 19-43 shows all of the McSPI interface signals in master mode.

Figure 19-43. McSPI Interface Signals in Master Mode

(1) Direction depends on bits SPIDATDIR1 and SPIDATDIR0 in MCSPI_SYST

mcspi-006

Table 19-193 describes the McSPI I/O in master mode.

Table 19-193. McSPI I/O Description (Master Mode)

Device-Level Signal Name	Module Signal Name	I/O ⁽¹⁾	Description
spim_sclk	SPICLK	O	SPI _m module serial clock output
spim_d[0]	SPIDAT[0]	O ⁽²⁾	SPI Data I/O. Can be configured either as input or as output depending on MCSPI_SYST[8] SPIDATDIR0.
spim_d[1]	SPIDAT[1]	I ⁽²⁾	SPI Data I/O. Can be configured either as input or as output depending on MCSPI_SYST[9] SPIDATDIR1.
spim_cs[i]	SPIEN[x]	O	SPI _m module chip-select i output

⁽¹⁾ I = Input; O = Output

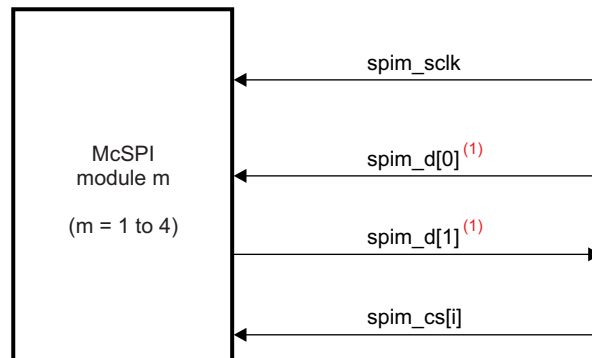

⁽²⁾ Example configuration only.

NOTE: For the spim_sclk signals to work properly, the INPUTENABLE bit of the appropriate CTRL_CORE_PAD_x registers should be set to 0x1 because of retiming purposes.

19.3.2.2 Basic McSPI Pins for Slave Mode

Figure 19-44 shows all of the McSPI interface signals in slave mode.

Figure 19-44. McSPI Interface Signals in Slave Mode

(1) Direction depends on bits SPIDATDIR1 and SPIDATDIR0 in MCSPI_SYST

mcspi-007

Table 19-194 describes the McSPI I/O in slave mode.

Table 19-194. McSPI I/O Description (Slave Mode)

Device-Level Signal Name	Module Signal Name	I/O ⁽¹⁾	Description
spim_sclk	SPICLK	I	McSPIm module serial clock input
spim_d[0]	SPIDAT[0]	I ⁽²⁾	SPI Data I/O. Can be configured either as input or as output depending on MCSPI_SYST[8] SPIDATDIR0.
spim_d[1]	SPIDAT[1]	O ⁽²⁾	SPI Data I/O. Can be configured either as input or as output depending on MCSPI_SYST[9] SPIDATDIR1.
spim_cs[i]	SPIEN[x]	I	McSPIm module chip-select i input. Can be selected through MCSPI_CH0CONF[22:21] SPIENSLV bit field

(1) I = Input; O = Output

(2) Example configuration only.

19.3.2.3 Multichannel SPI Protocol and Data Format

The synchronous SPI protocol allows a master device to initiate serial data transfers to a slave device. A slave select line (SPIEN[x]) allows selection of an individual slave SPI device. Slave devices that are not selected do not interfere with SPI bus activities.

McSPI offers the flexibility to modify the following parameters to adapt to the device features:

- **Word length**
 McSPI supports any SPI word ranging from 4 bits to 32 bits long (the MCSPI_CHxCONF[11:7] WL bit field).
 SPI word length can be changed between transmissions to allow the master device to communicate with peripheral slaves that have different requirements.
- **SPI enable (SPIEN[x], for channel x of instance m)**
 The polarity of the SPI enable signals is programmable (the MCSPI_CHxCONF[6] EPOL bit). SPIEN[x] signals can be active high or low.
 Assertion of the SPIEN[x] signals is programmable and can be done manually or automatically. The manual assertion mode is available in single master mode only. SPIEN[x] can be kept active between words with the MCSPI_CHxCONF[20] FORCE bit.
 Two consecutive words for two different slave devices can go along with active SPIEN[x] signals with different polarity.
- **Programmable start-bit**

In start-bit mode a start-bit is added before the SPI word length to indicate how the next SPI word must be handled. The start-bit is enabled by setting the `MCSPI_CHxCONF[23]` SBE bit to 1. The `MCSPI_CHxCONF[24]` SBPOL bit defines the polarity of the start-bit.

- Programmable SPI clock

- Bit rate

In master mode, the baud rate of the SPI serial clock is programmable using the 48-MHz reference clock (from the power, reset, and clock management [PRCM] module). [Table 19-195](#) lists the SPICLK bit rates obtained for data transfer when programming the clock divider (the `MCSPI_CHxCONF[5:2]` CLKD bit field).

Table 19-195. SPI Master Clock Rates

Divider	Clock Rate
1	48 MHz ⁽¹⁾
2	24 MHz ⁽¹⁾
4	12 MHz
8	6 MHz
16	3 MHz
32	1.5 MHz
64	750 kHz
128	375 kHz
256	~187 kHz
512	~93.7 kHz
1024	~46.8 kHz
2048	~23.4 kHz
4096	~11.7 kHz

⁽¹⁾ These frequencies are not necessarily supported by all SPI modules. For more information, see the *Timing Requirements and Switching Characteristics* chapter in the device data manual.

- Polarity and phase

The polarity (the `MCSPI_CHxCONF[1]` POL bit) and the phase (the `MCSPI_CHxCONF[0]` PHA bit) of the SPI serial clock (SPICLK) are configurable to offer four combinations. Software selects the right combination, depending on the device. See [Table 19-196](#) and [Figure 19-45](#).

Table 19-196. Phase and Polarity Combinations

Polarity (POL)	Phase (PHA)	SPI Mode	Description
0	0	Mode 0	SPICLK is inactive low and sampling occurs at the rising edge.
0	1	Mode 1	SPICLK is inactive low and sampling occurs at the falling edge.
1	0	Mode 2	SPICLK is inactive high and sampling occurs at the falling edge.
1	1	Mode 3	SPICLK is inactive high and sampling occurs at the rising edge.

Figure 19-45. Phase and Polarity Combinations

19.3.2.3.1 Transfer Format

In master and slave modes, the McSPI drives the data lines when SPIEN[x] is asserted.

Each word is transmitted starting with the most-significant bit (MSB).

This section explains the two cases of data transmission determined by the clock phase (PHA) and the type of data transmission using a start-bit (SBE) called the start-bit mode:

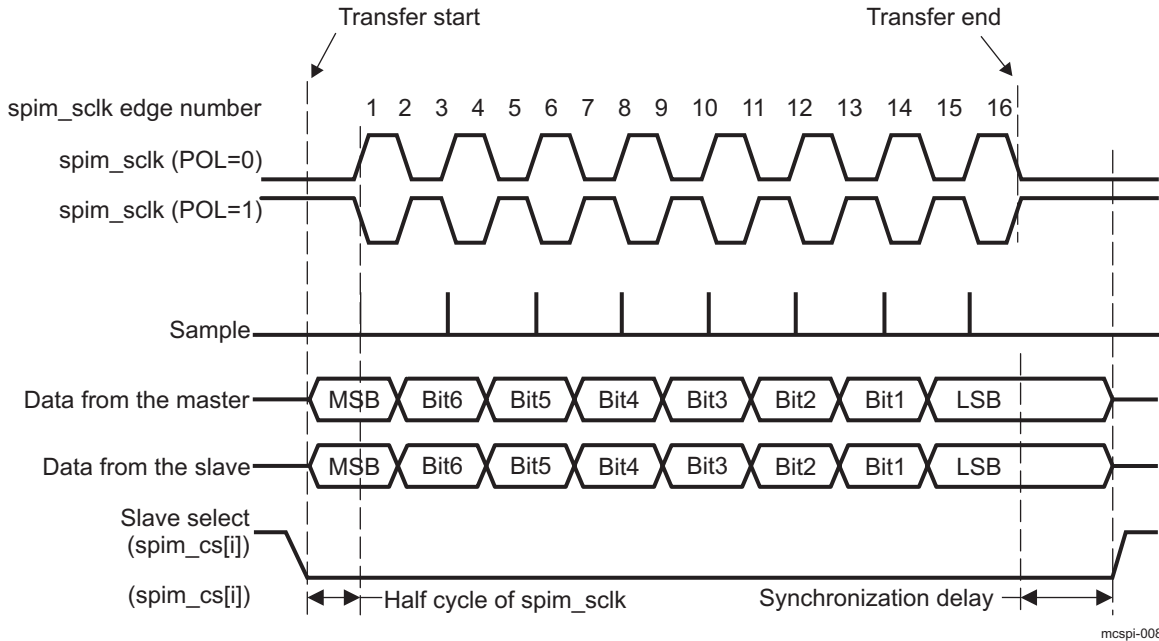

- Transmission in mode 0 and mode 2 (PHA = 0)

When PHA = 0, the first bit of the SPI word to transmit (on the master or the slave data output pin) is valid one-half cycle of SPICLK after the assertion of SPIEN.

Therefore, the first edge of the SPICLK line is used by the master to sample the first data bit sent by the slave. On the same edge, the first data bit sent by the master is sampled by the slave.

On the next SPICLK edge, the received data bit is shifted into the receive shift register and a new data bit is transmitted on the serial data line.

This process continues for a number of pulses on the SPICLK line defined by the SPI word length programmed in the master device, with data being latched on odd-numbered edges and shifted on even-numbered edges. See [Figure 19-46](#).

Figure 19-46. Full-Duplex Transfer Format With PHA = 0

- Transmission in mode 1 and mode 3 (PHA = 1)

When PHA = 1, the first bit of the SPI word to transmit (on the master or the slave data output pin) is valid on the following SPICLK edge (one-half cycle later). This is the sampling edge for the master and slave. A synchronization delay is added between the activation of SPIEN[x] and the first SPICLK edge. The received data bit is shifted into the shift register on the third SPICLK edge.

This process continues for a number of pulses on the SPICLK line defined by the SPI word length programmed in the master device, with data being latched on even-numbered edges and shifted on odd-numbered edges.

NOTE: The minimum synchronization delay is one cycle of SPICLK, if the frequency of SPICLK equals the frequency of SPI_m_FCLK (McSPI_m functional clock) in master mode. The minimum synchronization delay is one-half cycle of SPICLK, if the frequency of SPICLK is lower than the frequency of SPI_m_FCLK in the master and slave modes.

- Transmission with a start-bit (SBE = 1)

When the [MCSPI_CHxCONF\[23\]](#) SBE bit is set to 1, a start-bit is added before the MSB to indicate whether the next SPI word must be handled as a command or as data.

[Figure 19-47](#) shows an example of a data transfer with an extra start-bit.

Figure 19-47. Extended SPI Transfer With a Start-Bit (SBE = 1)

19.3.2.4 SPI in Master Mode

Figure 19-48 shows a case in master mode (full-duplex) where the McSPI module is connected with two slave devices.

Figure 19-48. McSPI Master Mode (Full Duplex)

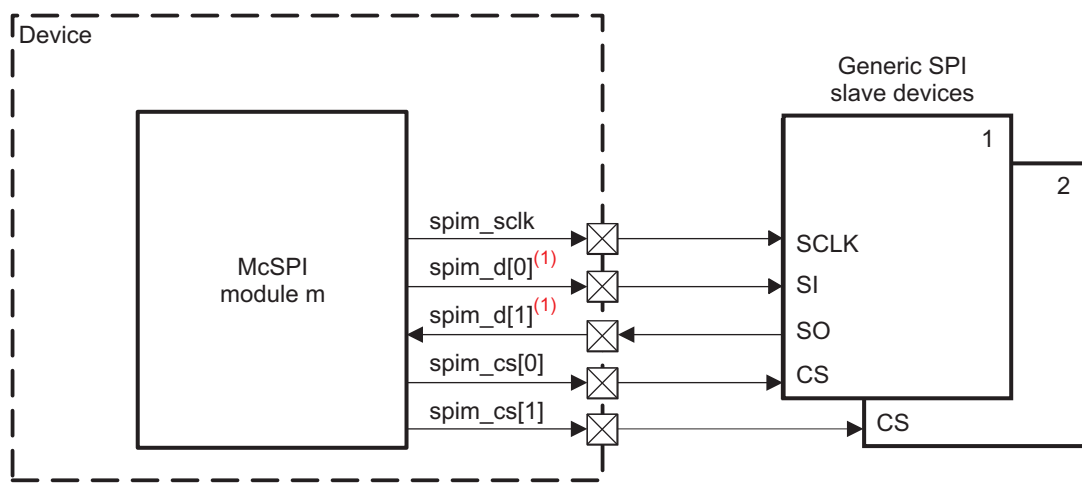

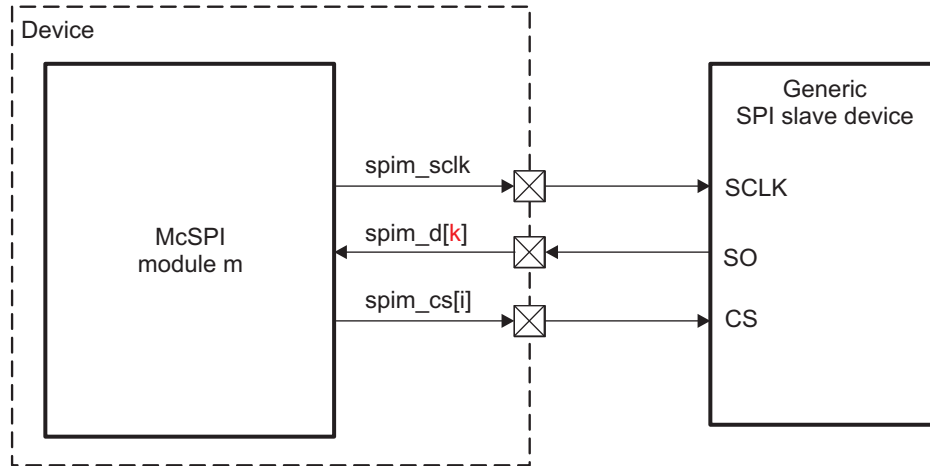

Figure 19-49 shows the master single mode, which can also be configured in receive-only mode.

Figure 19-49. McSPI Master Single Mode (Receive Only)

k = 0 or 1 depending on bits SPIDATDIR1 and SPIDATDIR0 in MCSPI_SYST

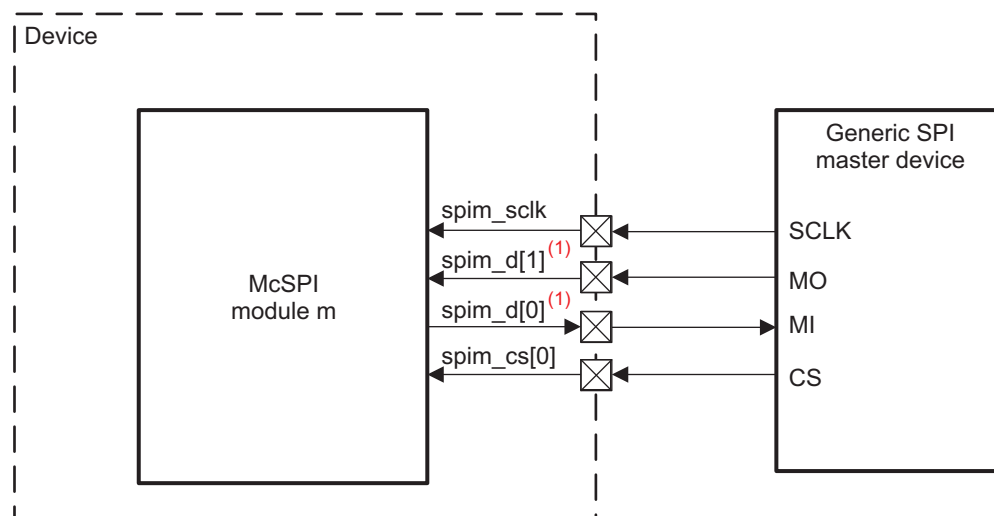

mcspi-003

19.3.2.5 SPI in Slave Mode

Figure 19-50 shows a case in slave mode (full-duplex).

NOTE: Only channel 0 can be configured as slave, but the chip-enable signal can be connected to any SPIEN[x] pin and then rerouted internally to channel 0 (the MCSPI_CHxCONF[22:21] SPIENSLV bit field [where x = 0]). For more information, see Section 19.3.4.4, *Slave Mode*.

Figure 19-50. McSPI Slave Mode (Full Duplex)

	MCSPI4_DREQ_RX0	DMA_CROSSBAR_71	-	McSPI module 4 - receive request channel 0
	MCSPI4_DREQ_TX1	DMA_CROSSBAR_177	-	McSPI module 4 - transmit request channel 1
	MCSPI4_DREQ_RX1	DMA_CROSSBAR_178	-	McSPI module 4 - receive request channel 1
	MCSPI4_DREQ_TX2	DMA_CROSSBAR_179	-	McSPI module 4 - transmit request channel 2
	MCSPI4_DREQ_RX2	DMA_CROSSBAR_180	-	McSPI module 4 - receive request channel 2
	MCSPI4_DREQ_TX3	DMA_CROSSBAR_181	-	McSPI module 4 - transmit request channel 3
	MCSPI4_DREQ_RX3	DMA_CROSSBAR_182	-	McSPI module 4 - receive request channel 3

NOTE: The Default Mapping column in [Table 19-199 McSPI Hardware Requests](#) shows the default mapping of module IRQ and DREQ source signals. These module IRQ and DREQ source signals can also be mapped to other lines of each device Interrupt or DMA controller through the IRQ_CROSSBAR and DMA_CROSSBAR modules, respectively. For more information about the IRQ_CROSSBAR module, see [Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#). For more information about the DMA_CROSSBAR module, see [Section 14.4.6.5, DMA_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#).

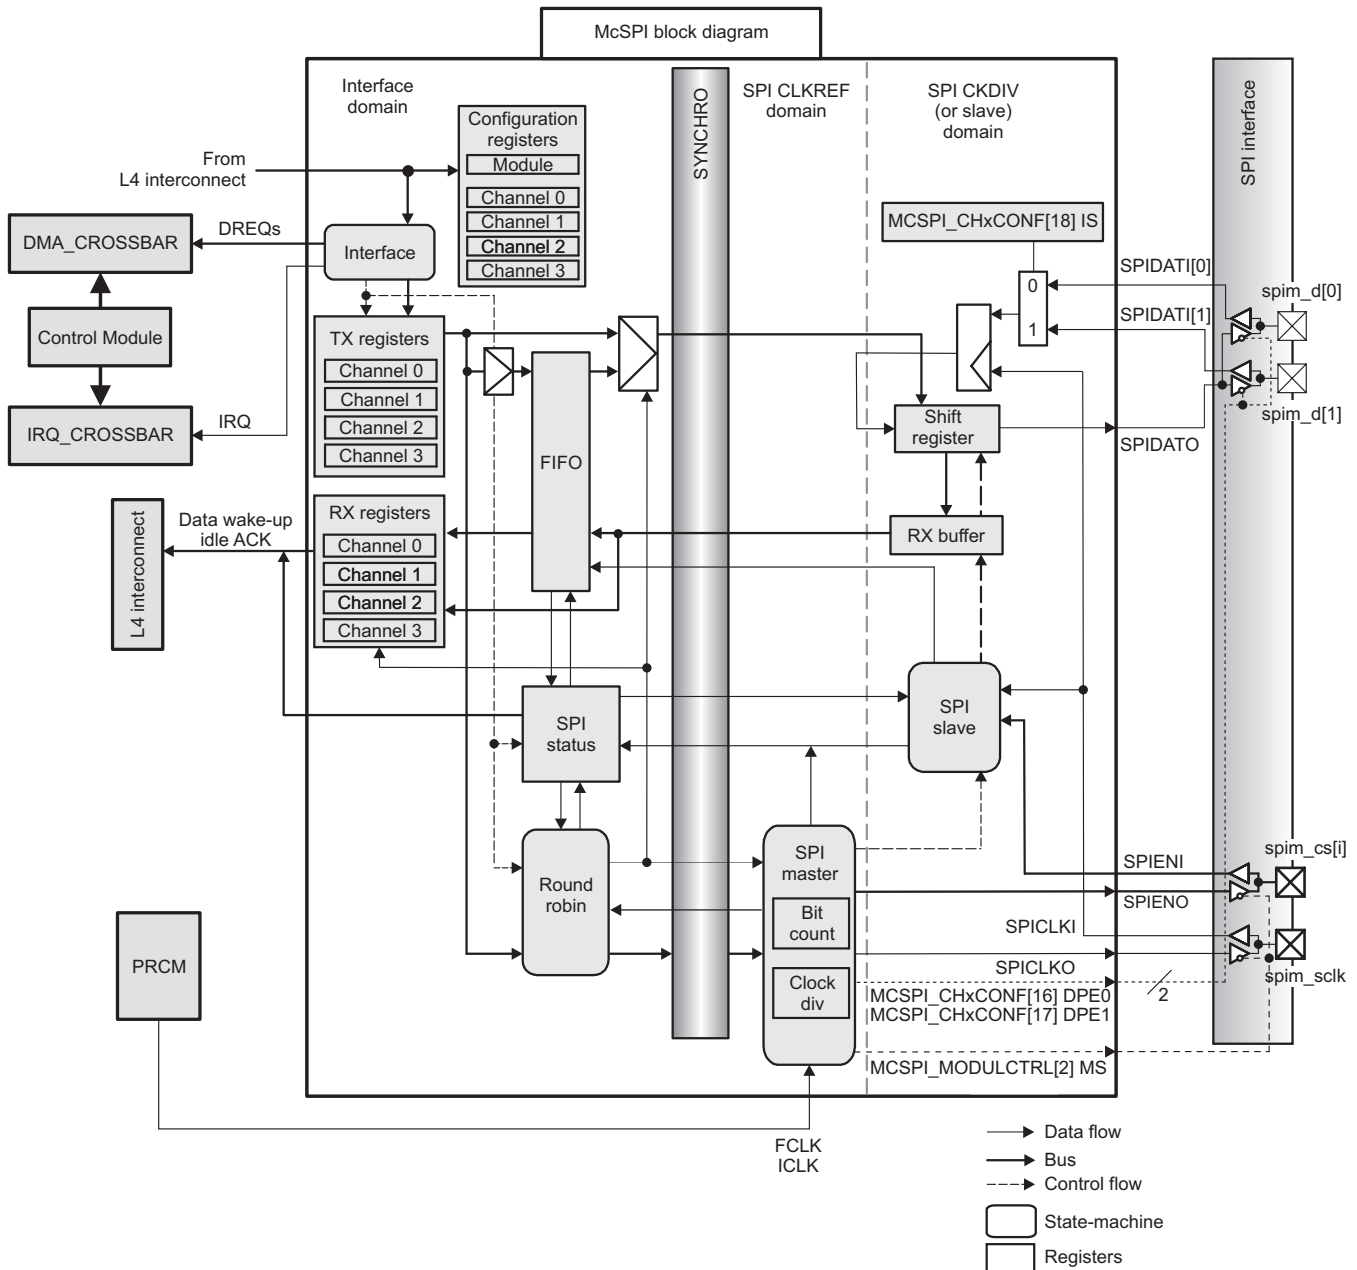

NOTE: For more information about the device interrupt controllers, see [Chapter 13, Interrupt Controllers](#). For more information about the device EDMA module, see [Chapter 12, Enhanced DMA](#).

19.3.4 McSPI Functional Description

19.3.4.1 McSPI Block Diagram

Figure 19-53 shows the McSPI module.

Figure 19-53. McSPI Block Diagram

19.3.4.2 Reset

The McSPI module can be reset either by hardware or by software reset. All configuration registers and all state machines are reset by the hardware reset signal (MCSPi_RST). McSPI can be reset by software through the [MCSPI_SYSCONFIG\[1\] SOFTRESET](#) bit. This bit has the same impact on the module as the hardware reset signal. The only exception is that the [MCSPI_SYSCONFIG](#) register is not affected by that software reset.

19.3.4.3 Master Mode

19.3.4.3.1 Master Mode Features

The McSPI master mode supports multichannel communication with up to four independent SPI communication channel contexts. The McSPI initiates a data transfer on the data lines (SPIDAT[0] and SPIDAT[1]) and generates clock (SPICLK) and control (SPIEN) signals.

Connected to multiple external devices, the McSPI exchanges data with one SPI device at a time through two main modes (available in slave mode):

- Two-data-pins interface mode (transmit-and-receive mode for full-duplex transmission)
- Single-data-pin interface mode (recommended for half-duplex transmission)

NOTE: There is a fixed chip select line allocation in multichannel master mode. Channel x SPIEN[x] is mapped to spim_cs[i] pin.

Two DMA request events (read and write) allow synchronized accesses of the DMA controller with the activity of McSPI.

Three interrupt events can be used for data transmission and reception in master mode (for more information about interrupts, see [Section 19.3.4.7.1, Interrupt Events in Master Mode](#)).

19.3.4.3.2 Master Transmit-and-Receive Mode (Full Duplex)

In full-duplex transmission, data is transmitted (shifted out serially on SPIDAT[0]) and received (shifted in serially on SPIDAT[1]) simultaneously on separate data lines.

The master transmit-and-receive mode is programmable per channel (the [MCSPI_CHxCONF\[13:12\]](#) TRM bit field).

Channel access to the shift registers for transmission/reception is based on the [MCSPI_TXx](#) transmitter register state, the [MCSPI_RXx](#) receiver register state, and round-robin arbitration.

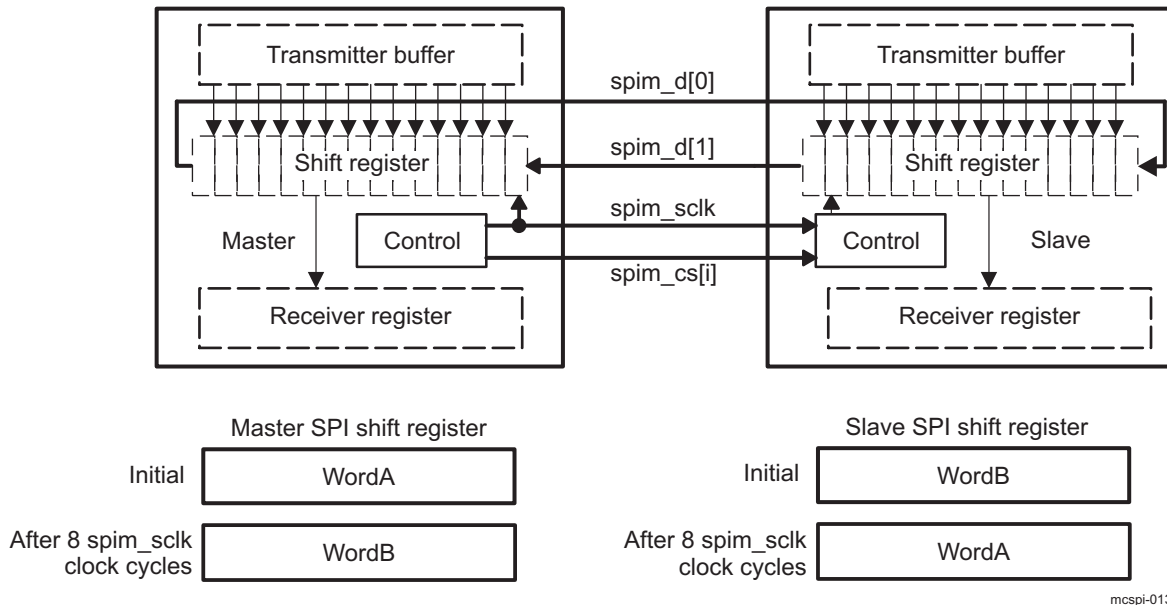

Channels that meet the following rules are included in the round-robin list of active channels scheduled for transmission and/or reception. The arbiter skips channels that do not meet the rules and searches in the rotation for the next enabled channel.

- **Rule 1:** Only enabled channels (the [MCSPI_CHxCTRL\[0\]](#) EN bit) can be scheduled for transmission and/or reception.
- **Rule 2:** If its [MCSPI_TXx](#) transmitter register is not empty (the [MCSPI_CHxSTAT\[1\]](#) TXS bit), an enabled channel can be scheduled when the shift register is assigned. If the [MCSPI_TXx](#) register is empty when the shift register is assigned, the [TXx_UNDERFLOW](#) event is activated, and the next enabled channel with new data to transmit is scheduled (see also transmit-only mode).
- **Rule 3:** An enabled channel can be scheduled if its receive register is not full (the [MCSPI_CHxSTAT\[0\]](#) RXS bit) when the shift register is assigned (see also receive-only mode). Therefore, the [MCSPI_RXx](#) register cannot be overwritten. The [SPI1.MCSPI_IRQSTATUS\[3\]](#) [RX0_OVERFLOW](#) bit is never set to this mode.

When SPI word transfer completes (the [MCSPI_CHxSTAT\[2\]](#) EOT bit is set), the updated [MCSPI_TXx](#) register of the next scheduled channel is loaded into the shift register. The serialization (transmit-and-receive) starts depending on the channel communication configuration. When serialization completes, the received data transfers to the channel receive register.

The serial clock (SPICLK) synchronizes shifting and sampling of the information on the two serial data lines (SPIDAT[0] and SPIDAT[1]). Each time a bit transfers out from the master, 1 bit transfers in from the slave.

[Figure 19-54](#) shows an example of a full-duplex system with a master device (McSPI module *m*) on the left and a slave device on the right. After eight cycles of the serial clock SPICLK, WordA transfers from the master to the slave. At the same time, WordB transfers from the slave to the master.

Figure 19-54. SPI Full-Duplex Transmission (Example)

19.3.4.3.3 Master Transmit-Only Mode (Half Duplex)

The master transmit-only mode prevents a device initiator from reading the `MCSPi_RXx` register (minimizing data movement) when only transmission is meaningful.

The master transmit-only mode is programmable per channel (the `MCSPi_CHxCONF[13:12]` TRM bit field). Transmission starts only after data is loaded into the `MCSPi_TXx` register.

Rule 1 and Rule 2, defined in Section 19.3.4.3.2, apply in this mode.

Rule 3, defined in Section 19.3.4.3.2, does not apply.

In master transmit-only mode, the `MCSPi_RXx` register state FULL does not prevent transmission and the `MCSPi_RXx` register is always overwritten with the new SPI word. This event is not significant when only transmission is meaningful. Thus, the `RX0_OVERFLOW` bit in the `MCSPi_IRQSTATUS` register is never set in this mode.

The hardware automatically disables the `RX_FULL` interrupt and the DMA read requests.

The transfer status is given by the `MCSPi_CHxSTAT[2]` EOT bit.

19.3.4.3.4 Master Receive-Only Mode (Half Duplex)

The master receive mode prevents a device initiator from refilling the `MCSPi_TXx` register (minimizing data movement) when only reception is meaningful.

The master receive mode is programmable per channel (the `MCSPi_CHxCONF[13:12]` TRM bit field).

The master receive-only mode enables channel scheduling only on the empty state of the `MCSPi_RXx` register.

Rule 1 and Rule 3, defined in Section 19.3.4.3.2, apply in this mode.

Rule 2, defined in Section 19.3.4.3.2, does not apply.

In the master receive-only mode, software must write dummy data to the `MCSPi_TXx` register. Only one dummy write is enough to receive any number of words from the slave. Software must ensure that the `MCSPi_TXx` register is always full (the `TXx_EMPTY` bits of `MCSPi_IRQSTATUS`) when receiving. The content of the `MCSPi_TXx` register is always loaded into the shift register when the shift register is assigned. After writing the dummy data to the `MCSPi_TXx` register, the `TXx_EMPTY` and `TXx_UNDERFLOW` bits in the `MCSPi_IRQSTATUS` register are never set in receive-only mode.

The [MCSPI_CHxSTAT\[2\]](#) EOT bit gives the status of serialization. The [RXx_FULL](#) bits of the [MCSPI_IRQSTATUS](#) register are set when received data is loaded from the shift register to the corresponding [MCSPI_RXx](#) register. The [MCSPI_IRQSTATUS\[3\]](#) [RX0_OVERFLOW](#) bit is never set in this mode.

19.3.4.3.5 Single-Channel Master Mode

When the McSPI is configured as a master device with a single enabled channel ([MCSPI_MODULCTRL\[2\]](#) [MS](#) = 0 and [MCSPI_MODULCTRL\[0\]](#) [SINGLE](#) = 1), the assertion of the [SPIEN\[x\]](#) signal is optional depending on device connected to the controller. In 3-pin mode ([MCSPI_MODULCTRL\[1\]](#) [PIN34](#) = 1) the controller starts transmitting data when a write to the [MCSPI_TXx](#) register or the FIFO is performed. In 4-pin mode ([MCSPI_MODULCTRL\[1\]](#) [PIN34](#) = 0) the assertion and de-assertion of [SPIEN\[x\]](#) is controlled by software using the [MCSPI_CHxCONF\[20\]](#) [FORCE](#) bit.

19.3.4.3.5.1 Programming Tips When Switching to Another Channel

When a single channel is enabled and data transfer is ongoing:

- Wait for the SPI word transfer to complete (wait until the [MCSPI_CHxSTAT\[2\]](#) EOT bit is set to 1) before disabling the current channel and enabling a different channel.
- Disable the current channel, and then enable the other channel.

19.3.4.3.5.2 Force SPIEN[x] Mode

Continuous transfers are allowed manually by keeping the [SPIEN\[x\]](#) signal active for successive SPI words transfer. Several sequences (configuration/enable/disable of the channel) can be run without deactivating the [SPIEN\[x\]](#) line. This mode is supported by all channels and any master sequence can be used (transmit-receive, transmit-only, receive-only).

Keeping the [SPIEN\[x\]](#) active mode is supported when:

- A single channel is used (with the [MCSPI_MODULCTRL\[0\]](#) [SINGLE](#) bit set to 1).
- Transfer parameters are loaded in the configuration register of the appropriate channel ([MCSPI_CHxCONF](#)).

The state of the [SPIEN\[x\]](#) signal is programmable:

- Writing 1 to the [MCSPI_CHxCONF\[20\]](#) [FORCE](#) bit drives the [SPIEN\[x\]](#) line high when the [MCSPI_CHxCONF\[6\]](#) [EPOL](#) bit is set to 0. [SPIEN\[x\]](#) is driven low when the [MCSPI_CHxCONF\[6\]](#) [EPOL](#) bit is set to 1.
- Writing 0 to the [MCSPI_CHxCONF\[20\]](#) [FORCE](#) bit drives the [SPIEN\[x\]](#) line low when the [MCSPI_CHxCONF\[6\]](#) [EPOL](#) bit is set to 0. [SPIEN\[x\]](#) is driven high when the [MCSPI_CHxCONF\[6\]](#) [EPOL](#) bit is set to 1.
- A single channel is enabled (the [MCSPI_CHxCTRL\[0\]](#) [EN](#) bit is set to 1). The first enabled channel activates the [SPIEN\[x\]](#) line.

When the channel is enabled, the [SPIEN\[x\]](#) signal activates with the programmed polarity. As in the multichannel master mode, the transfer start depends on the status of the [MCSPI_TXx](#) register (the [MCSPI_CHxSTAT\[1\]](#) [TXS](#) bit), the status of the [MCSPI_RXx](#) register (the [MCSPI_CHxSTAT\[1\]](#) [RXS](#) bit), and the defined mode (the [MCSPI_CHxCONF\[13:12\]](#) [TRM](#) bit field) of the channel enabled.

The [MCSPI_CHxSTAT\[2\]](#) EOT bit gives the transfer status of each SPI word. The [RXx_FULL](#) bit in the [MCSPI_IRQSTATUS](#) register is set when received data is loaded from the shift register to the [MCSPI_RXx](#) register.

A change in the configuration parameters is propagated directly on the SPI interface. If the [SPIEN\[x\]](#) signal is activated, ensure that the configuration is changed only between SPI words to avoid corrupting the current transfer.

NOTE: To avoid data corruption, [SPIEN](#) polarity and [SPICLK](#) phase and [SPICLK](#) polarity must not be modified when the [SPIEN\[x\]](#) signal is activated.

A delay between SPI words that requires the connected SPI slave device to switch from one configuration to another (for instance, from transmit-only to receive-only) must be handled by software.

At the end of the last SPI word, the channel must be deactivated (the `MCSPI_CHxCTRL[0]` EN bit set to 0) and `SPIEN[x]` can be forced to its INACTIVE state using the `MCSPI_CHxCONF[20]` FORCE bit.

Figure 19-55 and Figure 19-56 show successive transfers with `SPIEN[x]` maintained active low with a different configuration for each SPI word in single-data-pin and dual-data-pin interface modes, respectively.

Figure 19-55. Continuous Transfers With `SPIEN[x]` Maintained Active (Single-Data-Pin Interface Mode)

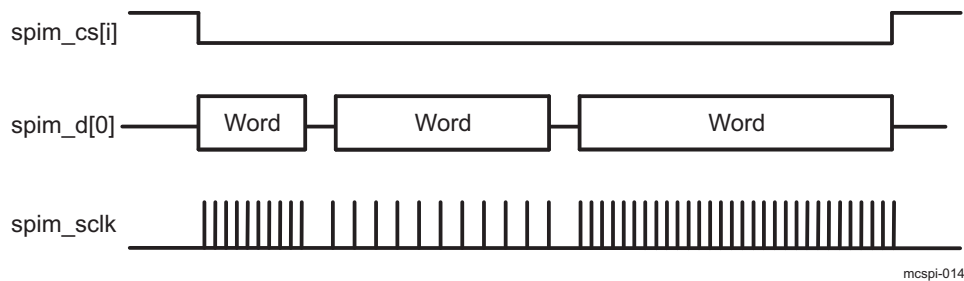

Figure 19-56. Continuous Transfers With `SPIEN[x]` Maintained Active (Dual-Data-Pin Interface Mode)

NOTE: The `SPIEN[x]` signal can be maintained active via software using the `MCSPI_CHxCONF[20]` FORCE bit only when the `MCSPI_MODULCTRL[0]` SINGLE bit is set to 0x1.

19.3.4.3.5.3 Turbo Mode

Turbo mode improves the throughput of the SPI interface when a single channel is enabled by allowing transfers until the shift register and the `MCSPI_RXx` register are full. Turbo mode is time saving when a transfer exceeds two words. This mode is programmable per channel (through the `SPI1.MCSPI_CHxCONF[9]` TURBO bit).

When several channels are enabled, the TURBO bit has no effect and the channel access to the shift registers remains as previously described.

In turbo mode, Rule 1 and Rule 2 apply, but Rule 3 does not (see Section 19.3.4.3.2, *Master Transmit-and-Receive Mode (Full Duplex)*). An enabled channel can be scheduled if its receive register is full (the `MCSPI_CHxSTAT[0]` RXS bit) when the shift-register is assigned until the shift register is full.

The `MCSPI_RXx` register cannot be overwritten in turbo mode. Consequently, the `MCSPI_IRQSTATUS[3]` RX0_OVERFLOW bit is never set in this mode.

19.3.4.3.6 Start-Bit Mode

In start-bit mode, an extended bit is added before the SPI word to indicate whether the next SPI word must be handled as a command or as data. This feature is available only in master mode. Start-bit mode cannot be used at the same time as turbo mode and/or force SPIEN[x] mode. In this case, only one channel can be used; round-robin arbitration is not possible.

This mode is programmable per channel by setting the [MCSPI_CHxCONF\[23\]](#) SBE bit to 1. The polarity of the extended bit is programmable per channel. When the [MCSPI_CHxCONF\[24\]](#) SBPOL bit is set to 0, the SPI word must be handled as a command. When the [MCSPI_CHxCONF\[24\]](#) SBPOL bit is set to 1, the SPI word must be handled as data. Moreover, start-bit polarity can be changed dynamically during start-bit transfer without disabling the channel for reconfiguration; in this case, users must configure the [MCSPI_CHxCONF\[24\]](#) SBPOL bit before writing the SPI word to be transmitted to the TX register.

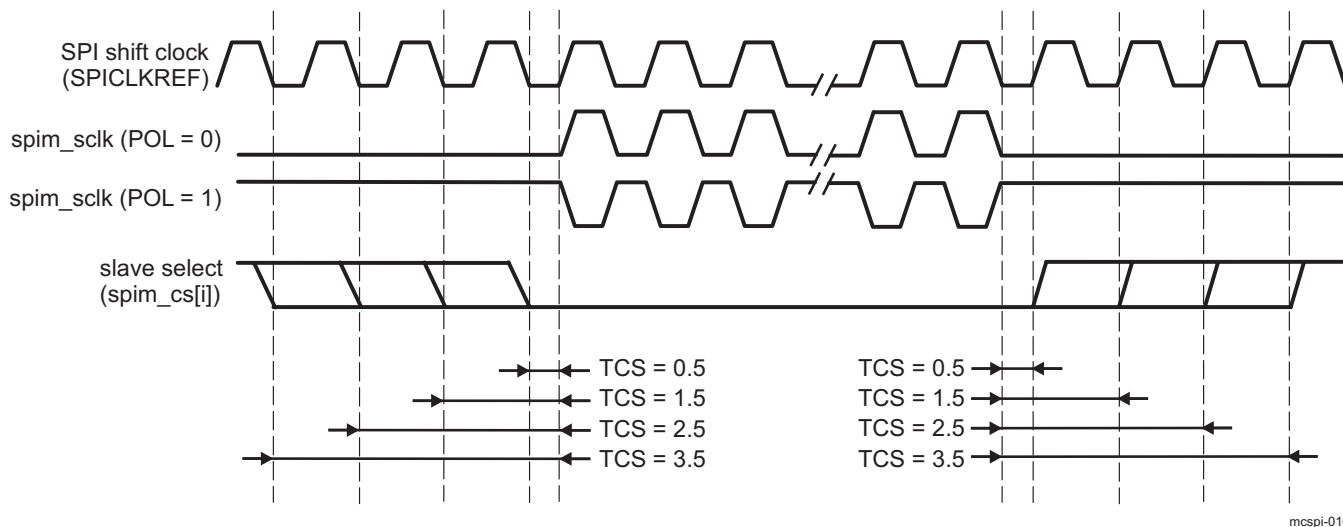

19.3.4.3.7 Chip-Select Timing Control

The chip-select (CS) timing control is available only in master mode with automatic CS generation (the [MCSPI_MODULCTRL\[0\]](#) SINGLE bit set to 0) to add a programmable delay between CS assertion and first clock edge, or CS removal and last clock edge. This option is available only in 4-pin mode when [MCSPI_MODULCTRL\[1\]](#) PIN34 set to 0.

This mode is programmable per channel through the [MCSPI_CHxCONF\[26:25\]](#) TCS0 bit field.

Figure 19-57 shows the CS SPIEN timing controls.

Figure 19-57. CS (SPIEN) Timing Controls

NOTE: Because of the design implementation for transfers using a clock divider ratio set to 1 (clock bypassed), a half cycle must be added to the value between CS assertion and the first clock edge with PHA = 1 or between CS removal and the last clock edge with PHA = 0.

19.3.4.3.8 Programmable SPI Clock

In master mode, the baud rate of the SPI serial clock is programmable.

An internal reference clock, SPIm_FCLK, is used as input of a programmable divider (the [MCSPI_CHxCONF\[5:2\]](#) CLKD bit field) to generate the bit rate of the serial output clock SPICLK. [Table 19-200](#) summarizes the supported divisor values.

Table 19-200. SPI Master Clock Rates

Divider	Clock Rate
1	48 MHz ⁽¹⁾
2	24 MHz ⁽¹⁾
4	12 MHz
8	6 MHz
16	3 MHz
32	1.5 MHz
64	750 kHz
128	375 kHz
256	~187 kHz
512	~93.7 kHz
1024	~46.8 kHz
2048	~23.4 kHz
4096	~11.7 kHz
8192 and higher: Division not supported	–

⁽¹⁾ These frequencies are not necessarily supported by all SPI modules. For more information, see the *Timing Requirements and Switching Characteristics* chapter in the device data manual.

19.3.4.3.8.1 Clock Ratio Granularity

By default, the clock division ratio is defined by the `MCSPI_CHxCONF[5:2]` CLKD bit field with power-of-2 granularity leading to a clock division in the range 1 to 4096; in this case, the duty cycle is always 50 percent. With the `MCSPI_CHxCONF[29]` CLKG bit, clock division granularity can be changed to one clock cycle; in that case the `MCSPI_CHxCTRL[15:8]` EXTCLK bit field is concatenated with the `MCSPI_CHxCONF[5:2]` CLKD bit field to give a 12-bit-wide division ratio in the range 1 to 4096.

When granularity is one clock cycle (the CLKG bit set to 1), for the odd value of the clock ratio, the clock high level lasts one clock cycle more than the low level, depending on the `MCSPI_CHxCONF[1]` POL and `MCSPI_CHxCONF[0]` PHA bits (see [Table 19-201](#)).

Table 19-201. CLKSPIO High/Low Time Computation

Clock Ratio F_{RATIO}	CLKSPIO High Time	CLKSPIO Low Time
1	T_{HIGH_REF}	T_{LOW_REF}
Even ≥ 2	$T_ref \times (F_{RATIO}/2)$	$T_ref \times (F_{RATIO}/2)$
Odd $\geq (POL = PHA)$	$T_ref \times (F_{RATIO} - 1)/2$	$T_ref \times (F_{RATIO} + 1)/2$
Odd $\geq (POL \neq PHA)$	$T_ref \times (F_{RATIO} + 1)/2$	$T_ref \times (F_{RATIO} - 1)/2$

NOTE: F_{RATIO} = SPICLK frequency (F_{OUT}) division ratio
 T_{HIGH} = SPICLK high time period
 T_{LOW} = SPICLK low time period
 T_ref = FCLK period
 T_{HIGH_REF} = FCLK high time period
 T_{LOW_REF} = FCLK low time period

If the CLKG bit is set to 1; F_{RATIO} = EXTCLK concatenated with CLKD + 1.

For odd ratio values, the duty cycle is calculated as follows:

$$\text{Duty_cycle} = (1 - 1/F_{RATIO})/2$$

[Table 19-202](#) shows examples of clock granularity with a clock source frequency of 48 MHz.

Table 19-202. Clock Granularity Examples

EXTCLK	CLKD	CLKG	F _{RATIO}	PHA	POL	T _{HIGH} (ns)	T _{LOW} (ns)	T _{PERIOD} (ns)	Duty Cycle	F _{OUT} (MHz)
X	0	0	1	X	X	10.4	10.4	20.8	50–50	48
X	1	0	2	X	X	20.8	20.8	41.6	50–50	24
X	2	0	4	X	X	41.6	41.6	83.2	50–50	12
X	3	0	8	X	X	83.2	83.2	166.4	50–50	6
0	0	1	1	X	X	10.4	10.4	20.8	50–50	48
0	1	1	2	X	X	20.8	20.8	41.6	50–50	24
0	2	1	3	1	0	41.6	20.8	62.4	66–33	16
0	2	1	3	1	1	20.8	41.6	62.4	33–66	16
0	3	1	4	X	X	41.6	41.6	83.2	50–50	12
5	0	1	81	1	0	852.8	832	1684.8	50.6–49.4	0.592
5	7	1	88	X	X	915.2	915.2	1830.4	50–50	0.545

19.3.4.4 Slave Mode

To select the McSPI slave mode, set the [MCSPI_MODULCTRL\[2\]](#) MS bit.

A McSPI slave device can be connected to up to four external SPI master devices but handles transactions with one SPI master device at a time.

In slave mode, the McSPI initiates data transfer on the data lines (SPIDAT[0] and SPIDAT[1]) when it is selected by an active control signal (SPIEN[x]) and receives an SPI clock (SPICLK) from the external SPI master device. Only channel 0 can be configured as a slave but through the [MCSPI_CH0CONF\[22:21\]](#) SPIENSLV bit field any of the SPIEN[x] signals can be used to select the McSPI module. In slave mode and when the [MCSPI_MODULCTRL\[1\]](#) PIN34 is set to 0x0 (default behavior), the McSPI uses the edge of SPIEN[x] to detect word length. For this reason, SPIEN[x] must become inactive between each word.

When the [MCSPI_MODULCTRL\[1\]](#) PIN34 is set to 0x0, the McSPI does not support SPIEN[x] active between SPI words. In this case, the McSPI uses the edge to detect word length.

When the [MCSPI_MODULCTRL\[1\]](#) PIN34 is set to 0x1, a multiword transfer can be performed without needing the external SPI master to deactivate SPIEN[x] between each word as in this case the McSPI module works in 3-pin slave mode and SPIEN[x] is not needed.

19.3.4.4.1 Dedicated Resources

Only channel 0 can be enabled in slave mode. In this section, register names such as [SPI1.MCSPI_CHxCTRL](#) stand for [SPI1.MCSPI_CH0CTRL](#), where x = 0 (channel 0 control register).

[Figure 19-58](#) shows an example of four slaves wired on a single master device.

Figure 19-58. Example of McSPI Slave With One Master and Multiple Slave Devices on Channel 0

(1) Direction depends on bits SPIDATDIR1 and SPIDATDIR0 in MCSPI_SYST

mcspi-017

Channel 0 in slave mode has the following resources:

- Its own channel enable, programmable with the [MCSPI_CHxCTRL\[0\] EN](#) bit (where $x = 0$). This channel must be enabled before transmission and reception.
- For this mode, the slave-select signal can be detected on any of the [SPIEN\[x\]](#) ports. This is programmable with the [MCSPI_CHxCONF\[22:21\] SPIENSLV](#) bit field (where $x = 0$).
- Its own transmitter register, [MCSPI_TXx](#) (where $x = 0$), on top of the common transmit shift register. If the [MCSPI_TXx](#) register is empty, the [MCSPI_CHxSTAT\[1\] TXS](#) bit (where $x = 0$) is set. If McSPI is selected by an external master (the active signal on the [SPIEN\[x\]](#) port assigned to channel 0), the [MCSPI_TXx](#) register content of channel 0 is always loaded into the shift register, whether its content is updated or not. The [MCSPI_TXx](#) register must be loaded before McSPI is selected by a master.
- Its own receiver register, [MCSPI_RXx](#) (where $x = 0$), on top of the common receive shift register. If the [MCSPI_RXx](#) register is full, the [MCSPI_CHxSTAT\[0\] RXS](#) bit (where $x = 0$) is set.

NOTE: The [MCSPI_TXx](#) and [MCSPI_RXx](#) registers of the other channels are not used. Reading from or writing to a channel register other than channel 0 has no effect.

- Its own communication configuration with the following parameters through the [MCSPI_CHxCONF](#) register (where $x = 0$):

- Transmit and receive modes, programmable with the TRM field
- Interface mode (two data pins or single data pin) and data pins assignment, both programmable with the IS and DPE bits. (The SPI modules are in slave mode after reset and must be properly configured for the modules to act in master mode.)
- SPI word length, programmable with the WL bits
- SPIEN[x] polarity, programmable with the EPOL bit
- SPICLK polarity, programmable with the POL bit
- SPICLK phase, programmable with the PHA bit

The SPICLK frequency of a transfer is controlled by the external SPI master connected to the McSPI slave device. The [MCSPI_CHxCONF\[5:2\] CLKD](#) bit field (where x = 0) is not used in slave mode.

NOTE: The configuration of the channel can be loaded in the [MCSPI_CHxCONF](#) register (where x = 0) only when the channel is disabled.

- Two DMA request events, read and write, synchronize read/write accesses of the DMA controller with the activity of McSPI. DMA requests are asserted using the [MCSPI_CHxCONF\[15\] DMAR](#) bit (where x = 0) for reading and the [MCSPI_CHxCONF\[14\] DMAW](#) bit (where x = 0) for writing.
- Four interrupt events (see [Section 19.3.4.7.2, Interrupt Events in Slave Mode](#))

19.3.4.4.2 Slave Transmit-and-Receive Mode

The slave receive mode is programmable (set the [MCSPI_CHxCONF\[13:12\] TRM](#) bit field [where x = 0] to 0x0).

In slave transmit-and-receive mode, the [MCSPI_TXx](#) register must be loaded before McSPI is selected by an external SPI master device.

After a channel is enabled, transmission and reception proceed with interrupt and DMA request events.

The [MCSPI_TXx](#) register content is always loaded in the shift register whether it is updated or not. The event TXx_UNDERFLOW is activated accordingly and does not prevent transmission.

When the SPI word transfer completes (the [MCSPI_CHxSTAT0\[2\] EOT](#) bit [where x = 0] is set to 1), the received data is transferred to the channel receive register.

To use McSPI as a slave transmit-only device, the RXx_FULL and RX0_OVERFLOW interrupts and DMA read requests must be disabled due to the state of the [MCSPI_RXx](#) register (see [Section 19.3.4.7.2, Interrupt Events in Slave Mode](#)).

19.3.4.4.3 Slave Transmit-Only Mode

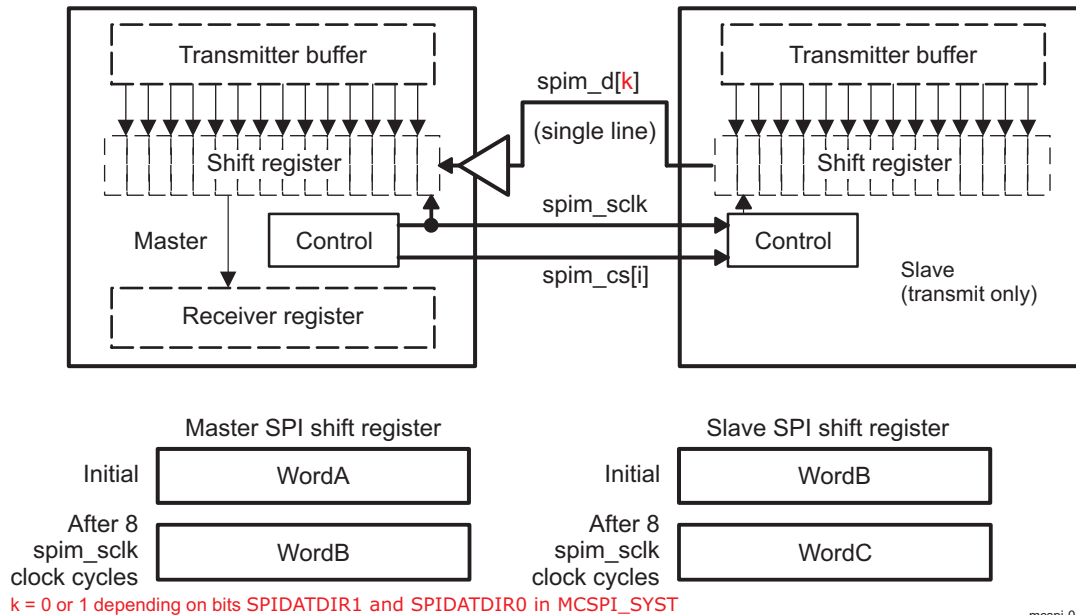

The slave transmit-only mode is programmable (set the [MCSPI_CHxCONF\[13:12\] TRM](#) bit field [where x = 0] to 0x2) and avoids the requirement for a device initiator to read the [MCSPI_RXx](#) register (minimizing data movement) only when transmission is meaningful.

To use the McSPI as a slave transmit-only device, the RXx_FULL and RX0_OVERFLOW interrupts and DMA read requests must be disabled due to the state of the [MCSPI_RXx](#) register.

When the SPI word transfer completes, the [MCSPI_CHxSTAT\[2\] EOT](#) bit is set (where x = 0).

[Figure 19-59](#) shows a half-duplex system with a master device on the left and a transmit-only slave device on the right. Each time a bit transfers out from the slave, 1 bit transfers in the master. After eight cycles of the serial clock SPICLK, WordB transfers from the slave to the master.

Figure 19-59. SPI Half-Duplex Transmission (Transmit-Only Slave)

mcspi-031

19.3.4.4.4 Slave Receive-Only Mode

The slave receive mode is programmable (set the `MCSPI_CHxCONF`[13:12] TRM bit field [where $x = 0$] to 0x1).

In receive-only mode, the `MCSPI_TXx` register must be loaded before the McSPI is selected by an external SPI master device. The `MCSPI_TXx` register content is always loaded into the shift register whether it is updated or not. The `TXx_UNDERFLOW` event is activated accordingly and does not prevent transmission.

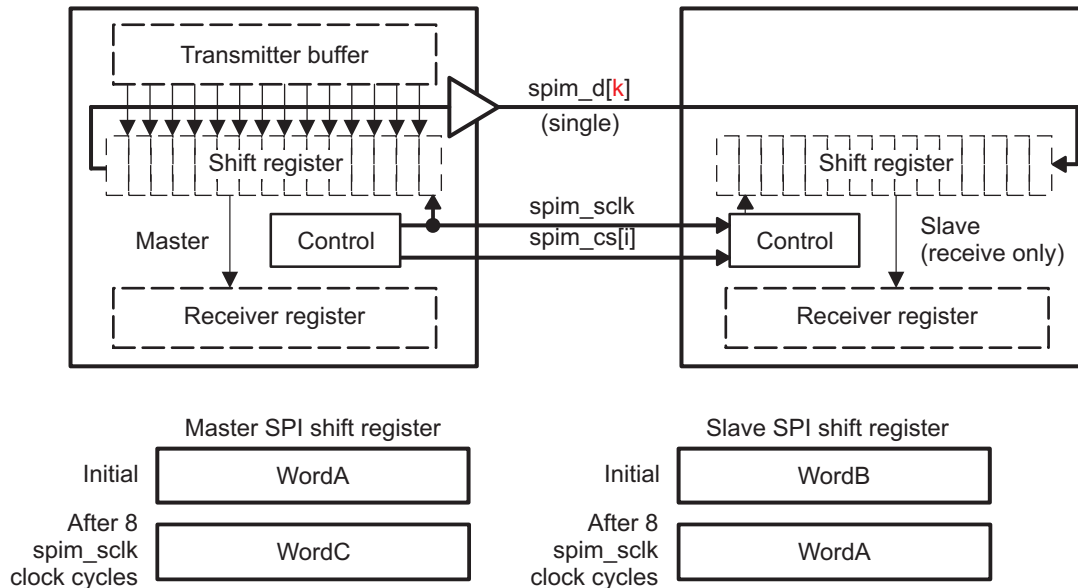

When the SPI word transfer completes (the `MCSPI_CHxSTAT0`[2] EOT bit [where $x = 0$] is set to 1), the received data is transferred to the channel receive register.

To use the McSPI as a slave receive-only device, the `TXx_EMPTY` and `TXx_UNDERFLOW` interrupts and the DMA write requests must be disabled due to the state of the `MCSPI_TXx` register.

For a full-duplex transmission, the serial clock (SPICLK) synchronizes shifting and sampling of the information on the single serial data line. For full duplex, two data lines are required. If SPICLK synchronizes on a single serial data line, the data line should be half-duplex.

Figure 19-60 shows a half-duplex system with a master device on the left and a receive-only slave device on the right. Each time a bit transfers out from the master, 1 bit transfers in from the slave. After eight cycles of the serial clock SPICLK, WordA transfers from the master to the slave.

Figure 19-60. SPI Half-Duplex Transmission (Receive-Only Slave)

`k = 0 or 1 depending on bits SPIDATDIR1 and SPIDATDIR0 in MCSPI_SYST`

mcspi-032

19.3.4.5 3-Pin or 4-Pin Mode

Depending on targeted application the SPI interface can be configured to use 3 or 4 pins through the `MCSPI_MODULCTRL[1]` PIN34 bit. If this bit is set to 0, McSPI is in 4-pin mode using the `SPICLK`, `SPIDAT[0]`, `SPIDAT[1]` and `SPIEN[x]` signals. If PIN34 is set to 1 the controller is in 3-pin mode and `SPIEN[x]` is not used. In this mode all options related to chip select management are useless (`EPOL`, `FORCE` and `TCS0` bits of `MCSPI_CHxCONF`). 3-pin and 4-pin operation applies to both master and slave modes.

19.3.4.6 FIFO Buffer Management

The McSPI controller has a built-in 128-byte buffer to unload the DMA or interrupt handler and improve data throughput.

This buffer can be used by only one channel at a time and is selected by setting the `MCSPI_CHxCONF[28]` FFER or `MCSPI_CHxCONF[27]` FFEW bit to 1. If several channels are selected and several FIFO enable bit fields are set to 1, the controller forces the buffer not to be used; the driver must set only one FIFO enable bit field.

The buffer can be used in the following modes:

- Master or slave mode
- Transmit-only, receive-only, or transmit-and-receive mode
- Single channel or turbo mode, or normal round-robin mode. In round-robin mode the buffer is used by only one channel.

Every word length (`MCSPI_CHxCONF[11:7]` WL) is supported.

In transmit-and-receive mode, the buffer can be used in transmit (see [Figure 19-61](#)) or receive (see [Figure 19-62](#)) directions, or in both directions. If only one direction is chosen in transmit-and-receive mode, the full buffer is used for this direction. In both directions, the buffer is split into two halves, one for each direction (see [Figure 19-63](#)).

Figure 19-61. Buffer Used in Transmit Direction Only

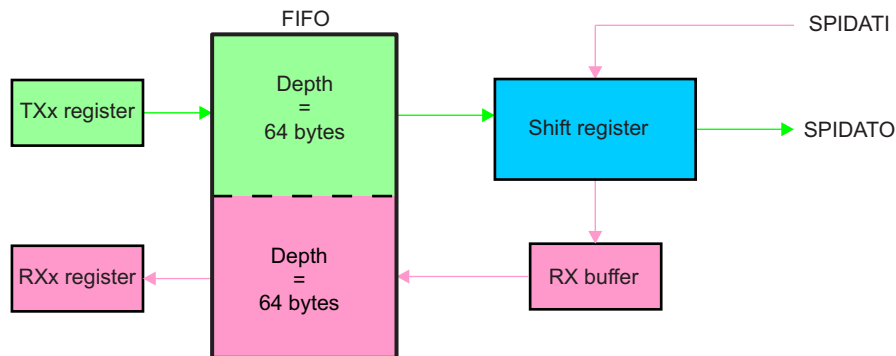

mcspi-102

Figure 19-62. Buffer Used in Receive Direction Only

mcspi-103

Figure 19-63. Buffer Used for Transmit and Receive Directions

mcspi-101

Two levels ([MCSPI_XFERLEVEL\[5:0\]](#) AEL and [MCSPI_XFERLEVEL\[13:8\]](#) AFL) rule the buffer management. The granularity of these levels is 1 byte; it is not aligned with the SPI word length. The driver must set these values as a multiple of the SPI word length defined in [MCSPI_CHxCONF\[11:7\]](#) WL. [Table 19-203](#) lists the number of bytes written in the FIFO, depending on the word length.

Table 19-203. FIFO Writes, Word Length Relationship

	SPI Word Length (WL)		
	$3 \leq WL \leq 7$	$8 \leq WL \leq 15$	$16 \leq WL \leq 31$
Number of bytes written in the FIFO	1 byte	2 bytes	4 bytes

The FIFO buffer pointers are reset when the corresponding channel is enabled or the FIFO configuration changes.

19.3.4.6.1 Buffer Almost Full

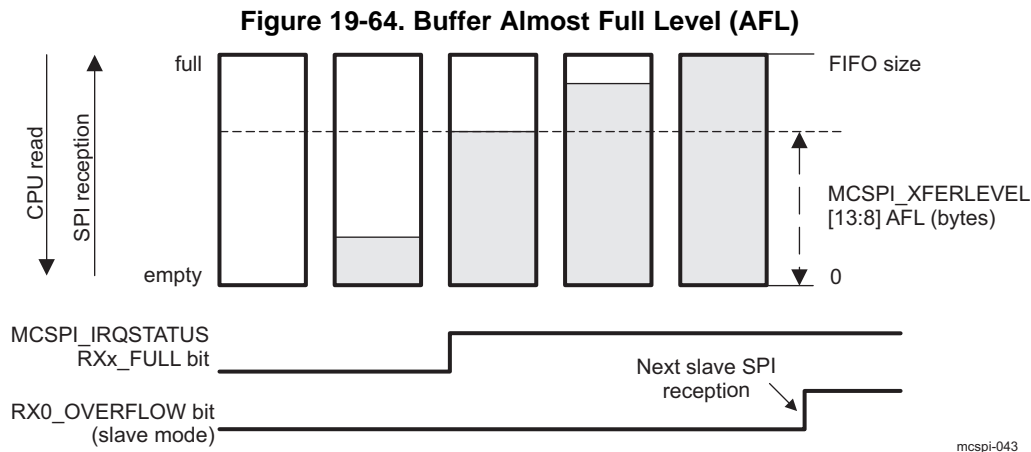

The `MCSPI_XFERLEVEL[15:8]` AFL bit field is needed when the buffer is used to receive an SPI word from a slave (the `MCSPI_CHXCONF[28]` FFER bit must be set to 1). It defines the almost-full buffer status. See Figure 19-64.

When the FIFO pointer reaches this level, an interrupt or a DMA request is sent to the `IRQ_CROSSBAR` and then to the desired `INTC` to enable the system to read `AFL + 1` bytes from the receive register.

NOTE: `AFL + 1` must correspond to a multiple value of the `MCSPI_CHXCONF[11:7]` WL bit field.

When DMA is used, the request is deasserted after the first receive register read.

No new request is asserted again as long as the system has not performed the correct number of read accesses.

NOTE: The `MCSPI_IRQSTATUS` register bits are not available in DMA mode. In DMA mode, the `SPIIm_DMA_RXx` request is asserted on the same conditions as the `MCSPI_IRQSTATUS RXx_FULL` flag.

19.3.4.6.2 Buffer Almost Empty

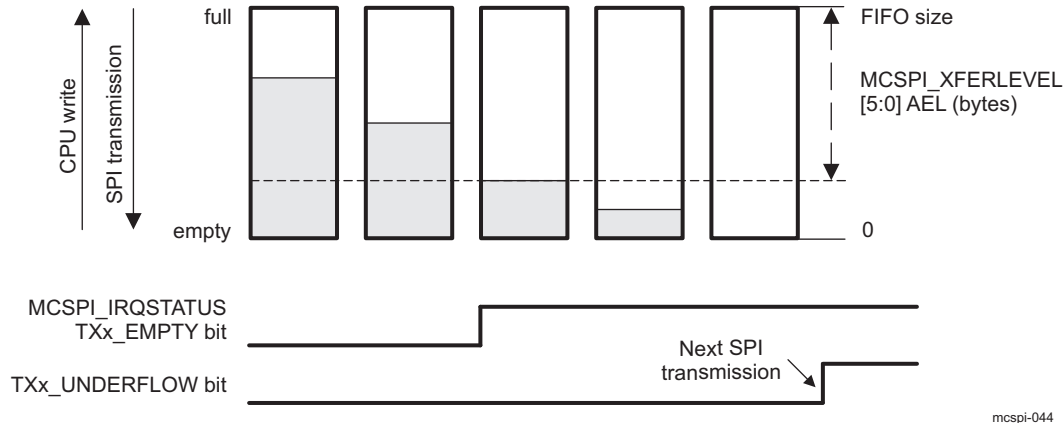

The `MCSPI_XFERLEVEL[7:0]` AEL bit field is needed when the buffer is used to transmit an SPI word to a slave (the `MCSPI_CHXCONF[27]` FFEW bit must be set to 1). It defines the almost-empty buffer status. See Figure 19-65.

When the FIFO pointer does not reach this level, an interrupt or a DMA request is sent to the `IRQ_CROSSBAR` and then to the desired `INTC` to enable the system to write `AEL + 1` bytes to the transmit register.

NOTE: `AEL + 1` must correspond to a multiple value of the `MCSPI_CHXCONF[11:7]` WL bit field.

When DMA is used, the request is deasserted after the first transmit register write.

No new request is asserted again as long as the system has not performed the correct number of write accesses.

Figure 19-65. Buffer Almost Empty Level (AEL)

NOTE: The [MCSPi_IRQSTATUS](#) register bits are not available in DMA mode. In DMA mode, the [SPIm_DMA_TXx](#) request is asserted on the same conditions as the [MCSPi_IRQSTATUS TXx_EMPTY](#) flag.

19.3.4.6.3 End of Transfer Management

When the FIFO buffer is enabled for a channel, the user must previously configure in the [MCSPi_XFERLEVEL](#) register the AEL and AFL levels and especially the [MCSPi_XFERLEVEL\[31:16\]](#) WCNT bit field to define the number of SPI words to be transferred using the FIFO before enabling the channel.

This counter lets the controller stop the transfer correctly after a defined number of SPI word transfers. If WCNT is set to 0x0000, the counter is not used and the user must stop the transfer manually by disabling the channel; in this case, the user does not know how many SPI transfers have been done. For received words, software must poll the [CHxSTAT\[5\] RXFFE](#) bit and read the [MCSPi_RXx](#) receive register to empty the FIFO buffer.

When the end-of-word count interrupt is generated (the [MCSPi_IRQSTATUS\[17\] EOW](#) bit is set), the user can disable the channel and poll the [MCSPi_CHxSTAT\[5\] RXFFE](#) bit to know the last SPI words in the FIFO buffer and read them.

No new request is asserted as long as the system has not performed the correct number of write accesses.

19.3.4.7 Interrupts

Each channel can issue interrupt events.

Each interrupt event has status bits in the [MCSPi_IRQSTATUS](#) register ([RXx_FULL](#), [TXx_UNDERFLOW](#), [TXx_EMPTY](#), etc.) (where $x = 0, 3$) that indicate whether service is required. Each status bit has an interrupt enable bit (a mask) in the [MCSPi_IRQENABLE](#) register ([RXx_FULL_ENABLE](#), [TXx_UNDERFLOW_ENABLE](#), [TXx_EMPTY_ENABLE](#), etc.).

When an interrupt occurs and a mask is later applied on it, the interrupt line is not asserted again, even if the interrupt source is not serviced.

The McSPI supports interrupt-driven and polling operations.

19.3.4.7.1 Interrupt Events in Master Mode

In master mode, the interrupt events related to the state of the [MCSPi_TXx](#) register are [TXx_EMPTY](#) and [TXx_UNDERFLOW](#). The interrupt event related to the state of the [MCSPi_RXx](#) register is [RXx_FULL](#).

19.3.4.7.1.1 TXx_EMPTY

The TXx_EMPTY event is activated when a channel is enabled and its MCSPI_TXx register is empty (transient event). Enabling a channel automatically triggers this event, except in master receive-only mode (see Section 19.3.4.3.4, *Master Receive-Only Mode*). When the FIFO buffer is enabled (the MCSPI_CHxCONF[27] FFEW bit is set to 1), the MCSPI_IRQSTATUS TXx_EMPTY bit is set as soon as there is enough space in the buffer to write a number of bytes defined by the MCSPI_XFERLEVEL[5:0] AEL bit field.

The MCSPI_TXx register must be loaded with data to remove the source of the interrupt; the MCSPI_IRQSTATUS TXx_EMPTY interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new TXx_EMPTY event is asserted as long as a device initiator has not performed the number of writes into the MCSPI_TXx register defined by the MCSPI_XFERLEVEL[5:0] AEL bit field. This device initiator must perform the correct number of writes.

19.3.4.7.1.2 TXx_UNDERFLOW

The event TXx_UNDERFLOW is activated when the channel is enabled and if the MCSPI_TXx register or the FIFO is empty (not updated with new data) when an external master device starts a data transfer with the McSPI (transmit and receive).

The TXx_UNDERFLOW is a harmless warning in master mode.

To avoid having a TXx_UNDERFLOW event at the beginning of a transmission, the TXx_UNDERFLOW event is not activated when no data has been loaded into the MCSPI_TXx register, because the channel is enabled. To avoid having a TXx_UNDERFLOW event, the MCSPI_TXx register must seldom be loaded.

The MCSPI_IRQSTATUS TXx_UNDERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

19.3.4.7.1.3 RXx_FULL

The RXx_FULL event is activated when a channel is enabled and the MCSPI_RXx register becomes filled (transient event). When the FIFO buffer is enabled (the MCSPI_CHxCONF[28] FFER bit is set to 1), RXx_FULL is asserted as soon as the number of bytes held in the FIFO to be read reaches the MCSPI_XFERLEVEL[13:8] AFL threshold.

The MCSPI_RXx register must be read to remove the source of the interrupt; the MCSPI_IRQSTATUS RXx_FULL interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new RXx_FULL event is asserted as long as a device initiator has not performed AFL + 1 reads into MCSPI_RXx. This device initiator must perform the correct number of reads.

19.3.4.7.1.4 End Of Word Count

The MCSPI_IRQSTATUS[17] EOW event (end of word count) is activated when the channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller performs the number of transfers defined in the MCSPI_XFERLEVEL[31:16] WCNT bit field. If WCNT is set to 0x0000, the counter is not enabled and this interrupt is not generated.

The end of word count interrupt also indicates that the SPI transfer is halted on the channel using the FIFO buffer as soon as MCSPI_XFERLEVEL[31:16] WCNT is not reloaded and the channel is not re-enabled.

The MCSPI_IRQSTATUS[17] EOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

19.3.4.7.2 Interrupt Events in Slave Mode

In slave mode, the interrupt events related to the state of the [MCSPI_TXx](#) register are [TXx_EMPTY](#) and [TXx_UNDERFLOW](#). The interrupt events related to the state of the [MCSPI_RXx](#) are [RXx_FULL](#) and [RX0_OVERFLOW](#) (channels 1, 2, and 3 do not have a receiver overflow status bit). See the [MCSPI_IRQSTATUS](#) register.

19.3.4.7.2.1 TXx_EMPTY

The [TXx_EMPTY](#) event is activated when a channel is enabled and its [MCSPI_TXx](#) register is empty. Enabling the channel automatically raises this event. If the FIFO buffer is enabled (the [MCSPI_CHxCONF\[27\]](#) FFEW bit is set to 1), the [TXx_EMPTY](#) event is asserted as soon as there is enough space in buffer to write a number of bytes defined by the [MCSPI_XFERLEVEL\[5:0\]](#) AEL bit field.

The [MCSPI_TXx](#) register must be loaded with data to remove the source of the interrupt; the [MCSPI_IRQSTATUS](#) [TXx_EMPTY](#) interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new [TXx_EMPTY](#) event is asserted as long as a device initiator has not performed the number of writes into the [MCSPI_TXx](#) register defined by [MCSPI_XFERLEVEL\[5:0\]](#) AEL bit field. This device initiator must perform the correct number of writes.

19.3.4.7.2.2 TXx_UNDERFLOW

The [TXx_UNDERFLOW](#) event is activated when a channel is enabled and if the [MCSPI_TXx](#) register is empty (not updated with new data) when an external master device starts a data transfer with the McSPI (transmit and receive).

When FIFO is enabled, the data emitted while the underflow event is raised is not the last data written in the FIFO but the next data in the FIFO (an old transmitted value or a dummy data in the FIFO has been reset).

[TXx_UNDERFLOW](#) indicates an error (data loss) in slave mode.

To avoid having a [TXx_UNDERFLOW](#) event at the beginning of a transmission, the [TXx_UNDERFLOW](#) event is not activated when no data has been loaded into the [MCSPI_TXx](#) register because the channel is enabled.

The [MCSPI_IRQSTATUS](#) [TXx_UNDERFLOW](#) interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

19.3.4.7.2.3 RXx_FULL

The [RXx_FULL](#) event is activated when a channel is enabled and the [MCSPI_RXx](#) register is being filled (transient event). When the FIFO buffer is enabled (the [MCSPI_CHxCONF\[28\]](#) FFER bit is set to 1), [RXx_FULL](#) is asserted as soon as the number of bytes held in the buffer to read defined by the [MCSPI_XFERLEVEL\[13:8\]](#) AFL bit field.

The [MCSPI_RXx](#) register must be read to remove the source of the interrupt; the [MCSPI_IRQSTATUS](#) [RXx_FULL](#) interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new [RXx_FULL](#) event is asserted as long as a device initiator has not performed $AFL + 1$ reads into [MCSPI_RXx](#). This device initiator must perform the correct number of reads.

19.3.4.7.2.4 RX0_OVERFLOW

The [RX0_OVERFLOW](#) event is activated in slave mode in transmit-and-receive mode or receive-only mode when a channel is enabled and the [MCSPI_RXx](#) register or FIFO is full when a new SPI word is received. The [MCSPI_RXx](#) register is always overwritten with the new SPI word. If the FIFO is enabled, data within the FIFO are overwritten; it must be considered as corrupted. The [RX0_OVERFLOW](#) event should not appear in slave mode using the FIFO.

The [RX0_OVERFLOW](#) event indicates an error (data loss) in slave mode.

The [MCSPI_IRQSTATUS](#)[3] `RX0_OVERFLOW` interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

19.3.4.7.2.5 End Of Word Count

The [MCSPI_IRQSTATUS](#)[17] EOW event (end of word count) is activated when the channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller performs the number of transfers defined in the [MCSPI_XFERLEVEL](#)[31:16] `WCNT` bit field. If `WCNT` is set to `0x0000`, the counter is not enabled and this interrupt is not generated.

The end of word count interrupt also indicates that the SPI transfer is halted on the channel using the FIFO buffer as soon as `WCNT` is not reloaded and the channel is not re-enabled.

The [MCSPI_IRQSTATUS](#)[17] EOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

19.3.4.7.3 Interrupt-Driven Operation

An interrupt enable bit in the [MCSPI_IRQENABLE](#) register can be set to enable each event to generate interrupt requests when the corresponding event occurs. Status bits are automatically set by hardware logic conditions.

When an event occurs (the single interrupt line is asserted), the following must be performed:

1. Read the [MCSPI_IRQSTATUS](#) register to identify which event occurred.
2. Read the [MCSPI_RXx](#) register that corresponds to the event to remove the source of an `RXx_FULL` event or write into the [MCSPI_TXx](#) register that corresponds to the event to remove the source of a `TXx_EMPTY` event. No action is required to remove the source of the `WKS` (wake-up), `TXx_UNDERFLOW`, and `RX0_OVERFLOW` events.
3. Set the corresponding bit of the [MCSPI_IRQSTATUS](#) register to 1 to clear an interrupt status and then release the interrupt line.

The interrupt status bit must always be reset after channel enabling and before events are enabled as interrupt sources.

19.3.4.7.4 Polling

When the interrupt capability of an event is disabled in the [MCSPI_IRQENABLE](#) register, the interrupt line is not asserted, but the status bits in the [MCSPI_IRQSTATUS](#) register can be polled by software to detect when the corresponding event occurs.

Once the expected event occurs:

- `RXx_FULL`: To remove the source of the event, the corresponding [MCSPI_RXx](#) register must be read.
- `TXx_EMPTY`: To remove the source of the event, it must be written into the corresponding [MCSPI_TXx](#) register.
- `WKS` (wake-up), `TXx_UNDERFLOW`, and `RX0_OVERFLOW`: No action is required to remove the source of the event.

To clear an interrupt, set the corresponding status bit of the [MCSPI_IRQSTATUS](#) register to 1. This does not affect the interrupt line state.

19.3.4.8 DMA Requests

Each McSPI channel, if enabled, can issue DMA requests. There are two DMA request lines per McSPI channel (one for read and one for write).

The DMA read request line is asserted when the McSPI channel is enabled and new data is available in the receive register of the McSPI channel. A DMA read request can be individually masked with the `SPI1.MCSPI_CHxCONF`[15] `DMAR` bit. The DMA read request line is deasserted when reading of the [MCSPI_RXx](#) register of the McSPI channel completes.

The DMA write request line is asserted when the McSPI channel is enabled and the `MCSPi_TXx` register of the McSPI channel is empty. A DMA write request can be individually masked with the `SPI1.MCSPi_CHxCONF[14]` DMAW bit. The DMA write request line is deasserted when loading of the `MCSPi_TXx` register of the channel completes.

19.3.4.9 Power Saving Management

Power consumption can be optimized by switching off internal clocks (interface and functional clock) when there is no activity. The McSPI is compliant with the idle and wake-up system handshake protocol.

19.3.4.9.1 Normal Mode

In normal mode, internal SPI module clocks are automatically switched off (autogated) when there is no activity in slave or master mode.

Autogating of the module interface clock and functional clock occurs when the following conditions are met:

- The `MCSPi_SYSCONFIG[0]` AUTOIDLE bit is set.
- In master mode, there is no data to transmit or receive in all channels.
- In slave mode, the McSPI is not selected by the external master and there are no register accesses.

Autogating of the module interface clock and functional clock stops when the following conditions are met:

- In master mode, an internal access occurs.
- In slave mode, an internal access occurs or the McSPI is selected by the external master.

19.3.4.9.2 Idle Mode

At the PRCM module level, when all conditions are met to shut off the `PER_48M_GFCLK` or `L4PER_L3_GICLK` output clock, the PRCM module automatically launches a hardware handshake protocol to ensure that the McSPI is ready to have its clocks switched off. Namely, the PRCM module asserts an IDLE request to the McSPI.

Although this handshake is completely hardware-oriented and out of software control, the method in which the McSPI module acknowledges the PRCM IDLE request is configurable through the `MCSPi_SYSCONFIG[4:3]` SIDLEMODE bit field.

The settings of the SIDLEMODE bit field and the related acknowledgment modes are:

- Force-idle mode (the `MCSPi_SYSCONFIG[4:3]` SIDLEMODE bit field is set to 0x0): The McSPI module acknowledges unconditionally the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully in this case because it does not prevent the loss of data when the clock is switched off.
- No-idle mode (the SIDLEMODE bit field is set to 0x1): The McSPI never acknowledges an IDLE request from the PRCM module and is safe from a module point of view because it ensures that the clocks remain active. However, it is not efficient to save power because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.
- Smart-idle mode (the SIDLEMODE bit field is set to 0x2): The McSPI acknowledges the IDLE request, basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, IRQs, or DMA requests are treated. This is the best approach for efficient system power management.

When configured in smart-idle mode, the McSPI also offers an additional granularity on the `PER_48M_GFCLK` and `L4PER_L3_GICLK` gating. The `MCSPi_SYSCONFIG[9:8]` CLOCKACTIVITY bit field determines which clock shuts down (the `PER_48M_GFCLK`, `L4PER_L3_GICLK`, neither clock, or both clocks).

The setting of the CLOCKACTIVITY bit field is used internally to the McSPI to determine on which part of the module the conditions to acknowledge the PRCM IDLE request are tested. For example, if `PER_48M_GFCLK` is not shut down on a PRCM IDLE request, the McSPI considers only `L4PER_L3_GICLK` and the associated pending activities before acknowledging the request.

Some McSPI features are associated with L4PER_L3_GICLK and others with PER_48M_GFCLK. Using the CLOCKACTIVITY bit field with the smart-idle mode ensures that the features associated with the clock that remains active are always enabled, even if the McSPI acknowledges an IDLE request.

The settings of the CLOCKACTIVITY bit field and the associated features are:

- CLOCKACTIVITY set to 00: ICLK off and FCLK off, ICLK and FCLK are considered for generating the acknowledge. This setting also means that FCLK and ICLK are likely to be shut down on a PRCM IDLE request.
- CLOCKACTIVITY set to 01: ICLK on and FCLK off, ICLK is not shut down on a PRCM IDLE request; only FCLK is concerned.
- CLOCKACTIVITY set to 10: ICLK off and FCLK on, FCLK is not shut down on a PRCM IDLE request; only ICLK is concerned.
- CLOCKACTIVITY set to 11: ICLK on and FCLK on, none of the clocks are shut down. This means the McSPI can potentially acknowledge the IDLE request without checking the internal functions linked to its clocks.

CAUTION

The PRCM module does not have a hardware means of reading the CLOCKACTIVITY settings. Therefore, software must ensure consistent programming between CLOCKACTIVITY and the PER_48M_GFCLK and L4PER_L3_GICLK control bits in the PRCM module. If the McSPI is disabled in the CM_FCLKEN and CM_ICLKEN PRCM registers while CLOCKACTIVITY is set to 11, nothing prevents the PRCM module from asserting its IDLE request, which is acknowledged regardless of the features associated with the McSPI clocks. This can lead to unpredictable behavior.

19.3.4.9.2.1 Wake-Up Event in Smart-Idle Mode

The module wake-up feature is enabled when the [MCSPI_SYSCONFIG\[2\]](#) ENAWAKEUP and [MCSPI_WAKEUPENABLE\[0\]](#) WKEN bits are set. Wake-up capability is relevant only when the module is configured in slave mode.

The module generates an asynchronous wake-up request to the system power manager to switch back the interface clock and the functional clock. A wakeup is requested when channel 0 is enabled and an asynchronous selection occurs on the mcs pim.csx port associated with channel 0 (see the definition for the [MCSPI_CHxCONF\[22:21\]](#) SPIENSLV bit field [where x = 0] in the register table description).

After the McSPI wake-up request, the system power manager must reactivate the interface clock:

- Before the beginning of the second SPI word serialization when the McSPI is in slave transmit-only mode or in slave transmit-and-receive mode
- Before the end of the second received SPI word in slave receive-only mode. To avoid data loss, the first received SPI word must be read from the [MCSPI_RXx](#) register (where x = 0) before the completion of the second SPI word serialization.

[Table 19-204](#) lists the supported cases in smart-idle mode.

Table 19-204. Smart-Idle Mode and Wake-Up Capabilities

Mode	Interface Clock	SPI Clock Ref	Functionality	Wake-Up Event
Master	Must be maintained	Must be maintained	Full functionality, but the module does not generate a new interrupt or DMA request until the system exits wake-up mode	No wake-up event
Slave	Can be switched off	Can be switched off	An SPI word can be transmitted and/or received, but the module does not generate any new interrupts or DMA requests until the system exits wake-up mode.	The module asynchronously sends a wake-up request if an event on the SPIEN[x] port associated with channel 0 is detected.

In wake-up mode, the interrupt and DMA request lines are no longer asserted.

Any access to the module in wake-up mode generates an error as long as the interface clock is alive.

19.3.4.9.2.2 Transitions From Smart-Idle Mode to Normal Mode

The McSPI detects the end of the wake period through the idle and wake-up hardware handshake protocol.

The interrupt status register (the [MCSPI_IRQSTATUS](#)[16] WKS bit) is updated with the event causing the wakeup; the wake-up event at the origin of the transition to the normal mode is converted to its corresponding interrupt when enabled by the [MCSPI_IRQENABLE](#)[16] WKE bit or the DMA request.

Interrupts and wake-up events have independent enable and disable controls, accessible through the [MCSPI_IRQENABLE](#) and [MCSPI_WAKEUPENABLE](#) registers. Software must ensure the overall consistency.

The interrupt status register [MCSPI_IRQSTATUS](#) is updated with the event causing the wakeup; the wake-up event at the origin of the transition to normal mode is converted to its corresponding interrupt request or DMA request. The module is fully operational.

19.3.4.9.2.3 Force-Idle Mode

Force-idle mode is enabled and exited as follows:

- Force-idle mode is enabled when the [MCSPI_SYSCONFIG](#)[4:3] SIDLEMODE bit field is set to 0x0.
 - In force-idle mode, the McSPI responds unconditionally to the IDLE request by deasserting unconditionally the interrupt and DMA request lines, if asserted. In addition, the wake-up capability is totally inhibited even if the [MCSPI_SYSCONFIG](#)[2] ENAWAKEUP and [MCSPI_WAKEUPENABLE](#)[0] WKEN bits are set.
 - The transition from normal mode to idle mode does not affect the interrupt event bits of the [MCSPI_IRQSTATUS](#) register.
 - In force-idle mode, because the module must be disabled, the interrupt and DMA request lines are likely deasserted. The interface clock and SPI clock provided to the McSPI can be switched off.
 - An IDLE request during an SPI data transfer can lead to an unexpected and unpredictable result. Software must avoid such a request.
- The module exits force-idle mode through the idle and wake-up hardware handshake protocol. The module is fully operational. The interrupt and DMA request lines are optionally asserted one clock cycle later.

19.3.5 McSPI Programming Guide

19.3.5.1 McSPI Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the McSPI module.

19.3.5.1.1 Global Initialization

19.3.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the McSPI module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the McSPI. For further information, see [Section 19.3.3, McSPI Integration](#) and [Section 19.3.2, McSPI Environment](#).

[Table 19-205](#) lists the information on the global initialization of the surrounding modules.

Table 19-205. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	MCSPI_FCLK functional clock must be enabled. See Section 3.1.1.1.2, Module-Level Clock Management , in Chapter 3, Power, Reset, and Clock Management .
L4 Interconnect	For information about L4_PER1 interconnect configuration, see Section 10.3, L4 Interconnects , in Chapter 10, Interconnect .
DMA_CROSSBAR	DMA_CROSSBAR configuration must be done to allow module DREQs to be mapped to certain device DMA line. For more information see Section 14.4.6.5, DMA_CROSSBAR Module Functional Description , in Chapter 14, Control Module .
EDMA	EDMA configuration must be done to enable the module DMA channel requests.
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description , in Chapter 14, Control Module .
Device INTCs	Device INTCs must be configured to enable the interrupt request generation. For more information see Chapter 13 Interrupt Controllers .

19.3.5.1.1.2 McSPI Global Initialization

19.3.5.1.1.2.1 Main Sequence – McSPI Global Initialization

The procedure in [Table 19-206](#) can be used to initialize McSPI when performing software reset.

Table 19-206. McSPI Global Initialization

Step	Register/Bit Field/Programming Model	Value
Perform a software reset.	MCSPISYSCONFIG[1] SOFTRESET	0x1
Wait until reset is finished?	MCSPISYSSTATUS[0] RESETDONE	=0x1

19.3.5.1.2 Operational Mode Configuration

19.3.5.1.2.1 McSPI Operational Modes

The selection of the working mode is done with the [MCSPICHXCONF](#) register. [Table 19-207](#) through [Table 19-209](#) list the possible operating modes and their configurations.

Table 19-207. McSPI Receive Mode Initialization

Step	Register/Bit Field/Programming Model	Value
Set receive mode.	MCSPI_CHxCONF[13:12] TRM	0x1
Set the word length.	MCSPI_CHxCONF[11:7] WL	0x8
Clock initialization and channel enabling	MCSPI_MODULCTRL[2] MS MCSPI_CHxCTRL[0] EN	0x0 0x1
Channels activated low during ACTIVE state	MCSPI_CHxCONF[6] EPOL	0x1
Clock held low during INACTIVE state	MCSPI_CHxCONF[1] POL	0x0
Data latched on odd-numbered edges of the SPI clock	MCSPI_CHxCONF[0] PHA	0x0
Reset the status bits.	MCSPI_IRQSTATUS	0x0

Table 19-208. McSPI Transmit Mode Initialization

Step	Register/Bit Field/Programming Model	Value
Set transmit mode.	MCSPI_CHxCONF[13:12] TRM	0x2
Set the word length.	MCSPI_CHxCONF[11:7] WL	0x8
Clock initialization and channel enabling	MCSPI_MODULCTRL[2] MS MCSPI_CHxCTRL[0] EN	0x0 0x1
Channels activated low during ACTIVE state	MCSPI_CHxCONF[6] EPOL	0x1
Clock held low during INACTIVE state	MCSPI_CHxCONF[1] POL	0x0
Data latched on odd-numbered edges of the SPI clock	MCSPI_CHxCONF[0] PHA	0x0
Reset the status bits.	MCSPI_IRQSTATUS	0x0

Table 19-209. McSPI Transmit-and-Receive Mode Initialization

Step	Register/Bit Field/Programming Model	Value
Set transmit and receive mode.	MCSPI_CHxCONF[13:12] TRM	0x0
Set the word length.	MCSPI_CHxCONF[11:7] WL	0x8
Clock initialization and channel enabling	MCSPI_MODULCTRL[2] MS MCSPI_CHxCTRL[0] EN	0x0 0x1
Channels activated low during ACTIVE state	MCSPI_CHxCONF[6] EPOL	0x1
Clock held low during INACTIVE state	MCSPI_CHxCONF[1] POL	0x0
Data latched on odd-numbered edges of the SPI clock	MCSPI_CHxCONF[0] PHA	0x0
Reset the status bits.	MCSPI_IRQSTATUS	0x0

19.3.5.1.3 Common Transfer Procedures Without FIFO – Polling Method

19.3.5.1.3.1 Receive-Only Procedure – Polling Method

Table 19-210 lists the receive-only procedure using the polling method. The McSPI is acting as slave.

Table 19-210. Receive-Only Procedure – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode	See Table 19-207.	
Start the channel.	MCSPI_CHxCTRL[0] EN	0x1
Wait until receive register is full?	MCSPI_RXx	=0x1
Stop the channel.	MCSPI_CHxCTRL[0] EN	0x0

19.3.5.1.3.2 Receive-Only Procedure – Interrupt Method

Table 19-211 lists the receive-only procedure using the interrupt method. The McSPI is acting as slave.

Table 19-211. Receive-Only Procedure – Interrupt Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 19-207.	
Start the channel.	MCSPi_CHxCTRL[0] EN	0x1
Enable the interrupt for the receiver register.	MCSPi_IRQENABLE[2] RX_FULL_ENABLE	0x1
Read the status register.	MCSPi_IRQSTATUS[2] RX_FULL	0x0
Disable the interrupt.	MCSPi_IRQENABLE[2] RX_FULL_ENABLE	0x0
Stop the channel.	MCSPi_CHxCTRL[0] EN	0x0
Read the receiver register.	MCSPi_RXx	0x-

19.3.5.1.3.3 Transmit-Only Procedure – Polling Method

Table 19-212 lists the transmit-only procedure using the polling method. The McSPI is acting as master.

Table 19-212. Transmit-Only Procedure – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 19-208	
Start the channel.	MCSPi_CHxCTRL[0] EN	0x1
Wait until end of transfer?	MCSPi_CHxSTAT[2:1]	=0x2
Stop the channel.	MCSPi_CHxCTRL[0] EN	0x0

19.3.5.1.3.4 Transmit-and-Receive Procedure – Polling Method

Table 19-212 lists the transmit-and-receive procedure using the polling method. The McSPI is acting as master and slave.

Table 19-213. Transmit-and-Receive Procedure – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 19-209.	
Start the channel.	MCSPi_CHxCTRL[0] EN	0x1
Wait until transmit/receive word?	MCSPi_CHxSTAT[2:0]	=0x3
Stop the channel.	MCSPi_CHxCTRL[0] EN	0x0

19.3.5.1.4 Common Transfer Procedures With FIFO – Polling Method

When using FIFO the McSPI module can start the transfer only after the first write request is released by writing the MCSPi_TXx register. The first write request can be managed by the IRQ routine or DMA handler. The end of transfer is more complex and depends on the transfer type. See Table 19-212 through Table 19-219.

19.3.5.1.4.1 Receive-Only Procedure With Word Count – Polling Method

Table 19-214. Receive-Only Procedure With Word Count – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 19-207.	
Start the channel.	MCSPi_CHxCTRL[0] EN	0x1
Wait until end of word count?	MCSPi_IRQSTATUS[17] EOW	=0x1

Table 19-214. Receive-Only Procedure With Word Count – Polling Method (continued)

Step	Register/Bit Field/Programming Model	Value
Stop the channel.	MCSPI_CHxCTRL[0] EN	0x0
Read from the receiver register.	MCSPI_RXx	0x-

19.3.5.1.4.2 Transmit-Only Procedure With and Without Word Count – Polling Method

Table 19-215. Transmit-Only Procedure Without Word Count – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 19-208 .	
Start the channel.	MCSPI_CHxCTRL[0] EN	0x1
Wait until end of word count?	MCSPI_IRQSTATUS[17] EOW	=0x1
Wait until end of transfer?	MCSPI_CHxSTAT[2] EOT MCSPI_CHxSTAT[3] TXFFE	=0x1 =0x1
Stop the channel.	MCSPI_CHxCTRL[0] EN	0x0

19.3.5.1.4.3 Transmit-Only Procedure With and Without Word Count – Interrupt Method

Table 19-216. Transmit-Only Procedure With Word Count – Interrupt Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 19-208 .	
Start the channel.	MCSPI_CHxCTRL[0] EN	0x1
Enable the interrupt for the transmit register.	MCSPI_IRQENABLE[4] TX_EMPTY_ENABLE	0x1
End of word count.	MCSPI_IRQSTATUS[17] EOW	=0x1
End of transfer	MCSPI_CHxSTAT[2] EOT MCSPI_CHxSTAT[3] TXFFE	=0x1 =0x1
Clear the interrupt.	MCSPI_IRQENABLE[17] EOW_ENABLE	=0x0
Disable the interrupt for the transmit register.	MCSPI_IRQENABLE[4] TX_EMPTY_ENABLE	0x0
Stop the channel.	MCSPI_CHxCTRL[0] EN	0x0

19.3.5.1.4.4 Transmit-and-Receive Procedure With Word Count – Polling Method

Table 19-217. Transmit-and-Receive Procedure With Word Count – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 19-209 .	
Start the channel.	MCSPI_CHxCTRL[0] EN	0x1
Wait until end of word count?	MCSPI_IRQSTATUS[17] EOW	=0x1
Stop the channel.	MCSPI_CHxCTRL[0] EN	0x0
Read from the receiver register.	MCSPI_RXx	0x-

19.3.5.1.4.5 Transmit-and-Receive Procedure With Word Count – Interrupt Method

Table 19-218. Transmit-and-Receive Procedure With Word Count – Interrupt Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 19-209 .	
Start the channel.	MCSPI_CHxCTRL[0] EN	0x1

Table 19-218. Transmit-and-Receive Procedure With Word Count – Interrupt Method (continued)

Step	Register/Bit Field/Programming Model	Value
Enable the interrupt for the receiver register.	MCSPI_IRQENABLE [2] RX_FULL_ENABLE	0x1
Enable the interrupt for the transmit register.	MCSPI_IRQENABLE [4] TX_EMPTY_ENABLE	0x1
End of word count?	MCSPI_IRQSTATUS [17] EOW	=0x1
Clear the interrupt.	MCSPI_IRQENABLE [17] EOW_ENABLE	=0x0
Disable the interrupt for the receiver register.	MCSPI_IRQENABLE [4] TX_EMPTY_ENABLE	0x0
Disable the interrupt for the transmit register.	MCSPI_IRQENABLE [2] RX_FULL_ENABLE	0x0
Stop the channel.	MCSPI_CHxCTRL [0] EN	0x0
Read from the receiver register.	MCSPI_RXx	0x-

19.3.5.1.4.6 Transmit-and-Receive Procedure Without Word Count – Polling Method

Table 19-219. Transmit-and-Receive Procedure Without Word Count – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 19-209 .	
Start the channel.	MCSPI_CHxCTRL [0] EN	0x1
Wait until end of transfer?	MCSPI_CHxSTAT [2] EOT MCSPI_CHxSTAT [3] TXFFE	=0x1 =0x1
Stop the channel.	MCSPI_CHxCTRL [0] EN	0x0
Read from the receiver register.	MCSPI_RXx	0x-

19.3.6 McSPI Register Manual

19.3.6.1 McSPI Instance Summary

Table 19-220. McSPI Instance Summary

Module Name	Base Address	Size
McSPI1	0x4809 8000	4 KiB
McSPI2	0x4809 A000	4 KiB
McSPI3	0x480B 8000	4 KiB

Address Offset	0x10		
Physical Address	0x4809 8010 0x4809 A010 0x480B 8010 0x480B A010	Instance	McSPI1 McSPI2 McSPI3 McSPI4
Description	Clock management configuration		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																												IDLEMODE	FREEEMU	SOFTRESET	

Bits	Field Name	Description	Type	Reset
31:4	RESERVED		R	0x0000000
3:2	IDLEMODE	Configuration of the local target state management mode. By definition, target can handle read/write transaction as long as it is out of IDLE state. 0x0: Force-idle mode: local target's IDLE state follows (acknowledges) the system's IDLE requests unconditionally, that is, regardless of the module's internal requirements. Backup mode, for debug only. 0x1: No-idle mode: local target never enters IDLE state. Backup mode, for debug only. 0x2: Smart-idle mode: local target's IDLE state eventually follows (acknowledges) the system's IDLE requests, depending on the IP module's internal requirements. Module shall not generate (IRQ- or DMA-request-related) wake-up events. 0x3: Smart-idle wake-up-capable mode: local target's IDLE state eventually follows (acknowledges) the system's IDLE requests, depending on the module's internal requirements. Module may generate (IRQ- or DMA-request-related) wake-up events when in IDLE state. Mode is relevant only if the appropriate IP module "swake-up" output(s) is (are) implemented.	RW	0x2
1	FREEEMU	Sensitivity to emulation (debug) suspend input signal. 0x0: Module is sensitive to emulation suspend. 0x1: Module is not sensitive to emulation suspend.	RW	0

Bits	Field Name	Description	Type	Reset
0	SOFTRESET	Software reset. (Optional) Write 0x0: No action Read 0x0: Reset done, no pending action Read 0x1: Reset (software or other) ongoing Write 0x1: Initiate software reset	RW	0

Address Offset	0x110		
Physical Address	0x4809 8110 0x4809 A110 0x480B 8110 0x480B A110	Instance	McSPI1 McSPI2 McSPI3 McSPI4
Description	This register allows controlling various parameters of the configuration interface and is not affected by software reset.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																CLOCKACTIVITY	RESERVED	SIDLEMODE	ENAWAKEUP	SOFTRESET	AUTOIDLE										

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Reads return 0	RW	0x000000
9:8	CLOCKACTIVITY	Clocks activity during wake-up mode period 0x0: Interface and functional clocks may be switched off. 0x1: Interface clock is maintained. Functional clock may be switched off. 0x2: Functional clock is maintained. Interface clock may be switched off. 0x3: Interface and functional clocks are maintained.	RW	0x0
7:5	RESERVED	Reads returns 0	RW	0x0
4:3	SIDLEMODE	Power management 0x0: If an IDLE request is detected, the McSPI acknowledges it unconditionally and goes in inactive mode. Interrupt, DMA requests and wake-up lines are unconditionally deasserted and the module wake-up capability is deactivated even if the [2] ENAWAKEUP bit is set. 0x1: If an IDLE request is detected, the request is ignored and the module does not switch to wake-up mode, and keeps on behaving normally. 0x2: If an IDLE request is detected, the module will switch to wake-up mode based on its internal activity, and the wake-up capability can be used if the bit [2] ENAWAKEUP is set. 0x3: Reserved - do not use.	RW	0x2
2	ENAWAKEUP	Wake-up feature control 0x0: Wake-up capability is disabled. 0x1: Wake-up capability is enabled.	RW	1
1	SOFTRESET	Software reset. During reads it always returns 0. 0x0: (write) Normal mode 0x1: (write) Set this bit to 1 to trigger a module reset. The bit is automatically reset by the hardware.	RW	0
0	AUTOIDLE	Internal interface clock-gating strategy 0x0: Interface clock is free-running. 0x1: Automatic interface clock gating strategy is applied, based on the interface activity.	RW	1

Bits	Field Name	Description	Type	Reset
31:18	RESERVED	Reads return 0	RW	0x0000
17	EOW	End of word count event when a channel is enabled using the FIFO buffer and the channel had sent the number of SPI word defined by MCSPI_XFERLEVEL[31:16] WCNT. Write 0x0: Event status bit unchanged Read 0x0: Event false Read 0x1: Event is pending Write 0x1: Event status bit is reset	RW W1toClr	0
16	WKS	Wake-up event in slave mode when an active control signal is detected on the SPIEN line programmed in the field MCSPI_CHxCONF[22:21] SPIENSLV Read 0x0: Event false Write 0x0: Event status bit unchanged Write 0x1: Event status bit is reset Read 0x1: Event is pending	RW W1toClr	0
15	RESERVED	Reads returns 0	RW	0
14	RX3_FULL	Receiver register is full or almost full. Only when Channel 3 is enabled Read 0x0: Event false Write 0x0: Event status bit unchanged Write 0x1: Event status bit is reset Read 0x1: Event is pending	RW W1toClr	0
13	TX3_UNDERFLOW	Transmitter register underflow. Only when Channel 3 is enabled. The transmitter register is empty (not updated by host or DMA with new data) before its time slot assignment. Exception: No TX_underflow event when no data has been loaded into the transmitter register since channel has been enabled. Read 0x0: Event false Write 0x0: Event status bit unchanged Write 0x1: Event status bit is reset Read 0x1: Event is pending	RW W1toClr	0
12	TX3_EMPTY	Transmitter register is empty or almost empty. Note: Enabling the channel automatically rises this event. Read 0x0: Event false Write 0x0: Event status bit unchanged Write 0x1: Event status bit is reset Read 0x1: Event is pending	RW W1toClr	0
11	RESERVED	Reads returns 0.	RW	0
10	RX2_FULL	Receiver register full or almost full. Channel 2 Read 0x0: Event false Write 0x0: Event status bit unchanged Write 0x1: Event status bit is reset Read 0x1: Event is pending	RW W1toClr	0
9	TX2_UNDERFLOW	Transmitter register underflow. Channel 2 Read 0x0: Event false Write 0x0: Event status bit unchanged Write 0x1: Event status bit is reset Read 0x1: Event is pending	RW W1toClr	0

Bits	Field Name	Description	Type	Reset
8	TX2_EMPTY	Transmitter register empty or almost empty. Channel 2 Read 0x0: Event false Write 0x0: Event status bit unchanged Write 0x1: Event status bit is reset Read 0x1: Event is pending	RW W1toClr	0
7	RESERVED	Reads returns 0	RW	0
6	RX1_FULL	Receiver register full or almost full. Channel 1 Read 0x0: Event false Write 0x0: Event status bit unchanged Write 0x1: Event status bit is reset Read 0x1: Event is pending	RW W1toClr	0
5	TX1_UNDERFLOW	Transmitter register underflow. Channel 1 Read 0x0: Event false Write 0x0: Event status bit unchanged Write 0x1: Event status bit is reset Read 0x1: Event is pending	RW W1toClr	0
4	TX1_EMPTY	Transmitter register empty or almost empty. Channel 1 Read 0x0: Event false Write 0x0: Event status bit unchanged Write 0x1: Event status bit is reset Read 0x1: Event is pending	RW W1toClr	0
3	RX0_OVERFLOW	Receiver register overflow (slave mode only). Channel 0 Read 0x0: Event false Write 0x0: Event status bit unchanged Write 0x1: Event status bit is reset Read 0x1: Event is pending	RW W1toClr	0
2	RX0_FULL	Receiver register full or almost full. Channel 0 Read 0x0: Event false Write 0x0: Event status bit unchanged Write 0x1: Event status bit is reset Read 0x1: Event is pending	RW W1toClr	0
1	TX0_UNDERFLOW	Transmitter register underflow. Channel 0 Read 0x0: Event false Write 0x0: Event status bit unchanged Write 0x1: Event status bit is reset Read 0x1: Event is pending	RW W1toClr	0
0	TX0_EMPTY	Transmitter register empty or almost empty. Channel 0 Read 0x0: Event false Write 0x0: Event status bit unchanged Write 0x1: Event status bit is reset Read 0x1: Event is pending	RW W1toClr	0

Bits	Field Name	Description	Type	Reset
31:12	RESERVED	Reads returns 0.	RW	0x00000
11	SSB	Set status bit 0x0: No action. Writing 0 does not clear already set status bits. This bit must be cleared before trying to clear a status bit of the MCSPI_IRQSTATUS register. 0x1: Force to 1 all status bits of MCSPI_IRQSTATUS register. Writing 1 into this bit sets to 1 all status bits in the MCSPI_IRQSTATUS register.	RW	0
10	SPIENDIR	Set the direction of the SPIEN[3:0] lines and SPICLK line. 0x0: Output (as in master mode) 0x1: Input (as in slave mode)	RW	0
9	SPIDATDIR1	Set the direction of the SPIDAT[1]. 0x0: Output 0x1: Input	RW	0
8	SPIDATDIR0	Set the direction of the SPIDAT[0]. 0x0: Output 0x1: Input	RW	0
7	WAKD	SWAKEUP output (signal data value of internal signal to system). The signal is driven high or low according to the value written into this bit. 0x0: The pin is driven low. 0x1: The pin is driven high.	RW	0
6	SPICLK	SPICLK line (signal data value) If [10] SPIENDIR = 1 (input mode direction), this bit returns the value on the CLKSPI line (high or low), and a write into this bit has no effect. If [10] SPIENDIR = 0 (output mode direction), the CLKSPI line is driven high or low according to the value written into this bit.	RW	0
5	SPIDAT_1	SPIDAT[1] line (signal data value) If [9] SPIDATDIR1 = 0 (output mode direction), the SPIDAT[1] line is driven high or low according to the value written into this bit. If [9] SPIDATDIR1 = 1 (input mode direction), this bit returns the value on the SPIDAT[1] line (high or low), and a write into this bit has no effect.	RW	0

Bits	Field Name	Description	Type	Reset
4	SPIDAT_0	SPIDAT[0] line (signal data value) If [8] SPIDATDIR0 = 0 (output mode direction), the SPIDAT[0] line is driven high or low according to the value written into this bit. If [8] SPIDATDIR0 = 1 (input mode direction), this bit returns the value on the SPIDAT[0] line (high or low), and a write into this bit has no effect.	RW	0
3	SPIEN_3	SPIEN[3] line (signal data value) If [10] SPIENDIR = 0 (output mode direction), the SPIEN[3] line is driven high or low according to the value written into this bit. If [10] SPIENDIR = 1 (input mode direction), this bit returns the value on the SPIEN[3] line (high or low), and a write into this bit has no effect.	RW	0
2	SPIEN_2	SPIEN[2] line (signal data value) If [10] SPIENDIR = 0 (output mode direction), the SPIEN[2] line is driven high or low according to the value written into this bit. If [10] SPIENDIR = 1 (input mode direction), this bit returns the value on the SPIEN[2] line (high or low), and a write into this bit has no effect.	RW	0
1	SPIEN_1	SPIEN[1] line (signal data value) If [10] SPIENDIR = 0 (output mode direction), the SPIEN[1] line is driven high or low according to the value written into this bit. If [10] SPIENDIR = 1 (input mode direction), this bit returns the value on the SPIEN[1] line (high or low), and a write into this bit has no effect.	RW	0
0	SPIEN_0	SPIEN[0] line (signal data value) If [10] SPIENDIR = 0 (output mode direction), the SPIEN[0] line is driven high or low according to the value written into this bit. If [10] SPIENDIR = 1 (input mode direction), this bit returns the value on the SPIEN[0] line (high or low), and a write into this bit has no effect.	RW	0

RESERVED																FDA	MOA	INITDLY			SYSTEM_TEST	MS	PIN34	SINGLE							

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Reads returns 0.	RW	0x000000
8	FDAA	<p>FIFO DMA address 256-bit aligned</p> <p>This bit is used when a FIFO is managed by the module and DMA connected to the controller provides only 256-bit aligned address. If this bit is set the enabled channel which uses the FIFO has its data managed through MCSPI_DAFTX and MCSPI_DAFRX registers instead of MCSPI_TXx and MCSPI_RXx registers.</p> <p>0x0: FIFO data managed by MCSPI_TXx and MCSPI_RXx registers.</p> <p>0x1: FIFO data managed by MCSPI_DAFTX and MCSPI_DAFRX registers.</p>	RW	0
7	MOA	<p>Multiple word interface access: this bit can only be used when a channel is enabled using a FIFO. It allows the system to perform multiple SPI word access for a single 32-bit interface word access. This is possible for WL < 16.</p> <p>0x0: Multiple word access disabled</p> <p>0x1: Multiple word access enabled with FIFO</p>	RW	0
6:4	INITDLY	<p>Initial SPI delay for first transfer: this field is an option only available in SINGLE master mode. The controller waits for a delay to transmit the first SPI word after channel enabled and corresponding TX register filled. This delay is based on SPI output frequency clock. No clock output provided to the boundary and chip select is not active in 4-pin mode within this period.</p> <p>0x0: No delay for first spi transfer.</p> <p>0x1: The controller wait 4 SPI bus clock</p> <p>0x2: The controller wait 8 SPI bus clock</p> <p>0x3: The controller wait 16 SPI bus clock</p> <p>0x4: The controller wait 32 SPI bus clock</p>	RW	0x0
3	SYSTEM_TEST	<p>Enables the system test mode</p> <p>0x0: Functional mode</p> <p>0x1: System test mode (SYSTEST)</p>	RW	0
2	MS	<p>Master/slave</p> <p>0x0: Master - The module generates the SPICLK and SPIEN[3:0].</p> <p>0x1: Slave - The module receives the SPICLK and SPIEN[3:0].</p>	RW	1
1	PIN34	<p>Pin mode selection:</p> <p>This bit is used in master or slave mode to configure the SPI pin mode (3-pin or 4-pin). If asserted the controller only uses SIMO, SOMI, and SPICLK clock pin for SPI transfers.</p> <p>0x0: SPIEN is used as a chip-select.</p> <p>0x1: SPIEN is not used. In this mode all related options to chip-select have no meaning.</p>	RW	0
0	SINGLE	<p>Single channel/Multi Channel (master mode only)</p> <p>0x0: More than one channel will be used in master mode.</p> <p>0x1: Only one channel will be used in master mode. This bit must be set in Force SPIEN[x] mode.</p>	RW	0

19.4 Quad Serial Peripheral Interface

19.4.1 Quad Serial Peripheral Interface Overview

The quad serial peripheral interface (QSPI™) module is a kind of SPI module that allows single, dual, or quad read access to external SPI devices. This module has a memory mapped register interface, which provides a direct interface for accessing data from external SPI devices and thus simplifying software requirements. The QSPI works as a master only.

The one QSPI in the device is primarily intended for fast booting from quad-SPI flash memories. Figure 19-66 shows the QSPI module overview.

Figure 19-66. QSPI Overview

The QSPI supports the following features:

- General SPI features:
 - Programmable clock divider
 - Six pin interface
 - Programmable length (from 1 to 128 bits) of the words transferred
 - Programmable number (from 1 to 4096) of the words transferred
 - 4 external chip-select signals
 - Support for 3-, 4-, or 6-pin SPI interface
 - Optional interrupt generation on word or frame (number of words) completion
 - Programmable delay between chip select activation and output data from 0 to 3 QSPI clock cycles
 - Programmable signal polarities
 - Programmable active clock edge
 - Software-controllable interface allowing for any type of SPI transfer
 - Control through L3_MAIN configuration port
- Serial flash interface (SFI) features:
 - Serial flash read/write interface
 - Additional registers for defining read and write commands to the external serial flash device
 - 1 to 4 address bytes
 - Fast read support, where fast read requires dummy bytes after address bytes; 0 to 3 dummy bytes can be configured.
 - Dual read support

- Quad read support
- Little-endian support (only for memory mapped registers used to configure QSPI controller and not SPI content accesses)
- Linear increment addressing mode only

The QSPI supports only dual and quad reads. Dual or quad writes are not supported. In addition, there is no "pass through" mode supported where the data present on the QSPI input is sent to its output.

NOTE: The QSPI module does not support cache line wrap mode.

19.4.2 QSPI Environment

Figure 19-67 shows a typical connection of the QSPI module to the external quad-SPI flash memory.

Figure 19-67. QSPI Connected to an External Quad-SPI Flash Memory

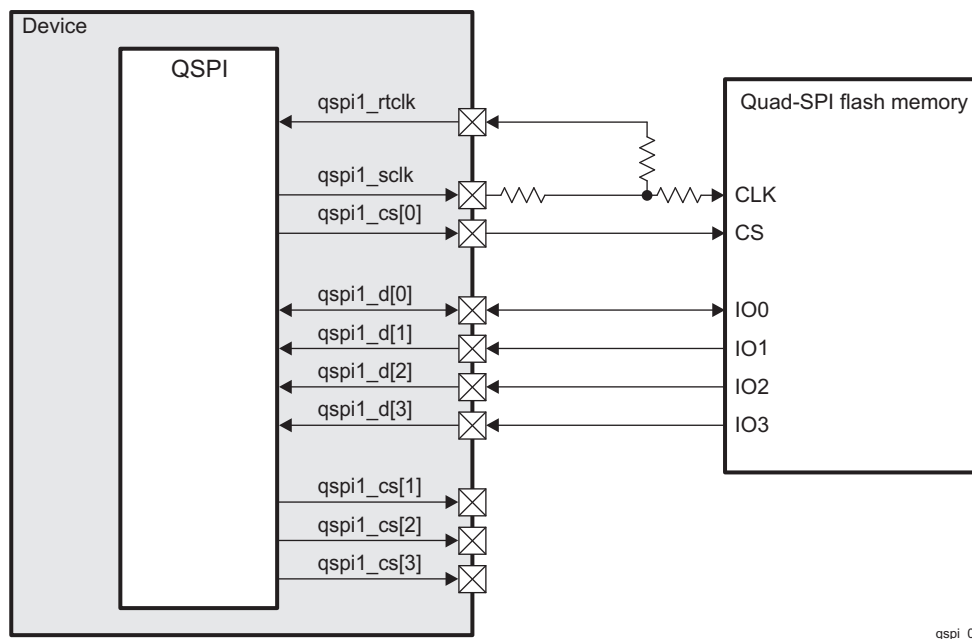

Table 19-260 lists and describes the QSPI I/O signals.

Table 19-260. QSPI I/O Signals

QSPI Signal/Pad name	I/O ⁽¹⁾	Description					
		3-pin ⁽²⁾ SPI Read (Single Read)	3-pin ⁽²⁾ SPI Write (Single Write)	4-pin ⁽²⁾ SPI Read (Single Read)	4-pin ⁽²⁾ SPI Write (Single Write)	4-pin ⁽²⁾ SPI Read (Dual Read)	6-pin ⁽²⁾ SPI Read (Quad Read)
qspi1_d[0]	IO	Used as SPI data input	Used as SPI data output	Not used	Used as SPI data output	Used as SPI data input 0	Used as SPI data input 0
qspi1_d[1]	I	Not used	Not used	Used as SPI data input	Not used	Used as SPI data input 1	Used as SPI data input 1
qspi1_d[2]	I	Not used	Not used	Not used	Not used	Not used	Used as SPI data input 2
qspi1_d[3]	I	Not used	Not used	Not used	Not used	Not used	Used as SPI data input 3
qspi1_sclk	O	Clock for the external SPI device					
qspi1_cs[0]	O	External SPI device chip-select 0					
qspi1_cs[1]	O	External SPI device chip-select 1					
qspi1_cs[2]	O	External SPI device chip-select 2					
qspi1_cs[3]	O	External SPI device chip-select 3					
qspi1_rtclk	I	The qspi1_sclk output must be connected to the qspi1_rtclk input, and is used for controlling the timing of the read return data when the QSPI module operates in Mode 0. In case Mode 3 is used, there is no need to connect the qspi1_sclk to the qspi1_rtclk.					

⁽¹⁾ I = Input; O = Output

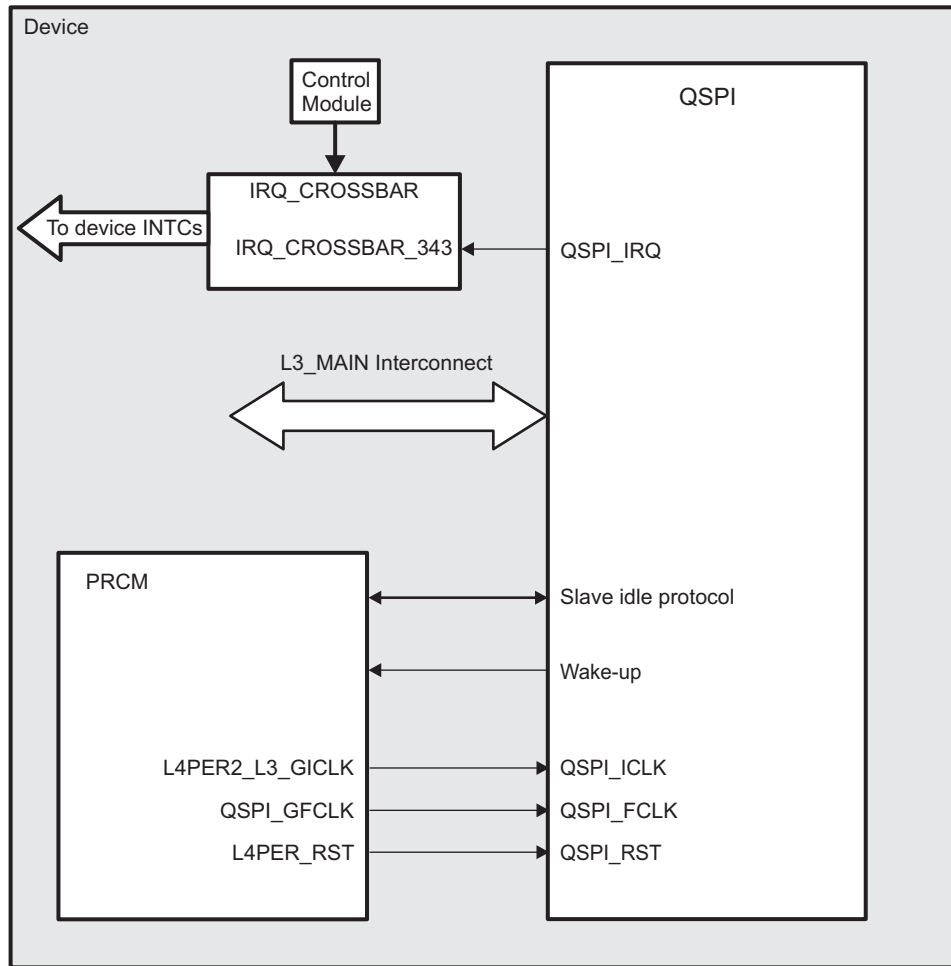

⁽²⁾ This is the pin count at the SPI flash memory side. The pin count at the device side is increased by one because of the qspi1_rtclk signal. References to the pin count throughout this chapter consider the pin count at the SPI flash memory side.

NOTE: In order to ensure proper timing, precise layout and routing requirements must be followed. For layout and routing requirements for all QSPI signals, see section “PCB Guidelines” of the device Data Manual.

19.4.3 QSPI Integration

Figure 19-68 shows the integration of the QSPI module in the device.

Figure 19-68. QSPI Integration

qspi_003

Table 19-261 through Table 19-263 summarize the integration of the QSPI in the device.

Table 19-261. QSPI Integration Attributes

Module Instance	Attributes

	QSPI_FCLK	QSPI_GFCLK	PRCM	Functional clock for the QSPI
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
QSPI	QSPI_RST	L4PER_RST	PRCM	Asynchronous reset signal for the QSPI

Table 19-263. QSPI Hardware Requests

Module Instance	Source Signal Name	Interrupt Requests		Description
		Destination	Default Mapping	
		IRQ_CROSSBAR Input		
QSPI	QSPI_IRQ	IRQ_CROSSBAR_343	–	QSPI interrupt request

NOTE: The Default Mapping column in [Table 19-263](#) shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device interrupt controller (INTC) through the IRQ_CROSSBAR module. For more information about the IRQ_CROSSBAR module, see [Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#). For more information about the device INTCs, see [Chapter 13, Interrupt Controllers](#).

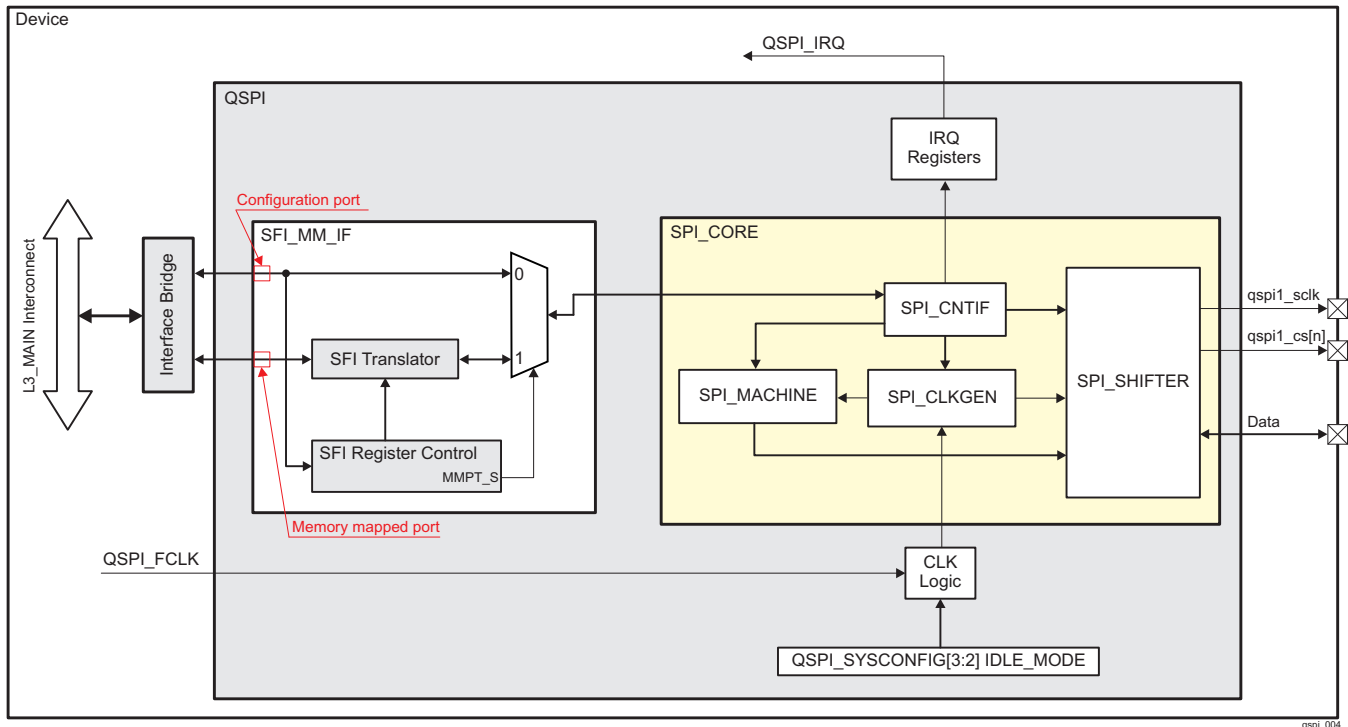

NOTE: For the description of the interrupt source, see [Section 19.4.4.3, QSPI Interrupt Requests](#).

19.4.4 QSPI Functional Description

19.4.4.1 QSPI Block Diagram

Initial device boot from external SPI flash memory can be accomplished through the QSPI module. The interface is a simple 4-wire SPI used for control or data transfers. The QSPI also supports a 3-wire SPI protocol where the qspi1_d[0] signal is used as a bidirectional for reads and writes. In addition, a 6-wire mode can be used to support quad read devices. [Figure 19-69](#) shows the QSPI block diagram.

Figure 19-69. QSPI Block Diagram

The QSPI is composed of two blocks. The first one is the SFI memory-mapped interface (SFI_MM_IF) and the second one is the SPI core (SPI_CORE). The SFI_MM_IF block is associated only with SPI flash memories and is used for specifying typical for the SPI flash memories settings (read or write command, number of address and dummy bytes, and so on) unlike the SPI_CORE block, which is associated with the SPI interface itself and is used to configure typical SPI settings (chip-select polarity, serial clock inactive state, SPI clock mode, length of the words transferred, and so on).

The SFI_MM_IF comprises the following two subblocks:

- SFI register control
- SFI translator

The SPI_CORE comprises the following four subblocks:

- SPI control interface (SPI_CNTIF)
- SPI clock generator (SPI_CLKGEN)
- SPI control state machine (SPI_MACHINE)
- SPI data shifter (SPI_SHIFTER)

In addition, an interface bridge connects the two ports (configuration port and memory-mapped port) of the SFI_MM_IF block to the L3_MAIN interconnect. There are no software controls associated with this interface bridge.

The QSPI supports long transfers through a frame-style sequence. In its generic SPI use mode, a word can be defined up to 128 bits and multiple words can be transferred during a single access. For each word, a device initiator must read or write the new data and then tell the QSPI to continue the current operation. Using this sequence, a maximum of 4096 128-bit words can be transferred in a single SPI read or write operation. This allows great flexibility when connecting the QSPI to various types of devices.

As opposed to the generic SPI use mode, the communication with serial flash-type devices requires sending a byte command, followed by sending bytes of data. Commands can be sent through the SPI_CORE block to communicate with a serial flash device; however, it is easier to do this using the SFI_MM_IF block because it is intended to ease the communication with serial flash devices. If the SPI_CORE is used to communicate with a serial flash device, software must load the command into the SPI data transfer register with additional configuration fields, perform the byte transfer, then place the data to be sent (or configure for receive) along with additional configuration fields, and perform that transfer. Reads and writes to serial flash devices are more specific. First, the read or write command byte is sent, followed by 1 to 4 bytes of address (corresponding to the address to read/write), then followed by the data write/receive phase. Data is always sent byte oriented. When the address is loaded, data can be continuously read or written, and the address will automatically increment to each byte address internally to the serial flash device.

NOTE: The SFI_MM_IF block only allows reading and writing to an externally connected SPI flash device. The SFI_MM_IF block does not allow reads or writes to internal configuration and status registers of the SPI flash device. These registers must be accessed through the features of the SPI_CORE block.

19.4.4.1.1 SFI Register Control

The SFI register control block consists of the following five configuration registers:

- [QSPI_SPI_SETUP0_REG](#)
- [QSPI_SPI_SETUP1_REG](#)
- [QSPI_SPI_SETUP2_REG](#)
- [QSPI_SPI_SETUP3_REG](#)
- [QSPI_SPI_SWITCH_REG](#)

The first four registers let the user define the following:

- Byte command for a serial flash read specified by the QSPI_SPI_SETUP_i_REG[7:0] RCMD bit field
- Byte command for a serial flash write specified by the QSPI_SPI_SETUP_i_REG[23:16] WCMD bit field
- Number of address bytes required for the particular type of serial flash specified by the

QSPI_SPI_SETUP_i_REG[9:8] NUM_A_BYTES bit field

- Number of “dummy bytes” that may be needed to support the fast read mode function of some serial flash devices. The QSPI_SPI_SETUP_i_REG[11:10] NUM_D_BYTES bit field specifies the number of “dummy bits.” In addition, the QSPI_SPI_SETUP_i_REG[28:24] NUM_D_BITS bit field can also specify the number of “dummy bits.”
- Whether the read command is single (normal), dual, or quad read mode command. This is specified by the QSPI_SPI_SETUP_i_REG[13:12] READ_TYPE bit field. (*i* is equal to 0, 1, 2 and 3 and means that the QSPI_SPI_SETUP_i_REG registers are associated with each of the four supported chip-selects [that is, four supported output SPI flash devices])

The QSPI_SPI_SWITCH_REG register acts as a static switch which allows the configuration port (shown in [Figure 19-69](#)) to connect directly to the SPI_CORE block, or allows the memory-mapped port (also shown in [Figure 19-69](#)) to connect to the SPI_CORE block. This is done using the QSPI_SPI_SWITCH_REG[0] MMPT_S bit.

In addition, the QSPI_SPI_SWITCH_REG[1] MM_INT_EN bit is used to enable or disable the word complete interrupt during operations using the memory-mapped port.

19.4.4.1.2 SFI Translator

The SFI translator block represents an FSM which, based on the configuration information loaded into the SFI register control block, converts each input read/write sequence into an SPI_CORE configuration sequence for access to the external serial flash memory.

A read sequence is converted into the following actions:

1. SPI chip-select goes active.
2. Read command byte is issued.
3. 1 to 4 address bytes, which correspond to the first address supplied, are issued.
4. 0 to 3 dummy bytes are issued, if “fast read” is supported.
5. Data bytes are read from the external SPI flash memory.
6. SPI chip-select goes inactive.

For linear addressing mode, action 5 is repeated until the byte count to be transferred reaches zero.

A write sequence is identical to a read sequence, except that a write sequence does not use dummy bytes.

Another important aspect with regard to writes is that a serial flash memory location can only be written to if the bits are erased in advance. Erased means the bits are set to 1. This means that writing only changes 1 contents to 0. It is not possible with this write to change the contents of a bit from 0 to 1. An erase command must be performed to do this operation. Erase commands cannot be executed on single byte locations. Depending on device types, there are page, block, and chip erase commands. To perform an erase command, the particular command must be sent over the SPI bus, and an internal register of the serial flash device must then be polled to determine when the erase completes. The erases must be done through the configuration port by software before performing any writes through the memory-mapped port. This means that writes are passed through to the serial flash device, but if the memory locations being modified are not properly erased before the write, the contents may not result in what was sent.

19.4.4.1.3 SPI Control Interface

The SPI control interface contains configuration registers used to configure the SPI core functionality of the QSPI. This block maintains all configuration settings for the SPI core (that is, settings specific for the SPI interface itself but not for the SPI flash memories).

The registers defined for this block are:

- The QSPI_PID register, which is read only and contains QSPI revision associated information
- The QSPI_SPI_CLOCK_CNTRL_REG register, which is used to control external SPI clock (qspi1_sclk)
- The QSPI_SPI_DC_REG register used to define the SPI clock mode and chip-select polarity for the four external SPI devices
- The QSPI_SPI_CMD_REG register used to control the operation of the SPI command. This register is

also used to configure and transfer data.

- Four data registers used for reading the data received and for writing the data to be transferred. These registers are:
 - [QSPI_SPI_DATA_REG](#)
 - [QSPI_SPI_DATA_REG_1](#)
 - [QSPI_SPI_DATA_REG_2](#)
 - [QSPI_SPI_DATA_REG_3](#)
 These four registers compose a 128-bit shift register.
- The [QSPI_SPI_STATUS_REG](#) register, which contains status information

All of these registers can only be written if the QSPI is not busy. This means that they can be written if the [QSPI_SPI_STATUS_REG\[0\]](#) BUSY bit is 0x0. The QSPI becomes busy when a write to the [QSPI_SPI_CMD_REG\[18:16\]](#) CMD bit field is performed. Writing to this bit field starts an SPI transaction and sets the [QSPI_SPI_STATUS_REG\[0\]](#) BUSY bit to 0x1. The CMD bit field can be written again when the BUSY bit is 0x0. In addition, the start of the SPI transaction is synchronized to the qspi1_sclk clock and clearing of the BUSY bit is synchronized to the QSPI_FCLK clock.

The register group [QSPI_SPI_DATA_REG_3](#), [QSPI_SPI_DATA_REG_2](#), [QSPI_SPI_DATA_REG_1](#) and [QSPI_SPI_DATA_REG](#) is treated as a single 128-bit word for shifting data in and out. The [QSPI_SPI_DATA_REG_3](#) register is used for the most significant bits and the [QSPI_SPI_DATA_REG](#) is used for the least significant bits. This applies for both reads and writes. For example, after reading a 128-bit word (WLEN = 0x7F) the most significant bit of the data read, that is bit 127, will be located at [QSPI_SPI_DATA_REG_3\[31\]](#) position and the least significant bit, that is bit 0 of the data read, will be located at the [QSPI_SPI_DATA_REG\[0\]](#) position.

The data written to this register group should be right justified so that a data pre-shifting is not required. The [QSPI_SPI_CMD_REG\[25:19\]](#) WLEN bit field determines the location of the most significant bit and the bit position that will be shifted out first during a write. In order to shift out byte data the WLEN bit field should be set to 0x7 and the data byte should be written to the lower byte of the [QSPI_SPI_DATA_REG](#) register. By setting the word length to 0x7 the [QSPI_SPI_DATA_REG](#) register will look like a pseudo 8-bit shift register. When the user wants to write 40-bit long word the WLEN bit field should be set to 0x27, the 32 least significant bits of data should be written to the [QSPI_SPI_DATA_REG](#) and the rest 8 most significant bits of data should be written to the lower byte of the [QSPI_SPI_DATA_REG_1](#) register. By setting WLEN to 0x27 these two registers will look like a pseudo 40-bit shift register. When the word length is greater than 64 bits the [QSPI_SPI_DATA_REG_2](#) register is also used and the previously described logic applies. The [QSPI_SPI_DATA_REG_3](#) register is used together with the other three data registers when the word length is greater than 96 bits.

When dual or quad read mode is used the number of the words transferred must be even. This number is configured through the [QSPI_SPI_CMD_REG\[11:0\]](#) FLEN bit field.

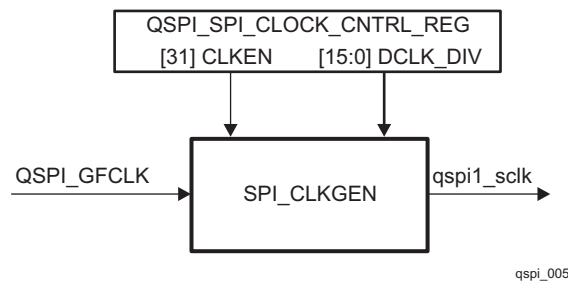

NOTE: The QSPI module does not support a "pass through" mode where the data present on qspi1_d[1] is sent to qspi1_d[0], when 4-pin non-dual read mode is used. This means that setting the [QSPI_SPI_CMD_REG\[18:16\]](#) CMD bit field to 0x1 causes the QSPI only to read from an external device using the qspi1_d[1] pad as an input and if a write to the same external device is desired, the CMD bit field should be set to 0x2, which causes the qspi1_d[0] pad to be used as an output.

19.4.4.1.4 SPI Clock Generator

The SPI clock generator uses the QSPI_FCLK clock as an input, and generates the qspi1_sclk, which is a divided version of the QSPI_FCLK clock. The divide ratio is a 16-bit value configured through the [QSPI_SPI_CLOCK_CNTRL_REG\[15:0\]](#) DCLK_DIV bit field and thus provides a division factor in a range from 1 to 65536. The QSPI_FCLK clock is divided by the DCLK_DIV value + 1 to provide the qspi1_sclk clock. When DCLK_DIV = 0x0 the QSPI_FCLK clock equals the DCLK clock. The value in the DCLK_DIV bit field applies only when the [QSPI_SPI_CLOCK_CNTRL_REG\[31\]](#) CLKEN bit is set to 0x1. [Figure 19-70](#) shows the SPI_CLKGEN block.

If the CLKEN bit is 0x0 the command specified in the [QSPI_SPI_CMD_REG\[18:16\]](#) CMD bit field is not executed and the [QSPI_SPI_STATUS_REG\[0\]](#) BUSY bit is not set. The command is executed only if the CLKEN bit is 0x1 before write to the CMD bit field.

Figure 19-70. SPI_CLKGEN Block

19.4.4.1.5 SPI Control State-Machine

The SPI control state-machine (SPI_MACHINE) manages the operation of the SPI_CORE block. SPI_MACHINE takes control and configuration information from the registers in the SPI_CNTIF block as input and provides control information to the SPI data shifter. This information is used to control the SPI data port. The SPI_MACHINE also generates status information, which is sent back to the SPI_CNTIF block.

Writing a valid value to the [QSPI_SPI_CMD_REG\[18:16\]](#) CMD bit field sets immediately the [QSPI_SPI_STATUS_REG\[0\]](#) BUSY bit to 0x1, activates the corresponding qspi1_cs[n] (n = 0 to 3) and starts the SPI data transaction. The BUSY bit is cleared automatically when [QSPI_SPI_CMD_REG\[25:19\]](#) WLEN number of bits are shifted in or out. If the value of the [QSPI_SPI_STATUS_REG\[27:16\]](#) WDCNT bit field is different than 0x0 and WLEN number of bits are shifted already, the SPI_MACHINE waits until another write to the CMD bit field is performed. If the command written to the CMD bit field is valid, then this decrements the value of the WDCNT bit field and starts shifting data in or out again. This is repeated until the WDCNT bit field reaches 0x0, that is, all words of the frame are shifted or till earlier frame termination occurs. While the SPI_MACHINE is waiting for write to the CMD bit field the corresponding qspi1_cs[n] (n = 0 to 3) remains active and the BUSY flag is set to 0x0. In addition, the bit length for each word can be changed during a frame from 1 to 128 bits using the [QSPI_SPI_CMD_REG\[25:19\]](#) WLEN bit field.

The SPI_MACHINE also provides a mechanism to terminate the frame earlier. This is done by writing an invalid command to the CMD bit field. An invalid command corresponds to the 0x0 and 0x4 (reserved) values of the CMD bit field. Writing one of these values when the the WDCNT bit field is not equal to 0x0 and when the BUSY flag is 0x0 terminates the frame earlier.

The corresponding qspi1_cs[n] (n = 0 to 3) becomes inactive when all words are shifted or when the frame terminates earlier.

19.4.4.1.6 SPI Data Shifter

The SPI data shifter handles the capture and generation of the SPI interface signals. Based on control signals from the SPI_MACHINE and SPI_CNTIF blocks, data is shifted in or out on falling or rising edge of qspi1_sclk clock depending on the SPI clock mode selected. [Table 19-264](#) lists the four defined clock modes of operation for the QSPI.

Table 19-264. SPI Clock Modes Definition

Mode	Settings in the QSPI_SPI_DC_REG Register		Description
	Value of the CKP bits	Value of the CKPH bits	
0	0	0	Data input captured on falling edge of qspi1_sclk clock. Data output generated on falling edge of qspi1_sclk clock
1	0	1	Data input captured on rising edge of qspi1_sclk clock. Data output generated on rising edge of qspi1_sclk clock

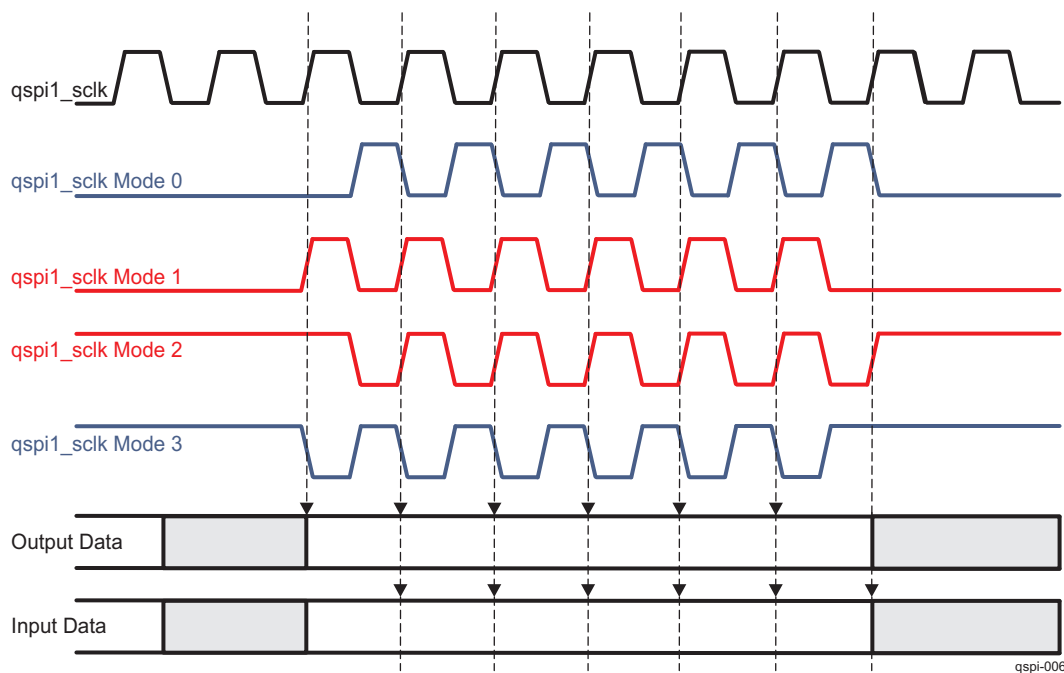

Table 19-264. SPI Clock Modes Definition (continued)

Mode	Settings in the QSPI_SPI_DC_REG Register		Description
	Value of the CKP bits	Value of the CKPH bits	
2	1	0	Data input captured on rising edge of qspi1_sclk clock. Data output generated on rising edge of qspi1_sclk clock
3	1	1	Data input captured on falling edge of qspi1_sclk clock. Data output generated on falling edge of qspi1_sclk clock

NOTE: Mode 1 and Mode 2 are not supported and should not be used.

The CKPi and CKPHi (i = 0 to 3) bits of the [QSPI_SPI_DC_REG](#) register control the clock modes. Each of these 4 bits corresponds to an output chip select.

[Figure 19-71](#) shows all four clock modes. In addition, through the DDi (i = 0 to 3) bits of the [QSPI_SPI_DC_REG](#) register the data can be delayed from one to three qspi1_sclk clock cycles after the corresponding qspi1_cs[n] (n = 0 to 3) goes active. The active state of each chip-select can also be controlled through the CSPi (i = 0 to 3) bits of the [QSPI_SPI_DC_REG](#) register.

Figure 19-71. SPI Clock Modes

19.4.4.2 QSPI Clock Configuration

The QSPI complies with the PRCM slave-idle protocol. The QSPI_FCLK clock is gated based on the values loaded in the [QSPI_SYSCONFIG\[3:2\]](#) IDLE_MODE bit field. Three modes are supported:

- Force-idle: The QSPI_FCLK clock is gated unconditionally by the QSPI.
- No-idle: The QSPI_FCLK clock is never gated by the QSPI.
- Smart-idle: The QSPI_FCLK clock is gated by the QSPI, depending on its internal requirements.

19.4.4.3 QSPI Interrupt Requests

The QSPI generates one interrupt request which is connected to the IRQ_CROSSBAR module. This interrupt request, QSPI_IRQ, is connected to the IRQ_CROSSBAR_343 input. The QSPI_IRQ interrupt line can be activated by one of the interrupt events listed in [Table 19-265](#).

Figure 19-72 shows a logical representation of the QSPI interrupt generation scheme.

Figure 19-72. Logical Representation of the QSPI Interrupt Generation Scheme

[QSPI_SPI_STATUS_REG\[1\] WC](#) and [QSPI_SPI_STATUS_REG\[2\] FC](#) are status bits indicating whether word or frame transfer is complete. Setting the corresponding interrupt enable bit (WIRQ or FIRQ) in the [QSPI_SPI_CMD_REG](#) register allows these events (WC and FC) to generate an interrupt. The WC and FC bits are reset every time the user writes to the [QSPI_SPI_CMD_REG](#) register or reads the [QSPI_SPI_STATUS_REG](#) register. This is done to keep control parameters from changing the interface protocol signals while a transfer is in progress. Additionally, the [QSPI_SPI_SWITCH_REG\[1\] MM_INT_EN](#) bit is used to enable or disable the word complete interrupt during operations using the memory-mapped port.

When the [QSPI_SPI_CMD_REG\[14\] WIRQ](#) and [QSPI_SPI_CMD_REG\[15\] FIRQ](#) bits are set to 0x1 the following applies:

- The QSPI activates its interrupt line only if the interrupts are enabled by setting to 0x1 the corresponding bits in the [QSPI_INTR_ENABLE_SET_REG](#) register. These interrupts can be disabled by setting the corresponding bits in the [QSPI_INTR_ENABLE_CLEAR_REG](#) register to 0x1.
- After an interrupt has been serviced, software must clear the corresponding status flag. This is done by setting the corresponding bit in the [QSPI_INTR_STATUS_ENABLED_CLEAR](#) register to 0x1, which also clears the corresponding bit in the [QSPI_INTR_STATUS_RAW_SET](#) register. The status flags in the [QSPI_INTR_STATUS_RAW_SET](#) register are set even if the corresponding interrupt is disabled unlike those in the [QSPI_INTR_STATUS_ENABLED_CLEAR](#) register, which are set only if the corresponding interrupt is enabled.
- The QSPI also generates an interrupt if a certain bit in the [QSPI_INTR_STATUS_RAW_SET](#) register is set to 0x1 and the corresponding interrupt is enabled through the [QSPI_INTR_ENABLE_SET_REG](#) register. This feature is useful during user software debugging. In addition, even if interrupts are not enabled a corresponding raw flag in the [QSPI_INTR_STATUS_RAW_SET](#) register is set to 0x1 when an IRQ condition occurs.
- Even if interrupts are not enabled, a certain status bit in the [QSPI_INTR_STATUS_RAW_SET](#) register can also be cleared by setting to 0x1 the corresponding bit in the

[QSPI_INTR_STATUS_ENABLED_CLEAR](#) register.

It must be considered that the previously described scenario applies if the [QSPI_SPI_CMD_REG\[14\]](#) WIRQ and [QSPI_SPI_CMD_REG\[15\]](#) FIRQ bits are set to 0x1.

NOTE: The QSPI_IRQ interrupt line is activated only if at least one of the following conditions is met:

- The word complete interrupt is enabled:
 - during operations using the memory-mapped port by setting to 0x1 both the [QSPI_SPI_SWITCH_REG\[1\]](#) MM_INT_EN and [QSPI_INTR_ENABLE_SET_REG\[1\]](#) WIRQ_ENA_SET bits.
 - during operations using the configuration port by setting to 0x1 both the [QSPI_SPI_CMD_REG\[14\]](#) WIRQ and [QSPI_INTR_ENABLE_SET_REG\[1\]](#) WIRQ_ENA_SET bits.
- The frame complete interrupt is enabled setting to 0x1 both the [QSPI_SPI_CMD_REG\[15\]](#) FIRQ and [QSPI_INTR_ENABLE_SET_REG\[0\]](#) FIRQ_ENA_SET bits.

The QSPI_IRQ interrupt line is also activated when both the conditions are met.

Table 19-265 lists the event flags and the corresponding mask bits of the sources which can cause interrupts.

Table 19-265. QSPI Events

Event Flag	Event Mask	Description
QSPI_INTR_STATUS_RAW_SET[1] WIRQ_RAW	QSPI_INTR_ENABLE_SET_REG[1] WIRQ_ENA_SET	Word complete interrupt event. Asserted each time after a word is transferred or received.
QSPI_INTR_STATUS_ENABLED_CLEAR[1] WIRQ_ENA	QSPI_INTR_ENABLE_CLEAR_REG[1] WIRQ_ENA_CLR	
QSPI_SPI_STATUS_REG[1] WC	QSPI_SPI_CMD_REG[14] WIRQ	
QSPI_INTR_STATUS_RAW_SET[0] FIRQ_RAW	QSPI_INTR_ENABLE_SET_REG[0] FIRQ_ENA_SET	Frame complete interrupt event. Asserted each time after a frame is transferred or received.
QSPI_INTR_STATUS_ENABLED_CLEAR[0] FIRQ_ENA	QSPI_INTR_ENABLE_CLEAR_REG[0] FIRQ_ENA_CLR	
QSPI_SPI_STATUS_REG[2] FC	QSPI_SPI_CMD_REG[15] FIRQ	

19.4.4.4 QSPI Memory Regions

Two memory regions are associated with the QSPI. The first memory region is dedicated to the configuration port. Using this memory region, all internal registers can be programmed and serial transfers made from the four supported external SPI devices. The L3_MAIN start address at which the configuration port is available is 0x4B30 0000. The second memory region is associated mainly with the memory-mapped port and is used for communication directly with one of the four supported external SPI devices. This memory region starts at 0x5C00 0000 and ends at 0x5FFF FFFF L3_MAIN address.

The CTRL_CORE_CONTROL_IO_2[10:8] QSPI_MEMMAPPED_CS bit field provides a functionality for remapping the previously described address space which starts at 0x5C00 0000 L3_MAIN address to one of the four supported chip selects or to the configuration registers. The CTRL_CORE_CONTROL_IO_2 register resides in the CTRL_MODULE_CORE.

It is important to keep in mind that the configuration port provides an access to all the QSPI registers listed in Table 19-267. These are configuration registers and also four data registers. The configuration registers are used to configure typical SPI and serial flash memory settings and the four data registers are used for read and write operations. When communicating with an external SPI device (but not an SPI flash memory) the SPI_CORE module should be used and the data exchanged is available through these four data registers, which can be accessed only through the configuration port. When a communication with an external SPI flash memory is desired, the memory-mapped port should be used.

In other words, to read from an external SPI flash memory, first configure the QSPI through the configuration port and then perform a read through the memory-mapped port.

Address Offset	0x0000 0070	Instance	QSPI
Physical Address	0x4B30 0070		
Description	The data received in this register is shifted to the LSB position and the content of the register is shifted to the left. This register acts as the fourth 32-bit register of the 128-bit shift in/out register. This register is cleared between reads or writes and can only be written when the QSPI module is not busy, as identified by the QSPI_SPI_STATUS_REG[0] BUSY bit.

19.5 Multichannel Audio Serial Port

This section describes the multichannel audio serial port (McASP).

19.5.1 McASP Overview

This section introduces the multichannel audio serial port (McASP) module and describes its main functions and connections in the device.

The McASP functions as a general-purpose audio serial port optimized to the requirements of various audio applications. The McASP module can operate in both transmit and receive modes. The McASP is useful for time-division multiplexed (TDM) stream, Inter-IC Sound (I2S) protocols reception and transmission as well as for an intercomponent digital audio interface transmission (DIT). The McASP has the flexibility to gluelessly connect to a Sony/Philips digital interface (S/PDIF) transmit physical layer component.

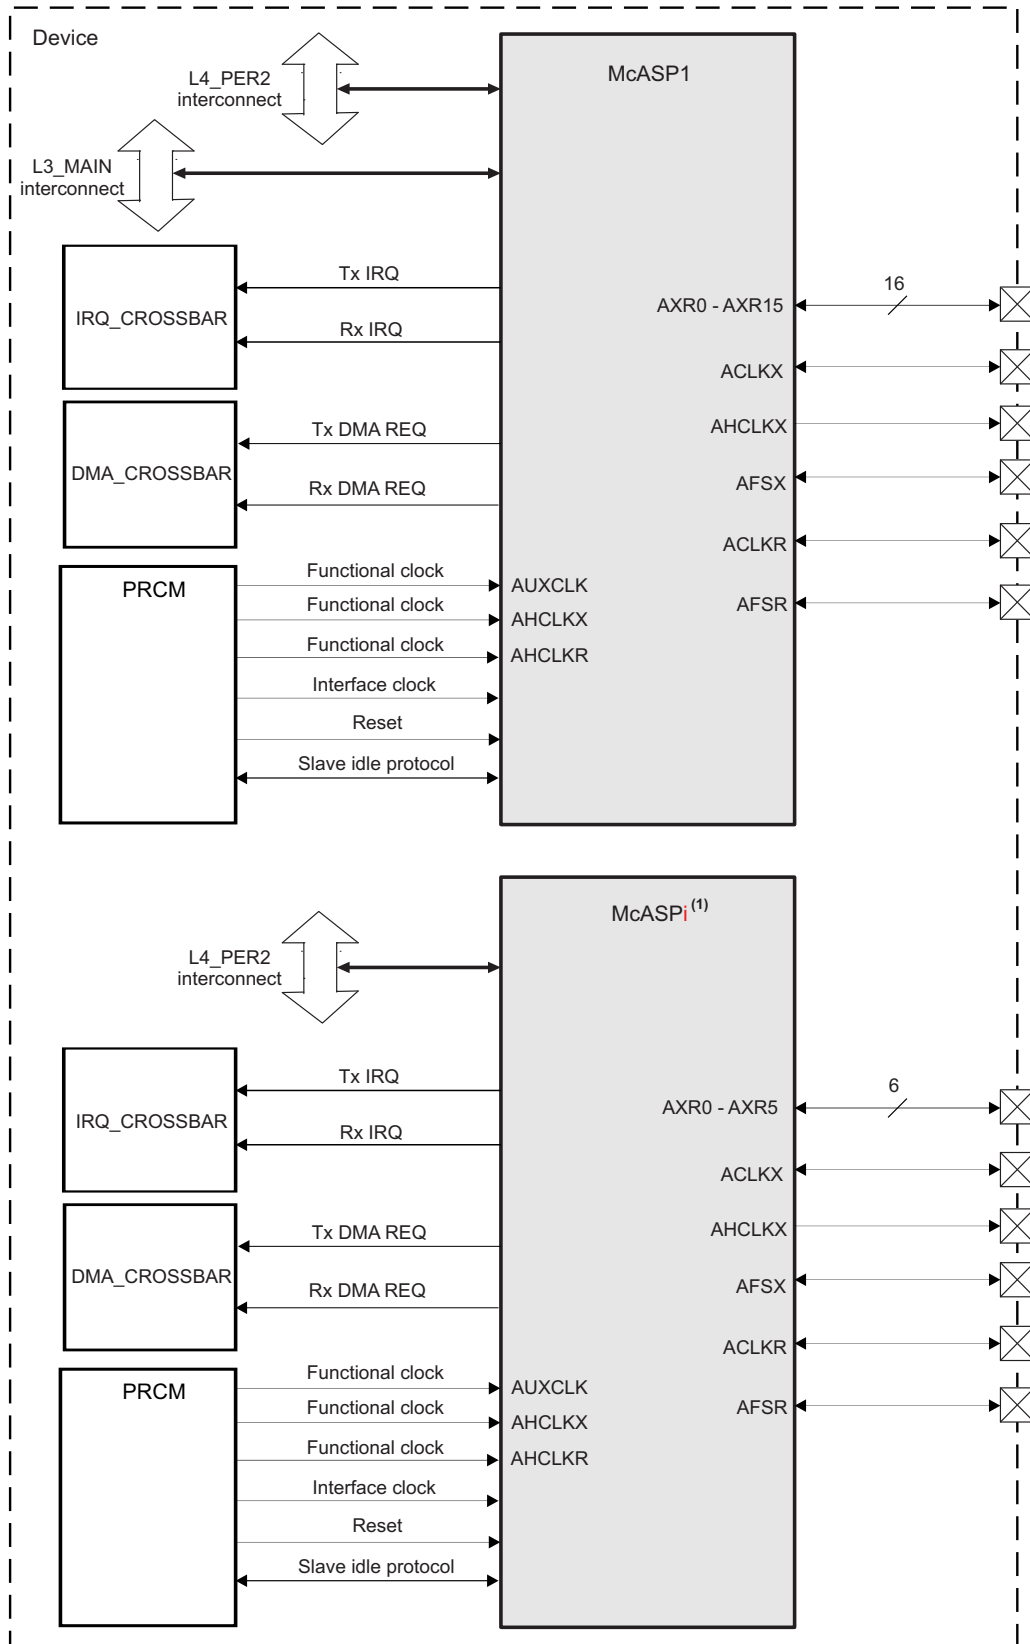

Although intercomponent digital audio interface reception (DIR) mode (i.e. S/PDIF stream receiving) is not natively supported by the McASP module, a specific TDM mode implementation for the McASP receivers allows an easy connection to external DIR components (for example, S/PDIF to I2S format converters).

The device have integrated three McASP modules with:

- McASP1 supporting up to 16 channels with independent TX/RX clock/sync domain
- McASP2 and McASP3 support up to 6 channels with independent TX/RX clock/sync domain.

[Figure 19-73](#) shows the McASP modules in the device.

Figure 19-73. McASP Modules Overview

mcasp-001

(1) $i = 2$ and 3

McASP module includes the following main features:

- McASP1 supports up to 16 channels and independent TX/RX clock/sync domains.
- Two modules (McASP2 and McASP3) supporting up to 6 channels each and independent TX/RX clock/sync domains.
- Independent serializer for each AXRx channel of each McASP_x module.
- Idle request/acknowledge protocol
- A single 32-bit buffer per serializer for transmit and receive operations
- 2 x interconnect slave interface ports:
 - A configuration (CFG) port supplied with an internal L4-interconnect interface clock
 - A slave DMA data port synchronized with functional clock
- Two independent clock generator modules for transmit and receive.
 - Clocking flexibility allows the McASP to receive and transmit at different rates. For example, the McASP can receive data at 48 kHz but output up-sampled data at 96 kHz or 192 kHz.
- McASP module functional clock can be generated:
 - internally (master mode)
 - supplied over McASP serial interface (slave mode)
 - has a controllable functional clock divide ratio
- Independent transmit and receive modules, each includes:
 - Programmable clock and frame sync generator.
 - TDM streams from 2 to 32, and 384 time slots.
 - Support for time slot sizes of 8, 12, 16, 20, 24, 28, and 32 bits.
 - Data formatter for bit manipulation.
- Glueless connection to audio analog-to-digital converters (ADC), digital-to-analog converters (DAC), codec, digital audio interface receiver (DIR), and S/PDIF transmit physical layer components.
- Wide variety of I2S and similar bit-stream format.
- Integrated digital audio interface transmitter (DIT):
 - S/PDIF, IEC60958-1, AES-3 formats.
 - Enhanced channel status/user data RAM.
- 384-slot TDM with external digital audio interface receiver (DIR) device.
 - For DIR reception, an external DIR receiver integrated circuit should be used with I2S output format and connected to the McASP receive section.
- Support for 2x DMA requests (one per direction):
 - 1 level-sensitive transmit direct memory access (DMA) request common for all of the McASP serializers
 - 1 level-sensitive receive direct memory access (DMA) request common for all of the McASP serializers
 - All transmit DMA requests are mapped to the device DMA crossbar
- One transmit interrupt request common for all serializers
- One receive interrupt request common for all serializers
- Each of the Rx and Tx interrupts is propagated to different host processors via the device Interrupt Crossbar

NOTE: Because a serializer receive and transmit channels data is shared on the same McASP data pin, user can choose to have either Tx or Rx function from a serializer, not both at the same time.

19.5.2 McASP Environment

This section describes the McASP application fields from an environment point of view (external connections), along with the McASP connectivity options. This section also lists all of the possible interfaces and describes the protocol and data format used in each case. Figure 19-74 shows the McASP modules in their environment in the device.

Figure 19-74. McASP Environment

(1) $i = 2$ and 3

19.5.2.1 McASP Signals

Table 19-308 describes the McASP pins, their corresponding signal names at device level and specifies their links to functions.

Table 19-308. McASP I/O Signals

Module Pin Name	Device Level Signal Name	I/O ⁽¹⁾	Description	Module Pin Reset Value
McASP1 module				
AXR0	mcasp1_axr[0]	I/O	Audio transmit/receive data - channel 0	HiZ
AXR1	mcasp1_axr[1]	I/O	Audio transmit/receive data - channel 1	HiZ
AXR2	mcasp1_axr[2]	I/O	Audio transmit/receive data - channel 2	HiZ
AXR3	mcasp1_axr[3]	I/O	Audio transmit/receive data - channel 3	HiZ
AXR4	mcasp1_axr[4]	I/O	Audio transmit/receive data - channel 4	HiZ
AXR5	mcasp1_axr[5]	I/O	Audio transmit/receive data - channel 5	HiZ
AXR6	mcasp1_axr[6]	I/O	Audio transmit/receive data - channel 6	HiZ
AXR7	mcasp1_axr[7]	I/O	Audio transmit/receive data - channel 7	HiZ
AXR8	mcasp1_axr[8]	I/O	Audio transmit/receive data - channel 8	HiZ
AXR9	mcasp1_axr[9]	I/O	Audio transmit/receive data - channel 9	HiZ
AXR10	mcasp1_axr[10]	I/O	Audio transmit/receive data - channel 10	HiZ
AXR11	mcasp1_axr[11]	I/O	Audio transmit/receive data - channel 11	HiZ
AXR12	mcasp1_axr[12]	I/O	Audio transmit/receive data - channel 12	HiZ
AXR13	mcasp1_axr[13]	I/O	Audio transmit/receive data - channel 13	HiZ
AXR14	mcasp1_axr[14]	I/O	Audio transmit/receive data - channel 14	HiZ
AXR15	mcasp1_axr[15]	I/O	Audio transmit/receive data - channel 15	HiZ
ACLKX	mcasp1_aclkx	I/O	Transmit bit clock	HiZ
AHCLKX	mcasp1_ahclkx	O	Transmit high-frequency master clock	HiZ
AFSX	mcasp1_fsx	I/O	Transmit frame synchronization	HiZ
ACLKR	mcasp1_aclkr	I/O	Receive bit clock	HiZ
AFSR	mcasp1_fsr	I/O	Receive frame synchronization	HiZ
McASP2 module				
AXR0	mcasp2_axr[0]	I/O	Audio transmit/receive data - channel 0	HiZ
AXR1	mcasp2_axr[1]	I/O	Audio transmit/receive data - channel 1	HiZ
AXR2	mcasp2_axr[2]	I/O	Audio transmit/receive data - channel 2	HiZ
AXR3	mcasp2_axr[3]	I/O	Audio transmit/receive data - channel 3	HiZ
AXR4	mcasp2_axr[4]	I/O	Audio transmit/receive data - channel 4	HiZ
AXR5	mcasp2_axr[5]	I/O	Audio transmit/receive data - channel 5	HiZ
ACLKX	mcasp2_aclkx	I/O	Transmit bit clock	HiZ
AHCLKX	mcasp2_ahclkx	O	Transmit high-frequency master clock	HiZ
AFSX	mcasp2_fsx	I/O	Transmit frame synchronization	HiZ
ACLKR	mcasp2_aclkr	I/O	Receive bit clock	HiZ
AFSR	mcasp2_fsr	I/O	Receive frame synchronization	HiZ
McASP3 module				
AXR0	mcasp3_axr[0]	I/O	Audio transmit/receive data - channel 0	HiZ
AXR1	mcasp3_axr[1]	I/O	Audio transmit/receive data - channel 1	HiZ
AXR2	mcasp3_axr[2]	I/O	Audio transmit/receive data - channel 2	HiZ
AXR3	mcasp3_axr[3]	I/O	Audio transmit/receive data - channel 3	HiZ
AXR4	mcasp3_axr[4]	I/O	Audio transmit/receive data - channel 4	HiZ
AXR5	mcasp3_axr[5]	I/O	Audio transmit/receive data - channel 5	HiZ
ACLKX	mcasp3_aclkx	I/O	Transmit bit clock	HiZ

⁽¹⁾ I = Input; O = Output; I/O = Bidirectional

Table 19-308. McASP I/O Signals (continued)

Module Pin Name	Device Level Signal Name	I/O ⁽¹⁾	Description	Module Pin Reset Value
AHCLKX	mcasp3_ahclkx	O	Transmit high-frequency master clock	HiZ
AFSX	mcasp3_fsx	I/O	Transmit frame synchronization	HiZ
ACLKR	mcasp3_aclkr	I/O	Receive bit clock	HiZ
AFSR	mcasp3_fsr	I/O	Receive frame synchronization	HiZ

NOTE: For the `mcaspx_aclkx`, `mcaspx_ahclkx` and `mcaspx_aclkr` signals to work properly, the `INPUTENABLE` bit of the appropriate `CTRL_CORE_PAD_x` registers should be set to 0x1 because of retiming purposes.

NOTE: The path from module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the Control Module registers. For more information, refer to the [Section 14.4.6.1, Pad Configuration Registers](#), and [Section 14.5, Control Module Register Manual](#), in [Chapter 14, Control Module](#).

NOTE: Except the pad configuration registers, additional Control Module registers have to be configured to map McASP2 and McASP3 signals to the device pads. The `MUXMODE` field of the corresponding pad configuration register has to be set to 0xF and the corresponding bit in [CTRL_CORE_SMA_SW_14](#) and [CTRL_CORE_SMA_SW_15](#) has to be set to 0x1.

NOTE: A serializer AXR data pin is shared between the transmit and receive logic of that serializer. The direction of data is determined in the [MCASP_PDIR](#) and the function (Tx or Rx) is selected in the corresponding serializer control register [MCASP_XRSRCTLn](#).

19.5.2.2 Protocols and Data Formats

19.5.2.2.1 Protocols Supported

The McASP supports a wide variety of protocols:

- Transmit section supports:
 - Wide variety of I2S and similar bit-stream formats.
 - TDM streams from 2 to 32 time slots.
 - S/PDIF, IEC60958-1, AES-3 formats.
- Receive section supports:
 - Wide variety of I2S and similar bit-stream formats.
 - TDM streams from 2 to 32 time slots.
 - TDM stream of 384 time slots specifically designed for easy interface to external digital interface receiver (DIR) device transmitting DIR frames to McASP using the I2S protocol (one time slot for each DIR subframe).

The transmit and receive sections of the module may be individually programmed to support the following options on the basic serial protocol:

- Programmable clock and frame sync polarity (rising or falling edge): `ACLKR/X`, `AHCLKR/X`, and `AFSR/X`.
- Slot length (number of bits per time slot): 8, 12, 16, 20, 24, 28, 32 bits supported.
- Word length (bits per word): 8, 12, 16, 20, 24, 28, 32 bits; always less than or equal to the time slot

length.

- First-bit data delay: 0, 1, 2 bit clocks.
- Left/right alignment of word inside slot.
- Bit order: MSB first or LSB first.
- Bit mask/pad/rotate function.
 - Automatically aligns data internally in either Q31 or integer formats.
 - Automatically masks nonsignificant bits (sets to 0, 1, or extends value of another bit).

NOTE: In I2S mode, the transmit and receive sections can support simultaneous transfers on up to all serial data pins operating as 192 kHz stereo channels.

In DIT mode for McASP, additional features of the transmitters are:

- Transmit-only mode 384 time slots (subframe) per frame.
- Biphase encoded LVCMOS output
- Channel status RAM (384 bits).
- User data RAM (384 bits).
- Separate valid bit (V) for subframe A, B.
- Stereo Support Only (Mono means send data 2x via software)

In DIT mode, the transmitter can support a 192 kHz frame rate (stereo) on up to all serial data pins simultaneously (note that the internal bit clock for DIT runs two times faster than the equivalent bit clock for I2S mode, due to the need to generate Biphase Mark Encoded Data).

NOTE: The McASP does NOT natively support DIR-mode reception (i.e. receiving in the S/PDIF format). To allow this, the McASP can use a DIR-input to I2S-output converter implemented by an external device (i.e. external DIR component). To facilitate reception in this case, the TDM mode of McASP receivers logic is extended to support a non-standard 384-slot TDM stream.

NOTE: An external transceiver must be connected to the McASP port in the device to translate the electrical signals delivered by the McASP (1.2 V or 1.8 V LVCMOS levels) to the electrical levels of the S/PDIF standard.

19.5.2.2.2 Definition of Terms

The serial bitstream transmitted or received by a McASP serializer is a long sequence of 1s and 0s on an audio transmit/receive pins AXRn. However, the sequence has a hierarchical organization that can be described in terms of frames of data, slots, words, and bits.

A basic synchronous serial interface consists of three important components: clock, frame sync, and data. [Figure 19-75](#) shows two of the three basic components: the clock signal (ACLKX/ACLKR) and the data signals AXRn. [Figure 19-75](#) does not specify whether the clock is for transmit (ACLKX) or receive (ACLKR) because the definitions of terms apply to both receive and transmit interfaces. In operation, each transmitter and receiver uses the signals ACLKX and ACLKR as serial clock, respectively. Optionally, a receiver can use ACLKX as the serial clock when a transmitter and receiver (not from the same serializer) of the McASP are configured to operate synchronously.

- Bit:

A bit is the smallest entity in the serial data stream. The beginning and end of each bit is marked by an edge of the serial clock. The duration of a bit is a serial clock period. A '1' is represented by a logic high on AXRn pins for the entire duration of the bit. A 0 is represented by a logic low on an AXRn pin for the entire duration of the bit.

- Word:

A word is a group of bits that make up the data being transferred between the McASP and the external

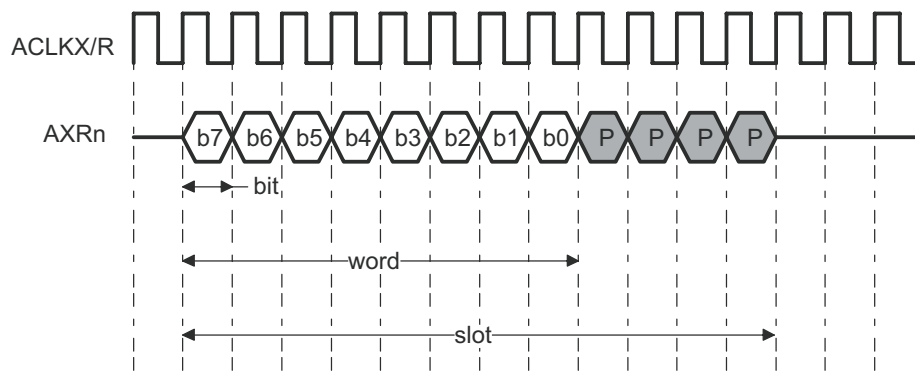

device. Figure 19-75 shows an 8-bit word.

- Slot:

A slot consists of the bits that make up the word and can consist of additional bits used to pad the word to a convenient number of bits for the interface between the McASP and the external device. In Figure 19-75, the audio data consists of only 8 bits of useful data (8-bit word), but it is padded with four 0s (12-bit slot) to satisfy the desired protocol in interfacing to an external device. Within a slot, the bits can be shifted out of the McASP on an AXRn pin with either MSB or LSB first.

When the word size is smaller than the slot size, the word can be aligned to the left of the slot (beginning) or to the right of the slot (end). The additional bits in the slot not belonging to the word can be padded with 0, 1, or with one of the bits (typically, the MSB or LSB) from the data word, i.e. left-aligned words within a slot are terminated with padding bits and right-aligned words within a slot are preceded by padding bits to fit in the slot size. Figure 19-76 shows these options.

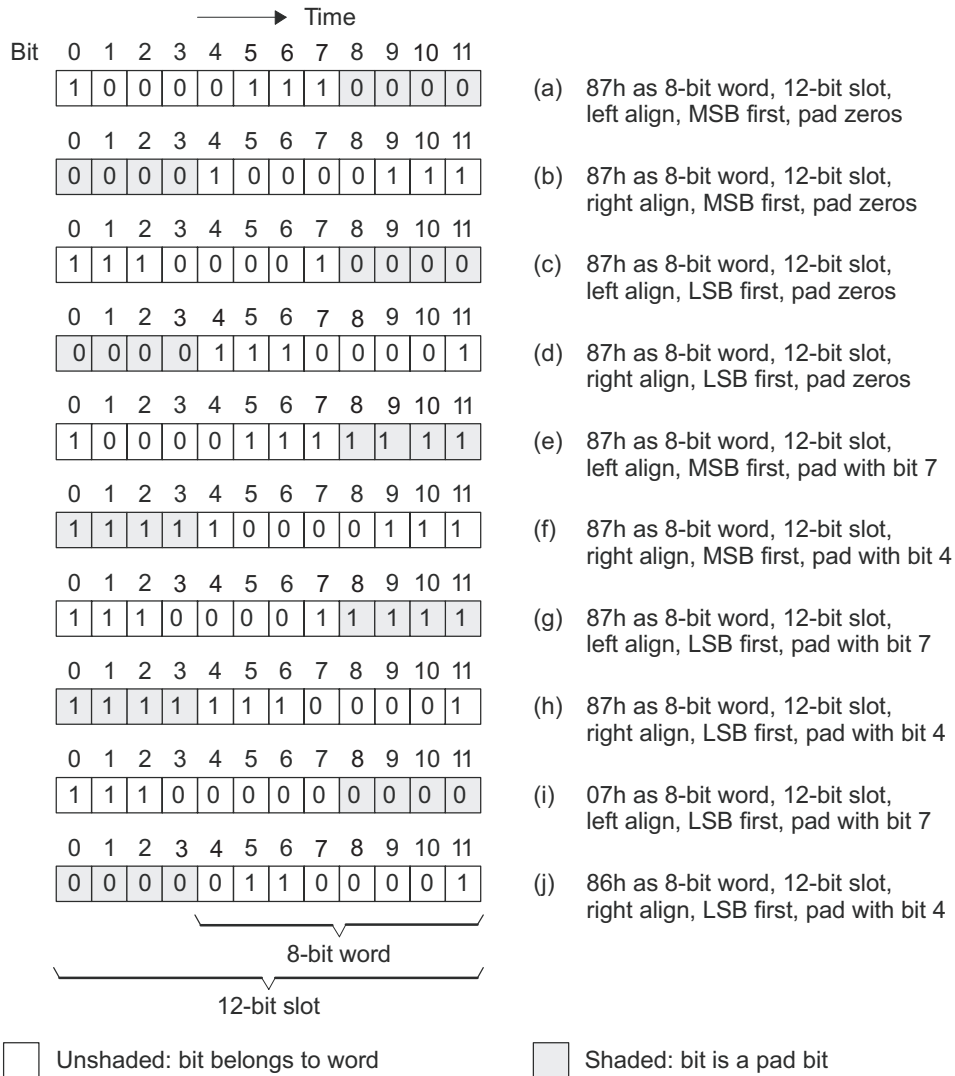

Figure 19-75. Definition of Bit, Word, and Slot

- (1) b7:b0 - bits. Bits b7 to b0 form a word.
- (2) P - pad bits. Bits b7 to b0, together with the 4 pad bits, form a slot.
- (3) In this example, the data is transmitted MSB first, left-aligned.
