Bits	Field Name	Description	Type	Reset
31:15	RESERVED		R	0x0
14	VDD_MM_I2C_DISABLE	This bit allows disabling I2C interface with powerIC for MM voltage (for debug purpose only). [warm reset insensitive] 0x0: Normal mode: I2C is enabled. 0x1: Debug mode: I2C is disabled.	RW	0x0
13	VDD_MPU_I2C_DISABLE	This bit allows disabling I2C interface with powerIC for MPU voltage (for debug purpose only). [warm reset insensitive] 0x0: Normal mode: I2C is enabled. 0x1: Debug mode: I2C is disabled.	RW	0x0
12	VDD_CORE_I2C_DISABLE	This bit allows disabling I2C interface with powerIC for CORE voltage (for debug purpose only). [warm reset insensitive] 0x0: Normal mode: I2C is enabled. 0x1: Debug mode: I2C is disabled.	RW	0x0
11:10	RESERVED		R	0x0
9	VDD_MM_PRESENCE	This bit control the presence of MM voltage in device. [warm reset insensitive] 0x0: MM voltage is not present as an individual voltage: MM voltage is merged with MPU voltage if VDD_MPU_presence=1. MM voltage is merged with CORE voltage if VDD_MPU_presence=0. 0x1: MM voltage is present on the device.	RW	0x1
8	VDD_MPU_PRESENCE	This bit control the presence of MPU voltage in device. [warm reset insensitive] 0x0: MPU voltage is not present as an individual voltage: MPU voltage is merged with MM voltage if VDD_MM_presence=1. MPU voltage is merged with CORE voltage if VDD_MM_presence=0. 0x1: MPU voltage is present on the device.	RW	0x1
7:6	RESERVED		R	0x0

Bits	Field Name	Description	Type	Reset
5:4	AUTO_CTRL_VDD_MM_L	This bit field specifies the state to which the hardware can automatically transition the VDD_MM_L voltage domain. 0x0: Voltage domain transitions are disabled. 0x1: Voltage domain transitions to SLEEP are enabled. 0x2: Voltage domain transitions to RET are enabled. 0x3: reserved	RW	0x0
3:2	AUTO_CTRL_VDD_MPU_L	This bit field specifies the state to which the hardware can automatically transition the VDD_MPU_L voltage domain. 0x0: Voltage domain transitions are disabled. 0x1: Voltage domain transitions to SLEEP are enabled. 0x2: Voltage domain transitions to RET are enabled. 0x3: reserved	RW	0x0
1:0	AUTO_CTRL_VDD_CORE_L	This bit field specifies the state to which the hardware can automatically transition the VDD_CORE_L voltage domain. 0x0: Voltage domain transitions are disabled. 0x1: Voltage domain transitions to SLEEP are enabled. 0x2: Voltage domain transitions to RET are enabled. 0x3: reserved	RW	0x0

Table 3-1228. PRM_PWRREQCTRL

Address Offset	0x0000 0014	Instance	DEVICE_PRM
Physical Address	0x4AE0 7D14		
Description	This register allows controlling the PWRREQ signal towards power IC.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																															
																PWRREQ_COND															

Bits	Field Name	Description	Type	Reset
31:2	RESERVED		R	0x0
1:0	PWRREQ_COND	Control upon which condition from MPU, MM and CORE voltage domains PWRREQ is de-asserted. 0x0: PWRREQ is never de-asserted 0x1: PWRREQ is de-asserted if all voltage domain are in SLEEP, RET or OFF state. Conversely, PWRREQ is asserted upon any voltage domain entering or staying in ON state. 0x2: PWRREQ is de-asserted if all voltage domain are in RET or OFF state. Conversely, PWRREQ is asserted upon any voltage domain entering or staying in ON or SLEEP state. 0x3: PWRREQ is de-asserted if all voltage domain are in OFF state. Conversely, PWRREQ is asserted upon any voltage domain entering or staying in ON or SLEEP or RET state.	RW	0x0

Table 3-1229. PRM_PSCON_COUNT

Address Offset	0x0000 0018	Instance	DEVICE_PRM
Physical Address	0x4AE0 7D18		
Description	This register allows controlling 2 parameters for power state controller. [warm reset insensitive]		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								HG_PONOUT_2_PGOODIN_TIME								PONOUT_2_PGOODIN_TIME								PCHARGE_TIME							

Bits	Field Name	Description	Type	Reset
31:24	RESERVED		R	0x0
23:16	HG_PONOUT_2_PGOODIN_TIME	The value 'NbCycles' set in this field determines the duration of the PONOUT to PGOODIN transition for power domain without DPS. The duration is computed as 8 x NbCycles of system clock cycles. Target is 10us.	RW	0x30
15:8	PONOUT_2_PGOODIN_TIME	The value 'NbCycles' set in this field determines the duration of the PONOUT to PGOODIN transition for power domain without DPS. The duration is computed as 8 x NbCycles of system clock cycles. Target is 10us.	RW	0x30
7:0	PCHARGE_TIME	Number of system clock cycles for the SRAM pre-charge duration. Target is 600ns.	RW	0x17

Table 3-1233. PRM_IO_PMCTRL

Address Offset	0x0000 0020	Instance	DEVICE_PRM
Physical Address	0x4AE0 7D20		
Description	This register allows controlling power management features of the IOs.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																GLOBAL_WUEN		RESERVED						WUCLK_STATUS	WUCLK_CTRL	RESERVED	IO_ON_STATUS	ISOOVR_EXTEND	RESERVED	ISOCLK_STATUS	ISOCLK_OVERRIDE

Bits	Field Name	Description	Type	Reset
31:17	RESERVED		R	0x0
16	GLOBAL_WUEN	Global IO wakeup enable. This is a gating condition to all individual IO WUEN coming from control module. Gating is done in the Spinner logic. 0x0: All individual IO WUEN are gated in the Spinner logic (overridden to 0). 0x1: All individual IO WUEN from control module are going to IOs.	RW	0x0
15:10	RESERVED		R	0x0
9	WUCLK_STATUS	Gives value of WUCLKOUT signal coming back from IO pad ring.	R	0x0
8	WUCLK_CTRL	Direct control on WUCLKIN signal to IO pad ring. 0x0: WUCLKIN signal is driven to 0. IO wakeup daisy chain is functional as well as IO whose wakeup feature is enabled. 0x1: WUCLKIN signal is driven to 1. IO wakeup daisy chain is reset and is latching current pad states and WUEN inputs.	RW	0x0
7:6	RESERVED		R	0x0
5	IO_ON_STATUS	Gives the functional status of the IO ring. 0x0: Part or all of the IOs are not in the ON state, that is are in isolation state. 0x1: All IOs are in the ON state.	R	0x1
4	ISOOVR_EXTEND	Control non-EMIF IO isolation extension upon a device wakeup from OFF mode. 0x0: Non-EMIF IO isolation is not extended. 'EMIF_ON' IO transition happens as soon as automatic restore is completed. 0x1: Non-EMIF IO isolation is extended. 'EMIF_ON' IO transition is stalled.	RW	0x0
3:2	RESERVED		R	0x0
1	ISOCLK_STATUS	Gives value of ISOCLKOUT signal coming back from IO pad ring.	R	0x0

Bits	Field Name	Description	Type	Reset
0	ISOCLK_OVERRIDE	Override control on ISOCLKIN signal to IO pad ring. Used at boot time when it is needed to change the mode of an IO from 1.8V default mode to 1.2V mode. When not overridden, this signal is controlled by hardware only. 0x0: ISOCLKIN signal is not overridden. 0x1: ISOCLKIN signal is overridden to active value ('1').	RW	0x0

3.11.39.2 EMU_CM Register Description

Table 3-1343. CM_EMU_CLKSTCTRL

Address Offset	0x0000 0000		
Physical Address	0x4AE0 7A00	Instance	EMU_CM
Description	This register enables the EMU domain power state transition. It controls the HW supervised domain power state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain. [warm reset insensitive]		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																CLKACTIVITY_EMU_SYS_CLK	RESERVED							CLKTRCTRL							

Bits	Field Name	Description	Type	Reset
31:9	RESERVED		R	0x0
8	CLKACTIVITY_EMU_SYS_CLK	This field indicates the state of the EMU_SYS_CLK clock in the domain. 0x0: Corresponding clock is definitely gated 0x1: Corresponding clock is running or gating/ungating transition is on-going	R	0x0
7:2	RESERVED		R	0x0
1:0	CLKTRCTRL	Controls the clock state transition of the EMU clock domain. 0x0: Reserved 0x1: Reserved 0x2: SW_WKUP: Start a software forced wake-up transition on the domain. 0x3: HW_AUTO: Automatic transition is enabled. Sleep and wakeup transition are based upon hardware conditions.	RW	0x2

Description	This register controls the IPU domain power state to reach upon a domain sleep transition		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								PERIPHMEM_ONSTATE	RESERVED	AESSMEM_ONSTATE	RESERVED						PERIPHMEM_RETSTATE	RESERVED	AESSMEM_RETSTATE	RESERVED	LOWPOWERSTATECHANGE	RESERVED	LOGICRETSTATE	POWERSTATE							

Bits	Field Name	Description	Type	Reset
31:22	RESERVED		R	0x0
21:20	PERIPHMEM_ONSTATE	PERIPHMEM memory state when domain is ON. 0x3: Memory bank is on when the domain is ON.	R	0x3
19:18	RESERVED		R	0x0
17:16	AESSMEM_ONSTATE	AESSMEM memory state when domain is ON. 0x3: Memory bank is on when the domain is ON.	R	0x3
15:11	RESERVED		R	0x0
10	PERIPHMEM_RETSTATE	PERIPHMEM memory state when domain is RETENTION. 0x0: Memory bank is off when the domain is in the RETENTION state. 0x1: Memory bank is retained when domain is in RETENTION state.	RW	0x0
9	RESERVED		R	0x0
8	AESSMEM_RETSTATE	AESSMEM memory state when domain is RETENTION. 0x0: Memory bank is off when the domain is in the RETENTION state. 0x1: Memory bank is retained when domain is in RETENTION state.	RW	0x1
7:5	RESERVED		R	0x0

Bits	Field Name	Description	Type	Reset
4	LOWPOWERSTATECHANGE	Power state change request when domain has already performed a sleep transition. Allows going into deeper low power state without waking up the power domain. 0x0: Do not request a low power state change. 0x1: Request a low power state change. This bit is automatically cleared when the power state is effectively changed or when power state is ON.	RW	0x0
3	RESERVED		R	0x0
2	LOGICRETSTATE	Logic state when power domain is RETENTION 0x0: Whole logic is off when the domain is in RETENTION state.	R	0x0
1:0	POWERSTATE	Power state control 0x0: OFF state 0x1: RETENTION state 0x2: INACTIVE state 0x3: ON State	RW	0x0

3.11.49.2 L3INIT_PRM Register Description

Table 3-1453. PM_L3INIT_PWRSTCTRL

Address Offset	0x0000 0000	Instance	L3INIT_PRM
Physical Address	0x4AE0 7300		
Description	This register controls the L3INIT power state to reach upon a domain sleep transition.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0								
RESERVED								GMAC_BANK_ONSTATE			L3INIT_BANK2_ONSTATE			L3INIT_BANK1_ONSTATE			RESERVED			GMAC_BANK_RETSTATE			L3INIT_BANK2_RETSTATE			L3INIT_BANK1_RETSTATE			RESERVED			LOWPOWERSTATECHANGE		RESERVED		LOGICRETSTATE		POWERSTATE	

Bits	Field Name	Description	Type	Reset
31:20	RESERVED		R	0x0
19:18	GMAC_BANK_ONSTATE	GMAC BANK state when domain is ON. 0x3: Memory bank is on when the domain is ON.	R	0x3
17:16	L3INIT_BANK2_ONSTATE	L3INIT BANK2 state when domain is ON. 0x3: Memory bank is on when the domain is ON.	R	0x3
15:14	L3INIT_BANK1_ONSTATE	L3INIT BANK1 state when domain is ON. 0x3: Memory bank is on when the domain is ON.	R	0x3
13:11	RESERVED		R	0x0
10	GMAC_BANK_RETSTATE	GMAC BANK state when domain is RETENTION. 0x1: Memory bank is retained when domain is in RETENTION state.	R	0x1
9	L3INIT_BANK2_RETSTATE	L3INIT BANK2 state when domain is RETENTION. 0x1: Memory bank is retained when domain is in RETENTION state.	R	0x1
8	L3INIT_BANK1_RETSTATE	L3INIT BANK1 state when domain is RETENTION. 0x0: Memory bank is off when the domain is in the RETENTION state.	R	0x0
7:5	RESERVED		R	0x0

Bits	Field Name	Description	Type	Reset
4	LOWPOWERSTATECHANGE	Power state change request when domain has already performed a sleep transition. Allows going into deeper low power state without waking up the power domain. 0x0: Do not request a low power state change. 0x1: Request a low power state change. This bit is automatically cleared when the power state is effectively changed or when power state is ON.	RW	0x0
3	RESERVED		R	0x0
2	LOGICRETSTATE	Logic state when power domain is RETENTION 0x0: Only retention registers are retained and remaining logic is off when the domain is in RETENTION state. 0x1: Whole logic is retained when domain is in RETENTION state.	RW	0x1
1:0	POWERSTATE	Power state control 0x0: OFF state 0x1: RETENTION state 0x2: INACTIVE state 0x3: ON State	RW	0x0

3.11.50.2 L4PER_PRM Register Description

Table 3-1485. PM_L4PER_PWRSTCTRL

Address Offset	0x0000 0000	Instance	L4PER_PRM
Physical Address	0x4AE0 7400		
Description	This register controls the L4PER power state to reach upon a domain sleep transition		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								NONRETAINED_BANK_ONSTATE		RETAINED_BANK_ONSTATE		RESERVED				NONRETAINED_BANK_RETSTATE		RETAINED_BANK_RETSTATE		RESERVED		LOWPOWERSTATECHANGE		RESERVED		LOGICRETSTATE		POWERSTATE			

Bits	Field Name	Description	Type	Reset
31:20	RESERVED		R	0x0
19:18	NONRETAINED_BANK_ONSTATE	NONRETAINED_BANK state when domain is ON. 0x3: Memory bank is on when the domain is ON.	R	0x3
17:16	RETAINED_BANK_ONSTATE	RETAINED_BANK state when domain is ON. 0x3: Memory bank is on when the domain is ON.	R	0x3
15:10	RESERVED		R	0x0
9	NONRETAINED_BANK_RETSTATE	NONRETAINED_BANK state when domain is RETENTION. 0x0: Memory bank is off when the domain is in the RETENTION state.	R	0x0
8	RETAINED_BANK_RETSTATE	RETAINED_BANK state when domain is RETENTION. 0x1: Memory bank is retained when domain is in RETENTION state.	R	0x1
7:5	RESERVED		R	0x0
4	LOWPOWERSTATECHANGE	Power state change request when domain has already performed a sleep transition. Allows going into deeper low power state without waking up the power domain. 0x0: Do not request a low power state change. 0x1: Request a low power state change. This bit is automatically cleared when the power state is effectively changed or when power state is ON.	RW	0x0
3	RESERVED		R	0x0
2	LOGICRETSTATE	Logic state when power domain is RETENTION 0x0: Only retention registers are retained and remaining logic is off when the domain is in RETENTION state. 0x1: Whole logic is retained when domain is in RETENTION state.	RW	0x1
1:0	POWERSTATE	Power state control 0x0: Reserved 0x1: RETENTION state 0x2: INACTIVE state 0x3: ON State	RW	0x3

3.11.51.2 MPU_PRM Register Description

Table 3-1649. PM_MPU_PWRSTCTRL

Address Offset	0x0000 0000	Instance	MPU_PRM
Physical Address	0x4AE0 6300		
Description	This register controls the MPU domain power state to reach upon a domain sleep transition. If the value programmed in this register correspond to a lower power state than the one programmed in MPU-SS for CPU0 and/or CPU1, then value of this register is overwritten in PRCM logic to limit the power state to enter. Notes: - Even if value of this register is overwritten in PRCM logic, value of this register remains unchanged. - If user programs MPU power domain to go to CSWRET, then he can not program L2\$ to OFF mode.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

It is functional if using separate functional clock 0x3: Module is disabled and cannot be accessed	R	0x3
15:2	RESERVED		R	0x0
1:0	MODULEMODE	Control the way mandatory clocks are managed. 0x1: Module is managed automatically by HW according to clock domain transition. A clock domain sleep transition put module into idle. A wakeup domain transition put it back into function. If CLKTRCTRL=3, any OCP access to module is always granted. Module clocks may be gated according to the clock domain state.	R	0x1

DSP Subsystems

This chapter describes the features and functions of the device integrated digital processing subsystems.

NOTE: Devices may include up to two identical instances of DSP subsystem (DSP1 and DSP2). Refer to the device *Data Manual* for number of DSP instances on a specific device. This chapter describes the two DSP device superset. For devices with a single DSP, the information on DSP2 can be ignored.

Topic	Page
4.1 DSP Subsystems Overview	1377
4.2 DSP Subsystem Integration	1382
4.3 DSP Subsystems Functional Description	1388
4.4 DSP Subsystem Register Manual	1425

4.1 DSP Subsystems Overview

The device includes two identical instances (DSP1 and DSP2) of a digital signal processor (DSP) subsystem, based on the TI's standard TMS320C66x™ DSP CorePac core.

The TMS320C66x DSP core enhances the TMS320C674x™ core, which merges the C674x™ floating point and the C64x+™ fixed-point instruction set architectures. The C66x DSP is object-code compatible with the C64x+/C674x DSPs.

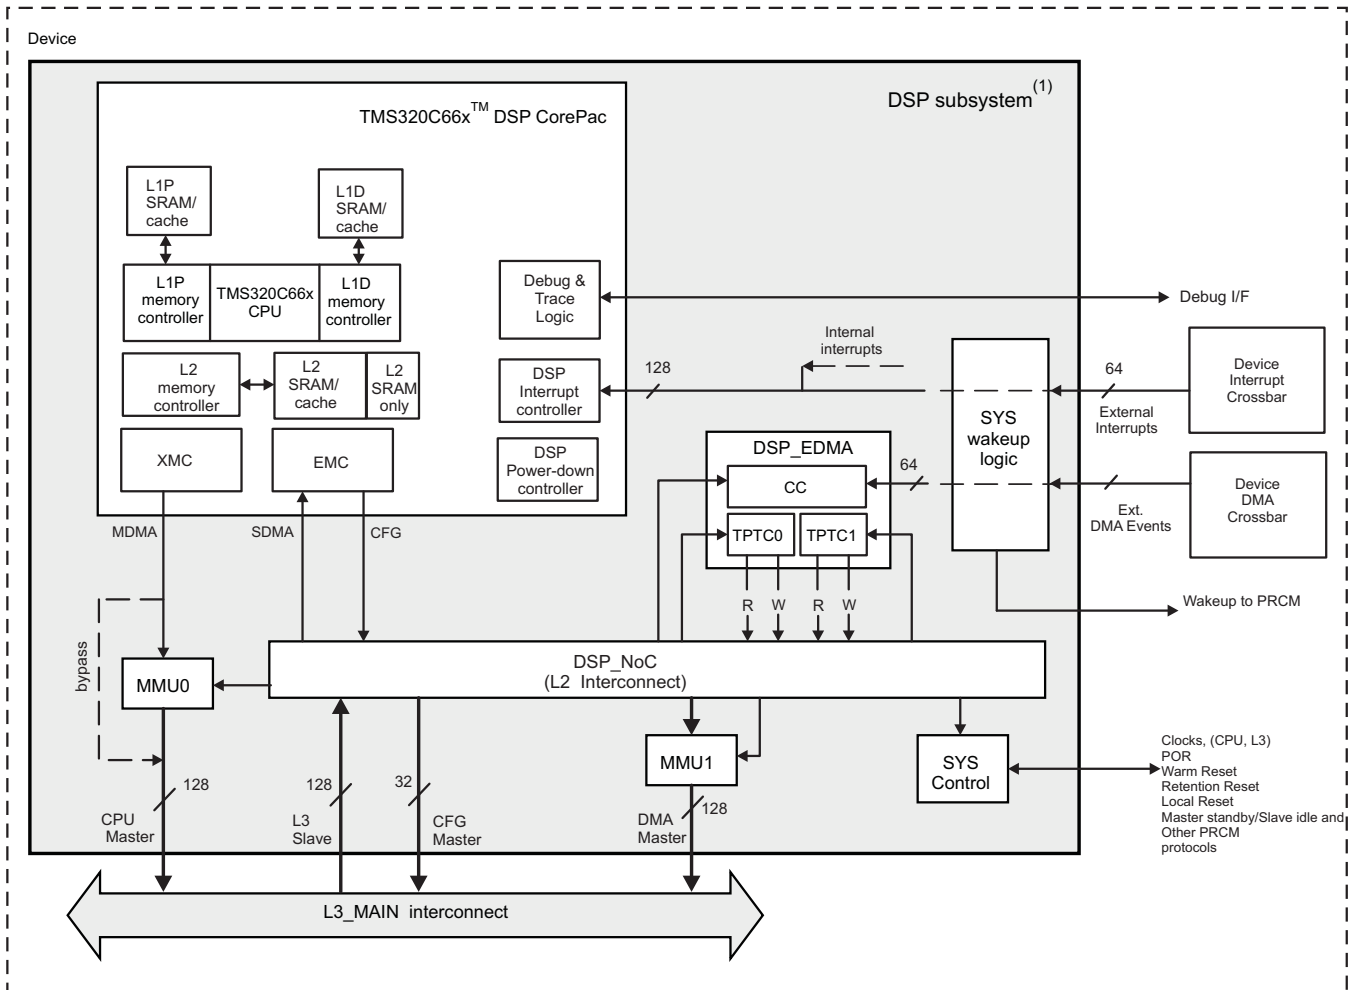

For more information on the TMS320C66x core CPU, see the *TMS320C66x DSP CPU and Instruction Set Reference Guide*, ([SPRUGH7](#)).

Each of the two DSP subsystems integrated in the device includes the following components:

- A TMS320C66x™ CorePac DSP core that encompasses :
 - L1 program-dedicated (L1P) cacheable memory
 - L1 data-dedicated (L1D) cacheable memory
 - L2 (program and data) cacheable memory
 - Extended Memory Controller (XMC)
 - External Memory Controller (EMC)
 - DSP CorePac located interrupt controller (INTC)
 - DSP CorePac located power-down controller (PDC)
- Dedicated enhanced data memory access engine - EDMA, to transfer data from/to memories and peripherals external to the DSP subsystems and to local DSP memory (most commonly L2 SRAM). The external DMA requests are passed through DSP system level (SYS) wakeup logic, and collected from the DSP1 / DSP2 dedicated outputs of the device DMA Events Crossbar for each of the two subsystems.
- A level 2 (L2) interconnect network (DSP NoC) to allow connectivity between different modules of the subsystem or the remainder of the device via the device L3_MAIN interconnect.
- Two memory management units (on EDMA L2 interconnect and DSP MDMA paths) for accessing the device L3_MAIN interconnect address space
- Dedicated system control logic (DSP_SYSTEM) responsible for power management, clock generation, and connection to the device power, reset, and clock management (PRCM) module

[Figure 4-1](#) is the DSP subsystem top-level architecture.

Figure 4-1. DSP Subsystem Highlight

dspss-001

NOTE: (1) : This diagram shows a single DSP instance. Each device may have **one or two identical DSP instances**, refer to corresponding *device Data Manual* for the specific device support.

4.1.1 DSP Subsystems Key Features

The TMS320C66x Instruction Set Architecture (ISA) is the latest for the C6000 family. As with its predecessors (C64x, C64x+ and C674x), the C66x is an advanced VLIW architecture with 8 functional units (two multiplier units and six arithmetic logic units) that operate in parallel. The C66x CPU has a total of 64 general-purpose 32-bit registers.

Some features of the DSP C6000 family devices are :

- Advanced VLIW CPU with eight functional units (two multipliers and six ALUs) which:
 - Executes up to eight instructions per cycle for up to ten times the performance of typical DSPs
 - Allows designers to develop highly effective RISC-like code for fast development time
- Instruction packing
 - Gives code size equivalence for eight instructions executed serially or in parallel
 - Reduces code size, program fetches, and power consumption
- Conditional execution of most instructions

- Reduces costly branching
- Increases parallelism for higher sustained performance
- Efficient code execution on independent functional units
 - Industry's most efficient C compiler on DSP benchmark suite
 - Industry's first assembly optimizer for fast development and improved parallelization
- 8-/16-/32-bit/64-bit data support, providing efficient memory support for a variety of applications
- 40-bit arithmetic options which add extra precision for vocoders and other computationally intensive applications
- Saturation and normalization to provide support for key arithmetic operations
- Field manipulation and instruction extract, set, clear, and bit counting support common operation found in control and data manipulation applications.

The C66x CPU has the following additional features :

- Each multiplier can perform two 16 × 16-bit or four 8 × 8 bit multiplies every clock cycle.
- Quad 8-bit and dual 16-bit instruction set extensions with data flow support
- Support for non-aligned 32-bit (word) and 64-bit (double word) memory accesses
- Special communication-specific instructions have been added to address common operations in error-correcting codes.
- Bit count and rotate hardware extends support for bit-level algorithms.
- Compact instructions: Common instructions (AND, ADD, LD, MPY) have 16-bit versions to reduce code size.
- Protected mode operation: A two-level system of privileged program execution to support higher-capability operating systems and system features such as memory protection.
- Exceptions support for error detection and program redirection to provide robust code execution
- Hardware support for modulo loop operation to reduce code size and allow interrupts during fully-pipelined code
- Each multiplier can perform 32 × 32 bit multiplies
- Additional instructions to support complex multiplies allowing up to eight 16-bit multiply/add/subtracts per clock cycle

The TMS320C66x has the following key improvements to the ISA :

- 4x Multiply Accumulate improvement for both fixed and floating point
- Improvement of the floating point arithmetic
- Enhancement of the vector processing capability for fixed and floating point
- Addition of domain-specific instructions for complex arithmetic and matrix operations

On the C66x ISA, the vector processing capability is improved by extending the width of the SIMD instructions. The C674x DSP supports 2-way SIMD operations for 16-bit data and 4-way SIMD operations for 8-bit data. C66x enhances this capabilities with the addition of SIMD instructions for 32-bit data allowing operation on 128-bit vectors. For example the QMPY32 instruction is able to perform the element to element multiplication between two vectors of four 32-bit data each.

C66x ISA includes a set of specific instructions to handle complex arithmetic and matrix operations.

- **TMS320C66x DSP CorePac memory components :**
 - A 32-KiB L1 program memory (L1P) configurable as cache and / or SRAM:
 - When configured as a cache, the L1P is a 1-way set-associative cache with a 32-byte cache line
 - The DSP CorePac L1P memory controller provides bandwidth management, memory protection, and power-down functions
 - The L1P is capable of cache block and global coherence operations
 - The L1P controller has an Error Detection (ED) mechanism, including necessary SRAM
 - The L1P memory can be fully configured as a cache or SRAM

- Page size for L1P memory is 2KB
- A 32-KiB L1 data memory (L1D) configurable as cache and / or SRAM:
 - When configured as a cache, the L1D is a 2-way set-associative cache with a 64-byte cache line
 - The DSP CorePac L1D memory controller provides bandwidth management, memory protection, and power-down functions
 - The L1D memory can be fully configured as a cache or SRAM
 - No support for error correction or detection
 - Page size for L1D memory is 2KB
- A 288-KiB (program and data) L2 memory, only part of which is cacheable:
 - When configured as a cache, the L2 memory is a 4-way set associative cache with a 128-byte cache line
 - Only 256 KiB of L2 memory can be configured as cache or SRAM
 - 32 KiB of the L2 memory is always mapped as SRAM
 - The L2 memory controller has an Error Correction Code (ECC) and ED mechanism, including necessary SRAM
 - The L2 memory controller supports hardware prefetching and also provides bandwidth management, memory protection, and power-down functions.
 - Page size for L2 memory is 16KB
- The **External Memory Controller (EMC)** is a bridge from the C66x CorePac to the rest of the DSP subsystem and device. It has :
 - a 32-bit configuration port (CFG) providing access to local subsystem resources (like DSP_EDMA, DSP_SYSTEM, etc) or to L3_MAIN resources accessible via the CFG address range.
 - a 128-bit slave-DMA port (SDMA) which provides accesses of system masters outside the DSP subsystem to resources inside the DSP subsystem or C66x DSP CorePac memories, i.e. when the DSP subsystem is the slave in a transaction.
- The Extended Memory Controller (XMC) processes requests from the L2 Cache Controller (which are a result of CPU instruction fetches, load/store commands, cache operations) to device resources via the C66x DSP CorePac 128-bit master DMA (MDMA) port :
 - Memory protection for addresses outside C66x DSP CorePac generated over device L3_MAIN on the MDMA port
 - Prefetch, multi-in-flight requests
- A DSP local **Interrupt Controller (INTC)** in the DSP C66x CorePac, interfaces the system events to the DSP C66x core CPU interrupt and exceptions inputs. Each DSP subsystem C66x CorePac interrupt controller supports up to 128 system events of which 64 interrupts are external to DSP subsystems, collected from the DSP1 /DSP2 dedicated outputs of the device Interrupt Crossbar.
- **Local Enhanced Direct Memory Access (EDMA) controller features:**
 - Channel controller (CC) : 64-channel, 128 PaRAM, 2 Queues
 - 2 x Third-party Transfer Controllers (TPTC0 and TPTC1):
 - Each TC has a 128-bit read port and a 128-bit write port
 - 2KiB FIFOs on each TPTC
 - 1-dimensional/2-dimensional (1D/2D) addressing
 - Chaining capability
- **DSP subsystems integrated MMUs:**
 - Two MMUs are integrated:
 - The MMU0 is located between DSP MDMA master port and the device L3_MAIN interconnect and can be optionally bypassed
 - The MMU1 is located between the EDMA master port and the device L3_MAIN interconnect
- A DSP local **Power-Down Controller (PDC)** is responsible to power-down various parts of the DSP C66x CorePac, or the entire DSP C66x CorePac.

- The DSP subsystems **System Control logic** provides:
 - Slave idle and master standby protocols with device PRCM for powerdown
 - OCP Disconnect handshake for init and target busses
 - Asynchronous reset
 - Power-down modes :
 - "Clockstop" mode featuring wake-up on interrupt event. The DMA event wake-up is managed in software.
- The device DSP subsystems are supplied by a PRCM DPLL, but each DSP1/2 **has integrated its own PLL module** outside the C66x CorePac for clock gating and division.
- **Each of the two device DSP subsystems has following port instances** to connect to remaining part of the device. See also [Figure 4-1](#):
 - A 128-bit initiator (DSP MDMA master) port for MDMA/Cache requests
 - A 128-bit initiator (DSP EDMA master) port for EDMA requests
 - A 32-bit initiator (DSP CFG master) port for configuration requests
 - A 128-bit target (DSP slave) port for requests to DSP memories and various peripherals
- **C66x DSP subsystems (DSPSS) safety aspects :**
 - Above mentioned memory ECC/ED mechanisms
 - MMUs enable mapping of only the necessary application space to the processor
 - Memory Protection Units internal to the DSPSS (in L1P,L1D and L2 memory controllers) and external to DSPSS (firewalls) to help define legal accesses and raise exceptions on illegal accesses
 - Exceptions: Memory errors, various DSP errors, MMU errors and some system errors are detected and cause exceptions. The exceptions could be handled by the DSP or by a designated safety processor at the chip level. Note that it may not be possible for the safety processor to completely handle some exceptions

Unsupported features on the C66x DSP core for the device are:

- The Extended Memory Controller MPAX (memory protection and address extension) 36-bit addressing is NOT supported

Known DSP subsystem powermode restrictions for the device are :

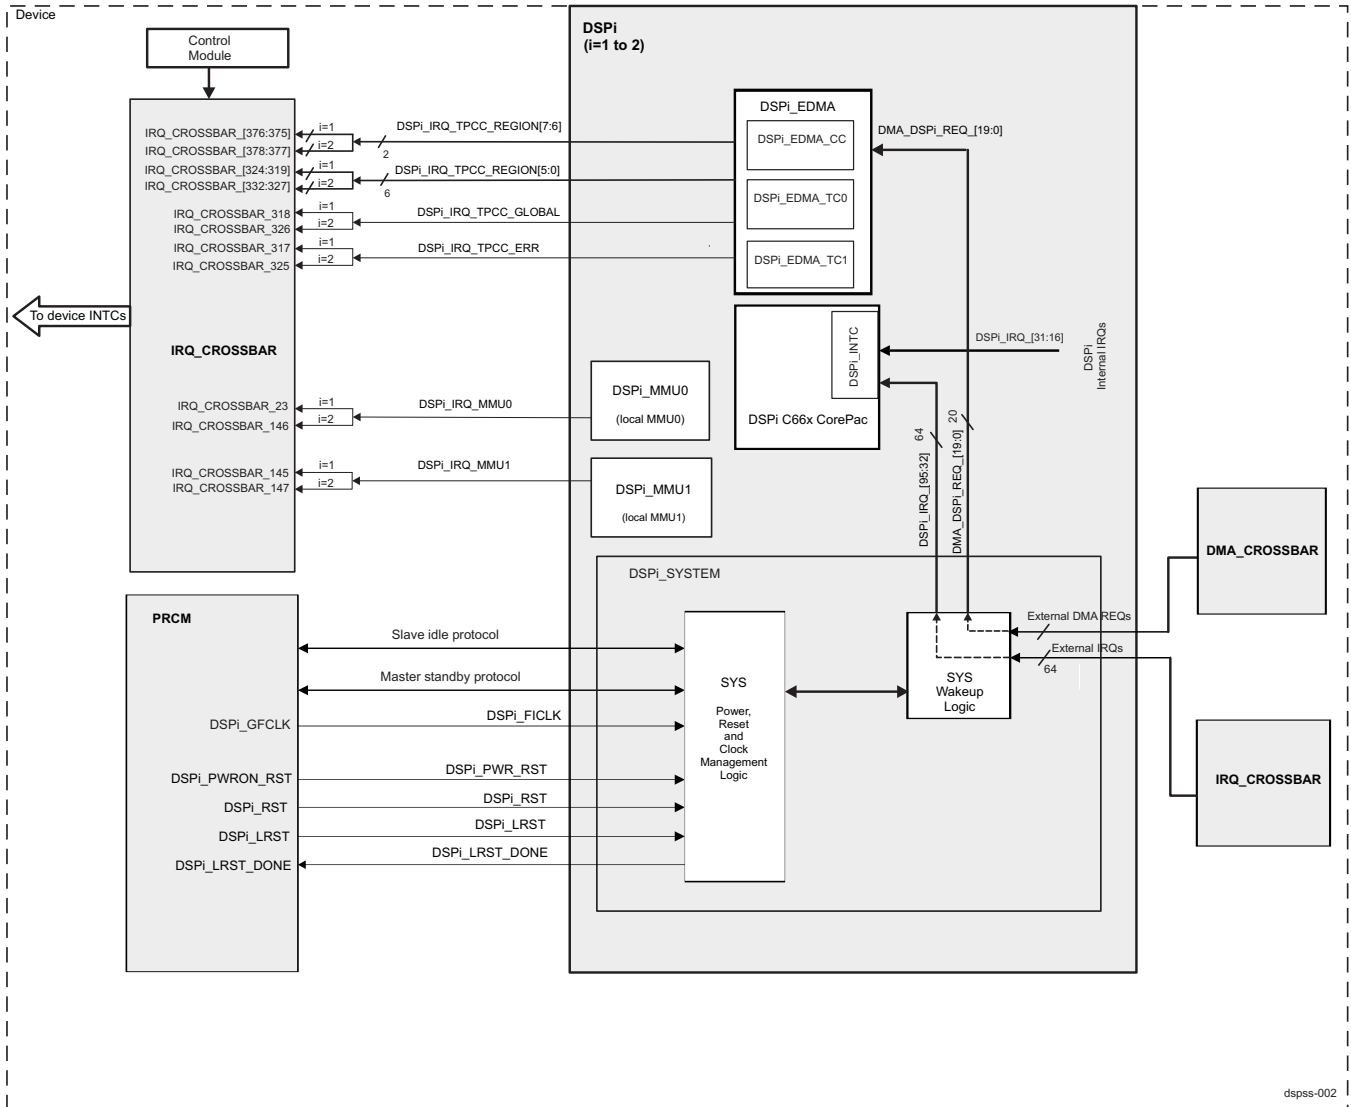

- "Full logic / RAM retention" mode featuring wake-up on both interrupt or DMA event (logic in "always on" domain). Only OFF mode is supported by DSP subsystem, **requiring full boot.**

4.2 DSP Subsystem Integration

This section describes the integration of the module in the device, including information about clocks, resets, and hardware requests.

Figure 4-2 shows the integration of the DSP subsystem.

Figure 4-2. DSP Subsystem Integration

NOTE: For more information about the slave idle protocol and the wake-up request, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 4-1 through Table 4-3 summarize the integration of the module in the device.

Table 4-1. DSP Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
DSP1	PD_DSP1	L3_MAIN
DSP2	PD_DSP2	L3_MAIN

Table 4-2. DSP Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
DSP1	DSP1_FICLK	DSP1_GFCLK	PRCM module	DSP1 subsystem gateable interface and functional clock.
DSP2	DSP2_FICLK	DSP2_GFCLK	PRCM module	DSP2 subsystem gateable interface and functional clock.

	DSP2_RST	DSP2_RST	PRCM module	
	DSP2_LRST	DSP2_LRST	PRCM module	
	DSP2_LRST_DONE ⁽¹⁾	DSP2_LRST_DONE	DSP2	

⁽¹⁾ Destination of this local reset monitoring signal is the PRCM

NOTE: For information about PRCM clock gating and management, see [Section 3.7.2, PD_DSP1 Description](#) and [Section 3.7.3, PD_DSP2 Description](#) in [Chapter 3, Power, Reset, and Clock Management](#).

The DSP1 / DSP2 generates a number of interrupt requests (IRQs) mapped via the device IRQ_CROSSBAR to other device interrupt controllers (outside DSP subsystem). They are described in [Table 4-3](#).

Table 4-3. DSP Hardware Requests

Module Instance	Source Signal Name	Interrupt Requests		Description
		Destination IRQ_CROSSBAR Input	Default Mapping	
DSP1	DSP1_IRQ_MMU0	IRQ_CROSSBAR_23	DSP1_IRQ_54 DSP2_IRQ_54	Interrupt from the DSP1 subsystem local MMU0 (DSP1_MMU0CFG).
	DSP1_IRQ_MMU1	IRQ_CROSSBAR_145	-	DSP1 subsystem local MMU1 (DSP1_MMUCFG1) interrupt. This IRQ source signal is not mapped by default to any device INTC.
	DSP1_IRQ_TPCC_ERR	IRQ_CROSSBAR_317	-	DSP1 subsystem aggregated ("OR-ed") error interrupt. This IRQ source signal is not mapped by default to any device INTC.
	DSP1_IRQ_TPCC_GLOBAL	IRQ_CROSSBAR_318	-	DSP1 subsystem EDMA channel controller global interrupt. This IRQ source signal is not mapped by default to any device INTC.
	DSP1_IRQ_TPCC_REGION0	IRQ_CROSSBAR_319	-	DSP1 subsystem EDMA channel controller REGION0 interrupt. This IRQ source signal is not mapped by default to any device INTC.
	DSP1_IRQ_TPCC_REGION1	IRQ_CROSSBAR_320	-	DSP1 subsystem EDMA channel controller REGION1 interrupt. This IRQ source signal is not mapped by default to any device INTC.
	DSP1_IRQ_TPCC_REGION2	IRQ_CROSSBAR_321	-	DSP1 subsystem EDMA channel controller REGION2 interrupt. This IRQ source signal is not mapped by default to any device INTC.

Table 4-3. DSP Hardware Requests (continued)

DSP1_IRQ_TPCC_REGION3	IRQ_CROSSBAR_322	-	DSP1 subsystem EDMA channel controller REGION3 interrupt. This IRQ source signal is not mapped by default to any device INTC.	
DSP1_IRQ_TPCC_REGION4	IRQ_CROSSBAR_323	-	DSP1 subsystem EDMA channel controller REGION4 interrupt. This IRQ source signal is not mapped by default to any device INTC.	
DSP1_IRQ_TPCC_REGION5	IRQ_CROSSBAR_324	-	DSP1 subsystem EDMA channel controller REGION5 interrupt. This IRQ source signal is not mapped by default to any device INTC.	
DSP1_IRQ_TPCC_REGION6	IRQ_CROSSBAR_375	-	DSP1 subsystem EDMA channel controller REGION6 interrupt. This IRQ source signal is not mapped by default to any device INTC.	
DSP1_IRQ_TPCC_REGION7	IRQ_CROSSBAR_376	-	DSP1 subsystem EDMA channel controller REGION7 interrupt. This IRQ source signal is not mapped by default to any device INTC.	
DSP2	DSP2_IRQ_MMU0	IRQ_CROSSBAR_146	-	DSP2 subsystem local MMU0 (DSP2_MMU0CFG) interrupt. This IRQ source signal is not mapped by default to any device INTC.
	DSP2_IRQ_MMU1	IRQ_CROSSBAR_147	-	DSP2 subsystem local MMU1 (DSP2_MMUCFG1) interrupt. This IRQ source signal is not mapped by default to any device INTC.
	DSP2_IRQ_TPCC_ERR	IRQ_CROSSBAR_325	-	DSP2 subsystem aggregated ("OR-ed") error interrupt. This IRQ source signal is not mapped by default to any device INTC.
	DSP2_IRQ_TPCC_GLOBAL	IRQ_CROSSBAR_326	-	DSP2 subsystem EDMA channel controller global interrupt. This IRQ source signal is not mapped by default to any device INTC.
	DSP2_IRQ_TPCC_REGION0	IRQ_CROSSBAR_327	-	DSP2 subsystem EDMA channel controller REGION0 interrupt. This IRQ source signal is not mapped by default to any device INTC.

Table 4-3. DSP Hardware Requests (continued)

DSP2_IRQ_TPCC_REGION1	IRQ_CROSSBAR_328	-	DSP2 subsystem EDMA channel controller REGION1 interrupt. This IRQ source signal is not mapped by default to any device INTC.
DSP2_IRQ_TPCC_REGION2	IRQ_CROSSBAR_329	-	DSP2 subsystem EDMA channel controller REGION2 interrupt. This IRQ source signal is not mapped by default to any device INTC.
DSP2_IRQ_TPCC_REGION3	IRQ_CROSSBAR_330	-	DSP2 subsystem EDMA channel controller REGION3 interrupt. This IRQ source signal is not mapped by default to any device INTC.
DSP2_IRQ_TPCC_REGION4	IRQ_CROSSBAR_331	-	DSP2 subsystem EDMA channel controller REGION4 interrupt. This IRQ source signal is not mapped by default to any device INTC.
DSP2_IRQ_TPCC_REGION5	IRQ_CROSSBAR_332	-	DSP2 subsystem EDMA channel controller REGION5 interrupt. This IRQ source signal is not mapped by default to any device INTC.
DSP2_IRQ_TPCC_REGION6	IRQ_CROSSBAR_377	-	DSP2 subsystem EDMA channel controller REGION6 interrupt. This IRQ source signal is not mapped by default to any device INTC.
DSP2_IRQ_TPCC_REGION7	IRQ_CROSSBAR_378	-	DSP2 subsystem EDMA channel controller REGION7 interrupt. This IRQ source signal is not mapped by default to any device INTC.

NOTE: The DSP1 / DSP2 does NOT generate any DMA requests towards other device DMA controllers outside DSP1 / DSP2 (device-level EDMA, etc.).

NOTE: The “**Default Mapping**” column in [Table 4-3, DSP Hardware Requests](#) shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR module. For more information about the IRQ_CROSSBAR module, see [Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#). For more information about the device interrupt controllers, see [Chapter 13, Interrupt Controllers](#).

NOTE:

- For a description of the interrupt source controls at DSP subsystem level, see [Section 4.3.4, DSP Interrupt Requests](#).
-

DSP1/DSP2 subsystem external interrupt sources: The default interrupt sources mapped by the device IRQ_CROSSBAR to the DSP1 / DSP2 interrupt controller lines are described in the [Chapter 13, Interrupt Controllers](#). The programmable muxing of various external interrupt sources to the DSP1_INTC.DSP1_IRQ_x and DSP2_INTC.DSP2_IRQ_x input lines (where x=32 to 95) is covered in the [Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description](#), of the [Chapter 14, Control Module](#).

DSP1/DSP2 subsystem internal interrupt sources: The mapping of DSP subsystem internal IRQ sources to DSP1_IRQ_x / DSP2_IRQ_x lines (where x=0 to 31 and x=96 to 127 for DSP subsystem internal event sources) is described in the [Section 4.3.4, DSP Interrupt Requests](#).

DSP1/DSP2 subsystem external DMA request sources: The [Table 4-6](#) and [Table 4-7](#) lists the default DSP1 and DSP2 external DMA request sources, respectively, routed via the device DMA_CROSSBAR to the DSP1_EDMA / DSP2_EDMA channel controller inputs (DMA_DSP1_DREQ_i / DMA_DSP2_DREQ_i).

4.3 DSP Subsystems Functional Description

4.3.1 DSP Subsystems Block Diagram

Each of the device two DSP subsystems - DSP1 and DSP2 is composed of a DSP C66x CorePac coupled with several other submodules that enable its integration in the device architecture. Device DSP subsystem provides :

- a 128-bit master data port (MDMA) on device L3_MAIN with a dedicated DSP subsystem local MMU (MMU0) on the path.
- a 32-bit master configuration port (CFG) on device L3_MAIN through which DSP host configures various device located peripherals (external to the DSP subsystem).
- a 128-bit slave DMA port (SDMA) on device L3_MAIN which allows external initiators (masters) to DSP to manipulate some portion of its config / status registers (those which are mapped in the L3_MAIN space) in the device
- a 128-bit master EDMA port - which allows the DSP_EDMA traffic controllers to initiate transfers on L3_MAIN.

The C66x DSP subsystem is illustrated in the [Figure 4-1](#).

4.3.2 DSP Subsystem Components

4.3.2.1 C66x DSP Subsystem Introduction

The key component of the C66x DSP subsystem is built on the TI's high performance TMS320C66x DSP CorePac which consists of a single TMS320C66x CPU (DSP_C0) processor along with a level 1 (L1P and L1D) cacheable SRAM and a level 2 (L2) cacheable SRAM memories interfaced via associated local L1P, L1D and L2 memory controllers, respectively. A DSP C66x CorePac includes also some other internal peripheral components, see [Section 4.3.2.2.3](#) for details.

This chapter provides an overview of the DSP subsystem and the following considerations associated with it :

- DSP C66x CorePac Core and L1 / L2 Memories
- DSP System control and configuration :
 - clock management
 - wake-up event generation
 - interrupt masking
- DSP Booting
- DSP subsystem internal memory and external memory (L3_MAIN) space views
- DSP INTC interrupts mapping, event combining and exception generation
- DMA requests mapping to EDMA channels and EDMA traffic routing
- Others

For more information on the TMS320C66x DSP CorePac, refer to the *TMS320C66x DSP CorePac User Guide*, ([SPRUGW0C](#)), the *TMS320C66x DSP Cache User Guide*, ([SPRUGY8](#)) and the *TMS320C66x DSP CPU and Instruction Set Reference Guide*, ([SPRUGH7](#)).

4.3.2.2 DSP TMS320C66x CorePac

The TMS320C66x DSP CorePac is illustrated on [Figure 4-1](#). It consists of a single DSP C66x CPU (DSP_C0) processor tightly coupled with level 1 - L1P (program), L1D (data) cacheable SRAM memories and level 2 (L2) cacheable SRAM memories. The C66x CorePac integrated memories are interfaced via associated local L1P, L1D and L2 memory controllers, respectively.

Additionally, the DSP C66x CorePac contains the following internal peripherals:

- an interrupt controller (DSP_INTC) to service DSP C66x CorePac internal and external interrupt events
- a power-down controller (DSP_PDC)
- an external memory controller - DSP_EMCC
- an extended memory controller - DSP_XMC_CTRL
- a bandwidth manager - BWM with local controls to the L1P-, L1D- and L2-memories
- an internal direct memory access controller - IDMA

The C66x CorePac DSP also instantiates Debug and Trace logic, part of which is implemented in the DSP core C66x CPU. For more details, refer to the [Chapter 26, On-Chip Debug Support](#).

4.3.2.2.1 DSP TMS320C66x CorePac CPU

The DSP C66x CorePac CPU includes following key components :

- A program fetch unit
- 16-/32-bit instruction dispatch unit, advanced instruction packing
- Instruction decode unit
- Two data paths, each with four functional units
- 64 x 32-bit general purpose registers
- Control logic and associated registers
- An internal interrupt and exception controller
- Test, emulation logic
- Internal DMA (IDMA) for transfers between internal memories

For more information on the TMS320C66x central processing unit, see the *TMS320C66x DSP CPU and Instruction Set Reference Guide*, ([SPRUGH7](#)).

4.3.2.2.2 DSP TMS320C66x CorePac Internal Memory Controllers and Memories

The TMS320C66x DSP CorePac implements a two-level internal cache-based memory architecture.

4.3.2.2.2.1 Level 1 Memories

Level 1 memory (L1) is split into separate program memory (L1P memory) and data memory (L1D memory). Each of the memories can be split into static RAM (normal addressable on-chip memory) and cache.

L1P memory is dedicated to TMS320C66x CPU program words storage and is interfaced via a dedicated L1P memory controller in the DSP C66x CorePac. User can choose to initialize one part of the L1P memory as cache and the other as SRAM. The entire 32 KiB memory is cacheable. The L1P features a dynamically configurable cache size (4 KiB, 8 KiB, 16 KiB and 32 KiB) defined via L1P controller configuration register - L1PCFG[2:0] L1PMODE bitfield. **Note that, the L1P controller maps the cache space by starting at the top of the L1P memory map (i.e. from most significant address) and working downwards. The L1P mapped SRAM size is 32 KiB minus the configured cache size.**

NOTE: The L1P cache / SRAM is ONLY read-accessible by the C66x CPU processor. The DSP C66x CorePac external DMAs (SDMA and EDMA) and internal DMA (IDMA) are the only initiators which can write to the L1P memory. The CPU may however write access and modify certain L1P cache/SRAM controller registers if such access is allowed for the register.

NOTE: In the device integrated DSP, at reset, the entire 32 KiB- L1P memory is initialized as a cache (reset value of L1PMODE=0x7).

For more information on the L1P cache/SRAM memories, refer to the *TMS320C66x DSP Cache User Guide*, ([SPRUGY8](#)).

L1D memory is used for level 1 CPU data storage and is interfaced via a dedicated L1D memory controller in the DSP C66x CorePac. User can choose to initialize one part of the L1D memory as cache and the other as SRAM. The entire 32 KiB memory is cacheable. The L1D features a dynamically configurable cache size (4 KiB, 8 KiB, 16 KiB and 32 KiB) defined via L1D configuration register - L1DCFG[2:0] L1DMODE bitfield. **Note that, the L1D controller maps the cache space by starting at the top of the L1D memory map (i.e. from most significant address) and working downwards. The L1D mapped SRAM size is 32 KiB minus the configured cache size.**

NOTE: In the device integrated DSP, at reset, the entire 32 KiB- L1D memory is initialized as a cache (i.e. reset value of L1DMODE = 0x7).

For more information on the L1D cache/SRAM memories, refer to the *TMS320C66x DSP Cache User Guide*, ([SPRUGY8](#)).

4.3.2.2.2 Level 2 Memory

The L2 memory can also be split into L2 RAM (normal addressable on-chip memory) and L2-cache for caching external to the DSP meagmodule memory locations. The on-chip integrated L2 memory total size is 288 KiB. The L2 memory is shared between data and program word sources within and outside the DSP C66x CorePac. The L2 memory is divided into two physical 128 bit-wide banks, accesses to which are interleaved on address LSB. Each of the two L2 banks is further split into 4 subbanks.

NOTE: Only 256 KiB of the L2 memory are cacheable in the device DSP. The remaining 32 KiB are always mapped as static RAM.

The L2 memory features a dynamically configurable cache size (32 KiB, 64 KiB, 128 KiB and 256 KiB) defined via L2 configuration register - L2CFG[2:0] L2MODE bitfield. The additional (to the 32KiB fixed SRAM L2) SRAM available is 256-KiB minus the cache size.

L2 memory controller is responsible for MDMA bus error events reporting. The DSP C66x CorePac MDMA bus error event is exported outside the C66x DSP CorePac in the subsystem, and can be enabled to trigger the ERRINT_IRQ aggregated interrupt output. See also corresponding "MDMAERREVT" event in the [Table 4-5](#).

NOTE: The MDMA bus error event is not exported outside DSP subsystem. However it is merged (OR-ed) along with other error event sources within the DSP subsystem to produce a single ERRINT_IRQ interrupt exported outside the DSP subsystem.

For more details on ERRINT_IRQ generation and associated event registers at DSP_SYSTEM level, refer to the [Section 4.3.4.2.2](#).

4.3.2.2.3 DSP C66x CorePac Internal Peripherals

The DSP C66x CorePac includes the following internal peripherals:

- DSP interrupt controller (DSP_INTC)
- DSP power-down controller (DSP_PDC)
- Bandwidth manager (DSP_BWM)
- Memory Protection Hardware
- Internal DMA (DSP_IDMA) controller

- External Memory Controller (DSP_EMCC)
- Extended Memory Controller (DSP_XMC_CTRL) including prefetch buffer logic
- Error Detection logic for the L1P memory
- Error Detection and Correction (ECC) logic for the L2 memory

This section briefly describes the DSP_INTC, DSP_PDC, DSP_BWM, DSP_IDMA, DSP_EMCC, DSP_XMC_CTRL controller, L1P Error detection and L2 ECC logic. For more information on the TMS320C66x DSP CorePac, see the *TMS320C66x DSP CorePac User Guide*, ([SPRUGW0C](#)).

4.3.2.2.3.1 DSP C66x CorePac Interrupt Controller (DSP INTC)

The DSP C66x CorePac includes an interrupt controller (DSP_INTC) and can receive a total of 128 system events as inputs. They include DSP-generated events and chip-level events.

In addition to these 128 events, a non-maskable (NMI) event (see the [Section 4.3.4.1.1](#)) and reset events are mapped to the DSP_INTC as well, and are routed straight through to the DSP CPU core.

For more details on the DSP_INTC functionalities and its corresponding control / status registers (part of the DSP_ICFG local configuration space), refer to the section *Interrupt Controller* within the *TMS320C66x DSP CorePac User Guide*, ([SPRUGW0C](#)).

For more details on input interrupt mappings and associated IRQ wake-up events, refer to the [Section 4.3.4.1](#).

For more information about the device DSP_INTC, see [Chapter 13, Interrupt Controllers](#). For more information on chip level IRQ mapping via the device IRQ_CROSSBAR module, see [Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#).

4.3.2.2.3.2 DSP C66x CorePac Power-Down Controller (DSP PDC)

The DSP C66x CorePac includes a power-down controller (PDC). The PDC can power-down all of the following components of the DSP C66x CorePac and internal memories of the DSP subsystem:

- C66x CPU
- L1P Memory
- L2 Memory
- Cache controllers
- Entire TMS320C66x DSP CorePac

Refer to the *Power-Down Controller* in the *TMS320C66x DSP CorePac User Guide*, ([SPRUGW0C](#)) for detailed descriptions of the DSP C66x CorePac components power-down control.

4.3.2.2.3.3 DSP C66x CorePac Bandwidth Manager (BWM)

The DSP C66x CorePac implements a bandwidth manager (BWM) to assure that some requestors do NOT block resources in the C66x CorePac DSP for extended periods of time.

Refer to the *Bandwidth Management Architecture* in the *TMS320C66x DSP CorePac User Guide*, ([SPRUGW0C](#)) for detailed descriptions of the DSP C66x CorePac components power-down control.

4.3.2.2.3.4 DSP C66x CorePac Memory Protection Hardware

The C66x Core Pac memory protection architecture introduces in the DSP a combination of DSP privilege levels and a memory system permission structure. This provides several benefits to the system, as follows:

The DSP C66x CorePac MP events are exported outside the DSP C66x CorePac in DSP subsystem, and can be enabled to trigger the ERRINT_IRQ aggregated interrupt output. See also corresponding memory protection fault events listed in the [Table 4-5](#).

NOTE: The memory protection exception events are not exported outside DSP subsystem. However they are merged (OR-ed) along with other error event sources within the DSP subsystem to produce a single ERRINT_IRQ interrupt exported outside the DSP subsystem.

For more details on ERRINT_IRQ generation and associated event registers at DSP_SYSTEM level, refer to the [Section 4.3.4.2.2](#).

NOTE: IDMA, DMA or System initiators should not issue read/write requests to regions of DSP L1P, L1D, or L2 memory configured as cache. In such cases the corresponding MPPA register should be set to 0x0 to disallow external read/write accesses.

Refer to the section *Memory Protection* in the *TMS320C66x DSP CorePac User Guide*, ([SPRUGW0C](#)) for detailed descriptions of the DSP C66x CorePac components power-down control.

4.3.2.2.3.5 DSP C66x CorePac Internal DMA (IDMA) Controller

The IDMA controller performs fast block transfers between any two memory locations local to the DSP C66x CorePac. Local memory locations are defined as those in Level 1 program (L1P), Level 1 data (L1D), and Level 2 (L2) memories, or in the external peripheral configuration (CFG) port.

The IDMA configuration / status registers themselves are part of the DSP_ICFG and are visible only to C66x CPU.

NOTE: The IDMA cannot transfer data to or from the internal DSP memory-mapped register space (DSP_ICFG).

The IDMA exception is mapped to the system level ERRINT_IRQ interrupt event. For more details, refer to the [Section 4.3.4.2.2](#) and the [Table 4-5](#).

The DSP C66x CorePac IDMA error event is exported outside the DSP C66x CorePac in the subsystem, and can be enabled to trigger the ERRINT_IRQ aggregated interrupt output. See also corresponding "EMC_IDMAERR" event in the [Table 4-5](#).

NOTE: The IDMA exception error event is not exported outside DSP subsystem. However it is merged (OR-ed) along with other error event sources within the DSP subsystem to produce a single ERRINT_IRQ interrupt exported outside the DSP subsystem.

For more details on ERRINT_IRQ generation and associated event registers at DSP_SYSTEM level, refer to the [Section 4.3.4.2.2](#).

The IDMA is fully described in the section *Internal Direct Memory Access (IDMA) Controller* of the *TMS320C66x DSP CorePac User Guide*, ([SPRUGW0C](#)).

4.3.2.2.3.6 DSP C66x CorePac External Memory Controller

The DSP C66x CorePac has an embedded External Memory Controller which acts as a bridge between the DSP C66x CorePac CPU and the remaining part of DSP subsystem. It implements two ports interfacing the DSP C66x CorePac environment:

- An external peripheral 32-bit CFG port which acts as an (DSP CPU cfg) initiator on the DSP_NoC L2 interconnect. It is the root source of all C66x CPU external configuration traffic (**excluding the DSP_ICFG traffic which takes place only within the DSP C66x CorePac**) towards the subsystem.
- An SDMA slave port which is a target on the L2 DSP_NoC interconnect. It generally accepts traffic initiated on DSP_NoC by the:
 - DSP_EDMA_TC0 and DSP_EDMA_TC1
 - DSP external slave port on the L3_MAIN

In summary:

- The CPU CFG port provides access to the memory-mapped registers which control various peripherals

and resources within the DSP subsystem, such as the MMUs, DSP_EDMA controllers, DSP system control and wakeup logic, DSP NoC itself, DSP external peripherals, etc.

- The DSP system masters found outside the DSP C66x CorePac such as the DSP_EDMA controllers (TC0 and TC1) or L3_MAIN masters (IPU1, etc.) access the SDMA slave port to reach resources inside the DSP C66x CorePac. In respect to the SDMA port, the DSP C66x CorePac is the slave in the transaction.

The DSP EMC controller adds following functionalities to the DSP C66x CorePac:

- Reporting errors related to the C66x CPU external peripheral configuration bus (associated registers)

NOTE: Regarding PrivID versus AID mapping functionality of the EMC, the C66x DSP CorePac is able to distinguish ONLY "local" vs "external" requests. The device integrated C66x DSP CorePac has the SDMA PrivID input tied-off to a value of 0x0. On DSP C66x CorePac SDMA port, this means that no distinguishing can be made between external requests which come over DSP_NoC interconnect from local DSP_EDMA and those coming from other initiators accessing DSP via the device L3_MAIN interconnect.

This limits the functionality of the internal memory protection registers.

The DSP C66x CorePac EMC error event is exported outside the DSP C66x CorePac in the subsystem, and is capable to trigger the ERRINT_IRQ aggregated interrupt output. See also corresponding **EMC_BUSERR** event in the [Table 4-5](#).

NOTE: The EMC configuration bus error event is not exported outside DSP subsystem. However it is merged (OR-ed) along with other error event sources within the DSP subsystem to produce a single ERRINT_IRQ interrupt exported outside the DSP subsystem.

For more details on ERRINT_IRQ generation and associated event registers at DSP_SYSTEM level, refer to the [Section 4.3.4.2.2](#).

For various DSP_NoC initiator vs target mappings, refer to the [Table 4-8](#).

Note that, there are DSP_NoC pressure (Mflag bus) controls in DSP_SYSTEM logic related to the C66x CPU CFG and DSP_NoC SDMA init traffic. They are described in the [Section 4.3.8.3](#).

The EMC functionalities / registers are fully described in the section *External Memory Controller (EMC)* of the *TMS320C66x DSP CorePac User Guide*, ([SPRUGW0C](#)).

4.3.2.2.3.7 DSP C66x CorePac Extended Memory Controller

The DSP C66x CorePac located extended memory controller (DSP_XMC_CTRL) implements a local DMA master port (MDMA) which provides the primary path for C66x CPU and cache requests to the device level memories such as (DDR or L3 SRAM) and peripheral / memory mapped register space. Via some additional logic, including DSP_SYSTEM controls and a local DSP MMU - DSP_MMU0 on the path (with option to bypass), C66x local MDMA port is mapped to the DSP subsystem CPU master port (i.e. MDMA master port of the DSP CPU on L3_MAIN). The DSP C66x Corepac MDMA port is mapped to the DSP Subsystem CPU Master Port (with DSP_MMU0 involved or not involved) to allow fast accesses (DSP_NoC not involved) to the external SDRAM (via the L3_MAIN) or to L3 SRAM (via the L3_MAIN).

The memory protection settings in MPAX defines types of the memory accesses permitted on various address ranges within DSP C66x CorePac 32-bit address map.

The DSP_XMC_CTRL also instantiates program and data prefetch buffer logic to reduce time during servicing read requests from the L1D, L1P and L2 memory controllers. The aim is to buffer program and data fetches from external L3_MAIN memory locations. While the program prefetch buffer is organized as 4 entry x 32 byte, the data prefetch buffer is organized in 8 slots, with 128 bytes per slot. The DSP_XMC_CTRL prefetch reduces the penalty associated with accesses to the L3_MAIN SDRAM upon L1P, L1D and L2-cache read-misses.

NOTE: the DSP_XMC_CTRL registers are part of the DSP_ICFG space, hence they are not accessible outside the DSP C66x CorePac (visible only to the C66x CPU).

In summary the DSP_XMC_CTRL provides :

- a master path from the DSP C66x CorePac level 2 cache / SRAM memory to device memory such as SDRAM or L3 SRAM or peripheral / MMR address space.
- memory protection on external address ranges related to L3_MAIN RAMs (via MPAX unit) :
 - 16 user-defined address ranges (MPAX segments) can be used to divide external memory space
- Address translation
- Data and Program prefetch buffer logic
- 12- address candidate buffer that acts as a "stream detection filter"

NOTE: The device DSP subsystem does NOT use the DSP C66x CorePac multicore shared memory controller (MSMC) port to add more static RAM within subsystem boundaries, i.e. no additional SRAM is available in the DSP except for the L1P, L1D and L2 memories. Only the DSP_XMC_CTRL controller MDMA port on the L3_MAIN interconnect is used to extend DSP available RAM memory via a direct or DSP_MMU0 translated access to the device EMIF DDR memories and OCMC RAMs.

NOTE: **Only the memory protection function of the DSP_XMC_CTRL MPAX unit is intergated** and used in the device DSP subsystem. The MDMA port 32-bit to 36-bit address extension function is NOT used in the device DSP because L3_MAIN address bus width is 32-bit. The DSP_MMU0 does NOT perform an address size (32b -> 36b) extension as well.

The XMC functionalities / registers are fully described in the section *Extended Memory Controller (XMC)* of the *TMS320C66x DSP CorePac User Guide*, ([SPRUGW0C](#)).

4.3.2.2.3.7.1 XMC MDMA Accesses at DSP System Level

4.3.2.2.3.7.1.1 DSP System MPAX Logic

The default configuration of MPAX registers provides a 32-bit view of system memory on L3_MAIN.

In summary, each MPAX segment (mentioned above) is programmed with a starting virtual base address, segment sizes from 4 GiB down to 4 KiB, replacement address (i.e., physical address); and permission attributes. Provided that DSP_MMU0 can be used to perform address translation, in most cases the replacement address will equal the base address (i.e., virtual == physical from DSP C66x CorePac perspective).

The system level implementation of MPAX logic allows the C66x CPU to change permission without being required to flush the cache.

The C66x CPU subsystem relies on the MPAXn.PERM field to properly configure the permissions for remote address ranges. The MDMA.rperm[6:0] signals are tie-off to a fixed value of 0x7F on the DSP C66x CorePac boundary.

4.3.2.2.3.7.1.2 MDMA Non-Post Override Control

The C66x corepac submits writes denoted as either "cacheable" or non-cacheable. Write accesses that are non-cacheable will be submitted as interconnect (L3_MAIN) non-posted writes; whereas write accesses that are cacheable are submitted as interconnect posted writes. An exception for the cache writes to L3_MAIN is that in the case of a cache block write-back operation (when actual cache evict busrts are actually issued towards L3_MAIN connected memory), a non-posted write is submitted.

NOTE: In order to provide a safety net for interconnects that may do aggressive reordering, a memory-mapped register SW control is provided - [DSP_SYS_BUS_CONFIG\[24\]](#) `NOPOSTOVERRIDE`. When set, this results in all write commands being issued as non-posted. This bit defaults to set, and thus the default behavior is for non-posted writes to be used exclusively.

4.3.2.2.3.8 L1P Memory Error Detection Logic

The L1P memory detection logic (no correction is implemented) uses a 4-bit parity per 256-bit location (1-bit parity per 64-bit line quadrant).

The L1P error detection logic features:

- L1P error detection command, status and address controls (registers)
- L1P_ED error detection exception / interrupt to the DSP_INTC upon DMA / IDMA access
- a direct exception event to C66x CPU (DSP_INTC not involved) upon parity error during a program fetch from L1P-cache
- L1P-cache error recovery

The L1P parity error detection event is exported outside the DSP C66x CorePac in the subsystem, and can be enabled to trigger the ERRINT_IRQ aggregated interrupt output. See also corresponding "PMC_ED" event in the [Table 4-5](#).

NOTE: The L1P error detection event is not exported outside DSP subsystem. However it is merged (OR-ed) along with other error event sources within the DSP subsystem to produce a single ERRINT_IRQ interrupt exported outside the DSP subsystem.

For more details on ERRINT_IRQ generation and associated event registers at DSP_SYSTEM level, refer to the [Section 4.3.4.2.2](#).

For more details on L1P error detection logic, refer to the section *L1P Error Detection*, of the *TMS320C66x DSP CorePac User Guide*, ([SPRUGW0C](#)).

4.3.2.2.3.9 L2 Memory Error Detection and Correction Logic

The L2 Memory error detection and correction logic (ECC) implements a distance-3 "detect 2, correct 1" Hamming code based error correction / detection algorithm. A 12-bit hamming code per 256-bit is used.

The L2 error detection and correction logic features:

- L2 error detection command, status and address controls (registers)
- L2 EDC enable
- L2 error detection event counter
- 2x L2 EDC exception / interrupts mapped to the DSP_INTC :
 - L2_ED1 = "error corrected" event
 - L2_ED2 = "error-not-corrected" event

The two L2 memory error correction events are exported outside the DSP C66x CorePac in the subsystem, and can be enabled to trigger the ERRINT_IRQ aggregated interrupt output. See also corresponding "UMC_ED1" and "UMC_ED2" events in the [Table 4-5](#).

NOTE: The L2 error detection events are not exported outside DSP subsystem. However they are merged (OR-ed) along with other error event sources within the DSP subsystem to produce a single ERRINT_IRQ interrupt exported outside the DSP subsystem.

For more details on ERRINT_IRQ generation and associated event registers at DSP_SYSTEM level, refer to the [Section 4.3.4.2.2](#).

For more details on L2 error detection and correction logic, refer to the section *L2 Error Detection and Correction* of the *TMS320C66x DSP CorePac User Guide*, ([SPRUGW0C](#)).

4.3.2.3 DSP Debug and Trace Support

The DSP subsystem offers full support for the native DSP C66x CorePac debug features. This includes Advanced Event Triggering (AET) and Trace.

4.3.2.3.1 DSP Advanced Event Triggering (AET)

AET capability can be used to debug complex problems as well as understand performance characteristics of user applications. AET provides the following capabilities:

- **Hardware Program Breakpoints:** specify addresses or address ranges that can generate events such as halting the processor or triggering the trace capture.
- **Data Watchpoints:** specify data variable addresses, address ranges, or data values that can generate events such as halting the processor or triggering the trace capture.
- **Counters:** count the occurrence of an event or cycles for performance monitoring.
- **State Sequencing:** allows combinations of hardware program breakpoints and data watchpoints to precisely generate events for complex sequences.

4.3.2.3.2 DSP Trace Support

Trace is a debug technology that provides a detailed, historical account of application code execution, timing, and data accesses. Trace collects, compresses, and exports debug information for analysis. Trace works in real-time and does not impact the execution of the system. Trace is supported via Code Composer Studio.

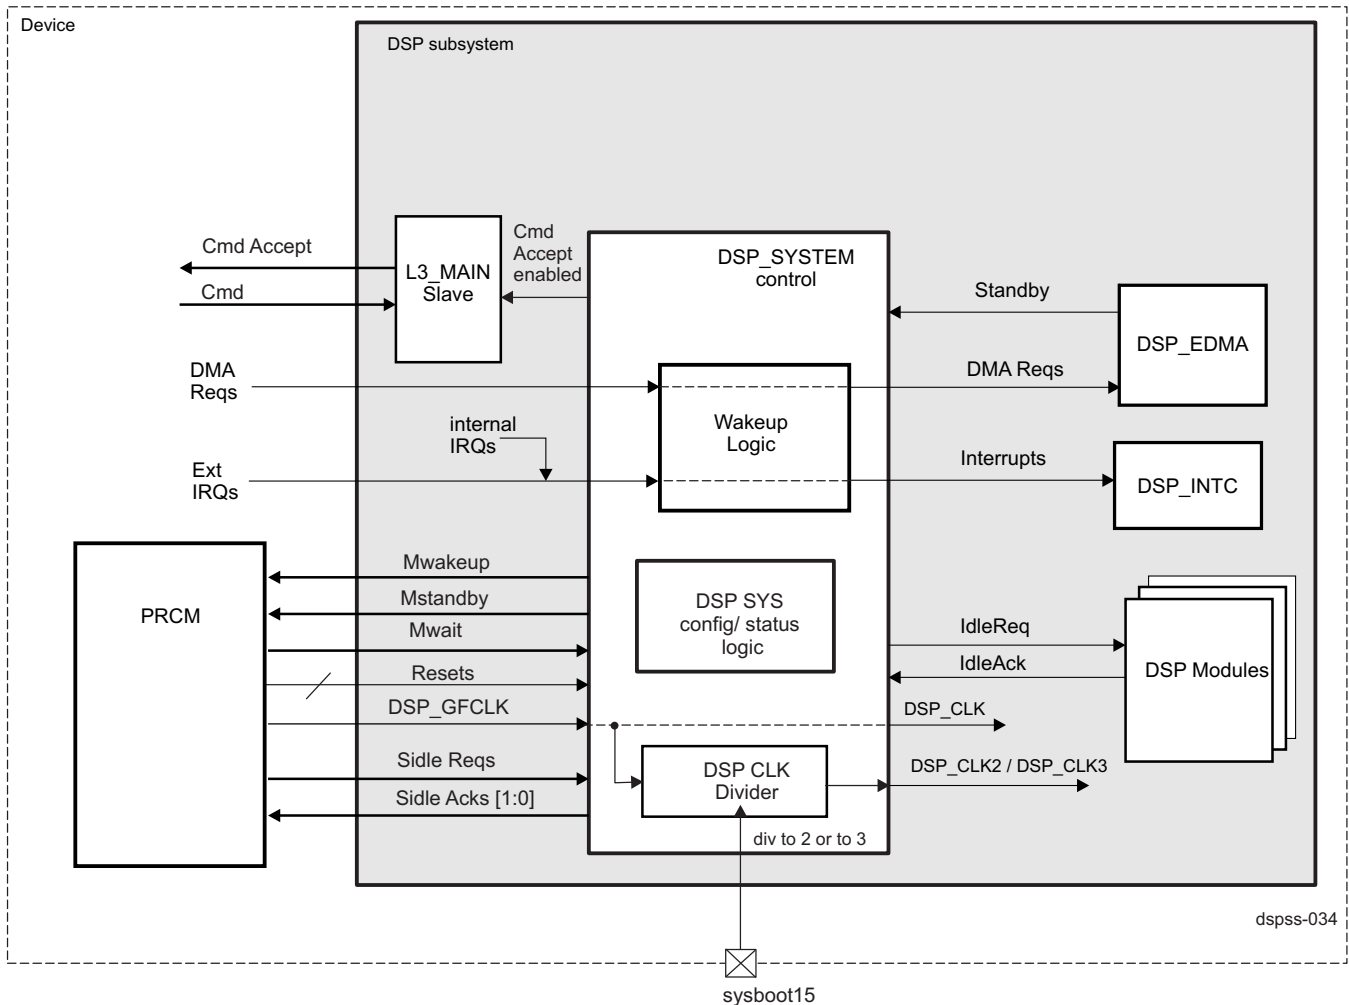

See also the [Chapter 26, On-Chip Debug Support](#).

4.3.3 DSP System Control Logic

The DSP_SYSTEM module controls the following functions:

- Generation of the divided clocks (DSP_CLK2 or DSP_CLK3) to all components of the DSP subsystem
- Synchronization of the DSP divided clocks
- PRCM module power handshaking
- Reset input resynchronization of the active-to-inactive transition to the CD1_CLK clock
- DSP subsystem top level configuration registers and its access from the DSP core.

[Figure 4-3](#) highlights the DSP_SYSTEM and its connectivities to the surrounding blocks within the subsystem and in the device.

Figure 4-3. DSP_SYSTEM Block Diagram

4.3.3.1 DSP System Clocks

The DSP1 and DSP2 subsystems inputs a primary non-divided clock (DSP1_FICLK / DSP2_FICLK) and based on it (DSP_CLK1), internally generates either **a divided by 2 clock** (DSP_CLK2) version or **a divided by 3 clock** (DSP_CLK3). The divided clock determines the operation rate of the DSP subsystem logic and bus interfaces. The division is defined upon device boot time through signal level externally applied on the device **sysboot15** input. The actual bit configuration is latched upon power-on reset in Control Module register CTRL_CORE_BOOTSTRAP[15] SYS_BOOT_15_CLOCK_DIVIDER boot status bit. For more details, refer to the [Section 14.4.6.13.1, System Boot Status Settings](#) of the chapter, *Control Module*.

NOTE: Only DSP_CLK3 clock is supported on this SoC. Upon boot time, sysboot15 set at '1' selects a DSP_CLK3 divided clock version for the DSP subsystem logic and bus interfaces. For proper device operation, sysboot15 must be tied to vdd.

The clock operating mode setting (DSP_CLK2 or DSP_CLK3) must be static just before and continually after reset deassertion. This signal will also drive the configuration to the DSP C66x CorePac for the XMC_MDMA_CLK, EMC_SDMA_CLK, and EMC_CFG_CLK configurations.

The DSPSS1 / DSPSS2 subsystem input clock frequency (DSP_CLK1) corresponds to the PRCM DSP1_GFCLK / DSP2_GFCLK frequency that is configured in the device PRCM registers.

NOTE: For valid DSP_CLK1 (and hence for DSP_CLK3 = DSP_CLK1 / 3) frequency range, see the Operating Performance Points section of the device Data Manual.

The [Section 4.3.2](#) also shows the distribution of the different DSP subsystems blocks within the two DSP local clock domains CD0_CLK (running on DSP_CLK frequency) and CD1_CLK (running on DSP_CLK2 or DSP_CLK3 frequency).

4.3.3.2 DSP Hardware Resets

The DSP uses the same reset sources than those mapped to the DSP C66x CorePac; i.e. DSP C66x CorePac reset inputs will be pinned out as DSP system reset inputs.

The [Table 4-4](#) summarizes the DSP hardware reset inputs and their functional descriptions.

Table 4-4. Summary of the DSP1 and DSP2 Hardware Resets

DSP1 reset input	DSP1 reset "done" output to PRCM	Description
DSP1_PWR_RST	-	This is power-on reset signal used inside DSP1 to reset mainly the emulation logic. It resets the entire DSP1 logic.
DSP1_RST	-	Reset signal used to reset all logic inside DSP1 except Emulation logic.
DSP1_LRST	-	Reset applied ONLY to the C66x CPU inside DSP1
-	DSP1_LRST_DONE	Indicates completion of the DSP1 local C66x CPU reset to device PRCM
DSP2 reset input	DSP2 reset "done" output to PRCM	Description
DSP2_PWR_RST	-	This is power-on reset signal used inside DSP2 to reset mainly the emulation logic. It resets the entire DSP2 logic.
DSP2_RST	-	Reset signal used to reset all logic inside DSP2 except Emulation logic.
DSP2_LRST	-	Reset applied ONLY to the C66x CPU inside DSP2
-	DSP2_LRST_DONE	Indicates completion of the DSP2 local C66x CPU reset to device PRCM

See also the [Section 4.2](#) for more information on the PRCM reset sources to DSP reset inputs connectivity.

Refer to the [Section 3.5.6.2](#), *DSP1 Subsystem Power-on Reset Sequence* and the [Section 3.5.6.4](#), *DSP2 Subsystem Power-on Reset Sequence* in the chapter, *Power, Reset and Clock Management* for more details on the DSP1 and DSP2 power-on reset sequence, respectively.

NOTE: In the case of DSP1 / DSP2 recovery from the "Powerdown-grid off", a full power-on-reset sequence is required before re-booting and resuming functional operation.

The DSP host (IPU) software must ensure that the PRCM functional clock DSP1_GFCLK / DSP2_GFCLK is enabled to the DSP1 / DSP2, respectively, prior to starting the DSP1 / DSP2 power-on reset sequence.

4.3.3.3 DSP Software Resets

During a software reset on the DSP, all resets described in [Table 4-4](#) are asserted, except for the power-on DSP_PWRON_RST signal which remains de-asserted in this case.

The DSP subsystem does NOT implement any local software reset controls. The software reset assertion and DSP_LRST completion monitoring is done in PRCM located registers (part of the DSP1_PRM / DSP2_PRM address space).

Refer to the [Section 3.5.6.3, DSP1 Subsystem Software Warm Reset Sequence](#) and the [Section 3.5.6.5, DSP2 Subsystem Software Warm Reset Sequence](#) in the chapter, *Power, Reset and Clock Manangement* for more details on the DSP1 and DSP2 software reset sequence and related software controls, respectively.

4.3.3.4 DSP Power Management

The supported power-down modes are:

- Slave idle and master standby protocols for powerdown
- "Disconnect from interconnect" handshake for init and target busses
- Clock Stop mode - wakeup on interrupt or DMA event
- Grid OFF mode : No power supply is switched-on

NOTE: Powerdown-retention mode is NOT supported by DSP subsystem. **The DSP recovery from the Powerdown-grid OFF mode requires full boot.**

The DSP C66x CorePac natively supports "CLKSTOP/Static Powerdown" and "POWERDOWN (Grid off)" modes of operation. Once the device PRCM restores clocks and power supply, then the DSP C66x CorePac can exit static-powerdown.

The DSP_SYSTEM wakeup logic is implemented in the "always-on" clock / power supply domain. This logic monitors new interrupts / events and will drive the IDLE wakeup request when a new interrupt / event occurs.

4.3.3.4.1 DSP System Powerdown Protocols

For each of the powerdown modes – Static or Powerdown-Grid Off, the device PRCM will control whether clocks are gated, or whether supplies are reduced or removed.

NOTE: In the case of "Powerdown-grid off", a full power-on-reset sequence is required before re-booting and resuming functional operation.

in the static powerdown modes - the DSP recognizes new level interrupts while in a clock-gated state (and drive wakeup request). During this powerdown mode all internal state will be retained, including DSP C66x CorePac, interconnect, EDMA, memories, etc.

The following protocols are implemented with PRCM:

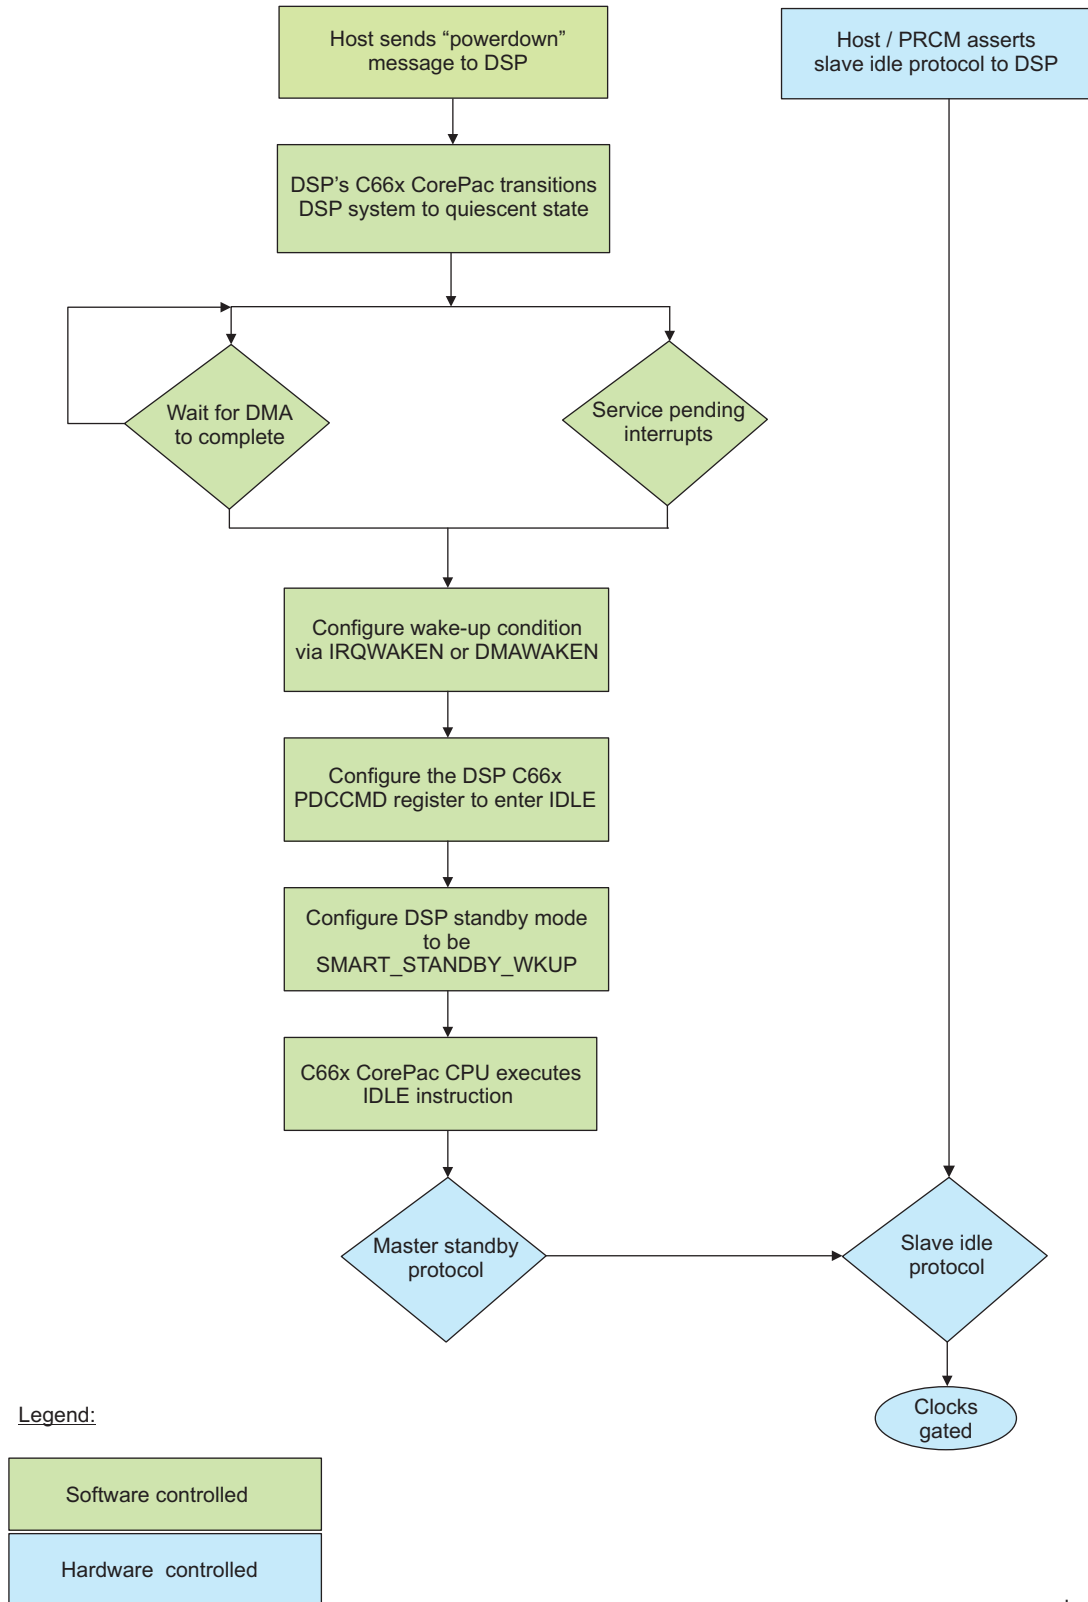

- Slave idle protocol with device PRCM for powerdown (wake-up capable)
- Master standby protocol with device PRCM for powerdown
- Interconnect disconnect for master and slave ports

The Master standby and slave idle protocols behaviour is controlled in the [DSP_SYS_SYSCONFIG](#) register.

4.3.3.4.2 DSP Software and Hardware Power Down Sequence Overview

Figure 4-4 highlights the high level flow-chart for entry into any of the DSP powerdown modes. The system host (typically) first informs the DSP that it should enter a powerdown mode. The host sends a software message (normally via system level mailbox+interrupt). In parallel, the PRCM (via host or DSP programming) will hardware assert an SIdleReq request to the DSP via the IDLE Protocol connection. At the next stage, the C66x CPU, in general, performs any software bookkeeping necessary to transition the DSP subsystem to a quiescent state. This may include : waiting for outstanding DMA transfers to complete, waiting for outstanding DMA transfers to complete, etc. The C66x processor should finally execute the IDLE instruction when it is ready to be powered-down. Assuming the [DSP_SYS_SYSCONFIG\[5:4\] STANDBYMODE](#) is enabled, then the hardware will transition to an idle state and notify to the system the intention to enter powerdown state to the system via the master standby and slave idle protocols. After IDLE and M standby handshake is completed, the DSP clocks are optionally gated; and supply rails are optionally reduced or turned off.

Figure 4-4. Extended Duration Sleep Software and Hardware Sequence

dspss-042

NOTE: The PM_DSPx_PWRSTCTRL[1:0] POWERSTATE bit field in device PRCM must be set to 0x3 (ON state) prior to performing the sequence shown in [Figure 4-4](#) for the transition to be successful.

4.3.3.4.3 DSP IDLE Wakeup

In order to facilitate auto-wakeup of DSP C66x, the IDLE protocol's wakeup capability is used. Wakeup operation is enabled if [DSP_SYS_SYSCONFIG\[3:2\] IDLEMODE](#) is set to 0x3.

In this mode, while in IDLE state, if an external input interrupt source is asserted (if enabled via the [DSP_SYS_IRQWAKEEN0 / DSP_SYS_IRQWAKEEN1](#) mask) or if an external DMA event source is asserted (if enabled via the [DSP_SYS_DMAWAKEEN0 / DSP_SYS_DMAWAKEEN1](#) mask) or if the DSP subsystem NMI input is asserted (**note that there is no wake enable mask for the non-maskable interrupt**) then the Mwakeup signal is asserted to the PRCM which is expected to observe the Mwakeup. Upon such assertion the PRCM enables the clocks, exiting the "Standby" and "Idle" states. at this point the C66x CPU is able to branch to the pending interrupt service routine. The Mwakeup is deasserted when all IRQ or DMA requests enabled in the [DSP_SYS_IRQWAKEEN0/1](#) and [DSP_SYS_DMAWAKEEN0/1](#) are deasserted.

The Wakeup logic controlling assertion of the Mwakeup request is completely asynchronous because in IDLE mode the clock may not be present. It relies on level sensitive interrupts.

NOTE: The DSP_EDMA must be manually removed from IDLE / Standby state. During that time, it is possible that the EDMA input event is no longer pending and may not have been recognized/latched as an EVENT to the EDMA. In that case, the user SW can enable the DSP_EDMA_WAKE_INT (in associated [DSP_SYS_EDMAWAKE0_IRQENABLE_SET](#) register) to recognize in the ([DSP_SYS_EDMAWAKE0_IRQSTATUS_RAW / DSP_SYS_EDMAWAKE0_IRQSTATUS](#)) which specific EDMA event was asserted and caused the wakeup condition. The DSP software can then trigger the corresponding DSP_EDMA channel manually (by setting the ESR) or by servicing the interrupt/event manually via reads and writes. For more details, refer to the [Section 4.3.5.1](#).

4.3.3.4.4 DSP SYSTEM IRQWAKEEN registers

The [DSP_SYS_IRQWAKEEN0 / DSP_SYS_IRQWAKEEN1](#) masking bits must be appropriately set for any valid interrupt mapped from device IRQ_CROSSBAR to the DSP subsystem boundary, to enable its path (passing through the DSP_SYSTEM wakeup logic) to the DSP local interrupt controller - DSP_INTC.

CAUTION

In order for a given interrupt to be serviced by the DSP (even when the Idle Instruction is NOT being executed), the Interrupt must be enabled in the corresponding [DSP_SYS_IRQWAKEEN0](#) or [DSP_SYS_IRQWAKEEN1](#) register.

4.3.3.4.5 DSP Automatic Power Transition

This section provides register details for configuring the DSP1 subsystem in automatic power transition mode. The same should be considered for DSP2 in corresponding PRCM and DSP2 related registers.

The DSP1 module is supposed to be configured to automatic management in PRCM.DSP1_CM_CORE_AON via setting the register CM_DSP1_DSP1_CLKCTRL[1:0] MODULEMODE bitfield to 0x1. The DSP1 clock domain is supposed to be configured in automatic "HW_AUTO" transition (setting bitfield CM_DSP1_CLKSTCTRL[1:0] CLKTRCTRL=0x3).

The power state (controls are in the PRCM.DSP1_PRM instance) to reach upon a sleep transition is configured in the PM_DSP1_PWRSTCTRL[1:0]POWERSTATE bitfield.

4.3.4 DSP Interrupt Requests

The DSP subsystem relies on the DSP C66x CorePac local interrupt controller - DSP_INTC for mapping the various input interrupts to the C66x CPU, that are :

- generated outside the DSP, by the device intergated modules and subsystems
- generated within the DSP subsystems but outside the DSP C66x CorePac
- generated by different components within the DSP C66x CorePac

In addition, a non-maskable input interrupt, direct mapped on a C66x processor NMI input is implemented. It is mapped via a register that resides within the device Control Module. Both the maskable interrupts and the non-maskable interrupts are synchronized internally.

Part of the DSP subsystem module generated interrupts which are output as follows:

- DSP_EDMA interrupts
- DSP_MMU0 and DSP_MMU1 interrupts
- Error interrupts

Figure 4-5 shows how are the interrupt sources organized. To manage and expand the interrupt capabilities of the DSP C66x CorePac (internal and external interrupt requests), the DSP subsystem includes two levels of interrupt control :

- The DSP C66x CorePac local Interrupt controller - DSP_INTC
- The System control logic - DSP_SYSTEM

Figure 4-5. DSP Subsystem Interrupt Management

4.3.4.1 DSP Input Interrupts

In summary, the DSP_INTC accepts up to 124 event inputs, and flexibly maps those down to 12 interrupt inputs to the DSP. The mapping can be 1:1 (input:output), or can use the event combiner to map multiple interrupts (within a 32-bit group) to one of the DSP interrupt inputs. In general, many of the 124 interrupt controller inputs are collected within the DSP C66x CorePac, and are NOT available at the DSP C66x CorePac boundaries.

The C66x CPU dropped event is exported outside the C66x CorePac in DSP subsystem, and can be enabled to trigger the ERRINT_IRQ aggregated interrupt output. See also corresponding "INTERR" event listed in the [Table 4-5](#).

NOTE: The dropped CPU event is not exported outside DSP subsystem. However it is merged (OR-ed) along with other error event sources within the DSP subsystem to produce a single ERRINT_IRQ interrupt exported outside the DSP subsystem.

For more details on ERRINT_IRQ generation and associated event registers at DSP_SYSTEM level, refer to the [Section 4.3.4.2.2](#).

Part of the input interrupts, generated by DSP peripherals that are located outside the DSP C66x CorePac - DSP_EDMA (DSP_EDMA_CC, DSP_EDMA_TC0, DSP_EDMA_TC1), DSP_MMU0, DSP_MMU1 and DSP_NoC, are also mapped to outputs at the DSP subsystem boundary, such that they can be exported to system hosts via the device IRQ_CROSSBAR.

Of particular interest, MMUs (DSP_MMU0 and DSP_MMU1) interrupts will typically be serviced by the device host instead of by the local DSP core.

Any interrupt input at DSP subsystem boundaries (i.e. excluding the DSP subsystem internal IRQ sources that reside in and outside the DSP C66x CorePac) can be used to wake-up the DSP subsystem from an IDLE state. This is described in the [Section 4.3.3.4.3](#) and is controlled by the DSP_SYSTEM logic register [DSP_SYS_SYSCONFIG \[3:2\] IDLEMODE](#) bitfield along with the [DSP_SYS_IRQWAKEEN0 / DSP_SYS_IRQWAKEEN1](#) registers.

CAUTION

The [DSP_SYS_IRQWAKEEN0 / DSP_SYS_IRQWAKEEN1](#) bits MUST be enabled for externally mapped interrupts (DSP_INTC[95:32]) to be serviced by the DSP regardless of the DSP power state (IDLE or non-IDLE).

The DSP C66x CorePac DSP_INTC registers are NOT readable by any entity other than the C66x CPU, because they are part of the DSP_ICFG C66x CorePac internal configuration space (see also the [Section 4.3.10](#)). Hereby, only the C66x itself is able to service these interrupt events. The only way for these interrupts to be cleared is for the DSP CPU to clear the state in the EVTFLAGi (where i=0 to 3) register, or via reset assertion.

NOTE: For cases where the DSP maps an interrupt directly, the DSP is not strictly required to clear the EVTFLAGi register. User software must take the extra step of clearing the EVTFLAGi to cause the corresponding output interrupt to be cleared and re-asserted upon a new input event assertion.

4.3.4.1.1 DSP Non-maskable Interrupt Input

The device DSP also supports a non-maskable interrupt (NMI) directly mapped to the NMI input of the C66x CPU. This line is also mapped to the NMEVT input of the DSP local INTC, and can be used as an exception signal, too. At system level, the NMI interrupt mapping to the DSP_INTC is controlled via the **device core Control Module** register as follows:

- CTRL_CORE_NMI_DESTINATION_2 [15:8] DSP1 = 0x1 enables the DSP1 to receive the NMI coming from the device **nmin** input.
- CTRL_CORE_NMI_DESTINATION_2 [23:26] DSP2 = 0x1 enables the DSP2 to receive the NMI

coming from the device **nmin** input.

For more details on the NMI receive enable bit mapping, refer to the [Section 14.5, Control Module Register Manual](#) in the chapter, *Control Module*.

4.3.4.2 DSP Event and Interrupt Generation Outputs

4.3.4.2.1 DSP MDMA and DSP EDMA Mflag Event Outputs

The Mflag events generated by DSP subsystem EVTOUT bus are represented in the [Figure 4-5](#).

A couple of the DSP EVTOUT bus outputs - EVTOUT[31] and EVTOUT[30] are used for generation of MFLAGs dedicated to the DSP MDMA and EDMA ports, respectively. DSP MFLAGs are connected directly to DMM and EMIF. The DSP MFLAGs participate in the DMM Emergency and EMIF MFLAG prioritization schemes. At the L3 Level Bandwidth regulators connected to the DSP MDMA and EDMA ports can be used to control DSP traffic versus other device traffic.

The device DSP subsystem is able to generate the 2 output Mflag events via the following DSP_SYSTEM module located registers :

- [DSP_SYS_EVTOUT_SET](#)[31:30]
- [DSP_SYS_EVTOUT_CLR](#)[31:30]

The current state of the outputs can be detected by reading any of these "pseudo" register bits.

NOTE: Only EVTOUT[31:30] outputs are implemented in the device, hence only bits [31:30] of the mentioned DSP_SYS_EVTOUT_x registers are used.

The [DSP_SYS_EVTOUT_SET](#) register unconditionally drives the corresponding output event to '1'. The [DSP_SYS_EVTOUT_CLR](#) register unconditionally drives the corresponding output event to a '0'.

4.3.4.2.2 DSP Aggregated Error Interrupt Output

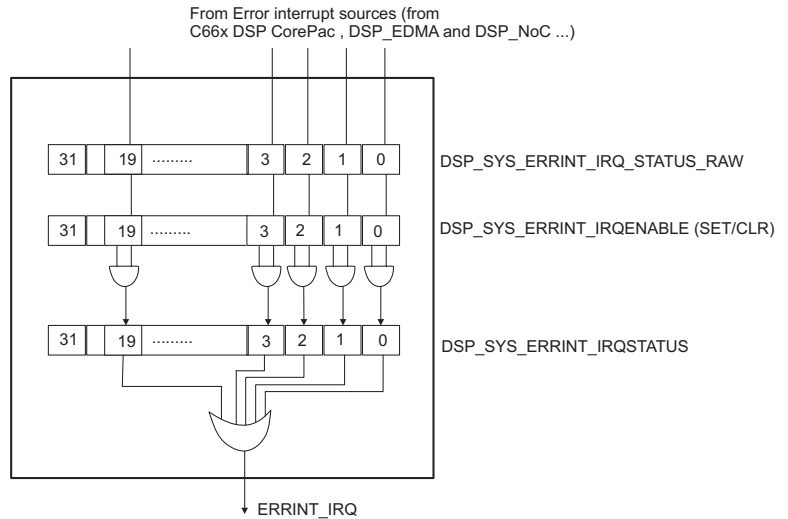

The aggregated error interrupt of the DSP subsystem is shown in the [Figure 4-5](#).

The subset of those events that correspond to: **DSP C66x CorePac generated error events**, **DSP_EDMA error interrupts** and **L2 DSP_NoC interconnect error interrupt**, is reduced by an OR-schematic to a single ERRINT_IRQ output interrupt which is made available on DSP subsystem boundary. It is expected that one of the DSP system hosts monitors the interrupts/error conditions in safety conscious systems.

[Figure 4-6](#) shows a functional representation of the DSP error interrupt "OR"-reduction logic. In summary, there exists an **unmasked status** ([DSP_SYS_ERRINT_IRQSTATUS_RAW](#)) register, two complementary enable bit-vector registers ([DSP_SYS_ERRINT_IRQENABLE_SET](#) / [DSP_SYS_ERRINT_IRQENABLE_CLR](#)), and a masked status register ([DSP_SYS_ERRINT_IRQSTATUS](#)). The ERRINT event is asserted when any enabled error interrupt input is asserted.

NOTE: The ERRINT_IRQ output can be programmatically mapped as the DSPi_IRQ_TPCC_ERR (where i=1 to 2) interrupt to all device (dsp hosts) interrupt controllers via the device IRQ_CROSSBAR. For more information on the IRQ_CROSSBAR module, see [Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#). For more information about the device interrupt controllers, see [Chapter 13, Interrupt Controllers](#).

Figure 4-6. ERRINT Diagram

dsps-043

The Table 4-5 details the mapping of error event output sources to the bit positions within the following DSP error event related registers :

- [DSP_SYS_ERRINT_IRQSTATUS_RAW](#)
- [DSP_SYS_ERRINT_IRQSTATUS](#)
- [DSP_SYS_ERRINT_IRQENABLE_SET](#)
- [DSP_SYS_ERRINT_IRQENABLE_CLR](#)

Following functional descriptions are valid for the above registers :

- **IRQ status raw register** - This register provides a per-event raw interrupt status vector. The Raw status is set even if the corresponding event is not enabled. Software can write '1' to set the (raw) status for debug purposes.
- **IRQ status register** - This register provides a per-event enabled interrupt status vector. The Enabled status is set if the corresponding event is enabled and the raw status is set. Software can write 1 to clear the (raw) status after the interrupt has been serviced. The clear takes effect even if the interrupt is not enabled.
- **IRQ enable register** - This register provides a per-event interrupt enable bit vector. Software can write 1 to set (i.e., enable the corresponding interrupt). Reads of this register return the actual state of the enable register (and is the same as reading the corresponding "IRQ Clear" - register)
- **IRQ clear register** - This register provides a per-event interrupt enable bit vector. Software can write 1 to clear (i.e., disable the corresponding interrupt). Reads of this register return the actual state of the enable register (and is the same as reading the corresponding "IRQ Set" register)

NOTE: A [DSP_SYS_ERRINT_IRQSTATUS_RAW](#) bit is set even if the corresponding event is NOT enabled in the [DSP_SYS_ERRINT_IRQENABLE_SET](#).

Table 4-5. DSP ERRINT Interrupt Mapping

Interrupt Number	Name	Description
0	tpcc_errint_level	DSP EDMA CC error interrupt
1	tptc_errint0_level	DSP EDMA TC0 error interrupt
2	tptc_errint1_level	DSP EDMA TC1 error interrupt
3	noc_errint_level	DSP L2 Interconnect (DSP_NoC) error interrupt

Table 4-5. DSP ERRINT Interrupt Mapping (continued)

Interrupt Number	Name	Description
4	INTERR	DSP C66x CorePac Dropped CPU Interrupt event
5	EMC_IDMAERR	DSP C66x CorePac Invalid IDMA Parameters
6	MDMAERREVT	DSP C66x CorePac VbusM Error Event
7	PMC_ED	DSP C66x CorePac Single bit error detected during DMA read
8	UMC_ED1	DSP C66x CorePac Corrected bit error detected
9	UMC_ED2	DSP C66x CorePac Uncorrected bit error detected
10	SYS_CMPA	DSP C66x CorePac CPU memory protection fault
11	PMC_CMPA	DSP C66x CorePac CPU memory protection fault
12	PMC_DMPA	DSP C66x CorePac DMA memory protection fault
13	DMC_CMPA	DSP C66x CorePac CPU memory protection fault
14	DMC_DMPA	DSP C66x CorePac DMA memory protection fault
15	UMC_CMPA	DSP C66x CorePac CPU memory protection fault
16	UMC_DMPA	DSP C66x CorePac DMA memory protection fault
17	EMC_CMPA	DSP C66x CorePac CPU memory protection fault
18	EMC_BUSERR	DSP C66x CorePac Bus Error Interrupt
19	Reserved	-
20	Reserved	-
21	Reserved	-
22	Reserved	-

Note that neither of the events, listed in [Table 4-5](#), is exported as a separate hardware interrupt off the DSP boundary.

4.3.4.2.3 Non-DSP C66x CorePac Generated Peripheral Interrupt Outputs

The non-DSP C66x CorePac interrupts generated by peripherals within the DSP subsystem are also summarized in the [Figure 4-5](#).

Besides the aggregated error event ERRINT_IRQ interrupts – DSPi_IRQ_TPCC_ERR (where i=1 to 2), interrupts (see also [Figure 4-5](#)) **generated individually by DSPSS peripherals located outside the DSP C66x CorePac**, are mapped as separate IRQ outputs at DSP boundaries. They are sourced by the DSP_EDMA_CC, DSP_EDMA_TC0, DSP_EDMA_TC1, DSP_MMU0, DSP_MMU1 and DSP_NoC and exported to other host INTCs via the device IRQ_CROSSBAR. Refer to the [Section 4.2](#), for more information on these DSP interrupt outputs mapping.

4.3.5 DSP DMA Requests

The DSP_EDMA_CC (channel controller) supports 64 hardware event inputs, that can be used to synchronize the 64 DMA channels. These event inputs are provided at the DSP subsystem boundary via the device DMA_CROSSBAR and can be mapped to sources within the device.

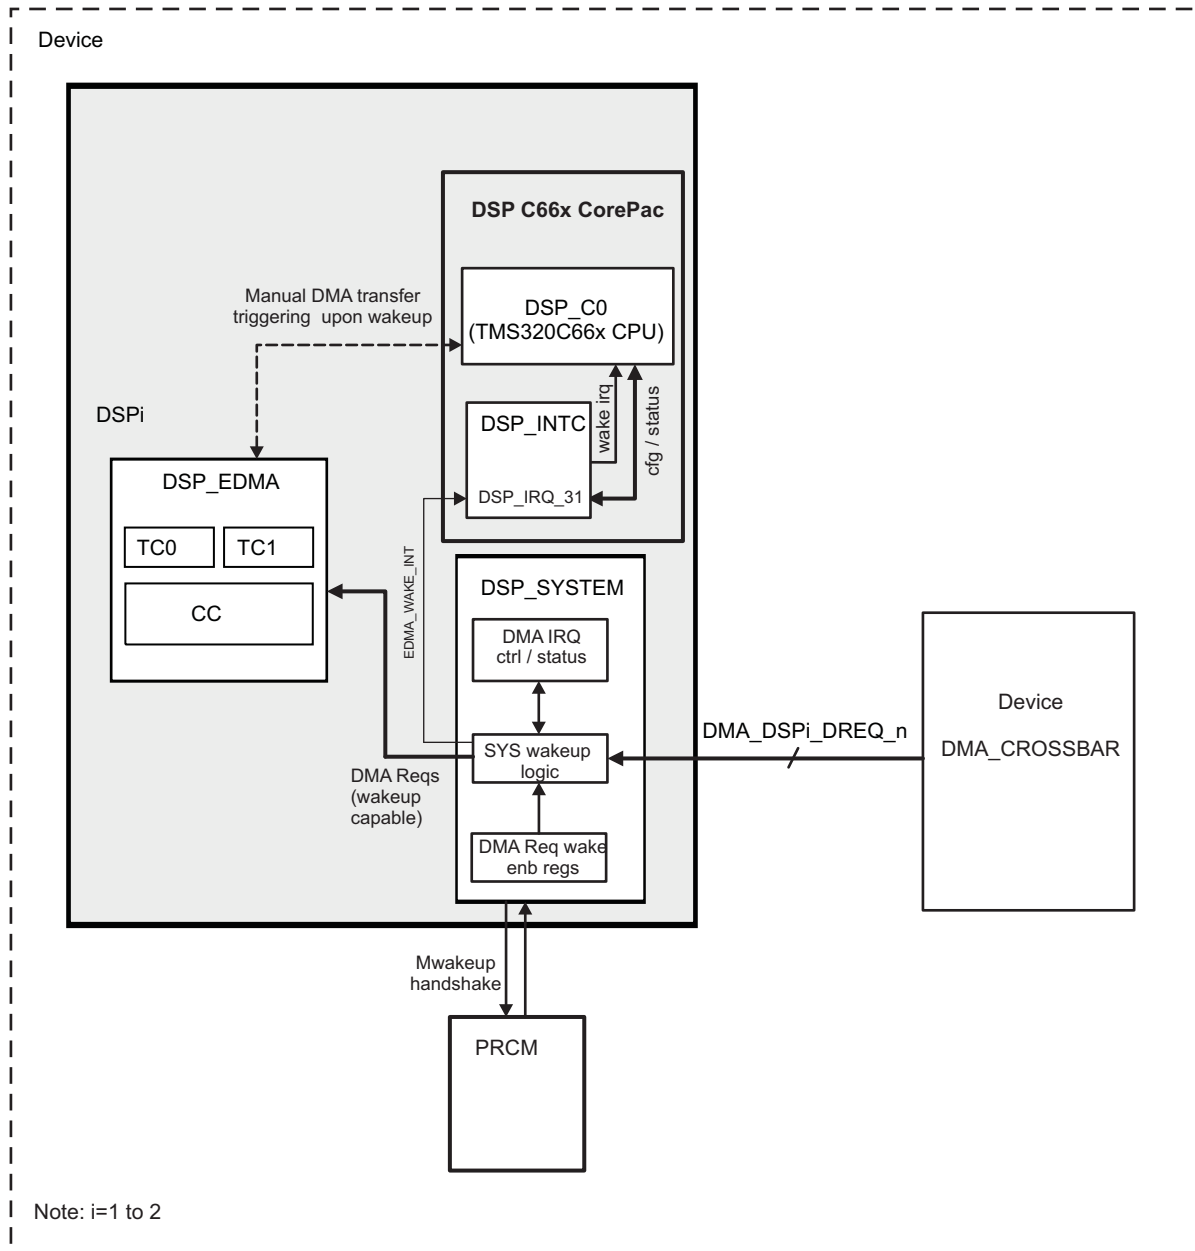

The DSP subsystem receives DMA requests from certain peripherals, such as the McASP module. The DMA requests path through the DSP logic is shown in [Figure 4-7](#).

Similar to the interrupts received at DSP subsystem boundary, the DSP EDMA requests are first routed through the wakeup generation logic of the DSP_SYSTEM module, hence, each DMA request received by the DSP subsystem can wakeup the system from DSP low power modes (including wakeup from DSP OFF mode). To enable the DMA requests mapped via the DMA_CROSSBAR to **DSP_EDMA_CC [19:0]** inputs, corresponding bits in range [19:0] of the register **DSP_SYS_DMAWAKEEN0** must be enabled in software.

CAUTION

The DMA request corresponding **DSP_SYS_DMAWAKEEN0** / **DSP_SYS_DMAWAKEEN1** MUST be enabled, for the DMA requests to be serviced by the DSP regardless of the DSP being in IDLE or active state.

Figure 4-7. DSP DMA Requests

dsps-005

Table 4-6 and Table 4-7 list the default DMA sources for the DSP1_EDMA and DSP2_EDMA controllers. In addition, DSP1_EDMA / DSP2_EDMA inputs (DMA_DSP1_DREQ_[19:0] / DMA_DSP2_DREQ_[19:0]) can alternatively be sourced through the associated DMA_CROSSBAR from one of the 256 multiplexed device DMA sources listed in . The CTRL_CORE_DMA_DSP1_DREQ_y_z / CTRL_CORE_DMA_DSP2_DREQ_y_z registers (where y and z are indexes of DSP1_EDMA / DSP2_EDMA input lines) in the Control Module are used to select between the default DMA sources and the multiplexed DMA sources.

For more details on the device DMA_CROSSBAR multiplexing registers structure, refer to Section 14.4.6.5, DMA_CROSSBAR Module Functional Description of chapter, Control Module.

Table 4-6. DSP1_EDMA Default Request Mapping

4.3.5.1 DSP EDMA Wakeup Interrupt

This section provides description of the registers used for the **EDMA wakeup interrupt** functionality, including the `EDMA_WAKE_INT` IRQ status and enable fields. The EDMA Wakeup Interrupt allows incoming EDMA events to be latched and an interrupt sent to the DSP (if enabled). This interrupt is generated in the `DSP_SYSTEM` as a single "OR-ed" output of all external DMA requests latched in DSP subsystem. This output is further synchronized to `DSP_FCLK` and mapped as the `EDMA_WAKE_INT` event to the `DSP_IRQ_31` input of the C66x DSP CorePac `DSP_INTC`. The C66x CPU is expected to service the interrupt by triggering the corresponding EDMA channel manually, or by servicing the request via normal reads and writes (instead of using the EDMA). This functionality is required since the EDMA is not capable of following the smart wakeup protocol.

NOTE: The `DSP_SYS_DMAWAKEEN0` / `DSP_SYS_DMAWAKEEN1` registers are used for enabling the assertion of the 'Mwakeup' asynchronous wakeup request to the device PRCM upon DMA requests reception. The interrupt functionality of the registers: `DSP_SYS_EDMAWAKE0_x` covered in this subsection is specifically for generating **an wake interrupt** to the DSP. In most cases, the enable mask for the two sets of registers should be set to the same value.

The `EDMAWAKE0` registers corresponding to the EDMA Events 19 thru 0 (msbit to lsb) are as follows:

- [DSP_SYS_EDMAWAKE0_IRQSTATUS_RAW](#)[19:0]
- [DSP_SYS_EDMAWAKE0_IRQSTATUS](#)[19:0]
- [DSP_SYS_EDMAWAKE0_IRQENABLE_SET](#)[19:0]
- [DSP_SYS_EDMAWAKE0_IRQENABLE_CLR](#)[19:0]

Following functional descriptions are valid for the above registers :

- **IRQ status raw register** - This register provides a per-event raw interrupt status vector. The Raw status is set even if the corresponding event is not enabled. Software can write '1' to set the (raw) status for debug purposes.
- **IRQ status register** - This register provides a per-event enabled interrupt status vector. The Enabled status is set if the corresponding event is enabled and the raw status is set. Software can write 1 to clear the (raw) status after the interrupt has been serviced. The clear takes effect even if the interrupt is not enabled.
- **IRQ enable register** - This register provides a per-event interrupt enable bit vector. Software can write 1 to set (i.e., enable the corresponding interrupt). Reads of this register return the actual state of the enable register (and is the same as reading the corresponding "IRQ Clear" - register)
- **IRQ clear register** - This register provides a per-event interrupt enable bit vector. Software can write 1 to clear (i.e., disable the corresponding interrupt). Reads of this register return the actual state of the enable register (and is the same as reading the corresponding "IRQ Set" register)

NOTE: A [DSP_SYS_EDMAWAKE0_IRQSTATUS_RAW](#) bit is set even if the corresponding event is NOT enabled in the [DSP_SYS_EDMAWAKE0_IRQENABLE_SET](#)[19:0].

4.3.6 DSP Intergated Memory Management Units

4.3.6.1 DSP MMUs Overview

A standalone memory management unit (`DSP_MMU0`) is included within the DSP1 (`DSP1_MMU0`) and DSP2 (`DSP2_MMU0`) subsystems boundaries. The `DSP_MMU0` is integrated on the C66x CPU MDMA path to the device `L3_MAIN` interconnect. This provides several benefits including protection of the system memories from corruption by DSP1 and DSP2 accidental accesses.

A standalone memory management unit (DSP_MMU1) is included within the DSP1 (DSP1_MMU1) and DSP2 (DSP2_MMU1) subsystems boundaries. The DSP_MMU1 is integrated on the EDMA data path which starts from the L2 DSP_NoC interconnect and leaves the DSP subsystem on the DSP EDMA master port. This provides several benefits including protection of the device L3_MAIN memory space from corruption by DSP1 and DSP2 DMA (DSP1_EDMA and DSP2_EDMA, respectively) accidental accesses.

Both DSP MMUs generate interrupts which are internally mapped to the DSP C66x CorePac DSP_INTC and output to the device IRQ_CROSSBAR. See also the [Section 4.2](#) and [Section 4.3.4](#).

CAUTION

In the case of a page fault, a DSP C66x CorePac CPU is unable to service it's own DSP_MMU0 and DSP_MMU1 interrupts . The device host processor is expected to manage any TLB patches as necessary.

Both DSP MMUs (on MDMA and EDMA paths respectively) have identical functionalities.

- 32-bit input and output address width (to match L3_MAIN address width)
- 32 TLB cache entries
- 32 + 1 tags
- 128-bit data bus for MDMA and EDMA

4.3.6.2 Routing MDMA Traffic through DSP MMU0

DSP C66x CPU traffic initiated on the DSP MDMA port can be optionally routed through the DSP_MMU0 on the 32-bit MDMA address path. This is controlled in two levels :

- **global** by the DSP_SYSTEM register [DSP_SYS_MMU_CONFIG \[0\]](#) MMU0_EN bit. This bit acts as a mux-select : setting it to 0b1 enables requests to use the DSP_MMU0; clearing this bit to 0b0 disables MMU table lookup and causes accesses to use the non-translated address (MMU bypass). By default the DSP_MMU0 is disabled in DSP_SYSTEM and MDMA port traffic bypasses the DSP_MMU0.
- **local** by MMU enable control in a dedicated DSP_MMU0 memory mapped register. It is used to enable the MMU functionality after the page tables are programmed for MMU operation. For details, refer to the [Chapter 16, Memory Management Units](#).

NOTE: For the DSP_MMU0 to operate, SW should enable it both at the DSP_SYSTEM global level and DSP_MMU0 local register level.

When enabling the DSP_MMU0, software must take care that no transactions are in flight through that MMU. This is typically handled by issuing a DSP "MFENCE" instruction operation. Note that the local enable bit inside the DSP_MMU0 must be configured as normal (refer to the [Chapter 16, Memory Management Units](#).)

For more information on the MFENCE operation, refer to the section, *C66x CPU Instruction Set of the TMS320C66x DSP CPU and Instruction Set*).

In addition, the DSP_MMU0 traffic can be aborted in case of a lockup via the [DSP_SYS_MMU_CONFIG \[8\]](#) MMU0_ABORT bit. In other words, this bit can be used to clear a hang condition that may occur if the DSP_MMU0 encounters a page fault that cannot be serviced.

For more information on device DSP_MMU0 functionality and register settings, refer to the [Section 16.3, MMU Functional Description](#) and [Section 16.5, MMU Register Manual](#), in the chapter, *Memory Management Units*, respectively.

4.3.6.3 Routing EDMA Traffic through DSP MMU1

The DSP_EDMA traffics initiated on the DSP EDMA master port can be optionally routed through the DSP_MMU1 on the EDMA address path. This is controlled in two levels :

- **global** by the DSP_SYSTEM register [DSP_SYS_MMU_CONFIG \[4\]](#) MMU1_EN bit. This bit acts as a

mux-select : setting it to 0b1 enables requests to use the DSP_MMU1; clearing this bit to 0b0 disables MMU table lookup and causes accesses to use the non-translated address (MMU bypass). By default the DSP_MMU1 is disabled in DSP_SYSTEM and EDMA traffic bypasses the DSP_MMU1.

- **local** by MMU enable control in a dedicated DSP_MMU1 memory mapped register. It is used to enable the MMU functionality after the page tables are programmed for MMU operation. For details, refer to the [Section 16.5, MMU Register Manual](#), in the [Chapter 16, Memory Management Units](#).

NOTE: For the DSP_MMU1 to operate, SW should enable it both at the DSP_SYSTEM global level and DSP_MMU1 local register level.

When enabling the DSP_MMU1, software must take care that no transactions are in flight through that MMU. This is typically handled by disabling any EDMA transactions prior to enabling the MMU. Note that the local enable bit inside the DSP_MMU1 must be configured as normal (refer to the [Chapter 16, Memory Management Units](#).)

For more information on the MFENCE operation, refer to the section, *C66x CPU Instruction Set of the TMS320C66x DSP CPU and Instruction Set*).

In addition, the DSP_MMU1 traffic can be aborted in case of a lockup via the [DSP_SYS_MMU_CONFIG \[12\] MMU1_ABORT](#) bit. In other words, this bit can be used to clear a hang condition that may occur if the DSP_MMU1 encounters a page fault that cannot be serviced.

For more information on device DSP_MMU1 functionality and settings, refer to the [Section 16.3, MMU Functional Description](#) and the [Section 16.5, MMU Register Manual](#), in the chapter, *Memory Management Units*, respectively.

4.3.7 DSP Integrated EDMA Subsystem

This section represents an overview of the DSP integrated EDMA functionalities, as well as the subsystem level and device related register controls. For more details on the EDMA functionalities and programming registers, refer to the [Chapter 12, Enhanced DMA](#).

4.3.7.1 DSP EDMA Overview

The enhanced-DMA subsystem which is part of the DSP1 (DSP1_EDMA) and the DSP2 (DSP2_EDMA) subsystems is the primary DMA engine for transfers between system memory (DDR and/or L3_MAIN SRAM) and DSP internal memories (L1s and L2).

The Channel Controller - DSP_EDMA_CC serves as the “user interface” of the DSP_EDMA. The two Transfer Controllers - DSP_EDMA_TC0 and DSP_EDMA_TC1 serve as the data transfer engines of the DSP_EDMA. The C66x CPU typically programs the Channel Controller, which in turn submits Transfer Requests (TR) to the appropriate Transfer Controller. Interrupts are posted in the DSP_EDMA_CC upon transfer completion (if requested), and signaled to the C66x. The EDMA TC completion interrupt is not supported/connected.

The DSP_EDMA is primarily used to perform block transfers between DSP C66x CorePac memories (mostly L2 memory) and system memory (mostly DDR or L3 SRAM).

The DSP_EDMA is configured with 2 Queues (in the CC). Two DSP_EDMA traffic controllers (TC) offer high performance and preemptability of transfers. For typical use cases, it is expected that low latency/small payload transfers) use Queue0/TC0 and high bandwidth/large payload transfers (e.g., DDR on L3_MAIN or DSP local L2 SRAM) will use Queue1/TC1.

DSP_EDMA_CC configuration in the device features :

- 64x EDMA channels
- 8x QDMA channels
- 64x interrupt channels
- 128x PaRAM entries
- 2x Event Queues
- 2x Traffic controllers

- memory protection support
- channel mapping capability
- 8x memory protected and Shadow Regions

DSP_EDMA_TC0/TC1 configuration in the device features :

- 2048 Byte FIFO support
- multitag support
- 16-bit data bus
- 4-level destination register depth
- 7-bit address for internal FIFOs
- 16 IDs for Read commands
- 16 IDs for Write commands

NOTE: The device DSP integrated EDMA controller instances (DSP_EDMA_CC, DSP_EDMA_TC0 and DSP_EDMA_TC1) are functionally identical with the device EDMA controller instances (EDMA_TPCC, EDMA_TPTC0 and EDMA_TPTC1). The only difference is that the DSP_EDMA instances are located at different physical addresses.

For more details on the DSP_EDMA_CC, DSP_EDMA_TC0 and DSP_EDMA_TC1 controllers functionalities, refer to [Section 12.4, EDMA Controller Functional Description](#), in [Chapter 12, Enhanced DMA](#).

The DSP_EDMA instances, their corresponding registers summary and descriptions are covered in the [Section 12.7, EDMA Register Manual](#) of the [Chapter 12, Enhanced DMA](#).

4.3.7.2 DSP System and Device Level Settings of DSP EDMA

DSP_EDMA traffic TC0 and TC1 controllers "Active" or "Idle" status: can be monitored in DSP_SYSTEM located :

- [DSP_SYS_STAT\[1\]](#) TC0_STAT bit
- [DSP_SYS_STAT\[2\]](#) TC1_STAT bit

The **default** burst size for both the DSP_EDMA_TC0 and DSP_EDMA_TC1 can be defined in DSP_SYSTEM register. This is achieved via programming :

- [DSP_SYS_BUS_CONFIG \[1:0\]](#) TC0_DBS
- [DSP_SYS_BUS_CONFIG \[5:4\]](#) TC1_DBS

There are also other DSP_EDMA controls associated with DSP_NoC interconnect pressure settings. For more details, refer to the [Section 4.3.8](#).

The 3 error events associated with the DSP_EDMA_CC, DSP_EDMA_TC0 and DSP_EDMA_TC1 are exported outside the DSP C66x CorePac in the subsystem, and are able to trigger the ERRINT_IRQ aggregated interrupt output. See also corresponding "tpcc_errint_level", "tptc_errint0_level" and "tptc_errint1_level" events, respectively in the [Table 4-5](#).

NOTE: The DSP_EDMA_CC, DSP_EDMA_TC0 and DSP_EDMA_TC1 events are NOT exported outside DSP subsystem. However they are merged (OR-ed) along with other error event sources within the DSP subsystem to produce a single ERRINT_IRQ interrupt exported outside the DSP subsystem.

For more details on ERRINT_IRQ generation and associated event registers at DSP_SYSTEM level, refer to the [Section 4.3.4.2.2](#).

The DSP_SYSTEM logic is assigned to route the external DMA requests to the EDMA hardware request inputs. Additionally, EDMA events can conditionally wake-up the DSP system from a low power mode, via software enabling DSP_SYSTEM MWakeup handshake with the device PRCM. This mechanism is described in the [Section 4.3.5](#).

The programmable muxing of various external DMA request sources to the DSP EDMA. DMA_DSP1_DREQ_x and DMA_DSP2_DREQ_x input lines (where x=0 to 19) is covered in the [Section 14.4.6.5, DMA_CROSSBAR Module Functional Description](#), of the [Chapter 14, Control Module](#).

DSP1/DSP2 subsystem external DMA request sources : For the default DSP1 / DSP2 external DMA request sources, routed via the device DMA_CROSSBAR to the DSP1_EDMA / DSP2_EDMA channel controller inputs (DMA_DSP1_DREQ_i / DMA_DSP2_DREQ_i), respectively, refer to the [Section 4.3.5](#).

4.3.8 DSP L2 interconnect Network

A 128-bit level 2 (L2) Interconnect from Arteris - FlexNoC® is instantiated in the DSP subsystem, outside the DSP C66x CorePac. It is signified as "DSP_NoC" throughout this chapter.

NOTE: The C66x master MDMA data does NOT flow through the DSP_NoC.

The system and local initiators on DSP_NoC are as follows :

- local C66x CPU 32-bit CFG master port which traffic is split via DSP_NoC fabric into several configuration target traffics inside and outside the DSP subsystem.
- SDMA initiator port on DSP_NoC which conveys accesses towards DSP Memories and memory-mapped registers initiated outside the DSP subsystem via the L3_MAIN interconnect.
- EDMA traffic controllers - TC0 read / write initiator ports
- EDMA traffic controllers - TC1 read / write initiator ports

NOTE: The DSP_ICFG space is not visible to SDMA initiators (DSP_EDMA or DSP hosts on L3_MAIN) with CFG traffic.

The targets on the DSP_NoC are as follows :

- DSP C66x CorePac SDMA port
- Internal CFG targets on the DSP_NoC :
 - DSP_MMU0 Cfg
 - DSP_MMU1 Cfg
 - DSP_SYSTEM Cfg
 - DSP_EDMA_CC Cfg
 - DSP_EDMA_TC0 Cfg
 - DSP_EDMA_TC1 Cfg
- 32-bit CFG port on L3_MAIN (it acts as master on the L3_MAIN)
- EDMA Target port which conveys EDMA bidi transfers outside the DSP (through or bypassing DSP_MMU1).

The [Table 4-8](#) summarizes the interconnections which can be established between DSP initiators and targets over the L2 DSP_NoC in the device. In this table HW implemented interconnections are marked with an asterics.

Table 4-8. DSP_NoC Defined Connectivities

		DSP_NoC Initiators			
		DSP C66x CorePac CFG init	EDMA_TC0 init	EDMA_TC1 init	SDMA init (mapped to SDMA port on L3_MAIN)
DSP_NoC Targets	DSP C66x CorePac SDMA (slave) port	n.a.	*	*	*
	DSP_MMU0 Cfg	*	n.a.	n.a.	*
	DSP_MMU1 Cfg	*	n.a.	n.a.	*
	DSP_SYSTEM Cfg	*	n.a.	n.a.	*
	DSP_EDMA_CC Cfg	*	n.a.	n.a.	*
	DSP_EDMA_TC0 Cfg	*	n.a.	n.a.	*
	DSP_EDMA_TC1 Cfg	*	n.a.	n.a.	*
	DSP_NoC Cfg	*	n.a.	n.a.	*
	Cfg port (Cfg Init on L3_MAIN)	*	n.a.	n.a.	n.a.
	Master DMA port (DSP DMA init on L3_MAIN)	n.a.	*	*	n.a.

A DSP_NoC error event (combination of several local to the interconnect events) is exported outside the DSP C66x CorePac in the subsystem, and can be enabled to trigger the ERRINT_IRQ aggregated interrupt output. See also corresponding "noc_errint_level" event in the [Table 4-5](#).

NOTE: The DSP_NoC event is NOT exported outside DSP subsystem. However it is merged (OR-ed) along with other error event sources within the DSP subsystem to produce a single ERRINT_IRQ interrupt exported outside the DSP subsystem.

For more details on ERRINT_IRQ generation and associated event registers at DSP_SYSTEM level, refer to the [Section 4.3.4.2.2](#).

4.3.8.1 DSP Public Firewall Settings

The DSP1 and DSP2 L2 Interconnect (DSP1_NoC and DSP2_NoC, respectively) implements two firewalls – dsp firewall0 (DSP_FW0) is used to protect DSP_MMU0's configuration space (which includes the TLB) and dsp firewall1 is used to protect DSP_MMU1's configuration space (which includes the TLB). Access permission is based on the privilege level, domain, ConnID, and access types of a request.

The default value of 0xFFFF_FFFF in the MRM region 0 permission registers:

- [L3_DSPSS_INIT_OCP_MMU0_CTRL_TARG_OCP_FW_503000_MRM_PERMISSION_REGION_LO_W_0](#)
- [L3_DSPSS_INIT_OCP_MMU0_CTRL_TARG_OCP_FW_503000_MRM_PERMISSION_REGION_HIG_H_0](#)
- [L3_DSPSS_INIT_OCP_MMU1_CTRL_TARG_OCP_FW_504000_MRM_PERMISSION_REGION_LO_W_0](#)
- [L3_DSPSS_INIT_OCP_MMU1_CTRL_TARG_OCP_FW_504000_MRM_PERMISSION_REGION_HIG_H_0](#)

permits any requestor to access the DSP_MMU0 and DSP_MMU1 configuration space.

For more information on the access region definitions, public privilege access, public user access and initiator permission settings, which are identical between DSP_NoC firewalls and L3_MAIN interconnect firewalls, refer to the [Section 10.2.3.7.3, L3_MAIN Firewall Functionality](#), in the, [Section 10.2, L3_MAIN Interconnect](#).

There are also several other DSP_NoC registers - [L3_DSPSS_INIT_OCP_MMU0_CTRL_TARG_OCP_FW_503000_LOGICAL_ADDR_ERRLOG_0](#), [L3_DSPSS_INIT_OCP_MMU0_CTRL_TARG_OCP_FW_503000_REGUPDATE_CONTROL](#) used for error handling, firewall reset and other purposes. These are functionally identical with the corresponding L3_MAIN interconnect registers, described in the [Section 10.2.3.8, L3_MAIN Interconnect Error Handling](#), in the [Section 10.2, L3_MAIN Interconnect](#).

The various firewall access control registers are part of the C66x CPU local accessible - DSP_FW_L2_NOC_CFG address space, and L3_MAIN initiators accessible DSP1/2_FW_L2_NOC_CFG configuration space. The corresponding MMU0 and MMU1 configuration space firewall registers (DSP_FW0 starting at offset **0x0000_0000** , and DSP_FW1 starting at offset **0x0000_1000**) are summarized and described in the [Section 4.4.4](#).

4.3.8.2 DSP NoC Flag Mux and Error Log Registers

The DSP_NoC registers (starting at offset \geq 0x0000_4000) are used for error logging and flag muxing purposes. The status information stored in there can be used for example to resolve issues related to DSP_NoC access conflicts, for debug purposes, etc.

For more information, refer to the [Section 10.2.3.5, Flag Muxing](#), in the [Section 10.2, L3_MAIN Interconnect](#).

4.3.8.3 DSP NoC Arbitration

A pressure based arbitration is implemented for the DSP_NoC interconnect.

A DSP_NoC local MFlag mechanism is used but it is SW controlled in the DSP_SYSTEM configuration space.

This is done via the register [DSP_SYS_BUS_CONFIG](#) bitfields :

- TC0_L2PRES - for DSP_EDMA_TC0 pressure control
- TC1_L2PRES - for DSP_EDMA_TC1 pressure control
- CFG_L2PRES - for the DSP C66x CorePac 32-bit CFG pressure control
- SDMA_L2PRES - for pressure control of the DSP system and L3_MAIN accesses targeting the DSP C66x CorePac SDMA slave port

The pressure for each port is signaled on a MFlag[1:0] bus and conveys a value of 0 (lowest), 1 (medium), or 3 (highest). A value of 0x2 is reserved/undefined.

NOTE: The default pressure level for all ports is 0x0 and is recommended for most systems. This results in round-robin arbitration across active requests.

4.3.9 DSP Boot Configuration

DSP1 subsystem boot vector input which defines the 22-bit DSP1 Boot Address is mapped to the device core control module register CTRL_CORE_CONTROL_DSP1_RST_VECT[21:0] DSP1_RST_VECT bitfield. DSP2 subsystem boot vector input which defines the 22-bit DSP2 Boot Address is mapped to the device core control module register CTRL_CORE_CONTROL_DSP2_RST_VECT[21:0] DSP2_RST_VECT bitfield. In general, the device host loads code to a given address location in the device system memory, sets the DSP1_RST_VECT / DSP2_RST_VECT bitfield to the address value, and then release the DSP1 / DSP2 from reset. At that point, the DSP1 / DSP2 will begin fetching code from that location.

NOTE: If the values of the control core module CTRL_CORE_CONTROL_DSP1_RST_VECT[21:0] / CTRL_CORE_CONTROL_DSP2_RST_VECT [21:0] register change, the values will be taken into account by DSP upon the next reset.

NOTE: Upon device boot time (a power-on reset applied), the device "sysboot15" input latched in the Control Module bootstrap register defines the value of DSP functional clock divider (2 or 3). For more details, refer to the [Section 4.3.3.1](#)

4.3.10 DSP Internal and External Memory Views

4.3.10.1 C66x CPU View of the Address Space

The **C66x CPU View** represents the view from the DSP, which result from program fetches, or load / store instructions. Accesses to DSP memories (L1P, L1D, L2) and to DSP Internal configuration space (DSP_ICFG) are intercepted within the DSP C66x CorePac (whether using local or global addresses).

The DSP C66x CorePac CFG (C66x CPU 32-bit master port) interface is strictly for non-cacheable loads and stores, and is intended to be used for I/O space or memory mapped registers (MMR) space. DSP C66x CorePac CFG accesses are routed / arbitrated by the DSP_NoC L2 interconnect. DSP C66x CorePac CFG accesses are mapped between 0x01C0_0000 and 0x0FFF_FFFF.

NOTE: The DSP C66x CorePac CFG initiator interface is strictly for non-cacheable loads and stores within MMR and I/O spaces.

DSP configuration accesses to **external to DSP subsystem** peripherals can be issued on either the DSP subsystem CFG Master port which is mapped to the device L3_MAIN or DSP 32-bit CFG "system" interface is connected to the chip level L3_MAIN interconnect and used to access L3_MAIN addresses that are mapped between 0x01C0_0000 and 0x0FFF_FFFF.

DSP accesses (to non-DSP memories like SDRAM on L3_MAIN) for addresses above 0x1000_0000 are handled via the DSP (XMC) MDMA 128-bit master interface and are routed to the DSP subsystem MDMA Initiator port either through DSP_MMU0 or bypassing MMU.

NOTE: In some cases, L3_MAIN peripherals may be mapped to both the MDMA bus and the CFG bus. In that case, there may be a latency advantage of using the CFG address for those peripherals

Table 4-9 shows the DSP C66x CPU memory view of the various DSP C66x CorePac internal and external resources.

Table 4-9. C66x CPU View Map

C66x CPU View (DSP C66x CorePac Internal only, MDMA or CFG init ports) ⁽¹⁾		Size	DSP Memory Region	Function
Start Address	End Address			
0x0080_0000	0x0084_7FFF	288 KiB	DSP_L2	DSP L2 SRAM (local)
0x00E0_0000	0x00E0_7FFF	32 KiB	DSP_L1P	DSP L1P SRAM (local)
0x00F0_0000	0x00F0_7FFF	32KiB	DSP_L1D	DSP L1D SRAM (local)
0x0180_0000	0x01BF_FFFF	4096 KiB	DSP_ICFG	DSP Internal CFG ⁽²⁾
0x01D0_0000	0x01D0_0FFF	4 KiB	DSP_SYSTEM	DSP_SYSTEM Memory Mapped Registers block
0x01D0_1000	0x01D0_1FFF	4 KiB	DSP_MMU0CFG	DSP MMU0 configuration / registers
0x01D0_2000	0x01D0_2FFF	4 KiB	DSP_MMU1CFG	DSP MMU1 configuration / registers
0x01D0_5000	0x01D0_5FFF	4 KiB	DSP_EDMA_TC0	DSP_EDMA Transfer Controller 0
0x01D0_6000	0x01D0_6FFF	4 KiB	DSP_EDMA_TC1	DSP_EDMA Transfer Controller 1
0x01D0_7000	0x01D0_7FFF	4 KiB	DSP_NoC	DSP L2 interconnect registers
0x01D1_0000	0x01D1_7FFF	32 KiB	DSP_EDMA_CC	DSP_EDMA Channel Controller
0x0200_0000	0x020F_FFFF	1 MiB	EVE	DSP configuration traffic to the EVE (mapped on the DSP CFG interface)
0x0210_0000	0x023F_FFFF	3 MiB	Reserved	Reserved
0x0330_0000	0x033F_FFFF	1 MiB	EDMA_TPCC	DSP configuration traffic to the EDMA_TPCC (mapped on the DSP CFG interface)
0x0340_0000	0x034F_FFFF	1 MiB	EDMA_TC0	DSP configuration traffic to the EDMA_TC0 (mapped on the DSP CFG interface)
0x0350_0000	0x035F_FFFF	1 MiB	EDMA_TC1	DSP configuration traffic to the EDMA_TC1 (mapped on the DSP CFG interface)
0x0800_0000	0x0800_FFFF	64 KiB	DSP_XMC_CTRL MMRs	DSP internal MMRs for XMC controller (non-cache)
0x0802_0000	0x080F_FFFF	896 KiB	MDMA non-cache	MDMA initiator (non-cache) to L3_MAIN (DSP_MMU0)
0x0810_0000	0x0BBF_FFFF	59 MiB		

⁽¹⁾ Only the C66x CPU view of device implemented functional memory regions are shown. The remaining regions are reserved.

⁽²⁾ The internal configuration space registers are visible ONLY to the C66x CPU (DSP_C0) within the DSP C66x CorePac, i.e. they are NOT visible to initiators outside the DSP C66x CorePac.

Table 4-9. C66x CPU View Map (continued)

C66x CPU View (DSP C66x CorePac Internal only, MDMA or CFG init ports) ⁽¹⁾		Size	DSP Memory Region	Function
Start Address	End Address			
0x1000_0000	0x10FF_FFFF	16 MiB	DSP1 L1P, L1D and L2 memories	An image of DSP1 C66x CorePac internal space - only L1P, L1D and L2 memories (global) ⁽³⁾
0x1000_0000	0x10FF_FFFF	16 MiB	DSP2 MDMA (cached)	DSP2 MDMA initiator (cached) to L3_MAIN (through DSP2_MMU0)
0x1100_0000	0x11FF_FFFF	16 MiB	DSP2 L1P, L1D and L2 memories	An image of DSP2 C66x CorePac internal space - only L1P, L1D and L2 memories (global) ⁽⁴⁾
			DSP1 MDMA (cached)	MDMA initiator (cached) to L3_MAIN (through DSP1_MMU0)
0x1200_0000	0x1FFF_FFFF	224 MiB	MDMA (cached)	DSP1 and DSP2 MDMA initiator (cached) to L3_MAIN (through DSP1_MMU0 / DSP2_MMU0, respectively)
0x2000_0000	0xFFFF_FFFF	3584 MiB	MDMA (cached)	DSP1 and DSP2 MDMA initiator (cached) to L3_MAIN (through DSP1_MMU0 / DSP2_MMU0, respectively)

⁽³⁾ The DSP1 CPU sees an image of its own memories in the 0x1000_0000 - 0x10FF_FFFF address range (the same mapped also at lower addresses 0x0080_0000 - 0x00F0_7FFF). On the other side, DSP2 CPU addresses, generated in the same range (with DSP2_MMU0 involved), are mapped to the DSP2 MDMA port (cached transfers to/from L3_MAIN connected system memories).

⁽⁴⁾ The DSP2 CPU sees an image of its own memories in the 0x1100_0000 - 0x11FF_FFFF address range (the same mapped also at lower addresses 0x0080_0000 - 0x00F0_7FFF). On the other side, DSP1 CPU addresses, generated in the same range (with DSP1_MMU0 involved), are mapped to the DSP1 MDMA port (cached transfers to / from L3_MAIN connected system memories).

Refer to the [Section 2.2, L3_MAIN Memory Space Mapping](#), in the chapter, *Memory Mapping*, for the addresses of the L3_MAIN space memory-mapped registers. Refer to the [Section 2.6, DSP Subsystem Memory Space Mapping](#) in the same chapter for a description of the DSP1 and DSP2 internal memory, additional memory, and peripherals that the DSP1 and DSP2 have access to.

4.3.10.2 DSP_EDMA View of the Address Space

EDMA is able to initiate internal accesses directly to the DSP memories via the DSP C66x CorePac SDMA bus. The access is conducted to the DSP C66x CorePac internal memories over the L2 DSP_NoC interconnect.

[Table 4-10](#) shows the DSP integrated EDMA controller memory view of the various DSP C66x CorePac internal and external resources.

Table 4-10. DSP EDMA Controller View Map

DSP_EDMA Controller View (EDMA master internal / external port)		Size	DSP Memory Region	Function
Start Address	End Address			
0x0080_0000	0x0084_7FFF	288 KiB	DSP_L2	DSP L2 SRAM (local)
0x00E0_0000	0x00E0_7FFF	32 KiB	DSP_L1P	DSP L1P SRAM (local)
0x00F0_0000	0x00F0_7FFF	32KiB	DSP_L1D	DSP L1D SRAM (local)
0x0802_0000	0x0BBF_FFFF	59 MiB	EDMA to L3_MAIN	EDMA initiator (DSP_MMU1)

Table 4-10. DSP EDMA Controller View Map (continued)

DSP_EDMA Controller View (EDMA master internal / external port)		Size	DSP Memory Region	Function
Start Address	End Address			
0x1000_0000	0x10FF_FFFF	16 MiB	DSP L1/L2	An image of DSP C66x CorePac internal space - only L1P, L1D and L2 memories (global) ⁽¹⁾
0x2000_0000	0xFFFF_FFFF	3584 MiB	DMA OCP	L3_MAIN interconnect memory via MMU1 / DMA OCP Initiator

⁽¹⁾ The internal configuration space registers DSP_ICFG are visible ONLY to the C66x CPU (DSP_C0) within the DSP C66x CorePac , i.e. they are NOT visible to the DSP_EDMA.

Access from EDMA to external resources on L3_MAIN are routed via DSP subsystem **EDMA initiator port**. **Note that these accesses are transferred through the DSP_MMU1 memory management unit.**

NOTE: The DSP_EDMA can NOT access the DSP_ICFG (DSP C66x CorePac internal) addresses.
 With the DSP_MMU1 disabled, the subset of the memory map used for DSP_EDMA internal accesses will NOT be visible. Thus only address which equal 0x2000_0000 and above will be considered as valid 32-bit addresses (i.e. L3_MAIN space accesses only).

Refer to the [Section 2.2, L3_MAIN Memory Space Mapping](#), in the chapter, *Memory Mapping*, for the addresses of the L3_MAIN space memory-mapped registers. Refer to the [Section 2.6, DSP Subsystem Memory Space Mapping](#) in the same chapter for a description of the DSP1 and DSP2 internal memory, additional memory, and peripherals that the DSP1 and DSP2 have access to.

4.3.10.3 L3_MAIN View of the DSP Address Space

System initiated accesses (i.e. external-to-DSP accesses over device L3_MAIN) to DSP are issued over the DSP SDMA target port.

NOTE: The MSB-bits of the address are truncated to only provide an 8 MiB view of the memory map within the DSP subsystem. Notice that the relative offsets of the DSP CFG space is different for the OCP SDMA target port relative to the DSP internal initiators.

The SDMA target bus is able to access internal subsystem address space (such as DSP_EDMA, DSP_MMU0, DPS_MMU1, etc.), or the DSP local memory address space. The SDMA target bus **is NOT able to access the DSP ICFG space (such as DSP_INTC, DSP_BWM, etc)** or the other initiator ports on the DSP subsystem boundary (i.e., accesses cannot go through DSPSS to get to the DSP_EDMA initiator port, L3_MAIN CFG initiator port).

The DSP slave DMA port memory map - [Table 4-11](#) shows an 8 MiB window (23-bit address) both from the SDMA Target bus (0x0000_0000 through 0x007F_FFFF), as well as the EDMA (0x0080_0000 through 0x00FF_FFFF). The DSP C66x CorePac internally views itself as a 16 MiB window where 0x0000_0000 through 0x007F_FFFF is reserved, L2 SRAM starts at 0x0080_0000, L1P SRAM starts at 0x00E0_0000, and L1D SRAM starts at 0x00F0_0000).

Table 4-11. SDMA Target Port Memory Map

System L3_MAIN View ⁽¹⁾		Size	DSP Memory Region	Function
Start Address	End Address			
0x0000_0000	0x0004_7FFF	288 KiB	DSP_L2	DSP L2 SRAM (local)
0x0050_0000	0x0050_0FFF	4 KiB	DSP_SYSTEM	DSP SYSTEM MMR Block
0x0050_1000	0x0050_1FFF	4 KiB	DSP_MMU0CFG	DSP MMU0 configuration / regs

⁽¹⁾ Only system (L3_MAIN) view over functionally used regions are shown. The remaining regions are reserved.

Table 4-11. SDMA Target Port Memory Map (continued)

System L3_MAIN View ⁽¹⁾		Size	DSP Memory Region	Function
Start Address	End Address			
0x0050_2000	0x0050_2FFF	4 KiB	DSP_MMU1CFG	DSP MMU1 configuration / regs
0x0050_5000	0x0050_5FFF	4 KiB	DSP_EDMA_TC0	DSP EDMA Transfer Controller 0
0x0050_6000	0x0050_6FFF	4 KiB	DSP_EDMA_TC1	DSP EDMA Transfer Controller 1
0x0050_7000	0x0050_7FFF	4 KiB	DSP_NoC	DSP L2 Interconnect registers
0x0051_0000	0x0051_7FFF	32 KiB	DSP_EDMA_CC	DSP EDMA Channel Controller
0x0060_0000	0x0060_7FFF	32 KiB	DSP_L1P	DSP L1P SRAM (local)
0x0070_0000	0x0070_7FFF	32 KiB	DSP_L1D	DSP L1D SRAM (local)

Refer to the [Section 2.2, L3_MAIN Memory Space Mapping](#), in the chapter, *Memory Mapping*, for the addresses of the L3_MAIN space memory-mapped registers. Refer to the [Section 2.6, DSP Subsystem Memory Space Mapping](#) in the same chapter for a description of the DSP1 and DSP2 internal memory, additional memory, and peripherals that the DSP1 and DSP2 have access to.

4.4 DSP Subsystem Register Manual

This section describes the DSP Subsystem instances registers.

4.4.1 DSP Subsystem Instance Summary

Table 4-12. DSP Subsystem Instance Summary

Module Name	Module Base Address	Size
DSP_ICFG	0x0180 0000 ⁽¹⁾	4 KiB
DSP_SYSTEM	0x01D0 0000 ⁽¹⁾	256 Bytes
DSP_FW_L2_NOC_CFG	0x01D0 3000 ⁽¹⁾	8576 Bytes
DSP1_SYSTEM	0x40D0 0000	256 Bytes
DSP1_FW_L2_NOC_CFG	0x40D0 3000	8576 Bytes
DSP2_SYSTEM	0x4150 0000	256 Bytes
DSP2_FW_L2_NOC_CFG	0x4150 3000	8576 Bytes

⁽¹⁾ The registers of DSP subsystem instances prefixed only with DSP in the name, and NOT DSP1 or DSP2, are NOT visible on the device L3_MAIN. They are visible only within the DSP_ICFG internal configuration space hence accessible only by the DSP C66x CPU.

NOTE: For more details on the DSP_MMU0 and DSP_MMU1 registers, as well as their :

- DSP_MMU0CFG and DSP_MMU1CFG physical addresses accesible only by DSP_C0 CPU core in the DSP subsystem
- DSP1_MMU0CFG and DSP1_MMU1CFG physical addresses visible on L3_MAIN
- DSP2_MMU0CFG and DSP2_MMU1CFG physical addresses visible on L3_MAIN

refer to [Section 16.5, MMU Register Manual](#), in [Chapter 16, Memory Management Units](#).

NOTE: For more details on the DSP_EDMA_CC, DSP_EDMA_TC0 and DSP_EDMA_TC1 registers, as well as their :

- DSP1_EDMA_CC, DSP1_EDMA_TC0 and DSP1_EDMA_TC1 physical addresses visible on L3_MAIN
- DSP2_EDMA_CC, DSP2_EDMA_TC0 and DSP2_EDMA_TC1 physical addresses visible on L3_MAIN

refer to [Section 12.7](#), *EDMA Register Manual*, in [Chapter 12](#), *Enhanced DMA*.

CAUTION

The L1P, L1D and L2 memory controller registers mapped in the L3_MAIN are limited to 32-bit data access; 16- and 8-bit access are not allowed and can corrupt register content.

4.4.2 DSP_ICFG Registers

4.4.2.1 DSP_ICFG Register Summary

NOTE: The DSP_ICFG addresses are visible only within the DSP core internal configuration space.

Table 4-13. DSP_ICFG Registers Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	DSP_ICFG Physical Address	Register Reset Value ⁽¹⁾

4.4.2.2 DSP_ICFG Register Description

For bitfield descriptions of all registers which reside within the DSP_ICFG configuration address space, refer to the *TMS320C66x DSP CorePac User Guide*, ([SPRUGW0C](#)).

4.4.3 DSP_SYSTEM Registers

4.4.3.1 DSP_SYSTEM Register Summary

NOTE: While the DSP1_SYSTEM and DSP2_SYSTEM addresses are part of the device L3_MAIN memory space, **the DSP_SYSTEM addresses are visible only within the DSP_ICFG internal configuration space (visible only to C66x CPU and debug logic).**

7:6	RESERVED	Reserved. Read returns 0.	R	0x0
		0x0: FORCE_STANDBY This mode is a backup mode intended to be used only if the smart-idle mode is bugged. When in this mode, the SAF asserts with minimal hardware condition the "STANDBY" status. It is the responsibility of the software to ensure that the SAF is in a correct quiet state before programming this mode. Additionally when in this mode, the SAF is not allowed to generate wakeup request.		
		0x1: NO_STANDBY This mode is a backup mode intended to be used only if the smart-idle mode is bugged. When in this mode, the SAF in C66xOSS asserts the "STANDBY" status.		
5:4	STANDBYMODE	0x2: SMART_STANDBY default. C66xOSS generates the standby status based upon all hardware internal status, namely after having performed all hardware operations necessary to be in a correct quiet state. Additionally when in this mode, the SAF is not allowed to generate wakeup request. 0x3: SMART_STANDBY_WKUP Same as Smart-Standby. (C66xOSS generates the standby status based upon all hardware internal status, namely after having performed all hardware operations necessary to be in a correct quiet state) . . Additionally when in this mode, the SAF is allowed to generate wakeup request	RW	0x2

Bits	Field Name	Description	Type	Reset
3:2	IDLEMODE	0x0: FORCE_IDLE This mode is a backup mode intended to be used only if the smart-idle mode is bugged. When in this mode, the IAF acknowledges a request to go idle from the power manager with minimal hardware condition. It is the responsibility of the software to ensure that the IAF are in a correct quiet state before requesting a force-idle transition. Additionally when in this mode, the IAF is not allowed to generate any wakeup request. 0x1: NO_IDLE When in this mode, the IAF disregards any request to go idle from the power manager. 0x2: SMART_IDLE default. When in this mode, the IAF acknowledges a request to go idle from the power manager after having performed all hardware operations necessary to be in a correct quiet state. Additionally when in this mode, the IAF is not allowed to generate any wakeup request 0x3: SMARTIDLEWKUP When in this mode, the IAF acknowledges a request to go idle from the power manager after having performed all hardware operations necessary for the IAF to be in a correct quiet state. Additionally when in this mode, the IAF is allowed to generate wakeup request.	RW	0x2

Table 4-30. DSP_SYS_IRQWAKEEN0

Address Offset	0x0000 0020	Instance	DSP_SYSTEM DSP1_SYSTEM DSP2_SYSTEM
Physical Address	0x01D0 0020 0x40D0 0020 0x4150 0020		
Description	The register provides a global interrupt wakeup enable bit vector that defines which input interrupts are used to cause a wake from powerdown state (via the slave idle protocol). IRQWAKEEN0 is for interrupt inputs 63 thru 32, and IRQWAKEEN1 is for interrupt inputs 95 thru 64. Internal interrupts cannot cause a wake condition since in this state there is no guaranteed clock and all sub-modules should be in idle state. Software can write 1 to set and 0 to clear the corresponding bit (i.e., enable the corresponding interrupt for wakeup). Reads of this register return the actual state of the enable register.

4.4.4 DSP_FW_L2_NOC_CFG Registers

This section covers the DSPSS level defined public firewall (DSP_MMU0, DSP_MMU1) and L2 interconnect (DSP_NoC) functional registers.

4.4.4.1 DSP_FW_L2_NOC_CFG Register Summary

NOTE: While the DSP1_FW_L2_NOC_CFG and DSP2_FW_L2_NOC_CFG addresses are part of the device L3_MAIN memory space, **the DSP_FW_L2_NOC_CFG addresses are visible only within the DSP_ICFG internal configuration space (visible only to C66x CPU and debug logic).**

Table 4-70. DSP_FW_L2_NOC_CFG and DSP1_FW_L2_NOC_CFG Registers Mapping Summary

Dual Cortex-M4 IPU Subsystem

This chapter describes the dual Cortex-M4 image processor unit (IPU) subsystem.

Topic	Page
5.1 Dual Cortex-M4 IPU Subsystem Overview	1470
5.2 Dual Cortex-M4 IPU Subsystem Integration.....	1473
5.3 Dual Cortex-M4 IPU Subsystem Functional Description.....	1477
5.4 Dual Cortex-M4 IPU Subsystem Register Manual	1495

5.1 Dual Cortex-M4 IPU Subsystem Overview

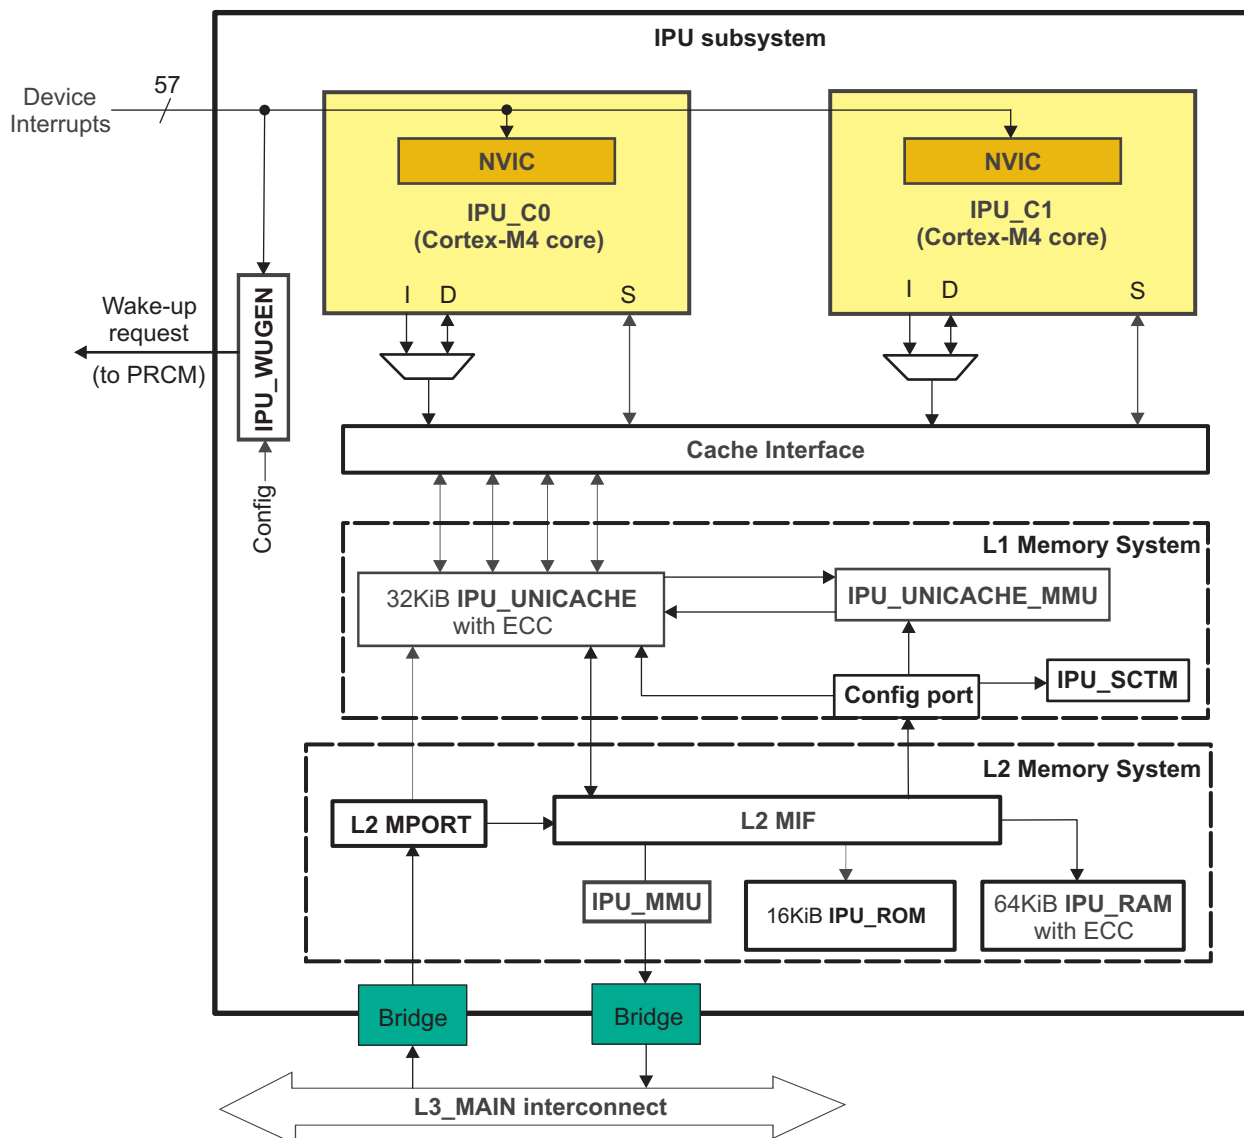

5.1.1 Introduction

The Imaging Processor Unit (IPU) subsystem contains two ARM® Cortex-M4 cores (IPU_C0 and IPU_C1) that share a common level 1 (L1) cache (called unicache). The two Cortex-M4 cores are completely homogeneous to one another. Any task possible using one Cortex-M4 core is also possible using the other Cortex-M4 core. Both Cortex-M4 cores could be used for tasks such as running RTOS, controlling ISP, SIMCOP, DSS, and other functions. It is software responsibility to distribute the various tasks between the Cortex-M4 cores for optimal performance. The integrated interrupt handling of the IPU subsystem allows it to function as an efficient control unit.

IPU is the boot master of this device with its own boot ROM.

Figure 5-1 is a high-level block diagram of the IPU subsystem.

Figure 5-1. IPU Subsystem Overview

5.1.2 Key Features

The key features of the IPU subsystem are:

- Two ARM Cortex-M4 microprocessors (IPU_C0 and IPU_C1):
 - ARMv7-M and Thumb®-2 instruction set architecture (ISA)
 - ARMv6 SIMD and digital signal processor (DSP) extensions
 - Single-cycle MAC
 - Integrated nested vector interrupt controller (NVIC) (also called IPU_Cx_INTC, where x = 0, 1)
 - Integrated bus matrix
 - Bus arbiter
 - Bit-banding – atomic bit manipulation
 - Write buffer
 - Memory interface (I and D) plus system interface (S) and private peripheral bus (PPB)
 - Registers:
 - Thirteen general-purpose 32-bit registers
 - Link register (LR)
 - Program counter (PC)
 - Program status register, xPSR
 - Two banked SP registers
 - Integrated power management
 - Extensive debug capabilities
- Unicache interface:
 - AHBLite to unicache interface
 - Instruction and data interface
 - Supports interleaved Cortex-M4 requests
- L1 cache (IPU_UNICACHE):
 - 32KiB divided into 16 banks
 - 4-way
 - Runs at twice the Cortex-M4 CPU frequency
 - Cache configuration lock/freeze/preload
 - Internal MMU:
 - 16-entry region-based address translation
 - Read/write control and access type control
 - Execute Never (XN) MMU protection policy
 - Little-endian format
 - OCP port for configuration and cache maintenance
- Subsystem counter timer module (SCTM) connected to unicache
- L2 master interface (MIF):
 - Splitter for access to memory or OCP ports
 - Interleaved bank request for fast memory access
- L2 internal memories:
 - 16KiB ROM (IPU_ROM); used for device boot/initialization
 - 64KiB banked RAM – IPU_RAM
- L2 MMU (IPU_MMU): 32 entries with Table Walking Logic (TWL)
- Wake-up generator (IPU_WUGEN): Generates wake-up request from external interrupts
- Two OCP ports at IPU boundary (connected to the L3_MAIN interconnect):

- Master port – allows the IPU to access system resources (memories and peripherals)
- Slave port – allows other requestors to access a part of the IPU internal memory space
- Power management:
 - Local power-management control: Configurable through the IPU_WUGEN registers.
 - Two sleep modes supported by Cortex-M4, controlled by its integrated interrupt controller (NVIC).
 - Cortex-M4 system is clock-gated in both sleep modes.
 - NVIC interrupt interface stays awake.
 - Supports L1 cache and L2 memories retention
- Error-Correcting Code (ECC) supported for both L1 unicache and L2 RAM
- Debug/emulation features supported

[Section 5.3](#) provides more details about the IPU features.

5.2 Dual Cortex-M4 IPU Subsystem Integration

This section describes the integration of the module in the device, including information about clocks, resets, and hardware requests.

Figure 5-2 shows the IPU integration in the device.

Figure 5-2. IPU Subsystem Integration

NOTE: In Figure 5-2, only interrupts external to IPU (that is, outside IPU boundary) are shown. The complete IPU interrupt mapping is presented in Chapter 13, *Interrupt Controllers*.

NOTE: For more information about the master standby and slave idle protocols, and the wake-up request, see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 5-1 through Table 5-3 summarize the integration of the module in the device.

Table 5-1. IPU Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
IPU	PD_IPU, PD_COREAON	L3_MAIN

Table 5-2. IPU Hardware Requests

Interrupt Requests				
Module Instance	Interrupt Name (Source)	IRQ_CROSSBAR Input (Destination)	Default Mapping	Description
IPU	IPU_IRQ_MMU	IRQ_CROSSBAR_395	N/A	IPU MMU fault interrupt. This IRQ is not mapped to any device interrupt controller by default, other than the IPU interrupt controller itself (IPU_IRQ_16 interrupt line). However, this IRQ can be mapped to other device interrupt controllers by properly configuring the corresponding IRQ_CROSSBAR related registers in the CTRL_MODULE.

Table 5-3. IPU Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
IPU	IPU1_GFCLK	IPU1_GFCLK	PRCM	IPU interface and functional clock(s). See Section 5.2.1 for details.
	IPU1_GFCLKDIV2	IPU1_GFCLK		
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
IPU	IPU_PWRON_RST	IPU_PWRON_RST	PRCM	Power-on reset. Resets the entire IPU subsystem (except SWJ-DP)
	IPU_RET_RST	IPU_RET_RST	PRCM	Retention reset to few retention logic inside the IPU_UNICACHE
	IPU_CPU0_RST	IPU_CPU0_RST	PRCM	IPU_C0 reset. Resets the entire processor (except all the debug logic in the processor and SWJ-DP)
	IPU_CPU1_RST	IPU_CPU1_RST	PRCM	IPU_C1 reset. Resets the entire processor (except all the debug logic in the processor and SWJ-DP)
	IPU_RST	IPU_RST	PRCM	Reset signal to the IPU_UNICACHE and the IPU_MMU

For more information about clocks, resets, and power domains, see [Chapter 3, Power, Reset, and Clock Management](#).

5.2.1 IPU Subsystem Clock Distribution

The IPU subsystem has two clock inputs:

- **IPU1_GFCLK**: Main source clock for IPU; feeds most of IPU internal modules:
 - IPU Unicache & MMU, L2 MIF & MPORT (all running on (1x) IPU_GFCLK)
 - Cortex-M4 cores, IPU_RAM, IPU_ROM (all running on (1/2x) IPU_GFCLK via internal divider)
- **IPU1_GFCLKDIV2**: This is IPU1_GFCLK externally divided by two; feeds IPU L2 MMU

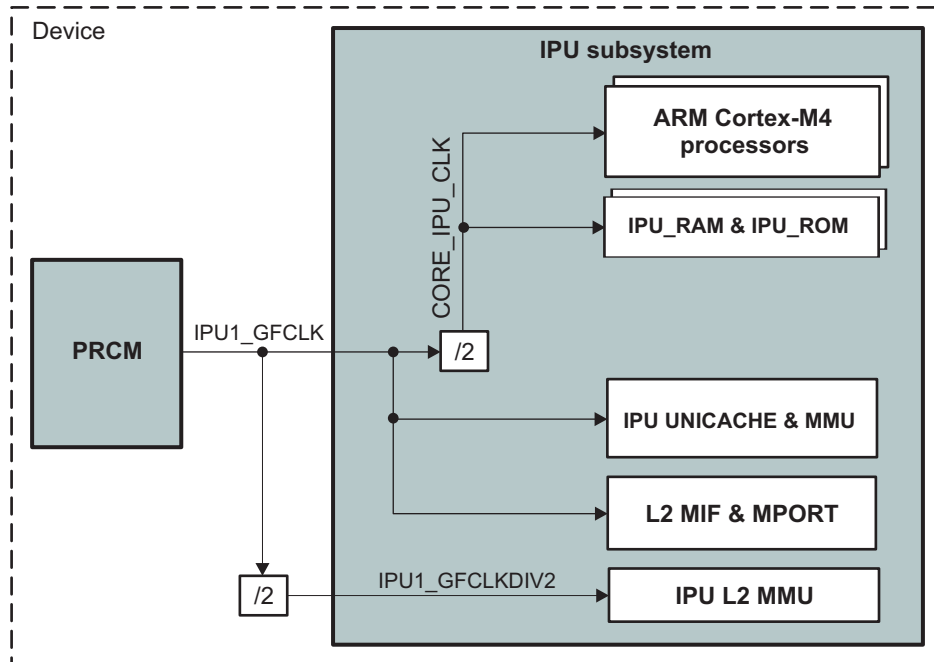

The IPU1_GFCLK itself can be derived from either:

- CORE_IPU_ISS_BOOST_CLK – main clock for IPU from DPLL_CORE, or
- DPLL_ABE_X2_CLK – alternative clock from DPLL_DDR

For more information, see [Chapter 3, Power, Reset, and Clock Management](#).

[Figure 5-3](#) shows the clocking scheme of the IPU subsystem.

Figure 5-3. IPU Subsystem Clocking Scheme

5.2.2 IPU Subsystem Reset Distribution

Three reset signals controlled by the PRCM module let the two Cortex-M4 processors and the rest of the IPU subsystem be reset independently. These three reset signals are: IPU_CPU0_RST, IPU_CPU1_RST, and IPU_RST. They can be controlled (assert/clear) by programming the following PRCM register bits:

- RM_IPU_RSTCTRL[0] RST_CPU0 – reset control for IPU_C0.
- RM_IPU_RSTCTRL[1] RST_CPU1 – reset control for IPU_C1.
- RM_IPU_RSTCTRL[2] RST_IPU – reset control for IPU_UNICACHE and IPU_MMU.

At bootup, both IPU_CPU0_RST and IPU_CPU1_RST will be released (without any programming of the RST_CPU0 and RST_CPU1 bits) and thus, both Cortex-M4 cores will start executing their code. Subsequently, the RST_CPU0 and RST_CPU1 bits can be written to control the two CPU resets independently.

For details about IPU power-on reset sequence, see [Chapter 3, Power, Reset, and Clock Management](#).

[Figure 5-4](#) shows the reset scheme of the IPU subsystem.

Figure 5-4. IPU Subsystem Reset Scheme

5.3 Dual Cortex-M4 IPU Subsystem Functional Description

5.3.1 IPU Block Diagram

The IPU subsystem integrates the following blocks:

- Two fully identical ARM Cortex-M4 cores:
 - Revision r0p1
 - Integrated interrupt controller (NVIC)
- Memory system:
 - L1 memory system
 - Cache interface
 - 32KiB L1 unicache – IPU_UNICACHE
 - L1 MMU, serving the role of an attribute MMU (AMMU) for the unicache (and thus, labelled also as IPU_UNICACHE_MMU)
 - Profiling counters for the unicache – SCTM
 - L2 memory system
 - L2 MMU – IPU_MMU
 - 16KiB L2 ROM (IPU_ROM)
 - 64KiB L2 banked RAM – IPU_RAM
 - L2 master port – MPORT
 - L2 master interface – MIF
- Wake-up generator – IPU_WUGEN
- Two OCP ports at IPU boundary (connected to the L3_MAIN interconnect):
 - Master port – allows the IPU to access system resources (memories and peripherals)
 - Slave port – allows other requestors to access a part of the IPU internal memory space. For more information about which IPU modules are accessible via L3_MAIN, refer to [Chapter 2, Memory Mapping](#).

The IPU subsystem is illustrated in [Figure 5-1](#).

5.3.2 Cortex-M4 Core

5.3.2.1 Cortex-M4 Microprocessor

Refer to ARM® *Cortex®-M4 Technical Reference Manual* for a detailed description of the Cortex-M4 microprocessor. The Cortex-M4 version used in this device is the r0p1 revision.

5.3.2.2 Nested Vectored Interrupt Controller (NVIC)

Each Cortex-M4 core includes an ARM Nested Vectored Interrupt Controller (NVIC) which facilitates low-latency exception and interrupt handling. All exceptions are handled and prioritized within the NVIC. In order to facilitate parallel processing, the interrupt mapping is the same for the two cores. Each Cortex-M4 core receives the same interrupts, except for a few IPU internal interrupts. The interrupts are dynamically prioritized with 16 levels of priority defined for each core. In addition, Cortex-M4 also has a Non-Maskable Interrupt (NMI) input. When it is asserted, the NMI interrupt service routine is executed unconditionally.

The IPU interrupt mapping and an overview of the NVIC are presented in [Chapter 13, Interrupt Controllers](#). For detailed description of NVIC functionality, refer to ARM *Cortex®-M4 Technical Reference Manual*.

NOTE: The NVIC module is also referenced as IPU_Cx_INTC (x = 0, 1) throughout this device TRM.

5.3.2.3 Cortex-M4 Configuration in this Device

Different configurations are possible for the Cortex-M4 core. [Table 5-4](#) lists the configuration for the Cortex M4 in this device (same configuration for both cores).

Table 5-4. Cortex-M4 Configuration

Parameter	Implementation
Number of interrupts	96 external interrupts (in addition to the 16 Cortex-M4 internal interrupts)
Number of bits of interrupt priority	4 bits (defining 16 levels of priority)
Floating Point Unit (FPU)	Not included
Memory Protection Unit (MPU)	Not included
Trace Port Interface Unit (TPIU)	Not included
Instrumentation Trace Macrocell (ITM)	Not included
Embedded Trace Macrocell (ETM)	Not included
SW-DP or SWJ-DP	SW JTAG-DP interface (supported outside core level)
Data Watchpoint and Trace (DWT)	Included; 4 data watchpoints and event monitors
Flash-Patch and Breakpoint (FPB)	Included; 8 hardware breakpoints with program patching
Architectural clock-gating	Enabled

In addition, the following Cortex-M4 features are not supported in this device:

- The Cortex-M4 calibration register (SYST_CALIB) which is used to reload the SYSTICK timer to generate a fixed interval is not supported in the Cortex-M4 core within the IPU subsystem. The TENMS field is not available due to the different frequencies during voltage scaling. The SYSTICK timer stops counting when the processor is halted during debugging.
- The Cortex-M4 self-reset feature controllable through the SYSRESETREQ bit in the Cortex-M4 AIRCR register is not supported at the processor level. Writing to this bit will have no effect in the IPU subsystem. This feature is supported at the PRCM level. The global PRCM module can reset the complete IPU subsystem writing to the corresponding register.

For more information about the Cortex-M4 SYST_CALIB and AIRCR registers, refer to the ARM *Cortex™-M4 Devices Generic User Guide*.

5.3.3 IPU Memory System

The IPU subsystem includes a 32KiB unified L1 cache (called IPU_UNICACHE) and a memory system built around the cache. The IPU memory system can be seen as a two-level hierarchical system:

- L1 memory system
- L2 memory system

The L1 memory system is the direct connection to the Cortex-M4 cores. It has the following features:

- Always runs on (1x) IPU_GFCLK frequency for both logic and memories
- Integrates a unified cache (IPU_UNICACHE) with a dedicated OCP port (for configuration and cache maintenance purposes). See [Section 5.3.3.2](#) for more information about IPU_UNICACHE.
- Integrates L1 MMU which serves the role of an attribute MMU for the IPU_UNICACHE
 - L1 cache lookups provide L1 and L2 cache attributes
 - CPU lookup provides write policy attributes only
 - L1 lookup for address translation, and prefetch (if used)
 - L2 lookup for address translation, and prefetch (if used)
 - Integrated maintenance between L1 and L2
 - See [Section 5.3.3.3](#) for more information about IPU_UNICACHE_MMU.
- Integrates a Subsystem Counter Timer Module (SCTM), with the ability to perform dynamic export of benchmarking data. See [Section 5.3.3.4](#) for more information about the SCTM.

The L2 memory system has the following features:

- Always runs on (1x) IPU_GFCLK frequency for logic and (1/2x) for memories
- Master port (MPORT) for slave or DMA accesses
 - Built in coherency query to L1 cache to ensure transfers to L2 RAM are coherent
 - MPORT accesses must always have: logical = physical addresses
- Memory Interface (MIF) for internal memories
 - Decodes memory space
 - Decodes configuration space
- 16KiB ROM
- 64KiB banked RAM
- L2 MMU with lookup to L1
 - Address translation, and prefetch attributes

5.3.3.1 Cache Interface

The cache interface converts the data from the AHBLite protocol (supported by Cortex-M4) to the unicache. The AHBLite protocol is part of the AMBA® specification. The AHBLite protocol has been defined to support single master with several slaves. Four slave ports are required on the unicache to support the four buses from the Cortex-M4 cores (two per core). The I and D connections from each Cortex-M4 are multiplexed but the Cortex-M4 core internally prevents any conflict on this connection.

Because the Memory Protection Unit is not present within the Cortex-M4 in this device, default cache policies which are provided through the sideband signals are not used to access the cache. The cacheability is provided through the AMMU present in the cache. AHBLite exclusive accesses are not supported at the unicache interface and an error is generated back to the interface when such access happens.

The ICode and DCode interface on each Cortex M4 are a 32-bit AHBLite bus interface. Instruction fetches and vector fetches from code memory space (0x00000000 – 0x1FFFFFFF) are performed over the ICode bus. Data and debug accesses to code memory space (0x00000000 – 0x1FFFFFFF) are performed over the DCode bus. Control logic in the Dcode interface converts unaligned data and debug accesses into two or three (depending on the size and alignment of the unaligned access) aligned accesses.

The cache interface converts the AHBLite protocol to cache requests, converting burst access to sequential access to the cache. Although the Cortex-M4 processor supports unaligned transfers, there is no unaligned transfer on this bus, because the bus interface on the processor core converts the unaligned transfers into aligned transfers (adding extra cycles if required).

Since a bus multiplexer is used between I and D bus, the transfers cannot take place at the same time on these buses and the Cortex-M4 handles the arbitration between the two buses. The data bus (D bus) accesses are given higher priority.

5.3.3.2 L1 Unified Cache (IPU_UNICACHE)

The unicache provides a multi-access cache which is scalable for number of slaves and size. Integrated coherency management is provided by sideband signals of slave interfaces, as well as a dedicated maintenance interface. The cache architecture is two pipeline stages, where the first stage is a tag memory access, and the second stage is a banked data array. Each slave has a dedicated tag to enable high-frequency access with no dynamic arbitration between slaves, and the banked data array reduces the probability of conflicts between slaves.

5.3.3.2.1 IPU_UNICACHE Configuration in the Device

Table 5-5 describes the IPU_UNICACHE configuration in the device.

Table 5-5. IPU_UNICACHE Configuration

Parameter	Value
Way	4
Size	32 KiB
Bank elements	32 bits
Bank number	16
Slave interface data size	32 bits
Master interface data size	64 bits
Line size	256 bits
MMU lookup	Included
Number of slaves	4
Number of masters	1
Number of fill/prefetch buffers	Four prefetch buffers
Slave types	Cache interface

5.3.3.2.2 IPU_UNICACHE Maintenance

The IPU_UNICACHE allows basic maintenance operations, which are performed through its OCP configuration port:

1. Preload ([CACHE_MAINT\[0\] PRELOAD](#))
2. Lock/Unlock ([CACHE_MAINT\[1\] LOCK](#); [CACHE_MAINT\[2\] UNLOCK](#))
3. Clean ([CACHE_MAINT\[3\] CLEAN](#))
4. Invalidate ([CACHE_MAINT\[4\] INVALIDATE](#))

Maintenance of the cache is performed between the start and end addresses (configurable via the [CACHE_MTSTART\[31:0\] START_ADDR](#) and [CACHE_MTEND\[31:0\] END_ADDR](#) bit fields, respectively). This allows for direct control of memory regions. All maintenance operations occur in the background and can generate an interrupt (if enabled via the [CACHE_MAINT\[5\] INTERRUPT](#) bit) when they complete. Such operations are protected by software semaphore, because only one operation at a time can be performed. The maintenance operations can also be performed using MMU small entries.

5.3.3.3 L1 MMU (IPU_UNICACHE_MMU)

The IPU_UNICACHE_MMU serves the role of an attribute MMU (AMMU) for the unicache. It provides the multi-access cache with region-based address translation, read/write control, access type control, and multi-level cache maintenance. The IPU_UNICACHE_MMU regions are register entry based to enable low-latency lookup and it is not a table-walking MMU.

The IPU_UNICACHE_MMU is connected directly to the unicache. There is a dedicated interface for a CPU to query cache policies for writes in supporting a pipeline write buffer that follows the write policies of the IPU_UNICACHE_MMU.

5.3.3.3.1 IPU_UNICACHE_MMU Configuration in the Device

Table 5-6 describes the IPU_UNICACHE_MMU configuration in the device.

Table 5-6. IPU_UNICACHE_MMU Configuration

Parameter	Values
Number of large pages	Four entries
Size of large pages	512 MiB or 32 MiB (configurable)
Number of medium pages	Two entries
Size of medium pages	256 KiB or 128 KiB (configurable)
Number of small pages	10 entries
Size of small pages	16 KiB or 4 KiB (configurable)
Number of patch pages	Not included
Size of line pages	256-bit
Number of comparison interfaces	4
Number of comparator sets	1
Write pipeline data comparison	Disabled
Number of IPU_UNICACHE maintenance interfaces	3
Size of entry address	32-bit

5.3.3.3.2 Page Attributes

As can be seen in Table 5-6, IPU_UNICACHE_MMU supports different page sizes: large, medium, and small. The number of large pages, number of medium pages, etc., is defined at design time. The size of the pages is configurable in the following IPU_UNICACHE_MMU registers:

- [CACHE_MMU_LARGE_POLICY_i\[1\] SIZE](#)
- [CACHE_MMU_MED_POLICY_j\[1\] SIZE](#)
- [CACHE_MMU_SMALL_POLICY_k\[1\] SIZE](#)

The different MMU page sizes can be used to create smaller policies within a larger region.

The logical source address is configured in:

- [CACHE_MMU_LARGE_ADDR_i\[31:25\] ADDRESS](#)
- [CACHE_MMU_MED_ADDR_j\[31:17\] ADDRESS](#)
- [CACHE_MMU_SMALL_ADDR_k\[31:12\] ADDRESS](#)

The logical source translated address is configured in:

- [CACHE_MMU_LARGE_XLTE_i\[31:25\] ADDRESS](#)
- [CACHE_MMU_MED_XLTE_j\[31:17\] ADDRESS](#)
- [CACHE_MMU_SMALL_XLTE_k\[31:12\] ADDRESS](#)

When the SIZE bit is set to 0, all the bits in the ADDRESS bit field of the corresponding logical source address and logical source translated address can be used.

When the SIZE bit is set to 1, the ADDRESS bit field of the corresponding logical source address and logical source translated address must be programmed only with addresses that can address the size of a second possible page.

5.3.3.3.3 Policy Support

The following policies are supported by the IPU_UNICACHE_MMU:

- L1 global execute only policy
- L1 global read only policy
- L1 global volatile policy
- Unique L1 and L2 cacheable / non-cacheable policies
- Unique L1 and L2 posted / non-posted policies
- Unique L1 and L2 allocate / non-allocate policies
- Unique L1 and L2 write through / write back policies
- L2 exclusion policy
- L1 or L2 address translation policy
- L1 or L2 prefetch policy

The various policies can be configured in the following registers:

- [CACHE_MMU_LARGE_POLICY_j](#) – for large pages
- [CACHE_MMU_MED_POLICY_j](#) – for medium pages
- [CACHE_MMU_SMALL_POLICY_k](#) – for small pages

5.3.3.4 Subsystem Counter Timer Module (SCTM)

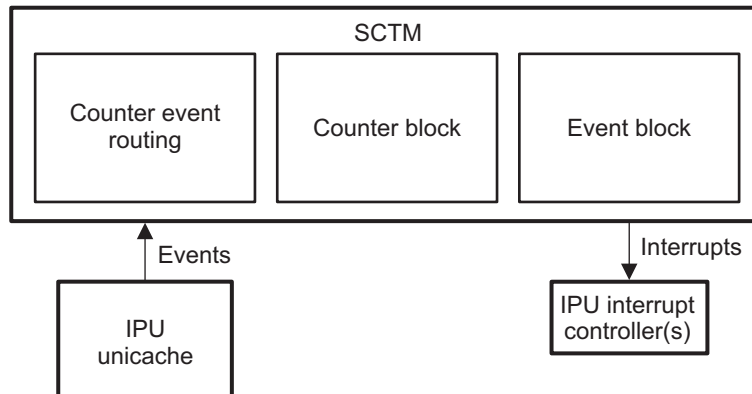

The Subsystem Counter Timer Module (SCTM) is a generic profile counter and timer module that provides the following functions:

- Counter functions:
 - Input events counting
 - Two counter modes:
 - Event counting
 - Duration counting
 - Counter chaining
- Timer functions:
 - Periodic intervals generation
 - Two timer modes:
 - Run-once mode
 - Restart mode
 - Events and/or interrupt generation

The SCTM has eight counters (two of which have timer functions). There are input events going into the SCTM and interrupt events going to the IPU INTC. For more information about the counter configuration and the SCTM input events, see [Section 26.7.1, IPU Subsystem Performance Monitoring](#), in [Chapter 26, On-Chip Debug Support](#). For more information about the mapping of the SCTM interrupt event signals to IPU interrupt controller inputs, see [Section 13.3.3, Interrupt Requests to IPU_Cx_INTC](#), in [Chapter 13, Interrupt Controllers](#).

[Figure 5-5](#) shows the SCTM block diagram.

Figure 5-5. SCTM Block Diagram

5.3.3.4.1 Counter Functions

5.3.3.4.1.1 Input Events

Signals from within the subsystem are routed to the SCTM and used to control the counters and timers in the module. The routing of the input events from the module boundary to an individual counter is accomplished through an input event multiplexer and is controlled by the [CACHE_SCTM_CTCR_WT_i\[20:16\] INPSEL](#) and [CACHE_SCTM_CTCR_WOT_j\[20:16\] INPSEL](#) bit fields.

NOTE: For more information about input events to the module boundary, see [Section 26.7.1.2, Cache Events](#), in [Chapter 26, On-Chip Debug Support](#).

5.3.3.4.1.2 Counters

There are individual 32-bit counters in the SCTM. The counters count when the input event signals are asserted.

5.3.3.4.1.2.1 Counting Modes

The counters in the SCTM support two mutually exclusive counting modes:

- Event mode: The counter increments each time a rising edge is detected on the designated input event signal.
- Duration mode: The counter continually increments when the event input is asserted.

5.3.3.4.1.2.2 Counter Overflow

When the counter reaches the terminal value (0xFFFFFFFF) it wraps and continues to increment. This is considered a timer overflow condition. The [CACHE_SCTM_CTCR_WT_i\[6\] OVRFLW](#) and [CACHE_SCTM_CTCR_WOT_j\[6\] OVRFLW](#) bits indicate that overflow has occurred. The overflow bit can be cleared by reading it. When chained, only the high-order counter overflows.

5.3.3.4.1.2.3 Counters and Processor State

The counters can be configured to alter their behavior based on the state of the CPU. The [CACHE_SCTM_CTCR_WT_i\[4\] FREE](#) and [CACHE_SCTM_CTCR_WOT_j\[4\] FREE](#) bits determine whether the counter will continue to operate when the processor enters debug halt state. When the FREE bit is set to 0, the counter stops incrementing while the debug halt input from the CPU is asserted. Normal operation resumes when the processor exits the debug halt state and the debug halt input is deasserted. When the FREE bit is set to 1, the state of the debug halt input is not used to control counter operation.

The `CACHE_SCTM_CTCR_WT_i[5]` IDLE and `CACHE_SCTM_CTCR_WOT_j[5]` IDLE bits determine whether the counter will continue to operate when the processor enters idle state (the processor is no longer executing instructions and is waiting for a wake-up event). When the IDLE bit is set to 0, the counter stops incrementing while the idle input from the CPU is asserted. Normal operation resumes when the processor exits the idle state and the idle input is deasserted. When the IDLE bit is set to 1, the state of the idle input is not used to control counter operation.

5.3.3.4.1.2.4 Chaining Counters

The individual 32-bit counters in the SCTM can be chained with an adjacent counter to form a 64-bit counter. Counters chained to a counter across an even-odd index boundary with the even counter contain the least-significant 32 bits of the 64-bit pairing. For example, counters 1 and 0 can be paired and counter 1 will contain bits 63:32 and counter 0 will contain bits 31:0. The high-order counter increments by 1 each time the low-order counter wraps.

Counters are chained by setting the `CACHE_SCTM_CTCR_WT_i[2]` CHAIN or `CACHE_SCTM_CTCR_WOT_j[2]` CHAIN bit for both counters. When chained, the counter control for both counters is taken from the `CACHE_SCTM_CTCR_WT_i` or `CACHE_SCTM_CTCR_WOT_j` register of the low-order counter. Other than the CHAIN bit, all other bits in the high-order `CACHE_SCTM_CTCR_WT_i` or `CACHE_SCTM_CTCR_WOT_j` register are ignored.

Chained counters can function only in counter mode. Timer mode is not supported.

The `CACHE_SCTM_CTCR_WT_i[7]` CHNSDW and `CACHE_SCTM_CTCR_WOT_j[7]` CHNSDW bits are used to indicate that a counter can provide atomics accessed when chained. These bits are valid only for counters with even indexes (the lower half of a 64-bit counter pair). When these bits are set, the counter can shadow the value of the lower half of the chained counter value at the same time the upper half of the counter is read. The shadowed value (not the current value) is returned when the value of the low-order counter is read. Therefore, when a chained counter has atomic read capability, an atomic counter value can be obtained simply by reading the high-order counter first, followed by the low-order counter. This order must always be observed to prevent reading stale counter values from the low-order counter. When counters are functioning independently, the shadow feature is deactivated and a read of the counter always returns the current value.

5.3.3.4.1.2.5 Enabling and Disabling Counters

After the counter is correctly configured, it can be started by setting the `CACHE_SCTM_CTCR_WT_i[0]` ENBL or `CACHE_SCTM_CTCR_WOT_j[0]` ENBL bit. At this point, the counter begins incrementing under the control of the configured event input. The counter can be disabled (counting stops) at any time by clearing the ENBL bit. Counters can be enabled and disabled dynamically during application flow.

Counters can also be enabled and disabled as groups through the `CACHE_SCTM_CTGNBL` register. This register provides control of the individual counter-enable in groups. This allows an application to enable or disable groups of counters in lockstep by setting corresponding bits to 1 (bit number corresponds to counter number).

5.3.3.4.1.2.6 Resetting Counters

The counters can be reset to their initial value (0x00000000) by writing 1 to the `CACHE_SCTM_CTCR_WT_i[1]` RESET or `CACHE_SCTM_CTCR_WOT_j[1]` RESET bit. If the counter is chained, the high-order and low-order counters are reset when the RESET bit is written for the low-order counter.

Counters can also be reset as groups through the `CACHE_SCTM_CTGRST` registers. These registers provide control of the individual counter reset in groups. This allows an application to reset groups of counters in lockstep.

5.3.3.4.2 Timer Functions

Counters 0 and 1 in the SCTM can function as timers. When operating as timers, interrupts and/or debug input events are generated when the value of the counter reaches a designated interval.

5.3.3.4.2.1 Periodic Intervals

The interval for a timer is contained in the `CACHE_SCTM_TINTVLR_i` register. There is a `CACHE_SCTM_TINTVLR_i` register for every timer-capable counter in the SCTM. Timers are initialized to 0. When the corresponding `CACHE_SCTM_CTCNTR_k` increments and matches the values designated in `CACHE_SCTM_TINTVLR_i`, the timer is considered to be triggered and events configured in `CACHE_SCTM_CTCR_WT_i` are generated.

Timers can function in one of two mutually exclusive modes:

- Run-once mode: The timer stops after the first interval match and is not re-enabled until the timer is reset to the initial value (0) by setting the `CACHE_SCTM_CTCR_WT_i[1]` RESET bit to 1.
- Restart mode: The timer automatically resets to the initial value (0) each time the designated interval is reached.

The `CACHE_SCTM_CTCR_WT_i[10]` RESTART bit is used to configure the timer mode.

5.3.3.4.2.2 Event Generation

Timers can generate interrupts and debug events. Interrupts are routed from the module boundary to the interrupt controller(s) in the subsystem. Debug events are routed as triggers to debug logic within the subsystem.

The generation of the interrupts is controlled by the `CACHE_SCTM_CTCR_WT_i[8]` INT bit. The generation of debug events is controlled by the `CACHE_SCTM_CTCR_WT_i[9]` DBG bit. The INT and DBG bits can be set simultaneously and both signals are generated on interval match.

If neither INT nor DBG is set, the timer function is disabled and the counter functions as a regular counter.

5.3.3.5 L2 MMU (IPU_MMU)

An additional MMU provides address translation for the accesses done from the IPU subsystem to the L3_MAIN interconnect. The main characteristics of this MMU are:

- 32 entries
- Compatible with ARMv6 architecture MMU translation tables (protection bits not used)
- Page-based or access-based endianness conversion
- Two-level descriptor hierarchy
- One intermediate page table
- Four page sizes (16 MiB, 1 MiB, 64 KiB, 4 KiB)
- Page table alignment on 128-byte boundary for ARM11® compatibility

The configuration of the IPU_MMU can be done from one of the Cortex-M4 cores or from the L3_MAIN interconnect slave port. The accesses done to configure the IPU_MMU cannot be part of a burst access.

For more information about the IPU_MMU, see [Chapter 16, Memory Management Units](#).

5.3.3.5.1 IPU_MMU Behavior on Page-Fault

Table 5-7. IPU_MMU Behavior on Page-Fault

Table-Walker Enabled	Table-Walker Disabled
Application	
Use Table-Walker to find translation. Update TLB cache if successful, set TRANSLATIONFAULT bit and interrupt if not. The following bits are used for the purpose: MMU_IRQENABLE[1] TRANSLATIONFAULT and MMU_IRQSTATUS[1] TRANSLATIONFAULT.	Set TLBMISS bit and interrupt and stall. The following registers are used for the purpose: MMU_IRQENABLE[0] TLBMISS and MMU_IRQSTATUS[0] TLBMISS.
Debug	

Table 5-7. IPU_MMU Behavior on Page-Fault (continued)

Table-Walker Enabled	Table-Walker Disabled
Application	
Use Table-Walker to find translation. Update TLB cache if successful (only if the MMU_CNTL[3] EMUTLBUPDATE bit is set), generate in-band bus error if not.	Set EMUMISS bit and interrupt and stall. The following bits are used for the purpose: MMU_IRQENABLE[2] EMUMISS and MMU_IRQSTATUS[2] EMUMISS.

The MMU fault interrupt line is connected to both Cortex-M4 cores (at IPU_IRQ_16 interrupt line) and is also propagated outside of the IPU subsystem and connected to an IRQ_CROSSBAR input (IRQ_CROSSBAR_395). The user can route this interrupt to other device processors by properly programming the corresponding Control Module registers.

The default behavior of the IPU_MMU previously described can be overridden by setting the MMU_GP_REG[0] BUS_ERR_BACK_EN bit to 1. Once this bit is set, all MMU faults (including TLB miss) return a bus error to the IPU subsystem (interrupt event XLATE_MMU_FAULT). This allows the end user to quickly establish the cause of the MMU fault by having appropriate code in the ISR.

5.3.3.6 L2 MPORT

The MPORT provides three functions:

- Configuration of the L2 MMU – only allowed during functional reset or IDLE
- Data transfer to L2 banked RAM
- Coherency control between L1 cache and L2 memory system:
 - a. Query on L1 cache to determine if line exists
 - b. Query interface cleans/invalidates line
 - c. Once query is complete, MPORT can complete transfer to L2 RAM

5.3.3.7 ECC Implementation

In IPU subsystem, ECC support is implemented for L1 cache and L2 RAM. This enables Single Error Correction (SEC) and Double Error Detection (DED) in the memories. Since read-modify-write support is not implemented for partial accesses, individual ECC code is generated for each granular memory block. This is how each row is organized into data and ECC blocks:

- **L1 Data:** Access granularity to L1 data cache memory is 8 bits. Hence, a 32-bit row is divided into 4 blocks and 5-bit ECC code is generated for each block (see [Figure 5-6](#))
- **L1 Tag:** As shown in [Figure 5-7](#), ECC code is generated individually for flag and tag bits. Lock and LRA flags can be accesses exclusively and hence ECC support for this bit is not possible.
- **L2 RAM:** For L2 RAM, 64-bit data can be accessed with a granularity of 8 bits and hence, 8 ECC blocks each of width 5-bits are implemented (see [Figure 5-8](#)).

Figure 5-6. L1 Data ECC

Figure 5-7. L1 Tag ECC

Figure 5-8. L2 RAM ECC

For all the ECC supported memories, error is detected/corrected for individual blocks and status is updated in the ECC registers in L1 unicache. As the errors can occur back-to-back, the registers are updated with the latest information. On SEC or DED event, interrupt is generated and propagated to both the Cortex-M4 cores. Also, in case of DED event in L1 data and L2 RAM, the error response is propagated along with the data so that it does not corrupt the system. If granular accesses are made to these memories, DED and error will still be reported for error occurring at other locations in the memory row. This is because entire row is read from the memory even for granular accesses. Moreover, DED event in L1 tag memory results in a tag miss and data is fetched from an external memory. The tag will still result in the hit if DED occurs in a way other than the one where hit condition occurred. However, DED interrupt will still be propagated to the register. In case of DED event in data or tag memory, it is recommended that the cache is invalidated by M4 in the interrupt service routine. For silicon validation, ECC blockimplementation also supports the individual masking of ecc or data block. On enabling the code/ data mask register, the data or ECC block can be corrupted and SEC / DED event can be validated accordingly.

5.3.4 IPU Power Management

5.3.4.1 Wake-Up Generator (IPU_WUGEN)

The IPU_WUGEN provides efficient power management by generating a wake-up request to the PRCM module when the IPU subsystem is in standby or full-idle mode and at least one enabled external interrupt becomes active. Upon assertion of the IPU wake-up request, the PRCM module will recover IPU functional clock (IPU_GFCLK) and thus, IPU will make a transition to active mode. In general, the IPU_WUGEN allows:

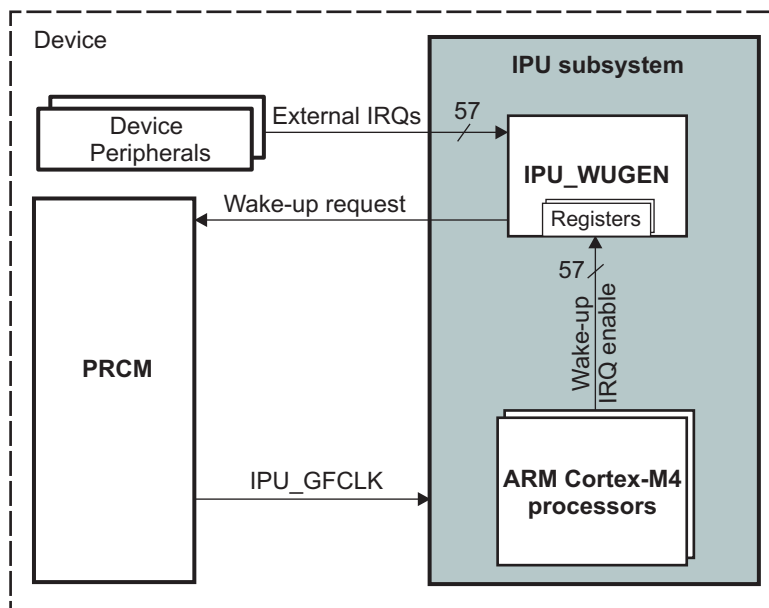

- Gating of the IPU subsystem clock dynamically, thus reducing power consumption
- Simplifying of dependencies in the PRCM module

Two retention registers are used to control which interrupts will cause a wake-up request generation:

- **WUGEN_MEVT0** – wake-up interrupt enable for interrupts mapped to the IPU_IRQ_[47:23] interrupt lines.
- **WUGEN_MEVT1** – wake-up interrupt enable for interrupts mapped to the IPU_IRQ_[79:48] interrupt lines.

Figure 5-9 is an overview of the IPU_WUGEN.

Figure 5-9. IPU_WUGEN Overview

5.3.4.2 Cortex-M4 Local Power Management

The Cortex-M4 processor provides two sleep modes to reduce power consumption:

- Sleep mode
- Deep-sleep mode

During sleep mode, the system clock can be stopped but the free running clock input should still be running to allow the processor to be woken by an interrupt or an event. The support of the sleep mode is done within the IPU subsystem. Deep-sleep mode also stops the processor clock but this can also be supported by the PRCM module. A combined signal is generated from the two Cortex-M4 processors in deep-sleep mode to initiate another power state and let the PRCM module handle the next power states. At this time, software must ensure that all IPU_UNICACHE background operations (for example, maintenance) are complete before PRCM asserts an idle request.

The sleep modes are invoked by wait for interrupt (WFI) or wait for event (WFE) instructions. For more information about entering/exiting sleep modes, see the *ARM Cortex™-M4 Devices Generic user Guide*.

5.3.4.3 STANDBY and IDLE Protocols

The IPU subsystem supports the STANDBY and IDLE power-management protocols. The following registers (part of the IPU_WUGEN register space) can be used to configure the different STANDBY and IDLE modes:

- [STANDBY_CORE_SYSCONFIG\[1:0\]](#) STANDBYMODE bit field. The default is smart wake-up STANDBY mode.
- [IDLE_CORE_SYSCONFIG\[1:0\]](#) IDLEMODE bit field. The default is smart wake-up IDLE mode.

NOTE: It is not recommended to change the default values of the STANDBY and IDLE modes in software.

5.3.4.4 Power Domains

The IPU subsystem is divided into two power domains (PD_IPU and PD_COREAON), which are controlled by the PRCM module.

The PD_IPU power domain is the main power domain and includes all the IPU subsystem components (two ARM Cortex-M4 processors, IPU_UNICACHE, IPU_ROM and IPU_RAM memories, and emulation\debug modules) except the IPU_WUGEN.

The PD_COREAON power domain is an always-on power domain. The PD_COREAON power domain contains the IPU_WUGEN, which generates a wake-up request from external interrupts. By this separate PD_COREAON power domain, the wake-up request can be generated even when the PD_IPU power domain is in OFF or RET state.

For information about the PD_IPU and PD_COREAON power domains, see [Chapter 3, Power, Reset, and Clock Management](#).

5.3.4.5 Voltage Domain

The IPU subsystem is located within the CORE voltage domain (VD_CORE). All IPU logic (Cortex-M4 cores, IPU_UNICACHE/MMU, IPU_WUGEN, etc...) is fed by VD_CORE. All IPU memory arrays are fed by on-chip memory (SRAM) LDO dedicated to the CORE domain – SLDO_CORE.

For information about VD_CORE and SLDO_CORE, see [Chapter 3, Power, Reset, and Clock Management](#).

5.3.4.6 Power States and Modes

[Table 5-8](#) lists the different power modes and the expected states for each power domain.

Table 5-8. IPU Subsystem Power Modes

	Functional Domain	Activity			Power Status	
		Core		IPU subsystem	PD_IPU Power Domain	PD_COREAON Power Domain
	Modules included	IPU_C0	IPU_C1	IPU_WUGEN		
Power modes	Active	Active	Active	Active	ON	ON
	IPU_C0 idle	Idle	Active	Active	ON	ON
	IPU_C1 idle	Active	Idle	Active	ON	ON
	Core standby	Idle	Idle	Active	ON	ON
	Full idle	Idle	Idle	Idle	ON	ON
	CSWR	Idle	Idle	Idle	ON/LOWV	ON/LOWV
	OSWR	Idle	Idle	Idle	RET	ON
	Power off	Idle	Idle	Idle	OFF	OFF

The different power modes and their features are:

- Active mode: All functional domains are operative.
- IPU_C0 and IPU_C1 idle mode:
 - Only the CPU core is idled (when running WFE/WFI instructions).
 - Only one Cortex-M4 core can be in this mode. Interrupts or events can wake-up the core.
 - Can go into sleep or deep-sleep mode. Potentially, both cores can be in sleep mode.
 - When both cores are in deep-sleep mode, a standby request is sent to the PRCM module.
 - Software must ensure that all IPU_UNICACHE background operations (for example, maintenance) are complete before the PRCM module asserts an idle request.
- Core standby mode
 - In this mode, both cores in the CORE functional domain are in idle mode (an interrupt cannot wake up either of the cores).
 - The PRCM module must have acknowledged its acceptance by an MWait signal.
 - After this handshake, all power management is under the control of the PRCM module.
- Full-idle mode:
 - In this mode, the IPU subsystem functional domain is also idled.
 - This mode is only reached by PRCM's initiative. When PRCM finds all conditions (by hardware and/or software configuration) are met to idle, it sends idle requests to the local PRCM, and it affects each functional domain.
 - After coming to this mode, power states can be moved deeper.
- CSWR mode:
 - In this mode, the logic supply voltage is lowered to reduce static power consumption by leakage current. Logic power switch in the PD_IPU power domain is still closed (ON); thus, all logic states are retained.
 - IPU_WUGEN is still active and can generate wake-up request to PRCM.
 - L1 and/or L2 memories can go independently in retention depending upon the settings done at PRCM level.
- OSWR mode:
 - In this mode, logic power switch is open (OFF); thus, most logic states are lost except the retention logics. Voltage level is typically lowered, but not necessarily.
 - Cache/L2 memory contents are retained
 - WUGEN is still active and can generate wakeup request to PRCM.
- Power off mode:
 - The voltage source is shut down. The logic states, including the retention logic, are lost.
 - The IPU_WUGEN is not operating and only the PRCM module can trigger the IPU subsystem wakeup.
 - Reset must be applied to the IPU subsystem to restart the two Cortex-M4 processors and the memory subsystem.

Figure 5-10 shows the power mode transitions in the IPU subsystem.

Figure 5-10. IPU Power Mode Transitions

Legend for Figure 5-10:

- 1 = WFE/WFI instruction
- 2 = Events/interrupts
- 3 = "Deep-sleep" generated
- 4 = L1/L2/IPU_WUGEN functional domain idled
- 5 = Wakeup (OCP)
- 6 = Wakeup (IRQ)
- 7 = PRCM
- 8 = PRCM or wakeup

5.3.5 IPU Interprocessor Communication (IPC)

5.3.5.1 Use of WFE and SEV

The IPU subsystem provides a multiprocessor communication interface for synchronizing tasks. The ARM processors have one output signal, TXEV (transmit event), for sending events and one input signal, RXEV (receive event), for receiving events. Figure 5-11 shows how TXEV and RXEV are connected in the IPU subsystem.

When a WFE instruction is executed, the processor enters into sleep mode waiting for an event and continues instruction execution when an external event is received. With an SEV (send event) instruction, one processor can wake up the other processor, which is in sleep mode.

The WFE and SEV instructions can help reduce the number of iterations around a lock acquire loop (a spinlock), and thereby reduce power consumption. The basic mechanism involves an observer that is in a spinlock executing a WFE instruction, which suspends execution on that observer until an asynchronous exception or an explicit event (sent by an observer using the SEV instruction) is seen by that observer. The observer that holds the lock uses the SEV instruction to send an event after a lock is released.

Figure 5-11. Event Communication Connection in IPU Subsystem

5.3.5.2 Use of Interrupt for IPC

Each Cortex-M4 core can interrupt the other Cortex-M4 core by setting up an interrupt register ([CORTEXM4_CTRL_REG](#)). This register is used to trigger the corresponding 'per core' HWSEM_M4_IRQ interrupt (interrupt number 19). Because the priority level for that interrupt can be defined, it is possible to choose the task level at which the interrupt will run. For example, if IPU_C0 was active and IPU_C1 was idle (WFI state), when IPU_C0 completes its task it sets the bit for IPU_C1 in the control register ([CORTEXM4_CTRL_REG\[16\] INT_CORTEX_2](#)) and goes into sleep mode. IPU_C1 wakes up seeing this interrupt, and starts running its task. After the completion of its task, IPU_C1 sets the interrupt for IPU_C0 ([CORTEXM4_CTRL_REG\[0\] INT_CORTEX_1](#)), and then goes into WFI state. This kind of handshake ensures that if IPU_C0 and IPU_C1 are accessing the same resources (memory, registers etc.), only one of the CPUs at a time is active.

5.3.5.3 Use of the Bit-Band Feature for Semaphore Operations

The two Cortex-M4 cores share the same memory system, and it is possible to use the bit-band feature to carry semaphore operations. Because the bit-band alias writes are locked read-modify-write transfers, provided that all tasks changed only the lock bit representing themselves, the lock bits of other tasks are not lost, even if two tasks try to write to the same memory location at the same time.

Each Cortex-M4 core supports two bit-band regions.

Bit-band 1 applies to the virtual address space 0x2000 0000–0x200F FFFF (1 MiB). This virtual address space can be mapped to any physical address and bit-banding will apply to that region. It is recommended that the user map the L2 IPU_RAM (64 KiB) to this virtual space and use it only for bit-banding operations. If required, the user can define other available small and medium pages over and above the L2 IPU_RAM virtual space and further extend the use of the bit-band feature.

Bit-band 2 applies to the virtual address space 0x4000 0000–0x400F FFFF (1 MiB). The first 16 KiB of this space (0x4000 0000–0x4000 3FFF) are already reserved for small (one page) pages and cannot be remapped by software. The bit-band alias that corresponds to this 16-KiB region (0x4200 0000–0x4207 FFFF) must also be treated as reserved and no access should be made. The rest of bit-band 2 can be used by appropriately defining the available small and medium pages. In this device, because it is likely that during normal AMMU programming all of L3_MAIN is mapped to this region, it is highly recommended that the user use only bit-band 1 for all purposes and bit-band 2 only if it is necessary.

5.3.5.4 Cortex-M4 Private Memory Space

Each Cortex-M4 processor has its own memory space (address range 0xE000_1000 – 0xE00F_FFFF), inaccessible by the other processor (and also by the L3_MAIN interconnect). Because the registers in this memory space are not shared, they do not require the bit-band feature (semaphore) to read from and write to them.

5.3.6 IPU Memory Mapping

The Cortex-M4 processor has a predefined memory map that specifies which bus interface is to be used when a memory location is accessed. The Cortex-M4 also features a bit-band support from which a special region is defined. For more details about the Cortex-M4 memory model, refer to ARM *Cortex™-M4 Technical Reference Manual*.

IPU memory map is presented in [Chapter 2, Memory Mapping](#).

5.3.7 IPU Boot Configuration

IPU is the boot master of this device. The device initialization is described in [Chapter 25, Initialization](#).

5.3.8 IPU Debug and Emulation Features

The IPU subsystem (and the Cortex-M4 core, in particular) provides some debug and emulation capabilities. They are described in [Chapter 26, On-Chip Debug Support](#).

5.4 Dual Cortex-M4 IPU Subsystem Register Manual

5.4.1 IPU Subsystem Instance Summary

Table 5-9 summarizes the IPU subsystem instances.

Table 5-9. IPU Subsystem Instance Summary

Module Name	Base Address (IPU Private Access)	Base Address (L3_MAIN Interconnect)	Size
IPU_UNICACHE_CFG	0x5508 0000	0x5888 0000	4 KiB
IPU_UNICACHE_SCTM	0x5508 0400	0x5888 0400	4 KiB

Description	Indicates address location of error occurrence in L2 RAM		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADDR_LOCATION																															

Bits	Field Name	Description	Type	Reset
31:0	ADDR_LOCATION	Indicates physical address where ECC error has occurred in L2RAM. The address reported is aligned to a 8 byte boundary	R	0x0000 0000

Address Offset	0x0000 0100 + (0x4 * i)	Instance	IPU_UNICACHE_SCTM_IPU
Physical Address	0x5508 0500 + (0x4 * i)		
Description	These registers contain the control and status settings for a single counter in the module. There will be a CTCR for every counter in the module (WT: with timer)		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								INPSEL				RESERVED				RESTART	DBG	INT	CHNSDW	OVRFLW	IDLE	FREE	DURMODE	CHAIN	RESET	ENBL					

Bits	Field Name	Description	Type	Reset
31:21	RESERVED	Reserved.	R	0x000
20:16	INPSEL	Counter Timer input selection 0: Constantly asserted input that results in a free-running counter/timer 1-31: Index of event input signal selected	RW	0x00
15:11	RESERVED	Reserved.	R	0x00
10	RESTART	Restart the timer after an interval match 0: The timer stops after the first interval match. It must be manually reset by software before it starts counting again (run-once timer mode). 1: The timer immediately resets to 0 and begins incrementing again based on the current input configuration (restart timer mode).	RW	0
9	DBG	Signal debug logic on interval match 0: No debug event is generated. 1: Upon interval match, generates a debug event on the corresponding debug output event signal	RW	0
8	INT	Generate interrupt on interval match 0: No interrupt is generated. 1: Upon interval match, generates an interrupt on the corresponding interrupt output event signal	RW	0
7	CHNSDW	Counter has a shadow register for chain reads. 0: The read of the corresponding counter register returns the current value. 1: Read of the high-order counter register, simultaneously loads the current value of the 32 LSBs into a shadow register. The read of the counter register that corresponds to this counter returns the value of the shadow register. This is applicable only when the counter is chained.	R	0
6	OVRFLW	Counter has wrapped since it was last read 0: The counter has not wrapped since the last read. 1: The counter has wrapped since the last read.	R	0
5	IDLE	Counter ignores processor IDLE state 0: The counter does not increment during IDLE state. 1: The counter continues to function during IDLE state; applicable if IDLEMODE = 1.	RW	0
4	FREE	Counter ignores processor debug halt state 0: The counter does not increment (decrement) during the debug halt state.	RW	0

Bits	Field Name	Description	Type	Reset
		1: The counter continues to function during debug halt state.		
3	DURMODE	Counter is in duration or occurrence mode 0: The counter operates in event mode. The counter increments by 1 each time a rising edge is seen on the designated input event signal. 1: The counter operates in duration mode. The counter increments every time a clock cycle is seen and the corresponding input event signal is asserted.	RW	0
2	CHAIN	Counter is chained to an adjacent counter 0: The counter is not chained. 1: Reserved	RW	0
1	RESET	Counter reset control 0: No effect 1: The corresponding counter is reset to the initial value and the OVERFLW bit is cleared. It continues to function if it is still enabled.	RW	0
0	ENBL	Counter enable control 0: The counter does not increment. 1: The counter increments as configured.	RW	0

Embedded Vision Engine

This chapter describes the embedded vision engine (EVE) for the device.

Topic	Page
6.1 Embedded Vision Engine (EVE) Subsystem	1530
6.2 ARP32 CPU and Instruction Set	1532
6.3 VCOP CPU and Instruction Set	1726

6.1 Embedded Vision Engine (EVE) Subsystem

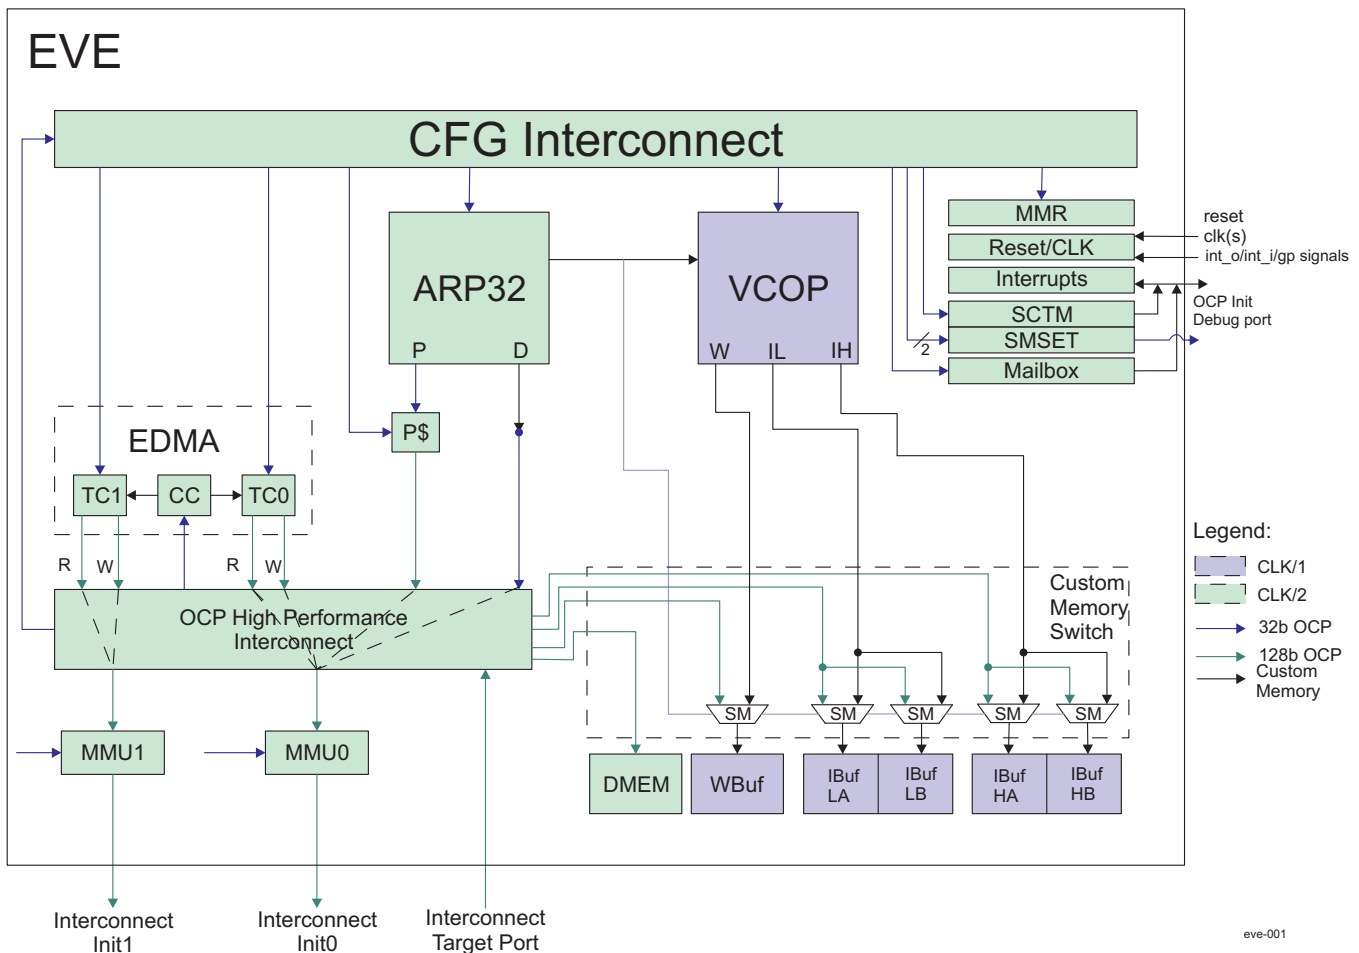

6.1.1 EVE Overview

The embedded vision engine (EVE) module is a programmable imaging and vision processing engine, intended for use in devices that serve customer electronics imaging and vision applications. Its programmability meets late-in-development or post-silicon processing requirements, and lets third parties or customers add differentiating features in imaging and vision products.

The device includes one instantiation of the EVE engine. A single EVE module consists of an ARP32 scalar core, a vector coprocessor (VCOP) vector core, and an Enhanced DMA (EDMA3) controller.

Figure 6-1 is a high-level block diagram of the EVE module.

Figure 6-1. EVE Overview

The ARP32 scalar core is the subsystem controller. It coordinates internal EVE interaction, as well as interaction with other components in the system on chip (SoC), like host processor and the DSP. The VCOP is a SIMD engine with built-in loop control and address generation.

The EDMA block is the local DMA. It is used for transferring data between system memories (typically SDRAM and/or L3 SRAM) and internal EVE memories.

Module interconnect is conceptually broken into two parts: A high-performance interconnect and a configuration interconnect. The high-performance interconnect serves as primary high bandwidth (partial) crossbar connection between the EDMA, ARP32, DMA, OCP initiator/target buses and EVE memories. The configuration interconnect provides connectivity to the various memory-mapped registers (MMR) within the EVE module.

The custom memory switch provides a statically muxed low-latency and high-bandwidth connection between the VCOP and the internal EVE memories. The custom memory switch also provides any accesses from the high-performance interconnect and EVE memories.

The interrupt controller (INTC) handles incoming interrupts, merging them with internal interrupt sources to drive the interrupt inputs of the ARP32 .

The MMR block includes control and status bits for general EVE functions that do not reside in other blocks, including reset and clock controller registers and memory static mux ownership.

The SCTM block includes debug logic that supports the counting and timing of various EVE level events, namely VCOP stall counts, VCOP access counts, ARP32 cache miss counts, and so on. The SMSET block provides software message tracing, as well as event tracking.

The reset-clock controller handles subsystem reset and power-management functions.

The EVE engine includes the following main features:

- Two 128-bit interconnect initiator ports used for:
 - Paging between system-level memory (L3 SRAM/DDR) and EVE memory (primarily IBUF, WBUF)
 - ARP32 program fetches to system memory (through program cache)
 - ARP32 load or store requests to system memory
 - ARP32 program cache-related read requests, including prefetch/preload requests
- 128-bit interconnect target port used for system-level host or DMA access to EVE memory or MMR space
- Scalar core (ARP32) with the following features:
 - 32KB program cache (direct mapped and prefetch)
 - 32KB data memory (DMEM)
- Vector core (VCOP):
 - 32KB working buffer (WBUF)
 - 16KB image buffer low copy A (IBUFLA)
 - 16KB image buffer low copy B (IBUFLB)
 - 16KB image buffer high copy A (IBUFHA)
 - 16KB image buffer high copy B (IBUFHB)
- EDMA channel controller (EDMACC): 128 PaRAM entries, 2 Queues
- EDMA transfer controllers: two instances, 2k FIFO each
- Memory Management Units (MMUs):
 - 32-entry TLB per MMU
 - Page walking with hardware
 - EDMA accesses and ARP32 program or data accesses to system memory space
 - Can limit EVE accesses to desired subset of system addresses
- Configuration interconnect for MMR and debug accesses
- High-performance interconnect for high throughput and high concurrency data transfers between connected endpoints
- Multiple interrupts for interrupt mapping, DMA event mapping, and interprocessor handshaking
- Support for slave idle and master standby protocols for clock gating
- No support for retention and memory array off modes
- Error detection on all memories:
 - Single bit error detect on DMEM, WBUF, IBUFLA, IBUFLB, IBUFHA, and IBUFHB
 - Double bit error detect on program cache
- Invalid instruction detection in the two processor units (ARP32 and VCOP)
- Debug support
 - Subsystem Counter Timer Module (SCTM) for counting and measuring of VCOP, EVE program

- cache, and EDMA performance-related state
- Software Messaging System Event Trace (SMSET) for trace of software messages and hardware events
- ARP32 debug support: State visibility, breakpoint, run control, cross-triggering
- VCOP debug support: State visibility and run control
- Interprocessor communication: Internal Mailbox for DSP/EVE communication

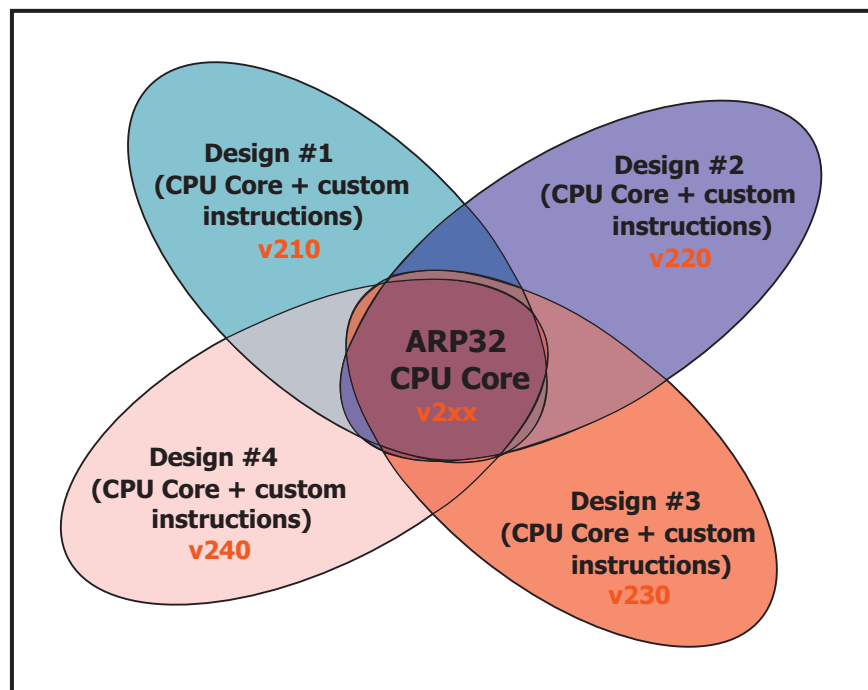

6.2 ARP32 CPU and Instruction Set

6.2.1 Overview

ARP32 refers to a family of customizable, embedded processors targeted for deeply embedded control applications that require high-performance at very-low system cost (die size) and dynamic power-consumption. Example of applications that can benefit using the ARP32 includes embedded video processing engine, computer vision, and video analytics processing engine.

Figure 6-2 illustrates the overlapping nature of the ARP32 CPU and feature set in different application contexts.

Figure 6-2. ARP32 Versions and ISA/Feature Space

6.2.2 Features

The main features of the ARP32 processor include:

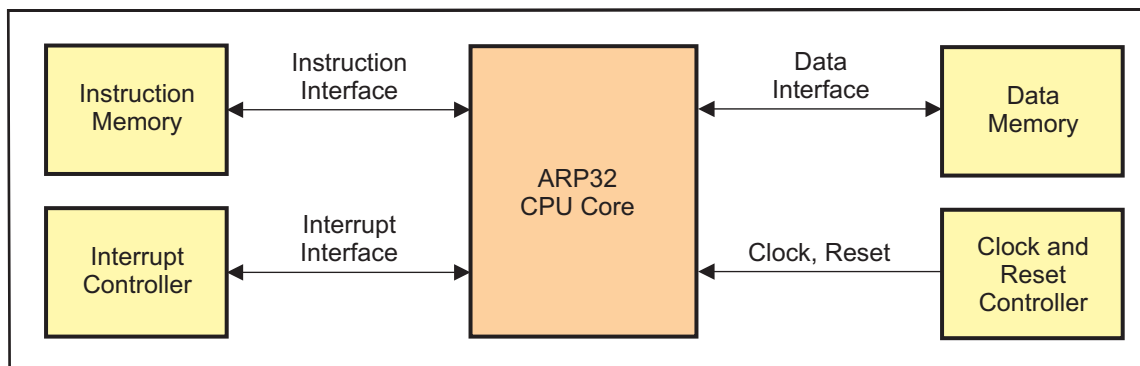

- Single issue RISC processor with Harvard memory architecture
- Highly efficient integer pipeline delivering high performance at low area and power cost
- Provides customization of instruction set to provide acceleration of a target application
- Supported by fully optimizing C/C++ compiler including intrinsic-driven usage of special custom instructions

It is recommended that ARP32 CPU users only use C/C++ language with the supported TI compiler and tools; assembly level programming is highly discouraged and may break future compatibility with the ARP32 processor family or its variants.

6.2.3 Block Diagram

Figure 6-3 shows the ARP32 core interfaces.

Figure 6-3. ARP32 CPU Block Diagram

6.2.4 Architecture

6.2.4.1 Interface Description

Table 6-1 provides the basic description of the interface signals of the core. The data and instruction memory interface implements a simple request-ready based handshake sufficient to directly interface TIs compiled SRAM memories.

There is no architectural clock-gating implemented within the ARP32 core. The clock control logic is implemented outside the ARP32 core assisted by signals driven by the CPU core via the **IDLE** instruction.

Table 6-1. Interface Signals

Signal	Direction	Width	Description
Clock, Reset			
cpu_fclk	In	1	Functional clock input
cpu_porz_i	In	1	Power On reset (active low)
cpu_resetz_i	In	1	Functional reset (active low)
cpu_standby_o	Out	1	CPU standby status (active high)

Table 6-1. Interface Signals (continued)

Signal	Direction	Width	Description
Data Interface			
cpu_dmem_enz_o	Out	1	Data memory request, active low
cpu_dmem_dbg_o	Out	1	Debug access qualifier for Data memory request
cpu_dmem_wrz_o	Out	1	Data memory write enable, active low (0: write, 1:read)
cpu_dmem_bez[3:0]	Out	4	Data memory byte enables, active low
cpu_dmem_addr_o[31:2]	Out	30	Data memory address (carries a word address)
cpu_dmem_wdata_o[31:0]	Out	32	Data memory write data
cpu_dmem_rdata_i[31:0]	In	32	Data memory read data
cpu_dmem_rdy_i	In	1	Data memory ready, active high
cpu_dmem_err_i	In	1	Data memory access error, active high, valid along with cpu_dmem_rdy_i
Instruction Interface			
cpu_imem_enz_o	Out	1	Instruction memory request, active low
cpu_imem_dbg_o	Out	1	Debug access qualifier for Instruction memory request
cpu_imem_wrz_o	Out	1	Instruction memory write enable, active low (0: write, 1:read)
cpu_imem_bez_o[3:0]	Out	4	Instruction memory byte enables, active low
cpu_imem_addr_o[31:2]	Out	30	Instruction memory address (carries a word address)
cpu_imem_wdata_i[31:0]	Out	32	Instruction memory write data
cpu_imem_rdata_i[31:0]	In	32	Instruction memory read data
cpu_imem_rdy_i	In	1	Instruction memory ready, active high
cpu_imem_err_i	In	1	Instruction memory access error, active high, valid along with cpu_imem_rdy_i
Interrupt Interface			
cpu_nmi_i	In	1	Non-maskable interrupt, active high
cpu_int4_i	In	1	Maskable interrupt 4, active high
cpu_int5_i	In	1	Maskable interrupt 5, active high
cpu_int6_i	In	1	Maskable interrupt 6, active high
cpu_int7_i	In	1	Maskable interrupt 7, active high

cpu_int9_i	In	1	Maskable interrupt 9, active high
cpu_int10_i	In	1	Maskable interrupt 10, active high
cpu_int11_i	In	1	Maskable interrupt 11, active high
cpu_int12_i	In	1	Maskable interrupt 12, active high
cpu_int13_i	In	1	Maskable interrupt 13, active high
cpu_int14_i	In	1	Maskable interrupt 14, active high
cpu_int15_i	In	1	Maskable interrupt 15, active high
cpu_iack_o	Out	1	Interrupt acknowledge, active high
cpu_inum_o	Out	4	Identifier of acknowledged interrupt

Table 6-2. Interface Signals

Signal	Direction	Width	Description
Clock, Reset			
cpu_fclk	In	1	Functional clock input
cpu_porz_i	In	1	Power On reset (active low)
cpu_resetz_i	In	1	Functional reset (active low)
cpu_standby_o	Out	1	CPU standby status (active high)

Table 6-2. Interface Signals (continued)

Signal	Direction	Width	Description
CPU Boundary Tie-off			
cpu_cpunum_i[3:0]	In	4	CPU instance identifier. Must be a constant tie-off.
Data Memory Interface			
cpu_dmem_enz_o	Out	1	Data memory request, active low
cpu_dmem_dbg_o	Out	1	Debug access qualifier for Data memory request
cpu_dmem_wrz_o	Out	1	Data memory write enable, active low (0: write, 1:read)
cpu_dmem_bez[3:0]	Out	4	Data memory byte enables, active low
cpu_dmem_addr_o[31:2]	Out	30	Data memory address (carries a word address)
cpu_dmem_wdata_o[31:0]	Out	32	Data memory write data
cpu_dmem_rdata_i[31:0]	In	32	Data memory read data
cpu_dmem_rdy_i	In	1	Data memory ready, active high
cpu_dmem_err_i	In	1	Data memory access error, active high, valid along with cpu_dmem_rdy_i
Instruction Memory Interface			
cpu_imem_enz_o	Out	1	Instruction memory request, active low
cpu_imem_dbg_o	Out	1	Debug access qualifier for Instruction memory request
cpu_imem_wrz_o	Out	1	Instruction memory write enable, active low (0: write, 1:read)
cpu_imem_bez_o[3:0]	Out	4	Instruction memory byte enables, active low
cpu_imem_addr_o[31:2]	Out	30	Instruction memory address (carries a word address)
cpu_imem_wdata_i[31:0]	Out	32	Instruction memory write data
cpu_imem_rdata_i[31:0]	In	32	Instruction memory read data
cpu_imem_rdy_i	In	1	Instruction memory ready, active high
cpu_imem_err_i	In	1	Instruction memory access error, active high, valid along with cpu_imem_rdy_i
Custom Instruction Interface			
cpu_ci_valid_o	Out	1	Custom instruction interface valid - qualifies all other custom instruction related output signals from CPU
cpu_ci_opcode_o[31:0]	Out	32	Custom Instruction word
cpu_ci_addr_o[31:0]	Out	32	Custom Instruction address (carries a byte address)
cpu_ci_srcdata1_o[31:0]	Out	32	Custom instruction source operand 1 value
cpu_ci_srcdata2_o[31:0]	Out	32	Custom instruction source operand 2 value
cpu_ci_accept_i	In	1	Custom instruction accept status
cpu_ci_dstdata_i[31:0]	In	32	Custom instruction destination operand value
cpu_ci_allowintr_i	In	1	Custom instructions are allowed to annulled during INTR processing
cpu_ci_allowhalt_i	In	1	CPU is allowed to be halted even when this custom instruction is not complete
cpu_ci_dpidle_i	In	1	Indicates the idle status of custom instruction datapath
Debug Interface: OCP Slave Port			
cpu_dbg_mcmd_i[2:0]	In	3	OCP master command
cpu_dbg_mreqdebug_i	In	1	OCP master command qualifier (0: non-debug access, 1: debug access)
cpu_dbg_maddr_i[11:2]	In	10	OCP master address (carries a word address)
cpu_dbg_mdata_i[31:0]	In	32	OCP master data
cpu_dbg_mbyteen_i[3:0]	In	4	OCP master byte enable
cpu_dbg_scmdaccept_o	Out	1	OCP Slave command accept
cpu_dbg_sresp_o[1:0]	Out	2	OCP Slave response
cpu_dbg_sdata_o[31:0]	Out	32	OCP Slave data

Table 6-2. Interface Signals (continued)

Signal	Direction	Width	Description
Debug Interface: Cross-Triggering			
cpu_emu0_i	In	1	EMU0 Trigger In
cpu_emu1_i	In	1	EMU1 Trigger In
cpu_emu0_o	Out	1	EMU0 Trigger Out
cpu_emu0en_o	Out	1	EMU0 Trigger Out Enable
cpu_emu1_o	Out	1	EMU1 Trigger Out
cpu_emu1en_o	Out	1	EMU1 Trigger Out Enable
Debug Interface: ICEPick Interface			
cpu_dbgenable_i	In	1	Debugger connected status input
cpu_dbgattn_o	Out	1	CPU halted status output
cpu_syncrun_i	In	1	Global run request input
cpu_syncrunack_o	Out	1	Global run request acknowledgement output
Debug Interface: Miscellaneous			
cpu_err_halt_i	In	1	CPU sub-system generated halt request due to fatal system error
cpu_dbg_reset_req_o	Out	1	Debugger initiated reset request to the CPU sub-system (active high)
Interrupt Interface			
cpu_nmi_i	In	1	Non-maskable interrupt, active high
cpu_int4_i	In	1	Maskable interrupt 4, active high
cpu_int5_i	In	1	Maskable interrupt 5, active high
cpu_int6_i	In	1	Maskable interrupt 6, active high
cpu_int7_i	In	1	Maskable interrupt 7, active high
cpu_int8_i	In	1	Maskable interrupt 8, active high

cpu_int10_i	In	1	Maskable interrupt 10, active high
cpu_int11_i	In	1	Maskable interrupt 11, active high
cpu_int12_i	In	1	Maskable interrupt 12, active high
cpu_int13_i	In	1	Maskable interrupt 13, active high
cpu_int14_i	In	1	Maskable interrupt 14, active high
cpu_int15_i	In	1	Maskable interrupt 15, active high
cpu_iack_o	Out	1	Interrupt acknowledge, active high
cpu_inum_o	Out	4	Identifier of acknowledged interrupt

6.2.4.1.1 Data Memory Interface

- The address sent out to data memory is always a word address. Access sizes smaller than word size are supported via byte enables.
- The CPU core asserts the memory request signal (active low, `cpu_dmem_enz_o`) along with corresponding address (`cpu_dmem_addr_o`) and read/write qualifier (active low, `cpu_dmem_wrz_o`) until a ready (active high, `cpu_dmem_rdy_i`) is received from the memory sub-system.
- For a zero-wait state access, the ready is expected next cycle to the request. Ready must be de-asserted to extend the access cycle for a higher wait state memory subsystem.
- For read accesses, the CPU samples the read data bus (`cpu_dmem_rdata_i[31:0]`) when ready is asserted. For write accesses, ready indicates write completion whereas read data bus is a don't care.
- For writes accesses, appropriate byte enables (active low, `cpu_dmem_bez[3:0]`) are asserted in request phase. This is the only way for the memory sub-system to identify access size of a write access. Byte steering is done by the core, hence the memory sub-system can use the ANY lanes of write data bus for easy selections/multiplexing of write data - for byte writes, the write data is duplicated on all four byte lanes of write data bus whereas for halfword writes, the write data is duplicated on both the halfword lanes of write data bus.
- For read accesses, access size is always 32b - the memory sub-system always returns 32b at the requested word address. CPU core selects the appropriate bytes based on access size and access address.

6.2.4.1.2 Instruction Memory Interface

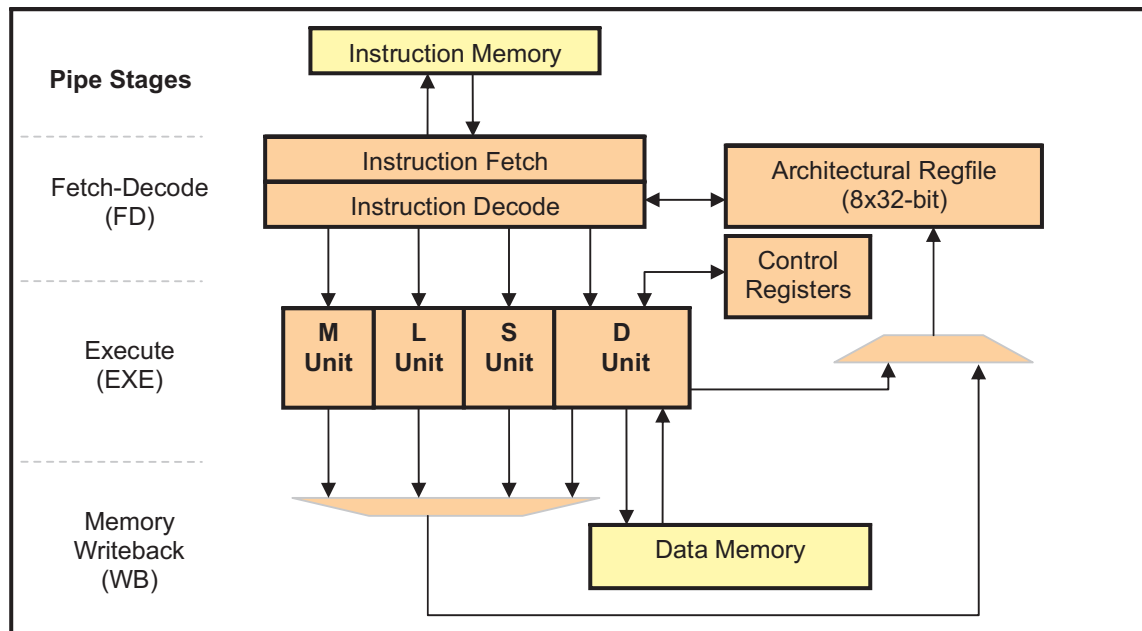

- The address sent out to the instruction memory is always a word address, access size is always a word (32 bits) and writes are not supported. Hence, byte enables and read/write qualifiers are not present for the instruction memory interface.
- The CPU core asserts the memory request signal (active low, `cpu_imem_enz_o`) along with the corresponding address (`cpu_imem_addr_o`) until a ready (active high, `cpu_imem_rdy_i`) is received from the memory subsystem.
- For a zero-wait state access, the ready is expected the next cycle to the request. Ready must be de-asserted to extend the access cycle for a higher wait state memory subsystem.
- The CPU samples the read data bus (`cpu_imem_rdata_i[31:0]`) when ready is asserted.

6.2.4.2 Pipeline

6.2.4.2.1 Overview

The ARP32 CPU implements a three-deep pipeline (see [Figure 6-4](#)): merged fetch-decode (FD), Execute (EXE), and Writeback (WB). The fetch-decode and writeback stages are overlapped.

Figure 6-4. ARP32 CPU Pipeline

6.2.4.2.2 Pipeline Operation

The first stage (FetchDecode/FD) of the pipe operates directly on the instruction memory read data input. This stage consists of the following:

- Instructions are decoded to determine
 - size of the instruction (32 bit/16 bit)
 - source operand, destination operand (in architectural and control register file)
 - if it is a blocking multi-execute cycle instruction
- Source operands are read from architectural register file

In the second stage (Execute/EXE) of the pipe:

- All arithmetic/data processing instructions are executed.
- For a single execute cycle instruction, the results are available at the end of this stage and are written back to architectural register file and control register file (if required).
- Instructions requiring data memory access (load, store, call, return etc) compute the access address in this cycle and place the memory access request on data memory bus (along with all other qualifiers). For write accesses, write data is also provided in this stage.

In the last stage (MemoryWriteback/WB) of the pipe:

- All instructions having data memory access request issued in EXE stage waits for the read data (for read accesses) or write completion notification (for write accesses) via the data memory 'ready' signal.
- If memory subsystem asserts the ready signal, the read data is updated to architectural register file

NOTE: The Writeback stage is really outside the processor core and is used for load/store instructions only. All other instructions complete at EXE stage updating the result. Hence, in some sense the pipe depth of the ARP32 processor is really 2 (Fetch-Decode, Execute).

Consider the following example code sequence in [Example 6-1](#). [Table 6-3](#) shows how the instructions flows through the pipe, highlighting the fact that only load/store instructions use the WB stage (others complete/retire at EXE).

Example 6-1. ARP32 CPU Pipeline Operation

```

MVK  0x100, R0      ; (I1) Move 0x100 into R0
MVKH 0x02000000, R0 ; (I2) Move 0x0200 into R0[31:16]
ADD  100, R0, R0    ; (I3) Add 100 to R0
LDW  *+R2(0), R3   ; (I4) Load a word to R3
ADD  4, R2, R2     ; (I5) Increment R2 to next word address
STW  R3, *+R4(0)   ; (I6) Store R3 to address pointed by R4
ADD  4, R4, R4     ; (I7) Increment R4 to next word address

```

Table 6-3. ARP32 CPU Pipeline Operation

Cycle	1	2	3	4	5	6	7	8	9
FD	MVK (I1)	MVKH (I2)	ADD (I3)	LDW (I4)	ADD (I5)	STW (I6)	ADD (I7)		
EXE		MVK (I1)	MVKH (I2)	ADD (I3)	LDW (I4)	ADD (I5)	STW (I6)	ADD (I7)	
WB						LDW (I4)		STW (I6)	

6.2.4.2.3 Pipeline Interlocks

The pipeline is fully interlocked – the CPU stalls in case of source operand registers have pending loads. Data bypassing for read-after-write dependency is implemented at the end of EXE and WB stages to increase instructions-per-cycle (IPC).

The load data has a single-cycle load use penalty since the load data is written back to register file at WB stage. In the following example, the ADD instruction stalls for a cycle to allow load to complete:

```

LDW  *+R0(0), R0    ; Load a word into R0
ADD  4, R0, R0     ; Increment R0 to the next word address
MVK  100, R1       ; Move a value 100 into R1

```

Since the CPU allows a nondependent instruction to continue executing, this stall is avoided, if the MVK (no dependency on the load data) instruction is placed in the load delay slot – the CPU executes all three instructions without a stall.

```

LDW  *+R0(0), R0    ; Load a word into R0
MVK  100, R1       ; Move a value 100 into R1
ADD  4, R0, R0     ; Increment R0 to the next word address

```

6.2.4.3 Data Format

The ARP32 CPU is an integer machine supporting three different data width/formats: byte, halfword, and word. A byte is 8 bits, a halfword is 16 bits, and a word is 32 bits – they directly map to native C data types: char, short, and int, respectively.

Each type is aligned with the corresponding size, that is, byte aligned to byte boundary, halfword aligned to 2-byte boundary, word aligned to 4-byte boundary. It is the compiler/toolchain and the programmers responsibility to maintain the access alignment all the time (for global and/or local variables).

The ARP32 core does not support unaligned access. If an unaligned access is attempted by software (via an appropriate instruction), the CPU ignores the lower 2 bits of the data memory (byte) address, thus forcing an alignment to the (truncated, floored) word address.

6.2.4.4 Endian Support

The ARP32 CPU supports only little-endian byte ordering in the memory subsystem (see [Figure 6-5](#)). A word loaded from the memory is loaded into a CPU register as follows:

- a byte or half word at address A is the least significant byte or half word within the word at that address
- a byte at address A is the least significant byte within the half word at that address

Figure 6-5. ARP32 CPU Little Endianness

	31	24 23	16 15	8 7	0
Word at address A	Byte [Addr + 3]	Byte [Addr + 2]	Byte [Addr + 1]	Byte [Addr + 0]	
Halfword at address A			Byte [Addr + 1]	Byte [Addr + 0]	

6.2.4.5 Architectural Register File

The ARP32 CPU contains an 8-entry, 32-bit architectural register file named R0-R7.

The architectural registers are read (for source operands) at the end of Fetch-decode (2 dedicated read ports available at fetch-decode for this) and written back at the end of execute stage (1 dedicated write port available at EXE for this). Additionally, for load instructions, the memory read data is written back to architectural register file at the end of writeback stage (1 dedicated write port available at WB for this) and for store instructions, the architectural register file is read (for write data) at the execute stage (via a dedicated read port available in EXE phase).

The register file contains logic to detect matching of write address in the execute stage and two read addresses in the decode stage for bypassing of result data to read data buses. The read data is flopped in the register file and routed to the execution unit in the execute stage.

6.2.4.6 CPU Control Registers

The control register file (CREG) contains registers that control or report status for the ARP32 CPU. [Table 6-4](#) lists the control registers contained in the control register file.

Control registers are accessed via **MVC**, **MVCH** instructions – this is the only mechanism for moving the contents of registers between the architectural register file and the control register file. Control registers are addressable via 5 bits in the *creg* field of the **MVC/MVCH** instructions. All control registers are defined as 32 bits – **MVC** + **MVCH** pair should be used to move immediate values to any control registers.

The following instructions are available in the **MVC/MVCH** family:

- **MVC** *ucst16, creg*
- **MVC** *areg, creg*
- **MVC** *creg, areg*
- **MVCH** *ucst16, creg*

Table 6-4. Control Registers

Acronym	Register Name	Section
CSR	Control Status Register	Section 6.2.4.6.1
IER	Interrupt Enable Register	Section 6.2.4.6.2
IFR	Interrupt Flag Register	Section 6.2.4.6.3
ISR	Interrupt Set Register	Section 6.2.4.6.4
ICR	Interrupt Clear Register	Section 6.2.4.6.5
NRP	Nonmaskable Interrupt Return Pointer Register	Section 6.2.4.6.6
IRP	Interrupt Return Pointer Register	Section 6.2.4.6.7
SP	Stack Pointer Register	Section 6.2.4.6.8
GDP	Global Data Pointer Register	Section 6.2.4.6.9
LR	Link Register	Section 6.2.4.6.10
LSA0	Loop 0 Start Address Register	Section 6.2.4.6.11
LEA0	Loop 0 End Address Register	Section 6.2.4.6.12
LCNT0	Loop 0 Iteration Count Register	Section 6.2.4.6.13
LSA1	Loop 1 Start Address Register	Section 6.2.4.6.14
LEA1	Loop 1 End Address Register	Section 6.2.4.6.15
LCNT1	Loop 1 Iteration Count Register	Section 6.2.4.6.16
LCNT0RLD	Loop 0 Iteration Count Reload Value Register	Section 6.2.4.6.17
SCSR	Shadow Control Status Register	Section 6.2.4.6.18
NMISCSR	NMI Shadow Control Status Register	Section 6.2.4.6.19
CPUID	CPU ID Register	Section 6.2.4.6.20
DPC	Decode Program Counter	Section 6.2.4.6.21
TSCH	Time-Stamp Counter (high 32 bits) Register	Section 6.2.4.6.22
TACL	Time-Stamp Counter (low 32 bits) Register	Section 6.2.4.6.22

Direct modification of the CREG entries is limited to a few special case instructions. For example, some forms of the **ADD** and **SUB** instructions directly modify the stack pointer (SP) to improve code execution performance.

A read of a control register (by **MVC** *creg*, *areg*) can be immediately followed by any other instruction using the same *areg* without causing a stall – the read data is forwarded to the next instruction in the pipeline. The following example illustrates the behavior:

```
// Read from IRP and push it stack
MVC  IRP, R0          ; Read IRP and place it in R0
STRF R0, R0          ; No stall, content of IRP is pushed to stack
```

A write to a control register is also bypassed to another instruction immediately following it and using the same *creg*. The following example illustrates the behavior:

```
// Update SP before a register push
MVC  5000, SP        ; Update SP to 5000
STRF R0, R0          ; No stall, R0 is pushed @5000
```

However, a write to a control register (by **MVC** *areg*, *creg*) has one exposed effective delay slot for an immediately following read from the same control register (by **MVC** *creg*, *areg*). The following examples illustrate the behavior:

```
// Write to LCNT0 and read it back
MVC  2000, LCNT0     ; Update LCNT0 again
NOP                                     ; without this NOP the next MVC will read UNPREDICTABLE value
MVC  LCNT0, R0       ; R0=2000
```

6.2.4.6.1 Control Status Register (CSR)

The control status register (CSR) contains control and status bits. The CSR is shown in Figure 6-6 and described in Table 6-5.

The condition code bits GT, LT, and EQ are not required to be one-hot. They may be set in any combinations using the **MVC** instruction or by combinations of **CMP** and instructions that update the EQ bit. However, execution of compare instructions enforces a one-hot condition for GT/LT/EQ.

Having more than one bit set does not affect conditional branch execution, as each branch compares only the respective condition bits, that is, the **BGE** instruction uses the CSR[4] and CSR[2] bits to determine if the branch is taken. The remaining condition bits have no effect on the **BGE** instruction.

Figure 6-6. Control Status Register (CSR)

LEGEND: R = Readable by the **MVC** instruction; W = Writeable by the **MVC** instruction; -n = value after reset

Table 6-5. Control Status Register (CSR) Field Descriptions

Bit	Field	Value	Description
31-14	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
13	DBZ	0-1	Divide-By-Zero. Status indicating if a Divide-By-Zero condition occurred since last time it was cleared. Once set, software MUST clear this bit. It is set only if the DBZE bit is set.
12	DBZE	0-1	Divide-By-Zero exception enable. When set to 1, CPU takes an UNDEF interrupt when a divide-by-zero condition is detected by DIV , DIVU , MOD , or MODU instructions. By default this bit is disabled.
11-8	INUM	0 1h 2h 3h 4h 5h 6h 7h 8h 9h Ah Bh Ch Dh Eh Fh	Interrupt Number. Indicates the interrupt ID of the last taken interrupt.
7	V	0-1	Overflow bit. Arithmetic operations that results in overflow or borrow set this bit. See individual instruction descriptions for instructions that modify the V bit.
6	SAT	0-1	Saturation bit. Arithmetic operations whose results have been saturated set this bit. See individual instruction descriptions for instructions that modify the SAT bit.
5	C	0-1	Carry bit. Arithmetic operations that results in carry out or borrow set this bit. See individual instruction descriptions for instructions that modify the C bit.

Table 6-5. Control Status Register (CSR) Field Descriptions (continued)

Bit	Field	Value	Description
4	GT	0-1	Greater-than bit. This bit is set or cleared based on the result of a CMP instruction. (GT = 1 if Rx > Ry; else GT = 0). See individual instruction descriptions for instructions that modify the GT bit.
3	LT	0-1	Less-than bit. This bit is set or cleared based on the result of a CMP instruction. (LT = 1 if Rx < Ry; else LT = 0). See individual instruction descriptions for instructions that modify the LT bit.
2	EQ	0-1	Equal bit. This bit is set to 1 if the result of an instruction execution results in a zero result or the result of a CMP instruction returns equality (EQ = 1 if Rx == Ry; else EQ = 0). See individual instruction descriptions for instructions that modify the EQ bit.
1	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
0	GIE	0 1	Global interrupt enable. Disables all interrupts, except the reset interrupt and NMI (nonmaskable interrupt). Enables all interrupts.

6.2.4.6.2 Interrupt Enable Register (IER)

The interrupt enable register (IER) enables and disables individual interrupts. The IER is shown in [Figure 6-7](#) and described in [Table 6-6](#).

Figure 6-7. Interrupt Enable Register (IER)

Table 6-6. Interrupt Enable Register (IER) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
15-4	IE _n	0 1	Interrupt enable. An interrupt triggers interrupt processing only if the corresponding bit is set to 1. Interrupt is disabled. Interrupt is enabled.
3-2	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
1	NMIE	0 1	Nonmaskable interrupt enable. An interrupt triggers interrupt processing only if the bit is set to 1. The NMIE bit is cleared at reset. After reset, software must set the NMIE bit to enable the NMI and to allow INT15-INT4 to be enabled by the GIE bit in CSR and the corresponding IER bit. The NMIE bit cannot be cleared manually; a write of 0 has no effect. The NMIE bit is also cleared by the occurrence of an NMI. All nonreset interrupts are disabled. All nonreset interrupts are enabled.
0	Reserved	1	Reserved. The reserved bit location is always read as 1. A value written to this field has no effect.

6.2.4.6.3 Interrupt Flag Register (IFR)

The interrupt flag register (IFR) contains the status of the maskable interrupts (INT15-INT4) and the NMI interrupt. Each corresponding bit in the IFR is set to 1 when that interrupt occurs; otherwise, the bits are cleared to 0. The IFR is shown in Figure 6-8 and described in Table 6-7.

The update to IFR via a write to the interrupt set register (ISR)/interrupt clear register (ICR) has one effective delay slot; IFR cannot be set/cleared using one **MVC** instruction (a write to ISR/ICR) and read the corresponding changed value of IFR via a very next **MVC** instruction. Software should use a **NOP** after a write to ISR/ICR, if the changed value has to be read immediately.

```
MVC  0x10, ISR      ; Set IFR[4]
NOP                                     ; a NOP to fill the delay slot
MVC  IFR, R0       ; R0 would contain 0x10
```

Figure 6-8. Interrupt Flag Register (IFR)

LEGEND: R = Readable by the **MVC** instruction; -n = value after reset

Table 6-7. Interrupt Flag Register (IFR) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
15-4	IF n	0 1	Interrupt flag. Indicates the status of the corresponding maskable interrupt. An interrupt flag may be manually set by setting the corresponding bit (IS n) in the interrupt set register (ISR) or manually cleared by setting the corresponding bit (IC n) in the interrupt clear register (ICR). Interrupt has not occurred. Interrupt has occurred.
3-2	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
1	NMIF	0 1	Nonmaskable interrupt flag. Interrupt has not occurred. Interrupt has occurred.
0	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.

6.2.4.6.4 Interrupt Set Register (ISR)

The interrupt set register (ISR) allows to manually set the maskable interrupts (INT15-INT4) in the interrupt flag register (IFR). Writing a 1 to any of the bits in ISR causes the corresponding interrupt flag (IF n) to be set in IFR. Writing a 0 to any bit in ISR has no effect. It is not possible to set any bit in ISR to affect NMI or reset. The ISR is shown in Figure 6-9 and described in Table 6-8.

NOTE: Any write to ISR (by the **MVC** instruction) effectively has one delay slot because the results cannot be read (by the **MVC** instruction) in IFR until two cycles after the write to ISR.

Any write to the interrupt clear register (ICR) is ignored by a simultaneous write to the same bit in ISR.

Figure 6-9. Interrupt Set Register (ISR)

LEGEND: R = Read only; W = Writeable by the **MVC** instruction; -n = value after reset

Table 6-8. Interrupt Set Register (ISR) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
15-4	IS n	0	Interrupt set. Corresponding interrupt flag (IF n) in IFR is not set.
		1	Corresponding interrupt flag (IF n) in IFR is set.
3-0	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.

6.2.4.6.5 Interrupt Clear Register (ICR)

The interrupt clear register (ICR) allows to manually clear the maskable interrupts (INT15-INT4) in the interrupt flag register (IFR). Writing a 1 to any of the bits in ICR causes the corresponding interrupt flag (IF n) to be cleared in IFR. Writing a 0 to any bit in ICR has no effect. Incoming interrupts have priority and override any write to ICR. It is not possible to set any bit in ICR to affect NMI or reset. The ISR is shown in Figure 6-10 and described in Table 6-9.

NOTE: Any write to ICR (by the **MVC** instruction) effectively has one delay slot because the results cannot be read (by the **MVC** instruction) in IFR until two cycles after the write to ICR.

Any write to ICR is ignored by a simultaneous write to the same bit in the interrupt set register (ISR).

Figure 6-10. Interrupt Clear Register (ICR)

LEGEND: R = Read only; W = Writeable by the **MVC** instruction; - n = value after reset

Table 6-9. Interrupt Clear Register (ICR) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
15-4	IC n	0	Interrupt clear. Corresponding interrupt flag (IF n) in IFR is not cleared.
		1	Corresponding interrupt flag (IF n) in IFR is cleared.
3-0	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.

6.2.4.6.6 Nonmaskable Interrupt (NMI) Return Pointer Register (NRP)

The NMI return pointer register (NRP) contains the return pointer that directs the CPU to the proper location to continue program execution after NMI processing. A branch using the address in NRP (**BNRP**) in your interrupt service routine returns to the program flow when NMI servicing is complete. The NRP is shown in [Figure 6-11](#) and described in [Table 6-10](#).

Figure 6-11. NMI Return Pointer Register (NRP)

LEGEND: R = Readable by the **MVC** instruction; W = Writeable by the **MVC** instruction; -x = value is indeterminate after reset

Table 6-10. NMI Return Pointer Register (NRP) Field Descriptions

Bit	Field	Value	Description
31	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
30-0	Return Address	0-7FFF FFFFh	Contains the return address. It is written by the CPU while taking an NMI. It is read by the CPU to execute the BNRP instruction.

6.2.4.6.7 Interrupt Return Pointer Register (IRP)

The interrupt return pointer register (IRP) contains the return pointer that directs the CPU to the proper location to continue program execution after processing a maskable interrupt (INT15-INT4, SWI, or UNDEF). A branch using the address in IRP (**BIRP**) in your interrupt service routine returns to the program flow when interrupt servicing is complete. The IRP is shown in [Figure 6-12](#) and described in [Table 6-11](#).

Figure 6-12. Interrupt Return Pointer Register (IRP)

LEGEND: R = Readable by the **MVC** instruction; W = Writeable by the **MVC** instruction; -x = value is indeterminate after reset

Table 6-11. Interrupt Return Pointer Register (IRP) Field Descriptions

Bit	Field	Value	Description
31	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
30-0	Return Address	0-7FFF FFFFh	Contains the return address. It is written by the CPU while taking an interrupt. It is read by the CPU to execute the BIRP instruction.

6.2.4.6.8 Stack Pointer Register (SP)

The stack pointer register (SP) may be directly updated by software using the **MVC** instruction. The SP points to the top of the stack and always contains a byte address. The programmer is responsible for ensuring the correct alignment of the SP. See [Section 6.2.4.14](#) for more details on stack pointer convention that must be followed. The SP is shown in [Figure 6-13](#).

Figure 6-13. Stack Pointer Register (SP)

LEGEND: R = Readable by the **MVC** instruction; W = Writeable by the **MVC** instruction; -n = value after reset

6.2.4.6.9 Global Data Pointer Register (GDP)

The GDP may be directly updated by software using the **MVC/MVCH** instruction. The GDP points to the start of the global data section (.bss section) and always contains a byte address. The programmer is responsible for ensuring that the convention described in [Section 6.2.4.15](#) is maintained. The GDP is shown in [Figure 6-14](#).

Figure 6-14. Global Data Pointer Register (GDP)

LEGEND: R = Readable by the **MVC** instruction; W = Writeable by the **MVC** instruction; -n = value after reset

6.2.4.6.10 Link Register (LR)

The link register (LR) contains the return address (a halfword address) for a **RET** instruction. A **CALL** instruction saves the last return address into the stack and updates LR with the return address. A **RET** instruction uses the current value of LR as the target address and restores the last return address into LR from the stack. The LR is shown in [Figure 6-15](#) and described in [Table 6-12](#).

Figure 6-15. Link Register (LR)

LEGEND: R = Readable by the **MVC** instruction; W = Writeable by the **MVC** instruction; -n = value after reset

Table 6-12. Link Register (LR) Field Descriptions

Bit	Field	Value	Description
31	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
30-0	Return Address	0-7FFF FFFFh	Contains the return address (a halfword address) for a RET instruction.

6.2.4.6.11 Loop 0 Start Address Register (LSA0)

The loop 0 start address register (LSA0) contains the start address (byte address) of Loop 0. Note that Loop 0 is the inner loop. The LSA0 is shown in [Figure 6-16](#) and described in [Table 6-13](#).

See [Section 6.2.4.17](#) for more details on hardware loop mechanism and usage of this register.

Figure 6-16. Loop 0 Start Address Register (LSA0)

LEGEND: R = Readable by the **MVC** instruction; W = Writeable by the **MVC** instruction; -n = value after reset

Table 6-13. Loop 0 Start Address Register (LSA0) Field Descriptions

Bit	Field	Value	Description
31-0	LSA0	0-FFFF FFFFh	Start address of Loop 0 (byte address).

6.2.4.6.12 Loop 0 End Address Register (LEA0)

The loop 0 end address register (LEA0) contains the end address (byte address) of Loop 0. Note that Loop 0 is the inner loop. The LEA0 is shown in [Figure 6-17](#) and described in [Table 6-14](#).

See [Section 6.2.4.17](#) for more details on hardware loop mechanism and usage of this register.

Figure 6-17. Loop 0 End Address Register (LEA0)

LEGEND: R = Readable by the **MVC** instruction; W = Writeable by the **MVC** instruction; -n = value after reset

Table 6-14. Loop 0 End Address Register (LEA0) Field Descriptions

Bit	Field	Value	Description
31-0	LEA0	0-FFFF FFFFh	End address of Loop 0 (byte address).

6.2.4.6.13 Loop 0 Iteration Count Register (LCNT0)

The loop 0 iteration count register (LCNT0) contains the iteration count of Loop 0. Note that Loop 0 is the inner loop. The LCNT0 is shown in [Figure 6-18](#) and described in [Table 6-15](#).

See [Section 6.2.4.17](#) for more details on hardware loop mechanism and usage of this register.

Figure 6-18. Loop 0 Iteration Count Register (LCNT0)

Bit	Field	Value	Description
31-0	LCNT0	0-FFFF FFFFh	Iteration count of Loop 0.

6.2.4.6.14 Loop 1 Start Address Register (LSA1)

The loop 1 start address register (LSA1) contains the start address (byte address) of Loop 1. Note that Loop 0 is the outer loop. The LSA1 is shown in [Figure 6-19](#) and described in [Table 6-16](#).

See [Section 6.2.4.17](#) for more details on hardware loop mechanism and usage of this register.

Figure 6-19. Loop 1 Start Address Register (LSA1)

Bit	Field	Value	Description
31-0	LSA1	0-FFFF FFFFh	Start address of Loop 1 (byte address).

6.2.4.6.15 Loop 1 End Address Register (LEA1)

The loop 1 end address register (LEA1) contains the end address (byte address) of Loop 1. Note that Loop 1 is the outer loop. The LEA1 is shown in [Figure 6-20](#) and described in [Table 6-17](#).

See [Section 6.2.4.17](#) for more details on hardware loop mechanism and usage of this register.

Figure 6-20. Loop 1 End Address Register (LEA1)

LEGEND: R = Readable by the **MVC** instruction; W = Writeable by the **MVC** instruction; -n = value after reset

Table 6-17. Loop 1 End Address Register (LEA1) Field Descriptions

Bit	Field	Value	Description
31-0	LEA1	0-FFFF FFFFh	End address of Loop 1 (byte address).

6.2.4.6.16 Loop 1 Iteration Count Register (LCNT1)

The loop 1 iteration count register (LCNT1) contains the iteration count of Loop 1. Note that Loop 1 is the outer loop. The LCNT1 is shown in [Figure 6-21](#) and described in [Table 6-18](#).

See [Section 6.2.4.17](#) for more details on hardware loop mechanism and usage of this register.

Figure 6-21. Loop 1 Iteration Count Register (LCNT1)

LEGEND: R = Readable by the **MVC** instruction; W = Writeable by the **MVC** instruction; -n = value after reset

Table 6-18. Loop 1 Iteration Count Register (LCNT1) Field Descriptions

Bit	Field	Value	Description
31-0	LCNT1	0-FFFF FFFFh	Iteration count of Loop 1.

6.2.4.6.17 Loop 0 Iteration Count Reload Value Register (LCNT0RLD)

The loop 0 iteration count reload value register (LCNT0RLD) contains the value that the loop 0 iteration count register (LCNT0) is reloaded during the outer loop rewind. LCNT0RLD is automatically updated by hardware when a write to LCNT0 is performed (via **MVC** instruction), thus LCNT0RLD does not need to be explicitly programmed during a loop setup. The LCNT0RLD is shown in [Figure 6-22](#) and described in [Table 6-19](#).

See [Section 6.2.4.17](#) for more details on hardware loop mechanism and usage of this register.

Figure 6-22. Loop 0 Iteration Count Reload Value Register (LCNT0RLD)

LEGEND: R = Readable by the **MVC** instruction; W = Writeable by the **MVC** instruction; -n = value after reset

Table 6-19. Loop 0 Iteration Count Reload Value Register (LCNT0RLD) Field Descriptions

Bit	Field	Value	Description
31-0	LCNT0RLD	0-FFFF FFFFh	Reload value of the loop 0 iteration count register (LCNT0).

6.2.4.6.18 Shadow Control Status Register (SCSR)

The shadow control status register (SCSR) contains a copy of the control status register (CSR) (of background code) in the interrupt context (except for an NMI). The SCSR is shown in Figure 6-23 and described in Table 6-20.

On acceptance of an interrupt (except for an NMI), the current state of the control status register (CSR) is copied to SCSR. On execution of a **BIRP** instruction, SCSR is copied back to CSR. SCSR facilitates fast interrupt response. A write to SCSR has no effect on machine operation.

Figure 6-23. Shadow Control Status Register (SCSR)

LEGEND: R = Readable by the **MVC** instruction; W = Writeable by the **MVC** instruction; -n = value after reset

Table 6-20. Shadow Control Status Register (SCSR) Field Descriptions

Bit	Field	Value	Description
31-14	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
13	DBZ	0-1	Shadow copy of CSR:DBZ bit.
12	DBZE	0-1	Shadow copy of CSR:DBZE bit.
11-8	INUM	0-Fh	Shadow copy of CSR:INUM field.
7	V	0-1	Shadow copy of CSR:V bit.
6	SAT	0-1	Shadow copy of CSR:SAT bit.
5	C	0-1	Shadow copy of CSR:C bit.
4	GT	0-1	Shadow copy of CSR:GT bit.
3	LT	0-1	Shadow copy of CSR:LT bit.
2	EQ	0-1	Shadow copy of CSR:EQ bit.
1	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
0	GIE	0-1	Shadow copy of CSR:GIE bit.

6.2.4.6.19 NMI Shadow Control Status Register (NMISCSR)

The NMI shadow control status register (NMISCSR) contains a copy of the control status register (CSR) (of background code) in the nonmaskable interrupt context. The NMISCSR is shown in Figure 6-24 and described in Table 6-21.

On acceptance of an NMI, the current state of the control status register (CSR) is copied to NMISCSR. On execution of a **BNRP** instruction, NMISCSR is copied back to CSR. NMISCSR facilitates correct servicing of an NMI even in a nested context. A write to NMISCSR has no effect on machine operation.

Figure 6-24. NMI Shadow Control Status Register (NMISCSR)

LEGEND: R = Readable by the **MVC** instruction; W = Writeable by the **MVC** instruction; -n = value after reset

Table 6-21. NMI Shadow Control Status Register (NMISCSR) Field Descriptions

Bit	Field	Value	Description
31-14	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
13	DBZ	0-1	Shadow copy of CSR:DBZ bit.
12	DBZE	0-1	Shadow copy of CSR:DBZE bit.
11-8	INUM	0-Fh	Shadow copy of CSR:INUM field.
7	V	0-1	Shadow copy of CSR:V bit.
6	SAT	0-1	Shadow copy of CSR:SAT bit.
5	C	0-1	Shadow copy of CSR:C bit.
4	GT	0-1	Shadow copy of CSR:GT bit.
3	LT	0-1	Shadow copy of CSR:LT bit.
2	EQ	0-1	Shadow copy of CSR:EQ bit.
1	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
0	GIE	0-1	Shadow copy of CSR:GIE bit.

6.2.4.6.20 CPU Identification Register (CPUID)

The CPU identification register (CPUID) contains the major and minor version ID. The CPUID is shown in [Figure 6-25](#) and described in [Table 6-22](#).

Figure 6-25. CPU Identification Register (CPUID)

LEGEND: R = Readable by the **MVC** instruction; W = Writeable by the **MVC** instruction; -n = value after reset; -x = value is indeterminate after reset

Table 6-22. CPU Identification Register (CPUID) Field Descriptions

Bit	Field	Value	Description
31-20	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
19-16	CPUNUM	0-Fh	Reflects the value on the t_cpunum_i[3:0] input port. The input port is sampled on reset release and kept constant – it is not sampled continuously.
15-12	Y_MINOR	0-Fh	Minor revision.
11-0	X_MAJOR	0-FFFh	Major revision.

6.2.4.6.21 Decode Program Counter Register (DPC)

The decode program counter register (DPC) contains the halfword address of the next instruction to be executed (or instruction currently at DEC stage of the pipe). The DPS is shown in [Figure 6-26](#) and described in [Table 6-23](#).

The DPC is a read-only register provided for debug purposes only. A read of DPC while the CPU is halted at a debug event shows the PC of the next instruction to be executed (after the CPU is resumed from a halted state). The debugger can use DPC to determine the halt location. Reading DPC from the debugger while the CPU is running has limited or no use.

An **MVC** instruction with DPC as write address is ignored by the CPU, no errors are generated.

A read of DPC via the **MVC** instruction returns the address of the **MVC** instruction itself. For example, in the following assembly instruction sequence, the read of DPC via the **MVC** instruction returns 0x101 in R1:

```
0x100   ADDD 1, R0, R0
0x101   MVC  DPC, R1   ; R1 gets 0x101
```

Figure 6-26. Decode Program Counter Register (DPC)

LEGEND: R = Read only; -n = value after reset

Table 6-23. Decode Program Counter Register (DPC) Field Descriptions

Bit	Field	Value	Description
31	Reserved	0	Reserved. The reserved bit location is always read as 0. A value written to this field has no effect.
30-0	Decode Program Counter	0-7FFF FFFFh	Contains the address of the next instruction to be executed.

6.2.4.6.22 Time Stamp Counter Registers (TSCL and TSCH)

The CPU contains a free running 64-bit counter that advances each CPU clock under normal operation. The counter is accessed as two 32-bit read-only control registers, TSCL ([Figure 6-27](#)) and TSCH ([Figure 6-28](#)).

Figure 6-27. Time Stamp Counter Register - Low Half (TSCL)

LEGEND: R = Readable by the **MVC** instruction; -n = value after reset

Figure 6-28. Time Stamp Counter Register - High Half (TSCH)

LEGEND: R = Readable by the **MVC** instruction; -n = value after reset

6.2.4.6.22.1 Initialization

The counter is cleared to 0 after reset, and counting is disabled. Subsequently, any write to TSCL initializes the counter to 0 (the write data is ignored) and enables the counter. A write to TSCH is completely ignored, without any side effect of enabling the time stamp counter (like that with TSCL). The counter remains enabled until the next CPU functional reset. Once enabled, there is no way to disable the counter or reinitialize the counter to 0.

6.2.4.6.22.2 Enabling Counting

The counter is enabled by writing to TSCL. The value written is ignored. Counting begins in the cycle after the **MVC** instruction executes. If executed with the count disabled, the following code sequence shows the timing of the count starting (assuming no stalls occur in the three cycles shown).

```
MVC  0, TSCL           ; Start the counter
MVC  TSCL, R0          ; R0 = 0
MVC  TSCL, R1          ; R1 = 1
```

6.2.4.6.22.3 Disabling Counting

Once enabled, counting cannot be disabled under program control. Counting is disabled in the following cases:

- After exiting the reset state.
- When the CPU is fully powered down.

6.2.4.6.22.4 Reading the Counter

Reading the full 64-bit count takes two sequential **MVC** instructions. A read from TSCL causes the upper 32 bits of the current count (the value of the counter when the corresponding **MVC** instruction is at Fetch/DEC stage) to be copied into TSCH. In normal operation, only this snapshot of the upper half of the 64-bit count is available to the programmer. The value read will always be the value copied at the cycle of the last **MVC TSCL, reg** instruction. If it is read with no TSCL reads having taken place since reset, then the reset value of 0 is read.

When reading the full 64-bit value, it must be ensured that no interrupts are serviced between the two **MVC** instructions if an ISR is allowed to make use of the time stamp counter. There is no way for an ISR to restore the previous value of TSCH (snapshot) if it reads TSCL, since a new snapshot is performed.

The following example shows the correct and recommended way of obtaining the full 64-bit value of the time stamp counter:

```
// Disable interrupts
MVC  CSR, R7           ; Get CSR into R7
CLR  0, 0, R7, R7      ; Clear R7[0]
MVC  R7, CSR           ; Copy R7 back to CSR (clears GIE)

// Read Counter
MVC  TSCL, R0          ; read lower 32b into R0
MVC  TSCH, R1          ; read upper 32b into R1

// Enable interrupts
MVC  CSR, R7           ; Get CSR into R7
SET  0, 0, R7, R7      ; Set R7[0]
MVC  R7, CSR           ; Copy R7 back to CSR (sets GIE)
```

6.2.4.7 CPU Shadow Registers

The ARP32 CPU implements a shadow copy for the following registers:

- All architectural registers: R0-R7
- Loop control registers: LSA n , LEA n , LCNT n

The shadow registers are used to save-off the main registers during an interrupt processing. When an interrupt is taken, the main registers are copied onto the corresponding shadow register by the CPU along with saving the interrupt return address in IRP/NRP. The original registers are restored back upon a return from interrupt – as a result of a **BIRP** or **BNRP** instruction execution.

As a result of this, as long as interrupts are not allowed to be nested, interrupt handler routines in the ARP32 CPU do not need to save of any registers on the stack, this significantly reduces the interrupt processing latency.

Table 6-24 provides the list of the shadow registers in the ARP32 CPU.

Table 6-24. CPU Shadow Registers

Acronym	Register Name	Description
SR0	Shadow R0	Shadow copy of R0
SR1	Shadow R1	Shadow copy of R1
SR2	Shadow R2	Shadow copy of R2
SR3	Shadow R3	Shadow copy of R3
SR4	Shadow R4	Shadow copy of R4
SR5	Shadow R5	Shadow copy of R5
SR6	Shadow R6	Shadow copy of R6
SR7	Shadow R7	Shadow copy of R7
SLSA0	Shadow Loop 0 Start Address	Shadow copy of LSA0
SLEA0	Shadow Loop 0 End Address	Shadow copy of LEA0
SLCNT0	Shadow Loop 0 Iteration Count	Shadow copy of LCNT0
SLSA1	Shadow Loop 1 Start Address	Shadow copy of LSA1
SLEA1	Shadow Loop 1 End Address	Shadow copy of LEA1
SLCNT1	Shadow Loop 1 Iteration Count	Shadow copy of LCNT1
SLCNT0RLD	Shadow Loop 0 Iteration Count Reload	Shadow copy of LCNT0RLD

Shadow registers are access via the **MVS** instruction:

- **MVS sreg, areg** - Read shadow register into an architectural register
- **MVS areg, sreg** - Write shadow register from an architectural register

The **MVS** instruction is executed by the S unit. Any write to the shadow registers (via a **MVS areg, sreg** instruction) has two exposed delay slots - a subsequent read from the same *sreg* (via a **MVS areg, sreg** instruction) must be separated by at least two instructions. Otherwise, the old value of *sreg* is read.

The read result (of a **MVS sreg, areg** instruction) is bypassed appropriately to a subsequent instruction using the same *areg* – there is no delay slot or stall in this case.

The following examples illustrate the behavior:

```
// Update SR0 and then read back (assume SR0 = 0x100, R0 = 0x200)
MVS  R0, SR0      ; Move R0 to SR0
NOP                               ; NOP to fill delay slot #1
MVS  SR0, R7      ; Move SR0 to R7, R7 = 0x100 (old value)

// Update SR0 and then read back (assume SR0 = 0x100, R0 = 0x200)
MVS  R0, SR0      ; Move R0 to SR0
NOP                               ; NOP to fill delay slot #1
NOP                               ; NOP to fill delay slot #2
MVS  SR0, R7      ; Move SR0 to R7, R7 = 0x200 (new value)
```

6.2.4.8 Functional Units

The ARP32 CPU contains the following main functional units:

- **L-Unit:** Performs all logical operations (AND/OR/XOR/NOT/shift and minimum/maximum), some bit level operations like bit rotation, signed/unsigned bit extraction, bit reversal, bit clear, bit set operations, left most bit detection, and saturation operation.
- **S-Unit:** Performs the move operations.
- **D-Unit:** Performs arithmetic operations that include compare less/greater than instructions, address calculation for load/store instructions, PC calculations for branch instructions, and stack pointer increment/decrement for **PUSH/POP** and **CALL/RETURN** instructions.
- **M-Unit:** Performs multiplication, division, and modulo operations.

6.2.4.9 Instruction Fetch

The ARP32 ISA has instructions that are either 16 bit or 32 bit; the mix being chosen to achieve optimal code size without sacrificing the performance (of the amount of actual work done per instruction per cycle).

The ARP32 CPU allows 16/32-bit instructions to be mixed freely without any overhead or switching between instruction decoding mode. The program counter (PC) always points to a halfword address aligned with an instruction boundary. However, the program fetch is always aligned with a word boundary. The ARP32 CPU always requests a 32-bit word from a word-aligned address over its 32-bit wide program interface. Internally, the CPU maintains a 16 bit single entry fetch buffer (FetchBuffer[15:0]) to store an unused instruction word or part of an instruction word.

This allows a simpler program memory subsystem design and allows area, power efficient implementation of tightly coupled program memory subsystem without incurring any overhead on code density.

Since instructions in the ARP32 CPU are either 16 bit or 32 bit and they are freely mixable, any 32-bit word fetched from the program memory (FetchWord[31:0]) may have the following cases:

- **The FetchWord contains two 16-bit instructions:** the first instruction (FetchWord[15:0]) is sent to the instruction decoder and the second instruction (FetchWord[31:16]) is stored in the FetchBuffer. The stored instruction is then sent to the instruction decoder at the next decode cycle. No program request is sent for a cycle (as the fetch buffer already contains the next instruction to be executed) unless there is a branch.
- **The FetchWord contains one 32-bit instruction:** the entire FetchWord is sent to the instruction decoder and the FetchBuffer is invalidated.
- **The FetchWord contains one 16-bit instruction and the lower halfword of the next 32-bit instruction:** the valid 16-bit instruction (in FetchWord[15:0]) is sent to the instruction decoder and the lower halfword of the next 32-bit instruction is stored in the FetchBuffer. A second fetch must be performed to fetch the upper halfword of the 32-bit instruction before it is decoded. The request for this second fetch is sent in the current cycle. When the corresponding FetchWord is available (for example, at the next cycle), its lower halfword constitutes the full 32-bit instruction word and is sent to the instruction decoder. The unused upper halfword of the current FetchWord is stored back to the FetchBuffer again.

Thus, for a sequential program with an arbitrary mix of 16-bit and 32-bit instructions, the instruction is executed without a single cycle of stall (due to unavailability of a whole instruction word for decoding) in the pipeline. However, if the target address of a program discontinuity (due to branch, call, return interrupt) is not word aligned and there exists a 32-bit instruction at the target address, a single 32-bit aligned fetch is not sufficient to fetch a full 32-bit instruction word. In this case, there is a stall/bubble cycle in the CPU pipeline. The fetch engine of the CPU issues an additional instruction fetch request at the next cycle to fulfill the required 32-bit instruction fetch and the CPU pipeline continues normally.

6.2.4.10 Alignment of 32-bit Instructions

The fetch engine of the ARP32 CPU supports 16-bit and 32-bit instructions to be aligned at any halfword boundary. For a sequential execution, CPU fetches and executes from such instruction stream without incurring any stall cycles. However, if a program discontinuity target contains an unaligned 32-bit instruction, the CPU stalls for a cycle.

NOTE: The following requirements are for efficient code generation, not functionally correct code generation. The ARP32 CPU supports having a 32-bit instruction at an unaligned discontinuity target – with the associated stall overhead. There are cases where this cannot be avoided – for example, an interrupt return to an unaligned 32-bit instruction.

This requires that for the most efficient programming of the ARP32 CPU, all programs contain 32-bit instructions to be aligned on a 32-bit boundary in the program memory. For the ARP32 C/C++ compiler/toolchain, this means that a 32-bit alignment is maintained for the following cases:

- All assembly level basic blocks that start with a 32-bit instruction
- All functions that start with a 32-bit instruction
- All HLA loop rewind targets (content of LSA_n registers) that contains a 32-bit instruction

If the previous conditions are met, the following most frequent cases where a program discontinuity happens, do not incur any additional stalls:

- Use of branch/call immediate instructions (**Bcc** *scst9*, **Bcc** *scst16*, or **CALL** *scst22*) for general program flow control
- Use of register call (**CALL** *src1*) for long calls to labels or function calls using function pointers
- Use of HLA for loop constructs and corresponding branch

6.2.4.11 Instruction Execution in Branch Delay Slot

The ARP32 CPU allows one delay slot for the following control flow instructions:

- branch (**Bcc** *scst9*, **Bcc** *scst16*, or **Bcc** *dst*)
- call (**CALL** *scst22* or **CALL** *src1*)
- return (**RET**)

There is no delay slot for SWI.

An instruction is placed in a branch delay slot as long as the restrictions mentioned in [Section 6.2.5.3](#) are maintained.

6.2.4.12 Address Space

The ARP32 CPU uses the convention that both instruction and data memory is byte addressable. The ARP32 CPU is capable of supporting full 32-bit instruction and data memory address space.

The ARP32 core is a pure Harvard architecture, separate instruction and data bus access the program and data memory space. However, while integrating the core, it is possible to unify the program and data space to make it a unified (modified Harvard) memory architecture.

6.2.4.13 Program Counter Convention

In the ARP32 CPU, the PC (program counter register) always contains halfword addresses. Correspondingly, all PC related registers (IRP, NRP) also contain a halfword address. The PC conventions used in pseudo code and other program snippets presume this convention, $PC = PC + 1$ indicates advancement of the PC by 1 entry, with each entry containing 2 bytes.

However, since program fetch is always of word size and word aligned, a word address is sent over the instruction fetch address bus (`cpu_imem_raddr_of[31:2]`).

This convention is used in most of the cases in the ISA where a PC related operation is implied. However, there are some use cases where an absolute byte address is needed to reference a location in program memory. Based on these considerations, the following rules/conventions are applied to PC related instructions and operations; the ARP32 compiler/toolchain and assembly code must maintain the following rules/conventions:

- For immediate branch instructions (**Bcc** *scst9* or **Bcc** *scst16*), the branch offset is treated as halfword offsets. This offset is directly added to the PC to calculate effective branch address (see immediate branch instructions).
- For immediate call instructions (**CALL** *scst22*), the call address is treated as PC relative halfword offset. This offset is directly added to the PC to calculate effective call address (see immediate call instructions).
- For register branch or call instructions (**Bcc** *src1* or **CALL** *src1*), the register content is treated as the absolute byte address of the branch/call destination. This address is first converted to a halfword address and then loaded to the PC.
- For set loop address instruction (**SLA** *ucst16, creg*), the immediate offset is treated as a PC relative halfword offset. This offset is directly added to the PC to calculate effective branch address (see immediate branch instructions).
- While setting up address in loop address registers (*LSAn*, *LEAn*) using the **MVC/MVCH** instructions (immediate or register forms), the value set in the loop address register is the absolute halfword address (of loop start/end instruction).
- A call instruction (**CALL** *src1* or **CALL** *scst22*) saves off a return address to the stack that is a halfword address. A corresponding return instruction (**RET**) loads this address directly onto the PC to return to the correct location.
- An interrupt saves off a return address to the IRP/NRP register that is a halfword address. A corresponding return instruction (**BIRP** or **BNRP**) loads this address directly onto the PC to return to the correct location.
- Interrupt Service Table (IST) entries are treated as a halfword address to the interrupt handler routine.

The PC is an architectural register, that is, it contains machine state, but is not directly accessible through the instruction set. Instruction execution has an effect on the PC, but the current PC value can not be read or written explicitly.

6.2.4.14 Stack Pointer Convention

The ARP32 CPU has a 32-bit stack pointer register (SP) and its content is always assumed to be a byte address. Any address computation using the SP value considers content of the SP as a byte address while computing an effective address of a byte/halfword/word access.

The ARP32 CPU is a descending stack machine. The ARP32 CPU programming model requires that the programmer and/or the compiler/toolchain maintain the following conventions:

- Stack pointer (SP) is initialized to a high address, it reduces to a lower address as it proceeds through function calls during program execution.
- Stack pointer (SP) must be always aligned to a 4-byte word address. It is software responsibility to keep the SP always aligned to 4-byte word address when allocating/de-allocating stack – there is no hardware support to do this alignment automatically. Since the ARP32 CPU does not support unaligned access, a stack pointer value not aligned to 4-byte boundary may result in access to unaligned addresses and thus produce unexpected result.
- In all cases where the CPU itself modifies the SP (call, return, **LDRF/STRF**), it always increments/decrements it by 4 (word aligned).

- Stack pointer (SP) always points to the next free location where an entry is stacked. For pushing anything onto stack, the CPU writes to the location the SP is currently pointing to and then post-decrements the SP. Similarly, while popping anything from the stack, the CPU pre-decrements the SP and then reads from the location (pre-decremented) the SP points to. For example:
 - Every **CALL** saves the return address to the location the SP is currently pointing to and then post-decrements the SP.
 - Every **RET** pre-decrements the SP and then loads the return address from the location updated SP points to.
- To allocate stack in a function (in the function prolog), reduce the SP by an amount equal to local stack frame size.
- Local variables, input arguments to functions and spilled variables all are accessed via the SP relative positive offset load/store instructions.
- To de-allocate stack in a function (in the function epilog), increase the SP by an amount equal to local stack frame size.

The ARP32 core does not save any context on stack during interrupt processing. The same stack layout and convention is applied to the interrupt handler function/procedure – except for additional register save requirements.

6.2.4.15 Global Data Pointer Convention

Global data pointer register (GDP) contains a byte address of the start of global data section. It is computed by the linker and assigned to a linker symbol that the boot routine must be used to initialize GDP.

6.2.4.16 Conditional Execution

On the ARP32 CPU, conditional execution is available only by using conditional branches.

Most data processing instructions and all compare instructions update the condition flags in control status register: CSR[2]EQ, CSR[3]LT, CSR[4]GT. Some instructions update all flags and some instructions only update a subset. See the instruction descriptions for the flags they affect. Instructions update the status bit relevant to it; other status bits are left unchanged.

Conditional branch instructions are executed, based on the condition flags set in another instruction, either:

- immediately after the instruction that updated the flags
- after any number of intervening instructions that have not updated the flags

See conditional branch instruction for more details.

6.2.4.17 Hardware Loop Acceleration

6.2.4.17.1 Overview

The ARP32 CPU implements a hardware loop assist (HLA) function to reduce cycles in critical inner loops that are typically spent in loop control operations such as loop index increment, decrement, compare, branch operations. Using an HLA mechanism, a zero-overhead rewind to the top of the loop is achieved for up to two levels of nested loops. The structure and operation of the HLA is conformable for easy mapping of loop constructs (for, while, do, etc.) available in C/C++.

Up to two levels of nested loops are supported. Additional levels of nesting are possible through standard software techniques.

In a two level nested loop construct, the inner most level is termed as Loop 0, while the outer level is termed Loop 1. For a single-level nested loop, only Loop 0 is used. Control registers associated with Loop 0 and Loop 1 control the operation of each level.

6.2.4.17.2 Loop Registers

HLA operation is setup and controlled by six control registers listed in [Table 6-25](#). Note that LSA_n and LEA_n registers contain/reflect the byte address.

Table 6-25. Hardware Loop Control Registers

Acronym	Register Name	Description
LSA0	Loop 0 Start Address Register	Contains the Start Address of Loop 0
LEA0	Loop 0 End Address Register	Contains the End Address of Loop 0
LCNT0	Loop 0 Iteration Count Register	Contains the Iteration Count of Loop 0
LSA1	Loop 1 Start Address Register	Contains the Start Address of Loop 1
LEA1	Loop 1 End Address Register	Contains the End Address of Loop 1
LCNT1	Loop 1 Iteration Count Register	Contains the Iteration Count of Loop 1
LCNT0RLD	Loop 0 Iteration Count Reload Value Register	Contains the LCNT0 reload value during outer loop rewind

6.2.4.17.3 Loop Setup Instructions

Loop control registers are accessed via the **MVC/MVCH** instructions like any other control registers.

To simplify and optimize loop setup in the most frequent compiler generated use cases, a separate instruction called set loop address (**SLA** *ucst16, creg*) is provided. The **SLA** instruction takes a PC-relative immediate positive halfword offset (*ucst16*) and writes the byte address of the location indicated by the $PC + ucst16$ value to the LSA_n and LEA_n registers.

Loop setup occurs in the following order:

- For a single-level loop (only Loop 0):
 1. Setup LSA0
 2. Setup LEA0
 3. Setup LCNT0
- For a two-level loop (Loop 0 and Loop 1):
 1. Setup LSA1
 2. Setup LEA1
 3. Setup LCNT1
 4. Setup LSA0
 5. Setup LEA0
 6. Setup LCNT0

HLA is not assured to work if the above order is not maintained.

6.2.4.17.4 Loop Operation

The loop setup process for each level of nesting consists of the following (in the specified order):

1. Setup loop start address register (LSA_n) with the byte address of the first instruction in the corresponding loop.
2. Setup loop end address register (LEA_n) with the byte address of the last instruction in the corresponding loop.
3. Setup loop iteration count register ($LCNT_n$) with the intended loop iteration count.

A loop becomes active as soon as a value greater than 1 is programmed in $LCNT_n$. The LSA_n and LEA_n registers are written when the corresponding **MVC/SLA** instruction is executed but the values are not used by the processor (for detecting loop rewind condition) until the corresponding loop becomes active.

When a loop becomes active ($LCNTn > 1$), the PC of the instruction at DEC phase is checked with the LEAn register. If they match, the CPU takes a zero-cycle overhead branch to the top of the loop provided by the LSA_n registers. The program fetch request to LSA_n is placed when the last instruction of a loop is at DEC. Thus there is no delay slot for the loop rewind branch, neither any stall or null cycle.

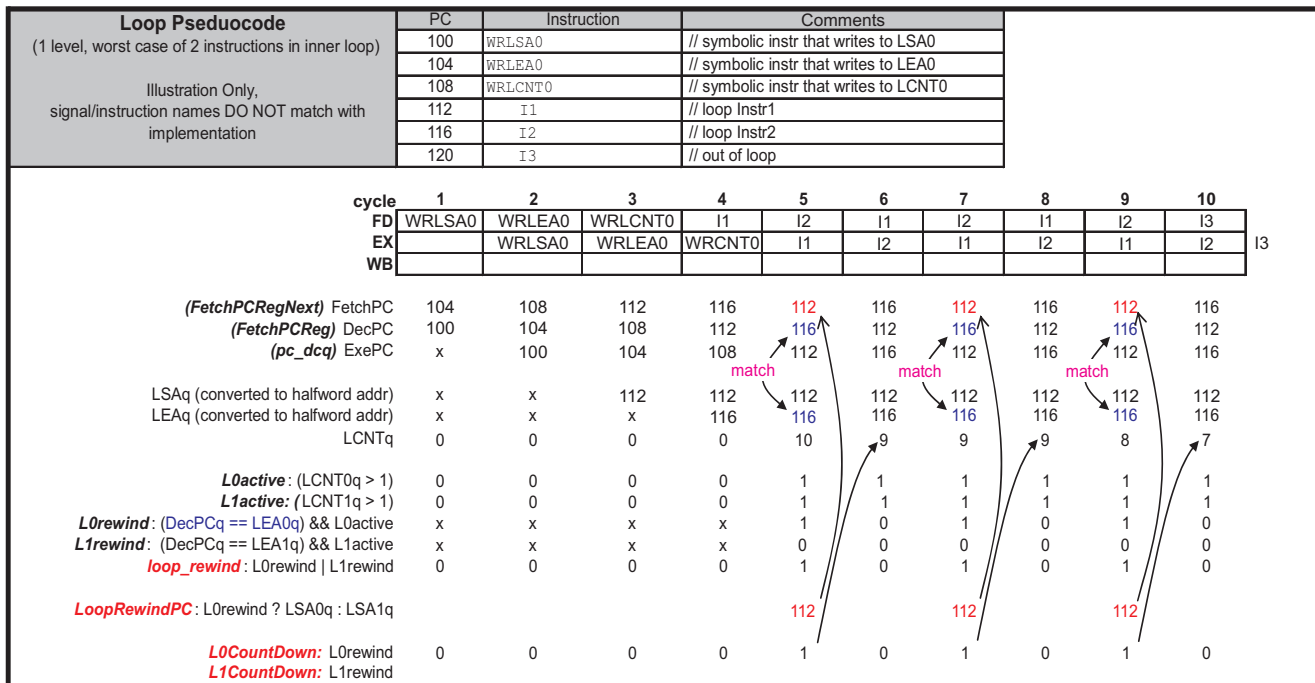

For $LCNTn = x$, the loop rewinds $x - 1$ times, effectively the loop body executes total x times ($x - 1$ rewinds and the last fall through pass). For $LCNTn = 1$, the loop body executes once (zero rewind). For $LCNTn = 0$, the loop is not considered active – the CPU just linearly executes – however, as a result, the loop body executes once (linear fall through). Note that $LCNTn = 0$ does not mean loop body would not be executed.

During operation, the $LCNTn$ registers are directly updated (decremented) with the remaining iteration count. The loop counters are updated along with the corresponding rewind-branch. At any time $LCNTn$ is read to determine how many iterations of the corresponding loop are still to be executed. When each level completes, the corresponding $LCNTn$ registers become zero, the LSA_n/LEA_n registers are left unchanged. Note that for $LCNTn = 1$, the loop body executes once and the loop counter is decremented when the last instruction of the corresponding loop is executed.

The $LCNT0RLD$ register is updated automatically by the CPU whenever a value is written to $LCNT0$ (for example, during loop setup). For a two-level nested loop, once the inner most level iteration completes and the CPU rewinds to the top of the outer loop, the $LCNT0$ is reloaded with the content of $LCNT0RLD$. Note that even if $LCNT0RLD$ is a programmer visible control register, it acts as a shadow register of $LCNT0$ (updated on any write to $LCNT0$) and must not be explicitly written during a loop setup.

There are no restrictions in embedding an HLA construct or instruction sequence, consisting of one or two levels of nested loops, into a larger level of nested loop implemented by normal software techniques.

Figure 6-29. Loop Operation

6.2.4.17.5 Call and Branch within Loop Context

Branches (**Bcc scst9**, **Bcc scst16**, or **Bcc dst**) within the loop are allowed, provided the conditions explicitly mentioned in [Section 6.2.5.3.2](#) are met.

Calls (**CALL scst22** or **CALL dst**) within the loop are generally not supported as the loop registers are not explicitly saved off when a CALL is executed within the loop context. However, software uses **CALL** instructions if the call tree does not contain any HLA usage within the caller code.

6.2.4.17.6 Dynamic Changes to Loop Iteration Count

A write to the LCNTn register within the loop body (of either of the loops) is used to dynamically change the iteration count, including pre-maturely terminating the corresponding level. Such a write to LCNTn instruction must be executed at least 2 instructions before the last (ending) instruction of the corresponding loop (x).

It is also possible to skip inner loop dynamically (per iteration of the outer loop) by simply branching across the inner loop within the outer loop context. It is not necessary to explicitly set the inner loop count to 0/1 (loop inactive values). Similarly, a branch out of the outer loop context is possible without setting the outer loop count to inactive values. This relies on the fact that even if the inner or outer loop count has not been set to an inactive value, a loop rewind does not happen unless the loop end PC (LEAn) is encountered.

These features (dynamically changing the loop iteration count, skipping inner/outer loop via branches) are used by the compiler to implement constructs such as last/continue/break and alike.

6.2.4.17.7 Interrupt Processing During HLA

Interrupts are not taken while the last instruction of a loop level is at DEC. Interrupts are taken after the loop rewind happens. The return address saved off during the interrupt processing points to the loop rewind address (LSAn). Consequently, a return from interrupt returns to the last rewind address (LSAn).

When taking an interrupt (irrespective if an HLA is active), the CPU saves off the six loop registers in the corresponding shadow registers. They are restored when interrupts are returned via the **BIRP/BNRP** instructions.

6.2.4.17.8 HLA Usage in Interrupt Context

Since loop context is fully saved by hardware while taking an interrupt, HLA is used within an ISR context freely without requiring any additional context save. For allowing nested interrupts, the shadow copies of HLA registers must be saved off to the stack explicitly along with other shadow registers. This helps achieve very-low interrupt latency in the ARP32 CPU under a single-level-nested-interrupt use model.

6.2.4.17.9 HLA Usage Restrictions

There are certain restrictions on HLA usage, see [Section 6.2.5.3.2](#).

6.2.4.17.10 HLA Mapping Examples

6.2.4.17.10.1 Loops With Single Level of Nesting

Example 6-2. C memset-like Loop, Single Level, Minimum Instructions

Pseudo C code:

```
int i, myarray[100];
for (i=0; i< 100; i++) {
    myarray[i] = 1;
}
```

Table 6-26. Example 1 of Generated Assembly Code (relevant instructions only)

Byte Address	Instruction	Comment
0x100	MVKS 1, R0	Write data
0x102	SLA 6, LSA0	First instr of loop0 is at #6 halfword offset LSA0 = 0x102 + hex(6 x 2) = 0x10E
0x106	SLA 5, LEA0	Last instr of loop0 is at #5 halfword offset LEA0 = 0x106 + hex(5 x 2) = 0x110
0x10A	MVC 100, LCNT0	iter count = 100
0x10E	STW R0, *++R1(1)	First instr of Loop 0
0x110	NOP	Last instr of Loop 0 (padding needed)

Table 6-27. Example 2 of Generated Assembly Code (relevant instructions only)

Byte Address	Instruction	Comment
0x100	MVKS 1, R0	Write data
0x102	SLA 6, LSA0	First instr of loop0 is at #6 halfword offset LSA0 = 0x102 + hex(6 x 2) = 0x10E
0x106	SLA 5, LEA0	Last instr of loop0 is at #5 halfword offset LEA0 = 0x106 + hex(5 x 2) = 0x110
0x10A	MVC 100, LCNT0	iter count = 100
0x10E	STW R0, *+R1(0)	First instr of Loop 0
0x110	ADD 4, R1, R1	Last instr of Loop 0 (padding needed)

Example 6-3. C memcpy-like Loop, Single Level, Minimum Instructions

Pseudo C code:

```
void MyMemcpyByWord (void *ptr1, void *ptr2, int size){
    int ii, dbwSize = size>>2;
    unsigned int *dst = ptr1;
    unsigned int *src = ptr2;
    for (ii=0 ; ii< dbwSize ; ii++)
        dst[ii] = src[ii];
}
```

Table 6-28. Example 1 of Generated Assembly Code (relevant instructions only)

Byte Address	Instruction	Comment
0x100	SLA 5, LSA0	First instr of loop0 is at #5 halfword offset LSA0 = 0x100 + hex(5 x 2) = 0x10A
0x104	SLA 4, LEA0	Last instr of loop0 is at #4 halfword offset LEA0 = 0x104 + hex(4 x 2) = 0x10C
0x108	MVC R1, LCNT0	iter count = "size" (passed via R1)
0x10A	LDW *++R2(1), R3	Load word from source (Loop 0, instr 1)
0x10C	STW R3, *++R4(1)	Store word to dest (Loop 0, instr 2)

Table 6-29. Example 2 of Generated Assembly Code (relevant instructions only)

Byte Address	Instruction	Comment
0x100	SLA 5, LSA0	First instr of loop0 is at #5 halfword offset LSA0 = 0x100 + hex(5 x 2) = 0x10A
0x104	SLA 6, LEA0	Last instr of loop0 is at #6 halfword offset LEA0 = 0x104 + hex(6 x 2) = 0x110
0x108	MVC R1, LCNT0	iter count = "size" (passed via R1)
0x10A	LDW *+R2(0), R3	Load word from source (Loop 0, instr 1)
0x10C	ADD 4, R2, R2	Increment src pointer
0x10E	STW R3, *+R4(0)	Store word to dest
0x110	ADD 4, R4, R4	Increment dest pointer (Loop 0, instr 4)

6.2.4.17.10.2 Loops With Two Levels of Nesting

Example 6-4. Two-level Nesting, Both Loops Ending at Same Instruction

Pseudo C code:

```

For (i=0; i<20; i++) {
  Instruction1 // size 16b
  Instruction2 // size 32b
  Instruction3 // size 32b
  Instruction4 // size 16b
  For (j=0; j<10; j++) {
    Instruction5 // size 16b
    Instruction6 // size 32b
    Instruction7 // size 16b
  }
}
  
```

Table 6-30. Example of Generated Assembly Code (relevant instructions only)

Byte Address	Instruction	Comment
0x100	SLA 18, LSA1	First instr of loop1 is at #18 halfword offset LSA1 = 0x100 + hex(18 x 2) = 0x124
0x104	SLA 19, LEA1	Last instr of loop0 is at #19 halfword offset LEA0 = 0x104 + hex(19 x 2) = 0x12A
0x108	MVC 20, LCNT1	iter count (=20) of loop1
0x10C	SLA 6, LSA0	First instr of loop0 is at #6 halfword offset LSA1 = 0x10C + hex(6 x 2) = 0x118
0x110	SLA 9, LEA0	First instr of loop0 is at #9 halfword offset LEA0 = 0x110 + hex(9 x 2) = 0x122
0x114	MVC 10, LCNT0	iter count (=10) of loop0
0x118	Instruction1	Loop1 start
0x11A	Instruction2	
0x11E	Instruction3	
0x122	Instruction4	
0x124	Instruction5	Loop0 start
0x126	Instruction6	
0x12A	Instruction7	Loop0 end, Loop1 end

Example 6-5. Two-level Nesting, Different Ending Instructions for Two Levels

Pseudo C code:

```

For (i=0; i<20; i++) {
    Instruction1    // size 16b
    Instruction2    // size 32b
    Instruction3    // size 32b
    Instruction4    // size 16b
    For (j=0; j<10; j++) {
        Instruction5 // size 16b
        Instruction6 // size 32b
        Instruction7 // size 16b
    }
    Instruction8    // size 32b
    Instruction9    // size 32b
    Instruction10   // size 16b
}
    
```

Table 6-31. Example of Generated Assembly Code (relevant instructions only)

Byte Address	Instruction	Comment

6.2.4.18 Interrupts

6.2.4.18.1 Overview

The ARP32 CPU supports various types of interrupts that include: reset, a non-maskable interrupt (NMI), 12 maskable interrupts (INT15-INT4), an undefined instruction interrupt (UNDEF), and a software interrupt (SWI). The following registers control the CPU behavior on receipt of an interrupt:

- Control Status Register (CSR)
- Interrupt Enable Register (IER)
- Interrupt Flag Register (IFR)
- Interrupt Set Register (ISR)
- Interrupt Clear Register (ICR)
- Nonmaskable Interrupt Return Pointer Register (NRP)
- Interrupt Return Pointer Register (IRP)

The SWI and UNDEF interrupts are special cases that do not have an associated input pin. The SWI interrupt mechanism is activated by decoding of the **SWI** instruction. The UNDEF interrupt is activated by detection of an undefined instruction.

On acknowledge of an enabled interrupt, the ARP32 CPU loads the contents of the interrupt service table entry associated with the interrupt into the PC.

Each interrupt type is discussed in the following sections; [Table 6-32](#) summarizes the ARP32 CPU interrupts.

Table 6-32. Interrupt Summary

Interrupt Name	Vector Address (byte)	Input Pin	Enable Control	Interrupt Return Pointer Register	Interrupt Return Instruction to be Used	Context Save and Restore Actions	
						By Hardware	By Software
Reset	00h	cpu_reset_i	Always Enabled	NA	NA	NA	NA
NMI	04h	cpu_nmi_i	IER:NMIE	NRP	BNRP	CSR to NMISCSR	R0-R7 to Stack, LSA _n to Stack, LEA _n to Stack, LCNT _n to Stack
SWI	08h	None	Always Enabled	IRP	BIRP	CSR to SCSR, R0-R7 to SR0-SR7, LSA _n to SLSA _n , LEA _n to SLEA _n , LCNT _n to SLCNT _n	None
UNDEF	0Ch	None	Always Enabled	IRP	BIRP	CSR to SCSR, R0-R7 to SR0-SR7, LSA _n to SLSA _n , LEA _n to SLEA _n , LCNT _n to SLCNT _n	None
INT4	10h	cpu_int4_i	CSR:GIE; IER:NMIE; IER:IE4	IRP	BIRP	CSR to SCSR, R0-R7 to SR0-SR7, LSA _n to SLSA _n , LEA _n to SLEA _n , LCNT _n to SLCNT _n	None
INT5	14h	cpu_int5_i	CSR:GIE; IER:NMIE; IER:IE5	IRP	BIRP	CSR to SCSR, R0-R7 to SR0-SR7, LSA _n to SLSA _n , LEA _n to SLEA _n , LCNT _n to SLCNT _n	None
INT6	18h	cpu_int6_i	CSR:GIE; IER:NMIE; IER:IE6	IRP	BIRP	CSR to SCSR, R0-R7 to SR0-SR7, LSA _n to SLSA _n , LEA _n to SLEA _n , LCNT _n to SLCNT _n	None

Table 6-32. Interrupt Summary (continued)

Interrupt Name	Vector Address (byte)	Input Pin	Enable Control	Interrupt Return Pointer Register	Interrupt Return Instruction to be Used	Context Save and Restore Actions	
						By Hardware	By Software
INT7	1Ch	cpu_int7_i	CSR:GIE; IER:NMIE; IER:IE7	IRP	BIRP	CSR to SCSR, R0-R7 to SR0-SR7, LSA _n to SLSA _n , LEA _n to SLEA _n , LCNT _n to SLCNT _n	None
INT8	20h	cpu_int8_i	CSR:GIE; IER:NMIE; IER:IE8	IRP	BIRP	CSR to SCSR, R0-R7 to SR0-SR7, LSA _n to SLSA _n , LEA _n to SLEA _n , LCNT _n to SLCNT _n	None
INT9	24h	cpu_int9_i	CSR:GIE; IER:NMIE; IER:IE9	IRP	BIRP	CSR to SCSR, R0-R7 to SR0-SR7, LSA _n to SLSA _n , LEA _n to SLEA _n , LCNT _n to SLCNT _n	None
INT10	28h	cpu_int10_i	CSR:GIE; IER:NMIE; IER:IE10	IRP	BIRP	CSR to SCSR, R0-R7 to SR0-SR7, LSA _n to SLSA _n , LEA _n to SLEA _n , LCNT _n to SLCNT _n	None
INT11	2Ch	cpu_int11_i	CSR:GIE; IER:NMIE; IER:IE11	IRP	BIRP	CSR to SCSR, R0-R7 to SR0-SR7, LSA _n to SLSA _n , LEA _n to SLEA _n , LCNT _n to SLCNT _n	None
INT12	30h	cpu_int12_i	CSR:GIE; IER:NMIE; IER:IE12	IRP	BIRP	CSR to SCSR, R0-R7 to SR0-SR7, LSA _n to SLSA _n , LEA _n to SLEA _n , LCNT _n to SLCNT _n	None
INT13	34h	cpu_int13_i	CSR:GIE; IER:NMIE; IER:IE13	IRP	BIRP	CSR to SCSR, R0-R7 to SR0-SR7, LSA _n to SLSA _n , LEA _n to SLEA _n , LCNT _n to SLCNT _n	None
INT14	38h	cpu_int14_i	CSR:GIE; IER:NMIE; IER:IE14	IRP	BIRP	CSR to SCSR, R0-R7 to SR0-SR7, LSA _n to SLSA _n , LEA _n to SLEA _n , LCNT _n to SLCNT _n	None
INT15	3Ch	cpu_int15_i	CSR:GIE; IER:NMIE; IER:IE15	IRP	BIRP	CSR to SCSR, R0-R7 to SR0-SR7, LSA _n to SLSA _n , LEA _n to SLEA _n , LCNT _n to SLCNT _n	None

6.2.4.18.2 Interrupt Processing

Figure 6-30 provides an illustration of different actions and events of interest during an interrupt processing. In this case, both INT4 and INT5 were asserted simultaneously, INT4 was selected as the winner and was taken after few cycles when all enable conditions (CSR[0]GIE, IER[1]NMIE, IER[n]) were met.

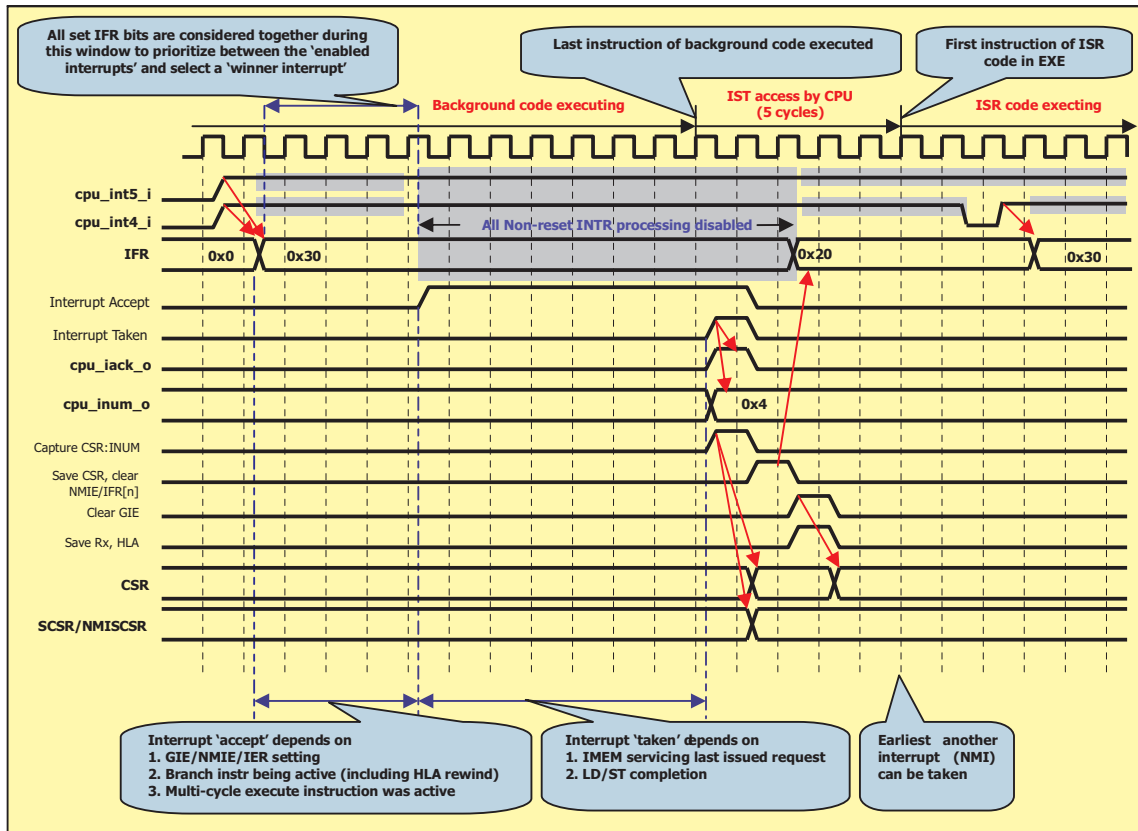

Note that the CPU entity signals/registers are shown in **bold** font; internal (and sometimes just conceptual) signals are shown in normal font.

The conceptual signal “Interrupt Accept” shows when a particular interrupt (in this case, INT4) is accepted to be taken next. This is generated by considering that all set bits of IFR, the interrupt priority, the enable conditions, and a safe cycle boundary within the CPU, where accepting an interrupt is safe.

The conceptual signal “Interrupt Taken” shows when a particular interrupt (in this case, INT4) is actually taken. The actions corresponding to an interrupt processing (IST access, context save, etc.) starts to take place within the CPU after this condition is achieved.

The delay between ‘Interrupt Accept’ and ‘Interrupt Taken’ is due to pending memory transaction on CPU instruction and data interfaces. The CPU waits for all outstanding instruction and data memory requests to be serviced before starting interrupt context save or IST access process.

Figure 6-30. Interrupt Processing

6.2.4.18.3 Interrupt Acknowledgment

The ARP32 CPU interrupts are sensitive to rising edge detected on the input interrupt pins (detected synchronously detected on the rising edge of the input clock). All interrupt pins are active high, with the exception of reset, which is active low and asynchronous.

The `cpu_iack_o` output signal is asserted high for a single cycle to indicate (to hardware external to the CPU core) that the CPU has begun processing an interrupt. The `cpu_inum_o` signal indicates the number of the interrupt that is being processed. The value driven on `cpu_inum_o` signal is also captured in the INUM field of the control status register (CSR).

Note that `cpu_jack_o` and `cpu_inum_o` are asserted for all interrupts (including reset). [Table 6-33](#) summarizes the `cpu_inum_o` values.

Table 6-33. `cpu_inum_o` Values

<code>cpu_inum_o[3:0]</code>	Interrupt
0h	Reset
1h	NMI
2h	SWI
3h	UNDEF
4h	INT4
5h	INT5
6h	INT6
7h	INT7
8h	INT8
9h	INT9
Ah	INT10
Bh	INT11
Ch	INT12
Dh	INT12
Eh	INT14
Fh	INT15

6.2.4.18.4 Interrupt Priorities

When two interrupts happen at the same time, they are serviced by the ARP32 in order of their priority. The priority level for each interrupt is listed in [Table 6-34](#).

Table 6-34. Interrupt Priorities

Priority	Interrupt
Highest	Reset
	NMI
	SWI
	INT4
	INT5
	INT6
	INT7
	INT8
	INT9
	INT10
	INT11
	INT12
	INT13
	INT14
	INT15
Lowest	UNDEF

6.2.4.18.5 Interrupt Service Table (IST)

Each entry of the interrupt service table (IST) contains a byte address that points to the beginning of the interrupt service routine for that interrupt. When the ARP32 CPU accepts an interrupt, the contents of the associated IST entry is read (IST[n]), converted to the corresponding halfword address, and then loaded into the PC creating an effective branch.

The starting address of the IST is always the address 00h in the instruction memory; the IST can not be relocated. The addresses (byte address) of each entry is shown in [Table 6-35](#).

IST entries are byte address(s) of the interrupt handler (interrupt service routine) functions. Since 4 bytes are allocated for each IST entry, the interrupt handlers are placed anywhere in the 32-bit program memory space and the ARP32 CPU directly branches to that address. This reduces interrupt latency significantly since an instruction need not be fetched/decoded/executed from an IST location, nor an intermediate routine/call/branch needs to be processed for a branch to relatively large distance.

In fact, the IST is an “array of pointers (each entry 32 bits) to interrupt handler functions in C/C++” placed at the instruction memory address 0, which is remapped to a physical address by using the memory management unit (MMU0) that services program cache requests.

Table 6-35. Interrupt Service Table (IST)

Byte Address	IST Entry
00h	Reset
04h	NMI
08h	SWI
0Ch	UNDEF
10h	INT4
14h	INT5
18h	INT6
1Ch	INT7
20h	INT8
24h	INT9
28h	INT10
2Ch	INT11
30h	INT12
34h	INT13
38h	INT14
3Ch	INT15

6.2.4.18.6 Interrupt Flags

The ARP32 CPU maintains the pending status of all non-reset external interrupts (NMI, INT15-INT4) in the corresponding bit in the interrupt flag register (IFR). A 1 indicates the corresponding interrupt is pending, reading a 0 indicates the corresponding interrupt is not pending (either is being processed or it has not occurred).

When a rising edge is detected on the input pins of external interrupts (NMI, INT15-INT4), the corresponding bits in IFR are set unconditionally in the next CPU clock cycle. When the CPU actually takes a particular interrupt, the corresponding IFR bit is cleared by the CPU. Thus at any point, reading IFR using the **MVC** instruction shows which input external interrupts is asserted or is not yet processed by the CPU (or in pending state).

The CPU checks the status of IFR bits to understand that an interrupt is asserted, and starts processing this interrupt. Processing of an interrupt involves checking for all associated enable conditions, prioritization between simultaneously asserted interrupts and actions to perform interrupt service table look up to finally achieve a branch to the interrupt service routine of the corresponding interrupt. The exact behavior and actions taken on each kind of interrupts are described in [Section 6.2.4.18.7](#).

It is possible to set one or more interrupt flags of maskable interrupts in IFR - by writing to the corresponding bit in the interrupt set register (ISR) - creating the same effect of an external interrupt assertion. This makes it possible for the software to raise a maskable interrupt. The following examples illustrate this:

Example 6-6. Setting Interrupt Flag

```
MVC  0x10, ISR      ; Set IFR[4] to raise INT4
```

Example 6-7. Setting Interrupt Flag

```
MVC  IFR, R0        ; Get current state
SET  5,5, R0, R0    ; Set R0:bit[5]
MVC  R0,  ISR       ; Set IFR[5] without changing other bits
```

NOTE: Setting of IFR by an external interrupt assertion has a higher priority than writing or clearing the IFR bits via the **MVC** instruction.

6.2.4.18.7 Interrupt Behavior

All maskable (INT15-INT4) and non-maskable (NMI) interrupt processing is triggered by the corresponding interrupt flag bit in the interrupt flag register (IFR). For SWI and UNDEF, a direct instruction decode (or non-decode) triggers interrupt processing. Once an interrupt is triggered, the CPU checks the corresponding enabling conditions (if any), does a priority resolution among simultaneously asserted interrupts, and then starts processing the interrupt.

The details of conditions for processing each type of interrupts and the actions taken by the CPU during and returning from the interrupts are described in the following subsections.

6.2.4.18.7.1 Reset Interrupt

Reset is the highest priority interrupt and is used to initialize the CPU to a known state. The reset interrupt is unique in a number of ways:

- `cpu_resetz_i` is an active-low signal and is treated asynchronously. All other interrupts are active-high signals, or activated via the instruction decoder.
- `cpu_resetz_i` must be held low for 4 clock cycles before it goes high again to reinitialize the CPU properly.
- `cpu_resetz_i` is not affected by branches or pending loads or any enable bits or any other condition applicable for processing other interrupts. The current instruction execution is aborted and the CPU registers are returned to their default state.
- Reset uses interrupt semantics, that is, loading of the IST table entry; however, it is not required to issue a **BIRP** instruction to exit reset processing.

6.2.4.18.7.2 Non-maskable Interrupt (NMI)

NMI is the second-highest priority interrupt and is generally used to alert the CPU of a serious hardware problem. For an NMI to be detected (and processed) by the ARP32 CPU, the non-maskable interrupt enable (NMIE) bit in the interrupt enable register (IER) must be set to 1. The NMIE bit is cleared to 0 at reset to prevent an NMI being taken prematurely (before system initialization). The NMI bit is set (to enable NMI) by software only after the system has been properly initialized and is ready to accept NMIs. The NMIE bit is also cleared at the occurrence of an NMI to prevent another NMI from being processed; it may be set again in the interrupt set register (ISR), to allow nested NMIs, by software after the CPU state has been saved properly in the previous NMI ISR. While the NMIE bit is cleared, all maskable interrupts (INT15-INT4) are also disabled.

When the NMIF bit is set, (as a result of an NMI assertion via `cpu_nmi_i` input pin), assuming the previous conditions are met, the ARP32 CPU is said to accept the interrupt and performs the following actions to process the NMI:

- CPU stops fetching further instruction from instruction memory
- CPU execute pipe is allowed to drain
 - Any load/store instructions (including **LDRF**, **STRF**, **CALL**, **RET**) currently executing are allowed to complete
 - Any instruction in the branch/call/return delay slot is allowed to complete
- The CSR[11:8]INUM field is updated with the NMI interrupt ID.
- The CSR content is copied to the NMISCSR.
- The IER[1]NMIE bit is cleared.
- The CSR[0]GIE bit is cleared.
- The IFR[1]NMIF bit in the IFR is cleared.
- The PC value of the next instruction to execute (after completion of the interrupt service routine) is stored to the NRP register. This is the interrupt return address.
- The `cpu_iack_o` is asserted for a cycle along with the corresponding interrupt ID on `cpu_inum_o`.
- An instruction fetch request to NMI IST location is sent and eventually the NMI IST entry is loaded into the PC. As a result, the CPU begins executing the NMI interrupt service routine.

To exit an NMI service routine, the **BNRP** instruction must be used. Execution of the **BNRP** instruction causes:

- The NMISCSR content is copied to the CSR.
- The PC loaded with the contents of the NRP.
- IER[1]NMIE bit is set.

6.2.4.18.7.3 SWI Interrupt

The **SWI** instruction is used to trigger the software interrupt. Software interrupts are always enabled. The SWI interrupt does not have a corresponding entry in the IFR, ICR, ISR, or IER, and it is not affected by the state of the CSR:GIE or IER[1]NMIE bits. An SWI does not have any delay slot. Decoding of SWI causes the following actions to be taken by the ARP32 CPU:

- The CSR:INUM field is updated with the SWI interrupt ID.
- The CSR content is copied to the SCSR.
- All architectural registers (R0-R7) and HLA registers (LSAn, LEAn, and LCNTn) are saved to the corresponding shadow registers.
- The CSR[0]GIE bit is cleared.
- The address of the next instruction (interrupt return address) to be stored to the IRP register.
- The `cpu_iack_o` is asserted for a cycle along with the corresponding interrupt ID on `cpu_inum_o`.
- An instruction fetch request to SWI IST location is sent and eventually the SWI IST entry is loaded into the PC. As a result, the CPU begins executing the SWI ISR.

To exit a SWI service routine, the **BIRP** instruction must be used. Execution of the **BIRP** instruction causes:

- The SCSR content is copied to the CSR.
- All architectural registers (R0-R7) and HLA registers (LSAn, LEAn, and LCNTn) are restored from the corresponding shadow registers.
- The PC loaded with the contents of the IRP.

6.2.4.18.7.4 Maskable Interrupts

The ARP32 CPU supports 12 maskable interrupts (INT15-INT4). For a maskable interrupt to be detected (and processed) by the ARP32 CPU:

- The global (maskable) interrupt enable (GIE) bit in the control status register (CSR) must be set to 1. The GIE bit is cleared to 0 at reset to prevent a maskable interrupt being taken prematurely (before system initialization). The GIE bit is set (to enable maskable interrupts) only after the system has been properly initialized and is ready to accept interrupts. The GIE bit is also cleared at the occurrence of an interrupt (NMI, INT15-INT4, SWI, and UNDEF) to prevent another interrupt from being processed; it may be set again in the ISR (to enable nested maskable interrupts) by software after the CPU state has been saved off properly.
- The IER:NMIE bit must be set.
- The corresponding enable bit in the interrupt enable register (IER) must also be set. IER bits allow enabling/disabling single maskable interrupt at a time.

When any of the IFR flag bits (IFR[15-4]) of maskable interrupts are set, (as a result of an maskable interrupt assertion via `cpu_int[15-4]_i` input pins), assuming the previous conditions are met, the ARP32 CPU accepts the highest priority interrupt and performs the following actions to process the interrupt:

- CPU stops fetching further instruction from instruction memory
- CPU execute pipe is allowed to drain
 - Any load/store instructions (including **LDRF**, **STRF**, **CALL**, **RET**) currently executing are allowed to complete
 - Any instruction in the branch/call/return delay slot is allowed to complete
- The CSR[11:8]INUM field is updated with the corresponding maskable interrupt ID.
- The CSR content is copied to the SCSR.
- All architectural registers (R0-R7) and HLA registers (LSAn, LEAn, and LCNTn) are saved to the corresponding shadow registers.
- The CSR[0]GIE bit is cleared.
- The associated bit in the IFR is cleared.
- The PC value of the next instruction to execute (after completion of the interrupt service routine) is stored to the IRP register. This is the interrupt return address.
- The `cpu_iack_o` is asserted for a cycle along with the corresponding interrupt ID on `cpu_inum_o`.
- An instruction fetch request to the corresponding IST location is sent and eventually the IST entry is loaded into the PC. As a result, the CPU begins executing the corresponding interrupt service routine.

To exit a maskable service routine, the **BIRP** instruction must be used. Execution of the **BIRP** instruction causes:

- The SCSR content is copied to the CSR.
- All architectural registers (R0-R7) and HLA registers (LSAn, LEAn, and LCNTn) are restored from the corresponding shadow registers.
- The PC loaded with the contents of the IRP.

6.2.4.18.7.5 UNDEF Interrupt

An UNDEF interrupt is triggered by either of the following conditions:

- The CPU decodes an undefined/unsupported instruction, an unmapped primary opcode in instruction word 7:0. This normally happen as a result of instruction memory getting corrupted. Note that not all kinds of invalid opcodes are detected by the CPU; for example, invalid fields other than the primary opcode of a valid instruction.
- The CPU executes a **DIV/DIVU/MOD/MODU** instruction where the divisor operand (`src1`) is 0.

An UNDEF interrupt causes the UNDEF IST entry to be loaded into the PC. UNDEF interrupts are always enabled, it does not have a corresponding entry in the IFR, ICR, ISR, or IER, and is unaffected by the state of the CSR[0]GIE or IER[1]NMIE bits.

The ARP32 CPU treats an UNDEF as an irrecoverable exception. It is not possible to correctly return from an UNDEF interrupt. The only way to recover from an UNDEF interrupt is to reset the CPU.

For example, when UNDEF is caused by an invalid instruction decode, the size of (undecoded) instruction under consideration is not determined unambiguously (since the ARP32 CPU supports freely mixable 16-bit and 32-bit instructions) and hence a recoverable return address is not saved to the IRP while taking an UNDEF interrupt.

The purpose of the UNDEF interrupt is to provide just the basic detection and diagnostic mechanism when such an irrecoverable fault occurs in the system. It is software responsibility to design such an UNDEF handler such that within the UNDEF handler context (without requiring to return from the UNDEF interrupt service routine), it can do diagnostic check(s), if any, and inform the external world (for example, a host CPU) that an irrecoverable fault/exception has happened within the ARP32 CPU that cannot be handled.

It is possible an **IDLE** instruction to be used in the UNDEF interrupt service routine to hold the processor in the UNDEF service routine, for debug purposes, and avoid returning to an incorrect instruction boundary (because of incorrect return address saved to IRP/NRP) causing further UNDEF(s).

Also a manipulation of the IRP to return to some known address (after clearing all machine state correctly, for example, CSR, SCSR), for example the C entry point (`__cinit_00`) with the expectation that the CPU practically re-executes from reset with all ISA initialization done freshly by the boot code at the entry point. However, it is still just a workaround considering that the root cause of instruction memory corrupt remains uncorrected.

When an undefined instruction is decoded by the ARP32 CPU it performs the following action:

- The CSR[11:8]INUM field is updated with the UNDEF interrupt ID.
- The CSR content is copied to the SCSR.
- All architectural registers (R0-R7) and HLA registers (LSAn, LEAn, and LCNTn) are saved to the corresponding shadow registers.
- The CSR[0]GIE bit is cleared.
- The address of the next instruction (interrupt return address) to be stored to the IRP register.
- The `cpu_iack_o` is asserted for a cycle along with the corresponding interrupt ID on `cpu_inum_o`.
- An instruction fetch request to the UNDEF IST location is sent and eventually the UNDEF IST entry is loaded into the PC. As a result, the CPU begins executing the UNDEF interrupt service routine.

To exit an UNDEF service routine, the **BIRP** instruction is used. Execution of the **BIRP** instruction causes:

- The SCSR content is copied to the CSR.
- All architectural registers (R0-R7) and HLA registers (LSAn, LEAn, and LCNTn) are restored from the corresponding shadow registers.
- The PC loaded with the contents of the IRP.

However, it is not assured to result in successfully returning to a correct instruction boundary. More UNDEF may follow immediately.

6.2.4.18.8 Interrupt Context Save and Restore

The ARP32 CPU supports extensive automatic context save and restore during interrupt processing to reduce the effective interrupt latency significantly.

While processing all maskable interrupts (INT15-INT4), SWI and UNDEF, the ARP32 CPU saves off all key registers into shadow registers and during an interrupt return, via the **BIRP** instruction, restores them back:

- The Control Status Register (CSR) is saved to Shadow Control Status Register (SCSR)
- All architectural registers (R0-R7) are saved to corresponding shadow registers (SR0-SR7)
- The HLA setup registers (LSAn, LEAn, LCNTn, LCNT0RLD) are saved to the corresponding shadow registers (SLSAn, SLEAn, SLCNTn, SLCNT0RLD)

Both saving and restoring happens in a single cycle in parallel to interrupt vector fetch or the return branch execution. Also, as long as interrupt nesting is not enabled, there is absolutely no need of any additional context save (or restore) by the software at the start (or end) of the interrupt service routine. Hence, these interrupts have extremely low effective latency and are considered fast.

While processing the non-maskable interrupt (NMI), however, the CPU does not do extensive context save and restore. Only the CSR register is saved off to NMISCSR and during an NMI return, via the **BNRP** instruction, CSR is restored back. So, at the beginning of an NMI ISR, the software ensures to save off the complete CPU state to stack and restore them back before issuing a **BNRP** instruction (to accomplish a return from NMI):

- All architectural registers (R0-R7)
- The HLA setup registers (LSAn, LEAn, LCNTn, LCNT0RLD)

Thus, the interrupt behavior of the ARP32 CPU makes all maskable interrupts (INT15-INT4), SWI, and UNDEF as fast, and non-maskable interrupt (NMI) as just correct. The maskable interrupts (INT15-INT4) are used as the functional interrupt(s) of the system and the NMI are used to handle/service System Error, Exception scenarios (for example, a bus fault on program or data access).

The following example illustrates the process of context save and restore within an NMI service routine. In this example, the `NMIHandler()` is the actual software NMI handler function and a single unified stack across background and interrupt handler code is intended.

`__NonMaskableInterruptHandlerWrapper:`

```

; Save off Arch regs first
STRF    R7, R0

; Save off HLA regs
MVC     LSA0,    R0
MVC     LEA0,    R1
MVC     LCNT0,   R2
MVC     LSA1,    R3
MVC     LEA1,    R4
MVC     LCNT1,   R5
MVC     LCNT0RLD, R6
STRF    R6, R0

; Now call the actual handler function
CALL    NMIHandler
NOP

; Restore HLA regs
LDRF    R0, R6
MVC     R0, LSA0
MVC     R1, LEA0
MVC     R2, LCNT0
MVC     R3, LSA1
MVC     R4, LEA1
MVC     R5, LCNT1
MVC     R6, LCNT0RLD

; Restore Arch regs
LDRF    R0, R7

; Return from NMI ISR
BNRP
NOP

```

Note that in the example, during context restore, a write to LCNT0 also gets written to LCNT0RLD. Hence, the LCNT0RLD register is restored after LCNT0 is restored.

6.2.4.18.9 Nested Interrupts

When an interrupt (INT15–INT4, SWI, and UNDEF) is taken, the CSR[0]GIE bit is cleared by the hardware and subsequently the GIE bit is restored on interrupt return via the **BIRP** instruction. Thus all maskable interrupts (INT15–INT4) are disabled within the interrupt service routine of maskable interrupts.

Also, when an NMI is taken, the IER[1]NMIE bit is cleared by the hardware and subsequently the IER[1]NMIE bit is restored on interrupt return via the **BNRP** instruction. Thus NMI and all maskable interrupts (INT15–INT4) are disabled within the NMI service routine.

So in general, nesting of interrupts (except the case of NMI within a maskable interrupt routine) is disabled. However, under software control, it is possible that the ARP32 CPU is configured to take fully nested interrupts.

The ARP32 CPU offers two programming models with respect to usage of interrupts in a nested or non-nested manner.

6.2.4.18.9.1 Non-nested Interrupt Model

In this programming model, the CSR[0]GIE (or IER[1]NMIE) bit is not enabled within interrupts service routine of maskable interrupts (INT15–INT4), SWI, or UNDEF interrupt (or NMI). Hence, maskable interrupts (INT15–INT4), SWI, and UNDEF are not nested. However, an NMI is taken as a nested interrupt within a maskable interrupt (INT15–INT4), SWI, or UNDEF.

While adopting this programming model, the following points must be noted:

- It is the software responsibility to not use an **SWI** instruction within an ISR context. Otherwise, SWI corrupts the shadow registers and results in an unpredictable behavior.
- An UNDEF interrupts may be taken. UNDEF interrupts are irrecoverable exception and cannot be recovered from (see [Section 6.2.4.18.7.5](#))
- NMI service routine follows the procedure described in [Section 6.2.4.18.8](#). An NMIE must not be enabled within an NMI service routine as nesting of NMI itself is not supported.

Note that this programming model offers fast response time to system events via the maskable interrupt lines (INT15–INT4) by fully exploiting the extensive automatic context save/restore feature of the ARP32 CPU (see [Section 6.2.4.18.8](#)).

6.2.4.18.9.2 Nested Interrupt Model

In this programming model, the CSR[0]GIE bit is enabled within the interrupts service routine of maskable interrupts (INT15–INT4), SWI, or UNDEF interrupt. Hence, it is possible that maskable interrupts are nested. An NMI can always be taken with all other non-NMI interrupts.

Before enabling the CSR[0]GIE bit (in ISR), the software must ensure proper context save of all CPU registers onto the stack:

- Architectural registers (R0-R7)
- Shadow registers (SR0-SR7)
- Key control registers: SCSR, IRP/NRP
- Optional control register: SP, IER

While adopting this programming model, the following points must be noted:

- The SP needs to be saved, if a separate stack for the interrupt service routine is required
- IER needs to be saved, if a different interrupt mask is expected within an ISR
- Once the GIE bit is enabled, even the current interrupt (the once being serviced) becomes enabled to be re-entered. If reentrant behavior is not intended, IER must be appropriately modified after saving it off to the stack.
- NMI service routine must follow the procedure described in [Section 6.2.4.18.8](#). An NMIE must not be enabled within an NMI service routine as nesting of NMI itself is not supported. All maskable interrupts (INT15–INT4) and NMI remain disabled within an NMI service routine.

The following example illustrates the process of context save and restore within a maskable interrupt service routine. In this example, it is assumed that the `InterruptHandler()` is the actual software interrupt handler function and a single unified stack across background and interrupt handler code is intended.

`__NonMaskableInterruptHandlerWrapper:`

```

; Save off Arch regs first
STRF  R7, R0

; Save off HLA shadow regs
MVS  SLSA0, R0
MVS  SLEA0, R1
MVS  SLCNT0, R2
MVS  SLSA1, R3
MVS  SLEA1, R4
MVS  SLCNT1, R5
MVS  SLCNTORLD, R6
STRF  R6, R0

; Save off SCSR, IRP
MVC  SCSR, R0
MVC  IRP, R1
STRF  R1, R0

; Now call the actual handler function
CALL  InterruptHandler
NOP

; Restore SCSR, IRP
LDRF  R0, R1
MVC  R0, SCSR
MVC  R1, IRP

; Restore HLA shadow regs
LDRF  R0, R6
MVS  R0, SLSA0
MVS  R1, SLEA0
MVS  R2, SLCNT0
MVS  R3, SLSA1
MVS  R4, SLEA1
MVS  R5, SLCNT1
MVS  R6, SLCNTORLD

; Restore Arch regs into shadow copies
LDRF  R0, R7
MVS  R0, SR0
MVS  R0, SR1
MVS  R0, SR2
MVS  R0, SR3
MVS  R0, SR4
MVS  R0, SR5
MVS  R0, SR6
MVS  R0, SR7

; Return from NMI ISR
BIRP
NOP

```

6.2.4.18.10 Non-nested Interrupt Latency

This section describes the best and worst case interrupt latencies in the non-nested interrupt programming model (described in [Section 6.2.4.18.9.1](#)).

6.2.4.18.10.1 Best Case Interrupt Latency

In the best case (and the most frequent case), the ARP32 CPU takes an interrupt as soon as (very next cycle) it is signaled at its boundary via the `cpu_int[15-4]_i` or `cpu_nmi_i` input ports. In this case, the ARP32 CPU takes as little as 5 cycles (from the cycle when the IFR bit gets set) to start executing the first instruction of the ISR:

- **Cycle 0:** `cpu_int[15-4]_i` or `cpu_nmi_i` assertion
- **Cycle 1:** corresponding IFR bit is set, interrupt enable conditions checked, interrupt priorities resolved, a winner interrupt is selected to be taken
- **Cycle 2:** `cpu_iack_o`, `cpu_inum_o` are asserted, program read request is sent to the corresponding IST address associate with the interrupt being serviced
- **Cycle 3:** program read data (IST content) is received and is loaded to PC
- **Cycle 4:** program read request is sent to the first instruction of the ISR routine
- **Cycle 5:** first instruction of the ISR routine is decoded
- **Cycle 6:** first instruction of the ISR routine is executed

Note that the ARP32 CPU saves off all architectural registers and other required CPU registers while taking the interrupt (in cycle 1) and as a result the ISR routine does not need to have any instructions to save off the machine state. The ISR routine directly starts executing code related to actual actions to be taken to service the interrupt.

6.2.4.18.10.2 Worst Case Interrupt Latency

Under certain cases, the ARP32 CPU blocks taking an interrupt, thus introducing variable interrupt latency. The following are the worst cases:

- When a load/store multiple (**LDRF**, **STRF**) instruction is at the EXE stage of the CPU pipeline and an interrupt is asserted. The interrupt is not taken until the **LDRF/STRF** instruction is completed, which takes several (variable) cycles.

In compiler-generated code, **LDRF/STRF** is normally used as a function context save/restore across function calls; a maximum of three save-on-entry (SOE) registers as per the ARP32 CPU EABI function calling convention. Thus, three load/stores would need to finish before the CPU takes an interrupt. Moreover, if the stack pointer points to a wait-stated memory, this register save/restore takes even longer. Also, the program fetch request to the IST is stalled if the corresponding memory region is not zero-wait state, thus, increasing interrupt latency further.

- When a blocking, multicycle execute (**DIV/DIVU/MOD/MODU**) instruction is at the EXE stage of the CPU pipeline and an interrupt is asserted. The interrupt is not taken until the instruction at EXE is completed, which takes 13 (fixed) cycles.

6.2.5 Instruction Set

This section provides a description of the instruction set. Unless otherwise explicitly mentioned, all instructions are a single execute cycle instruction. All instructions that are multicycle execute are mentioned explicitly.

6.2.5.1 Instruction Operation and Execution Notations

[Table 6-36](#) explains the symbols used in the instruction Pseudo Code descriptions.

All immediate values are unsigned (zero-extended) or signed (sign-extended) to match the relevant associated operand size. For example, zero (or sign) extended to 32 bits for operations with architectural registers (32 bit in size), zero-extended to 32 bits for operation with SP (32 bits in size), and zero-extended to the width of the PC for operations with the PC.

Although the instruction set architecture (ISA) does not contain a writable program counter (PC) register, in the description of some instructions (especially in the pseudo code), a conceptual register, PC, has been used. This is to simplify the description and does not imply existence of such a physical register.

Table 6-36. Instruction Pseudo Code Notations

Symbol	Meaning
AND	bitwise AND
areg	architectural register (R0-R7)
baseR	base address register
creg	control register
dst	destination operand
GDP	global data pointer register
lmb0(x)	leftmost 0 bit search of x
lmb1(x)	leftmost 1 bit search of x
lsbn	n least-significant bits (for example, lsb32)
opn	field within opcode that specifies a unique instruction
OR	bitwise OR
PC	program counter
sat	saturate
SP	stack pointer register
src1	source operand 1
src2	source operand 2
sreg	shadow register
ucstn	n-bit unsigned immediate constant field (for example, ucst6)
XOR	bitwise exclusive-OR
+	addition
-	subtraction
x	multiplication
/	division
%	modulo
~	logical inverse
++	increment by 1
==	equal to
>	greater than
>=	greater than or equal to
<	less than
<=	less than or equal to
<<	shift left
>>	shift right
&&	logical AND

6.2.5.2 Instruction Syntax and Opcode Notations

Table 6-37 defines the syntaxes and opcode fields used in the instruction descriptions.

Table 6-37. Instruction Syntax and Opcode Notations

Symbol	Meaning
<i>areg</i>	architectural register (R0-R7)
<i>baseR</i>	base address register
<i>cc</i>	condition code (LT, GT, EQ, LE, GE, NE)
<i>creg</i>	control register
<i>dst</i>	destination
GDP	global data pointer register
<i>opn</i>	opfield; field within opcode that specifies a unique instruction
<i>scstn</i>	n-bit signed constant field
<i>sreg</i>	shadow register
SP	stack pointer register
<i>src1</i>	source 1
<i>src2</i>	source 2
<i>ucstn</i>	n-bit unsigned constant field
x	don't care

6.2.5.3 Instruction Scheduling Restrictions

The ARP32 CPU architecture places the following restrictions on instruction scheduling that must be maintained. Whereas the compiler maintains these restrictions while generating assembly code for C/C++ programs, it is the responsibility of the programmer to maintain the restrictions for codes written directly in assembly.

6.2.5.3.1 Restrictions Applicable to a Branch Delay Slot

The following restrictions are applicable for an instruction in the delay slot of a branch (**Bcc** *scst9*, **Bcc** *scst16*, or **Bcc** *dst*), call (**CALL** *scst22* or **CALL** *src1*), and return (**RET**) instruction:

- 32-bit instructions are not allowed
- Another branch/call/return is not allowed
- **IDLE** instruction is not allowed
- **SWI** instruction is not allowed
- **LDRF/STRF** instructions with more than one register operand

Also, a branch delay slot cannot be the target of any branch/call/return.

6.2.5.3.2 Restrictions on Loops Using Hardware Loop Assist (HLA)

Loops setup using the HLA mechanism (Section 6.2.4.17) are required to maintain the following restrictions:

- Minimum number of instructions in Loop 0 is 2
- Branches (**Bcc/CALL/RET** + the delay slot instruction) cannot be placed at the end of a loop. This makes the loop rewind and branch target unambiguous.
- Last two instruction of any level cannot be a multi-slot load/store multiple (**LDRF/STRF**)
- Software cannot branch (**Bcc/CALL/RET**) to the last instruction of any loop, that is, the last instruction of any loop cannot be a branch target.

6.2.5.3.3 Restrictions on Other Types of Control Flow Instructions

The following restrictions are applicable for other types of control flow instructions:

- **SWI** instruction must be followed by a **NOP**
- **BIRP/BNRP** instructions must be followed by a **NOP**

6.2.5.3.4 Restrictions for Write Data Bypass to Control Register Reads

The following restrictions are applicable for write data bypass to control register reads:

- An **MVC** instruction that writes to a control register (**MVC areg, creg**; **MVC ucst16, creg**; or **MVCH ucst16, creg**), must not be followed by an **MVC** instruction (**MVC creg, areg**) that reads the same control register.
- An **SLA** instruction that writes to a control register (**SLA ucst16, LSA_n** or **SLA ucst16, LEA_n**) must not be followed by an **MVC** instruction (**MVC creg, areg**) that reads the same control register.
- An **SLA** instruction that writes to a control register (**SLA ucst16, LSA_n** or **SLA ucst16, LEA_n**) must not be followed by an **MVCH** instruction (**MVCH creg, areg**) that reads the same control register.

6.2.5.3.5 Restrictions for Write Data Bypass to Shadow Register Reads

The following restriction is applicable for write data bypass to shadow register reads:

- There are at least two instructions separating an **MVS** instruction writing to a shadow register (**MVS areg, sreg**) and another **MVS** instruction reading the same shadow register (**MVS sreg, areg**).

6.2.5.3.6 Restrictions for Link Register Update

The following restriction is applicable for link register update:

- Link registers cannot be read or written in the delay slot of a call (**CALL scst22** or **CALL src1**) and return (**RET**) instruction.

6.2.5.4 Instruction Set Encoding

The ARP32 ISA comprises of a mix of 16-bit and 32-bit instructions. An instruction packet is defined as a 32-bit field for a 32-bit instruction and a 16-bit field for a 16-bit instruction. The instruction decoder is sent an instruction packet every cycle.

6.2.5.5 Instruction Descriptions

Table 6-38 lists the instructions for the ARP32 CPU.

Table 6-38. Instruction Summary

Instruction	Description	Size
ABS src2, dst	Absolute value of a register	16-bit
ADD ucst16, src2, dst	Add 16-bit unsigned constant to a register	32-bit
ADD ucst16, SP	Add 16-bit unsigned constant to stack pointer, result to stack pointer	32-bit
ADD ucst16, SP, dst	Add 16-bit unsigned constant to stack pointer, result to register	32-bit
ADD ucst3, src2, dst	Add 3-bit unsigned constant to a register	16-bit
ADD src1, src2, dst	Signed addition of two register values	16-bit
AND ucst16, src2, dst	Bitwise AND 16-bit unsigned constant with a register	32-bit
AND src1, src2, dst	Bitwise AND two registers	16-bit
B dst	Indirect unconditional branch using a register	16-bit
BEQ dst	Indirect conditional branch using a register	16-bit
BGE dst	Indirect conditional branch using a register	16-bit
BGT dst	Indirect conditional branch using a register	16-bit
BLE dst	Indirect conditional branch using a register	16-bit

Table 6-38. Instruction Summary (continued)

Instruction	Description	Size
BLT dst	Indirect conditional branch using a register	16-bit
BNE dst	Indirect conditional branch using a register	16-bit
B scst9	Direct unconditional branch using a 9-bit signed constant offset	16-bit
BEQ scst9	Direct conditional branch using a 9-bit signed constant offset	16-bit
BGE scst9	Direct conditional branch using a 9-bit signed constant offset	16-bit
BGT scst9	Direct conditional branch using a 9-bit signed constant offset	16-bit
BLE scst9	Direct conditional branch using a 9-bit signed constant offset	16-bit
BLT scst9	Direct conditional branch using a 9-bit signed constant offset	16-bit
BNE scst9	Direct conditional branch using a 9-bit signed constant offset	16-bit
B scst16	Direct unconditional branch using a 16-bit signed constant offset	32-bit
BEQ scst16	Direct conditional branch using a 16-bit signed constant offset	32-bit
BGE scst16	Direct conditional branch using a 16-bit signed constant offset	32-bit
BGT scst16	Direct conditional branch using a 16-bit signed constant offset	32-bit
BLE scst16	Direct conditional branch using a 16-bit signed constant offset	32-bit
BLT scst16	Direct conditional branch using a 16-bit signed constant offset	32-bit
BNE scst16	Direct conditional branch using a 16-bit signed constant offset	32-bit
BIRP	Unconditional branch to interrupt return pointer	16-bit
BKPT	Software breakpoint	16-bit
BNRP	Unconditional branch to NMI return pointer	16-bit
CALL src1	Unconditional call using a register	16-bit
CALL scst22	Unconditional call using a 22-bit signed constant offset	32-bit
CLR ucst5_1, ucst5_2, src2, dst	Clear bit field bounded by two immediate values	32-bit
CLR src1, src2, dst	Clear bit field bounded by two register values	32-bit
CMP scst16, src2	Compare for equality, less than, greater than, 16-bit signed constant to a register	32-bit
CMP scst3, src2	Compare for equality, less than, greater than, 3-bit signed constant to a register	16-bit
CMP src1, src2	Signed compare for equality, less than, greater than, two register values	16-bit
CMPU ucst16, src2	Compare for equality, less than, greater than, 16-bit unsigned constant to a register	32-bit
CMPU ucst3, src2	Compare for equality, less than, greater than, 3-bit unsigned constant to a register	16-bit
CMPU src1, src2	Unsigned compare for equality, less than, greater than, two register values	16-bit
DIV src1, src2, dst	Signed division of two register values	32-bit
DIVU src1, src2, dst	Unsigned division of two register values	32-bit
EXT ucst5_1, ucst5_2, src2, dst	Extract and sign-extend a bit field bounded by two immediate values	32-bit
EXT src1, src2, dst	Extract and sign-extend a bit field bounded by two register values	32-bit
EXTU ucst5_1, ucst5_2, src2, dst	Extract and zero-extend a bit field bounded by two immediate values	32-bit
EXTU src1, src2, dst	Extract and zero-extend a bit field bounded by two register values	32-bit
IDLE	Idle until interrupt or reset	16-bit
LDB *+baseR[ucst3], dst	Load signed byte from memory with a 3-bit unsigned constant offset	16-bit
LDB *+baseR[ucst16], dst	Load signed byte from memory with a 16-bit unsigned constant offset	32-bit
LDB *+baseR[src1], dst	Load signed byte from memory with a register offset	16-bit
LDB *baseR++[ucst3], dst	Load signed byte from memory, postincrement memory with a 3-bit unsigned constant offset	16-bit
LDB *baseR++[src1], dst	Load signed byte from memory, postincrement memory with a register offset	16-bit

Table 6-38. Instruction Summary (continued)

Instruction	Description	Size
LDB *+SP[ucst6], dst	Load signed byte from memory with a SP-relative 6-bit unsigned constant offset	16-bit
LDB *+SP[ucst19], dst	Load signed byte from memory with a SP-relative 19-bit unsigned constant offset	32-bit
LDB *+GDP[ucst19], dst	Load signed byte from memory with a GDP-relative 19-bit unsigned constant offset	32-bit
LDBU *+baseR[ucst3], dst	Load unsigned byte from memory with a 3-bit unsigned constant offset	16-bit
LDBU *+baseR[ucst16], dst	Load unsigned byte from memory with a 16-bit unsigned constant offset	32-bit
LDBU *+baseR[src1], dst	Load unsigned byte from memory with a register offset	16-bit
LDBU *baseR++[ucst3], dst	Load unsigned byte from memory, postincrement memory with a 3-bit unsigned constant offset	16-bit
LDBU *baseR++[src1], dst	Load unsigned byte from memory, postincrement memory with a register offset	16-bit
LDBU *+SP[ucst6], dst	Load unsigned byte from memory with a SP-relative 6-bit unsigned constant offset	16-bit
LDBU *+SP[ucst19], dst	Load unsigned byte from memory with a SP-relative 19-bit unsigned constant offset	32-bit
LDBU *+GDP[ucst19], dst	Load unsigned byte from memory with a GDP-relative 19-bit unsigned constant offset	32-bit
LDH *+baseR[ucst3], dst	Load signed halfword from memory with a 3-bit unsigned constant offset	16-bit
LDH *+baseR[ucst16], dst	Load signed halfword from memory with a 16-bit unsigned constant offset	32-bit
LDH *+baseR[src1], dst	Load signed halfword from memory with a register offset	16-bit
LDH *baseR++[ucst3], dst	Load signed halfword from memory, postincrement memory with a 3-bit unsigned constant offset	16-bit
LDH *baseR++[src1], dst	Load signed halfword from memory, postincrement memory with a register offset	16-bit
LDH *+SP[ucst6], dst	Load signed halfword from memory with a SP-relative 6-bit unsigned constant offset	16-bit
LDH *+SP[ucst19], dst	Load signed halfword from memory with a SP-relative 19-bit unsigned constant offset	32-bit
LDH *+GDP[ucst19], dst	Load signed halfword from memory with a GDP-relative 19-bit unsigned constant offset	32-bit
LDHU *+baseR[ucst3], dst	Load unsigned halfword from memory with a 3-bit unsigned constant offset	16-bit
LDHU *+baseR[ucst16], dst	Load unsigned halfword from memory with a 16-bit unsigned constant offset	32-bit
LDHU *+baseR[src1], dst	Load unsigned halfword from memory with a register offset	16-bit
LDHU *baseR++[ucst3], dst	Load unsigned halfword from memory, postincrement memory with a 3-bit unsigned constant offset	16-bit
LDHU *baseR++[src1], dst	Load unsigned halfword from memory, postincrement memory with a register offset	16-bit
LDHU *+SP[ucst6], dst	Load unsigned halfword from memory with a SP-relative 6-bit unsigned constant offset	16-bit
LDHU *+SP[ucst19], dst	Load unsigned halfword from memory with a SP-relative 19-bit unsigned constant offset	32-bit
LDHU *+GDP[ucst19], dst	Load unsigned halfword from memory with a GDP-relative 19-bit unsigned constant offset	32-bit
LDW *+baseR[ucst3], dst	Load word from memory with a 3-bit unsigned constant offset	16-bit
LDW *+baseR[ucst16], dst	Load word from memory with a 16-bit unsigned constant offset	32-bit
LDW *+baseR[src1], dst	Load word from memory with a register offset	16-bit
LDW *baseR++[ucst3], dst	Load word from memory, postincrement memory with a 3-bit unsigned constant offset	16-bit

Table 6-38. Instruction Summary (continued)

Instruction	Description	Size
LDW *baseR++[src1], dst	Load word from memory, postincrement memory with a register offset	16-bit
LDW *+SP[ucst6], dst	Load word from memory with a SP-relative 6-bit unsigned constant offset	16-bit
LDW *+SP[ucst19], dst	Load word from memory with a SP-relative 19-bit unsigned constant offset	32-bit
LDW *+GDP[ucst19], dst	Load word from memory with a GDP-relative 19-bit unsigned constant offset	32-bit
LDRF op1, op2	Load register file from stack pointer	16-bit
LMBD ucst3, src2, dst	Left most bit detection	32-bit
MAX src1, src2, dst	Maximum of two signed register values	32-bit
MAXU src1, src2, dst	Maximum of two unsigned register values	32-bit
MIN src1, src2, dst	Minimum of two signed register values	32-bit
MINU src1, src2, dst	Minimum of two unsigned register values	32-bit
MOD src1, src2, dst	Signed modulo ($32 \% 32 = 32$)	32-bit
MODU src1, src2, dst	Unsigned modulo ($32 \% 32 = 32$)	32-bit
MPY src1, src2, dst	Signed multiplication of two register values ($32\text{-bit} \times 32\text{-bit} = 32\text{-bit}$)	32-bit
MPYU src1, src2, dst	Unsigned multiplication of two register values ($32\text{-bit} \times 32\text{-bit} = 32\text{-bit}$)	32-bit
MV src1, dst	Move register to register	16-bit
MVC areg, creg	Move architectural register to control register	16-bit
MVC creg, areg	Move control register to architectural register	16-bit
MVC ucst16, creg	Move 16-bit unsigned constant to control register	32-bit
MVCH ucst16, creg	Move 16-bit unsigned constant to upper bits of control register	32-bit
MVK ucst16, dst	Move 16-bit unsigned constant to register	32-bit
MVKH ucst16, dst	Move 16-bit unsigned constant to upper bits of register	32-bit
MVKLS scst16, dst	Move 16-bit signed constant to register	32-bit
MVKS scst6, dst	Move 6-bit signed constant to register	16-bit
MVS areg, sreg	Move architectural register to shadow register	16-bit
MVS sreg, areg	Move shadow register to architectural register	16-bit
NEG src2, dst	Negation	16-bit
NOP	No operation	16-bit
NOT src2, dst	Bitwise NOT	16-bit
OR ucst16, src2, dst	Bitwise OR 16-bit unsigned constant with a register	32-bit
OR src1, src2, dst	Bitwise OR two registers	16-bit
RET	Return from subroutine	16-bit
REV src1, src2, dst	Reverse a bit field bounded by two register values	32-bit
ROT src1, src2, dst	Rotate right	32-bit
ROTC src1, src2, dst	Rotate right through carry bit	32-bit
SADD src1, src2, dst	Signed addition of two register values with saturation	16-bit
SATN ucst3, src2, dst	Saturation to signed/unsigned n -bit value with sign/zero extend	32-bit
SET ucst5_1, ucst5_2, src2, dst	Set bit field bounded by two immediate values	32-bit
SET src1, src2, dst	Set bit field bounded by two register values	32-bit
SHL ucst5, src2, dst	Logical shift left by 5-bit unsigned constant	32-bit
SHL src1, src2, dst	Logical shift left by register value	16-bit
SHRA ucst5, src2, dst	Arithmetic shift right by 5-bit unsigned constant	32-bit
SHRA src1, src2, dst	Arithmetic shift right by register value	16-bit
SHRU ucst5, src2, dst	Logical shift right by 5-bit unsigned constant	32-bit
SHRU src1, src2, dst	Logical shift right by register value	16-bit
SLA ucst16, creg	Set loop address	32-bit

Table 6-38. Instruction Summary (continued)

Instruction	Description	Size
SSUB src1, src2, dst	Subtraction of two register values with saturation	16-bit
STB dst, *+baseR[ucst3]	Store byte to memory with a 3-bit unsigned constant offset	16-bit
STB dst, *+baseR[ucst16]	Store byte to memory with a 16-bit unsigned constant offset	32-bit
STB dst, *+baseR[src1]	Store byte to memory with a register offset	16-bit
STB dst, *baseR++[ucst3]	Store byte to memory, postincrement memory with a 3-bit unsigned constant offset	16-bit
STB dst, *baseR++[src1]	Store byte to memory, postincrement memory with a register offset	16-bit
STB dst, *+SP[ucst6]	Store byte to memory with a SP-relative 6-bit unsigned constant offset	16-bit
STB dst, *+SP[ucst19]	Store byte to memory with a SP-relative 19-bit unsigned constant offset	32-bit
STB dst, *+GDP[ucst19]	Store byte to memory with a GDP-relative 19-bit unsigned constant offset	32-bit
STH dst, *+baseR[ucst3]	Store halfword to memory with a 3-bit unsigned constant offset	16-bit
STH dst, *+baseR[ucst16]	Store halfword to memory with a 16-bit unsigned constant offset	32-bit
STH dst, *+baseR[src1]	Store halfword to memory with a register offset	16-bit
STH dst, *baseR++[ucst3]	Store halfword to memory, postincrement memory with a 3-bit unsigned constant offset	16-bit
STH dst, *baseR++[src1]	Store halfword to memory, postincrement memory with a register offset	16-bit
STH dst, *+SP[ucst6]	Store halfword to memory with a SP-relative 6-bit unsigned constant offset	16-bit
STH dst, *+SP[ucst19]	Store halfword to memory with a SP-relative 19-bit unsigned constant offset	32-bit
STH dst, *+GDP[ucst19]	Store halfword to memory with a GDP-relative 19-bit unsigned constant offset	32-bit
STW dst, *+baseR[ucst3]	Store word to memory with a 3-bit unsigned constant offset	16-bit
STW dst, *+baseR[ucst16]	Store word to memory with a 16-bit unsigned constant offset	32-bit
STW dst, *+baseR[src1]	Store word to memory with a register offset	16-bit
STW dst, *baseR++[ucst3]	Store word to memory, postincrement memory with a 3-bit unsigned constant offset	16-bit
STW dst, *baseR++[src1]	Store word to memory, postincrement memory with a register offset	16-bit
STW dst, *+SP[ucst6]	Store word to memory with a SP-relative 6-bit unsigned constant offset	16-bit
STW dst, *+SP[ucst19]	Store word to memory with a SP-relative 19-bit unsigned constant offset	32-bit
STW dst, *+GDP[ucst19]	Store word to memory with a GDP-relative 19-bit unsigned constant offset	32-bit
STHI ucst16, *+baseR[ucst6]	Store 16-bit halfword to memory with a 6-bit unsigned constant offset	32-bit
STRF op1, op2	Store register file to stack pointer	16-bit
SUB ucst16, src2, dst	Subtract 16-bit unsigned constant from a register	32-bit
SUB ucst16, SP	Subtract 16-bit unsigned constant from stack pointer, result to stack pointer	32-bit
SUB ucst16, SP, dst	Subtract 16-bit unsigned constant from stack pointer, result to register	32-bit
SUB ucst3, src2, dst	Subtract 3-bit unsigned constant from a register	16-bit
SUB src1, src2, dst	Signed subtraction of two register values	16-bit
SWI	Software interrupt	16-bit
XOR ucst16, src2, dst	Bitwise XOR 16-bit unsigned constant with a register	32-bit
XOR src1, src2, dst	Bitwise XOR two registers	16-bit

ABS ***Absolute Value***

Syntax **ABS** *src2, dst*
 Functional unit = L

Opcode 16 bit

Description The absolute value of *src2* is placed in *dst*. Note that *src2* is considered a signed 32-bit value.

Condition Codes CSR[2]EQ = (*dst* == 0)

Pseudo Code *dst* = (*src2* < 0)? -*src2*:*src2*

ADD *Add 16-Bit Unsigned Constant to Register*
Syntax **ADD** *ucst16, src2, dst*

Functional unit = D

Opcode 32 bit

Description Addition of a 16-bit unsigned constant (*ucst16*) with *src2* and store result to *dst*.

Condition Codes

CSR[2]EQ = (dst == 0)

CSR[5]C = {carry out} from (dst + {zero extend}ucst16)

CSR[7]V = {overflow} from (dst + {zero extend}ucst16)

Note that the carry (CSR:C) and overflow (CSR:V) bits are relevant to unsigned and signed operations, respectively. Appropriate bits are checked depending on if the operands are represented (or, interpreted) as unsigned or signed numbers.

Pseudo Code
 $dst = src2 + \{zero\ extend\}ucst16$

ADD *Add 16-Bit Unsigned Constant to Stack Pointer, Result to Stack Pointer*

Syntax **ADD** *ucst16*, **SP**
 Functional unit = D

Opcode 32 bit

Description Addition of a 16-bit unsigned constant (*ucst16*) with the stack pointer (SP) and store result to SP.

Condition Codes None

Pseudo Code $SP = SP + ucst16$

ADD Add 16-Bit Unsigned Constant to Stack Pointer, Result to Register
Syntax **ADD** *ucst16*, **SP**, *dst*

Functional unit = D

Opcode 32 bit

Description Addition of a 16-bit unsigned constant (*ucst16*) with the stack pointer (**SP**) and store result to *dst*.

Condition Codes

CSR[2]EQ = (*dst* == 0)
 CSR[5]C = {carry out} from (**SP** + *ucst16*)
 CSR[7]V = {overflow} from (**SP** + *ucst16*)
 Note that the carry (CSR:C) and overflow (CSR:V) bits are relevant to unsigned and signed operations, respectively. Appropriate bits are checked depending on if the operands are represented (or, interpreted) as unsigned or signed numbers.

Pseudo Code `dst = SP + ucst16`

ADD ***Add 3-Bit Unsigned Constant to Register***

Syntax **ADD** *ucst3, src2, dst*
 Functional unit = D

Opcode 16 bit

Description Addition of a 3-bit unsigned constant (*ucst3*) with *src2* and store result to *dst*.

Condition Codes CSR[2]EQ = (*dst* == 0)
 CSR[5]C = {carry out} from (*src2* + {zero extend}*ucst3*)
 CSR[7]V = {overflow} from (*src2* + {zero extend}*ucst3*)
 Note that the carry (CSR:C) and overflow (CSR:V) bits are relevant to unsigned and signed operations, respectively. Appropriate bits are checked depending on if the operands are represented (or, interpreted) as unsigned or signed numbers.

Pseudo Code *dst* = *src2* + {zero extend}*ucst3*

ADD *Signed Addition of Two Register Values*

Syntax **ADD** *src1, src2, dst*
 Functional unit = D

Opcode 16 bit

Description Signed addition of *src1* with *src2* and store result to *dst*.

Condition Codes CSR[2]EQ = (*dst* == 0)

CSR[5]C = {carry out} from (*src2* + *src1*)

CSR[7]V = {overflow} from (*src2* + *src1*)

Note that the carry (CSR[5]C) and overflow (CSR[7]V) bits are relevant to unsigned and signed operations, respectively. Appropriate bits are checked depending on if the operands are represented (or, interpreted) as unsigned or signed numbers.

The status of the CSR[5]C bit is used to synthesize multiword (wider) addition. To synthesize a multiword addition, subsequent instructions use the CSR[5]C bit as a carry in operand, performing a normal addition if CSR[5]C == 0 and adding one more than usual if CSR[5]C == 1.

For example, if register pairs R0/R1 and R2/R3 hold 64-bit values (where R0 and R2 hold the least-significant words), the following instructions leave the 64-bit sum in the register pair R4/R5:

```

ADD   R2, R0, R4      ; R4=R2+R0, sets CSR[C]
MVC   CSR, R6         ; leaves CSR[C] untouched
EXTU  5, 5, R6, R6    ; if (CSR[C]) R6=0x1 else R6=0x0
ADD   R3, R1, R5      ; R5=R3+R1
ADD   R5, R6, R5      ; R5=R5+1 if CSR[C] was set, else R5=R5
  
```

Note that the above example needs appropriate modification in order to generate correct carry/overflow applicable for the total 64-bit result.

Pseudo Code *dst* = *src2* + *src1*

AND *Bitwise AND 16-Bit Unsigned Constant with Register*
Syntax **AND** *ucst16, src2, dst*

Functional unit = L

Opcode 32 bit

Description Bitwise AND of a zero-extended 16-bit unsigned constant (*ucst16*) with *src2* and store result to *dst*.

Condition Codes CSR:EQ = (dst == 0)

Pseudo Code `dst = src2 AND {zero extend}ucst16`

AND *Bitwise AND Two Registers*

Syntax **AND** *src1, src2, dst*
Functional unit = L

Opcode 16 bit

Description Bitwise AND of *src1* with *src2* and store result to *dst*.

Condition Codes CSR:EQ = (*dst* == 0)

Pseudo Code *dst* = *src2* AND *src1*

B(cc) *Indirect Branch Using a Register*

Syntax **B(cc) *dst***
Functional unit = D

Opcode 16 bit

Syntax	Opcode
B <i>dst</i>	00 0111 1110
BLT <i>dst</i>	01 0111 1110
BGT <i>dst</i>	10 1111 1110
BEQ <i>dst</i>	01 1111 1110
BLE <i>dst</i>	11 0111 1110
BGE <i>dst</i>	11 1111 1110
BNE <i>dst</i>	10 0111 1110

Description Performs a branch to the address specified by the *dst* register. The contents of *dst* is treated as a byte address, it is converted to a halfword address before assigning to the PC. Note that the PC always contains a halfword address.

This instruction has one delay slot. See [Section 6.2.5.3.1](#) for restrictions on scheduling an instruction in this delay slot.

For conditional branches, if the associated conditional (cc) bit is set in the control status register (CSR), the branch is taken; otherwise, the PC is incremented by 1. Valid values for **cc** are:

- <blank> = unconditional
- LT = CSR[3]LT bit is set to 1
- GT = CSR[4]GT bit is set to 1
- EQ = CSR[2]EQ bit is set to 1
- LE = CSR[3]LT and CSR:EQ bits are set to 1
- GE = CSR[4]GT and CSR:EQ bits are set to 1
- NE = CSR[2]EQ bit is cleared to 0

Condition Codes None

Pseudo Code if (cond) PC = (*dst >> 1)
else PC = PC + 1

B(cc) *Direct Branch Using a 9-Bit Signed Constant Offset*

Syntax **B(cc)** *scst9*
Functional unit = D

Opcode 16 bit

Syntax	Opcode
B <i>scst9</i>	100 1010
BLT <i>scst9</i>	100 1011
BGT <i>scst9</i>	100 1110
BEQ <i>scst9</i>	100 1100
BLE <i>scst9</i>	100 1111
BGE <i>scst9</i>	101 0000
BNE <i>scst9</i>	100 1101

Description Performs a branch to the effective address formed by the signed addition of *scst9* with the current PC value. The offset is considered as a halfword offset. Note that the PC always contains a halfword address.

This instruction has one delay slot. See [Section 6.2.5.3.1](#) for restrictions on scheduling an instruction in this delay slot.

For conditional branches, if the associated conditional (cc) bit is set in the control status register (CSR), the branch is taken; otherwise, the PC is incremented by 1. Valid values for **cc** are:

- <blank> = unconditional
- LT = CSR[3]LT bit is set to 1
- GT = CSR[4]GT bit is set to 1
- EQ = CSR[2]EQ bit is set to 1
- LE = CSR[3]LT and CSR:EQ bits are set to 1
- GE = CSR[4]GT and CSR:EQ bits are set to 1
- NE = CSR[2]EQ bit is cleared to 0

Condition Codes None

Pseudo Code

```
if (cond)      PC = (PC + scst9)
else          PC = PC + 1
```

B(cc) *Direct Branch Using a 16-Bit Signed Constant Offset*

Syntax **B(cc)** *scst16*
Functional unit = D

Opcode 32 bit

Syntax	Opcode
B <i>scst16</i>	00 1000 1001
BLT <i>scst16</i>	01 0000 1001
BGT <i>scst16</i>	10 1000 1001
BEQ <i>scst16</i>	01 1000 1001
BLE <i>scst16</i>	11 0000 1001
BGE <i>scst16</i>	11 1000 1001
BNE <i>scst16</i>	10 0000 1001

Description Performs a branch to the effective address formed by the signed addition of *scst16* with the current PC value. The offset is considered as a halfword offset. Note that the PC always contains a halfword address.

This instruction has one delay slot. See [Section 6.2.5.3.1](#) for restrictions on scheduling an instruction in this delay slot.

For conditional branches, if the associated conditional (cc) bit is set in the control status register (CSR), the branch is taken; otherwise, the PC is incremented by 1. Valid values for **cc** are:

- <blank> = unconditional
- LT = CSR[3]LT bit is set to 1
- GT = CSR[4]GT bit is set to 1
- EQ = CSR[2]EQ bit is set to 1
- LE = CSR[3]LT and CSR:EQ bits are set to 1
- GE = CSR[4]GT and CSR:EQ bits are set to 1
- NE = CSR[2]EQ bit is cleared to 0

Condition Codes None

Pseudo Code if (cond) PC = (PC + *scst16*)
else PC = PC + 1

BIRP *Branch Using an Interrupt Return Pointer*

Syntax **BIRP**
 Functional unit = D

Opcode 16 bit

Description Performs an unconditional branch to the address in the interrupt return pointer register (IRP). The content of IRP is treated as a halfword address. The shadow control status register (SCSR) content is copied back to the control status register (CSR) as a result of this instruction.

This instruction has one delay slot. Only a NOP instruction is supported in a BIRP delay slot.

Condition Codes For context restore: CSR = SCSR

Pseudo Code PC = *IRP
 CSR = SCSR, Rn = SRn, LSA_n = SL_{SA}n, LE_An = SL_{EA}n, LCNT_n = SL_{CNT}n

BKPT ***Software Breakpoint***

Syntax **BKPT**
 Functional unit = S

Opcode 16 bit

Description The **BKPT** instruction is equivalent to a single instruction endless loop. The ARP32 CPU re-fetches this same instruction again until released through the debug interface.

Condition Codes None

Pseudo Code None

BNRP ***Branch Using NMI Return Pointer***

Syntax **BNRP**
 Functional unit = D

Opcode 16 bit

Description Performs an unconditional branch to the address in the nonmaskable interrupt return pointer register (NRP). The content of NRP is treated as a halfword address. The IER1 is set to 1 upon executing this instruction. The shadow control status register (SCSR) content is copied back to the control status register (CSR) as a result of this instruction.

This instruction has one delay slot. Only a NOP instruction is supported in a BNRP delay slot.

Condition Codes For context restore: CSR = NMISCSR

Pseudo Code PC = *NRP
 CSR = NMISCSR

CALL ***Call Using a Register***

Syntax **CALL** *src1*
 Functional unit = D

Opcode 16 bit

Description Store the link register (LR) to the location pointed to by the stack pointer (SP), decrement the SP, store PC + 2 into LR, then perform an unconditional branch to the address contained in *src1*. The contents of *src1* is treated as a byte address.
 This instruction has one delay slot. See [Section 6.2.5.3.1](#) for restrictions on scheduling an instruction in this delay slot.

Condition Codes None

Pseudo Code `*(SP) = LR; SP -=4; LR = PC + 2; PC = *src1 >> 1`

CALL *Call Using a 22-Bit Signed Constant Offset*

Syntax **CALL** *scst22*
Functional unit = D

Opcode 32 bit

Description Store the link register (LR) to the location pointed to by the stack pointer (SP), decrement the SP, store PC + 3 into LR, then perform an unconditional branch to the address specified by the PC relative immediate signed halfword offset (*scst22*).

This instruction has one delay slot. See [Section 6.2.5.3.1](#) for restrictions on scheduling an instruction in this delay slot.

Condition Codes None

Pseudo Code $*(SP) = LR; SP -= 4; LR = PC + 3; PC = PC + scst22$

CLR *Clear Bit Field Bounded by Two Immediate Values*
Syntax CLR *ucst5_1, ucst5_2, src2, dst*

Functional unit = L

Opcode 32 bit

31	30	29	28	27	26	25					21	20				16	15			13	12			10	9						0			
x	x	x	x	x	x		ucst5_1					ucst5_2					dst			src2			1	1	1	0	0	0	0	0	0	0	0	0
						5					5					3			3			opcode												

Description For $ucst5_1 \geq ucst5_2$, the field in *src2* as specified by *ucst5_2* to *ucst5_1* is cleared to all 0s and the resulting value of *src2* is written to *dst*. *src2* is left unchanged. *ucst5_2* is the LSB of the field and *ucst5_1* is the MSB of the field. In other words, *ucst5_2* and *ucst5_1* represent the beginning and ending bits, respectively, of the field to be cleared to all 0s. The LSB location of *src2* is bit 0 and the MSB location of *src2* is bit 31.

Valid values of *ucst5_1* and *ucst5_2* are:

- $0 \leq ucst5_1 \leq 31$; $0 \leq ucst5_2 \leq 31$
- $ucst5_1 \geq ucst5_2$

For $ucst5_1 < ucst5_2$, the result is undefined.

In the following example, *ucst5_2* is 15 and *ucst5_1* is 23.

Condition Codes CSR:EQ = (*dst* == 0)

Pseudo Code

```

dst = src2
for( i = 0; i < 32; i++) {
    if ( i >= ucst5_2 && i <= ucst5_1) dst[i] = 0;
};

```

CLR *Clear Bit Field Bounded by Two Register Values*

Syntax CLR *src1, src2, dst*

Functional unit = L

Opcode 32 bit

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	13	12	10	9	7	6	0								
x	x	x	x	x	x	x	x	x	x	x	1	0	0	0	1	<i>dst</i>			<i>src2</i>			<i>src1</i>			0	0	0	0	1	0	0
											3			3			3			<i>opcode</i>											

Description

For $src1[9:5] \geq src1[4:0]$, the field in *src2* as specified by *src1[4:0]* to *src1[9:5]* is cleared to all 0s and the resulting value of *src2* is written to *dst*. *src2* is left unchanged. *src1[4:0]* is the LSB of the field and *src1[9:5]* is the MSB of the field. In other words, *src1[4:0]* and *src1[9:5]* represent the beginning and ending bits, respectively, of the field to be cleared to all 0s. The LSB location of *src2* is bit 0 and the MSB location of *src2* is bit 31.

Valid values of *src1[9:5]* and *src1[4:0]* are:

- $0 \leq src1[9:5] \leq 31$; $0 \leq src1[4:0] \leq 31$
- $src1[9:5] \geq src1[4:0]$

For $src1[9:5] < src1[4:0]$, the result is undefined.

In the following example, *src1[4:0]* is 15 and *src1[9:5]* is 23.

Condition Codes CSR[2]EQ = (*dst* == 0)

Pseudo Code

```
dst = src2
for( i = 0; i < 32; i++) {
  if ( i >= src1[4:0] && i <= src1[9:5]) dst[i] = 0;
};
```

CMP *Compare for Equality, Less Than, Greater Than, 16-Bit Signed Constant to Register*

Syntax **CMP** *scst16*, *src2*
 Functional unit = D

Opcode 32 bit

Description Compares *src2* to a sign-extended 16-bit constant (*scst16*). The condition bits CSR:EQ, CSR:LT, and CSR:GT are updated based on the comparison.

Condition Codes CSR[2]EQ = (*src2* == {sign extend}(*scst16*))
 CSR[3]LT = (*src2* < {sign extend}(*scst16*))
 CSR[4]GT = (*src2* > {sign extend}(*scst16*))

Pseudo Code See Condition Codes

CMP *Compare for Equality, Less Than, Greater Than, 3-Bit Signed Constant to Register*

Syntax **CMP** *scst3, src2*
Functional unit = D

Opcode 16 bit

Description Compares *src2* to a sign-extended 3-bit constant (*scst3*). The condition bits CSR:EQ, CSR:LT, and CSR:GT are updated based on the comparison.

Condition Codes

CSR[2]EQ = (*src2* == {sign extend}(*scst3*))

CSR[3]LT = (*src2* < {sign extend}(*scst3*))

CSR[4]GT = (*src2* > {sign extend}(*scst3*))

Pseudo Code See Condition Codes

CMP ***Signed Compare for Equality, Less Than, Greater Than, Two Register Values***

Syntax **CMP** *src1, src2*
 Functional unit = D

Opcode 16 bit

Description Compares *src2* to *src1*. The condition bits CSR:EQ, CSR:LT, and CSR:GT are updated based on the comparison.

Condition Codes CSR[2]EQ = (*src2* == *src1*)
 CSR[3]LT = (*src2* < *src1*)
 CSR[4]GT = (*src2* > *src1*)

Pseudo Code See Condition Codes

CMPU *Compare for Equality, Less Than, Greater Than, 16-Bit Unsigned Constant to Register*

Syntax **CMPU** *ucst16, src2*
Functional unit = D

Opcode 32 bit

Description Compares *src2* to a zero-extended 16-bit constant (*ucst16*). The condition bits CSR:EQ, CSR:LT, and CSR:GT are updated based on the comparison. This is an unsigned comparison.

Condition Codes CSR[2]EQ = (*src2* == {zero extend}(*ucst16*))
CSR[3]LT = (*src2* < {zero extend}(*ucst16*))
CSR[4]GT = (*src2* > {zero extend}(*ucst16*))

Pseudo Code See Condition Codes

CMPU **Compare for Equality, Less Than, Greater Than, 3-Bit Unsigned Constant to Register**

Syntax **CMPU** *ucst3*, *src2*
 Functional unit = D

Opcode 16 bit

Description Compares *src2* to a zero-extended 3-bit constant (*ucst3*). The condition bits CSR:EQ, CSR:LT, and CSR:GT are updated based on the comparison. This is an unsigned comparison.

Condition Codes CSR[2]EQ = (*src2* == {zero extend}(*ucst3*))
 CSR[3]LT = (*src2* < {zero extend}(*ucst3*))
 CSR[4]GT = (*src2* > {zero extend}(*ucst3*))

Pseudo Code See Condition Codes

CMPU ***Unsigned Compare for Equality, Less Than, Greater Than, Two Register Values***

Syntax **CMPU** *src1, src2*
 Functional unit = D

Opcode 16 bit

Description Compares *src2* to *src1*. The condition bits CSR:EQ, CSR:LT, and CSR:GT are updated based on the comparison. This is an unsigned comparison.

Condition Codes CSR[2]EQ = (*src2* == *src1*)
 CSR[3]LT = (*src2* < *src1*)
 CSR[4]GT = (*src2* > *src1*)

Pseudo Code See Condition Codes

DIV *Signed Division of Two Register Values*

Syntax **DIV** *src1, src2, dst*
 Functional unit = M

Opcode 32 bit

Description Signed division of *src1* and *src2* and store result to *dst*. Divide by 0 raises UNDEF interrupt, *dst* is written with 0, CSR:EQ gets set.

Using **DIV** (integer division) and **SHRA** (arithmetic right shift) does not produce the same result for negative numbers. The quotient of **DIV** is rounded towards zero, whereas the quotient of **SHRA** is rounded towards negative infinity. For example, using the **DIV** instruction: $-9/4 = -2$, whereas using the **SHRA** instruction: $-9/4 = -3$.

Condition Codes CSR:EQ = (*dst* == 0)

Pseudo Code $dst = src2 / src1$

Cycles 14 execute cycles. This is a blocking multi-execute cycle instruction.

DIVU *Unsigned Division of Two Register Values*

Syntax **DIVU** *src1, src2, dst*
 Functional unit = M

Opcode 32 bit

Description Unsigned division of *src1* and *src2* and store result to *dst*. Divide by 0 raises UNDEF interrupt, *dst* is written with 0, CSR:EQ gets set.

Condition Codes CSR[2]EQ = (*dst* == 0)

Pseudo Code *dst* = *src2* / *src1*

Cycles 14 execute cycles. This is a blocking multi-execute cycle instruction.

EXT *Extract and Sign-Extend a Bit Field Bounded by Two Immediate Values*

Syntax `EXT ucst5_1, ucst5_2, src2, dst`
Functional unit = L

Opcode 32 bit

Description

For $ucst5_1 \geq ucst5_2$, the field in *src2* as specified by *ucst5_2* to *ucst5_1* is extracted and sign-extended to 32 bits and is written to *dst*. *src2* is left unchanged. *ucst5_2* is the LSB of the field and *ucst5_1* is the MSB of the field to be extracted. In other words, *ucst5_2* and *ucst5_1* represent the beginning and ending bits, respectively, of the field to be extracted. The LSB location of *src2* is bit 0 and the MSB location of *src2* is bit 31.

Valid values of *ucst5_1* and *ucst5_2* are:

- $0 \leq ucst5_1 \leq 31; 0 \leq ucst5_2 \leq 31$
- $ucst5_1 \geq ucst5_2$

For $ucst5_1 < ucst5_2$, the result is undefined.

In the following example, *ucst5_2* is 11 and *ucst5_1* is 19.

Condition Codes CSR:EQ = (dst == 0)

Pseudo Code

```

tmpdst = 0; j = 0;
for( i = 0; i < 32; i++) {
    if ( i >= ucst5_2 && i <= ucst5_1) tmpdst[j++] = src2[i];
};
dst = tmpdst[j] ? signext(tmpdst) : tmpdst ;

```

EXTU *Extract and Zero-Extend a Bit Field Bounded by Two Immediate Values*
Syntax `EXTU ucst5_1, ucst5_2, src2, dst`

Functional unit = L

Opcode 32 bit

31	30	29	28	27	26	25					21	20																						0		
x	x	x	x	x	x	x	ucst5_1					ucst5_2					dst			src2			1	0	1	0	0	0	0	0	0	0	0	0	0	0
						5					5					3			3			opcode														

Description

For $ucst5_1 \geq ucst5_2$, the field in *src2* as specified by *ucst5_2* to *ucst5_1* is extracted and zero-extended to 32 bits and is written to *dst*. *src2* is left unchanged. *ucst5_2* is the LSB of the field and *ucst5_1* is the MSB of the field to be extracted. In other words, *ucst5_2* and *ucst5_1* represent the beginning and ending bits, respectively, of the field to be extracted. The LSB location of *src2* is bit 0 and the MSB location of *src2* is bit 31.

Valid values of *ucst5_1* and *ucst5_2* are:

- $0 \leq ucst5_1 \leq 31; 0 \leq ucst5_2 \leq 31$
- $ucst5_1 \geq ucst5_2$

For $ucst5_1 < ucst5_2$, the result is undefined.

In the following example, *ucst5_2* is 11 and *ucst5_1* is 19.

Condition Codes CSR[2]EQ = (dst == 0)

Pseudo Code

```

tmpdst = 0; j = 0;
for( i = 0; i < 32; i++) {
  if ( i >= ucst5_2 && i <= ucst5_1) tmpdst[j++] = src2[i];
};
dst = tmpdst ;

```

EXTU *Extract and Zero-Extend a Bit Field Bounded by Two Register Values*

Syntax **EXTU** *src1, src2, dst*

Functional unit = L

Opcode 32 bit

31	30	29	28	27	26	25	24	23	22	21	20	16	15	13	12	10	9	7	6	0											
x	x	x	x	x	x	x	x	x	x	x	1	0	0	1	1	<i>dst</i>			<i>src2</i>			<i>src1</i>			0	0	0	0	1	0	0
												3			3			3			<i>opcode</i>										

Description

For $src1[9:5] \geq src1[4:0]$, the field in *src2* as specified by $src1[4:0]$ to $src1[9:5]$ is extracted and zero-extended to 32 bits and is written to *dst*. *src2* is left unchanged. $src1[4:0]$ is the LSB of the field and $src1[9:5]$ is the MSB of the field to be extracted. In other words, $src1[4:0]$ and $src1[9:5]$ represent the beginning and ending bits, respectively, of the field to be extracted. The LSB location of *src2* is bit 0 and the MSB location of *src2* is bit 31.

Valid values of $src1[9:5]$ and $src1[4:0]$ are:

- $0 \leq src1[9:5] \leq 31$; $0 \leq src1[4:0] \leq 31$
- $src1[9:5] \geq src1[4:0]$

For $src1[9:5] < src1[4:0]$, the result is undefined.

In the following example, $src1[4:0]$ is 11 and $src1[9:5]$ is 19.

Condition Codes CSR:EQ = (dst == 0)

Pseudo Code

```
tmpdst = 0; j = 0;
for( i = 0; i < 32; i++) {
    if ( i >= src1[4:0] && i <= src1[9:5]) tmpdst[j++] = src2[i];
};
dst = tmpdst ;
```

IDLE *Idle Until Interrupt or Reset*

Syntax **IDLE**
Functional unit = S

Opcode 16 bit

15	14	13	12	11	10	9									0
x	x	x	x	x	x	1	1	0	1	1	1	1	1	1	1

opcode

Description The **IDLE** instruction causes the CPU to wait for all pending instruction and data memory transactions to complete and then go to an idle state. The idle state is the equivalent of an endless loop. Termination of this loop occurs on an interrupt or reset. However, the CPU does not actually continue fetch/executing any actual instructions. On acceptance of an interrupt, PC + 1 is stored into the interrupt return pointer register (IRP), subsequent instruction execution after return from the interrupt begins at the instruction following the **IDLE** instruction.

For more details on usage of IDLE instruction, see [Section 6.2.6.3](#).

Pseudo Code None

LDB(U) *Load Byte from Memory with a 3-Bit Unsigned Constant Offset*

Syntax **LDB** **+baseR[ucst3], dst*
 or
LDBU **+baseR[ucst3], dst*
 Functional unit = D

Opcode 16 bit

Syntax	Opcode	Load Type
LDB <i>*+baseR[ucst3], dst</i>	101 1010	Load byte (sign-extended)
LDBU <i>*+baseR[ucst3], dst</i>	101 1000	Load byte unsigned (zero-extended)

Description Loads a byte (signed or unsigned) from memory (effective address) to *dst*. The memory address is formed from a base address register (*baseR*) and an offset (number of bytes) that is a 3-bit unsigned constant (*ucst3*). If an offset is not given, the assembler assigns an offset of zero. There must be brackets, [], around the specified offset, if using the optional offset parameter.

The square brackets, [], indicate that the *ucst3* is scaled by a left-shift of 0 bits. After scaling, *ucst3* is added to *baseR*. The result of the calculation is the effective address to be accessed in memory and the content loaded into *dst*.

The content is loaded into the 8 LSBs of *dst*. For the **LDB** instruction, the upper 24 bits of *dst* are sign-extended; for the **LDBU** instruction, the upper 24 bits of *dst* are zero-extended.

Condition Codes None

Pseudo Code $dst = *(baseR[ucst3])$

LDB(U) *Load Byte from Memory with a 16-Bit Unsigned Constant Offset*

Syntax **LDB** **+baseR[ucst16], dst*
or
LDBU **+baseR[ucst16], dst*
Functional unit = D

Opcode 32 bit

Syntax	Opcode	Load Type
LDB <i>*+baseR[ucst16], dst</i>	01 0000 1000	Load byte (sign-extended)
LDBU <i>*+baseR[ucst16], dst</i>	00 0000 1000	Load byte unsigned (zero-extended)

Description Loads a byte (signed or unsigned) from memory (effective address) to *dst*. The memory address is formed from a base address register (*baseR*) and an offset (number of bytes) that is a 16-bit unsigned constant (*ucst16*). If an offset is not given, the assembler assigns an offset of zero. Brackets, [], must surround the specified offset, if using the optional offset parameter.

The square brackets, [], indicate that the *ucst16* is scaled by a left-shift of 0 bits. After scaling, *ucst16* is added to *baseR*. The result of the calculation is the effective address to be accessed in memory and the content loaded into *dst*.

The content is loaded into the 8 LSBs of *dst*. For the **LDB** instruction, the upper 24 bits of *dst* are sign-extended; for the **LDBU** instruction, the upper 24 bits of *dst* are zero-extended.

Condition Codes None

Pseudo Code *dst = *(baseR[ucst16])*

LDB(U) *Load Byte from Memory with a Register Offset*

Syntax **LDB** **+baseR[src1], dst*
or
LDBU **+baseR[src1], dst*
Functional unit = D

Opcode 16 bit

Syntax	Opcode	Load Type
LDB <i>*+baseR[src1], dst</i>	101 0101	Load byte (sign-extended)
LDBU <i>*+baseR[src1], dst</i>	101 0011	Load byte unsigned (zero-extended)

Description Loads a byte (signed or unsigned) from memory (effective address) to *dst*. The memory address is formed from a base address register (*baseR*) and an offset (number of bytes) that is a register (*src1*). If an offset is not given, the assembler assigns an offset of zero. Brackets, [], must surround the specified offset, if using the optional offset parameter.

The square brackets, [], indicate that the *src1* is scaled by a left-shift of 0 bits. After scaling, *src1* is added to *baseR*. The result of the calculation is the effective address to be accessed in memory and the content loaded into *dst*.

The content is loaded into the 8 LSBs of *dst*. For the **LDB** instruction, the upper 24 bits of *dst* are sign-extended; for the **LDBU** instruction, the upper 24 bits of *dst* are zero-extended.

Condition Codes None

Pseudo Code `dst = *(baseR[src1])`

LDB(U) ***Load Byte from Memory, Postincrement with a 3-Bit Unsigned Constant Offset***

LDBU <i>*+SP[ucst6], dst</i>	110 0111	Load byte unsigned (zero-extended)

Description Loads a byte (signed or unsigned) from memory (effective address) to *dst*. The memory address is formed from the stack pointer (SP) and an offset (number of bytes) that is a 6-bit unsigned constant (*ucst6*). If an offset is not given, the assembler assigns an offset of zero. Brackets, [], must surround the specified offset, if using the optional offset parameter.

The square brackets, [], indicate that the *ucst6* is scaled by a left-shift of 0 bits. After scaling, *ucst6* is added to SP. The result of the calculation is the effective address to be accessed in memory and the content loaded into *dst*.

The content is loaded into the 8 LSBs of *dst*. For the **LDB** instruction, the upper 24 bits of *dst* are sign-extended; for the **LDBU** instruction, the upper 24 bits of *dst* are zero-extended.

Condition Codes None

Pseudo Code *dst = *(SP[ucst6])*

LDB(U) *Load Byte from Memory with a SP-Relative 19-Bit Unsigned Constant Offset*

Syntax **LDB** **+SP[ucst19], dst*
or
LDBU **+SP[ucst19], dst*
Functional unit = D

Opcode 32 bit

Syntax	Opcode	Load Type
LDB <i>*+SP[ucst19], dst</i>	01 0000 0111	Load byte (sign-extended)
LDBU <i>*+SP[ucst19], dst</i>	00 0000 0111	Load byte unsigned (zero-extended)

Description

Loads a byte (signed or unsigned) from memory (effective address) to *dst*. The memory address is formed from the stack pointer (SP) and an offset (number of bytes) that is a 19-bit unsigned constant (*ucst19*). If an offset is not given, the assembler assigns an offset of zero. Brackets, [], must surround the specified offset, if using the optional offset parameter.

The square brackets, [], indicate that the *ucst19* is scaled by a left-shift of 0 bits. After scaling, *ucst19* is added to SP. The result of the calculation is the effective address to be accessed in memory and the content loaded into *dst*.

The content is loaded into the 8 LSBs of *dst*. For the **LDB** instruction, the upper 24 bits of *dst* are sign-extended; for the **LDBU** instruction, the upper 24 bits of *dst* are zero-extended.

Condition Codes None

Pseudo Code `dst = *(SP[ucst19])`

LDB(U) **Load Byte from Memory with a GDP-Relative 19-Bit Unsigned Constant Offset**

Syntax **LDB** *****+GDP[*ucst19*], *dst*
or
LDBU *****+GDP[*ucst19*], *dst*
Functional unit = D

Opcode 32 bit

Syntax	Opcode	Load Type
LDB * +GDP[<i>ucst19</i>], <i>dst</i>	01 0000 0110	Load byte (sign-extended)
LDBU * +GDP[<i>ucst19</i>], <i>dst</i>	00 0000 0110	Load byte unsigned (zero-extended)

Description Loads a byte (signed or unsigned) from memory (effective address) to *dst*. The memory address is formed from the global data pointer register (GDP) and an offset (number of bytes) that is a 19-bit unsigned constant (*ucst19*). If an offset is not given, the assembler assigns an offset of zero. Brackets, [], must surround the specified offset, if using the optional offset parameter.

The square brackets, [], indicate that the *ucst19* is scaled by a left-shift of 0 bits. After scaling, *ucst19* is added to GDP. The result of the calculation is the effective address to be accessed in memory and the content loaded into *dst*.

The content is loaded into the 8 LSBs of *dst*. For the **LDB** instruction, the upper 24 bits of *dst* are sign-extended; for the **LDBU** instruction, the upper 24 bits of *dst* are zero-extended.

Condition Codes None

Pseudo Code *dst* = *(GDP[*ucst19*])

LDH(U) ***Load Halfword from Memory with a 3-Bit Unsigned Constant Offset***

Syntax **LDH** **+baseR[ucst3], dst*
or
LDHU **+baseR[ucst3], dst*
Functional unit = D

Opcode 16 bit

Syntax	Opcode	Load Type
LDH <i>*+baseR[ucst3], dst</i>	101 1011	Load halfword (sign-extended)
LDHU <i>*+baseR[ucst3], dst</i>	101 1001	Load halfword unsigned (zero-extended)

Description Loads a halfword (signed or unsigned) from memory (effective address) to *dst*. The memory address is formed from a base address register (*baseR*) and an offset (number of halfwords) that is a 3-bit unsigned constant (*ucst3*). If an offset is not given, the assembler assigns an offset of zero. Brackets, [], must surround the specified offset, if using the optional offset parameter.

The square brackets, [], indicate that the *ucst3* is scaled by a left-shift of 1 bit. After scaling, *ucst3* is added to *baseR*. The result of the calculation is the effective address to be accessed in memory and the content loaded into *dst*.

The content is loaded into the 16 LSBs of *dst*. For the **LDH** instruction, the upper 16 bits of *dst* are sign-extended; for the **LDHU** instruction, the upper 16 bits of *dst* are zero-extended.

Halfword addresses must be aligned on halfword (LSB is 0) boundaries.

Condition Codes None

Pseudo Code `dst = *(baseR[ucst3])`

LDH(U) *Load Halfword from Memory with a 16-Bit Unsigned Constant Offset*

Syntax **LDH** **+baseR[ucst16], dst*

LDH <i>*+SP[ucst19], dst</i>	01 1000 0111	Load halfword (sign-extended)
LDHU <i>*+SP[ucst19], dst</i>	00 1000 0111	Load halfword unsigned (zero-extended)

Description Loads a halfword (signed or unsigned) from memory (effective address) to *dst*. The memory address is formed from the stack pointer (SP) and an offset (number of halfwords) that is a 19-bit unsigned constant (*ucst19*). If an offset is not given, the assembler assigns an offset of zero. Brackets, [], must surround the specified offset, if using the optional offset parameter.

The square brackets, [], indicate that the *ucst19* is scaled by a left-shift of 1 bit. After scaling, *ucst19* is added to SP. The result of the calculation is the effective address to be accessed in memory and the content loaded into *dst*.

The content is loaded into the 16 LSBs of *dst*. For the **LDH** instruction, the upper 16 bits of *dst* are sign-extended; for the **LDHU** instruction, the upper 16 bits of *dst* are zero-extended.

Halfword addresses must be aligned on halfword (LSB is 0) boundaries.

Condition Codes None

Pseudo Code `dst = *(SP[ucst19])`

LDH(U) ***Load Halfword from Memory with a GDP-Relative 19-Bit Unsigned Constant Offset***

Syntax **LDH** *****+GDP[*ucst19*], *dst*
or
LDHU *****+GDP[*ucst19*], *dst*
Functional unit = D

Opcode 32 bit

Syntax	Opcode	Load Type
LDH * +GDP[<i>ucst19</i>], <i>dst</i>	01 1000 0110	Load halfword (sign-extended)
LDHU * +GDP[<i>ucst19</i>], <i>dst</i>	00 1000 0110	Load halfword unsigned (zero-extended)

Description Loads a halfword (signed or unsigned) from memory (effective address) to *dst*. The memory address is formed from the global data pointer register (GDP) and an offset (number of halfwords) that is a 19-bit unsigned constant (*ucst19*). If an offset is not given, the assembler assigns an offset of zero. Brackets, [], must surround the specified offset, if using the optional offset parameter.

The square brackets, [], indicate that the *ucst19* is scaled by a left-shift of 1 bit. After scaling, *ucst19* is added to GDP. The result of the calculation is the effective address to be accessed in memory and the content loaded into *dst*.

The content is loaded into the 16 LSBs of *dst*. For the **LDH** instruction, the upper 16 bits of *dst* are sign-extended; for the **LDHU** instruction, the upper 16 bits of *dst* are zero-extended.

Halfword addresses must be aligned on halfword (LSB is 0) boundaries.

Condition Codes None

Pseudo Code *dst* = *(GDP[*ucst19*])

LDW *Load Word from Memory with a 3-Bit Unsigned Constant Offset*
Syntax `LDW *+baseR[ucst3], dst`

Functional unit = D

Opcode 16 bit

Description

Loads a word from memory (effective address) to *dst*. The memory address is formed from a base address register (*baseR*) and an offset (number of words) that is a 3-bit unsigned constant (*ucst3*). If an offset is not given, the assembler assigns an offset of zero. Brackets, [], must surround the specified offset, if using the optional offset parameter.

The square brackets, [], indicate that the *ucst3* is scaled by a left-shift of 2 bits. After scaling, *ucst3* is added to *baseR*. The result of the calculation is the effective address to be accessed in memory and the content loaded into *dst*.

The entire content is loaded into *dst*.

Word addresses must be aligned on word (two LSBs are 0) boundaries.

Condition Codes None

Pseudo Code `dst = *(baseR[ucst3])`

LDW ***Load Word from Memory with a 16-Bit Unsigned Constant Offset***

Syntax **LDW** **+baseR[ucst16], dst*
 Functional unit = D

Opcode 32 bit

Description Loads a word from memory (effective address) to *dst*. The memory address is formed from a base address register (*baseR*) and an offset (number of words) that is a 16-bit unsigned constant (*ucst16*). If an offset is not given, the assembler assigns an offset of zero. Brackets, [], must surround the specified offset, if using the optional offset parameter.

The square brackets, [], indicate that the *ucst16* is scaled by a left-shift of 2 bits. After scaling, *ucst16* is added to *baseR*. The result of the calculation is the effective address to be accessed in memory and the content loaded into *dst*.

The entire content is loaded into *dst*.

Word addresses must be aligned on word (two LSBs are 0) boundaries.

Condition Codes None

Pseudo Code `dst = *(baseR[ucst16])`

LDW *Load Word from Memory with a Register Offset*

Syntax **LDW** **+baseR[src1], dst*
 Functional unit = D

Opcode 16 bit

Description Loads a word from memory (effective address) to *dst*. The memory address is formed from a base address register (*baseR*) and an offset (number of words) that is a register (*src1*). If an offset is not given, the assembler assigns an offset of zero. Brackets, [], must surround the specified offset, if using the optional offset parameter.

The square brackets, [], indicate that the *src1* is scaled by a left-shift of 2 bits. After scaling, *src1* is added to *baseR*. The result of the calculation is the effective address to be accessed in memory and the content loaded into *dst*.

The entire content is loaded into *dst*.

Word addresses must be aligned on word (two LSBs are 0) boundaries.

Condition Codes None

Pseudo Code `dst = *(baseR[src1])`

LDW ***Load Word from Memory, Postincrement with a 3-Bit Unsigned Constant Offset***
Syntax **LDW** **baseR++[ucst3], dst*

Functional unit = D

Opcode 16 bit

Description Loads a word from memory (effective address) to *dst*. The value of *baseR* is the effective address to be accessed in memory and the content loaded into *dst*. After accessing, an offset (number of words) that is a 3-bit unsigned constant (*ucst3*) is added to *baseR* at the end of the EXE phase. Brackets, [], must surround the specified offset, if using the optional offset parameter.

The entire content is loaded into *dst*.

Word addresses must be aligned on word (two LSBs are 0) boundaries.

Condition Codes None

Pseudo Code `dst = *(baseR++[ucst3])`

LDW *Load Word from Memory, Postincrement with a Register Offset*

Syntax **LDW** **baseR++[src1], dst*
Functional unit = D

Opcode 16 bit

Description Loads a word from memory (effective address) to *dst*. The value of *baseR* is the effective address to be accessed in memory and the content loaded into *dst*. After accessing, an offset (number of words) that is a register (*src1*) is added to *baseR* at the end of the EXE phase. Brackets, [], must surround the specified offset, if using the optional offset parameter.

The entire content is loaded into *dst*.

Word addresses must be aligned on word (two LSBs are 0) boundaries.

Condition Codes None

Pseudo Code `dst = *(baseR++[src1])`

LDW ***Load Word from Memory with a SP-Relative 6-Bit Unsigned Constant Offset***

Syntax **LDW** *****+SP[*ucst6*], *dst*

Functional unit = D

Opcode 16 bit

Description

Loads a word from memory (effective address) to *dst*. The memory address is formed from the stack pointer (SP) and an offset (number of words) that is a 6-bit unsigned constant (*ucst6*). If an offset is not given, the assembler assigns an offset of zero. Brackets, [], must surround the specified offset, if using the optional offset parameter.

The square brackets, [], indicate that the *ucst6* is scaled by a left-shift of 2 bits. After scaling, *ucst6* is added to SP. The result of the calculation is the effective address to be accessed in memory and the content loaded into *dst*.

The entire content is loaded into *dst*.

Word addresses must be aligned on word (two LSBs are 0) boundaries.

Condition Codes None

Pseudo Code *dst* = *(SP[*ucst6*])

LDW *Load Word from Memory with a SP-Relative 19-Bit Unsigned Constant Offset*
Syntax **LDW** **+SP[ucst19], dst*

Functional unit = D

Opcode 32 bit

Description

Loads a word from memory (effective address) to *dst*. The memory address is formed from the stack pointer (SP) and an offset (number of words) that is a 19-bit unsigned constant (*ucst19*). If an offset is not given, the assembler assigns an offset of zero. Brackets, [], must surround the specified offset, if using the optional offset parameter.

The square brackets, [], indicate that the *ucst19* is scaled by a left-shift of 2 bits. After scaling, *ucst19* is added to SP. The result of the calculation is the effective address to be accessed in memory and the content loaded into *dst*.

The entire content is loaded into *dst*.

Word addresses must be aligned on word (two LSBs are 0) boundaries.

Condition Codes None

Pseudo Code `dst = *(SP[ucst19])`

LDW *Load Word from Memory with a GDP-Relative 19-Bit Unsigned Constant Offset*

Syntax **LDW** **+GDP[ucst19], dst*
 Functional unit = D

Opcode 32 bit

Description Loads a word from memory (effective address) to *dst*. The memory address is formed from the global data pointer register (GDP) and an offset (number of words) that is a 19-bit unsigned constant (*ucst19*). If an offset is not given, the assembler assigns an offset of zero. Brackets, [], must surround the specified offset, if using the optional offset parameter.

The square brackets, [], indicate that the *ucst19* is scaled by a left-shift of 2 bits. After scaling, *ucst19* is added to GDP. The result of the calculation is the effective address to be accessed in memory and the content loaded into *dst*.

The entire content is loaded into *dst*.

Word addresses must be aligned on word (two LSBs are 0) boundaries.

Condition Codes None

Pseudo Code `dst = *(GDP[ucst19])`

LDRF ***Load Register File from Stack Pointer***

Syntax **LDRF** *op1*, *op2*
 Functional unit = D

Opcode 16 bit

Description The current base register file is loaded from the starting address specified by the preincremented value of the stack pointer (SP). *op1* specifies the ending register (last register loaded) and *op2* specifies the beginning register (first register loaded). All registers between *op1* and *op2* are loaded inclusive. The registers are loaded in order from highest register (*op2*) to lowest register (*op1*).

Valid values of *op1* and *op2* are: $op1 \leq op2$

For $op1 > op2$, results in unspecified behavior.

This is a multicycle blocking instruction. The number of cycles is determined by the registers, for example, **LDRF** R0, R5 requires 6 cycles to complete.

Condition Codes None

Pseudo Code

```
for ( i = op2; i <= op1 ; i-- ) {
  SP += 4;
  Ri = *SP;
}
```

LMBD *Left Most Bit Detection*
Syntax `LMBD ucst3, src2, dst`

Functional unit = L

Opcode 32 bit

Description The LSB of *ucst3* determines whether to search for a leftmost 1 or 0 in *src2*. The number of bits to the left of the first 1 or 0 when searching for a 1 or 0, respectively, is placed in *dst*.

- *ucst3* = 0, searches for leftmost 0 (count leading ones)
- *ucst3* = 1, searches for leftmost 1 (count leading zeros)
- Other values of *ucst3* are reserved. The result is undefined if reserved values are used.

 The following diagrams illustrate the operation of **LMBD** for several cases.

 When searching for 0 in *src2*, **LMBD** returns 0:

 When searching for 1 in *src2*, **LMBD** returns 4:

 When searching for 0 in *src2*, **LMBD** returns 32:

Condition Codes CSR:EQ = (dst == 0)

Pseudo Code

```
dst = if (ucst3 == 0), lmb0(src2)
dst = if (ucst3 == 1), lmb1(src2)
```

MAX *Maximum of Two Signed Register Values*
Syntax **MAX** *src1, src2, dst*

Functional unit = L

Opcode 32 bit

Description Performs a maximum operation on the signed values in *src1* and *src2*. The larger value is loaded in *dst*.

Condition Codes CSR:EQ = (*dst* == 0)

Pseudo Code $dst = (src2 > src1) ? src2 : src1$

MAXU *Maximum of Two Unsigned Register Values*
Syntax **MAXU** *src1, src2, dst*

Functional unit = L

Opcode 32 bit

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	13	12	10	9	7	6	0								
x	x	x	x	x	x	x	x	x	x	x	1	1	0	1	0	<i>dst</i>			<i>src2</i>			<i>src1</i>			0	0	0	0	1	0	0
																3			3			3			opcode						

Description Performs a maximum operation on the unsigned values in *src1* and *src2*. The larger value is loaded in *dst*.

Condition Codes CSR:EQ = (*dst* == 0)

Pseudo Code $dst = (src2 > src1) ? src2 : src1$

MIN *Minimum of Two Signed Register Values*

Syntax **MIN** *src1, src2, dst*
 Functional unit = L

Opcode 32 bit

Description Performs a minimum operation on the signed values in *src1* and *src2*. The smaller value is loaded in *dst*.

Condition Codes CSR:EQ = (*dst* == 0)

Pseudo Code *dst* = (*src2* < *src1*) ? *src2*:*src1*

MINU *Minimum of Two Unsigned Register Values*
Syntax **MINU** *src1, src2, dst*

Functional unit = L

Opcode 32 bit

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	13	12	10	9	7	6	0								
x	x	x	x	x	x	x	x	x	x	x	1	1	0	0	1	<i>dst</i>			<i>src2</i>			<i>src1</i>			0	0	0	0	1	0	0
																3			3			3			<i>opcode</i>						

Description Performs a minimum operation on the unsigned values in *src1* and *src2*. The smaller value is loaded in *dst*.

Condition Codes CSR:EQ = (dst == 0)

Pseudo Code $dst = (src2 < src1) ? src2 : src1$

MOD *Signed Modulo*

Syntax **MOD** *src1, src2, dst*
 Functional unit = M

Opcode 32 bit

Description Performs a signed modulo on the values in *src1* and *src2* and the resulting value is written to *dst*. Sign of the result is the same as *src2* (the dividend). *src1* = 0 (that is, a modulo 0 case), raises the UNDEF interrupt, *dst* is written with 0, and CSR:EQ is set.

Condition Codes CSR:EQ = (*dst* == 0)

Pseudo Code *dst* = *src2* % *src1*

Cycles 14 execute cycles. This is a blocking multi-execute cycle instruction.

MODU *Unsigned Modulo*
Syntax **MODU** *src1, src2, dst*

Functional unit = M

Opcode 32 bit

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	13	12	10	9	7	6	0								
x	x	x	x	x	x	x	x	x	x	x	0	1	1	1	0	<i>dst</i>			<i>src2</i>			<i>src1</i>			0	0	0	0	1	0	1
																3			3			3			<i>opcode</i>						

Description Performs an unsigned modulo on the values in *src1* and *src2* and the resulting value is written to *dst*. *src1* = 0 (that is, a modulo 0 case), raises the UNDEF interrupt, *dst* is written with 0, and CSR:EQ is set.

Condition Codes CSR:EQ = (*dst* == 0)

Pseudo Code $dst = src2 \% src1$

Cycles 14 execute cycles. This is a blocking multi-execute cycle instruction.

MPY *Signed Multiplication of Two Register Values*

Syntax **MPY** *src1, src2, dst*
 Functional unit = M

Opcode 32 bit

Description Performs a multiply on the signed values in *src1* and *src2*. Only the 32 least-significant bits of the result are retained and written to *dst*.

Condition Codes CSR:EQ = (dst == 0)

Pseudo Code `dst = lsb32(src2 × src1)`

MPYU ***Unsigned Multiplication of Two Register Values***
Syntax **MPYU** *src1, src2, dst*

Functional unit = M

Opcode 32 bit

Description Performs a multiply on the unsigned values in *src1* and *src2*. Only the 32 least-significant bits of the result are retained and written to *dst*.

Condition Codes CSR:EQ = (*dst* == 0)

Pseudo Code *dst* = lsb32(*src2* × *src1*)

MV *Move Register to Register*

Syntax **MV** *src1, dst*
 Functional unit = S

Opcode 16 bit

Description The contents of *src1* are copied to *dst*.

Condition Codes None

Pseudo Code `dst = src1`

MVC *Move Architectural Register to Control Register*

Syntax *MVC areg, creg*
 Functional unit = S

Opcode 16 bit

Description The content of the architectural register (*areg*) is moved to the control register (*creg*).

Condition Codes None

Pseudo Code *creg = areg*

MVC *Move Control Register to Architectural Register*

Syntax **MVC** *creg*, *areg*
Functional unit = S

Opcode 16 bit

Description The content of the control register (*creg*) is moved to the architectural register (*areg*).

Condition Codes None

Pseudo Code *areg* = *creg*

MVC ***Move 16-Bit Unsigned Constant to Control Register***

Syntax **MVC** *ucst16, creg*
 Functional unit = S

Opcode 32 bit

Description A 16-bit unsigned constant (*ucst16*) is moved to the control register (*creg*).

Condition Codes None

Pseudo Code *creg* = {zero extend}*ucst16*

MVCH *Move 16-Bit Unsigned Constant to Upper Bits of Control Register*

Syntax **MVCH** *ucst16, creg*

Functional unit = S

Opcode 32 bit

Description A 16-bit unsigned constant (*ucst16*) is moved to the upper halfword (bits 31-16) of the control register (*creg*). The lower halfword (bits 15-0) of *creg* is left unchanged.

Condition Codes None

Pseudo Code `creg[31:16] = ucst16`

MVK *Move 16-Bit Unsigned Constant to Register*

Syntax **MVK** *ucst16*, *dst*
 Functional unit = S

Opcode 32 bit

Description A 16-bit unsigned constant (*ucst16*) is moved to *dst*.

Condition Codes CSR:EQ = (*dst* == 0)

Pseudo Code *dst* = {zero extend}*ucst16*

MVKH **Move 16-Bit Unsigned Constant to Upper Bits of Register**

Syntax **MVKH** *ucst16*, *dst*

Functional unit = S

Opcode 32 bit

Description A 16-bit unsigned constant (*ucst16*) is moved to the upper halfword (bits 31-16) of *dst*. The lower halfword (bits 15-0) of *dst* is left unchanged.

Condition Codes CSR:EQ = (*dst* == 0)

Pseudo Code *dst*[31:16] = *ucst16*

MVKLS **Move 16-Bit Signed Constant to Register**

Syntax **MVKLS** *scst16*, *dst*
 Functional unit = S

Opcode 32 bit

Description A 16-bit constant (*scst16*) is sign extended and is moved to *dst*.

Condition Codes CSR:EQ = (*dst* == 0)

Pseudo Code *dst* = {sign extend}*scst16*

MVKS ***Move 6-Bit Signed Constant to Register***

Syntax **MVKS** *scst6*, *dst*
 Functional unit = S

Opcode 16 bit

Description A 6-bit signed constant (*scst6*) is sign extended and is moved to *dst*.

Condition Codes CSR:EQ = (*dst* == 0)

Pseudo Code *dst* = {sign extend}*scst6*

MVS *Move Architectural Register to Shadow Register*

Syntax **MVS** *areg, sreg*
Functional unit = S

Opcode 16 bit

Description The content of the architectural register (*areg*) is moved to the shadow register (*sreg*). This instruction has two exposed delay slots, the data written cannot be read back until the third cycle from the cycle when this instruction enters the EXE phase.

Condition Codes None

Pseudo Code *sreg = areg*

MVS *Move Shadow Register to Architectural Register*

Syntax **MVS** *sreg, areg*
 Functional unit = S

Opcode 16 bit

Description The content of the shadow register (*sreg*) is moved to the architectural register (*areg*).

Condition Codes None

Pseudo Code *areg* = *sreg*

NEG ***Negation***

Syntax **NEG *src2, dst***
 Functional unit = L

Opcode 16 bit

Description *src2* is subtracted from zero and the result is stored in *dst*.

Condition Codes CSR[2]EQ = (*dst* == 0)

Pseudo Code *dst* = 0 - *src2*

NOP ***No Operation***

Syntax **NOP**
 Functional unit = None

Opcode 16 bit

Description No operation.

Condition Codes None

Pseudo Code None

NOT *Bitwise NOT*

Syntax **NOT** *src2, dst*
 Functional unit = L

Opcode 16 bit

Description Performs a bitwise inversion of *src2* and stores the result in *dst*.

Condition Codes CSR[2]EQ = (*dst* == 0)

Pseudo Code *dst* = ~*src2*

OR *Bitwise OR 16-Bit Unsigned Constant with Register*

Syntax **OR** *ucst16, src2, dst*
 Functional unit = L

Opcode 32 bit

Description Bitwise OR of a zero-extended 16-bit unsigned constant (*ucst16*) with *src2* and store result to *dst*.

Condition Codes CSR[2]EQ = (dst == 0)

Pseudo Code `dst = src2 OR {zero extend}ucst16`

OR *Bitwise OR Two Registers*

Syntax **OR** *src1, src2, dst*
Functional unit = L

Opcode 16 bit

Description Bitwise OR of *src1* with *src2* and store result to *dst*.

Condition Codes CSR[2]EQ = (dst == 0)

Pseudo Code *dst* = *src2* OR *src1*

RET *Return from Subroutine*

Syntax **RET**
 Functional unit = D

Opcode 16 bit

Description Load the link register (LR) into the program counter (PC), increment the stack pointer (SP), then load the contents of the memory location pointed to by SP into LR. The content of LR and the content of the memory location pointed to by SP in this case is treated as an absolute halfword address.

This instruction has one delay slot. See [Section 6.2.5.3.1](#) for restrictions on scheduling an instruction in this delay slot.

Condition Codes None

Pseudo Code PC = LR; SP += 4; LR = *(SP)

REV *Reverse a Bit Field Bounded by Two Register Values*
Syntax **REV** *src1, src2, dst*

Functional unit = L

Opcode 32 bit

31	30	29	28	27	26	25	24	23	22	21	20	16	15	13	12	10	9	7	6	0											
x	x	x	x	x	x	x	x	x	x	x	1	0	1	0	0	<i>dst</i>			<i>src2</i>			<i>src1</i>			0	0	0	0	1	0	0
												3			3			3			<i>opcode</i>										

Description

For $src1[9:5] \geq src1[4:0]$, the field in *src2* as specified by $src1[4:0]$ to $src1[9:5]$ is bit reversed. The reversed bits are merged with the remaining (unchanged) bits in *dst* and are stored in *dst*. *src2* is left unchanged. $src1[4:0]$ is the LSB of the field and $src1[9:5]$ is the MSB of the field to be bit reversed. In other words, $src1[4:0]$ and $src1[9:5]$ represent the beginning and ending bits, respectively, of the field to be bit reversed. The LSB location of *src2* is bit 0 and the MSB location of *src2* is bit 31.

Valid values of $src1[9:5]$ and $src1[4:0]$ are:

- $0 \leq src1[9:5] \leq 31$; $0 \leq src1[4:0] \leq 31$
- $src1[9:5] \geq src1[4:0]$

For $src1[9:5] < src1[4:0]$, the result is undefined.

In the following example, $src1[4:0]$ is 11 and $src1[9:5]$ is 19.

Condition Codes CSR[2]EQ = (*dst* == 0)

Pseudo Code

```

dst = src2
pntr = src1[9:5];
for( i = 0; i < 32; i++) {
    if ( i >= src1[4:0] && i <= src1[9:5]){
        dst[i] = dst[pntr]
        --pntr;
    } else
        dst[i] = dst[i];
}

```

ROT *Rotate Right*

Syntax `ROT src1, src2, dst`
 Functional unit = L

Opcode 32 bit

31	30	29	28	27	26	25	24	23	22	21	20		16	15		13	12		10	9		7	6					0			
x	x	x	x	x	x	x	x	x	x	x	1	0	1	0	1	<i>dst</i>			<i>src2</i>			<i>src1</i>			0	0	0	0	1	0	0
												3			3			3			<i>opcode</i>										

Description *src1[4:0]* contains the number of bit positions that *src2* is to be rotated right. The new MSB value is defined by the previous LSB value of *src2*. The result is stored in *dst*. A *src1[4:0] = 0*, results in the **MV** *src1, dst* instruction.

In the following example, *src1[4:0]* is 9.

Condition Codes CSR[2]EQ = (dst == 0)

Pseudo Code

```
dst = src2
for( i = 1; i < src1; i++) {
    dst = { dst[0], dst[32-2: 1] };
}
```

ROTC *Rotate Right Through Carry Bit*
Syntax **ROTC** *src1, src2, dst*

Functional unit = L

Opcode 32 bit

Description *src1[4:0]* contains the number of bit positions that *src2* is to be rotated right through the Carry bit (CSR[5]C). The new MSB value is defined by the current SAT bit in the control status register (CSR). The rotated LSB of *src2* is moved to CSR[5]C. The result is stored in *dst*. A *src1[4:0] = 0*, results in the **MV** *src1, dst* instruction.

In the following example, *src1[4:0]* is 9.

Condition Codes CSR[2]EQ = (*dst* == 0)

CSR[5]C: see the Pseudo Code

Pseudo Code

```

tmp = src2
for( i = 1; i < src1; i++) {
    tmp = { CSR[C], tmp[32-2: 1] };
    CSR[C] = tmp[0] ;
}
dst = tmp;

```

SADD *Signed Addition of Two Register Values with Saturation*

Syntax **SADD** *src1, src2, dst*
 Functional unit = D

Opcode 16 bit

Description Signed addition of *src1* with *src2* with result saturation and stored to *dst*. If a saturate occurs, the SAT bit in the control status register (CSR) is set after *dst* is written.

Condition Codes CSR[2]EQ = (*dst* == 0)
 CSR[5]SAT = satP OR satN

Pseudo Code `tmp = src2 + src1`
 `satP = tmp > 231 - 1`
 `satN = tmp < -231`
 `dst = satP ? (231 - 1) : (satN ? -231 : tmp)`

SATN *Saturation to Signed/Unsigned N-Bit Value with Sign/Zero Extend*

Syntax **SATN** *ucst3, src2, dst*

Functional unit = L

Opcode 32 bit

31	30	29	28	27	26	25	24	23	22	21	20	19	18	16	15	13	12	10	9												0		
x	x	x	x	x	x	x	x	x	x	x	x	x	x	ucst3[2:0]			dst			src2			1	1	1	0	0	0	0	0	0	1	1
													3			3			3			opcode											

Description Saturation to signed/unsigned N-bit value and sign/zero extend to 32 bits. *src2* is saturated based on *ucst3*:

- *ucst3*[2] = 1 indicates signed saturation
- *ucst3*[2] = 0 indicates unsigned saturation
- *ucst3*[1:0] = 0 indicates saturation to 8 bit value
- *ucst3*[1:0] = 1 indicates saturation to 16 bit value
- *ucst3*[1:0] = other values (2 or 3) are reserved

src2 is considered a signed value that needs to be saturated to a signed or unsigned range. The result is undefined, if reserved values in *ucst3* are used.

Condition Codes CSR[2]EQ = (*dst* == 0)

Pseudo Code $dst = (src2 \leq -2^{(N-1)}) ? -2^{(N-1)} : ((src2 \geq 2^{(N-1)} - 1) ? 2^{(N-1)} - 1 : src2);$

SET *Set Bit Field Bounded by Two Immediate Values*

Syntax `SET ucst5_1, ucst5_2, src2, dst`

Functional unit = L

Opcode 32 bit

Description

For $ucst5_1 \geq ucst5_2$, the field in *src2* as specified by *ucst5_2* to *ucst5_1* is set to all 1s and the resulting value of *src2* is written to *dst*. *src2* is left unchanged. *ucst5_2* is the LSB of the field and *ucst5_1* is the MSB of the field. In other words, *ucst5_2* and *ucst5_1* represent the beginning and ending bits, respectively, of the field to be set to all 1s. The LSB location of *src2* is bit 0 and the MSB location of *src2* is bit 31.

Valid values of *ucst5_1* and *ucst5_2* are:

- $0 \leq ucst5_1 \leq 31; 0 \leq ucst5_2 \leq 31$
- $ucst5_1 \geq ucst5_2$

For $ucst5_1 < ucst5_2$, the result is undefined.

In the following example, *ucst5_2* is 15 and *ucst5_1* is 23.

Condition Codes CSR[2]EQ = (dst == 0)

Pseudo Code

```
dst = src2
for( i = 0; i < 32; i++) {
    if ( i >= ucst5_2 && i <= ucst5_2) dst[i] = 1;
};
```

SET *Set Bit Field Bounded by Two Register Values*
Syntax **SET** *src1, src2, dst*

Functional unit = L

Opcode 32 bit

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	13	12	10	9	7	6	0		
x	x	x	x	x	x	x	x	x	x	x	1	0	0	0	0	dst	src2	src1	0	0	0	0	1	0	0
											3			3			3			opcode					

Description

For $src1[9:5] \geq src1[4:0]$, the field in *src2* as specified by *src1[4:0]* to *src1[9:5]* is set to all 1s and the resulting value of *src2* is written to *dst*. *src2* is left unchanged. *src1[4:0]* is the LSB of the field and *src1[9:5]* is the MSB of the field. In other words, *src1[4:0]* and *src1[9:5]* represent the beginning and ending bits, respectively, of the field to be set to all 1s. The LSB location of *src2* is bit 0 and the MSB location of *src2* is bit 31.

Valid values of *src1[9:5]* and *src1[4:0]* are:

- $0 \leq src1[9:5] \leq 31$; $0 \leq src1[4:0] \leq 31$
- $src1[9:5] \geq src1[4:0]$

For $src1[9:5] < src1[4:0]$, the result is undefined.

In the following example, *src1[4:0]* is 15 and *src1[9:5]* is 23.

Condition Codes CSR[2]EQ = (*dst* == 0)

Pseudo Code

```
dst = src2
for( i = 0; i < 32; i++) {
    if ( i >= src1[4:0] && i <= src1[9:5]) dst[i] = 1;
};
```

SHL ***Logical Shift Left by 5-Bit Unsigned Constant***

Syntax **SHL** *ucst5, src2, dst*
 Functional unit = L

Opcode 32 bit

Description *src2* is left shifted by a 5-bit unsigned constant (*ucst5*) and the result is stored to *dst*.
 The shift in value is 0.

Condition Codes CSR[2] EQ = (*dst* == 0)

Pseudo Code *dst* = *src2* << *ucst5*

SHL *Logical Shift Left by Register Value*

Syntax SHL *src1*, *src2*, *dst*

Functional unit = L

Opcode 16 bit

Description *src2* is left shifted by an unsigned value (*src1*) and the result is stored to *dst*. The shift in value is 0. If the *src1* value is greater than 31, *dst* is cleared to 0.

Condition Codes CSR[2] EQ = (*dst* == 0)

Pseudo Code *dst* = (*src1* > 31) ? 0: (*src2* << *src1*)

SHRA *Arithmetic Shift Right by 5-Bit Unsigned Constant*
Syntax **SHRA** *ucst5, src2, dst*

Functional unit = L

Opcode 32 bit

Description *src2* is right shifted by a 5-bit unsigned constant (*ucst5*) and the result is stored to *dst*. The shift in value is the sign bit (bit 31) of *src2*.

 Using **DIV** (integer division) and **SHRA** (arithmetic right shift) does not produce the same result for negative numbers. The quotient of **DIV** is rounded towards zero, whereas the quotient of **SHRA** is rounded towards negative infinity. For example, using the **DIV** instruction: $-9/4 = -2$, whereas using the **SHRA** instruction: $-9/4 = -3$.

Condition Codes CSR[2] EQ = (*dst* == 0)

Pseudo Code $dst = \{sign\ extend\}\{src2 \gg ucst5\}$

SHRA *Arithmetic Shift Right by Register Value*

Syntax **SHRA** *src1, src2, dst*
 Functional unit = L

Opcode 16 bit

Description *src2* is right shifted by an unsigned value (*src1*) and the result is stored to *dst*. The shift in value is the sign bit (bit 31) of *src2*. If the *src1* value is greater than 31, *dst* is -1.

Using **DIV** (integer division) and **SHRA** (arithmetic right shift) does not produce the same result for negative numbers. The quotient of **DIV** is rounded towards zero, whereas the quotient of **SHRA** is rounded towards negative infinity. For example, using the **DIV** instruction: $-9/4 = -2$, whereas using the **SHRA** instruction: $-9/4 = -3$.

Condition Codes CSR[2] EQ = (*dst* == 0)

Pseudo Code $dst = (src1 > 31) ? \text{FFFF FFFFh} : \{\text{sign extend}\}\{src2 \gg src1\}$

SHRU *Logical Shift Right by 5-Bit Unsigned Constant*

Syntax **SHRU** *ucst5, src2, dst*

Functional unit = L

Opcode 32 bit

Description *src2* is right shifted by a 5-bit unsigned constant (*ucst5*) and the zero-extended result is stored to *dst*.

Condition Codes CSR[2] EQ = (*dst* == 0)

Pseudo Code *dst* = {zero extend}{*src2* >> *ucst5*}

SHRU *Logical Shift Right by Register Value*

Syntax **SHRU** *src1, src2, dst*

Functional unit = L

Opcode 16 bit

Description *src2* is right shifted by an unsigned value (*src1*) and the result is stored to *dst*. The shift in value is 0. If the *src1* value is greater than 31, *dst* is cleared to 0.

Condition Codes CSR[2] EQ = (*dst* == 0)

Pseudo Code `dst = (src1 > 31) ? 0: {zero extend}{src2 >> src1}`

SLA ***Set Loop Address***

Syntax **SLA** *ucst16, creg*
 Functional unit = S

Opcode 32 bit

Description Sets up loop bound address using a program counter (PC)-relative immediate positive offset. A zero-extended 16-bit unsigned immediate value (*ucst16*) is added to the PC of the instruction and is written to *creg*. Note that the offset is treated as a halfword offset. The only allowed *creg* registers for this instruction are: LSA0, LEA0, LSA1, and LEA1.

Condition Codes None

Pseudo Code $creg = PC + \{\text{zero extend}\}ucst16$

SSUB ***Subtraction of Two Register Values with Saturation***
Syntax **SSUB** *src1, src2, dst*

Functional unit = D

Opcode 16 bit

Description *src1* is subtracted from *src2* with result saturation and stored to *dst*. If a saturate occurs, the SAT bit in the control status register (CSR) is set after *dst* is written.

Condition Codes CSR[2] EQ = (*dst* == 0)
 CSR[6] SAT = satP OR satN

Pseudo Code `tmp = src2 - src1`
`satP = tmp > 231 - 1`
`satN = tmp < -231`
`dst = satP ? (231 - 1) : (satN ? -231 : tmp)`

STB *Store Byte to Memory with a 3-Bit Unsigned Constant Offset*

Syntax **STB** *dst*, **+baseR[ucst3]*

Functional unit = D

Opcode 16 bit**Description**

The 8 LSBs (byte) of *dst* are stored to memory (effective address). The memory address is formed from a base address register (*baseR*) and an offset (number of bytes) that is a 3-bit unsigned constant (*ucst3*). If an offset is not given, the assembler assigns an offset of zero. Brackets, [], must surround the specified offset, if using the optional offset parameter.

The square brackets, [], indicate that the *ucst3* is scaled by a left-shift of 0 bits. After scaling, *ucst3* is added to *baseR*. The result of the calculation is the effective address in memory that contains the content from *dst*.

Condition Codes None**Pseudo Code** $*(baseR[ucst3]) = *dst$

STB *Store Byte to Memory with a 16-Bit Unsigned Constant Offset*
Syntax **STB** *dst, *+baseR[ucst16]*

Functional unit = D

Opcode 32 bit

The memory address is formed from the global data pointer register (GDP) and an offset (number of words) that is a 19-bit unsigned constant (*ucst19*). If an offset is not given, the assembler assigns an offset of zero. You must type the brackets, [], around the specified offset, if you use the optional offset parameter.

The square brackets, [], indicate that the *ucst19* is scaled by a left-shift of 2 bits. After scaling, *ucst19* is added to GDP. The result of the calculation is the effective address in memory that contains the content from *dst*.

Word addresses must be aligned on word (two LSBs are 0) boundaries.

Condition Codes None

Pseudo Code $*(GDP[ucst19]) = *dst$

STHI *Store 16-Bit Halfword to Memory with a 6-Bit Unsigned Constant Offset*
Syntax `STHI ucst16, *+baseR[ucst6]`

Functional unit = S

Opcode 32 bit

Description The 16-bit unsigned constant (*ucst16*) is stored to memory (effective address). The memory address is formed from a base address register (*baseR*) and an offset (number of halfwords) that is a 6-bit unsigned constant (*ucst6*). If an offset is not given, the assembler assigns an offset of zero. You must type the brackets, [], around the specified offset, if you use the optional offset parameter.

The square brackets, [], indicate that the *ucst6* is scaled by a left-shift of 1 bit. After scaling, *ucst6* is added to *baseR*. The result of the calculation is the effective address in memory that contains *ucst16*.

Halfword addresses must be aligned on halfword (LSB is 0) boundaries.

Condition Codes None

Pseudo Code `*(baseR[ucst6]) = ucst16`

STRF ***Store Register File to Stack Pointer***

Syntax **STRF** *op1*, *op2*
 Functional unit = D

Opcode 16 bit

Description The current base register file is stored to the starting address specified by the postdecremented value of the stack pointer (SP). *op1* specifies the ending register (last register stored) and *op2* specifies the beginning register (first register stored). All registers between *op1* and *op2* are stored inclusive. The registers are stored in order from lowest register (*op2*) to highest register (*op1*).

Valid values of *op1* and *op2* are: $op1 \geq op2$
 For $op1 < op2$, results in unspecified behavior.

Condition Codes None

Pseudo Code

```
for ( i = op2; i <= op1 ; i++) {
    *(SP) = Ri;
    SP -= 4;
}
```

SUB *Subtract 16-Bit Unsigned Constant from Register*
Syntax **SUB** *ucst16, src2, dst*

Functional unit = D

Opcode 32 bit

Description Subtract a 16-bit unsigned constant (*ucst16*) from *src2* and store result to *dst*.

Condition Codes CSR[2]EQ = (dst == 0)

CSR[5]C = {not borrow} from (src2 - ucst16)

CSR[7]V = {overflow} from (src2 - ucst16)

Note that the carry (CSR[5]C) and overflow (CSR[7]V) bits are relevant to unsigned and signed operations, respectively. Appropriate bits are checked depending on if the operands are represented (or, interpreted) as unsigned or signed numbers.

Pseudo Code `dst = src2 - ucst16`

SUB **Subtract 16-Bit Unsigned Constant from Stack Pointer, Result to Stack Pointer**

Syntax **SUB** *ucst16*, SP
 Functional unit = D

Opcode 32 bit

Description Subtract a 16-bit unsigned constant (*ucst16*) from the stack pointer (SP) and store result to SP.

Condition Codes None

Pseudo Code $SP = SP - ucst16$

SUB ***Subtract 16-Bit Unsigned Constant from Stack Pointer, Result to Register***

Syntax **SUB** *ucst16*, **SP**, *dst*
 Functional unit = D

Opcode 32 bit

Description Subtract a 16-bit unsigned constant (*ucst16*) from the stack pointer (SP) and store result to *dst*.

Condition Codes CSR[2]EQ = (*dst* == 0)
 CSR[5]C = {not borrow} from (SP - *ucst16*)
 CSR[7]V = {overflow} from (SP - *ucst16*)
 Note that the carry (CSR:C) and overflow (CSR:V) bits are relevant to unsigned and signed operations, respectively. Appropriate bits are checked depending on if the operands are represented (or, interpreted) as unsigned or signed numbers.

Pseudo Code *dst* = SP - *ucst16*

SUB ***Subtract 3-Bit Unsigned Constant from Register***

Syntax **SUB** *ucst3, src2, dst*
 Functional unit = D

Opcode 16 bit

Description Subtract a 3-bit unsigned constant (*ucst3*) from *src2* and store result to *dst*.

Condition Codes CSR[2]EQ = (*dst* == 0)
 CSR[5]C = {not borrow} from (*src2* - *ucst3*)
 CSR[7]V = {overflow} from (*src2* - *ucst3*)
 Note that the carry (CSR:C) and overflow (CSR:V) bits are relevant to unsigned and signed operations, respectively. Appropriate bits are checked depending on if the operands are represented (or, interpreted) as unsigned or signed numbers.

Pseudo Code *dst* = *src2* - *ucst3*

SUB *Signed Subtraction of Two Register Values*

Syntax **SUB** *src1, src2, dst*
 Functional unit = D

Opcode 16 bit

Description Subtract *src1* from *src2* and store result to *dst*.

Condition Codes CSR[2]EQ = (dst == 0)
 CSR[5]C = {not borrow} from (src2 - src1)
 CSR[7]V = {overflow} from (src2 - src1)

Note that the carry (CSR[5]C) and overflow (CSR[7]V) bits are relevant to unsigned and signed operations, respectively. Appropriate bits are checked depending on if the operands are represented (or, interpreted) as unsigned or signed numbers.

The status of the CSR[5]C bit can be used to synthesize multiword (wider) subtraction. With the **SUB** instruction, the CSR[5]C bit is set if no borrow occurs and the CSR[5]C bit is cleared if a borrow occurs. In other words, for **SUB** instructions, the CSR[5]C bit represents a not borrow. To synthesize multiword subtractions, subsequent instructions can use the CSR[5]C bit as a NOT(borrow) operand, performing a normal subtraction if CSR[5]C == 1 and subtracting one more than usual if CSR[5]C == 0.

For example, if register pairs R0/R1 and R2/R3 hold 64-bit values (where R0 and R2 hold the least-significant words), the following instructions leave the 64-bit difference in the register pair R4/R5:

```

SUB  R2, R0, R4      ; R4=R0-R2, sets CSR[C]
MVC  CSR, R6        ; leaves CSR[C] untouched
EXTU 5, 5, R6, R6   ; if (CSR[C]) R6=0x1 else R6=0x0
BNEQ L1
SUB  R3, R1, R5      ; R5=R1-R3
SUB  1, R5, R5       ; R5=R5-1 if CSR[C] was NOT set
L1:  NOP             ; else R5=R5
  
```

Note that the above example needs appropriate modification in order to generate correct carry/overflow applicable for the total 64-bit result.

Pseudo Code `dst = src2 - src1`

SWI ***Software Interrupt***

Syntax **SWI**
 Functional unit = S

Opcode 16 bit

Description Subtract *src1* from *src2* and store result to *dst*.

Condition Codes SCSR = CSR; CSR[0] = 0

Pseudo Code PC = *(IMEM[IST[SWI]]); IRP = PC + 1;

XOR *Bitwise Exclusive-OR Unsigned 16-Bit Constant with Register*

Syntax `XOR ucst16, src2, dst`
 Functional unit = L

Opcode 32 bit

Description Bitwise exclusive-OR (XOR) of a zero-extended 16-bit unsigned constant (*ucst16*) with *src2* and store result to *dst*.

Condition Codes CSR[2]EQ = (dst == 0)

Pseudo Code `dst = src2 XOR {zero extend}ucst16`

XOR *Bitwise Exclusive-OR Two Registers*
Syntax `XOR src1, src2, dst`

Functional unit = L

Opcode 16 bit

Description Bitwise exclusive-OR (XOR) of *src1* with *src2* and store result to *dst*.

Condition Codes CSR[2]EQ = (dst == 0)

Pseudo Code `dst = src2 XOR src1`

6.2.6 Clock, Reset, and Dynamic Power Management

6.2.6.1 Introduction

The ARP32 CPU has a single clock domain (cpu_fclk) and two reset domains:

- An asynchronous Power-On-Reset (cpu_porz_i)
- An asynchronous CPU Functional Reset (cpu_resetz_i)

Both of the reset signals are used asynchronously inside the design. Both the leading and trailing edges of these reset signals are synchronized with the CPU input clock by the external clock/reset management logic.

To reduce dynamic power consumption, the ARP32 CPU gates all of its internal clocks based on debugger connection status and CPU idle/standby status:

- If the ARP32 CPU is in the IDLE state and the CPU standby indication is asserted, all internal clocks of the ARP32 CPU remain gated.
- If debug connection is established, indicated via the input port cpu_dbgenable_i, the ARP32 CPU unconditionally enables all its internal clocks.

6.2.6.2 CPU Reset Modes

[Table 6-39](#) summarizes the two reset signals of the ARP32 CPU and their effects. [Table 6-40](#) summarizes the different application of the two resets.

[Figure 6-31](#) illustrates the ARP32 CPU power-on-reset sequence.

If warm reset is applied without Power on reset, to avoid meta-stability issues within the CPU core, the functional clock to the CPU core must be stopped by external clock generation logic prior to Warm reset assertion and the functional clock must be restored prior to Warm reset de-assertion.

Table 6-39. CPU Reset Types

Reset Type	Signal Name	Reset Type	Does CPU Reset?	
			Debug Logic	Functional Logic
Power On Reset	cpu_porz_i	Async	Yes	No
Warm Reset	cpu_resetz_i	Async	No	Yes

Table 6-40. CPU Reset Modes

cpu_porz_i	cpu_resetz_i	Reset Mode	Application	Does CPU Reset?		Need Synchronization?	
				Debug Logic	Functional Logic	Assertion	De-assertion
0	0	Power On Reset	Reset at power up, full system reset	Yes	No	NA	Yes
0	1	Not supported	NA	NA	NA	NA	NA
1	0	Warm Reset	Reset of CPU core only, for example, watchdog reset	No	Yes	Yes	Yes
1	1	Normal	No reset, normal running mode	No	No	NA	NA

Figure 6-31. Power-On-Reset

6.2.6.3 Dynamic Power Management

The ARP32 CPU supports instruction driven transition to a low-power state that is used to trigger a CPU system-wide low-power state. This is accomplished by the **IDLE** instruction. Upon execution of the **IDLE** instruction, the ARP32 CPU waits for any pending instruction or data memory transaction to complete and then goes to an endless wait state.

When in idle state, the CPU output signal `cpu_standby_o` is asserted high. During this window, the CPU gates clocks to all of its registers (except the interrupt flag register (IFR)) to achieve maximum saving of dynamic power. It is assured that the ARP32 CPU does not issue any new transactions on either instruction or data memory interfaces during this window. So, peripherals external to the CPU that don't need to be active while the CPU is in IDLE are also clock gated during this window.

The CPU comes out of this wait state only via an enabled external interrupt (NMI, INT4-INT7) or reset. The `cpu_standby_o` signal is de-asserted as soon as one of the following events occurs:

- any of the interrupt flag register (IFR) bits are set
- a debug connection is established (`cpu_dbgenable_i` is asserted high)

Interrupt enable conditions (like GIE, IER, etc.) are not considered when de-asserting `cpu_standby_o`. Thus, a disabled interrupt being asserted at the CPU boundary causes the `cpu_standby_o` signal to be de-asserted but the CPU still remains in idle state until an enabled interrupt (or reset) occurs.

Figure 6-32 provides an illustrative waveform showing the CPU going into IDLE mode followed by a wakeup via INT4.

Figure 6-32. CPU Standby and Wakeup Procedure

6.2.7 Notes on Programming Model

6.2.7.1 Booting

The entry for reset in the ARP32 interrupt service table (IST) is setup such that the program flow after reset calls an initialization or boot code as soon as possible and performs at least the following functions:

- Initialize the stack pointer (SP) register.
- Initialize the global data pointer (GDP) register.
- Call 'main' function.

The following tasks are additionally performed if interrupt processing is needed from the very beginning; else, they are done as soon as the system is ready for (or expecting) interrupt processing:

- Initialize the interrupt enable register (IER) to enable the required maskable interrupts, as required.
- Initialize the interrupt enable register (IER) to enable the nonmaskable interrupt, if required.
- Initialize the control status register (CSR) to enable all the maskable interrupts globally.

6.2.7.2 Enabling and Disabling Interrupts

The ARP32 CPU provides a mechanism for easy and flexible interrupt control.

6.2.7.2.1 Globally Enabling or Disabling Maskable Interrupts

The global interrupt enable (GIE) bit in the control status register (CSR) allows programmers to enable or disable all maskable interrupts by controlling the value of a single bit. On the ARP32 CPU, programs must directly manipulate the GIE bit in CSR to disable and enable interrupts:

- CSR[0]GIE = 1 enables the maskable interrupts so that they are processed
- CSR[0]GIE = 0 disables the maskable interrupts so that they are not processed

For example, the following code sequence globally enables all maskable interrupts:

```
MVC  CSR, R0          ; Get CSR into R0
SET  0, 0, R0, R0    ; Set R0[0]
MVC  R0, CSR         ; Copy R0 back to CSR (sets GIE)
```

Similarly, the following code sequence globally disables all maskable interrupts:

```
MVC  CSR, R0          ; Get CSR into R0
CLR  0, 0, R0, R0    ; Clear R0[0]
MVC  R0, CSR         ; Copy R0 back to CSR (clears GIE)
```

As interrupt detection occurs in parallel with CPU execution, the CPU takes an interrupt in the cycle immediately following an **MVC** instruction that clears the GIE bit. However, CPU context save/restore behavior ensures that interrupts do not occur after subsequent instruction. Consider the following code example where the CPU takes an interrupt between instructions 1 and 2, between instructions 2 and 3, or between instructions 3 and 4. The CPU does not service an interrupt between instructions 4 and 5.

```
; assume GIE=1
MVC  CSR, R0          ;(1) Get CSR
AND  -2, R0, R0       ;(2) Get ready to clear GIE
MVC  R0, CSR         ;(3) Clear GIE
ADD  R0, R2, R3       ;(4)
ADD  R4, R4, R5       ;(5)
```

If the CPU services an interrupt between instructions 1 and 2 or between instructions 2 and 3, the SCSR[0]GIE bit holds the value 1 when arriving at the interrupt service routine. If the CPU services an interrupt between instructions 3 and 4, the SCSR[0]GIE bit holds the value 0. Thus, when the interrupt service routine resumes the interrupted code, it resumes with the GIE bit cleared (as a result of context restore of SCSR to CSR) as the interrupted code intended.

6.2.7.2 Enabling or Disabling Individual Interrupts

Software can enable and disable individual interrupts by setting and clearing the bits in the interrupt enable register (IER) that correspond to the individual interrupts. An interrupt can trigger interrupt processing only if the corresponding bit in the IER is set.

For example, the following code sequence enables INT4:

```
MVC  IER, R0      ; Get IER into R0
SET  4, 4, R0, R0 ; Set R0[4]
MVC  R0, IER      ; Copy R0 back to IER (sets IER[4])
```

Similarly, the following code sequence disables INT5:

```
MVC  IER, R0      ; Get IER into R0
CLR  5, 5, R0, R0 ; Clear R0[5]
MVC  R0, IER      ; Copy R0 back to IER (clears IER[5])
```

6.2.7.3 Stack Usage in Interrupt Service Routine

The ARP32 CPU has only one stack pointer and thus a unified stack is used for background and interrupt code. As a result, the programmer is responsible for maintaining a clean boundary of operations that modifies the stack pointer (for example, stack allocation and de-allocation for a function, context save onto stack via push/pop operations using the **LDRF/STRF** instructions).

Instructions/operations in the CPU that modify the stack pointer are designed so that an interrupt cannot disrupt the operations halfway through to completion. For example, a stack allocation and de-allocation for function can happen via the **ADD ucst16, SP** instruction that atomically modifies the stack. The return address save while taking a **CALL** or retrieving the return address while executing a **RET** is also atomic, and cannot be interrupted. The **LDRF/STRF** instructions used for single or multiple pop and push are also uninterruptable. The ARP32 C/C++ compiler uses these instructions to maintain the C/C++ stack and thus the sanity of the stack is always maintained.

Under certain scenarios, to save additional user context onto the stack, it is done via the **LDRF/STRF** instruction. **LDRF/STRF** modifies the stack pointer and hence results in the stack layout of a function to be not valid anymore. Hence, such additional context save/restore to the stack must happen at function boundaries only.

These considerations are important for assembly level programmers doing additional context save/restore (beyond what the ARP32 compiler does) and also to new custom instruction design for the ARP32 CPU if they depend on stack pointer relative operations.

6.2.7.4 General Restrictions

The ARP32 CPU has the following restrictions on the programming model:

- **Long Long (as 64 bit) is not supported natively in the architecture.** 'long long' is supported via emulation in the Run Time Support (RTS) library. Since this is non-standard and sub-optimal, use of long may severely degrade performance. Hence, it is highly recommended not to use the C 'long long' datatype.
- **64-bit arithmetic.** Add/sub of more than 32-bit values (operand or results) requires **ADDC/SUBC/BC** (addition with carry, subtraction with borrow, branch on carry) instructions that are not supported in the ARP32 CPU. Again, it is possible to emulate this in RTS but it is a sub-optimal implementation and it is not recommended.
- **Multi-threading via mutex is not supported in the architecture.** In the ARP32 CPU, it does not implement an "EXCLUSIVE access instruction" to implement a 'proper' mutex in RTS. A polling based multi-threading is still possible.

6.3 VCOP CPU and Instruction Set

NOTE: Throughout this section, various sample assembly code pieces are used to illustrate VCOP architecture and functionality. Programmers are expected to write code in VCOP Kernel-C, instead of in assembly.

6.3.1 Module Overview

The Embedded Vision Engine (EVE) module is a programmable imaging and vision processing engine, intended to be used in devices that serves consumer electronics imaging and vision applications. Its programmability allows late-in-development or post-silicon processing requirements to be met, and allows third party or customers to add differentiating features in imaging and vision products.

The EVE Module consists of an ARP32 scalar core, a VCOP vector core, and a DMA controller.

6.3.2 Features

- Interfaces
 - CLK/2 MHz custom interface with the scalar core
- Functionality
 - CLK MHz functional clock
 - Based on VICP coprocessor
 - Dual-issue, N-way SIMD per instruction
 - Scalable in N ways of SIMD, $N = \{2 | 4 | 8 | 16 | 32\}$
 - For the first version of VCOP $N = 8$
 - 16 entries x N ways x 40-bit register file
 - Binary morphology acceleration
 - N-way table lookup and histogram acceleration (capable of N lookups per cycle or N histograms per 4 cycle)
 - Up to 20-bit vector data memory address space
- Debug interface with visibility of loop variables and load/store pointers ([VCOP_LD_PTR_i](#)/[VCOP_ST_PTR_j](#)).

6.3.3 Block Diagram

The EVE subsystem contains an ARP32 scalar core, VCOP vector core, EDMA, memory blocks, memory switch, local interconnect, reset/clock, interrupt controller, SCTM and SMSET instrumentation blocks.

Figure 6-33 provides a block diagram.

Figure 6-33. EVE Block Diagram

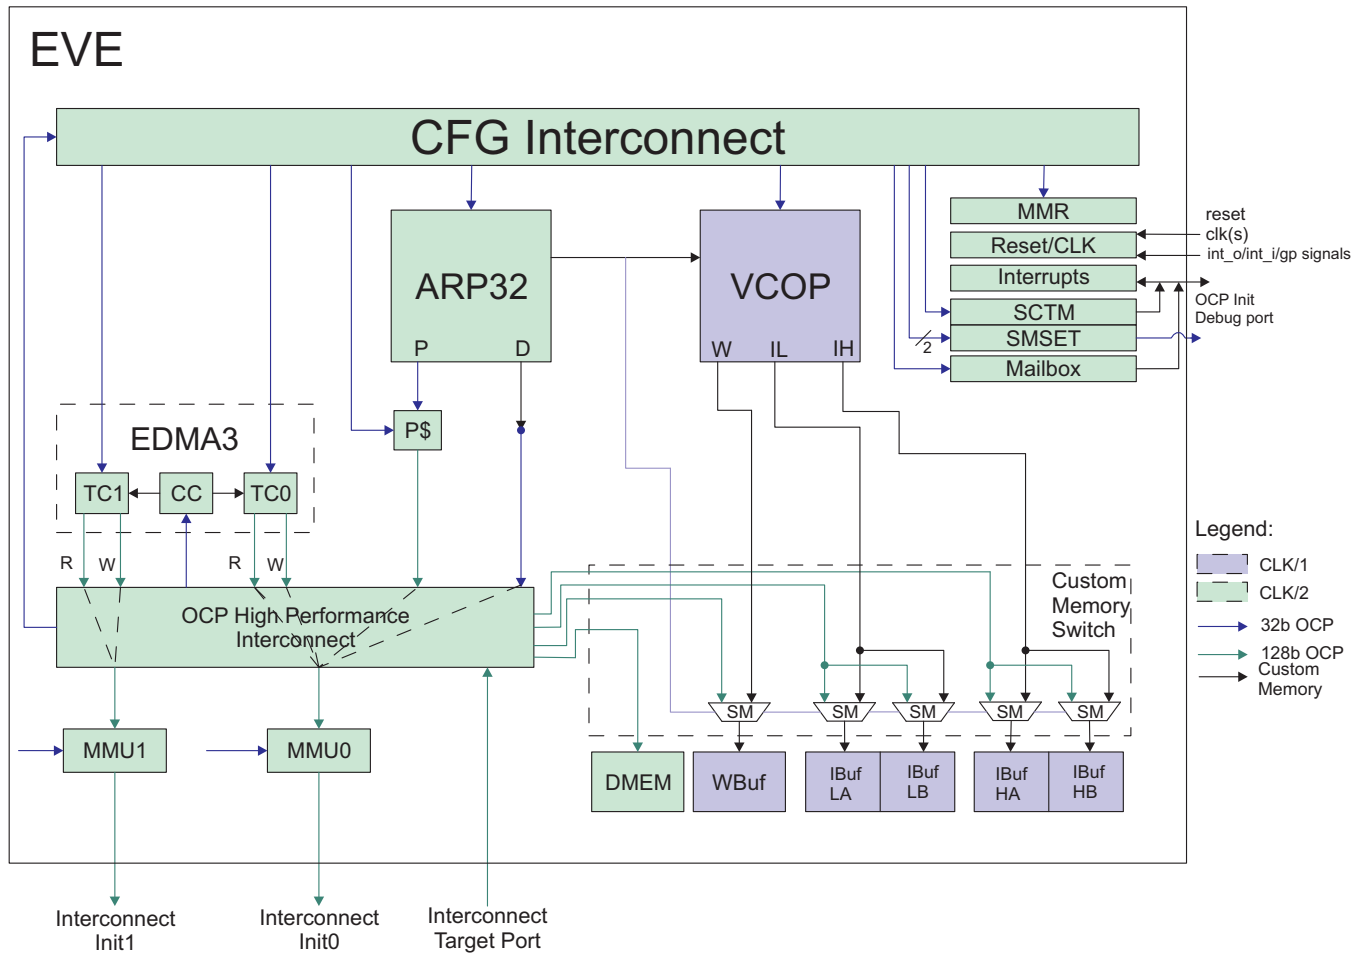

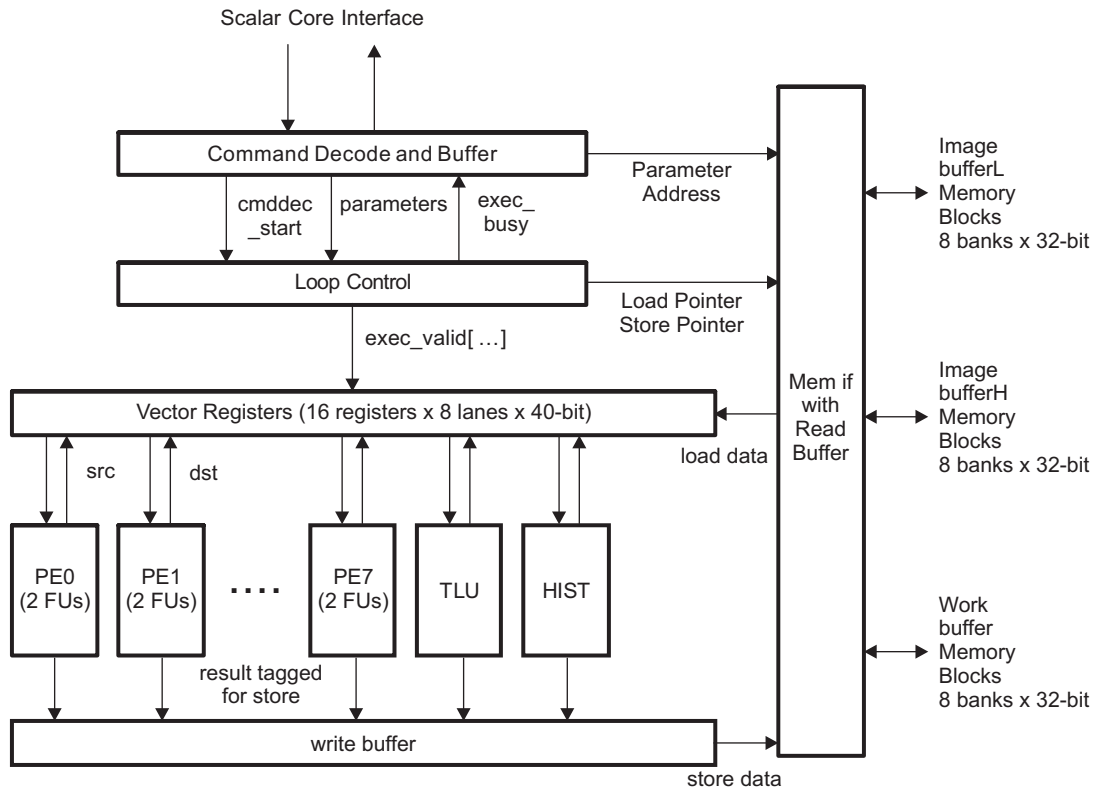

Figure 6-34 depicts the functional block diagram of EVE's Vector Coprocessor (VCOP).

Figure 6-34. VCOP Block Diagram

6.3.4 System Interfaces

6.3.4.1 Interrupts

The `vec_err_intn` interrupt is driven by the vector core and indicates that the vector core has encountered an error condition, see [Section 6.3.7.2.1 VCOP Register Manual](#) for details.

6.3.4.2 Configuration Bus Slave Port

VCOP has a configuration bus slave interface that follows the OCP 32-bit slave protocol. The interface enables module configuration, status, processor state readout during debug.

The interface operates in the same clock domain as `clk_eve_sca`, the scalar core and scalar/vector interface clock.

The memory map of the configuration bus is specified in [Section 6.3.7.2.1](#).

6.3.4.3 Performance Counter Interface

On the EVE level there is an SCTM module and an SMSET module to collect performance statistics.

SCTM is for counting signal active time and rise and fall transitions. SMSET is for conveying events to include into the system trace. [Table 6-41](#) lists the signals that are exported to SCTM or SMSET as indicated. All SCTM signals are level signals operating at full vector core speed (`clk_eve_vec`), and all SMSET signals are rising-edge triggered signals.

Table 6-41. Performance Counter Signal List

Signal	Destination	Description
vcop_busy	SCTM	Indicate VCOP busy, for measuring VCOP loading
vcop_idle_and_done	SCTM	Indicate VCOP idle and done, basically not(vcop_busy) and vec_done, for measuring slack in real-time schedule
vcop_wait_for_arp32	SCTM	Indicate VCOP idle and waiting for ARP32 to feed instruction, basically vec_rdy and not(vec_instr) and not(vcop_busy). This indicates VCOP under utilization that might be improved by reducing ARP32 interrupt services
vcop_arp32_awaits	SCTM	Indicate ARP32 has vector instruction ready and is waiting for VCOP to accept it, basically not(vec_rdy) and vec_valid. This indicates ARP32 idle time that might be utilized, however, not to the extent that vcop_wait_for_ARP32 time becomes significant.
vcop_overhead	SCTM	Indicate VCOP busy but not executing the loop, meaning exposed command decode (from decode-execute pipeline) and parameter access time. The former might be reduced by having more back-to-back loops, and the latter is unavoidable.
vcop_ld_stall_by_st	SCTM	Indicate LD stage is stalled by ST stage (forced write when write buffer is full). This means there is insufficient gaps in LD for ST to occur in the background, but this does not mean LD+ST is slowing down computation.
vcop_op_stall_by_ldst	SCTM	Indicate gaps in operation stage between iterations due to LD+ST, indicating extent of load/store bound (as opposed to compute-bound). This may be reduced by merging loops to reduce load/store.
vcop_op_stall_by_dependency	SCTM	Idle cycle inserted in operation stage due to dependency. This may be minimized by scheduling.
vcop_rd_ibufl	SCTM	Indicate VCOP reading from IBUFL
vcop_rd_ibufh	SCTM	Indicate VCOP reading from IBUFH
vcop_rd_wbuf	SCTM	Indicate VCOP reading from WBUF
vcop_wr_ibufl	SCTM	Indicate VCOP writing to IBUFL
vcop_wr_ibufh	SCTM	Indicate VCOP writing to IBUFH
vcop_wr_wbuf	SCTM	Indicate VCOP writing to WBUF
vcop_loop_start	SMSET	Indicate VCOP getting a VLOOP instruction
vcop_done	SMSET	Indicate VCOP executing a VWDONE instruction, copy of vec_done

6.3.4.4 Data Memory Map

The first instance of EVE has a data memory configuration and a memory-map as listed in [Table 6-42](#).

Memory maps for scalar and vector core are shown in [Figure 6-35](#). An optional MMR field, VEC_MEM_128KB, wraps the VCOP memory map around 128KB, aliasing the A and B sets to the same address range.

Table 6-42. EVE Vector Data Memory Map

Byte Address	Name	Description
0x00000 ~ 0x07FFF	WBUF	Vector working buffer, 32Kbytes
0x08000 ~ 0x0FFFF	reserved	Reserved for future expansion
0x10000 ~ 0x13FFF	IBUFLA	Image buffer low copy A, 16 Kbytes
0x14000 ~ 0x17FFF	IBUFHA	Image buffer high copy A, 16 Kbytes
0x30000 ~ 0x33FFF	IBUFLB	Image buffer low copy B, 16 Kbytes
0x34000 ~ 0x37FFF	IBUFHB	Image buffer high copy B, 16 Kbytes

Figure 6-35. EVE Memory Map

6.3.5 Functional Description

6.3.5.1 Scalar-Vector Architecture

The EVE subsystem consists of a scalar core as the subsystem controller, a vector core as the high-throughput coprocessor, shared memories, DMA, clock/reset and interrupt controllers. See the *EVE Subsystem Reference Guide* for details.

6.3.5.1.1 Scalar Core

The scalar core executes conventional RISC instructions. The scalar core is based on the ARP32 processor, which is based on ARP32.

See the *ARP32 CPU and Instruction Set Reference Guide* for more details.

6.3.5.1.2 Scalar-Vector Interaction

The EVE scalar and vector cores share one program memory, but can execute in parallel on separate threads. The scalar core has sole control of the program memory, so all vector instructions are accessed by the scalar core, recognized being a vector instruction, and relayed via the scalar/vector interface to the vector core for execution. The vector core executes a sequence of instructions (called a vector command) repeatedly, so typically can be busy executing and does not need further vector instructions for thousands of clock cycles at a time.

The vector core has temporary instruction storage. There is a pre-decode buffer of 64 words, plus a decoded buffer for two maximal-sized commands (see [Figure 6-36](#)). The vector core attempts to decode and fill the two commands first, and if vector instructions keep coming, fill the pre-decode buffer. Together the buffering holds 4 or more typical vector commands, and keep the vector core busy for a while, allowing the scalar core to switch context to serve interrupts when interrupts occur.

Figure 6-36. VCOP Instruction Buffering

6.3.5.2 Vector Core Overview

The vector core is a SIMD machine with built-in loop control and address generation. It is programmed in array or 2D block processing level. The vector core has the following resources:

- 4 nested for loops, with loop variables i1, i2, i3, and i4, plus an optional outer loop i0
- 8 address generators, each capable of 4-dimensional addressing, that is, the address pattern is: $\text{base} + i1 \times \text{const1} + i2 \times \text{const2} + i3 \times \text{const3} + i4 \times \text{const4}$
- 16-entry vector register file, each entry is N-way SIMD \times 40-bit signed (sign-extended or zero-padded from 8/16/32-bit signed/unsigned memory data, or from operation upon register data)
- Two general-purpose functional units, each N-way SIMD. Functional spec supports $N = \{2 \mid 4 \mid 8 \mid 16 \mid 32\}$, first instance $N = 8$.
- Table lookup unit supporting up to N parallel lookups.
- Histogram unit supporting up to N parallel histogram operations.
- 8 load units
- 8 store units

The vector core supports the following functions:

- Generic compute
- Table lookup
- Histogram and weighted histogram

6.3.5.2.1 Nested for Loop Model

EVE vector operation is controlled by a four-level nested for loop. Inside the loop, the behavior can be represented in sequential stages: load, arithmetic operation, store, and pointer update.

In each stage, a number of load, operation, stores, or pointer updates are carried out, with respect to the $16 \times N \times 40$ -bit vector register file. There is no dependency among loads, stores, or pointer updates; multiple loads unto the same register file is not allowed. Dependency among operations assumes 2 operations are carried out in parallel, with no delay slot for most operations, and 1 cycle of delay slot for some specific operations.

The vector register file, loop variables, address generators are replicated as needed in the hardware to support pipelining among the various stages.

[Example 6-8](#) shows a skeleton of the nested loop model. There are four loop variables, i1, i2, i3, and i4. A snapshots of the loop variables are contained in the following registers:

- [VCOP_I0_I1\[15:0\]](#) I0 - I0 loop variable
- [VCOP_I0_I1\[31:16\]](#) I1 - I1 loop variable
- [VCOP_I2_I3\[15:0\]](#) I2 - I2 loop variable
- [VCOP_I2_I3\[31:16\]](#) I3 - I3 loop variable
- [VCOP_I4\[15:0\]](#)I4 - I4 loop variable

Example 6-8. Nested Loop Model Skeleton

```

EVE_compute(...)
{
  for (i1=0; i1<=lpend1; i1++) {
    for (i2=0; i2<=lpend2; i2++) {
      for (i3=0; i3<=lpend3; i3++) {
        for (i4=0; i4<=lpend4; i4++) {

          for (k=0; k<num_inits; k++)
            initialize_vreg_from_parameters(...);

          for (k=0; k<num_loads; k++)
            load_vreg_from_local_memory(...);

          for (k=0; k<num_ops; k++)
            op(...);          // 2 functional units, executing 2 ops per cycle

          for (k=0; k<num_stores; k++)
            store_vreg_to_local_memory(...);

          for (k=0; k<num_agens; k++)
            update_agen(...);
        }
      }
    }
  }
}

```

Each stage is described in more details in the following sections.

Note that loads and stores are predicated on the loop variables matching specific conditions and are thus not always carried out at every i4 iteration.

Each i4 iteration takes a number of cycles equal to the maximal number of cycles spent in loads, arithmetic operations, and stores. Cycle count in the arithmetic operations is constant for each loop, but cycle count in load and store can change depending on pointer update, loop level, and read/write memory contention.

For example, with $lpend1 = 3$, $lpend2 = 1$, $lpend3 = 2$, and $lpend4 = 4$, the nested for loop executes in exactly $4 \times 2 \times 3 \times 5 = 120$ i4 iterations. For the first few iterations the loop variables progress as:

i1	i2	i3	i4
0	0	0	0
0	0	0	1
0	0	0	2
0	0	0	3
0	0	0	4
0	0	1	0
0	0	1	1
0	0	1	2
...			

6.3.5.2.2 Instruction Organization

Vector instructions cannot appear in the program stream in arbitrary order. Instructions are classified as:

- Control
 - Repeat end count
 - Parameter pointer
 - Write buffer switch
- Synchronization
 - Wait for ready
 - Wait for done
- Computation
 - VLOOP
 - Register initialization
 - Address generator
 - Load
 - Operations
 - Store

The sequencing rule is that computation instructions that form a loop are in one contiguous block, starting with `VCOP_VLOOP_PTR[31:0]VLOOP_PTR`. This block of computation instructions is called a vector command. Control, synchronization, and scalar instructions can appear in any order, except that they cannot appear inside a vector command.

6.3.5.3 Vector Control

The VCTRL instruction is used to convey control information to the vector core. The instruction syntax is:

VCTRL <i>scalar_register, control_register</i>

The control registers so far defined are 0: RPT_END and 1: PARAM_PTR (VCOP_PARAM).

6.3.5.3.1 Repeat End Count

A VCTRL instruction variation programs the repeat end count. The syntax is:

VCTRL <i>scalar_register, RPT_END</i>
--

Subsequent VLOOP is executed RPT_END + 1 times. Reset default is 0, or repeating just once, and is the normal mode of operation. At end of loop execution, RPT_END is automatically reset to 0, so if the subsequent is non-repeating, which is most of the cases, there is no need to issue another VCTRL RPT_END to reset it.

RPT_END is a 12-bit value; the largest value supported is 0:4095, allowing for up to 4096 iterations of the repeat loop.

Note that the VLOOP instruction that follows can be of any type (computer, table lookup, histogram).

The repeat mechanism can be viewed as enclosing VLOOP by an outer loop, i0. The difference between this i0 loop and the i1, i2, i3, i4 loops inside VLOOP is that parameter pointer is advanced at the end of VLOOP. The repeat feature allows the same program code to be executed with a different set of parameters each time.

The repeat feature is useful for performing the same processing steps on a list of data regions that are not spaced regularly and/or not having the same dimension. Instead of having a scalar loop around the repeated VLOOP, using the repeat feature reduces scalar/vector interaction and resulting overhead.

Software must allocate memory appropriately to allow results of these data blocks to be stored (sequentially or otherwise is under programmer's control).

6.3.5.3.2 Parameter Pointer

In addition to the vector instructions in PMEM, the vector core must read a parameter file in WBUF or IBUFL/IBUFH (depending on the pointer value) before it begins intended computation. The parameters include loop counts, address pointers to arrays, constants used in the computation, round/truncate shift count, saturation bounds, etc. The parameter pointer is located in [VCOP_PARAM_PTR](#)[31:0] PARAM_PTR.

Separation of configuration coded in the program memory versus configuration conveyed in data memory is essential, as this allows library functions to be constructed with reasonable code size and can serve a variety of need in applications. Loop counts and address pointers being conveyed via parameters is needed, so that, for example, one filter function works for various data/coefficient/output arrays and block and coefficient kernel sizes. Round/truncation shifts being convey via parameters means that, for example, the same filtering kernel program can work for filters with different radix point bit positions for filter coefficients.

Parameter registers are 16-bit per entry in the parameter file, up to 64 entries. The first 2 entries of the parameter file, P0 and P1, are hard-coded to constant values 0 and 1 respectively, as these are commonly used and it reduces code size by referring to these constants without taking up data memory space.

Parameters are referred to in the vector instructions either as single register, 16-bit parameter, or as a register pair, together make up 32-bit. Where a pair is used, the first parameter must be an even index, and contains the lower 16-bit of the 32-bit.

From an application development point of view, algorithm kernels are sometimes coded in one vector command per kernel, sometimes in several commands. Thus it is beneficial for the vector core to advance the parameter pointer automatically to reduce overhead. This requires a mechanism to specify or modify the parameter pointer when needed. This is addressed by the parameter pointer update feature through VCTRL.

A VCTRL instruction variation updates the parameter pointer for the subsequent VLOOP. The syntax is:

VCTRL <i>scalar_register</i> , PARAM_PTR
--

Unless updated again by VCTRL, the parameter pointer is advanced automatically at the end of VLOOP execution by the #PL field of VLOOP. Thus, parameter blocks for multiple consecutive VLOOPS can be placed consecutively in data memory, and no VCTRL [VCOP_PARAM_PTR](#) is needed except for the first VLOOP.

For efficiency of parameter access by VLOOP, the pointer value conveyed via VCTRL must be 32-bit aligned. The parameter length specified in VLOOP is also 32-bit aligned. Thus, at the beginning of any VLOOP, the pointer is 32-bit aligned.

Note that inside a VLOOP while parameters are pulled off to configure the loop, the parameter pointer is only 16-bit aligned.

For example, if 11 parameter registers are used in a vector command, P0..10, the encoded parameter length is $\text{ceiling}((11 - 2)/2) = 5$. The subsequent next vector command accesses parameter registers 5 32-bit words from the current vector command, leaving one 16-bit halfword in memory unused.

6.3.5.3.3 Switch Buffers

To minimize task-switching overhead, an instruction is added to write to buffer switch MMR. The instruction syntax is:

VSWITCHBUF <i>ucst20</i>

Where `ucst20` is a 20-bit immediate value to be written to a dedicated MMR for buffer switches.

This instruction is carried out by the scalar core, and vector core just ignores it.

Change made to the buffer switch is visible in MMR as well, as both `VSWITCHBUF` and generic scalar core store to the buffer switch MMR are both valid ways to program the buffer switches, only that `VSWITCHBUF` achieves lower latency. Both mechanisms are kept consistent in the simulator/ debugger toolset.

6.3.5.4 Vector-Scalar Synchronization

6.3.5.4.1 Wait for Vector Core Done

The `VWDONE` instruction is used as a synchronization barrier between scalar and vector core, and affects the scalar/vector interface signal `vec_done`. Upon reset, `vec_done` is true. Upon execution of `VWDONE` in the scalar core, the scalar stalls and waits for `vec_done`. The vector core, upon executing this instruction, implying all previous submitted vector instructions are all done, asserts `vec_done`. Once asserted, `vec_done` stays true until receiving a subsequent `VLOOP` that turns the vector busy and `vec_done` false again.

The `VWDONE` instruction is typically used before the scalar core switches shared memory to itself or DMA. Before it changes the switch it makes sure that the vector core is idle and thus not accessing the memory.

`VWDONE` must appear between vector commands in the program, not inside a vector command.

6.3.5.4.2 Wait for Vector Core Ready

The `VWRDY` instruction is used to stall the scalar core until vector core is ready to accept additional vector instructions. Vector core ignores this instruction.

Normally the scalar core can simply issues vector instruction, and when the vector core is not ready, `VCOP_STATUS[2]VEC_RDY = 0` the scalar core is automatically stalled. Having `VWRDY` allows inserting timer read before and after `VWRDY` to measure the time duration of vector core not being ready, for performance tuning purposes.

6.3.5.5 Vector Computation

6.3.5.5.1 Vector Loop

The `VLOOP` instruction marks the beginning of a vector command specifying a loop. Assembly format:

<code>VLOOP cmd_type , CL# : cmd_len , PL# : param_len</code>

The `cmd_type` field specifies whether it is the main compute (COMP), table lookup (TLU), or histogram (HIST).

Command length (`cmd_len`) and parameter length (`param_len`) in 32-bit words are encoded to facilitate quick parsing of the vector commands. The ending loop counts, `lpend1/2/3/4`, are encoded at fixed entries in the parameter file, `P2 = lpend1`, `P3 = lpend2`, `P4 = lpend3`, `P5 = lpend4`. This allows easy adaptation of EVE function to different array dimensions.

The first two entries of the parameter file have implicit values and are thus not conveyed in the data memory. `P0 = 0` and `P1 = 1`. **The `param_len` does not include these two entries.**

The binary code of `VLOOP` includes a `version` field, which allows a compiler/assembler to indicate which version of EVE hardware the vector command is compiled for. The first version has `version = 0`, the next version, `version = 1`, and so on. This allows future version of EVE to offer backward compatibility; that is, execute previous-version binary as is. For example, if a future version of EVE has 16-way SIMD, it can execute 8-way SIMD binary by disabling half of the datapath.

Each vector command can have:

- Up to 8 address generators
- Up to 16 vector register initialization
- Up to 8 loads
- Up to 40 operations
- Up to 8 stores

Maximal command length is 81 instructions (VLOOP + 16 VINITs + 8 VAGENS + 8 VLDs + 40 operations + 8 VSTs).

6.3.5.5.1.1 Retention of State Between VLOOPS

From one VLOOP to the next VLOOP, the following state information is retained:

- Parameter pointer, advanced by parameter length in the first VLOOP
- Vector register contents, whatever left over from the last iteration of the first VLOOP

The following state information is not retained, thus must be configured within each VLOOP:

- Parameter register file (must be reloaded from data memory)
- Agen configuration, such as association of the four counts to parameter registers
- Agen address counter (reset at the beginning of each VLOOP execution)

6.3.5.5.2 Vector Register Initialization

It is useful to initialize vector register with constants provided in the parameter file. As parameter file is scalar (not NWAY SIMD), each value is broadcast to all NWAY of the destination vector register.

Assembly syntax:

VINIT *type_init_loop preg, vreg*

The data *type* can be signed/unsigned halfword or word. In case of word, two parameter register entries (16-bit each) are used, first one being copied to the lower halfword, and the second one to the upper halfword.

For the word type initialization, *preg* specified is the lower halfword and must be even. For example, VINITWU_ONCE P10, V2 initializes V2 using (P11 << 16) + P10.

The *init_loop* field can be {ONCE, I234_ZERO, I34_ZERO, I4_ZERO, ALWS }.

The VINIT instruction is equivalent to initializing a specific vector register in the nested i1/i2/i3/i4 loop shown in [Section 6.3.5.3.2](#):

- ONCE is for initialization before the loop.
- I234_ZERO is for initialization inside the i1 loop, before entering the i2 loop.
- I34_ZERO is for initialization inside the i2 loop, before entering the i3 loop.
- I4_ZERO is for initialization inside the i3 loop, before entering the i4 loop.
- ALWS is for initialization inside the i4 loop, running every iteration.

The VINIT feature is used to initialize vector registers to certain initial values. For example, FIR filtering is implemented by iterating over filter taps with MADD instructions, and VINIT is used to initialize the accumulator to zero at the proper iteration, i4 for 1-D filter, and i3 for 2-D filter. Constants are brought into the computation loop with VINIT as well. For example, to scale an entire input array by a constant factor.

Note that VINIT broadcasts one value to all SIMD lanes. Initializing a vector register to multiple values is accomplished with a vector load (VLD) with zero address increment.

Sometimes it is useful to refer to loop variables in the computation. For example, to collect the maximal five values in an array and recording their indices, software can first do this in SIMD fashion to get to 5 sets of values and indices, then merge among SIMD lanes. Indices are readily copied from the loop variable i4, instead of spending cycles to compute with ALU operations.

VINIT provides this capability by extending the parameter count to cover loop variables:

- P64 = i0, the repeat outer loop enabled via VCTRL <scalar_reg>, RPT_END
- P65 = i1
- P66 = i2
- P67 = i3
- P68 = i4

When using these parameter counts, only the unsigned halfword type is supported.

6.3.5.5.3 Address Generator (agen)

In image, video, vision computation, there are often many operations performed on arrays of the same dimension; which can use the same addressing pattern (with different base addresses) in the memory read/write. The address generator resource is included to take advantage of this. One agen can be shared among multiple loads and/or multiple stores.

The VAGEN instruction has this assembly format:

VAGEN *agen*, [*pinc4*, *pinc3*, *pinc2*, *pinc1*]

Agen field is a label (A0..7) to identify one of 8 agen resources.

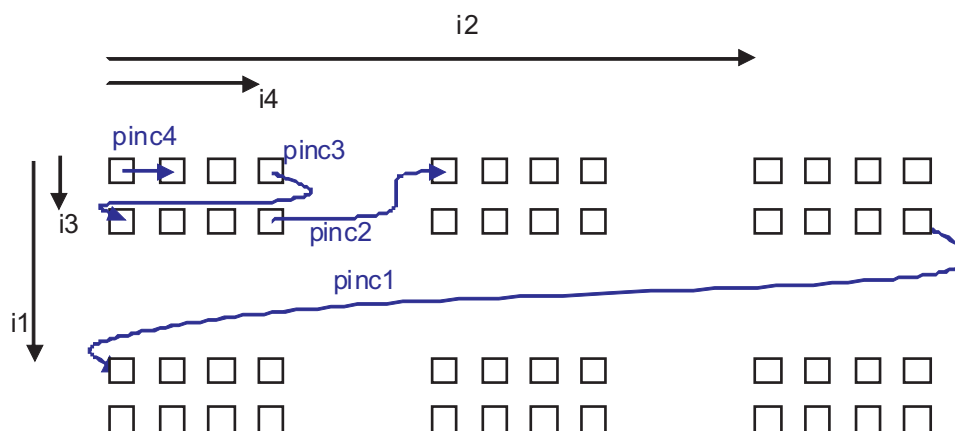

VAGEN is defined in strict linear order A0, A1, A2, till the last agen used in the command. The agens defined can be used (in loads and stores) in any order. It is allowed to share agen between load(s) and store(s).

The address increments represent:

- pinc4: inside the i4 loop, default
- pinc3: inside the i3 loop, when i4 matches the ending loop count
- pinc2: inside the i2 loop, when where i3 and i4 both match the ending loop counts
- pinc1: inside the i1 loop, when i2, i3, and i4 all match the ending loop counts

Figure 6-37 shows an example of $2 \times 3 \times 2 \times 4$ data object, addressed by the loop variables i1, i2, i3 and i4, with i1 being the outer-most loop. The address increments to access the object are shown in Figure 6-37.

Figure 6-37. Addressing a Four-Dimensional Data Object

In the VAGEN instruction, pointers to the parameter file are encoded, not the address increments themselves. Most data objects do not require 4-dimension addressing. For example, coefficient data for 2D FIR filter is normally stored consecutively, and advance by 1 data point most of the times, and wraps back at the end of i3 loop. Then $\text{pinc4} = \text{pinc3}$ is specified to one parameter register (initialized to 2 for 16-bit coefficients), and $\text{pinc2} = \text{pinc1}$ to another parameter register for the wrap-back. Thus, this scheme reduces command plus parameter data.

All address increments are in bytes. This allows misaligned halfword (16-bit) and word (32-bit) accesses that are some times needed in the processing.

Each address increment is encoded with one 16-bit parameter register, treated as signed value. The above example shows address increment moving forward, but in many cases, for example coefficients for filtering, negative increments are used.

Note that the address increments together specify addressing pattern of a single pointer, and the data distribution controls how consecutive memory data from that pointer, up to 32N-bit, are distributed among the SIMD dimension of the vector register entry.

In case multiple VAGEN instructions are issued for the same agen resource (for example, A0), the last one takes effect, and the preceding ones with the same agen resource is ignored.

6.3.5.5.4 Vector Load

The VLD instruction specifies the data distribution, data type, base address, agen, and the vector register to load the data to. Format of the VLD instruction in assembly is:

VLD *type_distribution base [agen], vreg*

The *base* field points to a pair of parameter registers (even/odd pair only), for example $\text{base} = \text{P8}$ to refer to the P8:P9 pair. The vector data memory space is 20-bit, with the lower 16-bit encoded in the even parameter register (P8 in this case), the upper 4-bit in the odd parameter register (P9 in this case).

The destination vector register specified in VLD must be an even register. VLD_DINTRLV loads into an even/odd pair of registers. VLD with any other distribution option loads into one register. There are up to eight VLD instructions in a loop to potentially load up all 16 registers. No register can be the destination of more than one VLD instruction in the same loop.

As EVE is an N-way SIMD machine, loading of N consecutive data points from local memory is supported, with each data point being a byte, short, or long (32-bit) word, either signed or unsigned.

In addition to loading N data points, EVE supports a few other distribution options. EVE supports the following:

- NPT: N data points, one to each way of SIMD
- 1PT: broadcasting one data point to all
- CIRC2: circuiting between two data points, useful for Bayer image processing
- DS2: downsample by 2; every other data point (**not available for word-size input**)
- US2: upsample by 2; repeat each input data point twice
- DINTRLV: deinterleave inputs; load 2N data points into two registers, deinterleave data items so that even items go to the first register, odd items go to the second register. Supported only for byte or halfword per data point, **not word data type**. Two registers must be an even/odd pair, but only the first register (even) is encoded in assembly and in instruction binary.
- CUST_P8: custom distribution as provided by {P8..} in the parameter file
- CUST_P16: custom distribution as provided by {P16..} in the parameter file
- CUST_P24: custom distribution as provided by {P24..} in the parameter file
- EXP: load with expansion using predicate register V0
- NBITS: N bits, one bit to each way of SIMD, regardless of the data type (for example, when N = 16, a halfword is read). Signed/unsigned data type affects how this bit is to be sign-extended. Unsigned means 0 -> 0, 1 -> 1, and signed means 0 -> 0, 1 -> -1. This is useful for expanding load and other cases where boolean arrays are packed.

For CUST_Pi options, number of bits required to specify the address offset for each way of SIMD depends on N, the number of ways of SIMD. Arbitrary distribution of N data items (each a byte, halfword, or word) is supported. For N = {2 | 4 | 8 | 16}, 4 bits is used to encode each destination. For N = 32, 5 bits is used; and each 16-bit parameter register supplies three fields (leaving 1 bit unused).

- N = 2, 2 × 4 = 8 bits, one parameter register required
- N = 4, 4 × 4 = 16 bits, one parameter register required
- N = 8, 8 × 4 = 32 bits, two parameter registers required
- N = 16, 16 × 4 = 64 bits, four parameter registers required
- N = 32, ceiling(32/3) = 11 parameter registers required

The DINTRLV option is supported so software can fully utilize the two function units for simple operation sequences, by processing 2N data points in parallel.

VLD instruction normally loads into one destination vector register. VLD_DINTRLV is the exception in that it loads into a pair of vector registers. Only even registers, V0, V2, ..., V14, can be referenced in the destination register field. In case of VLD_DINTRLV, the referenced register and the next register shall be the destination, for example V0 and V1.

The following data types are supported:

- B: signed byte
- BU: unsigned byte
- H: signed halfword (16-bit)
- HU: unsigned halfword
- W: signed word (32-bit)
- WU: unsigned word

Address offsets for each way of SIMD, as the function of distribution option and data type are shown in Table 6-43 and Figure 6-38, Figure 6-39, and Figure 6-40.

Table 6-43. VLD Data Distribution Options⁽¹⁾⁽²⁾

Distribution	vreg[r][0] gets	vreg[r][1] gets	vreg[r][2] gets	vreg[r][3] gets	vreg[r][4] gets	vreg[r][5] gets	vreg[r][6] gets	vreg[r][7] gets
NPT	data[0]	data[1]	data[2]	data[3]	data[4]	data[5]	data[6]	data[7]
1PT	data[0]	data[0]	data[0]	data[0]	data[0]	data[0]	data[0]	data[0]
CIRC2	data[0]	data[1]	data[0]	data[1]	data[0]	data[1]	data[0]	data[1]
DS2	data[0]	data[2]	data[4]	data[6]	data[8]	data[10]	data[12]	data[14]
US2	data[0]	data[0]	data[1]	data[1]	data[2]	data[2]	data[3]	data[3]
DINTRLV	vreg[r][0] = data[0], vreg[r+1][0] = data[1]	vreg[r][1] = data[2], vreg[r+1][1] = data[3]	vreg[r][2] = data[4], vreg[r+1][2] = data[5]	vreg[r][3] = data[6], vreg[r+1][3] = data[7]	vreg[r][4] = data[8], vreg[r+1][4] = data[9]	vreg[r][5] = data[10], vreg[r+1][5] = data[11]	vreg[r][6] = data[12], vreg[r+1][6] = data[13]	vreg[r][7] = data[14], vreg[r+1][7] = data[15]
CUST_Pi ⁽³⁾	data[pf[0]]	data[pf[1]]	data[pf[2]]	data[pf[3]]	data[pf[4]]	data[pf[5]]	data[pf[6]]	data[pf[7]]

⁽¹⁾ Table “data” is type-cast to the appropriate signed/unsigned byte/halfword/word so that correct offsets are applied.
⁽²⁾ This is a table of what data element gets loaded into each SIMD lane of a vector register, in the order lane 0 to lane 7. This does not reflect a debugger memory window hex display.
⁽³⁾ pf[0], pf[1], ... pf[7] refer to bit fields in the indicated parameter registers. For example, for the 8-way SIMD EVE, it takes two parameter registers for the distribution information, so for CUST_P8 use: distrib_info = (P9 << 16) | P8, and assign (distrib_info >> (4 × i)) & 0xF to pf[i].

Loads are automatically predicated. Loads are always performed at the very first iteration, and then subsequently upon any change in the associated agen address pointer.

See [Section 6.3.5.5.10](#) for address alignment requirement for various data type and distribution options.

LD_EXP is load with expansion, and is for reading a compacted (collated) array and expanding the elements to the original locations. It is the opposite of ST_COLLAT (collating store). Per-item address increment is implied by the load data type (1/2/4 bytes depending on byte/halfword/word type). The agen field is don't care. Per iteration, load pointer ([VCOP_LD_PTR_i/VCOP_ST_PTR_j](#)) is increment by number of non-zeroes in predicate register V2 times the data size. Agen is not used, and so the agen field is not required in the assembly code:

VLD *type_EXP base, vreg*

For example with this instruction, where V2 = {0, 0, 1, 0, 1, 1, 0, 0}, load_ptr = 0x100:

```
LDBU_EXP Pbase[A0], V1
```

There shall be, after this instruction:

```
V1 = {0, 0, mem[0x100], 0, mem[0x101], mem[0x102], 0, 0}, and load_ptr = 0x103
```

Load with expansion is restricted to be used in table lookup VLOOP. This is because the dependency (where the expanding load depends on predicated register data from another load) is more similar to table lookup, and thus it's feasible to achieve N data points per clock cycle inside table lookup pipeline. As in normal table lookup, no operation instructions are allowed in table lookup VLOOP.

Figure 6-38. Load Word Distribution Options

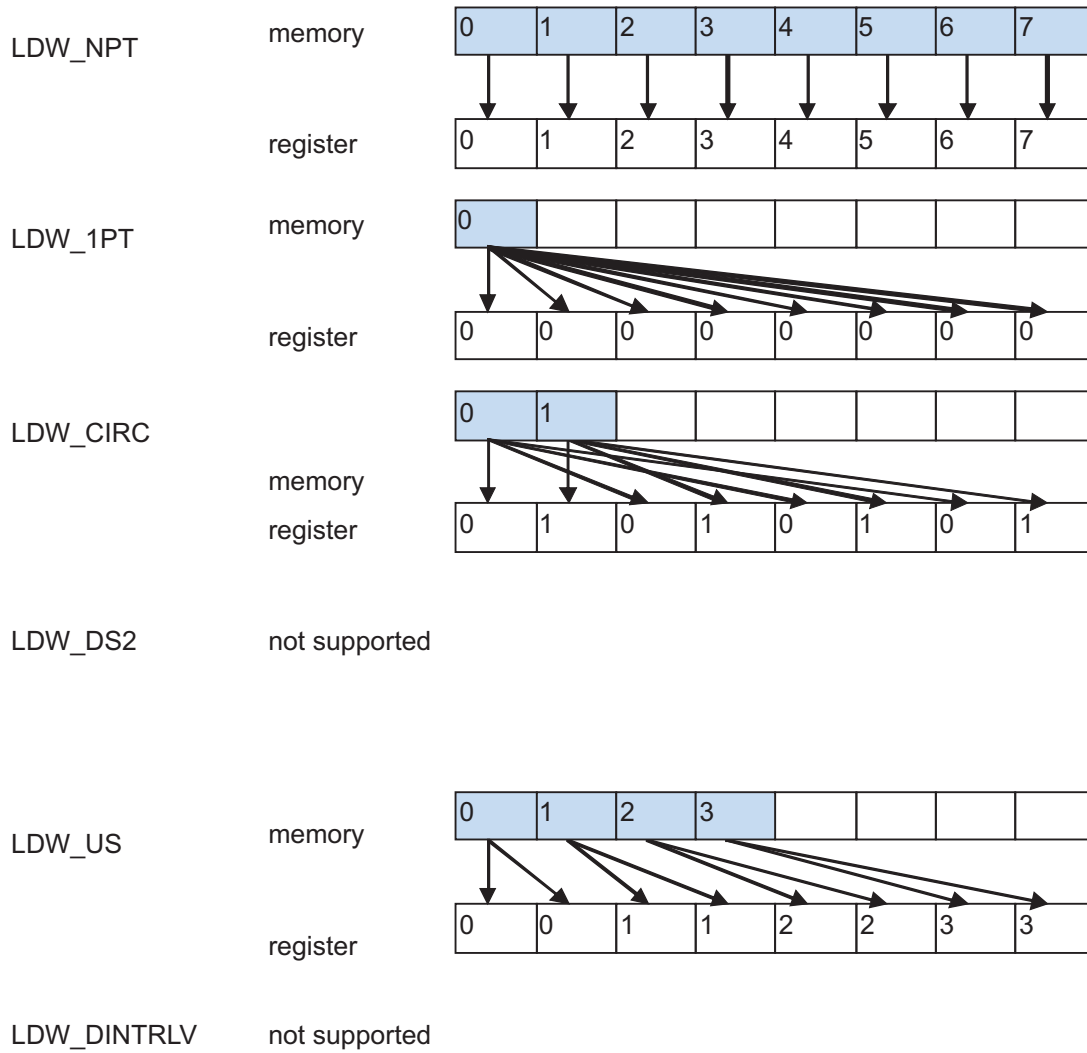

Figure 6-39. Load halfword Distribution Options

6.3.5.5.5 Vector Arithmetic/Logic Operations

Various arithmetic and logic operations are available in the compute command, which is indicated by starting the command with:

VLOOP COMP, *cmd_len*, *param_len*

Vector arithmetic/logic instructions have the following assembly formats, depending on whether it is 1-input-1-output, 2-input-1-output, 2-input-2-output, or 3-input-1-output, whether accumulator clearing is enabled, and whether rounding is enabled.

V<op_1i1o> src1, dst

V<op_2i1o> src1, src2, dst

V<op_2i1o> src1, src2, dst, RND: rnd_param

V<op_2i2o> src1/dst1, src2/dst2

V<op_2i2o> src1, src2/dst1, dst2

V<op_3i1o> src1, src2, src3, dst

V<op_3i1o> src1, src2, src3, dst, RND: rnd_param

All operations are 40-bit, except:

- Input to multiply (MPY, MADD, MSUB) is 17-bit data.
- BINLOG, BITC, BITDI, BITI, BITR are 32-bit instructions.
- BITPK, BITUNPK, SORT2, MIN, MAX are 33-bit instructions (to allow processing of up to 32-bit signed data)
- BITTR, bit transpose, bit width is limited to ways of SIMD, thus 8-bit data for 8-way SIMD.

The operations in [Table 6-44](#) are supported. See [Section 6.3.5.9](#) for details on each operation.

Table 6-44. VCOP Arithmetic/Logic Operations

Operation	#In- Out	#Bits	#Del	Syntax ⁽¹⁾	Note
VNOP		40		VNOP	
VADD	2-1	40		VADD src1, src2, dst	src1 + src2
VSUB	2-1	40		VSUB src1, src2, dst	src1 – src2
VABSDIF	2-1	40		VABSDIF src1, src2, dst	src1 – src2
VMPY	2-1	17/33	1	VMPY src1, src2, dst, RND:rnd_param	src1 * src2
VAND	2-1	40		VAND src1, src2, dst	src1 & src2
VOR	2-1	40		VOR src1, src2, dst	src1 src2
VXOR	2-1	40		VXOR src1, src2, dst	src2 ^ src2
VMIN	2-1	33		VMIN src1, src2, dst	min(src1, src2)
VMAX	2-1	33		VMAX src1, src2, dst	max(src1, src2)
VANDN	2-1	40		VANDN src1, src2, dst	src1 & (~src2)
VSHF	2-1	40/6		VSHF src1, src2, dst	src1 << src2, or src1 >> (-src2)
VRND	2-1	40/5	1	VRND src1, src2, dst	(src1 + (1 << (src2-1)) >> src2
VCMPSEQ	2-1	40		VCMPSEQ src1, src2, dst	(src1 == src2) ? 1 : 0
VCMPGT	2-1	40		VCMPGT src1, src2, dst	(src1 > src2) ? 1 : 0
VCMPGE	2-1	40		VCMPGE src1, src2, dst	(src1 >= src2) ? 1 : 0
VBINLOG	1-1	32	1	VBINLOG src1, dst	approximate binary log
VBITC	1-1	32	1	VBITC src1, dst	count one bits
VNOT	1-1	40		VNOT src1, dst	~src1

⁽¹⁾ The parameters src1, src2, src3, dst, dst2 refer to the vector register entry for source or destination.

Table 6-44. VCOP Arithmetic/Logic Operations (continued)

Operation	#In- Out	#Bits	#Del	Syntax ⁽¹⁾	Note
VMADD	3-1	17/40	1 / 2	VMADD src1, src2, src3, dst, RND: rnd_param	src3 + src1 * src2
VMSUB	3-1	17/40	1 / 2	VMSUB src1, src2, src3, dst, RND: rnd_param	src3 – src1 * src2
VADD3	3-1	40	1	VADD3 src1, src2, src3, dst	src1 + src2 + src3
VSAD	3-1	40	1	VSAD src1, src2, src3, dst	src3 + abs(src1 – src2)
VSEL	3-1	40		VSEL src1, src2, src3, dst	src1 ? src2 : src3
VAND3	3-1	40	1	VAND3 src1, src2, src3, dst	src1 & src2 & src3
VOR3	3-1	40	1	VOR3 src1, src2, src3, dst	src1 src2 src3
VSHFOR	3-1	40/6	1	VSHFOR src1, src2, src3, dst	src3 (src1 << src2) or src3 (src1 >> -src2)
VSORT2	2-2	33		VSORT2 src1/dst1, src2/dst2	dst1 = min(src1, src2) dst2 = max(src1, src2)
VBITPK	2-1	33	1	VBITPK src1, src2, dst	compare, bit-pack, broadcast
VBITUNPK	2-1	40	1	VBITUNPK src1, src2, dst	bit unpack
VEXITNZ		40		VEXITNZ level, src1	exit loop at end of iteration when (src1 != 0)
VCMOV		40		VCMOV cond, src1, dst	conditional move
VBITR	1-1	32	1	VBITR src1, dst	bit reverse
VBITI	2-1	32	1	VBITI src1, src2, dst	bit interleave
VBITDI	1-2	32		VBITDI src1, dst1, dst2	bit deinterleave
VABS	1-1	40		VABS src1, dst	abs(src1)
VADDH	2-1	40		VADDH src1, src2, dst	src1+ signext(src2[39:32])
VLMBD	3-1	40	1	VLMBD src1, src2, dst	left-most-bit-detect
VBITTR	1-1	NSIMD	1	VBITTR src1, dst	bit transpose
VSIGN	2-1	40		VSIGN src1, src2, dst	apply sign of src1 on src2
VADDSUB	2-2	40		VADDSUB src1/dst1, src2/dst2	dst1 = src1 + src2 dst2 = src1 – src2
VINTRLV	2-2	40		VINTRLV src1/dst1, src2/dst2	interleave
VDINTRLV	2-2	40		VDINTRLV src1/dst1, src2/dst2	deinterleave
VMINSETF	2-2	33		VMINSETF src1, src2/dst1, dst2	minimum and set flag
VMAXSETF	2-2	33		VMAXSETFsrc1, src2/dst1, dst2	maximum and set flag
VINTRLV2	2-2	40		VINTRLV2 src1/dst1, src2/dst2	interleave with 2-element frequency
VDINTRLV2	2-2	40		VDINTRLV2 src1/dst1, src2/dst2	deinterleave with 2-element frequency
VINTRLV4	2-2	40		VINTRLV2 src1/dst1, src2/dst2	interleave with 4-element frequency
VSHF16	1-2	33		VSHF16 src1, dst1, dst2	shift up 16 bits into 2 registers
VADIF3	3-1	40	1	VADIF3 src1, src2, src3, dst	add difference, dst = src1 – src2 + src3
VSWAP	3-2	40		VSWAP cond, src1/dst1, src2/dst2	conditional swap

Operations with two destinations must use two different destination registers, otherwise the outcome is undefined.

The accumulating register (being a source as well as the destination of an operation) must be src1 for 2-input-1-output operations, and must be src3 for 3-input-1-output operations.

The rounding parameter is needed for VMPY, VMADD and VMSUB instructions, and specifies an index to the parameter file, see [Section 6.3.5.9](#).

EVE hardware executes up to 2 operations in parallel per clock cycle. Assembly program (by programmer or by compiler) contains the parallel bar notation to indicate if an instruction is to be executed by itself, or is to be executed in parallel with another instruction.

VMADD, VMSUB instruction have two delay slots for the multiplication input, and one delay slot for the addition/subtraction input.

VMPY, VRND, VBINLOG, VBITC, VADD3, VSAD, VAND3, VOR3, VSHFOR, VBITPK, VBITUNPK, VBTR, VBITI, VLMBD, VBITTR, VADIF3 instructions have one delay slot.

All other operations do not have delay slots.

The hardware detects write/read dependency between pairs of instruction executed in parallel, but not inside each pair. When necessary for correctness, hardware inserts idle cycles automatically. Still to achieve good performance, software must try to schedule the operations to avoid automatic idle cycles.

There is a forwarding path *within each* functional unit and *between* the two functional units to forward from destination to source 3 (accumulator input) of 3-input-1-output operations.

Register forwarding, dependency checking and automatic idle cycle insertion work across iterations as well, from end of one iteration to the beginning of the next iteration. For example, the FIR filtering kernel executes in one cycle per iteration with the destination-to-source3 dependency across iterations.

```

VINITH_I34_ZERO    P0, V4
VLDH_NPT           P12[A0], V0
VLDH_1PT           P14[A1], V2
VMADD              V0, V2, V4, V4
VSTH_NPT_LAST_I34 V4, P16[A2], RND_SAT:P18

```

[Table 6-45](#) shows delay slots and automatically inserted idle cycles.

Table 6-45. Example of Operation Delay Slots

Time	VMPY	VMADD	VSUB	VMSUB	VAND	VOR	VADD
0	V0*V1						
1	V0*V1 => V7	V2*V3	V2-V6 => V6				
2		V2*V3 => p		V4*V5	V3 & V6 => V6		
3		V7 + p => V7		V4*V5 => p		wait for V7	
4				V7 - p => V7		wait for V7	
5						V1 V8 => V9	V6 + V7 => V6

Zero-delay slot operation executes in one cycle. VMPY, an one-delay slot operation takes two cycles to execute. VMADD and VMSUB, two-delay slot operations take 3 cycles for execution, but need its additional input only on the third cycle. The dependency between the two instructions (VMADD-VMSUB) on the additional operand does not introduce idle cycles, but VMSUB-VMAD dependency adds 2 idle cycles to execution per iteration.

6.3.5.5.6 Vector Store

The VST instruction specifies the data distribution, data type, base address (index to parameter file), *agen*, the vector register to get the store from, loop level when stores are to occur, and rounding/saturation configuration. Format of VST is:

[pred] VST*type_ distribution_wr_loop vreg, base[agen], RND_SAT: rnd_sat_param*

Storing of up to N data points from vector register to local memory is supported, with each data point being a byte, short, or long (32-bit) word, either signed or unsigned. Signed/unsigned information is used in performing saturation.

There are up to eight VST instructions in one loop, and each VST can be from the full vector register file, V0..V15. It is allowed to overlap the source registers, i.e., having more than one VST instructions storing out the same vector register. Also, in the extreme case of having all eight VST being interleaving stores, all 16 vector registers can be written out.

There is a further constraint on source registers for vector store. Only V0, V1, V2, and V3 can be stored without being the destination of any operation.

VCOP supports the following store patterns:

- NPT: For 8-way SIMD, 8 data points
- 1PT: write only the first SIMD unit
- DS2: downsample by 2; every-other SIMD units are written
- INTRLV: interleave outputs; store 2N data points from two registers interleaved. Two registers must be an {i, i+1} pair (i = 0..14), but only the first register (i) is encoded in assembly and in instruction binary. Byte and halfword types are supported, but not word type. It is NOT allowed to predicate interleaving stores. (If one must predicate interleaving store, use VINTRLV operation to interleave two sets of N data points, then use two predicated VST<type>_NPT.)
- OFFST_NP1: write out all N data points, in (N + 1) words = (4N + 4) bytes address increments (for transposition). Note that although address offset is word-aligned, storing to partial word, in case of byte and halfword types, are supported. In case of byte or halfword type, the 2 LSBs of address determines the byte or halfword within each word that VCOP writes data into.
- COLLAT: collating store, use predicate register to indicate store/not-store, up to N data items stored per cycle, *agen* is don't care, and hardware increments store address by the size implied by the data type. The *agen* field is not required in the assembly code:

[pred] VST*type_ COLLAT_wr_loop vreg, base, RND_SAT: rnd_sat_param*

- SDDA: sequential data-driven addressing, taking M cycles to store M data points (predication can lead to less than N stores), store Vreg[i] to address base + *agen* + V0[i] Note that *agen* can be used to vary the pointer, in addition to V0. Only unsigned address offset in V0 is supported.
- PDDA: parallel data-driven addressing. Use this mode when address offsets in V0 is such that all lanes enabled for store go to separate memory banks. Hardware executes the store of up to N data points in one cycle. In case there is bank conflict, outcome is indefinite, and an error interrupt is generated.
- SKIP: store N data points into every other elements in memory. Allowed for byte and halfword types, not for word type.

The following data types are supported:

- B: signed byte
- BU: unsigned byte
- H: signed halfword (16-bit)
- HU: unsigned halfword
- W: signed word (32-bit)
- WU: unsigned word

Table 6-46. EVE ST Data Distribution Options for NWAY = 8⁽¹⁾⁽²⁾

Distribution	vreg[r][0] goes to	vreg[r][1] goes to	vreg[r][2] goes to	vreg[r][3] goes to	vreg[r][4] goes to	vreg[r][5] goes to	vreg[r][6] goes to	vreg[r][7] goes to
NPT	dptr[0]	dptr[1]	dptr[2]	dptr[3]	dptr[4]	dptr[5]	dptr[6]	dptr[7]
1PT	dptr[0]	n/a	n/a	n/a	n/a	n/a	n/a	n/a
DS2	dptr[0]	n/a	dptr[1]	n/a	dptr[2]	n/a	dptr[3]	n/a
INTRLV	dptr[0] = vreg[r][0], dptr[1] = vreg[r+1][0]	dptr[2] = vreg[r][1], dptr[3] = vreg[r+1][1]	dptr[4] = vreg[r][2], dptr[5] = vreg[r+1][2]	dptr[6] = vreg[r][3], dptr[7] = vreg[r+1][3]	dptr[8] = vreg[r][4], dptr[9] = vreg[r+1][4]	dptr[10] = vreg[r][5], dptr[11] = vreg[r+1][5]	dptr[12] = vreg[r][6], dptr[13] = vreg[r+1][6]	dptr[14] = vreg[r][7], dptr[15] = vreg[r+1][7]
OFFST_NP1	dptr[0]	dptr[9]	dptr[18]	dptr[27]	dptr[36]	dptr[45]	dptr[54]	dptr[63]
COLLAT	none or *dptr++	none or *dptr++	none or *dptr++	none or *dptr++	none or *dptr++	none or *dptr++	none or *dptr++	none or *dptr++
SDDA/PDDA	dptr[V0[0]]	dptr[V0[1]]	dptr[V0[2]]	dptr[V0[3]]	dptr[V0[4]]	dptr[V0[5]]	dptr[V0[6]]	dptr[V0[7]]
SKIP	dptr[0]	dptr[2]	dptr[4]	dptr[6]	dptr[8]	dptr[10]	dptr[12]	dptr[14]

⁽¹⁾ Table “dptr” is type-cast to the appropriate signed/unsigned byte/halfword/word so that correct offsets are applied. dptr = base + agen.

⁽²⁾ Custom distribution is not supported for stores.

Stores are predicated to perform at the indicated loop level, with wr_loop selectable from:

- ALWS: write out on every i4 iteration
- LAST_I4: write out on the last i4 iteration, when i4 = lpend4
- LAST_I34: write out on the last i3 iteration, when i3 = lpend3 and i4 = lpend4
- LAST_I234: write out on the last i2 iteration, when i2 = lpend2, i3 = lpend3, and i4 = lpend4

Rounding and saturation arithmetic is available in the store pipeline to provide rounding and saturation without taking additional cycles.

Rounding and saturation parameters are provided in the parameter file to allow easy adaptation of EVE functions to different rounding and saturation configurations. The rnd_sat_param field in the instruction points to a parameter (instruction encoding limits this field to 5 bits, thus restricting it to P0..P31) that contains the following fields shown in [Figure 6-41](#).

Figure 6-41. VST Rounding and Saturation Parameters

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
sat_mode: 0 = NO_SAT 1 = SYMM 2 = ASYMM 3 = 4PARAM 4 = SYMM32 5 = ASYMM32			sat_bound_param: index to param that specifies saturation bound						rnd_mode: 0 = no rounding 1 = round 2 = truncate			rnd_shift: number of bits to round/shift down			

The following saturation modes are supported:

- NO_SAT: no saturation performed
- SYMM: signed symmetrical saturation [-bound, bound] (for unsigned store, [0, bound])
- ASYMM: signed asymmetrical saturation [-bound-1, bound] (for unsigned store, [0, bound]), useful for fixed bit width. For example, when bound = 1023, saturate to [-1024, 1023]
- 4PARAM: use 4 parameter registers to specify sat_high_cmp, sat_high_set, sat_low_cmp, sat_low_set.
- SYMM32: same as SYMM, except using a pair of parameters to specify a 32-bit bound
- ASYMM32: same as ASYMM, except using a pair of parameters to specify a 32-bit bound

Signed/unsigned designation is on the VST type, and signed/unsigned designation affects whether the bound parameter(s) are interpreted as signed or unsigned. The comparison is carried out between signed 40-bit register and such interpreted bounds.

When no rounding and saturation feature is needed, specifying RND_SAT: P0 is working, since constant 0 in these fields represents doing nothing.

Conditional store is specified by the pred field. Omission means no predication. Pred = V1, V2, V3 indicates that register V1, V2, V3 is used to predicate the store of each way of SIMD; store is executed when the register is not zero.

With the COLLAT distribution option, all SIMD ways are examined for conditional store. Truth in the predication register leads to the data item being stored and incrementing of the data pointer by size of the store type (1/2/4 bytes). False in the predication register leads to doing nothing. Thus, stored data items are compacted without leaving any gaps for the blocked data items.

With other distribution options, conditional store behaves differently. Agen is incremented as in unconditional stores. Truth in the predication register leads to the data item being stored, and false in the predication register leads to the data item being skipped. Thus, it is possible for the stored data items to contain gaps among them from the blocked data items.

The store stage hardware has separate resource for each VCOP data memory region (IBUFL, IBUFH, WBUF). Sequential data-driven store is executed in X cycles, X being the number of data items enabled in predication (or when predication is not used, N). The other store modes are executed in a single cycle per store (note that collating store executes in one cycle as well). All memory regions are carried out in parallel, but there is also potential memory contention with the load stage. There is write buffering in the store stage to reduce load/store contention to some degree. See [Section 6.3.5.6](#) for load/store buffering details.

6.3.5.5.7 Table Lookup Operation

Table lookup operation is indicated by starting the vector command with

VLOOP TLU, *CL#:cmd_len, PL#: param_len*

The table lookup operation uses a subset of the available resources and instructions:

- VAGEN (address generator): fixed A0 for data, A1 for table pointer, A2 for output.
- VLD (load): one for loading data into V2.
- VTLD (table load): for performing the lookup, using V2 as indices to load table entry into V0.
- VST (store): for storing outcome in V0.
- Full set of 4 levels for looping.

The table pointer is allowed to move via agen, to allow loop-variable-dependent manipulation of table base. For example, software might process three color components (RGB or YUV), each having a different table, in the same command, and use the outer loop variables to index among the color components and the corresponding tables.

Data is loaded with normal load into V2, for example:

```
VLDBU_1PT      data_base[A0], V2
```

The data load using VLD has access to a subset of load distribution options: {NPT, 1PT, DS2, US2}.

- 1PT works for single table configuration
- NPT works for all other cases of normal table lookup
- DS2 and US2 provides additional flexibility to downsample/upsample data

A special table load, VTLD, is used for the lookup:

VTLD*type_m TBL_ nPT tbl_base[tbl_agen][V2], V0, RND_SAT:rnd_sat*

Normally lookups only fetch one item per lookup. Multiple items are useful for bilinear and bicubic interpolations. The `_mTBL` field in VTLD specifies the number of parallel tables and the `_nPT` field in VTLD specifies the number of data items per lookup table.

There are constraints on `num_par_tbl`, `num_data_per_lu`, and the table data size:

- $\text{num_par_tbl} \times \text{num_data_per_lu} \leq N$ (ways of SIMD)
- $\text{num_data_per_lu} = \{1 \mid 2 \mid 4\}$ regardless of N (ways of SIMD)

Constraints for 8-way SIMD architecture are shown in [Table 6-47](#).

Table 6-47. Lookup Constraints for 8-Way SIMD

Table type	Num items per lookup, num_data_per_lu	Number of parallel tables, num_par_tbl			
		1	2	4	8
Byte	1	√	√	√	√
	2	√	√	√	
	4	√	√		
	8	√			
Half word	1	√	√	√	√
	2	√	√	√	
	4	√	√		
	8	√			
Word	1	√	√	√	√
	2	√	√	√	
	4	√	√		
	8	√			

Results are stored back to memory with a normal data store as in compute loop with simplification:

`VSTtype_distribution_ALWS V0, base[agen], RND_SAT: rnd_sat_param`

This VST has access to a subset of store distribution options: {NPT | SKIP}.

Number of data points that are stored per i4 iteration is $\text{num_data_per_lu} \times \text{num_par_tbl}$ from the table load, and this is an implicit predication.

For example, when there is table load `VTLDHU_1TBL_2PT`, the store `VSTHU_NPT` is not storing N points, but just 2 point.

In forming the indices for lookup, data are read in, rounded and saturated. Rounding and saturation parameters are specified in VTLD's `RND_SAT: rnd_sat` field. This field is 5-bit (like VST), so only P0..P31 is allowed. The same set of round/saturate parameters as the normal store, VST, are used. VTLD's `RND_SAT` is for round/saturate the data to form table lookup index. VST also contains a `RND_SAT` field, which is used to round/saturate looked up table entries before storing back to data memory.

Various other table lookup parameters are extracted from the instructions:

- Input data type is from `VLDtype`, and is limited to unsigned types.
- Table entry type is from `VTLDtype`, and can be signed or unsigned although the signed/ unsigned information is not used.
- Output type is from `VSTtype`, can be signed or unsigned, and can be different from the table entry type. Signed versus unsigned information is used for saturation.
- Input data distribution is from `VLD V2`, with SIMD units $0..\text{num_par_tbl}-1$ used for the lookup.
- Output distribution option is either NPT, storing consecutively (which may not be N points), or SKIP, storing to every other memory location.

- Table entries are read into the vector register SIMD lanes by iterating on `num_par_tbl` in the outer loop, and `num_data_per_lu` in the inner loop. For example, with `num_par_tbl = 2` and `num_data_per_lu = 4`, with `VSTBU_NPT` we have:

```
V0[0] = tbl_base[data0],      V0[1] = tbl_base[data0 + 1],
V0[2] = tbl_base[data0+2],    V0[3] = tbl_base[data0 + 3],
V0[4] = tbl_base[data1],      V0[5] = tbl_base[data1 + 1],
V0[6] = tbl_base[data1+2],    V0[7] = tbl_base[data1 + 3]
```

Table organization in memory depends on table type and `num_par_tbl`. The N physical banks of 32-bit memory is partitioned into `num_par_tbl` logical banks, and each parallel table is organized inside its own bank.

For example, when `NWAY = 8`, you can have 1, 2, 4, or 8 parallel tables. Data organization for these and byte, halfword, and word type entries is shown in [Figure 6-42](#).

A few examples of the table lookup operation follow. The NPT distribution for load and store works for normal lookup scenarios.

; single table, byte data, short table/output

```
VLOOP          TLU, #cmd_len, #param_len
VAGEN          A0, ...
VAGEN          A1, ...
VAGEN          A2, ...
VLDBU_1PT      data_base[A0], V2                ; load data to V0
VTLDHU_1TBL_1PT table_base[A1][V2], V0, RND_SAT: rnd_sat ; look up
VSTH_NPT_ALWS  V0, outp_base[A2], RND_SAT: rnd_sat_st ; store outcome
```

; 4 parallel tables, 2 items per table, short data, byte table/output

```
VLOOP          TLU, #cmd_len, #param_len
VAGEN          A0, ...
VAGEN          A1, ...
VAGEN          A2, ...
VLDHU_NPT      data_base[A0], V2                ; load data to V0
VTLDBU_4TBL_2PT table_base[A1][V2], V0, RND_SAT: rnd_sat ; look up
VSTB_NPT_ALWS  V0, outp_base[A2], RND_SAT: rnd_sat_st ; store outcome
```

Load with expansion can only be used in a table lookup loop. An example follows.

; load with expansion, short input data, unsigned byte flags, short expanded output

```
VLOOP          TLU, #cmd_len, #param_len
VAGEN          A0, ...
VAGEN          A2, ...
VLDBU_NPT      flag_base[A0], V2                ; load flags to V2
VLDH_EXP       input_base, V0                    ; load with expansion
VSTH_NPT_ALWS  V0, outp_base[A2], RND_SAT: rnd_sat_st ; store outcome
```

For example, in a particular iteration, suppose there are flags `V2 = {0, 0, 1, 0, 1, 1, 0, 0}`, and the expanding load pointer = `0x100` before the expanding load. After the expanding load:

```
V0 = {0, 0, mem[0x100], 0, mem[0x102], mem[0x104], 0, 0}
```

The pointer is advanced to `0x106`, incremented by 3 (number of nonzero flags) times the size of data type (2 bytes for halfword).

Optionally, predicated store can be used while writing the expanded outcome array, leaving `flag==0` data points unaltered.

```
VLOOP          TLU, #cmd_len, #param_len
VAGEN          A0, ...
VAGEN          A2, ...
VLDBU_NPT      flag_base[A0], V2                ; load flags to V2
VLDH_EXP       input_base, V0                    ; load with expansion
[V2] VSTH_NPT_ALWS V0, outp_base[A2], RND_SAT: rnd_sat_st ; store where V2 != 0
```

Performance of load with expansion is `NWAY` expanded data points per cycle when there is no memory contention, by pipelining the flag load, data load, and output store.

6.3.5.5.8 Histogram Operation

Histogram functionality includes normal histogram, in which the addressed bin entry is incremented by 1, and weighted histogram, in which the addressed bin entry is incremented by an element in the weight array input.

Histogram operation is indicated by starting the vector command with:

VLOOP HIST, *CL#*: *cmd_len* , *PL#*: *param_len*

The histogram operation uses a subset of the available resources and instructions:

- VAGEN (address generator): fixed A0 for data, optional A1 for histogram input/output pointer, A2 for weights
- VINIT (register initialization) for normal histogram, providing a fixed increment value (normally 1)
- VLD (load): one load for data, and in the case of weighted histogram, one additional load for weights
- VHLD (histogram load): load histogram bins
- VADD (add) to increment histogram bins
- VHST (histogram store): store histogram bins back to memory
- Full set of 4 levels for looping

For normal histogram, the increment value is initialized via a VINIT instruction on V4:

```
VINITHU_ONCE P1, V4
```

Data is loaded with normal load into V2, for example,

```
VLDBU_NPT data_base[A0], V2
```

Distribution options of VLD are {1PT, NPT, DS2, US2}. 1PT works for single histogram configuration, NPT works for 2, 4, or 8 parallel histograms.

Optional weights (for weighted histogram) are loaded with another normal load into V4, for example,

```
VLDBU_NPT weight_base[A1], V4
```

A special histogram load, VHLD, is used to read in the bins:

VHLD*type_mHIST* *hist_base[hist_agen][V2]*, **V0**, **RND_SAT**: *rnd_sat*

The bins are then incremented with normal VADD.

```
VADD V0, V4, V0
```

Results are stored back to the histogram memory with a special histogram store, VHST:

VHST*type_mHIST* **V0**, *hist_base[hist_agen][V2]*

Base and agen are supposed to be consistent between VHLD and VHST; otherwise, the outcome is undetermined.

Both signed and unsigned types are supported in data load, weight load, histogram load/store, to support unsigned histogram as well as weighted histogram with positive and negative weights.

Parameters for histogram are extracted from the instructions:

- Input data type is from VLD V2
- Input data distribution is from VLD V2, with SIMD units 0..num_par_hist-1 used for indexing histogram. NPT, 1PT, DS2, US2 distribution options are supported.
- Optional weight type is from VLD V4.
- Weight distribution behaves like data distribution, i.e., SIMD units 0..num_par_hist-1 used for incrementing parallel histogram bins
- Histogram data type is from VHLD and VHST, and the two instructions must be consistent in the data type, otherwise the outcome is indeterminate.

- `rnd_sat` in VHLD specifies round/truncate mode and how many bits to round off data before indexing the histogram, and also saturation mode and bound. This field is 5-bit (like VST and VTLD), so only P0..P31 is allowed.

The histogram command basically takes the data array, and processes `num_par_hist` data points at a time by assuming that many sets of parallel histogram bin storage. Each data value is rounded, saturated to generate a bin index. The address bin storage elements (which can be byte, halfword, or word) is then incremented by 1 or the weight, saturated to min/max values of that type, signed/unsigned byte/halfword/word:

- For unsigned byte, bin data is saturated to [0, 255].
- For signed byte, bin data is saturated to [-128, 127].
- For unsigned halfword, bin data is saturated to [0, 65535].
- For signed halfword, bin data is saturated to [-32768, 32767].
- For unsigned word, bin data is saturated to [0, 0xFFFF FFFF].
- For signed word, bin data is saturated to [-0x8000 0000, 0x7FFF FFFF].

There are restrictions on the weight data type (as indicated on the VLD into V4):

- Its signed/unsigned designation must agree with the histogram bin (as indicated in VHLD, VHST).
- Its size is limited to byte and halfword, and must be no bigger size than the histogram bin. Thus, for byte sized bins, only byte-sized weights are possible. For halfword or word sized bins, byte or halfword sized weights are possible.

C representation of histogram processing for a single histogram is as follows.

```
for (i=0; i<num_data; i++)
{
    data = data_base[i];
    bin = saturate(round(data));
    hist[bin]++;
}
```

Weighted histogram has the following C representation:

```
for (i=0; i<num_data; i++)
{
    data = data_base[i];
    bin = saturate(round(data));
    hist[bin] += weight[i];
}
```

Histogram organization in memory depends on histogram type and `num_par_hist`. The N physical banks of 32-bit memory is partitioned into `num_par_hist` logical banks, and each parallel histogram is organized inside its own bank, as with parallel lookup tables (see [Figure 6-42](#)).

The histogram command does not pre-initialize the histogram bin storage. The histogram command also does not sum up the parallel sets of storage into a single set; this is performed as a post-processing step.

Histogram operation takes 2M/P cycles plus some per-command overhead to process M data items with P parallel histograms (P = 1, 2, 4, or 8). As P parallel histograms takes P times the storage of a single histogram, it is a tradeoff of memory size and performance.

An example of histogram operation is:

```
; single histogram, byte data, short histogram, round down 2 bits, 33 bins
; rounding mode, shift, saturation bound coded in P7 using scalar instructions
```

```
VLOOP          HIST, CL#: cmd_len, PL#: param_len
VINITHU_ONCE   P1, V4                               ; initialize V4 = 1
VLDBU_NPT      data_base[A0], V2                     ; load data to V2
VHLDHU_1HIST   hist_base[A1][V2], V0, RND_SAT: P7 ; load hist entry into V0
VADD           V0, V4, V0                             ; increment entry
VHSTH_1HIST    V0, hist_base[A1][V2]                 ; store histogram entry
```

An example of weighted histogram operation is:

```
; single weighted histogram, byte data, byte weight, short histogram,
; round down 2 bits, 33 bins
; rounding mode, shift, saturation bound coded in P7 using scalar instructions
```

```
VLOOP          HIST, CL#: cmd_len, PL#: param_len
VLDBU_NPT     data_base[A0], V2          ; load data to V2
VLDBU_NPT     weight_base[A2], V4       ; load weights to V4
VHLDHU_1HIST  hist_base[A1][V2], V0, RND_SAT: P7 ; load hist entry into V0
VADD          V0, V4, V0                 ; increment entry by weights
VHSTH_1HIST   V0, hist_base[A1][V2]     ; store histogram entry
```

Table lookup and histogram loops are limited to use designated vector register and address generator resources as shown in [Table 6-48](#).

Table 6-48. Table Lookup and Histogram Hardware Resources

Loop type	Input/outputstream	Address generator	Vector register
table lookup	data	A0	V2
	table	A1	V0
	output	A2	V0
load with expansion	flag	A0	V2
	data	n/a	V0
	output	A2	V0
histogram	data	A0	V2
	histogram	A1	V0
	weight	A2	V4

6.3.5.5.9 Circular Buffer Addressing Support

In certain applications, it is desirable to maintain circular buffers for input data and intermediate results. Thus, circular buffer addressing is supported in VCOP.

- Support circular buffer in VLD and VST instructions in compute loops, table lookup loops, and histogram loops. No circular buffer in VTLD (table load) and VHLD/VHST (histogram bin load/store).
- Support is in pointer increment arithmetic, so no load or store in any iteration should straddle the circular buffer boundary.
- Support only 2's power buffer size from 1Kbytes, aligned to the size. For example, 1KB circular buffer can only start/end at 1KB alignment of the memory map.
- Support is in all memory regions.

Circular buffer addressing option is encoded in the `circ_buf` field taking up bits 23..20 of base address:

- 0: no circular buffer addressing
- 1: circular buffer size 1K bytes
- 2: circular buffer size 2K bytes
- 3: circular buffer size 4K bytes
- 4: circular buffer size 8K bytes
- 5: circular buffer size 16K bytes
- 6: circular buffer size 32K bytes
- 7~15: reserved

The base address does not need to be aligned to the circular buffer size, in the above example's case, 0x400. To avoid any single load/store straddle the circular buffer boundary, the base address and the pointer increments must all be aligned to the access size of each iteration.

For example, when loading N data points of halfword data, where N = 8. Access size = 16, so the base address and any pointer increment must be aligned to multiples of 16.

Hardware adjusts the memory address for circular buffering by this process:

```

circ_buf = (base >> 20) & 0xF;           // extract circ_buf
mask = (0x200 << circ_buf) - 1;         // mask = size of buffer - 1
cbuf = (base & 0xFFFFF) & ~mask;       // find base addr of buffer
addr = cbuf + (base + agen) & mask;     // add offset from base of buffer

```

For example, base = 0x10420, agen = 0xFF0.

1. Extract `circ_buf` field by `circ_buf = (base >> 20) & 0xF = 1`, indicating 1KB circular buffer size.
2. Set `mask = (0x200 << 1) - 1 = 0x3FF`, forming the bit mask that defines the circular addressing bits versus linear, non-circular bits.
3. Get rid of the `circ_buf` field by ANDing base with 0xFFFFF, then zero out the circular addressing bits by ANDing with the complement of mask, to get `cbuf = 0x400`, so the circular buffer is 0x400 ~ 0x7FF.
4. Next, add the address generator value to the base address, and AND with mask to find offset from the `cbuf` base. `(base + agen) & mask = (0x10420 + 0xFF0) & 0x3FF = 0x11410 & 0x3FF = 0x10`.
5. Finally, add the offset 0x10 to the circular buffer base 0x400 to get the final address, 0x410.

The `agen` is allowed to go over the circular buffer many times over to wrap back inside, and that `agen` can even go backward to wrap from the beginning to the end of the buffer.

6.3.5.5.10 Load/Store Address Alignment Constraints

Load/store pointer alignment constraints are summarized in [Table 6-49](#), for data load/store as well as table and histogram load/store, for various data types.

Table 6-49. Load and Store Address Alignment Constraints

Type of load/store and distribution	Byte type	halfword type	Word type
VLD_NPT	any	any	word-aligned
VLD_1PT	any	any	any
VLD_CIRC2	any	any	any
VLD_DS2	any	halfword-aligned	not supported
VLD_US2	any	any	any
VLD_DINTRLV	any	word-aligned	not supported
VLD_CUST_Pi	any	any	word-aligned
VLD_EXP	any	halfword-aligned	word-aligned
VST_NPT	any	halfword-aligned	word-aligned
VST_1PT	any	halfword-aligned	word-aligned
VST_DS2	any	halfword-aligned	word-aligned
VST_INTRLV	any	word-aligned	not supported
VST_OFFST_NP1	any	halfword-aligned	word-aligned
VST_COLLAT	any	halfword-aligned	word-aligned
VST_DDA	any	halfword-aligned	word-aligned
VST_SKIP	any	halfword-aligned	not supported
VTLD_1TBL_1PT	any	halfword-aligned	word-aligned
VTLD_mTBL_nPT (other than 1TBL_1PT)	32-byte-aligned	32-byte-aligned	32-byte-aligned
VHLD_mHIST	32-byte-aligned	32-byte-aligned	32-byte-aligned
VHST_mHIST	32-byte-aligned	32-byte-aligned	32-byte-aligned

The rationale is:

- For data load, in general any alignment is supported. Exception: When software loads 32 bytes, the pointer needs to be word-aligned.
- For data store, in general any alignment is supported for byte, halfword alignment for halfword, and word-alignment for word. Exception: When 32 or 64 bytes is stored, the value needs to be word-aligned. In case of LDH_DS2, the pointer must be 16-bit aligned.
- For table load with one table, 1-point lookup, the table base pointer can be of any alignment for byte, halfword alignment for halfword, and word-alignment for word.
- For table load with other configurations, only a 32-byte aligned table base is supported.
- Table store is really data store with 1, 2, 4, or 8 data points. The same alignment is supported as a data store, i.e., any alignment for byte, halfword alignment for halfword, and word-alignment for word.
- For histogram load/store, the histogram base pointer must be 32-byte aligned.

6.3.5.6 Load/Store Buffer and Scheduling

There is load data buffer associated with each VLD instruction in the loop to reduce memory reads and resulting contention and slow-down.

- Size of the buffer is 32 bytes, and is filled with 8 32-bit words on word alignment.
- When the requested data is not contained in the buffer (completely or partially), VCOP reads another 8 32-bit words from the first requested word.
- There is no sharing of data among separate load data buffers.

There is one common store data buffer, basically a shadow copy of all vector registers, for all the VST instructions in the loop to skew memory write timing to reduce memory contentions and resulting slow-down.

- The store data buffer is 16 × 8 × 40-bit in size.
- Vector registers are copied to the store data buffer at the end of i4 iteration, when there is any store to be performed for that iteration. In case stores are not all completed then, load and execution stages are stalled, until all stores are completed.
- Write data from multiple iterations of the same store instruction are not combined. For example, STB_NPT_ALWS causes a memory store of 8 bytes in each iteration.
- Write data from multiple stores of the loop, same iteration, are not combined.

Memory loads and stores are arbitrated for each memory port. There are three memory ports:

- WBUF: Dedicated to WBUF
- IBUFL: For IBULA and IBUFLB
- IBUFH: For IBUFHA and IBUFHB

Load store priorities are: force store > load > store. Force store is issued when the load and operation stages are stalled to free up the store stage so the hardware can advance to the next iteration. Other than force store, load has priority over normal store.

Example 6-9. 3-Tap Horizontal Filtering, Byte Type

```

VLDL_DINTRLV  Pdata[a0], V0           ; data, starts from 0x8000 (IBUFLA)
VLDL_1PT      Pcoef[a1], V2          ; coef, starts from 0x0 (WBUF)
VMADD         V0, V2, V4, V4
|| VMADD       V1, V2, V5, V5
VSTB_INTRLV   V4, Pout[a2], RND_SAT: rnd_sat_param ; output, start from 0x8400 (IBUFLA)

```

Table 6-50. Load and Store Buffering Example, Byte-Type Horizontal Filter

Cycle	LD stage	OP stage	ST stage
0	iter 0 LD0 need 0x8000..0x800F, read IBUFLA LD0_buf = {0x8000..0x801F} LD2 need 0x0, read WBUF LD2_buf = {0x0..0x1F}		
1	iter 1 LD0 need 0x8001..0x8010, from LD0_buf LD2 need 0x1, from LD2_buf	iter 0 MADD MADD	
2	iter 2 LD0 need 0x8002..0x8011, from LD0_buf LD2 need 0x2, from LD2_buf	iter 1 MADD MADD	iter 0
3	iter 3 LD0 need 0x8010..0x801F, from LD0_buf LD2 need 0x0, from LD2_buf	iter 2 MADD MADD	iter 1
4	iter 4 LD0 need 0x8011..0x8020, read IBUFLA LD0_buf = {0x8010..0x802F} LD2 need 0x1, from LD2_buf	iter 3 MADD MADD	iter 2 ST0 store 0x8400..0x840F queue the store

Table 6-50. Load and Store Buffering Example, Byte-Type Horizontal Filter (continued)

Cycle	LD stage	OP stage	ST stage
5	iter 5 LD0 need 0x8012..0x8021, from LD0_buf LD2 need 0x2, from LD2_buf	iter 4 MADD MADD	iter 3 store IBUFLA
6	iter 6 LD0 need 0x8020..0x802F, from LD0_buf LD2 need 0x0, from LD2_buf	iter 5 MADD MADD	iter 4
7	iter 7 LD0 need 0x8021..0x8030, read IBUFLA LD0_buf = {0x8020..0x803F} LD2 need 0x1, from LD2_buf	iter 6 MADD MADD	iter 5 ST0 store 0x8410..0x841F queue the store

Here LDB_DINTRLV is used to read 16 data points, to operate on 16 outputs in parallel. The hardware issues memory reads for iteration 0, 4, 7, etc, is able to supply data for subsequent hold data read in for subsequent LD; on average there is 1 read every 3 cycles. For coefficient, since only 3 bytes is used, just one read in iteration 0 is sufficient to supply data for the whole loop. Output is produced in iteration 2, 5, etc, and the store buffer delays the write until there is no read traction, avoiding read/write contention and slowdown.

Due to memory read/write timing, delayed slot in operation, and round/saturate feature in the store stage, the skew between load, operation, and store stages is more than what is shown in Table 6-50, but for calculating steady-state performance, simplified analysis like this is sufficient.

Example 6-10. Horizontal Filtering, Short Type

```

VLDH_NPT    Pdata0[a0], V0           ; data, start from 0x8000 (IBUFLA)
VLDH_NPT    Pdata1[a0], V2           ; data next row, start from 0x8080 (IBUFLA)
VLDH_1PT    Pcoef[a1], V4           ; coef, start from 0x0 (WBUF)
VMADD       V0, V4, V6, V6
|| VMADD     V2, V4, V7, V7
VSTH_NPT    V6, Pout0[a2], RND_SAT: rnd_sat_param ; start from 0x8400 (IBUFLA)
VSTH_NPT    V7, Pout1[a2], RND_SAT: rnd_sat_param ; start from 0x8480 (IBUFLA)
    
```

Software cannot issue VLDH_DINTRLV on odd halfwords, so use two LDH_NPT.

Table 6-51. Load and Store Buffering Example, Short-Type Horizontal Filter

Cycle	LD stage	OP stage	ST stage
0	iter 0 LD0 need 0x8000..0x800F, read IBUFLA LD0_buf = {0x8000..x801F} LD1 need 0x8080 .. 0x808F, stalled LD2 need 0..1, read WBUF LD2_buf = {0x0..0x1F}		
1	iter 0 LD1 read IBUFLA LD1_buf = {0x8080..0x809F}		
2	iter 1 LD0 need 0x8002..0x8011, from LD0_buf LD1 need 0x8082..0x8091, from LD1_buf LD2 need 2..3, from LD2_buf	iter 0 MADD MADD	
3	iter 2 LD0 need 0x8004..0x8013, from LD0_buf LD1 need 0x8084..0x8093, from LD1_buf LD2 need 4..5, from LD2_buf	iter 1 MADD MADD	iter 0
4	iter 3 LD0 need 0x8010..0x801F, from LD0_buf LD1 need 0x8090 .. 0x809F, from LD1_buf LD2 need 0..1, from LD2_buf	iter 2 MADD MADD	iter 1

Table 6-51. Load and Store Buffering Example, Short-Type Horizontal Filter (continued)

Cycle	LD stage	OP stage	ST stage
5	iter 4 LD0 need 0x8012..0x8021, read IBUFLA LD0_buf = {0x8010..0x802F} LD1 need 0x8092 .. 0x80A1, stall LD2 need 2..3, from LD2_buf	iter 3 MADD MADD	iter 2 ST0 store 0x8400..0x840F ST0 queued ST1 store 0x8480..0x848F ST1 queued
6	iter 4 LD1 read IBUFLA LD1_buf = {0x8090..0x80AF}	stalled	stalled
7	iter 5 LD0 need 0x8014..0x8023, from LD0_buf LD1 need 0x8094..0x80A3, from LD1_buf LD2 need 4..5, from LD2_buf	iter 4 MADD MADD	iter 3 ST0 write IBUFLA
8	iter 6 LD0 need 0x8020..0x802F, from LD0_buf LD1 need 0x80A0..0x80AF, from LD1_buf LD2 need 0..1, from LD2_buf	iter 5 MADD MADD	iter 4 ST1 write IBUFLA
9	iter 7 LD0 need 0x8022..0x8031, read IBUFLA LD0_buf = {0x20..x3F} LD1 need 0x80A2..0x80B1, stall LD2 need 2..3, from LD2_buf	iter 6	iter 5 ST0 store 0x8410..0x841F ST0 queued ST1 store 0x8490..0x849F ST1 queued
10	iter 7 LD1 read IBUFLA LD1_buf = {0x80A0..0x80BF}	stalled	stalled

In this loop, with 2 VLDH_NPT to sustain 16 multiply-accumulates per iteration, the load stage stalled due to memory contention in IBUFL from the 2 loads. The read buffer supplies data for 2 subsequent iterations in steady state, leaving 2 memory-read free cycles every 3 iterations. With output writing back to IBUFL, the store buffer effectively delays the memory writes to use these free memory slots. Each i4 loop of 3 iterations thus takes 4 cycles to complete.

6.3.5.7 VCOP Per-Loop Overhead

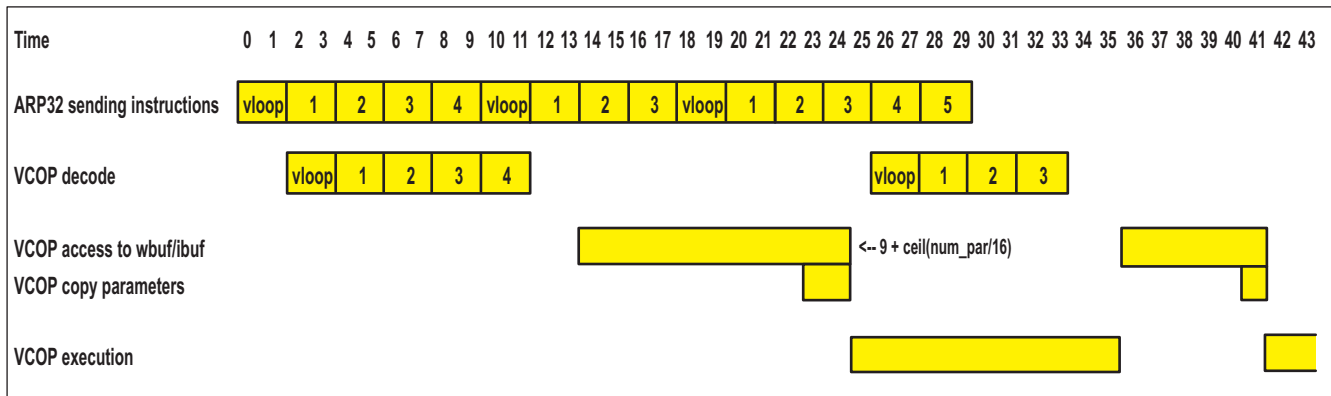

For each vector command specifying a loop, several overhead components are present. In general, developers are encouraged to run place into each loop as much processing as possible and run as many iterations as possible to reduce the percentage of time spent on overhead.

Overhead components are:

- Command decode time: it takes 2 cycles per instruction to decode, since scalar core is providing instructions at this rate. Command decode time can be hidden if ARP32 feeds these instructions while VCOP is executing a previous command.
- Parameter fetch time: it takes $9 + \text{ceiling}(\text{num_param}/16)$ cycles to fetch parameter from data memory (WBUF, IBUFL, or IBUFH).
- Execution pipeline ramp up/down time: it takes time to ramp up and down the long pipeline of VCOP. Minimal time for any loop is execution is about 17 cycles, due to the pipeline ramp up/down time.

Figure 6-43 shows a decode-parameter-fetch-execution time line.

Figure 6-43. Example of Operation Delay Slots

- t = 0, ARP32 sends VLOOP, followed by VCOP instructions in the loop, instructions go into FIFO.
- t = 2, VCOP pulls instruction out of FIFO, recognizes VLOOP.
- t = 10 (depend on command length), VCOP pulls last instruction of loop from FIFO.
- t = 10, ARP32 sends next command, starting from VLOOP.
- t = 14, VCOP starts access to parameter memory, 16 parameters/cycle.
- t = 18, ARP32 keeps sending vector commands, until program stream switches to scalar code, or VCOP pre-decode instruction FIFO becomes full (capacity is 64 words).
- t = 23 (14 + 9), VCOP starts to copy parameters into decoded command buffer.
- t = 25 (after parameter copy), VCOP starts executing the loop.
- t = 26 (sync to 250-MHz clock), VCOP pulls instruction out of FIFO, recognizes VLOOP.
- t = 32 (depend on command length), VCOP pulls last instruction of loop from FIFO.
- t = 36 (after prev loop finishes executing), VCOP starts to access parameter memory.

This is for showing the dependency among activities; execution time here is not realistic; it takes minimally 17 cycles to execute any loop, due to the pipeline depth.

6.3.5.8 VCOP Error Handling

Upon detection of erroneous instruction code, parameter, load/store address, or loop in execution exceeding programmed max iteration count, VCOP signals the error by generating an interrupt and registering the error source in the MMR [VCOP_ERROR](#). Refer to register manual for details.

Upon detection of error, VCOP:

1. Terminates current loop, leaving vloop_ptr, param_ptr, loop variables i0, i1, i2, i3, i4 in MMR.
2. Parses and clears vector instructions until encountering VWDONE.
3. Issues interrupt, assert vec_done = 1, deassert vec_rdy = 0 to block subsequent vector instructions.
4. Upon [VCOP_ERROR](#) status being cleared (by writing 1s to clear bits 10:0), VCOP becomes idle (assert [VCOP_STATUS](#)[2]VEC_RDY = 1) and ready to resume processing.
5. Alternatively, VCOP can be reset to resume processing.

Depending on the EVE-level memory switch setting, VCOP's access of the data memory space may be deemed invalid by the memory switch. When this happens, the memory switch signals VCOP to enter error handling state, as described above. VCOP does not send an error interrupt, as the memory switch is doing that (for invalid access from VCOP or from other masters).

6.3.5.9 Vector Operation Details

6.3.5.9.1 VABS

Assembly syntax: **VABS** *src1, dst*
 Operation: Absolute value
 Classification: 1-input 1-output
 Bit width: 40-bit
 Delay slot: no
 C statement: `dst = abs(src1);`

6.3.5.9.2 VABSDIF

Assembly syntax: **VABSDIF** *src1, src2, dst*
 Operation: absolute-difference
 Classification: 2-input 1-output
 Bit width: 40-bit
 Delay slot: no
 C statement: `dst = abs(src1 – src2);`

6.3.5.9.3 VADD

Assembly syntax: **VADD** *src1, src2, dst*
 Operation: addition
 Classification: 2-input 1-output
 Bit width: 40-bit
 Delay slot: no
 C statement: `dst = src1 + src2;`

6.3.5.9.4 VADDH

Assembly syntax: **VADDH** *src1, src2, dst*
 Operation: Add high
 Classification: 2-input 1-output
 Bit width: 40-bit
 Delay slot: no
 C statement: `dst = src1 + (src2 >> 32);`

6.3.5.9.5 VADDSUB

Assembly syntax: **VADDSUB** src1/dst1, src2/dst2
 Operation: Add-subtract
 Classification: 2-input 2-output
 Bit width: 40-bit
 Delay slot: no
 C statement: $dst1 = src1 + src2;$
 $dst2 = src1 - src2;$

6.3.5.9.6 VADD3

Assembly syntax: **VADD3** src1, src2, src3, dst (dst same as src3)
 Operation: Add 3 items,
 Classification: 3-input 1-output
 Bit width: 40-bit
 Delay slot: one
 C statement: $dst = src1 + src2 + src3;$

6.3.5.9.7 VADIF3

Assembly syntax: **VADIF3** src1, src2, src3, dst (dst same as src3)
 Operation: Add difference
 Classification: 3-input 1-output
 Bit width: 40-bit
 Delay slot: one
 C statement: $dst = src1 - src2 + src3;$

6.3.5.9.8 VAND

Assembly syntax: **VAND** src1, src2, dst
 Operation: Bitwise and
 Classification: 2-input 1-output
 Bit width: 40-bit
 Delay slot: no
 C statement: $dst = src1 \& src2;$

6.3.5.9.9 VANDN

Assembly syntax: **VANDN** src1, src2, dst
 Operation: Bitwise and-not
 Classification: 2-input 1-output
 Bit width: 40-bit
 Delay slot: no
 C statement: $dst = src1 \& \sim src2;$

6.3.5.9.10 VAND3

Assembly syntax: **VAND3** *src1, src2, src3, dst* (dst same as src3)
 Operation: Bitwise-and 3 items
 Classification: 3-input 1-output
 Bit width: 40-bit
 Delay slot: one
 C statement: `dst3 = src1 & src2 & src3;`

Using VAND3 accelerates a morphological erosion operation.

6.3.5.9.11 VBINLOG

Assembly syntax: **VBINLOG** *src1, dst*
 Operation: Binary log
 Classification: 1-input 1-output
 Bit width: 32-bit
 Delay slot: one
 C statement: As follows

VBINLOG computes an approximate binary log, by detecting the left-most 1 bit in the input, encoding the bit position in bits 31..28, and left-justifying the following input bits in bits 27..0. The detected position of bit 31 is encoded as 15 (bit position minus 16), bit 30 as 14, and so on, and bit 17 as 1. If the left-most 1 bit is not found in bits 31..17, 0 is coded.

The VBINLOG operation is a non-standard floating point representation. Say a 32-bit integer $x = 2^{\text{exp}} * (1 + \text{frac}/(2^{28}))$, where exp and frac are integers. If $(\text{exp} \geq 16)$, $\text{binlog}(x) = (\text{exp} - 16) * (2^{28}) + \text{frac}$, concatenating the 4-bit adjusted exponent, $\text{exp} - 16$, with the 28-bit fraction. Otherwise, the representation is subnormal, leaving 0 in the exponent and bits 16..0 of input left-justified in the fraction part of output, bits 27..0.

For example, the number 0x0700_0000 has leading 1 in bit 26, so the bit position is coded as $26 - 16 = 10 = 0xA$. The subsequent bits, two 1s immediately following the leading 1, left-justified in 28 bits or 7 hex digits, is 0xC00_0000. Thus the VBINLOG outcome of the number is 0xAC00_0000.

For a subnormal example, the number 0x8000 $< 2^{16}$ (is half of that), so its VBINLOG outcome is 0x0400_0000.

0	0	0	0	0	0	0	0	0	0	0	0	1	b18	b17	b16	b15	...	0	0	1	1	b18	b17	...	0		
0	0	0	0	0	0	0	0	0	0	0	0	0	1	b17	b16	b15	...	0	0	1	0	b17	b16	...	0		
0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	b16	b15	...	0	0	0	1	b16	b15	...	0		
0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	b16	b15	...	0	0	0	0	b16	b15	...	0		

Input of VBINLOG is 32-bit, and so is the outcome, not 40-bit. VLMBD supports full 40-bit input range leading bit detection. VBINLOG is useful in compressing dynamic range and preserving precision. VBINLOG followed by table lookup can be used to produce the reciprocal of a number.

6.3.5.9.12 **VBITC**

Assembly syntax: **VBIT** *src1, dst*
 Operation: Bit count
 Classification: 1-input 1-output
 Bit width: 32-bit
 Delay slot: one
 C statement: As follows

Count number of “1” bits in *src1*[31:0].

6.3.5.9.13 **VBITDI**

Assembly syntax: **VBITDI** *src1, dst1, dst2*
 Operation: Bit deinterleave
 Classification: 1-input 2-output
 Bit width: 32-bit
 Delay slot: 0
 C statement: As follows

Bit deinterleave is basically the inverse of bit interleave (VBITI).

For example,

```
src1 = 0x523(0000_0000_0000_0000_0000_1001_0010_0011)
```

Results in:

```
dst1 = 0x25 (0000_0000_0010_0101),  
dst2 = 0x11(0000_0000_0001_0001)
```

6.3.5.9.14 **VBITI**

Assembly syntax: **VBITI** *src1, src2, dst*
 Operation: Bit interleave
 Classification: 2-input 1-output
 Bit width: 32-bit
 Delay slot: one
 C statement: As follows

Bit interleave 16 LSBs of *src1* and *src2* (each), and write to *dst*.

For example,

```
src1 = 0x25 (0000_0000_0010_0101)  
src2 = 0x11(0000_0000_0001_0001)
```

Results in:

```
dst = 0x523(0000_0000_0000_0000_0000_1001_0010_0011)
```

6.3.5.9.15 VBITPK

Assembly syntax: **VBITPK** *src1, src2, dst*
 Operation: Bit-pack
 Classification: 2-input 1-output
 Bit width: 33-bit
 Delay slot: one
 C statement: As follows

Pack boolean ($src1[i] \geq src2[i]$) into bits in $dst[0]$, and broadcast $dst[0]$ to all SIMD lanes so that $dst[j] = dst[0]$, $1 \leq j \leq NSIMD$.

VBITPK is useful in accessing bit-packed data (binary images).

6.3.5.9.16 VBTR

Assembly syntax: **VBTR** *src1, dst*
 Operation: Bit reverse
 Classification: 1-input 1-output
 Bit width: 32-bit
 Delay slot: one
 C statement: As follows

Reverse bits in $src1[31:0]$ and write to dst .

6.3.5.9.17 VBITTR

Assembly syntax: **VBITTR** *src1, dst*
 Operation: Bit transpose
 Classification: 1-input 1-output
 Bit width: NSIMD-bit
 Delay slot: one

VBITTR, bit transpose, also called corner turn, takes $N \times N$ bits in the source, from N LSBs of each of the N registers, and transpose them. Here is an example:

Input:			Output:		
Lane	Value	Bit position	Lane	Value	Bit position
		0 1 2 3			0 1 2 3
0	1	1 0 0 0	0	5	1 0 1 0
1	2	0 1 0 0	1	6	0 1 1 0
2	3	1 1 0 0	2	8	0 0 0 1
3	4	0 0 1 0	3	0	0 0 0 0

6.3.5.9.18 **VBITUNPK**

Assembly syntax: **VBITUNPK** *src1, src2, dst*
 Operation: Bit-unpack
 Classification: 2-input 1-output
 Bit width: 33-bit
 Delay slot: one
 C statement: As follows

Unpack bits in *src1[0]*. Set *dst[i] = src2[i]* if the unpacked bit to lane *i* is 1, otherwise *dst[i] = 0*.

6.3.5.9.19 **VCMOV**

Assembly syntax: **VCMOV** *cond, src1[, src2|dst]*
 Operation: Conditional move
 Classification: special
 Bit width: 40-bit
 Delay slot: no
 C statement: As follows

cond = {I1234_ZERO, I234_ZERO, I34_ZERO, LAST_I4_ZERO, LAST_I34, LAST_I234, LAST_I1234}.

Move *src1* to *dst* in the iterations designated by *cond*. This is parallel move within each SIMD lane; *dst[i] = src1[i]* when condition is true. Otherwise, *dst[i] = src2[i]*. By always writing to the *dst* register, *dst* register does not need to be {V0, V1, V2, V3} (see [Section 6.3.5.5.6](#) for details on the store-without-being destination register constraint).

6.3.5.9.20 **VCMPEQ**

Assembly syntax: **VCMPEQ***src1, src2, dst*
 Operation: Compare equal
 Classification: 2-input 1-output
 Bit width: 40-bit
 Delay slot: no
 C statement: *dst = (src1 == src2) ? 1 : 0;*

6.3.5.9.21 **VCMPGE**

Assembly syntax: **VCMPGE** *src1, src2, dst*
 Operation: Compare greater-than-or-equal
 Classification: 2-input 1-output
 Bit width: 40-bit
 Delay slot: no
 C statement: *dst = (src1 >= src2) ? 1 : 0;*

6.3.5.9.22 **VCMPGT**

Assembly syntax: **VCMPGT** *src1, src2, dst*
 Operation: Compare greater-than
 Classification: 2-input 1-output
 Bit width: 40-bit
 Delay slot: no
 C statement: `dst = (src1 > src2) ? 1 : 0;`

6.3.5.9.23 **VDINTRLV**

Assembly syntax: **VDINTRLV** *{src1|dst1}, {src2|dst2}*
 Operation: Deinterleave
 Classification: 2-input 2-output
 Bit width: 40-bit
 Delay slot: no
 C statement: As follows

VDINTRLV is basically the inverse of VINTRLV.

For 8-way SIMD, this is used:

```

dst1[0] = src1[0];
dst2[0] = src1[1];
dst1[1] = src1[2];
dst2[1] = src1[3];
dst1[2] = src1[4];
dst2[2] = src1[5];
dst1[3] = src1[6];
dst2[3] = src1[7];
dst1[4] = src2[0];
dst2[4] = src2[1];
dst1[5] = src2[2];
dst2[5] = src2[3];
dst1[6] = src2[4];
dst2[6] = src2[5];
dst1[7] = src2[6];
dst2[7] = src2[7];
  
```

6.3.5.9.24 VDINTRLV2

Assembly syntax: **VDINTRLV2** {src1|dst1}, {src2|dst2}
 Operation: Deinterleave with 2-element frequency
 Classification: 2-input 2-output
 Bit width: 40-bit
 Delay slot: no
 C statement: As follows

VDINTRLV2 is basically the inverse of VINTRLV2.

For 8-way SIMD, this is used:

```

dst1[0] = src1[0];
dst1[1] = src1[1];
dst2[0] = src1[2];
dst2[1] = src1[3];
dst1[2] = src1[4];
dst1[3] = src1[5];
dst2[2] = src1[6];
dst2[3] = src1[7];
dst1[4] = src2[0];
dst1[5] = src2[1];
dst2[4] = src2[2];
dst2[5] = src2[3];
dst1[6] = src2[4];
dst1[7] = src2[5];
dst2[6] = src2[6];
dst2[7] = src2[7];
  
```

6.3.5.9.25 VEXITNZ

Assembly syntax: **VEXITNZ** level, src1
 Operation: Exit upon non-zero
 Classification: special
 Bit width: 40-bit
 Delay slot: no
 C statement: As follows

VEXITNZ is for early termination of VLOOP or in the repeat-loop level. The designated src1 register's 0th way is examined every time the instruction executes, and if it is not zero, the hardware terminates either at VLOOP level or at VRPT level, as indicated by the level parameter.

Parameter src1 is examined at the time the instruction executes, and an exit/no-exit decision is made. However, any exit/no-exit action is not taken immediately. For VEXITNZ VLOOP, subsequent instructions in the same iteration, remaining operations and all the stores, are executed, then the loop terminates. For VEXITNZ VRPT; all subsequent instructions in the same loop are executed, including the rest of the iteration, and all remaining iterations until i1, i2, i3, i4 all run to respective end counts, then the repeated loop terminates.

There can only be one VEXITNZ in each vector command; no mixing of VEXITNZ VLOOP and VEXITNZ VRPT. When the vector command is not repeated (RPT_END = 0), VEXITNZ VRPT behaves like VEXITNZ VLOOP.

6.3.5.9.26 *VINTRLV*

Assembly syntax: **VINTRLV** {src1|dst1}, {src2|dst2}
 Operation: Interleave
 Classification: 2-input 2-output
 Bit width: 40-bit
 Delay slot: no
 C statement: As follows

VINTRLV is basically interleaving among SIMD lanes.

For 8-way SIMD, this is used:

```

dst1[0] = src1[0];
dst1[1] = src2[0];
dst1[2] = src1[1];
dst1[3] = src2[1];
dst1[4] = src1[2];
dst1[5] = src2[2];
dst1[6] = src1[3];
dst1[7] = src2[3];
dst2[0] = src1[4];
dst2[1] = src2[4];
dst2[2] = src1[5];
dst2[3] = src2[5];
dst2[4] = src1[6];
dst2[5] = src2[6];
dst2[6] = src1[7];
dst2[7] = src2[7];
  
```

6.3.5.9.27 *VINTRLV2*

Assembly syntax: **VINTRLV2** {src1|dst1}, {src2|dst2}
 Operation: Interleave with 2-element frequency
 Classification: 2-input 2-output
 Bit width: 40-bit
 Delay slot: no
 C statement: As follows

VINTRLV is basically interleaving among SIMD lanes.

For 8-way SIMD, this is used:

```

dst1[0] = src1[0];
dst1[1] = src1[1];
dst1[2] = src2[0];
dst1[3] = src2[1];
dst1[4] = src1[2];
dst1[5] = src1[3];
dst1[6] = src2[2];
dst1[7] = src2[3];
dst2[0] = src1[4];
dst2[1] = src1[5];
dst2[2] = src2[4];
dst2[3] = src2[5];
dst2[4] = src1[6];
dst2[5] = src1[7];
dst2[6] = src2[6];
dst2[7] = src2[7];
  
```

6.3.5.9.28 **VINTRLV4**

Assembly syntax: **VINTRLV4** {*src1*|*dst1*}, {*src2*|*dst2*}
 Operation: Interleave with 4-element frequency
 Classification: 2-input 2-output
 Bit width: 40-bit
 Delay slot: no
 C statement: As follows

VINTRLV is basically interleaving among SIMD lanes.

For 8-way SIMD, this is used:

```

dst1[0] = src1[0];
dst1[1] = src1[1];
dst1[2] = src1[2];
dst1[3] = src1[3];
dst1[4] = src2[0];
dst1[5] = src2[1];
dst1[6] = src2[2];
dst1[7] = src2[3];
dst2[0] = src1[4];
dst2[1] = src1[5];
dst2[2] = src1[6];
dst2[3] = src1[7];
dst2[4] = src2[4];
dst2[5] = src2[5];
dst2[6] = src2[6];
dst2[7] = src2[7];
  
```

6.3.5.9.29 **VLMBD**

Assembly syntax: **VLMBD** *src1*, *src2*, *dst*
 Operation: Left-most bit detect
 Classification: 3-input 1-output
 Bit width: 40-bit
 Delay slot: one
 C statement: As follows

Depending on *src2* being zero or not, VLMBD searches for 0 or 1 in *src1*, starting from bit 39. Bit position where the first 0 or 1 occurs is returned, and -1 is returned if it's not found.

6.3.5.9.30 VMADD

Assembly syntax: **VMADD** *src1, src2, src3, dst, RND: rnd_param* (dst same as src3)
Operation: Multiply-add
Classification: 3-input 1-output
Bit width: 17-bit src1/src2, 40-bit src3/dst
Delay slot: 2 delay from src1/src2, 1 delay from src3
C statement: `dst = src3 + round_or_shift(src1 * src2, rnd_param)`

The RND field specifies a parameter, in which additional fields are read to support built-in round/shift feature in the operation:

Figure 6-45. VMPY, VMADD and VMSUB Rounding Parameters

Table 6-52. Parameter Indexed by rnd_param Field Descriptions

Bits	Name	Description
15-7	Reserved	
6-5	rnd_mode	Sets rounding mode: 0 No rounding 1 Round 2 Truncate 3 Left-shift
4-0	rnd_shift	Number of bits to round/shift, limited to: {8 15 16} Round/truncate 1 Left-shift

When rnd_mode = round or truncate, src1 * src2 is rounded down before the addition or subtraction.
When rnd_mode = left-shift, src1 * src2 is shifted up before the addition or subtraction. Note the restriction on the number of bits to shift.

6.3.5.9.31 VMAX

Assembly syntax: **VMAX** *src1, src2, dst*
Operation: Maximum
Classification: 2-input 1-output
Bit width: 33-bit
Delay slot: no
C statement: `dst = (src1 > src2) ? src1 : src2;`

6.3.5.9.32 VMAXSETF

Assembly syntax: **VMAXSETF** *src1*, {*src2*|*dst1*}, *dst2*
 Operation: Maximum and set flag
 Classification: 2-input 2-output
 Bit width: 33-bit
 Delay slot: no
 C statement: $dst1 = \max(src1, src2); dst2 = (src1 > src2) ? 1 : 0$

6.3.5.9.33 VMIN

Assembly syntax: **VMIN** *src1*, *src2*, *dst*
 Operation: Minimum
 Classification: 2-input 1-output
 Bit width: 33-bit
 Delay slot: no
 C statement: $dst = (src1 < src2) ? src1 : src2;$

6.3.5.9.34 VMINSETF

Assembly syntax: **VMINSETF** *src1*, {*src2*|*dst1*}, *dst2*
 Operation: Minimum and set flag
 Classification: 2-input 2-output
 Bit width: 33-bit
 Delay slot:
 C statement: $dst1 = \min(src1, src2);$
 $dst2 = (src1 < src2) ? 1 : 0;$

6.3.5.9.35 VMPY

Assembly syntax: **VMPY** *src1*, *src2*, *dst*, **RND:** *rnd_param*
 Operation: multiply
 Classification: 2-input 1-output
 Bit width: 17-bit input, 40-bit output
 Delay slot: one
 C statement: $dst = \text{round_or_shift}(src1 * src2, rnd_param);$

See [VMADD](#) for the RND field.

6.3.5.9.36 **VMSUB**

Assembly syntax: **VMSUB** *src1, src2, src3, dst, RND: rnd_param* (dst same as src3)
 Operation: Multiply-subtract
 Classification: 3-input 1-output
 Bit width: 17-bit src1/src2, 40-bit src3/dst
 Delay slot: 2 delay from src1/src2, 1 delay from src3
 C statement: `dst = src3 - round_or_shift(src1 * src2, rnd_param);`

See [VMADD](#) for the RND field.

6.3.5.9.37 **VNOP**

Assembly syntax: **VNOP**
 Operation: no operation
 Classification: n/a
 Bit width: n/a
 Delay slot: no
 C statement: n/a

NOP is used to pad the two operations per clock cycle operation pipeline, so the next operation is mapped to functional unit 1. This is used to align data dependency to within functional unit 0 or 1, to avoid idle cycles being inserted by hardware.

6.3.5.9.38 **VNOT**

Assembly syntax: **VNOT** *src1, dst*
 Operation: Bitwise complement
 Classification: 1-input 1-output
 Bit width: 40-bit
 Delay slot: no
 C statement: `dst = ~src1;`

6.3.5.9.39 **VOR**

Assembly syntax: **VOR** *src1, src2, dst*
 Operation: Bitwise or
 Classification: 2-input 1-output
 Bit width: 40-bit
 Delay slot: no
 C statement: `dst = src1 | src2;`

6.3.5.9.40 VOR3

Assembly syntax: **VOR3** *src1, src2, src3, dst* (dst same as src3)
 Operation: Bitwise-or 3 items
 Classification: 3-input 1-output
 Bit width: 40-bit
 Delay slot: one
 C statement: `dst3 = src1 | src2 | src3;`

Using VOR3 accelerates the morphological dilation operation.

6.3.5.9.41 VRND

Assembly syntax: **VRND** *src1, src2, dst*
 Operation: Round src1 by number of bits expressed in src2
 Classification: 2-input 1-output
 Bit width: 40-bit src1/dst, 5-bit src2, allowing rounding by 0 ~ 31 bits
 Delay slot: one
 C statement: `rnd_add = (src2 > 0) ? (1 << (src2 - 1)) : 0;`
`dst = (src1 + rnd_add) >> src2;`

A half-unit is added before the right-shift. For example, if src2 = 8, `dst = (src1 + 128) >> 8`.

Only src2[4:0] are read, so for example src2 = 40 causes a rounding by 8 bits, since src2[4:0] = 0x08.

6.3.5.9.42 VSAD

Assembly syntax: **VSAD** *src1, src2, src3, dst* (dst same as src3)
 Operation: Sum of absolute difference, `dst = |src1 - src2| + src3`
 Classification: 3-input 1-output
 Bit width: 40-bit
 Delay slot: one
 C statement: `dst = src3 + abs(src1 - src2);`

6.3.5.9.43 VSEL

Assembly syntax: **VSEL** *src1, src2, src3, dst* (dst same as src3)
 Operation: Select
 Classification: 3-input 1-output
 Bit width: 40-bit
 Delay slot: no
 C statement: `dst = src1 ? src2 : src3;`

6.3.5.9.44 VSHF

Assembly syntax: **VSHF** *src1, src2, dst*
 Operation: Arithmetic shift, shift left when *src2* > 0, shift right by $-src2$ when *src2* < 0
 Classification: 2-input 1-output
 Bit width: 40-bit *src1/dst*, 6-bit *src2*, allowing shifting by -32 ~ 31 bits
 Delay slot: no
 C statement: $dst = (src2 \geq 0) ? (src1 \ll src2) : (src1 \gg -src2);$

VSHF is an arithmetic shift, not logic shift, compared to conventional instruction sets that have both options. This is because VCOP performs sign extension in the load stage, and all signed/unsigned 8/16/32-bit operations are carried out with the 40-bit register file.

Only *src2*[5:0] are read, so for example *src2* = 32 causes a right-shift by 32 bits, since *src2*[5:0] = 0x20.

6.3.5.9.45 VSHFOR

Assembly syntax: **VSHFOR** *src1, src2, src3, dst* (*dst* same as *src3*)
 Operation: Shift-or
 Classification: 3-input 1-output
 Bit width: 40-bit *src1/src3*, 6-bit *src2*
 Delay slot: one
 C statement: $dst3 = (src2 \geq 0) ? (src3 | (src1 \ll src2)) : (src3 | (src1 \gg -src2));$

See [VSHF](#) for the supported range of *src2*.

6.3.5.9.46 VSHF16

Assembly syntax: **VSHF16** *src1, dst2, dst2*
 Operation: Shift-up 16 bits
 Classification: 1-input 2-output
 Bit width: 33-bit *src1*
 Delay slot: no
 C statement: $dst1 = (src1 \& 0xffff) \ll 16; dst2 = src1 \gg 16;$

Shift up *src1* by 16 bits, producing two destinations to hold the outcome, *dst1* having the lower unsigned 32-bit, and *dst2* having the signed upper portion, sign extended from *src1*[32] to full 40 bits in *dst2*.

VSHF16 is useful for 32 × 32 multiplication.

6.3.5.9.47 VSIGN

Assembly syntax: **VSIGN** *src1, src2, dst*
 Operation: Sign
 Classification: 2-input 1-output
 Bit width: 40-bit
 Delay slot: no
 C statement: $dst = (src1 == 0) ? 0 : ((src1 > 0) ? src2 : -src2);$

6.3.5.9.48 **VSORT2**

Assembly syntax: **VSORT2** *src1, src2, dst*
 Operation: Sort two items
 Classification: 2-input 2-output
 Bit width: 33-bit
 Delay slot: no
 C statement: $dst1 = \min(src1, src2);$
 $dst2 = \max(src1, src2);$

6.3.5.9.49 **VSUB**

Assembly syntax: **VSUB** *src1, src2, dst*
 Operation: Subtraction
 Classification: 2-input 1-output
 Bit width: 40-bit
 Delay slot: no
 C statement: $dst = src1 - src2;$

6.3.5.9.50 **VSWAP**

Assembly syntax: **VSWAP** *cond, {src1|dst1}, {src2|dst2}*
 Operation: Conditional swap
 Classification: 3-input 2-output
 Bit width: 1-bit cond, 40-bit src1 & src2
 Delay slot: no
 C statement: $if (cond \& 1) swap(src1, src2)$

Only the LSB of the vector register indicated by *cond* is checked. A swap/no-swap decision is made in each SIMD lane using the LSB of *cond* register in the lane.

6.3.5.9.51 **VXOR**

Assembly syntax: **VXOR** *src1, src2, dst*
 Operation: Bitwise exclusive-or
 Classification: 2-input 1-output
 Bit width: 40-bit
 Delay slot: no
 C statement: $dst = src1 \wedge src2;$

6.3.6 Debug Support

VCOP supports single stepping, one innermost (i4) iteration per step. Due to the deeply pipelined architecture, instruction-by-instruction single stepping support is not feasible.

Normally VCOP executes load in one stage of the pipeline, and operations and stores in the next stage of the pipeline. In single step mode, only one iteration is executed at a time, so there is no pipelining among iterations. The hardware executes all the loads, then operations and stores, then halts until instructed to continue on the next iteration. The single step operation is controlled via the [VCOP_CTRL](#) register. The operation is enabled by setting [VCOP_CTRL\[0\]STEP_EN](#) to 1. Setting [VCOP_CTRL\[1\]STEP_GO](#) to 1 the engine starts executing i4 iteration.

As outlined in the previous section, `step_en`, `step_go`, `step_rdy` register fields are provided for single stepping control. In addition, VCOP internal state is exported as read-only view as memory-map registers as well.

Interaction of debug driver, scalar core, and VCOP is as follows:

1. Debug driver enables debug mode by setting [VCOP_CTRL\[0\]STEP_EN](#) = 1 and wait for [VCOP_STATUS\[0\]STEP_RDY](#) = 1.
2. Scalar core sends the vector command to be single-stepped the normal fashion.
3. Vector core executes the vector command and stalls at the end of the first i4 iteration and assert [VCOP_STATUS\[0\]STEP_RDY](#).
4. When [VCOP_STATUS\[0\]STEP_RDY](#) =1, debug driver accesses buffer switch and switch WBUF, IBUFL/H memories to system bus.
5. Debug driver read out the memory contents to refresh on the debugger user interface.
6. Debug driver read out VCOP internal state to refresh on the debugger user interface.
7. Debug driver accesses buffer switch and switch memories to VCOP.
8. Debug driver triggers VCOP to take the next step by writing '1' to `step_go`, and wait for [VCOP_STATUS\[0\]STEP_RDY](#) = 1.
9. Repeat 3 through 8, until completion of the vector command or user input to stop single-stepping.
10. The debug driver disables the debug mode by setting [VCOP_CTRL\[0\]STEP_EN](#) = 0.
11. VCOP and scalar core continue to operate.

Imaging Subsystem

This chapter describes the Imaging Subsystem (ISS) in the device.

Topic	Page
7.1 ISS Overview	1788
7.2 ISS Interfaces	1910
7.3 ISS Image Signal Processor	2121
7.4 ISS Still Image Coprocessor	2908

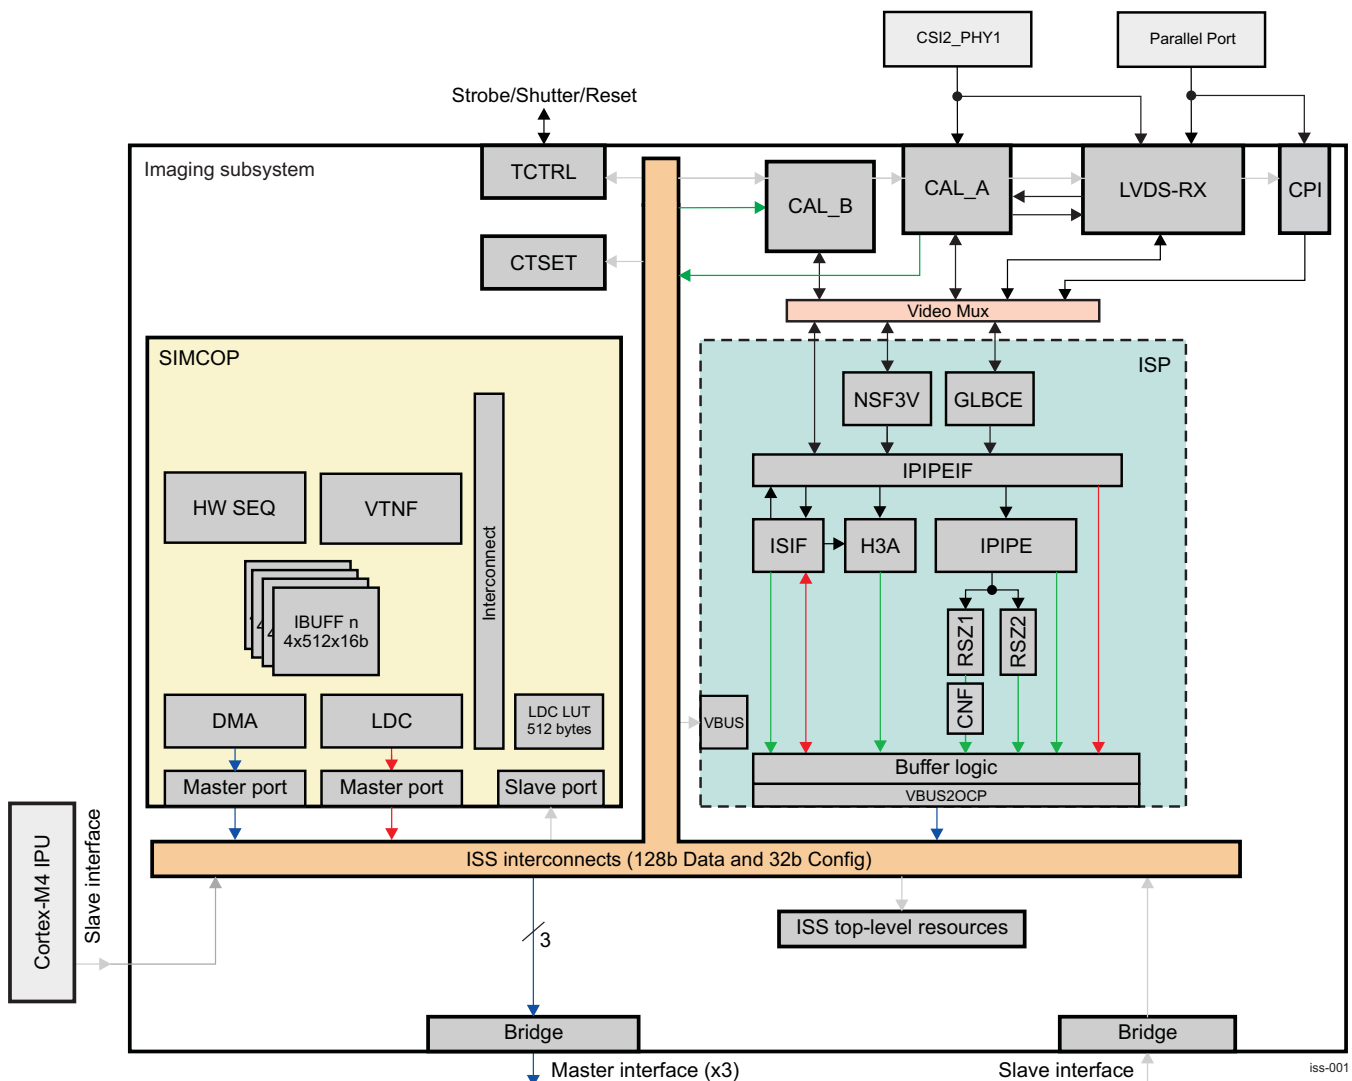

7.1 ISS Overview

The imaging subsystem (ISS) deals with the processing of the pixel data coming from an external image sensor or data from memory (image format encoding and decoding can be done to and from memory). With its subparts, such as interfaces and interconnects, image signal processor (ISP), and still image coprocessor (SIMCOP), the ISS is a key component for the following applications:

- Rear View Camera
- Front View Stereo Camera
- Surround View Camera

Figure 7-1 shows an overview of the ISS.

Figure 7-1. ISS Overview

The direction of the arrows in Figure 7-1 shows the command flow direction from the master (initiator) to the slave (target). The following color conventions are used for the connections:

- Blue: Bidirectional, 128-bit-wide interface data connection.
- Green: Write (ISS → system memory) data connection. Either 64-bit interface, 128-bit interface, or 32-bit MTC (inside ISP). Also read (from system memory) data connection for CAL_B module.
- Red: Read (system memory to ISS) data connection. 128-bit interface port or 32-bit MTC (inside ISP).
- Gray: 32-bit interface configuration connection.

- Solid black: Video port and camera interface related signals.
- Dotted black: Data flow stall control signal. Used to slow down ISP for memory-to-memory operation.

The ISS is mainly composed of CAL_A, LVDS-RX, and parallel (CPI) camera interfaces, CAL_B, ISP, and a block-based imaging accelerator (SIMCOP).

The ISS is designed to reach high throughput and low latency with large image sensors. In high-performance mode the ISP supports a pixel throughput of 212.8 MPix/s.

The ISS is tightly coupled with a low-interrupt latency microprocessor subsystem (Cortex®-M4 IPU) that runs a real-time operating system (OS) to reach optimal performance. Mainly, the Cortex-M4 IPU can quickly change the ISS configuration during frame blanking periods and run some sequencing tasks. ISS can also be configured using the device DMA controller. Typically, the DMA can be used to transfer large configuration tables used by the ISS (for example, Gamma tables and iMX software).

The ISS targets the following major use cases:

- Video / Preview
 - Up to 1080p60
 - Up to 2x 1080p30
- Stereo Video / Preview
 - Up to 2x 1080p30
- Zero or negative shutter lag still image capture
- Multi-camera use cases:
 - Up to 4 simultaneous cameras. ISP is time shared.

The ISS offers the following features:

- ISS interfaces:
 - Camera Adapter Layer (CAL_A) module, which serves as sensor capture interface supporting MIPI® CSI-2 protocol via external MIPI D-PHY module (CSI2_PHY1), and in addition provides write DMA capability
 - CAL_B module, serving as internal read DMA engine for memory-to-memory operations, without direct sensor capture interface capability
 - Parallel interface (CPI) (16 bits wide, with up to 212.8 MPix/s throughput, and supporting BT.656, SYNC modes)
 - LVDS receiver
 - 128-bit-wide data interface to L3_MAIN interconnect
 - The ISS relies on the centralized memory management unit (MMU). See [Chapter 16, Memory Management Unit](#).
- ISP:
 - On-the-fly or memory-to-memory processing
 - Up to 212.8 MPix/s throughput
 - Statistic data collection
 - Image pipe interface front-end raw data processing
 - High-ISO video noise filtering (NSF3V)
 - Global and local contrast enhancement accelerator (GLBCE)
 - RGB and YUV data processing through ISIF and IPIPE
 - Two image continuous real-time resizers
 - Chroma noise filter
- SIMCOP:
 - Memory-to-memory operation
 - Warping accelerator
 - Temporal video noise filter (VTNF)

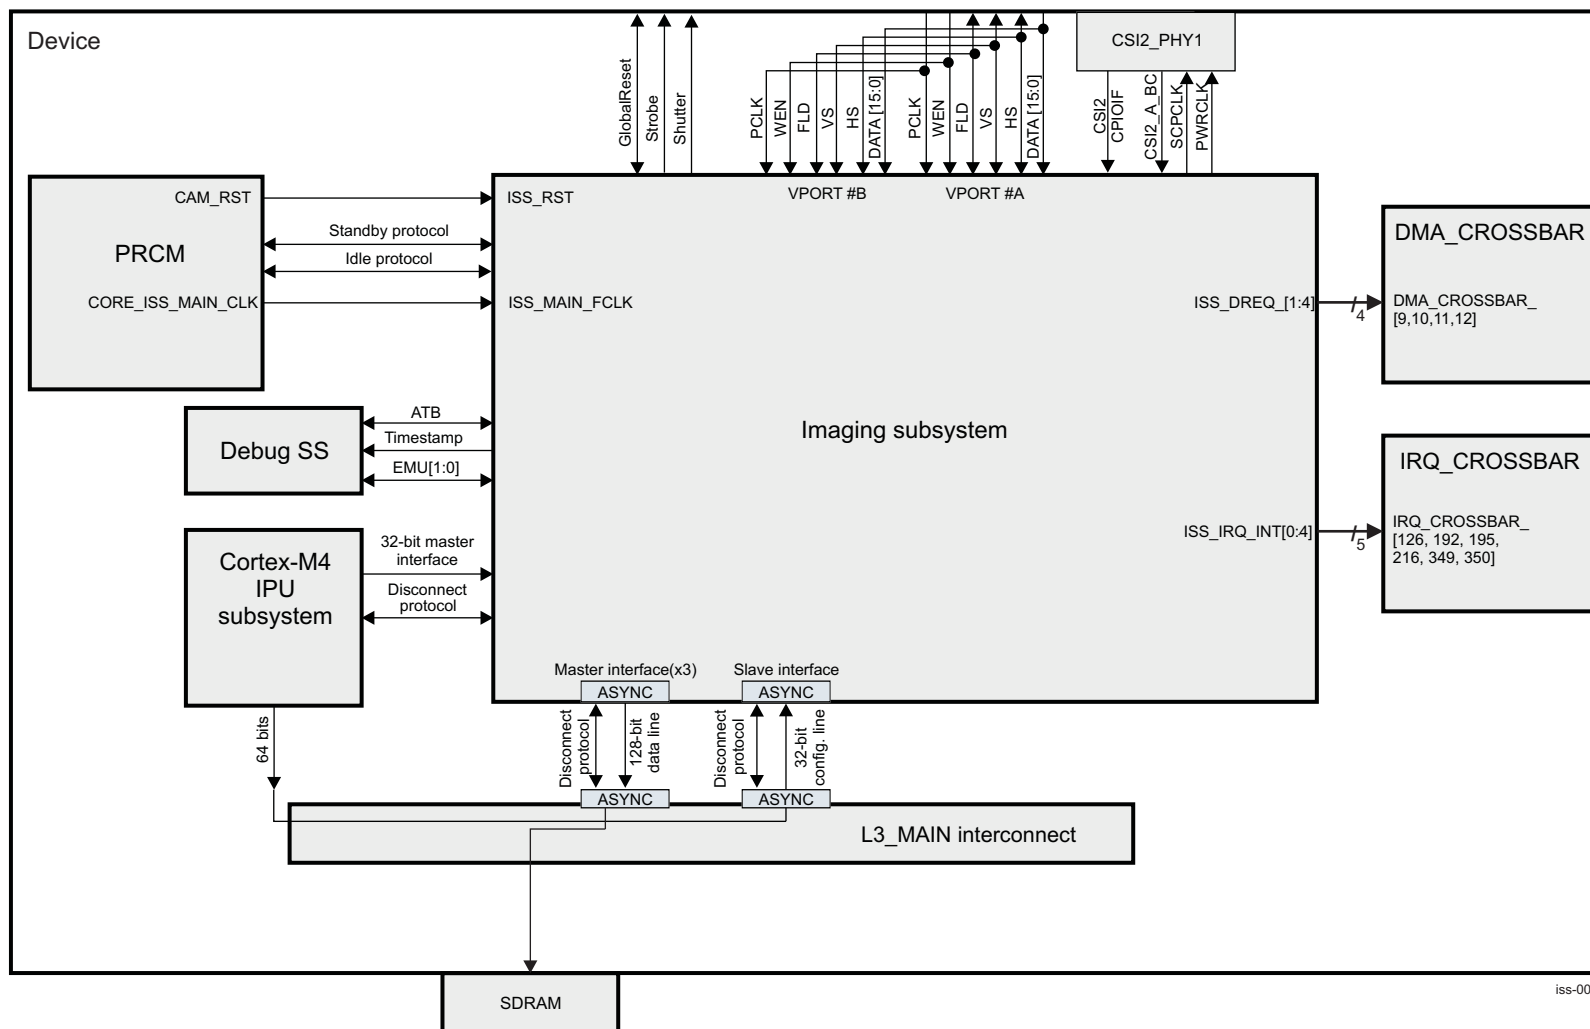

- Direct memory access (DMA) controller
- Hardware sequencer
- Mesh based lens distortion and perspective correction

7.1.1 ISS Integration

This section describes the integration of the module in the device, including information about clocks, resets, and hardware requests.

[Figure 7-2](#) shows the ISS integration.

Figure 7-2. ISS Integration

iss-002

NOTE: For more information about the IDLE hardware handshake and wake-up request, see , *Module-Level Clock Management*, in [Chapter 3, Power, Reset, and Clock Management](#).

This section gives an overview of typical uses of the module. For more information about the relationship of the power, reset, and clock management (PRCM) module to the ISS clocks and the reset settings, see the detailed functional description in [Chapter 3, Power, Reset, and Clock Management](#).

NOTE: For more information about the device clocks and how they are handled by the PRCM module before going into the ISS, see [Section 3.6.3.6, DPLL_CORE Description](#), and [Section 3.6.4.21, CD_ISS Clock Domain](#), in [Chapter 3, Power, Reset, and Clock Management](#).

The ISS also supports software reset. A software reset has the same function as a hardware reset, except that it does not reset the power-management protocols.

[Table 7-1](#) through [Table 7-3](#) summarize the integration of the module in the device.

Table 7-1. ISS Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
ISS	PD_ISS	No	L3_MAIN

Table 7-2. ISS Clocks and Resets

Clocks					
Module Instance	Destination Signal Name	Source Signal Name	Source	Description	
ISS	ISS_MAIN_FCLK	CORE_ISS_MAIN_CLK	PRCM	Functional clock for Camera interfaces, SIMCOP, ISP, and the interconnect (212.8 MHz @ OPP_NOM)	
	PCLK		External sensor	CPI interface pixel clock provided by an external sensor. The CAL module also have video port output, having its pixel clock. This pixel clock is generated from the functional clock (ISS_MAIN_FCLK). All pixel clock sources are multiplexed into a single clock provided to the ISP. The parallel interface performance requirement is 148.5 MHz at device level. However, at ISS level clock can reach 212.8 MHz. Software need to ensure that the pixel clock frequency are inclusive of the sensor and ISP blanking needs. There is a likelihood of sensor data capture overflow while feeding directly to ISP at pixel clock frequency same or close to that of the ISP.	
	CSI2_A_BC		CSI2_PHY1	Byte clock provided by the CSI2_PHY1. Used by the CAL_A module (PPI interface).	
	B_PCLK			CPI pixel clock provided by the camera. Connects to the LVDSRX module. There are certain limitations on the parallel port #B pixel clock. Refer to LVDS-RX section for more details.	
	SCPCLK			ISS	Used for PHY configuration. This is also used as PWRCLK for the PHY.
	PWRCLK			ISS	Used for PHY power handshake.

Table 7-2. ISS Clocks and Resets (continued)

Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
ISS	ISS_RST	CAM_RST	PRCM	ISS global reset

Table 7-3. ISS Hardware Requests

Interrupt Requests				
Module Instance	Source Signal Name	Destination IRQ_CROSSBAR Input	Default Mapping	Description
ISS	ISS_IRQ_INT0	IRQ_CROSSBAR_126	IPU_IRQ_27	Interrupt generated by ISS to IPU
	ISS_IRQ_INT1	IRQ_CROSSBAR_194	-	This IRQ source signal is not mapped by default to any device INTC.
	ISS_IRQ_INT2	IRQ_CROSSBAR_195	-	This IRQ source signal is not mapped by default to any device INTC.
	ISS_IRQ_INT3	IRQ_CROSSBAR_216	-	This IRQ source signal is not mapped by default to any device INTC.
	ISS_IRQ_INT4	IRQ_CROSSBAR_349	-	This IRQ source signal is not mapped by default to any device INTC.
	ISS_IRQ_INT5	IRQ_CROSSBAR_350	-	This IRQ source signal is not mapped by default to any device INTC.

DMA Requests				
Module Instance	Source Signal Name	Destination DMA_CROSSBAR Input	Default Mapping	Description
ISS	ISS_DREQ_1	DMA_CROSSBAR_9	DMA_EDMA_DRE Q_8	ISS EDMA request 1
	ISS_DREQ_2	DMA_CROSSBAR_10	DMA_EDMA_DRE Q_9	ISS EDMA request 2
	ISS_DREQ_3	DMA_CROSSBAR_12	DMA_EDMA_DRE Q_11	ISS EDMA request 3
	ISS_DREQ_4	DMA_CROSSBAR_13	DMA_EDMA_DRE Q_12	ISS EDMA request 4

NOTE: The “Default Mapping” column in [Table 7-3 ISS Hardware Requests](#) shows the default mapping of module IRQ and DREQ source signals. These module IRQ and DREQ source signals can also be mapped to other lines of each device Interrupt or DMA controller through the IRQ_CROSSBAR and DMA_CROSSBAR modules, respectively. For more information about the IRQ_CROSSBAR module, see [Section 14.4.6.4, IRQ_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#). For more information about the DMA_CROSSBAR module, see [Section 14.4.6.5, DMA_CROSSBAR Module Functional Description](#), in [Chapter 14, Control Module](#). For more information about the device interrupt controllers, see [Chapter 13, Interrupt Controllers](#). For more information about the device EDMA module, see [Chapter 12, Enhanced DMA](#).

7.1.1.1 ISS PRCM Interface Integration

7.1.1.1.1 ISS Clock Domains

The ISS has three asynchronous clock domains. Most of the logic uses ISS_MAIN_FLCK; the other clock domains are used for interfaces.

[Table 7-4](#) provides a high-level view of clocks. The frequencies provided are maximum values.

Table 7-4. ISS Local Clock Domains

Name	Description
PCLK	Parallel interface (CPI) pixel clock provided by the camera external sensor. The CAL_A and CAL_B also have video port output having its own pixel clock. This pixel clocks is generated from the functional clock (ISS_MAIN_FCLK). Then all pixel clock sources are multiplexed into one clock provided to the ISP. Up to 212.8 MHz for OPP_NOM.
CSI2_A_BC	Byte clock sourced from the CSI2 complex I/O (CSI2_PHY1) clock RXBYTECLKHS_A. Used by the CAL_A protocol engine. Up to 187.5 MHz for OPP_NOM.
ISS_MAIN_FLCK	Functional clock provided by the PRCM module. It is used by all ISS submodules and ISS top-level resources. Up to 212.8 MHz for OPP_NOM.

To save power, the ISS clocks can be divided at PRCM level. The PCLK must always be less or equal to the ISS_MAIN_FLCK. The internal configuration clock (CFGCLK, used for the internal ISS configuration network) is always half the ISS_MAIN_FLCK.

The functional clock of some submodules can be cut by software to reduce power consumption by cutting off or turning on the modules from the [ISS_CLKCTRL](#) register. Also, the pixel clocks sent by submodules to ISP can be cut off from the corresponding [ISS_CLKCTRL](#) bit-fields.

7.1.2 ISS Functional Description

This section provides only a top-level overview of the ISS. The ISS submodules are described in: [Section 7.2.1, ISS Interfaces](#), [Section 7.3, ISS ISP](#), and [Section 7.4, ISS SIMCOP](#).

7.1.2.1 ISS Interrupts

[Table 7-5](#) lists the events generated by the submodules and the top level of the ISS.

Each event that generates an interrupt can be individually enabled by setting the appropriate bit in the [ISS_HL_IRQENABLE_SET_i](#) register. The interrupt is disabled by setting the appropriate bit in the [ISS_HL_IRQENABLE_CLR_i](#) register.

When an event occurs, the corresponding bit in the [ISS_HL_IRQSTATUS_RAW_i](#) register is set regardless of whether or not the event is enabled. Bits in the [ISS_HL_IRQSTATUS_i](#) registers are set only when an enabled event occurs.

Software can clear a pending HS_VS_IRQ event by setting the [ISS_HL_IRQSTATUS_i\[17\]](#) HS_VS_IRQ bit. Events generated by submodules are automatically cleared at the ISS level when they are cleared at the submodule level.

7.1.2.1.1 ISS Interrupt Merger

The ISS merges the following eleven interrupt sources into six physical interrupt lines. All six lines support level and pulse modes.

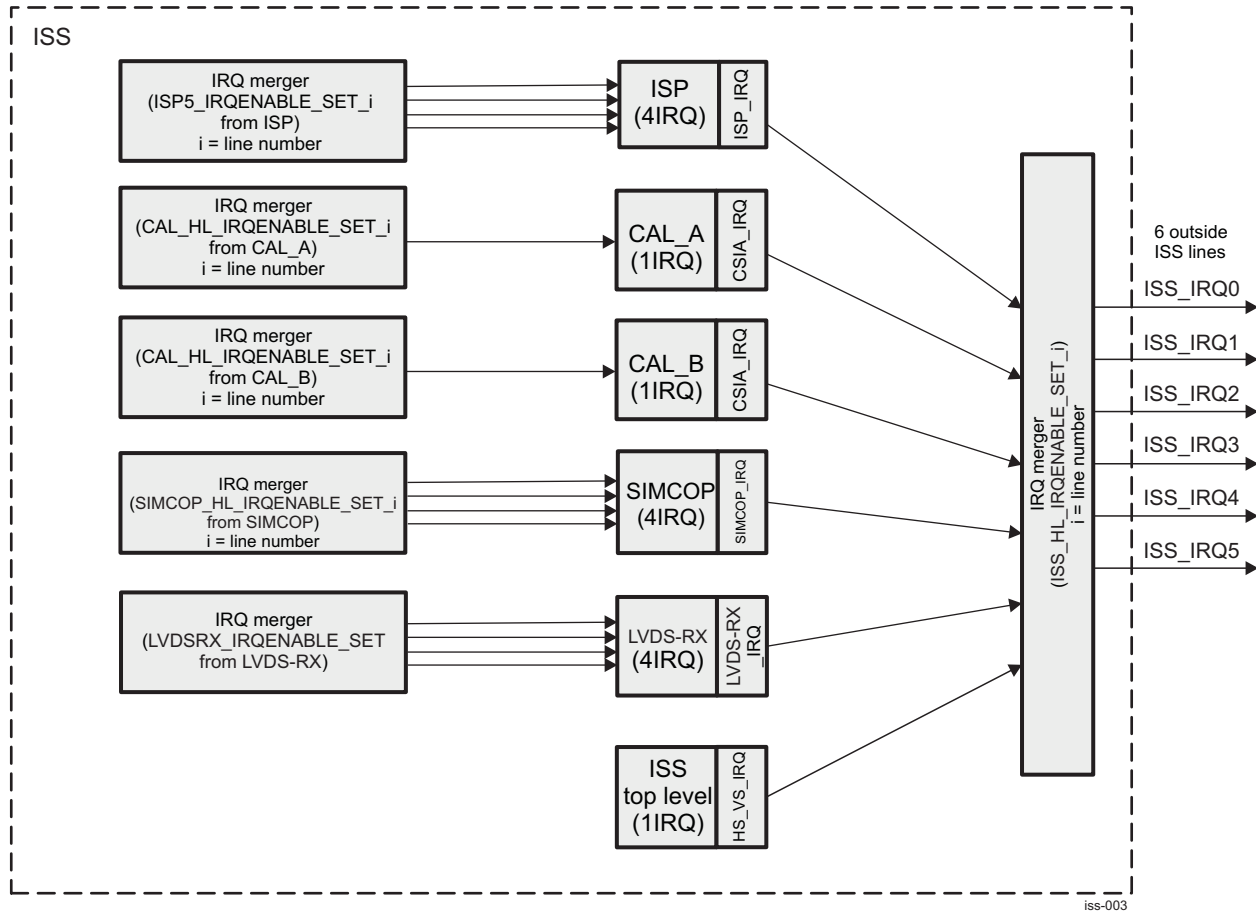

Table 7-5. ISS Interrupts

Interrupt	Source	Description
ISP_IRQ[3:0]	ISP	Interrupts generated by the ISP
CAL_A_IRQ	CAL_A	Interrupt generated by the CAL_A receiver
CAL_B_IRQ	CAL_B	Interrupt generated by the CAL_B receiver
SIMCOP_IRQ[3:0]	SIMCOP	Interrupts generated by SIMCOP
HS_VS_IRQ	ISS	HS or VS synchronization event. This event is triggered if a rising or falling edge is detected on the HS or VS signal. The rising or falling edge and the HS or VS signal selection are chosen using the ISP_CTRL[1:0] SYNC_DETECT bit field.
LVDSRX_IRQ	LVDS-RX	Interrupt generated by the LVDS-RX receiver

Software can select which interrupt sources are routed to each output line ([ISS_IRQ_\[0:5\]](#)). All six physical interrupt outputs have equivalent functions. Software can use different interrupt lines to group events together by type and therefore reduce interrupt latencies. Typically, one interrupt line is used for low-priority events (errors), and the other interrupt lines are used for high-priority events (for example, SIMCOP sequencing and end-of-frame events to trigger configuration load). The ISS internal interrupt request (IRQ) merger (see [Figure 7-3](#)) relies only on level interrupts provided by submodules. Pulse interrupts provided by submodules are ignored. All of the interrupts are routed to device interrupt crossbar. Software does not need to clear events from submodules at the ISS level: it clears only the events at the submodule level. The IRQ merger automatically clears the IRQ at ISS level (events generated by submodules are automatically cleared at ISS level when they are cleared at sub-module level).

NOTE: Only the HS_VS_IRQ top-level event is cleared at the ISS level.

Figure 7-3. ISS Interrupt Merger

NOTE: For more information about mapping the six lines to the device modules outside ISS, see [Table 7-3](#).

The ISP, SIMCOP, CAL_A, CAL_B, and HL ISS merger IRQ lines are configurable. Each interrupt can be mapped to the required line.

7.1.2.1.2 ISS Submodule Interrupts

The ISS shown in [Figure 7-3](#) and listed in [Table 7-3](#) can generate six interrupts.

7.1.2.1.2.1 ISS ISP Interrupts

[Table 7-6](#) summarizes events that cause ISP interrupts.

Table 7-6. ISS ISP Interrupts

Event and Register ⁽¹⁾	Description
ISP5_IRQENABLE_SET_i[[31] OCP_ERR_IRQ	An interface port error has been received on the ISP master port.
ISP5_IRQENABLE_SET_i[[29] IPIPE_INT_DPC_RNEW1	HD interrupt signal to indicate the need to renew the defect pixel correction (DPC) table with new entries. The second 128 entries in the DPC table must be updated when this event triggers. This event is triggered when the 255th entry in the look-up table (LUT) is used. This interrupt is not synchronous to the HD signal.

⁽¹⁾ i = 0 to 3

Table 7-6. ISS ISP Interrupts (continued)

Event and Register ⁽¹⁾	Description
ISP5_IRQENABLE_SET_[28] IPIPE_INT_DPC_RNEW0	VD interrupt signal to indicate the need to renew the DPC table with new entries. The first 128 entries in the DPC table must be updated when the event triggers. This event is triggered when the 127th entry in the LUT is used. This interrupt is not synchronous to the HD signal.
ISP5_IRQENABLE_SET_[27] IPIPE_INT_DPC_INI	Interrupt to signal the need to initialize the DPC table. The DPC table contains two tables of 128 entries. When this signal is used, software must ensure that the 256 table entries are updated with the DPC information.
ISP5_IRQENABLE_SET_[25] IPIPE_INT_EOF	End of frame interrupt signal
ISP5_IRQENABLE_SET_[24] H3A_INT_EOF	End of frame interrupt signal
ISP5_IRQENABLE_SET_[22] RSZ_INT_EOF1	See Section 7.1.3, ISS Register Manual , and Section 7.3.4, ISS ISP Register Manual .
ISP5_IRQENABLE_SET_[23] RSZ_INT_EOF0	See Section 7.1.3, ISS Register Manual , and Section 7.3.4, ISS ISP Register Manual .
ISP5_IRQENABLE_SET_[19] RSZ_FIFO_IN_BLK_ERR	See Section 7.1.3, ISS Register Manual , and Section 7.3.4, ISS ISP Register Manual .
ISP5_IRQENABLE_SET_[18] RSZ_FIFO_IN_OVF	See Section 7.1.3, ISS Register Manual , and Section 7.3.4, ISS ISP Register Manual .
ISP5_IRQENABLE_SET_[17] RSZ_INT_CYC_RZB	See Section 7.1.3, ISS Register Manual , and Section 7.3.4, ISS ISP Register Manual .
ISP5_IRQENABLE_SET_[16] RSZ_INT_CYC_RZA	See Section 7.1.3, ISS Register Manual , and Section 7.3.4, ISS ISP Register Manual .
ISP5_IRQENABLE_SET_[15] RSZ_INT_DMA	See Section 7.1.3, ISS Register Manual , and Section 7.3.4, ISS ISP Register Manual .
ISP5_IRQENABLE_SET_[14] RSZ_INT_LAST_PIX	See Section 7.1.3, ISS Register Manual , and Section 7.3.4, ISS ISP Register Manual .
ISP5_IRQENABLE_SET_[13] RSZ_INT_REG	See Section 7.1.3, ISS Register Manual , and Section 7.3.4, ISS ISP Register Manual .
ISP5_IRQENABLE_SET_[12] H3A_INT	Interrupt generated by the AF and AE/AWB blocks inside the H3A module. It indicates the end of processing a frame and is active high for one configuration bus clock cycle.
ISP5_IRQENABLE_SET_[11] AF_INT	AF inside generates an interrupt at the end of processing frame; a third interrupt is generated at the same time as the last process to finish.
ISP5_IRQENABLE_SET_[10] AEW_INT	AEW inside generates an interrupt at the end of processing frame; a third interrupt is generated at the same time as the last process to finish.
ISP5_IRQENABLE_SET_[9] IPIPEIF_IRQ	IPIPEIF module interrupt is generated at the start position of a frame and is active high for one configuration bus clock cycle.
ISP5_IRQENABLE_SET_[8] IPIPE_INT_HST	IPIPE module interrupt is generated when histogram is done.
ISP5_IRQENABLE_SET_[7] IPIPE_INT_BSC	IPIPE module interrupt is generated when boundary signal calculation is done.
ISP5_IRQENABLE_SET_[6] IPIPE_INT_DMA	IPIPE module interrupt is issued when the SDRAM transfer of boxcar is done. At this time, IPIPE EOF is sent to buffer logic.
ISP5_IRQENABLE_SET_[5] IPIPE_INT_LAST_PIX	IPIPE module interrupt is issued when the last pixel of a frame comes into IPIPE.
ISP5_IRQENABLE_SET_[4] IPIPE_INT_REG	IPIPE module interrupt is issued when the register update of the module is allowed.
ISP5_IRQENABLE_SET_[3] ISIF_INT_3	See Section 7.1.3, ISS Register Manual , and Section 7.3.4, ISS ISP Register Manual .
ISP5_IRQENABLE_SET_[2] ISIF_INT_2	See Section 7.1.3, ISS Register Manual , and Section 7.3.4, ISS ISP Register Manual .
ISP5_IRQENABLE_SET_[1] ISIF_INT_1	See Section 7.1.3, ISS Register Manual , and Section 7.3.4, ISS ISP Register Manual .

7.1.2.1.2.2 ISS CAL_A / CAL_B and CSI2_PHY1 Complex I/O Interrupts

The CAL_A and CAL_B modules also contains an high-level interrupt merger. For details on CAL_A / CAL_B interrupts and its IRQ merger refer to section *CAL Interrupt Events* in the *ISS Interfaces* subchapter.

7.1.2.1.2.3 ISS SIMCOP Interrupts

[Table 7-7](#) summarizes the SIMCOP high-level interrupts mapped to the outer boundaries of the SIMCOP. For more information about interrupts generated from inside the SIMCOP modules, see [Section 7.4, ISS Still Image Coprocessor](#).

Table 7-7. ISS SIMCOP High-Level Interrupts

Event and Register	Description
SIMCOP_HL_IRQENABLE_SET_i[19] CPU_PROC_START_IRQ	Interrupt used when CPU data processing is used in a macroblock processing pipeline. When the CPU receives this IRQ, data is ready to be processed. When the CPU finishes processing the data, it acknowledges by setting the SIMCOP_HWSEQ_CTRL.CPU_PROC_DONE bit.
SIMCOP_HL_IRQENABLE_SET_i[18] SIMCOP_DMA_IRQ1	Interrupt triggered by SIMCOP DMA
SIMCOP_HL_IRQENABLE_SET_i[16] OCP_ERR_IRQ	SIMCOP master port interface error
SIMCOP_HL_IRQENABLE_SET_i[14] DONE_IRQ	Event triggered when hardware sequencer finishes the sequence: <ul style="list-style-type: none"> The sequence step counter has reached the limit. All accelerator and DMA events for the last sequence step have been received.
SIMCOP_HL_IRQENABLE_SET_i[13] STEP3_IRQ	Event triggered when a SIMCOP Context 3 is activated by the hardware sequencer.
SIMCOP_HL_IRQENABLE_SET_i[12] STEP2_IRQ	Event triggered when a SIMCOP Context 2 is activated by the hardware sequencer.
SIMCOP_HL_IRQENABLE_SET_i[11] STEP1_IRQ	Event triggered when a SIMCOP Context 1 is activated by the hardware sequencer.
SIMCOP_HL_IRQENABLE_SET_i[10] STEP0_IRQ	Event triggered when a SIMCOP Context 0 is activated by the hardware sequencer.
SIMCOP_HL_IRQENABLE_SET_i[9] LDC_BLOCK_IRQ	A macroblock has been processed.
SIMCOP_HL_IRQENABLE_SET_i[1] LDC_FRAME_IRQ	A full frame has been processed.
SIMCOP_HL_IRQENABLE_SET_i[0] SIMCOP_DMA_IRQ0	Interrupt triggered by SIMCOP DMA

7.1.2.1.2.4 ISS LVDS-RX Interrupts

[Table 7-8](#) lists the event generation of the LVDS-RX module through the LVDS-RX interrupt enable register. The events are checked for status using the LVDSRX_IRQSTATUST_i registers. The interrupts can be disabled using LVDSRX_IRQENABLE_CLR_i register.

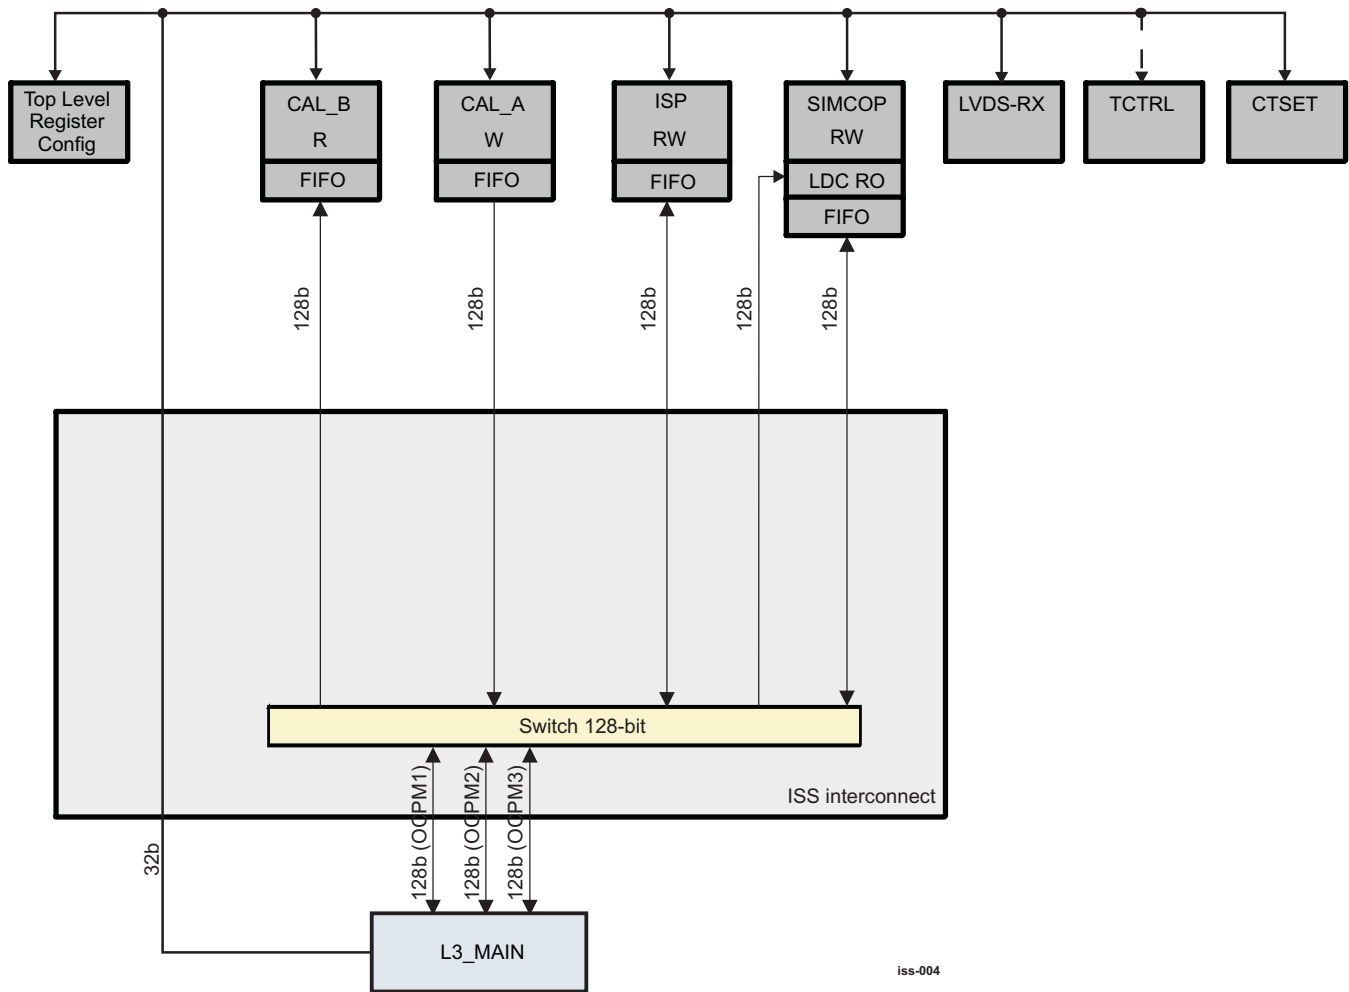

Table 7-8. ISS LVDSRX Interrupts

Event and Register	Description
LVDSRX_IRQENABLE_SET_i[9] CAMx_ERR7	Sync detected timeout reached
LVDSRX_IRQENABLE_SET_i[8] CAMx_ERR6	CRC error
LVDSRX_IRQENABLE_SET_i[7] CAMx_ERR5	Unexpected SOF
LVDSRX_IRQENABLE_SET_i[6] CAMx_ERR4	Unexpected SOL
LVDSRX_IRQENABLE_SET_i[5] CAMx_ERR3	Unexpected EOF
LVDSRX_IRQENABLE_SET_i[4] CAMx_ERR2	Unexpected EOL
LVDSRX_IRQENABLE_SET_i[3] CAMx_ERR1	Unexpected SOV
LVDSRX_IRQENABLE_SET_i[2] CAMx_ERR0	EOX not received
LVDSRX_IRQENABLE_SET_i[1] CAMx_EOF	End of frame timing
LVDSRX_IRQENABLE_SET_i[0] CAMx_SOF	Start of frame timing

7.1.2.2 ISS Interconnect

Section 7.1.2.1.1 shows the ISS local interconnect data network.

Figure 7-4. ISS Local Interconnect Data Network

The data network collects requests from CAL_A, CAL_B, ISP, and SIMCOP and forwards them to the L3_MAIN interconnect.

Table 7-9 summarizes what type of traffic can be generated by the different initiators on the ISS data interconnect and what targets can be addressed by those initiators.

Table 7-9. ISS Data Interconnect Connectivity Map

Initiator	Traffic type					Destination		
	RT / RD	RT / WR	NRT / RD	NRT / WR	2D	OCPM2	OCPM1 (RT)	OCPM3 (GP)
CAL_A / CAL_B		x	x	x		x	x	x
ISP	x	x	x	x		x	x	x
SIMCOP DMA			x	x	x	x		x
SIMCOP LDC			x			x		x

For destinations outside of the ISS, multiple routes are possible. Which one is chosen depends on the MReqInfo[1:0] field provided to the ISS data interconnect. Software can control the routing to some extent as shown in [Table 7-10](#)

Table 7-10. ISS Routing outside ISS boundaries

Initiator	MReqInfo (in)			Traffic type	0 OCPM2	Routing - MReqInfo [1:0] (out)	
	Control	Value	Routing Control Register			1 OCPM2 (RT)	2 OCPM3 (GP)
CAL_A / CAL_B	Directly controlled by the CAL_A / CAL_B hardware.	0	ISS_ROUTE1.CALx_0	Cport #0 used for non real time traffic. Used by the read DMA. May require 1D->2D translation. Usage of RT port for non RT traffic not recommended	x	x	x
		>0	ISS_ROUTEx.CALx_1 ISS_ROUTEx.CALx_7	Typically used for real time traffic from the camera. Generally doesn't require translation. May be non real time in specific use cases. SL2 may be used to artificially increase the FIFO size	x	x	x
ISP	Directly controlled by the ISP HW.	0	ISS_ROUTE3.I SP_IPIPEIF	IPIPEIF RD : RT when used for DFS for data directly received from the camera; but generally used as read DMA in M2M mode	x	x	x
		1	ISS_ROUTE3.I SP_LSC	LSC RD : RT when data is directly received from the camera; but generally used in M2M mode	x	x	x
		2	ISS_ROUTE3.I SP_RAW	ISIF RAW WR : RT when data is directly received from the camera; but generally used in M2M mode	x	x	x
		3	ISS_ROUTE3.I SP_BOXCAR	IPIPE BOXCAR WR: RT when data is directly received from the camera; but generally used in M2M mode	x	x	x
		4	ISS_ROUTE3.I SP_H3A	H3A WR : RT when data is directly received from the camera; but generally used in M2M mode	x	x	x
		5	ISS_ROUTE3.I SP_RSZA	RESIZER #A : RT when data is directly received from the camera; but generally used in M2M mode	x	x	x
		6	ISS_ROUTE3.I SP_RSZB	RESIZER #B : RT when data is directly received from the camera; but generally used in M2M mode	x	x	x
		7	NA	reserved	-	-	-
SIMCOP DMA	fixed		ISS_ROUTE3.SDMA	Non real time traffic. Chose route to minimize congestion	x		x
SIMCOP LDC	fixed		ISS_ROUTE3.LDC	Non real time traffic. Chose route to minimize congestion	x		x
Default							
Possible - depends on use case							
Not recommended							
Disallowed							

The above table shows MReqInfo[1:0] that are used to route the traffic. Moreover, ISS provides a different MReqInfo on the OCPM1 and OCPM2 to indicate the initiator ID to L3_MAIN. The [Table 7-11](#) lookup table inside the ISS is used to convert the 5-bit MReqInfo from the ISS into a 3-bit L3_MAIN MReqInfo. The lookup table is initialized with meaningful values but may be changed by software as shown below:

Table 7-11. ISS Initiator ID

ISS internal MReqInfo	Initiator	Register	Default L3_MAIN MReqInfo
0	ISP - IPIPEIF RD	ISS_REQINFO_MAP0_7.REQINFO_0	0
1	ISP - ISIF LSC	ISS_REQINFO_MAP0_7.REQINFO_1	0
2	ISP - ISIF RAW WR	ISS_REQINFO_MAP0_7.REQINFO_2	0
3	ISP - IPIPE BOXCAR	ISS_REQINFO_MAP0_7.REQINFO_3	0
4	ISP - H3A WR	ISS_REQINFO_MAP0_7.REQINFO_4	0
5	ISP - RSZ #A	ISS_REQINFO_MAP0_7.REQINFO_5	0
6	ISP - RSZ #B	ISS_REQINFO_MAP0_7.REQINFO_6	0
7	ISP - reserved	ISS_REQINFO_MAP0_7.REQINFO_7	0
8	reserved	ISS_REQINFO_MAP8_15.REQINFO_8	0
9	reserved	ISS_REQINFO_MAP8_15.REQINFO_9	0
10	SIMCOP DMA	ISS_REQINFO_MAP8_15.REQINFO_10	1
11	SIMCOP LDC	ISS_REQINFO_MAP8_15.REQINFO_11	1
12	reserved	ISS_REQINFO_MAP8_15.REQINFO_12	2
13	reserved	ISS_REQINFO_MAP8_15.REQINFO_13	3
14	reserved	ISS_REQINFO_MAP8_15.REQINFO_14	0
15	reserved	ISS_REQINFO_MAP8_15.REQINFO_15	0
16	CAL_A RD & WR CTX #0	ISS_REQINFO_MAP16_23.REQINFO_16	4
17	CAL_A WR CTX #1	ISS_REQINFO_MAP16_23.REQINFO_17	5
18	CAL_A WR CTX #2	ISS_REQINFO_MAP16_23.REQINFO_18	5
19	CAL_A WR CTX #3	ISS_REQINFO_MAP16_23.REQINFO_19	5
20	CAL_A WR CTX #4	ISS_REQINFO_MAP16_23.REQINFO_20	5
21	CAL_A WR CTX #5	ISS_REQINFO_MAP16_23.REQINFO_21	5
22	CAL_A WR CTX #6	ISS_REQINFO_MAP16_23.REQINFO_22	5
23	CAL_A WR CTX #7	ISS_REQINFO_MAP16_23.REQINFO_23	5
24	CAL_B RD & WR CTX #0	ISS_REQINFO_MAP24_31.REQINFO_24	6

Table 7-11. ISS Initiator ID (continued)

ISS internal MReqInfo	Initiator	Register	Default L3_MAIN MReqInfo
25	CAL_B WR CTX #1	ISS_REQINFO_MAP24_31.REQINFO_25	7
26	CAL_B WR CTX #2	ISS_REQINFO_MAP24_31.REQINFO_26	7
27	CAL_B WR CTX #3	ISS_REQINFO_MAP24_31.REQINFO_27	7
28	CAL_B WR CTX #4	ISS_REQINFO_MAP24_31.REQINFO_28	7
29	CAL_B WR CTX #5	ISS_REQINFO_MAP24_31.REQINFO_29	7
30	CAL_B WR CTX #6	ISS_REQINFO_MAP24_31.REQINFO_30	7
31	CAL_B WR CTX #7	ISS_REQINFO_MAP24_31.REQINFO_31	7

The default configuration has been optimized for typical memory to memory operation of ISP and SIMCOP while hard real time data is received from the camera. It shall be changed to qualify all ISP traffic as hard real time when the ISP operates in on-the-fly mode (i.e. low power scenarios where the ISP receives data directly from the camera). Other situations may also require changing the configuration from the default; for example to balance the load between the interface master ports.

A fair arbitration is used among pending transactions with the same priority level (i.e. same MFlag value). Higher priority paths (i.e. larger MFlag value) always win the arbitration when they present a request. However, higher MFlags don't "reserve" a datapath when there's no pending transaction.

CAL_A/CAL_B and ISP can generate MFlag. ISP can assert its MFlag either statically (through SW configuration) or dynamically (FIFO level based; with SW configurable thresholds). Statically forcing MFlag to 01 or 11 is strongly discouraged as it reduces overall system efficiency. This possibility is offered by the HW only to workaround lately discovered HW bugs.

Software must route real time traffic to OCPM1 master port and enable dynamic MFlag generation for best performance. MFlag>0 generation shall be disabled for non real time traffic through adequate settings in the initiator IP.

CAL_A/CAL_B, ISP, and SIMCOP can generate up to 16 tags per master port. The number of tags that can be used per initiator is set by software (in the corresponding x_TAG_CNT register bit-fields). The ISS interconnect compresses the 6 x 16 internal ISS tags into 16 tags. Tag compression occurs after the 128-bit switch. When all 16 tags are used, the switch output is stalled. This stalls requests from ISS internal initiators.

NOTE: There is another internal 32-bit configuration interconnect within the ISS. It runs on the internal CFGCLK, as explained in [Section 7.1.1.1.1, ISS Clock Domains](#). There is no physical link between the data and the configuration interconnect.

7.1.2.3 ISS Video Mux

The video mux connects video ports of different ISS sub-modules. [Figure 7-5](#) below summarizes all possible connections using the following conventions:

- Gray background indicates that this connection is meaningless:
 - Loop a module to itself (e.g. BYSout -> BYSin)
 - Create a connection that already exists (between NSF3V, GLBCE and ISP)
- White background indicates that a direct connection could potentially be implemented. But it is only implement if the box also contains a "X"
- Orange background indicates that a connection with width translation and/or frequency conversion is potentially possible (but not necessarily implemented)

- A letter indicates that a connection physically exists. It can be enabled by software. Read further for details about the connections

Figure 7-5. ISS Video Mux Possible connections

	CAL #A BYSout	CAL #A VP	CAL #B BYSout	CAL #B VP	CPI (Parallel)	NSF3V out	GLBCE out	LVDSRX out0	LVDSRX out1	LVDSRX out3
CAL #A BYSin						U	W	Y		AH
CAL #B BYSin						V	X		AB	
NSF3V in	D		I							
GLBCE in	E		J							
ISP in	F		K	L				AA	AD	AJ

iss-007

Connections are enabled by selecting a source for each destination by configuring the relevant `ISS_VMUX.[destination]` register. Before changing a connection, SW shall ensure that pixel clocks of the old and the new sources are inactive. That can be guaranteed by disabling the clock with the relevant bit in `ISS_CLKCTRL`. The video mux contains width and frequency conversion FIFO that should naturally drain their data. However, in some particular cases (e.g. path is stalled by the source and FIFO still contains data when the source is switched) it may be necessary to explicitly empty those using the `ISS_VMUX_RESET` register. In some cases, it may also be necessary to reset the data destination module to ensure that it starts from a clean state when the previous data stream was aborted. Once the video connection has been properly configured, SW should first enable the destination module and only enable the source module when the destination is ready to receive data.

It is possible that a given source is connected to multiple destinations (i.e. broadcast). Several paths support flow control (i.e. the source could be stalled when one of the destinations cannot accept the data to avoid data corruption). An error event is triggered when the source could not be stalled (because the data source doesn't support flow control).

The memory storage format used for the full resolution stream should match the format received from the camera. However, the format used by the CAL engines may be different.

Generally speaking, CAL_B can be used as general purpose pixel read DMAs and CAL_A as write DMA.

ISP and either NSF3V or GLBCE can operate independently from each other and may be used in memory to memory mode when they are attached to pixel read and/or write DMAs like CAL. The choice of the DMA depends on the use case requirements (i.e. available internal datapath, available processing resources, ...).

[Table 7-12](#) summarizes the characteristics of the different source and destination video ports managed by the video mux.

Table 7-12. ISS Video port summary

Port	Type	Max. CLK (Mhz)	Channels	Data width	HS	HE	VS	VE	FLD	WEN	STALL

7.1.2.4 ISS Clocks

The clocks of ISS submodules can be cut individually using the [ISS_CLKCTRL](#) register. Software can poll the module status reading the appropriate bit in the [ISS_CLKSTAT](#) register.

When software wants to enable a submodule:

- Software sets the appropriate bit in the [ISS_CLKCTRL](#) register.
- Hardware enables the submodule functional and interface clocks (expected to take a few cycles).
- Hardware sets the appropriate bit in the [ISS_CLKSTAT](#) register.

Software must enable the modules in the correct order. The hardware imposes no particular constraint. For example, when data must be provided by the CAL_A receiver and processed by the ISP, both modules must be enabled and correctly configured before data arrives. An example of configuration order is: enabling the CAL_A receiver powers up the CSI2_PHY1 complex I/O connected to the external sensor. Additionally, the ISP must be configured and the source interface must be selected. For details and the order of configuration, see the programming module of the particular submodule.

When software wants to shut down a submodule:

- Software ensures that the submodule is idle. Mainly:
 - The submodule must not generate new events.
 - The submodule must not have any pending events.
 - For initiators: The submodule must stop the generation of an interface bridge transaction.
- Software clears the appropriate bit in the [ISS_CLKCTRL](#) register.
- For modules having only a master port: Hardware waits until the submodule to be disconnected asserts the MStandBy signal on its master port. It asserts MWait of the submodule.

NOTE: The ISS does not assert the MWait signal when a shutdown of the module is not requested by software.

- Hardware cuts the submodule clocks.
- Hardware clears the appropriate bit in the [ISS_CLKSTAT](#) register.

[Table 7-14](#) describes the clock gating of the ISS submodule.

Table 7-14. ISS Submodule Clock Gating

ISS Resource	Feature On/Off Control
ISS top-level resources	Not applicable. ISS top-level resources cannot be cut. However, top-level resources support the autogating feature.
SIMCOP	ISS_CLKCTRL[0] SIMCOP
ISP	ISS_CLKCTRL[1] ISP
CAL_A	ISS_CLKCTRL[9] CAL_A
CAL_B	ISS_CLKCTRL[10] CAL_B
LVDS-RX	ISS_CLKCTRL[13] LVDSRX
ISS interconnect	These modules cannot be switched off individually. They are required for any processing performed by SIMCOP because they are on the main data path. However, they support autogating to reduce power consumption when activity is low.

When the clock of a submodule is cut and an interface bridge request for this module is received from the ISS configuration interconnect, the ISS clock manager temporarily enables the module clock to handle the access properly.

All ISS submodules are off after reset; software must enable them before they can be used.

7.1.2.5 ISS Reset

The ISS can accept a general software reset, propagated through all the hierarchy. This reset can be done to initialize the module and has the same effect as the hardware reset.

1. Set the [ISS_HL_SYSCONFIG\[0\]](#) SOFTRESET bit to 1.
2. Read the [ISS_HL_SYSCONFIG\[0\]](#) SOFTRESET bit to check whether it equals 0, which means the reset occurred.

If after five reads, [ISS_HL_SYSCONFIG\[0\]](#) SOFTRESET still returns 1, it can be assumed that an error occurred during the reset stage.

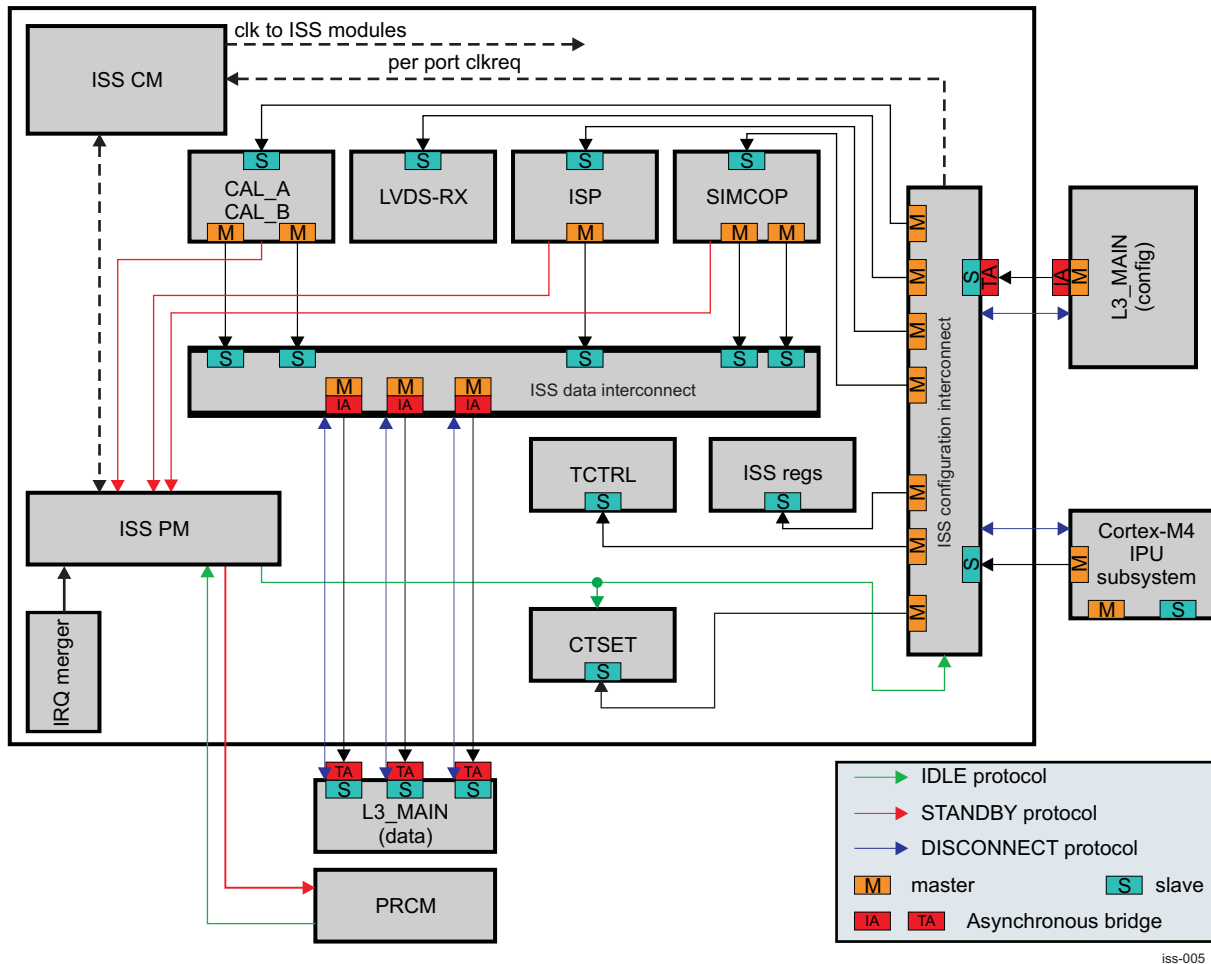

A software reset must not reset the power manager protocols (must not reset the IDLE and STANDBY generic IPs).

7.1.2.6 ISS Power Management

7.1.2.6.1 ISS Power-Management Infrastructure Overview

Figure 7-6 is an overview of the ISS power management.

Figure 7-6. ISS Power Management

iss-005

NOTE: For power savings, the PRCM module can request idle mode from the ISS. When the ISS is not functional, software must decide when the PRCM module can send the request. For more information, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

7.1.2.6.2 ISS STANDBY Mechanism

The power manager receives STANDBY information from the CAL_A, CAL_B, LVDS-RX, ISP, and SIMCOP modules. These modules assert a standby signal when they have no more transactions to perform. The ISS power manager acknowledges by asserting a wait signal.

When those modules are in standby mode, the ISS power manager initiates a STANDBY sequence for the ISS:

1. The ISS waits while the CAL_A, CAL_B, LVDS-RX, ISP, and SIMCOP MStandby is asserted.
2. The ISS power manager acknowledges by asserting the CAL_A, CAL_B, LVDS-RX, ISP, and SIMCOP MWait signal.
3. The ISS initiators assert only the MStandBy signal when they receive responses to all sent requests.

Therefore, when all initiators have asserted MStandBy, the ISS interconnect has no more pending traffic (although configurable, only nonposted writes must be used for error reporting).

4. The ISS power manager asserts the MStandBy signals connected to the system PRCM module.
5. The PRCM module acknowledges by asserting the MWait signal.

A functional standby transition can be aborted when one of the CAL_A, CAL_B, LVDS-RX, ISP, and SIMCOP modules deasserts the MStandBy signal.

When one of the CAL_A, CAL_B, LVDS-RX, ISP, and SIMCOP modules must perform accesses to the ISS interface master port, it deasserts the MStandBy signal. The ISS power manager executes the following sequence to leave the STANDBY state:

1. The ISS power manager deasserts the MStandby signal.
2. The ISS waits until the PRCM module deasserts the MWait signal.
3. The ISS deasserts the MWait signal of the module requesting access.

Abort of the standby-to-functional mode transition is not supported. The ISS power manager completes the standby-to-functional transition and then allows a new functional-to-standby transition.

Typically, the MStandby signal is used for two purposes. Software chooses one of the following behaviors through PRCM configuration:

- During blanking periods: The ISS asserts the MStandBy signal between frames when it has no more data to send. The PRCM module can use this information to switch off the L3_MAIN interconnect and save some dynamic power. However, the PRCM module is not allowed to cut the ISS functional clock in that case, because it is needed to receive the next frame.
- For ISS shutdown: The ISS asserts MStandBy when it has no more transactions to perform. The PRCM module then initiates an IDLE sequence. Once the ISS acknowledges the transition into idle mode, the PRCM module can cut the ISS clock and power.

The internal standby mode can be reached only when LVDS-RX, CAL_A, CAL_B, SIMCOP, ISP, and ISS data interconnect are in IDLE or STANDBY state. Choosing no-idle or no-standby mode for any of these modules prevents the ISS from going into STANDBY state.

Four modes for standby control are supported, configured through the [ISS_HL_SYSCONFIG](#) [5:4] STANDBYMODE register bit-field:

- Smart-standby-wakeup mode [STANDBYMODE = 0x3]: This is the mode normally used. When in this mode, the ISS asserts the MStandBy signal when the MStandBy of all ISS internal initiators is asserted and the ISS data interconnect are in IDLE state.
- Smart-standby mode (default) [STANDBYMODE = 0x2]: The ISS has no wake-up event. This mode is equivalent to smart-standby-wakeup mode.
- Force-standby mode [STANDBYMODE = 0x0]: This is a backup mode intended to be used only if smart-standby mode is bugged. When in this mode, the ISS asserts MStandBy unconditionally. Software must ensure that the ISS is in a correct quiet state before programming this mode.
- No-standby mode [STANDBYMODE = 0x1]: This is a backup mode intended to be used only if smart-standby mode is bugged. When in this mode, the ISS never asserts the MStandBy signal.

7.1.2.6.3 ISS IDLE Mechanism

The PRCM module can request the ISS to go into IDLE state when the ISS has asserted its MStandBy output.

In a normal case, software must ensure that the ISS is in a quiet state before allowing the PRCM module to send an IDLE request to the ISS:

- The ISS has no more traffic to generate.
- The ISS cannot generate any new interrupts.
- The ISS has no pending interrupts.

When an IDLE request is received from the PRCM module, the ISS power manager verifies that the ISS MWait input has been asserted and that all ISS interrupt outputs are deasserted. It then starts the STANDBY-to-IDLE transition:

1. Send IDLE request to the ISS configuration interconnect.
2. The ISS configuration interconnect requests disconnection of both ISS interface slave ports. Disconnection is done by the master:
 - It stops accepting new requests and drains currently ongoing ones.
 - It waits for completion of all ongoing transactions.
3. The ISS configuration interconnect acknowledges the IDLE transition.
4. The ISS power manager acknowledges the IDLE request from the PRCM module.
5. The PRCM module can cut the ISS clock and power.

The PRCM module first enables the ISS power and clock before requesting the ISS to go into functional state by deasserting the `SIdleReq` signal. The ISS power manager then executes the wake-up sequence:

1. Request the ISS interconnect to go into functional state.
2. The ISS interconnect connects the ISS slave ports.
3. The ISS interconnect acknowledges transition into functional mode.
4. The ISS power manager acknowledges transition into functional mode (ISS output `SIdleAck` = 00).

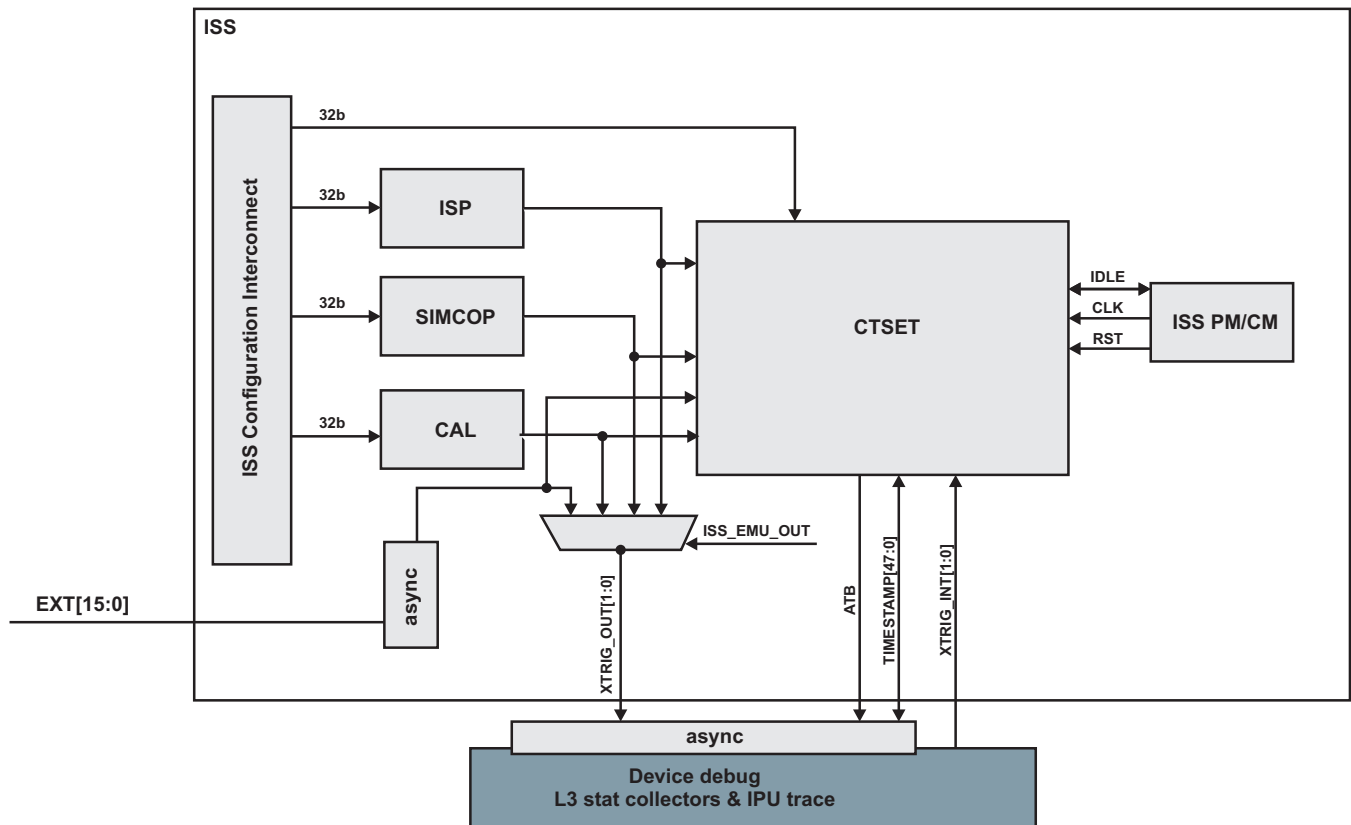

Four modes for IDLE control are supported, controlled through the `ISS_HL_SYSCONFIG[3:2]` IDLEMODE register bit-field:

- Smart-idle-wakeup mode [IDLEMODE = 0x3]: This is the mode normally used. When in this mode, the ISS acknowledges a request to go idle from the power manager after having performed all hardware operations necessary for the IAF to be in a correct quiet state.
- Smart-idle mode (default) [IDLEMODE = 0x2]: This is equivalent to smart-idle-wakeup mode.
- Force-idle mode [IDLEMODE = 0x0]: This is a backup mode intended to be used only if smart-idle mode is bugged. When in this mode, the ISS acknowledges a request to go idle from the power manager with no hardware condition. Software must ensure that the ISS is in a correct quiet state before requesting a force-idle transition.
- No-idle mode [IDLEMODE = 0x1]: When in this mode, the ISS disregards any request to go idle from the power manager.

7.1.2.6.4 ISS Debug Support

ISS integrates the CTSET module to trace internal events. A detailed specification of the CTSET module is available in [Figure 7-7](#). In addition, it exports two internal events that can be used to start / stop system level trace modules such as the L3 statistical collectors.

Figure 7-7. ISS CTSET Integration

iss-006

7.1.2.6.4.1 3ISS CTSET Event Selection

A simple n to 1 mux is used for XTRIG_OUT and Interrupt controller event selection. For CTSET event selection, up to 3 ISS events are mapped to one CTSET entry. The selection is done using the [ISS_CTRL1\[1:0\] CTSET_EVT](#) register. A logical or of all 3 sources is performed when [ISS_CTRL1\[1:0\] CTSET_EVT = 3](#). Otherwise, the event with the next lower identifier is selected. For example, when [ISS_CTRL1\[1:0\] CTSET_EVT = 2](#), CTSET events #0 ~ #47 map to 2:0 ~ 2:47 and events #48 ~ #249 map to 1:48 ~ 1:249.

7.1.2.6.4.2 ISS CTSET Emulation access to disabled sub-modules

Except for CAL, in case emulation accesses a non clocked resource, the ISS enables the clock temporarily to provide a valid OCP response. Therefore, emulation accesses can only be stalled for a few cycles even when the accessed resource is disabled. The ISS interconnect returns SResp=ERR when a request to CAL is received while it is disabled (i.e. the OCP ports are disconnected). ISS also provides MReqInfo qualifiers on OCPM1 and OCPM3 identifying the ISS internal initiator which has issued the request. This information can be used by L3 statistics collectors to filter requests per ISS internal initiator.

7.1.3 ISS Register Manual

7.1.3.1 ISS Instance Summary

Table 7-15 is the ISS instance.

Table 7-15. ISS Instance Summary

Bits	Field Name	Description	Type	Reset
31:30	RESERVED	This bit field is reserved and users should write the reset value to this bit location.	R	0x0
29	LVDSRX3_IRQ	Event generated by LVDSRX 0x0: No event pending 0x1: Event pending	R	0x0
28	LVDSRX2_IRQ		R	0x0
27	LVDSRX1_IRQ		R	0x0
26	LVDSRX0_IRQ	Event generated by LVDSRX 0x0: No event pending 0x1: Event pending	R	0x0
25	ICM_A_IRQ	This bit field is reserved and users should write the reset value to this bit location.	R	0x0
24	ICM_B_IRQ	This bit field is reserved and users should write the reset value to this bit location.	R	0x0
23	CAL_B_IRQ	Event generated by the CAL #B 0x0: No event pending 0x1: Event pending	R	0x0
22	CAL_A_IRQ	Event generated by the CAL #A 0x0: No event pending 0x1: Event pending	R	0x0
21	RESERVED	This bit field is reserved and users should write the reset value to this bit location.	R	0x0
20	BYS_B_IRQ	This bit field is reserved and users should write the reset value to this bit location.	R	0x0
19	VMUX_IRQ	Event generated by VMUX 0x0: No event pending 0x1: Event pending	R	0x0
18	BYS_A_IRQ	This bit field is reserved and users should write the reset value to this bit location.	R	0x0
17	HS_VS_IRQ	HS or VS synchronization event. This event is triggered if a rising or falling edge is detected on the HS or VS signal (after the video port mux). The rising or falling edge and the HS or VS signal selection is chosen with the ISS_CTRL.SYNC_DETECT bit field. 0x0: No action 0x1: Set event (debug)	RW	0x0
16	CCP2_IRQ8	This bit field is reserved and users should write the reset value to this bit location.	R	0x0

Bits	Field Name	Description	Type	Reset
15	SIMCOP_IRQ3	Event generated by SIMCOP 0x0: No event pending 0x1: Event pending	R	0x0
14	SIMCOP_IRQ2	Event generated by SIMCOP 0x0: No event pending 0x1: Event pending	R	0x0
13	SIMCOP_IRQ1	Event generated by SIMCOP 0x0: No event pending 0x1: Event pending	R	0x0
12	SIMCOP_IRQ0	Event generated by SIMCOP 0x0: No event pending 0x1: Event pending	R	0x0
11	BTE_IRQ	This bit field is reserved and users should write the reset value to this bit location.	R	0x0
10	CBUFF_IRQ	This bit field is reserved and users should write the reset value to this bit location.	R	0x0
9	CCP2_IRQ3	This bit field is reserved and users should write the reset value to this bit location.	R	0x0
8	CCP2_IRQ2	This bit field is reserved and users should write the reset value to this bit location.	R	0x0
7	CCP2_IRQ1	This bit field is reserved and users should write the reset value to this bit location.	R	0x0
6	CCP2_IRQ0	This bit field is reserved and users should write the reset value to this bit location.	R	0x0
5:4	RESERVED	This bit field is reserved and users should write the reset value to this bit location.	R	0x0
3	ISP_IRQ3	Combined interrupt event provided by the ISP. 0x0: No event pending 0x1: Event pending	R	0x0
2	ISP_IRQ2	Combined interrupt event provided by the ISP. 0x0: No event pending 0x1: Event pending	R	0x0
1	ISP_IRQ1	Combined interrupt event provided by the ISP. 0x0: No event pending 0x1: Event pending	R	0x0
0	ISP_IRQ0	Combined interrupt event provided by the ISP. 0x0: No event pending 0x1: Event pending	R	0x0

Table 7-43. ISS_CTRL1

Address Offset	0x0000 0094	Instance	ISS_TOP
Physical Address	0x5200 0094		
Description	ISS control register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																PPI_MODE		STALL_MODE			SENSOR_HUB_SYNC				BTE_WMEM		ENABLE_VMUX	RESERVED		CTSET_EVT	

Bits	Field Name	Description	Type	Reset
31:17	RESERVED	This bit field is reserved and users should write the reset value to this bit location.	R	0x0
16	PPI_MODE	Controls PPI interface - CAL mux at ISS level. CSI-2 #B 0x0: CSI-2 #A -- CAL #A-1 CSI-2 #B -- CAL #B-1 CSI-2 #C -- CAL #A-0 CSI-3 #D -- CAL #B-0 0x1: CSI-2 #A -- CAL #A-1 CSI-2 #B -- CAL #A-0 CSI-2 #C -- CAL #B-1 CSI-3 #D -- CAL #B-0	RW	0x0
15:13	STALL_MODE	Refer to the functional specification for details.	RW	0x0
12:7	SENSOR_HUB_SYNC	This bit field is reserved and users should write the reset value to this bit location. Selects which syn event to export to the sensor hub. Refer to the functional specification for details	RW	0x0
6:5	BTE_WMEM	This bit field is reserved and users should write the reset value to this bit location. Defines how much ISS-SL2 is attached to BTE as working memory 0x0: BTE has no working memory and can't be used 0x1: Complete ISS-SL2 used as BTE working memory	RW	0x1

Bits	Field Name	Description	Type	Reset
4	ENABLE_VMUX	Enables the video mux instead of legacy mode for ISP #A input and BYS connections. Other VMUX settings are not affected. 0x0: Legacy mode. ISP input is defined by ISS_CTRL.INPUT_SEL and ISS_CTRL.INPUT_SEL2 BYS connections are defined by the ISS_BYS register. 0x1: ISP #A and BYS connections are controlled by the ISS_VMUX register. That's the preferred mode for ADASL	RW	0x0
3:2	RESERVED	This bit field is reserved and users should write the reset value to this bit location.	R	0x0
1:0	CTSET_EVT	CTSET event selection. Refer to functional spec for details	RW	0x0

7.2 ISS Interfaces

7.2.1 ISS Interfaces Overview

Along with the submodules, ISS has two camera interfaces and a parallel interface within the ISS boundary. The Camera Adapter Layer (CAL_A) supports MIPI® CSI2 protocol with four data lanes. CAL_A is targeted as sensor capture interface and write DMA, while CAL_B is targeted as read DMA engine. The LVDS receiver (LVDS-RX) supports Sony / Aptina / Omnivision / Panasonic / AltaSens serial interfaces. The parallel interface (CPI) supports up to 16 data lanes. All interfaces can use the Image Signal Processor (ISP), but not concurrently. When one interface uses the ISP, the other must send data to memory. However, the ISP can still be used to process this data in memory-to-memory configuration. Time multiplexed processing is also possible.

[Figure 7-8](#) shows the ISS interfaces and interconnects.

Figure 7-8. ISS Interfaces and Interconnects Highlight

camss-006

7.2.1.1 ISS Interfaces Features

The imaging subsystem supports the following interface features:

- System interfaces and interconnects:
 - Two 32-bit-wide configuration interfaces:
 - Interface to Cortex™-M4 microprocessor unit (IPU): Synchronous to the functional clock
 - Interface to device EDMA controller: Asynchronous from the functional clock
 - 128-bit-wide data interface to level 3 (L3_MAIN) interconnect: Asynchronous from the functional clock
 - The ISS has a local interconnect that connects all modules inside the ISS
 - Timing Control module (TCTRL):
 - Camera global reset control
 - Control signal generation for flash prestrobe and strobe
- CAL module with up to 208 MPix/s throughput:
 - CAL_A interface:
 - PPI interface to CSI-2 PHY
 - Byte clock for data transfers up to 187.5 MHz (i.e. D-PHY 1.5 Gbps)
 - Programmable clock and data lane position
 - Serial Configuration Interface (SCP)
 - 32-bit slave configuration interface (OCPC) to the L4_PER2 interconnect
 - 128-bit master data interface (OCPO) to the L3_MAIN interconnect and system memory
 - CAL_B interface:
 - 32-bit slave configuration interface (OCPC) to the L4_PER2 interconnect
 - 128-bit master data interface (OCPO) to the L3_MAIN interconnect and system memory
 - Two functional modes:
 - On-the-fly mode: A byte stream received from PPI is interpreted as a CSI-2 stream. Pixels are extracted and sent to the system memory and/or video port
 - MIPI CSI-2 low level protocol support:
 - Up to 8 contexts (VCT + DT combinations)
 - Data lane merger
 - Error detection / correction (CRC/ECC)
 - Re-synchronization FIFO
 - Up to four [4] independent pixel processing contexts:
 - All primary and secondary MIPI CSI-2 formats supported
 - Extract pixels from byte stream
 - DPCM decompression (4 pixels/cycle for predictor1; 1 pixel/cycle for predictor2)
 - DPCM compression (2 pixels/cycle for predictor1; predictor2 is not supported)
 - Pixel packing into a byte stream (for memory storage)
 - Up to eight [8] independent write DMA contexts:
 - Write header, pixel or attribute data
 - Horizontal cropping
 - Pack data from independent streams into efficient OCP transactions
 - 1D and 2D addressing modes (only INCR bursts)
 - Resynchronize on line boundaries (for TxBuffer overflows)
 - Linear, circular and sub-sampled addressing modes
 - One read DMA engine:
 - Read DPCM decoder initialization and pixel data

- Send data through the complete processing pipeline
- YUV420 to YUV422 up-sampling
- Linear, circular and sub-sampled addressing modes
- LVDS receiver:
 - Support Sony / Aptina / Omnivision / Panasonic / AltaSens serial interfaces
 - Parallel LVDS interface support
 - Embedded sync decode
 - Capable for universal interface decoding
 - Programmable sync pattern, transmit pixel pattern for future sensor updates
 - Direct connection to complex IO (CSI2_PHY1)
 - 10 to 16 bits output
 - Video interface output
 - Up to 4Kx2K@60fps performance (~600Mpix/s)
 - Handling sensor specific WDR mode
 - Additional 16-bit parallel interface connected to CPI
- Camera Parallel Interface (CPI):
 - 8/12/16 bits wide
 - Up to 212.8 MPix/s
 - BT.656 and SYNC mode (HS, VS, FIELD, WEN)

7.2.2 ISS Interfaces Environment

7.2.2.1 ISS Interfaces Signal Descriptions

Table 7-316 summarizes the ISS I/O signals and corresponding interface modes.

Table 7-316. ISS Interfaces I/O Description

Signal Name	I/O ⁽¹⁾	Description	Serial Mode LVDS-RX	Parallel Mode LVDS-RX (through CPI)	Serial Mode CSI2	Parallel Mode CPI
cam_strobe	O	Flash strobe control signal	x	x	x	x
cam_shutter	O	Mechanical shutter control signal	x	x	x	x
cam_globalreset	I/O	Global reset release shutter signal	x	x	x	x
csi2_0_dx0	I	Serial mode: Differential clock positive input	x		x	
csi2_0_dy0	I	Serial mode: Differential clock negative input	x		x	
csi2_0_dx1	I	Serial mode: Differential data lane positive input	x		x

csi2_0_dx3	I	Serial mode: Differential data lane positive input	x		x	
csi2_0_dy3	I	Serial mode: Differential data lane negative input	x		x	
csi2_0_dx4	I	Serial mode: Differential data lane positive input	x		x	
csi2_0_dy4	I	Serial mode: Differential data lane negative input	x		x	
cpi_pclk	I	Parallel mode pixel clock input		x		x
cpi_wen	I	Parallel mode write enable signal input		x		x
cpi_fld	I/O	Parallel mode pixel clock field signal		x		x
cpi_vsync	I/O	Parallel mode vertical frame synchronization		x		x
cpi_hsync	I/O	Parallel mode horizontal frame synchronization		x		x
cpi_data[15:0]	I	Parallel mode data lanes (16 signals)		x		x

⁽¹⁾ I = Input; O = Output

NOTE: Lane polarity can be changed in complex I/O. For more information, see [Section 7.2.2.2, ISS Interface Modes](#).

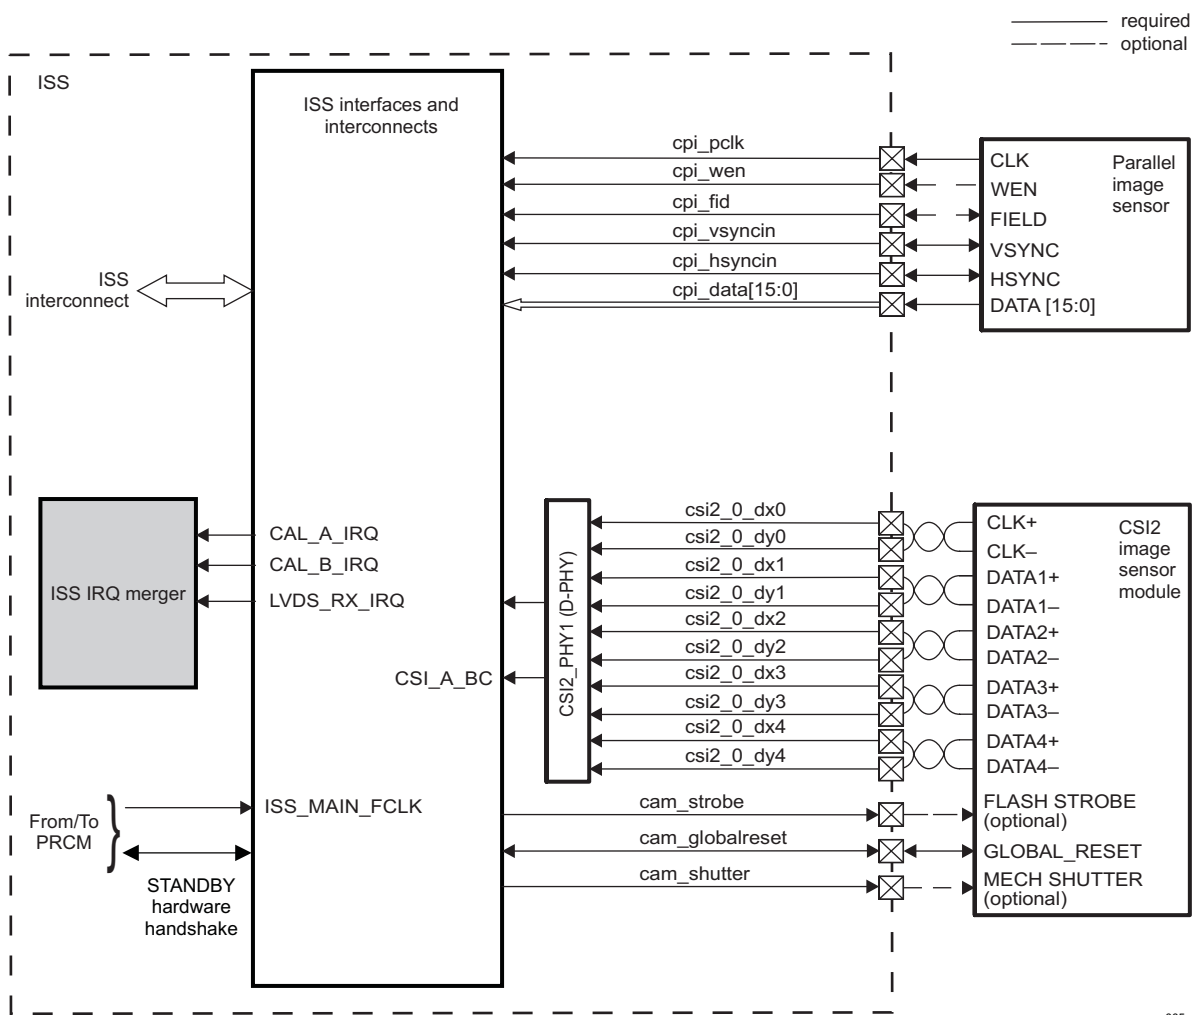

NOTE: At least one data lane must be configured for using the CAL_A and LVDS-RX interfaces. The signals are also configurable from the device Control Module. Thus, they are not required to be at a certain location to act as clock or data; this can be configured.

NOTE: CAL_A and LVDS-RX interfaces share the CSI2_PHY1 pins.

7.2.2.2 ISS Interfaces Modes

The camera subsystem can manage a parallel interface and up to two serial image sensors. Depending on the configuration of the shared pins, two of the interfaces can be active at the same time. However, only one data flow can use the ISP. Moreover, if the parallel interface is used, the data from it goes to ISP, while the other used interfaces must send data to memory. [Figure 7-9](#) shows an example block diagram of the interface configuration (CMOS sensor connected to LVDS-RX is not shown in this example since CAL_A and LVDS-RX share pads). Each serial port clock lane is configurable. The MIPI CSI2 protocol requires only a clock lane setup. The data lane configuration is optional.

Figure 7-9. ISS Interfaces CAL_A Serial and Parallel Interface Configuration

camss-005u

NOTE: Depending on the needs, `cam_strobe`, `cam_globalreset`, and `cam_shutter` can be connected to another image sensor module rather than the CSI2 image sensor module.

NOTE: Dedicated Power, Reset, and Clock Management (PRCM) module pins for power and ground are provided for external sensors: `vdda_csi` and `vssa_csi`.

A graphical representation of the pins for connecting external sensors to the ISS shows a variety of connectivity configurations that are possible by setting the CSI2_PHY1 immediately before the receivers (CAL_A and LVDS-RX), and a variety of output paths, including some sensor data through the receivers to memory or the ISP. [Table 7-317](#) lists some of the connectivity possibilities; the ISP can take only one input lane at a time. For more information about the operating properties and configuration of the CSI2_PHY1 module, see [Section 7.2.4, ISS CSI2 PHY](#).

Table 7-317. ISS Interfaces Connectivity Scheme Example Scenarios

Camera	Serial Cameras Only			Serial + Parallel Cameras			
	CAL_A with 1 Data Lanes on CSI2_PHY1	CAL_A with 4 Data Lanes on CSI2_PHY1	-	CPI 16-bit	CPI 16-bit	CPI 12-bit	CPI 8-bit
Camera 1	CAL_A with 1 Data Lanes on CSI2_PHY1	CAL_A with 4 Data Lanes on CSI2_PHY1	-	CPI 16-bit	CPI 16-bit	CPI 12-bit	CPI 8-bit
Camera 2	LVDS-RX with 1 Data Lane on CSI2_PHY1	-	LVDS-RX with 4 Data Lanes on CSI2_PHY1	LVDS-RX with 3 Data Lanes on CSI2_PHY1	CAL_A with 4 Data Lanes on CSI2_PHY1	LVDS-RX with 2 Data Lanes on CSI2_PHY1	CAL_A with 1 Data Lane on CSI2_PHY1
Camera 3	-	-	-	-	-	-	LVDS-RX with 1 Data Lane on CSI2_PHY1
Signals	Simultaneous	Simultaneous	Simultaneous	Simultaneous	Simultaneous	Simultaneous	Simultaneous
cam_strobe	x	x	x	x	x	x	x
cam_globalreset	x	x	x			x	x
cam_shutter	x	x	x	x	x	x	x
csi2_0_dx0	x	x	x	x	x	x	x
csi2_0_dy0	x	x	x	x	x	x	x
csi2_0_dx1	x	x	x	x	x	x	x
csi2_0_dy1	x	x	x	x	x	x	x
csi2_0_dx2	x	x	x	x	x	x	x
csi2_0_dy2	x	x	x	x	x	x	x
csi2_0_dx3	x	x	x	x	x	x	x
csi2_0_dy3	x	x	x	x	x	x	x
csi2_0_dx4	x	x	x		x		x
csi2_0_dy4	x	x	x		x		x
cpi_pclk				x	x	x	x
cpi_wen				x	x	x	x
cpi_fid				x	x	x	x
cpi_vsynchron				x	x	x	x
cpi_hsynchron				x	x	x	x
cpi_d[15:0]				x	x	x	x

NOTE: The ISP can take only one input at a time. The other inputs must go to memory and then be processed after the ISP processes the input that was received first.

In looking at the sample connections between the ISS through the receivers and external sensors, it is apparent that the lanes of the input can be adjusted for certain needs. For example, it is not necessary that the CAL_A has four data lanes connected at the same time. Because CAL_A and LVDS-RX share CSI2_PHY1 pins, they are restrictions on the number of input lanes. In this manner, external sensors can be connected any way possible for best performance and results.

7.2.3 ISS Camera Parallel Interface

7.2.3.1 CPI Generic Configuration Protocol and Data Format (8, 10, 12, 16 Bits)

The SYNC mode implements a generic parallel interface with the image sensor. The SYNC mode supports 8- to 16-bit-wide data signals.

In this configuration, no assumptions are made about the data format of pixels. The pixel data is presented on `cpi_data[15:0]`, where 1 pixel is sampled for every `cpi_pclk` rising edge (or falling edge, depending on the configuration of `cpi_pclk` polarity).

Additional pixel times between rows represent blanking periods. Active pixels are identified by a combination of two additional timing signals: horizontal synchronization (`cpi_hsync`) and vertical synchronization (`cpi_vsync`). During the image-sensor readout, these signals define when a row of valid data begins and ends, and when a frame starts and ends.

NOTE: For correct operation, the clock `cpi_pclk` must run during blanking periods (`cpi_hsync` and `cpi_vsync` inactive). The `cpi_pclk` must start before sending `cpi_data[15:0]` and start `cpi_vsync` and `cpi_hsync`.

Figure 7-10 and Figure 7-11 show the frame and data timing, based on synchronization signals in the parallel No BT configuration.

Figure 7-10. CPI Synchronization Signals and Frame Timing in SYNC Mode

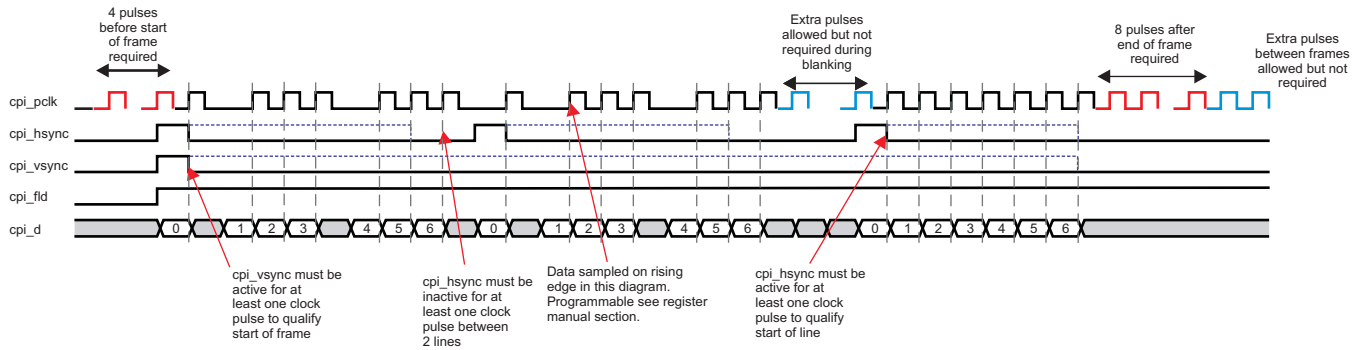

Figure 7-11. ISS Interfaces CPI Synchronization Signals and Data Timing in SYNC Mode

NOTE: The pixel clock can be gated to qualify valid pixels. It can also be gated during blanking periods to reduce power consumption. However, at least four clock pulses are required before sending active image data and synchronization information; eight clock pulses are required after the end of active video. Extra-clock pulses are allowed but not required during the line blanking periods.

Figure 7-12 shows the timing diagram of the SYNC move clock gating.

Figure 7-12. ISS Interfaces CPI SYNC Mode Clock Gating

camss-009

7.2.3.2 ISS Interfaces CPI ITU-R BT.656/1120 422 Protocol and Data Formats (8, 10 Bits)

The ISS CPI supports data in ITU-R BT.656 format. The ITU-R BT.656 standard specifies a method of transferring YUV4:2:2 data over an 8- or 10-bit video interface.

Figure 7-13 shows the data timing diagram with embedded synchronization signals.

Figure 7-13. ISS Interfaces CPI Data Timing With Embedded Synchronization Signals (8-Bit Case)

camss-010

In BT.656, the data words (8- or 10-bit) in which the 8 most-significant bits (MSBs) are all set to 1, or all set to 0, are reserved.

NOTE: The ITU-R BT.656 specification is for 525-line and 625-line, digital component video signals in compliance with ITU-R BT.601. See the CCIR document Rec. 656-1 for detailed information about the interface.

The data is multiplexed in the following order: Cb0 Y0 Cr0 Y1 Cb2 Y2 Cr2 Y3, etc., where the byte sequence Cb2n Y2n Cr2n refers to interleaved Luminance and Chroma samples and the following byte Y2n + 1 corresponds to the next Luminance sample.

The BT.656 protocol uses unique timing reference signals embedded in the video stream. The synchronization signals cpi_hsync and cpi_vsync are not needed. This reduces the number of wires required for a BT.656 video interface.

There are two timing reference codes: The start of active video (SAV) reference code precedes each video data block, and the end of active video (EAV) follows each video data block. Each timing reference signal consists of a 4-byte sequence in the following hexadecimal format: FF 00 00 XY. The first 3 bytes are a fixed preamble (see the ITU-R BT.656 specification). The fourth byte (XY) contains information defining field identification (F), blanking (V), and SAV/EAV information (H), and 4 parity bits calculated as a function of F, V, and H (see the ITU-R BT.656 specification).

Table 7-318 lists the video timing reference codes for SAV and EAV.

Table 7-318. ISS Interfaces CPI Video Timing Reference Codes for SAV and EAV

Data Bit Number	First Word (FF)	Second Word (00)	Third Word (00)	Fourth Word (XY)
9 (MSB)	1	0	0	1
8	1	0	0	F
7	1	0	0	V
6	1	0	0	H

Table 7-318. ISS Interfaces CPI Video Timing Reference Codes for SAV and EAV (continued)

Data Bit Number	First Word (FF)	Second Word (00)	Third Word (00)	Fourth Word (XY)
5	1	0	0	P3
4	1	0	0	P2
3	1	0	0	P1
2	1	0	0	P0
1	1	0	0	0
0	1	0	0	0

Table 7-319 describes the F, V, and H signals.

Table 7-319. ISS Interfaces CPI F, V, H Signal Descriptions

Signal	Value	Command
F	0	Field 1
	1	Field 2
V	0	0
	1	Vertical blank
H	0	SAV
	1	EAV

The resulting Hamming distance between any two code words is four, allowing two error detections and one error correction. To enable or disable the error-correcting capability, configure the ISIF_REC656IF[0] ECCFVH bit.

NOTE: The 2-bit errors are detected, but not flagged or corrected. Errors of more than 2 bits are not corrected or flagged.

Table 7-320 lists the F, V, and H protection (error-correction) bits.

Table 7-320. ISS Interfaces CPI F, V, H Protection (Error-Correction) Bits

F	V	H	P3	P2	P1	P0
0	0	0	0	0	0	0
0	0	1	1	1	0	1
0	1	0	1	0	1	1
0	1	1	0	1	1	0
1	0	0	0	1	1	1
1	0	1	1	0	1	0
1	1	0	1	1	0	0
1	1	1	0	0	0	1

When operating in ITU-R BT.656 mode, data is stored in SDRAM according to the format listed in Table 7-321 when the ISIF_REC656IF[1] R656ON bit is enabled.

Table 7-321. ISS Interfaces CPI ITU-R BT.656 Mode Data Format in SDRAM

b31		b0

7.2.4 ISS CSI2 PHY

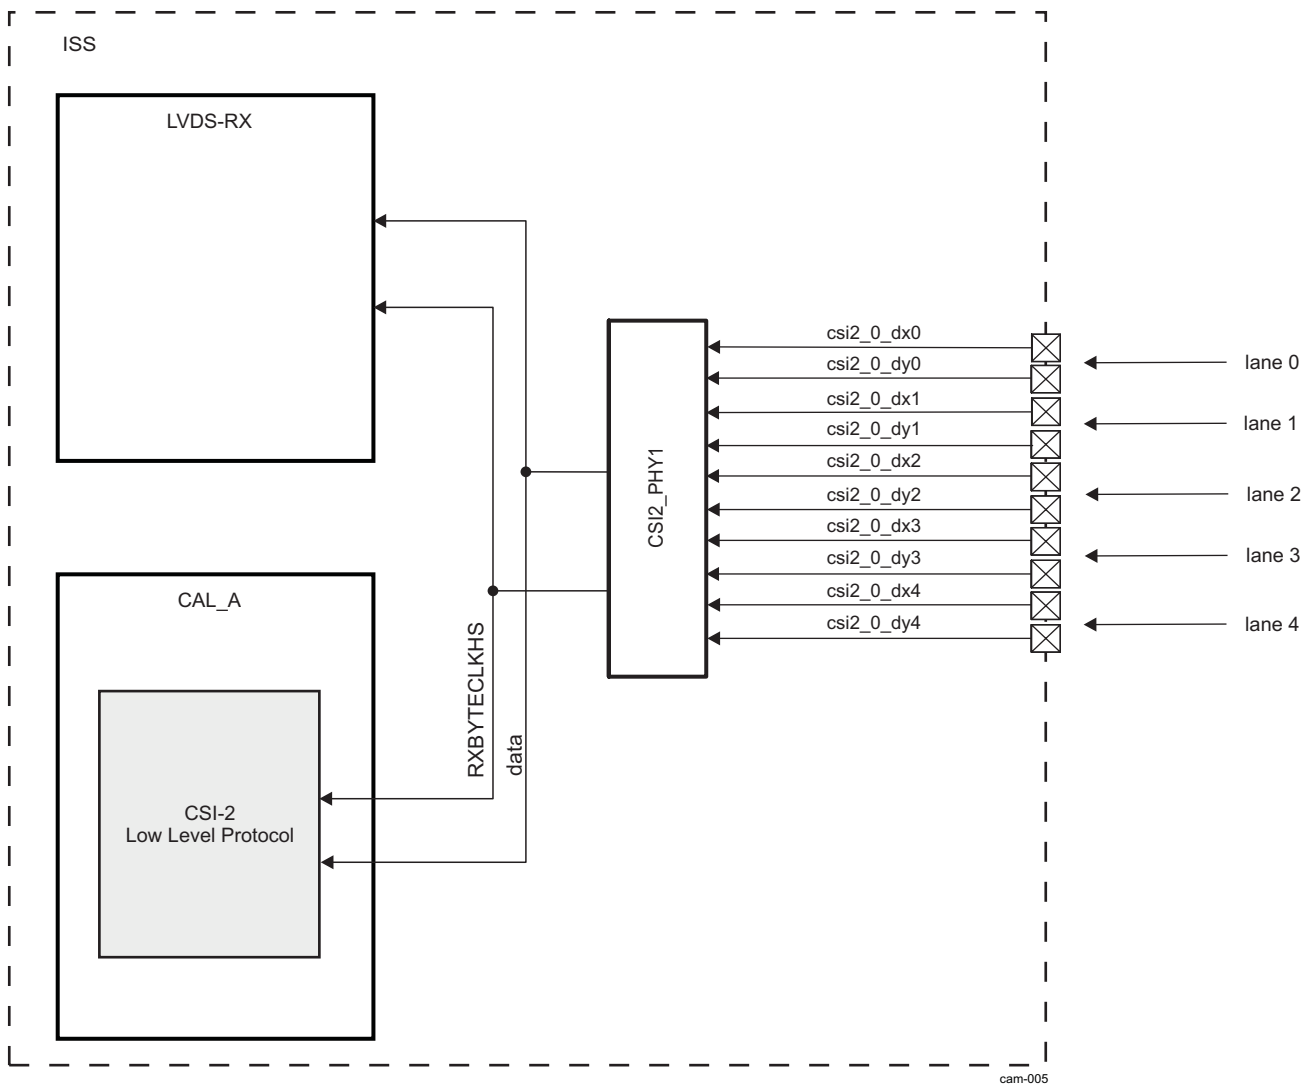

7.2.4.1 ISS CSI2 PHY Overview

There is one MIPI D-PHY compliant PHY receiver (CSI2_PHY1 or generally referenced to as CSI2 PHY) immediately before the CAL_A and LVDS-RX module, which acts as a physical connection and configuration of clock/data lanes with external sensors. A CSI2 PHY supports up to four configurations, depending on the required number of D-PHY data lane external sensors. The receiver is compatible with the *MIPI D-PHY Specification v1.00.00*. The selection of a CSI2 PHY in D-PHY mode must be done before reset and not on the fly.

The CSI2 PHY is controlled and must be configured first from the device Control Module for pad configuration. The differential data/clock lanes coming into the CSI2 PHY1 are configured from registers explained in [Section 7.2.4.2.3, CSI2 PHY Link Initialization Sequence](#).

There is one CSI2 PHY instance integrated in the device. As shown in [Figure 7-14](#), the CSI2_PHY1 contains four data lanes. [Figure 7-14](#) shows the CSI2 PHY, with its signals further covered in [Section 7.2.6.3.6.1, CSI2 Physical Layer](#).

Figure 7-14. ISS CSI2 PHY Diagram

NOTE: LANE 4 of CSI2_PHY1 can be used only as a data lane, never as a clock lane. All other configurations are possible.

CSI2_PHY1 represent the overall PHY solution for connecting external sensors to feed the CAL module. The MIPI D-PHY function can support up to four data lane modules and one clock lane module. Reverse direction escape mode is not supported. The lane module polarity and positions are configurable; that is, any lane module can be chosen as the clock lane module (except otherwise notified), and the DX/DY data pad for each lane module can be configured as DP or DN pins defined. The configuration and the selection of D-PHY mode, data/clock are done through the device Control Module (see [Chapter 14, Control Module](#)). The only exception is the four-data-lane use case, in which one corner lane is allowed to be only a data lane. the CSI2 CSI2_PHY1 can be configured through serial configuration protocol (SCP) interface.

7.2.4.2 ISS CSI2 PHY Functional Description

7.2.4.2.1 ISS CSI2 PHY Configuration

The CSI2 PHY converts the bitstream, divided into 1 up to 4 serial data lanes, and one clock lane, into a bitstream compatible with the CSI2 low level protocol within the CAL module .

The CSI2 low level protocol engine only provides the SCP clock when CSI2 PHY registers are accessed and `CAL_CTRL[21] PWRSCPCLK = 0`. However, the CSI2 PHY needs at least 3 SCP clock cycles to come out of the reset state. Therefore, SW must perform a dummy read of a CSI2 PHY register (32 SCP clock pulses) to complete the CSI2 PHY reset sequence. Alternatively, the SCP clock can be programmed to be free-running by setting `CAL_CTRL[21] PWRSCPCLK = 1` (not preferred).

The `CAL_CSI2_COMPLEXIO_IRQSTATUS_I` register logs complex I/O events of the following types:

- Line power-state change (all lanes in ultralow-power mode [ULPM], at least one lane exits ULPM, etc.)
- Error on one lane

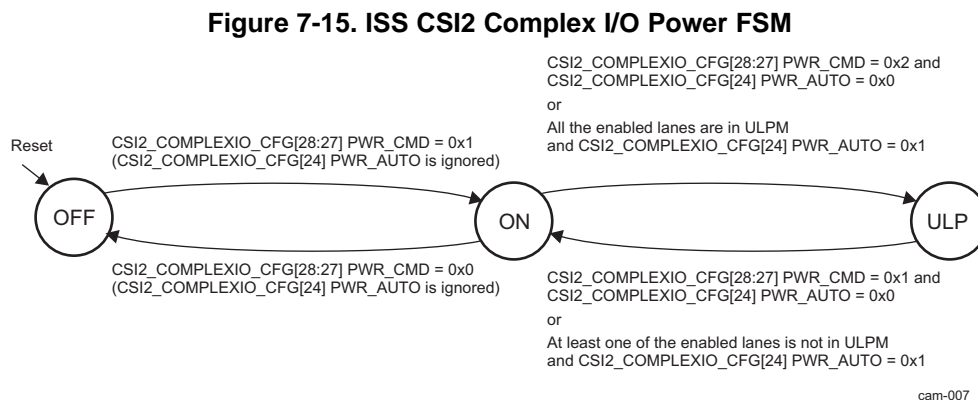

Some complex I/O parameters can be configured through the following registers:

- The `REG0` register reports completion of reset on the different parts of the module and configures the timing parameters.
- The `CAL_CSI2_COMPLEXIO_CFG_I` register contains the `PWR_AUTO` and `PWR_CMD` bit fields, which affect the power management of the complex I/Os.

The Complex I/O FSM has three power states: ON, OFF, and Ultralow Power (ULP). Two operation modes are available:.

- Automatic mode, when the `CAL_CSI2_COMPLEXIO_CFG_I[24] PWR_AUTO` bit is set to 1. The transitions between ON and ULP states is done automatically based on the received ULPM signals from the complex I/O for the active lanes defined in `CAL_CSI2_COMPLEXIO_CFG_I[] DATAx_POSITION` bit-field, where $x = [1...4]$.
- Manual mode, when the `CAL_CSI2_COMPLEXIO_CFG_I[24] PWR_AUTO` bit is set to 0 (default). The complex I/O power state is controlled by the `CAL_CSI2_COMPLEXIO_CFG_I[28:27] PWR_CMD` bit field. The allowed transitions are: OFF <-> ON and ON <-> ULP.

Figure 7-15 shows the complex I/O power finite state-machine (FSM).

Another register, [CAL_CSI2_TIMING_I](#), is used to control the power state of the complex I/O modules with regard to the differential line state. This register controls the mode of the three complex I/Os (RxMode and NoRxMode) and the delay between the differential lanes in STOP state and the complex I/O on NoRxMode. The [CAL_CSI2_TIMING_I\[15\] FORCE_RX_MODE_IO1](#) bit sets the complex I/O in RxMode or NoRxMode (stopped mode). The FORCE_RX_MODE_IO1 bit is automatically reset to 0 by hardware when the counter ends and the FSM returns to NoRxMode. Three bits ([CAL_CSI2_TIMING_I\[14\] STOP_STATE_X16_IO1](#), [CAL_CSI2_TIMING_I\[13\] STOP_STATE_X4_IO1](#), and the [CAL_CSI2_TIMING_I\[12:0\] STOP_STATE_COUNTER_IO1](#) bit field) configure the delay between line stop mode and complex I/O stop mode. The delay represents the number of functional clock cycles and can be calculated as follows:

$$\text{Total delay in functional clock cycles} = \text{CAL_CSI2_TIMING_I.STOP_STATE_COUNTER_IO1} \times (1 + \text{CAL_CSI2_TIMING_I.STOP_STATE_X16_IO1} \times 15) \times (1 + \text{CAL_CSI2_TIMING_I.STOP_STATE_X4_IO1} \times 3).$$

[Table 7-322](#) lists the possible values of the delay, in terms of the functional clock cycles, depending on the values of the STOP_STATE_X16_IO1 and STOP_STATE_X4_IO1 bits.

Table 7-322. ISS CSI2 PHY Possible Time-Out Value for RxMode Counter

STOP_STATE_X16_IO1	STOP_STATE_X4_IO1	Possible Delay Value (in Functional Clock Cycles)
0x0	0x0	8191 (with step of 1)
0x0	0x1	32764 (with step of 4)
0x1	0x0	131056 (with step of 16)
0x1	0x1	524224 (with step of 64)

The FORCERXMODE signal is used at initialization time (complex I/O). [Figure 7-16](#) describes the ForceRxMode and StopState FSM to assert and deassert the FORCERXMODE signal and to monitor STOPSTATE from the complex I/O.

Figure 7-16. ISS CSI2 PHY RxMode and StopState FSM

CAL asserts FORCERXMODE signal when the bit-field [CAL_CSI2_TIMING_I\[15\] FORCE_RX_MODE_IO1](#) is set by the SW. It can be reset by SW or automatically by HW when the time out occurs. At the same time the signal is asserted, the logic starts monitoring the StopState[0:4] signals corresponding only to the enabled lanes. When all of StopState signals for only the enabled lanes are asserted by the complex IO, the timer starts. When one of the signals, for the enabled lanes only, is not in StopState, the timer is reloaded and the logic re-starts monitoring the stop state signals. When the timer period is finished, the ForceRxMode signal is de-asserted.

7.2.4.2.2 ISS CSI2 PHY HiSPi Mode Configuration

In this mode, CSI2 PHY is used as HiSPi receiver. D-PHY mode functionality is disabled in this mode.

7.2.4.2.2.1 ISS CSI2 PHY Register Configuration for HiSPi (HiVCM)

- [REG3\[31\]](#) = 1'b1 (Override HSRXEN)
- [REG3\[30:26\]](#) = 5'b11111 (Override value for HSRX Enable, Based on the number of lanes some ENHSRX can be set to 0 also)
- [REG3\[25\]](#) = 1'b1 (Override HSRX Term Enable)

- **REG3[24:20]** = 5'b11111 (Override value for HS-RX Term Enable, Based on the number of lanes some HS-RX Enable can be set to 0 also)
- **REG3[4:3]** = 2'b11 (Override ENCCP override and override value to Corelane)
- **REG6[28:27]** = 2'b11 (To bypass HSSYNC and LPSoT sequence)
- **REG9[7]** = 1'b1 (This bit is for the HiSPI mux selection in the analog block)
- **REG9[6:4]** = Set 1's based on number of data lanes (these bits enables ENCCP in HISPI mode for ADDONs)

7.2.4.2.2 ISS CSI2 PHY Register Configuration for HiSPi (SLVS)

- **REG3[31]** = 1'b1 (Override HSRXEN)
- **REG3[30:26]** = 5'b11111 (Override value for HSRX Enable, Based on the number of lanes some ENHSRX can be set to 0 also)
- **REG3[25]** = 1'b1 (Override HSRX Term Enable)
- **REG3[24:20]** = 5'b11111 (Override value for HS-RX Term Enable, Based on the number of lanes some HS-RX Enable can be set to 0 also)
- **REG3[4:3]** = 2'b00 (Override ENCCP override and override value to Corelane)
- **REG6[28:27]** = 2'b11 (To bypass HSSYNC and LPSoT sequence)
- **REG9[7]** = 1'b0 (This bit is for the HiSPI mux selection in the analog block)
- **REG9[6:4]** = 4'b0000

7.2.4.2.3 ISS CSI2 PHY Register Configuration for HiSPi (sLVDS)

- **REG3[31]** = 1'b1 (Override HSRXEN)
- **REG6[30:26]** = 5'b11111 (Override value for HSRX Enable, Based on the number of lanes some ENHSRX can be set to 0 also)
- **REG3[25]** = 1'b1 (Override HSRX Term Enable)
- **REG3[24:20]** = 5'b11111 (Override value for HS-RX Term Enable, Based on the number of lanes some HS-RX Enable can be set to 0 also)
- **REG6[28:27]** = 2'b11 (To bypass HSSYNC and LPSoT sequence)
- **REG9[7]** = 1'b1 (This bit is for the HiSPI mux selection in the analog block)
- **REG9[6:4]** = Set 1's based on number of data lanes (these bits enables ENCCP in HISPI mode for ADDONs)

7.2.4.2.3 ISS CSI2 PHY MIPI D-PHY Link Initialization Sequence

The MIPI D-PHY initialization sequence is not implemented within CSI2 PHY. The CAL CSI2 low level protocol coordinates the PHY initialization. The controller must ensure that the CSI2 PHY is held in RESET/WAIT for RX mode until the D-PHY transmitter is powered up and the link comes to the defined state. The controller can use the STOPSTATE and FORCERXMODE signals of CSI2 PHY for this purpose. STOPSTATE indicates the line states, while FORCERXMODE forces the receiver state-machine into "wait for stop state". One possible initialization sequence is:

To fully initialize the CSI2 PHY, perform the following steps:

1. Configure all CSI2 low level protocol registers to be ready to receive signals/data from the CSI2 PHY:
 - i. Set **CAL_CSI2_COMPLEXIO_CFG_I[18:16]** DATA4_POSITION.
 - ii. Set **CAL_CSI2_COMPLEXIO_CFG_I[14:12]** DATA3_POSITION.
 - iii. Set **CAL_CSI2_COMPLEXIO_CFG_I[10:8]** DATA2_POSITION.
 - iv. Set **CAL_CSI2_COMPLEXIO_CFG_I[6:4]** DATA1_POSITION.
 - v. Set **CAL_CSI2_COMPLEXIO_CFG_I[2:0]** CLOCK_POSITION.
 - vi. Set the **CTRL_CORE_CAMERRX_CONTROL[2:1]** CSIPORTA_CAMMODE for CSI2_PHY1.

CAUTION

This must be done before the CSI2 PHY is active.

- vii. A dedicated internal clock gate control is present for each PHY. Enable/disable the internal CTRLCLK from the CTRL_CORE_CAMERRX_CONTROL register by setting the following bits:
 - [0] CSIPORTA_CTRLCLKEN for CSI2_PHY1
- 2. CSI2 PHY and link initialization sequence:
 - a. Deassert the CSI2 PHY reset.
 - i. Set [CAL_CSI2_COMPLEXIO_CFG_I\[30\]](#) RESET_CTRL to 0x1.

CAUTION

For the [CAL_CSI2_COMPLEXIO_CFG_I\[29\]](#) RESET_DONE bit to be set to 0x1 (reset completed), the external sensor must be active and sending the MIPI HS BYTECLK.

The following registers can be set only after deasserting the CSI2 PHY reset and before asserting the FORCERXMODE signal:

- [REG0](#)
 - [REG1](#)
 - [REG2](#)
 - [REG3](#)
 - [REG6](#)
 - [REG7](#)
 - [REG8](#)
 - [REG9](#)
 - [REG10](#)
- b. Assert the FORCERXMODE signal:
 - i. Set [CAL_CSI2_TIMING_I\[15\]](#) FORCE_RX_MODE_IO1 to 0x1.
 - c. Connect pulldown on link (DP/DN) by asserting the respective PIPD* signals (PIPD* = 0):
For CSI2_PHY1 pulldown on signals through the corresponding bit-fields in padconf register CTRL_CORE_SMA_SW_10.
 - d. Power up the CSI2 PHY:
 - a. Set [CAL_CSI2_COMPLEXIO_CFG_I\[28:27\]](#) PWR_CMD to 0x1.
 - e. Check whether the state status reaches the ON state:
 - [CAL_CSI2_COMPLEXIO_CFG_I\[26:25\]](#) PWR_STATUS = 0x1
 - f. Wait for STOPSTATE = 1 (for all enabled lane modules):
 - a. The timer is set through the [CAL_CSI2_TIMING_I\[14:0\]](#) bit field. The reset value can be kept.
 - b. Wait until [CAL_CSI2_TIMING_I\[15\]](#) FORCE_RX_MODE_IO1 = 0x0. It is automatically put at 0 when all enabled lanes are in STOPSTATE and the timer is finished.
 - g. Release PIPD* (PIPD* = 1).
For CSI2_PHY1 pullup on signals through the corresponding bit-fields in padconf register CTRL_CORE_SMA_SW_10.
3. The CSI2 PHY is initialized and ready/active in CSI-2 (D-PHY) mode.

7.2.4.2.4 ISS CSI2 PHY HiSPi Link Initialization Sequence

The HiSPi initialization sequence is not implemented within CSI2 PHY. The CAL CSI2 low level protocol coordinates the PHY initialization. The controller must ensure that the CSI2 PHY is held in RESET/WAIT for RX mode until the D-PHY transmitter is powered up and the link comes to the defined state. The controller can use the STOPSTATE and FORCERXMODE signals of CSI2 PHY for this purpose. STOPSTATE indicates the line states, while FORCERXMODE forces the receiver state-machine into "wait for stop state". One possible initialization sequence is:

To fully initialize the CSI2 PHY, perform the following steps:

1. Configure all CSI2 low level protocol registers to be ready to receive signals/data from the CSI2 PHY:
 - i. Set [CAL_CSI2_COMPLEXIO_CFG_I\[18:16\]](#) DATA4_POSITION.
 - ii. Set [CAL_CSI2_COMPLEXIO_CFG_I\[14:12\]](#) DATA3_POSITION.
 - iii. Set [CAL_CSI2_COMPLEXIO_CFG_I\[10:8\]](#) DATA2_POSITION.
 - iv. Set [CAL_CSI2_COMPLEXIO_CFG_I\[6:4\]](#) DATA1_POSITION.
 - v. Set [CAL_CSI2_COMPLEXIO_CFG_I\[2:0\]](#) CLOCK_POSITION.
 - vi. Set the CTRL_CORE_CAMERRX_CONTROL[2:1] CSIPORTA_CAMMODE for CSI2_PHY1.

CAUTION

This must be done before the CSI2 PHY is active.

- vii. A dedicated internal clock gate control is present for each PHY. Enable/disable the internal CTRLCLK from the CTRL_CORE_CAMERRX_CONTROL register by setting the following bits:
 - [0] CSIPORTA_CTRLCLKEN for CSI2_PHY1.
1. Set the CTRL_CORE_CAMERRX_CONTROL[2:1] CSIPORTA_CAMMODE to 2'b00.
2. Deassert the CSI2 PHY reset.
 - i. Set [CAL_CSI2_COMPLEXIO_CFG_I\[30\]](#) RESET_CTRL to 0x1.

CAUTION

For the [CAL_CSI2_COMPLEXIO_CFG_I\[29\]](#) RESET_DONE bit to be set to 0x1 (reset completed), the external sensor must to be active and sending the MIPI HS BYTECLK.

The following registers can be set only after deasserting the CSI2 PHY reset and before asserting the FORCERXMODE signal:

- [REG0](#)
 - [REG1](#)
 - [REG2](#)
 - [REG3](#)
 - [REG6](#)
 - [REG7](#)
 - [REG8](#)
 - [REG9](#)
 - [REG10](#)
3. Configure register as shown in [Section 7.2.4.2.2](#)
 4. Assert the FORCERXMODE signal:
 - i. Set [CAL_CSI2_TIMING_I\[15\]](#) FORCE_RX_MODE_IO1 to 0x1.
 5. Connect pull down on link (DP/DN) by asserting respective PIPD* signals (PIPD*=0).

For CSI2_PHY1 pulldown on signals through the corresponding bit-fields in padconf register CTRL_CORE_SMA_SW_10.

6. Power up the CSI2 PHY:
 - a. Set [CAL_CSI2_COMPLEXIO_CFG_I\[28:27\]](#) PWR_CMD to 0x1.
7. Check whether the state status reaches the ON state:
 - [CAL_CSI2_COMPLEXIO_CFG_I\[26:25\]](#) PWR_STATUS = 0x1
8. Wait for STOPSTATE = 1 (for all enabled lane modules):
 - a. The timer is set through the [CAL_CSI2_TIMING_I\[14:0\]](#) bit field. The reset value can be kept.
 - b. Wait until [CAL_CSI2_TIMING_I\[15\]](#) FORCE_RX_MODE_IO1 = 0x0. It is automatically put at 0 when all enabled lanes are in STOPSTATE and the timer is finished.
9. Release PIPD* (PIPD* = 1) through the corresponding bit-fields in padconf register CTRL_CORE_SMA_SW_10.

The CSI2 PHY is initialized and ready/active in HiSPi mode.

7.2.4.2.5 ISS CSI2 PHY Error Signals

In D-PHY mode, the CSI2 PHY supports the following error detection and signaling to the associated receiver:

- ERRSOTHS: Flags 1-bit errors in the HS start of transmission synchronization pattern. In this error scenario, the CSI2 PHY continues to receive the data and pass it to the receiver, but confidence in the data may be low, because of the 1-bit error seen in sync. This signal, if asserted, is high for one cycle of RXBYTECLKHS.
- ERRSOTSYNCHS: Flags multiple bit errors in the HS start of transmission synchronization pattern. In this case, the CSI2 PHY cannot achieve proper synchronization and does not pass the received data to the receiver. This signal, if asserted, is high for one cycle of RXBYTECLKHS.
- ERRCONTROL: Flags the control sequence error; that is, when the LP sequence observed on line is not recognized as a valid control sequence. This signal, if asserted, is high until the next change in the state of the LP line.
- ERRESC: Flags the escape entry error; that is, when the escape entry sequence is unrecognized. This signal, if asserted, is high until the next change in the state of the LP line.
- ERRSYNDESC: Flags the low-power data transmission synchronization error. This error is flagged if the number of bits received during a low-power data transmission is not a multiple of 8 bits. This signal, if asserted, is high until the next change in the state of the LP line. In case the number of received bits is 1 less than a multiple of 8, RXVALIDESC is also asserted together with ERRSYNDESC, and an erroneous data byte is output on RXDATAESC. In other cases of this error, RXVALIDESC is not asserted and an erroneous data byte is not sent out.

7.2.4.3 ISS CSI2 PHY Register Manual

7.2.4.3.1 ISS CSI2 PHY Instance Summary

Table 7-491 summarizes the CSI2_PHY1 instances.

Table 7-323. ISS CSI2 PHY Instance Summary

Module Name	L3_MAIN Base Address	Size
CAMERARX_CORE_0	0x5201 2800	64 bytes

NOTE: CAMERARX_CORE_0 is for CSI2_PHY1.

7.2.4.3.2 ISS CSI2 PHY Registers

7.2.4.3.2.1 ISS CSI2 PHY Register Summary

summarizes the CSI2 PHY register mapping.

7.2.5 ISS LVDS Receiver

7.2.5.1 ISS LVDS-RX Environment

This section describes the LVDS-RX application fields from an environment point of view (external connections). It describes the LVDS-RX connectivity options and lists all possible interfaces

Figure 7-17. LVDS-RX Environment

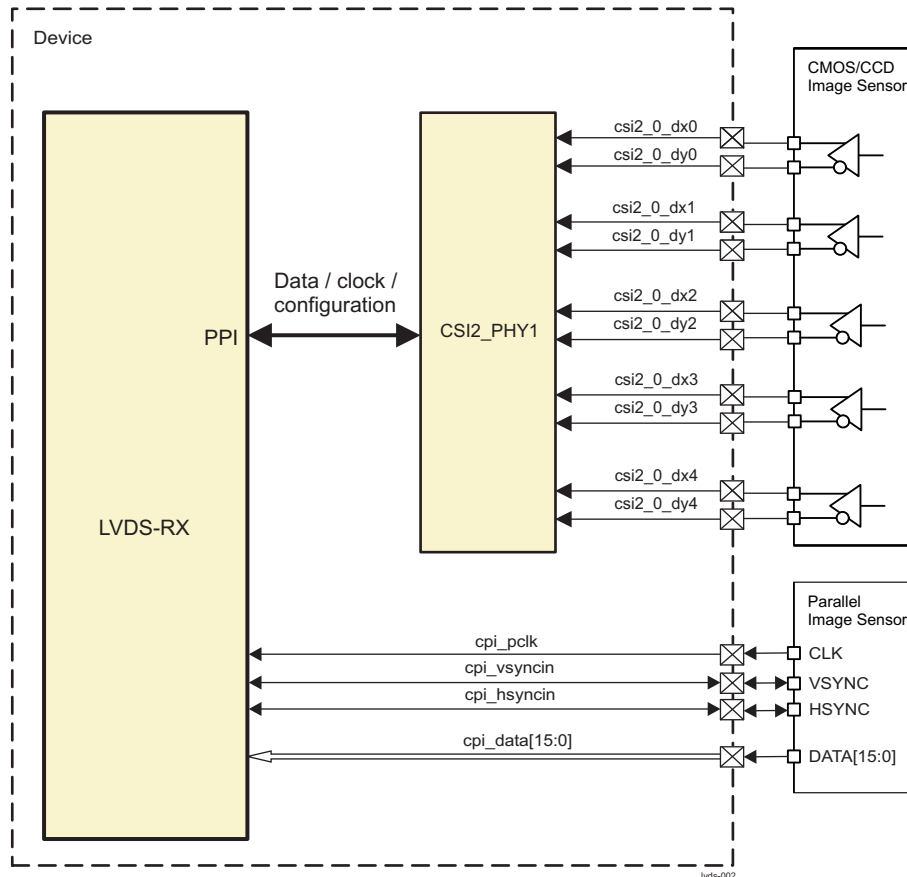

Table 7-343 summarizes the LVDS-RX CAL_A I/O signals.

Table 7-343. LVDS-RX CSI2_PHY1 I/O Description

Signal Name	I/O ⁽¹⁾	Description
csi2_0_dx0	I	Serial CMOS mode: Differential clock lane positive input
csi2_0_dy0	I	Serial CMOS mode: Differential clock lane negative input
csi2_0_dx1	I	Serial CMOS mode: Differential data lane positive input
csi2_0_dy1	I	Serial CMOS mode: Differential data lane negative input
csi2_0_dx2	I	Serial CMOS mode: Differential data lane positive input
csi2_0_dy2	I	Serial CMOS mode: Differential data lane negative input
csi2_0_dx3	I	Serial CMOS mode: Differential data lane positive input

⁽¹⁾ I = Input; O = Output

Table 7-343. LVDS-RX CSI2_PHY1 I/O Description (continued)

Signal Name	I/O ⁽¹⁾	Description
csi2_0_dy3	I	Serial CMOS mode: Differential data lane negative input
csi2_0_dx4	I	Serial CMOS mode: Differential data lane positive input
csi2_0_dy4	I	Serial CMOS mode: Differential data lane negative input

NOTE: The *Description* column in [Table 7-472](#) shows only the default function (data or clock lane) of each CSI2 differential pair. Refer to [Section 7.2.4, CSI2 PHY Functional Description](#), for more details on configurations available.

NOTE: LVDSRX module does not support SMIA or MIPI format such as CCP1, CCP2, CSI2 or CSI3 format. The module can decode various serial interface formats of CMOS image sensor and convert to video parallel interface format in order to feed ISP. Since pins are shared with CAL_A module, the names remain csi2_0.

[Table 7-344](#) summarizes the LVDS-RX Parallel Interface I/O signals.

Table 7-344. LVDS-RX Parallel Interface I/O Description

Signal Name	I/O ⁽¹⁾	Description

	LVDSRX_IRQ2	N/A (Configurable)	-	LVDS-RX
	LVDSRX_IRQ3	N/A (Configurable)	-	LVDS-RX
	LVDSRX_IRQ4	N/A (Configurable)	-	LVDS-RX

7.2.5.2.2 LVDS-RX Integration - PPI Interface

LVDS-RX does not directly connect to the sensor but to a complex I/O (CSI2_PHY1). LVDS-RX can connect to the complex I/Os through a PHY Protocol Interfaces (PPI). For more details on PPI interface configuration refer to [Section 7.2.4, CSI2 PHY Functional Description](#), and [Section 7.2.6.3.6.1, CSI2 Physical Layer](#).

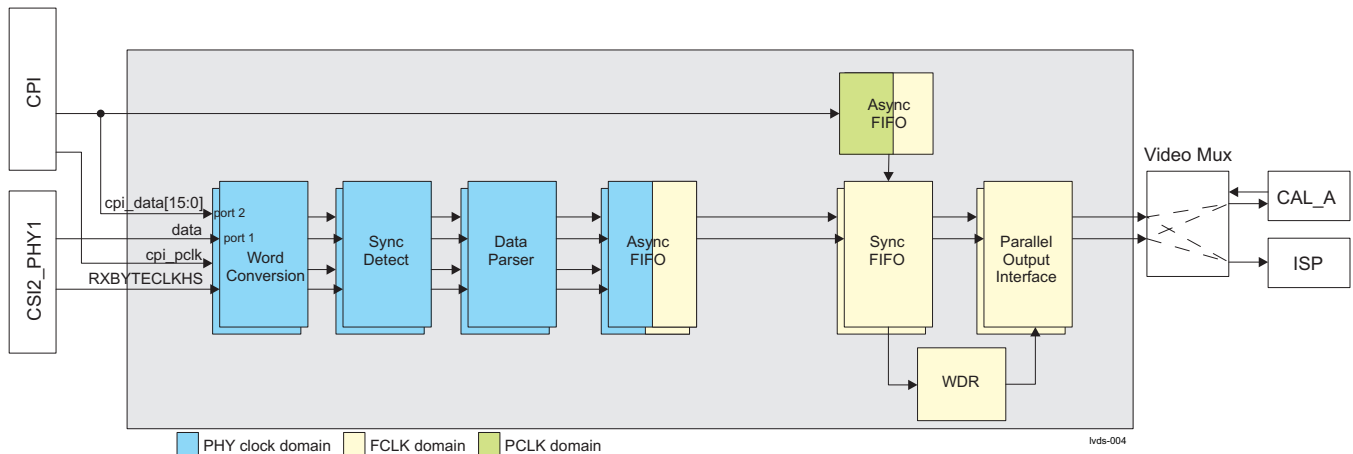

7.2.5.3 ISS LVDS-RX Functional Description

The LVDS serial sensor interface receiver (LVDS-RX) module can decode various serial interface formats of CMOS image sensor and convert to video parallel interface format in order to connect to ISP modules. LVDS-RX module doesn't support SMIA or MIPI format such as CCP1, CCP2, CSI2 or CSI3 format. It also provides an additional parallel interface connection.

The LVDS-RX supports PPI (PHY Protocol Interface) format and enables direct connection to CSI2_PHY1 MIPI D-PHY receiver. The LVDS-RX module interfaces to an external CMOS/CCD sensor which supports LVDS serial image interface through LVDS PHY.

LVDS-RX module has 4 lane D-PHY(complexIO) connections and it enables the connection the camera module. Figure 7-19 shows LVDS-RX block diagram.

Figure 7-19. LVDS-RX Functional Block Diagram

The LVDS-RX module port 1 takes the 8bit data coming from a CSI2 D-PHY receiver up to four data pairs, converts it to byte stream, extracts the sensor information, detects and extracts the synchronization codes, reformats the data and outputs it through the parallel output interface. The number of PHY lanes connected at the input must be set from the [LVDSRX_CAM1_CFG\[18:16\] NUM_LANE1](#) bitfield. The second port 2 takes data from the Camera Parallel Interface (CPI).

NOTE: The LVDS-RX has 2 sets of configuration registers for the two ports. Registers indexed "_0" and "_1" are for port 1 configuration, while registers indexed "_2" and "_3" are for port 2. For simplicity, the below functional description will link to register set corresponding to port 0 only.

7.2.5.3.1 LVDS-RX Word Conversion Module

The CSI2_PHY1 module is responsible for de-serializing the incoming data streams into 8bit words. It also generates 8it word clock, which divides bit clock by 8. There is various bit width of pixel. The Word Conversion block converts 8 bit word data to 10, 12, 14 or 16bit word data defined by [LVDSRX_CAM1_CFG\[10:8\] PIX_WIDTH](#). It then converts 8bit word clock to 10, 12, 14 or 16bit word clock (one cycle per word data). The frame size and line width must be set from the [LVDSRX_CAM1_FRMSIZE](#) to register. Moreover, start of frame, end of frame, start of line and end of line sync patterns must be configured from respectively [LVDSRX_CAM1_SYNCISOF](#), [LVDSRX_CAM1_SYNCIOF](#), [LVDSRX_CAM1_SYNCISOL](#), and [LVDSRX_CAM1_SYNCIOLOL](#) registers. Vertical blanking can also be set from the [LVDSRX_CAM1_SYNCISOV](#) register. After configuring, the input port must be set from the [LVDSRX_CAMCFG](#) register bitfields CAM1ENA or CAM2ENA for the two input LVDS-RX ports.

7.2.5.3.2 LVDS-RX Sync Detect Module

This module detects the LVDS serial I/F protocol synchronization codes and re-aligns the de-serialized data words so that the sync codes (and hence the transmitted data words) are aligned to word boundaries.

7.2.5.3.3 LVDS-RX Data Parser Module

This module is responsible for removing all non-payload data of various sensor formats - sync codes, filler codes, and checksums - and constructing the image lines and frames. It calculates checksums from the recovered data to be compared against the received data (HiSPi mode only). Checksum is enabled from `LVDSRX_CAM1_CFG[12]` CRCEEN. It also generates each of the error flags. Flag can be enabled from the `LVDSRX_IRQENABLE_SET_0` (where $i = 0$ to 3) and checked from the `LVDSRX_IRQSTATUS_0` registers.

7.2.5.3.4 LVDS-RX Async FIFO Module

The purpose of this module is the transfer of data from the recovered word clock domain to the functional clock domain (FCLK). The some sensor specifications allow a skew between the clocks (and hence data) transmitted by different PHY. This module is responsible for correcting for this skew and aligning data from different PHYs to a common word clock. LVDS-RX allows up to $2 \cdot UI$ (where $UI = \text{unit interval} = \text{the time to transmit a single bit}$) skew between different PHY configurations.

7.2.5.3.5 LVDS-RX Sync FIFO Module

The synchronous FIFO buffers recovered parallel data words until there are sufficient words available to output the number of words in a single FCLK cycle specified at compilation time.

7.2.5.3.6 LVDS-RX Parallel Output Interface Module

This final module is responsible for generating the horizontal sync (HS) and vertical sync (VS) signals and synchronizing those signals with the parallel data words read from the synchronous FIFO. The number of parallel data words (16bit) output in each output pixel clock cycle is fixed to 4 (4 pixels per cycle) in current ISS implementation.

7.2.5.3.7 LVDS-RX Wide dynamic range

APTINA sensor (MT9M023/ MT9M033) supports WDR mode for scenes that require high dynamic range image capture. Depending on the output mode, pixel data will be either: 20bit full linear, 12-bit companded piece-wise or 14-bit companded piece-wise. In the case of 12-bit and 14-bit modes, pixel data needs to be linearized to allow post-processing algorithms to behave as expected. Therefore, it needs to decompress the data to achieve full linear 20-bit output at receiver side.

Figure 7-20. LVDS-RX Converting Piece-wise Compressed Output to 20-Bit Full Linear Output

The knee points K1, K2 and boost gain G1,G2 are provided by configuration registers [LVDSRX_WDRGN](#), [LVDSRX_WDRKP1](#), [LVDSRX_WDRKP2](#).

Figure 7-21 shows an example of the WDR data compression at image sensor side. In this example, there are three knee points and three different gains in each area are applied.

Figure 7-21. LVDS-RX 12-16bit data decompression

Table 7-348. LVDS-RX 12-16bit data decompression register configuration

G2: gain in area $2(X1 - X2) = 2$	LVDSRX_WDRGN [3:0] WDRGN2 = 1

X1 = 1,024	LVDSRX_WDRGN [21:16] WDRNPXY1 = 4
X2 = 4,096	LVDSRX_WDRKP1 [9:0] WDRNPY2 = 16
X3 = 32,768	LVDSRX_WDRKP1 [25:16] WDRNPY3 = 128

This decompression is performed in WDR module. When pixel bit width is over 16bits after decompression, the word data is sent as 32bit data with LSB aligned.

Table 7-349.

Bit width	b63:b48	b47:b32	b31:b16	b15:b0
<= 16 bits	Pixel #4	Pixel #3	Pixel #2	Pixel #1
> 16 bits	Pixel #2		Pixel #1	

The data output format can be changed from the [LVDSRX_CAM1_CFG](#)[15] ALIGN bitfield. The default format is LSB alignment.

7.2.5.3.8 LVDS-RX Test Features

The LVDS-RX integrate a test feature to monitor the byte data going through. The test can be enabled from the [LVDSRX_CAMCFG](#)[16] CAM1TEST or CAM2TEST bitfield for the two input ports. After that, byte data can be monitored from the [LVDSRX_TEST1](#) or [LVDSRX_TEST2](#).

7.2.6 ISS Camera Adapter Layer

NOTE: This section describes the generic Camera Adapter Layer (CAL) module. There are two CAL modules (CAL_A and CAL_B) integrated in the device. The CAL_A is targeted as sensor capture interface (connected to CSI2_PHY1) and write DMA, while CAL_B is targeted as read DMA engine.

7.2.6.1 ISS CAL Environment

This section describes the CAL_A application fields from an environment point of view (external connections). It describes the CAL_A connectivity options and lists all possible interfaces

7.2.6.1.1 CAL_A Interface Signal Descriptions

Figure 7-22. CAL_A Environment

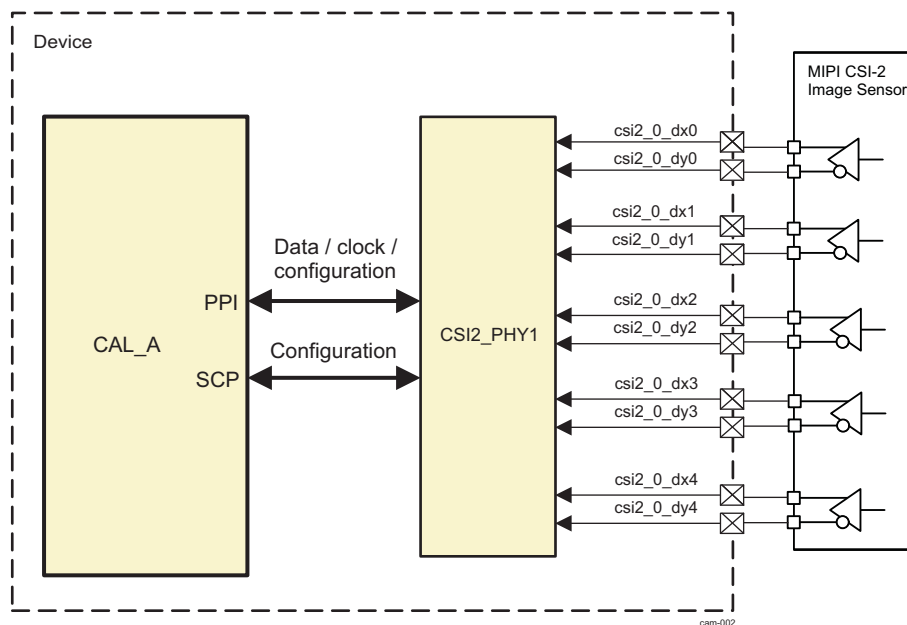

Table 7-472 summarizes the CAL_A I/O signals.

Table 7-472. CAL_A I/O Description

Signal Name	I/O ⁽¹⁾	Description
csi2_0_dx0	I	Serial CSI2 mode: Differential clock lane positive input
csi2_0_dy0	I	Serial CSI2 mode: Differential clock lane negative input
csi2_0_dx1	I	Serial CSI2 mode: Differential data lane positive input
csi2_0_dy1	I	Serial CSI2 mode: Differential data lane negative input
csi2_0_dx2	I	Serial CSI2 mode: Differential data lane positive input
csi2_0_dy2	I	Serial CSI2 mode: Differential data lane negative input
csi2_0_dx3	I	Serial CSI2 mode: Differential data lane positive input

⁽¹⁾ I = Input; O = Output

Table 7-472. CAL_A I/O Description (continued)

Signal Name	I/O ⁽¹⁾	Description
csi2_0_dy3	I	Serial CSI2 mode: Differential data lane negative input
csi2_0_dx4	I	Serial CSI2 mode: Differential data lane positive input
csi2_0_dy4	I	Serial CSI2 mode: Differential data lane negative input

NOTE: The *Description* column in [Table 7-472](#) shows only the default function (data or clock lane) of each CSI2 differential pair. Refer to [Section 7.2.4, CSI2 PHY Functional Description](#), for more details on configurations available.

7.2.6.2 ISS CAL Integration

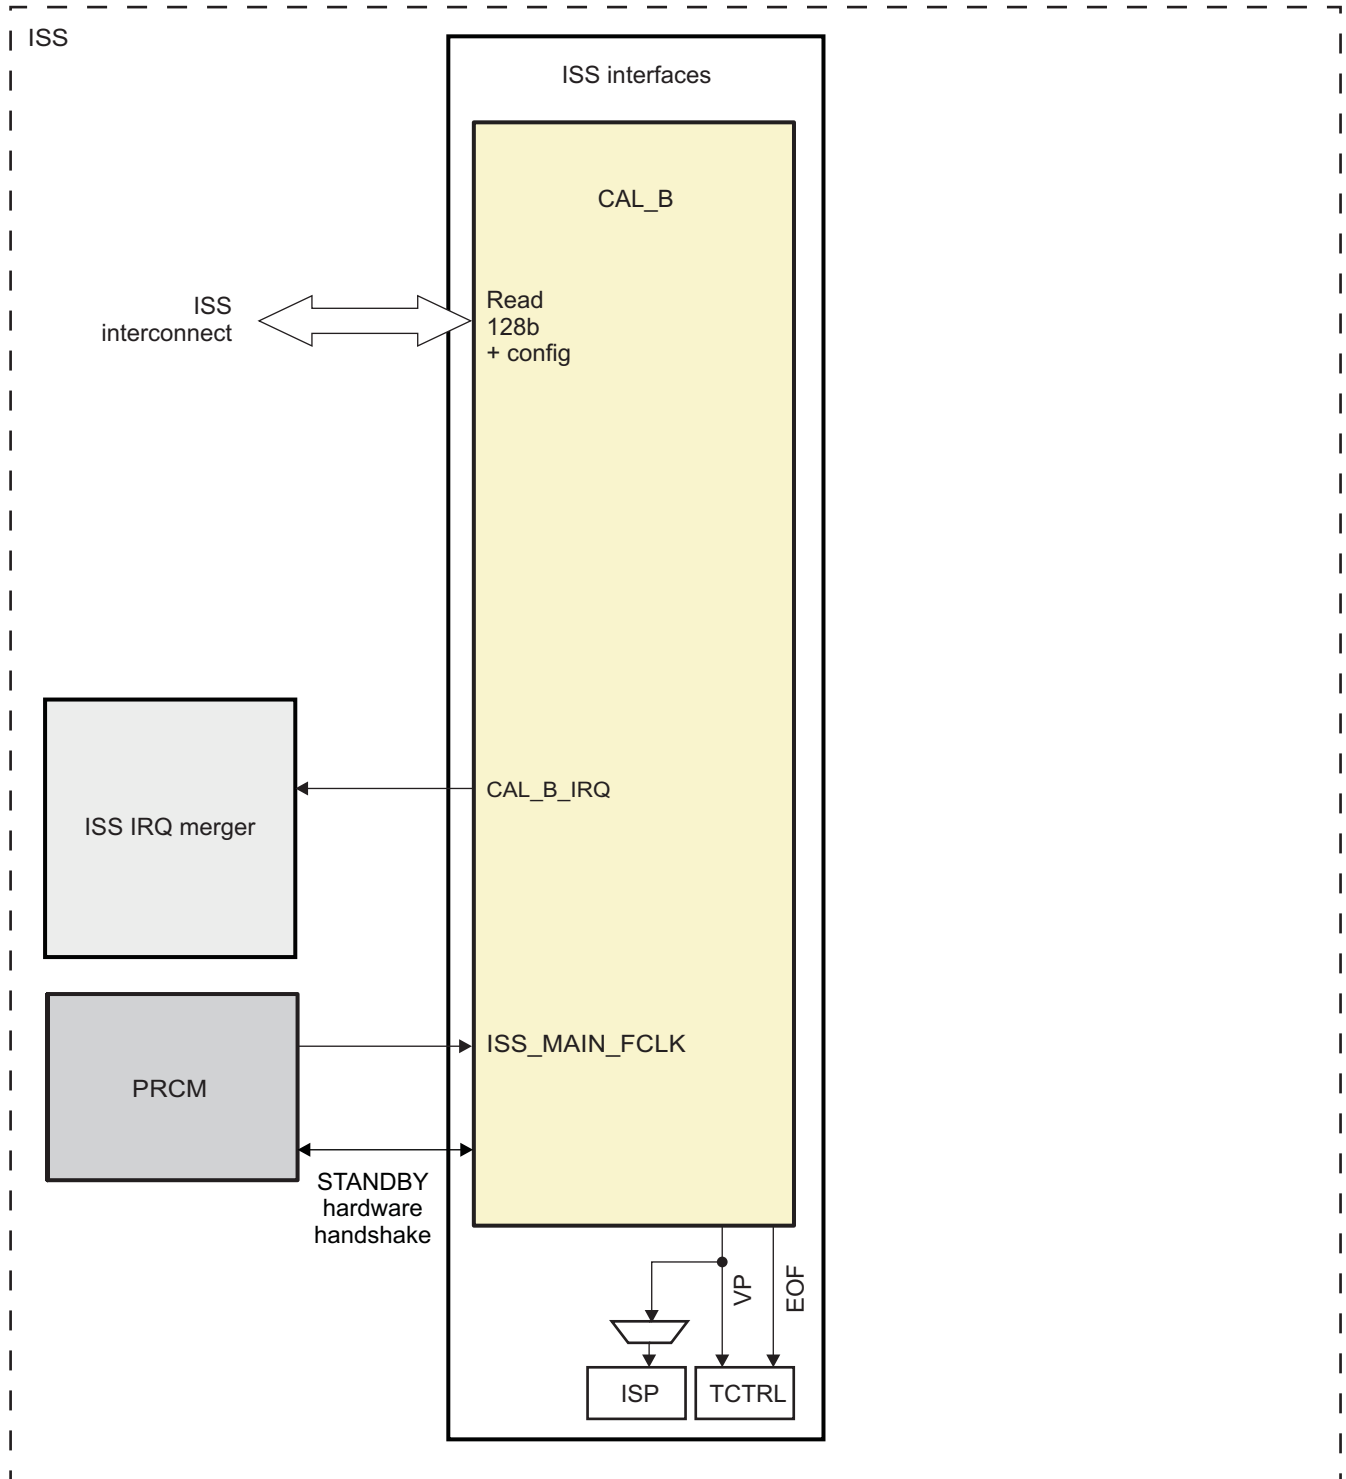

This section describes the integration of CAL_A and CAL_B in the device, including information about clocks, resets, and hardware requests.

Figure 7-23. CAL_A Integration

camss-352b

Figure 7-24. CAL_B Integration

camss-352c

NOTE: For more information about the IDLE hardware handshake, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

7.2.6.2.1 CAL Main Integration Attributes

This section describes the CAL integration in the device, including information about clocks, resets, and hardware requests.

Table 7-473 through Table 7-475 summarize the integration of the module in the device.

Table 7-473. CAL Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
CAL_A	PD_ISS	No	L3_MAIN for configuration and data transfers to system memory;
CAL_B	PD_ISS	No	L3_MAIN for configuration and data transfers from system memory;

Table 7-474. CAL Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
CAL_A	CAL_FCLK	ISS_MAIN_FCLK	ISS	Functional clock
	CAL_ICLK	ISS_MAIN_FCLK	ISS	Configuration clock equal to 1/2 of the CAL_FLCK.
	CAL_BYTECLKHS	RXBYTECLKHS	CSI2_PHY1	CSI2 High-Speed Receive Byte Clock
CAL_B	CAL_FCLK	ISS_MAIN_FCLK	ISS	Functional clock
	CAL_ICLK	ISS_MAIN_FCLK	ISS	Configuration clock equal to 1/2 of the CAL_FLCK.
CSI2 PHY	SCPCLK	CAL_SCPCLK	CAL	Configuration clock for CSI2_PHY1. Equal to 1/4 of the CAL_FLCK.
	PWRCLK	CAL_PWRCLK	CAL	Power management clock for CSI2_PHY1. Equal to 1/4 of the CAL_FLCK.

Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
CAL_A	CAL_RST	ISS_RST	ISS	CAL_A global hardware reset
CAL_B	CAL_RST	ISS_RST	ISS	CAL_B global hardware reset

Table 7-475. CAL Hardware Requests

Interrupt Requests				
Module Instance	Source Signal Name	Destination ISS_CROSSBAR Input	Default Mapping	Description
CAL_A	CAL_A_IRQ	N/A (Configurable)	-	CAL_A interrupt request
CAL_B	CAL_B_IRQ	N/A (Configurable)	-	CAL_A interrupt request

7.2.6.2.2 CAL Integration - Video Port

The CAL_A and CAL_B modules have each an output video port for data transfer to the ISP module.

Table 7-476 summarizes the video port interface signals

Table 7-476. CAL Video Port Signals

Signal name	I/O	Description
VP_PCLK	O	Output pixel clock. Synchronous to the functional clock. Mean clock rate defined by the CAL_VPORT_CTRL1[16:0] PCLK register bit-field.
VP_VS	O	Active during the first pixel of the frame
VP_VE	O	Active during the last pixel of the frame
VP_HS	O	Active during the first pixel of any line
VP_HE	O	Active during the last pixel of any line
VP_DATA[15:0]	O	When CAL_VPORT_CTRL1[31] WIDTH = 0: Pixel data for any position When CAL_VPORT_CTRL1[31] WIDTH = 1: Pixel data for position (X%2) = 0 MSBs padded with 0s when less than 16 bits are used.
VP_DATA[31:16]	O	When CAL_VPORT_CTRL1[31] WIDTH = 0: Stuffed with 0s for any position When CAL_VPORT_CTRL1[31] WIDTH = 1: Pixel data for position (X%2) = 1 MSBs padded with 0s when less than 16 bits are used.
VP_STALL	I	Hardwired to 0. Video port cannot be stalled from outside of CAL.

Software can control the minimum time between two consecutive VP_PCLK pulses using the [CAL_VPORT_CTRL1\[16:0\]](#) PCLK bit field. It can also impose minimum vertical and horizontal blanking using the [CAL_VPORT_CTRL1\[24:17\]](#) XBLK and [CAL_VPORT_CTRL1\[30:25\]](#) YBLK bit fields.

The video port can carry up to 2 pixels per cycle.

More details about the video port are described in [Section 7.2.6.3.14](#), *CAL Video Port*.

7.2.6.2.3 CAL Integration - PPI Interface

CAL_A does not connect directly to the sensor but via a complex I/O (CSI2_PHY1). CAL can connect to complex I/Os through a PHY Protocol Interfaces (PPI). For more details on PPI interface configuration refer to [Section 7.2.4](#), *ISS CSI2 PHY Functional Description*, and [Section 7.2.6.3.6.1](#), *CSI2 Physical Layer*.

7.2.6.3 ISS CAL Functional Description

7.2.6.3.1 CAL Block Diagram

Figure 7-25 and Figure 7-26 show a top-level overview block diagrams of the CAL_A and CAL_B modules, respectively.

Figure 7-25. CAL_A Block Diagram

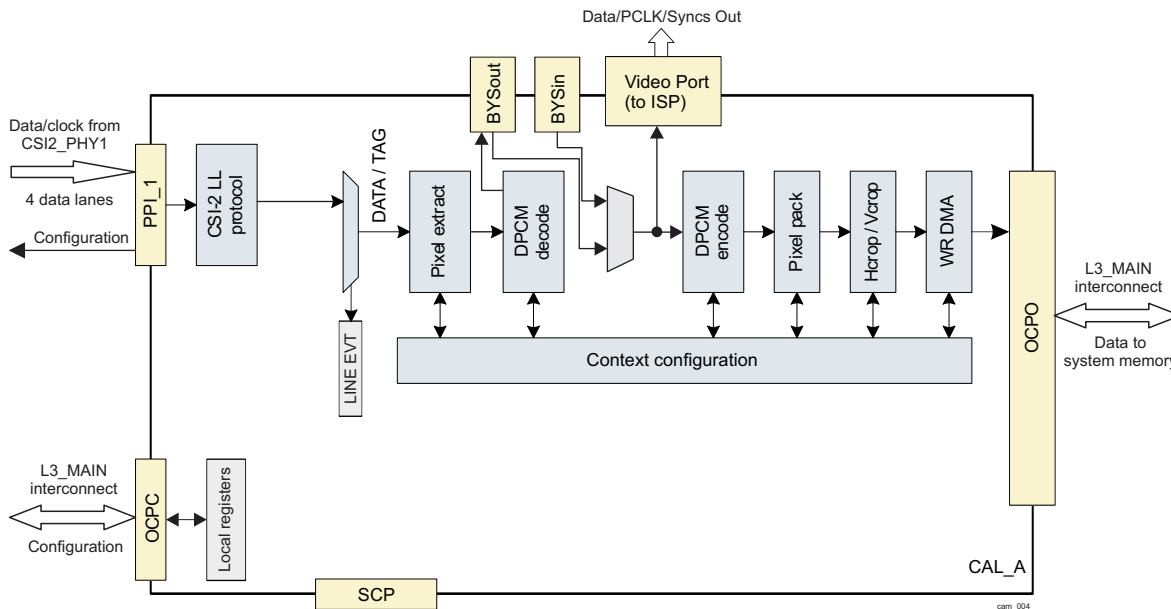

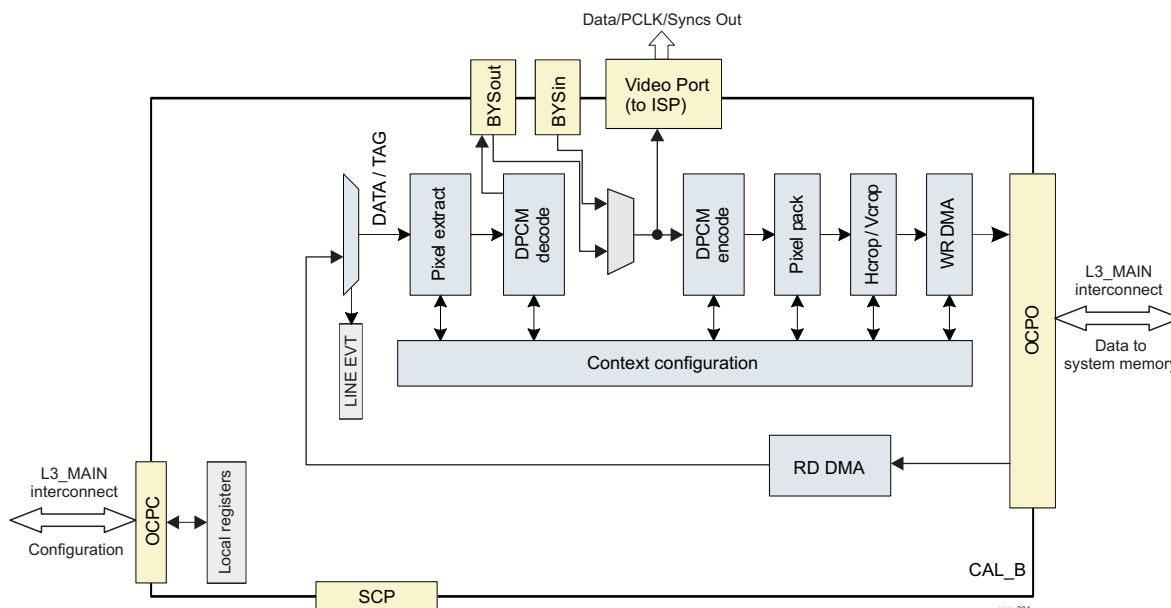

Figure 7-26. CAL_B Block Diagram

The CAL_A module is composed of 1 possible data source (CSI-2 low level protocol decoder) plus a data pipeline.

The CSI-2 LL protocol block receives data from a D-PHY receiver (CSI2 PHY, up to four data pairs), merges data from multiple lanes, detects and correct errors, extracts the virtual channel ID, detects and extracts the synchronization codes and re-formats the data into a stream understood by the CAL processing pipeline. Each PPI interface has a small FIFO to accommodate latencies to access the CAL pipeline.

The RD DMA block reads pixel data from memory and re-formats the data into a stream understood by the CAL processing pipeline.

The data from all sources is multiplexed with 64-bit granularity and sent to the CAL pipeline for further processing. The data pipeline forwards 64-bit wide data words as well as a 5-bit wide data qualifier + 4-bit validity qualifier + 5-bit CPORT number referred as TAG in this chapter.

The TAG is set by the data source and controls how the different stages in the processing pipeline behave. [Figure 7-27](#) summarizes possible values for the data qualifier and the corresponding behavior of the different processing stages:

Figure 7-27. CAL Data Pipeline TAGs

ID	Label	Description / generation	Pixel extraction	DPCM decode	DPCM encode	Pixel packing	Video Port	WRITE DMA
0	IDLE	Indicates no active data in the pipeline. Used to gate processing logic and save power	idle	idle	idle	idle	idle	idle
1	ATT_HDR_S	Attribute header (bytes 0~7)	bypass	bypass	bypass	bypass	idle	reset + write
2	ATT_HDR_E	Attribute header (bytes 8~15)	bypass	bypass	bypass	bypass	idle	write + flush
3	ATT_DAT_S	Attribute payload (bytes 16~23)	bypass	bypass	bypass	bypass	idle	reset + write
4	ATT_DAT	Attribute payload (bytes 23 ~ last-8)	bypass	bypass	bypass	bypass	idle	write
5	ATT_DAT_E	Attribute payload (bytes last-7 ~ last)	bypass	bypass	bypass	bypass	idle	write + flush
6	CTRL_HDR_S	EOP / Control packet (bytes 0~7)	bypass	bypass	bypass	bypass	idle	reset + write
7	CTRL_HDR_E	EOP / Control packet (bytes 8~15)	bypass	bypass	bypass	bypass	idle	write + flush
8	DPCM_INIT	Initialization data for the DPCM decoder (available at CAL module level, not used in the device)	bypass	init + discard	na	na	na	na
9	PIX_HDR_S	Data header (bytes 0~7)	bypass	bypass	bypass	bypass	idle	reset + write
10	PIX_HDR_E	Data header (bytes 8~15)	bypass	bypass	bypass	bypass	idle	write + flush
11	PIX_DAT_FS	Data payload (bytes 16~23, 1st line)	reset + process	reset + process	reset + process	reset + process	reset + output	reset + write
12	PIX_DAT_LS	Data payload (bytes 16~23, line 2 ~ n)	reset + process	reset + process	reset + process	reset + process	reset + output	next line + write
13	PIX_DAT	Data payload (bytes 24 ~ last-8)	process	process	process	process	output	write
14	PIX_DAT_FE	Data payload (bytes last-7 ~ last, line n)	process	process	process	process	output	write + flush
15	PIX_DAT_LE	Data payload (bytes last-7 ~ last, line 2 ~ n-1)	process	process	process	process	output	write + flush
16	FE_CODE	Frame end short packet received. Used for data received from PPI when the number of lines per frame is not known	bypass	bypass	bypass	bypass	frame end	frame end

cam_009

NOTE: [Figure 7-27](#) does not describe all possible configurations for the CAL pixel processing stages. Depending on the use case, each pixel processing stage (extraction, DPCM decoding/encoding, packing) can be individually configured or bypassed via a dedicated bit-field in the [CAL_PIX_PROC_i](#) register.

7.2.6.3.2 CAL Hardware and Software Reset

An active low asynchronous hardware reset is provided by the ISS. It is internally resynchronized to the functional clock domain.

A software reset is triggered by setting the [CAL_HL_SYSCONFIG\[0\]](#) SOFTRESET bit to 0x1. The CAL hardware ensures that the software reset is performed on clean OCP transactions boundaries and that no OCP protocol violation can occur due to the software reset. Mainly, it finishes ongoing OCP transactions and prevents generation of new ones.

The `CAL_HL_SYSCONFIG[0]` `SOFTRESET` bit is automatically cleared by hardware when the software reset has completed. The software reset will never complete, if outstanding OCP responses are not returned. This situation is only expected when the slave with which CAL is communicating fails. A hardware reset is reset in that case.

A software reset is faster than a hardware reset controlled by the device ISS module. In fact, to avoid OCP protocol violations, the ISS module first puts the CAL into Idle mode. The ISS can only perform a clean hardware reset once CAL has acknowledged the IDLE request. That only happens once the CAL has flushed all pending traffic. A software reset simply waits for the next clean OCP transaction boundary without finishing the frame.

OCPC is fully functional after a software reset.

7.2.6.3.3 CAL Clock Configuration

CAL receives one functional clock from ISS that is also used for the OCP ports. The configuration port (OCPC) operates at half the functional clock speed (clock enable signal used).

In addition, CAL receives one asynchronous clock for each PPI interface. This clock is generated from the bit clock received from the image sensor and converted into a byte clock by the CSI2 PHY.

CAL also provides the PWRSCP clock used to configure the CSI2 PHY. It corresponds to the CAL functional clock divided by 4 and is gated depending on functional needs.

7.2.6.3.4 CAL Power Management

CAL supports a IDLE protocol interface. It is used to ensure that the CAL clock / power can only be cut where there are no pending transactions. It is also used to ensure that CAL generates no more traffic before gating the functional clock. ISS sends an IDLE request to the CAL when the software requests CAL shutdown.

When CAL receives an IDLE request, it performs the following actions:

1. Finishes pending transactions:
 - a. All transactions on OCPI have been processed;
 - b. No more data needs to be fetched by the RD_DMA block. It first reads the complete frame and processes all data before it can acknowledge an IDLE request.
 - c. All data has been flushed out from the write buffer.
 - d. FE short packet has been received (but no new FS) on all enabled PPI virtual channels
2. Disconnects the OCPC and OCPO ports on clean transaction boundaries.
3. Acknowledges the IDLE request.

For more information on CS2 PHY power management, refer to [Section 7.2.4.2.1, CSI2 PHY Configuration](#).

7.2.6.3.5 CAL Interrupt Events

This section describes the interrupt events that can trigger the `CAL_x_IRQ` signal (see also [Section 7.2.6.2.1, CAL Main Integration Attributes](#)). The `CAL_x_IRQ` is merged at ISS top level IRQ merger.

NOTE: The CAL does not provide an event to detect Attribute Payload data at low level protocol level. Attribute data can only be sent to memory and therefore software can use the `IRQ_WDMA_START / END` events detected by the `WR_DMA` block.

[Table 7-477](#) lists the event generation and corresponding registers of the CSI2 Low Level Protocol engines.

Table 7-477. CSI2 Low Level Protocol Interrupts

Event and Register	Description
CAL_CSI2_COMPLEXIO_IRQENABLE_I[27] FIFO_OVF_IRQ	FIFO overflow error: This interrupt is triggered when a FIFO overflow is detected. An overflow can occur if there is a mismatch between the data input and output rates. In case of an overflow the module properly finishes the burst that has been started and does not issue any new OCP transactions on the master port. A reset of the module is required to restart correctly.
CAL_CSI2_COMPLEXIO_IRQENABLE_I[28] SHORT_PACKET_IRQ	Short packet reception (other than sync events: line start, line end, frame start, and frame end; only data types from 0x8 to 0xF are considered)
CAL_CSI2_COMPLEXIO_IRQENABLE_I[30] ECC_NO_CORRECTION_IRQ	ECC was not used to correct the header because the error is larger than 1 bit (short and long packets).
CAL_CSI2_VC_IRQENABLE_I[] ECC_CORRECTION_IRQ_x, where x = [0...3]	ECC was used to correct a 1-bit error (short packet only).
CAL_CSI2_VC_IRQENABLE_I[] FS_IRQ_x, where x = [0...3]	Frame start: This interrupt is triggered when a frame-start synchronization code is detected in the CSI2 data stream.
CAL_CSI2_VC_IRQENABLE_I[] FE_IRQ_x, where x = [0...3]	Frame end: This interrupt is triggered when a frame-end synchronization code is detected in the CSI2 data stream.
CAL_CSI2_VC_IRQENABLE_I[] LS_IRQ_x, where x = [0...3]	Line start: This interrupt is triggered when a line-start synchronization code is detected in the CSI2 data stream.
CAL_CSI2_VC_IRQENABLE_I[] LE_IRQ_x, where x = [0...3]	Line end: This interrupt is triggered when a line-end synchronization code is detected in the CSI2 data stream.
CAL_CSI2_VC_IRQENABLE_I[] CS_IRQ_x, where x = [0...3]	CS error: This interrupt is triggered when a mismatch between the transmitter and receiver checksums (payload) is detected.

Table 7-478 lists CSI2 Complex I/O event generation. The events are checked and controlled from the [CAL_CSI2_COMPLEXIO_IRQSTATUS_I](#) and [CAL_CSI2_COMPLEXIO_IRQENABLE_I](#) registers.

Table 7-478. CSI2 Complex I/O Interrupts

Event and Register	Description
CAL_CSI2_COMPLEXIO_IRQENABLE_I[0] ERRSOTHS1	Start of transmission error for lane 1
CAL_CSI2_COMPLEXIO_IRQENABLE_I[1] ERRSOTHS2	Start of transmission error for lane 2
CAL_CSI2_COMPLEXIO_IRQENABLE_I[2] ERRSOTHS3	Start of transmission error for lane 3
CAL_CSI2_COMPLEXIO_IRQENABLE_I[3] ERRSOTHS3	Start of transmission error for lane 4
CAL_CSI2_COMPLEXIO_IRQENABLE_I[4] ERRSOTHS3	Start of transmission error for lane 5
CAL_CSI2_COMPLEXIO_IRQENABLE_I[5] ERRSOTSYNCHS1	Start of transmission sync error for lane 1
CAL_CSI2_COMPLEXIO_IRQENABLE_I[6] ERRSOTSYNCHS2	Start of transmission sync error for lane 2
CAL_CSI2_COMPLEXIO_IRQENABLE_I[7] ERRSOTSYNCHS3	Start of transmission sync error for lane 3
CAL_CSI2_COMPLEXIO_IRQENABLE_I[8] ERRSOTSYNCHS3	Start of transmission sync error for lane 4
CAL_CSI2_COMPLEXIO_IRQENABLE_I[9] ERRSOTSYNCHS3	Start of transmission sync error for lane 5
CAL_CSI2_COMPLEXIO_IRQENABLE_I[10] ERRESC1	Escape entry error for lane 1
CAL_CSI2_COMPLEXIO_IRQENABLE_I[11] ERRESC2	Escape entry error for lane 2
CAL_CSI2_COMPLEXIO_IRQENABLE_I[12] ERRESC3	Escape entry error for lane 3
CAL_CSI2_COMPLEXIO_IRQENABLE_I[13] ERRESC4	Escape entry error for lane 4
CAL_CSI2_COMPLEXIO_IRQENABLE_I[14] ERRESC5	Escape entry error for lane 5
CAL_CSI2_COMPLEXIO_IRQENABLE_I[15] ERRCONTROL1	Control error for lane 1
CAL_CSI2_COMPLEXIO_IRQENABLE_I[16] ERRCONTROL2	Control error for lane 2
CAL_CSI2_COMPLEXIO_IRQENABLE_I[17] ERRCONTROL3	Control error for lane 3

Table 7-478. CSI2 Complex I/O Interrupts (continued)

Event and Register	Description
CAL_CSI2_COMPLEXIO_IRQENABLE_I [18] ERRCONTROL4	Control error for lane 4
CAL_CSI2_COMPLEXIO_IRQENABLE_I [19] ERRCONTROL5	Control error for lane 5
CAL_CSI2_COMPLEXIO_IRQENABLE_I [20] STATEULPM1	Lane 1 in ULPM
CAL_CSI2_COMPLEXIO_IRQENABLE_I [21] STATEULPM2	Lane 2 in ULPM
CAL_CSI2_COMPLEXIO_IRQENABLE_I [22] STATEULPM3	Lane 3 in ULPM
CAL_CSI2_COMPLEXIO_IRQENABLE_I [23] STATEULPM4	Lane 4 in ULPM
CAL_CSI2_COMPLEXIO_IRQENABLE_I [24] STATEULPM5	Lane 5 in ULPM
CAL_CSI2_COMPLEXIO_IRQENABLE_I [25] STATEALLULPMENTS	All active lanes are entering the ULPM.
CAL_CSI2_COMPLEXIO_IRQENABLE_I [26] STATEALLULPMEXIT	At least one active lane exited the ULPM.

Table 7-479. CAL Write DMA Interrupts

Event	Description
IRQ_WDMA_STARTx x= [0 ... CAL_HL_HWINFO [18:13] WCTX - 1]	Frame start. Triggered by the write DMA when a data word tagged as ATT_HDR_S, ATT_DAT_S, CTRL_HDR_S, PIX_HDR_S or PIX_DAT_FS has been detected by the write DMA. Typically used by SW to detect when shadowed registers can be updated for the next frame. Refer to section Section 7.2.6.3.12, CAL Write DMA , for more details.
IRQ_WDMA_ENDx x= [0 ... CAL_HL_HWINFO [18:13] WCTX - 1]	Frame end. Triggered by the write DMA when the FE tag has been received by the cropping stage and the last data of the last line has been sent to memory. Therefore, this event may be triggered after the last data has been written to memory when data has been discarded by the cropping feature. The FE corresponds to a data word tagged as ATT_HDR_E, ATT_DAT_E, CTRL_HDR_E, PIX_HDR_E, PIX_DAT_FE or FE_CODE. Typically used by SW to detect when all data of a header, attribute packet, control packet or pixel frame has been written to memory. This event is triggered when the last OCP transaction has been sent to memory but before the response for this OCP transaction has been received from the target. Therefore, there is a small delay between the moment where the event is triggered and the last data can be read back from the buffer. Typically that delay is compensated by IRQ detection latencies.
IRQ_WDMA_CIRCx x= [0 ... CAL_HL_HWINFO [18:13] WCTX - 1]	Circular event. Triggered when the number of lines defined by CAL_WR_DMA_OFST_k [23:22] CIRC_MODE has been sent to the OCP master port.

Table 7-480. CAL Line Number Interrupt

Event	Description
IRQ_LINE_NUMBER	Line number reached. The line number programmed in CAL_LINE_NUMBER_EVT [29:16] LINE register bit-field) is received on CPORT # CAL_LINE_NUMBER_EVT [4:0] CPORT.

Table 7-481. CAL Video Port EOF Interrupt

Event	Description
IRQ_VPORT_EOF	Event triggered when data tagged as PIX_DAT_FE is sent to the video port. Typically used by SW to detect when all data has been sent to the video port.

On CAL top level, the different events trigger IRQs, if they have been enabled using the [CAL_HL_IRQENABLE_SET_j](#) register. The status can be read from the [CAL_HL_IRQSTATUS_j](#) register. The event-to-register mapping is shown in [Figure 7-28](#).

- [IRQ_PPI1_VC](#) and [IRQ_PPI0_VC](#) refer to events controlled by [CAL_CSI2_VC_IRQENABLE_I](#) register and described in [Table 7-477, CSI2 Low Level Protocol Interrupts](#).
- [IRQ_PPI1](#) and [IRQ_PPI0](#) refer to events controlled by [CAL_CSI2_COMPLEXIO_IRQENABLE_I](#) and described in [Table 7-477, CSI2 Low Level Protocol Interrupts](#) and [Table 7-478, CSI2 Complex I/O Interrupts](#).

All events are merged into a single [CAL_IRQ](#) signal available at CAL boundary.

NOTE: [CAL_HL_IRQSTATUS_j](#) does not refer to events, but is used to collect events tracked in [CAL_CSI2_VC_IRQSTATUS_I](#) and [CAL_CSI2_COMPLEXIO_IRQSTATUS_I](#) registers, and enabled by [CAL_CSI2_VC_IRQENABLE_I](#) and [CAL_CSI2_COMPLEXIO_IRQENABLE_I](#) registers. SW must use them to detect, if a Complex I/O or PPI event is pending and then get event details from the relevant second level IRQ status register. SW must only clear those events by setting the relevant bits in the [CAL_CSI2_VC_IRQSTATUS_I](#) and [CAL_CSI2_COMPLEXIO_IRQSTATUS_I](#) registers. [CAL_HL_IRQSTATUS_j](#) is automatically cleared by the HW when no more enabled Complex I/O or PPI events are pending

cam-008

7.2.6.3.6 CAL CSI2 Low Level Protocol

CAL_A has two PPI interfaces that connect directly to two D-PHY instances of up to 4 lanes each. It also implements an OCP to SCP bridge to access the complex IO internal registers.

7.2.6.3.6.1 CSI2 Physical Layer

The CSI2 serial interface is a unidirectional differential serial interface with data/clock for the physical layer.

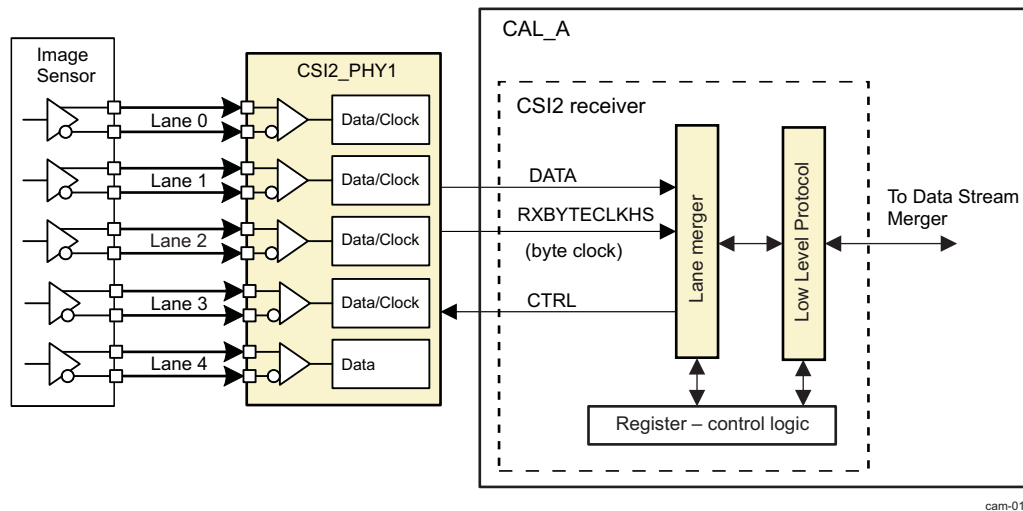

The maximum CSI2 data transfer capacity is 1500 Mbps per data lane. The speed of the link is reconfigurable by SW only when the CSI2 PHY is in "stop state" or in ULPM (ultra-low power mode).

Data-clock signaling consists of two to five differential signal pairs: from one to four data lanes and one clock lane. The minimum configuration is one data pair and one clock pair.

- The data signal carries the bit-serial data. The CSI2 transmitter in the image sensor sends the data in-quadrature with the dual-data rate (DDR) clock in HS mode; otherwise, the clock is extracted from the received data in LS (low speed) mode. Data is transmitted byte-wise, LSB first. The CSI2 complex I/O receives the data and sends the byte stream to the CSI2 LL protocol core.
- The clock signal carries the DDR clock signal.
- The SW has to configure the order of the data lanes to indicate the byte order while merging the received bytes for each CSI2 PHY into a byte stream.

Figure 7-29 is the CSI2 Low Level Protocol engine block diagram (it assumes there are four CSI2 image sensor data lines). The CSI2 receiver receives the byte data coming from a CSI2 D-PHY receiver (CSI2_PHY1 with up to four data pairs), converts it to byte stream, detects and corrects errors, extracts the virtual channel ID, detects and extracts the synchronization codes, reformats the data, and forwards it to the the CAL Data Stream Merger.

Figure 7-29. CSI2 Low Level Protocol Engine Block Diagram

Each physical lane can be a data or clock lane with a restriction to the fourth lane, which can only be data (see Section 7.2.4.1, *CSI2 PHY Overview*). The clock/data lane must be configured before transmission to indicate the byte order, while merging the received bytes into a byte stream shows the reachable speed per data lane function of data lane numbers.

Lanes are configured through the `CAL_CSI2_COMPLEXIO_CFG_I` registers. The `CAL_CSI2_COMPLEXIO_CFG_I[2:0]` `CLOCK_POSITION` bit field and the `CAL_CSI2_COMPLEXIO_CFG_I[3]` `CLOCK_POL` bit configure which lane transmits the clock and define its polarity. The `DATAx_POSITION` and `DATAx_POL` bit-fields configure the data lanes and their polarity, where `x` is the number of the data lane (`x = 1 to 4`). When the `DATAx_POSITION` field is set to 0, data lane `x` is not used.

CAUTION

Lane 4 (position 5) supports only data. The CLOCK_POSITION must not be set at position 5.

Table 7-482. CSI2_PHY1 I/O Description

Signal Name		I/O ⁽¹⁾	Description
csi2_0_dx0	lane 0 (position 1)	I	Serial data/clock input
csi2_0_dy0			
csi2_0_dx1	lane 1 (position 2)	I	Serial data/clock input
csi2_0_dy1			
csi2_0_dx2	lane 2 (position 3)	I	Serial data/clock input
csi2_0_dy2			
csi2_0_dx3	lane 3 (position 4)	I	Serial data/clock input
csi2_0_dy3			
csi2_0_dx4	lane 4 (position 5)	I	Serial data input only
csi2_0_dy4			

⁽¹⁾ I = Input

Lanes support the two operating modes:

- HS mode: High-speed transmit mode
- Off mode: Lane is off.

7.2.6.3.6.2 CSI2 Multi-lane Layer and Lane Merger

The layer consists of lane merger logic in order to merge the incoming serial stream into a byte stream. The bits are sent with LSB first. The number of active lanes is configurable through register. The order of the lanes at the CSI-2 receiver core is also configurable. The number of lanes can be changed only in ULPM or when all data lanes are in "stop state" (OFF mode).

The lane merger can merge up to four lanes into a single byte stream, and is not used for a single lane.

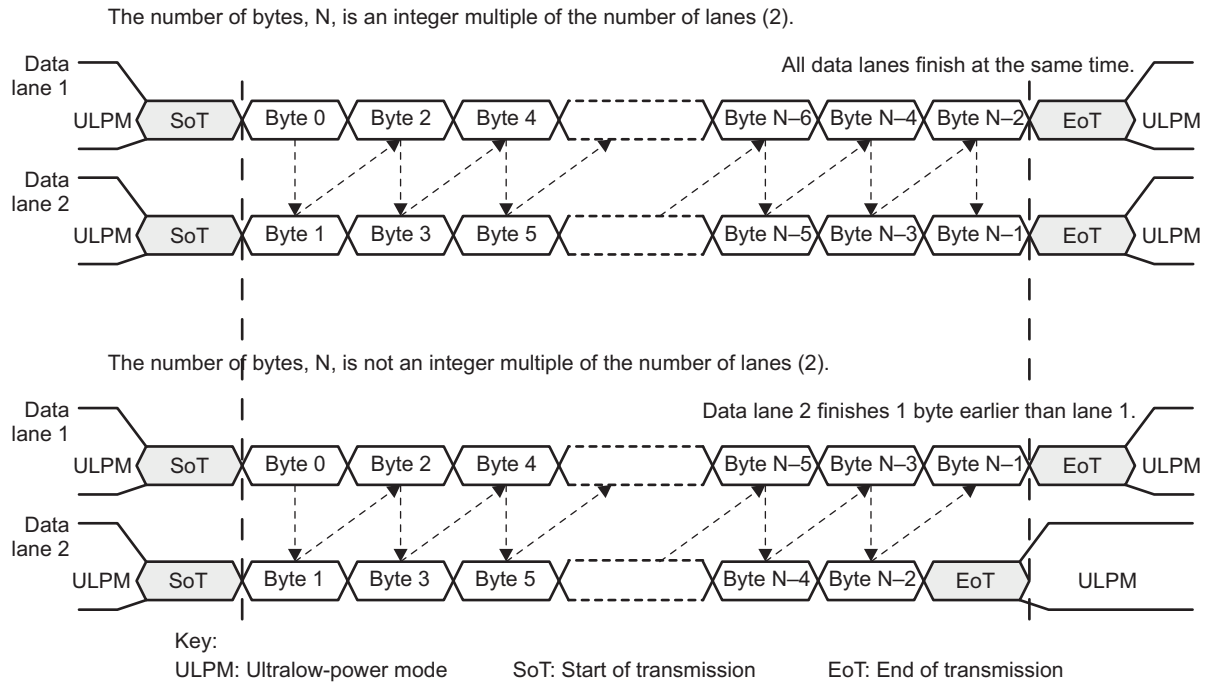

Figure 7-30 to Figure 7-33 show the byte position into each serial link for one to four data lane configurations. The byte stream always starts from lane 1. It finishes on one of the lanes, depending on the number of bytes to receive and the number of lanes.

Figure 7-30. CSI2 One Data-Lane Configuration

camss-240

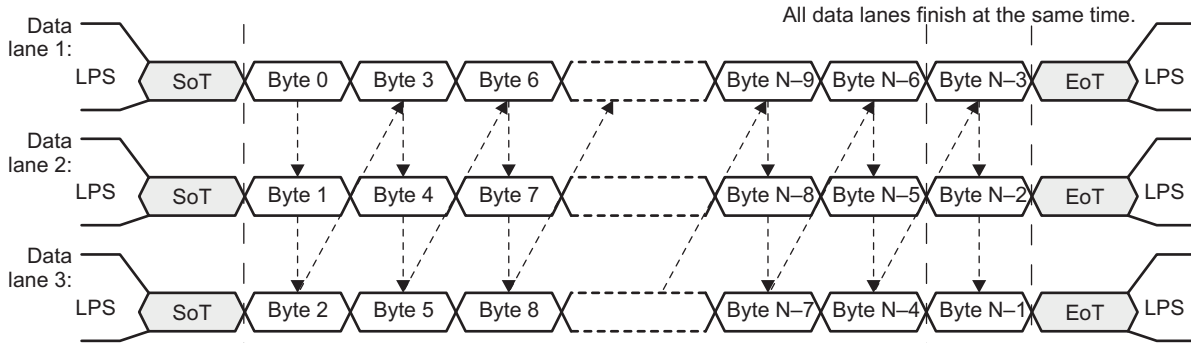

Figure 7-31. CSI2 Two Data-Lane Merger Configuration

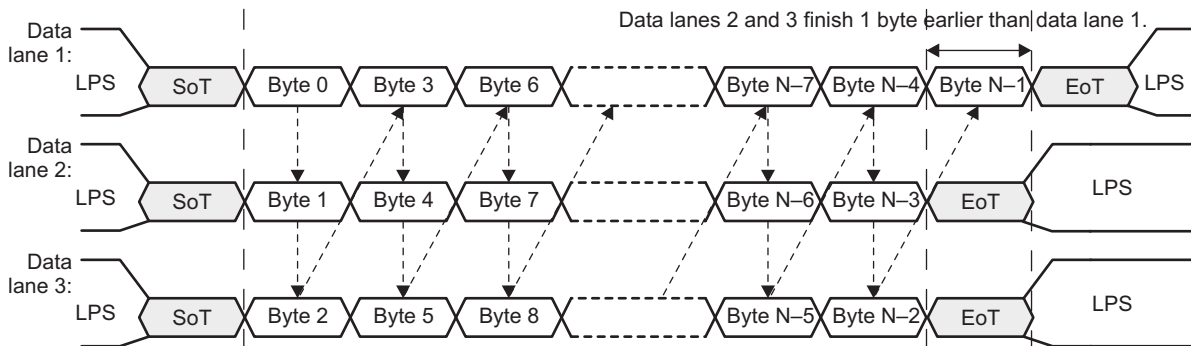

camss-239

Figure 7-32. CSI2 Three Data-Lane Merger Configuration

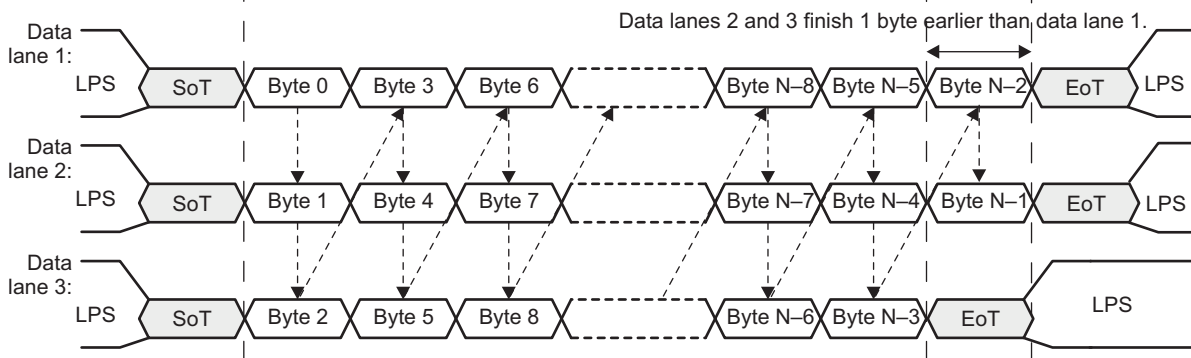

Number of bytes, N, transmitted is an integer multiple of the number of data lanes:

Number of bytes, N, transmitted is not an integer multiple of the number of data lanes (Example 1):

Number of bytes, N, transmitted is not an integer multiple of the number of data lanes (Example 2):

Key:
 LPM: Low-power mode SoT: Start of transmission EoT: End of transmission

camss-257

Figure 7-33. CSI2 Four Data-Lane Merger Configuration

7.2.6.3.6.3 CSI2 Protocol Layer

The low-level protocol (LLP) is a byte-oriented protocol from the lane merger layer. It supports short and long packet formats.

The CSI2 protocol layer defines how image-sensor data is transported onto the physical layer.

The feature set of the protocol layer implemented by the CSI2 receiver is:

- Transport of arbitrary data (payload-independent)
- 8-bit word size
- Support for up to four interleaved virtual channels on the same link
- Special packets for frame-start, frame-end, line-start, and line-end information
- Error-correction code (ECC) for 1-bit error correction or 2-bit error detection in the header
- 16-bit checksum code for payload error detection

Figure 7-34 shows the CSI2 protocol layer with short and long packets.

Figure 7-34. CSI2 Protocol Layer With Short and Long Packets

Key:
 ST: Start of transmission ET: End of transmission
 PH: Packet header PF: Packet footer
 ULPM: Ultralow-power mode SP: Short packet

camss-241

Two packets are always separated from each other with a sequence of ET, ULPM, and ST.

7.2.6.3.6.3.1 CSI2 Short Packet

A short packet is identified by data types 0x00 to 0x0F. A short packet can be used for frame or line synchronization or for generic data. A short packet contains only a Packet Header; a Packet Footer is not be present. Figure 7-35 shows the structure of a short packet.

Figure 7-35. CSI2 Short Packet Structure

camss-242

NOTE: CAL accepts but does not use the frame number or line numbers transmitted by the sensor as required by the MIPI CSI-2 standard.

The ECC byte allows single-bit errors to be corrected and 2-bit errors to be detected in the short packet.

Short packets apply to all contexts using the same virtual channel ID . The data type associated with the context is not used to distinguish which context is used when receiving short packets.

7.2.6.3.6.3.2 CSI2 Long Packet

A long packet is identified by data types 0x10 to 0x37. A long packet consists of three elements:

- A 32-bit packet header (PH)
- An application-specific data payload with a variable number of 8-bit data words
- A 16-bit packet footer (PF)

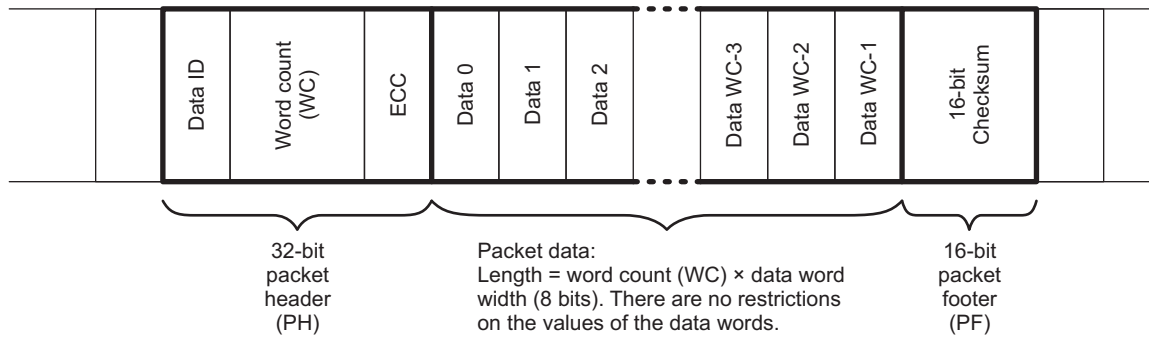

The packet header is further composed of three elements:

- An 8-bit data identifier
- A 16-bit word count field
- An 8-bit ECC

The packet footer has one element, a 16-bit checksum.

Figure 7-36 and Table 7-483 show the structure of a long packet.

Figure 7-36. CSI2 Long Packet Structure

camss-243

Table 7-483. CSI2 Long Packet Structure Description

Packet Part	Field Name	Size (Bits)	Description
Header	Data ID	8	Contains the virtual channel identifier for data and the data-type for the application specific payload data
	Word count	16	Number of 8-bit data words in the Data Payload between the end of the Packet Header and the start of the Packet Footer. Neither the Packet Header nor the Packet Footer are included in the Word Count.
	ECC	8	ECC for data ID and WC field. Allows 1-bit error recovery and 2-bit error detection.
Data	Data	WC-8	Application-specific payload (WC words of 8 bits)
Footer	Checksum	16	16-bit CRC for packet data

There are no restrictions on the size of the packet data, but each data format can impose additional restrictions on the length of the payload data (for example, a multiple of 4 bytes).

7.2.6.3.6.3.3 CSI2 ECC and Checksum Generation

The CSI2 receiver includes an ECC in the packet header and a checksum in the packet footer for long-packet transmission. These two fields can be used to detect and/or correct errors in the received packet.

7.2.6.3.6.3.3.1 CSI2 ECC

To detect and correct transmission errors of the header of short and long packets, an 8-bit ECC is included in the header of packets (short and long packet). It allows single-bit errors to be corrected and 2-bit errors to be detected in the packet header.

The ECC concerns all the fields for a short packet (data ID and short-packet data field) and the packet header for a long packet (data ID and word count). The ECC can only correct one error. Additional errors cannot be repaired, but they are flagged. After the end of the Packet Header, the receiver reads the next Word Count * 8-bit data words of the Data Payload. While reading the Data Payload the receiver does not look for any embedded sync codes. Therefore, there are no limitations on the value of a data word.

The CSI2 receiver ECC is compared against the CSI2 transmitter ECC embedded in the bitstream. If the ECC does not match, an interrupt is triggered.

For long and short packets, the correction is always done, if there is only one error per packet header.

An ECC error with or without correction can be reported at two levels, depending on the type of packet. [Table 7-484](#) describes the field in which events are logged. Logging cannot be disabled, but SW can set the corresponding bit in the [CAL_CSI2_VC_IRQENABLE_I](#) register to prevent event generation at a higher level.

Table 7-484. CSI2 ECC Event Logging

Short and Long Packet	
With correction	Global CAL_CSI2_VC_IRQSTATUS_I [<i>i</i>] ECC_CORRECTION_IRQ_x, where x = [0 to 3]
Without correction	Global CAL_CSI2_VC_IRQSTATUS_I [<i>i</i>] ECC_NO_CORRECTION_IRQ_x, where x = [0 to 3]

The ECC check can be disabled (short and long packet) by setting the [CAL_CSI2_PPI_CTRL_I](#)[2] ECC_EN bit to 0. Setting the bit to 1 enables the ECC check.

Refer to the MIPI CSI-2 1.0 standard for more details on ECC generation.

7.2.6.3.6.3.3.2 CSI2 Checksum

Once the CSI2 receiver has read the Data Payload, it reads the checksum in the Packet Footer. In the generic case, the length of the Data Payload is a multiple of 8-bit data words. In addition, each data format may impose additional restrictions on the length of the payload data, e.g. multiple of four bytes. Each byte is transmitted LSB first.

To detect errors in transmission of the payload of long packets, a 16-bit CRC checksum is computed on the payload of the long packets in the transmitter. This CRC is stored in the packet footer. The CSI2 receiver checksum is compared against the CSI-2 transmitter checksum. If the checksum does not match, an interrupt is triggered.

CRC errors are logged in the [CAL_CSI2_VC_IRQSTATUS_I](#)[*i*] CS_IRQ_x (where x = [0 to 3]) register bit-fields. Logging cannot be disabled, but SW can configure the corresponding bit in the [CAL_CSI2_VC_IRQENABLE_I](#) register to prevent event generation at a higher level.

Since the payload has been already transferred into memory, it is not possible to discard the data but only to generate an interrupt.

7.2.6.3.6.3.4 CSI2 Alignment Constraints

Payload data may be transmitted in any byte order restricted only by data format requirements. Multi-byte elements such as Word Count, Checksum and the Short packet 16-bit Data Field is transmitted LSB byte first.

7.2.6.3.6.3.5 CSI2 Data Identifier

The data identifier byte contains the virtual channel identifier (VC) value and the data-type (DT) value, as shown in [Figure 7-37](#). The VC value is contained in the 2 MSBs of the data identifier byte. The DT value is in the 6 LSBs of the data identifier byte.

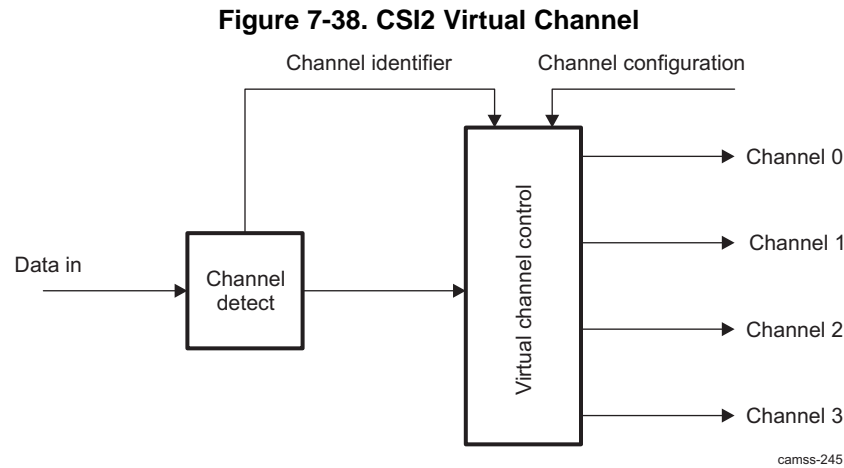

Figure 7-37. CSI2 Data Identifier Structure

camss-244

7.2.6.3.6.3.6 CSI2 Virtual Channel ID

The CSI2 protocol layer transports virtual channels. Virtual channels are built of frames. A frame can comprise embedded data and image-sensor data. Two contexts are used to send the two types of data (embedded and image-sensor) separately. Each frame is identified by unique mandatory synchronization codes: frame start and frame end. Line start and line end synchronization codes are optional for the transmitter. A set of registers is associated with each context defined by the virtual channel ID and the data type. [Figure 7-38](#) shows a virtual channel.

7.2.6.3.6.3.7 CSI2 Synchronization Codes

Each frame is clearly identified by a synchronization code for the start of frame and the end of frame. The start of line and end of line can be sent by the image sensor but it is optional.

In order to send the synchronization codes, the camera uses the short packets. Data reception from the image-sensor module uses four synchronization codes embedded in the serial bitstream:

- FSC: Identifies the start of a new frame
- LSC: Identifies the start of a new line; received for every line
- LEC: Identifies the end of a line; received for every line
- FEC: Identifies the end of the last line and the end of the current frame

[Table 7-485](#) summarizes the synchronization code values.

Table 7-485. CSI2 Synchronization Codes

Synchronization Code	Value	Comments
FSC	0x0	Mandatory
FEC	0x1	Mandatory
LSC	0x2	Optional
LEC	0x3	Optional
Reserved	0x4 to 0x7	Not used

7.2.6.3.6.3.8 CSI2 Generic Short Packet Codes

When the synchronization code value is from 0x8 to 0xF, the short packet is called a generic short packet. Short packets are not processed by the camera interface hardware. A generic short packet is stored in a register without the ECC and an interrupt can be generated. Therefore, generic short packets must be handled by software.

An interrupt (logged in [CAL_CSI2_COMPLEXIO_IRQSTATUS_I\[28\]](#) SHORT_PACKET register bit) indicates to the application the short packet event. Logging cannot be disabled, but SW can set the corresponding bit in the [CAL_CSI2_COMPLEXIO_IRQENABLE_I](#) register to prevent event generation at a higher level. It is SW responsibility to read the register [CAL_CSI2_SHORT_PACKET_I](#) before the next short packet with a code between 0x8 and 0xF. There is a single register for capturing the generic short packets since there is no data type in it to be associated with context.

7.2.6.3.6.3.9 CSI2 Frame Structure and Data

Each frame consists of short packets to indicate SOF and EOF. Optional short packets for start of line and end of line can be sent by the image sensor.

Some information before and after the picture data can be sent by the image sensor as SOF and EOF information. It is decoded by the receiver and is sent to the system memory through the OCPO port.

For each frame, the pixel data (arbitrary data or user-defined byte data) are valid only after an SOF short packet. If the data are invalid, they are discarded by the protocol engine.

A frame contains embedded data and image-sensor data. [Figure 7-39](#) shows where the embedded data and image-sensor data are in the frame. The frame is scanned in raster order starting from the top-left corner, as shown in [Figure 7-39](#) and [Figure 7-40](#). The following definitions for a frame apply:

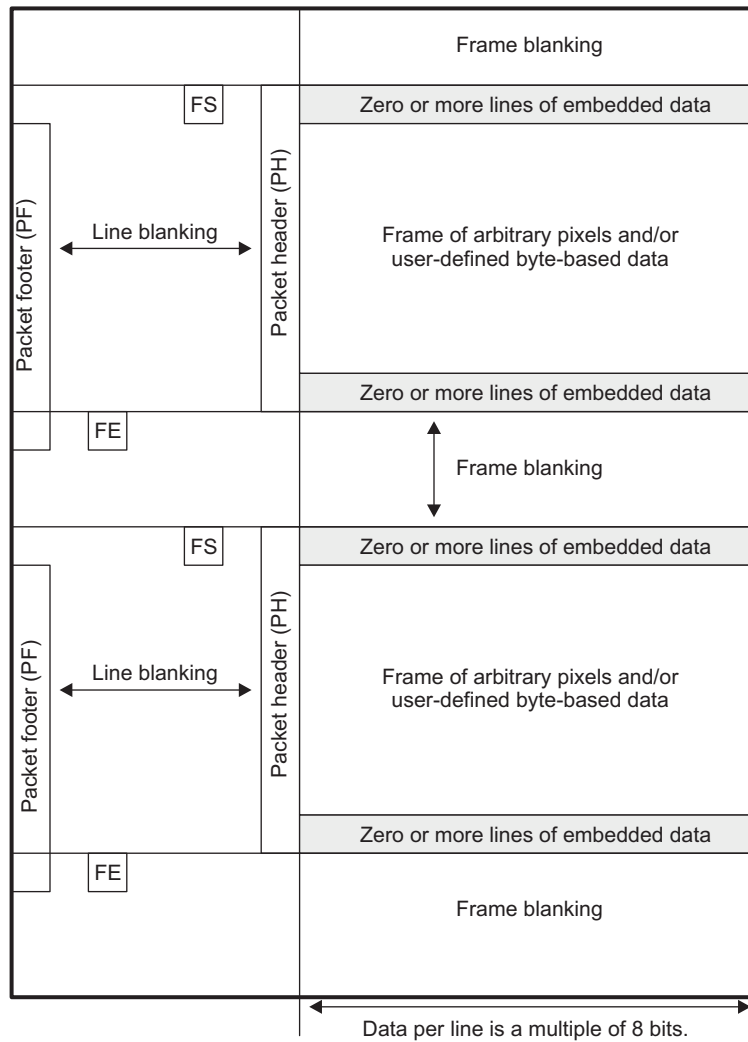

- Zero or more SOF status lines (SOF lines) can be embedded at the beginning of a CSI2 frame.
- The image data comprises pixels of the same or different data formats. The image embedded data is carried using separate data types and virtual channels (see [Section 7.2.6.3.6.3.10, CSI2 Virtual Channel and Context](#)).
- Zero or more EOF status lines (EOF lines) can be embedded at the end of a CSI2 frame.
- The SOF lines, pixel data, and EOF lines do not overlap.

The CSI2 receiver does not use the information in the status lines. However, it extracts it and stores it in memory for use by software.

Because the data types are different, the data is carried using separate data types called virtual channels. Those must be mapped to the adequate context. The CSI2 receiver uses a different context for embedded data and image-sensor data. See [Section 7.2.6.3.6.3.10, CSI2 Virtual Channel and Context](#).

Embedded data is supported as a context by the CSI2 receiver; therefore, there is no specific hardware support for embedded data.

Figure 7-39. CSI2 General Frame Structure (Informative)

Key:

PH: Packet header
FS: Frame start

PF: Packet footer
FE: Frame end

camss-246

Figure 7-40 shows the frame structure of a YUV4:2:2 interlaced video frame without embedded data.

Figure 7-40. CSI2 Digital Interlaced Video Frame (Informative)

Key:

- PH: Packet header
- FS: Frame start
- LS: Line start
- PF: Packet footer
- FE: Frame end
- LE: Line end

camss-247

The period between the LEC and the new LSC is called line blanking period. The time between the FEC and the new FSC is called frame blanking period. The receiver works with "near zero" line blanking period.

NOTE: The embedded information (SOF & EOF lines) is never compressed (no DPCM). The embedded information covers full lines. The embedded information is not encoded in the same data format as the pixel data. The CSI-2 receiver extracts the embedded information but does not modify the data format.

The pixel data can be compressed.

7.2.6.3.6.3.10 CSI2 Virtual Channel and Context

The CSI2 protocol layer transports virtual channels. The virtual channels separate different data flows interleaved in the same data stream. Each virtual channel is identified by a unique channel identification number in the packet header. This channel identification number is encoded in the 2-bit code.

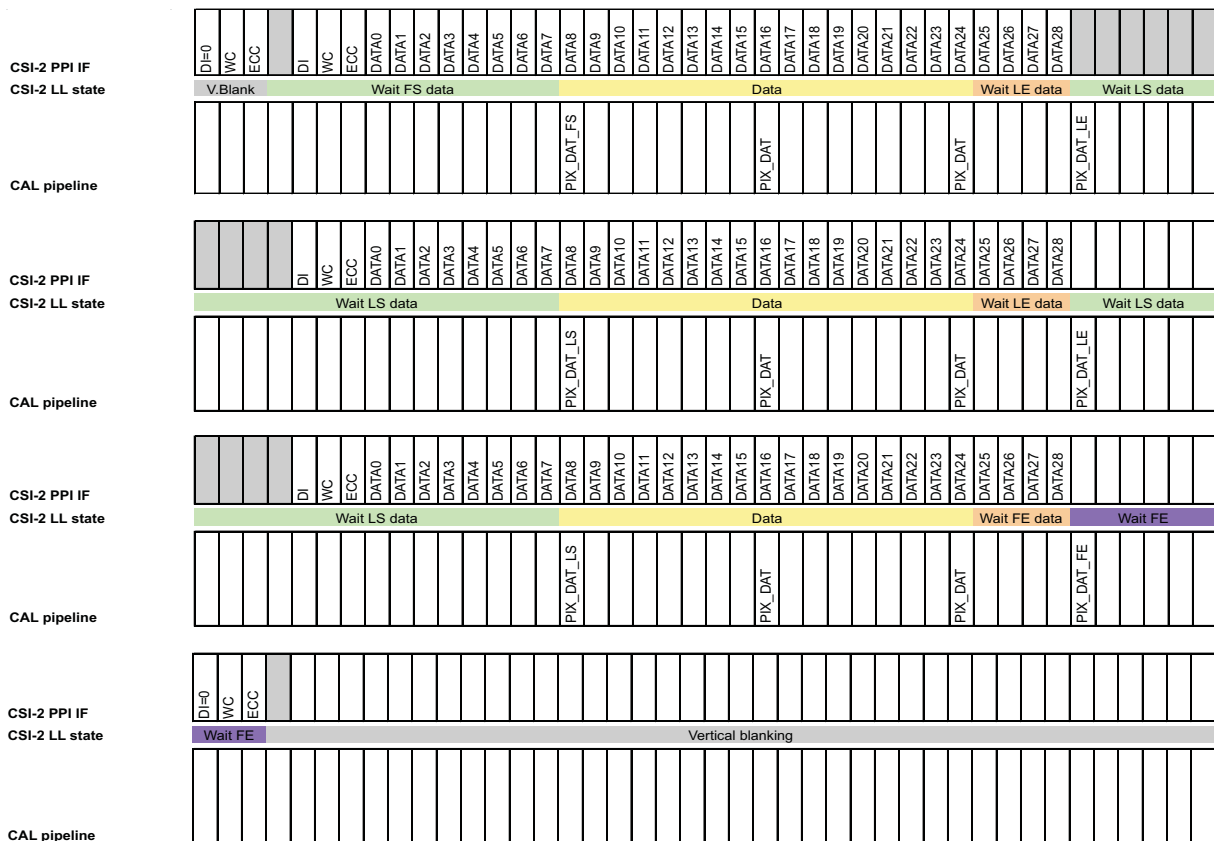

The CSI2 receiver monitors the channel identifier number and demultiplexes the interleaved data streams. The CSI2 receiver supports up to four concurrent virtual channels. The virtual channel values used for each channel are as follows:

- Virtual channel 0 -> 0x0
- Virtual channel 1 -> 0x1
- Virtual channel 2 -> 0x2
- Virtual channel 3 -> 0x3

7.2.6.3.6.4 CSI2 TAG Generation FSM

Figure 7-41 shows how the synchronization codes for the CAL internal pipeline are extracted from the CSI-2 stream. CSI-2 PPI IF corresponds to the byte stream after lane merge and PHY LS -> HS transition detection. CSI-2 LL state corresponds to the internal state of the TAG generation engine. CAL pipeline corresponds to the tags sent to the CAL processing pipeline.

Figure 7-41. CSI-2 LL Tag Generation Example - Line Mode

cam_010

Data is packed into words of 64-bits before it can be sent to the shared CAL processing pipeline. Each PPI has its own TAG generation & packing state machine. Both CSI2 PHYs are therefore independent and can operate simultaneously. Each PPI FSM has 8 copies of the CAL_CSI2_CTXy_I (y = [0 to 7], CAL_CSI2_CTX0_I through CAL_CSI2_CTX7_I) state registers (that is, contexts).

To use a context, SW must define:

- The used virtual channel (through CAL_CSI2_CTXy_I[7:0] VC register bit-field)
- The expected MIPI CSI-2 Data Type (through CAL_CSI2_CTXy_I[5:0] DT bit-field)
- The CPort ID to use (through CAL_CSI2_CTXy_I[12:8] CPORT bit-field) for the data, and if it should be tagged as Attribute (that is, Embedded) data or as Pixel data (through CAL_CSI2_CTXy_I[13] ATT bit).

Attribute data is tagged using ATT_DAT_S, ATT_DAT and ATT_E tags. Pixel data is tagged using PIX_DAT_FS, PIX_DAT, PIX_DAT_LE, PIX_DAT_LS, PIX_DAT_FE. Data reception is disabled by setting CAL_CSI2_CTXy_I[5:0] DT bit to 0.

The tag generation FSM accumulates words of up to 64-bits of data from the physical interface. Two SW selectable modes are supported:

- Line mode (set by CAL_CSI2_CTXy_I[14] PACK_MODE = 0). In this mode CAL generates frame (PIX_DAT_FS; PIX_DAT_FE) and line (PIX_DAT_LS, PIX_DAT_LE) synchronization codes using synchronization information provided by the CSI-2 transmitter. It pads words with 0's when the line end or frame end is reached and generates the adequate data validity qualifier (VQ). Line and frame starts always correspond to full 64-bit words (VQ=0x0). This is typically the mode to be used to receive pixel data.
- Frame mode (set by CAL_CSI2_CTXy_I[14] PACK_MODE = 1). In this mode CAL only generates PIX_DAT_FS and PIX_DAT_FE synchronization codes. PIX_DAT_LE and PIX_DAT_LS are replaced by PIX_DAT and adequate data validity qualifiers are generated to create a contiguous stream. This mode is typically used to receive a JPEG frame from a CSI-2 camera.

This appended dummy data can be cropped by the write DMA, or the hardware accelerator attached to the Video port. The shared CAL processing pipeline therefore always receives full 64-bit words. The line length is detected from the CSI-2 long packet header and mismatches are detected through CRC errors.

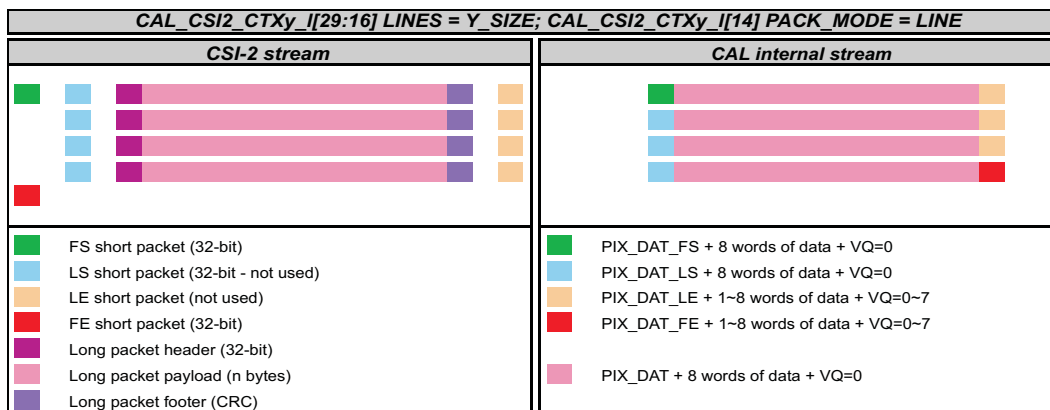

The tag generation FSM ensures that only valid TAG sequences can be provided to the shared CAL processing pipeline. FS, LS and LE codes are directly extracted from the CSI-2 stream. The FE code is not directly available and can be generated by two mechanisms:

- If SW knows the number of lines transmitted by the camera, it must write it into the CAL_CSI2_CTXy_I[29:16] LINES register bit-field. The tag generation FSM will send a FE TAG for the last received line of each frame instead of the LE TAG. This leads to regular video timings and avoids potential artifacts. CAL generates the FE_CODE tag when the FE short packet is received earlier than expected (for example, incorrect configuration or lines discarded due to transmission errors). The PIX_DATA_FE tag is generated at the end of the last line specified in CAL_CSI2_CTXy_I[29:16] LINES bit-field. Additional lines received for the same frame are discarded.
- If the number of lines is not known, SW must set the CAL_CSI2_CTXy_I[29:16] LINES register bit-field to 0. The tag generation FSM sends the PIX_DAT_LE TAG for the last line in the case and FE_CODE tag line when a FE short packet is received.

No LS/LE tags are generated when CAL_CSI2_CTXy_I[13] ATT = 1.

Figure 7-42 through Figure 7-45 illustrate the operation of the packing stage.

Figure 7-42. CSI-2 Packing – Example 1

cam_011

Figure 7-43. CSI-2 Packing – Example 2

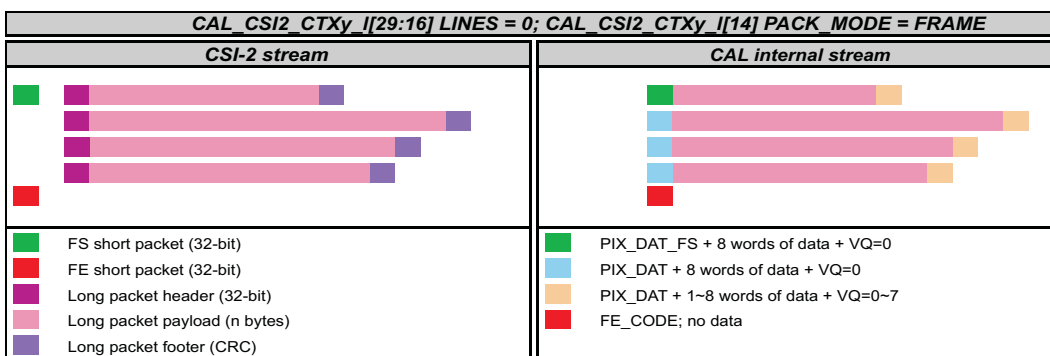

cam_012

Figure 7-44. CSI-2 Packing – Example 3

cam_013

Figure 7-45. CSI-2 Packing – Example 4

cam_014

Data is discarded and an FIFO_OVR event is triggered when the CAL shared pipeline cannot accept the data from PPI interfaces fast enough. The tag generation FSM ensures however that only valid tag sequences can be generated:

- Only a few words are dropped in the middle of a line: corresponding data words are dropped and synchronization TAGs (LE or FE) are transmitted normally. The line where the overflow has occurred is therefore corrupted (that is, pixels shifted left), but synchronization is recovered from the next line start.
- The overflow condition persists over a line or frame boundary: one or multiple lines/frames are dropped. HW waits until one word becomes available in the PPI FIFO and inserts a data word with TAG FE. It then waits for the next FS to resume normal operation.

No specific SW intervention is required to recover synchronization and the HW ensures that no protocol violations or accesses outside of allocated buffers could occur.

NOTE: Optional MIPI CSI-2 LS and LE short packets are ignored by CAL. They are allowed in the datastream from the camera, but are not used and not forwarded to the CAL shared processing pipeline.

CAL does not have a specific mechanism to ignore CRC checking. SW must simply disable the CS_IRQ event. CAL does not discard data with invalid CRC.

7.2.6.3.7 CAL Data Stream Merger

Two possible sources (2 x PPI, OCPI and RD DMA) can produce data that is sent through the shared CAL processing pipeline. The shared processing pipeline is time multiplexed at 64-bit word level. Data from the PPI interfaces cannot be stalled. It is therefore stored in a small FIFO (per each PPI) to compensate shared pipeline access latencies. Data from OCPI can be stalled to some extent as the external UniPro engine has its own FIFO. Data from the RD DMA is not timing critical.

A fixed priority arbitration scheme is used when data is ready from multiple sources. PPI_0 source is with highest priority, after that PPI_1.

PPI FIFOs are only intended to compensate internal pipeline access latencies. It is SW responsibility to ensure that the total pixel rates are compatible with CAL capabilities.

7.2.6.3.8 CAL Pixel Extraction

Software must configure which CPORT a given pixel processing context must process, by setting the [CAL_PIX_PROC_i\[23:19\]](#) CPORT register bit-field to the CPORT ID. The operation to perform is defined by the [CAL_PIX_PROC_i\[4:1\]](#) EXTRACT bit-field.

The data of a CPORT is forwarded without modification when pixel processing is disabled for that CPORT.

The pixel extraction stage receives up to 64 bits per cycle and can output either 64 bits (bypass) or 4 samples (6 ~ 16 bits per sample; 1 sample = 1 pixel for RAW data) per cycle.

Extracted pixels are left padded with 0's to fill 16-bit containers (for example, for RAW10: out[15:10]=0's and out[9:0]=data)

It only processes data tagged as DAT_PIX_FS, DAT_PIX_LS, DAT_PIX, DAT_PIX_FE, and DAT_PIX_LE (see [Figure 7-27](#), *CAL Data Pipeline TAGs*, for definitions). All other data types are simply forwarded (that is, output = input).

DAT_PIX_FS and DAT_PIX_LS tags reset the pixel extraction state-machine. That ensures proper recovery in case the pixel decoder goes out of sync for some reason (for example, TxBuffer overflow in the transmitter, wrong configuration, bad synchronization between hardware and software).

Four samples do not necessarily align with a complete 64-bit word and several bits remain unused. They are stored locally until enough data is available to extract four additional samples or the end of a line has been reached (that is, TAG = PIX_DAT_LE or PIX_DAT_FE). The last 64-bit word can be padded with 0's, if there is not enough data to generate 4 pixels after all data tagged as PIX_DAT_LE or PIX_DAT_FE has been processed.

The incoming dataflow (from OCPI or Read DMA) can be stalled to prevent data corruption:

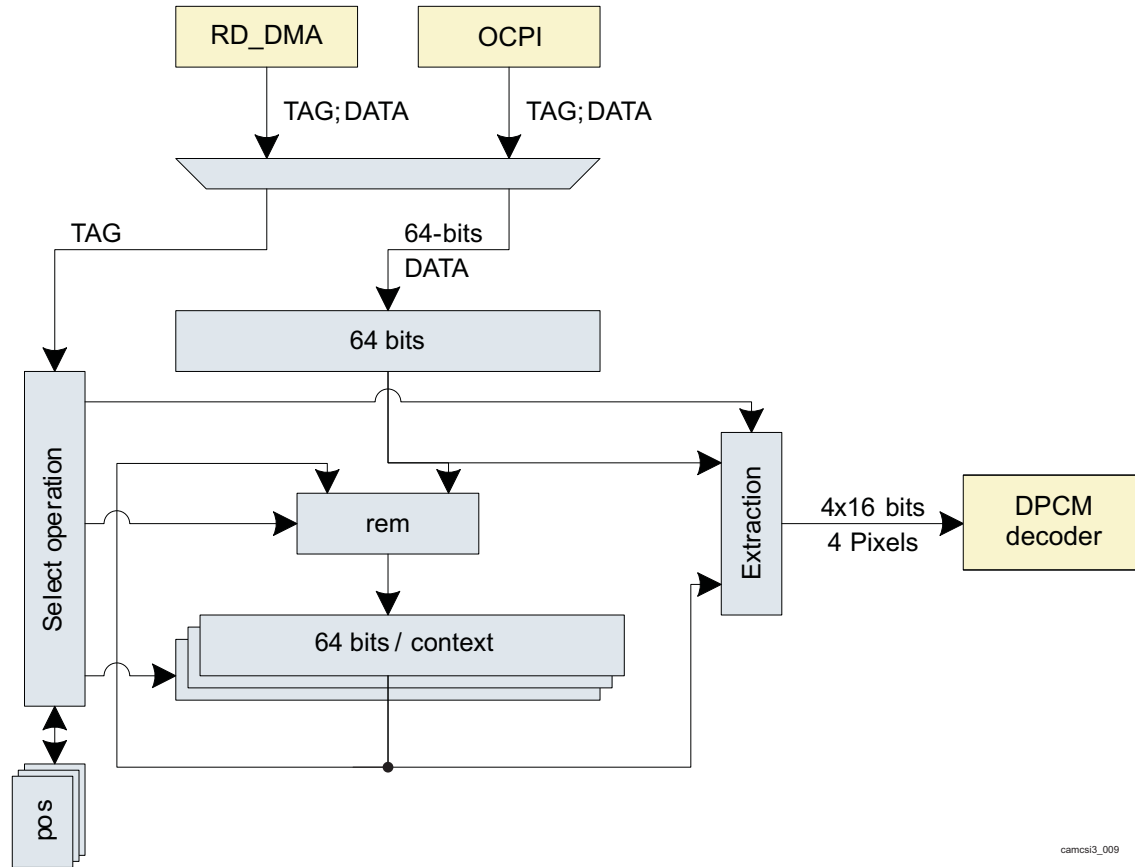

- When downstream modules cannot accept the data (that is, back-pressure from DPCM decoder)
- The extraction engine can only extract up to 4 pixels / cycle or forward complete 64-bit words without processing

Contexts can be interleaved with 64-bit word granularity (that is, two consecutive words can have different TAGs).

The number of contexts is as defined in the [CAL_HL_HWINFO\[12:8\]](#) PCTX register bit-field

Figure 7-46 shows the internal architecture of the pixel extraction module. It is composed of a 64-bit input buffer plus one 64-bit buffer per context (the number of contexts as defined in the CAL_HL_HWINFO[12:8] PCTX register bit-field). It has two computation units that extract four pixels per cycle and return the unused bits into the local storage.

Figure 7-46. CAL Pixel Extraction

NOTE: The pixel extraction engine does not process the VQ (data validity qualifier) generated by the CSI-2 data packing stage. It forwards the VQ when bypass mode is selected and replaces it by VQ=0 (all data valid) when data expansion is performed.

7.2.6.3.9 CAL DPCM Decoding and Encoding

The CAL DPCM decoder block only processes data tagged as DAT_PIX_FS, DAT_PIX_LS, DAT_PIX, DAT_PIX_LE and DAT_PIX_FE (as defined in Figure 7-27, CAL Data Pipeline TAGs). All other data types or data belonging to CPORTs where DPCM encode/decode is disabled, is simply forwarded. Software chooses which CPORT a given pixel processing context must process by setting the CAL_PIX_PROC_i[23:19] CPORT register bit-field to the CPORT ID. The DPCM decompression operation is selected through the CAL_PIX_PROC_i[9:5] DPCMD bit-field, and the DPCM compression operation is selected through the CAL_PIX_PROC_i[15:11] DPCME bit-field.

PIX_DAT_FS and PIX_DAT_LS tags initialize the DPCM encoder.

PIX_DAT_FS and PIX_DAT_LS tags initialize the DPCM decoder, except when the previous TAG received on that context was DPCM_INIT. DPCM_INIT copies the received word into the context status register of the DPCM decoder and discards the initialization word (that is, it is not forwarded to the next pipeline stage). The next word of four pixels received on that context is DPCM decoded and the usual initialization step is skipped. That feature is intended to enable DPCM decoding of an image in multiple vertical stripes without re-decoding each line from the beginning.

Table 7-486. CAL DPCM Formats

Codec	Predictor	Decode	Encode	Performance
10 - 8 - 10	Predictor 1	YES	YES	4 px/cyc
10 - 8 - 10	Predictor 2			
10 - 7 - 10	Predictor 1	YES		4 px/cyc
10 - 7 - 10	Predictor 2	YES		1 px/cyc
10 - 6 - 10	Predictor 1	YES		4 px/cyc
10 - 6 - 10	Predictor 2	YES		1 px/cyc
12 - 8 - 12	Predictor 1	YES	YES	4 px/cyc
12 - 8 - 12	Predictor 2			
12 - 7 - 12	Predictor 1	YES		4 px/cyc
12 - 7 - 12	Predictor 2			
12 - 6 - 12	Predictor 1	YES		4 px/cyc
12 - 6 - 12	Predictor 2			
14 - 10 - 14	Predictor 1	YES	YES	4 px/cyc
14 - 10 - 14	Predictor 2			
14 - 8 - 14	Predictor 1	YES	YES	4 px/cyc
14 - 8 - 14	Predictor 2			
16 - 12 - 16	Predictor 1	YES	YES	4 px/cyc
16 - 12 - 16	Predictor 2			
16 - 10 - 16	Predictor 1	YES	YES	4 px/cyc
16 - 10 - 16	Predictor 2			
16 - 8 - 16	Predictor 1	YES	YES	4 px/cyc
16 - 8 - 16	Predictor 2			

The DPCM encoder and decoder are independent. They preserve state for each of the pixel processing contexts (defined in `CAL_HL_HWINFO[12:8]` PCTX register bit-field), so that the encoder and the decoder context can be swapped with 4-pixel granularity.

The DPCM encoder and decoder can stall the incoming pixel from the pixel extraction block, if it arrives faster than what they can handle (that is, PREDICTOR2 selection or dataflow stalled by the pixel packing stage/write DMA).

7.2.6.3.10 CAL Stream Interleaving

CAL_A supports interleaving at pixel level of datastreams received from two cameras that are synchronized. Those two cameras are typically CSI-2 cameras attached to the PPI_0 and PPI_1 interfaces.

Figure 7-47 shows a physical view of the interleaving.

Figure 7-47. CAL_A PPI Interleaving - Physical View

cam_015

The actual interleaving is done after the DPCM decompression stage of the CAL processing pipeline and requires two linked pixel processing contexts. The interleaving feature is controlled by bit-fields [5:4] INTERLEAVE23 and [3:2] INTERLEAVE01 of the `CAL_CTRL1` register. CAL supports no interleaving, interleaving with 1 pixel granularity or interleaving with 4 pixel granularity.

Both PPI interfaces must be configured to forward the received bytestream to the internal processing pipeline using two separate CPORT IDs. The bytestream is then converted into words of 4 pixels by the two independent extraction contexts and DPCM decompressed. Up to this stage, the processing is identical to non interleaved mode.

Data generated by the two pixel processing contexts is stored in two small FIFOs when interleaving is enabled (bit-fields [5:4] INTERLEAVE23 and [3:2] INTERLEAVE01 of the CAL_CTRL1 register !=0). Otherwise, it is directly forwarded to the rest of the pipeline.

Figure 7-48 provides a logical view of a CAL stream interleaving.

Figure 7-48. CAL Stream Interleaving - Logical View

cam_016

The interleaver reads blocks of 2 or 4 pixels from the 2 FIFOs (physically stored in 16-bit containers) and interleaves the data with 1 pixel or 4 pixel granularity. Figure 7-49 below shows when pixels are read from the respective FIFOs (the number in the cell is the pixel position)

Figure 7-49. CAL Interleave FIFO reads

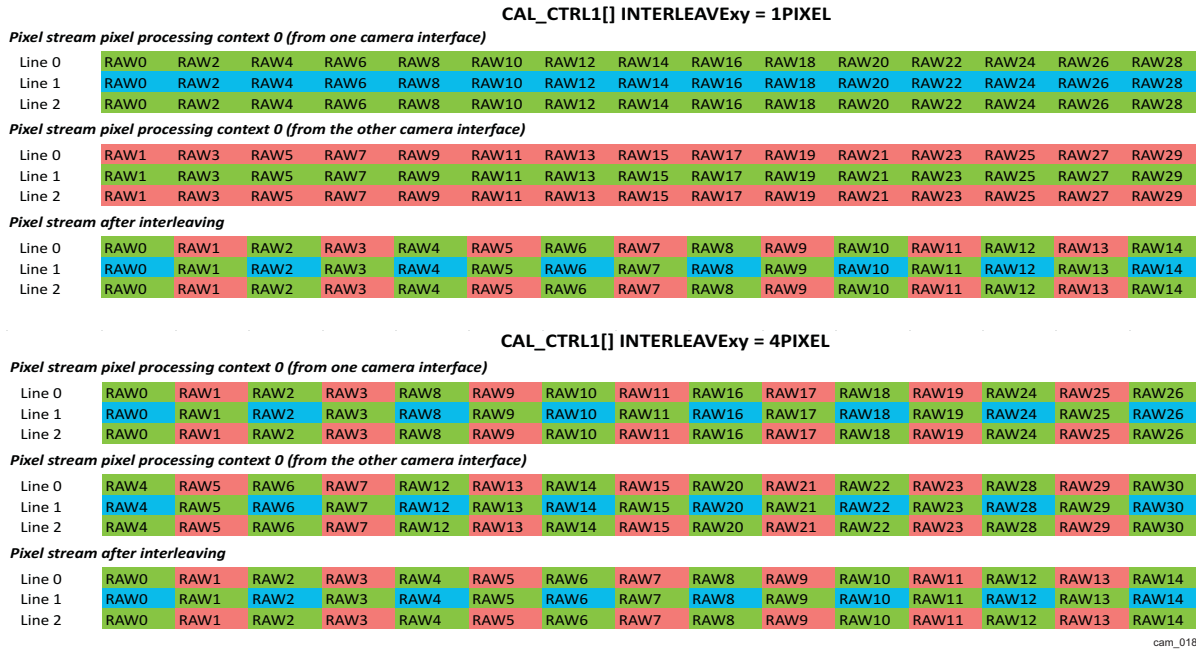

CAL_CTRL1[] INTERLEAVExy = 1

CYC	Read from FIFO0				Read from FIFO1			
0	0	1	2	3				
1					4	5	6	7
2	8	9	10	11				
3					12	13	14	15
4	16	17	18	19				
5					20	21	22	23

cam_017

Figure 7-50 illustrates the processing applied to a RAW pixel stream.

Figure 7-50. CAL Interleaver - Example of RAW Bayer Data

The datastream uses the pixel processing context #0 and its CPORT ID after interleaving.

NOTE: Bit-fields [5:4] INTERLEAVE23 and [3:2] INTERLEAVE01 of the `CAL_CTRL1` register must not be changed when the pixel processing contexts 0 or 1 are processing data.

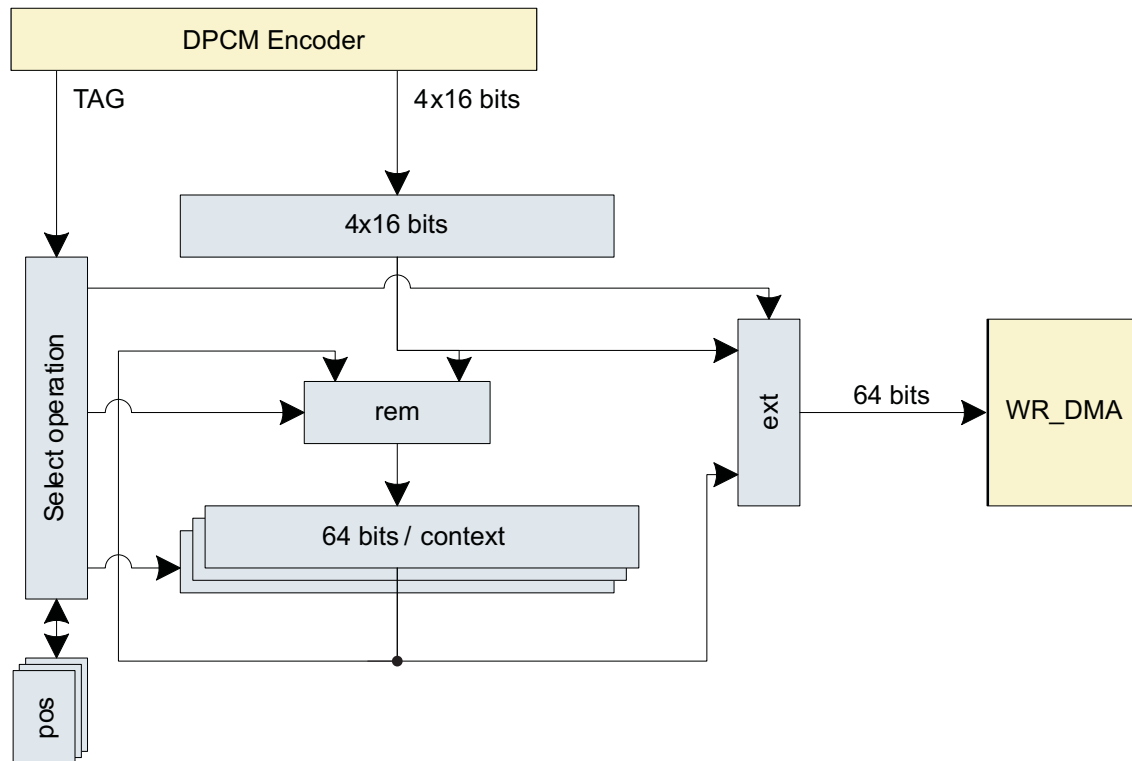

7.2.6.3.11 CAL Pixel Packing

Software selects which C-Port a given pixel processing context must process by setting the `CAL_PIX_PROC_i`[23:19] CPORT bit field to the CPORT ID. The operation to perform is defined by the `CAL_PIX_PROC_i`[18:16] PACK bit field.

The pixel packing stage only processes data tagged as `PIX_DAT_FS`, `PIX_DAT_LS`, `PIX_DAT`, `PIX_DAT_FE` and `PIX_DAT_LE`. All other data types or data belonging to a C-Port where pixel packing is disabled is simply forwarded. The packing stage is reset by `PIX_DAT_FS` and `PIX_DAT_LS` to recover synchronization in case it has been lost.

The pixel packing stage is flushed by a `PIX_DAT_FE`, `PIX_DAT_LE` and `PIX_DAT_LE` TAG: the last generated 64-bit word may be padded with 0's

Pixel packing is a symmetrical processing step to the pixel extraction (see [Section 7.2.6.3.8, CAL Pixel Extraction](#)). However, the list of supported formats is different. The pixel packing stage also has buffering to preserve temporary (that is, incomplete) data when contexts are switched. [Figure 7-51](#) below shows the internal architecture of the packing stage.

Figure 7-51. CAL Pixel Packing

camcsi2_010

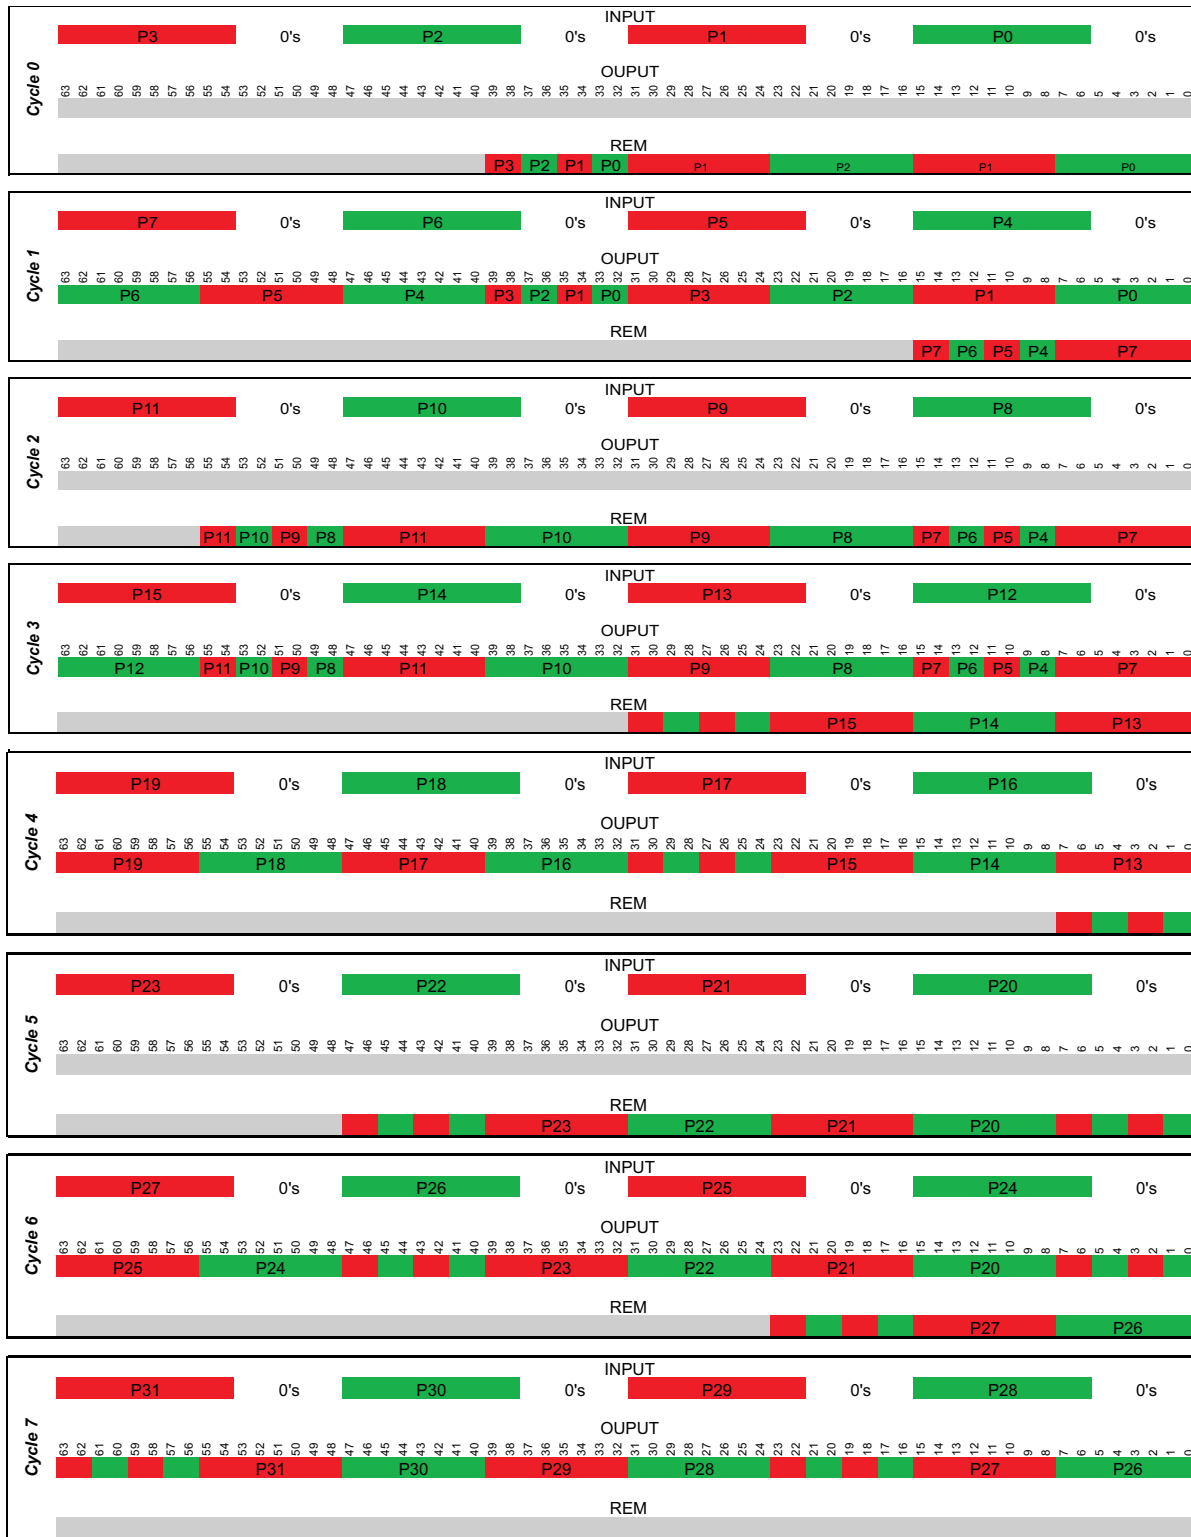

Supported packing modes are:

- RAW8 (8 bits per pixel)
- RAW10 (MIPI) (10 bits per pixel)
- RAW12 (linear) (12 bits per pixel)
- RAW12 (MIPI) (12 bits per pixel)
- RAW16 (16 bits per pixel)
- ARGB (32 bits per pixel)

The pixel packing engine does not process the VQ (data validity qualifier) generated by the CSI-2 data packing stage. It forwards the VQ when bypass mode is selected and replaces it by VQ=0 (all data valid) when data expansion is performed.

Figure 7-52 shows how the packing engine packs 32 consecutive pixels (equal to 8 active input cycles as 4 pixels are provided per cycle) into five 64-bit words ready to be sent to memory (REM).

Figure 7-52. CAL MIPI RAW10 Data Packing

camcs12-011

Figure 7-53 shows how the packing engine packs consecutive pixels (Px corresponds to a 16-bit pixel in the internal pipeline) into 64-bit words.

7.2.6.3.12 CAL Write DMA

NOTE: CAL_A is intended as an sensor interface and write to memory port.

7.2.6.3.12.1 CAL Write DMA Overview

The memory write DMA has WCTX (defined in [CAL_HL_HWINFO\[18:13\]](#) WCTX register bit-field) independent write contexts (that is, logical DMA channels). Each context receives a byte stream over a 64-bit wide bus as well as the TAG.

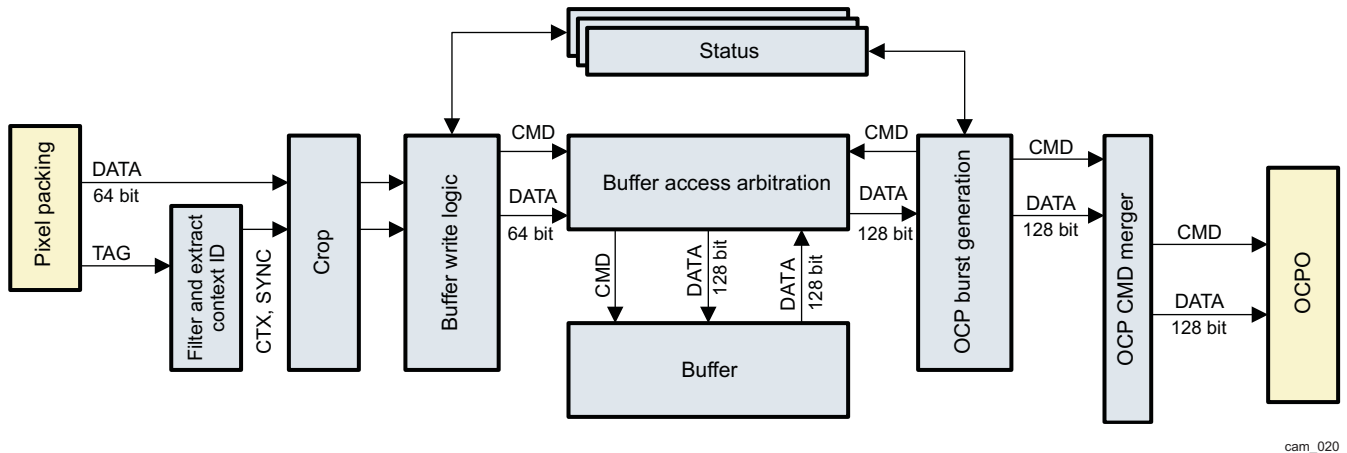

The write DMA filters incoming data using the CPORT number and data type contained in the TAG. Data is only processed, if it matches the CPORT number defined in the [CAL_WR_DMA_CTRL_k\[13:9\]](#) CPORT register bit-field and the data type defined in the [CAL_WR_DMA_CTRL_k\[8:6\]](#) DTAG bit-field. It also uses the received TAG to lookup the adequate context information and control the address generation logic.

Only one write context can process a given data word from the internal pipeline at the time. Said differently, the write DMA cannot be used to write two copies of the same data into separate locations. Software must prevent that two active write contexts have the same settings for `CAL_WR_DMA_CTRL_k[13:9]` CPORT and `CAL_WR_DMA_CTRL_k[8:6]` DTAG bit-fields.

Data that is not processed by the write DMA is discarded. Since the write DMA is the last stage in the CAL processing pipeline, it cannot forward data to a next stage.

Figure 7-54 shows a simplified block diagram of the write DMA engine.

Figure 7-54. CAL Pixel Packing – Data Storage in Memory

7.2.6.3.12.2 CAL Write DMA Data Cropping

It is possible to discard part of the received data for pixel and attribute data (that is, header and control data cannot be discarded). This is performed inside the write DMA cropping block. The feature is enabled by configuring:

- The position of the 1st byte to preserve in each line in the `CAL_WR_DMA_XSIZE_k[15:3]` XSKIP register bit-field
- The number of bytes to preserve for each line in the `CAL_WR_DMA_XSIZE_k[31:19]` XSIZE bit-field

The cropping block discards unwanted data and modifies data TAG to preserve integrity. For example, when pixel data is processed:

- PIX_DAT_FS => 1st word of a frame
- PIX_DAT_LS => 1st word of a line, except for the 1st line
- PIX_DAT_LE => last word of a line, except for the last line
- PIX_DAT_FE => last word of a frame
- PIX_DAT => any other pixel data

Cropping is mainly intended to enable partial DPCM decompression and to reduce storage requirements / power consumption when digital zoom is used. No dummy data will be written, if the programmed size is less than what is received. Refer to section Partial DPCM decompression for more details.

Cropping may also be used for attribute data. It cannot be used for header data. It is SW responsibility to not use cropping for header data. HW does not perform any additional checks.

The DMA accumulates data independently for contexts until an OCP write transaction can be generated. That is the case when enough data is available to generate a full burst or when the end of an image line has been reached.

NOTE: Data cropping is performed after the DPCM encoder. Therefore, horizontal skipping cannot be used when data is DPCM encoded. Otherwise, it will be not possible to decode the data, unless reference samples have been stored to resume decode.

7.2.6.3.12.3 CAL Write DMA Buffer Management

The DMA write buffer has two functions:

- Accumulate enough data to issue efficient OCP transactions
- Buffer data when it cannot be written to the OCPO port

Different write contexts do not have fixed locations in the write buffer to optimize the required buffer size. In fact, at a given point of time only some of the contexts are active while others are idle. There is no reserved space for unused contexts. Also, different contexts have different bandwidth requirements. Therefore, different amounts of data will pile up for different contexts when OCPO is stalled.

The buffer is divided into slots of $2^{(WDMA_SLOTSIZE+7)}$ bytes that are dynamically allocated to a context. CAL maintains some internal status information to manage the buffer:

- For each slot:
 - State (2 bits):
 - Empty
 - Open (ready to receive more data)
 - Closed (does not accept new data; ready for OCP burst generation)
 - Level (4 bits): amount of data currently stored in the data slot
 - Cleared when data has been sent to OCPO
 - Incremented by 8 bytes each time a new word of 64-bits is added
 - Destination Address (29 bits): destination address for an OCP burst
 - This value is computed when the 1st word of 64-bits is stored in the slot
 - All data of the slot is stored contiguously in memory. The HW allocates new slots to skip memory locations at line ends.
- For each context
 - Slot current in use (if applicable)
 - Destination address

The write DMA uses the data qualifier provided along with data words to pack data in the local working memory. It has a barrel shifter to pack data when lines ends do not correspond to 64-bit word boundaries and `CAL_CSI2_CTXy_I[14] PACK_MODE = 0x1` (Frame mode).

OCP bursts cannot span over multiple slots for design simplification. Refer to section OCP Transaction Generation for more details.

7.2.6.3.12.4 CAL Write DMA OCP Address Generation

7.2.6.3.12.4.1 Write DMA Buffer Base Address

The buffer base address (referred to as BASE, internal variable that cannot be read by SW) is automatically updated when an `ATT_HDR_S`, `ATT_DAT_S`, `CTRL_HDR_S`, `PIX_HDR_S` or `PIX_DAT_FS` is received by the write DMA using the following algorithm based around `CAL_WR_DMA_CTRL_k[2:0] MODE` register bit-field:

- `MODE = 0x0` (Disable): DMA is disabled
- `MODE = 0x1` (Ping/pong destination address on every frame):
 - `BASE = CAL_WR_DMA_ADDR_k`
 - `CAL_WR_DMA_ADDR_k = CAL_WR_DMA_ADDR_OLD`
 - `CAL_WR_DMA_ADDR_OLD = BASE`
- `MODE = 0x3` (Initialize start address for continuous mode. The first frame will be written at this address and consecutive frames will be appended):
 - `BASE = CAL_WR_DMA_ADDR_k`
 - `CAL_WR_DMA_ADDR_k = CAL_WR_DMA_ADDR_OLD`
 - `CAL_WR_DMA_ADDR_OLD = LINE_START` (See [Section 7.2.6.3.12.4.2, Write DMA Line Start](#))

Address, for further details)

- [CAL_WR_DMA_CTRL_k\[2:0\]](#) MODE = 0x2
- MODE = 0x2 (Continuously write data to memory):
 - BASE = LINE_START + [CAL_WR_DMA_OFST_k](#)
- MODE = 0x4 (Use [CAL_WR_DMA_ADDR_k](#) as base address)
 - BASE = [CAL_WR_DMA_ADDR_k](#)

After reset, [CAL_WR_DMA_ADDR_OLD](#) = 0x00000000. Software must update the [CAL_WR_DMA_ADDR_k](#) register after the first FE event with a valid destination address. Otherwise, data will be sent to address 0 which is typically not a valid destination.

7.2.6.3.12.4.2 Write DMA Line Start Address

The line start address is set to the base address when the base address is updated (that is, LINE_NUMBER = 0 at frame start). Otherwise, the line start address is updated upon reception of the PIX_DAT_LS tag depending on the [CAL_WR_DMA_OFST_k\[23:22\]](#) CIRC_MODE register bit-field and [CAL_WR_DMA_CTRL_k\[4:3\]](#) WR_PATTERN bit-field. [Table 7-487](#) summarizes how the line starts address (LINE_START) and line numbers are updated on every PIX_DAT_LS tag.

Table 7-487. Write DMA - Line Start Address Computation

CAL_WR_DMA_OFST_k[23:22] CIRC_MODE	CAL_WR_DMA_CTRL_k[4:3] WR_PATTERN	Description
0 (Disabled)	0 (Linear)	Linear buffer LINE_N = LINE_N + 1 LINE_START = LINE_START + CAL_WR_DMA_OFST_k[18:4] OFST
0 (Disabled)	2 (Write 2 lines, skip 2 lines)	Linear buffer + skip pattern if LINE_N #2 == 0: LINE_N = LINE_N + 1 LINE_START = LINE_START + CAL_WR_DMA_OFST_k[18:4] OFST else: LINE_N = LINE_N + 3 LINE_START = LINE_START + 3* CAL_WR_DMA_OFST_k[18:4] OFST
0 (Disabled)	3 (Write 2 lines, skip 4 lines)	Linear buffer + skip pattern if LINE_N #2 == 0: LINE_N = LINE_N + 1 LINE_START = LINE_START + CAL_WR_DMA_OFST_k[18:4] OFST else: LINE_N = LINE_N + 5 LINE_START = LINE_START + 5* CAL_WR_DMA_OFST_k[18:4] OFST
1 (1 Line) 2 (4 Lines) 3 (64 Lines)	0 (Linear)	Circular buffer if CIRC_MODE == 1: G = 1 elif CIRC_MODE == 2: G = 4 else: G = 64 if LINE_N == G* CAL_WR_DMA_OFST_k[31:24] CIRC_SIZE: LINE_N = 0 LINE_START = BASE else: LINE_N = LINE_N + 1 LINE_START = LINE_START + CAL_WR_DMA_OFST_k[18:4] OFST
different than 0	different than 0	Reserved. Do not use this combination.

NOTE: [CAL_WR_DMA_CTRL_k\[2:0\]](#) MODE must be set to 0x0 (disabled) or 0x4 (use [CAL_WR_DMA_ADDR_k](#) as base address), when [CAL_WR_DMA_OFST_k\[23:22\]](#) CIRC_MODE !=0.

7.2.6.3.12.4.3 Write DMA Data Address

Data received together with the ATT_HDR_S, ATT_DAT_S, CTRL_HDR_S, PIX_HDR_S, PIX_DAT_FS or PIX_DAT_LS tag is stored at the line start address (refer to section Line Start Address). For all other tags (ATT_HDR_E, ATT_DAT, ATT_DAT_E, PIX_HDR_E, CTRL_HDR_E, PIX_DAT, PIX_DAT_FE or PIX_DAT_LE), data is appended (that is, ADDR+ = 8, for each word of 64-bits).

Figure 7-55 illustrates how data is stored in memory when [CAL_WR_DMA_OFST_k\[23:22\]](#) CIRC_MODE = 0 (disabled) and [CAL_WR_DMA_CTRL_k\[4:3\]](#) WR_PATTERN = 0 (linear).

Figure 7-55. Write DMA - Framing

The write DMA channel with the lowest ID has the highest priority when multiple channels are ready to send data simultaneously.

Software can use [CAL_WR_DMA_XSIZE_k\[31:19\]](#) XSIZE = 0 in case the stream size is not known or exceeds the maximum range of the XSIZE bitfield. CAL skips the cropping feature in that case and sends all data to memory. However, software must still ensure that enough memory space has been allocated.

7.2.6.3.12.5 CAL Write DMA OCP Transaction Generation

The write DMA generates OCP write bursts of 1~8 x 16 bytes. A burst never crosses a 128 byte boundary. The maximum burst size is defined by the [CAL_CTRL\[6:5\]](#) BURSTSIZE register bit-field. The first and the last burst of a contiguous data block may use smaller burst sizes than defined in the BURSTSIZE bit-field. Bursts in the middle of the data block must use exactly the size defined in the BURSTSIZE bit-field.

7.2.6.3.12.6 CAL Write DMA Real Time Traffic

Traffic for which the pixel rate is imposed by the camera is qualified as hard real time traffic. Example of such hard real time traffic is data received from the camera (through PPI), optionally processed in the CAL and then sent to SDRAM using the OCPO port.

Hard real time traffic cannot be stalled for long periods of time. Indeed, the camera sends data at constant speed and it can only be stalled until FIFOs on the path are filled up. When FIFOs become full, data is discarded and the frame is therefore corrupted. To minimize the risk of real time data corruption, the device supports a mechanism that is activated by the MFlag generated by real time initiators.

MFlag generation must be disabled (through [CAL_CTRL\[20:13\]](#) MFLAGL = 0xFF and [CAL_CTRL\[31:24\]](#) MFLAGH = 0xFF), when CAL does not generate any real time traffic.

Static assertion of MFlag is only supported for debug purposes and must not be enabled for normal utilization (`CAL_CTRL[20:13] MFLAGL = 0x00` -> `MFlag=0x11`; `CAL_CTRL[20:13] MFLAGL = 0xFF` and `CAL_CTRL[30:24] MFLAGH = 0x00` -> `MFlag=0x01`).

Dynamic MFlag generation is to be used when the write DMA operates on real time data. In that case, the MFlag value depends on the number of slots (n) ready to generate transactions in the write DMA:

- MFlag = 00: SAFE ($n < \text{CAL_CTRL}[20:13] \text{MFLAGL}$)
- MFlag = 01: VULNERABLE ($\text{CAL_CTRL}[20:13] \text{MFLAGL} \leq n < \text{CAL_CTRL}[31:24] \text{MFLAGH}$)
- MFlag = 11: ENDANGERED ($\text{CAL_CTRL}[30:24] \text{MFLAGH} \leq n$)

Software must ensure that:

- $\text{CAL_CTRL}[20:13] \text{MFLAGL} \leq \text{CAL_CTRL}[30:24] \text{MFLAGH}$ (only 0x00 or 0x11 generated, when $\text{MFLAGL} = \text{MFLAGH}$)
- $\text{CAL_CTRL}[20:13] \text{MFLAGL} = 0x00, 0xFF$ or less or equal to $2^{(\text{CAL_HL_HWINFO}[3:0] \text{WFIFO} - 3)}$
- $\text{CAL_CTRL}[30:24] \text{MFLAGH} = 0x00, 0xFF$ or less or equal to $2^{(\text{CAL_HL_HWINFO}[3:0] \text{WFIFO} - 3)}$

7.2.6.3.13 CAL Read DMA

NOTE: CAL_B is intended as a read port and to feed the image pipe.

7.2.6.3.13.1 CAL Read DMA Overview

The read DMA is used to read pixel data from SDRAM and send it through the CAL_B processing pipeline. [Table 7-488](#) summarizes the mode combinations supported:

Table 7-488. CAL Supported Read DMA Mode Combinations

CIRC_MODE	RD_PATTERN	INIT	Description
0	LINEAR	0	Raster data from a single buffer
0	YUV420	0	YUV420 data from a two buffers
0	RD2SKIP2	0	Raster data from a single buffer with skip pattern
0	RD2SKIP4	0	Raster data from a single buffer with skip pattern
0	LINEAR	1	Raster data from a single buffer + DPCM initialization
0	YUV420	1	reserved.
0	RD2SKIP2	1	Raster data from a single buffer + skip pattern + DPCM initialization
0	RD2SKIP4	1	Raster data from a single buffer + skip pattern + DPCM initialization
>0	LINEAR	0	Raster data from a circular buffer
>0	YUV420	0	YUV420 data from a two circular buffers
>0	RD2SKIP2	0	reserved.
>0	RD2SKIP4	0	reserved.
>0	LINEAR	1	reserved.
>0	YUV420	1	reserved.
>0	RD2SKIP2	1	reserved.
>0	RD2SKIP4	1	reserved.

The read DMA fetches one to two streams simultaneously, depending on the chosen mode. Circular addressing and line skip patterns for both streams use the same algorithm than the write DMA (see [Section 7.2.6.3.12](#))

Reading of initialization data is optional and should be enabled before the read DMA is started by setting the `CAL_RD_DMA_CTRL[1]` INIT bit.

The read DMA is enabled by setting the `CAL_RD_DMA_CTRL[0]` GO bit. It sends the amount of data defined by configuration through the processing pipeline, triggers an `IRQ_RDMA_END` event and then returns into idle state until it is enabled again by SW.

7.2.6.3.13.2 CAL Read DMA Data Provided to Processing Pipeline

The read DMA generates adequate TAGs for proper control of the processing pipeline. It always uses the CPORT ID #0.

[Table 7-489](#) shows how data is sent through the CAL processing pipeline after it has been read from memory.

Table 7-489. CAL Read DMA

BUFF	POS X	POS Y	Read ADDR	SIZE	TAG
INIT		0	<code>CAL_RD_DMA_INIT_ADDR + 0 *</code> <code>CAL_RD_DMA_INIT_OFST</code>	8	DPCM_INIT
PIX	0	0	<code>CAL_RD_DMA_PIX_ADDR + 0 *</code> <code>CAL_RD_DMA_PIX_OFST + 0</code>	8	PIX_DAT_FS

PIX	16	(YSIZE-1)	<code>CAL_RD_DMA_PIX_ADDR + (YSIZE-1) *</code> <code>CAL_RD_DMA_PIX_OFST + 16</code>	8	PIX_DAT
PIX	(XSIZE-8)	(YSIZE-1)	<code>CAL_RD_DMA_PIX_ADDR + (YSIZE-1) *</code> <code>CAL_RD_DMA_PIX_OFST + (XSIZE-8)</code>	8	PIX_DAT_FE

7.2.6.3.13.3 CAL Read DMA Skipping Modes

CAL supports 2 line skipping read patterns. Those are mainly intended to provide vertically sub-sampled images. SW shall adjust the SDRAM start address to select the correct sub-sampled phase (i.e. +0 and +2 lines in RD2SKIP2 mode; +0, +2 and +4 lines in RD2SKIP4 mode). **CAL_RD_DMA_YSIZE** indicates the number of lines to read from SDRAM. It does therefore not include skipped lines.

7.2.6.3.13.4 CAL Read DMA YUV420 Support

CAL reads YUV420 NV12 or NV21 data from memory when `CAL_RD_DMA_CTRL2[5:4] RD_PATTERN = YUV420`. UV data is read twice and interleaved at byte level with Y data to provide YUV422 UYVY to the internal pipeline. The image size read from memory is `CAL_RD_DMA_XSIZE .XSIZE*8 bytes x CAL_RD_DMA_YSIZE .YSIZE lines` for the Y buffer and `CAL_RD_DMA_XSIZE .XSIZE*8 bytes x CAL_RD_DMA_YSIZE .YSIZE/2 lines` for the UV buffer. However, each UV line is read twice. The image size provided to the internal pipeline is `CAL_RD_DMA_XSIZE .XSIZE*16 bytes x CAL_RD_DMA_YSIZE .YSIZE lines`.

Figure 7-59. CAL Read DMA YUV420 Upsampling

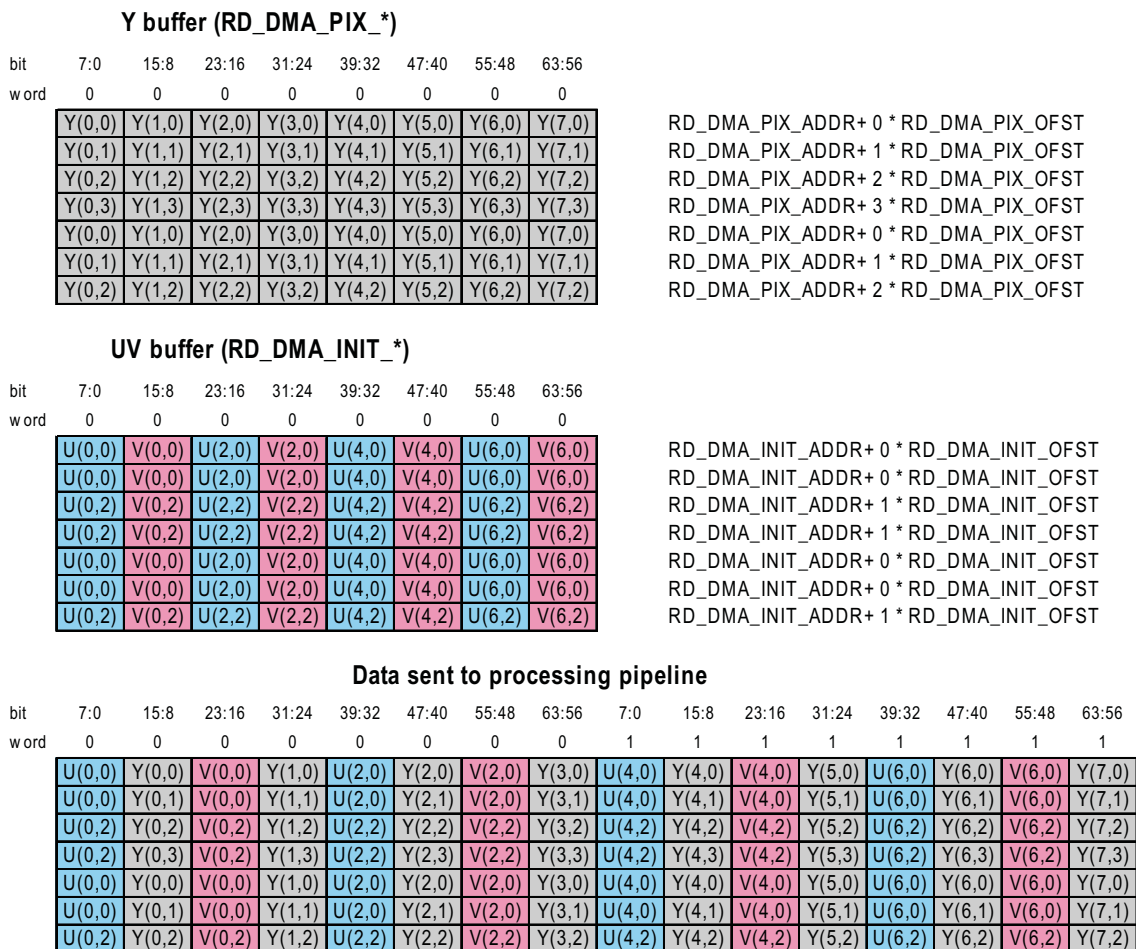

cam_025

NOTE: CAL duplicates chrominance data and does not interpolate it.

Circular mode can be combined with YUV420 upsampling. The spatial wrap point is the same for the Y and UV planes and UV lines are still read twice.

Figure 7-60. CAL Read DMA YUV420 Upsampling in Circular Mode

cam_026

7.2.6.3.13.5 CAL OCP Request Generation

The OCP request generation state machine loops through the 3 phases below for each image line until the complete image has been fetched.

- DPCM initialization data
 - [CAL_RD_DMA_CTRL](#) .INIT=1
 - Initialization data fetched as single request of 16 bytes
 - The source address must be 8 byte aligned. The RD DMA fetches 16 bytes (full OCP bus width) but only uses 8 of them (depending on bit 3 of the data fetch address)
 - [CAL_RD_DMA_CTRL](#) .INIT=0
 - This step is skipped
- Pixel data / Y data / UV data
 - When [CAL_RD_DMA_CTRL](#) .RD_PATTERN=YUV420, requests for Y and UV are interleaved at OCP burst boundary. Both streams share the same response FIFO and data is interleaved before sending it to the internal pipeline.
 - One ([CAL_RD_DMA_CTRL](#) .RD_PATTERN != YUV420) or two ([CAL_RD_DMA_CTRL](#) .RD_PATTERN=YUV420) smaller burst(s) is (are) issued to re-align OCP address to the burst boundary (defined by [CAL_CTRL](#) .BURST_SIZE)
 - "n" full sized bursts (defined by [CAL_CTRL](#) .BURST_SIZE) are issued to fetch the data in the

- middle of the line
- One (`CAL_RD_DMA_CTRL .RD_PATTERN/=YUV420`) or two (`CAL_RD_DMA_CTRL .RD_PATTERN=YUV420`) smaller burst(s) is (are) issued to fetch the remaining data at the line end (burst size is less than `CAL_CTRL .BURST_SIZE`).
 - A OCP can never cross a 128 byte boundary or be longer than the size define in `CAL_CTRL .BURST_SIZE`

Figure 7-61 shows a few graphical examples of OCP burst generation for pixel data.

Figure 7-61. CAL Read DMA OCP Request Generation for Pixel Data

Below is an example sequence of OCP transactions.

Parameters

`CAL_CTRL .BURST_SIZE` = 128

`CAL_RD_DMA_INIT_ADDR` = 0x00100020

`CAL_RD_DMA_INIT_OFST` = 0x00000008

`CAL_RD_DMA_PIX_ADDR` = 0x000027C0

`CAL_RD_DMA_PIX_OFST` = 0x000003E0

`CAL_RD_DMA_XSIZE` = 816

`CAL_RD_DMA_YSIZE` = 10

cam_028

The read DMA pipelines requests to OCPO for best performance. It has a FIFO to store prefetched data until it can be sent through the processing pipeline. It requests new data from SDRAM until the complete frame has been read. Requests can only be issued when:

- There is enough space in the FIFO to store the OCPO response
- OCPO is idle (i.e. write DMA requests have higher priority)
- No more than `CAL_RD_DMA_CTRL.TAG_CNT` read requests are outstanding
- No more than `CAL_CTRL.TAG_CNT` read+write requests are outstanding (note: 2 separate configuration registers are provided so that a certain number of tags can be reserved exclusively for write transactions)
- The last read request was issues more than `CAL_RD_DMA_CTRL.BW_LIMITER*8` clock cycles ago.

The read FIFO can only hold data from up to two consecutive images lines and their initialization data. Performance will be lower for very "small" lines when OCP latencies are "long" as the read FIFO will not prefetch "enough" data. Full performance is expected for image lines wider than 512 bytes.

7.2.6.3.13.6 CAL Read DMA Interrupt Flow Control

CAL exports several events to the Interrupt Controller and also supports the ICM flow control mechanism when ICM_CSTART=1. In this mode, the read DMA reads data in blocks of 1, 4, 16, or 64 lines (defined by the ICM_RD_DMA_CTRL2.CIRC_MODE register).

Read request generation is stalled until the CSTART pulse from Interrupt Controller is received. After reception of the CSTART pulse, read request are generated until the boundary of the block is reached. The circular event is then generated and also sent to Interrupt Controller (used as CDONE pulse).

Interrupt Controller sends the next CSTART pulse when enough data is ready to be read in the buffer. Only one CSTART signal is used to control read request generation for both streams supported by the read DMA. SW shall enable the RD DMA with Interrupt Controller support before enabling the corresponding CME in Interrupt Controller. That ensures that CAL does not receive CSTART pulses from the Interrupt Controller before it is ready to process them.

7.2.6.3.14 CAL Video Port

7.2.6.3.14.1 CAL Video Port Overview

Figure 7-63 shows the CAL video port internal architecture. It is composed of a timing generator and a FIFO.

The video port receives data + TAGs from the DPCM decoder stage. It filters the received data and only processes data that:

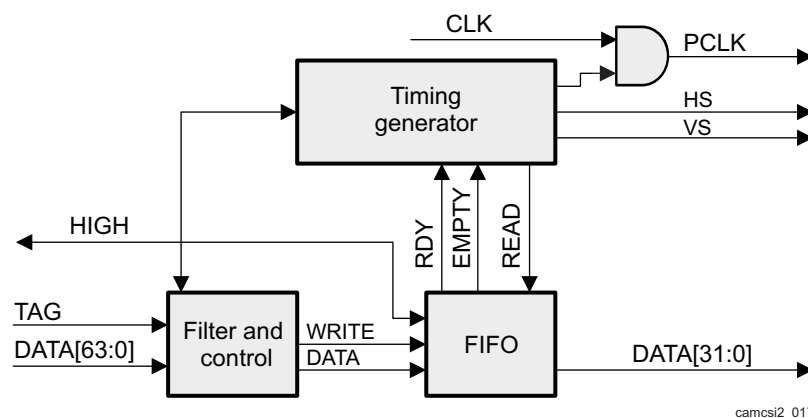

- Matches the CPORT ID defined by the CAL_VPORT_CTRL2[4:0] CPORT register bit-field
- Is tagged as PIX_DAT_FS, PIX_DAT_LS, PIX_DAT, PIX_DAT_LE or PIX_DAT_FE

In addition, it uses the FE_CODE tag to enter the vertical blanking period after the end of the horizontal blanking period when the vertical blanking period is not already started.

Other data is ignored by the video port (this does not affect the operation of other pipeline stages).

NOTE: Only one CPORT can use the video port and only pixel data can be sent to the video port (that is, control and attribute packets are ignored).

Figure 7-63. CAL Video Port and Timing Generator

The FIFO receives data from the internal processing pipeline at a variable rate (up to 4 pixels per cycle). The HIGH signal is asserted a few cycles before the FIFO becomes full. It is used to stall the incoming pixel flow. Therefore, no FIFO overflow can occur.

The timing generator is started after a PIX_DAT_FS tag, when the FIFO level exceeds the threshold defined in [CAL_VPORT_CTRL2\[31:18\] RDY_THR](#) bit field. This threshold is 0 by default but may be used to smooth the traffic on the video port .

The timing generator controls pixel reads from the FIFO. It only reads a pixel when:

- The current output position corresponds to an active location.
- Data is ready in the FIFO.

7.2.6.3.14.2 CAL Video Port Pixel Clock Generation

The video port pixel clock (VP_PCLK) is generated from the functional clock (CAL_FCLK). Software sets the peak pixel rate using the [CAL_VPORT_CTRL1\[16:0\] PCLK](#) register bit-field. The pixel rate is automatically controlled by the hardware, when data arrives from the RD_DMA.

The mean pixel clock rate on the video port can be given with the equation:

$$\text{VP_PCLK} = \text{CAL_FCLK} \times \text{CAL_VPORT_CTRL1[16:0] PCLK} / 65536$$

As VP_PCLK is generated from the CAL functional clock, some clock pulses are gated to reach the selected frequency. The following algorithm is used to generate the internal PCLK_EN signal:

1. ACC = [CAL_VPORT_CTRL1\[16:0\] PCLK](#)
2. If (ACC + [CAL_VPORT_CTRL1\[16:0\] PCLK](#) >= 65536) then PCLK_EN=1 else PCLK_EN=0
3. ACC = (ACC + [CAL_VPORT_CTRL1\[16:0\] PCLK](#)) % 65536
4. Go back to step #2

The configured pixel clock is used for active as well as for blanking periods.

7.2.6.3.14.3 CAL Video Port Video Timing Generator

The timing generator state-machine reuses the synchronization information received through TAGs to:

- Control state transitions
- Assert the VP_HS and VP_VS signals
- Detect when data is ready to be sent

For more details on the video port, refer to [Section 7.2.6.2.2, CAL Integration - Video Port](#).

The timing generator can be unconditionally reset in the following ways:

- A general hardware (by CAL_RST signal) or software (through the [CAL_HL_SYSCONFIG\[0\] SOFTRESET](#) register bit) reset
- Setting the [CAL_VPORT_CTRL2\[17\] FSM_RESET](#) bit

It is also reset by data tagged as PIX_DAT_FS when the [CAL_VPORT_CTRL2\[16\] FS_RESETS](#) bit is set. This bit is enabled by default, but may be disabled when vertical blanking times are very short and there is no risk of TX data dropping/desynchronizing.

Four VP_PCLK cycles are sent before the first active pixel . The video port state-machine then waits until four VP_PCLK cycles are sent after the last blanking cycle of the frame.

Active data is sent to the video port only when at least 4 × [CAL_VPORT_CTRL2\[31:18\] RDY_THR](#) pixels are available. That mechanism can be used to smooth the pixel rate on the video port, if input data arrives at bursty rate. The video port FIFO accumulates 4 × [CAL_VPORT_CTRL2\[31:18\] RDY_THR](#) after frame start before it sends the first pixel, and signal VP_VS = VP_HS = 1.

The video port can generate horizontal and vertical blanking in addition to pixels received from the CAL pipeline. The amount of blanking is defined by the [CAL_VPORT_CTRL1\[24:17\] XBLK](#) and [CAL_VPORT_CTRL1\[30:25\] YBLK](#) bit fields. The pixel clock is active at the chosen speed during blanking. VP_HS pulses are provided during vertical blanking. The pixel clock is cut during the idle period.

The timing generator is stalled (VP_PCLK = 0, state-machine stalled) when the current position is in the active video region (waiting for data), but no data is available. VP_PCLK is free running (at the speed defined by [CAL_VPORT_CTRL1\[16:0\] PCLK](#) bit-field) during horizontal and vertical blanking periods. No line PIX_DAT_HS, PIX_DAT_HE, PIX_DAT_VS, PIX_DAT_VE tags are expected by the video port state-machine during blanking periods.

NOTE: Software does not need to configure the size of the image for the video port. This information is extracted from the received datastream. Generally, to generate the vertical blanking, CAL counts the number of active pixels from the last image line.

The VP_VE signal is not generated when data comes from PPI interfaces, and no line or a too large number of lines have been configured in the CAL_CSI2_CTXy_j[29:16] LINES register bit-field. However, the PPI provides the FE_CODE tag when the FE short packet is received from the camera. The state machine enters into vertical blanking generation mode upon reception, in case of this tag (if it is not already in vertical blanking mode: in that case it has no effect).

7.2.6.3.15 CAL Registers Shadowing

Table 7-490 summarizes which CAL registers are shadowed.

Table 7-490. CAL Registers Shadowing

Register	Shadowed	Trigger	Additional Information
CAL_HL_REVISION	No	N/A	
CAL_HL_HWINFO	No	N/A	
CAL_HL_SYSCONFIG	No	N/A	
CAL_HL_IRQ_EOI	No	N/A	
CAL_HL_IRQSTATUS_RAW_j	No	N/A	
CAL_HL_IRQSTATUS_j	No	N/A	
CAL_HL_IRQENABLE_SET_j	No	N/A	
CAL_HL_IRQENABLE_CLR_j	No	N/A	
CAL_PIX_PROC_i[0] EN	Yes	FS @ pixel processing input	Format received on C-Port may change (for example between viewfinder and full frame). However, utilization of separate CPORTs is preferred (if camera sensor permits).
CAL_PIX_PROC_i other bits	No	N/A	Use separate contexts and EN bits, if pixel processing for a given CPORT must be changed on a frame by frame basis
CAL_CTRL	No	N/A	Typically not changed while there is active traffic
CAL_LINE_NUMBER_EVT	No	N/A	
CAL_VPORT_CTRL1	Yes	FS @ video port input	Blanking / PCLK settings may need to be changed on each frame; for example when binning / digital zoom settings change.
CAL_VPORT_CTRL2[] FSRESET bit	No	N/A	Control bit for debug only
CAL_VPORT_CTRL2 other bits	Yes	FS @ video port input	Pixel rate and source CPORT may need to change on the fly (that is, switch between camera modes that use separate CPORTs)
CAL_RD_DMA_CTRL	No	N/A	One-shot-operation only
CAL_RD_DMA_PIX_ADDR	No	N/A	One-shot-operation only
CAL_RD_DMA_PIX_OFST	No	N/A	One-shot-operation only
CAL_RD_DMA_XSIZE	No	N/A	One-shot-operation only
CAL_RD_DMA_YSIZE	No	N/A	One-shot-operation only
CAL_RD_DMA_INIT_ADDR	No	N/A	One-shot-operation only
CAL_RD_DMA_INIT_OFST	No	N/A	One-shot-operation only
CAL_WR_DMA_CTRL_k[1:0] MODE	Yes	FS @ CPORT = CAL_WR_DMA_CTRL_k[13:9] CPORT	Resolution may change for a given CPORT. That is not preferred but some sensors may require this mode.
CAL_WR_DMA_CTRL_k other bits	No	N/A	Use separate contexts and MODE bits, if size changes for a given CPORT.

Table 7-490. CAL Registers Shadowing (continued)

Register	Shadowed	Trigger	Additional Information
CAL_WR_DMA_ADDR_k	Yes	FS @ CPORT = CAL_WR_DMA_CTRL_k [13:9] CPORT	Output is typically double buffered so that CAL writes one buffer when the other buffer is read.

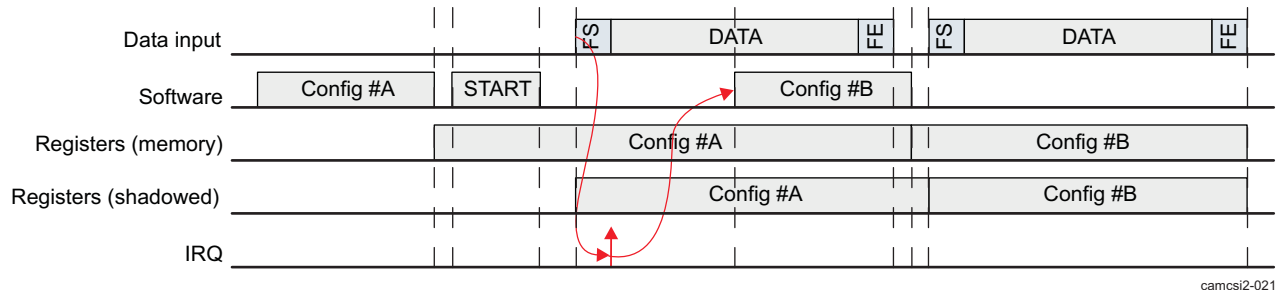

NOTE: Registers that are not shadowed are busy writable. Changes are immediately taken into account and may cause failure, if they are done while the hardware is using the register (that is, outside of the blanking periods).

For all shadowed registers, except [CAL_WR_DMA_ADDR_k](#), the content of the shadowed register is copied into the internal copy when the FS of the newly enabled stream is received by the corresponding engine. Said differently, new settings are taken into account just before they are needed. That maximizes time available to the software to change register settings. In particular, the first received FS copies initial settings into a shadow register.

The FS event is detected at the location in the pipeline where the setting applies. Said differently, the copy from shadow to working register does not occur exactly at the same time in all pipeline stages and there is no risk that the shadowing mechanism is activated too late or too early.

[Figure 7-64](#) shows an example. Software writes configuration #A and then starts the processing step. The value from the configuration register is copied into the shadowed register that is used by hardware when the PIX_DAT_FS tag is received by relevant pipeline stage. Software may use an IRQ to detect the frame start and provide the settings for the next frame. The frame start interrupt is triggered by the low-level protocol. This happens up to 8 cycles before the PIX_DAT_FS tag reaches the processing stage. Therefore, software must ensure that there is a delay of at least 8 functional clock cycles from the FS_IRQ to the configuration update. In a real world case, this delay is ensured by the IRQ controller plus software latency. Software must first read the [CAL_HL_IRQSTATUS_j](#) registers to detect which event has triggered the IRQ before it can update configuration registers.

Figure 7-64. CAL Registers Shadowing Example

camcsi2-021

The [CAL_WR_DMA_ADDR_k](#) register has a specific shadowing to avoid that multibuffer management is on the critical software path. For more details, see [Section 7.2.6.3.12.4](#), *Write DMA OCP Address Generation*.

Table 7-495. CAL_HL_HWINFO

Address Offset	0x0000 0004		
Physical Address	0x5201 2004 0x5201 3004	Instance	CAL_A CAL_B
Description	Information about the IP module's hardware configuration, i.e. typically the module's HDL generics (if any). Actual field format and encoding is up to the module's designer to decide.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
NPPI_CONTEXTS1	NPPI_CONTEXTS0	NCPORT				VFIFO				WCTX				PCTX				RFIFO				WFIFO									

Bits	Field Name	Description	Type	Reset
31:30	NPPI_CONTEXTS1	Number of contexts for PPI interface #1 Read 0x3: Read 0x2: PPI interface supported with 8 contexts Read 0x1: PPI interface supported with 4 contexts Read 0x0: PPI interface not supported	R	0x2
29:28	NPPI_CONTEXTS0	Number of contexts for PPI interface #0 Read 0x3: Read 0x2: PPI interface supported with 8 contexts Read 0x1: PPI interface supported with 4 contexts Read 0x0: PPI interface not supported	R	0x2
27:23	NCPORT	Number of supported CPORTs (including CPORT #0) minus 1. That number typically corresponds to the number of CPORTs that can provide data from OCPI. E.g. NCPORT=7 means that CAL implements 8 CPorts but one of them (CPORT0) is typically used for data read from memory and typically 7 (CPORT1~CPORT7) can be used for data received on OCPI Note: Equals NCPORT generic parameter minus 1	R	0x07
22:19	VFIFO	Video port FIFO size	R	0x9
18:13	WCTX	Number of implemented DMA write contexts	R	0x08
12:8	PCTX	Number of implemented pixel processing contexts	R	0x04
7:4	RFIFO	Read FIFO size 2 ^{RFIFO} words of 16 bytes	R	0x6
3:0	WFIFO	Write FIFO size 2 ^{WFIFO} words of 16 bytes	R	0x9

Address Offset	0x0000 0140	Instance	CAL_A CAL_B
Physical Address	0x5201 2140 0x5201 3140		
Description	Read DMA control register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PCLK																OCP_TAG_CNT						BW_LIMITER						INIT	GO		

Bits	Field Name	Description	Type	Reset
31:15	PCLK	Controls the data rate at which data is read from the read DMA FIFO and sent to the internal processing pipeline. Data rate = FCLK * 8 * PCLK / 2 ¹⁶ Bytes/s HW guarantees that data is never sent at faster rate than defined by this register. The data may be sent at slower rate when the RD DMA FIFO is empty or the processing pipeline is busy (data from OCPI has higher priority) Missed slots are not cummulated. Valid range: 0 .. 2 ¹⁶	RW	0x0 0000
14:11	OCP_TAG_CNT	Maximum allowed number of outstanding OCP read requests minus 1 (i.e. 0xF meand up to 16 outstanding requests)	RW	0x0
10:2	BW_LIMITER	Defines a minimum cycle count between to consecutive read requests issued by the RD DMA. Used to limit the SDRAM load in memory to memory mode. The pixel rate should be controlled at video port level when data read from memory is send to the video port. Valid range = 9..4095 cycles	RW	0x000

Bits	Field Name	Description	Type	Reset
1	INIT	Enable reading of DPCM decoder initialization data from SDRAM 0x0: Disabled 0x1: Enabled	RW	0
0	GO	Start data read from memory. This bit is set by SW and automatically cleared by HW when the frame has been processed. Write 0x0: No effect Write 0x1: Start read DMA Read 0x1: Read DMA BUSY / it is currently fetching data from memory and sends it to the processing pipeline Read 0x0: Read DMA idle / ready to receive the next start trigger from SW	RW	0

31:24	CIRC_SIZE	Circular buffer size minus one. Unit defined by the CIRC_MODE register. E.g. Circular buffer size = 16k lines when CIRC_SIZE=255 and CIRC_MODE=3	RW	0x00

Bits	Field Name	Description	Type	Reset
23:22	CIRC_MODE	Defines the granularity for circular buffer mode. Circular addressing mode shall be disabled (CIRC_MODE=0) when - CAL_WR_DMA_CTRL_k.MODE isn't CONST - for formats that don't have a concept of lines 0x0: Circular addressing mode disabled 0x1: 1 Line 0x3: 64 lines 0x2: 4 lines	RW	0x0
21:19	RESERVED		R	0x0
18:4	OFST	S14. Offset in words of 16 bytes.	RW	0x0000
3:0	RESERVED		R	0x0

Table 7-549. CAL_CSI2_PPI_CTRL_I

Address Offset	0x0000 0300 + (0x80 * I)	Index	I = 0 to 1
Physical Address	0x5201 2300 + (0x80 * I) 0x5201 3300 + (0x80 * I)	Instance	CAL_A CAL_B
Description	Controls the low level CSI-2 protocol interface (PPI)		
Type	RW		

Bits	Field Name	Description	Type	Reset
31:4	RESERVED		R	0x000 0000
3	FRAME	Set the modality in which IF_EN works. 0x0: If IF_EN = 0 the interface is disabled immediately. 0x1: If IF_EN = 1 the interface is disabled after all FEC sync code have been received for the active contexts.	RW	0
2	ECC_EN	Enables the Error Correction Code check for the received header (short and long packets for all virtual channel ids). 0x0: Disabled 0x1: Enabled	RW	0
1	RESERVED		R	0
0	IF_EN	Enables the physical interface to the module. 0x0: The interface is disabled. If CAL_CSI2_PPI_CTRL_I.FRAME = 0, it is disabled immediately. If CAL_CSI2_PPI_CTRL_I.FRAME = 1, it is disabled when all active contexts have received the FE sync code. 0x1: The interface is enabled immediately, the data acquisition starts on the next FS sync code.	RW	0

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0000
15	FORCE_RX_MODE_IO1	Control of ForceRxMode signal 0x0: De-assertion of ForceRxMode. The HW reset the bit at the end of the Force RX Mode assertion. The SW can reset the bit in order to stop the assertion of the ForceRXMode signal prior to the completion of the period. 0x1: Assertion of ForceRxMode	RW	0

Bits	Field Name	Description	Type	Reset
14	STOP_STATE_X16_IO1	Multiplication factor for the number of L3 cycles defined in STOP_STATE_COUNTER bit-field 0x0: The number of L3 cycles defined in STOP_STATE_COUNTER is multiplied by 1x 0x1: The number of L3 cycles defined in STOP_STATE_COUNTER is multiplied by 16x	RW	1
13	STOP_STATE_X4_IO1	Multiplication factor for the number of L3 cycles defined in STOP_STATE_COUNTER bit-field 0x0: The number of L3 cycles defined in STOP_STATE_COUNTER is multiplied by 1x 0x1: The number of L3 cycles defined in STOP_STATE_COUNTER is multiplied by 4x	RW	1
12:0	STOP_STATE_COUNTER_IO1	Stop State counter for monitoring. It indicates the number of L3 to monitor for Stop State before de-asserting ForceRxMode (Complex IO #1). The value is from 0 to 8191.	RW	0x1FFF

7.2.7 ISS Timing Control Module

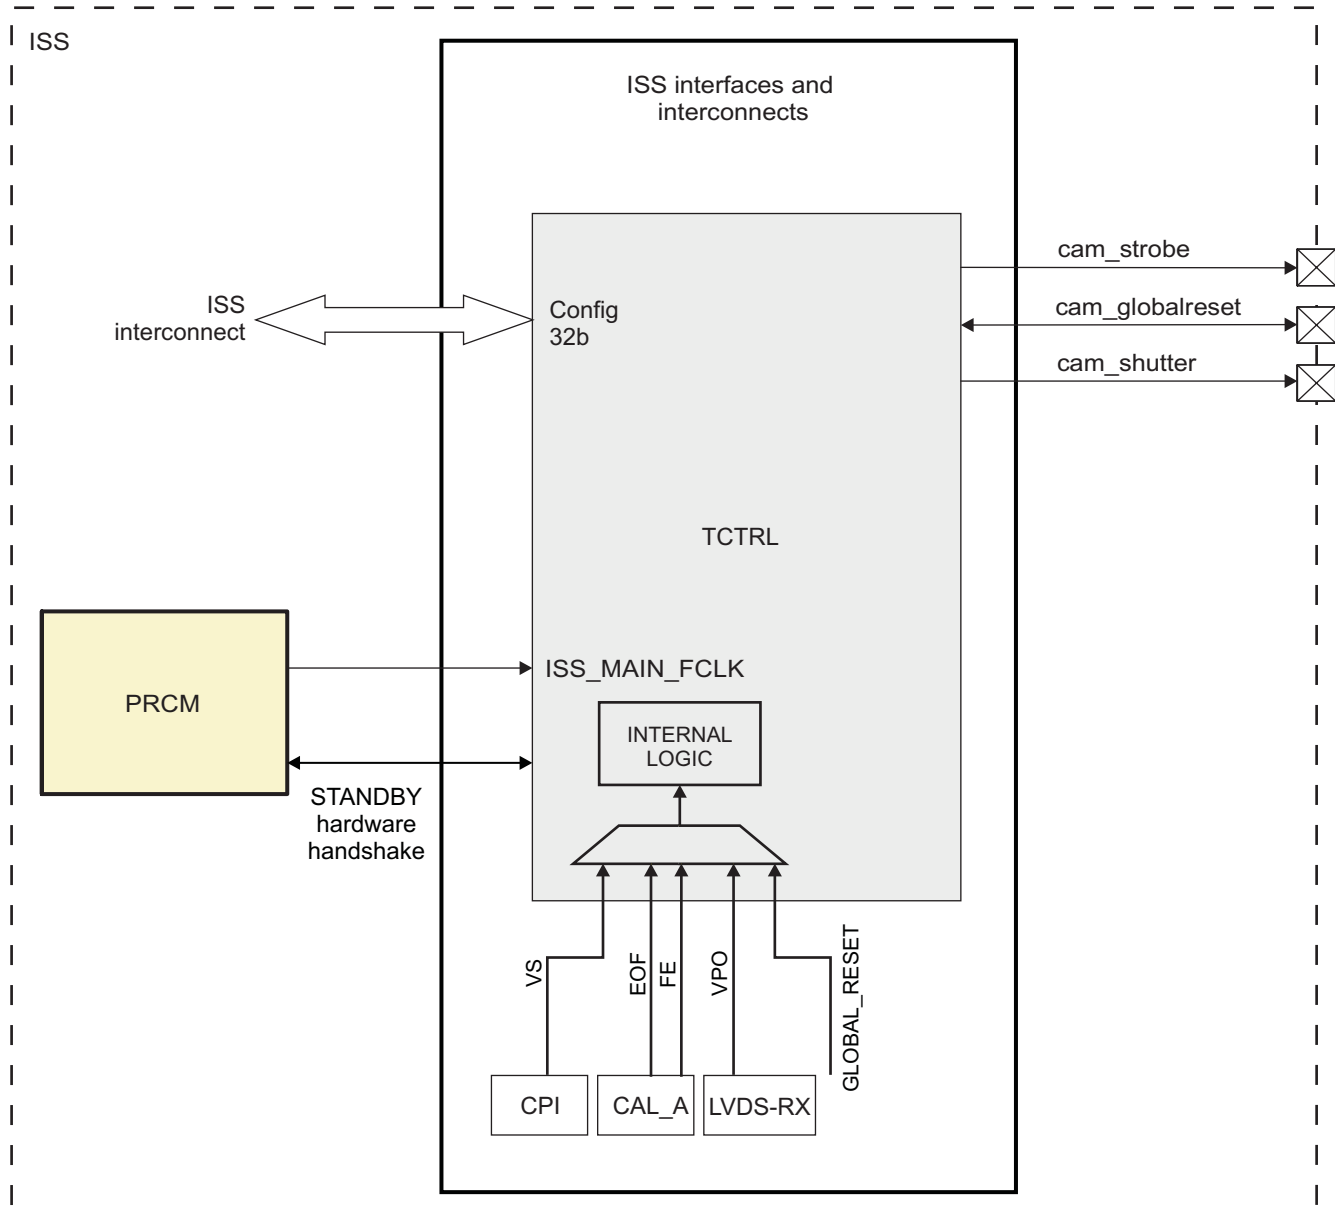

7.2.7.1 ISS TCTRL Environment

There are no particular environment attributes. See [Section 7.2.2, ISS Interfaces Environment](#).

7.2.7.2 ISS TCTRL Integration

[Figure 7-65](#) shows the integration of the TCTRL.

Figure 7-65. ISS TCTRL Integration

camss-355

For information about the power domain, clocks, reset, and hardware requests, see [Section 7.1.2.6, ISS Power Management](#).

7.2.7.3 ISS TCTRL Functional Description

7.2.7.3.1 ISS TCTRL Features

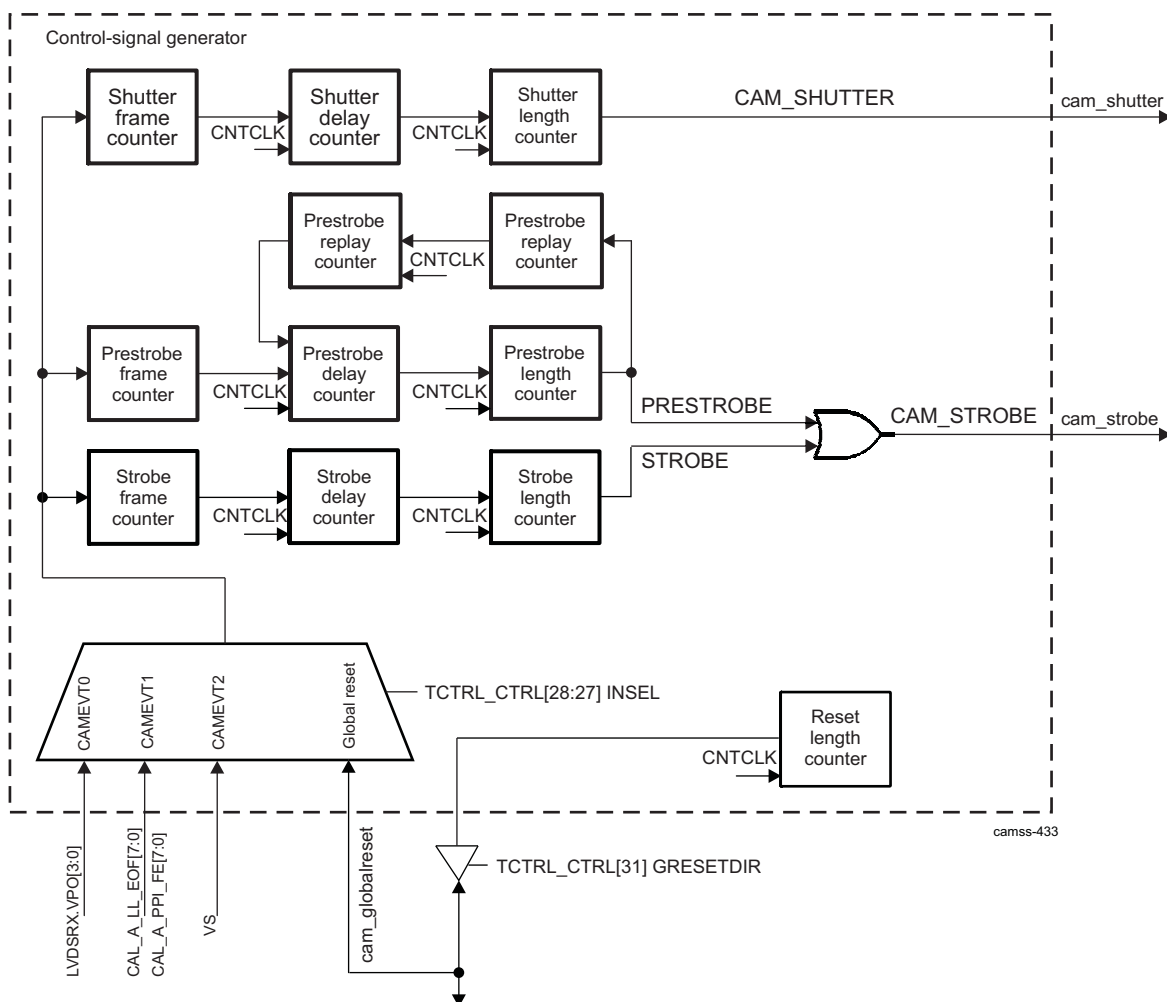

The TCTRL module receives synchronization events from one or multiple cameras and from an external global reset control mechanism. The synchronization event to be used is software configurable. The TCTRL generates the control signals (cam_strobe and cam_shutter) for the flash prestrobe, flash strobe, and mechanical shutters. It also provides a global reset output to erase sensor data before opening the mechanical shutter.

The TCTRL includes a timing generator and a control-signal generator.

7.2.7.3.2 ISS TCTRL Control-Signal Generator

The control-signal generator generates the prestrobe, strobe, and shutter signals: cam_strobe and cam_shutter. Figure 7-66 shows the principle of control-signal generation.

Figure 7-66. TCTRL Control-Signal Generation

The control-signal generator gathers precise timings for the cam_strobe and cam_shutter signals, to assert and deassert the signals at known times. The timing control-signal generator can be synchronized on the vertical synchronization signal coming from the LVDS-RX, CAL_A, Parallel interface (CPI), or on an externally generated cam_globalreset signal.

A multiplexer controls which of the LVDS-RX, CAL_A, or Parallel interfaces drives control-signal generation. This multiplexer can also select the externally generated cam_globalreset signal as the trigger event. The TCTRL_CTRL[31] GRESETDIR bit defines the direction of cam_globalreset.

- The externally generated cam_globalreset is used as a trigger when **TCTRL_CTRL[31] GRESETDIR = 0** and **TCTRL_CTRL[28:27] INSEL = 3** and **TCTRL_CTRL[20:19] INSEL_OVR = 0**.
- The internally generated cam_globalreset is used as a trigger when **TCTRL_CTRL[31] GRESETDIR = 1** and **TCTRL_CTRL[28:27] INSEL = 3**.

The cam_globalreset signal can also be generated internally by the control-signal generator under software control. In this case, the prestrobe and shutter signals are synchronized on internally generated cam_globalreset. The multiplexer controls whether control-signal generation must be triggered by the internal or external cam_globalreset.

The prestrobe-, strobe-, and shutter-control signals can be individually enabled at any time. These signals must not be disabled by software.

The clock divider generates the CNTCLK clock based on the functional clock (ISS_MAIN_FCLK). The clock divider is programmable. [Table 7-597](#) lists the possible frequencies as a function of the divisor values.

Table 7-597. ISS TCTRL Control-Signal Generator: CNTCLK Frequencies

Divisor Value TCTRL_CTRL[18:10] DIVC	CNTCLK Clock	CNTCLK Precision (ns)
0 (default)	Clock gated. No clock.	N/A
1	212.80 MHz	4.70
2	106.40MHz	9.40
3	70.93 MHz	14.10
4	53.20 MHz	18.80
...
510	0.42 MHz	2396.62
511	0.42 MHz	2401.32

There are three counters per control signal, plus three counters to control the pre-strobe generation, for a total of twelve counters. Each counter is programmable.

- The frame counter is decreased each time a full new frame is received.
 - A new frame is detected by the TCTRL module when CAMEVTx is received.
 - The frame counter determines how many whole frames must be ignored before the delay counter is triggered. The frame counters can be set to 0 to bypass the frame counters.
- The delay counter determines the control-signal activation delay. The counter is decreased at every CNTCLK clock cycle. When the counter reaches 0, the control signal is asserted. If the delay counter is set to 0, the control signal is asserted immediately.
- The activation-length counter determines the length of control-signal assertion. The counter is decreased at every CNTCLK clock cycle. When the counter reaches 0, the signal is deasserted and the control-signal enable bit is disabled. If the activation length is set to 0, the control signal is not asserted and the control-signal enable bit is disabled.

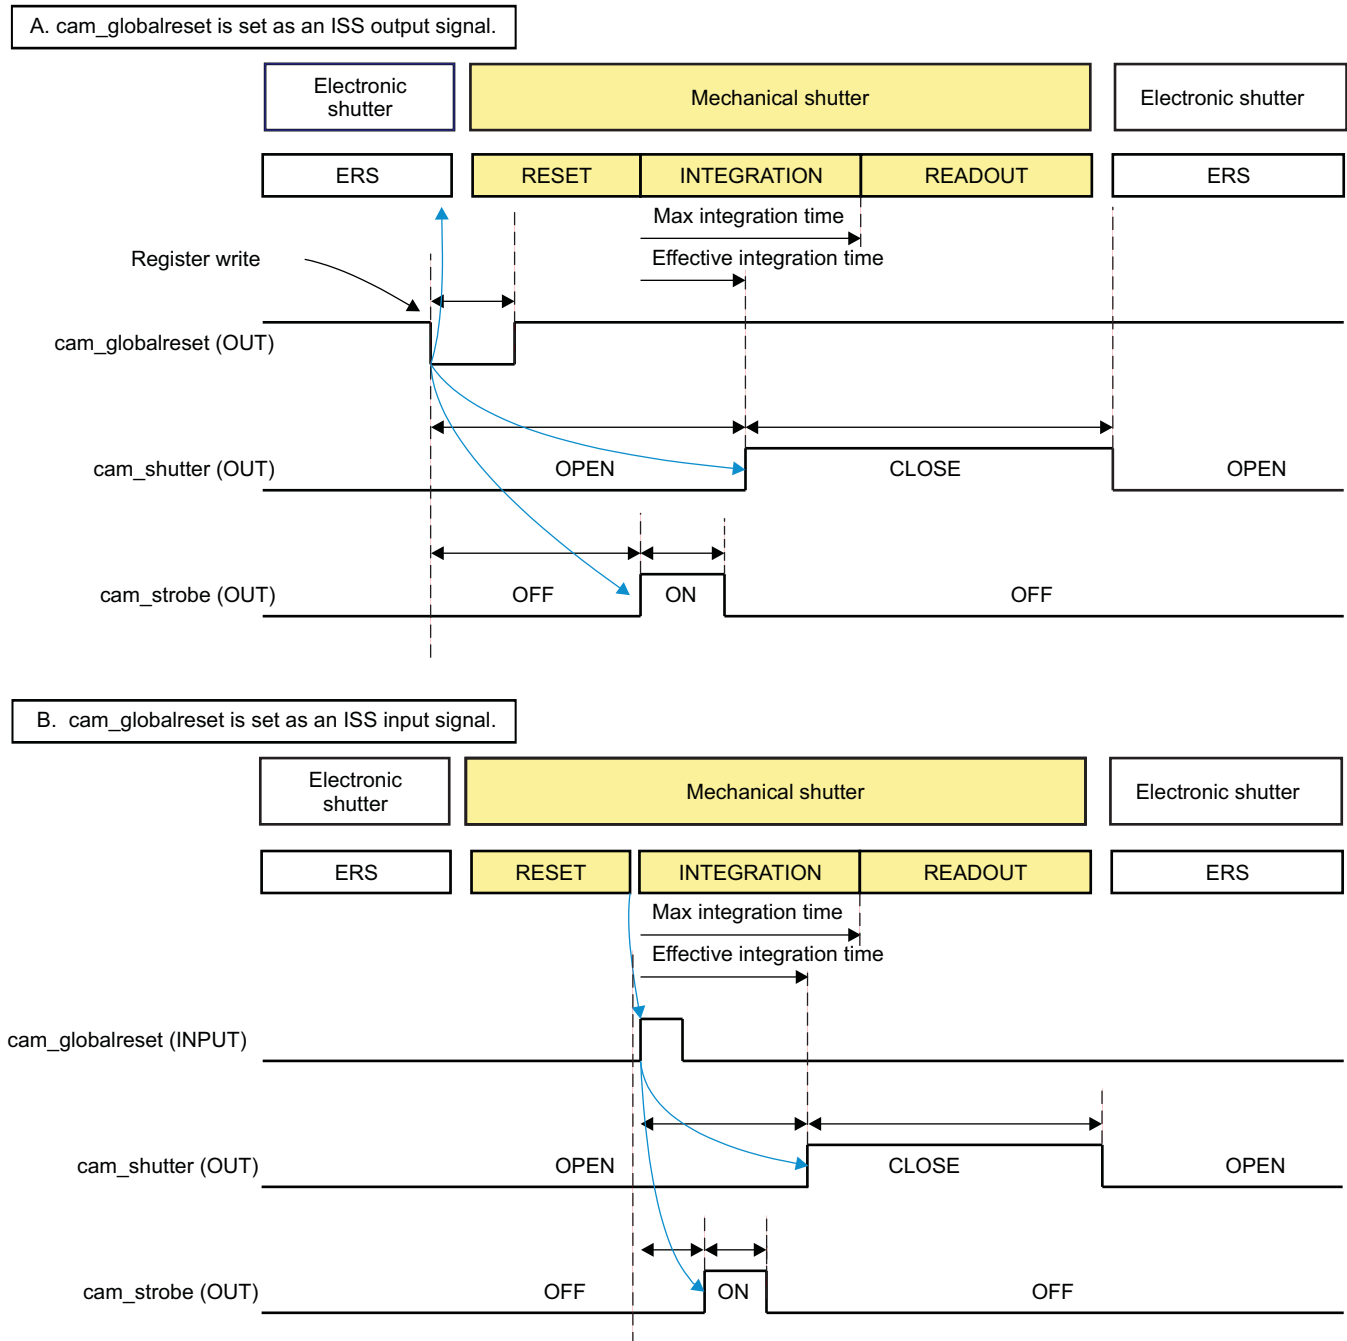

The polarity of the following signals can be individually selected:

- **TCTRL_CTRL[26] STRBPSTRBPOL** for the cam_strobe signals
- **TCTRL_CTRL[24] SHUTPOL** for the cam_shutter signal
- **TCTRL_CTRL[30] GRESETPOL** for cam_globalreset signal

Software can trigger the generation of cam_globalreset to the camera module. The length of signal-activation is programmable. The counter is decreased at every CNTCLK clock cycle. When the counter reaches 0, the signal is deasserted and the global reset enable bit is disabled (the **TCTRL_CTRL[29] GRESETEN** bit). If the activation length is set to 0, the control signal is not asserted and the control-signal enable bit is disabled. The polarity of cam_globalreset can be selected (the **TCTRL_CTRL[30] GRESETPOL** bit).

[Figure 7-67](#) shows the use of cam_globalreset set as an input or output signal. The cam_globalreset is asynchronous, edge-sensitive, and asserted for at least one interconnect clock cycle.

Figure 7-67. ISS TCTRL Use of cam_globalreset With Global Reset Release Camera Modules

camss-434

There are two types of shutter mechanisms: mechanical and electronic. A mechanical shutter is used only for high-resolution sensors. The three control signals (cam_globalreset, cam_shutter, and cam_strobe) are useful with a mechanical shutter. High frame rates can be achieved only with an electronic shutter. When an electronic shutter is used, none of the three control signals is used.

- Mechanical shutter mechanism:
 - Reset: All pixels of the sensor are reset to their black value. When the sensor has a global reset feature, the mechanical shutter can be open during reset.
 - Integration: The light received by the sensor is transformed into electrical charges that are stored inside pixels. At the end of the integration time, the shutter must be closed. Exposure time is

defined by the time between reset release and shutter close.

- Readout: The charges accumulated in pixels are converted to digital values that are sent to the camera receiver.
- Electronic rolling shutter (ERS) mechanism:
 - Each line of the sensor is reset separately and read after a fixed amount of time. Exposure time is defined by the time between reset and read.

7.2.7.4 ISS TCTRL Programming Model

The following settings must be done before enabling the TCTRL.

7.2.7.4.1 ISS TCTRL Camera-Control Signal Generator

Two configurations apply:

- First configuration: The control signals are based on the vertical synchronization information coming from the camera module or from externally generated cam_globalreset.
- Second configuration: The control signals are based on internally generated cam_globalreset.

7.2.7.4.1.1 ISS TCTRL Vertical Sync-Based Control-Signal Generation or Externally Generated cam_globalreset

To enable control-signal generation in the first configuration, follow the procedure listed in [Table 7-598](#).

Table 7-598. ISS TCTRL Enabling the Control-Signal Generation in First Configuration

Step	Bit Field	Value
Select the input that triggers the control signals. The trigger signal can come from the LVDS-RX, CAL_A, Parallel interface (CPI) or the externally generated cam_globalreset signal.	TCTRL_CTRL[28:27] INSEL	0x0: LVDS-RX 0x1: CAL_A 0x2: VS signal 0x3: Global reset

7.2.7.4.1.2 ISS TCTRL Internally Generated cam_globalreset-Based Control-Signal Generation

To enable control-signal generation in the second configuration, follow the procedure listed in [Table 7-599](#).

Table 7-599. ISS TCTRL Enabling the Control-Signal Generation in Second Configuration

Step	Bit Field	Value
Select the input to global reset, to loop back the internally generated CAM_GLOBALRESET. Vertical synchronization events do not trigger the CAM_STROBE and CAM_SHUTTER signals.	TCTRL_CTRL[28:27] INSEL TCTRL_CTRL[20:19] INSEL_OVR	0x3: Global reset 0x0: Use settings defined in INSEL
Set the global reset as output signal.	TCTRL_CTRL[31] GRESETDIR	0x1
The following bits are cleared automatically to 0 after the signal assertion:	<ul style="list-style-type: none"> TCTRL_CTRL[21] SHUTEN TCTRL_CTRL[22] PSTRBEN TCTRL_CTRL[23] STRBEN TCTRL_CTRL[29] GRESETEN 	0x0
Set the polarity of the CAM_SHUTTER, CAM_STROBE, and CAM_GLOBALRESET signals.	<ul style="list-style-type: none"> TCTRL_CTRL[24] SHUTPOL TCTRL_CTRL[26] STRBPSTRBPOL TCTRL_CTRL[30] GRESETPOL 	
Set the clock divisor value, which generates the CNTCLK clock. The clock is set by CNTCLK = ISS_MAIN_FCLK / TCTRL_CTRL[18:10] DIVC.	TCTRL_CTRL[18:10] DIVC	0x0: Disable CNTCLK 0 to 511: Divider
Set the frame counters.	<ul style="list-style-type: none"> TCTRL_FRAME[5:0] SHUT TCTRL_FRAME[11:6] PSTRB TCTRL_FRAME[17:12] STRB 	0: TCTRL does not delay any frame in input. 1 to 63
Set the delay counters.	<ul style="list-style-type: none"> TCTRL_SHUT_DELAY TCTRL_PSTRB_DELAY TCTRL_STRB_DELAY 	The possible values are 0 to $2^{25} - 1$ cycles. The cycles are at the CNTCLK clock frequency. The maximum signal duration is $(2^{25} - 1) \times 511/212.80 \text{ MHz} = 80.574784 \text{ s}$ (TCTRL_CTRL[18:10] DIVC = 511).

Table 7-599. ISS TCTRL Enabling the Control-Signal Generation in Second Configuration (continued)

Step	Bit Field	Value
Set the signal durations.	<ul style="list-style-type: none"> TCTRL_SHUT_LENGTH TCTRL_PSTRB_LENGTH TCTRL_STRB_LENGTH 	The possible values are 0 to $2^{24} - 1$ cycles. The cycles are at the CNTCLK clock frequency. The maximum signal duration for a 212.80 MHz input clock is $(2^{24} - 1) \times 511/212.80$ MHz = 40.287391 s (TCTRL_CTRL.DIVC = 511).
Set the cam_global_reset assertion time.	TCTRL_GRESET_LENGTH	The possible values are 0 to $2^{24} - 1$ cycles. The cycles are at the CNTCLK clock frequency. The maximum signal duration for a 212.80 MHz input clock is $(2^{24} - 1) \times 511/212.80$ MHz = 40.287391 s (TCTRL_CTRL.DIVC = 511).
Enable the CAM_SHUTTER signal.	TCTRL_CTRL[21] SHUTEN	0x1
Enable the PRESTROBE signal.	TCTRL_CTRL[22] PSTRBEN	0x1
Enable the CAM_STROBE signal.	TCTRL_CTRL[23] STRBEN	0x1
Enable the CAM_GLOBALRESET control-signal generation.	TCTRL_CTRL[29] GRESETEN	0x1

NOTE: Setting the following bits to 1 simultaneously leads to unpredictable behavior:

- TCTRL_CTRL[21] SHUTEN
- TCTRL_CTRL[22] PSTRBEN
- TCTRL_CTRL[23] STRBEN
- TCTRL_CTRL [29] GRESETEN

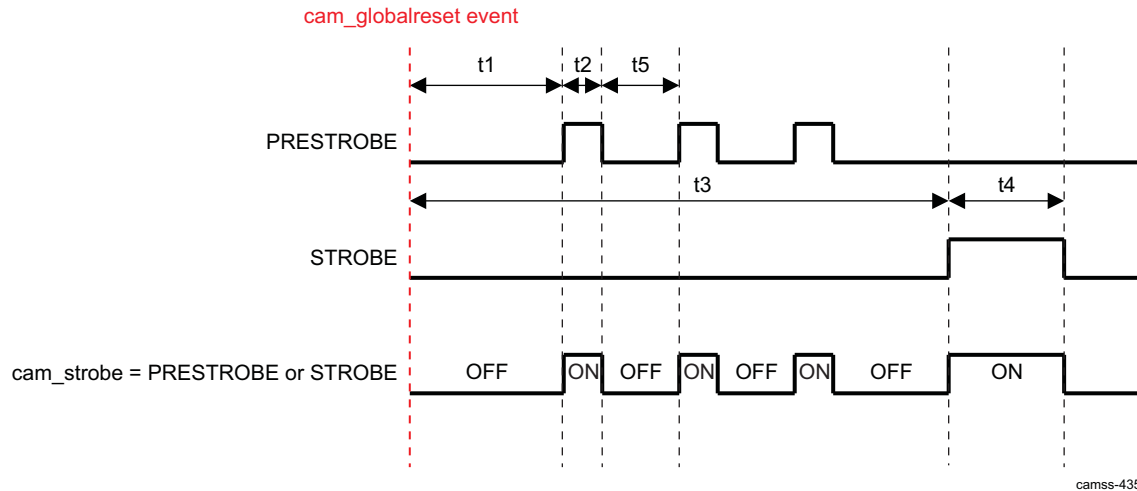

The following bits must be set before TCTRL_CTRL[29] GRESETEN is enabled:

- TCTRL_CTRL[21] SHUTEN
- TCTRL_CTRL[22] PSTRBEN
- TCTRL_CTRL[23] STRBEN

7.2.7.4.1.3 ISS TCTRL cam_strobe Signal Generation for Red-Eye Removal

The cam_strobe signal generation enables a strobe flash for red-eye removal. The process is shown in [Figure 7-68](#). The dotted line corresponds to known timings from which the delay counters start decreasing: cam_globalreset event.

Figure 7-68. cam_strobe Signal-Generation for Red-Eye Removal

- t1: Set by the [TCTRL_PSTRB_DELAY](#) register
- t2: Set by the [TCTRL_PSTRB_LENGTH](#) register
- t5: Set by the [TCTRL_PSTRB_REPLAY\[24:0\]](#) DELAY bit field. The number of times the pulse is repeated is controlled by the [TCTRL_PSTRB_REPLAY\[31:25\]](#) COUNTER bit field. In the previous example, [TCTRL_PSTRB_REPLAY\[31:25\]](#) COUNTER = 2.
 - The possible delay values are 0 to $2^{25} - 1$ cycle. The cycles are at the CNTCLK clock frequency. The maximum signal duration is $(2^{25} - 1) \times 511/212.80 \text{ MHz} = 80.574784 \text{ s}$ ([TCTRL_CTRL\[18:11\]](#) DIVC = 511).
 - The possible count values are 0 to 127 additional pulses.
- t3: Set by the [TCTRL_STRB_DELAY](#) register
- t4: Set by the [TCTRL_STRB_LENGTH](#) register

Table 7-622. TCTRL_CTRL

Address Offset	0x0000 0030	Instance	ISS_TCTRL
Physical Address	0x5200 00F0		
Description	TIMING CONTROL - CONTROL REGISTER		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
GRESETDIR	GRESETPOL	GRESETEN	INSEL	STRBPSTRBPOL	RESERVED	SHUTPOL	STRBEN	PSTRBEN	SHUTEN	RESERVED	DIVC											RESERVED									

Bits	Field Name	Description	Type	Reset
31	GRESETDIR	Sets the direction of the CAM_GLOBAL_RESET signal. 0x0: INPUT – CAM_GLOBALRESET is an input to the TIMING CONTROL module. The CAM_GLOBALRESET is externally generated. 0x1: OUTPUT – CAM_GLOBALRESET is an output of the TIMING CONTROL module. CAM_GLOBALRESET is internally generated. If GRESETEN is set to 1, the internally generated CAM_GLOBALRESET will trigger the generation of the PRESTROBE, STROBE and SHUTTER signals. The frame counters are ignored.	RW	0
30	GRESETPOL	Sets the polarity of the global reset signal: CAM_GLOBALRESET. It applies whatever the direction of the CAM_GLOBALRESET signal: input or output. 0x0: active high 0x1: active low	RW	0

Bits	Field Name	Description	Type	Reset
29	GRESETEN	Triggers the generation of the CAM_GLOBALRESET signal. The signal is asserted immediately. If enabled, the CAM_GLOBALRESET signal will be asserted for TCTRL_GRESET_LENGTH cycles. After the signal assertion, the enable bit is automatically cleared to 0. The polarity of the CAM_GLOBALRESET signal is set with TCTRL_CTRL.GRESETPOL . Enabling this bit triggers the generation of the CAM_SHUTTER and CAM_STROBE signals (if previously enabled). The frame counters must be set to 0 when this bit is set to 1 and GRESETDIR is set a OUTPUT.	RW	0
28:27	INSEL	Sets the mode that will trigger the SHUTTER, PRESTROBE and STROBE signals. 0x0: Synchronization event from camera 0 0x1: Synchronization event from camera 1 0x2: Synchronization event from camera 2 (serial interfaces muxed with the camera Parallel interface (CPI)) 0x3: GRESET – The CAM_GLOBALRESET input signal will trigger the SHUTTER, PRESTROBE and STROBE signals. In this mode, there are no frame counters. The delay counters start decrementing as soon as the CAM_GLOBALRESET signal is asserted. The polarity of the CAM_GLOBALRESET signal is set with TCTRL_CTRL.GRESETPOL .	RW	0x0
26	STRBPSTRBPOL	Sets the polarity of the strobe and prestrobe signals. 0x0: Active high 0x1: Active low	RW	0
25	RESERVED		R	0
24	SHUTPOL	Sets the polarity of the mechanical shutter signal: CAM_SHUTTER 0x0: Active high 0x1: Active low	RW	0
23	STRBEN	Flash strobe signal enable. If enabled, the STROBE signal will be asserted after TCTRL_FRAME.STRB frames have been received and a delay of TCTRL_STRB_DELAY cycles have passed. The STROBE signal is asserted for TCTRL_STRB_LENGTH cycles. After the signal assertion, the enable bit is automatically cleared to 0. This signal must not be disabled by software.	RW	0
22	PSTRBEN	Flash prestrobe signal enable. If enabled, the PRESTROBE signal will be asserted after TCTRL_FRAME.PSTRB frames have been received and a delay of TCTRL_PSTRB_DELAY cycles have passed. The PRESTROBE signal is asserted for TCTRL_PSTRB_LENGTH cycles. After the signal assertion, the enable bit is automatically cleared to 0. This signal must not be disabled by software.	RW	0
21	SHUTEN	Mechanical shutter signal enable. If enabled, the SHUTTER signal will be asserted after TCTRL_FRAME.SHUT frames have been received and a delay of TCTRL_SHUT_DELAY cycles have passed. The SHUTTER signal is asserted for TCTRL_SHUT_LENGTH cycles. After the signal assertion, the enable bit is automatically cleared to 0. This signal must not be disabled by software.	RW	0
20:19	RESERVED	Reserved.	RW	0x0

Bits	Field Name	Description	Type	Reset
18:10	DIVC	Sets the clock divisor value for the CNTCLK clock generation based on the CLK input clock. CNTCLK is an internal clock used by the TIMING CTRL module counters. Usually, CNTCLK = ISS_MAIN_FCLK / DIVC, except for some particular values shown hereafter. 0x0: No clock. CNTCLK is gated.	RW	0x000
9:0	RESERVED		R	0x000

Table 7-624. TCTRL_PSTRB_REPLAY

Address Offset	0x0000 0034	Instance	ISS_TCTRL
Physical Address	0x5200 00F4		
Description	TIMING CONTROL - PRESTROBE REPLAY REGISTER This register is used by the TIMING CTRL module to generate the prestrobe signal.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
COUNTER								DELAY																							

Bits	Field Name	Description	Type	Reset
31:25	COUNTER	Sets the number of PRESTROBE pulses after the original pulse. If this bit is set to 0, the PRESTROBE signal behavior is only controlled by TCTRL_FRAME_STRB , TCTRL_PSTRB_DELAY , and TCTRL_PSTRB_LENGTH . If TCTRL_PSTRB_LENGTH =0, there is no replay. This bit is useful when one wants to enable red-eye removal.	RW	0x00
24:0	DELAY	Sets the delay for the PRESTROBE signal reassertion in cycles of the CNTCLK clock. The CNTCLK frequency is generated with the TCTRL_CTRL.DIVC bit field. The possible values are 0 to $2^{25}-1$ cycles. If TCTRL_PSTRB_LENGTH =0, there is no replay. This bit field must not be set to 0 if the COUNTER is set to a value different of 0. This bit is useful when one wants to enable red-eye removal.	RW	0x0000000

7.3 ISS Image Signal Processor

This section describes the Image Signal Processor (ISP).

7.3.1 ISS ISP Overview

The image signal processor (ISP) is part of the image subsystem (ISS) of the device and is a key component for imaging and video applications. It describes all ISP modules in the device; that is, the video port (VP), image pipe interface (IPIPEIF), image pipe module (IPIPE), resizer (RSZ), hardware 3A (H3A), image sensor interface (ISIF), Global Local Brightness Contrast Enhancement and (GLBCE), Noise Filter 3V (NSF3V), Chroma Noise Filter (CNF), and buffer logic (BL). For better understanding, see the first top-level ISS diagram and feature list in [Section 7.1, ISS Overview](#).

7.3.1.1 ISS ISP Features

The video-processing hardware removes the need for expensive camera modules to perform processing functions. The ISS can support the following features:

- On-the-fly or memory-to-memory processing
- Up to 212.8 MHz pixel throughput
- Statistic data collection:
 - On-the-fly or memory-to-memory operation
 - Data collection for auto exposure
 - Data collection for auto white balance
 - Data collection for auto focus
 - Boundary signal calculation for video stabilization
- High-ISO Video Noise Filtering (NSF3V)
 - Up to 212.8 MPix/s
 - Bayer RGB, YUV422, and YUV420 formats
 - 12-bit datapath bit width
 - 2816 pixels input line memory size
 - Throughput of 1 data points per cycle, without the overhead
 - For Bayer, 1 pixel = 1 data point
 - For YUV422, 1 pixel = 2 data points
 - For YUV420, 1 pixel = 1.5 data points
 - Adaptive noise level threshold
 - Inter-color-luma-estimation affecting noise threshold
 - Soft thresholding
 - Edge enhancement
 - Radial shading gain
 - Desaturation for YUV
 - Use luma to drive chroma noise threshold in YUV422
 - Support output width = input width by replicating border pixels, requires at most 48 extra pixel of processing time per row
 - Separately replicate-or-trim support for left and right borders
 - Support output height = input height by replicating top/bottom border pixels, requires 7 extra rows of processing time
 - Interleaved processing options
 - Image framing
 - Single frame and video support, flexible interrupt configuration
- Global and Local Brightness Contrast Enhancement (GLBCE)

- Up to 212.8 MPix/s
- 2816 pixels line memory size
- Bayer image: 16-bit input, 12-bit output
- Backward compatibility with previous devices and ISP functionality when GLBCE is off
- IPIPE front end: RAW data processing:
 - On-the-fly or memory-to-memory processing
 - 16-bit-wide RAW Bayer data path between image and sensor linearization module
 - 12-bit-wide RAW Bayer data path between sensor linearization module and gamma correction module. Gamma correction module outputs 10-bit data.
 - Programmable Bayer RGB positions
 - Sensor data linearization for dynamic range extension
 - Programmable 2D lens shading compensation (LSC) correction
 - Per-pixel gain and offset control
 - Black level compensation
 - Boxcar filter
 - Data collection for histogram generation
 - Defect pixel correction (LUT_DPC) with look-up table (LUT)
 - Defect pixel correction (OTF_DPC) with on-the-fly detection and correction
 - 2D noise filtering
 - Green imbalance correction (GIC)
 - Digital gains and offset
 - 8- to 10-bit A-law decompression and 10- to 8-bit A-law compression
- IPIPE back end: RGB and YUV data processing:
 - RGB-to-RGB color correction
 - Gamma correction (GC)
 - RGB to YUV4:2:2: Color conversion, cosited Chroma filtering and downsampling
 - 2D edge enhancement (EE)
 - 3D LUT for color correction
 - False Chroma suppression (FCS)
- Two resizers:
 - Performance: input and output rates up to 212.8 MPix/s
 - YUV4:2:2 to RGB56, ARGB888, YUV4:2:2, and YUV4:2:0 data output
 - YUV4:2:0 to YUV4:2:0 data output
 - RAW to RAW data output
 - Range from x1/4096 to x20. Supports memory-to-memory rescaling.
- Chroma Noise Filter (CNF)
 - Removes residual chroma noise by filtering UV data component of the image with noise filter
 - 2816 pixels line memory size
 - Support 8-bit UV input (UV part of YUV420) One pixel per cycle and output UV format
 - CDS (Chroma Down Sampling) and CUS (Chroma Up Sampling)
 - CNF available for RSZ1 only

The ISP comprises the following modules:

- IPIPE interface (IPIPEIF)
- Image sensor interface (ISIF) accelerator
- Auto exposure, auto white balance, and auto focus engine (H3A)

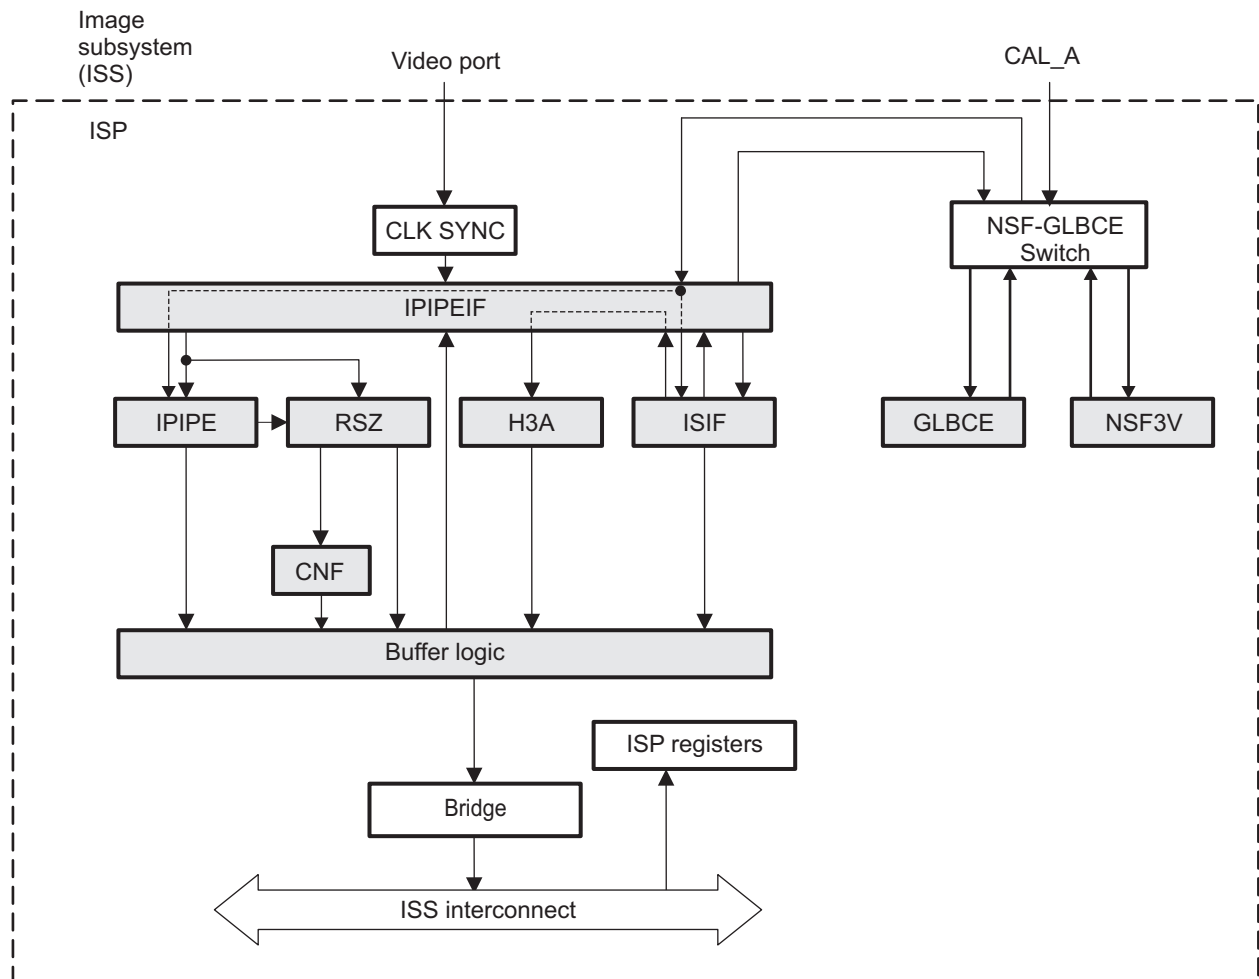

- Image pipe accelerator (IPIPE)
- Two resizer (RSZ) accelerators
- Buffer logic (BL): Receives module requests, performs arbitration, and creates read/write bursts to the memory subsystem

7.3.1.2 ISS ISP Block Diagram

Figure 7-69 is the ISP top-level block diagram. The ISS three simultaneous pixel flows (CAL_A, LVDS-RX, and parallel interface CPI), but only one of them at a time can use the video-processing hardware; the others can go directly to memory (CPI must always use ISP).

The ISP 128-bit master port and 32-bit slave port are connected to the level 3 interconnect (L3_MAIN).

Figure 7-69. ISS ISP Block Diagram

camisp-003

7.3.2 ISS ISP Integration

This section describes the integration of the ISP modules in the ISS and includes information about clocks, resets, and hardware requests.

The ISP is part of the ISS of the device and is a key component for imaging and video applications such as camera viewfinder, video record, and still image capture.

The ISS is coupled with a low-interrupt-latency imaging processor unit subsystem (Cortex-M4 IPU) running a real-time operating system to reach optimal performance. Primarily, the IPU can quickly change the ISS configuration during frame blanking periods and run some sequencing tasks. The ISS can also be configured using the device EDMA controller. Typically, the EDMA can be used to transfer large configuration tables used by the ISS (for example, Gamma tables).

7.3.2.1 ISS ISP PRCM Interface

The ISP and its internal modules, as integrated in the ISS, use the same power and clock management details. See , *ISS Functional Description*, for the ISP top-level power, reset, and clock management (PRCM) interface.

7.3.2.1.1 ISS ISP Clocks

The PRCM module, through the local power and clock management inside the ISS, provides a unique PCLK that can be enabled from the [ISP5_CTRL](#) register.

The modules inside the ISP require three clocks:

- PCLK: This clock is asynchronous to the other clocks. It is provided by the module sending the data to the IPIPEIF module on the VP. The frequency is up to 212.8 MHz.
- ISP_FCLK: This clock is sourced from ISS_MAIN_FCLK and is synchronous with the configuration clock domain. This is the clock used for the MTC interface. The frequency is up to 212.8 MHz.
- GCK_MMR: This is the clock for the configuration bus. It is created from the ISP_FCLK and runs at half the speed of the ISP_FCLK. The frequency is up to 106,4 MHz.

7.3.2.1.2 ISS ISP Reset

The ISP supports global software reset along with internal hardware reset, if needed.

Software reset is done through the [ISP5_SYSCONFIG\[1\]](#) SOFTRESET bit. Before issuing a software reset, the ISP must be in standby mode. The following must be done:

1. Ensure that the interfaces are stopped from sending data and/or the ISP modules are disabled. Before reset, the last interrupt triggered by the ISP when the frame processing completes is RSZ_INT_DMA. RSZ_INT_DMA must be used to enable clean termination of the processing. Software must wait a few hundred cycles to trigger a soft reset after RSZ_INT_DMA is asserted; this is to ensure that the BL is completely drained.
2. Ensure that [ISP5_SYSCONFIG\[5:4\]](#) STANDBYMODE = 2 (smart standby). Set the [ISP5_CTRL\[24\]](#) MSTANDBY bit to 1 and poll for [ISP5_CTRL\[20\]](#) MSTANDBY_WAIT = 1. Then, the soft reset can be applied ([ISP5_SYSCONFIG\[1\]](#) SOFTRESET = 1).

In case an ISP overflow event happens (for example, RSZ_FIFO_OVF, ISIF_OVF, etc.), it is not sufficient to reset the ISP. In that case a reset must occur at the ISS level. ISP underflow events do not require any special attention since these are internally managed by ISS stalling mechanism

7.3.2.2 ISS ISP Interrupt Tree

There are four ISP output interrupt lines that are mapped to the ISS top interrupt request (IRQ) merger (for more information, see , *ISS Interrupt Merger*). [Table 7-628](#) summarizes the ISP submodule interrupt events that can be mapped to the four ISP interrupt lines. An interrupt event can be enabled on any of the four interrupt lines through the [ISP5_IRQENABLE_SET_i](#) and [ISP5_IRQENABLE_SET2_i](#) registers (i = 0 to 3, one register per interrupt line). Each event must be enabled on only one interrupt line.

Table 7-628. ISS ISP Interrupt Tree Table

Register	Module	Destination	Comments	
ISP5_IRQENABLE_SET_i[9] IPIPEIF_IRQ	IPIPEIF	ISP to ISS merger four IRQ lines	See Section 7.3.2.3.1 .	
ISP5_IRQENABLE_SET_i[29] IPIPE_INT_DPC_RNEW1	IPIPE		See Section 7.3.2.4.1 .

ISP5_IRQENABLE_SET_i[2] ISIF_INT_2				
ISP5_IRQENABLE_SET_i[1] ISIF_INT_1				
ISP5_IRQENABLE_SET_i[0] ISIF_INT_0				

7.3.2.3 ISS ISP IPIPEIF Integration

7.3.2.3.1 ISS ISP IPIPEIF Interrupts

The IPIPEIF module generates two interrupts:

- IPIPEIF_IRQ: This event is triggered to the BL module when a new frame starts (VS signal). The interrupt is active high and is asserted for one GCK_MMR clock cycle.

The interrupts are enabled from the ISP5_IRQENABLE_SET_i[9] IPIPEIF_IRQ bit (where $i = 0$ to 3 for the line that will be mapped to the four lines of the ISP). Then, each line from the ISP is sent to the ISS top level, where it is muxed with other ISS modules for a total output of six interrupt lines. See *ISS Functional Description*.

For additional information on IPIPEIF events see [Section 7.3.3.4.16](#), *ISS ISP IPIPEIF Module Events and Status Checking*.

7.3.2.4 ISS ISP IPIPE Integration

7.3.2.4.1 ISS ISP IPIPE Interrupts

IPIPE can generate several interrupts:

- IPIPE_INT_DPC_RNEW0 and IPIPE_INT_DPC_RNEW1: This event is triggered when there is

permission to initialize LUT-DPC table lines 0 and 1.

- IPIPE_INT_DPC_INI: This event is triggered when the defect pixel correction (DPC) table is initialized.
- IPIPE_INT_HST: This event is triggered when the histogram is done.
- IPIPE_INT_BSC: This event is triggered when boundary signal calculation is done.
- IPIPE_INT_DMA: This event is triggered when the boxcar SDRAM transfer is done. On this timing, IPIPE_INT_EOF is sent to the BL. This event is active high for one GCK_MMR clock cycle.
- IPIPE_INT_LAST_PIX: This event is triggered when the last pixel of a frame comes into IPIPE. This event is active high for one GCK_MMR clock cycle. Also, this signal can not be used if DPC is used before NSF3V.
- IPIPE_INT_EOF: This event is triggered for end of frame.

The interrupts are enabled from the ISP5_IRQENABLE_SET_i register (where i = 0 to 3 for the line that will be mapped to the four lines of the ISP). Then, each line from the ISP is sent to the ISS top level, where it is muxed with other ISS modules for a total output of six interrupt lines. See , *ISS Functional Description*.

7.3.2.4.2 ISS ISP DMA Requests

The ISP generally outputs four direct memory access (DMA) requests, which can be used to read or write memories inside the IPIPE module. These memories are:

- BSC memory: This memory must be read during a vertical blanking period. It is used by the video stabilization application.
- HIST memory: This memory must be read during a vertical blanking period. It is used by the 3A application. The HIST data is double-buffered from frame-to-frame. Software must select the memory that is to be used by setting the IPIPE_HST_TBL[0] SEL bit.
- GAMMA memory: This memory must be set during a vertical blanking period. The imaging application typically uses multiple gamma tables.
- DPC memory: This memory must be set during a frame acquisition. The memory is not big enough to store all faulty pixels for a given frame.

To generate the DMA requests, the following events must be used:

- The IPIPE_INT_BSC event is used to generate the DMA request for the BSC memory. It maps on DMA line 1, ISS_DREQ_1.
- The IPIPE_INT_HST event is used to generate the DMA request for the HIST memory. It maps on DMA line 2, ISS_DREQ_2. The HIST data is double-buffered from frame-to-frame. Software must select the memory that is to be used by setting the IPIPE_HST_TBL[0] SEL bit. When the DMA request is set, it is required to read 4 KiB from the ping buffer address (0x2000) or the pong buffer address (0x3000). Software must ensure that when one buffer is selected no other accesses (for example, IPU) occur in the other buffer.
- The IPIPE_INT_LAST_PIX event is used to generate the DMA request for the GAMMA memory. This same event can also be used to initialize the DPC LUT (not the preferred method; it is better to use IPIPE_INT_DPC_INI). Basically, when the last pixel is output from the IPIPE module, it is safe to modify the IPIPE memories. It maps on DMA line 4, ISS_DREQ_4.
- The IPIPE_INT_DPC_INI event signals that DPC table memory initialization can occur. IPIPE_INT_DPC_INI is used to generate two back-to-back DMA requests, the first one mapping on IPIPE_INT_DPC_RNEW0 and the second one mapping on IPIPE_INT_DPC_RNEW1. After initialization (steady state), the IPIPE_INT_DPC_RNEW0 and IPIPE_INT_DPC_RNEW1 events are used to generate the DMA request for the DPC LUT renewal. It maps on DMA line 3, ISS_DREQ_3. To select which event is used to initialize the DPC (IPIPE_INT_LAST_PIX or IPIPE_INT_DPC_INI), set the ISP5_CTRL[25] DPC_EVT_INI bit.

NOTE: The size of the DPC table in RAM must be a multiple of the number of DMA requests. It ensures that during burst capture mode the DMA always loads the correct data from frame-to-frame. The DMA automatically warps back to the start of the table after all expected DMA requests are received. There is a total of $\text{ceil}(\text{nb_faulty_pixel}/128) + 2$ DMA requests per frame when the IPIPE_INT_DPC_INI EVENT is used. Hence, the size of the DPC table in the RAM is $(\text{ceil}(\text{nb_faulty_pixel}/128) + 2) \times 128 \times 32$ bits.

NOTE: If DMA channels are not used but the IPU is used, an error check must be performed for IPIPE HST. See [ISP5_CTRL\[26\] HST_RD_CHK](#) for details.

The DMA request assertion and deassertion to the EDMA is automatic and no software intervention is needed. The ISP contains two registers ([ISP5_DMAENABLE_SET](#) and [ISP5_DMAENABLE_CLR](#)) that must be used to enable or disable generation of the DMA requests.

The DMA request deassertion is based on late deassertion; that is, the DMA request is disabled only when all the data corresponding to the transfer size have been read or written. To deassert the DMA request and generate the hw_eoi signal, hardware counts the number of 32-bit accesses that are done in the memory range of the corresponding DMA request through the ISP slave port. When the number of accesses corresponding to the DMA request is done, the DMA request is cleared. Multiple DMA requests can be active simultaneously.

Software must not attempt to read or write in the memory range of the DMA requests that are enabled because CPU accesses, instead of EDMA accesses, will be counted. Software can freely access ISP memories for which the DMA request is disabled, and can access registers while the EDMA performs the transfers.

7.3.2.5 ISS ISP RSZ Integration

7.3.2.5.1 ISS ISP RSZ PRCM Interface

7.3.2.5.1.1 ISS ISP RSZ Reset

The RSZ module has no stand-alone software reset. RSZ must be reset at the ISP level. See [Section 7.3.2.1.2, ISS ISP Reset](#).

7.3.2.5.2 ISS ISP RSZ Interrupts

RSZ can generate several interrupts:

- RSZ_INT_EOF0: This event is triggered for end of frame.
- RSZ_INT_EOF1: This event is triggered for end of frame.
- RSZ_FIFO_IN_BLK_ERR: This event is triggered when the minimum vertical blanking period has not been respected, thus causing errors in the input data buffering submodule. This event is triggered when the RSZ_INT_REG event of frame N is triggered before RSZ_INT_DMA of frame N + 1. This event typically occurs at the transition between two frames because there is not enough vertical blanking between frames. Hardware cannot recover from this error. It requires a reset. It is a requirement that despite the error the RSZ module must finish correctly: ongoing requests are completed and further requests are blocked.
- RSZ_FIFO_OVF: This event typically occurs while processing a frame, because the VP pixel clock is too high. Because hardware cannot recover from this error, a reset is required. It is a requirement that despite the error the RSZ module must finish correctly: ongoing requests are completed and further requests are blocked.

This event signifies overflow in two different scenarios:

- In Bypass or Operating (normal/downscale) modes, the RSZ_FIFO_OVF event is triggered when an overflow occurs in the input circular data buffer. The rsz_stall_input signal can be asserted by programming appropriate thresholds to prevent input FIFO overflow.
- In Pass-through mode, the RSZ_FIFO_OVF event is triggered when an overflow occurs in the

output MTC buffer. There is no hardware mechanism to prevent overflow in Pass-through mode.

- **RSZ_INT_CYC_RZA/RSZ_INT_CYC_RZB:** This event is triggered as circular interrupt every time that [RSZ_IRQ_RZA/RSZ_IRQ_RZB](#) output lines are written to the RZA_SDR_Y/RZB_SDR_Y buffer. The range can go from 1 to 8192 lines. Usually, this value must be such that the circular buffer vertical size is a multiple of [RSZ_IRQ_RZA/RSZ_IRQ_RZA](#).
- **RSZ_INT_DMA:** This event is triggered when the last EOF (of the two MTC interfaces) is sent to the BL and the RSZ core returns to idle. This event is active high for one GCK_MMR clock cycle.
- **RSZ_INT_LAST_PIX:** This event is triggered when the last pixel of the valid area is received. This event is active high for one GCK_MMR clock cycle.
- **RSZ_INT_REG:** This event is triggered when the new value of the shadowed registers, if updated, takes effect on the next RSZ_INT_REG event. Then again, shadowed registers can be updated for the next frame after the RSZ_INT_REG event is triggered. This event is active high for one GCK_MMR clock cycle.

The interrupts are enabled from the `ISP5_IRQENABLE_SET_i` register (where $i = 0$ to 3 for the line that will be mapped to the four lines of the ISP). Then, each line from the ISP is sent to the ISS top level, where it is muxed with other ISS modules for a total output of six interrupt lines. See , *ISS Functional Description*.

7.3.2.6 ISS ISP H3A Integration

7.3.2.6.1 ISS ISP H3A Interrupts

H3A can generate the following interrupts:

- **H3A_INT:** This event is triggered at the end of the last window or last pixel, whichever completes last. This always triggers at the same time as `H3A_INT_EOF`.
- **H3A_INT_EOF:** This event is triggered and generated at the end of the last window. This event is active high for one GCK_MMR clock cycle.

The interrupts are enabled from `ISP5_IRQENABLE_SET_i` register (where $i = 0$ to 3 for the line that will be mapped to the four lines of the ISP). Then, each line from the ISP is sent to the ISS top level, where it is muxed with other ISS modules for a total output of six interrupt lines. See , *ISS Functional Description*.

7.3.2.7 ISS ISP ISIF Integration

7.3.2.7.1 ISS ISP ISIF Interrupts

The ISIF can generate several interrupts:

- **ISIF_INT_0:** This event is triggered when the VD0 interrupt on line 0 is configured. The VD0 interrupt can be configured based on the VD position. It is asserted after receiving the number of horizontal lines (horizontal pulse signals) set in `VDINT0`. For more information, see [Section 7.3.3.9.20.1](#).
- **ISIF_INT_1:** This event is triggered when the VD1 interrupt on line 1 is configured. The VD1 interrupt can be configured based on the VD position. It is asserted after receiving the number of horizontal lines (horizontal pulse signals) set in `VDINT1`. For more information, see [Section 7.3.3.9.20.1](#).
- **ISIF_INT_2:** This event is triggered when the VD2 interrupt on line 2 is configured. The VD2 interrupt can be configured based on the VD position. It is asserted after receiving the number of horizontal lines (horizontal pulse signals) set in `VDINT2`. SFor more information, see [Section 7.3.3.9.20.1](#).
- **ISIF_INT_3:** This event is triggered LSC interrupt is an interrupt issued by the 2D-LSC block. For more information, see [Section 7.3.3.9.10.1.5](#).

The interrupts are enabled from the `ISP5_IRQENABLE_SET_i` register (where $i = 0$ to 3 for the line that will be mapped to the four lines of the ISP). Then, each line from ISP is sent to the ISS top level where it is muxed with other ISS modules for a total output of six interrupt lines. See , *ISS Functional Description*.

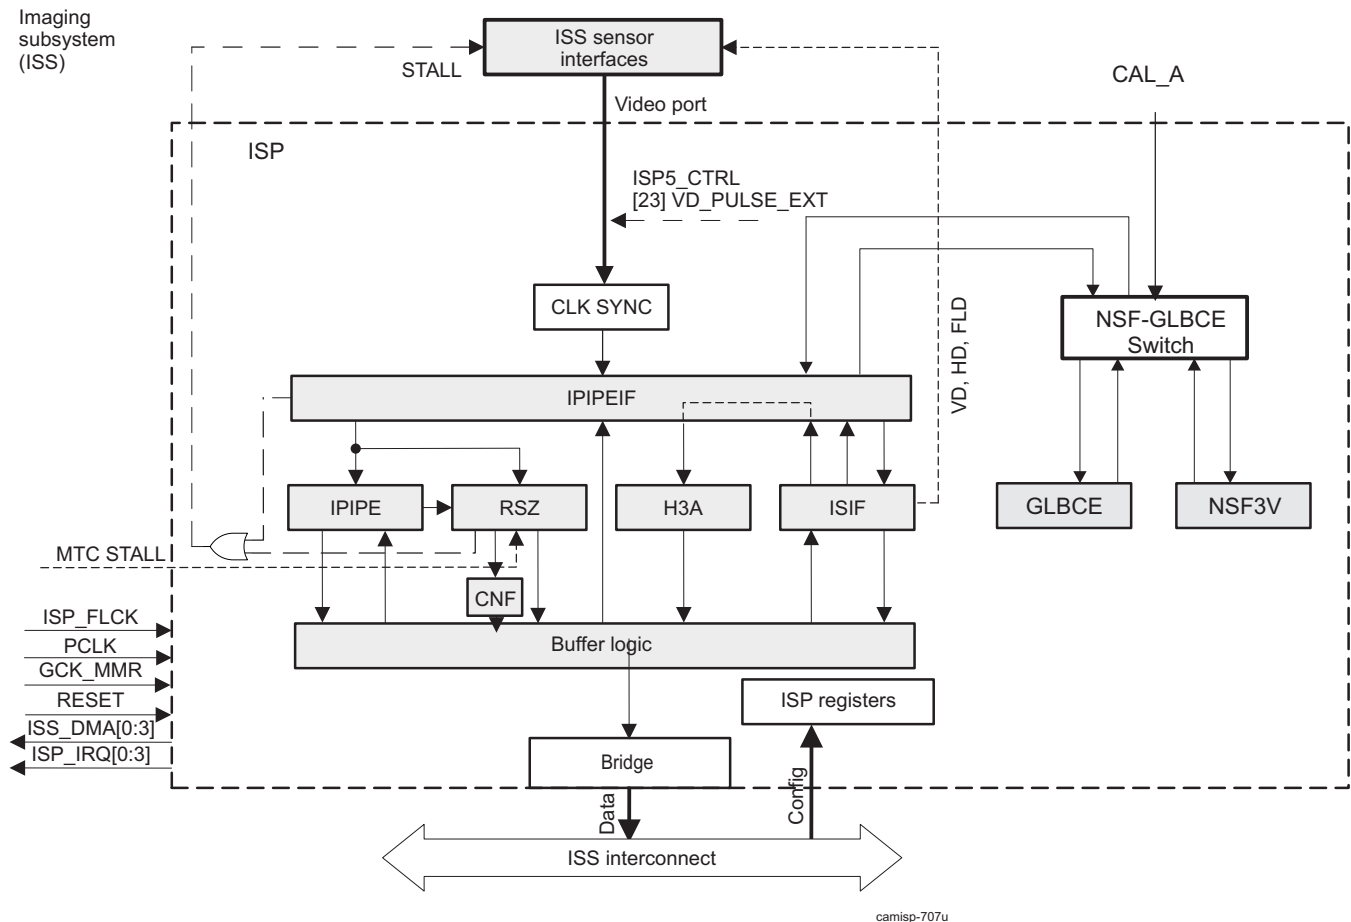

7.3.2.8 ISS ISP BL Integration

See [Section 7.3.2, ISS ISP Integration](#).

7.3.3 ISS ISP Functional Description

The functionality of the ISP is part of the overall performance of the ISS. For the top-level ISS diagram with ISP inside and for a features list, see [Section 7.1, ISS Overview](#). [Figure 7-70](#) is an overview of the ISP module. It outputs DMA and interrupt requests, has clocks coming in, and a stall signal to the interface receiver from the resizer. It also shows the top-level configuration for input to IPIPEIF. For the scaled-in functional details of each submodule inside the ISP, see its functional description section.

Figure 7-70. ISS ISP High-Level Diagram

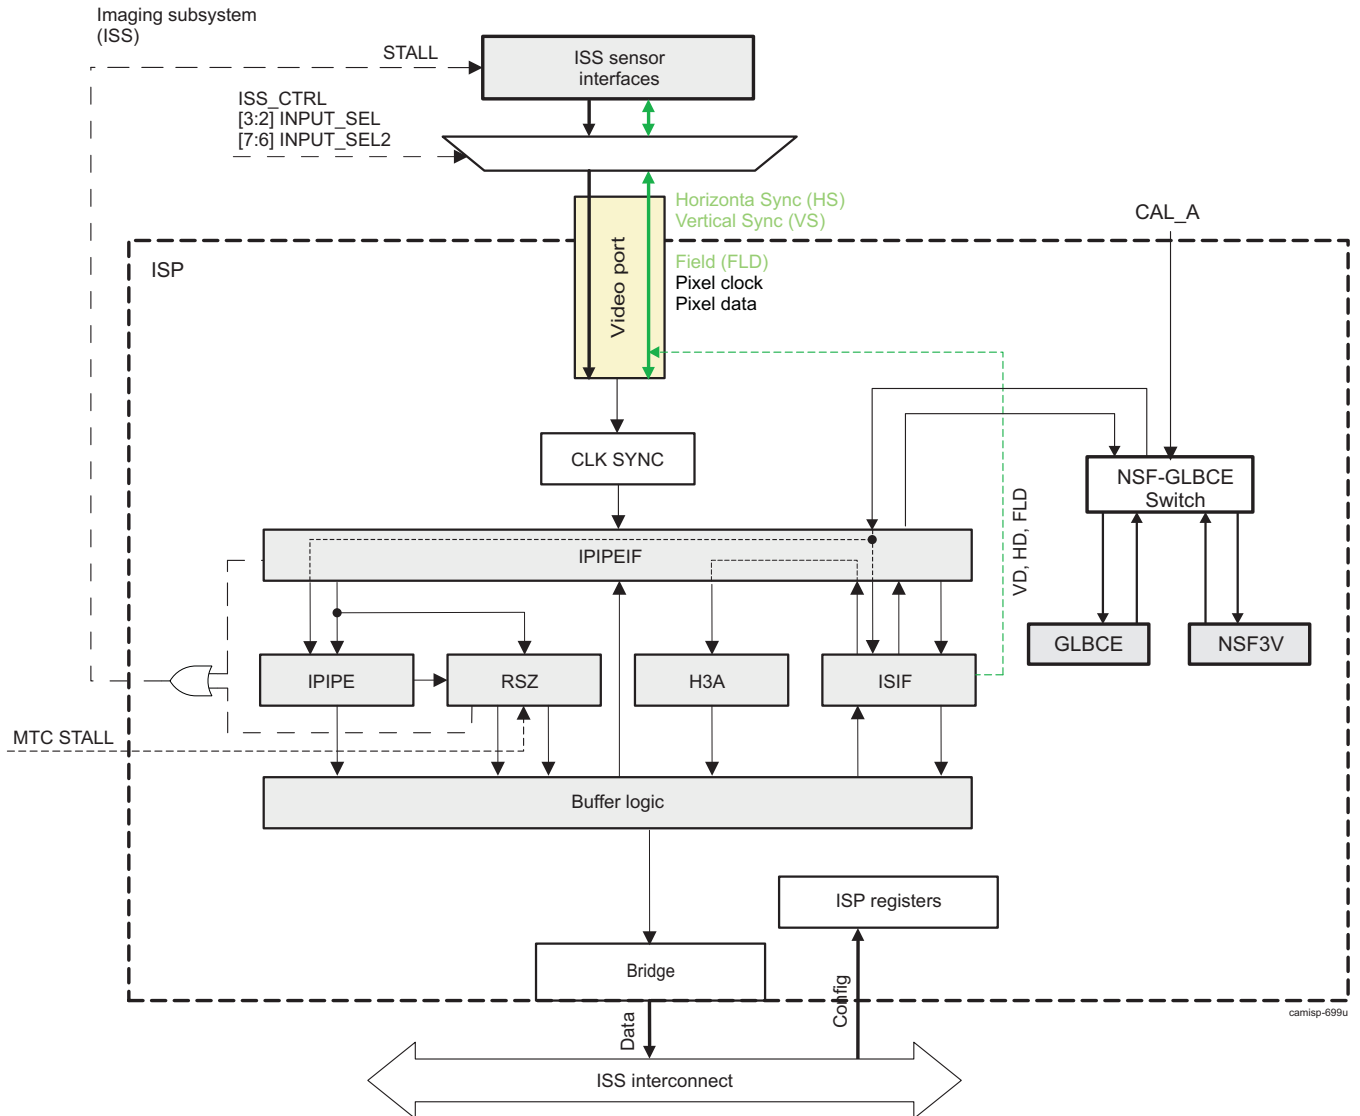

7.3.3.1 ISS ISP VP Functional Description

7.3.3.1.1 ISS ISP VP Overview

The VP supports a parallel interface that is used for interfacing with image sensors. The ISP VP can transport 8- to 16-bit RAW data and 8-/16-bit YCbCr data.

[Figure 7-71](#) shows the VP module connections to other submodules of the ISP.

Figure 7-71. ISS ISP VP High-Level Diagram

7.3.3.1.2 ISS ISP VP Data Formats

The VP can be used to connect external camera receivers to the ISS. Data paths inside the ISP hardware depend on the image format sourced by the sensor (RAW RGB, YUV4:2:2, JPEG, etc.). [Table 7-629](#) shows how the CAL_A/LVDS-RX/CPI modules are connected to the VP in function of the image format.

Table 7-629. ISS ISP VP Format Mapping

7.3.3.1.3 ISS ISP VP Top-Level Communication With CAL_A/LVDS-RX/CPI

At the ISS level, the VP is connected to the VP of the CAL_A/LVDS-RX/CPI interface modules. The selection, which interface VP is connected to the ISP is done on ISS top level through ISS_CTRL[3:2] INPUT_SEL and [7:6] INPUT_SEL2 register bit fields.

VP implementation differences force the introduction of a bridge between the CAL_A/LVDS-RX/CPI modules and the VP. The role of the bridge is to perform VD pulse extension. The CAL_A module assumes that the VD signal is active for at least one pixel clock cycle, and the CAL_A module assumes that the VD signal is asserted for four pixel clock cycles. However, the ISP assumes that the VD pulse is active on at least one line.

Figure 7-72 shows how the VD pulse extension works. Assume that VD-IN is the VD signal at the input of the pulse extension bridge, and VD-OUT is the VD signal at the output of the pulse extension bridge.

VD-OUT is asserted at the same time as VD-IN. VD-OUT is kept high until one full line is received. A line is delimited by two rising edges of the HD signal. VD-OUT is deasserted on the next cycle after the falling edge of the HD signal.

camss-691

The ISP5_CTRL[23] VD_PULSE_EXT bit controls whether the VD extension bridge is enabled or disabled. By default, the bridge is enabled. When the bridge is disabled, the VD pulse must be unmodified: VD-OUT = VD-IN. At the ISS level, it is expected that ISP5_CTRL[23] VD_PULSE_EXT = 1 when the VP gets data from the CAL_A/LVDS-RX module.

CAUTION

A minimum of four lines per frame is required on the VP when the VD pulse extension bridge is enabled; therefore, the VD extension bridge is not functional if a 1-/2-/3-line frame is sent to the VP.

7.3.3.1.4 ISS ISP VP Pixel Clock Inversion

The ISP always uses the rising edge of the pixel clock to sample the pixel data. The ISP provides the capability to invert the pixel clock so it can shift the resampling of a pixel clock period by half. This is controlled by the ISP5_CTRL[22] PCLK_INV bit. By default, the inversion is disabled. The pixel clock must be disabled at ISS level before setting the PCLK_INV bit to 0x1. This can be done through the proper ISS_CLKCTRL[] VPORTx_CLK register bit on ISS top level, depending on the interface (CAL_A/LVDS-RX/CPI) that is sending data on the ISP video port.

The 4 bits in [Table 7-630](#) are resynchronized from the GCK_MMR clock domain to the PCLK clock domain. There must be at least three clock cycles between the time these bits are modified and the HD/VD pulse for start of frame comes.

Table 7-630. ISS ISP VP GCK_MMR to PCLK Clock Resynchronization

Module	Register	Bit Field
ISP	ISP5_CTRL	VD_PULSE_EXT
ISIF	ISIF_MODESET	HDVDD
ISIF	ISIF_MODESET	FIDD
ISP	ISP5_CTRL	ISIF_CLK_ENABLE

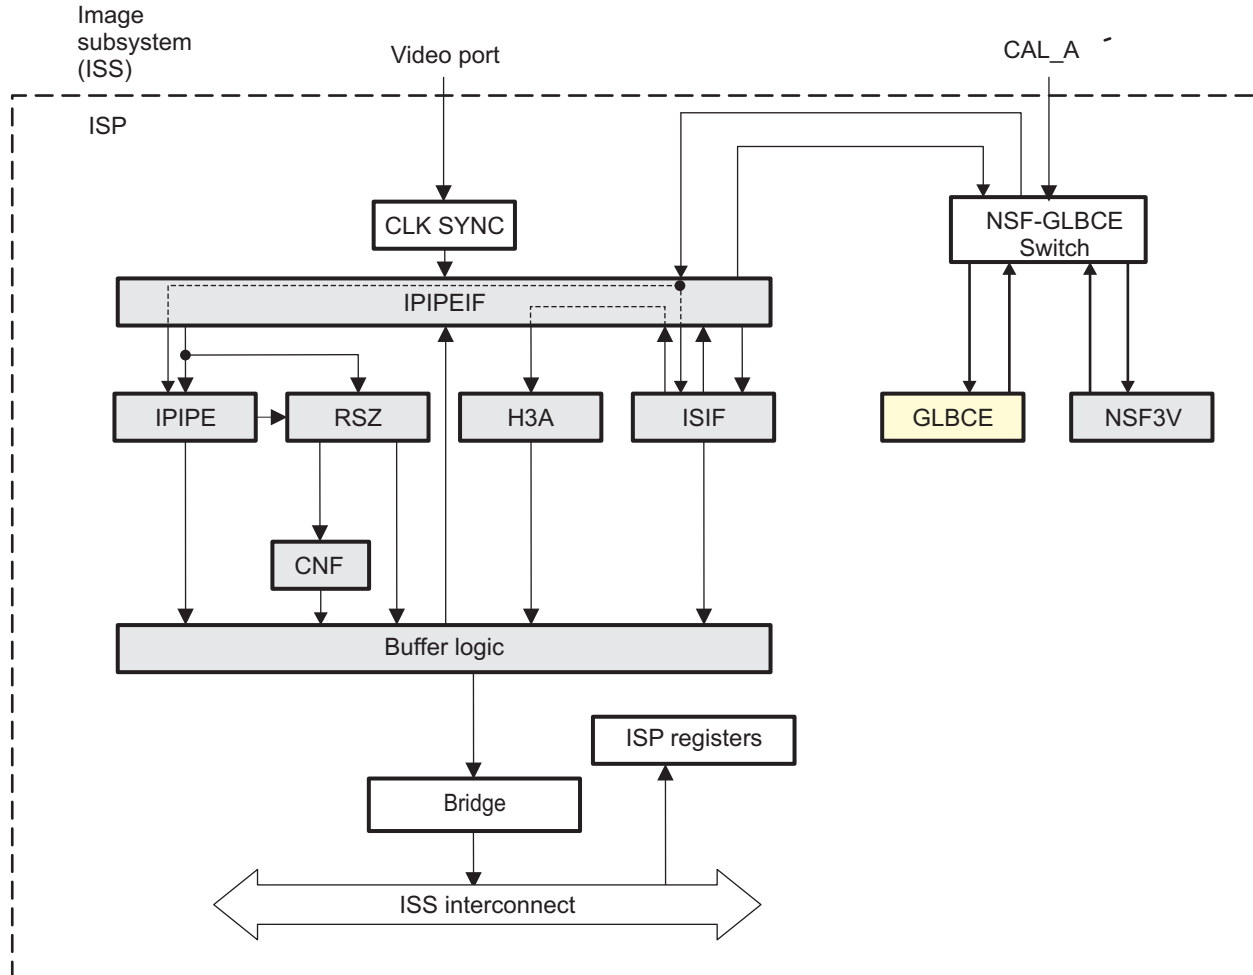

7.3.3.2 ISS ISP GLBCE Functional Description

7.3.3.2.1 ISS ISP GLBCE Overview

The Global Local Brightness Contrast Enhancement module performs dynamic range compression or tone mapping of an input image based on a model of the human visual system. It is used in a ISP to produce most natural images under a wide range of capture conditions, typically by revealing shadow detail which would otherwise be under-exposed in high contrast situations. The module supports:

- 212.8 MHz operation, 212.8 MPix/s processing (one pixel/cycle)
- Up to 2816 pixel/line
- Bayer image
- 12bit to 16 bit Input, 16 bit output
- Companded data (12-bit/14-bit to 20bit) is supported
- When GLBCE is off, ISP is backward compatible with previous devices

[Figure 7-73](#) show the GLBCE module connections to other submodules of the ISP.

Figure 7-73. ISS ISP GLBCE High-Level Diagram

camisp-003i

7.3.3.2.2 ISS ISP GLBCE Interface

Data flow control of GLBCE module is done by PCLK. While ACL is high, every PCLK is associated with a pixel data. GLBCE processes the image cycle by cycle, and output the data after certain cycles of latency.

When stall signal (SUS) comes in from CAL output port, switch forwards the stall signal to CAL input port. Upstream CAL port will stop sending data. No flow control is done at switch level or by GLBCE. Therefore, GLBCE block does not have suspend signal input/output.

7.3.3.2.3 ISS ISP GLBCE Core

The GLBCE Core is an iridix® core which performs "dynamic range compression" or "tone mapping" on an input image based on a model of the human visual system. It is used in a camera pipeline to produce the most natural images under a wide range of capture conditions, typically by revealing shadow detail which would otherwise be under-exposed in high contrast situations. The purpose of the transform is to map the image content from an input source such that it remains fully visible on an output display without loss of content. Note that iridix is specifically designed to preserve color, sharpness and boost contrast of the source image.

The iridix core is based on space-variant or pixel-by-pixel processing algorithms which construct a family of transforms based on the analysis of image content. The algorithms inside iridix are adaptive, meaning that a single set of parameters can be set to process any source image or any video sequence under different lighting conditions.

Iridix generates effective tone curves by analyzing the regions surrounding each pixel. The tone curves generated by iridix are based on an asymmetry curve which is then shaped and controlled by a number of parameters that control the gain limitation weighting towards shadows, mid tones and highlights.

7.3.3.2.3.1 ISS ISP GLBCE Core Key Parameters

Table 7-631 shows the key parameters within the iridix core. It is recommended that all parameters be set statically to their recommended values other than the iridix strength parameter, which should be controlled dynamically with scene content. The calculation of iridix strength is explained in Section 7.3.3.2.3.2.

Table 7-631. ISS ISP GLBCE Core Key Parameters

Parameter	Description
iridix strength	This register sets iridix processing strength.
	0x00: Video data will not be processed at all, and will pass to the output unchanged.
	0xFF: Maximum processing strength.
Variance space	This register affects the sensitivity of the transform to different areas of the image, and can be increased in order to emphasize small regions (e.g. faces). If this parameter is set to zero, the sensitivity to small areas is maximized (i.e. the transform becomes more local). When this parameter is set to 0xF, the transform deemphasizes small local details, and the transform becomes more global
Variance intensity	For a high-contrast image with shadows and highlights, a small value will cause iridix to adjust shadows and highlights almost independently. A large variance causes iridix to become progressively more global, meaning that the presence of highlights affects the processing of shadows and vice-versa.
Slope min limit	This register is used to restrict the slope of the tone curve generated by iridix. When this parameter is set to 0x00, the tone curve slope generated by iridix is not limited.
	When this value is set to 0xFF, iridix will not generate a tone curve with a slope less than 3/4. Intermediate values of slope limit are linear interpolation between minimum and maximum values.
	The recommended range of this parameter is 0-128
Slope max limit	This register is used to restrict the slope of the tone-curve generated by iridix. When this parameter is set to 0xFF, the tone curve slope generated by iridix is not limited.
	When this value is set to 0x00, iridix will not generate a tone-curve with slope greater than 16/15 (48°). Intermediate values of slope limit are linear interpolation between minimum and maximum values.
	The recommended range of this parameter is 0-160. For noisy images, lower values should be used.
Black level	The value stored in this register will be used as the zero level for iridix processing in all data channels. Data below this value will not be processed and remain unchanged.
White level	The value stored in this register will be used as the white level for iridix processing in all data channels. Data above this value will not be processed and remain unchanged.
Asymmetry LUT	This look-up-table is 33 words, each of which is 16-bits. The asymmetry function is used to balance the iridix effect between the dark and bright regions of the image.
Forward perceptual LUT	The iridix core works in a perceptually uniform space and thus when linear data is presented to the core, this look-up-table must be used to map the linear data to the perceptual space so that iridix can perform its perceptual functions.
Reverse perceptual LUT	The iridix core works in a perceptually uniform space and thus when linear data is required from the output of the core, this look-up-table must be used to map the data from the perceptual space back to linear space for further processing in the pipeline.

7.3.3.2.3.2 ISS ISP GLBCE Iridix Strength Calculation

This section describes how the dynamic parameter, iridix strength, is calculated.

NOTE: Dynamic range of a digital camera can be described as the ratio of maximum light intensity measurable (at pixel saturation), to minimum light intensity measurable (but above read-out noise). This is a very important concept to consider when computing iridix strength, because the gain applied by iridix is also proportional to the visible boost of noise in the image. The maximum gain applied by iridix should be determined by the dynamic range of the camera system. This is governed by the equation presented in this section.

With iridix strength is zero, all tone curves are linear for all images. As iridix strength is increased, the variation between curves in shadows, mid tones and highlights increases, resulting in increasing compression of global dynamic range.

Iridix strength is calculated as follows:

Figure 7-74. ISS ISP GLBCE Iridix strength formula

$$\text{irridix strength} = \text{Max}\left(0, \text{Min}\left(\frac{\text{IR_Gain_Target} - 1}{\text{IR_Gain_Max} - 1}, f(\text{analog gain})\right)\right) * 255$$

camisp-843

Where:

- IR_Gain_Target is the desired iridix gain to be applied to the image. This is calculated from the image's histogram on a per-frame basis by the ISP's auto exposure algorithm. The histogram is analysed to compute an exposure ratio for the desired global histogram shift. This computed exposure ratio is then used to feed a look-up-table which in turn generates the IR_Gain_Target parameter.
- IR_GainMax is the maximum iridix gain. If the fwd_percep_lut is disabled, then the IR_GainMax should be set to 64, and if the fwd_percep_lut is enabled, then the IR_Gainmax should be set to 16.
- f(analog gain) is a function that determines the maximum iridix strength in relation to noise. f(analog gain) is characterised as follows:

Figure 7-75. ISS ISP GLBCE Iridix f(analog gain) function

camisp-844

f(analog gain) should only be used when the ISP is in linear mode. Otherwise, it should be set to 1

7.3.3.2.3.3 ISS ISP GLBCE Iridix Configuration Registers

7.3.3.2.3.3.1 ISS ISP GLBCE Iridix Frame Width

Frame Width is the number of pixels in an active line and is controlled from [GLBCE_FRAME_WIDTH\[15:0\]](#) VAL. Recommended value 2560 (decimal)

7.3.3.2.3.3.2 ISS ISP GLBCE Iridix Frame Height

Frame Height is the number of pixels in an active line and is controlled from [GLBCE_FRAME_HEIGHT\[15:0\]](#) VAL. Recommended value 1920 (decimal)

7.3.3.2.3.3.3 ISS ISP GLBCE Iridix Control

This is the main control register for the iridix core is [GLBCE_CONTROL0](#) where GLBCE is enabled/disabled and the type of processing algorithm is selected.

7.3.3.2.3.3.4 ISS ISP GLBCE Iridix Control

This is the main control register for the iridix core is [GLBCE_CONTROL0](#) where GLBCE is enabled/disabled and the type of processing algorithm is selected. Recommended value 6 (decimal)

7.3.3.2.3.3.5 ISS ISP GLBCE Iridix Strength

[GLBCE_STRENGTH_IR\[7:0\]](#) VAL register sets the processing strength of the iridix core. Recommended value 128 (decimal)

7.3.3.2.3.3.6 ISS ISP GLBCE Iridix Variance

The [GLBCE_VARIANCE](#) parameter affects the sensitivity of the transform to different areas of the image, and can be increased in order to emphasize small regions (e.g. faces). [GLBCE_VARIANCE\[7:4\]](#) VARIANCEINTENSITY recommended value 12 (decimal). [GLBCE_VARIANCE\[3:0\]](#) VARIANCESPACE recommended value 7 (decimal).

7.3.3.2.3.3.7 ISS ISP GLBCE Iridix Dither

When the number of color gradations of a display device is small (for example 6 bits per color), pixel dithering can make gradients look smother. Dithering of the least significant bits is applied and then these bits can be later truncated. The three least significant bits (D2, D1, D0) of this [GLBCE_DITHER](#) register are responsible for the strength of dithering. There are 4 possible levels of dithering. Recommended value 0 (decimal)

7.3.3.2.3.3.8 ISS ISP GLBCE Iridix Amplification Limit

The parameters dark amplification limit and bright amplification limit are used to restrict the luminance space in which iridix can adaptively generate tone curves for each pixel. [GLBCE_LIMIT_AMPL\[7:4\]](#) BRIGHTAMPLIFICATIONLIMIT recommended value 0 (decimal). [GLBCE_LIMIT_AMPL\[3:0\]](#) DARKAMPLIFICATIONLIMIT recommended value 0 (decimal).

7.3.3.2.3.3.9 ISS ISP GLBCE Iridix Slope Min and Max

[GLBCE_SLOPE_MIN\[7:0\]](#) SLOPEMINLIMIT register is used to restrict the slope of the tone curve generated by iridix. Recommended value 64 (decimal).

[GLBCE_SLOPE_MAX\[7:0\]](#) SLOPEMAXLIMIT register is used to restrict the slope of the tone curve generated by iridix. Recommended value 72 (decimal).

7.3.3.2.3.3.10 ISS ISP GLBCE Iridix Black Level

The value stored in the Black Level register [GLBCE_BLACK_LEVEL\[15:0\]](#) VAL will be used as the zero level for iridix processing in all data channels. Data below the Black level will not be processed and remain unchanged. Recommended value 0 (decimal).

7.3.3.2.3.3.11 ISS ISP GLBCE Iridix White Level

The value stored in White Level register [GLBCE_WHITE_LEVEL\[15:0\]](#) VAL will be used as white level for iridix processing in all data channels. Data above White level will not be processed and stay unchanged. Recommended value 65535 (decimal).

7.3.3.2.3.3.12 ISS ISP GLBCE Iridix Asymmetry Function Look-up-table

The Asymmetry function is used to balance the iridix effect between the dark and bright regions of the image. The Asymmetry Function Lookup Table geometry is 33 words, each of which is 16-bits wide. [GLBCE_LUT_FI_00](#)

[GLBCE_LUT_FI_01](#)

... repeat until...

[GLBCE_LUT_FI_32](#)

Recommended values (decimal):

0:5377:10218:14600:18585:22224:25561:28631:31466:34092:36530:38801:40921:42904

 :61429:62322:63176:63995:64781:65535

The C-code for generating the Asymmetry LUT is shown below:

```
#include <math.h>

int AsymmetryTable[33];

void GenerateAsymmetry(int Asymmetry, int SecondPole)
{
    double x = (double(Asymmetry)+1)/257 * 2 - 1;
    int ai = int(0.5 + 255 * (1- 1/(1000*x*x*x) + x - ((x >= 0)*2)));
    double as = fabs(double(ai) / 255);
    double dp = double(SecondPole) / 255;
    int ii;

    for (ii = 0 ; ii < 33 ; ++ii)
    {
        if(ai >= 0)
        {
            x = double(ii) / 32;
        }
        else
        {
            x = double(32 - ii) / 32;
        }
        int y = int((dp+(1-dp)*pow((fabs(1-dp-x)/dp), 3)) * (x*(as+1)/(as+x) ) *
            65535.0 + 0.5);
        y = y < 0 ? 0 : y > 65535 ? 65535 : y;

        if (ai < 0)
        {
            y = 65535 - y;
        }
        AsymmetryTable[ii] = y;
    }
}
```

7.3.3.2.3.3.13 ISS ISP GLBCE Iridix Forward and Reverse Perceptual Functions Look-up-tables

The iridix core works in a perceptually uniform space and thus when linear data is presented to the core it needs to be processed with special perceptual functions. These are implemented as two perceptual LUTs namely: Forward Perceptual LUT and Reverse Perceptual LUT. Each LUT is made up of sixty-five 32-bit words.

[GLBCE_REV_PERCEPT_LUT_00](#)
[GLBCE_REV_PERCEPT_LUT_01](#)

... repeat until ...

[GLBCE_REV_PERCEPT_LUT_64](#)

Recommended values (in decimal) for Reverse LUT:

7.3.3.2.4 ISS ISP GLBCE Embedded Memory

GLBCE needs 2lines of line memories and 1 set of cache memories.

Table 7-632. ISS ISP GLBCE Memories

Memory	Qty	Type	Size	Clock	Description
glbce_line_mem	1	BRG	1408 x 64	FCLK	GLBCE line memory 2 lines x 32bit x 2816 required.
glbce_cache	8	BRG	16 bit x 1024	FCLK	GLBCE Cache memory (128 kbit) (8 set of 16 bit x 1024 entry) This memory is to OCP-Slave via MMR

7.3.3.2.5 ISS ISP GLBCE Programming Model

7.3.3.2.5.1 ISS ISP GLBCE Restriction

GLBCE has minimum input restriction of 480x240. The input must be at least this size.

After reset, GLBCE goes into initialization state of 554 clock cycles. While in this state, filtering flag is raised, and not input image may come into GLBCE module.

GLBCE LUTs must not be changed during the active frames. They can only be updated in vertical blanking. GLBCE_LUT_FI may be changed frame by frame depending on the GLBCE tuning method. Other LUTs (GLBCE_REV_PERCEPT_LUT_xx, GLBCE_FWD_PERCEPT_LUT_xx, and GLBCE_WDR_GAMMA_LUT_xx) are not expected to be updated dynamically except in very limited case.

7.3.3.2.5.1.1 ISS ISP GLBCE Recovery from Reset

GLBCE module needs certain number of cycles (554 cycles) of PCLK input after reset to regenerate the default table internally. Therefore, it requires special procedure after reset process (HW reset, ISP-Top level SW reset, and GLBCE level SW reset).

Typical procedure is as following, but other sources of PCLK may be used

- SW make sure PCLK is not provided to GLBCE right after reset (VMUX does not connect CAL and GLBCE)
- After GLBCE is reset, wait until GLBCE returns to normal status
- SW write `ISP_SWT_SEL[9:8]` GLBCE_SEL=1 (select GLBCE-CAL at ISP-Top) and Write "1" to `ISP5_CTRL[19]` GLBCE_CLK_ENABLE (Enable GLBCE clock)
- CAL starts generating PCLK in a dummy frame
- VMUX is switched to feed PCLK from CAL to GLBCE (This is after HS/VS, so GLBCE won't see them)
- Eventually GLBCE finishes initialization process, and generates filtering_done interrupt after ~5500 cycles (accurate cycle should be updated after DV completion). GLBCE is ready.
- SW detects filtering_done and stops PCLK generation by CAL
- SW may switch GLBCE_SEL to other values. Move to the next steps

7.3.3.2.5.1.2 General description of GLBCE processing

GLBCE block needs appropriate statistics information to be stored to its cache memory in prior to processing incoming frame. Usually, this takes a two-pass process.

1. GLBCE is configured for input frame-A
2. Frame-A is given to GLBCE
3. GLBCE processes the input frame-A
4. GLBCE generates statistic (statistics-A) data based on frame-A in vertical blanking period
5. (Optional process) statistics-A is read from cache memory and moved to SDRAM
6. GLBCE is configured for input frame-B
7. Frame-B is given to GLBCE

8. GLBCE processes the input frame-B with the statistics-A generated from frame-A
9. GLBCE generates statistics-B based on frame-B in vertical blanking period
10. (Optional process) statistics-B is read from cache memory and moved to SDRAM

Alternatively, GLBCE can process in the following manner

1. Pre-calculated Statistics-C is copied to GLBCE cache memory from SDRAM
2. GLBCE is programmed for input frame-D
3. Frame-D is given to GLBCE
4. GLBCE processes frame-D based on statistics-C
5. GLBCE generates statistics-D based on frame-D in vertical blanking period
6. (Optional process) statistics-D is read from cache memory and moved to SDRAM

In [Section 7.3.3.2.5.1.3](#), some examples closer to real world use cases are explained based on the above two processes.

7.3.3.2.5.1.3 Continuous Frame Processing

This is a very basic case, which does not need transferring statistics between cache memory and SDRAM. The most common example is video capture. In this case, the most straight forward way to run GLBCE, is to generate statistics from N-th frame, and apply it to (N+1)-th frame. The effect from using statistics of different frame should be small if the difference between frames is small. For example, it is expected this does not generate artifact, if the video frame rate is 30fps or larger. Below this rate, the single frame processing programming model explained in [Section 7.3.3.2.5.1.4](#) should be considered.

In the case of continuous frame processing, GLBCE is operated in the following manner:

1. GLBCE is programmed for incoming frame
2. Input frame comes in
3. GLBCE processes Input frame based on the statistics from the previous frame
4. GLBCE generates statistics based on the current input frame in the vertical blanking period
5. Repeat Step 1 through 4 as required

For the first frame of a set of sequential frames, Strength parameter should be 0, so GLBCE does not affect the image based on wrong statistics. SW may need to increase the strength value gradually after the first frame.

7.3.3.2.5.1.4 Single Image Processing

For a single image, GLBCE needs to process the image twice, once for statistics generation, and once for actual GLBCE process.

1. GLBCE is configured for the input image.
2. The image is given to GLBCE. (Output image from GLBCE should be suppressed, for example, by disabling IPIPE.)
3. Statistics is generated in vertical blanking period.
4. The input image is given to GLBCE again. Output image with right GLBCE is generated.

Also, GLBCE can take in small size image in the first pass to reduce processing time.

5. A small size version (IMG-S) of the input image (IMG-IN) is generated.
6. GLBCE is configured for the small size image (IMG-S).
7. The small size image (IMG-S) is given to GLBCE.
8. Statistics for the small size image is generated in vertical blanking period.
9. GLBCE is configured for the original input image (IMG-IN).
10. The original input image (IMG-IN) is given to GLBCE.

7.3.3.3 ISS ISP NSF3V Functional Description

7.3.3.3.1 ISS ISP NSF3V Overview

The Noise Filter 3V is the on-the-fly advanced noise filter algorithm and edge enhancement. Noise filtering reduces or removes noise in images without blurring details or image features. It is particularly useful for processing images captured under low-light settings through an image signal processor (ISP).

Edge enhancement enhances the sharpness of the image. Edge enhancement is usually applied lightly to avoid processing artifacts in the eventual ISP output image.

Noise filtering and edge enhancement can be processed in separate passes or in a combined pass. Typically, in low-light areas of the image, noise filtering is applied. In bright areas of the image, edge enhancement is applied.

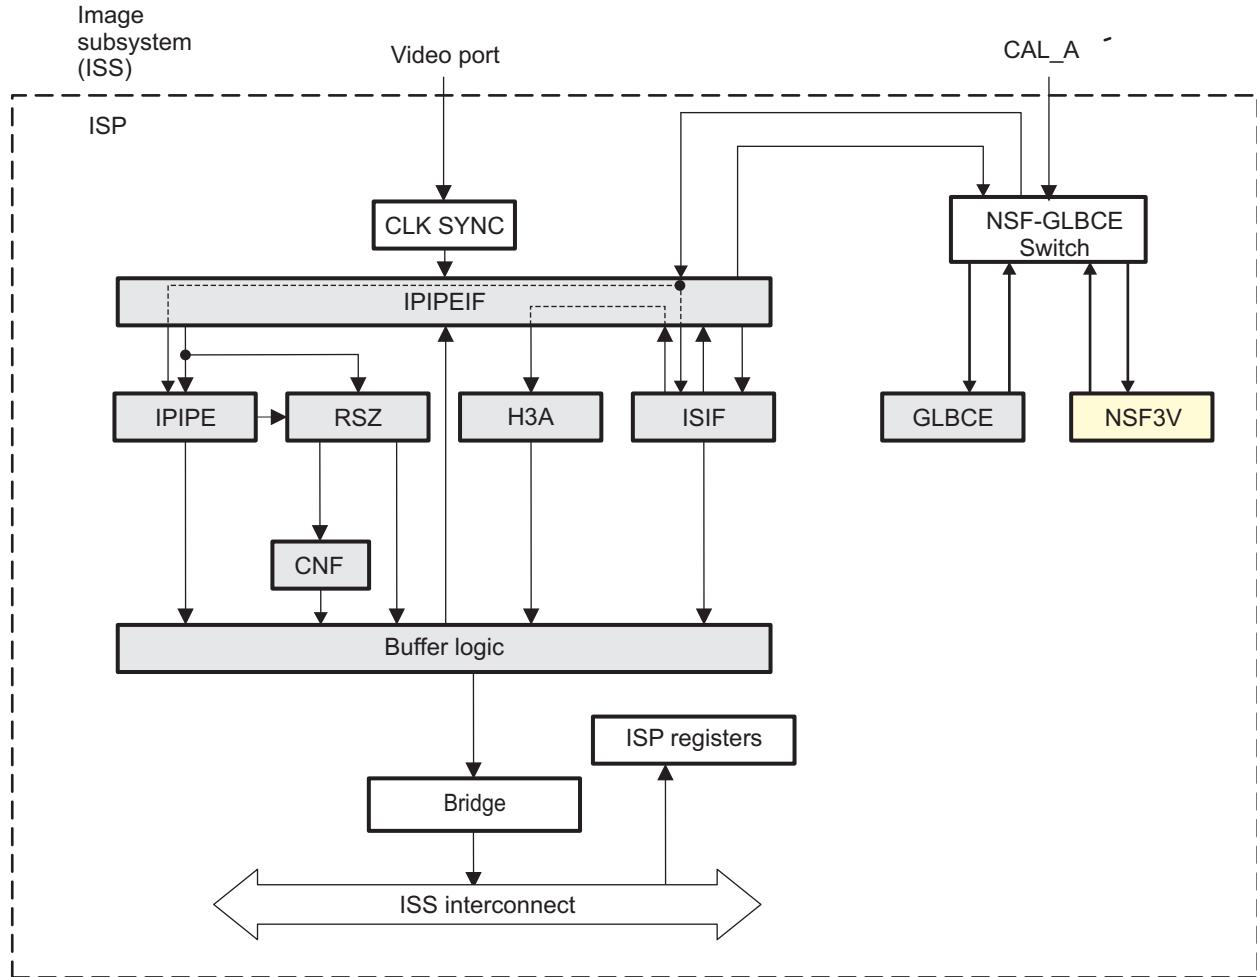

NSF3V operates on raw Bayer RGB data that it receives Bayer or YUV image data from IPIPEIF via Video Port, and processes the image and gives back the filtered image to ISIF. NSF3V is inserted into the path between IPIPEIF and ISIF. NSF3V can also work with CAL_A. Since no SDRAM round trip of data, the NSF3V can perform at 1pix/cycle. The module supports:

NSF3V functionality is not required to comply to any standard, as the noise filtering algorithm is proprietary.

- High-ISO Video Noise Filtering (NSF3V)
 - Up to 212.8 MPix/s
 - Bayer RGB, YUV422, and YUV420 formats
 - 12-bit datapath bit width
 - 2816 pixels input line memory size
 - Throughput of 1 data points per cycle, without the overhead
 - For Bayer, 1 pixel = 1 data point
 - For YUV422, 1 pixel = 2 data points
 - For YUV420, 1 pixel = 1.5 data points
 - Adaptive noise level threshold
 - Inter-color-luma-estimation affecting noise threshold
 - Soft thresholding
 - Edge enhancement
 - Radial shading gain
 - Desaturation for YUV
 - Use luma to drive chroma noise threshold in YUV422
 - Support output width = input width by replicating border pixels, requires at most 48 extra pixel of processing time per row
 - Separately replicate-or-trim support for left and right borders
 - Support output height = input height by replicating top/bottom border pixels, requires 7 extra rows of processing time
 - Interleaved processing options
 - Image framing
 - Single frame and video support, flexible interrupt configuration
 - When NSF3V and GLBCE are off, ISP is backward compatible with previous devices
 - DPC before NSF3V processing (DPC is switched between IPIPE and NSF3V)
 - NSF3-level image quality at 1080p120 throughput rate
 - NSF3 3x3-interleaving level image quality at 1080p60 throughput rate
 - Run in-line with ISP processing to reduce system traffic
 - Use luma to drive chroma thresholding for YUV422

[Figure 7-76](#) show the NSF3V module connections to other submodules of the ISP.

Figure 7-76. ISS ISP NSF3V High-Level Diagram

camisp-0036

NSF3V is instantiated 2 times in ISP. Full feature NSF3V, with all the operation modes, is used in the front end of ISP(as shown in the) and the integration supports the following dataflow options:

- CAL -> NSF3V -> CAL
- IPIPEIF -> NSF3V -> ISIF

The other instance are integrated in the backend of ISP, right after the ISP resizer output and inside the CNF block. The CNF block contains chroma downsampling and upsampling blocks before and after the NSF3V instance as shown in the [Figure 7-77](#).

Figure 7-77. ISS ISP NSF3V High-Level Diagram

camisp-810

7.3.3.3.2 ISS ISP NSF3V Register Shadowing

NSF3V module has a shadow copy of all the configuration registers, to allow changing the registers for the next frame, either for next single-frame or next frame in the video mode. A ready-to-reprogram interrupt (nsf3v_int_reprgm) is sent to indicate such time frame, and this shortly is after vertical start (VPin_VS) in input video port is received, and before the current frame is completed, indicated by nsf3v_int_outcmpl.

When hardware completes one frame of processing in the video mode, it clears NSF3V_CTRL[0] EN in the shadow copy only, so that software can indicate "this is the last frame" in the middle of the last frame processing, and the last frame would be processed to completion.

When hardware completes one frame of processing in one-shot mode, it clears NSF3V_CTRL[0] EN in both the config bus accessible copy and the shadow copy. This is to keep one-shot mode simple and truly one-shot; next frame should not be queued-up while the current frame is being processed

The configuration reprogramming time window from nsf3v_int_reprgm to nsf3v_int_outcmpl applies to all register fields except NSF3V_CTRL[0] EN in one-shot mode. Re-enabling NSF3V in one-shot mode (by writing 1 to NSF3V_CTRL[0] EN) should be performed AFTER nsf3v_int_outcmpl.

7.3.3.3.3 ISS ISP NSF3V Programming Model

7.3.3.3.3.1 ISS ISP NSF3V Initialization

Upon reset, NSF3V module is idle. When idle, NSF3V ignores VPin, and does not send anything on VPout (VS/HS/VE/HE/EN/DATA = 0).

For single-frame mode of operation, software initializes or changes various parameters, with NSF3V_CFG[7] ONESHOT = 1, then writes 1 to the NSF3V_CTRL[0] EN bit to enable processing of one frame. After NSF3V_CTRL[0] EN is written 1, the module is ready to accept a new frame from the input video port.

For video mode of operation, software initializes or changes various parameters, with NSF3V_CFG[7] ONESHOT = 0, then writes 1 to the NSF3V_CTRL[0] EN bit to enable processing of image frames

To exit video mode, software writes 0 to NSF3V_CTRL[0] EN, and after the current frame processing is completed, NSF3V become idle again.

To program NSF3V to process image frame(s), image width/height, algorithm/processing features, and algorithm parameters should be programmed, then NSF3V_CTRL[0] EN bit written 1, then proper ISP/ISS components configured to start sending image frame(s) to NSF3V.

NSF3V processing/algorithm parameters are as follows:

- Mode of operation (NSF3V_CFG[3:0] MODE), with these options: {BAYER, BAYER_I2x2, BAYER_I3x3, YUV422, YUV420Y, YUV420UV, YUV422_I, YUV420Y_I, YUV420UV_I}.
- Border replication (NSF3V_CFG[11] LBORDER_REP, NSF3V_CFG[12] RBORDER_REP, NSF3V_CFG[13] TBORDER_REP, NSF3V_CFG[14] BBORDER_REP). When enabled, replicate left, right, top, and bottom borders, respectively, to selectively keep the border's contribution to width/height, or reduce by the border width. See for border widths.
- Video port output data rate configured via NSF3V_VPOUT_CTRL[15:0] PCLK. Output EN signal would asserted and data (8/12/16-bit according to operation mode) at *functional clock* * NSF3V_VPOUT_CTRL[15:0] PCLK / 65536.

The following pseudo code sets a binary value on EN based on PCLK

```
ACC = 0;
while (1)
{
    wait_until_rising_edge_of_clock( );
    ACC += PCLK;
    EN = (ACC >= 65536);
    ACC = ACC % 65536;
}
```

CAUTION

Due to dependency, NSF3V requires horizontal and vertical blanking. Having blanking provided by the upstream module would suffice, but this adds inter-module dependency that can be difficult to debug. Having NSF3V drives its own output data rate would avoid this inter-module dependency.

NOTE: The SUSPEND signal from video port output would cause ignoring functional clock pulses and slowing down the output data rate.

- Edge enhancement enable ([NSF3V_CFG\[8\] EE_EN](#)).
- Radial shading gain enable ([NSF3V_CFG\[9\] SHD_EN](#)).
- Desaturation enable ([NSF3V_CFG\[10\] DESAT_EN](#)).
- YUV422 UV path hard thresholding enable ([NSF3V_CFG\[6\] HARD_THR_EN_422UV](#)).
- Image width and height in pixels ([NSF3V_DIM\[13:0\] IW](#), [NSF3V_DIM\[29:16\] IH](#)).
- Radial shading parameters ([NSF3V_SHD_ST.X/Y](#), [NSF3V_SHD_HA](#), [NSF3V_SHD_VA](#), [NSF3V_SHD_HSVS](#), [NSF3V_SHD_ADJ](#)). Note that SHD_ST.X/Y are in pixels and lines, as opposed to data points
- Noise threshold piece-wise linear function parameters: NSF3V_TN_C[0..3][0..5].S[0..3][XYS], C[0..3] for the 4 color planes, and S[0..3] for the 4 segments. Together there are 4x4x3 = 48 parameters, each taking up 16-bit. Each color's S0_X is fixed at 0.

- Soft thresholding function knee points u1, u2, u3 ([NSF3V_THR_KNEE.U\[1..3\]](#)).
- Soft thresholding suppression_max for each color/subband ([NSF3V_SUP_C\[0..3\]\[0..1\].L\[1..3\]_ \[LH, HH\]](#)), 4x3x2 = 24 parameters, each taking up a byte.
- Edge enhancement ee_max for each color/subband ([NSF3V_EE_C\[0..3\]_L\[1..3\]_ \[LH, HH\]](#)), 24 parameters
- Desaturation parameters ([NSF3V_CFG\[10\] DESAT_EN](#), [NSF3V_DS_THR\[\] .THR1/2](#), [NSF3V_DS_SLOPE\[\] SLOPE1/2](#))

7.3.3.4 ISS ISP IPIPEIF Functional Description

7.3.3.4.1 ISS ISP IPIPEIF Overview

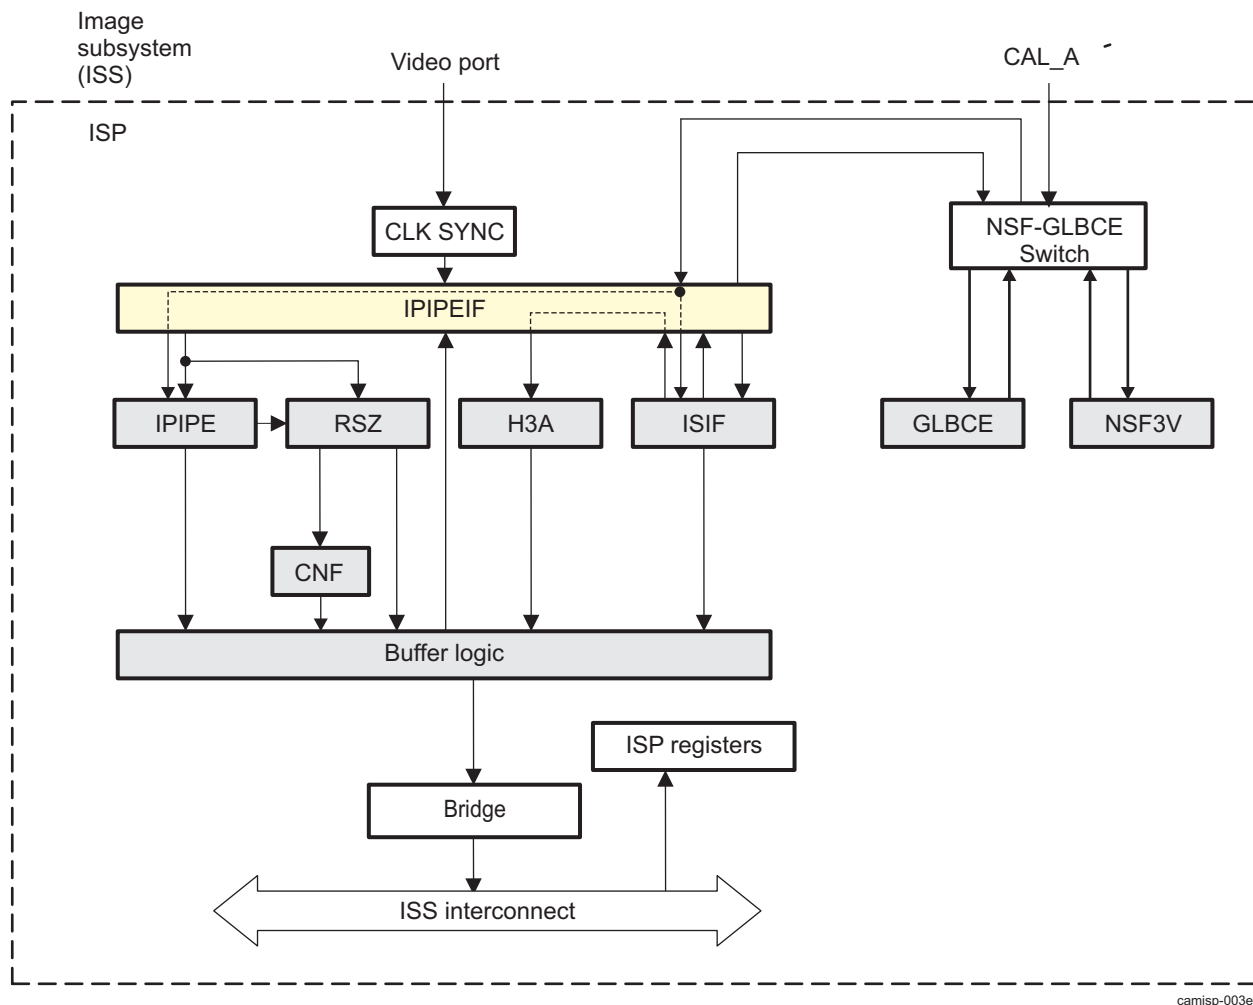

The IPIPEIF module provides data and synchronization signals (HD, VD) for the ISIF, IPIPE, RSZ, and H3A modules. The data source of this module is the VP, ISIF, or SDRAM using BL, and the selected data is output to ISIF, IPIPE, H3A, NSF-GLBCE Switch, and RSZ. This module supports:

- Up to 16-bpp data on the VP
- Up to 212.8-MHz pixel clock on the VP, up to 8K × 8K imaging resolution
- RAW and YUV data formats on the VP and BL ports
- Dark-frame subtract of 8-bit RAW image stored in SDRAM from image from VP
- Dark-frame subtract of 8-bit RAW image stored in SDRAM from image from ISIF
- Dark-frame subtract of 8-bit RAW image from VP from image read from SDRAM through the BL
- Simple defect correction to prevent the subtraction of defect pixels
- 8-10, 8-12 DPCM of 10-8, 12-8 DPCM compressed data in SDRAM
- Simple and advanced DPCM predictor
- Inverse A-Law decompression of RAW data 10-8 A-Law compressed from SDRAM
- 8-bit, 12-bit unpacking of 8-bit, 12-bit packed SDRAM data
- Gain multiply for output data to the IPIPE module

- Horizontal Bayer rescaler in the data paths to the IPIPE and H3A modules: Supports (1, 2, 1) averager filter and supports horizontal pixel decimation
- Data rate control when reading data from RAM: Fraction clock divider
- (1, 2, 1) averager filter and supports horizontal pixel decimation in the data path to the IPIPE for YUV data.
- Support stalling of data processing in response to external request
- Issues stall signal to halt the up-stream module when necessary (IPIPEIF_INPUT_STALL)
- WDR Merging and WDR image split (split 16-bit input into 2 12-bit images)

Figure 7-78 show the IPIPEIF module connections to other submodules of the ISP.

Figure 7-78. ISS ISP IPIPEIF High-Level Diagram

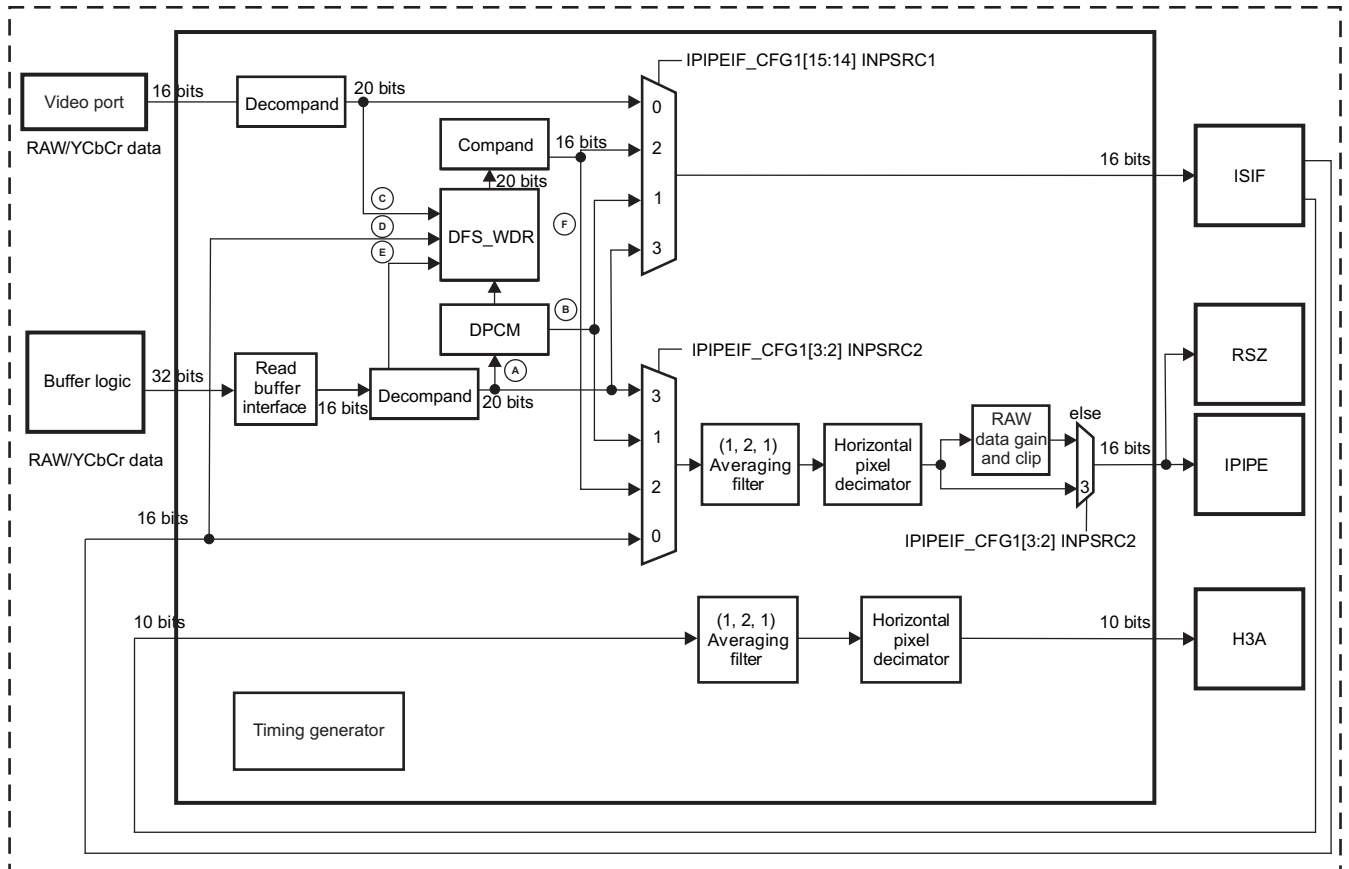

camisp-003e

7.3.3.4.2 ISS ISP IPIPEIF Top-Level Block Diagram

The following sections describe the function of each subblock in the IPIPEIF, as shown in Figure 7-79.

Figure 7-79. ISS ISP IPIPEIF Top-Level Block Diagram

camss-030b

NOTE: When the IPIPEIF receives data from the VP, the timing generator must be configured for HD, VD, and WEN. For more information, see [Section 7.3.3.4.5, ISS ISP IPIPEIF Timing Generation](#).

7.3.3.4.3 ISS ISP IPIPEIF Input Interface

The IPIPEIF module comprises two major interface blocks: VP and BL. The data types can be RAW or YUV.

7.3.3.4.3.1 ISS ISP IPIPEIF Input From VP

The VP typically receives data from the image sensor. At the ISS level, it is connected to the serial interface receivers.

7.3.3.4.3.2 ISS ISP IPIPEIF Input From BL

The BL is the interface with the memory (SDRAM). In that case, the SDRAM address and line offset registers must be programmed in units of 32 bytes.

- SDRAM start address (byte) = (IPIPEIF_ADDRU[10:0] ADDRU) << 16 + (IPIPEIF_ADDRL[15:0] ADDRL)
- SDRAM address offset (byte) = IPIPEIF_ADOFS[11:0] ADOFS

Two types of data can be stored in memory: pixel data and dark frame data.

For pixel data, the HD and VD signals are reconstructed with:

- [IPIPEIF_HNUM](#)
- [IPIPEIF_VNUM](#)
- [IPIPEIF_LPFR](#)
- [IPIPEIF_PPLN](#)

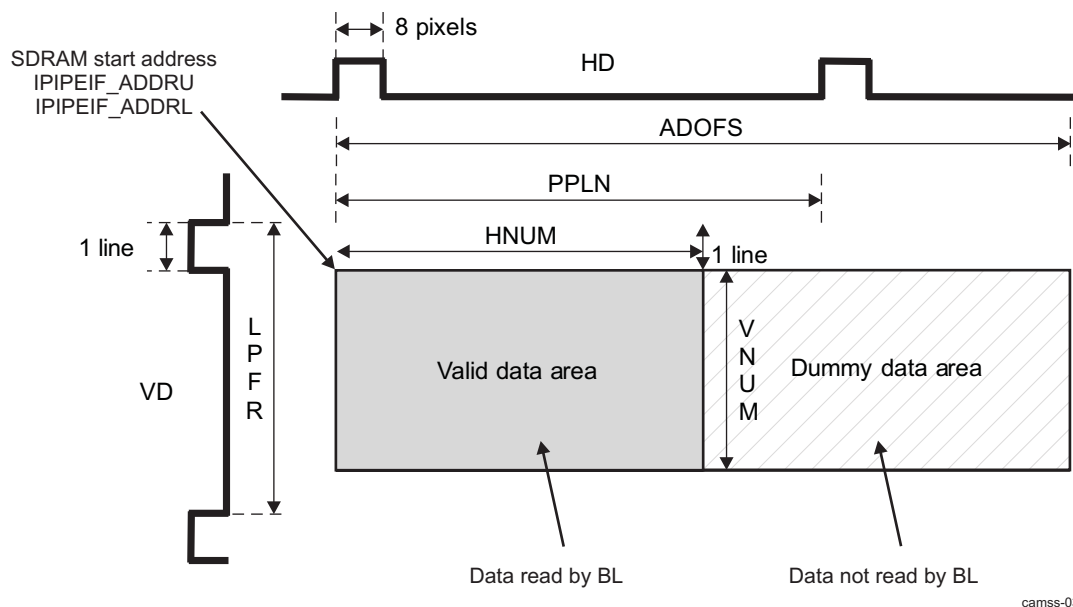

The [IPIPEIF_HNUM](#) and [IPIPEIF_VNUM](#) registers define the number of pixels per line and lines per frame to read from the SDRAM, and the [IPIPEIF_LPFR](#) and [IPIPEIF_PPLN](#) registers define the interval of VD and HD, respectively.

Vertical blanking for the frame is defined with the following equation: $\text{IPIPEIF_LPFR} - \text{IPIPEIF_VNUM} - 1$.

Horizontal blanking for the frame must be at least eight ISP_FCLK cycles, and is defined with the following equation: $\text{IPIPEIF_PPLN} - \text{IPIPEIF_HNUM} > 7$.

[Figure 7-80](#) shows the global frame definition for all SDRAM input modes, except for dark frame subtract.

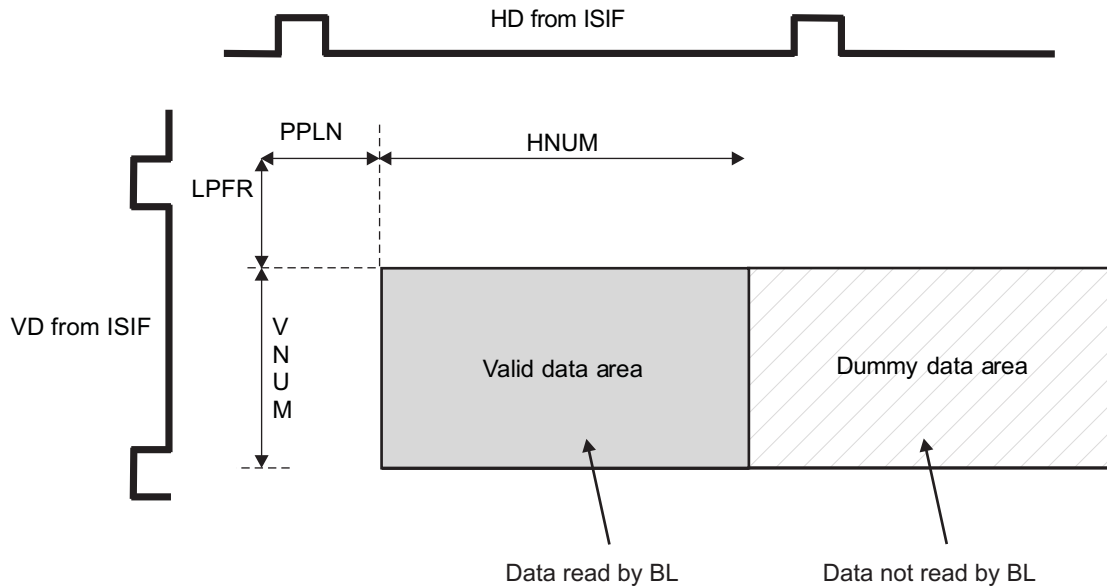

Figure 7-80. ISS ISP IPIPEIF Global Frame Definition in SDRAM Input Modes (Except Dark Frame)

camss-031

For dark frame data, the HD and VD signals come from the VP through the ISIF. The [IPIPEIF_PPLN](#) and [IPIPEIF_LPFR](#) registers must be used to indicate the horizontal and vertical start position of the subtraction from the ISIF data, as shown in [Figure 7-81](#). The value of the [IPIPEIF_LPFR\[12:0\]](#) LPFR bit field must be greater than 0 because the first line from the VP or ISIF cannot be subtracted from. The [IPIPEIF_HNUM](#) and [IPIPEIF_VNUM](#) registers must be used to set the number of valid pixels horizontally and the number of valid lines vertically.

Figure 7-81. ISS ISP IPIPEIF Global Frame Definition in Dark Frame Subtract Mode

camss-034

7.3.3.4.3.2.1 ISS ISP IPIPEIF Double-Buffer Input Function When Reading From BL

The IPIPEIF module supports a double-buffer input function. This feature is most useful when SDRAM space is limited, because it enables to read continuously from two buffers and to push data to the rest of the ISP (ISIF, H3A, etc.) for further processing.

Consider the following configuration where data are read from two buffers, A and B. The intent is not only to read continuously from these buffers but also to ensure that the ISP modules consider the data as being from the same frame; that is, VD is generated the first time buffer A is read, but it must not toggle until all the frames are read.

The IPIPEIF module can mask the VD sync signal by setting the `IPIPEIF_ENABLE[1] SYNCOFF` bit such that the IPIPEIF module drives the data to the ISP modules as if it is a continuous frame data.

In the following example, there are 16 lines per trigger and input circular addressing. $VNUM = 16$ (see [Figure 7-80](#)), and the VD signal is generated only for the first frame (see [Figure 7-82](#)).

Figure 7-82. ISS ISP IPIPEIF Double-Buffer Functionality

camss-615

7.3.3.4.4 ISS ISP IPIPEIF Data Path Selection

The data path configuration through the IPIPEIF module is set with the [IPIPEIF_CFG1\[15:14\] INPSRC1](#) and [IPIPEIF_CFG1\[3:2\] INPSRC2](#) bit fields. [Table 7-633](#) lists the possible combinations for these two bit fields.

Table 7-633. ISS ISP IPIPEIF IPIPEIF_CFG1[15:14] INPSRC1 and IPIPEIF_CFG1[3:2] INPSRC2 Possible Combinations

IPIPEIF_CFG1[15:14] INPSRC1	IPIPEIF_CFG1[3:2] INPSRC2	Description	Common Use
0	0	This data path is described in Section 7.3.3.4.4.1, ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 0.	Video record, view finder, on-the-fly still image capture applications
0	1	This data path is described in Section 7.3.3.4.4.2, ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 1.	Memory-to-IPIPE-to-memory operation
0	2	This data path is described in Section 7.3.3.4.4.3, ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 2.	Image capture with on-the-fly dark frame subtraction

Table 7-633. ISS ISP IPIPEIF IPIPEIF_CFG1[15:14] INPSRC1 and IPIPEIF_CFG1[3:2] INPSRC2 Possible Combinations (continued)

IPIPEIF_CFG1[15:14] INPSRC1	IPIPEIF_CFG1[3:2] INPSRC2	Description	Common Use
0	3	This data path is described in Section 7.3.3.4.4.4 , <i>ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 3</i> .	On-the-fly data acquisition done in VP, forwarded to the ISIF, and then to the H3A through IPIPEIF while data from memory is processed and forwarded to the IPIPE module and then stored in memory YUV4:2:2 or RAW data processing with the IPIPE and RSZ modules from memory to memory fetched by IPIPEIF
1	0	This data path is described in Section 7.3.3.4.4.5 , <i>ISS ISP IPIPEIF INPSRC1 = 1 and INPSRC2 = 0</i> .	Memory-to-ISIF-to-memory operation
1	1	This data path is possible but there is no use case associated.	N/A
1	2	This data path is not supported.	N/A
1	3	This data path is not supported.	N/A
2	0	This data path is described in Section 7.3.3.4.4.6 , <i>ISS ISP IPIPEIF INPSRC1 = 2 and INPSRC2 = 0</i> .	Dark frame subtraction is performed and data sent to the ISIF module for further processing, back to IPIPEIF, and then to IPIPE and RSZ.
2	1	This data path is not supported.	N/A
2	2	This data path is not supported.	N/A
2	3	This data path is not supported.	N/A
3	0	This data path is described in Section 7.3.3.4.4.7 , <i>ISS ISP IPIPEIF INPSRC1 = 3 and INPSRC2 = 0</i> .	Memory-to-ISIF-to-memory operation
3	1	This data path is not supported.	N/A
3	2	This data path is not supported.	N/A
3	3	This data path is possible but there is no use case associated.	N/A

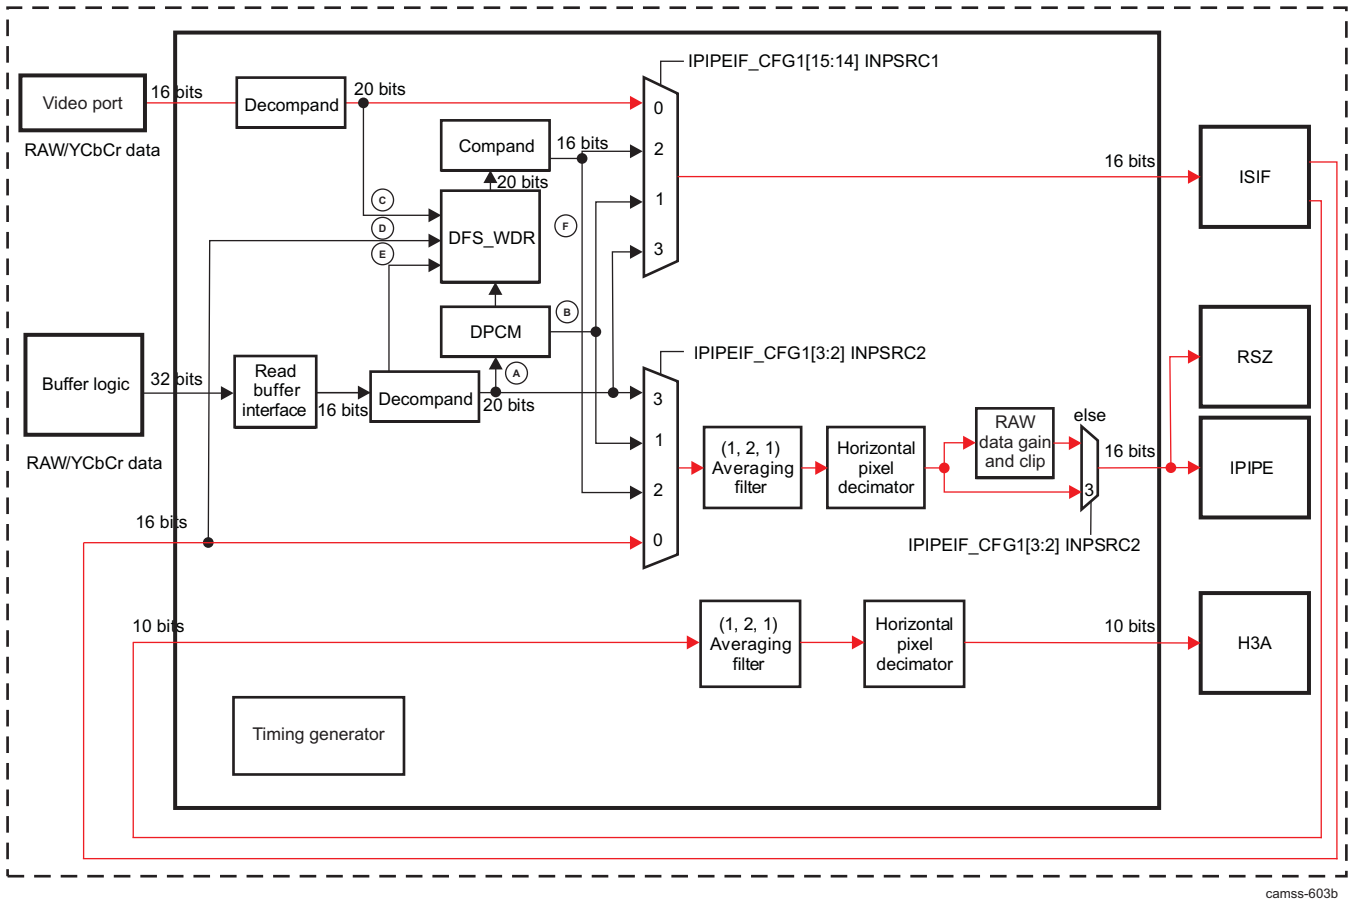

7.3.3.4.4.1 ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 0

Set the [IPIPEIF_CFG1\[15:14\] INPSRC1](#) bit field to 0 and the [IPIPEIF_CFG1\[3:2\] INPSRC2](#) bit field to 0.

This configuration can be used for the video record, viewfinder, and on-the-fly still image capture applications. The full ISP processing capability is used in a single pass.

[Figure 7-83](#) shows the data path.

Figure 7-83. ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 0 Data Path

camss-603b

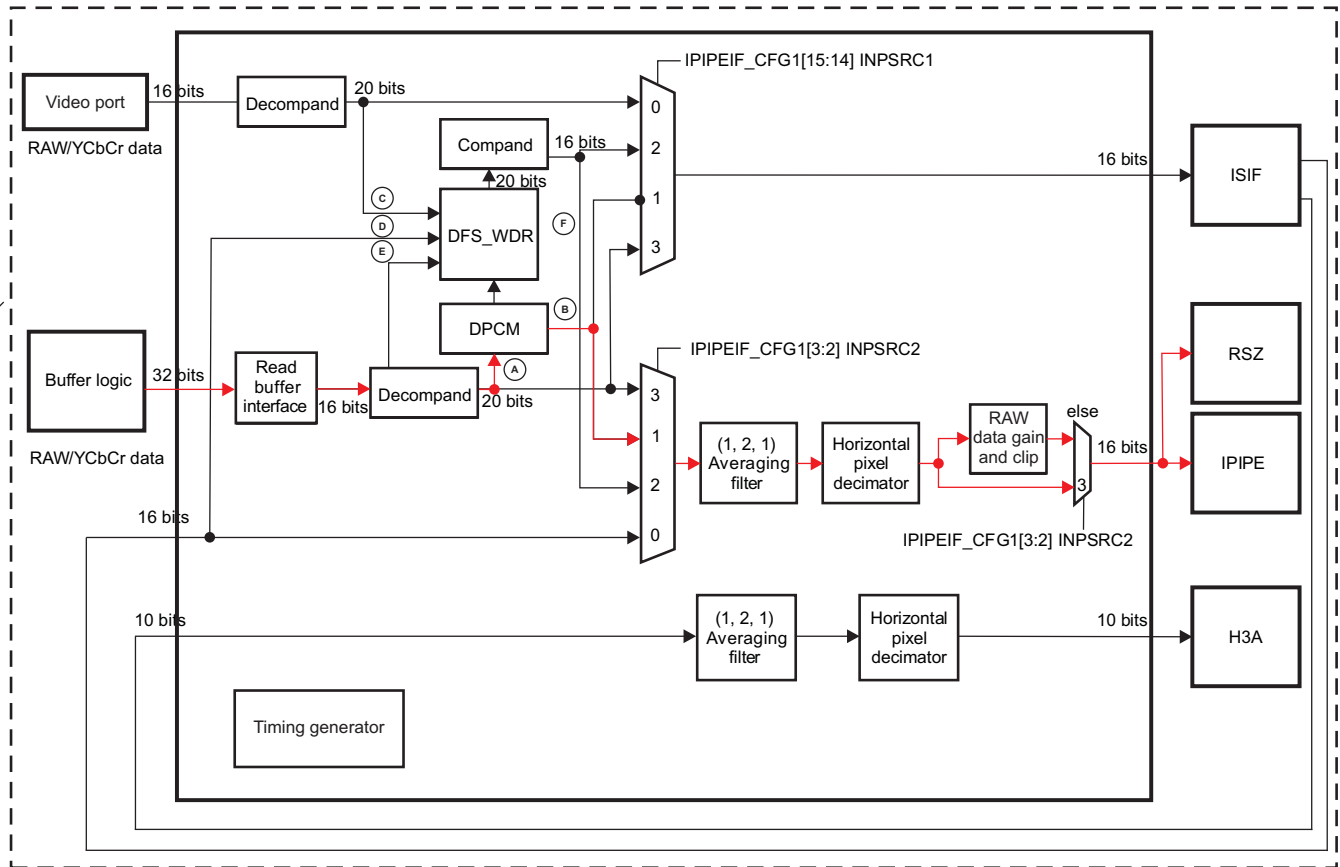

7.3.3.4.4.2 ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 1

Set the `IPIPEIF_CFG1[15:14] INPSRC1` bit field to 0 and the `IPIPEIF_CFG1[3:2] INPSRC2` bit field to 1. This configuration can be used to process data with the IPIPE module from memory to memory. The data stored in SDRAM can be decompressed (A-law or DPCM) before being forwarded to the IPIPE module.

NOTE: In this configuration, the ISIF and H3A modules are assumed to be disabled.

Figure 7-84 shows the data path.

Figure 7-84. ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 1 Data Path

camss-604b

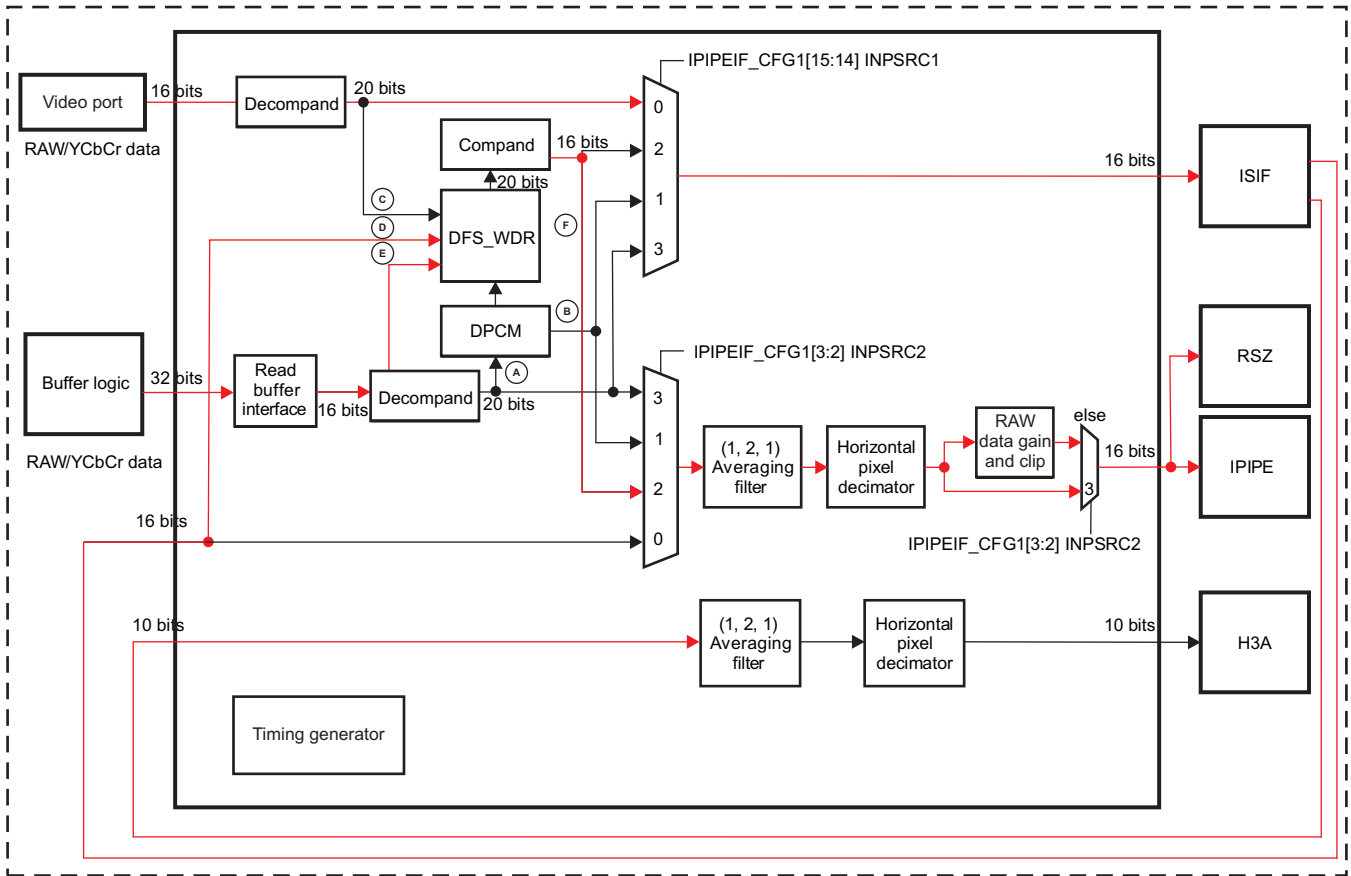

7.3.3.4.4.3 ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 2

Set the `IPIPEIF_CFG1[15:14] INPSRC1` bit field to 0 and the `IPIPEIF_CFG1[3:2] INPSRC2` bit field to 2.

This configuration can be used for image capture with on-the-fly dark-frame subtraction. In the first case, the dark frame can come from BL and data from the ISIF. In the second case, the dark frame can come from the VP and data from BL.

Figure 7-85 shows the data path.

Figure 7-85. ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 2 Data Paths

camss-610b

7.3.3.4.4 ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 3

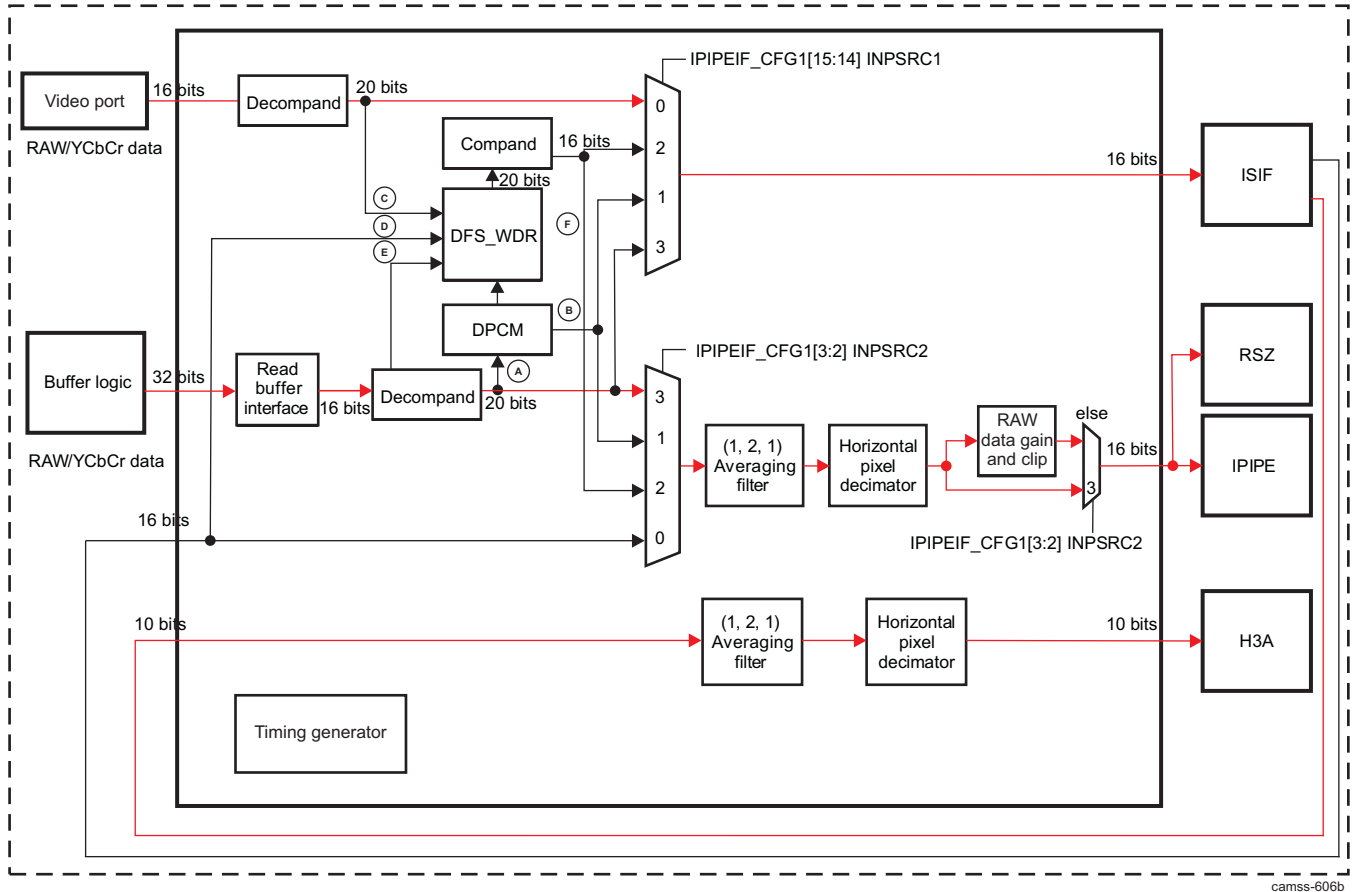

Set the IPIPEIF_CFG1[15:14] INPSRC1 bit field to 0 and the IPIPEIF_CFG1[3:2] INPSRC2 bit field to 3.

In the first case, on-the-fly data acquisition is done with the VP, forwarded to the ISIF, and then sent to the H3A through the IPIPEIF while data from memory is processed and forwarded to the IPIPE module and then stored in memory.

In the second case, the configuration can be used to process YUV4:2:2 or RAW data with the IPIPE and RSZ modules from memory-to-memory. The YUV4:2:2 or RAW data stored in the SDRAM is fetched and forwarded to the IPIPE and RSZ modules. ISIF and H3A are assumed to be disabled in this configuration.

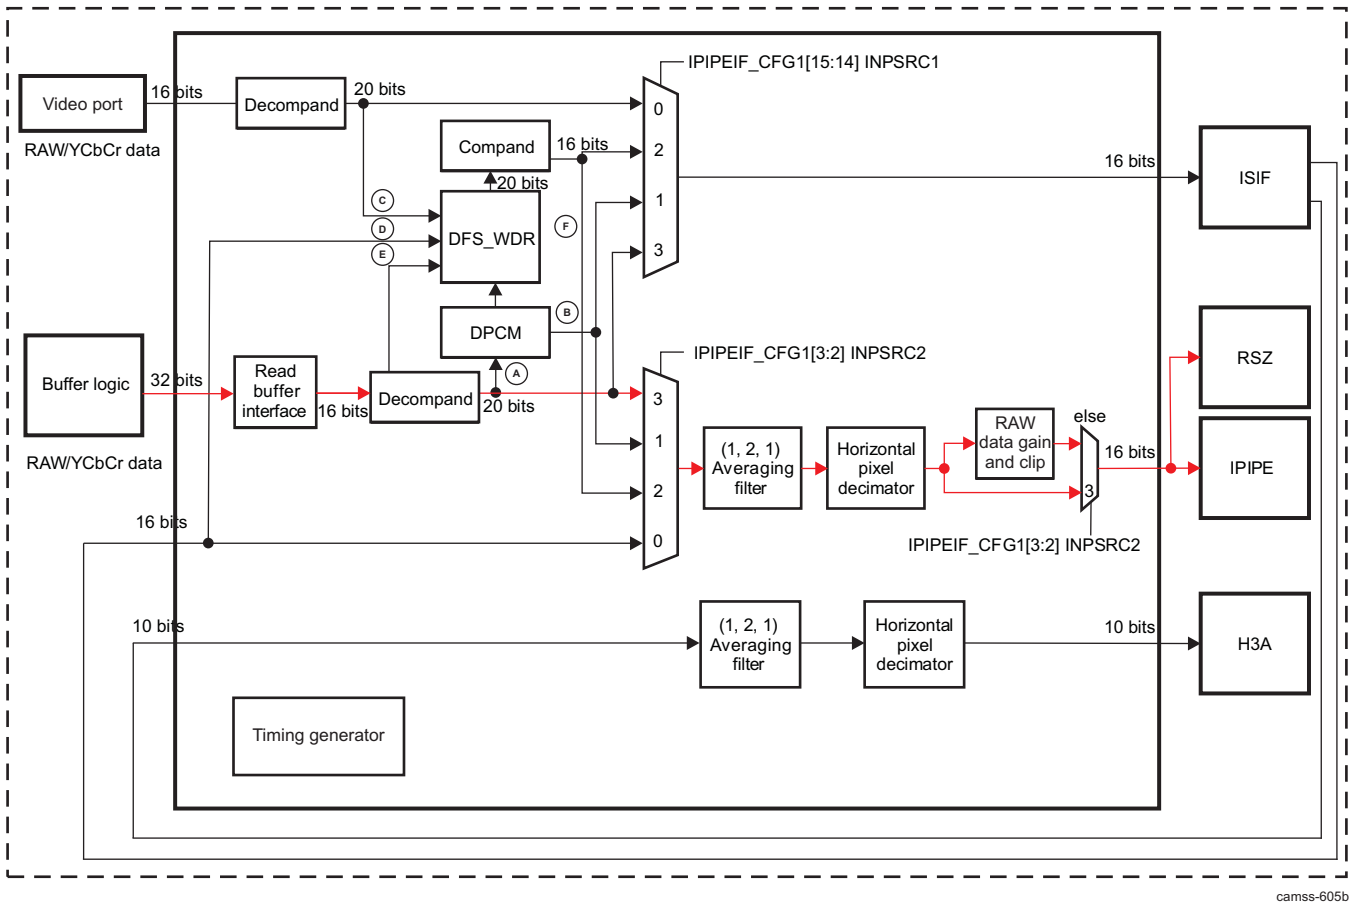

Figure 7-86 and Figure 7-87 show the two possible data paths.

Figure 7-86. ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 3 Data Paths: First Case

camss-606b

Figure 7-87. ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 3 Data Paths: Second Case

camss-605b

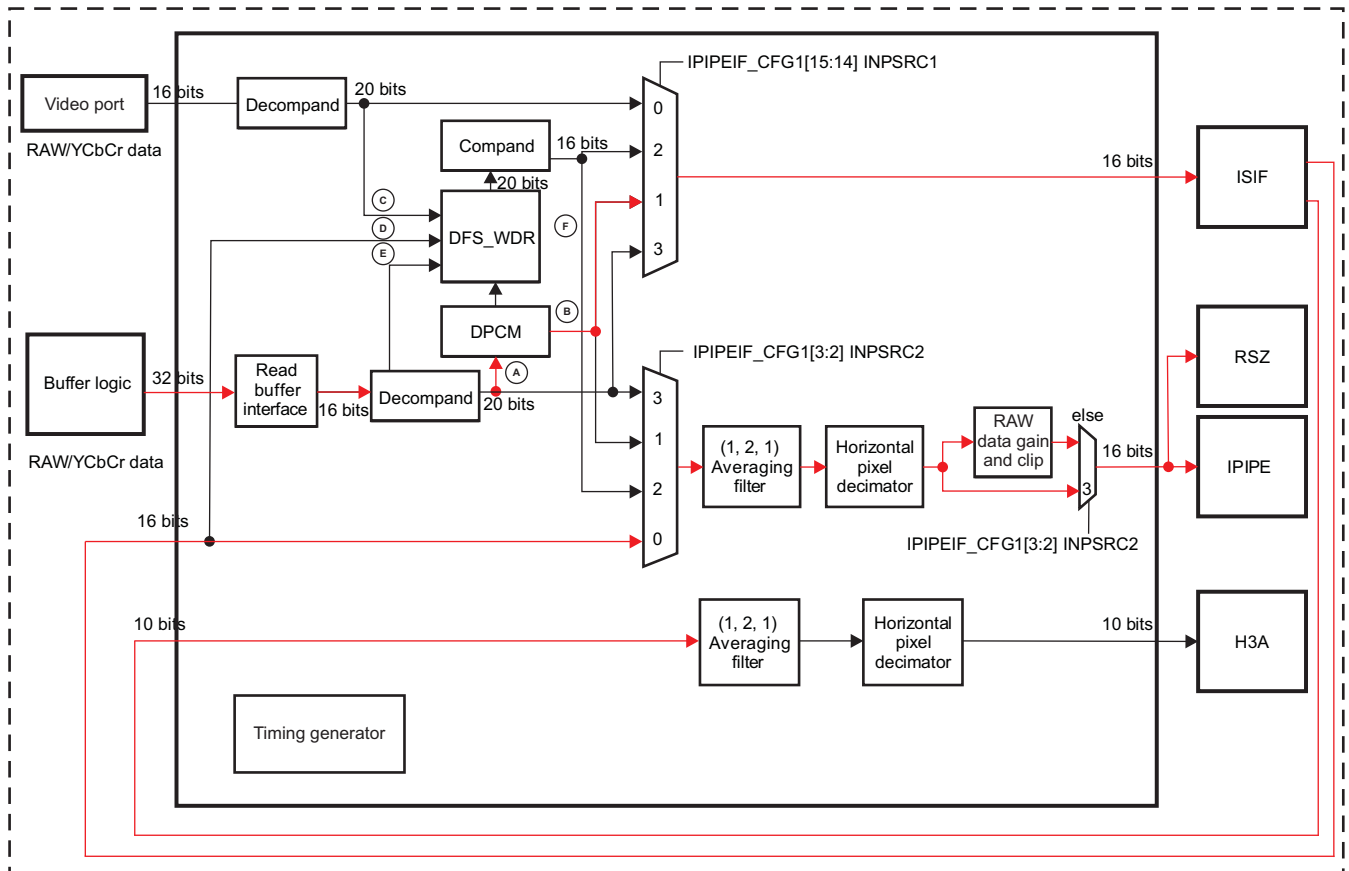

7.3.3.4.4.5 ISS ISP IPIPEIF INPSRC1 = 1 and INPSRC2 = 0

Set the IPIPEIF_CFG1[15:14] INPSRC1 bit field to 1 and the IPIPEIF_CFG1[3:2] INPSRC2 bit field to 0.

This configuration is a memory-to-memory operation. RAW data is read by the BL interface, decompressed, and pushed to the ISIF. The ISIF processes the data and sends it back to the IPIPEIF module before the data is pushed to the IPIPE and H3A modules.

Figure 7-88 shows the data path.

Figure 7-88. ISS ISP IPIPEIF INPSRC1 = 1 and INPSRC2 = 0 Data Path

camss-607b

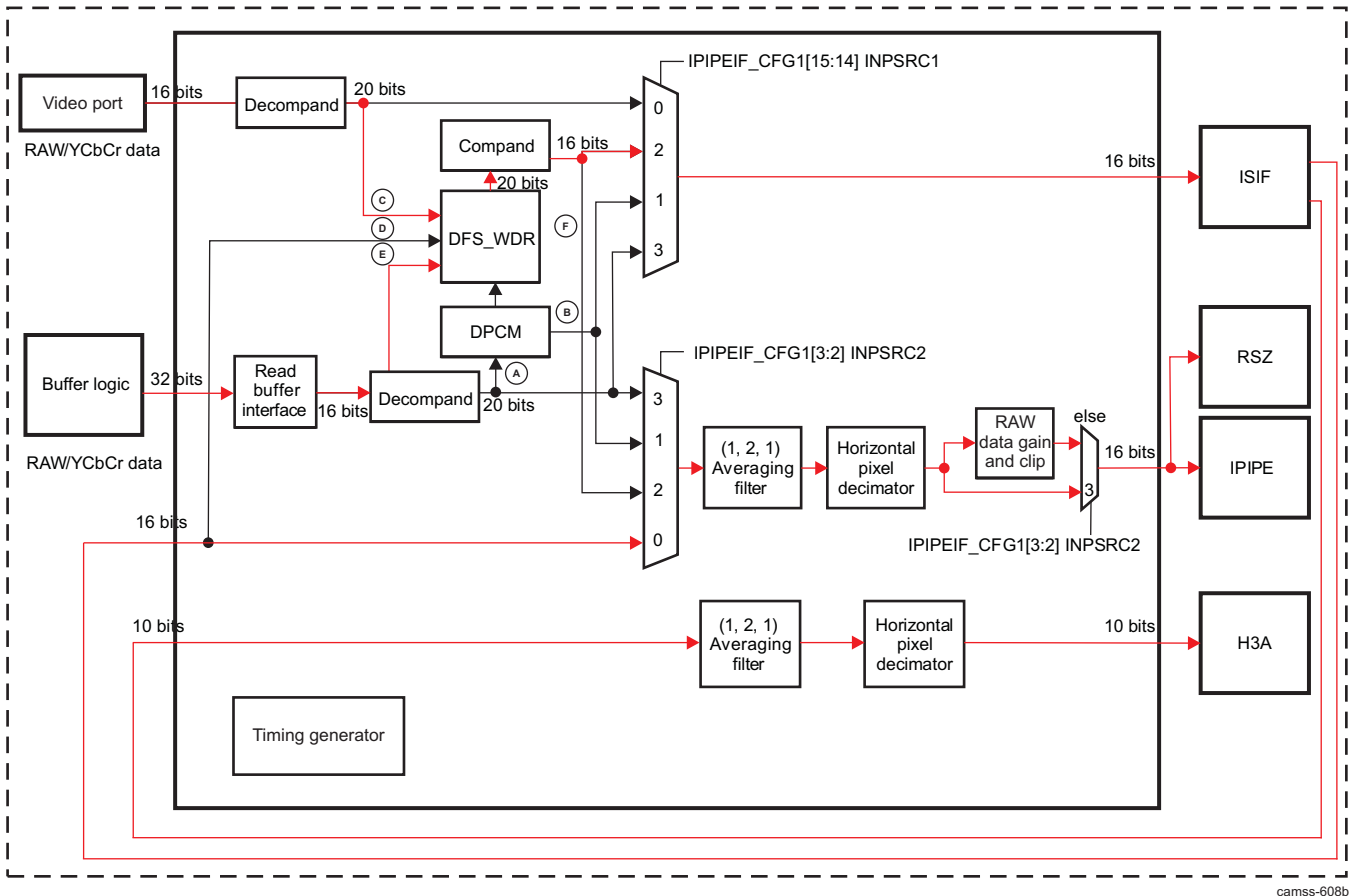

7.3.3.4.4.6 ISS ISP IPIPEIF INPSRC1 = 2 and INPSRC2 = 0

Set the IPIPEIF_CFG1[15:14] INPSRC1 bit field to 2 and the IPIPEIF_CFG1[3:2] INPSRC2 bit field to 0.

In this configuration, dark frame subtraction is performed and data is sent to the ISIF module. The ISIF processes the data and sends it back to the IPIPEIF module before the data is pushed to the IPIPE or RSZ modules. There are two possible dark frame subtractions: the first is with data coming from the VP and the dark frame coming from BL; the second is with data coming from BL and the dark frame coming from the VP.

Figure 7-89 shows the data path.

Figure 7-89. ISS ISP IPIPEIF INPSRC1 = 2 and INPSRC2 = 0 Data Path

camss-608b

7.3.3.4.7 ISS ISP IPIPEIF INPSRC1 = 3 and INPSRC2 = 0

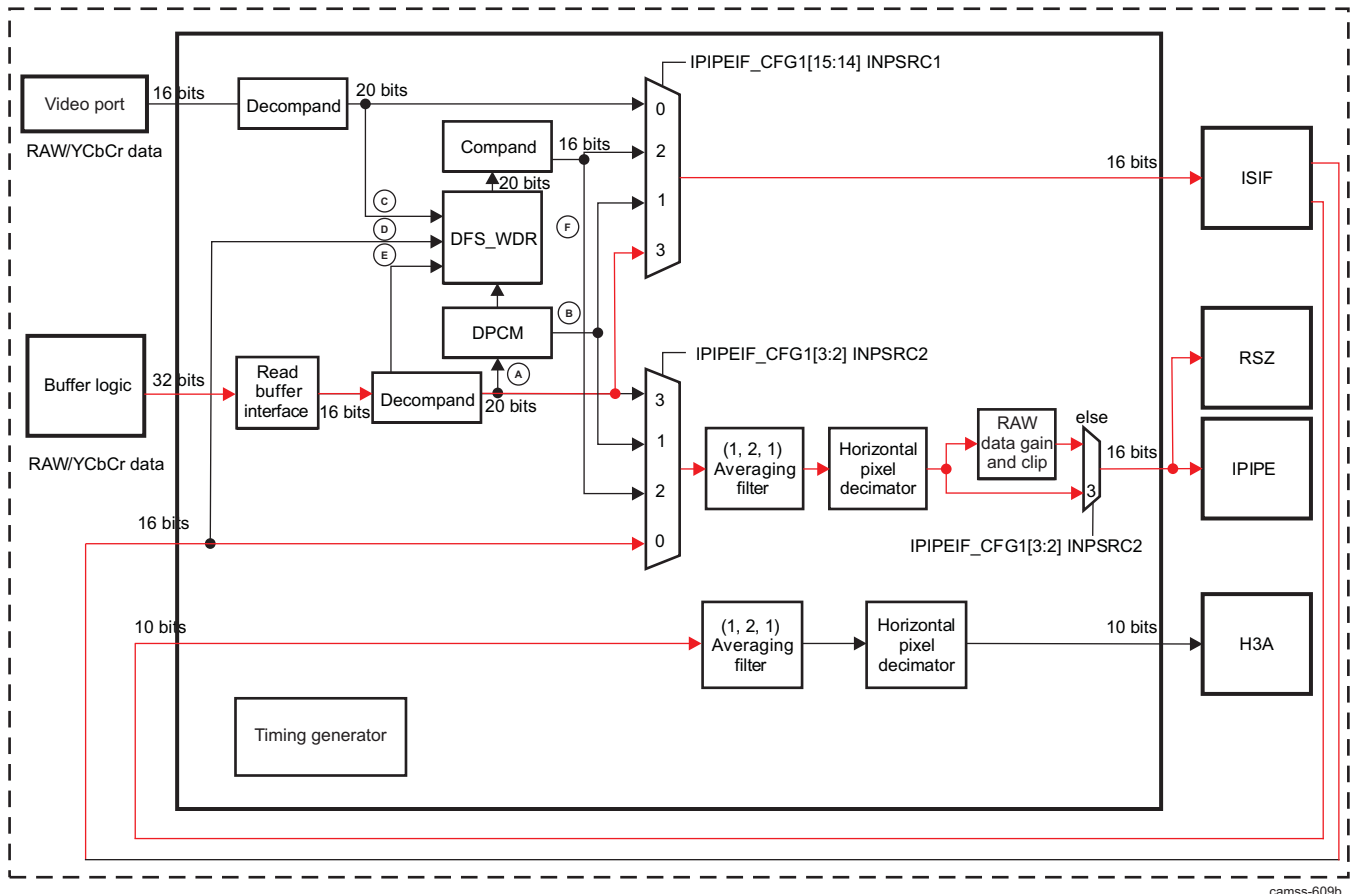

Set the `IPIPEIF_CFG1[15:14] INPSRC1` bit field to 3 and the `IPIPEIF_CFG1[3:2] INPSRC2` bit field to 0.

This configuration is a memory-to-memory operation. Data is loaded from the SDRAM. Input data is expected as 16 bpp. The ISIF processes the data and sends it back to the IPIPEIF module before the data is pushed to the IPIPE or RSZ module.

In this configuration data is assumed to be YUV only, and H3A and RAW data gain are assumed to be disabled.

Figure 7-90 shows the data path.

Figure 7-90. ISS ISP IPIPEIF INPSRC1 = 3 and INPSRC2 = 0 Data Path

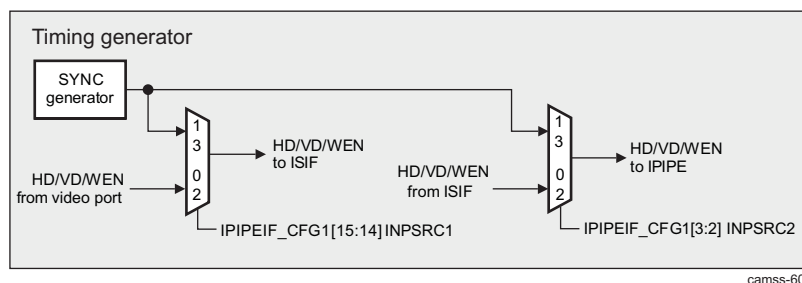

camss-609b

7.3.3.4.5 ISS ISP IPIPEIF Timing Generation

Figure 7-91 shows the ISS ISP IPIPEIF timing generator submodule.

Figure 7-91. ISS ISP IPIPEIF Timing Generator Submodule

camss-602

When the IPIPEIF module input source is from the VP (`IPIPEIF_CFG1[15:14] INPSRC1 = 0 or 2`) or the ISIF (`IPIPEIF_CFG1[3:2] INPSRC2 = 0 or 2`), the `IPIPEIF_CFG1[10] CLKSEL` bit must be set to 0 so that data is latched using the PCLK, HD, and VD signals from the VP.

When the IPIPEIF module input source is not from the VP (`IPIPEIF_CFG1[15:14] INPSRC1 = 1 or 3`), the `IPIPEIF_CFG1[10] CLKSEL` bit must be set to 1 so that the IPIPEIF module generates its proper PCLK, HD, and VD signals (through the use of the SYNC generator). The `IPIPEIF_CLKDIV` register is then used to select a divide ratio of the SDRAM (DMA) clock for the pixel clock frequency, which is used to clock the data into the PCLK. See [Section 7.3.3.4.5.1, ISS ISP IPIPEIF Fractional Clock Divider](#).

When the `IPIPEIF_CFG1[15:14]` INPSRC1 or `IPIPEIF_CFG1[3:2]` INPSRC2 bit field is not set to 0, the IPIPEIF SDRAM data reading and timing generation can be enabled (`IPIPEIF_ENABLE[0]` ENABLE) in one-shot mode or continuous mode (`IPIPEIF_CFG1[0]` ONESHOT).

7.3.3.4.5.1 ISS ISP IPIPEIF Fractional Clock Divider

When the input data of the IPIPEIF module does not come from the VP but from memory, it is useful to have control of the rate at which the data is fetched from memory to avoid overflow conditions or to avoid peak bandwidth requirements. The `IPIPEIF_CFG1[10]` CLKSEL bit is equal to 1 for fractional divider use.

The ISP clock `ISP_FCLK` is divided to generate the pixel clock, which goes to the ISIF and IPIPE modules when data is read from memory (`IPIPEIF_CFG1[15:14]` INPSRC1 = `IPIPEIF_CFG1[3:2]` INPSRC2 = 1 or 3). The `IPIPEIF_CLKDIV` register selects the divider ratio: M and N values in the `IPIPEIF_CLKDIV[15:0]` CLKDIV bit field.

Given an input clock of clock rate `ISP_FCLK`, the fractional clock divider generates an output clock with average clock rate f_{OUT} .

Where $f_{OUT} = ISP_FCLK \times M/N$, and M = 1 through 256, and N = 1 through 256.

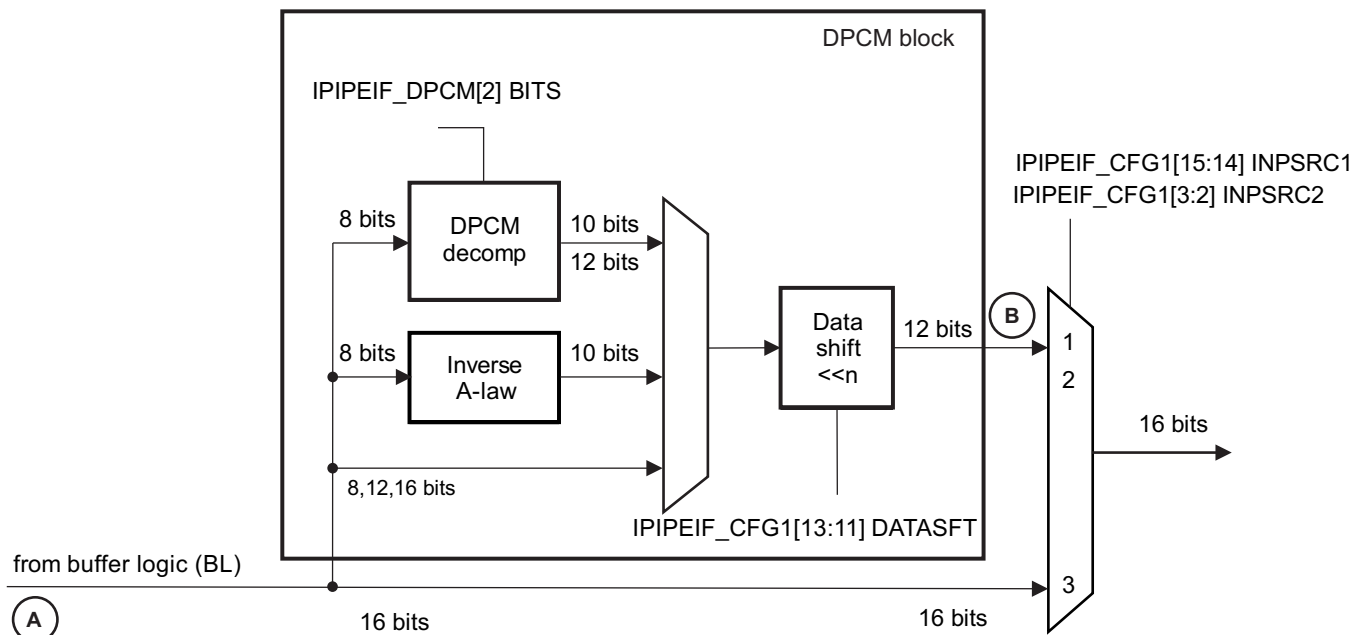

The fractional clock divider logic is synchronous and uses only the positive clock edge of the input clock.

7.3.3.4.6 ISS ISP IPIPEIF Decompression (DPCM) Subblock: Unpack and Decompression Function

The IPIPEIF module can read RAW data from memory. The RAW data can be previously packed/compressed into memory. Unpack, A-Law decompression, and DPCM decompression are available in the IPIPEIF module.

Figure 7-92 shows the DPCM subblock.

Figure 7-92. ISS ISP IPIPEIF DPCM Subblock

camss-032

Table 7-634 provides the possible configuration of the DPCM block.

Table 7-634. ISS ISP IPIPEIF DPCM Block Possible Configuration

Number of Bits per Pixel at DPCM Block Input	Number of Bits per Pixel at DPCM Block Output	Description	Registers
16	16	It can correspond to YUV4:2:2 or RAW16 data.	IPIPEIF_CFG1 [9:8] UNPACK = 0x0 In this configuration, IPIPEIF_CFG1 [3:2] INPSRC2 = 0x3. In this configuration data bypasses the DPCM block.
8	8	PACK8: YUV	IPIPEIF_CFG1 [9:8] UNPACK = 0x1 IPIPEIF_DPCM [0] ENA = 0x0 IPIPEIF_CFG1 [13:11] DATASFT = 0x01 In this configuration an 8-bit packed RAW data is used in DFS mode or YUV4:2:0 pass through. (See Section 7.3.3.4.14, ISS ISP IPIPEIF YUV4:2:2 8-bits Packed Data Input Coming From ISIF Module.)
8	10	DPCM10: The 8-bit input data are DPCM-decompressed in 10 bits.	IPIPEIF_CFG1 [9:8] UNPACK = 0x1 IPIPEIF_DPCM [0] ENA = 0x1 IPIPEIF_DPCM [2] BITS = 0x0 Set the IPIPEIF_DPCM [1] PRED ^{(1) (2)} IPIPEIF_CFG1 [13:11] DATASFT = 0x2
8	12	DPCM12: The 8-bit input data are DPCM-decompressed in 12 bits.	IPIPEIF_CFG1 [9:8] UNPACK = 0x1 IPIPEIF_DPCM [0] ENA = 0x1 IPIPEIF_DPCM [2] = 0x1 Set the IPIPEIF_DPCM [1] PRED ^{(1) (2)} IPIPEIF_CFG1 [13:11] DATASFT = 0x0
8	10	ALAW10: The 8-bit input data were previously A-law compressed. The 8 bits are A-law decompressed and padded with 0.	IPIPEIF_CFG1 [9:8] UNPACK = 0x2 IPIPEIF_CFG1 [13:11] DATASFT = 0x2
12	12	PACK12: The input is coded on 12 bits and is packed in the SDRAM. This mode is compatible with the ISIF module packing capability. If inverse A-law and DPCM decompression are not enabled, the data read from the SDRAM can be shifted by the IPIPEIF_CFG1 [13:11] DATASFT bit field to select which 12 bits to use. MSB input data bit must be shifted such that it corresponds to bit 11 after the shift.	IPIPEIF_CFG1 [9:8] UNPACK = 0x3 Set the IPIPEIF_CFG1 [13:11] DATASFT

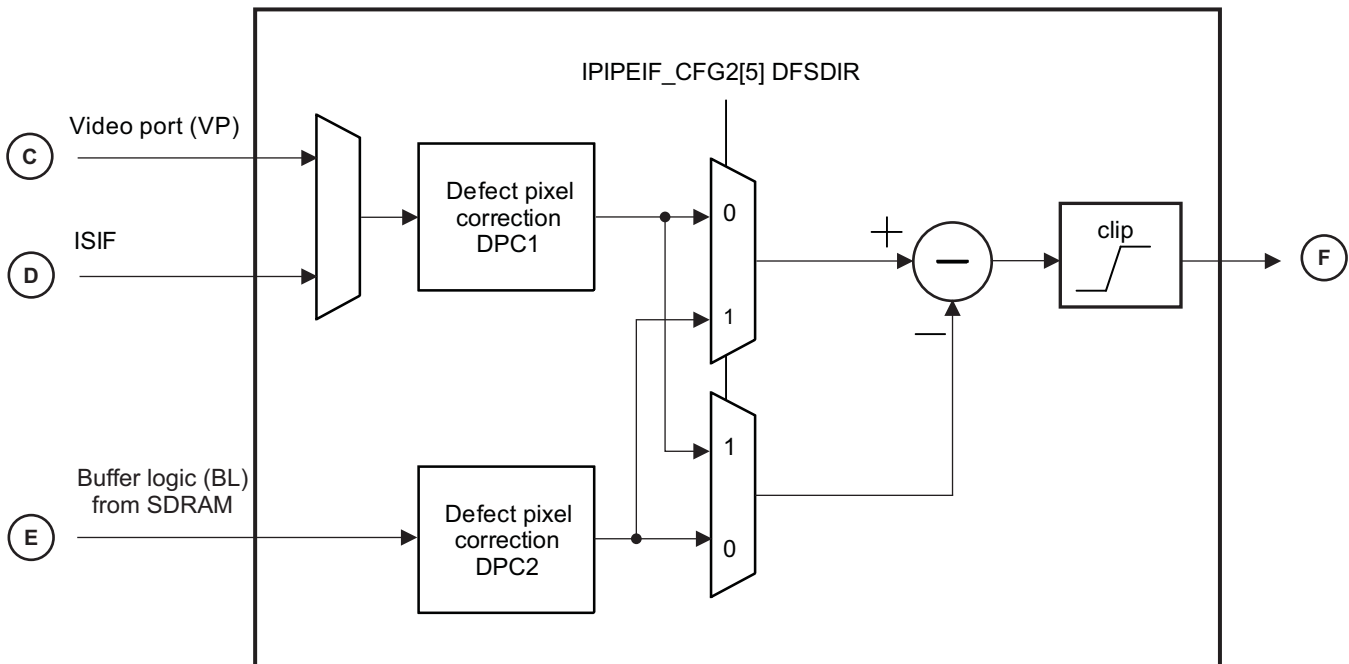

⁽¹⁾ The simple predictor uses only the value of the previous same color component as a prediction value. Therefore, only 2-pixel memory is required. It is typically used for 10–8–10 or 12–8–12 bit conversions.

⁽²⁾ The advanced predictor uses four previous pixel values, when the prediction value is evaluated. This means that the values of the other color components are also used, when the prediction value is defined. Therefore, the advanced predictor is slightly better than the simple predictor but consumes more power and memory. It can, however, improve image quality. It is typically used for 10–7–10 and 10–6–10 bit conversions.

7.3.3.4.7 ISS ISP IPIPEIF Dark-Frame Subtraction Functionality

Figure 7-93 shows the ISS ISP IPIPEIF dark-frame subtraction subblock.

Figure 7-93. ISS ISP IPIPEIF Dark-Frame Subtraction Subblock

camss-033

The dark-frame subtract (DFS) function is used to remove fixed pattern baseline noise from the sensor for a high-quality still image capture use case, where there is a mechanical shutter. Typically, the ISIF module previously writes a dark frame (frame captured when the shutter is closed) to SDRAM using 8 bits of linear data packed into 2 pixels per 16 bits.

In this mode, RAW data from the ISIF and SDRAM is used. Data can also be read from SDRAM with the [IPIPEIF_CFG1\[9:8\] UNPACK](#) bit field set to 1. Each pixel read from SDRAM is subtracted from each pixel sent from the VP or ISIF.

The mux at the input of the dark-frame subtraction subblock is implicitly controlled by the selection of the [IPIPEIF_CFG1\[15:14\] INPSRC1](#) and [IPIPEIF_CFG1\[3:2\] INPSRC2](#) bit fields:

- When [IPIPEIF_CFG1\[15:14\] INPSRC1](#) = 0x2, the selected input ports are VP and BL. Therefore, the dark frame operation can be:
 - Dark frame = VP – BL
 - Dark frame = BL – VP
- When [IPIPEIF_CFG1\[3:2\] INPSRC2](#) = 0x2, the selected input ports are ISIF and BL. Therefore, the dark frame operation can be:
 - Dark frame = ISIF – BL
 - Dark frame = BL – ISIF

The output of the DFS operation is 12 bits wide (U12Q0). There must be adequate SDRAM bandwidth if this feature is enabled. If the data fetched from memory arrives late, an underflow bit (IPIPEIF_DTUF) must be triggered to know it.

When SDRAM data underflow occurs, the data from SDRAM is coming in at a lower rate than the rate at which it is being read/requested by the IPIPEIF. In DFS operation mode, IPIPEIF reads data from both SDRAM and the VP/ISIF. To ensure not corrupting subsequent data processing downstream in the case of SDRAM data underflow, the IPIPEIF stalls the input data, storing remaining sensor data into an internal FIFO (16-deep), and then stops sending new data downstream. The IPIPEIF recommences DFS processing when data from SDRAM becomes available, by using the pixel data from the FIFO and that from SDRAM for processing. To avoid an overflow of the internal FIFO, the IPIPEIF deasserts the stall

only when the number of FIFO slots indicated by the `IPIPEIF_DTUDF[5:2]` FIFOWMRKLVL register bit field are free. A safe number of free locations can be configured taking into consideration the pixel clock frequency with respect to that of the functional clock, as the pixel clock speed is allowed to vary up to the functional clock speed. When the pixel clock and functional clock are equal, the stall deassertion can be programmed to occur when the 16-deep FIFO is empty.

7.3.3.4.7.1 ISS ISP IPIPEIF Defect Pixel Correction

NOTE: For DPC memory access locations, see [Section 7.3.3.11, ISS ISP Memory Mapping](#).

A simple DPC can be applied to the ISIF or VP input data path and SDRAM input data path, respectively. This DPC algorithm is intended to correct hot pixels during RAW dark frame acquisition or dark frame readout from SDRAM before dark frame subtraction.

The following code describes DPC algorithm:

```

If (image(n) < TH) || ((image(-2) > TH)&&(image(n+2)>TH)
    image(n) = image(n)
Else if image(-2) > TH
    image(n) = image(n+2)
Else if image(n+2) > TH
    image(n) = image(-2)
Else
    image(n) = (image(-2)+ image(n+2))/2

// Where TH is equal to IPIPEIF_DPC1[11:0] TH for DPC1
// Where TH is equal to IPIPEIF_DPC2[11:0] TH for DPC2

```

The `IPIPEIF_DPC1[12]` ENA bit enables DPC for the VP/ISIF input path, and the `IPIPEIF_DPC2[12]` ENA bit enables DPC for the SDRAM input path. The algorithm requires a threshold value that is set by the `IPIPEIF_DPC1[11:0] TH` or `IPIPEIF_DPC2[11:0] TH` bit field that is a 12-bit unsigned value.

7.3.3.4.7.2 ISS ISP IPIPEIF DFS Subtraction Direction

The `IPIPEIF_CFG2[5]` DFSDIR bit selects how the DFS subtraction is performed.

- Set the `IPIPEIF_CFG2[5]` DFSDIR bit to 0 when the RAW data is coming from the VP/ISIF and the dark frame is stored in SDRAM.
- Set the `IPIPEIF_CFG2[5]` DFSDIR bit to 1 when the RAW data is coming from SDRAM and the dark frame is coming from the VP/ISIF.

After subtraction, a clip ensures that the value is not negative.

[Table 7-635](#) lists the different modes supported in DFS.

Table 7-635. ISS ISP IPIPEIF DFS Modes Supported

Description	DFDIR Value
DFS of 8-bit RAW image stored in SDRAM from image from VP	<code>IPIPEIF_CFG2[5]</code> DFSDIR = 0x0
DFS of 8-bit RAW image stored in SDRAM from image from ISIF	<code>IPIPEIF_CFG2[5]</code> DFSDIR = 0x0
DFS of 8-bit RAW image from VP from image read from SDRAM through the BL	<code>IPIPEIF_CFG2[5]</code> DFSDIR = 0x1

NOTE: DFS input depends on the settings of INPSRC1 and INPSRC2.

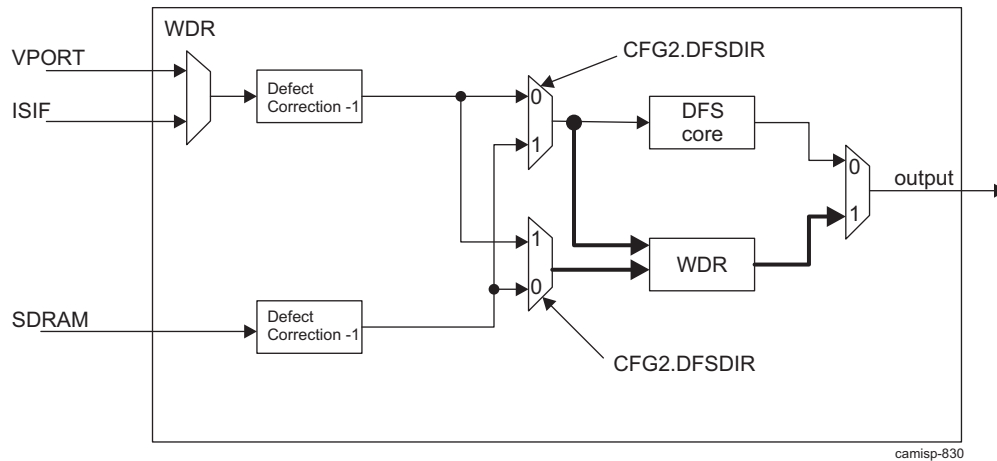

7.3.3.4.8 ISS ISP IPIPEIF Wide Dynamic Range WDR Merging Functionality

WDR Merging mode with VPORT/ISIF RAW Input with SDRAM Input (IPIPEIF_CFG1 .INPSRC1 =2 or IPIPEIF_CFG1 .INPSRC2 = 2, IPIPEIF_CFG4 .WDR=1)

7.3.3.4.8.1 ISS ISP IPIPEIF merging general description

In this mode, the input from VPORT/ISIF Port is merged with the input from SDRAM. The data flow is same as DFS mode, except the output is 16 bit. Also, the input streams were typically two 12bit pixel streams. All the other restrictions and notes about data flow in DFS process are also applied to WDR more.

Figure 7-94. ISS ISP IPIPEIF DFS/WDR sub block (WDR Mode)

7.3.3.4.9 ISS ISP IPIPEIF (1, 2, 1) Averaging Filter for IPIPE Data Path

The averaging filter acts as an anti-aliasing low-pass filter for the horizontal pixel decimator. Usually, when horizontal pixel decimation is enabled (IPIPEIF_CFG1[1] DECIM), the averaging filter must also be enabled to avoid aliasing artifacts. The averaging filter can be enabled by setting the IPIPEIF_CFG1[7] AVGFILT bit. It operates on every other pixel (same color) in RAW Bayer input or every Y component in YCbCr data in the following equation:

$$\text{output} = (\text{input}[i - 1] + 2 \times \text{input}[i] + \text{input}[i + 1]) \gg 2$$

The averaging filter operates on every other pixel (same color) in RAW Bayer input or YUV data.

If the data is YUV4:2:2, the option to average and decimate is given under the conditions listed in Table 7-636.

Table 7-636. ISS ISP IPIPEIF Averaging Filter Conditions for YUV4:2:2 Data

IPIPEIF_CFG1[3:2] INPSRC2	IPIPEIF_CFG2[3] YUV16	Comments
0	1	YUV4:2:2 data is coming from the ISIF module. Averager and decimation is possible on the data path to the IPIPE module.
1	1	YUV4:2:2 data is read from SDRAM. Averager and decimation is possible on the data path to the IPIPE module.
3		YUV4:2:2 data is read from SDRAM. Averager and decimation is possible on the data path to the IPIPE module.
Other value	Other value	For YUV4:2:2 data, averager and decimation is not possible on the data path to the IPIPE module.

The averager implements a (1, 2, 1) FIR filter on Luma and Chroma. The following registers have a part in the behavior of the YUV data averaging and decimation:

- [IPIPEIF_INIRSZ\[12:0\]](#) INIRSZ
- [IPIPEIF_CFG1\[7\]](#) AVGFILT
- [IPIPEIF_CFG1\[1\]](#) DECIM

7.3.3.4.10 ISS ISP IPIPEIF Horizontal Pixel Decimator (Downsizer) for IPIPE Data Path

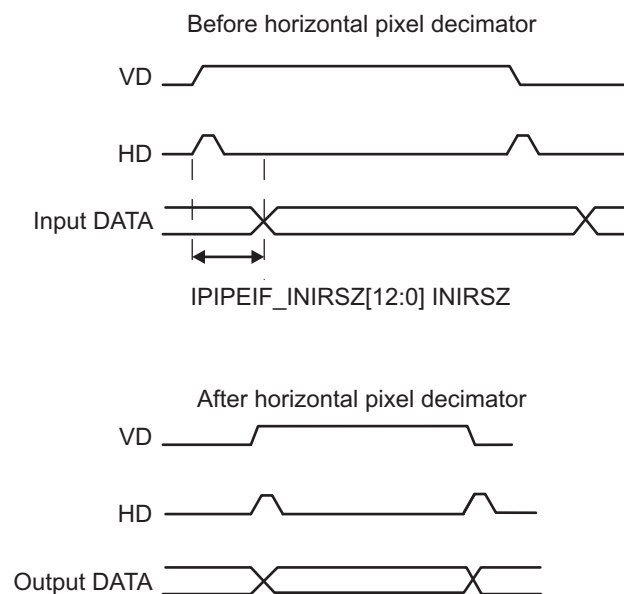

The IPIPE input is limited to 2816 pixels per horizontal line due to restrictions in the line memory width in the IPIPE.

To process image sensor resolutions with more than 2816 pixels per line with no resolution loss, vertical frame division mode (FDM) must be used; that is, the image must be divided into vertical chunks of less than 2816 pixels, and each chunk must be processed sequentially by the ISP. FDM is memory-to-memory processing and is not supported on the fly.

Alternatively, if a loss in resolution is acceptable, the line width decimator (the [IPIPEIF_CFG1\[1\]](#) DECIM bit) can be enabled to downsample the input lines to a width equal to or less than the 2816 pixel maximum. The resize ratio (16/RSZ) can be configured by programming the [IPIPEIF_RSZ\[6:0\]](#) RSZ bit field to be within the range from 16 to 112 to give a resampling range from 1x to 1/7x.

When ALNSYNC is enabled ([IPIPEIF_INIRSZ\[13\]](#) ALNSYNC = 0x1), the [IPIPEIF_INIRSZ\[12:0\]](#) INIRSZ pixels are skipped (from the HD position) before the horizontal pixel decimator, as shown in [Figure 7-95](#).

Figure 7-95. ISS ISP IPIPEIF Resizer Offset Definition

camss-614

7.3.3.4.11 ISS ISP IPIPEIF RAW Data Gain for IPIPE Data Path

A gain factor ranging from 0.00195(1/512) to 1.99805(1023/512) is multiplied to the RAW output of the IPIPEIF. The gain is not applied if the input data is YCbCr. The gain constant is set in the [IPIPEIF_GAIN\[9:0\]](#) GAIN bit field using U10Q9 format.

The output value is clipped after gain control through the value of the [IPIPEIF_OCLIP\[11:0\]](#) OCLIP bit field.

7.3.3.4.12 ISS ISP IPIPEIF (1, 2, 1) Averaging Filter for H3A Data Path

The averaging filter acts as an anti-aliasing low-pass filter for the horizontal pixel decimator. Usually, when horizontal pixel decimation is enabled (the [IPIPEIF_RSZ3A\[9\]](#) DECIM bit), the averaging filter must also be enabled to avoid aliasing artifacts. The averaging filter can also be used to reduce noise before H3A statistics generation. It operates on every other pixel (the same color) in a RAW Bayer input or every Y component in YCbCr data. The averaging filter can be enabled by setting the [IPIPEIF_RSZ3A\[8\]](#) AVGFILT bit, and it operates with the following equation:

$$\text{output} = (\text{input}[i - 1] + 2 \times \text{input}[i] + \text{input}[i + 1]) \gg 2$$

7.3.3.4.13 ISS ISP IPIPEIF Horizontal Pixel Decimator (Downsizer) for H3A Data Path

The H3A input is limited to 3008 pixels per horizontal line due to restrictions in the line memory width in the H3A.

To process image-sensor resolutions with more than 3008 pixels per line with no resolution loss, vertical FDM must be used; that is, the image must be divided into vertical chunks of less than 3008 pixels, and each chunk must be processed sequentially by the ISP. FDM is memory-to-memory processing and is not supported on the fly.

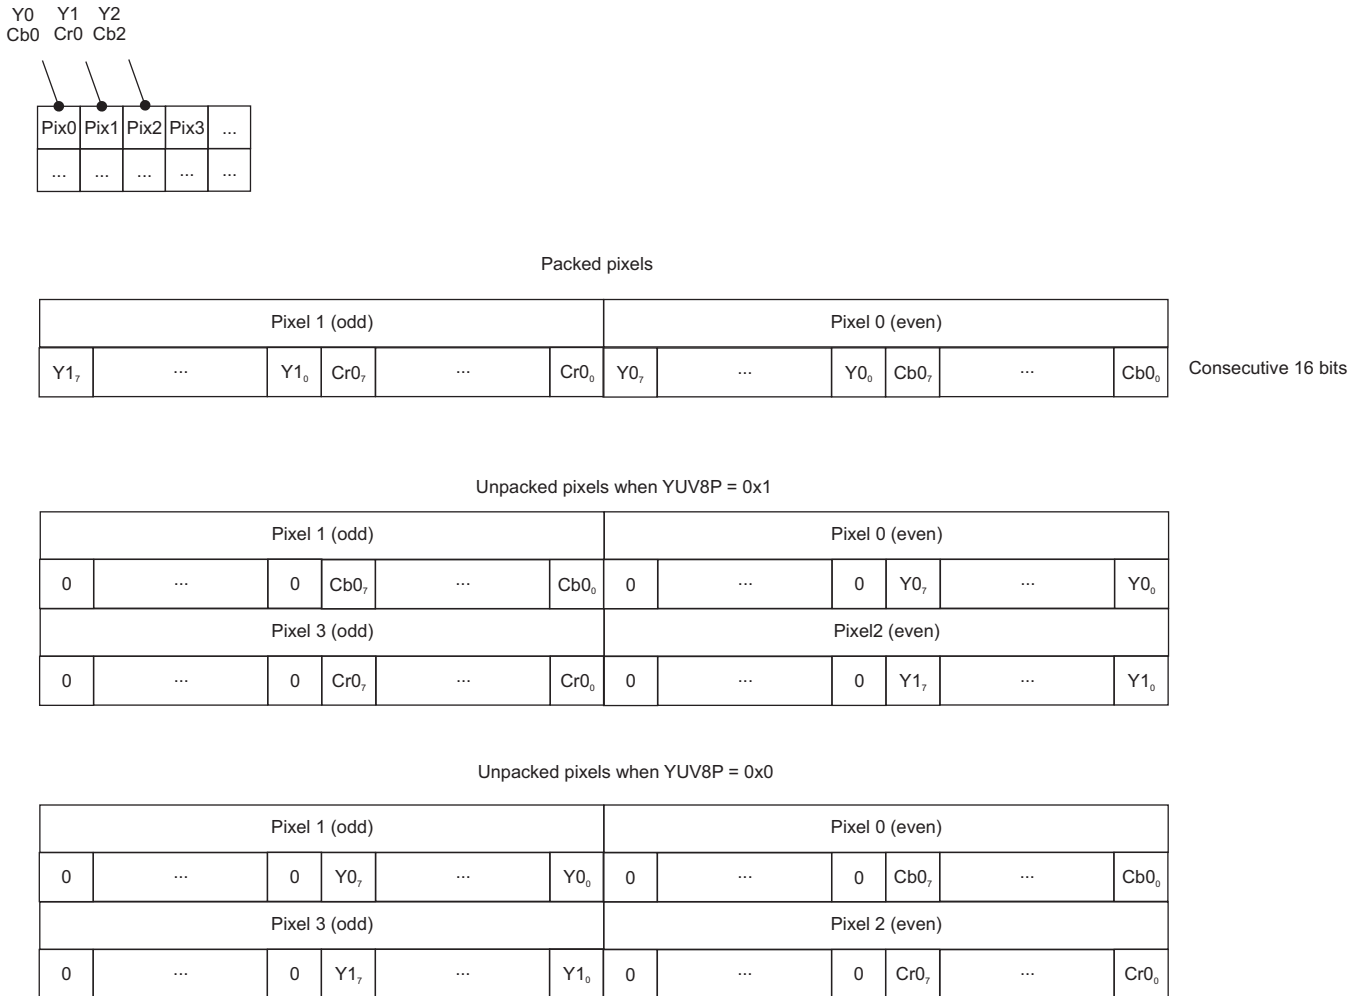

Alternatively, if loss of resolution is acceptable, the line width decimator (the [IPIPEIF_RSZ3A\[9\]](#) DECIM bit) can be enabled to downsample the input lines to a width equal to or less than the 3008 pixel maximum. The resize ratio (16/RSZ) can be configured by programming the [IPIPEIF_RSZ3A\[6:0\]](#) RSZ bit field to be within the range from 16 to 112 to give a resampling range from 1x to 1/7x.

When ALNSYNC is enabled ([IPIPEIF_INIRSZ3A\[13\]](#) ALNSYNC = 0x1), the [IPIPEIF_INIRSZ3A\[12:0\]](#) INIRSZ pixels are skipped (from the HD position) before the horizontal pixel decimator (see [Figure 7-95](#)).

7.3.3.4.14 ISS ISP IPIPEIF YUV4:2:2 8-bit Packed Data Input Coming From ISIF Module

This section applies when data coming from the ISIF is 8 bits ([IPIPEIF_CFG2\[6\]](#) YUV8 = 0x1). When [IPIPEIF_CFG1\[3:2\]](#) INPSRC2 = 0 and [IPIPEIF_CFG2\[3\]](#) YUV16 = 1, the 8-bit YUV data are transformed into 16-bit YUV data. The way the data are unpacked from 8 bits to 16 bits is controlled by the [IPIPEIF_CFG2\[7\]](#) YUV8P bit. See [Figure 7-96](#).

Figure 7-96. ISS ISP IPIPEIF YUV8P Settings

camss-616

7.3.3.4.15 ISS ISP IPIPEIF YUV4:2:0 Data Input for Memory-to-Memory Resize Operations

The ISP RSZ module can resize YUV4:2:0 data. The YUV4:2:0 data can come from the memory (through BL) or from the VP through the receiver modules, which reads data from SDRAM and pushes it to the IPIPEIF module VP. The possible data paths are:

- SDRAM → IPIPEIF (BL) → RESIZER → SDRAM
- SDRAM → CAL_A → IPIPEIF (VP) → RESIZER → SDRAM
- SDRAM → IPIPEIF (BL) → IPIPEIF → RESIZER → SDRAM
- SDRAM → CAL_A → IPIPEIF (BL) → IPIPEIF → RESIZER → SDRAM

When the data comes from BL, the IPIPEIF module must be set up to process the Luma data first, and then the Chroma data.

- For 420Y (first pass):
 - IPIPEIF_CFG1[15:14] INPSRC1 = 0x1 (SDRAM data input)
 - IPIPEIF_CFG1[3:2] INPSRC2 = 0x1 (SDRAM data input)
 - IPIPEIF_CFG1[13:11] DATASFT = 0x0 (no data shift)
 - IPIPEIF_CFG1[9:8] UNPACK = 0x1 (data packed on 8 bits)
 - IPIPEIF_CFG2[3] YUV16 = 0x1 (data_input[7:0] = 0 and data_input[15:8] = valid)
- For 420C (second pass):

- [IPIPEIF_CFG1\[15:14\]](#) INPSRC1 = 0x1 (SDRAM data input)
- [IPIPEIF_CFG1\[3:2\]](#) INPSRC2 = 0x1 (SDRAM data input)
- [IPIPEIF_CFG1\[13:11\]](#) DATASFT = 0x0 (no data shift)
- [IPIPEIF_CFG1\[9:8\]](#) UNPACK = 0x1 (data packed on 8 bits)
- [IPIPEIF_CFG2\[3\]](#) YUV16 = 0x0 (data_input[7:0] = valid and data_input[15:8] = 0)

7.3.3.4.16 ISS ISP IPIPEIF Module Events and Status Checking

The IPIPEIF module generates an IPIPEIF event through the IPIPEIF_IRQ interrupt at the end of each frame. This interrupt is set through the [ISP5_IRQENABLE_SET_i\[9\]](#) IPIPEIF_IRQ bit. The input interrupt source generation is selected through the [IPIPEIF_CFG2\[0\]](#) INTSW bit in a certain configuration. The following pseudo code describes INTSW.

```

if (IPIPEIF_CFG2[0] INTSW==0) // Interrupt source from VP
  if (IPIPEIF_CFG1[15:14] INPSRC1==1,2 or 3)
    if (CFG1.ONESHOT==1) // In one shot mode
      Interrupt happens at the end of frame
    else // In continuous mode
      Interrupt is the start position of VD which is generated by IPIPEIF timing generator
  else // IPIPEIF_CFG1[15:14] INPSRC1==0, data is from VP
    Interrupt is the start position of VD from VP

else // Interrupt source from ISIF: IPIPEIF_CFG2[0] INTSW==1
  if (IPIPEIF_CFG1[3:2] INPSRC2==1,2 or 3)
    if (CFG1.ONESHOT==1) // In one shot mode
      Interrupt happens at the end of frame
    else
      Interrupt is the start position of VD which is generated by IPIPEIF timing generator
  else // IPIPEIF_CFG1[3:2] INPSRC2==0, data is from ISIF
    Interrupt is the start position of VD from ISIF
  
```

In addition to this interrupt, the host must check the IPIPEIF_DTUF status flag of the [ISP5_IRQSTATUS_RAW2_i\[1\]](#) IPIPEIF_UDF bit (if this is enabled and mapped to the ISP IRQ lines) to see if an underflow occurred. For more information, see [ISS ISP IPIPEIF Interframe Operations](#).

If IPIPEIF reads image data from memory, IPIPEIF stalls data output by masking the clock at underflow. When the next data is available at the input side, IPIPEIF restarts sending data. Underflow does not occur in this operation.

In DFS operation (see [Section 7.3.3.4.7, ISS ISP IPIPEIF Dark-Frame Subtraction Functionality](#) for more information), if the data read from memory are not available before they are required, the behavior of IPIPEIF is as follows:

- If image data is being received from the parallel port (CPI), then underflow occurs. The event is flagged by IPIPEIF_UDF IRQ. The [ISP5_IRQSTATUS_RAW2_i\[1\]](#) IPIPEIF_UDF bit is also set.
- If image data is being received through a receiver module, then IPIPEIF raises IPIPEIF_STALL signal to stall CAL_A. The [IPIPEIF_DTUDF\[1\]](#) ENM2MSTALL bit controls whether the IPIPEIF raises IPIPEIF_STALL signal at underflow event or not.

7.3.3.5 ISS ISP IPIPE Functional Description

7.3.3.5.1 ISS ISP IPIPE Overview

- The input interface extracts the valid region from the Bayer RAW data:
 - Up to 12-bit input pixel resolution in Bayer format
 - 16bit (8bit Y + 8bit U or V) in YUV format
 - Requires at least 8 pixels for horizontal blanking and four lines for vertical blanking. In one-shot mode; 16 blanking lines after processing area are required.
 - The maximum horizontal and vertical offset of IPIPE processing area from synchronous signal is 65534.
 - Supports RGB Bayer pattern for input

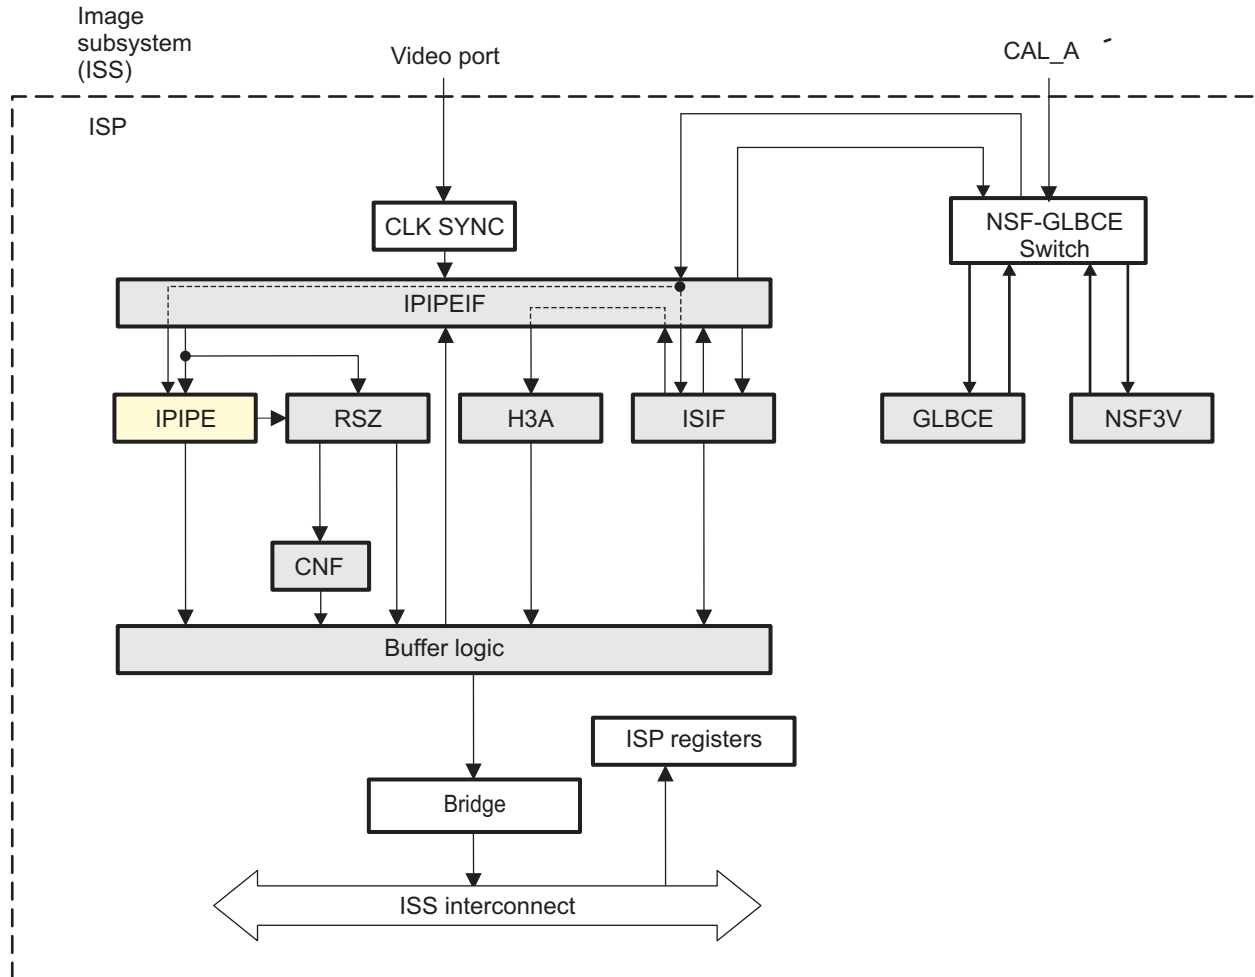

- The DPC module fixes defect pixels using two methods: LUT-based and on-the-fly adaptive.
- DPC works with NSF3V module
- The 2D noise-filter module reduces noise in RAW data.
- The green-imbalance-correction (GIC) module reduces Gb/Gr difference to remove line crawl noise.
- The white balance module applies offset and gain adjustments to each color.
- The color filter array (CFA) interpolation module implements CFA interpolation. The output from the CFA interpolation module is RGB-4:4:4 formatted data. CFA also reduces aliasing caused by undersampling by digital anti-aliasing (DAA).
- The RGB2RGB blending module applies a 3×3 matrix transform to the RGB data generated by the CFA interpolation module.
- The gamma correction module independently applies gamma correction to each RGB component. Gamma is implemented using a piece-wise linear interpolation approach with a 512-entry LUT for each color.
- The second RGB2RGB blending module applies a 3×3 matrix transform to the RGB data after gamma correction.
- 3D-LUT converts RGB data to RGB data using $9 \times 9 \times 9$ table and tetrahedral interpolation.
- The RGB2YCbCr conversion module applies 3×3 matrix transformation to the RGB data to convert it to YCbCr data. This module also implements offset. The global brightness and contrast enhancement module fixes brightness and contrast tone.
- The 4:2:2 conversion module applies the Chroma low-pass filter and downsampling to Cb and Cr to convert 4:4:4 data to 4:2:2 data.
- The 2D edge-enhancer module improves image clarity with a Luma nonlinear filter.
- The Chroma artifact reduction module reduces color artifacts using gain control and a 2D median filter.
- The output interface module transfers data from IPIPE to SDRAM in the form of one YCbCr (4:2:2 or 4:2:0), RGB (32/16 bits), or Bayer data.
- The histogram function can record histograms of up to four distinct areas into up to 256 bins.
- The boxcar function makes 1/8 or 1/16 size (1/64 or 1/256 in area) images.
- The boundary signal calculator (BSC) makes vectors of row and column summations.
- Convert YUV422 to full color RGB

IPIPE has four processing paths:

- Case 1: IPIPE reads CCD RAW data and applies all IPIPE functions and stores the YCbCr (or RGB) data to SDRAM.
- Case 2: IPIPE reads CCD RAW data and stores the Bayer data after white balance to SDRAM.
- Case 3: IPIPE reads YCbCr-4:2:2 data and applies edge enhance, Chroma suppression, and resize to output YCbCr data to SDRAM.
- Case 4: IPIPE reads YCbCr-4:2:0 data and applies resize to output YCbCr data to SDRAM.
- Enhanced YUV input support.
- Color conversion, tone-curve mapping, 3D-LUT, GBCE, Histogram, BSC are supported on YUV input.

[Figure 7-97](#) shows the connections from the IPIPE module to other submodules of the ISP.

Figure 7-97. ISS ISP IPIPE High-Level Diagram

camisp-003d

7.3.3.5.2 ISS ISP IPIPE Top-Level Block Diagram

The IPIPE is a programmable hardware image-processing module that generates image data in YCbCr-4:2:2 or YCbCr-4:2:0 format from RAW CCD/CMOS data. The IPIPE module supports output of Bayer data.

The IPIPE module supports RAW data in Bayer format, as shown in Figure 7-98. Other RGB formats or complementary color formats are not supported.

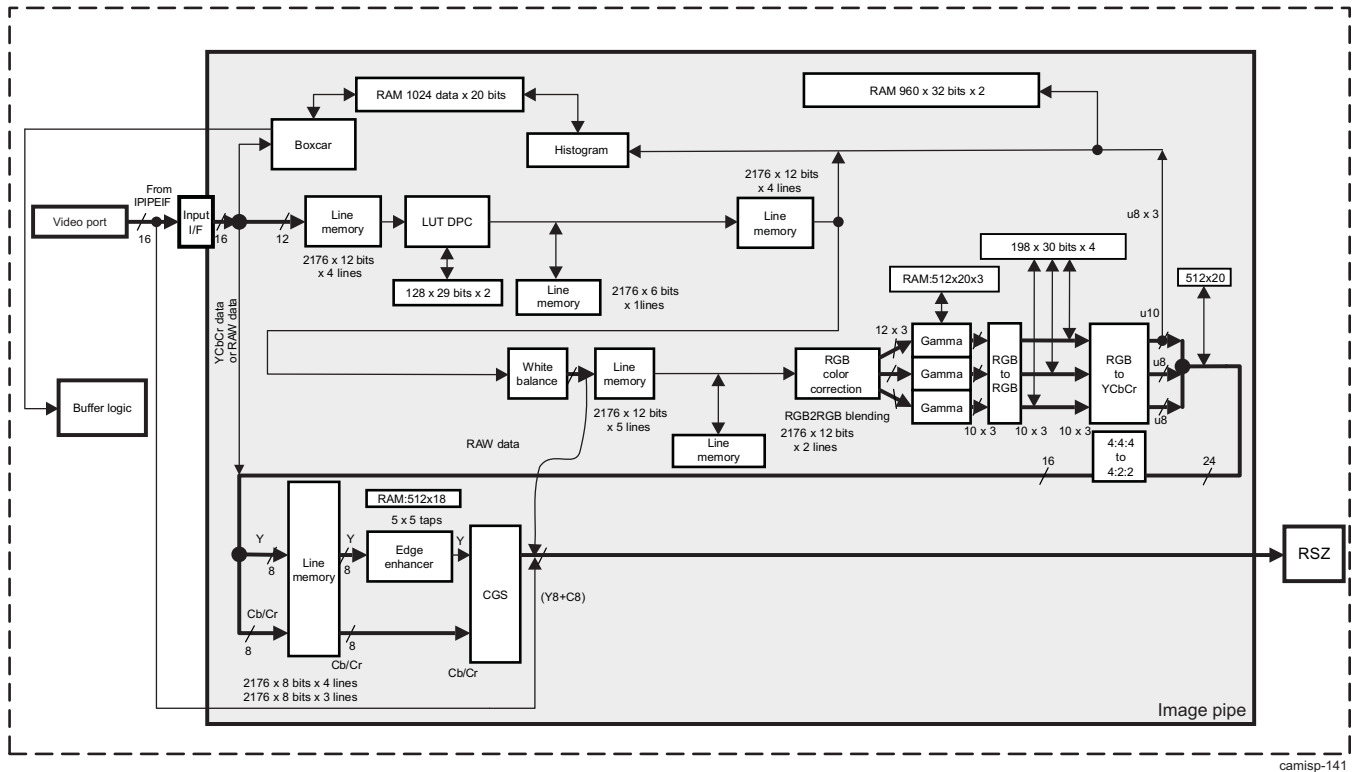

Figure 7-98. ISS ISP IPIPE Supported CFA Format

camisp-142

As shown in Figure 7-99, many internal modules are used to process Bayer data into YCbCr data.

Figure 7-99. ISS ISP IPIPE Module Block Diagram

camisp-141

7.3.3.5.3 ISS ISP IPIPE Input Interface

The IPIPE module receives 16-bit input data through the IPIPEIF module or from the NSF-GLBCE switch, which can be 12-bit RAW image data or 16-bit YCbCr data. The IPIPE module can work with up to 2816 pixels in each horizontal line, except in RAW pass-through mode. If the image width is larger than 2816, the image must be scaled down at the IPIPEIF module level. Otherwise, the input image must be split into several blocks.

The input image is accommodated with h-sync and v-sync signals (HD and VD). The cycles between one HD to the next HD must be 64 pclk or bigger.

If the input data is YCbCr, all there are three paths

- YUV422_MODE: All RGB processing modules are skipped, and only Edge Enhancer, Chroma Suppression, and Resizer are applied to the input data
- YUVtoRGB_MODE: YUV422 is converted to full color RGB, and all processes after RGB2RGB1 are applied. Also, histogram and BSC are measured.
- YUV444_MODE: YUV422 is up-sampled to YUV444, and all processes after GBCE are processed. Also BSC and Histogram are measured.

In RAW pass-through mode, images up to 8190 pixels per line can be processed. In RAW pass-through mode, the input data is written out directly to SDRAM.

The IPIPE module is enabled through the `IPIPE_SRC_EN[0]` EN bit.

The IPIPEIF module must be selected as the IPIPE module source with the `IPIPE_SRC_MODE[1]` WRT bit set to 1 from the input port of the IPIPEIF. This is required to enable and transfer data properly from the interface to the IPIPE.

The IPIPE module has two processing modes, which can be selected through the `IPIPE_SRC_MODE[0]` OST bit:

- One-shot mode: `IPIPE_SRC_MODE[0] OST = 0x1`

- Free-run mode: `IPIPE_SRC_MODE[0]` OST = 0x0

The input and output formats are selected in the `IPIPE_SRC_FMT[1:0]` FMT bit field (see [Table 7-637](#)).

Table 7-637. ISS ISP IPIPE Input and Output Selections

<code>IPIPE_SRC_FMT[1:0]</code> FMT	IPIPE Module Input	IPIPE Module Output
0x0	RAW Bayer	YCbCr or RGB
0x1	RAW Bayer	RAW Bayer
0x2	RAW Bayer	Disabled
0x3	YCbCr 16 bits	YCbCr

The 16-bit data input to the IPIPE module is in the formats (YCbCr-8bit is not allowed) shown in [Figure 7-100](#).

Figure 7-100. ISS ISP IPIPE Module Input Format

The window to process can be defined by its vertical and horizontal start position (`IPIPE_SRC_VPS` and `IPIPE_SRC_HPS`, respectively) and vertical and horizontal size (`IPIPE_SRC_VSZ` and `IPIPE_SRC_HSZ`, respectively). [Figure 7-101](#) shows the window settings for processing.

Figure 7-101. ISS ISP IPIPE Module Processing Window Settings

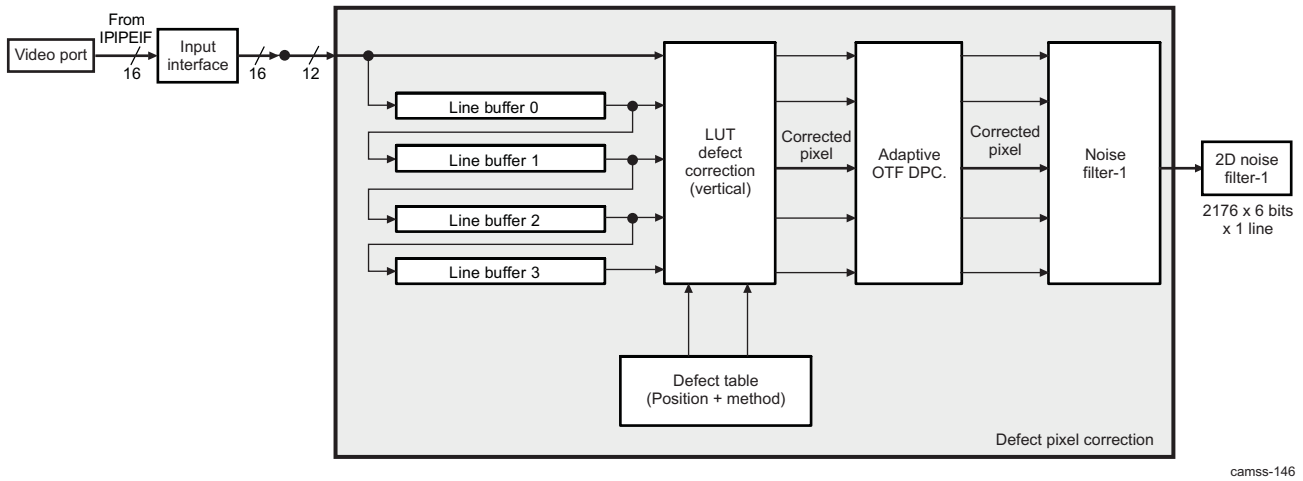

camss-639

7.3.3.5.4 ISS ISP IPIPE Defect Pixel Correction

NOTE: LUT DPC and OTF DPC can work with NSF3V using DPC port.

The DPC module corrects defect pixels using two methods: LUT-based method (LUT DPC) and on-the-fly adaptive method (OTF DPC). [Figure 7-102](#) shows defect pixel correction.

Figure 7-102. ISS ISP IPIPE Defect Pixel Correction

camss-146

7.3.3.5.4.1 ISS ISP IPIPE LUT Defect Pixel Correction (LUT DPC)

LUT DPC is the first stage of the IPIPE image-processing pipeline. The LUT DPC module corrects defects in input data. It supports up to a 256-defect point table. However, the table can be renewed as required during image processing. Therefore, the maximum amount of defect information is limited only by system-level performance.

The module uses two sets of 128 × 29 memories to hold defect information. The table contains the information of horizontal position (13 bits), vertical position (13 bits), and correction method (3 bits), as shown in Table 7-638. The LUT DPC is enabled through the IPIPE_DPC_LUT_EN[0] EN bit.

Table 7-638. ISS ISP IPIPE Defect Information Packing

Correction Method	Vertical Position	Horizontal Position
28...26	25...13	12...0

The information must be listed from left to right and from the top to bottom. The first position in the defect information table and the number of defects that are used can be specified. The address of the table must be programmed in the IPIPE_DPC_LUT_ADR[9:0] ADR bit field. Thus, the address of the first valid data is stated.

The LUT type can be:

- With a finite number of entries:
 - IPIPE_DPC_LUT_SEL[1] TBL = 0x0
 - The size of the LUT is set in the IPIPE_DPC_LUT_SIZ[9:0] SIZ bit field.
- With an infinite number of entries:
 - IPIPE_DPC_LUT_SEL[1] TBL = 0x1

The correction methods, set in Table 7-638, are described in Table 7-639.

Table 7-639. ISS ISP IPIPE Correction Method Description

Correction Method	d0 =	Comment
0	Black or white dot	Replace with a black (or white) dot to force OTF-DPC to work on the pixel. White or black dot replacement can be selected through the IPIPE_DPC_LUT_SEL[0] DOT field.
1	d4	Copy from left
2	d5	Copy from right

Table 7-639. ISS ISP IPIPE Correction Method Description (continued)

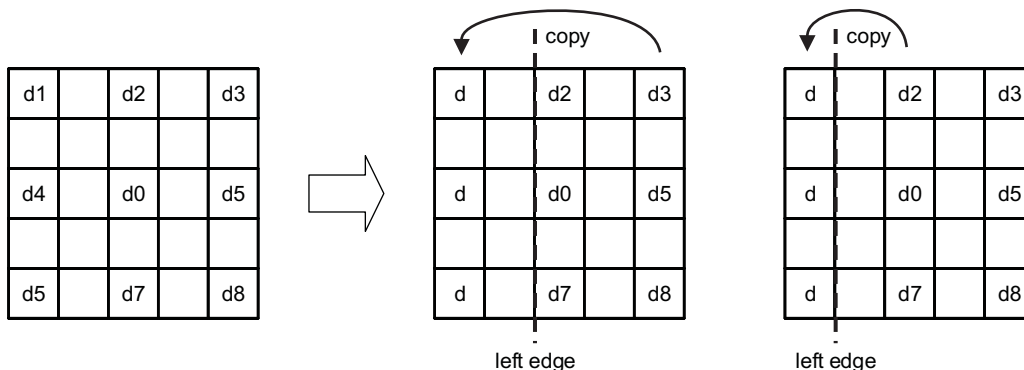

Correction Method	d0 =	Comment
3	$(d4 + d5)/2$	Horizontal interpolation
4	$(d2 + d7)/2$	Vertical interpolation
5	d2	Copy from top
6	d7	Copy from bottom
7	$(d2 + d4 + d5 + d7)/2$	2D interpolation

The pixels in the defect correction algorithm are numbered as shown in [Figure 7-103](#).

Figure 7-103. ISS ISP IPIPE Pixel Numbering in Defect Correction Algorithm

camisp-145

The pixels at the edges are mirrored as way described in [Figure 7-104](#). The figure shows the typical correction by overwriting far-edge pixels and mirroring them with other edge pixels. The example shows how by using a noise filter the correct-by-definition pixels are copied over bad pixels.

Figure 7-104. ISS ISP IPIPE Mirroring in Defect Correction and Noise Filter

(Right, top, and bottom edges have the same process.)

camisp-147

7.3.3.5.5 ISS ISP IPIPE DPC Interface

DPC is able to work with NSF3V module. In that case, the data comes from DPC input port and goes out from DPC output port. When DPC is working with NSF3V, DPC and NF-1 function are skipped inside IPIPE. In other words, DPC in NSF3V and DPC+NF-1 in IPIPE are mutually exclusive.

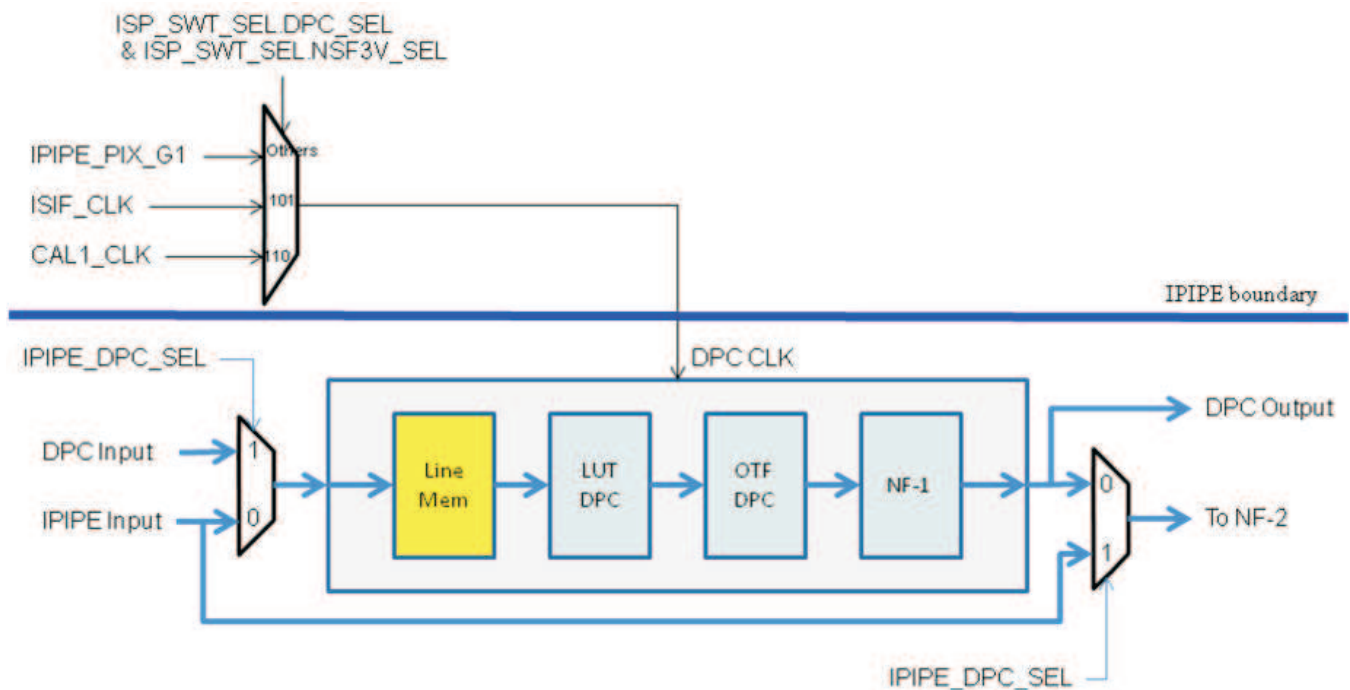

Also, it must be noted that the clock to DPC/NF-1 is driven by DPC_CLK instead of by pixel clock (PCLK) directly. If DPC works with the rest of IPIPE, DPC_CLK is exactly the same as PCLK. If DPC works with NSF3V, and if NSF3V works with ISP, DPC_CLK is same as ISIF_CLK. If DPC works with NSF3V, and if NSF3V works with CAL, DPC_CLK is same as CAL1_CLK. The DPC_CLK is generated at ISS level accordingly (ISS_MAIN_FCLK).

In addition, the image width must be 32 pixels or more if DPC works before NSF3V.

Table 7-640. ISS ISP IPIPE DPC_CLK

DPC Use Case	DPC_CLK source	Description
IPIPE	PCLK	Conventional case. DPC works inside IPIPE.
ISP-NSF3V	ISIF_FCLK	DPC works with NSF3V, and NSF3V works inside ISP. DPC gets the pixels from ISIF, and sends them to NSF3V. The image width must be 32 pixel or more.
CAL-NSF3V	CAL_FCLK	DPC works with NSF3V, and NSF3V works with CAL. DPC gets the pixels from CAL interface, and sends them to NSF3V. The image width must be 32 pixel or more.

Figure 7-105. ISS ISP IPIPE Data flow of DPC Interface

camisp-803

The input from DPC-input port must comply with IPIPE’s internal signal protocol.

There are several control signals beside 12-bit data signal (Table 6). These signals need to follow the IPIPE internal signal protocol. HD lasts for one clock. VD, VWE, and VWI can only change on HD signal. EN is asserted on the next clock of HD, and keeps high status for n-clocks, where n is the width of the valid image area. The size of the valid width (the length of asserted EN signal) must be consistent throughout each frame. EN cannot be negated in the middle of the line

When DPC works before NSF3V, ID signal from NSF3V path is used instead of the ones generated by IPIPE.

When DPC is used with NSF3V, there are a couple of points that SW must obey. First, NF-1 must be turned off (*IPIPE_D2F_1ST_EN* . EN=0). Second, since turning off LUT-DPC/OTF-DPC/NF-1 all off force IPIPE to skip line buffers, SW must make sure the change of latency caused by turning on/off LUT-DPC/OTF-DPC does not affect the following processes. To avoid this point, SW can virtually disable the OTF-DPC by setting in a way that OTF does not filter any pixel. One example of such setting is as following.

- DPC_OTF_TYP [TYP] =0
- DPC_OTF_TYP [ALG] =0

DPC_OTF_2_C_THR_x = 4095 (x=R, Gr, Gb, and B)

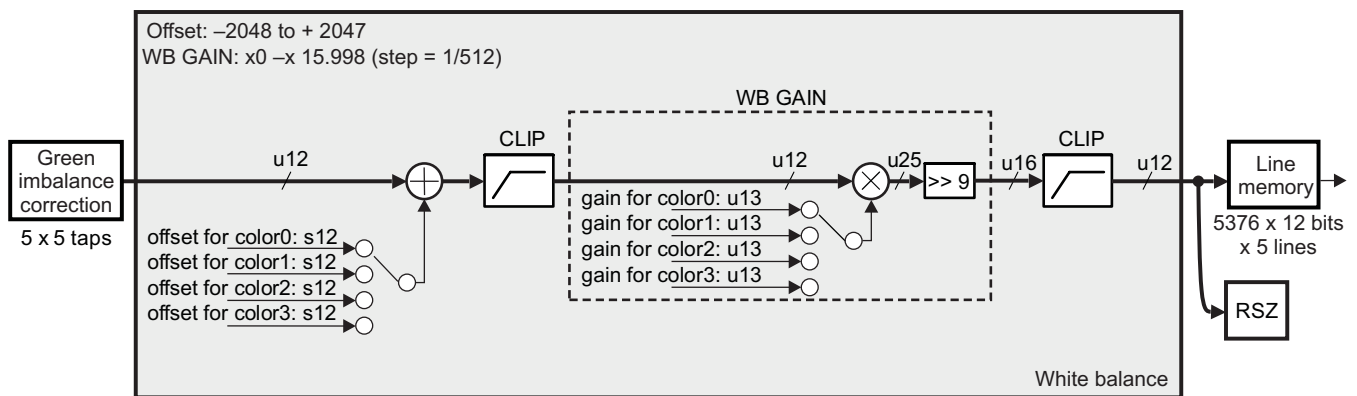

DPC_OTF_2_D_THR_x = 4095 (x=R, Gr, Gb, and B)

7.3.3.5.6 ISS ISP IPIPE White Balance

The white balance module executes white balance to each color component. White balance gain adjusts the ratio of each color existing in a CFA pattern. An offset can be applied before white balance correction (IPIPE_WB2_OFT_R, GR, Gb, or B registers).

Figure 7-106 is a block diagram of the white balance module. In the white balance gain adjuster, the RAW data is multiplied by a selected gain (IPIPE_WB2_WGN_R, Gr, Gb, or B registers) corresponding to the color. The white balance gain can be selected from four 13-bit values. Firmware can assign any combination of 4 pixels in horizontal and vertical directions. The precision of each gain is shown in the figure.

Figure 7-106. ISS ISP IPIPE White Balance

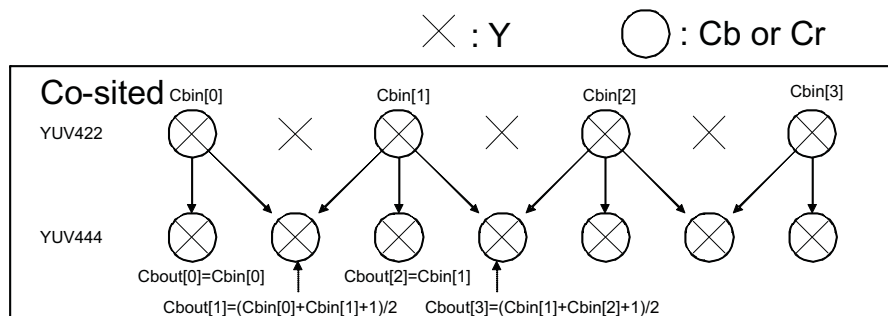

camisp-155

7.3.3.5.7 ISS ISP IPIPE YUV422to444

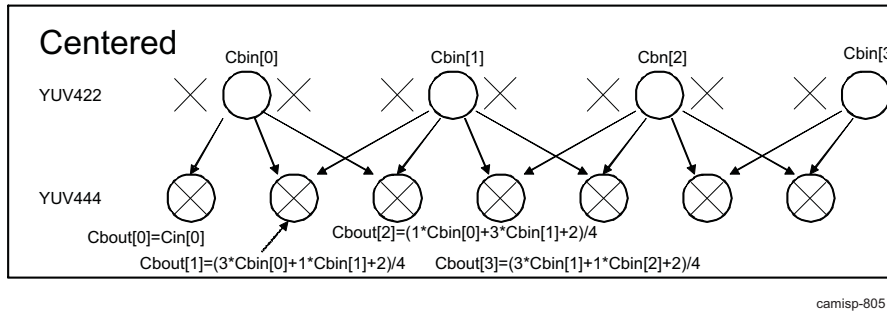

If the input is YUV422 and YUV444_MODE or YUVtoRGB_MODE is selected (SRC_FMT [FMT] =3, SRC_FMT [FMT2]=1 or 2), this module up-samples YUV422 to YUV444. (In YUVtoRGB_MODE, the next RGB2RGB module also converts YUV to RGB.) The module refers to SRC_FMT [FMT3] for the chroma sampling position. If the value is 0 (co-sited), the up-sampling is done in the way in Figure 7-107. If it is 1, it is done in the way Figure 7-108

Figure 7-107. ISS ISP IPIPE YUV422 to 444 in co-sited mode

camisp-804

Figure 7-108. ISS ISP IPIPE YUV422 to 444 in co-sited mode

7.3.3.5.8 ISS ISP IPIPE RGB2RGB Blending Module

The RGB2RGB blending module transforms the RGB data generated by the CFA interpolation module using a 3 x 3 square matrix transformation in combination with an added offset. The RGB-to-RGB blending is calculated using the formula shown in Figure 7-109. Each gain range is from -8 to +7.996 with step 1/256 = 0.004, and is set in the IPIPE_RGB1_MUL_RR to IPIPE_RGB1_MUL_BB registers. The offset range for each component is from -4096 to 4095, and is set in the IPIPE_RGB1_OFT_OR to IPIPE_RGB1_OFT_OB registers.

Figure 7-109. ISS ISP IPIPE RGB2RGB Conversion Formula

$$\begin{matrix}
 R_out \\
 G_out \\
 B_out
 \end{matrix}
 =
 \begin{matrix}
 gain_RR & gain_GR & gain_BR \\
 gain_RG & gain_GG & gain_BG \\
 gain_RB & gain_GB & gain_BB
 \end{matrix}
 \begin{matrix}
 R_in \\
 G_in \\
 B_in
 \end{matrix}
 +
 \begin{matrix}
 offset_R \\
 offset_G \\
 offset_B
 \end{matrix}$$

camss-650

If the input is YUV422 and RGB mode is selected (SRC_FMT [FMT]=3, SRC_FMT [FMT2]=2), this module is used as YUV444toRGB conversion.

In case of YUV input, RGB are replaced by YCbCr

- R_in = (ClipS9(Y_in+Y_offset)) << 4
- G_in = (ClipS9(Cb_in+Cb_offset)) << 4
- B_in = (ClipS9(Cr_in+Cr_offset)) << 4
 - ClipS9(x)=(x<-256 ? -256 : ((x>255) ? 255 : x)
 - Y/Cb/Cr_Offset are s9 (-256 to +255)
- R_in/G_in/B_in are expanded to S13 to support these modes

One typical equation for YUVtoRGB conversion is the following, which converts JPEG YUV to RGB.

Figure 7-110. ISS ISP IPIPE equation for YUVtoRGB conversion

$$\begin{pmatrix} R \\ G \\ B \end{pmatrix} = \begin{pmatrix} 0.299 & 0.587 & 0.114 \\ -0.168736 & -0.331264 & 0.5 \\ 0.5 & -0.418688 & -0.081312 \end{pmatrix}^{-1} \begin{pmatrix} Y_{in} \\ Cbin - 128 \\ Crin - 128 \end{pmatrix}$$

camisp-806

The matrix corresponding to this equation is

Figure 7-111. ISS ISP IPIPE equation for YUVtoRGB conversion matrix

$$\begin{pmatrix} 256 & 0 & 359 \\ 256 & -88 & -183 \\ 0.5 & 454 & 0 \end{pmatrix}$$

camisp-807

7.3.3.5.9 ISS ISP IPIPE Gamma Correction Module

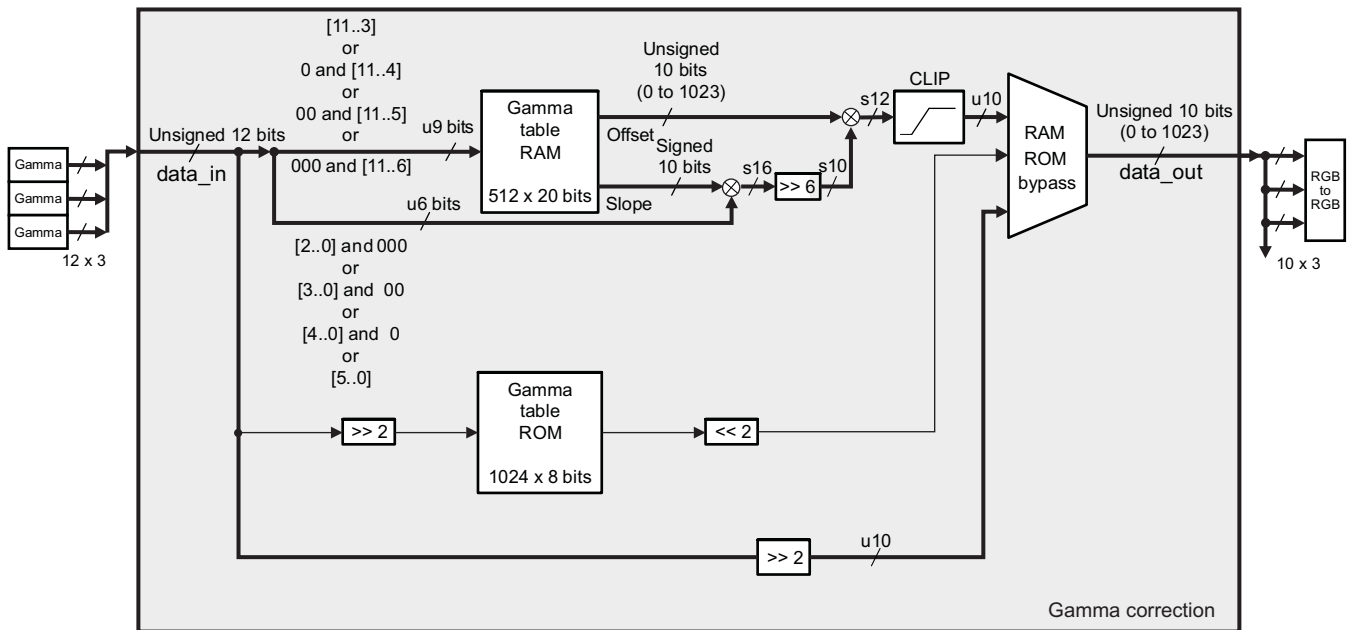

NOTE: For the memory access locations of the gamma correction module, see Section 7.3.3.11, ISS ISP Memory Mapping.

The gamma correction module performs gamma correction independently for each color in the RGB color space by using a piece-wise linear interpolation. ROM tables and RAM tables are selectable through the IPIPE_GMM_CFG[4] TBL bit. Each ROM table and RAM table has 512 entries, and each entry accommodates a 10-bit offset and 10-bit slope. The range of slope value is from -512 to +511. The ROM table has 1024 entries and an output 8-bit value.

Figure 7-112 is a block diagram of the gamma correction module. It is composed of two tables and one selector. When the BYPASS bit is asserted, the input data is divided by 16 (the IPIPE_GMM_CFG[0] BYPR, IPIPE_GMM_CFG[1] BYPG, and IPIPE_GMM_CFG[2] BYPB bits).

Figure 7-113 shows an example of the gamma curve. Figure 7-114 shows offset and slope packing.

Figure 7-112. ISS ISP IPIPE Gamma Correction Module Block Diagram

camss-158

Figure 7-114. ISS ISP IPIPE Gamma Table Offset and Slope Packing

7.3.3.5.10 ISS ISP IPIPE Second RGB2RGB Conversion Matrix

The second RGB2RGB blending module transforms the RGB data after gamma correction using the 3 × 3 square matrix transformation in combination with an added offset. The RGB-to-RGB blending is calculated using the formula shown in Figure 7-115. Each gain range is from -4 to +3.996 with step 1/256 = 0.004 (s3.8), and is set in the IPIPE_RGB2_MUL_RR to IPIPE_RGB2_MUL_BB registers. The offset is -1024 to 1023 (s11), and is set in the IPIPE_RGB2_OFT_OR to IPIPE_RGB2_OFT_OB registers.

Figure 7-115. ISS ISP IPIPE RGB2RGB Second Conversion Formula

$$\begin{aligned}
 R_{out} &= gain_{RR} \cdot R_{in} + gain_{GR} \cdot G_{in} + gain_{BR} \cdot B_{in} + offset_{R} \\
 G_{out} &= gain_{RG} \cdot R_{in} + gain_{GG} \cdot G_{in} + gain_{BG} \cdot B_{in} + offset_{G} \\
 B_{out} &= gain_{RB} \cdot R_{in} + gain_{GB} \cdot G_{in} + gain_{BB} \cdot B_{in} + offset_{B}
 \end{aligned}$$

camss-650

7.3.3.5.11 ISS ISP IPIPE RGB2YCbCr Conversion Matrix

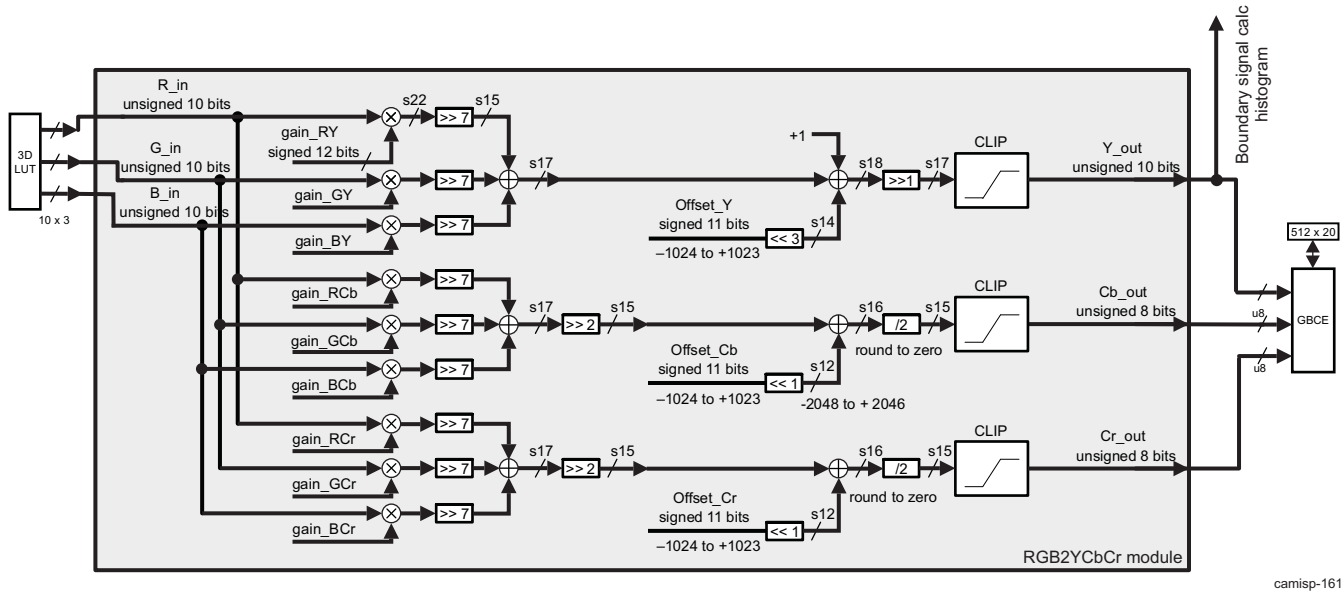

This module transforms the RGB data to YCbCr data format using a 3 × 3 matrix transformation in combination with an added offset. While transferring, the brightness control and contrast control can be adjusted using the IPIPE_YUV_ADJ[15:8] BRT and IPIPE_YUV_ADJ[15:8] CRT bit fields, respectively. Then, the transform is calculated using the formula shown in Figure 7-116. Each gain range is from -8 to +7.996 with step 1/256 = 0.004, configured in the IPIPE_YUV_MUL_RY to IPIPE_YUV_MUL_BCR registers. The offset is -1024 to +1023 for Y, Cb, and Cr, configured in the IPIPE_YUV_OFT_Y to IPIPE_YUV_OFT_CR registers. Figure 7-117 is the block diagram of the RGB to YCbCr blending module. The output is calculated by the equation.

Figure 7-116. ISS ISP IPIPE RGB2YCbCr Conversion Formula

$$\begin{aligned}
 Y_{out} &= gain_{RY} \cdot R_{in} + gain_{GY} \cdot G_{in} + gain_{BY} \cdot B_{in} + offset_{Y} \\
 Cb_{out} &= gain_{RCb} \cdot R_{in} + gain_{GCb} \cdot G_{in} + gain_{BCb} \cdot B_{in} + offset_{Cb} \\
 Cr_{out} &= gain_{RCr} \cdot R_{in} + gain_{GCr} \cdot G_{in} + gain_{BCr} \cdot B_{in} + offset_{Cr}
 \end{aligned}$$

camss-654
