Bit	Field	Type	Reset	Description
31-16	PPSE8_QUAD3_MSTID	R/W	0h	There are 16 bits for each quadrant in PPSE frame. These bits set the permission for maximum of 16 masters to address the peripheral mapped in each of the quadrant. The scheme is similar to the one described for PS MSTID in section 1.7.30. Readable in both user and privileged modes. 1 = The peripheral mapped in the quadrant can be addressed by master with matching Master-ID. 0 = The peripheral is locked for master with matching Master-ID. PCR responds with AERROR. Writable only in privileged mode 1 = Sets the corresponding bit. 0 = Clears the corresponding bit. Writes to unimplemented bits have no effect and reads yield 0.
15-0	PPSE8_QUAD2_MSTID	R/W	0h	There are 16 bits for each quadrant in PPSE frame. These bits set the permission for maximum of 16 masters to address the peripheral mapped in each of the quadrant. 31-16	PPCS13MSTID	R/W	0h	There are 16 bits for each frame in PPCS. These bits sets the permission for maximum of 16 masters to address the memory mapped in each of the frame. The scheme is similar to the one described for PCSm MSTID in section 1.7.33. Readable in both user and privileged modes. 1 = The memory mapped in respective frames can be addressed by master with matching Master-ID. 0 = The memory is locked for master with matching Master-ID. PCR responds with AERROR. Writable only in privileged mode 1 = Sets the corresponding bit. 0 = Clears the corresponding bit. Writes to unimplemented bits have no effect and reads yield 0.

Device Initialization

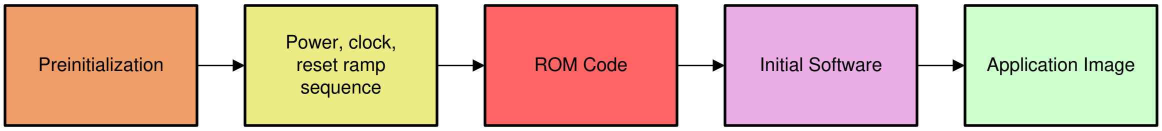

Figure 4-1. Device Initialization

The first two steps in the initialization process are hardware-oriented; however, they require an understanding of the process of configuring these system interface pins (balls on the device), which have software-configurable functionality. This configuration is an essential part of the chip configuration and is application-dependent. This chapter discusses these system-interface pins, the associated configuration registers, and memory structures that are vital to the correct initialization of the device.

4.2 Boot Process

4.2.1 ROM Code Overview

To accommodate various system scenarios, the ROM code supports several boot modes. These boot modes can be broadly classified as:

- Host boot modes
- Memory boot modes.

During a host boot, the device is configured to receive code from a host through the selected interface (such as UART). Either the host writes the application code directly into internal memory over UART, or the ROM code receives the application code on the selected interface and stores it in internal memory.

During a memory boot, the device transfers code from non-volatile memory to internal memory for execution.

In all boot modes, the entire boot operation can be partitioned into two sections:

- Hardware initialization phase
- Boot process

During initialization, the ROM code configures the device resources (PLLs, peripherals, pins) as needed to support the boot process. The resources used depend on the boot mode requirements. During the boot process, the boot image can be loaded into device memory and executed, depending on the boot peripheral. HSM ROM code performs code verification and allows or forbids the image execution.

The main configuration source for boot after power-up are the SOP mode pins sampled automatically after reset release and stored in device status registers. At ROM code startup, these pin values are read from the registers to create the boot peripheral list, and the boot configuration tables used later to initialize and startup the PLLs and boot peripherals.

4.2.2 Boot Modes

MCU ROM supports the functionality of loading the secondary boot loader (SBL). The SBL can be loaded through QSPI (primary/secondary SBL) and UART mode. The primary use case of QSPI programming through UART interface is to support the uniFlash utility. This mode programming may be applicable for certain use cases, such as initial FLASH programming in volume mass production, that can also be achieved with special in-circuit gang programming tools.

Primary functional boot mode is through QSPI FLASH. MCU ROM supports managing multiple (primary and backup) QSPI SBL images. It can identify the primary image, and switch to secondary image load if primary image load fails.

Table 4-1. Boot Modes and Boot Media

Boot Mode/Peripheral	Boot Media/Host	Notes
QSPI	QSPI flash	Download and boot SBL from QSPI flash. Attempt Primary SBL, followed by Secondary SBL if primary loading fails: If above is not successful
UART	External host	Download and boot SBL from UART. Device is expected to get SBL from UART. We will support the XMODEM protocol for download over UART.

For more information about various bootmode and flash device support please refer to application note.

4.2.3 SOP Mode Pins

Table 4-2 lists the functional mode pin settings to be done for the SOP lines of the device to boot using different peripheral. New SOP modes will be added later.

Table 4-2. Functional Mode Pin Settings

4.2.4 BOOT-ROM Architecture (RBL)

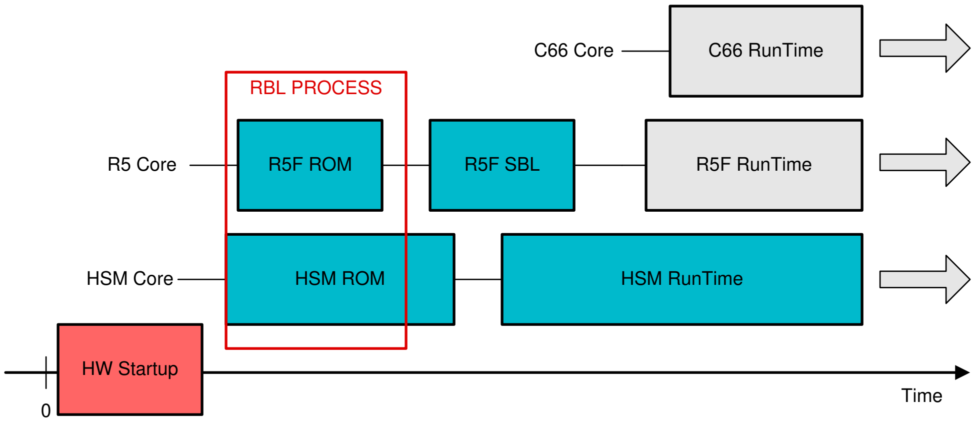

Figure 4-2. Boot Flow and Boot ROM Architecture

The RBL process goal is to load, verify, optionally decrypt, and launch an authentic R5F software image that accomplishes general-purpose/secure boot goals. The RBL process is implemented jointly by the R5F and HSM ROM as illustrated in Figure 4-2.

HSM ROM

This HSM ROM contains the first set of software instructions that is executed by any processor core on all AWR294x devices. All state changes in the device after the external reset is released but prior to the beginning of the HSM ROM code execution are purely a function of hardware logic. This hardware logic must perform sufficient ramp up and initialization to allow the Cortex M4 core of the HSM to leave reset and begin execution from its reset vector. The HSM ROM code is “time zero” software. The HSM ROM code is only intended to be used during the initial load of the secondary boot loader (SBL) and HSM RunTime image. HSM ROM is also responsible for providing Test/Debug capabilities when functional boot is interrupted.

R5F ROM

The R5F ROM code is only intended to be used during the initial load of the secondary boot loader (SBL). RBL can load the SBL content only to MSS_L2 area and at the end copies SBL's IVT (interrupt vector table) of 640B size to TCMA_RAM_CR5A before switching to SBL. This ROM-to-RAM (RBL to SBL) switching causes TCMA_ROM_CR5A eclipse to TCMA_RAM_CR5A i.e. 0x0000_0000 now maps to TCMA_RAM_CR5A memory area. Use of RBL at any other time in the lifecycle of a system is not supported. R5F ROM executes set of self-tests: PBIST (DATA SRAM, PROGRAM SRAM, and ROM Code Integrity) using a hardware-defined interface. If unsuccessful, the error condition is indicated, external ESM signal asserted, and boot does not proceed.

R5F SBL

This SBL can perform complete boot sequence on general purpose devices. Customers are expected to develop their own SBLs, supporting a wider range of requirements (such as different interfaces, additional protocols, different image formats, future update flow and so forth).

HSM RunTime/R5F Runtime/C66 RunTime

HSM RunTime is only applicable in case of Secured (HS) variant and out of scope of this document. R5F and C66 RunTime are user developed applications and loaded/executed by SBL.

4.2.5 R5F SBL Loading

The SBL process starts with R5F executing loaded and verified R5F SBL code.

The only service exposed to R5F SBL by HSM ROM is the API to load the HSM RunTime. All other HSM services are outside of the HSM ROM. The R5 Boot ROM and HSM Boot ROM work together to load the R5F SBL. When the R5F SBL has been successfully validated and loaded, the R5F Boot-ROM is eclipsed and the R5F SBL executes.

Figure 4-3 is the simplified sequence of the boot process. It is provided for illustration purposes only. An illustration of the SBL and HSM RunTime is similar to what is shown in Figure 4-3.

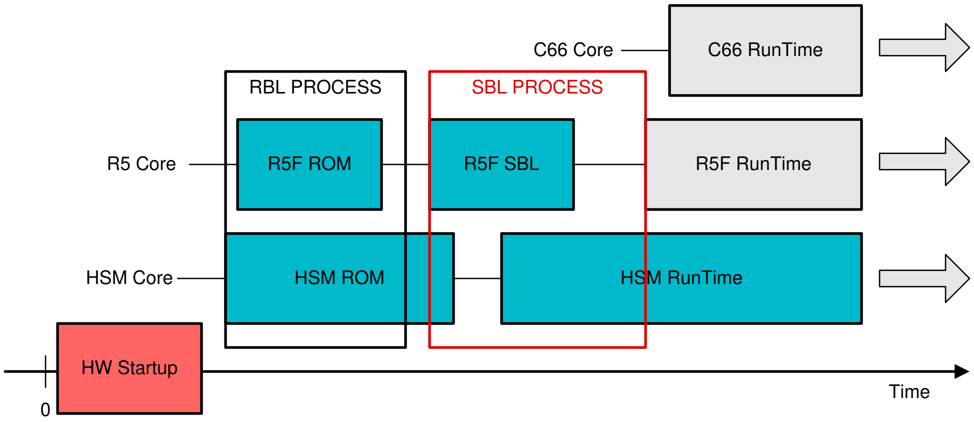

Figure 4-3. R5F SBL

HSM ROM configures the IPC interface, unhalts the R5F core, and then waits for a confirmation message from the R5F Core (over IPC). The R5F core sends a confirmation to the HSM ROM. The R5F ROM then configures the QSPI interface and reads the R5F SBL image from FLASH. The SBL image might or might not have integrity check enabled (based on the certificate). HSM ROM switches the memory map for R5F from ROM to RAM and resets the R5F to execute the SBL image. The HSM-ROM for GP devices is now locked (black-boxed). SBL can now load the multicore image (containing MSS & DSS application and RSS firware/patch images) to the corresponding RAMs and core soft-reset to jump to R5F RunTime. SBL or R5F RunTime can release out-of-reset & unhalt RadarSS and C66x subsysytems.

For more information about SBL and bootloading please refer to the application note

Note

R5F SBL is user spaced application, so SBL can be written as per customer requirement but within device capability. MMWAVE-MCUPLUS-SDK provides reference SBL implementation for AWR294x device.

Chapter 5

Device Configuration

5.1 Overview

PRCM manages clocks, resets, and power domain control of subsystems and modules inside the device. Additionally, configuration of certain device-level features is also performed through this module. PRCM has control and status registers to achieve this functionality. The Clock and Reset Management in AWR294x is distributed. The Main subsystem TOPRCM module controls all the Subsystem Resets and Clocks. The SubSystem RCM modules control their respective subsystem IPs

The available address space of PRCM is divided as in Figure 5-1.

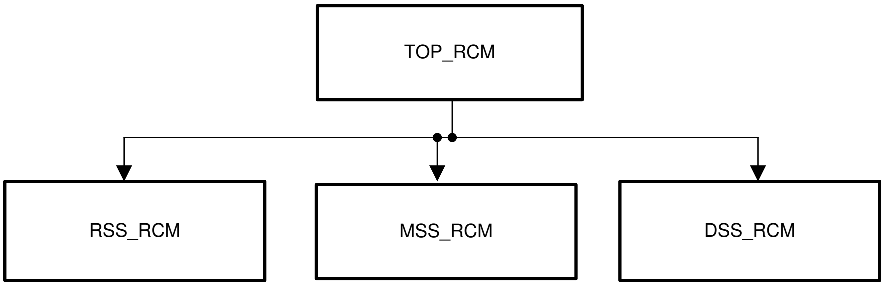

Figure 5-1. Device Configuration

Bit	Field	Type	Reset	Description
31-15	RESERVED	R	0h	Reserved Reads return 0x0 and writes have no effect. 0x0 = Functional Reset
14	SLICER_APLL_BYPASS_DRV	R/W	0h	Slicer APLL Bypass Drive This bit controls the drive strength of the APLL Bypass Slicer 0 = Low-power drive 1 = High-power drive 0x0 = Functional Reset
13	SLICER_APLL_BYPASS	R/W	0h	Slicer APLL Bypass This bit enables a high-speed slicer connected to CLKM which can be used to drive a high-speed clock directly as the SYNTH reference clock. 0 = Normal operation (bypass slicer disabled) 1 = APLL Bypass Slicer Enabled 0x0 = Functional Reset
12	XTAL_DETECT_XO_SLICER	R/W	0h	XTAL Detect Enable This bit connects a pullup and sense circuitry to CLKM to detect the presence or absence of a crystal. This operation will conflict with oscillator functionality, so this bit must be asserted only when the oscillator is disabled (CTRL_CLKTOP_REG 1 bit 2 must be ' 0'). After asserted, the internal XTAL_SENSE signal will reflect a ' 1' if a crystal is present (CLKM sees a high impedance) or ' 0' if CLKM is tied to ground. After the sense operation is detected, this bit must be cleared before the oscillator will function properly if enabled. 0 = Normal operation (pullup and sense circuitry are disconnected from CLKM, XTAL_SENSE outputs ' 1') 1 = XTAL sense function enabled (pullup and sense circuitry connected to CLKM, output of XTAL_SENSE reads ' 1' if high impedance, ' 0' if CLKM is tied to ground) 0x0 = Functional Reset
11	SLICER_DCCPL_XO_SLICER	R/W	0h	Slicer DC-Coupled Mode 0 = Normal operation (AC-couple CLKP to internal slicer) 1 = DC-couple CLKP to internal slicer to CLKP 0x0 = Functional Reset
10	SLICER_HIPWR_XO_SLICER	R/W	0h	Slicer High-power Mode This bit bypasses the input clock slicer current-starving/filtering circuitry to increase gain and reduce device phase-noise at the expense of power and reduced supply noise rejection. This permits the use of a high-speed external test clock (660MHz max). 0 = Normal operation (current-limiting present) 1 = High-power/high-speed test mode 0x0 = Functional Reset
9	FASTCHARGEZ_BIAS_XO_SLICER	R/W	0h	Bias Fast-charge Enable (Active Low) This bit bypasses the RC filtering on the XOSC/SLICER Bias to permit more rapid power-up. 0 = Bias fast-charge 1 = Normal operation (filtering present) 0x1 = Functional Reset

Bit	Field	Type	Reset	Description
31-11	RESERVED	R/W	0h	
10-8	TSTPATGENEN	R/W	0h	Enable for test pattern generator. This is used to Mux with the functional data from BSS. 000 -->Disable, 111-->Enable, Others are reserved.
7-0	TSTPATVLDCNT	R/W	8h	Number of DSS Interconnect clocks (200 MHz) between successive samples for the test pattern gen.

5.2.6.53 ADCBUFCFG1 Register (Offset = 824h) [Reset = 00010004h]

ADCBUFCFG1 is shown in Table 5-531.

Return to the Table 5-477.

Table 5-531. ADCBUFCFG1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-17	RESERVED	R/W	0h	
16	ADCBUFPIPOSEL	R	1h	TI Internal Feature Ping-pong select value from ADC Buffer Packing logic. Even in SW override mode, this register will indicate the ping-pong select signal generated from the ADC Buffer Packing logic and not the override value.
15	ADCBUFCONTSTOPPL	R/W	0h	Stop Pulse for Continuous mode. The data capture will stop once this register is set. Continous mode is expected to be only used for CZ and ADC Buffer Testpattern mode : Its a wspecial access type, write to this field will generate a pulse
14	ADCBUFCONTSTRTPL	R/W	0h	Start Pulse for Continuous mode. The data capture will start from Address 0 once this register is set. All the other configurations like Enable, Sample Count are expected to be programmed before this pulse. Continous mode is expected to be only used for CZ and ADC Buffer Testpattern mode : Its a wspecial access type, write to this field will generate a pulse
13	ADCBUFCONTMODEEN	R/W	0h	Continuous mode enable for ADC Buffer. This is set when a fixed number of samples have to be stored in Ping/Pong and not depend on Chirp time-lines (Eg: Analog Lab characterization to stream out continuous data from DFE). Continous mode is expected to be only used for CZ and ADC Buffer Testpattern mode
12	ADCBUFWRITEMODE	R/W	0h	This needs to be programmed to 0x1 in AR16xx 0 --> Interleaved, 1 --> Non-interleaved
11	ADCBUFPIPOOVRVAL	R/W	0h	TI Internal Feature SW override value for ADC Buffer Ping Pong select
10	ADCBUFPIPOOVRCNT	R/W	0h	TI Internal Feature Override control for ADC Buffer Ping Pong select
9	RX3EN	R/W	0h	Enable for Rx3 write
8	RX2EN	R/W	0h	Enable for Rx2 write
7	RX1EN	R/W	0h	Enable for Rx1 write
6	RX0EN	R/W	0h	Enable for Rx0 write
5	ADCBUFIQSWAP	R/W	0h	0 --> I is stored in LSB and Q is stored in MSB 1 --> Q is stored in LSB and I is stored in MSB
4	ADCBUFRL2CHINTRL	R/W	0h	TI reserved field. Do not touch
3	ADCBUFRLMODECHSEL	R/W	0h	TI Internal Feature 0 -->I channel, 1 --> Q channel
2	ADCBUFREALONLYMODE	R/W	1h	0-->Complex Data mode, 1-->Real data mode
1	ADCBUFPIPOSELINV	R/W	0h	TI Internal Feature Inversion control for ADC Buffer Ping-pong select. By default ADC Buffer write starts with Pong write. By setting this bit to 1, it will start from Ping write after reset.
0	ADCBUFWRSOURCE	R/W	0h	TI Internal Feature Write source for ADC Buffer. 0 --> DFE, 1 --> VIN

5.2.6.54 ADCBUFCFG1_EXTD Register (Offset = 828h) [Reset = 00000000h]

ADCBUFCFG1_EXTD is shown in Table 5-532.

Return to the Table 5-477.

Table 5-532. ADCBUFCFG1_EXTD Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	ADCBUFINTGENDLY	R/W	0h	TI Intenal Feature. No of clocks to delay the ping-pong switch and interrupt generation w.r.t ADC Valid fall pulse. This will enable dithering the DSP activity for successive ping-pong switch cycles. This will not delay the ping pong toggle which will happen immediately after ADC Valid fall.

5.2.6.55 ADCBUFCFG2 Register (Offset = 82Ch) [Reset = 0100XX00h]

ADCBUFCFG2 is shown in Table 5-533.

Return to the Table 5-477.

Table 5-533. ADCBUFCFG2 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-27	RESERVED	R/W	0h	
26-16	ADCBUFADDRX1	R/W	100h	128 bit Address offset to be added to the internal address pointer for Rx1 writes in Non-interleaved mode.
15-11	RESERVED	R/W	0h	
10-0	ADCBUFADDRX0	R/W	0h	128 bit Address offset to be added to the internal address pointer for Rx0 writes in Non-interleaved mode.

5.2.6.56 ADCBUFCFG3 Register (Offset = 830h) [Reset = 0300XX00h]

ADCBUFCFG3 is shown in Table 5-534.

Return to the Table 5-477.

Table 5-534. ADCBUFCFG3 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-27	RESERVED	R/W	0h	
26-16	ADCBUFADDRX3	R/W	300h	128 bit Address offset to be added to the internal address pointer for Rx3 writes in Non-interleaved mode.
15-11	RESERVED	R/W	0h	
10-0	ADCBUFADDRX2	R/W	200h	128 bit Address offset to be added to the internal address pointer for Rx2 writes in Non-interleaved mode.

5.2.6.57 ADCBUFCFG4 Register (Offset = 834h) [Reset = XX000400h]

ADCBUFCFG4 is shown in Table 5-535.

Return to the Table 5-477.

Table 5-535. ADCBUFCFG4 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	RESERVED	R/W	0h	
30	ADCBUFPNGSELTGLDIS	R/W	0h	TI Internal Feature 0 --> Delay Interrupt Gen and Ping/Pong toggle together based on cfg_interrupt_gen_delay, 1 --> Delay only Interrupt Gen based on cfg_interrupt_gen_delay. But toggle Ping/Pong select signal as soon as the write is complete.
29-26	RESERVED	R/W	0h	
25-21	ADCBUFNUMCHRPPONG	R/W	0h	Number of chirps to be stored in Pong buffer. This register should be programmed with one less than the actual number needed. This is used when data is written to Pong Memory. The value written to this field should be the same as that configured for Ping
20-16	ADCBUFNUMCHRPPING	R/W	0h	Number of chirps to be stored in Ping buffer. This register should be programmed with one less than the actual number needed. This is used when data is written to Pong Memory. The value written to this field should be the same as that configured for Pong
15-0	ADCBUFSAMPCNT	R/W	400h	No of samples to store in each Ping and Pong register in continuous mode of ADC Buffer. In real only mode this refers to the number of real samples and in complex mode, this refers to number of complex samples. This refers to the number of samples per channel. This counter increments once for every new sample from DFE (as long as 1 or more channels are enabled). The max allowed value varies depending on other configurations (No of channels enabled and real/complex data). Continous mode is expected to be only used for CZ and ADC Buffer Testpattern mode

5.2.6.58 ADCBUFINTGENDITHERDLY Register (Offset = 838h) [Reset = 00000000h]

ADCBUFINTGENDITHERDLY is shown in Table 5-536.

Bit	Field	Type	Reset	Description
31-1	RESERVED	R/W	0h	
0	sel	R/W	0h	writing: 1'b0: selects frame_start from DFE 1'b1: Selects frame_start from chirp_avail (adc capture complete)

5.2.6.60 CQCFG1 Register (Offset = C00h) [Reset = 4010000Xh]

CQCFG1 is shown in Table 5-538.

Return to the Table 5-477.

Table 5-538. CQCFG1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	RESERVED	R/W	0h	
30-22	CQ2BASEADDR	R/W	100h	128-bit Address offset which inidcates the start address for storing CQ0 (ADC/RxIF Saturation Detection) from the start of CQ memory. This is not the byte address offset but 128 bit address offset
21-13	CQ1BASEADDR	R/W	80h	128-bit Address offset which inidcates the start address for storing CQ0 (Signal Image Band Energy detection) from the start of CQ memory. This is not the byte address offset but 128 bit address offset
12-4	CQ0BASEADDR	R/W	0h	128-bit Address offset which inidcates the start address for storing CQ0 (Wide Band Energy detection) from the start of CQ memory. This is not the byte address offset but 128 bit address offset
3	CQ96BITPACKEN	R/W	0h	This is used to pack the CQ data into only the LSB 96 bits of each row of the CQ memory. This can be used in 3 channel mode of LVDS where the ADC data and Chirp Params occupy only LSB 96 bits of each memory row.
2	RESERVED	R/W	0h	
1-0	CQDATAWIDTH	R/W	0h	This is used to appropriately pack the valid CQ data bits in appropriate bits in the CQ memory. 00, 01->Raw 16, 10-->Raw 12, 11-->Raw14

5.2.6.61 CQCFG2 Register (Offset = C04h) [Reset = 0000XXXXh]

CQCFG2 is shown in Table 5-539.

Return to the Table 5-477.

Table 5-539. CQCFG2 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-18	RESERVED	R/W	0h	
17	CQ_CLK_GATE	R/W	0h	writing: 1'b0: ungates the clk to CQ logic 1'b1: Gates the clk to CQ logic
16	CQPIPOSELVAL	R/W	0h	Ping pong select override value for CQ Memory. 1 --> Read access from Chirp Info Slave of DSS Interconnect will be routed to ping memory and write access from CQ_W/DFE write will be routed to pong memory. 0 --> Read access from Chirp Info Slave of DSS Interconnect will be routed to pong memory and write access from CQ_W/DFE write will be routed to ping memory.
15-13	RESERVED	R/W	0h	
12	CQPIPOSELCNT	R/W	0h	Ping pong select override control for CQ Memory. 0 --> Ping-pong select comes from HW FSM (same as the ping-pong select for ADC Buffer)/DMMCQPINPONSEL 1 --> Ping pong select for CQ memory is taken from SW register (CQPIPOSELVAL)
11-9	RESERVED	R/W	0h	
8	CQ2TESTMODEEN	R/W	0h	TI Internal Feaure Test Mode enable for CQ2 (ADC/RxIF Saturation). Once enabled, each 8 bit data is same as Addr+1.
7-5	RESERVED	R/W	0h	
4	CQ1TESTMODEEN	R/W	0h	TI Internal Feaure Test Mode enable for CQ1 (SI). Once enabled, each 16 bit data is same as [2*Addr+1 for the MSB 8 bits and Addr+1 for the LSB 8 bits.
3-1	RESERVED	R/W	0h	
0	CQ0TESTMODEEN	R/W	0h	TI Internal Feaure Test Mode enable for CQ0 (WBE). Once enabled, each 16 bit data is same as [2*Addr+1 for the MSB 8 bits and Addr+1 for the LSB 8 bits.

3-1	RESERVED	R	0h	
0	dmma_sel	R/W	1h	writing 1'b0 : ensures all the accesses from DMMA are user-mode writing 1'b1 : ensures all the accesses from DMMA are privilege mode

5.2.7.442 R5_CONTROL Register (Offset = 800h) [Reset = 00XXXXXXh]

R5_CONTROL is shown in Table 5-1158.

Return to the Summary Table.

Table 5-1158. R5_CONTROL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-27	RESERVED	R	0h	
26-24	rom_wait_state	R/W	0h	writing '111' enables a single cycle wait state with respect to CR5A_clk for rom access. This needs to be set when R5 clock is at 400MHZ and Interconnect-clk is at 200MHZ. (because it is a timing issue in this scenario)
23-19	RESERVED	R	0h	
18-16	reset_fsm_trigger	R/W	0h	Write pulse bit field: writing 3'b111 will trigger the reset FSM. Reset FSM ensures reset to R5SS and inturn ensures the latching of lock_step and also mem_swap bit
15-11	RESERVED	R	0h	
10-8	lock_step_switch_wait	R/W	0h	writing 3'b111 ensures switch happens only after R5SS reset. Orelse it will be a immediate switch.
7-3	RESERVED	R	0h	
2-0	lock_step	R/W	7h	writing 3'b000 ensures R5 to be in Dual-Core mode. Note: The change happens after the R5SS reset assertion if R5_CONTROL_lock_step_switch_wait is set. Or else the switching to Dual-core happens on the fly.

5.2.7.443 R5_ROM_ECLIPSE Register (Offset = 804h) [Reset = 000000XXh]

R5_ROM_ECLIPSE is shown in Table 5-1159.

Return to the Summary Table.

Table 5-1159. R5_ROM_ECLIPSE Register Field Descriptions

Bit	Field	Type	Reset	Description
31-11	RESERVED	R	0h	
10-8	memswap_wait	R/W	0h	writing 3'b111 ensures ROM-Eclipsing happens only after R5SS reset. Orelse it will be a immediate change.
7-3	RESERVED	R	0h	
2-0	memswap	R/W	0h	writing '111' ensures eclipsing of CR5A_ROM immediately if memswap_wait is not set. If memswap_wait is set then ROM is eclipsed after R5SS reset assertion.

5.2.7.444 R5_COREA_HALT Register (Offset = 808h) [Reset = 00000007h]

R5_COREA_HALT is shown in Table 5-1160.

L1DEDCMD is shown in Table 5-1581.

Return to the Summary Table.

This write only register provides control for enabling and disabling the ECC logic ofr the DMC. This register controls the parameters which are accumulated for the Data and Tag RAMs in the DMC. Enabling the ECC allows the counting of recoverable and non-recoverable errors as well as registering the requestor and the address and cache states for any ECC errors which are reported.

5.2.11.77 L1DDCSTAT Register (Offset = 0003110Ch) [Reset = 00000001h]

L1DDCSTAT is shown in Table 5-1582.

Return to the Summary Table.

This read only regsister contains the current error data for Correctable ECC errors. The register provides information on whether the error was correctable or non-correctable, the requestor, and what position the error was located. . The error information is written upon the occurrence of the first ECC error encountered. CERR1 is set, and the values are retained. If any additional ECC errors occur, this is indicated by setting CERR2.

5.2.11.78 L1DDNCSTAT Register (Offset = 00031110h) [Reset = 00000001h]

L1DDNCSTAT is shown in Table 5-1583.

Return to the Summary Table.

This read only register contains the current error data for Correctable ECC errors. The register provides information on whether the error was correctable or non-correctable, the requestor, and what position the error was located. This register is similar to Error! Not a valid bookmark self-reference. with the exception of the bit position register fields, with two bit errors it is not possible to provide the locations. . The error information is written upon the occurrence of the first ECC error encountered. CERR1 is set, and the values are retained. If any additional ECC errors occur, this is indicated by setting CERR2.
Note: Non-correctable errors do not mean two bits in the 256 bit data word, but two bits+ of error in a single byte. The EDC is capable of correcting up to 8 bits in a single word if there are only single bit errors in each byte.

5.2.11.81 L1DDEDADDR Register (Offset = 0003111Ch) [Reset = 00000000h]

L1DDEDADDR is shown in Table 5-1586.

Return to the Summary Table.

The L1D Correctable Error Detection Address Register pair contain the additional information on correctable errors reported in the STATUS registers. The addresses for both correctable and noncorrectable errors are held in this register. The value contained in the addresss field is the lower 16 bits of the word boundary of the memory access. If the access is to 0x00F00020, the address field will read 0x0020, if the access is to 0x00F07FE0, the address field will read 0x7FE0.

5.2.11.82 L1DTEDADDR Register (Offset = 00031120h) [Reset = 00000000h]

L1DTEDADDR is shown in Table 5-1587.

Return to the Summary Table.

The L1D Correctable Error Detection Address Register pair contain the additional information on correctable errors reported in the STATUS registers. The address for both correctable and noncorrectable errors are held in this register. The value of the address is the index (or address on the RAM) of the RAM module.

5.2.11.83 L1DEDCNT Register (Offset = 00031124h) [Reset = 00000000h]

L1DEDCNT is shown in Table 5-1588.

Return to the Summary Table.

The L1D TAG Error Detection Error Count Register.stores the error counts for correctable and noncorrectable errors which occur in the L1D Cache Memories, these counts are accumulated regardless of the exception mapping in the L1DEDCMD (0x0182_1108) interrupt enable bits.
The counters capture the total number of correctable and non-correctable errors from both the DATA and TAG memories.

Table 5-1588. L1DEDCNT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	NCPECNT	R	0h	Non-correctable EDC error count. Shows the number of non-correctable errors which have occurred in the DMC memories since last reset. This counter is cleared by writing a zero value to the counter.
15-0	CPECNT	R	0h	Correctable EDC error count: Shows the number of correctable errors which have occurred in the DMC memories since last reset. This counter is cleared by writing a zero value to the counter.

5.2.11.84 L2TEDCMD Register (Offset = 00031128h) [Reset = 0000000Fh]

L2TEDCMD is shown in Table 5-1589.

Return to the Summary Table.

This write only register provides control for enabling and disabling the ECC logic ofr the UMC. This register controls the parameters which are accumulated for the Data and Tag RAMs in the DMC. Enabling the ECC allows the counting of recoverable and non-recoverable errors as well as registering the requestor and the address and cache states for any ECC errors which are reported.

5.3 Device Clock Architecture

5.3.1 Clock Overview

Figure 5-2 shows a high-level overview of the device clock architecture. The figure captures the key clock sources and the configuration options available to select the appropriate clock source. The detailed structure is captured under each PLL clocking section.

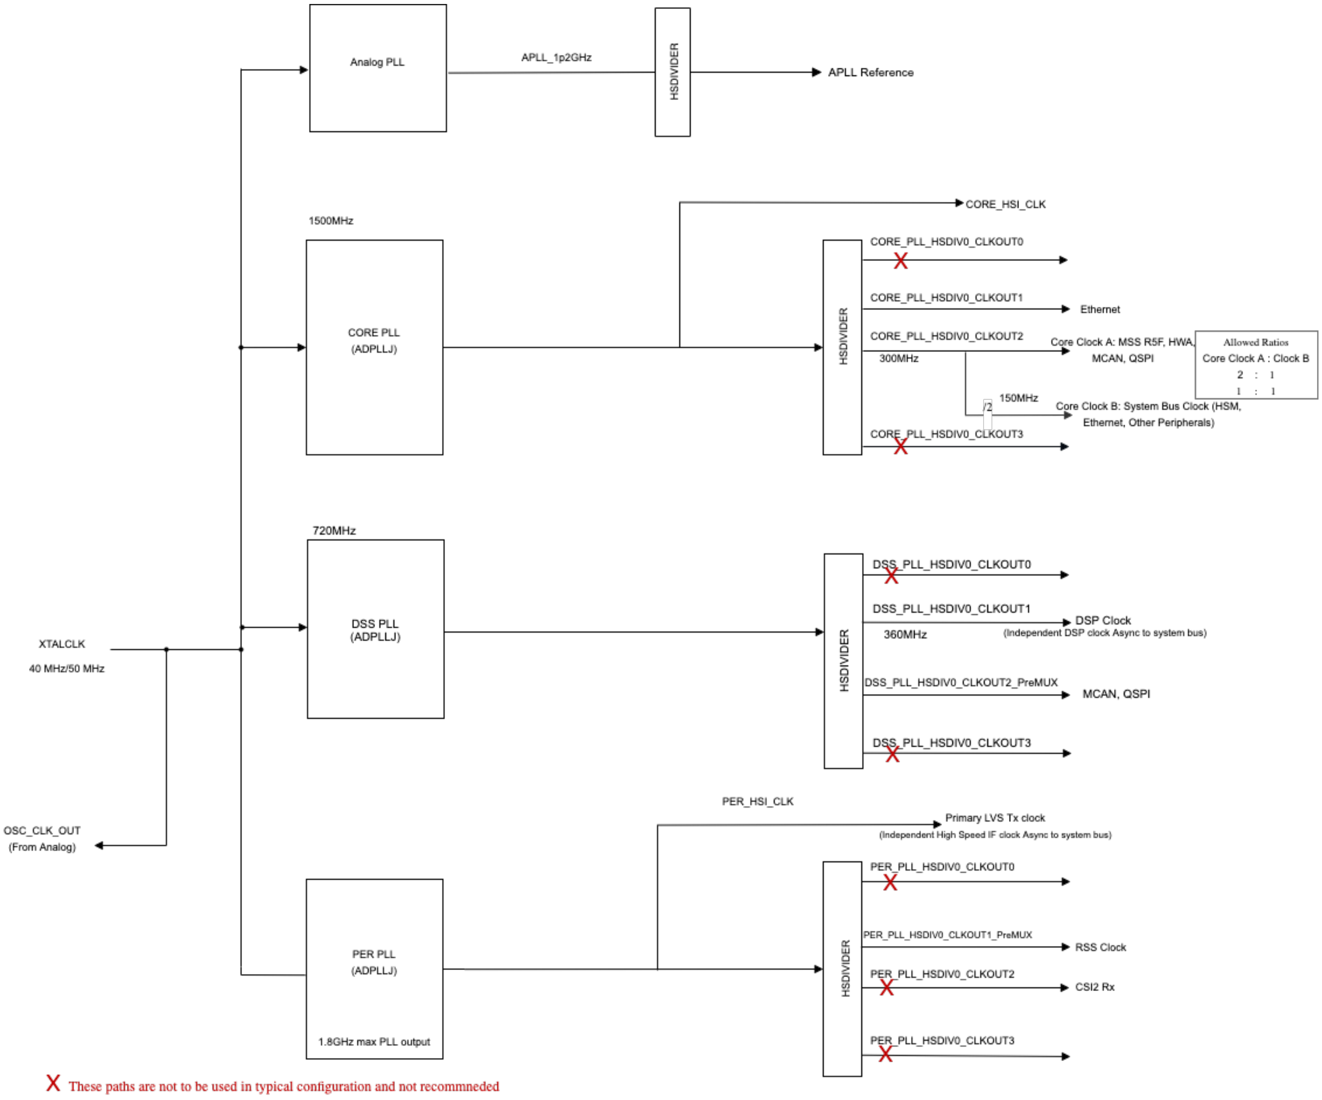

Figure 5-2. Clock Tree Configuration

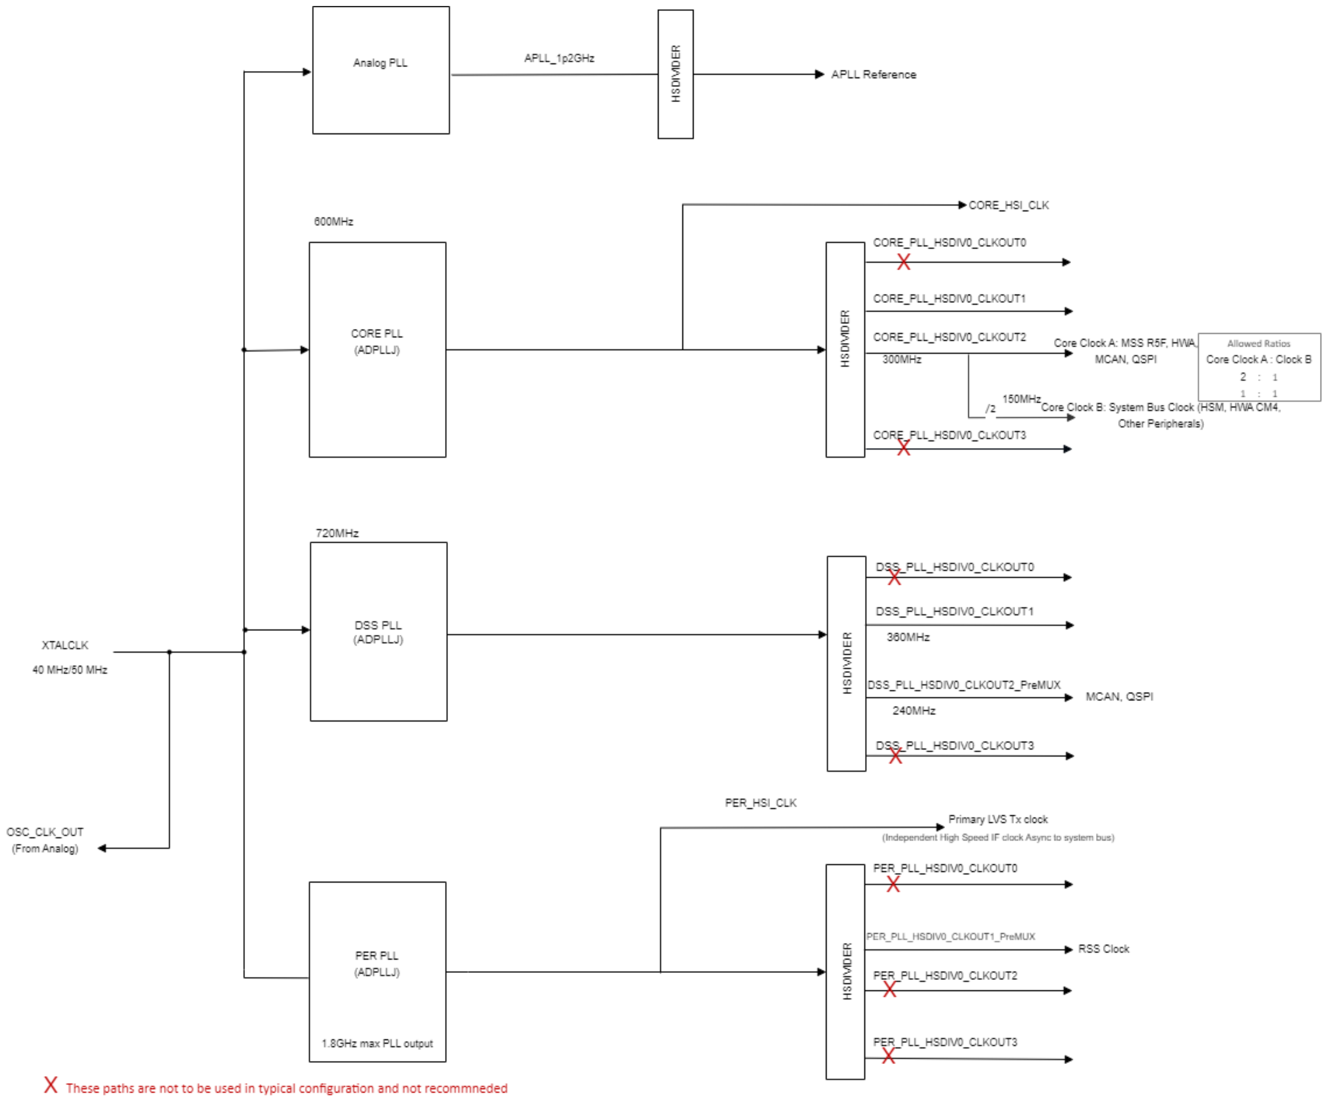

Figure 5-3. AWR2944LC Clock Tree Configuration

There are 2 clock sources for AWR294x

1. Crystal
2. External Clock source

The 40 MHz and 50 MHz crystals are supported.

The external crystal is connected to an oscillator that generates 40MHz/50MHz clock. This clock is fed to PLLs. There are 4 PLL’s

- Analog PLL - APLL
- Digital PLL for Core of type ADPLLJ → Core PLL
- Digital PLL for peripherals of type ADPLLJ → Per PLL
- Digital PLL for Core of type ADPLLJ → DSS PLL

There is a RC Oscillator that powers the chip before the crystal oscillator come up during the boot. This RC Oscillator is also the backup Oscillator when the crystal oscillator fails.

The Clocks generated by the PLLs & Oscillators are routed to various entities of the SOC by the use of clock multiplexors. To provide operating frequency of the clocks to various entities of the chip the clocks are divided with the help of the clock dividers.

The clock configuration involves configuring the PLLs, the multiplexors and the dividers at the right time in the boot sequence of the chip. Typically, the clock configuration is handled in the SBL (Secondary Boot loader) and configurations are retained through the lifecycle of the application. Though re-configurations of the clocks can be done at run time keeping in mind of the limitations of each PLL, it's not recommended to re-configure the clocks at run time.

5.3.2 Root Clocks

These are the clocks used as inputs to various clock multiplexers and eventually routed to peripherals

5.3.3 External Clocks

The clocks in the AWR294x device to the supported peripherals are as depicted in Figure 5-4.

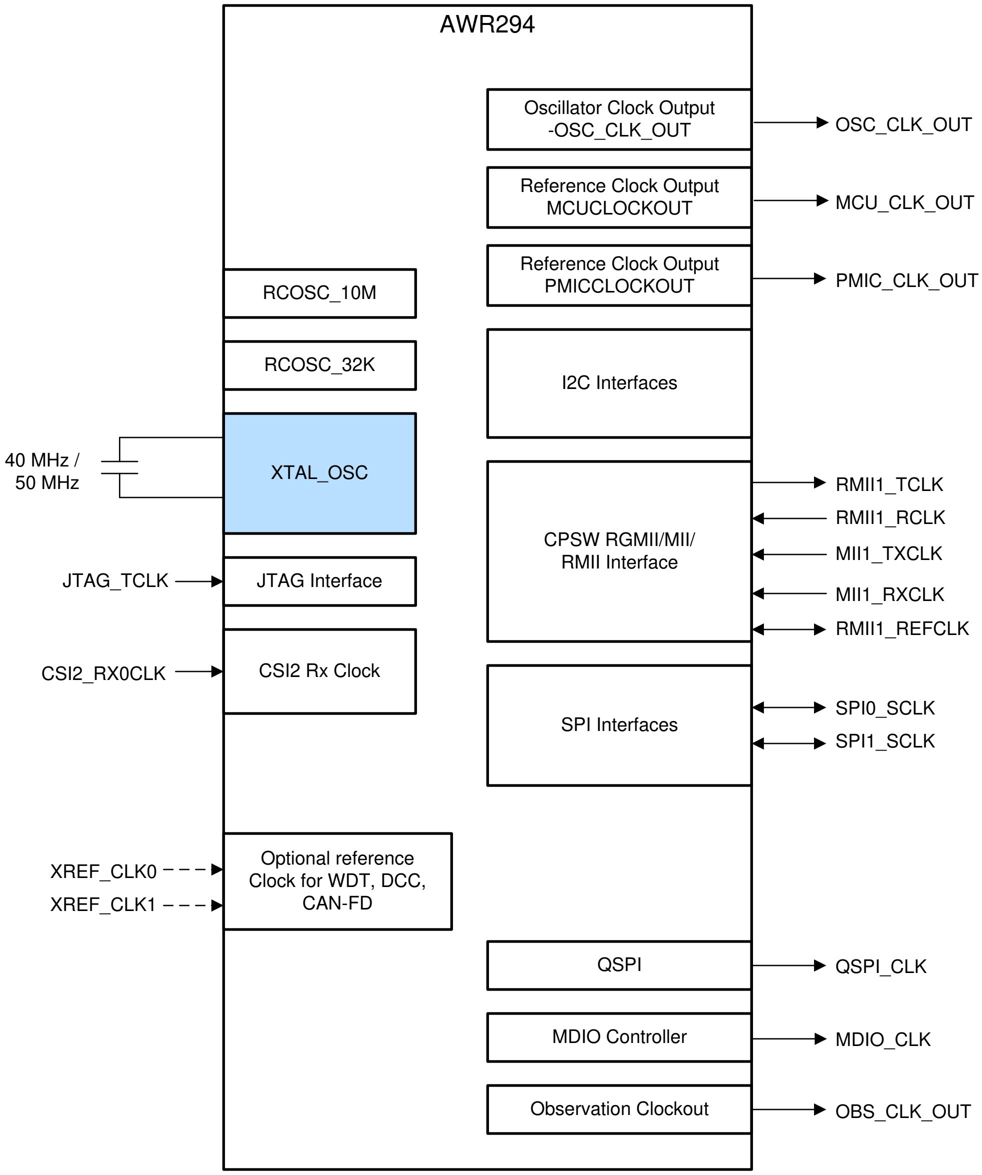

Figure 5-4. External Clocks

Note

RCOSC_10M , RCOSC_32K : these two clocks are internal and not available for application.

5.3.5 Analog Modules

5.3.5.1 ADPLL

General features of the ADPLL-J module are:

- Low Jitter Phase-Locked Loop
- RHEA, OCP, and Direct Access interface
- Programmable 8-bit input divider: N
- Programmable 12-bit integer, 18-bit fractional loop multiplier: M
- Programmable 7-bit post divider: M2
- Digital control and loop filter
- User-selectable multiple in-built oscillators for power-jitter optimization
- Primary output clock on digital core domain: CLKOUT = (M / (N+1))*CLKINP*(1/M2)
- Additional output clock on internal LDO domain: CLKOUTLDO = (M / (N+1))*CLKINP*(1/M2)
- Internal oscillator clock on internal LDO domain: CLKDCOLDO = (M / (N+1))*CLKINP
- Output clock gating control: CLKOUTEN / CLKOUTLDOEN / CLKOUTDCOLDOEN
- Digital LOCK indicators for frequency and phase lock
- Fast re-lock
- Input to output bypass on CLKOUT
- Bypass programmable 4-bit divider: N2: CLKOUT = CLKINP / (N2 + 1)
- Optional low frequency bypass clock control: ULOWCLKEN CLKOUT = CLKINPULOW
- Power management modes:
- Power down
- Idle bypass
- Stop Clock-input Bypass
- Retention
- Output clock Spread spectrum clocking supported

The ADPLLLJ is a low jitter PLL with a 2-GHz maximum output. ADPLLLJ has a predivide feature which allows user to divide, for instance, a 24-MHz or 26-MHz reference clock to 1 MHz and then multiply up to 2 GHz maximum. All PLLs will come-up in bypass mode at reset. SW needs to program all the PLL settings appropriately and then wait for PLL to be locked.

Spread Spectrum Clocking

The module supports spread spectrum clocking (SSC) on its output clocks. SSC is used to spread the spectral peaking of the clock to reduce any electromagnetic interference (EMI) that may be caused due to the clock's fundamental or any of its harmonics. When SSC is enabled the clock's spectrum is spread by the amount of frequency spread, and the attenuation is given by the ratio of the frequency spread (Δf) and the modulation frequency (fm), i.e., 10*log10(Δf/fm) dB.

Note

Please refer MMWAVE-MCUPLUS-SDK for reference implementation of this feature.

5.3.5.2 ADPLLJ Programming Model

5.3.5.2.1 ADPLLJ Programming Sequence

The following sequence is for PLL_PER. Similar registers exist for PLL_CORE and PLL_DSP.

1. Program the values M and N2 in TOP_RCM: PLL_PER_MN2DIV.
2. Program the values of N and M2 in TOP_RCM:PLL_PER_M2NDIV.
3. Program the Fractional M in TOP_RCM:PLL_PER_FRACDIV_FRACTIONALM.
4. Program the Sigma Delta Divider (SD) in TOP_RCM:PLL_PER_FRACDIV_REGSD.
5. Copy the NWELL TRIM from EFUSE to TOP_RCM:PLL_PER_CLKCTRL_NWELLTRIM.
6. Write 0x0 to TOP_RCM:PLL_PER_CLKCTRL_IDLE.
7. Write 0x1 to TOP_RCM:PLL_PER_TENABLE.
8. Write 0x1 to TOP_RCM:PLL_PER_CLKCTRL_TINTZ.
9. Write 0x0 to TOP_RCM:PLL_PER_TENABLE.
10. Write 0x1 to TOP_RCM: PLL_PER_TENABLEDIV.
11. Write 0x0 to TOP_RCM: PLL_PER_TENABLEDIV.
12. Poll Lock Status by reading TOP_RCM:PLL_PER_STATUS_PHASELOCK until it is 0x1.

5.3.5.2.2 HS Divider Programming Sequence

The following sequence is for PLL_PER. Similar registers exist for PLL_CORE and PLL_DSP.

1. Program the CLKOUT0 Divider value in TOP_RCM:PLL_PER_HSDIVIDER_CLKOUT0_DIV.
2. Program the CLKOUT0 Divider value in TOP_RCM:PLL_PER_HSDIVIDER_CLKOUT1_DIV.
3. Program the CLKOUT0 Divider value in TOP_RCM:PLL_PER_HSDIVIDER_CLKOUT2_DIV.
4. Program the CLKOUT0 Divider value in TOP_RCM:PLL_PER_HSDIVIDER_CLKOUT3_DIV.
5. Write 0x1 to TOP_RCM:PLL_PER_HSDIVIDER_TENABLEDIV.
6. Write 0x0 to TOP_RCM:PLL_PER_HSDIVIDER_TENABLEDIV.
7. Enable the CLKOUT0 by write 0x1 to TOP_RCM:PLL_PER_HSDIVIDER_CLKOUT0_GATE_CTRL.
8. Enable the CLKOUT0 by write 0x1 to TOP_RCM:PLL_PER_HSDIVIDER_CLKOUT1_GATE_CTRL.
9. Enable the CLKOUT0 by write 0x1 to TOP_RCM:PLL_PER_HSDIVIDER_CLKOUT2_GATE_CTRL.
10. Enable the CLKOUT0 by write 0x1 to TOP_RCM:PLL_PER_HSDIVIDER_CLKOUT3_GATE_CTRL.

5.3.5.2.3 M2 and N2 Change On-the-Fly

The dividers M2 and N2 are designed to change on the fly and provide a glitch-free frequency switch from the old to new frequencies. In other words, they can be changed while the PLL is in a locked condition, without having to switch to bypass mode. A status toggle bit will give an indication if the new divisor was accepted. These dividers can also be changed in bypass mode, and the new divisor value will be reflected on output after the PLL relocks. For more details, see the PLL configuration procedures for each PLL.

5.4 Memory Protection Unit (MPU) and Firewalls

5.4.1 Functional Operation

The MPU performs memory protection checking for a CBA bus. It inputs a VBUSM or VBUSP bus, then checks the address against the fixed and programmable regions to see if the access is allowed. If allowed, the transfer is passed unmodified to the output VBUSM or VBUSP bus. If the transfer is illegal (fails the protection check), then the MPU does not pass the transfer to the output bus but rather services the transfer internally back to the input bus (to prevent a hang) returning the fault status to the requestor as well as generating an interrupt about the fault.

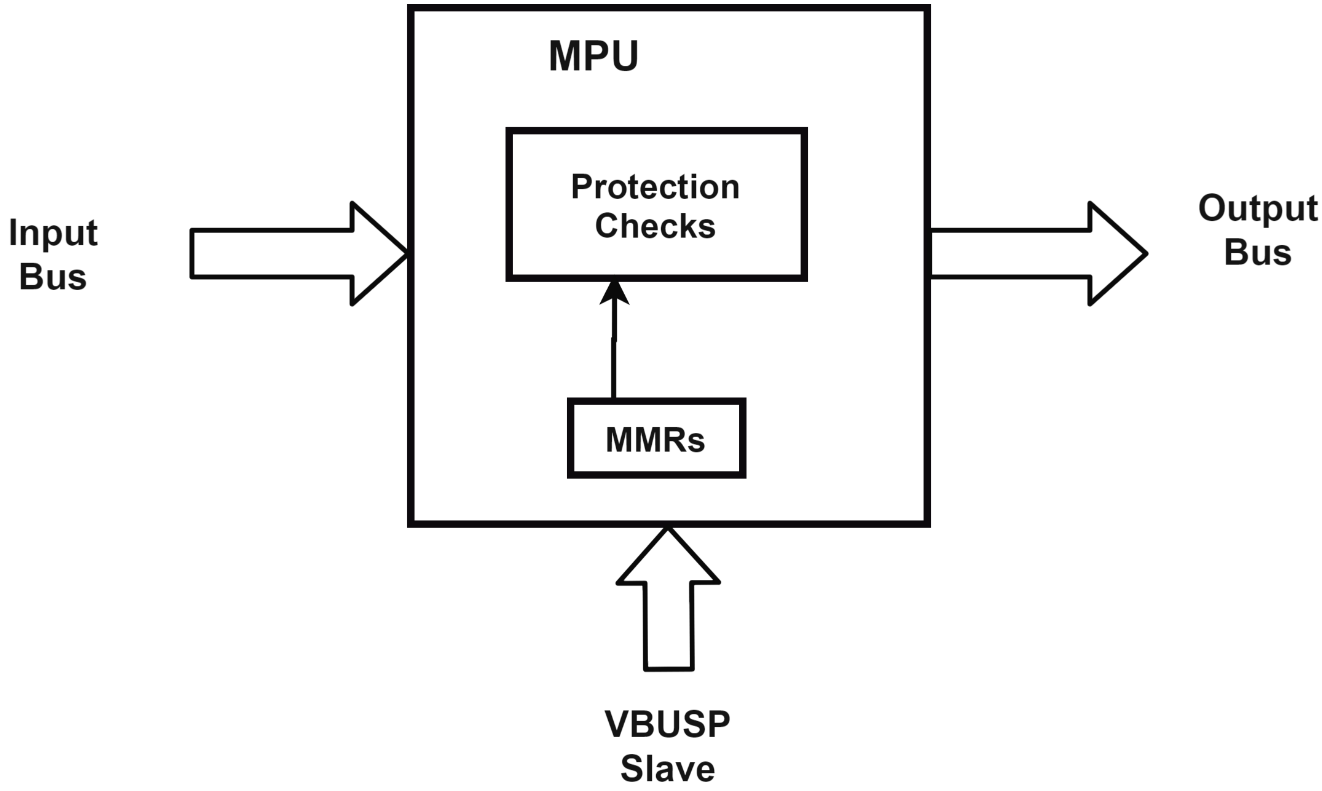

Figure 5-5. MPU Top Level Diagram

The first check is the transfer's privID against the AID settings. There is an AID register bit for each possible privID (0 to 15) and an AIDX that covers privIDs not configured. The privID is used to lookup the associated AID bit. If the AID bit is 0, then the range does not cover that privilege level and the range is not checked (although other ranges with different AID setting will) for this transfer. If the AID bit is 1, then the range does cover that privilege level and the permissions are checked. The transfer secure and debug parameters are checked against the MPPA values to detect an allowed access. The two bits (NS and EMU) provide 3 permission levels. If the NS is set, the range is non-secure and any security or debug level may access the range. If the NS is not set, the range is secure only and only secure level accesses are allowed. In secure mode, if the EMU is set, debug accesses are allowed. If the EMU is not set, debug accesses are not allowed. For non-debug accesses, the read, write, and execute permissions are also checked. There is a set of permissions for supervisor mode and another for user mode. The "priv" attribute of the transfer determines which is checked. If priv = 1, the supervisor rwx bits are checked against the "dir" and "dtype" attributes of the transfer (read is dir = 1 and dtype not instruction, write is dir = 0, execute is dir = 1 and dtype = instruction). If priv = 0, the user rwx bits are checked against the same attributes. If the associated rwx bit for the type of transfer is 1, the transfer is allowed, but if the rwx bit is 0, the transfer is not allowed.

The function outputs whether the transfer is allowed or not. If the transfer address range (start to end address, or those with AID bits = 0) does not match any range, the transfer is either allowed or disallowed based on the configuration mode of the MPU to "assumed allowed" or "assumed disallowed" mode. If any of the overlapped ranges does not allow the access, the access is not allowed. Only when all the overlapped ranges allow the access is the access allowed. The final permissions are the lowest of each type of permission from any hit range (so if a transfer hits 2 ranges, one that is rw and one that is rx, then the final permission is just r).

5.4.2 Firewalls

There are 2 types of firewalls in the system: access control firewalls and PrivID-based firewalls. The following sections clarify the usage of the firewalls.

Access control firewalls — These firewalls generally allow or disallow access to a particular entity. The different variations of these firewalls are:

- Configuration-based complete (read-write) access allow/disallow
- Configuration-based selected (read/write/read-write) access allow/disallow

The firewalls also support a “Lock” of the configuration, which is a sticky bit implementation that does not allow for any further updates to the configuration until the next power cycle.

PrivID based firewalls — The PrivID-based firewall is used to protect peripheral ports from unintentional access from controller ports. The transactions over the bus interconnect have an associated Privilege Identifier field with the read-write access used to determine the validity (allow-disallow) of the transaction. A high level view of the firewall is shown in Figure 5-6.

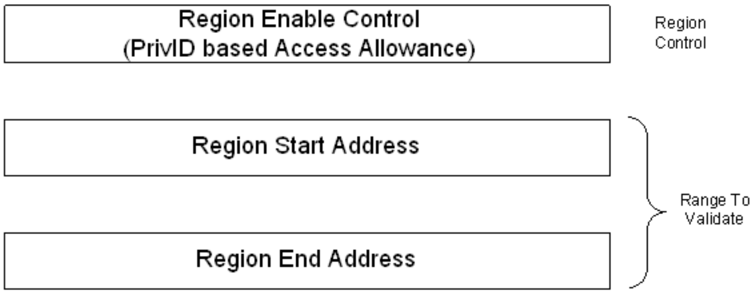

Figure 5-6. PrivID Firewall Overview

A region and the region controls are defined as to which controllers/PrivIDs would be allowed or disallowed access (based on modes). If the address range (start address to end address) of the input transfer overlaps with one of the regions, then the transfer parameters are checked against the address range permissions. These permissions are programmable and follow the MPPA (Memory Protection Permission Attribute) standard set by the Highlander Memory Management architecture. Additionally, the region controls also include read/write/execute permissions both in user/supervisor modes. Further, secure and debug modes can also be configured.

Thus, this section of the PCR controls the configurations of MPU regions in the device. The default_prog_mppa, default_prog_start_addr, default_prog_end_addr (for region 0 and 1) at the time of reset. It is controlled based on security manager’s signals soc_firewall_bypass and hsm_firewall_bypass.

0	prot_err_en	w1ts	0	Protection violation error enable. Write a 1 to set the enable. Writing a 0 has no effect.

5.4.4.6 Interrupt Enable Clear Register (Base Address + 0x01C)

The Interrupt Enable Clear register shows the interrupt enable and allows clearing of the interrupt enable. Reads return the Interrupt Enable register value, but writes can clear the interrupt enables.

Table 5-1682. Interrupt Enable Clear Register

Bits	Field	Type	Reset	Description
31:02	reserved	r/o	0	Always read as 0.
1	addr_err_en_clr	w1tc	0	Addressing violation error enable. Write a 1 to clear the enable. Writing a 0 has no effect.
0	prot_err_ en_clr	w1tc	0	Protection violation error enable. Write a 1 to clear the enable. Writing a 0 has no effect.

5.4.4.7 EOI Register (Base Address + 0x020)

The EOI register allows software to indicate when the end of interrupt service is complete. The eoi vector value is dependent on the interrupt handling.

Table 5-1683. EOI Register

Bits	Field	Type	Reset	Description
31:8	reserved	r/o	0	Always read as 0.
7:0	eoi_vector	r/w	0	EOI vector value. Write this with the interrupt distribution value in the chip. This drives the mpu_eoi_vector output signal.

5.4.4.8 Interrupt Vector Register (Base Address + 0x024)

The Interrupt Vector register displays the interrupt vector returned from interrupt distribution.

Table 5-1684. Interrupt Vector Register

31:0	intr_vec	r/o	0	Interrupt vector. Reads mpu_intr_vector input signal.

5.4.4.9 Programmable Address Start Register N (Base Address + 0x200, 0x210, 0x220, …)

The Programmable Address Start register holds the start address for the range. This register is writeable by a supervisor entity (priv = 1) only. If the NS bit is in non-secure mode (= 0) in the associated MPPA register, the register is also only writeable by a secure entity (secure = 1). The width of the field is determined by the comp_width parameter.

(Note: For GP device 'Bypass' is the default reset value and for HS-SE device 'Block' is the default reset value. For MPU_RSS_DSS2RSS and MPU_RSS_MSS2RSS the default reset value is 'Bypass' for all type of devices)

Refer to Default MPU Reset Configurations.

Table 5-1685. Programmable Address Start Register

Bits	Field	Type	Reset	Description
31:N	start_addrN	r/w	input	Start address for range N. Defaults to input signal value.
N-1:0	reserved	r/o	0	Always read as 0.

5.4.4.10 Programmable Address End Register N (Base Address + 0x204, 0x214, 0x224, …)

The Programmable Address End register holds the end address for the range. This register is writeable by a supervisor entity (priv = 1) only. If the NS bit is in non-secure mode (= 0) in the associated MPPA register, the register is also only writeable by a secure entity (secure = 1). The field width is determined by the comp_width parameter.

(Note: For GP device 'Bypass' is the default reset value and for HS-SE device 'Block' is the default reset value. For MPU_RSS_DSS2RSS and MPU_RSS_MSS2RSS the default reset value is 'Bypass' for all type of devices)

5.4.4.11 Programmable MPPA Register N (Base Address + 0x208, 0x218, 0x228, …)

The Programmable Address MPPA register holds the permissions for the region. This register is writeable by a non-debug supervisor entity (priv = 1) only. If the NS bit is in secure mode (= 0), the register is also only writeable by a non-debug secure entity (secure = 1). The NS bit is only writeable by a non-debug secure entity. For debug accesses, the register is writeable only when NS = 1 or EMU = 1.

(Note: For GP device 'Bypass' is the default reset value and for HS-SE device 'Block' is the default reset value. For MPU_RSS_DSS2RSS and MPU_RSS_MSS2RSS the default reset value is 'Bypass' for all type of devices)

Refer to Default MPU Reset Configurations.

5.4.4.14 Fault Clear Register (Base Address + 0x308)

The Fault Clear register allows the software to clear the current fault, so that another can be captured when this register is written.

Table 5-1690. Fault Clear Register

Bits	Field	Type	Reset	Description
31:1	reserved	r/o	0	Always read as 0.
0	fault_clr	w/o	0	Fault clear. Writing a 1 clears the current fault. Writing a 0 has no effect.

5.5 Power Domains

The device has two power domains:

- Always-on power domain: This power domain supplies power to entire device except for the DSP core. This domain cannot be switched off dynamically within the device.
- DSP power domain: The DSP core inside the DSP subsystem is placed on switchable power domain. This feature can be used to reduce power consumption of the device when the DSP core is not in use. By default, the state of this power domain is OFF.

5.5.1 DSP Power Domain

The C66x DSP is off by default on bootup. The DSS_RCM controls the power cycling of the DSP. Software can trigger a power on/off sequence by writing to the DSP_PD registers in DSS_RCM space.

5.5.1.1 Software Sequence To Power On DSP

1. Unmask the wakeup trigger related to DSS_DSP_WAKEUP. This is DSP interrupt number 16. Thus, unmask the 16th bit in the register DSS_RCM.DSP_PD_WAKEUP_MASK0 by writing 0xFFFEFFFF
2. Trigger DSP wakeup by writing 0x1 to register DSS_RCM.DSP_PD_TRIGGER_WAKU.
3. Poll DSS_RCM.DSP_PD_STATUS.STATE for the value 13. This indicates that the L2 memory can now be written to or preloaded with code.
4. Download the DSP code into L2.
5. Write 0x0 to DSS_RCM.DSP_PD_CTRL.PROC_HALT to unhalt the processor and begin execution.

5.5.1.2 Software Sequence To Power OFF DSP

1. Ensure that all previous registered events during the previous power down are cleared.
2. Set up the DSP interrupt routine for DSS_DSP_PDC_INT (Gem event number : 118) as below:
    a. Set the bit DSP_ICFG.PDCCMD.GEMPD.
    b. Execute the idle instruction
3. If DSP powers up in autonomous mode without the program download, set the DSS_REG.GEMPWRSMCFG4.PWRSMLRSTHALT bit to 0x0.
4. Unmask the events to use as wakeup events in DSS_RCM:DSP_PD_WAKEUP_MASK[0-2].

5. Unmask the events to receive as hardware event pulses after the next power up in DSS_RCM:DSP_PD_MISSED_EVENT_MASK [0-2].
6. Mask all interrupts from DSP by setting the DSS_RCM:DSP_PD_CTRL:DSP_PD_CTRL_INTERRUPT_MASK field to 0x1.
7. Trigger a power down by setting the DSS_RCM:DSP_PD_TRIGGER_SLEEPfield to 0x1, and wait in a while loop. This triggers the interrupt DSS_DSP_PDC_INT, followed by the power-down of the DSP core by the control module.
8. The state of the DSP power domain can be polled by other main subsystem R5F cores to ensure the DSP power down. DSS_RCM:DSP_PD_STATUS_PD_STATUS field

5.5.2 DSP Subsystem L3 Power Domain

The DSS L3 memory can be controlled from DSS_RCM registers by the software.

By default, all the L3 memory is Power ON.

When partially switching off banks, it is the software's responsibility to ensure that the banks are disabled from the last 256 KB bank, that is, DSS L3 BANK D1. A bank should not be powered off if all its higher banks are not powered off. For example, if DSS L3 BANK C1 is powered down, BANK D0 and D1 are also powered down.

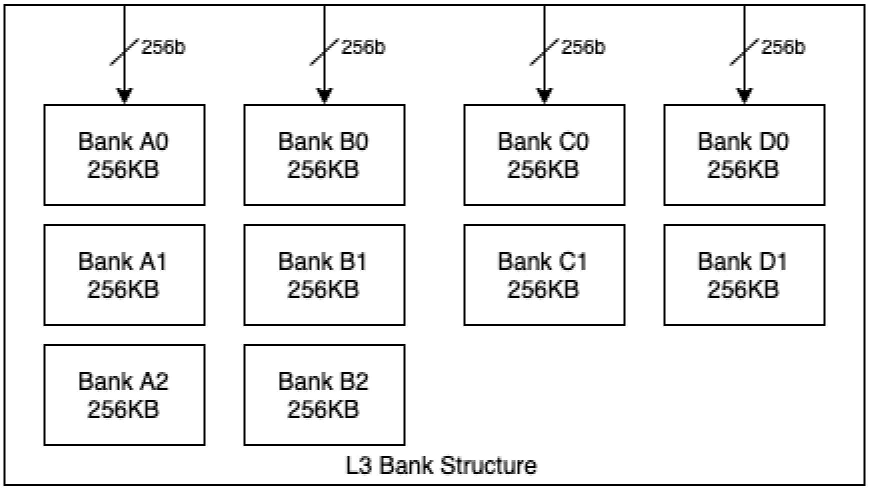

Figure 5-8. DSP Subsystem L3 Bank Structure

5.5.2.1 L3 Memory Bank Power Sequence

Below is the sequence to Power off a bank:

1. Write 0x7 to DSS_RCM:DSS_L3_BANK*_PD_CTRL_ISO field.
2. Write 0x0 to DSS_RCM:DSS_L3_BANK*_PD_CTRL_AONIN field.
3. Wait until DSS_RCM:DSS_L3_BANK*_PD_STATUS_AONOUT field is 0x0.
4. Write 0x0 to DSS_RCM:DSS_L3_BANK*_PD_CTRL_AGOODIN field.
5. Wait until DSS_RCM:DSS_L3_BANK*_PD_STATUS_AGOODOUT field is 0x0.

Below is the sequence to Power on a bank:

Sticky Bit Implementation

The L3 banks power control can be locked from further updates by writing 0x7 to the register DSS_RCM:DSS_L3_PD_CTRL_STCIKYBIT:SET field. Any update to the DSS_L3_BANK*_PD_CTRL, AONIN and AGOODIN fields do no have an impact on HW. The sticky bit is reset with Warm Reset.

The actualy HW control to the memory can be read by reading the fields DSS_L3_BANK*_PD_STATUS_AONIN and DSS_L3_BANK*_PD_STATUS_AGOODIN

5.5.3 MSS L2 Power Domain

The MSS L2 memory can be controlled from the MSS_RCM registers by the software. By default, all the MSS_L2 memory is Power ON.

5.5.3.1 Power Sequence

Below is the sequence to Power off a bank:

1. Write 0x7 to MSS_RCM:MSS_L2_BANK*_PD_CTRL_ISO field.
2. Write 0x0 to MSS_RCM:MSS_L2_BANK*_PD_CTRL_AONIN field.

3. Wait until MSS_RCM:MSS_L2_BANK*_PD_STATUS_AONOUT field is 0x0.
4. Write 0x0 to MSS_RCM:MSS_L2_BANK*_PD_CTRL_AGOODIN field.
5. Wait until MSS_RCM:MSS_L2_BANK*_PD_STATUS_AGOODOUT field is 0x0.

Below is the sequence to Power on a bank:

1. Write 0x7 to MSS_RCM:MSS_L2_BANK*_PD_CTRL_AONIN field.
2. Wait until MSS_RCM:MSS_L2_BANK*_PD_STATUS_AONOUT field is 0x1.
3. Write 0x7 to MSS_RCM:MSS_L2_BANK*_PD_CTRL_AGOODIN field.
4. Wait until MSS_RCM:MSS_L2_BANK*_PD_STATUS_AGOODOUT field is 0x1.
5. Write 0x0 to MSS_RCM:MSS_L2_BANK*_PD_CTRL_ISO field.

When a block is powered off, a bus error is generated on access. It is always safe to have decent delay between each step because memory might take some time before reaching to total power-on state.

The HWA can be controlled from DSS_RCM registers by SW. By Default, all the HWA is Power ON.

Power Sequence

Below is the sequence to Power off the HWA

1. Write 0x7 to DSS_RCM:DSS_HWA_PD_CTRL:ISO field
2. Write 0x0 to DSS_RCM:DSS_HWA_PD_CTRL:AONIN field
3. Wait till DSS_RCM:DSS_HWA_PD_STATUS:AONOUT field is 0x0
4. Write 0x0 to DSS_RCM:DSS_HWA_PD_CTRL:AGOODIN field
5. Wait till DSS_RCM:DSS_HWA_PD_STATUS:AGOODOUT field is 0x0

Below is the sequence to Power on the HWA

1. Write 0x7 to DSS_RCM:DSS_HWA_PD_CTRL:AONIN field
2. Wait till DSS_RCM:DSS_HWA_PD_STATUS:AONOUT field is 0x1
3. Write 0x7 to DSS_RCM:DSS_HWA_PD_CTRL:AGOODIN field
4. Wait till DSS_RCM:DSS_HWA_PD_STATUS:AGOODOUT field is 0x1
5. Write 0x0 to DSS_RCM:DSS_HWA_PD_CTRL:ISO field

It is always safe to have decent delay between each step because HWA might take some time before reaching to total power on state. So even though AONOUT is 1’b1 does not mean HWA is ON.

Registers

Below is the corrsesponing register controls for each block of memory

Bank 512KB	Bank Name	Control Register
0	HWA (Hard Macro)	DSS_RCM:DSS_HWA_PD_CTRL:AGOODIN DSS_RCM:DSS_HWA_PD_CTRL:AONIN DSS_RCM:DSS_HWA_PD_CTRL:ISO DSS_RCM:DSS_HWA_PD_STATUS

5.6 Resets

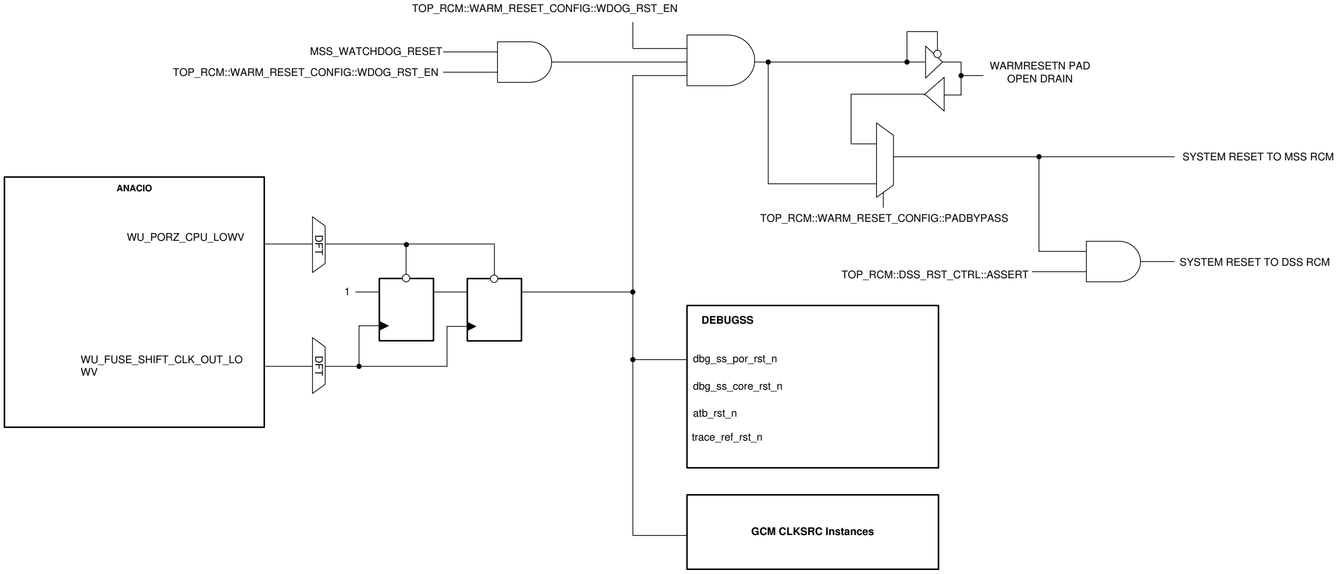

Figure 5-9. Resets

Two device resets are available that can be controlled from the device pins: the power-on reset pin NRESET and the bidirectional WARM_RESET signal. The warm reset signal is implemented as an I/O, so that an external monitor can be used to detect changes to the state of the internal warm reset control signal.

Reset Types and Sources

Table 5-1693. Reset Types and Sources

Reset Type	Reset Source	Description
Power On Reset	Device Pin NRESET	Reset triggered by the device reset pin NREST. This resets the entire device, including all subsystems and interfaces. This is an active low asynchronous Power ON reset signal, and must be asserted for minimum 20 usec to reset the device.

Table 5-1693. Reset Types and Sources (continued)

Reset Type	Reset Source	Description
Warm Reset	Software Reset (Register write), Watch Dog Reset, Device Pin WARM_RESET pin	This is an active low warm reset internally generated by the device, or triggered by device pin WARM_RESET. A write to the TOP_RCM. WARM_RESET_CONFIG[10:8] register or watch dog module can generate this reset; additionally, the external pin WARM_RESET can also be used to trigger this reset. Selection is controlled through the TOP_RCM.WARM_RESET_CONFIG register. The WARM_RESET pin is an open-drain failsafe IO which can be used to reset the device from the external world or to report the reset to the external world if it is generated by an internal source such as watchdog. A write to the TOP_RCM.WARM_RESET_CONFIG, as explained in register description, can create this reset. The watch dog module in the main subsystem can be configured to trigger this reset. Check the watch dog module description for details. This feature is enabled by the TOP_RCM.WARM_RESET_CONFIG register.

As listed in above table, various reset sources can generate the different resets used inside the device to reset various components and submodules. A Warm_rest excludes certain modules and spaces listed in this table from reset. These can only be reset by power-on reset.

Reset Domains

The device can be divided into various reset domains. The top reset domains cover the entire device and all of the subsystems. Additional subsystem-level reset domains are available, and can be reset independently based on resets mentioned in below table.

Table 5-1694. Reset Domains

Reset Domains	Description	Resets
Top reset domain	This top device-level reset domain resets entire device and all subsystems. All other reset domains are subdomains of this domain, and resetting this domain issues a reset to these subdomains. Only power-on reset can reset this domain, and it is immune to any other system reset type. Sub reset domain can be independently reset, as mentioned in the respective rows.	Power-on reset
Main subsystem reset domain	This reset subdomain controls the reset to the main susbsystem and the modules inside it. Resetting the top reset domain also resets this domain.	Power-on reset Warm reset

Table 5-1694. Reset Domains (continued)

Reset Domains	Description	Resets
Radar subsystem reset domain	This reset subdomain controls the reset to the radar susbsystem and all components inside it. Resetting the top reset domain also resets this domain.	Power-on reset Warm reset
DSP subsystem reset domain	This reset subdomain controls the reset to the DSP subsystem and all components inside it. Resetting the top reset domain also resets this domain.	Power-on reset Warm reset

Reset Cause Registers

Various reset cause registers are available that show the last reset issued to the device or subsystem, as shown b

Table 5-1695. Reset Cause Registers

Register	Description
MSS_RCM:MSS_RST_STATUS.MSS_RST_STATUS_CAUSE	Records the cause for the main SS reset domain reset
MSS_TOPRCM:SYS_RST_CAUSE_Register.SYS_RST_CAUSE_CAUSE	Records the cause for the top reset domain reset
DSS_RCM:DSP_RST_CAUSE_RegisterDSP_RST_CAUSE_LRST_CAUSE	Records the cause of the local reset of the DSP reset domain
DSS_RCM:DSP_RST_CAUSE.DSP_RST_CAUSE_GRST_CAUSE	Records the cause of the global reset of the DSP reset domain
DSS_RCM:DSP_RST_CAUSE.DSP_RST_CAUSE_POR_CAUSE	Records the cause of the POR reset of the DSP reset domain

Memories retained over warm reset

There are few set of registers MSS_CTRL:MSS_BOOT_INFO_REG0 to MSS_BOOT_INFO_REG7 registers (except MSS_BOOT_INFO_REG4) which application can use to store data which will retained over warm reset.

The device has a dedicated memory region MSS_RETRAM (start: 0xC5010000, size 2KB) which can be used to store data to be retained over warm reset BUT with a **caveat**: If this section is to be used with the expectation that data will be retained over a warm reset, it must be ensured that warm reset doesn't occur while this region is being written to. Doing so will create a glitch in the memory, possibly corrupting the data. As long as the application ensures that a reset could never happen while this region is being written to, it is safe to assume that the region will be retained over warm reset.
This is just a regular memory block on which the ROM bootloader **doesn't** run any PBIST tests. Application needs to have data integration mechanism (checksum/CRC) around the data stored on RETRAM. Application needs to do the memory initialization (writing MSS_CTRL:MSS_RETMEM_MEM_INIT register) of this area before storing any data.

Note

Usage of RET_MEM is only applicable with SW warm reset (trigger by register write) not with WDT warm reset (trigger with watchdog timer expired) as with WDT warm reset it is not possible to ensure non-access condition of RET_MEM with warm-reset event.

5.7 Temperature Sensor

The AWR294x device has multiple on-chip temperature sensors (TS) which are distributed in and around different components of silicon. The RF front-end of the device contains multiple TS, which RadarSS can access to measure the temperature for RX and TX components. The application can read these TS through RadarSS using the mmWaveLink API (AWR_RF_TEMPERATURE_GET_SB, rlRfGetTemperatureReport).

Note

Refer to the GPADC driver and unit-test application from MMWAVE-MCUPLUS-SDK for reference code to read these temperature sensors.

Chapter 6
Processors and Accelerators

Device includes the following processor core and accelerators:

- MCU Subsystem ARM Cortex lockstep R5F
- DSP Subsystem TI C66x DSP
- Radar Processing Hardware Accelerators
- Radar Subsystem ARM Cortex lockstep R4F

6.1 Main Subsystem Cortex R5F

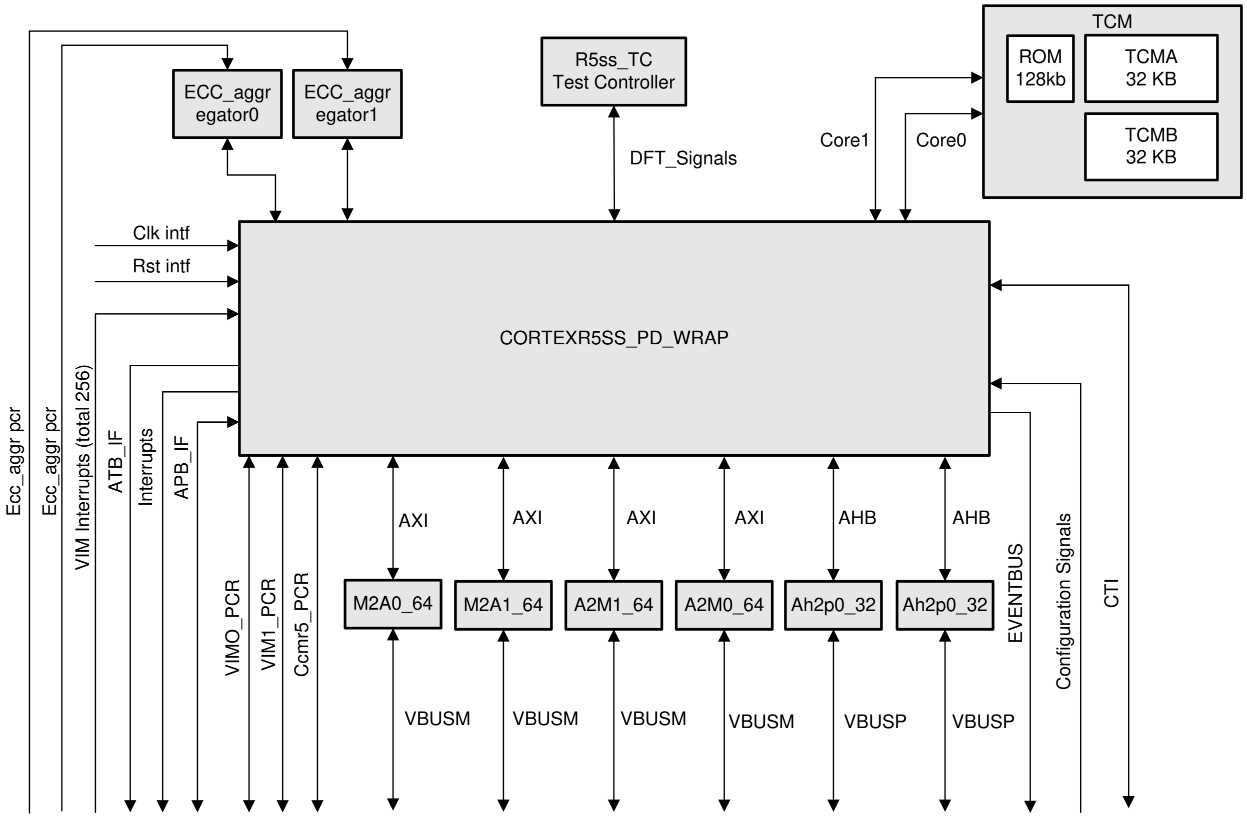

Figure 6-1. Main Subsystem

The Main SubSystem is a lock-step implementation of the Arm Cortex-R5F processor. It also includes accompanying memories (L1 caches and tightly-coupled memories), standard Arm® CoreSight™ debug and trace architecture, integrated Vectored Interrupt Manager (VIM), ECC Aggregators, and various other modules for protocol conversion and address translation for easy integration into the SoC.

6.1.1 Main ARM SubSystem Features

The MSS supports the following features:

- ARMv7-R architecture with the following extensions:
  - Basic SIMD extension for integer and floating-point vector operations
  - Vector Floating Point Version 3 (VFPv3) with Single/Double Precision
  - Dynamic branch prediction with a global history buffer, and a 4-entry return stack
- L1 memory architecture (per each CPU in split mode, or single lock-step CPU):
  - 16KByte I-Cache with 64-bit ECC
  - 16Kbyte D-cache with 32-bit ECC
- L2 Interface
  - 64-bit Controller interface for peripheral access
  - 64-bit Target interface for cache and TCM access
  - 32-bit Controller interface for MCU peripherals
  - ECC on data. Redudancy on Control bus
- Vectored Interrupt Manager with ECC protection on Vector Table RAM
  - VIM1 and VIM2 in lockstep pair when CPU cores are in lock step mode
  - VIM1 and VIM2 supports interrupt generation for its corresponding cores in dual core/split mode.
- Static (boot time) configuration for either lockstep mode or dual-CPU mode
- Mechanism to clock gate the CPU and comparator logic in a non-Lockstep mode.
- CPU Self-Test Controller for CPU core, VIM, and Comparator modules
- PBIST controller for test of all the RAMs
- Support to test ECC functionality in safety-critical applications
- Built in debug features
  - Up to 8 hardware breakpoints per CPU
  - Up to 8 watch points per CPU
- 32-bit Target Debug interface to access Debug components (CTI, ETM, ATB)
- Trace interface to a Core Sight ETM-R5
- Performance Monitoring Unit (PMU)
- Little Endian mode of operation

6.1.2 TCM Initialization

Auto-init module has been implemented for initializing the TCMs. Paths from TCMA and TCMB are timing-critical, so the initialization of these memories occur through the test path. Initialization of TCMA and TCMB occurs in parallel.

Below are the registers used for the TCM initialization

- Writing 1 to MSS_CTRL:MSS_<A/B>TCM_MEM_INIT:MSS_<A/B>TCM_MEM_INIT_MEM_INIT starts the mem-init for MSS_TCM<A/B>_CR5A/B.
- Reading 1 from MSS_CTRL: MSS_<A/B>TCM_MEM_INIT_DONE: MSS_<A/B>TCM_MEM_INIT_DONE_MEM_INIT_DONE confirms the end of initialization for MSS_TCM<A/B>_CR5A/B.
- Writing 1 to MSS_CTRL: MSS_<A/B>TCM_MEM_INIT_DONE: MSS_<A/B>TCM_MEM_INIT_DONE_MEM_INIT_DONE clears the field.
- Reading 1 from MSS_CTRL: MSS_<A/B>TCM_MEM_INIT_STATUS: MSS_<A/B>TCM_MEM_INIT_STATUS_MEM_STATUS confirms progress of initialization for MSS_TCM<A/B>_CR5A/B.

6.1.3 Resets

AWR294x supports the following resets:

- CR5SS_POR_RST: This is the full MCU R5F subsystem reset. It is also the Power On Reset.
- CR5ASS_RST: This reset is only for the Cortex R5F and the Vectored Interrupt Manager of the CoreA. None of the other logics are reset.
- CR5A_RST: This only reset the cortex of the R5F of the CoreA.

- VIMA_RST: This only reset the vectored interrupt manager of the CoreA.

6.1.3.1 R5F Subsystem Reset Trigger

For the safe reset of the R5F subsystem, follow this reset sequence:

1. Write 3’b111 to MSS_CTRL: R5_CONTROL: R5_CONTROL_RESET_FSM_TRIGGER starts the sequencer.
2. The sequencer is waiting for WFI from only CR5A if WFI_CHECKEN for corresponding resets is programmed. The sequencer isolates CR5SS when it receives WFI from CR5A.
3. The sequencer triggers CR5SS_POR_RST, which triggers resets to all resets mentioned in resets-table.
4. The intent is to reset CR5SS when it is in isolation. Thus, before Step 1, ensure MSS_RCM:RST2ASSERTDLY is programmed to 0;.
5. Reset is asserted for RST_ASSERDLY: RST_ASSERDLY_COMMON number of clock cycles, and released.

6.1.4 MSS_CCMR Registers

Table 6-1 lists the memory-mapped registers for the MSS_CCMR registers. All register offset addresses not listed in Table 6-1 should be considered as reserved locations and the register contents should not be modified.

6.2 C66x DSP Subsystem

This section describes the C66x Digital Signal Processor Subsystem (C66SS) in the device.

6.2.1 C66x DSP Subsystem

The purpose of this section is to provide an overview of the DSP subsystem (C66x CorePac) along with some integration details.

6.2.1.1 DSP Subsystem Overview

The DSP subsystem (C66x CorePac) supports the following key features:

- Fixed/Floating-point C66x CPU based on a superset of the C64x+ and C67x+ ISA
- Program Memory Controller (PMC):
  - 32KB Level 1 Program (L1P) Cache/SRAM
- Data Memory Controller (DMC):
  - 32KB L1 Data (L1D) Cache/SRAM
- L2 Memory Controller:
  - 384KB L2 RAM with up to 256KB of configurable into cache
- External Memory Controller (EMC):
  - Internal DMA (IDMA) engine
  - One 128-bit VBUSM slave port from DMA access at Div-by-2 clock
  - One 32-bit VBUSP master port to CFG access at Div-by-2 clock
- XMC (Extended Memory Controller):
  - One 256-bit port to L3 memory at Div-by-2 clock
- Multistream prefetch buffer
- Address extension/translation (32-bit to 36-bit)
- Memory protection for multiple segments
- Memory protection for all internal L1/L2 RAM
- Error Detection for L1P
- Error Detection and Correction for L1D
- Error Detection and Correction for all L2
- Integrated C66x CorePac interrupt controller (INTC) that works in conjunction with Chip-level Interrupt Controller (CIC) for distribution of system interrupts to the C66x core. Interrupts can be routed directly to the C66x core or through the CIC module in a flexible manner
- Integrated leakage and dynamic power management
- Debug/emulation capabilities:
  - Support for halt mode, real time and monitor mode debug capabilities
  - Support for processor instruction trace and system trace (**printf**-style debug)
- Error Detection for L1P Data and Tag RAMs
- Error Detection and Correction for L1D Data and Tag RAMs
- Error Detection and Correction for all L2 Data and Tag RAMs

Figure 6-2 shows an overview of the C66x CorePac.

6.2.1.4 DSP Subsystem Functional Description

For detailed DSP subsystem functional description, see the documents referenced in Section 6.2.1.1 .

6.2.1.5 DSP Subsystem Registers

Table 6-10 lists the memory-mapped registers for the C66x CorePac. All register offset addresses not listed in Table 6-10 should be considered as reserved locations and the register contents should not be modified. For base addresses of the DSP subsystem internal modules, see Chapter 2.

The C66x CorePac registers (DSP_ICFG) are described in detail in the *TMS320C66x DSP CorePac User Guide* (SPRUGW0).

6.2.2 C66x Cache Subsystem

The purpose of this section is to provide an overview of the C66x cache memory architecture and to specify its configuration in this device. Details on the C66x cache functionality can be found in the *TMS320C66x DSP Cache User Guide* (SPRUGY8).

The device contains a 384KB level-2 memory (L2), a 32KB level-1 program memory (L1P), and a 32KB level-1 data memory (L1D). Each memory has a unique location in the memory map (see Chapter 2).

After device reset, L1P and L1D cache are configured as all cache, by default. The L1P and L1D cache can be reconfigured via software through the L1PMODE field of the L1P Configuration Register (L1PMODE) and the L1DMODE field of the L1D Configuration Register (L1DCFG) of the C66x CorePac. L1D is a two-way set-associative cache, while L1P is a direct-mapped cache.

6.2.2.1 L1P Memory

The L1P memory configuration for this device is as follows:

- Region 0 size is 0K bytes (disabled)
- Region 1 size is 32K bytes with no wait states

Figure 6-3 shows the available SRAM/cache configurations for L1P.

Note

L1P can only be configured as cache.

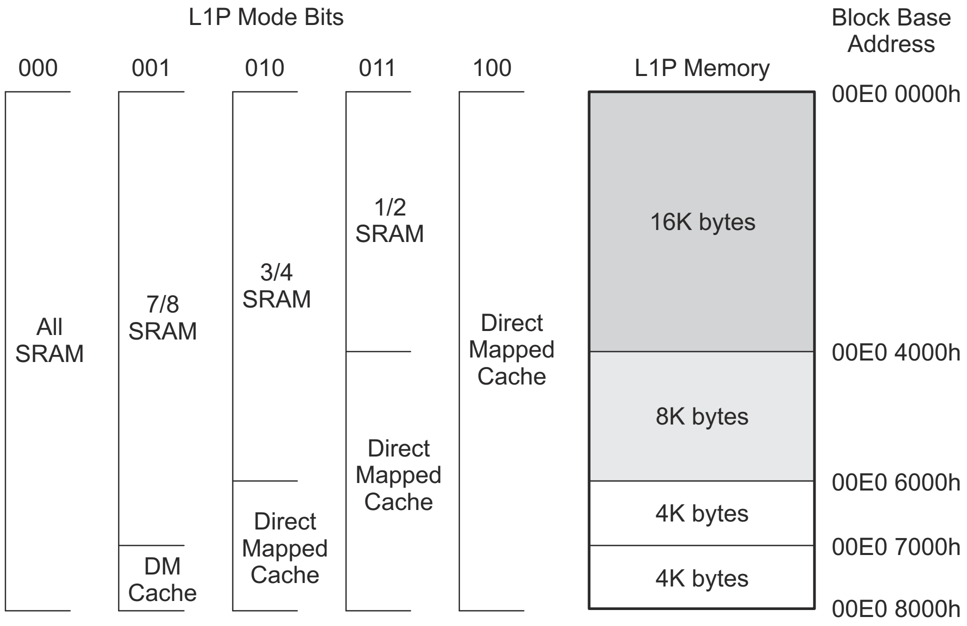

Figure 6-3. L1P Memory Configurations

6.2.2.2 L1D Memory

The L1D memory configuration for this device is as follows:

- Region 0 size is 0K bytes (disabled)
- Region 1 size is 32K bytes with no wait states.

Figure 6-4 shows the available SRAM/cache configurations for L1D.

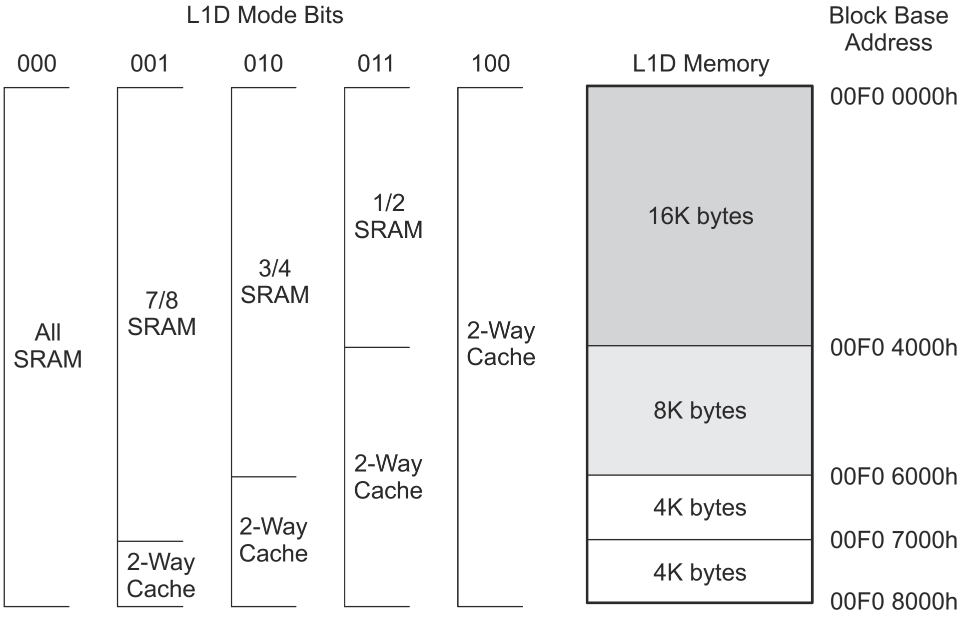

Figure 6-4. L1D Memory Configurations

6.2.2.3 L2 Memory

The L2 memory configuration for this device is as follows:

- 384KB of memory
- Local starting address is 0080 0000h.

L2 memory can be configured as all SRAM, all 4-way set-associative cache, or a mix of the two. The amount of L2 memory that is configured as cache is controlled through the L2MODE field of the L2 Configuration Register (L2CFG) of the C66x CorePac. Figure 6-5 shows the available SRAM/cache configurations for L2. By default, L2 is configured as all SRAM after device reset.

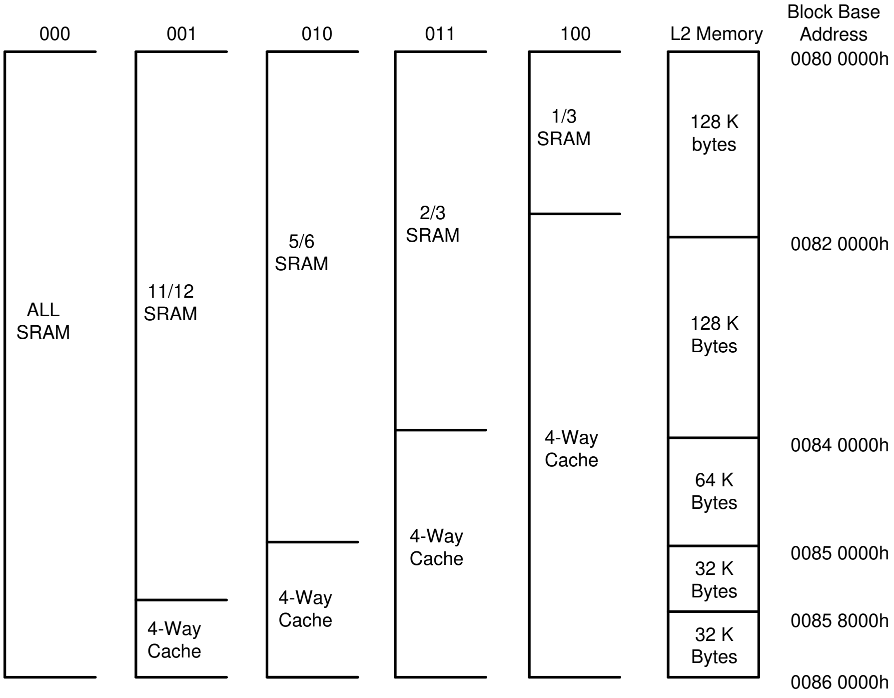

Figure 6-5. L2 Memory Configurations

6.2.2.4 DSP ECC Configuration

The device supports ECC/parity on all DSP internal SRAMs. All the ECC/parity features are enabled by default (that is, after device reset). Software can disable the features per SRAM type if not required.

Table 6-11 summarizes the ECC/parity support in DSP.

Table 6-11. DSP ECC/Parity Support

DSP Memory	ECC/Parity Support
L1P Data RAM	Parity
L1P Tag	Parity
L1D Data RAM	ECC-SECDED (Single Error Correction, Double Error Detection)
L1D Tag	ECC-SECDED
L2 Data RAM	ECC-SECDED
L2 Tag	ECC-SECDED

6.3 Radar Processing Hardware Accelerator

In addition to the DSP cores, the AWR294x device incorporates Radar Hardware Accelerators HWA 2.1 to offload the DSP from pre-processing computations.

6.3.1 Radar Accelerator Features Overview

- Flexible enough to offload almost all the operations from the initial compensation (DC estimation-correction, interference mitigation, and so forth) on raw ADC data before first dimension FFT until point cloud detection, with the least possible intervention from the DSP.
- Operating clock frequency is 300 MHz
- Data path bit-width of 24-bits (24-bit I)
- Input and output data formatter: scaling, truncation, head/tail sample skipping, zero padding/insertion of data, sample access pattern for DDMA use case.
- Capability to do all these operations in a single iteration: DC correction, interference zeroing out, complex multiplication, windowing, FFT, log, magnitude, stats computation with a capability of selecting/enabling or disabling/bypassing each of these computation blocks individually.
- 128KB local buffer/RAM split into eight 16KB banks, with each bank configurable as input or output for any compute/data transfer functionality.
- Flexible data flow and data sample arrangement to support efficient multi-dimensional operations and transpose accesses as required.
- Processing for inline (range FFT) and inter-frame (Doppler FFT, angle FFT, detection) threads simultaneously
- Support for CSI2 data input either in Rx interleaved or in serial manner
- Support for DC estimation and correction
- Support for interference mitigation
  - Estimation and zeroing out of the interference samples by estimating the average of the magniture of sudden spikes of vector elements, and applying scaled values as a threshold.
- Support for complex vector/scalar multiplications
- Support for a synthesizer channel combining and MIMO demodulation for DDMA
- Complex windowing – 2K samples window RAM with a capability to split 1KB ping- 1KB pong to allow programming new coefficients while older ones are used.
- Up to 2K point FFT with efficiency of 1 sample output per cycle and possibility to go higher in size until 4K/8K, with stitching (reduced efficiency).
- Doppler de-rotation of the FFT output
- Support for magnitude (absolute value) and Log-Magnitude computation.
- Nested loop support in PARAM sets
- Compression/decompression engine with block floating and exponential Golomb modes with performance of 1 complex sample processing per cycle
- Detection algorithm-specific accelerators (for example: CFAR CA/OS and other variants)

- 2D Local Maxima/Peak search algorithm with efficiency of 1 cell processing per cycle
- Lock-step state machine
- ECC on the PARAM RAMs and parity on local buffers

6.3.2 Radar Accelerator Architecture

The Radar accelerator details are covered in Chapter 28, which consists of 2 parts.

The first part covers the high-level architecture and key features such as windowing, FFT, and log-magnitude. The (optional) second part covers additional features such as CFAR, complex multiplication, advanced statistics, radar data compression engine, and so forth.

6.4 HWA Cortex M4

The AWR2944LC also incorporates a Cortex-M4 processor to configure and control the Hardware Accelerator module (HWA 2.1).

6.4.1 HWA Cortex M4 Features Overview

The ARM Cortex-M4 processor provides a core for a high-performance platform that meets the needs of minimal memory implementation and low power consumption, while delivering outstanding computational performance and exception system response to interrupts.

- 32-bit ARM Cortex-M4 operating at 200MHz
- Thumb-2 mixed 16/32-bit instruction set delivers the high performance expected of a 32-bit ARM core in a compact memory size usually associated with 8/16-bit devices
  - Single-cycle multiply instruction and hardware divide
  - Atomic bit manipulation (bit-banding), delivering maximum memory utilization and streamlined peripheral control
  - Unaligned data access, enabling data to be efficiently packed into memory
- 3-stage pipeline Harvard architecture characterized by separate buses for instruction and data
- Deterministic, high-performance interrupt handling for time-critical applications.
- Memory protection unit (MPU) to provide a privilegd mode for protected operating system functionality
- Little Endian instruction and data memory accesses
- Support for 64 interrupts

6.4.1.1 System Timer (SysTick)

The ARM Cortex-M4 includes an integrated system timer, SysTick. SysTick provides a simple, 24-bit, clear-on-write, decrementing, wrap-on-zero counter with a flexible control mechanism. The counter can be used as a Real-Time Operating System (RTOS) tick timer or as a simple counter.

6.4.1.2 Nested Vectored Interrupt Controller (NVIC)

The ARM Cortex-M4 closely integrates the ARM Nested Vectored Interrupt Controller (NVIC). The NVIC and Cortex-M4 prioritize and handle all interrupts in Handler Mode. The processor state is automatically stored to the stack on an interrupt and automatically restored from the stack at the end of the Interrupt Service Routine (ISR). The interrupt vector is fetched in parallel to the state saving, enabling efficient interrupt entry. The processor supports tail-chaining, meaning that back-to-back interrupts can be performed without the overhead of state saving and restoration.

- Deterministic, fast interrupt processing: always 12 cycles, or just 6 cycles with tail-chaining
- External non-maskable interrupt signal (NMI) available for immediate execution of NMI handler for safety critical applications
- Dynamically reprioritzable interrupts

6.4.1.3 System Control Block (SCB)

The SCB provides system implementation information and system control, including configuration, control, and reporting of system exceptions.

6.4.1.4 Memory Protection Unit (MPU)

The MPU supports the standard ARM7 Protected Memory System Architecture (PMSA) model. The MPU provides full support for protection regions, overlapping protection regions, access permissions, and exporting memory attributes to the system. The MPU improves system reliability by providing up to eight different regions and an optional predefined background region.

6.4.2 Integration of Cortex-M4 with DSS (HWA_CM4)

The Cortex-M4 processor is integrated with the Hardware Accelerator module (HWA) in the AWR294x. Both the HWA and Cortex-M4 are part of the DSP subsystem (DSS).

- The Cortex-M4 can access all HWA registers, including the paramset registers and registers of the accelerator engine blocks (e.g. histogram registers). The Cortex-M4 can trigger the HWA to start or stop operations.
- The HWA can trigger an interrupt to the Cortex-M4 at the end of any paramset. Two interrupts are available, which can be enabled by setting the CPU_INTR_EN1 and/or CPU_INTREN2 in any paramset. This is described in Section 28.2.1.3.
- The HWA can wait on a SW trigger. This can be enabled by setting the TRIGMODE field in the paramset to SW-triggered mode. In this mode, the paramset execution waits until the Cortex-M4 writes a particular SW register bit, described in Section 28.2.1.2.
- The HWA can trigger a DMA transfer of the contents from the HWA memory bank to L3 RAM.
- The Cortex-M4 can directly access L3 memory using the same address as used by the DSS.

Details of the HWA can be found in Chapter 28.

6.4.3 HWA Cortex-M4 Interrupt Sources

64 interrupts are implemented in the NVIC. Refer to Section 7.3 for the interrupt sources connected to the Cortex-M4 NVIC. The default priority of the interrupts are in the same order as the interrupt numbers, with lower numbers having higher priority.

- The DSP can trigger interrupts (DSS_DSP_SW_INT0 & DSSP_DSP_SW_INT1) on the Cortex-M4 by setting bits DSS_CTRL.DSS_SW_INT[0] & DSS_CTRL.DSS_SW_INT[1], respectively.
- The R5F can trigger interrupts(MSS_CR5_SW_INT0 & MSS_CR5_SW_INT1) on the Cortex-M4 by setting bits MSS_CTRL.MSS_SW_INT.MSS_SW_INT_PULSE[0] & MSS_CTRL.MSS_SW_INT.MSS_SW_INT_PULSE[1], respectively.

There are two DSS_CM4 interrupts to indicate the status of paramset execution on the HWA in both threads (contexts), as described below.

- Loop complete interrupt (DSS_HWA_THREAD1_LOOP_INT & DSS_HWA_THREAD2_LOOP_INT): If enabled on the Cortex-M4, these interrupts are generated once the loop completes in the HWA. Thread 1 refers to the background thread and Thread 2 is for the high priority thread.

6.4.4 HWA_CM4 Control Registers

The control registers are used to configure the Cortex-M4, including registers to initialize memory, mailbox, fault reporting, ECC, etc. Refer to #unique_142 for details.

6.4.5 Cortex-M4 Boot

The following sequence must be followed to boot the Cortex-M4.

Step No.	Step	Register/Bit Field Programming	Value
1	Ungate the clock to CM4	HWA_CM4_CTRL:HWA_CM4_CFG:HWA_CM4_CFG_CM4_CLK_GATE	0x0

Step No.	Step	Register/Bit Field Programming	Value
2	Deassert the reset for CM4	HWA_CM4_CTRL:HWA_CM4_CFG:HWA_CM4_CFG_CM4_SYS_RESET_HOLD	0x0

Refer to for details on the specific register fields.

To start up the CM4 in HWA, first the DSS needs to be woken up. The clocks need to be enabled. The CM4 memory needs to be initialized. Dummy code must be loaded in the CM4 memory range. Then, the CM4 can be brought out of reset using the steps listed in the table above. Code loading into the CM4 must be done by the MSS (SBL) as the CM4 memory (at address 0x2800 0000) is visible to the MSS.

6.5 Radar Subsystem

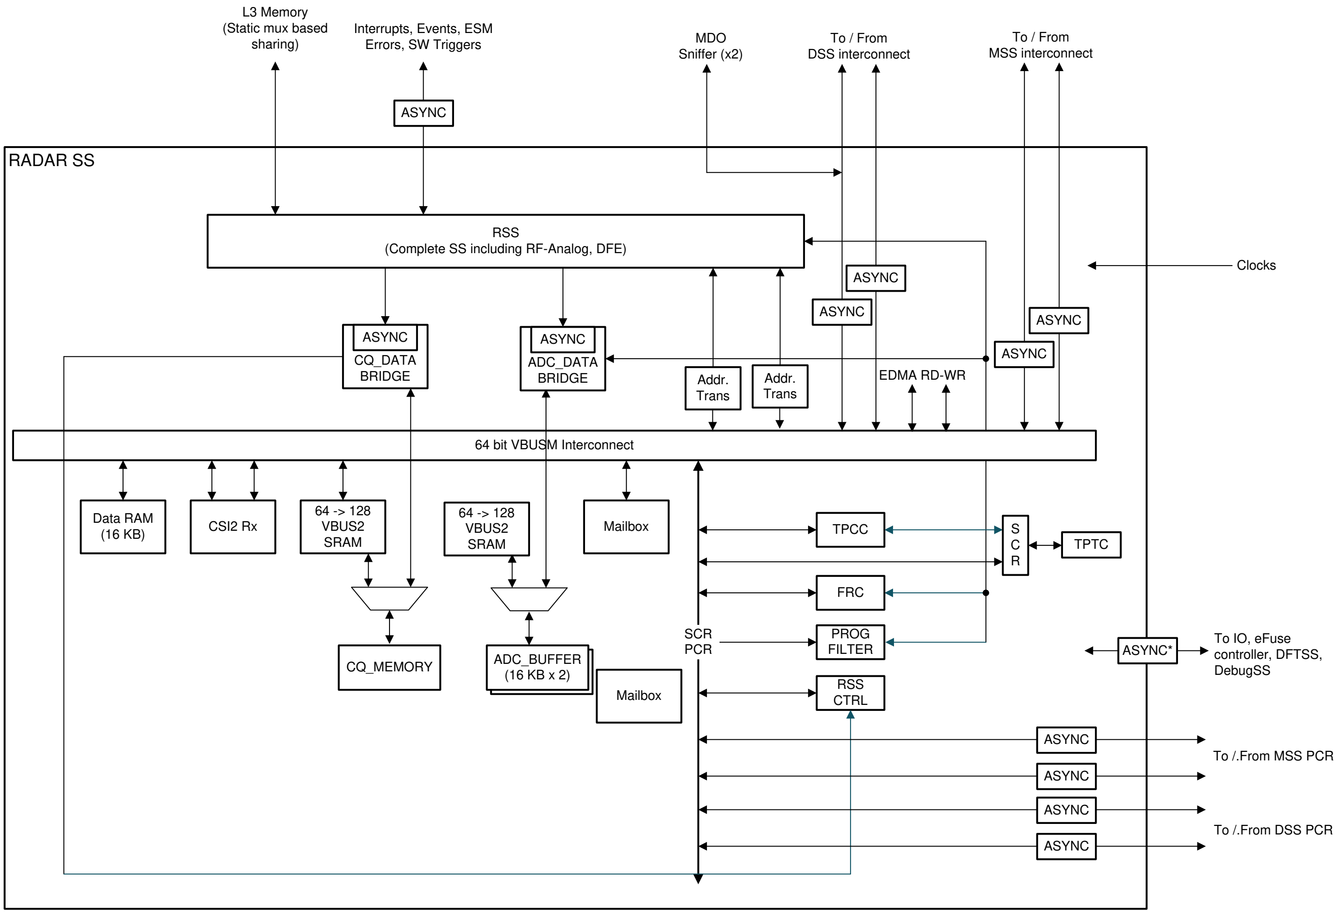

Figure 6-6. Block Diagram

6.5.1 BIST Subsystem

Figure 6-7 shows the BIST subsystem (BSS) block diagram.

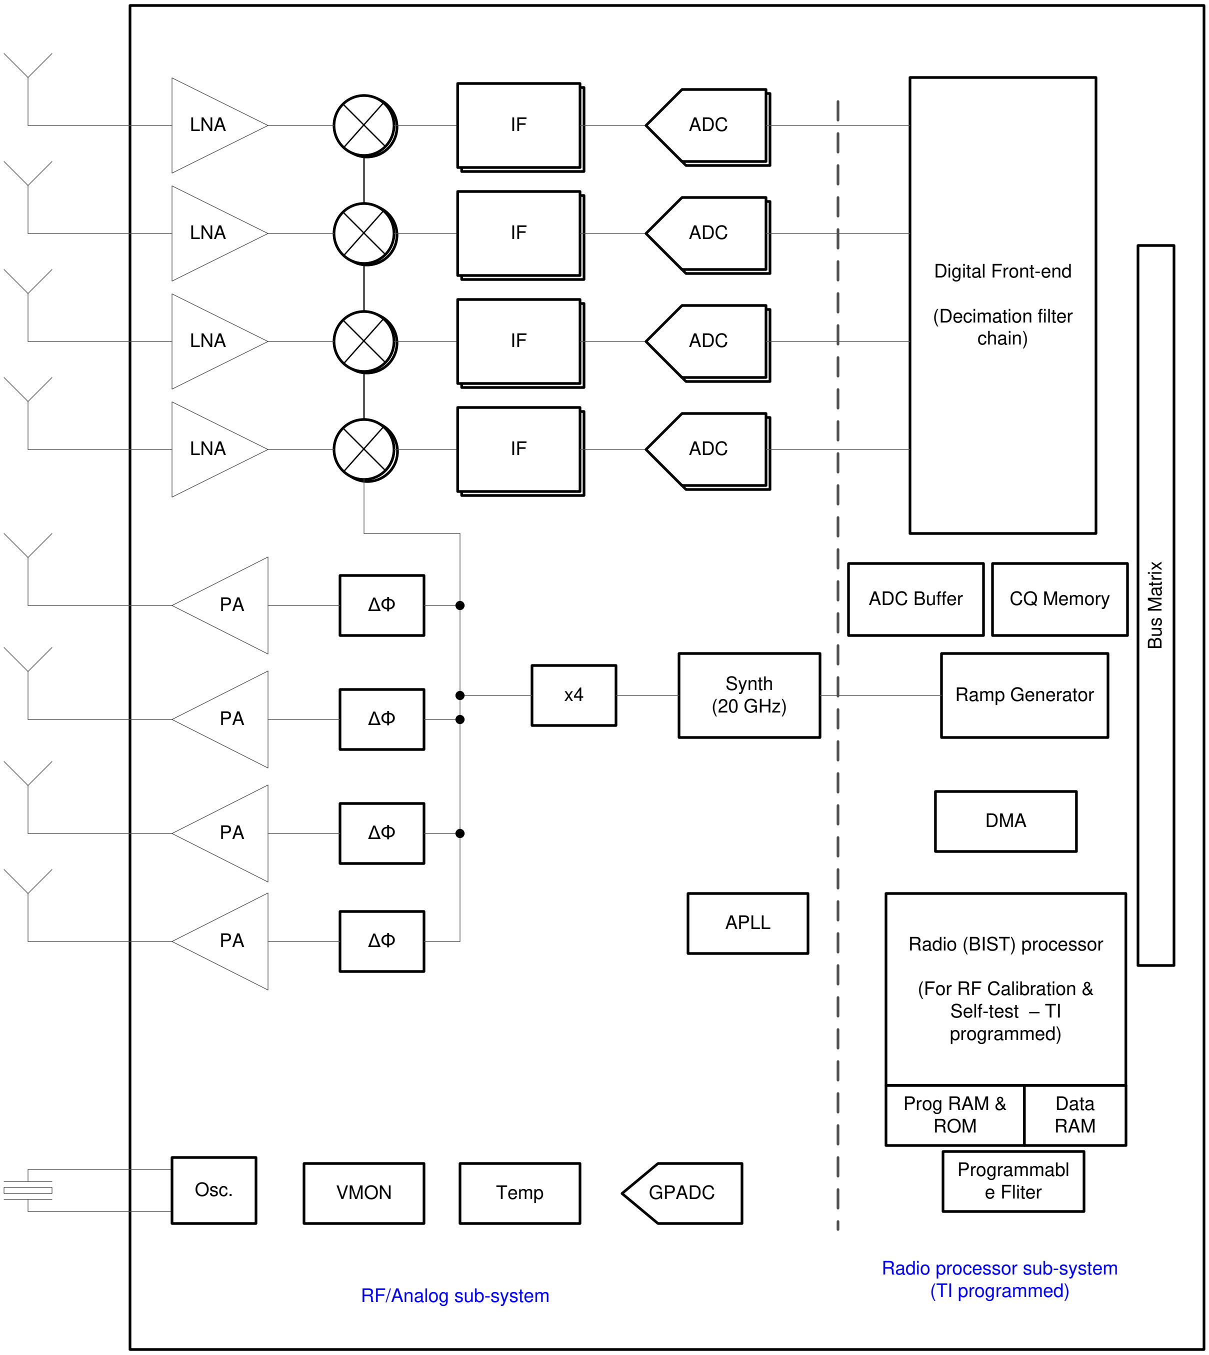

Figure 6-7. BIST Subsystem (BSS) Block Diagram

The BSS consists of the RF/Analog subsystem and the radio processor subsystem.

The RF/analog subsystem implements the frequency-modulated continuous-wave transceiver system with RF and analog circuitry – namely, the synthesizer, PA, LNA, mixer, IF, and ADC. This subsystem also includes the crystal oscillator and temperature sensors. The four transmit channels can be operated up to a maximum of two at a time simultaneously. The four receive channels can all be operated simultaneously.

The radio processor subsystem includes the digital front-end, the ramp generator, and an internal processor for controlling and configuring the low-level RF/analog and ramp generator registers, based on well-defined API messages from the main subsystem. This radio processor is programmed by TI, and addresses both RF calibration needs and some basic self-test and monitoring functions (BIST); this processor is not available directly for customer use. The digital front-end filters and decimates the raw sigma-delta ADC output, and provides the final ADC data samples at a programmable sampling rate.

BSS core is by default under reset on device power-up, SBL (secondary bootloader) or user application needs to follow below sequence to bootup BSS core

1. Prepare BSS core and memory
    a. RSS_CTRL.BSS_CONTROL[30:28] = 0x7 (AWR294x ES1), 0x0 AWR294x
    b. RSS_CTRL.BSS_CONTROL[11:0] = 0x111 (AWR294x ES1), 0x0 (AWR294x ES2)
    c. DSS_RCM.DSS_L3_BANKD1_PD_CTRL[2:0] = 0x0
    d. RSS_CTRL.BSS_TCM_MEMINIT[0] = 0x1
    e. wait RSS_CTRL.BSS_TCM_MEMINIT_DONE[0] to be value 1
    f. wait RSS_CTRL.BSS_TCM_MEMINIT_STATUS[0] to be 0
    g. RSS_PROC_CTRL.RSS_STATIC_MEM_MEMINIT[0] = 0x1
    h. wait RSS_PROC_CTRL.RSS_STATIC_MEM_MEMINIT_DONE[0] to be value 1
    i. RSS_CTRL.RSS_SHARED_MEM_MEMINIT[0] = 0x1 (only for AWR294x ES1)
    j. wait RSS_CTRL.RSS_SHARED_MEM_MEMINIT_DONE to be value 1 (only for AWR294x ES1)
2. Load the BSS firmware or Patch content from sFlash to corresponding BSS RAMs (addresses are part of FW/Patch header content).
3. Unhalt the BSS core
    a. MSS_CTRL.MSS_PBIST_KEY_RST[0] = 0x0 (for AWR294x ES2)
    b. RSS_PROC_CTRL.RSS_CR4_BOOT_INFO_REG0[31:16] = 0x0
    c. RSS_PROC_CTRL.RSS_CR4_BOOT_INFO_REG1[31:16] = 0x0

RSS_CR4_BOOT_INFO_REG2	Reserved	28h
RSS_CR4_BOOT_INFO_REG3	Boot time mailbox memory configuration by BSS. Bits 7:0 -> MSS Bits 15:8 -> DSS	2Ch
RSS_CR4_BOOT_INFO_REG4	Shadow copy of REG3 register	30h

Table 6-13. RSS_PROC_CTRL Registers (continued)

Register Name	Description	Offset
RSS_CR4_BOOT_INFO_REG5	Configure BSS Logger: current configuration is Disabled. To Enable the BSS logger, set b[2:0] to 0x1. The debug data is transferred to a programmable MSS L2 memory buffer with a size of 2KB. The BSS splits this 2KB into two halves (ping and pong) to copy the debug logger data.	34h
RSS_CR4_BOOT_INFO_REG6	Configure MSS L2 offset for BSS Logger. Set MSS L2 translated address offset for BSS. e.g. 0xC0260000 is the transaled address of MSS L2 memory 0x10260000. 2KB of memory is needed for BSS to transfer the BSS logger data. Applications are required to make sure the 2KB starting from 0x10260000 is reserved for BSS logger.	38h
RSS_CR4_BOOT_INFO_REG7	Reserved	3Ch
RSS_STATIC_MEM_MEMINIT	Start Memory intialization of memory. Write 0x1 to start memory initilization. Write 0x0 after ensuring Memory intilization is in progress or has completed.	40h
RSS_STATIC_MEM_MEMINIT_DONE	Status field. Read value 0x1 indicates previously triggered Memory intialization of memory is complte. Write 0x1 to clear status.	44h
RSS_STATIC_MEM_MEMINIT_STATUS	Status field. Read value 0x1 indicates previously triggered Memory intialization of memory is in progress.	48h

The programming of this BSS is abstracted at a TI-defined API interface. Figure 6-8 explains the high-level architecture and programming model.

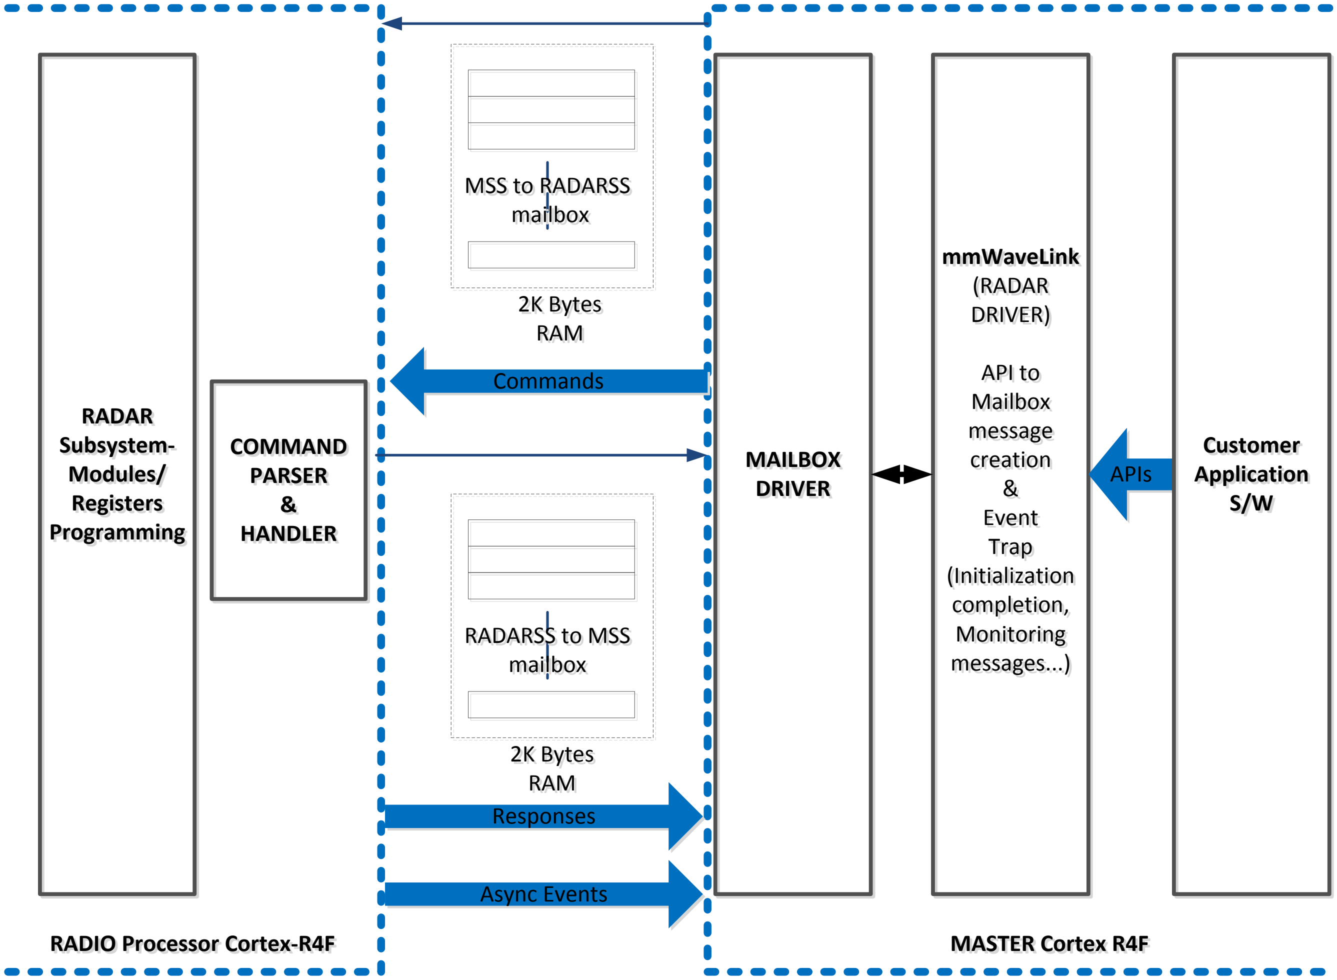

Figure 6-8. Programming Model

The radar subsystem is accessed through a well-defined set of APIs. The application software running on the main Cortex-R5F processor, through the API call, invokes the mmWaveLink-Radar driver, which then converts these APIs into mailbox-based messages. When a message is written into the mailbox memory, an interrupt is raised to the radio processor, which then passes the message and executes the command conveyed through the mailbox message. A mailbox message read event is raised to the main R5F to indicate the radio processor has read the message.

For more details, refer to the API interface control document (ICD).

Communication to BSS can also be done by C66x as well where user needs to implement communication protocol over mailbox to BSS using mmWaveLink library.

Note

On device bootup, RadarSS will be in the reset state. It is responsibility of SBL (secondary bootloader) or main-application (R5F), to bring RadarSS core (R4F) out of reset, load BSS firmware/patch and then un-halts (execute) it. Please refer SBL source code in MCU-PLUS-SDK-AWR294x for the right seqeunce.

6.5.2 Clock Subsystem

The AWR294x clock subsystem generates 76-81 GHz from an input reference of a 40-MHz crystal. The subsystem has a built-in oscillator circuit, followed by a clean-up PLL and an RF synthesizer circuit, as shown in Clocking Subsystem . The output of the RF synthesizer is then processed by an X4 multiplier to create the required frequency in the 76-81 GHz spectrum. The RF synthesizer output is modulated by the timing engine block to create the required waveforms for effective sensor operation. The timing engine is highly flexible and is programmed through the R4F-based radio controller subsystem. For details on waveforms and programming models, refer to the Radio Control API application note.

The clean-up PLL provides a reference clock for the host processor after system wakeup.

The clock subsystem has built-in mechanisms for detecting the presence of a crystal and monitoring the quality of the generated clock.

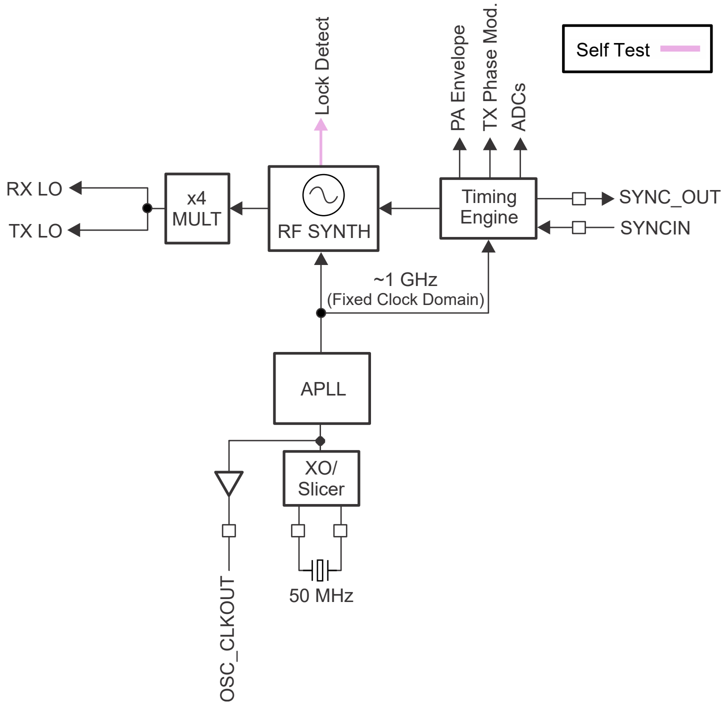

Figure 6-9. Clocking Subsystem

6.5.3 Transmit Subsystem

The transmit subsystem consists of four parallel transmit chains, each with independent phase and amplitude control, as shown in Figure 6-10. All transmit chains can be operational at the same time. The device supports binary phase modulation for MIMO radar and interference mitigation.

Each transmit chain is capable of delivering optimal power at the antenna port on the PCB, and supports programmable back-off for system optimization.

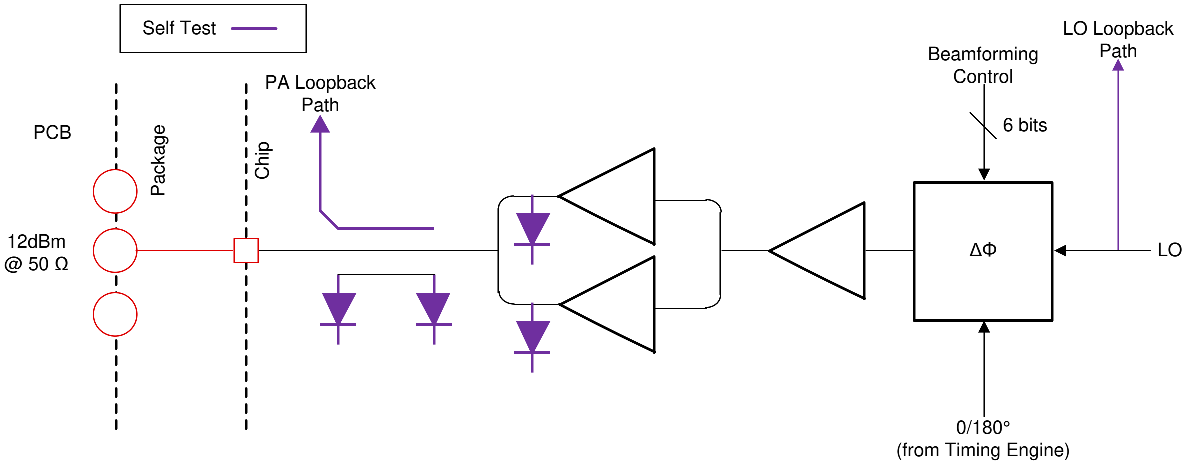

Figure 6-10. Transmit Subsystem

6.5.4 Receive Subsystem

The AWR294x receive subsystem consists of four parallel channels, as shown in Receive Subsystem (Per Channel). A single receive channel consists of an LNA, mixer, IF filtering, A2D conversion, and decimation. All four receive channels can be operational at the same time. An individual power down option is also available for system optimization.

The AWR294x device supports an I-Only baseband architecture for each receiver channel. The AWR294x is targeted for fast chirp systems. The bandpass IF chain has configurable lower cutoff frequencies above 350 kHz, and can support bandwidths up to 15 MHz.

6.5.5 Real(I-only) Receiver in AWR2944

In FMCW radar with complex baseband (IQ) receiver, the beat frequency signals from various objects are on one-side of the complex baseband spectrum as shown in the diagram below.

Therefore, a real-only receiver chain is sufficient for FMCW radar operation, including range, velocity, and angle estimation.

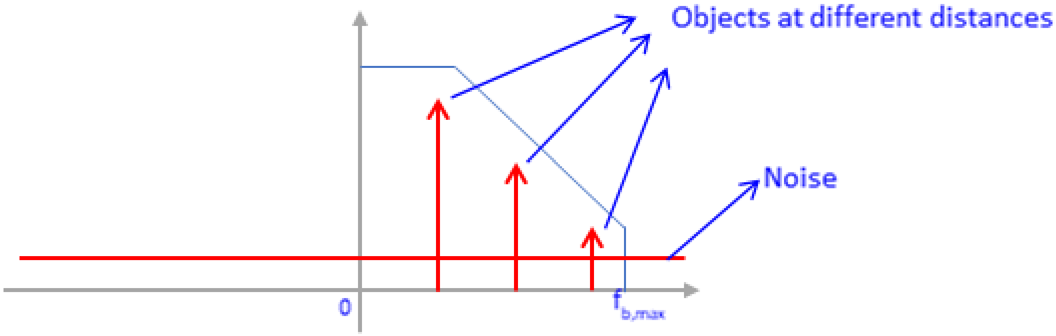

Figure 6-12. Complex Baseband Spectrum

Although theoretically, IQ receiver can provide 3 dB SNR improvement over I-only receiver, in practice, the SNR improvement is less than 1dB for IQ over I-only receiver, after taking into consideration the IQ splitter losses. Also, with circuit optimizations, the AWR2944 device is able to achieve comparable noise-figure with real-only implementation (in comparison with IQ architecture).

There is significant power and area savings for I-only architecture, and hence it is chosen as the architecture for single chip radar device like AWR2944. Using HWA 2.1, the interference detection and mitigation capability is also improved, and this enables interference-related glitches in the real ADC data to be suppressed.

Chapter 7

Interrupts

This section lists the various interrupts sources supported in the different subsystem of AWR294x device

Chapter 8

ADC Buffer

The ADC buffer is on-chip memory arranged as a ping-pong buffer, with ECC support for each ping and pong memory. The raw ADC output data from RADAR-SS is stored on this memory, to be consumed by the DSP, or by the hardware FFT accelerator for the post processing.

For the application software, the ADC buffer (either ping or pong) is seen as a single memory at the base address.

RadarSS generates Chirp Parameter (CP) and Chirp Quality (CQ) data along with ADC data. Interface Control Document (ICD) explains CP/CQ data format and steps to enable this feature. Refer ICD for the latest supported features towards CP/CQ/ADC of the device.

8.1 Functional Description

Figure 8-1 shows the block diagram of the ADC buffer scheme. The two data input sources to the ADC buffer are:

- Raw ADC output data from the digital front end (DFE)
- Ramp pattern data from the test pattern generator

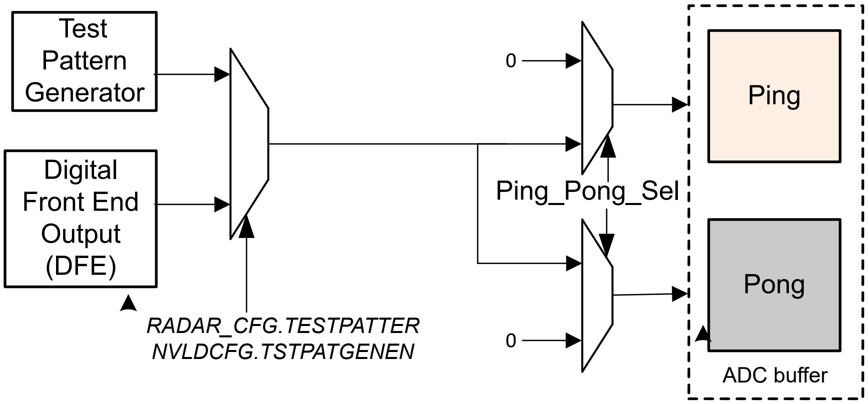

Figure 8-1. ADC Buffer Block Diagram

8.1.1 DFE Data Write Operation

The ADC buffer can be written from DFE in any of the three modes by configuring the control registers ADCBUFCFG1, ADCBUFCFG2, ADCBUFCFG3, and ADCBUFCFG4 in APP_HWA_ADCBUF_CTRL address space:

1. Single-chirp mode
2. Multi-chirp mode
3. Continuous mode

The DFE data from the three Rx channels can be independently enabled by programming the register ADCBUFCFG1.

In single-chirp mode, the FMCW chirp data from the DFE is written to the ADC buffer on a per chirp basis, and a chirp available interrupt is generated on the completion of the write data operation at the end of the chirp, as shown in Figure 8-2. ADC buffer control logic generates the Ping_Pong_Sel signal, as shown in Figure 8-2, which controls whether the data is written into either ping or pong buffer. Data write can start from either the ping or pong buffer.

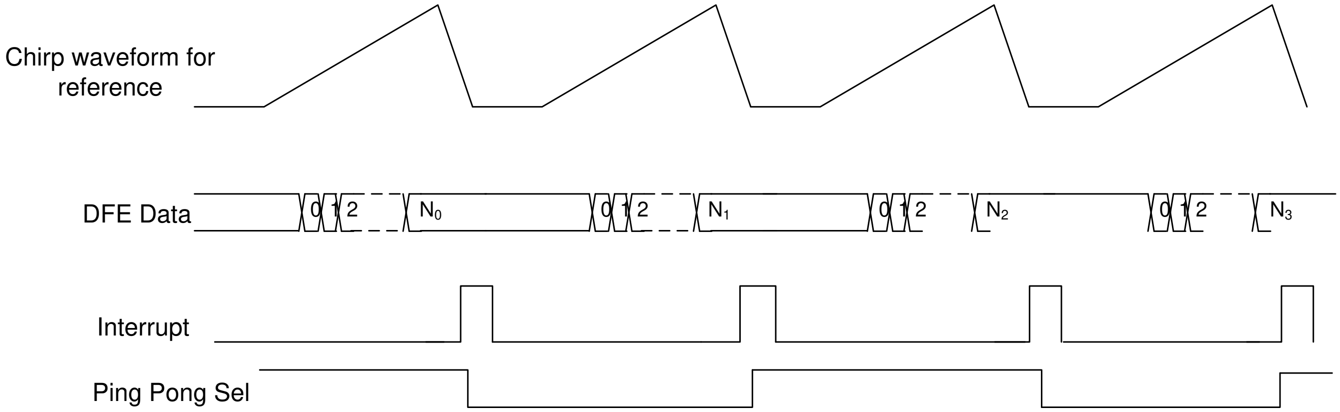

Figure 8-2. Single-Chirp Mode

In multi-chirp mode, ADC samples for N chirps are stored in a ping/pong buffer before the Ping Pong Select toggles and the Chirp Available Interrupt is generated. The number of chirps stored in the ping and the pong buffer are configured in the register field ADCBUFNUMCHRPPING.

ADC Buffer Single-Chirp and Multi-Chirp Mode Programming Sequence shows the programming sequence for the ADC buffer single-chirp and multi-chirp modes.

Note

Registers for ping and pong must be programmed with the same value for correct functionality.

Table 8-1. ADC Buffer Single-Chirp and Multi-Chirp Mode Programming Sequence

Steps	Register/Bit Field/Programming
Enable the Rx channels for which data will be captured in the ADC buffer	ADCBUFCFG1.RX0EN
	ADCBUFCFG1.RX1EN
	ADCBUFCFG1.RX2EN
Configure the ADC samples to be stored in interleaved or non-interleaved mode	ADCBUFCFG1.ADCBUFWRITEMODE
Configure whether real or complex samples are to be stored in the ADC buffer. (only real mode is supported in AWR294x)	ADCBUFCFG1.ADCBUFREALONLYMODE
Configure the number of samples to be stored in each ping/pong buffer as N	ADCBUFCFG4.ADCBUFNUMCHRPP1NG

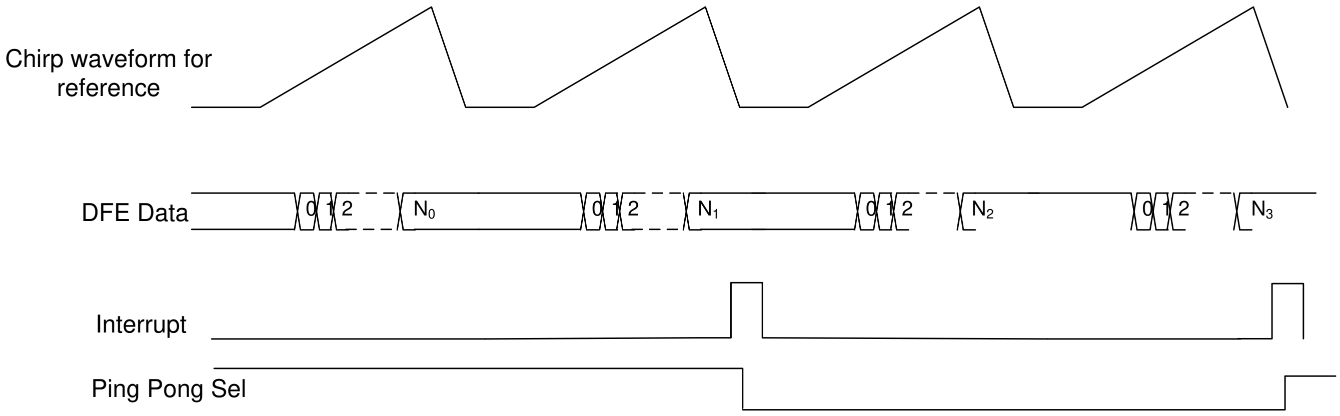

Figure 8-3. Multi-Chirp Mode

In continuous mode, where the FMCW transceiver is configured to output a single frequency tone in the range of X-Y GHz (where X is start and Y is end frequency supported by the device), 'N' ADC samples are stored in a ping/pong buffer before the Ping Pong Select toggles and the Chirp Available Interrupt is generated. The value N is configured in the field APP_HWA_ADCBUF_CTRL.ADCBUFCFG4.ADCBUFSAMPCNT. In real mode, this value N refers to the number of real samples per channel, and in complex mode, this refers to the number of complex samples per channel. This counter increments once for every new sample (as long as 1 or more Rx channels are enabled). Continous mode is expected to be only used for CZ and ADC buffer testpattern mode.

ADC Buffer Continuous Mode Programming Sequence shows the programming sequence for ADC buffer continuous mode.

Table 8-2. ADC Buffer Continuous Mode Programming Sequence

Steps	Register/Bit Field/Programming
Enable the Rx channels for which data will be captured in the ADC buffer	ADCBUFCFG1.RX0EN
	ADCBUFCFG1.RX1EN
	ADCBUFCFG1.RX2EN
Configure the ADC samples to be stored in interleaved or non-interleaved mode	ADCBUFCFG1.ADCBUFWRITEMODE
Configure whether real or complex samples are to be stored in the ADC buffer (only real mode is supported in AWR294x)	ADCBUFCFG1.ADCBUFREALONLYMODE
Configure the number of samples to be store in each ping/pong buffer	ADCBUFCFG4.ADCBUFSAMPCNT
Enable the ADC buffer in continuous mode	ADCBUFCFG1.ADCBUFCONTMODEEN
To start the capture of samples in the ADC buffer	ADCBUFCFG1.ADCBUFCONTSTRTPL
To stop the capture of samples in the ADC buffer	ADCBUFCFG1.ADCBUFCONTSTOPPL

8.1.2 Test Pattern Generator Support

An internal test pattern generator which outputs a ramp pattern helps during the initial software development and debug. The output of this module is muxed with the DFE data before sending it to the ADC buffers, as shown in Figure 8-1. Because this is meant for testing the path from the ADC buffer until the final output through LVDS, the ADC buffer configurations must be set to continuous streaming mode, in which the ping-pong switch is based on the number of samples. The test pattern generator can be configured by programming the register TESTPATTERNVLDCFG in the RADAR_CFG address space. Additional configurable registers are provided for configuring the ramp pattern output from the test pattern generator, such as offset at the start of ramp, step size, and so forth. Refer to the RSS_CTRL address space and test pattern generator-related registers for further information.

8.1.3 ADC Buffer Data Formats

The data is written in the following formats to the ADC buffer:

- Non-interleaved data format

8.1.3.1 Non-Interleaved Data Format

In non-interleaved mode storage, each channel data is stored in different memory locations, as shown in Table 8-3.

Table 8-3. Non-Interleaved Data Format

Ethernet SubSystem (MCU_CPSW0)

This chapter describes the Ethernet MAC (Media Access Controller). For conceptual purposes the below documentation refers to this MAC as being a two port CPSW with port 0 being the CPPI DMA host port and port 1 being the Ethernet port.

9.1 MCU_CPSW0 Overview

The two-port Ethernet MAC (MCU_CPSW0) subsystem provides Ethernet packet communication for the device and is configured in a similar manner as a two-port Ethernet switch. MCU_CPSW0 features the Reduced Gigabit Media Independent Interface (RGMII), Reduced Media Independent Interface (RMII), and the Management Data Input/Output (MDIO) interface for physical layer device (PHY) management.

The device has integrated two-port Ethernet Switch subsystem into device MCU domain named MCU_CPSW0.

Figure 9-1 shows the MCU_CPSW0 module overview.

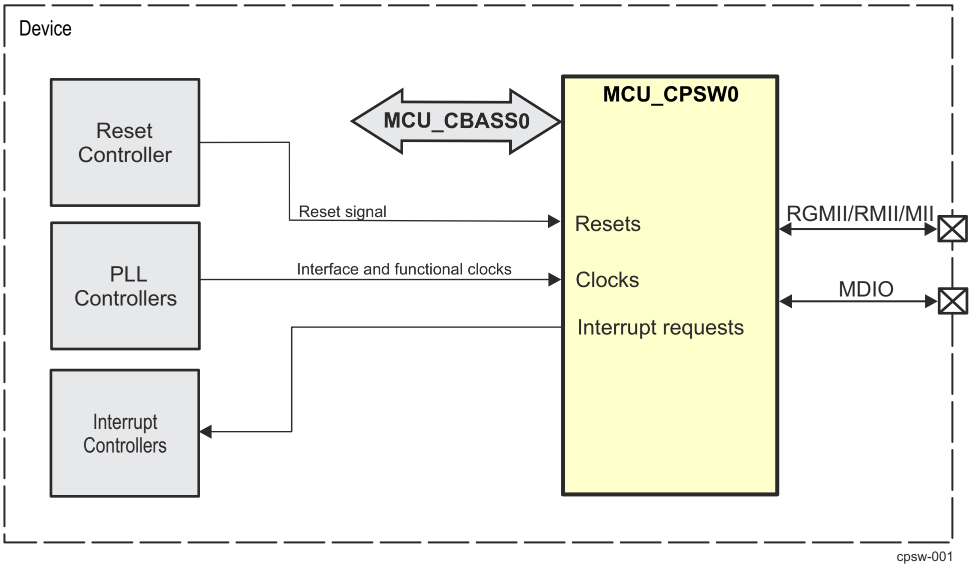

Figure 9-1. MCU_CPSW0 Overview

9.1.1 MCU_CPSW0 Features

The MCU_CPSW0 subsystem provides the following features:

- One Ethernet port with selectable MII, RMII and RGMII interfaces (port 1).
- One CPDMA CPPI DMA Host Interface (Port 0)
- Synchronous 10/100 Mbit operation
- Flexible logical FIFO-based packet buffer structure
- Eight priority level Quality Of Service (QOS) support (802.1p)
- Support for Audio/Video Bridging (P802.1Qav/D6.0) (**C**redit **B**ased **S**haper)
- Support for IEEE 1588 Clock Synchronization (2008 Annex D, Annex E and Annex F)
  - Timestamp module capable of time stamping external timesync events like Pulse-Per-Second and also generating Pulse-Per-Second outputs
  - CPTS module that supports time stamping for IEEE1588 with support for 4 hardware push events and generation of compare output pulses
- DSCP Priority Mapping (IPv4 and IPv6)
- Energy Efficient Ethernet (EEE) support (802.3az)
- Flow Control (802.3x) Support
- Non Blocking switch fabric
- Time Sensitive Network Support
  - IEEE 802.1Qbv/D2.2 Enhancements for Scheduled Traffic
- Address Lookup Engine (ALE)
  - Configurable number of addresses plus VLANs
  - Wire rate lookup
  - Host controlled time-based aging and/or auto-aging
  - Spanning tree support

  - L2 address lock and L2 filtering support
  - MAC authentication (802.1x)
  - Receive-based or destination-based Multicast and Broadcast rate limits
  - MAC address blocking
  - Source port locking
  - OUI (Vendor ID) host accept/deny feature
  - Configurable number of classifier/policers
  - VLAN support
    - 802.1Q compliant
      - Auto add port VLAN for untagged frames on ingress
      - Auto VLAN removal on egress and with pad to minimum frame size
- EtherStats and 802.3Stats Remote network Monitoring (RMON) statistics gathering (per port)
- Ethernet or Castignoli CRC selectable on Ethernet egress
- Digital Loopback supported (Ethernet egress to Ethernet ingress)
- OAM Loopback supported (FIFO Loopback - port ingress to egress including host port)
- CPSGMII Loopback Modes (Ethernet egress to Ethernet ingress)
- Maximum frame size of 2024 bytes (including VLAN)
- Management Data Input/Output (MDIO) module for PHY Management with Clause 45 support
- Programmable interrupt control with selected interrupt pacing
- Emulation support
- Full duplex mode supported in 10/100 Mbps. Half-duplex mode supported only in 10/100 Mbps modes only.
- RAM Error Detection and Correction (SECDED)
- InterVLAN Routing is supported - 4 routes per egress port.
- Automotive Security Features
  - VLANs can be configured to not allow fragmented IPv4 frames (that is, fragmented IPv4 traffic)
  - VLANs can be configured to only allow up to four different IPv4 Protocols or IPv6 Next Header values
  - Drop invalid source addresses, that is drop Source Addresses with bit 40 set (Multicast/Broadcast indicator on Destination Addresses)
  - Drop frames that the IEEE802.3 length is not contained within the frame. (Ether Types 0-1500)
  - Any source address can be secured to a port dropping any attempts from other ports to masquerade as a service
  - Any source or destination address can be blocked
  - Per port or per VLAN ingress checking, dropping traffic from non-member ports
  - Classification, policing on L2 and L3 information

9.1.2 MCU_CPSW0 Not Supported Features

The following MCU_CPSW0 features are not supported:

- Gigabit operation (1000 Mbps) is not supported
- Frames greater than 2024 bytes with VLAN
- GMII Mode
- SGMII Mode
- MACSEC
- Synchronous Ethernet
- Software reset
- Rate-limiting is not supported in half-duplex mode
- Dual VLAN switch operations are not supported
- RGMII Internal Delay Mode disabled.
- Priority based flow control is not supported.
- InterVLAN routed packets will be dropped if the FIFO room is insufficient regardless of receive 803.3x flow control.

9.1.3 Terminology

Terminology:

AVB	Audio Video Bridging
AVBTP	Audio Video Bridging Trasport Protocol
BMCA	Best Master Clock Algorithm
CFI	Canonical Format Indicator
CPPI	Communications Port Programming Interface
DLR	Device Level Ring
DSCP	Differentiated Services Code Point
EEE	Energy Efficient Ethernet

9.2 MCU_CPSW0 Environment

9.2.1 MCU_CPSW0 RMII Interface

Figure 9-2 shows a device with integrated RMII and MDIO interface connection in a typical system. The individual MCU_CPSW0 and MDIO signals for the RMII interface are summarized in Table 9-1.

For more information, refer to either the IEEE 802.3 standard or ISO/IEC 8802-3:2000(E).

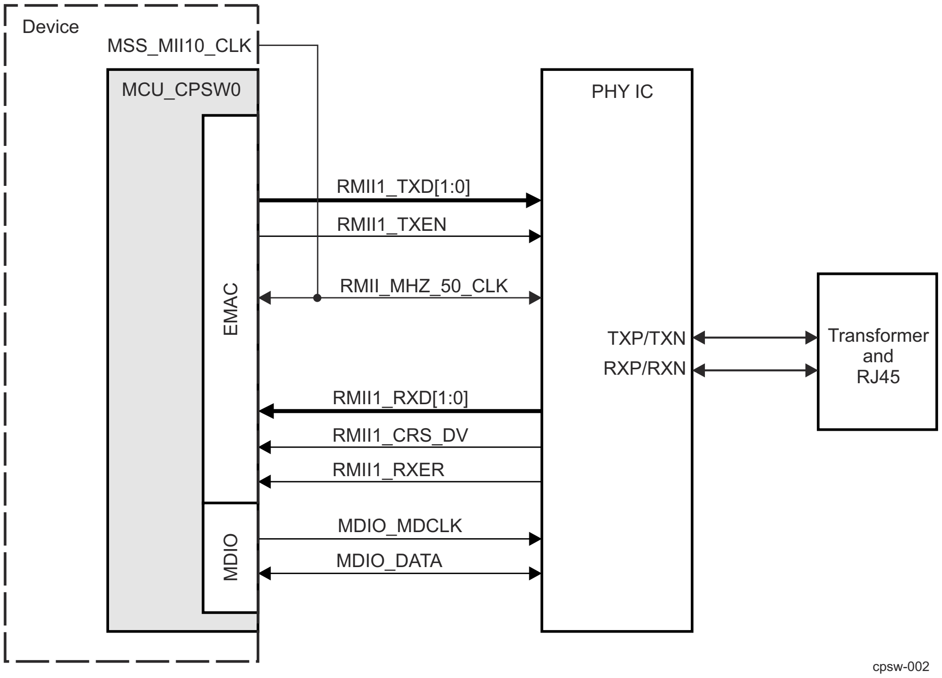

Figure 9-2. RMII Interface Typical Application

Table 9-1. RMII I/O Description

Signal	Device Pin	I/O(1)	Description
RMII_TXD[1:0]	MCU_RMII_TXD[1:0]	O	Transmit data. The transmit data pins are a collection of 2 bits of data. TXD0 is the least-significant bit (LSB). The signals are synchronized by RMII_MHZ_50_CLK and valid only when RMII_TXEN is asserted.
RMII_TXEN	MCU_RMII_TX_EN	O	RMII transmit enable. The transmit enable signal indicates that the MCU_RMII_TXD pins are generating data for use by the PHY. RMII_TXEN is synchronous to RMII_MHZ_50_CLK.
RMII_MHZ_50_CLK	MCU_RMII_REF_CLK	I	RMII 50MHz reference clock. The reference clock is used to synchronize all RMII signals. RMII_MHZ_50_CLK must be continuous and fixed at 50 MHz. This bit controls the clock source MSS_CTRL::CPSW_CONTROL::CPSW_CONTROL_RMII_REF_CLK_OE_N
RMII_RXD[1:0]	MCU_RMII_RXD[1:0]	I	Receive data. The receive data pins are a collection of 2 bits of data. RXD0 is the least-significant bit (LSB). The signals are synchronized by RMII_MHZ_50_CLK and valid only when RMII_CRS_DV is asserted and RMII_RXER is de-asserted.
RMII_CRS_DV	MCU_RMII_CRS_DV	I	Carrier sense/receive data valid. Multiplexed signal between carrier sense and receive data valid.
RMII_RXER	MCU_RMII_RX_ER	I	Receive error. The receive error signal is asserted to indicate that an error was detected in the received frame.
MDIO_MDCLK	MCU_MDIO_CLK	O	Management data clock (MDIO_MDCLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MCU_MDIO0_DATA pin.

Table 9-1. RMII I/O Description (continued)

Signal	Device Pin	I/O[1]	Description
MDIO_DATA	MCU_MDIO_DATA	I/O	MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MCU_MDIO0_DATA pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

Signal	Device Pin(s)	I/O[1]	Description
RGMII_TXD[3:0]	MCU_RGMII_TD[3:0]	O	The transmit data pins are a collection of 4 bits of data. TD0 is the least-significant bit (LSB). The signals are valid only when RGMII_TX_CTL is asserted.
RGMII_TX_CTL	MCU_RGMII_TX_CTL	O	Transmit Control/enable. The transmit enable signal indicates that the TD pins are generating data for use by the PHY.
RGMII_TXC	MCU_RGMII_TXC	O	The transmit reference clock. The clock is 2.5 MHz at 10 Mbps operation, 25 MHz at 100 Mbps operation, and 125 MHz at 1000 Mbps* of operation.
RGMII_RXD[3:0]	MCU_RGMII_RD[3:0]	I	The receive data pins are a collection of 4 bits of data. RD0 is the least-significant bit (LSB). The signals are valid only when RGMII_RX_CTL is asserted
RGMII_RX_CTL	MCU_RGMII_RX_CTL	I	The receive data valid/control signal indicates that the RD pins are nibble data for use by the EMAC.
RGMII_RXC	MCU_RGMII_RXC	I	The receive clock is a continuous clock that provides the timing reference for receive operations. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation, 25 MHz at 100 Mbps operation, 125 MHz at 1000 Mbps* of operation.

9.4 MCU_CPSW0 Functional Description

The two-port switch Ethernet subsystem modules (CPSW) are compliant to the IEEE Std 802.3 Specification. CPSW top level functional block diagram is shown in Figure 9-5.

9.4.1 Functional Block Diagram

The two-port Ethernet subsystem consists of:

- CPSW_2G
- One RGMII interface module
- One RMII interface module
- One Host Port 0 CPPI Packet Streaming Interface
- CPSW subsystem control registers (REG)
- One MDIO interface module
- One Interrupt Controller module

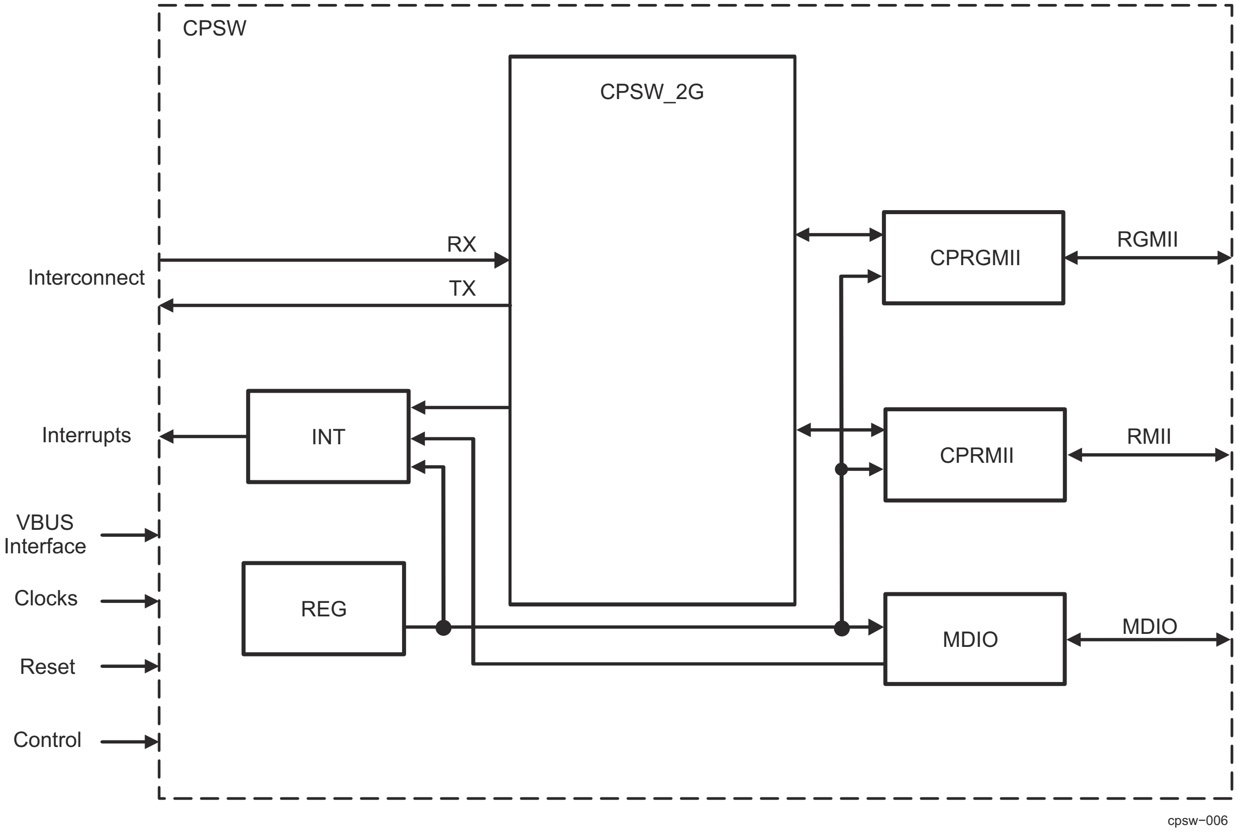

Figure 9-5. CPSW Top Level Block Diagram

9.4.2 CPSW Ports

The Ethernet Subsystem has two ports. Port 0 is the Host port (internal to the Subsystem). Port 1 is the external port connected to RGMII, or RMII interfaces as per the interface selected.

Naming conventions followed in this chapter:

- Port0 is referred to the CPPI CPDMA Host Port
- Port1 is referred to the interfaces RGMII/RMII

9.4.2.1 Ethernet Port Operation

9.4.2.1.1 Interface Mode Selection

The two-port switch (CPSW) Ethernet Subsystem has one 10/100/1000 Ethernet port with selectable MII, RMII, and RGMII interfaces. These interfaces can be enabled by **MSS_CTRL:CPSW_CONTROL:CPSW_CONTROL_PORT1_MODE_SEL**

For specific interface mode further features is selected by configuring the Ethernet bits (EXT_EN, GIG, FULLDUPLEX, IFCTL_A) in the **PN_MAC_CONTROL** register.

See the device-specific Datasheet for configuring the pin mux mode as per the interface selected.

CPSW_CONTROL_PORT1_MODE_SEL	Link Type
00	GMII/MII
01	RMII
10	RGMII

9.4.2.1.2 RMII Operation

The **IFCTL_A** bit determines the RMII link speed (0=10mbps, 1=100mbps). The **FULLDUPLEX** bit controls RMII duplexity. The **IFCTL_B** is not used.

9.4.2.1.3 RGMII Operation

Each port RGMII interface can operate in a forced mode or an in-band mode as determined by the **EXT_EN** bit. Forced mode is with **EXT_EN** cleared. In-band mode is with **EXT_EN** set.

9.4.2.1.3.1 RGMII In-Band Operation

A port CPRGMII is operating in the in-band mode of operation when the **EXT_EN** is set. The link status, duplexity, and speed are determined from the RGMII input data stream as defined in the RGMII specification and can be read in the **SS_RGMII1_STATUS** register. The link speed is indicated as shown in Table 9-5.

Table 9-5. RGMII Link Speed

SPEED(1:0)	Link Speed
00	10 Mbs mode
01	100 Mbs mode
10	1000 Mbs mode
11	reserved

Note

1000 Mbs mode is not supported for AWR294x

9.4.2.1.3.2 RGMII Forced Mode Operation

A RGMII is operating in the forced mode of operation when **EXT_EN** is cleared. In the forced mode of operation, the in-band data is ignored if present. The link status is forced set, the duplexity is set by the **FULLDUPLEX** bit, and the speed is set by the **GIG** bit. If the **GIG** bit is cleared, then operation is 100mbps mode (**SPEED(1:0)** = 01). 10mbps is not supported when operating in the forced mode.

Note

For AWR294x gigabit mode (**GIG** bit set) is not supported.

9.4.3 Clocking

9.4.3.1 Subsystem Clocking

CPSW clocking summary is shown in Section 9.3, *CPSW Integration*.

9.4.3.2 Interface Clocking

Data is transmitted and received with respect to the reference clocks of the interface pins.

9.4.3.2.1 RGMII Interface Clocking

RGMII_RXC, RGMII_TXC frequencies are:

- 2.5 MHz at 10 Mbps
- 25 MHz at 100 Mbps

9.4.3.2.2 RMII Interface Clocking

RMII interface clock RMII_50MHZ_CLK frequency is:

- 50 MHz at 10 Mbps
- 50 MHz at 100 Mbps

MCU_RMII1_REFCLK pin or internal RGMII_MHZ_50_CLK clock (default clock) can be selected through CTRLMMR_MCU_ENET_CLKSEL[0]RMII_CLK_SEL and one of these clocks can be used as the clock source for RMII interface. For more details on RMII clocking, please see Section 9.3, *CPSW Integration*.

CTRLMMR_MCU_CLKOUT0_CTRL[4]CLK_EN and CTRLMMR_MCU_CLKOUT0_CTRL[0]CLK_SEL bits are used to enable and select the clock source for MCU_CLKOUT pin.

9.4.3.2.3 MDIO Clocking

The MDIO clock is based on a divide-down of the interface (CPPI_ICLK) clock. The application software or driver must control the divide-down value.

See the CPSW_MDIO_CONTROL_REG register for configuring the Clock Divider ([15-0]CLKDIV) value.

9.4.4 Interrupt Functionality

Table 9-6. Interrupt Functionality

Interrupt	Description
MSS_CPSW_FH_INT	FHost (from host to Ethernet) interrupt
MSS_CPSW_TH_INT	THost (from Ethernet to host) interrupt
MSS_CPSW_TH_TRSH_INT	THost (from Ethernet to host) Threshold interrupt
MSS_CPSW_MISC_INT	Miscellaneous interrupt
MSS_CPSW_SERR	ECC SEC interrupt – output from CPSW ECC module. This interrupt is also included in the **MSS_CPSW_MISC_INT** if enabled or this interrupt can be used separately.
MSS_CPSW_UERR	ECC DED interrupt – output from CPSW ECC module. This interrupt is also included in the **MSS_CPSW_MISC_INT** if enabled or this interrupt can be used separately.

9.4.4.1 MSS_CPSW_TH_TRSH_INT Interrupt Description

The **MSS_CPSW_TH_TRSH_INT** interrupts are each an immediate (non-paced) pulse interrupt selected from the CPSW_2G **TH_THRESH_PEND[7:0]** interrupts. The THost threshold pending interrupt(s) is selected by setting one or more bits in the **SS_TH_THRESH_PULSE_EN_REG[7:0]** register. The masked interrupt status can be read in the **SS_TH_THRESH_PULSE_STATUS_REG[7:0]** register. Upon reception of an interrupt, software should perform the following:

- Read the SS_TH_THRESH_PULSE_STATUS_REG[7:0] register to determine which channel(s) caused the interrupt.
- Process THost packets in order to add more buffers to any channel that is below the threshold value.
- Write the CPSW_2G completion pointer(s) to acknowledge the CPDMA interrupt.
- Write 0x0 to the CPDMA_EOI_VECTOR register in the CPSW_2G slave address space to acknowledge the subsystem interrupt.

9.4.4.2 MSS_CPSW_TH_INT Interrupt Description

The **MSS_CPSW_TH_INT**interrupts are each a paced pulse interrupt selected from the CPSW_2G **TH_PEND[7:0]** interrupts. The THost pending interrupt(s) is selected by setting one or more bits in the **SS_TH_PULSE_EN_REG[7:0]** register. The masked interrupt status can be read in the **SS_TH_PULSE_STATUS_REG[7:0]** register. Upon reception of an interrupt, software should perform the following:

- Read the SS_TH_PULSE_STATUS_REG[7:0] register to determine which channel(s) caused the interrupt.
- Process THost packets for the interrupting channel(s) to acknowledge the CPDMA interrupt.
- Write the CPSW_2G completion pointer(s).
- Write 0x1 to the CPDMA_EOI_VECTOR_REG register in the CPSW_2G slave address space to acknowledge the subsystem interrupt.

9.4.4.3 MSS_CPSW_FH_INT Interrupt Description

The **MSS_CPSW_FH_INT** interrupts are each a pulse interrupt selected from the CPSW_2G **FH_PEND[7:0]** interrupts. The transmit pending interrupt(s) is selected by setting one or more bits in the **SS_FH_PULSE_EN_REG[7:0]** register. The masked interrupt status can be read in the **SS_FH_PULSE_STATUS_REG[7:0]** register. Upon reception of an interrupt, software should perform the following:

- Read the SS_FH_PULSE_STATUS_REG[7:0] register to determine which channel(s) caused the interrupt.
- Process THost packets for the interrupting channel(s).
- Write the CPSW_2G completion pointer(s) to acknowledge the CPDMA interrupt.
- Write 0x2 to the CPDMA_EOI_VECTOR_REG register in the CPSW_2G slave address space to acknowledge the subsystem interrupt.

9.4.4.4 MSS_CPSW_MISC_INT Interrupt Description

The **MSS_CPSW_MISC_INT** interrupts are each an immediate (non-paced) pulse interrupt selected from the miscellaneous interrupts (**DED_PEND, SEC_PEND, EVNT_PEND, STAT_PEND,HOST_PEND, MDIO_LINKINT,MDIO_USERINT**). The miscellaneous interrupt bits are enabled by setting one or more bits in the **SS_MISC_EN_REG** register. The masked interrupt status can be read in the **SS_MISC_STATUS_REG** register. Upon reception of an interrupt, software should perform the following:

- Read the **SS_MISC_STATUS_REG** register to determine the cause of the interrupt.
  - MDIO_USERINT is the logical “OR” of the CPSW_2G MDIO MDIO_USERINT[1:0].
  - MDIO_LINKINT is the logical “OR” of the CPSW_2G MDIO MDIO_LINKINT[1:0]
  - HOST_PEND is the CPSW_2G CPDMA host error interrupt.
  - STAT_PEND is the logical “OR” of the CPSW_2G statistics interrupt STAT_PEND[2:0].
  - EVNT_PEND is the CPSW_2G CPTS event interrupt.
  - SEC_PEND is the ECC Single bit error interrupt.
  - DED_PEND is the ECC double bit error interrupt.
- Process the interrupt.
- Write 0x3 to the CPDMA_EOI_VECTOR register in the CPSW_2G slave address space to acknowledge the subsystem interrupt.

9.4.4.5 ECC SEC ESM Interrupt (MSS_CPSW_SERR)

ESM interrupt indicating a CPSW_2G ECC single error has been detected and corrected. Although the **MSS_CPSW_SERR** value can be read in the **CPDMA_IN_VECTOR** register, there is no EOI associated with this interrupt. It is a direct output of the CPSW_2G ECC aggregator module. MSS can enable this interrupt from **SS_MISC_EN_REG[5]** and read status from **SS_TH_PULSE_STATUS_REG[5]**

9.4.4.6 ECC DED ESM Interrupt (MSS_CPSW_UERR)

ESM interrupt indicating a CPSW_2G ECC double error has been detected. Although the **MSS_CPSW_UERR** value can be read in the **CPDMA_IN_VECTOR** register, there is no EOI associated with this interrupt. It is a direct output of the CPSW_2G ECC aggregator module. MSS can enable this interrupt from **SS_MISC_EN_REG[6]** and read status from **SS_MISC_STATUS_REG[6]**.

9.4.4.7 THost Threshold Interrupts for CPDMA

Each of the eight THost channels has a corresponding THost threshold interrupt (**TH_THRESH_PEND[7:0]**). The THost threshold interrupts are level interrupts that remain asserted until the triggering condition is cleared by the host. Each of the eight threshold interrupts may be individually enabled by setting to one the appropriate bit in the **CPDMA_TH_INTSTAT_SET** register. Each of the eight channel interrupts may be individually disabled by clearing to zero the appropriate bit in the **CPDMA_TH_INTSTAT_CLR** register. The raw and masked interrupt receive interrupt status may be read by reading the **CPDMA_TH_INTSTAT_RAW** and **CPDMA_TH_INTSTAT_MASKED** registers respectively. A **TH_THRESH_PEND[7:0]** interrupt bit is asserted when enabled and when the channel's associated freebuffer count (**CPDMA_TH(0/7)_FREEBUFFER**) is less than or equal to the channel's associated flow control threshold register (**CPDMA_TH(0/7)_PENDTHRESH**. The threshold interrupts are intended to give the host an indication that resources are running low for a particular channel(s).

9.4.4.8 Thost Packet Completion Interrupts for CPDMA

The THost DMA controller has eight channels with each channel having a corresponding interrupt (**TH_PEND[7:0]**). The THost interrupts are level interrupts that remain asserted until cleared by the host. Each of the eight channel interrupts may be individually enabled by setting to one the appropriate bit in the **CPDMA_TH_INTSTAT_SET** register. Each of the eight channel interrupts may be individually disabled by clearing to zero the appropriate bit in the **CPDMA_TH_INTSTAT_CLR** register. The raw and masked interrupt interrupt status may be read by reading the **CPDMA_TH_INTSTAT_RAW** and **CPDMA_TH_INTSTAT_MASKED** registers respectively. When a packet transfer is complete, the CPDMA issues an interrupt to the host by writing the packet's last buffer descriptor address to the appropriate channel queue's **CPDMA_TH(0..7)_CP** completion pointer. The interrupt is generated by the write, regardless of the value written. Upon interrupt reception, the host processes one or more packets from the queue and then acknowledges one or more interrupt(s) by writing the address of the last buffer descriptor processed to the queue's associated **CPDMA_TH(0..7)_CP** Completion Pointer. If the host written buffer address value is different from the buffer address written by the port, then the level interrupt remains asserted which means that the CPDMA has transferred more packets than the host has processed interrupts for. If the host written buffer address value is equal to the port written value then the host has processed all packets that the CPDMA has transferred and the level interrupt is deasserted. The CPDMA write to the completion pointer actually stores the value. The host written value is actually not written to the register location. The host written value is compared to the register contents which was written by the CPDMA. If the two values are equal then the interrupt is removed, otherwise the interrupt remains asserted. The host may process multiple packets previous to acknowledging an interrupt, or the host may acknowledge interrupts for every packet.

9.4.4.9 Fhost Packet Completion Interrupts for CPDMA

The FHost DMA controller has eight channels with each channel having a corresponding interrupt (**FH_PEND[7:0]**). The FHost interrupts are level interrupts that remain asserted until cleared by the host. Each of the eight channel interrupts may be individually enabled by setting to one the appropriate bit in the **CPDMA_FH_INTSTAT_MASKED_SET** register. Each of the eight channel interrupts may be individually disabled by clearing to zero the appropriate bit in the **CPDMA_FH_INTSTAT_MASKED_CLR** register. The raw and masked interrupt status may be read by reading the **CPDMA_FH_INTSTAT_RAW** and **CPDMA_FH_INTSTAT_MASKED** registers respectively. When each packet transfer is complete, the CPDMA issues an interrupt to the host by writing the packet's last buffer descriptor address to the appropriate channel **CPDMA_FH(0..7)_CP** completion pointer register. The interrupt is generated by the write, regardless of the value written. Upon interrupt reception, the host processes one or more packets from the queue and then acknowledges an interrupt by writing the address of the last buffer descriptor processed to the queue's associated Fhost Completion Pointer. If the host written buffer address value is different from the buffer address written by the port, then the level interrupt remains asserted which means that the CPDMA has transferred more packets than the host has processed interrupts for. If the host written buffer address value is equal to the port written value then the host has processed all packets that the CPDMA has transferred and the level interrupt is deasserted. The CPDMA write to the completion pointer actually stores the value. The host written value is actually not written to the register location. The host written value is compared to the register contents which was written by the CPDMA and if the two values are equal then the interrupt is removed, otherwise the interrupt remains asserted. The host may process multiple packets previous to acknowledging an interrupt, or the host may acknowledge interrupts for every packet.

9.4.5 Media Independent Interfaces (XGMII/GMII)

For the purposes of this document, Ethernet transmit is egress and Ethernet receive is ingress.

9.4.5.1 Receive Control

Data received from the PHY is interpreted and forwarded by the MAC into the switch. Interpretation involves detection and removal of the preamble and start of frame delimiter, extraction of the address and frame length, data handling, error checking and reporting, cyclic redundancy checking (CRC), and statistics control signal generation.

9.4.5.1.1 Receive Inter-Frame Interval

The 802.3 required inter-packet gap (IPG) is 24 GMII clocks (96 bit times) for 10/100 Mbit modes, and 12 GMII clocks (96 bit times) for 1000 Mbit mode. However, the MAC can tolerate a reduced IPG (2 GMII clocks in 10/100 mode and 5 GMII clocks in 1000 mode) with a correct preamble and start frame delimiter.

This interval between frames must comprise (in the following order):

1. An Inter-Packet Gap (IPG).
2. A seven octet preamble (all octets 0x55).
3. A one octet start frame delimiter (0x5d).

9.4.5.1.2 Received Frame Classification

Received frames are proper (good) frames if they are between 64 and **PN_RX_MAXLEN** in length (inclusive) and contain no errors (code/align/CRC).

Received frames are long frames if their frame count exceeds the value in the **PN_RX_MAXLEN** register. The **PN_RX_MAXLEN** register reset (default) value is 1518 (dec). Long received frames are either oversized or jabber frames. Long frames with no errors are oversized frames. Long frames with CRC, code, or alignment errors are jabber frames.

Received frames are short frames if their frame count is less than 64 bytes. Short frames that contain no errors are runt frames. Short frames with CRC, code, or alignment errors are fragment frames. If **RX_CSF_EN** in **PN_MAC_CONTROL** is set, undersized frames from 33 to 63 bytes will be forwarded only to the host on a best effort basis (meaning that the ALE may or may not be able to keep up with the packet rate and the short packet may be dropped due to bandwidth limitations). If **RX_CSF_EN** and **RX_CEF_EN** in **PN_MAC_CONTROL** are set, fragment frames from 33 to 63 bytes will also be forwarded only to the host on a best effort basis. Ethernet port received frames shorter than 33 bytes are dropped in all cases.

A received long packet will always contain **PN_RX_MAXLEN** number of bytes transferred to memory (if **RX_CEF_EN** = 1). Examples with **PN_RX_MAXLEN** = 1518 is below:

- If the frame length is 1518, then the packet is not a long packet and there will be 1518 bytes transferred to memory.
- If the frame length is 1519, there will be 1518 bytes transferred to memory. The last three bytes will be the first three CRC bytes.
- If the frame length is 1520, there will be 1518 bytes transferred to memory. The last two bytes will be the first two CRC bytes.
- If the frame length is 1521, there will be 1518 bytes transferred to memory. The last byte will be the first CRC byte.
- If the frame length is 1522, there will be 1518 bytes transferred to memory. The last byte will be the last data byte.

9.4.5.2 Transmit Control

A jam sequence is output if a collision is detected on a transmit packet in half-duplex mode. If the collision was late (after the first 64 bytes have been transmitted) then the collision is ignored. If the collision is not late, then the controller will back off before retrying the frame transmission. When operating in full duplex mode the carrier sense (CRS) and collision sensing modes are disabled.

9.4.5.2.1 Adaptive Performance Optimization (APO)

The Ethernet MAC port incorporates Adaptive Performance Optimization (APO) logic that may be enabled by setting the **TX_PACE** bit in the **PN_MAC_CONTROL** register. Transmission pacing to enhance performance is enabled when set. Adaptive performance pacing introduces delays into the normal transmission of frames, delaying transmission attempts between stations, reducing the probability of collisions occurring during heavy traffic (as indicated by frame deferrals and collisions) thereby increasing the chance of successful transmission.

When a frame is deferred, suffers a single collision, multiple collisions or excessive collisions, the pacing counter is loaded with an initial value of 31. When a frame is transmitted successfully (without experiencing a deferral, single collision, multiple collision or excessive collision) the pacing counter is decremented by one, down to zero.

With pacing enabled, a new frame is permitted to immediately (after one IPG) attempt transmission only if the pacing counter is zero. If the pacing counter is non-zero, the frame is delayed by the pacing delay, a delay of approximately four inter-packet gap delays. APO only affects the IPG preceding the first attempt at transmitting a frame. It does not affect the back-off algorithm for retransmitted frames.

9.4.5.2.2 Inter-Packet-Gap Enforcement

The measurement reference for the IPG of 96 bit times is changed depending on frame traffic conditions. If a frame is successfully transmitted without collision, and **MCRS** is de-asserted within approximately 48 bit times of **MTXEN** being de-asserted, then 96 bit times is measured from **MTXEN**. If the frame suffered a collision, or if **MCRS** is not de-asserted until more than approximately 48 bit times after **MTXEN** is de-asserted, then 96 bit times (approximately, but not less) is measured from **MCRS**.

The Ethernet port transmit inter-packet gap (IPG) may be shortened by eight bit times when short gap is enabled and triggered. Setting the **TX_SHORT_GAP_ENABLE** bit each **PN_MAC_CONTROL** register enables the gap to be shortened when triggered. The condition is triggered when the ports associated transmit packet FIFO has a user defined number of FIFO blocks used. The associated transmit FIFO blocks used value determines if the gap is shortened, and so on. The **GAP_THRESH** register value determines the short gap threshold. If the FIFO blocks used is greater than or equal to the **GAP_THRESH** value then short gap is triggered.

9.4.5.2.3 Programmable Transmit Inter-Packet Gap

The transmit inter-packet gap (IPG) is programmable through the **PN_MAC_TX_GAP** register. The default value is decimal 12. The transmit IPG may be increased to the maximum value of 0x1ff. Increasing the IPG is not compatible with transmit pacing. The short gap feature will override the increased gap value, so the short gap feature may not be compatible with an increased IPG.

9.4.5.2.4 Back Off

The Ethernet Mac implements the 802.3 binary exponential back-off algorithm for half-duplex based collisions.

9.4.5.3 Emulation Control

The emulation control input (**TBEMUSUP**) and register bits (**SOFT** and **FREE** in the **PN_MAC_EMCONTROL** register)allow Mac operation to be suspended. When the emulation suspend state is entered, the MAC will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For receive, frames that are detected by the MAC after the suspend state is entered are ignored. Emulation control is implemented for compatibility with other peripherals. Table 9-7 shows the operations of emulation control input and register bits.

Table 9-7. Emulation Control Input and Register Bits

0	X	X	Normal Operation
1	0	0	Normal Operation
1	1	0	Emulation Suspend

Table 9-7. Emulation Control Input and Register Bits (continued)

TBEMUSUSP	SOFT	FREE	Description
1	X	1	Normal Operation

9.4.5.4 Command IDLE

The **CMD_IDLE** bit in the **PN_MAC_CONTROL** register allows MAC operation to be suspended by software. When the idle state is commanded, the MAC will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. Received frames that are detected after the suspend state is entered are ignored (dropped without any processing or statistics). Commanded idle is similar in operation to emulation control and hardware clock stop.

9.4.6 Software IDLE

The submodule software idle register bits enable CPSW operation to be completely or partially suspended by software control. There are two CPSW submodules that contain software idle register bits. Each of the two submodules may be individually commanded to enter the idle state. The idle state is entered at packet boundaries, and no further packet operations will occur on an idled submodule until the idle command is removed. The CPSW module enters the idle state when all two submodules are commanded to enter and have entered the idle state. Idle status is determined by reading or polling the two submodule idle bits. The CPSW_2G is in the idle state when all two submodules are in the idle state. The CPSW_SOFT_IDLE_REG[0] SOFT_IDLE bit may be set if desired after the submodules are in the idle state. The SOFT_IDLE bit causes packets to not be transferred from one FIFO to another FIFO internal to the switch.

9.4.7 CPSW_2G

The CPSW_2G RMII/ RGMII interface is compliant to the IEEE Std 802.3 Specification.

The CPSW_2G contains one Ethernet port interface (Ethernet port 1), one CPPI packet streaming interface host port (port 0), Common Platform Time Sync (CPTS), ALE Engine and Statistics (STATS). A top-level block diagram of the CPSW_2G is shown in Figure 9-6.

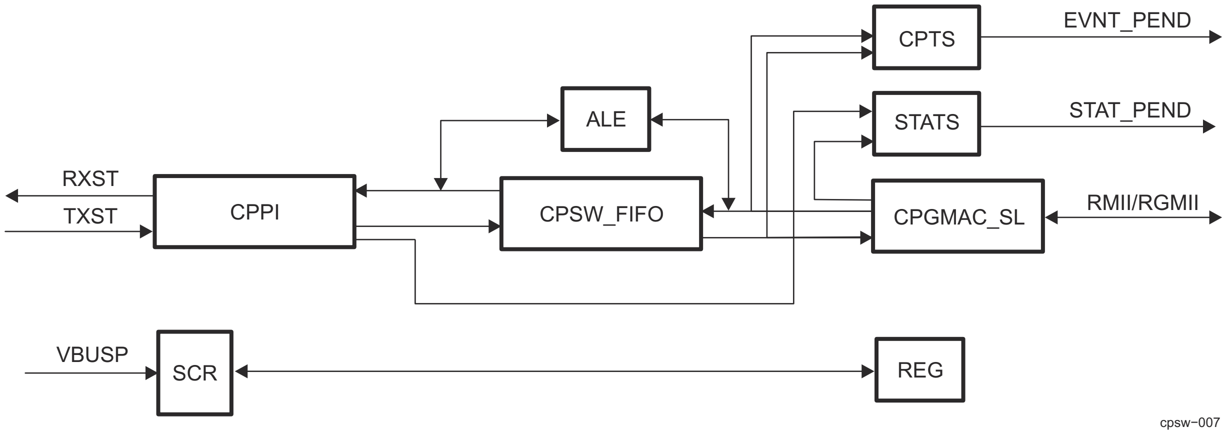

Figure 9-6. CPSW_2G Block Diagram

9.4.7.1 Address Lookup Engine (ALE)

The Address Lookup Engine (ALE) is a sub-block of the CPSW Switch and it processes all received packets and determines to which port(s) the packet should be forwarded. The ALE uses the incoming packet received port number, destination address, source address, length/type, and VLAN information to determine how the packet should be forwarded. The ALE outputs the port mask to the switch fabric that indicates the port(s) the packet should be forwarded to. The ALE is enabled when the ENABLE bit in the ALE_CONTROL_REG register is set. All packets are dropped when the ENABLE bit is cleared to 0.

9.4.7.1.1 Error Handling

In normal operation, the Ethernet port is configured to issue an abort, instead of an end of packet, at the end of a packet that contains an error (runt, frag, oversize, jabber, crc, alignment, code etc.) or at the end of a MAC control packet. However, when the PN_MAC_CONTROL_REG configuration bit(s) RX_CEF_EN, RX_CSF_EN, or RX_CMF_EN are set, error frames, short frames or MAC control frames have a normal end of packet instead of an abort at the end of the packet. When the ALE receives a packet that contains errors (due to a set header error bit), or a MAC control frame and does not receive an abort, the packet will be forwarded only to the host port (port 0). Packets with errors that are forwarded to the host have no VLAN untagging or drop due to rate limiting. No ALE learning occurs on packets with errors or mac control frames. Learning is based on source address and lookup is based on destination address. Directed packets from the host are not learned, updated, or touched.

9.4.7.1.2 Bypass Operations

The ALE may be configured to operate in bypass mode by setting the BYPASS bit in the ALE_CONTROL_REG register. When in bypass mode, all Ethernet port received packets are forwarded only to the host port (port 0). In bypass mode, the ALE processes host port transmit packets the same as in normal mode. In general, packets would be directed by the host in bypass mode.

9.4.7.1.3 OUI Deny or Accept

The ALE may be configured to operate in OUI deny mode by setting the enable_oui_deny bit in the ALE_CONTROL register. When in OUI deny mode, any packet with a non-matching OUI source address will be dropped to the host unless the packet destination address matches with a supervisory table entry. (Non-matching OUI source address broadcast/multicast packets will be dropped to the host unless the packet destination address is entered into the table with the super bit set. Non-matching OUI source address unicast packets will be dropped to the host unless the unicast destination address is in the table with block and Secure both set). When enable_oui_deny is cleared, any packet source address matching an OUI address table entry will be dropped to the host unless the destination address matches with a supervisory address table entry. (Broadcast packets matching the OUI source address will be dropped to the host unless the broadcast destination address is entered into the table with the super bit set. Unicast packets matching the OUI source address will be dropped to the host unless the unicast destination address is in the table with block and Secure both set)

9.4.7.1.4 Statistics Counting

ALE sends many statistics along with the frame routing so the CPSW can count them on a per port basis. The events specified through the CPSW_ALE_STAT_DIAG[3-0] STAT_DIAG field are individually counted in CPSW per port statistics counters.

9.4.7.1.5 Supervisory packets

Multicast supervisory packets are designated by the SUPER bit in the table entry. Unicast supervisory packets are indicated when BLOCK and SECURE are both set. Supervisory packets are not dropped due to rate limiting, OUI, or VLAN processing. The purpose of supervisory packets is to allow packets that would be otherwise blocked to be forwaded for special purposes.

9.4.7.1.6 ALE Lookup Table Entry Definitions

The ALE table contains multiple table entry types. Each table entry represents a free entry, an address, a VLAN, an address/VLAN pair, or an OUI address. Software should ensure that there are not double address entries in the table. The double entry used would be indeterminate. Reserved table bits must be written with zeroes.

Source Address learning occurs for packets with a unicast, multicast or broadcast destination address and a unicast or multicast (including broadcast) source address. Multicast source addresses have the group bit (bit 40) cleared before ALE processing begins, changing the multicast source address to a unicast source address. A multicast address of all ones is the broadcast address which may be added to the table. A learned unicast source address is added to the table with the following control bits:

Table 9-8. Learned Address Control Bits

Bit(s)	Value
Ageable	1
Touch	1
BLOCK	0
SECURE	0

If a received packet has a source address that is equal to the destination address then the following occurs:

- The address is learned if the address is not found in the table.
- The address is updated if the address is found.
- The packet is dropped.

Table Entry Type

IgnoreMbits

Ignore Multicast Bits - Indication that the Multicast Address has ignored bits.

Supervisory Packet (SUPER)

When set, this field indicates that the packet with a matching multicast destination address is a supervisory packet.

0: Non-supervisory packet

1: Supervisory packet

Port Mask(1:0) (PORT_MASK)

This 2-bit field is the port bit mask that is returned with a found multicast destination address. There may be multiple bits set indicating that the multicast packet may be forwarded to multiple ports (but not the receiving port).

Multicast Forward State (MCAST_FWD_STATE)

Indicates the port state(s) required for the received port on a destination address lookup in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state in order to forward the packet. If the transmit PORT_MASK has multiple set bits then each forward decision is independent of the other transmit port(s) forward decision.

The forward state test returns a true value if both the RX and TX ports are in the required state.

Table Entry Type (ENTRY_TYPE)

Address entry type. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

Packet Address (MULTICAST_ADDRESS)

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

Port Mask(1:0) (PORT_MASK)

This 2-bit field is the port bit mask that is returned with a found multicast destination address. There may be multiple bits set indicating that the multicast packet may be forwarded to multiple ports (but not the receiving port).

Multicast Forward State (MCAST_FWD_STATE)

Indicates the port state(s) required for the received port on a destination address lookup in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state in order to forward the packet. If the transmit PORT_MASK has multiple set bits then each forward decision is independent of the other transmit port(s) forward decision.

Table Entry Type (ENTRY_TYPE)

Address entry type. Unicast or multicast determined by address bit 40.

11: VLAN address entry. Unicast or multicast determined by address bit 40.

VLAN ID (VLAN_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

Packet Address (MULTICAST_ADDRESS)

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

Trunk

Trunk Indicator -

0 - the port bits in the entry are the port number

1 - the port bits in the entry are the trunk number

Port Number (PORT_NUMBER)

This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).

Block (BLOCK)

The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0 - Address is not blocked.

1 - Drop a packet with a matching source or destination address (secure must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

Secure (SECURE)

This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry port_number.

0 - Received port number is a don't care.

1 - Drop the packet if the received port is not the secure port for the source

address and do not update the address (block must be zero)

Unicast Type (UNICAST_TYPE)

This field indicates the type of unicast address the table entry contains.

00 - Unicast address that is not ageable.

01 - Ageable unicast address that has not been touched.

10 - OUI address - lower 24-bits are don't cares (not ageable).

11 - Ageable unicast address that has been touched.

Port Number (PORT_NUMBER)

This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).]

Block (BLOCK)

The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0 - Address is not blocked.

1 - Drop a packet with a matching source or destination address (secure must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/ Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

Secure (SECURE)

This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry PORT_NUMBER.

0 - Received port number is a don't care.

1 - Drop the packet if the received port is not the secure port for the source address and do not update the address (block must be zero)

Unicast Type (UNICAST_TYPE)

Member

VLAN Member list - This field indicates which port(s) are a member of the associated VLAN.

LmtNxtHdr

VLAN Limit Next Header Control - Causes frames to be dropped if the Protocol/Nxt Header does not match the ALE_NXT_HDR register values

UregIdx

VLAN Unregister Multicast Index - Index into VLAN_Mask_Mux register array that is used to create the unregistered multicast flood mask.

fwdutag

VLAN Forward Untagged Egress - Causes the packet VLAN tag to be removed on egress for the specified port(s).

NoFrag

LAN No IPv4 Fragmented frames Control - Causes IPv4 fragmented IP frames to be dropped.

RegIdx

VLAN Registered Multicast Index - Index into VLAN_Mask_Mux register array that is used to create the registered multicast flood mask.

iVLANID

Inner VLAN ID - This is the 12-bit Inner VLAN ID, normally referred to as C-VLANID

oVLANID

Outer VLAN ID - This is the 12-bit Outer VLAN ID, normally referred to as S-VLANID

IngressChk

VLAN Ingress Check - When set, if the receive port is not a member of this VLAN then the packet is dropped. This is similar to the vid_ingress_check bit in the ale_port_control register except this check is for this VLAN only (not all VLANs).

NoLrnMsk

VLAN No Learn Mask - When a bit is set in this mask, a packet with an unknown source address received on the associated port will not be learned (i.e. When a VLAN packet is received and the source address is not in the table, the source address will not be added to the table).

Inore Bits - Indicates the number of lower address bits (IPv4 or IPv6) to be ignored starting at bit zero. Ignored bits must be zero value in the table entry

9.4.7.1.7 ALE Policing and Classification

The ALE has a number of configurable policer engines. Each policer engine can be used for classification and or policing. Policing is an extension of the classifier function that allows for color marking and rate limiting due to classifier bandwidth measurement thresholds. Any policer engine can be used for classification alone by not using the bandwidth limiting thresholds. The policers_div_8 field in the ALE_Status register indicates the number of policers available to be used for classification or policing.

Each policer can be enabled to match on one or more of any of the below packet fields for classification. All but Port and Priority are index references to the ALE table entries.

ALE Policing

The policing function on each policer engine is implemented as dual-counter three-color marking engine as described in the IETF RFC2698. The first counter is the committed information rate (CIR) counter and the second counter is the peak information rate (PIR) counter. The policing function can use either or both counters. Based on the counter values the packet color is determined. The color is used to determine whether the packet is dropped or forwarded. The ALE has a local feature that can drop packets regardless of queue state.

The policing rates are determined by the below equations:

CIR policing rate in Mbit/s = ((ALE frequency in Mhz) * cir_idle_inc_val) / 32768

PIR policing rate in Mbit/s = ((ALE frequency in Mhz) * pir_idle_inc_val) / 32768

Each policer has 10 different match operations (see below Classification). Since multiple policing entries can be hit on a single packet this provides the ability to create precise traffic stream control.

9.4.7.1.7.1 ALE Classification

Each policer can be enabled to classify on one or more of any of the below packet fields for classification or policing. All but Port and Priority are index references to the ALE table entries.

- Port or Trunk Group Number
- Priority extracted from VLAN, mapped from DSCP if enabled or Default Port Priority
- Organization Network Unique identifier - ONU
- Destination Address - DA
- Source Address - SA
- Outer VLANID - S-VLANID
- Inner VLANID - C-VLANID
- Ether Type
- IP Source Address - IPSA with full CIDR masking for IPv4 and IPv6
- IP Destination Address - IPSA with full CIDR masking for IPv4 and IPv6

Multiple classifiers can match on a single packet. For example a classifier can be enabled to match on priority while another classifier could match on IP address. The ALE will return to the switch the highest classifier entries thread ID that matched with an enabled thread ID number. This could be used to further host routing of the packet.

9.4.7.1.7.1.1 Classifier to CPPI Transmit Flow ID Mapping

The ALE can generate a 6-bit transmit CPPI Flow ID based on classifier matches that can be used instead of the switch default transmit Flow ID mapping. The switch default flow ID is the remapped received packet priority (0 to 7). Thread and flow ID are used interchangeably for this since there is a single hardware thread (TXST_THREAD_MREADY) but there are 6-bits of FLOW_ID in the transmit CPPI INFO word 0. When enabled, the highest classifier match can map to a particular 6-bit flow ID value that is associated with the classifier. The ALE also supports an optional ALE default thread/flow ID value in the event that no classifiers match. Each thread/flow ID, including the ALE default thread/flow ID, has an enable such that the ALE default thread/Flow ID is used if enabled and if no matches occur (instead of the remapped received packet priority). If the ALE default is not enabled and no matches occur then the switch default value will be used. If multiple classifier matches occur, the highest match with a thread enable bit set will be used. The resultant flow ID has the CPSW_P0_FLOW_ID_OFFSET_REG register value added to it to determine the actual value in the INFO 0 Flow ID field.

Three registers are used for ALE classification thread/flow ID mapping configuration (CPSW_ALE_THREAD_DEF_REG, CPSW_ALE_THREAD_CTL_REG and CPSW_ALE_THREAD_VAL_REG). The three thread mapping registers are used independently and are separate from the other ALE policing registers. The CPSW_ALE_THREAD_CTL_REG register allows the CPSW_ALE_THREAD_VAL_REG register contents to be written to the selected classifier. There is a single CPSW_ALE_THREAD_DEF_REG that is used for all classifiers. The thread mapping registers can be written or changed at any time but any packets that are already processed will not have their thread altered.

9.4.7.1.8 Mirroring

The ALE supports three mirroring modes: destination port, source port and or table entry.

Destination port mirroring allows packets from any ingress port or trunk which ends up switching to a particular egress destination port or trunk to be mirrored to yet another egress destination port or trunk. For example any traffic from any port that is switched to port 'A' can be also mirrored to port 'B'. (MIRROR_DP=A, MIRROR_DEN=1h, MIRROR_TOP=B in the ALE_CONTROL register).

Source port mirroring allows packets received on any enabled ingress source port or trunk to be switched to the mirror egress port as well as the actual egress destination ports. For example traffic received on ingress port 'A' can be switched to egress port 'B' as well as the intended egress destination port.(MIRROR_SP=1h in the ALE_PORTn_CONTROL register, MIRROR_SEN=1h, MIRROR_TOP=B in the ALE_CONTROL register).

Table entry mirroring allows for any MAC Address, MAC Address with VLAN, ONU Address or VLAN entry that matches on ingress to be switched to the egress destination as well as the actual egress destination. For example all traffic for VLAN ID of 35 can be mirrored to port 'B'. That is any traffic switched on VLAN ID of 35 will be mirrored. ({VLAN ID of 35 in ALE Table entry index=C}, MIRROR_MIDX=C, MIRROR_MEN=1h, MIRROR_TOP=B)

In the event that mirrored packets are mirrored to or from a port that is also the mirror port the packet will not be duplicated or marked as a mirror packet since the packet has already been on the port as ingress or egress. The packet sent to the mirror port may have modified VLAN info based on the port and VLAN lookup table entries. The mirror port need not be a member of the VLAN ID it is mirroring, the ALE will forward traffic to the mirror port after ingress and egress filters are applied.

The switch may decide to drop any mirror traffic based on switch buffer thresholds as to prevent required traffic from becoming congested.

Port mirroring is controlled by register fields in ALE_CONTROL, ALE_CONTROL2 and the port control registers.

- MIRROR_DP - The destination port that will have its traffic mirrored (ALE_CONTROL_REG register).
- MIRROR_TOP - The port to which mirrored traffic is sent (ALE_CONTROL_REG register).
- MIRROR_MEN - The enable for mirroring traffic that matches a supported lookup table entry (ALE_CONTROL_REG register).
- MIRROR_DEN - The Enable for destination port mirroring (ALE_CONTROL_REG register).
- MIRROR_SEN - The Enable for source port mirroring (ALE_CONTROL_REG register).
- MIRROR_MIDX - The index of a lookup table entry that will be mirrored ALE_CONTROL2_REG register).
- Px_MIRROR_SP - The enable for the Source port to be mirrored. Although multiple source ports can be mirrored concurrently, a mirror traffic bandwidth issue may occur on the mirror egress port (ALE_PORTn_CONTROL register).

9.4.7.1.9 Trunking

The ALE supports port trunking of any port in any of four trunk groups. That is, four trunk groups can be supported with up to eight ports in each trunk group. There are no port adjacency rules for trunk groups. When ports are a member of a trunk group, addresses added and used in the lookup table will refer to the trunk group rather than port as indicated in the lookup table entries. If ports are removed from a trunk group, the ALE will redistribute the traffic based on the crc polynomial of enabled fields and the remaining ports within the trunk group. A trunk group may contain only one port. Packet priority, DA, SA, C-VLAN ID, IPv4SA, IPv4DA, IPv6SA, and/or IPv6DA can be used in the hash to generate destination port within the trunk group. If all hash enables are disabled, the packet can be directed to a particular port within the trunk group which allows for testing paths etc. A host directed frame is directed to the directed port regardless of trunk group settings.

Trunking is controlled through fields in the ALE_CONTROL2_REG register and in each ALE ALE_PORTn_CONTROL_REG register:

- TRK_EN_DST - Enable destination address hashing for trunk port calculation.
- TRK_EN_SRC - Enable source address hashing for trunk port calculation.
- TRK_EN_PRI - Enable priority hashing for trunk port calculation.
- TRK_EN_VLAN - Enable inner C-VLAN ID hashing for trunk port calculation.
- TRK_EN_SIP - Enable source IP address hashing for trunk port calculation.
- TRK_EN_DIP - Enable destination IP address hashing for trunk port calculation.
- TRK_BASE - Hashing formula starting value and test port offset.
- TRUNK_EN - Enable this port as a trunk group
- TRUNK_NUMBER - Trunk group number defines this port as a member of a particular trunk group.

9.4.7.1.10 DSCP

The ALE can map DSCP field to priority prior to classification matching. When enabled the DSCP is mapped via 64 priority entries such that any DSCP value can be mapped to any of the eight priorities. When a packet is received without a VLAN priority this remapped priority can be used instead of the default Port VLAN priority field. See P0_RX_DSCP_MAP_REG and PN_RX_DSCP_MAP_REG registers in the Register Manual section for DSCP mapping.

9.4.7.1.11 Packet Forwarding Processes

There are four processes that an incoming received packet may go through to determine packet forwarding. The processes are *Ingress Filtering*, *VLAN_Aware Lookup*, *VLAN_Unaware Lookup*, and *Egress.*

Packet processing begins in the Ingress Filtering process. Each port has an associated packet forwarding state that can be one of four values (Disabled, Blocked, Learning, or Forwarding). The default state for all ports is Disabled. The host sets the packet forwarding state for each port.

In the packet ingress process (receive packet process), there is a forward state test for unicast destination addresses and a forward state test for multicast addresses. The multicast forward state test indicates the port states required for the receiving port in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state for the packet to be forwarded for transmission. The MCAST_FWD_STATE indicates the required port state for the receiving port as indicated in the preceding table. The unicast forward state test indicates the port state required for the receiving port in order to forward the unicast packet. The transmit port must be in the Forwarding state in order to forward the packet. The BLOCK and SECURE bits determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state. The transmit port must be in the Forwarding state regardless. The forward state test used in the ingress process is determined by the destination address packet type (multicast/unicast).

In general, packets received with errors are dropped by the address lookup engine without learning, updating, or touching the address. The error condition and the abort are indicated by the Ethernet port to the ALE. Packets with errors may be passed to the host (not aborted) by a Ethernet port, if the port has the RX_CMF_EN, RX_CEF_EN, or RX_CSF_EN bit(s) set in the CPSW_PN_MAC_CONTROL_REG register. Error packets that are passed to the host by the Ethernet port are considered to be bypass packets by the ALE and are sent only to the host. Error packets do not learn, update, or touch addresses regardless of whether they are aborted or sent to the host. Packets with long or short errors received by the host are dropped. Packets with errors received by the host are forwarded as normal.

The following control bits are in the CPSW PN_MAC_CONTROL_REG register:

- [22] RX_CEF_EN - enables frames that are fragments, long, jabber, CRC, code, and alignment errors to be forwarded
- [23] RX_CSF_EN - enables short frames to be forwarded
- [24] RX_CMF_EN - enables MAC control frames to be forwarded.

9.4.7.2 CPPI CPDMA Host Interface

9.4.7.2.1 Functional Operation

For legacy reasons this document uses FHost (“cpsw ingress **F**rom **Host**”) interchangeably with host receive and THost (“cpsw egress **T**o **Host**”) interchangeably with host transmit.

Host Software sends and receives network frames via the CPDMA CPPI 3.0 compliant host interface. The host interface includes module registers and host memory data structures. The host memory data structures are buffer descriptors and data buffers. Buffer descriptors are data structures that contain information about a single data buffer. Buffer descriptors may be linked together to describe frames or queues of frames for transmission of data from the host to Ethernet and free buffer queues available for packet data from Ethernet to the host.

After reset, initialization, and configuration the host may initiate CPDMA host interface operations. FHost DMA operations (from host to Ethernet) are initiated by host writes to the appropriate FHost channel head descriptor pointer. The FHost DMA controller then fetches the first packet in the packet chain from memory in accordance with CPPI 3.0 protocol and proceeds with packet operations. The DMA controller fetches the packet data in 64-byte (maximum) bursts.

Host CPDMA THost operations are initiated by host writes to the appropriate THost channel head descriptor pointer after host initialization and configuration. The THost DMA controller writes Ethernet received packet data to external host memory in accordance with CPPI 3.0 protocol.

9.4.7.2.2 THost CPDMA Interface

The THost DMA (Ethernet to host) is an eight channel CPPI 3.0 compliant interface. Each priority/channel (priority and channel are used interchangeably) has a single queue for frame reception.

9.4.7.2.2.1 THost CPDMA Host Configuration

To configure the CPDMA for THost operations the host must perform the following:

- Initialize the CPDMA_TH(0..7)_HDP Registers to zero.
- Enable the desired THost interrupts in the CPDMA_TH_INTSTAT_SET register.
- Write the CPDMA_TH_BUFFER_OFFSET register value.
- Setup the channel(s) buffer descriptors in host memory as required by CPPI.
- Enable the CPDMA controller by setting the TH_EN bit in the CPDMA_TH_CONTROL register.

9.4.7.2.2.2 THost CPDMA Buffer Descriptors

A THost buffer descriptor is a contiguous block of four 32-bit data words aligned on a 32-bit word boundary.

Table 9-20. THost Buffer Descriptor format

Word Offset	Bit fields																															
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Field	Description
next_descriptor_pointer	Next Descriptor Pointer - The 32-bit word aligned memory address of the next buffer descriptor in the RX queue. This is the mechanism used to reference the next buffer descriptor from the current buffer descriptor. If the value of this pointer is zero then the current buffer is the last buffer in the queue. The host sets the **next_descriptor_pointer**.

Field	Description
buffer_pointer	Buffer Pointer - The byte aligned memory address of the buffer associated with the buffer descriptor. The host sets the **buffer_pointer**.
buffer_offset	Buffer Offset – Indicates how many unused bytes are at the start of the buffer. The buffer offset is reduced to 12-bits. A value of 0x0000 indicates that there are no unused bytes at the start of the buffer and that valid data begins on the first byte of the buffer. A value of 0x000F (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. The port writes the **buffer_offset** with the value from the **CPDMA_TH_BUFFER_OFFSET** register value. The host initializes the **buffer_offset** to zero for free buffers. The **buffer_length** must be greater than the **CPDMA_TH_BUFFER_OFFSET** register value. The buffer offset is valid only on **sop**.
buffer_length	Buffer Length – Indicates how many valid data bytes are in the buffer. The buffer length is reduced to 12-bits. Unused or protocol specific bytes at the beginning of the buffer are not counted in the Buffer Length field. The host initializes the **buffer_length**, but the port may overwrite the host initiated value with the actual buffer length value on SOP and/or EOP buffer descriptors. SOP buffer length values will be overwritten if the packet size is less than the size of the buffer or if the offset is nonzero. EOP buffer length values will be overwritten if the entire buffer is not filled up with data. The **buffer_length** must be greater than zero.
sop	Start of Packet - Indicates that the descriptor buffer is the first buffer in the packet. The port sets the **sop** bit. 0 - Not start of packet buffer 1 - Start of packet buffer
eop	End of Packet - Indicates that the descriptor buffer is the last buffer in the packet. The port sets the **eop** bit. 0 - Not end of packet buffer. 1 - End of packet buffer.
ownership	Ownership - Indicates ownership of the packet and is valid only on **sop**. This bit is set by the host and cleared by the port when the packet has been transferred. The host uses this bit to reclaim buffers. 0 - The packet is owned by the host 1 - The packet is owned by the port
eoq	End Of Queue - Set by the port to indicate that the RX queue empty condition exists. This bit is valid only on **eop**. The port determines the end of queue condition by a zero **next_descriptor_pointer**. 0 – The RX queue has more buffers available for reception. 1 - The Descriptor buffer is the last buffer in the last packet in the queue.
teardown_complete	Teardown Complete – Set by the port to indicate that the host commanded teardown process is complete, and the channel buffers may be reclaimed by the host. This bit is valid only on **sop**. 0 - The port has not completed the teardown process. 1 - The port has completed the commanded teardown process.
passed_crc	Passed CRC – Set by the port to indicate that the CRC was passed with the data. The **Packet_Length** includes the CRC bytes. The **passed_crc** bit is valid only on SOP. The **p0_tx_crc_remove** bit in the **CPDMA_Control** register determines if CPPI THost packets have a CRC included or not.
long	Jabber Frame – Indicates that the frame is a jabber frame and was not discarded because **rx_cef_en** was set in the ingress port **Pn_MAC_Control** register. Valid only on SOP.
short	Fragment Frame – Indicates that the frame is a fragment and was not discarded because **rx_cef_en** was set in the ingress port **Pn_MAC_Control** register. Valid only on SOP.
mac_ctl	Control Frame – Indicates that the frame is a MAC control frame and was not discarded because the **rx_cmf_en** bit was set inthe ingress port **Pn_Mac_Control** register. Valid only on SOP.

Field	Description
overrun	Overrun – Set by the port to indicate that the frame reception was aborted due to THost buffer overrun. This bit is valid only on SOP. 0 – no overrun occurred on the packet 1 – The packet was aborted due to overrun
pkt_error	Packet Contained Error on Ethernet Ingress. This field is valid on SOP. – 00 – no error 01 – CRC error on ingress 10 – Code error on ingress 11 – align error on ingress
vlan_encap	VLAN Encapsulated Packet – Indicates when set that the packet data contains a 32-bit VLAN header word that is included in the packet byte count. This field is set by the port to be the value of the **CPDMA_Control** register **th_vlan_encap** bit. If both **th_vlan_encap** and **th_ts_encap** are set then the VLAN is first. This encapsulated word also contains the ALE classification FLOW (threadval). This bit is valid on SOP.
ts_encap	Timestamp Encapsulated Packet – Indicates when set that the packet data contains a 64-bit timestamp (two 32-bit words with the lower 32-bit word first) that is included in the packet byte count. This field is set by the port to be the value of the **CPDMA_Control** register **th_ts_encap** bit. If both **th_vlan_encap** and **thost_ts_encap** are set then the VLAN is first. This bit is valid on SOP.
chksum_encap	Checksum Encapsulated Packet – Indicates when set that the packet data contains 4-bytes of THost checksum information at the end of the packet (last 4 bytes). The packet length includes the checksum bytes.
memory_protect_error	Memory Protect Error – An error was detected in the packet Castignoli protect CRC. The Packet should be dropped by the host.
from_port	From Port – Indicates the Ethernet ingress port number. This field is valid only on SOP.
packet_length	Packet Length – Specifies the number of bytes in the entire packet. Offset bytes are not included. The sum of the buffer_length fields should equal the packet_length. Valid only on SOP.

9.4.7.2.2.3 THost CPDMA Channel Teardown

The host commands a THost channel teardown by writing the channel number to the **CPDMA_TH_TEARDOWN** register. When a teardown command is issued to an enabled THost channel the following will occur:

- Any current frame in reception will complete normally.
- The teardown_complete bit will be set in the next THost buffer descriptor in the chain if there is one.
- The channel head descriptor pointer will be cleared to zero
- A THost interrupt for the channel will be issued to the host.
- The host should acknowledge a teardown interrupt with a 0xfffffffc acknowledge value

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by the set teardown complete buffer descriptor bit. The port does not clear any channel enables due to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with a 0xfffffffc acknowledge value (note that there is no buffer descriptor in this case). Software may read the interrupt acknowledge location to determine if the interrupt was due to a commanded teardown. The read value will be 0xfffffffc if the interrupt was due to a teardown command.

9.4.7.2.3 FHost CPDMA Interface

The FHost DMA is an eight channel CPPI 3.0 compliant interface. Priority between the eight queues may be either fixed or round robin as selected by **FH_PTYPE** in the **CPDMA_Control** register. If the priority type is fixed, then channel 7 has the highest priority and channel 0 has the lowest priority. Round robin priority proceeds from channel 0 to channel 7. Packet Data transfers occur on the TX_VBUSP interface in 64-byte maximum burst transfers. Any packet can be designated by the host to generate a host timesync event on Ethernet egress by setting the **host_event** bit in the packet buffer descriptor.

9.4.7.2.3.1 FHost CPDMA Host Configuration

To configure the CPDMA for FHost operations the host must do the following:

- Initialize the CPDMA_FH(0..7)_HDP registers to a zero value.
- Enable the desired ingress interrupts in the CPDMA_FH_INTSTAT_MASKED_SET register.
- Setup the transmit channel(s) buffer descriptors in host memory as defined in CPPI 3.0.
- Configure and enable the ingress operation as desired in the CPDMA_FH_Control register.
- Write the appropriate CPDMA_FH(0..7)_HDP registers with the appropriate values to start packet operations.

9.4.7.2.3.2 FHost CPDMA Buffer Descriptors

An FHost buffer descriptor is a contiguous block of four 32-bit data words aligned on a 32-bit word boundary.

Table 9-21. FHost Buffer Descriptor format

Word Offset	Bit fields																															
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

3	sop	eop	ownership	eoq	teardown_complete	pass_crc	crc_type	reserved				to_port_en	to_port				host_event	chksum_encap	reserved			packet_length										

Name	Description
next_descriptor_pointer	Next Descriptor Pointer - The 32-bit word aligned memory address of the next buffer descriptor in the FHost queue. This is the mechanism used to reference the next buffer descriptor from the current buffer descriptor. If the value of this pointer is zero then the current buffer is the last buffer in the queue. The host sets the **next_descriptor_pointer**.
buffer_pointer	Buffer Pointer - The byte aligned memory address of the buffer associated with the buffer descriptor. The host sets the **buffer_pointer**.
buffer_offset	Buffer Offset – Indicates how many unused bytes are at the start of the buffer. A value of 0x0000 indicates that no unused bytes are at the start of the buffer and that valid data begins on the first byte of the buffer. A value of 0x000F (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. The host sets the **buffer_offset** value (which may be zero to the buffer length minus 1). Valid only on **sop**.
buffer_length	Buffer Length – Indicates how many valid data bytes are in the buffer. Unused or protocol specific bytes at the beginning of the buffer are not counted in the Buffer Length field. The host sets the **buffer_length.** The **buffer_length** must be greater than zero.

Name	Description
sop	Start of Packet - Indicates that the descriptor buffer is the first buffer in the packet. 0 - Not start of packet buffer 1 - Start of packet buffer
eop	End of Packet - Indicates that the descriptor buffer is the last buffer in the packet. 0 - Not end of packet buffer. 1 - End of packet buffer.
ownership	Ownership - Indicates ownership of the packet and is valid only on **sop**. This bit is set by the host and cleared by the port when the packet has been transferred. The host uses this bit to reclaim buffers. 0 - The packet is owned by the host 1 - The packet is owned by the port
eoq	End Of Queue - Set by the port to indicate that all packets in the queue have been transferred and the FHost queue is empty. End of queue is determined by the port when the **next_descriptor_pointer** is zero on an **eop** buffer. This bit is valid only on **eop**. 0 - The FHost queue has more packets to transfer. 1 - The Descriptor buffer is the last buffer in the last packet in the queue.
teardown_complete	Teardown Complete – Set by the port to indicate that the host commanded teardown process is complete, and the channel buffers may be reclaimed by the host. This bit is valid only on **sop**. 0 - The port has not completed the teardown process. 1 - The port has completed the commanded teardown process.
crc_type	CRC Type – 0 – Ethernet CRC 1 – Castignoli CRC (if **$CPPI_Cast** = 1)
pass_crc	Pass CRC – Valid only on SOP 0 – A CRC is not included with the packet data. The Ethernet port(s) will generate the CRC on Ethernet egress. A CRC (or placeholder) at the end of the data is allowed, but not required, and the **buffer_count** and **packet_length** fields should not include the CRC bytes if they are present. 1 – A CRC is included with the host packet data. The **packet_length** and **buffer_count** fields should include the four CRC bytes. The host supplied CRC should be in the last four bytes of the data.
to_port	To Port – Port number to send the directed packet to. This field is set by the host. This field is valid on SOP. Directed packets go to the directed port, but an ALE lookup is performed to determine untagged egress in VLAN_AWARE mode. 1 – Send the packet to port 1 if **to_port_en** is asserted. 2 – Send the packet to port 2 if **to_port_en** is asserted.
to_port_en	To Port Enable – Indicates when set that the packet is a directed packet to be sent to the **to_port** field port number. This field is set by the host. The packet is sent to one port only (index not mask). This bit is valid on SOP. 0 – not a directed packet 1 – directed packet
host_event	Host Timesync Event – Generate a host timesync event on Ethernet egress. The upper 28-bits of the packet SOP buffer descriptor address are the domain[7:0], message_type[3:0], and sequence_id[15:0] in that order. 0 – The packet will not generate a host event on Ethernet egress 1 – The packet will generate a host event on Ethernet egress

Name	Description
chksum_encap	Checksum Encapsulated Packet – Indicates when set that the packet data contains 4-bytes of FHost checksum information at the start of the packet (first 4 bytes). The packet length includes the checksum bytes.
packet_length	Packet Length – Specifies the number of bytes in the entire packet. Offset bytes are not included. The sum of the buffer_length fields should equal the packet_length. Valid only on SOP. The packet length must be greater than zero. The packet data will be truncated to the packet length if the packet length is shorter than the sum of the packet buffer descriptor buffer lengths. A host error occurs if the packet length is greater than the sum of the packet buffer descriptor buffer lengths.

9.4.7.2.3.3 FHost CPDMA Channel Teardown

The host commands a FHost channel teardown by writing the channel number to the **CPDMA_FH_Teardown** register. When a teardown command is issued to an enabled FHost channel the following will occur:

- Any frame currently in transmission will complete normally
- The teardown complete bit will be set in the next sop buffer descriptor (if there is one).
- The channel head descriptor pointer will be set to zero.
- An interrupt will be issued to inform the host of the channel teardown.
- The host should acknowledge a teardown interrupt with a 0xfffffffc acknowledge value

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by the set teardown complete buffer descriptor bit. The port does not clear any channel enables due to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with a 0xfffffffc acknowledge value (note that there is no buffer descriptor in this case). Software may read the interrupt acknowledge location to determine if the interrupt was due to a commanded teardown. The read value will be 0xfffffffc if the interrupt was due to a teardown command.

9.4.7.2.4 VLAN Aware Mode

The CPSW is in VLAN aware mode when the CPSW Control register **vlan_aware** bit is set. In VLAN aware mode port 0 THost packets may or may not be VLAN encapsulated depending on the CPDMA_Control register **th_vlan_encap** bit. The header packet VLAN is generated as described in later sections of this specification. VLAN encapsulated receive packets have a 32-bit VLAN header encapsulation word added to the packet data. VLAN encapsulated packets are specified by a set **vlan_encap** bit in the packet buffer descriptor. The VLAN encapsulation header is included in the packet length and has the below format:

<table>
<tr><th colspan="32">32-bit VLAN Header Encapsulation Word</th></tr>
<tr><th>31</th><th>30</th><th>29</th><th>28</th><th>27</th><th>26</th><th>25</th><th>24</th><th>23</th><th>22</th><th>21</th><th>20</th><th>19</th><th>18</th><th>17</th><th>16</th><th>15</th><th>14</th><th>13</th><th>12</th><th>11</th><th>10</th><th>9</th><th>8</th><th>7</th><th>6</th><th>5</th><th>4</th><th>3</th><th>2</th><th>1</th><th>0</th></tr>
<tr><td colspan="3">hdr_pkt_priority</td><td>hdr_pkt_cfl</td><td colspan="12">hdr_pkt_vid</td><td colspan="6">flow</td><td colspan="2">pkt_type</td><td colspan="8">reserved</td></tr>
</table>

Field	Description
hdr_pkt_priority	Header Packet VLAN priority (7 is highest priority)
hrd_pkt_cfi	Header Packet VLAN CFI bit. The
hdr_pkt_vid	Header Packet VLAN ID.
flow	FLOW – A nonzero value indicates that the ALE matched a classifier with the **flow** (threadval).
pkt_type	Packet Type – Indicates whether the packet is a VLAN tagged, priority tagged or non-tagged packet. 00 – VLAN tagged packet 01 – reserved 10 – priority tagged packet 11 – non-tagged packet

9.4.7.2.5 VLAN Unaware Mode

The CPSW is in VLAN unaware mode when the CPSW Control register **vlan_aware** bit is cleared. Port 0 THost packets (egress) may or may not be VLAN encapsulated depending on the CPSW Control register **th_vlan_encap** bit.

9.4.7.2.6 CPDMA Command IDLE

The **cmd_idle** bit in the **CPDMA_Control** register allows CPDMA operation to be suspended. When the idle state is commanded, the CPDMA will stop processing THost and FHost frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For FHost, any frame in process will be completed. For THost, frames that are detected by the CPDMA after the suspend state is entered are ignored. No statistics will be kept for ignored frames. Commanded idle is similar in operation to emulation control and clock stop.

9.4.7.2.7 CPDMA CPPI 3.0 Interface Bandwidth

The HOST CPPI 3.0 FHost and THost interfaces are capable of supporting linerate on the Ethernet ports provided that the clock frequency is sufficient, and provided that the Host master VBUSP read/write latency is low.

9.4.8 CPPI Checksum Offload

The CPPI host port can be enabled to perform checksum offload on host port packet ingress and egress. UDP and TCP over IPV4 and IPV6 are supported. For the purposes of checksum description, the first packet byte (the first byte of the destination address) is byte 1 (not byte 0). That is, a 64 byte packet goes from byte 1 to byte 64. For all packet types, the **s_cn_switch** bit must be set for the **vlan_ltype_outer** to be supported. Because it's not now a dual vlan switch, A C-switch cannot have an outer VLAN. An S-switch can have an inner, an outer, or both (outer then inner).

9.4.8.1 CPPI THost Checksum Offload

When **p0_tx_chksum_en** is set in **P0_Control**, IPV4 and IPV6 UDP and TCP packets received on any Ethernet port and destined for port 0 egress are checked for correct checksum as described below. The EOP Thost buffer descriptor bit **chksum_encap** indicates whether or not the THost checksum information is included with the THost egress packet or not. If the checksum information is included in the packet the **packet_length** includes the four checksum information bytes. The byte counts below are shown for packets with no VLAN's. The byte counts vary with one or two packet VLANs. Packets received on an Ethernet port with errors are not checked for a correct checksum if they are passed to the host (no checksum information with the error packet).

9.4.8.1.1 IPV4 UDP

- Byte 15 Upper Nibble = 4 for IPV4
- Byte 15 Lower Nibble = IHL - Nibble with number of 32-bit words in IPV4 header (5 to 15 supported).
- Bytes 20:21 = fragment[15:0] – Bit 13 is the MF bit and bits 12:0 are the Fragment offset. A packet is a fragment if the MF bit is set or if the fragment offset is non-zero. The first packet fragment has MF=1 with a zero offset. Middle fragments have MF=1 with a nonzero offset. The last packet fragment has MF=0 with a

nonzero offset. Non-fragmented packets have MF=0 and a zero offset. A count is output for packet fragments but no errors are reported. First fragments have the UDP header included in the count. Middle and last fragments have only data included in the count (there is no UDP header).
- Byte 24 = 0x11 for UDP protocol.
- Received packet UDP checksum of zero means that there is no IPV4 checksum sent with the packet so no error will be issued.
- Received packet UDP checksum of 0xffff means that the checksum was calculated to be 0xffff or 0x0000 but was sent in the transmitted packet as 0xffff by the sending originating entity.

9.4.8.1.2 IPV4 TCP

- Byte 15 Upper Nibble = 4 for IPV4
- Byte 15 Lower Nibble = IHL - Nibble with number of 32-bit words in IPV4 header (5 to 15 supported).
- Bytes 20:21 = fragment[15:0] – Bit 13 is the MF bit and bits 12:0 are the Fragment offset. A packet is a fragment if the MF bit is set or if the fragment offset is non-zero. The first packet fragment has MF=1 with a zero offset. Middle fragments have MF=1 with a nonzero offset. The last packet fragment has MF=0 with a nonzero offset. Non-fragmented packets have MF=0 and a zero offset. A count is output for packet fragments but no errors are reported. First fragments have the UDP header included in the count. Middle and last fragments have only data included in the count (there is no TCP header).
- Byte 24 = 0x06 for TCP protocol.

9.4.8.1.3 IPV6 UDP

- Byte 15 upper nibble = 6 for IPV6.
- Byte 21 = 0x11 for UDP protocol as next header.
- Fragment extension headers are supported. First fragments have a fragment extension header (byte 21 = 0x2c) followed by a UDP header (byte 55 = 0x11). Middle and last fragments have a fragment extension header followed by data only (no UDP header). The first packet fragment has MF=1 with a zero offset. Middle fragments have MF=1 with a nonzero offset. The last packet fragment has MF=0 with a nonzero offset. Non-fragmented packets do not have a fragment extension header. A count is output for packet fragments but no errors are reported.
- Received packet UDP checksum of zero means that there is no IPV6 checksum sent with the packet so no error will be issued.
- Received packet UDP checksum of 0xffff means that the checksum was calculated to be 0xffff or 0x0000 but was sent in the transmitted packet as 0xffff by the sending originating entity.

9.4.8.1.4 IPV6 TCP

- Byte 15 upper nibble = 6 for IPV6.
- Byte 21 = 0x06 for TCP protocol as next header.
- Fragment extension headers are supported. First fragments have a fragment extension header (byte 21 = 0x2c) followed by a UDP header (byte 55 = 0x06). Middle and last fragments have a fragment extension header followed by data only (no TCP header). The first packet fragment has MF=1 with a zero offset. Middle fragments have MF=1 with a nonzero offset. The last packet fragment has MF=0 with a nonzero offset. Non-fragmented packets do not have a fragment extension header. A count is output for packet fragments but no errors are reported.

9.4.8.1.5 THost Checksum Encapsulation Word

The 4-byte checksum encapsulation word is included as the last 4-bytes of the THost packet data when EOP buffer descriptor **chksum_encap** is set. The **packet_length** includes the four encapsulation bytes.

Field	Name	Description
31:21	reserved	
20	ipv4_valid	IPV4 Valid – An IPV4 TCP or UDP packet was detected
19	**ipv6_valid**	IPV6 Valid – An IPV6 TCP or UDP Packet was detected
18	tcp_udp_n	TCP or UDP packet – Valid only when either the **ipv4_valid** or **ipv6_valid** bits are set. 0 – Indicates UDP packet was detected. 1 – Indicates TCP packet was detected.
17	fragment	Fragment – Indicates that an IP fragment was detected. Valid only when when either the **ipv4_valid** or **ipv6_valid** bits are set.
16	checksum_error	Checksum Error detected. Valid only when either the **ipv4_valid** or **ipv6_valid** bits are set.
15:0	checksum_add	Checksum Add Value – This is the value that was summed during the checksum computation. This value is 0xffff for IPV4/6 UDP/TCP packets with no checksum error.

9.4.8.2 CPPI FHost Checksum Offload

Packets sent from host port 0 (switch ingress) to any Ethernet port can have a checksum calculated and inserted into the Ethernet egress packet. The **rx_chksum_en** bit in the **P0_CONTROL** register must be set for receive checksum operation to be enabled. When enabled and when the **chksum_encap** SOP FHost buffer descriptor is set, the first four packet bytes contain the checksum information which determines how the checksum is calculated. The **checksum_result** field determines where the checksum is inserted in the egress packet. The checksum result location is adjusted by the egress port if a VLAN is to be inserted or removed on Ethernet port egress.

9.4.8.2.1 FHost Checksum Encapsulation Word

The 4-byte FHost checksum encapsulation word is included as the first four bytes of the packet data when **chksum_encap** is set in the FHost SOP buffer descriptor. The **packet_length** includes the four checksum encapsulation bytes.

Field	Name	Description
31:24	**checksum_result**	Checksum Result Byte Location – This is the packet byte number where the checksum result will be placed in the egress packet. The first packet byte which is the first byte of the destination address is byte 1 (not byte zero).
23:16	**checksum_start_byte**	Checksum Start Byte – This is the packet byte number to start the checksum calculation on. The first packet byte is byte 1.
15	**chksum_inv**	Checksum Invert Zero – When set, a zero checksum value will be inverted and sent as 0xffff.
14	reserved	
13:0	checksum_bytecount	Checksum Byte Count – This is the number of bytes to calculate the checksum on. The outgoing Ethernet packet will have a checksum inserted when this value is non-zero.

9.4.9 Egress Packet Operations

Each CPSW egress port (Ethernet and Host) is capable of performing egress packet processing operations. **Intra**VLAN processing either adds, removes, or replaces VLAN information or does nothing. **Inter**VLAN routing allows hardware routing between a limited number of VLANs - thereby allowing high-bandwidth or other routing operations to be offloaded from software to the CPSW (hardware). IntraVLAN processing and InterVLAN routing operations are mutually exclusive. In addition, OAM loopback allows the loopback packet source and destination addresses can be swapped on egress to facilitate OAM or generic testing operations.

9.4.9.1 IntraVLAN Processing

All ports (Ethernet and CPPI) process packet VLAN's identically on cpsw egress. CPSW ingress packet VLAN's are not modified on ingress regardless of the port type or VLAN mode.

9.4.9.1.1 VLAN Unaware Mode

An egress port is operating in the VLAN unaware mode when the **VLAN_AWARE** bit in the **CPSW_Control** register is cleared to zero. In VLAN unaware mode, transmit (egress) packets are not modified on egress (no IntraVLAN processing).

9.4.9.1.2 VLAN Aware Mode

An egress port is operating in the VLAN aware mode when the **VLAN_AWARE** bit in the **CPSW_Control** register is set. In VLAN aware mode, transmitted packet data is changed depending on the packet type, the packet priority (**pkt_pri**), and the VLAN information as shown in the below tables. The **vlan_ltype_sel** value is selected by the **s_cn_switch** bit in the **CPSW_Control** register and is either the **vlan_ltype_inner** (0x8100 default)or **vlan_ltype_outer** (0x88a8 default) value. The **force_untagged_egress** bit comes from the Address Lookup Engine (ALE) lookup:

VLAN Aware Mode Non Tagged Transmit Packet Processing	
Insert VLAN Case	Non-tagged input packets have the header packet VLAN inserted when the **force_untagged_egress** bit in the transmit packet header (from the ALE) is de-asserted. **The vlan_ltype_sel** length/type is inserted after the source address followed by the two byte header packet VLAN. The header packet VLAN is composed of the **hdr_pkt_pri**, the **hdr_pkt_cfi**,and the **hdr_pkt_vid**. The packet length/type field is output four bytes later than it is input and is not removed or replaced.
No Change Case	Non tagged input packets are output unchanged when the **force_untagged_egress** transmit packet header bit is asserted.

VLAN Aware Mode Priority Tagged Transmit Packet Processing	
Replace PRI/VID Case	Priority tagged input packets have the packet VLAN ID (VID) and the packet priority replaced with the **hdr_pkt_vid** and the **hdr_pkt_pri** when the transmit packet header **force_untagged_egress** bit (from the ALE) is de-asserted.
Remove VLAN Case	Priority tagged input packets have the 4-byte packet VLAN information removed when the transmit packet header **force_untagged_egress** bit (from the ALE) is asserted. **The vlan_ltype_sel** length/type is removed as is the two byte packet VLAN. Input 64-67 byte priority tagged packets go out with the VLAN removed and padded to 64-bytes. The input CRC bytes are used as the pad data. Input 64-byte priority tagged packets use all four input CRC bytes as pad, input 65-byte priority tagged packets use three of the input CRC bytes as pad, and so on.

VLAN Aware Mode VLAN Tagged Transmit Packet Processing	
Replace PRI Case	VLAN tagged input packets are output with the packet priority replaced with the **hdr_pkt_pri** when the transmit packet header **force_untagged_egress** bit is de-asserted.
Remove VLAN Case	VLAN tagged input packets have the 4-byte packet VLAN information removed when the transmit packet header **force_untagged_egress** bit is asserted. **The vlan_ltype_sel** length/type is removed as is the two byte packet VLAN. Input 64-67 byte VLAN tagged packets go out with the VLAN removed and padded to 64-bytes. The input CRC bytes are used as the pad data. Input 64-byte VLAN tagged packets use all four input CRC bytes as pad, input 65-byte VLAN tagged packets use three of the input CRC bytes as pad, and so on. The output CRC is generated when the VLAN is removed.

VLAN tagged ingress packets of 64 to 67-bytes will be padded to 64-bytes on egress (Ethernet and CPPI port egress) if the VLAN is to be removed on egress.

9.4.9.2 ALE Egress Opcode Operations

The Address Lookup Engine (ALE) can be setup to pass an 8-bit opcode to the destination port(s) egress packet processing logic. InterVLAN routing and OAM Source/Destination address swap are supported operation codes as shown in the below table.

ALE Egress OP Code	Egress Operation
0x00	No egress opcode (NOP)
0x01	InterVLAN (route) opcode 1
0x02	InterVLAN (route) opcode 2
0x03	InterVLAN (route) opcode 3
0x04	InterVLAN (route) opcode 4
0x05-0xFE	reserved
0xFF	DA/SA Swap opcode

9.4.9.2.1 InterVLAN Routing

The CPSW is capable of InterVLAN routing with a limited number of routes (InterVLAN opcode 1 to 4). The Address Lookup Engine (ALE) determines an InterVLAN egress opcode for each packet to be VLAN routed via a classifier/policer configured for the route. Non VLAN routed packets do not have an InterVLAN (egress) opcode. The ALE classifier/policer can use the ingress packet destination address, source address, VLAN, IPDA, and/or

IPSA to determine if a packet is to be VLAN routed or not. If a packet is to be routed, then the InterVLAN opcode is used on Ethernet packet egress with a total of 4 available VLAN routes (opcodes) per egress port. Each InterVLAN routing opcode contains the below fields in the opcode's associated **Pn_InterVLAN_OPX_x** registers (where **x** = A to D):

Field	Description
da[47:0]	Destination Address
sa[47:0]	Source Address
vid[11:0]	VLAN ID
replace_da_sa	When set, the routed packet Destination Address is replaced with **da[47:0]** and the packet Source Address is replaced with **sa[47:0]** from InterVLAN opcode x (the selected egress opcode).
replace_vid	When set, Replace the packet VLAN ID with **vid[11:0]** from InterVLAN opcode x (the selected egress opcode).
dest_force_untagged_egress	Remove the VLAN on the egress routed packet when set (associated with the destination VLAN). **Note** The ALE **force_untagged_egress** bit from the ALE is for the source VLAN and is ignored for an InterVLAN routed packet. On InterVLAN routed packets this bit is used because it is associated with the destination vlan. This **dest_force_untagged_egress** bit would not be set by software if the destination VLAN is different from the port VLAN since that might cause leaky VLANs.
decrement_ttl	When set, the Time To Live (TTL) field in the header is decremented: • IPV4 – Decrement the TTL byte and update the Header Checksum • IPV6 – Decrement the Hop Limit. note: The ALE will send any IPv4/6 packet with a zero or one TTL field to the host. When this bit is cleared the TTL/Hop Limit fields are not checked or modified.

9.4.9.2.2 OAM Source and Destination Address Swap

To facilitate OAM or generic testing, the ALE can be configured to loopback packets from Ethernet receive to Ethernet Transmit. Packets destined for OAM loopback have only the source address and destination addresses swapped. No other egress processing is performed. The ALE does not perform lookups for a port in OAM loopback mode, but directed packets are transferred as normal.

9.4.10 IEEE 1588 Clock Synchronization Support

The CPSW supports 1588 clock synchronization (annex D, annex E, and annex F). Ethernet GMII Transmit and receive time sync operation are supported. Time sync is double-step on egress but may be single-step on ingress.

9.4.10.1 1588 Receive (Ingress) Packet Operation

There are two CPSW egress time sync interfaces for each Ethernet port. The first is the TS_RX_MII interface and the second is the TS_RX_DEC interface. Both interfaces are generated in the switch and are input to the CPTS module. There are register bits in the CPSW that control time sync operations in addition to the registers in the CPTS module. The TS_RX_MII interface issues a record signal along with a handle to the CPTS controller for each packet that is received. The record signal is a single clock pulse indicating that a receive packet has been detected at the associated port MII interface. The handle value is incremented with each packet and rolls over to zero after 15. There are 16 possible handle values so there can be a maximum of 16 packets “in flight” from the TS_RX_MII to the TS_RX_DEC block at any given time. A handle value is reused (not incremented) for any received packet that is shorter than about 31 octets (including preamble). Handle reuse on short packets prevents any possible overrun condition if multiple fragments are consecutively received. The TS_RX_MII logic is in the receive wireside clock domain. There is no decode logic in the TS_RX_MII to determine if the packet is a time sync event packet or not. Each received packet generates a record signal and new handle. The handle is sent to the CPTS controller with the record pulse and the handle is also sent to the TS_RX_DEC block along with the packet. The packet decode is performed in the TS_RX_DEC block. The decode function is separated from the record function because in some systems the incoming packet can be encrypted. The decode function would be after packet decryption in those systems.

The TS_RX_DEC function decodes each received packet and determines if the packet meets the time sync event packet criteria. If the packet is determined to be a time sync event packet, then the time sync event is signaled to the CPTS controller via the TS_RX_DEC interface. If the packet is determined to be a time sync event packet and if the ALE did not drop the packet (the packet was to be sent to at least one port), then the ALE lookup is overridden and the packet is forced only to the host. The event signal is a single clock pulse indicating that the packet matched the time sync event packet criteria and that the associated packet handle, message type, and sequence ID are valid. No indication is given for received packets that do not meet the time sync event criteria. The 16-bit sequence ID is found in the time sync event packet at the sequence ID offset into the PTP message header (**pn_ts_seq_id_offset**). The 8-bit domain number is found in the time sync event packet at the domain offset into the PTP message header (**pn_ts_domain_offset**). A packet is determined to be a receive event packet under the following conditions.

Note

TS_RX_DEC and TS_RX_MII are internal interfaces that have no registers. They are included here for description purposes only.

9.4.10.1.1 Annex D (IPv4)

1. Receive annex D time sync is enabled (pn_ts_rx_annex_d_en is set in the Pn_TS_Ctl register).
2. One of the sequences below is true.
    - The first packet LTYPE matches 0x0800
    - The first packet LTYPE matches ts_vlan_ltype1 and ts_rx_vlan_ltype1_en is set and the second packet LTYPE matches 0x0800
    - The first packet LTYPE matches ts_vlan_ltype2 and ts_rx_vlan_ltype2_en is set and the second packet LTYPE matches 0x0800
    - The first packet LTYPE matches ts_vlan_ltype1 and ts_rx_vlan_ltype1_en is set and the second packet LTYPE matches ts_vlan_ltype2 and ts_rx_vlan_ltype2_en is set and the third packet LTYPE matches 0x0800
3. Byte 14 (the byte after the LTYPE) contains 0x45 (IP_VERSION). Note that the byte numbering assumes that there are no VLANs. The byte number is intended to show the relative order of the bytes.
4. Byte 20 contains 0bXXX00000 (5 lower bits zero) and Byte 21 contains 0x00 (fragment offset zero)
5. Byte 22 contains 0x01 (HOP Limit = 1) if the ts_ttl_nonzero bit in the switch Pn_TS_CTL_LTYPE2 register is zero, or byte 22 contains any value if ts_ttl_nonzero is set. Byte 22 is the TTL/HOP field.
6. Byte 23 contains 0x11 (Next Header UDP Fixed).
7. The ts_uni_en bit in the Pn_TS_Ctl_Ltype2 register is zero and Bytes 30 through 33 contain:
    - Decimal 224.0.1.129 and the ts_129 bit in the Pn_TS_Ctl_Ltype2 register is set, or
    - Decimal 224.0.1.130 and the ts_130 bit in the Pn_TS_Ctl_Ltype2 register is set, or
    - Decimal 224.0.1.131 and the ts_131 bit in the Pn_TS_Ctl_Ltype2 register is set, or
    - Decimal 224.0.1.132 and the ts_132 bit in the Pn_TS_Ctl_Ltype2 register is set, or
    - Decimal 224.0.0.107 and the ts_107 bit in the Pn_TS_Ctl_Ltype2 register is set

    Or:

    The ts_uni_en bit in the Pn_TS_Ctl_Ltype2 register is set and Bytes 30 through 33 contain any values.
8. Bytes 36 and 37 contain:
    - Decimal 0x01 and 0x3f respectively and the ts_319 bit in the Pn_TS_Ctl_Ltype2 register is set, or
    - Decimal 0x01 and 0x40 respectively and the ts_320 bit in the Pn_TS_Ctl_Ltype2 register is set.
9. The PTP message begins in byte 42.
10. The packet message type is enabled in the ts_msg_type_en field in Pn_TS_Ctl.

11. The packet was received without error (not long/short/mac_ctl/crc/code/align).

9.4.10.1.2 Annex E (IPv6)

1. Receive annex E time sync is enabled (pn_ts_rx_annex_e_en is set in the switch Pn_TS_Ctl register).
2. One of the sequences below is true.
    - The first packet LTYPE matches 0x86dd.
    - The first packet LTYPE matches ts_vlan_ltype1 and ts_rx_vlan_ltype1_en is set and the second packet LTYPE matches 0x86dd.
    - The first packet LTYPE matches ts_vlan_ltype2 andts_rx_vlan_ltype2_en is set and the second packet LTYPE matches 0x86dd.
    - The first packet LTYPE matches ts_vlan_ltype1 and ts_rx_vlan_ltype1_en is set and the second packet LTYPE matches ts_vlan_ltype2 and ts_rx_vlan_ltype2_en is set and the third packet LTYPE matches 0x86dd.
3. Byte 14 (the byte after the LTYPE) contains 0x6X (IP_VERSION in most significant nibble).
4. Byte 20 contains 0x11 (UDP Fixed Next Header).
5. Byte 21 contains 0x01 (HOP Limit = 1) if the ts_ttl_nonzero bit in the switch Pn_TS_Ctl_LType2 register is zero, or byte 21 contains any value if ts_ttl_nonzero is set. Byte 21 is the TTL/HOP field.
6. The ts_uni_en bit in the Pn_TS_Ctl_Ltype2 register is zero and Bytes 38 through 53 contain:
    - FF0M:0:0:0:0:0:0:0181 and the ts_129 bit in the Pn_TS_Ctl_Ltype2 register is set, or
    - FF0M:0:0:0:0:0:0:0182 and the ts_130 bit in the Pn_TS_Ctl_Ltype2 register is set, or
    - FF0M:0:0:0:0:0:0:0183 and the ts_131 bit in the Pn_TS_Ctl_Ltype2 register is set, or
    - FF0M:0:0:0:0:0:0:0184 and the ts_132 bit in the Pn_TS_Ctl_Ltype2 register is set, or
    - FF0M:0:0:0:0:0:0:006B and the ts_107 bit in the Pn_TS_Ctl_Ltype2 register is set (all values above are 16-bit hex numbers with M is enabled in the ts_mcast_type_en field in the Pn_TS_Ctl2 register.

    Or:

    The ts_uni_en bit in the Pn_TS_Ctl_Ltype2 register is set and Bytes 38 through 53 contain any value.
7. Bytes 56 and 57 contain (UDP Header in bytes 54 through 61):
    - Decimal 0x01 and 0x3f respectively and the ts_319 bit in the Pn_TS_Ctl_Ltype2 register is set, or
    - Decimal 0x01 and 0x40 respectively and the ts_320 bit in the Pn_TS_Ctl_Ltype2 register is set.
8. The PTP message begins in byte 62.
9. The packet message type is enabled in the ts_msg_type_en field in Pn_TS_Ctl.
10. The packet was received without error (not long/short/mac_ctl/crc/code/align).

9.4.10.1.3 Annex F (IEEE 802.3)

1. Receive Annex F time sync is enabled (ts_rx_annex_f_en is set in the switch Pn_TS_Ctl register).
2. One of the sequences below is true.
    - The first packet LTYPE matches ts_ltype1. LTYPE 1 should be used when only one time sync LTYPE is to be enabled.
    - The first packet LTYPE matches ts_ltype2 and ts_ltype2_en is set
    - The first packet LTYPE matches ts_vlan_ltype1 and ts_rx_vlan_ltype1_en is set and the second packet LTYPE matches pn_ts_ltype1
    - The first packet LTYPE matches ts_vlan_ltype1 and ts_rx_vlan_ltype1_en is set and the second packet LTYPE matches ts_ltype2 and ts_ltype2_en is set
    - The first packet LTYPE matches ts_vlan_ltype2 and ts_rx_vlan_ltype2_en is set and the second packet LTYPE matches pn_ts_ltype1
    - The first packet LTYPE matches ts_vlan_ltype2 and ts_rx_vlan_ltype2_en is set and the second packet LTYPE matches ts_ltype2 and ts_ltype2_en is set
    - The first packet LTYPE matches ts_vlan_ltype1 and ts_rx_vlan_ltype1_en is set and the second packet LTYPE matches ts_vlan_ltype2 and ts_tx_vlan_ltype2_en is set and the third packet LTYPE matches pn_ts_ltype1
    - The first packet LTYPE matches ts_vlan_ltype1 and ts_rx_vlan_ltype1_en is set and the second packet LTYPE matches ts_vlan_ltype2 and ts_rx_vlan_ltype2_en is set and the third packet LTYPE matches ts_ltype2 and ts_ltype2_en is set

3. The PTP message begins in the byte after the LTYPE.
4. The packet message type is enabled in the ts_msg_type_en field in the Pn_TS_Ctl register.
5. The packet was received without error (not long/short/mac_ctl/crc/code/align).

9.4.10.2 1588 Transmit Packet Operation

There are two CPSW transmit time sync interfaces for each Ethernet port. The first is the TS_TX_DEC interface and the second is the TS_TX_MII interface. Both interfaces are internal to the cpsw and are input to the CPTS module.

The TS_TX_DEC function decodes each packet to be transmitted and determines if the packet meets the time sync event packet criteria. If the packet is determined to be a time sync event packet, then the time sync event is signaled to the CPTS controller via the TS_TX_DEC interface (**pn_ts_tx_dec_evnt**, **pn_ts_tx_dec_hndl[3:0]**, **pn_ts_tx_dec_msg_type[3:0], pn_ts_tx_dec_seq_id[15:0]** and **pn_ts_rx_dec_domain[7:0]**). The event signal is a single clock pulse indicating that the packet matched the time sync event packet criteria and that the associated packet handle, message type, and sequence ID are valid. The 16-bit sequence ID is found in the time sync event packet at the sequence ID offset into the message header (**pn_ts_seq_id_offset**). The 8-bit domain number is found in the time sync event packet at the domain offset into the PTP message header (**pn_ts_domain_offset**). No indication is given for transmit packets that do not meet the time sync event criteria. The time sync event packet handle is also passed along with the packet to the TS_TX_MII with an indication that the packet is a time sync event packet. Unlike receive; only transmit event packets increment the handle value. The decode function is separated from the record function because some systems may encrypt the packet. The encryption is after the decode function on transmit (egress). A packet is determined to be a transmit event packet under the following conditions.

9.4.10.2.1 Annex D (IPv4)

1. Transmit time sync is enabled (ts_tx_annex_d_en is set in the switch Pn_TS_Ctl register).
2. One of the sequences below is true.
   - The first packet LTYPE matches 0x0800
   - The first packet LTYPE matches ts_vlan_ltype1 and ts_tx_vlan_ltype1_en is set (PN_TS_VLAN_LTYPE register) and the second packet LTYPE matches 0x0800
   - The first packet LTYPE matches ts_vlan_ltype2 and ts_tx_vlan_ltype2_en is set and the second packet LTYPE matches 0x0800
   - The first packet LTYPE matches ts_vlan_ltype1 and ts_tx_vlan_ltype1_en (PN_TS_CTL_REG) is set and the second packet LTYPE matches ts_vlan_ltype2 and ts_tx_vlan_ltype2_en is set and the third packet LTYPE matches 0x0800
3. Byte 14 (the byte after the LTYPE) contains 0x45 (IP_VERSION). Note that the byte numbering assumes that there are no VLANs. The byte number is intended to show the relative order of the bytes. If VLAN(s) are present then the byte numbers push down.
4. Byte 20 contains 0bXXX00000 (5 lower bits zero) and Byte 21 contains 0x00 (fragment offset zero)
5. Byte 22 contains 0x01 (HOP Limit = 1) if the ts_ttl_nonzero bit in the switch Pn_TS_Ctl_LType2 register is zero, or byte 22 contains any value if ts_ttl_nonzero bit is set. Byte 22 is the TTL/HOP field.
6. Byte 23 contains 0x11 (Next Header UDP Fixed).
7. The pn_ts_uni_en bit in the Pn_TS_Ctl_Ltype2 register is zero and bytes 30 through 33 contain:
   - Decimal 224.0.1.129 and the ts_129 bit in the Pn_TS_Ctl_Ltype2 register is set, or
   - Decimal 224.0.1.130 and the ts_130 bit in the Pn_TS_Ctl_Ltype2 register is set, or
   - Decimal 224.0.1.131 and the ts_131 bit in the Pn_TS_Ctl_Ltype2 register is set, or
   - Decimal 224.0.1.132 and the ts_132 bit in the Pn_TS_Ctl_Ltype2 register is set, or
   - Decimal 224.0.0.107 and the ts_107 bit in the Pn_TS_Ctl_Ltype2 register is set

   Or:

   The ts_uni_en bit in the Pn_TS_Ctl_Ltype2 register is set and Bytes 30 through 33 contain any values.
8. Bytes 36 and 37 contain:
   - Decimal 0x01 and 0x3f respectively and the ts_319 bit in the Pn_TS_CTL_Ltype2 register is set, or
   - Decimal 0x01 and 0x40 respectively and the ts_320 bit in the Pn_TS_CTL_Ltype2 register is set.
9. The PTP message begins in byte 42 (this is offset 0).

10. The packet message type is enabled in ts_msg_type_en field in the Pn_TS_Ctl register.
11. The packet was sent by the host (port 0).

9.4.10.2.2 Annex E (IPv6)

1. Transmit annex E time sync is enabled (ts_tx_annex_e_en is set in the Pn_TS_Ctl register).
2. One of the sequences below is true.
    - The first packet LTYPE matches 0x86dd.
    - The first packet LTYPE matches ts_vlan_ltype1 and ts_tx_vlan_ltype1_en is set and the second packet LTYPE matches 0x86dd.
    - The first packet LTYPE matches ts_vlan_ltype2 and ts_tx_vlan_ltype2_en is set and the second packet LTYPE matches 0x86dd.
    - The first packet LTYPE matches ts_vlan_ltype1 and ts_tx_vlan_ltype1_en is set and the second packet LTYPE matches ts_vlan_ltype2 and ts_tx_vlan_ltype2_en is set and the third packet LTYPE matches 0x86dd.
3. Byte 14 (the byte after the LTYPE) contains 0x6X (IP_VERSION in most significant nibble).
4. Byte 20 contains 0x11 (UDP Fixed Next Header).
5. Byte 21 contains 0x01 (HOP Limit = 1) if the ts_ttl_nonzero bit in the switch Pn_TS_Ctl_LType2 register is zero, or byte 21 contains any value if ts_ttl_nonzero is set. Byte 21 is the TTL/HOP field.
6. The ts_uni_en bit in the Pn_TS_Ctl_Ltype2 register is zero and Bytes 38 through 53 contain:
    - FF0M:0:0:0:0:0:0:0181 and the ts_129 bit in the Pn_TS_Ctl_Ltype2 register is set, or
    - FF0M:0:0:0:0:0:0:0182 and the ts_130 bit in the Pn_TS_Ctl_Ltype2 register is set, or
    - FF0M:0:0:0:0:0:0:0183 and the ts_131 bit in the Pn_TS_Ctl_Ltype2 register is set, or
    - FF0M:0:0:0:0:0:0:0184 and the ts_132 bit in the Pn_TS_Ctl_Ltype2 register is set, or
    - FF0M:0:0:0:0:0:0:006B and the ts_107 bit in the Pn_TS_Ctl_Ltype2 register is set (all values above are 16-bit hex numbers with M is enabled in the ts_mcast_type_en field in the Pn_TS_Ctl2 register.

    Or:

    The pn_ts_uni_en bit in the Pn_TS_Ctl_Ltype2 register is set and Bytes 38 through 53 contain any value.
7. Bytes 56 and 57 contain (UDP Header in bytes 54 through 61):
    - Decimal 0x01 and 0x3f respectively and the ts_319 bit in the Pn_TS_Ctl_Ltype2 register is set, or
    - Decimal 0x01 and 0x40 respectively and the ts_320 bit in the Pn_TS_Ctl_Ltype2 register is set.
8. The PTP message begins in byte 62.
9. The packet message type is enabled in the ts_msg_type_en field in Pn_TS_Ctl.
10. The packet was sent by the host (port 0).

9.4.10.2.3 Annex F (IEEE 802.3)

1. Transmit time sync is enabled (ts_tx_annex_f_en is set in the switch Pn_TS_Ctl register).
2. One of the sequences below is true.
    - The first packet LTYPE matches ts_ltype1. LTYPE 1 should be used when only one time sync LTYPE is to be enabled.
    - The first packet LTYPE matches ts_ltype2 and ts_ltype2_en is set
    - The first packet LTYPE matches ts_vlan_ltype1 and ts_tx_vlan_ltype1_en is set and the second packet LTYPE matches pn_ts_ltype1
    - The first packet LTYPE matches ts_vlan_ltype1 and ts_tx_vlan_ltype1_en is set and the second packet LTYPE matches ts_ltype2 and ts_ltype2_en is set
    - The first packet LTYPE matches ts_vlan_ltype2 and ts_tx_vlan_ltype2_en is set and the second packet LTYPE matches pn_ts_ltype1
    - The first packet LTYPE matches ts_vlan_ltype2 and ts_tx_vlan_ltype2_en is set and the second packet LTYPE matches ts_ltype2 and ts_ltype2_en is set
    - The first packet LTYPE matches ts_vlan_ltype1 and ts_tx_vlan_ltype1_en is set and the second packet LTYPE matches ts_vlan_ltype2 and ts_tx_vlan_ltype2_en is set and the third packet LTYPE matches pn_ts_ltype1

   - The first packet LTYPE matches ts_vlan_ltype1 and ts_tx_vlan_ltype1_en is set and the second packet LTYPE matches ts_vlan_ltype2 and ts_tx_vlan_ltype2_en is set and the third packet LTYPE matches ts_ltype2 and ts_ltype2_en is set
3. The packet message type is enabled in the ts_msg_type_en field in the Pn_TS_Ctl register.
4. The packet was sent by the host (port 0).

The TS_TX_MII interface issues a single clock record signal at the beginning of each transmitted packet. If the packet is a time sync event packet then a single clock event signal along with a handle will be issued before the next record signal for the next packet. The event signal will not be issued for packets that did not meet the time sync event criteria in the TS_TX_DEC function. If consecutive record indications occur without an interleaving event indication, then the packet associated with the first record was not a time sync event packet. The record signal is a single clock pulse indicating that a transmit packet egress has been detected at the associated port MII interface. The handle value is incremented with each time sync event packet and rolls over to zero after 7. There are 8 possible handle values so there can be a maximum of 8 time sync event packets “in flight” from the TS_TX_DEC to the TS_TX_MII block at any given time. The handle value increments only on time sync event packets. The TS_TX_MII logic is in the transmit wireside clock domain.

Note

TS_TX_DEC and TS_TX_MII are internal interfaces that have no registers. They are included for description purposes only.

9.4.11 Rate Limiting (Traffic Shaping) (P802.1Qav/D6.0)

Rate-limit mode is intended to allow some CPPI ingress channels and some Ethernet transmit (switch egress) priorities to be rate-limited. Non rate-limited traffic (bulk traffic) is allowed on lower priority non rate-limited channels and FIFO priorities. Rate-limited traffic must be configured to be sent to rate-limited queues (via packet priority handling). The allocated rates for rate-limited traffic must not be oversubscribed. For example, if port 1 is sending 15% rate limited traffic to port 2 priority 3, and port 0 is also sending 10% rate-limited traffic to port 2 priority 3, then the port 2 priority 3 egress rate must be configured to be 25% plus a percent or two for margin. The switch must be configured to allow some percentage of non rate-limited traffic. Non rate-limited traffic must be configured to be sent to non rate-limited queues. No packets from the host should be dropped, but non rate-limited Ethernet ingress traffic can be dropped. For rate limited priorities, the configured transfer rate includes the committed information rate and the excess information rate. The excess information rate will only be attempted to be sent when there is no packet backlog on every priority that does not have the excess information rate enabled. The committed information rate will be sent regardless of network traffic as long as the configuration is not oversubscribed. The excess information rate will be sent only when network conditions allow.

Credit Based Shaper (CBS)

CBS based traffic shaping is supported in the CPSW IP and can be enabled by either configuring it in the ***committed information rate*** register either in the CPPI port ingress or in the Ethernet port transmit. If the rate limiting is applied at the CPPI port ingress, then the CPDMA makes sure to transmit the data at the limited rate. If it is configured at the Ethernet port end the burst data may be buffered in the Ethernet FIFO before transmitting, care must be taken such that Ethernet FIFO does not overflow when rate limiting is set in Ethernet port.

The relation between CBS parameters and hardware register configuration is as follows:

- idleSlope is essentially the rate limit, i.e. idleSlope = CIR (committed information rate) in Mbps
- portTransmitRate is link speed or port speed which is 100Mbps in AWR2944
- sendSlope is calculated as, sendSlope = idleSlope - portTransmitRate (this is described in the spec)
- hicredit and locredit : credit is calculated based on the idleSlope and sendSlope, it is maintained internally in the hardware, this is not a configurable parameter to the user.

9.4.11.1 CPPI Port Ingress Rate Limiting

Port 0 FHost operations can be configured to rate limit the packet data for each channel (priority). FHost has 8 priorities for QOS. There is a committed information rate (**P0_Pri_CIR**) and an excess information rate for each priority (**P0_Pri_EIR**). Rate limiting is enabled for a priority when the committed information rate for the priority is non-zero. The excess information rate for a priority is enabled when the excess information rate for the priority is non-zero. The committed information rate must be non-zero if the excess information rate is configured to be non-zero. That is, there must be a configured non-zero committed information rate for there to be a configured non-zero excess information rate. Bulk traffic on other non-rate limited priorities does not impact the committed information traffic on a priority. However, bulk traffic on other non-rate limited priorities does impact the excess information rates. No bulk priority will be enabled to send unless there are **tx_host_blks_rem** number of unused blocks remaining in each of the Ethernet port transmit FIFOs. The “blocks remaining check” ensures that bulk traffic from the host will not block rate-limited traffic from the host. Rate limited channels must be the highest priority channels. For example, if two rate limited channels are required then priorities 7 and 6 should be configured for committed information (and excess information if desired). When any channels are configured to be rate-limited, the ingress priority type must be fixed. Round-robin priority type is not allowed when rate-limiting is configured for any priority. The configured transfer rate includes the inter-packet gap (12 bytes) and the preamble (8 bytes). The rate in Mbits/second for each priority is controlled by the below equation. If the configured excess information rate is zero, then only the committed information rate is transferred:

Priority Transfer rate in Mbit/s = ((((Frequency in MHZ) * **P0_Pri_CIR**) / 32768) +

(((Frequency in MHZ) * **P0_PriX_EIR**) / 32768))

Where the frequency is the **VBUSP_GCLK** frequency (350 for 350Mhz) and priX = pri0 to pri7. For example, 10Mbps on priority 7 would give the below:

10Mbps = ~ ((350 * 936) / 32768), at 350Mhz and **p0_pri7_cir** value = 936 (no excess information rate)

9.4.11.2 Ethernet Port Transmit Rate Limiting

Ethernet port transmit operations can be configured to rate limit egress data for each egress priority. There is a committed information rate (**Pn_PriX_CIR**) and an excess information rate for each priority (**Pn_PriX_EIR**). Rate limiting is enabled for a priority when the committed information rate for the priority is non-zero. The excess information rate for a priority is enabled when the excess information rate for the priority is non-zero. The committed information rate must be non-zero if the excess information rate is configured to be non-zero. That is, there must be a configured non-zero committed information rate for there to be a configured non-zero excess information rate. Bulk traffic on other non-rate limited priorities does not impact the committed information traffic on a priority. However, bulk traffic on other non-rate limited priorities does impact the excess information rates. Rate limited channels must be the highest priority channels. For example, if two rate limited channels are required then priorities 7 and 6 should be configured for committed information (and excess information if desired). The configured transfer rate includes the inter-packet gap (12 bytes) and the preamble (8 bytes). The rate in Mbits/second that each priority is configured to send is controlled by the below equation. If the excess information rate is disabled then the committed information rate only is transferred:

Priority Transfer rate in Mbit/s = ((((Frequency in MHZ) * **Pn_PriX_CIR**) / 32768) +

(((Frequency in MHZ) * **Pn_PriX_EIR**) / 32768))

Where the frequency is the **VBUSP_GCLK** frequency (350 for 350Mhz) and priX = pri0 to pri7. For example, 100Mbps on priority 7 would give the below:

100Mbps = ~ ((350 * 9360) / 32768), at 350Mhz and **pn_pri7_cir** value = 9360, with no excess information rate.

9.4.12 Transmit Priority Escalation

Bulk (non rate limited) traffic can be escalated in order to preclude starvation of lower bulk traffic priorities from higher bulk traffic priorities. Escalation is configured and enabled in the **PTYPE** register with the **pn_ptype_esc** and **esc_pri_ld_val** fields. Escalation can be enabled with rate limited priorities. The rate limited priorities are on the upper priorities starting with priority 7 and going down(consecutively), and therefore, the escalated priorities are on the lower bulk priorities.

9.4.13 Enhanced Scheduled Traffic (EST – P802.1Qbv/D2.2)

9.4.13.1 EST Overview

- When enabled and configured, EST allows express queue traffic to be scheduled (placed) on the wire at specific repeatable time intervals.
- EST operates on a repeating time interval generated by the CPTS EST function generator. For example, a 125us repeating time interval can be configured.
- Each Ethernet port has 128 EST fetch commands maximum in the global EST fetch RAM.
- Each 22-bit fetch command consists of a 14-bit fetch count (14 msb's) and an 8-bit priority fetch allow (8 lsb's) that will be applied for the fetch count time in wireside clocks.
- The configured port fetch commands are executed in sequence, beginning at port address zero each time through the time interval beginning at cycle start.
- EST allows non-scheduled express and prempt queue traffic to be cleared from the wire to ensure that the scheduled traffic is transmitted at the proper time (wire clear is performed with zero allow).
- EST can be used with or without premption. The pn_mac_prempt[7:0] value determines whether the priority is enabled on the express or prempt queue. Whether a priority is on the express or prempt queue only effects the wire clear time from an EST operation perspective.
- Software should not move priorities to the prempt queue unless preemption is configured, enabled, and verified - allowing preemption to occur.
- Express packet time stamp events can be enabled to assist software in configuring and timing EST operations.

9.4.13.2 EST Fetch RAM

- The EST fetch RAM is read/write in the CPSW configuration address space.
- Each Ethernet transmit port has 128 locations in the global EST fetch RAM.
  - Ethernet port 1 has EST fetch RAM addresses 0x000-0x1ff.
  - Ethernet port 2 has EST fetch RAM addresses 0x200-0x3ff, and so on.
- One buffer operation – When est_onebuf is set, the 128 port locations operate as one buffer. The est_bufact bit in Pn_FIFO_Status is the upper address bit of the port's fetch RAM address indicating whether operation is currently in the upper or lower 64 locations of the port's fetch RAM.
- Two buffer operation - When est_onebuf of PN_EST_CONTROL register is cleared there are two 64-location buffers with est_bufsel selecting the buffer to be used. When the buffer is switched by changing the est_bufsel value, the actual switch occurs on cycle start. The actual buffer being used is indicated by the est_bufact bit in Pn_FIFO_Status. Software should avoid writing the switched out buffer fetch RAM locations until it detects that the actual switch has occurred.
- The first address location in the port's fetch RAM space (location zero) is read at the beginning of each EST time interval (cycle start). Addresses are then read in ascending order for the duration of the interval. The port's address zero location is then read again at the beginning of the next cycle repeating the time interval packet operations.

9.4.13.3 EST Time Interval

- Each Ethernet port has an EST function (ESTF) generator in the CPTS submodule.
- The EST function generator generates the EST time interval as a configured number of CPTS reference clocks (CPTS_RCLK).
- The EST function generator rising edge is the cycle start time and the cycle repeats (cycle start occurs) after every time interval.
- The first fetch allow (8 lsb's of the fetch command from the EST fetch RAM) value is at the port's base address zero in the EST fetch RAM and is actually applied 16 wireside clocks after cycle start. The 16 clock delay allows the first fetch value to be fetched from the EST fetch RAM (prefetch time at cycle start).
- Each successive fetch allow is applied for the associated fetch count thereafter. The minimum non-zero fetch count is 16. The minimum value of 16 guarantees that the next fetch value has time to be fetched before the current fetch count is over. There are 64 maximum fetch values when est_onebuf=0, and 128 maximum fetch values when est_onebuf=1.
- The next cycle start then causes the fetch to once again start at the port's address zero location.

9.4.13.4 EST Fetch Values

- The 22-bit fetch value is made up of the 14-bit fetch count and the 8-bit fetch allow.
- The fetch time indicates the number of wireside clocks that the fetch allow will be active.
- The fetch count is in Ethernet wireside clocks which is bytes in gigabit mode (pn_gig=1) and nibbles in 10/100Mbps mode.
- When a fetch allow bit is set, the corresponding priority is enabled to begin packet transmission on an allowed priority subject to rate limiting. There is no requirement that the packet end in the time interval. The actual packet transmission on the wire may carry over into the next fetch count - which is the reason for the wire clear time in a fetch zero allow.
- When a fetch allow bit is cleared, the corresponding priority is not enabled to transmit for the fetch count time. However, if a packet were enabled in a previous fetch allow there the packet could finish in the current time interval.
- A non-zero fetch allow value with a non-zero fetch count causes the fetch allow value to be applied for the fetch count number of wireside clocks (minimum of 16 fetch count).
- A zero fetch count causes the associated fetch allow to be held for the duration of the cycle (until the next cycle start).
- A zero fetch allow with a non-zero fetch count is intended to clear the wire for a scheduled (timed) express packet in the next fetch. A zero fetch allow indicates that no packet can be started for transmission for the associated fetch count. However, packets that were started in the previous interval could still be on the wire. The associated fetch count must be sufficient to guarantee that the wire is cleared given that a packet on an allowed priority in the previous fetch could have been started on the previous clock and that there is hardware latency in the clear time. The timed packet should be sent on a priority that is enabled in the next fetch but disabled in the current zero allow fetch.
- EST Ram Configuration – The simplest EST configuration is for a single express packet on a single priority in the EST time interval. Ram Address 0 will be read at the start of each interval, the timed packet goes out in Ram Address 1 interval, and Ram Address 2 priorities are held for the duration of the cycle in this simple configuration.
  - Ram Address 0 – 0xD0000 (10/100 with 1518 max pkt length in previous allow)
    - This is a zero allow at the beginning of each cycle which clears the wire for the timed express packet in the next fetch. The zero allow time (0xD00 in this case) allows the wire to be cleared for the express packet. Setting this value lower might push out the timed express packet into the next interval. For a 2020 max packet size in the previous allow, this value should be 0x10F400. The number of clocks required for the zero allow is determined by the below equation.
      - Clocks in zero allow = Maximum ***Express*** packet length in previous allow (times 2 for 10/100) + decimal 292. (If preemption is configured and enabled then this minimum time is 0x100 if only prempt priorites are in the previous allow – which is not a normal case).
  - Ram Address 1 – 0x01080
    - This is a decimal 16 clock allow for the timed express packet on priority 7. The 16 clock allow value permits only a single packet to start in the time interval.
  - Ram Address 2 – 0x0007F
    - This is a zero fetch count that allows priorities 6 downto 0 for the duration of the EST time interval. This is the previous allow for the zero allow in Address 0 above.

9.4.13.5 EST Packet Fill

- Packet fill can (should) be configured and enabled to occur in the fetch count time associated with a fetched zero allow that preceeds a timed express packet. The intention with fill is that a smaller packet on a non-timed priority might be able to be inserted on the wire during the wire clear time which would increase wire utilization. Fill must be configured to ensure that any fill packet does not conflict with the timed express packet allowed in the next fetch. Incorrect configuration might push out in time any express timed packet which indicates that the fill margin needs to be increased.
- Fill Configuration
  - The est_fill_margin value in Pn_EST_Control should be written with a 0x100 value.

  - The est_prempt_comp value in Pn_EST_Control should be written with a 0x12 value (if IET is to be configured and enabled). This value times eight is the number of wireside clocks required to clear prempt packets off the wire at the end of a zero allow.
  - The est_fill_en bit in Pn_EST_Control should be set.

9.4.13.6 EST Time Stamp

- EST can be configured to generate CPTS timestamp events for selected express traffic.
- EST timestamp events use the CPTS host event type (event_type=7). EST timestamps will not override host sent timestamps for packets that were sent from the host with an enabled host timestamp.
- EST Events (host events EVENT_n_REG) contain the below information:
  - Time Stamp of the selected express packet.
  - The event port_number indicates the transmit port number.
  - The event event_type is decimal 7 (host event).
  - The event message_type indicates the packet transmit hardware switch priority.
  - The event sequence_id upper nibble indicates the packet receive port number.
  - The event sequence_id lower byte indicates the sequence number of the express packet in numerical order. The first event is event one, the second is event two and so on. The sequence id rolls over to zero after 0xff (8-bits).
  - The event domain is the value from the est_ts_domain[8:0] register.
- When est_ts_en is set, timestamp events will be generated on selected express traffic.
- When est_ts_first is also set, events will be generated only on the first express packet in each time interval. If est_ts_onepri is also set then the event will only be on the first est_ts_pri express packet in the time interval. If est_ts_onepri is clear then the event will be generated on the first express packet in the time interval on any priority.
- When est_ts_first is clear, events will be generated on every express packet. If est_ts_onepri is set then the event will be generated on every est_ts_pri express packet. If est_ts_onepri is clear then event will be generated on every express packet on any priority.

9.4.13.7 EST Packets Per Priority – (N = 2 only)

With a MAC configuration (**N** = 2), the number of packets allowed in a transmit FIFO priority can be selected by writing a non-zero value to **p0_rx_pkts_pri[7-0]**. The port 0 receive gap should then be enabled by setting the corresponding priority **rx_gap_en[7:0]**. The receive gap allows a packet to land in the transmit FIFO before another packet is allowed in which guarantees that only the selected number (max) of packets is allowed in on the specified priority. If the receive gap is not enabled, then there might be one or two more packets allowed in on the priority than the **p0_rx_pkt_pri[7:0]** value has selected.

9.4.14 DSCP

The ALE can map DSCP field to priority prior to port trunking hashing and policing/classification matching. When enabled the DSCP is mapped via 64 priority entries such that any DSCP value can be mapped to any of the eight priorities. When a packet is received without a VLAN priority this remapped priority can be used instead of the default Port VLAN priority field. See the Switch Port configuration for the registers describing DSCP mapping.

9.4.15 Packet Priority Handling

There are three priorities used inside the CPSW - the packet priority, the header packet priority, and the switch priority. The packet priority is the determined priority of the ingress packet. The header packet priorityis used as the outgoing VLAN priority if the packet is egressing from the switch with a VLAN tag. The switch prioritydetermines which of the eight FIFO priority queues the packet uses during egress.

The **vlan_ltype_sel** value below is selected by the **s_cn_switch** bit in the **CPSW_Control** register and is either the **vlan_ltype_inner** (0x8100 default) or **vlan_ltype_outer** (0x88a8 default) value.

9.4.15.1 Ethernet Port Ingress

Ethernet ingress packets have an ingress packet priority of 0 to 7 (with 7 being the highest priority). The packet priority is determined as follows:

1. If the first packet LTYPE = vlan_ltype_sel then the ingress packet priority is the packet priority (VLAN tagged and priority tagged packets).
2. Else if the first packet LTYPE = 0x0800 and byte 14 (following the LTYPE) is equal to 0x4X, and dscp_ipv4_en is set in Pn_Control, then the ingress packet priority is the 6-bit TOS field in byte 15 (upper 6-bits) mapped through the port's DSCP priority mapping registers (IPV4 packet).
3. Else if the first packet LTYPE = 0x86dd and the most significant nibble of byte 14 (following the LTYPE) is equal to 0x6, and dscp_ipv6_en is set in Pn_Control, then the ingress packet priority is the 6-bit priority (in the 6-bits following the upper nibble 0x6) mapped through the port's DSCP priority mapping registers (IPV6 packet).
4. Else the ingress packet priority is the source (ingress) port priority taken from the port's Pn_Port_VLAN register.

The packet priority is mapped through the ingress port's associated "packet priority to header packet priority mapping register" (**pn_rx_pri_map**) to obtain the header packet priority (**hdr_pkt_pri**). The header packet priority is then used as the actual transmit packet priority if the VLAN information is to be sent on egress. The header packet priority is mapped at each destination FIFO through the **pn_tx_pri_map** register (header priority to switch priority mapping register) to obtain the hardware switch priority (hardware queue 0 through 7).

9.4.15.2 CPPI Port FHost (Ingress)

FHost packets have a packet priority (0 to 7 with 7 being the highest priority). The FHost packet priority is determined as follows:

1. If the first packet LTYPE = vlan_ltype_sel then the FHost packet priority is the packet priority (VLAN tagged and priority tagged packets).
2. Else if the first packet LTYPE = 0x0800 and byte 14 (following the LTYPE) is equal to 0x4X, and p0_dscp_ipv4_en is set in P0_Control, then the FHost packet priority is the 6-bit TOS field in byte 15 (upper 6-bits) mapped through the port's DSCP priority mapping registers (IPV4 packet).
3. Else if the first packet LTYPE = 0x86dd and the most significant nibble of byte 14 (following the LTYPE) is equal to 0x6, and dscp_ipv6_en is set in P0_Control, then the FHost packet priority is the 6-bit priority (in the 6-bits following the upper nibble 0x6) mapped through the port's DSCP priority mapping registers (IPV6 packet).
4. Else the FHost packet priority is the source port priority taken from P0_Port_VLAN.

The ingress packet priority is mapped through the port's associated "packet priority to header packet priority mapping register" (**p0_rx_pri_map**) to obtain the header packet priority. The header packet priority is then used as the actual transmit packet priority if the VLAN information is to be sent on egress.

For CPPI FHost packets, the destination port hardware switch priority is the below selected value remapped through **p0_rx_pri_map**:

1. If the FHost packet is priority tagged or vlan tagged:
   - If rx_remap_vlan is clear then the the destination hardware switch priority is the CPPI FHost channel number.
   - If rx_remap_vlan is set then the the destination hardware switch priority is the packet priority value. Port transmit remapping (Pn_Tx_Pri_Map should remain the default value) is not compatible with this bit being set, but remapping can be configured on port 0 FHost. If N=2 (two port MAC) remapping should be done only on ingress for Ethernet and CPPI.
2. Else if the ingress packet has the first packet LTYPE = 0x0800 and byte 14 (following the LTYPE) is equal to 0x4X, and **dscp_ipv4_en** is set in **P0_Control**:
   - If rx_remap_dscp_v4 is clear then the destination hardware switch priority is the CPPI ingress priority.
   - If rx_remap_dscp_v4 is set then the destination hardware switch priority is the 6-bit TOS field in byte 15 (upper 6-bits) mapped through the port's DSCP priority mapping registers (IPV4 packet). Port 1 transmit remapping (Pn_Tx_Pri_Map should remain the default value) is not compatible with this bit being set, but remapping can be configured on port 0 ingress. If N=2 (two port MAC) remapping should be done only on ingress for Ethernet and CPPI.
3. Else if the ingress packet has the first packet LTYPE = 0x86dd and the most significant nibble of byte 14 (following the LTYPE) is equal to 0x6, and **dscp_ipv6_en** is set in **CPPI_P0_Control**:

  - If rx_remap_dscp_v6 is clear then the destination hardware switch priority is the CPPI ingress priority.
  - If rx_remap_dscp_v6 is set then the destination hardware switch priority is the 6-bit priority (in the 6-bits following the upper nibble 0x6) mapped through the port's DSCP priority mapping registers (IPV6 packet). Port 1 transmit remapping (Pn_Tx_Pri_Map should remain the default value) is not compatible with this bit being set, but remapping can be configured on port 0 ingress. If N=2 (two port MAC) remapping should be done only on ingress for Ethernet and CPPI.

4. Else the ingress packet is non-tagged and the destination hardware switch priority is the CPPI ingress channel number.

9.4.15.3 CPPI Port THost (Egress)

If the **thost_ch_override** bit in **CPDMA_Control** is clear then the CPDMA packet THost channel number is the port 0 hardware switch priority. If **thost_ch_overide** is set, then for packets with a classification match the THost channel number is the lower three bits of the 6-bit address lookup engine classification match value (**threadval[2:0]** in ALE register **THREADMAPVAL**). The **flow** value in the VLAN encapsulation word is all 6 bits of the **threadval** for classifier matches regardless of the setting of **thost_ch_override** if the encapsulation word is transferred.

9.4.16 Packet CRC Handling

Every cpsw ingress packet on all ports is checked for CRC correctness. Each packet is then given an internally generated Castignoli CRC for transport through the cpsw to egress port(s). The internally generated Castignoli CRC protects the packet from end to end through the cpsw. Ingress Packets with CRC errors are handled as indicated below.

9.4.16.1 Ethernet Port Ingress

Ethernet ports check each ingress packet CRC for correctness in all modes/speeds. The port can check for either Ethernet CRC for correctness as determined by the **crc_type** bit in the **Mac_Control** register. Ethernet packets received with a CRC error are dropped at the receive port unless the receive port **rx_cef_en** bit is set. Error packets are sent only to the host port. For packets with Ethernet ingress errors sent to the host, the error is indicated in the host egress buffer descriptor and the original packet CRC bytes are kept for CPDMA THost.

9.4.16.2 Ethernet Port Egress

Ethernet ports transmit egress packets with the CRC type selected by the **crc_type** bit in the **Pn_Mac_Control** register regardless of the packet's ingress CRC type. On Ethernet egress, after passing through the switch, the internally generated Castignoli CRC is checked for correctness and if correct the packet is output with the generated selected output CRC type. If the internally generated CRC is incorrect, due either to a bit flip in a memory (or logic) or an error CRC passed in on host ingress, then the generated egress CRC type is used with at least a single byte of the internally generated Castignoli CRC inverted to indicate the error. If the packet length including CRC is divisible by 4 then all 4 CRC bytes will be inverted on error. If there are three bytes remainder after dividing the packet length by 4 then three bytes will be inverted (and so on down to one byte remainder).

9.4.16.3 CPPI Port FHost

CPPI host port FHost packets can be passed in with or without a CRC. The FHost packet CRC type is indicated in the buffer descriptor word **crc_type** bit and can be Ethernet. The **p0_rx_pass_crc_err** bit in the **CPSW_Control** register determines if FHost packets with CRC errors are passed or dropped. Passed packets with CRC errors will be transmitted on Ethernet egress with a CRC error.

9.4.16.4 CPPI Port Egress (THost)

The **p0_tx_crc_remove** bit in the **CPSW_Control** register determines if all CPPI THost packets have a CRC included or not. THost packets not filtered on Ethernet ingress due to **pn_rx_cef_en** have the packet error CRC included (not replaced by the egress CRC type) if the CRC is not removed on egress. The error is indicated in the buffer descriptor. CPPI THost packets that detected a CRC error on the internally generated Castignoli CRC, due to a bit flip in logic or memory, will indicate the error with the **drop** bit set in the buffer descriptor.

9.4.17 Ethernet FIFO

Each transmit packet FIFO contains eight logical transmit queues (priority 0 through 7 with 7 the highest priority) regardless of the memory configuration. The receive logical FIFO is combined with the transmit logical FIFO into the same RAM instance. The receive FIFO is used for single packet reception and error detection and flow control runout. Packets are queued on transmit. Ethernet FIFO size is 20 KBytes.

9.4.18 Ethernet Receive Flow Control

When enabled and triggered, receive flow control is initiated to limit the Mac from further frame reception. Half-duplex mode receive flow control is collision based while full duplex mode issues 802.3X or Priority Based Flow Control (PFC) pause frames. In all cases, receive flow control prevents frame reception by issuing the flow control appropriate for the current mode of operation. Receive flow control is enabled by the **rx_flow_en** bit in the **Pn_Mac_Control** register, and **rx_flow_pri[7:0]** in **Pn_Pri_Ctl**. For 10/100 modes of operation, collision or IEEE 802.3X flow control is determined via the **fullduplex** bit in the **Pn_Mac_Control** register. The **fullduplex** bit must be set for Priority Based Flow Control.

9.4.18.1 MII (10/100) Collision Based Receive Buffer Flow Control

Collision-based receive buffer flow control provides a means of preventing frame reception when the port is operating in half-duplex mode (**fullduplex**is cleared in **Pn_Mac_Control)**. When receive flow control is enabled and triggered, the port will generate collisions for received frames. The jam sequence transmitted will be the twelve byte sequence C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3 (hex). The jam sequence will begin no later than approximately as the source address starts to be received. Note that these forced collisions will not be limited to a maximum of 16 consecutive collisions, and are independent of the normal back-off algorithm. Receive flow control does not depend on the value of the incoming frame destination address. A collision will be generated for any incoming packet, regardless of the destination address.

9.4.18.2 IEEE 802.3X (10/100/1G/10G) Receive Flow Control

IEEE 802.3x based receive flow control provides a means of preventing frame reception when the port is operating in full-duplex mode (**fullduplex**is set in **Pn_Mac_Control)**. When receive flow control is enabled and triggered, the port will transmit a pause frame to request that the sending station stop transmitting for the period indicated within the transmitted pause frame.

The Mac will transmit a pause frame to the reserved multicast address at the first available opportunity (immediately if currently idle, or following the completion of the frame currently being transmitted). The pause frame will contain the maximum possible value for the pause time (0xFFFF). The MAC will count the receive pause frame time (decrements 0xFF00 down to zero) and retransmit an outgoing pause frame if the count reaches zero. When the flow control request is removed, the MAC will transmit a pause frame with a zero pause time to cancel the pause request.

Note that transmitted pause frames are only a request to the other end station to stop transmitting. Frames that are received during the pause interval will be received normally (provided the Rx FIFO is not full at which time the receive FIFO will overrun and **Rx_Top_Of_FIFO_Drop** will increment).

Pause frames will be transmitted if enabled and triggered regardless of whether or not the port is observing the pause time period from an incoming pause frame.

The Mac will transmit pause frames as described below:

- The 48-bit reserved multicast destination address 01.80.C2.00.00.01.
- The 48-bit source address – Pn_SA(47:0) (PN_SA_L, PN_SA_H registers).
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 00.01
- The 16-bit pause time value FF.FF. A pause-quantum is 512 bit-times. Pause frames sent to cancel a pause request will have a pause time value of 00.00.
- Zero padding to 64-byte packet length (The MAC will transmit only 64 byte pause frames).
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

If **rx_flow_en** is cleared to zero while the pause time is nonzero, then the pause time will be cleared to zero and a zero count pause frame will be sent.

9.4.18.2.1 Flow Control Trigger

Receive flow control is triggered (when enabled), when the number of words in the receive FIFO is greater than or equal to **rx_flow_thresh**. The flow control packet runout is then contained in the remainder of the receive FIFO.

9.4.18.3 Ethernet Transmit Flow Control

9.4.18.3.1 IEEE 802.3X (10/100/1G/10G) Based Transmit Flow Control

Incoming pause frames are acted upon, when enabled, to prevent the Mac from transmitting any further frames. Incoming pause frames are only acted upon when the **fullduplex** and **tx_flow_en** bits in the **Pn_Mac_Control** register are set. Pause frames are not acted upon in half-duplex mode. Pause frame action will be taken if enabled, but normally the frame will be filtered and not transferred to memory. MAC control frames will be transferred to memory if the **rx_cmf_en** (Copy MAC Frames) bit in the **Pn_Mac_Control** register is set. The **tx_flow_en** and **fullduplex** bits effect whether or not MAC control frames are acted upon, but they have no effect upon whether or not MAC control frames are transferred to memory or filtered.

Pause frames are a subset of MAC Control Frames with an opcode field=0x0001. Incoming pause frames will only be acted upon by the port if:

- tx_flow_en is set in Pn_Mac_Control, and
- the frame’s length is 64 to rx_maxlen bytes inclusive, and
- the frame contains no crc error or align/code errors.

The pause time value from valid frames will be extracted from the two bytes following the opcode. The pause time will be loaded into the port’s transmit pause timer and the transmit pause time period will begin.

If a valid pause frame is received during the transmit pause time period of a previous transmit pause frame then:

- if the destination address is not equal to the reserved multicast address or any enabled or disabled unicast address, then the transmit pause timer will immediately expire, or
- if the new pause time value is zero then the transmit pause timer will immediately expire, else
- the port transmit pause timer will immediately be set to the new pause frame pause time value. (Any remaining pause time from the previous pause frame will be discarded).

If **tx_flow_en** in **Pn_Mac_Control** is cleared, then the pause-timer will immediately expire.

The port will not start the transmission of a new data frame any sooner than 512-bit times after a pause frame with a non-zero pause time has finished being received (**MRXDV** going inactive). No transmission will begin until the pause timer has expired (the port may transmit pause frames in order to initiate outgoing flow control). Any frame already in transmission when a pause frame is received will be completed and unaffected.

Incoming pause frames consist of the below:

- A 48-bit destination address equal to:
  - The reserved multicast destination address 01.80.C2.00.00.01, or
  - The Enet_Pn_SA[47:0] input mac source address.
- The 48-bit source address of the transmitting device.
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 00.01
- The 16-bit pause_time. A pause-quantum is 512 bit-times.
- Padding to 64-byte packet length.
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

The padding is required to make up the frame to a minimum of 64 bytes. The standard allows pause frames longer than 64 bytes to be discarded or interpreted as valid pause frames. The MAC will recognize any pause frame between 64 bytes and **rx_maxlen** bytes in length.

9.4.19 Energy Efficient Ethernet Support (802.3az)

Energy Efficient Ethernet (EEE) allows the external clock controller to turn off (in a glitch-less manner) the module input clock (**CLK**) during inactive periods as determined by network and host traffic. The module can then be awakened by host queued transmit packet(s) or by a port's external Ethernet PHY. The module EEE clock stop interface is used by the external controller to control module EEE operations. EEE is supported in MII/GMII/RGMII but not RMII, The chosen PHY must also support EEE. EEE operations are configured as shown below:

1. The 12-bit EEE clock pre-scale value is written to the switch EEE_Prescale register. The pre-scaler is used to clock all EEE related counters.
2. The port Idle to LPI count values (Pn_Idle2LPI) are written with the desired values.
3. The port LPI to Wake count values (Pn_LPI2Wake) are written with the desired values.
4. The eee_en bit is set in the switch CPSW_Control register.

Energy Efficient Ethernet operation can begin after configuration. The host allows the module to enter a low power state by asserting the **CLKSTOP_REQ** signal. There are no requirements on host queues or traffic in order for the host to assert or de-assert **CLKSTOP_REQ**.

Each Ethernet port has a transmit and a receive LPI (low power indicate) state. The receive LPI state is entered when the port's corresponding PHY indicates the LPI state via the MII/RGMII interface. The PHY indicates LPI by asserting **GMII_MRXER_SEL** with a **GMII_MRXD[7:0]** value of 0x01 while **GMII_MRXDV** is deasserted (inter-packet gap). The Ethernet transmit port indicates LPI after the **PX_Idle2LPI** value has been counted (the transmit port has gone idle for the configured amount of time). If another packet is received for transmit during the count then the count is restarted. When the transmit port has been idle for the Idle to LPI time, the transmit port enters the LPI state and indicates LPI to the associated PHY. The LPI is indicated to the external PHY by an asserted **GMII_MTXER** with a **GMII_MTXD[7:0]** value of 0x01. while **GMII_MTXEN** is deasserted (inter-packet gap). The CPPI LPI state includes transmit and receive. The CPPI LPI state is entered when the CPPI transmit and receive interfaces have both been idle for the Idle to LPI time (**P0_Idle2LPI**). The Idle to LPI time value for all ports must be large relative to the switch latency to ensure that the count is not able to complete between successive packets.

When all transmit and receive ports are in the LPI state (CPSW LPI state), the **CLKSTOP_ACK** signal is asserted, and the external clock controller is allowed to stop the input module clock (**CLK**). The clock must be stopped (and re-started) in a glitch-less manner. When **CLKSTOP_ACK** is asserted, the clockmay be turned on and off as desired by the host. The host is allowed to restart the clock, perform slave read/write operations to the module memory address space, and then turn off the clock again while **CLKSTOP_ACK** is asserted. The clock must be restarted for two clock periods before the assertion of **SLV_VBUSP_REQ** and must remain asserted for five clock periods after the de-assertion of **SLV_VBUSP_REQ**.

The host can remove and disable from re-entering the CPSW LPI state by restarting the module clock (in a glitch-less manner) and then de-asserting **CLKSTOP_REQ**. There must be at least one rising edge of the clockbefore **CLKSTOP_REQ** is de-asserted. The module **CLKSTOP_ACK** output signal will be deasserted on the clock after the de-assertion of **CLKSTOP_REQ**. The host may queue CPPI receive packets at any time without regard to the module LPI state. The Host must deassert **CLKSTOP_REQ** on wakeup for a minimum of two clock periods. If **CLKSTOP_REQ** is deasserted for less than 5 clock periods for a wakeup event from the host to a particular Ethernet port (or visa versa), then the wakeup event will not cause the other Ethernet ports to awaken.

The external Ethernet PHY's can also wakeup the external clock controller by removing the Ethernet receive LPI indication. If the module is in the CPSW Idle state with **CLKSTOP_ACK** asserted and the receive LPI indication is removed, the **CLKSTOP_WAKEUP** signal will be asynchronously asserted. On wakeup, the external clock controller must restart the clock and de-assert the **CLKSTOP_REQ** signal. The **CLKSTOP_WAKEUP** signal will be synchronously deasserted with **CLKSTOP_ACK**. There must be at least one positive edge of the clock before the **CLKSTOP_REQ** signal is deasserted. Upon the de-assertion of **CLKSTOP_REQ**, the Ethernet ports will count the **Pn_LPI2Wake** time for each port at which time the port is available for transmit.

9.4.20 Switch Latency

When the CPSW is configured as a store and forward switch, the switch latency is defined as the amount of time between the end of packet reception of the received packet to the start of the output packet transmit. The store and forward latency is shown in the below table:

Mode	Latency
Gig (1000)	880ns
100	1.3us
10	6.5us

9.4.21 Emulation Control

The emulation control input (**EMUSUSP**), emulation control register, and the submodule emulation control registers allow CPSW operation to be completely or partially suspended. The CPDMA Host port and each Ethernet port has associated emulation control registers. The submodule emulation control registers must be accessed to facilitate CPSW emulation control. The CPSW module enters the emulation suspend state if the switch level emulation control register and all submodules are configured for emulation suspend and the emulation suspend input is asserted. A partial emulation suspend state is entered if one or more submodules is configured for emulation suspend and the emulation suspend input is asserted. Emulation suspend occurs at packet boundaries. The emulation control feature is implemented for compatibility with other peripherals. The following table shows the operation of the emulation control input and register bits:

EMUSUSP	soft	free	Description
0	X	X	Normal Operation
1	0	0	Normal Operation
1	1	0	Emulation Suspend
1	X	1	Normal Operation

Note

Enable Suspend control (EMUSUSP) by MSS_CTRL: MSS_DBG_ACK_CTL0[26:24]

9.4.22 Software IDLE

The software idle register bits enable switch operation to be completely or partially suspended by software control. Each Ethernet port may be individually commanded to enter the idle state. The idle state is entered at packet boundaries, and no further packet operations will occur on an idled port until the idle command is removed. The CPSW software idle inhibits packets from starting to be unloaded from each port switch FIFO, but packets already in process are unaffected.

9.4.23 Common Platform Time Sync (CPTS)

The Common Platform Time Sync (CPTS) module is used to facilitate host control of time sync operations. It enables compliance with the IEEE 1588 standard for a precision clock synchronization protocol.

Main features of CPTS module are:

- Supports the selection of up to 32 external clock sources.
- Software control of time sync events via interrupt or polling.
- Supports 8 hardware timestamp push inputs.

- Supports timestamp counter compare output (TS_COMP).
- Supports timestamp counter bit output (TS_SYNC).
- Supports a configurable number of timestamp Generator bit outputs (TS_GENFn).
- Supports Ethernet Enhanced Scheduled Traffic Operations (TS_ESTFn).
- 64-bit timestamp mode with PPM and nudge adjustment.

9.4.23.1 CPTS Integration

This section describes CPTS module integration in the device, including information about clocks, resets, and hardware requests.

Figure 9-7 shows CPTS integration in the device.

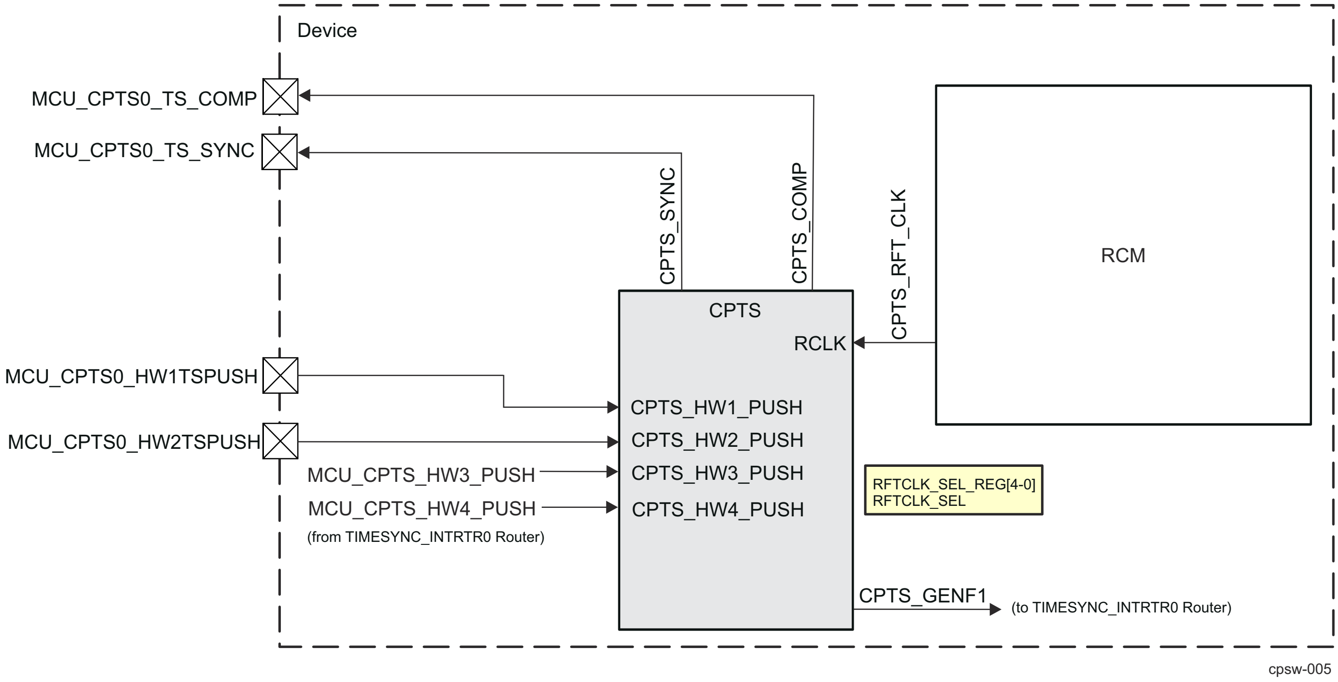

Figure 9-7. CPTS Integration

CPTS IEEE 1588 clock (RCLK) is selected through the CPSW_CPTS_RFTCLK_SEL_REG register.

Note

For more information about CPTS clocks and resets, see Table 9-3 in Section 9.3 *CPSW Integration*.

9.4.23.2 CPTS Architecture

Figure 9-8 shows the architecture of the CPTS module inside the CPSW Ethernet Subsystem. Time stamp values for every packet transmitted or received on either port of the CPSW are recorded. At the same time, each packet is decoded to determine if it is a valid time sync event. If so, an event is loaded into the Event FIFO for processing containing the recorded time stamp value when the packet was transmitted or received.

In addition, both hardware (HWx_TS_PUSH) and software (TS_PUSH) can be used to read the current time stamp value though the Event FIFO. The reference clock used for the time stamp (CPTS_RFT_CLK) can be derived from several sources.

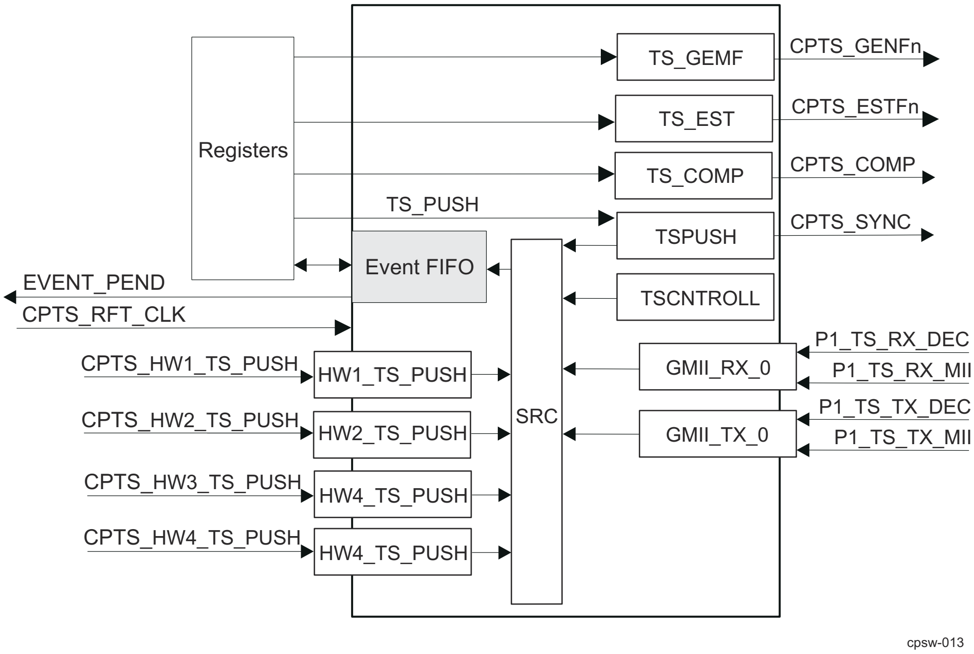

Figure 9-8. CPTS Block Diagram

Note

See Section 9.4.23.1, *CPTS Integration* for CPTS integration in the device.

9.4.23.3 CPTS Initialization

The CPTS module should be configured as follows:

1. Reset the CPTS module.
2. Write the **rftclk_sel[4:0]** value in the **RFTCLK_Sel** register with the desired reference clock multiplexor value. This value is allowed to be written only when the **cpts_en** bit in CPTS control register is cleared to zero.
3. Write a one to the **cpts_en** bit in the **TS_Control** register. The **RCLK** domain is in reset while this bit is low.
4. Enable the interrupt by writing a one to the **ts_pend** bit in the **Int_Enable** register (if using interrupts and not polling)..

9.4.23.4 32-bit Time Stamp Value

The **time_stamp** value is a 32-bit value that is cleared to zero when **cpts_en** is cleared to zero and increments on each **RCLK** rising edge when **cpts_en** is set to one. The time stamp value can be written via the time stamp load function (**TS_Load_En** and **TS_Load_Low_val** registers). Host software maintains the required number of upper bits of the time stamp value. The upper time stamp value is incremented by the host when the rollover event is detected. The **add_val[2:0]** of **TS_ADD_VAL** value must be zero in 32-bit mode. Nudge and PPM adjustments are not supported in 32-bit mode.

9.4.23.5 64-bit Time Stamp Value

The **time_stamp** value is a 64-bit value that is cleared to zero when **cpts_en** is cleared to zero and increments by the increment value (1 to 8) on each **RCLK** rising edge when **cpts_en** is set to one. The increment value is from 1 to 8 (1 + **ts_add_val[2:0]**). The default increment value is one. The time stamp value can be written via the time stamp load function (**TS_Load_En**, **TS_Load_Low_val**, and **TS_Load_High_val** registers). The **add_val** feature (TS_ADD_VAL_Reg) is included to allow 1ns timestamp operations with an **RCLK** rate less than 1Ghz.The below table shows the **RCLK** and **add_val** values for 1ns operations. The highest **RCLK** frequency possible should be used as allowed by the technology. Table 9-22 shows the RFTCLK_SEL and TS_ADD_VAL_REG values for 1ns operations.

Table 9-22. ADD_VAL feature

RFTCLK_SEL (MHz)	TS_ADD_VAL_REG[2-0]
1 GHz	0
500 MHz	1
333.33 MHz	2
250 MHz	3
200 MHz	4
166.66 MHz	5

9.4.23.6 64-Bit Timestamp Nudge

The 64-bit **time_stamp** value can be adjusted by writing the **ts_nudge_val[7:0]** register value which is a 2's complement value. A value of 0xff will subtract 1 **RCLK** from the next incremented **time_stamp[63:0]** value. A nudge value of 0x01 will add 1 **RCLK** to the next incremented **time_stamp[63:0]** value. For example, if the current **time_stamp** value is 0x0f06, and **add_val[2:0]**=3, the next incremented timestamp value would be 0x0f0a without a nudge and 0x0f0a +/- **tx_nudge_val[7:0]** with a nudge. The **ts_nudge** value is cleared to zero when the nudge has occurred.

9.4.23.7 64-bit Timestamp PPM

The 64-bit **time_stamp** can be adjusted by parts per million or by parts per hour. Writing a non-zero value to the **ts_ppm[41:0]** (PPM_High & PPM_High)value enables PPM operations. The adjustment is up or down depending on the **ppm_dir** bit (TS_control_Reg). The **time_stamp** value is increased by the PPM value when **ppm_dir** is cleared and decreased by the PPM value when **ppm_dir** is set.

Parts Per Million example:
To adjust for 100 parts per million the configured value for **ts_ppm[41:0]** is:

1,000,000/100 = decimal 10,000

Parts Per Hour example:
To adjust for 1 part per hour at 1 Ghz **RCLK** the configured value for **ts_ppm[41:0]** is: (1,000,0000,000hz/1pph) * (3600 seconds/hour) = hex 34630B8A000

9.4.23.8 Event FIFO

The event FIFO contains at least as many locations as two times the number of ports plus 6 locations. Software must service the event FIFO in a timely manner which prevents event FIFO overrun. No overrun indication will be given.

9.4.23.9 Timestamp Compare Output

The **TS_COMP** function is a software oriented feature that is intended to be replaced going forward by the hardware oriented GENF function. **TS_COMP** is not compatible with timestamp PPM or a non-zero **TS_ADD_VAL** value.

9.4.23.9.1 Non-Toggle Mode: 32-bit

The **TS_COMP** output is asserted for **ts_comp_length[31:0] RCLK** periods when the **time_stamp[31:0]** (EVENT_0_REG) value compares with the **ts_comp_val[31:0]** and the length value is non-zero. The **TS_COMP** rising edge occurs three **RCLK** periods after the values compare. A timestamp compare event is pushed into the event FIFO when **TS_COMP** is asserted. The polarity of the **TS_COMP** output is determined by the **ts_comp_polarity** bit. The output is asserted low when the polarity bit is low.

9.4.23.9.2 Non-Toggle Mode: 64-bit

64-bit mode operation is identical to 32-bit mode except that all 64-bits of the **timestamp[63:0]** are used (Event_0_reg and Event_3_reg) instead of only the lower 32-bits. The 64-bit timestamp cannot be allowed to rollover.

9.4.23.9.3 Toggle Mode: 32-bit

The **TS_COMP** output is asserted for **ts_comp_len[31:0] RCLK** periods when the **time_stamp[31:0]** value compares with the **ts_comp_low_val[31:0]** and the length value is non-zero. The **TS_COMP** toggles thereafter on **ts_comp_low_len[31:0] RCLK** periods. The length high or low can be adjusted by writing the **TS_COMP_NUDGE[7:0]** register value which is a 2's complement value. A value of 0xff will subtract 1 **RCLK** from the **ts_comp_length[31:0]** value. A value of 0x01 will add 1 **RCLK** to the **ts_comp_length[31:0]** value. Only a single high or low time is adjusted (nudged) and the **ts_comp_nudge** value is cleared to zero when the nudge has occurred. The **TS_COMP** output is asserted low when the **TS_Comp_Polarity** bit is low. No compare events and no **CPTS_EVNT** interrupts are generated in toggle mode. The **ts_comp_tog** bit must be set for toggle mode, and must be set before writing a non-zero value to **ts_comp_length[31:0]**.

9.4.23.9.4 Toggle Mode: 64-bit

64-bit mode operation is identical to 32-bit mode except that all 64-bits of the TIMESTAMP are used (EVENT_0_REG and EVENT_3_REG). In 32-bit mode only the lower 32-bits (EVENT_0_REG) are used.

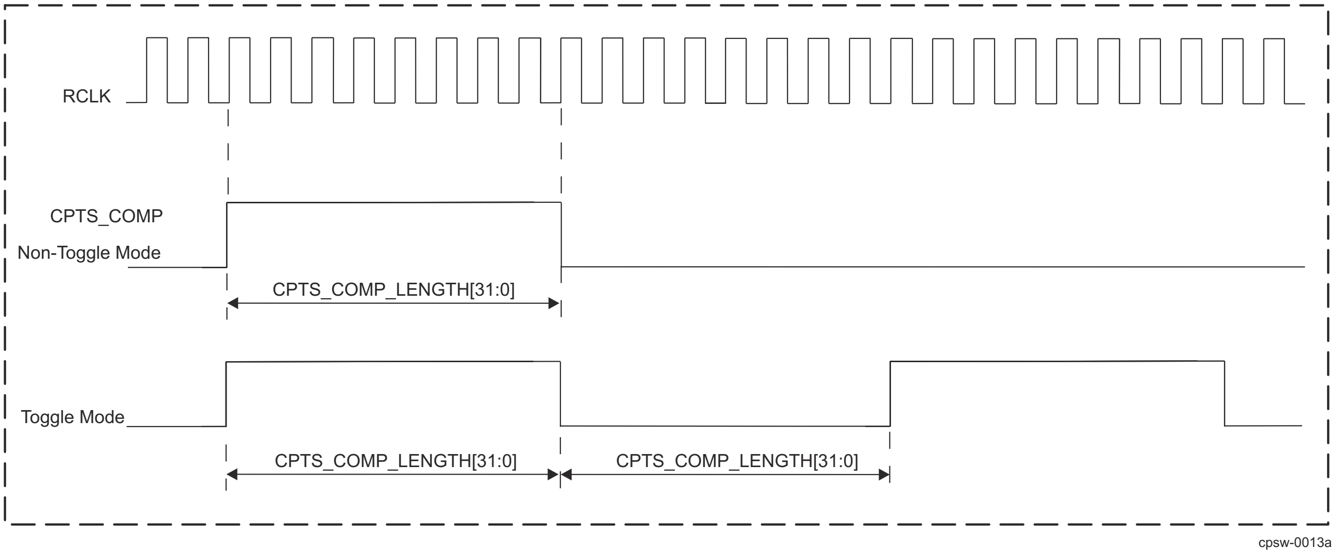

Figure 9-9. CPTS_COMP Output in Toggle and Non-Toggle Mode

9.4.23.10 Timestamp Sync Output

The CPTS_SYNC output is a selected bit of the [31-0]TIME_STAMP counter value. One of bits 17-31 can be selected in CPTS_CONTROL_REG[31-28] TS_SYNC_SEL. The CPTS_SYNC output is disabled when CPTS_CONTROL_REG[31-28] TS_SYNC_SEL is zero.

If the selected counter bit is 1 at the time when TS_SYNC_SEL value is written then a rising edge will not occur on the CPTS_SYNC output. A rising edge will occur on the CPTS_SYNC output upon the next transition to 1 of the selected counter bit. The TS_SYNC_SEL value must be written to zero before changing to a different non-zero value. No events are generated due to the CPTS_SYNC operation. The CPTS_SYNC output is two CPTS_RFT_CLK periods after the actual count value.

9.4.23.11 Timestamp GENFn Output

The CPTS_GENFn outputs have a programmable cycle (frequency) with a PPM feature and software nudge feature. The CPTS_GENFn output cycle is CPSW_GENF0_LENGTH_REG_l[31-0] CPTS_RFT_CLK periods (which is different than CPTS_COMP operation). Figure 9-10 represents the CPTS_GENFn output signal.

The CPTS_GENFn output cycle is CPSW_GENF0_LENGTH_REG_l[31-0] CPTS_RFT_CLK periods beginning when the 64-bit TIME_STAMP value compares with the 64-bit GENFn_COMP value (CPSW_GENF0_COMP_LOW_REG_l and CPSW_GENF0_COMP_HIGH_REG_l registers) and the length value is non-zero. The CPTS_GENFn output cycle repeats thereafter every CPSW_GENF0_LENGTH_REG_l[31-0] CPTS_RFT_CLK periods. The upper 32-bit word should be written first for 64-bit values. The length should be zero while the comparison value and other configuration parameters are being configured. The length should be written non-zero to enable operations last. The first cycle after comparison is active high when the CPSW_CPTS_CONTROL_REG[2] TS_COMP_POLARITY bit is low. No compare events and no CPTS_EVNT interrupts are generated.

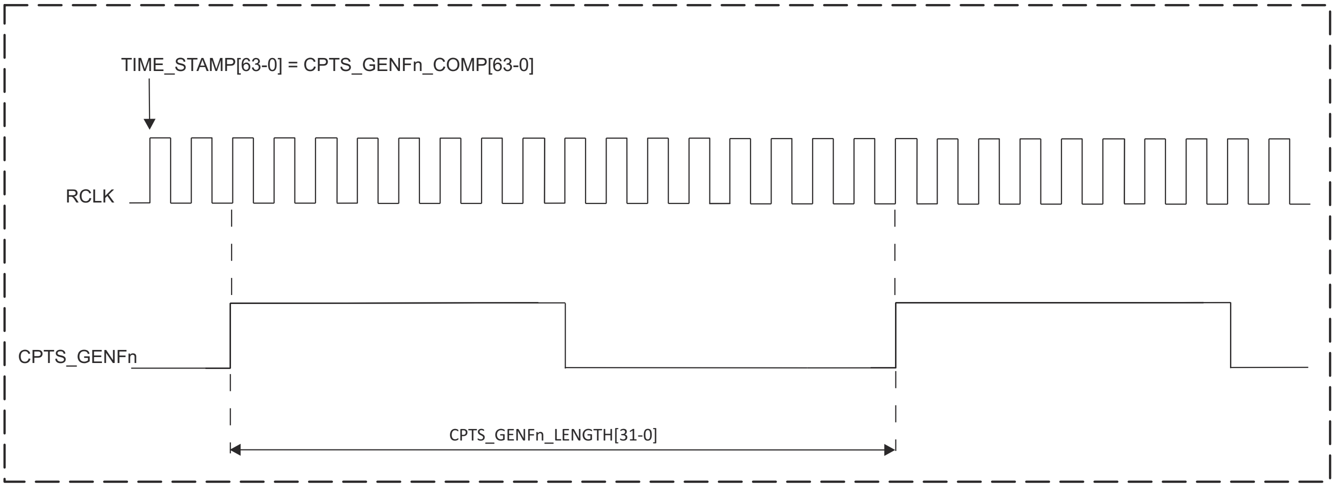

Figure 9-10. CPTS_GENFn Output Signal Diagram

9.4.23.11.1 GENFn Nudge

The cycle length can be adjusted by writing the CPSW_CPTS_TS_COMP_NUDGE_REG[7-0] NUDGE register value which is a two's complement value. A value of FFh will subtract 1 CPTS_RFT_CLK from the CPSW_GENF0_LENGTH_REG_l[31-0] value. A value of 1h will add 1 CPTS_RFT_CLK to the CPSW0_ESTF1_LENGTH_REG_l[23-0] value. The CPSW_CPTS_TS_COMP_NUDGE_REG[7-0] NUDGE value is cleared to zero when the nudge has occurred.

9.4.23.11.2 GENFn PPM

The CPTS_GENFn output cycle can be adjusted by parts per million or by parts per hour. Writing a non-zero value to CPSW_GENF0_PPM_LOW_REG_l/ CPSW_GENF0_PPM_HIGH_REG_l enables PPM operations. The PPM counter continually loads and decrements to zero and then loads again. A single CPTS_RFT_CLK adjustment is made when the PPM counter decrements to zero. The adjustment is up or down depending on the CPSW_ESTF1_CONTROL_REG[0] PPM_DIR bit. When PPM_DIR bit is set a single CPTS_RFT_CLK time is subtracted from the generate function counter which has the effect of increasing the generate function frequency by the PPM amount. When PPM_DIR bit is cleared a single CPTS_RFT_CLK time is added to the generate function counter which has the effect of decreasing the generate function frequency by the PPM amount.

Parts Per Million example:
To adjust for 100 parts per million the configured value for GENF_PPM[41-0] (through CPSW_GENF0_PPM_LOW_REG_l and CPSW_GENF0_PPM_HIGH_REG_l) is:
1,000,000/100 = 10,000(decimal)

Parts Per Hour example:
To adjust for 1 part per hour at 1 GHz CPTS_RFT_CLK the configured value for GENF_PPM[41-0] (through CPSW_GENF0_PPM_LOW_REG_l and CPSW_GENF0_PPM_HIGH_REG_l) is:
(1,000,0000,000Hz/1pph) * (3600 seconds/hour) = 34630B8A000 (hex)

9.4.23.12 Timestamp ESTFn

Each Ethernet port has a dedicated ESTFn generator which operates identically to the GENFn function.

9.4.23.13 Time Sync Events

Time Sync events are 96-bit values that are pushed onto the event FIFO and read by software in 32-bit reads. Four 32-bit registers, CPSW_CPTS_EVENT_0_REG through CPSW_CPTS_EVENT_3_REG hold the data of a time sync event. There are eight types of sync events:

- Time Stamp Push Event
- Time Stamp Counter Rollover Event (32-bit mode only)
- Time Stamp Counter Half-rollover Event (32-bit mode only)
- Hardware Time Stamp Push Event
- Ethernet Receive Event
- Ethernet Transmit Event
- Time Stamp Compare Event
- Host Transmit Event

Name	Description
time_stamp	Time Stamp – The timestamp is valid for transmit, receive, and time stamp push event types. The timestamp value is not valid for counter roll event types.

Name	Description
port_number	Port Number – indicates the port number of an Ethernet event (1 to 4 encoded) or the hardware push number (1 to 8 encoded).
event_type	Time Sync Event Type 0000 – Time Stamp Push Event 0001 – Time Stamp Rollover Event (32-bit mode only) 0010 – Time Stamp Half Rollover Event (32-bit mode only) 0011 – Hardware Time Stamp Push Event 0100 – Ethernet Receive Event 0101 – Ethernet Transmit Event 0110 – Time Stamp Compare Event 0111 – Host Event 1000 --- - reserved 1111
message_type	Message type – The message type value that was contained in an Ethernet transmit or receive time sync packet. This field is valid only for Ethernet transmit or receive events.
sequence_id	Sequence ID – The 16-bit sequence id is the value that was contained in an Ethernet transmit or receive time sync packet. This field is valid only for Ethernet transmit or receive events.
domain	Domain – The 8-bit domain is the value that was contained in an Ethernet transmit or receive time sync packet. This field is valid only for Ethernet transmit or receive events.
prempt_queue	Prempt Queue – 0 – The packet was received/transmitted on the express queue. 1 – The packet was received/transmitted on the prempt queue.

9.4.23.13.1 Time Stamp Push Event

Software can obtain the current time stamp value (at the time of the write) by initiating a time stamp push event. The push event is initiated by setting the TS_PUSH bit of the CPSW_CPTS_TS_PUSH_REG register. The time stamp value is returned in the event, along with a time stamp push event code. The upper 32-bits (CPSW_CPTS_EVENT_3_REG register) of the timestamp are zero in 32-bit mode.

9.4.23.13.2 Time Stamp Counter Rollover Event (32-bit mode only)

The CPTS module contains a 32-bit time stamp value (CPSW_CPTS_EVENT_0_REG). The counter upper bits are maintained by host software. The rollover event indicates to software that the time stamp counter has rolled over from 0xFFFF FFFF to 0x0000 0000 and the software-maintained upper count value should be incremented. This event occurs only in 32-bit mode.

9.4.23.13.3 Time Stamp Counter Half-rollover Event (32-bit mode only)

The CPTS includes a time stamp counter half-rollover event. The half-rollover event indicates to software that the time stamp value (CPSW_CPTS_EVENT_0_REG[31-0] TIME_STAMP) has incremented from 0x7FFF FFFF to 0x8000 0000. The half-rollover event is included to enable software to correct a misaligned event condition. This event occurs only in 32-bit mode.

The half-rollover event is included to enable software to determine the correct time for each event that contains a valid time stamp value, such as an Ethernet event. If an Ethernet event occurs around a counter rollover (full rollover), the rollover event could possibly be loaded into the event FIFO before the Ethernet event, even though the Ethernet event time was actually taken before the rollover. Figure 9-11 shows a misalignment condition. This misaligned event condition arises because an Ethernet event time stamp occurs at the beginning of a packet and time passes before the packet is determined to be a valid synchronization packet. The misaligned event condition occurs if the rollover occurs in the middle, after the packet time stamp has been taken, but before the packet has been determined to be a valid time sync packet.

Host software must detect and correct for misaligned event conditions. For every event time stamp after a rollover and before a half-rollover, software must examine the time stamp most significant bit. If bit 31 of the time stamp value is low (0x0000 0000 through 0x7FFF FFFF), then the event time stamp was taken after the rollover and no correction is required. If the value is high (0x8000 0000 through 0xFFFF FFFF), the time stamp value was taken before the rollover and a misalignment is detected. The misaligned case indicates to software that it must subtract one from the upper count value stored in software to calculate the correct time for the misaligned event. The misaligned event occurs only on the rollover boundary and not on the half-rollover boundary. Software only needs to check for misalignment from a rollover event to a half-rollover event.

When a rollover occurs, software increments the software time stamp upper value. The misaligned case indicates to software that the misaligned event time stamp has a valid upper value that is pre-increment, so one must be subtracted from the upper value to allow software to calculate the correct time for the misaligned event.

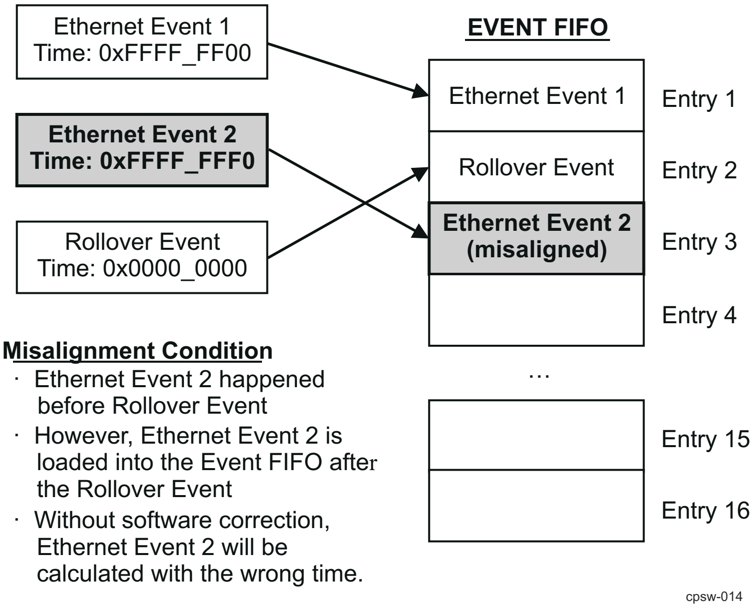

Figure 9-11. Event FIFO Misalignment Condition

9.4.23.13.4 Hardware Time Stamp Push Event

There are four hardware time stamp inputs (CPTS_HW[1:4]_TS_PUSH events) that can cause hardware time stamp push events to be loaded into the Event FIFO. Each time stamp input is mapped in the device as shown in Figure 9-7. The event is loaded into the event FIFO on the rising edge of the timer, and the PORT_NUMBER field in the CPSW_CPTS_EVENT_1_REG register indicates the hardware push input that caused the event (encoded).

The hardware time stamp inputs are asynchronous and are low frequency signals. The CPTS logic synchronizes and performs a rising edge detect on the incoming asynchronous input.

Each hardware time stamp input must be asserted for at least 10 periods of the selected CPTS_RFT_CLK clock. Each input can be enabled or disabled by setting the respective bits in the CPSW_CPTS_CONTROL_REG register.

Hardware time stamps are intended to be an extremely low frequency signals, such that the event FIFO does not overrun. Software must keep up with the event FIFO and ensure that there is no overrun, or events will be lost.

9.4.23.13.5 Ethernet Port Events

Packets transmitted or received on each Ethernet port can generate Ethernet Transmit Events or Ethernet Receive Events, respectively. The CPTS hardware will decode each packet to determine if it is a valid CPTS time sync event.

According to the IEEE 802.3 Ethernet standard, each Ethernet frame contains a 2-octet EtherType field to indicate which protocol is encapsulated in the PayLoad field, as shown in Figure 9-12. For standard time sync packets, this will contain the EtherType for the Precision Time Protocol (IEEE 1588), which is defined as 0x88F7. The CPTS hardware will compare this field to the TS_LTYPE1 field in the CPSW_PN_TS_SEQ_LTYPE_REG register or the TS_LTYPE2 field in CPSW_PN_TS_CTL_LTYPE2_REG register (depending on which enable bit was set) , which should also be programmed to 88F7h.

When a virtual LAN is used, an additional 4-octet 802.1Q tag is inserted in the Ethernet frame before the EtherType field, as shown in Figure 9-12. To indicate to the CPTS hardware that a virtual LAN is in use, the TS_TX_VLAN_LTYPE1_EN (or TS_TX_VLAN_LTYPE2_EN) enable bit must be set in the CPSW_PN_TS_CTL_REG register. The EtherType for the 802.1Q tag is defined as 0x8100, and the CPTS hardware will compare this value to the TS_VLAN_LTYPE1 (or TS_VLAN_LTYPE2 depending on which enable bit was set) field in the CPSW_PN_TS_VLAN_LTYPE_REG register, which should also be programmed to 0x8100.

When two stacked VLANs are used, two additional 4-octet 801.Q tags are inserted in the Ethernet frame before the EtherType field, as shown in Figure 9-12. In this case, both TS_VLAN_LTYPE1 and TS_VLAN_LTYPE2 must be enabled. The outer tag must match the value of the TS_VLAN_LTYPE1 field, and the inner tag must match the value of the TS_VLAN_LTYPE2 field.

9.4.23.13.5.1 Ethernet Port Receive Event

This section describes Ethernet port receive events. Ethernet port generates time synchronization events for valid received time sync packets. For every packet received on the Ethernet port, a timestamp will be captured by the receive module inside the CPTS for the corresponding port. The time stamp will be captured by the receive module regardless of whether or not the packet is a time synchronization packet to make sure that the time stamp is captured as soon as possible. The packet is sampled on both the rising and falling edges of the CPTS_RFT_CLK, and the time stamp will be captured once the start of frame delimiter for the receive packet is detected.

After the time stamp has been captured, the receive interface will begin parsing the packet to determine if it is a valid Ethernet time synchronization packet. The CPSW decoder determines if the packet is a valid Ethernet receive time synchronization event. The receive interface for the port will use the following criteria to determine if the packet is a valid Annex D, Annex E, or Annex F time synchronization Ethernet receive event:

Annex D (IPv4)

1. Receive annex D time sync is enabled (TS_RX_ANNEX_D_EN is set in the CPSW_PN_TS_CTL_REG register).
2. One of the sequences below is true.
    a. The first packet LTYPE matches 0x0800
    b. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches 0x0800
    c. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches 0x0800
    d. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the third packet LTYPE matches 0x0800
3. Byte 14 (the byte after the LTYPE) contains 0x45 (IPv4).

Note

The byte numbering assumes that there are no VLANs. The byte number is intended to show the relative order of the bytes.

4. Byte 20 contains 0bXXX00000 (5 lower bits zero) and Byte 21 contains 0x00 (fragment offset zero)
5. Byte 22 contains 0x01 (HOP Limit = 1) if the TS_TTL_NONZERO bit in the switch CPSW_PN_TS_CTL_LTYPE2_REG register is cleared to 0h, or byte 22 contains any value if CPSW_PN_TS_CTL_LTYPE2_REG is set to 1h. Byte 22 is the TTL/HOP field.
6. Byte 23 contains 0x11 (Next Header UDP Fixed).
7. The TS_UNI_EN bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is cleared to 0h and Bytes 30 through 33 contain:
    a. Decimal 224.0.1.129 and the TS_129 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
    b. Decimal 224.0.1.130 and the TS_130 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
    c. Decimal 224.0.1.131 and the TS_131 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
    d. Decimal 224.0.1.132 and the TS_132 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
    e. Decimal 224.0.0.107 and the TS_107 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set

    -OR-

    The TS_UNI_EN bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set and Bytes 30 through 33 contain any values.
8. Bytes 36 and 37 contain:

   a. Decimal 0x01 and 0x3F respectively and the TS_319 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set -OR-
   b. Decimal 0x01 and 0x40 respectively and the TS_320 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set.

9. The PTP message begins in byte 42.
10. The packet message type is enabled in the TS_MSG_TYPE_EN field in the CPSW_PN_TS_CTL_REG register.
11. The packet was received without error (not long/short/mac_ctl/CRC/code/align).

Annex E (IPv6)

1. Receive annex E time sync is enabled (TS_RX_ANNEX_E_EN bit is set in the switch CPSW_PN_TS_CTL_REG register).
2. One of the sequences below is true.
   a. The first packet LTYPE matches 0x86dd.
   b. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches 0x86dd
   c. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches 0x86dd
   d. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the third packet LTYPE matches 0x86dd
3. Byte 14 (the byte after the LTYPE) contains 0x6X (IPv6).
4. Byte 20 contains 0x11 (UDP Fixed Next Header).
5. Byte 21 contains 0x01 (Hop Limit = 1) if the TS_TTL_NONZERO bit in the switch CPSW_PN_TS_CTL_LTYPE2_REG register is cleared to 0h, or byte 21 contains any value if TS_TTL_NONZERO is set to 1h. Byte 21 is the TTL/HOP field.
6. The TS_UNI_EN bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is cleared to 0 and Bytes 38 through 53 contain:
   a. FF0M:0:0:0:0:0:0:0181 and the TS_129 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
   b. FF0M:0:0:0:0:0:0:0182 and the TS_130 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
   c. FF0M:0:0:0:0:0:0:0183 and the TS_131 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
   d. FF0M:0:0:0:0:0:0:0184 and the TS_132 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
   e. FF0M:0:0:0:0:0:0:006B and the TS_107 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set

   Note

   All values above are 16-bit hex numbers where M is enabled in the TS_MCAST_TYPE_EN field in the CPSW_PN_TS_CTL2_REG register.

   -OR-

   The TS_UNI_EN bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set to 1 and Bytes 38 through 53 contain any value.
7. Bytes 56 and 57 contain (UDP Header in bytes 54 through 61):
   a. Decimal 0x01 and 0x3F respectively and the TS_319 bit in the CPSW_PN_TS_CTL2_REG register is set, or
   b. Decimal 0x01 and 0x40 respectively and the TS_320 bit in the CPSW_PN_TS_CTL2_REG register is set.
8. The PTP message begins in byte 62.
9. The packet message type is enabled in the MSG_TYPE_EN field in the CPSW_PN_TS_CTL2_REG register.

10. The packet was received without error (not long/short/mac_ctl/CRC/code/align).

Annex F (IEEE 802.3)

1. Receive Annex F time sync is enabled (TS_RX_ANNEX_F_EN is set in the switch CPSW_PN_TS_CTL_REG register).
2. One of the sequences below is true:
    a. The first packet LTYPE matches TS_LTYPE1 in the CPSW_PN_TS_SEQ_LTYPE_REG register. LTYPE 1 should be used when only one time sync LTYPE is to be enabled.
    b. The first packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register and LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register.
    c. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_LTYPE1 in the CPSW_PN_TS_SEQ_LTYPE_REG register
    d. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register and TS_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register.
    e. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_LTYPE1 in the CPSW_PN_TS_SEQ_LTYPE_REG register.
    f. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register and TS_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register.
    g. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the third packet LTYPE matches TS_LTYPE1 in the CPSW_PN_TS_SEQ_LTYPE_REG register.
    h. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_RX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the third packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register and TS_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register
3. The PTP message begins in the byte after the LTYPE.
4. The packet message type is enabled in the TS_MSG_TYPE_EN field in the CPSW_PN_TS_CTL_REG register.
5. The packet was received without error (not long/short/mac_ctl/CRC/code/align).

If all of the criteria described above are met for either Annex D, Annex E, or Annex F, and the packet is determined to be a valid time synchronization packet, then the RX interface will push an Ethernet receive event into the event FIFO.

9.4.23.13.5.2 Ethernet Port Transmit Event

This section describes Ethernet port transmit events. For every packet transmitted on the Ethernet ports, the port transmit interface will begin parsing the packet to determine if it is a valid Ethernet time synchronization packet. The CPTS transmit interface for the port will use to the following criteria to determine if the packet is a valid time synchronization Ethernet transmit event. The CPSW decoder determines if the packet is a valid ethernet receive time synchronization event. To be a valid Ethernet transmit time synchronization event, the conditions listed below must be true for either Annex D, Annex E, or Annex F:

Annex D (IPv4)

1. Transmit time sync is enabled (TS_TX_ANNEX_D_EN is set in the CPSW_PN_TS_CTL_REG register).
2. One of the sequences below is true.

  a. The first packet LTYPE matches 0x0800
  b. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches 0x0800
  c. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches 0x0800
  d. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the third packet LTYPE matches 0x0800

3. Byte 14 (the byte after the LTYPE) contains 0x45 (IPv4).

Note

The byte numbering assumes that there are no VLANs. The byte number is intended to show the relative order of the bytes.

---

4. Byte 20 contains 0bXXX00000 (5 lower bits zero) and Byte 21 contains 0x00 (fragment offset zero)
5. Byte 22 contains 0x01 (HOP Limit = 1) if the TS_TTL_NONZERO bit in the switch CPSW_PN_TS_CTL_LTYPE2_REG register is cleared to 0h, or byte 22 contains any value if TS_TTL_NONZERO is set to 1h. Byte 22 is the TTL/HOP field.
6. Byte 23 contains 0x11 (Next Header UDP Fixed).
7. The TS_UNI_EN bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is cleared to 0h and Bytes 30 through 33 contain:
   a. Decimal 224.0.1.129 and the TS_129 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
   b. Decimal 224.0.1.130 and the TS_130 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
   c. Decimal 224.0.1.131 and the TS_131 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
   d. Decimal 224.0.1.132 and the TS_132 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
   e. Decimal 224.0.0.107 and the TS_107 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
   f. The TS_UNI_EN bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set and Bytes 30 through 33 contain any values.
8. Bytes 36 and 37 contain:
   a. Decimal 0x01 and 0x3F respectively and the TS_319 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
   b. Decimal 0x01 and 0x40 respectively and the TS_320 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set.
9. The PTP message begins in byte 42.
10. The packet message type is enabled in the TS_MSG_TYPE_EN field in the CPSW_PN_TS_CTL_REG register.
11. The packet was sent by host port 0.

Annex E (IPv6)

1. Transmit annex E time sync is enabled (TS_TX_ANNEX_E_EN bit is set in the switch CPSW_PN_TS_CTL_REG register).
2. One of the sequences below is true.
   a. The first packet LTYPE matches 0x86dd.
   b. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches 0x86dd
   c. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches 0x86dd
   d. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second

packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the third packet LTYPE matches 0x86dd

3. Byte 14 (the byte after the LTYPE) contains 0x6X (IPv6).
4. Byte 20 contains 0x11 (UDP Fixed Next Header).
5. Byte 21 contains 0x01 (Hop Limit = 1) if the TS_TTL_NONZERO bit in the switch CPSW_PN_TS_CTL_LTYPE2_REG register is cleared to 0h, or byte 21 contains any value if TS_TTL_NONZERO is set to 1h. Byte 21 is the TTL/HOP field..
6. The TS_UNI_EN bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is cleared to 0 and Bytes 38 through 53 contain:
    a. FF0M:0:0:0:0:0:0:0181 and the TS_129 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
    b. FF0M:0:0:0:0:0:0:0182 and the TS_130 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
    c. FF0M:0:0:0:0:0:0:0183 and the TS_131 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
    d. FF0M:0:0:0:0:0:0:0184 and the TS_132 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
    e. FF0M:0:0:0:0:0:0:006B and the TS_107 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set

    Note

    All values above are 16-bit hex numbers where M is enabled in the TS_MCAST_TYPE_EN field in the CPSW_PN_TS_CTL2_REG register.

    -OR-

    The TS_UNI_EN bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set to 1h and Bytes 38 through 53 contain any value.
7. Bytes 56 and 57 contain (UDP Header in bytes 54 through 61):
    a. Decimal 0x01 and 0x3F respectively and the TS_319 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set, or
    b. Decimal 0x01 and 0x40 respectively and the TS_320 bit in the CPSW_PN_TS_CTL_LTYPE2_REG register is set.
8. The PTP message begins in byte 62.
9. The packet message type is enabled in the TS_MSG_TYPE_EN field in the CPSW_PN_TS_CTL_REG register.
10. The packet was sent by host port 0.

Annex F (IEEE 802.3)

1. Transmit time sync is enabled (TS_TX_ANNEX_F_EN is set in the switch CPSW_PN_TS_CTL_REG register).
2. One of the sequences below is true:
    a. The first packet LTYPE matches TS_LTYPE1 in the CPSW_PN_TS_SEQ_LTYPE_REG register. LTYPE 1 should be used when only one time sync LTYPE is to be enabled.
    b. The first packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register and TS_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register.
    c. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register.
    d. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_LTYPE1 in the CPSW_PN_TS_SEQ_LTYPE_REG register.
    e. The first packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register.
    f. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet

LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register and TS_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register.

   g. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the third packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register.
   h. The first packet LTYPE matches TS_VLAN_LTYPE1 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE1_EN is set in the CPSW_PN_TS_CTL_REG register and the second packet LTYPE matches TS_VLAN_LTYPE2 in the CPSW_PN_TS_VLAN_LTYPE_REG register and TS_TX_VLAN_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register and the third packet LTYPE matches TS_LTYPE2 in the CPSW_PN_TS_CTL_LTYPE2_REG register and TS_LTYPE2_EN is set in the CPSW_PN_TS_CTL_REG register

3. The packet message type is enabled in the TS_MSG_TYPE_EN field in the CPSW_PN_TS_CTL_REG register.
4. The packet was sent by host port 0.

If all of the criteria described above are met, and the packet is determined to be a valid time synchronization packet, then the time stamp for the transmit event will not be generated until the start of frame delimiter of the packet is actually transmitted. The start of frame delimiter will be sampled on every rising and falling edge of the CPTS_RFT_CLK. Once the packet is transmitted, then the TX interface will push an Ethernet transmit event into the event FIFO.

Once a transmitted or received packet is determined to be a valid time sync packet, the Ethernet Transmit Event or Ethernet Receive Event is loaded onto the Event FIFO.

The CPTS_EVENT_1 register contains the Message Type and Sequence ID values from the original time sync packet. The CPTS_EVENT_0 (and CPTS_EVENT_3) register contains the time stamp value when the packet arrived at the corresponding port.

9.4.23.14 Timestamp Compare Event

Note

Timestamp compare events are generated for non-toggle mode only.

The CPTS can generate an event for a time stamp comparison in 32-bit or 64-bit mode.

9.4.23.14.1 32-Bit Mode

The CPTS_COMP output is also asserted when the event is generated. The event is generated when the 32-bit time stamp value (EVENT_0_REG) compares with the CPSW_CPTS_TS_COMP_VAL_REG register and the CPSW_CPTS_TS_COMP_LEN_REG value is non-zero. The CPSW_CPTS_TS_COMP_LEN_REG value should be written by software after the CPSW_CPTS_TS_COMP_VAL_REG register is written and should be zero when the comparison value is written.

9.4.23.14.2 64-Bit Mode

The CPTS_COMP output is also asserted when the event is generated. The event is generated when the 64-bit time stamp value (CPSW_CPTS_EVENT_0_REG and CPSW_CPTS_EVENT_3_REG) compares with the CPWS0_TS_COMP_VAL_REG and CPWS0_TS_COMP_HIGH_VAL_REG registers and the CPWS0_TS_COMP_LEN_REG value is non-zero. The CPWS0_TS_COMP_LEN_REG value should be written by software after the CPWS0_TS_COMP_VAL_REG register is written and should be zero when the comparison value is written.

9.4.23.15 Host Transmit Event

The host can send a packet to be transmitted on an Ethernet port that will generate a time synchronization event. The host sets the TSTAMP_EN bit and sends the DOMAIN, MESSAGE_TYPE, and SEQUENCE_ID in the additional control information that resides in the protocol specific section of the descriptor that is transmitted to the CPSW_2G. An event is then generated and placed on the event FIFO once the packet is transmitted. Host events allow the user to timestamp exactly when a software generated packet exits the device.

9.4.23.16 CPTS Interrupt Handling

The **TS_PEND** interrupt is enabled by writing a logic high to the **ts_int_enable** bit in the interrupt enable register. The raw interrupt value (before the enable) can be read by reading the **TS_Instat_raw** register. The enabled interrupt value can be read by reading the **TS_Instat_masked** register.

Software can process time sync events via interrupts in the following way:

1. Enable the **TS_PEND** interrupt by writing a logic high to bit zero of the **TS_Int_enable** register.
2. Upon interrupt, read the **Event_0-4** register values.
3. Write logic high to bit-0 of the **Event_Pop** register to pop the previously read value off of the event FIFO.
4. Process the end of interrupt as required by the upper level modules (outside the scope of CPTS).

Software has the option of processing more than a single event from the event FIFO in the interrupt service routine in the following way:

1. Enable the **TS_PEND** interrupt by writing a logic high to bit zero of the **TS_Int_enable** register.
2. Upon interrupt enter the CPTS service routine.
3. Read the **Event_0-4** register values.
4. Write a logic high to bit-0 of the **Event_Pop** register to pop the previously read value off of the event FIFO.
5. Wait for an amount of time greater than four **RCLK** periods plus four **VBUSP_CLK** periods.
6. Read bit 0 (**ts_pend_raw**) in the **TS_Intstat_raw** register to determine if another valid event is in the event FIFO. If bit zero is asserted then go to step 3. If bit 0 is not asserted then go to step 7.
7. Process the end of interrupt as required by the upper level modules (outside the scope of CPTS).

Software also has the option of disabling the interrupt and polling the **ts_intstat_raw** bit to determine if a valid event is on the event FIFO.

9.4.24 MII Management Interface (MDIO)

The MII Management interface module implements the 802.3 serial management interface to interrogate and control external Ethernet PHY using a two-wire bus.

Features Supported

- Clause 22 and CLuse 45 support
- Supports up to 32 PHY addresses.

- Two user access registers to control and monitor up to two PHYs simultaneously.
- VBUS 3.0 compliant slave interface for configuration and control.
- Each PHY can be individually enabled to be polled.
- The inter-poll gap between PHY polls can be changed.
- State Change Mode of operation to monitor up to 32 PHYs simultaneously.
- The MDIO interface can be manually controlled by software for GPIO operations.

9.4.24.1 MDIO Frame Formats

Clause 22

Table 9-24. MDIO Clause 22 Read Frame Format

Pre-amble	Start Delimiter	Operation Code	PHY Address	MMD Number	Turnaround	Data
FFFF FFFFh	01	10	AAAAA	RRRRR	Z0	DDDD.DDDD.DDDD.DDDD

Table 9-25. MDIO Clause 22 Write Frame Format

Pre-amble	Start Delimiter	Operation Code	PHY Address	MMD Number	Turnaround	Data
FFFF FFFFh	01	01	AAAAA	RRRRR	10	DDDD.DDDD.DDDD.DDDD

The default or idle state of the two wire serial interface is a logic one. All tri-state drivers should be disabled and the PHY’s pull-up resistor should pull the **MDIO** line to a logic one. Prior to initiating any other transaction, the station management entity shall send a preamble sequence of 32 contiguous logic one bits on the **MDIO** line with 32 corresponding cycles on **MDCLK** to provide the PHY with a pattern that it can use to establish synchronization. A PHY shall observe a sequence of 32 contiguous logic one bits on **MDIO** with 32 corresponding **MDCLK** cycles before it responds to any other transaction.

Preamble

The start of a frame is indicated by a preamble, which consists of a sequence of 32 contiguous bits all of which are a “1”. This sequence provides the PHY a pattern to use to establish synchronization.

Start Delimiter

The preamble is followed by the start delimiter which is indicated by a “01” pattern. The pattern assures transitions from the default logic one state to zero and back to one.

Operation Code

The operation code for a read is “10”, while the operation code for a write is a “01”.

PHY Address

The PHY address is 5 bits allowing 32 unique values. The first bit transmitted is the MSbit of the PHY address.

Register Address

The Register address is 5 bits allowing 32 registers to be addressed within each PHY. Refer to the 10/100 PHY address map for addresses of individual registers.

Turnaround

An idle bit time during which no device actively drives the MDIO signal shall be inserted between the register address field and the data field of a read frame in order to avoid contention. During a read frame, the PHY shall drive a zero bit onto MDIO for the first bit time following the idle bit and preceding the Data field. During a write frame, this field shall consist of a one bit followed by a zero bit.

Data

The Data field is 16-bits. The first bit transmitted and received is the MSbit of the data word.

Clause 45

Table 9-26 shows the address, Table 9-27 shows the read format and Table 9-28 shows the write format of the supported Clause 45 MII Management interface frames. Post-increment accesses are not supported.

Table 9-26. MDIO Clause 45 Address Frame Format

Pre-amble	Start Delimiter	Operation Code	PHY Address	MMD Number	Turnaround	Data
FFFF FFFFh	00	00	AAAAA	RRRRR	10	AAAA.AAAA.AAAA.AAAA

Table 9-27. MDIO Clause 45 Read Frame Format

Pre-amble	Start Delimiter	Operation Code	PHY Address	MMD Number	Turnaround	Data
FFFF FFFFh	00	11	AAAAA	RRRRR	Z0	DDDD.DDDD.DDDD.DDDD

Table 9-28. MDIO Clause 45 Write Frame Format

Pre-amble	Start Delimiter	Operation Code	PHY Address	MMD Number	Turnaround	Data
FFFF FFFFh	00	01	AAAAA	RRRRR	10	DDDD.DDDD.DDDD.DDDD

The default or idle state of the two wire serial interface is a logic one. All tri-state drivers should be disabled and the PHY’s pull-up resistor should pull the **MDIO** line to a logic one. Prior to initiating any other transaction, the station management entity shall send a preamble sequence of 32 contiguous logic one bits on the **MDIO** line with 32 corresponding cycles on **MDCLK** to provide the PHY with a pattern that it can use to establish synchronization. A PHY shall observe a sequence of 32 contiguous logic one bits on **MDIO** with 32 corresponding **MDCLK** cycles before it responds to any other transaction. The **MDIO User_Addr** registers must be written before a read or write operation is performed to set the address used in the operation. Each read or write operation has a preceeding address frame.

Preamble

The start of a frame is indicated by a preamble, which consists of a sequence of 32 contiguous bits all of which are a “1”. This sequence provides the PHY a pattern to use to establish synchronization. The preamble is required in clause 45 operation.

Start Delimiter

The preamble is followed by the start delimiter which is indicated by a “00” pattern.

Operation Code

The operation code for an address transaction is “00”, The operation code for a read is “11”, while the operation code for a write is a “01”.

PHY Address

The PHY address is 5 bits allowing 32 unique values. The first bit transmitted is the MSbit of the PHY address.

MMD Number

The MMD number is the 5-bits allowing 32 unique values. The first bit transmitted is the MSbit.

Turnaround

An idle bit time during which no device actively drives the MDIO signal shall be inserted between the register address field and the data field of a read frame in order to avoid contention. During a read frame, the PHY shall drive a zero bit onto MDIO for the first bit time following the idle bit and preceding the Data field. During a write frame, this field shall consist of a one bit followed by a zero bit.

Address

The address field is 16-bits on address operations. The first bit transmitted is the MSbit of the address word. Each read/write operation initiated has an automatic address operation initiated first that uses the **MDIO User_Addr0/1** register values as the 16-bit address.

Data

The Data field is 16-bits on read and write operations. The first bit transmitted and received is the MSbit of the data word.

9.4.24.2 MDIO Functional Description

The MDIO Management I/F will remain idle until enabled by setting the **enable** bit in the **MDIO Control** register. The module will then continuously poll the linkstatus bits from within the GenericStatusRegister of all enabled 32 PHY addresses. Individual PHY's can be enabled or disabled for polling thru the associated bit in the **Poll_En** register. The **MDIO Link** and **MDIO alive** register bit values are updated on the poll of each PHY. In Normal Mode, The link status of two of the 32 possible PHY addresses can also be determined using the **MLINK** pin inputs. The **linksel** bit in the **MDIO USER_PHY_SEL** register determines the status input that is used. A change in the link status of the two PHYs being monitored will set the appropriate bit in the **MDIO LinkIntRaw** register and the **MDIO LinkIntMasked** register, if enabled by the **linkint_enable** bit in the **MDIO User_Phy_Sel** register. In State Change Mode, a change in any PHY status will be indicated on the **MDIO LINKINT[0]** interrupt if enabled.

The **MDIO Alive** register is updated if the PHY acknowledged the read of the generic status register. In addition, any PHY register read transactions initiated by the host also update the **MDIO Alive** register bit associated with the PHY.

At any time, the host can initiate a transaction for the MDO module to undertake using the **data, phyadr, regadd/MMD,** and **write** fields in an **MDIO User_Access** register. When the host sets the **go** bit in this register, the MDIO module will begin the transaction without any further intervention from the host. Upon completion, the MDIO will clear the **go** bit and set the **userintraw** bit in the **MDIO User_Int_Raw** register corresponding to the **MDIO User_Access** register being used. The corresponding bit in the **MDIO User_Int_Masked** register may also be set depending on the mask setting in the **MDIO User_Int_Mask_Set** and **MDIO User_Int_Mask_Clear** registers. A round-robin arbitration scheme is used to schedule transactions which may queued by the host in different **MDIO User_Access** registers. The host should check the status of the **go** bit in the **MDIO User_Access** register before initiating a new transaction to ensure that the previous transaction has completed. The host can use the **ack** bit in the **MDIO User_Access** register to determine the status of a read transaction.

Software may use the MDIO module to setup the auto-negotiation parameters of each PHY attached to a MAC port, retrieve the negotiation results, and setup the **MAC Control** register in the corresponding MAC.

9.4.25 Reset Isolation

The CPSW supports reset isolation of the Ethernet switch ports. When the **ISOLATE** input is asserted the below occur simultaneously:

- The Host Port 0 is removed from ALE processing (packets received on ports 1 through N-1 will be dropped to port 0).
- FHost packets are dropped. Any packet currently in progress when ISOLATE is asserted is dropped due to a FHost packet code error (and possible a CRC or FRAG error).
- THost packets in queue are dropped.

The intent of reset isolation is to allow packets to switch between the Ethernet ports while the remainder of the system is undergoing a reset. Isolation assumes that the external host and logic connected to the port 0 host interface is reset and will not be in the middle of a packet when **ISOLATE** is de-asserted.

9.4.26 CPSW Initialization and Configuration

To configure the CPSW for operation the host must perform the following:

- Ensure that at least 2000 VBUSP_CLK periods are run after reset is de-asserted.
- Configure the CPSW Control register.

- Configure the Ethernet Port Source Address registers
- Configure the Statistics Port Enable registers
- Configure the ALE.
- Configure the Ethernet Ports.

9.4.27 Enet Mac Reset or XGMII/GMII Mode Change Configuration

- Set pn_cmd_idle in the Ethernet port Pn_Mac_Control registers.
- Wait for pn_Idle to be indicated in the Ethernet port Pn_Mac_Status registers.
- Set pn_soft_reset in the Ethernet port Pn_Soft_Reset registers.
- Wait for pn_soft_reset in the Pn_Soft_Reset registers to be cleared to confirm reset completion.
- Configure the Ethernet ports.

9.4.28 Memory Error Detection and Correction

The cpsw error detection and correction logic uses the IP ECC Aggregator Module. The ECC Aggregator allows the control of the cpsw RAMs as shown in the below table. ECC is always enabled. The cpsw FIFO RAMS implement ECC only on packet headers. The packet data is protected by Castignoli CRC (regardless of the input packet CRC type or output CRC type). The ALE and EST RAMs have complete ECC as normal.

9.4.28.1 Packet Header ECC

Only packet headers bits are protected by ECC in the cpsw RAMs. The **ECC_Error_Control1** register **ecc_row** is not implemented – **ecc_bit1** is implemented to determine which bit of the header is flipped for an SEC error when the **ecc_crc_mode** bit is cleared in the **CPSW_Control** register. The ECC status registers return the RAM address that was flipped (**ecc_row**) along with the **ecc_bit1** value. Forcing double bit errors in testing can cause indeterminate switch operation if multiple used packet header bits are flipped given that only single bit errors are fixed by the ECC logic. Header bits 207 downto 200 are not currently used in the switch and may be used to test double bit errors without the possibility of requiring a reset for the switch to recover from the double bit error. No header bits are flipped when **ecc_crc_mode** is set to one. Either the **pn_rx_ecc_err_en** or the **pn_tx_ecc_err_en** bit must be set in the **PN_Control** register to test ecc header errors.

The header ECC code is stored in bits 255 downto 208. If any bit is flipped in the ECC code, the flipped bit will be corrected, but the index of the flipped bit will be reported as bit zero. This implies that when the aggregator reports that there is a SEC on 'bit 0', it can mean two things: either SEC on data bit 0 or SEC somewhere inside the ECC code. Any packet header with ECC error issues a pulse on **ECC_PULSE_INTR** as does an ale ram ECC error.

9.4.28.2 Packet Protect CRC

Each ingress packet without error is passed through the cpsw with an internally generated Castignoli protect CRC. The protect CRC is checked on port egress for correctness and is replaced. If the CRC is correct (no RAM bit errors), then the packet is output with the selected port CRC type. If a protect CRC error is detected on THost then the **memory_protect_error** buffer descriptor bit will be asserted so that the packet is dropped to the host. If a protect CRC error is detected on Ethernet egress then the egress CRC will be generated on the packet and at least one byte of the CRC will be inverted on output. CRC memory protect errors do not assert the **ECC_PULSE_INTR** signal. CRC memory protect errors are counted in the associated port statistics registers and issue an interrupt on **STAT_PEND_INTR** if any CRC memory protect error occurs (and the statistics for that port are enabled). When the **ecc_crc_mode** bit in the **CPSW_Control** register is set, the **ecc_bit1** aggregator register will flip the associated column bit in any FIFO memory read operation, inducing a CRC protect error when the protect CRC is checked. No header bits are flipped when **ecc_crc_mode** is set. Either the **pn_rx_ecc_err_en** or the **pn_tx_ecc_err_en** bit must be set in the **PN_Control** register to test packet CRC errors.

9.4.28.3 Aggregator Ram Control

The ECC logic for each FIFO ram (receive and transmit) is divided into eight separate ECC encoders/decoders that encode/decode 26-bits of data each. Each of the 8 encoders (0 to 7) generates 6-bits of ECC code (48 code bits total), and each of the eight decoders (0 to 7) checks 6-bits of ECC code across the 26-bits of data (208 data bits total). The 48-bits of ECC code are passed through the ram in the upper 48 unused bits in the header word. The header data bits and ECC code bits are shown in the below table. The **ecc_bit1[15:0]** value returned on error is a 16-bit value that is the concatenation of 5-bits of zero, 3-bits of the encoder/decoder number (0 to 7), 3-bits of zero, and 5-bits of index into the indicated 26-bit encoder/decoder. For example, an **ecc_bit1** value of 0x0308 is bit-8 of encoder/decoder 3, which is header bit 86 (((26*3) + 8).

9.4.29 CPSW Network Statistics

The CPSW has statistics that record events associated with frame traffic on each port. STAT0 keeps statistics for PORT0, STAT1 for PORT1 and so on. All statistics are 32-bit registers. By convention the statistics registers are receive for ingress and transmit for egress for all ports.

If any bit in **stat_port_en** is set for a specific STAT module, the value written to a statistics register will be subtracted from the register value with the result being stored in the register. If a value greater than the statistics value is written, then zero will be written to the register (writing 0xffffffff will clear a statistics location). When all port enable bits are cleared to zero, all statistics registers are read/write (normal write direct, so writing 0x00000000 will clear a statistics location). All write accesses must be 32-bit accesses. In the below statistics descriptions, “the port” refers to any enabled port (with a corresponding set **stat_port_en** bit).

9.4.29.1 Rx (only) Statistics Descriptions

9.4.29.1.1 Good Rx Frames

The total number of good frames received on the port. A good frame is defined to be:

- any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and
- had no CRC error, alignment error or code error.

See the **Rx Align/Code Errors** and **Rx CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

9.4.29.1.2 Broadcast Rx Frames

The total number of good broadcast frames received on the port. A good broadcast frame is defined to be:

- any data or MAC control frame which was destined for address 0xFFFFFFFFFFFF only, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and
- had no CRC error, alignment error or code error.

See the **Rx Align/Code Errors** and **Rx CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

9.4.29.1.3 Multicast Rx Frames

The total number of good multicast frames received on the port. A good multicast frame is defined to be:

- any data or MAC control frame which was destined for any multicast address other than 0xFFFFFFFFFFFF, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and
- had no CRC error, alignment error or code error.

See the **Rx Align/Code Errors** and **Rx CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

9.4.29.1.4 Pause Rx Frames

The total number of IEEE 802.3X pause frames received by the port (whether acted upon or not). Such a frame:

- contained any unicast, broadcast, or multicast address, and
- contained the length/type field value 88.08 (hex) and the opcode 0x0001, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and
- had no CRC error, alignment error or code error, and
- pause frames are enabled on the port (pn_tx_flow_en = 1).

The port could have been in either half or full-duplex mode.

See the **Rx Align/Code Errors** and **Rx CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic

or

The total number of priority based flow control (802.1Qbb) pause frames received by the port (whether acted upon or not). Such a frame:

- contained any unicast, broadcast, or multicast address, and
- contained the length/type field value 88.08 (hex) and the opcode 0x0001, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and
- had no CRC error, and
- priority based flow control pause frames are enabled on the port.

See the **Rx CRC errors** statistic descriptions for definitions of CRC errors. Overruns have no effect upon this statistic

9.4.29.1.5 Rx CRC Errors

The total number of frames received on the port that experienced a CRC error. Such a frame:

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and
- had no code/align error, and
- had a CRC error.

Overruns have no effect upon this statistic.

A CRC error is defined to be:

- a frame containing an even number of nibbles, and
- fails the Frame Check Sequence test.

9.4.29.1.6 Rx Align/Code Errors

The total number of frames received (ingress) on the port that experienced an alignment error or code error. Such a frame:

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and
- had either an alignment error or a code error.

Over-runs have no effect upon this statistic.

An alignment error is defined to be:

- a frame containing an odd number of nibbles, and
- also fails the Frame Check Sequence test if the final nibble is ignored.

A code error is defined to be:

- A frame which has been discarded because the port's **MRXER** pindriven with a one for at least one bit-time's duration at any point during the frame's reception.

Note

RFC 1757 etherStatsCRCAlignErrors Ref. 1.5 can be calculated by summing **Rx Align/Code Errors** and **Rx CRC errors** (see below).

10G: For XGMII, packets are ended at the code error and only that number of bytes are kept when rx_cef is set (includes the code error bytes).

9.4.29.1.7 Oversize Rx Frames

The total number of oversized frames received on the port. An oversized frame is defined to be:

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was greater than pn_rx_maxlen in bytes, and
- had no CRC error, alignment error or code error.

See the **Rx Align/Code Errors** and **Rx CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

9.4.29.1.8 Rx Jabbers

The total number of jabber frames received on the port. A jabber frame is:

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was greater than pn_rx_maxlen bytes long, and
- had a CRC error, an alignment error, or a code error.

See the **Rx Align/Code Errors** and **Rx CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

9.4.29.1.9 Undersize (Short) Rx Frames

The total number of undersized frames received on the port. An undersized frame is defined to be:

- any data frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was less than 64 bytes long, and
- had no CRC error, alignment error or code error.

See the **Rx Align/Code Errors** and **Rx CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

9.4.29.1.10 Rx Fragments

The total number of frame fragments received on the port. A frame fragment is defined to be:

- any data frame (address matching does not matter), and
- was less than 64 bytes long, and
- had a CRC error, an alignment error, or a code error, and
- was not the result of a collision caused by half duplex, collision based flow control.

See the **Rx Align/Code Errors** and **Rx CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

9.4.29.1.11 Rx IPG Error

The total number of 10G frames received on a port that had a correct preamble but did not have at least five bytes of IDLE preceding the frame. This does not indicate if the frame with the IPG error was kept or ignored.

9.4.29.1.12 Rx Bottom Of FIFO Drop

Ethernet Ports

The total number of ingress frames on a port that overran the port's receive FIFO and were dropped (bottom of receive FIFO). Port 0 (CPPI transmit port) should not drop packets on ingress because port 0 ingress flow control should be enabled. The Ethernet ports will only drop packets in the receive FIFO when receive flow control is enabled and the sending port ignores sent pause frame and then overruns the receive FIFO. The overrun frame is defined to be:

- any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was any length (including <64 bytes and > pn_rx_maxlen bytes), and
- Was dropped on port 0 due to a lack of memory space in the receive FIFO

Note

This stat should be zero

Host Port 0

This statistic also counts frames dropped on port 0 that were 17 to 33 bytes (only for port 0). For Ethernet ports, the drop count for frames shorter than 33 bytes is included in the undersized or fragment count. Port 0 simply gives an indication that a packet with 33 bytes was dropped. No other statistics are counted for frames shorter than 33 bytes.

9.4.29.1.13 Portmask Drop

All Ports

The total number of ingress frames on a port that were dropped by the ALE (the ALE did not forward the packet to any port). The frame was defined to be:

- any data or MAC control frame
- Was any length greater than 32 bytes
- Was dropped by the ALE - ale_portmask = 0 (was not sent to any destination port)

- The frame could have been dropped due to error or other counted reason, so it could be counted elsewhere also.

Note

This stat does not count in the overall total as it includes every packet received greater than 32 bytes that had a zero **port_mask**.

9.4.29.1.14 Rx Top Of FIFO Drop

All Ports

The total number of frames received on a port that had a **START** of frame (SOF) overrun on any destination port egress (when attempting to load the packet from the top of the ingress port receive FIFO into any other port's transmit FIFO). If a multicast/broadcast packet is dropped by multiple destination ports then this statistic will increment by the number of ports that dropped the packet. Rx Top Of FIFO Drop is defined to be:

- any data or MAC control frame
- Was any length greater than 32 bytes
- Was dropped by the ALE - ale_portmask = 0 (was not sent to any destination port)
- The frame could have been dropped due to error or other counted reason, so it could be counted elsewhere also.

9.4.29.1.15 ALE Drop

All Ports

The total number of frames received on a port such that the destination address was not equal to the source address and the packet was not destined to the port it was received on, but the frame was not forwarded to any port (the **port_mask** was zero).

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was any length (including <64 bytes and > pn_rx_maxlen bytes), and
- had no CRC error, alignment error or code error, and
- the destination address was not equal to the source address, and
- The packet was not destined for the port it was receive on, and
- had a zero port_mask

9.4.29.1.16 ALE Overrun Drop

All Ports

The total number of frames received on a port that were dropped (zero **port_mask**) due to exceeding the maximum ALE lookup rate (Port 0 should not have ALE Overrun Drops because the ingress rate is controlled to prevent it). This statistic should be zero and when non-zero indicates a system clock issue or indicates that short packets were sent with **pn_rx_csf_en** at a rate that exceeded the maximum lookup rate.

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was any length (including <64 bytes and > pn_rx_maxlen bytes), and
- the maximum ALE lookup rate was exceeded so the lookup was aborted and the packet was dropped.

9.4.29.1.17 ALE Rate Limit Drop

All Ports

The total number of frames received on a port that were dropped (zero **port_mask**) due to receive rate limiting on this port or due to transmit rate limiting on any destination port (not sent to all expected destination ports if transmit rate limiting).

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and

- was any length (including <64 bytes and > pn_rx_maxlen bytes), and
- had no CRC error, alignment error or code error, and
- the receive rate was exceeded and the packet was dropped, or the transmit rate was exceeded to any destination port and the packet was dropped to one or more expected destination ports (indicates that the destinations were pruned due to rate limiting).

9.4.29.1.18 ALE VLAN Ingress Check Drop

The total number of frames received on a port that were dropped (zero **port_mask**) due to VLAN ingress check failure.

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was any length (including <64 bytes and > pn_rx_maxlen bytes), and
- had no CRC error, alignment error or code error, and
- the VLAN ID ingress check failed (the receive port was not in the group), and
- The address lookup did not return a match with the super bit set

9.4.29.1.19 ALE DA=SA Drop

The total number of frames received on a port that were dropped (zero **port_mask**) due to destination address equal to source address.

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was any length (including <64 bytes and > pn_rx_maxlen bytes), and
- had no CRC error, alignment error or code error, and
- The destination address was equal to the source address
- The source address was not an entry in the table.

9.4.29.1.20 Block Address Drop

The total number of frames received on a port that were dropped (zero **port_mask**) due to the destination or source address being blocked.

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was any length (including <64 bytes and > pn_rx_maxlen bytes), and
- had no CRC error, alignment error or code error, and
- the source or destination address matched a table entry with the block bit set.

9.4.29.1.21 ALE Secure Drop

The total number of frames received on a port that were dropped (zero **port_mask**) due to a secure violation (the source address is owned by a different receive port).

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was any length (including <64 bytes and > pn_rx_maxlen bytes), and
- had no CRC error, alignment error or code error, and
- the source address is an entry in the table with the secure bit set and a port number for a different receive port.

9.4.29.1.22 ALE Authentication Drop

The total number of frames received on a port that were dropped (zero **port_mask**) due to authentication failure.

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was any length (including <64 bytes and > pn_rx_maxlen bytes), and
- had no CRC error, alignment error or code error, and
- enable_auth_mode is set, and
- the source address is not equal to the destination address, and

- the source address is not a table entry, and
- the destination address is not a table entry with the super bit set.

9.4.29.1.23 ALE Unknown Unicast

The total number of frames received on a port that had a unicast destination address with an unknown source address. The frame is defined to be:

- was any data frame with a unicast destination address, and
- the source address was not a table entry, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and
- had no CRC error, alignment error or code error.

> **Note**
>
> The ALE Unknown Unicast Bytecount statistic is the number of bytes contained in the ALE Unknown Unicast frames.

9.4.29.1.24 ALE Unknown Multicast

The total number of frames received on a port that had a multicast destination address with an unknown source address. The frame is defined to be:

- was any data frame with a multicast destination address, and
- the source address was not a table entry, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and
- had no CRC error, alignment error or code error.

> **Note**
>
> The ALE Unknown Multicast Bytecount statistic is the number of bytes contained in the ALE Unknown Multicast frames.

9.4.29.1.25 ALE Unknown Broadcast

The total number of frames received on a port that had a Broadcast destination address with an unknown source address. The frame is defined to be:

- was any data frame with a broadcast destination address, and
- the source address was not a table entry, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and
- had no CRC error, alignment error or code error.

> **Note**
>
> The ALE Unknown Broadcast Bytecount statistic is the number of bytes contained in the ALE Unknown Broadcast frames.

9.4.29.1.26 ALE Policer Match

The total number of frames received on a port that had a matched a policer. The frame is defined to be:

- any data frame, and
- matched a condition on a policer, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and
- had no CRC error, alignment error or code error.

9.4.29.1.27 ALE Policer Match Red

The total number of frames received on a port that had matched a policer and the condition was red. The frame is defined to be:

- any data frame, and
- matched a policer with the condition red, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and

- had no CRC error, alignment error or code error.

9.4.29.1.28 ALE Policer Match Yellow

The total number of frames received on a port that had matched a policer and the condition was yellow. The frame is defined to be:

- any data frame, and
- matched a policer with the condition yellow, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and
- had no CRC error, alignment error or code error.

9.4.29.1.29 IET Receive Assembly OK

The total number of correctly received and re-assembled premptable frames.

- any premptable frame received
- was any size, and
- was correctly received and re-assembled without error.

9.4.29.1.30 IET Receive Assembly Error

The total number of premptable received frames with IET assembly errors.

- any frame received
- was any size, and
- was a non-initial fragment that mismatched the frame count or fragment count (went to the assembly error state in the IET receive state machine).

9.4.29.1.31 IET Receive SMD Error

The total number of received frames rejected due to an unknown SMD value or received frames rejected with an SMD-C when no frame is in progress.

- any frame received
- was any size, and
- was rejected because of an unknown SMD value or SMD-C with no frame in progress.

Note

If **iet_en** is not set, this statistic counts any received frame with any non express SMD.

9.4.29.1.32 IET Receive Merge Fragment Count

The total number of received non-initial fragments that did not have an assembly error. The IET stat aMACMergeFragCountRx is derived by adding the Receive Assembly Error count to this value.

- any frame received
- was any size, and
- was a non-initial fragment that did not contain an assembly error.

9.4.29.1.33 Rx Octets

The total number of bytes in all good frames received on the port. A good frame is defined to be:

- any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- was of length 64 to pn_rx_maxlen bytes inclusive, and
- had no CRC error, alignment error or code error.

See the **Rx Align/Code Errors** and **Rx CRC errors** statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

9.4.29.2 Tx (only) Statistics Descriptions

The maximum and minimum transmit frame size is software controllable.

Thost overruns (**P0_Tx_SOF_OVERRUN** and **P0_Tx_MOF_OVERRUN**) have no effect on Tx statistics. They are counted separately.

9.4.29.2.1 Good Tx Frames

The total number of good frames transmitted on the port. A good frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and
- was any length, and
- had no late or excessive collisions, no carrier loss and no underrun.

9.4.29.2.2 Broadcast Tx Frames

The total number of good broadcast frames transmitted on the port. A good broadcast frame is defined to be:

- any data or MAC control frame destined for address 0xFFFFFFFFFFFF only, and
- was of any length, and
- had no late or excessive collisions, no carrier loss and no underrun

9.4.29.2.3 Multicast Tx Frames

The total number of good multicast frames transmitted on the port. A good multicast frame is defined to be:

- any data or MAC control frame destined for any multicast address other than 0xFFFFFFFFFFFF, and
- was of any length, and
- had no late or excessive collisions, no carrier loss and no underrun.

9.4.29.2.4 Pause Tx Frames

This statistic indicates the number of IEEE 802.3X pause frames transmitted by the port.

Pause frames cannot contain a CRC error because they are created in the transmitting MAC, so these error conditions have no effect upon the statistic. Pause frames sent by software will not be included in this count.

Since pause frames are only transmitted in full duplex carrier loss and collisions have no effect upon this statistic.

Transmitted pause frames are always 64 byte multicast frames so will appear in the **Tx Multicast Frames** and **64octect Frames** statistics.

9.4.29.2.5 Collisions

This statistic records the total number of times that the port experienced a collision. Collisions occur under two circumstances.

1. When a transmit data or MAC control frame:
    - was destined for any unicast, broadcast or multicast address, and
    - was any size, and
    - had no carrier loss and no underrun, and
    - experienced a collision. A jam sequence is sent for every non-late collision, so this statistic will increment on each occasion if a frame experiences multiple collisions (and increments on late collisions).

    CRC errors have no effect upon this statistic.
2. When the port is in half-duplex mode, flow control is active, and a frame reception begins.

9.4.29.2.6 Single Collision Tx Frames

The total number of frames transmitted on the port that experienced exactly one collision. Such a frame:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address, and
- was any size, and
- had no carrier loss and no underrun, and
- experienced one collision before successful transmission. The collision was not late.

CRC errors have no effect upon this statistic.

9.4.29.2.7 Multiple Collision Tx Frames

The total number of frames transmitted on the port that experienced multiple collisions. Such a frame:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address, and
- was any size, and
- had no carrier loss and no underrun, and
- experienced 2 to 15 collisions before being successfully transmitted. None of the collisions were late.

CRC errors have no effect upon this statistic.

9.4.29.2.8 Excessive Collisions

The total number of frames for which transmission was abandoned due to excessive collisions. Such a frame:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address, and
- was any size, and
- had no carrier loss and no underrun, and
- experienced 16 collisions before abandoning all attempts at transmitting the frame. None of the collisions were late.

CRC errors have no effect upon this statistic.

9.4.29.2.9 Late Collisions

The total number of frames on the port for which transmission was abandoned because they experienced a late collision. Such a frame:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address, and
- was any size, and
- experienced a collision later than 512 bit-times into the transmission. There may have been up to 15 previous (non-late) collisions which had previously required the transmission to be re-attempted. The Late Collisions statistic dominates over the single, multiple and excessive Collisions statistics - if a late collision occurs the frame will not be counted in any of these other three statistics.

CRC errors, carrier loss, and underrun have no effect upon this statistic.

9.4.29.2.10 Deferred Tx Frames

The total number of frames transmitted on the port that first experienced deferment. Such a frame:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address, and
- was any size, and
- had no carrier loss and no underrun, and
- experienced no collisions before being successfully transmitted, and
- found the medium busy when transmission was first attempted, so had to wait.

CRC errors have no effect upon this statistic

See RFC1623 Ref. 2.6 dot3StatsDefferredTransmissions.

9.4.29.2.11 Carrier Sense Errors

The total number of frames on the port that experienced carrier loss. Such a frame:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address, and
- was any size, and
- the carrier sense condition was lost or never asserted when transmitting the frame (the frame is not retransmitted). This is a transmit only statistic. Carrier Sense is a don’t care for received frames. Transmit frames with carrier sense errors are sent until completion and are not aborted.
- CRC errors and underrun have no effect upon this statistic.

9.4.29.2.12 Tx Octets

The total number of bytes in all good frames transmitted on the port. A good frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and

- was any size, and
- had no late or excessive collisions and no carrier loss.

9.4.29.2.13 Transmit Priority 0-7

The total number of frames transmitted on the port from transmit FIFO priority 0-7. Collision retries do not affect this statistic. Pause frames do not affect this statistic.

- any frame transmitted from priority 0-7, and
- was less than or equal to cpsw_tx_pri(0-7)_maxlen.
- Collision retries are not counted in this statistic
- Pause frames are not counted in this statistic.
- Carrier sense errors do not affect this statistic.

Note

The Transmit Priority 0-7 Bytecount statististic is the number of bytes contained in the frames of the Transmit Priority 0-7 statistic.

9.4.29.2.14 Transmit Priority 0-7 Drop

The total number of transmit frames on the port that overran the transmit FIFO priority 0-7 and were dropped. This count includes frames dropped due to **cpsw_tx_pri(0-7)_maxlen**.

- any frame destined to be transmitted from priority 0-7, and
- was any size, and
- was dropped due to priority 0-7 FIFO overrun (Start of packet overrun).
- Was dropped due to frame size larger than cpsw_tx_pri(0-7)_maxlen.

Note

The Transmit Priority 0-7 Drop Bytecount statististic is the number of bytes contained in the frames of the Transmit Priority 0-7 Drop statistic.

9.4.29.2.15 Transmit Memory Protect Errors

The total number of transmit frames on the port that had a memory protect CRC error on egress.

- any frame destined to be transmitted, and
- was any size, and
- Had a memory protect CRC error on egress.

Frames to the host with memory protect errors are indicated to be dropped with a set receive buffer descriptor **drop** bit. Ethernet frames will have at least one byte of the generated port type CRC inverted on egress.

This statistic is 8-bits wide only and will not rollover but will limit at 0xff.

A non-zero value in this statistic will issue a **STAT_PEND_INTR** interrupt for the associated port.

9.4.29.2.16 IET Transmit Merge Fragment Count

The total number of non-initial premptable transmit fragments on premptable transmit.

- any frame destined to be transmitted on the premptable port, and
- was any size, and
- was a non-initial fragment.

9.4.29.2.17 IET Transmit Merge Hold Count

The total number of premptable frames that were prempted and reassembled by the assertion of **pn_mac_hold** in the **Enet_Pn_IET_Control** register or were prempted by EST. The IET statistic aMACMergeHoldCount can be derived and maintained by software.

- any frame destined to be transmitted on the premptable port, and
- was any size, and
- was prempted by the assertion of pn_mac_hold, or
- was prempted by Enhanced Scheduled Traffic (EST).

9.4.29.3 Rx and Tx (shared) Statistics Descriptions

9.4.29.3.1 Net Octets

The total number of bytes of frame data received and transmitted on the port. Each frame counted:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address (address match does not matter), and
- was of any size (including <64 byte and > pn_rx_maxlen byte frames).

Also counted in this statistic are:

- every byte transmitted before a carrier-loss was experienced,
- every byte transmitted before each collision was experienced, (i.e. multiple retries are counted each time),
- every byte received if the port is in half-duplex mode until a jam sequence was transmitted to initiate flow control. (The jam sequence was not counted to prevent double-counting).

Error conditions such as alignment errors, CRC errors, code errors, overruns and underruns do not affect the recording of bytes by this statistic.

The objective of this statistic is to give a reasonable indication of Ethernet utilization.

9.4.29.3.2 Rx + Tx 64 Octet Frames

The total number of 64-byte frames received and transmitted on the port. Such a frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and
- did not experience late collisions, excessive collisions, or carrier sense error, and
- was exactly 64 bytes long. (If the frame was being transmitted and experienced carrier loss that resulted in a frame of this size being transmitted, then the frame will be recorded in this statistic).

CRC errors, code/align errors and overruns do not affect the recording of frames in this statistic.

9.4.29.3.3 Rx + Tx 65-127 Octet Frames

The total number of frames of size 65 to 127 bytes received and transmitted on the port. Such a frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and
- did not experience late collisions, excessive collisions, or carrier sense error, and
- was 65 to 127 bytes long.

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

9.4.29.3.4 Rx + Tx 128-255 Octet Frames

The total number of frames of size 128 to 255 bytes received and transmitted on the port. Such a frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and
- did not experience late collisions, excessive collisions, or carrier sense error, and
- was 128 to 255 bytes long.

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

For Rx reference only, see RFC1757 Ref. 1.13 etherStatsPkts128to255Octets.

9.4.29.3.5 Rx + Tx 256-511 Octet Frames

The total number of frames of size 256 to 511 bytes received and transmitted on the port. Such a frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and
- did not experience late collisions, excessive collisions, or carrier sense error, and
- was 256 to 511 bytes long.

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.Rx + Tx 512-1023 Octet Frames

The total number of frames of size 512 to 1023 bytes received and transmitted on the port. Such a frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and
- did not experience late collisions, excessive collisions, or carrier sense error, and
- was 512 to 1023 bytes long.

CRC errors, code/align errors and overruns do not affect the recording of frames in this statistic.

9.4.29.3.6 Rx + Tx 1024_Up Octet Frames

The total number of frames of size 1024 to **pn_rx_maxlen** bytes for receive or 1024 up for transmit on the port. Such a frame is defined to be:

- any data or MAC control frame which was destined for any unicast, broadcast or multicast address, and
- did not experience late collisions, excessive collisions, or carrier sense error, and
- was 1024 to pn_rx_maxlen bytes long on receive, or any size on transmit.

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

1. “AND” is assumed horizontally across the table between all conditions which form the statistic (marked y or n) except where (y|y), meaning “OR” is indicated. Parentheses are significant.
2. “-“ indicates conditions which are ignored in the formations of the statistic.
3. Statistics marked “Rx+Tx” are formed by summing the Rx and Tx statistics, each of which is formed independently.
4. The non-pause column refers to all MAC control frames (i.e. frames with length/type=88.08) with opcodes other than 0x0001. The pauseframe column refers to MAC frames with the opcode=0x0001.
5. The multicast, broadcast and unicast columns in the table refer to non-MAC Control/non-pause frames (i.e. data frames)
6. “%” If either a MAC control frame or pause frame has a multicast or broadcast destination address then the appropriate statistics will be updated.
7. “%” If either a MAC control frame or pause frame has a multicast or broadcast destination address then the appropriate statistics will be updated.
8. “y^” Frame fragments are not counted if less than 8 bytes.
9. flow coll. are half-duplex collisions forced by the MAC to achieve flow-control. A collision will be forced during the first 8 bytes so should not show in frame fragments. Some of the ‘-‘s in this column might in reality be ‘n’s.
10. The rx_overruns stat show above is for rx_mof_overruns and rx_sof_overruns added together.

1. “AND” is assumed horizontally across the table between all conditions which form the statistic (marked y or n) except where (y|y), meaning “OR” is indicated. Parentheses are significant.
2. “-“ indicates conditions which are ignored in the formations of the statistic.
3. Statistics marked “Rx+Tx” are formed by summing the Rx and Tx statistics, each of which is formed independently.
4. Pause(MAC) frames are issued in the MAC as perfect (no CRC error) 64 byte frames in full duplex only, so cannot collide
5. “%” If a CPU sourced MAC control frame has a multicast or broadcast destination address then the appropriate statistics will be updated.
6. “+” indicates collisions which are “summed” (i.e. every collision is counted in the Collisions statistic). Jam sequences used for half-duplex flow control are also counted.
7. “$” Every byte written on the wire during each retry attempt is also counted in addition to frames which experience no collisions or carrier loss.

8. The flow collision type is for half-duplex collisions forced by the MAC to achieve flow control. Some of the '-'s in this column might in reality be 'n's. To prevent double-counting, Net Octects are unaffected by the jam sequence – the 'received' bytes, however, are counted. (see Rx Statistics table).
9. When the transmit Tx FIFO is drained due to the MAC being disabled or link being lost, then the frames being purged will not appear in the Tx statistics.

9.4.30 CPPI Streaming Packet Interface

The receive streaming interface on port 0 of the CPSW is responsible for receiving packet for Ethernet egress data from the packet streaming switch in the NAVSS. The CPPI receive port is equivalent to an Ethernet port with the difference being that the data is provided to the CPSW in the 128-bit streaming interface data format instead RGMII data format.

In addition to the packet data, the receive streaming interface also can provide additional control information that resides in the information words of the descriptor that was transmitted to the CPSW.

The tables below show the information that may be passed along with which descriptor information word to put it in.

9.4.30.1 Port 0 CPPI Transmit Packet Streaming Interface (CPSW_2G Egress)

INFO Word 0–3 and Status Data Word 0–3 (on EOP) are the only non-payload data word types that are transferred. Long packets are truncated at the CPWS0_PN_RX_MAXLEN_REG[13-0] RX_MAXLEN byte value of the ingress port (only the CPWS0_PN_RX_MAXLEN_REG number of bytes are kept if long packets are transferred due to CPWS0_PN_MAC_CONTROL_REG register copy error frames set - RX_CEF_EN). MAC control frames are only transferred if the receiving Ethernet port has the CPWS0_PN_MAC_CONTROL_REG[24] RX_CMF_EN bit set.

INFO Words are a contiguous block of four 32-bit data words aligned on a 32-bit word boundary.

23	PASS_CRC	This bit is cleared to zero (no CRC passed) when the P0_TX_CRC_REMOVE bit in the CPSW_CONTROL_REG register is set (and the egress packet has no errors). When the remove bit is cleared to zero then this bit is cleared and no CRC is passed with the output packet. The packet length includes the CRC if it is present.
22	CRC_TYPE	The packet CRC type. The type of CRC passed is determined by CRC_TYPE field in the CPSW_PN_MAC_CONTROL_REG register (not by the type of CRC the packet had on Ethernet port ingress). Host PD Word 1. Protocol Specific Flags: bits[27-24]. 0h: Ethernet CRC 1h: Castagnoli CRC

Bit	Field	Description
7-0	FLOW_ID	This is the packet output transmit streaming interface flow. The default flow ID can be overridden by ALE classification (Thread mapping). The switch default flow is the 3-bit “From Port” value concatenated with the 3-bit “Switch Priority” {From_Port[2:0], Switch_Priority[2:0]} as shown below: Host PD (Packet Descriptor) Word 1. Flow ID: bits[13-0]. 0h: The packet was received on Ethernet port 1 1h: The packet was received on Ethernet port 2 Switch Priority – The actual hardware switch priority that the packet was stored in on the CPPI transmit FIFO.

The packet length must be greater than zero. The packet data will be truncated to the packet length if the packet length is shorter than the sum of the packet buffer descriptor buffer lengths. A host error occurs if the packet length is greater than the sum of the packet buffer descriptor buffer lengths.

9.4.30.2 CPPI Receive Packet Streaming Interface (CPSW Ingress)

Info Word 0/1/2/3 (INFO1 and INFO3 are ignored) are transferred on SOP. If a timestamp word (Extended Packet Info Word 0/1/2/3) is to be transferred it must be after SOP and before any packet data is transferred. Any following non-data type words will be dropped. The EOP word must be payload data.

Input receive packets cannot be aborted by the host. The INFO Word bit descriptions and Extended Packet INFO Word bit descriptions are shown below. The PASS_CRC bit indicates that the CRC is passed with the packet data. Packets that have a passed CRC that is an error CRC will be output on the Ethernet port with at least one CRC byte inverted to indicate the error if P0_RX_PASS_CRC_ERR bit is set, otherwise they are dropped. The packet is a directed packet when any of the TO_PORT bits are nonzero. A packet may be directed only to a single port. The packet will be sent to the port number indicated. For directed packets the lookup process is skipped to determine the destination. However, in vlan aware mode (when VLAN_AWARE bit in the CPSW_CONTROL_REG register is set to 1h) the lookup is performed to determine untagged egress. Packets longer then the value in CPSW_P0_RX_MAXLEN_REG[13-0] RX_MAXLEN bit field are dropped. Packets shorter than 60-Bytes are padded to 64-Bytes (after adding pad and CRC) if P0_RX_PAD bit in the CPSW_CONTROL_REG register is set and if PASS_CRC is clear, otherwise they are dropped. This means that packets shorter than 64-Bytes are dropped if the PASS_CRC info bit is set regardless of P0_RX_PAD bit (packets are padded only if they are short and do not have CRC).

A RX INFO word is a contiguous block of four 32-bit data words aligned on a 32-bit word boundary.

Note

RX Control Data Words [0..2] are mapped to Host Packet Descriptor Protocol Specific Words if (TCHAN[a]_TCFG.tx_filt_pswords = 0) and (Host PD Word 1.Protocol Specific Region Location.bit[28] = 0h) and (Host PD Word 1.Protocol Specific Valid Word Count.bits[22-27] = 4h)

Bit	Field	Description
31-24	CHECKSUM_RESULT	This is the packet byte number where the checksum result will be placed in the egress packet. The first packet byte which is the first byte of the destination address is Byte 1 (not byte zero).

Bit	Field	Description
23-16	CHECKSUM_START_BYTE	This is the packet byte number to start the checksum calculation on. The first packet byte is Byte 1.
15	CHECKSUM_INV	When set, a zero checksum value will be inverted and sent as FFFFh.
14	RESERVED	Reserved.
13-0	CHECKSUM_BYTECOUNT	This is the number of bytes to calculate the checksum on. The outgoing Ethernet packet will have a checksum inserted when this value is non-zero.

Other INFO words are not taken into account.

9.4.30.3 CPPI Checksum Offload

The CPPI host port can be enabled to perform checksum offload on host port packet ingress and egress. UDP (User Datagram Protocol) and TCP (Transmission Control Protocol) over IPV4 and IPV6 are supported. For the purposes of checksum description, the first packet byte (the first byte of the destination address) is byte 1 (not byte 0). That is, a 64 byte packet goes from byte 1 to byte 64. For all packet types, the S_CN_SWITCH bit in the CPSW_CONTROL_REG register must be set for the Outer VLAN L type to be supported.

9.4.30.3.1 CPPI Transmit Checksum Offload

IPV4 and IPV6 UDP and TCP packets that are received on any Ethernet port and destined for port 0 egress are checked for correct checksum as described below. The byte counts below are shown for packets with no VLAN’s. The byte counts vary with one or two packet VLAN's. Packets received on an Ethernet port with errors are not checked for a correct checksum if they are passed to the host.

9.4.30.3.1.1 IPV4 UDP

- Byte 15 Upper Nibble = 4 for IPV4
- Byte 15 Lower Nibble = IHL - Nibble with number of 32-bit words in IPV4 header (5 to 15 supported).
- Bytes 20-21 = fragment[15-0] – Bit 13 is the MF bit and bits [12-0] are the Fragment offset. A packet is a fragment if the MF bit is set or if the fragment offset is non-zero. The first packet fragment has MF=1 with a zero offset. Middle fragments have MF=1 with a nonzero offset. The last packet fragment has MF=0 with a nonzero offset. Non-fragmented packets have MF=0 and a zero offset. A count is output for packet fragments but no errors are reported. First fragments have the UDP header included in the count. Middle and last fragments have only data included in the count (there is no UDP header).
- Byte 24 = 0x11 for UDP protocol.
- Received packet UDP checksum of zero means that there is no IPV4 checksum sent with the packet so no error will be issued.
- Received packet UDP checksum of 0xFFFF means that the checksum was calculated to be 0xFFFF or 0x0000 but was sent in the transmitted packet as 0xFFFF by the sending originating entity.

9.4.30.3.1.2 IPV4 TCP

- Byte 15 Upper Nibble = 4 for IPV4
- Byte 15 Lower Nibble = IHL - Nibble with number of 32-bit words in IPV4 header (5 to 15 supported).
- Bytes 20-21 = fragment[15-0] – Bit 13 is the MF bit and bits [12-0] are the Fragment offset. A packet is a fragment if the MF bit is set or if the fragment offset is non-zero. The first packet fragment has MF=1 with a zero offset. Middle fragments have MF=1 with a nonzero offset. The last packet fragment has MF=0 with a nonzero offset. Non-fragmented packets have MF=0 and a zero offset. A count is output for packet fragments but no errors are reported. First fragments have the UDP header included in the count. Middle and last fragments have only data included in the count (there is no TCP header).
- Byte 24 = 0x06 for TCP protocol.

9.4.30.3.1.3 IPV6 UDP

- Byte 15 upper nibble = 6 for IPV6.
- Byte 21 = 0x11 for UDP protocol as next header.

- Fragment extension headers are supported. First fragments have a fragment extension header (byte 21 = 0x2C) followed by a UDP header (byte 55 = 0x11). Middle and last fragments have a fragment extension header followed by data only (no UDP header). The first packet fragment has MF=1 with a zero offset. Middle fragments have MF=1 with a nonzero offset. The last packet fragment has MF=0 with a nonzero offset. Non-fragmented packets do not have a fragment extension header. A count is output for packet fragments but no errors are reported.
- Received packet UDP checksum of zero means that there is no IPV6 checksum sent with the packet so no error will be issued.
- Received packet UDP checksum of 0xFFFF means that the checksum was calculated to be 0xFFFF or 0x0000 but was sent in the transmitted packet as 0xFFFF by the sending originating entity.

9.4.30.3.1.4 IPV6 TCP

- Byte 15 upper nibble = 6 for IPV6.
- Byte 21 = 0x06 for TCP protocol as next header.
- Fragment extension headers are supported. First fragments have a fragment extension header (byte 21 = 0x2C) followed by a UDP header (byte 55 = 0x06). Middle and last fragments have a fragment extension header followed by data only (no TCP header). The first packet fragment has MF=1 with a zero offset. Middle fragments have MF=1 with a nonzero offset. The last packet fragment has MF=0 with a nonzero offset. Non-fragmented packets do not have a fragment extension header. A count is output for packet fragments but no errors are reported.

9.4.30.4 CPPI Receive Checksum Offload

Packets sent from host port 0 (switch ingress) to any Ethernet port can have a checksum calculated and inserted into the Ethernet egress packet. The RX_CHECKSUM_EN bit in the CPSW_P0_CONTROL_REG register must be set for receive checksum operation to be enabled. When bit RX_CHECKSUM_EN is enabled, Control Data Word 2 input on CPPI receive PSI interface determines how the checksum is calculated. The CHECKSUM_RESULT field in Control Data Word 2 determines where the checksum is inserted. The checksum result location is adjusted by the egress port if a VLAN is to be inserted or removed on Ethernet port egress.

9.4.31 Egress Packet Operations

Note

InterVLAN routing is supported on SR2.0 only.

Each CPSW egress port (Ethernet and Host) is capable of performing egress packet processing operations. IntraVLAN processing either adds, removes, or replaces VLAN information or does nothing. InterVLAN routing allows hardware routing between a limited number of VLANs - thereby allowing high-bandwidth or other routing operations to be offloaded from software to the CPSW (hardware). IntraVLAN processing and InterVLAN routing operations are mutually exclusive. In addition, the packet source and destination addresses can be swapped on egress to facilitate OAM or generic testing operations.

9.5 MCU_CPSW0 Programming Guide

9.5.1 Initialization and Configuration of CPSW Subsystem

To configure the CPSW Ethernet Subsystem for operation, the host must perform the following:

1. Select the Interface (RMII, or RGMII) Mode. See the CTRLMMR_MCU_ENET_CTRL[1-0] MODE_SEL register.
2. Configure pads (pin muxing), as per the interface selected. Refer to *Pad Configuration Registers* and the device-specific Datasheet.
3. Enable the CPSW Ethernet Subsystem clocks. See Section 9.3, *CPSW Integration*
4. Ensure that at least 2000 CPPI_ICLK periods are run after reset is de-asserted.
5. Configure the CPSW_CONTROL_REG register
6. Configure the Ethernet Port Source Address registers (CPSW0_PN_SA_L_REG and CPSW_PN_SA_H_REG)
7. Configure the CPSW statistic port enable register CPSW_STAT_PORT_EN_REG

8. Configure the ALE (Section 9.4.7.1, *Address Lookup Engine*)
9. Configure the MDIO (Section 9.5.3.1, *Initializing the MDIO Module*)
10. Configure Ethernet port, as per the desired mode of operations

9.5.2 CPSW Reset

To reset the CPMAC_SL, the host must perform the following:

1. Set CMD_IDLE in the Ethernet port CPSW_PN_MAC_CONTROL_REG register
2. Wait for IDLE to be indicated in the Ethernet port CPSW_PN_MAC_STATUS_REG register
3. Configure the Ethernet ports.

9.5.3 MDIO Software Interface

9.5.3.1 Initializing the MDIO Module

The following steps are performed by the application software or device driver to initialize the MDIO device:

1. Configure the PREAMBLE and CLKDIV bits in the MDIO Control register (CPSW_MDIO_CONTROL_REG).
2. Enable the MDIO module by setting the ENABLE bit in CPSW_MDIO_CONTROL_REG.
3. The MDIO PHY alive status register (MDIO CPSW_MDIO_ALIVE_REG) can be read in polling fashion until a PHY connected to the system responded, and the MDIO PHY link status register (MDIO CPSW_MDIO_LINK_REG) can determine whether this PHY already has a link.
4. Set the appropriate PHY addresses in the MDIO user PHY select register (CPSW_MDIO_USER_PHY_SEL_REG_k, where k = 0 or 1), and set the LINKINT_ENABLE bit to enable a link change event interrupt if desirable.
5. Set the appropriate LINKSEL bit in the CPSW_MDIO_USER_PHY_SEL_REG_k register (where k = 0 or 1).
6. Set the appropriate USERINTMASKSET bit field in the CPSW_MDIO_USER_INT_MASK_SET_REG register.
7. If an interrupt on general MDIO register access is desired, set the corresponding bit in the MDIO user command complete interrupt mask set register (MDIO CPSW_MDIO_USER_INT_MASK_SET_REG) to use the MDIO user access register (MDIO CPSW_MDIO_USER_ACCESS_REG_k, where k = 0 or 1).

9.5.3.2 Writing Data To a PHY Register

The MDIO module includes a user access register (MDIO CPSW_MDIO_USER_ACCESS_REG_k, where k = 0 or 1) to directly access a specified PHY device.To write a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (MDIO CPSW_MDIO_USER_ACCESS_REG_k) is cleared.
2. Write to the GO, WRITE, REGADR, PHYADR, and DATA bits in MDIO CPSW_MDIO_USER_ACCESS_REG_k corresponding to the PHY and PHY register SW wants to write.
3. The write operation to the PHY is scheduled and completed by the MDIO module. Completion of the write operation can be determined by polling the GO bit in MDIO CPSW_MDIO_USER_ACCESS_REG_k for a 0.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (CPSW_MDIO_USER_INT_RAW_REG) corresponding to MDIO CPSW_MDIO_USER_ACCESS_REG_k used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (CPSW_MDIO_USER_INT_MASK_SET_REG), then the bit is also set in the MDIO user command complete interrupt register (CPSW_MDIO_USER_INT_MASKED_REG) and an interrupt is triggered on the host processor.

9.5.3.3 Reading Data From a PHY Register

The MDIO module includes a user access register (MDIO CPSW_MDIO_USER_ACCESS_REG_k, where k = 0 or 1) to directly access a specified PHY device. To read a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (CPSW_MDIO_USER_ACCESS_REG_k, where k = 0 or 1) is cleared.
2. Write to the GO, REGADR, and PHYADR bits in the CPSW_MDIO_USER_ACCESS_REG_k register corresponding to the PHY and PHY register SW wants to read.
3. The read data value is available in the DATA bit field in MDIO CPSW_MDIO_USER_ACCESS_REG_k register after the module completes the read operation on the serial bus. Completion of the read operation

can be determined by polling the GO and ACK bits in CPSW_MDIO_USER_ACCESS_REG_k register. After the GO bit has cleared, the ACK bit is set on a successful read.

4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (CPSW_MDIO_USER_INT_RAW_REG) corresponding to MDIO CPSW_MDIO_USER_ACCESS_REG_k used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (CPSW_MDIO_USER_INT_MASK_SET_REG), then the bit is also set in the MDIO user command complete interrupt register (CPSW_MDIO_USER_INT_MASKED_REG) and an interrupt is triggered on the host processor.

9.6.626 ALE_MOD_VER Register (Offset = 0003E000h) [Reset = 00290105h]

ALE_MOD_VER is shown in Table 9-658.

Return to the Summary Table.

The Module and Version Register identifies the module identifier and revision of the ALE_2g32 module.

Table 9-658. ALE_MOD_VER Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	MODULE_ID	R	29h	ALE_2g32 module ID.
15-11	RTL_VERSION	R	0h	RTL Version.
10-8	MAJOR_REVISION	R	1h	Major Revision.
7-6	CUSTOM_REVISION	R	0h	Custom Revision.
5-0	MINOR_REVISION	R	5h	Minor Revision.

9.6.627 ALE_ALE_STATUS Register (Offset = 0003E004h) [Reset = XXXX00X0h]

ALE_ALE_STATUS is shown in Table 9-659.

Return to the Summary Table.

The ALE status provides information on the ALE configuration and state. The ~iramdepth is used to determine how IPv6 entries are stored in the table. IPv6 entries are stored in two entries where IPv6 Entry hi is designated by the odd slice index and lo is designated by the even slice index. The slice index is above the ram depth like {SlixeIndex,RamIndex}. So for a 64 deep RAM index of 0x005, the Hi portion of the IPv6 entry is located at 0x005|0x040 and the Lo portion is located at 0x005&(~0x040).

Table 9-659. ALE_ALE_STATUS Register Field Descriptions

Bit	Field	Type	Reset	Description
31	UREGANDREGMSK12	R	0h	When set, the unregistered multicast field is a mask versus an index on 12 bit boundary in the ALE table.
30	UREGANDREGMSK08	R	0h	When set, the unregistered multicast field is a mask versus an index on 8 bit boundary in the ALE table.
29-16	RESERVED	R	0h	
15-8	POLCNTDIV8	R	0h	This is the number of Classifiers the ALE implements divided by 8. A value of 4 indicates 32 policer engines total.
7	RAMDEPTH128	R	0h	The number of ALE entries per slice of the table when this is set it indicates the depth is 128 if both ramdepth128 and ramdepth32 are zero the depth is 64.
6	RAMDEPTH32	R	0h	The number of ALE entries per slice of the table when this is set it indicates the depth is 32 if both ramdepth128 and ramdepth32 are zero the depth is 64.
5	RESERVED	R	0h	
4-0	KLUENTRIES	R	0h	This is the number of table entries total divided by 1024. A value of 1 indicates 1024 table entries. A value of 8 indicates 8192 table entries.

9.6.628 ALE_ALE_CONTROL Register (Offset = 0003E008h) [Reset = XXXXXX00h]

ALE_ALE_CONTROL is shown in Table 9-660.

Return to the Summary Table.

The ALE Control Register is used to set the ALE modes used for all ports.

Table 9-660. ALE_ALE_CONTROL Register Field Descriptions

Bit	Field	Type	Reset	Description
31	ENABLE_ALE	R/W	0h	Enable ALE 0 - Drop all packets 1 - Enable ALE packet processing
30	CLEAR_TABLE	R/W	0h	Clear ALE address table - Setting this bit causes the ALE hardware to write all table bit values to zero. Software must perform a clear table operation as part of the ALE setup/configuration process. Setting this bit causes all ALE accesses to be held up for 64 clocks while the clear is performed. Access to all ALE registers will be blocked (wait states) until the 64 clocks have completed. This bit cannot be read as one because the read is blocked until the clear table is completed at which time this bit is cleared to zero.
