Complex bit access types are encoded to fit into small table cells. Table 16-63 shows the codes that are used for access types in this section.

Table 16-63. INPUT_XBAR_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
WOnce	W Once	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

Access Type	Code	Description
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

Complex bit access types are encoded to fit into small table cells. [Table 16-182](#) shows the codes that are used for access types in this section.

Table 16-182. OUTPUT_XBAR_EXT64_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1S	W1S	Write 1 to set
WOnce	WOnce	Write Set once
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

17.1 Introduction

The analog modules on this device include the Analog-to-Digital Converter (ADC), Temperature Sensor, Buffered Digital-to-Analog Converter (DAC), and Comparator Subsystem (CMPSS).

17.1.1 Features

The analog subsystem has the following features:

- Flexible voltage references:
 - The ADCs are referenced to VREFHix and VREFLOx pins.
 - VREFHIA pin voltage can be driven in externally or can be generated by an internal bandgap voltage reference. VREFHIB and VREFHIC can be connected to the internal reference using an external on-board connection.
 - The internal voltage reference range can be selected to be 0 V to 3.3 V or 0 V to 2.5 V.
 - The buffered DACs are referenced to VREFHix and VSSA
 - Alternately, these DACs can be referenced to the VDAC pin and VSSA
 - The comparator DACs are referenced to VDDA and VSSA
 - Alternately, these DACs can be referenced to the VDAC pin and VSSA
- Flexible pin usage
 - Buffered DAC outputs, comparator subsystem inputs, and digital inputs (AIOs)/outputs (AGPIOs) are multiplexed with ADC inputs
 - Internal connection to V_{REFLO} on ADCA and ADCC for offset self-calibration

17.1.2 Block Diagram

The following analog subsystem block diagrams show the connections between the different integrated analog modules to the device pins. These pins fall into two categories: analog module inputs/outputs and reference pins.

The reference pins, VREFHIA to VREFHIC and VREFLOA to VREFLOC, can be used to supply an external voltage reference to the associated ADCs. VREFHIA can also be used to supply the voltage reference to DAC A, and VREFHIB can be used to supply the voltage reference to DAC C. An internal voltage reference is available and connects to VREFHIA. To use the internal voltage reference on ADC B, ADC C or DAC C, connect VREFHIA to VREFHIB and/or VREFHIC externally.

The VDAC reference pin can be used to set an alternate range for DAC A and DAC C, and for the DACs inside the CMPSS modules (the CMPSS DACs are referenced to VDDA and VSSA by default). Using this pin as a reference prevents the channel from being used as an ADC input (but the ADC can be used to sample the VDAC voltage, if desired). The choice of reference is configurable per module for each CMPSS or buffered DAC; the selection is made using the module's configuration registers.

Some analog pins support digital functionality through muxed AIOs and AGPIOs. AIOs only support digital input functionality, while AGPIOs support full digital input and output functionality.

The following notes apply to all packages:

- Not all analog pins are available on all devices. See the device data sheet to determine which pins are available.
- See the device data sheet to determine the allowable voltage range for VREFHI and VREFLO.
- An external capacitor is required on the VREFHI pins. See the device data sheet for the specific value required.
- For buffered DAC modules, VSSA is the low reference whether VREFHix or VDAC is selected as the high reference.
- For CMPSS modules, VSSA is the low reference whether VDAC or VDDA is selected as the high reference.

Note

If all ADCs are operating in internal VREF mode, then VREFHIA, VREFHIB, and VREFHIC must be manually connected externally.

Input connections to the CMPSS modules are selectable through a programmable input mux. Figure 17-2 shows the CMPSS input connections. Table 17-1 shows the mapping of ADC input signals to CMPSS mux inputs.

- To configure the CPH_POSIN input mux for CMPSSx, write to the CMPxHPMXSEL field in the CMPHPMXSEL or CMPHPMXSEL1 analog subsystem register.
- To configure the CPH_NEGIN input mux for CMPSSx, write to the CMPxHNMXSEL field in the CMPHNMXSEL analog subsystem register.
- To configure the CPL_POSIN input mux for CMPSSx, write to the CMPxLPMXSEL field in the CMPLPMXSEL or CMPLPMXSEL1 analog subsystem register.
- To configure the CPL_NEGIN input mux for CMPSSx, write to the CMPxLNMXSEL field in the CMPLNMXSEL analog subsystem register.

17.2 Optimizing Power-Up Time

The analog-to-digital converters (ADC) and buffered digital-to-analog converters (DAC) share a common reference circuit. If needed, an application using one or more of these modules can optimize power-up time by taking advantage of the shared reference. Once one of the modules using the shared reference has been initialized in internal reference mode, the power-up time for subsequent modules can be optimized by subtracting the reference power-up time from the minimum power-up time requirement.

For instance, if ADCA requires $t_{ADCPUIINT}$ to power up in internal reference mode, and $t_{ADCPUEXT}$ to power up in external reference mode, the application does not need to wait $t_{ADCPUIINT}$ to power up a second ADC instance such as ADCC in internal reference mode. In this case, the application can simply wait for $t_{ADCPUEXT}$ after powering up ADCC, even though both ADCs are used in internal reference mode. In the same scenario, if the application wished to use DACA in internal reference mode, the required wait time after power-up is $t_{DACPUEXT}$, not the longer $t_{DACPUINT}$.

There is also a wait time associated with power-up in internal reference mode when switching between 2.5-V and 3.3-V range. See the device data sheet for wait time values.

17.3 Digital Inputs on ADC Pins (AIOs)

Some GPIOs are multiplexed with analog pins and only have digital input functionality. These are also referred to as AIOs. Pins with only an AIO option on this port can only function in input mode. See the device data sheet for list of AIO signals. By default, these pins function as analog pins and the GPIOs are in a high-impedance state. The GPyAMSEL register is used to configure these pins for digital or analog operation.

Note

If digital signals with sharp edges (high dv/dt) are connected to the AIOs, cross-talk can occur with adjacent analog signals. Therefore, limit the edge rate of signals connected to AIOs if adjacent channels are being used for analog functions.

17.4 Digital Inputs and Outputs on ADC Pins (AGPIOs)

Some GPIOs are multiplexed with analog pins and have digital input and output functionality. These are also referred to as AGPIOs. Unlike AIOs, AGPIOs have full input and output capability.

By default, the AGPIOs are not connected and must be configured. [Table 17-5](#) shows how to configure the AGPIOs. To enable the analog functionality, set the register AGPIOTRLx from analog subsystem. To enable the digital functionality, set the register GPxAMSEL from the *General-Purpose Input/Output (GPIO)* chapter.

Table 17-5. AGPIO Configuration

AGPIOTRLx.GPIOy (Default = 0)	GPxAMSEL.GPIOy (Default = 1)	Pin Connected To:	
		ADC	GPIOy
0	0	-	Yes
0	1	- ⁽¹⁾	- ⁽¹⁾
1	0	-	Yes
1	1	Yes	-

(1) By default there are no signals connected to AGPIO pins. One of the other rows in the table must be chosen for pin functionality.

Note

If digital signals with sharp edges (high dv/dt) are connected to the AGPIOs, cross-talk can occur with adjacent analog signals. The user must therefore limit the edge rate of signals connected to AGPIOs, if adjacent channels are being used for analog functions.

18.1 Introduction

The ADC module is a successive approximation (SAR) style ADC with selectable resolution of either 16 bits or 12 bits. The ADC is composed of a core and a wrapper. The core is composed of the analog circuits which include the channel select MUX, the sample-and-hold (S/H) circuit, the successive approximation circuits, voltage reference circuits, and other analog support circuits. The wrapper is composed of the digital circuits that configure and control the ADC. These circuits include the logic for programmable conversions, result registers, interfaces to analog circuits, interfaces to the peripheral buses, post-processing circuits, and interfaces to other on-chip modules.

Each ADC module consists of a single sample-and-hold (S/H) circuit. The ADC module is designed to be duplicated multiple times on the same chip, allowing simultaneous sampling or independent operation of multiple ADCs. The ADC wrapper is start-of-conversion (SOC) based (see [Section 18.3](#)).

18.1.2 Features

Each ADC has the following features:

- Selectable resolution of 12 bits or 16 bits
- Ratiometric external reference set by VREFHI and VREFLO pins
- Selectable internal reference of 2.5V or 3.3V
- Single-ended signal conversions
- Differential mode support
- Input multiplexer with up to 26 channels (single-ended) or 10 channels (differential)
- External channel mux option to expand available ADC channels
- 16 configurable SOCs
- 16 individually addressable result registers
- Two trigger repeater modules, enabling customizable hardware oversampling and undersampling modes with little or no CPU overhead
- Multiple trigger sources
 - S/W (with available global synchronization for multiple ADCs) - software immediate start
 - All ePWMs - ADCSOC A or B
 - GPIO XINT2
 - CPU Timers 0/1/2 (from each C28x core present)
 - ADCINT1/2
 - ECAP events in capture mode (CEVT1, CEVT2, CEVT3, and CEVT4) and APWM mode (period match, compare match, or both)
- Four flexible PIE interrupts
- Burst mode
- Four post-processing blocks, each with:
 - Saturating offset calibration
 - Error from set-point calculation
 - High, low, and zero-crossing compare, with interrupt and ePWM trip capability
 - Trigger-to-sample delay capture
 - Aggregation functions: max, min, sum, and average (binary shift)
 - Absolute value function
- Result safety checkers to compare SOC results on same ADC or multiple ADC instances

Note

Not every channel is pinned out from all ADCs. Check the device data sheet to determine which channels are available.

18.1.3 Block Diagram

Figure 18-1 shows the block diagram for the ADC core and ADC wrapper.

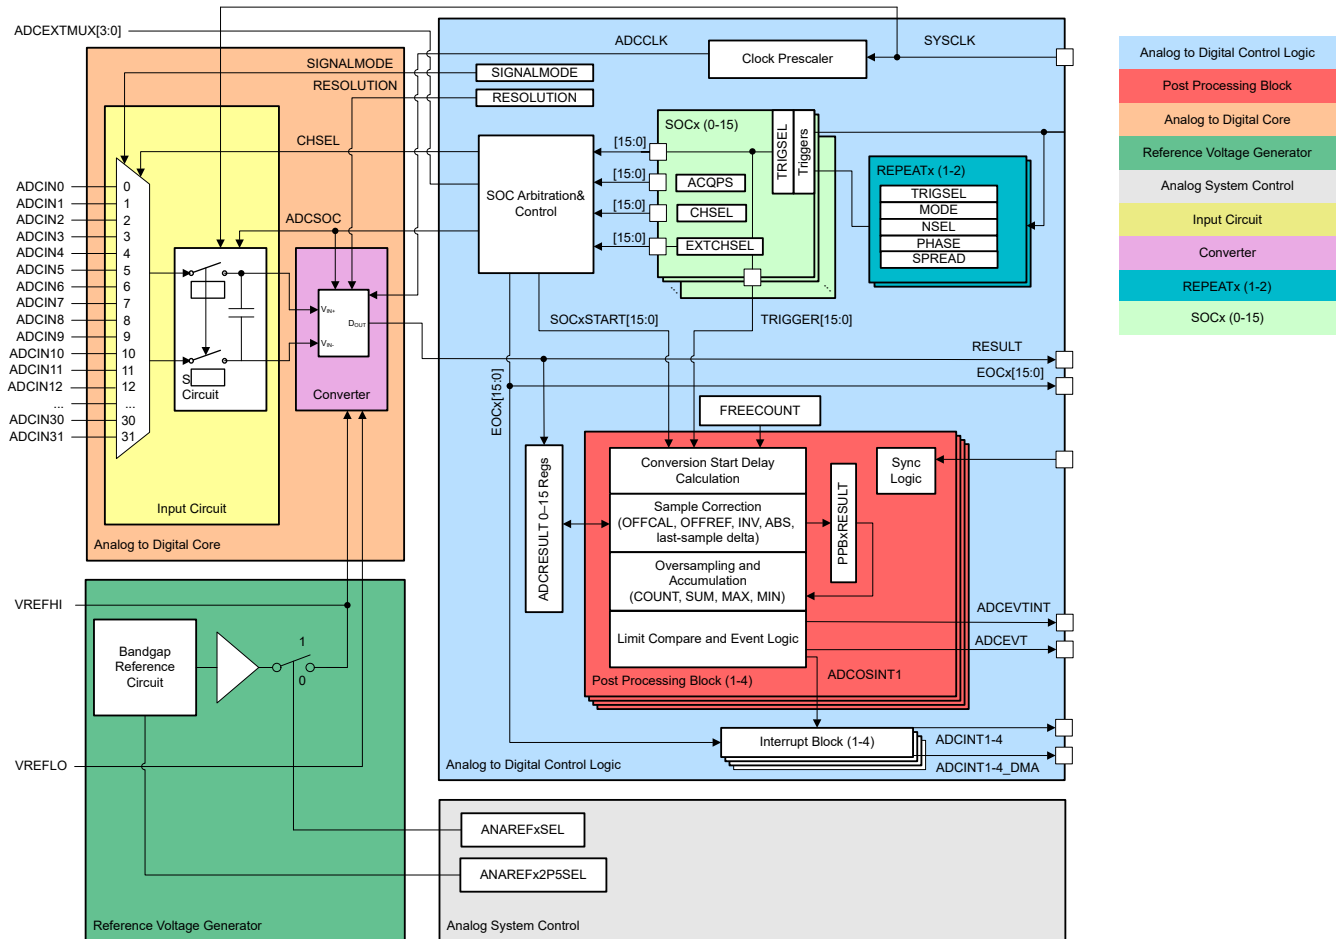

Figure 18-1. ADC Module Block Diagram

Note

The ADC block diagram reflects the number of ADC channels internally configurable on the device. The actual number of available external ADC inputs varies depending on part and package.

18.2 ADC Configurability

Some ADC configurations are individually controlled by the SOCs, while others are globally controlled per ADC module. [Table 18-1](#) summarizes the basic ADC options and their level of configurability. The subsequent sections discuss these configurations.

Table 18-1. ADC Options and Configuration Levels

Options	Configurability
Clock	Per module ⁽¹⁾
Resolution	Per module ⁽¹⁾
Signal mode	Per module
Reference voltage source	Per module (external or internal) ⁽²⁾
Trigger source	Per SOC ⁽¹⁾
Converted channel	Per SOC
Acquisition window duration	Per SOC ⁽¹⁾
EOC location	Per module
Burst Mode	Per module ⁽¹⁾

- (1) Writing these values differently to different ADC modules can cause the ADCs to operate asynchronously. See [Section 18.14.1](#) for guidance on when the ADCs are operating synchronously or asynchronously.
- (2) Lower pin count packages can share one VREFHI pin among multiple ADCs. In this case, the ADCs that share a reference pin must have their reference modes configured identically

18.2.1 Clock Configuration

The base ADC clock is provided directly by the system clock (SYSCLK). SYSCLK is used to generate the ADC acquisition window. The register ADCCTL2 has a PRESCALE field that determines the ADCCLK. ADCCLK is used to clock the converter, and is only active during the conversion phase. At all other times, including during the sample-and-hold window, the ADCCLK signal is gated off.

In 16-bit mode, the core requires approximately 29.5 ADCCLK cycles to process a voltage into a conversion result, while in 12-bit mode, this process requires approximately 10.5 ADCCLK cycles. The choice of resolution also determines the necessary duration of the acquisition window, see [Section 18.14.2](#).

Note

To determine an appropriate value for ADCCTL2.PRESCALE, see the device data sheet to determine the maximum SYSCLK and ADCCLK frequency.

18.2.2 Resolution

The resolution of the ADC determines how finely the analog range is quantized into digital values. This ADC supports a configurable resolution of 16 bits or 12 bits.

The resolution can be configured by using either the `AdcSetMode()` or `ADC_setMode()` functions, depending on the header files used, provided in C2000ware in `F28p65x_Adc.c`. These functions make sure that the correct trim is loaded into the ADC trim registers, and must be called at least once after a device reset. Do not configure the resolution by directly writing to the ADCCTL2 register.

The resolution can be changed at any time when the ADC is idle (no active or pending SOCs). No wait time is necessary after changing the resolution before conversions can be initiated. If SOCs are active or pending when the resolution is changed, those SOCs can produce incorrect conversion results.

18.2.3 Voltage Reference

18.2.3.1 External Reference Mode

Each ADC has a VREFHI input and a VREFLO input. In external reference mode, these pins are used as a ratiometric reference to determine the ADC conversion input range.

See [Section 18.14.6](#) for information on how to supply the reference voltage.

Note

- On devices with no external VREFLO pin, VREFLO is internally connected to the device analog ground, VSSA.
 - See the device data sheet to determine the allowable voltage range for VREFHI and VREFLO.
 - The external reference mode requires an external capacitor on the VREFHI pin. See the device data sheet for the specific value required.
-

18.2.3.2 Internal Reference Mode

In internal reference mode, the device drives a voltage out onto the VREFHI pin. The VREFHI and VREFLO pins then set the ADC conversion range.

The internal reference voltage can be configured to be either 2.5 V or 1.65 V. When the 1.65-V internal reference voltage is selected, the ADC input signal is internally divided by 2 before conversion, which effectively makes the ADC conversion range from VREFLO to 3.3 V.

The ADC supports internal reference selection in 12-bit resolution mode.

Note

The internal reference mode also requires an external capacitor on the VREFHI pin. See the device data sheet for the specific value required.

18.2.3.3 Ganged References

On some packages, the voltage reference pins for multiple ADCs can be combined. In this case, it is necessary to configure the ganged references identically when selecting external versus internal reference mode and for selecting an internal reference voltage range of 3.3 V or 2.5 V.

For example, if ADC B and ADC C reference pins are combined and the desired reference mode is 2.5 V internal reference mode, the following reference configuration code can be run:

```
//ADCB VREFHI and ADCC VREFHI share a pin
//ADCB VREFLO and ADCC VREFLO share a pin
//Both references must be explicitly configured
//Both references must be configured identically
SetVREF(ADC_ADCB, ADC_INTERNAL, ADC_VREF2P5);
SetVREF(ADC_ADCC, ADC_INTERNAL, ADC_VREF2P5);
```

Internal device hardware makes sure multiple references do not drive conflicting voltages onto the same pin. Because of this, references can be configured in any order or over any amount of time.

18.2.3.4 Selecting Reference Mode

The voltage reference mode must be configured by using either the `ADC_setVREF()` or the `SetVREF()` functions, depending on the header files used, provided in C2000Ware. Using either of these functions makes sure that the correct trim is loaded in the ADC trim registers. This function must be called at least once after a device reset. Do not configure the voltage reference mode by directly writing to the ANAREFCTL register.

18.2.4 Signal Mode

The ADC supports two signal modes: single-ended and differential.

In single-ended mode, the input voltage to the converter is sampled through a single pin (ADCIN_x), referenced to VREFLO.

In differential signaling mode, the input voltage to the converter is sampled through a pair of input pins, one of which is the positive input (ADCIN_{xP}) and the other is the negative input (ADCIN_{xN}). The actual input voltage is the difference between the two (ADCIN_{xP} – ADCIN_{xN}).

NOTES:

- In differential signal mode, VREFLO must be connected to VSSA.
- In differential signal mode, the common mode voltage is $V_{CM} = (ADCIN_{xP} + ADCIN_{xN})/2$

The data sheet for a particular device places some requirements on how close this voltage needs to be to: $(VREFHI + VREFLO)/2$

Note: The above condition is not met by connecting the negative input to VSSA or VREFLO.

- Differential signaling mode is advantageous because noise encountered on both inputs is largely canceled. The effect can be maximized by routing the positive and negative traces for the same differential input as close together as possible and keeping them symmetrical with respect to the signal reference.

The signal mode must be configured by using either the ADC_setMode() or AdcSetMode() functions, depending on the header files used, provided in C2000ware in F28006x_Adc.c. These functions make sure that the correct trim is loaded into the ADC trim registers. These functions must be called at least once after a device reset. The signal mode must not be configured by writing to the ADCCTL2 register directly.

18.2.5 Expected Conversion Results

Based on a given analog input voltage, the expected digital conversion is given in [Table 18-2](#) and [Table 18-3](#). Fractional values are truncated.

	when $ADCINyP - ADCINyN \geq (VREFHI - VREFLO)$	$ADCRESULTx = 65535$

18.2.6 Interpreting Conversion Results

Based on a given ADC conversion result, the corresponding analog input is given in [Table 18-4](#) and [Table 18-5](#). This corresponds to the center of the possible range of analog voltages that can produce this conversion result.

18.3 SOC Principle of Operation

The ADC triggering and conversion sequencing is accomplished through configurable start-of-conversions (SOCs). Each SOC is a configuration set defining the single conversion of a single channel. In that set, there are three configurations: the trigger source that starts the conversion, the channel to convert, and the acquisition (sample) window duration. Upon receiving the trigger configured for a SOC, the wrapper makes sure that the specified channel is captured using the specified acquisition window duration.

Multiple SOCs can be configured for the same trigger, channel, and acquisition window as desired. Configuring multiple SOCs to use the same trigger allows the trigger to generate a sequence of conversions. Configuring multiple SOCs to use the same trigger and channel allows for oversampling. Oversampling can also be achieved using a single trigger source by configuring the trigger repeater module. See [Section 18.3.2.2](#) for more information.

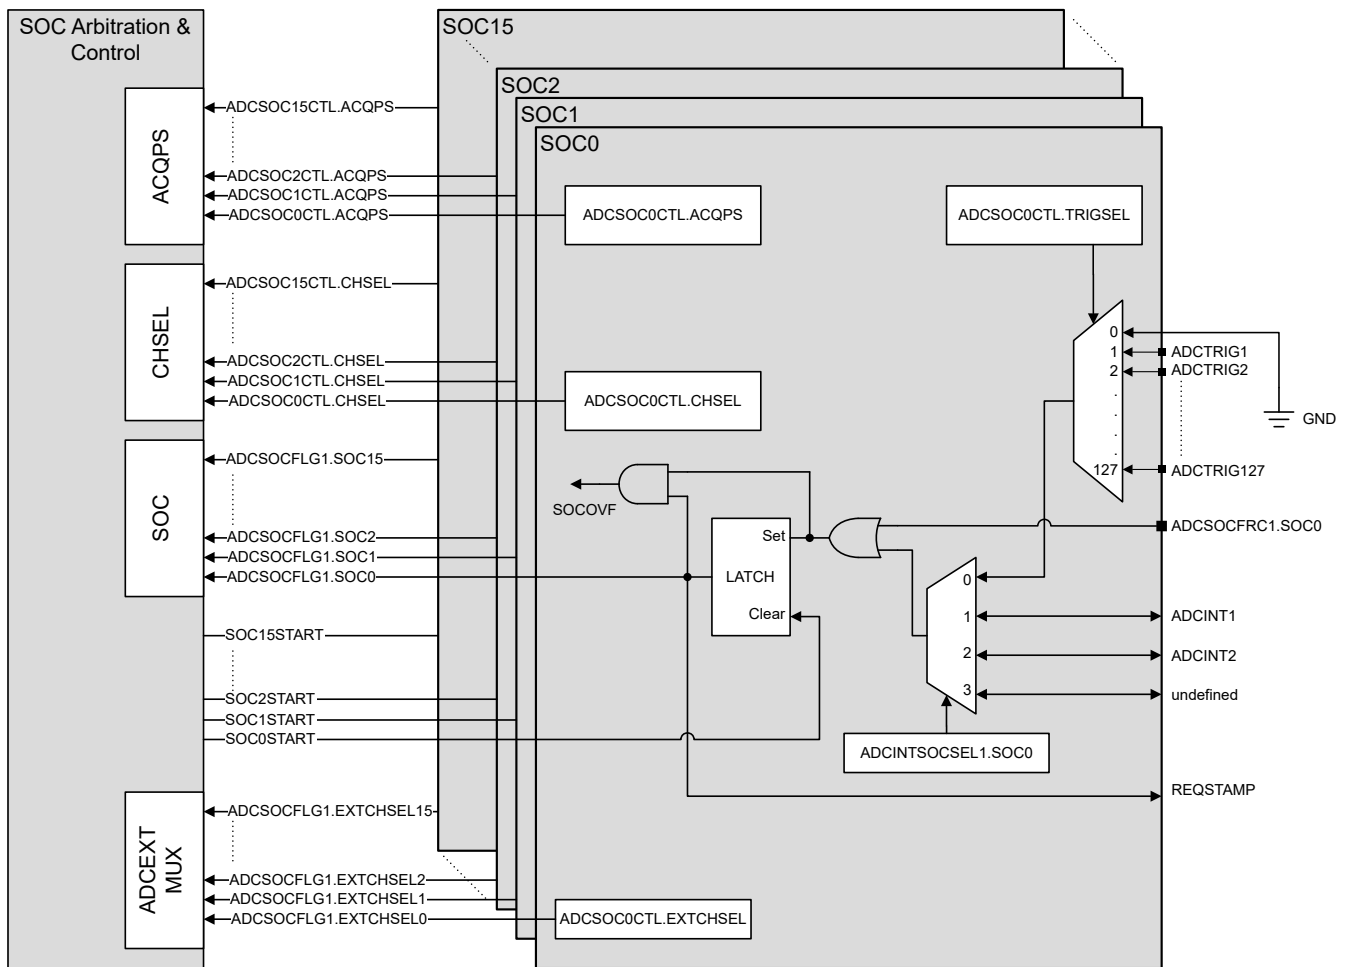

Figure 18-2. SOC Block Diagram

18.3.1 SOC Configuration

Each SOC has its own configuration register, ADCSOCxCTL. Within this register, SOCx can be configured for trigger source, channel to convert, optional external channel mux selection, and acquisition (sample) window duration.

18.3.2 Trigger Operation

Each SOC can be configured to start on one of many input triggers. The primary trigger select for SOCx is in the ADCSOCxCTL.TRIGSEL register, which can select between:

- Disabled (software only)
- CPU Timers 0/1/2 (from each C28x core present)
- GPIO: Input X-Bar INPUT5
- ADCSOCA or ADCSOCA from each ePWM module
- eCAP events
- Either of the two trigger repeater blocks. This can be used to achieve oversampling, undersampling, or to apply a trigger delay.
- A global synchronous software trigger. This is achieved by configuring the ADCSOCFRCGBSEL and ADCSOCFRCGB analog subsystem registers.

In addition, each SOC can also be triggered when the ADCINT1 flag or ADCINT2 flag is set. This is achieved by configuring the ADCINTSOCSEL1 register (for SOC0 to SOC7) or the ADCINTSOCSEL2 register (for SOC8 to SOC15). This is useful for creating continuous conversions.

18.3.2.1 Global Software Trigger

This ADC supports synchronous global software triggers. Synchronous global triggers allow the application to trigger SOCx on multiple ADC instances that are exactly simultaneous in time. To generate a global software trigger, configure the analog subsystem register ADCSOCFRCGBSEL to select the ADC instances to be triggered, then write to ADCSOCFRCGB to trigger the desired SOCx simultaneously on each ADC.

For example, to trigger SOC0, SOC1, and SOC2 on ADCA and ADCC:

1. Set ADCSOCFRCGBSEL.ADCA = 1 and ADCSOCFRCGBSEL.ADCC = 1 by writing 0x5 to the ADCSOCFRCGBSEL register.
2. Trigger SOCx 0, 1 and 2 by writing 0x7 to the ADCSOCFRCGB register.

18.3.2.2 Trigger Repeaters

Each ADC instance contains two trigger repeater modules. These modules can select any of the regular ADC triggers that are selectable by the ADCSOCxCTL.TRIGGER register, and generate a number of repeat pulses as configured in the REPxN.NSEL register. [Figure 18-3](#) shows a functional block diagram of the ADC trigger repeater module.

Each repeater module can apply four types of trigger modifications:

- Oversampling mode
- Undersampling mode
- Phase delay
- Re-trigger spread

Each of these trigger modification features is explained in detail in the following sections.

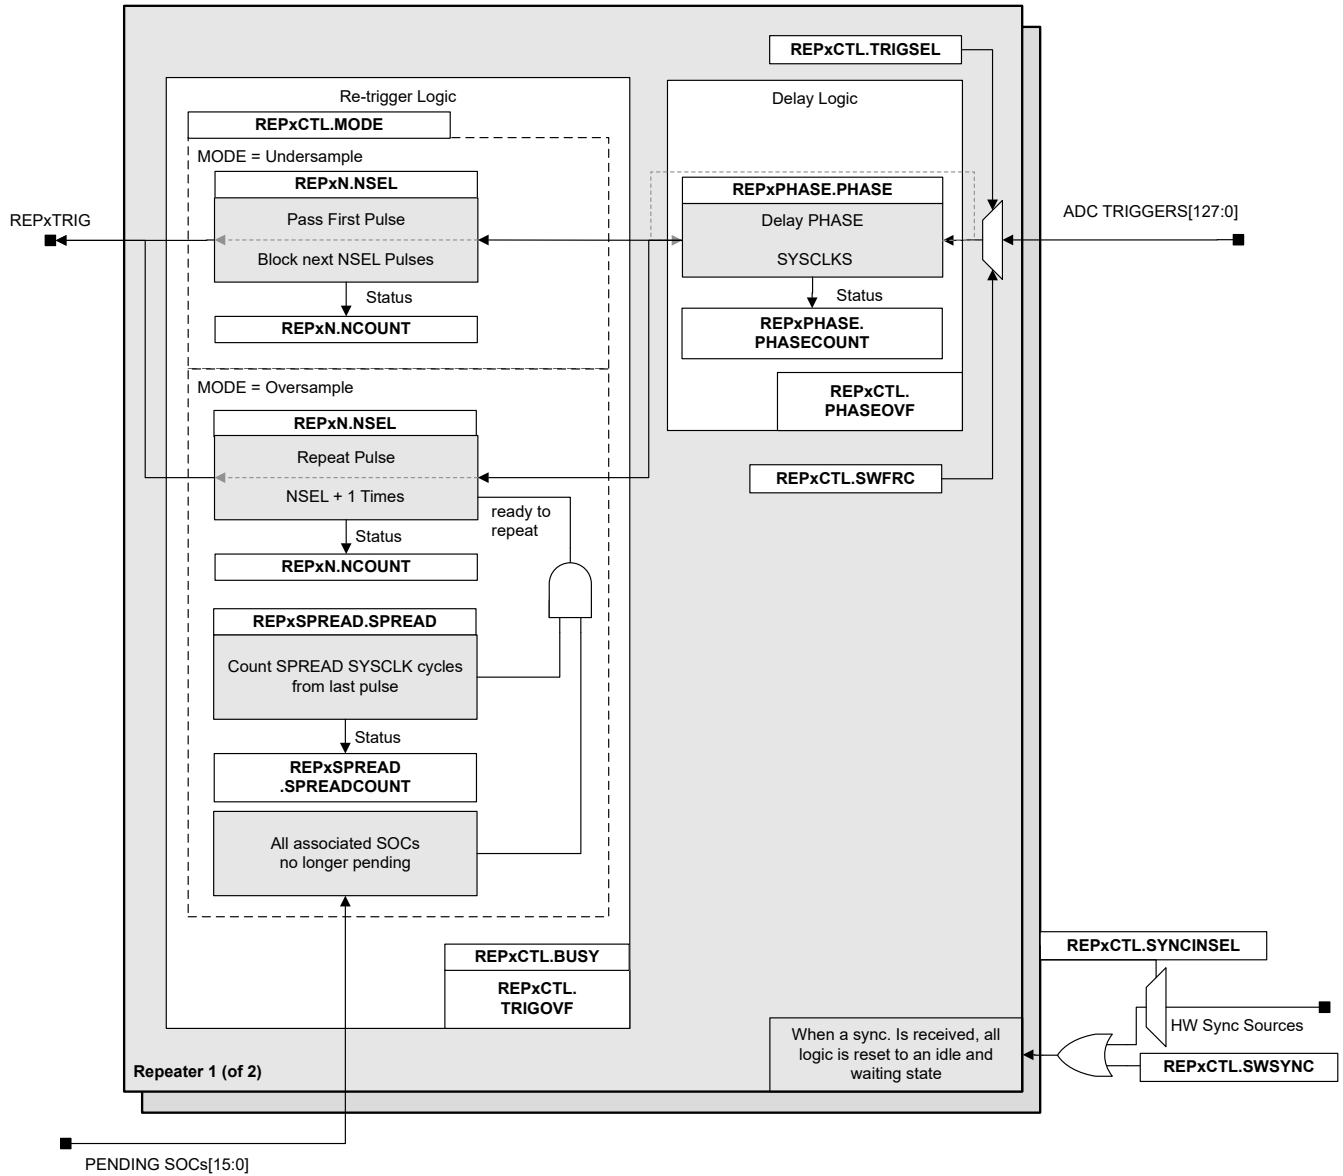

Figure 18-3. ADC Trigger Repeater Block Diagram

18.3.2.2.1 Oversampling Mode

In this mode, the repeater module passes the initial trigger through to the output. As soon as all SOCs configured to receive the trigger are in progress or completed, the repeater issues the trigger again. The process repeats until the configured number of trigger pulses (NSEL + 1) have been issued.

This mode allows the application to easily perform multiple back-to-back samples from a single trigger pulse. When used in conjunction with the aggregation options in the post-processing block, this mode enables oversampling, averaging, or peak detection. Figure 18-4 shows an example of oversampling SOCs generated from a single ePWM trigger.

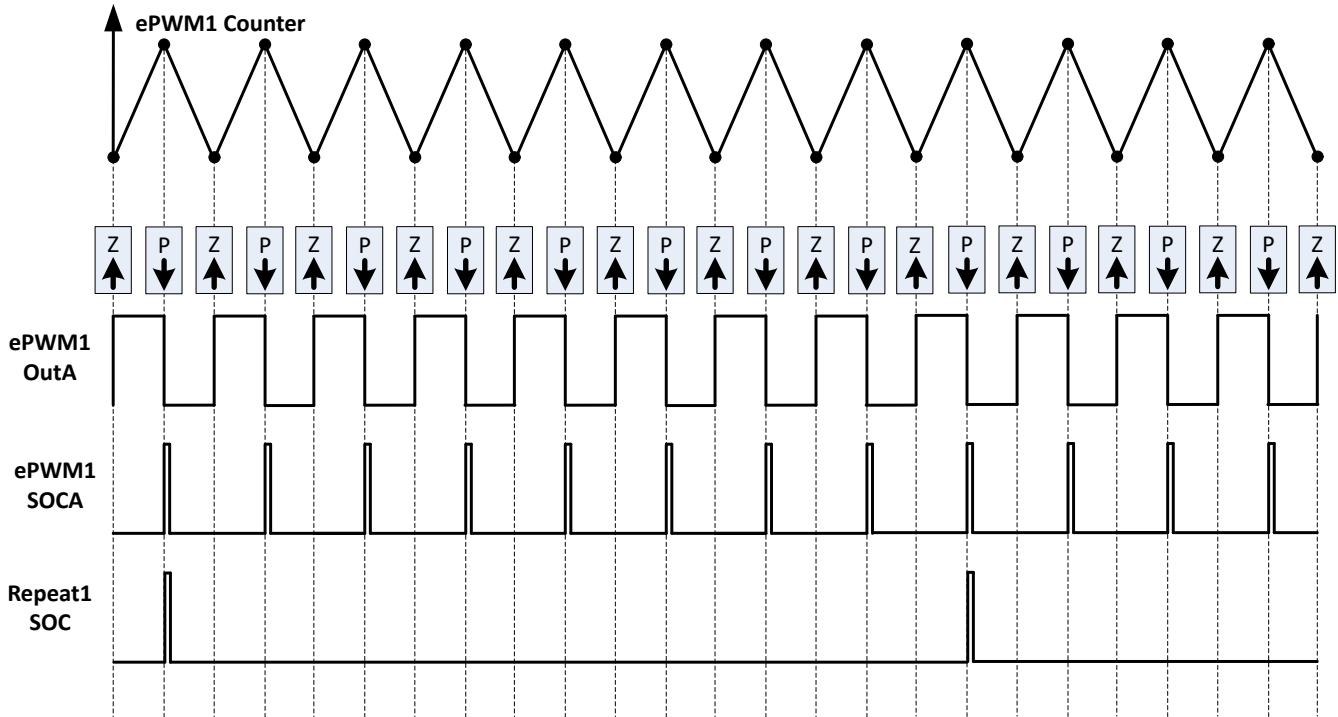

TRIGGER = ePWM SOCA, NSEL = 3, PHASE = 0, MODE = Oversampling, SPREAD = 0

Figure 18-4. Oversampled ADC Trigger Example

18.3.2.2.2 Undersampling Mode

In this mode, the repeater module passes the initial trigger through to the output, and then blocks subsequent triggers until the configured number of trigger pulses (NSEL + 1) arrive. The result is that only 1 in every (NSEL + 1) pulses passes through to the output. [Figure 18-5](#) shows an example of undersampled SOCs from multiple ePWM triggers.

This mode enables the application to scale down the trigger frequency for one or more SOCs. This is useful for charge-sharing input drivers which have increased error with higher sampling frequencies.

TRIGGER = ePWM SOCA, NSEL = 7, PHASE = 0, MODE = Undersampling, SPREAD = (don't care)

Figure 18-5. Undersampled ADC Trigger Example

Note

Oversampling and undersampling modes are mutually exclusive for each repeater module. However, multiple repeater modules can (and are intended to) be used in different modes concurrently.

18.3.2.2.3 Trigger Phase Delay

The repeater module can delay the initial trigger by a specified number of SYSCLK cycles. This feature can be used in combination with oversampling or undersampling modes, or as a standalone delay by setting NSEL = 0. The phase delay does not affect the timing between subsequent repeated oversampled triggers—it only delays the initial trigger. When PHASE = 0, the initial trigger arrives at the same time as an unmodified trigger. [Figure 18-6](#) shows an example of phase delay combined with oversampling. [Figure 18-7](#) shows an example of a standalone phase delay with a single SOC trigger.

Phase delay enables the application to tie the trigger start point to an ePWM event while allowing for a necessary sampling delay (for example, settling time). In addition, when phase delay is combined with oversampling functionality, a single trigger can generate an interleaved burst of conversions across multiple ADCs. To achieve this, set PHASE in increments of $(t_{\text{sample}}/n_{\text{interleaved_ADCs}})$. [Figure 18-8](#) shows an example of interleaving 12 samples across 3 ADCs.

TRIGGER = ePWM SOCA, NSEL = 3, PHASE = 100, MODE = Oversampling, SPREAD = 0

Figure 18-6. Oversampled ADC Trigger Example with Phase Delay

TRIGGER = ePWM SOCA, NSEL = 0, PHASE = 100, MODE = (either), SPREAD = (don't care)

Figure 18-7. ADC Trigger Example with Phase Delay

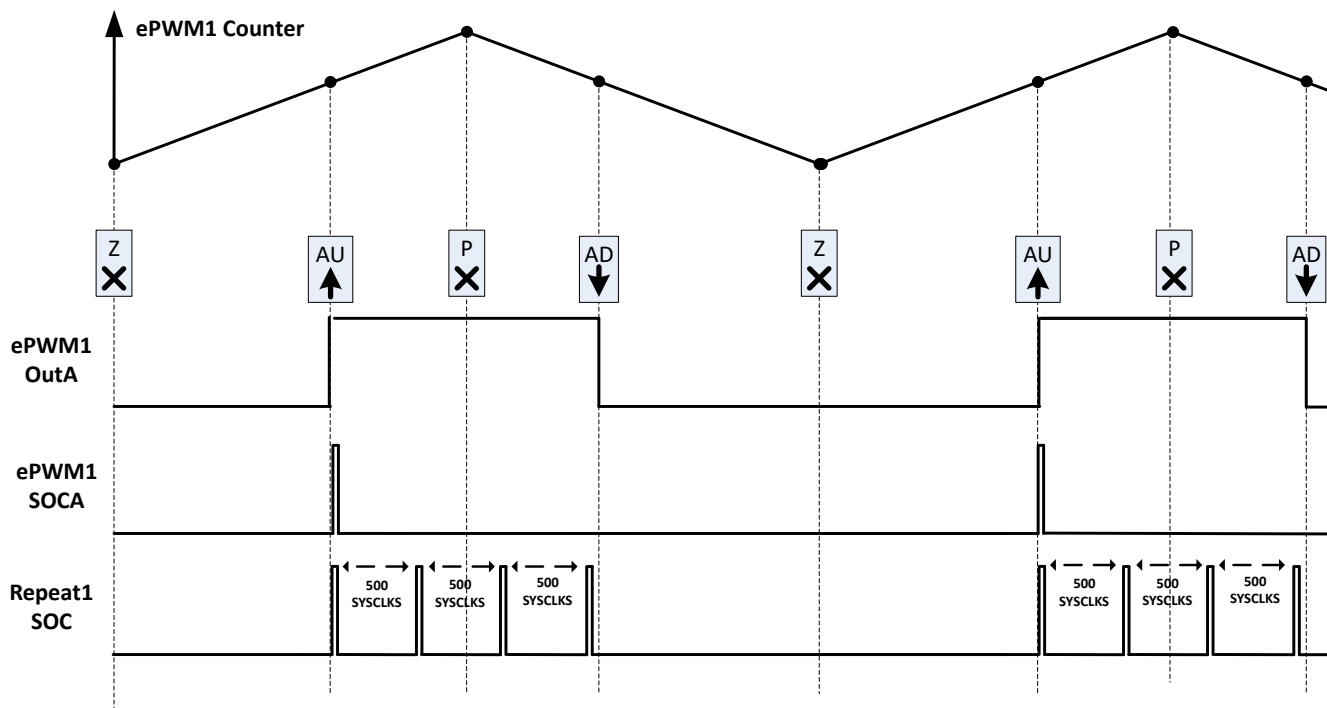

TRIGGER = ePWM SOCA, NSEL = 3, MODE = Oversampling, PHASE = (varies per ADC), SPREAD = 0

Figure 18-8. ADC Interleaved Trigger Example (12 Samples Across 3 ADCs)

18.3.2.2.4 Re-trigger Spread

If additional time between samples is desired, the application can configure SPREAD equal to the number of SYSCLK cycles desired between samples. Figure 18-9 shows an example of oversampling from an ePWM trigger with a 500-cycle spread between samples.

- By default, SPREAD = 0, and samples are re-triggered as soon as all associated SOCs are no longer pending.
- If SPREAD is set to a value smaller than the time needed for the associated SOCs to complete, then the ADC performs the triggered conversions back-to-back, and SPREAD is effectively 0.
- SPREAD has no effect in undersampling mode, or when NSEL = 0.

TRIGGER = ePWM SOCA, NSEL = 3, MODE = Oversampling, PHASE = 0, SPREAD = 500

Figure 18-9. ADC Repeated Trigger Example with Sample Spread

18.3.2.2.5 Trigger Repeater Configuration

To configure ADC oversampling or undersampling using the trigger repeater module, follow this procedure:

1. Set up the SOC by writing to ADCSOCxCTL. Specify one of the two repeater modules (REP1TRIG or REP2TRIG) as the trigger source.
2. Configure the repeater module by writing to the REPxCTL register:
 - a. Configure oversampling or undersampling mode using the MODE bit.
 - b. Specify the desired SOC trigger source in the TRIGGER field.
 - c. If desired, configure a sync source for the repeater module in the SYNCINSEL field. A sync event resets all repeater registers to a ready and waiting state, while preserving NSEL, PHASE and MODE. A software-initiated sync is also possible by writing 1 to the SWSYNC bit. [Table 18-6](#) contains a list of possible sync sources for the trigger repeater.
 - d. If desired, clear any previously set phase and trigger overflow flags by writing to the PHASEOVF and TRIGGEROVF bits.
3. Configure the trigger repeat count by writing to the REPxN.NSEL register. The repeater module supports up to 128 repeats for each trigger.
4. Configure the repeater phase delay by writing to the REPxPHASE.PHASE register.
5. To configure a re-trigger spread delay in oversampling mode, write the desired delay value in SYSCLK cycles to the REPxSPREAD.SPREAD register.
6. Configure the PPBLIMIT register. This register defines how many samples the post-processing block accumulates before loading the partial sum value in ADCPPBxPSUM into ADCPPBXSUM.
7. The post-processing block (PPB) and trigger repeater module have independent sync source configurations. To configure the PPB sync source, write to the ADCPPBxCONFIG2 register. For more information on how to configure the ADC post-processing block, see [Section 18.8](#).

Note

When NSEL = 0, the repeater module essentially acts as a pass-through for SOC triggers, but is still useful for applying phase delay. SOC triggers are passed through in both oversampling mode and undersampling mode, even if there are still pending SOC. In this scenario, the ADC sets a the trigger overflow flag for the individual SOC itself (ADCSOCOVF1.SOCx), not the repeater module. On the other hand, when oversampling with NSEL > 0, the ADC sets the oversampled trigger overflow flag (REPxCTL.TRIGGEROVF) if a trigger arrives while there are pending SOC.

When NSEL = 0, the repeater module does not set the REPxCTL.MODULEBUSY indicator. In this scenario, the application must make sure that all associated SOC flags have completed before enabling oversampling or undersampling mode by setting NSEL > 0.

18.3.2.2.5.1 Register Shadow Updates

To avoid latency or processing delays between triggers, the application can write updated values to the NSEL, PHASE and SPREAD registers while the repeater module is still actively working. When a new SOC trigger is received, these values are loaded into the NCOUNT, PHASECOUNT and SPREADCOUNT registers, which then count down to zero as each SOC is triggered by the repeater module.

In addition, the application can change the repeater module's oversampling or undersampling mode by writing to the REPxCTL.MODE register while the repeater is actively working, without affecting the current operation. The repeater module loads the value of REPxCTL.MODE into REPxCTL.ACTIVEMODE when a new SOC trigger is received.

18.3.2.2.6 Re-Trigger Logic

The repeater module determines when to re-trigger based on the values of ADCSOCxCTL.TRIGSEL and the SOC flags in ADCSOCFLG1. A repeat trigger is issued when all SOCs configured to be triggered by the repeater module instance are no longer pending. Figure 18-10 describes the trigger repeat logic. Because the SOC pending flag goes low at the end of the sample and hold phase, the module has plenty of time to re-trigger conversions without introducing any latency between repeat conversions.

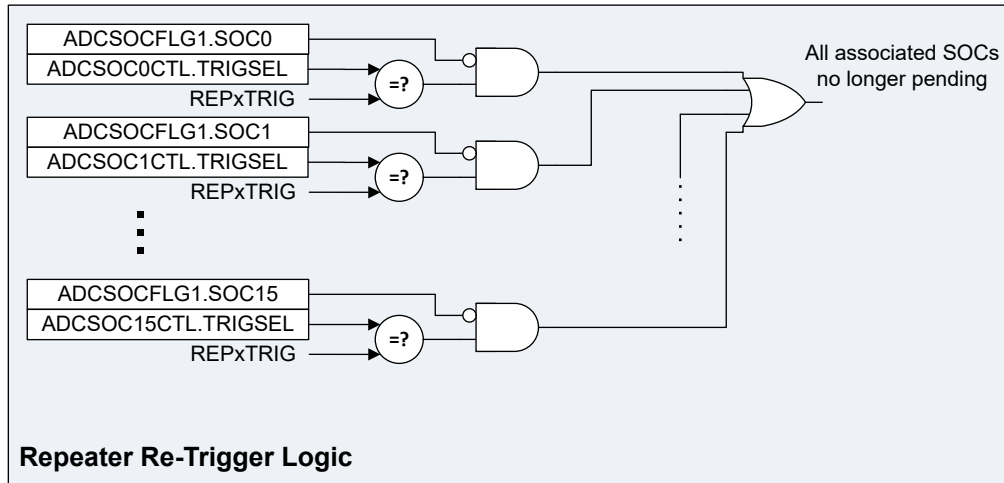

Figure 18-10. Trigger Repeater Repeat Logic

Re-triggering in Burst Mode

If the ADC is in burst mode, and the repeater is selected as the BURSTTRIG source, then the repeater fires a re-trigger pulse whenever there are no high-priority associated SOCs pending, and there are no round-robin SOCs pending.

18.3.2.2.7 Multi-Path Triggering Behavior

With the trigger repeater modules, it is possible to have one trigger source take multiple paths to set SOCs in various ways. For example, ePWM1 can directly trigger SOC3 and SOC4, while one repeater block uses ePWM1 to generate oversampling triggers on SOCs 0-2, and the second repeater block generates undersampled triggers to SOC5. Assuming all SOCs are configured for round-robin priority and the various triggers all arrive in the same cycle, the conversion order is SOC0 to SOC5 in increasing order; this is then followed by the oversampled conversions on SOC0-SOC2.

18.3.3 ADC Acquisition (Sample and Hold) Window

External signal sources vary in their ability to drive an analog signal quickly and effectively. To achieve rated resolution, the signal source needs to charge the sampling capacitor in the ADC core to within 0.5 LSBs of the signal voltage. The acquisition window is the amount of time the sampling capacitor is allowed to charge and is configurable for SOCx by the ADCSOCxCTL.ACQPS register.

ACQPS is a 9-bit register that can be set to a value between 0 and 511, resulting in an acquisition window duration of:

$$\text{Acquisition window} = (\text{ACQPS} + 1) \cdot (\text{System Clock (SYSCLK) cycle time})$$

- The acquisition window duration is based on the System Clock (SYSCLK), not the ADC clock (ADCCLK).
- The selected acquisition window duration must be at least as long as one ADCCLK cycle.
- The data sheet specifies a minimum acquisition window duration (in nanoseconds). The user is responsible for selecting an acquisition window duration that meets this requirement.

18.3.4 ADC Input Models

For single-ended operation, the ADC input characteristics for values in the single-ended input model (see [Figure 18-11](#)) can be found in the device data sheet.

Figure 18-11. Single-Ended Input Model

For differential operation, the ADC input characteristics for values in the differential input model (see [Figure 18-12](#)) can be found in the device data sheet.

These input models must be used along with actual signal source impedance to determine the acquisition window duration. See [Section 18.14.2](#) for more information.

Figure 18-12. Differential Input Model

18.3.5 Channel Selection

Each SOC can be configured to convert any of the ADC channels. This behavior is selected for SOCx by the ADCSOCxCTL.CHSEL register. Depending on the signal mode, the selection is different. For single-ended signal mode, the value in CHSEL selects a single pin as the input. For differential signal mode, the value in CHSEL selects an even-odd pin pair to be the positive and negative inputs. This is summarized in [Table 18-7](#).

18.3.5.1 External Channel Selection

The ADCSOCxCTRL.EXTCHSEL field for each SOC can be used to automatically control an external mux with digital output pins ADCxEXTMUX[3:0]. This functionality enables the application to add additional ADC channels using an external mux, with minimal software overhead. The ADCxEXTMUX[3:0] outputs can be mapped to GPIO pins by configuring the GPIO output crossbar accordingly. The EXTCHSEL field supports up to 4-bit muxes, but fewer mux selection output pins can be configured if desired.

To select a specific channel on the external mux, configure ADCSOCxCTRL.CHSEL to select the ADC pin that is connected to the mux output, and configure ADCSOCxCTRL.EXTCHSEL to select the desired mux input channel. There are a variety of potential mux topologies possible. A basic example can be a single external mux connected to a single ADC input channel. This setup is illustrated in Figure 18-13.

- To select ADCxIN0.4, the user configures the SOC with CHSEL = 0 and EXTCHSEL = 4.
- To select ADCxIN3, the user configures the SOC with CHSEL = 3. The value of EXTCHSEL does not affect the conversion.

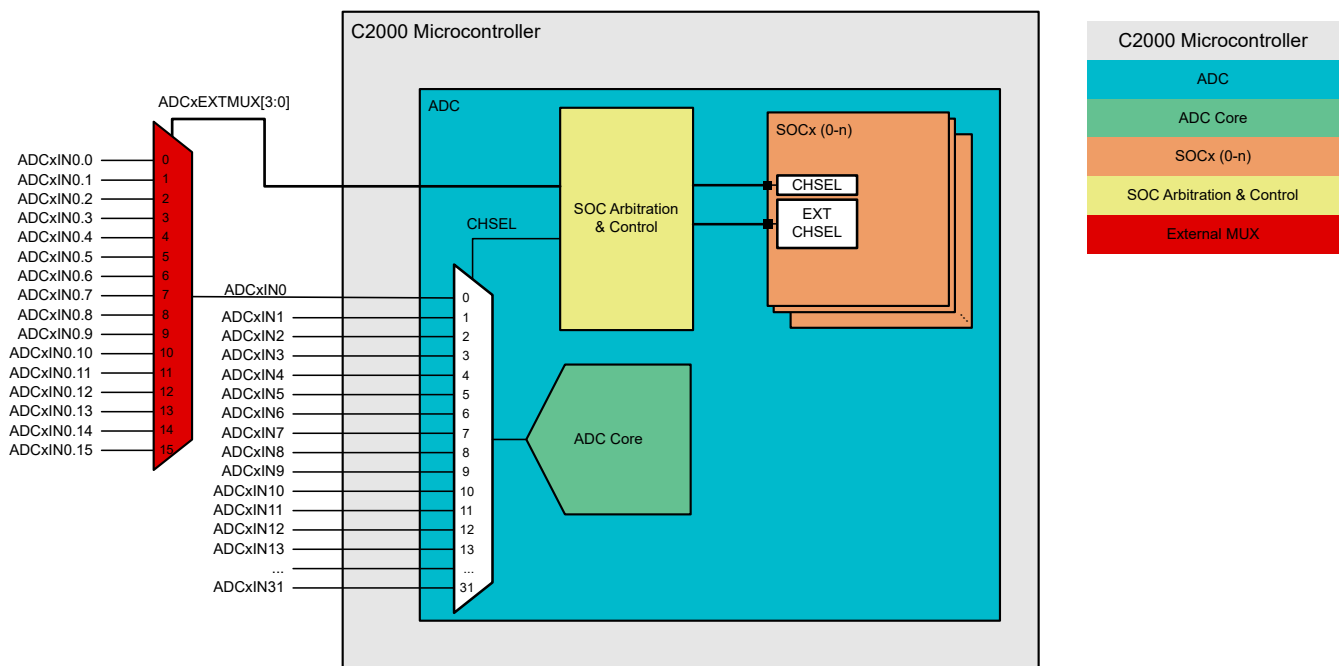

Figure 18-13. ADC with External Input Mux

Another example can be to use multiple external muxes connected to different ADC inputs. This setup is illustrated in Figure 18-14.

- To select ADCxIN0.4, the user configures the SOC with CHSEL = 0 and EXTCHSEL = 4.
- To select ADCxIN3.2, the user configures the SOC with CHSEL = 3 and EXTCHSEL = 2.
- To select ADCxIN5, the user configures the SOC with CHSEL = 5. The value of EXTCHSEL does not affect the conversion.

This scheme saves one digital mux pin, at the expense of using two small muxes instead of a single large mux, and a second ADC input pin.

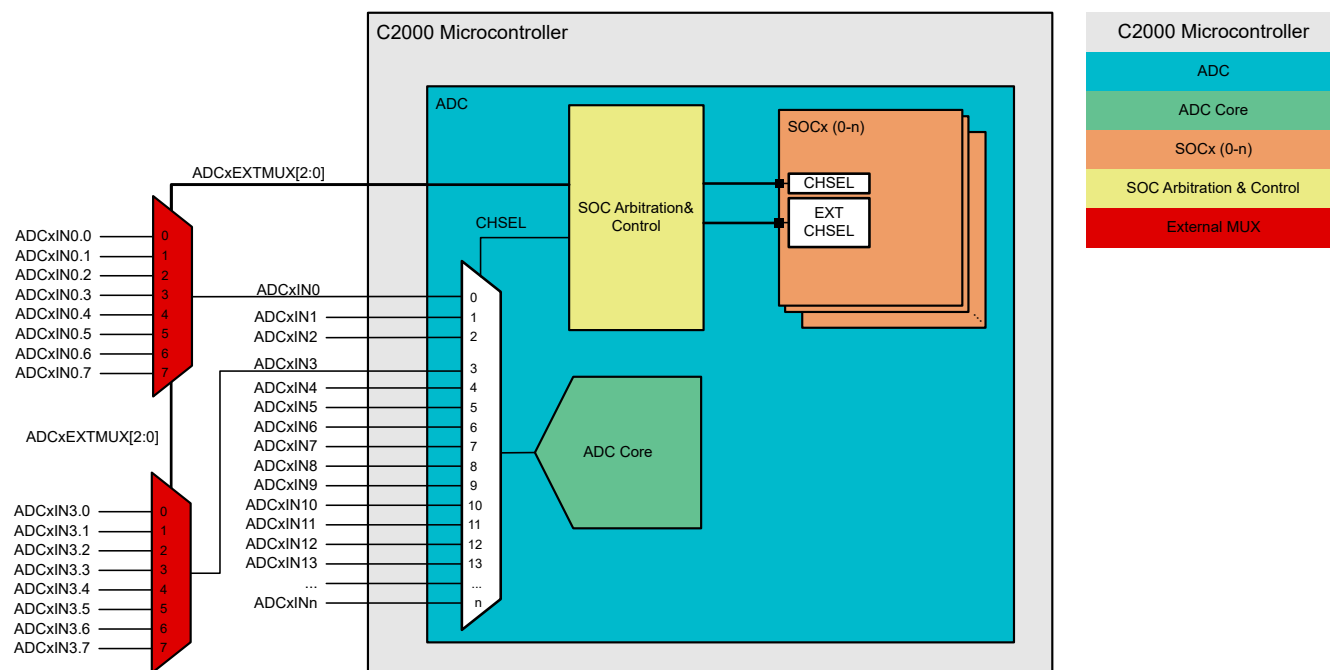

Figure 18-14. ADC with Multiple External Input Muxes and Shared Selection

When using an external channel mux, make sure to comprehend the mux selection and switching delay in the sample/hold time requirement for the SOC. This requirement includes the propagation delay for the output X-BAR (if this is used to configure the mux selection pin), any mux switching delays, and the total resistance and capacitance added to the ADC input network by the external mux device. For more information on calculating the acquisition window size, see [Section 18.14.2](#).

Note

While the external channel selection can technically be used to select up to 16 times the number of total ADC pins (by placing a 16-input mux on each external ADC channel), the system incurs significant added overhead if the total number of channels (internal and external) exceeds 16 – the total number of available SOCx available on the ADC instance. A sensible option is to map the ADCxEXTMUX outputs to ADC pins (AGPIOs). For instance, using one ADC input to sample an external mux output, and 4 inputs for external channel selection, the application effectively gains an additional 11 ADC inputs (from 5 to 16 pins), without using up any additional device pins.

Externally multiplexed ADC channels lose the ability to practically use the analog comparators in the comparator subsystem. However, the digital limit compares in the post-processing block can still be used to generate interrupts and/or PWM trips. For more information, see [Section 18.8](#).

18.3.5.1.1 External Channel Selection Timing

The ADCxEXTMUX output follows two possible timing schemes, depending on the setting of the EXTMUXPRESELECTEN bit in the ADCCTL1 register:

- When EXTMUXPRESELECTEN is set to 0, the ADCxEXTMUX output changes at the beginning of the associated SOC's sample and hold period. The applied external mux setting is maintained until the start of the next SOC sample-and-hold period. This is the default configuration at reset. Examples of SOC timings in this mode are shown in [Figure 18-15](#) and [Figure 18-17](#). When external mux preselect is disabled, make sure to configure the SOC acquisition window duration to account for both external mux settling time and internal channel settling time.
- When EXTMUXPRESELECTEN is set to 1, the ADCxEXTMUX output changes at least one SYSCLK cycle after the end of the sample and hold period. At this point, the ADC sets the external mux selection based on the next highest priority SOC that is pending. If no SOC is pending, then the mux selection is based on the next highest priority SOC, based on the current SOC priority scheme (see [Section 18.5](#) for more information on SOC priority schemes). Examples of SOC timings in this mode are shown in [Figure 18-16](#) and [Figure 18-18](#). Enabling preselect mode enables the application to avoid increasing the acquisition window duration due to external mux switching and settling delays.

Note

When EXTMUXPRESELECTEN is enabled, setting SOC0 as high priority without actually triggering SOC0 conversions is a good way to define an idle value for ADCxEXTMUX. SOC0 always has the highest priority when no SOCs are pending, so the value of ADCSOC0CTL.EXTCHSEL is always pushed onto the mux select pins by default.

Figure 18-15. ADC External Channel Select Timing Example

In [Figure 18-15](#), the ADC is configured as follows:

- SOC1 and SOC2 are triggered from ePWM1A;
- No high priority SOCs are defined.

The ADC performs the SOC operation sequence in the following order:

1. The initial ePWM1A trigger arrives, setting the SOC1 and SOC2 to pending. SOC1 gains priority, and the sample-and-hold period for SOC1 begins. The ADC pushes the value of ADCSOC1CTL.EXTCHSEL onto the ADCxEXTMUX pins at the same time when the SOC1 sample-and-hold begins.
2. At the end of the sample-and-hold for SOC1, the conversion begins. ADCxEXTMUX remains unchanged until the start of the next SOC sample-and-hold period.

3. In this example case, there are no asynchronous high priority triggers defined, so SOC2 sample-and-hold starts as soon as SOC1 conversion ends. The ADC pushes ADCSOC2CTL.EXTCHSEL onto the ADCxEXTMUX pins.
4. At the end of the sample-and-hold for SOC2, there are no more pending SOC's. SOC2 begins conversion, and ADCxEXTMUX is unchanged.
5. The SOC2 conversion ends. There are no pending SOC's or triggers, so ADCxEXTMUX remains unchanged.

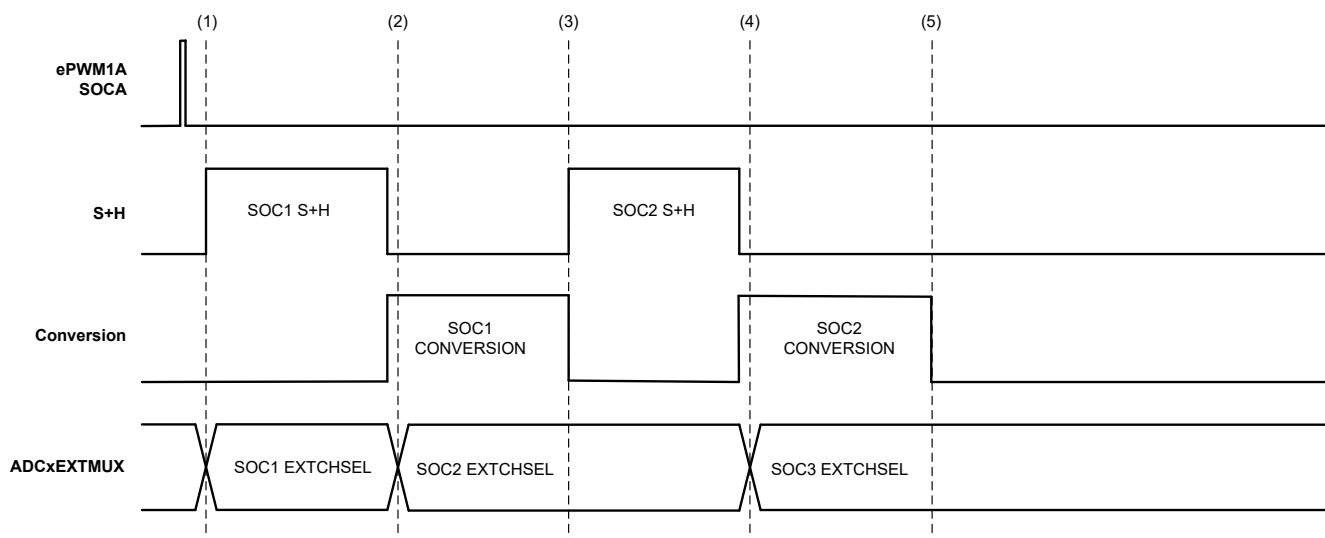

Figure 18-16. ADC External Channel Timing Example in Preselect Mode

In [Figure 18-16](#), the ADC is configured as follows:

- SOC1 and SOC2 are triggered from ePWM1A;
- No high priority SOC's are defined.

The ADC performs the SOC operation sequence in the following order:

1. The initial ePWM1A trigger arrives, setting the SOC1 and SOC2 to pending. SOC1 gains priority, and the sample-and-hold period for SOC1 begins. The ADC pushes the value of ADCSOC1CTL.EXTCHSEL onto the ADCxEXTMUX pins at the same time when the SOC1 sample-and-hold begins.
2. At the end of the sample-and-hold for SOC1, the highest priority SOC that is pending is SOC2, so the ADC pushes the value of ADCSOC2CTL.EXTCHSEL onto the ADCxEXTMUX pins.
3. In this example case, there are no asynchronous high priority triggers defined, so SOC2 sample-and-hold starts as soon as SOC1 conversion ends. The ADC pushes ADCSOC2CTL.EXTCHSEL onto the ADCxEXTMUX pins again, but this is already the current value so there is no change.
4. At the end of the sample-and-hold for SOC2, there are no more pending SOC's. SOC3 has the next highest priority by way of the round-robin pointer, so the ADC pushes the value of ADCSOC3CTL.EXTCHSEL onto ADCxEXTMUX. In this case, the application can set ADCSOC3CTL.EXTCHSEL = ADCSOC1CTL.EXTCHSEL. Although SOC3 is not actually used, this makes sure that the external mux channel is already preselected when the next ePWM1 SOC arrives.
5. The SOC2 conversion ends. There are no pending SOC's or triggers, so ADCxEXTMUX remains unchanged.

Figure 18-17. ADC External Channel Select Timing Example with Asynchronous Trigger

In [Figure 18-17](#), the ADC is configured as follows:

- SOC1 and SOC2 are triggered from ePWM1A;
- SOC0 is triggered from CPUTIMER1, and has a high priority.

With this configuration, the ADC performs the SOC operation sequence in the following order:

1. The initial ePWM1A trigger arrives, setting the SOC1 and SOC2 flags to pending. SOC1 gains priority, and the SOC1 sample-and-hold period begins. The ADC pushes the value of ADCSOC1CTL.EXTCHSEL onto the ADCxEXTMUX pins at the same time when the SOC1 sample-and-hold begins.
2. At the end of the sample-and-hold for SOC1, the SOC1 conversion begins. ADCxEXTMUX remains unchanged until the start of the next SOC sample-and-hold period.
3. CPUTIMER1 issues a trigger asynchronously, setting the SOC0 flag to pending.
4. Since SOC0 has high priority, SOC0 converts next instead of SOC2. The ADC pushes ADCSOC0CTL.EXTCHSEL onto ADCxEXTMUX when the sample-and-hold period for SOC0 starts.
5. At the end of the sample-and-hold period for SOC0, the conversion for SOC0 begins. ADCxEXTMUX remains unchanged until the start of the next SOC sample-and-hold period.
6. At the end of the conversion for SOC0, SOC2 is the next pending SOC. SOC2's sample-and-hold period begins, and ADCSOC2CTL.EXTCHSEL is pushed onto the ADCxEXTMUX pins.
7. The SOC2 conversion begins, and there are no pending SOC's left. ADCxEXTMUX remains unchanged until a new SOC trigger arrives.

Figure 18-18. ADC External Channel Timing Example in Preselect Mode with Asynchronous Trigger

In [Figure 18-18](#), the ADC is configured as follows:

- SOC1 and SOC2 are triggered from ePWM1A;
- SOC0 is triggered from CPUTIMER1, and has a high priority.

With this configuration, the ADC performs the SOC operation sequence in the following order:

1. The initial ePWM1A trigger arrives, setting the SOC1 and SOC2 flags to pending. SOC1 gains priority, and the SOC1 sample-and-hold period begins. The ADC pushes the value of ADCSOC1CTL.EXTCHSEL onto the ADCxEXTMUX pins at the same time when the SOC1 sample-and-hold begins.
2. At the end of the sample-and-hold for SOC1, the highest priority SOC that is pending is SOC2, so the ADC pushes the value of ADCSOC2CTL.EXTCHSEL onto the ADCxEXTMUX pins.
3. CPUTIMER1 issues a trigger asynchronously, setting the SOC0 flag to pending.
4. Since SOC0 has high priority, SOC0 converts next instead of SOC2. The ADC overwrites the previous speculative external mux selection (ADCSOC2CTL.EXTCHSEL) with ADCSOC0.EXTCHSEL when the sample-and-hold period for SOC0 starts. In situations like this where asynchronous triggers are possible, make sure to set the acquisition window size of the priority SOC large enough to allow for both external mux settling and internal channel settling.
5. At the end of the sample-and-hold period for SOC0, the highest priority SOC that is pending is SOC2, so the ADC pushes EXTCHSEL value for SOC2 onto the ADCxEXTMUX pins. SOC0 begins converting.
6. At the end of the SOC0 conversion, SOC2 is the next highest-priority pending SOC, and so SOC2's sample-and-hold period begins. The ADC again pushes ADCSOC2CTL.EXTCHSEL onto the ADCxEXTMUX pins, but since this is already the current value, the mux pins are unchanged.
7. At the end of the sample-and-hold period for SOC2, there are no SOC's pending. SOC0 has the next highest priority, since the ADC has been configured to give SOC0 high priority. The ADC pushes ADCSOC0CTL.EXTCHSEL onto the ADCxEXTMUX pins.

18.4 SOC Configuration Examples

The following sections provide some specific examples of how to configure the SOCs to produce some conversions.

18.4.1 Single Conversion from ePWM Trigger

To configure ADCA to perform a single conversion on channel ADCINA1 when the ePWM timer reaches the period match, a few things are necessary. First, ePWM3 must be configured to generate an SOCA or SOCB signal (in this statement, SOC refers to a signal in the ePWM module). See the *Enhanced Pulse Width Modulator Module (ePWM)* chapter on how to do this. Assume that SOCB was chosen.

SOC5 is chosen arbitrarily. Any of the 16 SOCs can be used.

Assuming a 100 ns sample window is desired with a SYSCLK frequency of 200 MHz, then the acquisition window duration must be $100 \text{ ns} / 5 \text{ ns} = 20$ SYSCLK cycles. The ACQPS field must therefore be set to $20 - 1 = 19$.

```
AdcaRegs.ADCSOC5CTL.bit.CHSEL = 1;    //SOC5 converts ADCINA1
AdcaRegs.ADCSOC5CTL.bit.ACQPS = 19;   //SOC5 uses a sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC5CTL.bit.TRIGSEL = 10; //SOC5 begins conversion on ePWM3 SOCB
```

As configured, when ePWM3 matches the period and generates the SOCB signal, the ADC begins sampling channel ADCINA1 (SOC5) immediately if the ADC is idle. If the ADC is busy, ADCINA1 begins sampling when SOC5 gains priority (see [Section 18.5](#)). The ADC control logic samples ADCINA1 with the specified acquisition window width of 100 ns. Immediately after the acquisition is complete, the ADC begins converting the sampled voltage to a digital value. When the ADC conversion is complete, the results are available in the ADCRESULT5 register (see [Section 18.13](#) for exact sample, conversion, and result latch timings).

18.4.2 Multiple Conversions from CPU Timer Trigger

This example shows how to sample multiple signals with different acquisition window requirements. CPU1 Timer 2 is used to generate the trigger. To see how to configure the CPU timer, see the *System Control and Interrupts* chapter.

A good first step when designing a sampling scheme with many signals is to list out the signals and their required acquisition window. From this, calculate the necessary number of SYSCLK cycles for each signal, then the ACQPS register setting. This is shown in [Table 18-8](#), where a SYCLK of 200 MHz is assumed (5 ns cycle time).

Table 18-8. Example Requirements for Multiple Signal Sampling

Signal Name	Acquisition Window Requirement	Acquisition Window (SYSCLK Cycles)	ACQPS Register Value
Signal 1	>120 ns	120 ns/5 ns = 24	24 – 1 = 23
Signal 2	>444 ns	444 ns/5 ns = 89 (round up)	89 – 1 = 88
Signal 3	>110 ns	110 ns/5 ns = 22	22 – 1 = 21
Signal 4	>291 ns	291 ns/5 ns = 59 (round up)	59 – 1 = 58

Next decide which ADC pins to connect to each signal. This is highly dependent on the application board layout. Once the pins are selected, determining the value of CHSEL is straightforward (see [Table 18-9](#)).

Table 18-9. Example Connections for Multiple Signal Sampling

Signal Name	ADC Pin	CHSEL Register Value
Signal 1	ADCINA5	5
Signal 2	ADCINA0	0
Signal 3	ADCINA3	3
Signal 4	ADCINA2	2

With the information tabulated, generate the SOC configurations:

```

AdcaRegs.ADCSOC0CTL.bit.CHSEL = 5;           //SOC0 converts ADCINA5
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 23;         //SOC0 uses a sample duration of 24 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 3;        //SOC0 begins conversion on CPU1 Timer 2
AdcaRegs.ADCSOC1CTL.bit.CHSEL = 0;         //SOC1 converts ADCINA0
AdcaRegs.ADCSOC1CTL.bit.ACQPS = 88;        //SOC1 uses a sample duration of 89 SYSCLK cycles
AdcaRegs.ADCSOC1CTL.bit.TRIGSEL = 3;        //SOC1 begins conversion on CPU1 Timer 2
AdcaRegs.ADCSOC2CTL.bit.CHSEL = 3;         //SOC2 converts ADCINA3
AdcaRegs.ADCSOC2CTL.bit.ACQPS = 21;        //SOC2 uses a sample duration of 22 SYSCLK cycles
AdcaRegs.ADCSOC2CTL.bit.TRIGSEL = 3;        //SOC2 begins conversion on CPU1 Timer 2
AdcaRegs.ADCSOC3CTL.bit.CHSEL = 2;         //SOC3 converts ADCINA2
AdcaRegs.ADCSOC3CTL.bit.ACQPS = 58;        //SOC3 uses a sample duration of 59 SYSCLK cycles
AdcaRegs.ADCSOC3CTL.bit.TRIGSEL = 3;        //SOC3 begins conversion on CPU1 Timer 2
    
```

As configured, when CPU1 Timer 2 generates an event, SOC0, SOC1, SOC2, and SOC3 eventually is sampled and converted, in that order. The conversion results for ACINA5 (Signal 1) are in ADCRESULT0. Similarly, The results for ADCINA0 (Signal 2), ADCINA3 (Signal 3), and ADCINA2 (Signal 4) are in ADCRESULT1, ADCRESULT2, and ADCRESULT3, respectively.

Note

It is possible, but unlikely, that the ADC can begin converting SOC1, SOC2, or SOC3 before SOC0 depending on the position of the round-robin pointer when the CPU Timer trigger is received. See [Section 18.5](#) to understand how the next SOC to be converted is chosen.

18.4.3 Software Triggering of SOCs

At any point, whether or not the SOCs have been configured to accept a specific trigger, a software trigger can set the SOCs to be converted. This is accomplished by writing bits in the ADCSOCFRC1 register.

Software triggering of the previous example without waiting for the CPU1 Timer 2 to generate the trigger can be accomplished by the statement:

```
AdcaRegs.ADCSOCFRC1.all = 0x000F;           //set SOC flags for SOC0 to SOC3
```

18.5 ADC Conversion Priority

When multiple SOC flags are set at the same time, one of two forms of priority determines the converted order. The default priority method is round-robin. In this scheme, no SOC has an inherent higher priority than another. Priority depends on the round-robin pointer (RRPOINTER). The RRPOINTER reflected in the ADCSOCPRIORITYCTL register points to the last SOC converted. The highest priority SOC is given to the next value greater than the RRPOINTER value, wrapping around back to SOC0 after SOC15. At reset the value is 16 since 0 indicates a conversion has already occurred. When RRPOINTER equals 16 the highest priority is given to SOC0. The RRPOINTER is reset when the ADC module is reset or when the reset value is written to the SOCPRIORITY register. The ADC module is reset by writing and clearing the SOFTPRES bit corresponding to the ADC instance.

An example of the round-robin priority method is given in [Figure 18-19](#).

The SOCPRIORITY field in the ADCSOCPRIORITYCTL register can be used to assign high priority from a single to all of the SOCs. When configured as high priority, an SOC interrupts the round-robin wheel after any current conversion completes and inserts in as the next conversion. After the conversion completes, the round-robin wheel continues where the conversion was interrupted. If two high priority SOCs are triggered at the same time, the SOC with the lower number takes precedence.

High priority mode is assigned first to SOC0, then in increasing numerical order. The value written in the SOCPRIORITY field defines the first SOC that is not high priority. In other words, if a value of 4 is written into SOCPRIORITY, then SOC0, SOC1, SOC2, and SOC3 are defined as high priority, with SOC0 the highest.

An example using high priority SOC's is given in [Figure 18-20](#).

- A** After reset, SOC0 is highest priority SOC ; SOC7 receives trigger ; SOC7 configured channel is converted immediately .
- B** RRPOINTER changes to point to SOC 7 ; SOC8 is now highest priority SOC .
- C** SOC2 & SOC12 triggers rcvd . simultaneously ; SOC12 is first on round robin wheel ; SOC12 configured channel is converted while SOC2 stays pending .
- D** RRPOINTER changes to point to SOC 12 ; SOC2 configured channel is now converted .
- E** RRPOINTER changes to point to SOC 2 ; SOC3 is now highest priority SOC .

18.6 Burst Mode

Burst mode allows a single trigger to walk through the round-robin SOCs one or more at a time. Setting the bit BURSTEN in the ADCBURSTCTL register configures the ADC wrapper for burst mode. This causes the TRIGSEL field to be ignored, but only for SOCs that are configured for round-robin operation (not high priority). Instead of the TRIGSEL field, all round-robin SOCs are triggered based on the BURSTTRIG field in the ADCBURSTCTL register. Upon reception of the burst trigger, the ADC wrapper does not set all round-robin SOCs to be converted, but only (ADCBURSTCTL.BURSTSIZE + 1) SOCs. The first SOC to be set is the SOC with the highest priority based on the round-robin pointer, and subsequent SOCs are set until BURSTSIZE SOCs have been set.

Note

When configuring the ADC for burst mode, the user is responsible for ensuring that each burst of conversions is allowed to complete before the next burst trigger is received. The value of (ADCBURSTCTL.BURSTSIZE + 1) must be less than or equal to the number of SOCs configured for round-robin priority. If the previous burst is not complete at the time when a new burst trigger arrives, for each SOC that was already pending and receives a new trigger, the corresponding overflow flag in ADCSOCOVF1 is set.

For example, if SOCPRIORITY = 12, that is, SOC12, SOC13, SOC14, and SOC15 are in round-robin, ADCBURSTCTL.BURSTSIZE setting must be ≤ 3 for burst mode to operate correctly.

18.6.1 Burst Mode Example

Burst mode can be used to sample a different set of signals on every other trigger. In the following example, ADCIN7 and ADCIN5 are converted on the first trigger from CPU1 Timer 2 and every other trigger thereafter. ADCIN2 and ACIN3 are converted on the second trigger from CPU1 Timer 2 and every other trigger thereafter. All signals are converted with 20 SYSCLK cycle wide acquisition windows, but different durations can be configured for each SOC as desired.

```

AdcaRegs.BURSTCTL.BURSTEN = 1;           //Enable ADC burst mode
AdcaRegs.BURSTCTL.BURSTTRIG = 3;         //CPU1 Timer 2 will trigger burst of conversions
AdcaRegs.BURSTCTL.BURSTSIZE = 1;        //conversion bursts are 1 + 1 = 2 conversions long
AdcaRegs.SOCPRICL.bit.SOCPRIORITY = 12; //SOC0 to SOC11 are high priority
AdcaRegs.ADCSOC12CTL.bit.CHSEL = 7;      //SOC12 will convert ADCINA7
AdcaRegs.ADCSOC12CTL.bit.ACQPS = 19;     //SOC12 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC13CTL.bit.CHSEL = 5;      //SOC13 will convert ADCINA5
AdcaRegs.ADCSOC13CTL.bit.ACQPS = 19;     //SOC13 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC14CTL.bit.CHSEL = 2;      //SOC14 will convert ADCINA2
AdcaRegs.ADCSOC14CTL.bit.ACQPS = 19;     //SOC14 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC15CTL.bit.CHSEL = 3;      //SOC15 will convert ADCINA3
AdcaRegs.ADCSOC15CTL.bit.ACQPS = 19;     //SOC15 will use sample duration of 20 SYSCLK cycles

```

When the first CPU1 Timer 2 trigger is received, SOC12 and SOC13 are converted immediately if the ADC is idle. If the ADC is busy, SOC12 and SOC13 are converted once their SOCs gain priority. The results for SOC12 and SOC13 are in ADCRESULT12 and ADCRESULT13, respectively. After SOC13 completes, the round-robin pointer gives the highest priority to SOC14. Because of this, when the next CPU1 Timer 2 trigger is received, SOC14 and SOC15 is set as pending and eventually converted. The results for SOC14 and SOC15 are in ADCRESULT14 and ADCRESULT15, respectively. Subsequent triggers continue to toggle between converting SOC12 and SOC13, and converting SOC14 and SOC15.

While the above example toggles between two sets of conversions, three or more different sets of conversions can be achieved using a similar approach.

18.6.2 Burst Mode Priority Example

An example of priority resolution using burst mode and high-priority SOC's is presented in [Figure 18-21](#).

Example when $SOC_PRIORITY = 4$, $BURSTEN = 1$, and $BURSTSIZE = 1$

- A** After reset, SOC4 is 1st on round robin wheel; BURSTTRIG trigger is received; SOC4 & SOC5 are set and configured channels converted immediately.
- B** RRPOINTER changes to point to SOC5; SOC6 is now 1st on round robin wheel.
- C** BURSTTRIG & SOC1 triggers rcvd. simultaneously; SOC1, SOC6, and SOC7 are set; SOC1 interrupts round robin wheel and SOC1 configured channel is converted while SOC6 and SOC7 stay pending.
- D** RRPOINTER stays pointing to 5; SOC6/SOC7 configured channels are now converted.
- E** RRPOINTER changes to point to SOC7; SOC8 is now 1st on round robin wheel, waiting for BURSTTRIG.

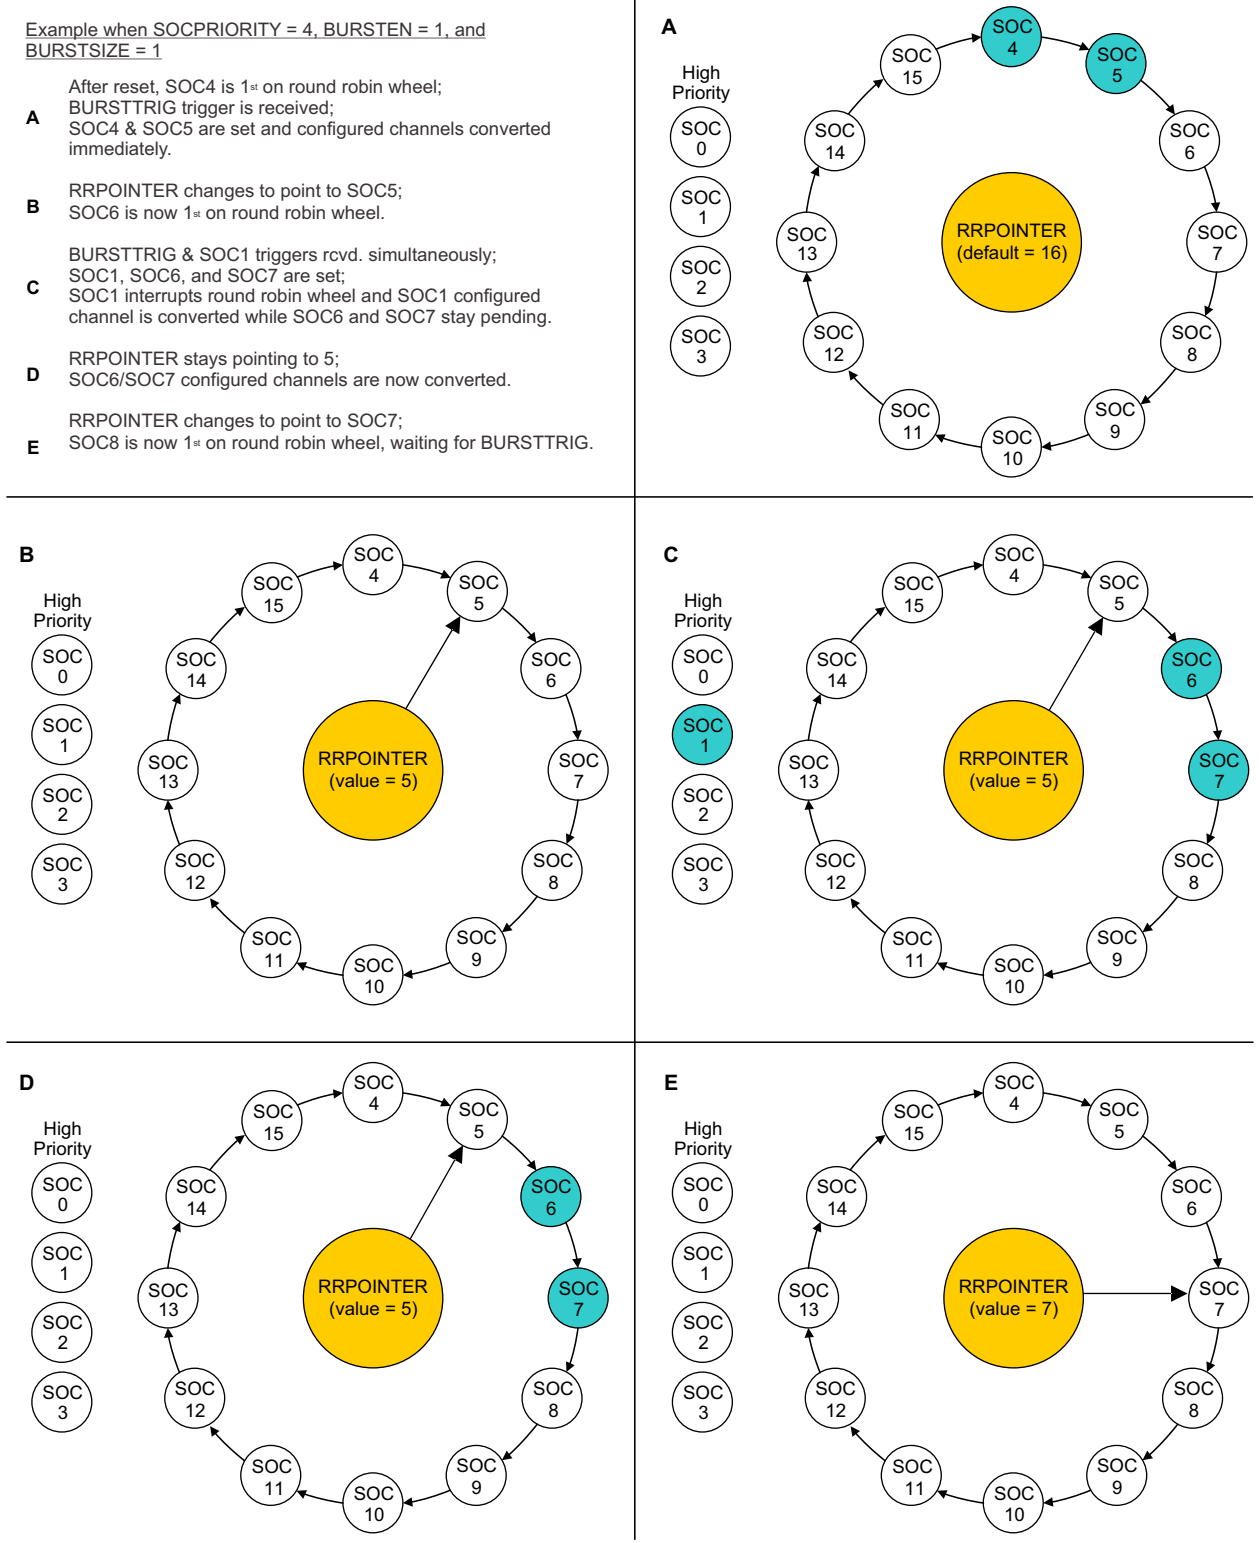

Figure 18-21. Burst Priority Example

18.7 EOC and Interrupt Operation

Each SOC has a corresponding end-of-conversion (EOC) signal. This EOC signal can be used to trigger an ADC interrupt. The ADC can be configured to generate the EOC pulse at either the end of the acquisition window or at the end of the voltage conversion. This is configured using the bit INTPULSEPOS in the ADCCTL1 register. See [Section 18.13](#) for exact EOC pulse location.

Each ADC module has 4 configurable ADC interrupts. These interrupts can be triggered by any of the 16 EOC signals. The flag bit for each ADCINT can be read directly to determine if the associated SOC is complete or the interrupt can be passed on to the PIE. Each ADCINT flag also has a corresponding ADCINTxRESULT flag. The ADCINTxRESULT flag is only set when results corresponding to the EOC are latched. This is useful for interrupt service routines or CLA tasks with early interrupt timing configured, allowing the application code to perform some pre-processing or setup work, and then acting on the ADC conversion result as soon as the result is latched.

It is also possible to generate an ADC interrupt based on a PPB oversampling logic event, such as when the sample count matches the configured limit. There are four oversampling interrupt (OSINT) flags available in each module for this purpose. Any of the ADCINT flags can be configured for an OSINT by configuring the INTxSEL field the corresponding ADCINTSELxNy register.

Note

The ADCCTL1.ADCBSY bit being clear does not indicate that all conversions in a set of SOCs have completed, only that the ADC is ready to process the next conversion. To determine if a sequence of SOCs is complete, link an ADCINT flag to the last SOC in the sequence and monitor that ADCINT flag.

Figure 18-22 shows a block diagram of the ADC interrupt structure.

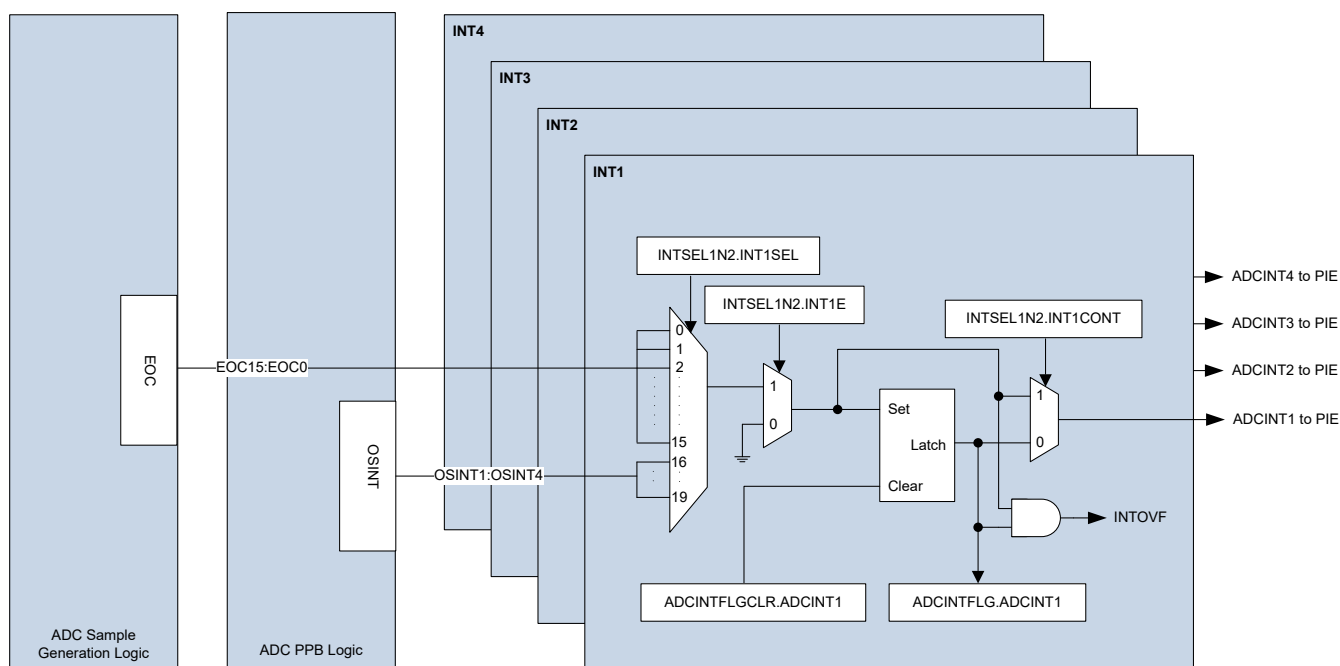

Figure 18-22. ADC EOC Interrupts

18.7.1 Interrupt Overflow

If the EOC signal sets a flag in the ADCINTFLG register, but that flag is already set, an interrupt overflow occurs. By default, overflow interrupts are not passed on to the PIE module. When an overflow occurs on a given flag in the ADCINTFLG register, the corresponding flag in the ADCINOVF register is set. This overflow flag is only used to detect that an overflow has occurred; the flag does not block further interrupts from propagating to the PIE module.

When an ADC interrupt overflow occurs, the application must check the appropriate ADCINTOVF flag inside the ISR or in the background loop and take appropriate action when an overflow is detected. The following code snippets demonstrate how to check the ADCINOVF flag inside the ISR after attempting to clear the ADCINT flag.

```
// Clear the interrupt flag
AdcaRegs.ADCINTFLGCLR.bit.ADCINT1 = 1;    //clear INT1 flag for ADC-A

// check if an overflow has occurred
if(1 == AdcaRegs.ADCINTOVF.bit.ADCINT1)    //ADCINT overflow occurred
{
    AdcaRegs.ADCINTOVFCLR.bit.ADCINT1 = 1  //Clear overflow flag
    AdcaRegs.ADCINTFLGCLR.bit.ADCINT1 = 1  //Re-clear ADCINT flag
}
```

```
//
// Clear the interrupt flag
//
ADC_clearInterruptStatus(ADCA_BASE, ADC_INT_NUMBER1);

//
// check if an overflow has occurred
//
if(true == ADC_getInterruptOverflowStatus(ADCA_BASE, ADC_INT_NUMBER1))
{
    ADC_clearInterruptOverflowStatus(ADCA_BASE, ADC_INT_NUMBER1);
    ADC_clearInterruptStatus(ADCA_BASE, ADC_INT_NUMBER1);
}
```

18.7.2 Continue to Interrupt Mode

The INTxCONT bits in the ADCINTSEL1N2 and ADCINTSEL3N4 registers configure how interrupts are handled when an ADCINTFLG has not yet been cleared from a prior interrupt. This mode is disabled by default and additional overlapping interrupts are not issued to the PIE. By activating this mode, ADC interrupts always reach the PIE. If interrupts occur while ADCINTFLG is set, the ADCINTOVF register remains set regardless of the configuration of the INTxCONT bits.

18.7.3 Early Interrupt Configuration Mode

Enabling early interrupt mode can allow the application to enter the ADC interrupt service routine before the ADC results are ready. This allows the application to do any necessary pre-work so that the application can act on the ADC results immediately when the ADC results become available. If the timing of the early interrupt is too early, then the application needs to waste time until the updated ADC results become available. To prevent this situation, the time the ADC interrupt is entered in early interrupt mode is configurable by way of the DELAY field in the ADCINTCYCLE register.

- To use the configurable interrupt time, the ADC must be in early interrupt mode. To achieve this, clear the bit INTPULSEPOS to 0 in ADCCTL1.
- The DELAY value in the ADCINTCYCLE register sets the number of additional SYSCLK cycles after the falling edge of the SOC pulse before the ADCINT flag is set.
- If the value of DELAY goes beyond EOC, the ADC interrupt is generated along with EOC.
- Writing values to DELAY when INTPULSEPOS is set to 1 does not have any effect on the interrupt generation.

To determine exactly when the ADC result has been latched into the ADCRESULT register, poll the ADCINTxRESULT flag bit in the ADCINTFLG register.

18.8 Post-Processing Blocks

Each ADC module contains four post-processing blocks (PPB). These blocks can be associated with any of the 16 RESULT registers using the ADCPPBxCONFIG.CONFIG bit field. The post-processing blocks have the ability to:

- Remove an offset associated with the ADCIN channel
- Subtract out a reference value
- Aggregate successive samples using sum, max, and min calculations
- Automatically calculate average of oversampled conversions without CPU overhead, when sample count is a power of 2
- Transform the conversion result into an absolute value
- Flag a zero-crossing point, with the option to trip a PWM and generate an interrupt
- Flag a high or low compare limit, with the option to trip a PWM and generate an interrupt
- Record the delay between the associated SOC trigger and when sampling actually begins

Figure 18-23 presents the structure of each PPB. Subsequent sections explain the use of each submodule.

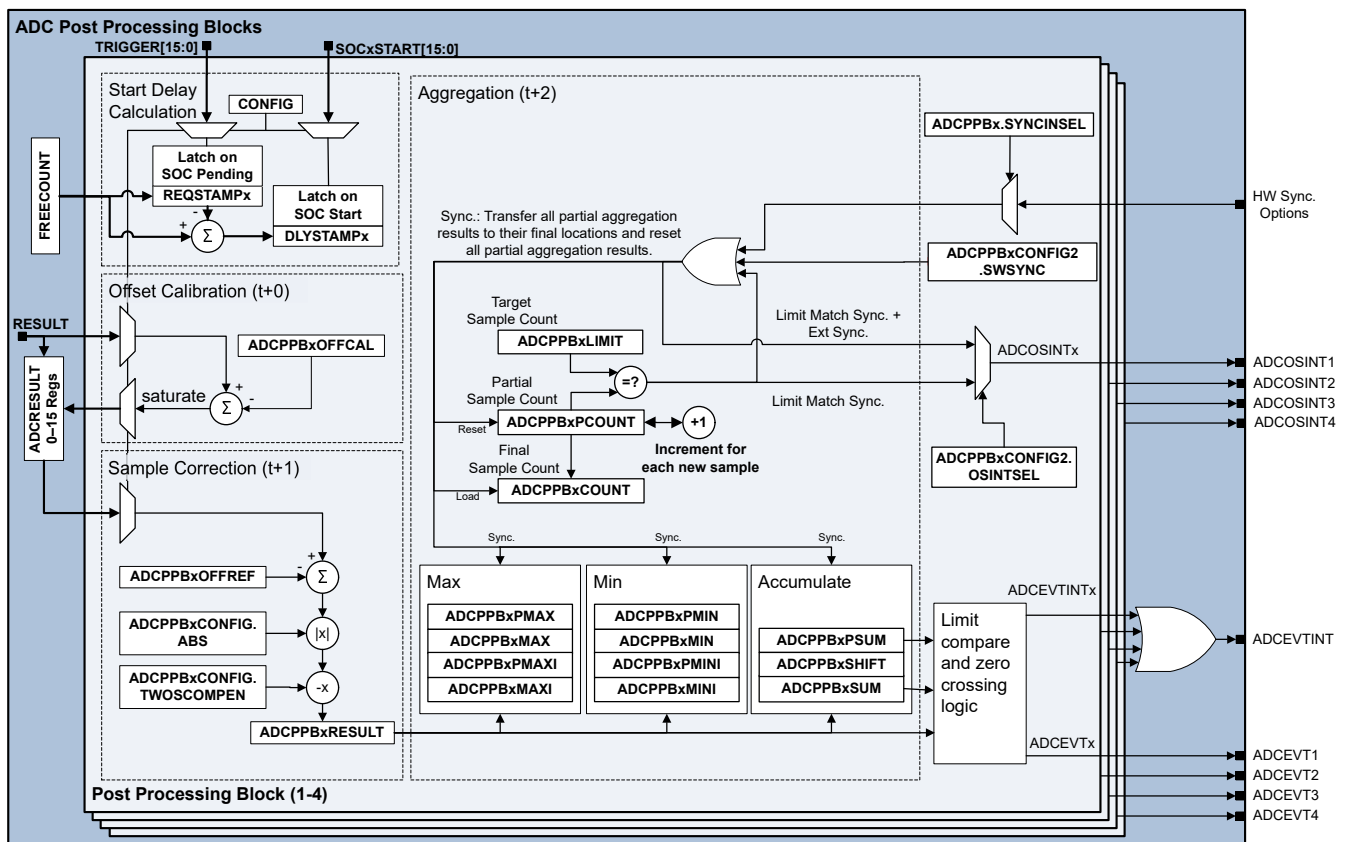

Figure 18-23. ADC PPB Block Diagram

18.8.1 PPB Offset Correction

In many applications, external sensors and signal sources produce an offset. A global trimming of the ADC offset is not enough to compensate for these offsets, which vary from channel to channel. The post-processing block can remove these offsets with zero overhead, saving numerous cycles in tight control loops.

Offset correction is accomplished by first pointing the ADCPPBxCONFIG.CONFIG to the desired SOC, then writing an offset correction value to the ADCPPBxOFFCAL.OFFCAL register. The post-processing block automatically adds or subtracts the value in the OFFCAL register from the raw conversion result and stores the value in the ADCRESULT register. This addition/subtraction saturates at 0 on the low end and either 4095 or 65535 on the high end for 12-bit or 16-bit mode, respectively.

Note

- Writing a 0 to the OFFCAL register effectively disables the offset correction feature, passing the raw result unchanged to the ADCRESULT register.
 - It is possible to point multiple PPBs to the same SOC. In this case, the OFFCAL value that is actually applied comes from the PPB with the lowest number.
-

18.8.2 PPB Error Calculation

In many applications, an error from a set point or expected value must be computed from the digital output of an ADC conversion. In other cases, a bipolar signal is necessary or convenient for control calculations. The PPB can perform these functions automatically, reducing the sample to output latency and reducing software overhead.

Error calculation is accomplished by first pointing the ADCPPBxCONFIG.CONFIG to the desired SOC, then writing a value to the ADCPPBxOFFCAL.OFFREF register. The post-processing block automatically subtracts the value in the OFFREF register from the ADCRESULT value and stores the value in the ADCPPBxRESULT register. This subtraction produces a sign-extended 32-bit result. It is also possible to selectively invert the calculated value before storing in the ADCPPBxRESULT register by setting the TWOSCOMPEN bit in the ADCPPBxCONFIG register.

If desired, the absolute value of the ADC result after the offset reference calculation can be obtained by setting the ADCPPBxCONFIG.ABSEN bit. The absolute value is computed before evaluating the TWOSCOMPEN logic, so setting both TWOSCOMPEN and ABSEN always results in a negative value stored in ADCPPBxRESULT.

Note

- In 12-bit mode, do not write a value larger than 12 bits to the ADCPPBxOFFREF register.
 - Since the ADCPPBxRESULT register is unique for each PPB, it is possible to point multiple PPBs to the same SOC and get different results for each PPB.
 - Writing a 0 to the ADCPPBxOFFREF register effectively disables the error calculation feature, passing the ADCRESULT value unchanged to the ADCPPBxRESULT register.
-

18.8.3 PPB Limit Detection and Zero-Crossing Detection

Many applications perform a limit check against the ADC conversion results. The PPB can automatically perform a check against high and low limits, or whenever ADCPPBxRESULT changes sign. Based on these comparisons, the PPB can generate a trip to the PWM and an interrupt automatically, lowering the sample to

ePWM latency and reducing software overhead. This functionality also enables safety-conscious applications to trip the ePWM based on an out-of-range ADC conversion without any CPU intervention.

To enable this functionality, first point the ADCPPBxCONFIG.CONFIG to the desired SOC, then write a value to one or both of the registers ADCPPBxTRIPHI.LIMITHI and ADCPPBxTRIPLO.LIMITLO (zero-crossing detection does not require further configuration). Whenever these limits are exceeded, the PPBxTRIPHI bit or PPBxTRIPLO bit is set in the ADCEVTSTAT register. Note that the PPBxZERO bit in the ADCEVTSTAT register is gated by end-of-conversion (EOC), not by the sign change in the ADCPPBxRESULT register. The ADCEVTCLR register has corresponding bits to clear these event flags. The ADCEVTSEL register has corresponding bits which allow the events to propagate through to the PWM. The ADCEVTINTSEL register has corresponding bits that allow the events to propagate through to the PIE.

One PIE interrupt is shared between all the PPBs for a given ADC module as shown in [Figure 18-24](#).

[Figure 18-25](#) illustrates the ADC limit compare and zero-crossing logic.

Note

- If different actions need to be taken for different PPB events from the same ADC module, then the ADCEVTINT ISR has to read the PPB event flags in the ADCEVTSTAT register to determine which event caused the interrupt.
- If different ePWM trips need to be generated separately for high compare, low compare, and zero-crossing, this can be achieved by pointing multiple PPBs to the same SOC.
- The zero-crossing detect circuit considers a result of zero to be positive.

18.8.4 PPB Sample Delay Capture

When multiple control loops are running asynchronously on the same ADC, there is a chance that an ADC request from two or more loops collide, causing one of the samples to be delayed. This shows up as a measurement error in the system. By knowing when this delay occurs and the amount of delay that has occurred, software can employ extrapolation techniques to reduce the error.

To this effect, each PPB has the field DLYSTAMP in the ADCPPBxSTAMP register. This field contains the number of SYSCLK cycles between when the associate SOC was triggered and when the SOC began converting.

This is achieved by having a global 12-bit free running counter based off of SYSCLK, which is in the field FREECOUNT in the ADCCOUNTER register. When the trigger for the associated SOC arrives, the value of this counter is loaded into the bit field ADCPPBxTRIPLO.REQSTAMP. When the actual sample window for that SOC begins, the value in REQSTAMP is subtracted from the current FREECOUNT value and stored in DLYSTAMP.

Note

If more than 4096 SYSCLK cycles elapse between the SOC trigger and the actual start of the SOC acquisition, the FREECOUNT register can overflow more than once, leading to incorrect DLYSTAMP value. Be cautious when using very slow conversions to prevent this from happening.

The sample delay capture does not function, if the associated SOC is triggered using software. The sample delay capture, however, correctly records the delay, if the software triggering of a different SOC causes the SOC associated with the PPB to be delayed

18.8.5 PPB Oversampling

This ADC has built-in support for oversampling in the post-processing block, including an accumulator, min/max for peak detection, and outlier removal. The oversampling support module exists at the output of the sample correction module, as shown in [Figure 18-23](#). The oversampling module works by accumulating results in partial registers until either the sample count limit defined in the ADCPPBxLIMIT register is reached, an external hardware sync event occurs, or the software forces a sync event by writing to the SWSYNC bit in the ADCPPBxCONFIG2 register. The application can configure the PPB to sync from any of the hardware sources defined in [Table 18-10](#) by writing to the SYNCINSEL field of the ADCPPBxCONFIG2 register.

18.8.5.1 Accumulation, Average, Minimum, and Maximum Functions

At the end of each ADC sample conversion, the PPB updates the partial result registers ADCPPBxPSUM, ADCPPBxPMIN, and ADCPPBxPMAX with the newly processed conversion result from the ADCPPBxRESULT register, and the partial conversion count register (ADCPPBxPCOUNT) increments by 1. When the partial conversion count equals the limit defined in ADCPPBxLIMIT, or the PPB receives a hardware or software sync signal, the PPB takes the following actions:

1. The PPB loads the values of the respective partial result registers into the final result registers ADCPPBxSUM, ADCPPBxMIN, and ADCPPBxMAX.
2. The PPB loads the partial count in ADCPPBxPCOUNT into the final conversion count register ADCPPBxCOUNT.
3. The partial count register and partial result registers reset to zero.
4. The ADC generates an oversampling interrupt (OSINTx) event pulse, which triggers a CPU interrupt if so configured in the ADCINTSEL1N2 or ADCINTSEL3N4 registers.

The PPB can also be configured to generate an oversampling interrupt when there is a hardware or software sync event. To trigger an OSINTx pulse when a sync event occurs, write 1 to the OSINTSEL bit in the ADCPPBxCONFIG2 register.

The PPB can automatically compute the average of the accumulated samples if ADCPPBxLIMIT is set to a power of 2 (up to a maximum of 1024 samples). To perform automatic averaging over 2^n samples, set the SHIFT field in the ADCPPBxCONFIG2 register to n . When this field is set, the PPB divides the value of ADCPPBxPSUM by 2^n before loading into ADCPPBxSUM.

To compute an average from the accumulated sum when the number of samples is not a power of 2, divide the value of ADCPPBxSUM by the value of ADCPPBxCOUNT using the CPU.

Note

When using a sync signal to the repeater module and post-processing block to reset the ADC, note that the repeater sync signal does not stop or abort any pending SOCs. If both sync signals are issued simultaneously, any additional pending SOCs can propagate through the post-processing block after the sync signal has been issued. To fully clear or reset the ADC when using the repeater and PPB accumulation logic together:

1. Disable the repeater module trigger source.
 2. Reset the trigger repeater by issuing a sync signal to the repeater module.
 3. Wait for any pending SOCs to complete.
 4. Finally, issue a sync signal to the post-processing block to complete the ADC reset.
-

18.8.5.2 Outlier Rejection

The post-processing block enables the application to easily perform outlier rejection, by eliminating the largest and smallest samples during each SOC burst. To eliminate outliers, the following formula can be used in a software routine or ISR:

$$\text{Average} = \frac{(\text{ADCPPBxSUM} - \text{ADCPPBxMAX} - \text{ADCPPBxMIN})}{(\text{ADCPPBxCOUNT} - 2)} \quad (2)$$

18.9 Result Safety Checker

For safety-critical applications, this device provides the ability to automatically compare ADC conversion results from multiple ADC modules against each other for consistency. The number of available safety checker tiles is specified in the device data sheet. Each ADC checker tile captures conversion results from the associated ADCs as soon as the conversions are complete, and compares the absolute value of the difference to the configured tolerance. If the computed delta is out of range, the checker can generate a trip event signal that is sent to an ePWM or output crossbar, and can also trigger an CPU interrupt. Figure 18-26 illustrates the structure and operation of an ADC result safety checker tile.

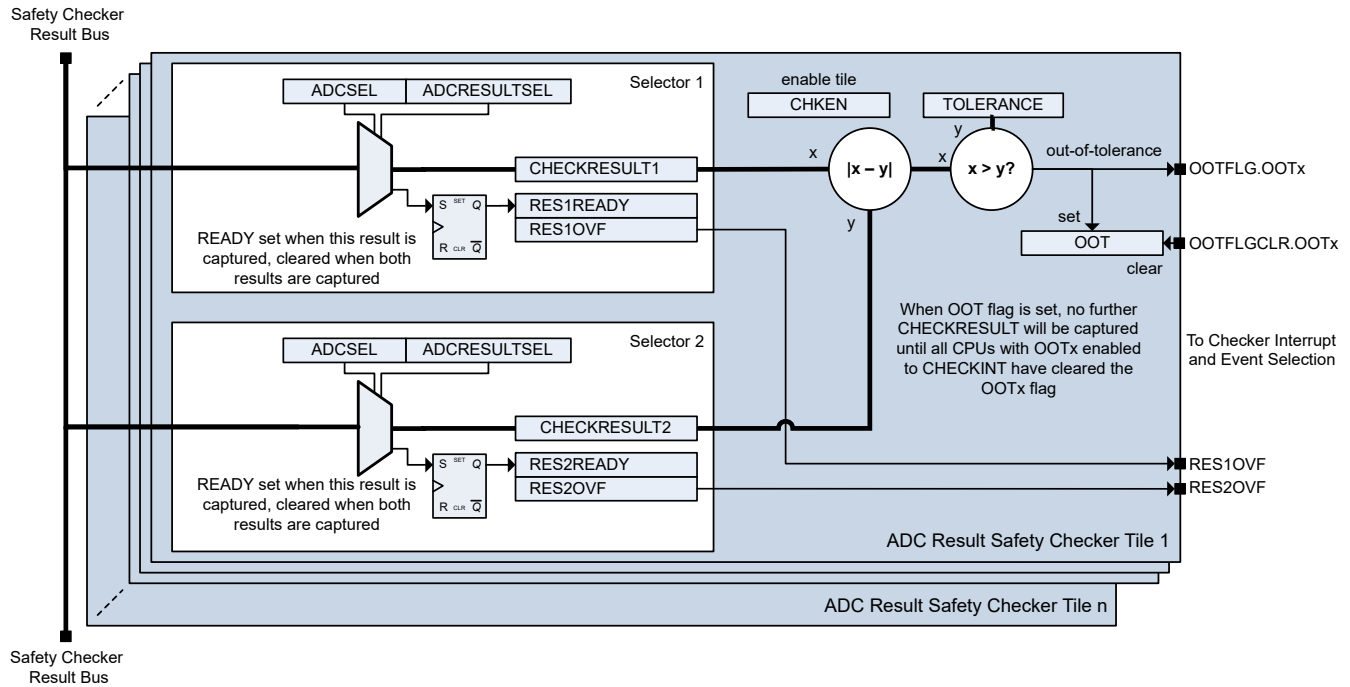

Figure 18-26. ADC Safety Checker Tile Diagram

18.9.1 Result Safety Checker Operation

Each ADC result safety checker tile can be configured to automatically compare two ADC conversion results against a set tolerance value, and generate an interrupt if an out-of-tolerance (OOT) event occurs. The selected results can be from the same ADC instance, or from different ADCs. The safety checker tiles exist outside of the ADC module, enabling the user application to compare results from two separate ADCs. To enable result safety checking, the application must first configure one or more ADCs to enable output of the desired results to the safety checker bus, and then configure the safety checker tile to compare those results.

To configure an ADC result safety checker tile:

1. Enable output of the desired ADC results for each ADC by writing to the ADC_REGSn.ADCSAFECHECKRESEN register. For each SOC, any one of the conversion result, PPB result, or PPB sum can be enabled for output to the safety checker bus by writing to ADCSAFECHECKRESEN.SOCxCHKEN.
2. Select the first result to compare by writing to the ADC_SAFECHECK_REGSn.ADCRESSEL1 register. Write to the ADCRESSEL1.ADCSEL field to select the ADC instance to test, and write to the ADCRESSEL1.ADCRESULTSEL field to select the corresponding SOC conversion result from that ADC to compare.
3. Select the second result to compare by writing to the ADC_SAFECHECK_REGSn.ADCRESSEL2 register. Write to ADCRESSEL2.ADCSEL to select the ADC instance to test, and write to ADCRESSEL2.ADCRESULTSEL to select the SOC conversion result from that ADC to compare. Any one of the SOC results, PPB module results or PPB sums can be selected in the ADCRESULTSEL field.
4. Configure the checker tolerance by writing to the ADC_SAFECHECK_REGSn.TOLERANCE register. The safety check result is out of tolerance if the difference between the two conversion results exceeds the value configured in TOLERANCE.
5. Enable the checker tile by writing 1 to ADC_SAFECHECK_REGSn.CHECKCONFIG.CHKEN.
6. Optionally, write 1 to ADC_SAFECHECK_REGSn.CHECKCONFIG.SWSYNC to force a reset of any currently set result safety checker event flags.

Each of the two result selectors waits for the configured ADC result to become available on the bus. When an ADC result becomes available, the checker reads the result into the CHECKRESULTx register, and sets the CHECKSTATUS.RESxRDY flag. Once both results are available, the checker clears the RESxRDY flags, compares the two results against each other, and sets the CHECKSTATUS.OOT flag if the configured tolerance is exceeded. This flag is also reflected in the corresponding bit for the selected checker tile in the OOTFLG register, and can be cleared by writing 1 to the corresponding bit in the OOTFLGCLR register. The checker does not perform any new comparisons while the OOT flag is set; to enable new comparisons, the flag must be cleared.

If two conversion results arrive in one selector before the other selector result becomes available, the checker sets the RESxOVF flag. This overflow flag does not prevent the comparison from occurring—it is for information only. To clear the overflow flag, write 1 to the corresponding bit for the selected checker tile in the RESxOVFCLR register.

18.9.2 Result Safety Checker Interrupts and Events

Each ADC result safety checker tile can generate an interrupt signal from out-of-tolerance (OOT) flags and result overflow flags (RESxOVF). These events are aggregated into a single interrupt signal, CHECKINT. [Figure 18-27](#) shows a block diagram of the result checker interrupt aggregation. To enable a checker flag as a source for CHECKINT, write 1 to the corresponding bit in the CHECKINTSEL1, CHECKINTSEL2 or CHECKINTSEL3 register. To clear a previously set checker interrupt flag, write 1 to the CHECKINTFLGCLR.CHECKINTCLR register.

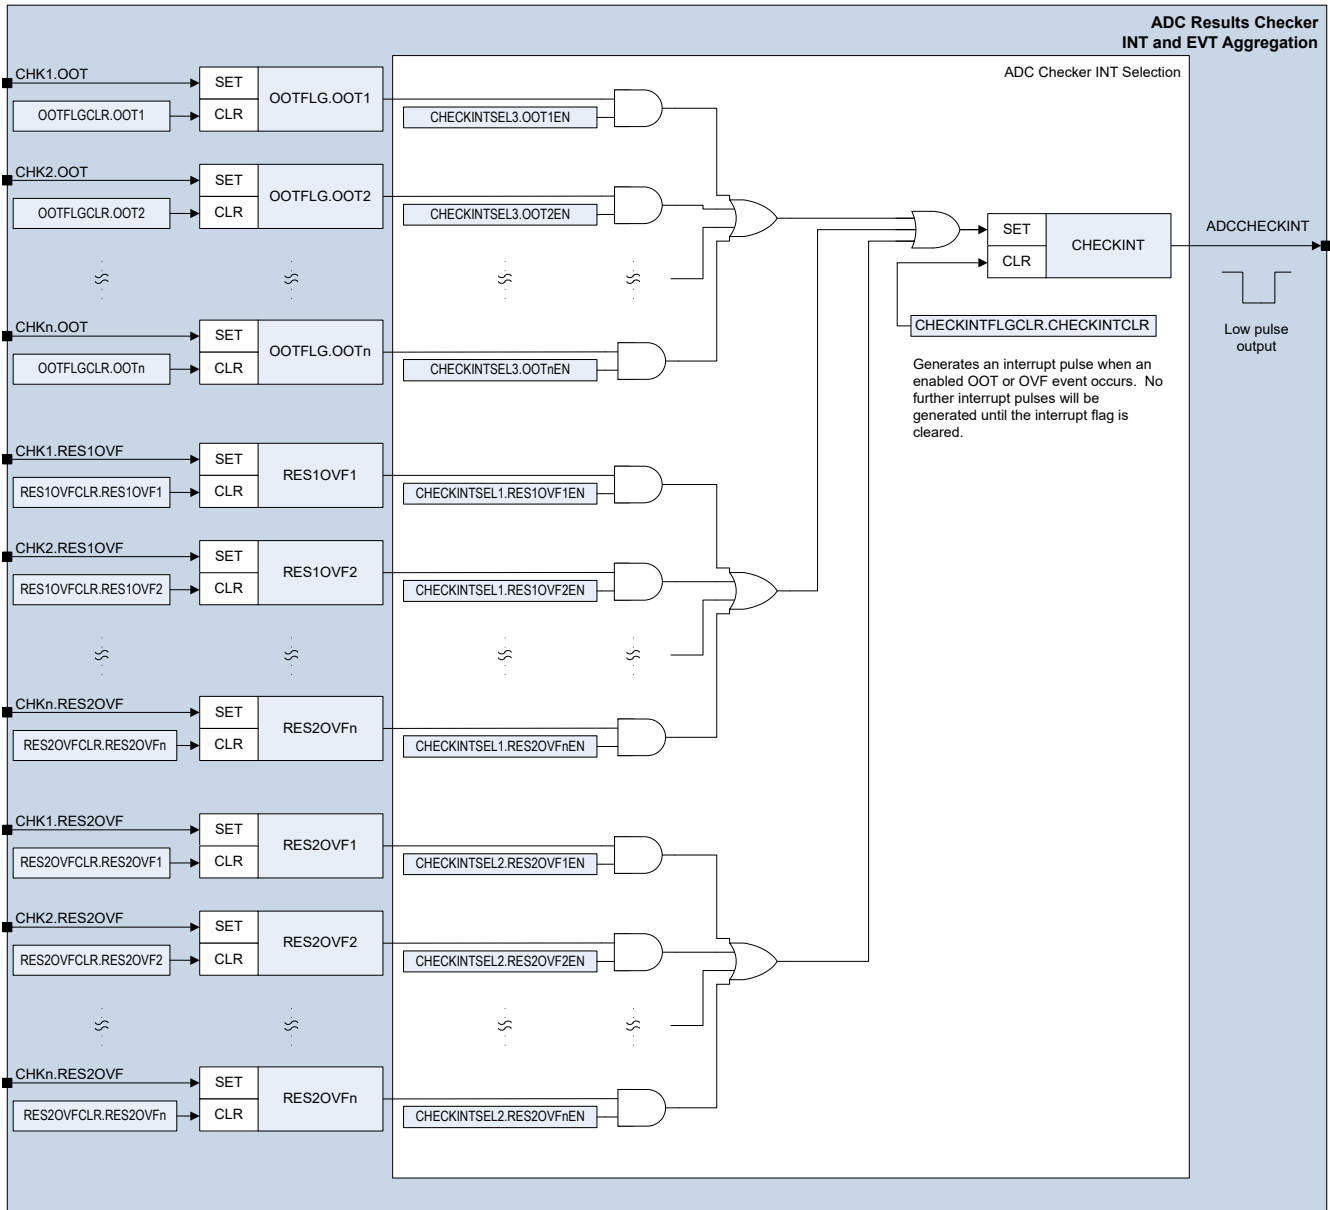

Figure 18-27. ADC Result Checker Interrupt Aggregation

In addition, safety checker tiles can also generate events that can be sent to the X-BAR, so that automatic hardware actions such as an ePWM trip can be generated. This device has 4 checker event signals (CHECKEVTx) that can be generated. For each event signal, any number of checker tile OOT or OVF flags can be aggregated into the single event signal. [Figure 18-28](#) shows a block diagram of the ADC result checker event aggregation. To enable a checker flag as a source for a CHECKEVT signal, write 1 to the corresponding bit in the CHECKEVTxSEL1, CHECKEVTxSEL2 or CHECKEVTxSEL3 registers.

18.10 Opens/Shorts Detection Circuit (OSDETECT)

The opens/shorts detection circuit (OSDETECT) can be used to detect pin faults in the system. The circuit connects to the ADC input after the channel select multiplexer but before the S+H circuit as shown in Figure 18-29.

Note

- The divider resistance tolerances can vary widely; hence, this feature must not be used to check for conversion accuracy.
- See the data sheet for implementation and availability of analog input channels.
- Due to high drive impedance, a S+H duration much longer than the ADC minimum is needed.

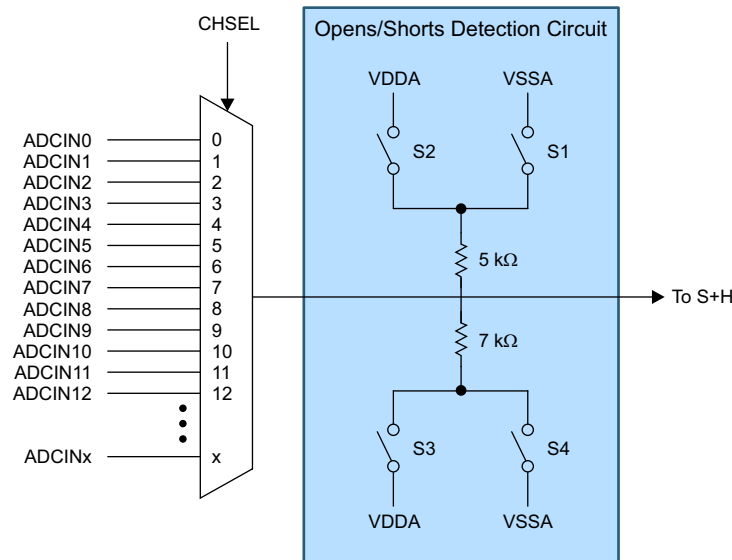

Figure 18-29. Opens/Shorts Detection Circuit

The circuit can be operated by writing a value to the DETECTCFG field in the ADCOSDETECT register. This causes the circuit to source a voltage onto the input during the S+H phase of any conversion. The voltage and drive strength of the OSDETECT circuit for different DETECTCFG settings is given in Table 18-11.

18.10.1 Implementation

A representative circuit with the OSDETECT implementation consists of the signal source with series resistance R_S , shunt capacitor C_P , the equivalent OSDETECT resistance $R_{OSDETECT}$ and voltage $V_{OSDETECT}$ is shown in Figure 18-30 and can be used as a basis to calculate the signal level going in to the sampling capacitor. $R_{OSDETECT}$ and $V_{OSDETECT}$ are the equivalent input resistance and voltage source contributed by the OSDETECT circuit with values shown in Table 18-11 for the different configuration settings. Refer to Figure 18-30 when deriving the input signal to S/H if signal source V_S is driving while the OSDETECT feature is enabled.

Figure 18-30. Input Circuit Equivalent with OSDETECT Enabled

The input impedance R_S and C_P are integral parts of the signal source or can have been implemented in the design to precondition the signal or to control signal settling time to meet S/H requirements. The input path has to be considered when using the OSDETECT feature, as this affects the conversion results. For instance, driving an input signal when this feature is enabled connects signal V_S to the OSDETECT circuit through R_S and affects the ADC results. Larger C_P values (in the order greater than hundreds of pF) require using higher ACQPS to make sure the signal at the input has settled prior to conversion.

To enable the circuit:

1. Configure the ADC for conversion (for example, channel, SOC, ACQPS, prescaler, trigger, and so on).
2. Set up the ADCOSDETECT register for the desired voltage divider connection as shown in Table 18-11.
3. Initiate a conversion and inspect the conversion result.

Interpret the results based on what is driving on the input side and what are the values of R_S and C_P . If the V_S signal can be disconnected from the input pin, the circuit can be used to detect open and shorted input pins as described in the following sections.

18.10.2 Detecting an Open Input Pin

By cycling through the various OSDETECT settings, the input signal is pulled towards the sourced voltages. An input with good drive strength (pin not open) is minimally affected. However, if the pin is open, the sampled voltages is close to the source voltages specified in Table 18-11.

18.10.3 Detecting a Shorted Input Pin

By cycling through the various OSDETECT settings, the input signal is pulled towards the sourced voltages. An input with finite drive strength (pin not shorted) is pulled toward each sourced voltage. However, if the pin is shorted, the signal remains at the same voltage.

18.11 Power-Up Sequence

Upon device power-up or system level reset, the ADC is powered down and disabled. When powering up the ADC, use the following sequence:

1. Set the bit to enable the desired ADC clock in the PCLKCR13 register.
2. Set the desired ADC clock divider in the PRESCALE field of ADCCTL2.
3. Power up the ADC by setting the ADCPWDNZ bit in ADCCTL1.
4. Allow a delay before sampling. See the data sheet for the necessary time.

If multiple ADCs are powered up simultaneously, steps 1 and step 3 can each be done for all ADCs in one write instruction. Also, only one delay is necessary as long as the delay occurs after all the ADCs have begun powering up.

18.12 ADC Calibration

During the fabrication and test process, Texas Instruments calibrates the gain, offset, and linearity of the ADCs and the offset of the buffered DACs. These trim settings are embedded into TI reserved OTP memory and can be loaded using C-callable functions.

- The `Device_cal()` function copies the trim values for ADC from OTP memory to their respective trim registers.
- The trim functions in `Device_cal()` are callable in C2000Ware as `ADC_setOffsetTrim()`, `ADC_setINLTrim()` and `DAC_setOffsetTrim()`. These functions fetch trim values from the TI reserved OTP memory source locations where the values are stored during test process as well as the analog module register destinations where the trim values are copied to.

Until the appropriate factory trim is loaded, the ADC and other analog modules are not specified to operate within the data sheet specifications. Similarly, if trim values other than the factory settings are placed into the trim registers, the ADC (and other modules) is not specified to operate within the data sheet specifications.

The boot ROM calls the calibration functions so trim values must be initially populated without user intervention. However, if the trims are cleared due to a module reset or modified for some other reason, then the user can call the calibration functions (defined in the header files).

18.12.1 ADC Zero Offset Calibration

ADC offset error is determined and calibrated during factory testing however users still have the option to perform offset calibration if the end application specifically requires this. This section describes how to perform offset calibration using internal VREFLO connection for single-ended operation and external channels for differential-ended operation. Consult ADC register descriptions for ADCCTL2.OFFTRIMMODE, ADCOFFTRIM, ADCOFFTRIM2 and ADCOFFTRIM3 for proper offset correction. C2000Ware function ADC_setMode() sets the value of OFFTRIMMODE to 1 which applies different offset from the three offset registers depending on conversion mode and channel type (even/odd) used. The ADCOFFTRIM register referred to in the succeeding paragraphs can be ADCOFFTRIM, ADCOFFTRIM2 or ADCOFFTRIM3.

Zero offset error is defined as the difference from 0 that occurs when converting a voltage at VREFLO (single-ended operation) or the difference from (maximum code/2) when converting $ADCINxP = ADCINxN$ (differential mode). The zero offset error can be positive or negative. To correct this error, an adjustment of equal magnitude and opposite polarity is written into the ADCOFFTRIM register. The value contained in this register is applied before the results are available in the ADC result registers. This operation is fully contained within the ADC core, so the timing of the results is not affected and the full dynamic range of the ADC is maintained for any trim value.

Note

Regardless of the converter resolution, the size of each ADCOFFTRIM step is $(VREFHI-VREFLO)/65536$.

Use the following procedure to re-calibrate the ADC offset in 12-bit single-ended mode:

1. Set ADCOFFTRIM to +112 steps (0x70). This adds an artificial offset to account for negative offset that can reside in the ADC core.
2. Perform some multiple of 16 conversions on VREFLO (internal connection), accumulating the results (for example, 32×16 conversions = 512 conversions). Use the maximum value of ACQPS to ensure longer settling time to account for parasitic impedance of internal VREFLO connections. In order to connect to internal VREFLO channels, use driverlib function ADC_setupSOCRefloChannel(). After VREFLO conversion has taken place, use function ADC_disableIntRefloConnection() to disconnect the input multiplex from the internal VREFLO connection.
3. Divide the accumulated result by the multiple of 16 (for example, for 512 conversions, divide by 32).
4. Set ADCOFFTRIM to 112 – result from step 3.

Use the following procedure to recalibrate the ADC offset in 16-bit/12-bit differential mode:

1. Set ADCOFFTRIM to no adjustment (0x00).
2. Short $ADCINxP$ and $ADCINyN$ together (external connection) to a voltage near $Vrefcm$ and accumulate some multiple of 16 conversions (for example, 32×16 conversions = 512 conversions).
3. Divide the accumulated result by the number of conversions (for example, for 512 conversions, divide by 512 for 16-bit mode or divide by 32 for 12-bit mode).
4. Set ADCOFFTRIM to 0 – result from step 3).

18.13 ADC Timings

The process of converting an analog voltage to a digital value is broken down into an S+H phase and a conversion phase. The ADC sample and hold circuits (S+H) are clocked by SYSCLK while the ADC conversion process is clocked by ADCCLK. ADCCLK is generated by dividing down SYSCLK based on the PRESCALE field in the ADCCTL2 register.

The S+H duration is the value of the ACQPS field of the SOC being converted, plus one, times the SYSCLK period. The user must make sure that this duration exceeds both 1 ADCCLK period and the minimum S+H duration specified in the data sheet. The conversion time is approximately 10.5 ADCCLK cycles in 12-bit mode and 29.5 ADCCLK cycles in 16-bit mode. The exact conversion time is always a whole number of SYSCLK cycles. See the timing diagrams and tables in [Section 18.13.1](#) for exact timings.

18.13.1 ADC Timing Diagrams

The following diagrams show the ADC conversion timings for two SOC's given the following assumptions:

- SOC0 and SOC1 are configured to use the same trigger.
- No other SOC's are converting or pending when the trigger occurs.
- The round robin pointer is in a state that causes SOC0 to convert first.
- ADCINTSEL is configured to set an ADCINT flag upon end of conversion for SOC0 (whether this flag propagates through to the CPU to cause an interrupt is determined by the configurations in the PIE module).

[Table 18-12](#) describes the parameters in the following timing diagrams. [Table 18-13](#) and [Table 18-14](#) list the ADC timings.

Table 18-12. ADC Timing Parameter Descriptions

Parameter	Description
t_{SH}	<p>The duration of the S+H window.</p> <p>At the end of this window, the value on the S+H capacitor becomes the voltage to be converted into a digital value. The duration is given by $(ACQPS + 1)$ SYSCLK cycles. ACQPS can be configured individually for each SOC, so t_{SH} is not necessarily the same for different SOC's.</p> <p>Note: The value on the S+H capacitor is captured approximately 5 ns before the end of the S+H window regardless of device clock settings.</p>
t_{LAT}	<p>The time from the end of the S+H window until the ADC results latch in the ADCRESULTx register.</p> <p>If the ADCRESULTx register is read before this time, the previous conversion results are returned.</p>
t_{EOC}	<p>The time from the end of the S+H window until the S+H window for the next ADC conversion can begin. In 16-bit mode, this coincides with the latching of the conversion results, while in 12-bit mode, the subsequent sample can start before the conversion results are latched.</p>
t_{INT}	<p>The time from the end of the S+H window until an ADCINT flag is set (if configured).</p> <p>If the INTPULSEPOS bit in the ADCCTL1 register is set, t_{INT} coincides with the end of conversion (EOC) signal.</p> <p>If the INTPULSEPOS bit is 0, and the OFFSET field in the ADCINTCYCLE register is not 0, then there is a delay of OFFSET SYSCLK cycles before the ADCINT flag is set. This delay can be used to enter the ISR or trigger the DMA exactly when the sample is ready.</p> <p>If the INTPULSEPOS bit is 0, t_{INT} coincides with the end of the S+H window. If t_{INT} triggers a read of the ADC result register (directly through DMA or indirectly by triggering an ISR that reads the result), care must be taken to make sure the read occurs after the results latch (otherwise, the previous results are read).</p>
t_{DMA}	<p>The time from the end of the S+H window until a DMA read of the ADC conversion result is triggered, when ADCCTL1.TDMAEN = 1.</p> <p>If TDMAEN is set to 0, then the DMA trigger occurs at T_{INT}. In certain conditions, the ADCINT flag can be set before the ADCRESULT value is latched. To make sure that the DMA read occurs after the ADCRESULT value has been latched, write 1 to ADCCTL1.TDMAEN to enable DMA timings.</p>

18.13.2 Post-Processing Block Timings

The value of ADCRESULT is always available at time t_{LAT} , as specified in [Section 18.13.1](#). The value of ADCPPBxRESULT, and the limit and zero-crossing comparisons are available 1 SYSCLK cycle later, as long as multiple PPB instances do not point to the same SOC. [Table 18-15](#) shows PPB result availability timings when there are no SOCs shared between multiple PPBs. In cases where multiple PPBs point to the same SOC, PPB results become available sequentially, starting with the lowest numbered PPB. The first ADCPPBxRESULT becomes available 1 SYSCLK cycle after t_{LAT} , and each subsequent ADCPPBxRESULT becomes available 1 SYSCLK cycle after the previous PPB has completed the limit and zero-crossing comparison. The serialized PPB results are therefore spaced 2 or 3 SYSCLK cycles apart, depending on whether the comparison uses ADCPPBxRESULT or PSUM/SUM respectively. This timing is as shown in [Table 18-16](#). PPB aggregation values (PSUM, SUM, PCOUNT, COUNT, PMAX, MAX, PMIN, MIN, PMINI, MINI, PMAXI, MAXI) are available 1 cycle after the associated ADCPPBxRESULT becomes available.

Furthermore, the LIMIT and zero-crossing compares occur 1 cycle after the compared results become available. In the case that the comparison is done against ADCPPBxRESULT, the comparison occurs 1 SYSCLK cycle after ADCPPBxRESULT becomes available. In the case that the comparison is done against PSUM or SUM, the comparison occurs 2 SYSCLK cycles after ADCPPBxRESULT is available.

18.14 Additional Information

The following sections contain additional practical information.

18.14.1 Ensuring Synchronous Operation

For best performance, all ADCs on the device must be operated synchronously. The device data sheet specifies the performance in both synchronous and asynchronous mode for those parameters which differ between the modes of operation.

To make sure synchronous operation, all ADCs on the device must operate in lockstep. This is accomplished by writing configurations to all ADCs that cause the sampling and conversion phases of all ADCs to be exactly aligned. The easiest way to accomplish this is to write identical values to the SOC configurations for each ADC for trigger select and ACQPS (S+H duration). In addition, synchronous ADCs must also configure identical values for the SOC priority control, burst mode, burst trigger, and burst size.

18.14.1.1 Basic Synchronous Operation

The following example configures two SOC's each on ADCA and ADCC with identical trigger select and ACQPS values. This results in synchronous operation between ADCA and ADCC. For devices with more than two ADCs, the same principles can be used to synchronize all the ADCs.

Example: Basic Synchronous Operation

```

AdcaRegs.ADCSOC0CTL.bit.CHSEL = 4; //SOC0 will convert ADCINA4
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 19; //SOC0 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10; //SOC0 will begin conversion on ePWM3 SOCB
AdccRegs.ADCSOC0CTL.bit.CHSEL = 0; //SOC0 will convert ADCINC0
AdccRegs.ADCSOC0CTL.bit.ACQPS = 19; //SOC0 will use sample duration of 20 SYSCLK cycles
AdccRegs.ADCSOC0CTL.bit.TRIGSEL = 10; //SOC0 will begin conversion on ePWM3 SOCB

AdcaRegs.ADCSOC1CTL.bit.CHSEL = 4; //SOC1 will convert ADCINA4
AdcaRegs.ADCSOC1CTL.bit.ACQPS = 30; //SOC1 will use sample duration of 31 SYSCLK cycles
AdcaRegs.ADCSOC1CTL.bit.TRIGSEL = 10; //SOC1 will begin conversion on ePWM3 SOCB
AdccRegs.ADCSOC1CTL.bit.CHSEL = 1; //SOC1 will convert ADCINC1
AdccRegs.ADCSOC1CTL.bit.ACQPS = 30; //SOC1 will use sample duration of 31 SYSCLK cycles
AdccRegs.ADCSOC1CTL.bit.TRIGSEL = 10; //SOC1 will begin conversion on ePWM3 SOCB
    
```

Figure 18-35. Example: Basic Synchronous Operation

Several things can be noted from Figure 18-35. First, while the ACQPS values must be the same for SOC's with the same number, different ACQPS values can be used for SOC's with different numbers. Because of this, synchronous operation does not require a single global S+H time, but instead only channels sampled simultaneously require identical S+H durations. Another important point from this example is that any channel select value can be used for any SOC. Finally, this example assumes round-robin operation. If high-priority SOC's are to be used, the priority must be configured the same on all ADCs.

18.14.1.2 Synchronous Operation with Multiple Trigger Sources

As long as each set of SOCs has identical trigger select and ACQPS settings, multiple trigger sources can be used while still achieving synchronous operation.

The following example demonstrates synchronous operation between ADCA and ADCC while using three SOCs and two trigger sources. Figure 18-36 demonstrates that any combination of relative trigger timings still results in synchronous operation.

Example: Synchronous Operation with Multiple Trigger Sources

```

AdcaRegs.ADCSOC0CTL.bit.CHSEL = 4; //SOC0 will convert ADCINA4
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 19; //SOC0 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10; //SOC0 will begin conversion on ePWM3 SOCB
AdccRegs.ADCSOC0CTL.bit.CHSEL = 0; //SOC0 will convert ADCINC0
AdccRegs.ADCSOC0CTL.bit.ACQPS = 19; //SOC0 will use sample duration of 20 SYSCLK cycles
AdccRegs.ADCSOC0CTL.bit.TRIGSEL = 10; //SOC0 will begin conversion on ePWM3 SOCB

AdcaRegs.ADCSOC1CTL.bit.CHSEL = 4; //SOC1 will convert ADCINA4
AdcaRegs.ADCSOC1CTL.bit.ACQPS = 30; //SOC1 will use sample duration of 31 SYSCLK cycles
AdcaRegs.ADCSOC1CTL.bit.TRIGSEL = 10; //SOC1 will begin conversion on ePWM3 SOCB
AdccRegs.ADCSOC1CTL.bit.CHSEL = 1; //SOC1 will convert ADCINC1
AdccRegs.ADCSOC1CTL.bit.ACQPS = 30; //SOC1 will use sample duration of 31 SYSCLK cycles
AdccRegs.ADCSOC1CTL.bit.TRIGSEL = 10; //SOC1 will begin conversion on ePWM3 SOCB

AdcaRegs.ADCSOC2CTL.bit.CHSEL = 0; //SOC2 will convert ADCINA0
AdcaRegs.ADCSOC2CTL.bit.ACQPS = 19; //SOC2 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC2CTL.bit.TRIGSEL = 2; //SOC2 will begin conversion on CPU Timer1
AdccRegs.ADCSOC2CTL.bit.CHSEL = 2; //SOC2 will convert ADCINC2
AdccRegs.ADCSOC2CTL.bit.ACQPS = 19; //SOC2 will use sample duration of 20 SYSCLK cycles
AdccRegs.ADCSOC2CTL.bit.TRIGSEL = 2; //SOC2 will begin conversion on CPU Timer1
    
```

Figure 18-36. Example: Synchronous Operation with Multiple Trigger Sources

Note that any trigger source that can be selected in the TRIGSEL field can be used except for software triggering. There is no way to issue the software triggers for all ADCs simultaneously, so likely results in asynchronous operation. ADCINT1 or ADCINT2 can also be used as a trigger as long as the ADCINTSOCSEL1 and ADCINTSOCSEL2 registers are configured identically for all ADCs and software triggering is not used to start the chain of conversions.

18.14.1.3 Synchronous Operation with Uneven SOC Numbers

If only one trigger source is used, one ADC can use more SOC numbers than the other ADCs while still operating synchronously.

Example: Synchronous Operation with Uneven SOC Numbers

```

AdcaRegs.ADCSOC0CTL.bit.CHSEL = 4; //SOC0 will convert ADCINA4
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 19; //SOC0 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10; //SOC0 will begin conversion on ePWM3 SOCB
AdccRegs.ADCSOC0CTL.bit.CHSEL = 0; //SOC0 will convert ADCINCO
AdccRegs.ADCSOC0CTL.bit.ACQPS = 19; //SOC0 will use sample duration of 20 SYSCLK cycles
AdccRegs.ADCSOC0CTL.bit.TRIGSEL = 10; //SOC0 will begin conversion on ePWM3 SOCB

AdcaRegs.ADCSOC1CTL.bit.CHSEL = 4; //SOC1 will convert ADCINA4
AdcaRegs.ADCSOC1CTL.bit.ACQPS = 30; //SOC1 will use sample duration of 31 SYSCLK cycles
AdcaRegs.ADCSOC1CTL.bit.TRIGSEL = 10; //SOC1 will begin conversion on ePWM3 SOCB
AdccRegs.ADCSOC1CTL.bit.CHSEL = 1; //SOC1 will convert ADCINC1
AdccRegs.ADCSOC1CTL.bit.ACQPS = 30; //SOC1 will use sample duration of 31 SYSCLK cycles
AdccRegs.ADCSOC1CTL.bit.TRIGSEL = 10; //SOC1 will begin conversion on ePWM3 SOCB

AdcaRegs.ADCSOC2CTL.bit.CHSEL = 0; //SOC2 will convert ADCINA0
AdcaRegs.ADCSOC2CTL.bit.ACQPS = 19; //SOC2 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC2CTL.bit.TRIGSEL = 10; //SOC2 will begin conversion on ePWM3 SOCB
    
```

Figure 18-37. Example: Synchronous Operation with Uneven SOC Numbers

Note that if the trigger comes again before all SOCs have completed their conversions, ADCC begins converting immediately on SOC0 while ADCA does not start converting SOC0 again until SOC2 is complete. This results in asynchronous operation, so care must be taken to not overflow the trigger.

Figure 18-38. Example: Asynchronous Operation with Uneven SOC Numbers – Trigger Overflow

18.14.1.4 Synchronous Operation with Different Resolutions

Configuring different ADCs to use different resolutions results in asynchronous operation. This occurs because the conversion time for 12-bit mode and 16-bit mode are different. Synchronous operation requires both the start and end of the conversion phase to be aligned, so even using the same S+H window duration does not result in synchronous operation.

Example: Asynchronous Operation with Different Resolutions

```
//ADCA = 12-bit mode
AdcaRegs.ADCSOC0CTL.bit.CHSEL = 4;      //SOC0 will convert ADCINA4
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 50;     //SOC0 will use sample duration of 51 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10;   //SOC0 will begin conversion on ePWM3 SOCB

//ADCB = 16-bit mode
AdcbRegs.ADCSOC0CTL.bit.CHSEL = 0;      //SOC0 will convert ADCINB0/B1
AdcbRegs.ADCSOC0CTL.bit.ACQPS = 50;     //SOC0 will use sample duration of 51 SYSCLK cycles
AdcbRegs.ADCSOC0CTL.bit.TRIGSEL = 10;   //SOC0 will begin conversion on ePWM3 SOCB
```

Figure 18-39. Example: Asynchronous Operation with Different Resolutions

To achieve synchronous operation while using both 12-bit and 16-bit resolution, conversions must be done in parallel at one resolution. Once conversions are complete at one resolution, the CPU must switch the resolution on all ADCs and then cause another trigger (this trigger must not be a software SOC force, as all ADCs cannot be started simultaneously using this method).

Figure 18-40. Example: Synchronous Operation with Different Resolutions

18.14.1.5 Non-overlapping Conversions

If conversion timings can be made sure to not overlap by the user, then it is not necessary to configure all SOC0s identically on all ADCs to achieve performance equivalent to synchronous operation. For example, if the two ADC triggers in a system come from two ePWM sources that are always 180-degrees out-of-phase, then SOC0 can be used for both ADCA and ADCC with different trigger sources and different ACQPS values.

Example: Operation with Non-overlapping Conversions

```
//ePWM3 SOCA and SOCB are 180 degrees out of phase
AdcaRegs.ADCSOC0CTL.bit.CHSEL = 4; //SOC0 will convert ADCINA4
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 19; //SOC0 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10; //SOC0 will begin conversion on ePWM3 SOCB
AdccRegs.ADCSOC0CTL.bit.CHSEL = 0; //SOC0 will convert ADCINC0
AdccRegs.ADCSOC0CTL.bit.ACQPS = 19; //SOC0 will use sample duration of 20 SYSCLK cycles
AdccRegs.ADCSOC0CTL.bit.TRIGSEL = 9; //SOC0 will begin conversion on ePWM3 SOCA
```

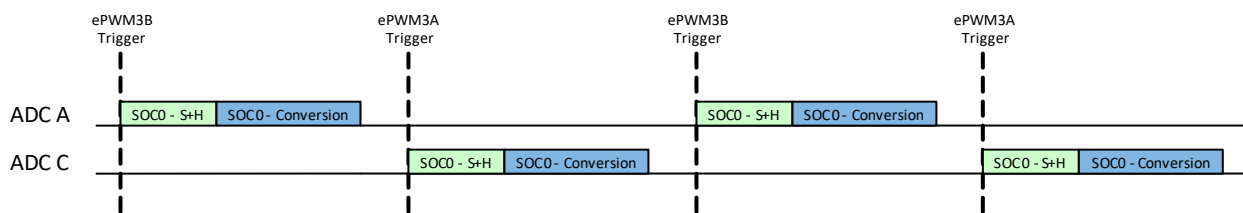

Figure 18-41. Example: Synchronous Equivalent Operation with Non-Overlapping Conversions

18.14.2 Choosing an Acquisition Window Duration

For correct operation, the input signal to the ADC must be allowed adequate time to charge the sample and hold capacitor, Ch. Typically, the S+H duration is chosen such that the sampling capacitor is charged to within 1/2 LSB or 1/4 LSB of the final value, depending on the tolerable settling error.

The best methodology to determine the required settling time is to simulate the ADC and ADC driving circuits to make sure adequate settling performance. See [ADC Input Circuit Evaluation for C2000 MCUs](#) and [Charge-Sharing Driving Circuits for C2000 ADCs](#) for additional guidance on ADC signal conditioning circuit design and evaluation.

An approximation of the required settling time can also be determined using an RC settling model. The time constant for the model is given by the equation:

$$\tau = (R_S + R_{on}) \times C_h + R_S \times (C_S + C_p) \tag{3}$$

And the number of time constants needed is given by the equation:

$$k = \ln\left(\frac{2^n}{\text{settling error}}\right) - \ln\left(\frac{C_S + C_P}{CH}\right) \tag{4}$$

So the total S+H time must be set to at least:

$$t = k \cdot \tau \tag{5}$$

Where the following parameters are provided by the ADC input model in the device data sheet:

- n = ADC resolution (in bits)
- R_{ON} = ADC sampling switch resistance (provided in Ω)
- C_H = ADC sampling capacitor (provided in pF)
- C_p = ADC channel parasitic input capacitance (provided in pF)

And the following parameters are dependent on the application design:

- settling error = tolerable settling error (in LSBs)
- R_s = ADC driving circuit source impedance (typically in Ω or $k\Omega$)
- C_s = capacitance on ADC input pin (typically in pF or nF)

For example, assuming the following parameters:

- n = 12-bits
- R_{ON} = 500 Ω
- C_H = 12.5 pF
- C_p = 12.7 pF
- settling error = $\frac{1}{4}$ LSB
- R_s = 180 Ω
- C_s = 150 pF

The time constant is calculated as:

$$\tau = (180\Omega + 500\Omega) \times 12.5pF + 180\Omega \times (150pF + 12.7pF) = 37.8ns \quad (6)$$

And the number of required time constants is:

$$k = \ln\left(\frac{2^{12}}{0.25}\right) - \ln\left(\frac{150pF + 12.7pF}{12.5pF}\right) = 9.70 - 2.57 = 7.13 \quad (7)$$

So the S+H time must be set to at least: 37.8 ns \times 7.13 = 270 ns

If SYSCLK = 200 MHz, then each SYSCLK cycle is 5 ns. S+H duration is 270 ns/5 ns = 54 SYSCLK cycles, so ACQPS for this input is set to at least CEILING(54.0) – 1 = 53.

While this gives a rough estimate of the required acquisition window, a better method is to setup a circuit with the ADC input model, a model of the source impedance/capacitance, and any board parasitics in SPICE (or similar software) and simulate to verify that the sampling capacitor settles to the desired accuracy.

Note

The device data sheet specifies a minimum ADC S+H window duration. Do not use an ACQPS value that gives a duration less than this specification.

18.14.3 Achieving Simultaneous Sampling

While each ADC does not have dual S+H circuits, it is easy to achieve simultaneous sampling. This is accomplished by setting the SOC triggers on two or more ADC modules to use the same trigger source. The following example demonstrates simultaneous sampling on 3 ADCs based on an ePWM3 event. ADCINA3, ADCINB2, and ADCINC5 are sampled. An acquisition window of 20 SYSCLK cycles is used, but different durations are possible.

```

AdcaRegs.ADCSOC0CTL.bit.CHSEL = 3;           //SOC0 will convert ADCINA3
AdcaRegs.ADCSOC0CTL.bit.ACQPS = 19;          //SOC0 will use sample duration of 20 SYSCLK cycles
AdcaRegs.ADCSOC0CTL.bit.TRIGSEL = 10;        //SOC0 will begin conversion on ePWM3 SOCB
AdcbRegs.ADCSOC0CTL.bit.CHSEL = 2;           //SOC0 will convert ADCINB2
AdcbRegs.ADCSOC0CTL.bit.ACQPS = 19;          //SOC0 will use sample duration of 20 SYSCLK cycles
AdcbRegs.ADCSOC0CTL.bit.TRIGSEL = 10;        //SOC0 will begin conversion on ePWM3 SOCB
AdccRegs.ADCSOC0CTL.bit.CHSEL = 5;           //SOC0 will convert ADCINC5
AdccRegs.ADCSOC0CTL.bit.ACQPS = 19;          //SOC0 will use sample duration of 20 SYSCLK cycles
AdccRegs.ADCSOC0CTL.bit.TRIGSEL = 10;        //SOC0 will begin conversion on ePWM3 SOCB

```

When the ePWM3 trigger is received, all three ADCs begin converting in parallel immediately. All results are stored in the ADCRESULT0 register for each ADC. Note that this assumes that all ADCs are idle when the trigger is received. If one or more ADCs is busy, the samples do not happen at exactly the same time.

18.14.4 Result Register Mapping

The ADC results and the ADC PPB results are duplicated for each memory bus controller in the system. Bus controllers include all CPUs, DMAs, and CLAs present on the specific part family and part number. For each bus controller, no access configuration is needed to allow read access to the result registers and no contention occurs in cases where multiple bus controllers try to read the ADC results simultaneously.

18.14.5 Internal Temperature Sensor

The internal temperature sensor measures the junction temperature of the device. The output of the sensor can be sampled with the ADC through an internal connection. This can be enabled on channel ADCIN13 on ADCA, ADCIN18 on ADCB, and on the CMPSS3_HP4 and CMPSS5_HP4 inputs by setting the ENABLE bit in the TSNSCTL register.

To convert the temperature sensor reading into a temperature, pass the temperature sensor reading to the ADC_getTemperatureC() function in the ADC driverlib.

Note

To sample the temperature sensor, the ADC must be in single-ended 12-bit mode.

If the temperature sensor is sampled in 16-bit mode, this can cause incorrect ADC results.

18.14.6 Designing an External Reference Circuit

Figure 18-42 shows the basic organization of the external voltage reference generation circuitry. A single reference voltage generation source must be shared by all ADC modules. This minimizes reference voltage mismatch between ADC modules. The reference voltage must then be buffered by a precision op-amp with good bandwidth and low output impedance before being driven into the reference pin. A capacitor between the high and low reference pins must be placed on the PCB as close to the pins as practical to help absorb high-frequency currents. A series resistor (typically $<1\Omega$) in series with this capacitor can be necessary to make sure op-amp stability.

It is also possible to share two reference pins between one op-amp driver. This organization is shown in Figure 18-43. This gives slightly reduced performance compared to the case where each reference pin has a dedicated op-amp buffer, but it can still be possible to achieve all ADC specifications in the data sheet.

18.14.7 ADC-DAC Loopback Testing

For system diagnostic or functional safety purposes, the user application can perform a loopback test of the ADC module to verify that the ADC is converting correctly. Using the output of the DAC in the first CMPSS module, the device can be configured to supply a series of known voltages to the input of the converter, and the conversion result verified against expected results. Loopback test mode is enabled by setting the bit corresponding to the ADC module under test in the ADCLOOPBACK register in the analog subsystem module to 1. Figure 18-44 shows the connection between the CMPSS DAC output and the ADC.

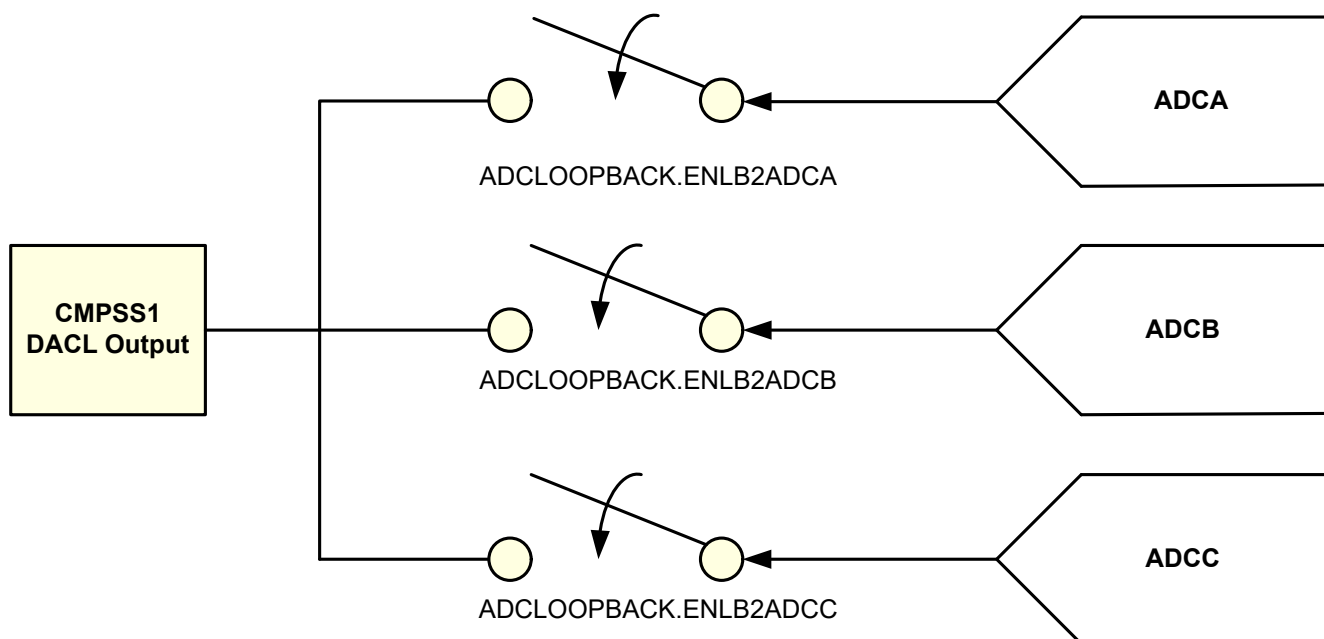

Figure 18-44. CMPSS to ADC Loopback Connection

In ADC loopback test mode, the following special considerations apply:

- The ADC module always samples the CMPSS1 DACL output, regardless of what channel is selected in the ADCSOCxCTL.CHSEL field.
- The minimum sampling window size (ACQPS) when converting the DAC output is 2.56 μ s (512 SYSCLK cycles at 200 MHz SYSCLK).
- The output resolution of the CMPSS DAC is 6 bits. The lower 6 bits of the input DACVAL are discarded.
- ADC loopback test mode affects CMPSS trip voltages. Avoid enabling ADC loopback mode during regular CMPSS operation.

For more information on the CMPSS module and how to configure the CMPSS DAC, see the *Comparator Subsystem (CMPSS)* chapter.

18.14.8 Internal Test Mode

For diagnostic purposes, the ADC can sample various internal node voltages using a special input selection mux called INTERNALTEST. When internal test mode is enabled, the INTERNALTEST mux selection overrides the ADC-A input channel mux: ADC-A samples the INTERNALTEST selection instead of the channel selected by ADCSOCxCTL.CHSEL. Internal test mode can be used to sample the VDDCORE voltage, VREFLO, VDDA, VSSA, and the CMPSS DAC outputs.

To enable internal test mode, write the desired node selection to the TESTSEL field of the INTERNALTESTCTL analog subsystem register. For safety, INTERNALTESTCTL includes a write key field that must be simultaneously written with the value 0xA5A5 for writes to take effect; otherwise, writes to this register are ignored.

When using internal test mode, the following special considerations apply:

- INTERNALTESTCTL.TESTSEL overrides the value of ADCSOCxCTL.CHSEL on ADCA when a non-zero value is configured. To disable internal test mode, write 0 to the TESTSEL field.
- The minimum sampling window size (ACQPS) when converting INTERNALTEST is 2.56 μ s (512 SYSCLK cycles at 200 MHz SYSCLK).
- The effective resolution of the CMPSS DAC outputs to INTERNALTEST is 7 bits.

For more information on the CMPSS module and how to configure the CMPSS DAC, see the *Comparator Subsystem (CMPSS)* chapter.

18.14.9 ADC Gain Balancing

Using the INTERNALTEST mux, gain balancing between multiple ADCs can be performed. By calculating the relative gain error between the ADCs, conversion results can be post-processed in software such that each ADC has the same output for each equivalent input.

To activate gain calibration mode, configure the TESTSEL field of the INTERNALTESTCTL analog subsystem register to select ENZ_CALIB_GAIN_3P3V. In this mode, the voltage sampled by all ADCs when triggered is (VREFHI * 0.9), overriding the channel selection in ADCSOCxCTL.CHSEL. To turn off gain calibration mode and return to normal operation, configure the TESTSEL field of INTERNALTESTCTL to 0.

18.15.1.1 ADC Software Triggering

FILE: adc_ex1_soc_software.c

This example converts some voltages on ADCA and ADCC based on a software trigger.

The ADCC will not convert until ADCA is complete, so the ADCs will not run asynchronously. However, this is much less efficient than allowing the ADCs to convert synchronously in parallel (for example, by using an ePWM trigger).

18.15.1.2 ADC ePWM Triggering

FILE: adc_ex2_soc_epwm.c

This example sets up ePWM1 to periodically trigger a conversion on ADCA.

External Connections

- A0 should be connected to a signal to convert

Watch Variables

- *myADC0Results* - A sequence of analog-to-digital conversion samples from pin A0. The time between samples is determined based on the period of the ePWM timer.

18.15.1.3 ADC Temperature Sensor Conversion

FILE: adc_ex3_temp_sensor.c

This example sets up the ePWM to periodically trigger the ADC. The ADC converts the internal connection to the temperature sensor, which is then interpreted as a temperature by calling the `ADC_getTemperatureC()` function.

18.15.1.4 ADC Synchronous SOC Software Force (*adc_soc_software_sync*)

FILE: adc_ex4_soc_software_sync.c

This example converts some voltages on ADCA and ADCC using input 5 of the input X-BAR as a software force. Input 5 is triggered by toggling GPIO0, but any spare GPIO could be used. This method will ensure that both ADCs start converting at exactly the same time.

18.15.1.7 ADC PPB Offset (*adc_ppb_offset*)

FILE: *adc_ex7_ppb_offset.c*

This example software triggers the ADC. Some SOCs have automatic offset adjustment applied by the post-processing block. After the program runs, the memory will contain ADC & post-processing block(PPB) results.

External Connections

- A2, C2 pins should be connected to signals to convert

Watch Variables

18.15.1.8 ADC PPB Limits (*adc_ppb_limits*)

FILE: *adc_ex8_ppb_limits.c*

This example sets up the ePWM to periodically trigger the ADC. If the results are outside of the defined range, the post-processing block will generate an interrupt.

The default limits are 1000LSBs and 3000LSBs. With VREFHI set to 3.3V, the PPB will generate an interrupt if the input voltage goes above about 2.4V or below about 0.8V.

External Connections

- A0 should be connected to a signal to convert

Watch Variables

18.15.1.9 ADC PPB Delay Capture (*adc_ppb_delay*)

FILE: *adc_ex9_ppb_delay.c*

This example demonstrates delay capture using the post-processing block.

Two asynchronous ADC triggers are setup:

- ePWM1, with period 2048, triggering SOC0 to convert on pin A0
 - ePWM2, with period 9999, triggering SOC1 to convert on pin A2
- Each conversion generates an ISR at the end of the conversion. In the ISR for SOC0, a conversion counter is incremented and the PPB is checked to determine if the sample was delayed.
- After the program runs, the memory will contain:

conversion : the sequence of conversions using SOC0 that were delayed

- *delay* : the corresponding delay of each of the delayed conversions

18.15.1.10 ADC ePWM Triggering Multiple SOC

FILE: *adc_ex10_multiple_soc_epwm.c*

This example sets up ePWM1 to periodically trigger a set of conversions on ADCA and ADCC. This example demonstrates multiple ADCs working together to process a batch of conversions using the available parallelism across multiple ADCs.

ADCA Interrupt ISRs are used to read results of both ADCA and ADCC.

External Connections

- A0, A1, A2 and C2, C3, C4 pins should be connected to signals to be converted.

Watch Variables

18.15.1.11 ADC Burst Mode

FILE: *adc_ex11_burst_mode_epwm.c*

This example sets up ePWM1 to periodically trigger ADCA using burst mode. This allows for different channels to be sampled with each burst.

Each burst triggers 3 conversions. A0 and A1 are part of every burst while the third conversion rotates between A2, A3, and A4. This allows high importance signals to be sampled at high speed while lower priority signals can be sampled at a lower rate.

ADCA Interrupt ISRs are used to read results for ADCA.

External Connections

18.15.1.14 ADC PPB PWM trip (*adc_ppb_pwm_trip*)

FILE: adc_ex14_ppb_pwm_trip.c

This example demonstrates EPWM tripping through ADC limit detection PPB block. ADCAINT1 is configured to periodically trigger the ADCA channel 2 post initial software forced trigger. The limit detection post-processing block (PPB) is configured and if the ADC results are outside of the defined range, the post-processing block will generate an ADCxEVTy event. This event is configured as EPWM trip source through configuring EPWM XBAR and corresponding EPWM's trip zone and digital compare sub-modules. The example showcases

- one-shot
- cycle-by-cycle
- and direct tripping of PWMs through ADCAEVT1 source via Digital compare submodule.

The default limits are 0LSBs and 3600LSBs. With VREFHI set to 3.3V, the PPB will generate a trip event if the input voltage goes above about 2.9V.

Table 18-19. ADC_RESULT_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

W1S	W 1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

15	TDMAEN	R/W	0h	Enable Alternate DMA Timings. This bit controls when the DMA is triggered. 0 DMA is triggered at the same time as the CPU interrupt 1 DMA is always triggered at tDMA regardless of whether the ADC is in early interrupt mode or late interrupt mode Reset type: SYSRSn
14	EXTMUXPRESELECTEN	R/W	0h	If the ADC SOC sequence is deterministic, the ADCEXTMUX pins can be set earlier: at the end of the S+H window of the previous conversion instead of the beginning of the S+H window of the current conversion. This allows some of the external mux settling time to be pipelined with the previous conversion's conversion time. However, this will not work in the case where high-priority SOCs can arrive asynchronously. 0 ADCEXTMUX pins only change at beginning of S+H window 1 ADCEXTMUX pins are set after the end of S+H window based on pending SOCs Reset type: SYSRSn
13	ADCBSY	R	0h	ADC Busy. Set when ADC SOC is generated, cleared by hardware four ADC clocks after negative edge of S/H pulse. Bit	Field	Type	Reset	Description
7	TRIGGEROVF	R/W1C	0h	ADC Trigger Repeater 1 Oversampled Trigger Overflow. Indicates that a trigger was dropped because a trigger arrived while the repeater was still generating repeated oversampled triggers (NCOUNT was not 0 or SOCs associated with Repeater 1 were still pending). Writing a 1 will clear this flag. Note: This flag won't be set in undersampling mode or when NSEL = 0 if a trigger arrives before the previous SOCs have completed, the trigger will be passed and the overflow flags of the SOCs that were still pending will be set. Note: If software sets the clear bit on the same cycle that hardware is trying to set the flag bit, then hardware has priority and the overflow bit will not be set Reset type: SYSRSn
6	PHASEOVF	R/W1C	0h	ADC Trigger Repeater 1 Phase Delay Overflow. Indicates that a trigger was dropped because a trigger arrived when the phase delay logic was still waiting to send the delayed trigger (PHASECOUNT was not 0). Writing a 1 will clear this flag. Note: If software sets the clear bit on the same cycle that hardware is trying to set the flag bit, then hardware has priority and the overflow bit will not be set Reset type: SYSRSn
5	RESERVED	R	0h	Reserved
4	RESERVED	R	0h	Reserved
3	MODULEBUSY	R	0h	ADC Trigger Repeater 1 Module Busy indicator. In oversampling mode: 0 = Repeater 1 is idle and can accept a new repeated trigger in oversampling mode 1 = Repeater 1 still has repeated triggers remaining (NCOUNT > 0) or associated SOCs are still pending (SOCBUSY is 1) If a new oversampled trigger is received while the module is still busy, the TRIGGEROVF bit will be set and the trigger will be ignored. Reset type: SYSRSn
2	RESERVED	R	0h	Reserved
1	ACTIVEMODE	R	0h	When a trigger is received in oversampling or undersampling mode the value of MODE is copied to ACTIVEMODE. ACTIVEMODE determines if the repeater will repeat of filter triggers. Changes to MODE while the repeater is working therefore won't cause any changes in functionality until the module becomes idle and then a new trigger is received. 0 = module is oversampling 1 = module is undersampling Reset type: SYSRSn
0	MODE	R/W	0h	ADC trigger repeater 1 mode selection. Select either oversampling or undersampling mode. In oversampling mode, when the trigger selected by REP1CTL.TRIGSEL is received, the repeater will repeat the trigger REP1N.NSEL + 1 times. In undersampling mode, when the trigger selected by REP1CTL.TRIGSEL is received the first time, the repeater will pass the trigger through. Table 18-146. REP2CTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
7	TRIGGEROVF	R/W1C	0h	ADC Trigger Repeater 2 Oversampled Trigger Overflow. Indicates that a trigger was dropped because a trigger arrived while the repeater was still generating repeated oversampled triggers (NCOUNT was not 0 or SOCs associated with Repeater 2 were still pending). Writing a 1 will clear this flag. Note: This flag won't be set in undersampling mode or when NSEL = 0 if a trigger arrives before the previous SOCs have completed, the trigger will be passed and the overflow flags of the SOCs that were still pending will be set. Note: If software sets the clear bit on the same cycle that hardware is trying to set the flag bit, then hardware has priority and the overflow bit will not be set Reset type: SYSRSn
6	PHASEOVF	R/W1C	0h	ADC Trigger Repeater 2 Phase Delay Overflow. Indicates that a trigger was dropped because a trigger arrived when the phase delay logic was still waiting to send the delayed trigger (PHASECOUNT was not 0). Writing a 1 will clear this flag. Note: If software sets the clear bit on the same cycle that hardware is trying to set the flag bit, then hardware has priority and the overflow bit will not be set Reset type: SYSRSn

4	RESERVED	R	0h	Reserved
3	MODULEBUSY	R	0h	ADC Trigger Repeater 2 Module Busy indicator. In oversampling mode: 0 = Repeater 2 is idle and can accept a new repeated trigger in oversampling mode 1 = Repeater 2 still has repeated triggers remaining (NCOUNT > 0) or associated SOCs are still pending (SOCBUSY is 1) If a new oversampled trigger is received while the module is still busy, the TRIGGEROVF bit will be set and the trigger will be ignored. Reset type: SYSRSn
2	RESERVED	R	0h	Reserved
1	ACTIVEMODE	R	0h	When a trigger is received in oversampling or undersampling mode the value of MODE is copied to ACTIVEMODE. ACTIVEMODE determines if the repeater will repeat of filter triggers. 4	RES1OVF5	R-0/W1S	0h	ADC results safety checker 5 result 1 overflow flag clear. Used to clear RES1OVF status from CHECK5. In the case of a safety checker interrupt, clear all serviced OOT or OVF flags first, then clear the global interrupt flag (in the CHECKINTFLG register) using the CHKINTFLGCLR register. In the case of a safety checker X-bar event, clear all associated OOT or OVF flags to clear the event. Reset type: SYSRSn
3	RES1OVF4	R-0/W1S	0h	ADC results safety checker 4 result 1 overflow flag clear. Used to clear RES1OVF status from CHECK4. In the case of a safety checker interrupt, clear all serviced OOT or OVF flags first, then clear the global interrupt flag (in the CHECKINTFLG register) using the CHKINTFLGCLR register. In the case of a safety checker X-bar event, clear all associated OOT or OVF flags to clear the event. Reset type: SYSRSn
2	RES1OVF3	R-0/W1S	0h	ADC results safety checker 3 result 1 overflow flag clear. Used to clear RES1OVF status from CHECK3. In the case of a safety checker interrupt, clear all serviced OOT or OVF flags first, then clear the global interrupt flag (in the CHECKINTFLG register) using the CHKINTFLGCLR register. In the case of a safety checker X-bar event, clear all associated OOT or OVF flags to clear the event. Reset type: SYSRSn
1	RES1OVF2	R-0/W1S	0h	ADC results safety checker 2 result 1 overflow flag clear. Used to clear RES1OVF status from CHECK2. In the case of a safety checker interrupt, clear all serviced OOT or OVF flags first, then clear the global interrupt flag (in the CHECKINTFLG register) using the CHKINTFLGCLR register. In the case of a safety checker X-bar event, clear all associated OOT or OVF flags to clear the event. Reset type: SYSRSn
0	RES1OVF1	R-0/W1S	0h	ADC results safety checker 1 result 1 overflow flag clear. Used to clear RES1OVF status from CHECK1. In the case of a safety checker interrupt, clear all serviced OOT or OVF flags first, then clear the global interrupt flag (in the CHECKINTFLG register) using the CHKINTFLGCLR register. In the case of a safety checker X-bar event, clear all associated OOT or OVF flags to clear the event. Reset type: SYSRSn

Complex bit access types are encoded to fit into small table cells. Table 18-213 shows the codes that are used for access types in this section.

Table 18-213. ADC_SAFECHECK_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R-0	R-0	Read Returns 0s
Write Type		
W	W	Write
W1S	W1S	Write 1 to set
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

Chapter 19

Buffered Digital-to-Analog Converter (DAC)

The buffered digital-to-analog converter (DAC) is an analog module that can output a programmable, arbitrary reference voltage.

19.1 Introduction	3588
19.2 Using the DAC	3589
19.3 Lock Registers	3590
19.4 Software	3591
19.5 DAC Registers	3591

19.1 Introduction

The buffered DAC module consists of an internal 12-bit DAC and an analog output buffer that is capable of driving an external load. For driving even higher loads than typical, a trade-off can be made between load size and output voltage swing. For the load conditions of the buffered DAC, see the device-specific data sheet. The buffered DAC is a general-purpose DAC that can be used to generate a DC voltage in addition to AC waveforms such as sine waves, square waves, triangle waves and so forth. Software writes to the DAC value register can take effect immediately or can be synchronized with EPWMSYNCPER events.

19.1.2 Features

Each buffered DAC has the following features:

- 12-bit programmable internal DAC
- Selectable reference voltage source
- x1 and x2 gain modes when using internal VREFHI
- Ability to synchronize with EPWMSYNCPER

19.1.3 Block Diagram

The block diagram for the buffered DAC is shown in [Figure 19-1](#).

Figure 19-1. DAC Module Block Diagram

19.2 Using the DAC

The internal DAC's reference voltage source, DACREF, is selectable between VDAC and VREFHI. The x2 gain mode is only available when VREFHI is set as DACREF and internal reference mode is used, which can be configured by DACCTL[MODE] register. The internal reference circuit generates 1.65V and 2.5V. To select either 2.5V or 1.65V, configure ANAREF2P5 register and set ANAREFSEL register to 0 (see the *Analog Subsystem* chapter on how to switch to internal reference mode). Even though the buffered DAC has an x2 gain mode, the maximum output voltage from the buffered DAC is not greater than VDDA. Table 19-1 lists the gain mode combinations supported by the buffered DAC. In this table, x = A or B, X = Don't Care, VDAC/ VREFHI = 2.5v, VDDA = 3.3v, and DACVAL = 4095.

Table 19-1. DAC Supported Gain Mode Combinations

DACREFSEL	ANAREFSEL	ANAREF2P5	Reference Source	Reference Voltage (V)	Mode	Maximum DAC Output (V)	Support Status
0	X	X	External	VDAC	0	2.5	Supported
0	X	X	External	VDAC	1	2.5	Not Supported
1	0	0	Internal	1.65	0	1.65	Not Supported
1	0	0	Internal	1.65	1	3.3	Supported
1	0	1	Internal	2.5	0	2.5	Supported
1	0	1	Internal	2.5	1	2.5	Not Supported
1	1	X	External	VREFHI	0	2.5	Supported
1	1	X	External	VREFHI	1	2.5	Not Supported

Two sets of DACVAL registers, DACVALA and DACVALS, are present in the buffered DAC module. DACVALA is a read-only register that actively controls the buffered DAC value. DACVALS is a writable shadow register that loads into DACVALA either immediately or synchronized with the next EPWMSYNCPER event. If the clock to the buffered DAC is disabled while the buffered DAC is outputting a voltage, the output voltage remains unaffected, but DACVALA and DACVALS is no longer updated with register writes. Enabling the clock to the buffered DAC restores the DAC to the state before the clock was disabled.

The output of the internal DAC is calculated with the following equation:

$$DACOUT = \frac{DACVALA * DACREF}{4096} \quad (8)$$

The output buffer of the buffered DAC can exhibit non-linear behavior near the supply rails (VDDA/VSSA). To determine the linear range of the buffered DAC, see the device-specific data sheet.

19.2.1 Initialization Sequence

1. Enable the buffered DAC clock.
2. Set DACREF with DACREFSEL.
3. Power up the buffered DAC with DACOUTEN.
4. Wait for the power-up time to elapse before outputting a voltage. To determine the power-up time of the buffered DAC, see the device data sheet.
5. For predictable behavior of the buffered DAC, consecutive writes to DACVALS must be spaced apart according to the settling time of the buffered DAC. To determine the settling time of the buffered DAC, see the device data sheet.

19.2.2 DAC Offset Adjustment

Zero offset error is defined as the difference between the voltage at midcode (2048) and 1.25V (for 2.5-V reference voltage). DAC offset error is calibrated at 2.5-V reference voltage and loaded into the DAC offset trim register as part of the `Device_cal()` function. If the DAC is used at any reference voltage other than 2.5V, the offset trim must be adjusted to make sure the offset error performance stays within the device-specific data sheet limits. The DAC offset register is a 16-bit register that contains the 8-bit signed offset trim in the lower half of the register. Use the function call `DAC_tuneOffsetTrim()` found in `C2000Ware` to adjust the offset.

19.2.3 EPWMSYNCPER Signal

EPWMSYNCPER comes from the Time-Base submodule of the EPWM. For a detailed description of how this signal is generated, refer to the *Time-Base Submodule* section of the *Enhanced Pulse Width Modulator (ePWM)* chapter.

The EPWMSYNCPER signal that loads DACVALA when DACCTL [LOADMODE] = 1 is a level trigger load. If TBCTR and TBPRD of the EPWM are both 0, EPWMSYNCPER is held at a high level and DACVALA is immediately loaded from DACVALS irrespective of the value of DACCTL [LOADMODE]. Due to this, configure the EPWM first before setting DACCTL [LOADMODE] to 1.

Note

The name of the sync signal that the GPDAC receives from the EPWM has been updated from PWMSYNC to EPWMSYNCPER (SYNCPER/PWMSYNCPER/EPWMxSYNCPER) to avoid confusion with the other EPWM sync signals EPWMSYNCI and EPWMSYNCO. For a description of these signals, see the *Enhanced Pulse Width Modulator (ePWM)* chapter.

19.3 Lock Registers

A DACLOCK register is provided to prevent spurious writes from modifying the DACCTL, DACVALS, and DACOUTEN registers. Once a register is protected through DACLOCK, write access are locked out until the device is reset.

19.4.1.1 Buffered DAC Enable

FILE: buffdac_ex1_enable.c

This example generates a voltage on the buffered DAC output, DACOUTA/ADCINA0 and uses the default DAC reference setting of VDAC.

ExternalConnections

- When the DAC reference is set to VDAC, an external reference voltage must be applied to the VDAC pin. This can be accomplished by connecting a jumper wire from 3.3V to ADCINB0.

19.4.1.2 Buffered DAC Random

FILE: buffdac_ex2_random.c

This example generates random voltages on the buffered DAC output, DACOUTA/ADCINA0 and uses the default DAC reference setting of VDAC.

ExternalConnections

- When the DAC reference is set to VDAC, an external reference voltage must be applied to the VDAC pin. This can be accomplished by connecting a jumper wire from 3.3V to ADCINB0.

19.4.1.3 Buffered DAC Sine (buffdac_sine)

FILE: buffdac_ex3_waveform.c

This example generates a sine wave on the buffered DAC output, DACOUTA/ADCINA0 (HSEC Pin 9) and uses the default DAC reference setting of VDAC.

When the DAC reference is set to VDAC, an external reference voltage must be applied to the VDAC pin. This can be accomplished by connecting a jumper wire from 3.3V to ADCINB0.

Chapter 20 Comparator Subsystem (CMPSS)

The Comparator Subsystem (CMPSS) consists of analog comparators and supporting circuits that are useful for power applications such as peak current mode control, switched-mode power, power factor correction, voltage trip monitoring, and so forth.

See the [C2000 Real-Time Control Peripheral Reference Guide](#) for a list of all devices with modules of the same type, to determine the differences between the types, and for a list of device-specific differences within a type.

20.4 Ramp Generator	3605
20.5 Digital Filter	3609
20.6 Using the CMPSS	3610
20.7 Software	3612
20.8 CMPSS Registers	3613

20.1 Introduction

The comparator subsystem is built around a number of modules. Each subsystem contains two comparators, two reference 12-bit DACs, and two digital filters. The subsystem also includes two ramp generators. The ramp generators ramp up and down. Comparators are denoted "H" or "L" within each module where "H" and "L" represent high and low, respectively. Each comparator generates a digital output which indicates whether the voltage on the positive input is greater than the voltage on the negative input. The positive input of the comparator is driven from an external pin (see the *Analog Subsystem* chapter for mux options available to the CMPSS). The negative input can be driven by an external pin or by the programmable reference 12-bit DAC. Each comparator output passes through a programmable digital filter that can remove spurious trip signals. An unfiltered output is also available if filtering is not required.

Two ramp generator circuits are optionally available to control the reference 12-bit DAC values for the high and low comparators in the subsystem. The DAC along with a wrapper can be used to generate a ramp which is used for slope compensation in Peak Current Mode Control (PCMC) and other applications. The subsystem also works with the EPWM to support Diode Emulation Mode.

20.1.2 Features

Each CMPSS includes:

- Two analog comparators
- Two independently programmable reference 12-bit DACs
- Dual decrementing/incrementing ramp generators
- Two digital filters, max filter clock prescale = 2^{24}
- Ability to synchronize submodules with EPWMSYNCPER
- Ability to extend clear signal with EPWMBLANK
- Ability to synchronize output with SYSCLK
- Ability to latch output
- Ability to invert output
- Option to use hysteresis on the input
- Option for negative input of comparator to be driven by an external signal or by the reference DAC
- The DAC reference voltage can be set to VDDA or VDAC
- External connection to CMPSS filters
- Diode emulation support
- Ramp generator prescaler
- CMPSS Type-6 supports connection with ePWM Type-5
- CMPSS based Low Power Mode (LPM) wakeup

20.1.3 Block Diagram

The block diagram for the CMPSS is shown in Figure 20-1.

- CTRIPx(x= "H" or "L") signals are connected to the ePWM X-BAR for ePWM trip response. See the *Enhanced Pulse Width Modulator (ePWM)* chapter for more details on the ePWM X-BAR mux configuration.
- CTRIPxOUTx(x= "H" or "L") signals are connected to the Output X-BAR for external signaling. See the *General-Purpose Input/Output (GPIO)* chapter for more details on the Output X-BAR mux configuration.

20.2 Comparator

The comparator generates a high digital output when the voltage on the positive input is greater than the voltage on the negative input, and a low digital output when the voltage on the positive input is less than the voltage on the negative input. The comparator is illustrated in Figure 20-2.

Figure 20-2. Comparator Block Diagram

Voltages	Output
Voltage A > Voltage B	1
Voltage A < Voltage B	0

20.3 Reference DAC

Each reference 12-bit DAC can be configured to drive a reference voltage into the negative input of the respective comparator. The reference 12-bit DAC output is internal only and cannot be observed externally.

Two sets of DACxVAL registers, DACxVALA and DACxVALS, are present for each reference 12-bit DAC. DACxVALA is a read-only register that actively controls the reference 12-bit DAC value. DACxVALS is a writable shadow register that loads into DACxVALA either immediately or synchronized with the next EPWMSYNCPER event. The high and low reference 12-bit DAC (DACx) can optionally source the register DACxVALA value from the ramp generator instead of the register DACxVALS.

The operating range of the reference 12-bit DAC is bounded by DACREF and VSSA. The high-voltage reference is VDDA by default, but the high voltage reference can be configured to be VDAC using the COMPDACHCTL register. The reference 12-bit DAC is illustrated in [Figure 20-3](#).

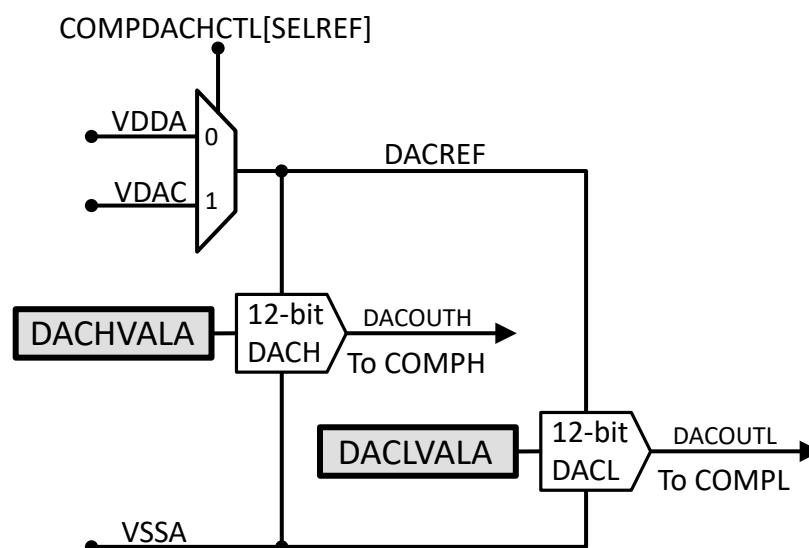

Figure 20-3. Reference DAC Block Diagram

The output of the reference 12-bit DAC can be calculated as:

$$DACOUT = \frac{(1 + DACVALA) * DACREF}{4096} \quad (9)$$

Note

- In the situations where both the DACH and DACL are driving the high and low comparators, a trip on one comparator can temporarily disturb the DAC output of the other comparator. The amount and length of time of this disturbance is specified in the device data sheet as “CMPSS DAC output disturbance” and “CMPSS DAC disturbance time”, respectively.

Users must design their system carefully so that if the input signal crosses either DACH or DACL and trips the associated comparator, the input signal stays more than a “CMPSS DAC output disturbance” away from the other comparator trip point for “CMPSS DAC disturbance time”.

- The DACH setting must always be higher than the DACL setting. If the user is not using the DACL, the DACLVALS register must be set to 0 to avoid the comparator COMPL from tripping and affecting the DACH. In this case, there is no limitation on the DACHVALS setting. Accordingly, when not using the DACH, the user must set the DACHVALS register to the maximum.
- The CMPSS instance can be enabled before programming the reference DAC values.

20.4 Ramp Generator

This section discusses the characteristics and behavior of the ramp generator.

20.4.1 Ramp Generator Overview

The ramp generator produces a falling or rising ramp input for the high-reference 12-bit DAC and the low-reference 12-bit DAC when selected. In this mode, the reference 12-bit DAC uses the most-significant 12 bits of the RAMPSTS countdown register as the input. The low 4 bits of the RAMPSTS countdown register effectively act as a prescale for the falling or rising ramp rate configurable with RAMPxSTEPVALA. There is an additional dedicated prescaler for the ramp generator configurable with the RAMPCLKDIV register.

The ramp generator is enabled by setting DACSOURCE = 1. When DACSOURCE = 1 is selected, the value of RAMPSTS is loaded from RAMPxREFS and the register remains static until the selected TRIGSYNC signal is received. After receiving the selected TRIGSYNC signal, the value of RAMPxSTEPVALA is subtracted from RAMPSTS on every subsequent SYSCLK cycle.

To prevent the subtraction from commencing a SYSCLK cycle after a TRIGSYNC event, the RAMPDLYA register that serves as a delay counter can be used to hold off the RAMPSTS subtraction or addition. On receiving a TRIGSYNC event, the value of RAMPDLYA is decremented by one on every SYSCLK cycle until the register reaches zero. So, the RAMPSTS subtraction only begins when RAMPDLYA is zero. Similarly, in increment mode (RAMPDIR=1), the RAMPSTS addition only begins when RAMPDLYA is zero.

Note

- For the ramp decrement mode of operation, set the registers COMPXINV and RAMPDIR to 0, and for the ramp increment mode of operation, set the registers COMPXINV and RAMPDIR to 1.
-

20.4.2 Ramp Generator Behavior

The ramp generator makes state changes on every rising edge of DACSOURCE, TRIGSYNC, and COMPSTS.

On the rising edge of DACSOURCE: the registers RAMPxREFA, RAMPxSTEPVALA, and RAMPDLYA are loaded with their shadow registers. Also, the register RAMPSTS is loaded with RAMPxREFS.

On the rising edge of the selected TRIGSYNC: the registers RAMPxREFA, RAMPxSTEPVALA, and RAMPDLYA are loaded with their shadow registers. Also, the register RAMPSTS is loaded with RAMPxREFS and starts decrementing in the decrement mode (RAMPDIR=0) or incrementing in the increment mode (RAMPDIR=1) when RAMPDLYA counter reaches zero.

On the rising edge of COMPSTS with RAMPLOADSEL = 1: the registers RAMPxREFA, RAMPxSTEPVALA, and RAMPDLYA are loaded with their shadow registers. Also, the register RAMPSTS is loaded with RAMPxREFS and stops decrementing in the decrement mode (RAMPDIR=0) or incrementing in the increment mode (RAMPDIR=1).

On the rising edge of COMPSTS with RAMPLOADSEL = 0: the register RAMPSTS is loaded with RAMPxREFA. So, the register RAMPSTS stops decrementing and incrementing in the decrement mode and the increment mode, respectively.

Additionally, if the value of RAMPSTS reaches zero and the ramp generator is in the decrement mode (RAMPDIR=0), the RAMPSTS register remains static at zero until the next TRIGSYNC is received. If the ramp generator is in the increment mode (RAMPDIR=1) and the value of RAMPSTS reaches 0xFFFF, the RAMPSTS register value remains at that value until the next TRIGSYNC is received. These state changes are illustrated in the ramp generator block diagram in Figure 20-4.

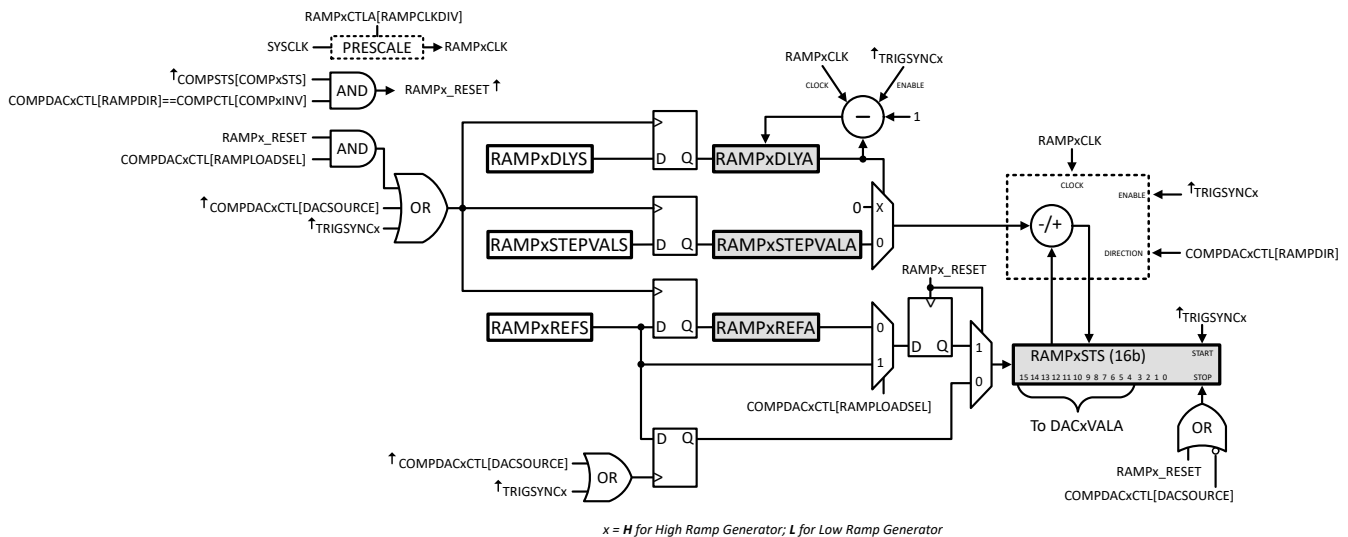

Figure 20-4. Ramp Generator Block Diagram

20.4.3 Ramp Generator Behavior at Corner Cases

Since the ramp generator makes state changes on every rising edge of TRIGSYNC and COMPHSTS, the following behavior can be expected on instances when these two events occur simultaneously or very close together.

Case 1: COMPHSTS rising edge occurs one or more cycles before TRIGSYNC rising edge. RAMPSTS stops decrementing on COMPHSTS rising edge event. RAMPSTS starts decrementing on TRIGSYNC rising edge event when RAMPDLYA reaches 0.

Case 2: COMPHSTS rising edge occurs simultaneously as TRIGSYNC rising edge. EPWMSYNCPER rising edge event takes precedence and RAMPSTS starts decrementing when RAMPDLYA reaches 0. COMPHSTS rising edge event is ignored and does not halt RAMPSTS.

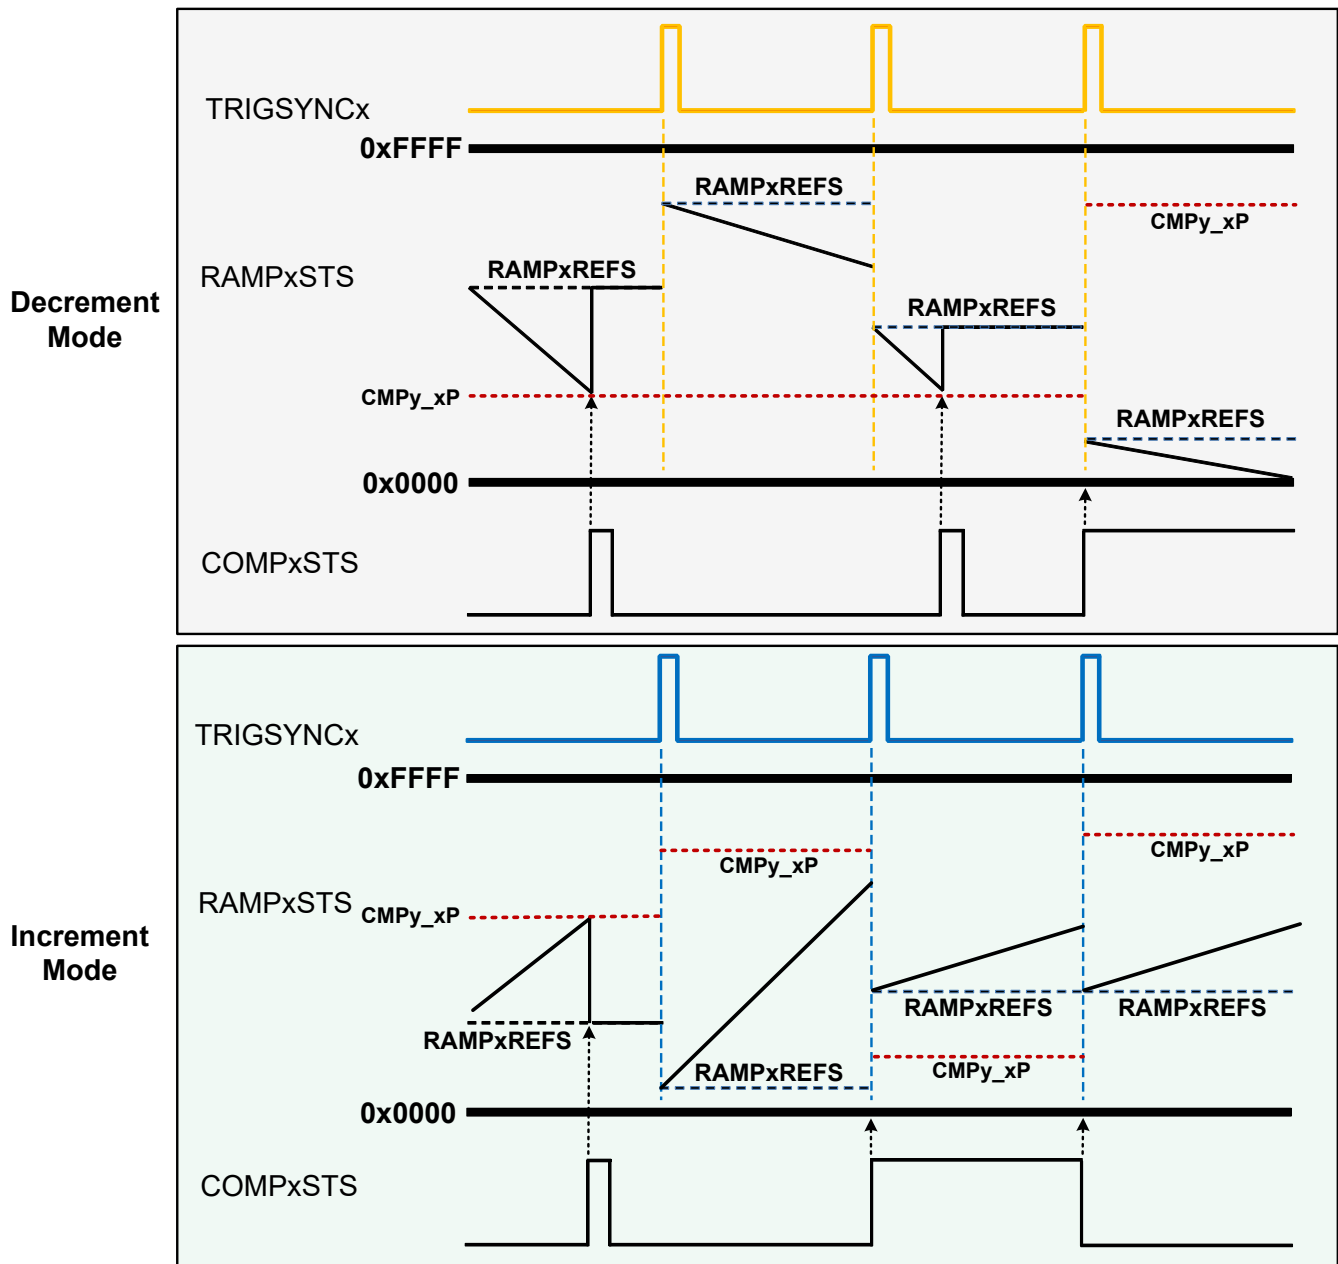

Case 3: COMPHSTS rising edge occurs one or more cycles after TRIGSYNC rising edge but before RAMPDLYA reaches 0. RAMPSTS does not decrement when RAMPDLYA reaches 0.

Case 4: COMPHSTS rising edge occurs simultaneously as RAMPDLYA reaches 0 from TRIGSYNC rising edge. RAMPSTS does not decrement.

This behavior is also illustrated in [Figure 20-5](#).

Note

For the ramp decrement mode of operation, set the registers COMPXINV and RAMPDIR to 0, and for the ramp increment mode of operation, set the registers COMPXINV and RAMPDIR to 1.

x = H for High Ramp Generator; L for Low Ramp Generator
 y = CMPSS module number

Figure 20-5. Ramp Generator Behavior

20.5 Digital Filter

The digital filter works on a window of FIFO samples (SAMPWIN) taken from the input. The filter output resolves to the majority value of the sample window, where majority is defined by the threshold (THRESH) value. If the majority threshold is not satisfied, the filter output remains unchanged.

For proper operation, the value of THRESH must be greater than $SAMPWIN / 2$ and less than or equal to SAMPWIN.

A prescale function (CLKPRESCALE) determines the filter sampling rate, where the filter FIFO captures one sample every prescale system clocks. Old data from the FIFO is discarded.

Note that for SAMPWIN, THRESH and CLKPRESCALE, the internal number used by the digital filter is + 1 in all cases. In essence, samples = SAMPWIN + 1, threshold = THRESH + 1 and prescale = CLKPRESCALE + 1.

A conceptual model of the digital filter is shown in Figure 20-6.

Figure 20-6. Digital Filter Behavior

Equivalent C code of the filter implementation is:

```

if (FILTER_OUTPUT == 0) {
    if (Num_1s_in_SAMPWIN >= THRESH) {
        FILTER_OUTPUT = 1;
    }
}
else {
    if (Num_0s_in_SAMPWIN >= THRESH) {
        FILTER_OUTPUT = 0;
    }
}

```

20.5.1 Filter Initialization Sequence

For proper operation of the digital filter, the following initialization sequence is recommended:

1. Configure and enable the comparator for operation.
2. Configure the digital filter parameters for operation:
 - Set SAMPWIN for the number of samples to monitor in the FIFO window.
 - Set THRESH for the threshold required for majority qualification.
 - Set CLKPRESCALE for the digital filter clock prescale value.
3. Initialize the sample values in the digital FIFO window by setting FILINIT.
4. Clear COMPSTS latch using COMPSTSCLR, if the latched path is desired.
5. Configure the CTRIP and CTRIPOUT signal paths.
6. If desired, configure the destination module, for example, ePWM, GPIO, and so on to accept the filtered signals.

20.6 Using the CMPSS

20.6.1 LATCHCLR, EPWMSYNCPER, and EPWMBLANK Signals

The LATCHCLR signal holds the digital filter, synchronization block, and the latch output in reset (0) after the required delays. The LATCHCLR signal is activated in software using xLATCHCLR (x = H or L). The LATCHCLR signal can also be activated by EPWMSYNCPER when xSYNCCLREN (x = H or L) is set. If a longer LATCHCLR signal is required, the EPWMBLANK signal can be used to extend the LATCHCLR signal by setting BLANKEN.

EPWMSYNCPER and EPWMBLANK (BLANKWDW) come from the Time-Base and Digital Compare submodules of the EPWM, respectively. For a detailed description of how these two signals are generated, refer to the respective submodule section in the *Enhanced Pulse Width Modulator (ePWM)* chapter.

The EPWMSYNCPER signal that loads DACxVALA when COMPDACHCTL[SWLOADSEL] = 1 is a level trigger load. If TBCTR and TBPRD of the EPWM are both 0, EPWMSYNCPER is held at level high and DACxVALA is loaded immediately from DACxVALS irrespective of the value of COMPDACHCTL[SWLOADSEL]. Due to this, configure the EPWM first before setting COMPDACHCTL[SWLOADSEL] to 1.

Note

The name of the sync signal that the CMPSS receives from the EPWM has been updated from PWMSYNC to EPWMSYNCPER (SYNCPER/PWMSYNCPER/EPWMxSYNCPER) to avoid confusion with the other EPWM sync signals EPWMSYNCL and EPWMSYNCO. For a description of what are these signals, see the *Enhanced Pulse Width Modulator (ePWM)* chapter.

20.6.2 Synchronizer, Digital Filter, and Latch Delays

The synchronization block adds a delay of 1-2 sysclks. If the digital filter is bypassed (all filter settings are 0), the digital filter adds a delay of 2 sysclks. The latch adds 1 sysclk delay.

20.6.3 Calibrating the CMPSS

The CMPSS has two sources of offset errors: comparator offset error and compdac offset error. In the data sheet the comparator offset error is referred to as **Input referred offset error** and compdac offset error is referred to as **Static offset error**. See the device data sheet for their values.

If both inputs of the comparator are driven from a pin, only the comparator offset error applies. However if the inverting input of the comparator is driven from the compdac, then only the compdac offset error applies. This is because the compdac offset error includes comparator offset error.

Due to the offset errors, the CMPSS must be calibrated to make sure trips happen at the expected levels. The following flow outlines how the calibration can be performed if the inverting input of the comparator is driven from the compdac.

Notes before calibration:

1. A static DC signal is required on the non-inverting input of the comparator.
2. Hysteresis can be disabled for calibration and can be re-enabled after calibration is complete.
3. A noisy input can make calibration difficult, so use the latch with non-zero filter settings depending on how noisy is the signal on the non-inverting input.

This approach sweeps down the compdac:

1. Set the starting compdac value to max, 0xFFFF.
 - Optional: Instead of setting the starting compdac value to maximum, set to **Vtarget + Static offset error + Margin**. Where **Vtarget** is the approximate DC voltage on the non-inverting input, **Static offset error** is the compdac offset error specification and **Margin** is some amount of guard band. This can lead to a faster calibration but only works if **Vtarget** is known. Alternatively, if **Vtarget** is unknown, the ADC can be used to convert **Vtarget**.
2. Decrement compdac value by 1.
3. Wait for compdac to settle.
4. Clear latch.
5. Wait for possible latch set.
6. If latch is set, trip code is found exit.
 - Optional: The trip code can be double checked by:
 - a. Increasing compdac value by 1.
 - b. Clear latch.
 - c. Wait for possible latch set.
 - d. Latch can be unset.
7. If latch is unset, go back to step 2 and repeat.

It is also possible to calibrate the CMPSS, if both inputs of the comparator are driven from a pin. For this case, the flow stays the same but the voltage on the inverting pin of the comparator is swept externally.

20.6.4 Enabling and Disabling the CMPSS Clock

If the clock to the CMPSS module is disabled while the comparator is active, the following behavior can be expected:

- The comparator remains unaffected and continues to trip from voltages on the inputs.
- If the reference 12-bit DAC is driving the negative input of the comparator, the voltage on the negative input remains static and unaffected but DACVALA can no longer be updated from the ramp generator or DACVALS.
- The ramp generator, synchronize block and digital filter freeze on their current states.

Enabling the clock to the CMPSS restores the clock to the state before the clock was disabled.

20.7.1 CMPSS Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/cmpss

Cloud access to these examples is available at the following link: dev.ti.com [C2000Ware Examples](#).

20.7.1.1 CMPSS Asynchronous Trip

FILE: cmpss_ex1_asynch.c

This example enables the CMPSS1 COMPH comparator and feeds the asynchronous CTRIPOUTH signal to the GPIO14/OUTPUTXBAR3 pin and CTRIPH to GPIO15/EPWM8B.

CMPSS is configured to generate trip signals to trip the EPWM signals. CMPIN1P is used to give positive input and internal DAC is configured to provide the negative input. Internal DAC is configured to provide a signal at VDD/2. An EPWM signal is generated at GPIO15 and is configured to be tripped by CTRIPOUTH.

When a low input(VSS) is provided to CMPIN1P,

- Trip signal(GPIO14) output is low
- PWM8B(GPIO15) gives a PWM signal

When a high input(higher than VDD/2) is provided to CMPIN1P,

- Trip signal(GPIO14) output turns high
- PWM8B(GPIO15) gets tripped and outputs as high

External Connections

- Give input on CMPIN1P (HSEC Pin 15)
- Outputs can be observed on GPIO14 and GPIO15 using an oscilloscope

Watch Variables

- None

20.7.1.2 CMPSS Digital Filter Configuration

FILE: cmpss_ex2_digital_filter.c

This example enables the CMPSS1 COMPH comparator and feeds the output through the digital filter to the GPIO14/OUTPUTXBAR3 pin.

CMPIN1P is used to give positive input and internal DAC is configured to provide the negative input. Internal DAC is configured to provide a signal at VDD/2.

When a low input(VSS) is provided to CMPIN1P,

- GPIO14 output is low

When a high input(higher than VDD/2) is provided to CMPIN1P,

- GPIO14 output turns high

Enhanced Capture (eCAP) and High Resolution Capture (HRCAP)

This chapter describes the enhanced capture (eCAP) module and the high resolution capture (HRCAP) module, which are used in systems where accurate timing of external events is important.

The enhanced capture (eCAP) module is a Type 3 eCAP.

The high resolution capture (HRCAP) module is part of the eCAP module. HRCAP measures the width of external pulses to a higher degree of accuracy than the eCAP module.

See the [C2000 Real-Time Control Peripheral Reference Guide](#) for a list of all devices with an eCAP and HRCAP module of the same type, to determine the differences between the types, and for a list of device-specific differences within a type. A detailed description of all referenced functions can be found in the C2000Ware documentation.

21.1 Introduction

21.1.1 Features

The features of the eCAP module include:

- Speed measurements of rotating machinery (for example, toothed sprockets sensed by way of Hall sensors)
- Elapsed time measurements between position sensor pulses
- Period and duty cycle measurements of pulse train signals
- Decoding current or voltage amplitude derived from duty cycle encoded current/voltage sensors

The eCAP module features described in this chapter include:

- 4-event time-stamp registers (each 32 bits)
- Edge polarity selection for up to four sequenced time-stamp capture events
- Interrupt on either of the four events
- Single-shot capture of up to four event time-stamps
- Continuous mode capture of time stamps in a four-deep circular buffer
- Absolute time-stamp capture
- Difference (Delta) mode time-stamp capture
- When not used in capture mode, the eCAP module can be configured as a single-channel PWM output

The capture functionality of the Type 1 eCAP is enhanced from the Type 0 eCAP with the following added features:

- Event filter reset bit
 - Writing a 1 to ECCTL2[CTRFILTRESET] clears the event filter, the modulo counter, and any pending interrupts flags. Resetting the bit is useful for initialization and debug. Note that this is not applicable for signal monitoring interrupts, which do not get affected by the event filter reset bit.
- Modulo counter status bits
 - The modulo counter (ECCTL2 [MODCNRSTS]) indicates which capture register is loaded next. In the Type 0 eCAP, to know the current state of the modulo counter was not possible
- DMA trigger source
 - eCAPxDMA was added as a DMA trigger. CEVT[1-4] can be configured as the source for eCAPxDMA.
- Input multiplexer
 - ECCTL0 [INPUTSEL] selects one of 128 input signals, which are detailed in [Section 21.3](#).
- EALLOW protection
 - EALLOW protection was added to critical registers. To maintain software compatibility with Type-0, configure DEV_CFG_REGS.ECAPTYPE to make these registers unprotected.

The capture functionality of the Type 2 eCAP is enhanced from the Type 1 eCAP with the following added features:

- Added ECAPxSYNCINSEL register
 - ECAPxSYNCINSEL register is added for each eCAP to select an external SYNCIN. Every eCAP can have a separate SYNCIN signal.

The capture functionality of the Type 3 eCAP is enhanced from the Type 2 eCAP with the following added features:

- Two signal monitoring units to monitor edge, pulse width, and period
 - Signal monitoring can optionally be tightly coupled with ePWM global load strobes and trip events
- Increased the number of multiplexed capture inputs from 128 to 256
- DMA event generation capability in PWM mode of operation
- ADC SOC generation capability, to trigger ADC conversion

21.2 Description

The eCAP module represents one complete capture channel that can be instantiated multiple times, depending on the target device. In the context of this guide, one eCAP channel has the following independent key resources:

- Capture inputs can be connected using the Input X-BAR
- 256:1 input multiplexer
- Output X-BAR is used to configure output in APWM mode
- 32-bit time base (counter)
- 4 x 32-bit time-stamp capture registers (CAP1-CAP4)
- Four-stage sequencer (modulo4 counter) that is synchronized to external events, eCAP pin rising/falling edges.
- Modulo counter status register (MODCNTRSTS) to indicate sequencer state
- Independent edge polarity (rising/falling edge) selection for all four events
- Input capture signal prescaling (from 2-62 or bypass)
- One-shot compare register (two bits) to freeze captures after 1-4 time-stamp events
- Control for continuous time-stamp captures using a four-deep circular buffer (CAP1-CAP4) scheme
- Interrupt capabilities on any of the four capture events
- Separate DMA trigger
- EALLOW protection to control registers
- Signal monitoring capability for edge, pulse width, and period
- DMA event generation capability in APWM mode
- ADC SOC event generation capability, to trigger ADC conversion

21.3 Configuring Device Pins for the eCAP

The Input X-BAR connects the device pins to the module as input. Any GPIO on the device can be configured as an input. The GPIO input qualification can be set to synchronous or asynchronous mode by setting the GPxQSELn register bits. Using synchronized inputs can help with noise immunity but affects the eCAP accuracy by ± 2 cycles. The internal pull-ups can be configured in the GPyPUD register. Since the GPIO mode is used, the GPyINV register can invert the signals.

New to the Type 1 eCAP module, a 128:1 input multiplexer must also be configured (see [Figure 21-3](#)). This multiplexer can select a variety of inputs detailed in [Table 21-1](#) by configuring ECCTL0.INPUTSEL.

The Output X-BAR must be used to connect output signals to the OUTPUTXBARx output locations. The GPIO mux must then be configured to connect the OUTPUTXBARx lines to any of several IO pins with the GPIO mux. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux, GPIO settings, and XBAR configuration.

Note

ECAPxIN has to be at least $2 \times \text{SYSCLK}$ -cycles wide to be properly captured by the eCAP module; otherwise, the input pulse can get missed from sampling by the SYSCLK.

21.4 Capture and APWM Operating Mode

Use the eCAP module resources to implement a single-channel PWM generator (with 32-bit capabilities) when the eCAP module is not being used for input captures. The counter operates in count-up mode, providing a time-base for asymmetrical pulse width modulation (PWM) waveforms. The CAP1 and CAP2 registers become the active period and compare registers, respectively, while CAP3 and CAP4 registers become the period and compare shadow registers, respectively. Figure 21-1 is a high-level view of both the capture and auxiliary pulse-width modulator (APWM) modes of operation.

Figure 21-2 further describes the output of the eCAP in APWM mode based on the CMP and PRD values.

- A. A single pin is shared between CAP and APWM functions. In capture mode, the pin is an input; in APWM mode, the pin is an output.
- B. In APWM mode, writing any value to CAP1/CAP2 active registers also writes the same value to the corresponding shadow registers CAP3/CAP4. This emulates immediate mode. Writing to the shadow registers CAP3/CAP4 invokes the shadow mode.

- A. The HRCAP submodule is not available on all eCAP modules; in this case, the high-resolution muxes and hardware are not implemented.

Figure 21-3. eCAP Block Diagram

21.5.1 Event Prescaler

An input capture signal (pulse train) can be prescaled by $N = 2-62$ (in multiples of 2) or can bypass the prescaler. This is useful when very high frequency signals are used as inputs. Figure 21-4 shows a functional diagram and Figure 21-5 shows the operation of the prescale function. The event prescaler can be reset by setting the ECCTL2.CTRFILTRESET register bit.

- A. When a prescale value of 1 is chosen (ECCTL1[13:9] = 0,0,0,0,0), the input capture signal bypasses the prescale logic completely.
- B. The first Rise edge after Prescale configuration change is not passed to Capture logic, prescaler value takes into effect on the second rising edge after the configuration.

Figure 21-4. Event Prescale Control

Figure 21-5. Prescale Function Waveforms

21.5.2 Glitch Filter

A glitch filter is included to reduce internal and external noise glitches on the source signal being measured by the eCAP.

The glitch filter can be used to filter out glitches of a specified time period in terms of SYSCLK cycles. The supported range is from 1 to 15 cycles. By default, the glitch filter is disabled (ECCCTL0[QUALPRD]=0) to maintain compatibility.

Note

The glitch filter can be disabled when using HRCAP as the filter changes the pulse width of the signal. Also note that when enabled, the glitch filter delays the signal by QUALPRD+1, which must be accounted for in applications utilizing the feature.

21.5.3 Edge Polarity Select and Qualifier

Functionality and features include:

- Four independent edge polarity (rising edge/falling edge) selection muxes are used, one for each capture event.
- Each edge (up to 4) is event qualified by the Modulo4 sequencer.
- The edge event is gated to the respective CAPx register by the Mod4 counter. The CAPx register is loaded on the falling edge.

21.5.4 Continuous/One-Shot Control

Operation of eCAP in Continuous/One-Shot mode:

- The Mod4 (2-bit) counter is incremented using edge qualified events (CEVT1-CEVT4).
- The Mod4 counter continues counting (0->1->2->3->0) and wraps around unless stopped.
- During one-shot operation, a 2-bit stop register (STOP_WRAP) is used to compare the Mod4 counter output, and when equal, stops the Mod4 counter and inhibits further loads of the CAP1-CAP4 registers. In this mode, if TSCCTR counter is configured to reset on capture event (CEVTx) by configuring ECCTL1.CTRRSTx bit, the operation still keeps resetting the TSCCTR counter on capture event (CEVTx) after the STOP_WRAP value is reached and re-arm (REARM) has not occurred.

The continuous/one-shot block controls the start, stop and reset (zero) functions of the Mod4 counter, using a mono-shot type of action that can be triggered by the stop-value comparator and re-armed using software control.

Once armed, the eCAP module waits for 1-4 (defined by stop-value) capture events before freezing both the Mod4 counter and contents of CAP1-4 registers (time stamps).

Re-arming prepares the eCAP module for another capture sequence. Also, re-arming clears (to zero) the Mod4 counter and permits loading of CAP1-4 registers again, providing the CAPLDEN bit is set.

In continuous mode, the Mod4 counter continues to run (0->1->2->3->0, the one-shot action is ignored, and capture values continue to be written to CAP1-4 in a circular buffer sequence.

Figure 21-6. Details of the Continuous/One-shot Block

21.5.5 32-Bit Counter and Phase Control

This counter provides the time-base for event captures, and is clocked using the system clock.

A phase register is provided to achieve synchronization with other counters using a hardware and software forced sync. This is useful in APWM mode when a phase offset between modules is needed.

On any of the four event loads, an option to reset the 32-bit counter is given. This is useful for time difference capture. The 32-bit counter value is captured first, then the counter value is reset to 0 by any of the LD1-LD4 signals.

21.5.6 CAP1-CAP4 Registers

These 32-bit registers are supplied by the 32-bit counter timer bus, CTR[0-31], and are loaded (capture a time-stamp) when their respective LD inputs are strobed.

Control bit CAPLDEN can inhibit loading of the capture registers. During one-shot operation, this bit is cleared (loading is inhibited) automatically when a stop condition occurs, StopValue = Mod4.

CAP1 and CAP2 registers become the active period and compare registers, respectively, in APWM mode.

CAP3 and CAP4 registers become the respective shadow registers (APRD and ACMP) for CAP1 and CAP2 during APWM operation.

21.5.7 eCAP Synchronization

eCAP modules can be synchronized with each other by selecting a common SYNCIN source. SYNCIN source for eCAP can be either software sync-in or external sync-in. The external sync-in signal can come from eCAP, X-Bar or EPWM. The SWSYNC of the eCAP module is logical ORed with the SYNC signal as shown in Figure 21-7. The SYNC signal is defined by the selection of ECAPxSYNCINSEL[SEL] as shown in Figure 21-8.

Note

ECAPxSYNCOUT going to their own ECAPSYNCIN multiplexer is disabled. For example, ECAP1SYNCOUT cannot be a sync in to ECAP1, but ECAP1SYNCOUT can be a sync in to ECAP2, ECAP3, and so on.

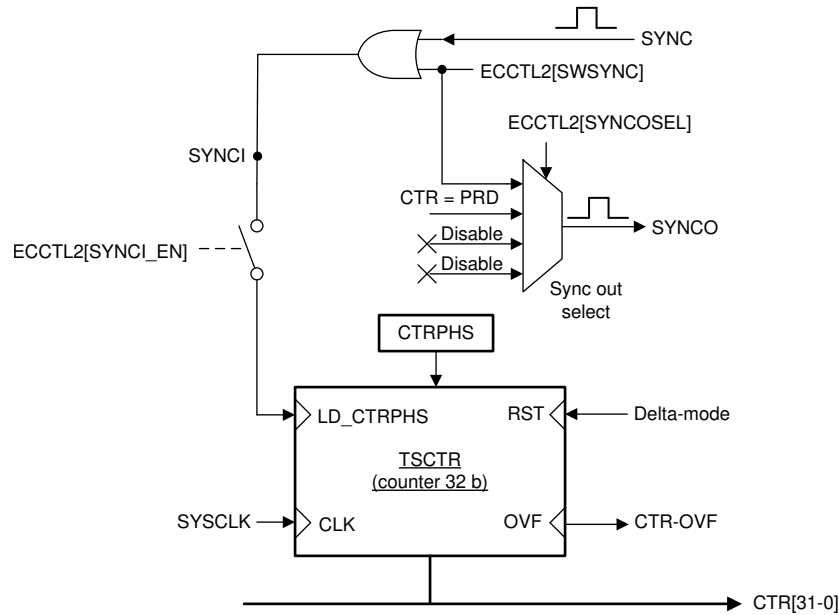

Figure 21-7. Details of the Counter and Synchronization Block

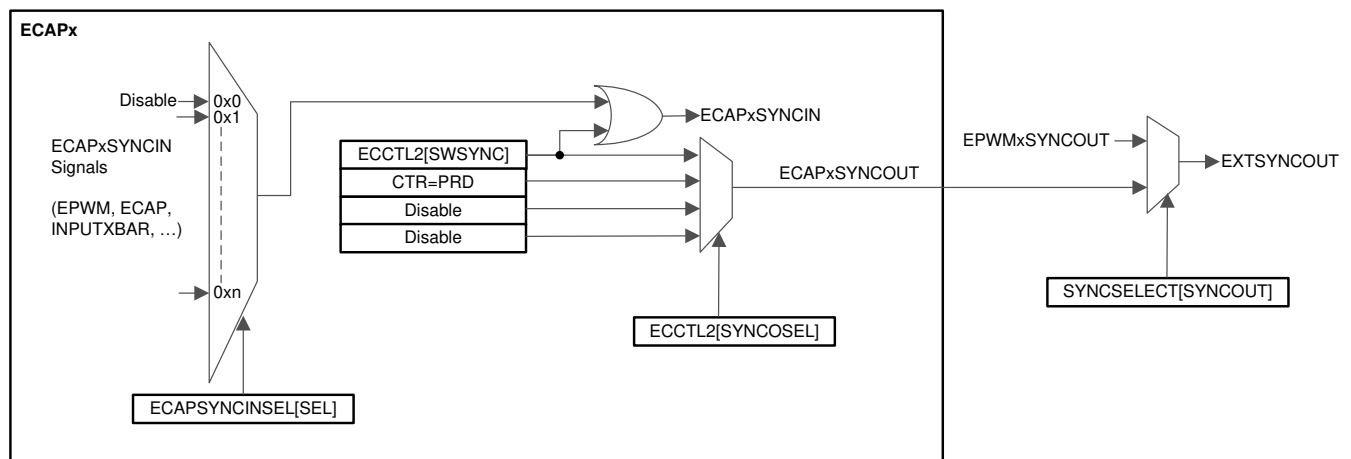

Figure 21-8. eCAP Synchronization Scheme

21.5.7.1 Example 1 - Using SWSYNC with ECAP Module

Implement the following steps to use SWSYNC with ECAP1 and ECAP2.

- Configure ECAP[1..2].ECAPSYNCINSEL.SEL = 0x0 to disable external SYNCIN coming to eCAP1.
- Configure ECAP[1..2].ECCTL2.SWSYNC = 0x1, to force Software Synchronization of the TSCTR counter.

To use SWSYNC with other eCAP modules, make sure that the previous eCAP chain is not generating a SYNCOUT signal that interferes with the software synchronization.

21.5.8 Interrupt Control

Operation and features of the eCAP interrupt control include (see [Figure 21-9](#)):

- An interrupt can be generated on capture events (CEVT1-CEVT4, CTROVF) or APWM events (CTR = PRD, CTR = CMP).
- An interrupt can be generated on signal monitoring errors (MUNIT_1_ERROR_EVT1, MUNIT_1_ERROR_EVT1, MUNIT_2_ERROR_EVT1, MUNIT_2_ERROR_EVT2)
- A counter overflow event (FFFFFFFF->00000000) is also provided as an interrupt source (CTROVF).
- The capture events are edge and sequencer-qualified (ordered in time) by the polarity select and Mod4 gating, respectively.
- One of these events can be selected as the interrupt source (from the eCAPx module) going to the PIE and CLA.
- Seven interrupt events (CEVT1, CEVT2, CEVT3, CEVT4, CNTOVF, CTR=PRD, CTR=CMP) can be generated.
- An additional four interrupt events (MUNIT_1_ERROR_EVT1, MUNIT_1_ERROR_EVT1, MUNIT_2_ERROR_EVT1, MUNIT_2_ERROR_EVT2) can be generated from the signal monitoring unit.
- The interrupt enable register (ECEINT) is used to enable/disable individual interrupt event sources. The interrupt flag register (ECFLG) indicates if any interrupt event has been latched and contains the global interrupt flag bit (INT). An interrupt pulse is generated to the PIE only if any of the interrupt events are enabled, the flag bit is 1, and the INT flag bit is 0. The interrupt service routine must clear the global interrupt flag bit and the serviced event using the interrupt clear register (ECCLR) before any other interrupt pulses are generated. All interrupt flags are cleared upon an event filter reset by writing a 1 to ECCTL2[CLRFILTRESET]. To force an interrupt event, use the interrupt force register (ECFRC). This is useful for test purposes.

Note

The CEVT1, CEVT2, CEVT3, CEVT4 flags are only active in capture mode (ECCTL2[CAP/APWM == 0]). The CTR=PRD, CTR=CMP flags are only valid in APWM mode (ECCTL2[CAP/APWM == 1]). CNTOVF flag is valid in both modes.

Figure 21-9. Interrupts in eCAP Module

21.5.9 DMA Interrupt

On Type 0 eCAP modules, the CPU was required to begin data transfers using DMA. New to the Type 1 eCAP, a separate DMA Trigger (ECAP_DMA_INT) enables continuous transfer of capture data from eCAP registers to on-chip memory using DMA. Any one of the four available interrupt events (LD1, LD2, LD3, and LD4) can be selected as the trigger source for ECAP_DMA_INT using ECCTL2 [DMAEVTSEL].

New to the Type 3 eCAP is the ability to trigger DMA events in APWM mode. Any one of three available events (period match, compare match, or both) can be selected as the trigger source for ECAP_DMA_INT using ECCTL2 [DMAEVTSEL].

21.5.10 ADC SOC Event

Type 3 introduces the capability to generate ADC SOC events in capture mode and in APWM mode of operation. The ability to start ADC conversions allows for increased APWM functionality, as well as the ability to synchronize capture events with ADC samples.

In capture mode, one of the four available interrupt events (CEVT1, CEVT2, CEVT3, and CEVT4) can be selected as ECAP_SOC_EVT using ECCCTL0[SOCEVTSEL].

In APWM mode, any one of three available events (period match, compare match, or both) can be selected as ECAP_SOC_EVT using ECCCTL0[SOCEVTSEL].

21.5.11 Shadow Load and Lockout Control

In capture mode, this logic inhibits (locks out) any shadow loading of CAP1 or CAP2 from APRD and ACMP registers, respectively.

In APWM mode, shadow loading is active and two choices are permitted:

- Immediate - APRD or ACMP are transferred to CAP1 or CAP2 immediately upon writing a new value.
- On period equal, CTR[31:0] = PRD[31:0].

21.5.12 APWM Mode Operation

Main operating highlights of the APWM section:

- The time-stamp counter bus is made available for comparison by way of 2 digital (32-bit) comparators.
- When CAP1/2 registers are not used in capture mode, their contents can be used as Period and Compare values in APWM mode.
- Double buffering is achieved using shadow registers APRD and ACMP (CAP3/4). The shadow register contents are transferred over to CAP1/2 registers, either immediately upon a write, or on a CTR = PRD trigger.
- In APWM mode, writing to CAP1/CAP2 active registers also writes the same value to the corresponding shadow registers CAP3/CAP4. This emulates immediate mode. Writing to the shadow registers CAP3/CAP4 invokes the shadow mode.
- During initialization, write to the active registers for both period and compare. This automatically copies the initial values into the shadow values. For subsequent compare updates during run-time, use the shadow registers.

Figure 21-10. PWM Waveform Details Of APWM Mode Operation

The behavior of APWM active high mode (APWMPOL == 0) is as follows:

CMP = 0x00000000, output low for duration of period (0% duty)

CMP = 0x00000001, output high 1 cycle

CMP = 0x00000002, output high 2 cycles

CMP = PERIOD, output high except for 1 cycle (<100% duty)

CMP = PERIOD+1, output high for complete period (100% duty)

CMP > PERIOD+1, output high for complete period

The behavior of APWM active low mode (APWMPOL == 1) is as follows:

CMP = 0x00000000, output high for duration of period (0% duty)

CMP = 0x00000001, output low 1 cycle

CMP = 0x00000002, output low 2 cycles

CMP = PERIOD, output low except for 1 cycle (<100% duty)

CMP = PERIOD+1, output low for complete period (100% duty)

CMP > PERIOD+1, output low for complete period

21.5.13 Signal Monitoring Unit

The signal monitoring unit can be used for edge, pulse width, and period monitoring of ECAP input signals. This allows for detection that is useful for many applications. For example, EPWM pulse width boundary monitoring can be accomplished for safety applications.

The high-level features of the signal monitoring unit include:

- Measure pulse width (high or low) and check if it is in expected range
- Measure period (rise-to-rise or fall-to-fall) and check if it is in expected range
- Monitor signal edge (rise or fall) and check if it occurs in a user-programmed time window

21.5.13.1 Pulse Width and Period Monitoring

The signal monitoring unit has the ability to measure pulse width (either low or high) or period (rise-to-rise edge or fall-to-fall edge) and automatically generate an error when the pulse width is outside of a programmable expected range.

The expected pulse width range is programmable using the following configuration registers (or their respective shadow registers):

- MUNIT_#_MIN programs the minimum pulse width capture value
- MUNIT_#_MAX programs the maximum pulse width capture value

Any pulse width outside of these programmed bounds triggers one of two error events:

- MUNIT_#_ERROR_EVT1 generated when measured pulse width is less than MUNIT_#_MIN
- MUNIT_#_ERROR_EVT2 generated when measured pulse width is greater than MUNIT_#_MAX

The following diagram provides an example in which the measured pulse width exceeds the MAX value, generating an ERROR_EVT2 event.

Figure 21-12. ECAP Signal Monitoring Unit Pulse Width Error Example

Configuration Requirements

To enable this mode, the following settings must be configured:

- Absolute mode must be set for the ECAP counter, so that the counter is free running and does not get reset on any capture events
- Continuous mode must be enabled (one-shot mode can be used, but is not recommended given the short duration)
- Sync feature for the counter must be disabled (ECCTL2.SYNCI_EN = 0)
- A minimum of two captures must be enabled (ECCTL2.STOP_WRAP >= 1, and at least CAP1 and CAP2 enabled)

- Capture Edge (ECCTL1.CAPxPOL) of used capture modules (any of CAP1 to CAP4) must be configured to capture two edges of interest
 - High pulse: one rising edge and one falling edge
 - Low pulse: one rising edge and one falling edge
 - Period rise-to-rise: two rising edges
 - Period fall-to-fall: two falling edges

Note

If a pulse width is greater than the MAX value, a second edge can arrive late or never even occur. Because of this, the DISABLE_EARLY_MAX_ERR field in the MUNIT_#_CTL register can be used to choose when a MAX error occurs. By setting the bit to 0, an error is generated as soon as the pulse width is greater than the specified maximum value. By setting the bit to 1, an error is generated when the second event has occurred.

21.5.13.2 Edge Monitoring

The signal monitoring unit has the ability to monitor and check if a rise or fall edge occurs within a specified time window and automatically generate an error when an edge occurs outside of this window.

The time window of an expected edge event can be programmed using the following configuration registers (or their respective shadow registers):

- MUNIT_#_MIN programs the minimum pulse width capture value
- MUNIT_#_MAX programs the maximum pulse width capture value

Any edge that occurs outside of these programmed bounds triggers the following error event:

- MUNIT_#_ERROR_EVT1 generated when edge occurs outside the bounds of MUNIT_#_MIN and MUNIT_#_MAX.

Additionally, ERROR_EVT2 is generated if either MIN or MAX did not occur between two sync events.

The following diagram provides an example in which a rising edge does not occur during the expected window, generating an ERROR_EVT1 event.

Figure 21-13. ECAP Signal Monitoring Unit Edge Error Example

Configuration Requirements

To enable this mode, the following settings must be configured:

- The ECAP counter must be synced with an EPWM module
- Absolute mode must be set for the ECAP counter, so that the counter is free running and does not get reset on any capture events
- Continuous mode can be enabled (one-shot mode can be used, but is not recommended given the modes short duration)
- A minimum of one capture can be enabled (ECCTL2.STOP_WRAP \geq 0, and at least CAP1 enabled)
- Capture Edge (ECCTL1.CAPxPOL) of used capture modules (any of CAP1 to CAP4) must be configured to capture an edge of interest
- The time window defined using MIN and MAX can not cross the sync boundary

Note

The following are important considerations when configuring the edge monitoring feature:

- If the EPWM counter or ECAP counter are loaded with a non-zero phase value, the MIN and MAX values must be adjusted accordingly in SW. This also applies when the glitch filter is enabled, as the glitch filter delays the signal by QUALPRD+1
- The edge monitoring logic restarts on a sync event. This is to avoid any deadlock in case MIN, MAX, or both events do not occur between two sync events. ERROR_EVT2 is generated, if MIN or MAX match did not occur between two sync events
- The time window defined using MIN and MAX can not cross the sync boundary

21.6 Application of the eCAP Module

The following sections provide applications examples to show how to operate the eCAP module.

21.6.1 Example 1 - Absolute Time-Stamp Operation Rising-Edge Trigger

Figure 21-14 shows an example of continuous capture operation (Mod4 counter wraps around). In this figure, TSCTR counts-up without resetting and capture events are qualified on the rising edge only, this gives period (and frequency) information.

On an event, the TSCTR contents (time-stamp) is first captured, then Mod4 counter is incremented to the next state. When the TSCTR reaches FFFFFFFF (maximum value), the Mod4 counter wraps around to 00000000 (not shown in Figure 21-14), if this occurs, the CTROVF (counter overflow) flag is set, and an interrupt (if enabled) occurs. Captured Time-stamps are valid at the point indicated by the diagram (after the fourth event); hence, event CEVT4 can conveniently be used to trigger an interrupt and the CPU can read data from the CAPx registers.

Figure 21-14. Capture Sequence for Absolute Time-stamp and Rising-Edge Detect

21.6.2 Example 2 - Absolute Time-Stamp Operation Rising- and Falling-Edge Trigger

In Figure 21-15, the eCAP operating mode is almost the same as in the previous section except capture events are qualified as either rising or falling edge, this now gives both period and duty cycle information, that is: Period1 = $t_3 - t_1$, Period2 = $t_5 - t_3$, ...and so on. Duty Cycle1 (on-time %) = $(t_2 - t_1) / \text{Period1} \times 100\%$, and so on. Duty Cycle1 (off-time %) = $(t_3 - t_2) / \text{Period1} \times 100\%$, and so on.

Figure 21-15. Capture Sequence for Absolute Time-stamp with Rising- and Falling-Edge Detect

21.6.3 Example 3 - Time Difference (Delta) Operation Rising-Edge Trigger

Figure 21-16 shows how the eCAP module can be used to collect delta timing data from pulse train waveforms. Here Continuous Capture mode (TSCTR counts-up without resetting, and Mod4 counter wraps around) is used. In Delta-time mode, TSCTR is reset back to zero on every valid event. Here capture events are qualified as rising edge only. On an event, TSCTR contents (Time-Stamp) is captured first, and then TSCTR is reset to zero. The Mod4 counter then increments to the next state. If TSCTR reaches FFFFFFFF (maximum value), before the next event, the Mod4 counter wraps around to 00000000 and continues, a CNTOVF (counter overflow) flag is set, and an interrupt (if enabled) occurs. The advantage of Delta-time mode is that the CAPx contents directly give timing data without the need for CPU calculations, that is, Period1 = T_1 , Period2 = T_2 , and so on. As shown in Figure 21-16, the CEVT1 event is a good trigger point to read the timing data, T_1 , T_2 , T_3 , T_4 are all valid here.

Figure 21-16. Capture Sequence for Delta Mode Time-stamp and Rising Edge Detect

21.6.4 Example 4 - Time Difference (Delta) Operation Rising- and Falling-Edge Trigger

In Figure 21-17, the eCAP operating mode is almost the same as in previous section except capture events are qualified as either rising or falling edge, this now gives both period and duty cycle information, that is: $\text{Period1} = T_1 + T_2$, $\text{Period2} = T_3 + T_4$, and so on. $\text{Duty Cycle1 (on-time \%)} = T_1 / \text{Period1} \times 100\%$, $\text{Duty Cycle1 (off-time \%)} = T_2 / \text{Period1} \times 100\%$, and so on.

During initialization, write to the active registers for both period and compare. This action automatically copies the init values into the shadow values. For subsequent compare updates during run-time, the shadow registers must be used.

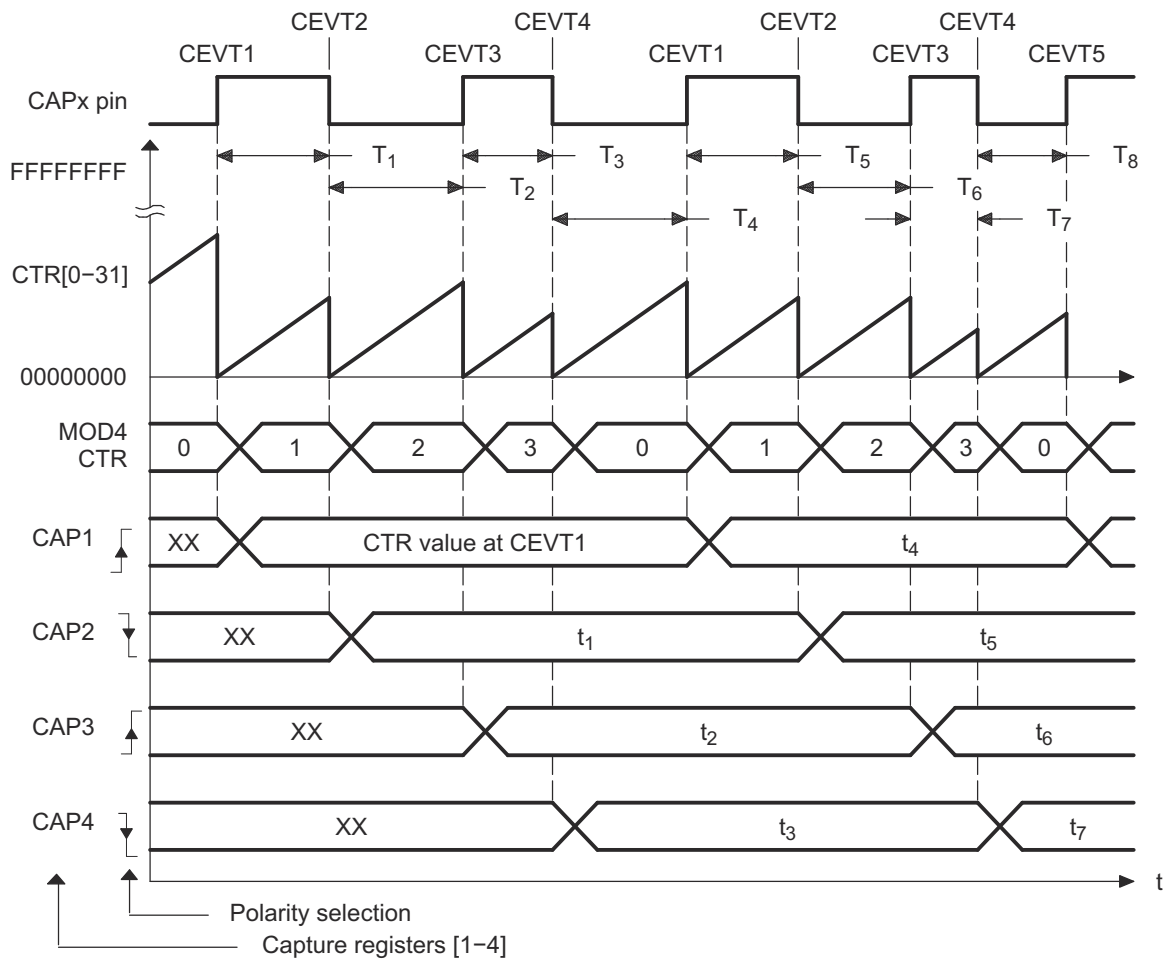

Figure 21-17. Capture Sequence for Delta Mode Time-stamp with Rising- and Falling-Edge Detect

21.7 Application of the APWM Mode

In this example, the eCAP module is configured to operate as a PWM generator. Here, a very simple single-channel PWM waveform is generated from the APWMx output pin. The PWM polarity is active high, which means that the compare value (CAP2 reg is now a compare register) represents the on-time (high level) of the period. Alternatively, if the APWMPOL bit is configured for active low, then the compare value represents the off-time.

21.8 High Resolution Capture (HRCAP) Module

This section describes the High Resolution Capture module.

21.8.1 Introduction

Uses for the HRCAP module include:

- Capacitive touch applications
- High-resolution period and duty cycle measurements of pulse train cycles
- Instantaneous speed measurements
- Instantaneous frequency measurements
- Voltage measurements across an isolation boundary
- Distance/sonar measurement and scanning
- Measuring flow

Getting Started Materials

- [Leveraging High Resolution Capture \(HRCAP\) for Single Wire Data Transfer Application Report](#)

21.8.1.2 Features

The HRCAP module includes the following features:

- Pulse-width capture in either non-high-resolution or high-resolution modes
- Absolute mode pulse-width capture
- Continuous or one-shot capture
- Interrupt on either falling or rising edge
- Continuous mode capture of pulse widths in 4-deep buffer
- Hardware calibration logic for precision high-resolution capture

All of the previous resources are available on any pin using the Input X-BAR.

21.8.1.3 Description

Improvements from the Type 0 HRCAP are:

- Simplified calibration scheme:
 - HRCAP is always functional; never offline to perform calibration
 - Calibration is always running in the background; drastically reduced software overhead to calibrate
- Reduced software overhead to compute fractional bits
- Fractional and integer portions are packed into 32 bits
- All eCAP hardware is accessible when using the HRCAP enhancements. See [Section 21.8.3](#) for practical considerations.
- Usage of the HRCAP is now unified with the eCAP

The HRCAP enhancement has been added to eCAP 6 and eCAP 7 to allow signals to be captured asynchronously to SYSCLK. Each HRCAP submodule includes one capture channel in addition to a hardware calibration block. All eCAP hardware is accessible when using the HRCAP enhancements; however, using the Event Filter or the Input Qualifier is not valid, as these are synchronous to SYSCLK.

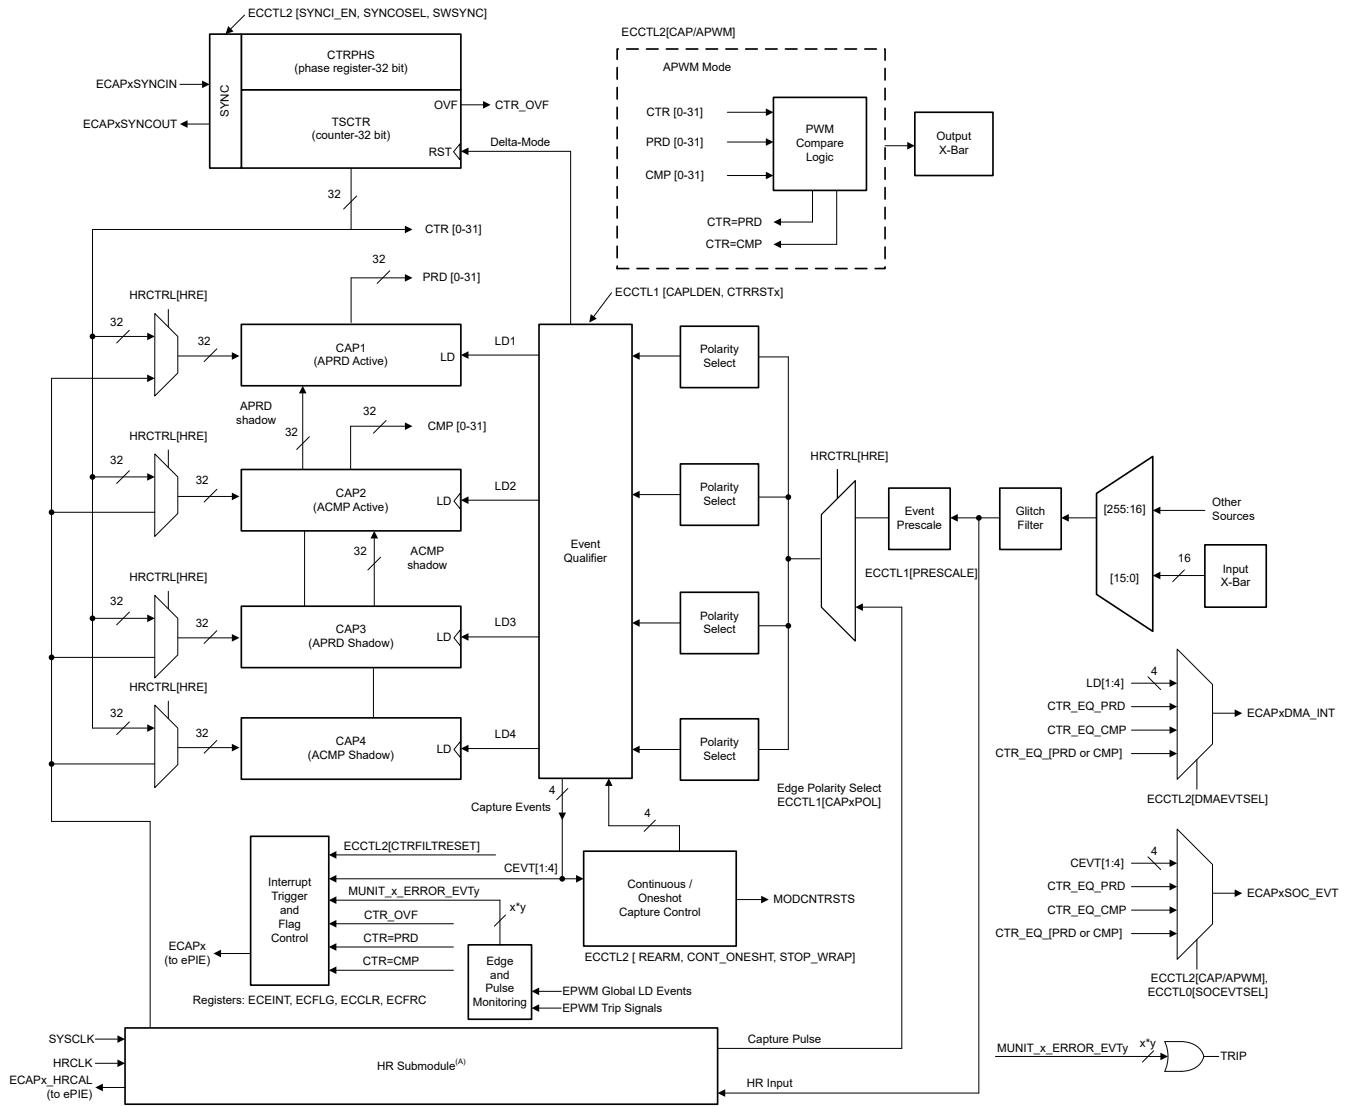

Each HRCAP-capable channel has the following independent key resources:

- All hardware of the respective eCAP
- High-resolution calibration logic
- Dedicated calibration interrupt

21.8.2 Operational Details

[Figure 21-19](#) shows the various components that implement the high-resolution capture functionality of the eCAP module. Note that existing eCAP resources are reused, which requires that the eCAP module is set up before using the HRCAP enhancements. For simplicity, absolute timestamp measurements are recommended. See [Section 21.8.3](#) for more details.

All HRCAP measurements are relative-time measures, in terms of minimum step size. Calibration hardware as well as software functions, have been provided to convert relative-time measurements to time-converted measurements in terms of seconds. The calibration hardware and software is only required if time-converted measurements are required.

A. The HRCAP submodule is not available on all eCAP modules; in this case, the high-resolution muxes and hardware are not implemented.

Figure 21-19. HRCAP Operations Block Diagram

21.8.2.1 HRCAP Clocking

Unlike previous Type-0 HRCAP modules, the Type-1 eCAP, with HRCAP functionality, does not require a second PLL. However, the module still requires both SYSCLK and a second asynchronous clock source called HRCLK. The HRCLK is sensitive to changes in both temperature and voltage. For this reason, when using time-converted measurements, it is required to make periodic continuous calibrations.

21.8.2.2 HRCAP Initialization Sequence

Following are the HRCAP initialization sequence steps. When using the HRCAP to take relative-time measurements, only steps 1-5 are required. When using the HRCAP to take time-converted measurements, all steps are required.

1. Enable HRCLK using `HRCAP_enableHighResolutionClock()`
2. Delay 1 μ S
3. Enable HR mode using `HRCAP_enableHighResolution()`
4. Delay 1 μ S
5. Configure the eCAP module as desired, including interrupts
6. Set calibration period using `HRCAP_setCalibrationPeriod()`
7. Enable continuous calibration using `HRCAP_setCalibrationMode()`
8. Enable interrupts using `HRCAP_enableCalibrationInterrupt()`
9. Start calibration using `HRCAP_startCalibration()`

21.8.2.3 HRCAP Interrupts

The HRCAP enhancements leverage the existing eCAP interrupts (see *Interrupt Control* in the ECAP chapter) in addition to HRCALINT, which is used exclusively by the hardware calibration block. HRCALINT can be triggered by the following conditions:

1. SYSCLKCTR = HRCALIBPERIOD
2. SYSCLKCTR or HRCLKCTR experience an overflow condition

Figure 21-20 shows this logic.

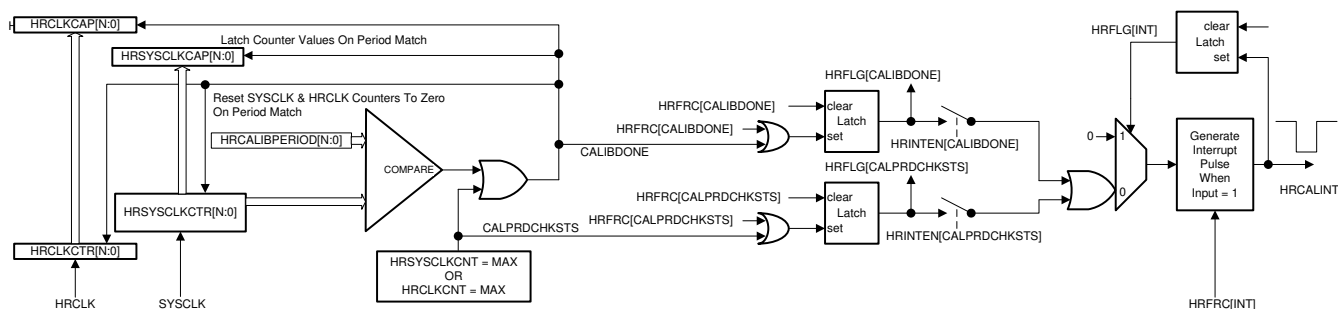

Figure 21-20. HRCAP Calibration

21.8.2.4 HRCAP Calibration

Note

For HRCAP calibration to work, the system needs to operate at SYSCLK frequency > 100 MHz.

The following section applies only to time-converted measurements; calibration for relative-time measurements is not required. All values captured by the HRCAP submodule are in number of HRCLK cycles. The HRCLK speed varies widely with temperature and voltage, thus a scale factor is required to convert the capture value to the SYSCLK domain. For the same reason, it is required to periodically recalculate the scale factor. The HRCAP submodule has a calibration block to reduce software overhead when calculating a scale factor between HRCLK and SYSCLK.

The calibration block contains the following key resources:

- **HRSYSCLKCNT:** A 32-bit counter connected to SYSCLK. The counter starts counting when CALIBSTART is set.
- **HRCLKCNT:** A 32-bit counter connected to HRCLK. The counter starts counting when CALIBSTART is set.
- **HRCALIBPERIOD:** Calibration period, calibration is stopped when HRSYSCLKCNT is equal to the value in this register.
- **HRSYSCLKCAP:** On a calibration period match, the value of HRSYSCLKCNT is captured into HRSYSCLKCAP.
- **HRCLKCAP:** On a calibration period match, the value of HRCLKCNT is captured into HRCLKCAP.
- **HRCALINT:** An interrupt that occurs on a calibration period match, or when one of the counter registers experiences an overflow condition.

The calibration logic consists of two free-running counters; one clocked by HRCLK(HRCLKCTR) and one clocked by SYSCLK(HRSYSCLKCTR). When HRSYSCLKCTR is equal to HRCALIBPERIOD, the calibration block captures and resets both counter values, then triggers an interrupt, indicating a new scale factor is ready to be calculated. The scale factor can be found by dividing HRSYSCLKCAP by HRCLKCAP (see [Equation 10](#)). A DriverLib function, HRCAP_getScaleFactor, has been provided to determine the scale factor. This function can be called inside of the calibration interrupt service routine. If one of the counters experiences overflow, the CALPRDCHKSTS flag is set. The full details of the calibration block are described in [Figure 21-20](#).

$$ScaleFactor = \frac{HRSYSCLKCAP}{HRCLKCAP} \quad (10)$$

Note

- Even with calibration, noise on the 1.2-V VDD supply negatively affects the standard deviation of the HRCAP submodule. Care can be taken to make sure that the 1.2-V supply is clean, and that noisy internal events such as enabling and disabling clock trees have been minimized while using the HRCAP submodule.
 - When HRCLK > SYSCLK, calibration stops immaturely to mitigate improper calibration, SYSCLK must be set to at least 100 MHz.
-

21.8.2.4.1 Applying the Scale Factor

A DriverLib function has been provided to apply the scale factor to a capture value, `HRCAP_getEventTimeStampNanoseconds()`. [Equation 11](#) shows how to convert a raw count to seconds without using the DriverLib function.

$$Measurement(ns) = \frac{RawCount \times scaleFactor}{128} * SysClkPrd(ns) \quad (11)$$

Table 21-2. Scale Factor

Parameter	Explanation
RawCount	Capture value as read from ECAP_REGS_CAP1-4
ScaleFactor ⁽¹⁾	The Scale factor as calculated from Equation 11
128	Constant determined by the hardware of the HRCAP submodule
SysClkPrd(nS)	Period of the system clock
Measurement(nS)	Signal converted to nS

(1) The scale factor is not automatically applied to captured values. The user is required to apply the scale factor to all captured values as shown in [Equation 11](#).

21.8.3 Known Exceptions

In HRCAP mode:

- Enabling and disabling core clocks negatively affects the standard deviation of the HRCAP submodule. Do not enable or disable core clocks while taking measurements.
- TSCTR is not writable; however, TSCTR can be reset using `ECCTL2[CTRFILTRESET]`
- Input synchronization is not applicable when using the HRCAP enhancements, because the HRCAP submodule is asynchronous to SYSCLK.
- The Event Filter functionality is not applicable for HRCAP, which defeats the purpose of HRCAP as the Event Filter's output is synchronous to SYSCLK.
- The best practice is to use absolute time mode for high-resolution mode. If time difference mode is used, it can lead to inaccurate results if the fractional value is not taken into consideration for capture events that have reset the time base counter.
 - Actual Capture Value = (Capture Value) – (fractional value of reference event that reset the counter)
- For high-frequency input signals, the CPU can not be able to cope with the speed of the captures. In such a case, one-shot mode is recommended. This mode allows the device to capture up to four edges before waiting to be serviced when the CPU is ready. This is applicable for the eCAP as well; however, in that case the event filter can be used to reduce the rate of captures.

21.9.1 ECAP Examples

NOTE: These examples are located in the [C2000Ware](#) installation at the following location:
C2000Ware_VERSION#/driverlib/DEVICE_GPN/examples/CORE_IF_MULTICORE/ecap

Cloud access to these examples is available at the following link: [dev.ti.com C2000Ware Examples](#).

21.9.1.1 eCAP APWM Example

FILE: `ecap_ex1_apwm.c`

This program sets up the eCAP module in APWM mode. The PWM waveform will come out on GPIO5. The frequency of PWM is configured to vary between 10Hz and 20Hz using the shadow registers to load the next period/compare values.

21.9.1.2 eCAP Capture PWM Example

FILE: `ecap_ex2_capture_pwm.c`

This example configures ePWM3A for:

- Up count mode
- Period starts at 500 and goes up to 8000
- Toggle output on PRD

eCAP1 is configured to capture the time between rising and falling edge of the ePWM3A output.

External Connections

- eCAP1 is on GPIO16
- ePWM3A is on GPIO4
- Connect GPIO4 to GPIO16.

Watch Variables

- `ecap1PassCount` - Successful captures.
- `ecap1IntCount` - Interrupt counts.

21.9.1.3 eCAP APWM Phase-shift Example

FILE: `ecap_ex3_apwm_phase_shift.c`

This program sets up the eCAP1 and eCAP2 modules in APWM mode to generate the two phase-shifted PWM outputs of same duty and frequency value. The frequency, duty and phase values can be programmed of choice by updating the defined macros. By default 10 Khz frequency, 50% duty and 30% phase shift values are used. eCAP2 output leads the eCAP1 output by 30%. GPIO5 and GPIO6 are used as eCAP1/2 outputs and can be probed using analyzer/CRO to observe the waveforms.

21.9.1.4 eCAP Software Sync Example

FILE: `ecap_ex4_sw_sync.c`

This example configures ePWM3A for:

- Up count mode
- Period starts at 500 and goes up to 8000
- Toggle output on PRD

eCAP1, eCAP2 and eCAP3 are configured to capture the time between rising and falling edge of the ePWM3A output.

External Connections

- eCAP1, eCAP2, eCAP3 are on GPIO16
- ePWM3A is on GPIO4

- Connect GPIO4 to GPIO16.

Watch Variables

- *ecapPassCount* - Successful captures.
- *ecap3IntCount* - Interrupt counts.

21.9.1.5 eCAP Signal Monitor Example

FILE: `ecap_ex5_signal_monitor.c`

This example configures ePWM1A for:

- Up-down count mode
- Period value : 4000 (16000 sysclk)
- CMPA value : 2000 (8000 sysclk)
- The low-pulse width will be ~16000 sysclk

eCAP1 configuration:

- Absolute mode
- Continous mode (one-shot mode can be used but limited duration)
- 4 captures are enabled
- Low Pulse width monitoring : Rising to falling edge

This example generates an error event `ERROR_EVT1` as the actual low-pulse width does not occur during the expected window and trip the PWM signal. The monitor window can be changed by changing the monitor min and max value.

Note: When `ecapMonitorMin < 16000` and `ecapMonitorMax > 16000`, this example will not generate `Error_Evt`. When `ecapMonitorMin, ecapMonitorMax > 16000`, `Error_Evt1` will be generated. When `ecapMonitorMin, ecapMonitorMax < 16000`, `Error_Evt2` will be generated.

External Connections

- eCAP1 is on GPIO16
- ePWM1A is on GPIO0
- Connect GPIO0 to GPIO16.

Watch Variables

- *ecapMonitorMin* - Min value for the signal monitoring window (`ecapMonitorMin < 16000 sysclk`)
- *ecapMonitorMax* - Max value for the signal monitoring window (`ecapMonitorMax > 16000 sysclk`)

The interrupt enable bits (CEVT1, ...) block any of the selected events from generating an interrupt. Events will still be latched into the flag bit (ECFLG register) and can be forced/cleared via the ECFRC/ECCLR registers. The proper procedure for configuring peripheral modes and interrupts is as follows:

- Disable global interrupts
- Stop eCAP counter
- Disable eCAP interrupts
- Configure peripheral registers
- Clear spurious eCAP interrupt flags
- Enable eCAP interrupts
- Start eCAP counter
- Enable global interrupts

Register Array Variables		

Table 21-21. ECAP_SIGNAL_MONITORING Access Type Codes (continued)

Access Type	Code	Description
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

Chapter 22 Enhanced Pulse Width Modulator (ePWM)

The enhanced pulse width modulator (ePWM) peripheral is a key element in controlling many of the power electronic systems found in both commercial and industrial equipment. These systems include digital motor control, switch mode power supply control, uninterruptible power supplies (UPS), and other forms of power conversion. The ePWM peripheral can also perform a digital-to-analog (DAC) function, where the duty cycle is equivalent to a DAC analog value; it is sometimes referred to as a power DAC.

This chapter is applicable for ePWM type 5. Type 5 EPWM is fully compatible with type 4 EPWM. See the [C2000 Real-Time Control Peripheral Reference Guide](#) for a list of all devices with an ePWM module of the same type, to determine the differences between the types, and for a list of device-specific differences within a type.

22.1 Introduction

This chapter includes an overview and information about each submodule:

- [Time Base \(TB\) Submodule](#)
- [Counter Compare \(CC\) Submodule](#)
- [Action Qualifier \(AQ\) Submodule](#)
- [Dead-Band Generator \(DB\) Submodule](#)
- [PWM Chopper \(PC\) Submodule](#)
- [Trip Zone \(TZ\) Submodule](#)
- [Diode Emulation \(DE\) Submodule](#)
- [Minimum Dead-Band \(MINDB\) and Illegal Combo Logic \(ICL\) Submodule](#)
- [Event Trigger \(ET\) Submodule](#)
- [Digital Compare \(DC\) Submodule](#)

The ePWM Type 5 is functionally compatible to Type 4. Type 5 has the following enhancements in addition to the Type 4 features:

- **PWM SYNC Related Enhancements:** Additional external sync option is added in to the EPWMSYNCSEL register. This allows for the configuration of up to 3 independent sync chains with external sync options.
- **Linking and Global Load Enhancements:** DBRED:DBREDHR and DBREDHR and DBFED:DBFEDHR have the ability to be linked across ePWM modules.

Global load pulse selection for shadow to active load can now occur when the time-base counter equals CMPCU, CMPCD, CMPDU, or CMPDD.

- **XCMP Complex Waveform Generator:** XCMP mode has been added to allow for generation of multiple ePWM pulses, with high resolution, in a given ePWM cycle. Up to 8 new compare registers are added to achieve this functionality.
- **Digital Compare Submodule Enhancements:** Event detection within the digital compare capture module is able to detect an occurrence of a trip event in a configured time window.

Pulse selection for blanking and capture alignment now includes a blanking window mix selection (BLANKPULSEMIX). This is added for LLC topologies where blanking window settings need to be changed on the fly - providing greater configurability to do this.

- **Trip-Zone Submodule Enhancements:** A CAPEVENT signal can generate a CBC or One-shot trip event.
- **Diode Emulation Submodule:** The diode emulation mode was added to provide hardware features and the necessary hooks into other IPs to implement a robust diode mode sense and control in a noisy environment.
- **Minimum Dead-Band and Illegal Combo Logic Submodule:** The minimum dead-band logic was added to provide the ability to configure the minimum dead-band duration between a complimentary set of ePWMs.

To detect and make sure that under no circumstances, the ePWM states result in potentially hazardous combinations, a Look Up Table (LUT) has been added that can be used to re-configure the ePWM outputs.

- **Event Trigger Submodule Enhancements:** To enable unevenly spaced over-sampling of the ePWM period, the event trigger module trigger select is modified such that multiple events can trigger SOCA, SOCB, and INT events (ETINTMIX).

The ePWM Type 4 is functionally compatible to Type 2 (a Type 3 does not exist). Type 4 has the following enhancements in addition to the Type 2 features:

- **Register Address Map:** Additional registers are required for new features on ePWM Type 4. The ePWM register address space has been remapped for better alignment and easy usage.
- **Delayed Trip Functionality:** Changes have been added to achieve deadband insertion capabilities to support, for example, delayed trip functionality needed for peak current mode control type application scenarios. This has been accomplished by allowing comparator events to go into the Action Qualifier as a trigger event (Events T1 and T2). If comparator T1 / T2 events are used to edit the PWM, changes to the PWM waveform do not take place immediately. Instead, the waveform synchronizes to the next TBCLK.
- **Dead-Band Generator Submodule Enhancements:** Shadowing of the DBCTL register to allow dynamic configuration changes.

- **One Shot and Global Load of Registers:** The ePWM Type 4 allows one shot and global load capability from shadow to active registers to avoid partial loads in, for example, multiphase applications. ePWM Type 4 also allows a programmable prescale of shadow to active load events. ePWM Type 4 Global Load can simplify ePWM software by removing interrupts and ensuring that all registers are loaded at the same time.
- **Trip-Zone Submodule Enhancements:** Independent flags have been added to reflect the trip status for each of the TZ sources. Changes have been made to the trip-zone submodule to support certain power converter switching techniques like valley switching.
- **Digital Compare Submodule Enhancements:** Blanking window filter register width has been increased from 8 to 16 bits. DCCAP functionality has been enhanced to provide more programmability.
- **PWM SYNC Related Enhancements:** The ePWM Type 4 allows PWM SYNCOUT generation based on CMPC and CMPD events. These events can also be used for PWMSYNC pulse selection.

The ePWM Type 2 is fully compatible to Type 1. Type 2 has the following enhancements in addition to the Type 1 features:

- **High-Resolution Dead-Band Capability:** High-resolution capability is added to dead-band RED and FED in half-cycle clocking mode.
- **Dead-Band Generator Submodule Enhancements:** The ePWM Type 2 has features to enable both RED and FED on either PWM outputs. Provides increased dead band with 14-bit counters and dead-band / dead-band high-resolution registers are shadowed
- **High-Resolution Extension available on ePWMxB outputs:** Provides the ability to enable high-resolution period and duty cycle control on ePWMxB outputs. This is discussed in more detail in [Section 22.18](#).
- **Counter Compare Submodule Enhancements:** The ePWM Type 2 allows interrupts and SOC events to be generated by additional counter compares CMPC and CMPD.
- **Event Trigger Submodule Enhancements:** Prescaling logic to issue interrupt requests and ADC start of conversion expanded up to every 15 events. It allows software initialization of event counters on SYNC event.
- **Digital Compare Submodule Enhancements:** Digital Compare Trip Select logic [DCTRIPSEL] has up to 12 external trip sources selected by the Input X-BAR logic in addition to an ability to OR all of them (up to 14 [external and internal sources]) to create the respective DCxEVTs.
- **Simultaneous Writes to TBPRD and CMPx Registers:** This feature allows writes to TBPRD, CMPA:CMPAHR, CMPB:CMPBHR, CMPC and CMPD of any ePWM module to be tied to any other ePWM module, and also allows all ePWM modules to be tied to a particular ePWM module if desired.
- **Shadow to Active Load on SYNC of TBPRD and CMP Registers:** This feature supports simultaneous writes of TBPRD and CMPA/B/C/D registers.

An effective PWM peripheral must be able to generate complex pulse width waveforms with minimal CPU overhead or intervention and must be highly programmable and very flexible while being easy to understand and use. The ePWM unit described here addresses these requirements by allocating all needed timing and control resources on a per PWM channel basis. Cross coupling or sharing of resources has been avoided; instead, the ePWM is built up from smaller single channel submodules with separate resources that can operate together as required to form a system. This modular approach results in an orthogonal architecture and provides a more transparent view of the peripheral structure, helping users to understand the operation quickly.

In this document, the letter x within a signal or submodule name is used to indicate a generic ePWM instance on a device. For example, output signals EPWMxA and EPWMxB refer to the output signals from the ePWMx instance. Thus, EPWM1A and EPWM1B belong to ePWM1 and likewise EPWM4A and EPWM4B belong to ePWM4.

Type0 to Type1 Enhancements

- **Increased Dead-Band Resolution:** Dead-band clocking has been enhanced to allow half-cycle clocking to double resolution.
- **Enhanced Interrupt and SOC Generation:** Interrupts and ADC start-of-conversion can now be generated on both the TBCTR == zero and TBCTR == period events. This feature enables dual edge PWM control. Additionally, the ADC start-of-conversion can be generated from an event defined in the digital compare submodule.
- **High-Resolution Period Capability:** Provides the ability to enable high-resolution period. This is discussed in more detail in [Section 22.18](#).
- **Digital Compare Submodule:** The digital compare submodule enhances the event triggering and trip zone submodules by providing filtering, blanking and improved trip functionality to digital compare signals. Such features are essential for peak current mode control and for support of analog comparators.

Note

The name of the sync signal that goes to the CMPSS has been updated from PWMSYNC to EPWMSYNCPER (SYNCPER/PWMSYNCPER/EPWMxSYNCPER) to avoid confusion with the other EPWM sync signals EPWMSYNCI and EPWMSYNCO. For a description of these signals, see [Table 22-2](#).

22.1.2 Submodule Overview

The ePWM module represents one complete PWM channel composed of two PWM outputs: EPWMxA and EPWMxB. Multiple ePWM modules are instantiated within a device as shown in [Figure 22-1](#). Each ePWM instance is identical with one exception. Some instances include a hardware extension that allows more precise control of the PWM outputs. This extension is the high-resolution pulse width modulator (HRPWM) and is described in [Section 22.18](#). See the device data sheet to determine which ePWM instances include this feature. Each ePWM module is indicated by a numerical value starting with 1. For example, ePWM1 is the first instance and ePWM3 is the third instance in the system and ePWMx indicates any instance.

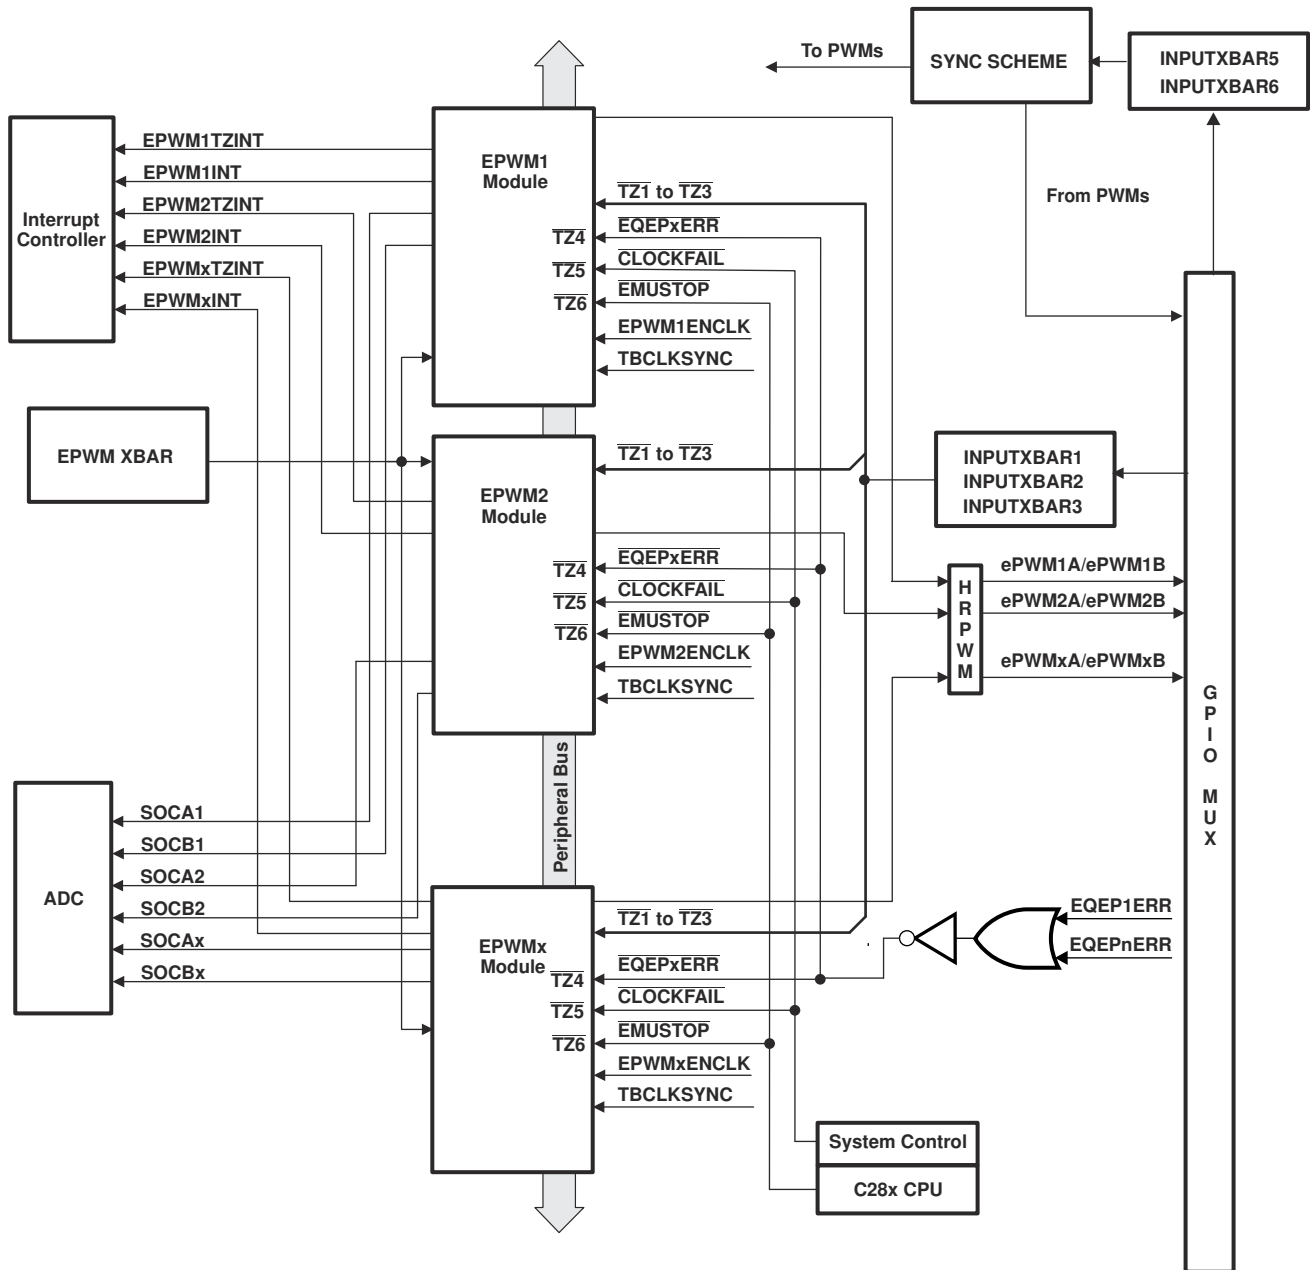

The ePWM modules are chained together by way of a clock synchronization scheme that allows them to operate as a single system when required. Additionally, this synchronization scheme can be extended to the capture peripheral submodules (eCAP). The number of submodules is device-dependent and based on target application needs. Submodules can also operate standalone.

Each ePWM module supports the following features:

- Dedicated 16-bit time-base counter with period and frequency control
- Two PWM outputs (EPWMxA and EPWMxB) that can be used in the following configurations:
 - Two independent PWM outputs with single-edge operation
 - Two independent PWM outputs with dual-edge symmetric operation
 - One independent PWM output with dual-edge asymmetric operation
- Asynchronous override control of PWM signals through software.
- Programmable phase-control support for lag or lead operation relative to other ePWM modules.
- Hardware-locked (synchronized) phase relationship on a cycle-by-cycle basis.
- Dead-band generation with independent rising and falling edge delay control.
- Programmable trip zone allocation of both cycle-by-cycle trip and one-shot trip on fault conditions.
- A trip condition can force either high, low, or high-impedance state logic levels at PWM outputs.
- All events can trigger both CPU interrupts and ADC start of conversion (SOC)
- Programmable event prescaling minimizes CPU overhead on interrupts.
- PWM chopping by high-frequency carrier signal, useful for pulse transformer gate drives.

Each ePWM module is connected to the input/output signals shown in [Figure 22-1](#). The signals are described in detail in subsequent sections.

The order in which the ePWM modules are connected can differ from what is shown in [Figure 22-1](#). See [Section 22.4.3.3](#) for the synchronization scheme for a particular device. Each ePWM module consists of ten submodules and is connected within a system by way of the signals shown in [Figure 22-2](#).

A. This signal exists only on devices with an eQEP submodule.

Figure 22-1. Multiple ePWM Modules

Figure 22-2. Submodules and Signal Connections for an ePWM Module

Figure 22-3 shows more internal details of a single ePWM module. The main signals used by the ePWM module are:

- **PWM output signals (EPWMxA and EPWMxB)**

The PWM output signals are made available external to the device.

- **Trip-zone signals ($\overline{TZ1}$ to $\overline{TZ6}$)**

These input signals alert the ePWM module of fault conditions external to the ePWM module. Each submodule on a device can be configured to either use or ignore any of the trip-zone signals. The $\overline{TZ1}$ to $\overline{TZ3}$ trip-zone signals can be configured as asynchronous inputs through the GPIO peripheral using the Input X-BAR logic, refer to Figure 22-75. $\overline{TZ4}$ is connected to an inverted EQEPx error signal (EQEPxERR), which can be generated from any one of the EQEP submodule (for those devices with an EQEP module). $\overline{TZ5}$ is connected to the system clock fail logic, and $\overline{TZ6}$ is connected to the EMUSTOP output from the CPU. This allows configuring a trip action when the clock fails or the CPU halts.

- **Time-base synchronization input (EPWMxSYNCl), output (EPWMxSYNCO), and peripheral (EPWMxSYNCPER) signals**

Each ePWM module can be synchronized with other ePWM modules or other peripherals, using EPWMSYNCINSEL. Each ePWM module can also generate a synchronization output signal. The source of the EPWMxSYNCO can be selected and enabled by EPWMSYNCOEN and TBCTL2.OSHTSYNCPER. For more information, see Section 22.4.3.3.

Each ePWM module also generates another PWMSYNC signal called EPWMxSYNCPER. EPWMxSYNCPER goes to the GPDAC and CMPSS for synchronization purposes. Functionality is configured using the HRPCTL register, but has no relation with the HRPWM. For more information on how EPWMxSYNCPER is used by the GPDAC and CMPSS, see their respective chapters.

- **ADC start-of-conversion signals (EPWMxSOCA and EPWMxSOCB)**

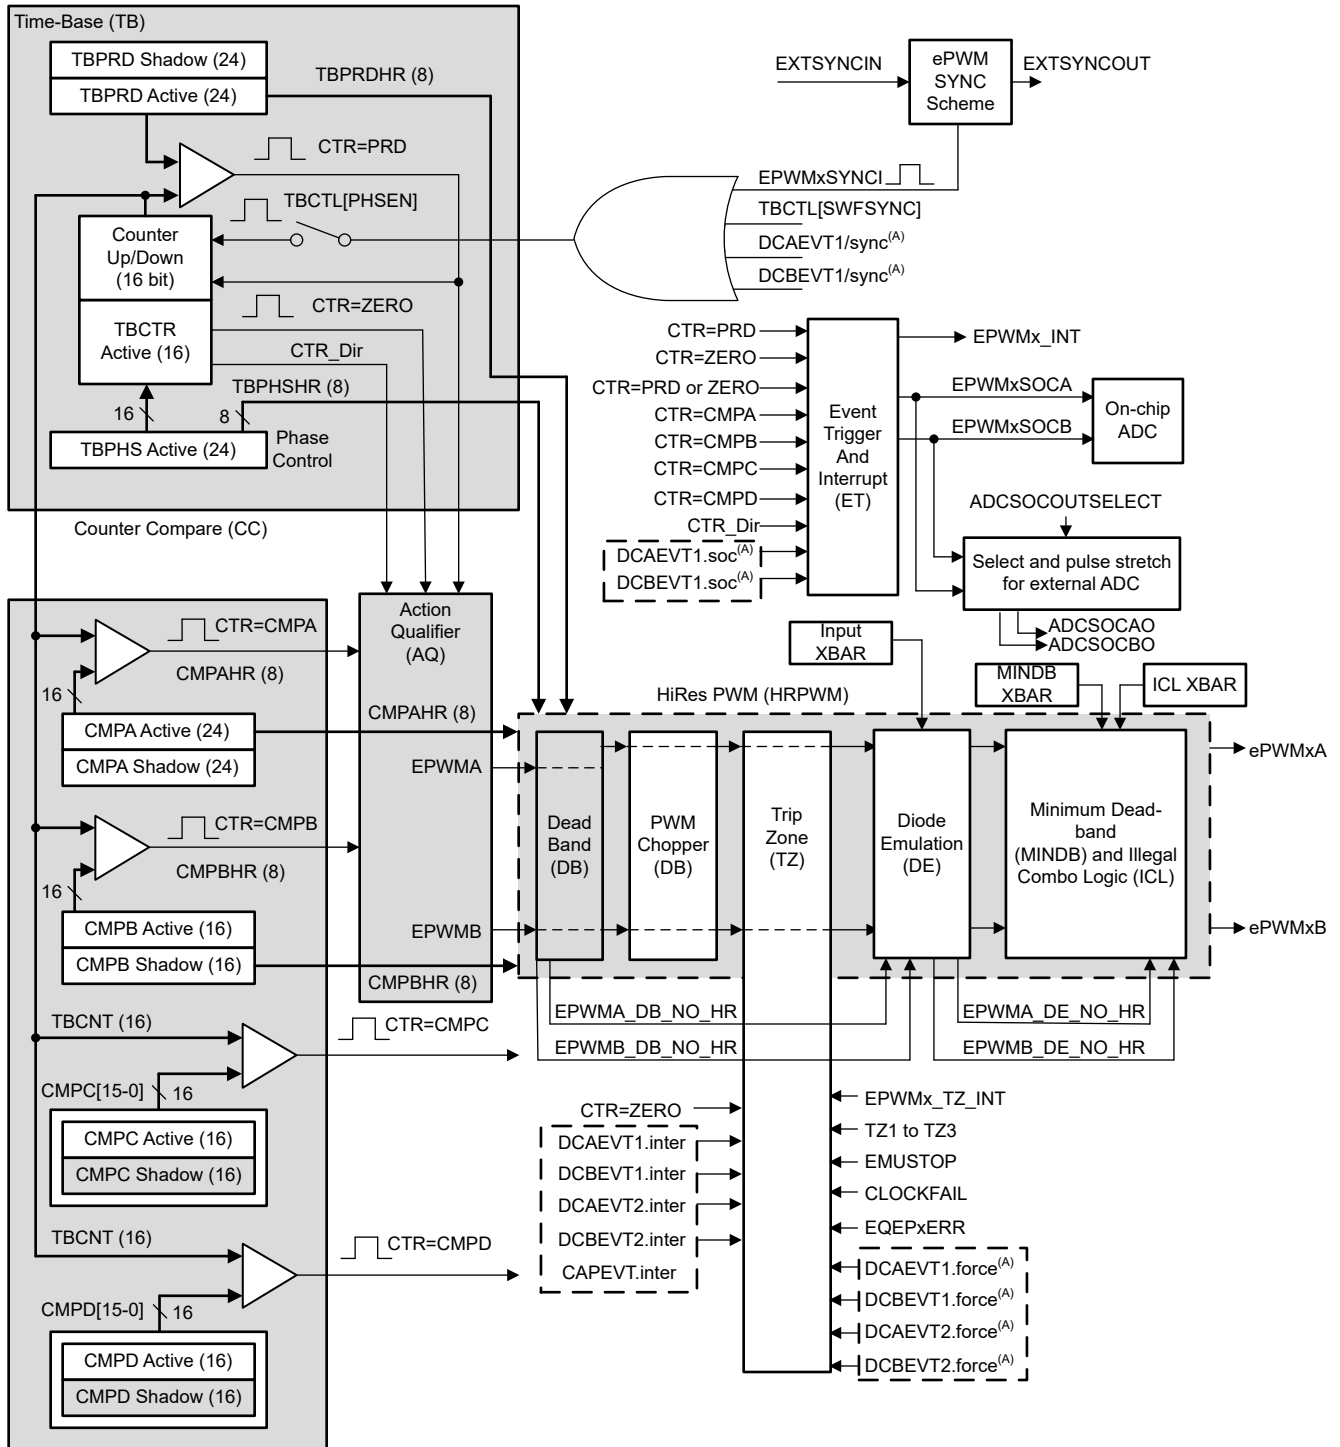

Each ePWM module has two ADC start of conversion signals. Any ePWM module can trigger a start of conversion. Whichever event triggers the start of conversion is configured in the event-trigger submodule of the ePWM.

- **Comparator output signals (COMPxOUT)**

Output signals from the comparator module can be fed through the Input X-BAR and EPWM X-BAR to one or all of the 15 trip inputs [TRIPIN1 - TRIPIN15] and in conjunction with the trip zone signals can generate digital compare events.

- **Peripheral bus**

The peripheral bus is 32-bits wide and allows both 16-bit and 32-bit writes to the ePWM register file.

A. These events are generated by the ePWM Digital Compare (DC) submodule based on the levels of the TRIPIN inputs.

Figure 22-3. ePWM Modules and Critical Internal Signal Interconnects

22.2 Configuring Device Pins

To connect the device input pins to the module, the Input X-BAR and EPWM X-BAR must be used. Some examples of when an external signal can be needed are TZx, TRIPx, and EXTSYNCIN. Any GPIO on the device can be configured as an input. The GPIO input qualification can be set to asynchronous mode by setting the appropriate GPxQSEL register bits to 11b. The internal pullups can be configured in the GPyPUD register. Since the GPIO mode is used, the GPyINV register can invert the signals.

The GPIO mux registers must be configured for this peripheral. To avoid glitches on the pins, the GPyGMUX bits must be configured first (while keeping the corresponding GPyMUX bits at the default of zero), followed by writing the GPyMUX register to the desired value.

See the *General-Purpose Input/Output (GPIO)* chapter for more details on GPIO mux, GPIO settings, and XBAR configuration.

22.3 ePWM Modules Overview

Ten submodules are included in every ePWM peripheral. Each of these submodules performs specific tasks that can be configured by software.

[Table 22-1](#) lists the key submodules together with a list of their main configuration parameters. For example, if you need to adjust or control the duty cycle of a PWM waveform, see the counter-compare submodule in [Section 22.5](#) for relevant details.

22.4 Time-Base (TB) Submodule

Each ePWM module has their own time-base submodule that determines all of the event timing for the ePWM module. Built-in synchronization logic allows the time-base of multiple ePWM modules to work together as a single system.

Figure 22-4 illustrates the time-base submodule within the ePWM.

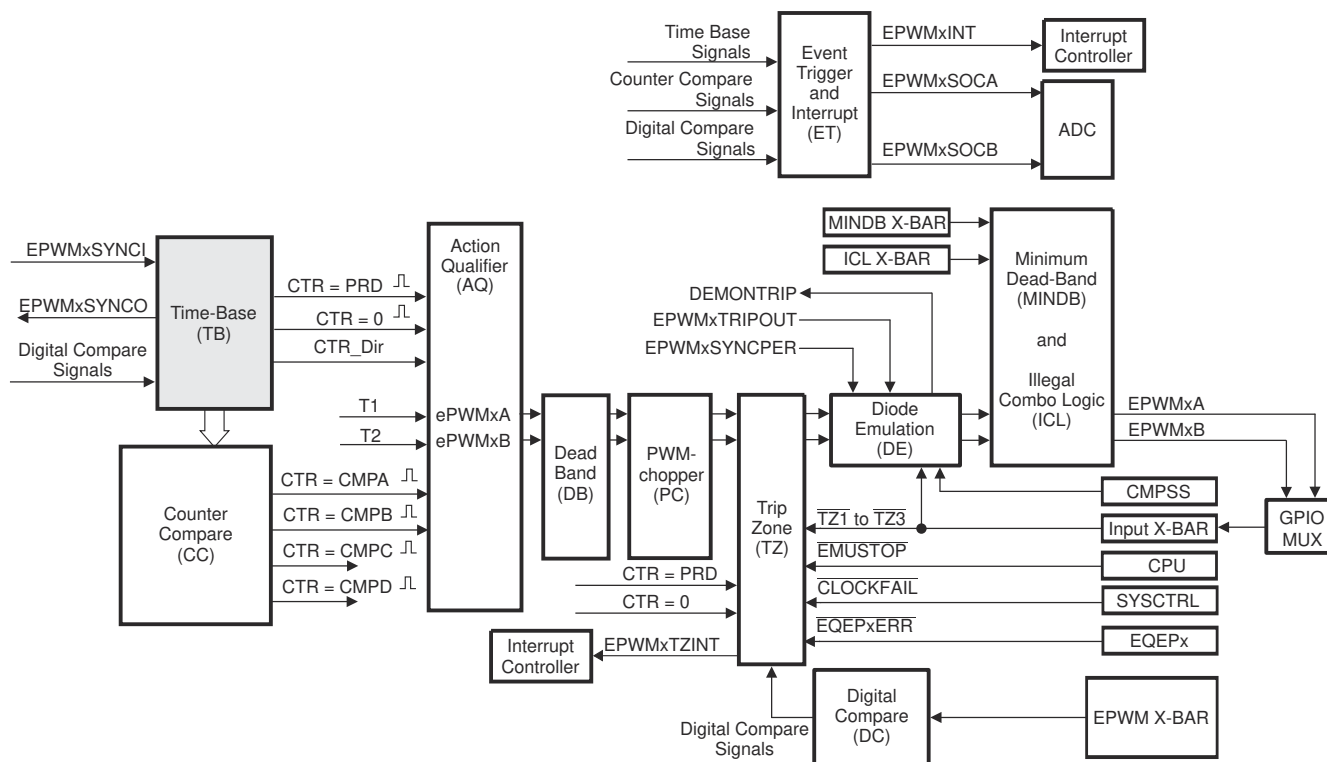

Figure 22-4. Time-Base Submodule

22.4.1 Purpose of the Time-Base Submodule

The time-base submodule can be configured for the following:

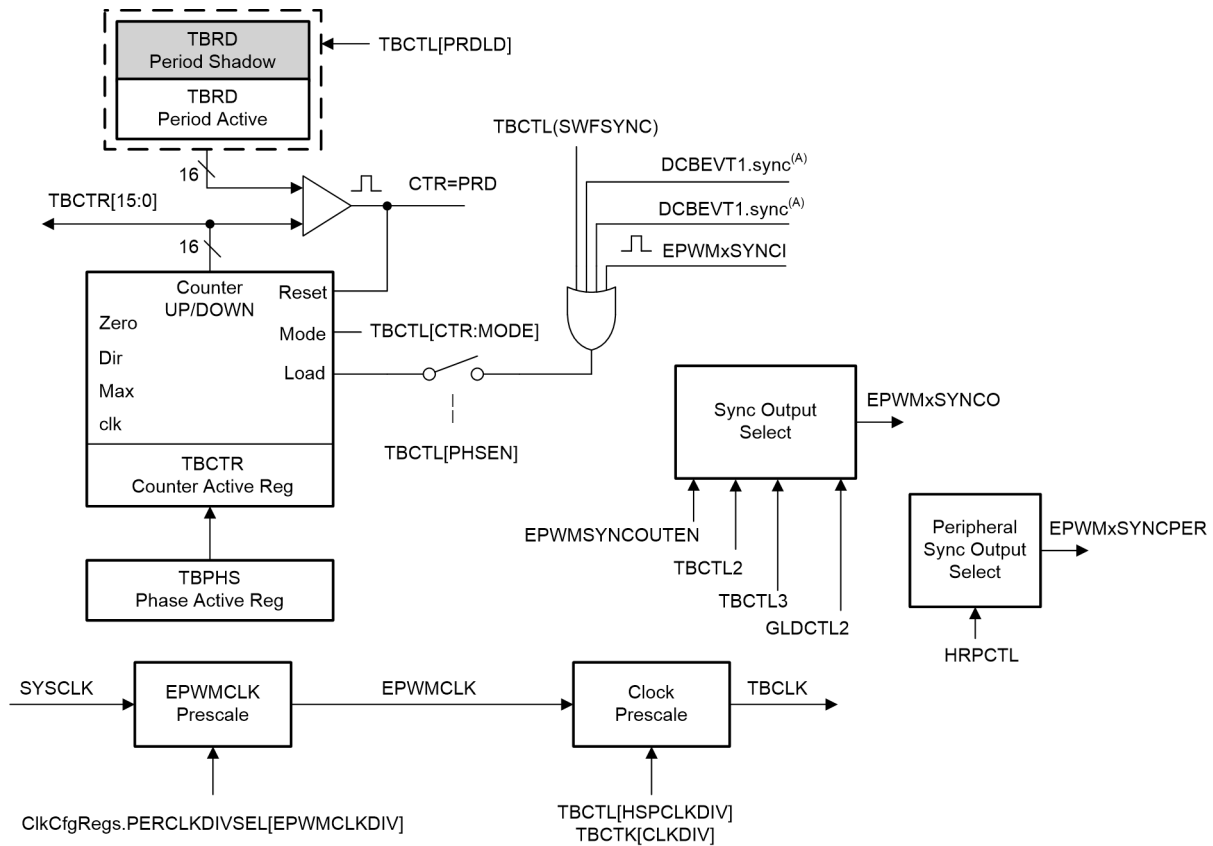

- Specify the ePWM time-base counter (TBCTR) frequency or period to control how often events occur.
- Manage time-base synchronization with other ePWM modules.
- Maintain a phase relationship with other ePWM modules.
- Set the time-base counter to count-up, count-down, or count-up-and-down mode.
- Generate the following events:
 - CTR = PRD: Time-base counter equal to the specified period (TBCTR = TBPRD).
 - CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00).
- Configure the rate of the time-base clock; a prescaled version of the ePWM clock (EPWMCLK). This allows the time-base counter to increment/decrement at a slower rate.

Note

If required by the application code to update the TBCTR value through software while the TBCTR is counting, note that the time-base module needs at least 1 TBCLK cycle for the time-base related events to be realized. Hence, the TBCTR can be written with $TBCTR = PRD - 1$ instead of $TBCTR = PRD$ (in case the counter is counting up) and can be written as $TBCTR = 1$ instead of $TBCTR = 0$ (in case the counter is counting down) for the events to be realized.

22.4.2 Controlling and Monitoring the Time-Base Submodule

The block diagram in Figure 22-5 shows the critical signals and registers of the time-base submodule. Table 22-2 provides descriptions of the key signals associated with the time-base submodule.

A. These signals are generated by the digital compare (DC) submodule.

Figure 22-5. Time-Base Submodule Signals and Registers

Table 22-2. Key Time-Base Signals

Signal	Description
EPWMxSYNCl	Time-base synchronization input. Input pulse used to synchronize the time-base counter with the counter of other ePWM modules. For more information on all of the signals available for synchronization, see EPWMSYNClNSEL. For information on the synchronization order of a particular device, see Section 22.4.3.3 .
EPWMxSYNCO	Time-base synchronization output. This output pulse is used to synchronize the counter of other ePWM modules. Using EPWMSYNCOUEN, TBCTL2, TBCTL3 and GLDCTL2, the source of the output pulse is selected.
EPWMxSYNCPER	Time-base peripheral synchronization output. This output signal is used to synchronize the GPDAC and CMPSS to the EPWM. The output signal can be configured using the HRPCTL register. Note that this signal has no relation with the HRPWM.
CTR = PRD	Time-base counter equal to the specified period. This signal is generated whenever the counter value is equal to the active period register value. That is when TBCTR = TBPRD.
CTR = Zero	Time-base counter equal to zero This signal is generated whenever the counter value is zero. That is when TBCTR equals 0x00.
CTR = CMPB	Time-base counter equal to active counter-compare B register (TBCTR = CMPB). This event is generated by the counter-compare submodule and used by the synchronization out logic
CTR_dir	Time-base counter direction. Indicates the current direction of the ePWM's time-base counter. The signal is high when the counter is increasing and the signal is low when the counter is decreasing.
CTR_max	Time-base counter equal max value. (TBCTR = 0xFFFF) Generated event when the TBCTR value reaches the maximum value. This signal is only used only as a status bit
TBCLK	Time-base clock. This is a prescaled version of the ePWM clock (EPWMCLK) and is used by all submodules within the ePWM. This clock determines the rate at which time-base counter increments or decrements.

22.4.3 Calculating PWM Period and Frequency

The frequency of PWM events is controlled by the time-base period (TBPRD) register and the mode of the time-base counter. Figure 22-6 shows the period (T_{Pwm}) and frequency (F_{Pwm}) relationships for the up-count, down-count, and up-down-count time-base counter modes when the period is set to 4 (TBPRD = 4). The time increment for each step is defined by the time-base clock (TBCLK) which is a prescaled version of the ePWM clock (EPWMCLK).

The time-base counter has three modes of operation selected by the time-base control register (TBCTL):

- **Up-Down Count Mode:** In up-down count mode, the time-base counter starts from zero and increments until the period (TBPRD) value is reached. When the period value is reached, the time-base counter then decrements until the counter reaches zero. At this point, the counter repeats the pattern and begins to increment.
- **Up-Count Mode:** In up-count mode, the time-base counter starts from zero and increments until the counter reaches the value in the period register (TBPRD). When the period value is reached, the time-base counter resets to zero and begins to increment once again.
- **Down-Count Mode:** In down-count mode, the time-base counter starts from the period (TBPRD) value and decrements until the counter reaches zero. When the counter reaches zero, the time-base counter is reset to the period value and begins to decrement once again.

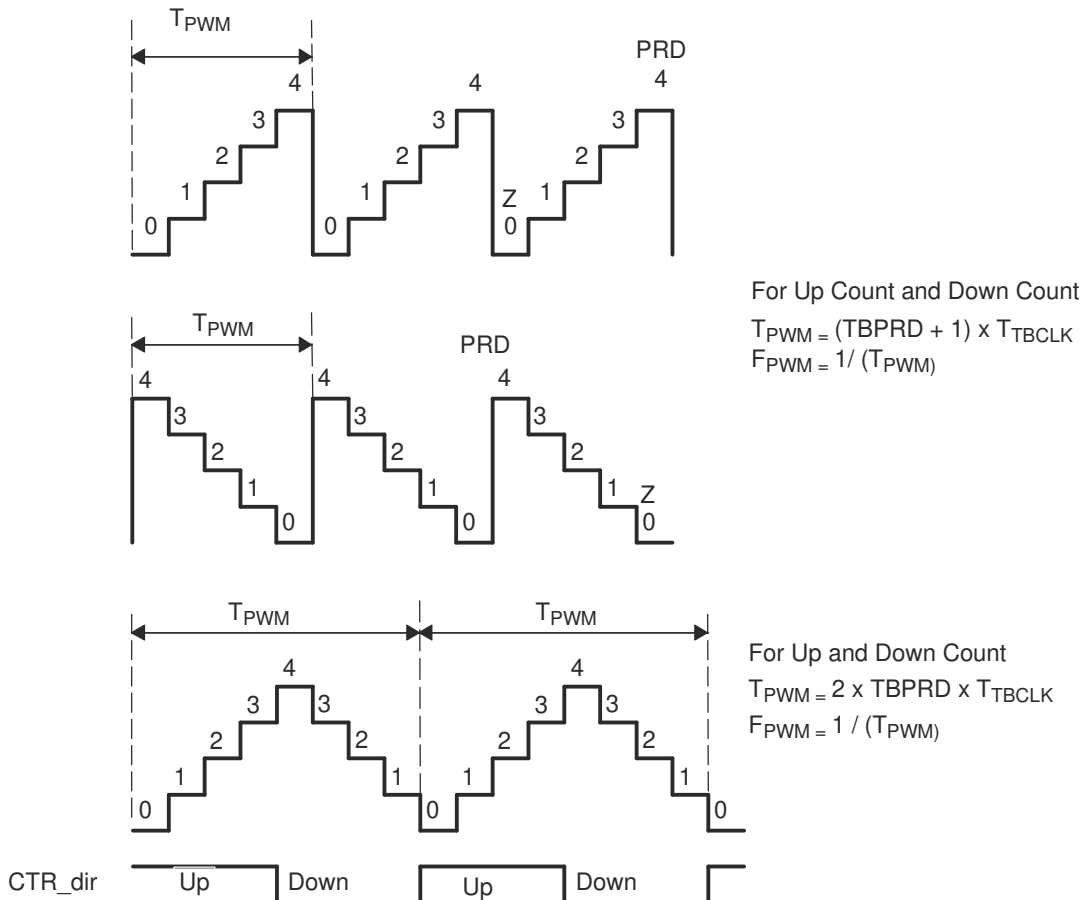

Figure 22-6. Time-Base Frequency and Period

22.4.3.1 Time-Base Period Shadow Register

The time-base period register (TBPRD) has a shadow register. Shadowing allows the register update to be synchronized with the hardware. The following definitions are used to describe all shadow registers in the ePWM module:

- **Active Register:** The active register controls the hardware and is responsible for actions that the hardware causes or invokes.
- **Shadow Register:** The shadow register buffers provide a temporary holding location for the active register and have no direct effect on any control hardware. At a strategic point in time, the shadow register content is transferred to the active register. This prevents corruption or spurious operation due to the register being asynchronously modified by software.

The memory address of the shadow period register is the same as the active register. Which register is written to or read from is determined by the TBCTL[PRDL] bit. This bit enables and disables the TBPRD shadow register as follows:

- **Time-Base Period Shadow Mode:** The TBPRD shadow register is enabled when TBCTL[PRDL] = 0. Reads from and writes to the TBPRD memory address go to the shadow register. The shadow register contents are transferred to the active register (TBPRD (Active) ← TBPRD (shadow)) when the time-base counter equals zero (TBCTR = 0x00) and/or a sync event as determined by the TBCTL2[PRDLDSYNC] bit. The PRDLDSYNC bit is valid only if TBCTL[PRDL] = 0. By default the TBPRD shadow register is enabled. The sources for the SYNC input is explained in [Section 22.4.3.3](#).

The global load control mechanism can also be used with the time-base period register by configuring the appropriate bits in the global load configuration register (GLDCFG). When global load mode is selected the transfer of contents from shadow register to active register, for all registers that have this mode enabled, occurs at the same event as defined by the configuration bits in Global Shadow to Active Load Control Register (GLDCTL). Global load control mechanism is explained in [Section 22.4.7](#).

- **Time-Base Period Immediate Load Mode:** If immediate load mode is selected (TBCTL[PRDL] = 1), then a read from or a write to the TBPRD memory address goes directly to the active register.

22.4.3.2 Time-Base Clock Synchronization

The TBCLKSYNC bit in the peripheral clock enable registers allows all users to globally synchronize all enabled ePWM modules to the time-base clock (TBCLK). When set, all enabled ePWM module clocks are started with the first rising edge of TBCLK aligned. For perfectly synchronized TBCLKs, the prescalers for each ePWM module must be set identically.

The proper procedure for enabling ePWM clocks is as follows:

1. Enable ePWM module clocks in the PCLKCRx register
2. Set TBCLKSYNC= 0
3. Configure ePWM modules
4. Set TBCLKSYNC= 1

22.4.3.3 Time-Base Counter Synchronization

The ePWM synchronization scheme allows for increased flexibility of synchronization of the ePWM modules. Each ePWM module has a synchronization input (SYNCl), a synchronization output (SYNCO) and a peripheral synchronization output (SYNCPER). In Figure 22-7, EXTSYNClN1 is sourced from INPUTXBAR5 and EXTSYNClN2 is sourced from INPUTXBAR6, which can be configured to select any GPIO as the synchronization input. Refer to Section 22.4.3.4 for a list of all sync inputs including INPUTXBAR5 and INPUTXBAR6. Figure 22-8 shows the sources that can be used for EXTSYNCOUOut.

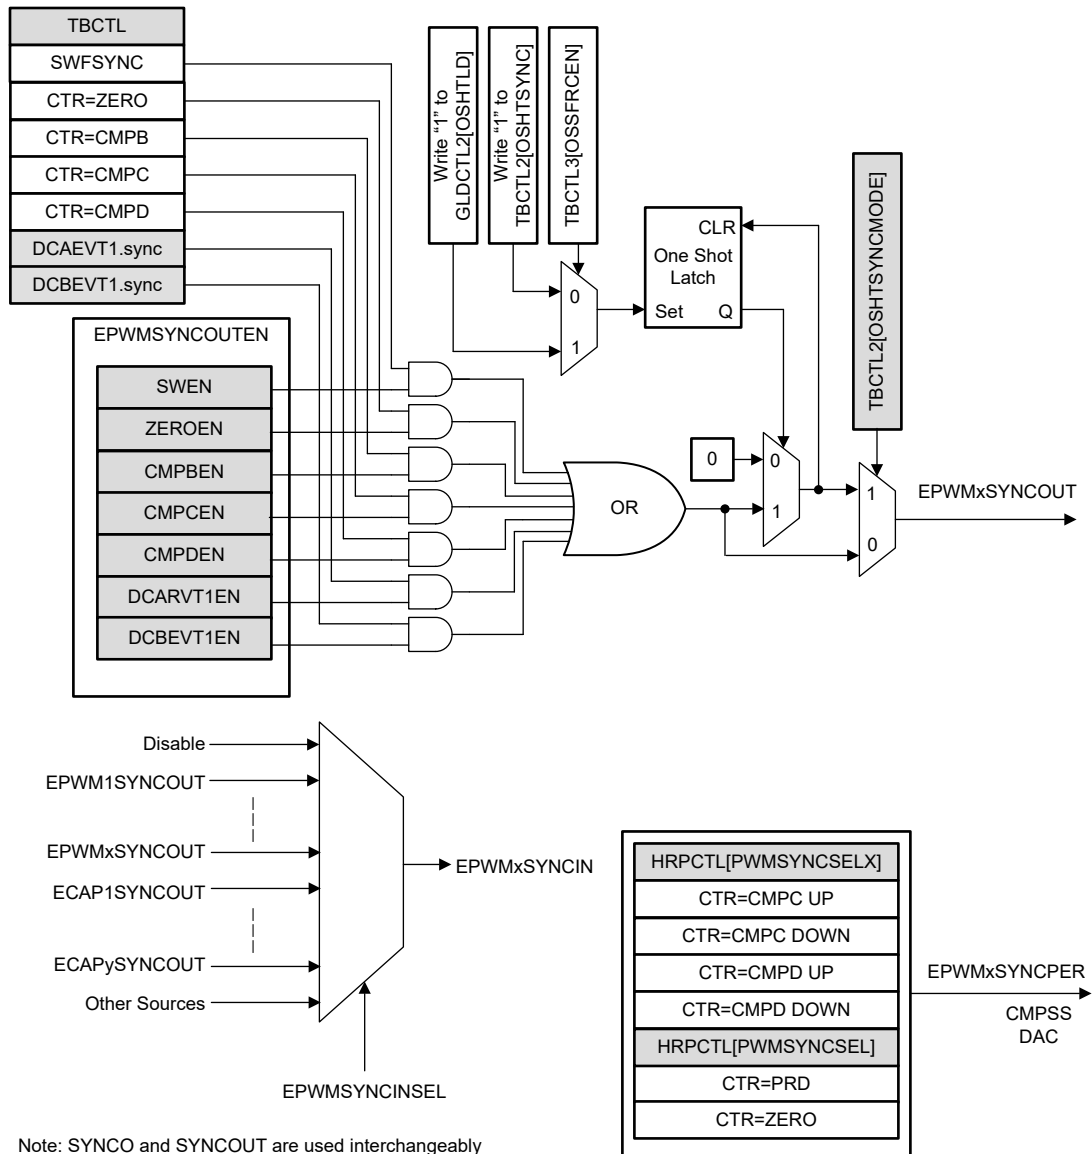

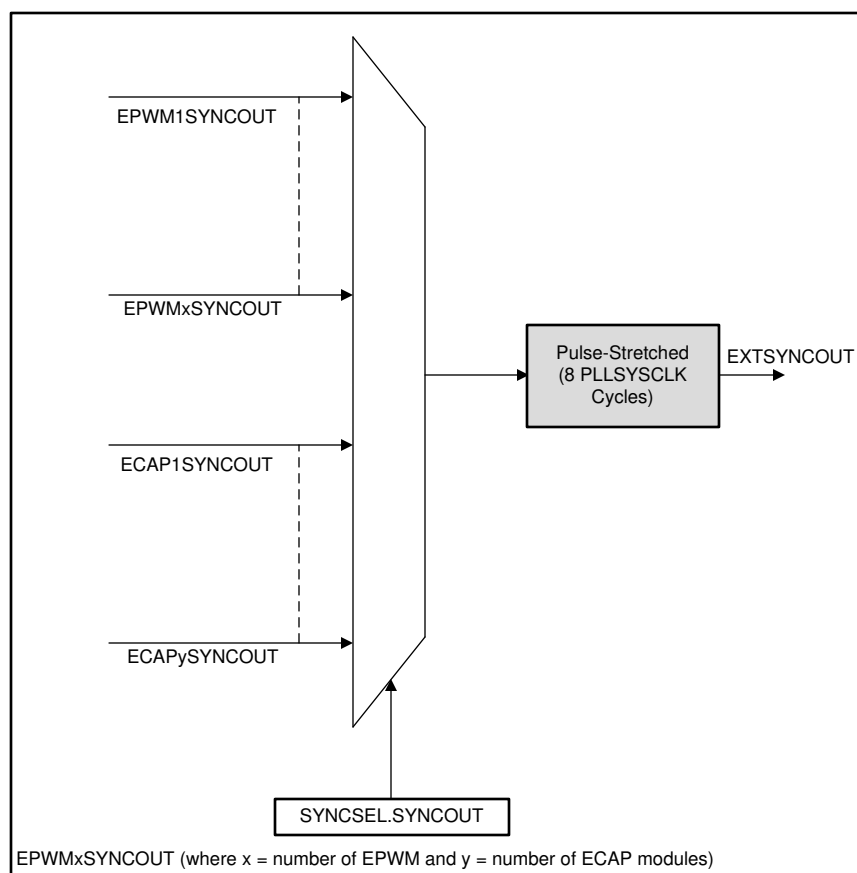

Figure 22-7. Time-Base Counter Synchronization Scheme

Figure 22-8. ePWM External SYNC Output
Note

See the data sheet for the number of ePWM and eCAP modules available on your specific device.

Each ePWM module can be configured to use or ignore the synchronization input. If the TBCTL[PHSEN] bit is set, then the time-base counter (TBCTR) of the ePWM module is automatically loaded with the phase register (TBPHS) contents when one of the following conditions occur:

- **EPWMxSYNCl: Synchronization Input Pulse:** The value of the phase register is loaded into the counter register when an input synchronization pulse is detected (TBPHS → TBCTR). This operation occurs on the next valid time-base clock (TBCLK) edge.
- **Software Forced Synchronization Pulse:** Writing a 1 to the TBCTL[SWFSYNC] control bit invokes a software forced synchronization. This pulse is ORed with the synchronization input signal, and therefore has the same effect as a pulse on EPWMxSYNCl.
- **Digital Compare Event Synchronization Pulse:** DCAEVT1 and DCBEVT1 digital compare events can be configured to generate synchronization pulses which have the same affect as EPWMxSYNCl.

Note

If the EPWMxSYNCl signal is held high, the sync does not continuously occur. The EPWMxSYNCl is rising edge activated.

This feature enables the ePWM module to be automatically synchronized to the time base of another ePWM module. Lead or lag phase control can be added to the waveforms generated by different ePWM modules to synchronize them. In up-down-count mode, the TBCTL[PHSDIR] bit configures the direction of the time-base counter immediately after a synchronization event. The new direction is independent of the direction prior to the

synchronization event. The PHSDIR bit is ignored in count-up or count-down modes. See [Figure 22-9](#) through [Figure 22-12](#) for examples.

Clearing the TBCTL[PHSEN] bit configures the ePWM to ignore the synchronization input pulse.

22.4.4 Phase Locking the Time-Base Clocks of Multiple ePWM Modules

The TBCLKSYNC bit can be used to globally synchronize the time-base clocks of all enabled ePWM modules on a device. This bit is part of the device's clock enable registers and is described in the *System Control and Interrupts* section of this manual. When TBCLKSYNC = 0, the time-base clock of all ePWM modules is stopped (default). When TBCLKSYNC = 1, all ePWM time-base clocks are started with the rising edge of TBCLK aligned. For perfectly synchronized TBCLKs, the prescaler bits in the TBCTL register of each ePWM module must be set identically. The proper procedure for enabling the ePWM clocks is:

1. Enable the individual ePWM module clocks. This is described in the *System Control and Interrupts* chapter.
2. Set TBCLKSYNC= 0. This stops the time-base clock within any enabled ePWM module.
3. Configure the prescaler values and desired ePWM modes.
4. Set TBCLKSYNC = 1.

22.4.5 Simultaneous Writes to TBPRD and CMPx Registers Between ePWM Modules

For variable frequency applications, there is a need for simultaneous writes of TBPRD and CMPx registers between ePWM modules. This prevents situations where a CTR = 0 or CTR = PRD pulse forces a shadow to active load of these registers before all registers are updated between ePWM modules (resulting in some registers being loaded from new shadow values while others are loaded from old shadow values). To support this, an ePWM register linking scheme for TBPRD:TBPRDHR, CMPA:CMPAHR, CMPB:CMPBHR, CMPC, and CMPD registers between PWM modules has been added.

Refer to the register description for EPWMXLINK to see the linked register bit-field values for corresponding ePWM. An example of using the EPWMXLINK is linking ePWM2 CMPA with CMPA of ePWM1 through ePWM2's EPWMXLINK[CMPALINK] register bit-field. In this case, a write to CMPA of ePWM1 also changes the CMPA value for ePWM2.

22.4.6 Time-Base Counter Modes and Timing Waveforms

The time-base counter operates in one of four modes:

- Up-count mode that is asymmetrical
- Down-count mode that is asymmetrical
- Up-down-count that is symmetrical
- Frozen where the time-base counter is held constant at the current value

To illustrate the operation of the first three modes, the following timing diagrams show when events are generated and how the time-base responds to an EPWMxSYNCl signal.

22.4.7 Global Load

Figure 22-13 shows the signals and registers associated with the global load feature.

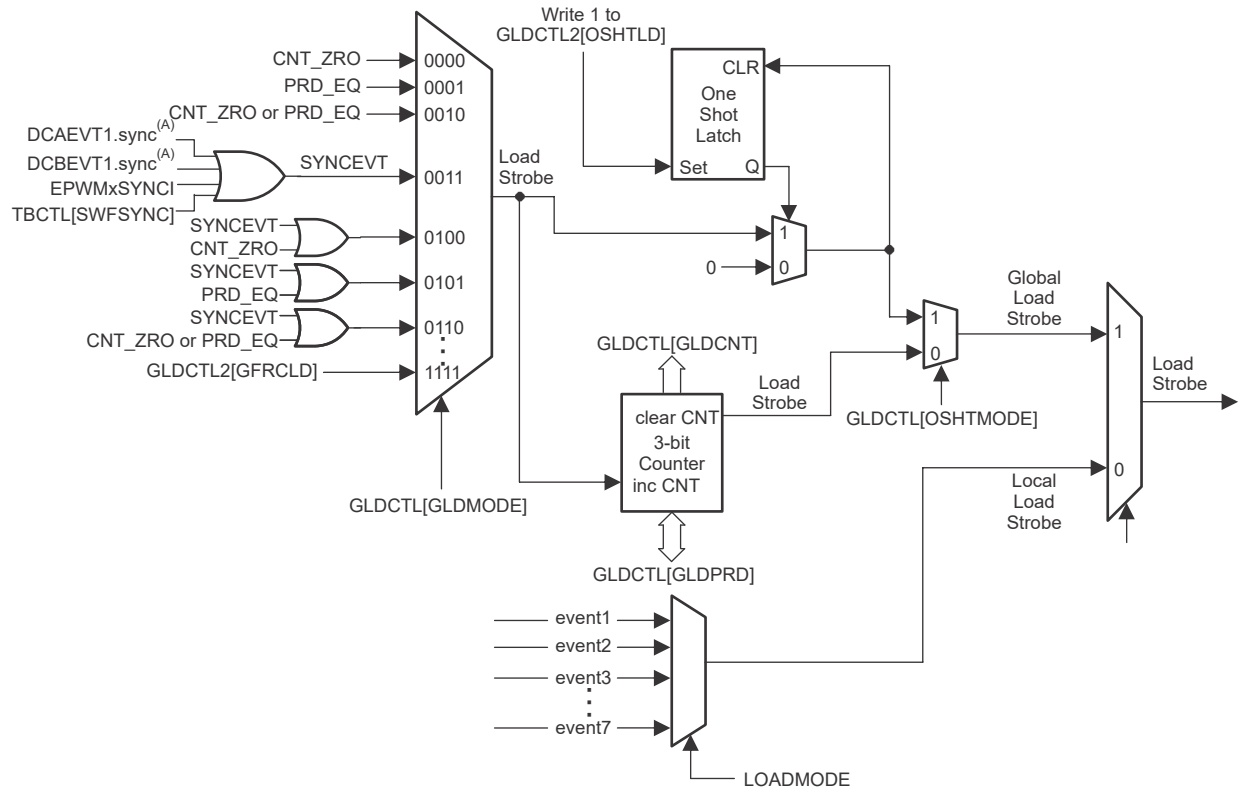

Figure 22-13. Global Load: Signals and Registers

Note

The SYNCEVT signal is only propagated through when PHSEN is SET.

When this feature is enabled, the transfer of contents from the shadow register to the active register, for all registers that have this mode enabled, occurs at the same event as defined by the configuration bits in Global Shadow to Active Load Control Register (GLDCTL[GLDMODE]). When GLDCTL[GLD] = 1, shadow to active load event selection bits for individual shadowed registers are ignored and global load mode takes effect for the corresponding registers enabled by GLDCFG[REGx].

When GLDCTL[GLD] = 1 and GLDCFG[REGx] = 0, global load mode does not affect the corresponding register (REGx). Shadow to active load event selection bits for individual shadowed registers decide how the transfer of contents from shadow register to active register takes place.

22.4.7.1 Global Load Pulse Pre-Scalar

This feature provides the capability to choose shadow to active transfers to happen once in 'N' occurrences of selected global load pulse (GLDCTL[GLDMODE]). This pre-scale functionality is not available for registers that cannot or are not configured to use the global load mechanism (that is, GLDCTL[GLD] = 0 or GLDCFG[REGx] = 0).

22.4.7.2 One-Shot Load Mode

This feature allows users to cause the shadow register to active register transfers to occur once. When $GLDCTL2[OSHTLD] = 1$ the shadow to active register transfer, for registers that are configured to use the global load mechanism, takes place on the event selected by $GLDCTL[GLDMODE]$.

Software force loading of contents from shadow register to active register is possible by using $GLDCTL2[GFRCLD]$. The $GLDCTL2$ register can also be linked across multiple PWM modules by using $EPWMXLINK[GLDCTL2LINK]$. This, along with the one-shot load mode feature discussed above, provides a method to correctly update multiple PWM registers in one or more PWM modules at certain PWM events or, if desired, in the same clock cycle. This is very useful in variable frequency applications and/or multi-phase interleaved applications.

22.4.7.3 One-Shot Sync Mode

To enable the one-shot sync mode to generate a SYNCOUT pulse, configure the $TBCTL2[OSHTSYNCMODE]$ bit and set the $TBCTL2[OSHTSYNC]$ bit as shown in [Figure 22-14](#).

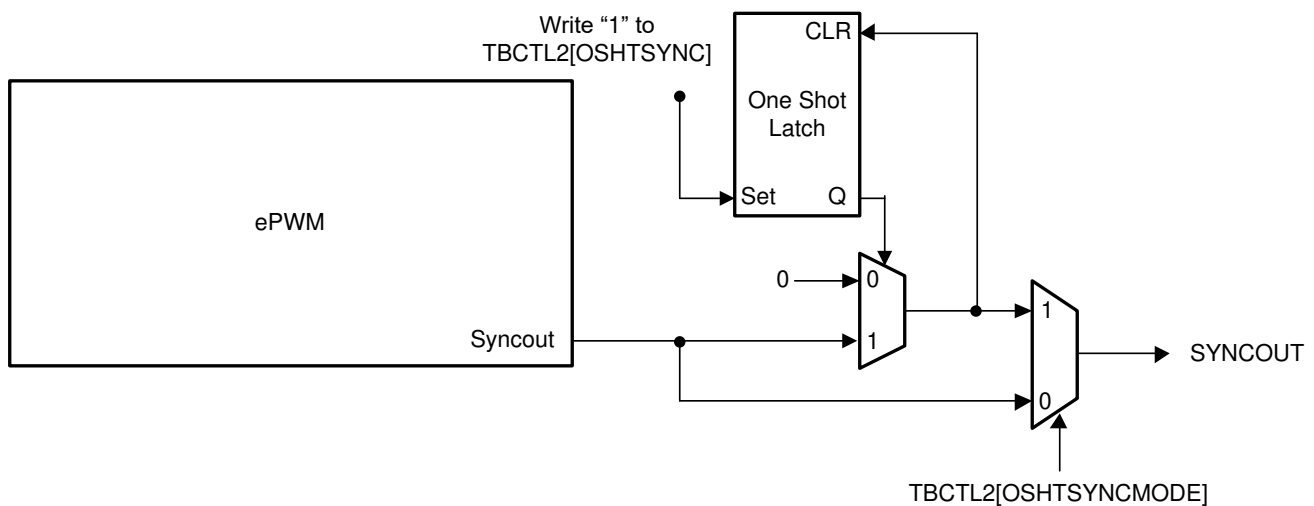

Figure 22-14. One-Shot Sync Mode

22.5 Counter-Compare (CC) Submodule

Figure 22-15 illustrates the counter-compare submodule within the ePWM.

Figure 22-15. Counter-Compare Submodule

22.5.1 Purpose of the Counter-Compare Submodule

The counter-compare submodule takes as input the time-base counter value. This value is continuously compared to the counter-compare A (CMPA), counter-compare B (CMPB), counter-compare C (CMPC), and counter-compare D (CMPD) registers. When the time-base counter is equal to one of the compare registers, the counter-compare unit generates an appropriate event.

The counter-compare:

- Generates events based on programmable time stamps using the CMPA, CMPB, CMPC, and CMPD registers:
 - CTR = CMPA: Time-base counter equals counter-compare A register (TBCTR = CMPA)
 - CTR = CMPB: Time-base counter equals counter-compare B register (TBCTR = CMPB)
 - CTR = CMPC: Time-base counter equals counter-compare C register (TBCTR = CMPC)
 - CTR = CMPD: Time-base counter equals counter-compare D register (TBCTR = CMPD)
- Controls the PWM duty cycle, if the action-qualifier submodule is configured appropriately using counter-compare A (CMPA) and counter-compare B (CMPB)
- Shadows new compare values to prevent corruption or glitches during the active PWM cycle

22.5.2 Controlling and Monitoring the Counter-Compare Submodule

The counter-compare submodule operation is shown in Figure 22-16.

- A. These events are generated by the ePWM digital compare (DC) submodule based on the levels of the TRIPIN inputs (for example, CMPSSx and TZ signals).

Figure 22-16. Detailed View of the Counter-Compare Submodule

22.5.3 Operational Highlights for the Counter-Compare Submodule

The counter-compare submodule is responsible for generating events that can be used in the action-qualifier and event-trigger submodules. There are four independent compare events:

1. CTR = CMPA: Time-base counter equal to counter-compare A register (TBCTR = CMPA).
2. CTR = CMPB: Time-base counter equal to counter-compare B register (TBCTR = CMPB).
3. CTR = CMPC: Time-base counter equal to counter-compare C register (TBCTR = CMPC). This event can be used to generate an event in the event trigger submodule only.
4. CTR = CMPD: Time-base counter equal to counter-compare D register (TBCTR = CMPD). This event can be used to generate an event in the event trigger submodule only.

For up-count or down-count mode, each event occurs only once per cycle. For up-down count mode, each event occurs twice per cycle if the compare value is between 0x00-TBPRD; and once per cycle if the compare value is equal to 0x00 or equal to TBPRD. These events are applied to the action-qualifier submodule where the events are qualified by the counter direction and converted into actions if enabled. Refer to [Section 22.6.1](#) for more details.

The counter-compare registers CMPA and CMPB each have an associated shadow register. Shadowing provides a way to keep updates to the registers synchronized with the hardware. When shadowing is used, updates to the active registers only occur at strategic points. This prevents corruption or spurious operation due to the register being asynchronously modified by software. The memory address of the active register and the shadow register is identical. The register that is written to or read from is determined by the CMPCTL[SHDWAMODE] and CMPCTL[SHDWBMODE] bits. These bits enable and disable the CMPC shadow register and CMPD shadow register, respectively. The behavior of the two load modes is:

Shadow Mode:

The shadow mode for the CMPA is enabled by clearing the CMPCTL[SHDWAMODE] bit and the shadow register for CMPB is enabled by clearing the CMPCTL[SHDWBMODE] bit. Shadow mode is enabled by default for both CMPA and CMPB.

If the shadow register is enabled then the content of the shadow register is transferred to the active register on one of the following events as specified by the CMPCTL[LOADAMODE], CMPCTL[LOADBMODE], CMPCTL[LOADASYNC], and CMPCTL[LOADBSYNC] register bits:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
- Both CTR = PRD and CTR = Zero
- SYNC event caused by DCAEVT1 or DCBEVT1 or EPWMxSYNCl or TBCTL[SWFSYNC]
- Both SYNC event or a selection made by LOADAMODE/LOADBMODE

Only the active register contents are used by the counter-compare submodule to generate events to be sent to the action-qualifier.

Note

Refer to [Section 22.6.5](#) for valid configurations of CMPA/CMPB and LOADAMODE/LOADBMODE.

Immediate Load Mode:

If the immediate load mode is selected (that is, CMPCTL[SHDWAMODE] = 1 or CMPCTL[SHDWBMODE] = 1), then a read from or a write to the register goes directly to the active register.

Additional Comparators

The counter-compare submodule on ePWMs type 2 and later are responsible for generating two additional independent compare events based on two compare registers, which is fed to Event Trigger submodule:

1. CTR = CMPC: Time-base counter equal to counter-compare C register (TBCTR = CMPC).
2. CTR = CMPD: Time-base counter equal to counter-compare D register (TBCTR = CMPD).

The counter-compare registers CMPC and CMPD each have an associated shadow register. By default this register is shadowed. The memory address of the active register and the shadow register is identical. The value in the active CMPC and CMPD register is compared to the time-base counter (TBCTR). When the values are equal, the counter compare module generates a “time-base counter equal to counter compare C or counter compare D” event respectively. Shadowing of this register is enabled and disabled by the CMPCTL2[SHDWCMODE] and CMPCTL2[SHDWDMODE] bit. These bits enable and disable the CMPC shadow register and CMPD shadow register respectively. The behavior of the two load modes is described below:

Shadow Mode:

The shadow mode for the CMPC is enabled by clearing the CMPCTL2[SHDWCMODE] bit and the shadow register for CMPD is enabled by clearing the CMPCTL2[SHDWDMODE] bit. Shadow mode is enabled by default for both CMPC and CMPD.

If the shadow register is enabled then the content of the shadow register is transferred to the active register on one of the following events as specified by the CMPCTL2[LOADCMODE], CMPCTL2[LOADDMODE], CMPCTL2[LOADCSYNC], and CMPCTL2[LOADDSYNC] register bits:

- CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
- CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
- Both CTR = PRD and CTR = Zero
- SYNC event caused by DCAEVT1 or DCBEVT1 or EPWMxSYNCl or TBCTL[SWFSYNC]
- Both SYNC event or a selection made by LOADCMODE/LOADDMODE

Only the active register contents are used by the counter-compare submodule to generate events to be sent to the action-qualifier.

Immediate Load Mode:

If the immediate load mode is selected (that is, CMPCTL2[SHDWCMODE] = 1 or CMPCTL2[SHDWDMODE] = 1), then a read from or a write to the register goes directly to the active register.

Global Load Support

The global load control mechanism can also be used for all counter-compare registers by configuring the appropriate bits in the global load configuration register (GLDCFG). When the global load mode is selected the transfer of contents from shadow register to active register, for all registers that have this mode enabled, occurs at the same event as defined by the configuration bits in the Global Shadow to Active Load Control Register (GLDCTL). The global load control mechanism is explained in [Section 22.4.7](#).

22.5.4 Count Mode Timing Waveforms

The counter-compare module can generate compare events in all three count modes:

- Up-count mode: used to generate an asymmetrical PWM waveform.
- Down-count mode: used to generate an asymmetrical PWM waveform.
- Up-down-count mode: used to generate a symmetrical PWM waveform.

To best illustrate the operation of the first three modes, the timing diagrams in [Figure 22-17](#) through [Figure 22-20](#) show when events are generated and how the EPWMxSYNCl signal interacts.

An EPWMxSYNCl external synchronization event can cause a discontinuity in the TBCTR count sequence. This can lead to a compare event being skipped. This skipping is considered normal operation and must be taken into account.

22.6 Action-Qualifier (AQ) Submodule

The action-qualifier submodule has the most important role in waveform construction and PWM generation. The action-qualifier submodule decides which events are converted into various action types, thereby, producing the required switched waveforms at the EPWMxA and EPWMxB outputs.

Figure 22-21 illustrates the action-qualifier submodule within the ePWM.

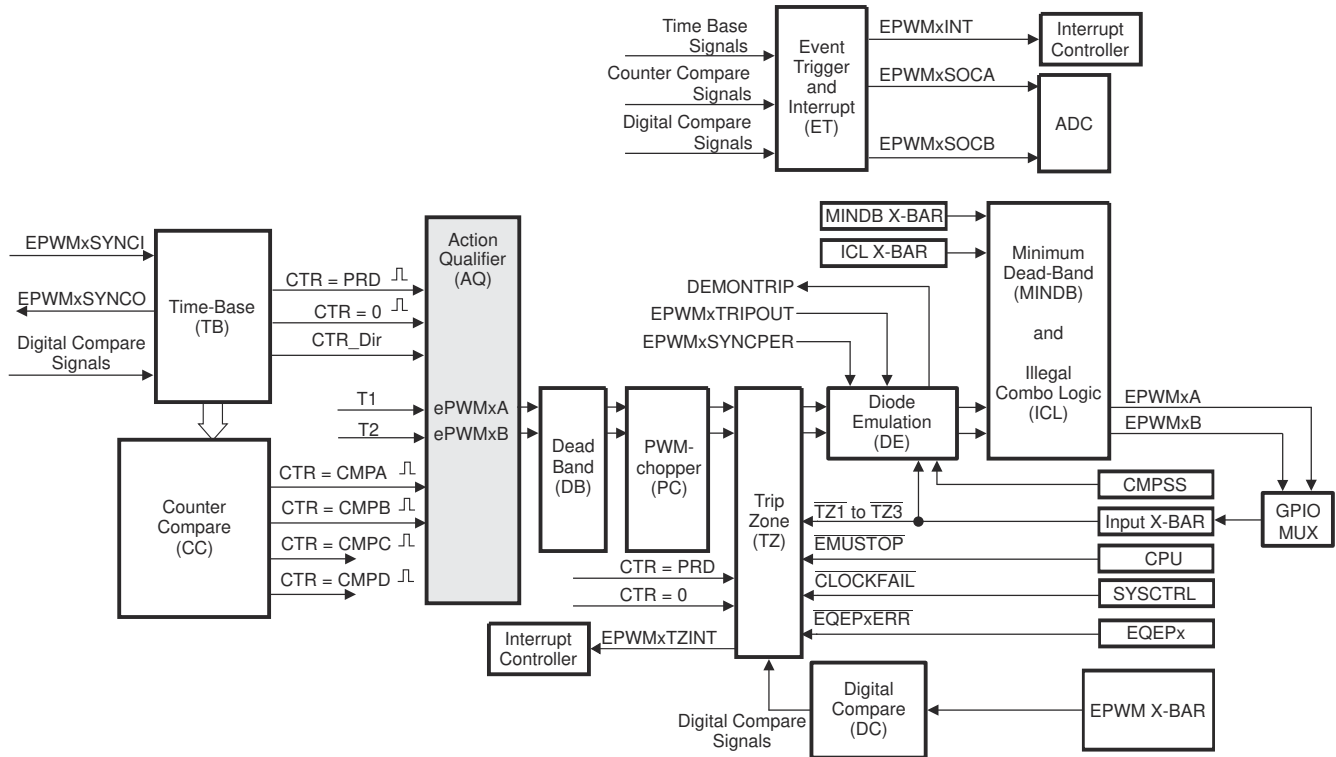

Figure 22-21. Action-Qualifier Submodule

22.6.1 Purpose of the Action-Qualifier Submodule

The action-qualifier submodule is responsible for the following:

- Qualifying and generating actions (set, clear, toggle) based on the following events:
 - CTR = PRD: Time-base counter equal to the period (TBCTR = TBPRD).
 - CTR = Zero: Time-base counter equal to zero (TBCTR = 0x00)
 - CTR = CMPA: Time-base counter equal to the counter-compare A register (TBCTR = CMPA)
 - CTR = CMPB: Time-base counter equal to the counter-compare B register (TBCTR = CMPB)
- T1, T2 events: Trigger events based on comparator, trip or syncin events
- Managing priority when these events occur concurrently
- Providing independent control of events when the time-base counter is increasing and when it is decreasing

22.6.2 Action-Qualifier Submodule Control and Status Register Definitions

The action-qualifier submodule operation is shown in [Figure 22-22](#) and monitored by way of the registers in [Section 22.20](#).

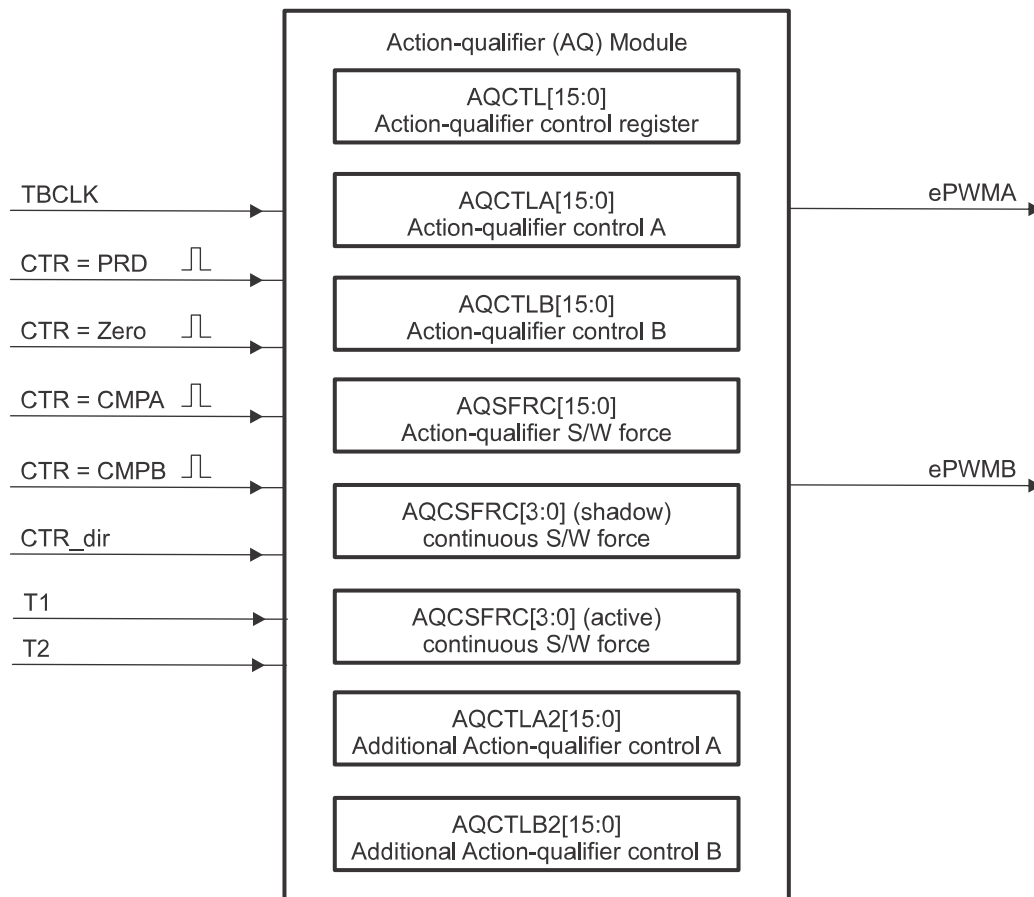

Figure 22-22. Action-Qualifier Submodule Inputs and Outputs

For convenience, the possible input events are summarized again in [Table 22-4](#).

Table 22-4. Action-Qualifier Submodule Possible Input Events

Signal	Description	Registers Compared
CTR = PRD	Time-base counter equal to the period value	TBCTR = TBPRD
CTR = Zero	Time-base counter equal to 0	TBCTR = 0x00
CTR = CMPA	Time-base counter equal to the counter-compare A	TBCTR = CMPA
CTR = CMPB	Time-base counter equal to the counter-compare B	TBCTR = CMPB
T1 event	Based on comparator, trip, or syncin events	None
T2 event	Based on comparator, trip, or syncin events	None
Software forced event	Asynchronous event initiated by software	

The software forced action is a useful asynchronous event. This control is handled by the AQSFRC and AQCSFRC registers.

Note

If the CSFA is not used in shadow mode, the RLDCSF bit must be configured to disable shadow mode.

The action-qualifier submodule controls how the two outputs EPWMxA and EPWMxB behave when a particular event occurs. The event inputs to the action-qualifier submodule are further qualified by the counter direction (up or down). This allows for independent action on outputs on both the count-up and count-down phases.

The possible actions imposed on outputs EPWMxA and EPWMxB are:

- **Set High:** Set output EPWMxA or EPWMxB to a high level.
- **Clear Low:** Set output EPWMxA or EPWMxB to a low level.
- **Toggle:** If EPWMxA or EPWMxB is currently pulled high, then pull the output low. If EPWMxA or EPWMxB is currently pulled low, then pull the output high.
- **Do Nothing:** Keep outputs EPWMxA and EPWMxB at same level as currently set. Although the "Do Nothing" option prevents an event from causing an action on the EPWMxA and EPWMxB outputs, this event can still trigger interrupts and ADC start of conversion. See the description in [Section 22.13](#) for details.

Actions are specified independently for either output (EPWMxA or EPWMxB). Any or all events can be configured to generate actions on a given output. For example, both CTR = CMPA and CTR = CMPB can operate on output EPWMxA. All qualifier actions are configured using the control registers found in the *ePWM Registers* section.

For clarity, the illustrations in this chapter use a set of symbolic actions. These symbols are summarized in [Figure 22-23](#). Each symbol represents an action as a marker in time. Some actions are fixed in time (zero and period) while the CMPA and CMPB actions are moveable and their time positions are programmed by way of the counter-compare A and B registers, respectively. To turn off or disable an action, use the "Do Nothing option"(the default at reset).

SW force	TB Counter equals			Trigger Events			Actions
	Zero	Comp A	Comp B	Period	T1	T2	
							Do Nothing
							Clear Lo
							Set Hi
							Toggle

Figure 22-23. Possible Action-Qualifier Actions for EPWMxA and EPWMxB Outputs

The Action Qualifier Trigger Event Source Selection register (AQTSRCSEL) is used to select the source for T1 and T2 events. T1/T2 selection and configuration of a trip/digital-compare event in Action Qualifier submodule is independent of the configuration of that event in the Trip-Zone submodule. A particular trip event can or cannot

be configured to cause trip action in the Trip Zone submodule, but the same event can be used by the Action Qualifier to generate T1/T2 for controlling PWM generation.

22.6.3 Action-Qualifier Event Priority

It is possible for the ePWM action qualifier to receive more than one event at the same time. In this case, events are assigned a priority by the hardware. The general rule is events occurring later in time have a higher priority and software forced events always have the highest priority. The event priority levels for up-down count mode are shown in [Table 22-5](#). A priority level of 1 is the highest priority and level 10 is the lowest. The priority changes slightly depending on the direction of TBCTR.

Table 22-5. Action-Qualifier Event Priority for Up-Down-Count Mode

Priority Level	Event If TBCTR is Incrementing TBCTR = Zero up to TBCTR = TBPRD	Event If TBCTR is Decrementing TBCTR = TBPRD down to TBCTR = 1
1 (Highest)	Software forced event	Software forced event
2	T1 on up-count (T1U)	T1 on down-count (T1D)
3	T2 on up-count (T2U)	T2 on down-count (T2D)
4	Counter equals CMPB on up-count (CBU)	Counter equals CMPB on down-count (CBD)
5	Counter equals CMPA on up-count (CAU)	Counter equals CMPA on down-count (CAD)

7	T1 on down-count (T1D)	T1 on up-count (T1U)
8 (Lowest)	T2 on down-count (T2D)	T2 on up-count (T2U)

[Table 22-6](#) shows the action-qualifier priority for up-count mode. In this case, the counter direction is always defined as up; therefore, down-count events never are taken.

6	Counter equal to CMPA on down-count (CAD)
7 (Lowest)	Counter equal to period (TBPRD)

It is possible to set the compare value greater than the period. In this case, the action takes place as shown in [Table 22-8](#).
