  - a. [31:16] LINE\_COUNT -> define desired value
  - b. [15:0] BYTE\_COUNT -> define desired value
2. Set the Virtual Channel to the one that is enabled, and set enable in register CSIRX\_STREAM0\_MONITOR\_CTRL.
  - a. [15] FRAME\_MON\_EN -> set to '1'
  - b. [14:11] FRAME\_MON\_VC -> define VC used
  - c. [4] LB\_EN -> set to '1'
  - d. [3:0] LB\_VC -> set to VC used

Software should now use the interrupts in register CSIRX\_MONITOR\_IRQS. To be able to do that you will need to allow those interrupts through the mask register CSIRX\_MONITOR\_IRQS\_MASK\_CFG.

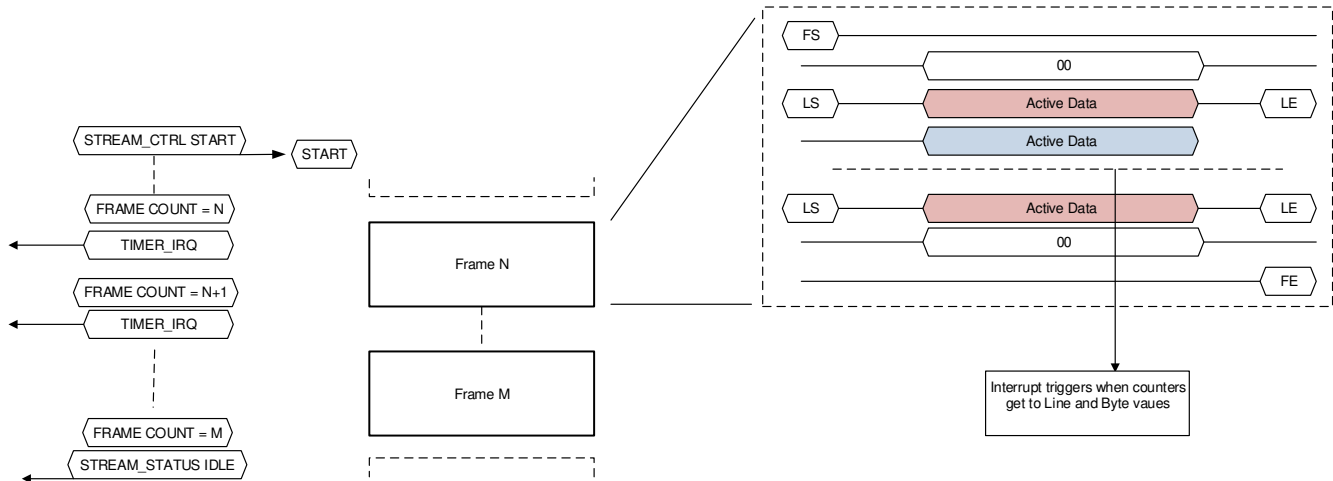

1. By default, the CSIRX\_MONITOR\_IRQS\_MASK\_CFG register is set to all '0', meaning all interrupts are disabled.
  - a. [7] STREAM0\_LINE\_CNT\_ERROR\_IRQM -> set to '1'
  - b. STREAM0\_LB\_IRQM [1] -> set to '1'
2. Create an interrupt handler to read from CSIRX\_MONITOR\_IRQS.
  - a. [7] STREAM0\_LINE\_CNT\_ERROR\_IRQ -> read, if '1', line count error interrupt is triggered
  - b. [1] STREAM0\_LB\_IRQ -> read, if '1', line/byte counter interrupt is triggered

Note that the interrupt will trigger on each frame when it reaches byte number BYTE\_COUNT in line number LINE\_COUNT.

To ensure correct functionality, it is highly recommended that the input device (i.e. camera) should be configured after the CSI\_RX\_IF has been configured and enabled.

Software must make sure all the Virtual Channel fields in the registers explained above are set to the correct VC being used by the stream.

**Figure 12-386. Line/Byte Counters Interrupt Flow Diagram**

#### 12.6.1.4.8.13 Example Controller Programming Sequence (Single Stream Operation)

The single stream operation will provide the smallest multi-lane IP configuration with the reduced registers configuration removing some control and status registers. The stream will not require a large FIFO configuration and the clock rates will be matched to simplify the implementation to single pixel transfers using all the available interface bits, (i.e. up to 32).

**Figure 12-387. Basic Single Stream Use Case Illustration**

For single pixel stream configuration, elastic buffer, RAW8 Data type on VC2, one pixel per cycle:

1. Configure the number of DPHY\_RX lanes:
  - a. See CSIRX\_STATIC\_CFG register
2. Set Error Interrupt mask:
  - a. See CSIRX\_ERROR\_IRQS\_MASK\_CFG register
3. Set the Pixel Interface and FIFO configuration. See CSIRX\_STREAM0\_CFG - CSIRX\_STREAM3\_CFG.
  - a. Set [9-8] FIFO\_MODE to select the elastic buffer configuration -> '1'

- b. Set the FIFO fill level that will determines the FIFO depth that must be reached before data is output -> 0x0000
  - c. Select the number of pixels to be output on each cycle -> '0'.
  - d. Set the type of stream interface to "pixel" mode -> '0'
4. Select the virtual channel and data types to be processed. See CSIRX\_STREAM0\_DATA\_CFG - CSIRX\_STREAM3\_DATA\_CFG register.
  - a. Set [31-16] VC\_SELECT and virtual channel bits if not supporting all virtual channels -> 1h, 2h
  - b. Set [7] ENABLE\_DT0 and [5-0] DATATYPE\_SELECT0 values for one or both data types (default all DT) -> 0h, 1h, 2Ah
5. Enable the stream to begin processing the incoming data from the DPHY\_RX. See CSIRX\_STREAM0\_CTRL - CSIRX\_STREAM3\_CTRL.
  - a. Set [0] START bit -> '1'

The stream will begin to pass pixel data matching the configuration on the next frame start.

#### 12.6.1.4.8.14 CSI\_RX\_IF Programming Restrictions

The following CSI\_RX\_IF programming restrictions apply:

- Full line buffer mode is not supported.
- LS/LE detection has a restriction to be disabled
- Only use Pixel transmit mode can be used, never packet mode
  - In pixel mode only single, dual, or quad mode can be used. It is not allowed to mix these based on data format or virtual channels.
- LSB alignment only
- Video port(VP) stream interfaces must be programmed in the CSI\_RX\_IF to meet the following restrictions:
  - Raw 8-16 formats only
  - Dual pixel mode
  - Filtering for single virtual channel and single data type

#### Note

CSI\_RX\_IF has a limitation that any line must fully be exported on its stream interface before a new line or even end of frame is sent on the D-PHY interface. To meet this requirement, software will need to take into account export rates on stream interface(single, dual, quad modes) at 500MHz versus D-PHY 32-bits @ byte clock frequency to know when a new line or end of frame can be sent in after last line was sent over D-PHY interface.

Table 12-301 shows the CSI\_RX\_IF programming requirements for pixel modes and data sizes.

**Table 12-301. CSI\_RX\_IF Programming requirements for pixel modes and data sizes**

Format	Pixel transmit mode used	Size	Details
RAW(6-8), user defined 8-bit	Single	0	
RAW(6-8), user defined 8-bit	Dual	1	
RAW(6-8), user defined 8-bit	Quad	2	
RAW(10-16), user defined 16-bit	Single	1	
RAW(10-16), user defined 16-bit	Dual	2	
RAW20	Single	2	
YUV422-8	Single	0	must set dual mode=0
YUV422-8	Dual	0	must set dual mode=1
YUV422-10	Single	1	
YUV420-8	Single	0	must set dual mode=0
YUV420-8	Dual	0	must set dual mode=1
YUV420-10	Single	1	

#### 12.6.1.4.8.15 CSI\_RX\_IF Real-time operating requirements

Care must be taken on blanking requirements for next line, end of frame, or start of frame. The previous packets(long or short) must be fully consumed before any new line, end of frame, or start frame can be sent over the CSI interface. Software will get various error conditions if these are not met. Below are some sample equations to determine this blanking time. Note that this is not blanking data. High level details are that the internal FIFO must be completely empty prior to sending any thing new into it. below are some sample equations to determine how much time is needed to empty the FIFO and blanking time needed. Byte clock rates, pixel data type, and export modes play into the calculation as well.

$$\text{Byte\_clock\_rate} \times 8 \times \#\text{lanes} \times \text{Tcsi} = \text{pixel\_clock\_rate} \times \text{BPP} \times \text{Tpix} = \text{total bits} \quad (22)$$

BPP = Bits Per Pixel. This number is how many bits are sent per pixel clock cycle is based on single, dual, quad modes and data type.

Tcsi = Time for csi interface to complete 1 line

Tpix = Time for pixel interface to complete 1 line

Tpix16 = Tpix+16/pixel\_clock\_rate

(Tpix16-Tcsi) = required blanking time on CSI interface

Tpix16-Tcsi <= 0 implies 0

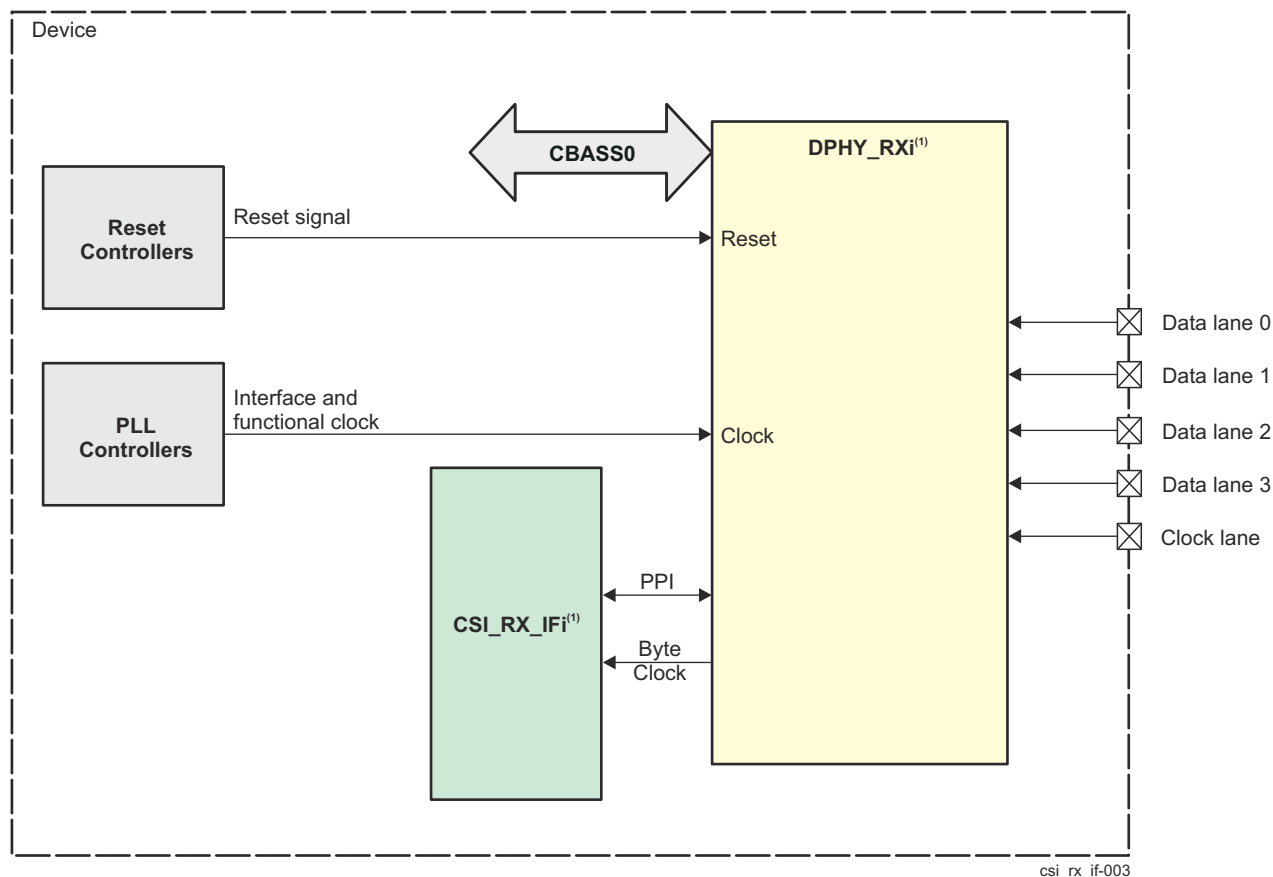

## 12.6.2 MIPI D-PHY Receiver (DPHY\_RX)

The following sections describe the MIPI D-PHY receiver (DPHY\_RX) module(s) in the device.

### 12.6.2.1 DPHY\_RX Overview

The integration of the DPHY\_RX camera physical port module allows the device to grab video streams from external sensor cameras and other CSI2 compliant sources.

Figure 12-388 shows the DPHY\_RX module overview.

A. i represents a DPHY\_RX instance. See the device datasheet for available domains and DPHY\_RX instances.

**Figure 12-388. DPHY\_RX Module Overview**

#### 12.6.2.1.1 DPHY\_RX Features

The DPHY\_RX module supports the following features:

- Compliant to MIPI D-PHY standard v1.2
- Supports up to 4 data and 1 clock lanes
- Supports up to 2.5 Gbps (with deskew) and 1.5 Gbps (without deskew) per data lane
- Clock lane control / interface logic type is **CIL-SCNN** for HS and low power receiving:
  1. **(S)** Peripheral
  2. **Clock**
  3. **N/A** forward, **N/A** reverse escape mode features
- Data lane control / interface logic type is **CIL-SFAN** for HS and low power receiving:
  1. **(S)** Peripheral
  2. **Forward** direction only for high speed mode
  3. **All** forward direction escape mode features are supported
  4. **No** reverse direction escape mode features are supported

- Data lanes can be independently operated in HS or ULP mode
- Swapping of DP/DN signals within each clock/data pair (Facilitated by CSI\_RX\_IF controller)

#### 12.6.2.1.2 Unsupported Features

See the *Module Integration* section for information about unsupported features.

---

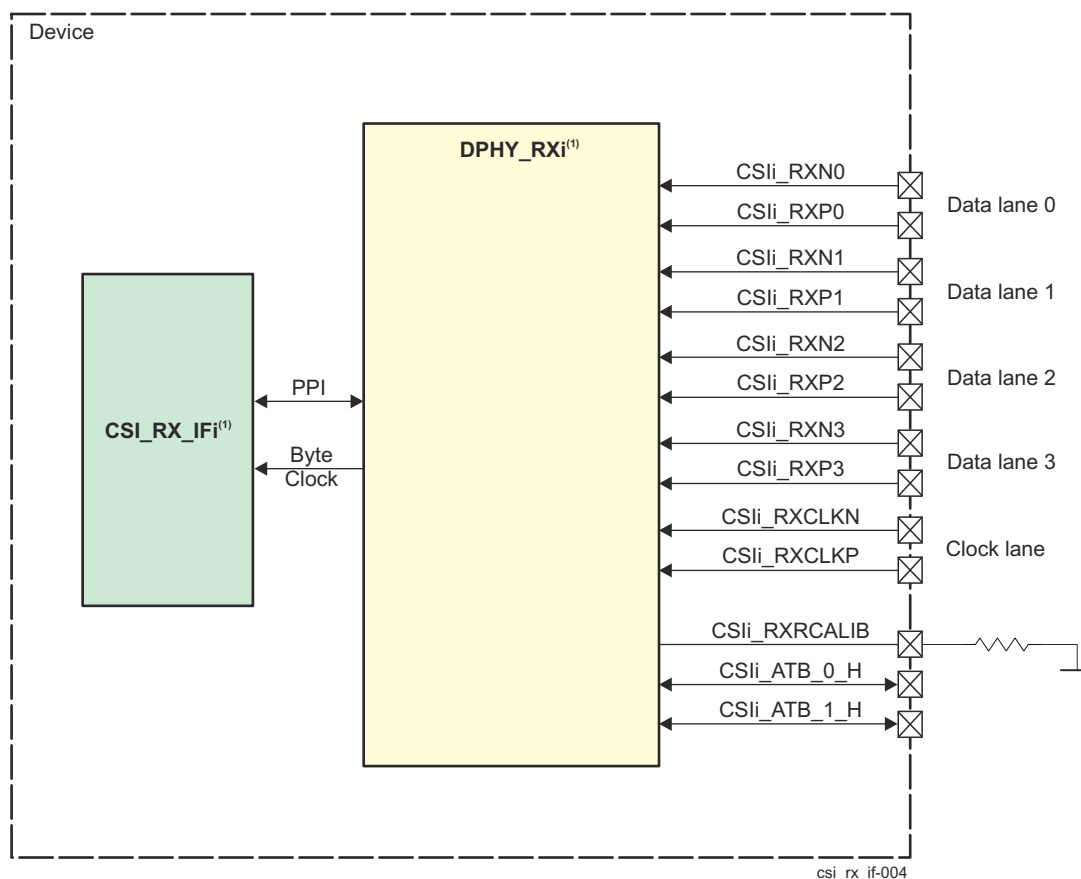

#### Note

Some features may not be available. See *Module Integration* for more information.

---

### 12.6.2.2 DPHY\_RX Environment

This section describes the DPHY\_RX application fields from an environment point of view (external connections).

A. i represents a DPHY\_RX instance. See the device datasheet for available domains and DPHY\_RX instances.

**Figure 12-389. DPHY\_RX Enviroment**

[Table 12-302](#) describes the external signals of the DPHY\_RX.

**Table 12-302. DPHY\_RX I/O Signals**

Device Level Signal	I/O	Description
<b>DPHY_RXi<sup>(1)</sup></b>		
CSii <sup>(1)</sup> _RXN0	I	Lane 0 Receive Differential Data (Negative)
CSii <sup>(1)</sup> _RXP0	I	Lane 0 Receive Differential Data (Positive)
CSii <sup>(1)</sup> _RXN1	I	Lane 1 Receive Differential Data (Negative)
CSii <sup>(1)</sup> _RXP1	I	Lane 1 Receive Differential Data (Positive)
CSii <sup>(1)</sup> _RXN2	I	Lane 2 Receive Differential Data (Negative)
CSii <sup>(1)</sup> _RXP2	I	Lane 2 Receive Differential Data (Positive)
CSii <sup>(1)</sup> _RXN3	I	Lane 3 Receive Differential Data (Negative)
CSii <sup>(1)</sup> _RXP3	I	Lane 3 Receive Differential Data (Positive)
CSii <sup>(1)</sup> _RXCLKN	I	Lane 3 Receive Differential Clock (Negative)
CSii <sup>(1)</sup> _RXCLKP	I	Lane 3 Receive Differential Clock (Positive)
CSii <sup>(1)</sup> _RXRCALIB	A	Pin for external calibration resistor. An external resistor must be connected between this pin and package ground. Refer to the device-specific Datasheet for a recommended resistor value.

(1) i represents a DPHY\_RX instance. See the device datasheet for available domains and DPHY\_RX instances

#### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

### 12.6.2.3 Integration

See the *Module Integration* section for information about clocks, resets and hardware requests.

## 12.6.2.4 DPHY\_RX Functional Description

### 12.6.2.4.1 DPHY\_RX Programming Guide

#### 12.6.2.4.1.1 Overview

This section details specific steps on how to program the DPHY\_RX

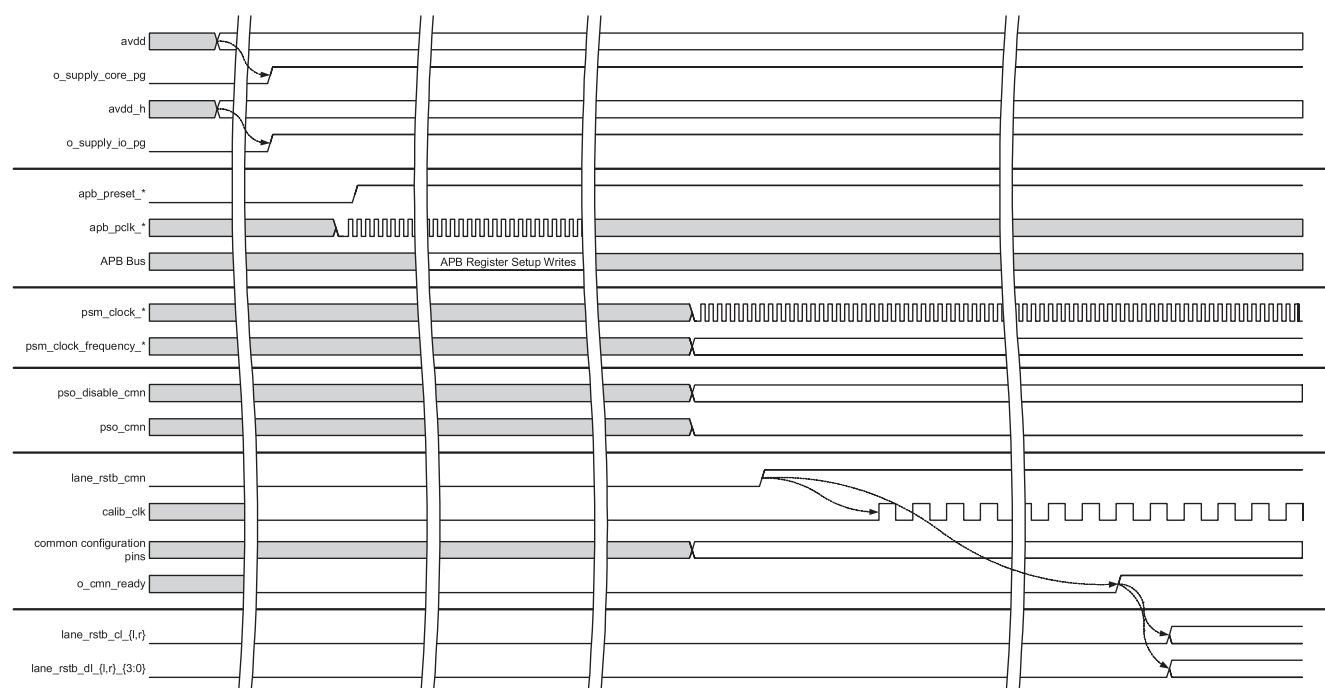

#### 12.6.2.4.1.2 Initial Configuration Programming

The DPHY\_RX operation shows the registers that are written during the startup sequence.

This section provides description and timing diagrams for DPHY\_RX operation. Unless otherwise described in this subsection, the DPHY\_RX PPI interface is compliant with the timing diagrams described in the MIPI D-PHY v1.2 specification.

#### 12.6.2.4.1.2.1 Start-up Sequence Timing Diagram

The common configuration pins noted in [Figure 12-390](#) are ipconfig\_cmnn, pll\_ipdiv, pll\_fbdiv, pll\_opdiv, psm\_clock\_freq\_cmnn. Drive these pins as per the pin description given in PHY pin list.

**Figure 12-390. Common Power Up and Initialization Timing Diagram**

**Figure 12-391. Lane Power Up and Initialization Timing Diagram**

**Figure 12-392. PHY Disable Timing Diagram**

For initial set up, the DPHY\_RX must be configured/set (registers and configuration input pins) for the common module prior to releasing it from reset, and the lane modules prior to releasing them from reset. Registers shall be configured (as required) between releasing the APB from reset and releasing the common / lanes from reset.

Note that in some cases, the option exists to configure a function using either a pin or a register. In such cases, both options will be specified and the you can select the preferred option.

#### 12.6.2.4.1.3 Common Configuration

**Table 12-303. Common Configuration-Related Setup**

Configuration Register / Pin	Configuration Requirement
PHY Pin: psm_clock_freq PHY Register: DPHY_RX_VBUS2APB_PCS_TX_DIG_TBIT 1	Set the PMA state machine clock frequency divider. Set either the pin or the register, as specified in the respective description, for the required PMA state machine clock.
PHY Pin: ipconfig_cmn PHY Register: DPHY_RX_MMR_SLV_LANE[11-9] IPCONFIG_CMN	Set the clock lane configuration. Set as specified in the description for the required clock lane configuration.

**Table 12-303. Common Configuration-Related Setup (continued)**

Configuration Register / Pin	Configuration Requirement
PMA Register: DPHY_RX_VBUS2APB_CMN0_CMN_DIG_T BIT2[0] O_CMN_SSM_EN, DPHY_RX_VBUS2APB_CMN0_CMN_DIG_T BIT2[10] O_CMN_RX_MODE_EN	Enable the startup state machines for TX mode of operation. Set both register bits to 1'b1.
PHY Register: DPHY_RX_VBUS2APB_PCS_TX_DIG_TBIT 2	Set the required power island phase 2 time. Set the register to 32'hAAAAAAAA.
PHY Register: DPHY_RX_VBUS2APB_PCS_TX_DIG_TBIT 3[7:4] POWER_SW_2_TIME_CL_R, DPHY_RX_VBUS2APB_PCS_TX_DIG_TBIT 3[3:0] POWER_SW_2_TIME_CL_L	Set the required power island phase 2 time. Set the register to 8'hAA

#### 12.6.2.4.1.4 Lane Configuration

**Table 12-304. Lane Configuration-Related Setup**

Configuration Register / Pin	Configuration Requirement
PHY Register: DPHY_RX_VBUS2APB_PCS_TX_DIG_TBIT 0	Set the lane band control value. Set the register fields, as specified in the register description for the required data rate.

### 12.6.3 MIPI D-PHY Transmitter (DPHY\_TX)

This section describes the features and functions of the shared MIPI D-PHY Transmitter (DPHY\_TX).

#### 12.6.3.1 DPHY\_TX Subsystem Overview

The DPHY\_TX module provides one option for video output interfacing by implementing a four-lane MIPI D-PHY Transmitter.

The device includes one or more instances of DPHY\_TX module. See Module Integration for specifics.

##### 12.6.3.1.1 DPHY\_TX Features

The DPHY\_TX0 module supports the following main features:

- Compliance to MIPI D-PHY standard version 1.2.
- Supports up to 4 data lanes and 1 clock lane.
- Supports High Speed up to 2.5 Gbps (with deskew) and 1.5 Gbps (without deskew) per data lane.
- Supports Escape mode:
  - Remote triggers
  - LP-DT up to 10 Mbps
  - ULPS mode
- Clock Lane **Control** / Interface **Logic** type is **CIL-MCNN**: [HS-TX, LP-TX]
  1. **(M)** Controller
  2. **Clock**
  3. **N/A** forward, **N/A** reverse escape mode features.
- Data Lane **Control** / Interface **Logic** type is **CIL-MFAA**: [HS-TX, LP-TX, LP-RX, LP-CD]
  1. **(M)** Controller
  2. **Forward** direction only for High Speed mode
  3. **All** forward direction escape mode features are supported
  4. **All** reverse direction escape mode features are supported.
- Data Lanes can be independently operated in HS or ULP mode.
- Includes a CMN block with reference generators / resistor calibration and an integrated PLL.
- Fault detection:

- Contention detection (for example, when RX and TX sides of same link drive opposite LP levels).
- Sequence error detection (corruption on lanes).

#### 12.6.3.1.2 Unsupported Features

See the *Module Integration* section for information about unsupported features.

---

#### Note

Some features may not be available. See *Module Integration* for more information.

---

#### 12.6.3.2 Integration

See the *Module Integration* section for information about clocks, resets and hardware requests.

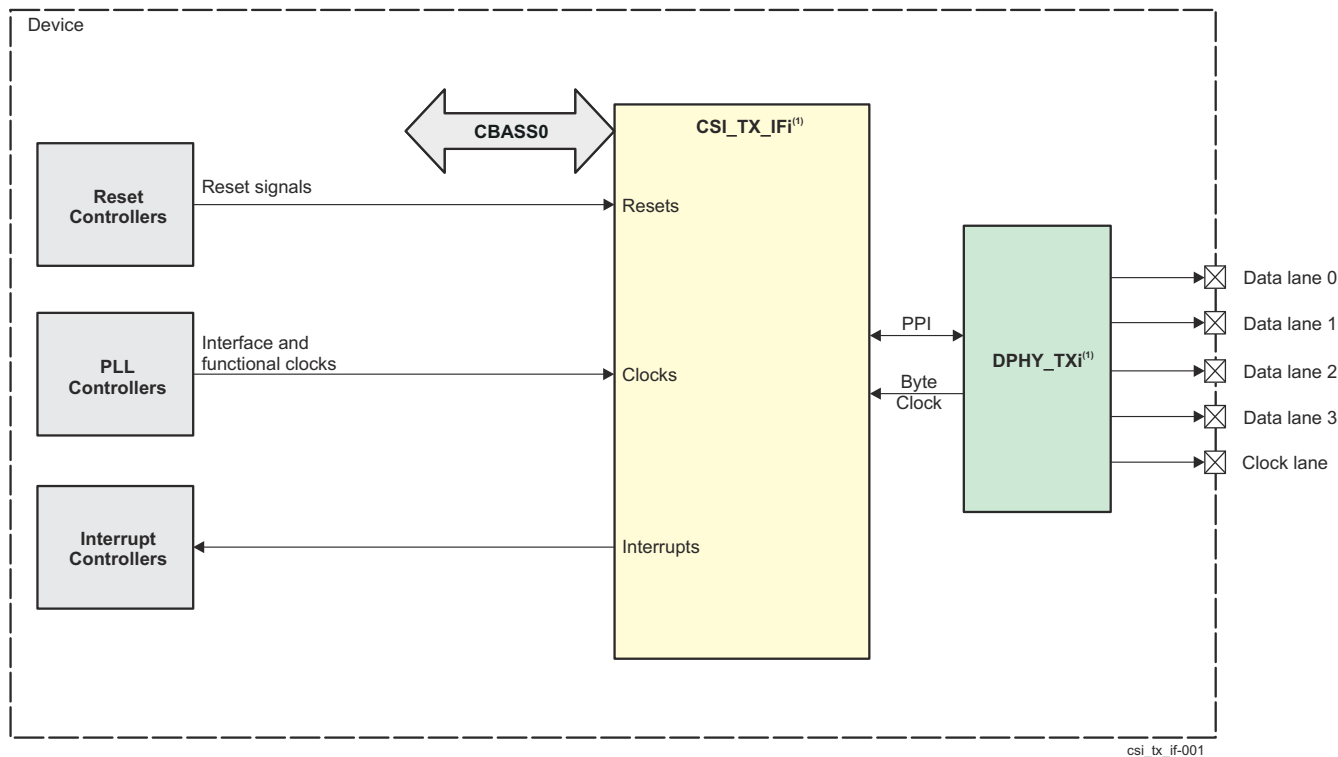

## 12.6.4 Camera Streaming Interface Transmitter (CSI\_TX\_IF)

The following sections describe the camera streaming transmitter interface (CSI\_TX\_IF) module in the device.

### 12.6.4.1 CSI\_TX\_IF Overview

The integration of the CSI\_TX\_IF module allows the device to stream out video data from memory, or retransmit from the CSI receivers as an optional loopback output for diagnostics, debug, and test purposes.

Figure 12-393 shows the CSI\_TX\_IF module overview.

A.  $i = 0$  to  $1$

**Figure 12-393. CSI\_TX\_IF Module Overview**

#### 12.6.4.1.1 CSI\_TX\_IF Ports

This section describes the CSI\_TX\_IF ports related to clocks, resets, and hardware requests.

**Table 12-305. CSI\_TX\_IF Clocks and Resets**

Clocks	
Module Clock Input	Description
CSI_TX_MAIN_CLK	Main functional(sometimes referred to as pixel clock) clock.
CSI_TX_VBUS_CLK	The VBUS clock runs at always half the speed of the CSI_TX_MAIN_CLK.
CSI_TX_ESC_CLK	20 MHz max clock input for low speed data transmission and some control signals.
DPHY_TXBYTECLKHS	The byte clock is the clock supplied by the DPHY_TX.
Resets	
Module Reset Input	Description
CSI_TX_RST	Asynchronous module global reset, driving all collateral asynchronous resets of the 4 clock domains to the low state.

**Table 12-306. CSI\_TX\_IF Hardware Requests**

Interrupt Requests
--------------------

**Table 12-306. CSI\_TX\_IF Hardware Requests (continued)**

Module Interrupt Signal	Description	Type
CSI_TX_IF_CSI_INTERRUPT_0	Global interrupt that various re-synchronized sources converge into interrupt generation.	Level
CSI_TX_IF_CSI_LEVEL_0	Error interrupt that is generated under the following conditions: <ul style="list-style-type: none"> <li>Retransmit error on Stream2 (packet error on the stream interface)</li> <li>Retransmit error on Stream3 (packet error on the stream interface)</li> </ul>	Level
CSI_TX_IF_CSI_FATAL_0	ASF port fatal interrupt. Level sensitive.	Level
CSI_TX_IF_CSI_NONFATAL_0	ASF port non-fatal interrupt. Level sensitive.	Level
CSI_TX_IF_CDNS_RAM_CORR_LEVEL_0	Interrupt on internal FIFO RAM	Level
CSI_TX_IF_CDNS_RAM_UNCORR_LEVEL_0	Interrupt on internal FIFO RAM	Level
CSI_TX_IF_CORR_LEVEL_0	Interrupt on internal FIFO RAM	Level
CSI_TX_IF_UNCORR_LEVEL_0	Interrupt on internal FIFO RAM	Level

### 12.6.4.2 CSI\_TX\_IF Features

The CSI\_TX\_IF module supports the following features:

- Compliant to MIPI CSI v1.3, MIPI CSI v2.1, and MIPI D-PHY v2.1
- Data rate up to 2.5 Gbps per lane (wire rate)
- Supports 1, 2, 3, or 4 Data Lane connection to DPHY\_TX
- Programmable formats including YUV422, RGB, Raw, and User Defined (over 25 different formats supported); Limitations apply depending on the stream used
- 16 virtual channel support
- Configurable input streams supported:
  - Stream0:** DMA interface through a 128-bit PSI\_L connection for transfers from memory **OR** CSI\_RX retransmit:
    - 128bit wide pixel data with bursting
    - ByteValid per byte in Last Data Phase (LDP)
    - 32 thread IDs supported (virtual channel & data type combinations); Flexible number of threads (32 Max).
    - Unpacking PSI\_L data and converting to CSI video format
    - Internal FF based FIFO and external RAM based buffer
  - Stream1:** Color bar video data generator
    - 2 pixel wide
    - YUV422 8-bit format support only
    - Configurable frame/line size via registers
    - 1 programmable virtual channel
    - Internal FF based FIFO; No external buffer.
- Functional and data path error interrupts
- ECC support on external RAMs

#### 12.6.4.2.1 CSI\_TX\_IF Legacy Compatibility

The following lists changes that must be considered compared to previous generation CSI\_TX\_IF:

- YUV420 is not supported, YUV420 configuration registers/bitfields are not used
- Word count must be programmed in the CSI\_TX\_IF, not in the TX Core.
- CSI\_TX\_IF compatibility mode must be used in Stream0 when retransmitting from CSI\_RX\_IF

### 12.6.4.3 CSI\_TX\_IF Environment

The CSI\_TX\_IF has no dedicated pins. At the device level, the CSI\_TX\_IF video output goes through the shared(with DSS\_DSI) DPHY\_TX. See chapter *Shared MIPI D-PHY Transmitter (DPHY\_TX)*.

Software must take the following notes in consideration

- Interleaved data formats on single virtual channel and frame are supported.
- All PSI\_L threads that open a frame must be closed before a new PSI\_L thread can start a new frame. Until all channels close the frame other threads will be stalled.
- DATA is assumed in a specific organization for CSI\_TX\_IF to export data correctly. See memory organization details in *CSI\_TX\_IF Data Memory Organization Details*.
- Threads can only switch after full lines are received. PSI\_L pushback will occur on all other threads.
- Thread priority is 0 - 31 and after a line is received will be re-arbitrated in that order for the next thread to send.

Registers CSI\_TX\_IF\_L2L\_DELAY\_j control the line start to next line start. Also register CSI\_TX\_IF\_L2L\_DELAY\_j control the last line of frame to next start of frame first line start of next frame. Buffering of PSI\_L data is 2k×128 RAM.

**Stream0 (from CSI\_RX\_IF)** is a loopback stream from the CSI receiver muxed with PSI\_L data stream.

**Stream1** streams data from the Color Bar generator. It supports YUV422 8bit format only.

CSI\_TX\_IF\_COLOR\_PARAM register is used to control height and width information. Width is divided by 8 for each color section. Colors are defined below. Transfers are done on the Stream1 interface in 32-bit packed 8-bit pixel format(required programming in CSI\_TX\_IF core). Virtual channel and data type is configurable in CSI\_TX\_IF\_COLOR\_CNTL register. Data selection inside CSI\_TX\_IF controller maps data type information. CSI\_TX\_IF\_COLOR\_START\_DELAY register can configure delays from enabled to start. CSI\_TX\_IF\_COLOR\_LINE\_DELAY, and CSI\_TX\_IF\_COLOR\_FRAME\_DELAY register can delay last line to first line of new frame. Once enabled, it will continuously send out frames until disabled. Once disabled, it will stop at end of current frame. [Table 12-307](#) shows the Color Bar format.

**Table 12-307. CSI\_TX\_IF Color Bar format details**

Color	Y	CB	CR
White	235	128	128
Yellow	162	44	142
Cyan	131	156	44
Green	112	72	58
Magenta	84	184	198
Red	65	100	212
Blue	35	212	114
Black	16	128	128

csi\_tx\_if-015

**Figure 12-396. CSI\_TX\_IF PSI\_L Color Bar sample output**

### Note

It is a requirement that only PSI\_L/DMA, color bar, or CSI\_RX\_IF loopback streams are not active at the same point in time. The intended use model is not to have multiple combinations active at any given time. The main issue with this is that RAMs are not sized for concurrent operation and will likely overflow resulting in data loss.

#### 12.6.4.4.2 CSI\_TX\_IF Hardware and Software Reset

An active low asynchronous hardware reset is provided to CSI\_TX\_IF by device LPSC. It is internally re-synchronized to the functional clock domain.

A software reset is triggered by configuring the CSI\_TX\_IF\_TX\_CONF[1] SOFT\_RESET\_REQUEST bit-field for protocol reset and/or module reset.

#### 12.6.4.4.3 CSI\_TX\_IF Clock Configuration

There are four clock domain in the CSI\_TX\_IF.

1. The CSI\_TX\_MAIN\_CLK(or also referred to as pixel clock) runs most of the logic. It needs to be same frequency as CSI\_RX\_MAIN\_CLK main clock (500MHz). When CSI\_TX\_MAIN\_CLK is operating lower than 312.5MHz, then the clock is essentially limiting the clock rate of the DPHY\_TX. Said another way, CSI\_TX\_MAIN\_CLK must be at least the DPHY\_TXBYTECLKHS rate else FIFOs will overflow, crashing the module.
2. The CSI\_TX\_VBUS\_CLK is the interface configuration clock that runs at half the speed of the CSI\_TX\_MAIN\_CLK (250MHz).
3. The DPHY\_TXBYTECLKHS is the clock supplied by the DPHY\_TX PLL and is divided down to byte clock. The DPHY\_TX is designed for max of 10gbps. This translates to a max byte clock of 312.5MHz. The clock is inactive when DPHY\_TX is not in HS operation.
4. The CSI\_TX\_ESC\_CLK escape clock runs at 20MHz. CSI\_TX\_ESC\_CLK is rarely used by the CSI\_TX\_IF, usually is only to clock in some low speed control signals from DPHY\_TX. The ESC interface is a low speed DPHY common link to the camera/sensor.

Table 12-308 shows the CSI\_TX\_IF and DPHY\_TX inter-clock dependencies.

**Table 12-308. CSI\_TX\_IF Inter-clock Dependencies**

	CSI_TX_MAIN_CLK	CSI_TX_VBUS_CLK	DPHY_TXBYTECLKHS	CSI_TX_ESC_CLK
Min freq	DPHY_TXBYTECLKHS freq	CSI_TX_MAIN_CLK / 2 freq	N/A	N/A
Max freq	500MHz	CSI_TX_MAIN_CLK / 2 freq	312.5MHz	20MHz

#### 12.6.4.4.4 CSI\_TX\_IF Interrupt Events

##### 12.6.4.4.4.1 CSI\_TX\_IF Interrupt Events

This section describes the register configuration of the interrupt events that can trigger the several CSI\_TX\_IF interrupt signals. For detailed description and mapping of the interrupt to the device interrupt processors see *CSI\_TX\_IF Integration*.

The interrupts are generally handled within the INTD module of the CSI\_TX\_IF, although there are several interrupt registers in the ECC\_AGGR for ECC errors and in the VBUS2APB for stream monitoring errors/flags.

Table 12-309 lists the event generation and corresponding registers of the CSI\_TX\_IF controller.

**Table 12-309. CSI\_TX\_IF Interrupt Events Cross Table**

Event	Mask Register	Status Register	Description
CSI_TX_IF_MAIN_0_CSI_INTERRUPT	CSI_TX_IF_IRQ_MASK CSI_TX_IF_DPHY_IRQ_MASK	CSI_TX_IF_IRQ CSI_TX_IF_DPHY_IRQ_MASK	Global interrupt that various re-synchronized sources converge into interrupt generation. Read the status register bitfields to trace the source of the event.
CSI_TX_IF_MAIN_0_CSI_LEVEL	CSI_TX_IF_IRQ_MASK CSI_TX_IF_DPHY_IRQ_MASK	CSI_TX_IF_IRQ CSI_TX_IF_DPHY_IRQ_MASK	Error interrupt that is generated under the following conditions: <ul style="list-style-type: none"> <li>Retransmit error</li> <li>Unselected stream error. An unselected DMA path or CSI_RX_IF loopback path is sending data when not selected</li> </ul> Read the status register bitfields to trace the source of the event.
CSI_TX_IF_MAIN_0_CORR_LEVEL	CSI_TX_IF_ASF_INT_MASK	CSI_TX_IF_ASF_SRAM_CORR_FAULT_STATUS	Interrupt on internal FIFO RAM. Read the status register bitfields to trace the source of the event.
CSI_TX_IF_MAIN_0_UNCORR_LEVEL	CSI_TX_IF_ASF_INT_MASK	CSI_TX_IF_ASF_SRAM_UNCORR_FAULT_STATUS	Interrupt on internal FIFO RAM. Read the status register bitfields to trace the source of the event.
CSI_TX_IF_MAIN_0_CSI_FATAL	CSI_TX_IF_ASF_INT_MASK	CSI_TX_IF_ASF_INT_STATUS	ASF port fatal interrupt. Level sensitive. Set CSI_TX_IF_ASF_FATAL_NONFATAL_SELECT for whether fatal or non-fatal ASF interrupt is triggered. If any of the CSI_TX_IF_ASF_INT_STATUS bit is set, the CSI_RX_CSI_FATAL or CSI_RX_CSI_NONFATAL event signal is asserted.
CSI_RX_CSI_NONFATAL	CSI_TX_IF_ASF_INT_MASK	CSI_TX_IF_ASF_INT_STATUS	ASF port fatal interrupt. Level sensitive. Set CSI_TX_IF_ASF_FATAL_NONFATAL_SELECT for whether fatal or non-fatal ASF interrupt is triggered. If any of the CSI_TX_IF_ASF_INT_STATUS bit is set, the CSI_RX_CSI_FATAL or CSI_RX_CSI_NONFATAL event signal is asserted.

#### 12.6.4.4.5 CSI\_TX\_IF Data Memory Organization Details

Figure 12-397 shows the YUV422-8 data organization in memory.

csi\_tx\_if-007

**Figure 12-397. CSI\_TX\_IF YUV422-8 Memory Data Organization**

[Figure 12-398](#) shows the YUV422-10 data organization in memory.

csi\_tx\_if-008

**Figure 12-398. CSI\_TX\_IF YUV422-10 memory data organization**

#### 12.6.4.4.6 CSI\_TX\_IF PSI\_L (DMA) Interface

The PSI\_L (DMA) interfaces is common for both CSI\_RX\_IF and CSI\_TX\_IF, see chapter *Camera Streaming Interface Receiver (CSI\_RX\_IF) and MIPI DPHY Receiver (DPHY\_RX)*, subsection *CSI\_RX\_IF PSI\_L (DMA) Interface*.

#### 12.6.4.4.7 CSI\_TX\_IF ECC Protection Support

The CSI\_TX\_IF has two ECC aggregators, one for byte clock (DPHY\_TXBYTECLKHS) and the other one for all other clocks. The ECC is a mechanism for providing increased system reliability (via reduction of memory soft errors) by allowing single bit errors to be detected and corrected and double bit errors to be detected.

The ECC protection on the CSI\_TX\_IF RAM provides Single Error Correction and Double Error Detection (SEC/DED). This logic detects and corrects a single bit error (1 bit error per ECC word or per ECC data segment). For memories that contain critical and/or persistent data, automatic (immediate or delayed) write-back of the corrected data to the corresponding memory address is supported. In addition, the ECC also supports multiple options for partial word writes, such as read-modify-write or multiple ECC code segments per word.

The ECC protection also provides Double Error Detection (DED). This logic only detects (does not correct) double errors (2 bit errors per ECC word or per ECC data segment).

The ECC aggregators on the CSI\_TX\_IF subsystem level consolidates the ECC configuration and status bits for all the ECC supported memories in the subsystem. They provide a single EOI-handshake based interrupt to the interrupt processors (for both single and double error detections) and a standard 32-bit VBUS interface for configuring and querying the ECC register set, see *CSI\_RX\_IF\_ECC Registers*. For complete details on the features and functions of the ECC aggregator, see *ECC Aggregator*.

#### 12.6.4.5 CSI\_TX\_IF Programming Guide

##### Note

Software must keep the CSI\_TX\_IF\_CONTROL1[0] PIXEL\_RESET register in the asserted state in the control register until all CSI\_TX\_IF controller registers are programmed. Only after all CSI\_TX\_IF controller programming can software de-assert CSI\_TX\_IF\_CONTROL1 register. If software has to reprogram any CSI\_TX\_IF controller registers it MUST have the control CSI\_TX\_IF\_CONTROL1 register reset asserted.

It is a restriction that LS/LE detection is disabled.

#### 12.6.4.5.1 CSI\_TX\_IF Programming (Configuration Mode)

Although it is always possible to read/write all control registers, it is strongly recommended writing to the control registers only while configuration mode is active. To enter configuration mode, the CSI\_TX\_IF\_TX\_CONF[2] CONFIGURATION\_REQUEST bit must be set. CSI\_TX\_IF enters configuration mode when transmission of any ongoing frame has ended and the configuration request bit is set. Configuration mode is the default state after reset. While configuration mode is active, the CSI\_TX\_IF\_STATUS[2] CONFIGURATION\_ACTIVE bit is set. Traffic at the pixel interface is ignored during configuration mode, and it is safe to write to control registers and change configuration.

To exit configuration mode, the CONFIGURATION\_REQUEST bit in the CSI\_TX\_IF\_TX\_CONF register must be cleared. The CSI\_TX\_IF then starts normal operation, with first new frame incoming after configuration mode exit.

During configuration mode, all interrupts are disabled.

---

#### Note

A mandatory assertion of soft reset occurs following the de-assertion of CONFIGURATION\_REQUEST. This ensures the controller is in a known state and all the parameters set in the configuration registers have been loaded correctly into the internal state. The DPHY\_TXBYTECLKHS must be active before the configuration request is completed.

---

#### 12.6.4.5.2 CSI\_TX\_IF System Initialization Programming

The power up/reset release of the system will clear all the register values to their reset conditions. Software must perform programming of the virtual channel and data type registers to match the system operation if the reset conditions do not match the required values. Software must ensure that all the data type select registers are programmed with valid values for the pixel\_dt\_sel\_if parameter used.

The CSI\_TX\_IF registers for all the DPHY\_TX related control and delays must be set before starting the system. The DPHY\_TX delays must be calculated using the system clock periods associated with CSI\_TX\_ESC\_CLK and DPHY\_TXBYTECLKHS. The wait burst time must be calculated using the relevant DPHY\_TX data sheet to ensure that all the lanes begin new requests at the same point.

Software must configure the FIFO fill level control registers, if required to suit clock ratios used and the desired payload control configurations. When all registers are programmed the configuration can be made active. The pixel streams can then start requests.

---

#### Note

The CSI\_TX\_IF is configured at design time, such that the reset values adopt a generic preferred Power\_On state. This reduces the programming steps required by the system for the general use case scenario.

---

#### 12.6.4.5.3 CSI\_TX\_IF Lane Control Programming

The CSI\_TX\_IF links to the DPHY\_TX clock and data lanes. After power up, software must identify that the DPHY\_TX is powered on and the DPHY\_TX PLL has locked. The DPHY\_TX controls for swapping the DP/DN control can be modified using the CSI\_TX\_IF\_DPHY\_CFG1 register if required.

Software must then program the enable for the clock lane and each data lane that is required. The DPHY\_TX lane signals can be checked using the CSI\_TX\_IF\_DPHY\_STATUS register to identify that the lane is in STOPSTATE and is ready for High Speed transmission. This register can also be used to identify when ULPS is active.

#### 12.6.4.5.4 CSI\_TX\_IF Virtual Channel and Data Type Management

The following section provides information on how the configuration of virtual channels and data types may be used in conjunction with one or more stream inputs to meet the system requirements.

#### 12.6.4.5.4.1 CSI\_TX\_IF Data Type Interleaving

The CSI\_TX\_IF can support interleaving of data types by configuring the pixel\_dt\_sel\_if inputs at the pixel interface to select the required data type and pixel count values.

#### 12.6.4.5.4.2 CSI\_TX\_IF Data Type Interleaving with Multiple Interfaces

The CSI\_TX\_IF will perform data type interleaving with one, two, or more pixel interfaces. In this scenario, Stream0 will be the master and one or more streams may be ganged together as slaves to the master stream. Therefore, for all the ganged streams, the virtual channel signals must be configured to the same value and the pixel streams must have the same active frame valid cycle (that is the virtual\_channel\_if\* and frame\_valid\_if\* must be wired in parallel). The STREAM\_IF\*\_SLAVE\_MODE bit in the STREAM\_IF\*\_CFG registers must also be set for all slaved streams. This ensures that only one frame start and frame end are generated for all the ganged streams. Note that the pixel 0 interface is always the master and slave bits exist for the other streams, in the control registers, to determine if they are to operate in master or slave mode.

In the case where streams are ganged together as master and slave(s), all ganged interfaces must have the same virtual channel value, but the pixel\_dt\_sel\_if inputs must be set to different values. Again, each of the interfaces can have the pixel\_dt\_sel\_if input change on a line by line basis, so that interleaving is done with all the ganged streams.

#### Note

Each stream must have exclusive use of the data types allocated to it.

Data type interleaving is only done when the frame is valid (CSI\_TX\_IF\_DEBUG\_PROT\*\_FSM[11] FRAME\_VALID\_IF\* bitfield input is asserted). The virtual channel will be sampled on the first cycle after the rising edge of the FRAME\_VALID\_IF input and this virtual channel will be used for all the packets originating from that stream during that frame. The FRAME\_VALID\_IF input must be the same on all ganged stream interfaces.

#### 12.6.4.5.4.3 CSI\_TX\_IF Virtual Channel Interleaving

The CSI\_TX\_IF can support interleaving of virtual channels by using two or more pixel interfaces and configuring the value of the virtual channels signal differently on each interface. The data streams can then be controlled using the pixel\_dt\_sel\_if inputs to select the data type for the lines. In this scenario, each pixel interface must have exclusive use of the virtual channel. Each stream will generate its own frame start and frame end synchronisation packets. In this case, all the stream protocol modules employing virtual channel interleaving must be configured as masters by clearing the STREAM\_IF\*\_SLAVE\_MODE bit in the STREAM\_IF\*\_CFG registers.

Note that the virtual channel control input is sampled at the rising edge of the frame\_valid\_if input, and thereafter remains fixed for that frame, therefore the virtual channel cannot be switched on a line-by-line basis for any single pixel interface. While it is possible to switch the Virtual Channel control input from frame to frame, the timing-critical switching required here would indicate a requirement for hardware rather than software control.

#### 12.6.4.5.4.4 CSI\_TX\_IF Virtual Channel and Data Type Interleaving

The CSI\_TX\_IF may be configured to perform a combination of the scenarios outlined in the previous sections if sufficient streams are available. One or more streams may be ganged with Stream0 to perform data type interleaving on the same virtual channel, whilst the remaining streams may be left autonomous to perform virtual channel interleaving.

In this case, the same rules governing the use of the virtual channels and data types must be observed. In this scenario, the virtual channel signals will be configured to the single value required for the ganged group (as they need to be controlled within the same frame valid active signal) and different values for those left to be autonomous (as they may generate their own frame start and frame end events). The slave stream for each virtual channel can have a different data type selected, and this may change on a line-by-line (or packet-by-packet) basis.

#### 12.6.4.5.5 CSI\_TX\_IF Line Control

The line control block uses the DPHY\_TXBYTECLKHS from the DPHY\_TX PPI interface to take the line data from the packet interface FIFO and transfer the bytes to the active lanes of the DPHY\_TX. The block detects when the DPHY\_TX is ready to transmit high speed data and the pixel stream has packets available.

The line control block performs pixel stream arbitration using the line control arbitration block when more than one pixel stream is generated in the configuration. The block performs all the clock and data lane control required to activate the high-speed transmission and return the lane to ULPS state as required.

##### 12.6.4.5.5.1 CSI\_TX\_IF Line Control Arbitration

The CSI\_TX\_IF controller uses a simple arbitration scheme for configurations with more than one pixel interface.

The arbitration has 2 levels; the first is a round-robin scheme and if no streams are granted by this a priority based scheme is used. The arbitration will select the first stream making a request if there is only one stream waiting or the first in the round robin after a stream has completed transmission. This means that there may be one cycle where the round-robin selector moves across a stream position that is not requesting to transmit.

The re-arbitration boundary is between packets except where line sync is used. In this case the line start packet, long packet and line end are grouped together.

The selected stream will pass the line data from the stream FIFO to the line control block for distribution to the active PPI lanes of the DPHY\_TX.

#### 12.6.4.5.6 CSI\_TX\_IF Lane Manager FSM

Data distribution to the available lanes is controlled via the lane manager FSM.

The state descriptions can be found in [Table 12-310](#).

**Table 12-310. CSI\_TX\_IF Lane Manager FSM State Description**

State (line_fsm_st_r)	Description
LINE_FSM_IDLE	Wait for new transmission to be ready. When start_hs_transmission_c is asserted then go to the transmission state per enabled lanes (lanes_enable_r)
LINE_FSM_BURST_1L	Transmit burst data over lane 0 until end of the burst. When end then go to the LINE_FSM_BURST_END state if EPD is not enabled, otherwise go to the LINE_FSM_LRTE_EPD_SPACER state.
LINE_FSM_BURST_2L	Transmit burst data over lanes 0 and 1 until end of the burst. When end then go to the LINE_FSM_BURST_END state if EPD is not enabled, otherwise go to the LINE_FSM_LRTE_EPD_SPACER state.
LINE_FSM_BURST_4L	Transmit burst data over all lanes until end of the burst. When end then go to the LINE_FSM_BURST_END state if EPD is not enabled, otherwise go to the LINE_FSM_LRTE_EPD_SPACER state.
LINE_FSM_LRTE_EPD_SPACER	Insert spacer packets across each active lane. When finished, if EPD Option 1 then go to the LINE_FSM_LRTE_EPD_PDQ state, otherwise go to the LINE_FSM_IDLE state.
LINE_FSM_LRTE_EPD_PDQ	Tell D-PHY to initiate HS-IDLE state and insert PDQ.
LINE_FSM_BURST_END	Wait for being ready for new burst transmission. In this state counter counts until WAIT_BURST_TIME value in the register is reached.

#### 12.6.4.5.7 CSI\_TX\_IF Data Lane Control FSM

Data lanes control uses a simple FSM to sequence entry and exit of Ultra Low Power mode. This FSM observes inputs from the control registers and based on these inputs it generates PPI outputs for ULP mode.

[Table 12-311](#) shows the state descriptions.

**Table 12-311. CSI\_TX\_IF Data Lanes Control FSM State Description**

State (ulps_data_fsm_st_r)	Description
DATA_LN_IDLE	Idle state. In this state HS transmission can be issued if the Clock Lane is in HS mode.
DATA_LN_ULPS_REQ	Request to enter ULP state. Waiting for activation ULP confirmed by the ppi_ulps_active_not_dl input.

**Table 12-311. CSI\_TX\_IF Data Lanes Control FSM State Description (continued)**

State (ulps_data_fsm_st_r)	Description
DATA_LN_ULPS_ACTIVE	ULPS for Data Lanes is active. Waiting for the ulps_req_sync signal being low to exit ULPS.
DATA_LN_ULPS_EXIT	ULPS exiting, waiting for the time defined in the CSI_TX_IF_DPHY_ULPS_WAKEUP register.

#### 12.6.4.5.8 CSI\_TX\_IF Application Examples

This section details specific steps on how to program the CSI\_TX\_IF.

##### 12.6.4.5.8.1 CSI\_TX\_IF D-PHY Control and Configuration

The DPHY\_TX will use a PLL to provide the bit clock for transmission. The CSI\_TX\_IF controller uses the associated byte clock as a primary clock source and this must be active and stable before the CSI\_TX\_IF is ready to transmit high speed data.

Software must perform the programming of the PLL dividers and monitor the lock status. Software must also ensure the correct sequence of programming the PLL, DPHY\_TX and CSI\_TX\_IF to guarantee the clocks are active and resets are released, following the start-up sequence described in DPHY\_TX chapter (See chapter *Shared MIPI D-PHY Transmitter (DPHY\_TX)*).

##### 12.6.4.5.8.2 CSI\_TX\_IF Clock and Data Lane Enable

The DPHY\_TX lanes are controlled using the CSI\_TX\_IF\_DPHY\_CFG register. The clock enable will be asserted once the DPHY\_TX is configured, PLL is programmed and locked and the lanes are enabled. Enabling the clock lane will then make the TX clock module stay in stop state with the DP/DN pads in LP11. The TX clock high speed ready state will be detected once the TX clock lane has completed the preamble and begun to drive the high speed clock.

The configured number of data lanes will be enabled at the same time as enabling the TX clock. The data lane will remain in LP until the high-speed clock is stable and the CSI\_TX\_IF makes the request for the data lane transitions from stop state to active (LP11-LP01-LP00).

##### 12.6.4.5.8.3 CSI\_TX\_IF DP/DN Signal Swap

The DPHY\_TX may have the capability to swap the data pin polarity or invert the clock lane polarity - the CSI\_TX\_IF\_DPHY\_CFG1 register is available within the controller for driving these pad level controls (using the DPHY\_DIFF\_INVERT\_\* fields). The DPHY\_TX will identify any contention issues with the transmitter and flag this using the contention signals and error interrupt - this may be used by software to determine if the data pin or clock lane polarity switching is required or not (by optimizing to the minimum, preferably zero, rate of occurrence of contention issues).

In the DPHY\_TX, the IO pads for the clock and data lanes support swapping of the polarity of the signals DP-DN. All dphy\_differential\_invert\_\* outputs should be treated as asynchronous. Note that, if these signals need to be asserted, they should be asserted before releasing the DPHY\_TX reset.

Each lane can be controlled independently with the CSI\_TX\_IF\_DPHY\_CFG and CSI\_TX\_IF\_DPHY\_CFG1 registers.

##### 12.6.4.5.9 CSI\_TX\_IF DPHY\_TX Status

The status of clock and data lanes is available in the read only CSI\_TX\_IF\_DPHY\_STATUS register. The clock lane fields show the condition of the ppi\_tx\_ulps\_active\_not\_cl and ppi\_stopstate\_cl PPI inputs. The data lane fields show the ppi\_ulps\_active\_not\_dl\* and ppi\_stopstate\_dl\* PPI inputs.

All the status signals are based on the active enabled lane configuration.

The DPHY\_TX can signal error conditions for each lane for contention in low power transitions and signal errors at the start of high speed transitions, using the CSI\_TX\_IF\_DPHY\_IRQ register. The signals can be used to generate an error interrupt event if the relevant bits are set in the CSI\_TX\_IF\_DPHY\_IRQ\_MASK register. The flag can be cleared by writing to the CSI\_TX\_IF\_DPHY\_IRQ register.

#### 12.6.4.5.10 CSI\_TX\_IF ULPS Operation

Each lane can be put in ultra-low power state (ULPS) by software configuration. The ULPS mode requires all the following conditions:

- The lane must be in stop state.
- For data lanes, no data must be pending in the CSI\_TX\_IF module.

#### 12.6.4.5.11 CSI\_TX\_IF System Frame Rate Measurement

The CSI\_TX\_IF provides an interrupt event to signal when the frame start (FS) and frame end (FE) packets are sent to the DPHY\_TX. These events are generated on a stream basis for each virtual channel and allow a system configured to perform virtual channel interleaving to capture the events, and to derive the frame rate achieved based on the flow control and clock configuration.

The system performance will be impacted by the FIFO sizing and any flow control mechanism used by the pixel streams, so this provides a mechanism for checking that the system is scaled correctly.

#### 12.6.4.5.12 CSI\_TX\_IF Configuration for PSI\_L

Table 12-312 lists the settings that must be programmed before enabling CSI\_TX\_IF controller and sending PSI\_L data.

**Table 12-312. CSI\_TX\_IF Configuration table for PSI\_L**

Format	Pixel transmit mode used	Size	Details
YUV420-8	single	0	Must set YUV420 mode in CSI_TX_IF_DMACNTX_j
YUV420-10	single	1	Must set YUV420 mode in CSI_TX_IF_DMACNTX_j
YUV422-8	single	0	Must set YUV422 mode in CSI_TX_IF_DMACNTX_j
YUV422-10	single	1	Must set YUV422 mode in CSI_TX_IF_DMACNTX_j
YUV422-8	packed	2	Must set YUV422 mode in CSI_TX_IF_DMACNTX_j
RGB888, RGB666	single	2	
RGB565, RGB555, RGB444	single	1	
RAW6-7 <sup>(1)</sup>	single	0	
RAW8 <sup>(1)</sup>	dual	1	
RAW8 <sup>(1)</sup>	quad	2	
RAW10 <sup>(1)</sup>	single	1	
RAW10 <sup>(1)</sup>	dual	2	
RAW12 <sup>(1)</sup>	single	1	No packing
RAW12 <sup>(1)</sup>	dual	2	No packing
RAW12(packed) <sup>(1)</sup>	single	0	Must set CSI_TX_IF_DMACNTX_j[23] PACK12_CFG = 1
RAW12(packed) <sup>(1)</sup>	dual	1	Must set CSI_TX_IF_DMACNTX_j[23] PACK12_CFG = 1
RAW14 <sup>(1)</sup>	single	1	
RAW14 <sup>(1)</sup>	dual	2	
RAW16 <sup>(1)</sup>	single	1	
RAW20 <sup>(1)</sup>	single	2	

(1) User defined/blanking/generic data types are programmed the same way as RAW data types.

#### 12.6.4.5.13 CSI\_TX\_IF Configuration for Color Bar

The following lists the Color Bar configuration requirements:

- Color bar must be set to packed YUV422-8 format, this is an extended datatype in CSI\_TX\_IF controller.
- Software must program CSI\_TX\_IF controller before enabling the color bar from the CSI\_TX\_IF\_COLOR\_CNTL[0] EN bit-field.
- Program CSI\_TX\_IF\_COLOR\_LINE\_DELAY, CSI\_TX\_IF\_COLOR\_FRAME\_DELAY, CSI\_TX\_IF\_COLOR\_START\_DELAY, and CSI\_TX\_IF\_COLOR\_PARAM registers with appropriate configurations. Update CSI\_TX\_IF\_COLOR\_CNTL with virtual channel and data type desired and enable it.

#### 12.6.4.5.14 CSI\_TX\_IF Error Recovery

When an underflow error occurs, software must reset the entire CSI\_TX\_IF by SoC PSC reset and restart over.

#### 12.6.4.5.15 CSI\_TX\_IF Power up/down Sequence

The following lists the power up/down sequence requirements:

1. Software must ensure no more PSI\_L traffic is directed toward the CSI\_TX\_IF module.
2. Software must then go through a tear down process on PSI\_L gasket inside CSI\_TX\_IF wrapper. Refer to chapter *PSI\_L* for tear down process.
3. Software must then check the stream idle values so that they are idle in the CSI\_TX\_IF\_CONTROL1 register.
4. Software must then stop all traffic inside the CSI\_TX\_IF controller and wait till it is idle.
5. After that software can then proceed to do PSC power down routine.

## 12.7 Timer Modules

### 12.7.1 Global Timebase Counter (GTC)

This section describes the global timebase counter (GTC) in the device.

#### 12.7.1.1 Global Timebase Counter (GTC)

This section describes the Global Timebase Counter (GTC) in the device.

##### 12.7.1.1.1 GTC Overview

The GTC module provides a continuous running counter that can be used for time synchronization and debug trace time stamping.

##### 12.7.1.1.1.1 GTC Features

The GTC supports the following features:

- 64-bit up counter
- No rollover during the lifetime of the device
- Compatible with ARMv8 system counter requirements:
  - Disabled at power-up
  - Register definition and memory map aligned to ARMv8 definition
  - Implements memory-mapped counter control and status frames
- Outputs reflected binary (Gray) encoded timer value for system timer bus distribution to other modules
- Selectable counter bit output as a push event that can be used by CPTS modules, timers or interface protocols

##### 12.7.1.1.1.2 Unsupported Features

See the *Module Integration* section for information about unsupported features.

---

#### Note

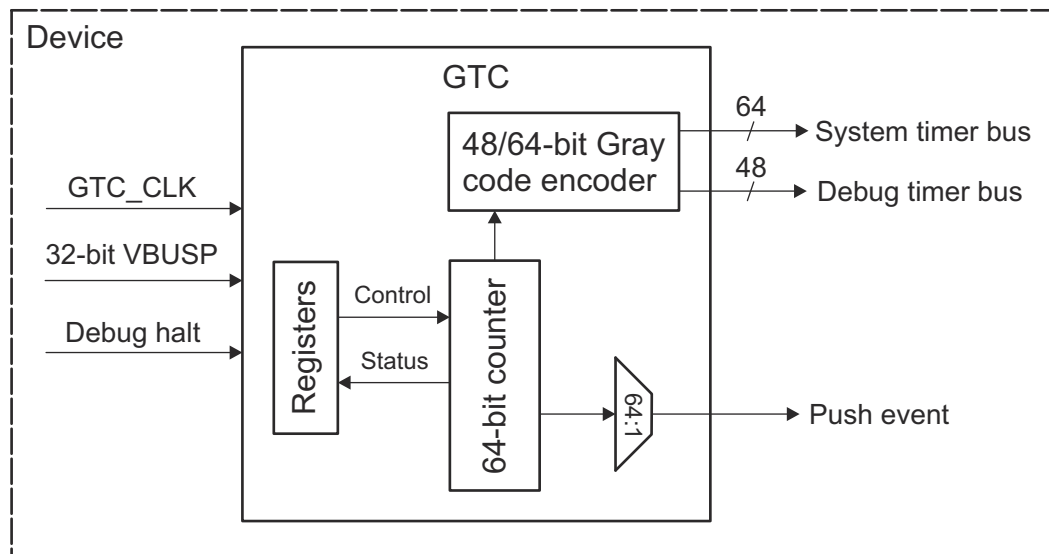

Some features may not be available. See *Module Integration* for more information.

---

### 12.7.1.2 GTC Functional Description

#### 12.7.1.2.1 GTC Block Diagram

The GTC is essentially comprised of a 64-bit up counter, a Gray encoder, a 64-bit multiplexer, and memory-mapped control registers. Figure 12-402 shows a high-level block diagram of the GTC.

**Figure 12-402. GTC Block Diagram**

#### 12.7.1.2.2 GTC Counter

The counter is a 64-bit binary up counter that increments on every GTC\_CLK rising edge. The source for GTC\_CLK is selected through a mux which is controlled via the CTRLMMR\_GTC\_CLKSEL[2-0] CLK\_SEL register bit field.

The counter is disabled by default (at power-on-reset) and increments only when enabled by setting the *GTC\_CFG1\_CNTCR*[0] EN bit to '1'. The current counter value is readable via the combined COUNTVALUE bit field of both *GTC\_CFG1\_CNTCV\_HI* (upper 32 bits) and *GTC\_CFG1\_CNTCV\_LO* (lower 32 bits) registers.

When counting is disabled, a new counter value can be loaded via a software write to the combined COUNTVALUE bit field. In this case, when the counter gets re-enabled, it will start counting from the last value written to this field.

The counter can be optionally configured to stop incrementing when a debug halt signal is issued, by writing a '1' to the *GTC\_CFG1\_CNTCR*[1] HDBG bit. This condition is indicated through the *GTC\_CFG1\_CNTSR*[1] DBGH status bit.

##### 12.7.1.2.2.1 Steps to Clear the Counter Value to Zero

1. Disable the GTC
2. Clear GTC\_CNTCV\_LO (First)
3. Clear GTC\_CNTCV\_HI (Second)
4. Enable the GTC

Once the GTC is enabled, the GTC\_CNTCV\_HI bit will be cleared to zero.

#### 12.7.1.2.3 GTC Register Partitioning

The ARMv8 architecture spec requires specific system-level components, each with one or two register frames. To accommodate this, the GTC memory-mapped registers (MMRs) are divided into four separate regions (4KB each):

- Peripheral MMRs (GTC0\_GTC\_CFG0): This region includes standard peripheral identification registers and any other control registers not associated with the ARMv8 system timer functions.

- Counter control MMRs (GTC0\_GTC\_CFG1): This region includes registers that provide control over the operation of the system timer.
- Counter status MMRs (GTC0\_GTC\_CFG2): This region includes registers that provide a mechanism for reading the status of the system timer.
- Timer control MMRs (GTC0\_GTC\_CFG3): This region includes registers that identify and provide a control mechanism for memory-mapped timer implementations. For this device, no memory-mapped timers are implemented and only the minimum registers required to indicate the presence of no timers are necessary.

### 12.7.2 RTI-Windowed Watchdog Timer (WWDT)

This section describes the Windowed Watchdog Timer (WWDT), implemented by using the Digital Windowed Watchdog (DWWDT) function of the Real Time Interrupt (RTI) module in the device.

#### CAUTION

The RTI module shall be used to serve only as a Digital Windowed Watchdog (DWWDT).

The Real Time Interrupt module provides timer functionality for operating systems and for benchmarking code. The module incorporates several counters, which define the timebases needed for scheduling in the operating system.

This module is specifically designed to fulfill the requirements for OSEK (“Offene Systeme und deren Schnittstellen für die Elektronik im Kraftfahrzeug”; “Open Systems and the Corresponding Interfaces for Automotive Electronics”) as well as OSEK/Time compliant operating systems.

The timers also provide the ability to benchmark certain areas of code by reading the counter contents at the beginning and the end of the desired code range and calculating the difference between the values.

#### 12.7.2.1 RTI Features

The RTI modules include the following main features:

- Windowed Watchdog Timer (WWDT) feature.
- Two independent 64 bit counter blocks (counter block0 or counter block1). Each block consists of
  - One 32 bit up counter
  - One 32 bit free running counter
  - Two capture registers for capturing the prescale and free running counter on a special event.
- Free running counter 0 can be incremented by either the internal prescale counter or by an external event.
- Four configurable compare registers for generating operating system ticks . Each event can be driven by either counter block0 or counter block1.
- Fast enabling/disabling of events.
- RTI clock input derived from any of the available clock sources, selectable in the System Module
- Optional capability to drive a pulse-width modulated signal out on an interrupt line.

#### 12.7.2.2 Unsupported Features

See the *Module Integration* section for information about unsupported features.

#### Note

Some features may not be available. See *Module Integration* for more information.

### 12.7.2.3 RTI Functional Description

The MCU\_RT10 and RTI modules are hereinafter referred to as RTI module.

#### 12.7.2.3.1 RTI Digital Windowed Watchdog

---

##### Note

Some of the RTI features described in this section may not be supported on this family of devices. For more information, see *RTI Not Supported Features*.

---

---

##### Note

Digital windowed watchdog (DWWD) timer is implemented using the digital windowed watchdog function of the RTI modules. Real time interrupt functionality is not supported. In this mode, the timer should default to disabled and user can adjust the period as desired before enabling the watchdog.

---

In addition to the time-out boundary configurable via the digital watchdog (DWD), some applications may also want to configure the start-time boundary of the watchdog. This is enabled by the digital windowed watchdog (DWWD) feature.

#### Functional Behavior

The DWWD opens a configurable time window in which the watchdog must be serviced. Any attempt to service the watchdog outside this time window, or a failure to service the watchdog in this time window, will cause the watchdog to generate either a reset or a non-maskable interrupt to the CPU. This is controlled by configuring the RTI\_RTIDWWDRXNCTRL register. As stated earlier, when the watchdog needs to be enabled by software, the watchdog counter is disabled on a system reset. When the DWWD is configured to generate a non-maskable interrupt on a window violation, the watchdog counter continues to count down. The RTI\_INTR\_WWD interrupt handler needs to clear the watchdog violation status flag(s) and then service the watchdog by writing the correct sequence in the watchdog key RTI\_RT1WDKEY register. This service will cause the watchdog counter to get reloaded from the preload value and start counting down. If the RTI\_INTR\_WWD handler does not service the watchdog in time, it could count down all the way to zero and wrap around. No second exception for a time out is generated in this case.

#### Configuration of DWWD

The DWWD preload value (same as DWD preload) can only be configured when the DWWD counter is disabled. The window size and watchdog reaction to a violation can be configured even after the watchdog has been enabled. Any changes to the window size and watchdog reaction configurations will only take effect after the next servicing of the DWWD.

**Figure 12-403. RTI Digital Windowed Watchdog Timing Example**

**Figure 12-404. RTI Digital Windowed Watchdog Operation Block Diagram**

### 12.7.2.3.1.1 RTI Debug Mode Behavior

---

#### Note

Some of the RTI features described in this section may not be supported on this family of devices. For more information, see *RTI Not Supported Features*.

---

Once the system enters debug mode, the behavior of the RTI depends on the RTI\_RTIGCTRL[15] COS bit. If the bit is cleared and debug mode is active, all counters will stop operation. If the bit is set to one, all counters will be clocked normally and the RTI will work like in normal mode.

The DWD counter will not decrement in debug mode and will hold its current value, regardless of the RTI\_RTIGCTRL[15] COS bit.

---

#### Note

The user must not service the watchdog while in debug mode.

---

### 12.7.2.3.1.2 RTI Low Power Mode Operation

The operation of the RTI module is guaranteed in run, doze and snooze mode. In sleep or hibernate mode all clocks will be switched off and the RTI module will not work.

In doze and snooze modes all parts of the RTI are active, since it has to be able to wake up the device with compare and timebases interrupts. Capturing events generated by the interrupt module is also possible since in both modes the peripheral modules are able to generate interrupts, which can trigger capture events. The RTI module will generate compare and timebases interrupts. The compare interrupts will periodically wake up the device.

---

#### Note

In the special case of doze mode with DPLL off, RTI\_FCLK might have a different period than with DPLL enabled, since RTI\_FCLK will be derived from the oscillator output. It has to be ensured that the RTI\_ICLK to RTI\_FCLK ratio is at least 3:1.

---

The DWD/DWWD remains active when the device enters low power mode as long as the RTI\_FCLK is kept active.

Whenever the LPSC that controls an RTI is in any state other than Enable (see , *Module States*), the RTI cannot count or generate interrupts. For more information, see , *Power Control Modules*.

During standard SoC warm reset the RTI and the rest of the SoC are reset. In this case, the RTI counters are stopped and interrupts are not issued. During reset-isolated warm reset, if an R5FSS is put in reset-isolation, then the associated RTI also becomes reset isolated. As such, the R5FSS and the RTI are not reset, but RTI stops counting and cannot generate interrupts until R5FSS is taken out of CLKSTOP (brought to Enable state).

### 12.7.2.3.2 RTI Digital Watchdog

---

#### Note

Some of the RTI features described in this section may not be supported on this family of devices. For more information, see *RTI Not Supported Features*.

---

Some applications might use a digital watchdog (DWD) integrated in the RTI module. The digital watchdog generates resets after a programmable period, if no correct key sequence is written to the RTI\_RTIWDKEY register. [Figure 12-405](#) shows the digital watchdog functional block.

**Figure 12-405. RTI Digital Watchdog Functional Block Diagram**

The digital watchdog functionality is implemented such that it can be enabled by software.

The DWD starts counting down from the reset value of the RTI\_RTIDWDCNTR (DWD Counter Register). The DWD preload register can be configured at any time by the application according to the desired time-out period.

When enabled by software, the digital watchdog is disabled after system reset. If it should be used, it has to be enabled by writing A98559DAh to the RTI\_RTIDWDCTRL register. The DWD timeout period must be configured using the DWD preload register before the DWD is enabled. The DWD cannot be disabled by the application once it is enabled.

#### Note

When the DWD is enabled by software, any system reset will disable the DWD. This reset could have been generated by the watchdog itself.

If the correct key sequence is written to the RTI\_RTIDWDKEY register (E51Ah followed by A35Ch), the 25-bit DWD Down Counter is reloaded with the 12-bit preload value stored in RTI\_RTIDWDPRLD register. If any incorrect value is written to the RTI\_RTIDWDKEY register, a watchdog reset will occur immediately. A reset will also be generated, when the DWD Down Counter is decremented to 0.

The user has to take into account that the write to the RTI\_RTIDWDKEY register takes 3 RTI\_ICLK cycles. This needs to be considered for the DWD expiration calculation.

The DWD Down Counter will be decremented with RTI\_FCLK frequency. If the RTI\_FCLK is switched off via the disable registers of the Clock management, the DWD counter stops decrementing. The DWD module cannot generate a reset under this condition.

**Figure 12-406. RTI Digital Watchdog Operation**

The expiration time of the DWD Down Counter can be determined with following equation:

$$t_{exp} = (RTI\_RTIDWDPRLD + 1) \times 2^{13} / RTI\_FCLK \quad (23)$$

where  $RTI\_RTIDWDPRLD = 0 \dots 4095$

### 12.7.2.3.3 RTI Counter Operation

#### Note

Some of the RTI features described in this section may not be supported on this family of devices. For more information, see *RTI Not Supported Features*.

Figure 12-407 shows the RTI module counter blocks. The RTI module supports two counter blocks.

rti-004

**Figure 12-407. RTI Counters Block Diagram**

Each block consists of two 32 bit up counters - Up Counter (UC) and Free Running Counter (FRC). The Up Counter (RTI\_RTICAUC0 or RTI\_RTICAUC1 register) is driven by the RTI\_FCLK and counts up until the compare value in the Compare Up Counter register (RTI\_RTICPUC0 or RTI\_RTICPUC1) is reached. When the compare matches, the second counter (RTI\_RTICAFRC0 or RTI\_RTICAFRC1 register), which is a free running counter, is incremented. At the same time UCx is reset to zero.

To ensure the consistency of the counters, when both counter value have to be determined, the Free Running Counter has to be read first. This will ensure that at the CPU read cycle, the Up Counter value is stored in the counter register. The second read is done on the Up Counter register, which holds then the value of the counter cycle of the previous read on the Free Running Counter register.

Both blocks provide also a capture feature on external events. Two capture sources can trigger the capture event. Which event triggers block 0 or block 1 is configurable from the RTI\_RTICAPCTRL register. The sources are coming from the interrupt manager, in order to be able to generate a capture event when one of the peripheral modules has generated an interrupt. The peripheral, which can generate an event is configured in the interrupt manager. When the event is detected, UCx and FRCx are stored in Capture Up Counter (RTI\_RTICAUC0 or RTI\_RTICAUC1) and Capture Free Running Counter (RTI\_RTICAFRC0 or RTI\_RTICAFRC1) registers. The read order of the captured values has to be like the order of the actual counters. So the CAFRCx has to be read first and the CAUCx registers has to be read after the CAFRCx value

was determined. While the CAFRCx is read the CAUCx value is loaded into a shadow register to ensure data consistency, if during the two reads of the captured data another capture event happens. If the application fails to read the two registers before a second capture event happens, the previous data will be overwritten.

Figure 12-408 shows the block diagram for one compare block. The RTI module supports four compare blocks.

Figure 12-408. RTI Compare Block Diagram

rtd-005

In order to generate interrupt requests to the interrupt manager, there are four compare registers (RTI\_RTICOMP0, RTI\_RTICOMP1, RTI\_RTICOMP2, and RTI\_RTICOMP3). Each of the compare registers can be configured to work either on FRC0 (Counter block0) or FRC1 (Counter block1). When the counter value matches the compare value, an interrupt is generated. This sets an interrupt request line to the interrupt manager. The compare value gets updated automatically with the value stored in Update Compare (RTI\_RTIUDCP0, RTI\_RTIUDCP1, RTI\_RTIUDCP2, and RTI\_RTIUDCP3) registers when the compare matches. This gives the ability to generate periodic interrupts/DMA requests without having to update the compare value by software.

An optional feature allows an application to program another compare value which is then used to clear the interrupt request line. This feature is supported by four compare clear registers (RTI\_RTICOMP0CLR, RTI\_RTICOMP1CLR, RTI\_RTICOMP2CLR, and RTI\_RTICOMP3CLR). When the counter value matches the compare clear value, the interrupt line is cleared. This clears the interrupt request line to the interrupt manager. The compare clear value gets updated automatically with the value stored in Update Compare (RTI\_RTIUDCPx) registers when the compare matches.

## 12.7.3 Real-Time Clock (RTC)

### 12.7.3.1 RTC Overview

The basic purpose for the RTC is to keep time of day. The other equally important purpose of RTC is for Digital Rights management. Some degree of tamper proofing is needed to ensure that simply stopping, resetting, or corrupting the RTC does not go unnoticed so that if this occurs, the application can re-acquire the time of day from a trusted source. The final purpose of the RTC is to wake the rest of chip up from a power down state.

#### 12.7.3.1.1 RTC Features

The real-time clock (RTC) provides the following features:

- With Analog IP block
  - 2 digital voltage domains with integrated LVL/ISO cells
    - CORE or volatile domain, same as core SOC
    - RTC or Always ON domain
  - Without Analog IP block
    - 1 digital voltage domain, no lvl.iso
- 15 bit 32768Hz counter
- 48 bit seconds counter with +/- 1 30uS upto +/- 1 S drift adjustment every 4048 Seconds
- 256 bits of Scratch PAD
- 1 ON\_OFF compare event, 48-bits
- 1 OFF\_ON compare event, 48-bits
- 2 event outputs OFF\_ON and ON\_OFF to CORE
- Support active external 32768 Hz and inactive/gated 32768 Hz
- This allows HOST PROCESSOR to use some of the counter registers as general purpose
- CORE protection logic which enables loose ISO assertion
- Functional lockout, unlock by special vbusp sequence
- DFT lockout, unlock by special 1500 sequence
- HOST PROCESSOR can issue OFF now cmd
- HOST PROCESSOR can update MMRs without polling, thanks to HW Shadow/Auto Sync
- HOST PROCESSOR can read time without polling, thanks to HW Shadow/Auto Sync
- External IOs (*Optional*)
  - 4 wakeup inputs with active high/low including optional debounce
    - Async wake up supported
  - 1 pmic\_enable output
- Analog Interface (*Optional*)
  - 32 bit Analog Config output
  - ISO input
  - 32KHz input

#### 12.7.3.1.2 Unsupported Features

See the *Module Integration* section for information about unsupported features.

#### Note

Some features may not be available. See *Module Integration* for more information.

#### 12.7.3.2 RTC Integration

This device includes a Real-Time (RTC) module to allow easy tracking of time and date and the generation of real time alarms.

The following tables provide pin level detail for each of the interfaces on this module.

[Table 12-313](#) describes the 1500 Interface for the DFT unlock circuit.

**Table 12-313. 1500 Interface**

Signal Name	Direction	Default Value	Description
jtag_wrck	In	1'd0	1500 wrapper clock
jtag_wrstn_n	In	1'd1	1500 wrapper reset (active low)
jtag_wsi	In	1'd0	1500 wrapper serial input
jtag_selectwir	In	1'd0	1500 select wrapper instruction register
jtag_shiftwr	In	1'd0	1500 shift wrapper register

**Table 12-313. 1500 Interface (continued)**

Signal Name	Direction	Default Value	Description
jtag_updatewr	In	1'd0	1500 update wrapper register
jtag_capturewr	In	1'd0	1500 capture wrapper register
jtag_wso	Out	1'd0	1500 wrapper serial out

Table 12-314 describes the PMIC Control External Wakeup and PMIC ON/OFF Control IOs.

**Table 12-314. PMIC Control IOs**

Signal Name	Direction	Default Value	Description
pmic_ext_wakeup0_io	In	1'd0	RTC Wakeup0
pmic_ext_wakeup1_io	In	1'd0	RTC Wakeup1
pmic_ext_wakeup2_io	In	1'd0	RTC Wakeup2
pmic_ext_wakeup3_io	In	1'd0	RTC Wakeup3
pmic_pmic_enable_io	Out	1'd1	RTC PMIC Enable 1 = ON 0 = OFF

**Table 12-315. Analog Interface**

Signal Name	Direction	Default Value	Description
ana_osc32k_clk	In	NA	Analog 32768 buffered Crystal clock If no analog, provide a near 32768 clock
ana_iso	In	1'd0	Analog ISO 1 = Isolated 0 = Not Isolated If no analog, tie 1'b0
ana_porz	In	NA	Analog PowerOnReset 1 = not asserted 0 = asserted This will assert when ON/BAT domain is powering up If no analog, then you can connect same reset which was used for rst_mod_g_rst_n You can also use por_rst_n class, it's a don't care
ana_cfg[31:0]	Out	TBD	Analog config If no analog, NC

**Table 12-316. PSC Interface**

Signal	Direction	Default Value	Description
pwri_clkstop_idle	Out	1'd1	The IP is in IDLE state, output of an IP
pwrs_clkstop_req	In	1'd0	Clock stop request

**Table 12-316. PSC Interface (continued)**

Signal	Direction	Default Value	Description
pwr_clkstop_ack	Out	1'd0	Clock stop acknowledge
pwrw_clkstop_wakeup	Out	1'd0	Wakeup It requires clock stop protocol to be active and active vclk_clk
pwr_clk_clk_en	In	1'd1	Clock-gate enable to IP
pwr_clk_clk_en_ack	Out	pwr_clk_clk_en	Clock-gate enable acknowledge from IP

Table 12-317 describes the Main IP DFT Interface.

**Table 12-317. IP DFT Interface**

Signal Name	Direction	Default Value	Description
dft_partition_en	In	1'd0	dft_partition_en
dft_scan_en	In	1'd0	dft_scan_en
dft_clk_force_en	In	1'd0	dft_clk_force_en
dft_async_rst_sel	In	1'd0	dft_async_rst_sel
dft_test_async_rst_n	In	1'd1	dft_test_async_rst_n
dft_tft_mcp_dis	In	1'd0	Assert High to block MCP path
dft_local_clk_en	In	1'd0	dft_local_clk_en
dft_mode_atpg	In	1'd0	ATPG

The reset shown in Table 12-318 only goes to the core domain.

**Table 12-318. Reset Interface**

Signal Name	Direction	Default Value	Description
rst_mod_g_rst_n	In	1'd1	Module level main reset

The clock shown in Table 12-319 is used for all VBUS ports ref pll clock.

**Table 12-319. VBUS Clock Interface**

Signal Name	Direction	Default Value	Description
vclk_clk	In	1'd0	Single ended clock Nom freq 50MHz
vclk_cs_func_clk_en	In	1'd0	catscan enable on kp_ti_ipg_clk_l1

The clock shown in Table 12-320 is a buffered copy from the crystal oscillator clock.

**Table 12-320. OSC 32768Hz Clock Interface**

Signal Name	Direction	Default Value	Description
osc_32k_clk	Out	1'd0	Buffered clock out from ana_osc32k_clk

The clock shown in Table 12-321 is for the core domain in DFT mode.

**Table 12-321. DFT Clock Interface**

Signal Name	Direction	Default Value	Description
dftclk_clk	In	1'd0	Single ended clock

pr1_slv_byten[3:0]	In	{4{1'b1}}	Byte Enables
pr1_slv_wdata[31:0]	In	32'd0	Write Data
pr1_slv_wready	Out	1'b1	Write Ready
pr1_slv_rdatap[31:0]	Out	32'd0	Read Data (Pipelined)
pr1_slv_rready	Out	1'b1	Read Ready
pr1_slv_emudbg	In	1'b0	Emulation Debug Attribute

### 12.7.3.3 RTC Functional Description

#### 12.7.3.3.1 RTC Block Diagram

**Figure 12-409. RTC Block Diagram**

The RTC is composed of 3 major blocks, DIG\_CORE, DIG\_ON, and LVL\_ISO.

##### 12.7.3.3.1.1 DIG\_CORE uARCH

The DIG\_CORE block is on the CORE power domain which will power OFF/ON when the SOC powers OFF/ON. It contains, CORE IF logic, Shadow MMRs and MMR Sync logic.

The MMR Sync logic has 2 modes of operation

- Refresh/Sync after Core Reset
- Sync after HOST PROCESSOR Updates Shadow MMRs

##### Refresh/Sync after Core Reset Deassertion

After every Core Reset event, the MMR Sync logic we refresh ALL Shadow MMRs by copying the contents of ON MMRs into the Shadow MMRs.

##### Core Reset DeAssertion

The internal state machine Reads All MMRs in linear order

- If(GENRAL\_CTL..32K\_CLK\_EN = 1)

- Max delay of 2 32768Hz period delay
- If(GENRAL\_CTL..32K\_CLK\_EN = 0)
  - Max delay 1.2uS = 32 \* vbus\_clk period delay(27MHz)
  - It will not wait for high to low 32768 event to read MMRs

The internal state machine Sets SYNCPEND.RD\_DONE bit when the copy from the ON domain is completed. The host processor needs to wait for this status bit assertion before it reads the other MMRs

### Sync after HOST PROCESSOR Updates Shadow MMRs

host processor UNLOCK

host processor Wrts to MMRs

The ON domain MMRs will get updated after a finite delay

- If(GENRAL\_CTL..32K\_CLK\_EN = 1)
  - Max delay of 2 32768Hz period delay
- If(GENRAL\_CTL..32K\_CLK\_EN = 0)
  - Max delay 8uS = 32 \* vbus\_clk period delay
  - It will not wait for high to low 32768 event to read MMRs

The internal state machine sets SYNCPEND.WR\_DONE bit. This needs to get cleared before the next **HOST PROCESSOR Updates Shadow MMRs**

---

#### Note

The CORE domain has its own copy of the sub-second counter and second counter along with the compensation logic. The 2 domains will always be in sync after a reset or after host processor does a update to the counters or compensation

---

#### 12.7.3.3.1.2 DIG\_ON uARCH

The DIG\_ON block is in the always ON domain, the power is provided by the ANALOG Block. It contains the always ON MMRs which will preserve state of the Shadow MMRs when the CORE is OFF state.

The 15 bit 32768Hz counter and the 48 bit second counter maintains count when the CORE is OFF. It has 2 comparators one for OFF\_ON and one for ON\_OFF event. It has External Wakeup events which can get de-bounced to control the PMIC\_ENABLE. It controls the PMIC\_ENABLE output which can change state based on ON\_OFF, OFF\_ON, and HOST PROCESSOR OFF now events.

The functional lockout and the dft lockout (1500) logic resides in this domain.

#### 12.7.3.3.1.3 ISO\_LVL uARCH

The ISO\_LVL module constrains all DIG\_CORE <-> DIG\_ON Level/Isolation cells between these 2 domains. They use tibox to instantiate them. If No Analog support, then SOC integration team will not add in these RTC.

#### 12.7.3.3.1.4 DIG\_CORE to DIG\_ON updates uARCH

---

#### Note

If No Analog support, then DIG\_CORE and DIG\_ON will be on a common V domain.

---

This section defines how the DIG\_CORE Shadow MMRs maintain coherences with the DIG\_ON Live MMR domain. All vbusp transactions terminate in the DIG\_CORE block. All vbusp write transaction which require DIG\_ON updates is completed by the Shadow to Live HW sequencer.

This HW sequencer has 2 modes of operation.

- Immediate Write Mode
  - When GENRAL\_CTL..32K\_OSC\_DEP\_EN = 0
  - It will start the write updates immediately

- Delayed Write Mode
  - When `GENRAL_CTL.32K_OSC_DEP_EN = 1`
  - It will start the write updates after the first 32khz\_clk high to low transition

In Delayed Write Mode

For example, HOST PROCESSOR updates `OFF_ON_S_CNT_LSW` and `OFF_ON_S_CNT_MSW`.

After the HOST PROCESSOR completes the `OFF_ON_S_CNT_MSW`, the HW sequencer will start the process of updating the `DIG_ON` domain at the first available 32khz\_clk is low cycle.

---

**Note**

32khz\_clk is already low, the circuit will wait next low cycle to insure we have the full low period to do all pending updates. The HOST PROCESSOR can observe the `SYNCPEND.WR_DONE` bit, when set the write operations has completed to the `DIG_ON` domain

---

---

**Note**

If `GENRAL_CTL.32K_CLK_EN = 0`, then the HW sequencer will not wait for 32khz\_clk high to low event, since this will force 32khz\_clk low. This removes the dependency of an active 32768Hz clock

---

ALL MMR write transaction require full 4 Bytes writes in order to reduce the logic size of the `DIG_ON` domain.

**RULE:** Require 4 Bytes writes (less logic and iso)

---

**Note**

ON domain MMRs have a write lock protection circuit to prevent corruption of the `DIG_ON` domain during a power down event since ISO assertion can be late.

---

Due to this fact, the HOST PROCESSOR must first unlock write access by performing the unlock sequence, by simply writing Kick0 and Kick1 with the correct pattern and sequence. After this is done, the RTC is in an unlock date. The HOST PROCESSOR will need to relocking by writing any pattern to Kick1

### 12.7.3.3.2 CPU Interrupt Support

#### 12.7.3.3.2.1 CPU Interrupts

The RTC can produce one HW event output active high level and active high pulse. This one output will assert on 3 internal HW events.

1. Timer ON\_OFF event
2. Timer OFF\_ON event
3. External Wakeup event

HOST PROCESSOR can read the Interrupt MMR status to determine which events caused the RTC event output to assert. `vbus_clk` can be on or off, the active high level will assert on either scenario. The 32768Hz clock must be active to cause a ON\_OFF or OFF\_ON event. The External Wakeup event can occur without 32768Hz clock if debounce is not enabled.

The Interrupt MMR programing model uses the standard Keystone3 schema which allows HOST PROCESSOR to issue debug event. Also, the enabling of the events are backed up in the ON domain, so HOST PROCESSOR will not enable to enable events on every power cycle of the CORE domain.

#### 12.7.3.3.3 Programming Usage Guide

##### 12.7.3.3.3.1 No Analog Support

#### DIG\_ON domain MMR Write Rules

- UnLock `DIG_CORE` (Wrt Kick0 and Wrt Kick1)

- Keep it UnLock
- Write all MMRs in the same address order has MMRs from low to high
  - For example . Wrt Scratch Storage 0 through Scratch Storage 7
- HOST PROCESSOR poles until SYNCPEND.WR\_PEND is 0
  - Max completion is 60 uSeconds when GENRAL\_CTL. 32K\_OSC\_DEP\_EN is set
  - Max completion is 10 uSeconds when GENRAL\_CTL. 32K\_OSC\_DEP\_EN is clr
- HOST PROCESSOR is not allowed to perform new write without waiting for clearing of SYNCPEND.WR\_PEND

### After every new power up of the SOC

- Unlock RTC by writing correct pattern in Kick0 and Kick1
- Keep it UnLock
- HOST PROCESSOR can verify that 32Khz\_osc\_clk is toggling by reading SYNCPEND. 32K\_CLK\_OBS
- Should not be required, since the 32Khz\_osc\_clk will always will be active
- HOST PROCESSOR sets GENRAL\_CTL.32K\_OSC\_DEP\_EN
- Wait for 60 uSec
- Initialize ALL RTC MMRs in the DIG\_ON domain in the same order as the address map
- The RTCs MMRs do not have a reset state in general, only a few required MMRs bits have one.
- HOST PROCESSOR must initialize all bits of the MMRs which reside in DIG\_ON domain
  - le wrt <value>@0x00, <value>@0x04, <value>@0x08 ....<value>@0x50
- HOST PROCESSOR poll SYNCPEND.WR\_PEND until null
  - This means all DIG\_ON domain MMRs have been written to

RTC is now in an operational state and fully configured.

### 32768 MHz time adjustment

- HOST PROCESSOR UnLock RTC(required for writes to DIG\_ON domain)
- HOST PROCESSOR can readSUB\_S\_CNT(1st), S\_CNT\_LSW(2nd), S\_CNT\_MSW(3rd)
- HOST PROCESSOR can write new time by writing to SUB\_S\_CNT(1st), S\_CNT\_LSW(2nd), S\_CNT\_MSW(3rd)
- HOST PROCESSOR ReLock RTC(writing 0x0000\_0000 to KICK1)
- HOST PROCESSOR poll SYNCPEND.WR\_PEND until null

### 32768 MHz time drift adjustment

- HOST PROCESSOR UnLocks RTC(required for writes to DIG\_ON domain)
- HOST PROCESSOR can readSUB\_S\_CNT(1st), S\_CNT\_LSW(2nd), S\_CNT\_MSW(3rd)
- SW determines drift rate
- HOST PROCESSOR updates or enables drift adjustment by HOST PROCESSOR write new COMP\_LSB and COMP\_MSB
- HOST PROCESSOR ReLock RTC(writing 0x0000\_0000 to KICK1)
- HOST PROCESSOR poll SYNCPEND.WR\_PEND until null

#### 12.7.3.3.2 With Analog Support

### DIG\_ON domain MMR Write Rules

- UnLock DIG\_CORE (Wrt Kick0 and Wrt Kick1)
- Write all MMRs in the same address order has MMRs from low to high
- For example . Wrt Scratch Storage 0 through Scratch Storage 7
- ReLock DIG\_CORE (Wrt 0x0000\_0000 to Kick1)
- HOST PROCESSOR poles until SYNCPEND.WR\_PEND is 0
  - Max completion is 60 uSeconds when GENRAL\_CTL. 32K\_OSC\_DEP\_EN is set
  - Max completion is 10 uSeconds when GENRAL\_CTL. 32K\_OSC\_DEP\_EN is clr
- HOST PROCESSOR is not allowed to perform new write without waiting for clearing of SYNCPEND.WR\_PEND

### First Time Powered ON(DIG\_ON)

- Unlock RTC by writing correct pattern in Kick0 and Kick1
- HOST PROCESSOR updates ANALOG\_CTRL MMR
  - Set the correct parameters
  - Enable 32768Hz OSC
  - Wait for 3 seconds to allow the 32768Hz OSC to lock
- HOST PROCESSOR can verify that 32Khz\_osc\_clk is toggling by reading SYNCPEND. 32K\_CLK\_OBS
- HOST PROCESSOR sets GENERAL\_CTL.32K\_OSC\_DEP\_EN
- HOST PROCESSOR ReLock DIG\_CORE (Wrt 0x0000\_0000 to Kick1)

Initialize ALL RTC MMRs in the DIG\_ON domain in the same order as the address map except for the first 2 writes which should always be to the 2 KICK0/KICK1 MMRs to unlock write transaction and the last write which should relock by writing 0x0 to KICK1

- The RTCs MMRs do not have a reset state in general, only a few required MMRs bits have one.
- HOST PROCESSOR must initialize all bits of the MMRs which reside in DIG\_ON domain
- HOST PROCESSOR UnLock
- le wrt <value>@0x00, <value>@0x04, <value>@0x08 ....<value>@0x50
- HOST PROCESSOR ReLock RTC(writing 0x0000\_0000 to KICK1)
- HOST PROCESSOR poll SYNCPEND.WR\_PEND until null
- This means all DIG\_ON domain MMRs have been written to

RTC is now in an operational state and fully configured

### 32768 MHz time adjustment

- HOST PROCESSOR UnLock RTC(required for writes to DIG\_ON domain)
- HOST PROCESSOR can readSUB\_S\_CNT(1st), S\_CNT\_LSW(2nd), S\_CNT\_MSW(3rd)
- HOST PROCESSOR can write new time by writing to SUB\_S\_CNT(1st), S\_CNT\_LSW(2nd), S\_CNT\_MSW(3rd)
- HOST PROCESSOR ReLock RTC(writing 0x0000\_0000 to KICK1)
- HOST PROCESSOR poll SYNCPEND.WR\_PEND until null

### 32768 MHz time drift adjustment

- HOST PROCESSOR UnLocks RTC(required for writes to DIG\_ON domain)
- HOST PROCESSOR can readSUB\_S\_CNT(1st), S\_CNT\_LSW(2nd), S\_CNT\_MSW(3rd)
- SW determines drift rate
- HOST PROCESSOR updates or enables drift adjustment by
  - HOST PROCESSOR write new COMP\_LSB and COMP\_MSB
- HOST PROCESSOR ReLock RTC(writing 0x0000\_0000 to KICK1)
- HOST PROCESSOR poll SYNCPEND.WR\_PEND until null

### Update OFF\_ON and/or ON\_OFF times

- HOST PROCESSOR poll SYNCPEND.WR\_PEND until null (ACTION PRE vs POST)
- HOST PROCESSOR UnLocks RTC(required for writes to DIG\_ON domain)
- HOST PROCESSOR update OFF\_ON\_S\_CNT\_LSW/MSW and/or ON\_FF\_S\_CNT\_LSW/MSW
- HOST PROCESSOR can update SCRATCH0/7
- HOST PROCESSOR update GENERAL\_CTL to enable if required
- HOST PROCESSOR ReLock RTC(writing 0x0000\_0000 to KICK1)
- HOST PROCESSOR poll SYNCPEND.WR\_PEND until null

---

#### Note

The new OFF time must be at least 2 seconds in the future

---

### OFF NOW

- HOST PROCESSOR UnLocks RTC(required for writes to DIG\_ON domain)
- Optional (HOST PROCESSOR can update SCRATCH0/7)

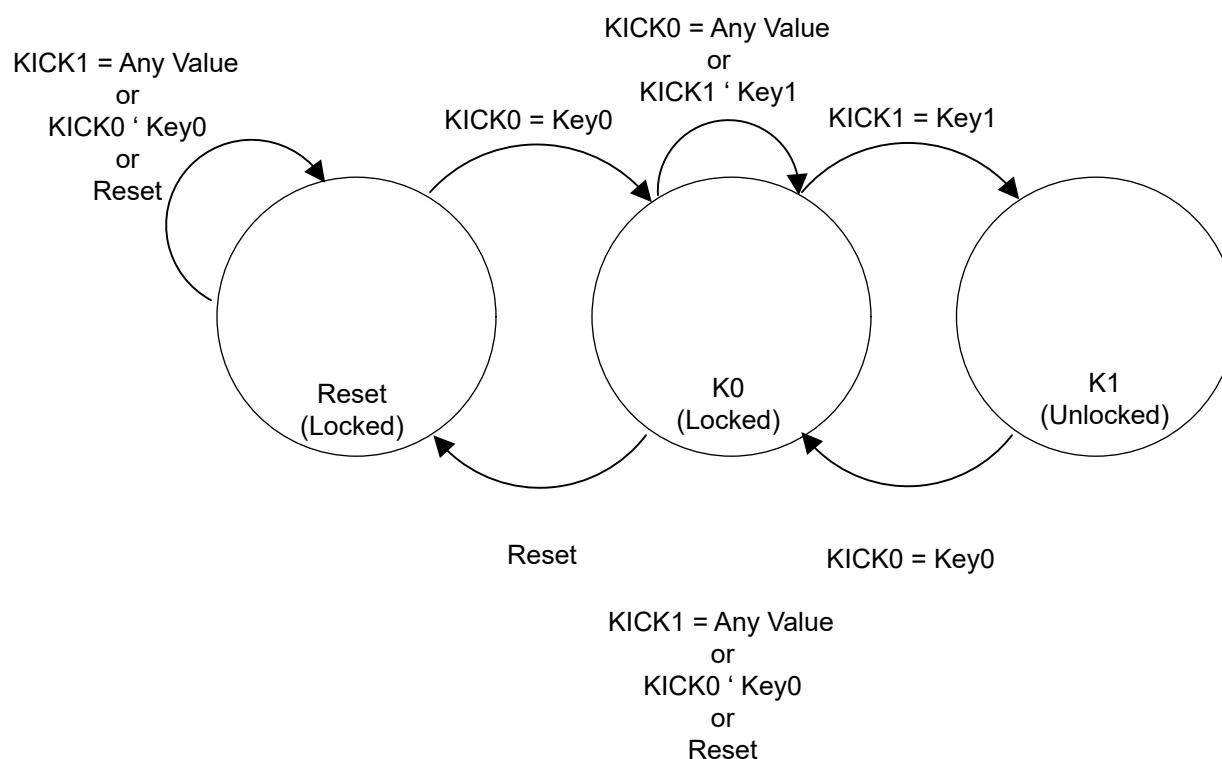

- HOST PROCESSOR issues a SW\_OFF in GENRAL\_CTL
- HOST PROCESSOR does a dead loop, wait for power OFF

#### Note

Note any Write to SW\_OFF will cause a Auto ReLock

#### 12.7.3.3.3.2.1 MMR Spurious WRT Protection

The module also contains a kicker mechanism (Figure 12-410) to prevent any spurious writes from changing the register values. This mechanism requires two MMR writes to the Kick0 and Kick1 registers with exact data values before the kicker lock mechanism is released. Once released, the MMRs are writeable. The Kick0 data is 83E7 0B13h; the Kick1 data is 95A4 F1E0h. Note that it remains in an unlocked state until an OCP reset or invalid data pattern is written to one of the Kick0 or Kick1 registers.

- Key0 = 83E7 0B13h
- Key1 = 95A4 F1E0h
- Locked = Write protection enabled
- Unlocked = Write protection disabled

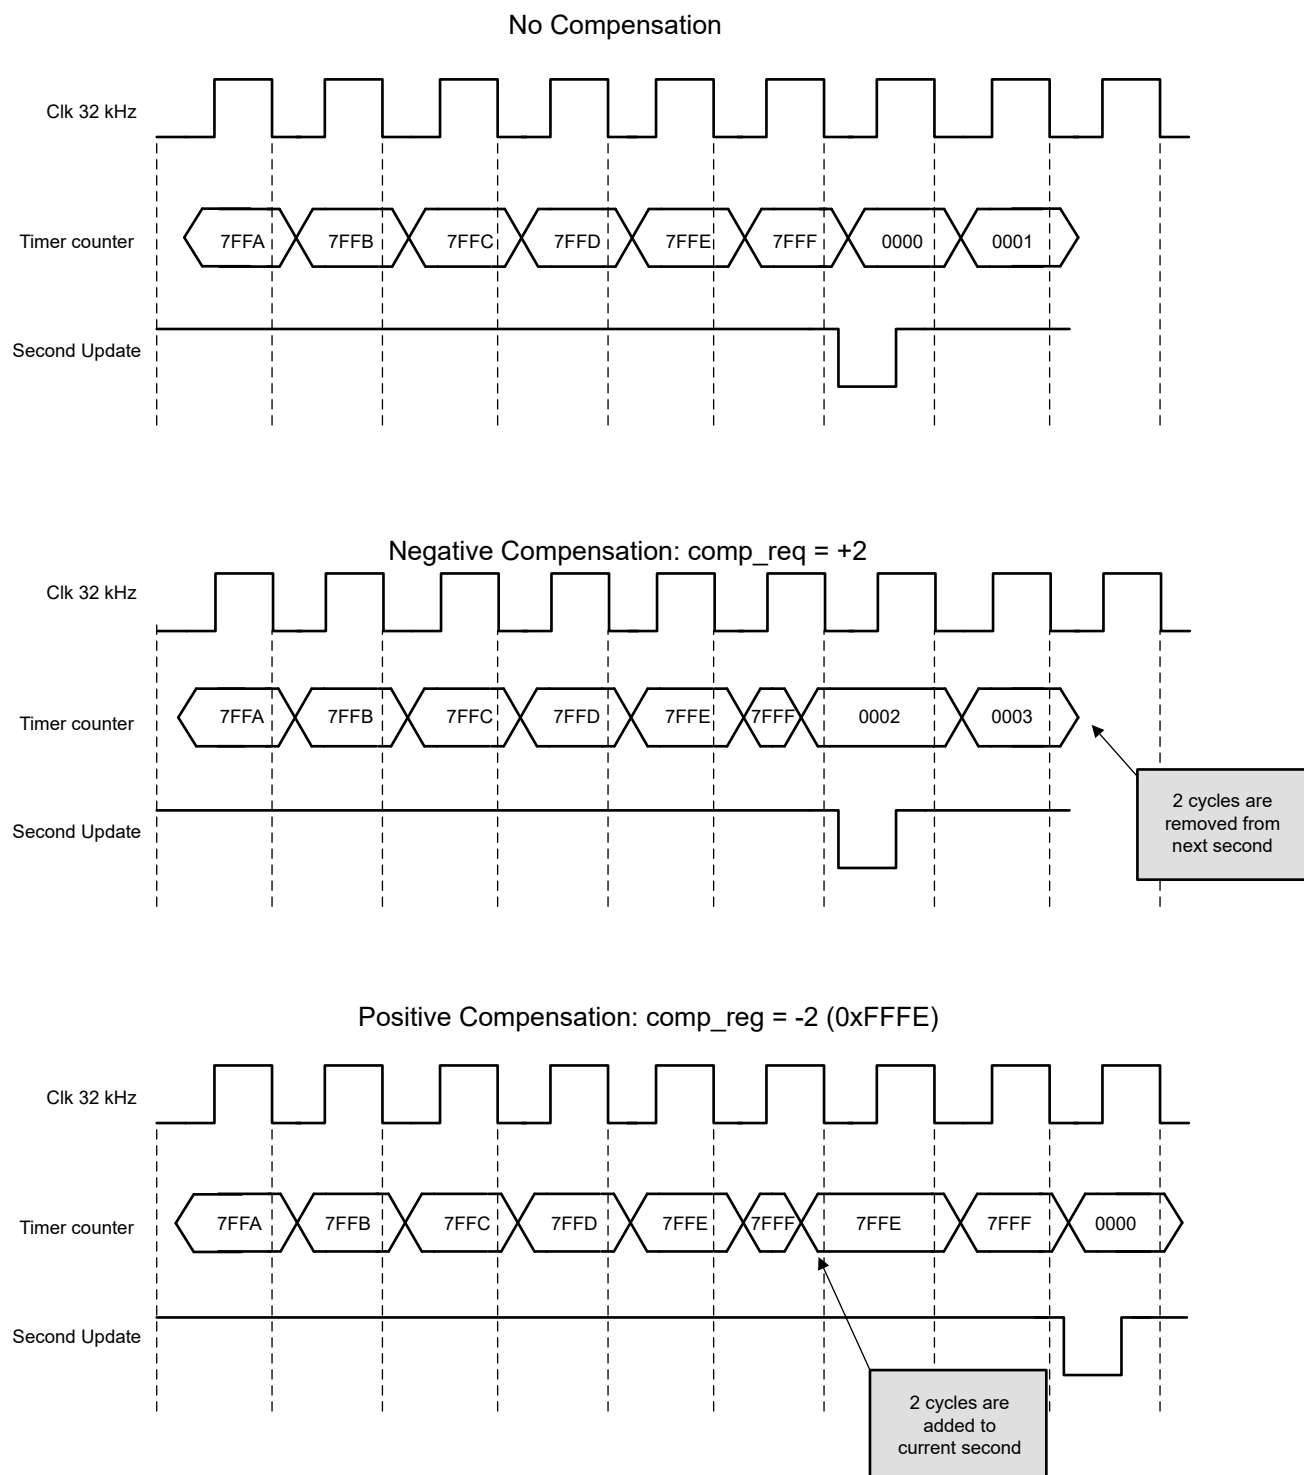

**Figure 12-410. Kick Register State Machine Diagram**

- S0 is the Reset/Idle state
- S1 is an wrt cycle of 83E7 0B13h at Kick0 completed state
- S2 is the UNLOCK MMR WRT state
- S0 → S1 when wrt cycle of 83E7 0B13h at Kick0
- S1 → S2 when wrt cycle of 95A4 F1E0h at Kick1
- S1 → S0 when reset event
- S2 → S0 when reset event OR OCP wrt cycle of NOT 83E7 0B13h at Kick0 OR OCP wrt cycle at Kick1
- S2 → S1 when wrt cycle of 83E7 0B13h at Kick0

#### **12.7.3.3.2.2 Crystal Compensation**

In order to compensate for any inaccuracy of the 32768HZ oscillator, the HOST can perform a calibration of the oscillator frequency, calculate the drift compensation versus one-hour period and load the compensation registers with the drift compensation value. If the COMP\_REG value is positive, compensation occurs after the second change event. COMP\_REG cycles are removed from the next second. If the COMP\_REG value is negative, compensation occurs before the second change event. -COMP\_REG cycles are added to the current second. This enables to compensate with a 132 kHz period accuracy each 4096 Seconds. The waveform below summarizes positive and negative compensation effect.

**Figure 12-411. Compensation Illustration**

### 12.7.3.3.4 Scratch Registers

The RTC provides eight general-purpose registers (SCRATCHx\_REG) that can be used to store 32-bit words -- these registers have no functional purpose for the RTC. Software using the RTC may find the SCRATCHx registers to be useful in indicating RTC states. For example, the SCRATCHx\_REG registers may be used to indicate write-protection lock status or unintentional power downs. To indicate write-protection, the software

should write a unique value to one of the SCRATCHx\_REG registers when write-protection is disabled and another unique value when write-protection is enabled again. In this way, the lock-status of the registers can be determined quickly by reading the SCRATCH register. To indicate unintentional power downs, the software should write a unique value to one of the SCRATCHx\_REG registers when RTC is configured and enabled. If the RTC is unintentionally powered down, the value written to the SCRATCH register is cleared. For more information, see *RTCSS Registers*.

#### 12.7.3.3.5 KS3 Clock Stop Protocol

The IP is compliant to KS3 Clock Stop Protocol, please refer to its spec.

For this IP

- pwri\_clkstop\_idle = !( RD\_PEND or WR\_PEND or EVENT\_OFF\_ON or EVENT\_ON\_OFF)
- If any of these MMRs are set, pwri\_clkstop\_idle = 0 or busy
- pwrs\_clkstop\_ack will not assert per spec unless pwrs\_clkstop\_req == 1 and pwri\_clkstop\_idle == 1
- pwrw\_clkstop\_wakeup will not assert unless pwrs\_clkstop\_ack == 1 AND vclk\_clk is active

It will assert rtc\_event\_pend\_intr asserts

- The integration guideline is to always use rtc\_event\_pend\_intr for wakeup event since it has NO dependencies on clock stop protocol nor active vclk\_clk is required, just 32k\_clk needs to be active

## 12.7.4 Timers

This section describes the Timer modules for the device.

### 12.7.4.1 Timers Overview

All timers include specific functions to generate accurate tick interrupts to the operating system.

Each timer can be clocked from several different independent clocks. The selection of clock source is made from registers in the MCU\_CTRL\_MMR0/CTRL\_MMR0.

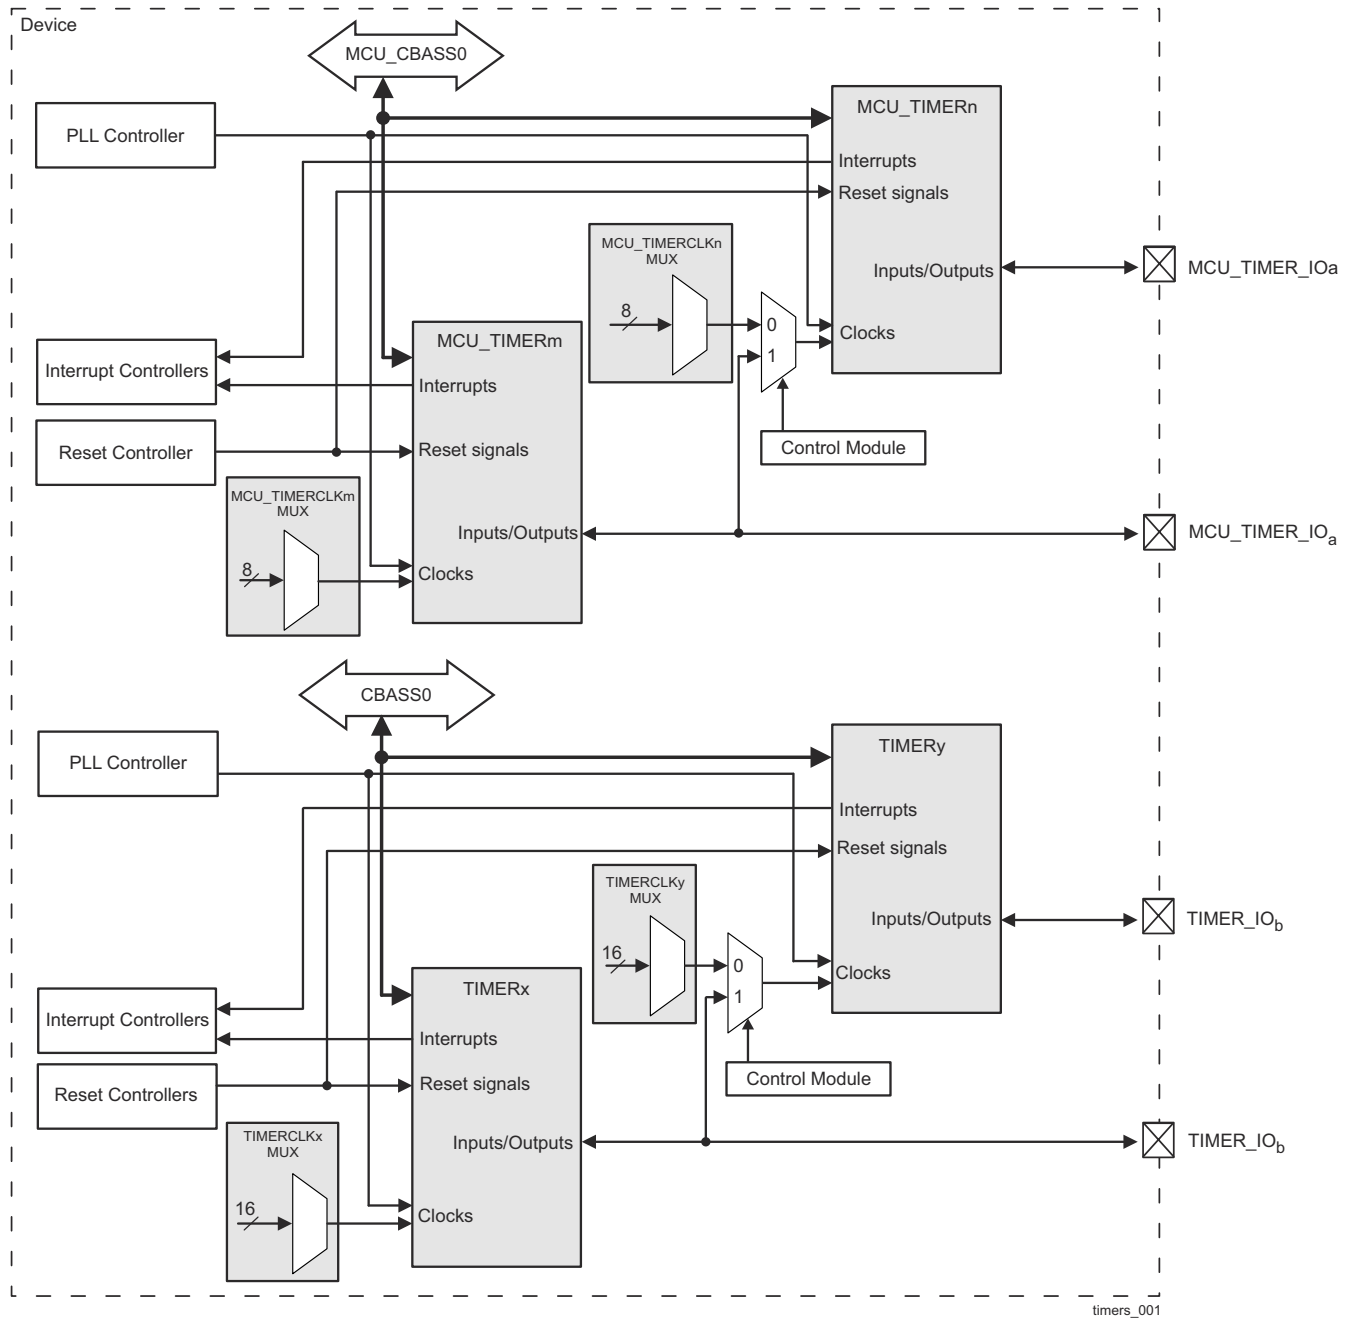

In the MCU domain the device provides 4 timer pins, one for each instance, to be used as MCU Timer Capture inputs or as MCU Timer PWM outputs.

In the MAIN domain the device provides 11 timer pins, one for each instance, to be used as Timer Capture inputs or as Timer PWM outputs.

Each odd numbered timer instance from each of the domains may be optionally cascaded with the previous even numbered timer instance from the same domain to form up to a 64-bit timer. For example, TIMER1 may be cascaded to TIMER0, MCU\_TIMER1 may be cascaded to MCU\_TIMER0, etc.

When cascaded, TIMERi acts as a 32-bit prescaler to TIMERi+1, as well as MCU\_TIMERn acts as a 32-bit prescaler to MCU\_TIMERn+1. TIMERi / MCU\_TIMERn must be configured to generate a PWM output edge at the desired rate to increment the TIMERi+1 / MCU\_TIMERn+1 counter.

[Figure 12-412](#) is an overview of the timers.

m = even instances of MCU Timer.

x = even instances of Timer.

#### Note

n = odd instances of MCU Timer.

#### Note

y = odd instances of Timer.

**Figure 12-412. Timers Overview**

#### 12.7.4.1.1 Timers Features

The following are the main features of the timer controllers:

- Target interface supports:
  - 32-bit data bus width
  - 32-bit access supported
  - 10-bit address bus width
  - Write nonposted transaction mode supported
- Interrupts generated on overflow, compare, and capture
- Free-running 32-bit upward counter
- Compare and capture modes
- Autoreload mode
- Start/stop mode
- Programmable divider clock source ( $2^n$ , where  $n = [0-8]$ )
- Dedicated input trigger for capture mode and dedicated output trigger/PWM signal
- On-the-fly read/write register (while counting)
- Generates a 1-ms tick clock with a 32.768 kHz functional clock sourced from the LFOSC

#### 12.7.4.1.2 Unsupported Features

See the *Module Integration* section for information about unsupported features.

---

#### Note

Some features may not be available. See *Module Integration* for more information.

---

### 12.7.4.2 Timers Environment

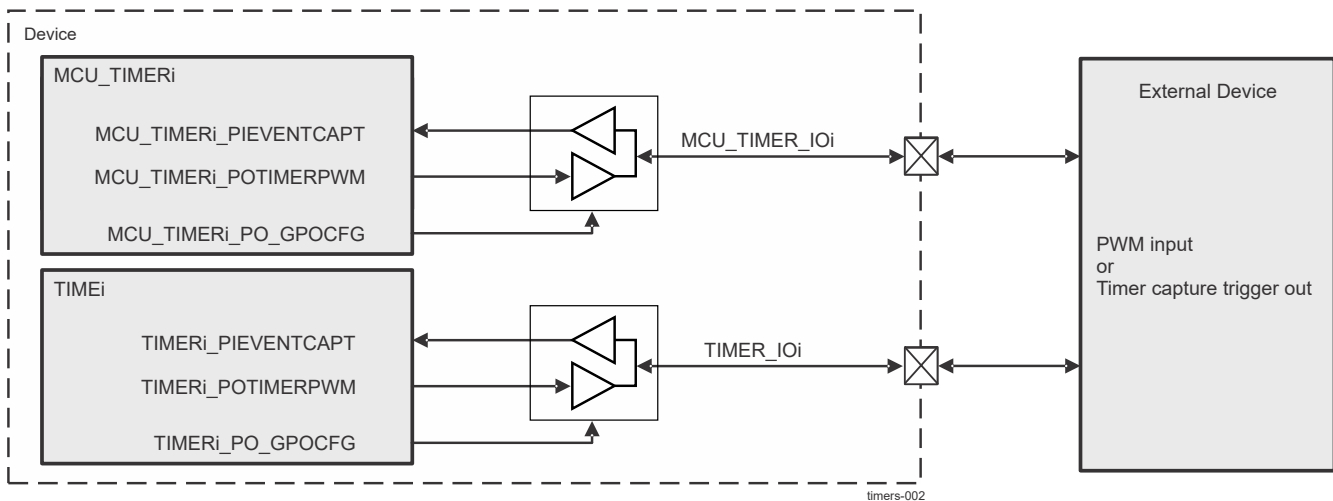

The MCU\_TIMER[3-0] and TIMER[11-0] modules are hereinafter referred to as timer module.

This section describes the timers external connections (environment).

#### 12.7.4.2.1 Timer External System Interface

Each timer can send or receive stimulus to/from the external (off-chip) system. In the device all timers are configured to output a PWM pulse or receive an external event signal used as a trigger to capture the current timer count.

Figure 12-413 shows the external system interface for the timers, and Table 12-325 describes the timer inputs and outputs.

#### Note

i represents a TIMER instance. See the device datasheet for available domains and TIMER instances.

**Figure 12-413. Timers External System Interface**

**Table 12-325. Timer I/O Signals**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description	Module Pin Reset Value <sup>(2)</sup>
<b>MCU_TIMERi<sup>(2)</sup></b>				
MCU_TIMER_IOi <sup>(2)</sup>	MCU_TIMERi <sup>(2)</sup> _PIEVENTCAPT	I/O	MCU_TIMERi <sup>(2)</sup> trigger input or	0
	MCU_TIMERi <sup>(2)</sup> _POTIMERPWM		MCU_TIMERi <sup>(2)</sup> output	
<b>TIMERi<sup>(2)</sup></b>				
TIMER_IOi <sup>(2)</sup>	TIMERi <sup>(2)</sup> _PIEVENTCAPT	I/O	TIMERi <sup>(2)</sup> trigger input or	0
	TIMERi <sup>(2)</sup> _POTIMERPWM		TIMERi <sup>(2)</sup> PWM output	

(1) When configured for that function; I = Input, O = Output

(2) i represents a TIMER instance. See the device datasheet for available domains and TIMER instances.

#### Note

Each MCU\_TIMER\_PO\_GPOCFG and TIMER\_PO\_GPOCFG signals are used as an output enable to control the function of the MCU\_TIMER\_IO[3-0], and respectively TIMER\_IO[11-0], as the PWM output (PO\_GPOCFG = 0) or capture input (PO\_GPOCFG = 1).

---

**Note**

For more information about device level signals (pull-up/down resistors, buffer type, and others), see tables *Pin Attributes* in the device-specific Datasheet.

---

**12.7.4.3 Integration**

See the *Module Integration* section for information about clocks, resets and hardware requests.

#### 12.7.4.4 Timers Functional Description

Each timer contains a free-running upward counter with autoreload capability on overflow. The timer counter can be read and written on-the-fly (while counting). Each timer includes compare logic to allow an interrupt event on a programmable counter matching value. A dedicated output signal can be pulsed or toggled on either an overflow or a match event. This offers time-stamp trigger signaling or PWM signal sources. A dedicated input signal can be used to trigger an automatic timer counter capture or an interrupt event on a programmable input signal transition. A programmable clock divider (prescaler) allows reduction of the timer input clock frequency. All internal timer interrupt sources are merged into one module interrupt line and one wake-up line.

Each internal interrupt source can be independently enabled and disabled by a dedicated bit in the DMTIMER1MS\_IRQSTATUS\_SET and DMTIMER1MS\_IRQSTATUS\_CLR register for the interrupt features, and a dedicated bit of the DMTIMER1MS\_IRQWAKEEN register for a wake-up. In addition, timers have a mechanism implemented to generate an accurate tick interrupt.

For each timer implemented in the device, there are two possible clock sources:

- 32-kHz clock (sourced from the LFOSC)
- System clock

For more information of the selection of the input clock source, see *Clocking*.

Each timer supports three functional modes:

- Timer mode
- Capture mode
- Compare mode

The capture and compare modes are disabled by default after core reset.

##### 12.7.4.4.1 Timer Block Diagram

[Figure 12-414](#) is a block diagram of the timers.

Figure 12-414. Timer Block Diagram

#### 12.7.4.4.2 Timer Power Management

##### Note

Some of the timers features described in this section may not be supported on this family of devices. For more information, see *Module Integration* for specifics..

The way the timer acknowledges the LPSC clock stop request is configurable through the DMTIMER1MS\_TIOCP\_CFG[3-2] IDLEMODE bit field.

Table 12-326 lists the IDLEMODE settings and the related acknowledgment modes.

Table 12-326. IDLEMODE Settings

IDLEMODE Value	Selected Mode	Description
00	Force-idle	The clock stop request is unconditionally acknowledged from the timer, regardless of its internal operations. This mode must be used carefully, because it does not prevent the loss of data when the clock is switched off.

**Table 12-326. IDLEMODE Settings (continued)**

IDLEMODE Value	Selected Mode	Description
01	No-idle	The clock stop request is never acknowledged from the timer. This mode is safe from a module point of view but is not efficient from a power-saving perspective because the clocks remain active.
10	Smart-idle	The timer acknowledges the clock stop request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and interrupt requests are treated. This is the best approach to efficient system power management.
11	Smart-idleWakeup	The module behaves like in Smart-idle mode, with the exception, that it can issue a wake-up request in sleep mode, if the functional clock is not cut off.

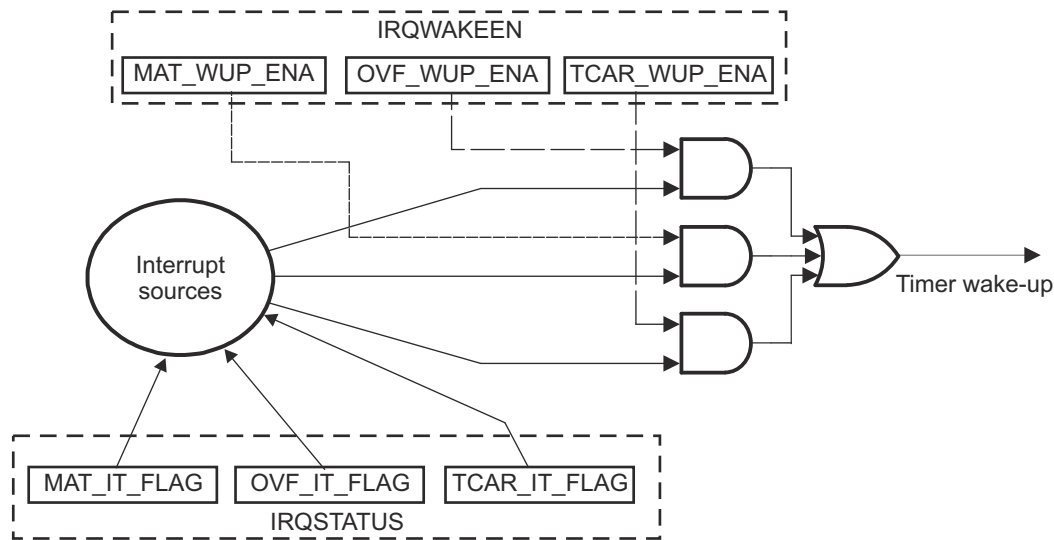

#### 12.7.4.4.2.1 Wake-Up Capability

##### Note

Some of the timers features described in this section may not be supported on this family of devices. For more information, see *Timers Not Supported Features*.

If the DMTIMER1MS\_TIOCP\_CFG[3-2] IDLEMODE bit field sets the smart-idle mode or smart-idle with wake-up mode, the timer evaluates its internal capability to have the interface clock switched off. When there is no further internal activity (no pending interrupt sources: match, overflow, or timer capture events), the clock stop acknowledge signal is asserted and the timer enters sleep mode, ready to issue a wake-up request if configured in smart-idle with wake-up mode.

Figure 12-415 shows the wake-up request generation.

timers-006

**Figure 12-415. Wake-Up Request Generation**

The timer wake-up-enable register allows masking of the expected source of the wake-up event that generates a wake-up request. The register is synchronously programmed with the interface clock before the Clock management sends a clock stop request. The expected source of the wake-up event is an overflow (DMTIMER1MS\_TCRR), a timer match (the compare result of DMTIMER1MS\_TCRR and DMTIMER1MS\_TMAR matches the counter value), and a timer capture (detection of an external pulse transition of the correct polarity on the TIMER\_PIEVENTCAPT).

When the wake-up event is issued, the associated interrupt status bit is set in the timer status register (DMTIMER1MS\_IRQSTATUS). The pending wake-up event is reset when the set status bit is overwritten with 1.

### Note

The status bit must be reset to re-enter idle mode.

#### 12.7.4.4.3 Timer Software Reset

DMTIMER1MS\_TIOCP\_CFG[0] SOFTRESET bit can initiate a software reset of the timer. This bit is autocleared to 0 when the reset is complete.

Before accessing or using the timer, the local host must ensure that internal reset is released by reading the DMTIMER1MS\_TIOCP\_CFG[0] SOFTRESET bit. This bit monitors the internal reset status.

#### 12.7.4.4.4 Timer Interrupts

The timer can issue an overflow interrupt, a timer match interrupt, and a timer capture interrupt. Each internal interrupt source can be independently enabled and disabled in the interrupt-enable register (DMTIMER1MS\_IRQSTATUS\_SET) and disabled in the interrupt-disable register (DMTIMER1MS\_IRQSTATUS\_CLR). When the interrupt event is issued, the associated interrupt status bit is set in the timer status register (DMTIMER1MS\_IRQSTATUS).

#### 12.7.4.4.5 Timer Mode Functionality

The timer is an upward counter that can be started and stopped at any time through the timer control register (the DMTIMER1MS\_TCLR[0] ST bit). The timer counter register (DMTIMER1MS\_TCRR) can be loaded when stopped or on-the-fly (while counting). DMTIMER1MS\_TCRR can be loaded directly by a DMTIMER1MS\_TCRR write access with a new timer value. DMTIMER1MS\_TCRR can also be loaded with the value held in the timer load register (DMTIMER1MS\_TLDR) by a trigger register (DMTIMER1MS\_TTGR) write access. The loading of DMTIMER1MS\_TCRR is done regardless of the written value of DMTIMER1MS\_TTGR. The value of DMTIMER1MS\_TCRR can be read when stopped or captured on-the-fly by a DMTIMER1MS\_TCRR read access. The timer is stopped and the counter value is set to 0 when the module reset is asserted. The timer is maintained at stop after the reset is released.

In one-shot mode (the DMTIMER1MS\_TCLR[1] AR bit is set to 0), the counter is stopped after counting overflow occurs (the counter value remains at 0).

When the autoreload mode is enabled (the DMTIMER1MS\_TCLR[1] AR bit is set to 1), DMTIMER1MS\_TCRR is reloaded with the value of DMTIMER1MS\_TLDR after a counting overflow occurs.

### CAUTION

Do not put the overflow value (0xFFFF FFFF) in the DMTIMER1MS\_TLDR register because it can lead to undesirable results.

An interrupt can be issued on overflow if the overflow interrupt-enable bit is set in the timer interrupt-enable register (the DMTIMER1MS\_IRQSTATUS\_SET[1] OVF\_EN\_FLAG bit is set to 1). A dedicated output pin (POTIMERPWM) can be programmed in the DMTIMER1MS\_TCLR[12] PT bit through the DMTIMER1MS\_TCLR[11-10] (PT and TRG bits) to generate one positive pulse (prescaler duration) or to invert the current value (toggle mode) when an overflow occurs. The DMTIMER1MS\_TCLR[12] PT bit selects pulse/toggle modulation (the DMTIMER1MS\_TCLR[11-10] TRG bit field selects trigger mode).

Figure 12-416 shows the DMTIMER1MS\_TCRR timing value.

**Figure 12-416. DMTIMER1MS\_TCRR Timing Value**

#### 12.7.4.4.5.1 1-ms Tick Generation

The interrupt period is not exactly 1 ms, because the timer input clock is 32.768 kHz. If the clock counts up to 32, it obtains a 0.977-ms period; if it counts up to 33, it obtains a 1.007-ms period. For large granularity, the error is cumulative and can generate important deviations from the standard value.

To minimize the error between a true 1-ms tick and the tick generated by the 32.768-kHz timer, the sequencing of periods less than 1 ms and periods greater than 1 ms must be shuffled. An additional 1-ms block is used to correct this error. See [Figure 12-417](#).

#### Note

The only available source for a 32.768-kHz clock is the LFOSC. The HFOSC is not capable of generating a true 32.788-kHz frequency.

In this implementation, the increment sequencing is automatically managed by the timer to minimize the error. The user must define only the value of the timer positive increment register (the DMTIMER1MS\_TPIR[31-0] POSITIVE\_INC\_VALUE bit field) and the timer negative increment register (the DMTIMER1MS\_TNIR[31-0] NEGATIVE\_INC\_VALUE bit field). An automatic adaptation mechanism is used to simplify the programming model.

timers-009

**Figure 12-417. Block Diagram of the 1-ms Tick Module**

The DMTIMER1MS\_TPIR, DMTIMER1MS\_TNIR, and DMTIMER1MS\_TCVR registers and adders Add1, Add2, and Add3 are used to define whether the next value loaded in the timer counter register (the DMTIMER1MS\_TCRR[31-0] TIMER\_COUNTER bit field) is the value of the DMTIMER1MS\_TLDR[31-0] LOAD\_VALUE bit field (period less than 1 ms) or the value of DMTIMER1MS\_TLDR[31-0] LOAD\_VALUE –1 (period greater than 1 ms).

Table 12-327 lists the value loaded in the DMTIMER1MS\_TCRR according to the sign of the result of Add1, Add2, and Add3.

MSB = 0: Positive value; MSB = 1: Negative value

**Table 12-327. Value Loaded in DMTIMER1MS\_TCRR to Generate 1-ms Tick**

Add1 MSB	Add2 MSB	Add3 MSB	Value of DMTIMER1MS_TCRR Register
0	0	0	DMTIMER1MS_TLDR[31-0] LOAD_VALUE bit field
0	0	1	DMTIMER1MS_TLDR[31-0] LOAD_VALUE bit field
0	1	0	DMTIMER1MS_TLDR[31-0] LOAD_VALUE bit field
0	1	1	DMTIMER1MS_TLDR[31-0] LOAD_VALUE –1
1	0	0	N/A
1	0	1	N/A
1	1	0	DMTIMER1MS_TLDR[31-0] LOAD_VALUE –1
1	1	1	DMTIMER1MS_TLDR[31-0] LOAD_VALUE –1

The values of the DMTIMER1MS\_TPIR and DMTIMER1MS\_TNIR registers are calculated using the following formulas:

- Positive increment value =  $(\text{INTEGER}[F_{\text{clk}} \times T_{\text{tick}}] + 1) \times 1\text{e}6 - (F_{\text{clk}} \times T_{\text{tick}} \times 1\text{e}6)$
- Negative increment value =  $(\text{INTEGER}[F_{\text{clk}} \times T_{\text{tick}}] \times 1\text{e}6) - (F_{\text{clk}} \times T_{\text{tick}} \times 1\text{e}6)$

---

#### Note

$F_{\text{clk}}$  clock frequency (kHz)

$T_{\text{tick}}$  tick period (ms)

---

The timer overflow counter register (DMTIMER1MS\_TOCR) and the timer overflow wrapping register (DMTIMER1MS\_TOWR) are used to filter interrupts. When the timer overflows, it increments the 24-bit DMTIMER1MS\_TOCR. When the values in the 24-bit DMTIMER1MS\_TOCR match the values in the 24-bit DMTIMER1MS\_TOWR and the timer overflow is asserted, the DMTIMER1MS\_TOCR is reset and an interrupt is generated to the DMTIMER1MS\_IRQSTATUS register.

---

#### Note

DMTIMER1MS\_TOWR has to be set to requested value. For example, if no interrupt needs to be masked DMTIMER1MS\_TOWR must be set to 0, if one interrupt needs to be masked DMTIMER1MS\_TOWR must be set to 1, if two interrupts need to be masked DMTIMER1MS\_TOWR must be set to 2 and so on.

It is important to have in mind that the case when FFFFFFF interrupts need to be masked is not possible.

---

With the conversion block in reset state (the positive increment register, negative increment register, and counter value register are zeroed), the programming model and the behavior of timers remain unchanged.

For 1-ms tick with a 32.768-kHz clock:

- DMTIMER1MS\_TPIR[31-0] POSITIVE\_INC\_VALUE = 232,000
- DMTIMER1MS\_TNIR[31-0] NEGATIVE\_INC\_VALUE = -768,000
- DMTIMER1MS\_TLDR[31-0] LOAD\_VALUE = 0xFFFF FFE0

---

#### Note

Any value of the tick period can be generated with the appropriate value of the DMTIMER1MS\_TPIR, DMTIMER1MS\_TNIR, and DMTIMER1MS\_TLDR.

By default, the DMTIMER1MS\_TPIR, DMTIMER1MS\_TNIR, DMTIMER1MS\_TCVR, DMTIMER1MS\_TOCR, and DMTIMER1MS\_TOWR and the associated logic are in reset mode (all 0s) and have no effect on the programming model.

---

#### 12.7.4.4.6 Timer Capture Mode Functionality

When a transition is detected on the module input pin (PIEVENTCAPT), the timer value in the DMTIMER1MS\_TCRR can be captured and saved in the DMTIMER1MS\_TCAR1 or DMTIMER1MS\_TCAR2 register function of the mode selected in the DMTIMER1MS\_TCLR[13] CAPT\_MODE bit. The edge detection circuitry monitors transitions on the input pin (PIEVENTCAPT).

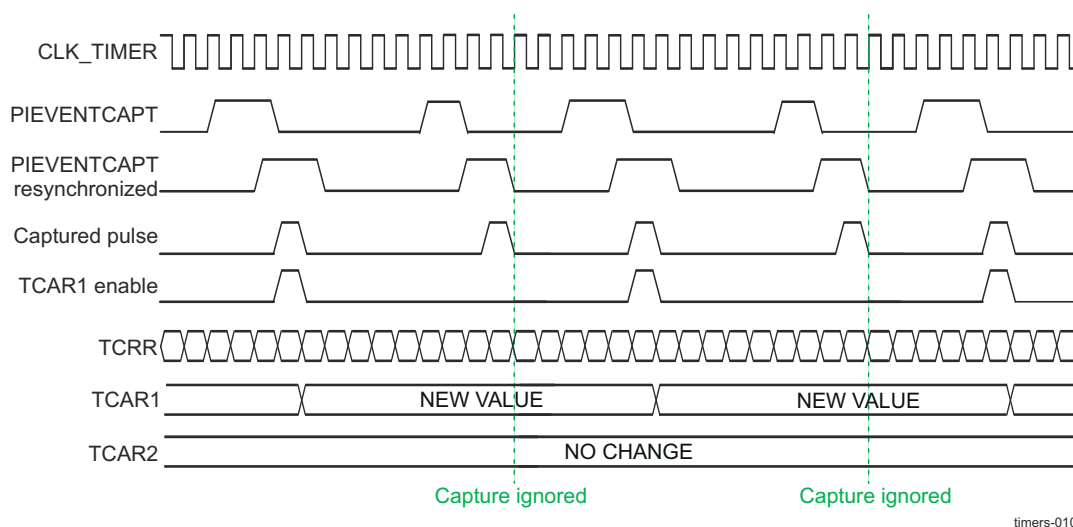

The rising edge, falling edge, or both, can be selected in the DMTIMER1MS\_TCLR[9-8] TCM bit field to trigger the timer counter capture. The module sets the DMTIMER1MS\_IRQSTATUS[2] TCAR\_IT\_FLAG bit when an active edge is detected, and at the same time, the counter value DMTIMER1MS\_TCRR is stored in timer capture register DMTIMER1MS\_TCAR1 or DMTIMER1MS\_TCAR2, as follows:

- If the DMTIMER1MS\_TCLR[13] CAPT\_MODE bit is 0, on the first enabled capture event, the value of the counter register is saved in the DMTIMER1MS\_TCAR1 register, and the next events are ignored (no update

- on the DMTIMER1MS\_TCAR1 register and no interrupt triggering) until the detection logic is reset or the DMTIMER1MS\_IRQSTATUS[2] TCAR\_IT\_FLAG is cleared by writing 1 to it.
- If the DMTIMER1MS\_TCLR[13] CAPT\_MODE bit is 1, on the first enabled capture event, the value of the counter register is saved in the DMTIMER1MS\_TCAR1 register, and on the second enabled capture event, the value of the counter register is saved in the DMTIMER1MS\_TCAR2 register. If a capture interrupt is enabled, the interrupt triggers on the second event capture. All other events are ignored (no update on DMTIMER1MS\_TCAR1/DMTIMER1MS\_TCAR2 and no interrupt triggering) until the detection logic is reset or the DMTIMER1MS\_IRQSTATUS[2] TCAR\_IT\_FLAG bit is cleared by writing 1 to it. This mechanism is useful for period calculation of a clock, if that clock is connected to the PIEVENTCAPT input pin.

The edge detection logic is reset (a new capture is enabled) when the active capture interrupt is served. The DMTIMER1MS\_IRQSTATUS[2] TCAR\_IT\_FLAG bit is cleared by writing 1 to it or when the edge detection mode bits (the DMTIMER1MS\_TCLR[9-8] TCM bit field) are changed from no-capture mode detection to any other mode. The timer functional clock (input to prescaler) is used to sample the input pin (PIEVENTCAPT). A negative or positive pulse input can be detected when the pulse time is greater than the functional clock period. An interrupt is issued on edge detection if the capture interrupt-enable bit is set in the DMTIMER1MS\_IRQSTATUS\_SET[2] TCAR\_EN\_FLAG bit. See the examples in [Figure 12-418](#) and [Figure 12-419](#).

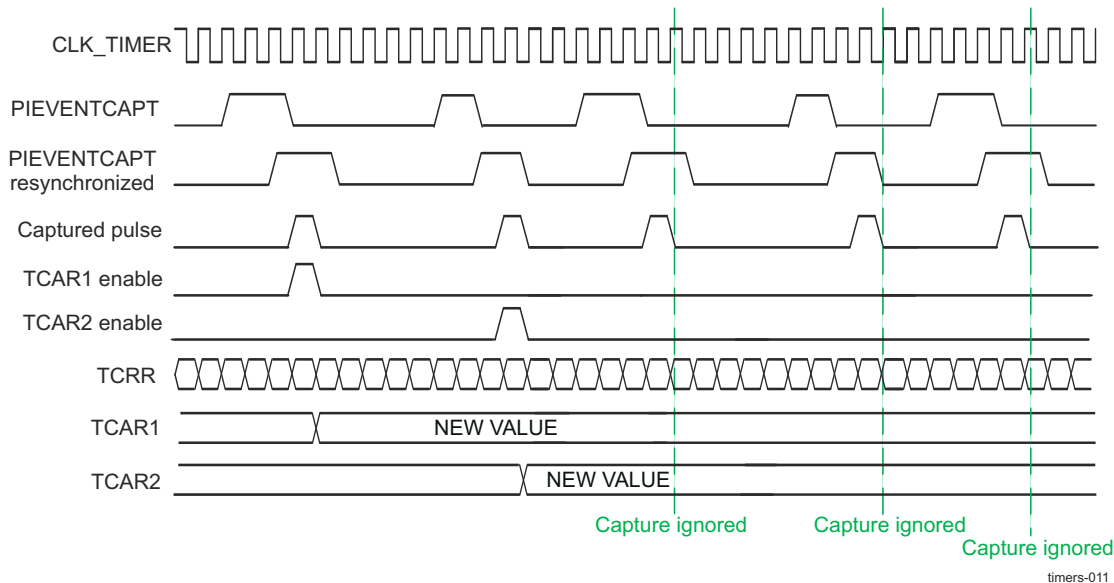

In [Figure 12-418](#), the value of the DMTIMER1MS\_TCLR[9-8] TCM bit field is 1h, and the DMTIMER1MS\_TCLR[13] CAPT\_MODE bit is 0. Only the rising edge of PIEVENTCAPT triggers a capture in the DMTIMER1MS\_TCAR1 and DMTIMER1MS\_TCAR2 registers, and only the DMTIMER1MS\_TCAR1 register updates.

**Figure 12-418. Capture Wave Example for DMTIMER1MS\_TCLR[13] CAPT\_MODE = 0**

In [Figure 12-419](#), the value of the DMTIMER1MS\_TCLR[9-8] TCM bit field is 1h, and the DMTIMER1MS\_TCLR[13] CAPT\_MODE bit is 1. Only the rising edge of PIEVENTCAPT triggers a capture in the DMTIMER1MS\_TCAR1 register on the first enabled event, and the DMTIMER1MS\_TCAR2 register updates on the second enabled event.

**Figure 12-419. Capture Wave Example for DMTIMER1MS\_TCLR[13] CAPT\_MODE = 1**

#### 12.7.4.4.7 Timer Compare Mode Functionality

When the compare-enable register DMTIMER1MS\_TCLR[6] CE bit is set to 1, the timer value (the DMTIMER1MS\_TCRR[31-0] TIMER\_COUNTER bit field) is continuously compared to the value held in the timer match register (DMTIMER1MS\_TMAR). The value of the DMTIMER1MS\_TMAR[31-0] COMPARE\_VALUE bit field can be loaded at any time (timer counting or stopped). When the DMTIMER1MS\_TCRR and the DMTIMER1MS\_TMAR values match, an interrupt is issued, if the DMTIMER1MS\_IRQSTATUS\_SET[0] MAT\_EN\_FLAG bit is set.

To prevent any unwanted interrupts due to reset value matching effect, write a compare value to the DMTIMER1MS\_TMAR before setting the DMTIMER1MS\_TCLR[6] CE bit.

The dedicated output pin (POTIMERPWM) can be programmed in the DMTIMER1MS\_TCLR[12] PT bit through the DMTIMER1MS\_TCLR[11-10] TRG bit field to generate one positive pulse (timer clock duration) or to invert the current value (toggle mode) when an overflow or a match occurs.

#### 12.7.4.4.8 Timer Prescaler Functionality

A prescaler can be used to divide the timer counter input clock frequency. The prescaler is enabled when the DMTIMER1MS\_TCLR[5] PRE bit is set. The DMTIMER1MS\_TCLR[4-2] PTV bit field sets the  $2^n$  division ratio (prescaler value is  $2^{(PTV + 1)}$ ). The prescaler counter is reset when the timer counter is stopped or reloaded on-the-fly.

Table 12-328 lists the prescaler/timer reload values versus contexts.

**Table 12-328. Prescaler/Timer Reload Values Versus Contexts**

Context	Prescaler	Timer Counter
Overflow (when autoreload is on)	Reset	DMTIMER1MS_TLDR[31-0]
DMTIMER1MS_TCRR write	Reset	DMTIMER1MS_TCRR[31-0]
DMTIMER1MS_TTGR write	Reset	DMTIMER1MS_TLDR[31-0]
Stop	Reset	Frozen

#### 12.7.4.4.9 Timer Pulse-Width Modulation

The timer can be configured to provide a programmable PWM output. The timer PWM (POTIMERPWM) output pin can be configured to toggle on an event. The DMTIMER1MS\_TCLR[11-10] TRG bit field determines on

which register value the PWM pin toggles. Either overflow or both overflow and match can be selected to toggle the timer PWM pin when a compare condition occurs.

### Note

In toggle mode, when DMTIMER1MS\_TCLR[11-10] TRG = 0x2 (overflow and match), the first event that toggles the PWM line is an overflow event.

The DMTIMER1MS\_TCLR[7] SCPWM bit can be programmed to set or clear the timer PWM output signal only while the counter is stopped or the trigger is off. This allows setting the output pin to a known state before modulation starts. Modulation synchronously stops when the DMTIMER1MS\_TCLR[11-10] TRG bit field is cleared and overflow occurs. This allows fixing a deterministic state of the output pin when modulation stops.

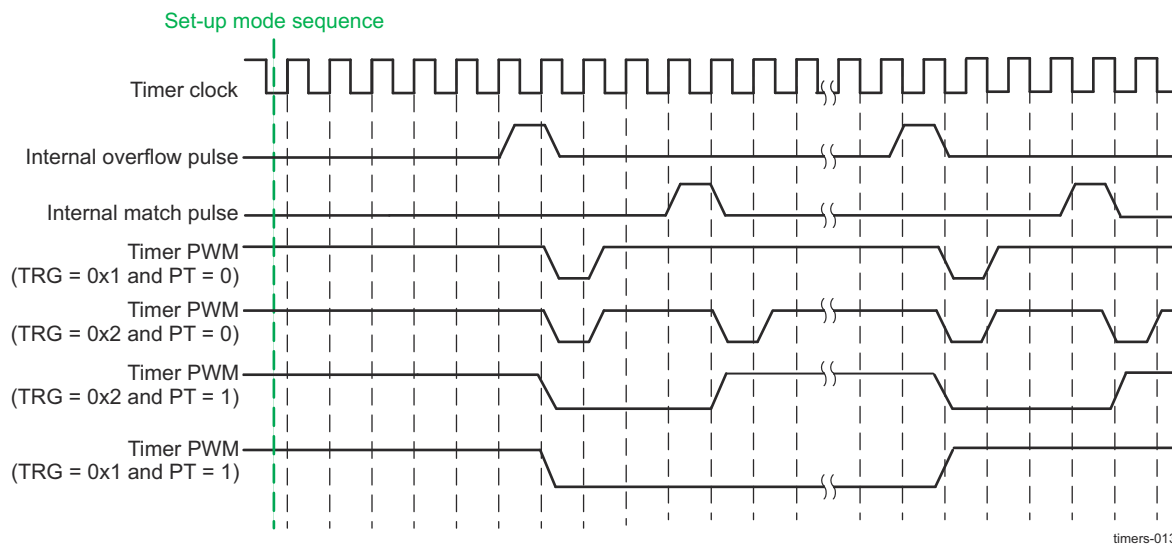

In [Figure 12-420](#), the internal overflow pulse is set each time the (0xFFFF FFFF – DMTIMER1MS\_TLDR[31-0] LOAD\_VALUE + 1) value is reached, and the internal match pulse is set when the counter reaches the value of DMTIMER1MS\_TMAR. Depending on the value of the DMTIMER1MS\_TCLR[12] PT bit and DMTIMER1MS\_TCLR[11-10] TRG bit field, the timer provides pulse or PWM event on the output pin (POTIMERPWM).

The DMTIMER1MS\_TLDR and DMTIMER1MS\_TMAR must keep values below the overflow value (0xFFFF FFFF) by at least two units. If the PWM trigger events are both overflow and match, the difference between the values kept in the DMTIMER1MS\_TMAR and the value in the DMTIMER1MS\_TLDR must be at least two units. When match event is used, the compare mode DMTIMER1MS\_TCLR[6] CE bit must be set.

In [Figure 12-420](#), the DMTIMER1MS\_TCLR[7] SCPWM bit is set to 0. In [Figure 12-421](#), the DMTIMER1MS\_TCLR[7] SCPWM bit is set to 1. To obtain the desired wave form, start the counter at 0xFFFF FFFE value (to ensure an overflow first) or adjust the line polarity (DMTIMER1MS\_TCLR[7] SCPWM bit).

**Figure 12-420. Timing Diagram of PWM With DMTIMER1MS\_TCLR[7] SCPWM Bit = 0**

**Figure 12-421. Timing Diagram of PWM With DMTIMER1MS\_TCLR[7] SCPWM Bit = 1**

#### 12.7.4.4.10 Timer Counting Rate

The timer rate is defined by the following values:

- Value of the prescaler fields (the DMTIMER1MS\_TCLR[5] PRE bit and DMTIMER1MS\_TCLR[4-2] PTV bit field)
- Value loaded into the DMTIMER1MS\_TLDR

Table 12-329 lists the prescaler clock ratio values.

**Table 12-329. Prescaler Clock Ratio Values**

DMTIMER1MS_TCLR[5] PRE	DMTIMER1MS_TCLR[4-2] PTV	Divisor (PS)
0	X	1
1	0	2
1	1	4
1	2	8
1	3	16
1	4	32
1	5	64
1	6	128
1	7	256

Thus, the timer overflow rate is expressed as:

$$\text{OVF\_Rate} = (0\text{x}\text{FFFF FFFF} - \text{DMTIMER1MS\_TLDR} + 1) \times (\text{timer-functional clock period}) \times \text{PS}$$

With (timer-functional clock period) = 1/(timer-functional clock frequency) and PS = 2<sup>(PTV + 1)</sup> if prescaler is enabled, or PS = 1 if prescaler is disabled.

### CAUTION

Internal resynchronization causes any write to the DMTIMER1MS\_TCLR[1] ST bit to have some latency before the register is updated:

2.5 × functional clock cycles write\_DMTIMER1MS\_TCLR\_latency 3.5 × functional clock cycles

Remember to consider this latency whenever the timer must be started or stopped by a software change to the DMTIMER1MS\_TCLR[1] ST bit.

### CAUTION

- In non-PWM mode, DMTIMER1MS\_TLDR must be maintained at less than or equal to 0xFFFF FFFE.
- In PWM mode, DMTIMER1MS\_TLDR must be maintained at less than or equal to 0xFFFF FFDD.

For example, with a timer clock input of 32 kHz and the DMTIMER1MS\_TCLR[5] PRE bit set to 0, the timer output period is as listed in [Table 12-330](#).

**Table 12-330. Value and Corresponding Interrupt Period**

DMTIMER1MS_TLDR[31-0] LOAD_VALUE	Interrupt Period
0x0000 0000	37 h
0xFFFF 0000	2 s
0xFFFF FFF0	500 μs
0xFFFF FFFE	62.5 μs

#### 12.7.4.4.11 Timer Under Emulation

During emulation mode, the timer continues to run according to the value of the DMTIMER1MS\_TIOCP\_CFG[1] EMUFREE bit.

If the DMTIMER1MS\_TIOCP\_CFG[1] EMUFREE bit is set to 1, timer execution is not stopped in emulation mode and the interrupt is still generated when overflow or match is reached.

If the DMTIMER1MS\_TIOCP\_CFG[1] EMUFREE bit is set to 0, the prescaler and timer are frozen and both resume on exit from emulation mode. The asynchronous external input pin (MCU\_TIMER\_IO[9-0] or TIMER\_IO[7-0]) is internally synchronized on two timer-clock rising edges.

#### 12.7.4.4.12 Accessing Timer Registers

All accesses are posted mode, under the assumption that  $\text{freq}(\text{timer clock}) < \text{freq}(\text{interface clock})/4$ , until software reconfiguration. In addition, it is not recommended to access the timer registers prior to the PLLs generating the timer and interface clocks have been configured and the clocks have stabilized. All registers are 32 bits wide, accessible through the configuration interface with 32-bit access (read/write).

Write operations to the following functional registers must be complete (the MSB must be written even if the MSB data is not used):

- DMTIMER1MS\_TCLR
- DMTIMER1MS\_TCR
- DMTIMER1MS\_TLDR
- DMTIMER1MS\_TTGR
- DMTIMER1MS\_TMAR
- DMTIMER1MS\_TPIR
- DMTIMER1MS\_TNIR
- DMTIMER1MS\_TCV
- DMTIMER1MS\_TOCR
- DMTIMER1MS\_TOWR

The following registers are not affected by the posted/nonposted mode selection; the write/read operation is effective and acknowledged (command accepted) after one interface clock cycle from command assertion:

- DMTIMER1MS\_TIDR
- DMTIMER1MS\_TIOCP\_CFG
- DMTIMER1MS\_IRQSTATUS
- DMTIMER1MS\_IRQSTATUS\_RAW
- DMTIMER1MS\_IRQSTATUS\_SET
- DMTIMER1MS\_IRQSTATUS\_CLR
- DMTIMER1MS\_IRQWAKEEN
- DMTIMER1MS\_TWPS
- DMTIMER1MS\_TSICR

#### **12.7.4.4.12.1 Writing to Timer Registers**

The host uses the configuration interface to write to the following registers synchronously with the timer interface clock:

- DMTIMER1MS\_TLDR
- DMTIMER1MS\_TCRR
- DMTIMER1MS\_TCLR
- DMTIMER1MS\_TIOCP\_CFG
- DMTIMER1MS\_IRQSTATUS
- DMTIMER1MS\_IRQSTATUS\_SET
- DMTIMER1MS\_IRQSTATUS\_CLR
- DMTIMER1MS\_IRQWAKEEN
- DMTIMER1MS\_TTGR
- DMTIMER1MS\_TSICR
- DMTIMER1MS\_TMAR
- DMTIMER1MS\_TPIR
- DMTIMER1MS\_TNIR
- DMTIMER1MS\_TCVR
- DMTIMER1MS\_TOCR
- DMTIMER1MS\_TOWR

#### **12.7.4.4.12.1.1 Write Posting Synchronization Mode**

This mode is used if the DMTIMER1MS\_TSICR[2] POSTED bit is set to 1 (default value).

This mode uses a posted write scheme to update any internal register (DMTIMER1MS\_TCLR, DMTIMER1MS\_TCRR, DMTIMER1MS\_TLDR, DMTIMER1MS\_TTGR, DMTIMER1MS\_TMAR, DMTIMER1MS\_TPIR, DMTIMER1MS\_TNIR, DMTIMER1MS\_TCVR, DMTIMER1MS\_TOCR, and DMTIMER1MS\_TOWR). Therefore, the write transaction is immediately acknowledged on the configuration interface, although the effective write operation occurs later because of a resynchronization in the timer clock domain. The advantage is that neither the interconnect, nor the device that requested the write transaction is stalled.

For each register, a status bit is provided in the timer write-posted status (DMTIMER1MS\_TWPS) register. In this mode, it is mandatory that software check this status bit before any write access. If a write is attempted to a register with a previous access pending, the previous access is discarded without notice.

The timer module updates the value of the timer counter register synchronously with the interface clock. Consequently, any read access to DMTIMER1MS\_TCRR does not add any resynchronization latency; the current value is always available.

---

**Note**

Because the overflow IRQ is generated when the value of DMTIMER1MS\_TCR reaches 0xFFFF FFFF, and not when it changes its value to the value after overflow, it is necessary to wait a delay of  $(1 \times PS \times \text{timer functional clock period})$  before any read access to DMTIMER1MS\_TCR to ensure a correct reading of its content.

---

---

**Note**

If DMTIMER1MS\_TTGR register is written during a posted write to DMTIMER1MS\_TCR, the value to be written to DMTIMER1MS\_TCR will be discarded.

If a posted write to DMTIMER1MS\_TCR is started, the user must not write to DMTIMER1MS\_TPIR or DMTIMER1MS\_TNIR before the DMTIMER1MS\_TCR write is finished, because the value of DMTIMER1MS\_TCR is re-evaluated, so both the value to be written, and the recalculated value will be discarded.

---

If a write access is pending for a register, reading from this register does not yield a correct result. Software synchronization must be used to avoid incorrect results.

Functional frequency range:  $\text{freq}(\text{timer clock}) < \text{freq}(\text{interface clock})/4$ .

#### **12.7.4.4.12.1.2 Write Nonposting Synchronization Mode**

This mode is used if the DMTIMER1MS\_TSICR[2] POSTED bit is set to 0. It uses a nonposted write scheme to update any internal register. Therefore, the write transaction is not acknowledged on the configuration interface until the effective write operation occurs after the resynchronization in the timer functional clock domain. The drawback is that the interconnect and the device that requested the write transaction are stalled during this period.

The same full resynchronization scheme is used for a read transaction, and the same stall period applies. A register read following a write to the same register is always coherent.

This mode is functional regardless of the ratio between the configuration interface frequency and the timer clock frequency.

#### **12.7.4.4.12.2 Reading From Timer Counter Registers**

---

**Note**

LSB/MSB accesses cannot be interleaved (that is, the sequence LSB register 1, LSB register 2, MSB register 1, MSB register 2 is not supported).

---

The DMTIMER1MS\_TCR is a 32-bit “atomic datum” and its 16-bit capture is done on the 16-bit LSB first to allow atomic LSB16 + MSB16 capture. This capture scheme is also performed for the DMTIMER1MS\_TCAR1 and DMTIMER1MS\_TCAR2 registers as they can be changed due to internal processes too.

#### **12.7.4.4.12.2.1 Read Posted**

This mode is functional regardless of the ratio between the configuration interface frequency and the functional clock frequency. The recommended functional frequency range is  $\text{freq}(\text{timer}) < \text{freq}(\text{interface clock})/4$ .

Read posted mode is used if DMTIMER1MS\_TSICR[2] POSTED = 0x1 or DMTIMER1MS\_TSICR[3] READ\_MODE is set to 0. This mode uses a posted-read scheme for reading any internal timer register. The read transaction is immediately acknowledged on the configuration interface, prior to the value to be read has been resynchronized. With this method, neither the interconnect nor the device that requested the read transaction are stalled.

Read posted mode applies to DMTIMER1MS\_TCRR, DMTIMER1MS\_TCAR1, DMTIMER1MS\_TCAR2, DMTIMER1MS\_TCVR, and DMTIMER1MS\_TOWR, which needs resynchronization from functional to interface clock domains.

Note that in Posted mode, if the DMTIMER1MS\_TCRR is read immediately after wake-up and the interface clock is off during idle state, then it is possible to get an old value from just before going to idle state due to the fact the interface clock is needed for synchronization.

In order to avoid this situation, another synchronization mechanism is used for the first read operation after idle state. The DMTIMER1MS\_TSICR[4] READ\_AFTER\_IDLE bit is used to enable/disable the mechanism.

When the synchronization mechanism is disabled (READ\_AFTER\_IDLE bit is set to 1), first read transaction takes only 2 interface clock cycles, but the read value of DMTIMER1MS\_TCRR could be wrong.

When the synchronization mechanism is enabled (READ\_AFTER\_IDLE bit is set to 0), first read value of DMTIMER1MS\_TCRR is correct, but the read transaction takes more than 2 interface clock cycles.

#### 12.7.4.4.12.2.2 Read Non-Posted

This mode is functional regardless of the ratio between the configuration interface frequency and the functional clock frequency. Recommended functional frequency range is  $\text{freq}(\text{timer}) \geq \text{freq}(\text{interface clock})/4$ .

Read non-posted mode is used if DMTIMER1MS\_TSICR[2] POSTED = 0x0 and DMTIMER1MS\_TSICR[3] READ\_MODE = 0x1. This mode uses a non-posted read scheme for reading internal timer registers. The read transaction is not acknowledged on the configuration interface until the effective read operation occurs, after the resynchronization in the timer clock domain. The result is that both the interconnect and the device that requested the read transaction are stalled during this period.

This mode applies to DMTIMER1MS\_TCRR, DMTIMER1MS\_TCAR1, DMTIMER1MS\_TCAR2, DMTIMER1MS\_TCVR, and DMTIMER1MS\_TOWR, which need resynchronization from functional to interface clock domains.

#### 12.7.4.4.13 Timer Posted Mode Selection

A choice between two synchronization modes is made taking into account the frequency ratio and the stall periods that can be supported by the system, without impacting the global performance.

The posted mode selection applies only to registers that require synchronization on or from the timer clock domain. For write operation, the registers affected by posted and non-posted selection are DMTIMER1MS\_TCLR, DMTIMER1MS\_TLDR, DMTIMER1MS\_TCRR, DMTIMER1MS\_TTGR, DMTIMER1MS\_TMAR, DMTIMER1MS\_TPIR, DMTIMER1MS\_TNIR, DMTIMER1MS\_TCVR, DMTIMER1MS\_TOCR, and DMTIMER1MS\_TOWR. For read operation, the registers affected by this selection are: DMTIMER1MS\_TCRR, DMTIMER1MS\_TCAR1, DMTIMER1MS\_TCAR2, DMTIMER1MS\_TCVR, and DMTIMER1MS\_TOWR.

The interface clock domain synchronous registers DMTIMER1MS\_TIDR, DMTIMER1MS\_TIOCP\_CFG, DMTIMER1MS\_IRQSTATUS, DMTIMER1MS\_IRQSTATUS\_SET, DMTIMER1MS\_IRQWAKEEN, DMTIMER1MS\_TWPS, and DMTIMER1MS\_TSICR are not affected by posted and non-posted mode selection. The operation (read or write) is effective and acknowledged after one interface clock cycle from the command assertion.

The configuration of posted or non-posted mode can be changed (overwritten) by software by writing in DMTIMER1MS\_TSICR[2] POSTED bit. The DMTIMER1MS\_TSICR[3] READ\_MODE defines how the read operation is performed when the module is configured in non-posted mode (see DMTIMER1MS\_TSICR). The following cases are possible:

- DMTIMER1MS\_TSICR[2] POSTED = 0x1 and DMTIMER1MS\_TSICR[3] READ\_MODE = x (don't care): read and write operations are expected in posted mode.
- DMTIMER1MS\_TSICR[2] POSTED = 0x0 and DMTIMER1MS\_TSICR[3] READ\_MODE = 0x0: the write operation is executed in non-posted mode and read is executed in posted mode.

- DMTIMER1MS\_TSICR[2]POSTED = 0x0 and DMTIMER1MS\_TSICR[3] READ\_MODE = 0x1: write is executed in non-posted mode and read is executed in non-posted mode.

#### 12.7.4.5 Timers Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the module.

##### 12.7.4.5.1 Timer Global Initialization

###### 12.7.4.5.1.1 Main Sequence – Timer Module Global Initialization

[Table 12-331](#) identifies the main steps for initializing the timer module when the module is to be used for the first time.

**Table 12-331. Timer Module Global Initialization**

Step	Register/Bit Field/Programming Model	Value
Execute software reset.	DMTIMER1MS_TIOCP_CFG[0] SOFTRESET	0x1
Wait until reset release?	DMTIMER1MS_TIOCP_CFG[0] SOFTRESET	0x0
Configure idle mode.	DMTIMER1MS_TIOCP_CFG[3-2] IDLEMODE	0x-
Enable wake-up interrupt events.	DMTIMER1MS_IRQWAKEEN[2-0]	0x-
Select posted mode.	DMTIMER1MS_TSICR[2] POSTED	0x-

##### 12.7.4.5.2 Timer Operational Mode Configuration

###### 12.7.4.5.2.1 Timer Mode

###### 12.7.4.5.2.1.1 Main Sequence – Timer Mode Configuration

[Table 12-332](#) lists the steps in the timer mode configuration.

**Table 12-332. Timer Mode Configuration**

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	DMTIMER1MS_TCLR[1] AR	0x-
Set prescale timer value.	DMTIMER1MS_TCLR[4-2] PTV	0x-
Enable prescaler.	DMTIMER1MS_TCLR[5] PRE	0x1
Enable overflow interrupt.	DMTIMER1MS_IRQSTATUS_SET[1] OV_F_EN_FLAG	0x1
Load timer counter value.	DMTIMER1MS_TCRR	0x-
Load timer load value.	DMTIMER1MS_TLDR	0x-
Start the timer.	DMTIMER1MS_TCLR[0] ST	0x1

###### 12.7.4.5.2.2 Timer Compare Mode

###### 12.7.4.5.2.2.1 Main Sequence – Timer Compare Mode Configuration

[Table 12-333](#) lists the steps in the timer compare mode configuration.

**Table 12-333. Timer Compare Mode Configuration**

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	DMTIMER1MS_TCLR[1] AR	0x-
Set prescale timer value.	DMTIMER1MS_TCLR[4-2] PTV	0x-
Enable prescaler.	DMTIMER1MS_TCLR[5] PRE	0x1
Enable match interrupt.	DMTIMER1MS_IRQSTATUS_SET[0] MAT_EN_FLAG	0x1
Load timer counter value.	DMTIMER1MS_TCRR	0x-
Load timer compare value.	DMTIMER1MS_TMAR	0x-
Enable compare mode.	DMTIMER1MS_TCLR[6] CE	0x1
Start the timer.	DMTIMER1MS_TCLR[0] ST	0x1

### 12.7.4.5.2.3 Timer Capture Mode

#### 12.7.4.5.2.3.1 Main Sequence – Timer Capture Mode Configuration

Table 12-334 lists the steps in the timer capture mode configuration.

**Table 12-334. Timer Capture Mode Configuration**

Step	Register/Bit Field/Programming Model	Value
Initialize capture mode.	See <a href="#">Section 12.7.4.5.2.3.2</a> .	
Enable capture interrupt.	DMTIMER1MS_IRQSTATUS_SET[2] TCAR_EN_FLAG	0x1
Start the timer.	DMTIMER1MS_TCLR[0] ST	0x1
Detect event.	See <a href="#">Section 12.7.4.5.2.3.3</a> .	

#### 12.7.4.5.2.3.2 Subsequence – Initialize Capture Mode

Table 12-335 lists the steps to initialize capture mode.

**Table 12-335. Initialize Capture Mode**

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	DMTIMER1MS_TCLR[1] AR	0x-
Set prescale timer value.	DMTIMER1MS_TCLR[4-2] PTV	0x-
Enable prescaler.	DMTIMER1MS_TCLR[5] PRE	0x1
Select TIMER[11-0] or MCU_TIMER[3-0] Capture input at device pins TIMER_IO[11-0] for TIMER[11-0] or at pins MCU_TIMER_IO[3-0] for MCU_TIMER[3-0].	DMTIMER1MS_TCLR[14] GPO_CFG	0x1
Select single or second event capture.	DMTIMER1MS_TCLR[13] CAPT_MODE	0x-
Select transition capture mode.	DMTIMER1MS_TCLR[9-8] TCM	0x-

#### 12.7.4.5.2.3.3 Subsequence – Detect Event

Table 12-336 lists the steps in detecting an event.

**Table 12-336. Detect Event**

Step	Register/Bit Field/Programming Model	Value
Wait until event detected?	DMTIMER1MS_IRQSTATUS[2] TCAR_IT_FLAG	= 0x1
Read timer capture value.	DMTIMER1MS_TCAR1 and/or DMTIMER1MS_TCAR2	
Clear capture interrupt request.	DMTIMER1MS_IRQSTATUS[2] TCAR_IT_FLAG	0x1

### 12.7.4.5.2.4 Timer PWM Mode

#### 12.7.4.5.2.4.1 Main Sequence – Timer PWM Mode Configuration

Table 12-337 lists the steps in the timer PWM mode configuration.

**Table 12-337. Timer PWM Mode Configuration**

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	DMTIMER1MS_TCLR[1] AR	0x-
Set prescale timer value.	DMTIMER1MS_TCLR[4-2] PTV	0x-
Enable prescaler.	DMTIMER1MS_TCLR[5] PRE	0x1
Select trigger output mode.	DMTIMER1MS_TCLR[11-10] TRG	0x-
Select pulse or toggle modulation PWM mode.	DMTIMER1MS_TCLR[12] PT	0x-
Select TIMER[11-0] or MCU_TIMER[3-0] PWM output at device pins TIMER_IO[11-0] for TIMER[11-0] or at pins MCU_TIMER_IO[3-0] for MCU_TIMER[3-0].	DMTIMER1MS_TCLR[14] GPO_CFG	0x0
Configure PWM output pin default value.	DMTIMER1MS_TCLR[7] SCPWM	0x-

**Table 12-337. Timer PWM Mode Configuration (continued)**

Step	Register/Bit Field/Programming Model	Value
Load timer load value.	DMTIMER1MS_TLDR	0x-
Load timer compare value.	DMTIMER1MS_TMAR	0x-
Enable compare.	DMTIMER1MS_TCLR[6] CE	0x1
Start the timer.	DMTIMER1MS_TCLR[0] ST	0x1

## 12.8 Internal Diagnostics Modules

### 12.8.1 Dual Clock Comparator (DCC)

This section describes the Dual Clock Comparator (DCC) modules in the device.

#### 12.8.1.1 DCC Overview

The Dual Clock Comparator (DCC) is used to determine the accuracy of a clock signal during the time execution of an application. Specifically, the DCC is designed to detect drifts from the expected clock frequency. The desired accuracy can be programmed based on calculation for each application. The DCC measures the frequency of a selectable clock source using another input clock as a reference.

The device has instances of DCC modules.

[Figure 12-422](#) shows the DCC modules overview.

dcc-001

1.  $i = 0$  to number of instances in MCU Domain.
2.  $i = 0$  to number of instances in MAIN Domain.

**Figure 12-422. DCC Modules Overview**

#### 12.8.1.1.1 DCC Features

The DCC uses two independent clock sources to detect when one is out of specification. Each DCC module implements the following features:

- Two independent counter blocks count clock pulses from each clock source
- Each counter block is programmable, however, for proper operation the counters must be programmed with seed values that respect the ratio of the two clock frequencies
- Configurable timebase for error signal
- Error signal generation when one of the clocks is out of specification
- Clock frequency measurement

#### 12.8.1.1.2 Unsupported Features

See the *Module Integration* section for information about unsupported features.

---

**Note**

Some features may not be available. See *Module Integration* for more information.

---

## 12.8.1.2 DCC Functional Description

### 12.8.1.2.1 DCC Counter Operation

#### Note

For detailed DCC compute calculations, refer to [Continuous Monitor of the PLL Frequency With the DCC App Note](#).

The DCC has two parallel counters that count clock pulses for two independent clock sources:

- Counter0 generates a fixed-width counting window (VALID0) after a pre-programmed number of pulses (COUNT0). The values for VALID0 and COUNT0 can be programmed in DCC2\_DCCVALIDSEED0 and DCC2\_DCCCNTSEED0 registers respectively.
- Counter1 generates a fixed-width pulse (1 cycle) after a pre-programmed number of pulses (COUNT1). This pulse sets an error signal if Counter1 does not reach 0 during the time when VALID0 is running. The seed value for COUNT1 can be programmed in DCC2\_DCCCNTSEED1 register.

The error signal is generated by any one of the following conditions:

- Clock1 expires before the COUNT0 reaches 0.
- Clock1 expires after both COUNT0 and VALID0 reach 0.
- Clock1 not present.
- Clock0 not present.

Any of these errors causes the counters to stop counting. An application must then read out the counter values to determine what caused the error. Once the error is detected, the counters are stopped after 3 FICLK and 2 source clock cycles due to the cross clock domain synchronisation.

Reloads or restarts occur under two conditions:

- The module is reset or restarted through software (that is, software starts the module after reset, or software checks an error condition and decides to restart the module).
- COUNT0, COUNT1, and VALID0 all reach 0 without error.

#### CAUTION

The DCC module does not check jitter for Clock0 or Clock1.

As the counter preset signal is synchronized to either of the source clock domains, the counters begin downcounting after two corresponding source clock cycles.

The error signal is captured to the FICLK domain. There is 1 FICLK period uncertainty on either side of the fixed width counting window (VALID0) in generating the error signal since the counters work in different clock domains. This should be accounted for when setting the count value for VALID0.

Figure 12-423 through Figure 12-427 shows examples of counters relationship and error generation.

**Figure 12-423. DCC Clock0 and Clock1 With no Error**

**Figure 12-424. DCC Clock1 slower than Clock0 results in an error and stops counting**

**Figure 12-425. DCC Clock1 faster than Clock0 results in an error and stops counting**

**Figure 12-426. DCC Clock1 not present results in an error and stops counting**

**Figure 12-427. DCC Clock0 not present results in an error and stops counting**

#### 12.8.1.2.2 DCC Low Power Mode Operation

The DCC module does not function in Low Power Mode. It is the responsibility of software to stop the module before entering low power mode and to restart the module after exiting low power mode.

#### 12.8.1.2.3 DCC Suspend Mode Behavior

The DCC module will continue running regardless of the state of emulation. All registers are readable via emulation reads.

#### 12.8.1.2.4 DCC Single-Shot Mode

The DCC can be programmed to count down one time using single-shot mode. In this mode, the DCC stops operation when both COUNT0 and VALID0 reach 0.

At the end of one sequence in single-shot mode the DCC2\_DCCGCTRL[3-0] DCCENA bitfield is set to disabled, which stops further counting. Single-shot mode is enabled from the DCC2\_DCCGCTRL[11-8] SINGLESOT bitfield.

At the end of one sequence in single-shot mode, if there is no error which stops counting, then the done status bit is set in the DCC2\_DCCSTATUS[1] DONEFLG bitfield and a done interrupt DCC\_x\_INT is generated. Software must clear the done bit before restarting the counting.

#### 12.8.1.2.5 DCC Continuous mode

When DCC runs in continuous mode both the counts shall get reloaded with seed value upon completion of counts without error. If the counts end in error DCC stops the operation and counts are not reloaded.

##### 12.8.1.2.5.1 DCC Continue on Error

During debug, if there are events which are causing clocks to be anomalous over short period covering more than one evaluation window then it would be important to capture trajectory of error event and period around such event. To allow capturing the successive error events DCC can be programmed to continue after error. [3-0] CONT\_ON\_ERR shall be set to value other than "0101" to enable this mode. It is recommended to write "1010" to avoid single soft errors.

##### 12.8.1.2.5.2 DCC Error Count

DCC also counts the number of error pulses generated since reset or since last time the error count is cleared. This is read/write register for CPU to clear when new trace of number of errors is required to be maintained.

#### 12.8.1.2.6 DCC Control and count hand-off across clock domains

As the counters run in two different selectable clock domains and the register interface runs on the fixed bus clock domain, control signals and counter value hand-off have synchronizers implemented. These add to the margins of error while comparing the counts.

1. With all three counts synchronized to FICLK domain for comparison error detection there is delay in terms of FICLK domain.
2. Based on the error signal, the enable for the counters is synchronized back to the respective clock domains of the counters, which adds latency in terms of clock periods which are different, this would create a skew between start of count. Depending upon frequency ratios of the clocks used, the difference between two could vary.

Application needs to consider the worst case delay differences while measuring the clocks.

#### 12.8.1.2.7 DCC Error Trajectory record

Once the clock errors out, the host can read the counter values to determine the extent of error to analyze type of failure. For short window comparisons this would become difficult, specially if there are back to back errors due to some transient event. Secondly, for random events which can cause an interrupt during the critical phase of application running, then event if not recorded may get overwritten and also not provide meaningful trace of error.

##### 12.8.1.2.7.1 DCC FIFO capturing for Errors

DCC provides the FIFO for capturing COUNT0, VALID0, and COUNT1 information which captures all three counts upon "Error" event. For "Done" event no results are captured by default.

##### 12.8.1.2.7.2 DCC FIFO in continuous capture mode

To track the VALID0 counter values regardless of "Error" or not, FIFOs can be configured to capture the count for each compare window. This is useful in validation and characterization exercise. [11-7] FIFO\_NONERR control when set to value other than "0101" this mode is set; it is recommended to write "1010" to avoid single soft errors. Note, this capture is applicable only in continuous mode and not in single shot mode.

##### 12.8.1.2.7.3 DCC FIFO Details

The FIFO is 4 deep for each count and updates new count information for all the non-full FIFOs. Information is updated on every configured trigger of error or cycle completion. If full, the next values are not written till at-least one entry is read. Application owns responsibility to read the FIFOs uniformly to keep synchronisation between three entries of the FIFO. Both empty and full indications for individual FIFOs is provided through the .

##### 12.8.1.2.7.4 DCC FIFO Debug mode behavior

Upon debug access, the FIFO pointers should not advance hence not impacting the functional behavior. This requirement is same as other functional blocks in the device.

#### 12.8.1.2.8 DCC Count read registers

DCC has provision to read the counts during operation. This is performed using , , and registers. Read from these registers in default mode allows reading the present value of count. This is useful when in single shot mode or mode where DCC stops upon error.

These registers can be used to read the FIFO through the [7-4] FIFO\_READ configuration. Reads on the empty FIFO shall provide the contents of last pointed location. Application shall track the empty/full conditions of the FIFOs to track the count records consistently.

Regardless of FIFO\_READ configuration, the FIFO internally keeps updating records based on configured triggers till full.

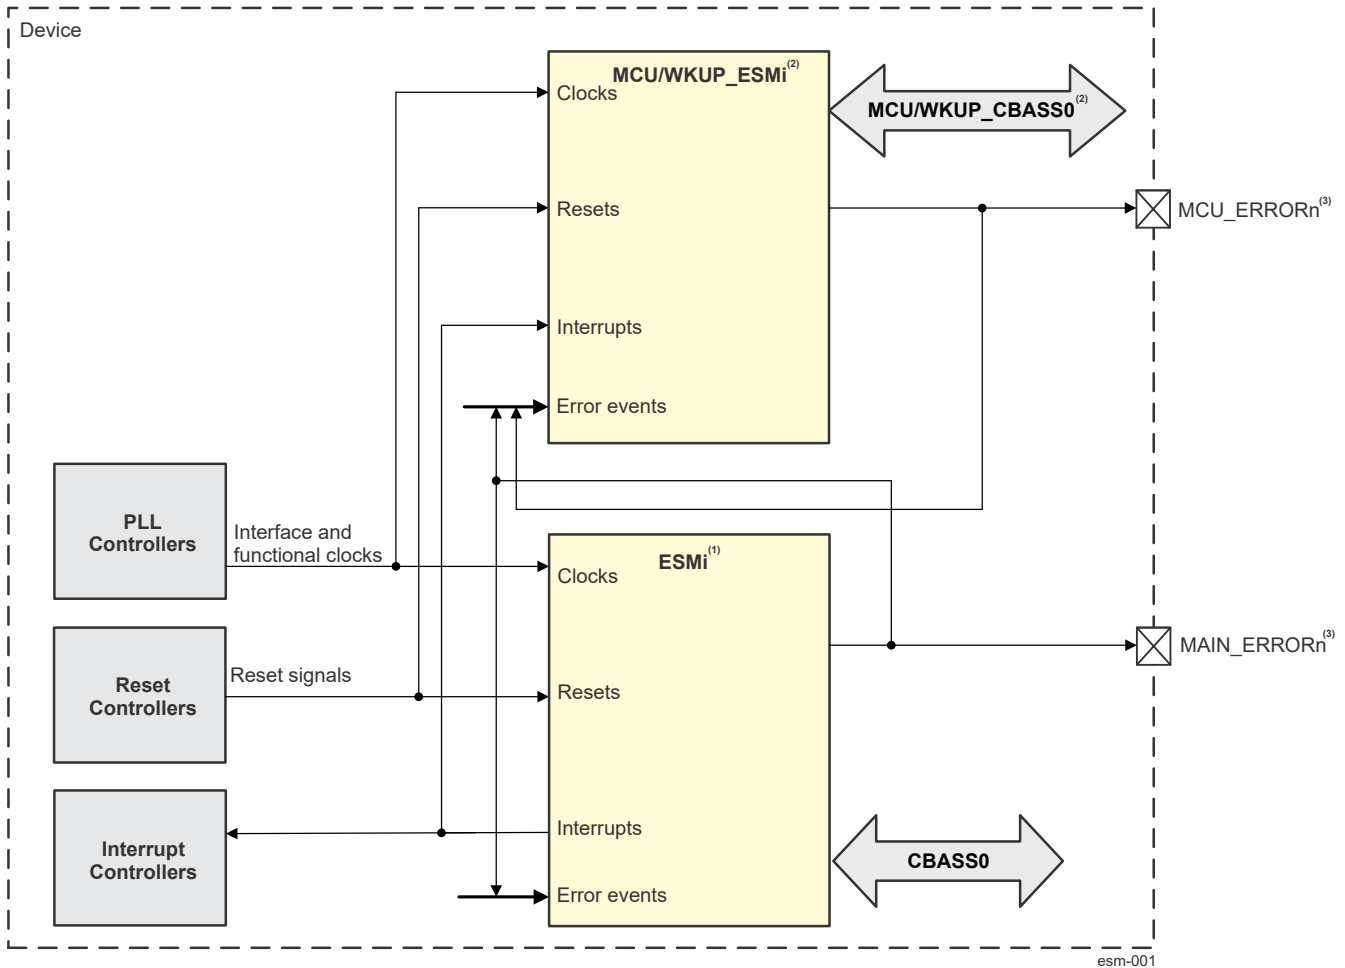

## 12.8.2 Error Signaling Module (ESM)

This section describes the Error Signaling Module (ESM) in the device.

### 12.8.2.1 ESM Overview

The Error Signaling Module (ESM) aggregates events and/or errors from throughout the device into one location. It can signal both low and high priority interrupts to a processor to deal with an event and/or manipulate an I/O error pin to signal an external hardware that an error has occurred. Therefore an external controller is able to reset the device or keep the system in a safe, known state.

Figure 12-428 shows the ESM modules overview.

1. i represents a valid instance of ESM in a domain. Consult the device datasheet for available domains and ESM instances.
2. i represents a valid instance of ESM in a MCU or WKUP domain. Consult the device datasheet for available domains and ESM instances.
3. Not all pins are valid for all devices. Consult the device datasheet for specifics.

#### Note

The MAIN\_ERRORn pin, if valid, is used for observation only.

**Figure 12-428. ESM Modules Overview**

#### 12.8.2.1.1 ESM Features

Each ESM module implements the following features:

- Up to 1024 error event inputs
  - Implemented in groups of 32 events
  - Level or Pulse inputs (Pulse inputs are triple redundant)
- Selectable low and high priority interrupt error pin prioritization of each error event
- Error pin to signal severe device failure
  - Support of level or PWM modes
- Configurable timebase for error signal
- Error forcing capability
- Internal redundant flops on critical fields

#### 12.8.2.1.2 Unsupported Features

See the *Module Integration* section for information about unsupported features.

---

#### Note

Some features may not be available. See *Module Integration* for more information.

---

### 12.8.2.2 ESM Environment

The MCU\_ESM0 and ESM0 modules are hereinafter referred to as ESM module.

This section describes the ESM external connections (environment).

Figure 12-429 shows the ESM pins used for typical connections with external devices.

1. i represents a valid instance of ESM in a domain. See the device specific datasheet for available domains and ESM instances.
2. i represents a valid instance of ESM in a MCU or WKUP domain. See the device specific datasheet for available domains and ESM instances.
3. Not all pins are valid. See the device datasheet for specifics.

#### Note

The MAIN\_ERRORn pin, if valid, is used for observation only.

**Figure 12-429. ESM Modules Environment**

#### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

### 12.8.2.3 Integration

See the *Module Integration* section for information about clocks, resets and hardware requests.

### 12.8.2.4 ESM Functional Description

The Error Signaling Module (ESM) centralizes fault reports. It provides mechanisms to classify errors by severity and to provide programmable error response. The error classification in the ESM is determined by programmed configuration for each individual error input. For each individual error input the configuration can be set to assert an output error pin, or generate an interrupt to a CPU, or both. When an individual error input is configured to generate an interrupt, the configuration will also select whether the interrupt that is generated will be one of high priority or low priority.

By reporting the faults in a central location, the system may determine what caused the fault and what action can be taken. In general, the faults can be split into two categories:

- Corrected faults
- Non-corrected faults

The ESM reports errors in two ways:

- An interrupt to a processor in the device. This allows the device to analyze and try to recover from an error.
- An external ERROR pin. This allows the system outside of the SoC to monitor for potentially fatal errors(errors that the device cannot self-recover from). Moreover, the external I/O (ERROR pin) can operate in level or PWM modes. In level mode, the output will remain asserted (active low) for a minimum period of time. After that period of time, if the error has been cleared by an internal processor, the pin will go inactive (high). If it does not go inactive in that time, then an external agent should intervene, as there may be an unrecoverable error. In PWM mode, the error will cause the output pin to maintain its value for a minimum period of time. After that period of time, if the error has been cleared by an internal processor, the pin will continue the PWM pattern. If it does not go inactive in that time, then an external agent should intervene, as there may be an unrecoverable error.

Both mechanisms can be used at the same time for the same fault, signaling both an interrupt and the external ERROR pin. This allows the device to attempt to recover, but if it fails, then the external system is still alerted. If it succeeds, then it can remove the ERROR pin assertion so that the external system knows that a potentially unsafe condition was avoided.

Lastly, the ESM does not specify any methods of intervention, only the process of alerting internal CPUs and external monitor(s) of an existing error event.

[Figure 12-430](#) shows the ESM module block diagram. Note that not all instances may be pinned out in the device. For more information, see [Section 12.8.2.2, ESM Environment](#).

Figure 12-430. ESM Block Diagram

#### 12.8.2.4.1 ESM Interrupt Requests

The ESM module generates three output interrupts to the device interrupt controllers:

- Configuration error interrupt (see [Section 12.8.2.4.1.1](#))
- High priority error interrupt (see [Section 12.8.2.4.1.2](#))
- Low priority error interrupt (see [Section 12.8.2.4.1.3](#))

The error interrupt outputs are provided so that a processor in the device can be signaled to intervene when an error event occurs. Each error event input can be enabled, via software, to cause an error interrupt to occur (via the ESM\_INTR\_EN\_SET $_j$  register). Additionally, each error event input can be programmed to influence either the low priority (default) interrupt or the high priority interrupt (via the ESM\_INT\_PRIO $_j$ ). The low priority interrupt is intended for events that are of interest, but do not require immediate intervention. For example, an indication that there was a single bit error that was corrected may signal a low priority interrupt, so that information can be collected for statistical purposes. A high priority interrupt is intended for events that need immediate attention. For example, an indication that there was an uncorrected two-bit error may be signaled as a high priority interrupt.

##### 12.8.2.4.1.1 ESM Configuration Error Interrupt

The configuration error interrupt (ESM\_INT\_CFG\_LVL\_0) indicates that there is an inconsistency in the configuration of one (or more) error group  $j$  registers (MMRs).

In such inconsistency in the internal copies of any of the MMRs caused by fault associated with error group  $j$ , the corresponding raw status will be set in the ESM\_ERR\_RAW register. If the corresponding bit is enabled in the ESM\_ERR\_EN\_SET register, a configuration error interrupt will be triggered.

When a configuration error interrupt is received, the acting processor must perform the following steps:

1. Read the ESM\_ERR\_STS register to determine which group has a configuration error
2. Write the correct values to the following group registers:

---

**Note**

If there has been a configuration error, the values in the below registers cannot be guaranteed to be correct anymore. Therefore, software should maintain a copy of the correct values prior to an error to ensure that they can be re-programmed with the correct configuration.

---

- a. ESM\_INTR\_EN\_SET\_j
  - b. ESM\_INTR\_EN\_CLR\_j
  - c. ESM\_INT\_PRIO\_j
  - d. ESM\_PIN\_EN\_SET\_j
  - e. ESM\_PIN\_EN\_CLR\_j
3. Service any pending interrupts in steps 4, 5, and 6 below
- 

**Note**

The raw status of any pending interrupts may be inconsistent. Servicing the interrupt will return it to consistency via the error group ESM\_RAW\_j register.

---

- 4. Write 0x1 to the appropriate bits in the ESM\_ERR\_STS register. This step will clear the raw status
  - a. If the error event is still asserted (or re-asserted) the raw status will be set back to 0x1
  - b. If there are no additional errors, the level interrupt will go low
- 5. Write the end of interrupt vector to the ESM\_EOI register
  - a. If there are additional configuration error interrupts pending, then a new pulse will be generated and the level interrupt will remain asserted
  - b. If there are no additional low priority error interrupts pending, there will be no new pulse.

**12.8.2.4.1.2 ESM Low Priority Error Interrupt**

Events mapped to the low priority error interrupt (ESM\_INT\_LOW\_LVL\_0) are intended to be events of interest that should be addressed eventually, not events that require immediate attention. An example would be an event indicating a corrected error. The system may want to track this for statistical purposes, but it does not require immediate attention.

Any error event can be mapped to the low priority error interrupt. A low priority error interrupt will be generated when an event is enabled to cause an interrupt (via the ESM\_INTR\_EN\_SET\_j register) and mapped to the low priority error interrupt (via ESM\_INT\_PRIO\_j register) and the raw status is set (via the ESM\_RAW\_j register).

When a low priority error interrupt is received, the acting processor must perform the following steps:

- 1. Read the ESM\_LOW\_PRI register
    - a. If both [31-16]PLS and [15-0]LVL bit fields are equal to 0xFFFF, then interrupt is no longer asserted and the interrupt routine has ended.
    - b. If either [31-16]PLS or [15-0]LVL bit fields are not equal to 0xFFFF, software has two options for determining what event to service:
      - i. First option: Record the value in [31-16]PLS and [15-0]LVL bit fields. Determine which is higher priority. This is based on the global event map number of the highest priority low priority error event
- 

**Note**

The global event map is neither defined by nor maintain in ESM. The global event map must be defined and maintained by software using software determined memory resources. It is conceivable that the global event map will be predefined and loaded during the execution of a secondary boot loader.

---

- ii. Second option:
  - 1. Read the ESM\_LOW register to determine which event group(s) have pending low priority error interrupts

2. Read the desired error group  $j$  ESM\_STS\_  $j$  register
  3. Identify which low priority interrupt to service
2. Determine, based on the global event map for the device, where the error event came from
3. Service the error event based on the IP's specification:
  - a. The system may take several actions including (but not limited to):
    - i. Fixing the error
    - ii. Resetting the errored IP peripheral
    - iii. Resetting the device
    - iv. Communicating outside the device via the error pin for outside intervention

The rest of the steps assume that the error has been handled and the system wants to clear the error event. Clearing the error event depends on whether the event is a level (see [Section 12.8.2.4.1.2.1](#)) or pulse (see [Section 12.8.2.4.1.2.2](#)) event.

#### 12.8.2.4.1.2.1 ESM Low Priority Error Level Event

When a low priority error level event has to be cleared, the acting processor must perform the following steps:

1. Clear the low priority error level event at the source
2. Write 0x1 to the appropriate bit in the error group  $j$  of the ESM\_STS\_  $j$  register. This step will clear the raw status
  - a. If the error event is still asserted (or re-asserted) the raw status will be set back to 0x1
  - b. If there are no error events, the level will de-assert

#### Note

There is a possible software race condition if software manages to write to the Clear register before the de-asserted level from the source has been synchronized to the ESM clock. If this is an issue, software may perform a read-back at the source IP before writing the clear register to insure order.

3. Write the end of interrupt vector to the ESM\_EOI interrupt register
  - a. If there are low priority error level events enabled and pending, then a new pulse will be generated
  - b. If there are no additional low priority error level events enabled and pending, there will be no new pulse
4. Write a CLEAR (0x5) to the ESM\_PIN\_CTRL register. This step is optional if the event is not enabled to influence the error pin (error group  $j$  ESM\_PIN\_EN\_SET\_  $j$  register), but may be done regardless as an extra CLEAR is not harmful.

#### 12.8.2.4.1.2.2 ESM Low Priority Error Pulse Event

When a low priority error pulse event has to be cleared, the acting processor must perform the following steps:

1. Write 0x1 to the appropriate bit in the error group  $j$  of the ESM\_STS\_  $j$  register. This will clear the raw status and will de-assert the level interrupt.
2. Write the end of interrupt vector to the ESM\_EOI interrupt register
  - a. If there are additional low priority error pulse events enabled and pending, then a new pulse will be generated and the level interrupt will remain asserted
  - b. If there are no additional low priority error pulse events enabled and pending, there will be no new pulse
3. Clear the error event at the source. The source may generate a new pulse which will show up as a new error event at the ESM
4. Write a CLEAR (0x5) to the ESM\_PIN\_CTRL register. This step is optional if the event is not enabled to influence the error pin (error group  $j$  ESM\_PIN\_EN\_SET\_  $j$  register), but may be done regardless as an extra CLEAR is not harmful.

#### 12.8.2.4.1.3 ESM High Priority Error Interrupt

Events mapped to the high priority error interrupt are intended to be events that require immediate intervention from the system because a potentially dangerous error has occurred. An example would be an event indicating an uncorrected error. The system will want to diagnose the issue and intervene to ensure there are no violations.

Any error event can be mapped to the high priority error interrupt. A high priority error interrupt will be generated when an event is enabled to cause an interrupt (via the ESM\_INTR\_EN\_SET\_j) register and mapped to the high priority interrupt (via the ESM\_INT\_PRIO\_j) register and the raw status is set (via the ESM\_RAW\_j).

When a high priority error interrupt is received, the acting processor must perform the following steps:

1. Read the ESM\_HI\_PRI register
  - a. If both [31-16] PLS and [15-0] LVL bit fields are equal to 0xFFFF, then interrupt is no longer asserted and the interrupt routine has ended.
  - b. If either [31-16] PLS or [15-0] LVL bit fields are not equal to 0xFFFF, software has two options for determining what event to service:
    - i. First option: Record the value in [31-16] PLS and [15-0] LVL bit fields. Determine which is higher priority. This is based on the global event map number of the highest priority high priority error event.

---

#### Note

The global event map is neither defined by nor maintain in ESM. The global event map must be defined and maintained by software using software determined memory resources. It is conceivable that the global event map will be predefined and loaded during the execution of a secondary boot loader.

---

- ii. Second option:
    1. Read the ESM\_HI register to determine which event group(s) have pending high priority error interrupts
    2. Read the desired error group j/ESM\_STS\_j register
    3. Identify which high priority error interrupt to service
2. Determine, based on the global event map for the device, where the error event came from
3. Service the error event based on the IP's specification:
  - a. The system may take several actions including (but not limited to):
    - i. Fixing the error
    - ii. Resetting the errored IP peripheral
    - iii. Resetting the device
    - iv. Communicating outside the device via the error pin for outside intervention

The rest of the steps assume that the error has been handled and the system wants to clear the error event. Clearing the error event depends on whether the event is a level (see [Section 12.8.2.4.1.3.1](#)) or pulse (see [Section 12.8.2.4.1.3.2](#)) event.

#### 12.8.2.4.1.3.1 ESM High Priority Error Level Event

When a high priority error level event has to be cleared, the acting processor must perform the following steps:

1. Clear the error event at the source
2. Write 0x1 to the appropriate bit in the error group j of the ESM\_STS\_j register. This step will clear the raw status
  - a. If the error event is still asserted (or re-asserted) the raw status will be set back to 0x1
  - b. If there are no error events, the level will de-assert

---

#### Note

There is a possible software race condition if software manages to write to the Clear register before the de-asserted level from the source has been synchronized to the ESM clock. If this is an issue, software may perform a read-back at the source IP before writing the clear register to insure order.

---

3. Write the end of interrupt vector to the ESM\_EOI interrupt register
  - a. If there are high priority error level events enabled and pending, then a new pulse will be generated
  - b. If there are no additional high priority error level events enabled and pending, there will be no new pulse

4. Write a CLEAR (0x5) to the ESM\_PIN\_CTRL register. This step is optional if the event is not enabled to influence the error pin (error group  $j$  ESM\_PIN\_EN\_SET\_  $j$  register, but may be done regardless as an extra CLEAR is not harmful.

#### 12.8.2.4.1.3.2 ESM High Priority Error Pulse Event

When a high priority error pulse event has to be cleared, the acting processor must perform the following steps:

1. Write 0x1 to the appropriate bit in the error group  $j$  of the ESM\_STS\_  $j$  register. This will clear the raw status and will de-assert the level interrupt.
2. Write the end of interrupt vector to the ESM\_EOI interrupt register
  - a. If there are high priority error pulse events enabled and pending, then a new pulse will be generated and the level interrupt will remain asserted
  - b. If there are no additional high priority error pulse events enabled and pending, there will be no new pulse
3. Clear the error event at the source. The source may generate a new pulse which will show up as a new error event at the ESM
4. Write a CLEAR (0x5) to the ESM\_PIN\_CTRL register. This step is optional if the event is not enabled to influence the error pin (error group  $j$  ESM\_PIN\_EN\_SET\_  $j$  register), but may be done regardless as an extra CLEAR is not harmful.

#### 12.8.2.4.2 ESM Error Event Inputs

The ESM can have up to 1024 error event inputs, configurable by groups of 32. For the mapping of system interrupt error events to ESM interrupt inputs, see *Interrupt Sources*.

Level error events (active high) are synchronized to the ESM clock. This synchronized value is captured in to a flop.

Pulse error events use rising edge detection. Each pulse error event has 3 redundant inputs. Each input has its own edge detection logic. Multiple transmission protects against Single Event Upsets (SEUs, transient errors) causing a pulse to be lost during transmission and against failure of the edge detection logic. Once an edge has been detected on any of the three inputs, the ESM\_RAW\_  $j$  status is set. Subsequent pulses are likely to come concurrently or quickly enough that software will not have reacted yet. This logic is intentionally biased against false negatives and towards false positives. An SEU that causes an event where none actually occurred will cause software to be called in to action. Software must observe that there is no real error and clear the false status.

#### 12.8.2.4.3 ESM Error Pin Output

The error pin output (ERR\_O) is used to signal an external agent that it needs to (or may need to) intervene because of an error. Each error event input can be programmed, via software, to influence the error pin output (via the ESM\_PIN\_EN\_SET\_  $j$  register). The error pin output is active low or PWM based on the ESM\_EN[7-4] PWM\_EN field. This bit field should only be modified when the ESM is disabled, based on the ESM\_EN register.

During Power-On Reset (POR), the error pin is active (asserted low) and the device drives this via a weak internal pull-down. The I/O is under the control of the device. When POR is removed from the ESM, it will be driving the error pin so the device can hand over control to the ESM. The user may also add an external pull-down that is only active when the device is in reset.

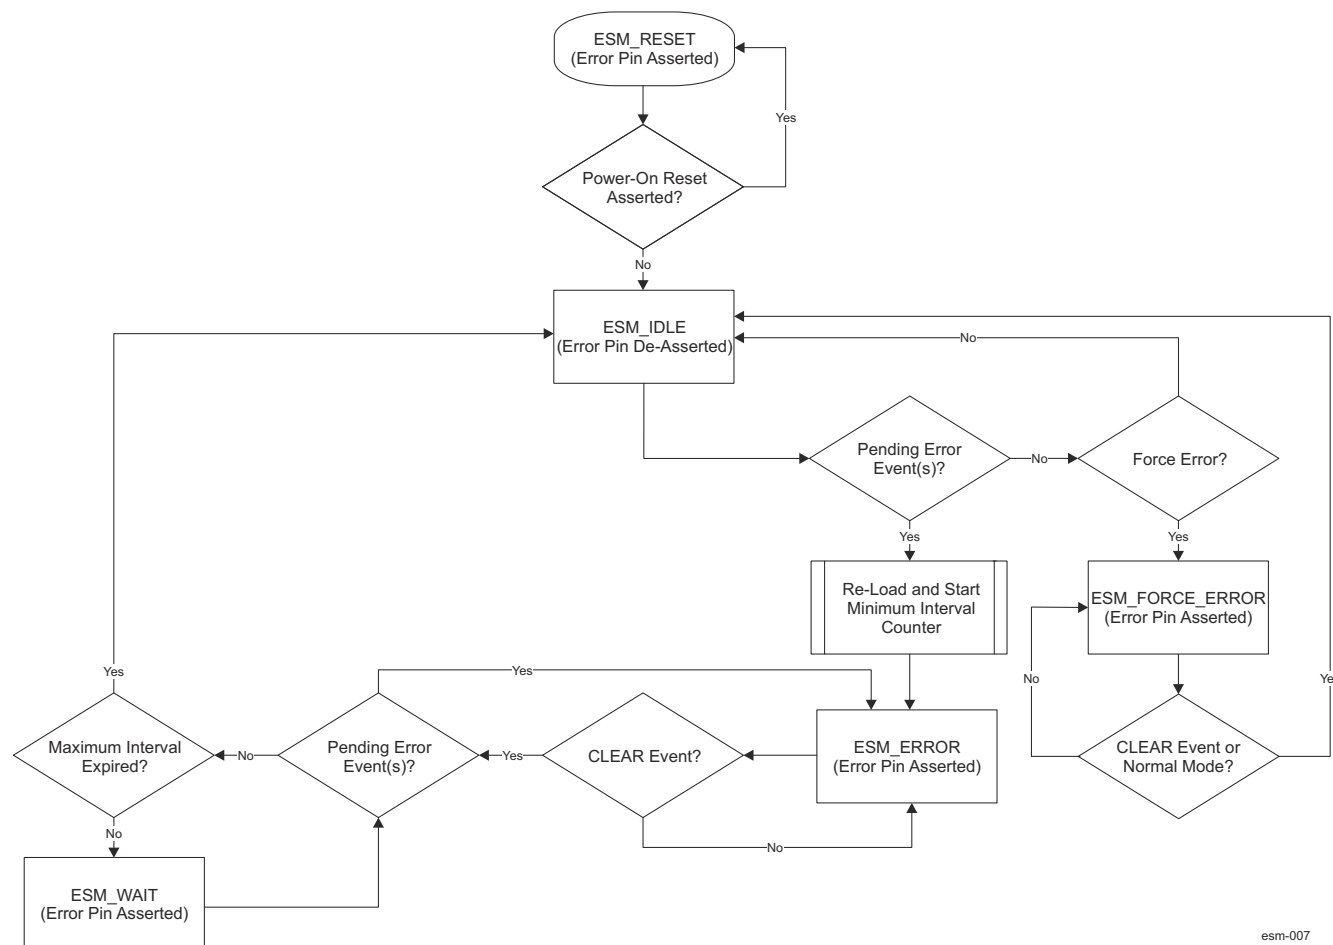

During a warm reset the state of the error pin is unchanged, that is the error pin logic is only reset by a POR. The device leaves the I/O active during a warm reset.

The ESM has also a software error forcing capability on the error pin. That is, a force error can be set via the ESM\_EN[3-0] KEY bit field.

### CAUTION

The isolation value for the ERR\_O output of ESM is active (0). This is intended and supposed to protect against an accidental transition to a low power state. If the actual low power mode transition is intended, the PMIC should be made aware by software to ignore the ESM error signal. Otherwise device resets will be asserted from companion chip.

Figure 12-431 describes the behavior of the error pin. Not shown is that a reset (Power-On-Reset only) will immediately transition the error pin to the ESM\_RESET state and a Global Soft Reset will immediately transition the error pin to the ESM\_IDLE state. A pending error interrupt event is any error event with the raw state set and the error pin Influence enabled. There are two types of "clear" events associated with servicing the error pin. The first is to clear the status of the pending event (see Section 12.8.2.4.1 for how to clear level and pulse pending events). The second is the CLEAR event meant to de-assert the error pin.

esm-007

**Figure 12-431. ESM Error Pin State Flowchart**

If an error event happens that has been programmed to influence the error pin, the error pin will assert (active low) for a minimum time (as programmed by the ESM\_PIN\_CNTR\_PRE register). In order for the error pin to de-assert, the following 3 things must happen:

1. The minimum time interval must expire
2. The event that caused the error pin to assert must be cleared (see Section 12.8.2.4.1)
3. A CLEAR (0x5) must be written to the ESM\_PIN\_CTRL register.

### Note

Step 3 should happen after step 2, but either (or both) of these steps may happen before or after step 1.

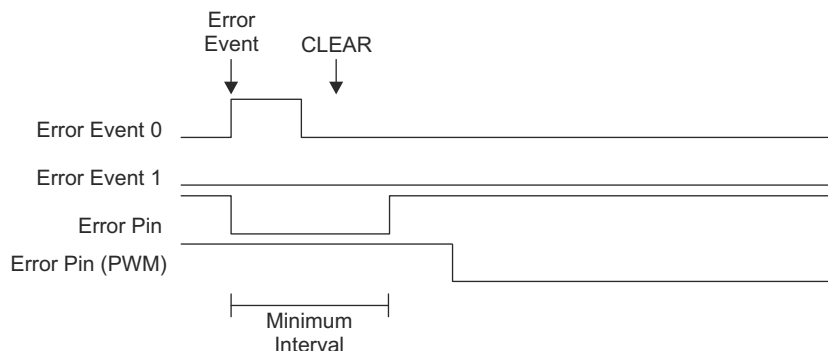

Figure 12-432 shows a typical error pin assertion.

esm-008

**Figure 12-432. ESM Error Pin Assertion**

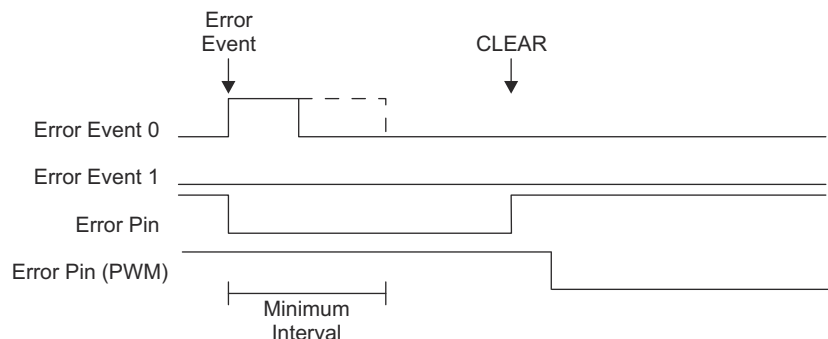

If, during the minimum time, CLEAR is written to the error key, then the error pin will de-assert after the minimum time interval, as shown in Figure 12-433.

esm-009

**Figure 12-433. ESM Error Pin Assertion with CLEAR during Minimum Interval**

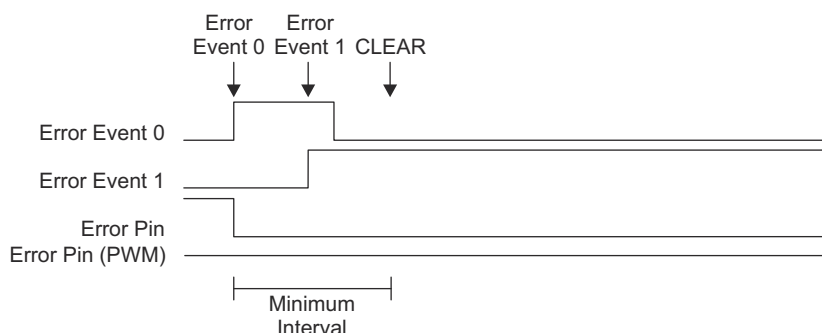

If CLEAR is not written till after the minimum time interval, the error pin will de-assert when CLEAR is written. This is regardless of whether the error interrupt event itself is removed before or after the minimum time interval, as shown by the dotted line in Figure 12-434.

esm-010

**Figure 12-434. ESM Error Pin Asserting with CLEAR after Minimum Interval**

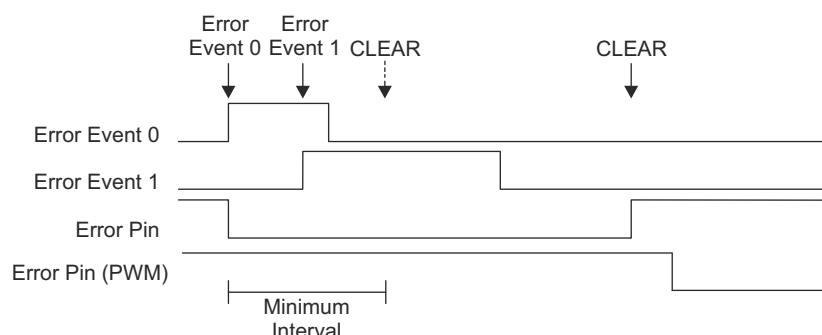

When in the ESM\_ERROR state and a CLEAR event happen, if there are still pending error events, the ESM stays in the ESM\_ERROR state with the error pin asserted. Multiple error events when in the ESM\_ERROR state do not reset the minimum time interval counter as shown in [Figure 12-435](#).

esm-011

**Figure 12-435. ESM Error Pin Asserting with Interval Reset by Additional Error Event(s)**

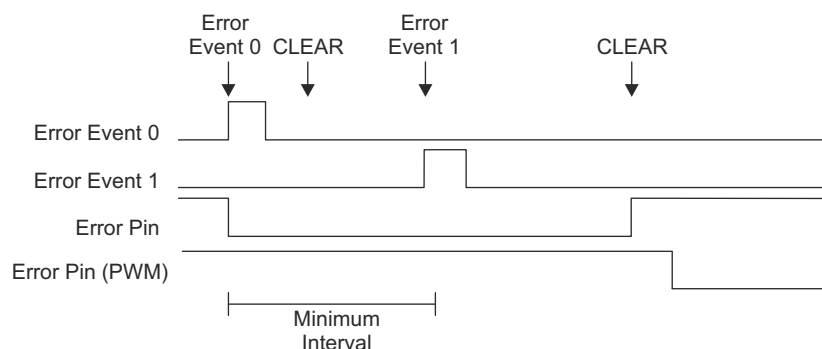

A CLEAR event causes a re-evaluation of whether there are any pending error events. As such, a single CLEAR can be used to clear the error pin after multiple error events. Multiple CLEAR events can occur (such as the one with the dotted arrow shown in [Figure 12-436](#)), but are not necessary. No matter how many error events occur nor when (or how many) CLEAR events occur, the error pin will always be asserted for at least the minimum time interval

esm-012

**Figure 12-436. ESM Error Pin Asserting with Single CLEAR for Multiple Events**

If all error events are cleared and the ESM is in the ESM\_WAIT state, waiting for the minimum time interval to expire, and a new error interrupt event occurs, the ESM will go back to the ESM\_ERROR state. The minimum time interval will not reset, but a new CLEAR event will be required as shown in [Figure 12-437](#).

esm-013

**Figure 12-437. ESM Error Pin Asserting with New Error During Minimum Time Interval**

Table 12-338 shows some common scenarios of how the error pin as well as the two associated registers (ESM\_PIN\_CTRL and ESM\_PIN\_STS) will be set.

**Table 12-338. ESM Error Pin Scenarios**

Scenario	Error Pin State Value	ESM_PIN_CTRL[3-0] KEY	ESM_PIN_STS[0] VAL status value	Additional Notes
POR Asserted	0	N/A	N/A	Registers are inaccessible. Device disables the I/O and pulls down internally.
After de-assertion of POR	1	0x0 (Normal Mode)	0x0	-
After de-assertion of Warm Reset (error was not asserted when reset asserted)	1	0x0 (Normal Mode)	0x0	-
After de-assertion of Warm Reset (error was asserted when reset asserted)	0	0x0 (Normal Mode)	0x1	-
Force error pin	0	0xA (Force Error Mode)	0x0	Forcing error on the pin via software.

#### 12.8.2.4.4 PWM Mode

If the error output pin is in PWM mode then when no error is detected it will toggle according to programmable MMR widths for high and low periods. When an error occurs, the error pin stops toggling and remains constant until the error is cleared. An external PMIC that is detecting the PWM toggles can identify the error if the pin stops toggling. The periods should be programmed such that they fit within the expectation of the external PMIC.

#### 12.8.2.4.5 ESM Minimum Time Interval

The minimum time interval is the minimum amount of time that the error pin will be asserted (active low) when an enabled error interrupt event happens. This value is system dependent, but should be enough time so that the external monitoring agent can always see the error pin asserted, but short enough so that if all of the error events are cleared, then the error pin can be de-asserted before the external agent decides to intervene. This is highly dependent on the application and the Fault Tolerant Time Interval.

The Minimum Time Interval counter is clock cycle based, therefore the time of the interval is a combination of the value in the ESM\_PIN\_CNTR\_PRE register and the clock frequency of the ESM. Software must calculate the value accordingly. The Minimum Time Interval should be set according to the needs of the application.

#### 12.8.2.4.6 ESM Protection for Registers

The configuration for each error group  $j$  of registers are backed up by 3 flops in order to protect against single or double-bit errors. When written, all 3 bits are set to the same value. When read (and for functioning of the internal state machines) the value is the OR of all 3 bits. Whenever any of the bits disagree, the Configuration Error interrupt is asserted (if enabled). The registers covered by this mechanism are:

- ESM\_ERR\_RAW
- ESM\_ERR\_STS
- ESM\_ERR\_EN\_SET
- ESM\_ERR\_EN\_CLR
- ESM\_RAW<sub>j</sub>
- ESM\_STS<sub>j</sub>
- ESM\_INTR\_EN\_SET<sub>j</sub>
- ESM\_INTR\_EN\_CLR<sub>j</sub>
- ESM\_INT\_PRIO<sub>j</sub>
- ESM\_PIN\_EN\_SET<sub>j</sub>
- ESM\_PIN\_EN\_CLR<sub>j</sub>

The error pin control register ESM\_PIN\_CTRL contains a multi-bit field KEY. The key value ensures normal operation on the error pin and that an error even will be generated if one occurs. Software should periodically

read check the KEY bit field value and make sure it is 0x0. If the value is not 0x0, software must re-write it to this key value (unless in test mode forcing an error on the pin) to ensure the normal operation. [Table 12-339](#) lists the KEY values and their respective meaning.

**Table 12-339. ESM Error Pin Control Values**

ESM_PIN_CTRL[3-0] KEY	Description
N/A	Registers are inaccessible. Device disables the I/O and pulls down internally.
0x0 (Normal)	Normal operation mode - Error pin will activate when an enabled error event occurs.
0xA (Force Error)	Force error mode - Forces the error pin active. To clear the error pin (return to the ESM_IDLE state) write this field back to normal mode (writing a CLEAR event will also work). Force error mode must be set only while in IDLE. Attempting force error while in another state will have no effect.
0x5 (CLEAR)	CLEAR Event - generates a CLEAR event to the ESM state machine. KEY will return to normal mode (0x0) on the next cycle.
Other Values	All other values - Normal mode. Writing any of these values will have no effect. When reading any of these values indicates that one or more bits have experienced a single event upset, software should write the field back to 0x0. The ESM will continue to operate in normal mode.

The error pin counter pre-load register ESM\_PIN\_CNTR\_PRE should also be read and checked periodically by software.

#### 12.8.2.4.7 ESM Clock Stop

The ESM can only be put in to clock stop if all of the internal state machines are idle and the [3-0] KEY bit field for the global enable command is cleared in the ESM\_EN register.

### 12.8.3 Memory Cyclic Redundancy Check (MCRC) Controller

This chapter describes the Memory Cyclic Redundancy Check (MCRC) controller in the device.

#### 12.8.3.1 MCRC Overview

VBUSM CRC controller is a module which is used to perform CRC (Cyclic Redundancy Check) to verify the integrity of a memory system. A signature representing the contents of the memory is obtained when the contents of the memory are read into MCRC Controller. The responsibility of MCRC controller is to calculate the signature for a set of data and then compare the calculated signature value against a pre-determined good signature value. MCRC controller provides four channels to perform CRC calculation on multiple memories in parallel and can be used on any memory system.

##### 12.8.3.1.1 MCRC Features

MCRC has the following features:

- Four channels to perform background signature verification on any memory subsystem
- Data compression on 8-, 16-, 32-, and 64-bit data size
- Maximum-length PSA (Parallel Signature Analysis) register constructed based on 64-bit primitive polynomial
- Each channel has a CRC Value Register which contains the pre-determined CRC value
- Use timed base event trigger from timer to initiate DMA data transfer
- Programmable 20-bit pattern counter per channel to count the number of data patterns for compression
- Three modes of operation:
  - Auto
  - Semi-CPU
  - Full-CPU
- For each channel, CRC can be performed either by MCRC Controller or by CPU
- Automatically performs signature verification without CPU intervention in AUTO mode
- Generates interrupt to CPU in Semi-CPU mode to allow CPU to perform signature verification itself
- Generates CRC fail interrupt in AUTO mode if signature verification fails
- Generates Timeout interrupt if CRC is not performed within the time limit
- Generates DMA request per channel to initiate CRC value transfer
- An 128-byte block burst address for the PSA register to DMA without constant mode bus attribute

##### 12.8.3.1.2 Unsupported Features

See the *Module Integration* section for information about unsupported features.

---

#### Note

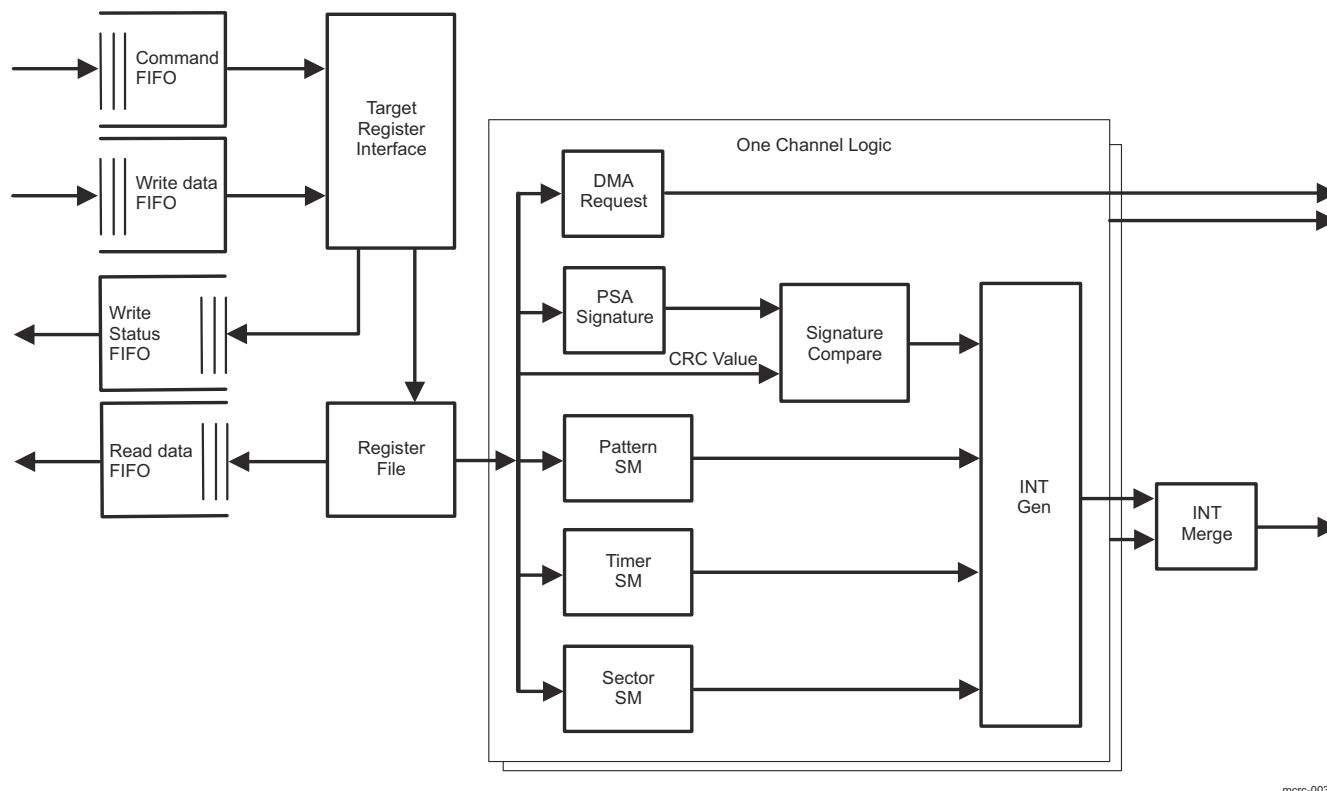

Some features may not be available. See *Module Integration* for more information.

### 12.8.3.2 MCRC Functional Description

#### 12.8.3.2.1 MCRC Block Diagram

Figure 12-438 shows the MCRC internal blocks.

**Figure 12-438. MCRC Block Diagram**

- **Command FIFO:** The Command FIFO pipelines the commands to the target register interface. The Command and Write FIFOs allow the data to be coincident for processing. If there is no space for writes in the Write Status FIFO or no space in the Read Data FIFO for reads, the command processing will be halted until there is space in the appropriate FIFO. This FIFO is 4 elements deep.
- **Write FIFO:** The Write FIFO pipelines the write data to the target register interface. The Command and Write FIFOs allow the data to be coincident for processing. If there is no space for writes in the Write Status FIFO or no space in the Read Data FIFO for reads, the command processing will be halted until there is space in the appropriate FIFO. This FIFO is 2 elements deep.
- **Write Status FIFO:** The Write Status FIFO pipelines the write status back to the VBUSM. A write status will be issued on the final data phase of a write command. This FIFO is 2 elements deep.
- **Read Data FIFO:** The Read Data FIFO pipelines the read data back to the VBUSM. This FIFO is 3 elements deep.
- **Target Register Interface:** The Target Register Interface directs the written data to the register file.
- **PSA Signature:** The PSA Signature creates the signature of the data written. This data will then be compared to the CRC Value or read by software to determine goodness.
- **Pattern State Machine:** The Pattern State Machine determines when a block of data has been serviced.
- **Timer State Machine:** The Timer State Machine determines when overrun and under-run events are detected.
- **Sector State Machine:** The Sector State Machine determines when a sector error should be captured so the software can determine the errant block of data.
- **Signature Compare:** The Signature Compare block compares the current signature to the CRC Value register and sends the result to the Interrupt Generation block.

### 12.8.3.2.2 MCRC General Operation

There are four channels in MCRC controller and for each channel there is a PSA (Parallel Signature Analysis) Signature Register (MCRC64\_0\_PSA\_SIGREGL1-4) and a CRC (Cyclic Redundancy Check) Value Register (MCRC64\_0\_CRC\_REGL1-4).

A memory can be organized into multiple sectors with each sector consisting of multiple data patterns. A data pattern can be a 8-, 16-, 32-, or 64-bit data. MCRC module performs the signature calculation and compares the signature to a pre-determined value. The PSA Signature Register compresses an incoming data pattern into a signature when it is written. When one sector of data patterns are written into PSA Signature Register, a final signature corresponding to the sector is obtained. CRC Value Register stores the pre-determined signature corresponding to one sector of data patterns. The calculated signature and the pre-determined signature are then compared to each other for signature verification. To minimize CPU's involvement, data patterns transfer can be carried out at the background of CPU using DMA controller. DMA is setup to transfer data from memory of which the contents to be verified to the memory mapped PSA Signature Register. When DMA transfers data to the memory mapped PSA Signature Register, a signature is generated.

A programmable 20-bit data pattern counter is used for each channel to define the number of data patterns to calculate for each sector. Signature verification can be performed automatically by MCRC controller in AUTO mode or by CPU itself in Semi-CPU or Full-CPU mode. In AUTO mode, a self-sustained CRC signature calculation can be achieved without any CPU intervention.

### 12.8.3.2.3 MCRC Modes of Operation

MCRC Controller can operate in AUTO, Semi-CPU, and Full-CPU modes.

#### 12.8.3.2.3.1 AUTO Mode

In AUTO mode, MCRC Controller in conjunction with DMA controller can perform CRC without CPU intervention. A sustained transfer of data to both the PSA Signature Register (MCRC64\_0\_PSA\_SIGREGL1-4) and a CRC (Cyclic Redundancy Check) Value Register (MCRC64\_0\_CRC\_REGL1-4) are performed in the background of CPU. When a mismatch is detected, an interrupt is generated to the CPU. A 16-bit, current sector ID register (MCRC64\_0\_CRC\_CURSEC\_REG1-4) is provided to identify which sector causes a CRC failure.

#### 12.8.3.2.3.2 Semi-CPU Mode

In Semi-CPU mode, DMA controller is also utilized to perform data patterns transfer to PSA Signature Register (MCRC64\_0\_PSA\_SIGREGL1-4). Instead of performing signature verification automatically, the CRC controller generates a compression complete interrupt to CPU after each sector is compressed. Upon responding to the interrupt the CPU performs the signature verification by reading the calculated signature stored at the PSA Sector Signature Register (MCRC64\_0\_PSA\_SECSIGREGL1-4) and compare it to a pre-determined CRC value.

#### 12.8.3.2.3.3 Full-CPU Mode

In Full-CPU mode, the CPU does the data patterns transfer and signature verification all by itself. When CPU has enough throughput, it can perform data patterns transfer by reading data from the memory system to the PSA Signature Register (MCRC64\_0\_PSA\_SIGREGL1). After certain number of data patterns are compressed, the CPU can read from the PSA Signature Register and compare the calculated signature to the pre-determined CRC signature value. In Full-CPU mode, neither interrupt nor DMA request is generated. All counters are also disabled.

### 12.8.3.2.4 PSA Signature Register

The 64-bit PSA Signature Register (MCRC64\_0\_PSA\_SIGREGL1-4 and MCRC64\_0\_PSA\_SIGREGLH1-4) is based on the primitive polynomial found in (EQ 1) to produce the maximum length LFSR (Linear Feedback Shift Register).

$$f(x) = x^{64} + x^4 + x^3 + x + 1 \quad (24)$$

- A. More details of the 64-bit primitive polynomial can be found at W. Stahnke, Primitive binary polynomials, Math. Comp. 27 (1973), 977–980.

There is one PSA Signature Register per CRC channel. PSA Signature Register can be both read and written. When it is written, it can either compress the data or just capture the data depending on the state of CHI\_MODE bits (where i = 1 to 4). If CHI\_MODE=0x0 (Data Capture), a seed value can be planted in the PSA Signature Register without compression. Other modes other than Data Capture will result with the data compressed by PSA Signature Register when it is written. Each channel can be planted with different seed value before compression starts. When PSA Signature Register is read, it gives the calculated signature.

MCRC Controller should be used in conjunction with the on-chip DMA controller to produce optimal system performance. The incoming data pattern to PSA Signature Register is typically initiated by the DMA controller. When DMA is properly setup, it would read data from the pre-determined memory system and write them to the memory mapped PSA Signature Register. Each time PSA Signature Register is written a signature is generated. CPU itself can also perform data transfer by reading from the memory system and perform write operation to PSA Signature Register if CPU has enough throughput to handle data patterns transfer.

After a system reset and when AUTO mode is enabled, MCRC Controller automatically generates a DMA request to request the pre-determined CRC value corresponding to the first sector of memory to be checked.

In AUTO mode, when one sector of data patterns is compressed, the signature stored at the PSA Signature Register is first copied to the PSA Sector Signature Register (MCRC64\_0\_PSA\_SECSIGREGL1-4) and PSA Signature Register is then cleared out to all zeros. An automatic signature verification is then performed by comparing the signature stored at the PSA Sector Signature Register to the CRC Value Register (MCRC64\_0\_CRC\_REGL1-4). After the comparison the MCRC Controller can generate a DMA request. Upon receiving the DMA request the DMA controller will update the CRC Value Register by transferring the next pre-determined signature value associated with the next sector of memory system. If the signature verification fails then MCRC Controller can generate a CRC fail interrupt.

In Full-CPU mode, no DMA request and interrupt are generated at all. The number of data patterns to be compressed is determined by CPU itself. Full-CPU mode is useful when DMA controller is not available to perform background data patterns transfer. Software can periodically generate a software interrupt to CPU and use CPU to accomplish data transfer and signature verification.

MCRC Controller supports double word, word, half word and byte access to the PSA Signature Register. During a non-doubleword write access, all unwritten byte lanes are padded with zeros before compression. Note that comparison between PSA Sector Signature Register and CRC Value Register is always in 64 bits because a compressed value is always expressed in 64 bits.

There is a software reset per channel for PSA Signature Register. When set, the PSA Signature Register is reset to all zeros.

PSA Signature Register is reset to zero under the following conditions:

- System reset
- PSA Software reset
- One sector of data patterns are compressed

#### 12.8.3.2.5 PSA Sector Signature Register

After one sector of data is compressed, the final resulting signature calculated by PSA Signature Register is transferred to the 64-bit PSA Sector Signature Register (MCRC64\_0\_PSA\_SECSIGREGL1-4 and MCRC64\_0\_PSA\_SECSIGREGH1-4). PSA Signature Register is a read-only register. During Semi-CPU mode, the host CPU must read from the PSA Sector Signature Register instead of reading from PSA Signature Register for signature verification to avoid data coherency issue. The PSA Signature Register can be updated with new signature before the host CPU is able to retrieve it.

In Semi-CPU mode, no DMA request is generated. When one sector of data patterns is compressed, CRC controller first generates a compression complete interrupt. Responding to the interrupt, CPU will read the PSA Sector Signature Register and compare it to the known good signature or write the signature value to another memory location to build a signature file. In Semi-CPU mode, CPU must perform the signature verification in a manner to prevent any overrun condition. The overrun condition occurs when the compression complete

interrupt is generated after one sector of data patterns is compressed and CPU has not read from the PSA Sector Signature Register to perform necessary signature verification before PSA Sector Signature Register is overridden with a new value. An overrun interrupt can be enabled to generate when overrun condition occurs.

#### 12.8.3.2.6 CRC Value Register

Associated with each channel there is a 64-bit CRC Value Register (MCRC64\_0\_CRC\_REGL1-4 and MCRC64\_0\_CRC\_REGH1-4).

The CRC Value Register stores the pre-determined CRC value. After one sector of data patterns is compressed by PSA Signature Register, MCRC Controller can automatically compare the resulting signature stored at the PSA Sector Signature Register with the pre-determined value stored at the CRC Value Register if AUTO mode is enabled. If the signature verification fails, MCRC Controller can be enabled to generate an CRC fail interrupt. When the channel is set up for Semi-CPU mode, CRC controller first generates a compression complete interrupt to CPU. Upon servicing the interrupt, CPU will then read the PSA Sector Signature Register and then read the corresponding CRC value stored at another location and compare them. CPU must not read from the CRC Value Register during Semi-CPU or Full-CPU mode because the CRC Value Register is not updated during these two modes.

In AUTO mode, for first sector's signature, DMA request is generated when mode is programmed to AUTO. For subsequent sectors, DMA request is generated after each sector is compressed. Responding to the DMA request, DMA controller reloads the CRC Value Register for the next sector of memory system to be checked. The user software needs to configure the DMA to ensure that the DMA first writes to the MCRC64\_0\_CRC\_REGL1 followed by the MCRC64\_0\_CRC\_REGH1 register in during the AUTO Mode.

When CRC Value Register is updated with a new CRC value, an internal flag is set to indicate that CRC Value Register contains the most current value. This flag is cleared when CRC comparison is performed. Each time at the end of the final data pattern compression of a sector, MCRC Controller first checks to see if the corresponding CRC Value Register has the most current CRC value stored in it by polling the flag. If the flag is set then the CRC comparison can be performed. If the flag is not set then it means the CRC Value Register contains stale information. A CRC underrun interrupt is generated. When an underrun condition is detected, signature verification is not performed.

MCRC Controller supports double word, word, half word and byte access to the CRC Value Register. As noted before comparison between PSA Sector Signature Register and CRC Value Register during AUTO mode is carried out in 64 bits.

#### 12.8.3.2.7 Raw Data Register

The raw or un-compressed data written to the PSA Signature Register is also saved in the 64-bit Raw Data Register (MCRC64\_0\_RAW\_DATAAREGL1-4 and MCRC64\_0\_RAW\_DATAAREGH1-4). This register is read only.

#### 12.8.3.2.8 Example DMA Controller Setup

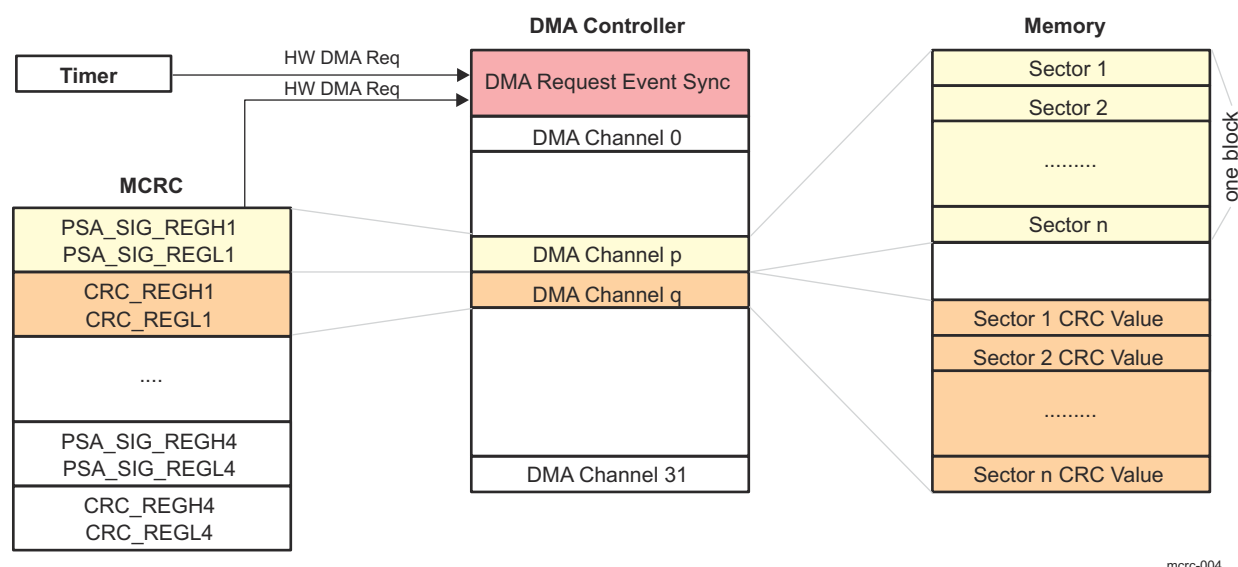

DMA controller needs to be setup properly in either AUTO or Semi-CPU mode as DMA controller is used to transfer data patterns. Hardware or a combination of hardware and software DMA triggering are supported.

##### 12.8.3.2.8.1 AUTO Mode Using Hardware Timer Trigger

There are two DMA channels associated with each CRC channel when in AUTO mode. One DMA channel is setup to transfer data patterns from the source memory to the PSA Signature Register (MCRC64\_0\_PSA\_SIGREGL1-4). The second DMA channel is setup to transfer the pre-determined signature to the CRC Value Register (MCRC64\_0\_CRC\_REGL1-4). The trigger source for the first DMA channel can be either by hardware or by software. As illustrated in [Figure 12-439](#), a timer can be used to trigger a DMA request to initiate transfer from the source memory system to PSA Signature Register. In AUTO mode, MCRC Controller also generates DMA request after one sector of data patterns is compressed to initiate transfer of the next CRC value corresponding to the next sector of memory. Thus a new CRC value is always updated in the CRC Value Register (MCRC64\_0\_CRC\_REGL1-4) by DMA synchronized to each sector of memory.

A block of system memory is usually divided into many sectors. All sectors are the same size. The sector size is programmed in the MCRC64\_0\_CRC\_PCOUNT\_REG1-4 and the number of sectors in one block is programmed in the MCRC64\_0\_CRC\_SCOUNT\_REG1-4 of the respective channel. MCRC64\_0\_CRC\_PCOUNT\_REG1-4 multiplies MCRC64\_0\_CRC\_SCOUNT\_REG1-4 and multiplies transfer size of each data pattern should give the total block size in number of bytes.

The total size of the memory system to be examined is also programmed in the respective transfer count register inside DMA module. The DMA transfer count register is divided into two parts. They are element count and frame count. Note that a hardware DMA request can be programmed to trigger either one frame or one entire block transfer. In [Figure 12-439](#), a hardware DMA request from a timer is used as a trigger source to initiate DMA transfer. If all four CRC channels are active in AUTO mode then a total of four DMA requests would be generated by MCRC Controller.

**Figure 12-439. AUTO Mode Using Hardware Timer Trigger**

#### 12.8.3.2.8.2 AUTO Mode Using Software Trigger

The data patterns transfer can also be initiated by software. CPU can generate a software DMA request to activate the DMA channel to transfer data patterns from source memory system to the PSA Signature Register. To generate a software DMA request CPU needs to set the corresponding DMA channel in the DMA software trigger register. Note that just one software DMA request from CPU is enough to complete the entire data patterns transfer for all sectors. Please see [Figure 12-440](#) for illustration.

mrcr-005

**Figure 12-440. AUTO Mode With Software CPU Trigger**

#### 12.8.3.2.8.3 Semi-CPU Mode Using Hardware Timer Trigger

During Semi-CPU mode, no DMA request is generated by CRC controller. Therefore, no DMA channel is allocated to update CRC Value Register. CPU should not read from CRC Value Register in semi-CPU mode as it contains stale value. Note that no signature verification is performed at all during this mode. Similar to AUTO mode, either by hardware or by software DMA request can be used as a trigger for data patterns transfer. [Figure 12-441](#) illustrates the DMA setup using semi-CPU mode with hardware timer trigger.

mrcr-006

**Figure 12-441. Semi-CPU Mode With Hardware Timer Trigger**

**Table 12-340. DMA Request and Counter Logic Operation According to CRC Mode**

CRC Mode	DMA Request	Pattern Counter	Sector Counter	Timeout Counter
AUTO	Active	Active	Active	Active
Semi-CPU	Inactive	Active	Active	Active
Full CPU	Inactive	Inactive	Inactive	Inactive

### 12.8.3.2.9 Pattern Count Register

There is a 20-bit data pattern counter for every CRC channel. The data pattern counter is a down counter and can be pre-loaded with a programmable value stored in the Pattern Count Register (MCRC64\_0\_CRC\_PCOUNT\_REG1-4). When the data pattern counter reaches zero, a compression complete interrupt is generated in Semi-CPU mode and an automatic signature verification is performed in AUTO mode. In AUTO only, DMA request is generated to trigger the DMA controller to update the CRC Value Register.

#### Note

The data pattern count must be divisible by the total transfer count as programmed in DMA controller. The total transfer count is the product of element count and frame count.

### 12.8.3.2.10 Sector Count Register/Current Sector Register

Each channel contains a 16-bit sector counter. The sector count register stores the number of sectors. Sector counter is a free running counter and is incremented by one each time when one sector of data patterns is compressed. When the signature verification fails, the current value stored in the sector counter is saved into current sector register (MCRC64\_0\_CRC\_CURSEC\_REG1-4). If signature verification fails, CPU can read from the current sector register to identify the sector which causes the CRC mismatch. To aid and facilitate the CPU in determining the cause of a CRC failure it is advisable to use the following equation during CRC and DMA setup.

$$\text{CRC Pattern Count} \times \text{CRC Sector Count} = \text{DMA Element Count} \times \text{DMA Frame Count} \quad (25)$$

The current sector register is frozen from being updated until both the current sector register is read and CRC fail (CHi\_CRC\_FAIL) status bit is cleared by CPU. If CPU does not respond to the CRC failure in a timely manner before another sector produces a signature verification failure, the current sector register is not updated with the new sector number. An overrun interrupt is generate instead. If current sector register is already frozen with an erroneous sector and emulation is entered with SUSPEND signal goes to high then the register still remains frozen even it is read.

In Semi-CPU mode, the current sector register is used to indicate the sector for which the compression complete has last happened.

Current sector register is reset when the PSA software reset is enabled.

#### Note

Both data pattern count and sector count registers must be greater than or equal to one for the counters to count. After reset, pattern count and sector count registers default to zero and the associated counters are inactive.

### 12.8.3.2.11 Interrupts

CRC generate several types of interrupts per channel. Associated with each interrupt there is a interrupt enable bit (see MCRC64\_0\_CRC\_INTS). No interrupt is generated in Full-CPU mode.

- Compression complete interrupt
- CRC fail interrupt
- Overrun interrupt
- Underrun interrupt
- Timeout interrupt

**Table 12-341. Interrupt Conditions Per CRC Mode**

CRC Mode	Compression Complete	CRC Fail	Overrun	Underrun	Timeout
AUTO	No	Yes	Yes	Yes	Yes
Semi-CPU	Yes	No	Yes	No	Yes

**Table 12-341. Interrupt Conditions Per CRC Mode (continued)**

CRC Mode	Compression Complete	CRC Fail	Overrun	Underrun	Timeout
Full-CPU	No	No	No	No	No

#### 12.8.3.2.11.1 Overrun Interrupt

Overrun Interrupt is generated in either AUTO or Semi-CPU mode. During AUTO mode, if a CRC fail is detected then the current sector number is recorded in the current sector register (MCRC64\_0\_CRC\_CURSEC\_REG1-4). If CRC fail status bit is not cleared and current sector register is not read by the host CPU before another CRC fail is detected for another sector then an overrun interrupt is generated. During Semi-CPU mode, when the data pattern counter finishes counting, it generates a compression complete interrupt. At the same time the signature is copied into the PSA Sector Signature Register (MCRC64\_0\_PSA\_SECSIGREGL1-4). If the host CPU does not read the signature from PSA Sector Signature Register before it is updated again with a new signature value then an overrun interrupt is generated.

#### 12.8.3.2.11.2 Timeout Interrupt

To ensure that the memory system is examined within a pre-defined time frame and no loss of incoming data there is a 24-bit timeout counter per CRC channel. The timeout counter can be pre-loaded with two different pre-load values, watchdog timeout pre-load value (MCRC64\_0\_CRC\_WDTPOLD1-4) and block complete timeout pre-load value (MCRC64\_0\_CRC\_BCTOPLD1-4). The timeout counter is clocked by a prescaler clock which is permanently running at division 64 of FICLK clock.

Watchdog timeout pre-load register (MCRC64\_0\_CRC\_WDTPOLD1-4) is used to check if DMA does supply a block of data responding to a request in a given time frame. Block complete timeout pre-load register (MCRC64\_0\_CRC\_BCTOPLD1-4) is used to check if one complete block of data patterns are compressed within a specific time frame. The timeout counter is first pre-loaded with MCRC64\_0\_CRC\_WDTPOLD1-4 after either AUTO or Semi-CPU mode is selected and starts to down count. If the timeout counter expires before DMA transfers any data pattern to PSA Signature Register then a timeout interrupt is generated. An incoming data pattern before the timeout counter expires will automatically pre-load the timeout counter with MCRC64\_0\_CRC\_BCTOPLD1-4 the block complete timeout pre-load value.

Block complete timeout pre-load value is used to check if one block of data patterns are compressed within a given time limit. If the timeout counter pre-loaded with MCRC64\_0\_CRC\_BCTOPLD1-4 value expires before one block of data patterns are compressed a timeout interrupt is generated. When one block (pattern count × sector count) of data patterns are compressed before the counter has expired, the counter is pre-loaded with MCRC64\_0\_CRC\_WDTPOLD1-4 value again. If the timeout counter is pre-loaded with zero then the counter is disable and no timeout interrupt is generated.

#### 12.8.3.2.11.3 Underrun Interrupt

Underrun interrupt only occurs in AUTO mode. The interrupt is generated when the CRC Value Register is not updated with the corresponding signature when the data pattern counter finishes counting. During AUTO mode, MCRC Controller generates DMA request to update CRC Value Register in synchronization to the corresponding sector of the memory. Signature verification is also performed if underrun condition is detected. And CRC fail interrupt is generated at the same time as the underrun interrupt.

#### 12.8.3.2.11.4 Compression Complete Interrupt

Compression complete interrupt is generated in Semi-CPU mode only. When the data pattern counter reaches zero, the compression complete flag is set and the interrupt is generated

#### 12.8.3.2.11.5 Interrupt Offset Register

MCRC Controller only generates one interrupt request to interrupt manager. An interrupt offset register (MCRC64\_0\_CRC\_INT\_OFFSET\_REG) is provided to indicate the source of the pending interrupt with highest priority. [Table 12-342](#) shows the offset interrupt vector address of each interrupt in an ascending order of priority.

**Table 12-342. Interrupt Offset Mapping**

Interrupt Condition	Offset Value
Phantom	0x0
Ch1 CRC Fail	0x1
Ch2 CRC Fail	0x2
Ch3 CRC Fail	0x3
Ch4 CRC Fail	0x4
reserved	0x5-0x8
Ch1 Compression Complete	0x9
Ch2 Compression Complete	0xA
Ch3 Compression Complete	0xB
Ch4 Compression Complete	0xC
reserved	0xD-0x10
Ch1 Overrun	0x11
Ch2 Overrun	0x12
Ch3 Overrun	0x13
Ch4 Overrun	0x14
reserved	0x15-0x18
Ch1 Underrun	0x19
Ch2 Underrun	0x1A
Ch3 Underrun	0x1B
Ch4 Underrun	0x1C
reserved	0x1D-0x20
Ch1 Timeout	0x21
Ch2 Timeout	0x22
Ch3 Timeout	0x23
Ch4 Timeout	0x24

### 12.8.3.2.11.6 Error Handling

When an interrupt is generated, host CPU must take appropriate actions to identify the source of error and restart the respective channel in DMA and MCRC module. To restart a CRC channel user must perform the following steps in the ISR:

1. Write to software reset bit in MCRC64\_0\_CRC\_CTRL0 register to reset the respective PSA Signature Register
2. Reset the CHi\_MODE bits to 0 in MCRC64\_0\_CRC\_CTRL2 register as Data capture mode
3. Set the CHi\_MODE bits in MCRC64\_0\_CRC\_CTRL2 register to desired new mode again
4. Release software reset

The host CPU must use byte write to restart each individual channel.

### 12.8.3.2.12 Power Down Mode

MCRC module can be put into power down mode when the power down control bit MCRC64\_0\_CRC\_CTRL1[0] PWDN is set. The module wakes up when the PWDN bit is cleared. When MCRC controller is in power down mode, no data tracing alone will happen.

### 12.8.3.2.13 Emulation

A read access from a register in functional mode can sometimes trigger a certain internal event to follow. For example, reading interrupt offset register triggers an event to clear the corresponding interrupt status flag. During emulation when SUSPEND signal is high, a read access from any register should only return the register contents to the bus and should not trigger or mask any event as it would have in functional mode. This is

to prevent debugger from reading the interrupt offset register, that is, during refreshing screen and cause the corresponding interrupt status flag to get cleared. Timeout counters are stopped to generate timeout interrupts in emulation mode. No VBUSM bus error will be generated if reading from the unimplemented locations. .

CEMUDBG is the VBUSM suspend signal which need not explicitly indicate that whether CPU is in suspend mode or not. In data trace mode, a separate suspend signal CPU\_EMUSP, is used to indicate MCRC controller that the CPU is in suspend mode or not.

### 12.8.3.3 MCRC Programming Examples

#### 12.8.3.3.1 Example: Auto Mode Using Time Based Event Triggering

A large memory area with 2 Mbyte (256 k × 32-bit [doubleword]) is to be checked in the background of CPU. CRC is to be performed every 1 Kbyte (128 doubleword). Therefore there will be 2048 pre-recorded CRC values. For illustration purpose, we map MCRC64\_0\_CRC\_REGL1 register to DMA channel 1 and MCRC64\_0\_PSA\_SIGREGL1 register to DMA channel 2. Let's assume all DMA transfers are carried out in 64-bit transfer size.

##### 12.8.3.3.1.1 DMA Setup

- Setup DMA channel 1 with the starting address from which the pre-determined CRC values are stored. Setup the destination address to the MCRC64\_0\_CRC\_REGL1. Put the source address at post increment addressing mode and put the destination address at constant addressing mode. Use hardware DMA request for channel 1 to trigger a frame transfer.
- Setup DMA channel 2 with the source address from which the contents of memory to be verified. Setup the destination address to the MCRC64\_0\_PSA\_SIGREGL1. Program the element transfer count to 128 and the frame transfer count to 2048. Program the read and write element size to 64 bits. Put the source address at post increment addressing mode and put the destination address at constant address mode. Use hardware DMA request for channel 2 to trigger an entire block transfer.

##### 12.8.3.3.1.2 Timer Setup

The timer can be any general purpose timer which is capable of generating a time based DMA request.

- Setup Timer to generate DMA request associated with DMA channel 2. For example, software can setup the timer to generate a DMA request every 10 ms.

##### 12.8.3.3.1.3 CRC Setup

- Program the pattern count MCRC64\_0\_CRC\_PCOUNT\_REG1 to 128
- Program the sector count MCRC64\_0\_CRC\_SCOUNT\_REG1 to 2048
- For example, we want the entire 2 Mbytes to be compressed within 5 ms. We can program the block complete timeout pre-load (MCRC64\_0\_CRC\_BCTOPLD1-4) value to 15625 (5 ms / (1 FICLK period × 64)) if CRC is operating at 200 MHz.
- Enable AUTO mode and all interrupts.

After AUTO mode is selected MCRC Controller automatically generates a DMA request on channel 1. Around the same time the timer module also generates a DMA request on DMA channel 2. When the first incoming data pattern arrives at the MCRC64\_0\_PSA\_SIGREGL1/H1, the MCRC Controller will compress it. After some time, the DMA controller would update the CMCRC\_CRC\_REGL1/H1 with a pre-determined value matching the calculated signature for the first sector of 128 64-bit data patterns. After one sector of data patterns are compressed, the MCRC Controller generate a CRC fail interrupt if signature stored at the MCRC64\_0\_PSA\_SECSIGREGL1/H1 does not match the MCRC64\_0\_CRC\_REGL1/H1 Register. MCRC Controller generates a DMA request on DMA channel 1 when one sector of data patterns are compressed. This routine will continue until the entire 2 Mbytes are consumed. If the timeout counter reached zero before the entire 2 Mbytes are compressed, a timeout interrupt is generated. After 2Mbytes are transferred, the DMA can generate an interrupt to CPU. The entire operation will continue again when DMA responds to the DMA request from both the timer and MCRC Controller. The CRC is performed totally without any CPU intervention.

#### 12.8.3.3.2 Example: Auto Mode Without Using Time Based Triggering

A small but highly secured memory area with 1 Kbytes is to be checked in the background of CPU. CRC is to be performed every 1 Kbytes. Therefore, there is only one pre-recorded CRC value. For illustration purpose, we map channel 1 MCRC64\_0\_CRC\_REGL1/H1 to DMA channel 1 and channel 1 MCRC64\_0\_PSA\_SIGREGL1/H1 to DMA channel 2. Assume all transfers carried out by DMA are in 64-bit transfer size.

#### 12.8.3.3.2.1 DMA Setup

- Setup DMA channel 1 with the source address from which the pre-determined CRC value is stored. Setup the destination address to the MCRC64\_0\_CRC\_REGL1 Register. Put the source address at constant addressing mode and put the destination address at constant addressing mode. Use hardware DMA request for channel 1.
- Setup DMA channel 2 with the source address from which the memory area to be verified. Setup the destination address to the MCRC64\_0\_PSA\_SIGREGL1/H1. Program the element transfer count to 128 and the frame transfer count to 1. Put the source address at post increment addressing mode and put the destination address at constant address mode. Generate a software DMA request on channel 2 after CRC has completed its setup. Enable autoinitiation for DMA channel 2.

#### 12.8.3.3.2.2 CRC Setup

- Program the MCRC64\_0\_CRC\_PCOUNT\_REG1 to 128
- Program the MCRC64\_0\_CRC\_SCOUNT\_REG1 to 1
- Leaving the timeout count MCRC64\_0\_CRC\_BCTOPLD1 register with the reset value of zero means no timeout interrupt is generated
- Enable AUTO mode and all interrupts

After AUTO mode is selected the MCRC Controller automatically generates a DMA request on channel 1. At the same time the CPU generates a software DMA request on DMA channel 2. When the first incoming data pattern arrives at the MCRC64\_0\_PSA\_SIGREGL1/H1, the MCRC Controller will compress it. After some time, the DMA controller would update the MCRC64\_0\_CRC\_REGL1/H1 with a pre-determined value matching the calculated signature for the first sector of 128 64-bit data patterns. After one sector of data patterns are compressed, the MCRC Controller generate a CRC fail interrupt if signature stored at the MCRC64\_0\_PSA\_SECSIGREGL1/H1 does not match the MCRC64\_0\_CRC\_REGL1/H1. MCRC Controller generate a DMA request on DMA channel 1 again after one sector is compressed. After 1 Kbytes are transferred, the DMA can generate an interrupt to CPU. Responding to the DMA interrupt CPU can restart the CRC routine by generating a software DMA request onto channel 2 again.

#### 12.8.3.3.3 Example: Semi-CPU Mode

If DMA controller is available in a system the CRC module can also operate in semi-CPU mode. This means that CPU can still make use of the DMA to perform data patterns transfer to CRC controller in the background. The difference between semi-CPU mode and AUTO mode is that CRC controller does not automatically perform the signature verification. CRC controllers generates a compression complete interrupt to CPU when the one sector of data patterns are compressed. CPU needs to perform the signature verification itself.

A memory area with 2 Mbytes is to be verified with the help of the CPU. CRC operation is to be performed every 1 Kbyte. Since there are 2 Mbytes (256 K doublewords) of memory to be check and we want to perform a CRC every 1 Kbytes (128 doublewords) and therefore there must be 2048 pre-recorded CRC values. In Semi-CPU mode, the MCRC64\_0\_CRC\_REGL1/H1 is not updated and contains indeterminate data.

#### 12.8.3.3.3.1 DMA Setup

- Setup DMA channel 1 with the source address from which the memory area to be verified are mapped. Setup the destination address to the MCRC64\_0\_PSA\_SIGREGL1/H1. Put the starting address at post increment addressing mode and put the destination address at constant address mode. Use hardware DMA request to trigger an entire block transfer for channel 1. Disable autoinitiation for DMA channel 1.

#### 12.8.3.3.3.2 Timer Setup

The timer can be any general purpose timer which is capable of generating a time-based DMA request.

- Setup Timer to generate DMA request associated with DMA channel 1. For example, software can setup the timer to generate a DMA request every 10 ms.

#### 12.8.3.3.3.3 CRC Setup

- Program the MCRC64\_0\_CRC\_PCOUNT\_REG1 to 128
- Program the MCRC64\_0\_CRC\_SCOUNT\_REG1 to 2048

- For example, we want the entire 2 Mbytes to be compressed within 5 ms. We can program the block complete timeout pre-load value MCRC64\_0\_CRC\_BCTOPLD1 to 15625 (5 ms / (1 FICLK period × 64)) if CRC is operating at 200 MHz
- Enable AUTO mode and all interrupts.

The timer module first generates a DMA request on DMA channel 1 when it is enabled. When the first incoming data pattern arrives at the MCRC64\_0\_PSA\_SIGREGL1/H1, the CRC controller will compress it. After one sector of data patterns are compressed, the CRC controller generate a compression complete interrupt. Upon responding to the interrupt the CPU would read from the MCRC64\_0\_PSA\_SECSIGREGL1/H1. It is up to the CPU on how to deal with the PSA value just read. It can compare it to a known signature value or it can write it to another memory location to build a signature file or even transfer the signature out of the device via SCI or SPI. This routine will continue until the entire 2 Mbytes are consumed. The latency of the interrupt response from CPU can cause overrun condition. If CPU does not read from MCRC64\_0\_PSA\_SECSIGREGL1 before the PSA value is overridden with the signature of the next sector of memory, an overrun interrupt will be generated by CRC controller.

#### 12.8.3.3.4 Example: Full-CPU Mode

In a system without the availability of DMA controller, the CRC routine can be operated by CPU provided the CPU has enough throughput. CPU needs to read from the memory area from which CRC is to be performed.

A memory area with 2 Mbytes is to be checked with the help of the CPU. CRC operation is to be performed every 1 Kbyte. In CPU mode, the MCRC64\_0\_CRC\_REGL1/H1 is not updated and contains indeterminate data.

##### 12.8.3.3.4.1 CRC Setup

- All control registers can be left in their reset state. Only enable Full-CPU mode.

CPU itself reads from the memory and write the data to the MCRC64\_0\_PSA\_SIGREGL1/H1 inside MCRC Controller. When the first incoming data pattern arrives at the MCRC64\_0\_PSA\_SIGREGL1/H1, the MCRC Controller will compress it. After n data patterns are compressed, CPU can read from the MCRC64\_0\_PSA\_SIGREGL1/H1. It is up to the CPU on how to deal with the PSA signature value just read. It can compare it to a known signature value stored at another memory location.

## 12.8.4 ECC Aggregator

This section describes the common ECC aggregator functionality.

### 12.8.4.1 ECC Aggregator Overview

To increase functional and system reliability the memories (for example, FIFOs, queues, SRAMs and others) in many device modules and subsystems are protected by error correcting code (ECC). This is accomplished through an ECC aggregator and ECC wrapper. The ECC aggregator is connected to these memories (hereinafter ECC RAMs) and involved in the ECC process. Each memory is surrounded by an ECC wrapper which performs the ECC detection and correction. The wrapper communicates via serial interface with the aggregator which has memory mapped configuration interface.

The ECC aggregator is also connected to interconnect ECC components that protect the command, address and data buses of the system interconnect. ECC is calculated for the data bus and parity and redundancy for the command and address buses. Each interconnect ECC component has the same serial interface for communication with the aggregator as the ECC wrapper. An ECC aggregator may be connected to both endpoints - the ECC wrapper and interconnect ECC component.

The ECC aggregator, ECC wrapper and interconnect ECC component are considered as single entity and are hereinafter referred to as ECC aggregator unless otherwise explicitly specified.

See *Module Integration* for device modules and subsystems which have ECC aggregator.

#### 12.8.4.1.1 ECC Aggregator Features

The ECC aggregator has the following features:

- Reduces memory software errors via single error correction (SEC) and double error detection (DED)
- Provides a mechanism to control and monitor the ECC protected memories in a module or subsystem
- SEC and DED over the system interconnect data bus and parity and redundancy for the system interconnect command and address buses
- Generates an interrupt for correctable error
- Generates an interrupt for non-correctable error
- Supports inject only mode for diagnostic purposes
- Supports software readable status for single and double-bit ECC errors and associated information such as row address where error has occurred and data bits that have been flipped
- Supports up to 256 ECC endpoints. An ECC endpoint can be either ECC RAM or interconnect ECC component.
- Detects single bit error via parity checking on:
  - Memory mapped configuration interface FIFO
  - Serial interface FIFO
  - Serial interface transaction
- Single bit error detection via parity checking results in a non-correctable error interrupt
- Supports timeout mechanism on transactions over the ECC serial interface. Timeout occurrence results in a non-correctable error interrupt.
- Certain control bits have redundancy and if a bit flips an interrupt is generated

#### 12.8.4.1.2 Unsupported Features

See the *Module Integration* section for information about unsupported features.

---

#### Note

Some features may not be available. See *Module Integration* for more information.

---

#### 12.8.4.2 Integration

See the *Module Integration* section for information about clocks, resets and hardware requests.

### 12.8.4.3 ECC Aggregator Functional Description

This section describes the architecture and functional details of the ECC aggregator.

#### 12.8.4.3.1 ECC Aggregator Block Diagram

Figure 12-442 shows the ECC aggregator block diagram.

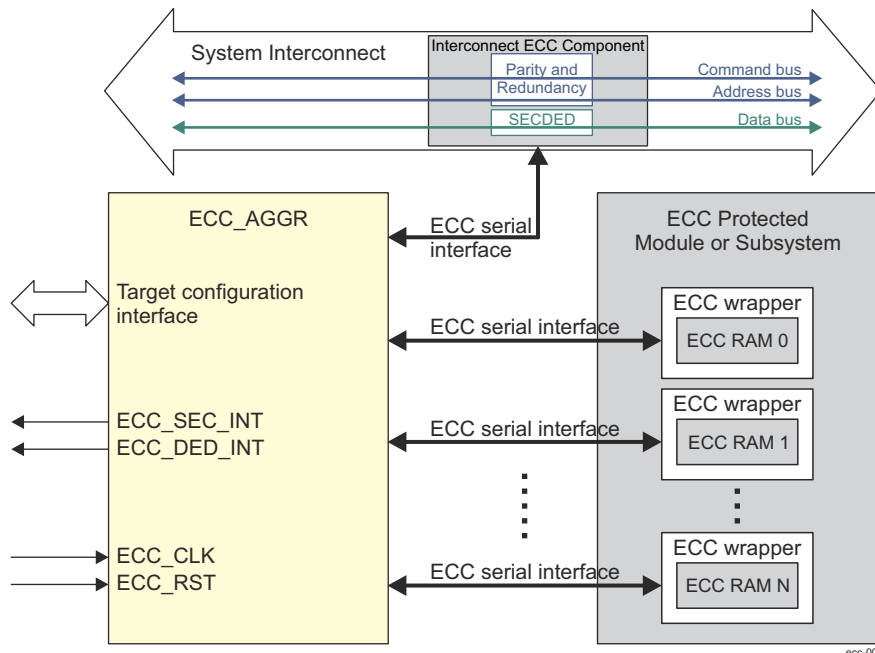

Figure 12-442. ECC Aggregator Block Diagram

The ECC aggregator is connected to one or more ECC endpoints each of which has assigned a unique ID used when the endpoint is accessed for status information or configuration. The ECC aggregator provides software access to all ECC related registers through its memory mapped target configuration interface while the serial interface is used to communicate with the ECC endpoints. Upon detection of single or double-bit error the corresponding interrupt line is asserted.

#### 12.8.4.3.2 ECC Aggregator Register Groups

The ECC aggregator has ECC control, status and interrupt registers for each ECC endpoint in a module or subsystem. These registers are memory mapped and occupy 1 KB address space although part of it may contain reserved locations. The registers are split in the following types:

- **Global registers.** They are common to all ECC endpoints associated with the ECC aggregator and include the ECC\_VECTOR and ECC\_REV registers. Each ECC endpoint has assigned a unique ID. When this ID is written to the ECC\_VECTOR[10-0] ECC\_VECTOR field the corresponding endpoint is selected either for control or for status reading.
- **ECC control and status registers.** These registers are specific to each ECC endpoint and reside in the range from address offset 0x10 to 0x28, if the endpoint is ECC RAM or from 0x10 to 0x24, if the endpoint is interconnect ECC component. They are memory mapped but are accessed through the ECC serial interface. They are also selected by the ECC endpoint ID written to the ECC\_VECTOR[10-0] ECC\_VECTOR field. Because of latency on the serial interface the ECC control and status registers are read by performing special sequence as described in [Section 12.8.4.3.3](#). These registers have also different functionality for both types of endpoints - ECC RAM and interconnect ECC component.
- **Interrupt registers.** They include interrupt status, interrupt enable, interrupt disable, and EOI registers. For more information, see *Interrupts*.

### Note

For description of each register, see *ECC\_AGGR Registers*.

#### 12.8.4.3.3 Read Access to the ECC Control and Status Registers

Read accesses to the ECC control and status registers for each ECC endpoint represent read operations over the ECC serial interface and are triggered by performing the following sequence:

1. Software writes the following in the ECC\_VECTOR register:
  - The ECC endpoint ID in the ECC\_VECTOR[10-0] ECC\_VECTOR field to select particular ECC endpoint.
  - The register read address in the ECC\_VECTOR[23-16] RD\_SVBUS\_ADDRESS field to select which register has to be read through the ECC serial interface.
  - A value of 0x1 in the ECC\_VECTOR[15] RD\_SVBUS bit to trigger read operation through the ECC serial interface.
2. Software polls the ECC\_VECTOR[24] RD\_SVBUS\_DONE bit to check if it is 0x1. This indicates that the read operation on the ECC serial interface has completed.
3. Software reads the data from the register previously selected by the ECC\_VECTOR[23-16] RD\_SVBUS\_ADDRESS field.

The following is an example for serial read operation:

1. Write 0x0010 8005 to the ECC\_VECTOR register. This sends read request to the ECC\_WRAP\_REV or ECC\_CBASS\_REV register (address = 0x10) associated with ECC endpoint with ID = 5.
2. Poll the ECC\_VECTOR[24] RD\_SVBUS\_DONE bit until value of 0x1 is read.
3. Read the ECC\_WRAP\_REV or ECC\_CBASS\_REV register to get its value.

#### 12.8.4.3.4 Serial Write Operation

Write operations over the ECC serial interface are performed as follows:

1. Software specifies the ECC endpoint ID in the ECC\_VECTOR[10-0] ECC\_VECTOR field. The ECC\_VECTOR[23-16] RD\_SVBUS\_ADDRESS field is a don't care but the ECC\_VECTOR[15] RD\_SVBUS bit must be set to 0x0.
2. Software performs regular write operation to the desired address. If the ECC endpoint ID has already been specified, step 1 can be skipped. Unlike serial read operations it is not necessary to always specify the endpoint ID before performing serial write operation.

The following is an example for serial write operation:

1. Write 0x0000 0008 to the ECC\_VECTOR register.
2. Write 0x0000 000F to the ECC\_CTRL register. This sends write request with data 0x0000 000F to the ECC\_CTRL register associated with ECC RAM with ID = 8.

#### 12.8.4.3.5 Interrupts

The ECC aggregator generates the following interrupts:

- Correctable interrupt (ECC\_SEC\_INT) where hardware can correct the error but notifies the system in case of SEC.
- Non-correctable interrupt (ECC\_DED\_INT) where hardware cannot correct the error in cases of DED, parity check, redundancy check or timeout occurrence.

The following is the sequence for servicing interrupts:

- Software enables the interrupts for an ECC endpoint by writing 0x1 to the corresponding bit of the following interrupt enable registers:
  - ECC\_SEC\_ENABLE\_SET\_REG0 through ECC\_SEC\_ENABLE\_SET\_REG7 for the correctable interrupt
  - ECC\_DED\_ENABLE\_SET\_REG0 through ECC\_DED\_ENABLE\_SET\_REG7 for the non-correctable interrupt
- On receiving an interrupt, software checks which ECC endpoint has caused the error by reading the following interrupt status registers:

- ECC\_SEC\_STATUS\_REG0 through ECC\_SEC\_STATUS\_REG7 for the correctable interrupt
- ECC\_DED\_STATUS\_REG0 through ECC\_DED\_STATUS\_REG7 for the non-correctable interrupt
- Software performs serial read operations as described in [Section 12.8.4.3.3](#) to read the following status registers that contain details about the error:
  - If the endpoint is ECC RAM:
    - ECC\_ERR\_STAT1
    - ECC\_ERR\_STAT2
    - ECC\_ERR\_STAT3
  - If the endpoint is interconnect ECC component:
    - ECC\_CBASS\_ERR\_STAT1
    - ECC\_CBASS\_ERR\_STAT2
- After the interrupt has been serviced, depending on the error type, software should clear the corresponding status bits in the ECC\_ERR\_STAT1 and ECC\_ERR\_STAT3 registers or in the ECC\_CBASS\_ERR\_STAT1 register. Software has to poll these registers to guarantee that status bits are cleared as there is no other indication for write completion over the ECC serial interface.  
The value of the \*\_PEND\_CLR fields in the ECC\_CBASS\_ERR\_STAT1 register must be read and then written back to decrement the count of each field back to 0x0. A further error capture into the ECC\_CBASS\_ERR\_STAT1 register does not occur unless all its fields are 0x0. The decrement value should not be larger than the read value. If a field in the ECC\_CBASS\_ERR\_STAT1 register should not be modified, write a value of 0x0 to that field.
- Software writes 0x1 to the corresponding end of interrupt register to clear the interrupt:
  - ECC\_SEC\_EOI\_REG for the correctable interrupt
  - ECC\_DED\_EOI\_REG for the non-correctable interrupt

#### 12.8.4.3.6 Inject Only Mode

There are modules that already perform the ECC generation and checking as part of their data path. In this case, the ECC wrapper may be configured in inject only mode, if needed. In this mode the ECC wrapper does not perform ECC detection and correction. The inject only mode allows users to inject single or double-bit errors so that the module logic can be tested for diagnostic purposes.

#### Note

There is no software control to enable inject only mode. It is configured via tie-off value. Inject only and ECC modes are mutually exclusive.

The interconnect ECC component also supports error injection mode. There is error injection logic for testing of the error checking logic (checkers). The injection logic can be configured to inject either single or double bit error and what data pattern to be used for injection (ECC\_CBASS\_CTRL[11-8] ECC\_PATTERN). The ECC\_CBASS\_ERR\_CTRL1 and ECC\_CBASS\_ERR\_CTRL2 registers should be written first to setup the injection. Then, either the ECC\_CBASS\_CTRL[3] FORCE\_SE or the ECC\_CBASS\_CTRL[4] FORCE\_DE bit must be set to 0x1 to start the injection. Both bits must not be set at the same time. If the injection should continue in incrementing mode, then the ECC\_CBASS\_CTRL[5] FORCE\_N\_BIT bit should be set to 0x1. Once the FORCE\_N\_BIT is set, then each successive injection can simply write the ECC\_CBASS\_CTRL register to set the FORCE\_SE or FORCE\_DE again. Reading 0x0 from either the FORCE\_SE or the FORCE\_DE bit indicates that the injection has completed, as these bits automatically clear when the checker indicates that it has performed the injection. The time for an injection to complete is not guaranteed, so some delay is needed between successive injections.

#### 12.8.4.4 ECC Aggregator Configurations

**Table 12-343. Properties of ECC Aggregator Instance COMPUTE\_CLUSTER0**

RAM ID Name	RAM ID	ECC Type	Inject Type	Accessi ble Flag	Row Width	RAM Size
CPU0_A53_DUAL_U_IDATA_SDRAM_BANK0_LO_ECC_S VBUS	0	ECC Wrapper	Inject only	Yes	42	10 KB

## 12.9 Display Subsystem and Peripherals

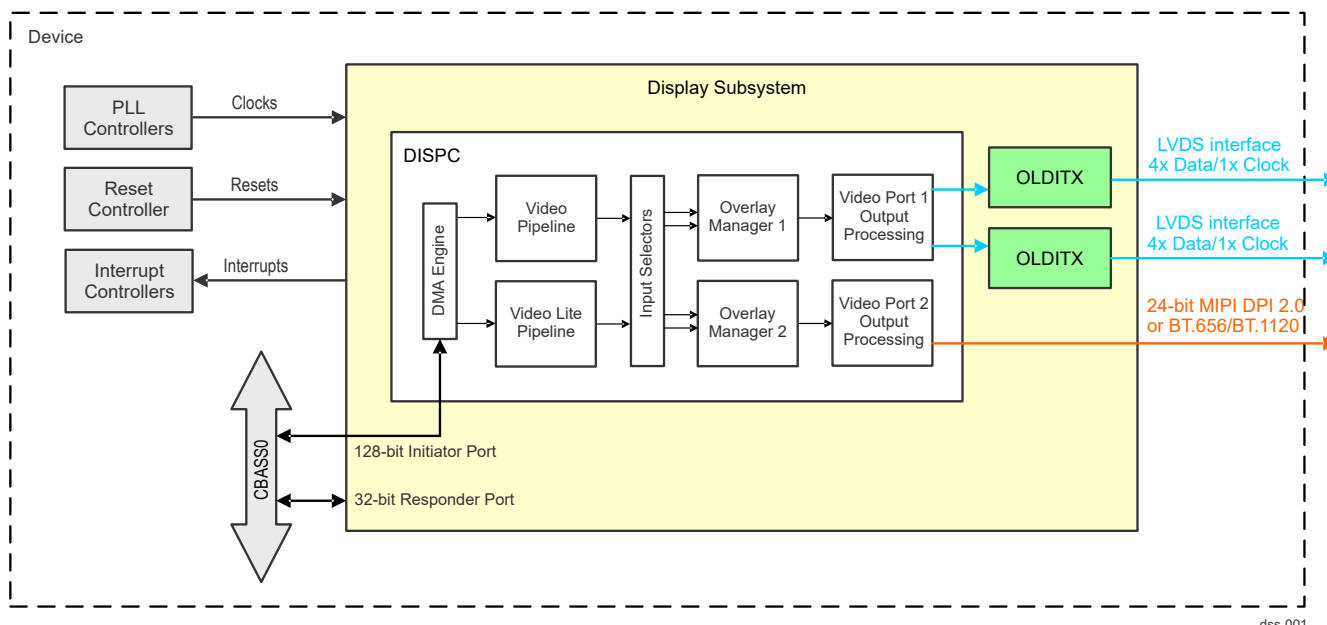

## 12.9.1 Display Subsystem (DSS)

This section describes the Display Subsystem (DSS) in the device.

### 12.9.1.1 DSS Overview

The Display Subsystem (DSS) is a flexible, multi-pipeline subsystem that supports high-resolution display outputs. DSS includes input pipelines providing multi-layer blending with transparency to enable on-the-fly composition. Various pixel processing capabilities are supported, such as color space conversion and scaling, among others. DSS includes a DMA engine, which allows direct access to the frame buffer (device system memory). Display outputs can connect seamlessly to an Open LVDS Display Interface transmitter (OLDITX), or can directly drive device pads as a Display Parallel Interface (DPI).

Figure 12-443 is a high-level overview of the display subsystem.

dss-001

**Figure 12-443. DSS Overview**

#### 12.9.1.1.1 DSS Features

The Display Subsystem module includes the following features:

- Two display outputs
  - Up to 24-bit per pixel parallel or embedded sync output
  - Up to 200MHz pixel clock
  - Supports
    - 1920x1080@60fps
    - 1x 2048x1080 + 1x 1280x720 (constrained by DDR bandwidth)
  - Support for RGB/YUV422 modes
  - Support for progressive/interlaced modes
  - Two display pipelines support 2x OpenLDI 4-data/1clk link (either shared to provide a 4K display or mirroring the same display - independent displays on each OLDI are not supported)
- Two input display processing pipelines
  - One video pipeline supporting full RGB and 8/10-bit YUV data formats with 3/5-tap 16-phase scaler capable of 0.25x to 16x resizing.
  - One video\_lite pipeline supporting full RGB and 8/10 YUV data formats (no resizing support)
- Two Overlay Managers with multi layer alpha blending
- One DMA controller capable of supporting up to 2K input source width.

- 48-bit addressing (256 TB reach)
- On-the-fly X/Y-axis flip of the source (Flip/Mirror mode support)
- Safety check (freeze frame detection and data correctness check)

---

**Note**

Some features may not be available. See *Module Integration* for more information.

---

**12.9.1.1.2 Unsupported Features**

See the *Module Integration* section for information about unsupported features.

### 12.9.1.2 DSS Environment

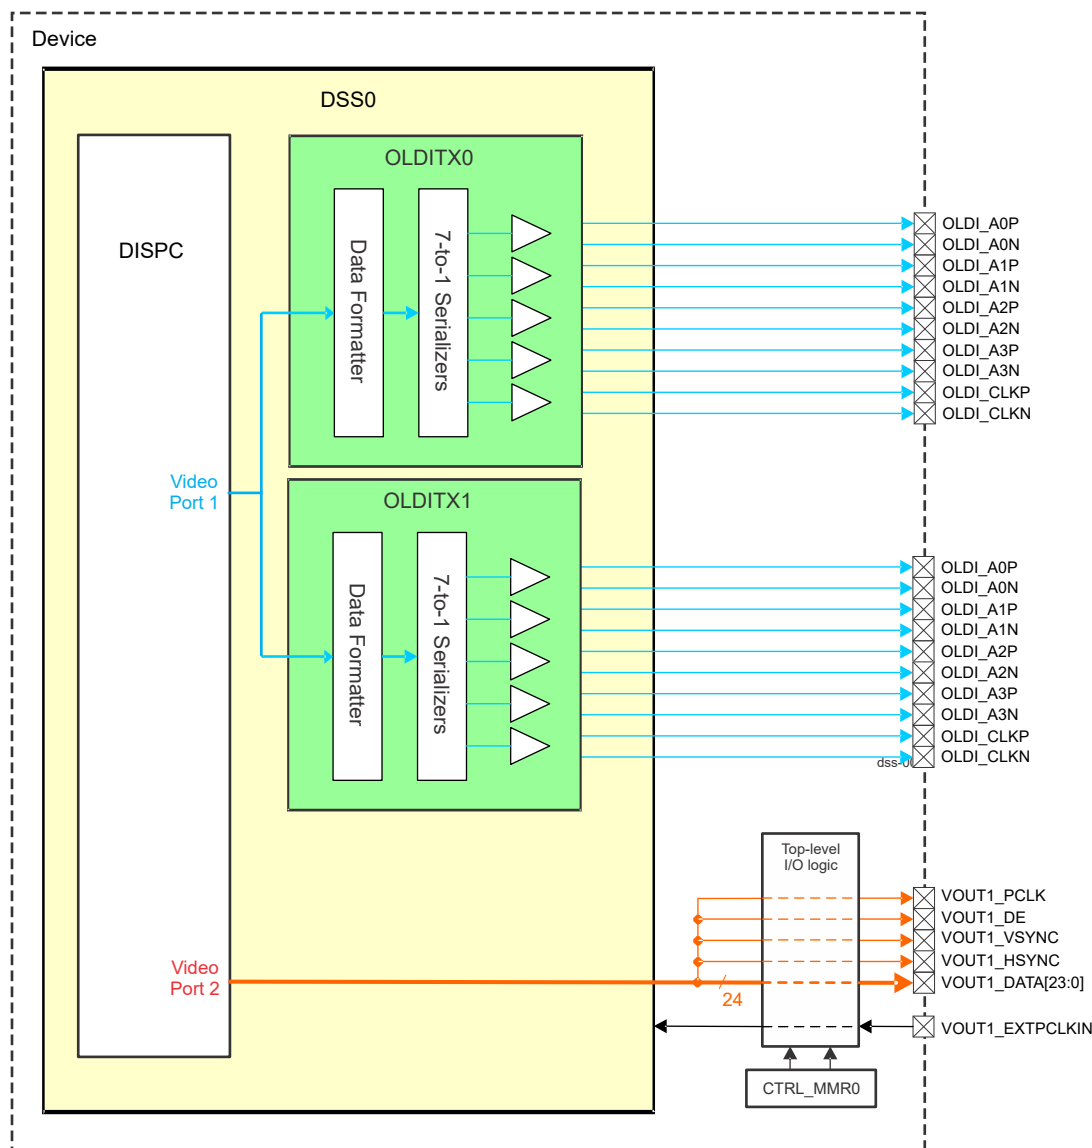

This section describes the interfaces handled by the display subsystem.

DSS supports two types of display interfaces:

- Display parallel interface via DISPC Video Port 2 (VP2) output. For more information, see [Section 12.9.1.2.1](#)
- Two low-voltage differential signaling (LVDS) interfaces, each with four data lanes and one clock lane, via Open LDI Transmitters (OLDITX0 and OLDITX1) connected to DISPC Video Port 1 (VP1) output. For more information, see [Section 12.9.1.2.2](#).

For more information on video ports configuration, see [Section 12.9.1.4.1.10, DISPC Video Port Outputs](#).

Figure 12-444 is a diagram of the DSS external connections.

**Figure 12-444. DSS Environment**

### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

#### 12.9.1.2.1 DSS Parallel Interface

The DISPC Video Port 2 (VP2) outputs the required data and control signals to device pads to support the following display interface modes:

- Parallel MIPI DPI 2.0 (Digital Pixel Interface): RGB 16/18/24-bit output with separate sync signals.
- BT.656/BT.1120 interface: YUV422 output (8/10-bit modes) with embedded syncs.

Table 12-416 describes the DISPC VP2 output signals.

**Table 12-416. DSS Signals for MIPI DPI 2.0 or BT.656/BT.1120**

Module Pin	Device Level Signal	Type <sup>(1)</sup>	Description	Module Pin Reset Value
DSS_DPI2_DATA[23:0]	VOUT1_DATA[23:0]	O	Pixel data output. RGB data for MIPI DPI 2.0 interface. YUV data for BT.656/BT.1120 interfaces.	0
DSS_DPI2_PCLK	VOUT1_PCLK	O	Pixel clock output. The maximum interface frequency is 165MHz.	0
DSS_DPI2_VSYNC	VOUT1_VSYNC	O	Vertical synchronization. The frame synchronization pulse (vsync) toggles after all the lines in a frame are transmitted and a programmable number of line clock cycles has elapsed at the beginning and the end of each frame.	0
DSS_DPI2_HSYNC	VOUT1_HSYNC	O	Horizontal synchronization. The line synchronization pulse (hsync) toggles after all pixels in a line are transmitted and a programmable number of pixel clock wait-states has elapsed at the beginning and the end of each line.	0
DSS_DPI2_DE	VOUT1_DE	O	Pixel data output-enable signal to indicate when data must be latched using the pixel clock.	0

(1) I = Input, O = Output, I/O = Input/Output

### Note

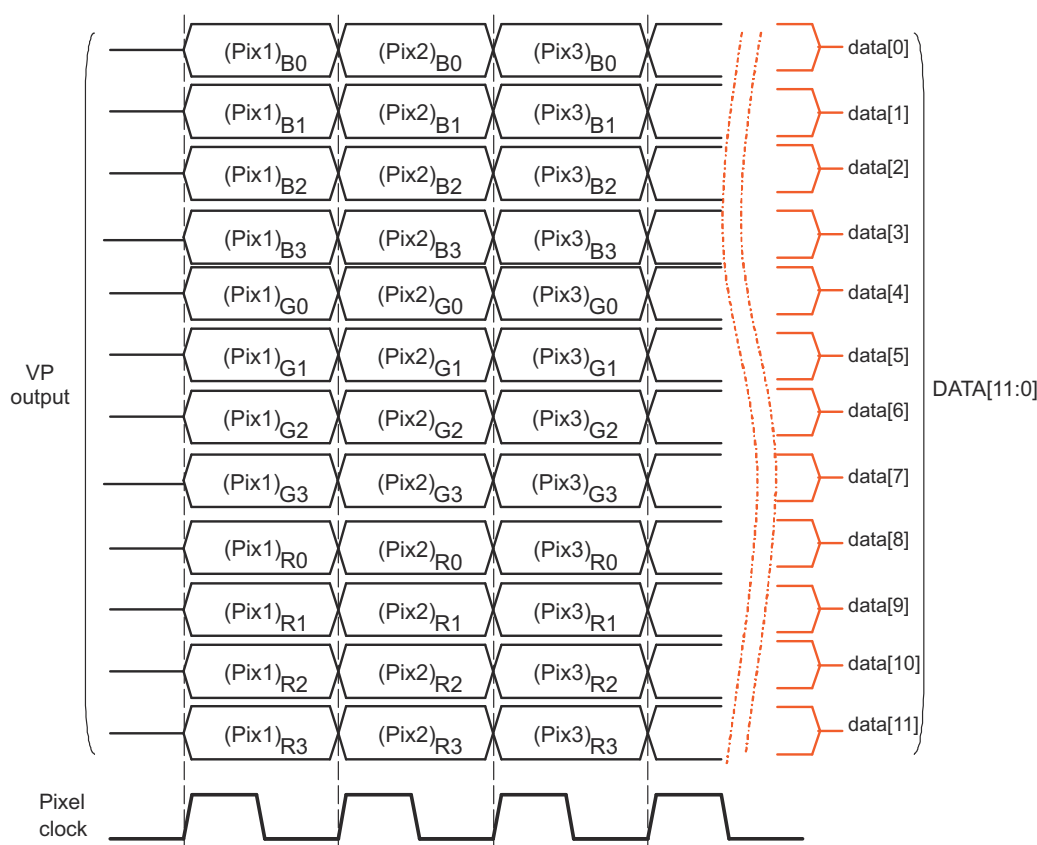

The effective output pixel clock rate for interleaved data formats (that is, BT.656 output mode or TDM (Time Division Multiplexed) output mode) will be either 1/2 or 1/3 of the maximum pixel clock rate, respectively, depending on the interleaving ratio.

#### 12.9.1.2.1.1 Pixel Data Formats

This section describes the pixel data bus for RGB formats and shows timing diagrams of transactions and synchronizations.

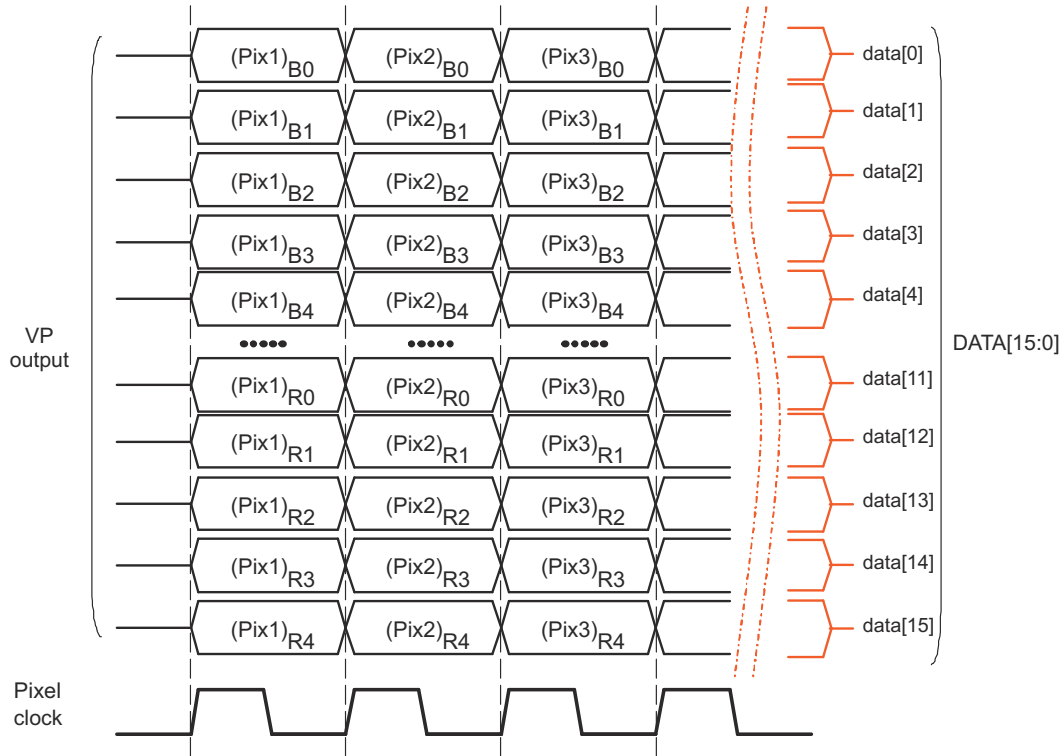

For the active matrix display type, one pixel per pixel clock is displayed. The diagrams represent the configuration of assertion of the data on the rising edge of the pixel clock. It is possible to program the interface timing to output the data on the falling edge of the pixel clock.

Figure 12-445 through Figure 12-448 show the interface to 12-, 16-, 18-, and 24-bit RGB active matrix displays. Each vertical line represents one output pixel. The width of the data bus can be configured through DSS0\_CONTROL[10-8] DATALINES register bitfield.

**Figure 12-447. DISPC Video Port Pixel Data - 18-bit RGB Active Matrix**

dispc-053

**Figure 12-448. DISPC Video Port Pixel Data - 24-bit RGB Active Matrix**

#### 12.9.1.2.1.2 Display Timing Diagrams

Figure 12-449 through Figure 12-452 show examples with timing diagrams of synchronization signals and pixel clocks for active matrix panels. The DISPC video ports directly drive these signals, which are related to the programmable fields listed in Table 12-417. For more information, see also Section 12.9.1.4.1.10.7, *DISPC VP Timing Generator and Display Panel Settings*.

**Table 12-417. DISPC Video Port Register Fields for Active Matrix Display**

Name	Register	Description
PPL	DSS0_SIZE_SCREEN[11-0] PPL value + 1	Pixels per line
LPP	DSS0_SIZE_SCREEN[27-16] LPP value + 1	Lines per panel
HBP	DSS0_TIMING_H[31-20] HBP value + 1	Horizontal back porch
HFP	DSS0_TIMING_H[19-8] HFP value + 1	Horizontal front porch
HSW	DSS0_TIMING_H[7-0] HSW value + 1	Horizontal synchronization pulse width
VBP	DSS0_TIMING_V[31-20] VBP value	Vertical back porch
VFP	DSS0_TIMING_V[19-8] VFP value	Vertical front porch
VSW	DSS0_TIMING_V[7-0] VSW value + 1	Vertical synchronization pulse width
ALIGN	DSS0_POL_FREQ[18] ALIGN	Alignment between HSYNC and VSYNC assertion
ONOFF	DSS0_POL_FREQ[17] ONOFF	HSYNC and VSYNC pixel clock control
RF	DSS0_POL_FREQ[16] RF	HSYNC and VSYNC pixel clock edge control
IEO	DSS0_POL_FREQ[15] IEO	Invert output enable
IPC	DSS0_POL_FREQ[14] IPC	Invert PCLK
IHS	DSS0_POL_FREQ[13] IHS	Invert HSYNC
IVS	DSS0_POL_FREQ[12] IVS	Invert VSYNC

- Active matrix timing configuration 1:
  - DSS0\_POL\_FREQ[17] ONOFF = 0
  - DSS0\_POL\_FREQ[16] RF = 0

The HSYNC and VSYNC signals are driven on the opposite edge of PCLK from the pixel data.

- DSS0\_POL\_FREQ[15] IEO = 0

- The DE signal is active high.
- DSS0\_POL\_FREQ[14] IPC = 0
- The pixel data are driven on the rising edge of PCLK.
- DSS0\_POL\_FREQ[13] IHS = 0
- The HSYNC signal is active high.
- DSS0\_POL\_FREQ[12] IVS = 0
- The VSYNC signal is active high.
- DSS0\_POL\_FREQ[18] ALIGN = 0
- The VSYNC and HSYNC assertion is not aligned.

**Figure 12-449. DISPC Display Timing Diagram of Configuration 1 (Start of Frame)**

**Figure 12-450. DISPC Display Timing Diagram of Configuration 1 (Between Lines)**

**Figure 12-451. DISPC Display Timing Diagram of Configuration 1 (Between Frames)**

**Figure 12-452. DISPC Display Timing Diagram of Configuration 1 (End of Frame)**

- Active matrix timing configuration 2:

- DSS0\_POL\_FREQ[17] ONOFF = 1
- DSS0\_POL\_FREQ[16] RF = 1

The HSYNC and VSYNC signals are driven on the rising edge of PCLK.

- DSS0\_POL\_FREQ[15] IEO = 1

The DE signal is active low.

- DSS0\_POL\_FREQ[14] IPC = 1

The pixel data is driven on the falling edge of PCLK.

- DSS0\_POL\_FREQ[13] IHS = 1

The HSYNC signal is active low.

- DSS0\_POL\_FREQ[12] IVS = 1

The VSYNC signal is active low.

- DSS0\_POL\_FREQ[18] ALIGN = 0

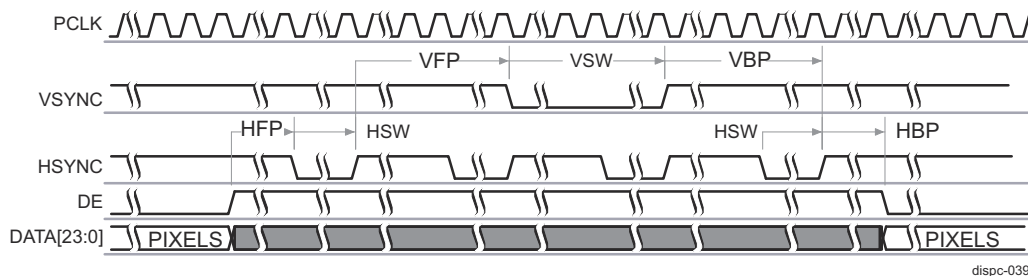

The VSYNC and HSYNC assertion is not aligned.

**Figure 12-453. DISPC Display Timing Diagram of Configuration 2 (Start of Frame)**

**Figure 12-454. DISPC Display Timing Diagram of Configuration 2 (Between Lines)**

**Figure 12-455. DISPC Display Timing Diagram of Configuration 2 (Between Frames)**

**Figure 12-456. DISPC Display Timing Diagram of Configuration 2 (End of Frame)**

- Active matrix timing configuration 3:

- DSS0\_POL\_FREQ[17] ONOFF = 1
- DSS0\_POL\_FREQ[16] RF = 1

The HSYNC and VSYNC signals are driven on the rising edge of PCLK.

- DSS0\_POL\_FREQ[15] IEO = 0

The DE signal is active high.

- DSS0\_POL\_FREQ[14] IPC = 0

The pixel data are driven on the rising edge of PCLK.

- DSS0\_POL\_FREQ[13] IHS = 0

The HSYNC signal is active high.

- DSS0\_POL\_FREQ[12] IVS = 0

The VSYNC signal is active high.

- DSS0\_POL\_FREQ[18] ALIGN = 0

The VSYNC and HSYNC assertion is not aligned.

### 12.9.1.2.2 DSS LVDS Interface

The LVDS display interface is provided via two single-link OLDITX modules, which receives parallel RGB pixel data and synchronization signals from DSS DISPC Video Port 1 (VP1). The VP1 pixel data format and timings are the same as described for VP2 in [Section 12.9.1.2.1.1](#) and [Section 12.9.1.2.1.2](#), respectively. OLDITX works only with 18-bit or 24-bit RGB input source data.

The OLDITX translates 21-bit or 28-bit wide video and sync data into 3-bit or 4-bit wide serial data, 7-bits deep. The 24-bit serialized RGB pixel data is transmitted on four LVDS data lanes, clocked by one clock lane. OLDITX can also be configured to transmit only 18-bit RGB data (6-bits/pixel color component) on three LVDS lanes, when connected to a low-resolution display panel. In 18-bit configuration, only three LVDS data lanes and one clock lane are active. The fourth data lane is disabled.

[Table 12-418](#) describes the OLDITX output LVDS signals.

**Table 12-418. DSS OLDITX Signals for LVDS Interface**

Module Pin	Device Level Signal	Type <sup>(1)</sup>	Description	Module Pin Reset Value
OLDI_DATA0X	OLDI_A0P	O	OLDI differential data lane A0 (+)	-
OLDI_DATA0Y	OLDI_A0N	O	OLDI differential data lane A0 (-)	-
OLDI_DATA1X	OLDI_A1P	O	OLDI differential data lane A1 (+)	-
OLDI_DATA1Y	OLDI_A1N	O	OLDI differential data lane A1 (-)	-
OLDI_DATA2X	OLDI_A2P	O	OLDI differential data lane A2 (+)	-
OLDI_DATA2Y	OLDI_A2N	O	OLDI differential data lane A2 (-)	-
OLDI_DATA3X	OLDI_A3P	O	OLDI differential data lane A3 (+)	-
OLDI_DATA3Y	OLDI_A3N	O	OLDI differential data lane A3 (-)	-
OLDI_CLOCKX	OLDI_CLKP	O	OLDI differential clock lane CLK (+)	-

**Table 12-418. DSS OLDITX Signals for LVDS Interface (continued)**

Module Pin	Device Level Signal	Type <sup>(1)</sup>	Description	Module Pin Reset Value
OLDI_CLOCKY	OLDI_CLKN	O	OLDI differential clock lane CLK (-)	-

(1) I = Input, O = Output, I/O = Input/Output

Table 12-419 shows the supported LVDS pixel components mapping for 18-bit and 24-bit output data modes. The OLDI mapping type is defined in DSS0\_DSS\_OLDI\_CFG[3-1] MAP register field as follows:

- Type A = Single-link 18-bit. MAP = '000'.
- Type B = Single-link 24-bit JEIDA. MAP = '001'.
- Type C = Single-link 24-bit. MAP = '010'.
- Type D = Dual-link 18-bit. MAP = '100'.
- Type E = Dual-link 24-bit JEIDA. MAP = '101'.
- Type F = Dual-link 24-bit. MAP = '110'.

**Table 12-419. DSS OLDITX LVDS Data Format**

Mode	Single-link	Single-link	Single-link	Dual-link	Dual-link	Dual-link
	18-bit	24-bit JEIDA	24-bit	18-bit	24-bit JEIDA	24-bit

(1) Not used - output disabled.

(2) Reserved for other video channel (Single-Link Mode)

Figure 12-461 and Figure 12-462 show the LVDS data output bit format (that is, the pixel bit numbers onto LVDS interface bit numbers). The rising edge of the LVDS clock occurs two LVDS sub-symbols before the current cycle of data. The clock is composed of a 4 LVDS sub-symbol high time and a 3 LVDS sub-symbol low time.

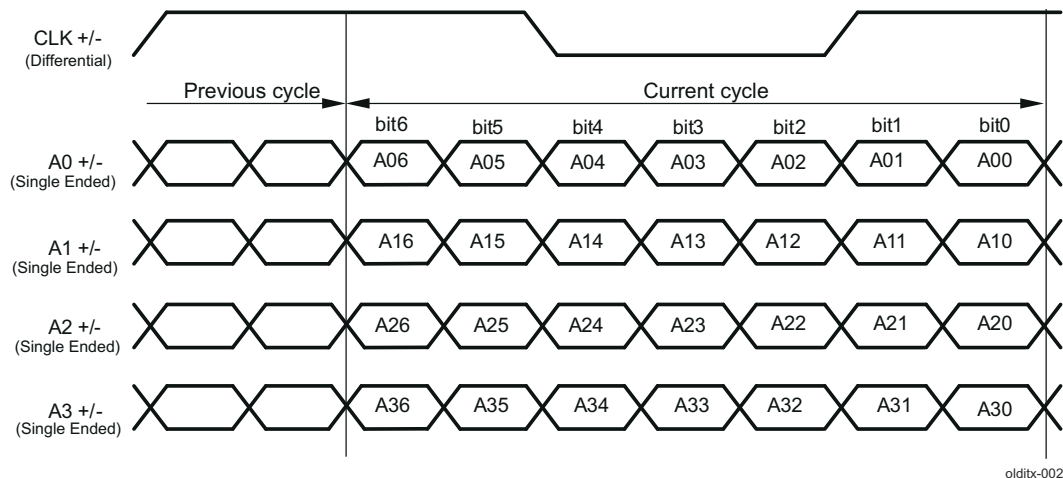

oldtx-001

**Figure 12-461. DSS OLDITX Pixel Bit Numbers on LVDS Output (Single-Link)**

**Figure 12-462. DSS OLDITX Pixel Bit Numbers on LVDS Output (Dual-Link)**

Figure 12-463 and Figure 12-464 show the OLDITX input data mapped to LVDS output and the serial bit positions.

**Figure 12-463. DSS OLDITX Inputs Mapped to LVDS Outputs**

olditx-003

**Figure 12-464. DSS OLDITX LVDS Serial Bit Positions**

The OLDITX LVDS signal lines support a minimum bit time of 0.866 ns. This corresponds to a maximum pixel clock rate of 165 MHz (for a single link operation). A bit time period (known as TUI or Time Unit Interval) consists of several timing parameters:

- TCCS (Transmitter Channel-to-Channel Skew) - refers to the max skew across the differential data pairs within a link (in a single-link mode).
- SW - setup and hold time (internal data sample window) in the receiver.
- RSKM (Receiver Input Skew Margin) - the total time margin that remains after subtracting the sampling window (SW) size and the transmitter channel-to-channel skew (TCCS) from the time unit interval (TUI).

For more information on the OLDITX LVDS timing parameters, refer to device-specific Datasheet.

### 12.9.1.3 Integration

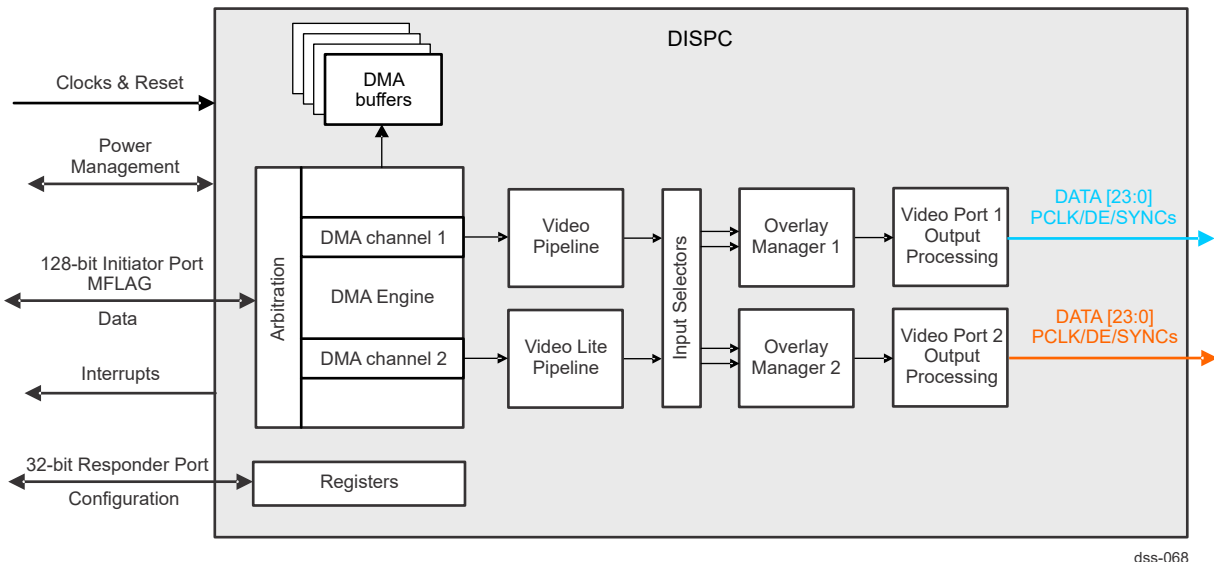

See the *Module Integration* section for information about clocks, resets and hardware requests.

### 12.9.1.4 DSS Functional Description

#### 12.9.1.4.1 DISPC Functional Description

##### 12.9.1.4.1.1 DISPC Overview

Figure 12-465 is a simplified block diagram of DISPC.

**Figure 12-465. DISPC Architecture Overview**

The DISPC integrated within DSS is capable of fetching pixel data from the device system memory through its single initiator port, performing various pixel processing, and then providing the processed pixels to an external display panel. The internal DMA engine tightly coupled to the DISPC is used for the pixel data transfer from system memory (frame buffer). The DISPC DMA engine is in charge of scheduling the memory requests. Several processes are configurable in order to manage the video pipeline features (color space conversion, up-sampling, down-sampling) and overlay features. The internal timing generator logic generates the video port output signals based on VESA DMT and CEA-861 standards. The DISPC video port output can be connected to display panels either directly (for MIPI DPI 2.0 or BT.656/BT.1120 support), or through Open LDI transmitter.

#### Note

DISPC does not support any tiled frame buffer, nor any compressed frame buffer. DISPC has no internal capability to support rotation of the frame buffer.

#### Note

The display resolution is programmable and can be any width in the range [1:4096] pixels. The following limitations apply, related to the type of display or the processing done:

- Active Matrix screen + dithering forces a width multiple of 2 pixels
- Active Matrix + TDM may force a width multiple of 2 pixels

The display buffers in the system memory must consist of contiguous pixels.

##### 12.9.1.4.1.2 DISPC Clocks

DISPC has one clock domain for its internal logic and separate domains for each video port output.

The DISPC functional clock (DSS\_FUNC\_CLK) serves as the internal logic clock and also acts as the interface clock for the DISPC initiator and responder ports to system interconnect. There is no internal divisor on this clock.

The DISPC pixel clocks (DPI\_x\_IN\_CLK) serve as the clocks for the DISPC video port outputs to OLDITX0 and OLDITX1 modules (VP1 pixel clock DPI\_0\_IN\_CLK) or for the parallel display interface (VP2 pixel clock DPI\_1\_IN\_CLK). There are no internal divisors on the pixel clocks.

The frequency of DSS\_FUNC\_CLK clock must be greater or equal to the DPI\_x\_IN\_CLK clocks, in order to get the DISPC internal logic to function properly. The frequency of the DPI\_x\_IN\_CLK clocks depend on the output display resolution and required frame rate. For the maximum supported frequency ratings, refer to device-specific Datasheet.

All input clocks are asynchronous to each other. They can be generated by different sources.

The DSS0\_COMMON\_DSS\_SYSCONFIG[0] AUTOCLKGATING register bit is set by default to allow the auto-gating of the interface and functional clocks. The AUTOCLKGATING bit can be reset to disable the auto-gating of the clocks, if required.

DISPC provides also a clock-gating control on sub-module level, via configuration of the DSS0\_COMMON\_DISPC\_CLKGATING\_DISABLE register fields.

#### 12.9.1.4.1.3 DISPC Resets

DISPC receives a single hardware reset signal. For more information, see *DSS Integration*.

To perform a software reset on the DISPC, set the DSS0\_COMMON\_DSS\_SYSCONFIG[1] SOFTRESET bit to 0x1. The DSS0\_COMMON\_DSS\_SYSSTATUS[0] DISPC\_FUNC\_RESETDONE bit indicates that the software reset is complete (for the DISPC internal logic) when its value is 0x1. When the software reset completes, the DSS0\_COMMON\_DSS\_SYSCONFIG[1] SOFTRESET bit is automatically reset. Software must ensure that the software reset completes before performing DISPC operations.

The completion of the software reset for the video ports logic is indicated in the DSS0\_COMMON\_DSS\_SYSSTATUS[3-1] DISPC\_VP\_RESETDONE register bit-field.

#### 12.9.1.4.1.4 DISPC Power Management

DISPC supports a power management protocol with the device Power Sleep Controller (PSC).

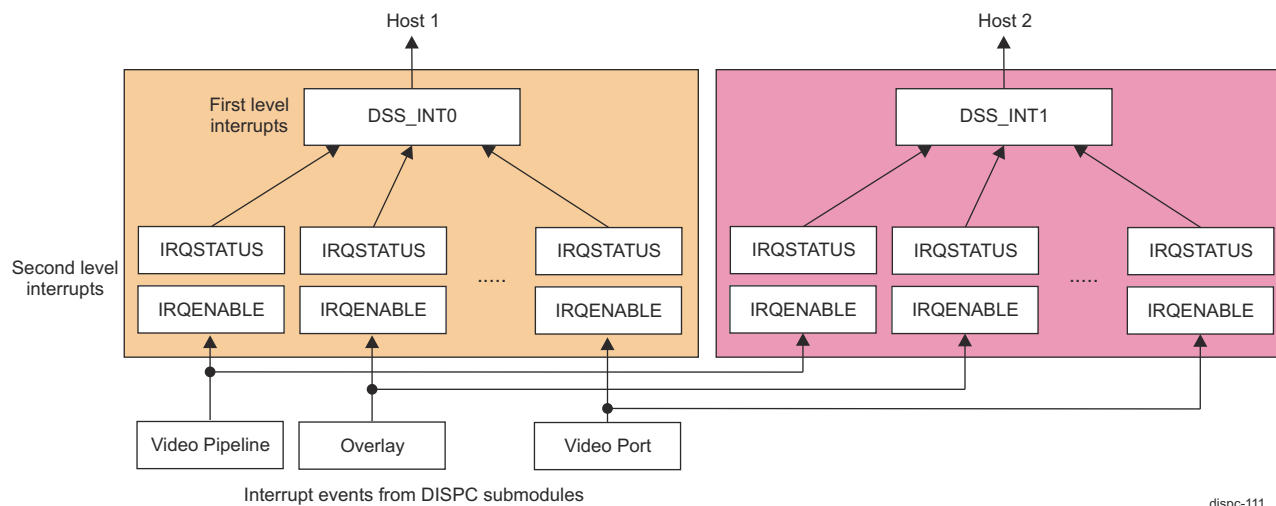

The (software) sequence, while performing a *clkstop\_req* to DISPC, is as follows:

1. Disable DISPC by programming the [0] ENABLE bit of DSS0\_VP\_CONTROL register to 0.
2. DISPC hardware completes the output of the current frame. Then hardware sets the DSS0\_COMMON\_DSS\_SYSSTATUS[9] DISPC\_IDLE\_STATUS register bit to 1.
3. Poll the DSS\_IDLE\_STATUS bit to ensure that DISPC is in idle mode.
4. PSC initiates *clkstop\_req* to DISPC.
5. DISPC hardware acknowledges with *clkstop\_ack* immediately.

#### 12.9.1.4.1.5 DISPC Interrupt Requests

DISPC supports two active-high level sensitive interrupt output lines: DSS\_INT0 and DSS\_INT1. All DISPC sub-module interrupt events are fully mapped to both of these interrupts, as shown in Figure 12-466. There are two sets of IRQ aggregating registers, one set for each interrupt line, which enable fully independent monitoring and control of the interrupt events by two processor hosts at device level.

**Figure 12-466. DISPC Interrupts Generation**

Each of the interrupt signals indicates that one or more interrupt events are detected by the hardware. Each event is independently maskable for each interrupt output.

There are two level of interrupt events. The first level is used to indicate common events and is also source for the second level of interrupts. The second level of interrupt events consists of status and enable interrupt registers for each video pipeline and each video port.

Table 12-420 describes the first level of interrupt events with associated mask and status register fields. Each interrupt event is captured in an interrupt status register. Equivalent IRQSTATUS\_RAW registers exist, which are updated even if interrupts are not enabled. This allows software to get access to updated status for all interrupt events.

**Table 12-420. DISPC Interrupts - First Level**

Interrupt Name	DSS_INT0 Interrupt Mask DSS0_COMMON_DISPC_IRQENAB LE_SET	DSS_INT0 Interrupt Status DSS0_COMMON_DISPC_IRQSTAT US	DSS_INT1 Interrupt Mask DSS0_COMMON1_DISPC_IRQ ENABLE_SET	DSS_INT1 Interrupt Status DSS0_COMMON1_DISPC_IRQ STATUS	Description

#### 12.9.1.4.1.6 DISPC DMA Engine

The DISPC DMA engine:

- Requests and supplies data from system memory to the VID and VIDL pipelines through the system interconnect, based on the configuration of the video pipeline settings.
- Is fully programmable and fetches pixel data via 128-bit requests using 1D burst.

Each pipeline has a dedicated DMA buffer and channel with independent settings. If a pipeline is disabled (that is, not used), then its DMA buffer can be assigned to another pipeline by configuring the DSS0\_COMMON\_DISPC\_GLOBAL\_BUFFER register. For example, unused buffers for VIDL pipeline can be used by VID pipeline.

Each DMA channel supports a total of 8 line buffers, each of which can store 1280 32-bit pixels.

- The size of the DMA buffer associated to the video lite pipeline (VIDL1) is 8x320x128-bit.
- The size of the DMA buffer associated to the video pipeline (VID) is 8x320x128-bit.

The DMA engine fetches encoded pixels from the system memory only when the video layer is enabled (a valid configuration has been programmed for the video layer), that is, the video window is present and the video pipeline is active.

##### 12.9.1.4.1.6.1 DISPC DMA Addressing and Bursts

For each line to be fetched, the DMA engine address generator:

- Calculates the pixel address
- Aligns the address
- Determines byte enable pattern
- Determines 1D burst length

The meaning of the address bits is as follows:

- Bits [31-0]: system (DDR) memory address (pixel address)
- Bits [37-32]: 32 bits + address extension

The address extension bits are defined by the programmable parameter DSS0\_VID\_BA\_EXT\_0/DSS0\_VID\_BA\_EXT\_1 and DSS0\_VID\_BA\_UV\_EXT\_0/DSS0\_VID\_BA\_UV\_EXT\_1 registers, optionally used to extend the BA memory addressing to 48-bit addressed external memory space (that is, to extend DISPC address space into 4GB+ space).

The DDR scan pixel addresses are generated by the DMA engine in order to read data from the system memory. The base address defines the start address of the first pixel, and then the address is incremented based on the number of pixels per line, offset between two consecutive lines and number of lines. The DSS0\_VID\_ROW\_INC register allow the access to a frame using 1D bursts (but as a two-dimensional block) by adding a fixed address offset at the end of a line. The ROW\_INC can also be used to skip lines from the input frame.

The byte address of each pixel in the frame buffer located in the system memory is determined by:

Pixel address = base\_address + x × (bpp/8) + y × (width × (bpp/8) + increment), where:

- "base\_address" corresponds to the base address defined by:
  - DSS0\_VID\_BA\_0/DSS0\_VID\_BA\_1[31-0] BA register bit-fields for all formats, and Y frame buffer in case of YUV-NV12 format. Optional extension bits in DSS0\_VID\_BA\_EXT\_0/DSS0\_VID\_BA\_EXT\_1 registers.
  - DSS0\_VID\_BA\_UV\_0/DSS0\_VID\_BA\_UV\_1[31-0] BA register bit-fields for UV frame buffer in case of YUV-NV12 format. Optional extension bits in DSS0\_VID\_BA\_UV\_EXT\_0/DSS0\_VID\_BA\_UV\_EXT\_1 registers.
- "bpp" corresponds to the number of bits per pixel defined by the DSS0\_VID\_ATTRIBUTES[6-1] FORMAT register bit-field.
- "width" corresponds to the number of pixels per line defined by the DSS0\_VID\_PICTURE\_SIZE[11-0] MEMSIZEX + 1 register bit-field.
- "increment" corresponds to the number of bytes to skip between two contiguous lines defined by the DSS0\_VID\_ROW\_INC[31-0] ROWINC – 1 register bit-field.
- "x" corresponds to the pixel position on the x-axis.

- "y" corresponds to the pixel position on the y-axis.

#### Note

Since the base address is aligned on pixel size boundary the horizontal resolution is one pixel. In case of YUV422 formats, the resolution is 4 bytes (2 pixels). In case of RGB24 packed format the resolution is 4 pixels. In case of Y frame buffer (YUV-NV12 format) the resolution is one byte. The vertical resolution is one line.

In case of YUV422 format, the number of pixels per line shall be a multiple of 2 pixels and the size of a pixel shall be considered as 2 bytes. In case of YUV420-NV12 or YUV420-NV21 format, the Y buffer shall be considered as an 8-bit frame buffer, and the CbCr shall be considered as a 16-bit frame buffer. The pixel size is 1 byte and 2 bytes, respectively for Y and CbCr.

For YUV420-NV12 or YUV420-NV21 format, the pixel values are defined in two separate buffers (Y and UV buffers). The first buffer consists of Y values (8 bits for each Y sample). The second buffer consists of CbCr values (16 bits for each pair of CbCr samples). The base address of the Y and UV buffers are as defined earlier in this section.

In case of interlaced mode, DSS0\_VID\_BA\_0 and DSS0\_VID\_BA\_UV\_0 registers define the base address of the even field, and DSS0\_VID\_BA\_1 and DSS0\_VID\_BA\_UV\_1 registers define the base address of the odd field.

The number of bytes to skip between pixels and between lines are defined using DSS0\_VID\_PIXEL\_INC and DSS0\_VID\_ROW\_INC registers, respectively. They define the values to be used for the Y buffer. For the CbCr buffer, the DSS0\_VID\_ROW\_INC\_UV register define the values.

Table 12-425 summarizes the register settings for a simple access of a picture in the system memory.

**Table 12-425. DISPC Register Settings for Accessing Image in Internal Memory**

Video Pipeline Registers	Value
DSS0_VID_BA_0 <sup>(1)</sup> and DSS0_VID_BA_1 <sup>(2)</sup>	The physical base address (PBA) of image in the memory for all formats and Y buffer.
DSS0_VID_BA_EXT_0 and DSS0_VID_BA_EXT_1	Address extension bits of PBA for all formats and Y buffer.
DSS0_VID_BA_UV_0 <sup>(1)</sup> and DSS0_VID_BA_UV_1 <sup>(2)</sup>	The physical base address (PBA) of UV buffers image in the memory.
DSS0_VID_BA_UV_EXT_0 and DSS0_VID_BA_UV_EXT_1	Address extension bits of PBA for UV buffers.
DSS0_VID_PIXEL_INC	1 or other in pixel incremental value.
DSS0_VID_ROW_INC	1 or other in row incremental value. Used for Y buffer.
DSS0_VID_ROW_INC_UV	1 or other in row incremental value. Used for UV buffer.

(1) Base address of even field, in case of interlaced mode.

(2) Base address of odd field, in case of interlaced mode.

An interconnect request (128 bits) corresponds to one or several pixels, depending on the bits per pixel. Therefore, the DMA engine determines the appropriate burst sequence to optimize the fetching of each new line. The DMA engine must prevent a single burst from crossing two lines. The DMA engine supports only 1D burst. 1D burst is used, if the fetch data is linear in memory. The size of the burst can be one of the following values: 1x128-bit, 2x128-bit, 4x128-bit, or 8x128-bit. Because the burst size must be aligned to the burst boundary, in case of misalignment, the DMA engine may issue one or more smaller burst requests.

#### 12.9.1.4.1.6.2 DISPC Read DMA Buffers

When the vertical front porch (VFP) period starts after the last horizontal front porch (HFP) of the last line, the DMA buffers are flushed according to the video port output associated with the particular video pipeline. The DMA engine restarts fetching data from the memory through the DSS Initiator port. Enabling or disabling the DISPC flushes the DMA buffers.

Programmable high and low thresholds, independent for each DMA buffer, are used by the DMA engine to start and stop requesting data through the Initiator port.

- When low threshold (set in the DSS0\_VID\_BUF\_THRESHOLD [15-0] BUFLOWTHRESHOLD register bit-field) is reached, the DMA engine starts a request on the device interconnect to fill the DMA buffer.
- When high threshold (set in the DSS0\_VID\_BUF\_THRESHOLD [31-16] BUFHIGHTHRESHOLD register bit-field) is reached, the DMA engine stops requesting encoded pixels.

#### Note

The configuration of thresholds for optimal performance can be defined using the DSS0\_VID\_BUF\_SIZE\_STATUS [15-0] BUFSIZE register field value, as follows:

- For high threshold: BUFSIZE (in number of 128-bit words) – 1
- For low threshold: BUFSIZE (in number of 128-bit words) – burst size (in number of 128-bit words)

The following limitations for BUFLOWTHRESHOLD values must be also considered:

- If the scaler in VID pipeline is disabled, BUFLOWTHRESHOLD can be programmed as low as interconnect latency and pixel output rate allow it.
- If the scaler in VID pipeline is enabled, BUFLOWTHRESHOLD must be programmed to guarantee that at least four full lines can be stored.

To avoid underflow at the beginning of a frame and have sufficient encoded pixel data to start some processing, a preloading of the DMA buffer is configurable between a fixed value of bytes and the high threshold value. The preload ensures a minimum number of pixels present in the buffer. When the preload value is reached, the associated channel will start pulling pixels out of the DMA buffer. To enable the preload based on the value entered in the DSS0\_VID\_PRELOAD [11-0] PRELOAD register bit-field, the DSS0\_VID\_ATTRIBUTES [19] BUFPRELOAD register bit must be set to 0x0.

The vertical blanking between two frames must be long enough to allow fetching the number of pixels defined by the DSS0\_VID\_PRELOAD register and preloading the whole video pipeline. If the value set in the preload register is greater than some overflow conditions detected by the hardware, then data will start to be read from the video DMA buffer before the preload value is reached. If SYNCLOST\_IRQ event occurs the video buffer needs to be increased (buffer merge). Preload value must be greater or equal to low threshold, and smaller or equal to high threshold value.

#### Note

When self-refresh mode is selected (which means that the data in the DMA buffer are used for multiple frames) the DMA buffers are not flushed at the end of each frame. Each DMA buffer has an independent control for selecting the self-refresh mode. For more information, see [Section 12.9.1.4.1.6.8.2, DISPC DMA Ultra-Low Power Mode](#).

#### 12.9.1.4.1.6.3 DISPC Flip/Mirror Support

DISPC supports on-the-fly source image flip along the x/y-axis for 8-bit/component formats (ARGB or YUV) to create a mirror effect on the source data. The DMA engine reads the source frame from right to left by requesting burst transfers for each line in negative address increments while performing each burst transfer as a linear incremental burst. The read data is repacked and stored in the line buffer incrementally - effectively storing the frame as a flipped image for the processing pipeline. The configuration of the flip/mirror operation is explained in [Table 12-426](#).

**Table 12-426. DISPC Flip/Mirror Configuration**

Flip Direction	FLIP Bit	Base Address	Byte Increment
Along Y-axis (vertical mirror)	1	Start of window	1
Along X-axis (horizontal mirror)	0	Start of last line of the window	-(2*(width of the line in bytes))

**Table 12-426. DISPC Flip/Mirror Configuration (continued)**

Flip Direction	FLIP Bit	Base Address	Byte Increment
Along both X-axis and Y-axis (horizontal and vertical mirror)	1	Start of last line of the window	-{2(width of the line in bytes)}

In [Table 12-426](#):

- The FLIP bit is located in DSS0\_VID\_ATTRIBUTES register.
- The base address of the video buffer must be configured as explained in [Section 12.9.1.4.1.6.1, DISPC DMA Addressing and Bursts](#).
- The number of bytes to increment at the end of the row in the video buffer can be configured through DSS0\_VID\_ROW\_INC and DSS0\_VID\_ROW\_INC\_UV registers. For more information, see [Section 12.9.1.4.1.6.1, DISPC DMA Addressing and Bursts](#), and [Section 12.9.1.4.1.6.4, DISPC DMA Predecimation](#).

#### 12.9.1.4.1.6.4 DISPC DMA Predecimation

The predecimation process consists of downscaling an image by fetching only the necessary pixels out of the memory. Vertical and horizontal predecimation are possible:

- Vertical predecimation: The picture stored in memory can be predecimated vertically by skipping lines. Burst mode is used to fetch the data when skipping lines. Only the lines that will be used by the DISPC are fetched from memory; the other lines are skipped. The DMA engine sends requests only for the useful lines using 1D burst. The base address indicates the first valid pixel to fetch from memory. The number of lines to skip is set in the DSS0\_VID\_ROW\_INC and DSS0\_VID\_ROW\_INC\_UV registers.
- Horizontal predecimation: When fetching data from memory, it is possible to skip 1 out of 2 pixels, up to 1 of 2047 pixels, by setting the DSS0\_VID\_PIXEL\_INC register to the number of pixels to skip (n), multiplied by the size of a pixel (in bytes), +1. The condition to generate a burst is that there is at least one useful pixel per 128-bit OCP request. Therefore, when the pixels are 16/32-bit, the maximum number of pixels that can be skipped is 8/4. If PixelWidthInBytes+BytesToSkip is greater than 16, the programmed burst is changed into single request.

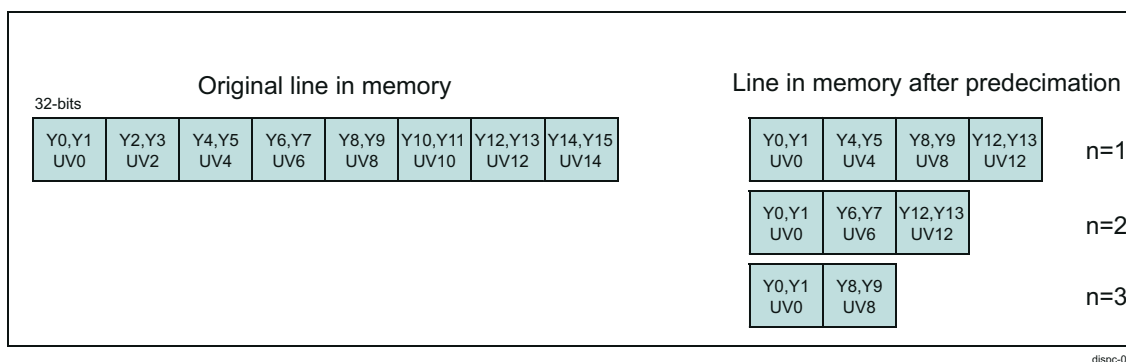

No decimation is supported when the input format is 1, 2, 4, or 8-bit BITMAP.

For RGB and YUV420 data formats, each pixel data container in memory holds 1 pixel. Thus, when configuring the DSS0\_VID\_PIXEL\_INC register, the value of n equals the number of pixels to skip:

- For RGB format, one pixel data container = 32 bits = 1 pixel
- For YUV format:
  - One Y pixel data container = 8 bits = 1 pixel
  - One UV pixel data container = 16 bits = 1 pixel

For YUV422 format, each 32-bit pixel data container holds the Luma components for 2 pixels, and the Chrominance component of 1 pixel (see [Figure 12-467](#)). Therefore, for the valid values of the PIXELINC bit field in the case of the following YUV422 format, caution must be taken because n equals the number of pixel data containers to skip, and not the number of pixels:

- For n = 1, PIXELINC = 5
- For n = 2, PIXELINC = 9
- For n = 3, PIXELINC = 13
- For n = 4, PIXELINC = 17, etc.

**Figure 12-467. DISPC YUV422 Predecimation**

#### 12.9.1.4.1.6.5 DISPC DMA MFLAG Mechanism

The MFLAG mechanism allows a dynamic increase of the priority of DISPC real-time traffic, when required, based on the fullness of the DISPC DMA read buffers.

The MFLAG mechanism is used when fullness of the DMA buffers is critical (close to underflow). The mechanism is implemented for all DMA buffers of the video pipelines.

Programmable buffer thresholds (forming hysteresis) are used to indicate when a local MFLAG signal is generated. The 1-bit MFLAG signal is generated on DISPC Initiator port in order to inform the system that the outstanding requests from DISPC shall be considered with higher priority in order to get faster interconnect responses. The MFLAG signal is asynchronous to any ongoing interconnect transaction.

Each pipeline maintains its own MFLAG bit. The MFLAG bit is asserted depending on the fullness of the DMA buffers associated with the pipeline and depending on the thresholds programmed by software. All MFLAG signals are OR-ed together to generate the single 1-bit MFLAG for the Initiator port connected to the DISPC DMA engine.

The threshold for video pipelines corresponds to the fullness of the associated DMA buffer, and is defined by two threshold parameters:

- **HT\_MFLAG:** High threshold.
  - For read access from video pipelines, when the pipeline buffer reaches the programmed value, the associated local MFLAG signal goes low (deasserted).
  - This threshold can be programmed in the DSS0\_VID\_MFLAG\_THRESHOLD [31-16] HT\_MFLAG register field.
- **LT\_MFLAG:** Low threshold.
  - For read access from video pipelines, when the pipeline buffer reaches the programmed value, the associated local MFLAG signal goes high (asserted).
  - This threshold can be programmed in the DSS0\_VID\_MFLAG\_THRESHOLD [15-0] LT\_MFLAG register field.

Summary of the MFLAG value, based on DMA read buffer fullness:

- If DMA read buffer fullness < LT\_MFLAG, then MFLAG signal = 1
- If LT\_MFLAG < DMA read buffer fullness < HT\_MFLAG, then MFLAG signal = 1
- If DMA read buffer fullness > HT\_MFLAG, then MFLAG signal = 0

By default, the MFLAG mechanism is disabled (DSS0\_COMMON\_DISPC\_GLOBAL\_MFLAG\_ATTRIBUTE[1-0] MFLAG\_CTRL register field = 0x0), and the MFLAG signal is low (de-asserted). The arbitration scheme for the pipelines is the same as described in [Section 12.9.1.4.1.6.7, DISPC DMA Arbitration](#). That is, round-robin either between high-priority pipelines, or between normal-priority pipelines (if all pipelines are of normal priority).

When the MFLAG\_CTRL register field is set to 0x2, the MFLAG mechanism is enabled, and the MFLAG signal is dynamically set to 0 or 1, depending on DMA buffer fullness and programmed threshold levels, as explained previously in this section. In this case, the arbitration scheme for the pipelines is round-robin between those

high-priority pipelines, which have asserted their local MFLAG signals. If there are no high-priority pipelines with their local MFLAG signals asserted, then the arbitration scheme is the same as described in [Section 12.9.1.4.1.6.7, DISPC DMA Arbitration](#).

The DSS0\_COMMON\_DISPC\_GLOBAL\_MFLAG\_ATTRIBUTE[6] MFLAG\_START bit defines the following additional rules for the MFLAG mechanism:

- If the MFLAG\_START bit is set to 0x0 (default value), then when the DMA buffer is empty at the beginning of the frame, the MFLAG signal of each pipeline is kept at 0 until PRELOAD is reached (for more information on preloading, see [Section 12.9.1.4.1.6.2, DISPC Read DMA Buffers](#)). Then, based on the setting of the DSS0\_COMMON\_DISPC\_GLOBAL\_MFLAG\_ATTRIBUTE[1-0] MFLAG\_CTRL register field, the MFLAG signal is generated and DISPC internal logic is arbitrating between pipeline requests.
- If the MFLAG\_START bit is set to 0x1, then even in the beginning of the frame when the DMA buffer is empty, the configuration of DSS0\_COMMON\_DISPC\_GLOBAL\_MFLAG\_ATTRIBUTE[1-0] MFLAG\_CTRL register field determines the generation of the MFLAG signal.

#### 12.9.1.4.1.6.6 DISPC DMA Priority Requests Control

The DSS0\_COMMON\_DSS\_CBA\_CFG register controls the priority level for DMA requests going out to the memory through the system interconnect.

As explained in [Section 12.9.1.4.1.6.5, DISPC DMA MFLAG Mechanism](#), the DISPC Initiator port generates a 1-bit MFLAG output signal to raise the priority of all requests made on that port, if any of its DMA buffers runs critically low (determined by a set of user programmable threshold values for each buffer).

DSS uses the MFLAG signal from DISPC to set a 3-bit priority level output (*Mpriority*) for the Initiator port to either a low or high value (configurable in DSS0\_COMMON\_DSS\_CBA\_CFG[2-0] PRI\_LO and [5-3] PRI\_HI register fields with optional values of 0~7) as follows:

- When MFLAG = 0, the PRI\_LO register field determines the value of the Mpriority output for the normal transactions.
- When MFLAG = 1, the PRI\_HI register field determines the value of the Mpriority output for the high-priority transactions.

This Mpriority output directly drives the respective input of the system interconnect port, which corresponds to the DISPC DMA Initiator port.

#### CAUTION

Upon a hardware reset, DSS0\_COMMON\_DSS\_CBA\_CFG[2-0] PRI\_LO and [5-3] PRI\_HI register fields are set by default to 4 and 1, respectively. Afterwards, these priority level register fields can only be modified by a secure host.

#### 12.9.1.4.1.6.7 DISPC DMA Arbitration

The read requests sent to the system interconnect are pipelined and arbitrated in a round-robin scheme. The default arbitration scheme can be modified by setting the priority attribute of each pipeline as defined in the DSS0\_VID\_ATTRIBUTES[23] ARBITRATION register bit.

By default, all pipelines have the same priority (normal priority), which means all pipeline requests are treated in a round-robin order manner. If one or more pipelines require a higher number of requests going to the system interconnect, its priority can be moved up to high priority. In this case, the high-priority pipeline is granted access before any pipeline in normal priority. If more than one active pipeline is in high priority, then the behavior is the same as all active pipelines in normal priority. Normal active pipelines are not treated until all high active pipelines are finished. The ARBITRATION bit cannot be modified during the entire frame.

#### 12.9.1.4.1.6.8 DISPC DMA Power Modes

##### 12.9.1.4.1.6.8.1 DISPC DMA Low Power Mode

Each DMA buffer can be associated to the pipeline or merged with other DMA buffers. The total number of DMA buffers for each individual pipeline is from 0 (pipeline inactive) to number of pipelines (in that case all the DMA buffers are associated to a single pipeline) supported by the DMA engine.

The user is responsible for configuring correctly the number of DMA buffers to guarantee no underflow. The DMA buffers allocated to each pipeline shall be greater or equal to the minimum required DMA buffer to support the throughput and the system latency.

When the size of the buffer is changed, the thresholds shall be re-programmed by the user to reflect the new DMA buffer configuration. Increasing the size of the buffer used enables to put the interconnect and the system memory in standby for a longer period, therefore, leading to a possible system power reduction.

The low power mode of the DISPC DMA can also be achieved by keeping the thresholds (bit-fields [31-16] BUFHIGHTHRESHOLD and [15-0] BUFLOWTHRESHOLD of DSS0\_VID\_BUF\_THRESHOLD register) farther apart. The farther they are there will be longer periods of idling on the DMA fetch interface resulting in lower power. The user needs to ensure a minimum value of BUFLOWTHRESHOLD, so that there is no underflow.

##### 12.9.1.4.1.6.8.2 DISPC DMA Ultra-Low Power Mode

In ultra-low power mode, the system interconnect is used to fill up the DMA buffers to store all the data required to display a full frame. Then, the system interconnect is not used anymore to fetch new pixels for the following frames. The data are fetched once into the DMA buffer and then the following frames re-use the DMA buffer to display on the screen.

The programming of the ultra-low power mode is independent for each pipeline and is achieved via the DSS0\_VID\_ATTRIBUTES[24] SELFREFRESH register bit. One pipeline may have all frame pixels into the DMA buffer and other pipeline may have to refill the DMA buffers along the display scan, because the frame buffer is too big to be stored in the DMA buffer.

Two ultra-low power modes can be entered, manual or automatic mode:

- **Manual self-refresh mode:** Starting self-refresh mode is done manually by setting the SELFREFRESH bit to 0x1 after capturing a frame in the DMA buffers. Self-refresh mode is stopped by setting the SELFREFRESH bit to 0x0. Software must first disable the SELFREFRESH bit during at least one frame in order to capture the data (by setting the GOBIT register bit of the video port the pipeline is associated with). Once the DSS0\_VP\_CONTROL[5] GOBIT bit has been set, the software must read the GOBIT bit to ensure that the frame has been loaded into the buffer, then it can set the SELFREFRESH bit to 1. Once SELFREFRESH is enabled, the fetch of data from the system memory is stopped for the following frames. The software needs to reset the SELFREFRESH bit in order to restart fetching data from system memory.
- **Automatic self-refresh mode:** By setting the DSS0\_VID\_ATTRIBUTES[17] SELFREFRESHAUTO bit to 0x1, the transition from disabled to enabled for self-refresh mode is controlled by hardware. This allows the software to reset the SELFREFRESH bit to "disabled", and then automatically after the fetch of the first frame the hardware switches back SELFREFRESH bit to "enabled". The SELFREFRESH must be disabled during at least one frame in order to capture the data, so software must reset the bit to 0 every time the data in the DMA buffer needs to be updated. The hardware reads the data inside the DMA buffer without accessing the interconnect and system memory during the frame, then modifies the SELFREFRESH bit to reflect the current state of the self-refresh mode by setting the bit to 0x1.

##### 12.9.1.4.1.7 DISPC Pixel Data Formats

The video pipelines support various types of memory formats, as listed in [Table 12-427](#).

For BITMAP formats the nibble mode (pixels in each byte are packed in reverse order) can be enabled by setting the DSS0\_VID\_ATTRIBUTES[10] NIBBLEMODE register bit to 0x1.

The pixel data format can be selected by loading the corresponding value from [Table 12-427](#) in the DSS0\_VID\_ATTRIBUTES [6-1] FORMAT register field.

**Table 12-427. DISPC Supported Pixel Data Formats**

FORMAT Register Field Value		Pixel Format <sup>(4)</sup>	Component Bit Depth
Alpha	Alpha-X		
0x00	0x20	ARGB16-4444	4

0x17	NA	BGR565A8 <sup>(1)</sup>	5(R,B), 6(G), separate 8(A)
Packed	Planar	Pixel Format	Component Bit Depth
0x3E	NA	YUV422-YUV2	8/10/12 <sup>(3)</sup>
0x3F	NA	YUV422-UYVY	8/10/12 <sup>(3)</sup>
NA	0x3D	YUV420-NV12	8/10/12 <sup>(3)</sup>
NA	See <sup>(2)</sup>	YUV420-NV21	8/10/12

- (1) The video pipelines support an optional 8-bit Alpha plane (separate buffer), if the pixel format of the source/destination buffer is either RGB16-565 or BGR16-565.
- (2) NV21 formats for YUV420 are indirectly supported through chroma swapping during the color space conversion.
- (3) 10bit/12bit versions of these YUV formats are also supported in both packed and unpacked (in 16-bit container) formats. For unpacked formats, both LSB or MSB alignments are supported. These configurations are set using a separate configuration register DSS0\_VID\_ATTRIBUTES2). Default is 8-bit packed format support.
- (4) All RGB formats with alpha component include both pre/non-pre-multiplied data support. Also, alpha can be disabled to work as X (can be replaced with global alpha value).

Figure 12-468 shows the pixel data memory organization for the bitmap pixel formats.

## YUV 4:2:0 – NV12 (12-bit) (0x3D)

dispc-312

**Figure 12-479. DISPC YUV 12-bit Pixel Formats 2**

Figure 12-480 through Figure 12-482 show the pixel data memory organization for the YUV 10-bit/12-bit unpacked pixel formats in 16-bit container, together with some specific register settings.

YUV 10-bit/12-bit unpacked formats have the same component packing order as 8-bit formats except that each component is stored in a 16-bit container (with MSB or LSB bits within the 16-bit container not used depending on the MSB/LSB alignment).

ATTRIBUTES2.YUV\_SIZE = 1 or 2 (10b or 12b)

ATTRIBUTES2.YUV\_MODE = 1 (Unpacked)

ATTRIBUTES2.YUV\_ALIGN = 0 or 1 (LSB or MSB aligned)

YUV422 (1-plane)

10-bit unpacked LSB aligned

YUV2 4:2:2 – 10bit (0x3E)

**Figure 12-481. DISPC YUV 10-bit/12-bit Unpacked Pixel Formats 2**

### 12.9.1.4.1.8 DISPC Video Pipelines

DISPC includes two input pipelines:

- Video pipeline (VID)
- Video lite pipeline (VIDL1)

The video pipeline (VID) consists of:

- VC-1 range mapping unit for YUV422/YUV420 input formats;
- Replication logic for ARGB input formats;
- One 256 x 24-bit entries Color Look-up Table (CLUT);
- Polyphase-filter based resizer (scaler) supporting chroma upsampling;
- Color Space Conversion (CSC) unit (YUV to RGB), which can be used also for programmable BCHS (Brightness/Contrast/Hue/Saturation) control;

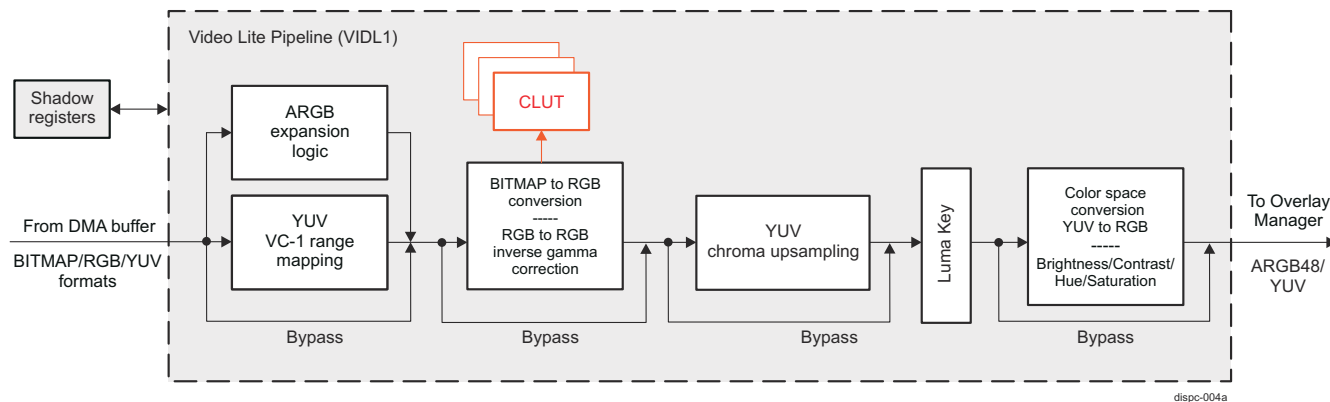

The video lite pipeline (VIDL1) is identical to the video pipeline (VID), except for:

- Polyphase-filter based resizer (scaler) is not included;
- Chroma upsampling is done using dedicated YUV420-to-422 and YUV422-to-444 upsamplers (instead of using the scaler);

Each pipeline processing block can be independently bypassed.

**Figure 12-483. DISPC Video Pipeline Configuration**

**Figure 12-484. DISPC Video Lite Pipeline Configuration**

The input of each pipeline is connected to the video DMA buffer controller. Each pipeline pixel output is always connected to the overlay managers (OVR1 and OVR2). Each pipeline configuration supports various BITMAP, RGB (ARGB and RGBA), and YUV formats, as listed in [Table 12-427, DISPC Pixel Data Formats](#).

The 256-entry CLUT is either used to convert BITMAP (1, 2, 4, or 8-bit indexed formats) into RGB format, or for RGB to RGB inverse gamma correction. For a BITMAP format data, scaling is not supported. Scaling and color

look-up table features are mutually exclusive. If the color look-up feature is enabled, then video pipeline scaler has to be disabled.

For chroma sub-sampled YUV formats (YUV422 and YUV420-NV12/NV21):

- VID pipeline: the scaler unit upsamples the chrominance data using both vertical and horizontal polyphase filters;
- VIDL1 pipeline: dedicated YUV420 to YUV422, and YUV422 to YUV444 chroma upsamplers are used;

For ARGB source data with less than/equal to 10-bit component data size the replication logic (ARGB expansion) converts the data to ARGB48 by replicating the MSBs into the LSBs:

- When scaling is disabled (or no scaler supported), the resulting ARGB48 data is directly provided to the pipeline output;
- When vertical scaling is engaged, the resulting ARGB48 data is first truncated to ARGB8888, and then converted to ARGB10101010 (by MSBs replication into LSBs), before being fed to the vertical scaler input;
- When vertical scaling is disabled, but horizontal scaling is engaged, the resulting ARGB48 data is directly provided to the horizontal scaler input;

A pipeline can be enabled by setting the DSS0\_VID\_ATTRIBUTES[0] ENABLE register bit. If the video pipeline is disabled, the video window does not exist on the screen and the whole video pipeline and its DMA are inactive. Prior to enabling the video layer a valid configuration has to be set by the user.

#### Note

The DISPC input pipelines, VID and VID1L, will be commonly referred to as *video pipeline (VID)* in the following sections. Any differences in their functionality will be highlighted.

#### 12.9.1.4.1.8.1 DISPC VID Replication Logic

The replication logic (ARGB expansion) converts ARGB pixel formats into ARGB48 format by replicating the MSBs into the LSBs. The logic is always enabled.

Table 12-428 shows how some of the ARGB formats supported by video pipelines are remapped into ARGB48 by default.

**Table 12-428. DISPC VID Replication: ARGB Pixel Formats Remapping into ARGB48-12121212**

Formats	A[11:0]	R[11:0]	G[11:0]	B[11:0]

RGBA16-4444	A[3:0]A[3:0]A[3:0]	R[3:0]R[3:0]R[3:0]	G[3:0]G[3:0]G[3:0]	B[3:0]B[3:0]B[3:0]
ARGB32-8888	A[7:0]A[7:4]	R[7:0]R[7:4]	G[7:0]G[7:4]	B[7:0]B[7:4]

#### 12.9.1.4.1.8.2 DISPC VID VC-1 Range Mapping Unit

The VC-1 range mapping unit is used when the video frame picture is decoded using a VC-1 codec by the video accelerator. It remaps the Y, Cb, and Cr components to the full range (from the reduced data range) before displaying. The unit is used primarily for YUV4:2:0-NV12 (NV21) pixel format, but also can be applied to YUV4:2:2 pixel formats (YUV2 and UYVY).

The VC-1 range mapping unit is enabled by setting the DSS0\_VID\_ATTRIBUTES2 [0] VC1ENABLE bit to 0x1. The VC-1 range mapping must be enabled only for 8 bits/component YUV input data.

The DSS0\_VID\_ATTRIBUTES2 [3:1] VC1\_RANGE\_Y and [6:4] VC1\_RANGE\_CBCR bit fields are two 3-bit values programmed by the user.

The equations for the mapping process are:

$$Y_{out} = \text{CLIP}((((Y_{int} - 128) \times (VC1\_RANGE\_Y + 9) + 4) / 8) + 128)$$

$$C_b = \text{CLIP}((((C_b - 128) \times (VC1\_RANGE\_CBCR + 9) + 4) / 8) + 128)$$

$$C_r = \text{CLIP}((((C_r - 128) \times (VC1\_RANGE\_CBCR + 9) + 4) / 8) + 128)$$

#### Note

The input and output pixel values are unsigned (Y, Cr, and Cb).

The function CLIP () clips to 0 or 255 when minimum or maximum, respectively, is reached. Otherwise, the resulting output remains identical.

#### 12.9.1.4.1.8.3 DISPC VID Color Look-Up Table (CLUT)

The video pipeline supports a look up table to perform either of the following operations:

- Conversions of BITMAP formats (1, 2, 4, or 8-bit indexed) into RGB24 format (CLUT mode), or
- Inverse gamma correction on non-linear RGB source data (gamma mode)

The look-up table consists of 3 separate 256 x 8-bit memories and is indexed either by the source BITMAP data or by R/G/B component data. The table is loaded through direct register access by writing to the CLUT registers.

The sequence to load the table is:

1. SW writes (only writes are supported) 32-bit values using single access, or burst access in linear increment burst mode, into DSS0\_VID\_CLUT\_0 through DSS0\_VID\_CLUT\_15 registers. The LSB 24 bits [23:0] are used for the value, and the MSB 8 bits [31:24] are used for the index into the table (see [Figure 12-485](#)).
2. Loop to Step 1, if there is a new access to the CLUT registers. Software can access other registers between two accesses to the CLUT registers.

SW needs to ensure that there is no visible effect when modifying the table, since it is not under hardware control.

The usage of the look-up table in CLUT mode is activated when a BITMAP format is selected in the DSS0\_VID\_ATTRIBUTES[6:1] FORMAT register bit-field.

The usage of the look-up table for RGB inverse gamma correction can be enabled by setting DSS0\_VID\_ATTRIBUTES[30] GAMMAINVERSION register bit.

**Figure 12-485. DISPC VID CLUT/Gamma Data Memory Organization**

#### Note

Scaling and color look-up table features are mutually exclusive. If color look-up feature is enabled, then video pipeline scaler has to be disabled.

#### 12.9.1.4.1.8.4 DISPC VID Chrominance Resampling

##### 12.9.1.4.1.8.4.1 Chrominance Resampling for VID Pipeline

The chrominance resampling from 8-bpc or 10-bpc to 12-bit color components is always performed using filtering (the scaler unit filter). Chrominance resampling and rescaling can be combined to support native rescaling of YUV formats.

The usage of the scaler unit for resampling the chrominance of YUV420 and YUV422 is shown in [Figure 12-486](#) and [Figure 12-487](#), respectively. The settings of the scaler unit to perform chrominance resampling are described in [Section 12.9.1.4.1.8.5, DISPC VID Scaler Unit](#).

**Figure 12-486. DISPC VID YUV420 to ARGB48 Using Scaler Unit for Resampling Chrominance**

**Figure 12-487. DISPC VID YUV422 to ARGB48 Using Scaler Unit for Resampling Chrominance**

The vertical scaler is not a mandatory block for resampling the chrominance of YUV422 data, as shown in [Figure 12-487](#).

#### 12.9.1.4.1.8.4.2 Chrominance Resampling for VIDL1 Pipeline

VIDL1 pipeline does not include a scaler unit. Chroma upsampling is done using dedicated YUV420 to YUV422, and YUV422 to YUV444 chroma upsamplers.

VIDL1 pipeline converts YUV420 (chroma) data to YUV422 (chroma) using a simple vertical average filter (average of two adjacent chroma lines to generate a missing line except for the very bottom line which is generated by repeating the previous chroma line). If the video image is a sub-image of a larger video frame data, then the vertical Luma line offset from the top should be an even number.

VIDL1 pipeline converts YUV422 data to YUV444 format using a 4-tap filter (implementing the Catmull-Rom algorithm) to generate missing chroma data as shown below:

$$\text{Cout}[2*i] = \text{Cin}[i]$$

$$\text{Cout}[2*i+1] = \text{CLIP} \left( -1/16 * \text{Cin}[i-1] + 9/16 * \text{Cin}[i] + 9/16 * \text{Cin}[i+1] - 1/16 * \text{Cin}[i+2] \right)$$

The missing chroma data is generated as a simple weighted average of the surrounding 4 chroma values, which is equivalent to a 4x1 filter kernel with values: [-1/16, 9/16, 9/16, -1/16]. In this algorithm, edge effects are treated by repeating the first and last pixel.

#### 12.9.1.4.1.8.5 DISPC VID Scaler Unit

#### Note

Only VID pipeline includes a resizer unit (scaler). VIDL1 pipeline does not include a scaler.

The programmable scaler filter works with all supported video formats, including formats with alpha channel. Alpha channel is scaled with the same parameters as RGB color components. For the YUV formats, Y and Cb/Cr are processed independently. An RGB 64-bit source (16 bits per component) is truncated to 8-bit, if scaler is enabled. Otherwise, it will be truncated to ARGB48 format in the scaler bypass mode. 10-bit/12-bit YUV source is also truncated to 8-bit, since the scaler is enabled to either upsample the chroma component and/or resize the YUV frame data directly.

The filter is based on a finite impulse response (FIR) filter with 16 phases. The filter is a 5-tap for horizontal filtering, and can be configured for 3 or 5 taps for vertical filtering. The filtering can be used for various processing:

- Up-sampling of the picture
- Down-sampling of the picture
- Anti-aliasing reduction
- Chrominance resampling in case of YUV data formats

The following limitations must be considered:

- The up-sampling ratio is up to x16.
- The down-sampling ratio using 3-tap configuration is down to x0.5 for RGB format.
- The down-sampling ratio using 5-tap configuration is down to x0.25 for RGB format.

### Note

The user must set the correct size and position of the original video before resize in order for the up-sampled/down-sampled video to be displayed inside the screen boundaries.

Figure 12-488 shows an example of video up-sampling, with corresponding video window attributes.

**Figure 12-488. DISPC Video Window Attributes**

The video window attributes can be configured in the following register bit-fields:

- Source data format (input to the scaler unit) in DSS0\_VID\_ATTRIBUTES [6-1] FORMAT bit-field
- Video picture width in system memory (frame buffer) in DSS0\_VID\_PICTURE\_SIZE [11-0] MEMSIZEX bit-field. The window width is from 1 up to 4096 pixels. All the integer values in the range [1:4096] are allowed except for YUV 422 formats. In case of YUV2422 and UYVY422 formats the width has to be a multiple of 2 pixels.
- Video picture height in system memory (frame buffer) in DSS0\_VID\_PICTURE\_SIZE [27-16] MEMSIZEY bit-field. The window width is from 1 up to 4096 pixels. All the integer values in the range [1:4096] are allowed.
- Video window width at pipeline output (after resizing) in DSS0\_VID\_SIZE [11-0] SIZEX bit-field. The window width is from 1 up to 4096 pixels. All the integer values in the range [1:4096] are allowed up to the screen width minus the horizontal start location of the window on the screen.

- Video window height at pipeline output (after resizing) in DSS0\_VID\_SIZE [27-16] SIZEY bit-field. The window height is from 1 up to 4096 pixels. All the integer values in the range [1:4096] are allowed up to the screen height minus the vertical start location of the window on the screen.
- Video window overlay X-position in DSS0\_OVR\_ATTRIBUTES\_0 [17-6] POSX bit-field. See [Section 12.9.1.4.1.9, DISPC Overlay Managers](#).
- Video window overlay Y-position in DSS0\_OVR\_ATTRIBUTES\_0 [30-19] POSY bit-field. See [Section 12.9.1.4.1.9, DISPC Overlay Managers](#).
- For configuration of LPP and PPL video port output display parameters, see [Section 12.9.1.4.1.10.7, DISPC VP Timing Generator and Display Panel Settings](#).

For vertical up-sampling and down-sampling in a 3-tap configuration, the equations are:

<p style="text-align: center;">For RGB formats</p> $Aout(n) = \left( \sum_{i=-1}^{i=1} Ci(\Phi) \times Ain(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $Rout(n) = \left( \sum_{i=-1}^{i=1} Ci(\Phi) \times Rin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $Gout(n) = \left( \sum_{i=-1}^{i=1} Ci(\Phi) \times Gin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $Bout(n) = \left( \sum_{i=-1}^{i=1} Ci(\Phi) \times Bin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$	<p style="text-align: center;">For YUV formats</p> $Yout(n) = \left( \sum_{i=-1}^{i=1} Cyi(\Phi_y) \times Yin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $Cbout(n) = \left( \sum_{i=-1}^{i=1} Cci(\Phi_c) \times Cbin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $Crout(n) = \left( \sum_{i=-1}^{i=1} Cci(\Phi_c) \times Crin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$
--	---

Component	Vertical	Horizontal
Cwidth (Coefficient Width)	10 bits	10 bits
InWidth (Input Width)	10 bits	12 bits
OutWidth (Output Width)	12 bits	12 bits

dispc-013

(26)

For vertical and horizontal up-sampling and down-sampling in a 5-tap configuration, the equations are:

<p style="text-align: center;">For RGB formats</p> $Aout(n) = \left( \sum_{i=-2}^{i=2} Ci(\Phi) \times Ain(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $Rout(n) = \left( \sum_{i=-2}^{i=2} Ci(\Phi) \times Rin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $Gout(n) = \left( \sum_{i=-2}^{i=2} Ci(\Phi) \times Gin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $Bout(n) = \left( \sum_{i=-2}^{i=2} Ci(\Phi) \times Bin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$	<p style="text-align: center;">For YUV formats</p> $Yout(n) = \left( \sum_{i=-2}^{i=2} Cyi(\Phi_y) \times Yin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $Cbout(n) = \left( \sum_{i=-2}^{i=2} Cci(\Phi_c) \times Cbin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$ $Crout(n) = \left( \sum_{i=-2}^{i=2} Cci(\Phi_c) \times Crin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$
--	---

Component	Vertical	Horizontal
Cwidth (Coefficient Width)	10 bits	10 bits
InWidth (Input Width)	10 bits	12 bits
OutWidth (Output Width)	12 bits	12 bits

dispc-012

(27)

### Note

The pixel (n + 1) is the previous pixel with respect to pixel (n). The line (n + 1) is the previous line with respect to line (n).

The coefficients Ci() depend on the phase between input and output pixels.

The coefficients are different for Y and Cr/Cb filtering because the calculations are independent due to the chrominance resampling for YUV422 and YUV420.

First, the vertical filter is applied to the encoded input pixel data, and then the horizontal filter is applied on the resulting pixel values to generate the output pixel values. The vertical input of the filter consists of:

- Six lines of  $1280 \times 32$  bits for 5-tap configuration
- Three lines of  $2560 \times 32$  bits for 3-tap configuration

Table 12-429 lists some of the scaler supported configurations.

**Table 12-429. DISPC VID Line Buffer Width for Scaler Unit**

Pixel Format	Maximum Input Width (Pixels) for 5-tap	Maximum Input Width (Pixels) for 3-tap
32 bits per pixel (ARGB32-8888, ARGB-2101010, etc.)	1280 pixels wide <sup>(1)</sup>	2560 pixels wide
YUV420, YUV422	2560 pixels wide	4096 pixels wide

- (1) For the 5-tap configuration, the 6th video line is used on the output of the horizontal scaler, so that horizontal down-scaling can be supported with a minimum clock ratio equal to 1. The maximum output width is limited to 1280 pixels in order to be able to support clock ratio of 1 due to the 6th video line buffer. The 6th video line is also used in order to start the next output line generation while the video pipeline output is being stalled by the overlay manager (either due to display in blanking period and/or in background pixel period). The 6th line buffer is actually 48-bit wide to allow storage of ARGB48 format pixel data.

At the beginning of frame scaling processing, the first line may be duplicated multiple times depending on the initial vertical phase programmed for the poly-phase filter.

At the end of frame scaling processing the last line is duplicated, if the scaling logic requires loading more lines and the last line has been reached.

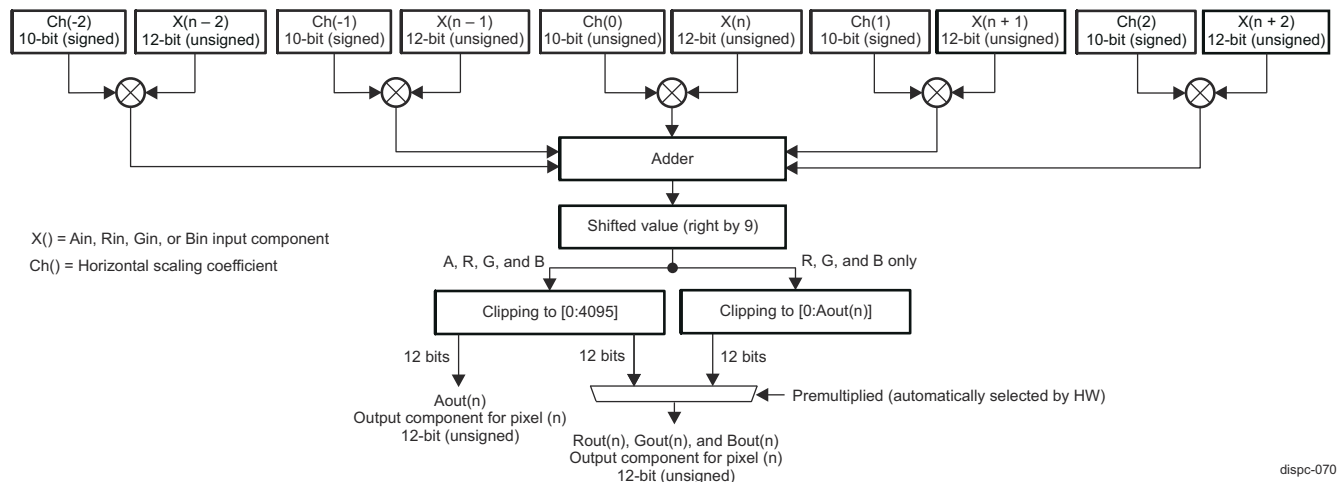

Similarly, the first pixel may be duplicated multiple times depending on the initial horizontal phase programmed for the poly-phase filter. The last pixel is duplicated, if the scaling logic requires loading more pixels and the last pixel has been reached.

The programmable coefficients of the polyphase filters are signed 10-bit values (except for the central coefficient, which is unsigned). The vertical video scaler has a 10-bit input and a 12-bit output. The horizontal scaling stage takes the resulting 12-bit input and produces 12-bit output.

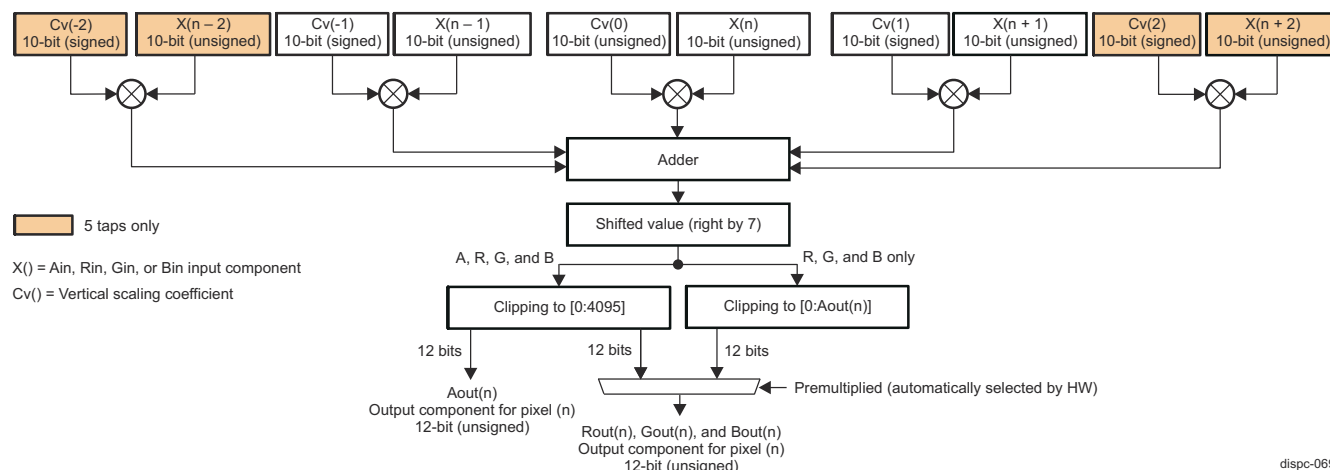

Figure 12-489 and Figure 12-490 show the scaler macro-architecture for components A, R, G, and B. Figure 12-491 and Figure 12-492 show the scaler macro-architecture for components Y, Cr, and Cb.

### Note

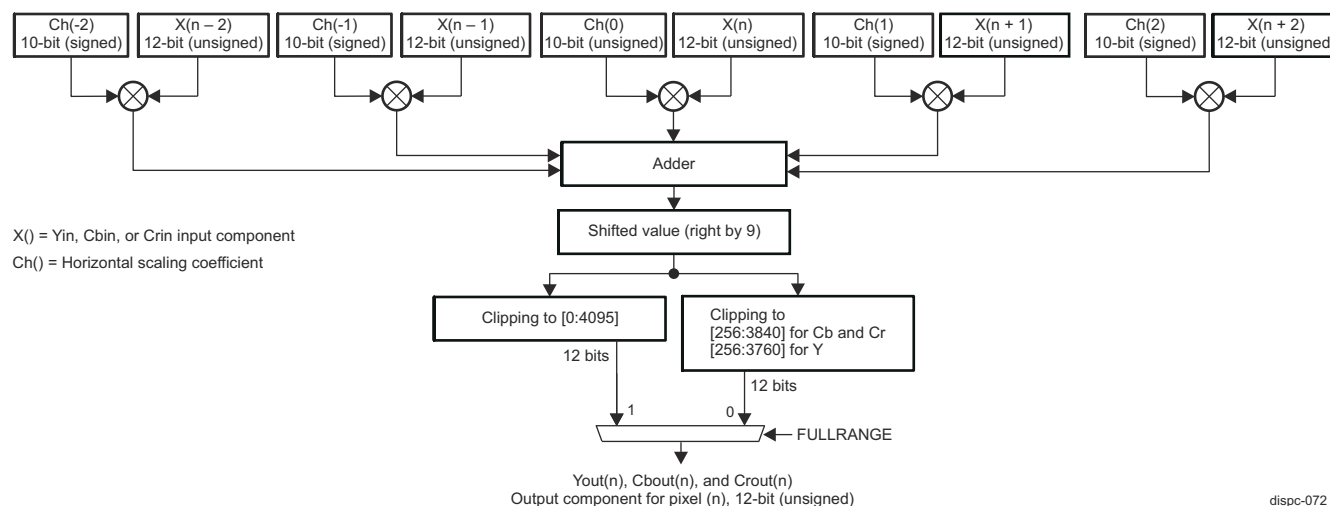

The scaling and CSC clipping is set by the same bit, DSS0\_VID\_ATTRIBUTES[11] FULLRANGE.

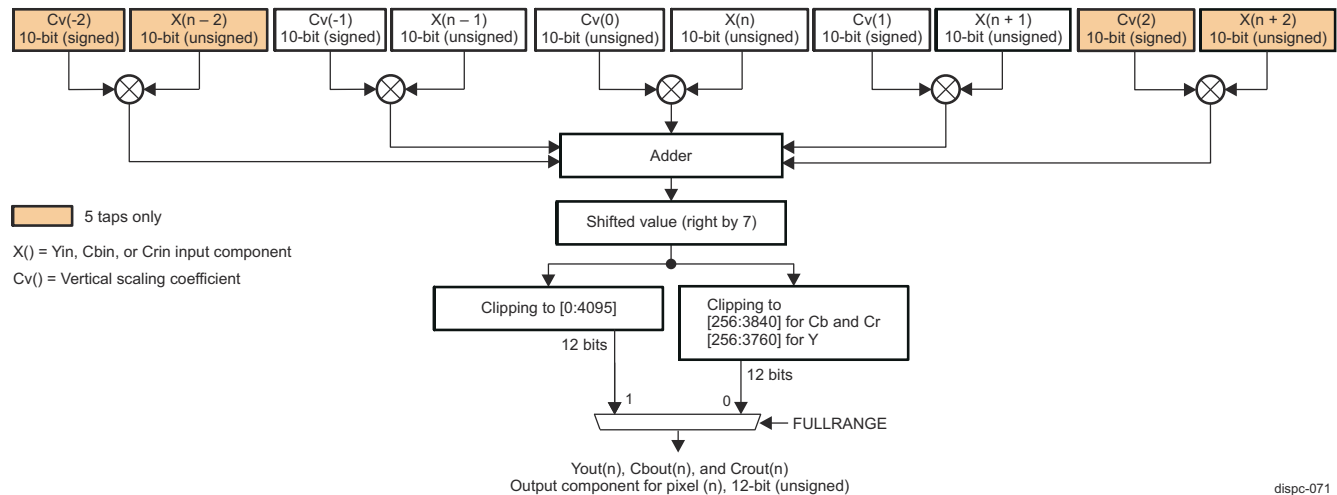

**Figure 12-489. DISPC VID Macro-Architecture of the Horizontal Scaling for A, R, G, and B Components (5-tap Restriction)**

**Figure 12-490. DISPC VID Macro-Architecture of the Vertical Scaling for A, R, G, and B Components (5 and 3 taps)**

**Figure 12-491. DISPC VID Macro-Architecture of the Horizontal Scaling for Y, Cr, and Cb Components (5-tap Restriction)**

**Figure 12-492. DISPC VID Macro-Architecture of the Vertical Scaling for Y, Cr, and Cb Components (5 and 3 taps)**

Table 12-430 list the register fields in the function of the coefficients for the VID horizontal scaler in the DSS0\_VID\_FIR\_COEF\_H0\_0 to DSS0\_VID\_FIR\_COEF\_H0\_8, and DSS0\_VID\_FIR\_COEF\_H12\_0 to DSS0\_VID\_FIR\_COEF\_H12\_15 registers.

### Note

In Table 12-430, the cells without color are duplicated from the grey cells.

Similar table approach applies to the vertical scaler (registers DSS0\_VID\_FIR\_COEF\_V0\_0 to DSS0\_VID\_FIR\_COEF\_V0\_8, and DSS0\_VID\_FIR\_COEF\_V12\_0 to DSS0\_VID\_FIR\_COEF\_V12\_15 are used).

Similar table approach applies to the coefficients for Cb/Cr filtering in case of YUV format (registers DSS0\_VID\_FIR\_COEF\_H0\_C\_0 to DSS0\_VID\_FIR\_COEF\_H0\_C\_8, and DSS0\_VID\_FIR\_COEF\_H12\_C\_0 to DSS0\_VID\_FIR\_COEF\_H12\_C\_15, and DSS0\_VID\_FIR\_COEF\_V0\_C\_0 to DSS0\_VID\_FIR\_COEF\_V0\_C\_8 and DSS0\_VID\_FIR\_COEF\_V12\_C\_0 to DSS0\_VID\_FIR\_COEF\_V12\_C\_15 are used) .

The VID scaler unit vertical and/or horizontal sampling is selected by configuring the DSS0\_VID\_ATTRIBUTES[8-7] RESIZEENABLE bit field.

Prior to enabling the video up/down-sampling block a valid configuration has to be set by the user. After configuring the required VID registers change the DSS0\_VP\_CONTROL[5] GOBIT register bit of the video port the video pipeline is associated with. The software has to wait before setting the GO bit that the hardware has reset the bit. The software reset is not recommended since the application cannot guarantee to be able to reset it before the H/W.

The following fields define the configuration of the video up-sampling/down-sampling block in the VID pipeline for ARGB and YUV formats:

- Vertical upsampling and downsampling increment value in the [23-0] FIRVINC bit field of DSS0\_VID\_FIRV (for ARGB and Y) and DSS0\_VID\_FIRV2 (for CbCr) registers. The unsigned integer value range is  $2^{23}$ . Software calculates the value using the following equation:

$$FIRVINC = 2^{21} * \left( \frac{MEMSIZEY+1}{SIZEY+1} \right)$$

dispc-066

- Horizontal upsampling and downsampling increment value in the [23-0] FIRHINC bit field of the DSS0\_VID\_FIRH (for ARGB and Y) and DSS0\_VID\_FIRH2 (for CbCr) registers. The unsigned integer value range is [1:16384]. Software calculates the value using the following equation:

$$FIRHINC = 2^{21} * \left( \frac{MEMSIZEH+1}{SIZEH+1} \right)$$

dispc-067

- Vertical up/downsampling accumulator value in the [23-0] VERTICALACCU bit field of the DSS0\_VID\_ACCUV\_0 and DSS0\_VID\_ACCUV\_1 (for ARGB and Y), and DSS0\_VID\_ACCUV2\_0 and DSS0\_VID\_ACCUV2\_1 (for CbCr) registers. The accumulator value indicates on which phase the vertical filtering starts. The DSS0\_VID\_ACCUV\_0 register is used for progressive output, while for interlace output both DSS0\_VID\_ACCUV\_0 and DSS0\_VID\_ACCUV\_1 registers are used. The DSS0\_VID\_ACCUV2\_0 and DSS0\_VID\_ACCUV2\_1 registers are used in the same manner for progressive or interlace output.

- Vertical upsampling and downsampling line buffer configuration via the DSS0\_VID\_ATTRIBUTES[21] VERTICALTAPS bit: The default value at reset time is 0x0 (3-tap configuration is used). If the bit field is reset, the 3-tap configuration is used.
- Horizontal upsampling and downsampling accumulator value in the [23-0] HORIZONTALACCU bit field of the DSS0\_VID\_ACCUH\_0 and DSS0\_VID\_ACCUH\_1 (for ARGB and Y), and DSS0\_VID\_ACCUH2\_0 and DSS0\_VID\_ACCUH2\_1 (for CbCr) registers. The accumulator value indicates on which phase the horizontal filtering starts. The register DSS0\_VID\_ACCUH\_0 is used for progressive output, while for interlace output both DSS0\_VID\_ACCUH\_0 and DSS0\_VID\_ACCUH\_1 registers are used. The DSS0\_VID\_ACCUH2\_0 and DSS0\_VID\_ACCUH2\_1 are used in the same manner for progressive or interlace output.

Table 12-431 lists the scaler vertical and horizontal accumulator values and phases.

**Table 12-431. DISPC VID Scaler Vertical and Horizontal Accumulator Phases**

Accumulator Value (MSB bits)	Phases f
0	0
256 or -3840	1
512 or -3584	2
768 or -3328	3
1024 or -3072	4
1280 or -2816	5
1536 or -2560	6
1792 or -2304	7
2048 or -2048	8
2304 or -1792	9
2560 or -1536	10
2816 or -1280	11
3072 or -1024	12
3328 or -768	13
3584 or -512	14
3840 or -256	15

- Vertical upsampling and downsampling central coefficients:
  - For ARGB and Y, the vertical upsampling and downsampling central coefficients are defined in the DSS0\_VID\_FIR\_COEF\_V0\_0 to DSS0\_VID\_FIR\_COEF\_V0\_8 registers. There are 9 registers for the 16 phases with 1 coefficient for each of them. Symmetrical implementation is used, so only 9 coefficients are used. Each register contains one 10-bit unsigned coefficient (the central one).
  - Four CbCr, the vertical upsampling and downsampling central coefficients are set in DSS0\_VID\_FIR\_COEF\_V0\_C\_0 to DSS0\_VID\_FIR\_COEF\_V0\_C\_8 registers.
- Vertical upsampling and downsampling coefficients:
  - For ARGB and Y, the vertical upsampling and downsampling coefficients are defined in the DSS0\_VID\_FIR\_COEF\_V12\_0 to DSS0\_VID\_FIR\_COEF\_V12\_15 registers. There are 16 registers for the 16 phases with 2 coefficient for each of them, so a total of 32 programmable coefficients for the vertical up/down-sampling block. Each register contains two 10-bit signed coefficients.
  - Four CbCr, the vertical upsampling and downsampling coefficients are set in DSS0\_VID\_FIR\_COEF\_V12\_C\_0 to DSS0\_VID\_FIR\_COEF\_V12\_C\_15 registers.
- Horizontal upsampling and downsampling central coefficients:
  - For ARGB and Y, the horizontal upsampling and downsampling central coefficients are defined in the DSS0\_VID\_FIR\_COEF\_H0\_0 to DSS0\_VID\_FIR\_COEF\_H0\_8 registers. There are 9 registers for the 16 phases with 1 coefficient for each of them. Symmetrical implementation is used, so only 9 coefficients are used. Each register contains one 10-bit unsigned coefficient (the central one).

- Four CbCr, the horizontal upsampling and downsampling central coefficients are set in DSS0\_VID\_FIR\_COEF\_H0\_C\_0 to DSS0\_VID\_FIR\_COEF\_H0\_C\_8 registers.
- Horizontal upsampling and downsampling coefficients:
  - For ARGB and Y, the horizontal upsampling and downsampling coefficients are defined in the DSS0\_VID\_FIR\_COEF\_H12\_0 to DSS0\_VID\_FIR\_COEF\_H12\_15 registers. There are 16 registers for the 16 phases with 2 coefficient for each of them, so a total of 32 programmable coefficients for the horizontal up/down-sampling block. Each register contains two 10-bit signed coefficients.
  - Four CbCr, the horizontal upsampling and downsampling coefficients are set in DSS0\_VID\_FIR\_COEF\_H12\_C\_0 to DSS0\_VID\_FIR\_COEF\_H12\_C\_15 registers.

The YUV filtering is based on the equations of the ARGB filtering. In addition to the registers used for ARGB filtering configuration, a second set of registers for filtering is used. The first set of registers is used for Y configuration (instead of ARGB configuration) and the second set of registers is used for CbCr filtering configuration. The two sets of registers can be the same when the YUV format is not converted to RGB after filtering. When the RGB conversion is required after filtering, then the chrominance needs to be re-sampled with a different filtering configuration because:

- Chrominance samples are offset to the luminance samples. That is, DSS0\_VID\_FIRH2 and DSS0\_VID\_FIRV2, and DSS0\_VID\_ACCUV2\_0/DSS0\_VID\_ACCUV2\_1 and DSS0\_VID\_ACCUH2\_0/DSS0\_VID\_ACCUH2\_1 registers need to be configured differently than DSS0\_VID\_FIRH and DSS0\_VID\_FIRV, and DSS0\_VID\_ACCUH\_0/DSS0\_VID\_ACCUH\_1 and DSS0\_VID\_ACCUV\_0/DSS0\_VID\_ACCUV\_1 registers used for the luminance filtering.
- Chrominance is sub-sampled by two horizontally only in case of YUV422, and horizontally and vertically in case of YUV420. The coefficients for the vertical chrominance re-sampling are identical to the coefficients for vertical luminance filtering in case of YUV422. The coefficients for the horizontal and vertical chrominance re-sampling are different than the ones for luminance filtering in case of YUV420.

#### 12.9.1.4.1.8.6 DISPC VID Color Space Conversion YUV to RGB

The Color Space Conversion (CSC) unit converts the video-encoded pixel values from YUV444 format into ARGB48 format (12-bit value per component A, R, G, and B, with A fixed at 0xFFFF).

In case of YUV420 or YUV422 formats, a chrominance resampling to YUV444 is performed before converting the YUV into RGB values (see [Section 12.9.1.4.1.8.4, DISPC VID Chrominance Resampling](#)). The YUV422/YUV420 to YUV444 chrominance resampling is a pre-processing to the color space conversion.

[Figure 12-493](#) and [Figure 12-494](#) show the  $3 \times 3$  11-bit coefficients used to convert from YUV444 into ARGB48. The value of A component is fixed at 0xFFFF in the output. The coefficients are set according to the standard used to encode the pixel data in YUV color space. [Table 12-432](#) summarizes the coefficients with their respective register bit fields.

**Table 12-432. DISPC VID CSC - YUV to RGB Register Settings**

Coefficients	Register Fields
R <sub>Y</sub>	DSS0_VID_CSC_COEF0[10-0] C00
R <sub>Cr</sub>	DSS0_VID_CSC_COEF0[26-16] C01
R <sub>Cb</sub>	DSS0_VID_CSC_COEF1[10-0] C02
G <sub>Y</sub>	DSS0_VID_CSC_COEF1[26-16] C10
G <sub>Cr</sub>	DSS0_VID_CSC_COEF2[10-0] C11
G <sub>Cb</sub>	DSS0_VID_CSC_COEF2[26-16] C12
B <sub>Y</sub>	DSS0_VID_CSC_COEF3[10-0] C20
B <sub>Cr</sub>	DSS0_VID_CSC_COEF3[26-16] C21
B <sub>Cb</sub>	DSS0_VID_CSC_COEF4[10-0] C22
Y offset	DSS0_VID_CSC_COEF5[15-3] PREOFFSET1
Cr offset	DSS0_VID_CSC_COEF5[31-19] PREOFFSET2
Cb offset	DSS0_VID_CSC_COEF6[15-3] PREOFFSET3

- Limited video data range conversion

If the active range for the luminance samples (Y) is [256:3760] and for the chrominance samples (Cb and Cr) is [256:3840], the following equation in [Figure 12-493](#) (based on 11-bit coefficients) must be used to convert the YUV to RGB. To clip the values of R, G, and B output components to the full output data range [0:4095], set the DSS0\_VID\_ATTRIBUTES[11] FULLRANGE bit to 0x1.

$$\begin{bmatrix} R_{OUT} \\ G_{OUT} \\ B_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} R_Y & R_{cr} & R_{cb} \\ G_Y & G_{cr} & G_{cb} \\ B_Y & B_{cr} & B_{cb} \end{bmatrix} * \begin{bmatrix} Y_{IN} - 256 \\ Cr_{IN} - 2048 \\ Cb_{IN} - 2048 \end{bmatrix}$$

dispc-005

**Figure 12-493. DISPC VID CSC YCbCr to RGB Equation (Limited Video Range), 12-Bit Outputs**

In [Figure 12-493](#), the offset values (-256, -2048, -2048) are also programmed via corresponding register bit-fields shown in [Table 12-432, DISPC VID CSC - YUV to RGB Register Settings](#).

- Full video data range conversion

If the active range for the luminance samples (Y) and chrominance samples (Cb and Cr) is [0:4095], the following equation in [Figure 12-494](#) (based on 11-bit coefficients) must be used to convert the YUV to RGB. To clip the values of R, G, and B output components to the full output data range [0:4095], set the DSS0\_VID\_ATTRIBUTES[11] FULLRANGE bit to 0x1.

$$\begin{bmatrix} R_{OUT} \\ G_{OUT} \\ B_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} R_Y & R_{cr} & R_{cb} \\ G_Y & G_{cr} & G_{cb} \\ B_Y & B_{cr} & B_{cb} \end{bmatrix} * \begin{bmatrix} Y_{IN} \\ Cr_{IN} - 2048 \\ Cb_{IN} - 2048 \end{bmatrix}$$

dispc-006

**Figure 12-494. DISPC VID CSC YCbCr to RGB Equation (Full Video Range), 12-Bit Outputs**

In [Figure 12-494](#), the offset values (0, -2048, -2048) are also programmed via corresponding register bit-fields shown in [Table 12-432, DISPC VID CSC - YUV to RGB Register Settings](#).

#### Note

In case of YUV420-NV21 data, the coefficients for Cr and Cb must be swapped in order to correctly support YUV420-NV21 format.

The scaling and CSC clipping is set by the same bit, DSS0\_VID\_ATTRIBUTES[11] FULLRANGE.

#### 12.9.1.4.1.8.7 DISPC VID Brightness/Contrast/Saturation/Hue Control

The brightness/contrast/saturation controls are implemented in the same Color Space Conversion (CSC) block by making adjustments to the conversion coefficients and input/output offset values as shown in [Figure 12-495](#):

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \begin{bmatrix} m * A0 & m * k * B0 & m * k * C0 \\ m * A1 & m * k * B1 & m * k * C1 \\ m * A2 & m * k * B2 & m * k * C2 \end{bmatrix} \begin{bmatrix} Y + Y\_offset\_adj \\ Cr + Cr\_offset \\ Cb + Cb\_offset \end{bmatrix} + \begin{bmatrix} R\_offset \\ G\_offset \\ B\_offset \end{bmatrix}$$

dispc-101

**Figure 12-495. DISPC VID Brightness/Contrast/Saturation Equation for YUV to RGB**

In [Figure 12-495](#) the following terminology is used:

- A/B/C coefficients and the offset parameters are for YUV to RGB conversion. See [Table 12-433](#) below for coefficients and offsets mapping to register fields.

- The gain term (m) is used for contrast control. The allowed range is:  $0 < m \leq 2.0$  (where  $m=1$  means contrast bypass).
- The gain term (k) is used for saturation control. The allowed range is:  $0 < k \leq 2.0$  (where  $k=1$  means saturation bypass).
- The brightness offset (b) is added to  $Y\_offset\_adj$ . The allowed range (for 8-bit example) is:  $-128 \leq b \leq +127$  (where  $b=0$  means brightness bypass).

The hue adjustment can also be built into the above equation (Figure 12-495) to comprehend the following Cb/Cr hue angle adjustments:

$$Cb\_hue\_adj = (Cb \cdot \cos \emptyset + Cr \cdot \sin \emptyset)$$

$Cr\_hue\_adj = (Cr \cdot \cos \emptyset - Cb \cdot \sin \emptyset)$ , where  $\emptyset$  is the desired hue angle (with  $\emptyset=0$  meaning hue adjustment bypass)

The final combined matrix equation for controlling brightness/contrast/saturation/hue (BCSH) during YUV to RGB conversion is shown in Figure 12-496

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \begin{bmatrix} m \cdot A0 & m \cdot k \cdot [B0 \cdot \cos(Hue) + C0 \cdot \sin(Hue)] & m \cdot k \cdot [C0 \cdot \cos(Hue) - B0 \cdot \sin(Hue)] \\ m \cdot A1 & m \cdot k \cdot [B1 \cdot \cos(Hue) + C1 \cdot \sin(Hue)] & m \cdot k \cdot [C1 \cdot \cos(Hue) - B1 \cdot \sin(Hue)] \\ m \cdot A2 & m \cdot k \cdot [B2 \cdot \cos(Hue) + C2 \cdot \sin(Hue)] & m \cdot k \cdot [C2 \cdot \cos(Hue) - B2 \cdot \sin(Hue)] \end{bmatrix} \begin{bmatrix} Y + Y\_offset\_adj \\ Cr + Cr\_offset \\ Cb + Cb\_offset \end{bmatrix} + \begin{bmatrix} R\_offset \\ G\_offset \\ B\_offset \end{bmatrix}$$

dispc-102

**Figure 12-496. DISPC VID Brightness/Contrast/Saturation/Hue Equation for YUV to RGB**

Gain and offset terms in the above equation (Figure 12-496) are programmed in the hardware registers as adjusted CSC coefficients (11-bit signed) and offset values (13-bit signed) to control the brightness, contrast, saturation and hue. Mapping of the coefficients and offsets to register fields is provided in Table 12-433. Outputs are clipped to keep the output values in the proper range.

**Table 12-433. DISPC VID BCSH Register Settings for YUV to RGB**

Coefficients	Register Fields
A0	DSS0_VID_CSC_COEF0[10-0] C00
B0	DSS0_VID_CSC_COEF0[26-16] C01
C0	DSS0_VID_CSC_COEF1[10-0] C02
A1	DSS0_VID_CSC_COEF1[26-16] C10
B1	DSS0_VID_CSC_COEF2[10-0] C11
C1	DSS0_VID_CSC_COEF2[26-16] C12
A2	DSS0_VID_CSC_COEF3[10-0] C20
B2	DSS0_VID_CSC_COEF3[26-16] C21
C2	DSS0_VID_CSC_COEF4[10-0] C22
Y offset	DSS0_VID_CSC_COEF5[15-3] PREOFFSET1
Cr offset	DSS0_VID_CSC_COEF5[31-19] PREOFFSET2
Cb offset	DSS0_VID_CSC_COEF6[15-3] PREOFFSET3
R offset	DSS0_VID_CSC_COEF6[31-19] POSTOFFSET1
G offset	DSS0_VID_CSC_COEF7[15-3] POSTOFFSET2
B offset	DSS0_VID_CSC_COEF7[31-19] POSTOFFSET3

For RGB input formats, the same CSC block can be used to adjust contrast, brightness, saturation, and hue using the matrix equation from Figure 12-497.

$$\begin{bmatrix} Rout \\ Gout \\ Bout \end{bmatrix} = \begin{bmatrix} m * A0 & m * k * [B0 * \cos(Hue) + C0 * \sin(Hue)] & m * k * [C0 * \cos(Hue) - B0 * \sin(Hue)] \\ m * A1 & m * k * [B1 * \cos(Hue) + C1 * \sin(Hue)] & m * k * [C1 * \cos(Hue) - B1 * \sin(Hue)] \\ m * A2 & m * k * [B2 * \cos(Hue) + C2 * \sin(Hue)] & m * k * [C2 * \cos(Hue) - B2 * \sin(Hue)] \end{bmatrix} \begin{bmatrix} a0 & b0 & c0 \\ a1 & b1 & c1 \\ a2 & b2 & c2 \end{bmatrix} \begin{bmatrix} Rin \\ Gin \\ Bin \end{bmatrix} + \begin{bmatrix} R\_offset \\ G\_offset \\ B\_offset \end{bmatrix}$$

Coefficients a/b/c are related to A/B/C (for RGB to YUV and YUV to RGB conversions) as follows:

$$\begin{bmatrix} a0 & b0 & c0 \\ a1 & b1 & c1 \\ a2 & b2 & c2 \end{bmatrix} = \begin{bmatrix} A0 & B0 & C0 \\ A1 & B1 & C1 \\ A2 & B2 & C2 \end{bmatrix}^{-1}$$

dispc-103

**Figure 12-497. DISPC VID Brightness/Contrast/Saturation/Hue Equation for RGB Input**

In [Figure 12-497](#) the following specifics apply:

- A/B/C coefficients and the RGB offset parameters mapping to register fields is provided in [Table 12-433](#).
- The gain term (m) is used for contrast control. The allowed range is:  $0 < m \leq 2.0$  (where  $m=1$  means contrast bypass).
- The gain term (k) is used for saturation control. The allowed range is:  $0 < k \leq 2.0$  (where  $k=1$  means saturation bypass).
- The brightness is controlled by the RGB offset values.
- The Hue angle is used to adjust hue. Hue  $\emptyset=0$  means hue adjustment bypass.

Outputs are clipped to keep the output values in the proper range.

#### 12.9.1.4.1.8.8 DISPC VID Luma Key Support

The video pipeline supports luma key transparency for Blue-ray video layer composition. When enabled, Y value of each pixel will be checked against luma key range values. The range values are defined in DSS0\_VID\_LUMAKEY register fields, as follows:  $[11-0] \text{ LUMAKEYMIN} < Y < [27-16] \text{ LUMAKEYMAX}$ . If this condition is true, then the pixel alpha value will be forced to zero (transparent) to make the pixel transparent during the blending process in the overlay manager.

#### 12.9.1.4.1.9 DISPC Overlay Managers

An overlay manager (OVR) is responsible for compositing selected input layers together to generate the final display output frame. DISPC implements two identical overlay managers (see [Figure 12-465](#), *DISPC Architecture Overview*):

- OVR1, with output connected to Video Port (VP1).
- OVR2, with output connected to Video Port (VP2).

Each OVR is preceded by a programmable input pipeline selector which re-maps the outputs of the selected input pipeline according to the overlay manager z-order configuration.

The output of each OVR is connected to the Color Phase Rotation (CPR) unit through a gamma table of the corresponding video port.

**Figure 12-498. DISPC Overlay Manager and Input Selector**

### Note

The DISPC overlay managers, OVR1 and OVR2, will be commonly referred to as *overlay manager (OVR)* in the following sections.

#### 12.9.1.4.1.9.1 DISPC Overlay Input Selector

The overlay input selector before the overlay manager is a n-input to n-output crossbar switch. As such, any input can be connected to any output in the selector. The selection is based on the z-order layer selection in the overlay configuration through the following register fields:

- DSS0\_OVR\_ATTRIBUTES\_0[4-1] CHANNELIN field for layer 0, z-order 0
- DSS0\_OVR\_ATTRIBUTES\_1[4-1] CHANNELIN field for layer 1, z-order 1

The z-order determines the order in which the selected layers are blended together to generate the final output by the overlay manager:

- The lowest enabled order input is the bottom-most layer, just above the background color
- The highest enabled order input is the top-most layer

The OVR input selector also passes the following attributes from the selected input pipeline to the corresponding selector output port:

- Source pipeline size attributes:
  - Number of pixels per line (from DSS0\_VID\_SIZE [11-0] SIZEX register field)
  - Number of lines (from DSS0\_VID\_SIZE [27-16] SIZEY register field)
- Source pipeline global blending level (from DSS0\_VID\_GLOBAL\_ALPHA register)

Then, the overlay manager uses the above listed attributes as input layer attributes along with POSX and POSY overlay manager configuration parameters. POSX and POSY can be configured as follows:

- For layer 0, z-order 0, in DSS0\_OVR\_ATTRIBUTES\_0[17-6] POSX and [30-19] POSY register fields
- For layer 1, z-order 1, in DSS0\_OVR\_ATTRIBUTES\_1[17-6] POSX and [30-19] POSY register fields

### Note

The output of an input pipeline can be mapped to more than one overlay manager simultaneously, if and only if the following conditions are true:

- All video port timing generators controlling the overlay managers are identically programmed (same frame width/height with same blanking parameters running at same frame rate) and clocked by the same pixel clock source, and ...
- The pipeline output is positioned on each display output at the same frame position.

The software is responsible for managing the pipeline assignment and setting up the video port timing generators properly in order to avoid any resource conflicts that may cause the DSS to lock up (sync loss).

#### 12.9.1.4.1.9.2 DISPC Overlay Mechanism

The overlay mechanism consists of displaying more than one layer (VID and/or VIDL1 pipeline layers) using:

- A priority rule based on the display Z-order (selected by configuring the overlay input selector, as described in [Section 12.9.1.4.1.9.1](#))
- Transparency color keys configuration (destination and source transparency)
- Alpha blending values (using the alpha component of each pixel or a global alpha value set by the user)
- Size and position attributes of the source window data, as described in [Section 12.9.1.4.1.9.1](#)

The overlay manager is configured using the Z-order parameter. The Z-order value defined for each pipeline indicates the visibility order to the window on the screen. If the Z-order value of window A is lower than the Z-order to layer B, then layer A is displayed below layer B. The transparency color keys and the alpha blending factors are then used to blend the layers together (see [Section 12.9.1.4.1.9.2.1, Overlay Alpha Blender](#), and [Section 12.9.1.4.1.9.2.2, Overlay Transparency Color Keys](#)).

Figure 12-499 gives an example of how input pipeline frame outputs are merged together to generate the final display output.

**Figure 12-499. DISPC Overlay Example and Display Attributes**

As shown in Figure 12-499, each input pipeline generates one rectangular sub-frame output in ARGB48 format. The overlay is responsible for positioning the sub-frame in the display output frame (specified by DSS0\_VP\_SIZE\_SCREEN[11-0] PPL and [27-16] LPP video port register fields), using the overlay window position parameters (specified by DISPC\_OVR\_ATTRIBUTES\_0/DISPC\_OVR\_ATTRIBUTES\_1 [17-6] POSX and [30-19] POSY overlay register fields), and the window size parameters (specified by DSS0\_VID\_SIZE[11-0] SIZEX and [27-16] SIZEY pipeline register fields). When the overlay manager does not require the input pipeline data (either because it is currently outputting the background color pixel or it is being stalled by the VP output module), the overlay manager stalls the input pipeline.

When there are no video-encoded pixels at a specific position, the programmable solid background color appears. The solid background color is set in the DSS0\_OVR\_DEFAULT\_COLOR and DSS0\_OVR\_DEFAULT\_COLOR2 registers.

The entire pixels of the video window have to be inside the display screen. Depending on the width of the buffer to be displayed in the video layer and the position, the width must be adjusted by software to limit the right edge of the window inside the display screen. The same is also true for the video layer height in the input pipe line configuration.

### 12.9.1.4.1.9.2.1 Overlay Alpha Blender

The alpha blending value is defined by:

- The component value A when using an ARGB or RGBA pixel format (alpha in the source pixel data is converted to 8-bit alpha value in the input pipeline logic):
  - For ARGB-1555, the alpha blending is defined using a 1-bit value. It is converted into an 8-bit value by duplicating the 1-bit value (see [Table 12-434](#)).
  - For ARGB-4444, the alpha blending is defined using a 4-bit value. It is converted into an 8-bit value by duplicating the 4-bit value (see [Table 12-434](#)).
  - If the pixel format contains no alpha blending value, the pixel alpha value is considered to be 0xFF, and if alpha is equal to 0xFF, there is no multiplication.
  - For BITMAP or YUV formats, there is no alpha blending factor associated with each pixel value. Only the global alpha blending factor associated with the window displaying the BITMAP or YUV format is used.
- The global alpha blending value can be set in the DSS0\_VID\_GLOBAL\_ALPHA register of the input pipeline, and is updated in synch with the selected output channel.
- The modulated alpha blending value (that is, a total alpha blending value, when a combination of the pixel alpha blending value A and a global alpha blending are present) is determined as:  $\text{Alpha} = (\text{Pixel Alpha} \times \text{Global Alpha}) / 256$ .

[Table 12-434](#) shows the remapping and the percentage of alpha blending achieved.

**Table 12-434. DISPC Overlay Alpha Blending – ARGB**

Alpha Blending 1-Bit Value (ARGB16-1555)	Alpha Blending 4-Bit Value (ARGB16-4444)	Alpha Blending 8-Bit Value (Converted Value)	% Blending
0x0	0x0	0x00	100% (transparent)
N/A	0x1	0x11	93.33%
N/A	0x2	0x22	86.6%
N/A	...	...	...
N/A	0xE	0xEE	6.6%
0x1	0xF	0xFF	0% (opaque)

### Premultiplied Alpha

The image ARGB may have its RGB component already premultiplied with the alpha (AR'G'B') where:

- $R' = A * R$
- $G' = A * G$
- $B' = A * B$

In that case, the processing is as follows:

- Color components of premultiplied layers are multiplied with the global alpha, if global alpha is not equal to 0.
- Color components of the composed underlying layer are multiplied with  $(1 - A * \text{global alpha})$ .

The additional premultiplied alpha option is accessible through the DSS0\_VID\_ATTRIBUTES [28] PREMULTIPLYALPHA register bit of the input pipeline. The following settings are available:

- PREMULTIPLYALPHA bit = 0: Source is not premultiplied with alpha. Full blending is done in the overlay manager.
- PREMULTIPLYALPHA bit = 1: Source is premultiplied with alpha. Partial blending is done.

### Note

There is no alpha blending between the background and the next layer (layer-0) above it.

Layer-0 cannot be pre-multiplied, if the overlay output is driving the display, since that layer (or the background color) defines the bottom most layer. In this case, layer-0 alpha is 1 always.

#### 12.9.1.4.1.9.2.2 Overlay Transparency Color Keys

The overlay manager supports two color transparency modes - source and destination. These modes cannot be active at the same time.

The source transparency is tied to the top most layer, so the layer to have this transparency applied to has to be mapped to the highest z-ordered input (layer-1) of the overlay manager. The destination transparency is tied to the bottom most layer, so the layer to have this transparency applied to has to be mapped to the lowest z-ordered input (layer-0) of the overlay manager.

The source and destination transparencies are defined as following:

- Source color transparency: Top layer pixel that meets the source transparency color check is made transparent.
- Destination color transparency: Top layer pixel is made transparent, only if the bottom layer pixel does not meet the destination transparency color check.

The transparency color key is enabled via the DSS0\_OVR\_CONFIG[10] TCKLCDENABLE register bit.

The minimum transparency color values are specified in the TRANSCOLORKEY field of the DSS0\_OVR\_TRANS\_COLOR\_MIN and DSS0\_OVR\_TRANS\_COLOR\_MIN2 registers.

The maximum transparency color values are specified in the TRANSCOLORKEY field of the DSS0\_OVR\_TRANS\_COLOR\_MAX and DSS0\_OVR\_TRANS\_COLOR\_MAX2 registers.

The transparency color key values defined in the registers are compared with the pixel values. If each color component (R, G, and B) is in the range defined by MIN and MAX, then there is a match. If at least one of the color component is not in the range, then there is no match.

##### • Source transparency color key

The values of the source transparency color key define the range of encoded pixel data considered as a transparent pixel. The encoded pixel values with the source color key value inside the valid range are not visible, and the encoded pixel values of the under layers or solid background color are visible.

The source transparency color key can be used with YUV and RGB formats (ARGB, RGB, RGBA, xRGB, and RGBx). In that case the A information is ignored for the comparison between the pixel value and the color key value. It is possible to use YUV formats with some care, since the comparison is between the input pixel value of the overlay manager from pipeline and the color key value. The YUV data is converted to RGB format. The user must consider the color space conversion processing in order to define the RGB color key value used for the comparison, in case the original format is YUV.

The scaler can be enabled as a preprocessor in the video pipelines. The pixel scaling processing can be considered in order to define the color key value to be used after the rescaling for the comparison between the input pixel value to the overlay manager and the color key value.

The source transparency color key mode is selected by setting the DSS0\_OVR\_CONFIG[11] TCKLCDSELECTION register bit to 0x1.

[Figure 12-500](#) shows an example of source transparency color key usage. The pixels with the transparency color key are not displayed. Instead, pixels of the resulting layer underneath are shown.

**Figure 12-500. DISPC Overlay Source Transparency Color Key Example**

- **Destination transparency color key**

The destination transparency color key values define the range of the encoded pixels in layer-0 (bottom layer), which are not going to be displayed. That is, the encoded pixel values matching the destination color key value range are pixels not visible on the screen. Pixels at the same position in the layers above layer-0 are visible. The destination transparency color key is applicable in the layer in the background only when there is an overlap between the layer in background position and the layer just above it, otherwise, the destination transparency color key is ignored. See [Section 12.9.1.4.1.9.2, DISPC Overlay Mechanism](#), for details on layer position depending on the Z-order parameter.

The destination transparency color key can be used only with RGB formats (ARGB, RGB, xRGB, RGBA, and RGBx). In that case the A information is ignored for the comparison between the pixel value and the color key value. It is possible to use YUV formats with some care since the comparison is between the input pixel value of the overlay manager from pipeline and the color key value. The YUV data is converted to RGB format. The user must consider the color space conversion processing in order to define the RGB color key value used for the comparison in case the original format is YUV.

The scaler can be enabled as a preprocessor in the pipelines. The pixel scaling processing must be considered in order to define the color key value to be used after rescaling for the comparison between the input pixel value to the overlay manager and the color key value.

The source transparency color key mode is selected by setting the DSS0\_OVR\_CONFIG[11] TCKLCDSELECTION register bit to 0x0.

[Figure 12-501](#) shows an example of the destination color key usage. The pixels from layer-0 (bottom layer) equal to the transparency color key are not displayed and are replaced by the pixels from layer-1 (top layer). All other layer-0 pixels, different from the transparency color key, are displayed over layer-1.

**Figure 12-501. DISPC Overlay Destination Transparency Color Key Example**

#### 12.9.1.4.1.9.3 Overlay 3D Support

In order to support S3D (Stereoscopic 3D) by combining in hardware left and right frames into the same output frame, the following configurations (defined by HDMI 1.4b standard specification) can be used:

- Separate pipeline mode: Left/Right or Top/Bottom. One layer is used for left/top and another layer is used for right/bottom.

#### 12.9.1.4.1.9.4 Overlay Color Bar Insertion

Each overlay manager supports a simple internal color bar insertion in each display output path to enable testing of display output interface without using the frame buffer data from the memory.

The colors are: White, Yellow, Cyan, Green, Magenta, Red, Blue, Black, as shown in below. These make three primary colors, three secondary colors, white, and black.

**Figure 12-502. DISPC Overlay Internal Color Bar**

When the DSS0\_OVR\_CONFIG[1] COLORBAREN register bit is set to 1, the overlay output data is replaced by the predefined ARGB48 color bar data.

When color bar mode is used, the color space conversion matrix should be appropriately programmed, so that it can convert the full-range RGB to the desired color format.

**Table 12-435. DISPC Overlay Color Bar Table**

Color	G	B	R
White	0xFFFF	0xFFFF	0xFFFF
Yellow	0xFFFF	0	0xFFFF
Cyan	0xFFFF	0xFFFF	0
Green	0xFFFF	0	0
Magenta	0	0xFFFF	0xFFFF
Red	0	0	0xFFFF
Blue	0	0xFFFF	0
Black	0	0	0

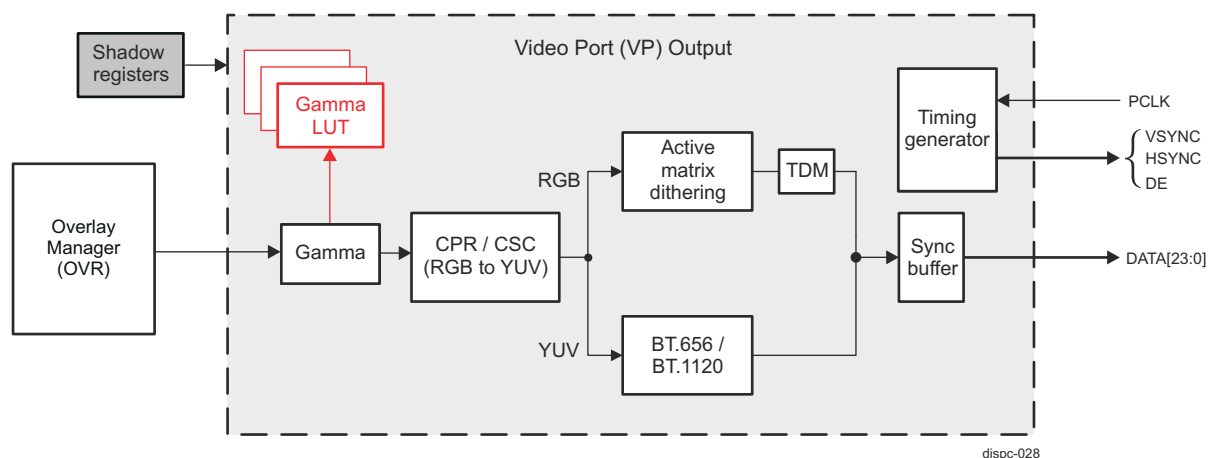

#### 12.9.1.4.1.10 DISPC Video Port Outputs

DISPC implements two identical Video Port (VP) outputs:

- VP1 processes data received from Overlay Manager 1 (OVR1)
- VP2 processes data received from Overlay Manager 2 (OVR2)

A VP output path consists of several processing blocks (see [Figure 12-503](#)):

- Gamma correction unit
- Color phase rotation (CPR) unit, also used for RGB to YUV color space conversion (CSC)
- Active matrix dithering with TDM (multiple cycle output format)
- BT.656/BT.1120
- Timing generator
- Async buffer

**Figure 12-503. DISPC VP Output Architecture**

The CSC processing can be configured to occur either before or after the gamma correction in the VP output module via the DSS0\_VP\_CONFIG[26] COLORCONVPOS register bit. For RGB to YUV color space conversion, the conversion must be done after the gamma correction. For other RGB output applications, the conversion must be done before the final gamma correction.

#### Note

The DISPC video port (VP) outputs, VP1 and VP2, will be commonly referred to as *video port (VP)* in the following sections.

#### 12.9.1.4.1.10.1 DISPC VP Gamma Correction Unit

The VP supports a look up table to perform the gamma correction on the display output. The look up table consists of 3 separate 256x8-bit memories, which are indexed by R/G/B component data.

When performing gamma correction, the selected encoded pixel values from the video pipeline path are sent by the overlay manager to the gamma curve table. Each R/G/B component of the encoded pixel value is used as a pointer to index 1 out of 256 x 24-bit gamma curve entries in the table. Each 8-bit component is replaced with the 8-bit table value corresponding to R, G, or B component. The table is loaded by software via the DSS0\_VP\_GAMMA\_TABLE\_0 through DSS0\_VP\_GAMMA\_TABLE\_15 registers. It is possible to load only part of the table. For each access to the table, the 24-bit value is associated with index in the table by concatenating the 24-bit value (LSB of 32-bit access) and the 8-bit index value (MSB of the 32-bit access).

The sequence to load the gamma table is:

1. SW writes (only writes are supported) 32-bit gamma correction values using single access, or burst access in linear increment burst mode, into the 64-byte region starting at DSS0\_VP\_GAMMA\_TABLE\_0 register address. The LSB 24 bits [23:0] are used for the value, and the MSB 8 bits [31:24] are used for the index into the table.
2. Loop to step #1, if there is a new access to the gamma table register. The software can access other registers between two accesses to the gamma table register.

Software needs to ensure that there is no visible effect when modifying the table, since it is not under hardware control.

The usage of the gamma table is activated by setting DSS0\_VP\_CONFIG[2] GAMMAENABLE register bit.

Figure 12-504 describes the format of one of the gamma curve values in the memory.

**Figure 12-504. DISPC VP Output Gamma Table Write Data Format**

#### 12.9.1.4.1.10.2 DISPC VP Color Phase Rotation Unit

If required, a color phase rotation (CPR) processing can be applied on the "gamma" data before the spatial/temporal dithering.

The CPR can be selected to correct the non-pure white backlight of the display panel by using a programmable matrix to convert the 36-bit RGB pixel value into a new 36-bit RGB pixel value. The matrix is programmed through a set of nine 11-bit signed coefficients. The output of the calculation is clipped to [0:4095]. The CPR is enabled by setting the DSS0\_VP\_CONFIG[15] CPR bit to 0x1.

The CPR processing is expressed by the equation shown in Figure 12-505. Table 12-436 lists all coefficients with their respective register bitfields for settings.

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} R_r & R_g & R_b \\ G_r & G_g & G_b \\ B_r & B_g & B_b \end{bmatrix} * \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix}$$

dispc-023

**Figure 12-505. DISPC VP CPR Matrix**

**Table 12-436. DISPC VP CPR and CSC Coefficients with Associated Register Fields**

Register Field	Color Phase Rotation	Color Space Conversion RGB to YUV
DSS0_VID_CSC_COEF0[10-0] C00	RR	YR

**Table 12-436. DISPC VP CPR and CSC Coefficients with Associated Register Fields (continued)**

Register Field	Color Phase Rotation	Color Space Conversion RGB to YUV

DSS0_VID_CSC_COEF6[31-19] POSTOFFSET1	-	R offset
DSS0_VID_CSC_COEF7[15-3] POSTOFFSET2	-	G offset
DSS0_VID_CSC_COEF7[31-19] POSTOFFSET3	-	B offset

#### 12.9.1.4.1.10.3 DISPC VP Color Space Conversion - RGB to YUV

The RGB to YUV color space conversion (CSC) in the video port is done by using the same programmable logic used for CPR. If CPR is also required, then the process can be combined with the CSC processing by adjusting matrix coefficients. [Table 12-436](#) lists the associated coefficients with their respective register bit-fields. The CSC processing is enabled by setting the DSS0\_VP\_CONFIG[24] COLORCONVENABLE register bit.

The color space conversion can be selected in order to convert from 36-bit RGB to YUV444. The conversion matrix is programmed through a set of nine 11-bit signed coefficients. The result is clipped to [256:3760] for the luminance and [256:3840] for the chrominance, when a full-range YUV output is not desired (equivalent to clipping to [16..235] and [16..240] in 8-bit video). In this case the DSS0\_VP\_CONFIG[25] FULLRANGE register bit must be set to 0x0.

$$\begin{bmatrix} Y_{OUT} \\ Cr_{OUT} \\ Cb_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} Y_R & Y_G & Y_B \\ Cr_R & Cr_G & Cr_B \\ Cb_R & Cb_G & Cb_B \end{bmatrix} * \begin{bmatrix} R_{IN} \\ G_{IN} \\ B_{IN} \end{bmatrix} + \begin{bmatrix} 256 \\ 2048 \\ 2048 \end{bmatrix}$$

dispc-098

**Figure 12-506. DISPC VP CSC RGB to YUV Matrix (FULLRANGE=0)**

If the programmed active range for the luminance samples (Y) and chrominance samples (Cb and Cr) is [0:4095], then the values Y, Cb, and Cr are clipped to the range [0:4095]. The following equation gives the 11-bit coefficients of the RGB to YUV color space conversion, for full-range (when DSS0\_VP\_CONFIG[25] FULLRANGE = 0x1).

$$\begin{bmatrix} Y_{OUT} \\ Cr_{OUT} \\ Cb_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} Y_R & Y_G & Y_B \\ Cr_R & Cr_G & Cr_B \\ Cb_R & Cb_G & Cb_B \end{bmatrix} * \begin{bmatrix} R_{IN} \\ G_{IN} \\ B_{IN} \end{bmatrix} + \begin{bmatrix} 0 \\ 2048 \\ 2048 \end{bmatrix}$$

dispc-099

**Figure 12-507. DISPC VP CSC RGB to YUV Matrix (FULLRANGE=1)**

In order to provide YUV422 data to the BT.656 or BT.1120 blocks, the YUV444 format is further converted to YUV422 by sub-sampling the chrominance values. The hardware does this by averaging two-by-two the

chrominance samples. The conversion from YUV444 to YUV422 is performed when the color space conversion in the VP is enabled.

#### 12.9.1.4.1.10.4 DISPC VP BT.656 and BT.1120 Modes

Each VP output can be configured in BT.656 or BT.1120 mode. The following standards are not supported in BT.656 mode:

- BT.470 (Support for conventional Analog TV Systems)
- BT.803 (The avoidance of interference generated by digital television studio equipment)
- BT.1364 (Format of ancillary data signals carried in digital component studio interfaces)

Unsupported formats when BT.1120 mode is used:

- BT.1364 (Support for Ancillary Data during blanking period)

BT.656/BT.1120 modes use embedded EAV/SAV syncs.

Enabling BT.656 or BT.1120 format for a VP output is done by setting DSS0\_VP\_CONFIG[20] BT656ENABLE or [21] BT1120ENABLE register bit, respectively

#### Note

It is not possible to enable BT.656 and BT.1120 mode simultaneously on the same output.

Figure 12-508 shows signal mapping on video port DATA[23:0] output data bus. Bits 9 to 0 are dedicated for BT.656 mode (10-bit). In BT.656 mode however, for compatibility with existing 8-bit interfaces, the two LSBs are ignored and only bits [9-2] are effectively used.

23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Unused														BT.656									

**Figure 12-508. DISPC VP Data Mapping for BT.656 Mode**

Figure 12-509 shows signal mapping on video port DATA[23:0] output data bus for BT.1120 mode. Bits [19-10] (CbCr) and [9-0] (Y) are used in 20-bit mode. Bits [19-12] (CbCr) and [9-2] (Y) are used in 16-bit mode (YCbCr422).

**Figure 12-509. DISPC VP Data Mapping for BT.1120 Mode**

VP outputs support both interlace and progressive content in BT.656/BT.1120 modes. For more information on timings configuration, see [Section 12.9.1.4.1.10.7, DISPC VP Timing Generator and Display Panel Settings](#).

#### Note

In progressive BT.656/BT.1120 mode the maximum output resolution will be limited, as it requires two pixel clock cycles to send out one pixel.

#### 12.9.1.4.1.10.4.1 DISPC BT Mode Blanking

During the transmission of the video signal, the portion of the stream in-between active video data segments is known as the horizontal blanking interval.

Strictly speaking this entire region is the blanking interval, but this interval also includes the EAV and SAV codes. The remaining bytes of information in a digital blanking interval are filled with values corresponding to the

blanking levels of the Cb, Y and Cr signals respectively, and in accordance with the standard multiplex sequence for the stream (CbYCrY...). The blanking levels are as follows:

- Cb = 80h
- Y = 10h
- Cr = 80h.

The sequence in the BLANKING region of the data stream is therefore: 80h, 10h, 80h, 10h.....80h, 10h

For more details on setting the blanking timing values for BT.1120 and/or BT.656 mode, see [Section 12.9.1.4.1.10.7](#), *DISPC VP Timing Generator and Display Panel Settings*.

#### 12.9.1.4.1.10.4.2 DISPC BT Mode EAV and SAV

The End of Active Video (EAV) and Start of Active Video (SAV) parts of the stream are timing codes. Their function can be summarized as follows:

- EAV – marks the end of the active video data within the current line and therefore also the start of the subsequent line.
- SAV – heralds the start of the active video data within the current line.

These codes are embedded within the BT.656 video data stream, thereby eliminating the need for additional timing signals (HSYNC, VSYNC) to be included as part of the interface.

Both EAV and SAV codes are comprised of a sequence of four bytes ( FFh – 00h – 00h - XY). The first three bytes in the sequence constitute a fixed preamble. The fourth byte, contains information about the field being transmitted (Field 1 or Field 2 in an interlaced video signal), the state of field blanking (Vertical) and the state of line blanking (Horizontal). The bit assignment for this byte of the code is shown in [Figure 12-510](#), with the function of each bit described in [Table 12-437](#).

MSB				LSB			
1	F	V	H	P3	P2	P1	P0

**Figure 12-510. DISPC BT Mode Bit-Assignment for the Fourth Byte of EAV/SAV Codes**

**Table 12-437. DISPC BT Mode Bit Function**

Bit	Symbol	Function
7	1	Always set to '1'.
6	F	Field bit. 0 – Field 1 1 – Field 2
5	V	Vertical Blanking Status bit. This bit goes High during a vertical field blanking interval, otherwise it remains Low.
4	H	Horizontal Blanking Status bit. 0 – byte is part of SAV code (i.e. stream is entering an active video data region for the current line) 1 – byte is part of EAV code (i.e. stream has entered a horizontal blanking interval - start of a new line)
3	P3	Protection bit 3
2	P2	Protection bit 2
1	P1	Protection bit 1
0	P0	Protection bit 0

The protection bits allow for detection and correction of 1-bit errors and the detection of 2-bit errors. The status of P3, P2, P1 and P0 depend on the states of bits F, V, and H. This dependency is shown in [Table 12-438](#).

**Table 12-438. DISPC BT Mode Status of Protection Bits in Function of F, V, and H**

F	V	H	P3	P2	P1	P0
0	0	0	0	0	0	0

**Table 12-438. DISPC BT Mode Status of Protection Bits in Function of F, V, and H (continued)**

F	V	H	P3	P2	P1	P0
0	0	1	1	1	0	1
0	1	0	1	0	1	1
0	1	1	0	1	1	0
1	0	0	0	1	1	1
1	0	1	1	0	1	0
1	1	0	1	1	0	0
1	1	1	0	0	0	1

#### 12.9.1.4.1.10.5 DISPC VP Spatial/Temporal Dithering

The active spatial/temporal dithering logic can be enabled to minimize the color banding when displaying the data on an LCD panel with color depth lower than 24-bit. The dithering logic is integrated after the color/gamma conversion blocks and before the TDM (Time Division Multiplexed) block. The spatial/temporal dithering algorithm is based on the (x,y) pixel position and frame rate control (the value of removed bits and the frame number). The dithering logic can process the pixels over one frame, two frames, or four frames. The number of frames is selected by setting the DSS0\_VP\_CONTROL[31-30] SPATIALTEMPORALDITHERINGFRAMES register field. In the case of a single frame, only spatial processing is applied. In case of multiple frames, both spatial and temporal processing are applied to the pixels. The number of frame is initialized before enabling the spatial/temporal dithering logic. It must be never changed by the software while the spatial/temporal logic is enabled. The spatial/temporal dithering logic is enabled by setting the DSS0\_VP\_CONTROL[7] STDITHERENABLE bit to 0x1.

#### Note

- If the interface data bus is smaller than the pixel format size and spatial/temporal dithering is not enabled, the MSBs of the pixel color components are output on the interface data bus.
- If the interface data bus is larger than the pixel format size, then by programming the pixel components replication active/inactive the MSB is replicated to the LSB of the interface data bus.

#### 12.9.1.4.1.10.6 DISPC VP Multiple Cycle Output Format (TDM)

The pixels (only RGB components) after the active matrix dithering unit are formatted on one or multiple cycles (from 1 to 3 cycles). On three cycles, two pixels can concatenate and send to the panel. The cycle format is selected through the DSS0\_VP\_CONTROL[24-23] TDMCYCLEFORMAT bit field. The number of bits for each cycle is set in the DSS0\_VP\_DATA\_CYCLE\_0 register for the first cycle, the DSS0\_VP\_DATA\_CYCLE1 register for the second cycle, and the DSS0\_VP\_DATA\_CYCLE2 register for the third cycle. The output interface data bus width, when TDM mode is enabled (DSS0\_VP\_CONTROL[20] TDMENABLE register bit = 1), can be 8, 9, 12, or 16 bits, configurable through the DSS0\_VP\_CONTROL[22-21] TDMPARALLELMODE register field.

When the TDM is disabled (DSS0\_VP\_CONTROL[20] TDMENABLE = 0), the video port output interface data bus width is configured through the DSS0\_VP\_CONTROL[10-8] DATALINES register field.

When using TDM mode, only up to 24 bits per pixel can be output on the interface. For higher color depth, only the upper bits are kept before converting each pixel into TDM output.

Figure 12-511 through Figure 12-514 show various examples of TDM settings in the function of pixel data formats and the interface data bus width.

**Figure 12-514. DISPC VP TDM 16-Bit Interface Settings**

#### 12.9.1.4.1.10.7 DISPC VP Timing Generator and Display Panel Settings

Each video port output has a dedicated timing generator supporting progressive and interlaced mode. It is clocked using the pixel clock and is configured to generate the video data and sync signals to match the desired video display standard timings.

Two-level configuration for enabling the video ports exists:

- Via the individual DSS0\_VP\_CONTROL[0] ENABLE register bit for each VP. It allows each VP to be independently controlled by two different hosts.
- Via the common DSS0\_COMMON\_DISPC\_GLOBAL\_OUTPUT\_ENABLE[2-0] VP\_ENABLE register field. It allows two or more VP timing generators to be in sync by enabling them simultaneously with a single register write.

Both ENABLE and VP\_ENABLE register fields must be set in order for a VP (timing generator) to start.

Figure 12-515 shows the timing generator display parameters.

**Figure 12-515. DISPC VP Display Timing Parameters**

The width of VP output data bus is configured in the DSS0\_VP\_CONTROL[10-8] DATALINES register field, when TDM feature is disabled. When TDM is enabled, the width of the output data bus is defined according to [Section 12.9.1.4.1.10.6, DISPC VP Multiple Cycle Output Format \(TDM\)](#).

The size of the display panel is defined by:

- Number of lines per frame, DSS0\_VP\_SIZE\_SCREEN[27-16] LPP bit field, with a value from 1 to 4096
- Number of pixels per line, DSS0\_VP\_SIZE\_SCREEN[11-0] PPL bit field, with a value from 1 to 4096

Standard HSYNC/VSYSNC timing generation is programmable as follows:

- Horizontal front porch is set in the DSS0\_VP\_TIMING\_H[19-8] HFP bit field.
- Horizontal back porch is set in the DSS0\_VP\_TIMING\_H[31-20] HBP bit field.
- Horizontal synchronization pulse width is set in the DSS0\_VP\_TIMING\_H[7-0] HSW bit field.
- Vertical front porch is set in the DSS0\_VP\_TIMING\_V[19-8] VFP bit field.
- Vertical back porch is set in the DSS0\_VP\_TIMING\_V[31-20] VBP bit field.
- Vertical synchronization pulse width is set in the DSS0\_VP\_TIMING\_V[7-0] VSW bit field.

When the output is in BT.1120 or BT.656 mode, the following timing constants are mapped onto the DSS0\_VP\_TIMING\_H and DSS0\_VP\_TIMING\_V registers:

- Progressive mode:
  - Horizontal blanking (12 bits) is set in the {DSS0\_VP\_TIMING\_V[3-0] VSW, DSS0\_VP\_TIMING\_H[7-0] HSW} register fields (up to 2048 bytes of horizontal blanking supported).

- Vertical frame blanking No 1 is set in the DSS0\_VP\_TIMING\_V[19-8] VFP bit field.
- Vertical frame blanking No 2 is set in the DSS0\_VP\_TIMING\_V[31-20] VBP bit field.
- Number of lines per frame is set in the DSS0\_VP\_SIZE\_SCREEN[27-16] LPP bit field.
- Number of pixels per line is set in the DSS0\_VP\_SIZE\_SCREEN[11-0] PPL bit field.
- Interlaced mode:
  - Horizontal blanking (12 bits) is set in the {DSS0\_VP\_TIMING\_V[3-0] VSW, DSS0\_VP\_TIMING\_H[7-0] HSW} register fields (up to 2048 bytes of horizontal blanking supported).
  - Vertical field blanking No.1 for Even Field is set in the DSS0\_VP\_TIMING\_H[19-8] HFP bit field.
  - Vertical field blanking No.2 for Even Field is set in the DSS0\_VP\_TIMING\_H[31-20] HBP bit field.
  - Vertical field blanking No.1 for Odd Field is set in the DSS0\_VP\_TIMING\_V[19-8] VFP bit field.
  - Vertical field blanking No.2 for Odd Field is set in the DSS0\_VP\_TIMING\_V[31-20] VBP bit field.
  - Number of lines per field (even) is set in the DSS0\_VP\_SIZE\_SCREEN[27-16] LPP bit field.
  - Delta number of odd field compared to even field (in a single line) is set in the DSS0\_VP\_SIZE\_SCREEN[15-14] DELTA\_LPP bit field. The DELTA\_LPP field only controls the output channel and not the size of the field fetched from the frame buffer in memory. This field must be set to zero for YUV420 format.
  - Number of pixels per line is set in the DSS0\_VP\_SIZE\_SCREEN[11-0] PPL bit field.

Horizontal/vertical synchronization and output enable signals polarity are programmable by setting the DSS0\_VP\_POL\_FREQ[12] IVS, [13] IHS, and [15] IEO register bits. These signals can be gated by setting the DSS0\_VP\_CONFIG[7] VSYNCGATED and [6] HSYNCGATED register bits. In addition, the alignment between VSYNC and HSYNC signals can be programmed via the DSS0\_VP\_POL\_FREQ[18] ALIGN register bit.

The latch of data can be driven on the rising or falling edge of the pixel clock by setting the DSS0\_VP\_POL\_FREQ[14] IPC register bit. The drive of the SYNC and VSYNC signals in the function of the pixel clock is done by setting the DSS0\_VP\_POL\_FREQ[16] RF bit.

#### Note

To set the pixel clock, CTRL\_MMR\_DPIO\_CLK\_CTRL[8] DPIO\_CLK\_CTRL\_DATA\_CLK\_INVDIS setting should always be opposite the DSS0\_VP\_POL\_FREQ[14] IPC setting, and CTRL\_MMR\_DPIO\_CLK\_CTRL[9] DPIO\_CLK\_CTRL\_SYNC\_CLK\_INVDIS setting should always be opposite the DSS0\_VP\_POL\_FREQ[16] RF setting.

For example, if CTRL\_MMR\_DPIO\_CLK\_CTRL[8] DPIO\_CLK\_CTRL\_DATA\_CLK\_INVDIS is set to 0, DSS0\_VP\_POL\_FREQ[14] IPC should be set to 1.

Each VP output can be configured in progressive output mode or interlaced output mode. The selection is done by writing into the bit-field DSS0\_VP\_CONFIG[22] OUTPUTMODEENABLE register bit. The default setting is for progressive mode. The selection can be changed only when the corresponding VP output is disabled. The configuration is independent for each VP output. It is possible to change the configuration of one of the VP outputs while the other VP is enabled.

The pixel clock for each VP output can be gated by setting the DSS0\_VP\_CONFIG[5] PIXELCLOCKGATED register bit.

The hold time of the pixels on the data bus is determined in clock cycles by the DSS0\_VP\_CONTROL[16-14] HT register field.

#### 12.9.1.4.1.11 DISPC Safety Features

For safety critical system applications, DSS supports the following safety features in hardware:

- Data correctness check: To verify intended data is shown correctly on the display.
- Freeze frame detection: To notify a possible frame freeze, when there is no change in the display frame over multiple frame periods.

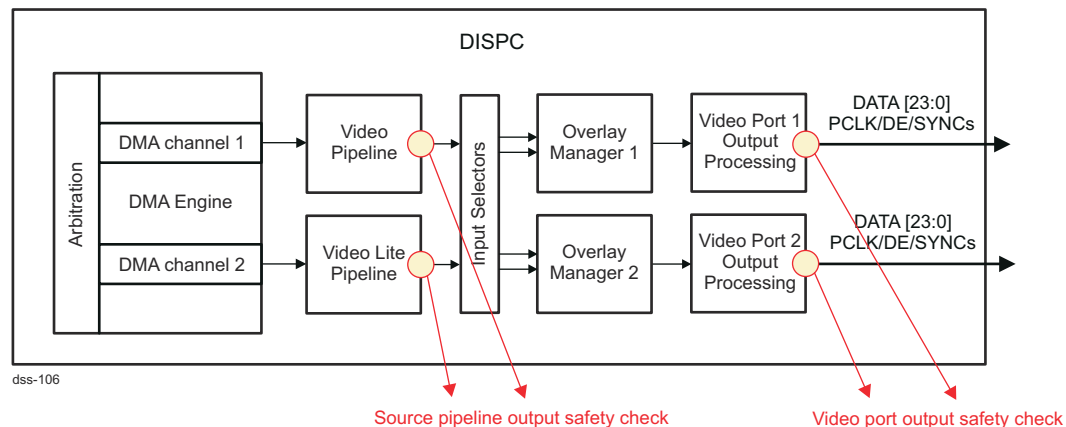

These features are implemented by collecting signatures from user-defined regions within each pipeline output frame and the final display output frame, and comparing them to reference signatures provided by the user

(software) and/or to previously saved signatures. The signature from each region is generated by using a MISR (Multiple Input Signature Register) module.

#### 12.9.1.4.1.11.1 Safety Check Regions

DSS supports the following safety check regions to implement the safety features:

- Video pipelines: One safety check region at the output of each video pipeline.
- Video port outputs: Up to four sub-regions within the active video output area of the final display output of each video port.

**Figure 12-516. DISPC Safety Check Regions**

Table 12-439 lists the parameters supported by each of the safety check regions, together with the associated register control fields.

**Table 12-439. DISPC Safety Check Regions Parameters**

Safety Region Parameter	Video Pipeline Control Register	Video Port Sub-region 0 Control Register	Video Port Sub-region 1 Control Register	Video Port Sub-region 2 Control Register	Video Port Sub-region 3 Control Register
X position	DSS0_VID_SAFETY_POSITION_N[11-0] POSX	DSS0_VP_SAFETY_POSITION_0[11-0] POSX	DSS0_VP_SAFETY_POSITION_1[11-0] POSX	DSS0_VP_SAFETY_POSITION_2[11-0] POSX	DSS0_VP_SAFETY_POSITION_3[11-0] POSX
Y position	DSS0_VID_SAFETY_POSITION_N[27-16] POSY	DSS0_VP_SAFETY_POSITION_0[27-16] POSY	DSS0_VP_SAFETY_POSITION_1[27-16] POSY	DSS0_VP_SAFETY_POSITION_2[27-16] POSY	DSS0_VP_SAFETY_POSITION_3[27-16] POSY
Width	DSS0_VID_SAFETY_SIZE[11-0] SIZEX	DSS0_VP_SAFETY_SIZE_0[11-0] SIZEX	DSS0_VP_SAFETY_SIZE_1[11-0] SIZEX	DSS0_VP_SAFETY_SIZE_2[11-0] SIZEX	DSS0_VP_SAFETY_SIZE_3[11-0] SIZEX
Height	DSS0_VID_SAFETY_SIZE[27-16] SIZEY	DSS0_VP_SAFETY_SIZE_0[27-16] SIZEY	DSS0_VP_SAFETY_SIZE_1[27-16] SIZEY	DSS0_VP_SAFETY_SIZE_2[27-16] SIZEY	DSS0_VP_SAFETY_SIZE_3[27-16] SIZEY

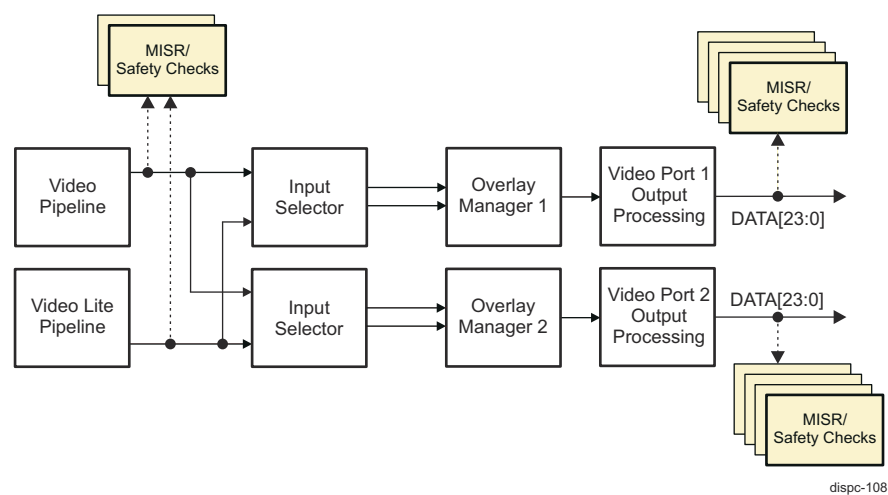

Figure 12-517 shows examples of one safety region in the video pipeline output stage and up to 4 possible regions in the final video port output stage.

**Figure 12-517. DISPC Safety Check Region Examples**

The safety region in the video pipeline captures data only if the embedded alpha data is not equal to 0 (that is, non-transparent pixels). The safety regions in the display video port output captures all active video pixels within the region boundary. The (up to four) regions in the display output should be typically non-overlapping areas of the screen, but the hardware does not restrict them to be non-overlapping.

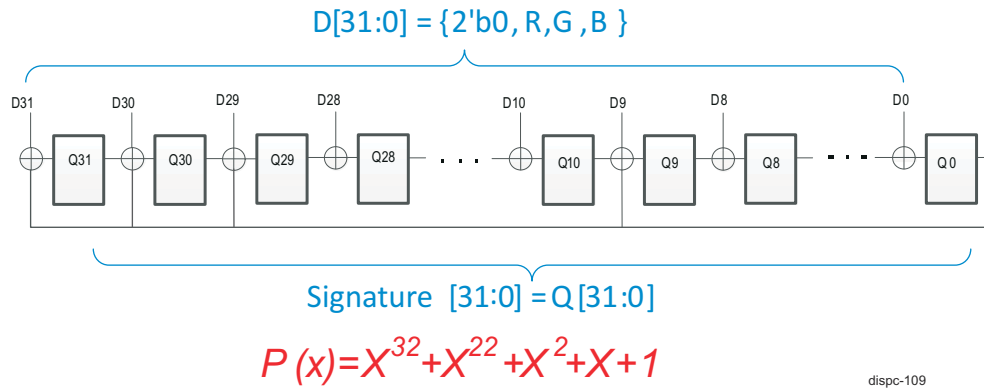

Figure 12-518 shows the locations within DISPC data path where the data is analyzed.

**Figure 12-518. DISPC Safety Check Locations**

#### 12.9.1.4.1.11.2 Safety Signature Generator Using MISR

A 32-bit multiple input signature register (MISR) with 32-bit Galois LFSR polynomial,  $P(x)=X^{32}+X^{22}+X^2+X+1$ , is used to capture a signature of active video pixel data (the 10 MSB bits of each color component) for each safety region, as shown in Figure 12-519 and the algorithm below it.

**Figure 12-519. DISPC Safety 32-bit MISR Implementation**

The MISR (32-bit Galois LFSR based) signature generation algorithm is as follows:

Tap\_polynomial = 32'hE000\_0200

lfsr\_q = seed // initial LFSR value - any non zero value should work

For each (pixel data in the safety region) {

data\_in[31:0] = { 2'b0, r,g,b } // 10 MSB bits of R,G,B components

lfsr\_d = (data\_in(lfsr\_q >> 1))

If (lfsr\_q[0]) lfsr\_d = lfsr\_d<sup>Tap\_polynomial</sup>

lfsr\_q = lfsr\_d

}

signature = lfsr\_q

All MISRs are initialized at the beginning of each frame with a non-zero "seed" value either with the default constant value (0xFFFF\_FFFF) or with the programmable seed configuration value in SAFETY\_LFSR\_SEED register for each group of regions (refer to Table 12-439, *DISPC Safety Check Regions Parameters*). Note that a same seed must be used to compare signatures between two frames. If different than the default seed value is desired, then a SEEDSELECT parameter must be set before the corresponding SAFETY\_LFSR\_SEED register is configured with the customer seed value.

All captured signatures from safety regions are memory mapped to read-only registers SAFETY\_CAPT\_SIGNATURE for each video port (refer to Table 12-439, *DISPC Safety Check Regions Parameters*). A SAFETY\_CAPT\_SIGNATURE register is updated with the signature from each sub-region at the end of every frame. This register returns the signature of the last frame data when the MISR is enabled. When MISR is disabled, this register is cleared.

The MISR aliasing (faulty signature matches fault-free signature) probability is:

$$(2^{(L-n)}-1)/(2^L-1) \approx 2^{(L-n)}/2^L = 2^{-n} \text{ for large } L, \text{ where}$$

n = length of signature register

L = length of input sequence

Using the above approximation, the result is:

n=4, aliasing probability = 6.25%

n=16, aliasing probability = 0.0015%

...

n=32 (as in DISPC MISR), aliasing probability is  $\sim 2^{-32}$  (negligible)

#### 12.9.1.4.1.11.3 Safety Checks

If the data correctness check is enabled (see [Table 12-439, DISPC Safety Check Regions Parameters](#)):

- When a new signature is generated, it is compared against the reference signature provided by the software. A SAFETY\_REF\_SIGNATURE register must be configured with a reference signature data, see [Table 12-439, DISPC Safety Check Regions Parameters](#).
- If signatures do not match, an interrupt event is generated to indicate data mismatch.

If the freeze frame detection is enabled (see [Table 12-439, DISPC Safety Check Regions Parameters](#)):

- When a new signature is generated, it is first compared against the saved signature (from previous frame).
- If signatures match, an internal counter used to keep track of the number of frames with no data change (for the region) is incremented.
- If signatures do not match, the counter is cleared.
- If the counter value is greater than the user programmed freeze frame detection threshold value (see [Table 12-439, DISPC Safety Check Regions Parameters](#)), an interrupt event (VIDSAFETYREGION\_IRQ or VPSAFETYREGION\_IRQ, see [Section 12.9.1.4.1.5, DISPC Interrupt Requests](#)) is generated to indicate a possible freeze frame detection. The threshold value must be configured with the maximum number of identical successive frames allowed before an interrupt is generated.
- After the comparison, the signature is saved as the previous signature.
- The counter is cleared when the interrupt event is generated or when freeze frame detection check is disabled.

This frame freeze is different from the display frozen due to pipeline lock up. In that case, the DISPC will generate an SYNCLOST\_IRQ and/or DMA VIDBUFFERUNDERFLOW\_IRQ interrupt. The freeze frame detection is for source data frozen while the DSS is working normally.

The two safety checks are continuously performed over multiple frames as long as their mode enable register bits are set.

#### 12.9.1.4.1.11.4 Safety Check Limitations

The safety check will only be available when the DISPC is outputting RGB/YUV component data with separate sync signals. The safety functions are not available for following modes:

- YUV422 embedded sync modes (BT.656 and BT.1120)
- RGB TDM (Time Division Multiplex) mode

#### 12.9.1.4.1.12 DISPC Security Management

##### 12.9.1.4.1.12.1 Security Implementation

DSS supports the following security features:

- Secure mode configuration
- Illegal connection prevention

#### Secure Mode

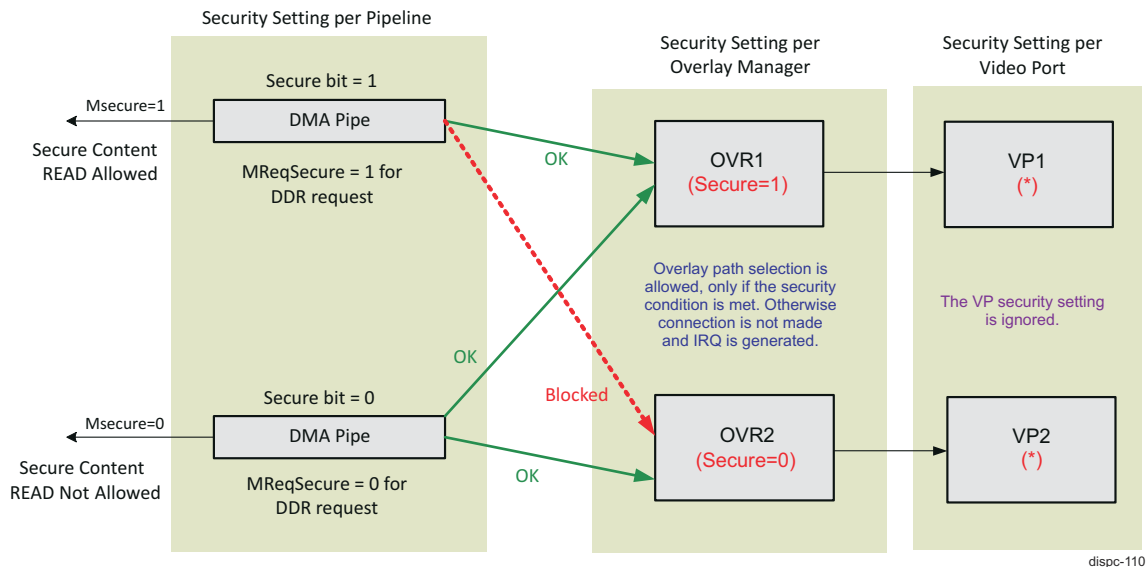

DISPC supports a secure mode configuration register (DSS0\_COMMON1\_DISPC\_SECURE) which defines the "secure mode: attribute of each pipeline, overlay manager, and video port instance in DISPC. This register can only be modified by a host with an appropriate secure privilege (MReqSecure=1). When the secure bit corresponding to an instance is set by a secure host, the instance is deemed to be in "secure mode" and the DISPC hardware prevents the output of the instance getting connected to a non-secure downstream module. Also, any DMA transfer initiated by a secure pipeline will have its OCP in-band signal MReqSecure set to HIGH to indicate that is a secure mode transaction request.

By default, all pipelines, overlay managers, and video port instances are in a "non-secure mode". The DSS0\_COMMON1\_DISPC\_SECURE register bits are active, only when the DSS0\_COMMON1\_DISPC\_SECURE\_DISABLE[0] SECURE\_DISABLE register bit is configured properly to 0x0. When the SECURE\_DISABLE bit is set to 0x1, the DSS0\_COMMON1\_DISPC\_SECURE register bits are non-active and DISPC will behave as non-secure module.

### Illegal Connection Prevention

DISPC hardware enforces the following rules to prevent an illegal connection:

- Secure input pipeline can only connect to a secure overlay manager: If any host (secure or non-secure) configures an overlay manager input selection to connect a secure input pipeline to a non-secure overlay manager, then the DISPC hardware will block the connection and issue a "security violation" interrupt (SECURITYVIOLATION\_IRQ) to alert the host.

**Figure 12-520. DISPC Secure Bit Setting and Illegal Connection Block**

#### 12.9.1.4.1.12.2 Secure Mode Configuration

The secure bit of DSS0\_COMMON1\_DISPC\_SECURE register is set/reset by a secure transaction. When the secure bit has been set, the software in "secure mode" is responsible for checking the DISPC configuration. The secure bit is propagated by DISPC to the system Interconnect in order to qualify all DISPC requests as secure or non-secure requests, based on the secure bits defined in the control register.

When DISPC accesses the frame buffer, in the case the secure bit has been reset and the frame buffer has been set secure, the display controller will receive an "error" in response of non-secure requests.

#### 12.9.1.4.1.13 DISPC Shadow Registers

Some DISPC registers are termed *shadow registers*. The shadow registers allow the software to modify them at any time, without direct effect on the DISPC hardware configuration. When all the values for a given configuration are written into the shadow registers, software must set only one register bit to validate the configuration. When the hardware reaches the end of the current frame and sees that the bit has been set by software, the new configuration is now the configuration used by the hardware.

The DSS0\_VP\_CONTROL[5] GOBIT bit enables the hardware to use the new configuration, for all shadow registers associated with each VP output.

The registers are statically associated to a particular output (for example, timing registers) or dynamically associated to one output at a time (for example, video registers).

### 12.9.1.4.2 OLDITX Functional Description

#### 12.9.1.4.2.1 OLDITX Overview

The OpenLDI transmitter (OLDITX) supports serialized RGB pixel data transmission between host and flat panel display over LVDS (Low Voltage Differential Sampling) interface. The LVDS interface complies with ANSI/TIA/EIA644-A standard (Electrical Characteristics of Low Voltage Differential Signaling (LVDS) Interface Circuits). The OLDITX consists of 7-to-1 data serializers, and 4-data and 1-clock LVDS outputs. The OLDITX translates 21 or 28-bit wide video/sync data into LVDS data, 3 or 4 bits wide and 7 bits deep. At a maximum pixel rate of 170 MHz, the speed of a single LVDS data lane is 1.19 Gbps providing a total throughput of 4.76 Gbps over a single OLDI link.

Figure 12-521 shows the high level overview of the OLDITX module.

**Figure 12-521. OLDITX Block Diagram**

#### 12.9.1.4.2.2 OLDITX Clocks

OLDITX receives one pixel clock, OLDI\_FWD\_P\_CLK. The pixel clock rate is 1/7 of serial clock rate in single-link mode and 2/7 of serial clock rate in dual-link mode.

OLDITX receives one serial clock (OLDI\_PLL\_CLK) to perform 7-to-1 serialization. OLDI\_PLL\_CLK is 3.5x or 7x OLDI\_FWD\_P\_CLK frequency, where 25MHz < OLDI\_FWD\_P\_CLK (freq) < 170MHz.

For more details on OLDITX clocks, see *DSS Integration*.

#### 12.9.1.4.2.3 OLDITX Resets

There are two resets for the OLDITX module:

- Hardware reset, OLDITX\_RST.
- Software reset, OLDITX\_SW\_RST, driven by DSS0\_VP\_DSS\_OLDI\_CFG[12] SOFTRST register bit. The software reset is combined with OLDITX\_RST to drive the reset to all the sub-modules.

The reset status of OLDITX module can be read in DSS0\_COMMON\_DSS\_SYSSTATUS[5] OLDI\_RESETDONE register bit.

#### 12.9.1.4.2.4 OLDITX Input Interface

The input to the OLDITX is a standard DPI interface bus (direct output of a DSS DISPC video port), which consists of the following signals:

- VSync and HSync sync signals
- DE, data enable (active video signal)
- RGB[23:0] parallel data

OLDITX receives 18-bit or 24-bit RGB input source data from the DSS DISPC video port. The DSS interface is clocked on the rising edge of OLDI\_FWD\_P\_CLK pixel clock (whose frequency is exactly 1/7 of the

OLDI\_PLL\_CLK serial clock). The DATA, VS, HS, and DE signals are treated as data to be mapped onto the LVDS output shifter. The start of accepting and processing the DSS interface data happens after DSS0\_VP\_DSS\_OLDI\_CFG[0] ENABLE bit is asserted to 0x1 and synchronized to the internal pixel clock.

#### 12.9.1.4.2.4.1 OLDITX 24-bit RGB Input

The 24-bit RGB input source data (either non-dithered or dithered to 24-bit) coming from the DSS DISPC video port is expected to have the components mapping shown in [Table 12-440](#). The DSS0\_VP\_DSS\_OLDI\_CFG[8] MSB register bit must be set for 24-bit input.

**Table 12-440. OLDITX 24-bit RGB Input for 24-bit LVDS Output**

23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R[7:0]								G[7:0]								B[7:0]							

Both 18-bit and 24-bit LVDS output mappings are supported with this 24-bit input format. For 18-bit LVDS output mapping however, the 6 MSB bits of each component are mapped to the output as shown in [Table 12-441](#). OLDITX does not support dithering to reduce 24-bit RGB input to 18-bit RGB LVDS output. If dithering is required, then DSS DISPC must perform the dithering and send the data to OLDITX as an 18-bit panel data as shown in [Section 12.9.1.4.2.4.2, OLDITX 18-bit RGB Input](#).

**Table 12-441. OLDITX 24-bit RGB Input for 18-bit LVDS Output**

23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R[5:0]						Unused		G[5:0]						Unused		B[5:0]						Unused	

#### 12.9.1.4.2.4.2 OLDITX 18-bit RGB Input

The 18-bit RGB source data (typically dithered to 18-bit) coming from the DSS DISPC video port is expected to have the component mapping shown in [Table 12-442](#). The DSS0\_VP\_DSS\_OLDI\_CFG[8] MSB register bit must be set for 18-bit input. Only 18-bit LVDS output mapping is supported with this input type.

**Table 12-442. OLDITX 18-bit RGB Input**

23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Unused						R[5:0]						G[5:0]						B[5:0]					

#### 12.9.1.4.2.5 OLDITX Output Mode Configuration

OLDITX0 and OLDITX1 support:

- Single link output mode: This is a single stream format for which up to four serial data lanes (four LVDS pairs) are used to transmit a video stream. An additional lane is used to transmit the pixelclock.
- 2x Single-link (duplication) output mode: This is a dual stream format for which up to four serial data lanes are used to transmit each video stream (8 total). An additional lane is used to transmit each pixel clock.
- Dual link output mode: This is a single stream format which up to eight serial data lanes are used to transmit a video stream. An additional two lanes are used to transmit the pixelclock.

A single OpenLDI interface is capable of driving up to WUXGA (1920x1200@60p, 162 MHz pixel clock) resolution, and can be used as long as the receiving display or link bridge device can accept the video output from the device through a single OLDI link. Typically, only display resolutions less than 1366x768 require a single link interface. Adding the second interface for dual-link operation does not increase available bandwidth, but decreases required pixel clock by half.

The sequence of bringing up OLDITX in single link mode is as follows:

1. Configure all PLLs that provide the required OLDITX clocks (see *Module Integration*).
2. Keep OLDITX\_SW\_RST in the default reset state 0 (controlled via DSS0\_VP\_DSS\_OLDI\_CFG[12] SOFTRST register bit).
3. Configure the following parameters:

- Input video data and pixel clock source, in DSS0\_VP\_DSS\_OLDI\_CFG[4] SRC register bit
  - OLDITX module enable, in DSS0\_VP\_DSS\_OLDI\_CFG[0] ENABLE register bit
  - DE input polarity, in DSS0\_VP\_DSS\_OLDI\_CFG[7] DEPOL register bit
  - Combining of links, in DSS0\_VP\_DSS\_OLDI\_CFG[11] DUALMODESYNC register bit:
    - Zero for single-link(s)
    - One for dual-link
  - Link mode, in DSS0\_VP\_DSS\_OLDI\_CFG[5] MODE register bit:
    - Zero for single stream
    - One for stream duplication
  - Mapping of video to LVDS channel (for single link mode), in DSS0\_VP\_DSS\_OLDI\_CFG[3-1] MAP register field:
    - A, B, or C Types for single-link
    - D, E, or F Types for dual-link
  - Input data format (for 18-bit LVDS output), in DSS0\_VP\_DSS\_OLDI\_CFG[8] MSB register bit
  - Test pattern enable (must be 0 for normal operation), in DSS0\_VP\_DSS\_OLDI\_CFG[13] TPATCFG register bit
4. Software checks that the PLLs are stable and locked.
  5. Release OLDITX\_SW\_RST = 1 (by configuring DSS0\_VP\_DSS\_OLDI\_CFG[12] SOFTRST register bit).
  6. Software waits for DSS0\_COMMON\_DSS\_SYSSTATUS[5] OLDI\_RESETDONE register bit = 1.
  7. DSS sends RGB data.

Typically, OLDITX should be configured to send out 24-bit RGB data on four LVDS data lanes. But, it can also be configured (via DSS0\_VP\_DSS\_OLDI\_CFG[3-1] MAP register field) to send only 18-bit RGB data (6-bits/component) on three LVDS lanes, when connecting to a low resolution monitor. In this configuration, only 4 LVDS pairs (3 data lanes + 1 clock lane) are active, while the 4th data lane is disabled. When OLDITX is configured to send out 18-bit LVDS-mapped data, then the DSS0\_VP\_DSS\_OLDI\_CFG[8] MSB register bit must be used to select the format of the input source data bus (for more information, see [Section 12.9.1.4.2.4, OLDITX Input Interface](#)).

### Note

Software may change the mode of operation by first asserting low the OLDITX\_SW\_RST reset, then follow the sequence described in this section.

Software needs to ensure that OLDITX\_SW\_RST is asserted low, if the PLLs are not locked.

For more information on LVDS data format mapping and LVDS data output bit format, see [Section 12.9.1.2.2, DSS LVDS Interface](#).

#### 12.9.1.4.2.6 OLDITX Loopback Test Mode

OLDITX supports data loopback mode to check for DC faults in the digital (parallel to serial conversion logic) and analog (LVDS transmitter) data signal path.

In the loopback test mode, the sending module (DSS DISPC) drives all OLDITX input signals (data and sync) to either all 1s or 0s. All 1s and all 0s will be captured as a static 1 or 0 at the output of the LVDS loopback receiver (enabled only during the test mode). To ensure that there are no faults in the parallel to serial conversion logic path, a simple pattern check of 1s or 0s is performed on the serializer data and reported back along with the LVDS loopback value. These signals are then passed back to DSS and mapped to the DSS0\_VP\_DSS\_OLDI\_LB[9-0] LBRDATA register field for test software to read.

For loopback testing of the clock differential output signals, OLDITX drives all 0s or 1s pattern (based on the DSS0\_VP\_DSS\_OLDI\_CFG[10] LBDATA register bit configuration) instead of the normal clock pattern, when the loopback test is enabled.

Since there is no de-serializer in the loopback path, the loopback mode is intended for facilitating a system diagnostic testing with a constant data output (all 0s or 1s) at low-speed. In normal operation, the loopback mode must be disabled.

When loopback is enabled in DSS0\_VP\_DSS\_OLDI\_CFG[9] LBEN register bit, the loopback of data in this order from MSB to LSB {all\_0\_1[4:0], oldi\_ch\_ret\_clock, oldi\_ch\_ret\_data[3:0]} will be returned in DSS0\_VP\_DSS\_OLDI\_LB[9:0] LBRDATA register field.

### Verifying loopback

Set up OLDITX for a single mode and select the DSS input data. Configure the parameters as shown for either Case 1 or Case 2 below. Set DSS0\_VP\_DSS\_OLDI\_CFG[9] LBEN = 1 and enable OLDITX to start sending data. Check after 10 pixel clock periods.

Case 1, all 0's stuck-at test:

- DSS0\_VP\_DSS\_OLDI\_CFG[3-1] MAP = 000
- DSS0\_VP\_DSS\_OLDI\_CFG[10] LBDATA = 0
- OLDI\_0\_DATA[23:0] = all 0's (this is input data from DSS)
- OLDI\_0\_HS, OLDI\_0\_VS, OLDI\_0\_DE = 0's (these are input signals from DSS)

Check:

- DSS0\_VP\_DSS\_OLDI\_LB[9-5] LBRDATA = 11111
- DSS0\_VP\_DSS\_OLDI\_LB[4-0] LBRDATA = 00000

Case 2, all 1's stuck-at test:

- DSS0\_VP\_DSS\_OLDI\_CFG[3-1] MAP = 000
- DSS0\_VP\_DSS\_OLDI\_CFG[10] LBDATA = 1
- OLDI\_0\_DATA[23:0] = all 1s (this is input data from DSS)
- OLDI\_0\_HS, OLDI\_0\_VS, OLDI\_0\_DE = 1's (these are input signals from DSS)

Check:

- DSS0\_VP\_DSS\_OLDI\_LB[9-5] LBRDATA = 11111
- DSS0\_VP\_DSS\_OLDI\_LB[4-0] LBRDATA = 11111

Note that DSS0\_VP\_DSS\_OLDI\_LB[3] LBRDATA = 1. In functional operation, the LVDS A30:A36 in 18-bit single mode are not being driven by input data, rather all 0's. In loopback mode, each of A30:A36 is driven by OLDI\_0\_DE. In other single modes, the "reserved or NA" bit fields, as described in the LVDS data format mapping tables in [Section 12.9.1.2.2, DSS LVDS Interface](#), are driven by OLDI\_0\_DE in loopback mode.

## 12.9.2 MIPI Display Serial Interface (DSI) Controller

### 12.9.2.1 DSI Block Diagram

The MIPI DSI v1.3.1 Transmitter Controller (DSITX) provides an interface that receives data and control from the host processor display system using either the DPI or SDI input bus interfaces. The DSITX will translate the incoming pixel information and control signals into an internal packed byte format, in the case of DPI, or pass in the prepacked SDI byte format, before the internal byte format data is packetized and sent to the MIPI DSI Compatible display via the MIPI D-PHY physical interface. It supports video and command mode displays and can work in multi-display mode using virtual channel identification on the packets.

The DSITX controller provides two interfaces for connection to a display panel. Normal operation for a panel supporting DCS commands can be done using either SDI interface, or using the APB (Advanced Peripheral Bus) access to DIRECT\_CMD registers. Video streaming applications can only use the SDI or DPI interface. The DSI controller supports flow control using the SDI video interface.

The DSITX implements the stream arbitration and low-level protocol layer functionalities required by MIPI DSI specification v1.3. It supports up to 4 x 2.5 Gbps D-PHY data lanes in a single-link configuration and handles the byte lane mapping per use case (1, 2, 3, or 4-lanes).

The DSITX controller block diagram is illustrated in [Figure 12-522](#).

Figure 12-522. DSITX Controller Block Architecture

### 12.9.2.2 DSI Clocking

The DSI receives all the clocks from DISPC or DPHY\_TX modules. There are no other dedicated PLLs. For more details on DSI clocks mapping at DSS and SoC level, see *DSI Integration*.

The DSI requires multiple clocks running asynchronously, that are shown in [Table 12-443](#).

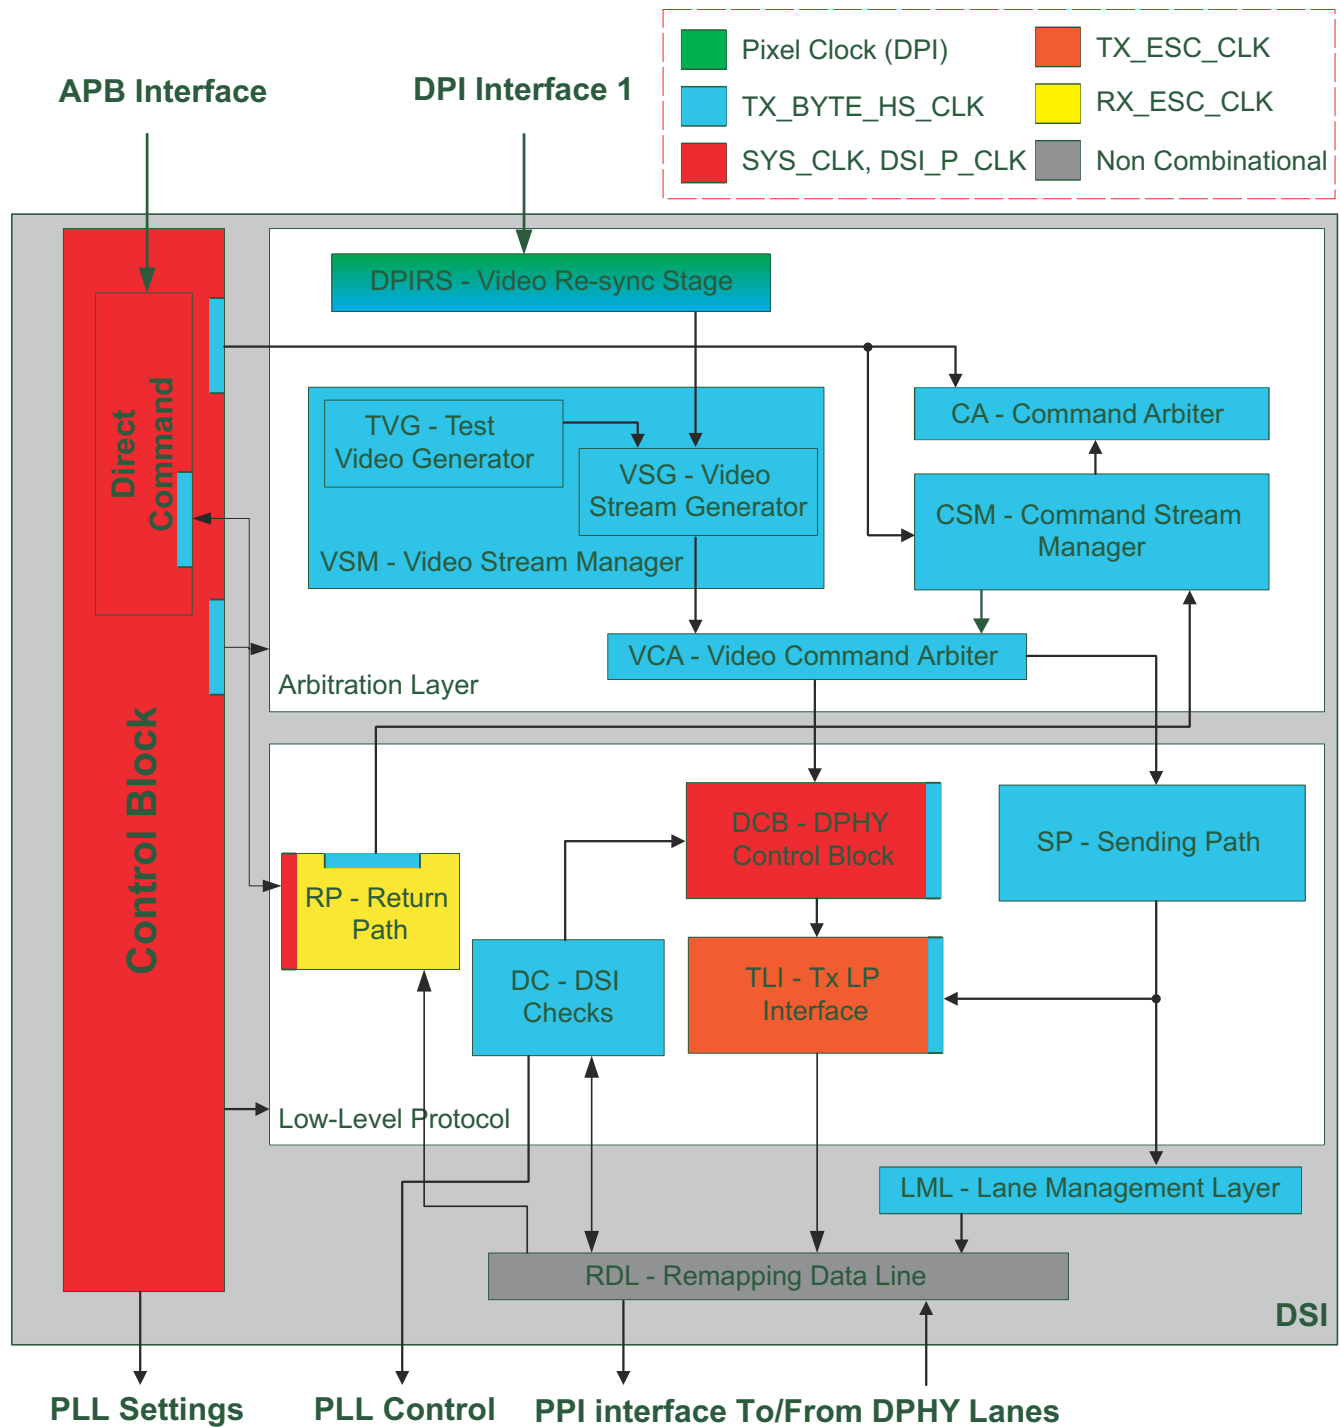

Table 12-443. DSI Clocking

Clock	Direction	Min	Max	Constraints	Description
dpi_0_clk (Async to all other clocks)	Input	7 MHz	425 MHz	$F_{\text{pixel\_clk}} = F_{\text{tx\_byte\_hs\_clk}} \times \text{active\_lanes} \times 8 / (\text{bits\_per\_pixel})$	Used for DPI interface only. Frequency range depends on expected data rate with respect of number of data lanes, data lane frequency and frame rate

**Table 12-443. DSI Clocking (continued)**

Clock	Direction	Min	Max	Constraints	Description
sys_clk (Async to all other clocks)	Input	7 MHz	250 MHz	1. Cannot be slower than $\text{tx\_byte\_hs\_clk} \times \text{datapath\_size} / \text{if\_datasize}$ (risk of underrun) in SDI mode. 2. Must be greater than: $\text{rx\_esc\_clk} \times 8$ . 3. Speed should be sufficient to provide enough data in SDI operation. 4. Must be faster than the $\text{tx\_byte\_hs\_clk}$ for Direct command operation.	Main functional clock Also used for the VBUS/APB interface
dphy_0_tx_byte_hs_clk (Async to all other clocks)	Input	10 MHz	312.5 MHz	The max value in SDI interface operation depends on sys_clk: can't exceed sys_clk freq x if_datasize datapath_size Otherwise 312.5 MHz to match the 2.5Gbps limit on DPHY v1.3 specification	DPHY PPI Byte Clock Frequency set by the DPHY and its High Speed input clock ( $\text{tx\_byte\_hs\_clk} = \text{dphy bit rate} / 8$ ) Maximum limit due to risk of underrun
dphy_0_tx_esc_clk (Async to all other clocks)	Input	1 MHz	20 MHz	No minimum limit is given by the DSI itself - while regular function mode max limit is 20 MHz	TX Escape Clock
dphy_0_rx_esc_clk (Async to all other clocks)	Input	1 MHz	10 MHz	No minimum limit is given by the DSI itself - while regular function mode max limit is 10 MHz	RX Escape Clock

Figure 12-523 describes the clock scheme and domains of the DSI\_TX.

**Figure 12-523. DSITX Clock Scheme and Domains**

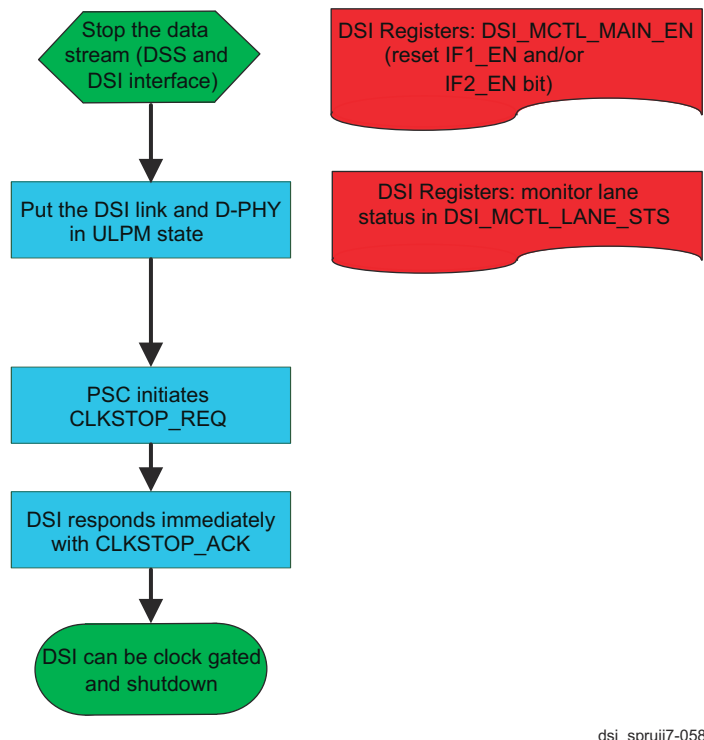

### 12.9.2.3 DSI Reset

The DSI has one active low reset input. The entire internal logic is reset by this reset. Internal resets (synchronous and asynchronous) for different clock domains are generated internally (synchronized to the respective clock domain).

### 12.9.2.4 DSI Power Management

The DSI implements a power management protocol to interface to a PSC (Power and Sleep Controller) module SoC level.

Figure 12-524 shows the expected sequence from SW while performing a *clkstop\_req* to the DSI.

**Figure 12-524. DSI Clock Gate / Power Off Procedure**

### 12.9.2.5 DSI Interrupts

Table 12-444 shows the interrupts that are generated by the DSI module.

**Table 12-444. DSI Interrupts**

Interrupt (n = 0)	Description	Source Module	Source Signal Name
dsi_#n_func_intr	DSI-#n Func Interrupt	DSI Controller	dsi_irq_n
dsi_#n_safety_error_fatal_intr	DSI #n Internal Diagnostic Fatal interrupt	DSI Controller	asf_int_fatal
dsi_#n_safety_error_nonfatal_intr	DSI #n Internal Diagnostic Non-fatal interrupt	DSI Controller	asf_int_nonfatal
ecc_intr_uncorr_level_sys_intr	ECC aggr uncorrectable error	-	-

### 12.9.2.6 DSI Internal Interfaces

#### 12.9.2.6.1 Video Input Interfaces

DSITX supports following video streaming interfaces:

- DPI (Uncompressed video stream)
- SDI (Serial Display Interface)

The DSI does not require DSI sub-link support. Therefore, only one video mode source is supported.

### 12.9.2.6.3 SDI (Serial Data Interface)

DSITX uses a SDI interface (32-bit) to receive active video data from an internal frame memory using a DMA or other data pull mechanism. The interface uses req/ready handshake signaling to control the data flow.

The DSITX SDI Interface supports one of the following modes:

- Command-only

SDI-DSI Interface requires following signals:

- dsi\_if\_valid
- dsi\_if\_stall
- dsi\_if\_start (Line Start)
- dsi\_if\_frame\_sync (frame\_sync)
- dsi\_if\_data

The SDI interface of DSI\_TX receives data directly from DSS VP output and is functional when the user configures the DSS to operate in COMMAND\_STALLMODE (DSS0\_VP\_CONTROL[11] STALLMODE = '1' and DSS0\_VP\_CONTROL[12] STALLMODETYPE = '0').

#### 12.9.2.6.3.1 Secure Display Support

Only secure peripherals can be connected to a secure DPI (VP) output of DSS. In order to support this requirement, the DSS exports a secure qualifier to the DSI\_TX. Inside the DSI a SECURE register is implemented (DSI\_WRAP\_DPI\_SECURE), which contains SECURE bits, [0] DPI\_0\_SECURE and [1] DPI\_0\_SECURE\_VIOLATION, corresponding to the DPI port. These SECURE bits can only be set or reset by a secure host (vbusp transactions with secure qualifier set).

The behavior of DSI module for different settings of SECURE register bit and SECURE qualifier from DSS is as shown below:

**Table 12-446. Secure Display Support**

SECURE Register Bit (DSI)	SECURE mqualifier (DSS)	Security Violation Status	Comments
0	0	0	Data is passed (non-secure DSS data through non-secure DSI)
1	0	0	Data is passed (non-secure DSS data through secure DSI)
1	1	0	Data is passed (secure DSS data through secure DSI)
0	1	1	<b>Security Violation.</b> Data is blocked (secure DSS data through non-secure DSI)

Once a security violation is detected, it is captured in the DSI\_WRAP\_DPI\_SECURE[1] DPI\_0\_SECURE\_VIOLATION register status bit.

### 12.9.2.7 DSI Programming Guide

This section describes the programming guidelines for the DSI Controller and D-PHY.

The goal of this section is to present more in detail how the DSI link should be used at application level plus some scenarios of use of the DSI link (start-up, display switch on/off, dual-display).

#### 12.9.2.7.1 Application Guidelines

The purpose of this section is to provide guidelines on how to drive the DSI host controller, provide general sequence of operations and some typical application notes.

All DSI\_VID\_xxx registers must be programmed, if required, before the write to the DSI\_VID\_MAIN\_CTL register.

All DSI\_MCTL\_DPHY\_xxx registers must be programmed, if required, before the write to the DSI\_MCTL\_MAIN\_DATA\_CTL register to set the [0] LINK\_EN bit.

#### 12.9.2.7.1.4 Panel Configuration Using Command Mode

The DSI controller can provide DCS command access using either the SDI interface or through the APB interface control of the DIRECT COMMAND registers (see [Table 12-447](#)). The panel registers will be programmed using the LP mode before the high-speed video is enabled. Commands can either be sent using the command interface or through the Command FIFO using the APB registers.

The command FIFO access is done through the APB Command mode registers by forming packets of DCS commands. The DCS commands can be found in the MIPI DCS specification or the display panel data sheet.

DCS commands are essentially register write or read transfers to panel registers. The initialization of a panel will require APB register writes to fill the FIFO with the DCS commands. The commands can be grouped into a long packet by sending the packet split into 4 bytes to fill the FIFO using a write to the DSI\_DIRECT\_CMD\_WRDAT register.

**Table 12-447. DSI Direct Command Mode Registers**

DSI Register	Description
DSI_DIRECT_CMD_SEND	Direct Command - trigger the direct command sending - write only
DSI_DIRECT_CMD_MAIN_SETTINGS	Direct Command - main settings
DSI_DIRECT_CMD_STS	Direct Command - status - read only
DSI_DIRECT_CMD_RD_INIT	Direct Command - stop read operation
DSI_DIRECT_CMD_WRDAT	Direct Command - data to write byte 0 to 3
DSI_DIRECT_CMD_FIFO_RST	Direct Command- reset the write FIFO pointer

Each DCS command packet to be sent can be built by first selecting the packet configuration using the DSI\_DIRECT\_CMD\_MAIN\_SETTINGS. The DCS Command data types are defined in the DSI specification based on the number of parameters that are expected to be sent. Configuration of a panel display will normally use DCS write data types.

[Table 12-448](#) shows the DSI\_DIRECT\_CMD\_MAIN\_SETTINGS register bit description.

**Table 12-448. DSI Main Settings Register Description**

DSI_DIRECT_CMD_MAIN_SETTINGS Register Bit	Description
[24] CMD_LP_EN	Enables LP sending for the command request.
[23:16] CMD_SIZE	Size of the command in case of write command - when written value is bigger than 0x10, the value is rounded to 0x10 for write - when size is bigger to 0x2 for read it is rounded to 0x2.
[15:14] CMD_ID	In case of read/write command, Virtual Channel of the command.
[13:8] CMD_HEAD	In case of read/write command, data type of the command:
	0x05 DCS Write 0 parameters Short Packet
	0x15 DCS Write 1 parameter Short packet
	0x39 DCS Long Write N parameters Long Packet
[3] CMD_LONGNOTSHORT	This bit must be tied to one.
[2:0] CMD_NAT	Nature of the direct command: 000: write command.

Once the packet is loaded, issue a DIRECT\_CMD\_SEND (via the DSI\_DIRECT\_CMD\_SEND register) and the data will be sent in LP mode.

### 12.9.2.7.1.5 VIDEO Interface Configuration

The DSI video operation requires the configuration of the VSG and TVG registers to match the panel configuration. The two video interface options will also require careful selection of the clock and registers to achieve error free video streaming.

The DSITX controller supports the mechanism for initial skew calibration for D-PHY data rates greater than 1.5 Gbps.

### DPI Video Interface Operation

The time taken to output a frame on the PPI needs to match what is coming in on the DPI. This is best achieved by using the recommended clock ratio between the pixel and byte clocks. If this is the case, then the blanking and active data periods must be matched up. The DSI controller will match its frame timing to the incoming DPI **VSYNC**, if it is programmed to generate a frame of slightly less than the same size when the VFP blanking is considered.

The controller works by transitioning to LP during the last programmed line of VFP. It will then remain in LP until the start of the next frame. So, programming the controller to match the DPI, but with at least one fewer line of VFP should result in a reliable configuration.

Program the DSI vertical size registers as follows:

- VSA = DPI\_VSI (lines, minimum of 2)
- VBP = DPI\_VBP (lines, minimum of 0)
- VACT = DPI\_VACT (lines)
- VFP < DPI\_VFP (minimum of 1)

The timing should also be matched per line, therefore the blanking and active periods should match. DPI horizontal timing is measured in pixels, whereas the DSI controller uses bytes. If any of the DPI related interrupts are triggered, then this highlights that the FIFO depth and/or the vsync\_delay settings require to be tuned to the current configuration. Simulating the core operation with the expected clocks is the best way to ensure the FIFO depth and vsync\_delay is suitable.

The relationship therefore depends upon the pixel format, which could be 24, 18 or 16 bpp. Additionally, the PPI short packets and packet headers that are inserted by the controller must be accounted for. HSA should be reduced by 14 bytes to account for the HSS short packet (4 bytes), the long blanking packet header and footer (4 + 2 bytes) and the HSE short packet (4 bytes). HBP should be reduced by 12 to account for the header and footer on the blanking packet (6 bytes) plus the header on the active data packet (6 bytes). HFP should be reduced by 6 bytes to account for the long packet header and footer. Finally, for lines with no active data, the BLKLINE\_PULSE\_PCK is the total size minus 20 bytes (14 for HSA, 6 for the remaining blanking which is all combined into a single packet).

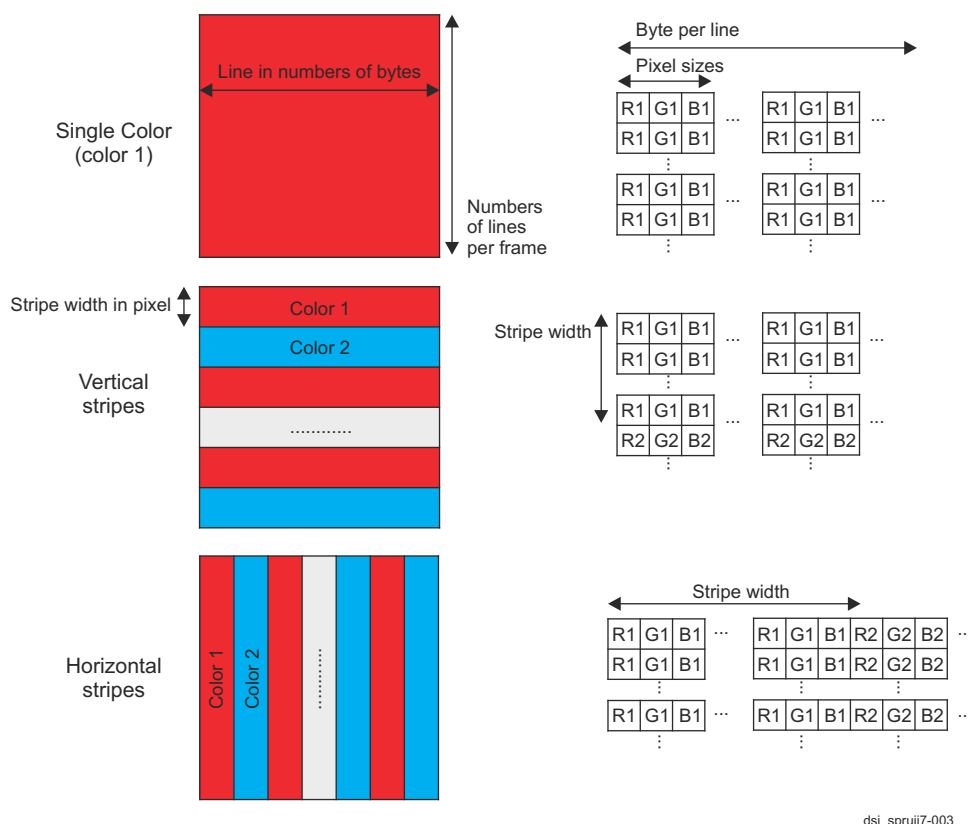

Program the DSI horizontal size registers as follows:

- HSA = (DPI\_HSA × bpp/8) - 14
- HBP = (DPI\_HBP × bpp/8) - 12
- HACT = (DPI\_HACT × bpp/8) NOTE: (DPI\_HACT × bpp/32) must be an integer.
- HFP = (DPI\_HFP × bpp/8) - 6
- BLKLINE\_PULSE\_PCK = ((DPI\_HSA + DPI\_HBP + DPI\_HACT + DPI\_HFP) × bpp/8) - 20;

### TVG Generator

The TVG oversees generating dummy data (to display something even if there is no video stream running). It is also able to ease verification or validation of the DSI without having a complete environment (application or verification test bench). The controller has a Test Video Generator that can be programmed to generate a set of test colour patterns based on the display panel that will be used. The panel parameters for horizontal and vertical resolution along with the frame rate and pixel colour depth need to be set based on the datasheet information for the panel.

Figure 12-527 presents TVG MODE patterns.

**Figure 12-527. TVG MODE Patterns**

The TVG generates a data stream in the same format than the one specified for the normal functional video stream (as set in VSG register). The content of that flow is specified by registers. Those registers specify the following information: Image size: Number of bytes per line (see TVG\_LINE\_SIZE[14:0] register) and number of lines per frame (TVG\_NBLINE[12:0]).

Image kind: Single color, vertical stripes or horizontal stripes (see TVG\_MODE[1:0] register). Stripe width: Significant when a stripe mode is enabled. Possible values are 1, 2, 4, 8, 16, 32, 64 and 128 (see TVG\_STRIPE\_SIZE[2:0] register).

Pixel kind: 16 bits RGB, 18 bits RGB, 18 bits loosely RGB, 24 bits RGB, 30 bits RGB or 36 bits RGB (see VID\_PIXEL\_MODE[3:0] register).

Color one: Color used in single color mode or first color when in stripe mode. 12 bits per component R/G/B. For formats using fewer bits than 12, the least significant ones are the ones considered (see COL1\_GREEN[11:0], COL1\_RED[11:0], COL1\_BLUE[11:0] registers).

Color two: Color two when in stripe mode. 12 bits per component R/G/B. For formats using fewer bits than 12, the least significant are the one considered. (see COL2\_GREEN[11:0], COL2\_RED[11:0], COL2\_BLUE[11:0] registers). Start pulse and stop handshake (+ stop mode) (see TVG\_CTL register).

An example of the sequence is as follows:

- Select TVG for video stream generation instead of SDI 1 interface:
  - IF1\_EN bit to 0 (stall signal at 1) in MCTL\_MAIN\_EN.
- Select video mode for interface 1 in MCTL\_MAIN\_DATA\_CTL:
  - TVG\_SEL bit to 1 in MCTL\_MAIN\_DATA\_CTL register to select stream from TVG.
- Select generated frame format in TVG\_CTL register:
  - Image format (single color, H stripes, V stripes) in TVG\_MODE field.

- Image color selection in TVG\_COLOR1, TVG\_COLOR1\_BIS, TVG\_COLOR2, VG\_COLOR2\_BIS.
- Stripes size in TVG\_STRIPE\_SIZE field.
- Image size in TVG\_IMG\_SIZE register.

**Note:** The number of lines per frame and number of bytes per line. It is required that TVG settings on active area match VSG settings on active area. Any mismatch will create an error that is detected in the VSG and forces recovery mode in TVG, stopping test frame generation.

- Select TVG stop mode with TVG\_STOPMODE field of TVG\_CTL:
  - TVG video stream generation start/stop controlled by the TVG\_RUN bit in TVG\_CTL register. Polling TVG run status from the TVG\_RUNNING bit in TVG\_STS register is useful when setting TVG\_RUN to 0. TVG video stream generation does not stop instantaneously (depends on TVG stop mode), so this should be checked to confirm the TVG has stopped.

#### 12.9.2.7.2 Application Considerations

The following sections outline the normal operation of the DSITX controller and the programming and sequences require to operate the DSITX controller for normal video and command operation.

##### 12.9.2.7.2.1 D-PHY Timings Control

Several DPHY timing constraints must be respected by the system, which are described in this section. When a switch in ULP is requested, the application should be aware that the D-PHY needs 1 ms to leave this state (this timing is guaranteed by the DSI itself). It makes no sense to start an ULP request if the expected time in ULP is short.

When PLL power down is asserted, the system should continue to assert for a specific minimum period of time (PLL internal requirement – please refer to DPHY documentation). Please note that shutting down the PLL implies that no clock is present on tx\_byte\_hs\_clk input and thus the DSI link is stopped; even if the system-side interface clocks remain active, no more HS transfers can be done.

Force\_stop, ppi\_c\_force\_tx\_stop (clock lane) and ppi\_d\_force\_tx\_stop (1 per data lane), can be useful to resolve certain deadlock situations, for example: DSI target does not give back control to controller, or critical DPHY error. When a 'force stop mode' is issued by the application, the system should maintain this state on the bus to ensure the request is correctly considered by the D-PHY cells and the **stop\_state** is asserted and direction signal is deasserted.

reg\_wait\_burst\_time (for the LML) must be programmed to ensure that two HS bursts are separated by at least 100 ns. The value will be based on the period of the tx\_byte\_clk cycle.

VCA: When trying to interleave commands to video stream, it is assumed that only write/read commands and BTA request are sent (no TE). The reason is that such transfers are slow and difficult to predict in term of duration. They could take longer than the slots available for video. The read commands are unpredictable and may cause some break in the video stream, however, they can still be used, if an appropriate response time can be guaranteed. It is the responsibility of the system integrator and the application to plan and implement recovery procedures when the video stream is stalled due to a read that takes too long.

##### 12.9.2.7.2.2 Control Block

Most of the register contents must be resynchronized against a DSI internal clock (tx\_hs\_byte\_clk). This means there is a certain time to pass data from one clock domain to the other. If two writes in the same register are too close, the register itself is updated but the synchronization may fail.

The formula to calculate the number of system clock periods between two writes is:

$$\text{nb\_cycle}(\text{dsi\_p\_clk}) = 6 * (\text{f}_{\text{dsi\_p\_clk}} / \text{f}_{\text{tx\_byte\_hs\_clk}} + 1)$$

The application must respect a period of TX ns between two write accesses to the same register (there is no issue writing different registers back-to-back).

[Table 12-449](#) shows an example of required time between two write accesses.

**Table 12-449. Example of Required Time between Two Write Accesses**

$f_{dsi\_p\_clk}$	$f_{tx\_byte\_hs\_clk}$	TX minimum time between 2 writes accesses
200 MHz	106 MHz	~ 90 ns
160 MHz	10 MHz	~ 650 ns
200 MHz	10 MHz	~ 650 ns

Another place where asynchronous behaviour may interfere with programming in the CB is the direct command status register `DIRECT_CMD_STS`. Some of the bits of this register are set when a pulse (that lasts one clock period) coming from `tx_hs_byte_clk` domain is observed (after resynchronization on `dsi_p_clk`) and is reset when the clear bit is written. In use case where `tx_byte_hs_clk` is slow (10 MHz range), the bit can be read and a clear attempted before the end of the source pulse. This can result in the re-assertion of the bit immediately after it is cleared. For that reason, it is recommended to wait for a while between reading the bits of the `DIRECT_CMD_STS` register and clearing them.

## Application Issues

Some register fields cannot take all the possible values but are restricted to a certain number of combinations (mode control). The DSI controller does not check that all the fields match a valid setup so it is the responsibility of the system integrator and the application to check that the written values are amongst the permitted combinations. Amongst the register fields that fall in to this category are most of the mode settings (stop mode, recovery mode, direct command type, image sizes, etc.)

## Programming Coherency

The application level must ensure that the register configurations are valid for the system to operate correctly. There are several possible combinations are possible in the CB registers however should be avoided. A few examples:

- No HS transfer should be enabled when PLL is shut-off.
- TVG should not be run when the video interface is running.
- No access (from interface or from register) should be attempted while TBG is active.
- Prior to shut-down of the DPHY PLL, application should verify that the DSI link is in proper state. If the bit that enables BTA is not set and that any operation implying a BTA is sent, the system is stalled. Then the bit that enables BTA must be aligned with application needs. Moreover, read enable or TE enable cannot be set if `bta_en` is not set (these operations cannot be enabled when BTA is not enabled).
- TE feature must not be enabled in SDI interface.

### 12.9.2.7.2.3 Video Coherency

In video mode, there are a lot of sizes defined for the video stream generation. This data corresponds to the payload of the various generated packets and not to their duration. However, they are closely linked. It is the responsibility of the system integrator and the application to use correct sizes to ensure the correct video timing and behaviour, because the system may use 1 to 4 active data lanes with a fixed number of bytes for the header/checksum overhead. In the same way, when programming D-PHY time (to switch from LP to HS), the application must consider D-PHY time plus overhead due to LLP and LML crossing time (see [Section 12.9.2.7.7.2, Video stream settings \(VSG\)](#)).

## VSG Control

Start and stop sequences can take a long time to be performed. If the requests are not maintained up to the time the status bit are indicating effective start or stop, they can be ignored and the VSG may not have started or stopped as expected by application. It is then up to the application to carefully manage the request and to verify that requests are being processed before changing the state of the VSG.

## Test Generator:

The DSITX provides test generator to provide a video data stream. When using TVG, all sources can be used (provided VCA permits it) however the SDI interface must not be programmed to send video data and must be restricted to command mode.

The pixel modes supported are: RGB 16-, 18-, 24-, 30- and 36-bit; YCbCr422 16-bit; and YCbCr420 12-bit (note that additional YCbCr422 20-bit and YCbCr420 24-bit may be supported using SDI interface, but are restricted to command mode only).

The supported display sizes are listed below:

- QQVGA (160 x 120) - 15/20/30/60 fps - RGB 16-18-24 (-30 and 36) bits per pixels
- QCIF (176x144), QCIF + (176x208 and 176x220) - 15/20/30/60 fps - RGB 16-18 and 24 bits per pixels
- QVGA (320x240) - 15/20/30/60 fps - RGB R16-18 and 24 bits per pixels
- CIF (352x288), CIF + (352x416 or 352x440) - 15/20/30/60 fps - RGB 16-18 and 24 bits per pixels
- 1/2 VGA (320x480) and 2/3 VGA (640x320) - 15/20/30/60 fps - RGB 16-18 and 24 bits per pixels
- VGA (640x480) - 15/20/30/60 fps - RGB 16-18-24(-30 and 36) bits per pixels
- WVGA (800x480 - 848x480 - 854x480 - 852x480) - RGB 15/20/30/60 fps - 16-18 and 24 bits per pixels
- SVGA (800x600) - 15/20/30/60 fps - RGB 16-18 and 24 bits per pixels
- QHD (960x540) - 15/20/30/60 fps - RGB 16-18 and 24 bits per pixels
- XVGA (1024x768) - 15/20/30/60 fps - 16-18 and 24 bits per pixels
- Full HD (1920x1080) - 15/20/30/60 fps - 16-18 and 24 bits per pixels
- WUXGA(1920x1200) - 15/20/30/60/(120 fps – 16 bpp only) 16, 18 and 24 bits per pixels
- 4Kx4K(4096x4096) - 15/20/30 fps - 16-18 and 24 bits per pixels

### 12.9.2.7.3 Start-up Procedure

The start-up sequence described in [Figure 12-528](#) assumes that the rest of the chip is ready (all clocks are present except tx\_byte\_hs\_clk, application it is ready...) and that the DSI is ready (reset de-asserted).

The following is the most common start up sequence:

Firstly, application layer programs and enables the PLL, then waits for a period for the PLL to lock (minimum time will be defined by the PHY documentation). At the end of the minimum wait period, the application layer should poll the PLL lock status register periodically to confirm lock status, repeating until confirmed. At the end of this step, it is assumed that a clock is present on the tx\_byte\_hs\_clk input (this step may be replaced by an interrupt-based alternative if available from the selected DPHY or provided in the system integration logic).

During the time taken by the PLL to lock, the application can program the configuration registers and prepare the DSI link. This can also be done after the PLL is locked. It should at least configure enough to be able to use LP mode to send direct commands.

Enable clock and data lane(s) per the needs. This action is only concerned with programming registers that control the D-PHY lane enable signal. The active lane configuration with the DSI\_MCTL\_MAIN\_PHY\_CTL and DSI\_MCTL\_MAIN\_EN registers must be programmed to match, i.e. for two data lanes (0 and 1).

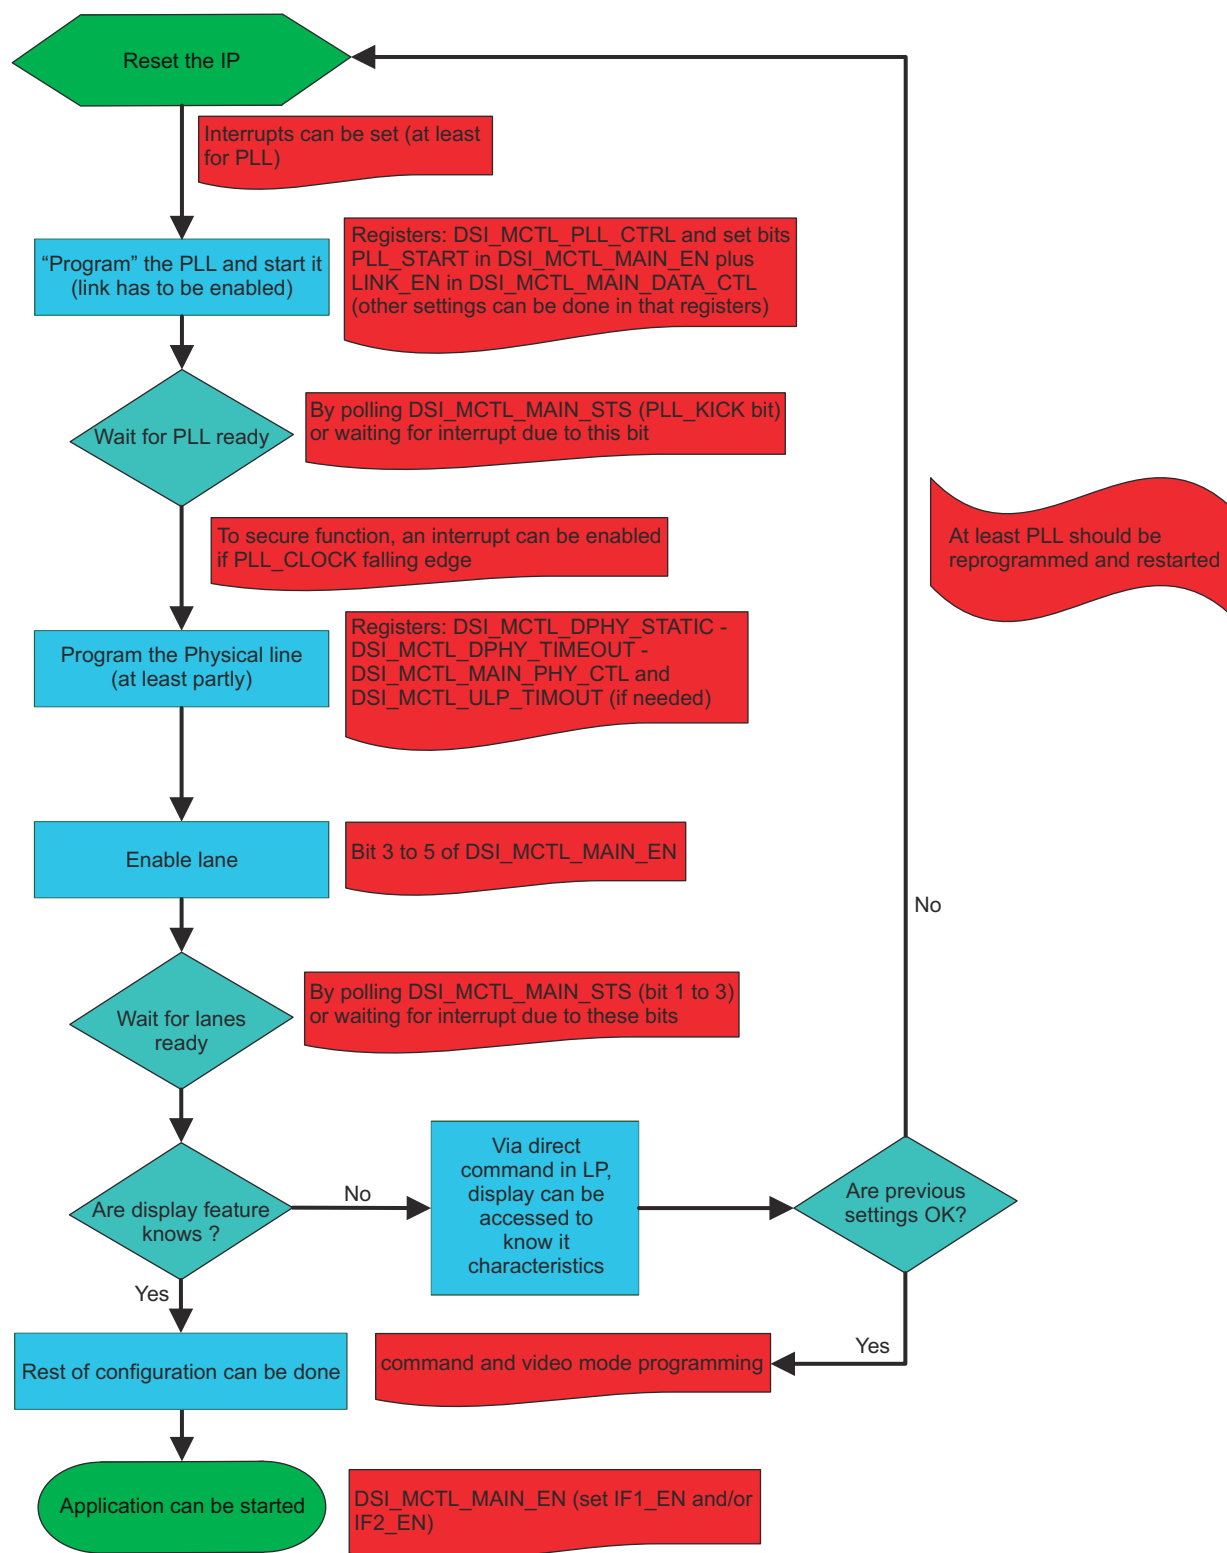

- DSI\_MCTL\_MAIN\_PHY\_CTL (0x08) register – LANE3/4\_EN - bits[2:1] set to zero to disable lanes 2/3.
- DSI\_MCTL\_MAIN\_EN (0x24) register – DAT3/4\_EN fields - bits[6:5] set to zero to disable lanes 2/3.

Start the lane in the DCB. The DCB state machine puts the lanes in the correct state to be ready.

At this step, the DSI link should be able to access to display - at least in LP mode. If the system (DSI link and display) is fully programmed, code to display image can be started. If display characteristics must be read from the display and the system is programmed in LP mode, this is time to read the displays parameters to allow correct programming of the DSI. A new round of programming can then take place to set-up the system, based on the parameters which have been read fro the display.

The DSI internal setting is now completed and it is ready to accept data. The application can now enable the interface so that the stall signal is removed and that DSI link can accept data.

When the procedure described above is terminated, it does not imply that display itself is ready. At this stage, the D-PHY and DSI link are ready to send/receive data to/from display and thus application may still need to initialize the display itself.

dsi\_spruij7-005

Figure 12-528. Start-up Procedure Summary

#### 12.9.2.7.4 Interrupt Management

There are numerous error and status conditions that can be monitored via the interrupt mechanism. The edge on which these conditions are generated is programmable.

Each interrupt source has four associated registers:

1. The status register itself "<sts\_reg>"
2. a control register "<sts\_reg>\_ctl" to control corresponding interrupt behaviour
3. a flag register "<sts\_reg>\_flag" to observe when interrupt/event has been triggered
4. A clear register "<sts\_reg>\_clr" to clear the event flag register.

The decision of which status bits (<sts\_bit>) can generate interrupt is taken when the corresponding enable bit "<sts\_bit>\_en" is set in the status control register. In the same register the status bit edge "<sts\_bit>\_edge" states on which edge of the status bit the interrupt is triggered. When the selected edge is observed, the flag bit "<sts\_bit>\_flag" is set. The interrupt signal is an OR of all flag bits that are enabled. When the register "<sts\_reg>\_clr" is written with the bit "<sts\_bit>\_clr", the "<sts\_bit>\_flag" is cleared.

##### 12.9.2.7.4.1 Error and Status Registers

The error register bank handles storing all error flags that are identified. It also stores some status bits that must be observable and detectable by the application. These status and error registers can generate an interrupt on the rising or falling edge if this generation is enabled.

This mechanism is different depending on the nature of the status or error bits. For those that are generated in the DSI block (basically all status and error bits except direct command), the status bits cannot be easily controlled and toggle according to the internal status meaning only the current value is observed in the status/error register itself.

If the interrupt generation is enabled with the associated enable bit, a rising edge (associated edge bit set to 0) or a falling edge (associated edge bit set to 1) of that status bit toggles the corresponding flag bit. At the end, all the flag bits are put together with an OR to generate the interrupt signal. The flag register can be reset by writing in the clear register.

The described behavior can be summarized by the following pseudo-HDL. The signal named signal\_sts\_bit is the bit that is observable by reading status bit.

- reg\_sts\_q is the status register (accessible via APB)
- reg\_flag\_sts\_q is the flag register
- clear\_the\_flag is set when the register clear is written
- edge\_sts\_ctl is the edge bit
- enable\_sts\_ctl is the enable bit

```
reg_sts_d <= signal_sts_bit;
```

```
reg_flag_sts_d <= '0' WHEN clear_the_flag = '1' ELSE
```

- '1' WHEN (reg\_sts\_q = '0' AND reg\_sts\_d = '1' AND edge\_sts\_ctl = '0') ELSE – detect rising
- '1' WHEN (reg\_sts\_q = '1' AND reg\_sts\_d = '0' AND edge\_sts\_ctl = '1') ELSE – detect falling
- reg\_flag\_sts\_q;

```
irq_n <= NOT (OR_OF_ALL(reg_flag_sts_q AND enable_sts_ctl));
```

The code is slightly different in cases where the observed bit is a generated condition (in the control block), as is the case for the direct command status and error flags. The status/error information is automatically generated but is cleared only when writing in the corresponding clear bit. The interrupt generation behaves similarly to the error condition cases, however, as the status falling edge is observed only when the bit is cleared, it is not possible to use the falling edge detection on flag (however the code is kept as-is to provide a standard implementation method). This leads to the following code:

- reg\_sts\_d <= '0' WHEN clear\_the\_flag = '1' ELSE
- '1' WHEN the\_sts\_bit (Note 1) = '1' AND reg\_sts\_q = '0' ELSE -- (see Note)

- reg\_sts\_q;
- reg\_flag\_sts\_d <= '0' WHEN clear\_the\_flag = '1' ELSE
  - '1' WHEN (reg\_sts\_q = '0' AND reg\_sts\_d = '1' AND edge\_sts\_ctl = '0') ELSE – detect rising
  - '1' WHEN (reg\_sts\_q = '1' AND reg\_sts\_d = '0' AND edge\_sts\_ctl = '1') ELSE – detect falling
- reg\_flag\_sts\_q;
- int <= NOT(OR\_OF\_ALL(reg\_flag\_sts\_q AND enable\_sts\_ctl));

**Note:** In some case (pulse generated), the rising edge detection is not done and the code becomes simply '1' WHEN signal\_sts\_bit = '1' ELSE...

#### 12.9.2.7.4.2 Interrupt Management for Direct Command Registers

The following direct command status bits/registers are only set when error is generated and only cleared when the clear bit is written:

- all the status bits of the register DSI\_DIRECT\_CMD\_RD\_STS
- all the status bits of the register DSI\_DIRECT\_CMD\_STS
- all the status bits except bit 0 (cmd\_transmission) of the register DSI\_DIRECT\_CMD\_STS

As these registers are reset only when the clear register is written, it is not possible to detect the falling edge on them to generate interrupts. Only the rising edges can generate the interrupt.

**Note:** There can be issues with detection when using the bits for all the signals that are a pulse generated in the tx\_byte\_hs\_clk domain. When the speed of that clock is slower in relation to dsi\_p\_clk, it is possible to have the interrupt set, the bit read and the clear attempted before the end of the tx\_byte\_hs\_clk pulse, after the clear, the bit is set again.

#### 12.9.2.7.5 Direct Command Usage

The direct command mechanism is a way to send commands (with a maximum size of direct\_cmd\_fifodepth bytes) by writing and reading registers. It allows commands to be sent that are not allowed through the SDI-DSI interface (DSI commands, triggers), to perform read operations or to send DCS / generic write / generic read operations when the DSI link is not fully programmed and cannot use the SDI interface for commands.

Figure 12-529 shows direct command management sequence.

Basically, the procedure to do so is as follows:

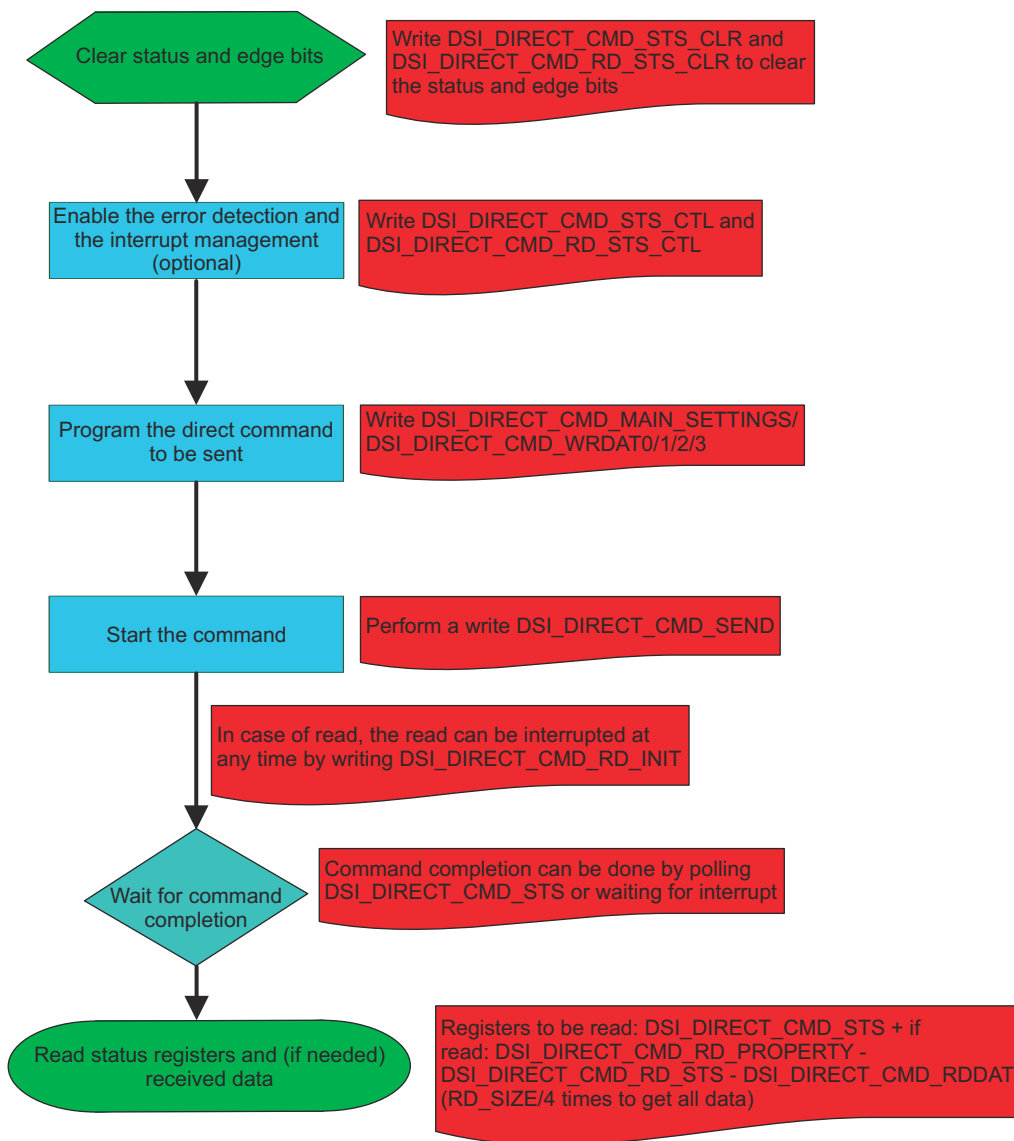

- Clear the status bits (when reading the status bits, only the DSI reads the current access status).
- Program the various registers that define the command to send.
- Write the direct\_cmd\_send register. Writing in that register (any value) triggers the command sending mechanism.

The command should be started only if the command request is amongst the defined ones for DCS or Generic Write or Read with 0, 1, or more parameters:

- DCS Write codes 0x05, 0x15, 0x39
- DCS Read codes 0x06
- Generic Write codes 0x03, 0x13, 0x23, 0x29
- Generic Read codes 0x04, 0x14, 0x24

**Note:** The direct\_cmd\_main\_settings register can use other data type values for cmd\_head to support future types and no check is performed for invalid types.

- Wait for the assertion of the command\_completed bit in the direct\_cmd\_sts register (or any of the relevant bits that indicate a specific command termination). Instead of polling the registers, it is possible to enable the corresponding interrupts and wait for its detection.
- Read the received data and (if any) the different status bits.

dsi\_spruij7-006

**Figure 12-529. Direct Command Management**

There are several checks performed when sending a direct command to verify that requested command sizes are supported and to check that the requested command exists (otherwise the request to send the command is ignored).

- For Short packets commands the DCS and Generic Read and Write the data size is rounded to maximum of 2.
- For Long packet DCS and Generic Read and Write the data size is rounded to the maximum size of the FIFO.
- No checks are made for the write FIFO having the expected number of bytes programmed into the CMD\_SIZE in the dir\_cmd\_main register. In this case the data written out will loop back through the value in the FIFO.

At completion of a read command, registers can be read (they contain read data and/or errors detected during the communication) and trigger events are sent to the application to announce the request completion (using the status and error register bank).

When a read request is performed, the read data is put in the RP FIFO. If more bytes are sent, they are ignored and errors are set accordingly. The received read can then be accessed by reading several times the register that gives an access to the FIFO.

For every new command, several status bits are present: one signals that a command is being transmitted (cmd\_transmission). When the command is complete, several bits can be toggled to signal it (write\_completed, trigger\_completed, te\_received, read\_completed and read\_completed\_with\_err).

Some complex commands provide intermediate information. For BTA requests, there is a bit that signals when the BTA request has been sent (BTA\_completed) and another one that signals when the DSI is controller of the D-PHY interface again (BTA\_finished). For commands that imply a BTA, some other bits specify whether specific data has been received (such as trigger, acknowledge with or without error).

#### 12.9.2.7.5.1 Trigger Mapping Information

Triggers are one of the groups of direct commands that can be sent and received using the DPHY in Low Power escape mode. The trigger\_val[3:0] bits (in the registers DIRECT\_CMD\_MAIN\_SETTINGS and DIRECT\_CMD\_STS) are used to define which of the four possible trigger entry codes has to be sent or has been received. The register fields described above are copied in signal ppi\_d1\_tx\_trigger\_esc[3:0] (for trigger\_val[3:0] of DIRECT\_CMD\_MAIN\_SETTINGS) or are a copy of ppi\_d1\_rx\_trigger\_esc[3:0] (for trigger\_val[3:0] of DIRECT\_CMD\_STS). Only one bit out of the four should be set else the D-PHY behavior is not very precisely defined. [Table 12-450](#) gives the trigger mapping in the system.

**Table 12-450. Trigger Mapping**

Trigger name	Trigger entry code	trigger_val	meaning in TX direction	meaning in RX direction
trigger 0 - reset	01100010	1b0001	Reset	Not affected by DSI spec
trigger 1 - unknown 3	01011101	1b0010	Not affected by DSI spec	TE response <sup>(1)</sup>
trigger 2- unknown 4	00100001	1b0100	Not affected by DSI spec	Acknowledge with no error <sup>(1)</sup>
trigger 3 - unknown 5	10100000	1b1000	Not affected by DSI spec	Not affected by DSI spec

(1) These triggers are not observed in the trigger\_val field of the direct\_cmd\_sts register because they are used by the DSI link for a specific purpose.

**Trigger Reset** – This will request from the display and expects an immediate reset of the DSI command/video mode with all pending requests in TX sending path FIFO for transfer to be discarded.

**Acknowledge** – This is a response to DSITX controller. The host processor may request a command acknowledge and error information related to any transmission by asserting Bus Turnaround with the transmission. The peripheral shall respond with ACK Trigger Message if there are no errors and with Acknowledge and Error Report packet if any errors were detected in previous transmissions. Appropriate flags shall be set to indicate what errors were detected on the preceding transmissions.

If the transmission was a Read request, the peripheral shall return READ data without issuing additional ACK Trigger Message or an Acknowledge and Error Report packet if no errors were detected. If there was an error in the Read request, the peripheral shall return the appropriate Acknowledge and Error Report unless the error was a single-bit correctable error. In that case, the peripheral shall return the requested READ data packet followed by Acknowledge and Error Report packet with appropriate error bits set.

**Tearing Effect** - The Tearing effect on the display is avoided by having synchronization information from the display. It is used only in command mode. Users are responsible for selecting the command mode for the VC using the TE feature and selecting the polling or automatic mechanism.

The user is responsible for ensuring that there is a delay after a trigger is issued by the host to the panel, before any other action, message or trigger is performed. When the host issues a reset trigger, the system will expect the controller to stop and re initialise the clock and data links. All other triggers issued by the host will be application specific and are outside the scope of this document.

#### 12.9.2.7.5.2 Command Mode Settings

The command mode is enabled on the SDI interface. This is controlled using the register `mctl_main_en`. Other settings can be set using the registers: `mctl_main_data_ctrl` (to decide about TE usage, read enable...); and `cmd_mode_ctl` (Virtual Channel of the command packets, arbitration between requests of the two interfaces, possibility to use LPDT, TE timer programming and padding value in case of an error).

When programming Direct READ commands, a BTA request is sent automatically following the read transmission, for the peripheral to respond – it is therefore not necessary to explicitly send a BTA request at that time. The system must allow the BTA request to be completed and the bus returned to the host before issuing any new read or write command. The system must either: poll the `read_completed` (and `read_completed_with_err`) status bits; or, wait for an interrupt caused by these bits before issuing any new command.

When programming Direct WRITE commands, it is advisable to ensure that each transaction can complete successfully before moving on to a subsequent command. There are two recommended methods to achieve this, either: explicitly request a BTA between write transactions while checking for the associated interrupt or polling the appropriate status flag (this method also provides the added security of an ACK response from the peripheral); or allowing a gap between commands sufficient to allow completion of the first before commencing with the second. The recommended approximate gap time required to ensure that all commands complete successfully is equivalent to 100 TX ESC byte periods. If required (for instance, to minimize the start-up time), it is also possible to calculate the minimum delay time required for each transaction, based on the TX escape clock frequency used in the application and the length of each command (no active video transmission should be enabled at the time – a typical use case would be peripheral parameter configuration). As with read operations, any write operation followed by an explicit BTA request must allow the BTA to be completed and the bus returned to the host before issuing any new read or write command.

For single parameter commands, the upper bytes of the 32-bit value written to the Direct Command write data register (`direct_cmd_wrdat`) should be masked to zero to comply with the DSI specification requirement that unused parameter locations are set to zero. For zero parameter writes, assuming there have been previous write commands sent, it is necessary to clear the sending path FIFO by writing to the `direct_cmd_fifo_rst` register to clear the data path, then write a zero value to the `direct_cmd_wrdat` register to send the zero parameter write command.

**Note:** Failure to follow these procedures may result in non-zero data in the unused parameter locations; this may or may not affect the peripheral, however it is recommended to use the process described to ensure compliance with the DSI specification in this regard.

If STOP mode is forced during a command mode read or write transaction, all outstanding transactions should be considered lost and all status and error flags should be disregarded and cleared. Similarly, if an LPDT read data operation is stopped by writing to the `STOP_READ_OPERATION` field of the `DIRECT_CMD_RD_INIT` register, the status for the aborted read operation should be disregarded and cleared before resuming normal operation.

#### 12.9.2.7.5.3 Bus Turnaround Sequence

The command operation can request a read or an acknowledge response from the panel after a long sequence of packets is sent. The Bus turnaround is also used to control the Tearing Effect control.

When a Bus Turnaround is requested from the command stream manager, the DPHY will be given a turn request. The request will make the DPHY interface perform a sequence of LP states (LP11-10-00-10-00) to indicate that it is releasing control of the DP/DN signals. The DPHY Direction signal will change once it detects the Panel side driving the LP00-10-11 states. The panel will then be able to send any response packets (see section 0) and release the bus by issuing a bus turnaround sequence to the controller DPHY. The DSITX controller DPHY will detect the sequence and change the direction signal once the pattern is sent and LP00 state is valid for 2-3 TX\_ESC\_CLK cycles.

Figure 12-530 shows Bus turnaround timing sequence from controller to panel and panel to controller.

**Figure 12-530. Bus Turnaround Timing Sequence from Controller to Panel and Panel to Controller**

#### 12.9.2.7.5.4 Tearing Effect Control

The DSI command control for a tearing effect request can be performed using the polling method or automatically. The enable bits for BTA and TE must be enabled for the mechanism to be performed with either the SDI or DIRCMD interface. For automatic operation, the DSI will send a first BTA, and then waits for BTA reception and if no TE has been received during the first BTA<sup>(1)</sup>, it sends another BTA and then waits for TE. There are three possible error conditions that can happen (but only the two first are detected by the DSITX controller and passed to registers):

- If the display answers to the second BTA with another BTA and thus does not send the TE - this means that the display does not support TE generation OR that TE generation mechanism has not been enabled (reg\_err\_no\_te).
- If the TE has not arrived within a given programmable period – this means that the TE request arrived too late and that the Display Application Processor is not synchronized with the display. The error reported is reg\_err\_te\_miss but the system continues to wait until the TE is received.<sup>(2)</sup>
- If a time-out has been detected by the DSI showing that a problem happened during the BTA and that the system is forced back to idle without BTA – in this case, a BTA without TE is seen and the CSM generates a reg\_err\_no\_te (as for first case).

For the polling method to request a tearing effect (TE polling mode is enabled with te\_hw\_polling\_en = 1) the DSI sends a first BTA, waits for peripheral TE + BTA, if only BTA has been received after the first BTA, it keeps sending BTAs until peripheral responds to the BTA by a TE + BTA instead of BTA only; in this specific mode reg\_err\_no\_te will never be asserted. To stop sending BTA and waiting for TE a force stop<sup>(3)</sup> is needed.

**Note 1:** TE received is checked on the first BTA in case a BTA was the last command issued by the DSI link (BTA or read command sent via direct command interface).

**Note 2:** Again to support the cases where a BTA was emitted just before the TE request, the TE windows is counted on the first BTA (in case the display understands this BTA as the TE request and thus may emit too late the TE), and is restarted after the second BTA.

**Note 3:** The time to wait before forcing a stop should be around the duration of a frame. The reason is that if you miss the TE time at the end of the current frame, you've to wait till the end of the next frame before new TE can be sent by display.

The following table describes the TE timeout counter operation, Programming of the IP. The counter value should be calculated based on the tx\_byte\_clk period.

**Table 12-451. TE Timeout Programming**

te_timeout(11)	te_timeout(10)	timeout value
0	0	$256 \times \text{te\_timeout}<9:0>$
0	1	$512 \times \text{te\_timeout}<9:0>$
1	0	$1024 \times \text{te\_timeout}<9:0>$

**Table 12-451. TE Timeout Programming (continued)**

te_timeout(11)	te_timeout(10)	timeout value
1	1	$2048 \times te\_timeout<9:0>$

#### 12.9.2.7.5.5 Tearing Effect Control on Panels with Frame Buffer

Display panels will use command mode sequencing when an on-board frame buffer is used to store the video image rather than using the video streaming and synchronisation packets to control the update of the image information. This means that the host display driver must know when the panel is processing the image and avoid changing pixel information before it is updated. The mechanism is known as the tearing effect. The DSITX controller can support two schemes as outlined in the MIPI DSI specification.

#### TE control using the Polling Method

For polling to the display module, the host processor shall detect the current scan line information with a DCS command such as **get\_scan\_line** to avoid Tearing Effects. DSITX controller will issue a READ using this command until it gets to the expected value for the last line.

#### DCS Command - get\_scanline (45h)

##### Command

**Direction** H->D

**Hex Code** 0 1 0 0 0 1 0 1 45h

##### Parameter 1

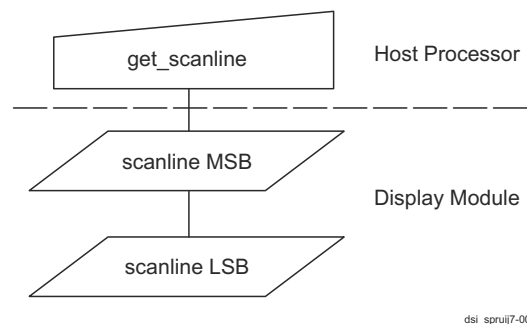

**Direction** D->H

**Hex Code** N15 N14 N13 N12 N11 N10 N9 N8 XXh

##### Parameter 2

**Direction** D->H

**Hex Code** N7 N6 N5 N4 N3 N2 N1 N0 XXh

**Figure 12-531. get\_scan\_line Command**

#### Description

The display module returns the current scanline, N, used to update the display device. The total number of scanlines on a display device is defined as VSYNC + VBP + VACT + VFP. The first scanline is defined as the first line of V Sync and is denoted as Line 0.

In Sleep Mode, the value returned by **get\_scanline** is undefined. See [MIPI-DPI] for definitions of VSYNC, VBP, VACT, and VFP.

- In 2D mode, the scanline value of the display memory and the display panel is the same.
- In 3D Mode, the scanline value of the display memory and the display panel can be different; **get\_scanline** shall return the current scanline of the display panel.

## Restrictions

None

## TE control using the Automatic Method

For TE-reporting from the display module, the TE-reporting function is enabled and disabled by three DCS commands to the display module controller: `set_tear_on`, `set_tear_scanline`, and `set_tear_off`. See [MIPI-DCS] for details.

`set_tear_on` and `set_tear_scanline` are sent to the display module as DSI Data Type 0x15 (DCS Short Write, one parameter) and DSI Data Type 0x39 (DCS Long Write/write\_LUT), respectively. The host processor ends the transmission with Bus Turn-Around asserted, giving bus possession to the display module.

Since the display module DSI Protocol layer does not interpret DCS commands, but only passes them through to the display controller, it responds with a normal Acknowledge and returns bus possession to the host processor. In this state, the display module cannot report TE events to the host processor since it does not have bus possession.

To enable TE-reporting, the host processor shall give bus possession to the display module without an accompanying DSI command transmission after TE reporting has been enabled. This is accomplished by the host processor protocol logic asserting (internal) Bus Turn-Around signal to its D-PHY functional block. The PHY layer will then initiate a Bus Turn-Around sequence in LP mode, which gives bus possession to the display module.

Since the timing of a TE event is unknown to the host processor, the host processor shall give bus possession to the display module and then wait for up to one video frame period for the TE response. During this time, the host processor cannot send new commands, or requests to the display module, because it does not have bus possession.

## DCS Command - `set_tear_on` (35h)

### Command

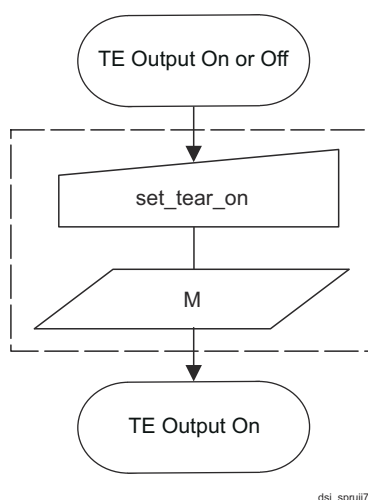

Direction H->D

Hex Code 35h

### Parameter

Direction H->D

Hex Code X X X X X X M XXh

dsi\_sprui7-009

**Figure 12-532. `set_tear_on` Command - 1**

## Description

This command turns on the display module Tearing Effect output signal on the TE signal line. The TE signal is not affected by changing set\_address\_mode bit B4. set\_tear\_on has one parameter that describes the Tearing Effect Output Line mode.

If M = 0 (Mode 0):

The Tearing Effect Output line consists of V-Blanking information only.

**Figure 12-533. set\_tear\_on Command - 2**

If M = 1 (Mode 1):

The Tearing Effect Output Line consists of both V-Blanking and H-Blanking information.

**Figure 12-534. set\_tear\_on Command - 3**

The Tearing Effect Output line shall be active low when the display module is in Sleep mode. See [MIPI- DPI] for definitions of tvdl, tvdh, thdl and thdh.

## Restrictions

This command takes effect on the frame following the current frame. Therefore, if the Tearing Effect (TE) output is already ON, the TE output shall continue to operate as programmed by the previous set\_tear\_on, or set\_tear\_scanline, command until the end of the frame.

## DCS Command - set\_tear\_scanline (44h)

### Command

Direction H->D

Hex Code 0 1 0 0 0 1 0 0 44h

### Parameter 1

Direction H->D

Hex Code N15 N14 N13 N12 N11 N10 N9 N8 XXh

### Parameter 2

Direction H->D

Hex Code N7 N6 N5 N4 N3 N2 N1 N0 XXh

**Figure 12-535. set\_tear\_scanline Command - 1**

### Description

This command turns on the display module Tearing Effect output signal on the TE signal line when the display module reaches line N. The TE signal is not affected by changing set\_address\_mode bit B4.

The Tearing Effect Line On has one parameter that describes the Tearing Effect Output Line mode.

After issuing a set\_tear\_scanline command to the display module, the Tearing Effect output signal, e.g. as in DBI- 2 systems, shall be a delayed version of V-Blanking information as illustrated in [Figure 12-536](#).

**Figure 12-536. set\_tear\_scanline Command - 2**

Note that set\_tear\_scanline with N = 0 is equivalent to set\_tear\_on with M = 0. The Tearing Effect Output line shall be active low when the display module is in Sleep mode. See [MIPI-DBI] for definitions of tvdl and tvdh and [MIPI-DSI] for definition of display module line numbers. In 2D mode, the scanline value of the display memory and the display panel is the same.

### Restrictions

This command takes effect on the frame following the current frame. Therefore, if the Tear Effect (TE) output is already ON, the TE output shall continue to operate as programmed by the previous set\_tear\_on, or set\_tear\_scanline, command until the end of the frame.

### DCS Command - set\_tear\_off (34h)

#### Command

Direction H->D

Hex Code 0 0 1 1 0 1 0 0 34h

Parameters None

## Description

This command turns off the display module Tearing Effect output signal on the TE signal line.

dsi\_spruij7-014

**Figure 12-537. set\_tear\_off Command**

## Restrictions

This command has no effect when the Tearing Effect output is already off.

### 12.9.2.7.5.6 Return Path Operation

The DSI Return Path behaves like a target, by collecting data from the DPHY receive interface when the DPHY is configured to accept a transmission from the peripheral. The RP receives 6 signals from the DPHY (see [Table 12-452](#)).

The data (and trigger) reception is inactive if the DPHY PPI direction signal is at low level. When it is active, data is received using the RX ESC\_CLK clock (the clock is transmitted with the data itself - see D-PHY protocol description from MIPI) and may stop if there is a pause in the data transmission but data is generated on clock falling edge. New data is available on rx\_data\_esc on a rising edge of the clock, if both rx\_lpd\_t\_esc and rx\_valid\_esc are asserted.

**Table 12-452. Interface Between Return Path and DPHY**

Signal Name	I/O	From/To	Description
rx_lpd_t_esc	I	DPHY	Escape Low Power data receive mode This active high signal is asserted to indicate that the lane module is in low-power data receive mode. While in this mode, received data bytes are driven onto the rx_data_esc output when rx_valid_esc is active. The lane module remains in this mode with rx_lpd_t_esc asserted until a stop state is detected on the lane interconnect.
rx_trigger_esc(3:0)	I	DPHY	Escape trigger received These signals indicate that an escape trigger command has been received. Only one of these signals will be asserted at any time and the signal will remain asserted until the lane module returns to stop state.
rx_data_esc(7:0)	I	DPHY	Escape receive data For Low Power data receptions, this eight-bit value is driven by the D-PHY and is valid on rising edges of rx_clk_esc with rx_valid_esc asserted. The bit connected to rx_data_esc[0] was received first.
rx_valid_esc	I	DPHY	Escape receive data valid This signal indicates that the lane module is driving data on rx_data_esc and expects the protocol layers to take the data at the current rising edge of rx_clk_esc. There is no "ready" signal to throttle the receive data.

**Table 12-452. Interface Between Return Path and DPHY (continued)**

Signal Name	I/O	From/To	Description
stop_state_dl1	I	DPHY	Lane is in stop state This signal indicates that the lane module is in STOP state. Note that this signal is asynchronous to any clock in the protocol interface.
direction	I	DPHY	Lane direction. When this signal is high, the lane module is in receive mode. When direction is low, the lane module is in transmit mode. (Mnemonic: 1 = Input, 0 = Output.)

The received data messages are identified as one of two possible types:

- Trigger
- Read packet

**Trigger** messages are passed almost directly to the register (reg\_req = reg\_trigger = 1 and reg\_rd\_data<3:0> equals to trigger value during one clock cycle). However, triggers are decoded to see if they are a TE trigger or an acknowledge with no error.

- The TE data is passed separately to the CSM using csm\_te\_received pin. It needs to be resynchronized with tx\_byte\_clk byte clock because of the CSM working clock domain.
- The acknowledge is only passed to register using reg\_req and reg\_ack pins. All other trigger values are passed undecoded to the registers without any processing. It is the responsibility of the application to decode and decide what to do with them.

**Read Packet:** When data is received, the system waits for the 4 bytes of the **HEADER**, and performs an ECC correction (if it is enabled) and then decodes the packets.

The following cases are considered when the system performs the ECC check:

- If the received command is not in the list of legal display opcodes, (i.e. errors in the packet header), it discards that packet and all further incoming bytes, even if they are legal packets (until the next BTA - i.e. direction change). It sends errors to the register bank (err\_undecodable and uncorrectable\_err). This may also result in an EOT error being reported as no further bytes have been decoded. But even if ECC correction shows an uncorrected error, decoding is attempted (if the errors are in the ECC byte or in the payload bytes, the opcode can be understood and data correctly recovered). In this case only err\_uncorrectable error bit is sent to register and it falls in the situation of regular commands (acknowledge with error or read).
- If "an acknowledge with error", the two status bytes are sent to the registers (reg\_req = 1 and reg\_ack\_err = 1 and reg\_rd\_data<15:0> contains the correct value).
- If the message type is a short read (either DCS or generic), data is passed to the registers (2 bytes without any specific decoding). Interface signals must be set accordingly and the two bytes are sent to registers (reg\_req = reg\_start = reg\_end = reg\_read = 1 with data and dscnotgen set accordingly). Size information is decoded in the first byte of the received packet depending on the data type information and then sent to register using reg\_size port.
- If a long read, the size is sent to the register using reg\_size. The system goes to **LONG state**. All data received are sent to register using reg\_data and are used for checksum detection. If during receive, return packet fifo (in control block) becomes full (rd\_data\_fifo\_full), the error flag err\_oversize must be set. All remaining data is used for checksum calculation but are not transferred to registers. When the number of received bytes is equal to the packet size, the system will check the **CHECKSUM**. The two checksum bytes are never transferred to register. They are used to make checksum detection and indicate err\_checksum status.
- If the transfer is shorter than the size specified in the header, the error err\_wrong\_length is issued along with any subsequent errors such as err\_missing\_eot (if needed). The case where it is longer drives to a tentative checksum decoding that generates an error and by a tentative to decode a new header (that is in fact a part of the previous packet) that drives to an error err\_undecodable and the throwing of the rest of the received bytes (with corresponding errors such as err\_missing\_eot).

- If it is an EoT packet, it is not passed to the control block. The following data is ignored (if any). If the system is waiting for **EoT**, this is the only action. If system is not waiting for EoT packet, the err\_eot\_with\_err is sent.
- If after an "acknowledge with error", the system waits for EoT packet and counts 4 bytes but is not able to decode them, it emits an err\_eot\_with\_err and err\_undecodable.
- If direction is removed at a "wrong" time (i.e before the fourth byte of a small packet, the system stops to works but emit errors to the register: err\_receive with eventually err\_missing\_eot.

The DSI is designed to support multi-peripheral integration, the virtual channel of the received packet is also stored in register using reg\_vc port.

The application FW layer is responsible of all read actions, it is assumed that once a read is requested, application reads return packets before requesting other read actions. Based on this assumption, the receive FIFO implemented in the register block is cleared each time a read action is started. All data not read before the new read command are lost.

A re-initialization of the return path is also performed using register access on reg\_init\_rp.

All errors related to short or long received data packets should be captured in the register when the direction changes (to capture all errors at the same time and not generate several errors and possibly several interrupts on the same reverse transaction). As soon as an error is detected on a packet, the error must be recorded and maintained up to the end of the packet transfer.

The maximum packet size supported by the DSI return path is 16 bytes. If a longer packet is received, only the first 16 bytes are available (by register way) for application.

#### **12.9.2.7.5.7 EoT Packet Management**

The DSI protocol states that, in the sending path, only the HS transmission requires use of EoT packet. For transfer from display to host, it is not recommended to use EoT but it is possible. The host needs to be able to detect the EoT packet and then behaves accordingly.

In case the display makes use of the EoT packet, the bit disp\_eot\_gen must be set to one. In that case, if after the ECC correction, the packet header is 0x08, we've detected an EoT packet and all bytes that may arrive between this packet and the direction change must be ignored.

If additional data is received between the EOT packet and the next BTA (end of read process), or if an unwanted EOT packet is detected, the unwanted bytes must be rejected and err\_receive is asserted.

If the EoT packet is not detected although it should be present, the error err\_missing\_eot is set. If after an "acknowledge with error", 4 bytes are received before BTA but are not identified as EoT (because of errors), it is assumed these 4 bytes are the EoT. In that case, the error err\_eot\_with\_err has to be set with err\_undecodable.

#### **12.9.2.7.5.8 ECC Correction**

The DSITX controller uses the packet header ECC information to detect and correct one error, and can detect two or more errors without correction.

#### **12.9.2.7.5.9 LP Transmission and BTA**

The DSI host may send a command sequence and then request an acknowledge message from the panel. The host will send the command and release the bus by performing a BTA sequence. The panel will then respond with an acknowledge message (or error response) followed by a BTA to return the bus to the host. This sequence is illustrated in Overview of a Display Subsystem.

Overview of a Display Subsystem.

Figure 12-538 shows LP transmission timing diagram.

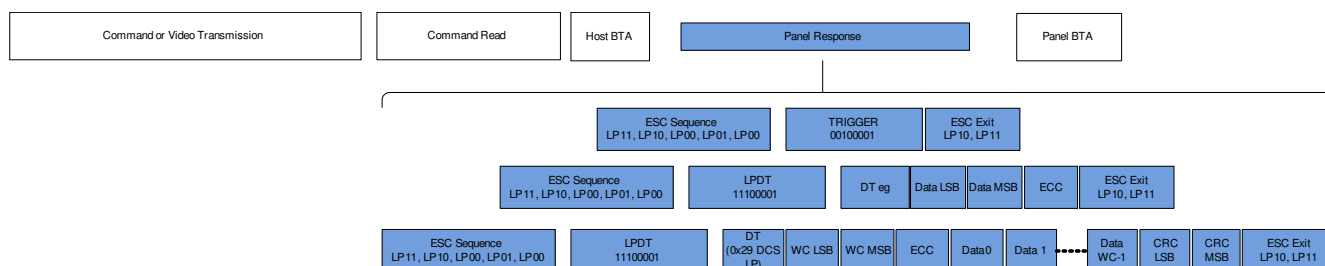

dsi\_spruij7-015

**Figure 12-538. LP Transmission Timing Diagram for Host Read and Trigger ACK**

The Host will not be able to transmit any other packets once the BTA is sent to the panel and will expect either an ACK trigger or response LPDT message with a payload. The system must ensure there is sufficient time to send any command and issue the BTA, receive the response (Trigger, Short or long packet) and accept the BTA from the panel, if this request is made in the line blanking intervals.

Figure 12-539 presents panel read response sequences.

**Figure 12-539. Panel Read Response Sequences**

The panel response time will be based on the tx\_esc\_clk used inside the panel and the expected number of bytes for the payload. The expected responses are illustrated in the blocks in the MIPI DSI standard.

#### 12.9.2.7.6 Low-power Management

There are several low-power scenarios which consist of switching off various parts of the design:

1. Switch D-PHY cells in ULP mode when there are no data to be sent (bits clk\_lane\_ulpm\_en, dat1\_ulpm\_en, dat2\_ulpm\_en, dat3\_ulpm\_en and dat4\_ulpm\_en in register mctl\_main\_en set to one with ULP mode enabled in register mctl\_main\_phy\_ctl). Please, note that the time to leave ULP state is 1 ms and needs to be set in clock cycles in the register mctl\_ulpout\_time.
2. Switch the DPHY byte/bit clock PLL off (refer to DPHY documentation for control sequence). In this case, the D-PHY cell can only transmit data in LPDT thus maximum bandwidth is 10 Mb/s.
3. More drastic methods are to shut-down some parts of the design. The D-PHY and the DSI themselves can be shut down.

When D-PHY and DSI are both shut-down and the display is powered down, the restart is a normal start procedure as described in [Section 12.9.2.7.3, Start-up procedure](#).

When only the D-PHY is stopped, it is placed in either the stop or ULP state. Restarting the D-PHY is similar to the regular start-up procedure, however, after the lanes are enabled by the DSI Controller (clk\_lane\_en, dat1\_en, dat2\_en, dat3\_en and dat4\_en in register mctl\_main\_en are set), the D-PHY generates a rising edge on the stopstate signal to indicate to the DSI Controller that the enable request has been effective within the D-PHY. After that the start-up procedure may continue up to the point that the DSI link is ready to begin transmission.

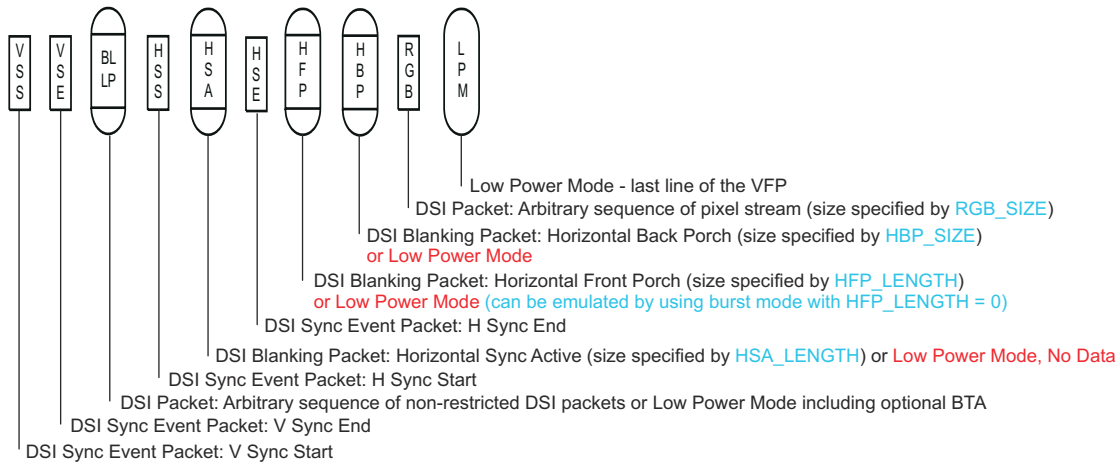

Note that when setting the D-PHY into the ULP state, the application needs to wait enough time between the time it sets the ULP request in register and the time the D-PHY is disabled – this ensures that the ULP request is detected on the D-PHY interface.

### 12.9.2.7.7 Video Mode Settings

All values contained in the Control Block (CB) registers must be set with meaningful values and are expressed with a range of different units: clock cycles, bytes, number of lines.

#### 12.9.2.7.7.1 Video Stream Presentation

In Figure 12-540, it shows the list of packets that can be part of a video stream and the associated register fields. In the four following figures (Figure 12-541, Figure 12-542, Figure 12-543, Figure 12-544), different video streams that can be generated are presented.

ds1-017

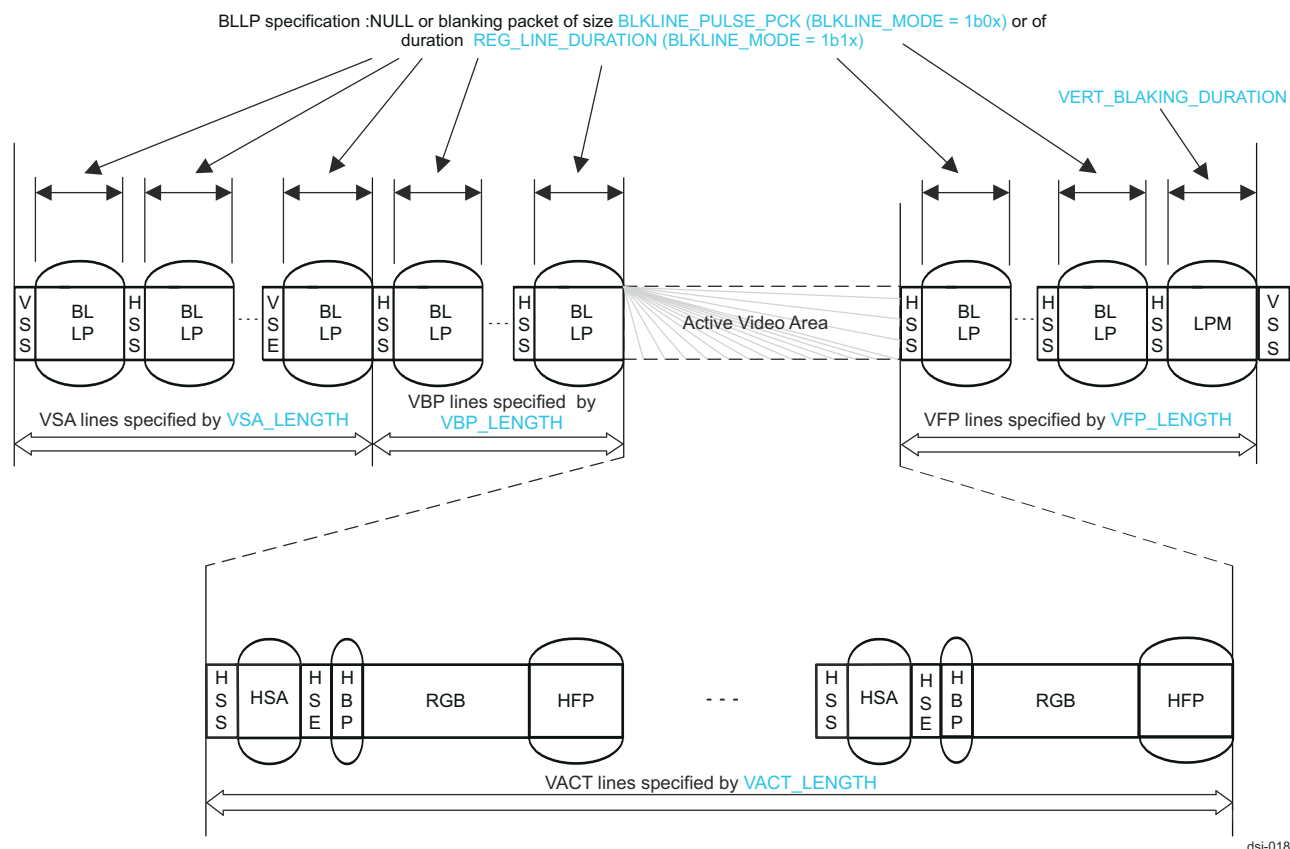

**Figure 12-540. DSI Packet Terminology**

**Red text** - behaviour not possible.

**Blue text** - register fields used to specify the packet size.

The BLLP (Blanking – Low Power) periods allow the DPHY link to perform the following sequences:

- Host Transmit blanking packets in HS.
- Host Transmit command packets in HS or LP (Escape mode).
- Host Transmit packets using interleaving to a different virtual Channel in HS or LP (Escape mode).
- Host performs BTA and waits for response packets from the panel using Escape Mode followed by a panel BTA.

**Figure 12-541. Video Pulse Mode (Non-Burst) Timing Diagram**

### Note

This sequence is no longer specified in the MIPI spec Version 1.02.00 28-Jun-2010 but supported by the DSI-controller.

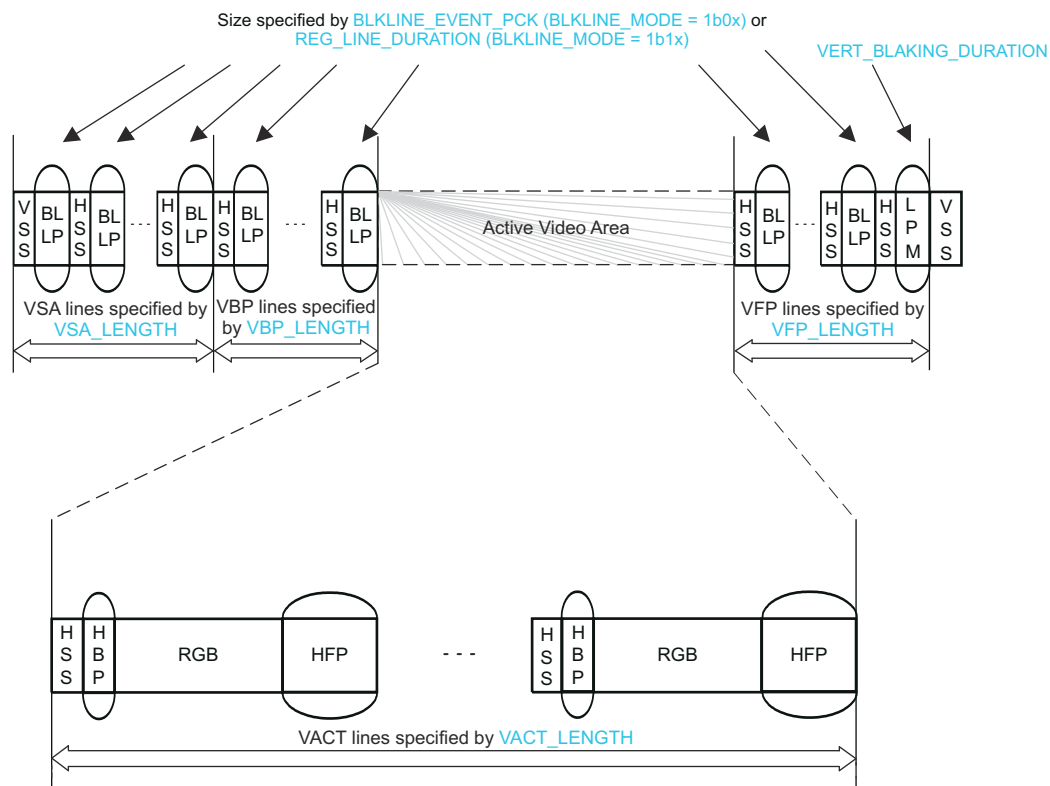

### Figure 12-542. Video Pulse Mode (Non-Burst)

### Note

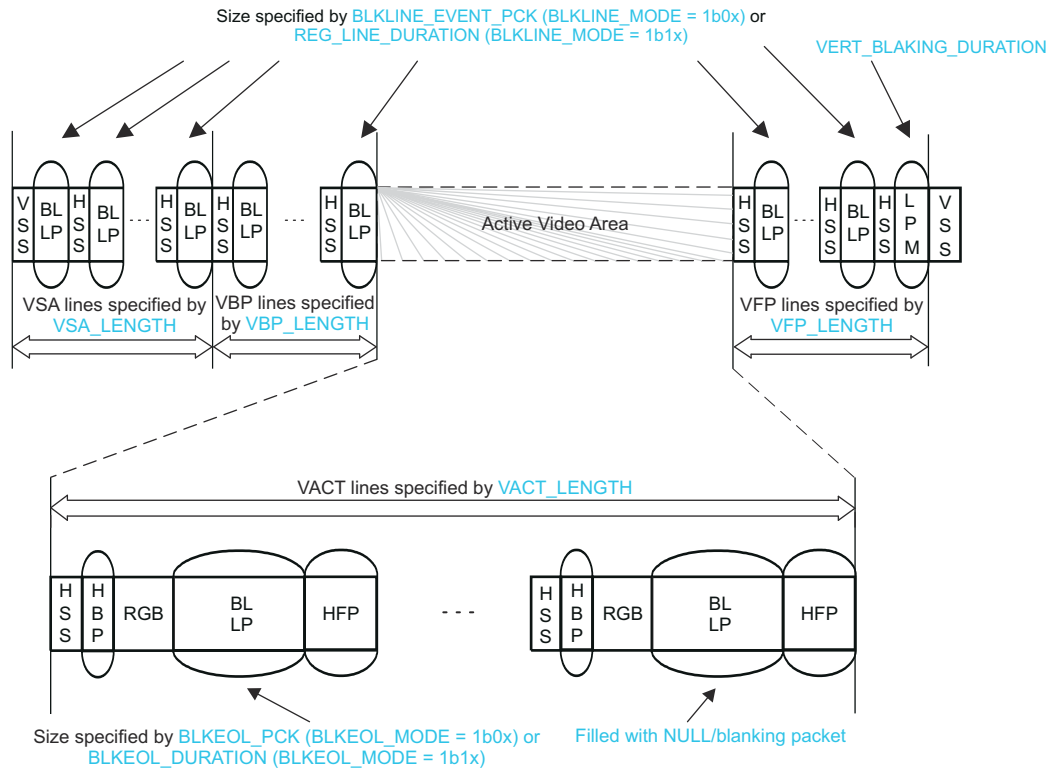

In the MIPI spec 1.02.00 June 2010, the line (VSE/HSA/HSE/BLLP) has been moved from VSA lines part to the VBP lines part. The sequence is the same but in the design the VSA lines has one more line and the VBP lines has one line less. This must be considered during the VSA and VBP register programming if the DSI MIPI spec 1.02.00 is used as reference.

dsi-020

**Figure 12-543. Video Event Mode (Non-Burst)**

burst\_mode = sync\_pulse\_active = sync\_pulse\_horizontal = 0 - all spec versions.

dsi-021

**Figure 12-544. Video Sync Event in Burst Mode**

burst\_mode = 1 and sync\_pulse\_active = sync\_pulse\_horizontal = 0 - all spec versions.

Burst Mode operation requires the tx\_byte\_clk to be set to double the bit rate compared to the non-burst case. The calculations for the video parameters must then be increased to match the higher rate. The DPI FIFO must also be large enough to store at least half of the active line bytes before the output transmission begins otherwise it will underrun.

#### 12.9.2.7.7.2 Video Stream Settings (VSG)

The following is all the registers that need to be set before using the video in SDI or DPI interface operation.

- vid\_vsize1, 2
- vid\_hsize1, 2
- vid\_blksize1, 2
- vid\_pck\_time
- vid\_dphy\_time
- vid\_error\_color1, 2
- vid\_vca\_setting1, 2
- vid\_main\_ctl – programmed last in sequence of vid registers to apply to DSI registers

This section addresses the dependencies between all video registers, and details how the TVG and VCA registers must be set per VSG registers.

#### vid\_main\_ctl

- header information must correspond with the vid\_pixel\_mode used to control the generation of the recovery streams. The header information is used to be enable management of future cases where the DSI link could be used to pass streams with formats that differ feom those currently supported directly.
- sync\_pulse\_horizontal can only be asserted if sync\_pulse\_active = 1.

When `sync_pulse_active` is set to one, the HSYNC pulses are emulated only during the active part of the frame. When both `sync_pulse_horizontal` and `sync_pulse_active` are set, the HSYNC pulses are present on all lines of the frame.

**vid\_vsize** - the variables are expressed in line numbers in this register.

- `vsa_length` should be at least one (in order VSG can insert at least the vertical synchronization start VSS line) and greater or equal to 2 when pulse mode (`sync_pulse_active` = 1).
- `vbp_length` 0 to 63.
- `vfp_length` must be greater than 0.
- `vact_length` must be greater than 0.
- `vid_hsize1`: - the numbers are expressed in number of bytes (the fields are specifying the payload).

**vid\_hsize1** - the numbers are expressed in number of bytes (the fields are specifying the payload of the corresponding packet).

- `hsa_length` need to be at least set to one if pulse mode is enabled. The expected normal operating range is 1 to 255, large values for the HAS length will impact on the size of the DPI FIFO required.
- `hbp_length` can have any value. However, when set to 0, a HBP packet is generated with 0 payload.

**vid\_hsize2** - again the fields are specifying the payload of the corresponding packet (in byte).

- `hfp_length` can have any value. However, when set to 0, no HFP blanking packet is generated.
- `rgb_size` must match the number of pixel per line of the display multiplied by the number of byte per pixel.

**vid\_blksize1** - still specifying size of the payload in byte.

- `blkline_event_pck` defines the payload length of the blanking or NULL packet to be inserted in blanking line (with sync event). This value is used when `reg_blkline_mode` = 0b01 or 0b00 and when `sync_pulse_active` = 0. It is also needed by the VSG when `reg_blkline_mode` = 0b1x. Its value depends on the `hbp`, `rgb`, `blkeol`, and `hfp` packet length.
- `blkline_event_pck` defines the payload length of the blanking or NULL packet to be inserted in blanking line (with sync event). This value is used when `reg_blkline_mode` = 0b01 or 0b00 and when `sync_pulse_active` = 0. It is also needed by the VSG when `reg_blkline_mode` = 0b1x. Its value depends on the `hbp`, `rgb`, `blkeol`, and `hfp` packet length.

-- 32767 = 0x7FFF = max value on 15 bits and -100 to take

`margin blkeol_pck < 32767 - hfp_length - hbp_length - hsa_length - rgb_size - 100;`

The `blkeol_pck` (and `blkeol_duration`) must be adapted to the `reg_wakeup_time` in case VCA is authorized to go back in LP.

**vid\_blksize2** - still specifying size of the payload in byte.

- `blkline_pulse_pck` has almost the same definition than `blk_event_pck` but it concerns blanking lines with sync pulse.

**vid\_pck\_time** - specifies duration in clock cycles.

- `blkeol_duration`: `blkeol_duration = div_round_up(1)((blkeol_pck + 6), lane_nb);`
- `vert_blanking_duration` is no longer used and can always be set to 0. It remains present in the design for legacy reason.

**Note 1:** The function `div_round_up` is a function that performs a division then round the result to the first entire number superior or equal to the division result.

**vid\_dphy\_time:** specifies duration in clock cycles. These are values that have external dependencies and thus need to be calculated first (and rest of VSG programming is calculated from these values).

**reg\_line\_duration:** depends on display type and size and of its programming (in some display, the blanking sizes can be adapted to provide a given number of frame per second with one of the D-PHY possible clock frequency (as PLL can only generate a given number of discrete frequencies).

**if (pulse mode) {**

```

line_length = (blkline_pulse_pck + 6);
}
else (event mode) {
line_length = (blkline_event_pck + 6);
if (burst_mode and burst_lp and lane_nb == 2 and
hsa_length[0:0] == 1 and hfp_length[0:0] == 1)
line_length = line_length - 1;
}
result = div_round_up(line_length, lane_nb);

```

**Note 1:** The function `div_round_up` is a function that performs a division then round the result to the first entire number superior or equal to the division result.

Additional Notes about the line duration:

- If line length (in bytes) is a multiple of the number of lanes enabled, DSI will never face any timing jitter except due to the resynchronization in SP/DCB.
- If line length (in bytes) is NOT a multiple of the number of lanes enabled For Non LP operation, there should not have any problem since the line is once longer, once shorter than the "normal" value. For example: if line length is 491 bytes, it will be 245 then 246 in clock cycles with 2 lanes for an average value of 245.5.

For LP enabled operation, the controller cannot allow underflow of the line and frame timing. With the previous example, the LP line length in clock cycles will be 246 since we cannot start the HS transmission in the middle of a clock cycle. And there is no mechanism to have one line in 245 and the next one in 246 cycles. For LP see section 0.

**reg\_wakeup\_time** must be shorter than line duration and depends on the D-PHY cell plus some pipelines delays inserted by the DSI link. This value strongly depends on the DPHY PLL programming and configuration, and is a mix of both internal and external analog and digital timing factors, therefore it is very difficult to provide an exact formula. The recommended approach to selecting a suitable value for this parameter is to characterize behaviour in at the system level environment using simulation, emulation (e.g. Palladium) or validation (e.g. FPGA).

The DPHY needs 100 ns + time for THXS-EXIT to go to Low Power mode.

The timing for the clock lane TXRequestHS going active to the TXReadyHS will be determined by the DPHY DDR bit rate clock frequency. The timing will be the total number of DDR bit clk cycles for the TXRequestHS to be detected and the clock lane to transition to High Speed, so  $TLPX + TCLK\_PREPARE + TCLK\_ZERO$ . Additional time is required between the clock lane driving HS clocks and the Data Lanes being activate,  $TCLK\_PRE$ . All of these parameters can be calculated from the DPHY datasheet.

Figure 12-545 shows timing diagram for clock lane activation/deactivation.

**Figure 12-545. Timing Diagram for Clock Lane Activation/Deactivation**

The data lane request follows a similar timing sequence from the TX\_Request\_HS to TX\_Ready\_HS, TLPX + THS-PREPARE + THS\_ZERO. The data lane requests will be activated once the clock lane is ready, i.e TX\_Ready\_HSCLK is high.

Figure 12-546 shows timing diagram for data lane activation/deactivation.

**Figure 12-546. Timing Diagram for Data Lane Activation/Deactivation**

**Table 12-453. Timing Parameters**

Parameter	Description	Min	Max	Example 650 Mbps (UI = 1.538 ns)
TLPX	Transmitted length of any Low- Power state period.	50 ns		50 ns
TCLK-PREPARE	Time that the transmitter drives the Clock Lane LP-00 Line state immediately before the HS-0 Line state starting the HS transmission.	38 ns	95 ns	38-95 ns
TCLK-PREPARE + TCLK-ZERO	TCLK-PREPARE + time that the transmitter drives the HS-0 state prior to starting the Clock.	300 ns		300 ns
Wakeup Time CL				388-445 ns
TCLK-PRE	Time that the HS clock shall be driven by the transmitter prior to any associated Data Lane beginning the transition from LP to HS mode.	8 UI		12.3 ns

**Table 12-453. Timing Parameters (continued)**

Parameter	Description	Min	Max	Example 650 Mbps (UI = 1.538 ns)
THS-PREPARE	Time that the transmitter drives the Data Lane LP-00 Line state immediately before the HS-0 Line state starting the HS transmission.	40 ns + 4 × UI	85 ns + 6 × UI	~ 46-95 ns
THS-PREPARE + THS-ZERO	THS-PREPARE + time that the transmitter drives the HS-0 state prior to transmitting the Sync sequence.	145 ns + 10 × UI		160 ns
Wakeup Time DL				~ 270 ns

So the wakeup time values expressed as tx\_byte\_clk (12.3ns) cycles, CL = 36 and CLKPRE + DL = 22.

Figure 12-547 shows wakeup time timing diagram.

**Figure 12-547. Wakeup Time Timing Diagram**

Here is the example of the calculation done for the system running at **650 MHz**.

```
if (clk_continuous == TRUE) {
    wakeup_time_cl = 0x1;
} else {
    wakeup_time_cl = 0x24;
};

wakeup_time_dsi = 0xA; -- from request on VSG to request HS on DL1 (+ 1 for VSG internal cycle)
wakeup_time_dl = 0x14; -- from stop state falling edge to tx_ready rising edge
reg_wakeup_time = wakeup_time_dsi + wakeup_time_cl + wakeup_time_dl + (hs_host_eot × 4 / lane_nb)
```

**Note:** It is not necessary to program all the register values every time because some of them are used only in some modes. For instance, blkline\_event\_pck and blkline\_pulse\_pck are used depending on the way SYNC is generated, and then in pulse mode, there is no need to program blkline\_event\_pck and vice-versa.

### 12.9.2.7.7.3 VCA Configuration

The VCA setting done in two registers: vid\_vca\_setting\_1 and vid\_vca\_setting\_2. Their programming must respect the following rules:

- vid\_vca\_setting\_1:

- max\_burst\_limit specifies the size of the bigger packet that generates the following sequence RGB + packet + NULL packet + BLK packet; it must be linked with blkeol\_pck (same size minus the smaller NULL packet). It is equal to blkeol\_pck - 6.
  - burst\_lp can be set to 1'b1 if blkeol\_pck > 2 × reg\_wakeup\_time × lane\_number (reg\_wakeup\_time is only specifying the time to go from LP to HS thus need to consider the time to go from HS to LP too).
- vid\_vca\_setting\_2:
  - exact\_burst\_limit: as it specifies (in byte) the payload of the packet that generates a sequence RGB + packet + HFP, it must have the same value as of blkeol\_pck when the DSI link is in burst mode.
  - max\_line\_limit specifies the maximum size of a packet that generates HSS + (HSA + HSE) + packet + NULL packet. It then depends on line\_duration, hsa\_length regardless if the system is using pulse or event synchronizing. Its size is linked to vert\_blanking\_duration.

```

if (sync_pulse_active == 0) {
-- size of the payload of the inserted packet followed by a NULL pkt
max_line_limit = (blkline_event_pck-6);
};
if (sync_pulse_active == 1) {
-- size of the payload of the inserted packet followed by a NULL pkt
max_line_limit = gen_blkline_pulse_pck-6;

```

Another constraint to respect when using VCA is to ensure that only supported operations are sent from command side when video is active. For instance, no TE should be attempted, because it could break the video stream (TE completion time can be long). Command messages can be inserted into the LP states provided there is sufficient space for the message bytes and any associate bytes for the header and CRC, if a long packet type.

#### 12.9.2.7.7.4 TVG Configuration

The TVG has a single register: tvg\_img\_size that should complies with the following rules against VSG settings:

tvg\_line\_size: must be equal to rgb\_size set for VSG

tvg\_nblne: must be equal to vact\_length set for VSG

The TVG generates a data stream in the same format than the one specified at the output of the VRS. The content of that flow is specified by the following registers:

- Image size - TVG\_LINE\_SIZE[14:0] and TVG\_NBLINE[12:0] registers: Number of bytes per line and number of lines per frame.
- Image kind - TVG\_MODE[1:0] register: Single color, vertical stripes or horizontal stripes.
- Stripe width - TVG\_STRIPE\_SIZE[2:0] register: Significant when a stripe mode is enabled. Possible values are 1, 2, 4, 8, 16, 32, 64 and 128.
- Pixel kind VID\_PIXEL\_MODE[3:0] register: 16 bits RGB, 18 bits RGB, 18 bits loosely RGB, 24 bits RGB, 30 bits RGB or 36 bits RGB.
- Color one - COL1\_GREEN[11:0], COL1\_RED[11:0], COL1\_BLUE[11:0] registers: Color used in single color mode or first color when in stripe mode. 12 bits per component R/G/B. For formats using fewer bits than 12, the least significant ones are the ones considered.
- Color two - COL2\_GREEN[11:0], COL2\_RED[11:0], COL2\_BLUE[11:0] registers: Color two when in stripe mode. 12 bits per component R/G/B. For formats using fewer bits than 12, the least significant are the one considered.
- Start pulse and stop handshake (+ stop mode) (see TVG\_CTL register).

The Test Video Generator can be programmed to generate a set of test colour patterns based on the display panel that will be used. The panel parameters for horizontal and vertical resolution along with the frame rate and pixel colour depth need to be set based on the datasheet information for the panel.

Figure 12-548 presents TVG MODE patterns.

**Figure 12-548. TVG MODE Patterns**

An example of the sequence is as follows:

- Select TVG for video stream generation instead of DPI/SDI 1 interface.
  - IF1\_EN bit to 0 (SDI stall signal at 1) in MCTL\_MAIN\_EN.
- Select video mode for interface 1 in MCTL\_MAIN\_DATA\_CTL.
  - TVG\_SEL bit to 1 in MCTL\_MAIN\_DATA\_CTL register to select stream from TVG.
- Select generated frame format in TVG\_CTL register.
  - Image format (single color, H stripes, V stripes) in TVG\_MODE field.
  - Image color selection in TVG\_COLOR1, TVG\_COLOR1\_BIS, TVG\_COLOR2, VG\_COLOR2\_BIS.
  - Stripes size in TVG\_STRIPE\_SIZE field.
  - Image size in TVG\_IMG\_SIZE register.

**Note:** The TVG settings on active area for the number of lines per frame and number of bytes per line must match VSG settings on active area. Any mismatch will create an error that is detected in the VSG and forces recovery mode in TVG, stopping test frame generation.

- Select TVG stop mode with TVG\_STOPMODE field of TVG\_CTL.
  - TVG video stream generation start/stop controlled by the TVG\_RUN bit in TVG\_CTL register.
  - Polling TVG run status from the TVG\_RUNNING bit in TVG\_STS register is useful when setting TVG\_RUN to 0. TVG video stream generation does not stop the instantaneously (depends on TVG stop mode), so this should be checked to confirm the TVG has stopped.

#### 12.9.2.7.8 DPI To DSI Programming

The DPI interface will normally be driven from a graphics driver that will be configured to match a frame geometry and refresh rate for a panel display. The DPI driver will use the expected refresh rate and geometry for the active and blanking parts of a frame to determine the pixel rate clock. The DSITX controller will then translate this to match the incoming byte information to send across the DSI DPHY link.

A system will always expect the bandwidth of the incoming pixels × BPP to match the transmission of bytes from the DSI DPHY based on the number of active lanes. The relationship of DPI clock to TX byte clock must ideally hold with the following formula:

$$F_{\text{pixel\_clk}} = F_{\text{tx\_byte\_clk}} \times \text{active\_lanes} \times 8 \div \text{bits\_per\_pixel};$$

The DSI will supply packets to the DPHY interface using the internal sequencing and counters clocked from the tx\_byte clock. The normal system operation will mean that the DSI must always have the correct number of tx\_byte clock cycles to match the number of pixel clock cycles. This means that all the events used for the packet generation will be directly impacted by the delay that exists in the DPHY High Speed request to ready.

The DSITX controller relies upon the DPHY PLL being programmed and locked before starting the DPI video. The DSITX controller can then be configured and enabled (clock lane and data lanes) before starting the video transmission.

The DSITX controller will begin data transmission with a High Speed request after it receives the falling edge of the VSYNC on the DPI interface. The controller will then begin to build the bytes for the VSYNC packets (VSS, HSA, Blanking packets) during the delay period before the ready is returned from the DPHY. This delay will add an interval effect on all the packets that follow.

The DPI FIFO size must be sufficient to buffer all the incoming pixel data during the active line stage while the DSITX controller continues to send the previous lines packet information due to this interval effect.

**Figure 12-549. Timing Diagram**

The DPI and DSI system may not be able to guarantee the exact frequency on the pixel clock input or tx\_byte clock from the DPHY. The DSI configuration can be adjusted to support a small deviation in frequencies using the size of the HFP packet so that it changes the alignment of packets on the active lanes to absorb the different pixel clock cycles during the line. More details are given in section 0.

#### 12.9.2.7.8.1 DSI and DPHY Operation

The DPI FIFO is used to buffer all the active pixel data from the DPI interface during the active line. The depth of the FIFO must be selected to allow the pixel to be stored after the DPHY request to ready delay is introduced at the start of every frame. The FIFO will fill to a depth based on the tx\_byte clock cycles used from the point where VSYNC is identified to the response from the DPHY link after it has exited Low Power and entered the zeroes state on the active data lanes.

Figure 12-550 presents DPI interface to DSI DPHY timing diagram.

**Figure 12-550. DPI Interface to DSI DPHY Timing Diagram**

The timing diagram above illustrates how the packets are generated for a DPHY with two and with four lanes activated. The diagram shows that the tx\_byte clock changes based on the number of lanes, and that the configuration register values for the number of bytes used for HSA, HBP and HFP will remain the same.

The register values calculated for each of the line synchronization stages needs to take the number of bytes used to form the packet into account so that the timing for each stage aligns to the timing of the DPI input and most importantly that the total number of bytes exactly matches the number of byte clock cycles. The values used for the Horizontal Front porch must be larger than the combined horizontal sync and back porch to allow the DPI FIFO to empty.

The basic rule is that the values used for the DSI will be based on the  $\text{DPI} \times \text{BPP}/8$ .

The DPI graphics driver must be configured with horizontal values that can be directly translated to DSI packet payloads.

- The minimum values for the DPI HSA must convert to be greater than:
  - Non-Burst Sync Pulses – 15 bytes
  - Non-Burst Sync Events – 11 bytes
- The minimum values for the DPI HBP must convert to be greater than:
  - Non-Burst Sync Pulses – 7 bytes
  - Non-Burst Sync Events – 7 bytes

These values will then form the number of tx\_byte\_clk cycles used to send the bytes over the number of active lanes. So, for an RGB888, DSI configuration the minimum values will be:

- $\text{HSA} = \text{roundup}(15/3) = 5$
- $\text{HBP} = \text{roundup}(11/3) = 4$

The diagram below, D-PHY Timings Control (see [Figure 12-551](#)), illustrates the byte mapping for a four lane DPHY link. In this example, the calculation for the horizontal sync stage aligns exactly across the four byte lanes.

- HSS – Four Bytes
- HSA – Blank Packet with Header (4) + HSA\_Count + CRC(2)
- HSE – Four Bytes

The next stage is the horizontal back porch:

- HBP – Blank Packet with Header (4) + HBP\_Count + CRC(2)

The value used in the HBP count can be used to account for the Header bytes used in the active data packet in next stage, although it is best to add this to the HFP stage calculation and allow time to empty the FIFO.

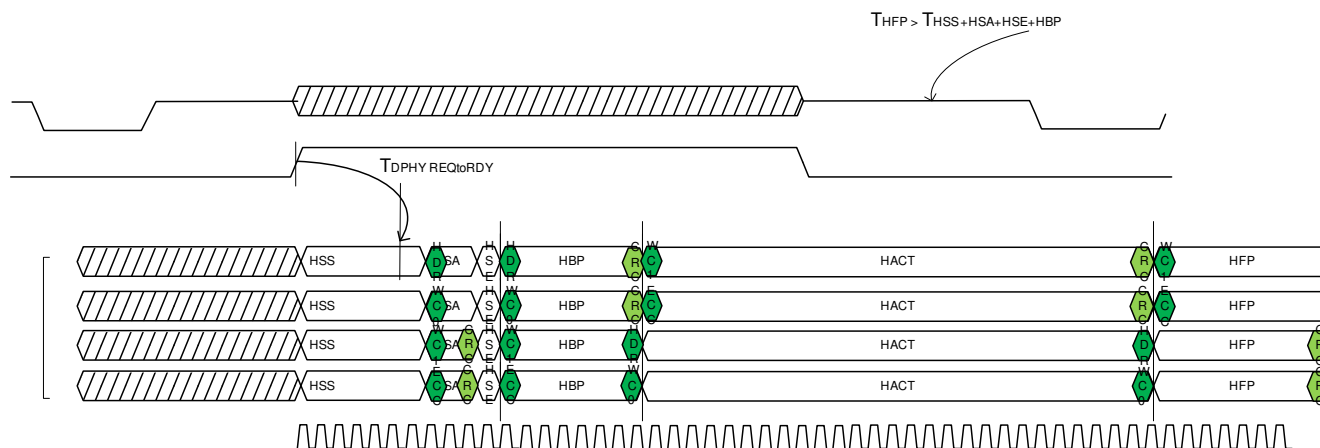

**Figure 12-551. Horizontal Line Packet Timing Diagram**

The Active part of the line will be a fixed size based on the line size and BPP, and include the six bytes for the packet header and CRC. The final stage is the horizontal front porch.

- HFP – Blank Packet with Header (4) + HFP\_Count + CRC(2)

The HFP value should be adjusted to ensure that the number of tx\_byte clock cycles for the horizontal line exactly matches the pixel clock cycles for the line times the BPP.

The timing diagram below, Control Block, illustrates the byte alignment changing when the HBP calculated is two bytes shorter than the previous case. This leads to the active and front porch packet headers beginning two bytes earlier, however the HFP count is adjusted to keep the end of the line on exactly the same tx\_byte\_clk cycle count.

**Figure 12-552. Horizontal Line Packet - Shorter HBP - Longer HFP Timing Diagram**

The recommendation is to ensure that the total bytes for each horizontal line results in an exact integer tx\_byte clock cycles (Total\_bytes MOD num\_of\_lanes = zero), except for the case where the clocks are not exactly matched.

#### 12.9.2.7.8.2 Pixel Clock to TX\_BYTE\_CLK Variation

The selection of the Pixel clock rate and DPHY Bit clock rate should ideally match based on the ratio of bpp on the pixel side compared to the tx\_byte\_clk. The timing for the horizontal sync, back and front porch will also be configured to allow the pixel data to be transferred without any over or underflow of the DPI FIFO.

The DPI FIFO fill level register (DPI\_CFG) can be used to track that the parameters are sufficient and that any clock variation can still be handled by the FIFO depth. This register will show the pixel data held in the buffer, so during the HSA and HBP packet generation stages DPI pixel data will be stored and this value will increment. Once the data packet is being generated, the DPI\_CFG level will remain constant, as the buffer is emptied at the same bandwidth as it is filled. Finally, the value will reduce to zero during the HFP stage.

The packet length of the HFP can be adjusted to help absorb small differences in the pixel\_clk to tx\_byte\_clk relationship. The DSITX controller will concatenate all of the packets during High Speed transmission, so for example adding to the byte value of the HFP will make the bytes at the end of the packet move to align on another lane.

The packets that follow will then be concatenated and aligned to the next available lane, so if the tx\_byte\_clk is faster than the expected pixel clock times bpp the extra byte will delay the start of the new line tx\_byte\_clk × extra\_byte/lanes.

Figure 12-553, Video coherency, illustrates the impact of increasing the HFP by one byte so that the next line begins ¼ tx\_byte clock later. This allows averaging out across the line length of small differences in the pixel to tx\_byte clocks when the tx\_byte clock is not ideally matched to the expected pixel clock multiplied by bpp.

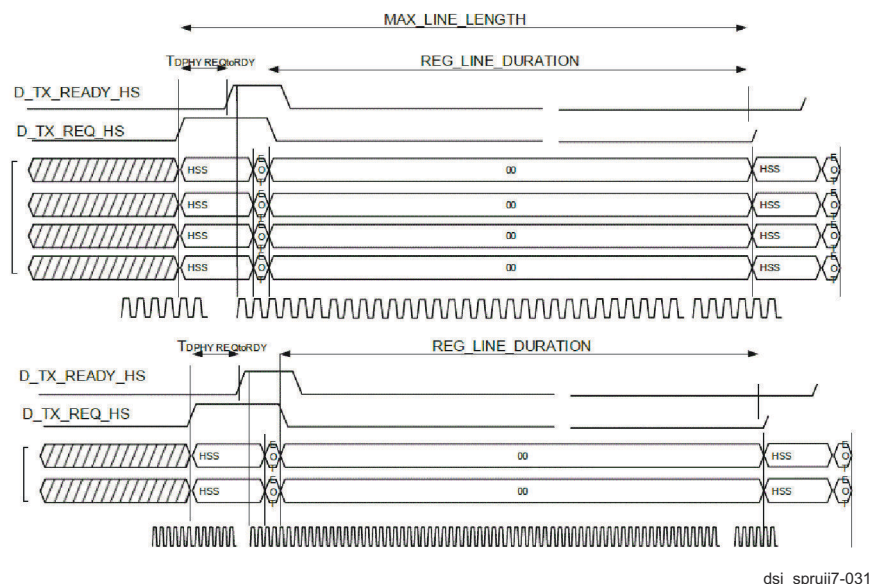

dsi\_spruij7-030

**Figure 12-553. Packet Alignment Control Using HFP Byte Increase - tx\_byte\_clk Faster than Ideal Rate**

The DPI\_CFG register will show any clock misalignment as an increasing/decreasing value for the FIFO fill level on each line of pixels (must be read mid-line for an accurate reading of the level). When the byte count adjustment is made, the DPI\_CFG register will return to the original fill level value every four lines.

#### 12.9.2.7.8.3 LP Operation

The DSITX controller can be configured to perform a transition between LP state and HS state during the horizontal lines which have long periods of blanking. The registers controlling the timing for the DPHY wakeup time and the reg\_line\_duration must be programmed to exactly match the DPI cycles of the horizontal line to the tx\_byte\_clk cycles required for the number of active lanes selected.

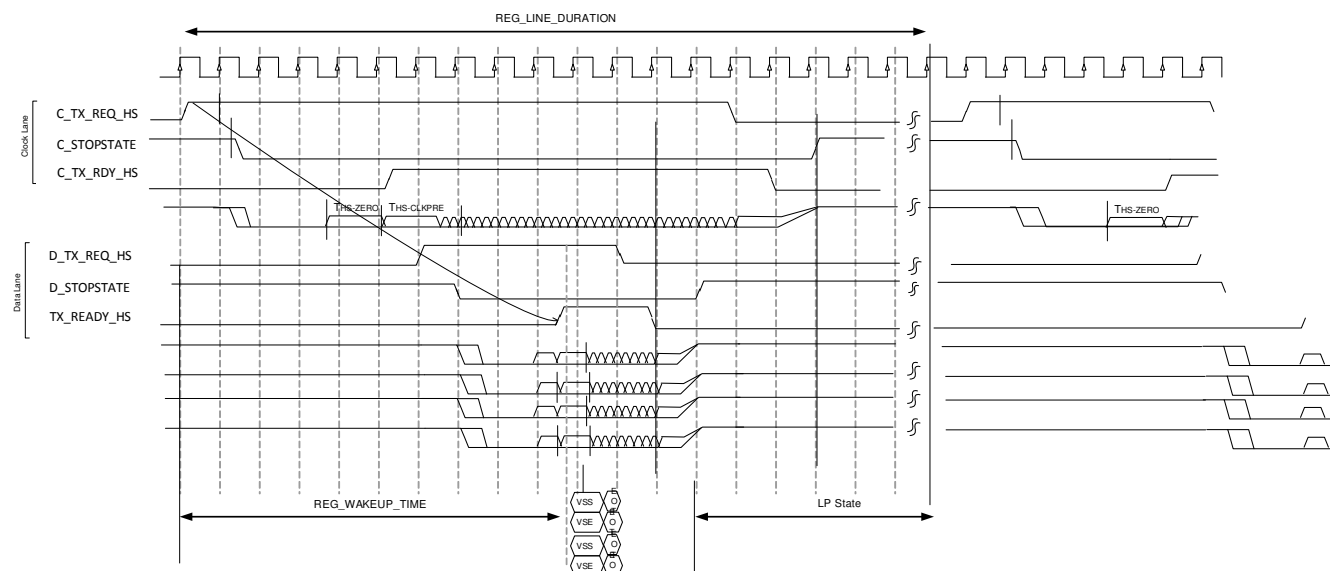

**Figure 12-554. Low Power Operation with Four and Two Active Lanes**

The LP operation for each vertical blanking line will require the reg\_line\_duration to be configured to match the following:

- Max\_line\_length (in tx\_byte\_clk cycles see 2.2.4) minus Eot (if enabled), also minus further 10 if CLOCK lane is non-continuous.

Note REG\_WAKEUP\_TIME is used internally to adjust the cycles for each vertical LP line.

**Figure 12-555. REG\_LINE\_DURATION Timing Example for LP Operation**

#### 12.9.2.7.8.4 DPI Interface Burst Operation

The DSITX controller can support burst operation on the DPI interface provided the DPI FIFO size is large enough to store the line pixel data with enough data to not underflow. The burst operation will use a tx\_byte\_clk that is faster than normal event based operation, so the DPI FIFO size will be impacted by the ratio of the pixel\_clk and BPP input to the tx\_byte\_clk and number of lanes on the output.

The recommended operation is to set the DSI HSA and DSI HFP registers to zero, and adjust the DSI HBP size to control the number of bytes prefilled in the DPI FIFO before the burst is sent.

Figure 12-556 shows DPI operation with event burst mode.

Figure 12-556. DPI Operation with Event Burst Mode

#### 12.9.2.7.9 Programming the DSITX Controller to Match the Incoming DPI Stream

The time taken to output a frame on the PPI needs to match what is coming in on the DPI. This is best achieved by using the recommended clock ratio between the pixel and byte clocks. Assuming that is the case, then the blanking and active data periods must be matched up.

For each frame of video the time will be:

$$(V_{\text{total}} * H_{\text{total}})_{\text{@pixel\_clk}} = (V_{\text{total}} * H_{\text{total}})_{\text{@tx\_byte\_clk}} \times \text{bits\_per\_pixel}/8;$$

So for example, the time for a full HD frame 1920x1080 with reduced blanking in RGB565 will be:

$$2200 \times 1200 \text{ pixels} = 2200 \times 1200 \text{ tx\_bytes} \times 16/8;$$

The DSITX controller will match its frame timing to the incoming DPI vsync, as long as it is programmed to generate a frame of slightly less than the same size when the VFP blanking is considered. The controller works by transitioning to LP during the last programmed line of VFP. It will then remain in LP until the start of the next frame. So programming the controller to match the DPI, but with at least one fewer line of VFP should result in a reliable configuration.

##### 12.9.2.7.9.1 Vertical Timing

The DSITX controller will generate vertical packets for each part of the frame beginning with the VSS and VSE combined with blanking packets to fill the VSA. The blanking packets for the pulse mode program the DSI vertical size registers as follows:

- VSA = DPI\_VSI (lines, minimum of 2 → VSS and VSE)
- VBP = DPI\_VBP (lines, minimum of 0)
- VACT = DPI\_VACT (lines)
- VFP < DPI\_VFP (minimum of 1)

DPI horizontal timing is measured in pixel clocks, whereas the DSITX controller uses byte clocks. The horizontal timing should also be matched per line; therefore the blanking and active periods of each line should match. The relationship therefore depends upon the pixel format, which could be 24, 18 or 16 bpp. The timing for a horizontal line for the DPI driver side will be the number of pixel cycles for the **HLINE** = (HSA + HBP + HACT +

HFP) and this will form **HLINE** × bpp/8 bytes for the controller. These bytes will then be sent using 1, 2, 3 or 4 data lanes, so the DSITX controller will required 1, 1/2, 1/3, 1/4 this number of tx\_byte\_clk cycles respectively.

e.g a DPI with HSA = 12, HBP = 12, HACT = 1920, HFP = 24 and 16bpp will be 1968 pixel clocks for each horizontal line.

This gives the DSI horizontal lines 3936 bytes to transmit and would use 984 tx\_byte\_clks on a four lane system, or 1312 on a three lane system etc..

The horizontal configuration uses different registers depending on the Mode (Pulse or Event) and the control of the BLKLINE\_MODE register bit.

- Non-Burst Mode with Sync Pulses – enables the peripheral to accurately reconstruct original video timing, including sync pulse widths.

Note that for accurate reconstruction of timing, packet overhead including Data ID, ECC, and Checksum bytes should be taken into consideration.

- Non-Burst Mode with Sync Events – similar to above, but accurate reconstruction of sync pulse widths is not required, so a single Sync Event is substituted.
- Burst mode – RGB pixel packets (active video) portion are time-compressed, leaving more time during a scan line for LP mode (saving power) or for multiplexing other transmissions onto the DSI link.

ds1-034

**Figure 12-557. Vertical Timing**

#### 12.9.2.7.9.2 Horizontal Timing for Non-Burst Mode with Sync Pulses

Sync Pulse Mode uses the Short packet and Long packet structures to accurately track the DPI interface timing. Figure 12-558 illustrates the packet sequence for a single frame.

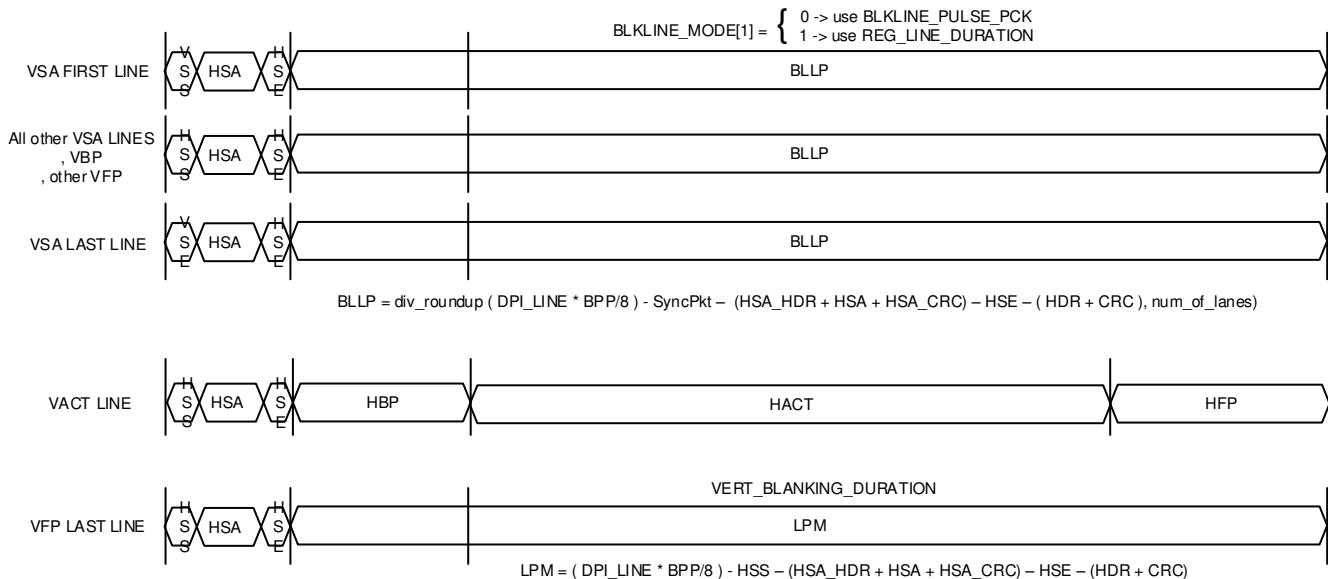

dsi-035

**Figure 12-558. Vertical Timing**

The DSITX controller registers for this mode are used to generate the exact number of bytes required for each horizontal line based on the DPI line configuration and the BPP for the colour pixel data.

The packet structure for each type of line during the frame is shown below, Trigger Mapping Information. The calculation of the total number of bytes in any horizontal line must always be  $HLINE \times bpp/8$  bytes.

**Figure 12-559. Non-Burst Mode With Sync Pulse Line Structures**

The DSI short packets and packet headers that are inserted by the controller must be accounted for:

- HSA should be reduced by 14 bytes to account for the HSS short packet (4 bytes), the long blanking packet header and CRC footer (4 + 2 bytes) and the HSE short packet (4 bytes).
- HBP should be reduced by 12 to account for the header and footer on the blanking packet (6 bytes) plus the header/footer on the active data packet (6 bytes).
- HFP should be reduced by 6 bytes to account for the long packet header and CRC footer.

Finally for lines with no active data, the controller will use either:

- **BLKLINE\_PULSE\_PCK**: Total line size ( $H_{LINE} \times \text{bpp}/8$ ) in bytes minus the HSA 20 bytes (14 for HSA header and CRC, 6 for the remaining blanking which is all combined into a single packet).
- **REG\_LINE\_DURATION**: Total line size ( $H_{LINE} \times \text{bpp}/8$ ) in tx\_byte\_clk cycles minus the calculated HSA in tx\_byte\_clk cycles ( $HSA \times \text{bpp}/8$  minus 14 bytes (14 for HSA header and CRC) minus the EOT packet (4 bytes) if required, divided by number of lanes). This should be aligned to the number of active lane so rounding the value so that  $REG\_LINE\_DURATION \bmod \text{Lanes}$  equals zero.
- **VERT\_BLANKING\_DURATION**: Total line size ( $H_{LINE} \times \text{bpp}/8$ ) in tx\_byte\_clk cycles minus the calculated HSA in tx\_byte\_clk cycles ( $HSA \times \text{bpp}/8$  minus 14 bytes (14 for HSA header and CRC) divided by number of lanes).

Program the DSI horizontal size registers as follows:

$\text{burst\_mode} = 0$  and  $\text{sync\_pulse\_active} = \text{sync\_pulse\_horizontal} = 1$ ;

$HSA = (DPI\_HSA \times \text{bpp}/8) - 14$  – DPI HSA min value 5 for RGB888

$HBP = (DPI\_HBP \times \text{bpp}/8) - 12$  – DPI HBP min value 5 for RGB888

$HACT = (DPI\_HACT \times \text{bpp}/8)$

$HFP = (DPI\_HFP \times \text{bpp}/8) - 6$  – DPI HFP min value 10 for RGB888

**Note:**  $(DPI\_HACT \times \text{bpp}/32)$  must be an integer. Total Line Length =  $\text{div\_roundup}((H_{LINE} \times \text{bpp}/8), \text{num of lanes})$ ;

$(BLKLINE\_PULSE\_PCK) \text{ bytes} = (H_{LINE} \times \text{bpp}/8) - 20 - HSA$ ;

$(REG\_LINE\_DURATION)_{\text{tx\_byte\_clks}} = \text{Total Line Length} - \text{div\_roundup}((HSA \times \text{bpp}/8) - 14, \text{number of lanes})$ ;

$(VERT\_BLANKING\_DURATION)_{\text{tx\_byte\_clks}} = \text{Total Line Length} - \text{div\_roundup}((HSA \times \text{bpp}/8) - 14, \text{number of lanes})$ ;

For example; a DPI with  $HSA = 12$ ,  $HBP = 12$ ,  $HACT = 1920$ ,  $HFP = 24$  and 16bpp will be 1968 pixel clocks for each horizontal line. This give each DSI  $H_{LINE}$  of 3936 bytes. So for 4 lanes, 984 tx\_byte\_clk cycles;

$HSA = (12 \times 16/8) - 14 = 10$

$HBP = (12 \times 16/8) - 12 = 12$

$HACT = (1920 \times 16/8) = 3840$

$HFP = (24 \times 16/8) - 6 = 42$

Total Line =  $\text{div\_roundup}((12 + 12 + 1920 + 24) \times 16/8, 4) = 984 \text{ tx\_byte\_clk cycles} = 3936 \text{ bytes}$ ;

$BLKLINE\_PULSE\_PCK = (3936) - 20 - 10 = 3906$

$REG\_LINE\_DURATION = 984 - \text{div\_roundup}(12 \times 2, 4) = 978$

$VERT\_BLANKING\_DURATION = 984 - \text{div\_roundup}(12 \times 2, 4) = 978$

Confirming the calculation for each line with  $BLKLINE\_MODE = 0$ ;

$VSS = VSSPkt + HSAPkt + HSEPkt + BLK\_LINE\_PULSE\_PCKPkt = 4 + (4 + 10 + 2) + 4 + (4 + 3906 + 2) = 3936$ ;

$VSA_{Line} = HSSPkt + HSAPkt + HSEPkt + BLK\_LINE\_PULSE\_PCKPkt = 4 + (4 + 10 + 2) + 4 + (4 + 3906 + 2) = 3936$ ;

$VSE = VSEPkt + HSAPkt + HSEPkt + BLK\_LINE\_PULSE\_PCKPkt = 4 + (4 + 10 + 2) + 4 + (4 + 3906 + 2) = 3936$ ;

$VACT = HSSPkt + HSAPkt + HSEPkt + HBPPkt + HACTPkt + HFPPkt = 4 + (4 + 10 + 2) + 4 + (4 + 12 + 2) + (4 + 3840 + 2) + (4 + 42 + 2) = 3936$ ;

$$\text{VFP} = \text{HSSPk} + \text{HSAPk} + \text{HSEPk} + \text{BLK\_LINE\_PULSE\_PCKPk} = 4 + (4 + 10 + 2) + 4 + (4 + 3906 + 2) = 3936;$$
$$\text{VFPLast} = \text{HSSpkt} + \text{HSAPkt} + \text{HSEPKT} + \text{VERT\_BLANKING\_DURATION} = 4 + (4 + 10 + 2) + 4 + (978 \times 4) = 3936;$$

Confirming the calculation for each line with `BLKLINE_MODE = 1` matches the `tx_byte` cycles;

VSS = VSSPkt + HSAPkt + HSEPkt + REG\_LINE\_DURATION = div\_roundup((4 + (4 + 10 + 2) + 4), 4) + 978 = 984;

$$\text{VSALine} = \text{HSSPkt} + \text{HSAPkt} + \text{HSEPKt} + \text{REG\_LINE\_DURATION} = \text{div\_roundup}((4 + (4 + 10 + 2) + 4), 4) + 978 = 984;$$

```
VSE = VSEPk + HSEPk + REG_LINE_DURATION = div_roundup((4 + (4 + 10 + 2) + 4), 4) + 978 = 984;
```

$$\text{VACT} = \text{HSSPkt} + \text{HSAPkt} + \text{HSEPKt} + \text{HBPPkt} + \text{HACTPkt} + \text{HFPPkt} = \text{div\_roundup}((4 + (4 + 10 + 2) + 4 + (4 + 12 + 2) + (4 + 3840 + 2) + (4 + 42 + 2)) = \text{div\_roundup}((3936, 4) = 984;$$

VFP = HSSPkt + HSAPkt + HSEPk + REG\_LINE\_DURATION = div\_roundup((4 + (4 + 10 + 2) + 4), 4) + 978 = 984;

$$\text{VFPLast} = \text{HSSPkt} + \text{HSAPkt} + \text{HSEpkt} + \text{VERT\_BLANKING\_DURATION} = \text{div\_roundup}((4 + (4 + 10 + 2) + 4 + (3912), 4) = 984;$$

### 12.9.2.7.9.3 Event Mode Horizontal Timing

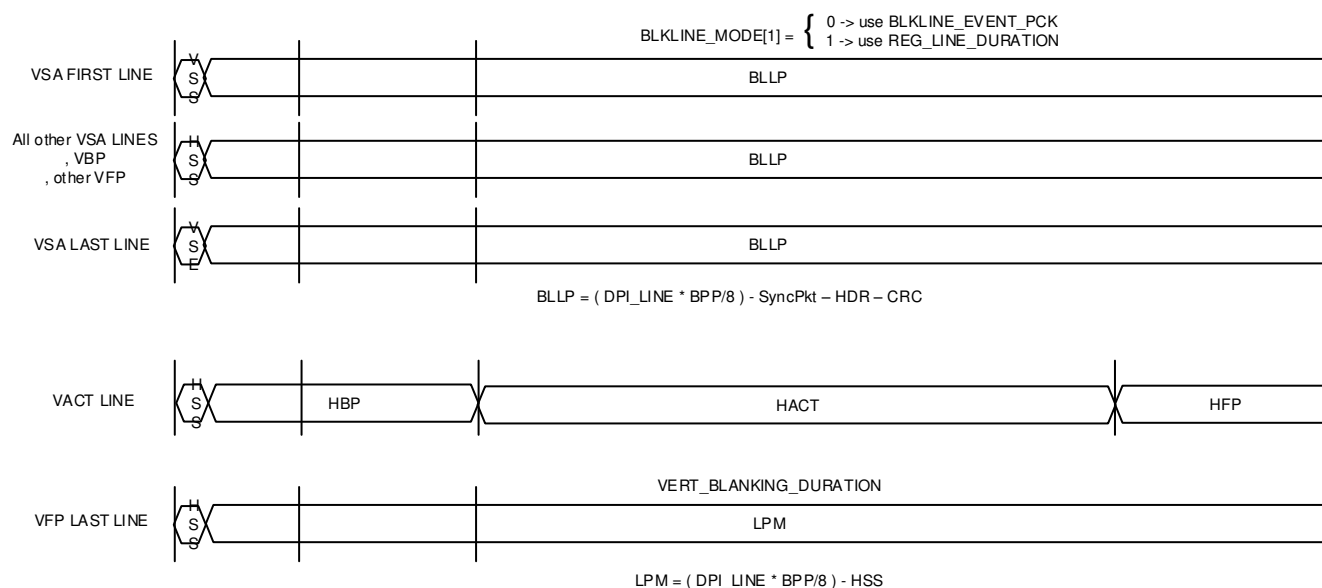

Non Burst Event Mode uses the Short packet and Long packet structures to track the DPI interface timing without accurate reconstruction of sync pulse widths, so a single Sync Event is substituted. [Figure 12-560](#) illustrates the packet sequence for a single frame.

The DSITX controller registers for this mode are used to generate the exact number of bytes required for each horizontal.

**Figure 12-560. Horizontal Timing - 1**

line based on the DPI line configuration and the BPP for the colour pixel data. The packet structure for each type of line during the frame is shown in [Figure 12-561](#):

**Figure 12-561. Horizontal Timing - 1**

The DSI short packets and packet headers that are inserted by the controller must be accounted for:

- VSS/VSE/HSS short packet (4 bytes).
- HBP should account for the header and footer on the blanking packet (6 bytes) plus the header on the active data packet (2 bytes). This will match the DPI\_HSA + DPI\_HBP minus the Sync Short packet.
- HFP should be reduced by 6 bytes to account for the long packet header and CRC footer and footer of the active data.

Finally, for lines with no active data, the controller will use either:

- BLKLINE\_EVENT\_PCK: Total line size (HLINE × bpp/8) in bytes minus 10 bytes (4 for VSS/VSE/HSS, 6 for the remaining blanking header/footer which is all combined into a single packet).
- REG\_LINE\_DURATION: Total line size div\_roundup(HLINE × bpp/8, num\_of\_lanes) in tx\_byte\_clk cycles minus tx\_byte cycles for the 8 bytes (4 for VSS/VSE/HSS, and 4 for EOT). This should be aligned to the number of active lane so round the value so that REG\_LINE\_DURATION MOD Lanes equals zero.
- VERT\_BLANKING\_DURATION: Total line size div\_roundup(HLINE × bpp/8, num\_of\_lanes) in tx\_byte\_clk cycles minus tx\_byte cycles for the 4 bytes (4 for HSS).

Program the DSI horizontal size registers as follows:

burst\_mode = 0 and sync\_pulse\_active = sync\_pulse\_horizontal = 0;

- HSA = 0
- HBP = ((DPI\_HSA + DPI\_HBP) × bpp/8) - 12 - DPI HSA + HBP min value 5 for RGB888
- HACT = (DPI\_HACT × bpp/8)
- HFP = (DPI\_HFP × bpp/8) - 6 - DPI HFP min value 10 for RGB888

**Note:** (DPI\_HACT × bpp/32) must be an integer. Total Line Length = div\_roundup((HLINE × bpp/8), num of lanes).

(BLKLINE\_EVENT\_PCK) bytes} = (HLINE × bpp/8) - 10

(REG\_LINE\_DURATION) tx\_byteclks} = Total Line Length - div\_roundup(8, number of lanes)

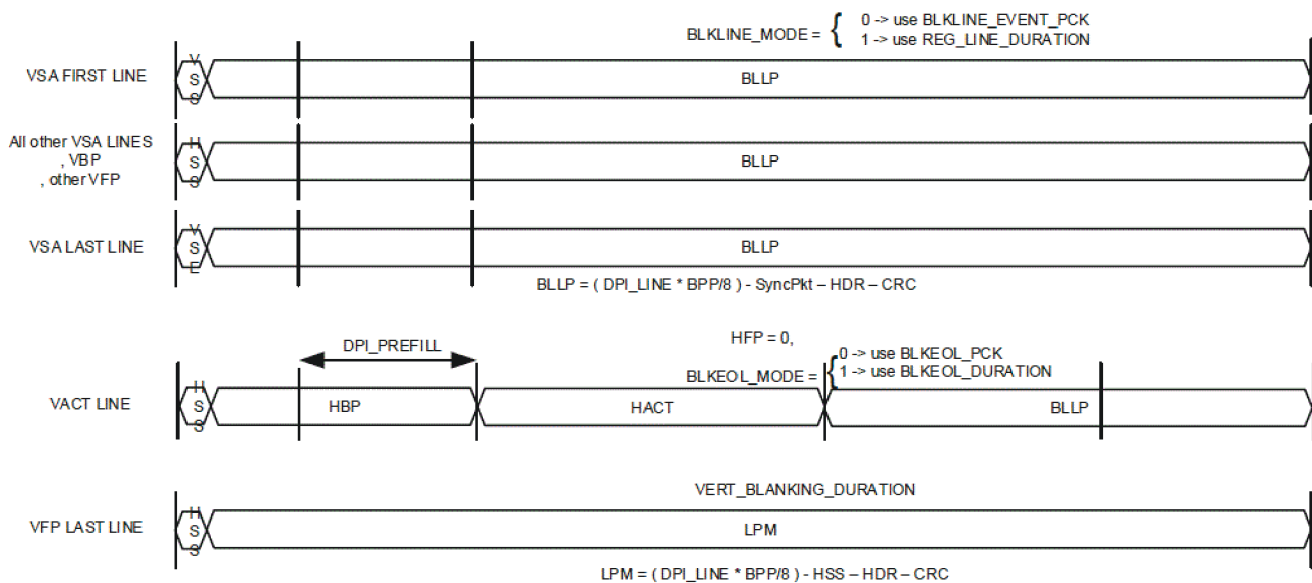

(VERT\_BLANKING\_DURATION) tx\_byteclks} = Total Line Length - div\_roundup(4, number of lanes)

For example: a DPI with HSA = 12, HBP = 12, HACT = 1920, HFP = 24 and 16bpp will be 1968 pixel clocks for each horizontal line. This give each DSI HLINE of 3936 bytes.

HSA = 0

The packet structure for each type of line during the frame is shown below, with the DSI HFP = 0 to select BLLP operation.

dsi\_spruij7-040

**Figure 12-563. Burst Event Mode Horizontal Timing - 2**

The DSI short packets and packet headers that are inserted by the controller for active lines must be accounted for:

- VSS/VSE/HSS short packet (4 bytes).
- HBP should account for the header and footer on the blanking packet (6 bytes) plus the header/footer on the active data packet (6 bytes). This will match the DPI\_HSA + DPI\_HBP minus the Sync Short packet. In this case the DPI must also reduce the HSA and HFP timing.
- BLLP uses BLKEOL\_PCK or BLKEOL\_DURATION and will change depending on the HFP use case:
  - HFP can be zero to extend the BLKEOL\_x values(recommended).
  - or a non-zero value to transmit a Blanking Packet instead of LP state. The Blanking Packet HFP should be reduced by 6 bytes to account for the long packet header and CRC footer.
  - The host\_eot state will cause the BLLP to either add and EOT cycle or not. The BLKEOL\_PCK or BLKEOL\_DURATION value will need to be adjusted to include this extra cycle if host\_eot is disabled.

Finally for lines with no active data, the controller will use either:

- BLKLINE\_EVENT\_PCK in bytes, excluding the header and crc.
- REG\_LINE\_DURATION or VERT\_BLANKING\_DURATION.
- Both are the total expected tx\_byte\_clk cycle for the line minus the number of cycles required to send the header packet bytes (4 for VSS/VSE/HSS) over the active lanes.

Program the DSI horizontal size registers as follows:

burst\_mode = 1 and sync\_pulse\_active = sync\_pulse\_horizontal = 0;

- HSA = 0
- HBP = (2 \* (DPI\_HSA + DPI\_HBP) \* bpp/8) - 12 + DPI FIFO Prefill
- HACT = (DPI\_HACT \* bpp/8) NOTE: (DPI\_HACT \* bpp/32) must be an integer.
- HFP = Zero

Total Line Length = div\_roundup((HLINE \* bpp/8), num of lanes);

(BLKLINE\_EVENT\_PCK)} = (HLINE \* bpp/8) \* 2 - 4

$(\text{REG\_LINE\_DURATION})\} = \text{Total Line Length} \times 2 - \text{div\_roundup}(4, \text{number of lanes})$

$(\text{VERT\_BLANKING\_DURATION})\} = \text{Total Line Length} \times 2 - \text{div\_roundup}(4, \text{number of lanes})$

$(\text{BLKEOL\_DURATION})\} = \text{Total Line Length} \times 2 - \text{TX\_BYTE\_CYCLES}$

$(\text{BLKEOL\_PCK}) \text{ bytes} = \text{Total Line Length} \times 2 - (\text{HACT} + \text{HBP} + \text{HSS})$

**Note:**  $\text{TX\_BYTE\_CYCLES} = \text{TX Byte clock cycles to send Active Line bytes on the number of active lanes} = \text{div\_roundup}(\text{HBP} + \text{HACT}, \text{number of lanes})$ .

### Burst Operation Frame Configuration

Burst mode operation can be used to save power provided the system configuration can support the higher tx\_byte clock rate. The user should consider if the power saving during LP states is more than reducing the number of active lanes and running in non-burst mode.

The burst mode can only be used if the controller configuration can support it; either using SDI video interface, of DPI interface with a buffer size large enough to prefill the data. The video driver timing from the DPI side will also need to be changed.

dsi\_spruij7-041

**Figure 12-564. DSITX Controller Video Frames for Burst Mode Compared with DPI Driver Side**

For example:

The VESA configuration for a 1920x1200 frame at 60-frames per second with normal blanking would have a pixel clock at 193.25 MHz, HSA 200 pixels, HBP 336 pixels, HFP 136 pixels and total line 2592 pixels. This would need to be reconfigured to move the active area earlier in the horizontal line for the DSITX controller, so could be changed to; HSA 20 pixels, HBP 30 pixels, HFP 622 pixels. This would allow the HFP LP state to be almost  $\frac{1}{4}$  of the line ( $622/2592$ ).

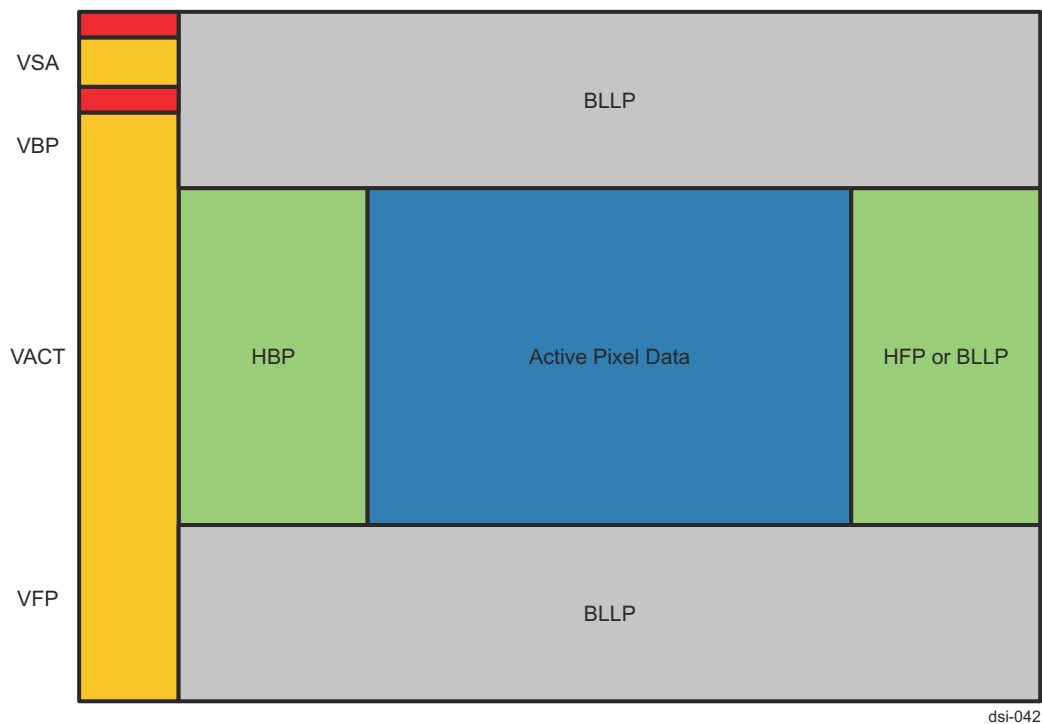

#### 12.9.2.7.9.5 Burst Mode Operation

The DSI IP offers different options for behavior in the BLLP areas:

- Insertion of blanking or null packets.
- Switch to LP (power saving).
- Insertion of commands (if any) + blanking or null packet.

Figure 12-565 shows burst mode operation.

**Figure 12-565. Burst Mode Operation**

The user should balance the increase in the clock frequencies for transmission of the active display, against the power saving by using BLLP(Null) or LP state.

For Burst with the LP state the register fields must be programmed for `burst_lp = 1` and `reg_blkeol_mode = 2'b2`.

### Command Insertion Operation

The DSITX can use the burst operation to allow the blanking/LP stages to be used for DCS/GEN command insertion by programming the size of the space available after the sync of each line.

Only one command packet can be passed within each video line. The decision to insert a command in a video line is done at the beginning of the slot just after the previous video packet. If a command arrives in the middle of the slot, it is not processed in that line, the decision to accept the command will be taken in the next line.

If the packet does not fit in a short slot (size bigger than `reg_max_burst_limit` and not equal to `reg_exact_burst_limit`), it is delayed up to next long slot. The signal `reg_err_burstwrite` is flagged (it is only an information that can help application software control). If its length is longer than `reg_max_line_limit`, it is discarded and the error `reg_err_linewrite` is generated.

Read commands and BTA requests are only passed during long slots, as there is no way to calculate their duration exactly. In the case where their duration takes longer time than the vertical blanking period, the error `reg_err_longread` is flagged.

**Figure 12-566. Burst Mode Command Locations During Video Frame**

### Command Insertion Registers in Burst Operation

The burst operation requires the configuraton of the registers to control the size of the packets that will fit in the space available on each type of horizontal line.

In VSA, VBP or VFP: Insertion of short and long command packets, read or BTA are allowed.

dsi-045

- In VACT: Only short packets can be inserted.
- Command, if inserted, is inserted right after the HSA or HSE or the video packet.
- Only one command can be inserted by line.

- When a command is inserted on a video line, no switch to LP but Null packet insertion.
- Trigger and TE insertion not supported.

VID\_VCA\_SETTING1 register:

[16] BURST\_LP: After an active line, in burst mode, the system can switch in LP (1) or should complete the line with NULL packet (0).

VID\_VCA\_SETTING1 register:

[15:0] MAX\_BURST\_LIMIT: Maximum length of a packet (number of bytes) that can be passed during the blanking period at the end of an active line (in burst mode) followed by a NULL packet with no data (6 bytes).

VID\_VCA\_SETTING2 register:

[15:0] EXACT\_BURST\_LIMIT: Exact maximum size of the burst packet (packet that fits after pixel data in burst mode), that is with no Null packet insertion afterwards.

VID\_VCA\_SETTING2 register:

[31:16] MAX\_LINE\_LIMIT: The "maximum" packet (number of bytes) that can be passed during the vertical blanking period.

If the packet does not fit in a short slot (size bigger than MAX\_BURST\_LIMIT and not equal to EXACT\_BURST\_LIMIT), it is delayed up to next long slot.

- If the packet length is longer than MAX\_LINE\_LIMIT, it is thrown away (an error is asserted).

[Table 12-454](#) outlines the expected behaviour of each packet type during the video frame.

**Table 12-454. Behavior of the DSITX Transmission when Both Video and Command are Running**

Packet type	Packet Size	Behavior	Error Flagged
VACT Active Line - Read and BTA do not pass			
No packet	-	LP mode null packet sent	
Short packet		Packet passed followed by a null packet	
Long packet	size < reg_max_burst_limit	Packet passed followed by a null packet	

**Table 12-454. Behavior of the DSITX Transmission when Both Video and Command are Running  
(continued)**

Packet type	Packet Size	Behavior	Error Flagged
Long packet	size = reg_exact_burst_limit	Packet passed	
Long packet	reg_max_burst_limit < size < reg_exact_burst_limit	Packet delayed, LP mode packet delayed, null packet sent	Burstwrite Burstwrite
Long packet	reg_exact_burst_limit < size <= reg_max_line_limit	packet is delayed to non-active part of frame: Packet delayed, LP mode packet delayed, null packet sent	Burstwrite Burstwrite
Packet type	Packet Size	Behavior	Error Flagged
Long packet	size > reg_max_line_limit	Packet thrown, LP mode packet thrown, null packet sent	Linewrite Linewrite
Read packet	-	Packet delayed, LP mode Packet delayed, null packet sent	-
BTA request	-	Packet delayed, LP mode Packet delayed, null packet sent	-
VSA, VBP, VFP - Long packet, read and BTA can be passed			
No packet	-	LP mode	-
Short packet	-	Packet passed followed by a null packet	-
Long packet	size < reg_max_burst_limit	Packet passed followed by a null packet	
Long packet	size > reg_exact_burst_limit	packet thrown, LP mode	Linewrite
Read packet	read completed (direction) before end of slot	Packet passed	
Read packet	read not completed (direction) before end of slot	Packet passed	Longread If operation lasts too long
BTA request	-	Packet passed	Longread If operation lasts too long

Note that for burst operation with Low Power, the command will be sent as a high-speed packet even if the request is made to send as Low Power. Also, the next active line will return to using LP during the HFP phase if no other commands are requested.

#### 12.9.2.7.9.6 Example Configurations

1. Here is an example for a VGA frame with 24bpp @60fps using non burst pulse sync mode: With blanking, total size 500 lines, each line is 800 pixels.

400000 DPI cycles/frame @ 24 MHz pixel clock <-> 300000 DSI cycles/frame @ 18 MHz byte clock;

800 DPI cycles/line @ 24 MHz <-> 600 DSI cycles/line @ 18 MHz;

**Table 12-455. DPI and DSI Parameters - 1**

Parameter	DPI	DSI
VSA	5	5
VBP	5	5
VACT	480	480

**Table 12-455. DPI and DSI Parameters - 1 (continued)**

Parameter	DPI	DSI
VFP	10	5
HSA	40	106 (120-14)
HBP	40	108 (120-12)
HACT	640	1920
HFP	80	234 (240-6)
HTOTAL	800 pixel cycles	2400 bytes

burst\_mode = 0

sync\_pulse\_active = 1

sync\_pulse\_horizontal = 1

BLKLINE\_PULSE\_PCK = 2380 (2400-20)

REG\_LINE\_DURATION = 2380

VERT\_BLANKING\_DURATION = 2384

**Note:** The controller will send 4 VFP lines then transition to LP for the duration equivalent to 6 lines.

2. Here are some example values for a 24fps UHD frame size with 24bpp using non-burst event mode: With blanking, total size 2250 lines, each line is 4000 pixels.

9000000 DPI cycles/frame @ 216 MHz pixel clock <-> 6750000 DSI cycles/frame @ 162 MHz byte clock

4000 DPI cycles/line @ 216 MHz <-> 3000 DSI cycles/line @ 162 MHz

**Table 12-456. DPI and DSI Parameters - 2**

Parameter	DPI	DSI
VSA	2	2
VBP	0	0
VACT	2160	2160
VFP	40	1
HSA	40	0
HBP	40	228 (120 + 120 - 12)
HACT	3840	11520
HFP	80	234 (240 - 6)
HTOTAL	4000	12000

burst\_mode = 0

sync\_pulse\_active = 0

sync\_pulse\_horizontal = 0

BLKLINE\_EVENT\_PCK = 11990 (12000-10)

REG\_LINE\_DURATION = 11990

VERT\_BLANKING\_DURATION = 11996

**Note:** After the active data the controller will transition immediately to LP for the duration equivalent to 88 lines, giving the maximum power saving between lines.

If any of the DPI related interrupts are triggered, then this highlights that the FIFO depth and/or the vsync\_delay settings require to be tuned to the current configuration. Simulating the core operation with the expected clocks is the best way to ensure.

#### 12.9.2.7.9.7 Stereoscopic Video Support

The DSI controller can support stereoscopic display format (SDF) using both command and video modes.

- Command Mode
  - APB Direct Command 3D Commands – Use get\_3D\_control with Read
  - SDI Command Mode – DCS Writes
- Video Mode – Single Link Operation
  - VSYNC Parameter1 Definition (L/R, Mode, Format)
  - SDI Video Mode
  - DPI Video Mode – Video stream will expect to follow expected format; frame, line, pixel
    - 3DVSNC = 0 not currently supported.

The DSI must be configured to enable the 3D operation and identify the format that is being used using the register control to enable the 3D features and the configuration that matches the video stream from the system.

The SDF format requires the system to provide frame and synchronisation information using the two parameter fields within the vertical sync short packet (VSS).

Configured the DSI mctl\_3dvideo\_ctl register to match format – L/R Pixel, L/R Line, L/R Frame Drive video stream based on orientation and format.

**Note:** DSI Controller will not perform any on-the-fly pixel manipulation for L-R ordering.

#### Example Video Operation

For a 3D video stream where the DSI video is given the combined images as one continuous large frame, the VSYNC packet would identify that the left image is sent first, it is a line based format and in landscape mode (see [Table 12-457](#)).

**Table 12-457. Example Video Operation**

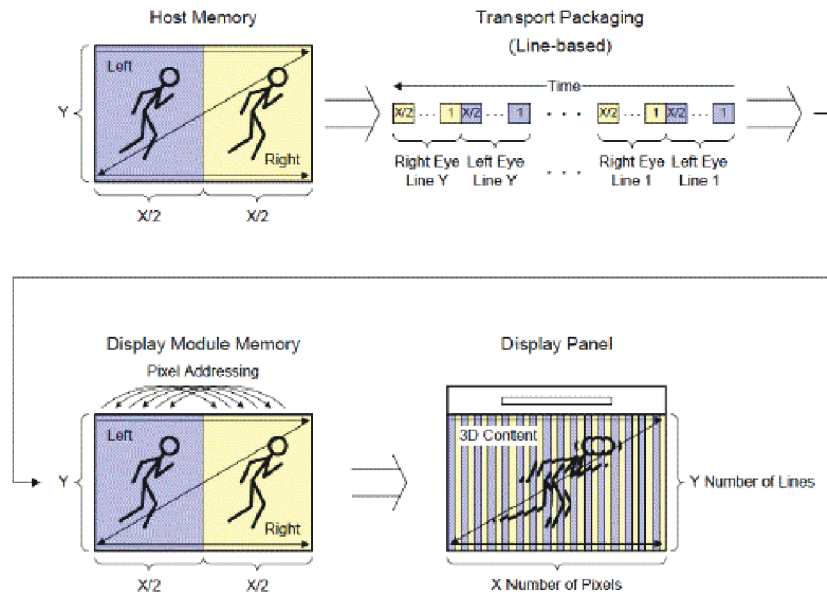

Position	D7	D6	D5	D4	D3	D2	D1	D0
Value	0	0	0	0	0	0	1	0
Description	Rsvd	Rsvd	Left First	No Sync	Line-based		Landscape	

mctl\_3dvideo\_ctl (0x20)

**Table 12-458. VSYNC Parameter 1**

[7]	vid_vsync_3d_en	1
[5]	vid_vsync_3d_lr	0
[4]	vid_vsync_3d_second_en	1
[3:2]	vid_vsync_3dformat	00
[1:0]	vid_vsync_3dmode	10

The video stream would then be configured in the DSI to be twice the line length of the normal image.

dsi\_spruij7-050

**Figure 12-567. Example DPI Image Format for SDF Combining Left And Right Pixels**

**Note:** The vertical operation DSI controller will expect the system to provide the left and right as two individual frames with SYNC to allow the blanking to be generated. The DSI does not insert the vertical blanking area when VSYNC = 0.

dsi-051

**Figure 12-568. 3D Image format for 3DVSNC splitting first and second images**

### 12.9.2.7.10 DSITX Video Stream Variable Refresh

The DSITX Controller can be programmed to allow the video stream sequence from a video source to halt between frames and enter Low Power state. The DPI video stream can halt before the new VSYNC is sent and remain in this state until the host video system wants to begin transmitting the new frame.

The DSITX will not perform the normal frame recovery mechanism when this is enabled, however it will continue to recover from line errors until the end of the frame.

**Table 12-459. DSITX Video Stream Variable Refresh**

Variable refresh rate operation enable control	Configures how the video generation timing is controlled.0, 1 DPI mode operation supports = 1 (enabled). For SDI operation, this parameter can optionally be set to FALSE (= 0) when the system clock and tx_byte_clk are generated from the same reference clock source, or TRUE to allow variable refresh rate control.

This chapter describes the on-chip debug support.

<b>13.1 On-Chip Debug Overview.....</b>	<b>2450</b>
<b>13.2 On-Chip Debug Features.....</b>	<b>2450</b>
<b>13.3 On-Chip Debug Functional Description.....</b>	<b>2451</b>

## 13.1 On-Chip Debug Overview

This chapter describes the properties and capabilities of the various features available through the On-Chip Debug framework deployed on this device.

The On-Chip Debug framework enables various Debug and Trace use-cases, including:

- **JTAG Tooling** – Access to on-chip debug resources is supported by an IEEE 1149.1 (JTAG) compliant interface that is supported by an Arm® CoreSight™ DAP JTAG-DP.
- **Self-Hosted Tooling** – code running on programmable cores within the device is able to use on-chip debug resources to enable embedded tooling solutions.
- **PCB-level interconnect testing** – IEEE 1149.1 and IEEE 1149.6 compliant Boundary Scan supports product level integration testing
- **Low Power Operation** – When on-chip JTAG and debug management logic is in a low power state, activity sensed on the JTAG interface will cause this logic to be placed in a functional state.
- **Stop Mode debugging** – Debug of embedded processors is supported using various mechanisms that can halt the pipeline of a CPU. Breakpoints (Software and Hardware), Watchpoints, Cross-Triggering, and On-demand (e.g. user requested) halt request mechanisms may be supported based on the capabilities of a given processor.
- **Debug-aware Peripherals** – Peripheral awareness of processor execution state allows safe suspension of peripheral operation. Supported by select peripherals.
- **Synchronized Debug** – Wide deployment of Cross-Triggering allows multiple processors and/or debug elements to be grouped together to process various actions based on a common event occurrence.
- **Processor Trace** – Support for the generation of a trace stream with the encoding of processor state that may include some combination of program flow, timing details (execution and stall), and memory references (address and/or data) with the goal of facilitating processor state reconstruction for debug purposes.
- **Software Messaging Trace** – Support for software messaging trace where embedded code running within the device can be instrumented to use memory writes to send important debug information to a trace stream.
- **System Traffic Trace** – Strategically selected points in the SoC topology are instrumented with trace-capable bus probes that support transaction trace, read-latency monitoring, and throughput computation.
- **Trace Correlation (through timestamping)** – Support for the correlation of different trace streams is enabled through the use of a common global timestamp that is distributed to supported trace sources.
- **Trace data movement** – Trace data movement on chip is supported using standard Arm ATB trace infrastructure components. Concurrent use of the trace bus by multiple trace sources is supported, with each trace source identifiable through a unique ID. An Arm® CoreSight™ Trace Router supports sending a trace stream off-chip (TPIU), to dedicated memory on-chip (TBR), or broadcasted to both (TPIU + TBR).
- **On-Chip trace collection via dedicated buffer** – An on-chip trace buffer is supported by logic that implements capturing trace data until either the memory fills (stop-on-full, system-bridge) or continuously until a request to stop is received (circular buffer). Interleaving of multiple trace streams is made possible through the use of a standardized encoding that embeds trace data along with the corresponding trace source ID.
- **Trace export over TPIU** – Trace data is exported over device LVCMOS pins using a standard protocol that embeds trace data along with the corresponding trace source ID.

## 13.2 On-Chip Debug Features

The On-Chip Debug framework provides a comprehensive hardware platform for a rich debug and development experience. The On-Chip Debug framework supports these features:

- An IEEE 1149.1 (JTAG and Boundary Scan) compliant device interface
- Cross-triggering and Debug boot mode device interface
- Trace port device interface
- Advanced power, reset, and clock management to facilitate debug across complex low power modes
- Breakpoint-based debug
- Cross-triggering
- Program flow trace
- System traffic monitoring trace
- Software instrumentation trace

- Trace export via trace port device interface
- Trace capture on-chip via dedicated buffer with options to support stop-on-full, circular-buffer, or data hand-off to various peripherals
- Arm® CoreSight™ compliant debug components deployed to streamline 3rd party tooling support

#### Note

Some features may not be available. See *Module Integration* for more information.

## 13.3 On-Chip Debug Functional Description

### 13.3.1 On-Chip Debug Block Diagram

A logical partitioning of the On-Chip Debug features deployed on this device is illustrated in [Figure 13-1](#).

**Figure 13-1. On-Chip Debug Block Diagram**

### 13.3.2 Device Interfaces

On-Chip Debug features are supported through three device interfaces:

- **JTAG:** IEEE 1149.1 compliant interface that provides access to Boundary Scan and acts as the primary interface for off-chip access to On-Chip debug resources (See [Section 13.3.2.1](#))
- **Trigger and Debug Boot Mode:** Multi-functional interface that supports product level cross-triggering and debug-related boot modes (See [Section 13.3.6](#), [Section 13.3.4](#))
- **Trace Port:** Arm TPIU compliant Trace Port interface is used to facilitate export of trace (See [Section 13.3.10](#))

Texas Instruments supports a variety of eXtended Development System (XDS™) JTAG controllers with various debug capabilities beyond only JTAG support. The following document is a good reference for guidelines: [Emulation and Trace Headers](#). More information can also be found here: [XDS Target Connection Guide](#).

The previous link connects to TI community resources. Linked contents are provided “AS IS” by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see [TI's Terms of Use](#).

#### 13.3.2.1 JTAG Interface

**Table 13-1. JTAG Interface Signals**

SignalName	I/OType <sup>(1)</sup>	Description
TRSTn	I	<i>Test Reset.</i> Initializes and disables the test interface.
TCK	I	<i>Test Clock.</i> Controls the timing of the test interface independently from any system clocks. TCK is pulsed by the equipment controlling the test and not by the tested device.
TMS	I	<i>Test Mode Select.</i> Controls the transitions of the test interface state machine.
TDI	I	<i>Test Data Input.</i> Supplies the data to the JTAG registers.
TDO	O/Z	<i>Test Data Output.</i> Used to serially output the data from the JTAG registers to the equipment controlling the test.

(1) I = Input; I/O = Input or output; O = Output; O/Z = Output or three-state

#### 13.3.2.2 Trigger and Debug Boot Mode Interface

**Table 13-2. Trigger and Debug Boot Mode Interface Signals**

Signal Name	I/O Type <sup>(1)</sup>	Description
EMU0	I/O	Channel 0 trigger or boot mode select
EMU1	I/O	Channel 1 trigger or boot mode select

(1) I = Input; I/O = Input or output; O = Output; O/Z = Output or three-state

### 13.3.2.3 Trace Port Interface

**Table 13-3. Trace Port Signals**

Pin Name	TPIU Signal Name	I/O Type <sup>(1)</sup>	Description
TRC_CLK	TRACECLK	O	TraceClock
TRC_CTL	TRACECTL	O	TraceControl
TRC_DATA[n:0]	TRACEDATA[n:0]	O	TraceData [n:0]

(1) I = Input; I/O = Input or output; O = Output; O/Z = Output or three-state

#### Note

Note that the Trace Port interface signals are associated with device pins that are multiplexed with other signal functions.

### 13.3.3 Debug and Boundary Scan Access and Control

On-Chip debug resources are made available through three mechanisms:

- JTAG access via DAP and related APs
- JTAG access via Boundary Scan TAP
- Embedded access to debug resources via SoC address space

#### DAP

Off-chip debug tools are able to access On-Chip debug resources via the JTAG interface when not in Boundary Scan mode (see below). A CoreSight™ Compliant DAP architecture provides access via a DP and a collection of APs:

- SWJ-DP: Arm® CoreSight™ compliant SWJ Debug Port provides support for a JTAG interface with a 4-bit IR

#### Note

Even though an SWJ-DP is implemented on-chip, only JTAG is supported. This device does not support SWD.

- APB-AP: Arm® CoreSight™ APB Access Port provides access to the Debug-APB address space which is the primary configuration space for On-Chip Debug resources.
- AXI-AP: Arm® CoreSight™ AXI Access Port provides access to the SoC address space, allowing visibility and control over system resources.
- Config-AP: TI Configuration AP supports access to SoC debug management registers
- Power-AP: TI Configuration AP supports advanced power, reset, and clock management. (See [Section 13.3.5](#))

[Table 13-4](#) describes the APSEL assignment for this device.

**Table 13-4. DAP APSEL Assignment**

APSEL	AP	Description
0	Config-AP	TI AP - Reserved
1	APB-AP	Provides access to Debug Config Plane
2	AXI-AP	Provides access to SoC Address Space
3	Power-AP	TI AP - Extended Power/Reset/Clock Control
4-5	Reserved	Reserved for future use
6	SEC-AP	TI AP - Authentication Interface
10-31	Reserved	Reserved for future use

### Boundary Scan

This device supports boundary scan using an IEEE 1149.1 compliant JTAG TAP that is made visible through the use of a compliance-enable mode (see [Section 13.3.4](#)). IEEE 1149.1 and 1149.6 Boundary Scan support are defined in device-specific BSDL files that can be found in the respective device's product folder on ti.com.

## SoC Address Space

The device architecture provides access to On-Chip debug resources through the SoC Address Space. This includes access to all DAP Access Ports (APs) as well as the Debug-APB address space.

### 13.3.4 Debug Boot Modes and Boundary Scan Compliance

The EMU1 and EMU0 device pins are used to convey debug boot mode behavior and can also be used as part of a boundary scan compliance sequence to enable boundary scan features.

#### Debug Boot Mode

EMU1 and EMU0 are sampled when MCU\_PORz is de-asserted and the decoded value determines the debug boot mode behavior as detailed in [Table 13-5](#).

**Table 13-5. Debug Boot Modes**

Sample Time	EMU1	EMU0	Boot Mode	Behavior
MCU_PORz deassertion	0	0	Reserved	Reserved for future use
	0	1	Reserved	Reserved for future use
	1	0	Wait-In-Reset (WIR)	Device will remain quiescent until a debug connection is established and the debugger releases WIR. This mode is useful for debugging boot sequences.
	1	1	Normal	Device boots normally. Debug can connect at any time but the context will be post-boot.

#### Boundary Scan Compliance

EMU1 and EMU0 are sampled when TRSTz is de-asserted and the decoded value determines the debug boot mode behavior as detailed in [Table 13-6](#).

**Table 13-6. Boundary Scan Compliance**

Sample Time	EMU1	EMU0	Boundary Scan Compliance	Behavior
TRSTn deassertion	0	1	Boundary Scan Enabled	The device's Boundary Scan TAP is connected to the device's JTAG interface.
	0	0		
	1	0	Boundary Scan Disabled	The device's SWJ-DP is connected to the device's JTAG interface.
	1	1		

### 13.3.5 Power, Reset, Clock Management

This device includes advanced power, reset, and clock management debug capabilities, including:

- **Wakeup support for debug logic:** logic within the device is able to sense JTAG activity and ensure that debug logic is on and able to service JTAG requests.
- **Reset isolation:** critical configuration and trace datapaths and logic are not sensitive to warm reset
- **Configuration independence:** debug configuration occurs over a debug-only interconnect, separate from SoC traffic to ensure debug logic remains available even during deadlock scenarios.
- **Power-AP:** a CoreSight™ compliant Access Port (AP) developed by TI that provides a standard interface for debug tooling to access status and control over power, reset, and clocking for the system and various LPSC-defined sub-domains.

### 13.3.6 Debug Cross Triggering

This device supports an Arm® CoreSight™ compliant four-channel programmable on-chip Cross Triggering network. In addition to the four-channel on-chip network, this device implements two channels of product level triggering via the EMU0 and EMU1 device pins.

Conceptually, each channel of Cross Triggering can be viewed as mapping of a user-defined set of events to a user-defined set of actions, where the occurrence of any event in the set-of-events results in the generation of the set-of-actions. [Table 13-7](#) provides a domain-level summary of the supported events and actions.

**Table 13-7. Domain-Level Summary of Triggering Capability**

Domain	Events	Actions
Product-Level	Zero detected on EMU0 input pin	EMU0 output pin driven to Zero
	Zero detected on EMU1 input pin	EMU1 output pin driven to Zero
SoC Debug	TBR Acquisition Complete	TPIU insert trigger packet
	TBR Embedded buffer is full	TPIU start flush process
	System reset asserted	TBR insert trigger packet
	Bus Probe-n match	TBR start flush process
	STM write to a TRIG location	Bus Probe-n Start
	STM write to a trigger-enabled stimulus port	Bus Probe-n Stop
	has halted	– halt request
	PMU generated interrupt	– resume request
	ETM External Out (EXTOUT) trigger	ETM External In (EXTIN) trigger
A53SS0	A53SS0 core-n has halted	A53SS0 core-n – halt request
	PMU generated interrupt	A53SS0 core-n – resume request
	ETM trigger	CTI interrupt
	--	ETM External In (EXTIN) trigger

### 13.3.7 WKUP\_R5F Debug

The WKUP\_R5F includes an Arm Cortex R5F with embedded debug capability, including:

- Independent debug configuration
- ROM Table
- Basic debug functionality
- Cross Triggering
- PMU: Performance Monitor Unit
- ETM: Embedded Trace Macrocell

A summary of the WKUP\_R5F debug capabilities is detailed in [Table 13-8](#).

**Table 13-8. WKUP\_R5F Debug Capabilities**

Capability	Feature	Notes
Basic Debug	Independent debug configuration	Debug resource configuration is performed over a configuration interface that is isolated from functional traffic
	ROM table	Facilitates discovery of debug resources within debug configuration address space
	Processor halt	Support user-requested entry into the suspended state
	Single step	Execution of a single instruction before entering the suspended state
	Software breakpoints	Software breakpoints are supported via opcode replacement
	Hardware breakpoints	Eight Debug Breakpoint resources support hardware breakpoints
	Hardware watchpoints	Eight Debug Watchpoint resources support data address breakpoints
	Core register access	Access to processor core registers
	System memory access	Access to memory from perspective of CPU
	Vector catch	Halting in response to an exception
	Arm® TrustZone® debug authentication	Provisioning for DBGEN and NIDEN
Cross Triggering	Debug state	Support for controlling execution state (run, halt) via triggers and creating triggers upon entry into debug state
	PMU	PMU interrupt trigger
	ETM	Five ETM external triggers (one ETM Trigger, two external out event triggers, two external in event triggers)
PMU	Profile Counters	Three counters can be used to count different events available for gathering statistics on the operation of the processor and memory system
	Cycle Counter	One dedicated counter available for counting CPU clock cycles
ETM	Triggering Infrastructure	Comprehensive triggering infrastructure supports use of comparators (address, data value, context ID), counters, sequencer state, an external inputs and outputs to control the enabling of trace.
	Instruction trace	Supports tracing of instruction flow
	Cycle-accurate tracing	Supports inclusion of a precise cycle count of executed instructions.
	Branch broadcast tracing	Support for tracing branch address details even in circumstances where that information might be discoverable from object code
	Data tracing	Support for data address and data value tracing

### 13.3.8 A53SS0 Debug

The A53SS0 is a multi-core Arm Cortex-A53 subsystem with embedded debug capability and features, including:

- Independent debug configuration
- ROM Table
- Basic debug functionality
- Cross Triggering
- PMU: Performance Monitor Unit
- ETM: Embedded Trace Macrocell

A summary of the A53SS0 debug capabilities and features is detailed in [Table 13-9](#).

**Table 13-9. A53SS0 Debug Capabilities**

Capability	Feature	Notes
Basic Debug	Independent debug configuration	Debug resource configuration is performed over a configuration interface that is isolated from functional traffic
	ROM table	Facilitates discovery of debug resources within debug configuration address space
	Processor halt	Support user-requested entry into the suspended state
	Single step	Execution of a single instruction before entering the suspended state
	Software breakpoints	Software breakpoints are supported via opcode replacement
	Hardware breakpoints	Six Debug Breakpoint resources support hardware breakpoints
	Hardware watchpoints	Four Debug Watchpoint resources support data address breakpoints
	Core register access	Access to processor core registers
	System memory access	Access to memory from perspective of CPU
	Vector catch	Halting in response to an exception
	Arm® TrustZone® debug authentication	Provisioning for DBGEN, NIDEN, SPIDEN, SPNIDEN, SUIDEN, and SUNIDEN
Cross Triggering	Debug state	Support for controlling execution state (run, halt) via triggers and creating triggers upon entry into debug state
	PMU	PMU interrupt trigger
	ETM	Four ETM external triggers
	CPU	CTI interrupt into CPU
PMU	Profile Counters	Six counters can be used to count different events available for gathering statistics on the operation of the processor and memory system
	Cycle Counter	One dedicated counter available for counting CPU clock cycles
ETM	Instruction trace with cycle counting	Support for tracing instruction execution with timing information
	Branch broadcast tracing	Support for tracing branch address details even in circumstances where that information might be discoverable from object code
	Return stack tracing	Support for tracing of the return stack
	Stall Control	Support for stalling the A53 processor to avoid ETM overflows
	Global timestamping	Support for attaching a global timestamp to trace traffic

### 13.3.9 SoC Debug and Trace

This device includes debug capabilities deployed at the system level, including:

- Software messaging trace
- Debug-aware peripherals
- Traffic monitoring with bus probes
- Global timestamping for trace

More details for each of these capability areas can be found in the corresponding sections below.

#### 13.3.9.1 Software messaging trace

Software messaging trace is supported on this device by an MIPI STP-V2 compliant Arm® CoreSight™ STM with supporting logic that maps initiator IDs to specific STP Major Source IDs. The following device initiators support software messaging:

- A53SS0 cores
- MCU\_

#### 13.3.9.2 Debug-Aware Peripherals

Select peripherals support a debug feature that allows them to react to the debug state of a controlling processor. For instance, a timer peripheral that is allocated to a particular processor could be configured to stop counting when the associated processor is in the halted state. This device includes programmable support

for shared peripherals that allows the developer to select the processor whose debug state a given peripheral should receive.

A list of the processors and peripherals that support this debug model can be found in [Table 13-10](#).

**Table 13-10. Debug-Aware Peripheral Support**

Supported Processors	Supported Peripherals
A53SS0 cores	GTC
	TIMER instances
	EPWM instances
	MCAN instances
	I2C instances
--	MCRC64 instances
--	ECAP instances
--	EQEP instances
--	
--	
--	RTI/WWDT instances

### 13.3.9.3 Traffic Monitoring With Bus Probes

Traffic monitoring bus probes are deployed at strategic points in the system interconnect and support the following capabilities:

- MIPI STP-V2 compliant trace messaging support with global timestamping support
- Latency Statistics Collection: Statistics on the timeliness of responses to read requests are collected during a sampling window and then read by a profiling entity (application thread or encoded into a trace message)
- Throughput Statistics Collection: Statistics on the amount of data moving across an interface are collected during a sampling window and then read by a profiling entity (application thread or encoded into a trace message)
- Transaction Trace: Information about specific transactions occurring at a probed location are captured and encoded into a trace message
- Complex filtering support allows discrimination of traffic being monitored
- Cross-Trigger support for enabling and disabling probe monitoring

[Table 13-11](#) details the locations in the system interconnect that are probed:

**Table 13-11. Bus Probe Points**

Probe Point	Bus Monitoring Details
A53SS0 Write Initiator	Provides visibility to all write requests initiated by A53SS0
A53SS0 Read Initiator	Provides visibility to all read requests initiated by A53SS0
A53SS0 ACP Target	Monitors traffic to the A53SS0 ACP port
DDR Target	Monitors traffic to DDR
GMPC Target	Monitors traffic to GPMC
FSS Target	Monitors traffic to FSS0

### 13.3.9.4 Global timestamping for trace

Support for a global timestamp for use by debug is enabled by a 48-bit continuous timestamp managed by the device's GTC. This 48-bit global timestamp is readable by embedded software, via the GTC, and distributed across the device to various trace sources where it is used as a time reference when timestamping trace streams. Trace sources that support global timestamping, include:

- A53SS0 cores: ETM
- STM

- Bus Probes

### 13.3.10 Trace Traffic

Trace traffic originates from a trace source, is distributed across the device using Arm® CoreSight™ compliant trace infrastructure components, and reaches one of two possible trace sinks.

#### 13.3.10.1 Trace Sources

A summary of the trace sources present on this device is included in [Table 13-12](#).

**Table 13-12. Trace Sources**

Domain	Trace Source
SoC Debug	Bus Probes
	STM
A53SS0	ETM (each core)

#### 13.3.10.2 Trace Infrastructure

Trace distribution is accomplished using standard Arm® CoreSight™ compliant trace infrastructure components:

- CoreSight™ Trace Funnels (CSTF): Non-programmable CSTFs are used at points of interleaving where multiple trace sources converge and form a single stream of trace traffic. This device includes one instance of a programmable CSTF that is deployed immediately before the TPIU.
- CoreSight™ Trace Replicator (CSREP): A programmable CSREP is used as a routing device, that can be used to forward trace traffic, based on its ID, to one, both, or none of the device trace sinks.

#### 13.3.10.3 Trace Sinks

Two trace sinks are supported on this device:

- Arm® CoreSight™ TPIU: TPIU supports export of trace off-chip via LVCMOS device pins (See 1.3.3.3) for capture by an external receiver.
- TI Trace Buffer Router (TBR) with 64KB of storage: the TBR can function as a trace buffer or as a system bridge. As a trace buffer, the TBR can be setup to capture trace data until the internal buffer fills or it can operate as a circular buffer that will capture continuously. When configured as a system bridge the TBR's storage becomes an elastic buffer that supports the concurrent queueing and dequeuing of trace traffic. The system bridge mode supports interrupt and event notification capabilities that support integration with device level CPUs and/or DMAs to support a variety of use cases, including, for e.g., relocation of trace data to DDR and off-chip export over USB.

### 13.3.11 Application Support

TI includes a set of system level debug facilities in the Debug Subsystem of devices known as Chip Tools (CTools). For easy integration of A53 processor trace and system trace into applications, a set of libraries commonly referred to as CToolsLib are provided. CToolsLib is a collection of embedded target APIs/libraries focused on enabling easy access to the CTools. CToolsLib encompasses the following libraries to assist in trace integration:

- STM Library
- CP Tracer Library
- TBR Library
- ETM Library

For more information about these libraries, downloadable files, and other useful links, please visit the [CToolsLib Wiki site](#).
