Description	The bank of registers configure the down/up/down-scaling coefficients for the vertical resize of the video picture associated with the video window 3 for the phases from 0 to 7. It is used for Crb and Cr setting. It is used only when the pixel format at the input of the filter is one of the YUV formats. If the pixel format at the input of the filter is ARGB (all ARGB, RGB, RGBA are converted to ARGB32-8888 by the color space conversion before going to the filter is the color space conversion is done before the filter). When the register is not used by the hardware, any value can be used for the bit fields. Shadow register, updated on VFP start period of primary LCD or VFP start period of the secondary LCD or VFP start period of the third LCD or EVSYNC or when DISPC_CONTROL2.GOWB is set to 1 by software and current WB frame is finished (no more data in the write-back pipeline). The synchronization event is defined based on the output using the pipeline: primary LCD, secondary LCD, third LCD, TV output or write-back to the memory

11.3 High-Definition Multimedia Interface

This section introduces the high-definition multimedia interface (HDMI) module and describes its main functions and connections in the device.

Note

All the HDMI features described in this chapter may not be supported in software. For example, 3D-frame packing is not supported. Refer to the software development kit (SDK) for which HDMI features are supported.

11.3.1 HDMI Overview

Figure 11-103 shows an overview of the HDMI module.

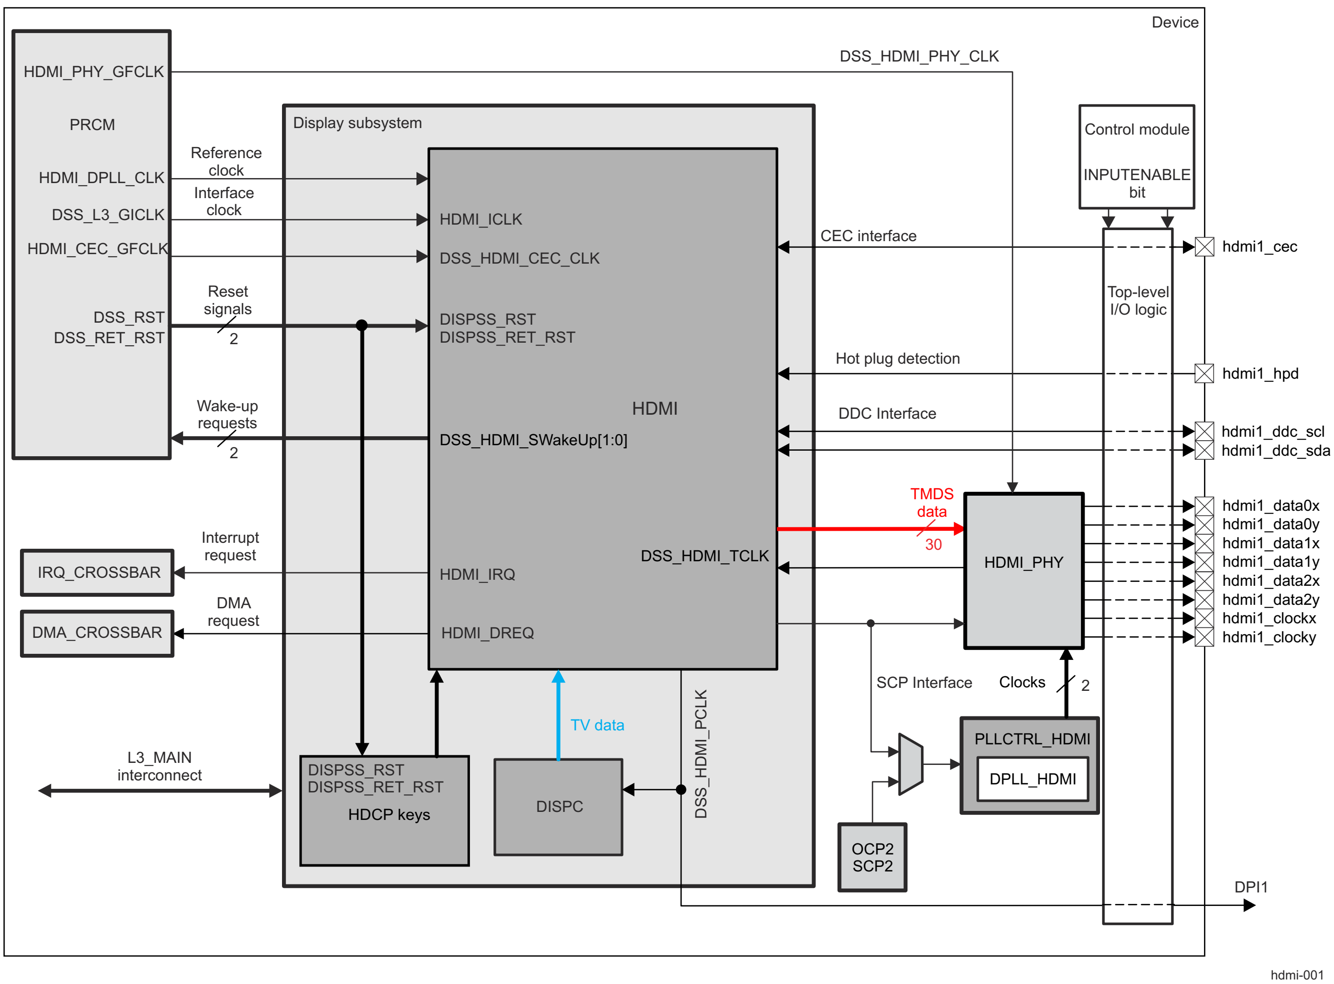

Figure 11-103. HDMI Overview

11.3.1.1 HDMI Main Features

The HDMI module provides the following main features:

- HDMI 1.4a, HDCP 1.4, and DVI 1.0 compliant
  - Includes support for the 3D stereoscopic frame-packing formats of the HDMI v1.4a standard (1080p24Hz, 720p50Hz, 720p60Hz + side-by-side half structure: 1080p60Hz)
- EIA/CEA-861-D video format support (See Table 11-359 for more information.)
- VESA® display monitor timing (DMT) video format support(See Table 11-360 for more information.)

- Support for deep-color mode:
  - 10-bit color component deep-color modes up to 1080p @ 60 Hz
  - 12-bit color component deep-color modes up to 720p/1080i @ 60 Hz
  - 16-bit/component color depth is not supported
- Support for x.v.Color (x.v.Color data from memory outputted by HDMI. No processing, pass-through mode only)
- Supports up to 148.5-MHz pixel clock with deep-color modes (10-bit or 12-bit)
- Supports up to 186 MHz pixel clock with no deep-color mode (8-bit)
- Video formats: 24-bit RGB input
  - 24/30/36-bit RGB/YCbCr 4:4:4 (deep color) output
  - 16/20/24-bit YCbCr 4:2:2 output
- Uncompressed multichannel (up to eight channels) audio (L-PCM) support.
- Master inter-integrated circuit (I^2C™) interface for display data channel (DDC) connection
- Consumer electronic control (CEC) interface
- Integrated transition minimized differential signaling (TMDS®) and TMDS error reduction coding (TERC4) encoders for data island support
- Integrated TMDS physical layer (PHY) (three TMDS differential data lanes + TMDS differential clock lane)
  - Up to 1.86 Gbps per lane at (1080p @ 60 Hz at 10 bits/component)

11.3.1.2 HDMI Video Formats and Timings

11.3.1.2.1 HDMI CEA-861-D Video Formats and Timings

Table 11-359 presents the video timings supported by the HDMI module, according to the CEA-861-D standard:

Table 11-359. HDMI Video Timings (CEA-861-D)

Refresh Rate	Resolution
24 Hz (Low field rate)	1920 x 1080p
50 Hz	1920 x 1080p
	1920 x 1080i
	2880 x 576p
	2880 x 288p
	1440 x 576p
	1440 x 288p
	1280x720p
	720 x 576p
59.94 Hz	1920 x 1080p
	1920 x 1080i
	1280 x 720p
	2880 x 480p
	2880 x 240p
	1440 x 480p
	1440 x 480i
	1440 x 240p
	720 x 480p
	640 x 480p

Table 11-359. HDMI Video Timings (CEA-861-D) (continued)

Refresh Rate	Resolution
60 Hz	1920 x 1080p 1920 x 1080i 2880 x 480p 2880 x 240p 1280 x 720p 1440 x 480p 1440 x 480i 1440 x 240p 1280 x 720p 720 x 576p 720 x 480p 640 x 480p
200 Hz	720 x 576p
239 Hz	720 x 480p
240 Hz	720 x 480p

11.3.1.2.2 VESA DMT Video Formats and Timings

Table 11-360 lists the video timings supported by the HDMI module and based on the VESA DMT standard:

Table 11-360. HDMI Video timings (VESA DMT)

Refresh Rate	Resolution
60 Hz	640 x 480p 800 x 600p 848 x 480p 1024 x 768p 1280 x 768p
	1280 x 800p
	1280 x 960p
	1280 x 1024p
	1360 x 768p
	1366 x 768p
	1400 x 1050p
	1440 x 900p
	1680 x 1200p
	1680 x 1050p
	1920 x 1080p
60 Hz (reduced blanking)	1280 x 768p
	1280 x 800p
	1400 x 1050p
	1440 x 900p
	1680 x 1050p
	1920 x 1200p

Note

Custom resolutions may work, but are not supported by the device. Using non-standard values can lead to noncompliance with the HDMI interface standard.

Chapter 12
3D Graphics Accelerator

This chapter is a basic overview and describes the integration of the 3D graphics processing unit (GPU) subsystem in the device.

Note

The GPU subsystem is an instantiation by Texas Instruments of the PowerVR® SGX544 core from Imagination Technologies Limited.

This document contains materials that are © Imagination Technologies Limited.

USSE and PowerVR are trademarks or registered trademarks of Imagination Technologies Limited.

12.1 GPU Overview.......... 2902
12.2 GPU Integration.......... 2905
12.3 GPU Functional Description.......... 2907
12.4 GPU Register Manual.......... 2910

12.1 GPU Overview

The 3D graphics processing unit (GPU) accelerates 2-dimensional (2D) and 3-dimensional (3D) graphics and compute applications. It is based on the PowerVR® SGX544-MP2 core from Imagination Technologies Limited. The SGX544-MP2 core is a multicore (dual-core) evolution of the PowerVR SGX544 GPU.

SGX is a new generation of programmable PowerVR graphics and video IP cores. The PowerVR SGX is a scalable architecture which efficiently processes a number of differing multimedia data types concurrently :

- Pixel Data
- Vertex Data
- General Purpose Processing

The dual core GPU splits geometry and pixel rendering among the cores to improve performance proportional to the number of cores.

Figure 12-1 shows the device GPU subsystem.

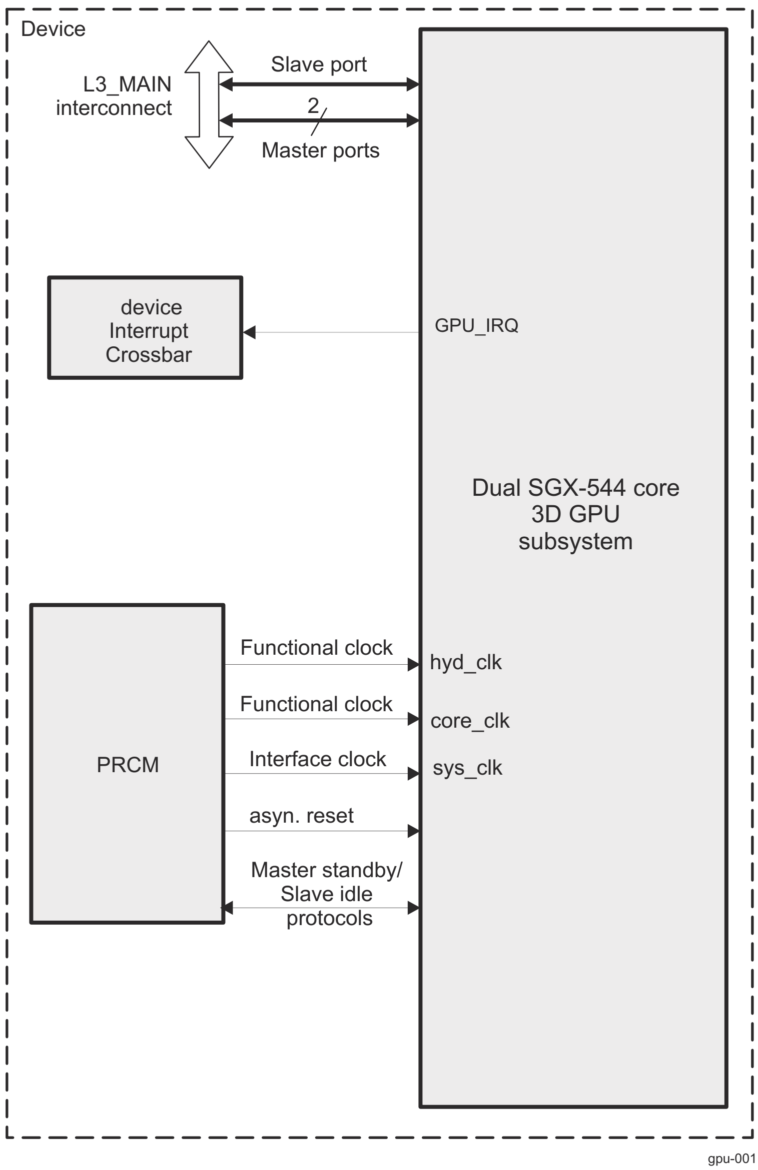

Figure 12-1. GPU Overview

12.1.1 GPU Features Overview

- API support for industry standards:
  - OpenCL™-EP 1.1
  - Direct3D® Feature Level 9.3
- Multicore GPU architecture:
  - 2 × SGX544 cores
  - Shared system level cache of 128 KiB (64 KiB per SGX-544 core)
- Tile-based deferred rendering architecture:
  - Reduces external bandwidth to SDRAM
- Universal Scalable Shader Engine (USSE™):
  - Multithreaded engine incorporating vertex and pixel shader functionality
  - Automatic load balancing of vertex and pixel processing tasks
- Present and texture load accelerator (PTLA):
  - Enables to move, rotate, twiddle, and scale texture surfaces
  - Supports RGB, ARGB, YUV4:2:2, and YUV4:2:0 surface formats
  - Supports bilinear upscale
  - Supports source color key
- Fully virtualized memory addressing for operating system (OS) in a unified memory architecture:
  - Memory management unit (MMU)
  - Up to 4-GiB virtual address space

The 3D-GPU subsystem generates a single (aggregate) interrupt connected to the device Interrupt Crossbar. This allows for this interrupt to be programmatically mapped to multiple device host interrupt controllers (see Section 12.2).

12.1.2 Graphics Feature Overview

- Texture support:
  - Cube map
  - Projected textures
  - Non-square textures
- Texture formats:
  - RGBA 8888, 565, 1555, and 1565
  - Monochromatic 8, 16, 16f, 32f, and 32int
  - Dual channel, 8:8, 16:16, and 16f:16f
  - Compressed textures:
    - PVRTC-i 2 bpp
    - PVRTC-i 4 bpp
    - PVRTC-ii 2 bpp
    - PVRTC-ii 4 bpp
    - ETC1
    - DXT 1-5 and BC 4-5
  - Programmable support for YUV formats:
    - Programmable matrix in hardware, coefficients on 12 bits
    - YUV4:2:2, YUV4:2:0, two planes (NV12 or NV21); YUV4:2:0, three planes
- Resolution support:
  - Frame buffer maximum = 4096 × 4096
  - Texture maximum size = 4096 × 4096
- Texture filtering:
  - Bilinear, trilinear
  - Independent minimum and mag control

- Anti-aliasing:
  - 4× multisampling
  - Programmable sample positions

Note

TI provides the DXT1-5 and BC4-5 texture compression technology for use only with a Microsoft Windows operating system. A separate license is required for the use of this technology (also referred to as S3 texture compression technology) with any other operating system.

12.2 GPU Integration

This section describes the integration of the module in the device, including information about clocks, resets, and hardware requests.

Figure 12-2 shows the GPU integration.

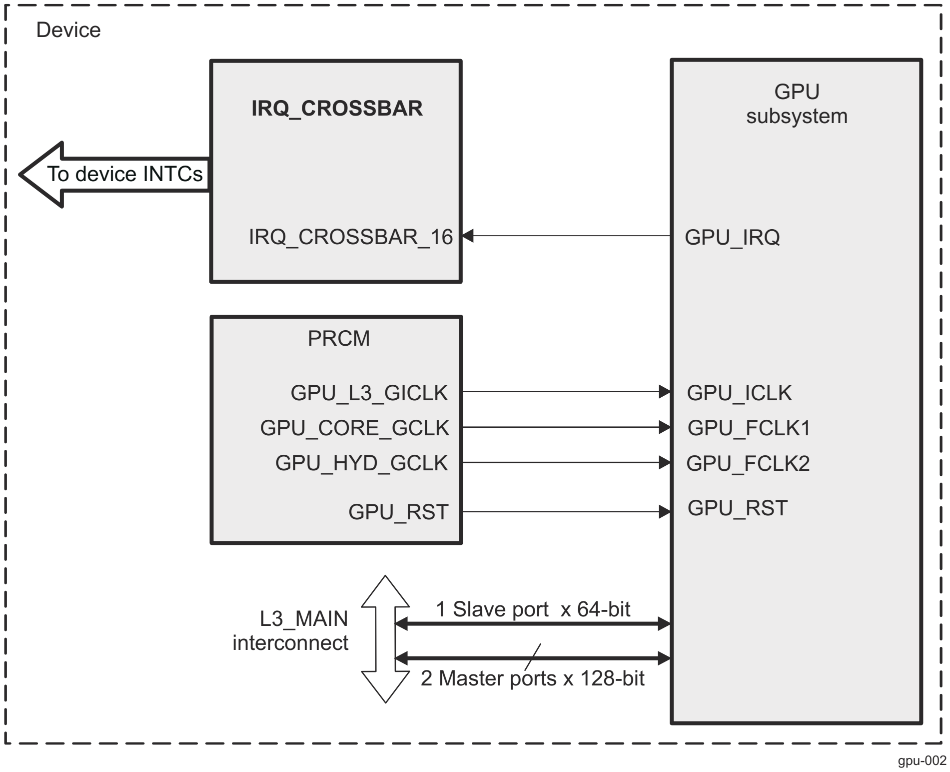

Figure 12-2. GPU Integration

The GPU subsystem is connected to the level 3 (L3_MAIN) interconnect by two 128-bit master and a 64-bit slave interfaces.

Table 12-1 through Table 12-3 summarize the integration of the module in the device.

Table 12-1. GPU Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
GPU	PD_GPU	L3_MAIN

Table 12-2. GPU Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**

GPU	GPU_FCLK1	GPU_CORE_GCLK	PRCM	GPU functional clock of the internal graphic cores
GPU	GPU_FCLK2	GPU_HYD_GCLK	PRCM	GPU functional clock of the internal L2-cache controller and memories
Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
GPU	GPU_RST	GPU_RST	PRCM	GPU non-retention reset signal

Table 12-3. GPU Hardware Requests

Interrupt Requests				
Module Instance	**Source Signal Name**	**IRQ_CROSSBAR Input**	**Default Mapping**	**Description**
GPU	GPU_IRQ	IRQ_CROSSBAR_16	MPU_IRQ_21 DSP1_IRQ_47 DSP2_IRQ_47	GPU interrupt request mapped to the device Interrupt Crossbar

Note

The "**Default Mapping**" column in Table 12-3, *GPU Hardware Requests* shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR module.
For more information about the IRQ_CROSSBAR module, see Section 18.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 18, *Control Module*.
For more information about the device interrupt controllers, see Chapter 17, *Interrupt Controllers*.

Note

No DMA and no wake-up requests are generated by the GPU subsystem.

12.3 GPU Functional Description

12.3.1 GPU Block Diagram

The GPU subsystem is based on the PowerVR SGX544-MP2 core. Multicore GPU can split geometry and pixel rendering among the cores to improve performance proportional to the number of cores. The graphics software engineer programming the device GPU does not have to deal with the multiple cores, this is done by the graphics drivers. The multiple cores are completely hidden behind the standard high-level graphics APIs that are supported by the graphics core. The GPU architecture comprises the following elements:

- SGX544 cores
- PTLA
- Cross bar
- System-level cache (SLC)

Figure 12-3 shows the GPU top-level block diagram.

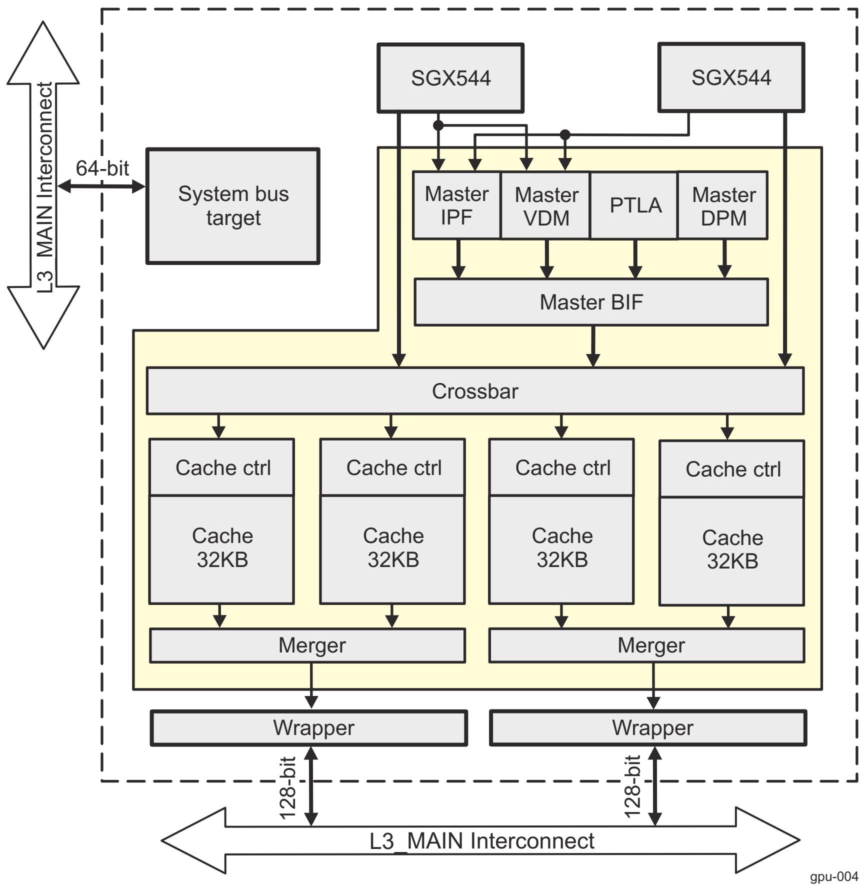

Figure 12-3. GPU Block Diagram

The SGX544-MP2 has 2× SGX544 cores. Graphics rendering is automatically load-balanced between the 2× SGX544 cores. It is possible to disable one or two of the cores if required. The glue logic is used to enable the multicore architecture. The crossbar enables any SGX544 core to access the SLC. The SLC is a 128-KiB unified multibanked cache with four banks of 32 KiB. The cache line size is 64 bytes. The SGX544 core accesses are interleaved in the different banks.

12.3.2 GPU Clock Configuration

The GPU subsystem operates from three clocks: an interface clock (GPU_ICLK) and two functional clocks (GPU_FCLK1 and GPU_FCLK2). The power, reset, and clock management (PRCM) module generates and distributes the clocks inside the device.

- The GPU_ICLK manages the data transfer on the L3_MAIN master and slave ports.

  The GPU_ICLK frequency is selected based on the L3_MAIN interconnect clock frequency of the whole device. For more information about the interface clock, see *CD_GPU Clock Domain*, in the *Power, Reset, and Clock Management*.

  When no longer required by the GPU subsystem, GPU_ICLK can be disabled by software at the PRCM level. For more information, see *PD_GPU Description*, in the *Power, Reset, and Clock Management*.

  Note

  GPU_ICLK is cut only if the GPU is ready to go into IDLE state.

- GPU_FCLK1 and GPU_FCLK2 are the functional clocks and are used inside the GPU subsystem to generate clock signals to multiple GPU clock domains. The GPU_FCLK1 input supplies clock to the internal graphics cores and the GPU_FCLK2 input supplies clock to the shared-cache memories and controllers.

  Using the clock source selection and the digital phase-locked loop (DPLL) settings, GPU_FCLK1 and GPU_FCLK2 frequencies can be adjusted.

  The GPU_FCLK1 and GPU_FCLK2 clocks are provided by the peripheral DPLL and the core DPLL, as described in *CD_GPU Clock Domain* in the *Power, Reset, and Clock Management*. Selection is made at the PRCM level.

  When no longer needed by the GPU subsystem, GPU_FCLK1 and GPU_FCLK2 can be cut by software at the PRCM level if the module is ready to enter IDLE state. For more information, see *PD_GPU Description* in the *Power, Reset, and Clock Management*.

12.3.3 GPU Software Reset

The GPU subsystem has its own reset domain. Global reset of the GPU is performed by activating the GPU_RST signal in the GPU_RST domain.

Note

The APIs delivered with the GPU provide a software reset functionally equivalent to a hardware reset.

12.3.4 GPU Power Management

The GPU subsystem has its own power domain (GPU power domain - PD_GPU).

The GPU handles automatic clock gating performed on the multiple internal module clock domains.

In addition, software-controlled clock gating is managed inside the GPU and handled by the related API delivered with the module.

For additional information about the GPU power domain, see Section 3.7.10, *PD_GPU Description* in the Chapter 3, *Power, Reset, and Clock Management*.

12.3.5 GPU Thermal Management

There is a dedicated thermal sensor to monitor operating temperature of the GPU subsystem in the chip. The GPU temperature processing logic is located within the device CTRL_MODULE_CORE and is capable to generate a thermal alert interrupt which can be mapped to all (host) interrupt controllers within the device, via the device IRQ_CROSSBAR. The thermal logic can also generate a thermal shut-down warm reset event to the device PRCM. For further details on the GPU thermal management operation features and register settings, refer to the Section 18.4.6.2, *Thermal Management Related Registers* of the Chapter 18, *Control Module*.

12.3.6 GPU Interrupt Requests

The GPU subsystem can generate one interrupt signal - GPU_IRQ mapped to the IRQ_CROSSBAR_16 input of the device interrupt crossbar.

For more details on programmable configuration of the GPU_IRQ mapping to the different device host interrupt controllers, refer to the Chapter 18, *Control Module* and the Chapter 17, *Interrupt Controllers*.

12.4 GPU Register Manual

CAUTION

All GPU registers are limited to 32-bit data accesses; 8- and 16-bit accesses are not allowed because they can corrupt register content.

12.4.1 GPU Instance Summary

Table 12-4. GPU Instance Summary

Chapter 13

2D Graphics Accelerator

This chapter describes the advanced bit blitter 2-dimensional (2D) graphics accelerator (BB2D) for the device.

Note

The BB2D subsystem is an instantiation by Texas Instruments of the GC320™ core from Vivante Corp.

This document contains materials that are © Vivante Corp.

GC320 is a trademark or registered trademark of Vivante Corp.

13.1 BB2D Overview 2927
13.2 BB2D Integration 2929
13.3 BB2D Functional Description 2931
13.4 BB2D Register Manual 2933

13.1 BB2D Overview

The 2D graphics accelerator subsystem accelerates 2D graphics applications. The 2D graphics accelerator subsystem is based on the GC320 2D GPU core from Vivante Corporation. The hardware acceleration is brought to numerous 2D applications, including on-screen display and touch screen user interfaces, graphical user interfaces (GUIs) and menu displays, flash animation, and gaming.

Figure 13-1 shows the BB2D subsystem.

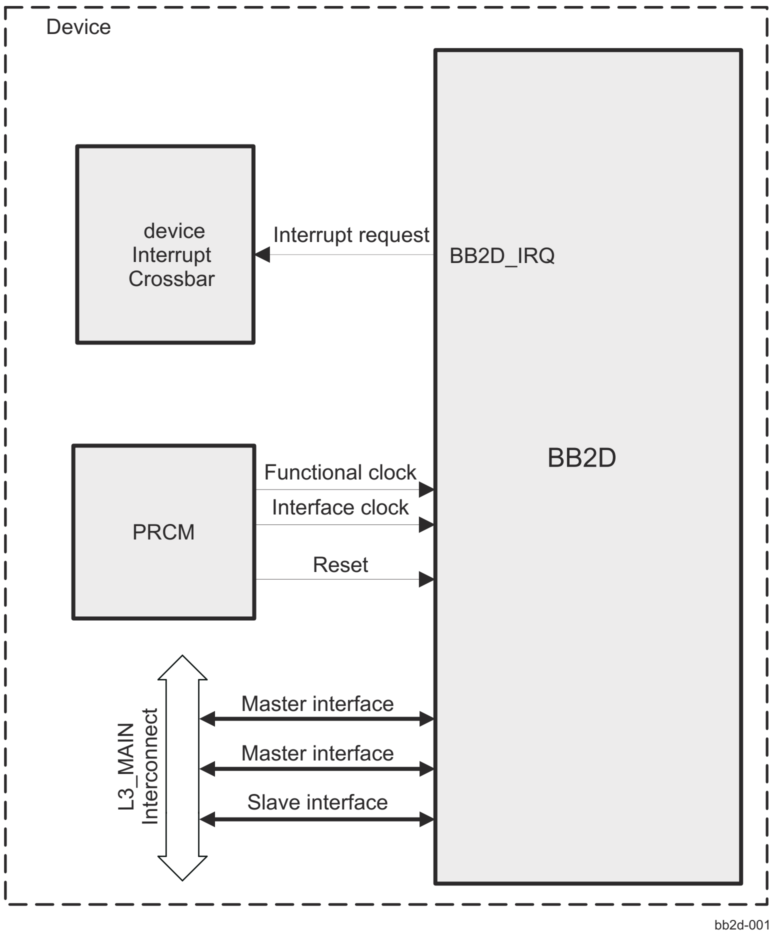

Figure 13-1. BB2D Overview

13.1.1 BB2D Key Features Overview

- API support:
  - OpenWF™, DirectFB
  - GDI/DirectDraw™
  - Flash
- **BB2D architecture:**
  - BitBlt and StretchBlt
  - DirectFB hardware acceleration
  - ROP2, ROP3, ROP4 full alpha blending and transparency
  - Clipping rectangle support
  - Alpha blending includes Java® 2 Porter-Duff compositing rules
  - 90-, 180-, 270-degree rotation on every primitive
  - YUV-to-RGB color space conversion
  - Programmable display format conversion with 14 source and 7 destination formats

  - High-quality 9-tap, 32-phase filter for image and video scaling at 1080p
  - Monochrome expansion for text rendering
  - 32 K × 32 K coordinate system
- **Hardware acceleration for DirectFB**:
  - High-speed video scaler
  - ROP2/3/4
  - Rectangle filling and drawing
  - Line drawing
  - Simple blitting
  - Stretch blitting
  - Blending with alpha channel (per-pixel alpha)
  - Blending with alpha factor (alpha modulation)
  - Nine source and destination blending functions
  - Porter-Duff rules support
  - Premultiplied alpha support
  - Colorized blitting (color modulation)
  - Source color keying
  - Destination color keying

The device BB2D generates a single (aggregate) interrupt request connected to the device Interrupt Crossbar. This allows for this interrupt to be programmatically mapped to multiple device host interrupt controllers (see Section 13.2).

13.2 BB2D Integration

This section describes subsystem integration in the device, including information about clocks, resets, and hardware requests.

Figure 13-2 shows BB2D integration.

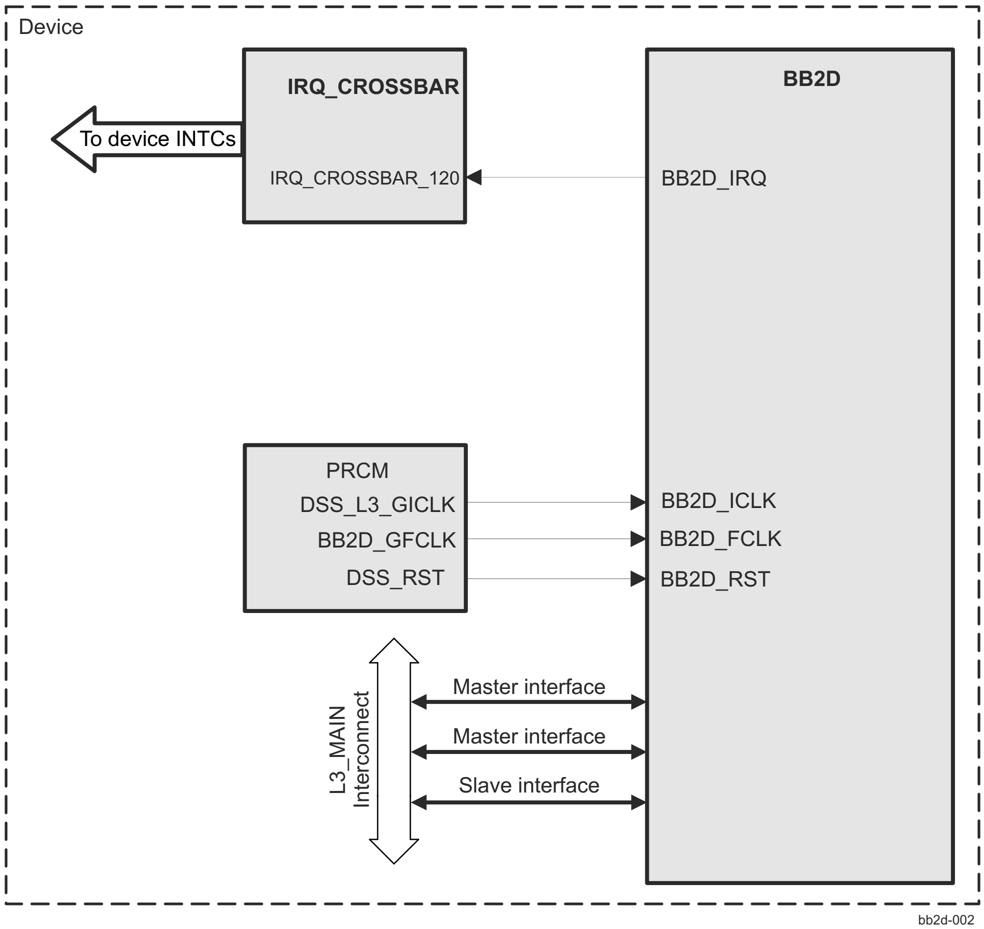

Figure 13-2. BB2D Integration

The BB2D subsystem is connected to the level 3 (L3_MAIN) interconnect by two 128-bit master interfaces and one 32-bit slave interface.

Table 13-1 through Table 13-3 summarize the integration of the subsystem in the device.

Table 13-1. BB2D Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
BB2D	PD_DSS	L3_MAIN

Table 13-2. BB2D Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
BB2D	BB2D_ICLK	DSS_L3_GICLK	PRCM	BB2D interfaces clock
	BB2D_FCLK	BB2D_GFCLK	PRCM	BB2D functional clock.
Resets				

Table 13-2. BB2D Clocks and Resets (continued)

Module Instance	Destination Signal Name	Source Signal Name	Source	Description
BB2D	BB2D_RST	DSS_RST	PRCM	BB2D non-retention reset signal

Table 13-3. BB2D Hardware Requests

Interrupt Requests				
Module Instance	**Source Signal Name**	**Destination IRQ_CROSSBAR Input**	**Default Mapping**	**Description**
BB2D	BB2D_IRQ	IRQ_CROSSBAR_120	MPU_IRQ_125 IPU1_IRQ_65 IPU2_IRQ_65	BB2D interrupt request to the device interrupt crossbar

Note

The "**Default Mapping**" column in Table 13-3, *BB2D Hardware Requests* shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR module.
For more information about the IRQ_CROSSBAR module, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.
For more information about the device interrupt controllers, see *Interrupt Controllers*.

Note

No DMA and no wake-up requests are generated by the BB2D module.

13.3 BB2D Functional Description

13.3.1 BB2D Block Diagram

The BB2D subsystem is based on the following main blocks:

- Host interface: Allows the BB2D core to communicate with external memory and the MPU through the L3_MAIN interconnect. In this block, data crosses clock domain boundaries.
- Memory controller: Internal memory unit that is the block-to-host interface for memory requests
- Graphics pipeline front-end: Inserts high-level primitives and commands into the graphics pipeline.
- 2D drawing and scaling engine: Draws 2D graphics primitives and rasterizes 2D images.
- Pixel engine: manipulates and filters pixels in rendered images. BB2D has four pixel pipes.

Figure 13-3 shows the BB2D top-level block diagram.

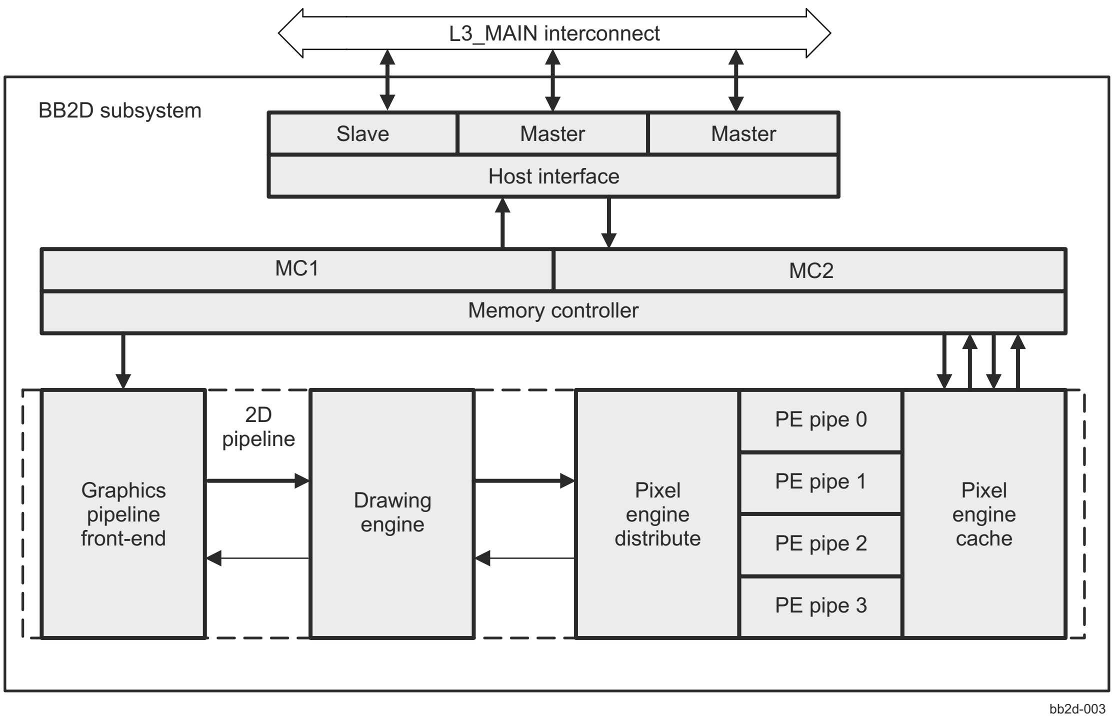

Figure 13-3. BB2D Block Diagram

13.3.2 BB2D Clock Configuration

The BB2D subsystem operates from two clocks: an interface clock (BB2D_ICLK) and functional clock (BB2D_FCLK). The power, reset, and clock management (PRCM) module generates and distributes the clocks inside the device.

- The BB2D_ICLK interface clock manages the data transfer on the L3_MAIN master and slave ports.

  The BB2D_ICLK frequency is selected based on the whole device L3_MAIN interconnect clock frequency. For more information on the interface clock, see *CD_DSS Clock Domain* , in the chapter, *Power, Reset and Clock Management* .

  When BB2D_ICLK is no longer required by the BB2D subsystem, it can be disabled by software at the PRCM level.

  Note

  BB2D_ICLK is cut only if the BB2D is ready to go into IDLE state.

- The BB2D_FCLK functional clock is used inside the BB2D subsystem to generate clock signals to multiple BB2D clock domains. The BB2D automatically gates clocks to domains, that are not currently in use.

Using the clock source selection and the DPLL settings, the frequency of BB2D_FCLK can be adjusted.

When BB2D_FCLK is no longer needed by the BB2D subsystem, it can be cut by software at the PRCM level, if the module is ready to enter IDLE state.

13.3.3 BB2D Software Reset

The BB2D subsystem is part of the DSS reset domain. A global reset of the BB2D is performed by activating the BB2D_RST signal in the DSS_RST domain.

Note

The APIs delivered with the BB2D provide a software reset functionally equivalent to a hardware reset.

13.3.4 BB2D Power Management

The BB2D subsystem is part of the DSS power domain (PD_DSS). For additional information about PD_DSS, see *PD_DSS Description* in the *Power, Reset, and Clock Management*.

Note

The BB2D handles automatic clock gating performed on the multiple internal clock domains.

When 2D operations are complete, software may set the GCGPOUT0[0] GCHOLD bit to 1 to enter a low-power state. Setting GCHOLD to 1 moves the BB2D operational state into IDLE. Once in IDLE state, the system standby hardware signal (mstandby) is asserted.

13.4 BB2D Register Manual

CAUTION

All BB2D registers are limited to 32-bit data accesses; 8- and 16-bit accesses are not allowed because they can corrupt register content.

Bits	Field Name	Description	Type	Reset
31	ENHANCE_VR	Enhance VR and add a mode to walk 16 pixels in 16-bit mode in vertical pass to improve cache hit rate when rotating 90/270.	R	1
30	CORRECT_STENCIL	Correct stencil behavior in depth only.	R	1
29	A8_TARGET_SUPPORT	2D engine supports A8 target.	R	0
28	NEW_TEXTURE	New texture unit is available.	R	0
27	HIERARCHICAL_Z	Hierarchiccal Z is supported.	R	1
26	BYPASS_IN_MSAA	Shader supports bypass mode when MSAA is enabled.	R	0
25	VAA	VAA is available or not.	R	0
24	BUG_FIXES0		R	1
23	SHADER_MSAA_SIDEBAND	Put the MSAA data into sideband fifo.	R	0
22	MC_20	New style MC with separate paths for color and depth.	R	0
21	DEFAULT_REG0	Unavailable registers will return 0.	R	1
20	EXTRA_SHADER_INSTRUCTIONS1	Sqrt, sin, cos instructions are available.	R	1
19	SHADER_GETS_W	W is sent to SH from RA.	R	1
18	VG_21	Minor updates to VG pipe (Event generation from VG, TS, PE). Tiled image support.	R	0
17	VG_FILTER	VG filter is available.	R	0
16	EXTRA_SHADER_INSTRUCTIONS0	Floor, ceil, and sign instructions are available.	R	1
15	COMPRESSION_FIFO_FIXED	If this bit is not set, the FIFO counter should be set to 50. Else, the default should remain.	R	1
14	TS_EXTENDED_COMMANDS	New commands added to the tessellator.	R	0
13	VG_20	Major updates to VG pipe (TS buffer tiling. State masking.).	R	0
12	SUPER_TILED_32X32	32 × 32 super tile is available.	R	1
11	SEPARATE_TILE_STATUS_WHEN_INTERLEAVED	Use 2 separate tile status buffers in interleaved mode.	R	1
10	TILE_STATUS_2BITS	2 bits are used instead of 4 bits for tile status.	R	1
9	RENDER_8K	Supports 8K render target.	R	1
8	CORRECT_AUTO_DISABLE	Reserved.	R	0
7	PE20_2D	2D PE 2.0 is present.	R	1
6	FAST_CLEAR_FLUSH	Proper flush is done in fast clear cache.	R	1
5	SPECIAL_MSAA_LOD	Special LOD calculation when MSAA is on.	R	1
4	CORRECT_TEXTURE_CONVERTER	Driver hack is not needed.	R	1
3	TEXTURE8_K	Supports 8K × 8K textures.	R	1
2	ENDIANNESS_CONFIG	Configurable endianness support.	R	1
1	DUAL_RETURN_BUS	Dual Return Bus from HI to clients.	R	1
0	FLIP_Y	Y flipping capability is added to resolve.	R	1

Table 13-20. GCRESETMEMCOUNTERS

Address Offset	0x0000 003C		
Physical Address	0x5900 003C	**Instance**	BB2D
Description	Writing 1 will reset the counters and stop counting. Write 0 to start counting again.		
Type	W

Table 13-48. GCDISPLAYPRIORITY

Address Offset	0x0000 0434		
Physical Address	0x5900 0434	**Instance**	BB2D
Description	Controls the priority of the display controller requests. This works like a PWM. One register gives the period, and the other gives the ON time. When PWM is ON, display requests are accepted if both display and the other request is valid. If it is OFF, the other request will be accepted. If only one request is valid, it takes the bus regardless of the PWM bit.

Chapter 14

Interconnect

This chapter describes the device interconnect.

Note

The level 3 (L3) interconnect is an instantiation of the NoC interconnect from Arteris, Inc. Arteris is a registered trademark of Arteris, Inc.

This document contains materials that are ©Arteris, Inc., and that constitute proprietary information of Arteris, Inc.

All materials and trademarks are used under license from Arteris, Inc. For additional information, see the Arteris Reference manuals, or contact Arteris, Inc.

NoC is an abbreviation for Network On Chip.

Note

The level 4 (L4) interconnects are instantiations of the Sonics3220™ interconnect from Sonics, Inc.

This document contains materials that are ©2003-2010 Sonics, Inc., and that constitute proprietary information of Sonics, Inc.

SonicsLX and Sonics3220, are trademarks or registered trademarks of Sonics, Inc. All such materials and trademarks are used under license from Sonics, Inc. For additional information, see the SonicsLX or Sonics3220 Reference manuals, or contact Sonics, Inc.

SLX is an abbreviation for SonicsLX®.

14.1 Interconnect Overview....................2967
14.2 L3_MAIN Interconnect....................2970
14.3 L4 Interconnects....................3126

14.1 Interconnect Overview

14.1.1 Terminology

The following terminology is critical to understanding the interconnect:

- Initiator: Module able to initiate read and write requests to the chip interconnect (typically: processors, DMA, etc.).
- Target: Unlike an initiator, a target module cannot generate read/write requests to the chip interconnect, but it can respond to these requests. However, it may generate interrupts or a DMA request to the system (typically: peripherals, memory controllers).

Note

A module can have several separate ports; therefore, a module can be an initiator and a target.

- Agent: Each connection of one module to one interconnect is done using an agent, which is an adaptation (sometimes configurable) between the module and the interconnect. A target module is connected by a target agent (TA), and an initiator module is connected by an initiator agent (IA).
- Interconnect: The decoding, routing, and arbitration logic that enables the connection between multiple initiator modules and multiple target modules connected on it. Quality of service (QoS) is guaranteed.
- Register target (RT): Special TA used to access the interconnect internal configuration registers
- Data-flow signal: Any signal that is part of a clearly identified transfer or data flow (typically: command, address, byte enables, etc.). Signal behaviour is defined by the protocol semantics.
- Sideband signal: Any signal whose behaviour is not associated to a precise transaction or data flow.
- Out-of-band error: Any signal whose behaviour is associated to a device error-reporting scheme, as opposed to in-band errors.

Note

Interrupt requests and DMA requests are not routed by the interconnect in the device.

- Firewall: A programmable feature integrated in a target agent or L4 interconnect to prevent unauthorized access to or from a module. A firewall can be configured using three criteria:
  - Initiator requesting access
  - Address space access
  - Type of access
- ConnID: Any transaction in the system interconnect is tagged by an in-band qualifier ConnID, which uniquely identifies the initiator at a given interconnect point. A ConnID is transmitted in band with the request and is used for firewall and error-logging mechanism.
- Firewall comparison mechanism: A comparison made in the firewall between access in-band qualifiers and access permissions that are programmed in the firewall configuration registers. If the comparison is successful, access is allowed; otherwise, access is denied.
- MCmd qualifier: Command bus that indicates the type of transfer requested. Table 14-1 lists the commands encoded. For information specific to L3 Interconnect error logging, see Table 14-20 *L3 Firewall Error-Logging Registers*

Table 14-1. MCmd Qualifier Description

MCmd[2:0]	Transaction Type
0 0 0	Idle
0 0 1	Write
0 1 0	Read
0 1 1	ReadEx
1 0 0	Read link
1 0 1	Write nonposted

Table 14-1. MCmd Qualifier Description (continued)

MCmd[2:0]	Transaction Type
1 1 0	Write conditional
1 1 1	Write broadcast

- MReqInfo qualifier: Four MReqInfo qualifiers describe the access during the use of the firewall comparison mechanism, as described in Table 14-2.

Table 14-2. MReqInfo Qualifier Description

Qualifiers	Description
MReqType	0: Data access
	1: Opcode fetch
MReqSupervisor	0: User mode
	1: Supervisor mode
MReqDebug	0: Functional access
	1: Debug access

- Register that configures the combination of the MReqInfo, allowing access permission to the target module (TM) based on the MReqInfo in-band qualifier values.
- SError: Target that indicates an error condition to the initiator.
- SResp qualifier: Response from the target to the initiator concerning the transaction, as described in Table 14-3.

Table 14-3. SResp Qualifier Description

SResp[1:0]	Description
0 0	No response
0 1	Data valid/accept
1 0	Not used
1 1	Error

- MTagID: Interconnect qualifier generated by the L3_MAIN masters which purpose is to identify whether reordering is allowed or not relative to other transactions. Strong ordering is ensured by using same MTagID values between transactions. Reordering is allowed by using different MTagID values between transactions. The MTagID values may or may not be changed by the interconnect, but the intended reordering restriction must match what came from the master. In other words, the interconnect allocates dynamically MTagID values in such a way that the intended reordering restrictions from each master are honored.

14.1.2 Architecture Overview

The device memory hierarchy includes four levels:

- L1 is internal to the CPUs. It concerns data exchange with the internal Level1 cache memory subsystem, and it is the closest memory to the microprocessor unit (MPU) core and the IVA core.
- L2 is included in the IPU subsystem and the MPU subsystem.
- The chip-level interconnect consists of one L3 interconnect and five L4 interconnects. It enables communication among the modules and subsystems in the device.

Figure 14-1 shows an overview of the L3 and L4 interconnect architecture.

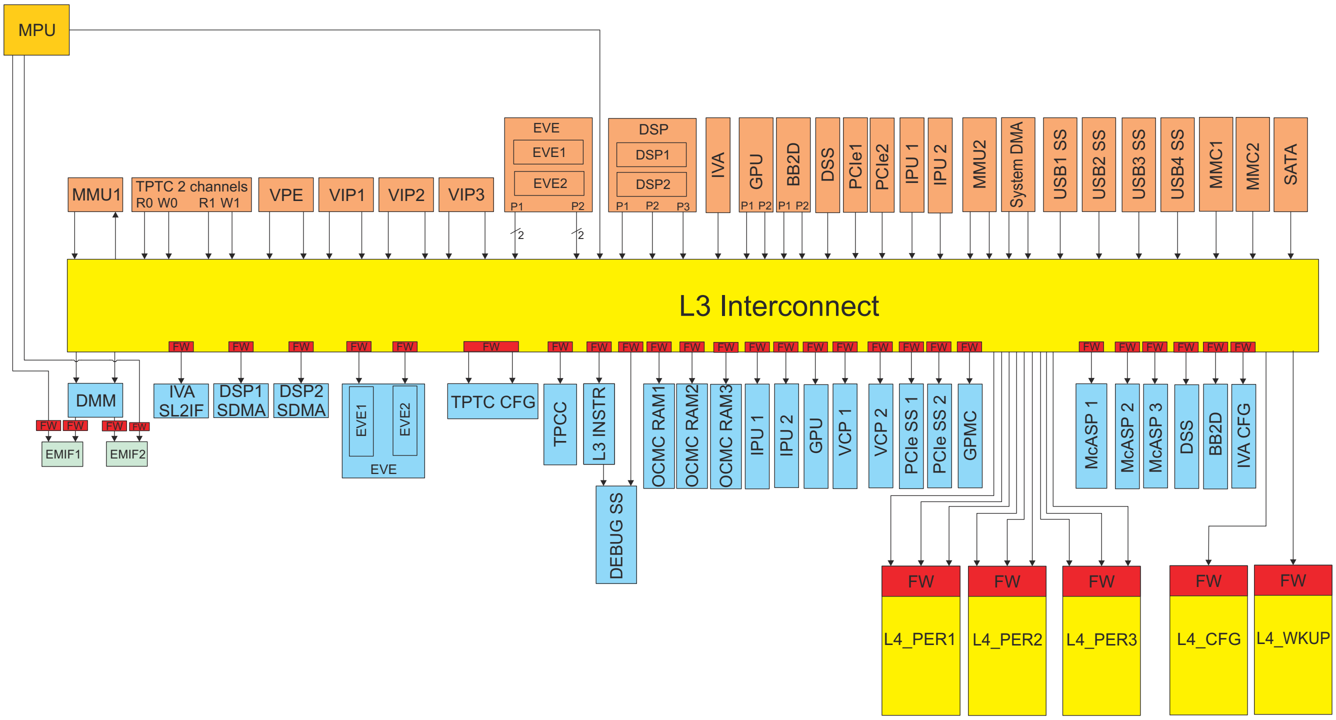

Figure 14-1. Interconnect Overview

- L3 handles many types of data transfers, especially exchanges with system-on-chip/external memories. L3 transfers data with a maximum width of 128 bits from the initiator to the target. The L3 interconnect is a little-endian platform
- The L4 is composed of the following:
  – L4_CFG: Includes the majority of the firewall configuration interface for level 3 (L3) system modules and peripheral interconnect;
  – L4_PER: Includes the main peripherals that require system direct memory access (sDMA) access. L4_PER has three instances L4_PER1, L4_PER2 and L4_PER3. Each of these three instances has three ports connecting it to L3_MAIN interconnect:
    - L4_PER1_P1, L4_PER1_P2, L4_PER1_P3
    - L4_PER2_P1, L4_PER2_P2, L4_PER2_P3
    - L4_PER3_P1, L4_PER3_P2, L4_PER3_P3

    Through L3_MAIN interconnect, different initiators can access each of these L4_PERx_Pi ports. For information regarding which initiator accesses which L4_PERx_Pi port, see Figure 14-3.
  – L4_WKUP: Includes peripherals attached to the WKUP power domain.

Modules are connected to the interconnect through an IA for the initiator module and a TA for target modules. Each module/subsystem connection is statically configured to tune the access, depending on the characteristics of the module.

To unauthorize a module or L4 interconnect access, some TAs include configurable firewalls (FWs). A firewall restricts or filters the accesses allowed to an initiator according to different access criteria. The firewalls can usually be configured by software.

The L3 and L4 interconnect default settings are fully functional; they enable all possible functional data paths and a minimal default protection setting.

14.2 L3_MAIN Interconnect

This section describes the L3_MAIN interconnect and its components. With the exception of register points, each component includes functions for the request and response networks.

14.2.1 L3_MAIN Interconnect Overview

The L3_MAIN interconnect links cores in a flexible topology that couples low power with high performance. Innovative physical structures and advanced protocols ensure bandwidth and latency to individual IP cores, providing dedicated connections between IP cores and logical connections over a shared interconnect.

The main features of the L3_MAIN interconnects are:

- NIUs: Master NIUs for the IAs and slave NIUs for the TAs
- A partially depleted cross-bar exchange network
- A special internal slave NIU for accessing L3_MAIN interconnect configuration registers
- QoS management for real-time hardware operators, while maintaining optimal memory latency for CPU access to memory resources
- True little-endian platform
- Transaction errors tracking and logging registers
- All signaling support for chip-level power-management infrastructure
- One interrupt line signaling transaction error
- One interrupt line for reporting statistical events on the L3_MAIN interconnect

Figure 14-2 shows an overview of the L3 interconnect and the peripherals attached to it.

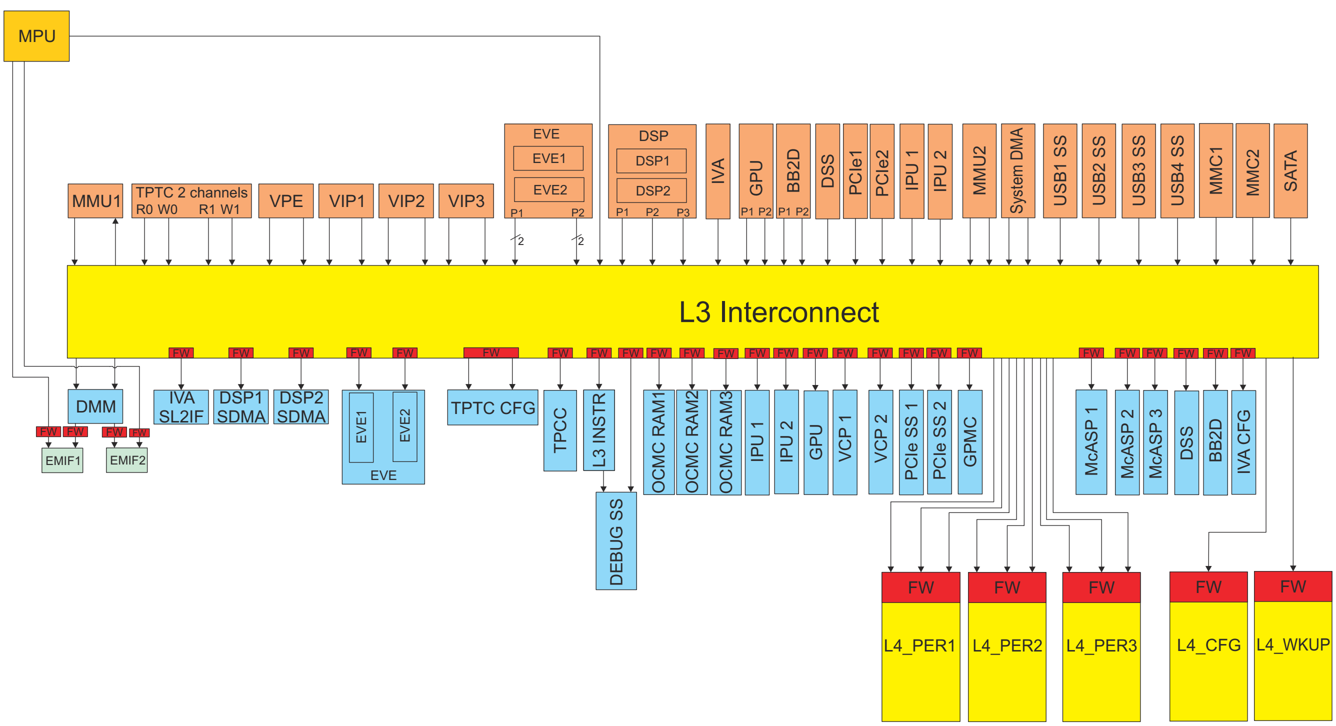

Figure 14-2. L3_MAIN Interconnect Overview

14.2.2 L3_MAIN Interconnect Integration

Table 14-4 through Table 14-6 summarize the integration of the module in the device.

Table 14-4. L3_MAIN Integration Attributes

Module Instance	Attributes
	Power Domain

Table 14-4. L3_MAIN Integration Attributes (continued)

L3_MAIN	PD_COREAON

Table 14-5. L3_MAIN Clocks and Resets

Module Instance	Destination Signal Name	Source Signal Name	Source	Description
Clocks				
L3_MAIN	L3_CLK1	L3MAIN1_L3_GICLK	PRCM	Functional and interface clock
	L3_CLK2	L3INSTR_L3_GICLK	PRCM	Functional and interface clock
Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
L3_MAIN	L3_CORE_RET_RST	CORE_PWRON_RET_RST	PRCM	Reset of L3_MAIN interconnect registers
	L3_CORE_RST	CORE_RST	PRCM	Reset of L3_MAIN interconnect

Table 14-6. L3_MAIN Hardware Requests

Module Instance	Source Signal Name	Destination IRQ_CROSSBAR Input	Default Mapping	Description
Interrupt Requests				
L3_MAIN	L3_MAIN_IRQ_DBG_ERR	IRQ_CROSSBAR_4	MPU_IRQ_9	Interrupt indicating debug error occurrence.
			DSP1_IRQ_35	
			DSP2_IRQ_35	
	L3_MAIN_IRQ_APP_ERR	IRQ_CROSSBAR_5	MPU_IRQ_10(1)	Interrupt indicating application error occurrence.
			DSP1_IRQ_36	
			DSP2_IRQ_36	
			EVE1_IRQ_4	
			EVE2_IRQ_4	
			IPU1_IRQ_46	
			IPU2_IRQ_46	
	L3_MAIN_IRQ_STAT_ALARM	IRQ_CROSSBAR_11	MPU_IRQ_16	Statistic collector alarm interrupt
			DSP1_IRQ_42	
			DSP2_IRQ_42	

(1) The L3_MAIN_IRQ_APP_ERR interrupt is directly mapped to the MPU_IRQ_10 line bypassing IRQ_CROSSBAR_5. In all other cases IRQ_CROSSBAR_5 is used to map L3_MAIN_IRQ_APP_ERR to the corresponding INTC.

Note

The “**Default Mapping**” column in Table 14-6 *L3_MAIN Hardware Requests* shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR module.
For more information about the IRQ_CROSSBAR module, see Section 18.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 18, *Control Module*.
For more information about the device interrupt controllers, see Chapter 17, *Interrupt Controllers*.

14.2.3 L3_MAIN Interconnect Functional Description

14.2.3.1 Module Use in L3_MAIN Interconnect

The L3_MAIN interconnect network components have ConnID values for each master NIU or slave NIU. The ID uniquely identifies the master NIU or the slave NIU for an interconnect transfer. The interconnect uses ConnIDs for a number of purposes, including the following:

- Slave NIUs for error logging
- Power disconnect slave NIU for error logging
- Eight FLAGMUXes to mask interrupts
- STATCOLL for configuring and monitoring: The STATCOLL components compute the traffic statistics within a user-defined window and periodically report to the user through the debug interface.
- Bandwidth regulator for configuration

14.2.3.2 Module Distribution

Master NIUs and slave NIUs provide the interface to connect the different modules to their associated interconnect.

Table 14-7 and Table 14-8 list all the modules and subsystems with their associated agents. The agents are listed for each L3_MAIN interconnect domain.

14.2.3.2.1 L3_MAIN Interconnect Agents

Any initiator or target core is connected to the L3_MAIN interconnect through an NIU. NIUs act as entry points to the L3_MAIN interconnect, and also include various programming registers. Table 14-7 lists the supported master NIU ports.

Table 14-7. Master NIUs

Master NIU	Description
MPU_INIT	MPU initiator port. One 64b OCP initiator port, and two 128b ports connected directly to the EMIF, bypassing L3
DSP1_INIT	DSP Initiator port. One 128b MDMA interconnect initiator port (used also for cache requests) One EDMA initiator port per instance
DSP2_INIT	DSP Initiator port. One 128b MDMA interconnect initiator port (used also for cache requests) One EDMA initiator port per instance
EVE1_INIT	Embedded Vision Engine 1 (EVE1) initiator port. Two 128b interconnect initiator ports (P1/P2)
EVE2_INIT	Embedded Vision Engine 1 (EVE2) initiator port. Two 128b interconnect initiator ports (P1/P2)
IVA_INIT	Image and video accelerator (IVA) initiator port. One 128b initiator port
GPU_P1_INIT	GPU 128b initator port 1
GPU_P2_INIT	GPU 128b initiator port 2
BB2D_P1_INIT	2D Graphics accelerator 128b initiator port 1
BB2D_P2_INIT	BB2D 128b initiator port 2
DSS_INIT	Display SubSystem initiator port. One 128b initiator port
VIP1_INIT	VIP initiator ports. Two 128b initiator ports
VIP2_INIT	VIP initiator ports. Two 128b initiator ports
VIP3_INIT	VIP initiator ports. Two 128b initiator ports
VPE_P1_INIT	VPE 128b initiator port 1
VPE_P2_INIT	VPE 128b initiator port 2
PCIE1_INIT	PCIe 64b initiator port
PCIE2_INIT	PCIe 64b initiator port

Table 14-7. Master NIUs (continued)

Master NIU	Description
TPTC1_INIT	EDMA_TC1 initiator port. Two 128b initiator ports(one read port and one write port)
TPTC2_INI	EDMA_TC2 initiator port. Two 128b initiator ports(one read port and one write port)
MMU1_INIT	MMU initiator port.One 128b initiator port
MMU2_INIT	MMU initiator port. One 128b initiator port
IPU1_INIT	IPU initiator port. One 64b initiator port
IPU2_INIT	IPU initiator port. One 64b initiator port
DMA_SYSTEM_INIT	Two 64b initiator ports per instance (one read port and one write port)
GMAC_SW_INIT	GMAC_SW 32b initiator port
MMC1_INIT	MMC initiator port. One 32b initiator port
MMC2_INIT	MMC2 32b initiator port
SATA_INIT	SATA 32b initiator port
MLBSS_INIT	MLB 32b initiator port
USB1_INIT	USB3.0 initiator port. One 64b OTG initiator port
USB2_INIT	USB2.0 initiator port. One 64b OTG initiator port
USB3_INIT	USB2.0 initiator port. One 64b OTG initiator port
USB4_INIT	USB2.0 initiator port. One 64b OTG initiator port
IEEE1500_INIT	IEEE1500 32b initiator port
DEBUGSS_INIT	Debug subsystem 32b initiator port

Table 14-8 lists the supported slave NIU ports.

Table 14-8. Slave NIUs

Slave NIU	Description
DSP_TARG	DSP 128b target port per instance
DMM_P1_TARG	Dynamic memory management128b target port 1
DMM_P2_TARG	Dynamic memory management 128b target port 2
IVA_CONFIG_TARG	Video accelerator subsystem 32b configuration target port
IVA_SL2IF_TARG	Video accelerator subsystem 128b SL target port
L4_CFG_TARG	L4 CFG 32b target port

14.2.3.2.2 L3_MAIN Connectivity Matrix

The L3 interconnect is divided into two clock domains L3_CLK1 and L3_CLK2. CLK1 domain is further splitted into two sub groups:

- L3_CLK1_1: Low-power domain
- L3_CLK1_2: Peripherals and multimedia
- L3_CLK2: Instrumentation (debug)

The two clock elements (CLK1 and CLK2) are implemented in a different clock domain.

14.2.3.2.2.1 Clock Domain Mapping of the L3_MAIN Interconnect Modules

Each clock domain (CLK1 and CLK2) has it own host, flag mux, slave NIUs, and bandwidth regulators. Table 14-9 lists the relationships between these domains and these elements.

14.2.3.2.2.2

Figure 14-3 shows the functional paths between the L3_MAIN master NIUs and the L3_MAIN and L3 slave NIU agents. The functional paths in L3_MAIN are indicated by the following:

- A cell contains the letter C when a functional path exists.
- A cell is empty when a functional path does not exist.

Figure 14-3. Connectivity Matrix

14.2.3.2.3 Master NIU Identification

A master NIU ID (ConnID) is assigned to every module in the device. The ID uniquely identifies the master NIU for an interconnect transfer (see Table 14-10). The interconnect uses ConnID values for a number of purposes, including:

- Master source identification for the protection mechanism
- Response route generation

- Firewall error logging
- L3_MAIN interconnect error logging

Table 14-10. ConnID Values

8-bit ConnID (hex)	4-bit ConnID (hex)	Master NIU
0	0	MPU
10	1	CS_DAP
20	2	DSP1 MDMA

B0	B	USB1 (USB3.0_SS)
B4	B	USB2 (USB2_SS)
B8	B	USB3 (USB2_ULPI_SS1)

Table 14-10. ConnID Values (continued)

8-bit ConnID (hex)	4-bit ConnID (hex)	Master NIU
BC	B	USB4 (USB2_ULPI_SS2)
CC	C	SATA
D2	D	EVE1 P2
D6	D	EVE2 P2

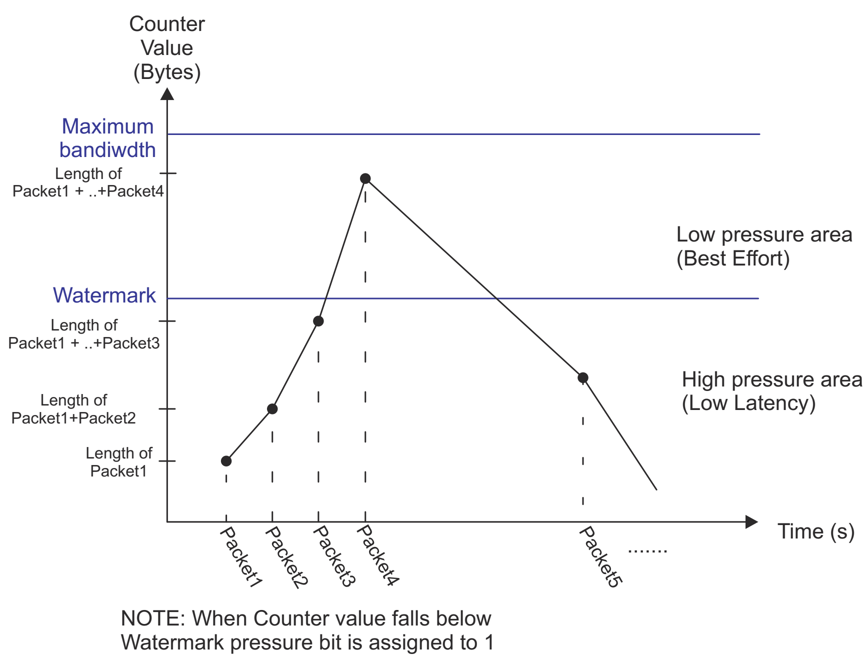
The 8-bit ConnID values are used by error decoding to distinguish the different initiators, see Section 14.2.3.8.5, *Example for Decoding Standard/Custom Errors Logged in L3_MAIN*. They are also used by the EMIF controller. The 4-bit ConnID values are used by the firewalls to allow or not an access to a slave NIU, see Table 14-18.

14.2.3.3 Bandwidth Regulators

The bandwidth regulators prevent master NIUs from consuming too much bandwidth of a link, or a slave NIU that is shared between several data flows: packets are then transported at a slower rate. The value of a bandwidth can be programmed in the bandwidth regulator. When the bandwidth is below the programmed value, the pressure bit is set to 1, giving priority to this master. When the bandwidth is above the programmed value, the pressure bit is set to 0 and the concerned master has the same weight as others.

A counter is used to store the sum of data lengths (in bytes) of each packet passing through the bandwidth regulator, and a value equal to the expected bandwidth is subtracted from the counter at each clock cycle. The value of the counter is compared to a programmable threshold (called Watermark), and this comparison determines whether the packet is processed with high pressure for minimum latency or low pressure for best effort processing.

The bandwidth regulator monitors the traffic using open connections between the initiators and the targets. If there is insufficient bandwidth allocated to the connection, the bandwidth regulator can increase the pressure on connections. Generally, the connection is a dataflow between master and slave NIUs. In some cases, the bandwidth regulator is attached to the master and monitors single dataflow to a target (single connection).



When Counter Value (bytes) falls below Watermark, the pressure bit is assigned to 1

Figure 14-4. Bandwidth Regulator Pressure Settings

The bandwidth regulator effective resolution is set to 8.3125 MBps

The following is an example of bandwidth regulator settings:

Suppose the bandwidth regulator is set to run at 200 MHz and the application requires an expected bandwidth of 165.888 MBps (±5 MBps), computed through a moving window of 5 µs (1000 cycles). To attribute high pressure on all packet requests, the watermark could be set to the maximum bandwidth needed in the 5-µs window.

Considering the example, the settings of the bandwidth regulator are:

- L3_BW_REGULATOR_WATERMARK[11:0] WATERMARK = moving window × expected bandwidth = 829.44 bytes = 0x33D
- L3_BW_REGULATOR_BANDWIDTH[15:0] BANDWIDTH = ceil(165.888/8.3125) = ceil(19.956) = 20d = 0x14

The bandwidth registers regulate the packet flow by applying flow control on the RX port, thus ensuring that the traffic does not exceed the allocated bandwidth. The next packet is sent only when an internal timer expires. The registers in this group are:

- L3_BW_REGULATOR_WATERMARK: Gives the amount of data allowed to exceed the average bandwidth during a short time period
- L3_BW_REGULATOR_PRESS: Describes the pressure applied to outgoing packets
- L3_BW_REGULATOR_CLEARHISTORY: Resets the traffic counter when set to 1. This register is used after an update in the L3_BW_REGULATOR_BANDWIDTH and L3_BW_REGULATOR_WATERMARK registers (see Section 14.2.5.1.7, *L3 BW Regulator Register Summary and Description*).

Bandwidth regulators are mainly used to give priority to the following masters: DSP1 MDMA, DSP2 MDMA, EVE1 and EVE2 (both ports per instance), IVA, MMU2, PCIe, DSP1 EDMA, DSP2 EDMA, GMAC SW, BB2D.

Priority to: DSP1_CFG, DSP2_CFG, DSS, GPU_P1, GPU_P2, IPU1, IPU2, MLB, MMC1, MMC2, MMU 2 initiator ports, MPU initiator port, PCIe1 and PCIe2 initiator ports, TPTC1 and TPTC2 (RD and WR initiator ports), USB3 initiator port, VIP1_P1/P2, VIP2_P1/P2, VIP3_P1/P2 initiator ports is given by setting their internal MFlag signal.

14.2.3.4 Bandwidth Limiters

The bandwidth limiter is added to control the bandwidth of the EDMA_TC1_RD, EDMA_TC1_WR, EDMA_TC2_RD, EDMA_TC2_WR, VPE, BB2D and GPU module. This prevents a large number of RD requests being processed together, thus avoiding a large number of RD responses.

The bandwidth limiter regulates the packet flow in the L3_MAIN interconnect by applying flow control when a user-defined bandwidth limit is reached. The next packet is served only after an internal timer expires, thus ensuring that traffic does not exceed the allocated bandwidth. Bandwidth limiter can be used with a watermark mechanism that allows traffic to temporarily exceeds the peak bandwidth.

The registers in this group are:

- L3_BW_LIMITER_WATERMARK_0: Gives the amount of data allowed to exceed the average bandwidth during a short time period. To set the actual watermark to n bytes, the register must be set to n + 1.
- L3_BW_LIMITER_CLEARHISTORY: Resets the traffic counter when set to 1.
- L3_BW_LIMITER_BANDWIDTH_FRACTIONAL and L3_BW_L_BANDWIDTH_INTEGER: These two registers are used to set the average payload bandwidth.

Example of setting the Bandwidth Limiters:

L3_BW_LIMITER_BANDWIDTH_FRACTIONAL must be set to BandwidthConf [4 down to 0] and L3_BW_LIMITER_BANDWIDTH_INTEGER contains the remaining BandiwdthConf bits, shifted to the right. BandwidthConf = AverageBandwidth / EffectiveResolution, where EffectiveResolution parameter is set to 8.3125 MHz at design time.

AverageBandwidth is a parameter representing the value to which the payload bandwidth must be limited in average; this parameter depends on the use case and is the reason that makes the content of the registers variable. In addition the maximum packet length is 8 cells, that is 32 bytes.

Assuming that the use case requires that in average the payload bandwidth is limited to 200 MB/s, then registers must be set to the following values:

BandwidthConf = 200 MBps / 8.3125 MHz = 38 (0x26)

L3_BW_LIMITER_BANDWIDTH_FRACTIONAL = LSBs [4 down to 0] of BandwidthConf = 0x6.

L3_BW_LIMITER_BANDWIDTH_INTEGER = the remaining bits of BandwidthConf shifted to the right = 0x1.

By setting L3_BW_LIMITER_WATERMARK to 65 (L3_BW_LIMITER_WATERMARK_0 = 0x41), the bandwidth limiter is able to send three packets consecutively during peaks, therefore exceeding the peak traffic with two packets (64 bytes)

14.2.3.5 Flag Muxing

The flag mux generator collects information such as errors and interrupts from slave NIUs and the interconnect firewall. The result signals are then sent to the MPU interrupt controller (INTC) without interfering with the interconnect traffic. Using the L3_FLAGMUX_MASK registers can prevent the flag mux from seeing certain events.

The unit has a standard COREREG register for identification of the attached core type. The L3_FLAGMUX_STDHOSTHDR_VERSIONREG register identifies the characteristics of the attached core. Use unit-specific registers (MASK bit 0 or bit 1 of the flag inputs, and L3_FLAGMUX_REGERR bit 0 or bit 1) to read the input errors. Each register is dedicated to reporting the bit corresponding to the register number; for example, L3_FLAGMUX_REGERR0 reports on bit 0, and L3_FLAGMUX_REGERR1 reports on bit 1. Any given L3_FLAGMUX_REGERR register reports the same bit for all flag source inputs (see Table 14-170).

There are three flag muxs (CLK1_FLAGMUX_CLK1_1, CLK1_FLAGMUX_CLK1_2 and CLK2_FLAGMUX_CLK2_1) collecting information from targats in each clock domain in L3_MAIN interconnect (CLK1_1, CLK1_2 and CLK2_1). Both CLK1_FLAGMUX_CLK1_1 and CLK1_FLAGMUX_CLK1_2 flag muxes are located in the CLK1_2 clock domain (with base address 0x4480 0000).

Also there is a separate mux (L3_FMAGMUX_CLK1MERGE) that merges the inputs from CLK1_1 and CLK1_2 flag muxes. Its functionality is similar to the functionality of the other L3_FLAGMUXES:

- L3_FLAGMUX_CLK1MERGE_COREREG and L3_FLAGMUX_STDHOSTHDR_VERSIONREG registers are used to identify the attached core and its characteristics.
- L3_FLAGMUX_CLK1MERGE_MASK0 is used to mask (enable) application error sources
- L3_FLAGMUX_CLK1MERGE_REGERR0 is used to check which application error sources are active
- L3_FLAGMUX_CLK1MERGE_MASK1 is used to mask debug error sources
- L3_FLAGMUX_CLK1MERGE_REGERR1 is used to check which debug error sources are active

Following is a block diagram of the flag mux organization in L3_MAIN interconnect:

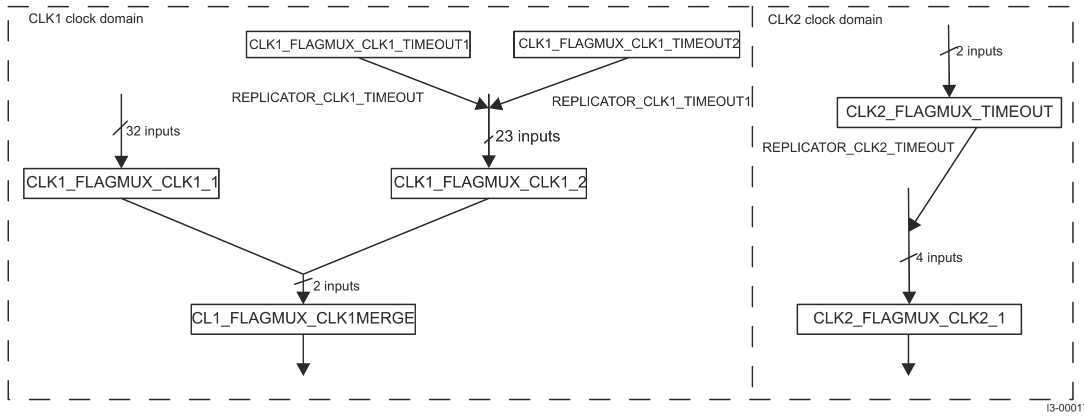


Figure 14-5. Flag Mux Structure

14.2.3.5.1 Flag Mux Time-out

If a target does not respond after a fixed number of clock cycles, an error time-out flag is generated, in case it is enabled. The value of the flag is always 3 if a time-out error is present.

To enable time-out for each target, set the corresponding bit in L3_FLAGMUX_TIMEOUT_MASK0 register to 1. See Table 14-11.

CLK2_1 Time-out FlagMux		0	L3_INSTR
	1	DEBUGSS_CT_TBR	

For example, to enable all targets in CLK1_1, write 0x3FL3_FLAGMUX_TIMEOUT1_MASK0; to enable all targets in CLK1_2, write 0x1F FFFFL3_FLAGMUX_TIMEOUT2_MASK0. To enable only OCMC_RAM1 (target in CLK1_2) write 0x1L3_FLAGMUX_TIMEOUT2_MASK0. If an error time-out occurs, read the registers L3_FLAGMUX_TIMEOUT1_REGERR0 and L3_FLAGMUX_TIMEOUT2_REGERR0 to determine the source of error concerning Table 14-11. CLK2 time-outs are reported through CLK1_FLAGMUX_CLK2_1 status registers (L3_FLAGMUX_REGERR0, L3_FLAGMUX_REGERR1) and masked through L3_FLAGMUX_MASK0 and L3_FLAGMUX_MASK1 registers.

Similarly, to enable a target in CLK2_1, write the appropriate value (as described in Table 14-11) in L3_FLAGMUX_TIMEOUT_MASK0.

If an error time-out occurs in CLK2_1, read the L3_FLAGMUX_TIMEOUT_REGERR0 register to determine the source of error concerning Table 14-11.

14.2.3.6 Statistic Collectors Group

Statistic collectors are internal masters that share the same master address as the master NIUs. These components compute the traffic statistics within a defined window and periodically report through the DEBUG interface. The key features of the statistic collector are:

- Nonintrusive monitoring
- Programmable filters and counters
- Collects results at a programmable time interval

Event detectors are programmed through the L3_STCOL_REQEVT and L3_STCOL_RSPEVT configuration registers for request and response ports, respectively. The following events can be identified:

- Word transfer
- WAIT cycles
- Flow control
- Payload transfers
- Latency measurements

Performance monitoring is enabled through the L3_STCOL_EN register. The L3_STCOL_SOFTEN register enables software to monitor the performance. Event muxes are programmed through the L3_STCOL_EVTMUX_SEL0 configuration register, which determines which port will be monitored by a filter configured by the filter registers (see Section 14.2.5.1.9).

Filters are programmed through the L3_STCOL_FILTER_i_GLOBALEN configuration register, along with additional selection criteria programmed through the mask/match registers (see Table 14-235). A filter can be configured to accept or reject:

- Read operations
- Write operations
- Errors
- Addresses

Filter operation is programmed through the L3_STCOL_OP registers (see Table 14-235).

There are ten statistic collectors used to monitor the traffic on DRAM (EMIF1, EMIF2, MA_MPU_P1 and MA_MPU_P2), MPU, MMU, TPTC, VIP, VPE, EVE Subsystem, DSP MDMA/EDMA, IVA, GPU, BB2D, DSS, IPU, OCMC RAM, USB, PCIe Subsystem, DSP CFG, MMC, SATA, VCP, GPMC, and McASP ports. For more detailed descriptions of statistic collectors, see Section 33.10.7.1, *L3 Target Load Monitoring*, and Section 33.10.7.2, *L3 Master Latency Monitoring*.

14.2.3.7 L3_MAIN Protection and Firewalls

Device protection relies on L3 firewalls and their configuration.

14.2.3.7.1 L3_MAIN Firewall Reset

The values of L3_MAIN firewall registers on reset are tied in hardware or exported from the control module registers.

Values exported from the control module are intended to give defined rights to the firewalls at reset and thus ensure the content after going out of reset.

The L3_MAIN firewall registers are located in the CORE AON power domain and thus no retention capability is needed. The control module registers are reset by a cold reset only, whereas the L3_MAIN firewall registers are reset by clearing the REGUPDATE_CONTROL[1] FW_LOAD_REQ bit. When the REGUPDATE_CONTROL[1] FW_LOAD_REQ bit comes back automatically to 1, the exported values are loaded.

CAUTION

Before reprogramming the firewall registers and/or before using the FW_LOAD_REQ mechanism, the request must be asserted by configuring the REGUPDATE_CONTROL[0] BUSY_REQ bit.

To load the exported values at run time:

1. Set the REGUPDATE_CONTROL[0] BUSY_REQ bit to 0x1 to ensure that no transaction can reach the slave NIU (suspend).
2. Clear the REGUPDATE_CONTROL[1] FW_LOAD_REQ bit by writing 0x1 to it.
3. Wait until the REGUPDATE_CONTROL[1] FW_LOAD_REQ bit is reset to 0x1 by hardware.
4. Set the REGUPDATE_CONTROL[0] BUSY_REQ bit to 0x0 to allow transactions to reach the slave NIU (resume).

To reprogram the firewall registers at run time:

1. Write 0x1 to the REGUPDATE_CONTROL register.
2. Update the firewall registers.
3. Write 0x0 to the REGUPDATE_CONTROL register.

Note

While reprogramming the firewall registers at run time it must be taken into account that the REGUPDATE_CONTROL[1] FW_LOAD_REQ bit is written as '0' because a value of '1' reloads the firewall default values.

Note

At reset, exported values from the control module can modify hardware reset values.

14.2.3.7.1.1 L3_MAIN Firewall – Exported Reset Values

Table 14-12 and Table 14-13 list the exported reset values and mapping, respectively.

Table 14-12. L3_MAIN Firewall Exported Reset Values

MRM_PERMISSION_REGION_LOW_j **[15:12]**	MRM_PERMISSION_REGION_LOW_j **[11:0]**
0x0	0xFFF
0xF	0xFFF
0x0	0xFFF
0x2	0xFFF

14.2.3.7.2 Power Management

As part of the system-wide power-management scheme, the L3_MAIN interconnect goes into IDLE state after receiving a request from the power, reset, and clock management (PRCM) module after all commands are serviced. This function is handled by hardware.

To reduce power consumption, the L3_MAIN interconnect automatically performs internal clock autogating. This is managed by hardware; no software configurations or settings are required.

L3_MAIN supports a partial retention scheme. Retention is performed on the follwoing registers:

- Statistic collectors
- Bandwidth regulators
- Firewalls

This process prevents reconfiguration after a clock domain switches off.

14.2.3.7.3 L3_MAIN Firewall Functionality

The access to the slave NIUs is granted only to master NIUs according to in-band attributes sent in each transaction crossing the L3_MAIN interconnect, such as:

- MCMD: Specifies the type of access (read or write) required by the master NIU
- ConnID: Used to determine the permission of the master NIU
- MReqInfo: Transaction attribute adding information about the access type

Table 14-15 lists the MReqInfo values.

Table 14-15. MReqInfo Values

Qualifier	Access Definition	Access Description
MReqType	00: Processor data access 01: Processor instruction access 10: DMA access 11: Other	Indicates whether the request is for processor instruction fetch, processor data access or DMA access
MReqDebug	0: Functional 1: Debug	When set, indicates that the request has been issued by a master NIU in DEBUG state
MReqSupervisor	0: User 1: Privilege	When set, indicates that the request is qualified with the supervisor attribute. It can be provided by a processor running in supervisor mode or by a module that inherited this attribute from the processor (DMA channel with a supervisor attribute).

The firewall comparison mechanism enables access to a protected slave NIU only when a correct combination of three MReqInfo in-band parameters is transmitted.

MReqInfo is a combination of a fixed 3-bit pattern that corresponds to a combination of the parameters MReqDebug, MReqType, and MReqSupervisor. See Table 14-16.

14.2.3.7.3.1 Protection Regions

Each slave NIU address space is subdivided into protection regions (maximum of 10). The regions are configurable with a size of 4-KiB granularity. The firewalls can also be multiport while using the description of the same regions for dual access memories or to support interleaving mechanisms on several memories.

Table 14-17 lists the number of protected regions and ports for each slave NIU.

Table 14-17. Slave NIU Firewall and Region Configuration

Domain	Slave NIU	Firewall	Number of Regions	Number of Ports
CLK1	DSP1_SDMA	DSP1_SDMA_FW	1	1
	DSP2_SDMA	DSP2_SDMA_FW	1	1
	DSS	DSS_FW	8	1
	EVE1	EVE1_FW	1	1
	EVE2	EVE2_FW	1	1
	GPMC	GPMC_FW	8	1
	GPU	GPU_FW	1	1
	BB2D	BB2D_FW	1	1

	QSPI	QSPI_FW	1	1
	TPCC	TPCC_FW	1	1
	TPTC	TPTC_FW	2	2
	VCP1	VCP1_FW	1	1
	VCP2	VCP2_FW	1	1
CLK2	L3_INSTR	L3_INSTR_FW	2	1
	DEBUGSS_CT_TBR	DEBUGSS_CT_TBR_FW	1	1

Two types of regions are distinguished in a slave NIU firewall:

- Default region: Available in all slave NIUs. The default region covers the entire slave NIU address range. Other firewall-configured regions must reset or overlay the default region, because it always has the lowest priority.

- Normal region: The number of normal regions varies in a slave NIU; they have identical capabilities (see Table 14-17).

Each region has the following characteristics:

- Start address: Physical slave NIU start address
- End address: Physical slave NIU end address
- Specific access rights (see Section 14.2.3.7.3.3, *Protection Mechanism per Region Examples*)
- Priority level from 0 (lowest) to 10 (highest)

Depending on its priority level, a region can override the settings of another region; the access rights of the region with the highest priority apply. All regions have a fixed (not configurable) priority level that corresponds to their number: Region 1 has priority level 1, region 2 has priority level 2, and so on.

Figure 14-6 shows the priority level with associated regions. This priority level scheme allows multiplying the flexibility and capability of the firewall. Figure 14-6 shows a 7-region firewall setting that creates 16 regions (twice the number of regions created than originally available).

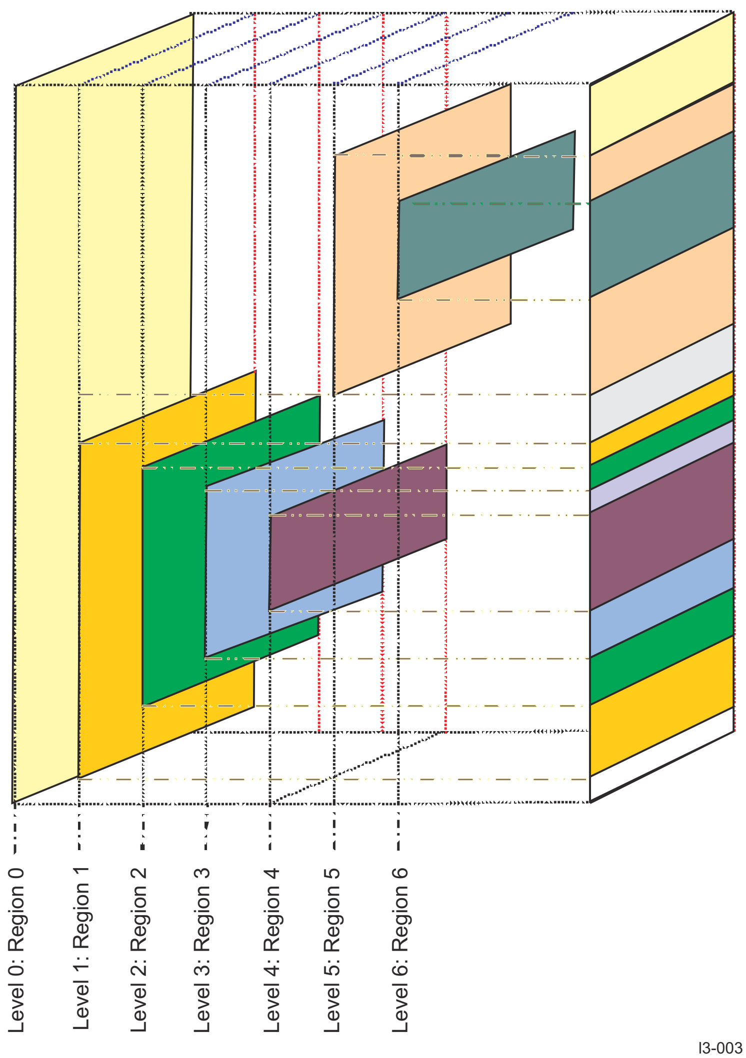

Figure 14-6. L3 Interconnect Region Overlay and Priority Level Overview

The address range covered by the regions is defined in the START_REGION_i and END_REGION_i registers. The boundary checks are done on a minimum size of 4-KiB pages; thus, bits [11:0] of those 32-bit registers are not checked.

The address space size of the slave NIUs ([bits [31:12]) depends on the size of the slave NIU to protect (that is, if a memory is only 48KiB, then the size is defined through bits [16:12] of the slave NIU start and end address registers of the firewall region (START_REGION_i[16:12] and END_REGION_i[16:12]).

On multiport firewalls (EMIF_OCP_FW), the checking of each REGION {0, n} can activate on one or several ports at the same time. However, if interleaving is not desired on some parts of the protected memory space, it is possible to apply or not apply region checking on selected ports using the region enable/disable on port instance capability of the END_REGION_i register.

Most slave NIUs support only one input port (port 0) except:

- The MA_MPU firewall (MA_MPU_NTTP_FW) which has two ports:
  – Port 0 for access from the MPU to EMIF1
  – Port 1 for access from the MPU to EMIF2
- The EMIF firewall which has two ports:
  – Port 0 for access from the DMM to EMIF1
  – Port 1 for access from the DMM to EMIF2
- The EDMA_TC firewall which has two ports:
  – Port 0 logs errors in the ERROR_LOG_0 register for the traffic to EDMA_TPTC0 module generated by the MPU, DSP1/2, EVE1/2, IPU1/2, DMA_SYSTEM, MLB, PCIESS1/2, MMU1/2 and DAP modules.
  – Port 1 logs errors in the ERROR_LOG_1 register for the traffic to EDMA_TPTC1 module generated by the MPU, DSP1/2, EVE1/2, IPU1/2, DMA_SYSTEM, MLB, PCIESS1/2, MMU1/2 and DAP modules.

A region can be applied or not to each port independently. To enable and disable the regions:

- For port 0: Set/clear the END_REGION_i[0] END_REGION_i_ENABLE_CORE0 bit (for all L3_MAIN firewalls).
- For port 1: Set/clear the END_REGION_i[1] END_REGION_i_ENABLE_CORE1 bit (for MA_MPU, EMIF and EDMA_TC firewalls).

The EMIF firewall (EMIF_OCP_FW) uses 16 GiB address space and protects both the SDRAM and the EMIF configuration registers. The EMIF firewall allows defining access restrictions per region. The region can apply to:

- Both EMIF1 and EMIF2 controllers (interleaving mode)
- Only the EMIF1 controller
- Only the EMIF2 controller

This per-region capability is defined by configuring the END_REGION_i[1:0] bit field for:

- Both EMIF1 and EMIF2 (interleaving mode): END_REGION_i[0] END_REGION_i_ENABLE_CORE_0 = 0x1 and END_REGION_i[1]END_REGION_i_ENABLE_CORE_1 = 0x1
- Only EMIF1: END_REGION_i[0] END_REGION_i_ENABLE_CORE_0 = 0x1
- Only EMIF2: END_REGION_i[1] END_REGION_i_ENABLE_CORE_1 = 0x1

The protection regions for EMIF firewall are configurable with a size of 4-KiB granularity (the same applies to the MA_MPU_NTTP_FW). The address range covered by the regions is defined in the START_REGION_i and END_REGION_i registers. Since EMIF firewall sees 16 GiB address space but these two registers have only 32 bits, the START_REGION_i/END_REGION_i[31] bit is mapped to bit [33] of the EMIF address space, that is, bits [31:10] of START_REGION_i/END_REGION_i are mapped to EMIF Address [33:12]. START_REGION_i/ END_REGION_i [9:0] are not checked for the minimum page size of 4 KiB.

The start address in the EMIF address space for accessing the EMIF configuration registers is 0x3_0000_0000. If protection of these registers is needed, that address must be right shifted by 2 bits and then the result (0xC000_0000) must be written to the START_REGION_i register. The REGUPDATE_CONTROL[19:16] FW_ADDR_SPACE_MSB bit field indicates how many bits are shifted in the firewall address space. In case of EMIF_OCP_FW and MA_MPU_NTTP_FW, 2 bits are shifted. If target address space is ≤ 4 GiB then REGUPDATE_CONTROL[19:16] FW_ADDR_SPACE_MSB is 0x0 and the START_REGION_i/END_REGION_i [31:12] bits match target physical address [31:12]. Bits [11:0] are ignored by the firewall. These bits are not involved in the address check. To match address spaces greater than 4 GiB but keep the minimum page size of

4 KiB some of the START_REGION_i/END_REGION_i [11:0] bits must also be configured. In the EMIF case bits [11:10] are also used.

For example, the EMIF1 configuration registers are accessible through system base address 0x4C00_0000. But the EMIF_OCP_FW sees them at start address 0x3_0000_0000. As previously mentioned that address must be shifted before being programmed to the START_REGION_i register. In this case the programmed value should be 0xC000_0000. This has to be taken into account.

14.2.3.7.3.2 L3_MAIN Firewall Registers Overview

Table 14-18 and Table 14-19 list the L3_MAIN firewall permission-setting registers.

Table 14-18. L3_MAIN Firewall Read/Write Permission-Setting Register

Register Name	Bits	Field Name	4-bit ConnID Value (hex) (see Table 14-10)	Field Modifiability
MRM_PERMISSION_REGION_HIGH_j	31	W	ConnID = F write permission	RW
	30	R	ConnID = F read permission	RW
	29	W	ConnID = E write permission	RW
	28	R	ConnID = E read permission	RW
	27	W	ConnID = D write permission	RW
	26	R	ConnID = D read permission	RW
	25	W	ConnID = C write permission	RW
	24	R	ConnID = C read permission	RW
	23	W	ConnID = B write permission	RW
	22	R	ConnID = B read permission	RW
	21	W	ConnID = A write permission	RW
	20	R	ConnID = A read permission	RW
	19	W	ConnID = 9 write permission	RW
	18	R	ConnID = 9 read permission	RW
	17	W	ConnID = 8 write permission	RW
	16	R	ConnID = 8 read permission	RW
	15	W	ConnID = 7 write permission	RW
	14	R	ConnID = 7 read permission	RW
	13	W	ConnID = 6 write permission	RW
	12	R	ConnID = 6 read permission	RW
	11	W	ConnID = 5 write permission	RW
	10	R	ConnID = 5 read permission	RW
	9	W	ConnID = 4 write permission	RW
	8	R	ConnID = 4 read permission	RW
	7	W	ConnID = 3 write permission	RW
	6	R	ConnID = 3 read permission	RW
	5	W	ConnID = 2 write permission	RW
	4	R	ConnID = 2 read permission	RW
	3	W	ConnID = 1 write permission	RW
	2	R	ConnID = 1 read permission	RW
	1	W	ConnID = 0 write permission	RW
	0	R	ConnID = 0 read permission	RW

Table 14-19. L3_MAIN Firewall Permission-Setting Register

Register name	Type of Permission	Bits	Field Name	Description	Field Modifiability
MRM_PERMISSION_REGION_LOW_j	Reserved	31:16		Reserved	
	Debug	15	DEBUG	PUBLIC PRIVILEGE DOMAIN DEBUG ALLOWED	RW
		14	DEBUG	PUBLIC USER DOMAIN DEBUG ALLOWED	RW
	Reserved	13:12		Reserved	
	Access	11	READ	PUBLIC PRIVILEGE READ ACCESS ALLOWED	RW
		10	WRITE	PUBLIC PRIVILEGE WRITE ACCESS ALLOWED	RW
		9	EXE	PUBLIC PRIVILEGE EXE ACCESS ALLOWED	RW
		8	READ	PUBLIC USER READ ACCESS ALLOWED	RW
		7	WRITE	PUBLIC USER WRITE ACCESS ALLOWED	RW
		6	EXE	PUBLIC USER ECXE ACCESS ALLOWED	RW

14.2.3.7.3.3 Protection Mechanism per Region Examples

The access permission of each region is configurable and defined through the MRM_PERMISSION_REGION_HIGH_j and MRM_PERMISSION_REGION_LOW_j registers (see Section 14.2.3.7.3.2, *L3_MAIN Firewall Registers Overview*).

Master NIU permissions:

1. To give read access to the master NIU with 4-bit ConnID = n(1), set the MRM_PERMISSION_REGION_HIGH_j[n × 2] R bit.
2. To give write access to the master NIU with 4-bit ConnID = n(1), set the MRM_PERMISSION_REGION_HIGH_j[n × 2 + 1] W bit.

   (1) - n should be first converted from hex to decimal value

Debug permissions:

1. To give privilege debug access, set the MRM_PERMISSION_REGION_LOW_j[15] DEBUG bit.
2. To give user debug access, set the MRM_PERMISSION_REGION_LOW_j[14] DEBUG bit.

User, read, write, and executable permissions:

1. To give privileged read access, set the MRM_PERMISSION_REGION_LOW_j[11] READ bit.
2. To give privileged write access, set the MRM_PERMISSION_REGION_LOW_j[10] WRITE bit.
3. To give privileged executable access, set the MRM_PERMISSION_REGION_LOW_j[9] EXE bit.
4. To give user read access, set the MRM_PERMISSION_REGION_LOW_j[8] READ bit.
5. To give user write access, set the MRM_PERMISSION_REGION_LOW_j[7] WRITE bit.
6. To give user executable access, set the MRM_PERMISSION_REGION_LOW_j[6] EXE bit.

Example: To provide debug write privilege access to the master NIU with 4-bit ConnID = 0x7, set the following bits:

- MRM_PERMISSION_REGION_HIGH_j[15] W
- MRM_PERMISSION_REGION_LOW_j[15] DEBUG

14.2.3.7.3.4 L3_MAIN Firewall Error Logging

If a protection violation error is detected, the following signals are generated:

- An in-band error (SRESP = ERROR) is generated to the master NIU of the access.
- An out-band error is sent to the control module
- An interrupt is generated to the Cortex-A15 INTC.

The L3_MAIN interconnect does not differentiate errors generated by firewalls from all other supported types of errors.

An in-band error is generated by modules each time an access is not allowed. When an in-band error is sent back into the transaction it is seen as an external prefetch or data abort by the initiator, depending on whether the transaction was an instruction fetch or a data access.

Information about in-band errors is logged into two registers:

- ERROR_LOG_k: Logs the information about the start/end address of the hit region and the qualifiers of the transaction
- LOGICAL_PHYSICAL_ADDRESS_ERRLOG_k[31:12]: Logs the address of the failed access

Note

When a multiport firewall is implemented, these registers are duplicated for each port.

Table 14-20 lists the L3_MAIN firewall error-logging registers.

Table 14-20. L3 Firewall Error-Logging Registers

Register Name	Register Field Name	Field Modifiability	Parameter Comments
ERROR_LOG_k (When multiport firewall is implemented the error log register is duplicated for each port.)	RESERVED[31:24]	Read only	Reads return 0s.
	BLK_BURST_VIOLATION[23]	Read/write	Read 0x1: 2D burst not allowed or exceeds allowed size. Write to clear the ERROR_LOG and LOGICAL_PHYSICAL_ADDRESS_ERRLOG registers.
	RESERVED[22]	Read only	Read return 0s.
	REGION_START_ERRLOG[21:17]	Read/write	Read: Wrong access hit this region number. Write to clear the ERROR_LOG and LOGICAL_PHYSICAL_ADDRESS_ERRLOG registers.
	REGION_END_ERRLOG[16:12]	Read/write	Read: Wrong access hit this region number. Write to clear the ERROR_LOG and LOGICAL_PHYSICAL_ADDRESS_ERRLOG registers.
	REQINFO_ERRLOG[11:0]	Read/write	Mapping of the error according to the reqinfo vector: ConnID [3:0] MCMD [0] [3] MReqDebug [1] MReqSupervisor [0] MReqType

L3 firewall errors can be cleared by writing to the ERROR_LOG_k register in the firewall that recorded the error. Clearing the ERROR_LOG_k register deasserts the corresponding error if it exists.

The L3 firewall register ERROR_LOG_k must be cleared before clearing the SEC_ERR_STATUS_FUNC_1/2 and SEC_ERR_STATUS_DEBUG_1/2 registers in the control module.

When a protection violation occurs, an interrupt is sent to the IRQ_CROSSBAR. An in-band error is sent back, and an error is logged in the SEC_ERR_STATUS_FUNC_1/2 and SEC_ERR_STATUS_DEBUG_1/2 registers, depending on the functional mode:

- In application mode:
  - SEC_ERR_STATUS_FUNC_1[1] – L3 RAM protection violation
  - SEC_ERR_STATUS_FUNC_1[2] – GPMC protection violation

  - SEC_ERR_STATUS_FUNC_1[3] – EMIF protection violation
  - SEC_ERR_STATUS_FUNC_1[4] – IVA protection violation
  - SEC_ERR_STATUS_FUNC_1[5] – IPU protection violation
  - SEC_ERR_STATUS_FUNC_1[6] – IVA SL2 protection violation
  - SEC_ERR_STATUS_FUNC_1[8] – SYSTEM DMA protection violation
  - SEC_ERR_STATUS_FUNC_1[10] – DSPDMA slave NIU protection violation
  - SEC_ERR_STATUS_FUNC_1[13] – GPU protection violation
  - SEC_ERR_STATUS_FUNC_1[14] – DSS protection violation
  - SEC_ERR_STATUS_FUNC_1[16] – L4_PER1 protection violation
  - SEC_ERR_STATUS_FUNC_1[17] – L4_CFG protection violation
  - SEC_ERR_STATUS_FUNC_1[18] – DEBUG subsystem protection violation
  - SEC_ERR_STATUS_FUNC_1[22] – L4_WKUP protection violation
  - SEC_ERR_STATUS_FUNC_1[23] – BB2D protection violation
  - SEC_ERR_STATUS_FUNC_1[26] – CT_TBR protection violation
  - SEC_ERR_STATUS_FUNC_1[28] – EVE1 protection violation
  - SEC_ERR_STATUS_FUNC_1[29] – EVE2 protection violation
  - SEC_ERR_STATUS_FUNC_2[0] – DSP1 protection violation
  - SEC_ERR_STATUS_FUNC_2[1] – DSP2 protection violation
  - SEC_ERR_STATUS_FUNC_2[2] – OCMC_RAM2 protection violation
  - SEC_ERR_STATUS_FUNC_2[3] – OCMC_RAM3 protection violation
  - SEC_ERR_STATUS_FUNC_2[4] – L4_PER2 protection violation
  - SEC_ERR_STATUS_FUNC_2[5] – L4_PER3 protection violation
  - SEC_ERR_STATUS_FUNC_2[6] – IPU2 protection violation
  - SEC_ERR_STATUS_FUNC_2[7] – PCIESS1 protection violation
  - SEC_ERR_STATUS_FUNC_2[8] – PCIESS2 protection violation
  - SEC_ERR_STATUS_FUNC_2[11] – MCASP1 protection violation
  - SEC_ERR_STATUS_FUNC_2[12] – MCASP2 protection violation
  - SEC_ERR_STATUS_FUNC_2[13] – MCASP3 protection violation
  - SEC_ERR_STATUS_FUNC_2[16] – EDMA_TPTC1 protection violation
  - SEC_ERR_STATUS_FUNC_2[17] – EDMA_TPCC protection violation
  - SEC_ERR_STATUS_FUNC_2[22] – QSPI protection violation
  - SEC_ERR_STATUS_FUNC_2[23] – EDMA_TPTC2 protection violation
- In debug mode:
  - SEC_ERR_STATUS_DEBUG_1[1] – L3 RAM protection violation
  - SEC_ERR_STATUS_DEBUG_1[2] – GPMC protection violation
  - SEC_ERR_STATUS_DEBUG_1[3] – EMIF protection violation
  - SEC_ERR_STATUS_DEBUG_1[4] – IVA protection violation
  - SEC_ERR_STATUS_DEBUG_1[5] – IPU protection violation
  - SEC_ERR_STATUS_DEBUG_1[6] – IVA SL2 protection violation
  - SEC_ERR_STATUS_DEBUG_1[8] – SYSTEM DMA protection violation
  - SEC_ERR_STATUS_DEBUG_1[10] – DSPDMA slave NIU protection violation
  - SEC_ERR_STATUS_DEBUG_1[13] – GPU protection violation
  - SEC_ERR_STATUS_DEBUG_1[14] – DSS protection violation
  - SEC_ERR_STATUS_DEBUG_1[16] – L4_PER1 protection violation
  - SEC_ERR_STATUS_DEBUG_1[17] – L4_CFG protection violation
  - SEC_ERR_STATUS_DEBUG_1[18] – DEBUG subsystem protection violation
  - SEC_ERR_STATUS_DEBUG_1[22] – L4_WKUP protection violation
  - SEC_ERR_STATUS_DEBUG_1[23] – BB2D protection violation
  - SEC_ERR_STATUS_DEBUG_1[26] – CT_TBR protection violation
  - SEC_ERR_STATUS_DEBUG_1[28] – EVE1 protection violation
  - SEC_ERR_STATUS_DEBUG_1[29] – EVE2 protection violation
  - SEC_ERR_STATUS_DEBUG_2[0] – DSP1 protection violation
  - SEC_ERR_STATUS_DEBUG_2[1] – DSP2 protection violation
  - SEC_ERR_STATUS_DEBUG_2[2] – OCMC_RAM2 protection violation

- SEC_ERR_STATUS_DEBUG_2[3] – OCMC_RAM3 protection violation
- SEC_ERR_STATUS_DEBUG_2[4] – L4_PER2 protection violation
- SEC_ERR_STATUS_DEBUG_2[5] – L4_PER3 protection violation
- SEC_ERR_STATUS_DEBUG_2[6] – IPU2 protection violation
- SEC_ERR_STATUS_DEBUG_2[7] – PCIESS1 protection violation
- SEC_ERR_STATUS_DEBUG_2[8] – PCIESS2 protection violation
- SEC_ERR_STATUS_DEBUG_2[11] – McASP1 protection violation
- SEC_ERR_STATUS_DEBUG_2[12] – McASP2 protection violation
- SEC_ERR_STATUS_DEBUG_2[13] – McASP3 protection violation
- SEC_ERR_STATUS_DEBUG_2[16] – EDMA_TPTC1 protection violation
- SEC_ERR_STATUS_DEBUG_2[17] – EDMA_TPCC protection violation
- SEC_ERR_STATUS_DEBUG_2[22] – QSPI protection violation
- SEC_ERR_STATUS_DEBUG_2[23] – EDMA_TPTC2 protection violation

For more information, see Chapter 18, *Control Module*.

14.2.3.7.3.5 L3_MAIN Firewall Default Configuration

Table 14-21 summarizes the configuration of the L3_MAIN firewalls.

Table 14-21. L3_MAIN Firewalls Default Configurations

Device/Region: 0						
Permission Type	**Reset Value**	**Reset Value**	**Reset Type**	**Run Time**	**Firewall Register (where j = 0)**	**Control Module Register**

14.2.3.8 L3_MAIN Interconnect Error Handling

Error logging is enabled in the L3_MAIN interconnect. The three major types of errors are:

- Slave NIU errors
- Firewall errors (see Section 14.2.3.7.3.4, *L3_MAIN Firewall Error Logging*)
- Flag mux errors

14.2.3.8.1 Global Error-Routing Scheme

Figure 14-7 shows the L3_MAIN global error-routing scheme.

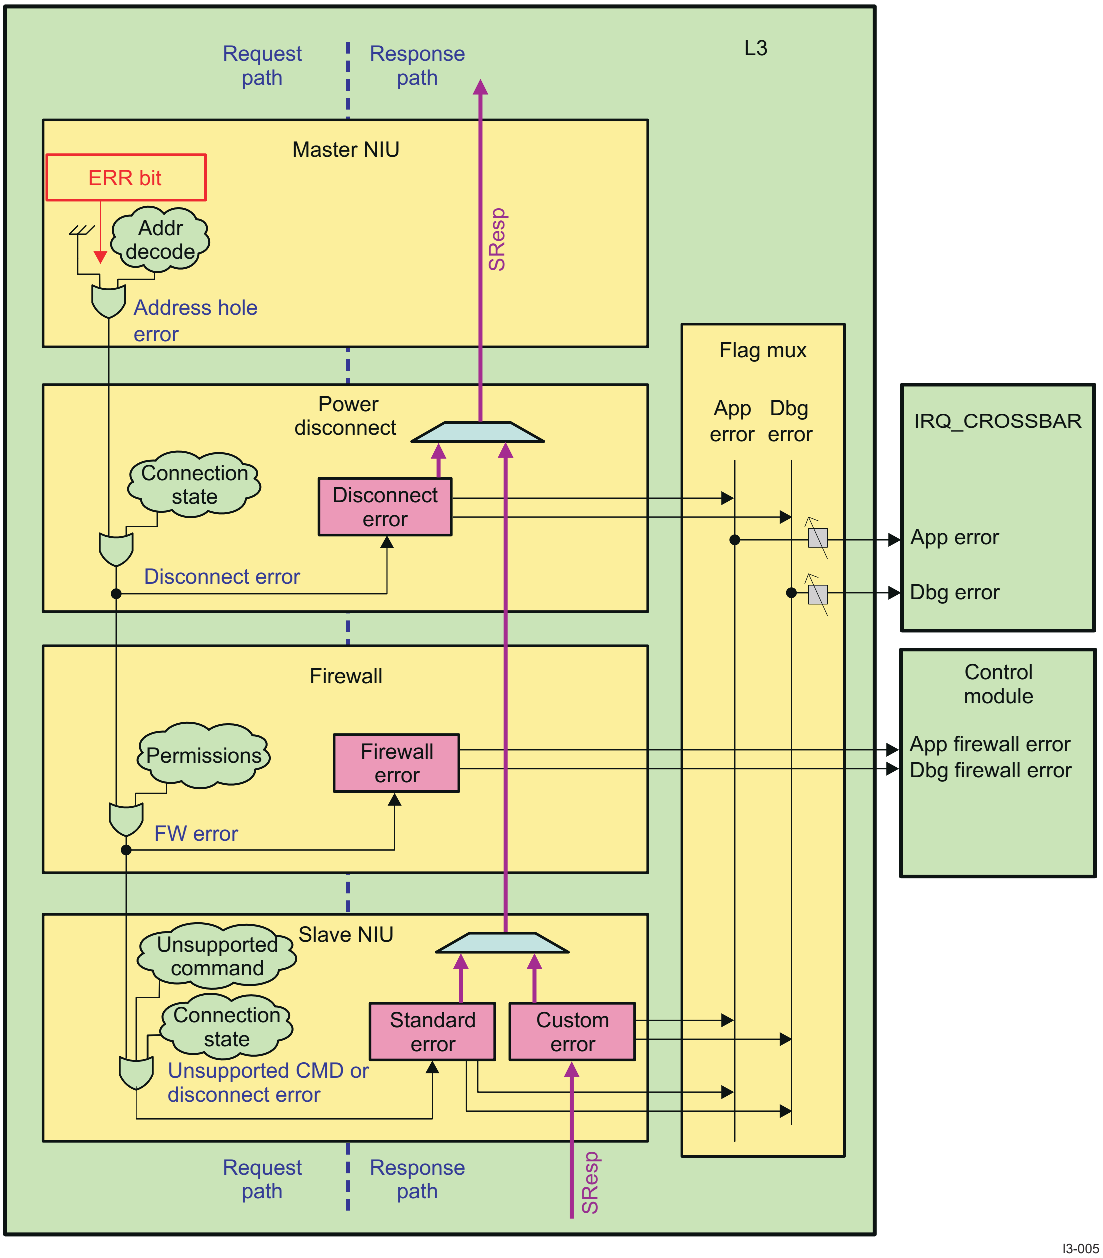

Figure 14-7. L3_MAIN Global Error-Routing Scheme

14.2.3.8.2 Slave NIU Error Logging

Error logging is implemented only at slave NIUs. Because the interconnect does not support master NIU error logging, an erroneous packet must be created and sent to one of the slave NIUs. The slave NIU that receives an erroneous packet is predictable but can change per master (see Table 14-23).

Table 14-23. L3_MAIN Connectivity and Holes Error Routing

Master	Connectivity and Holes Errors Logged Into Slave NIUs
All initiators except DSP1_CFG and DSP2_CFG	GPMC_TARG
DSP1_CFG	EVE1_TARG
DSP2_CFG	

The slave NIU can be configured to report standard errors (errors generated within the interconnect):

- Firewall error: Protection violation; this error indicates that a request was rejected by a firewall and is reported to the control module. For more information, see Section 14.2.3.7.3.4, *L3_MAIN Firewall Error Logging.*
- Address hole: This error reports an unknown address for a request. The address map is local to each master NIU; therefore, an address hole error is reported each time a master NIU requests an access to a slave NIU to which it is not logically connected, even if this address exists in the global L3_MAIN address map. This error is detected only once per burst.
- Unsupported commands: This error reports that the master NIU sent a command that cannot be processed, because the slave NIU cannot accept it and no conversion to another command is possible. This error is detected only once per burst.
- Report custom errors: Basically, when the slave answer is SResp = ERR
- Report severity level, for standard error and custom errors:
  - None: Error logging for this type of error is disabled.
  - Error: Error is logged for this type of error.
  - Fault: Error is logged and interrupt is generated for this type of error.
- Generate interrupt on 2 bits depending on the MReqDebug qualifier:
  - Application error - FAULT[0]
  - Debug error - FAULT[1]

  By default, all slave NIUs are configured with standard and custom error levels set to FAULT. The errors are reported on the two flag muxes (see Figure 14-7), depending on the access type, application or debug. For more information, see Section 14.2.3.8.3, *Flag Mux Error Logging*.

  The slave NIU power-disconnect component also has error logging enabled, because in this case the slave NIU is in a clock domain that is switched off and therefore cannot catch the error. By nature, this component can generate only standard errors. By default, it is configured with the error level set to FAULT.

  Wake up on demand: If an error packet reaches a slave NIU that is set with MDiscBehave = 1 (wake up on demand), then the active signal is asserted and L3 processes the error generation when the slave is awake. Although this is inefficient, it simplifies NIU implementation and should not be a problem because errors are supposed to occur only during software debug.

14.2.3.8.3 Flag Mux Error Logging

All fault signals are sent to a flag mux component. There are four important FLAGMUX registers:

- L3_FLAGMUX_MASK0: Masks application error sources
- L3_FLAGMUX_MASK1: Masks debug error sources
- L3_FLAGMUX_REGERR0: Checks which application error sources are active
- L3_FLAGMUX_REGERR1: Checks which debug error sources are active

The two L3_FLAGMUX_MASK registers mask bit 0 or bit 1 of the flag inputs, and the L3_FLAGMUX_REGERR registers read input errors. Each register is dedicated to reporting the bit corresponding to the register number.

Table 14-24 describes the mapping of the flags to the corresponding sources.

Table 14-24. Interconnect Flag Mapping

	Flag Mux Input	Source	
CLK1_1 Flag Mux	1	DMM_P1

Table 14-24. Interconnect Flag Mapping (continued)

	Flag Mux Input	Source
	21	QSPI
	23	CLK1_TARG_PWR_DISC_CLK2
CLK2_1 Flag Mux	0	L3_INSTR
	1	DEBUGSS_CT_TBR
	2	HOST_CLK2_1
	3	REPLICATOR_CLK2_TIMEOUT

Note

Missing inputs in Table 14-24 are reserved. Writing in them has no effect.

14.2.3.8.4 Severity Level of Standard and Custom Errors

The slave NIU registers are important for error logging.

- The L3_TARG_STDERRLOG_SVRTSTDLVL register shows the severity level for standard errors. According to the severity level, error logging is disabled, enabled with level ERROR, or enabled with level ERROR and flag FAULT.
- The L3_TARG_STDERRLOG_SVRTCUSTOMLVL register shows the severity level for custom errors.
- The L3_TARG_STDERRLOG_MAIN register (the main register for error-logging management) shows the validity of the logged information, standard or custom.
- The L3_TARG_STDERRLOG_HDR register stores packets in case of a standard error.
- The L3_TARG_STDERRLOG_MSTADDR register returns the MSTADDR field of the logged packet.
- The L3_TARG_STDERRLOG_SLVADDR register returns the SLVADDR field of the stored packet.
- The L3_TARG_STDERRLOG_INFO register saves the information field of the logged packet.

14.2.3.8.5 Example for Decoding Standard/Custom Errors Logged in L3_MAIN

Following is a procedure that must be followed for identifying Standard/Custom errors logged in L3_MAIN:

- Read the *_STDERRLOG_MAIN registers (L3_HOST_STDERRLOG_MAIN & L3_TARG_STDERRLOG_MAIN):
  – bit[0]STDERRLOG_MAIN_ERRLOGVLD = 0 -> NO ERROR
  – bit[0]STDERRLOG_MAIN_ERRLOGVLD = 1 -> ERROR
  – Error type is visible through:
    - bit[1]STDERRLOG_MAIN_ERRTYPE = 0 -> Standard Error (FW error, Address Hole, Unsupported command, OCP disconnect)
    - bit[1]STDERRLOG_MAIN_ERRTYPE = 0 -> Custom Error
- Standard Error:
  – Read L3_TARG_STDERRLOG_HDR[3:0] STDERRLOG_HDR_OPCODE
  – Read L3_TARG_STDERRLOG_MSTADDR[7:0] STDERRLOG_MSTADDR - > 8-bit NTTP master address used to distinguish the different initiators (see Table 14-10). That master address is also referred to as ConnID or MConnID.
  – Read L3_TARG_STDERRLOG_SLVADDR[4:0] STDERRLOG_SLVADDR -> NTTP Slave Address of the logged packet
  – Read L3_TARG_STDERRLOG_INFO[7:0]STDERRLOG_INFO -> see Section 14.1.1, *Terminology* for details.

The procedure for Custom error is the same, but the *_STDERRLOG_CUSTOMINFO_* registers should be read.

14.2.4 L3_MAIN Interconnect Programming Guide

14.2.4.1 L3 _MAIN Interconnect Low-Level Programming Models

This section describes the low-level hardware programming sequences for configuring and using the L3_MAIN interconnect module.

14.2.4.1.1 Global Initialization

14.2.4.1.1.1 Global Initialization of Surrounding Modules

This section identifies the requirements for initializing the surrounding modules when the L3_MAIN interconnect module is to be used for the first time after a device reset. The initialization of surrounding modules is based on the integration and environment of the L3_MAIN interconnect. For more information, see Section 14.2.2, *L3_MAIN Interconnect Integration* .

Table 14-25. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	For information about the configuration of the PRCM module, see Chapter 3, *Power, Reset, and Clock Management*.
Control module	For information about the configuration of the control module, see Chapter 18, *Control Module*.
Device INTCs	Device INTCs must be configured to enable the interrupt request generation. For more information see Chapter 17, *Interrupt Controllers*.
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see Section 18.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 18, *Control Module*.

14.2.4.2 Operational Modes Configuration

14.2.4.2.1 L3_MAIN Interconnect Error Analysis Mode

14.2.4.2.1.1 Main Sequence: L3_MAIN Interconnect Error Analysis Mode

The information required to analyze an error source is logged in several registers. The number of registers to access depends on the error source.

Figure 14-8 shows the software sequence required in most cases.

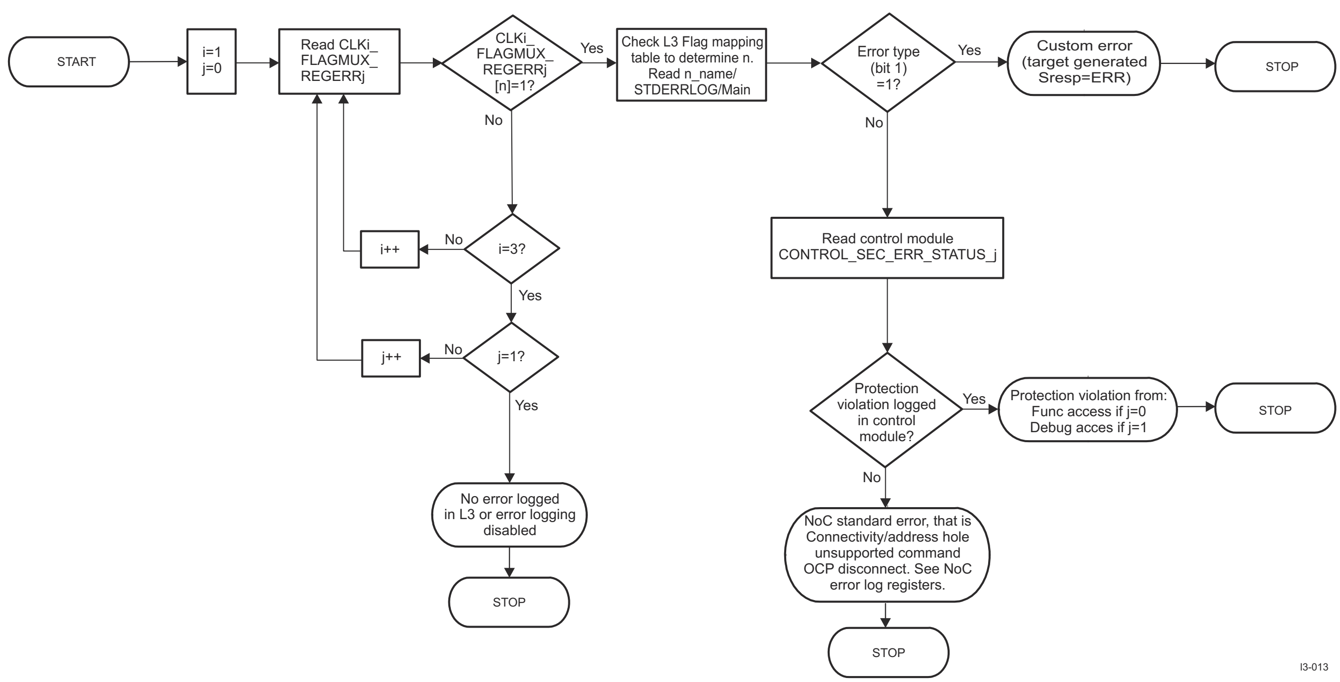

Figure 14-8. Typical Error Analysis Sequence

Note

In case flag is set due to timeout flagmux, user can check the status in CONTROL_SEC_ERR_STATUS for that Timeout Flagmux.

Table 14-26 lists the subprocess call summary for error analysis mode in the main sequence.

Table 14-26. Subprocess Call Summary for Main Sequence – Error Analysis Mode

Subprocess	Cross-Reference
L3 interconnect error analysis	See Section 14.2.4.2.1, *L3_MAIN Interconnect Error Analysis Mode.*
L3_MAIN interconnect protection violation error identification	See Section 14.2.4.2.1.1.2, *Subsequence: L3_MAIN Interconnect Protection Violation Error Identification.*
L3_MAIN interconnect unsupported command/address hole error identification	See Section 14.2.4.2.1.1.3, *Subsequence: L3_MAIN Interconnect Standard Error Identification.*
L3_MAIN interconnect reset FLAGMUX and module	See Section 14.2.4.2.1.1.4, *Subsequence: L3_MAIN Interconnect FLAGMUX Configuration.*

14.2.4.2.1.1.1 Subsequence: L3_MAIN Custom Error Identification

The procedure listed in Table 14-27 describes custom error identification.

Table 14-27. Custom Error Identification

Step	Register/Bit Field/Programming Model	Value
IF: Is custom error detected?	L3_TARG_STDERRLOG_MAIN[1] STDERRLOG_MAIN_ERRTYPE	=0x1
Read information field of the response packet.	L3_TARG_STDERRLOG_CUSTOMINFO_INFO[7:0] STDERRLOG_CUSTOMINFO_INFO	xxx
Read the address of the initiator that caused error.	L3_TARG_STDERRLOG_CUSTOMINFO_MSTADDR[10:0] STDERRLOG_CUSTOMINFO_MSTADDR	xxx
Read the type of operation (read/write).	L3_TARG_STDERRLOG_CUSTOMINFO_OPCODE[1:0] STDERRLOG_CUSTOMINFO_OPCODE	xxx
ENDIF		

14.2.4.2.1.1.2 Subsequence: L3_MAIN Interconnect Protection Violation Error Identification

The procedure listed in Table 14-28 describes protection violation error identification and where it is logged in the control module registers. Two types of errors are logged: application errors and debug errors.

Table 14-28. L3_MAIN Protection Violation Error Identification

Step	Register/Bit Field/Programming Model	Value
Read the burst violation.	ERROR_LOG_k[23] 2D_BURST_VIOLATION	xxx
Read the initiator ID.	ERROR_LOG_k[3:0] ConnID	xxx
Read the command that caused the error.	ERROR_LOG_k[7] MCMD	xxx
Read the address of the request that caused the error.	ERROR_LOG_k[31:12] SLVOFS_LOGICAL	xxx
IF: Is it an application error?	L3_FLAGMUX_REGERR0 [31:0] REGERROR0	0x0
Read the status bits to see which module firewall has worked.	CONTROL.SEC_ERR_STATUS_FUNC_1[20:0]	xxx
Clear the status bits.	CONTROL.SEC_ERR_STATUS_FUNC_1[20:0]	xxx
Clear the status bit.	L3_TARG_STDERRLOG_MAIN [31] STDERRLOG_MAIN_CLRLOG	0x0
ELSE IF	L3_FLAGMUX_REGERR1[7:0] REGERROR1	= 0x1
Read the status bits to see the module.	CONTROL.SEC_ERR_STATUS_DEBUG_1[20:0]	xxx
Clear the status bits.	CONTROL.SEC_ERR_STATUS_DEBUG_1[20:0]	xxx
Clear the status bit.	L3_TARG_STDERRLOG_MAIN[31] STDERRLOG_MAIN_CLRLOG	0x0
ENDIF		

Table 14-28. L3_MAIN Protection Violation Error Identification (continued)

Step	Register/Bit Field/Programming Model	Value
Clear the burst violation.	ERROR_LOG_k[23] 2D_BURST_VIOLATION	0x0
Clear the error status.	ERROR_LOG_k[21:17] REGION_START_ERRLOG	0x00

14.2.4.2.1.1.3 Subsequence: L3_MAIN Interconnect Standard Error Identification

The procedure listed in Table 14-29 describes the identification of standard errors inside the L3_MAIN interconnect. The standard errors are: unsupported command, address hole, and disconnect.

Table 14-29. L3_MAIN Standard Error Identification

Step	Register/Bit Field/Programming Model	Value
IF: Is an error detected?	L3_TARG_STDERRLOG_MAIN[18] STDERRLOG_MAIN_ERRCNT	= 0x1
Read the corresponding flag.	L3_FLAGMUX_REGERR0[31:0] REGERROR0	xxx
Read the corresponding flag.	L3_FLAGMUX_REGERR1[31:0] REGERROR1	xxx
Localize the slave NIU that generated the error.	See Table 14-24.	
ELSE		
Clear the error log.	L3_TARG_STDERRLOG_MAIN[31] STDERRLOG_MAIN_CLRLOG	0x0
Clear the severity error status.	L3_TARG_STDERRLOG_SVRTSTDLVL[1:0] STDERRLOG_SVRTSTDLVL_0	0x2
ENDIF		

14.2.4.2.1.1.4 Subsequence: L3_MAIN Interconnect FLAGMUX Configuration

The procedures listed in Table 14-30 and Table 14-31 give information about the configuration of FLAGMUX masks.

Table 14-30. FLAGMUX Configuration

Step	Register/Bit Field/Programming Model	Value
Set the FLAGMUX masks to mask an event.	L3_FLAGMUX_MASK031:0] MASK0 L3_FLAGMUX_MASK1[31:0] MASK1	xxx
Read the REGERR bits to see if an error is recorded.	L3_FLAGMUX_REGERR0[31:0] REGERR0 L3_FLAGMUX_REGERR1[31:0] REGERR1	xxx
Clear the slave NIU error log and the FLAGMUX error.	L3_TARG_STDERRLOG_MAIN[31] STDERRLOG_SVRTSTDLVL_0	0x1

Table 14-31. FLAGMUX Time-out Configuration (for CLK1_1 and CLK1_2)

Step	Register/Bit Field/Programming Model	Value
Enable time-out for target.	L3_FLAGMUX_TIMEOUTx_MASK0[24:0] MASK0 (1)	xxx
Read the REGERR bits to see if an error is recorded.	L3_FLAGMUX_TIMEOUTx_REGERR0[24:0] REGERR0 (1)	xxx

(1) x = 1 for CLK1_FLAGMUX_CLK1_1
x=2 for CLK1_FLAGMUX_CLK1_2
Bit fields are [24:0] for CLK1_FLAGMUX_CLK1_1, [20:0] for CLK1_FLAGMUX_CLK1_2

Table 14-32. FLAGMUX Time-out Configuration (for CLK2_1)

Step	Register/Bit Field/Programming Model	Value
Enable time-out for target.	L3_FLAGMUX_TIMEOUT_MASK0[1:0] MASK0	xxx
Read the REGERR bits to see if an error is recorded.	L3_FLAGMUX_TIMEOUT_REGERR0[1:0] REGERR0	xxx

14.2.5 L3_MAIN Interconnect Register Manual

14.2.5.1 L3_MAIN Register Group Summary

The registers in the L3 interconnect are divided into eight groups:

- Firewall registers (see Section 14.2.5.1.1)
- HOST registers (see Section 14.2.5.1.2)
- TARG registers (see Section 14.2.5.1.3)
- FLAGMUX registers (see Section 14.2.5.1.4 thru Section 14.2.5.1.6)
- BW registers (see Section 14.2.5.1.7 and Section 14.2.5.1.8.1)
- STATCOLL registers (see Section 14.2.5.1.9)

14.2.5.1.1 L3_MAIN Firewall Registers Summary and Description

Table 14-110. L3_TARG_STDHOSTHDR_VERSIONREG

Address Offset	See Table 14-97.		
Physical Address	See Table 14-97 to Table 14-107	**Instance**	See Table 14-97 to Table 14-107
Description			
Type	R		

31:24	23:0
STDHOSTHDR_VERSIONREG_ REVISIONID	STDHOSTHDR_VERSIONREG_COREPARAMSCHECKSUM

Bits	Field Name	Description	Type	Reset
31:24	STDHOSTHDR_VERSIONREG_REVISIONID	The Revision Identifier field is a constant reporting the core generator revision number. Type: Constant. Reset value: 0x0.	R	0x00
23:0	STDHOSTHDR_VERSIONREG_COREPARAMSCHECKSUM	Reserved. Type: Reserved. Reset value: Reserved.	R	0x000000

Table 14-111. Register Call Summary for Register L3_TARG_STDHOSTHDR_VERSIONREG

L3_MAIN Interconnect

- L3_MAIN TARG Register Summary and Description: [0] [1] [2] [3] [4] [5] [6] [7] [8] [9] [11]

Table 14-112. L3_TARG_STDHOSTHDR_MAINCTLREG

Address Offset	See Table 14-97.		
Physical Address	See Table 14-97 to Table 14-107	**Instance**	See Table 14-97 to Table 14-107
Description			
Type	RW		

31:4	3	2	1	0
RESERVED	STDHOSTSTHDR_MAINCTLREG_CM	STDHOSTSTHDR_MAINCTLREG_FLT	RESERVED	STDHOSTSTHDR_MAINCTLREG_EN

Bits	Field Name	Description	Type	Reset
31:4	RESERVED	Reserved	R	0x0000000
3	STDHOSTHDR_MAINCTLREG_CM	Reserved for internal testing. Must be set to 0. Type: Control. Reset value: 0x0.	R	0
2	STDHOSTHDR_MAINCTLREG_FLT	Asserted when a Fault condition is detected: if the unit includes Error Logging, Flt is asserted when the FltCnt register field indicates a Fault, and deasserted when FltCnt is reset. If no Error Logging is implemented, this bit becomes unit-dependent. In all cases, Flt bit and Flt pin (service network) have the same logical level. Type: Status. Reset value: X.	R	0
1	RESERVED	Reserved	R	0
0	STDHOSTHDR_MAINCTLREG_EN	Sets the global core enable. Note: A disabled master does not generate any NTTP requests, and a disabled slave replies with an error packet to any request it receives. Type: Control. Reset value: 0x1.	RW	1

14.3 L4 Interconnects

This section details the device L4 interconnects.

14.3.1 L4 Interconnect Overview

The device uses three separate L4 interconnect structures to connect peripheral modules. All L4s handle transfers with peripherals but are located in distinct power domains.

Figure 14-9 is an overview of the L4 interconnects and the peripherals attached to them.

The L4 interconnect is composed of the following interconnects:

- L4_CFG: Includes the majority of the configuration interface for L3_MAIN system modules and peripheral interconnect
- L4 PER: Includes the main peripherals that require sDMA access. L4_PER is further divided into three sub-interconnects: L4_PER1, L4_PER2 and L4_PER3. As shown in Figure 14-9, each of these L4_PERx sub-interconnects is connected to L3_MAIN initiators via three ports:
  - L4_PER1_P1, L4_PER1_P2, L4_PER1_P3
  - L4_PER2_P1, L4_PER2_P2, L4_PER2_P3
  - L4_PER3_P1, L4_PER3_P2, L4_PER3_P3

  L3_MAIN initiators access the L4_PERx peripherals through these ports. All peripherals attached to L4_PER1 are visible from all three L4_PER1 ports; this is also correct for L4_PER2 and L4_PER3. For information on which initiator can access which L4_PERx port, see Figure 14-3.
- L4_WKUP: Includes peripherals attached to the WKUP power domain

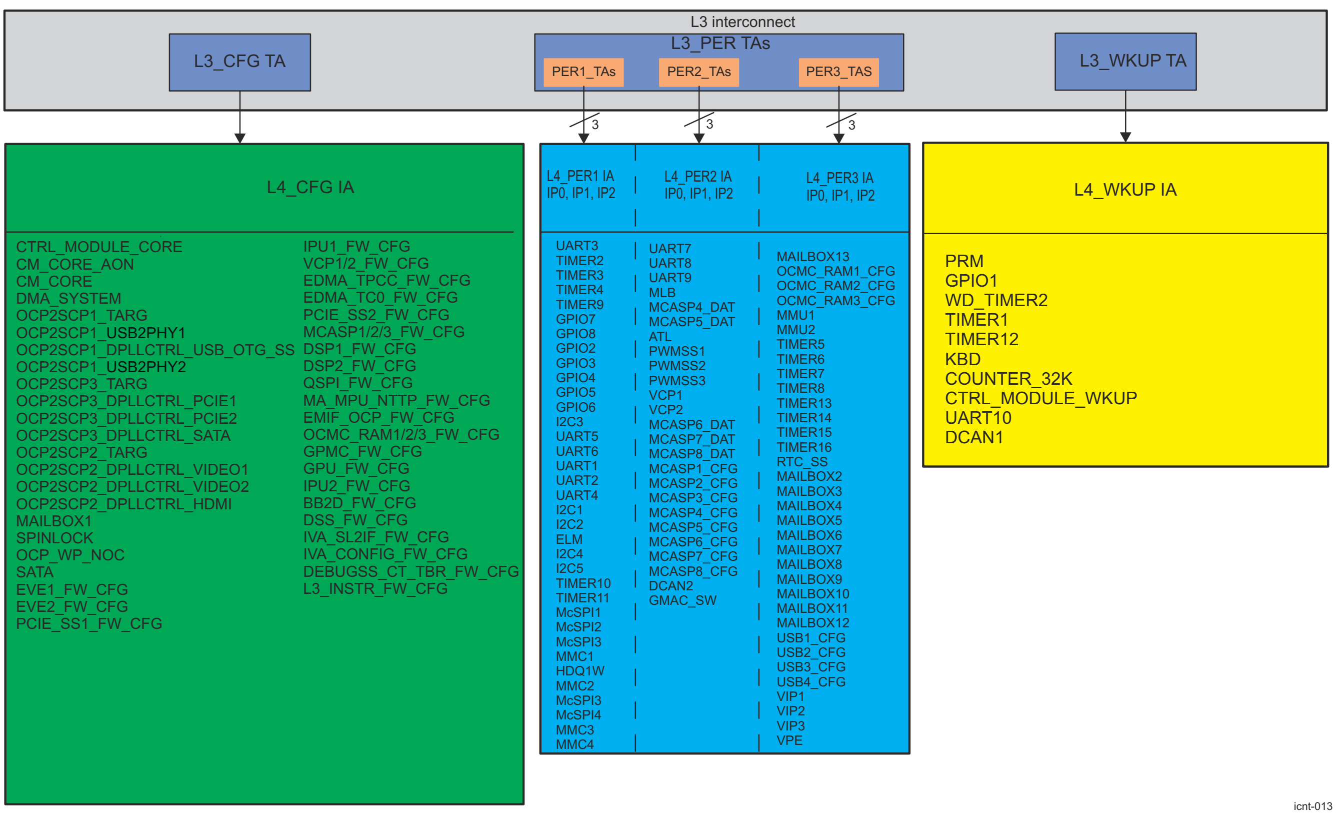

Figure 14-9. L4 Interconnect Overview

The main features of the L4 interconnects are:

- Eleven ports from L3_MAIN interconnect onto 5 parallel L4 interconnects
- From one to three 32-bit initiator ports for each L4 interconnect instance (11 in total)

- 8-, 16-, or 32-bit data, single, or burst transactions
- Little-endian platform
- Non-blocking architecture with fair arbitration between masters
- Target interfaces: Fully synchronous or divided synchronous clock frequencies
- L4_CFG and L4_PER1, L4_PER2, L4_PER3 frequency equals half of L3 frequency
- Protection logic that provides user-configurable access control to targets by each initiator

14.3.2 L4 Interconnect Integration

Table 14-377 and Table 14-378 summarize the integration of the module in the device.

Table 14-377. Integration Attributes

Module Instance	Attributes
	Power Domain
L4_PER1, L4_PER2, L4_PER3	PD_COREAON
L4_CFG	PD_COREAON
L4_WKUP	PD_WKUPAON

14.3.3 L4 Interconnect Functional Description

14.3.3.1 Module Distribution

IAs and TAs provide the interface to connect the different modules to their associated interconnect.

Table 14-379 through Table 14-388 list all the modules and subsystems with their associated agents. The agents are listed for each L4 interconnect domain.

14.3.3.1.1 L4_PER1 Interconnect Agents

The L4_PER1 interconnect handles transfers only to peripherals in the PER power domain. Table 14-379 lists the L4_PER1 TAs.

Table 14-379. L4_PER1 TAs

Module Target Name	Description
UART3_TARG	Universal Asynchronous Receiver/Transmitter target port
TIMER2_TARG	General Purpose Timer 2 target port
TIMER3_TARG	TIMER3 target port
TIMER4_TARG	TIMER4 target port
TIMER9_TARG	TIMER9 target port
GPIO7_TARG	General-Purpose Interface 7 target port
GPIO8_TARG	GPIO8 target port
GPIO2_TARG	GPIO2 target port
GPIO3_TARG	GPIO3 target port
GPIO4_TARG	GPIO4 target port
GPIO5_TARG	GPIO5 target port
GPIO6_TARG	GPIO6 target port
I2C3_TARG	Inter-Integrated Circuit 3 target port
UART5_TARG	UART5 target port
UART6_TARG	UART6 target port
UART1_TARG	UART1 target port
UART2_TARG	UART2 target port
UART4_TARG	UART4 target port
I2C1_TARG	I2C1 target port
I2C2_TARG	I2C2 target port
ELM_TARG	Error Location Module target port
I2C4_TARG	I2C4 target port
I2C5_TARG	I2C5 target port
TIMER10_TARG	TIMER10 target port
TIMER11_TARG	TIMER11 target port
MCSPI1_TARG	Multi-channel Serial Peripheral Interface 1 target port
MCSPI2_TARG	McSPI2 target port
MMC1_TARG	MMC1 target port
HDQ1W_TARG	HDQ1W target port
MMC2_TARG	MMC2 target port
MMC3_TARG	MMC3 target port
MCSPI3_TARG	McSPI3 target port
MCSPI4_TARG	McSPI4 target port
MMC4_TARG	MMC4 target port

Four ports communicate between the L3_MAIN interconnect and the L4_PER1 interconnect to allow the L3_MAIN initiators to access the L4_PER1 targets. Table 14-380 lists the L4_PER1 initiator TAs.

For the list of initiators authorized to access the L4_PER1, peripherals, see Section 14.2.3.2.2, *Connectivity Matrix*.

Table 14-380. L4_PER1 IAs

Module Iniator Name	Description
L3_MAIN_IP0_INIT	L3 sDMA RD interconnect port
L3_MAIN_IP1_INIT	L3 sDMA WR interconnect port
L3_MAIN_IP2_INIT	L3 MPU susbystem interconnect port

14.3.3.1.2 L4_PER2 Interconnect Agents

The L4_PER2 interconnect handles transfers only to peripherals in the PER power domain. Table 14-381 lists the L4_PER2 TAs.

Table 14-381. L4_PER2 TAs

Module Target Name	Description
UART7_TARG	UART7 target port
UART8_TARG	UART8 target port
UART9_TARG	UART9 target port
MLB_TARG	Media Local Bus target port
MCASP4_DAT_TARG	Multi-Channel Audio Serial Port - DAT target port
MCASP5_DAT_TARG	MCASP5_DAT target port
ATL_TARG	Audio Tracking Logic target port
PWMSS1_TARG	Pulse-Width Modulation Subsystem1 target port
PWMSS2_TARG	PWMSS2 target port
PWMSS3_TARG	PWMSS3 target port
VCP1_CFG_TARG	Viterby Coder/Decoder 1 target port
VCP2_CFG_TARG	Viterby Coder/Decoder 2 target port
MCASP6_DAT_TARG	MCASP6_DAT target port
MCASP7_DAT_TARG	MCASP7_DAT target port
MCSAP8_DAT_TARG	MCASP8_DAT target port
MCASP1_CFG_TARG	MCASP1_CFG target port
MCASP2_CFG_TARG	MCASP2_CFG target port
MCASP3_CFG_TARG	MCASP3_CFG target port
MCASP4_CFG_TARG	MCASP4_CFG target port
MCASP5_CFG_TARG	MCASP5_CFG target port
MCASP6_CFG_TARG	MCASP6_CFG target port
MCASP7_CFG_TARG	MCASP7_CFG target port
MCASP8_CFG_TARG	MCASP8_CFG target port
DCAN2_TARG	DCAN2 target port
GMAC_SW_TARG	Ethernet Controller target port

Three ports communicate between the L3_MAIN interconnect and the L4_PER2 interconnect to allow the L3_MAIN initiators to access the L4_PER2 targets. Table 14-382 lists the L4_PER2 initiator TAs.

For the list of initiators authorized to access the L4_PER2 peripherals, see Section 14.2.3.2.2, *Connectivity Matrix*.

Table 14-382. L4_PER2 IAs

Module Iniator Name	Description
L3_MAIN_IP0_INIT	L3 sDMA RD interconnect port
L3_MAIN_IP1_INIT	L3 sDMA WR interconnect port
L3_MAIN_IP2_INIT	L3 MPU susbystem interconnect port

14.3.3.1.3 L4_PER3 Interconnect Agents

The L4_PER3 interconnect handles transfers only to peripherals in the PER power domain. Table 14-383 lists the L4_PER3 TAs.

Table 14-383. L4_PER3 TAs

Module Target Name	Description
TIMER5_TARG	TIMER5 target port
TIMER6_TARG	TIMER6 target port
TIMER7_TARG	TIMER7 target port
TIMER8_TARG	TIMER8 target port
TIMER13_TARG	TIMER13 target port
TIMER14_TARG	TIMER14 target port
TIMER15_TARG	TIMER15 target port
TIMER16_TARG	TIMER16 target port
VIP1_TARG	Video Input Parser(VIP) 1 target port
VIP2_TARG	VIP2 target port
VIP3_TARG	VIP3 target port
VPE_TARG	VPE target port
RTC_SS_TARG	Real-Time Clock (RTC) target port
MBX2_TARG	Mailbox 2 target port
MBX3_TARG	Mailbox 3 target port
MBX4_TARG	Mailbox 4 target port
MBX5_TARG	Mailbox 5 target port
MBX6_TARG	Mailbox 6 target port
MBX7_TARG	Mailbox 7 target port
MBX8_TARG	Mailbox 8 target port
MBX12_TARG	Mailbox 12 target port
MBX9_TARG	Mailbox 9 target port
MBX10_TARG	Mailbox 10 target port
MBX11_TARG	Mailbox 11 target port
USB4_CFG_TARG	USB4 configuration port
SATA_TARG	SATA target port
USB2_CFG_TARG	USB2 configuration port
OCMC_RAM1_TARG	On-Chip Memory Controller RAM1 target port
USB1_CFG_TARG	USB1 configuration target port
USB3_CFG_TARG	USB3 configuration target port
OCMC_RAM2_TARG	OCMC_RAM2 target port
OCMC_RAM3_TARG	OCMC_RAM3 target port
MMU1_TARG	Memory Management Unit 1 target port
MMU2_TARG	MMU2 target port
MBX13_TARG	Mailbox 13 target port

Three ports communicate between the L3_MAIN interconnect and the L4_PER3 interconnect to allow the L3_MAIN initiators to access the L4_PER3 targets. Table 14-384 lists the L4_PER3 initiator TAs.

For the list of initiators authorized to access the L4_PER3 peripherals, see Section 14.2.3.2.2, *Connectivity Matrix*.

Table 14-384. L4_PER3 IAs

Module Iniator Name	Description
L3_MAIN_IP0_INIT	L3 sDMA RD interconnect port
L3_MAIN_IP1_INIT	L3 sDMA WR interconnect port
L3_MAIN_IP2_INIT	L3 MPU susbystem interconnect port

14.3.3.1.4 L4_CFG Interconnect Agents

The L4_CFG interconnect handles only transfers to peripherals in the CORE power domain. Table 14-385 lists the TAs.

Table 14-385. L4_CFG TAs

Module Target Name	Description
CTRL_MODULE_CORE_TARG	Control Module core target
CM_CORE_AON_TARG	CORE_AON module
CM_CORE_TARG	CM_CORE module

TIMER12_TARG	Timer 12
KBD_TARG	Keyboard controller
COUNTER_32K_TARG	Counter 32k timer
CTRL_MODULE_WKUP_TARG	Control Module Wakeup module
UART10_TARG	UART10 module
DCAN1_TARG	CAN1 module

Table 14-388. L4_WKUP IAs

Module Iniator Name	Description
L3_MAIN_IP0	L3 interconnect port

14.3.3.2 Power Management

As part of the system-wide power-management scheme, the L4 interconnects go into IDLE state after receiving a request from the PRCM module after all commands are serviced. This function is handled by hardware. For more information, see Chapter 3, *Power, Reset, and Clock Management*.

To reduce power consumption, each L4 interconnect automatically performs internal clock autogating. This is managed by hardware; no software configurations or settings are required.

L4_CFG, L4_PER1, L4_PER2, L4_PER3, and L4_WKUP are located in the always-on power domain and no retention is needed for these L4 interconnects.

14.3.3.3 L4 Firewalls

Figure 14-10 is an internal view of the L4 interconnects in the overall interconnect. This architecture, with one initiator subsystem centralizing all initiator master requests and distributing them to all target modules (peripherals), enables the L4 interconnect firewall functions to be centralized at the L4 initiator subsystem level. The L4 firewall filters the accesses based on the configurable protection groups defined in the L4 address protection (AP) registers. Each module or TA is assigned to a protection group. The configuration is also defined in the L4 AP and is programmable on a module-per-module basis.

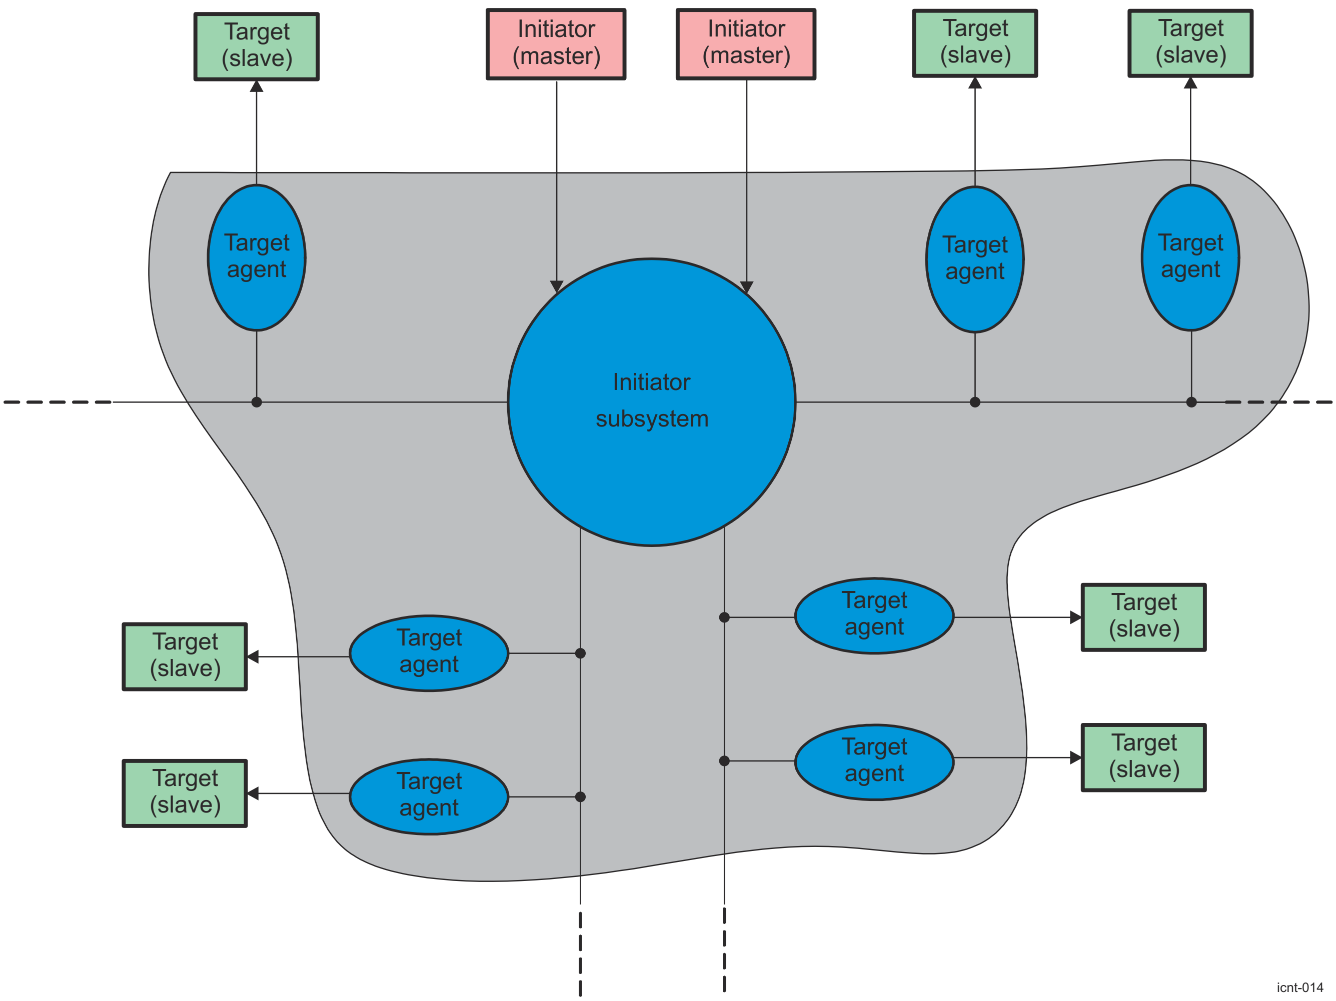

Figure 14-10. L4 Initiator-Target Connectivity

Note

As Figure 14-10 shows, targets are attached to branches. Branches do not impact the function of the L4 interconnect but are present to simplify timing closure and reduce active power consumption.

Because of the large address spaces and the number of peripherals connected to an L4 interconnect, two parameters are used to set up access permission:

- Programmable groups for initiators:
  – Eight protection groups for the L4 interconnect
- Segments divided into regions
  – 85 regions for the L4_PER1 interconnect
  – 63 regions for the L4_PER2 interconnect
  – 97 regions for the L4_PER3 interconnect
  – 129 regions for the L4_CFG interconnect
  – 44 regions for the L4_WKUP interconnect

Protection group members are TAs with the same protection settings. A region is programmed to allow access to a unique selectable protection group. For better protection, different regions are grouped into protection group regions and associated with a protection group member.

14.3.3.3.1 Protection Group

A protection group is defined by its initiators (or members) and MReqInfo is allowed. Two registers define these two settings:

- The 64-bit CONNID_BIT_VECTOR field L4_AP_PROT_GROUP_MEMBERS_k_L and L4_AP_PROT_GROUP_MEMBERS_k_H registers define which initiator belongs to a group. A protection group is accessible by an initiator when the bit position corresponding to its ConnID is set to 1 in the CONNID_BIT_VECTOR field. Table 14-389 lists all the ConnIDs available at the L4 levels.
- The ENABLE field L4_AP_PROT_GROUP_ROLES_k_L register lists all possible MReqInfo combinations associated with the L4_AP_PROT_GROUP_MEMBERS register. Setting a Req bit in this register determines the initiators type of access. For more information, see Section 14.2.3.7.3, *L3_MAIN Firewall Functionality*. Two MReqInfos are used in L4 interconnects: MReqDebug and MReqSupervisor.

Note

Permissions are identical for read and write accesses in L4 interconnect.

k indicates the protection group number.

L indicates the region number.

Table 14-389. L4 ConnID Definition

ConnID	Initiator
0	Cortex-A15 MPU subsystem
1	Debug subsystem
2	DSP1 subsystem (CFG, EDMA, MDMA), DSP2 (EDMA)
3	IVAHD, DSP2(CFG, MDMA)
4	EVE1, EVE2
5	Reserved
6	IPU1/2; SYSTEM_DMA
7	EDMA
8	DSS, MLB, MMU1, MMU2, PCIE1 and PCIE2
9	VIP1, VIP2, VIP3, VPE

Table 14-389. L4 ConnID Definition (continued)

ConnID	Initiator
A	MMC1, MMC2, GPU, BB2D, GMAC
B	USB1, USB2, USB3, USB4
C	SATA
D	Reserved
E	Reserved
F	Resered

Figure 14-11 is an example of CONNID_BIT_VECTOR.

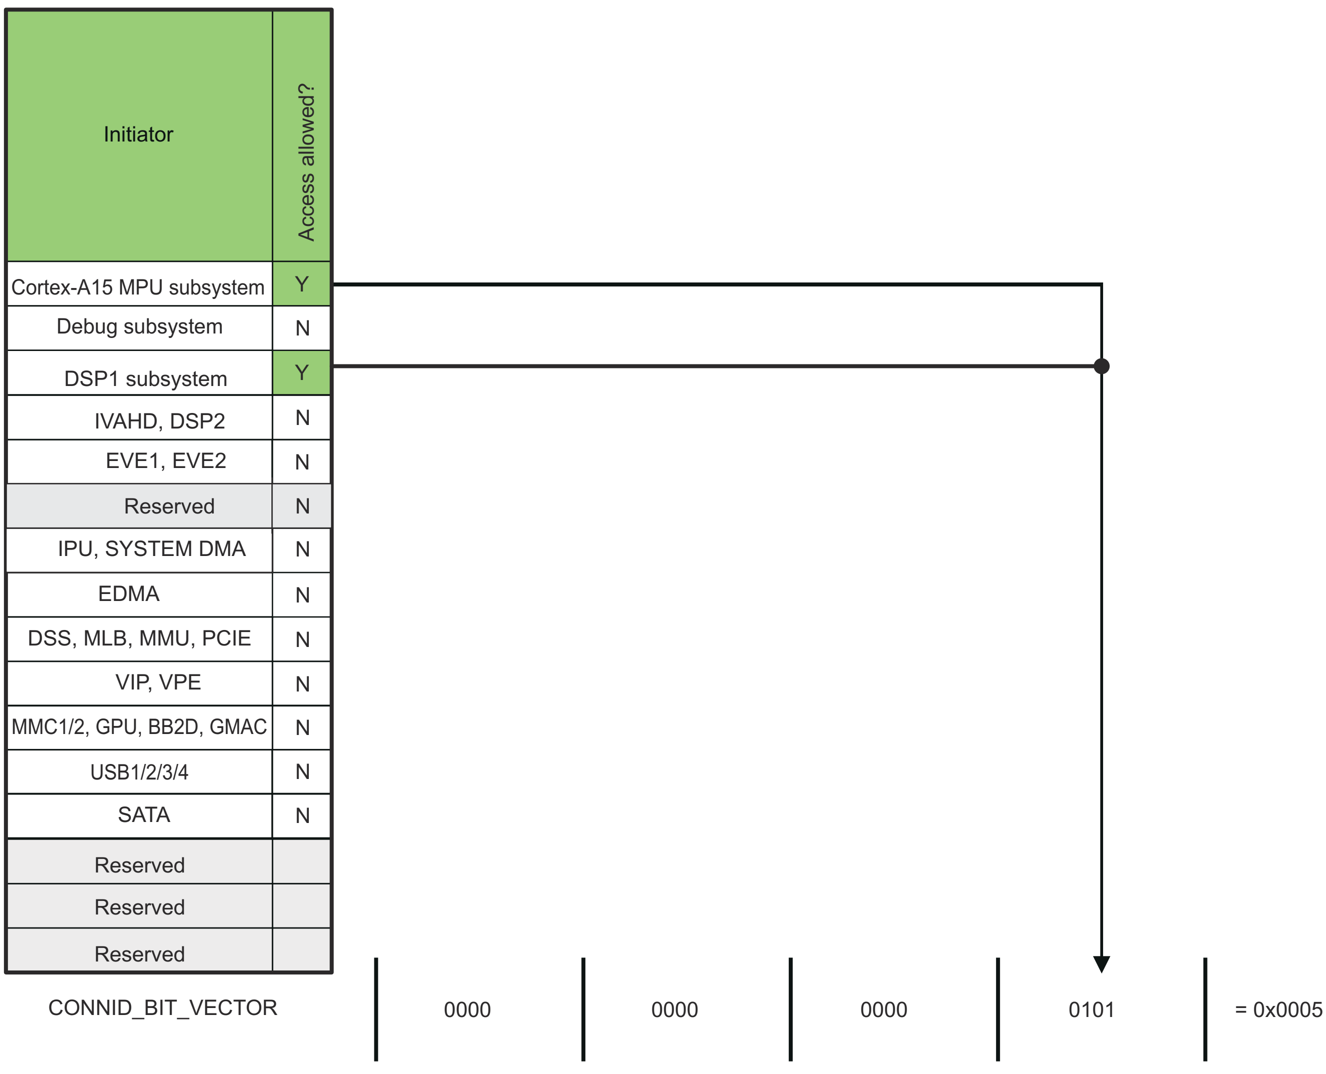

Figure 14-11. Example of CONNID_BIT_VECTOR L4_AP_PROT_GROUP_MEMBERS_k

Setting bits 0 and 2 in the PROT_GROUP_MEMBERS_L register defines a group initiator that can access targets in protection group 1, and includes the following:

- Cortex-A15 MPU subsystem
- DSP subsystem

Protection group 1 can be applied to multiple protection regions with no limitation. Each protection region that is configured with protection group 1 enables permission access only to the two initiators.

The L4_AP_REGION_i_H PROT_GROUP_ID field determines the region to which the protection group member is attached.

The values of some CONNID_BIT_VECTOR and ENABLE fields are exported by the system control module (SCM) at reset or are user writable (see Figure 14-11 for more information).

Table 14-390 and Table 14-393 list the default configuration of the various groups for each L4 interconnect. For each group, some modules or regions are associated with it using default initiator members.

Table 14-390. L4_PER1 Firewall Default Configuration

Note

For EXPORTED default values see CONTROL_SEC_ LOAD_FW_EXPORTED_VALUE register in Chapter 18, *Control Module*

14.3.3.3.2 Segments and Regions

The protection mechanism for L4 interconnects is based on a hierarchical segmentation, as shown in Figure 14-12. By default, some regions are attached to specific protection group members. This specificity lets users set up the permission access to certain types of modules requiring the same access protection without managing region allocation.

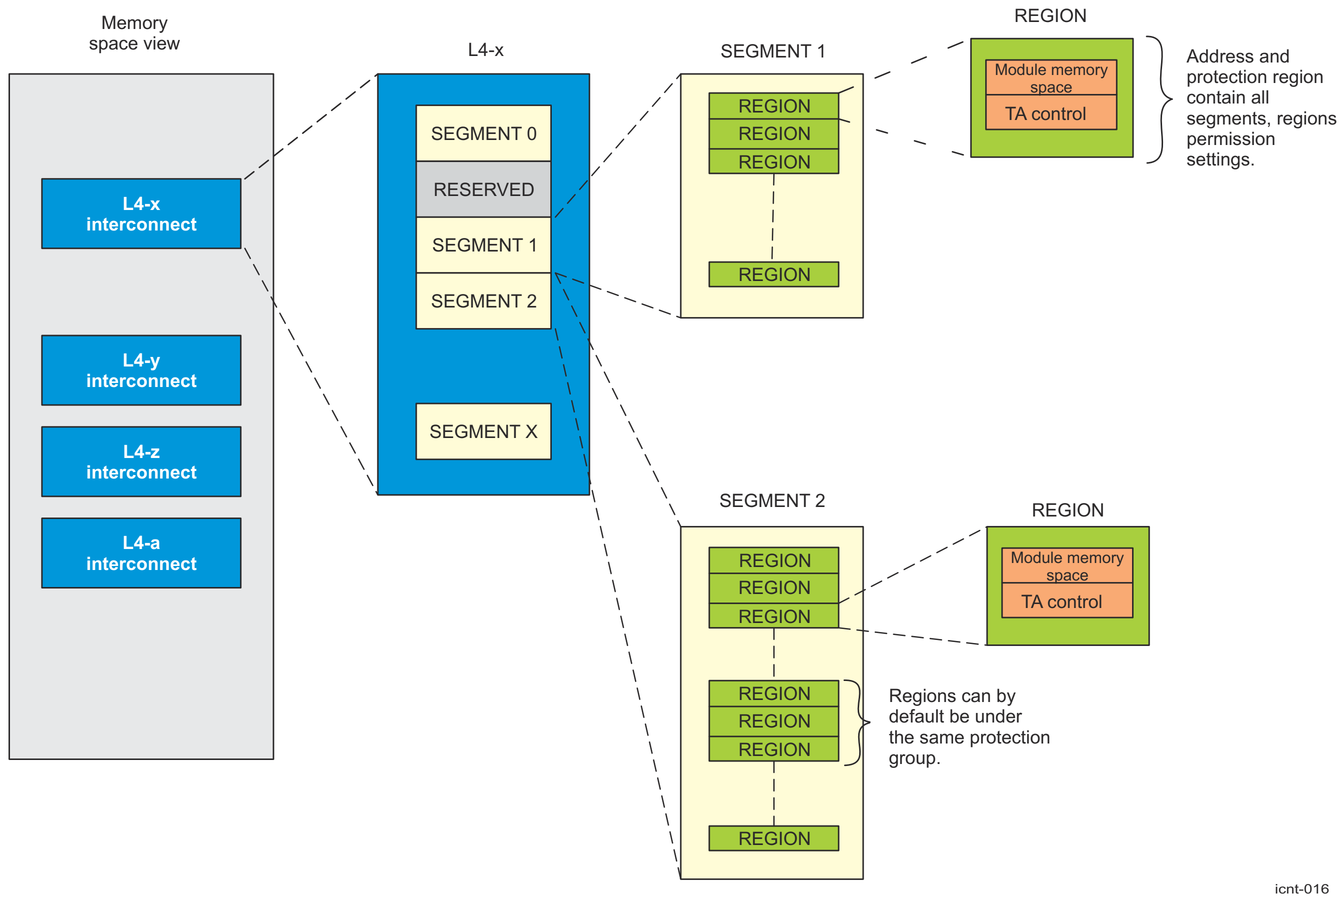

Figure 14-12. L4 Segmentation

All interconnect address spaces are covered by regions. Table 14-395 through Table 14-399 list the module mapping with their addresses, region numbers, and default protection group allocated to them.

Note

Module refers to the configuration registers of the module.

TA (Target Agent) refers to the interconnect configuration registers of the TA associated with the module.

14.3.3.3.3 L4 Firewall Address and Protection Register Settings

Table 14-400 lists the settings of the AP registers relative to an L4 interconnect firewall. These values are computed based on the physical implementation of each L4 interconnect.

Table 14-400. L4 Firewall Register Description Overview

Register Type	Register Name	Bits	Field	Description
Segment	L4_AP_SEGMENT_i_L [(2)]	31:0	BASE	Segment base address
	L4_AP_SEGMENT_i_H [(2)]	5:0	SIZE	Segment size equals to 2^{SIZE}
Protection groups	L4_AP_PROT_GROUP_MEMBERS_k_L [(3)]	15:0	CONNID_BIT_VECTOR	For L4ConnID, see Table 14-389.
	L4_AP_PROT_GROUP_ROLES_k_L [(3)] L4_AP_PROT_GROUP_ROLES_k_H	31:0	ENABLE	See for REQ_INFO description. [(1)]
Region setting	L4_AP_REGION_l_L [(4)]	20:0	BASE	Defines the base address of region with respect to its segment base address
	L4_AP_REGION_l_H [(4)]	31:28	MADDRSPACE	Target interconnect MAddrSpace
		26:24	SEGMENT_ID	Segment ID number of the region
		22:20	PROT_GROUP_ID	Protection group member attached to the region
		18:17	BYTE_DATA_WIDTH_EXP	Determines the number of bytes in an access
		14:8	PHY_TARGET_ID	Physical target ID
		6:1	SIZE	Size of the region equals to 2^{SIZE}
		0	ENABLE	Enables the region protection

(1) For L4 interconnects, only MReqDebug and MReqSupervisor are available.
(2) i = 0 to 1 for PER1_AP
i = 0 for PER2_AP
i = 0 for PER3_AP
i = 0 to 2 for CFG_AP
i = 0 to 3 for WKUP_AP
(3) k = 0 to 7 for PER1_AP
k = 0 to 7 for PER2_AP
k = 0 to 7 for PER3_AP
k = 0 to 7 for CFG_AP
k = 0 to 7 for WKUP_AP
(4) l = 0 to 84 for PER1_AP
l = 0 to 56 for PER2_AP
l = 0 to 96 for PER3_AP
l = 0 to 128 for CFG_AP
l = 0 to 43 for WKUP_AP

14.3.3.4 L4 Error Detection and Reporting

14.3.3.4.1 IA and TA Error Detection and Logging

The L4 interconnect provides mechanisms for handling internally detected errors or errors reported by modules attached to the L4 target ports.

Note

L4_IA denotes the IA for all L4 interconnects: L4_PER1, L4_PER2, L4_PER3, L4_CFG, and L4_WKUP.

L4_TA denotes the TA for all L4 interconnects: L4_PER1, L4_PER2, L4_PER3, L4_CFG, and L4_WKUP.

The L4 interconnects handle four types of errors:

- No target core found or address hole, detected and logged at IA
- Unsupported command, detected and logged at IA
- Protection violation, detected and logged at IA (see Section 14.3.3.3, *L4 Firewalls*)
- Target does not service a request before a time-out expires. The error is detected and logged at TA (see Section 14.3.3.4.2, *Time-Out*).

Table 14-401 lists the value of the L4_IA_ERROR_LOG_L[25:24] CODE bit field stored when an error occurs.

Table 14-401. L4 CODE Bit Field Definition

CODE (bits 1:0)	Error Type	REQ_INFO	Secondary	ConnID	CMD
0	No error				
1	Unsupported command	x	x	x	x
2	Address hole	x	x	x	x
3	Protection violation	x		x	x

- No target core found/address hole: This error indicates that a request was addressed to a hole in the L4 address map. When this error occurs, an in-band error response is returned to the L3 level. The error is also logged into the L4_IA_AGENT_STATUS_L[27] INBAND_ERROR bit. Additionally, an address hole error code is logged to the L4_IA_ERROR_LOG_L[25:24] CODE bit field.
- Unsupported command: This error indicates that the command type of the request is not supported by the accessed target register. The error is logged into the L4_IA_AGENT_STATUS_L[27] INBAND_ERROR bit. An unsupported command error code is written to the L4_IA_ERROR_LOG_L[25:24] CODE bit field for the initiator interface.
- Protection violation: This error indicates that a request is not issued from an allowed initiator member or is issued with the inappropriate ReqInfo qualifiers associated with the target region. This error is reported using an in-band error and is written to the L4_IA_AGENT_STATUS_L[27] INBAND_ERROR bit. A protection violation error code is saved into the L4_IA_ERROR_LOG_L[25:24] CODE bit field for the same initiator interface. A protection violation is also logged in the L4_IA_AGENT_STATUS_L[31] PROT_ERROR_SECONDARY or [30] PROT_ERROR_PRIMARY bit when in debug or applicative mode, respectively.

  The L4_IA_ERROR_LOG_L[30] SECONDARY bit indicates whether the error occurred in application or debug.

  The L4_IA_ERROR_LOG_H[15:0] REQ_INFO bit field returns the type of access (REQ_INFO qualifier) that caused the error.

  The L4_IA_ERROR_LOG_L[13:8] CONNID bit field returns the ID of the initiator that caused the error.

  The L4_IA_ERROR_LOG_ADDR_L[31:0] ADDR register logs the address for error conditions.

14.3.3.4.2 Time-Out

A time-out mechanism can be enabled at the interconnect level and on a per-target basis. If the mechanism is enabled for a TA and interconnect and commands are not accepted or responses are not returned within the expected delay, the L4 interconnect generates an error event.

Note

The time-out mechanism is not available on the L4_WKUP interconnect, but L4_WKUP time-outs are detected in CFG_TA_L4WKUP of the L4_CFG interconnect.

The error is logged in the L4_TA_AGENT_STATUS_L[8] REQ_TIMEOUT bit. The affected TA enters an error state that causes it to send an error response to any new request targeted at it. To recover from this state, system software must reset the TA. The time-out is counted starting from the moment a command is presented to the target, regardless of the target response to this command.

The L4 interconnect implements a centralized time-base circuit that broadcasts a set of four periodic pulse signals to all connected TAs. The time-base circuit offers four possible sets of four time-base signals. The time-base signals are selected by programming the L4_LA_NETWORK_CONTROL_L[10:8] TIMEOUT_BASE bit field.

The selected time-base signals are available at any TA. Each TA can be programmed to refer to one of these four time-base signals, using the L4_TA_AGENT_CONTROL_L[10:8] REQ_TIMEOUT bit field. These four signals are referred to as 1X time-base, 4X time-base, 16X time-base, and 64X time-base.

Table 14-402 lists all values in number of L4 clock cycles.

Table 14-402. L4 Time-out Link and TA Programming

<table>
<tr><th></th><th colspan="5">L4_TA_AGENT_CONTROL_L
[10:8] REQ_TIMEOUT</th></tr>
<tr><th>L4_LA_NETWORK_CONTROL_L[10:8]
TIMEOUT_BASE</th><th>0</th><th>1</th><th>2</th><th>3</th><th>4</th></tr>
<tr><td>0</td><td colspan="5">All L4 time-out features are disabled.</td></tr>
<tr><td>1</td><td rowspan="4">Locally disabled</td><td>64</td><td>256</td><td>1024</td><td>4096</td></tr>
<tr><td>2</td><td>256</td><td>1024</td><td>4096</td><td>16,384</td></tr>
<tr><td>3</td><td>1024</td><td>4096</td><td>16,384</td><td>65,536</td></tr>
<tr><td>4</td><td>4096</td><td>16,384</td><td>65,536</td><td>262,144</td></tr>
</table>

The default reset value is 0x2 for REQ_TIMEOUT and 0x4 for TIMEOUT_BASE, implying 16,384 clock cycles.

A time-out condition is detected when the command acceptance or the response is not received after a delay of from one to three time-base periods.

Example:

- L4 frequency = 65-MHz, 15.3-μs period
- TIMEOUT_BASE = 4 in the L4_LA_NETWORK_CONTROL_L register
- REQ_TIMEOUT = 2 in the L4_TA_AGENT_CONTROL_L for TA A
- REQ_TIMEOUT = 4 in the L4_TA_AGENT_CONTROL_L for TA B

At agent A, the time-base unit is 16,384 cycles. A time-out is issued when a request to the attached module is not accepted, or no response is sent after a delay of 252 μs to 756 μs.

At agent B, the time-base unit is 262,144 cycles. A time-out is issued when a request to the attached module is not accepted or no response is sent after a delay of 4 ms to 12 ms.

When a time-out condition is detected, the TA logs the error in the L4_TA_AGENT_STATUS_L[8] REQ_TIMEOUT bit, and it also reports the error to the IA, which forwards it to the L3 interconnects.

After the time-out is detected and logged, the behavior of the attached module is ignored. A new request targeting the module arriving at the timed-out TA receives an error response. If the request is addressed to the agent internal registers, it is processed normally.

To recover from a time-out error, software is assumed to first reset the faulty module and then the TA using the L4_TA_AGENT_CONTROL_L[0] OCP_RESET bit.

14.3.3.4.3 Error Reporting

Figure 14-13 shows the error-reporting scheme used in the L4 interconnects. All L4 in-band errors are reported to their respective L3 TA, where errors are converted in an out-of band error signal (the L3 applicative and debug composite flags) going to the L3 INTCs.

Two levels of mask are present to report the error at INTC level:

- At the applicative and debug composite flag, to enable interrupt reporting, the following bits must be set:
  – L4_CFG in L3_FLAGMUX_MASK0 and L3_FLAGMUX_STATUS1
  – L4_PER in L3_FLAGMUX_MASK0 and L3_FLAGMUX_STATUS1
- At the L3 TA level, see Section 14.2.1, *L3 Interconnect*.

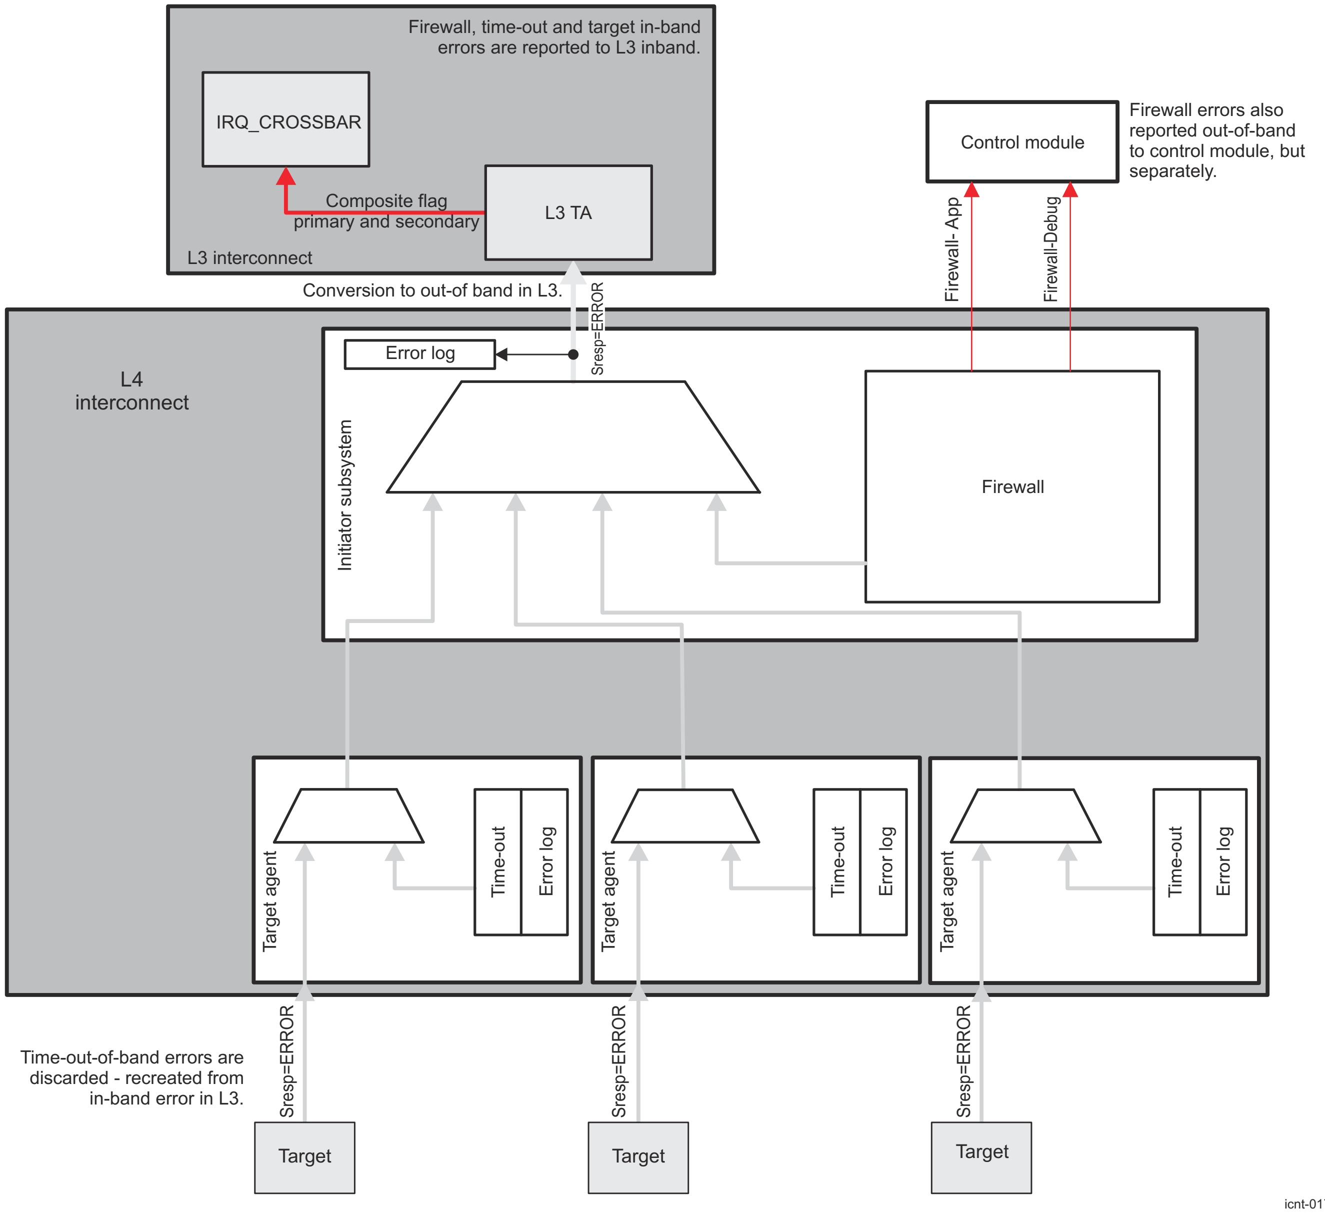

Figure 14-13. L4 Error Reporting

14.3.3.4.4 Error Recovery

Setting the L4_TA_AGENT_CONTROL_L[0] OCP_RESET bit to 1 initiates the software reset period. Software reset must be asserted for at least 16 cycles of the target module interface clock, which can be a divided clock with respect to the L4 clock.

During the software reset period:

- Requests sent to the target module receive error responses. Therefore, if the faulty request is part of a DMA transfer, it is necessary to stop the DMA to prevent unwanted errors.
- Requests sent to the TA register block are processed as usual.
- The L4_TA_AGENT_STATUS_L[8] REQ_TIMEOUT status bit is cleared.

Setting the L4_TA_AGENT_CONTROL_L[0] OCP_RESET bit to 0 terminates the software reset period.

Reset the attached module to complete the recovery.

14.3.3.4.5 Firewall Error Logging in the Control Module

When a protection violation occurs, an interrupt is send to the INTCs (if enabled). An in-band error is sent back to L3 IA and an out-of-band error can also be logged in the CONTROL.CONTROL_SEC_ERR_STATUS register in the SCM. These out-of-band errors are enabled and disabled at the L4 IA level by setting the L4_IA_AGENT_CONTROL_L[31][30] PROT_ERROR_SECONDARY_REP or PROT_ERROR_PRIMARY_REP bit to 1 for debug and application mode, respectively.

At the control module level, two logging registers are used, depending on the mode:

- In application mode or primary error reporting:
  - SEC_ERR_STATUS_FUNC_1[16] = L4_PER1 protection violation
  - SEC_ERR_STATUS_FUNC_2[4] = L4_PER2 protection violation
  - SEC_ERR_STATUS_FUNC_2[5] = L4_PER3 protection violation
  - SEC_ERR_STATUS_FUNC_1[17] = L4_CFG protection violation
  - SEC_ERR_STATUS_FUNC_1[22] = L4_WKUP protection violation
- In debug mode or secondary error reporting:
  - SEC_ERR_STATUS_DEBUG_1[16] = L4_PER1 protection violation
  - SEC_ERR_STATUS_DEBUG_2[4] = L4_PER2 protection violation
  - SEC_ERR_STATUS_DEBUG_2[5] = L4_PER3 protection violation
  - SEC_ERR_STATUS_DEBUG_1[17] = L4_CFG protection violation
  - SEC_ERR_STATUS_DEBUG_1[22] = L4_WKUP protection violation

Figure 14-14 shows the global protection error reporting to the control module.

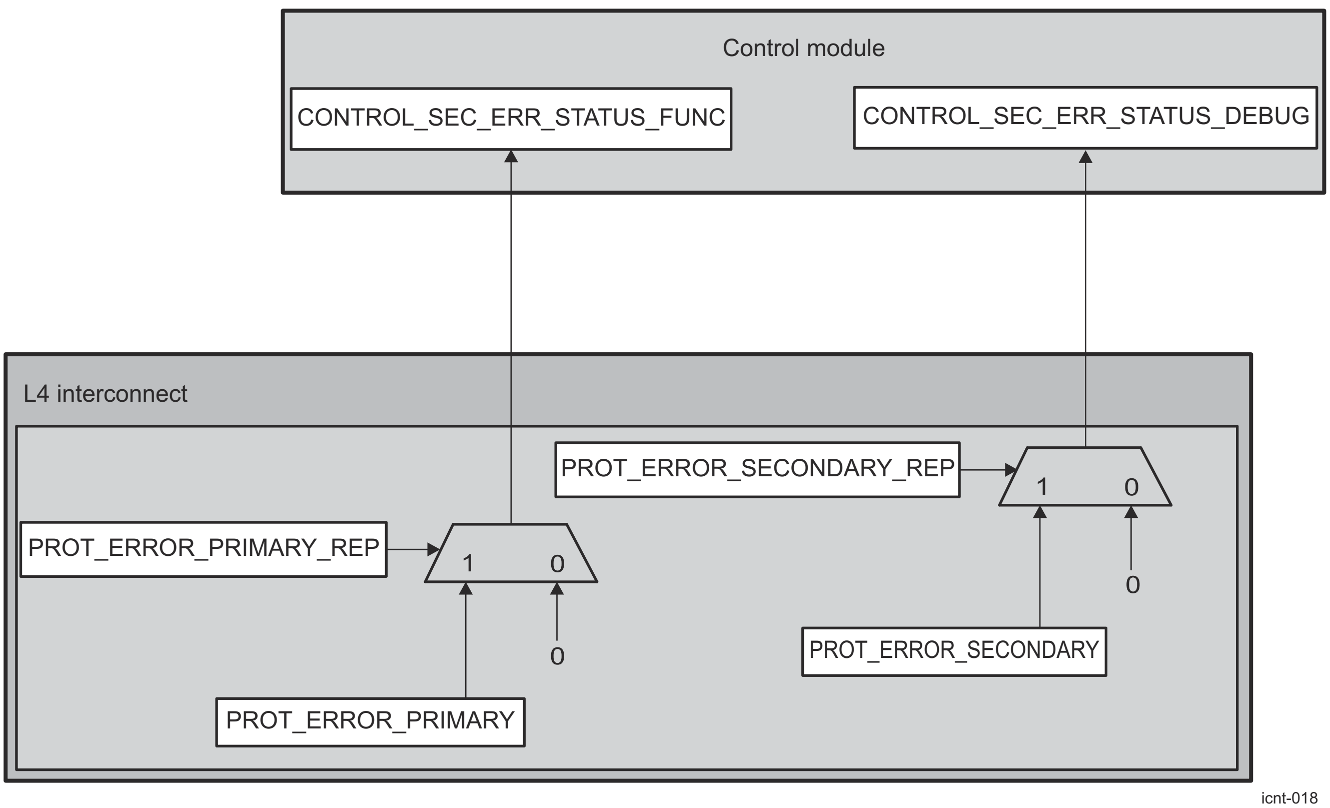

Figure 14-14. Protection Violation Out-of-Band Error Reporting

14.3.4 L4 Interconnect Programming Guide

14.3.4.1 L4 Interconnect Low-level Programming Models

This section describes the low-level hardware programming sequences for configuring and using the L4 interconnect module.

14.3.4.1.1 Global Initialization

14.3.4.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the L4 interconnect module is used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the L4 interconnect. For more information, see Section 14.3.2, *L4 Interconnect Integration*.

Table 14-403 lists the surrounding modules.

Table 14-403. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	For more information about the configuration of the module, see Section 3.6, in *Power, Reset, and Clock Management*.
Control module	For more information about the configuration of the module, see Chapter 18, *Control Module*.
Device INTCs	Device INTCs must be configured to enable the interrupt request generation. For more information see Chapter 17, *Interrupt Controllers*.
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see Section 18.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 18, *Control Module*.
L3 interconnect	For more information about the interconnect configuration, see Section 14.2.1, *L3 Interconnect*.

14.3.4.1.2 Operational Modes Configuration

14.3.4.1.2.1 L4 Interconnect Error Analysis Mode

14.3.4.1.2.1.1 Main Sequence: L4 Interconnect Error Analysis Mode

The information required to analyze an error source is logged in several registers. The number of registers to access depends on the error source.

Figure 14-15 shows the software sequence required in most cases.

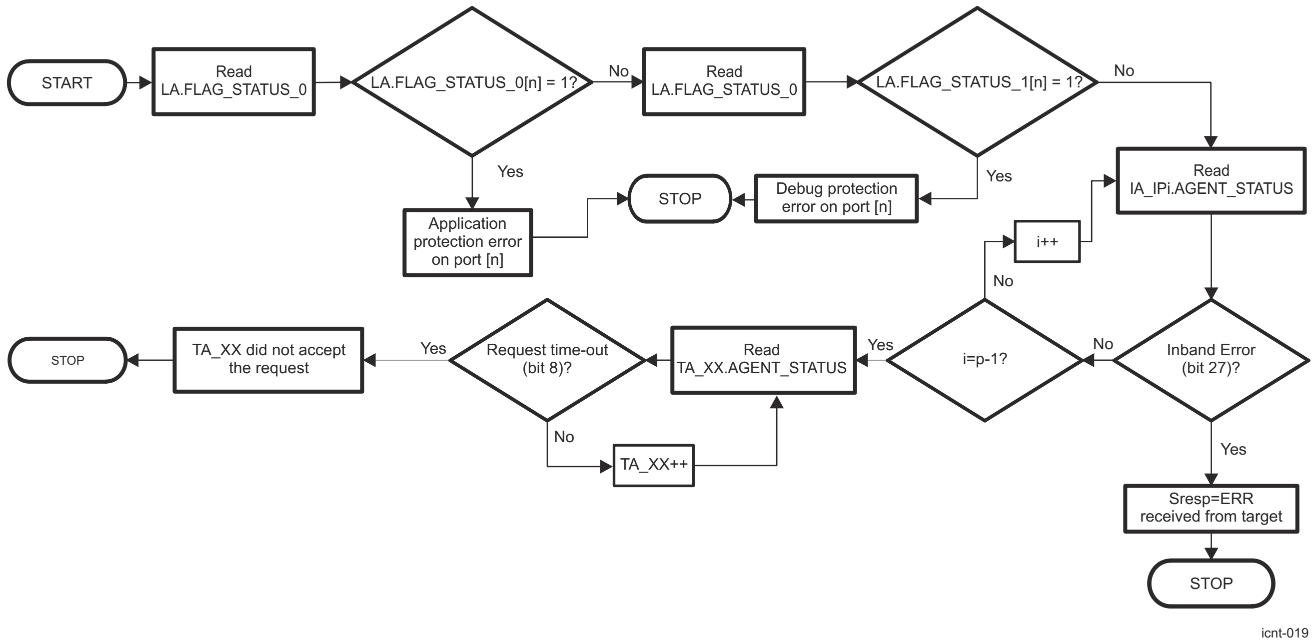

Figure 14-15. Typical Error Analysis Sequence

Note

L4 interconnects don't log any address or other specific information for a custom error returned from any target IP. They rather pass an error response up to the master supposed to analyze it.

In case of posted writes, the master access completes before it actually completed at the end slave level, this way no error response is sent back to the master, making it impossible to have a direct way of uderstanding the origin of L4 error during posted writes. However, even though no address is logged, an error flag is generated and needs to be processed.

14.3.4.1.2.1.2 Subsequence: L4 Interconnect Protection Violation Error Identification

This procedure describes the protection violation error identification (see Table 14-404).

Table 14-404. Protection Violation Error Identification

Step	Register/Bit Field/Programming Model	Value
Read multiple errors detection.	L4_IA_ERROR_LOG_L[31] MULTI	x
Read initiator ID.	L4_IA_ERROR_LOG_L[13:8] CONNID	xxxxx
Read command that cause the error.	L4_IA_ERROR_LOG_L[2:0] CMD	xxx
Read address of request that caused the error.	L4_IA_ERROR_LOG_ADDR_L[31:0] ADDR	xxxxxxxxx
IF: Is it a primary error?	L4_IA_AGENT_STATUS_L[30] PROT_ERROR_PRIMARY	=0x1
Read status bits.	CONTROL.CONTROL_SEC_ERR_STATUS_FUNC	xx
Write 1 to clear status bits.	CONTROL.SEC_ERR_STATUS_FUNC_1 [16][17][22] CONTROL.SEC_ERR_STATUS_FUNC_2 [4][5]	xxxx
Write 1 to clear IA status bit.	L4_IA_AGENT_STATUS_L[30] PROT_ERROR_PRIMARY	0x1
ELSE		
Read status bits.	CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG	xx
Write 1 to clear status bits.	CONTROL.SEC_ERR_STATUS_DEBUG_1 [16][17] [22] CONTROL.SEC_ERR_STATUS_DEBUG_2 [4][5]	xxx

Table 14-404. Protection Violation Error Identification (continued)

Step	Register/Bit Field/Programming Model	Value
Write 1 to clear IA status bit	L4_IA_AGENT_STATUS_L[31] PROT_ERROR_SECONDARY	0x1
ENDIF		
Write 1 to clear multiple errors detection.	L4_IA_ERROR_LOG_L[31] MULTI	0x1
Write 1 to clear in-band error status.	L4_IA_AGENT_STATUS_L[24] INBAND_ERROR	0x1

14.3.4.1.2.1.3 Subsequence: L4 Interconnect Unsupported Command/Address Hole Error Identification

This procedure describes the identification of unsupported command/address hole error (see Table 14-405).

Table 14-405. Unsupported Command/Address Hole Error Identification

Step	Register/Bit Field/Programming Model	Value
Read multiple errors detection.	L4_IA_ERROR_LOG_L[31] MULTI	x
Read initiator ID.	L4_IA_ERROR_LOG_L[11:8] CONNID	xxxx
Read command that caused the error.	L4_IA_ERROR_LOG_L[2:0] CMD	xxx
Read address of request that caused the error.	L4_IA_ERROR_LOG_ADDR_L[31:0] ADDR	xxxxxxxx
Read secondary status.	L4_IA_ERROR_LOG_L[30] SECONDARY	x
Write 1 to clear secondary status.	L4_IA_ERROR_LOG_L[30] SECONDARY	0x1
Write 1 to clear multiple errors detection.	L4_IA_ERROR_LOG_L[31] MULTI	0x1
Write 1 to clear inband error status.	L4_IA_AGENT_STATUS_L[24] INBAND_ERROR	0x1

14.3.4.1.2.1.4 Subsequence: L4 Interconnect Reset TA and Module

This procedure describes the reset TA and module (see Table 14-406).

Table 14-406. Reset TA and Module

Step	Register/Bit Field/Programming Model	Value
Reset TA.	L4_TA_AGENT_CONTROL_L[0] OCP_RESET	0x1
Wait until target module clock = 16 cycles.		
Write 0 to clear TA time-out status.	L4_TA_AGENT_CONTROL_L[10:8] REQ_TIMEOUT	0x0
Write 0 to clear TA reset.	L4_TA_AGENT_CONTROL_L[0] OCP_RESET	0x0
Reset the attached module.[(1)]		

(1) For more information, see the respective module chapter.

14.3.4.1.2.2 L4 Interconnect Time-Out Configuration Mode

14.3.4.1.2.2.1 Main Sequence: L4 Interconnect Time-Out Configuration Mode

This procedure describes the time-out configuration sequence (see Table 14-407).

Table 14-407. Time-Out Configuration

Step	Register/Bit Field/Programming Model	Value
Disable time-out.	L4_LA_NETWORK_CONTROL_L[10:8] TIMEOUT_BASE	0x0
Clear TA time-out error status.[(1)]	L4_TA_AGENT_STATUS_L[8] REQ_TIMEOUT	0x1
Set time-out at TA level.[(1)]	L4_TA_AGENT_CONTROL_L[10:8] REQ_TIMEOUT	xxx
Set time-out base.	L4_LA_NETWORK_CONTROL_L[10:8] TIMEOUT_BASE	xxx

(1) Required for each TA.

14.3.4.1.2.3 L4 Interconnect Firewall Configuration Mode

14.3.4.1.2.3.1 Main Sequence: L4 Interconnect Firewall Configuration Mode

This procedure describes the firewall configuration sequence (see Table 14-408).

Table 14-408. Firewall Configuration

Step	Register/Bit Field/Programming Model	Value
Define the members of protection group k.(1)	L4_AP_PROT_GROUP_MEMBERS_k_L[15:0] CONNID_BIT_VECTOR	xxx
Define the access type of a protection group k.(1)	L4_AP_PROT_GROUP_ROLES_k_L[15:0] ENABLE	xx
Set region affiliation to protection group.(2)	L4_AP_REGION_l_L[22:20] PROT_GROUP_ID	xxx

(1) Required for each protection group.
(2) Required for each region.

14.3.5 L4 Interconnects Register Manual

Table 14-409 through Table 14-413 list all L4 register blocks for IA, TA, AP, and LA. Each module instance is shown with the module register mapping and bit and bit field definitions.

14.3.5.1 L4 Interconnects Instance Summary

Physical Address	See Table 14-442 to Table 14-483	**Instance**	See Table 14-442 to Table 14-483
Description	Enable error reporting		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED							SERROR_REP	RESERVED											REQ_TIMEOUT			RESERVED									OCP_RESET

Bits	Field Name	Description	Type	Reset
31:25	RESERVED	Read returns 0.	R	0x00
24	SERROR_REP	Enable logging of error	R	0x0

Bits	Field Name	Description	Type	Reset
23:11	RESERVED	Read returns 0.	R	0x0
10:8	REQ_TIMEOUT	Time-out Bound. Values are: 0 - No time-out 1 - 1x base cycles. 2 - 4x base cycles. 3 - 16x base cycles. 4 - 64x base cycles.	RW	0x0
7:1	RESERVED	Read returns 0.	R	0x00
0	OCP_RESET	The OCP_RESET field controls the OCP reset signal to the attached core. Setting this bit clears any pending transfers and resets the OCP interface. The bit must be cleared to deassert the OCP reset signal. When the software reset feature is available on a target agent, the target agent OCP must also have a reset signal directed to the target core.	RW	0

Address Offset	0x0000 0024		
Physical Address	0x4800 0824 0x4840 0824 0x4880 0824 0x4A00 0824 0x4AE0 0824	**Instance**	PER1_LA PER2_LA PER3_LA CFG_LA WKUP_LA
Description	Control interconnect global power control		
Type	RW		

31:25	24	23:21	20	19:9	8	7:0
RESERVED	CLOCK_GATE_DISABLE	RESERVED	THREAD0_PRI	RESERVED	EXT_CLOCK	RESERVED

Bits	Field Name	Description	Type	Reset
31:25	RESERVED	Read returns 0.	R	0x00
24	CLOCK_GATE_DISABLE	When set to 1 this field disables all clock gating.	RW	0
23:21	RESERVED	Read returns 0.	R	0x0
20	THREAD0_PRI	Sets thread priority. If the field is set to 0, the default, all initiator threads are treated the same. Setting the THREAD0_PRI field to 1 assigns a higher arbitration priority to thread 0 of the first initiator OCP interface. To avoid starvation, arbitration is imposed by the initiator subsystem. When multiple requests from different initiator threads are dispatched to targets simultaneously, the oldest request is dispatched first. If thread 0 is assigned a higher priority, a request on thread 0 always wins arbitration. Assigning thread 0 of the first initiator OCP the highest priority on a request or response can result in the starvation of other threads.	R	1
19:9	RESERVED	Read returns 0.	R	0x000
8	EXT_CLOCK	Global external clock control. When set to 1, the ext_clk_off_i signal on the initiator subsystem instructs the entire L4 to shut off.	R	1
7:0	RESERVED	Read returns 0.	R	0x00

14.3.5.5.2 L4 Address Protection (L4 AP) Register Description

Table 14-531 through Table 14-556 describe the L4 AP registers.

Table 14-531. L4_AP_COMPONENT_L

Address Offset	0x000		
Physical Address	0x4800 0 000 0x4840 0 000 0x4880 0 000 0x4A00 0 000 0x4AE0 0 000	**Instance**	PER1_AP PER2_AP PER3_AP CFG_AP WKUP_AP
Description	Contains a component code and revision, which are used to identify the hardware of the component.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CODE																REV															

Bits	Field Name	Description	Type	Reset
31:16	CODE	Interconnect code	R	See (1).

Bits	Field Name	Description	Type	Reset
15:0	REV	Component revision code	R [2]	See [1].

(1) TI Internal Data
(2) For L4_PER1 and L4_WKUP, when k = 2 to 7 the access type of CONNID_BIT_VECTOR is RW.
For L4_PER2, L4_PER3 and L4_CFG, when k = 1 to 7 the access type of CONNID_BIT_VECTOR is RW.

Chapter 15

Memory Subsystem

This chapter introduces the memory subsystem of the device.

15.1 Memory Subsystem Overview 3212
15.2 Dynamic Memory Manager 3217
15.3 EMIF Controller 3303
15.4 General-Purpose Memory Controller 3446
15.5 Error Location Module 3582
15.6 On-Chip Memory (OCM) Subsystem 3605

15.1 Memory Subsystem Overview

Figure 15-1 shows a functional diagram of all memory subsystems in the device.

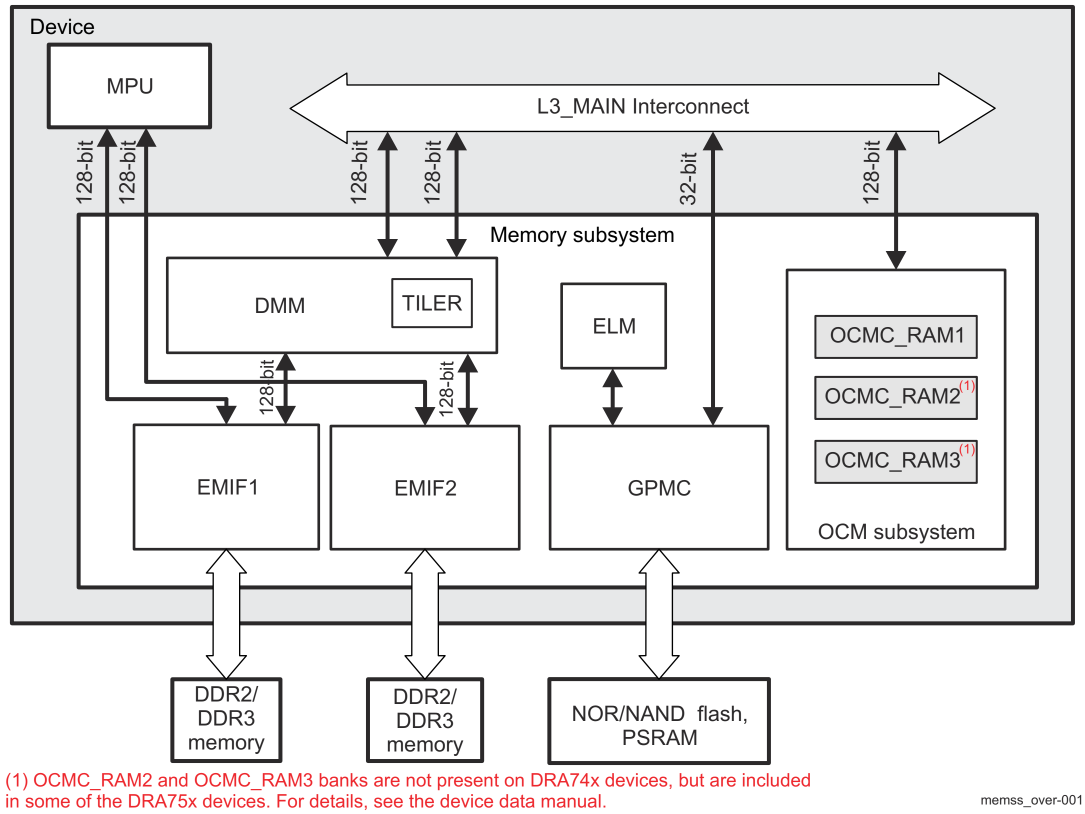

Figure 15-1. Memory Subsystem Functional Diagram

15.1.1 DMM Overview

The dynamic memory manager (DMM) module is typically located immediately in front of the SDRAM controllers (EMIFs), as shown in Figure 15-1, *Memory Subsystem Functional Diagram*.

In a broad sense, the DMM manages various aspects of memory accesses such as:

- Initiator-indexed priority generation
- Multizone SDRAM interleaving configuration
- Block object transfer optimization – tiling
- Centralized low-latency page translation – MMU-like feature

The dynamic qualifier for memory management highlights the software configurability, and hence the runtime nature, of the four aspects of memory management handled by the DMM.

From a functional perspective, the role of the DMM is to:

- Add initiator-based priority to any incoming requests
- Perform to/from tiling conversions of tiled requests
- Make on-the-fly basic transforms, such as quadrant rotations and mirroring
- Optionally, provide a low-latency page-based translation to handle memory fragmentation – MMU
- Distribute the traffic on all attached memory controllers according to the interleaving configuration

The main features of the DMM are:

- Programmable multizone DRAM mapping and interleaving configuration
- Programmable initiator-based request priority extension

- Multichannel memory transfer optimization
- Single SDRAM page request generation
- Low-latency interconnect port
- Page-grained address translation to manage memory fragmentation
- Automatic synchronized reloading of the address translation table

15.1.2 TILER Overview

The tiling and isometric lightweight engine for rotation (TILER) is a submodule of the DMM and is therefore described in Section 15.2, *Dynamic Memory Manager*.

The TILER is intended to improve bidimensional (tiled) block transfer efficiency. It is, therefore, a module aimed at:

- Primarily, efficient handling of 2-dimension (2D) data mapped in tiles, such as video or graphics macroblocks
- Optionally, managing the memory fragmentation and zero-copy physical frame-buffer swapping through a page-grained translation
- Making isometric (distance preserving) transforms, such as 90-, 180-, or 270-degree rotations, with a horizontal or vertical reflection

The lightweight qualifier of this engine highlights its limited support of isometric transforms, as:

- Rotation performs only basic quadrant rotations by some multiple of 90 degrees.
- Reflection is limited to horizontal and vertical flip.
- Translation is restricted to a 4-KiB page granularity.

Written differently, the functionality of the TILER is to map a 2D virtually addressed interconnect request into one or more physically addressed interconnect requests by:

- Transforming the virtual address, data, and byte-enable to match the requested 0-, 90-, 180-, or 270-degree orientation in a tiled 2D addressing space
- Optionally, translating the oriented tiled address by a page-specific vector to manage memory fragmentation and physical object aliasing

The main features of the TILER are:

- Efficiency improvement of 2D block access on SDRAMs
- Optimized interlaced access on tiled frames
- 2D virtual-to-physical address translation of SDRAM bidimensional objects to handle rotation
- Page-grained address translation to manage memory fragmentation and physical buffer aliasing
- Unlimited number of 2D tiled objects supported in any (0, 90, 180, or 270 degrees) orientation
- Full bandwidth use by minimizing the size of raster-based initiator buffers
- Optimization of multichannel memory transfers
- Interconnect request granularity balance (in X and Y directions)

15.1.3 EMIF Overview

The two external memory interface (EMIF) modules are typically located near the DMM module, as shown in Figure 15-1, *Memory Subsystem Functional Diagram*.

The EMIF module provides connectivity between DDR memory types and manages data bus read/write accesses between external memories and device subsystems which have master access to the L3_MAIN interconnect and DMA capability.

Each EMIF module has the following capabilities:

- Supports JEDEC standard-compliant DDR2-SDRAM and DDR3-SDRAM memory types
- 2-GiB SDRAM address range over one chip-select. This range is configurable through the dynamic memory manager (DMM) module
- Supports SDRAM devices with one, two, four or eight internal banks
- Supports SDRAM devices with single die (one chip select supported)
- Data bus widths:

  - 128-bit L3_MAIN (system) interconnect data bus width
  - 128-bit port for direct connection with MPU subsystem
  - 32-bit SDRAM data bus width
  - 16-bit SDRAM data bus width used in narrow mode
- Supported CAS latencies:
  - DDR3: 5, 6, 7, 8, 9, 10 and 11
  - DDR2: 2, 3, 4, 5, 6 and 7
- Supports 256-, 512-, 1024-, and 2048-word page sizes
- Supported burst length: 8
- Supports sequential burst type
- SDRAM auto initialization from reset or configuration change
- Supports self refresh and power-down modes for low power
- Partial array self-refresh mode for low power when DDR3 is used
- Output impedance (ZQ) calibration for DDR3
- Supports on-die termination (ODT) for DDR2 and DDR3
- Supports prioritized refresh
- Programmable SDRAM refresh rate and backlog counter
- Programmable SDRAM timing parameters
- Write and read leveling/calibration and data eye training for DDR3.
- ECC on the SDRAM data bus for EMIF1 only:
  - 7-bit ECC over 32-bit data
  - 6-bit ECC over 16-bit data when narrow mode is used
  - 1-bit error correction and 2-bit error detection
  - Programmable address ranges to define ECC protected region
  - ECC calculated and stored on all writes to ECC protected address region
  - ECC verified on all reads from ECC protected address region
  - Statistics for 1-bit ECC and 2-bit ECC errors
  - The total width of the ECC DDR data bus is 8 bits

The EMIF modules do not support:

- Burst chop for DDR3
- Interleave burst type
- Auto precharge because of better Bank Interleaving performance
- OCD calibration for DDR2
- CAS Read Latency of 2 and CAS Write Latency of 1 for DDR2
- DLL disabling from EMIF side
- SDRAM devices with more than one die, or topologies which require more than one chip select on a single EMIF channel

15.1.4 GPMC Overview

The General Purpose Memory Controller (GPMC) is an external memory controller of the device. Its data access engine provides a flexible programming model for communication with all standard memories.

The GPMC supports the following various access types:

- Asynchronous read/write access
- Asynchronous read page access (4, 8, and 16 Word16)
- Synchronous read/write access
- Synchronous read/write burst access without wrap capability (4, 8 and 16 Word16)
- Synchronous read/write burst access with wrap capability (4, 8 and 16 Word16)
- Address-data-multiplexed (AD) access
- Address-address-data (AAD) multiplexed access
- Little- and big-endian access

The GPMC can communicate with a wide range of external devices:

- External asynchronous or synchronous 8-bit wide memory or device (non burst device)
- External asynchronous or synchronous 16-bit wide memory or device
- External 16-bit non-multiplexed NOR flash device
- External 16-bit address and data multiplexed NOR Flash device
- External 8-bit and 16-bit NAND flash device
- External 16-bit pseudo-SRAM (pSRAM) device

The main features of the GPMC are:

- 8- or 16-bit-wide data path to external memory device
- Supports up to eight CS regions of programmable size and programmable base addresses in a total address space of 1 GiB
- Supports transactions controlled by a firewall
- On-the-fly error code detection using the Bose-ChaudhurI-Hocquenghem (BCH) (t = 4, 8, or 16) or Hamming code to improve the reliability of NAND with a minimum effect on software (NAND flash with 512-byte page size or greater)
- Fully pipelined operation for optimal memory bandwidth use
- The clock to the external memory is provided from GPMC functional clock divided by 1, 2, 3, or 4
- Supports programmable autoclock gating when no access is detected
- Independent and programmable control signal timing parameters for setup and hold time on a per-chip basis. Parameters are set according to the memory device timing parameters, with a timing granularity of one GPMC functional clock cycle.
- Flexible internal access time control (WAIT state) and flexible handshake mode using external WAIT pin monitoring
- Support bus keeping
- Support bus turnaround
- Prefetch and write posting engine associated with a device DMA controller to achieve full performance from the NAND device with minimum effect on NOR/SRAM concurrent access

Note

Page mode is available only in nonmultiplexed mode.

15.1.5 ELM Overview

In the case of NAND modules with no internal correction capability, sometimes referred to as bare NAND, the correction process can be delegated to the error location module (ELM) used in conjunction with the GPMC.

The ELM supports the following features:

- 4, 8, and 16 bits per 512-byte block error location based on BCH algorithm
- Eight simultaneous processing contexts
- Page-based and continuous modes
- Interrupt generation when error location process completes:
  – When the full page has been processed in page mode
  – For each syndrome polynomial (checksum-like information) in continuous mode

15.1.6 OCM Overview

The on-chip memory (OCM) subsystem consists of the following OCM controllers (OCMC):

- Up to three OCMC connected to an on-chip RAM. Presence of RAM banks is device part number dependent. Refer to device Data Manual for more information.

An OCM Controller supports the following features:

- L3_MAIN data interface:
  – Used for maximum throughput performance
  – 128-bit data bus width
  – Burst supported

- L4 interface:
  - Used for access to configuration registers
  - 32-bit data bus width
  - Only single accesses supported
  - The L4 associated OCMC clock is two times lower than the L3 associated OCMC clock
- Error correction and detection:
  - Single error correction and dual error detection
  - 9-bit Hamming error correction code (ECC) calculated on 128-bit data word which is concatenated with memory address bits
  - Hamming distance of 4
  - Enable/Disable mode control through a dedicated register
  - Single bit error correction on a read transaction
  - Exclusion of repeated addresses from correctable error address trace history
  - ECC valid for all write transactions to an enabled region
  - Sub-128-bit writes supported via read modify write
- ECC Error Status Reporting:
  - Trace history buffer (FIFO) with depth of 4 for corrected error address
  - Trace history buffer with depth of 4 for non correctable error address and also including double error detection
  - Interrupt generation for correctable and uncorrectable detected errors
- ECC Diagnostics Configuration:
  - Counters for single error correction (SEC), double error detection (DED) and address error events (AEE)
  - Programmable threshold registers for exceptions associated with SEC, DED and AEE counters
  - Register control for enabling and disabling of diagnostics
  - Configuration registers and ECC status accessible through L4 interconnect
- Circular buffer for sliced based VIP frame transfers:
  - Up to 12 programmable circular buffers mapped with unique virtual frame addresses
  - On the fly (with no additional latency) address translation from virtual to OCMC circular buffer memory space
  - Virtual frame size up to 8 MiB and circular buffer size up to 1 MiB
  - Error handling and reporting of illegal CBUF addressing
  - Underflow and Overflow status reporting and error handling
  - Last access read/write address history
- Two Interrupt outputs configured independently to service either ECC or CBUF interrupt events

The OCM controllers do not have a memory protection logic and do not support endianism conversion.

15.2 Dynamic Memory Manager

15.2.1 DMM Overview

The function of the dynamic memory manager (DMM) is to:

- Add initiator-based priority to any incoming requests
- Perform to-and-from tiling and subtiling conversions of tiled requests
- Make on-the-fly basic transforms, such as quadrant rotations and mirroring
- Optionally provide a low-latency page-based translation to handle memory fragmentation – memory management unit (MMU)
- Distribute the traffic on all attached memory controllers according to the interleaving configuration

The DMM is introduced also in Section 15.1.1, *DMM Overview* of Section 15.1, *Memory Subsystem Overview*.

The functions of the TILER are:

- Primary handling efficiently 2-dimensional (2D) data mapped in tiles, such as video or graphics macroblocks
- Optionally managing the memory fragmentation and zero-copy physical frame buffers swapping through a page-grained translation
- Allowing optimized interlaced accesses on tiled frames
- Making (distance preserving) transforms, such as 90-, 180-, or 270-degree rotations, with a horizontal or vertical reflection
- Interleaving the memory accesses among the two memory controllers (also called EMIF).

The TILER is also introduced in Section 15.1.2, *TILER Overview* of Section 15.1, *Memory Subsystem Overview*.

Figure 15-2 is an overview of the DMM and TILER in the device.

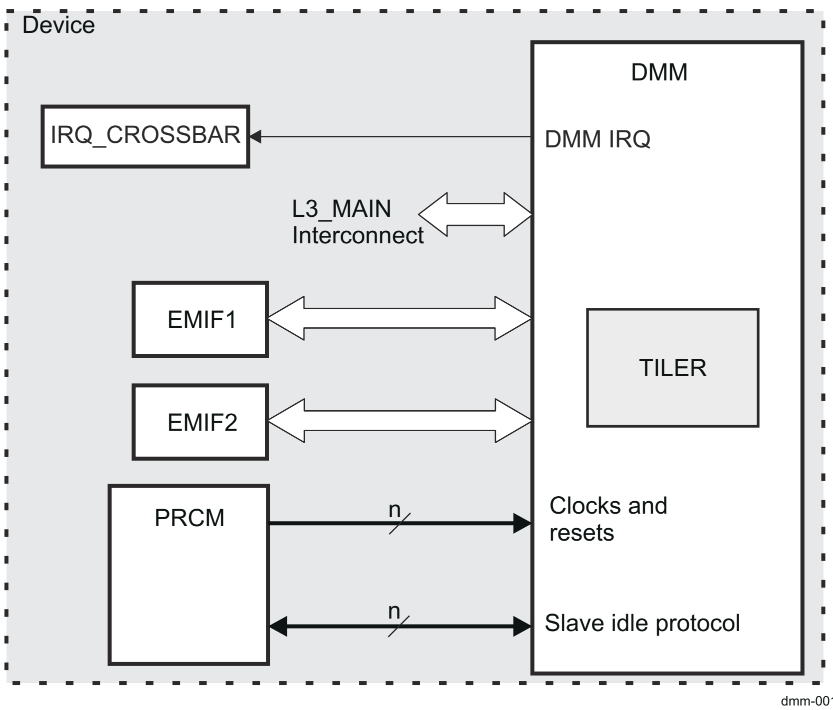

Figure 15-2. DMM and Tiler Overview

15.2.2 DMM Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

- Slave idle protocol (the DMM supports only smart-idle mode)

- No master standby protocol
- No wake-up request
- No system direct memory access (sDMA) requests
- One interrupt line for interrupt request (IRQ)
- One functional clock

Figure 15-3 shows the integration of DMM in the device.

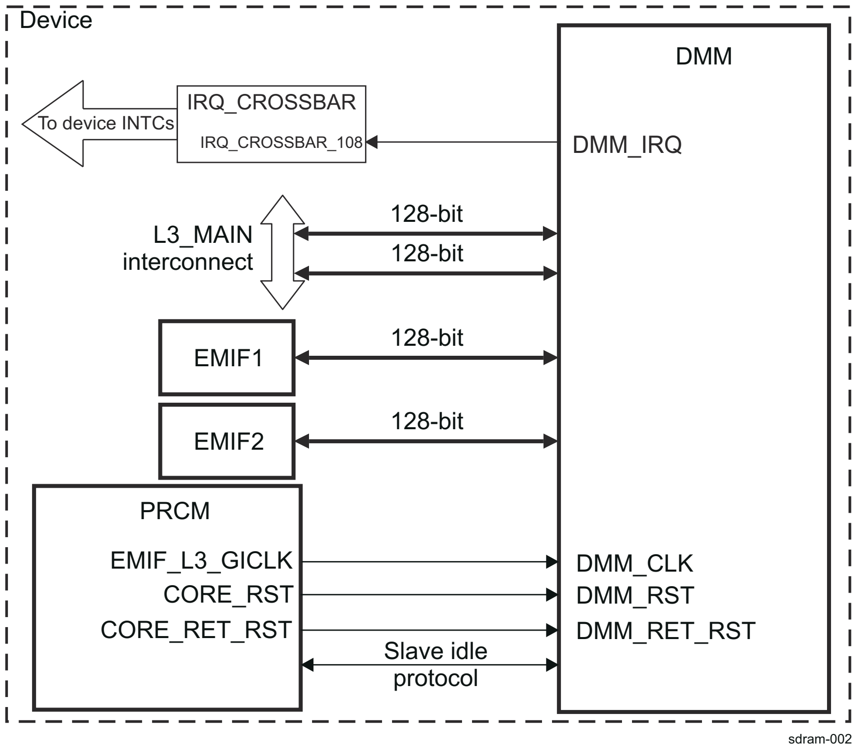

Figure 15-3. DMM Integration

Note

For more information about the slave idle protocol, see *Power, Reset, and Clock Management*.

Table 15-1 through Table 15-3 summarize the integration of DMM in the device.

Table 15-1. DMM Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
DMM	PD_COREAON	No	L3_MAIN

Table 15-2. DMM Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description

15.2.3 DMM Functional Description

15.2.3.1 DMM Block Diagram

shows the DMM macro architecture. The DMM consists of six blocks:

- Two TILERs, each with its own interconnect slave port for converting requests back and forth between the input virtual addressing mode and the output physical tiled addressing mode. The tiling conversions of requests, write data, and responses is performed entirely in the TILER blocks.
- Two reordering buffer and initiator nodes (ROBINs), each with its own interconnect master port to initiate requests to the SDRC and allow tiled data, tiled response, and split response reconstruction. The ROBIN block manages only the reordering buffer and performs data reordering due to the orientation.
- A physical address translator (PAT) for managing the memory fragmentation
- A priority extension generator (PEG) to generate priorities required by the SDRC; these priorities are not used in the DMM.
- A local interconnect and synchronization agent (LISA) to synchronize all DMM subsystems and provide access to their configuration registers

Figure 15-4 is a block diagram of the DMM.

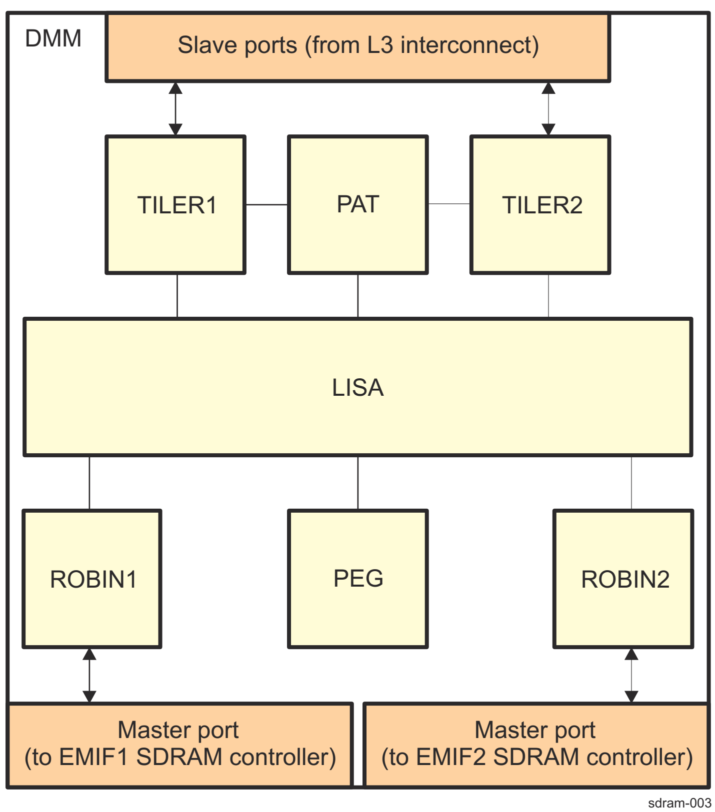

Figure 15-4. DMM Block Diagram

CAUTION

The interconnect must ensure that virtually addressed requests target only a TILER port.

15.2.3.2 DMM Clock Configuration

Table 15-5 describes the DMM clocks.

Table 15-5. DMM Clocks

Signal	I/O(1)	Description
DMM_CLK	I	Functional and interface clock

(1) I = Input; O = Output

The DMM is concerned with SDRC management and is in the MEMIF clock domain among the SDRCs. The DMM is a fully synchronous module, which uses the clock and clock-enable signals provided in the MEMIF clock domain to generate its interface and functional clocks.

To configure DMM_CLK control and settings, see Table 15-2.

15.2.3.3 DMM Power Management

DMM power is supplied by the CORE power domain, and DMM power management complies with system power-management guidelines.

Table 15-6 describes the power-management features available for the DMM module.

Table 15-6. DMM Local Power-Management Features

Feature	Registers	Description
Slave idle modes	DMM_SYSCONFIG[3:2] SIDLEMODE bit field	Only smart-idle wake-up mode is available.

Some of the DMM module registers are affected by the save-and-restore (SAR) mechanism. For more information about SAR, see *Power, Reset, and Clock Management*.

15.2.3.4 DMM Interrupt Requests

Errors in PAT area refill registers are reported through the DMM_PAT_STATUS_i[15:10] ERROR bit field (see Table 15-7).

Table 15-7. DMM Hardware Status Features

Feature	Type	Register	Description
PAT error flags	Read-only	DMM_PAT_STATUS_i[15:10] ERROR (where i = 0 to 3)	Unexpected update of the PAT area refill registers

Table 15-8 lists the event flags, and their masks, that can cause module interrupts.

Table 15-8. Events

Interrupt	Event Flag	Event Mask
ERR_LUT_MISS3	DMM_PAT_IRQSTATUS[31] ERR_LUT_MISS3 DMM_PAT_IRQSTATUS_RAW[31] ERR_LUT_MISS3	DMM_PAT_IRQENABLE_SET[31] ERR_LUT_MISS3 DMM_PAT_IRQENABLE_CLR[31] ERR_LUT_MISS3

15.2.3.5 DMM

15.2.3.5.1 DMM Concepts

The DMM introduces the concepts of dynamic mapping and DMM atomic units.

15.2.3.5.1.1 Dynamic Mapping

The DMM manages its internal memory space as an ordered set of up to four sections. Figure 15-5 shows the DMM sections and memory mapping.

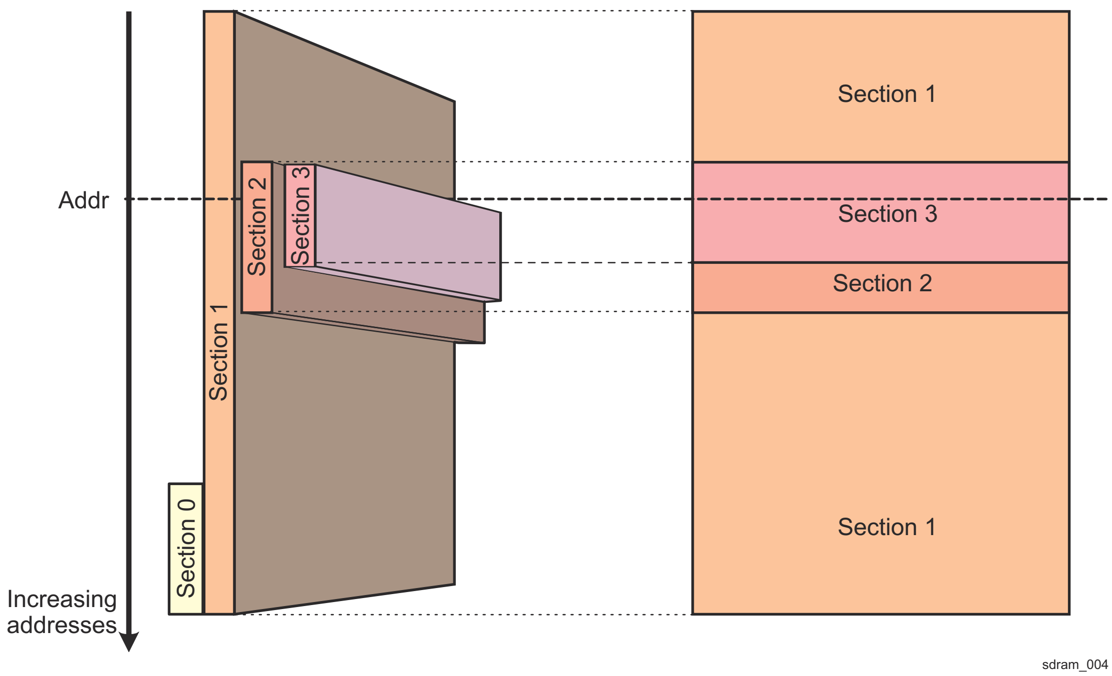

Figure 15-5. DMM Sections and Memory Mapping

In the DMM, a section is:

- A segment of 16MiB to 2GiB, which is power-of-two in size and aligned to that size in the system map
- An area with a constant interleaving scheme: constant interleaving granularity on a constant set of SDRC (EMIF) targets
- Given a priority equal to its index: the higher the index, the higher the priority

Note

Whenever a request hits more than one DMM section, it follows the interleaving scheme of the section having the highest index.

The interleaving configuration of the DMM, its section-based dynamic memory mapping, is shown on the right in Figure 15-5. In this example, a request at the system address Addr follows the interleaving scheme of section 3, although it hits sections 1, 2, and 3. Similarly, the DMM configuration given in this example prevents any request from using the interleaving scheme of section 0, because section 0 is fully masked by section 1, which has a higher priority.

Each of the four sections is configured through a DMM_LISA_MAP_i register, where i = 0 to 3.

Note

The DMM and EMIF registers (see *EMIF Controller*) are declared in two extra static DMM sections of the highest priority so that they cannot be masked by any standard programmable DMM section.

Note

The DMM atomic size is:

- 1KiB in noninterleaved sections
- Equal to the interleaving granularity (128, 256, or 512 bytes) in interleaved sections

15.2.3.5.1.2 Address Mapping

The address mapping inside the DMM is configurable through up to four sections. A DMM section description fits in a single register (DMM_LISA_MAP_i). Each section is defined based on:

- Its system address: The base address of the decoding range for the section
- Its size: The encoding is the number of bits used in the upper 8 bits of the incoming system address
- Its physical address: The base address of the memory range access in the external memory controller
- Its address space: The address space used on the external memory controller (for the DMM) when hitting this section. For details, see *Local Interface* in *EMIF Controller*.
- The target memory controller. A section may hit a single or pair of controllers.
- Its interleaving definition

The address decoding is priority-based. In case of overlapping sections, only the highest-order one is hit. Register memory spaces have priority over regular memory sections. In case of four sections, the priority order is therefore:

1. Registers
2. DMM_LISA_MAP_3
3. DMM_LISA_MAP_2
4. DMM_LISA_MAP_1
5. DMM_LISA_MAP_0

All register-related addresses are reserved and fixed in the overall address mapping:

- DMM registers: 0x4E00_0000 to 0x4FFF_FFFF
- EMIF1 registers: 0x4C00_0000 to 0x4CFF_FFFF
- EMIF2 registers: 0x4D00_0000 to 0x4DFF_FFFF

There is no overlapping between register sections.

Note

Section decoding happens after PAT address translation in the case of TILER. In non-bypass mode, the system address considered for TILER accesses is the virtual address computed based on the PAT translation tables.

The DMM_LISA_LOCK register is used to lock the configuration once set. If written to 1, the LOCK bit prevents further writes to all DMM_LISA_MAP_i registers. The LOCK bit cannot be written back to 0. A reset is required to reprogram the sections.

15.2.3.5.1.3 Address Translation

The PAT engine of the DMM is composed of a 32-k entry physical address translation vector table and one or two refill engines. The refill engine is a specialized DMA for refilling the content of the PAT table.

The address translation mechanism is available only when the incoming request hits a page mode or tiled mode container; that is, when the incoming address targets the TILER or its aliased view in the system addressing space. Otherwise, the PAT logic is bypassed so that the resulting physical address corresponds to the input address.

The PAT engine supports multiple address translation schemes, called views, which can be bound to one or more initiators through a view mapping mechanism.

15.2.3.5.1.3.1 PAT View Mappings

The PAT engine can have up to 16 groups of initiators that share a set of four PAT views. The connection from an initiator to a PAT view is made through the DMM_PAT_VIEW register. Given that each PAT view index is coded on 4 bits, the DMM_PAT_VIEW register is a 64-bit register split into two 32-bit registers (DMM_PAT_VIEW0 for the first eight PAT view indexes and DMM_PAT_VIEW1 for the last eight PAT view indexes.

The PAT view index that corresponds to the initiator having the value i as the 4 most-significant bits (MSBs) of its L3 ConnID uses the view referenced in entry i of the DMM_PAT_VIEW. For example, the initiator 0xC7 uses the thirteenth view index of the DMM_PAT_VIEW register, the fifth view index in the DMM_PAT_VIEW1 register.

The PAT view index of the initiator i is found in the Vi field. The Wi field is aimed at writing the corresponding Vi. When writing to the DMM_PAT_VIEW registers, the only Vi view indexes that are updated are those having their corresponding Wi bit, and byte enable, set. The Wi bits are always read as 0. For instance, to set the PAT view indexes V3 and V7 to 2 and 1, respectively, the DMM_PAT_VIEW0 register must be written with 5000 6000h.

15.2.3.5.1.3.2 PAT View Map Base Address

The PAT view map base address defines the base address of all PAT translated addresses.

Bit [31] of all PAT translated addresses is set to BASE_ADDR. For example, if the DMM_PAT_VIEW_MAP_BASE register is set to 8000 0000h, all PAT translated addresses will have bit [31] set to 1 so that the translated addresses range from 8000 0000h to FFFF FFFFh. All reserved bits of this DMM PAT base address register are read to 0.

15.2.3.5.1.3.3 PAT Views

A PAT view defines the kind of physical address translation to perform for each mode accesses (page, 8-bit, 16-bit and 32-bit). Each mode of each PAT view can be configured to use a container-grained translation or page-mode translation.

15.2.3.5.1.3.3.1 PAT Direct Access Translation

The container-grained translation is named the direct access. In this mode, the translation vector is given directly by the CONT_x bit field that corresponds to the accessed mode.

- A page mode access uses the vector contained in the DMM_PAT_VIEW_MAP_i[26:24] CONT_PAGE bit field concatenated with 1 (bit 27 of translated address).
- A 32-bit mode access uses the vector contained in the DMM_PAT_VIEW_MAP_i[18:16] CONT_32 bit field concatenated with 0 (bit 27 of translated address).
- A 16-bit mode access uses the vector contained in the DMM_PAT_VIEW_MAP_i[10:8] CONT_16 bit field concatenated with 0 (bit 27 of translated address).
- An 8-bit mode access uses the vector contained in the DMM_PAT_VIEW_MAP_i[2:0] CONT_8 bit field concatenated with 0 (bit 27 of translated address).

Figure 15-6, *PAT Direct Access Translation* describes PAT direct access translation .

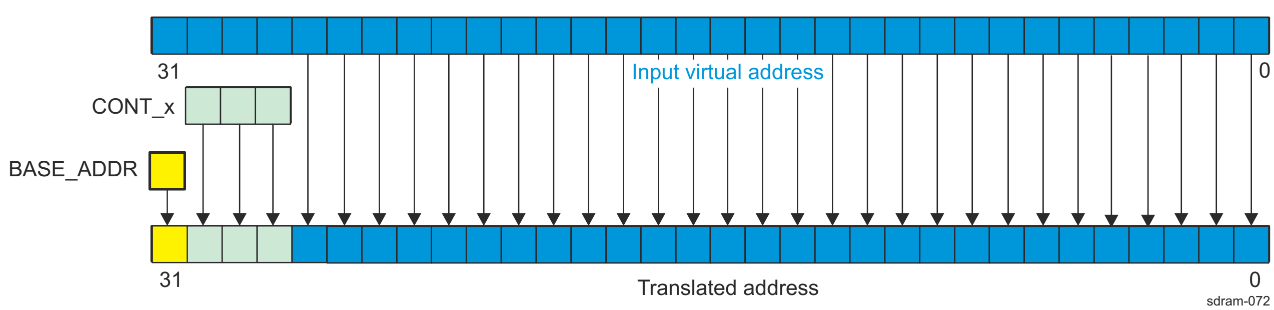

Figure 15-6. PAT Direct Access Translation

15.2.3.5.1.3.3.2 PAT Indirect Access Translation

The page-grained translation is named the indirect access. In this mode the translation vector is found in the internal 32-k entry physical address translation vector table at the index given by bits [26:12] of the input virtual address, and the DMM_PAT_VIEW_MAP_i CONT_x bit field references the internal physical address translation table to use. Because the DMM uses only one such table, in this mode the CONT_x bit field must be written as 0. See Figure 15-7.

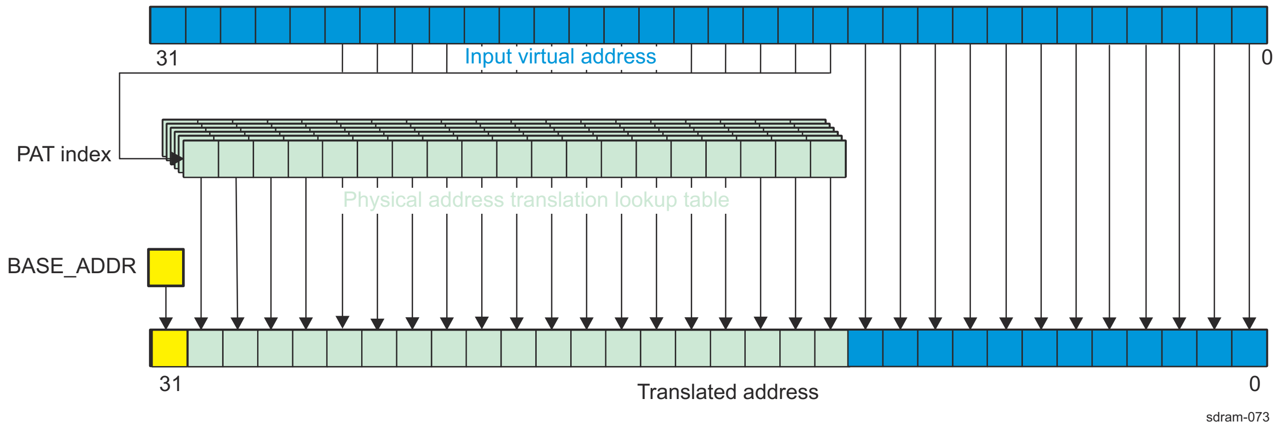

Figure 15-7. PAT Indirect Access Translation

Each entry of the PAT lookup table (LUT) is a 19-bit vector that replaces bits [30:12] of the input virtual address. The PAT index aimed at selecting the vector in the table consists of bits [26:12] of the input virtual address.

The mode associated to the transaction is used to define if the upper or lower half of the LUT is effectively used:

- If the mode is 8-, 16- or 32-bit, the lower part of the LUT (indexes 0x0000 to 0x7FFF; that is, lines 0 to 127) is used.
- If the mode is page, the upper part of the LUT (indexes 0x8000 to 0xFFFF; that is, ines 128 to 256) is used.

This means the PAT index used is the concatenation of 0 and address bits 12 to 26 in 8-, 16- or 32-bit mode, and the concatenation of 1 and address bits 12 to 26 in page mode.

Using different LUT indexes depending on the mode enables the user to define a larger tiled space, with the constraint that half of the space can be used only in 8-, 16- or 32-bit mode and the other half only in page mode. If the user wishes to preserve software compatibility with the case CONT_HGHT = 128, it is required to mirror the configuration for the lower half of the LUT on the upper half of the LUT. In that way, all views see the same address decoding through PAT.

15.2.3.5.1.3.3.3 PAT View Configuration

There are four different views in a DMM, each with its own DMM_PAT_VIEW_MAP_i register for defining the kind of address translation to perform.

The PAT view type of each mode is selected by the ACCESS_x bit field in the DMM_PAT_VIEW_MAP_i register, i being the index of the considered view. When this field is set to 1, the indirect access scheme is used; otherwise, the PAT performs the address translation in a direct way with the corresponding CONT_x vector.

When configuring a mode in a view to use the indirect access, the corresponding CONT_x bit field must be filled with 0.

15.2.3.5.1.3.3.4 PAT Address Translation LUT

The PAT LUT does not have the same geometry as the DMM container. The PAT LUT has 256 lines of 256 entries of 19 bits each. The geometry of the DMM container is 256 × 128 entries.

- The lower 128MiB are restricted for use with 8-, 16-, and 32-bit modes.
- The upper 128MiB are restricted for use with page mode.

See Figure 15-8.

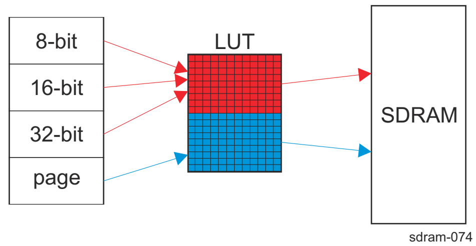

Figure 15-8. Physical Address Translation Table

15.2.3.5.1.3.3.5 Direct Access to the PAT Table Vectors

The PAT table is typically refilled with specialized DMA called refill engines. Some direct read and write access to the content of this table is granted when disabling the use of one or the other refill engine by writing 1 in the MODEi field of the DMM_PAT_CONFIG register that corresponds to the refill engine i to disable.

In this mode, often called the debug mode, the data read in or written to the DMM_PAT_DATA_i register corresponds to the vector in the PAT table, whose index is in the X0 and Y0 fields of the DMM_PAT_AREA_i register.

15.2.3.5.1.3.3.6 Automatic Refill Through the Refill Engines

See Section 15.2.4.1, *PAT Use Cases*.

15.2.3.5.2 DMM Transaction Flows

15.2.3.5.2.1 Nontiled Transaction Flow

Each nontiled interconnect transaction that reaches the DMM on a TILER port is subject to the same processing.

The TILER blocks consider separated request, data, and response paths. An overview of each path follows and more detailed information is in Section 15.2.3.5.3, *DMM Internal Macro-Architecture*.

On the request path, the flow consists of:

- Allocating a TILER response context for the timely generation of the appropriate responses
- Splitting 2D requests in a collection of 1D requests – TILER ports
- Splitting requests at DMM unit boundaries; the split granularity is provided by the LISA mapping registers
- Allocating an available buffer in the appropriate ROBIN, for both read and write requests
- In case of a write request, allocating and updating a TILER write context to direct the incoming write data into the relevant reordering buffer
- Generating the initiator-indexed priority extension by use of the PEG block

On the write data path, the flow consists of forwarding incoming data to the relevant reordering buffer in accordance with the corresponding TILER write context.

On the response path, responses are returned when:

- At least one response has entered each related buffer, in case of read requests.
- All related responses have returned from the SDRC, in case of write requests.
- No other previous pending response with the same tag exists.

15.2.3.5.2.2 Tiled Transaction Flow

Similarly, each tiled interconnect transaction that reaches the DMM is subject to the same processing.

The TILER blocks consider separated request, data, and response paths. An overview of each path follows, and more detailed information is in Section 15.2.3.5.3, *DMM Internal Macro-Architecture*.

On the request path, the processing phase consists of:

- Decoding the address to qualify whether the request targets the TILER or the memory directly
- Transforming TILER-specific requests to their natural representation; the address, width, and height are modified accordingly

On the request path, the generation phase consists of:

- Allocating a TILER response context for the timely generation of the appropriate responses
- Splitting malformed: The request stride differs from the container stride and from the double of this container stride – tiled 2D requests in a collection of 1D requests
- Splitting tiled requests at tile boundaries
- Performing the page-based address translation by use of the PAT block
- Allocating an available buffer in the appropriate ROBIN, for read and write requests
- In case of a write request, allocating and updating a TILER write context to direct the incoming write data into the relevant reordering buffer
- Generating the initiator-indexed priority extension by use of the PEG block

On the data path, any incoming data is transformed in accordance with the corresponding TILER write context and sent to the appropriate reordering buffer.

On the response path, responses are returned when:

- A minimal number of responses have entered the corresponding buffers, in case of read requests.
- All related responses have returned from the SDRCs, in case of write requests.
- No other previous pending response with the same tag exists.

15.2.3.5.3 DMM Internal Macro-Architecture

This section describes the DMM internal macro-architecture, specifically:

- Input request decoding
- PAT and synchronized translation table reloading
- Output request and response generation
- Memory mapping in the system addressing space, including interleaving
- Tag management
- Priority handling
- Contexts
- Maximum allowed burst size
- Reconstruction buffer dimensioning

15.2.3.5.3.1 LISA Description

The LISA is a full crossbar aimed at setting priorities, managing tags, and mapping memory.

The interconnect routes are:

- TILER requests on the ROBIN initiator nodes
- TILER write data on the ROBIN write buffers
- ROBIN read data to the relevant TILER initiators

The LISA block registers are DMM_LISA_MAP_i (where i = 0 to 3) and DMM_LISA_LOCK.

When two ROBINs are in use, the two ports are interleaved at a programmable boundary from 128 bytes or more (configurable with the DMM_LISA_MAP_i[19:18] SDRC_INTL bit field).

15.2.3.5.3.2 PAT Description

The PAT block maps physical pages to each TILER container page. The internal address translation memories used in the PAT block are designed with RFFs. It consists of:

- A memory-based LUT which has the same geometry as the container pages
- A refill engine for modifying entries in a given area of the internal LUT

A PAT descriptor is a singly-linked list node (see Figure 15-9) that contains:

- A description of the LUT area to reload
- A description of how to reload the defined LUT area
- A pointer to the location where the corresponding LUT entries are stored

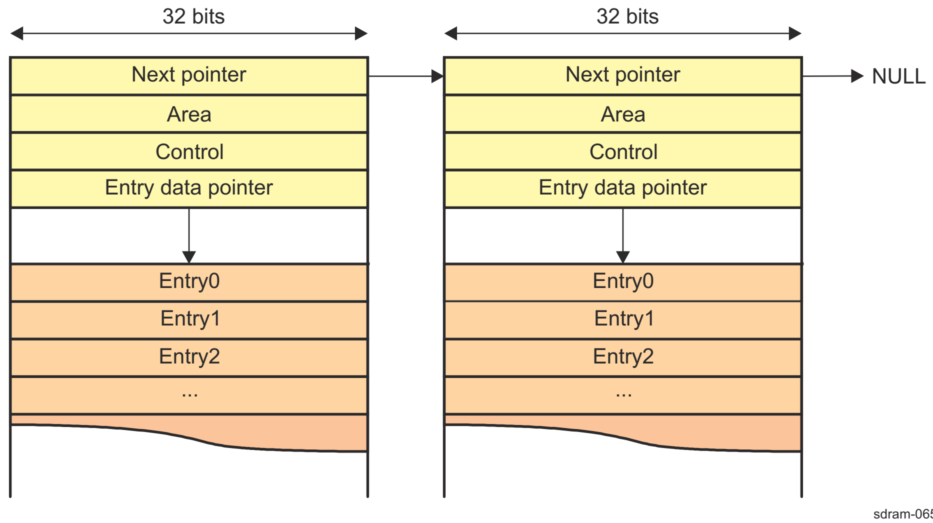

Figure 15-9. PAT Descriptors

PAT descriptors are chained and processed until a NULL pointer is encountered. The PAT bank allocation scheme allows the updating of four consecutive entries of a line in a single cycle regardless of the refilling orientation.

The PAT descriptor structure directly maps the following registers (where i = 0 to 3):

- DMM_PAT_DESCR_i
- DMM_PAT_AREA_i
- DMM_PAT_CTRL_i
- DMM_PAT_DATA_i

The PAT refill engine can be started either of the following:

- Filling manually all the necessary registers:
  – DMM_PAT_AREA_i with the (x0, y0) (x1, y1) area definition
  – DMM_PAT_DATA_i with the physical address of the corresponding area entry table
  – DMM_PAT_CTRL_i[6:4] DIRECTION bit field with the relevant (S, Y, X) direction of the area refill
  – DMM_PAT_CTRL_i[0] START bit with 1
- Writing the physical address of a memory-mapped PAT descriptor in DMM_PAT_DESCR_i register, which updates:
  – DMM_PAT_AREA_i with the area value of the descriptor
  – DMM_PAT_DATA_i with the data value of the descriptor
  – DMM_PAT_CTRL_i with the control value of the descriptor
  – DMM_PAT_DESCR_i with the next value of the descriptor

The data part of the PAT refill starts only when the DMM_PAT_CTRL_i[0] START bit is asserted.

The DMM_PAT_STATUS_i register can be used to determine whether the process has completed without errors.

15.2.3.5.3.3 PEG Description

The PEG is a dynamic software-programmable, initiator-indexed table of priorities. Its unique role is to bind a priority to an initiator on the fly. The mapping of each initiator to the table (split into eight registers) is based on its 6-MSB group ConnID (see *L3_MAIN Connectivity Matrix*, in *Interconnect*).

When an interconnect request enters the DMM, its priority is extracted from the PEG LUT.

The 64 priority entries are software-programmable with the DMM_PEG_PRIO_k register. A priority of 0 defines the highest priority and a priority of 7 defines the lowest priority. At reset, all priorities are set to 4.

These registers are each split into eight 4-bit fields, each field mapping an entry of the LUT with:

- The 3-bit priority coded on the 3 least-significant bits (LSBs): P field
- A $\overline{W}$ field-specific active-low local write enable bit, always read as 0, on the MSB. The role of the $\overline{W}$ bit is to allow the modification of a single entry without requiring a read-modify-write sequence. Because its $\overline{W}$ bits are always read as 0, writing back the modified register updates all priority fields of the register.

Table 15-9 lists the initiator ConnIDs that are mapped to PEG priority register fields (P/W).

Table 15-9. ConnIDs vs PEG Priority Register Fields

Registers	P0/W0	P1/W1	P2/W2	P3/W3	P4/W4	P5/W5	P6/W6	P7/W7
DMM_PEG_PRIO_0	0	1	2	3	4	5	6	7
DMM_PEG_PRIO_1	8	9	10(0xA)	11(0xB)	12(0xC)	13(0xD)	14(0xE)	15(0xF)
DMM_PEG_PRIO_2	16(0x10)	17(0x11)	18(0x12)	19(0x13)	20(0x14)	21(0x15)	22(0x16)	23(0x17)
DMM_PEG_PRIO_3	24(0x18)	25(0x19)	26(0x1A)	27(0x1B)	28(0x1C)	29(0x1D)	30(0x1E)	31(0x1F)
DMM_PEG_PRIO_4	32(0x20)	33(0x21)	34(0x22)	35(0x23)	36(0x24)	37(0x25)	38(0x26)	39(0x27)
DMM_PEG_PRIO_5	40(0x28)	41(0x29)	42(0x2A)	43(0x2B)	44(0x2C)	45(0x2D)	46(0x2E)	47(0x2F)
DMM_PEG_PRIO_6	48(0x30)	49(0x31)	50(0x32)	51(0x33)	52(0x34)	53(0x35)	54(0x36)	55(0x37)
DMM_PEG_PRIO_7	56(0x38)	57(0x39)	58(0x3A)	59(0x3B)	60(0x3C)	61(0x3D)	62(0x3E)	63(0x3F)

Although this priority information is generated before entering the LISA block, it is not used internally in the local interconnect arbitration but is forwarded to the EMIF as MReqInfo, where it indicates the command priority.

It is also possible to give a priority for the internal PAT engine through the DMM_PEG_PRIO_PAT register.

15.2.3.5.3.4 LISA Interconnect Arbitration

When Mflag[i][63:0] ≠ 0 is signaled at TILERi or both TILERs, the transactions of TILERi or both TILERs form an additional new group called the high priority group. Within this group, reads and writes are sorted and arbitrated the same way as in the normal priority group. Arbitration between transactions out of the high priority group and out of the normal priority group is based on a weighted round-robin algorithm. Weight is software selectable using the DMM_EMERGENCY[20:16] WEIGHT bit field. Weight selection is considered static (that is, behavior is undefined when software changes the weight, and DMM is not empty of transaction).

The counter that is implemented to support the weighted round-robin is enabled as long as emergency signaling is present. The counter increments by one each time a command (from the normal or the high priority group) is pushed to ROBIN. The counter wraps on DMM_EMERGENCY[20:16] WEIGHT value. One command from the normal priority group is serviced in any of the following scenarios:

- The counter is enabled and wraps.
- The counter is enabled, has not reached its wrap value, and no command is queued in the high priority group (a case where one device module is signaling emergency but its requests have not yet reached the TILERs).
- The counter is disabled.

Setting the DMM_EMERGENCY[0] ENABLE bit to 1 enables the emergency arbitration scheme.

Note

It is recommended to set the DMM_EMERGENCY[0] ENABLE bit to 1, and the DMM_EMERGENCY[20:16] WEIGHT bit to 0x8. This provides better and faster recovery behavior, and benefits system performance.

15.2.3.5.3.5 ROBIN Description

The ROBIN is a block that provides some working buffering for converting data and responses to-and-from between raster and tiled organizations, and a master port to connect to the EMIF.

The ROBIN block:

- Forwards requests
- Writes data and buffers responses

- Keeps write data ordering
- Performs intraword tiling and orientation transforms
- Handles tags

15.2.3.5.3.6 TILER Description

The main function of the TILER is request conversion caused by tiling .

The TILER block:

- Decodes the address to qualify whether the request targets the TILER or the memory directly
- Converts TILER-specific requests to their natural representation; address, width, and height are modified accordingly
- Allocates an internal response context for the timely generation of appropriate responses
- Splits tiled requests at tile boundaries and not-tiled requests at DMM atomic section boundaries
- Requests the page-based address translation
- Requests buffer allocation in the appropriate ROBIN
- In case of a write request, allocates and updates an internal write context to direct the incoming write data into the relevant reordering buffer

The interdependent tiling and isometric transform concepts introduced in the TILER are described in the following section.

15.2.3.6 TILER

15.2.3.6.1 TILER Concepts

This section describes the concepts behind the TILER transforms, through a top-down approach starting from the main object container.

15.2.3.6.1.1 TILER Rationale

This section is a synthesis of all TILER concepts, giving one rule per TILER structure level.

Figure 15-10 shows the TILER address space structure for tiled modes.

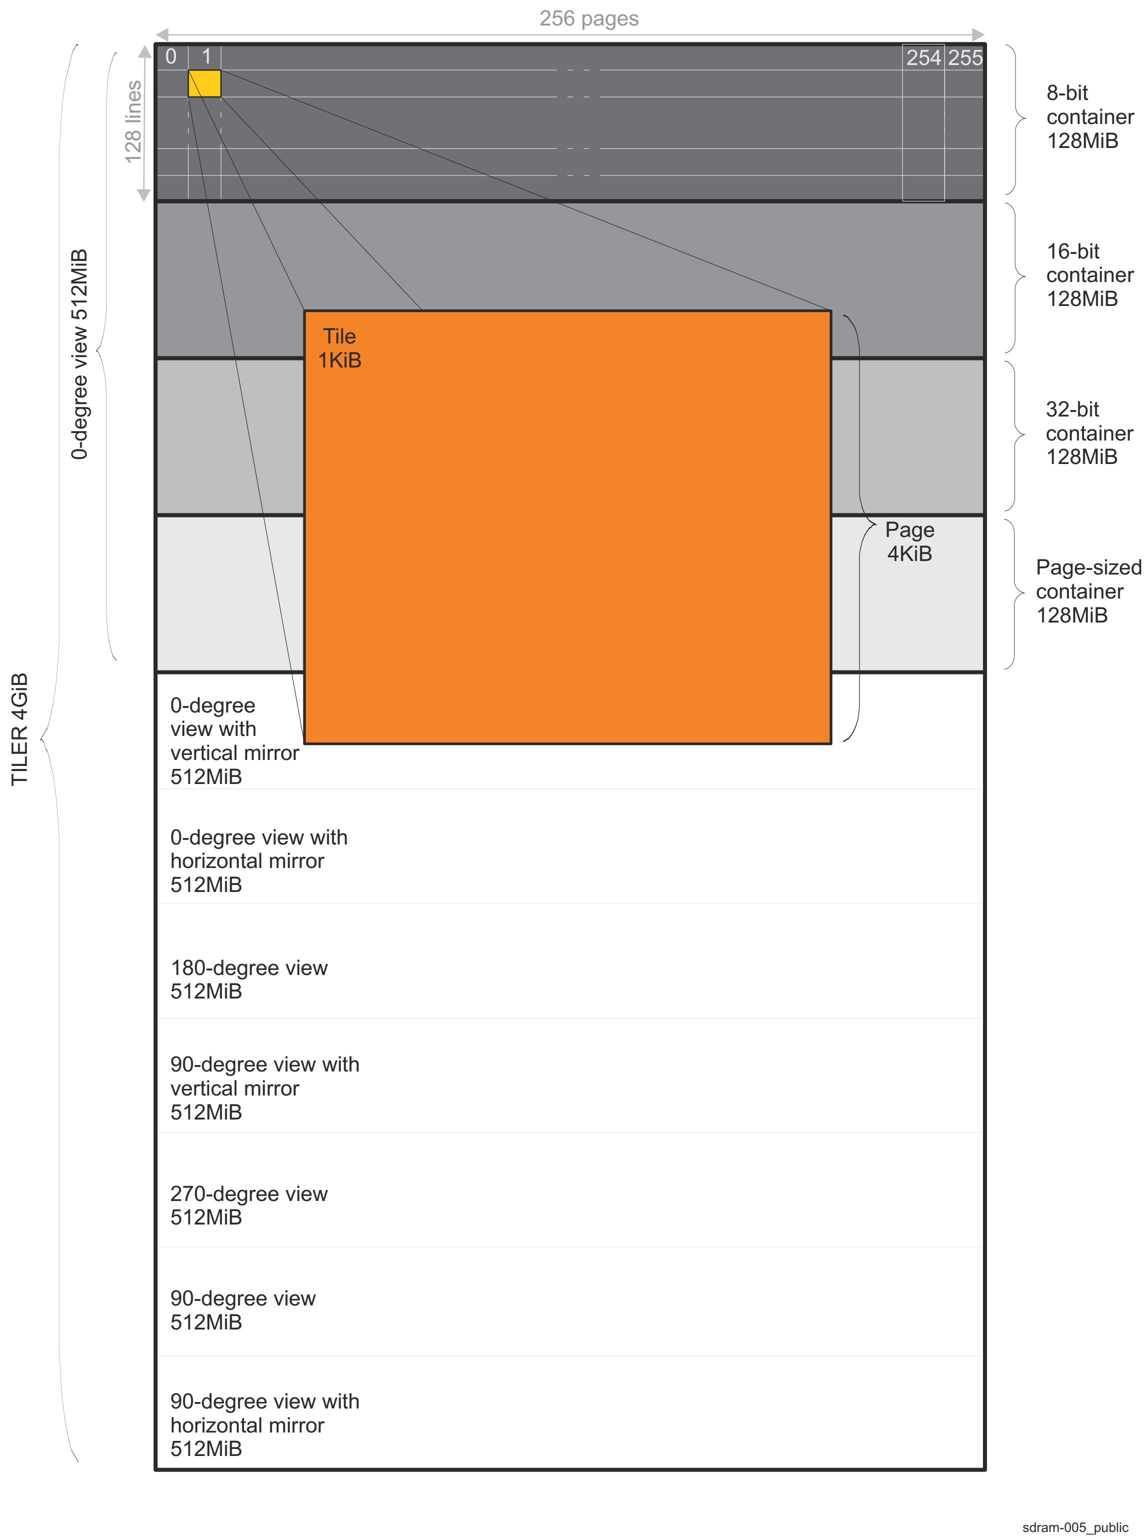

Figure 15-10. TILER Address Space Structure for Tiled Modes

15.2.3.6.1.1.1 The TILER is a 4-GiB Virtual Address Space Composed of Eight Views

There is one view for each of the eight possible ways of scanning a frame-buffer:

- From left to right and then from top to bottom

- From right to left and then from top to bottom
- From left to right and then from bottom to top
- From right to left and then from bottom to top
- From top to bottom and then from left to right
- From top to bottom and then from right to left
- From bottom to top and then from left to right
- From bottom to top and then from right to left

15.2.3.6.1.1.2 A View is a 512-MiB Virtual Address Space Composed of Four Containers

There is one container per element size to allow correct access patterns in any of the eight possible orientations. The container is the entity where all objects of a given element type are allocated.

The element is the entity of maximum size (8, 16, 32 bits, or page-sized), which is invariant in any orientation.

15.2.3.6.1.1.3 A Container is a 128-MiB Virtual Address Space

A container is composed of an array of 128 lines of 256 pages of 4kiB each.

The page defines the granularity of physical memory allocation through a PAT unit – MMU.

15.2.3.6.1.1.4 A Page is a 4-kiB Virtual Address Space

A page is composed of two lines. Each line consists of two tiles.

15.2.3.6.1.1.5 A Tile is a 1-kiB Address Space

The tile is designed to offer bidimensional data locality in a single SDRAM page. In this respect, it is sized to 1kiB; that is, to the size of the smallest SDRAM page.

15.2.3.6.1.1.6

15.2.3.6.1.1.7 A Subtile is a 128-Bit Address Space

A subtile is composed of:

- In 8-bit tiled mode: An array of four horizontal lines of four elements of 8 bits
- In 16-bit tiled mode: An array of two horizontal lines of four elements of 16 bits
- In 32-bit tiled mode: An array of two horizontal lines of two elements of 32 bits

The subtile structure is designed to increase the SDRAM access payload on macroblock requests; that is, to minimize the required line buffering of raster-based initiators to handle on-the-fly rotation, and to improve interlaced accesses to tiled frame-buffers.

15.2.3.6.1.2 TILER Modes

The TILER supports three major modes, bypass, page, and tiled. Each mode has a specific output request generation.

15.2.3.6.1.2.1 Bypass Mode

This mode is transparent from the TILER perspective. However, from the DMM perspective:

- 2D block bursts are broken down on a line basis in a set of incremental bursts.
- Incremental bursts, including those issued by a 2D block burst breakdown, are split at the DMM atomic unit of the section hit by the burst at:
  - The interleaving granularity of the section (128, 256, or 512 bytes) in interleaved sections
  - 1-kiB boundary in noninterleaved sections

15.2.3.6.1.2.2 Page Mode

This mode uses the DMM address translation mechanism for nontiled accesses. In this respect it is similar to bypass mode:

- 2D block bursts are broken down on a line basis in a set of incremental bursts.

- Incremental bursts, including those issued by a 2D block burst breakdown, are split at:
  - The interleaving granularity of the section (128, 256, or 512 bytes) in interleaved sections
  - 1-kiB boundary in noninterleaved sections

15.2.3.6.1.2.3 Tiled Mode

Tiled mode has two major breakdown algorithms:

- One for well-formed 2D block requests that conform to the orientation, mode, and stride listed in Table 15-10
- One for 1D incremental requests and ill-formed 2D block requests

Table 15-10. Well-Formed Tiled Mode 2D Block Requests

Orientation			Mode		Stride	Description
S	$\overline{Y}$	$\overline{X}$	M1	M0	(bytes)	
0	x	x	0	0	16,384	Plain access to an 8-bit progressive frame in 0 or 180 degrees
					32,768	Field access to an 8-bit interlaced frame 0 or 180 degrees
			0	1	32,768	Plain access to a 16-bit progressive frame in 0 or 180 degrees
					65,536	Field access to a 16-bit interlaced frame 0 or 180 degrees
			1	0	32,768	Plain access to a 32-bit progressive frame in 0 or 180 degrees
					65,536	Field access to a 32-bit interlaced frame 0 or 180 degrees
1	x	x	0	0	8192	Plain access to an 8-bit progressive frame in 90 or 270 degrees
					16,384	Field access to an 8-bit interlaced frame 90 or 270 degrees
			0	1	8192	Plain access to a 16-bit progressive frame in 90 or 270 degrees
					16,384	Field access to a 16-bit interlaced frame 90 or 270 degrees
			1	0	16,384	Plain access to a 32-bit progressive frame in 90 or 270 degrees
					32,768	Field access to a 32-bit interlaced frame 90 or 270 degrees

Similar to the bypass and page modes, ill-formed 2D block requests are broken down on a line basis in a set of incremental bursts. In tiled mode, however, these incremental virtual bursts do not translate to 1D physical burst requests.

15.2.3.6.1.3 Object Container Definition

The object container is the unique addressable entry point of the TILER. It is a 128-MiB virtual address space, where all objects of a same kind and orientation are allocated.

Four main types of containers are present in the TILER, each referred by a mode:

- 8-bit element mode, for efficiently accessing bidimensional arrays of 8-bit data
- 16-bit element mode, for efficiently accessing bidimensional arrays of 16-bit data
- 32-bit element mode, for efficiently accessing bidimensional arrays of 32-bit data
- Page mode, for efficient 1D accesses

Figure 15-11 shows the TILER object containers and views.

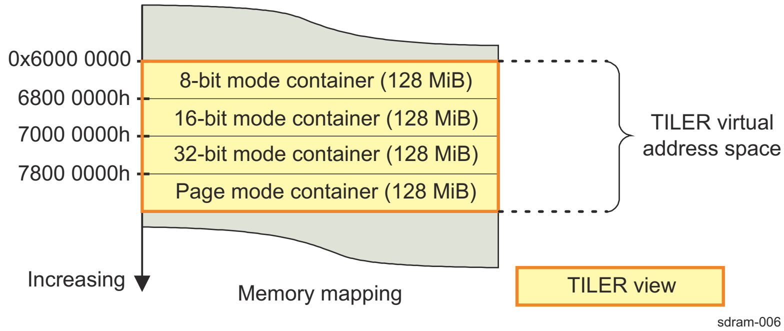

Figure 15-11. TILER Object Containers and Views

The 512-MiB virtual address space composed of four 128-MiB object containers of different modes is called a view. Because eight orientations are available per mode, the TILER actually manages 32 kinds of containers.

The physical memory footprint of a 512-MiB TILER view is directly subject to the nature of the PAT unit.

A unique PAT LUT is instantiated in the DMM. This table is shared by all TILER modes. Hence, each of the four modes cannot be given its own private page-grained PAT LUT. A maximum of 128MiB of objects among all TILER modes can be managed as shown in Figure 15-12.

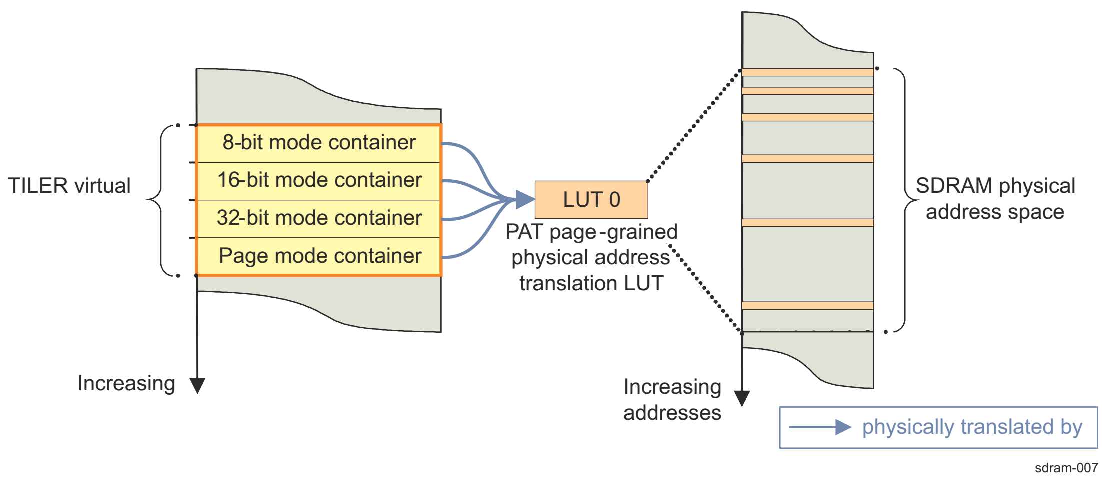

Figure 15-12. TILER Memory Footprint With PAT and Shared Physical Address Translation LUT

Although each of the four modes has its own separate virtual 128-MiB object container, these containers are all mapped to the same piecewise 128-MiB physical address space, and are then not physically separated. Consequently, a memory-related system constraint is that no more than 128-MiB of objects can be available simultaneously in a TILER view.

Note

Software must ensure that any object allocated in a mode does not physically overlap with any other object, even in another mode.

15.2.3.6.1.4 Page Definition

A TILER page defines the granularity of object allocation in virtual TILER containers.

Because the subpage structure is mode-specific, the page is the smallest granularity common to all modes, making it the granularity to consider in the TILER resource manager for object allocation.

15.2.3.6.1.4.1 Container Geometry With 4-kiB Pages

Because the size of the page is 4kiB, any 128-MiB object container is a set of 32,768 pages, organized in an array of 256 columns and 128 rows, as shown in Figure 15-13.

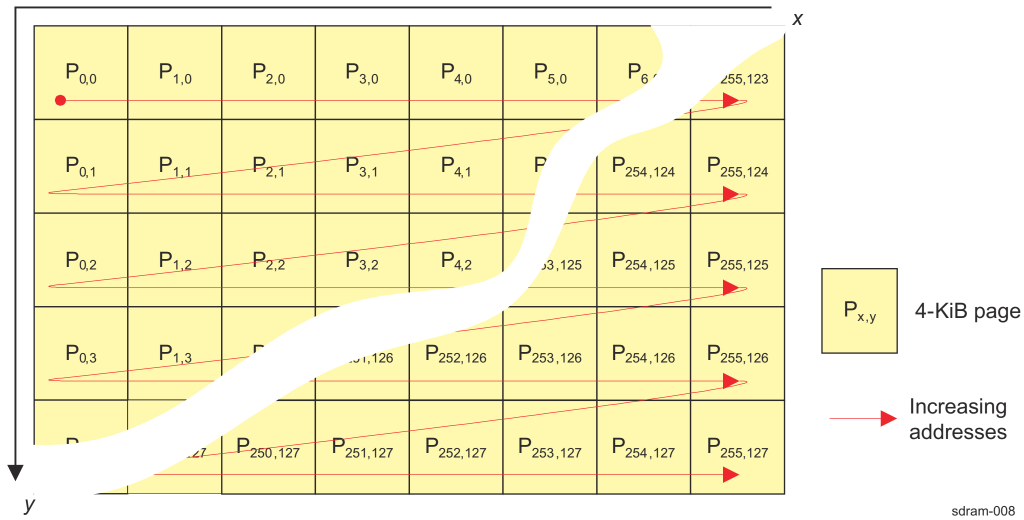

Figure 15-13. Object Container Geometry With 4-kiB Pages

This array of pages is mapped to the system address space, as shown in Figure 15-14.

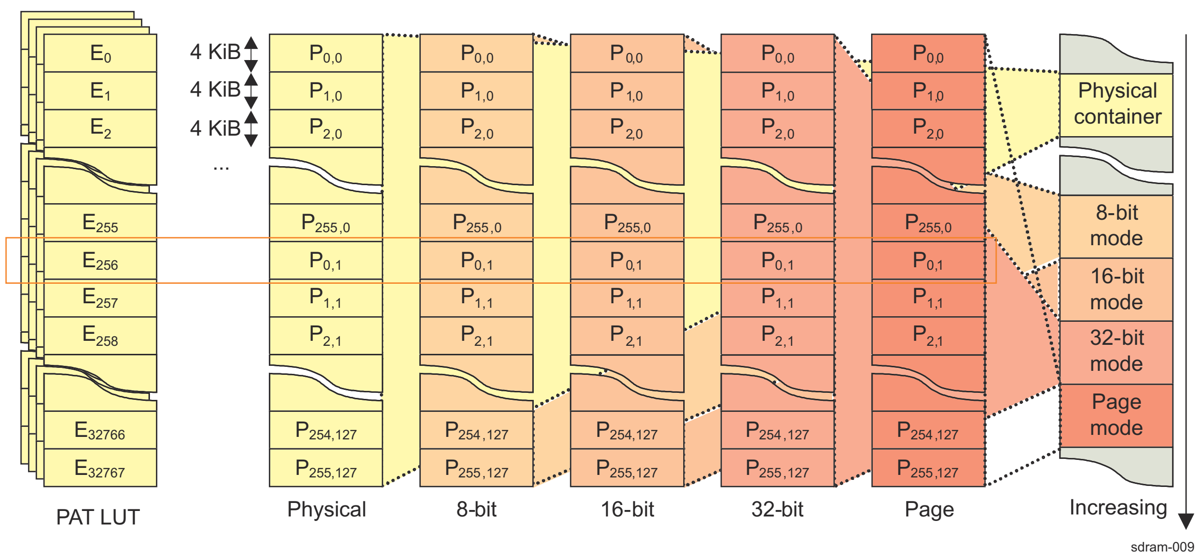

Figure 15-14. TILER Page Mapping When Using 4-kiB Pages

In any 128-MiB object container, the 4-kiB page Px,y at column x (where 0 =< x < 256) and row y (where 0 =< y < 128), is found at an offset of 4096.(x+256.y) bytes from the base address of the related object container.

Similarly, the page Px,y at column x (where 0 =< x < 256) and row y (where 0 =< y < 128), is translated by the LUT entry Ex+256.y found at the index x+256.y.

15.2.3.6.1.4.2 Container Geometry and Page Mapping Summary

The TILER has a page size of 4096 bytes. The page $P_{x,y}$:

- Has max_x = 256 and max_y = 128
- Is found at an offset of 4096.(x + max_x.y) bytes from the base address of the related object container
- Is translated by the entry at the index (x + max_x.y) of the LUT

15.2.3.6.1.5 Orientation

This section describes the eight on-the-fly orientation-related isometric transforms, which correspond to all available changes of orthonormal basis in the bidimensional space of the TILER container.

Figure 15-15 shows isometric transforms in the TILER container

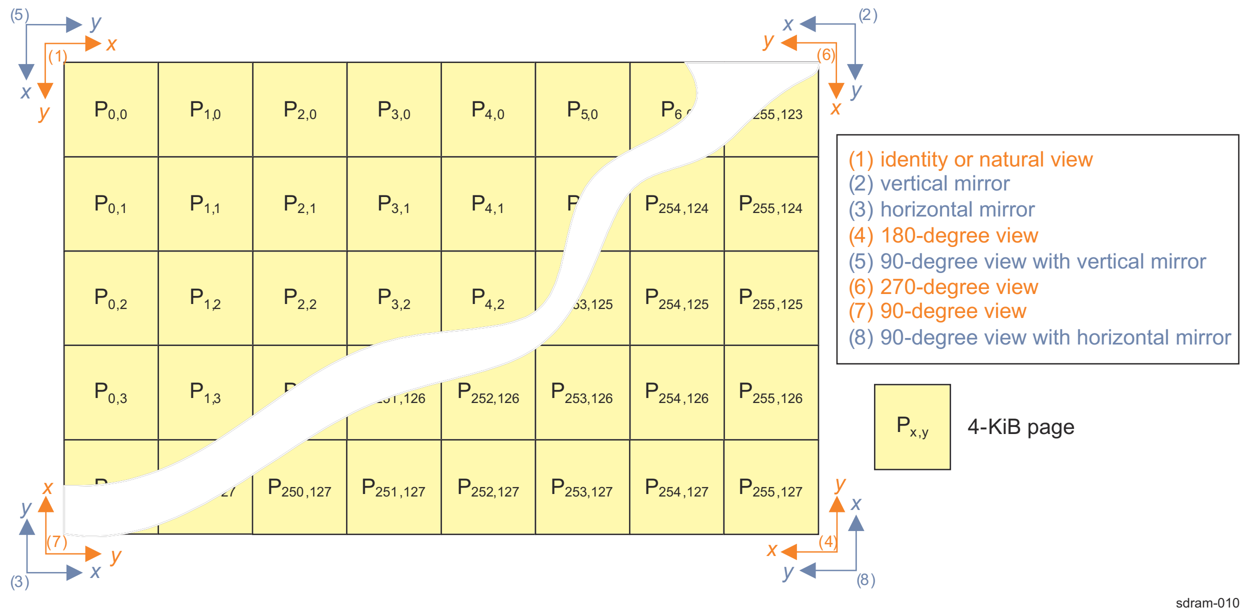

Figure 15-15. Isometric Transforms in the TILER Container

Mathematically speaking, all these transforms correspond to the composition of a 0-, 90-, 180-, or 270-degree rotation with an optional reflection. The nature of this orientation is based on the three following binary parameters:

- *X* to change the direction of the$_x$ axis of the TILER container
- *Y* to change the direction of the$_y$ axis of the TILER container
- *S* to swap the modified$_x$ and$_y$ axis

Hereafter in this document the term orientation refers to any composition of a "quadrant" rotation with an optional horizontal (flip-flop) or vertical mirroring.

15.2.3.6.1.6 Tile Definition

A tile is a subdivision of a page that is aimed at:

- Representing a 2D block to better balance accesses in both directions
- Ensuring that any tiled access that fits within a tile is made atomic in the SDRC and fits in a single SDRAM memory page
- Minimizing the number of SDRAM page openings per 2D block transfer

The tile is defined as a 1-kiB 2D block, and a 4-kiB page as an array of two lines of two tiles each.

When the considered page is in an interleaved DMM section, it is necessary that:

- The DMM memory interleaving size of tiled accesses is set to 1kiB (a tile size) so that any tiled request that fits within a tile, fits in a single SDRAM memory page.
- Any request that spans two or four tiles is distributed on a maximum number of SDRCs.

15.2.3.6.1.7 Subtiles

15.2.3.6.1.7.1 Subtiling Definition

To summarize, a subtile is a subtle refinement of a tile whose purpose is to:

- Lower the size (length × height) of 128-bit bursts in case of relatively small 2D block requests, such as video macroblocks
- Better balance the granularity in the two directions
- Better balance the accesses in the two (x and y) directions
- Minimize the size of the line buffer of the raster-based initiators to handle isometric transforms efficiently

A subtile is defined as a 128-bit 2D block, and a tile as an array of eight lines of eight subtiles, as shown in Figure 15-16.

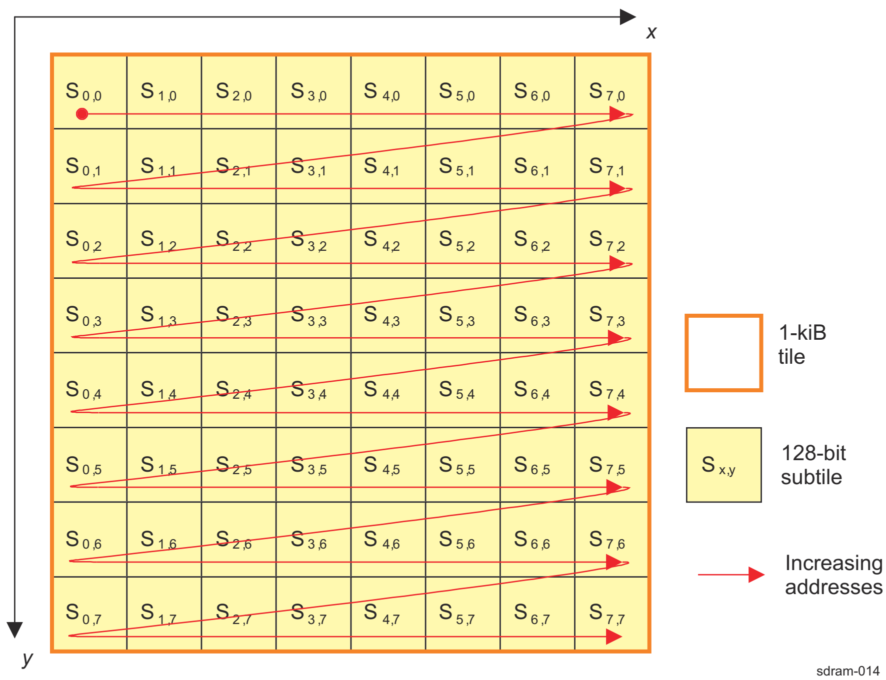

Figure 15-16. Tile Geometry

In any tile, the subtile Sx,y at column x (0 =< x < 8) and row y (0 =< y < 8) is found at an offset of 16.(x + 8.y) bytes from the base address of the related tile. Besides, this array organization of subtiles is common to each tiled mode. For instance, the subtile S0,1 is always located at an offset of 128 bytes (that is, 16.(0 + 8 x 1)) from the base address of the related tile.

Figure 15-17 shows the subtile mapping.

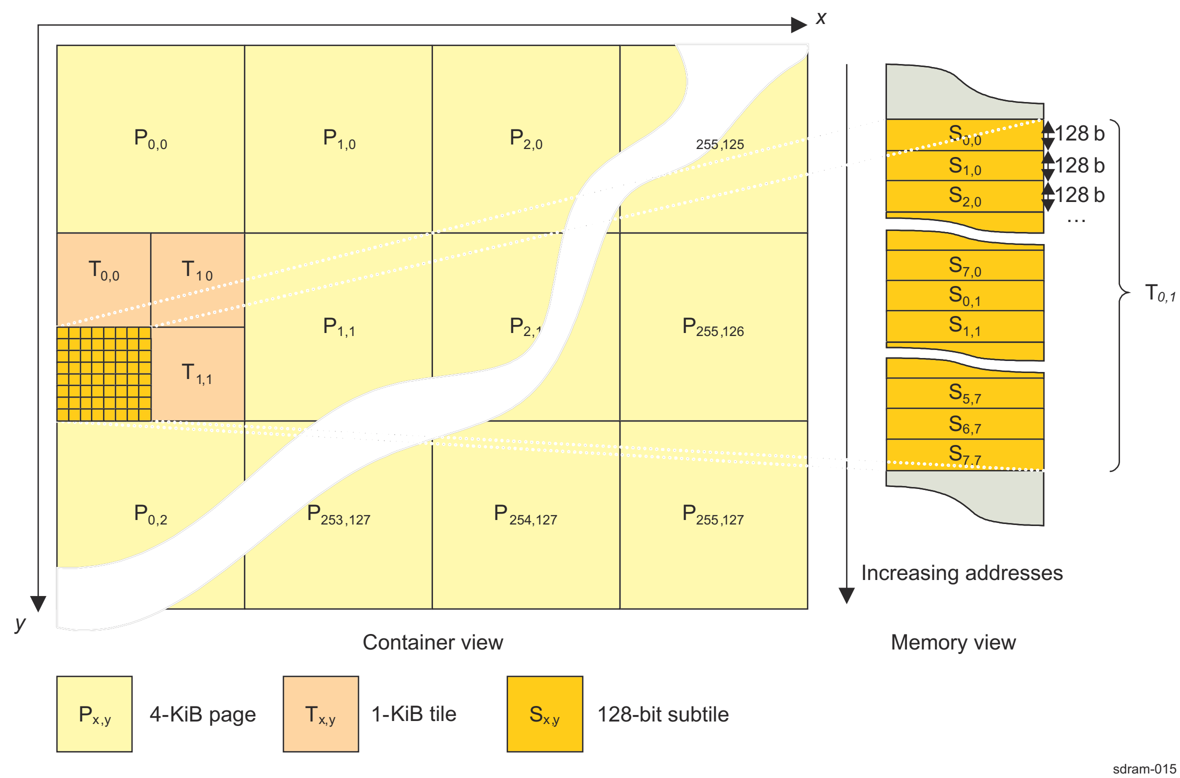

Figure 15-17. Subtile Mapping

15.2.3.6.1.8 TILER Virtual Addressing

The TILER can be virtually accessed in four different modes: 8-, 16-, 32-bit, and page modes. Each mode defines the element granularity to apply isometric transforms, as summarized in Table 15-11.

Table 15-11. Coding and Description of TILER Modes

Mode	Name	Granularity (Element Size)
0	8-bit tiled mode	8 bits
1	16-bit tiled mode	16 bits
2	32-bit tiled mode	32 bits
3	Page mode	4096 bytes

For instance, making a vertical mirror of a 16-byte horizontal line that contains the word 000102030405060708090A0B0C0D0E0Fh, leads to:

- 0F0E0D0C0B0A09080706050403020100h in 8-bit tiled mode
- 0E0F0C0D0A0B08090607040502030001h in 16-bit tiled mode
- 0C0D0E0F08090A0B0405060700010203h in 32-bit tiled mode
- 000102030405060708090A0B0C0D0E0Fh in page mode – unchanged because the element granularity is 4 KiB

Besides, because each of the eight orientations is available for any of the four modes, the TILER has 32 addressing possibilities (see Table 15-12).

Table 15-12. Coding and Description of TILER Orientations

S	$\overline{Y}$	$\overline{X}$	Description	Alternate description
0	0	0	0-degree view	Natural view
0	0	1	0-degree view with vertical mirror	180-degree view with horizontal mirror
0	1	0	0-degree view with horizontal mirror	180-degree view with vertical mirror

Table 15-12. Coding and Description of TILER Orientations (continued)

S	$\overline{Y}$	$\overline{X}$	Description	Alternate description
0	1	1	180-degree view	
1	0	0	90-degree view with vertical mirror	270-degree view with horizontal mirror
1	0	1	270-degree view	
1	1	0	90-degree view	
1	1	1	90-degree view with horizontal mirror	270-degree view with vertical mirror

15.2.3.6.1.8.1 Page Mode Virtual Addressing and Characteristics

When used in page mode, the 128-MiB TILER space is seen as an orientation-specific sequence of 32,768 pages of 4kiB each. The access sequence inside a page is left unchanged.

Therefore, in page mode, the TILER is accessed similarly to any 128-MiB memory, with a 27-bit byte-based address.

Note

From here forward, the address is noted as *a* (see Figure 15-18).

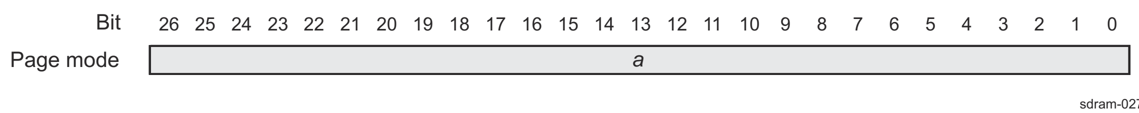

Figure 15-18. Page Mode Virtual Addressing

15.2.3.6.1.8.2 Tiled Mode Virtual Addressing and Characteristics

When used in tiled mode, the 128-MiB TILER space is seen as a giant frame-buffer, the container. The addressing and characteristics of this giant frame-buffer depend on:

- The tiled mode, which defines the considered atomic element size
- The orientation, which potentially swaps its x and y axis, and hence the container geometry

Table 15-13 summarizes the container characteristics in tiled mode.

Table 15-13. Tiled Mode Container Characteristics

Orientation			Element Size (Bits)	Width (Elements)	Height (Elements)	Stride (Bytes)	
S	$\overline{Y}$	$\overline{X}$				Progressive	Interlaced
0	x	x	8	16,384	8192	16,384	32,768
			16	16,384	4096	32,768	65,536
			32	8192	4096	32,768	65,536
1	x	x	8	8192	16,384	8192	16,384
			16	4096	16,384	8192	16,384
			32	4096	8192	16,384	32,768

As a result, the coordinate (x_0, y_0) of a pixel in an oriented view is translated in a virtual address, as shown in Figure 15-19 and Figure 15-20.

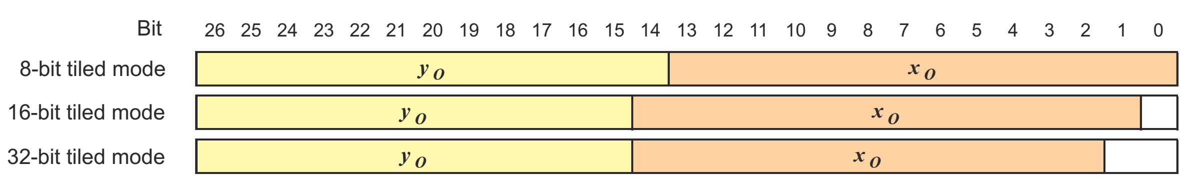

Figure 15-19. Tiled Mode Addressing in 0- or 180-Degree Orientation (S = 0)

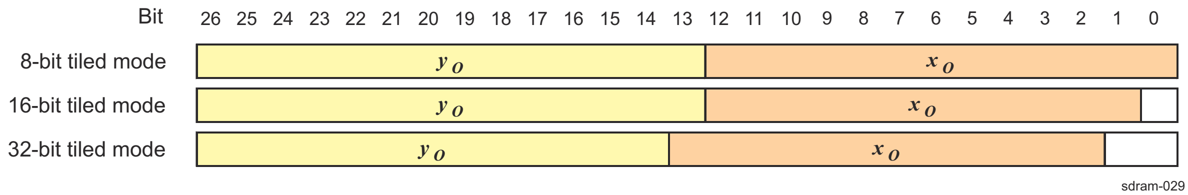

Figure 15-20. Tiled Mode Addressing in 90- or 270-Degree Orientation (S = 1)

15.2.3.6.1.8.3 Element Ordering in the TILER Container

This section describes how elements (8-, 16-, or 32-bit data or a 4-kiB page) are ordered in the container. In other words, this section describes how the path of incrementing virtual addresses is mapped in the container.

Regardless of the mode, and hence the element size, the sequence for ordering the elements in their related container is strictly similar and depends only on the related orientation. In other words:

- Mode is concerned with element granularity.
- Orientation is concerned with change of orthornormal basis for ordering the elements in the mode-specific container.

A corollary to the previous statements is that in a given mode the internal structure of an element is unchanged regardless of the orientation. In page mode for instance, the offset of a word inside a page is invariant by orientation; the content of a page is always accessed in the same manner.

In the following sections, the natural container orthonormal basis is referenced as:

$$(\vec{x}_N, \vec{y}_N)$$

sdram-030

and the oriented orthonormal basis is referenced as:

$$(\vec{x}_O, \vec{y}_O)$$

sdram-031

15.2.3.6.1.8.3.1 Natural View or 0-Degree View (Orientation 0)

This orientation defined by S = 0, $\overline{Y}$ = 0, and $\overline{X}$ = 0 means that the operated change of basis is:

$$\begin{cases} \vec{x}_O = \vec{x}_N \\ \vec{y}_O = \vec{y}_N \end{cases}$$

sdram-032

In any TILER mode, the elements are ordered from left to right and then from top to bottom in their container, as shown in Figure 15-21 and Figure 15-22.

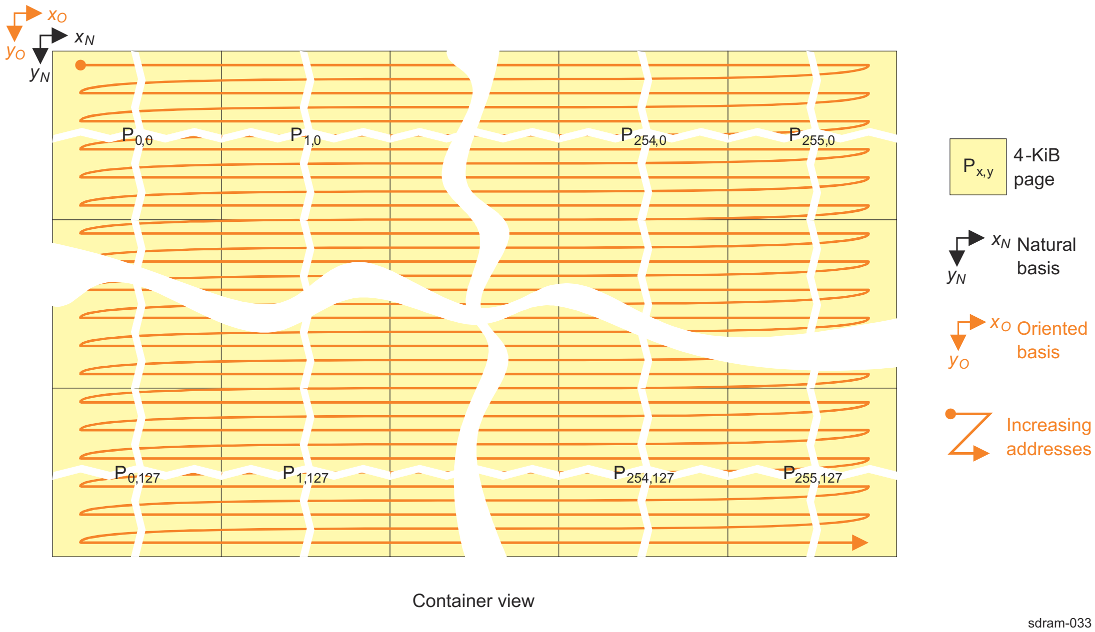

Figure 15-21. Tiled Mode Ordering of Elements in Natural View

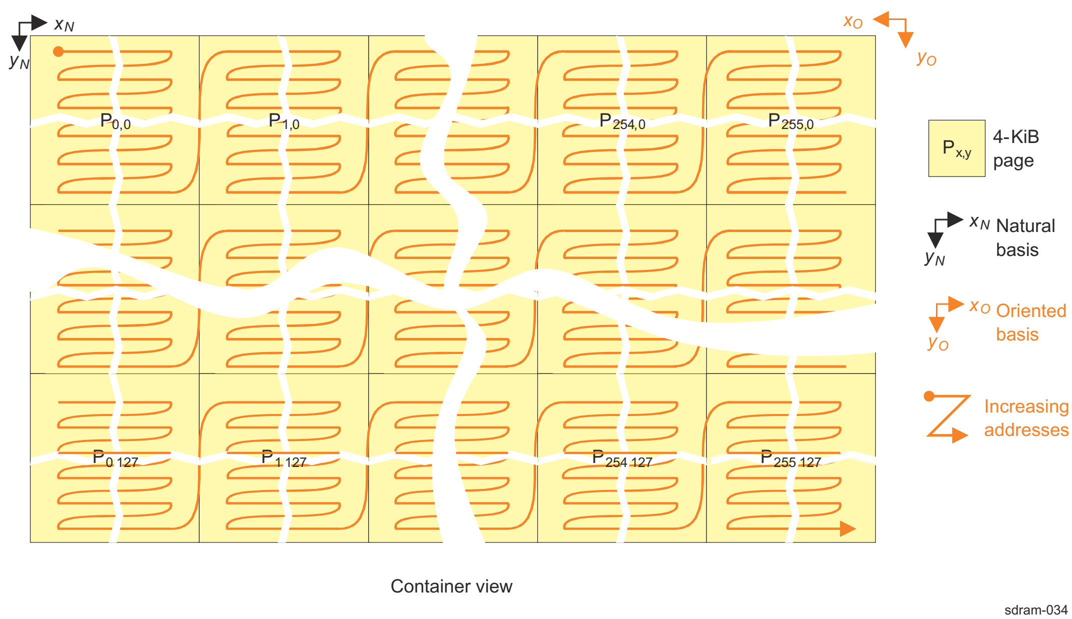

Figure 15-22. Page Mode Ordering of Elements in Natural View

15.2.3.6.1.8.3.2 0-Degree View With Vertical Mirror or 180-Degree View With Horizontal Mirror (Orientation 1)

This orientation defined by S = 0, $\overline{Y}$ = 0, and $\overline{X}$ = 1 and means that the operated change of basis is:

$$\begin{cases} \vec{x}_O = -\vec{x}_N \\ \vec{y}_O = \vec{y}_N \end{cases}$$

sdram-035

In any TILER mode, the elements are then ordered from right to left and then from top to bottom in their container, as shown in Figure 15-23 and Figure 15-24.

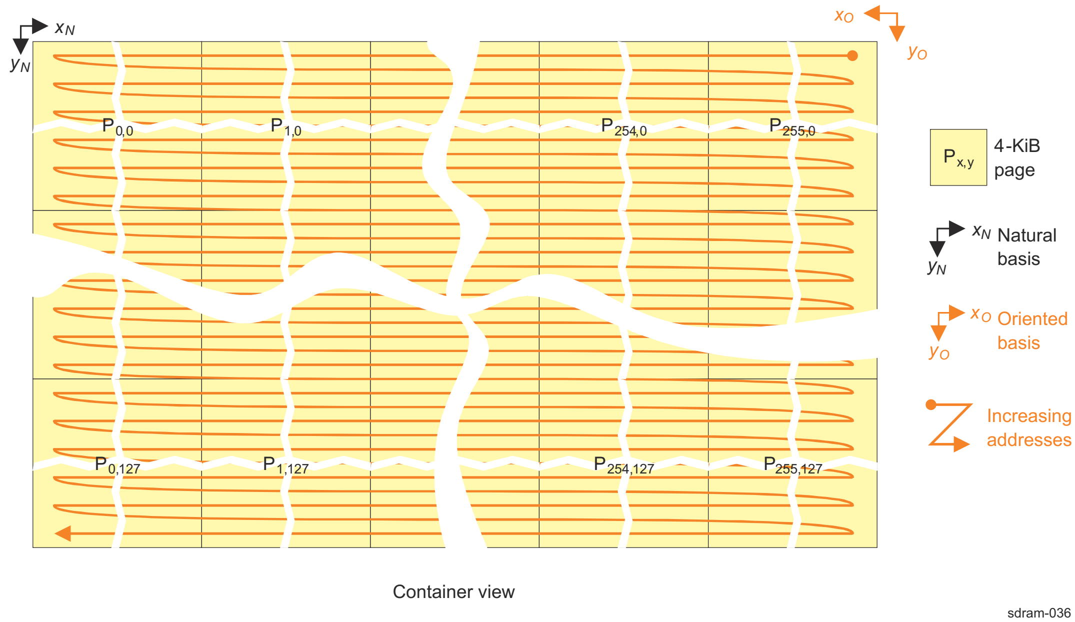

Figure 15-23. Tiled Mode Ordering of Elements in 0-Degree View With Vertical Mirror

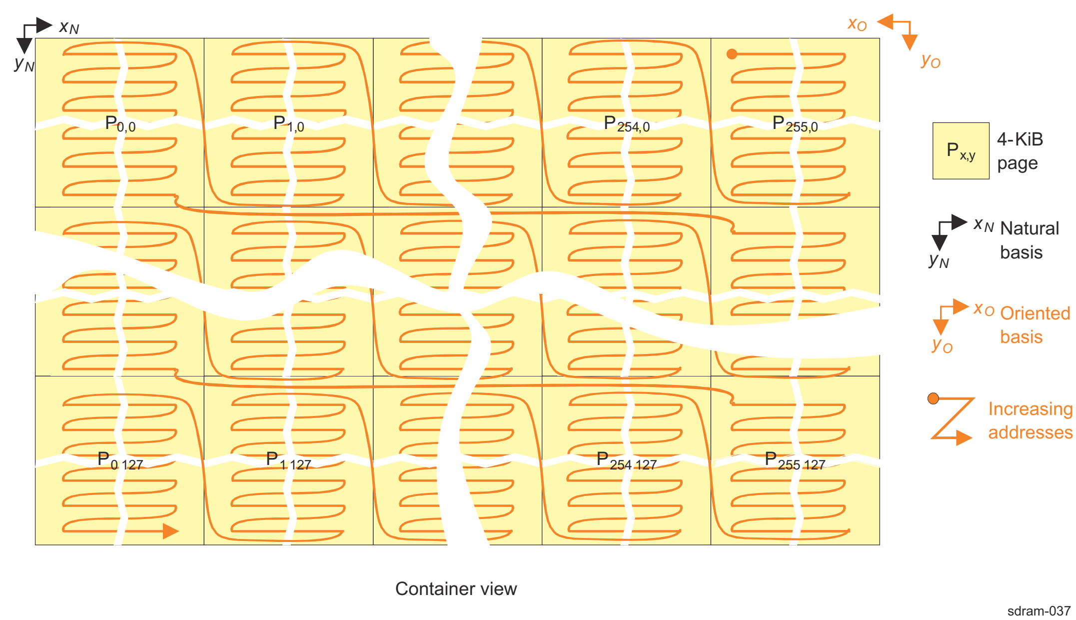

Figure 15-24. Page Mode Ordering of Elements in 0-Degree View With Vertical Mirror

15.2.3.6.1.8.3.3 0-Degree View With Horizontal Mirror or 180-Degree View With Vertical Mirror (Orientation 2)

This orientation defined by S = 0, $\overline{Y}$ = 1, and $\overline{X}$ = 0 and means that the operated change of basis is:

$$\begin{cases} \vec{x}_O = \vec{x}_N \\ \vec{y}_O = -\vec{y}_N \end{cases}$$

sdram-038

In any TILER mode, the elements are ordered from left to right and then from bottom to top in their container, as shown in Figure 15-25 and Figure 15-26.

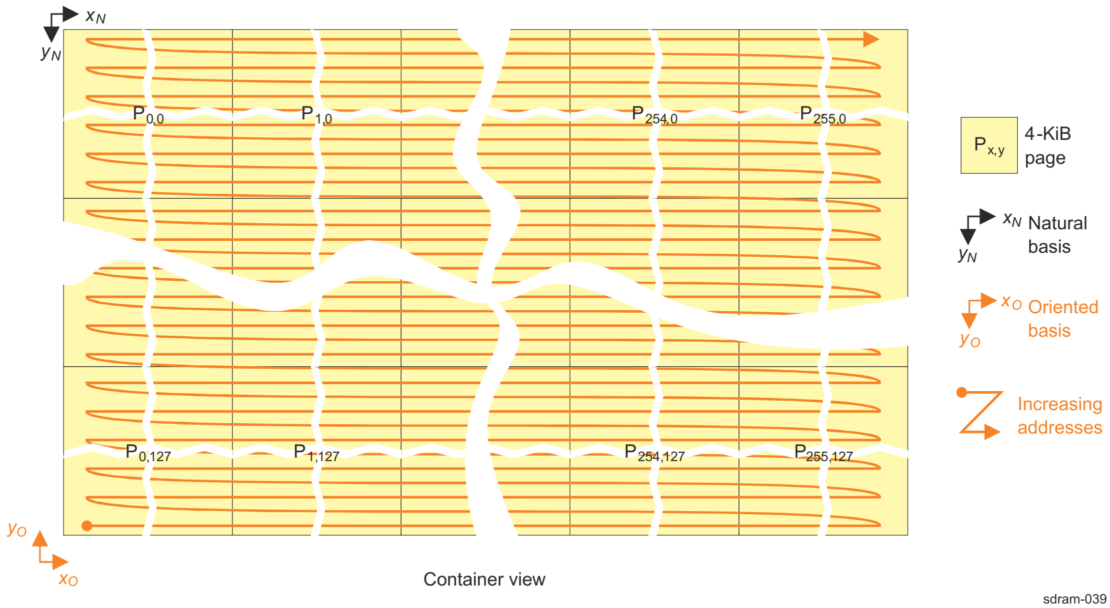

Figure 15-25. Tiled Mode Ordering of Elements in 0-Degree View With Horizontal Mirror

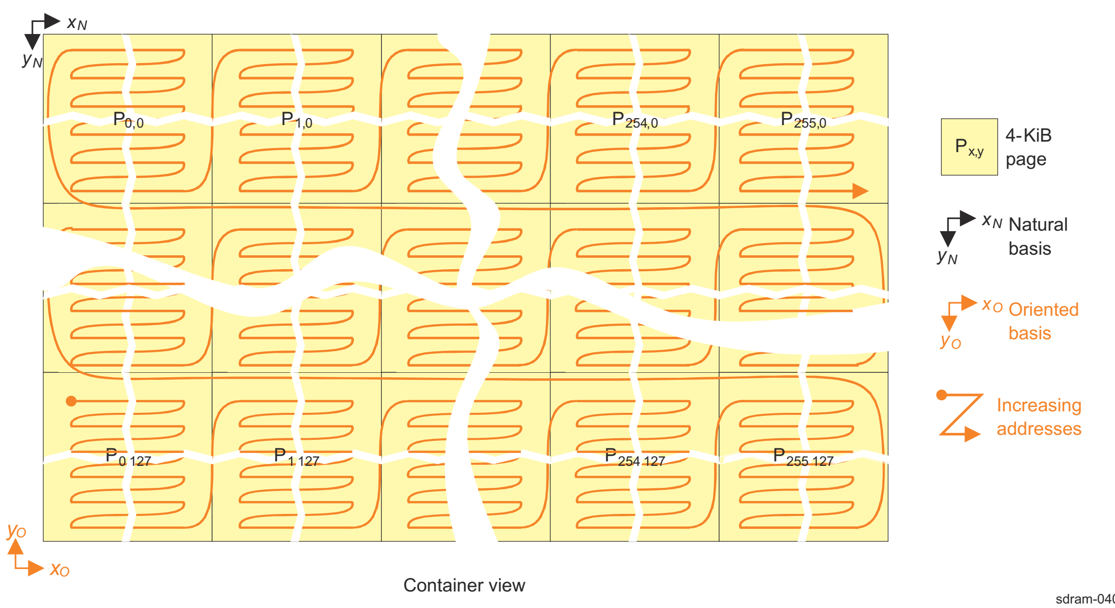

Figure 15-26. Page Mode Ordering of Elements in 0-Degree View With Horizontal Mirror

15.2.3.6.1.8.3.4 180-Degree View (Orientation 3)

This orientation defined by S = 0, $\overline{Y}$ = 1, and $\overline{X}$ = 1 and means that the operated change of basis is:

$$\begin{cases} \vec{x}_O = -\vec{x}_N \\ \vec{y}_O = -\vec{y}_N \end{cases}$$

sdram-041

In any TILER mode, the elements are ordered from right to left and then from bottom to top in their container, as shown in Figure 15-27 and Figure 15-28.

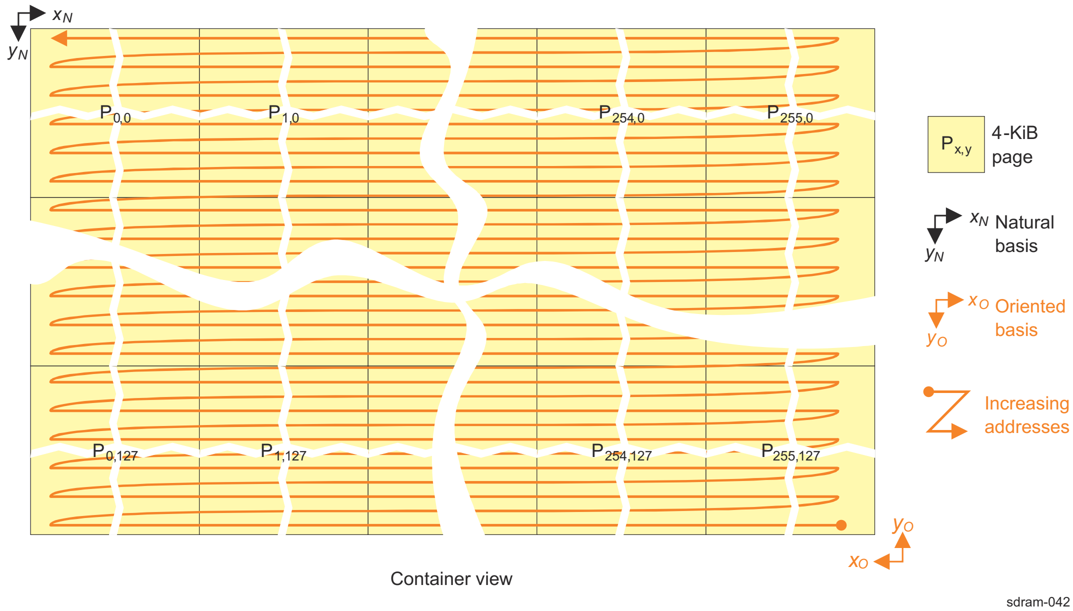

Figure 15-27. Tiled Mode Ordering of Elements in 180-Degree View

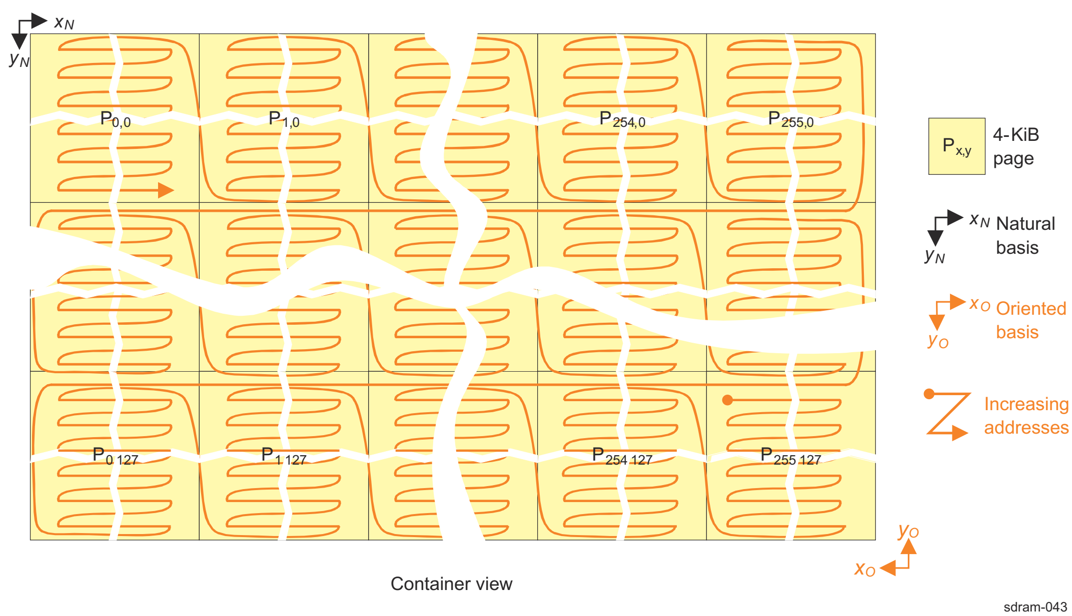

Figure 15-28. Page Mode Ordering of Elements in 180-Degree View

15.2.3.6.1.8.3.5 90-Degree View With Vertical Mirror or 270-Degree View With Horizontal Mirror (Orientation 4)

This orientation defined by S = 1, $\overline{Y}$ = 0, and $\overline{X}$ = 0 and means that the operated change of basis is:

$$\begin{cases} \vec{x}_O = \vec{y}_N \\ \vec{y}_O = \vec{x}_N \end{cases}$$

sdram-044

In any TILER mode, the elements are ordered from top to bottom and then from left to right in their container, as shown in Figure 15-29 and Figure 15-30.

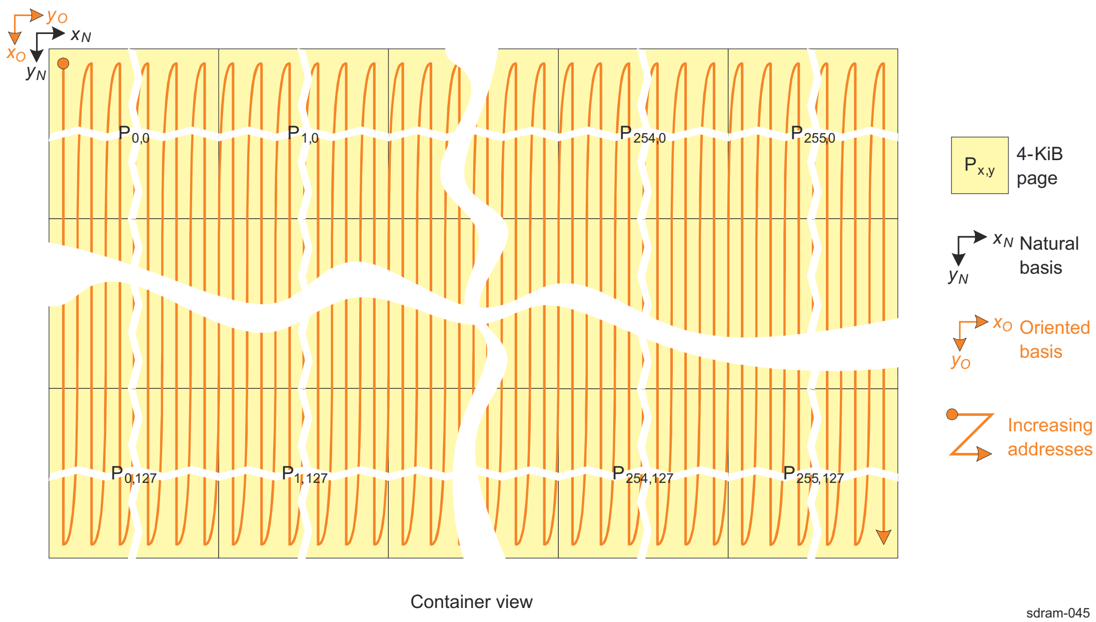

Figure 15-29. Tiled Mode Ordering of Elements in 90-Degree View With Vertical Mirror

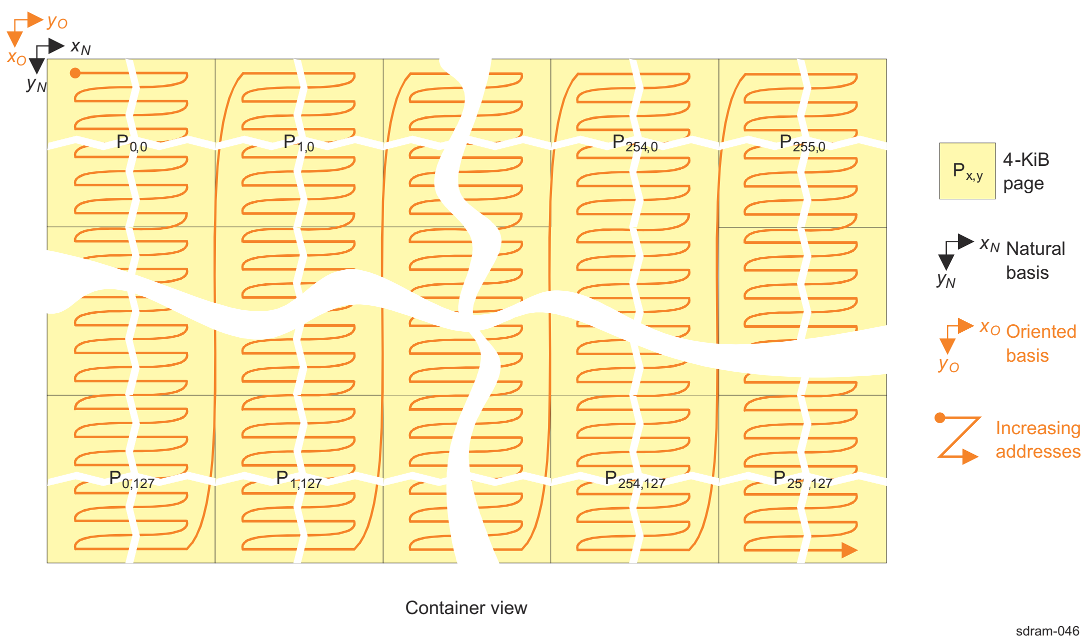

Figure 15-30. Page Mode Ordering of Elements in 90-Degree View With Vertical Mirror

15.2.3.6.1.8.3.6 270-Degree View (Orientation 5)

This orientation defined by S = 1, $\overline{Y}$ = 0, and $\overline{X}$ = 1 and means that the operated change of basis is:

$$\begin{cases} \vec{x}_O = \vec{y}_N \\ \vec{y}_O = -\vec{x}_N \end{cases}$$

sdram-047

In any TILER mode, the elements are ordered from top to bottom and then from right to left in their container, as shown in Figure 15-31 and Figure 15-32.

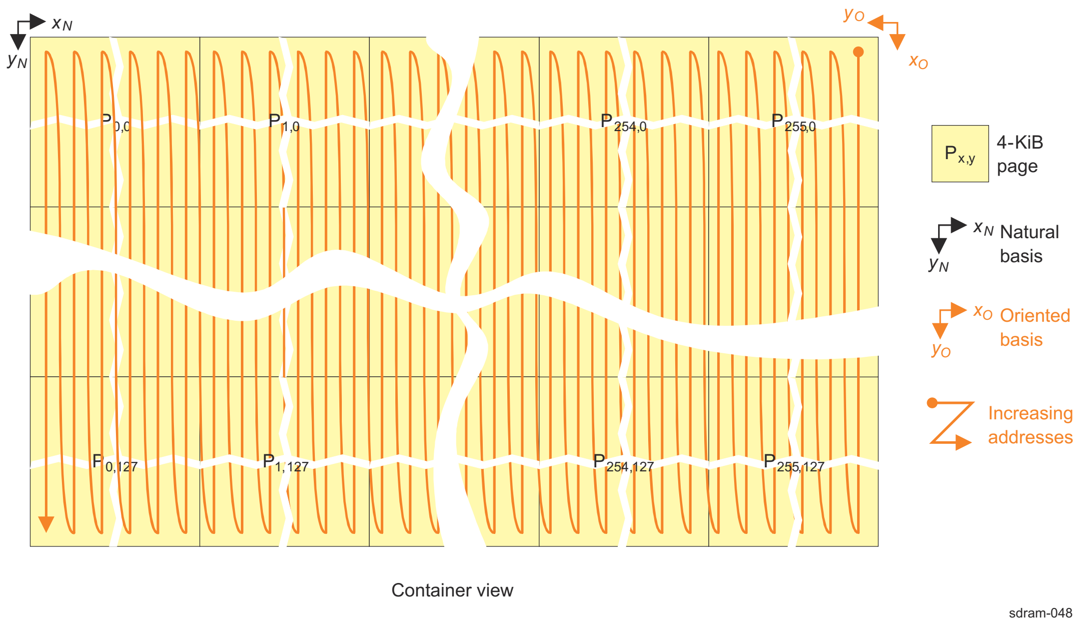

Figure 15-31. Tiled Mode Ordering of Elements in 270-Degree View

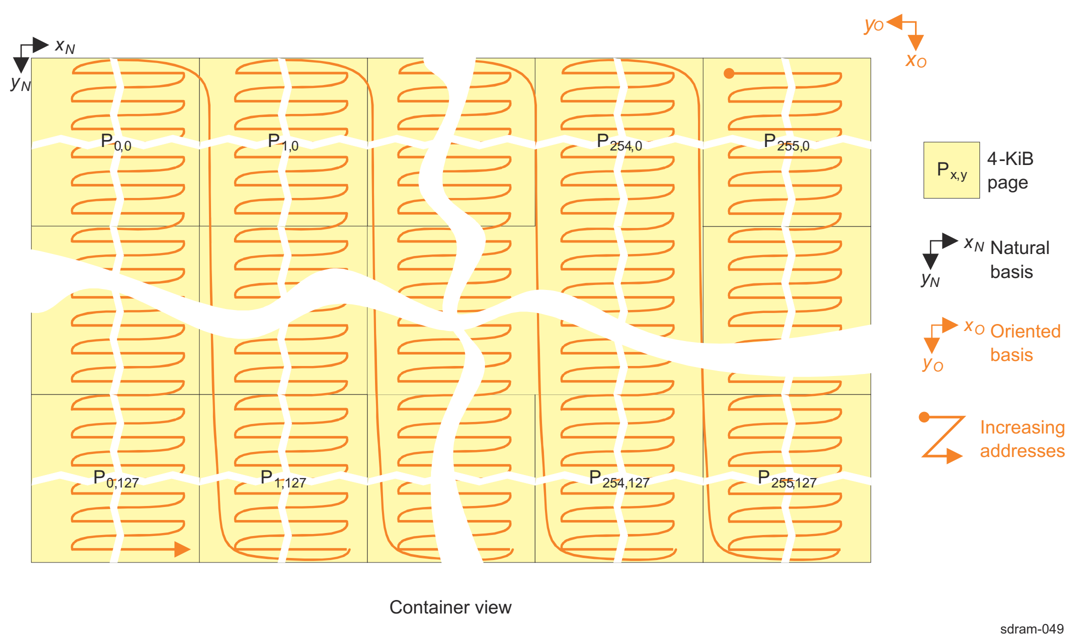

Figure 15-32. Page Mode Ordering of Elements in 270-Degree View

15.2.3.6.1.8.3.7 90-Degree View (Orientation 6)

This orientation defined by S = 1, $\overline{Y}$ = 1, and $\overline{X}$ = 0 and means that the operated change of basis is:

$$\begin{cases} \vec{x}_O = -\vec{y}_N \\ \vec{y}_O = \vec{x}_N \end{cases}$$

sdram-050

In any TILER mode, the elements are ordered from bottom to top and then from left to right in their container, as shown in Figure 15-33 and Figure 15-34.

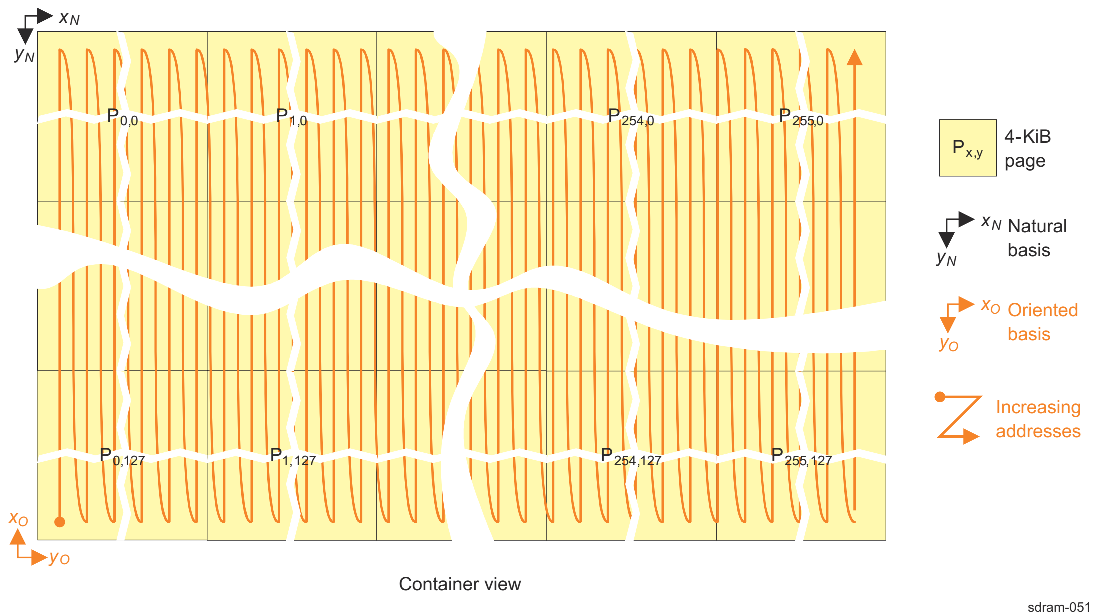

Figure 15-33. Tiled Mode Ordering of Elements in 90-Degree View

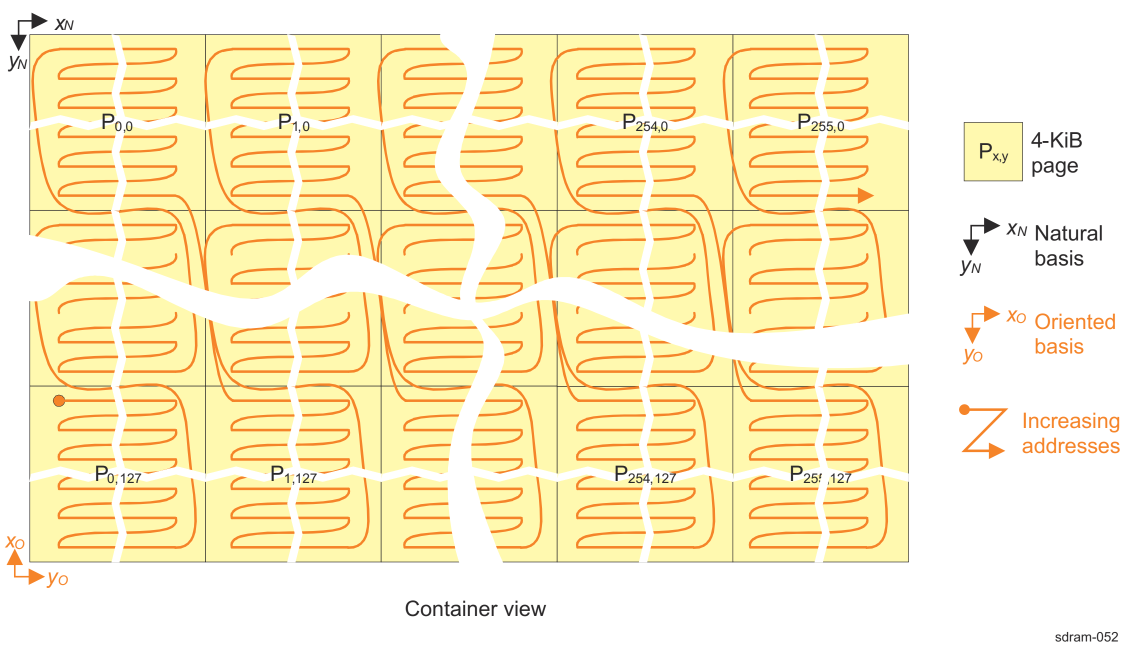

Figure 15-34. Page Mode Ordering of Elements in 90-Degree View

15.2.3.6.1.8.3.8 90-Degree View With Horizontal Mirror or 270-Degree View With Vertical Mirror (Orientation 7)

This orientation defined by S = 1, $\overline{Y}$ = 1, and $\overline{X}$ = 1 and means that the operated change of basis is:

$$\begin{cases} \vec{x}_O = -\vec{y}_N \\ \vec{y}_O = -\vec{x}_N \end{cases}$$

sdram-053

In any TILER mode, the elements are ordered from bottom to top and then from right to left in their container, as shown in Figure 15-35 and Figure 15-36.

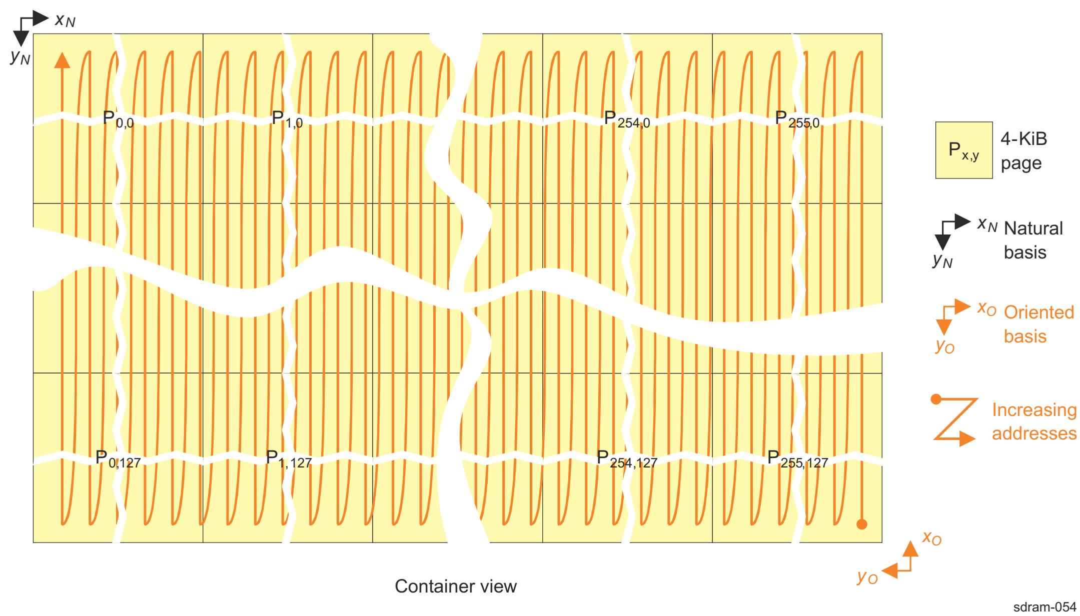

Figure 15-35. Tiled Mode Ordering of Elements in 90-Degree View With Horizontal Mirror

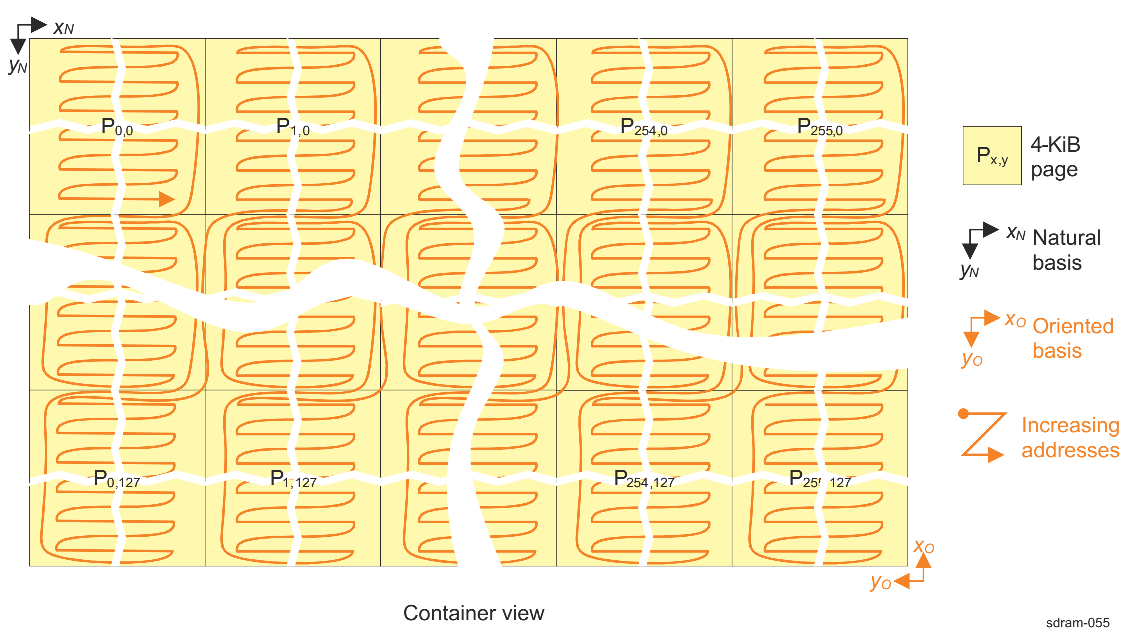

Figure 15-36. Page Mode Ordering of Elements in 90-Degree View With Horizontal Mirror

15.2.3.6.2 TILER Macro-Architecture

The TILER requires a 4-GiB addressing space to map its 128-MiB physical container in four modes and eight orientations. Because its addressing space alone fills the 4-GiB global system address map, the TILER addressing space cannot enter as-is into the system address map. Besides, putting in place a register-based mechanism per initiator to specify the orientation of the following accesses and then reducing the TILER addressing space to a single 512-MiB view is not an option; this is because most of the bandwidth-hungry initiators require simultaneous accesses to the TILER container in different views.

As a result, 32 bits are not enough to address all these requests, because the TILER port must convey not only virtually addressed requests to the "oriented" TILER containers but also physically addressed requests to the attached SDRCs. A thirty-third address bit is necessary to distinguish the two separated address maps, as shown in Figure 15-37.

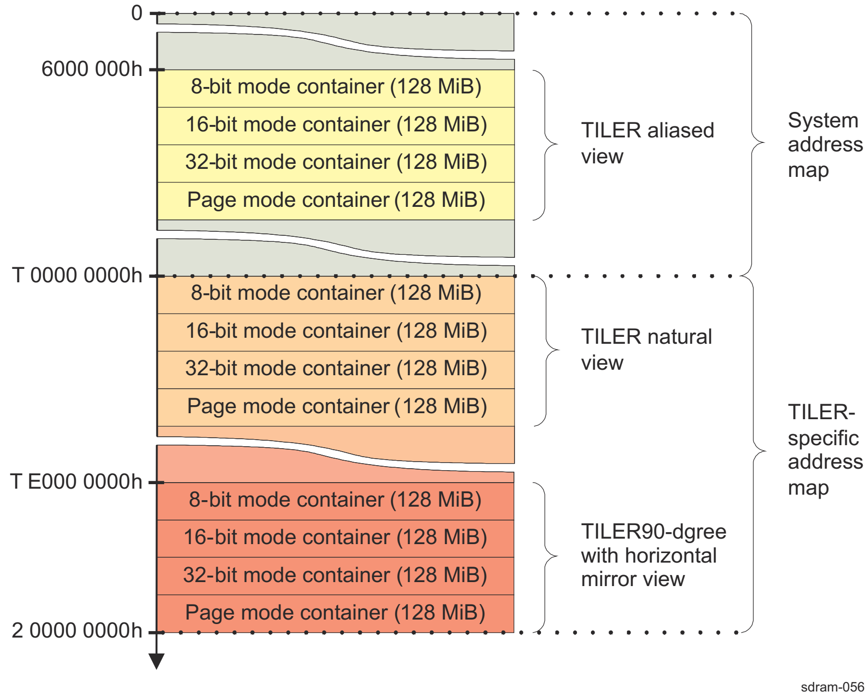

Figure 15-37. TILER Port Address Map

Still, having separated systems and TILER-specific address maps is not sufficient. In a system many existing and external IP blocks still rely on a 32-bit address and would then be limited to one or the other 4-GiB addressing space. To overcome this limitation, one 512-MiB view is aliased in the system address map as (see Table 15-14 and Figure 15-38).

Table 15-14. TILER Aliased View in the L3 Interconnect Mapping

Start Address (hex)	End Address (hex)	Size
0x6000_0000	0x7FFF_FFFF	512 MiB

From all incoming requests, TILER requests are filtered as having an address that fits one of the following:

- The address format in the TILER-specific address map given in Table 15-15
- The address format of the aliased view in the system address map given in Table 15-16

Other requests are forwarded directly to the SDRC in TILER bypass mode.

Table 15-15. Address Format in the TILER-Specific Address Map

32	31	30	29	28	27	26 ... 4	3 ... 0
T	Orientation			Mode		Virtual address	
1	S	$\bar{Y}$	$\bar{X}$	M1	M0	A26 ... A4	0

Table 15-16. Address Format of the TILER Aliased View in the System Address Map

32	31	30	29	28	27	26 ... 4	3 ... 0
T	TILER aliasing			Mode		Virtual address	
0	0	1	1	M1	M0	A26 ... A4	0

In these address formats:

- The thirty-third bit, noted T, is aimed at distinguishing the standard 4-GiB system address map from the 4-GiB TILER-specific address map.
- The orientation bits, noted S, $\overline{Y}$, and $\overline{X}$, define the request orientation, as specified in Table 15-12.
- The mode bits, noted M1 and M0, define the request mode, as specified in Table 15-11.
- The remaining 27 bits, noted A0 to A26, define the mode and orientation specific virtual address, as defined in Figure 15-18, Figure 15-19, and Figure 15-20.

The orientation of the aliased TILER view is extracted from an initiator-indexed LUT, as shown in Figure 15-38.

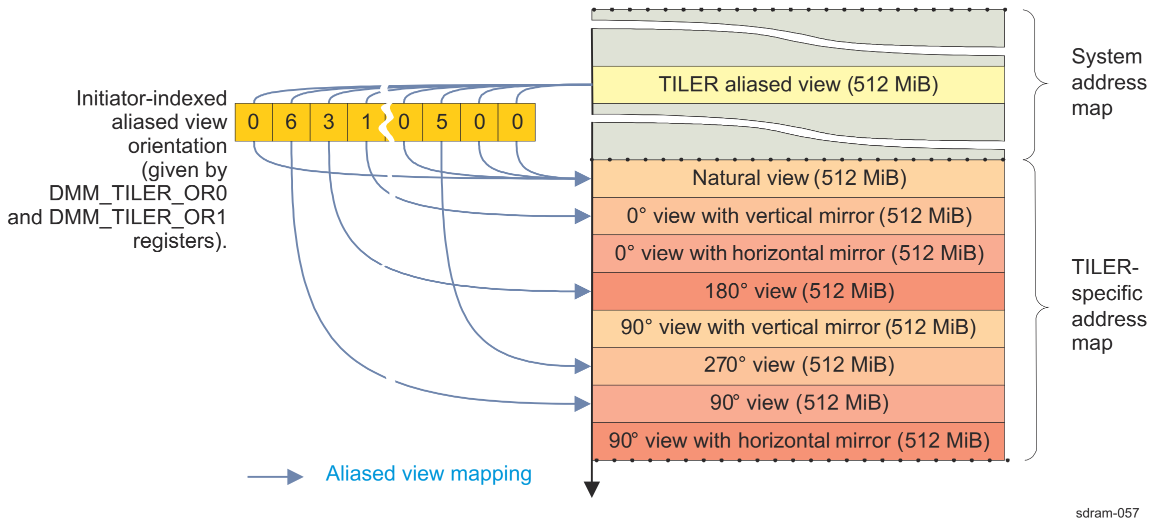

Figure 15-38. TILER Aliased View Orientation

As shown in Figure 15-38, an internal initiator-indexed LUT stores the current orientation of the aliased view for each initiator.

When an interconnect request hits the TILER aliased view in the system address map, the request initiator orientation is extracted from the LUT and the request address is translated according to this orientation: the T bit is set and bits [31:29] are replaced with the orientation.

Regarding the dimensioning of this LUT, given that initiators simultaneously accessing multiple views use the TILER-specific address map, and many initiators do not need to access any view or can be restricted to accessing only the natural view, only a limited number of initiators are likely to dynamically modify the orientation of its aliased TILER view.

The orientation LUT is limited to 16 entries. These 16 orientation entries are mapped on the two 32-bit DMM_TILER_OR0 and DMM_TILER_OR1 registers.

The first eight entries of the LUT are mapped in the DMM_TILER_OR0 register, and the last eight entries are mapped in the DMM_TILER_OR1 register. Therefore, given an index x, the orientation related to this index is given in the ORx field.

Each of these registers is split into eight 4-bit fields, each field mapping an entry of the LUT with:

- An S, $\overline{Y}$, $\overline{X}$ orientation code on the 3 LSBs
- An $\overline{W}$ field-specific active-low local write-enable bit, always read as 0, on the MSB.

The registers fields that correspond to initiators that do not need any dynamic configuration of their aliased view orientation must be specified as reserved fields, and only written with zeros.

The $\overline{W}$ bit allows the modification of a single entry without requiring a read-modify-write sequence. This approach is then more accommodating:

- In a system where multiple initiators can modify their own fields in the registers
- With initiators unable to make the read-modify-write sequence, such as DMA

Still, the $\overline{W}$ bit is active-low to keep the compatibility with the usual read-modify-write sequence. When reading an aliased view orientation register, because all its $\overline{W}$ bits are read as 0, if these bits are untouched by the modification—as they should be—writing back the modified register updates all orientation fields of the register.

15.2.3.6.3 TILER Guidelines for Initiators

15.2.3.6.3.1 Buffered Raster-Based Initiators

15.2.3.6.3.1.1 Buffer Size

The necessary minimum buffer size depends on the SDRAM prefetch size and on initiator support in terms of the following:

- Element size
- Orientation
- Maximum number of elements per line in all supported element sizes and orientations

Let N be the maximum number of elements per line for a given mode (element size) and orientation, P be the SDRAM memory prefetch size in bytes, and *max* be the function returning the maximum of the two parameters. The minimum necessary line buffer size to handle all resolutions in a given mode and orientation is listed in Table 15-17.

Table 15-17. Minimum Buffer Size to Efficiently Handle Lines of up to N Elements

	0- or 180- Degree Orientation (S = 0)	90- or 270-Degree Orientation (S = 1)
8-bit mode	4 × N bytes	*max* (4,P/4) × N bytes
16-bit mode	None	*max* (8,P/2) × N bytes
32-bit mode	None	*max* (8,P/2) × N bytes

This minimal buffer size can be reached only with an advanced FIFO management scheme. The standard ping-pong buffer requires twice this buffer size.

Note

Given their nature, field accesses to an interlaced frame-buffer require buffers twice as small as in the standard progressive case.

For instance, an initiator that must handle only a single progressive frame-buffer in any orientation of:

- Up to 1920 × 1080 in YUV4:2:0
- Up to 1600 × 1200 in 16-bit RGB565
- Up to 800 × 600 in 32-bit ARGB

requires a line buffer of at least 15,360 bytes because:

- 4 × 1920 + 4 × 2960 = 15,360 bytes required for a 3-plane YUV4:2:0 frame of 1920 × 1080
- 4 × 1920 + 8 × 960 = 15,360 bytes required for a 2-plane YUV4:2:0 frame of 1920 × 1080
- 8 × 1600 = 12,800 bytes required for a 16-bit RGB565 frame of 1600 × 1200
- 8 × 800 = 6400 bytes required for a 32-bit ARGB frame of 800 × 600

and a line buffer of at least 30,720 bytes when using a simple ping-pong buffer scheme.

15.2.3.6.3.1.2 Performance

Table 15-18 lists the ratio of effective data-to-transferred data at the external memory interface for the buffered raster-based initiators in each mode and orientation when using a 32-bit DDR2 or DDR3 memory.

Table 15-18. Memory Data Payload for Buffered Raster-Based Initiators on 32-Bit DDR2 or DDR3

	0- or 180-Degree Orientation (S = 0)		90- or 270-Degree Orientation (S = 1)	
	Progressive	**Interlaced**	**Progressive**	**Interlaced**
8-bit mode	100%	50%	100%	50%
16-bit mode	100%	50%	100%	50%
32-bit mode	100%	50%	100%	50%
Page mode	100%	N/A	100%	100%

When using 32-bit DDR2 or DDR3 SDRAMs, whenever all previous guidelines are fulfilled, there is no penalty for these initiators to access a tiled object in any orientation, except for accesses to an interlaced frame in any orientation where the memory bandwidth is twice the requested bandwidth.

When using DDR2 or DDR3 SDRAMs, all accesses, except interlaced accesses, are equally efficient and offer the full possible memory bandwidth.

Similarly, page mode does not introduce any performance hit.

15.2.4 DMM Use Cases and Tips

15.2.4.1 PAT Use Cases

Five ways to use PAT are:

- Simple manual area refill: Section 15.2.4.1.1
- Single auto-configured area refill: Section 15.2.4.1.2
- Chained auto-configured area refill: Section 15.2.4.1.3
- Synchronized auto-configured area refill: Section 15.2.4.1.4
- Cyclic synchronized auto-configured area refill: Section 15.2.4.1.5

Note

PAT refill area must be fully contained within either the LUT lower half or the LUT upper half. It must not span over both areas. That is, y0 MS

bit y0[7] must be equal to y1 MSbit y1[7] when defining the area descriptor.

15.2.4.1.1 Simple Manual Area Refill

The following must be performed to create a 16-byte aligned memory-mapped entry table containing all entries of the defined area (see Figure 15-39):

1. Write the DMM_PAT_AREA_i register with the relevant (x0, y0) (x1, y1) area definition.
2. Write the DMM_PAT_DATA_i register with the physical address of the created entry table.
3. Write the DMM_PAT_CTRL_i register with the requested refill direction and assert the DMM_PAT_CTRL_i[0] START bit with the requested refill direction D and with the LUT ID L if multiple LUTs are present in the system.
4. The refill is done when the DMM_PAT_STATUS_i[3] DONE bit is set.
5. A new refill can be initiated when the DMM_PAT_STATUS_i[0] READY bit is set.

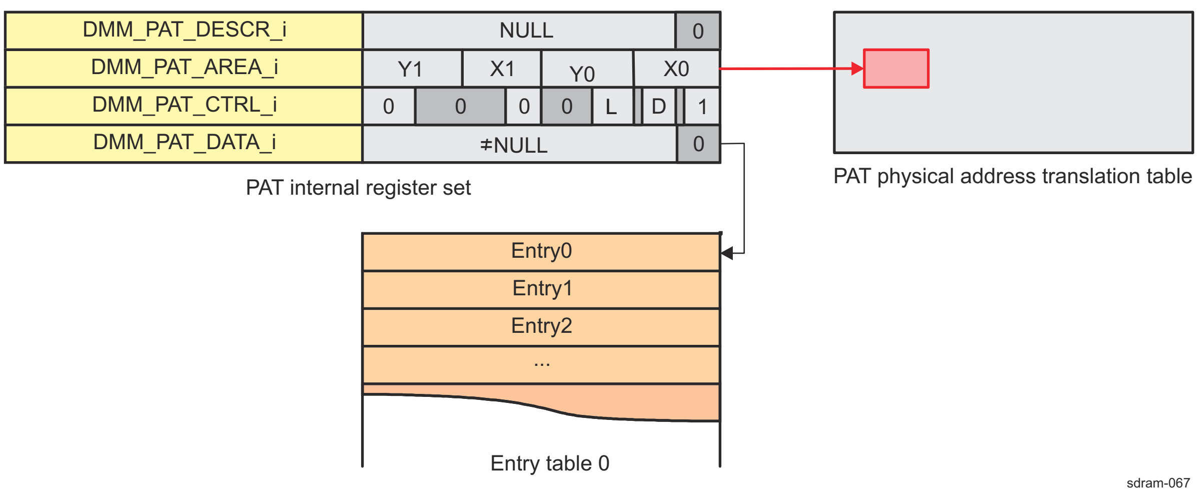

Figure 15-39. Simple Manual Area Refill Scheme

15.2.4.1.2 Single Auto-Configured Area Refill

The following must be performed to create a 16-byte aligned memory-mapped entry table containing all entries of the defined area (see Figure 15-40):

1. Create a 16-byte aligned memory-mapped descriptor structure where:
   - The next field is set to NULL.
   - The area field is set with the relevant (x0, y0) (x1, y1) area definition.

- The ctrl field is set with the requested direction D, with the requested LUT ID L if multiple LUTs are present in the system, and the START bit is asserted to start refilling as soon as this descriptor enters the PAT refill engine.
- The data field is set to the physical address of the created entry table.

2. Write the DMM_PAT_DESCR_i register with the physical address of the created descriptor.
3. The refill is done when the DMM_PAT_STATUS_i[3] DONE bit is set.
4. A new refill can be initiated when the DMM_PAT_STATUS_i[0] READY bit is set.

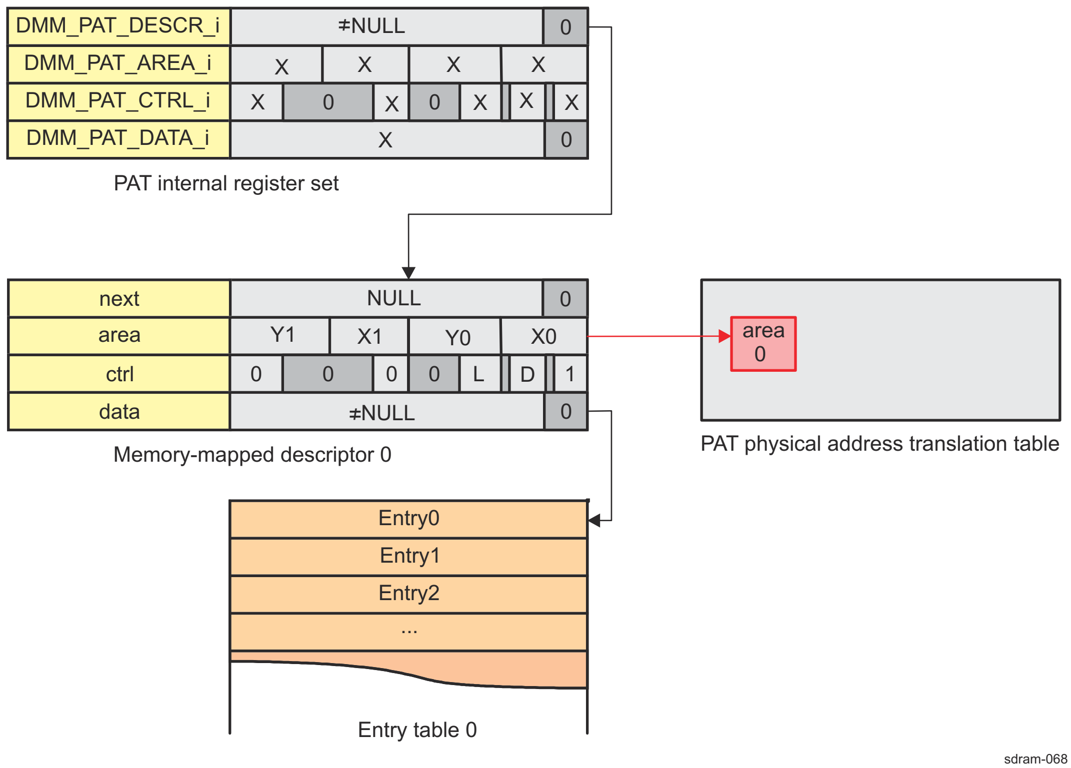

Figure 15-40. Single Auto-Configured Area Refill Scheme

15.2.4.1.3 Chained Auto-Configured Area Refill

The following must be performed to create one 16-byte aligned memory-mapped entry table per area containing the entries for the corresponding area (see Figure 15-41):

1. Create one 16-byte aligned memory-mapped descriptor structure per area where:
   - The next field is set to the physical address of the next descriptor or NULL for the last one.
   - The area field is set with the relevant (x0, y0) (x1, y1) area definition.
   - The ctrl field is set with the requested direction D, with the requested LUT ID L if multiple LUTs are present in the system, and the START bit is asserted to start refilling as soon as the previous area refill is done.
   - The data field is set to the physical address of the corresponding entry table.
2. Write the DMM_PAT_DESCR_i register with the physical address of the first created descriptor.
3. Each area refill is done when the DMM_PAT_STATUS_i[3] DONE bit is set.
4. All area refills are done when the DMM_PAT_STATUS_i[0] READY bit is set.
5. A new refill can be initiated when the DMM_PAT_STATUS_i[0] READY bit is set.

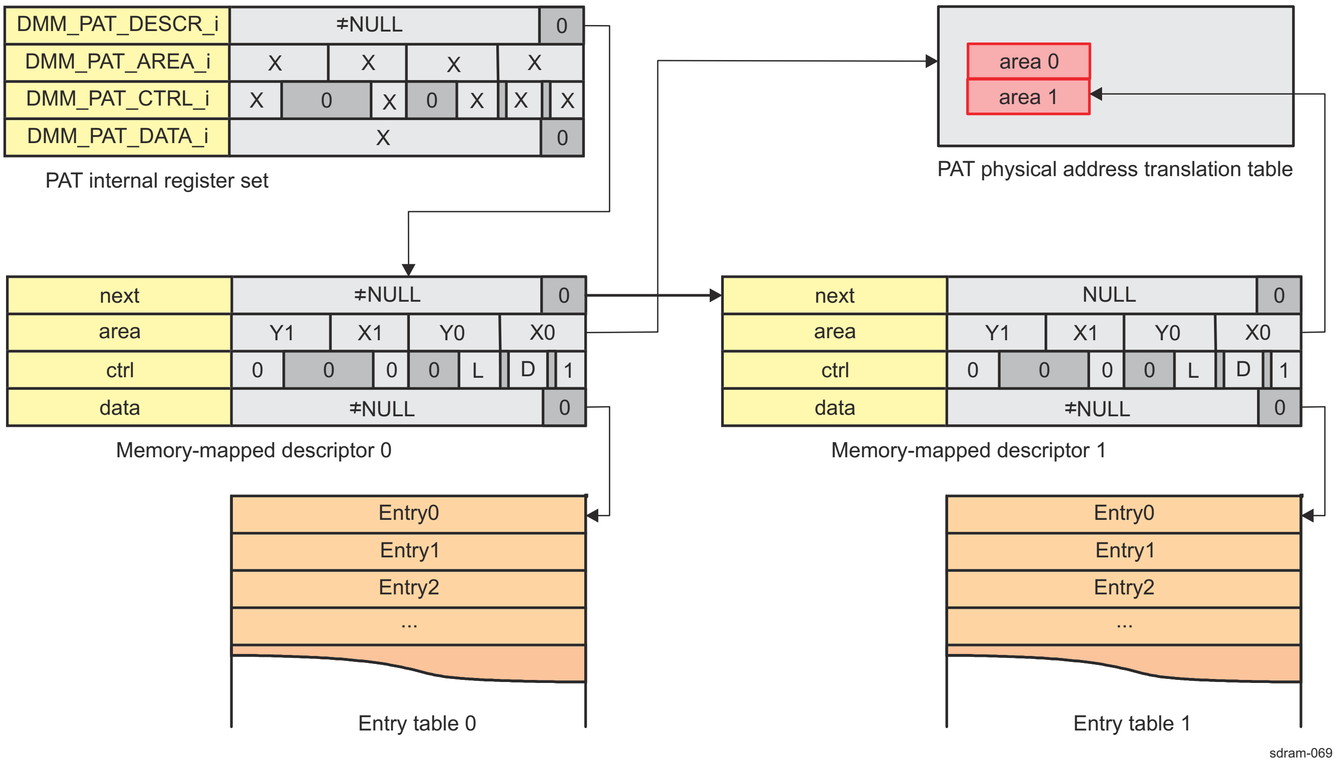

Figure 15-41. Chained Auto-Configured Area Refill Scheme

15.2.4.1.4 Synchronized Auto-Configured Area Refill

The following must be performed to create one 16-byte aligned memory-mapped entry table per area containing the entries for the corresponding area (see Figure 15-42):

1. Create one 16-byte aligned memory-mapped descriptor structure per area where:
   - The next field is set to the physical address of the next descriptor or NULL for the last one.
   - The area field is set with the relevant (x0, y0) (x1, y1) area definition.
   - The ctrl field is set with the synchronizing initiator identifier I, the SYNC bit is asserted, the requested direction D and the requested LUT ID L if multiple LUTs are present in the system, and the START bit is asserted to start refilling as soon as the previous area refill is done and initiator I has made one access in the previous area.
   - The data field is set to the physical address of the corresponding entry table.
2. Write the DMM_PAT_DESCR_i register with the physical address of the first created descriptor.
3. Each area refill is done when the DMM_PAT_STATUS_i[3] DONE bit is set.
4. All area refills are done when the DMM_PAT_STATUS_i[0] READY bit is set.
5. A new refill can be initiated when the DMM_PAT_STATUS_i[0] READY bit is set.

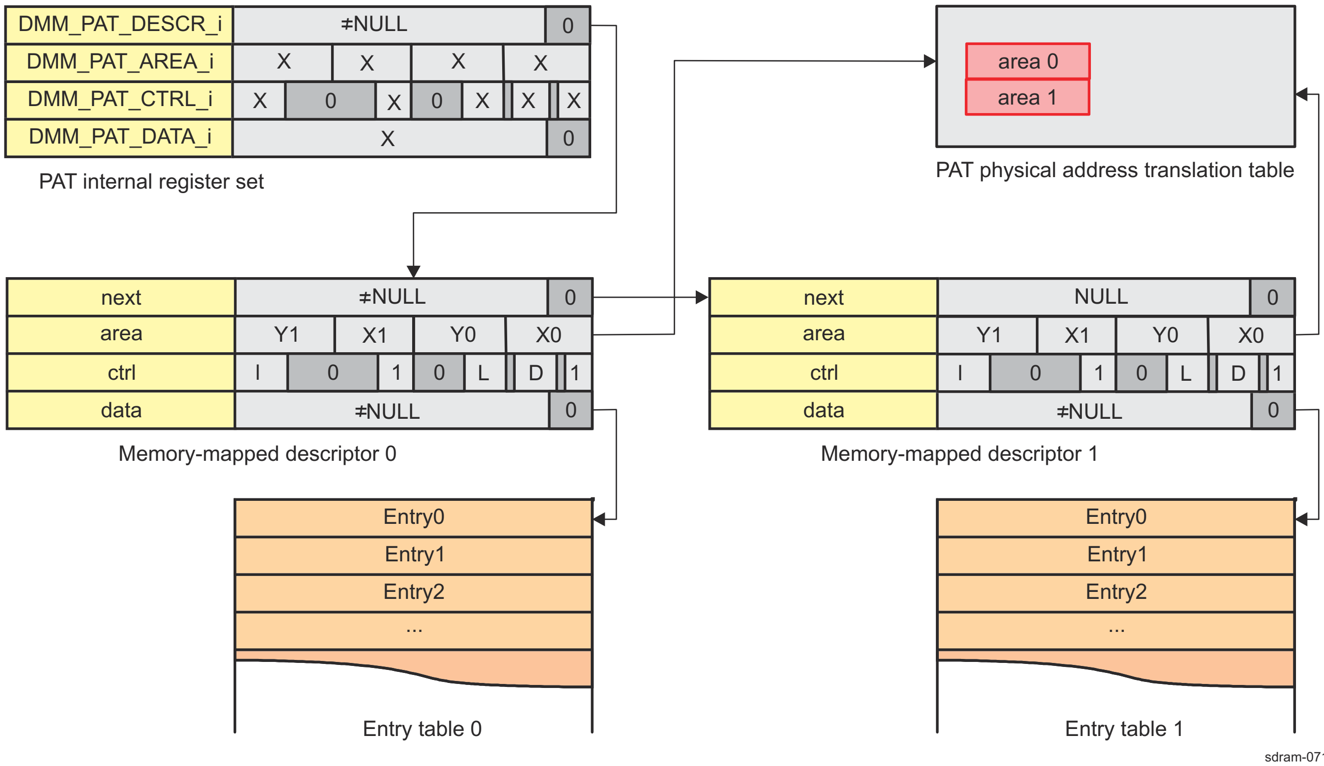

Figure 15-42. Synchronized Auto-Configured Area Refill Scheme

15.2.4.1.5 Cyclic Synchronized Auto-Configured Area Refill

The following must be performed to create one 16-byte aligned memory-mapped entry table per area containing the entries for the corresponding area (see Figure 15-43):

1. Create one 16-byte aligned memory-mapped descriptor structure per area where:
   - The next field is set to the physical address of the next descriptor in the circular list.
   - The area field is set with the relevant (x0, y0) (x1, y1) area definition.
   - The ctrl field is set with the synchronizing initiator identifier I, the SYNC bit asserted, the requested direction D and requested LUT ID L if multiple LUTs are present in the system, and the START bit is asserted to start refilling as soon as the previous area refill is done and initiator I has made one access in the previous area.
   - The data field is set to the physical address of the corresponding entry table.
2. Write the DMM_PAT_DESCR_i register with the physical address of the initial descriptor.
3. Each area refill is done when the DMM_PAT_STATUS_i[3] DONE bit is set.
4. A new refill can be initiated by writing any value to the DMM_PAT_DESCR_i register to abort the current one.

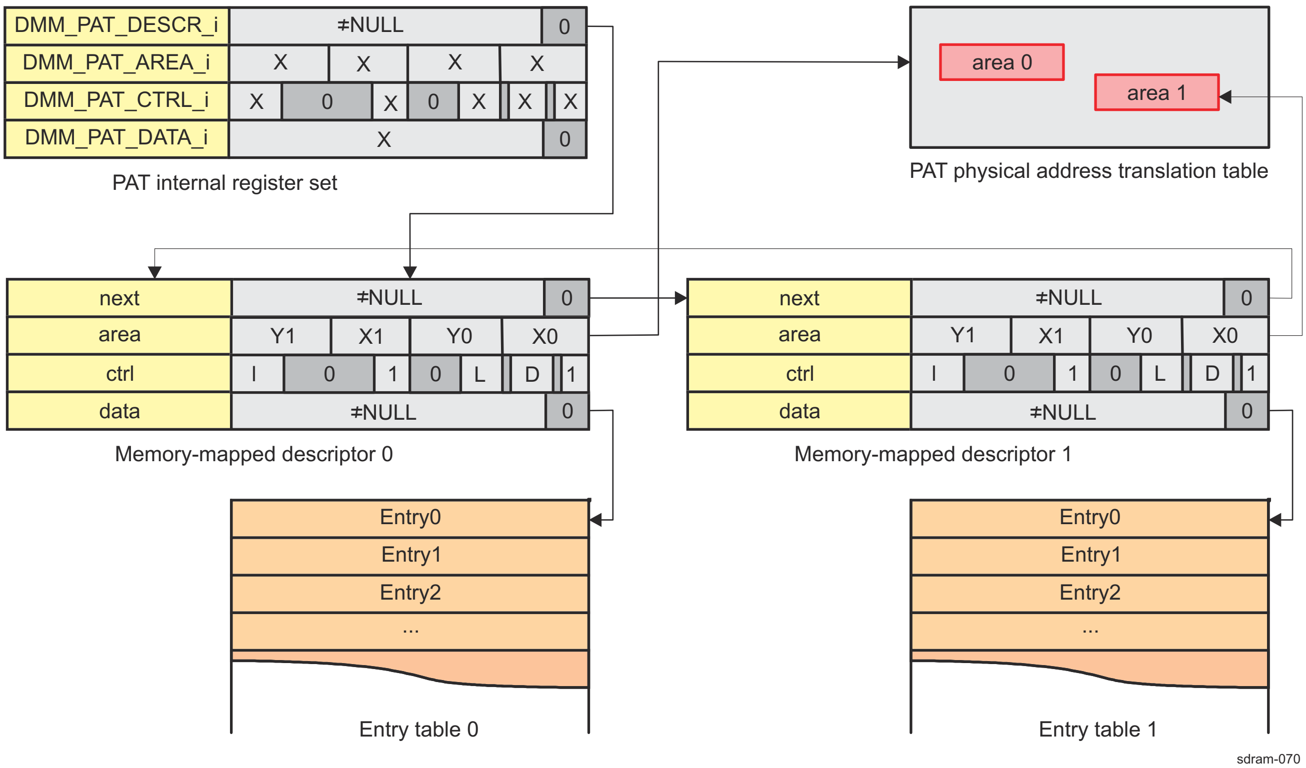

Figure 15-43. Cyclic Synchronized Auto-Configured Area Refill Scheme

---

Note

Never use circular lists of descriptors where all descriptors have the DMM_PAT_CTRL_i[0] START bit set and there is no synchronization. This leads to an endless continuous refill.

15.2.4.2 Addressing Management with LISA

15.2.4.2.1 Case 1: Use of One Memory Controller

In this example, assume there is 1 GiB of external memory evenly spread onto two address spaces. The address range for address space 0 must start at offset 0x2000_0000 (see Table 15-19).

Table 15-19. Address Definition

Address Range	Memory Controller	Memory Controller Address Space(1)	Memory Controller Address Range
0x8000_0000 to 0x9FFF_FFFF	EMIF1	0x0	0x0000_0000 to 0x1FFF_FFFF
0xA000_0000 to 0xBFFF_FFFF	EMIF1	0x0	0x2000_0000 to 0x3FFF_FFFF

(1) For memory controller address spaces, see *Local Interface* in *EMIF Controller*.

This configuration requires two nonoverlapping sections to be set. They can be defined in any order because there is no concern with priority in this case (see Table 15-20):

Table 15-20. Configuration

Bit Field	Section 0 (DMM_LISA_MAP_0)	Section 1 (DMM_LISA_MAP_1)
[31:24] SYS_ADDR	0x80	0xA0
[22:20] SYS_SIZE	0x5	0x5
[19:18] SDRC_INTL	0x0 (not applicable)	0x0 (not applicable)
[17:16] SDRC_ADDRSPC	0x0	0x0
[9:8] SDRC_MAP	0x1 (only EMIF1)	0x1 (only EMIF1)

Table 15-20. Configuration (continued)

Bit Field	Section 0 (DMM_LISA_MAP_0)	Section 1 (DMM_LISA_MAP_1)
[7:0] SDRC_ADDR	0x00	0x20

To check whether an address hits a section, use the 8 upper address bits of the address and mask them with the hit mask: $2^8–2^{SYS\_SIZE}$. If the result is equal to SYS_ADDR, the section is hit.

To define the physical address to be issued to the memory controller, use the 8 upper address bits of the system address, mask them with the address mask: $2^{SYS\_SIZE}–1$, and OR them with SDRC_ADDR. This gives the resulting 8 upper physical address bits. All lower address bits are forwarded unchanged.

Request to address 0x99AE_37F0:

- Upper address bits: 0x99
- Hit mask: $2^8–2^5$ = 0xE0
- Masked upper address bits: 0x80, that is, hits section 0
- Address mask: $2^5–1$ = 0x1F
- Masked upper address bits: 0x19
- OR with SDRC_ADDR: 0x19
- Physical address: 0x19AE_37F0

This request is forwarded to address 0x19AE_37F0, address space 1 of the memory controller.

Request to address 0xB7FF_0340:

- Upper address bits: 0xB7
- Hit mask: $2^8–2^5$ = 0xE0
- Masked upper address bits: 0xA0, that is, hits section 1
- Address mask: $2^5–1$ = 0x1F
- Masked upper address bits: 0x17
- OR with SDRC_ADDR: 0x37
- Physical address: 0x37FF_0340

This request is forwarded to address 0x37FF_0340, address space 0 of the memory controller.

15.2.4.2.2 Case 2: Use of Two Memory Controllers

In the case of 512 MiB interleaved at 128-byte boundaries and 256 MiB noninterleaved on the second memory controller, one address space per memory controller, we have the following results (see Table 15-21).

Table 15-21. Address Definition

Address Range	Memory Controller	Memory Controller Address Space(1)	Memory Controller Address Range
0x8000_0000 to 0x9FFF_FFFF	EMIF1 and EMIF2, interleaved at 128-byte boundaries	0x0 on both controllers	0x0000_0000 to 0x0FFF_FFFF on both controllers
0xA000_0000 to 0xAFFF_FFFF	EMIF2 only	0x0	0x1000_0000 to 0x1FFF_FFFF

(1) For memory controller address spaces, see *Local Interface* in *EMIF Controller*.

Two sections are used to map such a configuration (see Table 15-22).

Table 15-22. Configuration

Bit Field	Section 0 (DMM_LISA_MAP_0)	Section 1 (DMM_LISA_MAP_1)
[31:24] SYS_ADDR	0x80	0xA0
[22:20] SYS_SIZE	0x5	0x4
[19:18] SDRC_INTL	0x1	0x0 (not applicable)
[17:16] SDRC_ADDRSPC	0x0	0x0
[9:8] SDRC_MAP	0x3	0x2
[7:0] SDRC_ADDR	0x00	0x10

Detecting a section hit is the same for the interleaved case as for the single controller case: To check whether an address hits a section, use the 8 upper address bits of the address and mask them with the hit mask: $2^8–2^{SYS\_SIZE}$. If the result is equal to SYS_ADDR, the section is hit.

The physical address generation is modified for the interleaved case. In case of 256-byte interleaving, the first chunk of 256 bytes is mapped to the first controller, the second chunk to the second controller, and so on. This results in system address bit 8 to be decoded as the controller indicator, 0 for the first controller, and 1 for the second controller (system address bit 7 is used for interleaving at the 128-byte boundary, and bit 9 for 512 bytes). This bit is not included in the computed physical address, meaning the upper system address bits [31:9] are shifted to bits [30:8] when generating the physical address.

The rest of the address generation is handled the same as for the single controller case: to define the physical address to be issued to the memory controller, use the 8 upper address bits of the system address, mask them with the address mask: $2^{SYS\_SIZE}–1$, and OR them with SDRC_ADDR. This gives the resulting 8 upper physical address bits. All lower address bits are forwarded unchanged.

Request to address 0x99AE_37F0:

- Upper address bits: 0x99
- Hit mask: $2^8–2^5$ = 0xE0
- Masked upper address bits: 0x80, that is, hits section 0
- Address mask: $2^5–1$ = 0x1F
- Masked upper address bits: 0x19
- Full masked address: 0x19AE_37F0
- Bit 7 is 1, that is, targets the second memory controller
- Full masked shifted address (suppressing bit 7): 0x0CD7_1BF0 (see Section 15.2.4.2.2.1)
- OR upper physical address bits with SDRC_ADDR: 0x0CD7_1BF0
- Physical address: 0x0CD7_1BF0

This request is forwarded to address 0x0CD7_1BF0, address space 0, of the second memory controller.

15.2.4.2.2.1 Address Upper Bits Shifting

Table 15-23 describes shifting the address upper bits.

Table 15-23. Address Upper Bits Shifting

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

0	0	0	1	1	0	0	1	1	0	1	0	1	1	1	0	0	0	1	1	0	1	1	1	1	1	1	1	0	0	0	0
Address After Interleaving																															
0	0	0	0	1	1	0	0	1	1	0	1	0	1	1	1	0	0	0	1	1	0	1	1	1	1	1	1	0	0	0	0

15.2.5 DMM Basic Programming Model

The programming model section:

- Describes how objects can be addressed in all TILER modes and orientations
- Explains how the physical containers and PAT LUT can be shared between different modes
- Does not give an exhaustive description of the TILER and DMM registers, because these are described in Section 15.2.3.5, *DMM*, and Section 15.2.3.6, *TILER*.

15.2.5.1 Global Initialization

This section identifies the requirements for initializing the surrounding modules when the DMM is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the DMM (see Table 15-24).

Table 15-24. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	The module interface and functional clocks must be enabled. See *Power, Reset, and Clock Management.*
Image processing unit (IPU)	IPU interrupt controller (INTC) configuration must be done to enable the interrupts from the DMM. See *Interrupt Controllers.*
Main processing unit (MPU)	MPU INTC configuration must be done to enable interrupts from the DMM. See *Interrupt Controllers.*
L3_MAIN interconnect	Data interface

15.2.5.2 DMM Module Global Initialization

Theprocedure in Table 15-25 initializes the DMM after a power-on reset (POR).

Table 15-25. DMM Global Initialization

Step	Register/Bit Field/Programming Model	Value
Configure the DMM for smart-idle power management mode.	DMM_SYSCONFIG[3:2] IDLE_MODE	0x2

15.2.5.3 DMM Operational Modes Configuration

15.2.5.3.1 Different Operational Modes

The TILER can be virtually accessed in four different modes: 8-, 16-, 32-bit, and page modes. Each mode defines the element granularity to apply isometric transforms (see Table 15-26).

Table 15-26. Coding and Description of TILER Modes

Mode	Name	Granularity (Element Size)
0	8-bit tiled mode	8 bits
1	16-bit tiled mode	16 bits
2	32-bit tiled mode	32 bits
3	Page mode	4096 bytes

15.2.5.3.2 Configuration Settings and LUT Refill

The procedure in Table 15-27 provides the configuration settings and LUT refill.

Table 15-27. Configuration Settings and LUT Refill

Step	Register/Bit Field/Programming Model	Value
PAT configuration refill Engine 0	DMM_PAT_CONFIG[0] MODE0	xxx
PAT configuration refill Engine 1	DMM_PAT_CONFIG[1] MODE1	xxx
Set DMM PAT view register value for each initiator.	DMM_PAT_VIEW0 Vx DMM_PAT_VIEW1 Vx	xxx

Table 15-27. Configuration Settings and LUT Refill (continued)

Step	Register/Bit Field/Programming Model	Value
Set DMM PAT write enable for the initiators.	DMM_PAT_VIEW0 Wx DMM_PAT_VIEW1 Wx	xxx
Choosing container type and access method	DMM_PAT_VIEW_MAP_i	xxx
Define the base address of all view mappings.	DMM_PAT_VIEW_MAP_BASE[31] BASE_ADDR	xxx
Set area definition for DMM physical address translator.	DMM_PAT_AREA_i	xxx
Set the physical address of the current table refill entry data or entry data when in manual mode.	DMM_PAT_DATA_i[31:4] ADDR	xxx
Define the direction of this PAT table refill (S Y X), different from 0x011.	DMM_PAT_CTRL_i[6:4] DIRECTION	xxx
Start a PAT table refill.	DMM_PAT_CTRL_i[0] START	0x1

15.2.5.3.3 Interleaving Settings

The procedure in Table 15-28 provides the interleaving settings.

Table 15-28. Interleaving Settings

Step	Register/Bit Field/Programming Model	Value
Set DMM system section address MSB.	DMM_LISA_MAP_i[31:24] SYS_ADDR	xxx
Set DMM system section size.	DMM_LISA_MAP_i[22:20] SYS_SIZE	xxx
Set SDRC interleaving mode.	DMM_LISA_MAP_i[19:18] SDRC_INTL	xxx
Set SDRC address space.	DMM_LISA_MAP_i[17:16] SDRC_ADDRSPC	xxx
Set SDRC mapping.	DMM_LISA_MAP_i[9:8] SDRC_MAP	xxx
Set SDRC address MSB.	DMM_LISA_MAP_i[7:0] SDRC_ADDR	xxx
Enable/disable DMM memory mapping lock.	DMM_LISA_LOCK[0] LOCK	xxx

15.2.5.3.4 Aliased Tiled View Orientation Settings and LUT Refill

The procedure in Table 15-29 provides the settings for aliased tiled view and LUT refill.

Table 15-29. Aliased Tiled View Orientation Settings and LUT Refill

Step	Register/Bit Field/Programming Model	Value
Set DMM TILER orientation for each initiator.	DMM_TILER_OR0 ORx DMM_TILER_OR1 ORx	xxx
Set DMM TILER write enable for the initiators.	DMM_TILER_OR0 Wx DMM_TILER_OR1 Wx	xxx
Define the base address of all view mappings.	DMM_PAT_VIEW_MAP_BASE[31] BASE_ADDR	xxx
DMM PAT initiator for synchronization	DMM_PAT_CTRL_i[31:28] INITIATOR	xxx
Set DMM PAT table reload synchronization.	DMM_PAT_CTRL_i[16] SYNC	xxx
Set DMM PAT LUT index (when more than one LUTs).	DMM_PAT_CTRL_i[9:8] LUT_ID	xxx
Define the direction of this PAT table refill (S Y X).	DMM_PAT_CTRL_i[6:4] DIRECTION	xxx
Start a PAT table refill.	DMM_PAT_CTRL_i[0] START	0x1

15.2.5.3.5 Priority Settings

The procedure in Table 15-30 provides the sequence to set priorities.

Table 15-30. Priority Settings

Step	Register/Bit Field/Programming Model	Value
Set priority for each initiator.	DMM_PEG_PRIO_k Px	xxx
Set write enable for P_PAT field.	DMM_PEG_PRIO_PAT[4] W_PAT	xxx
Set priority for PAT engine.	DMM_PEG_PRIO_PAT[2:0] W_PAT	xxx

15.2.5.3.6 Error Handling

The procedure in Table 15-31 provides the sequence for error handling.

Table 15-31. Error Handling

Step	Register/Bit Field/Programming Model	Value
Enable interrupt for selected type of error.	DMM_PAT_IRQENABLE_SET[15:9] DMM_PAT_IRQENABLE_SET[7:0]	xxx
When interrupt occurs		
Disable type of error to handle.	DMM_PAT_IRQENABLE_CLR[15:9] DMM_PAT_IRQENABLE_CLR[7:0]	xxx
Check error status.	DMM_PAT_IRQSTATUS[15:9] DMM_PAT_IRQSTATUS[7:0]	xxx

15.2.5.3.7 PAT Programming Model

The PAT maps the tiled data anywhere in the 4-GiB physical address range, with a PAGE granularity. (The TILER page is the granularity of physical memory allocation in the TILER container. Each page is 4kiB).

A PAT view defines the kind of PAT to perform for each page, 8-, 16-, and 32-bit mode access. Each mode in each PAT view can be programmed in two different modes: direct translation and indirect translation.

15.2.5.3.7.1 PAT in Direct Translation Mode

In this mode, the PAT performs a translation of the 128-MiB virtual container as a whole in the physical address space (that is, in the SDRAM). This mode is used only for debug or in case of a DMM without a PAT.

15.2.5.3.7.2 PAT in Indirect Translation Mode

This is the most commonly used mode. In this mode, the PAT performs a translation of each 4-KiB page individually. In this way the 128-MiB virtual address space can be scattered in the whole 2 GiB of the physical address space. This is achieved by using a 32,678-word LUT that converts each page index (32,768 possible values) into 19 address bits that represent this page address in the physical memory. The main characteristic of this mode is there is no constraint on the use of the physical memory except that it is uses a multiple of 4-KiB areas located at 4-KiB boundaries in the physical memory. In this mode, the translation vector is in the internal 32-k entry PAT vector table at the index given by bits [26:12] of the input virtual address, and CONT_x = 0.

Programming sequence:

1. Set the DMM_PAT_VIEW0 register (or DMM_PAT_VIEW1, depending on the L3 CONN_ID of the initiator that is to perform the tiled accesses) with the appropriate value. For example, if the L3 CONN_ID equals 0, then the DMM_PAT_VIEW0 register must be programmed with the value 0x0000_0001 (PAT view 1 selected for initiator 0).
2. Set DMM_PAT_VIEW_MAP_BASE[31] = 0x8000_0000 (must always be programmed at 1 to select the upper 2 GiB of the physical address space that corresponds to the external memory).
3. Set all 16-bit tiled accesses in indirect translation mode by setting at least the field ACCESS_16 to 1 (DMM_PAT_VIEW_MAP_1 = 0x0000_8000), program DMM_PAT_VIEW_MAP_1 at 0x8080_8080.

15.2.5.4 Addressing an Object in Tiled Mode

This section describes how a frame-buffer with a top-left pixel at (x0,y0) in the natural view container and a bottom right pixel at (x1,y1) in the natural view container is addressed in any tiled mode and orientation.

15.2.5.4.1 Frame-Buffer Addressing

Note

In this section, the (x,y) coordinates are given in pixel units.

Given an (S, $\overline{Y}$, $\overline{X}$) orientation, the (x,y) coordinates of the first pixel of the frame in the oriented view (where W = the width and H = the height in pixels of the container in the considered frame mode) is:

$(x,y) = (x_{or}, y_{or})$ when S, (y_{or}, x_{or}) otherwise
with:
$x_{or} = x_0$ when $\overline{X}$, $W\text{-}1\text{-}x_1$ otherwise
$y_{or} = y_0$ when $\overline{Y}$, $H\text{-}1\text{-}y_1$ otherwise

Given a (M_1, M_0) TILER mode where M_1 # 0 or M_0 # 0, the size in bytes of a pixel is 2^{2M1+M0}.

Therefore, given an (S, $\overline{Y}$, $\overline{X}$) orientation and a $n(M_1, M_0)$ TILER mode where M_1 # 0 or M_0 # 0, the byte offset of the base address of the considered oriented frame in its container is:
base_address($(x_0, y_0), (x_1, y_1)$, (S, $\overline{Y}$, $\overline{X}$), (M_1, M_0)) = $(y_{or}W + x_{or})\ P_5$ when S, $(x_{or}H + y_{or})\ P_5$ otherwise
with:
$x_{or} = x_0$ when $\overline{X}$, $W\text{-}1\text{-}x_1$ otherwise
$y_{or} = y_0$ when $\overline{Y}$, $H\text{-}1\text{-}y_1$ otherwise
$P_5 = 2^{2M1+M0}$

In its natural orientation, the TILER container consists of 8192 lines of 16,384 pixels of 8 bits, or 4096 lines of 16,384 pixels of 16 bits, or 4096 lines of 8192 pixels of 32 bits.

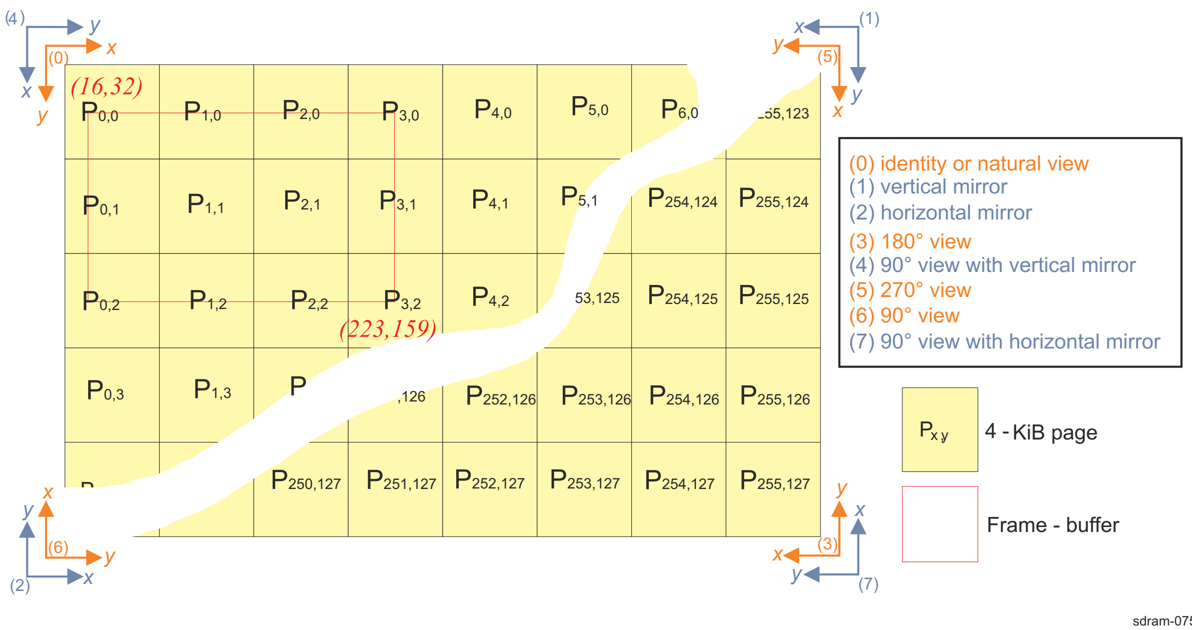

Figure 15-44. Example of 8-Bit Frame-Buffer Addressing in any Orientation

This frame-buffer address generation is independent from the page size. For instance, the 8-bit frame-buffer shown in Figure 15-44 that ranges from the top-left pixel at (16, 32) to the bottom-right pixel at (223, 159) in the natural orientation view, corresponds to the 29-bit view address offsets and full 33-bit TILER addresses given in Table 15-32.

Table 15-32. 29-Bit View Address Offset and 33-Bit Full TILER Address for an 8-Bit Frame-Buffer

S	$\overline{Y}$	$\overline{X}$	x_{or}	y_{or}	29-Bit Address Offset in View	Full 33-Bit TILER Address
0	0	0	16	32	00080010h	100080010h
0	0	1	16,160	32	00083F20h	120083F20h
0	1	0	16	8032	07D80010h	147D80010h
0	1	1	16,160	8032	07D83F20h	167D83F20h
1	0	0	16	32	00020020h	180020020h
1	0	1	16,160	32	07E40020h	1A7E40020h
1	1	0	16	8032	00021F60h	1C0021F60h
1	1	1	16,160	8032	07E41F60h	1E7E41F60h

In this example the TILER is addressed in 8-bit mode, which translates to addresses with all mode bits (bits 27 and 28) cleared in the 29-bit address offset in view and in the full 33-bit TILER address.

15.2.5.4.2 TILER Page Mapping

Let:

- c (c = 0, 1, or 2) be the TILER page configuration (0 for 4-kiB pages, 1 for 16-kiB pages, and 2 for 64-kiB pages)
- (x_0, y_0) be the top-left pixel and (x_1, y_1) be the bottom-right pixel of a frame in its natural orientation
- W be the width and H the height in pixels of the container in the considered frame mode

The top-left page coordinates (P_{x0}, P_{y0}) and bottom-right page coordinates (P_{x1}, P_{y1}) that correspond to the frame are given by: $P_{x0} = (64.x_0.2^{2-c}) / W$, $P_{y0} = (32.y_0.2^{2-c}) / H$, $P_{x1} = (64.x_1.2^{2-c}) / W$ and $P_{y1} = (32.y_1.2^{2-c}) / H$.

In its natural orientation, the TILER container consists of 8192 lines of 16,384 pixels of 8 bits, or 4096 lines of 16,384 pixels of 16 bits, or 4096 lines of 8192 pixels of 32 bits.

Note

The page area type has the same structure as the DMM_PAT_AREA_i registers. For instance, the 8-bit frame-buffer described in Figure 15-44 and ranging from the top-left pixel at (16, 32) to the bottom-right pixel at (223, 159) in the natural orientation view, is mapped from the top-left page at P0,0 to the bottom-right page P3,2.

15.2.5.5 Addressing an Object in Page Mode

In page mode, the orientation modifies only the sequence of accessed pages, not their content. In this respect the orientation must be seen as a way to optimize the one-dimensional (1D) object allocation in a TILER container by allowing a 1D object spanning multiple pages to map a set of adjacent pages in any direction. For instance, a 1.25-MiB object, mapped on 320 pages of 4kiB can be allocated in a TILER container in any of the eight orientations (see Section 15.2.3.6.1.8.3, *Element Ordering in the TILER Container*).

The initial page can be chosen freely among all pages. In this respect, the address offset of a page in a TILER container is expressed as:

Let:

- c (c = 0, 1 or 2) be the TILER page configuration (0 for 4-kiB pages, 1 for 16-kiB pages, and 2 for 64-kiB pages)
- (S, $\overline{Y}$, $\overline{X}$) be the orientation of the considered 1D object in page mode
- (P_x, P_y) be the coordinate of the initial page in the natural orientation view

The byte offset of the base address of the considered initial page in its oriented container is:
base_address((P_x, P_y), (S, $\overline{Y}$, $\overline{X}$)) = $4096.(64.y_{or}.2^{2-c} + x_{or}).2^{2.c}$ when S, $4096.(32.x_{or}.2^{2-c} + y_{or}).2^{2.c}$ otherwise with:
$x_{or} = P_x$ when $\overline{X}$, $64.2^{2-c}-1-P_x$ otherwise
$y_{or} = P_y$ when $\overline{Y}$, $32.2^{2-c}-1-P_y$ otherwise

For instance, a 1D object starting from the page P32,63 in the natural orientation view on a DMM using 4-kiB pages, corresponds to the 29-bit view address offsets and full 33-bit TILER addresses given in Table 15-33.

Table 15-33. 29-Bit View Address Offset and 33-Bit Full TILER Address for a 1D Object

S	$\overline{Y}$	$\overline{X}$	x_{or}	y_{or}	29-Bit Address Offset in View	Full 33-Bit TILER Address
0	0	0	32	63	1BF20000h	11BF20000h
0	0	1	223	63	1BFDF000h	13BFDF000h
0	1	0	32	64	1C020000h	15C020000h
0	1	1	223	64	1C0DF000h	17C0DF000h
1	0	0	32	63	1903F000h	19903F000h

Table 15-33. 29-Bit View Address Offset and 33-Bit Full TILER Address for a 1D Object (continued)

S	$\overline{Y}$	$\overline{X}$	x_{or}	y_{or}	29-Bit Address Offset in View	Full 33-Bit TILER Address
1	0	1	223	63	1EFBF000h	1BEFBF000h
1	1	0	32	64	19040000h	1D9040000h
1	1	1	223	64	1EFC0000h	1FEFC0000h

In this example the TILER is addressed in page mode, which translates to addresses with mode bits (bits 27 and 28) set in the 29-bit address offset in view and full 33-bit TILER address.

15.2.5.6 Sharing Containers Between Different Modes

When allocating objects in TILER containers, ensure that no two objects physically overlap.

In this respect, and to ease the object allocation and deallocation, it is strongly advised to share a TILER page only for different objects that do both of the following:

- Belong to the same mode
- Have the same lifetime (that is, are allocated and deallocated simultaneously)

Two objects of different modes can physically overlap if:

- One physical page is mapped twice in two different locations of the DMM LUT.
- The two objects share the DMM LUT and the intersection of their two page set is not empty.

  These two issues can be easily avoided by allocating a physical page only once in the DMM LUT.

  The second issue is a bit more difficult, especially if the allocation of objects in the various TILER containers must be dynamic. Managing the fragmentation within a flat memory model in a space-constrained system is not straightforward, and is the main reason for the existence of MMUs in most current processors, which adds yet another constraint to the problem (the y dimension, which makes it even more difficult).

Returning to the CPU-analogy, the memory fragmentation issue is mostly solved by using a virtual memory space larger than the actual physical memory space and a virtual-to-physical translation system. This allows contiguous virtual memory allocation when sufficient physical memory is available and the larger contiguous physical buffer is smaller than the requested memory allocation.

Similarly, the DMM answer to this object allocation in the TILER containers is two-fold:

- The DMM must have sufficient virtual address space in all modes to permit a static allocation of a pool of virtual buffers in all TILER modes for all TILER-aware initiators.
- Each TILER-aware initiator must dynamically manage its own pool of virtual buffers.

15.2.6 DMM Register Manual

This section provides information about the DMM registers. Table 15-34 describes the DMM instance.

15.2.6.1 DMM Instance Summary

Table 15-34. DMM Instance Summary

15.3 EMIF Controller

This section describes mainly the features and functions of the two external memory interface (EMIF) controllers and also their associated PHYs.

15.3.1 EMIF Controller Overview

The EMIF controller provides connectivity between the device and DDR2 type or DDR3 type of memories and manages data bus read/write accesses between external memories and the device subsystems which have access to the L3_MAIN interconnect and DMA capability too.

The EMIF features are introduced in Section 15.1.3 *EMIF Overview* of Section 15.1 *Memory Subsystem Overview*.

The device includes two EMIF controllers. Each controller supports up to 2 GiB of SDRAM over one chip select. As a result the total physical available SDRAM space is 4 GiB. Figure 15-45 shows an overview of these EMIF controllers and also the connections to the other surrounding modules. As can be seen on Figure 15-45 the two EMIFs are not directly available on device pads. That is, they are not directly connected to the external SDRAMs. There are DDR PHYs and then DDR I/Os between each EMIF controller and external SDRAM. The EMIF controller, the DDR PHYs and the DDR I/Os work like a single unit to manage data exchanges to and from external memories. To achieve successful data transaction between an internal device initiator and external SDRAM all these three components must be used.

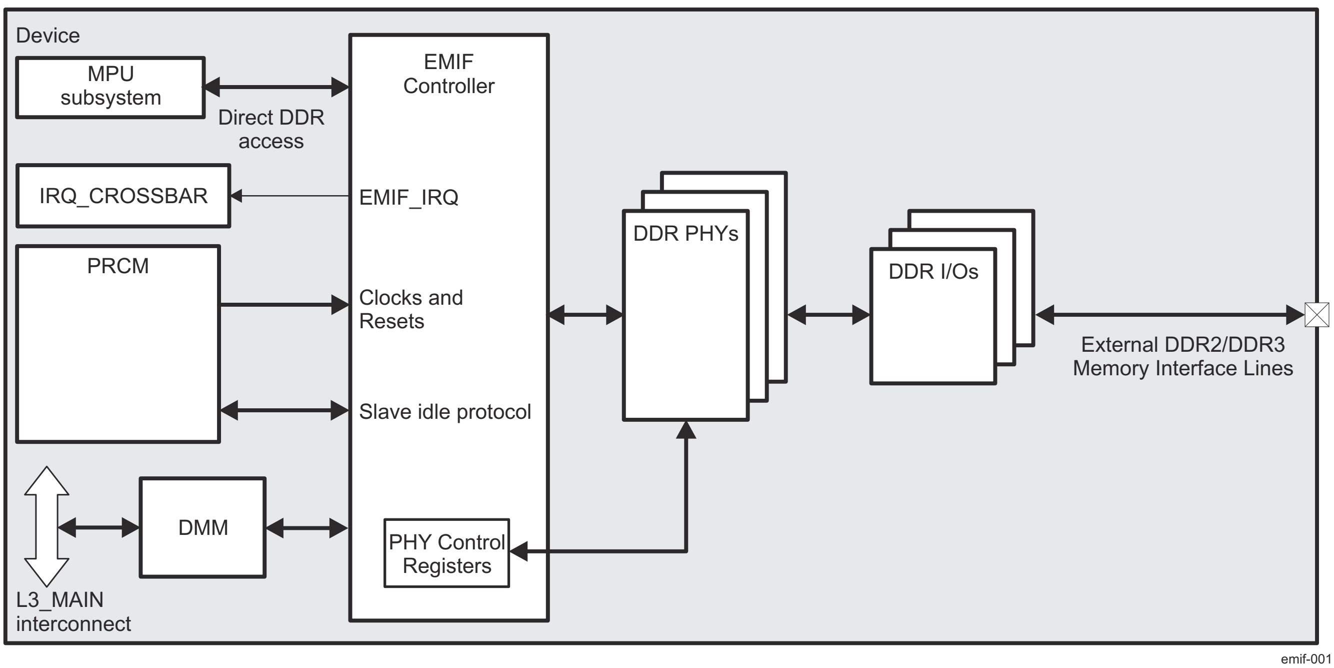

Figure 15-45. EMIF Controller Overview

15.3.2 EMIF Module Environment

This section describes the external connections of the two EMIF modules.

Figure 15-46 shows an example EMIF DDR2/DDR3 configuration without ECC memory connected.

Figure 15-47 shows an example EMIF DDR2/DDR3 configuration with ECC memory connected.

For simplification the DDR PHYs and DDR I/Os are not shown. Only the I/O signals and their corresponding EMIF pins are shown.

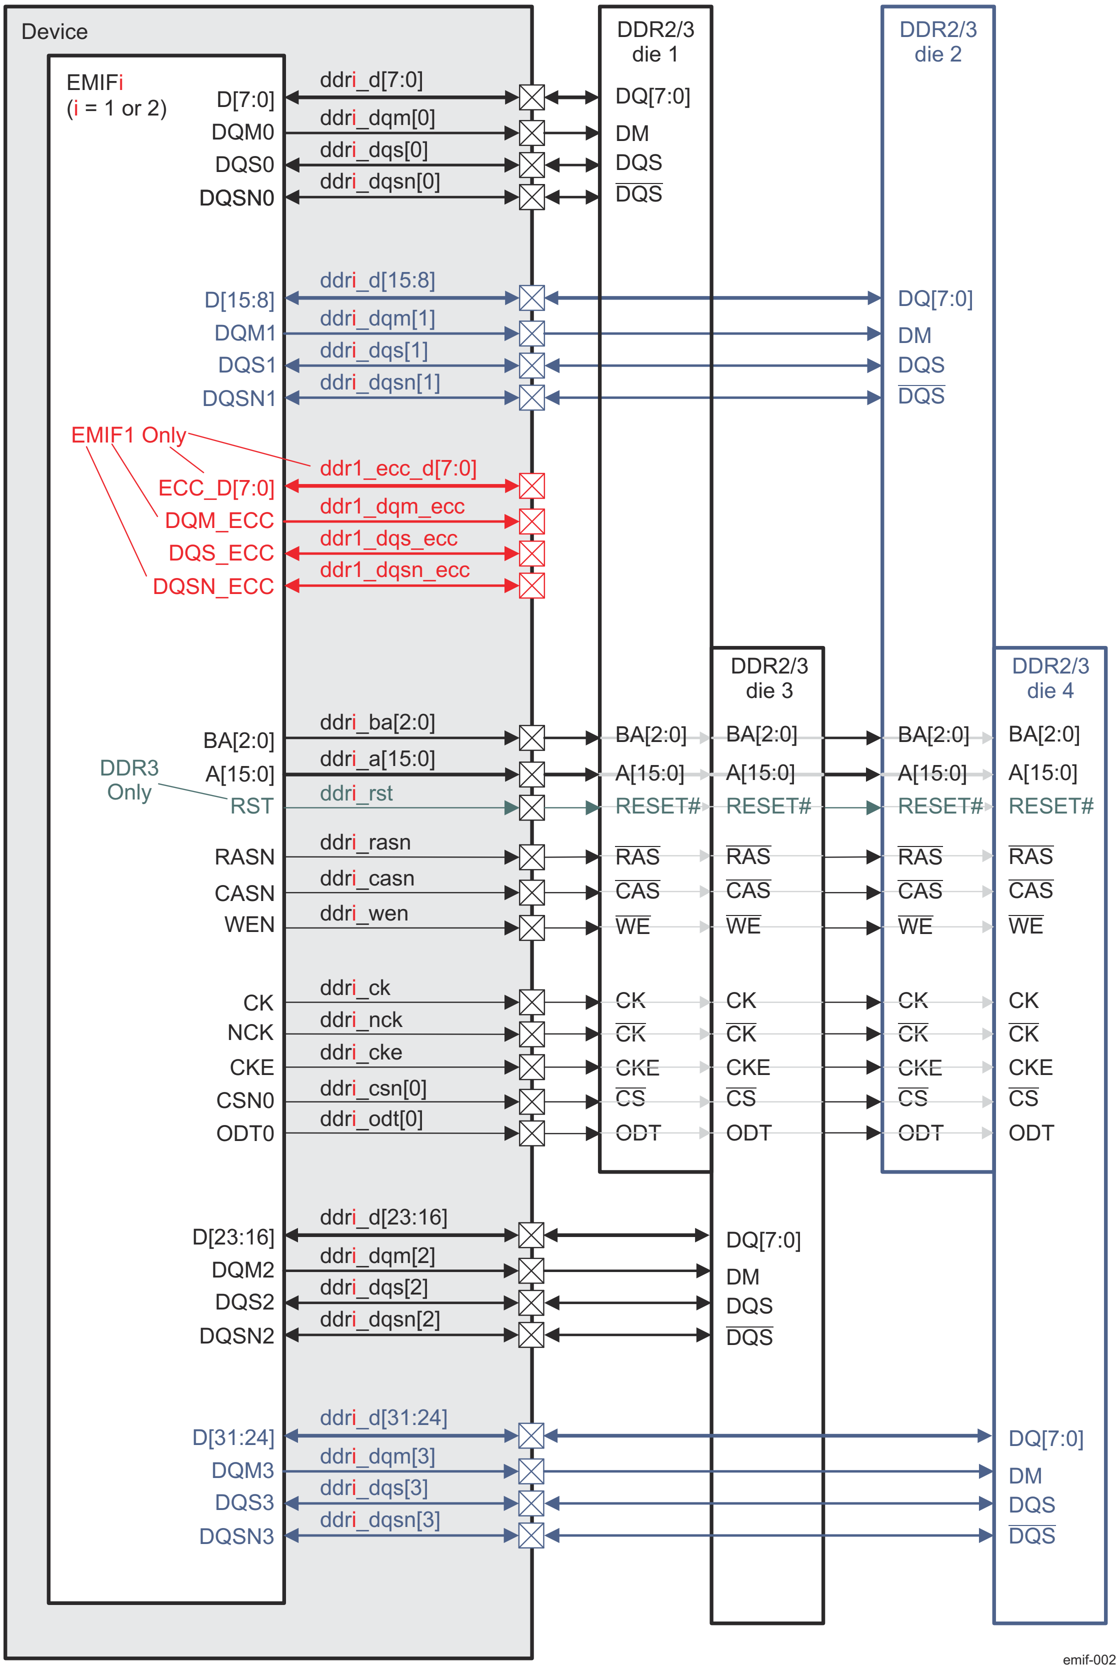

Figure 15-46. EMIF DDR2/DDR3 Configuration Without ECC

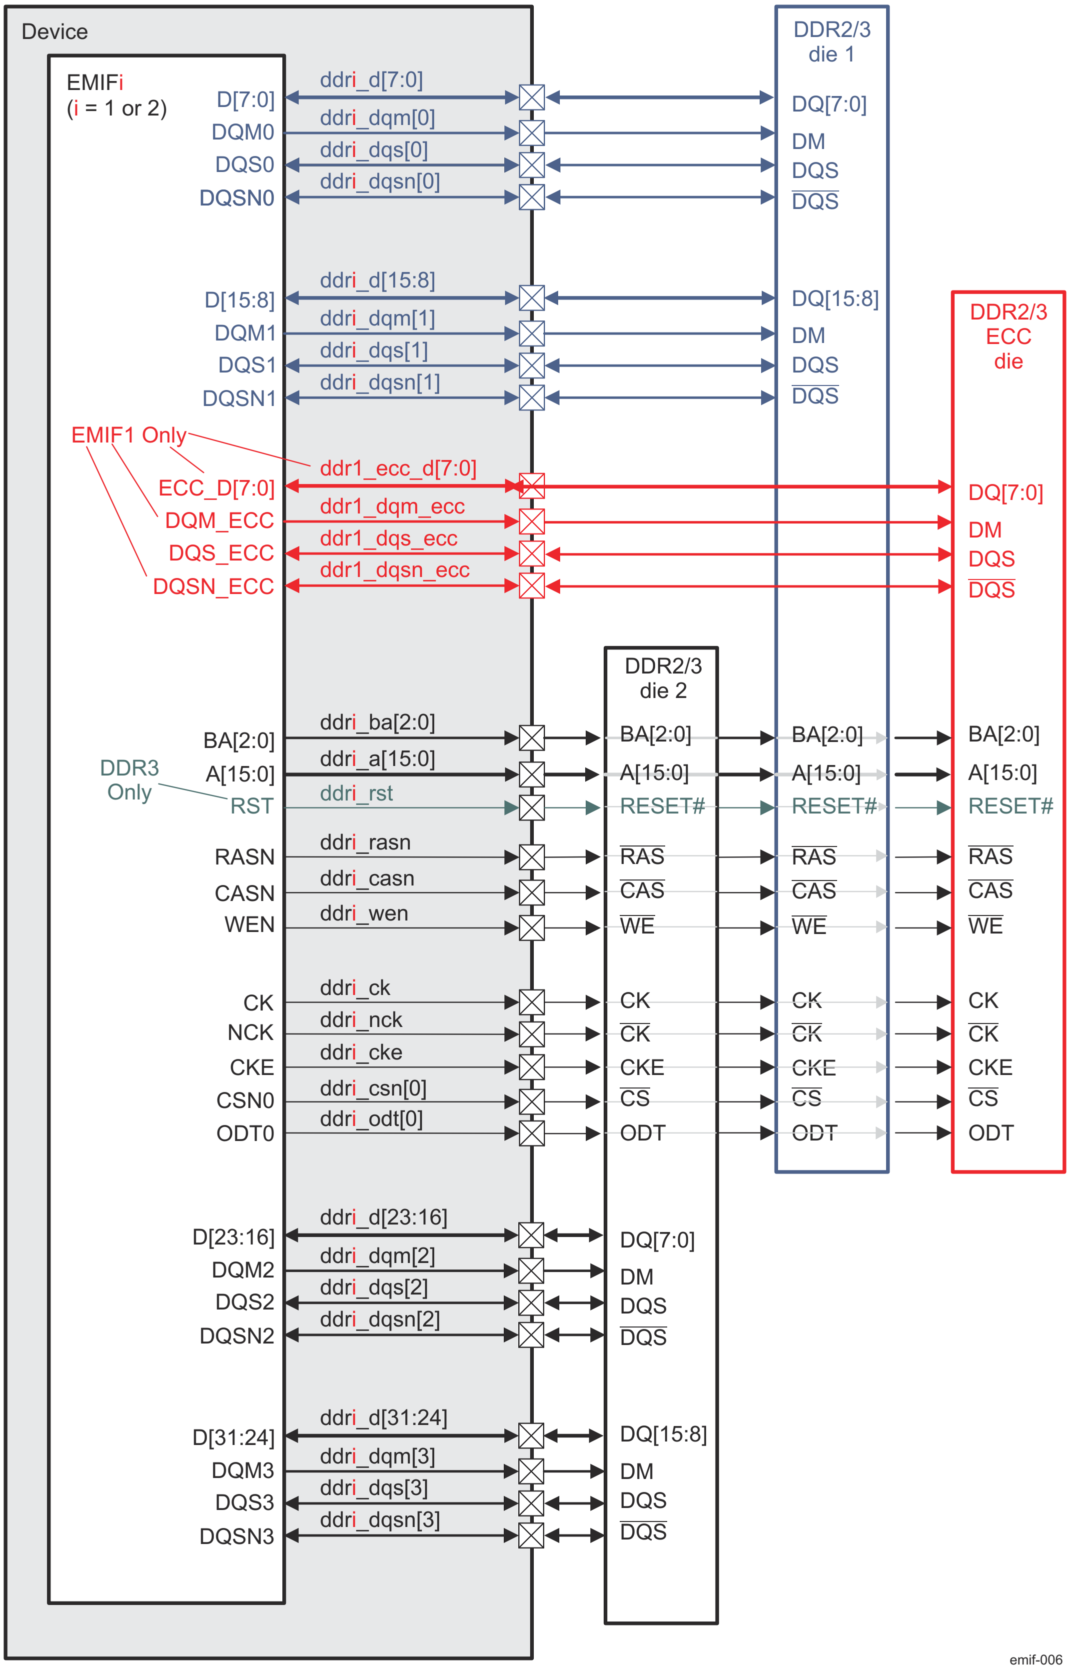

Figure 15-47. EMIF DDR2/DDR3 Configuration With ECC

Table 15-66 describes the EMIF module associated I/O signals used for connection to DDR2 and DDR3 memory types.

Table 15-66. EMIF Module I/O signals

EMIF Pin Name	Device DDR2 and DDR3 I/O Signal Names	I/O(1)	Description
		EMIF1 Data PHYs	
D[31:0]	ddr1_d[31:0]	I/O	Data bus
DQM[3:0]	ddr1_dqm[3:0]	O	Data mask
DQS[3:0]	ddr1_dqs[3:0]	I/O	Data strobe
DQSN[3:0]	ddr1_dqsn[3:0]	I/O	Data strobe invert
ECC_D	ddr1_ecc_d[7:0]	I/O	Data bus used for ECC (EMIF1 Only)
DQM_ECC	ddr1_dqm_ecc	O	Data mask used for ECC (EMIF1 Only)
DQS_ECC	ddr1_dqs_ecc	I/O	Data strobe used for ECC (EMIF1 Only)
DQSN_ECC	ddr1_dqsn_ecc	I/O	Data strobe invert used for ECC (EMIF1 Only)
		EMIF1 Command PHYs	
A[15:0]	ddr1_a[15:0]	O	Row/column address bus
BA[2:0]	ddr1_ba[2:0]	O	Bank select
CK	ddr1_ck	O	Differential clock
NCK	ddr1_nck	O	Differential clock
CSN[0]	ddr1_csn[0]	O	Active low rank select signal (chip select)
CKE	ddr1_cke	O	Clock enable
CASN	ddr1_casn	O	Command
RASN	ddr1_rasn	O	Command
WEN	ddr1_wen	O	Command
RST	ddr1_rst	O	Active low asynchronous reset (DDR3 only)
ODT[0]	ddr1_odt[0]	O	On-die termination enable signal
		EMIF2 Data PHYs	
D[31:0]	ddr2_d[31:0]	I/O	Data bus
DQM[3:0]	ddr2_dqm[3:0]	O	Data mask
DQS[3:0]	ddr2_dqs[3:0]	I/O	Data strobe
DQSN[3:0]	ddr2_dqsn[3:0]	I/O	Data strobe invert
		EMIF2 Command PHYs	
A[15:0]	ddr2_a[15:0]	O	Row/column address bus
BA[2:0]	ddr2_ba[2:0]	O	Bank select
CK	ddr2_ck	O	Differential clock
NCK	ddr2_nck	O	Differential clock
CSN[0]	ddr2_csn[0]	O	Active low rank select signal (chip select)
CKE	ddr2_cke	O	Clock enable
CASN	ddr2_casn	O	Command
RASN	ddr2_rasn	O	Command
WEN	ddr2_wen	O	Command
RST	ddr2_rst	O	Active low asynchronous reset (DDR3 only)
ODT[0]	ddr2_odt[0]	O	On-die termination enable signal

(1) I = Input; O = Output

The CKE memory pad is dynamically driven by the EMIF module according to the memory interface activity. It can also be forced to tri-state by a dedicated Control Module register. For more information, see Section 15.3.4.17 *Forcing CKE to tri-state*.

Note

The index numbers 1 and 2 which are part of the EMIF DDR2 and DDR3 associated signals listed in Table 15-66 *EMIF Associated I/O signals*, column "**Device DDR2 and DDR3 I/O Signal Names**" should not be confused with DDR1 and DDR2 types of memories. They are used to indicate whether the corresponding signal is associated with EMIF1 or with EMIF2 controller. For example, ddr1_csn[0] signal is the chip select associated with EMIF1 and ddr2_csn[0] is the chip select associated with EMIF2.

The DDR memory connected to the DDR ECC bus does NOT need to be the same part number as the DDR memories connected to the DDR data bus. However, some constraints do apply. When selecting a memory for the DDR ECC bus, the following restrictions must be adhered to.

Compared to the DDR memories on the data bus, the DDR ECC memory must:

- Match the same DDR type (DDR3, DDR2, etc.) and speed grade
- Have an equal number of internal banks
- Have an equal number of columns
- Have a greater or equal number of rows

In addition,

- Unused pins should be properly tied off as described in the routing guidelines of the device data manual.
- EMIF register settings should be configured to satisfy the larger minimum timing requirements and the smaller maximum timing requirements between the two different DDR memories to ensure that all DDR memories connected to the EMIF channel are running within their specified range.

Note

For a full list of supported DDR device types, frequencies, and topologies, refer to the routing guidelines of the device data manual.

15.3.3 EMIF Module Integration

This section describes the integration of the EMIF modules in the device and includes information about clocks, resets, and hardware requests.

Figure 15-48 shows the integration of the two EMIF modules in the device.

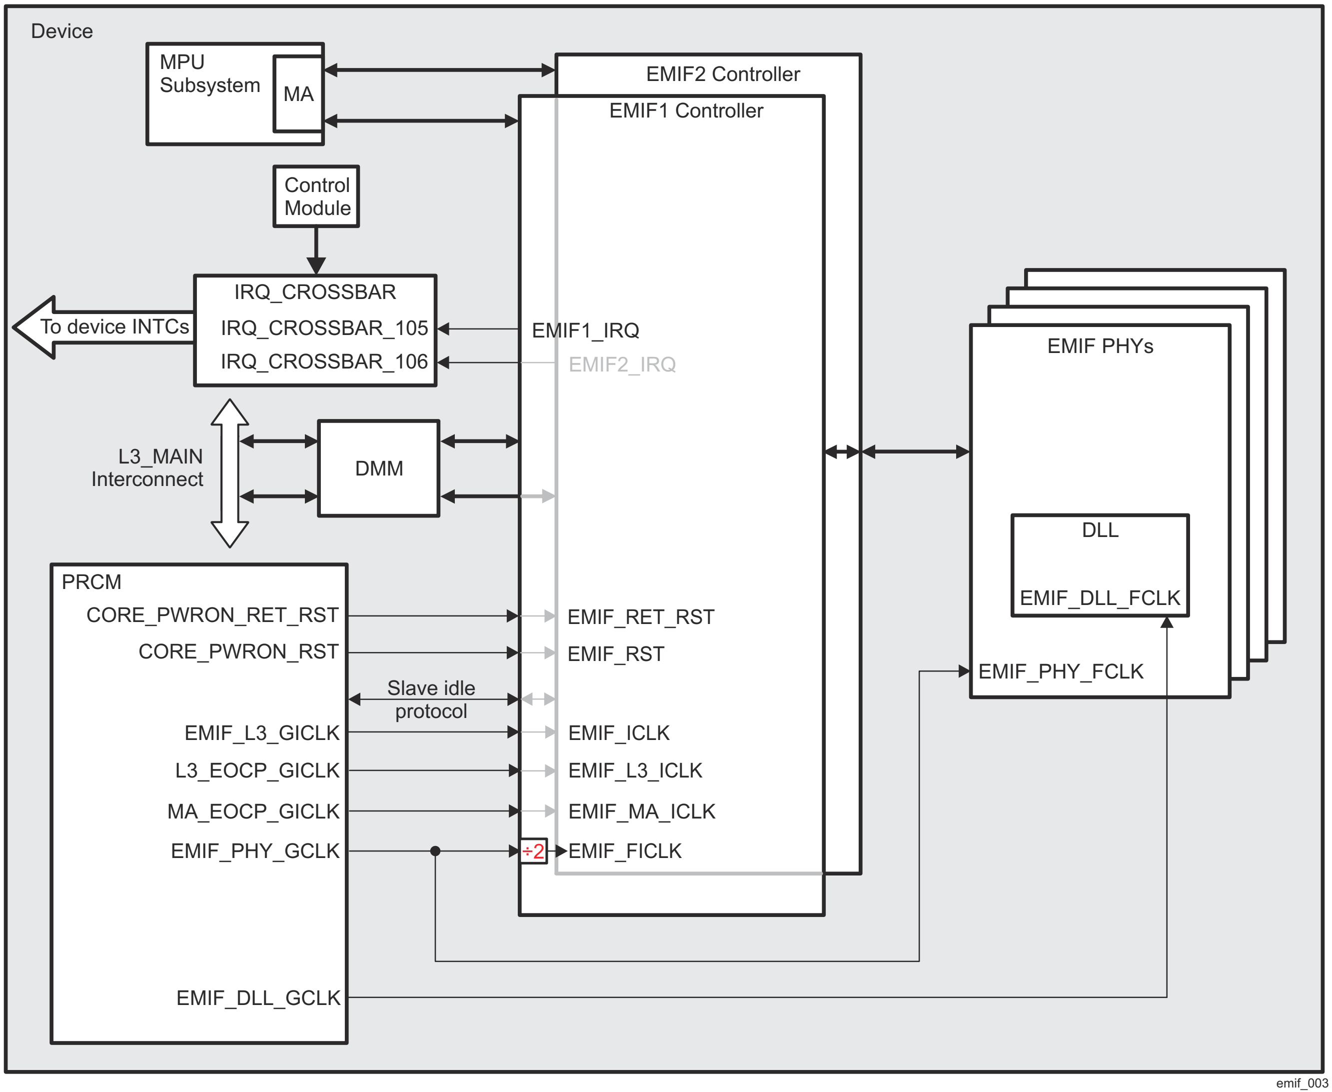

Figure 15-48. EMIF Modules Integration

Note

For more information about the slave idle protocol, see Section 3.1.1.1.3, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 15-67 through Table 15-69 summarize the integration of the EMIF modules in the device.

Table 15-67. EMIF Integration Attributes

Module Instance	Attributes		
	Power Domain	**Wake-Up Capability**	**Interconnect**

Table 15-67. EMIF Integration Attributes (continued)

EMIF1	PD_COREAON	No	EMIF1 Controller is accessible via L3_MAIN interconnect but not directly, and only through the DMM.
EMIF2	PD_COREAON	No	EMIF2 Controller is accessible via L3_MAIN interconnect but not directly, and only through the DMM.

Table 15-68. EMIF Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
EMIF1/ EMIF2	EMIF_ICLK	EMIF_L3_GICLK	PRCM	Interface clock for EMIF1/EMIF2 Controller used for driving the L3 interface logic and for SDRAM Read Data FIFO.
	EMIF_L3_ICLK	L3_EOCP_GICLK	PRCM	Interface clock for EMIF1/ EMIF2 Controller which frequency is equal to EMIF_L3_GICLK interface clock. Used for command/write data pre-FIFO to Command/Write Data FIFO paths when MPU is idle.
	EMIF_MA_ICLK	MA_EOCP_GICLK	PRCM	Additional interface clock for EMIF1/ EMIF2 Controller which frequency is equal to MPU_GCLK/4. Used for command/write data pre-FIFO to Command/Write Data FIFO paths when the MPU is active.
	EMIF_PHY_FCLK	EMIF_PHY_GCLK	PRCM	Common functional clock for the EMIF1/EMIF2 associated PHYs. This clock is equal to the DDR2/ DDR3 clock rate.
	EMIF_FICLK	EMIF_PHY_GCLK/2	PRCM	Functional and interface clock for EMIF1/EMIF2 Controller. This clock runs at half the DDR2/ DDR3 clock rate.
	EMIF_DLL_FCLK	EMIF_DLL_GCLK	PRCM	Common functional clock for all DLLs associated with the EMIF1/ EMIF2 PHYs.
Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
EMIF1/ EMIF2	EMIF_RET_RST	CORE_PWRON_RET_RST	PRCM	Power-on reset
	EMIF_RST	CORE_PWRON_RST	PRCM	Power-on reset

Note

The two clocks MA_EOCP_GICLK and L3_EOCP_GICLK are mutually exclusive. EMIF controllers are clocked by EMIF_MA_ICLK when MPU interface is active. When system interface is active, EMIF_L3_ICLK clock is used. This action is done automatically by the PRCM.

Table 15-69. EMIF Hardware Requests

Interrupt Requests				
Module Instance	**IRQ Source Name**	**IRQ_CROSSBAR Input**	**Default IRQ Source Mapping**	**Description**

Table 15-69. EMIF Hardware Requests (continued)

EMIF1	EMIF1_IRQ	IRQ_CROSSBAR_105	MPU_IRQ_110	EMIF1 interrupt request
EMIF2	EMIF2_IRQ	IRQ_CROSSBAR_106	MPU_IRQ_111	EMIF2 interrupt request

Note

The “**Default IRQ Source Mapping**” column in Table 15-69 *EMIF Hardware Requests* shows the default mapping of the IRQ sources listed in column “**IRQ Source Name**” to a certain interrupt line of one of the device interrupt controllers. These IRQ sources can also be mapped to other interrupt lines of each device interrupt controller through the IRQ_CROSSBAR module. For more information about the IRQ_CROSSBAR module, see Section 18.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 18, *Control Module*. For more information about the device interrupt controllers, see Chapter 17, *Interrupt Controllers*.

Note

For the description of the interrupt source, see Section 15.3.4.5, *Interrupt Requests*.

15.3.4 EMIF Functional Description

15.3.4.1 Block Diagram

The EMIF module provides an interface to DDR2 and DDR3 SDRAM memories.

Figure 15-49 shows the interconnection between the EMIF module and the other modules.

Digital locked loops (DLLs) are used to delay the input DQS signals during reads so that these strobe signals can be used to latch incoming data on the DQ pins, as required by the DDR standard.

Physical layers (PHYs) convert single-data rate (SDR) signals to DDR signals.

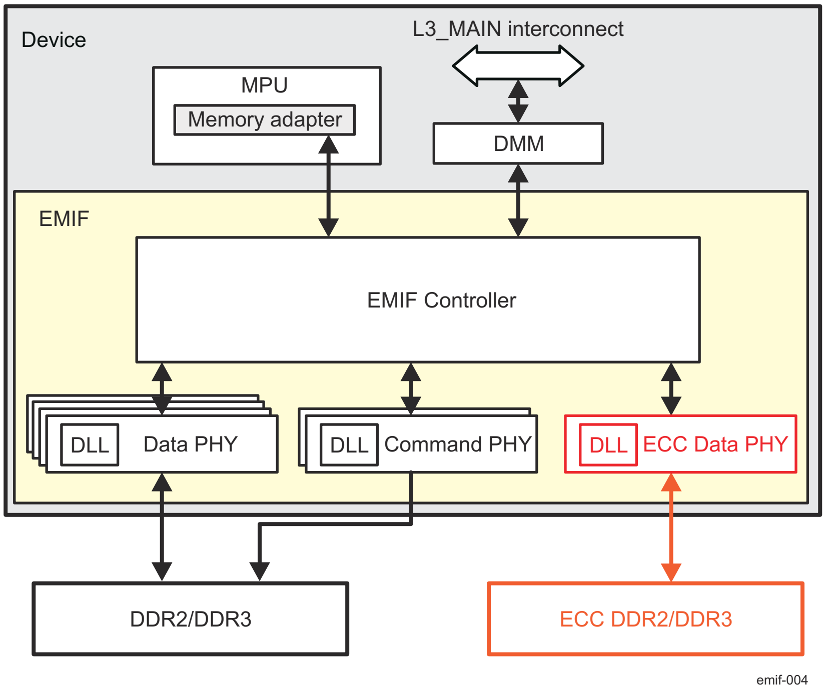

Figure 15-49. EMIF Block Diagram

15.3.4.1.1 Local Interface

The EMIF supports two local (on-chip) interfaces:

- System interface (from L3_MAIN interconnect)
- MPU interface (from MPU subsystem)

System interface is used to request all external memory device accesses, to access the EMIF registers, and to transfer all data to and from the EMIF controller. MPU interface is used to process memory accesses. Table 15-70 shows the MAddrSpace mapping.

Table 15-70. MAddrSpace Mapping

MAddrSpace(1)	Chip-Select	Description	Exclusions
0x0	CSN0	SDRAM(s)	
0x1	N/A	Reserved.	
0x2	N/A	Reserved. Any access to this area will generate an error on the L3 interface. This can be used by the software to track any unwanted access to the section defined in the DMM_LISA_MAP_i register.	Not visible thtough the MPU port
0x3	N/A	Internal registers	Not visible through the MPU port

(1) See DMM_LISA_MAP_i [17:16] SDRC_ADDRSPC register bitfield in Section 15.2, *Dynamic Memory Manager*.

15.3.4.1.2 FIFO Description

The EMIF module contains the following FIFOs:

- Command FIFO
- Write data FIFO
- Return command FIFO
- Two read data FIFOs

Figure 15-50 shows the overall architecture of the EMIF FIFOs.

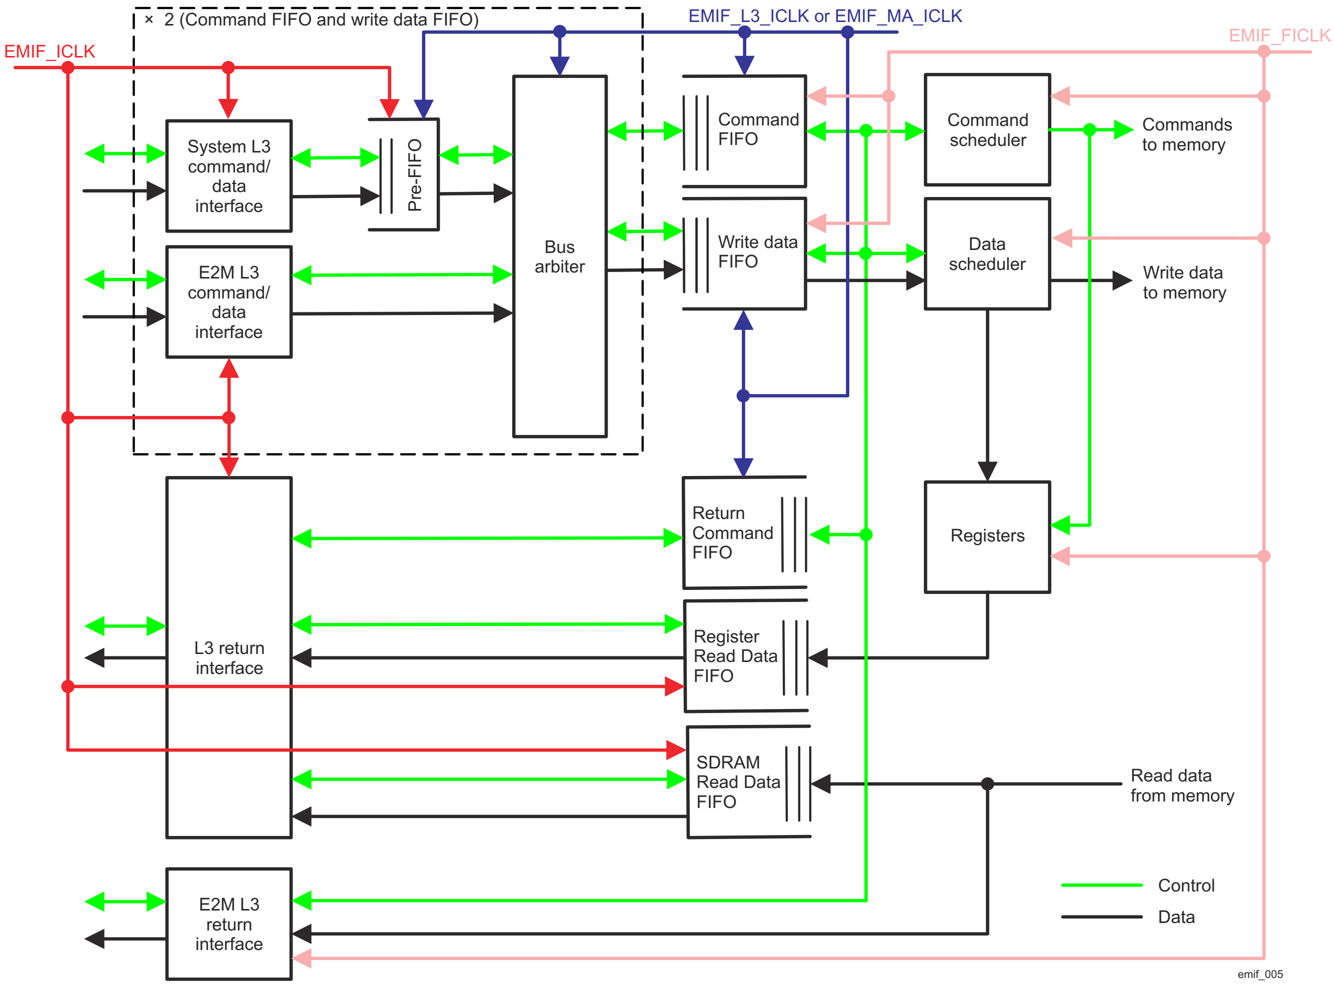

Figure 15-50. FIFO Block Diagram

Table 15-71 lists the allocation of the entries.

Table 15-71. FIFO Allocation

Parameter	System Local Interface Entries	MPU Local Interface Entries
Pre Command FIFO	6	4
Command FIFO	Programmable [(1)]	Programmable [(1)]
Pre Write FIFO	6	8
Write Data FIFO (256-bit)	Up to (19 × 256 bits) + 6	Up to 19 + 8
Return Command FIFO	22	24
SDRAM Read Data FIFO	22	24

Table 15-71. FIFO Allocation (continued)

Parameter	System Local Interface Entries	MPU Local Interface Entries
Register Read Data FIFO	2	0

(1) The total number of entries in the command FIFO is 10.

The command FIFO is shared between the two local interfaces, whereas there are two different FIFOs for every other type, one dedicated to each local interface.

The command FIFO stores all the commands coming in on the local command interface. The allocation of entries in the command FIFO is programmable per local interface using the following bit fields:

- EMIF_OCP_CONFIG[27:24] SYS_THRESH_MAX
- EMIF_OCP_CONFIG[23:20] MPU_THRESH_MAX

15.3.4.1.3 MPU Port Restrictions

The EMIF MPU port is defined only to process memory requests. All register accesses are processed through the system port of the EMIF. The EMIF MPU port does not support 2D or register requests required or provided by the system interface. The MPU port has a fixed ConnID equal to 0x0. The access burst length of the MPU port must not exceed 7.

To maintain coherency, the following rules must be followed:

- Any command arriving on MPU or system interface that matches an address in the command FIFO is executed after the command in the command FIFO
- The matching address is any address within a 2,000-address boundary
- On a 2D transfer, the starting address is the compared address. The computed addresses of the 2D transfer are not considered in address overlapping.
- Any command arriving within a 10-cycle window of another, from the different interfaces that do not match any address in the command FIFO, but may match command addresses arriving on a different interface, can be executed in any order.

15.3.4.1.4 Arbitration of Commands in the Command FIFO

The EMIF looks at all the commands stored in the command FIFO to schedule commands to the external memory. All commands with the same MTagID on a particular local interface complete in order. The EMIF does not ensure ordering between commands with different MTagIDs or between commands from two local interfaces.

However, the EMIF does maintain data coherency. Therefore, the EMIF blocks a command, regardless of priority or the local interface, if that command is to the same block address (2048 bytes) as an older command that is not complete. Thus, the EMIF may have one pending read or write for each MTagID. For information about MTagID, see Section 14.1.1, *Terminology* in Chapter 14, *Interconnect*. Among all pending reads, the EMIF selects all reads that have their corresponding SDRAM banks already open. Similarly, among all pending writes, the EMIF selects all writes that have their corresponding SDRAM banks already open. Accesses to memory mapped registers are treated as accesses that have open banks.

As a result of this reordering, the EMIF may now have several pending reads and writes that have their corresponding banks open. The EMIF then selects the highest priority read from pending reads, and the highest priority write from pending writes. If two or more commands have the highest priority, the EMIF selects the oldest command. As a result, the EMIF may now have the next read and a write command. If the return command FIFO and the read data FIFO have space and the external bus conflict is resolved, the EMIF performs the final read command before the final write command. If the return command FIFO has space but the read data FIFO is full, the EMIF performs the final write command before the final read command. Resolution of external bus conflict means all the SDRAM command-to-command counters are satisfied and the read-to-write or write-to-read turnaround time is met.

The EMIF does not support tag interleaving. In other words, for an local interface, the EMIF completes executing an local command before it switches to another command. The EMIF can, however, interleave execution between commands from two local interfaces.

The data coherency inside the EMIF is ensured only in a single level of local infrastructure. For example, if a write from a secondary local bus segment is blocked by a bridge element, the read from a tertiary bus can still beat the write to the EMIF. In such a case, to confirm that a write from master A has landed before a read from master B is performed, master A must wait for the write status from the EMIF before indicating to master B that the data is ready to be read. If master A does not use the local wait status, it must do the following:

1. Perform the required write.
2. Perform a dummy write to the EMIF_REVISION register.
3. Perform a dummy read to the EMIF_REVISION register.
4. Indicate to master B that the data is ready to be read after completion of read in Step 3. The completion of read in Step 3 ensures that the previous writes were done.

Apart from reads and writes, the EMIF must also open and close SDRAM banks and maintain the refresh counts for an SDRAM. The priority of SDRAM commands with respect to refresh levels are:

1. SDRAM refresh request when refresh-must level is reached (highest priority)
2. ZQ calibration
3. Leveling
4. local request for a read or write
5. local request for a write
6. SDRAM activate commands
7. SDRAM deactivate commands
8. SDRAM power-down request
9. SDRAM refresh request when refresh-may or release level is reached
10. SDRAM self-refresh request (lowest priority)

To avoid continuous blocking effect which can be caused by a continuous stream of high-priority commands which thus block the lower priority commands, the EMIF momentarily raises the priority of the oldest command over all other commands when the time for the oldest command configured through the EMIF_COS_CONFIG[7:0] PR_OLD_COUNT bit field expires.

It should be taken into account that while performing the scheduling algorithm described, the EMIF may also encounter a condition in which continuous stream of SDRAM commands to a row in an open bank can block commands to another row in the same bank.

In addition to this scheduling, the highest priority condition is a reset command. If this condition occurs, the EMIF abandons what it is currently doing and begins its start-up sequence. In this case, commands and data stored in the FIFOs are lost. The EMIF also starts its start-up sequence whenever the EMIF_SDRAM_CONFIG register is written and the EMIF_SDRAM_REFRESH_CONTROL[31] INITREF_DIS bit is set to 0. In this case, commands and data stored in the FIFOs are not lost. The EMIF ensures that in-flight read or write transactions to the SDRAM are complete before starting the initialization sequence.

All the accesses to an SDRAM are pipelined to maximize use of the external bus. All of these are done while fulfilling the access timing requirements of an SDRAM.

15.3.4.2 Clock Management

15.3.4.2.1 EMIF_FICLK Overview

The EMIF can gate EMIF_FICLK. There is an internal mechanism that can stop EMIF_FICLK automatically. EMIF_FICLK is stopped only after the SDRAM is put into self-refresh mode and the power-idle protocol on the local bus completes. The EMIF_FICLK frequency can be changed only after putting the external SDRAM in self-refresh mode.

The EMIF waits for the DLL lock before performing any memory access.

EMIF_FICLK frequency is equal to half of the EMIF_PHY_FCLK frequency.

15.3.4.2.2 EMIF Dependency on MPU Clock Rate

The EMIF Write Data FIFO and Command FIFO clocks are derived from the MPU clock (specifically, EMIF_MA_ICLK = MPU_GCLK/4) any time the MPU is active. As such, the DDR Peak Write bandwidth scales in proportion to the MPU clock frequency. At lower MPU clock frequencies (< 1 GHz), the Write Data FIFO limits writes to less than peak DDR bandwidth (assuming DDR3-1066 operating conditions.)

The SDRAM Read Data FIFO is always clocked by the EMIF_ICLK, so there is no relationship for read bandwidth relative to the MPU operating frequency.

The Command FIFO bandwidth is also controlled by the EMIF_MA_ICLK. However, because the command bandwidth is much lower than the data bandwidth, there is no visible bandwidth scaling for the command interface (and as a result, the read interface can be fully used).

The total available bandwidth is not affected for most systems. The write bandwidth is limited on an internal path, not on the DDR pins. The DDR pin bandwidth is still available for reads. Because most systems have higher bandwidth requirements for read relative to write, the available DDR bandwidth is still usable.

15.3.4.3 Reset

The EMIF does not support a software reset.

The EMIF supports a global warm reset mode, during which the EMIF keeps the SDRAM content. Upon a request from the PRCM module indicating a need to enter global warm reset mode, the EMIF does the following:

1. During leveling operation, EMIF will immediately exit this mode and automatically perform a write to the MR1 register of DDR3 memory to disable the leveling at the memory side too.
2. EMIF completes the ongoing access, and then puts the SDRAM in self-refresh mode. If the EMIF_SDRAM_REFRESH_CONTROL[31] INITREF_DIS field is set to 1, the EMIF does not put SDRAM in self-refresh mode.
3. EMIF clears all its FIFO contents.
4. EMIF does not wait for all interrupts to be serviced.

To exit the global warm reset:

1. If the EMIF was in Self Refresh state, it will exit Self Refresh state.
2. If leveling was enabled at the time of a global warm reset, a PHY reset must occur to bring the PHY back into a known state, as it may have been left in a leveling state upon warm reset assertion. To guarantee that the SDRAM memory clocks are off when issuing PHY reset, software can use the EMIF_POWER_MANAGEMENT_CONTROL register to enter self refresh before asserting the PHY reset.

15.3.4.4 System Power Management

15.3.4.4.1 Power-Down Mode

The EMIF supports SDRAM power-down mode for low power. The EMIF automatically puts the SDRAM into power-down mode after it is idle for EMIF_POWER_MANAGEMENT_CONTROL[15:12] PD_TIM number of DDR clock cycles and the EMIF_POWER_MANAGEMENT_CONTROL[10:8] LP_MODE bit field is set to 0x4. In power-down mode, the EMIF does not stop the clocks to the SDRAM. The EMIF maintains CKE pin low to maintain the power-down mode.

If refresh-must level is not reached before power-down entering, EMIF will not precharge all SDRAM banks before it issues the power-down command. As a result of this EMIF puts the SDRAM in active power-down mode. If refresh-must level is reached before power-down entering, EMIF will precharge all SDRAM banks and before it issues the power-down command, EMIF issues refreshes until refresh-release level is reached. As a result of this EMIF puts the SDRAM in precharge power-down mode.

When the SDRAM is in power-down mode, the EMIF services register accesses normally.

If the SDRAM is in power-down mode and one of the following occurs, the EMIF brings SDRAM out of power-down mode:

- EMIF_POWER_MANAGEMENT_CONTROL[10:8] LP_MODE bit field is changed from 0x4 to some other value.
- An SDRAM access is requested.
- The refresh-must level is reached.

If refresh-must level brings the SDRAM out of power-down mode, EMIF puts it in power-down again when the refreshes are complete and keeps this state until the next SDRAM request.

To exit power-down, the EMIF:

1. Drives CKE high after t_cke + 1 cycles have elapsed since the power-down command was issued. The value of t_cke is taken from EMIF_SDRAM_TIMING_2[2:0] T_CKE bit field.
2. Waits for EMIF_SDRAM_TIMING_2[30:28] T_XP + 1 cycles
3. Enters its idle state and can issue any commands

15.3.4.4.2 Self-Refresh Mode

The EMIF supports SDRAM self-refresh mode for low power. The EMIF automatically puts the SDRAM into self-refresh mode after the EMIF is idle for EMIF_POWER_MANAGEMENT_CONTROL[7:4] SR_TIMING number of DDR clock cycles and the EMIF_POWER_MANAGEMENT_CONTROL[10:8] LP_MODE bit field is set to 0x2. The EMIF will complete all pending refreshes before it puts the SDRAM into self-refresh. Therefore, after the expiration of SR_TIMING, the EMIF will start issuing refreshes to complete the refresh backlog, and then issue a self-refresh command to the SDRAM.

In self-refresh mode, the EMIF automatically stops the SDRAM clock. The EMIF drives CKE pin low to maintain self-refresh mode.

When the SDRAM is in self-refresh mode, the EMIF services register accesses normally.

If the SDRAM is in self-refresh mode and one of the following occurs, the EMIF brings SDRAM out of self-refresh mode:

- The EMIF_POWER_MANAGEMENT_CONTROL[10:8] LP_MODE bit field is changed from 0x2 to some other value.
- SDRAM access is requested.
- EMIF_SDRAM_TIMING_2[2:0] T_CKE + 1 cycles have elapsed since the last self-refresh command.

To exit self-refresh, for DDR2, the EMIF:

1. Enables the SDRAM clock
2. Drives CKE pin high
3. Waits EMIF_SDRAM_TIMING_2[24:16] T_XSNR + 1 cycles
4. Starts a refresh cycle in the next cycle.
5. Enters its idle state and can issue any other command except write or read command. A write or a read command is issued only after EMIF_SDRAM_TIMING_2[15:6] T_XSRD + 1 cycles clock cycles have elapsed since pin CKE is driven high.

To exit self-refresh, for DDR3, the EMIF does the following:

1. Enables the SDRAM clock
2. Drives CKE pin high
3. Waits EMIF_SDRAM_TIMING_2[24:16] T_XSNR + 1 cycles
4. Starts a refresh cycle in the next cycle. EMIF also services all refreshes down to the refresh-release level.
5. Enters its idle state and can issue any other command except write or read command. A write or a read command is issued only after EMIF_SDRAM_TIMING_2[15:6] T_XSRD + 1 cycles clock cycles have elapsed since pin CKE is driven high.

To use partial array self-refresh, the EMIF_SDRAM_REFRESH_CONTROL[26:24] PASR bits must be appropriately programmed. The EMIF performs bank interleaving when EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 0x0. Because the SDRAM is partially refreshed during partial array self-refresh, for software ease, it is recommended that the IBANK_POS bit field to be set to 0x1, 0x2, or 0x3 depending on the scheme used. If IBANK_POS is set to 0x0, software must move critical data into the banks that are going to be refreshed during partial array self-refresh.

15.3.4.5 Interrupt Requests

Each EMIF controller is able to generate one interrupt request which is connected to the IRQ_CROSSBAR module.Totally, there are two interrupt lines connected to two IRQ_CROSSBAR inputs. EMIF1 produces EMIF1_IRQ and EMIF2 produces EMIF2_IRQ. These interrupt lines can be asserted by one of the interrupt events listed in Table 15-72.

Each EMIF controller generates an interrupt on its interrupt line only if the interrupts are enabled by setting to 0x1 the corresponding bits in the EMIF_SYSTEM_OCP_INTERRUPT_ENABLE_SET register. These interrupts can be disabled by setting to 0x1 the corresponding bits in the EMIF_SYSTEM_OCP_INTERRUPT_ENABLE_CLEAR register. After the interrupt has been serviced the corresponding status flag must be cleared by software. This is done by setting to 0x1 the corresponding bit in the EMIF_SYSTEM_OCP_INTERRUPT_STATUS register which also clears the corresponding bit in the EMIF_SYSTEM_OCP_INTERRUPT_RAW_STATUS register. The status flags in the EMIF_SYSTEM_OCP_INTERRUPT_RAW_STATUS register are set even if the corresponding interrupt is disabled unlike those in the EMIF_SYSTEM_OCP_INTERRUPT_STATUS register, which are set only if the corresponding interrupt is enabled. An interrupt is also generated by the EMIF controller, if certain bit in the EMIF_SYSTEM_OCP_INTERRUPT_RAW_STATUS register is set to 0x1 and the corresponding interrupt is enabled through the EMIF_SYSTEM_OCP_INTERRUPT_ENABLE_SET register. This feature is useful when user software debugging is performed. In addition, even if interrupts are not enabled, certain status bit in EMIF_SYSTEM_OCP_INTERRUPT_RAW_STATUS register can be cleared by setting to 0x1 the corresponding bit in the EMIF_SYSTEM_OCP_INTERRUPT_STATUS register.

The EMIF sets both the EMIF_SYSTEM_OCP_INTERRUPT_RAW_STATUS[0] ERR_SYS and EMIF_SYSTEM_OCP_INTERRUPT_STATUS[0] ERR_SYS bits to 0x1, if access request for an unsupported command type, an unsupported addressing mode or an access request to an unsupported MAddrSpace is received. If such an error occurs, it is due to bad programming of the DMM. For more information about addressing, see Section 15.2, *Dynamic Memory Manager*.

The EMIF sets both the EMIF_SYSTEM_OCP_INTERRUPT_RAW_STATUS[3] WR_ECC_ERR_SYS and EMIF_SYSTEM_OCP_INTERRUPT_STATUS[3] WR_ECC_ERR_SYS bits to 0x1, if a write access with byte count that is not multiple of the ECC quanta or with a non ECC quanta aligned address is performed within the address range protected by the ECC.

The EMIF sets both the EMIF_SYSTEM_OCP_INTERRUPT_RAW_STATUS[4] TWOBIT_ECC_ERR_SYS and EMIF_SYSTEM_OCP_INTERRUPT_STATUS[4] TWOBIT_ECC_ERR_SYS bits to 0x1, if 2-bit ECC error for a read access performed within the address range protected by the ECC occurs.

The EMIF sets both the EMIF_SYSTEM_OCP_INTERRUPT_RAW_STATUS[5] ONEBIT_ECC_ERR_SYS and EMIF_SYSTEM_OCP_INTERRUPT_STATUS[5] ONEBIT_ECC_ERR_SYS bits to 0x1, if the threshold for 1-bit ECC error is reached. For more information about the EMIF ECC feature, see Section 15.3.4.14, *Error Correction And Detection Feature*.

Table 15-72 lists the event flags and their corresponding event mask bits of the sources which can cause module interrupts.

Table 15-72. Events

Event Flag	Event Mask	Description
EMIF_SYSTEM_OCP_INTERRUPT_RAW_STATUS[5] ONEBIT_ECC_ERR_SYS/ EMIF_SYSTEM_OCP_INTERRUPT_STATUS[5] ONEBIT_ECC_ERR_SYS	EMIF_SYSTEM_OCP_INTERRUPT_ENABLE_SET[5] ONEBIT_ECC_ERR_SYS/ EMIF_SYSTEM_OCP_INTERRUPT_ENABLE_CLEAR[5] ONEBIT_ECC_ERR_SYS	Interrupt if one bit ECC error threshold is reached
EMIF_SYSTEM_OCP_INTERRUPT_RAW_STATUS[4] TWOBIT_ECC_ERR_SYS/ EMIF_SYSTEM_OCP_INTERRUPT_STATUS[4] TWOBIT_ECC_ERR_SYS	EMIF_SYSTEM_OCP_INTERRUPT_ENABLE_SET[4] TWOBIT_ECC_ERR_SYS/ EMIF_SYSTEM_OCP_INTERRUPT_ENABLE_CLEAR[4] TWOBIT_ECC_ERR_SYS	Interrupt for two bit error detection

Table 15-72. Events (continued)

Event Flag	Event Mask	Description
EMIF_SYSTEM_OCP_INTERRUPT_RAW_STATUS[3] WR_ECC_ERR_SYS/ EMIF_SYSTEM_OCP_INTERRUPT_STATUS[3] WR_ECC_ERR_SYS	EMIF_SYSTEM_OCP_INTERRUPT_ENABLE_SET[3] WR_ECC_ERR_SYS/ EMIF_SYSTEM_OCP_INTERRUPT_ENABLE_CLEAR[3] WR_ECC_ERR_SYS	Interrupt for memory access made to a non-quanta aligned location or done with byte count not multiple of the ECC quanta
EMIF_SYSTEM_OCP_INTERRUPT_RAW_STATUS[0] ERR_SYS/ EMIF_SYSTEM_OCP_INTERRUPT_STATUS[0] ERR_SYS	EMIF_SYSTEM_OCP_INTERRUPT_ENABLE_SET[0] EN_ERR_SYS/ EMIF_SYSTEM_OCP_INTERRUPT_ENABLE_CLEAR[0] EN_ERR_SYS	Interrupt for command or address error

15.3.4.6 SDRAM Refresh Scheduling

The EMIF uses two counters to schedule the Refresh (REF) commands: a 13-bit decrementing refresh interval counter and a 4-bit refresh backlog counter. The interval counter is used to define the rate at which connected SDRAM devices are refreshed. It is loaded with the value of the EMIF_SDRAM_REFRESH_CONTROL[15:0] REFRESH_RATE bit field at reset (only the 13 LSBs are taken). The interval counter decrements by 1 each cycle until it reaches 0x0, at which point it reloads from the EMIF_SDRAM_REFRESH_CONTROL[15:0] REFRESH_RATE bit field and restarts decrementing. The counter also reloads and restarts decrementing whenever the EMIF_SDRAM_REFRESH_CONTROL[15:0] REFRESH_RATE bit field is updated.

The refresh backlog counter records the number of the outstanding REF commands which the EMIF controller currently has. The backlog counter increments by 1 each time the interval counter reloads (unless it has reached its maximum value of 8). The backlog counter decrements by 1 each time the EMIF issues a REF command (unless it is already 0). For the range of values that the backlog counter can take, there are three levels of urgency with which the EMIF must perform refresh cycle in which it issues REF commands:

1. Refresh-may level is reached when the backlog count is greater than 0x0, which indicates that there is a refresh backlog and if the EMIF is not busy and there are no open SDRAM banks, the EMIF must perform refresh cycle.
2. Refresh-release level is reached when the backlog count is greater than 0x4, which indicates that the refresh backlog is getting bigger and if the EMIF is not busy it must perform refresh cycle even if there is an open SDRAM bank.
3. Refresh-must level is reached when the backlog count is greater than 0x7, which indicates that the refresh backlog is becoming excessive and the EMIF must perform refresh cycle before any new memory access request being serviced. The EMIF starts servicing new memory accesses after the refresh-release level is cleared.

The two counters do not operate when SDRAM is in self-refresh mode. They start tracking the missed refreshes (the outstanding REF commands) only after initialization is complete.

The time between two REF commands is set through the EMIF_SDRAM_TIMING_3[12:4] T_RFC bit field.

15.3.4.7 SDRAM Initialization

Note

To avoid error responses from the EMIF controller the SDRAM initialization must be performed per 16-Byte blocks if EMIF_SDRAM_CONFIG[15:14] NARROW_MODE = 0x0 or per 8-Byte blocks if EMIF_SDRAM_CONFIG[15:14] NARROW_MODE = 0x1.

15.3.4.7.1 DDR2 SDRAM Initialization

On coming out of reset, the EMIF controller begins the DDR2 initialization sequence after a write to any one of the following three registers, providing that the corresponding listed conditions are met.

1. EMIF_SDRAM_CONFIG
   a. Condition 1: EMIF_SDRAM_REFRESH_CONTROL[31] INITREF_DIS = 0 (that is, cleared before the write to EMIF_SDRAM_CONFIG)

2. EMIF_SDRAM_TIMING_1
   a. Condition 1: EMIF_SDRAM_REFRESH_CONTROL[31] INITREF_DIS = 0 (that is, cleared before the write to EMIF_SDRAM_TIMING_1) AND
   b. Condition 2: The write access modifies register bit field T_WR (bits 20:17)
3. EMIF_SDRAM_REFRESH_CONTROL
   a. Condition 1: EMIF_SDRAM_REFRESH_CONTROL[31] INITREF_DIS = 0 AND
   b. Condition 2: The write access modifies register bit field SRT (bit 29), ASR (bit 28), or PASR (bits 26:24).

For the first DDR2 initialization sequence, the EMIF controller performs the following actions:

1. Drives the CKE pin low.
2. After 16 SDRAM refresh rate intervals, issues a NOP command with CKE pin held high. The SDRAM refresh rate is as defined in the EMIF_SDRAM_REFRESH_CONTROL[15:0] REFRESH_RATE bit field.
3. After 1 SDRAM refresh rate interval, issues Precharge all Banks command.
4. Issues EMRS command to the DDR2 EMR(2) register (bits BA[2:0] = 0x2) with bits A[15:0] = 0x0.
5. Issues EMRS command to the DDR2 EMR(3) register (bits BA[2:0] = 0x3) with bits A[15:0] = 0x0.
6. Issues EMRS command to the DDR2 EMR(1) register (bits BA[2:0] = 0x1) with bits A[15:0] set as in Table 15-73.

Table 15-73. Load Value For The EMR(1) Register During DDR2 SDRAM Initialization

Bits	Value	Description
A[15:13]	0x0	Reserved
A[12]	0x0	Output buffer enabled
A[11]	0x0	RDQS disable
A[10]	EMIF_SDRAM_CONFIG[23] DDR2_DDQS	Differential DQS enable value
A[9:7]	0x0	Exit OCD calibration mode
A[6], A[2]	EMIF_SDRAM_CONFIG[26:24] DDR_TERM	DDR2 termination resistor value. For DDR2 the EMIF_SDRAM_CONFIG[26] bit is not used.
A[5:3]	0x0	Additive latency = 0
A[1]	EMIF_SDRAM_CONFIG[19:18] SDRAM_DRIVE	SDRAM drive strength. For DDR2 the EMIF_SDRAM_CONFIG[19] bit is not used.
A[0]	EMIF_SDRAM_CONFIG[20] DDR_DISABLE_DLL = 0x0	Enable DLL

7. Issues MRS command to the DDR2 MR register (BA[2:0] = 0x0) with A[15:0] set as in Table 15-74.

Table 15-74. Load Value For The MR Register During DDR2 SDRAM Initialization

Bits	Value	Description
A[15:13]	0x0	Reserved
A[12]	0x0	Active power down exit time - fast exit
A[11:9]	EMIF_SDRAM_TIMING_1[20:17] T_WR	Write recovery for autoprecharge
A[8]	0x1	DLL reset
A[7]	0x0	Normal mode
A[6:4]	EMIF_SDRAM_CONFIG[13:10] CL	CAS latency value. For DDR2 the EMIF_SDRAM_CONFIG[13] bit is not used.
A[3]	0x0	Sequential burst type
A[2:0]	0x3	Burst length of 8

8. After 267 clock cycles, issues Precharge all Banks command.
9. After two Refresh commands, issues MRS command to the DDR2 MR register (BA[2:0] = 0x0) with A[15:0] set as in Table 15-75.

Table 15-75. Another Load Value For The MR Register During DDR2 SDRAM Initialization

Bits	Value	Description
A[15:9]	Equal to Step 7	
A[8]	0x0	No DLL reset
A[7:0]	Equal to Step 7	

10. Issues EMRS command to the DDR2 EMR(1) register (bits BA[2:0] = 0x1) with bits A[15:0] equal to Step 6.
11. The EMIF enters its IDLE state.

The EMIF updates the DDR Mode registers if the DDR2 initialization sequence is triggered again. However, the EMIF controller starts from Step 3.

The EMIF does not perform any transactions until the DDR2 initialization sequence is complete.

When the EMIF comes out of reset, the delay time in Step 2 resulting from the 16 refresh rate intervals + 8 cycles is approximately 16 × REFRESH_RATE / input frequency.

Note

The values of the bit fields in the EMIF_SDRAM_CONFIG register are loaded by the control module at reset. These values can be modified by the configuration header (CH) feature of the ROM code or by the initial boot image running from an external booting memory or internal RAM. They must not be modified during run time, because they reflect the used hardware SDRAM memory configurations.

15.3.4.7.2 DDR3 SDRAM Initialization

On coming out of reset, the EMIF controller begins the DDR3 initialization sequence after a write to any one of the following three registers, providing that the corresponding listed conditions are met.

1. EMIF_SDRAM_CONFIG
   a. Condition 1: EMIF_SDRAM_REFRESH_CONTROL[31] INITREF_DIS = 0 (that is, cleared before the write to EMIF_SDRAM_CONFIG)
2. EMIF_SDRAM_TIMING_1
   a. Condition 1: EMIF_SDRAM_REFRESH_CONTROL[31] INITREF_DIS = 0 (that is, cleared before the write to EMIF_SDRAM_TIMING_1) AND
   b. Condition 2: The write access modifies register bit field T_WR (bits 20:17)
3. EMIF_SDRAM_REFRESH_CONTROL
   a. Condition 1: EMIF_SDRAM_REFRESH_CONTROL[31] INITREF_DIS = 0 AND
   b. Condition 2: The write access modifies register bit field SRT (bit 29), ASR (bit 28), or PASR (bits 26:24).

For the first DDR3 initialization sequence, the EMIF controller performs the following actions:

1. After 7 SDRAM refresh rate intervals, de-asserts the RST pin.
2. After 16 SDRAM refresh rate intervals, issues a NOP command with CKE pin held high. The SDRAM refresh rate is as defined in the EMIF_SDRAM_REFRESH_CONTROL[15:0] REFRESH_RATE bit field.
3. After 1 SDRAM refresh rate interval, issues MRS command to the DDR3 MR2 register (bits BA[2:0] = 0x2) with bits A[15:0] set as in Table 15-76

Table 15-76. Load Value For The MR2 Register During DDR3 SDRAM Initialization

Bits	Value	Description
A[15:11]	0x0	Reserved
A[10:9]	EMIF_SDRAM_CONFIG[22:21] DYN_ODT	Dynamic ODT value

Table 15-76. Load Value For The MR2 Register During DDR3 SDRAM Initialization (continued)

Bits	Value	Description
A[8]	0x0	Reserved
A[7]	EMIF_SDRAM_REFRESH_CONTROL[29] SRT	Self-refresh temperature range
A[6]	EMIF_SDRAM_REFRESH_CONTROL[28] ASR	Auto self-refresh enable
A[5]	0x0	Reserved
A[4:3]	EMIF_SDRAM_CONFIG[17:16] CWL	CAS write latency
A[2:0]	EMIF_SDRAM_REFRESH_CONTROL[26:24] PASR	Partial array self-refresh

4. After T_RFC + 1 DDR clock cycles, issues MRS command to the DDR3 MR3 register (bits BA[2:0] = 0x3) with A[15:0] = 0x0
5. After T_RFC + 1 DDR clock cycles, issues MRS command to the DDR3 MR1 register (BA[2:0] = 0x1) with A[15:0] set as in Table 15-77

Table 15-77. Load Value For The MR1 Register During DDR3 SDRAM Initialization

Bits	Value	Description
A[15:13]	0x0	Reserved
A[12]	0x0	Output buffer enabled
A[11]	0x0	TDQS disable
A[10]	0x0	Reserved
A[9], A[6], A[2]	EMIF_SDRAM_CONFIG[26:24] DDR_TERM	DDR3 termination resistor value
A[8]	0x0	Reserved
A[7]	0x0	Write leveling disabled
A[5], A[1]	EMIF_SDRAM_CONFIG[19:18] SDRAM_DRIVE	SDRAM drive strength
A[4:3]	0x0	Additive latency = 0
A[0]	EMIF_SDRAM_CONFIG[20] DDR_DISABLE_DLL = 0x0	Enable SDRAM DLL

6. After T_RFC + 1 DDR clock cycles, issues MRS command to the DDR3 MR0 register (BA[2:0] = 0x0) with A[15:0] set as in Table 15-78

Table 15-78. Load Value For The MR0 Register During DDR3 SDRAM Initialization

Bits	Value	Description
A[15:13]	0x0	Reserved
A[12]	0x0	Slow exit. The DDR3 SDRAM DLL is “OFF” after entering precharge power-down.
A[11:9]	EMIF_SDRAM_TIMING_1[20:17] T_WR	Write recovery for autoprecharge
A[8]	0x1	DLL reset
A[7]	0x0	Normal mode
A[6:4], A[2]	EMIF_SDRAM_CONFIG[13:10] CL	Value for CAS latency
A[3]	0x0	Nibble sequential read burst type

Table 15-78. Load Value For The MR0 Register During DDR3 SDRAM Initialization (continued)

Bits	Value	Description
A[1:0]	0x0	Burst length of 8

7. After T_RFC + 1 DDR clock cycles, issues a ZQCL command to start long ZQ calibration
8. Waits for t_{DLLK} and t_{ZQinit} to complete
9. Issues REF command
10. The EMIF enters its IDLE state.

The EMIF updates the DDR Mode registers if the DDR3 initialization sequence is triggered again. However, the EMIF controller first issues a precharge command and then starts from Step 3.

The EMIF does not perform any transactions until the DDR3 initialization sequence is complete.

When the EMIF comes out of reset, the delay time in Step 2 resulting from the 16 refresh rate intervals + 8 cycles is approximately 16 × REFRESH_RATE / input frequency.

15.3.4.8 DDR3 Read-Write Leveling

The EMIF supports one type of write/read leveling for DDR3 - full leveling.

The full leveling consists of three parts:

1. Write leveling
2. Read data eye training
3. Read DQS gate training

Write leveling

The goal of write leveling is to locate the delay between the rising edge of the write DQS signal and the rising edge of the SDRAM memory clock (CK). When this delay is identified, the system is able to accurately align the write DQS signal with the DDR3 memory clock. During Write leveling, the ODT function must be on and proper ODT values must be selected at the external memory side by setting Rtt_Nom (A9, A6, A2) bits in MR1 register of the external DDR3 memory. For more information about write leveling, see the *DDR3 SDRAM Standard*, section *Write leveling*.

Read data eye training

Through the read data eye training the delay between the rising edge of the read DQS signal and the rising and falling edges of the associated DQ data eye is determined. By identifying these delays, the midpoint between them can be calculated and thus the rising edge of the read DQS signal can be accurately centered within the DQ data eye.

Read DQS gate training

Read DQS Gate training is used for timing the internal read window during a read operation as opposed to the write leveling and read data eye training which are used for skew compensation of external signals. The goal of read DQS gate training is to locate the shortest delay that can be applied to each DQS gate such that it functions properly, then find the longest delay that can be applied to each DQS gate and keep its proper function again, and then align the midpoint of the DQS gate delay between these two.

15.3.4.8.1 Full Leveling

The EMIF does not perform full leveling after initialization upon reset. Full leveling must be triggered by software after the EMIF's registers are properly configured.

Full leveling is triggered by setting the EMIF_READ_WRITE_LEVELING_CONTROL[31] RDWRLVLFULL_START bit to 0x1. The leveling execution order is as follows:

1. Write leveling
2. Read DQS gate training
3. Read data eye training

After leveling procedure has finished the EMIF_READ_WRITE_LEVELING_CONTROL[31] RDWRLVLFULL_START bit clears itself automatically.

Note

SDRAM Refreshes must be disabled before triggering full leveling.

Note

The EMIF_EXT_PHY_CONTROL_2 through EMIF_EXT_PHY_CONTROL_21 registers have to be configured only in case of software leveling.

15.3.4.8.2 Software Leveling

In case of software leveling, the following registers must be configured:

- EMIF_EXT_PHY_CONTROL_2 to EMIF_EXT_PHY_CONTROL_6 containing the PHY_REG_FIFO_WE_SLAVE_RATIO value
- EMIF_EXT_PHY_CONTROL_26 to EMIF_EXT_PHY_CONTROL_30 containing the REG_PHY_GATELVL_INIT_RATIO value
- EMIF_EXT_PHY_CONTROL_25 containing the DQ offset value

The bit fields of the EMIF_EXT_PHY_CONTROL_2 to EMIF_EXT_PHY_CONTROL_6 registers must be loaded with same values. The bit fields of the EMIF_EXT_PHY_CONTROL_26 to EMIF_EXT_PHY_CONTROL_30 registers must also be loaded with same values.

The REG_PHY_DQ_OFFSET fields in register EMIF_EXT_PHY_CONTROL_25 must be loaded with 0x40. That value corresponds to quarter cycle shift between the DQS signals and the data to be written to the SDRAM.

To calculate the PHY_REG_FIFO_WE_SLAVE_RATIO value one of the following two formulas can be used:

- 0x80 + 2*[(Board Delay in ps)*0x100]/(Clock Period in ps). This formula is used when the EMIF_DDR_PHY_CONTROL_1[18] PHY_INVERT_CLKOUT bit is set to 0x1.
- 2*[(Board Delay in ps)*0x100]/(Clock Period in ps). This formula is used when the EMIF_DDR_PHY_CONTROL_1[18] PHY_INVERT_CLKOUT bit is set to 0x0.

The Board Delay in the previously described formulas is measured directly from the board. It depends on the trace length. When the calculated value for PHY_REG_FIFO_WE_SLAVE_RATIO is greater than 0x20, then a value of 0x27 must be used. That means, 0x27 must be loaded in registers EMIF_EXT_PHY_CONTROL_2 to EMIF_EXT_PHY_CONTROL_6.

To calculate the REG_PHY_GATELVL_INIT_RATIO value the following formula is used:

REG_PHY_GATELVL_INIT_RATIO = PHY_REG_FIFO_WE_SLAVE_RATIO – 0x20

When the calculated value for REG_PHY_GATELVL_INIT_RATIO is less than 0x0, then a value of 0x0 must be used. When the calculated value is greater than or equal to 0x0, then that value is used for registers EMIF_EXT_PHY_CONTROL_26 to EMIF_EXT_PHY_CONTROL_30.

In addition, when read DQS gate training is not performed the PHY_REG_FIFO_WE_SLAVE_RATIO value is used. When read DQS gate training is performed REG_PHY_GATELVL_INIT_RATIO is used and PHY_REG_FIFO_WE_SLAVE_RATIO is don't care.

Note

Software leveling is not recommended to be used. Hardware leveling must be used instead.

15.3.4.9 EMIF Access Cycles

By default, the EMIF keeps its SDRAM $\overline{CS}$ signal high. To direct a command to only one of the SDRAMs, EMIF asserts its $\overline{CS}$ signal to the SDRAM for the duration of the command.

The EMIF always performs burst accesses to the SDRAM. Multiple SDRAM bursts may need to service a single local burst request. Table 15-79 through Table 15-82 show a few examples how EMIF performs SDRAM accesses for a linear incrementing transaction type. T0, T1, etc. are clock cycles. R0 is read starting at column 0, R8 is read starting at column 8, and R16 is read starting at column 16. D0-1 is the data from column 0 and 1, D2-3 is the data from column 2 and 3, and so on.

Table 15-79. 64-Byte Linear Read Starting at Address 0x0 (DDR2 and DDR3)

T0	T1	T2	T3	T4	T5	T6	T7	T8	T9	T10	T11
R0				R8							
				D0-1	D2-3	D4-5	D6-7	D8-9	D10-11	D12-13	D14-15

Table 15-80. 64-Byte Linear Read Starting at Address 0x8 (DDR2)

T0	T1	T2	T3	T4	T5	T6	T7	T8	T9	T10	T11	T12	T13	T14	T15
R2		R4		R8				R16							
				D2-3	Unused	D4-5	D6-7	D8-9	D10-11	D12-13	D14-15	D16-17	Unused	Unused	Unused

Table 15-81. 64-Byte Linear Read Starting at Address 0x10 (DDR2 and DDR3)

T0	T1	T2	T3	T4	T5	T6	T7	T8	T9	T10	T11	T12	T13
R4		R8				R16							
				D4-5	D6-7	D8-9	D10-11	D12-13	D14-15	D16-17	D18-19	Unused	Unused

Table 15-82. 64-Byte Linear Read Starting at Address 0x18 (DDR2 and DDR3)

T0	T1	T2	T3	T4	T5	T6	T7	T8	T9	T10	T11	T12	T13
R6		R8				R16							
				D6-7	Unused	D8-9	D10-11	D12-13	D14-15	D16-17	D18-19	D20-21	Unused

The EMIF uses the unused data phases in the preceding figures by issuing successive read commands if there are reads to open banks pending in the command FIFO.

The write data conversion from SDR to DDR is done outside the EMIF.

15.3.4.10 Turnaround Time

Table 15-83 lists the turnaround time that EMIF introduces on the data bus for various back-to-back accesses. The EMIF takes advantage of the CAS latencies and packs the commands as close as possible on the control bus to introduce the following turnaround time on the data bus.

Table 15-83. Turnaround Time

Current Access	Next Access	Turnaround Time (Number of DDR Clock Cycles)
SDRAM write	SDRAM read	EMIF_SDRAM_TIMING_1[2:0] T_WTR + 1 + CL
SDRAM read	SDRAM write	EMIF_SDRAM_TIMING_1[31:29] T_RTW + 1

15.3.4.11 PHY DLL Calibration

When running in normal locked mode, the PHY DLL gets a reference clock (EMIFi_DLL_FCLK) from the PRCM, which is used by the DLL master to lock to the right frequency and provide the control code for a full period phase shift to the slave. The slave uses this code as a control for its internal delay line to produce the required delay for the signal considered.

When working in locked mode, the delay lines only get an updated control value from the master DLLs when an explicit dll_calib command is issued by the EMIF controller. Failure to send such commands on a timely basis will result in inaccurate delay-line information if there is a significant voltage and temperature drift in the system. It is recommended to issue at least one command every 100 µs. EMIF automatically sends ctrl_update commands for:

- Refresh Exit
- Self Refresh Exit
- phy_ready asserted during initialization

The PHY also internally generates a control value update upon completion of a leveling operation. Control is also added when leveling is not used and there are gradual voltage changes during frequency change. The EMIF_DLL_CALIB_CTRL register can be programmed to generate a phy_dll_calib for a periodic interval based on EMIF_FICLK cycles, so allow continued memory access as voltage is changing. A safe window of no activity will be guaranteed for this periodic generation of phy_dll_calib. In addition, a one shot generator for phy_pll_calib has also been added that will generate a single phy_dll_calib by setting the EMIF_MISC_REG[0] DLL_CALIB_OS bit to 1.

15.3.4.12 SDRAM Address Mapping

From the system point of view, the external SDRAM is seen as one block of SDRAM. If two external 64-MiB devices are used, a 128-MiB memory block is observed. If two external 32-MiB devices are used, a 64-MiB block is observed.

Table 15-84 shows the SDRAM address space.

Table 15-84. SDRAM Addressing Space

Module Name	Base Address	Size
EMIF1 | EMIF2-CS0-SDRAM(1)	0x8000 0000	0 to 1GiB, programmable in DMM (see Section 15.2, *Dynamic Memory Manager*)

(1) The addressing space is interleaved on two SDRAM memory controllers (EMIF1, EMIF2), each activating itsCS0 line. These CSs can address 64, 128, 256, 512, 1024, or 2048MiB. Interleaving occurs at 128-byte granularity. EMIF1-CS0 base address is always 0x8000 0000 at reset, and occupies a 1-GiB address space at reset (interleaving disabled at reset).

When addressing SDRAM, if the EMIF_SDRAM_CONFIG[28:27] IBANK_POS bit field is set to 0, the EMIF uses the following two bit fields to determine the mapping from the source address to the SDRAM row, column and bank:

- EMIF_SDRAM_CONFIG[6:4] IBANK
- EMIF_SDRAM_CONFIG[2:0] PAGESIZE

If the EMIF_SDRAM_CONFIG[28:27] IBANK_POS bit field is set to 1, 2, or 3, the EMIF uses the following three bit fields to determine the mapping from the source address to the SDRAM row, column and bank:

- EMIF_SDRAM_CONFIG[6:4] IBANK
- EMIF_SDRAM_CONFIG[2:0] PAGESIZE
- EMIF_SDRAM_CONFIG[9:7] ROWSIZE

In all cases the EMIF considers its SDRAM address space to be a single logical block, regardless of the number of physical devices.

15.3.4.12.1 Address Mapping for IBANK_POS = 0 and EBANK_POS = 0

For EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 0 and EMIF_SDRAM_CONFIG_2[27] EBANK_POS = 0, Table 15-85 lists which source address bits (MAddr) are mapped to the SDRAM row, column and bank bits for all combinations of IBANK and PAGESIZE.

Table 15-85. Local Address to SDRAM Address Mapping for IBANK_POS = 0 and EBANK_POS = 0

MAddr[31:N] N = 1 if 16-bit data bus width; N = 2 if 32-bit data bus width					
row address		bank address		column address	
ROWSIZE value	row width (bits)	IBANK value	bank[2:0] width (bits)	PAGESIZE value	col width (bits)
In this case the ROWSIZE bit field is not used	16	0	0	0	8
		1	1	1	9
		2	2	2	10
		3	3	3	11

Note

The ROWSIZE bit field is unused in case of IBANK_POS = 0 and EBANK_POS = 0.

For EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 0, the effect of the address-mapping scheme is that as the source address increments across the SDRAM pages, EMIF moves to page with the same number as in the previous bank. This movement across the banks continues until the same page is accessed in all banks and then EMIF moves to the next page in the first bank. The EMIF uses this movement across internal banks while remaining on the same page to maximize the number of the open SDRAM banks within the overall SDRAM space.

Thus, the EMIF can keep a maximum of 8 banks open at a time, and can interleave among all of them.

15.3.4.12.2 Address Mapping for IBANK_POS = 1 and EBANK_POS = 0

Table 15-86 list the local address to SDRAM address mapping when IBANK_POS = 1 and EBANK_POS = 0.

Table 15-86. Local Address to SDRAM Address Mapping for IBANK_POS = 1 and EBANK_POS = 0

MAddr[31:N] N = 1 if 16-bit data bus width; N = 2 if 32-bit data bus width							
bank address[2]		row address		bank address[1:0]		column address	
IBANK value	bank[2] width (bits)	ROWSIZE value	row width (bits)	IBANK value	bank[1:0] width (bits)	PAGESIZE value	col width (bits)
0	0	0	9	0	0	0	8
1	0	1	10	1	1	1	9
2	0	2	11	2	2	2	10
3	1	3	12	3	2	3	11
		4	13				
		5	14				
		6	15				
		7	16				

For EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 1, the EMIF interleaves banks the same as for EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 0 but the interleaving of banks is limited to four banks. Thus, the EMIF can keep a maximum of 8 banks open at a time but can interleave among only 4 of them.

15.3.4.12.3 Address Mapping for IBANK_POS = 2 and EBANK_POS = 0

Table 15-87 list the local address to SDRAM address mapping when IBANK_POS = 2 and EBANK_POS = 0.

Table 15-87. Local Address to SDRAM Address Mapping for IBANK_POS = 2 and EBANK_POS = 0

MAddr[31:N] N = 1 if 16-bit data bus width; N = 2 if 32-bit data bus width							
bank address[2:1]		row address		bank address[0]		column address	
IBANK value	bank[2:1] width (bits)	ROWSIZE value	row width (bits)	IBANK value	bank[0] width (bits)	PAGESIZE value	col width (bits)
0	0	0	9	0	0	0	8

Table 15-87. Local Address to SDRAM Address Mapping for IBANK_POS = 2 and EBANK_POS = 0 (continued)

MAddr[31:N] N = 1 if 16-bit data bus width; N = 2 if 32-bit data bus width							
bank address[2:1]		row address		bank address[0]		column address	
IBANK value	bank[2:1] width (bits)	ROWSIZE value	row width (bits)	IBANK value	bank[0] width (bits)	PAGESIZE value	col width (bits)
1	0	1	10	1	1	1	9
2	1	2	11	2	1	2	10
3	2	3	12	3	1	3	11
		4	13				
		5	14				
		6	15				
		7	16				

For EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 2, the EMIF interleaves banks the same as for EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 0 but the interleaving of banks is limited to two banks. Thus, the EMIF can keep a maximum of 8 banks open at a time but can interleave among only 2 of them.

15.3.4.12.4 Address Mapping for IBANK_POS = 3 and EBANK_POS = 0

Table 15-88 list the local address to SDRAM address mapping when IBANK_POS = 3 and EBANK_POS = 0.

Table 15-88. Local Address to SDRAM Address Mapping for IBANK_POS = 3 and EBANK_POS = 0

MAddr[31:N] N = 1 if 16-bit data bus width; N = 2 if 32-bit data bus width					
bank address		row address		column address	
IBANK value	bank width (bits)	ROWSIZE value	row width (bits)	PAGESIZE value	col width (bits)
0	0	0	9	0	8
1	1	1	10	1	9
2	2	2	11	2	10
3	3	3	12	3	11
		4	13		
		5	14		
		6	15		
		7	16		

If EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 3, the bank interleaving is not possible for EMIF.

15.3.4.12.5 Address Mapping for IBANK_POS = 0 and EBANK_POS = 1

Table 15-89 list the local address to SDRAM address mapping when IBANK_POS = 0 and EBANK_POS = 1.

Table 15-89. Local Address to SDRAM Address Mapping for IBANK_POS = 0 and EBANK_POS = 1

MAddr[31:N] N = 1 if 16-bit data bus width; N = 2 if 32-bit data bus width					
row address		bank address		column address	
ROWSIZE value	row width (bits)	IBANK value	bank width (bits)	PAGESIZE value	col width (bits)
0	9	0	0	0	8
1	10	1	1	1	9
2	11	2	2	2	10
3	12	3	3	3	11
4	13				
5	14				
6	15				

Table 15-89. Local Address to SDRAM Address Mapping for IBANK_POS = 0 and EBANK_POS = 1 (continued)

MAddr[31:N] N = 1 if 16-bit data bus width; N = 2 if 32-bit data bus width					
row address		bank address		column address	
ROWSIZE value	row width (bits)	IBANK value	bank width (bits)	PAGESIZE value	col width (bits)
7	16				

For EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 0, and EMIF_SDRAM_CONFIG_2[27] EBANK_POS = 1, the EMIF can keep a maximum of 8 banks open at a time and can interleave among all of them.

15.3.4.12.6 Address Mapping for IBANK_POS = 1 and EBANK_POS = 1

Table 15-90 list the local address to SDRAM address mapping when IBANK_POS = 1 and EBANK_POS = 1.

Table 15-90. Local Address to SDRAM Address Mapping for IBANK_POS = 1 and EBANK_POS = 1

MAddr[31:N] N = 1 if 16-bit data bus width; N = 2 if 32-bit data bus width							
bank address[2]		row address		bank address[1:0]		column address	
IBANK value	bank[2] width (bits)	ROWSIZE value	row width (bits)	IBANK value	bank[1:0] width (bits)	PAGESIZE value	col width (bits)
0	0	0	9	0	0	0	8
1	0	1	10	1	1	1	9
2	0	2	11	2	2	2	10
3	1	3	12	3	2	3	11
		4	13				
		5	14				
		6	15				
		7	16				

For EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 1, and EMIF_SDRAM_CONFIG_2[27] EBANK_POS = 1, the EMIF can keep a maximum of 8 banks open at a time but can interleave among only 4 of them.

15.3.4.12.7 Address Mapping for IBANK_POS = 2 and EBANK_POS = 1

Table 15-91 list the local address to SDRAM address mapping when IBANK_POS = 2 and EBANK_POS = 1.

15.3.4.12.8

Table 15-91. Local Address to SDRAM Address Mapping for IBANK_POS = 2 and EBANK_POS = 1

MAddr[31:N] N = 1 if 16-bit data bus width; N = 2 if 32-bit data bus width							
bank address[2:1]		row address		bank address[0]		column address	
IBANK value	bank[2:1] width (bits)	ROWSIZE value	row width (bits)	IBANK value	bank[0] width (bits)	PAGESIZE value	col width (bits)
0	0	0	9	0	0	0	8
1	0	1	10	1	1	1	9
2	1	2	11	2	1	2	10
3	2	3	12	3	1	3	11
		4	13				
		5	14				
		6	15				
		7	16				

For EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 2 and EMIF_SDRAM_CONFIG_2[27] EBANK_POS = 1, the EMIF can keep a maximum of 8 banks open at a time but can interleave among only 2 of them.

15.3.4.12.9 Address Mapping for IBANK_POS = 3 and EBANK_POS = 1

Table 15-92 list the local address to SDRAM address mapping when IBANK_POS = 3 and EBANK_POS = 1.

Table 15-92. Local Address to SDRAM Address Mapping for IBANK_POS = 3 and EBANK_POS = 1

		6	15		
		7	16		

For EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 3 and EMIF_SDRAM_CONFIG_2[27] EBANK_POS = 1, the bank interleaving is not possible for EMIF.

15.3.4.13 DDR3 Output Impedance Calibration

The EMIF controller supports automatic output impedance (ZQ) calibration for DDR3 memories. This feature is supported by DDR3 and not supported by DDR2 memories. The ZQ calibration can be enabled by setting to 0x1 the EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[30] ZQ_CS0EN bit. The EMIF supports three types of ZQ calibration commands:

- ZQINIT: ZQ calibration command during initialization
- ZQCL: ZQ calibration long command
- ZQCS: ZQ calibration short command

The EMIF automatically issues ZQINIT command during DDR3 memory initialization. It also issues ZQCS command each time the EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[15:0] ZQ_REFINTERVAL bit field expires. In other words, the ZQ_REFINTERVAL defines the interval between two ZQCS commands. When ZQCS command is issued, the EMIF waits and blocks any other command for EMIF_SDRAM_TIMING_3[20:15] ZQ_ZQCS + 1 number of DDR clock cycles.

If the EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[28] ZQ_SFEXITEN bit field is set to 0x1, the EMIF issues ZQCL command every time it exits self-refresh, active power-down and precharge power-down modes. When ZQCL command is issued, the EMIF waits and blocks any other command for (EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[17:16] ZQ_ZQCL_MULT + 1) × (EMIF_SDRAM_TIMING_3[20:15] ZQ_ZQCS + 1) number of DDR clock cycles.

The ZQINIT is a non periodic command issued only once during DDR3 initialization as opposed to the ZQCL and ZQCS calibration commands which are issued by the EMIF periodically at regular intervals.

15.3.4.14 Error Correction And Detection Feature

For data integrity, the EMIF1 supports ECC on the data written or read from the SDRAM and is enabled by programming the EMIF_ECC_CTRL_REG register. ECC accesses are allowed for the both SYS and the MPU ports. 7-bit ECC is calculated over 32-bit data when in 32-bit DDR mode. 6-bit ECC is calculated over 16-bit data when in 16-bit DDR mode. The ECC is calculated for all accesses that are within the address ranges protected by ECC. The address ranges are specified in the EMIF_ECC_ADDRESS_RANGE_1 and EMIF_ECC_ADDRESS_RANGE_2 registers. Both registers have identical bits and functionality. This provides flexibility allowing two non-overlapping memory regions to be ECC protected.

The system must ensure that any burst access with starting address in the ECC protected region must not cross over to the un-protected region and vice-versa. The ECC is stored inside the SDRAM during writes. If a write access with byte count that is not a multiple of ECC quanta or with a non quanta aligned address is performed within the address range protected by ECC, the EMIF will send out a write ECC error interrupt. The EMIF will also report an error on the SYS and MPU response interface. In this case, the EMIF will perform the write to the SDRAM. However, the ECC value written to the SDRAM will be corrupted. The EMIF will also log the MConnID, MCmd, MBurstSeq, and MAddrSpace for the first error transaction in the EMIF_OCP_ERROR_LOG register .

The ECC quanta is either 32 bit or 16 bit based on the EMIF_SDRAM_CONFIG[15:14] NARROW_MODE bit field. For 32 bit mode (128 bits per EMIF clock cycle), an ECC quanta is 32 bits. For 16 bit narrow mode (64 bits per EMIF clock cycle), the ECC quanta is 16 bits.

Once ECC is enabled, the entire protected region must be initialized with data. These writes must be quanta-sized and quanta-aligned.

The ECC is read and verified during reads . For 1-bit ECC error in the data, the EMIF will correct the data and send it on the SYS or MPU return interface. The EMIF will log the starting address of the SDRAM burst in an internal 4 deep address FIFO. The internal FIFO will store the first four 1-bit ECC errors. The 1-Bit ECC Error Address Log register will display the address on top of the internal FIFO. The software must write a 0x1 to the EMIF_1B_ECC_ERR_ADDR_LOG register to pop the FIFO and display the next address stored. For subsequent reads in the ECC regions, the FIFO will be loaded with the address for the next 1-bit ECC error if it is not full. It must be noted that no address comparison will be performed, that is, if a single address has ECC errors back-to-back, that address will be logged twice.

The number of 1-bit ECC errors can be counted using the EMIF_1B_ECC_ERR_CNT register. The EMIF also supports programming a threshold and a window in the EMIF_1B_ECC_ERR_THRSH register. The window is programmed in number of refresh periods. When the programmed window value is 0x0, that is, window is disabled, and the internal error count meets the programmed threshold, the EMIF will generate a 1-bit ECC error interrupt. When the programmed window value is non-zero, that is, window is enabled, the EMIF will generate a 1-bit ECC error interrupt only if the internal error count meets the programmed threshold in that window. The internal error count is reset every time the window expires. The software can use this to gauge the degree of 1-bit ECC errors occurring in the system.

For diagnosis, the EMIF supports a 1-Bit ECC data error distribution register (EMIF_1B_ECC_ERR_DIST_1) that represent whether an error has occurred in a given data channel location. This is advantageous to detect whether the errors are random or systemic. The distribution registers will be overlay of all 1-bit ECC errors until the software clears the register. Therefore, multiple bits could be set as a result of multiple 1-bit ECC errors occurring over multiple read accesses.

For 2-bit ECC errors in the data, the EMIF will generate a 2-bit ECC error interrupt. For any bit errors in the address, the EMIF will generate an address error interrupt. It must be noted that the EMIF will neither correct the data for these uncorrectable errors. Along with generating the interrupts, the EMIF will also report an error on the SYS or MPU return interface. In this case the EMIF will send the resultant data from the ECC correction logic. The read data received from the memory may have further been corrupted by the ECC correction logic since it will have attempted to correct the read data but failed due to uncorrectable error.

For all uncorrectable ECC errors listed above, the EMIF will log the starting address of the SDRAM burst in the EMIF_2B_ECC_ERR_ADDR_LOG register. This register will show the address of the first uncorrectable error. After the software clears the register, it will be loaded with the address for the next uncorrectable error.

In the event that the EMIF detects a single bit ECC error, although the error is corrected on the returned data, the data in the SDRAM is not corrected. It is the responsibility of the system software to correct the ECC error at that location. To the extent possible, the system software should correct multiple bit errors with the caveat that the returned data was not corrected but corrupted by the ECC correction logic.

15.3.4.15 Class of Service

The class of service mechanism can be enabled by setting to 0x1 the EMIF_READ_WRITE_EXECUTION_THRESHOLD[31] MFLAG_OVERRIDE bit. In this case EMIF services the order of commands given by the class of service rules described in the following paragraphs. If MFLAG_OVERRIDE is set to 0x0 then class of service does not apply. When MFLAG_OVERRIDE is 0x0 and the MFLAG is high then the EMIF alternates between one command coming from the MPU interface and one from the System interface and so forth. The MFLAG value is ignored if MFLAG_OVERRIDE is 0x1.

The commands in the Command FIFO can be mapped to two classes of service namely 1 and 2. The mapping of commands to a particular class of service can be done based on the priority or the master ID. The mapping based on priority can be done by setting the appropriate values in the EMIF_PRIORITY_TO_CLASS_OF_SERVICE_MAPPING register. The mapping based on master ID can be done by setting the appropriate values of master ID and the masks in the EMIF_CONNECTION_ID_TO_CLASS_OF_SERVICE_1_MAPPING and EMIF_CONNECTION_ID_TO_CLASS_OF_SERVICE_2_MAPPING registers. There are 3 master ID and mask values that can be set for each class of service. In conjunction with the masks, each class of service can have a maximum of 144 master IDs mapped to it. For example, a master ID value of 0xFF along with a mask value of 0x3 will map all master IDs from 0xF8 to 0xFF to that particular class of service.

Each class of service has an associated latency counter (EMIF_COS_CONFIG[23:16] COS_COUNT_1 and EMIF_COS_CONFIG[15:8] COS_COUNT_2). When the latency counter for a command expires, that is, reaches the value programmed for the class of service that the command belongs to, that command is executed next. If there is more than one command that has expired latency counter, the command with the highest priority is executed first. One exception to this rule is, if the EMIF_COS_CONFIG[7:0] PR_OLD_COUNT value expires for the oldest command in the queue. That command is executed first irrespective of priority or class of service. This is done to prevent the continuous blocking effect.

The EMIF_COS_CONFIG[7:0] PR_OLD_COUNT value is used to identify when the oldest command in the command FIFO has timed out. At this point during the arbitration process, this oldest command is issued regardless of the priority of the other commands in the FIFO. This feature is disabled when writing 0x0 to the EMIF_COS_CONFIG[7:0] PR_OLD_COUNT bit field. After issuing the oldest command, the other remaining commands in the FIFO are reordered by age. The next oldest command in the FIFO is given highest priority again and issued after the EMIF_COS_CONFIG[7:0] PR_OLD_COUNT value expires. If a new value in the PR_OLD_COUNT bit field is written during counting, that is, before PR_OLD_COUNT expires, the counter keeps working but if this value is smaller the oldest command is issued sooner and if this value is larger the oldest command is issued later.

The master ID mapping allows the same master ID to be put in both class of service 1 and 2. Also, a transaction might belong to one class of service if viewed by master ID and might belong to another class of service if viewed by priority. In these cases, the command will belong to both class of service. The EMIF will try executing the command as soon as possible, when the smaller of the two counters (EMIF_COS_CONFIG[23:16] COS_COUNT_1 and EMIF_COS_CONFIG[15:8] COS_COUNT_2) expires.

15.3.4.16 Performance Counters

The EMIF_PERFORMANCE_COUNTER_1 and EMIF_PERFORMANCE_COUNTER_2 registers are used to monitor or calculate the EMIF Controller bandwidth and efficiency. These counters are able to count events such as accesses made to EMIF, Activate (ACT) commands sent to SDRAM, read and write accesses made to EMIF, and other events. Each counter counts independently of the other. In addition to the ability of events counting, the counters can also filter the events from a particular master or address space. The events counting and filter enabling are configured using the EMIF_PERFORMANCE_COUNTER_CONFIG register. The filter value used is configured through the EMIF_PERFORMANCE_COUNTER_MASTER_REGION_SELECT register. Each counter can be configured independently.

Table 15-93 lists all the events that can be counted and whether a filter can be applied to a particular event. A filter is applied to an event if the following bits are set to 0x1 for that event:

- For Performance Counter 1: EMIF_PERFORMANCE_COUNTER_CONFIG[15] CNTR1_MCONNID_EN and EMIF_PERFORMANCE_COUNTER_CONFIG[14] CNTR1_REGION_EN;
- For Performance Counter 2: EMIF_PERFORMANCE_COUNTER_CONFIG[31] CNTR2_MCONNID_EN and EMIF_PERFORMANCE_COUNTER_CONFIG[30] CNTR2_REGION_EN.

Table 15-93. Performance Counter Filter Configuration

CNTRn_CFG[1]	CNTRn_REGION_EN	CNTRn_MCONNID_EN	Description
0x0	0x0	0x0 or 0x1	Count the accesses made to EMIF
0x1	0x0	0x0 or 0x1	Count the Activate (ACT) commands sent to SDRAM
0x2	0x0 or 0x1	0x0 or 0x1	Count the read accesses made to EMIF
0x3	0x0 or 0x1	0x0 or 0x1	Count the write accesses made to EMIF
0x4	0x0	0x0	Count number of EMIF_FICLK clock cycles during which the local Command FIFO is full
0x5	0x0	0x0	Count number of EMIF_FICLK clock cycles during which the local Write Data FIFO is full
0x6	0x0	0x0	Count number of EMIF_FICLK clock cycles during which the local Read Data FIFO is full
0x7	0x0	0x0	Count number of EMIF_FICLK clock cycles during which the local Return Command FIFO is full
0x8	0x0 or 0x1	0x0 or 0x1	Count number of priority elevations
0x9	0x0	0x0	Count number of EMIF_FICLK clock cycles that a command was pending
0xA	0x0	0x0	Count number of EMIF_FICLK cycles used by the EMIF controller for reads and writes.
0xB - 0xF	0x0	0x0	Reserved for future use.

(1) n = 1 or 2

Note

When the MReqDebug qualifier is set to 0x1 for a particular local command, the performance counters are not incremented for that particular command if the CNTRn_CFG values are equal to 0x0, 0x1, 0x2, 0x3, or 0xA.

Note

The EMIF performance counters cannot distinguish between single access and burst access. In both cases they are incremented by 1. If the actual SDRAM bandwidth of an initiator has to be measured the EMIF performance counters may not be sufficient.

15.3.4.16.1 Performance Counters General Examples

- **General Example for Counting All Write Accesses made to EMIF**
  If the EMIF_PERFORMANCE_COUNTER_1 register is used to count all write accesses made to EMIF from master with connection ID equal to 0x86 (this is the system MMU) the following steps should be performed:
  – To enable the writes counting, the EMIF_PERFORMANCE_COUNTER_CONFIG[3:0] CNTR1_CFG bit field must be set to 0x3.
  – The EMIF_PERFORMANCE_COUNTER_MASTER_REGION_SELECT[15:8] MCONNID1 bit field must be set to 0x86.
  – To enable filtering, the EMIF_PERFORMANCE_COUNTER_CONFIG[15] CNTR1_MCONNID_EN bit must be set to 0x1.

  With this configuration EMIF_PERFORMANCE_COUNTER_1 counts every write made to the EMIF from master 0x86 to any address space. This does not include accesses from other masters and commands other than writes.
- **General Example for Counting Total Accesses made to EMIF**
  If the EMIF_PERFORMANCE_COUNTER_2 register is used to count total accesses made to EMIF regardless of the address space or master the following steps should be performed:

- To enable counting of all accesses to the SDRAM, the EMIF_PERFORMANCE_COUNTER_CONFIG[19:16] CNTR2_CFG bit field must be set to 0x0.
- To disable filtering, both the EMIF_PERFORMANCE_COUNTER_CONFIG[31] CNTR2_MCONNID_EN and EMIF_PERFORMANCE_COUNTER_CONFIG[30] CNTR2_REGION_EN bits must be set to 0x0.

  With this configuration EMIF_PERFORMANCE_COUNTER_2 counts every access made to the EMIF. This includes all accesses from all masters and to any address space.

- **General Example for Counting All Read Accesses made to EMIF**
  If the EMIF_PERFORMANCE_COUNTER_1 register is used to count all read accesses made to EMIF from master with connection ID equal to 0x86 (this is the system MMU) to address space 0x0 the following steps should be performed:
  - To enable the reads counting, the EMIF_PERFORMANCE_COUNTER_CONFIG[3:0] CNTR1_CFG bit field must be set to 0x2.
  - The EMIF_PERFORMANCE_COUNTER_MASTER_REGION_SELECT[15:8] MCONNID1 bit field must be set to 0x86
  - The EMIF_PERFORMANCE_COUNTER_MASTER_REGION_SELECT[1:0] REGION_SEL1 bit field must be set to 0x0.
  - To enable filtering, both the EMIF_PERFORMANCE_COUNTER_CONFIG[15] CNTR1_MCONNID_EN and the EMIF_PERFORMANCE_COUNTER_CONFIG[14] CNTR1_REGION_EN bits must be set to 0x1.

    With this configuration, EMIF_PERFORMANCE_COUNTER_1 counts every read made to the EMIF from master 0x86 to address space 0x0. This does not include accesses from other masters or to other address spaces and does not include commands other than reads.

15.3.4.17 Forcing CKE to tri-state

The CKE pad can be forced to tri-state when the corresponding bit in the CTRL_CORE_SMA_SW_0 register is set to 0x1. For the ddr1_cke pad this is the CTRL_CORE_SMA_SW_0[0] EMIF1_CKE_GATING_CTRL bit and for the ddr2_cke pad the CTRL_CORE_SMA_SW_0[1] EMIF2_CKE_GATING_CTRL bit. This functionality facilitates fast resume by allowing a strong external pull-down resistor to hold the CKE memory pad low thus keeping the SDRAM in self-refresh while the device is completely powered off. Figure 15-51 and the following example sequence provide more details how this functionality can be used:

- When device is running configure EMIF for self refresh. As a result it drives CKE low.
- Disable V_{TT} supply (can be controlled through a device GPIO pad).
- Ramp down all power rails to the device. When power is already off, EMIF doesn't drive CKE low. The external pull-down does this instead. Note that only V_{TT} must be off. All SDRAM supplies (including V_{REF}) must be on.
- After these three steps the device is completely powered off and the SDRAM is in self-refresh. The waking-up from this state is system specific.
- To resume from self-refresh the CKE pad must be forced to tri-state by writing 0x1 to one of the CKE_GATING_CTRL bits previously mentioned. Then EMIF must be configured for self-refresh so that its state becomes consistent with the actual SDRAM state.
- Write 0x0 to the corresponding CKE_GATING_CTRL bit to release CKE driver from tri-state. This allows EMIF to take control over CKE which is now driven low as EMIF has already been configured for self-refresh.
- Enable V_{TT} supply.
- Access the SDRAM to bring it out of self refresh and resume application.

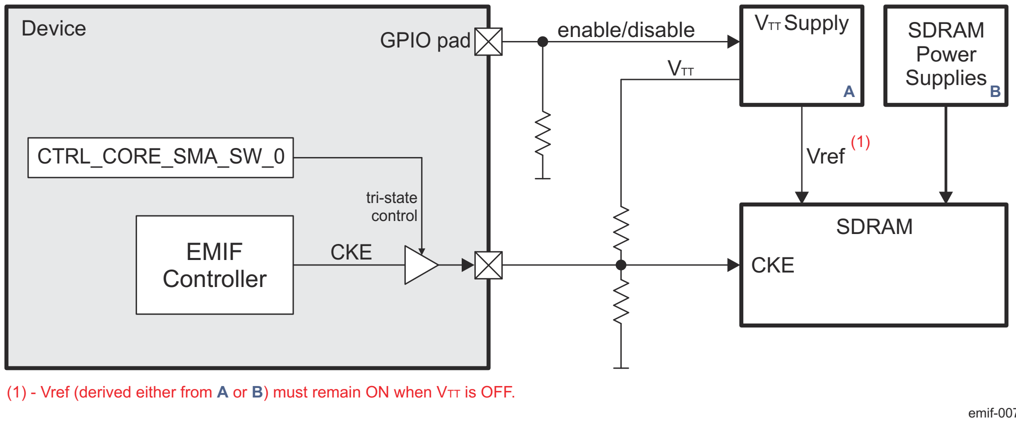

Figure 15-51. Example for Using the CKE Tri-state Functionality

---

Note

In case the device is powered off but the SDRAM is in self-refresh (as previously described) it must be taken into account that the SDRAM RESET# signal has to be controlled externally to preserve the SDRAM contents. This is needed as ddr1_rst/ddr2_rst signal is not controlled by the CTRL_CORE_SMA_SW_0 register and therefore cannot be used.

15.3.5 EMIF Programming Guide

15.3.5.1 EMIF Low-Level Programming Models

This section describers the low-level hardware programming sequences for the configuration and use of the EMIF module.

The following programming sequences are doubled, when the two EMIF modules (EMIF1 and EMIF2) are used.

15.3.5.1.1 Global Initialization

Table 15-94. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	The module interface and functional clocks must be enabled. See Chapter 3, *Power, Reset, and Clock Management*.
DMM	The EMIF is a slave to the DMM. The DMM must be enabled and configured. See Section 15.2, *Dynamic Memory Manager*.
Device INTCs	Device INTCs must be configured to enable the interrupt request generation. For more information see Chapter 17, *Interrupt Controllers*.
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see Section 18.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 18 , *Control Module*.

15.3.5.1.1.1 EMIF Configuration Sequence

Table 15-95 shows all steps needed to configure and use the EMIF.

Table 15-95. EMIF Configuration Sequence

Step	Register/ Bit Field	Value
Configure DPLL_DDR to the required frequency:		
· **IF** DPLL_DDR is locked:	CM_IDLEST_DPLL_DDR[0] ST_DPLL_CLK	0x1
Unlock DPLL_DDR	CM_CLKMODE_DPLL_DDR[2:0] DPLL_EN	0x6
· **ENDIF**		
· Configure the DPLL multiplier and divider factors	CM_CLKSEL_DPLL_DDR[18:8] DPLL_MULT and CM_CLKSEL_DPLL_DDR[6:0] DPLL_DIV	0x-
· Configure the M2 post-divider factor	CM_DIV_M2_DPLL_DDR[4:0] DIVHS	0x-
· Configure the H11 post-divider factor	CM_DIV_H11_DPLL_DDR[5:0] DIVHS	0x-
· Lock the DPLL_DDR	CM_CLKMODE_DPLL_DDR[2:0] DPLL_EN	0x7
Disable DLL Override	CM_DLL_CTRL[0] DLL_OVERRIDE	0x0
Configure the output impedance, slew rate and weak pull resistors of the DDR IO cells. For more information, see Section 18.4.6.10 *Software Controls for the DDR2/ DDR3 I/O Cells*.	For EMIF1:	0x-
	· CTRL_CORE_CONTROL_DDRCACH1_0	
	· CTRL_CORE_CONTROL_DDRCH1_0	
	· CTRL_CORE_CONTROL_DDRCH1_1	
	· CTRL_CORE_CONTROL_DDRCH1_2	
	For EMIF2:	
	· CTRL_CORE_CONTROL_DDRCACH2_0	
	· CTRL_CORE_CONTROL_DDRCH2_0	
	· CTRL_CORE_CONTROL_DDRCH2_1	

Table 15-95. EMIF Configuration Sequence (continued)

Step	Register/ Bit Field	Value
If needed, configure the Vref-Generation Cells. For more information, see Section 18.4.6.11 *Reference Voltage for the Device DDR2/DDR3 Receivers*.	For EMIF1:	0x-
	· CTRL_CORE_CONTROL_DDRIO_0	
	For EMIF2:	
	· CTRL_CORE_CONTROL_DDRIO_1	
Set the number of DQ samples required for read leveling	CTRL_WKUP_EMIF1_SDRAM_CONFIG_EXT[15:14] EMIF1_REG_PHY_NUM_OF_SAMPLES	0x3
	CTRL_WKUP_EMIF2_SDRAM_CONFIG_EXT[15:14] EMIF2_REG_PHY_NUM_OF_SAMPLES	0x3
Choose SDRAM read response on only one DQ bit during read leveling	CTRL_WKUP_EMIF1_SDRAM_CONFIG_EXT[12] EMIF1_REG_PHY_ALL_DQ_MPR_RD_RESP	0x0
	CTRL_WKUP_EMIF2_SDRAM_CONFIG_EXT[12] EMIF2_REG_PHY_ALL_DQ_MPR_RD_RESP	0x0
Configure ODT for the device DDR IOs	CTRL_WKUP_EMIF1_SDRAM_CONFIG_EXT [6:5] EMIF1_PHY_RD_LOCAL_ODT	0x1 for 60 Ohms
		0x2 for 80 Ohms
		0x3 for 120 Ohms
	CTRL_WKUP_EMIF2_SDRAM_CONFIG_EXT [6:5] EMIF2_PHY_RD_LOCAL_ODT	0x1 for 60 Ohms
		0x2 for 80 Ohms
		0x3 for 120 Ohms
IF ECC is used **OR IF** special [(6)] use-cases:		
Enable ECC	CTRL_WKUP_EMIF1_SDRAM_CONFIG_EXT[16] EMIF1_EN_ECC	0x1
ENDIF		
Based on the memory type other bits from CTRL_WKUP_EMIF1_SDRAM_CONFIG_EXT/ CTRL_WKUP_EMIF2_SDRAM_CONFIG_EXT can also be configured.		
Read the EMIF_IODFT_TLGC register	EMIF_IODFT_TLGC	RD_VAL_1
Read the EMIF_DDR_PHY_CONTROL_2 register	EMIF_DDR_PHY_CONTROL_2	RD_VAL_2
IF External warm reset or global warm software reset has occurred:	PRM_RSTST[5]EXTERNAL_WARM_RST or	0x1
	PRM_RSTST[1] GLOBAL_WARM_SW_RST	0x1
Reset the DDR PHY	EMIF_IODFT_TLGC[10] RESET_PHY	0x1
ENDIF		
Program the necessary ratio values to the EMIF_EXT_PHY_CONTROL_1 register	EMIF_EXT_PHY_CONTROL_1[19:10] PHY_REG_CTRL_SLAVE_RATIO1	0x80 if PHY_INVERT_CLKOUT = 0x0 or 0x100 if PHY_INVERT_CLKOUT = 0x1
	EMIF_EXT_PHY_CONTROL_1[9:0] PHY_REG_CTRL_SLAVE_RATIO0	0x80 if PHY_INVERT_CLKOUT = 0x0 or 0x100 if PHY_INVERT_CLKOUT = 0x1
Program the shadow register of EMIF_EXT_PHY_CONTROL_1	EMIF_EXT_PHY_CONTROL_1_SHADOW	EMIF_EXT_PHY_CONTROL_1

Step	Register/ Bit Field	Value
Program the shadow register of EMIF_SDRAM_TIMING_2	EMIF_SDRAM_TIMING_2_SHADOW (4)	EMIF_SDRAM_TIMING_2
Configure the timing parameters in EMIF_SDRAM_TIMING_3 (4)		0x-
Program the shadow register of EMIF_SDRAM_TIMING_3	EMIF_SDRAM_TIMING_3_SHADOW (4)	EMIF_SDRAM_TIMING_3
Program the EMIF_LPDDR2_NVM_TIMING (5) and EMIF_LPDDR2_NVM_TIMING_SHADOW (5) registers. **NOTE: These registers are not supported. They are kept only for code compatibility.**		0x0
Disable automatic power management	EMIF_POWER_MANAGEMENT_CONTROL[10:8] LP_MODE	0x0
Define the number of DDR clock cycles after which the EMIF puts the external SDRAM in Power Down mode when EMIF is idle	EMIF_POWER_MANAGEMENT_CONTROL[15:12] PD_TIM	0x-
Define the number of DDR clock cycles after which the EMIF puts the external SDRAM in Self Refresh mode when EMIF is idle	EMIF_POWER_MANAGEMENT_CONTROL[7:4] SR_TIM	0x-
Program the shadow register of EMIF_POWER_MANAGEMENT_CONTROL	EMIF_POWER_MANAGEMENT_CONTROL_SHADOW	EMIF_POWER_MANAGEMENT_CONTROL
Configure the System and MPU maximum number of commands in the command FIFO	EMIF_OCP_CONFIG[27:24] SYS_THRESH_MAX	0x-
	EMIF_OCP_CONFIG[23:20] MPU_THRESH_MAX	0x-
Program the EMIF_IODFT_TLGC register	EMIF_IODFT_TLGC	RD_VAL_1
Determine the required wait time after a phy_dll_calib is generated before another command can be sent	EMIF_DLL_CALIB_CTRL[19:16] ACK_WAIT	0x-
Determine the interval between phy_dll_calib generation	EMIF_DLL_CALIB_CTRL[8:0] DLL_CALIB_INTERVAL	0x-
Program the shadow register of EMIF_DLL_CALIB_CTRL	EMIF_DLL_CALIB_CTRL_SHADOW	EMIF_DLL_CALIB_CTRL
Define the interval (number of refresh periods) between ZQCS commands	EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[15:0] ZQ_REFINTERVAL	0x-
Define the number of ZQCS intervals that build the ZQCL duration	EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[17:16] ZQ_ZQCL_MULT	0x-
Enable issuing of ZQCL on Self- Refresh, Active Power-Down, and Precharge Power-Down exit	EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[28] ZQ_SFEXITEN	0x1
Enable ZQ calibration for CS0	EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[30] ZQ_CS0EN	0x1
Program the EMIF_TEMP_ALERT_CONFIG (5) register. **NOTE: This register is not supported on this device. It is kept only for code compatibility.**		0x-
Program the EMIF_READ_WRITE_LEVELING_RAMP_WINDOW register. **NOTE: Incremental leveling is not supported on this device.**		0x-
IF Memory type == DDR3 **AND** SDRAM content doesn't need to be maintained:		
Enable read-write leveling	EMIF_READ_WRITE_LEVELING_RAMP_CONTROL[31] RDWRLVL_EN	0x1
ELSE:		
Disable read-write leveling	EMIF_READ_WRITE_LEVELING_RAMP_CONTROL[31] RDWRLVL_EN	0x0
ENDIF		
Program bits [30:0] of EMIF_READ_WRITE_LEVELING_RAMP_CONTROL **NOTE: Incremental leveling is not supported on this device.**		0x-
Program the EMIF_READ_WRITE_LEVELING_CONTROL register		0x0

Table 15-95. EMIF Configuration Sequence (continued)

Step	Register/ Bit Field	Value
Define the read latency for the read data from SDRAM in number of DDR clock cycles	EMIF_DDR_PHY_CONTROL_1[4:0] READ_LATENCY	0x- (typical value >= (CL + 4))
Configure whether the MDLL lock is asserted based on single sample or average of 16 samples	EMIF_DDR_PHY_CONTROL_1[9] PHY_FAST_DLL_LOCK	0x-
Define the maximum number of delay line taps variation while maintaining the master DLL lock. The recommended value is 0x10	EMIF_DDR_PHY_CONTROL_1[17:10] PHY_DLL_LOCK_DIFF	0x10
Configure whether the clock to the SDRAM is inverted or not	EMIF_DDR_PHY_CONTROL_1[18] PHY_INVERT_CLKOUT	0x-
When leveling is used set PHY_DIS_CALIB_RST to 0x0	EMIF_DDR_PHY_CONTROL_1[19] PHY_DIS_CALIB_RST	0x0
Program the slave delay line delays to support 2× mode	EMIF_DDR_PHY_CONTROL_1[21] PHY_HALF_DELAYS	0x1
IF Memory type == DDR3:		
Unmask read data eye training, DQS gate training and write leveling training during full leveling	EMIF_DDR_PHY_CONTROL_1[27] RDLVL_MASK	0x0

Copy EMIF_PHY_STATUS_17 through EMIF_PHY_STATUS_26 to EMIF_EXT_PHY_CONTROL_12 through EMIF_EXT_PHY_CONTROL_21		
Mask read data eye training, DQS gate training and write leveling training to disable the use of registers EMIF_PHY_STATUS_7 through EMIF_PHY_STATUS_26 registers	EMIF_DDR_PHY_CONTROL_1[27:25]	0x7
Program the shadow register of EMIF_DDR_PHY_CONTROL_1	EMIF_DDR_PHY_CONTROL_1_SHADOW	EMIF_DDR_PHY_CONTROL_1
Disable read-write leveling	EMIF_READ_WRITE_LEVELING_RAMP_CONTROL[31] RDWRLVLFULL_START	0x0
ENDIF		
Clear the ECC control register	EMIF_ECC_CTRL_REG	0x0
ENDIF		
Configure the LISA_MAP registers based on the EMIF1/EMIF2 usage and EMIF interleaving modes. For more information see Section 15.2.4.2, *Addressing Management with LISA*.	DMM_LISA_MAP_i (i = 0 to 3)	0x-
	MA_LISA_MAP_i (i = 0 to 3)	0x-

(1) These values are only used when CM_DLL_CTRL[0] DLL_OVERRIDE is set to 0x1. This is used only for debug purposes.
(2) The values of these fields do not depend on the board topology.
(3) These fields control the delay between the corresponding DQ byte lane and DQS/DQSN pair. Their values should correspond to delay of 1/4 clock cycle to center the DQ relative to the rising/falling edges of DQS/DQSN. Regardless of topology, it is recommended that all the DQ bits are skew matched to the corresponding DQS/DQSN pair.
(4) Values loaded in these registers depend on OPP.
(5) Writes to these registers do not have any impact. It's up to the user to skip these steps.
(6) In some special use-cases with features like suspend to RAM where EMIF may be reset but SDRAM content needs to be maintained correctly across such an event. In such cases, when EMIF is configured at first boot with hardware leveling enabled, the hardware leveling output from EMIF_PHY_STATUS_x registers is copied to the EMIF_EXT_PHY_CONTROL_x registers. When EMIF comes back from a reset state and needs to be reconfigured without losing SDRAM content, the EMIF_READ_WRITE_LEVELING_RAMP_CONTROL[31] RDWRLVL_EN bit must be 0 and hardware leveling must not be triggered. In this case, the EMIF_EXT_PHY_CONTROL_2 through EMIF_EXT_PHY_CONTROL_21 registers take effect. Here it is expected that SDRAM is moved to self-refresh mode before EMIF enters reset state and SDRAM content is maintained correctly by appropriate circuitry external to the SoC.

15.3.5.1.2 Operational Modes Configuration

15.3.5.1.2.1 EMIF Output Impedance Calibration Mode

Table 15-96. EMIF Output Impedance Calibration Mode

Step	Register/ Bit Field / Programming Model	Value
Enable ZQ callibration for CS0.	EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[30] ZQ_CS0EN	0x1
Define the interval (number of refresh periods) between ZQCS commands.	EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[15:0] ZQ_REFINTERVAL	0x-
Define the number of ZQCS intervals that build the ZQCL duration.	EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[17:16] ZQ_ZQCL_MULT	0x-
Enable the issuing of ZQ-Long Command on Self-Refresh, Active Power-Down, and Precharge Power-Down exit.	EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[28] ZQ_SFEXITEN	0x1

15.3.5.1.2.2 EMIF SDRAM Self-Refresh

Table 15-97. EMIF SDRAM Self-Refresh Entering

Step	Register/ Bit Field / Programming Model	Value
Define the number of DDR clock cycles after which the EMIF puts the external SDRAM in Self Refresh mode, when EMIF is idle.	EMIF_POWER_MANAGEMENT_CONTROL[7:4] SR_TIM	0x-
Enable the Self-Refresh mode	EMIF_POWER_MANAGEMENT_CONTROL[10:8] LP_MODE	0x2
Write the shadow register of EMIF_POWER_MANAGEMENT_CONTROL	EMIF_POWER_MANAGEMENT_CONTROL_SHADOW	0x-

Table 15-98. EMIF SDRAM Self-Refresh Exiting

Step	Register/ Bit Field / Programming Model	Value
Change LP_MODE bitfield from 0x2 to any value.	EMIF_POWER_MANAGEMENT_CONTROL[10:8] LP_MODE	0x-
Write the shadow register of EMIF_POWER_MANAGEMENT_CONTROL	EMIF_POWER_MANAGEMENT_CONTROL_SHADOW	0x-

15.3.5.1.2.3 EMIF SDRAM Power-Down Mode

Table 15-99. EMIF SDRAM Power-Down Mode Entering

Step	Register/ Bit Field / Programming Model	Value
Define the number of DDR clock cycles after which the EMIF puts the external SDRAM in Power Down mode, when EMIF is idle.	EMIF_POWER_MANAGEMENT_CONTROL[15:12] PD_TIM	0x-
Enable (enter) the Power-down mode	EMIF_POWER_MANAGEMENT_CONTROL[10:8] LP_MODE	0x4
Write the shadow register of EMIF_POWER_MANAGEMENT_CONTROL	EMIF_POWER_MANAGEMENT_CONTROL_SHADOW	0x-

Table 15-100. EMIF SDRAM Power-Down Mode Exiting

Step	Register/ Bit Field / Programming Model	Value
Change LP_MODE bitfield from 0x4 to any value.	EMIF_POWER_MANAGEMENT_CONTROL[10:8] LP_MODE	0x-
Write the shadow register of EMIF_POWER_MANAGEMENT_CONTROL	EMIF_POWER_MANAGEMENT_CONTROL_SHADOW	0x-

15.3.5.1.2.4 EMIF ECC Configuration

Table 15-101 lists the ECC configuration settings.

Table 15-101. EMIF ECC Configuration

Step	Register/ Bit Field / Programming Model	Value
Before configuring the EMIF ECC registers, the ECC must be enabled from the Control Module	CTRL_WKUP_EMIF1_SDRAM_CONFIG_EXT [16] EMIF1_EN_ECC	0x1
Configure the address ranges which have to be ECC protected	EMIF_ECC_ADDRESS_RANGE_1 and EMIF_ECC_ADDRESS_RANGE_2 (1)	0x-
Enable the first ECC protected address range	EMIF_ECC_CTRL_REG[0] REG_ECC_ADDR_RGN_1_EN	0x1
Enable the second ECC protected address range	EMIF_ECC_CTRL_REG[1] REG_ECC_ADDR_RGN_2_EN(1)	0x1
Configure whether the EMIF accesses within the address ranges defined by EMIF_ECC_ADDRESS_RANGE_1 and EMIF_ECC_ADDRESS_RANGE_2 are ECC protected (=0x1) or the EMIF accesses outside these address ranges are ECC protected (=0x0).	EMIF_ECC_CTRL_REG[30] REG_ECC_ADDR_RGN_PROT	0x-
(Optional) Configure the thresholds to generate 1-bit error interrupt	EMIF_1B_ECC_ERR_THRSH	0x-
Enable ECC	EMIF_ECC_CTRL_REG[31] REG_ECC_EN	0x1
Initialize the ECC protected memory regions with quanta-sized and quanta-aligned data		
Clear the status flags and other status history	EMIF_1B_ECC_ERR_CNT	Read the register value and write it back to clear
	EMIF_1B_ECC_ERR_DIST_1	0xFFFF FFFF
	EMIF_2B_ECC_ERR_ADDR_LOG	0x1
	EMIF_SYSTEM_OCP_INTERRUPT_STATUS [5:3]	0x7

(1) It is not mandatory to enable both address ranges. This is provided for flexibility, allowing two non-overlapping ECC protected regions to be created.

Note

If ECC is used the following must be taken into account to avoid unexpected behavior and possible errors:

- The memory interleaving must be disabled through setting the DMM_LISA_MAP_i[19:18] SDRC_INTL bit field to 0x0.
- The xxx_RATIO8 and xxx_RATIO9 bit fields are associated with the ECC data PHY and in case of software leveling must be loaded with values same as in the xxx_RATIO0 through xxx_RATIO7 bit fields from registers EMIF_EXT_PHY_CONTROL_x.

Note

Software leveling is not recommended to be used. Hardware leveling must be used instead.

15.3.6 EMIF Register Manual

Table 15-102 lists the EMIF instance.

15.3.6.1 EMIF Instance Summary

Table 15-102. EMIF Instance Summary

Module Name	Base Address	Size
EMIF1	0x4C00 0000	16 MiB
EMIF2	0x4D00 0000	16 MiB

15.3.6.2 EMIF Registers

Many register values are programmed with full-speed DDR clock cycles, whereas EMIF always runs at half the speed of this clock. Because EMIF is only capable of decrementing these values at half speed (taking into account the minus 1 programming model) the following model applies for data issued on a lower bus:

- REG_VALUE = 0 → 2 DDR clocks
- REG_VALUE = 1 → 2 DDR clocks
- REG_VALUE = 2 → 4 DDR clocks
- REG_VALUE = 3 → 4 DDR clocks
- REG_VALUE = 4 → 6 DDR clocks
- REG_VALUE = 5 → 6 DDR clocks
- REG_VALUE = 6 → 8 DDR clocks
- REG_VALUE = 7 → 8 DDR clocks

Activate and deactivate commands use the upper bus. Register values associated with these operations follow the general rule:

- REG_VALUE = 0 → 1 DDR clocks
- REG_VALUE = 1 → 2 DDR clocks
- REG_VALUE = 2 → 2 DDR clocks
- REG_VALUE = 3 → 4 DDR clocks
- REG_VALUE = 4 → 4 DDR clocks
- REG_VALUE = 5 → 6 DDR clocks
- REG_VALUE = 6 → 6 DDR clocks

Note

Shadow registers are loaded on any frequency change or SidleReq/SidleAck transition at the point where the EMIF has put SDRAM into self-refresh mode.

Table 15-103 summarizes the EMIF register mapping.

15.3.6.2.1 EMIF Register Summary

Table 15-103. EMIF Registers Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	EMIF1 Physical Address	EMIF2 Physical Address

- EMIF Register Summary: [2]

Table 15-106. EMIF_STATUS

Address Offset	0x0000 0004		
Physical Address	0x4C00 0004 0x4D00 0004	**Instance**	EMIF1 EMIF2

Table 15-106. EMIF_STATUS (continued)

Description	SDRAM Status Register (STATUS)
Type	R

31	30	29	28:7	6	5	4	3	2	1:0
BE	DUAL_CLK_MODE	FAST_INIT	RESERVED	RDLVLGATETO	RDLVLTO	WRLVLTO	RESERVED	PHY_DLL_READY	RESERVED

Bits	Field Name	Description	Type	Reset
31	BE	Big endian mode select for 8 and 16-bit devices, set to 1 for big endian or 0 for little endian operation. In current implementation, only 32-bit devices are supported - this bit is don't care.	R	0
30	DUAL_CLK_MODE	Dual Clock mode. Defines whether the EMIFi_L3_ICLK and EMIF_FICLK clock are asynchronous. EMIFi_L3_ICLK and EMIF_FICLK clock are asynchronous, if set to 1.	R	0
29	FAST_INIT	Fast Init. Defines whether the EMIF fast initialization mode has been enabled. Fast initialization is enabled if set to 1.	R	0
28:7	RESERVED	Reserved	R	0x00 0000
6	RDLVLGATETO	Read DQS Gate Training Timeout. Value of 1 indicates read DQS gate training has timed out because read DQS gate training done was not received from the PHY.	R	0
5	RDLVLTO	Read Data Eye Training Timeout. Value of 1 indicates read data eye training has timed out because read data eye training done was not received from the PHY.	R	0
4	WRLVLTO	Write Leveling Timeout. Value of 1 indicates write leveling has timed out because write leveling done was not received from the PHY.	R	0
3	RESERVED		R	0
2	PHY_DLL_READY	DDR PHY Ready. The DDR PHY is ready for normal operation, if set to 1.	R	0
1:0	RESERVED	Reserved	R	0x0

Table 15-107. Register Call Summary for Register EMIF_STATUS

EMIF Controller

- EMIF Register Summary: [4]

Table 15-108. EMIF_SDRAM_CONFIG

Address Offset	0x0000 0008		
Physical Address	0x4C00 0008 0x4D00 0008	**Instance**	EMIF1 EMIF2
Description	SDRAM Config Register. A write to this register will cause the EMIF to start the SDRAM initialization sequence. **CAUTION:** This register is loaded with values by control module at device reset.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SDRAM_TYPE	IBANK_POS	DDR_TERM	DDR2_DDQS	DYN_ODT	DDR_DISABLE_DLL	SDRAM_DRIVE	CWL	NARROW_MODE	CL	ROWSIZE	IBANK	RESERVED	PAGESIZE

Bits	Field Name	Description	Type	Reset
31:29	SDRAM_TYPE	SDRAM Type selection. This field is loaded from e-fuse. Set to 2 for DDR2 Set to 3 for DDR3 All other values are reserved.	RW	0x0
28:27	IBANK_POS	Internal bank position. See Section 15.3.4.12, *SDRAM Address Mapping*.	RW	0x0
26:24	DDR_TERM	DDR3 termination resistor value. Set to 0 to disable termination. For DDR3, set to 1 for RZQ/4, set to 2 for RZQ/2, set to 3 for RZQ/6, set to 4 for RZQ/12, and set to 5 for RZQ/8. All other values are reserved.	RW	0x0
23	DDR2_DDQS	DDR2 differential DDQS enable. NOT SUPPORTED. Set to 1 for compatibility.	RW	0
22:21	DYN_ODT	DDR3 Dynamic ODT. NOT SUPPORTED. Set to 0 to turn off dynamic ODT.	RW	0x0
20	DDR_DISABLE_DLL	Disable DLL select. Set to 1 to disable DLL inside SDRAM.	RW	0
19:18	SDRAM_DRIVE	SDRAM drive strength.For DDR3, set to 0 for RZQ/6 and set to 1 for RZQ/7. All other values are reserved.	RW	0x0
17:16	CWL	DDR3 CAS Write latency. Value of 0, 1, 2, and 3 (CAS write latency of 5, 6, 7, and 8) are supported. Use the lowest value supported for best performance. All other values are reserved.	RW	0x0
15:14	NARROW_MODE	SDRAM data bus width. Set to 0 for 32-bit data bus width. Set to 1 for 16-bit data bus width. All other values are reserved.	RW	0x0
13:10	CL	CAS Latency (referred to as read latency (RL) in some SDRAM specs). The value of this field defines the CAS latency to be used when accessing connected SDRAM devices. Values of 2, 3, 4 and 5 (CAS latency of 2, 3, 4 and 5) are supported for DDR2. Values of 2, 4, 6, 8, 10, 12 and 14 (CAS latency of 5, 6, 7, 8, 9, 10 and 11) are supported for DDR3. All other values are reserved.	RW	0x0

Bits	Field Name	Description	Type	Reset
9:7	ROWSIZE	Row Size. Defines the number of row address bits of connected SDRAM devices. Set to 0 for 9 row bits, Set to 1 for 10 row bits, Set to 2 for 11 row bits, Set to 3 for 12 row bits, Set to 4 for 13 row bits, Set to 5 for 14 row bits, Set to 6 for 15 row bits, Set to 7 for 16 row bits. This field is only used when EMIF_SDRAM_CONFIG[28:27] IBANK_POS field is set to 1, 2, or 3 or EBANK_POS field in EMIF_SDRAM_CONFIG_2 register is set to 1.	RW	0x0
6:4	IBANK	Internal Bank setup. Defines number of banks inside connected SDRAM devices. Set to 0 for 1 bank, Set to 1 for 2 banks, Set to 2 for 4 banks, Set to 3 for 8 banks. All other values are reserved.	RW	0x0
3	RESERVED		R	0
2:0	PAGESIZE	Page Size. Defines the internal page size of connected SDRAM devices. Set to 0 for 256-word page (8 column bits), Set to 1 for 512-word page (9 column bits), Set to 2 for 1024-word page (10 column bits), Set to 3 for 2048-word page (11 column bits). All other values are reserved.	RW	0x0

Table 15-112. EMIF_SDRAM_REFRESH_CONTROL

Address Offset	0x0000 0010		
Physical Address	0x4C00 0010 0x4D00 0010	**Instance**	EMIF1 EMIF2
Description	SDRAM Refresh Control Register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
INITREF_DIS	RESERVED	SRT	ASR	RESERVED	PASR			RESERVED								REFRESH_RATE															

Bits	Field Name	Description	Type	Reset
31	INITREF_DIS	Initialization and Refresh disable. When set to 1, EMIF will disable SDRAM initialization and refreshes, but will carry out SDRAM write/read transactions.	RW	1
30	RESERVED		R	0
29	SRT	DDR3 Self Refresh temperature range. Set to 0 for normal operating temperature range and set to 1 for extended operating temperature range when the ASR field is set to 0. This bit must be set to 0 if the ASR field is set to 1. A write to this field will cause the EMIF to start the SDRAM initialization sequence.	RW	0

Bits	Field Name	Description	Type	Reset
28	ASR	DDR3 Auto Self Refresh enable. Set to 1 for auto Self Refresh enable. Set to 0 for manual Self Refresh reference indicated by the SRT field. A write to this field will cause the EMIF to start the SDRAM initialization sequence.	RW	0
27	RESERVED		R	0
26:24	PASR	Partial Array Self Refresh. These bits get loaded into the Extended Mode Register of DDR3 during initialization. For DDR3, set to 0 for full array, set to 1 or 5 for 1/2 array, set to 2 or 6 for 1/4 array, set to 3 or 7 for 1/8 array, and set to 4 for 3/4 array to be refreshed. All other values are reserved. A write to this field will cause the EMIF to start the SDRAM initialization sequence.	RW	0x0
23:16	RESERVED		R	0x00
15:0	REFRESH_RATE	Refresh Rate. Value in this field is used to define the rate at which connected SDRAM devices will be refreshed. SDRAM refresh rate = REFRESH_RATE / EMIF_PHY_FCLK. A 533-MHz DDR clock rate system that requires a 7.8 µs refresh rate would need 7.8 × 533 = 4157 or 0x103D value to be written. To avoid lock-up situations, the programmer must not program REFRESH_RATE < (6 × EMIF_SDRAM_TIMING_3[12:4] T_RFC). **Note** **NOTE:** The SDRAM refresh rate can be changed on-the-fly by writing to this field. When changing the SDRAM refresh rate all timing parameters that use the refresh rate value have to be recalculated. For example, tRASmax specified in the EMIF_SDRAM_TIMING_3[3:0] T_RAS_MAX field must be recalculated.	RW	0x0000

Address Offset	0x0000 0098		
Physical Address	0x4C00 0098 0x4D00 0098	**Instance**	EMIF1 EMIF2
Description	Control register to force idle window time to generate a phy_dll_calib that can be used for updating PHY DLLs during voltage ramps. NOTE: Should always be loaded via the shadow register.		
Type	RW		

31–20	19–16	15–9	8–0
RESERVED	ACK_WAIT	RESERVED	DLL_CALIB_INTERVAL

Bits	Field Name	Description	Type	Reset
31:20	RESERVED		R	0x000

Bits	Field Name	Description	Type	Reset
19:16	ACK_WAIT	The ack_wait determines the required wait time after a phy_dll_calib is generated before another command can be sent. Value program is in terms of EMIF_FICLK cycle count. **CAUTION:** 5 must be the minimum value ever programmed.	RW	0x9
15:9	RESERVED		R	0x00
8:0	DLL_CALIB_INTERVAL	This field determines the interval between phy_dll_calib generation. This value is multiplied by a precounter of 16 EMIF_FICLK cycles. Program this field one less the value you are targeting; program 1 to achieve interval of 2 (minimum interval supported). Programming zero turns off function. Note the final intervals between dll_calib generation is also a function of ACK_WAIT. Final periodic interval is calculated by: ((DLL_CALIB_INTERVAL + 1) × 16) + ACK_WAIT	RW	0x000

Table 15-182. EMIF_DDR_PHY_CONTROL_1

Address Offset	0x0000 00E4		
Physical Address	0x4C00 00E4 0x4D00 00E4	**Instance**	EMIF1 EMIF2
Description	PHY control register 1		
Type	RW		

31-28	27	26	25	24-22	21	20	19	18	17-10	9	8-5	4-0
RESERVED	RDLVL_MASK	RDLVLGATE_MASK	WRLVL_MASK	RESERVED	PHY_HALF_DELAYS	PHY_CLK_STALL_LEVEL	PHY_DIS_CALIB_RST	PHY_INVERT_CLKOUT	PHY_DLL_LOCK_DIFF	PHY_FAST_DLL_LOCK	RESERVED	READ_LATENCY

Bits	Field Name	Description	Type	Reset
31:28	RESERVED	Reserved	RW	0x0
27	RDLVL_MASK	Writing a 1 to this field will mask read data eye training during full leveling command, plus drives reg_phy_use_rd_data_eye_level control low to allow user to use programmed ratio values.	RW	0
26	RDLVLGATE_MASK	Writing a 1 to this field will mask dqs gate training during full leveling command, plus drives reg_phy_use_rd_dqs_level control low to allow user to use programmed ratio values.	RW	0
25	WRLVL_MASK	Writing a 1 to this field will mask write leveling training during full leveling command, plus drives reg_phy_use_wr_level control low to allow user to use programmed ratio values.	RW	0
24:22	RESERVED	Reserved	RW	0x0
21	PHY_HALF_DELAYS	Adjust slave delay line delays to support 2× mode 1: 2× mode (MDLL clock is half the rate of PHY) 0: 1× mode (MDLL clock rate is same as PHY)	RW	0
20	PHY_CLK_STALL_LEVEL	Enable variable idle value for delay lines. Enable during normal operations to avoid differential aging in the delay lines.	RW	0
19	PHY_DIS_CALIB_RST	Disable the dll_calib (internally generated) signal from resetting the Read Capture FIFO pointers and portions of data PHYs. Debug only. Note: dll_calib is generated by 1. EMIF_MISC_REG[0] DLL_CALIB_OS set to 1,or 2. by the PHY when it detects that the clock frequency variation has exceeded the bounds set by PHY_DLL_LOCK_DIFF or 3. periodically throughout the leveling process.	RW	0
18	PHY_INVERT_CLKOUT	Inverts the polarity of DRAM clock. 0: core clock is passed on to DRAM 1: inverted core clock is passed on to DRAM	RW	0

Bits	Field Name	Description	Type	Reset
17:10	PHY_DLL_LOCK_DIFF	The maximum number of delay line taps variation while maintaining the master DLL lock. When the PHY is in locked state and the variation on the clock exceeds the variation indicated by this field, the lock signal is de-asserted and a dll_calib signal is generated. To prevent the dll_calib signal from being asserted in the middle of traffic when the clock jitter exceeds the variation, this register needs to be set to a value which will ensure that the lock will not be lost. Recommended value is 16.	RW	0x02
9	PHY_FAST_DLL_LOCK	Controls master DLL to lock fast or average logic must be part of locking process. Set to 1 before OPP transition commences, and set back to 0 after OPP transition completes. 1: MDLL lock is asserted based on single sample 0: MDLL lock is asserted based on average of 16 samples.	RW	0
8:5	RESERVED	Reserved	RW	0x00
4:0	READ_LATENCY	This field defines the read latency for the read data from SDRAM in number of DDR clock cycles. This field is used by the EMIF as well as the PHY. READ_LATENCY = RL + reg_phy_rdc_we_to_re -1. EMIF uses above equation to calculate reg_phy_rdc_we_to_re and forward it to the PHY. For DDR3, the true RL is used, not the decoded value. See JEDEC spec.	RW	0x01E

15.4 General-Purpose Memory Controller

This section describes the features and functions of the device GPMC controller.

15.4.1 GPMC Overview

The general-purpose memory controller (GPMC) is a unified memory controller dedicated for interfacing with external memory devices like:

- Asynchronous SRAM-like memories and application-specific integrated circuit (ASIC) devices
- Asynchronous, synchronous, and page mode (available only in nonmultiplexed mode) burst NOR flash devices
- NAND flash
- Pseudo-SRAM devices

Figure 15-52 shows the GPMC module overview.

The GPMC features are introduced in Section 15.1.4, *GPMC Overview* of Section 15.1, *Memory Subsystem Overview*.

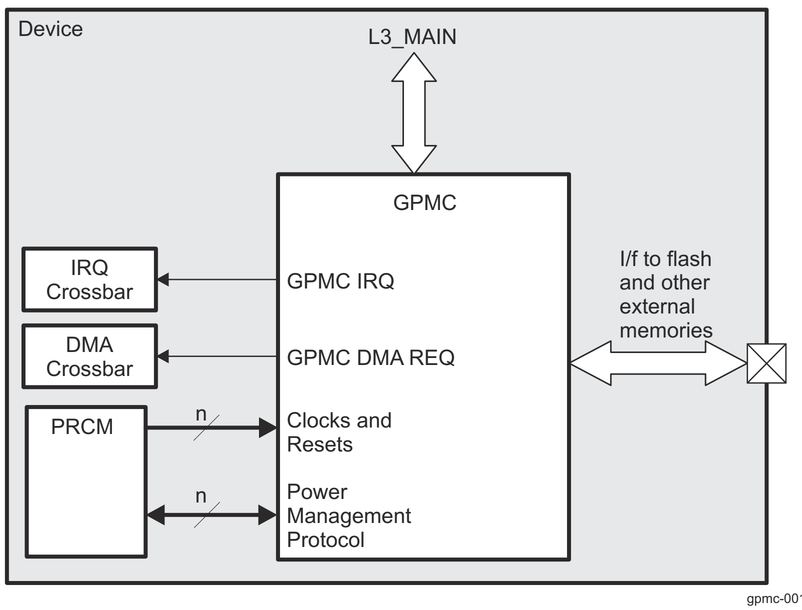

Figure 15-52. GPMC Overview

15.4.2 GPMC Environment

This section describes the GPMC application fields from an environment point of view (external connections). It describes GPMC connectivity options, and gives three possible interfaces.

15.4.2.1 GPMC Modes

This section shows three GPMC external connections options:

- Figure 15-53 shows a connection between the GPMC and a 16-bit synchronous address/data-multiplexed (or AAD-multiplexed, but this protocol uses fewer address pins) external memory device.
- Figure 15-54 shows a connection between the GPMC and a 16-bit synchronous nonmultiplexed external memory device.
- Figure 15-55 shows a connection between the GPMC and an 8-bit synchronous non-multiplexed external memory device.
- Figure 15-56 shows a connection between the GPMC and a 8-bit NAND device.

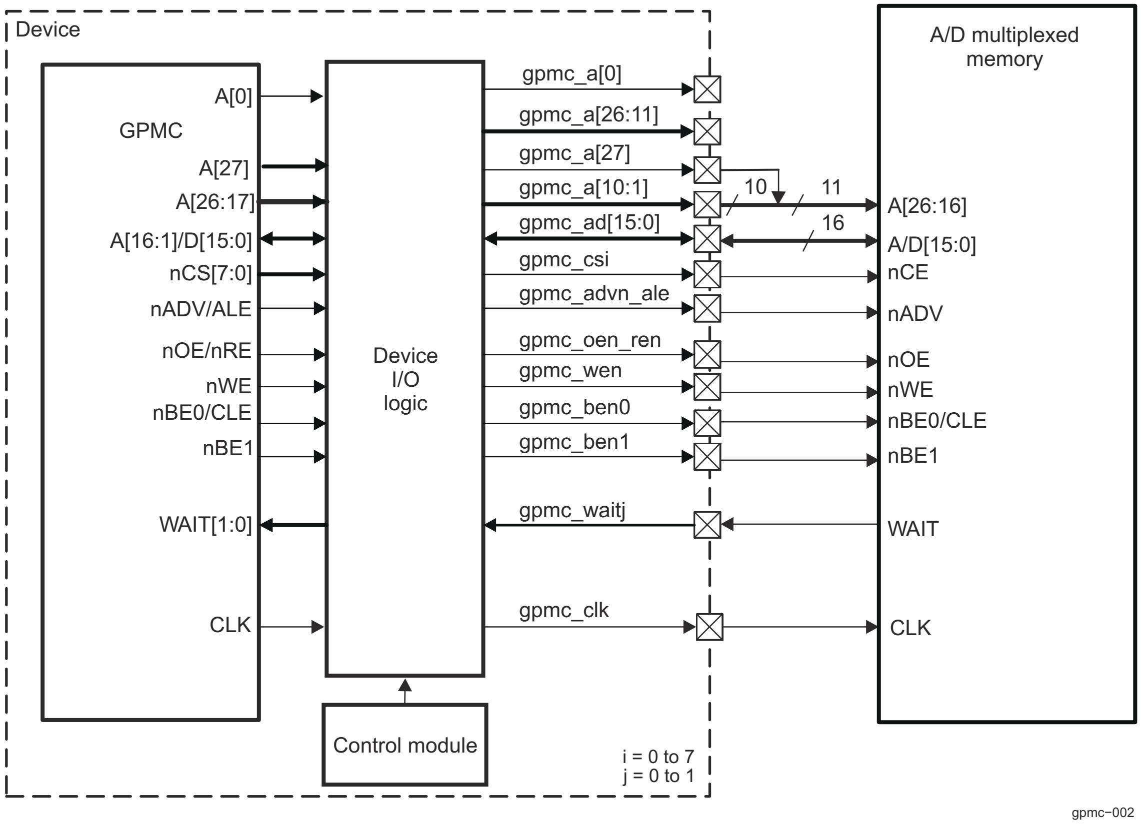

Figure 15-53. GPMC to 16-Bit Address/Data-Multiplexed Memory

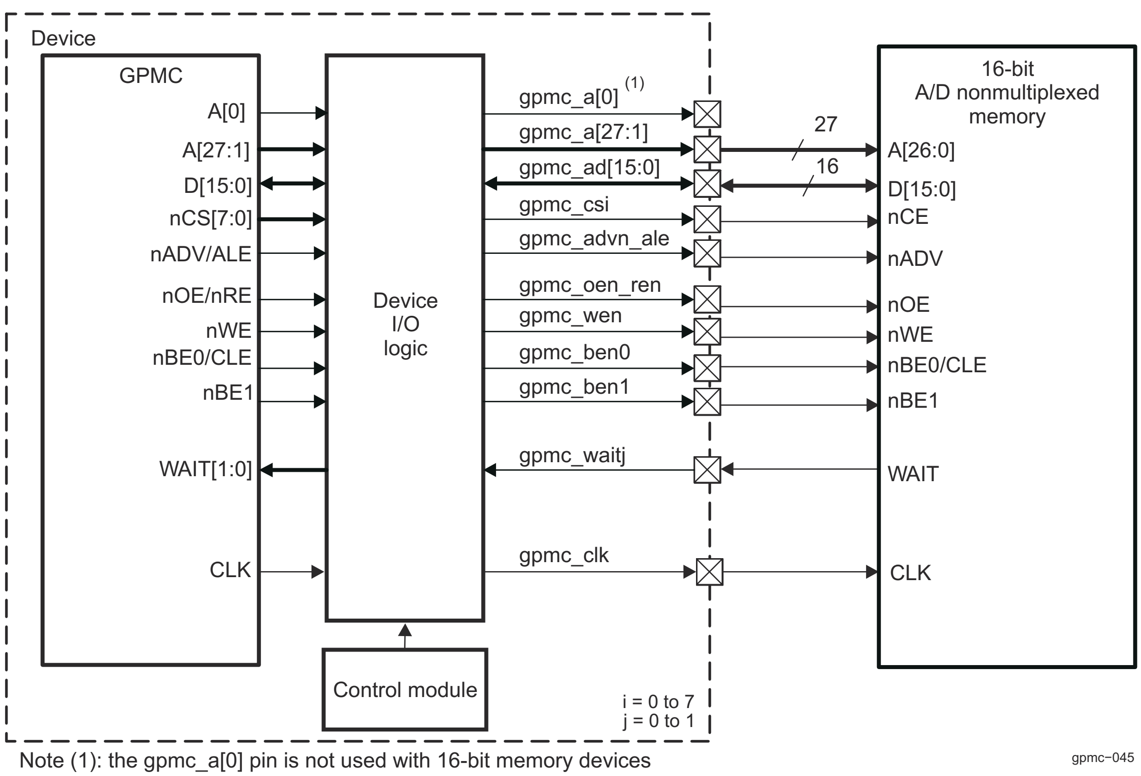

Figure 15-54. GPMC to 16-Bit Nonmultiplexed Memory

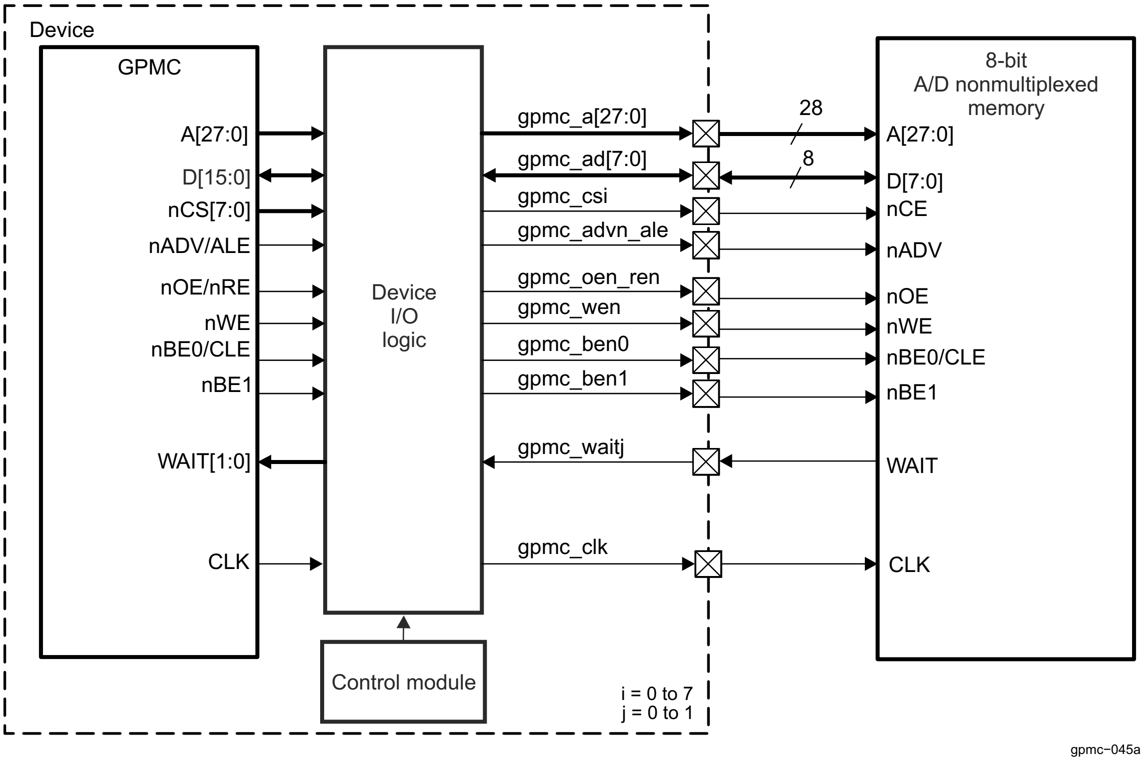

Figure 15-55. GPMC to 8-Bit Nonmultiplexed Memory

15.4.2.2 GPMC Signals

Table 15-414 lists the GPMC subsystem input/output (I/O) pins.

Table 15-414. GPMC I/O Description

Pin Name	Device Signal	I/O(1)	Description
A[27:0]	gpmc_a[27:0]	O	28-bit output address bus
A[16:1]/D[15:0]	gpmc_ad[15:0]	I/O	Multiplexed address/data
nCS[7:0]	gpmc_cs[7:0]	O	Chip-selects (active low)
CLK	gpmc_clk	O	Clock generated for the external memory or device
nADV/ALE	gpmc_advn_ale	O	Address valid (active low). Also used as address latch enable (active high) for NAND protocol memories.
nOE/nRE	gpmc_oen_ren	O	Output enable (active low). Also used as read enable (active low) for NAND protocol memories.
nWE	gpmc_wen	O	Write enable (active low)
nBE0/CLE	gpmc_ben0	O	Lower-byte enable (active low). Also used as command latch enable for NAND protocol memories.
nBE1	gpmc_ben1	O	Upper-byte enable (active low).
WAIT[1:0]	gpmc_wait[1:0]	I	External wait signal for NOR and NAND protocol memories. The wait signals can be mapped on any of the chip-select.

(1) I = Input; O = Output

Note

For the gpmc_clk signal to work properly, the INPUTENABLE bit of the appropriate CTRL_CORE_PAD_x register should be set to 0x1 because of retiming purposes.

Note

On SR2.0 devices the internal PU/PD resistors on pads gpmc_a[27:24, 22:19] can be permanently disabled. For more information, see *Permanent PU/PD disabling (SR 2.0 only)* in *Control Module*.

Table 15-415 shows the use of address and data GPMC controller pins based on the type of external device.

Table 15-415. GPMC Pin Multiplexing Options

(1) Used to effectively address 8-bit (only) non-multiplexed memories

With all device types, the GPMC does not drive unnecessary address lines. They stay at their reset value of 0x00.

Address mapping supports address/data-multiplexed 16-bit-wide devices:

- The NOR flash memory controller still supports nonmultiplexed address and data memory devices.
- Multiplexing mode can be selected through the GPMC_CONFIG1_i[9:8] MUXADDDATA bit field (where i = 0 to 7).
- Asynchronous page mode is not supported for multiplexed address and data devices.

15.4.3 GPMC Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

- No master standby protocol
- Supports slave idle protocol with device PRCM
- Supports Auto Idle
- No wake-up request
- One direct memory access request mapped via the device DMA crossbar (DMA_CROSSBAR) to all device integrated DMA controllers
- One interrupt request mapped via the device interrupt crossbar (IRQ_CROSSBAR) to all device integrated interrupt controllers (MPU_INTC, etc.)
- One clock for functional and interface domains

Figure 15-57 shows GPMC integration.

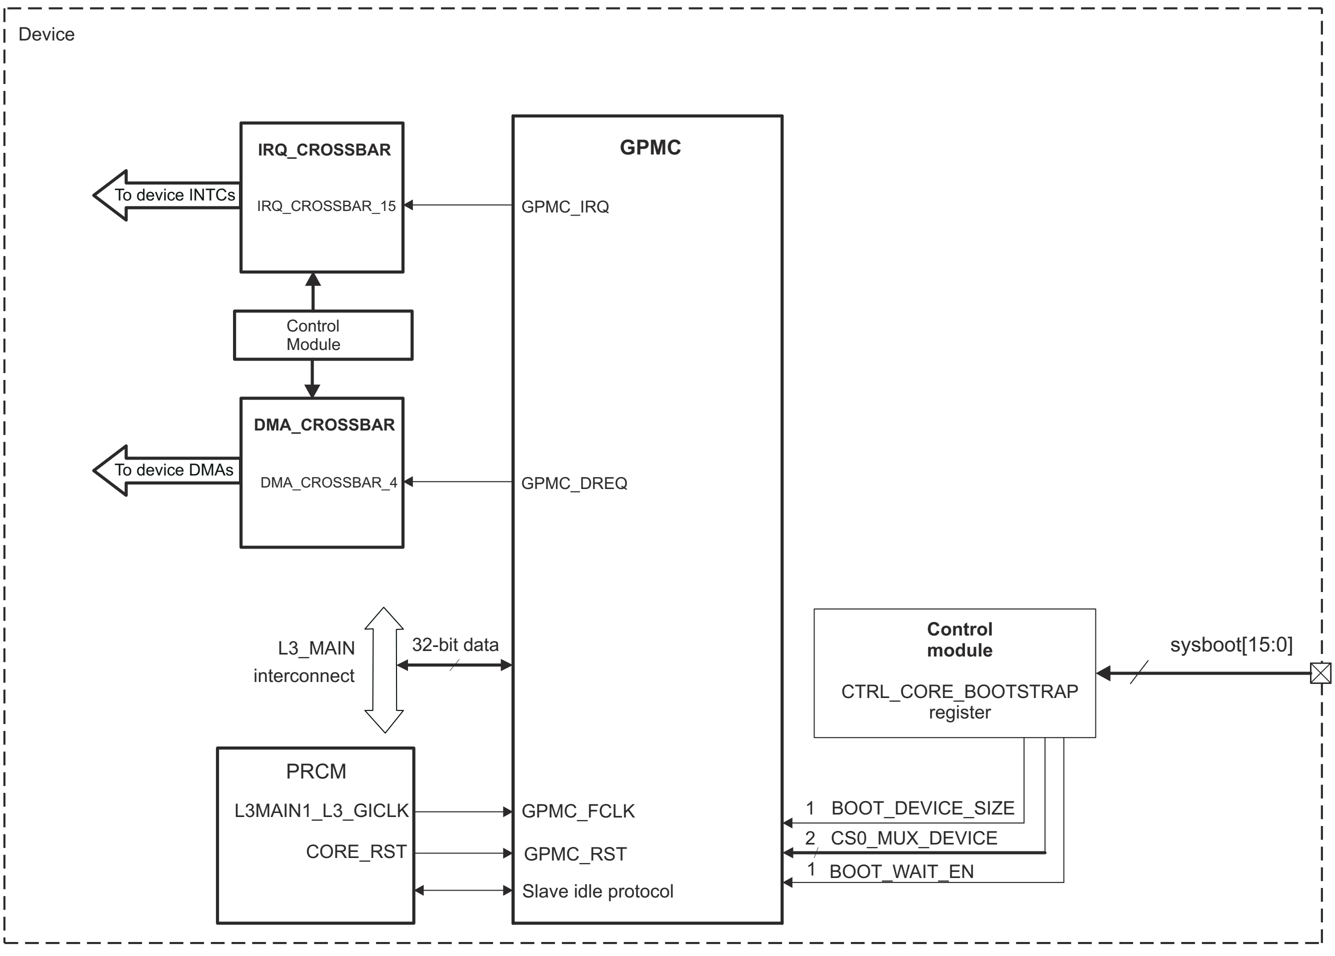

Figure 15-57. GPMC Integration

Table 15-416, Table 15-417 and Table 15-418 summarize the integration of the module in the device.

Table 15-416. GPMC Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
GPMC	PD_COREAON	No	L3_MAIN

Note

- For the description of the operation performance point (OPP) configuration, see *Module Level Clock Management*, in *Power, Reset, and Clock Management*.
- For information about frequencies associated with each OPP, see the device data manual.

Table 15-417. GPMC Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
GPMC	GPMC_FCLK	L3MAIN1_L3_GICLK	PRCM	Functional clock
Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
GPMC	GPMC_RST	CORE_RET_RST	PRCM	GPMC reset

Note

For the clock description, see Section 15.4.4.2, *GPMC Clock Configuration*.

Table 15-418. GPMC Hardware Requests

Interrupt Requests				
Module Instance	**Source Signal Name**	**Destination IRQ_CROSSBAR Input**	**Default Mapping**	**Description**
GPMC	GPMC_IRQ	IRQ_CROSSBAR_15	MPU_IRQ_20 DSP1_IRQ_46 DSP2_IRQ_46	GPMC interrupt
DMA Requests				
Module Instance	**Source Signal Name**	**Destination DMA_CROSSBAR Input**	**Default Mapping**	**Description**
GPMC	GPMC_DREQ	DMA_CROSSBAR_4	DMA_EDMA_DREQ_3 DMA_SYSTEM_DREQ_3	DMA request from GPMC prefetch engine.

Note

The “**Default Mapping**” column in Table 15-418 *GPMC Hardware Requests* shows the default mapping of module IRQ and DREQ source signals. These module IRQ and DREQ source signals can also be mapped to other lines of each device Interrupt or DMA controller through the IRQ_CROSSBAR and DMA_CROSSBAR modules, respectively.
For more information about the IRQ_CROSSBAR module, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.
For more information about the DMA_CROSSBAR module, see *DMA_CROSSBAR Module Functional Description*, in *Control Module*.
For more information about the device interrupt controllers, see *Interrupt Controllers*.
For more information about the device DMA_SYSTEM module, see Section 16.1, *System DMA*.
For more information about the device EDMA module, see Section 16.2, *Enhanced DMA*.

Note

For the description of the interrupt source, see Section 15.4.4.5, *GPMC Interrupt Requests*.

15.4.4 GPMC Functional Description

The GPMC basic programming model offers maximum flexibility to support various access protocols for each of the eight configurable chip-selects. Use optimal chip-select settings, based on the characteristics of the external device:

- Different protocols can be selected to support generic asynchronous or synchronous random-access devices (NOR flash, SRAM) or to support specific NAND devices.
- The address and data bus can be multiplexed on the same external bus.
- Read and write access can be independently defined as asynchronous or synchronous.
- System requests (byte, 16-bit word, burst) are performed through single or multiple accesses. External access profiles (single, multiple with optimized burst length, native- or emulated-wrap) are based on external device characteristics (supported protocol, bus width, data buffer size, native-wrap support).
- System burst read or write requests are synchronous-burst (multiple-read or multiple-write). When neither burst nor page mode is supported by external memory or ASIC devices, system burst read or write requests are translated to successive single synchronous or asynchronous accesses (single reads or single writes). 8-bit wide devices are supported only in single synchronous or single asynchronous read or write mode.
- To simulate a programmable internal-wait-state, an external wait pin can be monitored to dynamically control external access at the beginning (initial access time) of and during a burst access.

Each control signal is controlled independently for each chip-select. The internal functional clock of the GPMC (GPMC_FCLK) is used as a time reference to specify the following:

- Read- and write-access duration
- Most GPMC external interface control-signal assertion and deassertion times
- Data-capture time during read access
- External wait-pin monitoring time
- Duration of idle time between accesses, when required

15.4.4.1 GPMC Block Diagram

Figure 15-58 shows the GPMC functional block diagram. The GPMC consists of six blocks:

- L3 interconnect port interface
- Address decoder, GPMC configuration, and chip-select configuration register file
- Access engine
- Prefetch and write-posting engine
- Error correction code engine (ECC)
- External device/memory port interface

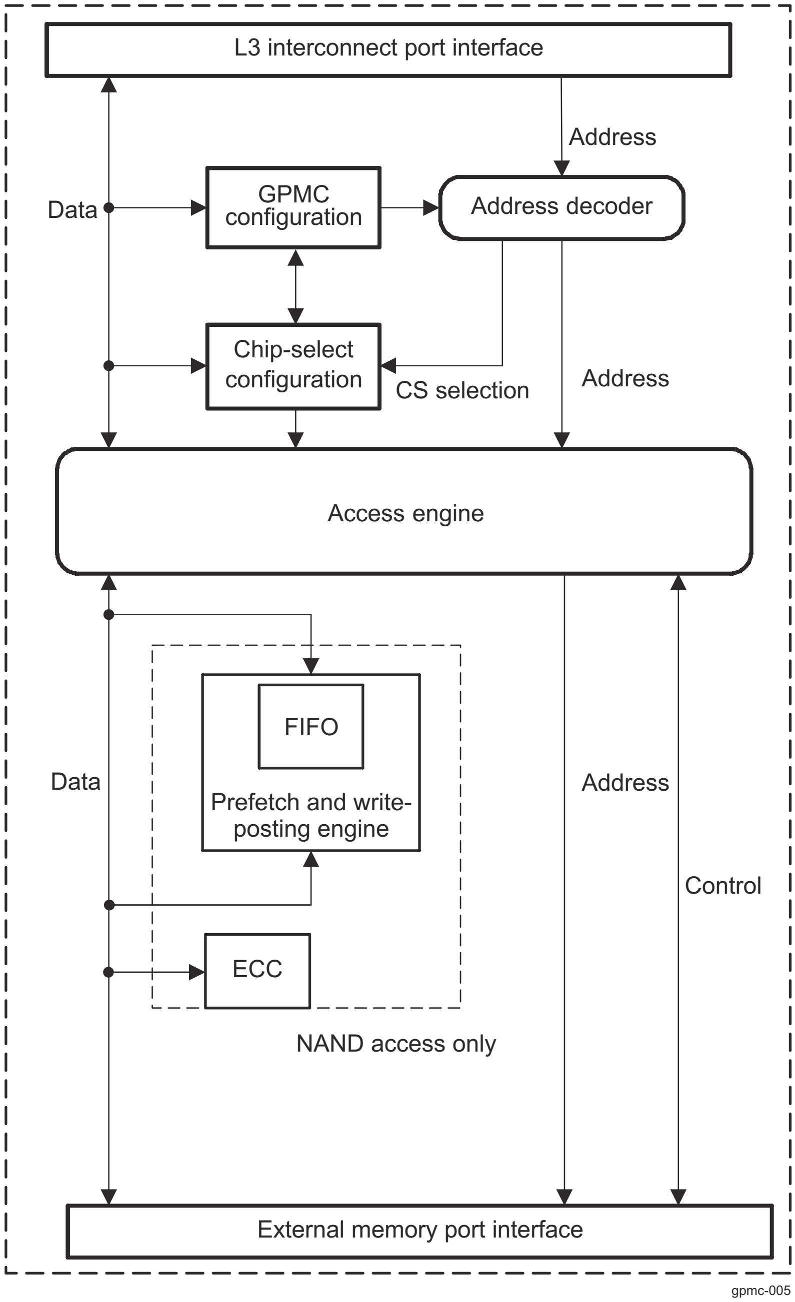

Figure 15-58. GPMC Block Diagram

The GPMC can access various external devices. The flexible programming model allows a wide range of attached device types and access schemes.

Based on the programmed configuration bit fields stored in the GPMC registers, the GPMC can generate the timing of all control signals depending on the attached device and access type.

Given the chip-select decoding and its associated configuration registers, the GPMC selects the appropriate control signal timing for the device type.

15.4.4.2 GPMC Clock Configuration

Table 15-419 describes the GPMC clocks.

Table 15-419. GPMC Clocks

Signal	I/O[1]	Description
GPMC_FCLK	I	Functional and interface clock
gpmc_clk	O	External clock provided to synchronous external memory devices

(1) I = Input; O = Output

The gpmc_clk is generated by the GPMC from the internal GPMC_FCLK clock. The source of the GPMC_FCLK is described in Table 15-417. The gpmc_clk is configured using the GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER bit field (where i = 0 to 7), as shown in Table 15-420.

Table 15-420. gpmc_clk Configuration

Source Clock	GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER	gpmc_clk Generated Clock Provided to External Memory Device
GPMC_FCLK	00	GPMC_FCLK
	01	GPMC_FCLK/2
	10	GPMC_FCLK/3
	11	GPMC_FCLK/4

15.4.4.3 GPMC Software Reset

The GPMC can be reset by software through the GPMC_SYSCONFIG[1] SOFTRESET bit. Setting the bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. Hardware and software resets initialize all GPMC registers and the finite state-machine (FSM) immediately and unconditionally. The GPMC_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. Software must ensure that the software reset completes before performing GPMC operations.

15.4.4.4 GPMC Power Management

GPMC power is supplied by the CORE power domain, and GPMC power management complies with system power-management guidelines.

Table 15-421 describes the power-management features available for the GPMC module.

Note

- For information about source clock gating and sleep/wake-up transitions, see *Clock Management*, in *Power, Reset, and Clock Management*.
- For descriptions of the EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see *Clock Management Functional Description*, in *Power, Reset, and Clock Management*.

Table 15-421. GPMC Local Power-Management Features

Feature	Registers	Description
Clock autogating	GPMC_SYSCONFIG[0] AUTOIDLE	This bit allows a local power optimization inside the module, by gating the GPMC_FCLK clock upon the internal activity.
Slave idle modes	GPMC_SYSCONFIG[4:3] SIDLEMODE	Force-idle, no-idle and smart-idle wake-up modes are available.
Clock activity	N/A	Feature not available
Master standby modes	N/A	Feature not available
Global wake-up enable	N/A	Feature not available
Wake-up sources enable	N/A	Feature not available

15.4.4.5 GPMC Interrupt Requests

The GPMC generates one interrupt request (see Figure 15-57).

Table 15-422 lists the event flags, and their mask, that can cause module interrupts.

Table 15-422. GPMC Interrupt Events

Event Flag	Event Mask	Sensitivity	Description
GPMC_IRQSTATUS[9] WAIT1EDGE DETECTIONSTATUS	GPMC_IRQENABLE[9] WAIT1EDGE DETECTIONENABLE	Edge	Wait1 edge detection interrupt: Triggered if a rising or falling edge is detected on the gpmc_wait1 signal. The rising or falling edge detection of Wait1 is selected through the GPMC_CONFIG[9] WAIT1PINPOLARITY bit.
GPMC_IRQSTATUS[8] WAIT0EDGE DETECTIONSTATUS	GPMC_IRQENABLE[8] WAIT0EDGE DETECTIONENABLE	Edge	Wait0 edge detection interrupt: Triggered if a rising or falling edge is detected on the gpmc_wait0 signal. The rising or falling edge detection of Wait0 is selected through the GPMC_CONFIG[8] WAIT0PINPOLARITY bit.
GPMC_IRQSTATUS[1] TERMINAL COUNTSTATUS	GPMC_IRQENABLE[1] TERMINAL COUNTENABLE	Level	Terminal count event: Triggered on prefetch process completion; that is, when the number of currently remaining data to be requested reaches 0
GPMC_IRQSTATUS[0] FIFOEVENTSTATUS	GPMC_IRQENABLE[0] FIFOEVENTENABLE	Level	FIFO event interrupt: Indicates available FIFO levels for write-posting mode and prefetch mode. GPMC_PREFETCH_CONFIG1[2] DMAMODE must be set to 0.

15.4.4.6 L3 Interconnect Interface

The GPMC L3 interconnect interface is a pipelined interface including a 16 × 32-bit word write buffer.

Any system host can issue external access requests through the GPMC.

The device system can issue the following requests through this interface:

- One 8-, 16-, or 32-bit interconnect access (read/write)
- Two incrementing 32-bit interconnect accesses (read/write)
- Two wrapped 32-bit interconnect accesses (read/write)
- Four incrementing 32-bit interconnect accesses (read/write)
- Four wrapped 32-bit interconnect accesses (read/write)
- Eight incrementing 32-bit interconnect accesses (read/write)
- Eight wrapped 32-bit interconnect accesses (read/write)

Only linear burst transactions are supported; interleaved burst transactions are not supported. Only power-of-two-length precise bursts 2 × 32, 4 × 32, 8 × 32, and 16 × 32, with the burst base address aligned on the total burst size, are supported (this limitation applies to incrementing bursts only).

This interface also provides one interrupt and one DMA request line for specific event control.

It is recommended to program the GPMC_CONFIG1_i[24:23] ATTACHEDDEVICEPAGELENGTH bit field according to the page length of the effective attached device and to enable the GPMC_CONFIG1_i[31] WRAPBURST bit if the attached device supports wrapping burst.

It is possible, however, to emulate wrapping burst on a nonwrapping memory by providing relevant addresses within the page or by splitting transactions. Bursts larger than the memory page length are chopped into multiple burst transactions. Because of the alignment requirements, a page boundary is never crossed.

15.4.4.7 GPMC Address and Data Bus

The current application supports GPMC connection to NAND devices and to address/data-multiplexed memories or devices. Connection to address/data-nonmultiplexed memories or devices is supported with an address range up to 256 MB (that is, 28 address bits in 8-bit mode or 27 address bits in 16-bit mode).

Depending on the GPMC configuration of each chip-select, address and data bus lines that are not required for a particular access protocol are not updated (changed from current value) and are not sampled when input (input data bus).

- For address/data-multiplexed and AAD-multiplexed NOR devices, the address is multiplexed on the data bus.
- 8-bit-wide NOR devices do not use GPMC I/O: gpmc_ad[15:8] for data (they are used for address if needed).

- 16-bit-wide NAND devices do not use GPMC I/O: gpmc_a[27:0].
- 8-bit-wide NAND devices do not use GPMC I/O: gpmc_a[27:0] and GPMC I/O: gpmc_ad[15:8].

15.4.4.7.1 GPMC I/O Configuration Setting

Note

In this section and the following sections, the i in GPMC_CONFIGx_i stands for the GPMC chip-select i, where i = 0 to 7.

To select a NAND device, program the following register fields:

- GPMC_CONFIG1_i[11:10] DEVICETYPE = 0b10
- GPMC_CONFIG1_i[9:8] MUXADDDATA = 0b00

To select an address/data-multiplexed device, program the following register fields:

- GPMC_CONFIG1_i[11:10] DEVICETYPE = 0b00
- GPMC_CONFIG1_i[9:8] MUXADDDATA = 0b10

To select an address/address/data-multiplexed device, program the following register fields:

- GPMC_CONFIG1_i[11:10] DEVICETYPE = 0b00
- GPMC_CONFIG1_i[9:8] MUXADDDATA = 0b01

To select an address/data-nonmultiplexed device, program the following register fields:

- GPMC_CONFIG1_i[11:10] DEVICETYPE = 0b00
- GPMC_CONFIG1_i[9:8] MUXADDDATA = 0b00

15.4.4.7.2 GPMC CS0 Default Configuration at Device Reset

To ensure a correct, fast external boot (see *Fast External Booting*, in *Initialization*) with a GPMC access on device reset, several pins are sampled:

- The "sysboot0" through "sysboot5" pins (device boundary) define the sequence of interfaces and devices to use for booting (i.e. SYSBOOT[5:0] vector). They are sampled by the control module at reset and used later by the device ROM code. For more information, see *Sysboot Configuration*, in *Initialization*.
- Additional pins are used to configure reset values in the GPMC_CONFIG1_i register (where i = 0) as explained in the following and in Table 15-423:
  - The *bootdevicesize* input pin (at the GPMC boundary) defines the size of the attached device on chip-select 0 (CS0) and is used to configure the GPMC_CONFIG1_i[13:12] DEVICESIZE bit field (where i = 0). The BOOT_DEVICE_SIZE signal is propagated from the device Control Module. Its value 0b0 (8-bit memories) or 0b1 (16-bit memories) can be externally determined upon booting by **user hardware** via the device external input signal - "sysboot13".
  - The *cs0muxdevice* input pin (at the GPMC boundary) selects whether or not the device attached to CS0 is an address/data-multiplexed device. The input pin is used to configure the GPMC_CONFIG1_i[9:8] MUXADDDATA bit field (where i = 0). The CS0_MUX_DEVICE[1:0] signal is propagated from the Control Module. Its value 0x0 **(non-muxed memory attached)** or 0x2 **(Addr-Data Mux memory attached)** can be externally determined upon booting by **user hardware** via combining the device external input signals - "sysboot12" and "sysboot11", i.e. SYSBOOT[12:11].
  - The *bootwaiten* input pin (at the GPMC boundary) enables the monitoring on CS0 of the wait pin at device reset release time for read accesses. The input pin is used to configure the GPMC_CONFIG1_i[22] WAITREADMONITORING bit (where i = 0). The BOOT_WAIT_EN signal is propagated from the Control Module. Its value 0x0 **(wait pin is not monitored for read accesses)** or 0x1 **(wait pin is monitored for read accesses)** can be externally determined upon booting by **user hardware** via the device external input signal - "sysboot10".

Note

If WAIT pin monitoring function is enabled upon booting (i.e. BOOT_WAIT_EN="1"), the default (power-on-reset) monitored input for CS0 is always the device gpmc_wait0 input.

Table 15-423. Boot Control Interface Input Signals Description

Signal Name	Width	Description
BOOT_DEVICE_SIZE	1	Size of the device attached on CS0 0b00: 8-bit 0b01: 16-bit 0b10: Reserved (not used) 0b11: Reserved (not used)
CS0_MUX_DEVICE	2	Multiplexing mode of the device on CS0 0b00: Nonmultiplexed device on CS0 0b01: AAD-multiplexed device on CS0 (address-address-data) 0b10: Address/data-multiplexed device on CS0 0b11: Reserved
BOOT_WAIT_EN	1	Wait monitoring on CS0 at device reset release time for read accesses 0: Wait pin is not monitored 1: Wait pin is monitored

CAUTION

Using the internal boot code, the entire CS0 configuration can be modified before the first CS0 access. For more information, see *Memory Booting*, and *Image Format*, in *Initialization*. This modification of internal boot code is necessary for two external devices:

- NAND device attached to CS0
- Nonmultiplexed memory device attached to CS0

At reset time, the device can boot from the internal ROM.

The reset values of the timing control parameters are defined to cope with direct boot on address and data-multiplexed NOR flash devices, nonmultiplexed NOR flash devices, or any asynchronous device with large timing margins, assuming a low GPMC_FCLK frequency (for example, 19.2 MHz) at boot time.

For a multiplexed access, the address 16 low-order bits are presented onto gpmc_ad[15:0], while the high-order bits are presented onto gpmc_a[26:16]. If the external chip interface to the memories uses a 16-bit data bus, the high-order address bits are sampled on the address bus.

The reset values of timing parameters used at boot time are:

- CSONTIME = 1
- CSRDOFFTIME = 16
- ADVONTIME = 4
- ADVRDOFFTIME = 5
- OEONTIME = 6
- OEOFFTIME = 16
- RDACCESSTIME = 15
- RDCYCLETIME = 17

For an AAD-multiplexed access, all address bits are passed onto the data bus using two nADV rising edges. The first rising edge latches the address most-significant bit (MSB) down to bit 17, while the second rising edge latches address bits 16 down to 1. This configuration is only used for 16-bit memories.

The reset values of these timing parameters used at boot time are:

- ADVAADMUXONTIME = 1
- ADVAADMUXRDOFFTIME = 2

- OEAADMUXONTIME = 1
- OEAADMUXOFFTIME = 3

15.4.4.8 Address Decoder and Chip-Select Configuration

Addresses are decoded accordingly with the address request of the chip-select and the content of the chip-select base address register file, which includes a set of global GPMC configuration registers and eight sets of chip-select configuration registers.

The GPMC configuration register file is memory-mapped and can be read or written with byte, 16-bit word, or 32-bit word accesses. The register file must be configured as a noncacheable, nonbufferable region to prevent any desynchronization between host execution (write request) and the completion of register configuration (write completed with register updated). Section 15.4.7, *GPMC Register Manual*, provides the GPMC register locations. For the map of GPMC memory locations, see *Memory Mapping*.

After the chip-select is configured, the access engine accesses the external device, drives the external interface control signals, and applies the interface protocol based on user-defined timing parameters and settings.

15.4.4.8.1 Chip-Select Base Address and Region Size

Any external memory or ASIC device attached to the GPMC external interface can be accessed by any device system host within the GPMC 512-MiB address space. For more information, see *Memory Mapping*.

Note

Even though GPMC supports total address space of 1GB, only 512MB are physically available in this device.

The GPMC 512-MiB address space can be divided into a maximum of eight chip-select regions with programmable base address and programmable chip-select size. The chip-select size is programmable from 16 MiB to 256 MiB (must be a power-of-two) and is defined by the mask field. Attached memory smaller than the programmed chip-select region size is accessed through the entire chip-select region (aliasing).

Each chip-select has a 6-bit base address encoding and 4-bit decoding mask, which must be programmed according to the following rules:

- The programmed chip-select region base address must be aligned on the chip-select region size address boundary and is limited to a power-of-two address value. During access decoding, the value of the register base address is used to compare the address with the address bit line mapping, as shown in Figure 15-59 (with A0 as the device system byte-address line). The base address is programmed through the GPMC_CONFIG7_i[5:0] BASEADDRESS bit field.
- The register mask is used to exclude some address lines from the decoding. A register mask bit field set to 0 suppresses the associated address line from the address comparison (incoming address bit line is don't care). The value of the register mask must be limited to the subsequent value, based on the desired chip-select region size. Any other value has an undefined result. When multiple chip-select regions with overlapping addresses are enabled concurrently, access to these chip-select regions is cancelled and a GPMC access error is posted. The mask field is programmed through the GPMC_CONFIG7_i[11:8] MASKADDRESS bit field.

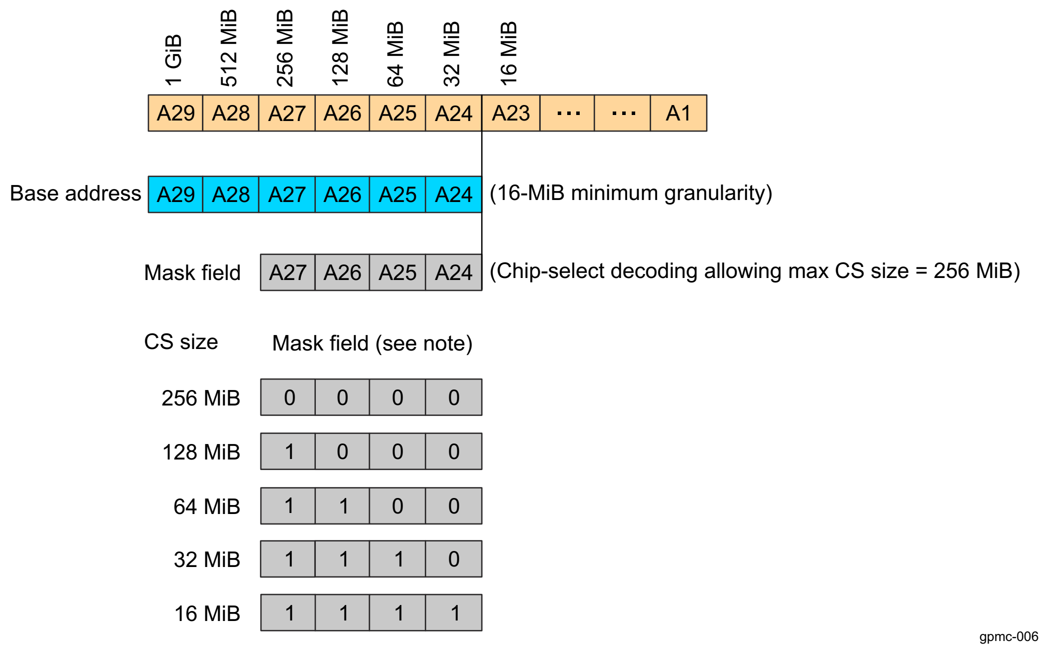

Figure 15-59. Chip-Select Address Mapping and Decoding Mask

Following is an example mapping that divides the 512MB memory reach into two 256MB regions:

- 1st 256MB region – 0x0000 0000 to 0x0FFF FFFF – program base address for that chip select equal to 0x0
- 2nd 256MB region – 0x1000 0000 to 0x1FFF FFFF – program base address for that chip select equal to 0x10

Chip-select configuration (base and mask address or any protocol and timing settings) must be performed while the associated chip-select is disabled through the GPMC_CONFIG7_i[6] CSVALID bit (where i stands for the GPMC chip-select value, 0 to 7). In addition, a chip-select configuration can be disabled only if there is no ongoing access to that chip-select. This requires monitoring the activity of the prefetch or write-posting engine if the engine is active on the chip-select. Also, the write buffer state must be monitored to wait for any posted write completion to the chip-select.

Any access attempted to a nonvalid GPMC address region (CSVALID disabled or address decoding outside a valid chip-select region) is not propagated to the external interface and a GPMC access error is posted. In case of overlapping chip-selects, an error is generated and no access occurs on either chip-select.

CS0 is the only chip-select region enabled after a power up or GPMC reset.

CAUTION

Although the GPMC interface can drive up to eight chip-selects, the frequency specified for this interface is for a specific load. If this load is exceeded, the maximum frequency cannot be reached. One solution is to implement a board with buffers to allow the slowest device to maintain the total load on the lines .

15.4.4.8.2 Access Protocol

15.4.4.8.2.1 Supported Devices

The access protocol of each chip-select can be independently specified through the GPMC_CONFIG1_i[11:10] DEVICETYPE parameter (where i = 0 to 7) for:

- Random-access synchronous or asynchronous memory, such as NOR flash and SRAM
- NAND flash asynchronous devices

Note

For more information about the NAND flash GPMC basic programming model and NAND support, see Section 15.4.4.12, *NAND Device Basic Programming Model*, and Section 15.4.4.12.1, *NAND Memory Device in Byte or Word16 Stream Mode*.

15.4.4.8.2.2 Access Size Adaptation and Device Width

Each chip-select can be independently configured through the GPMC_CONFIG1_i[13:12] DEVICESIZE bit field (where i = 0 to 7) to interface with a 16- or 8-bit-wide device. System requests with data width greater than the external device data bus width are split into successive accesses according to the external device data-bus width and little-endian data organization.

15.4.4.8.2.3 Address/Data-Multiplexing Interface

For random synchronous or asynchronous memory interfacing (DEVICETYPE = 0b00), an address- and data-multiplexing protocol can be selected through the GPMC_CONFIG1_i[9:8] MUXADDDATA bit field (where i = 0 to 7). The nADV signal must be used as the external device address latch control signal. For the associated chip-select configuration, nADV assertion and deassertion time and nOE assertion time must be set to the appropriate value to meet the address latch setup/hold time requirements of the external device. See Section 15.4.3, *GPMC Integration*.

Note

This address/data-multiplexing interface is not applicable to NAND device interfacing. NAND devices require a specific address, command, and data-multiplexing protocol. See Section 15.4.4.12, *NAND Device Basic Programming Model*.

15.4.4.8.3 External Signals

Note

The "DIR" (direction control) output signal is NOT pinned out on any of the device pads. It is an internal signal only representing a signal direction on the GPMC data bus.

15.4.4.8.3.1 Wait Pin Monitoring Control

GPMC access time can be dynamically controlled using an external gpmc_wait pin when the external device access time is not deterministic and cannot be defined and controlled using only the GPMC internal RDACCESSTIME, WRACCESSTIME, and PAGEBURSTACCESSTIME wait-state generator.

The GPMC features two input wait pins: gpmc_wait1, and gpmc_wait0. These pins allow control of external devices with different wait pin polarity. They also allow the overlap of wait pin assertion from different devices without affecting access to devices for which the wait pin is not asserted.

- The GPMC_CONFIG1_i[17:16] WAITPINSELECT bit field (where i = 0 to 7) selects which input gpmc_wait pin is used for the device attached to the corresponding chip-select.
- The polarity of the wait pin is defined through the WAITxPINPOLARITY bit of the GPMC_CONFIG register. A wait pin configured to be active low means that low level on the WAIT signal indicates that the data is not ready and that the data bus is invalid. When a wait pin is inactive, data is valid.

The GPMC access engine can be configured per chip-select to monitor or not the wait pin of the external memory device, based on the access type: read or write.

- The GPMC_CONFIG1_i[22] WAITREADMONITORING bit defines whether or not the wait pin must be monitored during read accesses.
- The GPMC_CONFIG1_i[21] WAITWRITEMONITORING bit defines whether or not the wait pin must be monitored during write accesses.

The GPMC access engine can be configured to monitor the wait pin of the external memory device asynchronously or synchronously with the GPMC_CLK clock, depending on the access type: synchronous or asynchronous (the GPMC_CONFIG1_i[29] READTYPE and GPMC_CONFIG1_i[27] WRITETYPE bits).

15.4.4.8.3.1.1 Wait Monitoring During Asynchronous Read Access

When wait pin monitoring is enabled for read accesses (WAITREADMONITORING), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the wait-deasserted state.

During asynchronous read accesses with wait pin monitoring enabled, the wait pin must be at a valid level (asserted or deasserted) for at least two GPMC clock cycles before RDACCESSTIME completes, to ensure correct dynamic access-time control through wait pin monitoring. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

In this context, RDACCESSTIME is used as a wait invalid timing window and is set to such a value that the wait pin is at a valid state two GPMC clock cycles before RDACCESSTIME completes.

Similarly, during a multiple-access cycle (for example, asynchronous read page mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-deasserted state. Wait monitoring pipelining is also applicable to multiple accesses (access within a page).

- Wait monitored as active freezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, wait monitored as asserted extends the current access time in the page. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- Wait monitored as inactive unfreezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, wait monitored as inactive completes the current access time and starts the next access phase in the page. The data bus is considered valid, and data are captured during this clock cycle. In case of a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their related control timing value and according to the CYCLETIME counter status.

When a delay larger than two GPMC clocks must be observed between wait-pin deactivation time and data valid time (including the required GPMC and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data-capture time and the effective unlock of the CYCLETIME counter. This extra delay can be programmed in the GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME bit field (where i = 0 to 7).

Note

- The WAITMONITORINGTIME parameter does not delay the wait pin active or inactive detection, nor does it modify the two GPMC clocks pipelined detection delay.
- This extra delay is expressed as a number of GPMC_CLK clock cycles, even though the access is defined as asynchronous, and no GPMC_CLK clock is provided to the external device. Still, because GPMCFCLKDIVIDER is used as a divider for the GPMC clock, it must be programmed to define the correct WAITMONITORINGTIME delay.

Figure 15-60 shows wait behavior during an asynchronous single read access.

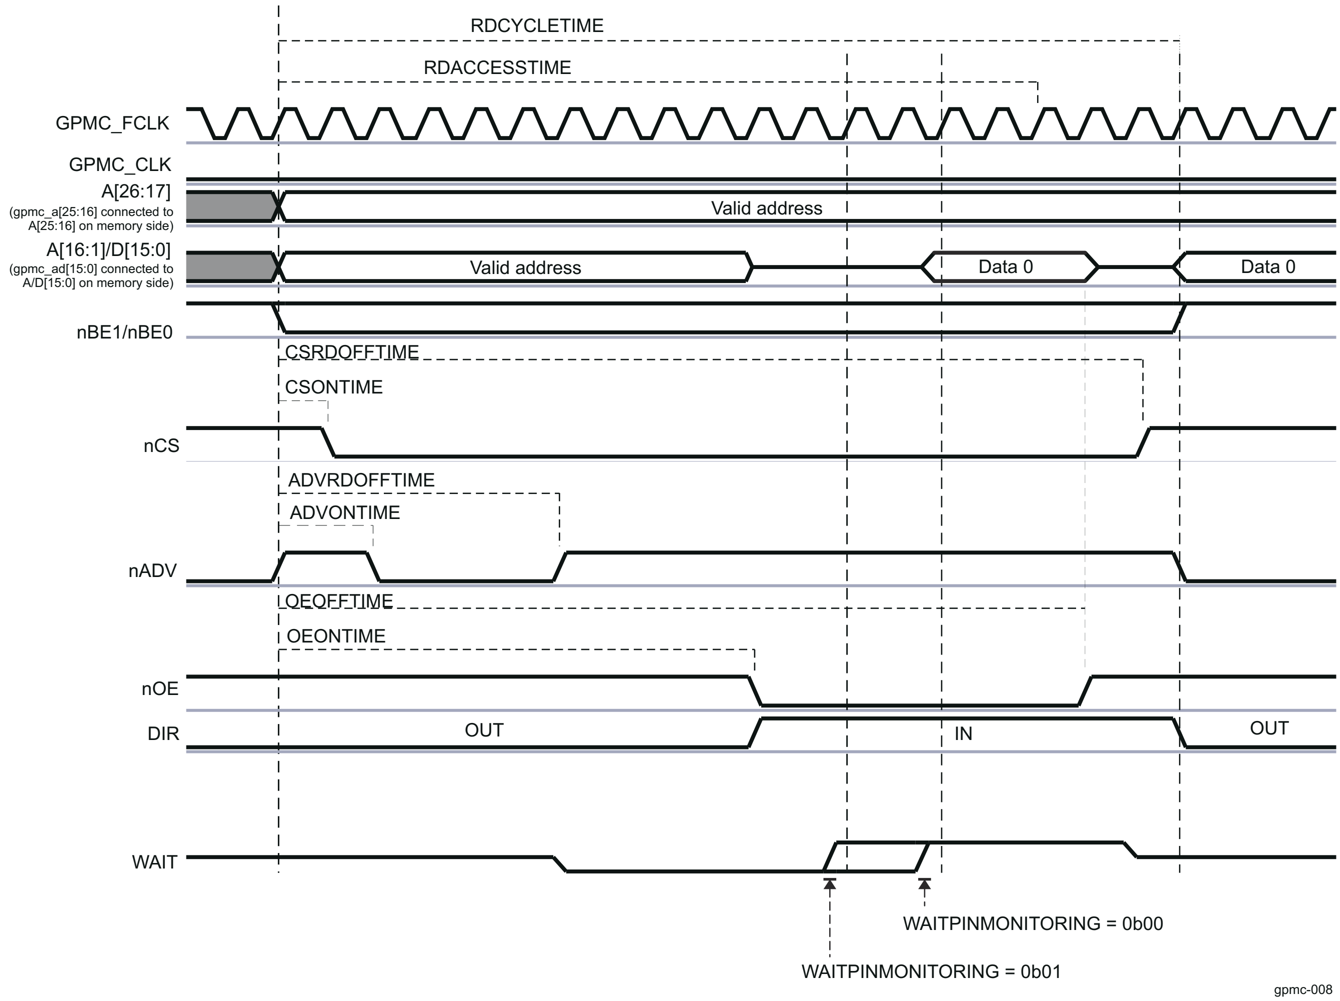

Figure 15-60. Wait Behavior During an Asynchronous Single Read Access (GPMCFCLKDivider = 1)

Note

The WAIT signal is active low. GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME = 0b00, or 0b01.

15.4.4.8.3.1.2 Wait Monitoring During Asynchronous Write Access

When wait pin monitoring is enabled for write accesses (GPMC_CONFIG1_i[21] WAITWRITEMONITORING bit = 0x1), the wait invalid timing window is defined by the WRACCESSTIME field. WRACCESSTIME must be set so that the wait pin is at a valid state two GPMC clock cycles before WRACCESSTIME completes. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

- Wait monitored as active freezes the CYCLETIME counter. This informs the GPMC that the data bus is not captured by the external device. The control signals are kept in their current state. The data bus still drives the data.
- Wait monitored as inactive unfreezes the CYCLETIME counter. This informs that the data bus is correctly captured by the external device. All signals, including the data bus, are controlled according to their related control timing value and to the CYCLETIME counter status.

When a delay larger than two GPMC clock cycles must be observed between wait-pin deassertion time and the effective data write into the external device (including the required GPMC data setup time and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data write time into the external device and the effective unfreezing of the CYCLETIME counter. This extra delay can be programmed in the GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME bit field (where i = 0 to 7).

Note

- The WAITMONITORINGTIME parameter does not delay the wait pin assertion or deassertion detection, nor does it modify the two GPMC clock cycles pipelined detection delay.
- This extra delay is expressed as a number of GPMC_CLK clock cycles, even though the access is defined as asynchronous, and even though no clock is provided to the external device. Still, because the GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER bit field is used as a divider for the GPMC clock, it must be programmed to define the correct WAITMONITORINGTIME delay.

15.4.4.8.3.1.3 Wait Monitoring During Synchronous Read Access

During synchronous accesses with wait pin monitoring enabled, the wait pin is captured synchronously with GPMC_CLK, using the rising edge of this clock.

The WAIT signal can be programmed to apply to the same clock cycle in which it is captured. Alternatively, it can be sampled one or two GPMC_CLK cycles ahead of the clock cycle to which it applies. This pipelining is applicable to the entire burst access and to all data phases in the burst access. This wait pipelining depth is programmed in the GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME bit field (where i = 0 to 7), and is expressed as a number of GPMC_CLK clock cycles.

In synchronous mode, when wait pin monitoring is enabled (the GPMC_CONFIG1_i[22] WAITREADMONITORING bit), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the wait-deasserted state detection.

Depending on the programmed value of WAITMONITORINGTIME, the wait pin must be at a valid level, either asserted or deasserted:

- In the same clock cycle the data is valid if WAITMONITORINGTIME = 0 (at RDACCESSTIME completion)
- In the WAITMONITORINGTIME x (GPMCFCLKDIVIDER + 1) GPMC_FCLK clock cycles before RDACCESSTIME completion if WAITMONITORINGTIME is not equal to 0

Similarly, during a multiple-access cycle (burst mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the WAIT-INACTIVE state. The wait pipelining-depth programming applies to the whole burst access.

- Wait monitored as active freezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in a lock state), wait monitored as active extends the current access time in the burst. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- Wait monitored as inactive unfreezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in lock state), wait monitored as inactive completes the current access time and starts the next access phase in the burst. The data bus is considered valid, and data are captured during this clock cycle. In a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their relative control timing value and the CYCLETIME counter status.

Figure 15-61 shows wait behavior during a synchronous read burst access.

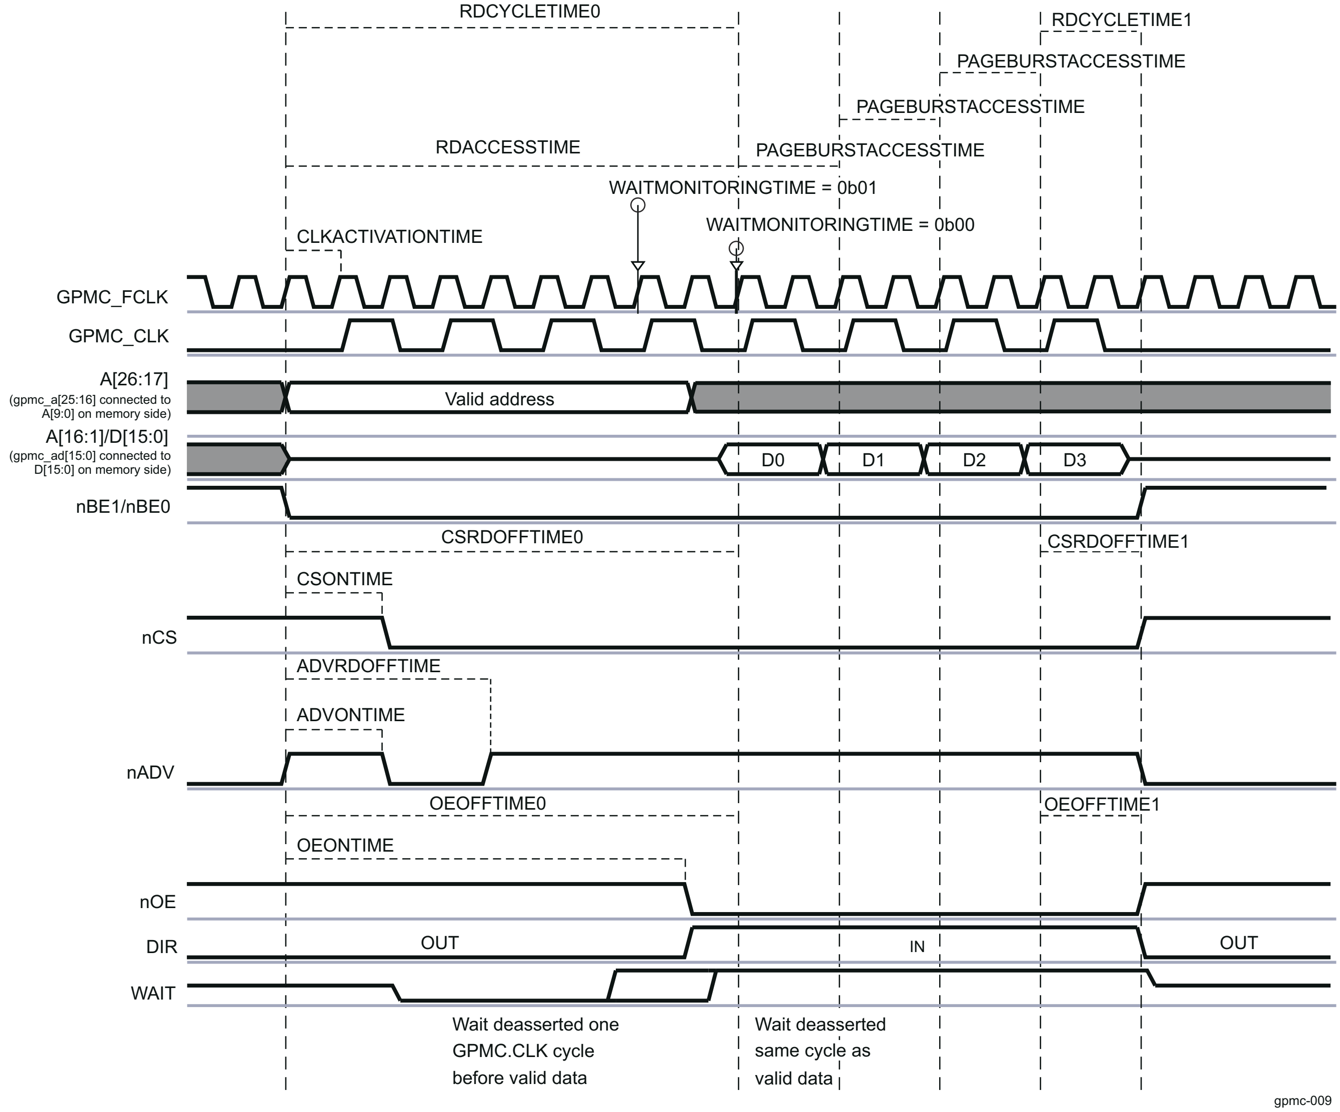

Figure 15-61. Wait Behavior During a Synchronous Read Burst Access

---

Note

The WAIT signal is active low. WAITMONITORINGTIME = 00, 01.

15.4.4.8.3.1.4 Wait Monitoring During Synchronous Write Access

During synchronous accesses with wait pin monitoring enabled (the WAITWRITEMONITORING bit), the wait pin is captured synchronously with GPMC_CLK, using the rising edge of this clock.

If enabled, external wait pin monitoring can be used in combination with WRACCESSTIME to delay the GPMC_CLK capture edge of the effective memory device.

Wait-monitoring pipelining depth is similar to synchronous read access:

- At WRACCESSTIME completion if WAITMONITORINGTIME = 0
- In the WAITMONITORINGTIME x (GPMCFCLKDIVIDER + 1) GPMC_FCLK cycles before WRACCESSTIME completion if WAITMONITORINGTIME is not equal to 0

Wait-monitoring pipelining definition applies to whole burst accesses:

- Wait monitored as active freezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, wait monitored as active indicates that the data bus is not being captured by the external device. Control signals are kept in their current state. The data bus is kept in its current state.
- Wait monitored as inactive unfreezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, wait monitored as inactive indicates the effective data capture of the bus by the external device and starts the next access of the burst. In case of a single access or if this was the last access in a multiple access cycle, all signals, including the data bus, are controlled according to their related control timing value and the CYCLETIME counter status.

Note

Wait monitoring is supported for all configurations except GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME = 0x0 (where i = 0 to 7) for write bursts with a clock divider of 1 or 2 (the GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER bit field is equal to 0x0 or 0x1, respectively).

15.4.4.8.3.1.5 Wait With NAND Device

For information about the use of the wait pin for communication with a NAND flash external device, see Section 15.4.4.12.2, *NAND Device-Ready Pin*.

15.4.4.8.3.1.6 Idle Cycle Control Between Successive Accesses

15.4.4.8.3.1.6.1 Bus Turnaround (BUSTURNAROUND)

To prevent data-bus contention, an access that follows a read access to a slow memory/device must be delayed (in other words, control the nCS/nOE deassertion to data bus in high-impedance delay).

The bus turnaround is a time-out counter starting after nCS or nOE deassertion time, whichever occurs first, and delays the next access start-cycle time. The counter is programmed through the GPMC_CONFIG6_i[3:0] BUSTURNAROUND bit field (where i = 0 to 7).

After a read access to a chip-select with a nonzero BUSTURNAROUND, the next access is delayed until the BUSTURNAROUND delay completes, if the next access is one of the following:

- A write access to any chip-select (the same or different chip-select from which the data was read)
- A read access to a different chip-select than the chip-select from which the data was read access
- A read or write access to a chip-select associated with an address/data-multiplexed device

Note

Bus keeping starts after bus turnaround completion so that DIR changes from IN to OUT after bus turnaround. The bus does not have enough time to go into high-impedance even though it can be driven with the same value before bus turnaround timing.

BUSTURNAROUND delay runs in parallel with GPMC_CONFIG6_i[3:0] CYCLE2CYCLEDELAY bi field delays. BUSTURNAROUND is a timing parameter for the ending chip-select access, while CYCLE2CYCLEDELAY is a timing parameter for the following chip-select access. The effective minimum delay between successive accesses is driven by these delay timing parameters and by the access type of the following access (see Figure 15-62 through Figure 15-64).

Another way to prevent bus contention is to define an earlier nCS or nOE deassertion time for slow devices or to extend the value of RDCYCLETIME. Doing this prevents bus contention, but it also affects all accesses of this specific chip-select.

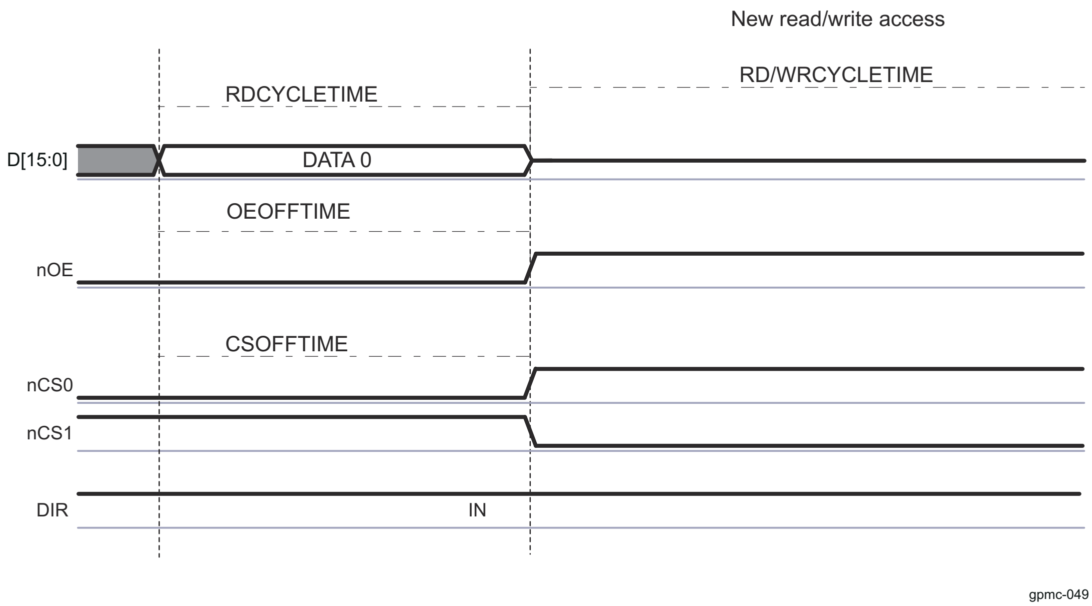

Figure 15-62. Read-to-Read for an Address-Data Multiplexed Device, on Different Chip-Select, Without Bus Turnaround (nCS Attached to a Fast Device)

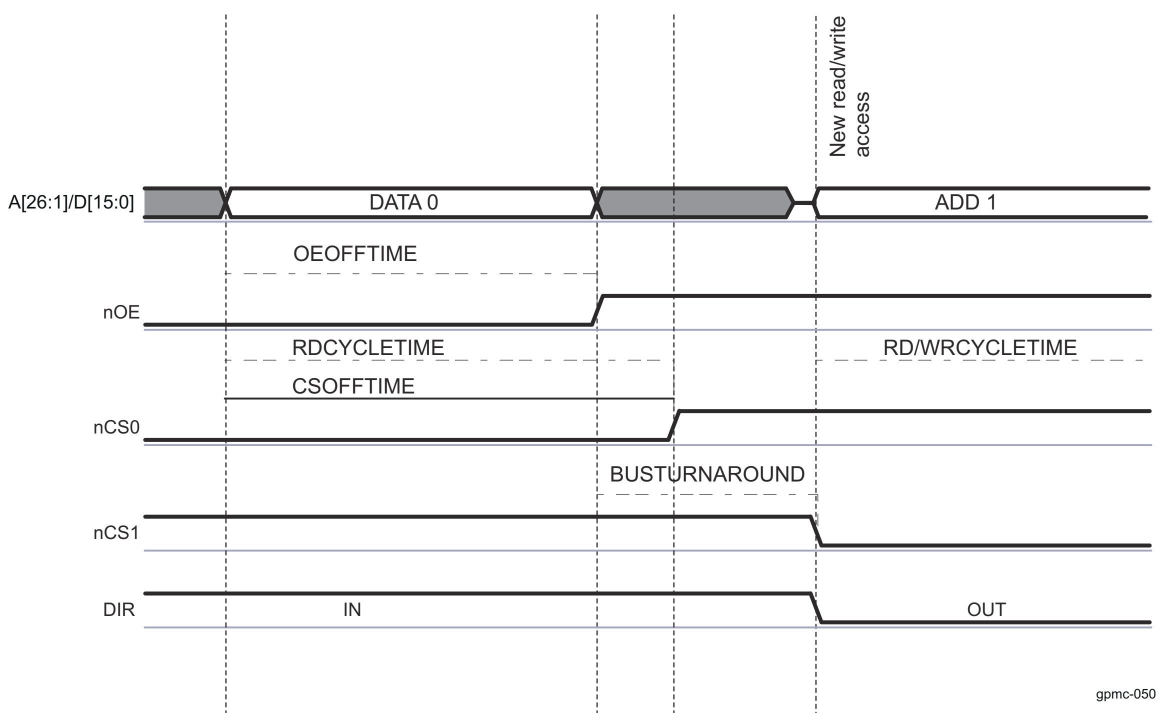

Figure 15-63. Read- to-Read/Write for an Address-Data Multiplexed Device, on Different Chip-Select, With Bus Turnaround

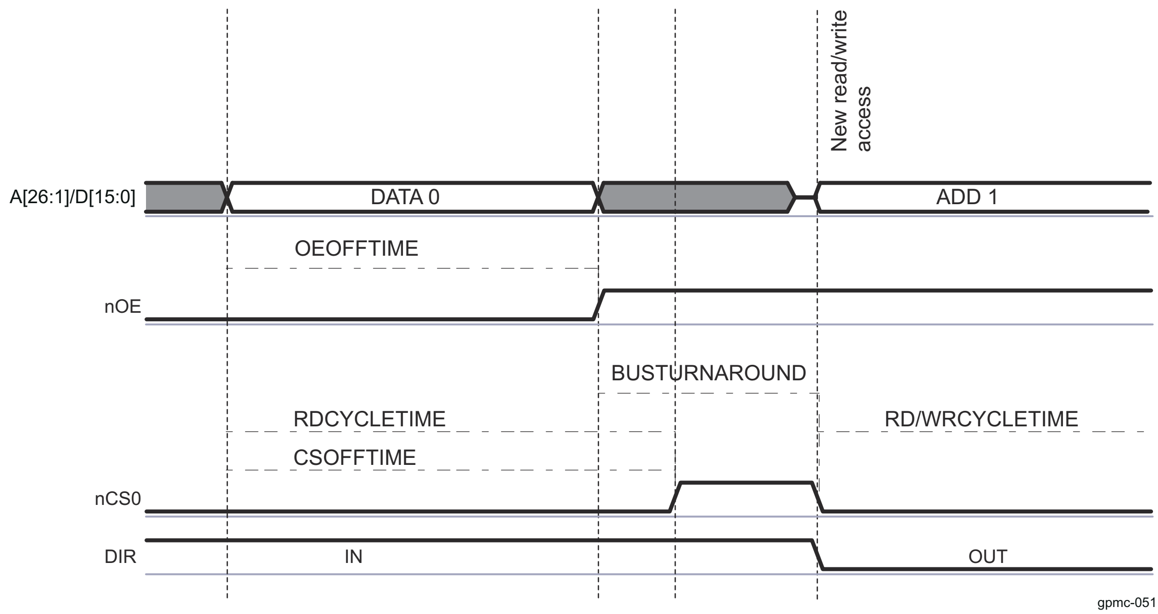

Figure 15-64. Read-to-Read/Write for a Address-Data or AAD-Multiplexed Device, on Same Chip-Select, With Bus Turnaround

15.4.4.8.3.1.6.2 Idle Cycles Between Accesses to Same Chip-Select (CYCLE2CYCLESAMECSEN, CYCLE2CYCLEDELAY)

Some devices require a minimum chip-select signal inactive time between accesses. The GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSEN bit (where i = 0 to 7) enables insertion of a minimum number of GPMC_FCLK cycles, defined by the GPMC_CONFIG6_i[11:8] CYCLE2CYCLEDELAY bit field, between successive accesses of any type (read or write) to the same chip-select.

If CYCLE2CYCLESAMECSEN is enabled, any subsequent access to the same chip-select is delayed until its CYCLE2CYCLEDELAY completes. The CYCLE2CYCLEDELAY counter starts when CSRDOFFTIME/ CSWROFFTIME completes.

The same applies to successive accesses occurring during 32-bit word or burst accesses split into successive single accesses when the single-access mode is used (GPMC_CONFIG1_i[30] READMULTIPLE = 0 or GPMC_CONFIG1_i[28] WRITEMULTIPLE = 0).

All control signals (CS, ADV#/ALE, BE0#/CLE, WE#, and GPMC.CLK) are kept inactive (ADV#/ALE, BE0#/CLE, and GPMC.CLK at low level; and CS, OE#/RE, and WE at high level) during the idle GPMC.FCLK cycles. This prevents back-to-back accesses to the same chip-select without idle cycles between accesses.

15.4.4.8.3.1.6.3 Idle Cycles Between Accesses to Different Chip-Select (CYCLE2CYCLEDIFFCSEN, CYCLE2CYCLEDELAY)

Because of the pipelined behavior of the system, successive accesses to different chip-selects can occur back-to-back with no idle cycles between accesses. Depending on the control signals (nCS, nADV/ALE, nBE0/ CLE, nOE/RE, nWE) assertion and deassertion timing parameters and on the device timing parameters, the assertion times of some control signals may overlap between the successive accesses to a different chip-select. Similarly, some control signals (WE, OE/RE) may not respect required transition times.

To work around overlapping and to observe the required control-signal transitions, a minimum of CYCLE2CYCLEDELAY inactive cycles is inserted between the access being initiated to this chip-select and the previous access ending for a different chip-select. This applies to any type of access (read or write).

If the GPMC_CONFIG6_i[6] CYCLE2CYCLEDIFFCSEN bit is enabled, the chip-select access is delayed until CYCLE2CYCLEDELAY cycles have expired since the end of a previous access to a different chip-select.

CYCLE2CYCLEDELAY count starts at CSRDOFFTIME/CSWROFFTIME completion. All control signals are kept inactive during the idle GPMC_FCLK cycles.

Note

CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDIFFCSEN must be set in the GPMC_CONFIG6_i registers to get idle cycles inserted between accesses on this chip-select and after accesses to a different chip-select, respectively.

The CYCLE2CYCLEDELAY delay runs in parallel with the BUSTURNAROUND delay. The BUSTURNAROUND is a timing parameter defined for the ending chip-select access, whereas CYCLE2CYCLEDELAY is a timing parameter defined for the starting chip-select access. The effective minimum delay between successive accesses is based on the larger delay timing parameter and on access type combination, because bus turnaround does not apply to all access types. For more information about bus turnaround, see Section 15.4.4.8.3.1.6.1, *Bus Turnaround (BUSTURNAROUND)*.

Table 15-424 describes the configuration required for idle cycle insertion.

Table 15-424. Idle Cycle Insertion Configuration

1st Access Type	BUSTURNAROUND Timing Parameter	Second Access Type	Chip-Select	Add/Data Multiplexed	CYCLE2CYCLE SAMECSEN Parameter	CYCLE2CYCLE DIFFCSEN Parameter	Idle Cycle Insertion Between the Two Accesses
R/W	= 0	R/W	Any	Any	0	x	No idle cycles are inserted if the two accesses are well pipelined.
R	> 0	R	Same	Nonmuxed	x	0	No idle cycles are inserted if the two accesses are well pipelined.
R	> 0	R	Different	Nonmuxed	0	0	BUSTURNAROUND cycles are inserted.
R	> 0	R/W	Any	Muxed	0	0	BUSTURNAROUND cycles are inserted.
R	> 0	W	Any	Any	0	0	BUSTURNAROUND cycles are inserted.
W	> 0	R/W	Any	Any	0	0	No idle cycles are inserted if the two accesses are well pipelined.
R/W	= 0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted.
R/W	= 0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted.
R/W	> 0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is max (BUSTURNAROUND, CYCLE2CYCLEDELAY).
R/W	> 0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is maximum (BUSTURNAROUND, CYCLE2CYCLEDELAY).

15.4.4.8.3.1.7 Slow Device Support (TIMEPARAGRANULARITY Parameter)

All access-timing parameters can be multiplied by 2 by setting the GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY bit (where i stands for the GPMC chip-select value, 0 to 7). Increasing all access timing parameters allows support of slow devices.

15.4.4.8.3.2 Reset

No reset signal is sent to the external memory device by the GPMC. For more information about external-device reset, see *Power, Reset, and Clock Management*.

The PRCM module provides an input pin, global_rst_n, to the GPMC:

- The global_rst_n pin is activated during device warm reset and cold reset.
- The global_rst_n pin initializes the internal state-machine and the internal configuration registers.

15.4.4.8.3.3 Byte Enable (nBE1/nBE0)

Byte enable signals (nBE1/nBE0) are:

- Valid (asserted or nonasserted according to the incoming system request) from access start to access completion for asynchronous and synchronous single accesses
- Asserted low from access start to access completion for asynchronous and synchronous multiple read accesses
- Valid (asserted or nonasserted, according to the incoming system request) synchronously to each written data for synchronous multiple write accesses

15.4.4.8.4 Error Handling

When an error occurs in the GPMC, the error information is stored in the GPMC_ERR_TYPE register and the address of the illegal access is stored in the GPMC_ERR_ADDRESS register. The GPMC keeps only the first error abort information until the GPMC_ERR_TYPE register is reset. Subsequent accesses that cause errors are not logged until the error is cleared by hardware with the GPMC_ERR_TYPE[0] ERRORVALID bit.

- ERRORNOTSUPPADD occurs when an incoming system request address decoding does not match any valid chip-select region, or if two chip-select regions are defined as overlapped, or if a register file access is tried outside the valid address range of 1KiB.
- ERRORNOTSUPPMCMD occurs when an unsupported command request is decoded at the L3 interconnect interface.
- ERRORTIMEOUT: A time-out mechanism prevents the system from hanging. The start value of the 9-bit time-out counter is defined in the GPMC_TIMEOUT_CONTROL register and enabled with the GPMC_TIMEOUT_CONTROL[0] TIMEOUTENABLE bit. When enabled, the counter starts at start-cycle time until it reaches 0 and data is not responded to from memory, and then a time-out error occurs. When data are sent from memory, this counter is reset to its start value. With multiple accesses (asynchronous page mode or synchronous burst mode), the counter is reset to its start value for each data access within the burst.

The GPMC does not generate interrupts on these errors. True abort to the MPU or interrupt generation is handled at interconnect level.

15.4.4.9 Timing Setting

The GPMC offers maximum flexibility to support various access protocols. Most of the timing parameters of the protocol access used by the GPMC to communicate with attached memories or devices are programmable on a chip-select basis. Assertion and deassertion times of control signals are defined to match the attached memory or device timing specifications and to get maximum performance during accesses. For more information about GPMC_CLK and GPMC_FCLK see Section 15.4.4.9.6, *GPMC_CLK*.

Note

In the following sections, the start access time refers to the time at which the access begins.

15.4.4.9.1 Read Cycle Time and Write Cycle Time (RDCYCLETIME / WRCYCLETIME)

The GPMC_CONFIG5_i[4:0] RDCYCLETIME and GPMC_CONFIG5_i[12:8] WRCYCLETIME bit fields (where i = 0 to 7) define the address bus and byte-enable valid times for read and write accesses. To ensure a correct duty cycle of GPMC_CLK between accesses, RDCYCLETIME and WRCYCLETIME are expressed in GPMC_FCLK cycles and must be multiples of the GPMC_CLK cycle. The RDCYCLETIME and WRCYCLETIME bit fields can be set with a granularity of 1 or 2 through the GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY bit.

When RDCYCLETIME or WRCYCLETIME completes, if they are not already deasserted, all control signals (nCS, nADV/ALE, nOE/RE, nWE, and BE0/CLE) are deasserted to their reset values, regardless of their deassertion time parameters.

An exception to this forced deassertion occurs when a pipelined request to the same chip-select or to a different chip-select is pending. In such a case, it is not necessary to deassert a control signal with deassertion time parameters equal to the cycle-time parameter. This exception to forced deassertion prevents any unnecessary glitches. This requirement also applies to BE signals, thus avoiding an unnecessary BE glitch transition when pipelining requests.

Note

All control signals (CS, ADV#/ALE, BE0#/CLE, WE#, and GPMC.CLK) are kept inactive (ADV#/ALE, BE0#/CLE, and GPMC.CLK at low level; and CS, OE#/RE, and WE at high level) during the idle GPMC.FCLK cycles.

If no inactive cycles are required between successive accesses to the same chip-select or a different chip-select (GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSEN = 0 or GPMC_CONFIG6_i[6] CYCLE2CYCLEDIFFCSEN = 0, where i = 0 to 7), and if assertion-time parameters associated with the pipelined access are equal to 0, asserted control signals (nCS, nADV/ALE, nBE0/CLE, nWE, and nOE/RE) are kept asserted. This applies to any read/write to read/write access combination.

If inactive cycles are inserted between successive accesses (that is, CYCLE2CYCLESAMECSEN = 1 or CYCLE2CYCLEDIFFCSEN = 1), the control signals are forced to their respective default reset values for the number of GPMC_FCLK cycles defined in CYCLE2CYCLEDELAY.

15.4.4.9.2 nCS: Chip-Select Signal Control Assertion/Deassertion Time (CSONTIME / CSRDOFFTIME / CSWROFFTIME / CSEXTRADELAY)

The GPMC_CONFIG2_i[3:0] CSONTIME bit field (where i = 0 to 7) defines the nCS signal-assertion time relative to the start access time. It is common for read and write accesses.

The GPMC_CONFIG2_i[12:8] CSRDOFFTIME (read access) and GPMC_CONFIG2_i[20:16] CSWROFFTIME (write access) bit fields define the nCS signal deassertion time relative to start access time.

The CSONTIME, CSRDOFFTIME, and CSWROFFTIME parameters apply to synchronous and asynchronous modes. CSONTIME can be used to control an address and byte-enable setup time before chip-select assertion. CSRDOFFTIME and CSWROFFTIME can be used to control an address and byte-enable hold time after chip-select deassertion.

nCS signal transitions, as controlled through CSONTIME, CSRDOFFTIME, and CSWROFFTIME, can be delayed by a half-GPMC_FCLK period by enabling the GPMC_CONFIG2_i[7] CSEXTRADELAY bit. This half-GPMC_FCLK period provides more granularity on the nCS assertion and deassertion time to ensure proper setup and hold time relative to GPMC_CLK. CSEXTRADELAY is especially useful in configurations where GPMC_CLK and GPMC_FCLK have the same frequency, but it can also be used for all GPMC configurations. If enabled, CSEXTRADELAY applies to all parameters that control nCS transitions.

The CSEXTRADELAY bit must be used carefully to avoid control signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than the nCS signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

15.4.4.9.3 nADV/ALE: Address Valid/Address Latch Enable Signal Control Assertion/ Deassertion Time (ADVONTIME / ADVRDOFFTIME / ADVWROFFTIME / ADVEXTRADELAY/ADVAADMUXONTIME/ ADVAADMUXRDOFFTIME/ADVAADMUXWROFFTIME)

The GPMC_CONFIG3_i[3:0] ADVONTIME field (where i = 0 to 7) defines the nADV/ALE signal-assertion time relative to start access time. It is common to read and write accesses.

The GPMC_CONFIG3_i[12:8] ADVRDOFFTIME (read access) and GPMC_CONFIG3_i[20:16] ADVWROFFTIME (write access) bit fields define the nADV/ALE signal-deassertion time relative to start access time.

ADVONTIME can be used to control an address and byte-enable valid setup time control before nADV/ALE assertion. ADVRDOFFTIME and ADVWROFFTIME can be used to control an address and byte-enable valid hold time control after nADV/ALE deassertion. ADVRDOFFTIME and ADVWROFFTIME apply to synchronous and asynchronous modes.

The nADV/ALE signal transitions as controlled through ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME can be delayed by a half-GPMC_FCLK period by enabling the GPMC_CONFIG3_i[7] ADVEXTRADELAY bit. This half-GPMC_FCLK period provides more granularity on nADV/ALE assertion and deassertion time to ensure proper setup and hold time relative to GPMC_CLK. The ADVEXTRADELAY configuration parameter is especially useful in configurations where GPMC_CLK and GPMC_FCLK have the same frequency, but can be used for all GPMC configurations. If enabled, ADVEXTRADELAY applies to all parameters controlling nADV/ALE transitions.

ADVEXTRADELAY must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than nADV/ALE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

GPMC_CONFIG3_i[6:4] ADVAADMUXONTIME, GPMC_CONFIG3_i[26:24] ADVAADMUXRDOFFTIME, and GPMC_CONFIG3_i[30:28] ADVAADMUXWROFFTIME parameters have the same functions as ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME, but apply to the first address phase in the AAD-multiplexed protocol. The user must ensure that ADVAADMUXxxOFFTIME is programmed to a value less than or equal to ADVxxOFFTIME. Functionality in AAD-multiplexed mode is undefined if the settings do not comply with this requirement. ADVAADMUXxxOFFTIME can be programmed to the same value as ADVONTIME if no high nADV pulse is needed between the two AAD-multiplexed address phases, which is the typical case in synchronous mode. In this configuration, nADV is kept low until it reaches the correct ADVxxOFFTIME.

For more information about the use of ADVONTIME, ADVRDOFFTIME, ADVWROFFTIME, and ADVAADMUXRDOFFTIME and ADVAADMUXWROFFTIME for command latch enable (CLE) and address latch enable (ALE) use for a NAND flash interface, see Section 15.4.4.12, *NAND Access Description*.

15.4.4.9.4 nOE/nRE: Output Enable/Read Enable Signal Control Assertion/Deassertion Time (OEONTIME / OEOFFTIME / OEEXTRADELAY / OEAADMUXONTIME / OEAADMUXOFFTIME)

The GPMC_CONFIG4_i[3:0] OEONTIME bit field (where i = 0 to 7) defines the nOE/nRE signal assertion time relative to start access time. It applies only to read accesses.

The GPMC_CONFIG4_i[12:8] OEOFFTIME bit field defines the nOE/nRE signal deassertion time relative to start access time. It applies only to read accesses. nOE/nRE is not asserted during a write cycle.

The OEONTIME, OEOFFTIME, OEAADMUXONTIME, and OEAADMUXOFFTIME parameters apply to synchronous and asynchronous modes. OEONTIME can be used to control an address and byte enable valid setup time control before nOE/nRE assertion. OEOFFTIME can be used to control an address and byte-enable valid hold time control after nOE/nRE assertion.

The OEAADMUXONTIME and OEAADMUXOFFTIME parameters have the same functions as OEONTIME and OEOFFTIME, but apply to the first OE assertion in the AAD-multiplexed protocol for a read phase, or to the only OE assertion for a write phase. The user mut ensure that OEAADMUXOFFTIME is programmed to a value less than OEONTIME. Functionality in AAD-multiplexed mode is undefined if the settings do not comply with this requirement. OEAADMUXOFFTIME must never be equal to OEONTIME because the AAD-multiplexed protocol requires a second address phase with the nOE signal deasserted before nOE can be asserted again to define a read command.

The nOE/RE signal transitions as controlled through OEONTIME, OEOFFTIME, OEAADMUXONTIME, and OEAADMUXOFFTIME can be delayed by a half-GPMC_FCLK period by enabling the GPMC_CONFIG4_i[7] OEEXTRADELAY bit. This half-GPMC_FCLK period provides more granularity on the nOE/RE assertion and deassertion time to ensure proper setup and hold time relative to GPMC_CLK. If enabled, OEEXTRADELAY applies to all parameters controlling nOE/nRE transitions.

OEEXTRADELAY must be used carefully, to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program RDCYCLETIME and WRCYCLETIME to be greater than the nOE/RE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

Note

When the GPMC generates a read access to an address-/data-multiplexed device, it drives the address bus until nOE assertion time.

15.4.4.9.5 nWE: Write Enable Signal Control Assertion/Deassertion Time (WEONTIME / WEOFFTIME / WEEXTRADELAY)

The GPMC_CONFIG4_i[19:16] WEONTIME bit field (where i = 0 to 7) defines the nWE signal-assertion time relative to start access time. The GPMC_CONFIG4_i[28:24] WEOFFTIME bit field defines the nWE signal-deassertion time relative to start access time. These bit fields apply only to write accesses. nWE is not asserted during a read cycle.

WEONTIME can be used to control an address and byte-enable valid setup time control before nWE assertion. WEOFFTIME can be used to control an address and byte-enable valid hold time control after nWE assertion.

nWE signal transitions as controlled through WEONTIME, and WEOFFTIME can be delayed by a half-GPMC_FCLK period by enabling the GPMC_CONFIG4_i[23] WEEXTRADELAY bit. This half-GPMC_FCLK period provides more granularity on nWE assertion and deassertion time to ensure proper setup and hold time relative to GPMC_CLK. If enabled, WEEXTRADELAY applies to all parameters controlling nWE transitions.

The WEEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the WRCYCLETIME bit field to be greater than the nWE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

15.4.4.9.6 GPMC_CLK

GPMC_CLK is the external clock provided to the attached synchronous memory or device.

- The GPMC_CLK clock frequency is the GPMC_FCLK functional clock frequency divided by 1, 2, 3, or 4, depending on the GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER bit field (where i = 0 to 7), with a guaranteed 50-percent duty cycle. For information about the duty cycle error, see the device data manual.
- The GPMC_CLK clock is activated only when the access in progress is defined as synchronous (read or write access).
- The GPMC_CONFIG1_i[26:25] CLKACTIVATIONTIME bit field (where i = 0 to 7) defines the number of GPMC_FCLK cycles from start access time to GPMC_CLK activation.
- The GPMC_CLK clock is stopped when cycle time completes and is asserted low between accesses.
- The GPMC_CLK clock is kept low when access is defined as asynchronous.

CAUTION

When the cycle time completes, the GPMC_CLK may be high because of the GPMCFCLKDIVIDER bit field. To ensure correct stoppage of the GPMC_CLK clock within the required 50-percent duty cycle, the user must extend the RDCYCLETIME or WRCYCLETIME value.

Note

To ensure a correct external clock cycle, the following rules must be applied:

- (RDCYCLETIME CLKACTIVATIONTIME) must be a multiple of (GPMCFCLKDIVIDER + 1).
- The PAGEBURSTACCESSTIME value must be a multiple of (GPMCFCLKDIVIDER + 1).

15.4.4.9.7 GPMC_CLK and Control Signals Setup and Hold

Control-signal transition (assertion and deassertion) setup and hold values with respect to the GPMC_CLK edge can be controlled in the following ways:

- For the GPMC_CLK signal, the GPMC_CONFIG1_i[26:25] CLKACTIVATIONTIME bit field (where i = 0 to 7) allows setup and hold control of control-signal assertion time.
- The use of a divided GPMC_CLK allows setup and hold control of the control-signal assertion and deassertion times.
- When GPMC_CLK runs at the GPMC_FCLK frequency so that GPMC_CLK edge and control-signal transitions refer to the same GPMC_FCLK edge, the control-signal transitions can be delayed by a half-GPMC_FCLK period to provide minimum setup and hold times. This half-GPMC_FCLK delay is enabled with the CSEXTRADELAY, ADVEXTRADELAY, OEEXTRADELAY, or WEEXTRADELAY parameter. This delay must be used carefully to prevent control-signal overlap between successive accesses to different chip-selects. This implies that the RDCYCLETIME and WRCYCLETIME are greater than the last control-signal deassertion time, including the extra half-GPMC_FCLK cycle.

15.4.4.9.8 Access Time (RDACCESSTIME / WRACCESSTIME)

The read/write access time durations can be programmed independently through the GPMC_CONFIG5_i[20:16] RDACCESSTIME and GPMC_CONFIG6_i[28:24] WRACCESSTIME bit fields (where i = 0 to 7). This allows nOE and GPMC data-capture timing parameters to be independent of nWE and memory device data capture timing parameters. The RDACCESSTIME and WRACCESSTIME bit fields can be set with a granularity of 1 or 2 through the GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY bit.

15.4.4.9.8.1 Access Time on Read Access

In asynchronous read mode, for single and paged accesses, the GPMC_CONFIG5_i[20:16] RDACCESSTIME bit field (where i = 0 to 7) defines the number of GPMC_FCLK cycles from start access time to the GPMC_FCLK rising edge used for the first data capture. RDACCESSTIME must be programmed to the rounded greater value (in GPMC_FCLK cycles) of the read access time of the attached memory device.

In synchronous read mode, for single or burst accesses, RDACCESSTIME defines the number of GPMC_FCLK cycles from the start access time to the GPMC_FCLK rising edge corresponding to the GPMC_CLK rising edge used for the first data capture.

GPMC_CLK, which is sent to the memory device for synchronization with the GPMC controller, is internally retimed to correctly latch the returned data. The GPMC_CONFIG5_i[4:0] RDCYCLETIME bit field must be greater than RDACCESSTIME to let the GPMC latch the last return data using the internally retimed GPMC_CLK.

The external WAIT signal can be used in conjunction with RDACCESSTIME to control the effective GPMC data-capture GPMC_FCLK edge on read access in asynchronous and synchronous modes. For more information about wait monitoring, see Section 15.4.4.8.3.1, *Wait Pin Monitoring Control*.

15.4.4.9.8.2 Access Time on Write Access

In asynchronous write mode, the GPMC_CONFIG6_i[28:24] WRACCESSTIME timing parameter is not used to define the effective write access time. Instead, it is used as a wait invalid timing window and must be set to a correct value so that the gpmc_wait pin is at a valid state two GPMC_CLK cycles before WRACCESSTIME completes. For more information about wait monitoring, see Section 15.4.4.8.3.1, *Wait Pin Monitoring Control*.

In synchronous write mode , for single or burst accesses, WRACCESSTIME defines the number of GPMC_FCLK cycles from the start access time to the GPMC_CLK rising edge used by the memory device for the first data capture.

The external WAIT signal can be used in conjunction with WRACCESSTIME to control the effective memory device data-capture GPMC_CLK edge for a synchronous write access. For more information about wait monitoring, see Section 15.4.4.8.3.1, *Wait Pin Monitoring Control*.

15.4.4.9.9 Page Burst Access Time (PAGEBURSTACCESSTIME)

The GPMC_CONFIG5_i[27:24] PAGEBURSTACCESSTIME bit field (where i = 0 to 7) can be set with a granularity of 1 or 2 through theGPMC_CONFIG1_i[4] TIMEPARAGRANULARITY bit.

15.4.4.9.9.1 Page Burst Access Time on Read Access

In asynchronous page read mode, the delay between successive word captures in a page is controlled through the PAGEBURSTACCESSTIME bit field. The PAGEBURSTACCESSTIME parameter must be programmed to the rounded greater value (in GPMC_FCLK cycles) of the read access time of the attached device.

In synchronous burst read mode, the delay between successive word captures in a burst is controlled through the PAGEBURSTACCESSTIME bit field.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective GPMC data-capture GPMC_FCLK edge on read access. For more information about wait monitoring, see Section 15.4.4.8.3.1, *Wait Pin Monitoring Control*.

15.4.4.9.9.2 Page Burst Access Time on Write Access

Asynchronous page write mode is not supported. PAGEBURSTACCESSTIME is irrelevant in this case.

In synchronous burst write mode, PAGEBURSTACCESSTIME controls the delay between successive memory device word captures in a burst.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective memory device data capture GPMC_CLK edge in synchronous write mode. For more information about wait monitoring, see Section 15.4.4.8.3.1, *Wait Pin Monitoring Control*.

15.4.4.9.10 Bus Keeping Support

At the end cycle time of a read access, if no other access is pending, the GPMC drives the bus with the last data read after RDCYCLETIME completes to prevent bus floating and reduce power consumption.

After a write access, if no other access is pending, the GPMC keeps driving the data bus after WRCYCLETIME completes with the same data to prevent bus floating and power consumption.

15.4.4.10 NOR Access Description

For each chip-select configuration, the read access can be specified as asynchronous or synchronous access through the GPMC_CONFIG1_i[29] READTYPE bit (where i = 0 to 7). For each chip-select configuration, the write access can be specified as synchronous or asynchronous access through the GPMC_CONFIG1_i[27] WRITETYPE bit where (i = 0 to 7).

Asynchronous and synchronous read and write access time and related control signals are controlled through timing parameters that refer to GPMC_FCLK. The primary difference of synchronous mode is the availability of a configurable clock interface (GPMC_CLK) to control the external device. Synchronous mode also affects data-capture and wait-pin monitoring schemes in read access.

For more information about asynchronous and synchronous access, see the descriptions of GPMC_CLK, RdAccessTime, WrAccessTime, and wait pin monitoring.

For more information about timing-parameter settings, see the sample timing diagrams in this chapter.

Note

The address bus and nBE[1:0] are fixed for the duration of a synchronous burst read access, but they are updated for each beat of an asynchronous page-read access.

15.4.4.10.1 Asynchronous Access Description

This section describes:

- Asynchronous single-read operation on an address/data multiplexed device
- Asynchronous single write operation on an address/data-multiplexed device
- Asynchronous single read operation on an AAD-multiplexed device
- Asynchronous single write operation on an AAD-multiplexed device
- Asynchronous multiple (page) read operation on a non-multiplexed device

In asynchronous operations GPMC_CLK is not provided outside the GPMC and is kept low.

15.4.4.10.1.1 Access on Address/Data Multiplexed Devices

15.4.4.10.1.1.1 Asynchronous Single-Read Operation on an Address/Data Multiplexed Device

Figure 15-65 shows an asynchronous single read operation on an address/data-multiplexed device.

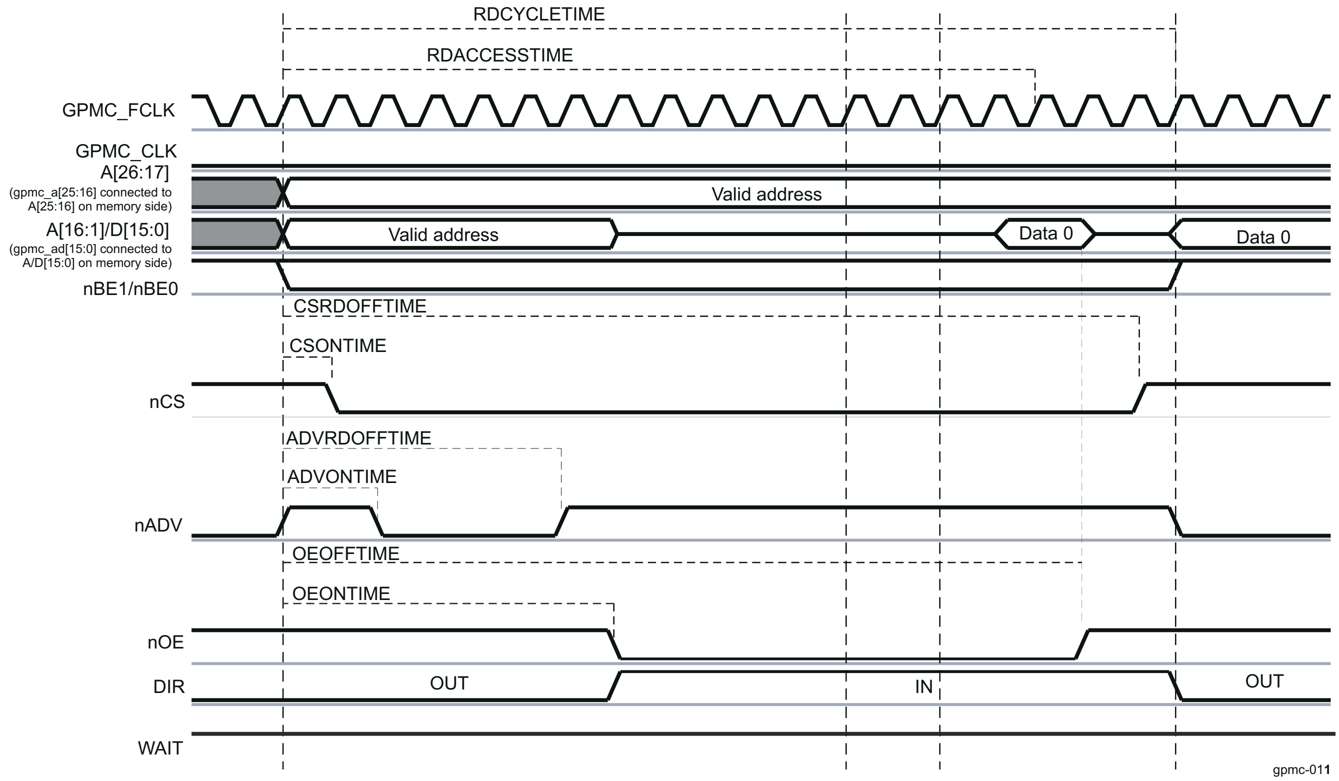

Figure 15-65. Asynchronous Single Read on an Address/Data-Multiplexed Device

For formulas to calculate timing parameters, see Section 15.4.5.6.1, *GPMC Timing Parameters Formulas*.

Table 15-456 lists the timing bit fields to set up to configure the GPMC in asynchronous single-read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For more information, see Section 15.4.4.8.2.3, *Address/Data-Multiplexing Interface*.

Address bits (A[16:1] from a GPMC perspective, A[15:0] from an external device perspective) are placed on the address/data bus, and the remaining address bits gpmc_a[27:16] are placed on the address bus. The address phase ends at nOE assertion, when the DIR signal goes from OUT to IN.

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC_CONFIG2_i[3:0] CSONTIME bit field. It controls the address setup time to nCS assertion.
  - nCS deassertion time is controlled by the GPMC_CONFIG2_i[12:8] CSRDOFFTIME bit field. It controls the address hold time from nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME bit field.
  - nADV deassertion time is controlled by the GPMC_CONFIG3_i[12:8] ADVRDOFFTIME bit field.
- Output enable signal nOE:
  - nOE assertion indicates a read cycle.
  - nOE assertion time is controlled by the GPMC_CONFIG4_i[3:0] OEONTIME bit field.
  - nOE deassertion time is controlled by the GPMC_CONFIG4_i[12:8] OEOFFTIME bit field.
- Read data is latched when RDACCESSTIME completes. Access time is defined in the GPMC_CONFIG5_i[20:16] RDACCESSTIME bit field.

- Direction signal DIR: DIR goes from OUT to IN at the same time that nOE is asserted.
- The end of the access is defined by the GPMC_CONFIG5_i[4:0] RDCYCLETIME parameter.

In the GPMC, when a 16-bit wide device is attached to the controller, a 32-bit word write access is split into two 16-bit word write accesses. For more information about GPMC access size and type adaptation, see Section 15.4.4.10.5, *System Burst Versus External Device Burst Support*.

Between two successive accesses, if an nCS pulse is needed:

- The GPMC_CONFIG6_i[11:8] CYCLE2CYCLEDELAY bit field can be programmed with the GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSEN bit enabled.
- The CSWROFFTIME and CSONTIME parameters also allow a chip-select pulse, but this affects all other types of access.

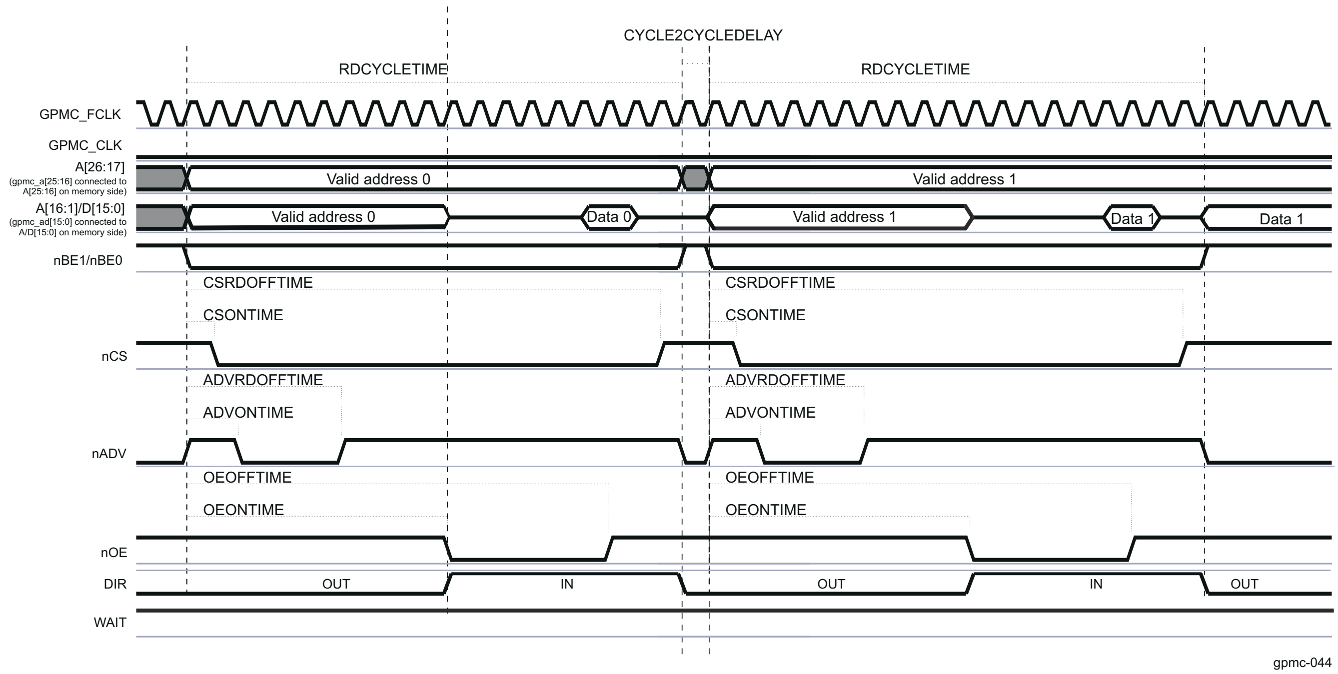

Figure 15-66. Two Asynchronous Single-Read Accesses on an Address/Data-Multiplexed Device (32-Bit Read Split Into 2 x 16-Bit Read)

15.4.4.10.1.1.2 Asynchronous Single-Write Operation on an Address/Data-Multiplexed Device

Figure 15-67 shows an asynchronous single-write operation on an address/data-multiplexed device.

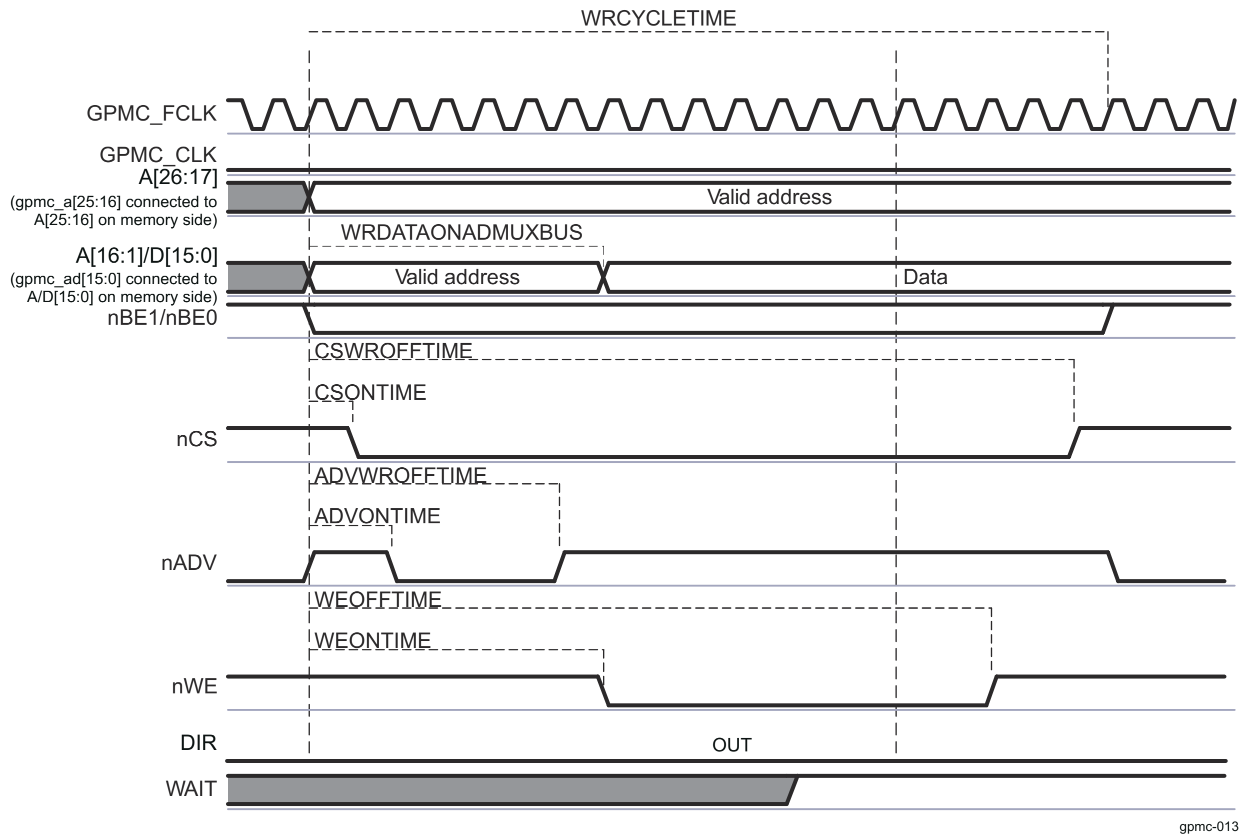

Figure 15-67. Asynchronous Single-Write on an Address/Data-Multiplexed Device

For formulas to calculate timing parameters, see Section 15.4.5.6.1, *GPMC Timing Parameters Formulas*.

Table 15-456 lists the timing bit fields to set up to configure the GPMC in asynchronous single-write mode.

When the GPMC generates a write access to an address/data-multiplexed device, it drives the address bus until nWE assertion time. For more information, see Section 15.4.4.8.2.3, *Address/Data-Multiplexing Interface*.

The nCS and nADV signals are controlled in the same way as for a asynchronous single-read operation on an address/data-multiplexed device.

- Write enable signal nWE:
  - nWE assertion indicates a write cycle.
  - nWE assertion time is controlled by the GPMC_CONFIG4_i[19:16] WEONTIME bit field.
  - nWE deassertion time is controlled by the GPMC_CONFIG4_i[28:24] WEOFFTIME bit field.
- Direction signal DIR: DIR signal is OUT during the entire access.
- The end of the access is defined by the GPMC_CONFIG5_i[12:8] WRCYCLETIME parameter.

Address bits A[16:1] (GPMC point of view) are placed on the address/data bus at the start of cycle time, and the remaining address bits A[26:17] are placed on the address bus.

Data is driven on the address/data bus at a GPMC_CONFIG6_i[19:16] WRDATAONADMUXBUS time.

Note

Write multiple access in asynchronous mode is not supported. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

After a write operation, if no other access (read or write) is pending, the data bus keeps its previous value. See Section 15.4.4.9.10, *Bus Keeping Support*.

15.4.4.10.1.1.3 Asynchronous Multiple (Page) Write Operation on an Address/Data-Multiplexed Device

Write multiple (page) access in asynchronous mode is not supported for address/data-multiplexed devices.

If the GPMC_CONFIG1_i[28] WRITEMULTIPLE bit is enabled (0x1) with the GPMC_CONFIG1_i[27] WRITETYPE bit as asynchronous (0x0), the GPMC processes single asynchronous accesses.

For accesses on nonmultiplexed devices, see Section 15.4.4.10.3, *Asynchronous and Synchronous Accesses in Nonmultiplexed Mode*.

15.4.4.10.1.2 Access on Address/Address/Data-Multiplexed Devices

15.4.4.10.1.2.1 Asynchronous Single Read Operation on an AAD-Multiplexed Device

Figure 15-68 shows an asynchronous single-read operation on an AAD-multiplexed device.

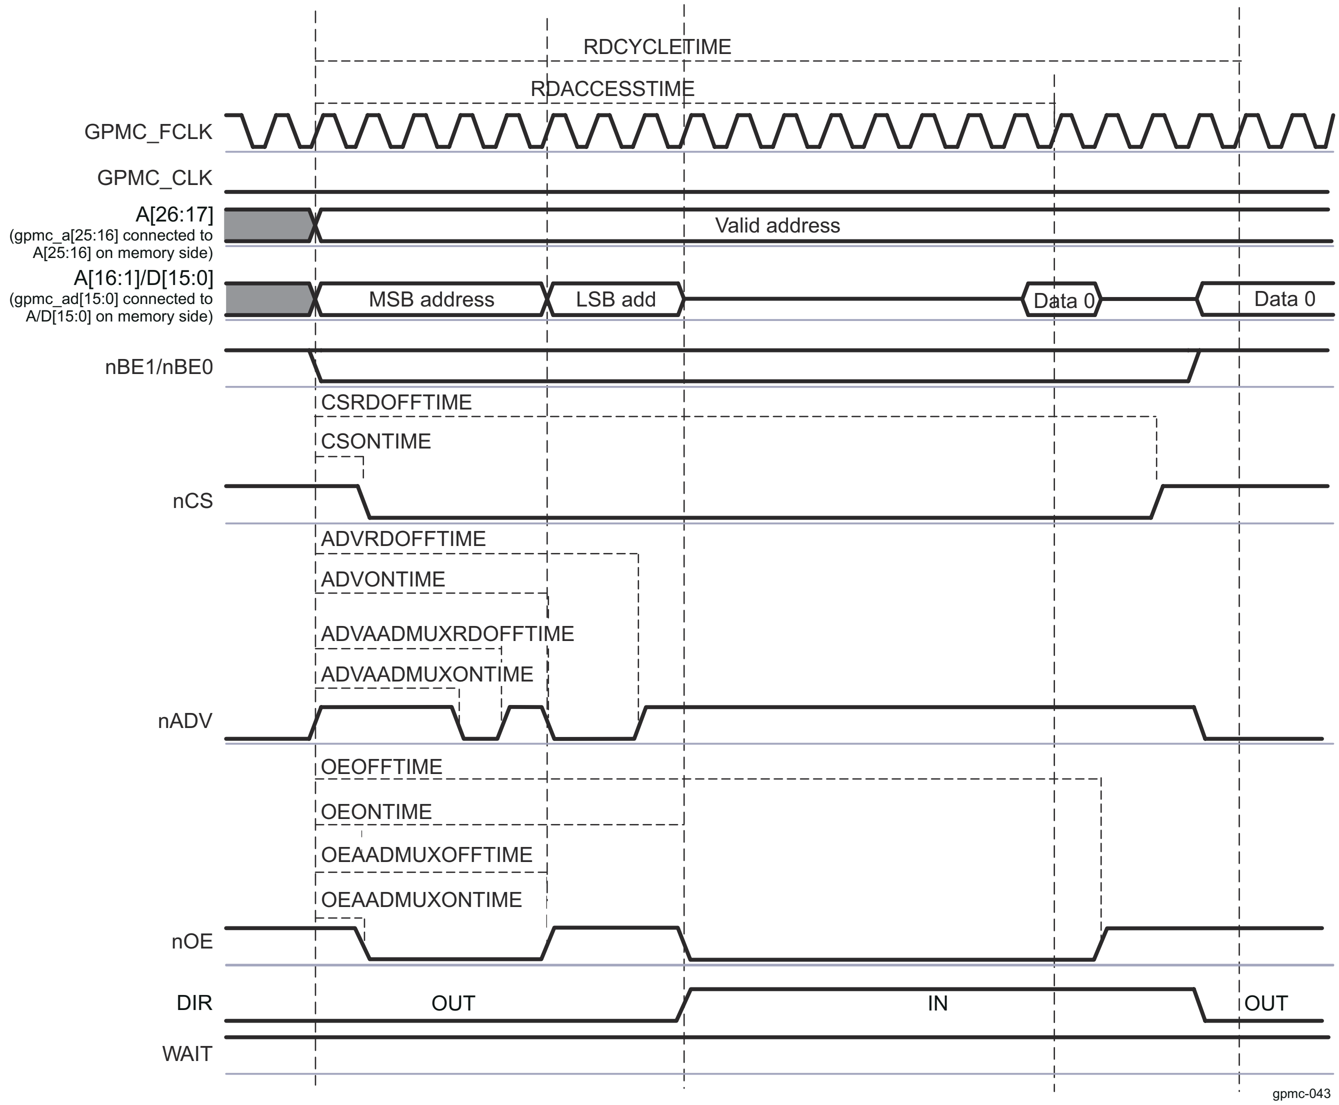

Figure 15-68. Asynchronous Single Read on an AAD-Multiplexed Device

For formulas to calculate timing parameters, see Section 15.4.5.6.1, *GPMC Timing Parameters Formulas*.

Table 15-456 lists the timing bit fields to set up to configure the GPMC in asynchronous single write mode.

When the GPMC generates a read access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The first address phase ends at the first nOE deassertion time. The second phase for LSB address is qualified with nOE driven high. The second address phase ends at the second nOE assertion time, when the DIR signal goes from OUT to IN.

The nCS and DIR signals are controlled in the same way as for an asynchronous single-read operation on an address/data-multiplexed device.

- Address valid signal nADV. nADV is asserted and deasserted twice during a read transaction:
  - nADV first assertion time is controlled by the GPMC_CONFIG3_i[6:4] ADVAADMUXONTIME bit field.

  - nADV first deassertion time is controlled by the GPMC_CONFIG3_i[26:24] ADVAADMUXRDOFFTIME bit field.
  - nADV second assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME bit field.
  - nADV second deassertion time is controlled by the GPMC_CONFIG3_i[12:8] ADVRDOFFTIME bit field.
- Output Enable signal nOE. nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
  - nOE first assertion time is controlled by the GPMC_CONFIG4_i[6:4] OEAADMUXONTIME bit field.
  - nOE first deassertion time is controlled by the GPMC_CONFIG3_i[15:13] OEAADMUXOFFTIME bit field.
  - nOE second assertion time is controlled by the GPMC_CONFIG4_i[3:0] OEONTIME bit field.
  - nOE second deassertion time is controlled by the GPMC_CONFIG4_i[12:8] OEOFFTIME bit field.

15.4.4.10.1.2.2 Asynchronous Single-Write Operation on an AAD-Multiplexed Device

Figure 15-69 shows an asynchronous single-write operation on an AAD-multiplexed device.

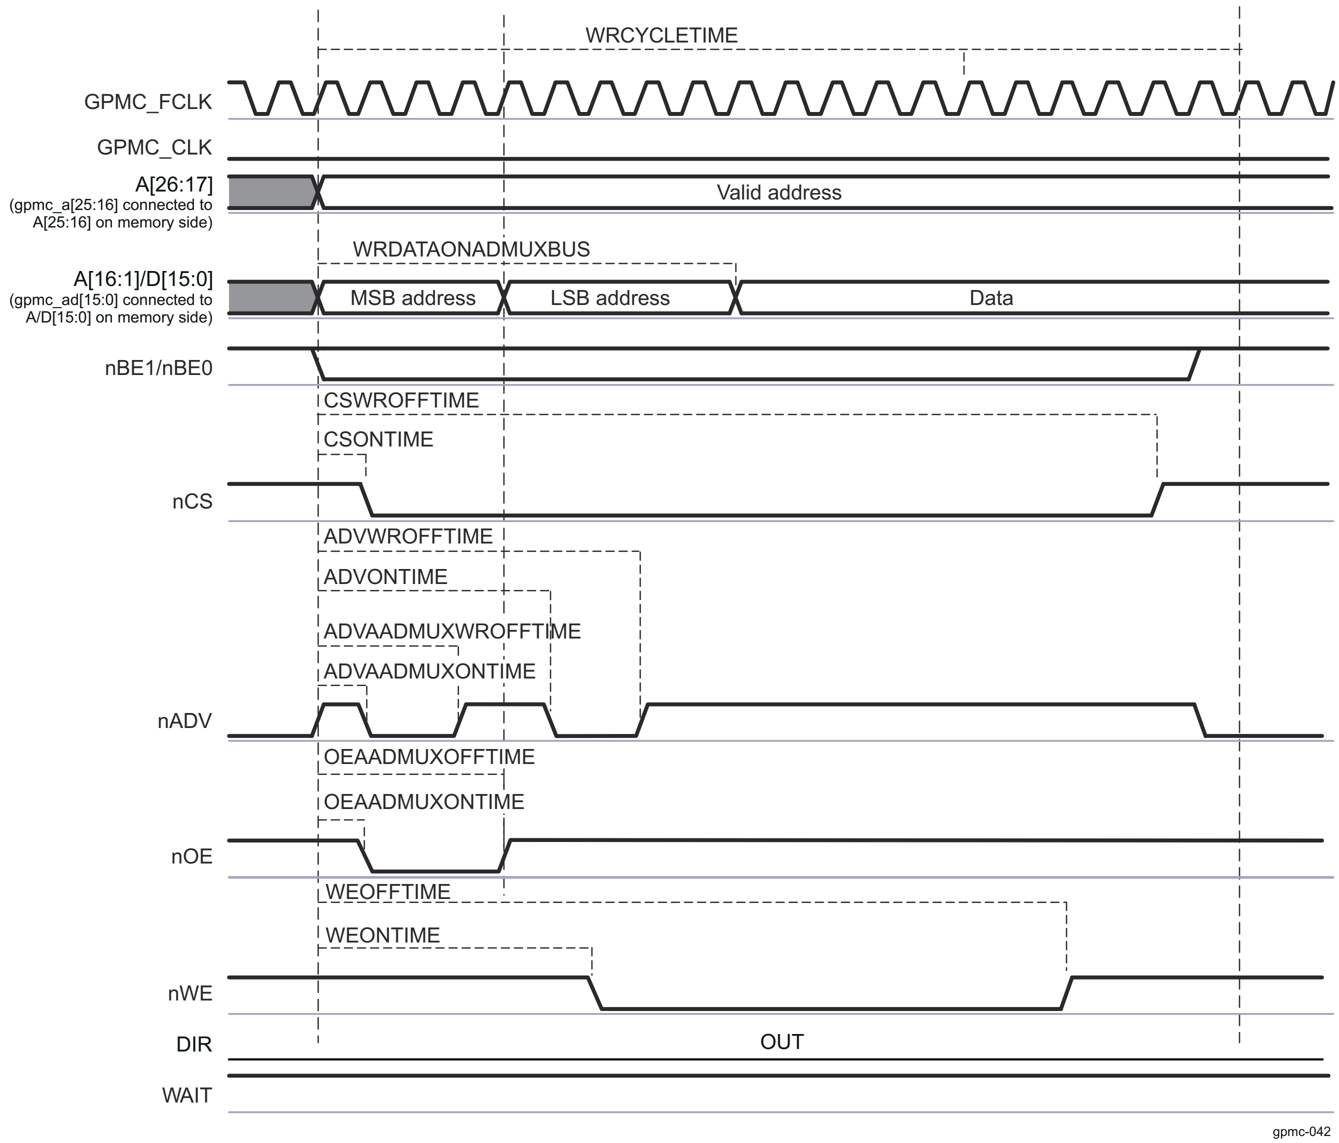

Figure 15-69. Asynchronous Single Write on an AAD-Multiplexed Device

For formulas to calculate timing parameters, see Section 15.4.5.6.1, *GPMC Timing Parameters Formulas*.

Table 15-456 lists the timing bit fields to set up to configure the GPMC in asynchronous single-write mode.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS, nWE, and DIR signals are controlled in the same way as for an asynchronous single-write operation on an address/data-multiplexed device. See Table 15-447.

- Address valid signal nADV is asserted and deasserted twice during a write transaction:
  - nADV first assertion time is controlled by the GPMC_CONFIG3_i[6:4] ADVAADMUXONTIME bit field.
  - nADV first deassertion time is controlled by the GPMC_CONFIG3_i[30:28] ADVAADMUXWROFFTIME bit field.
  - nADV second assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME bit field.
  - nADV second deassertion time is controlled by the GPMC_CONFIG3_i[20:16] ADVWROFFTIME bit field.
- Output enable signal nOE is asserted during the address phase of a write transaction:
  - nOE assertion time is controlled by the GPMC_CONFIG4_i[6:4] OEAADMUXONTIME bit field.
  - nOE deassertion time is controlled by the GPMC_CONFIG3_i[15:13] OEAADMUXOFFTIME bit field.

The address bits for the first address phase are driven onto the data bus until nOE deassertion. Data is driven onto the address/data bus at the clock edge defined by the GPMC_CONFIG6_i[19:16] WRDATAONADMUXBUS parameter.

15.4.4.10.1.2.3 Asynchronous Multiple (Page) Read Operation on an AAD-Multiplexed Device

Write multiple (page) access in asynchronous mode is not supported for AAD-multiplexed devices.

If the GPMC_CONFIG1_i[28] WRITEMULTIPLE bit is enabled (0x1) with the GPMC_CONFIG1_i[27] WRITETYPE bit as asynchronous (0x0), the GPMC processes single asynchronous accesses.

For accesses on nonmultiplexed devices, see Section 15.4.4.10.3, *Asynchronous and Synchronous Accessed in Nonmultiplexed Mode*.

15.4.4.10.2 Synchronous Access Description

This section describes read and write synchronous accesses on address/data-multiplexed devices. All information in this section can be applied to any type of memory (nonmultiplexed, address and data-multiplexed, or AAD-multiplexed) with the difference limited to the address phase. For accesses on nonmultiplexed devices, see Section 15.4.4.10.3, *Asynchronous and Synchronous Accessed in Nonmultiplexed Mode*.

In synchronous operations:

- The GPMC_CLK clock is provided outside the GPMC when accessing the memory device.
- The GPMC_CLK clock is derived from the GPMC_FCLK clock using the GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER bit field. In the following section i stands for the chip-select number, i = 0 to 7.
- The GPMC_CONFIG1_i[26:25] CLKACTIVATIONTIME bit field specifies that the GPMC_CLK is provided outside the GPMC for 0 to 2 GPMC_FCLK cycles after start access time until RDCYCLETIME or WRCYCLETIME completes.

15.4.4.10.2.1 Synchronous Single Read

Figure 15-70 and Figure 15-71 show a synchronous single-read operation with GPMCFCLKDIVIDER equal to 0 and 1, respectively.

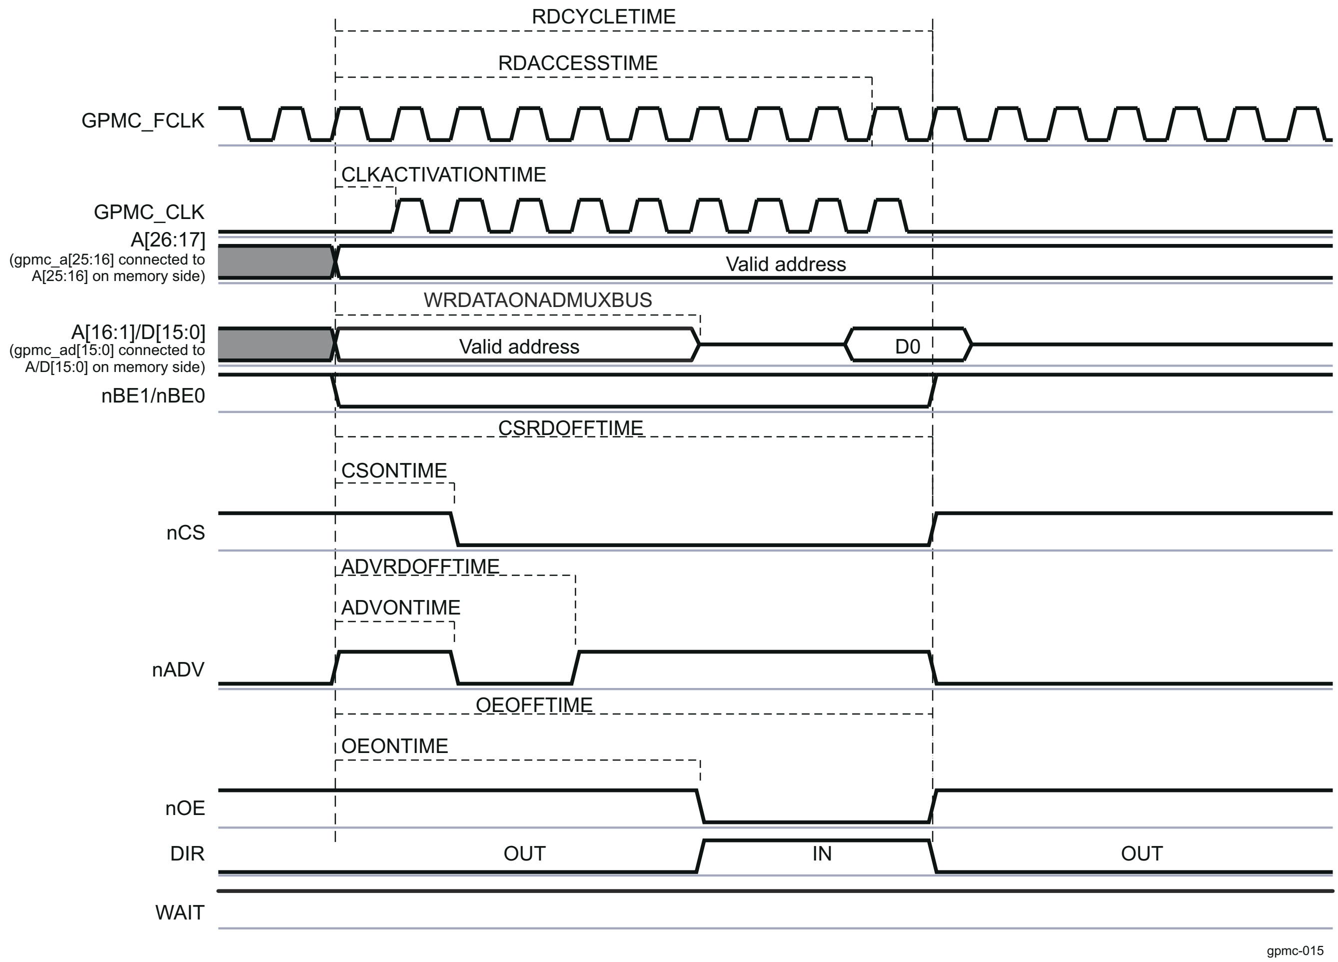

Figure 15-70. Synchronous Single Read (GPMCFCLKDIVIDER = 0)

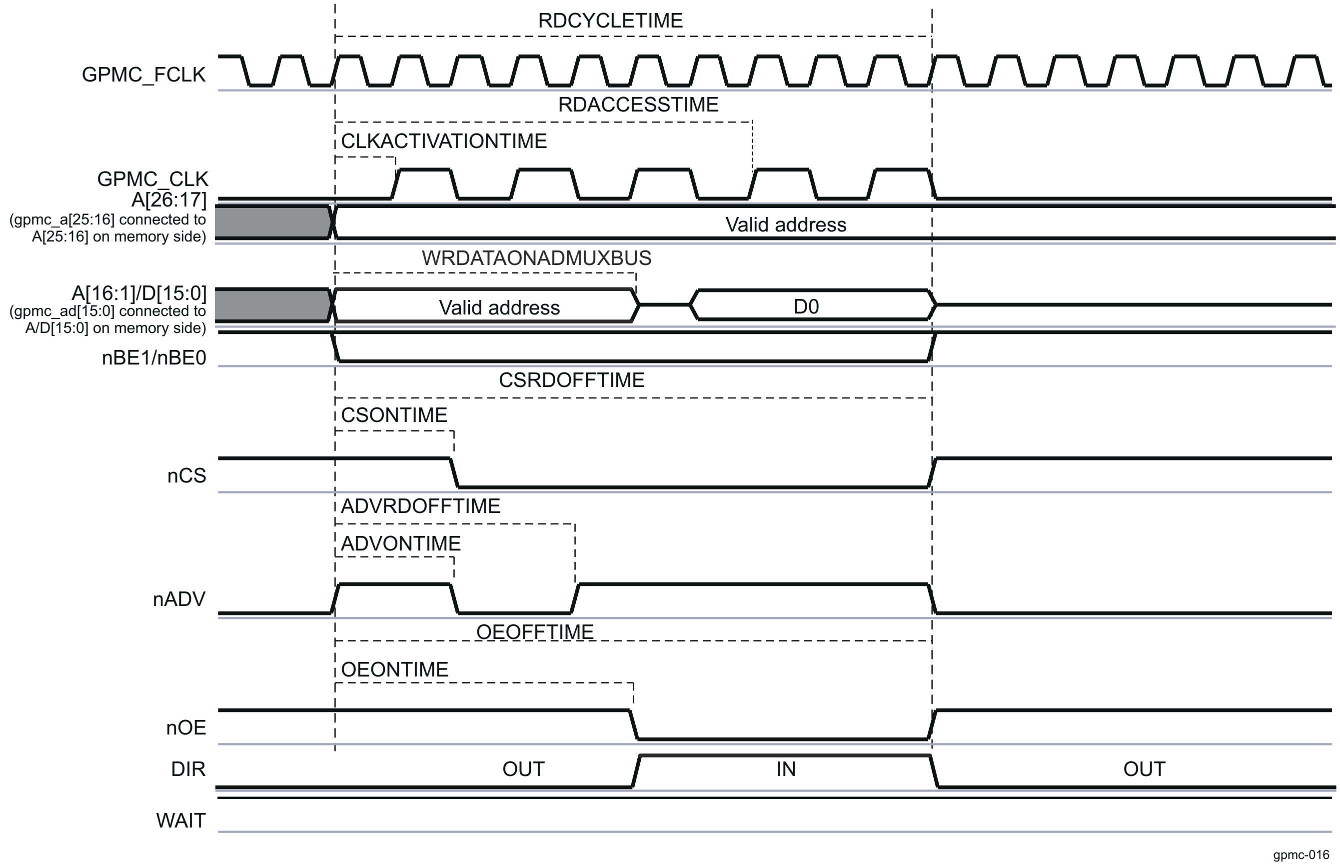

Figure 15-71. Synchronous Single Read (GPMCFCLKDIVIDER = 1)

For formulas to calculate timing parameters, see Section 15.4.5.6.1, *GPMC Timing Parameters Formulas*.

Table 15-456 lists the timing bit fields to set up to configure the GPMC in asynchronous single-read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For more information, see Section 15.4.4.8.2.3, *Address/Data-Multiplexing Interface*.

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC_CONFIG2_i[3:0] CSONTIME bit field and ensures address setup time to nCS assertion.
  - nCS deassertion time is controlled by the GPMC_CONFIG2_i[12:8] CSRDOFFTIME bit field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME bit field.
  - nADV deassertion time is controlled by the GPMC_CONFIG3_i[12:8] ADVRDOFFTIME bit field.
- Output enable signal nOE:
  - nOE assertion indicates a read cycle.
  - nOE assertion time is controlled by the GPMC_CONFIG4_i[3:0] OEONTIME bit field.
  - nOE deassertion time is controlled by the GPMC_CONFIG4_i[12:8] OEOFFTIME bit field.
- Initial latency for the first read data is controlled by GPMC_CONFIG5_i[20:16] RDACCESSTIME bit field or by monitoring the WAIT signal.
- Total access time (the GPMC_CONFIG5_i[4:0] RDCYCLETIME bit field) corresponds to RDACCESSTIME plus the address hold time from nCS deassertion, plus time from RDACCESSTIME to CSRDOFFTIME.
- Direction signal DIR: DIR goes from OUT to IN at the same time as nOE assertion.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS and DIR signals are controlled in the same way as for a synchronous single-read operation on an address/data-multiplexed device.

- Address valid signal nADV is asserted and deasserted twice during a read transaction:
  - nADV first assertion time is controlled by the GPMC_CONFIG3_i[6:4] ADVAADMUXONTIME bit field.
  - nADV first deassertion time is controlled by the GPMC_CONFIG3_i[26:24] ADVAADMUXRDOFFTIME bit field.
  - nADV second assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME bit field.
  - nADV second deassertion time is controlled by the GPMC_CONFIG3_i[12:8] ADVRDOFFTIME bit field.
- Output Enable signal nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
  - nOE first assertion time is controlled by the GPMC_CONFIG4_i[6:4] OEAADMUXONTIME bit field.
  - nOE first deassertion time is controlled by the GPMC_CONFIG3_i[15:13] OEAADMUXOFFTIME bit field.
  - nOE second assertion time is controlled by the GPMC_CONFIG4_i[3:0] OEONTIME bit field.
  - nOE second deassertion time is controlled by the GPMC_CONFIG4_i[12:8] OEOFFTIME bit field.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See Section 15.4.4.9.10, *Bus Keeping Support*.

15.4.4.10.2.2 Synchronous Multiple (Burst) Read (4-, 8-, 16-Word16 Burst With Wraparound Capability)

Figure 15-72 and Figure 15-73 show a synchronous multiple-read operation with GPMCFCLKDivider equal to 0 and 1, respectively.

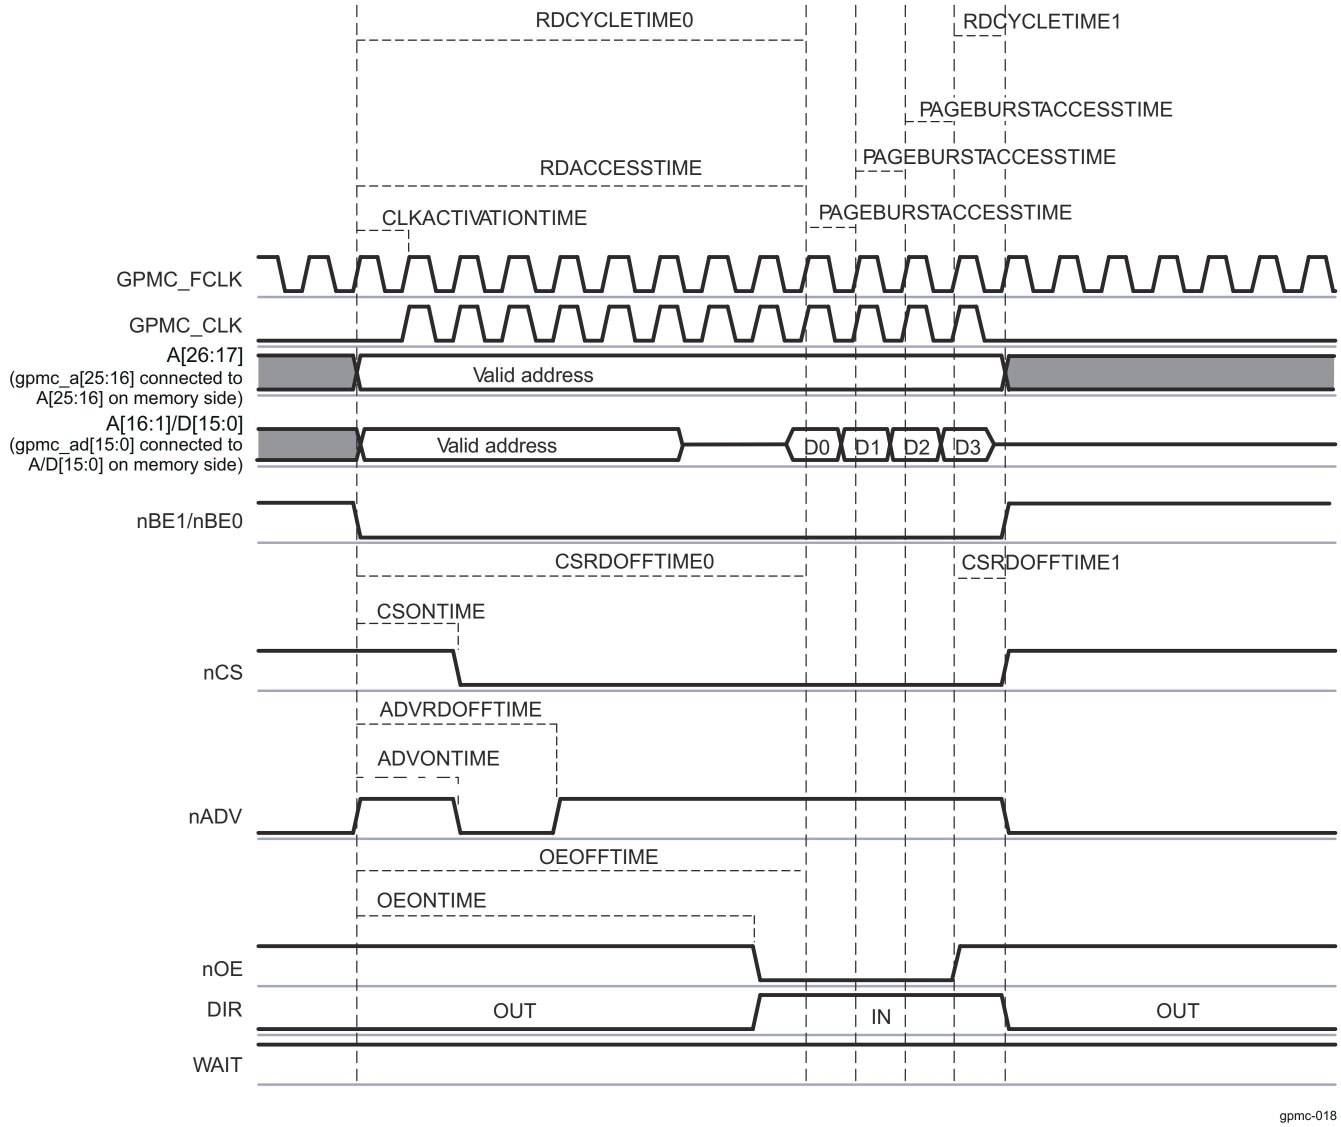

Figure 15-72. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 0)

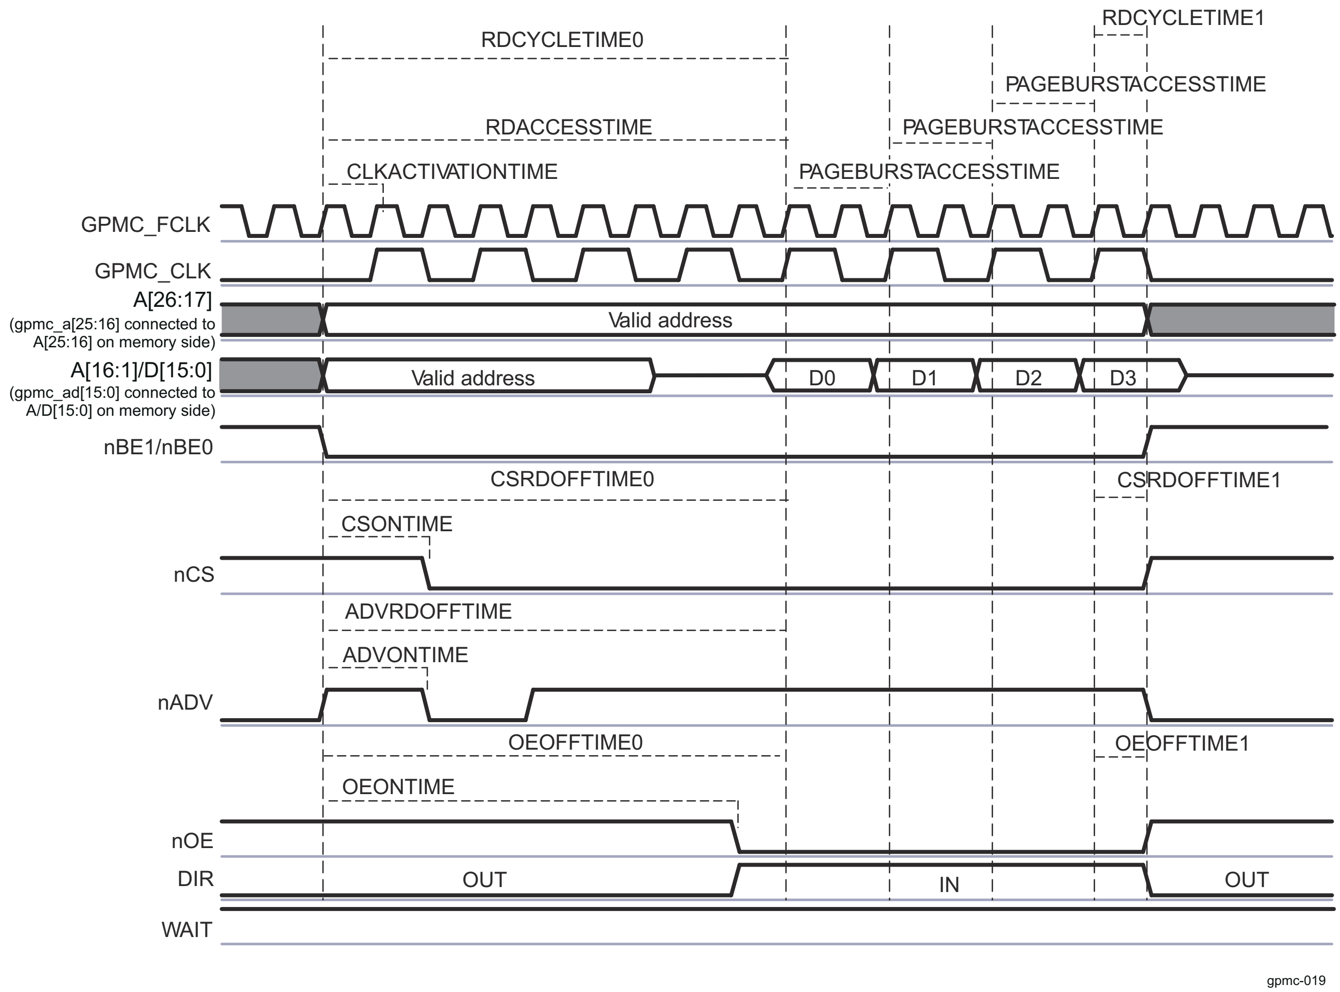

Figure 15-73. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 1)

When the GPMC_CONFIG5_i[20:16] RDACCESSTIME bit field completes, control-signal timings are frozen during the multiple data transactions, corresponding to the GPMC_CONFIG5_i[27:24] PAGEBURSTACCESSTIME bit field multiplied by the number of remaining data transactions.

The nCS, nADV, nOE, and DIR signals are controlled in the same way as for a synchronous single-read operation. See Table 15-442.

Initial latency for the first read data is controlled by RDACCESSTIME or by monitoring the WAIT signal. Successive read data are provided by the memory device every one or two GPMC_CLK cycles. The PAGEBURSTACCESSTIME parameter must be set accordingly with the GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER bit field and the memory-device internal configuration. Depending on the device page length, the GPMC checks the device page crossing during a new burst request and purposely inserts initial latency (of RDACCESSTIME) when required.

Total access time GPMC_CONFIG5_i[4:0] RDCYCLETIME corresponds to RDACCESSTIME plus the address hold time from nCS deassertion. In Figure 15-73, the programmed value of RDCYCLETIME equals RDCYCLETIME0 + RDCYCLETIME1.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See Section 15.4.4.9.10, *Bus Keeping Support*.

Burst wraparound is enabled through the GPMC_CONFIG1_i[31] WRAPBURST bit and allows a 4-, 8-, or 16-Word16 linear burst access to wrap within its burst-length boundary through the GPMC_CONFIG1_i[24:23] ATTACHEDDEVICEPAGELENGTH bit field.

15.4.4.10.2.3 Synchronous Single Write

Burst write mode is used for synchronous single or burst accesses.

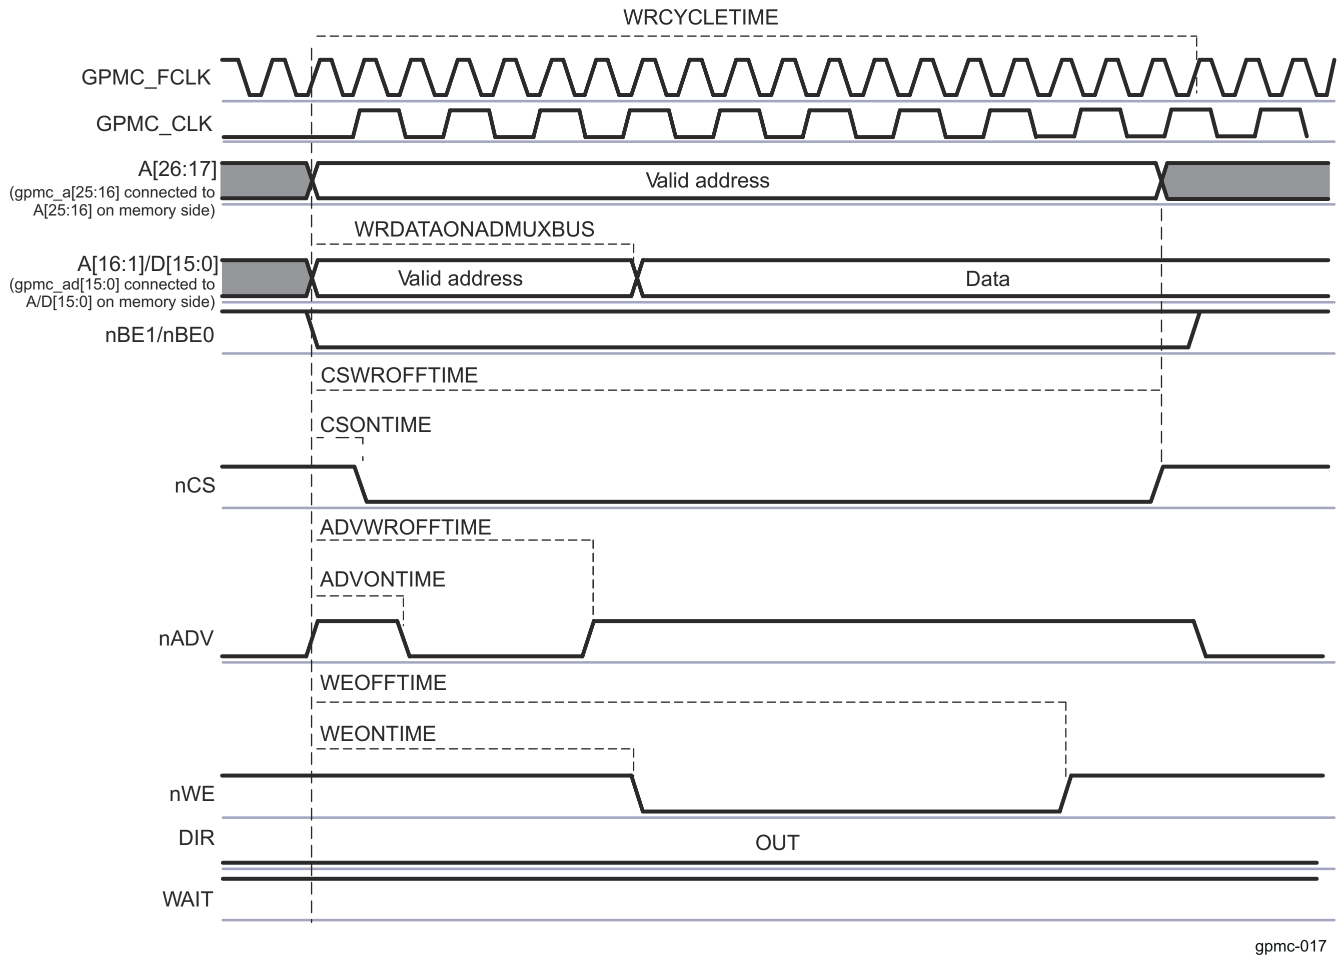

Figure 15-74. Synchronous Single Write on an Address/Data-Multiplexed Device

When the GPMC generates a write access to an address/data-multiplexed device, it drives the data bus (with address bits A[16:1]) until the GPMC_CONFIG6_i[19:16] WRDATAONADMUXBUS bit field time. The first data of the burst is driven on the address/data bus at WRDATAONADMUXBUS time.

15.4.4.10.2.4 Synchronous Multiple (Burst) Write

Synchronous burst write mode provides synchronous single or consecutive accesses.

Figure 15-75 shows a synchronous burst write access when the chip-select is configured in address/data-multiplexed mode.

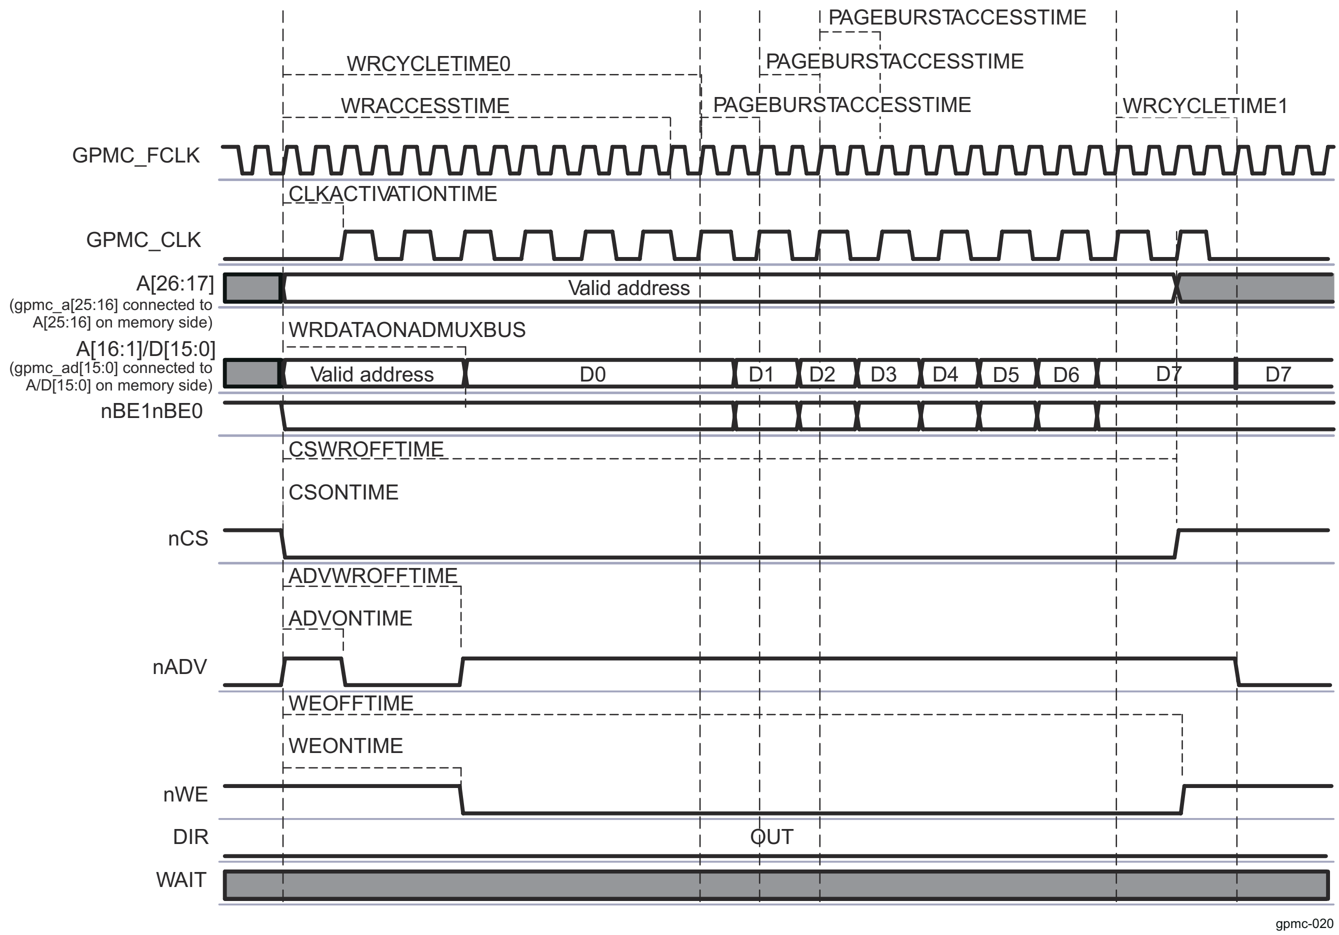

Figure 15-75. Synchronous Multiple Write (Burst Write) in Address/Data-Multiplexed Mode

Figure 15-76 shows the same synchronous burst write access when the chip-select is configured in address/ address/data-multiplexed (AAD-multiplexed) mode.

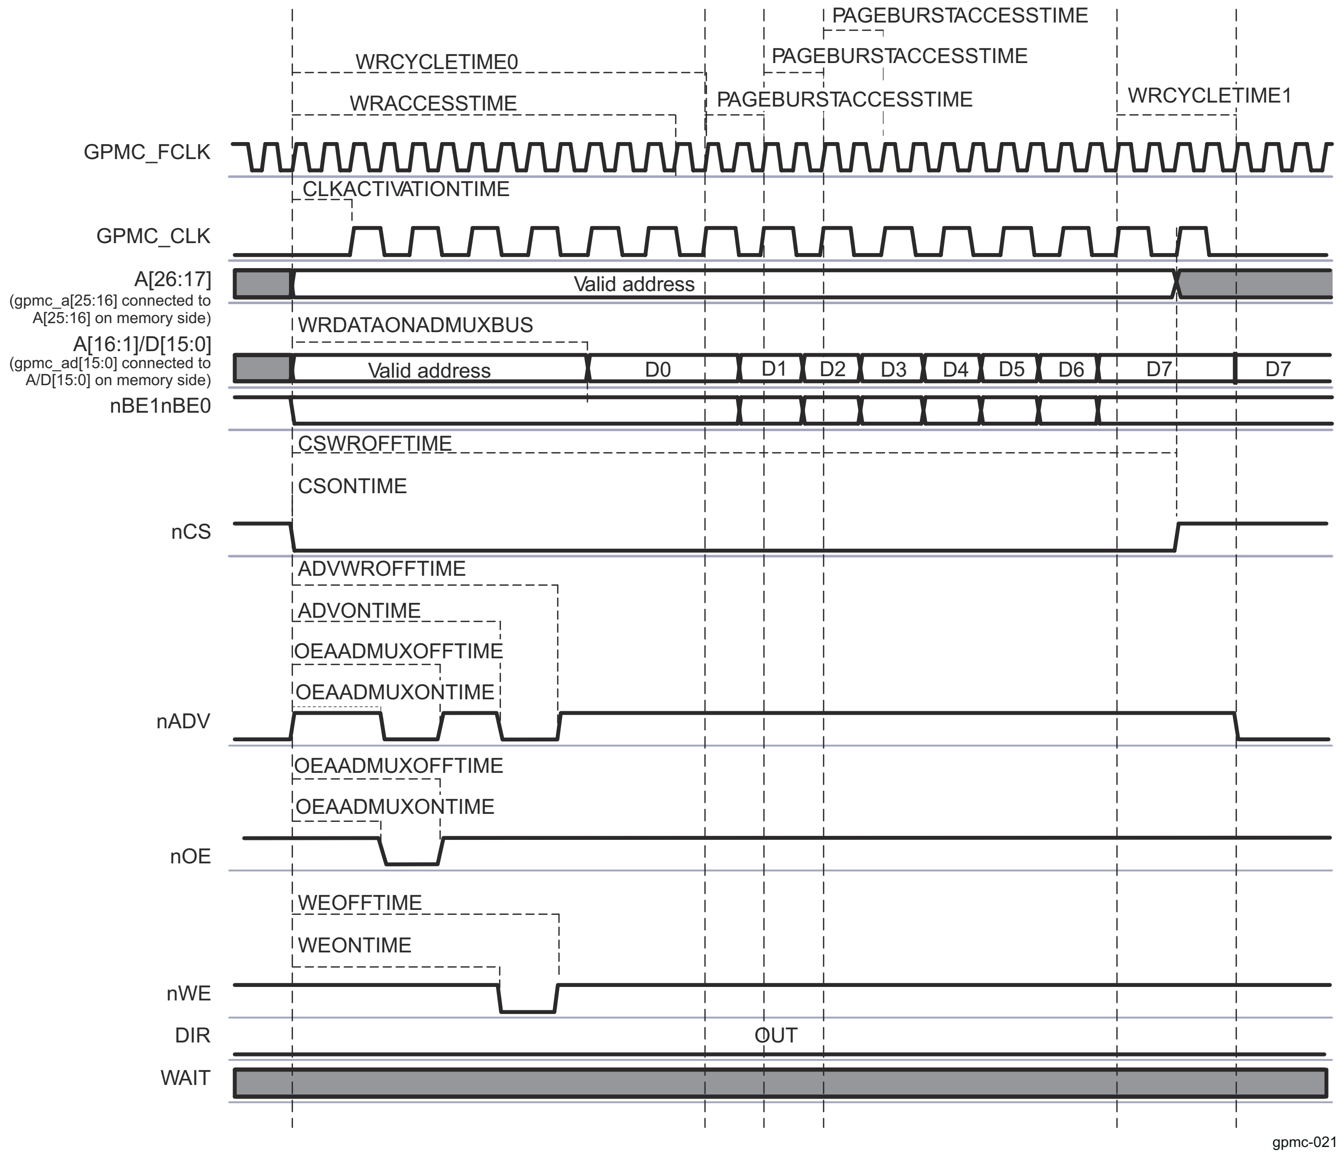

Figure 15-76. Synchronous Multiple Write (Burst Write) in Address/Address/Data-Multiplexed Mode

The first data of the burst is driven on the A/D bus at the GPMC_CONFIG6_i[19:16] WRDATAONADMUXBUS bit field.

When WRACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to the GPMC_CONFIG5_i[27:24] PAGEBURSTACCESSTIME bit field multiplied by the number of remaining data transactions.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For more information, see Section 15.4.4.8.2.3, *Address/Data-Multiplexing Interface*.

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC_CONFIG2_i[3:0] CSONTIME bit field (where i = 0 to 7) and ensures address setup time to nCS assertion.
  - nCS deassertion time controlled by the GPMC_CONFIG2_i[20:16] CSWROFFTIME bit field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME bit field.

  - nADV deassertion time is controlled by the GPMC_CONFIG3_i[20:16] ADVWROFFTIME bit field.
- Write enable signal nWE:
  - nWE assertion indicates a read cycle.
  - nWE assertion time is controlled by the GPMC_CONFIG4_i[19:16] WEONTIME bit field.
  - nWE deassertion time is controlled by the GPMC_CONFIG4_i[28:24] WEOFFTIME bit field.

Note

The nWE falling edge must not be used to control the time when the burst first data is driven in the address/data bus, because some new devices require the nWE signal to be low during the address phase.

- Direction signal DIR is OUT during the entire access.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS, and DIR signals are controlled as previously described..

- Address valid signal nADV is asserted and deasserted twice during a read transaction:
  - nADV first assertion time is controlled by the GPMC_CONFIG3_i[6:4] ADVAADMUXONTIME bit field.
  - nADV first deassertion time is controlled by the GPMC_CONFIG3_i[26:24] ADVAADMUXRDOFFTIME bit field.
  - nADV second assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME bit field.
  - nADV second deassertion time is controlled by the GPMC_CONFIG3_i[12:8] ADVRDOFFTIME bit field.
- Output Enable signal nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
  - nOE first assertion time is controlled by the GPMC_CONFIG4_i[6:4] OEAADMUXONTIME bit field.
  - nOE first deassertion time is controlled by the GPMC_CONFIG4_i[15:13] OEAADMUXOFFTIME bit field.
  - nOE second assertion time is controlled by the GPMC_CONFIG4_i[3:0] OEONTIME bit field.
  - nOE second deassertion time is controlled by the GPMC_CONFIG4_i[12:8] OEOFFTIME bit field.

First write data is driven by the GPMC at GPMC_CONFIG6_i[19:16] WRDATAONADMUXBUS, when in address/data-multiplexed configuration. The next write data of the burst is driven on the bus at WRACCESSTIME + 1 during GPMC_CONFIG5_i[27:24] PAGEBURSTACCESSTIME GPMC_FCLK cycles. The last data of the synchronous burst write is driven until GPMC_CONFIG5_i[12:8] WRCYCLETIME completes.

- WRACCESSTIME is defined in the GPMC_CONFIG6_i[28:24] bit field.
- The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMCFCLKDIVIDER and the memory-device internal configuration.

Total access time GPMC_CONFIG5_i[12:8] WRCYCLETIME corresponds to WRACCESSTIME plus the address hold time from nCS deassertion. In Figure 15-75, the programmed value of WRCYCLETIME equals WRCYCLETIME0 + WRCYCLETIME1. WRCYCLETIME0 and WRCYCLETIME1 delays are not actual parameters and are only a graphical representation of the full WRCYCLETIME value.

After a write operation, if no other access (read or write) is pending, the data bus keeps the previous value. See Section 15.4.4.9.10, *Bus Keeping Support*.

15.4.4.10.3 Asynchronous and Synchronous Accesses in Nonmultiplexed Mode

Page mode is available only in nonmultiplexed mode.

- Asynchronous single-read operation on a nonmultiplexed device
- Asynchronous single-write operation on a nonmultiplexed device
- Asynchronous multiple- (page mode) read operation on a nonmultiplexed device
- Synchronous operations on a nonmultiplexed device

15.4.4.10.3.1 Asynchronous Single-Read Operation on Nonmultiplexed Device

Figure 15-77 shows an asynchronous single-read operation on a nonmultiplexed device.

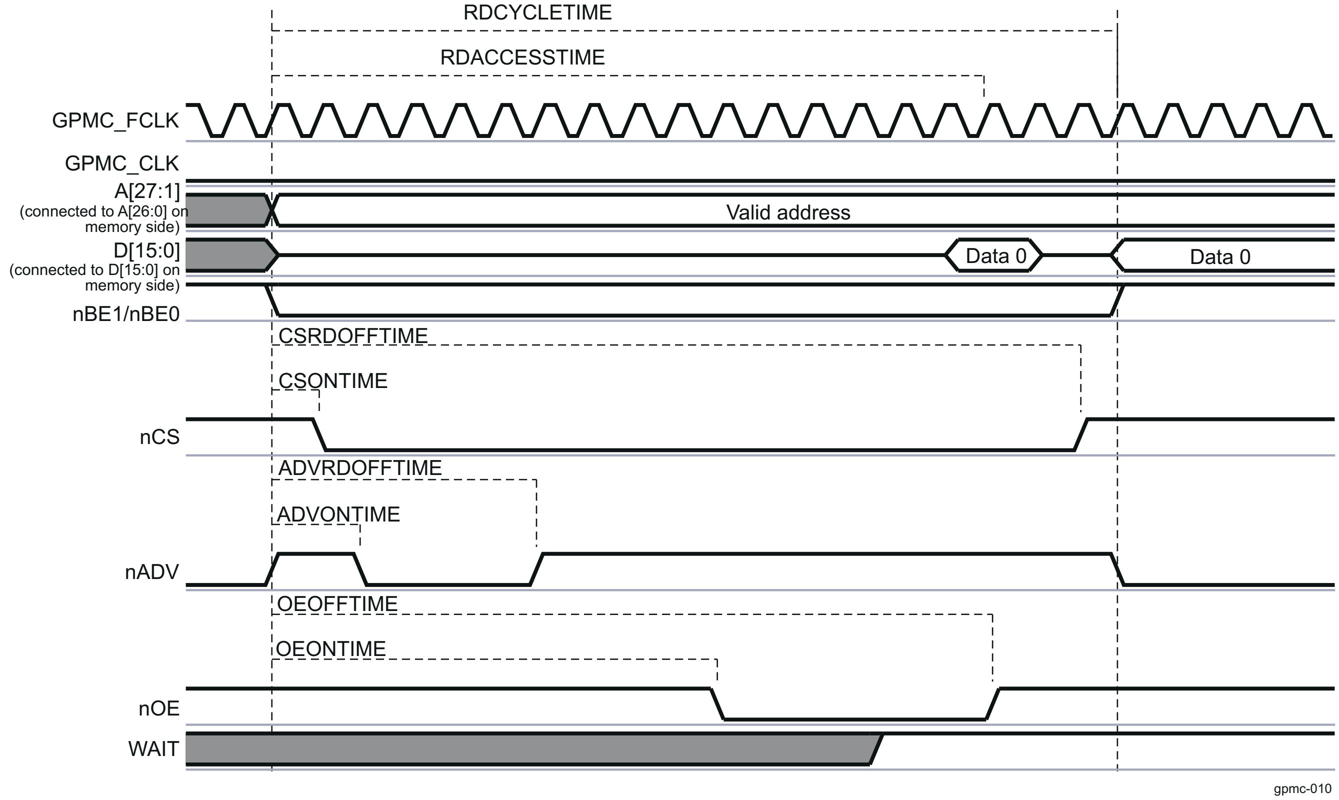

Figure 15-77. Asynchronous Single Read on an Address/Data-Nonmultiplexed Device

The 27-bit address (For a 16-bit data memory device, hence GPMC A[0] is not necessary to be output) is driven onto the address bus A[27:1] and the 16-bit data is driven onto the data bus D[15:0].

Read data is latched at GPMC_CONFIG1_5[20:16] RDACCESSTIME completion time. The end of the access is defined by the GPMC_CONFIG1_5[4:0] RDCYCLETIME parameter.

The nCS, nADV, nOE, and DIR signals are controlled in the same way as address/data-multiplexed accesses (see Table 15-447).

15.4.4.10.3.2 Asynchronous Single-Write Operation on Nonmultiplexed Device

Figure 15-78 shows an asynchronous single-write operation on a nonmultiplexed device.

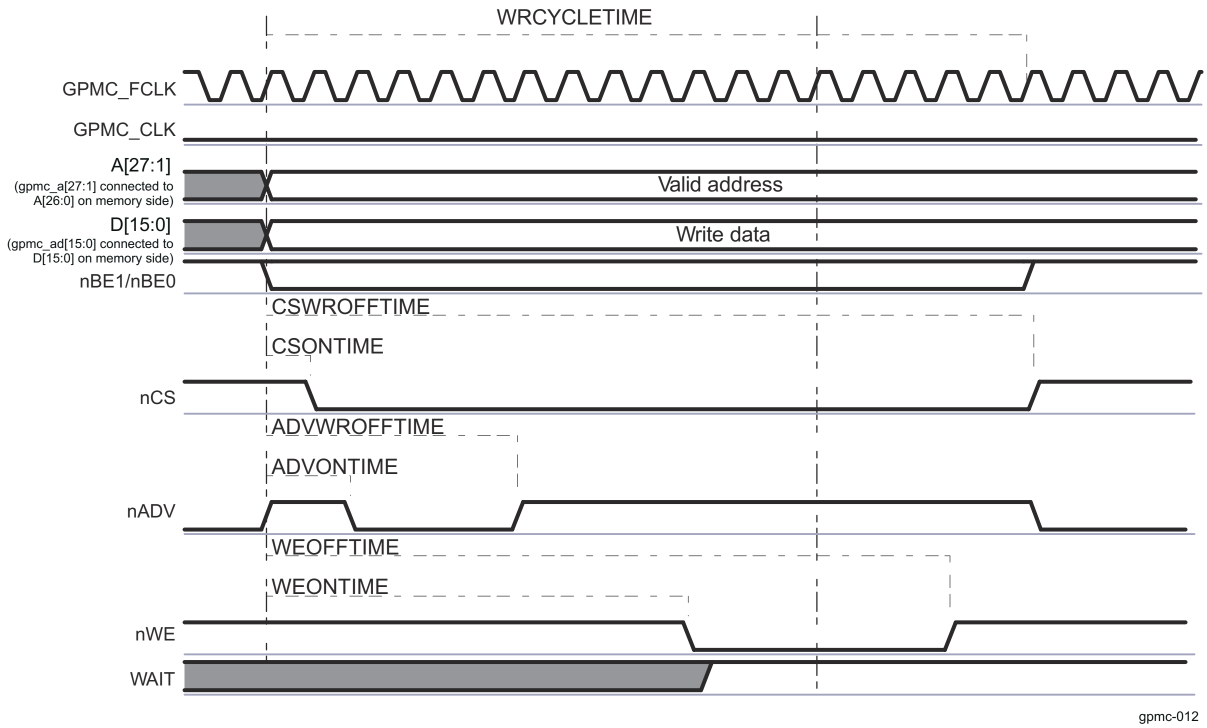

Figure 15-78. Asynchronous Single Write on an Address/Data-Nonmultiplexed Device

The nCS, nADV, nWE, and DIR signals are controlled in the same way as address/data-multiplexed accesses (see Table 15-447).

15.4.4.10.3.3 Asynchronous Multiple (Page Mode) Read Operation on Nonmultiplexed Device

Figure 15-79 shows an asynchronous multiple-read operation on a nonmultiplexed device in which two word32 host read accesses to the GPMC are split into one multiple- (page mode of 4 word16) read access to the attached device.

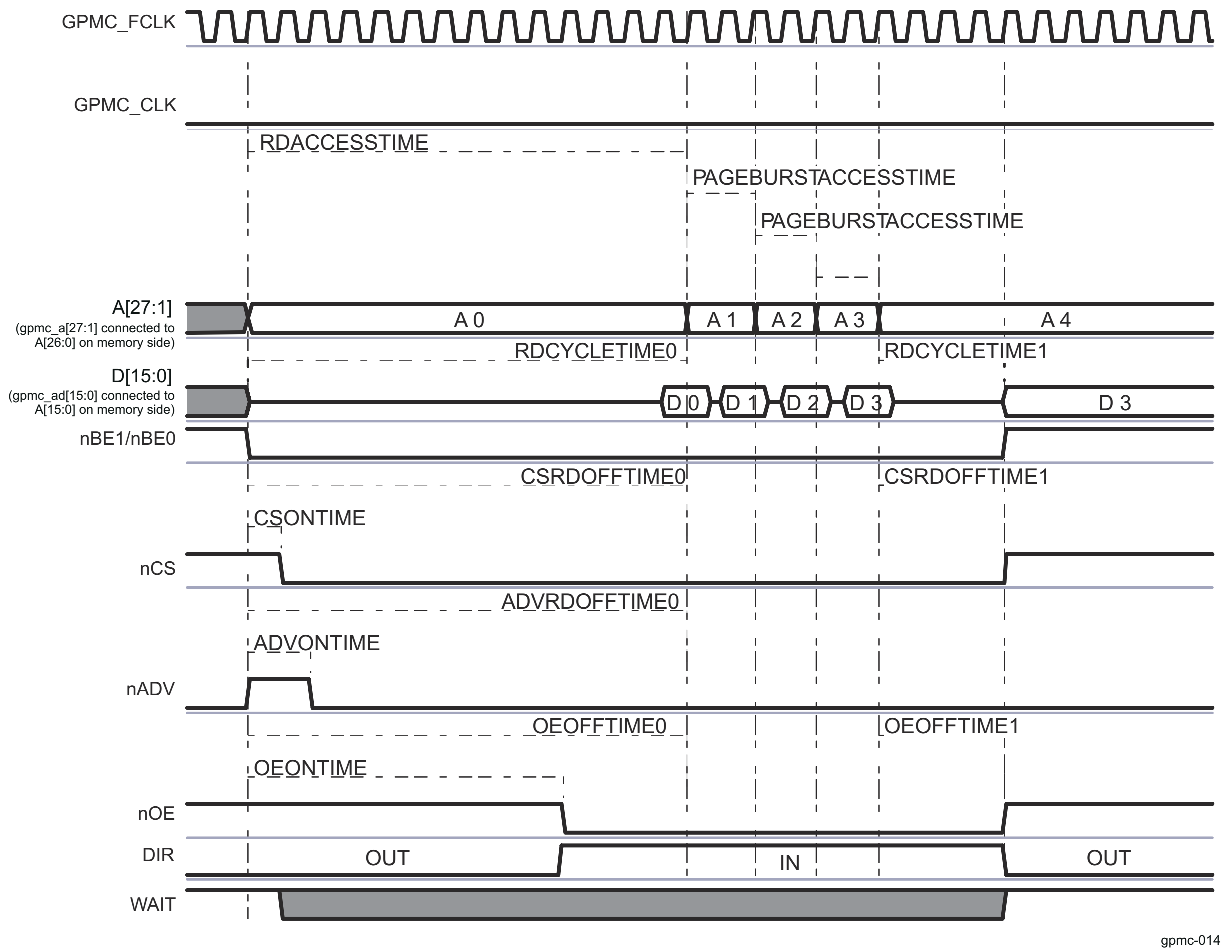

Figure 15-79. Asynchronous Multiple (Page Mode) Read

Note

The WAIT signal is active low.

The nCS, nADV, nOE, and DIR signals are controlled in the same way as address/data-multiplexed accesses (see Table 15-447).

When RDACCESSTIME completes, control signal timings are frozen during the multiple data transactions, corresponding to PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

Read data is latched at GPMC_CONFIG5_i[20:16] RDACCESSTIME completion time (where i = 0 to 7). The end of the access is defined by the GPMC_CONFIG5_i[4:0] RDCYCLETIME parameter.

During consecutive accesses, the GPMC increments the address after each data read completes.

Delay between successive read data in the page is controlled by the GPMC_CONFIG5_i[27:24] PAGEBURSTACCESSTIME parameter. Depending on the device page length, the GPMC can control device page crossing during a burst request and insert initial RDACCESSTIME latency. Page crossing is possible only with a new burst access, meaning a new initial access phase is initiated.

Total access time RDCYCLETIME corresponds to RDACCESSTIME, plus the address hold time, starting from the nCS deassertion.

- The read cycle time is defined in the GPMC_CONFIG5_i[4:0] RDCYCLETIME bit field.

- In Figure 15-79, the programmed value of RDCYCLETIME equals RDCYCLETIME0 (before paged accesses) + RDCYCLETIME1 (after paged accesses).

15.4.4.10.3.4 Synchronous Operations on a Nonmultiplexed Device

All information for this section is equivalent to similar operations for address/data-multiplexed or AAD-multiplexed accesses. The only difference resides in the address phase. See Section 15.4.5.3, *GPMC Configuration in NOR Mode*.

15.4.4.10.4 Page and Burst Support

Each chip-select can be configured to process system single or burst requests into successive single accesses or asynchronous page/synchronous burst accesses, with appropriate access size adaptation.

Depending on the external device page or burst capability, read and write accesses can be independently configured through the GPMC. The GPMC_CONFIG1_i[30] READMULTIPLE and GPMC_CONFIG1_i[28] WRITMULTIPLE bits (where i = 0 to 7) are associated with the READTYPE and WRITETYPE parameters.

Note

- Asynchronous write page mode is not supported.
- 8-bit-wide device support is limited to nonburstable devices (READMULTIPLE and WRITEMULTIPLE are ignored).
- Not applicable to NAND device interfacing

15.4.4.10.5 System Burst vs External Device Burst Support

The device system can issue the following requests to the GPMC:

- Byte, 16-bit word, 32-bit word requests (byte-enable-controlled). This is always a single request from the interconnect point of view.
- Incrementing fixed-length bursts of two, four, and eight words
- Wrapped (critical word access first) fixed-length burst of two, four, or eight words

To process a system request with the optimal protocol, the READMULTIPLE (and READTYPE) and WRITEMULTIPLE (and WRITETYPE) parameters must be set according to the burstable capability (synchronous or asynchronous) of the attached device.

The GPMC access engine issues only fixed-length bursts. The maximum length that can be issued is defined per chip-select by the GPMC_CONFIG1_i[24:23] ATTACHEDDEVICEPAGELENGTH bit field (where i = 0 to 7). When the value of ATTACHEDDEVICEPAGELENGTH is less than the length of the system burst request (including the appropriate access size adaptation according to the device width), the GPMC splits the system burst request into multiple bursts. Within the specified 4-, 8-, or 16-word value, the value of the ATTACHEDDEVICEPAGELENGTH bit field must correspond to the maximum length burst supported by the memory device configured in fixed-length burst mode (as opposed to continuous burst mode).

To get optimal performance from memory devices that natively support 16 Word16-length-wrapping burst capability (critical word access first), the ATTACHEDDEVICEPAGELENGTH parameter must be set to 16 words and the GPMC_CONFIG1_i[31] WRAPBURST bit (where i = 0 to 7) must be set to 1. Similarly DEVICEPAGELENGTH is set to 4 and 8 for memories supporting 4 and 8 Word16-length-wrapping burst, respectively.

When the memory device does not offer (or is not configured to offer) native 16 Word16-length-wrapping burst, the WRAPBURST parameter must be cleared, and the GPMC access engine emulates the wrapping burst by issuing the appropriate burst sequences according to the value of ATTACHEDDEVICEPAGELENGTH.

When the memory device does not support native-wrapping burst, there is usually no difference in behavior between a fixed-burst length mode and a continuous-burst mode configuration (except for a potential power increase from a memory-speculative data prefetch in a continuous burst read). However, even though continuous burst mode is compatible with GPMC behavior, because the GPMC access engine issues only fixed-length burst and does not benefit from continuous burst mode, it is best to configure the memory device in fixed-length burst mode.

The memory device maximum-length burst (configured in fixed-length burst wrap or nonwrap mode) usually corresponds to the memory device data buffer size. Memory devices with a minimum of 16 half-word buffers are the most appropriate (especially with wrap support), but memory devices with smaller buffer size (4 or 8) are also supported, assuming that the GPMC_CONFIG1_i[24:23] ATTACHEDDEVICEPAGELENGTH bit field is set accordingly to 4 or 8 words.

The device system issues only requests with addresses or starting addresses for nonwrapping burst requests; that is, the request size boundary is aligned. In case of an eight-word-wrapping burst, the wrapping address always occurs on the eight-word boundary. As a consequence, all words requested must be available from the memory data buffer when the buffer size is equal to or greater than the value of ATTACHEDDEVICEPAGELENGTH. This usually means that data can be read from or written to the buffer at a constant rate (number of cycles between data) without wait-states between data accesses. If the memory does not behave this way (nonzero wait-state burstable memory), wait pin monitoring must be enabled to dynamically control data access completion within the burst.

Note

When the system burst request length is less than the value of ATTACHEDDEVICEPAGELENGTH, the GPMC proceeds with the required accesses.

15.4.4.11 pSRAM Access Specificities

pSRAM devices are SRAM-pin-compatible low-power memories that contain a self-refreshed DRAM memory array. The GPMC_CONFIG1_i[11:10] DEVICETYPE bit field (where i = 0 to 7) must be set to 0b00.

The pSRAM device uses the NOR protocol. It supports the following operations:

- Asynchronous single read
- Asynchronous page read
- Asynchronous single write
- Synchronous single read and write
- Synchronous burst read
- Synchronous burst write (not supported by NOR flash memory)

pSRAM devices must be powered up and initialized in a predefined manner according to the specifications of the attached device.

pSRAM devices can be programmed to use either mode: fixed or variable latency. pSRAM devices can automatically schedule autorefresh operations, which force the GPMC to use its WAIT signal capability when read or write operations occur during an internal self-refresh operation, or they can automatically include the autorefresh operation in the access time. These devices do not require additional WAIT signal capability or a minimum nCS high pulse width between consecutive accesses to ensure that the correct internal refresh operation is scheduled.

15.4.4.12 NAND Access Description

NAND (8-bit and 16-bit) memory devices using a standard NAND asynchronous address/data-multiplexing scheme can be supported on any chip-select with the appropriate asynchronous configuration settings.

As for any other type of memory compatible with the GPMC interface, accesses to a chip-select allocated to a NAND device can be interleaved with accesses to chip-selects allocated to other external devices. This interleaved capability limits the system to *chip enable don't care* NAND devices, because the chip-select allocated to the NAND device must be deasserted if accesses to other chip-selects are requested.

15.4.4.12.1 NAND Memory Device in Byte or 16-bit Word Stream Mode

NAND devices require correct command and address programming before data array read or write accesses. The GPMC does not include specific hardware to translate a random address system request into a NAND-specific multiphase access. In that sense, GPMC NAND support, as opposed to random memory-map device support, is data stream-oriented (byte or 16-bit word).

The GPMC NAND programming model relies on a software driver for address and command formatting with the correct data address pointer value according to the block and page structure. Because of NAND structure and protocol interface diversity, the GPMC does not support automatic command and address phase programming, and software drivers must access the NAND device ID to ensure that correct command and address formatting are used for the identified device.

NAND device data read and write accesses are achieved through an asynchronous read or write access. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Any chip-select region can be qualified as a NAND region to constrain the nADV/ALE signal as ALE (ALE active high, default state value at low) during address program access, and the nBE0/CLE signal as CLE (CLE active high, default state value at low) during command program access. GPMC address lines are not used (the previous value is not changed) during NAND access.

15.4.4.12.1.1 Chip-Select Configuration for NAND Interfacing in Byte or Word Stream Mode

The GPMC_CONFIG7_i register (where i = 0 to 7) associated with a NAND device region interfaced in byte or word stream mode can be initialized with a minimum size of 16MiB, because any address location in the chip-select memory region can be used to access a NAND data array. The NAND flash protocol specifies an address sequence where address bits are passed through the data bus in a series of write accesses with the ALE pin asserted. After this address phase, all operations are streamed and the system requests address is irrelevant.

CAUTION

To allow correct command, address, and data-access controls, the GPMC_CONFIG1_i register associated with a NAND device region must be initialized in asynchronous read and write modes with the parameters listed in Table 15-425. Failure to comply with these settings corrupts the NAND interface protocol.

Table 15-425. Chip-Select Configuration for NAND Interfacing

Bit Field	Register	Value	Comments
WRAPBURST	GPMC_CONFIG1_i[31] (1)	0	No wrap
READMULTIPLE	GPMC_CONFIG1_i[30]	0	Single access
READTYPE	GPMC_CONFIG1_i[29]	0	Asynchronous mode
WRITEMULTIPLE	GPMC_CONFIG1_i[28]	0	Single access
WRITETYPE	GPMC_CONFIG1_i[27]	0	Asynchronous mode
CLKACTIVATIONTIME	GPMC_CONFIG1_i[26:25]	0b00	
ATTACHEDDEVICEPAGELENGTH	GPMC_CONFIG1_i[24:23]	Don't care	Single-access mode
WAITREADMONITORING	GPMC_CONFIG1_i[22]	0	Wait not monitored by GPMC access engine
WAITWRITEMONITORING	GPMC_CONFIG1_i[21]	0	Wait not monitored by GPMC access engine
WAITMONITORINGTIME	GPMC_CONFIG1_i[19:18]	Don't care	Wait not monitored by GPMC access engine
WAITPINSELECT	GPMC_CONFIG1_i[17:16]		Select which wait is monitored by edge detectors
DEVICESIZE	GPMC_CONFIG1_i[13:12]	0b00 or 0b01	8- or 16-bit interface

Table 15-425. Chip-Select Configuration for NAND Interfacing (continued)

Bit Field	Register	Value	Comments
DEVICETYPE	GPMC_CONFIG1_i[11:10]	0b10	NAND device in stream mode
MUXADDDATA	GPMC_CONFIG1_i[9:8]	0b00	Nonmultiplexed mode
TIMEPARAGRANULARITY	GPMC_CONFIG1_i[4]	0	Timing achieved with best GPMC clock granularity
GPMCFCLKDIVIDER	GPMC_CONFIG1_i[1:0]	Don't care	Asynchronous mode

(1) i = 0 to 7

The GPMC_CONFIG1_i to GPMC_CONFIG4_i registers (where i = 0 to 7) associated with a NAND device region must be initialized with the correct control-signal timing value according to the NAND device timing parameters.

15.4.4.12.1.2 NAND Device Command and Address Phase Control

NAND devices require multiple address programming phases. The MPU software driver must issue the correct number of command and address program accesses, according to the device command set and the device address-mapping scheme.

NAND device-command and address-phase programming is achieved through write requests to the GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i register locations (where i = 0 to 7) with the correct command and address values. These locations are mapped in the associated chip-select register region. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Command and address values are not latched during the access and cannot be read back at the register location.

- Only write accesses must be issued to these locations, but the GPMC does not discard any read access. Accessing a NAND device with nOE and CLE or ALE asserted (read access) can produce undefined results.
- Write accesses to the GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i register locations must be posted for faster operations (where i = 0 to 7). The GPMC_CONFIG[0] NANDFORCEPOSTEDWRITE bit enables write accesses to these locations as posted, even if they are defined as nonposted.

A write buffer is used to store write transaction information before the external device is accessed:

- Up to eight consecutive posted write accesses can be accepted and stored in the write buffer.
- For nonposted write, the pipeline is one deep.
- An GPMC_STATUS[0] EMPTYWRITEBUFFERSTATUS bit stores the empty status of the write buffer.

The GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i registers (where i = 0 to 7) are 32-bit word locations, which means any 32-or 16-bit word access is split into 4- or 2-byte accesses if an 8-bit-wide NAND device is attached. For multiple-command phase or multiple-address phase, the software driver can use 32- or 16-bit word access to these registers, but it must consider the splitting and little-endian ordering scheme. When only one byte command or address phase is required, only byte write access to the GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i registers can be used, and any of the four byte locations of the registers is valid.

The same applies to a GPMC_NAND_COMMAND_i and a GPMC_NAND_ADDRESS_i (where i = 0 to 7) 32-bit word write access to a 16-bit-wide NAND device (split into two 16-bit word accesses). In the case of a 16-bit word write access, the MSByte of the 16-bit word value must be set according to the NAND device requirement (usually 0). Either 16-bit word location or any one of the four byte locations of the registers is valid.

15.4.4.12.1.3 Command Latch Cycle

Writing data at the GPMC_NAND_COMMAND_i location (where i = 0 to 7) places the data as the NAND command value on the bus, using a regular asynchronous write access.

- nCE is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- CLE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.

- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE and nRE (nOE) are maintained inactive.

Figure 15-80 shows the NAND command latch cycle.

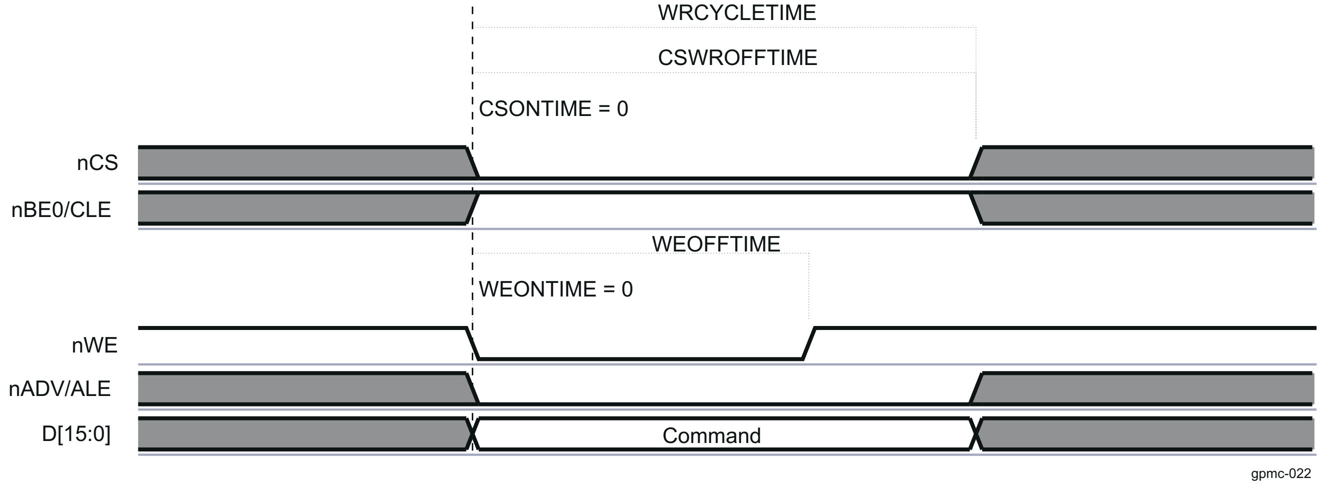

Figure 15-80. NAND Command Latch Cycle

Note

CLE is shared with the nBE0 output signal and has an inverted polarity from BE0. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, nBE0 (also nBE1) must not toggle, because it is shared with CLE.

NAND flash memories do not use byte-enable signals.

15.4.4.12.1.4 Address Latch Cycle

Writing data at the GPMC_NAND_ADDRESS_i location (where i = 0 to 7) places the data as the NAND partial address value on the bus, using a regular asynchronous write access.

- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- ALE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- CLE and nRE (nOE) are maintained inactive.

Figure 15-81 shows the NAND address latch cycle.

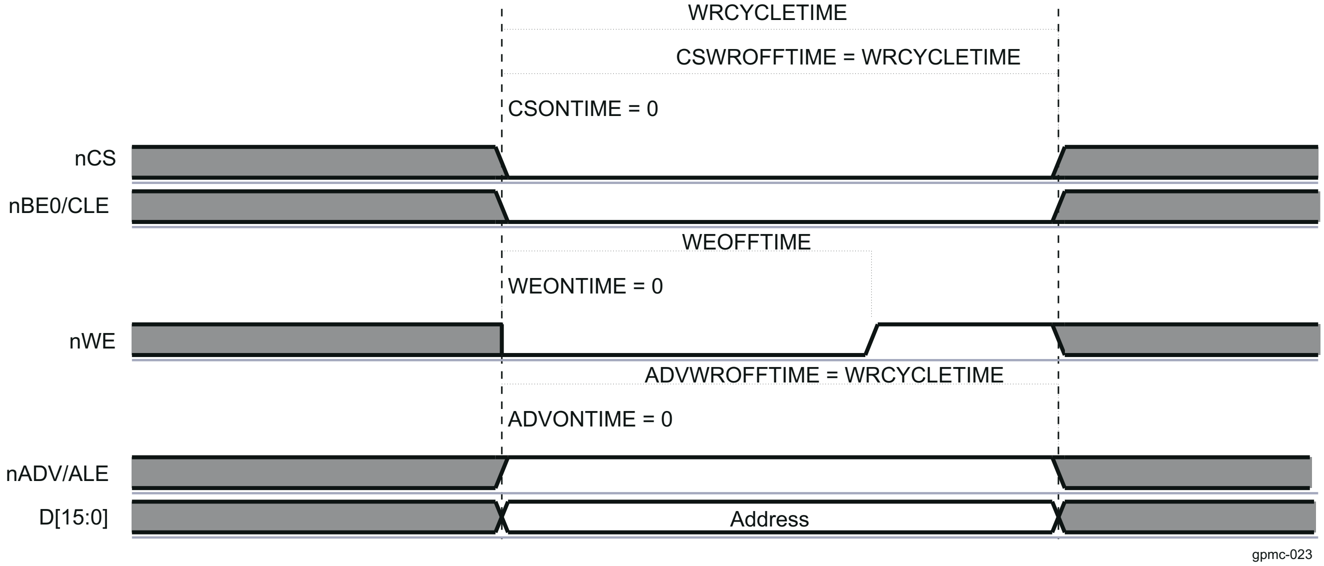

Figure 15-81. NAND Address Latch Cycle

Note

ALE is shared with the nADV output signal and has an inverted polarity from ADV. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, ALE is kept stable.

15.4.4.12.1.5 NAND Device Data Read and Write Phase Control in Stream Mode

NAND device data read and write accesses are achieved through a read or write request to the chip-select-associated memory region at any address location in the region or through a read or write request to the GPMC_NAND_DATA_i location (where i = 0 to 7) mapped in the chip-select-associated control register region. GPMC_NAND_DATA_i is not a true register, but an address location to enable nRE or nWE signal control. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Reading data from the GPMC_NAND_DATA_i location or from any location in the associated chip-select memory region activates an asynchronous read access.

- nCS is controlled by the CSONTIME and CSRDOFFTIME timing parameters.
- nRE is controlled by the OEONTIME and OEOFFTIME timing parameters.
- To take advantage of nRE high-to-data invalid minimum timing value, RDACCESSTIME can be set so that data are effectively captured after nRE deassertion. This allows optimization of NAND read access cycle time completion. For optimal timing parameter settings, see the NAND device and the device timing parameters.

ALE, CLE, and nWE are maintained inactive.

Figure 15-82 shows the NAND data read cycle.

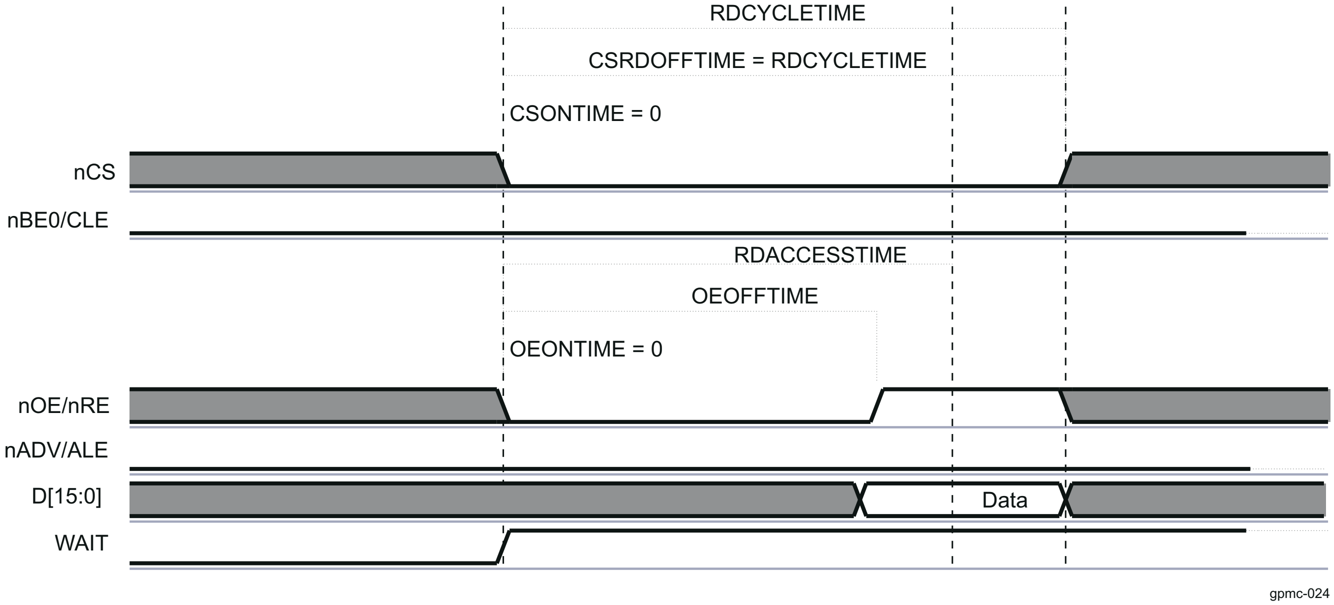

Figure 15-82. NAND Data Read Cycle

Writing data to the GPMC_NAND_DATA_i location or to any location in the associated chip-select memory region activates an asynchronous write access.

- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE, CLE, and nRE (nOE) are maintained inactive.

Figure 15-83 shows the NAND data write cycle.

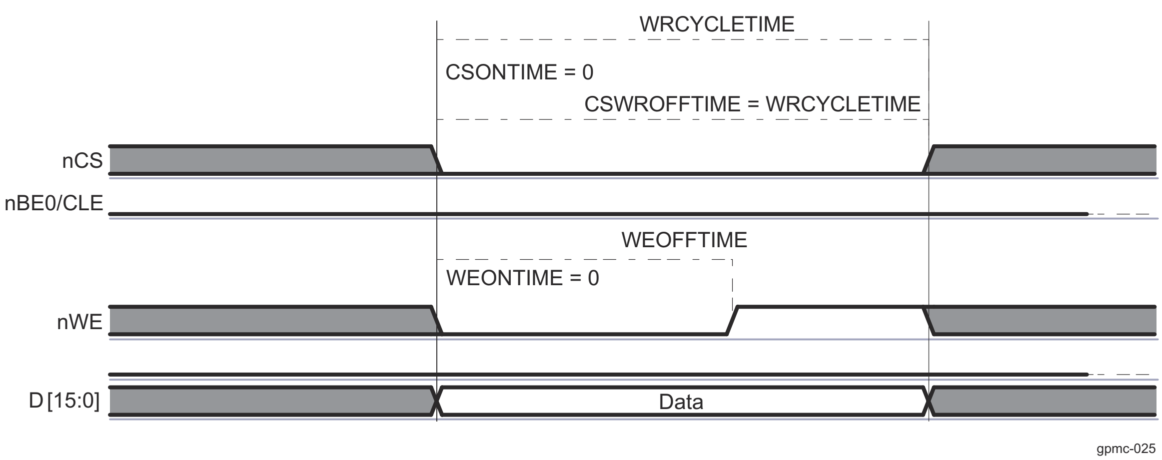

Figure 15-83. NAND Data Write Cycle

15.4.4.12.1.6 NAND Device General Chip-Select Timing Control Requirement

For most NAND devices, read data access time is dominated by nCS-to-data-valid timing and has faster nRE-to-data-valid timing. Successive accesses with nCS deassertions between accesses are affected by this timing constraint. Because accesses to a NAND device can be interleaved with other chip-select accesses, there is no certainty that nCS always stays low between two accesses to the same chip-select. Moreover, an nCS deassertion time between the same chip-select NAND accesses is likely to be required as follows: the nCS deassertion requires programming CYCLETIME and RDACCESSTIME according to the nCS-to-data-valid critical timing.

To get full performance from NAND read and write accesses, the prefetch engine can dynamically reduce the following on back-to-back NAND accesses (to the same memory) and suppress the minimum nCS high pulse width between accesses:

- RDCYCLETIME
- WRCYCLETIME
- RDACCESSTIME
- WRACCESSTIME
- CSRDOFFTIME
- CSWROFFTIME
- ADVRDOFFTIME
- ADVWROFFTIME
- OEOFFTIME
- WEOFFTIME

For more information about optimal prefetch engine access, see Section 15.4.4.12.4, *Prefetch and Write-Posting Engine*.

Some NAND devices require minimum write-to-read idle time, especially for device-status read accesses following status-read command programming (write access). If such write-to-read transactions are used, a minimum nCS high pulse width must be set. For this, CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDELAY must be set according to the appropriate timing requirement to prevent any timing violation.

NAND devices usually have an important nRE high-to-data bus in three-state mode. This requires a bus turnaround setting (BUSTURNAROUND = 1) so that the next access to a different chip-select is delayed until the BUSTURNAROUND delay completes. Back-to-back NAND read accesses to the same NAND flash are not affected by the programmed bus turnaround delay.

15.4.4.12.1.7 Read and Write Access Size Adaptation

15.4.4.12.1.7.1 8-Bit-Wide NAND Device

Host 16- and 32-bit word read and write access requests to a chip-select associated with an 8-bit-wide NAND device are split into successive read and write byte accesses to the NAND memory device. Byte access is ordered according to little-endian organization. A NAND 8-bit-wide device must be interfaced on the D0D7 interface bus lane. GPMC data accesses are justified on this bus lane when the cs is associated with an 8-bit-wide NAND device.

15.4.4.12.1.7.2 16-Bit-Wide NAND Device

Host 32-bit word read and write access requests to a chip-select associated with a 16-bit-wide NAND device are split into successive read and write 16-bit word accesses to the NAND memory device. 16-bit word access is ordered according to little-endian organization.

Host byte read and write access requests to a 16-bit-wide NAND device are completed as 16-bit accesses on the device itself, because there is no byte-addressing capability on 16-bit-wide NAND devices. This means that the NAND device address pointer is incremented on a 16-bit word basis and not on a byte basis. For a read access, only the requested byte is given back to the host, but the remaining byte is not stored or saved by the GPMC, and the next byte or 16-bit word read access gets the next 16-bit word NAND location. For a write access, the invalid byte part of the 16-bit word is driven to FF, and the next byte or 16-bit word write access programs the next 16-bit word NAND location.

Generally, byte access to a 16-bit-wide NAND device must be avoided, especially when ECC calculation is enabled. 8- or 16-bit ECC-based computations are corrupted by a byte read to a 16-bit-wide NAND device, because the nonrequested byte is considered invalid on a read access (not captured on the external data bus; FF is fed to the ECC engine) and is set to FF on a write access.

Host requests (read/write) issued in the chip-select memory region are translated in successive single or split accesses (read/write) to the attached device. Therefore, incrementing 32-bit burst requests are translated in multiple 32-bit sequential accesses following the access adaptation of the 32-bit to 8- or 16-bit device.

15.4.4.12.2 NAND Device-Ready Pin

The NAND memory device provides a ready pin to indicate data availability after a block/page opening and to indicate that data programming is complete. The ready pin can be connected to one of the wait GPMC input pins; data read accesses must not be tried when the ready pin is sampled inactive (device is not ready) even if the associated chip-select WAITREADMONITORING bit field is set. The duration of the NAND device busy state after the block/page opening is so long (up to 50 micro second) that accesses occurring when the ready pin is sampled inactive can stall GPMC access and eventually cause a system time-out.

Note

If a read access to a NAND flash is done using wait monitoring mode, the device is blocked during a page opening, and so is the GPMC. If the correct settings are used, other chip-selects can be used while the memory processes the page opening command.

To avoid a time-out caused by a block/page opening delay in NAND flash, disable the wait pin monitoring for read and write accesses (that is, set the GPMC_CONFIG1_i[21] WAITWRITEMONITORING and GPMC_CONFIG1_i[22] WAITREADMONITORING bits to 0, where i = 0 to 7), and use one of the following methods instead:

- Use software to poll the WAITxSTATUS bit (where x = 0 to 2) of the GPMC_STATUS .
- Configure an interrupt that is generated on the WAIT signal change (through the GPMC_IRQENABLE register bits[11:8]).

Even if the READWAITMONITORING bit is not set, the external memory nR/B pin status is captured in the programmed wait bit in the GPMC_STATUS register.

The READWAITMONITORING bit method must be used for other memories than NAND flash, if they require the use of a WAIT signal.

15.4.4.12.2.1 Ready Pin Monitored by Software Polling

The ready signal state can be monitored through the GPMC_STATUS WAITxSTATUS bit (where x = 0 to 2). Software must monitor the ready pin only when the signal is declared valid. Refer to the NAND device timing parameters to set the correct software temporization to monitor ready only after the invalid window is complete from the last read command written to the NAND device.

15.4.4.12.2.2 Ready Pin Monitored by Hardware Interrupt

Each gpmc_wait input pin can generate an interrupt when a wait-to-no-wait transition is detected. Depending on whether the GPMC_CONFIG WAITxPINPOLARITY bits (where x = 0 to 2) is active low or active high, the wait-to-no-wait transition is a low-to-high external WAIT signal transition or a high-to-low external WAIT signal transition, respectively.

The wait transition pin detector must be cleared before any transition detection. This is done by writing 1 to the WAITxEDGEDETECTIONSTATUS bit (where x = 0 to 2) of the GPMC_IRQSTATUS register according to the gpmc_wait pin used for the NAND device-ready signal monitoring. To detect a wait-to-no-wait transition, the transition detector requires a wait active time detection of a minimum of two GPMC_FCLK cycles. Software must incorporate precautions to clear the wait transition pin detector before wait (busy) time completes.

A wait-to-no-wait transition detection can issue a GPMC interrupt if the WAITxEDGEDETECTIONENABLE bit in the GPMC_IRQENABLE register is set and if the WAITxEDGEDETECTIONSTATUS bit field in the GPMC_IRQSTATUS register is set.

The WAITMONITORINGTIME bit field does not affect wait-to-no-wait transition time detection.

It is also possible to poll the WAITxEDGEDETECTIONSTATUS bit field in the GPMC_IRQSTATUS register according to the gpmc_wait pin used for NAND device ready signal monitoring.

15.4.4.12.3 ECC Calculator

The GPMC includes an error code correction (ECC) calculator circuitry that enables ECC calculation on the fly during data read or data program (that is, write) operations. The page size supported by the ECC calculator in one calculation/context is 512 bytes.

The user can choose from two different algorithms with different error correction capabilities through the GPMC_ECC_CONFIG[16] ECCALGORITHM bit:

1. Hamming code for 1-bit error code correction on 8- or 16-bit NAND flash organized with page size greater than 512 bytes
2. Bose-Chaudhurl-Hocquenghem (BCH) code for 4- to 16-bit error correction

The GPMC does not handle the error code correction directly. During writes, the GPMC computes parity bits. During reads, the GPMC provides enough information for the processor to correct errors without reading the data buffer all over again.

The Hamming code ECC is based on a 2-dimensional (2D) (row and column) bit parity accumulation. This parity accumulation is accomplished on the programmed number of bytes or 16-bit words read from the memory device, or is written to the memory device in stream mode.

Because the ECC engine includes only one accumulation context, it can be allocated to only one chip-select at a time through the GPMC_ECC_CONFIG[3:1] ECCCS bit field. Even if two chip-selects use different ECC algorithms, one the Hamming code and the other a BCH code, they must define separate ECC contexts because some of the ECC registers are common to all types of algorithms.

15.4.4.12.3.1 Hamming Code

All references to ECC in this subsection refer to the 1-bit error correction Hamming code.

The ECC is based on a 2D (row and column) bit parity accumulation known as the Hamming code. The parity accumulation is done for a programmed number of bytes or 16-bit word read from the memory device or written to the memory device in stream mode.

There is no automatic error detection or correction, and the software NAND driver must read the multiple ECC calculation results, compare them to the expected code value, and take the appropriate corrective actions according to the error handling strategy (ECC storage in spare byte, error correction on read, block invalidation).

The ECC engine includes a single accumulation context. It can be allocated to a single designated chip-select at a time, and parallel computations on different chip-selects are not possible. Because it is allocated to a single chip-select, the ECC computation is not affected by interleaved GPMC accesses to other chip-selects and devices. The ECC accumulation is sequentially processed in the order of data read from or written to the memory on the designated chip-select. The ECC engine does not differentiate read accesses from write accesses and does not differentiate data from command or status information. Software must ensure that only relevant data are passed to the NAND flash memory while the ECC computation engine is active.

The starting NAND page location must be programmed first, followed by an ECC accumulation context reset with an ECC enabling, if required. The NAND device accesses discussed in the following sections must be limited to data read or write until the specified number of ECC calculations is complete.

15.4.4.12.3.1.1 ECC Result Register and ECC Computation Accumulation Size

The GPMC includes up to nine ECC result registers (GPMC_ECCj_RESULT, where j = 1 to 9) to store ECC computation results when the specified number of bytes or 16-bit words has been computed.

The ECC result registers are used sequentially: one ECC result is stored in one ECC result register on the list, the next ECC result is stored in the next ECC result register on the list, and so forth, until the last ECC computation. The value of the GPMC_ECCj_RESULT register is valid only when the programmed number of bytes or 16-bit words has been accumulated, which means that the same number of bytes or 16-bit words has been read from or written to the NAND device in sequence.

The GPMC_ECC_CONTROL[3:0] ECCPOINTER bit field must be set to the correct value to select the ECC result register to be used first in the list for the incoming ECC computation process. The ECCPointer can be read to determine which ECC register is used in the next ECC result storage for the ongoing ECC computation. The value of the GPMC_ECCj_RESULT register (where j = 1 to 9) can be considered valid when ECCPOINTER equals j + 1. When the GPMC_ECCj_RESULT register (where j = 9) is updated, ECCPOINTER is frozen at 10, and ECC computing is stopped (ECCENABLE = 0).

The ECC accumulator must be reset before any ECC computation accumulation process. The GPMC_ECC_CONTROL[8] ECCCLEAR bit must be set to 1 (nonpersistent bit) to clear the accumulator and all ECC result registers.

For each ECC result (each GPMC_ECCj_RESULT register, where j = 1 to 9), the number of bytes or 16-bit words used for ECC computing accumulation can be selected from between two programmable values.

The ECCjRESULTSIZE bits (where j = 1 to 9) in the GPMC_ECC_SIZE_CONFIG register select which programmable size value (ECCSIZE0 or ECCSIZE1) must be used for this ECC result (stored in the GPMC_ECCj_RESULT register).

The ECCSIZE0 and ECCSIZE1 bit fields allow selection of the number of bytes or 16-bit words used for ECC computation accumulation. Any even values from 2 to 512 are allowed.

Flexibility in the number of ECCs computed and the number of bytes or 16-bit words used in the successive ECC computations enables different NAND page error-correction strategies. Usually based on 256 or 512 bytes and on 128 or 256 16-bit word, the number of ECC results required is a function of the NAND device page size. Specific ECC accumulation size can be used when computing the ECC on the NAND spare byte.

For example, with a 2-KiB data page, 8-bit-wide NAND device, eight ECCs accumulated on 256 bytes can be computed and added to one extra ECC computed on the 24 spare bytes area where the eight ECC results used for comparison and correction with the computed data page ECC are stored. The GPMC then provides nine GPMC_ECCj_RESULT registers (j = 1 to 9) to store the results. In this case, ECCSIZE0 is set to 256, and ECCSIZE1 is set to 24; the ECC[1:8] RESULTSIZE bits are set to 0, and the ECC9RESULTSIZE bit is set to 1.

15.4.4.12.3.1.2 ECC Enabling

The GPMC_ECC_CONFIG[3:1] ECCCS bit field selects the allocated chip-select. The GPMC_ECC_CONFIG[0] ECCENABLE bit enables ECC computation on the next detected read or write access to the selected chip-select.

The following fields must not be changed or cleared while an ECC computation is in progress:

- CCPOINTER
- ECCCLEAR
- ECCSIZE
- ECCjRESULTSIZE (where j = 1 to 9)
- ECC16B
- ECCCS

The ECC accumulator and ECC result register must not be changed or cleared while an ECC computation is in progress.

Table 15-426 describes the ECC enable settings.

Table 15-426. ECC Enable Settings

Bit Field	Register	Value	Comments
ECCCS	GPMC_ECC_CONFIG	0–3	Selects the chip-select where ECC is computed
ECC16B	GPMC_ECC_CONFIG	0/1	Selects column number for ECC calculation
ECCCLEAR	GPMC_ECC_CONTROL	0–7	Clears all ECC result registers
ECCPOINTER	GPMC_ECC_CONTROL	0–7	A write to this bit field selects the ECC result register where the first ECC computation is stored. Set to 1 by default.

Table 15-426. ECC Enable Settings (continued)

Bit Field	Register	Value	Comments
ECCSIZE1	GPMC_ECC_SIZE_CONFIG	0x00–0xFF	Defines ECCSIZE1
ECCSIZE0	GPMC_ECC_SIZE_CONFIG	0x00–0xFF	Defines ECCSIZE0
ECCjRESULTSIZE (j from 1 to 9)	GPMC_ECC_SIZE_CONFIG	0/1	Selects the size of ECCn result register
ECCENABLE	GPMC_ECC_CONFIG	1	Enables the ECC computation

15.4.4.12.3.1.3 ECC Computation

The ECC algorithm is a multiple parity bit accumulation computed on the odd and even bit streams extracted from the byte or Word16 streams. The parity accumulation is split into row and column accumulations, as shown in Figure 15-84 and Figure 15-85. The intermediate row and column parities are used to compute the upper level row and column parities. Only the final computation of each parity bit is used for ECC comparison and correction.

P1o = bit7 XOR bit5 XOR bit3 XOR bit1 on each byte of the data stream
P1e = bit6 XOR bit4 XOR bit2 XOR bit0 on each byte of the data stream

P2o = bit7 XOR bit6 XOR bit3 XOR bit2 on each byte of the data stream
P2e = bit5 XOR bit4 XOR bit1 XOR bit0 on each byte of the data stream

P4o = bit7 XOR bit6 XOR bit5 XOR bit4 on each byte of the data stream
P4e = bit3 XOR bit2 XOR bit1 XOR bit0 on each byte of the data stream

Each column parity bit is XORed with the previous accumulated value.

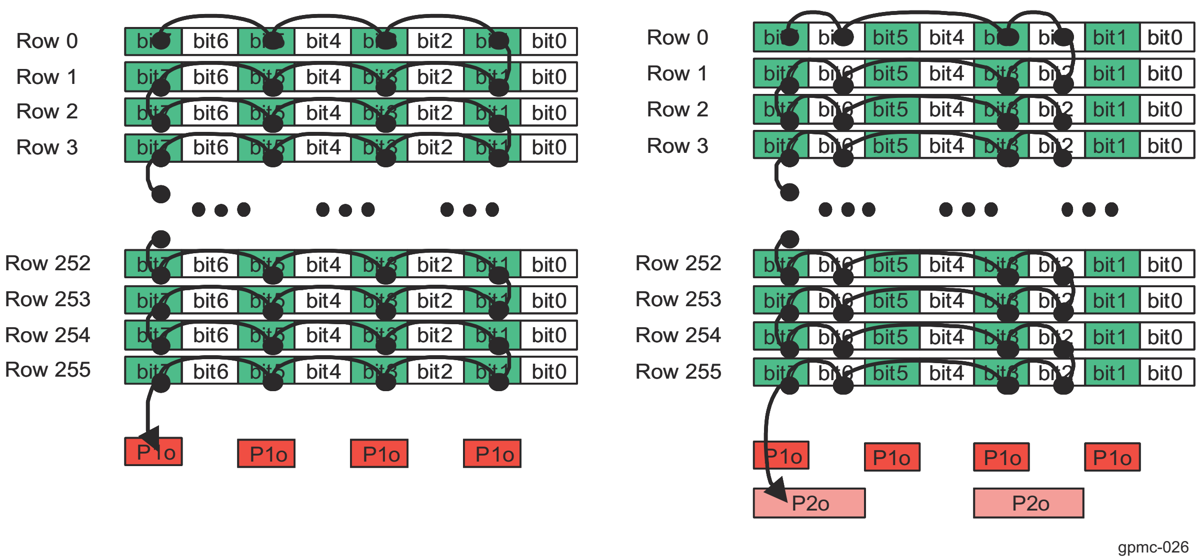

Figure 15-84. Hamming Code Accumulation Algorithm (1/2)

For line parities, the bits of each new data are XORed together, and line parity bits are computed as described below:

P8e = row0 XOR row2 XOR row4 XOR ... XOR row254
P8o = row1 XOR row3 XOR row5 XOR ... XOR row255

P16e = row0 XOR row1 XOR row4 XOR row5 XOR ... XOR row252 XOR row 253
P16o = row2 XOR row3 XOR row6 XOR row7 XOR ... XOR row254 XOR row 255

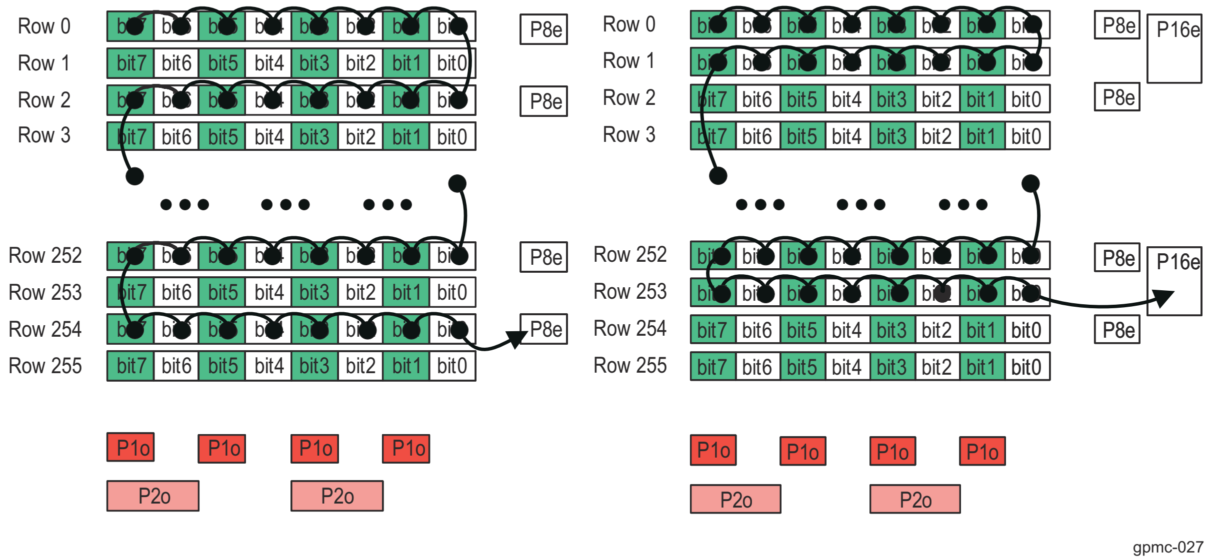

Figure 15-85. Hamming Code Accumulation Algorithm (2/2)

Unused parity bits in the result registers are set to 0.

Figure 15-86 shows ECC computation for a 256-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and sixteen row parity bits (P8o-P16o-P32o--P1024o for odd parities, and P8e-P16e-P32e--P1024e for even parities).

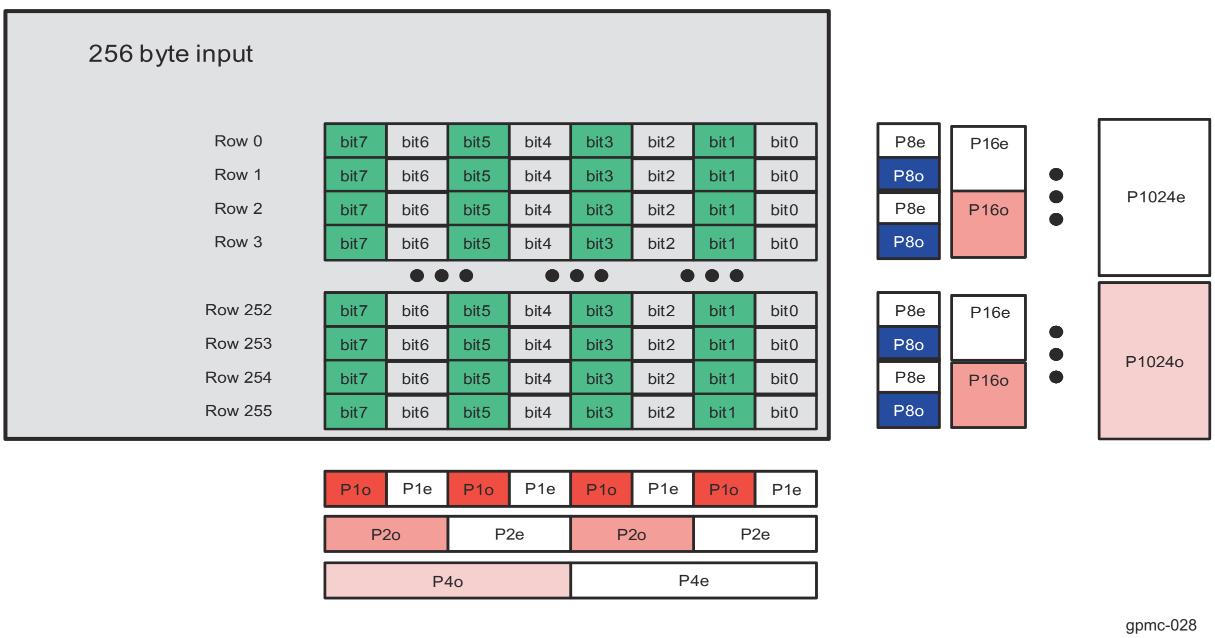

Figure 15-86. ECC Computation for a 256-Byte Data Stream (Read or Write)

Figure 15-87 shows ECC computation for a 512-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and eighteen row parity bits (P8o-P16o-P32o--P1024o- - P2048o for odd parities, and P8e-P16e-P32e--P1024e- P2048e for even parities).

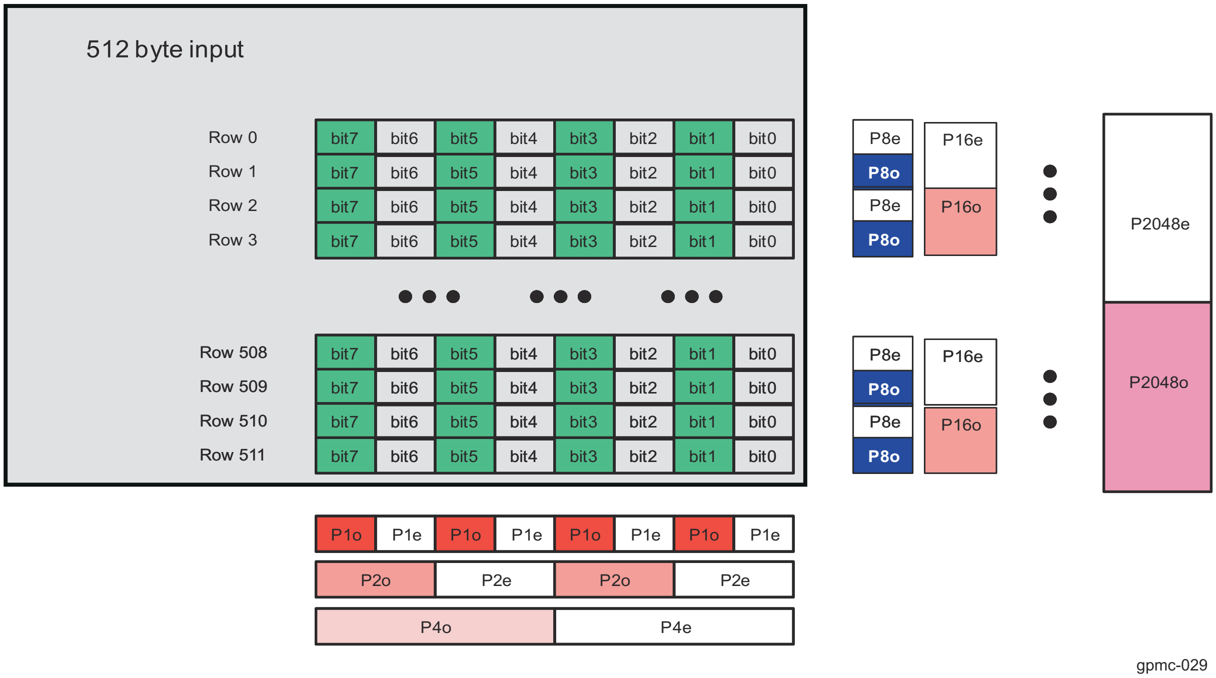

Figure 15-87. ECC Computation for a 512-Byte Data Stream (Read or Write)

For a 2-KiB page, four 512 bytes ECC calculations plus 1 for the spare area are required. Results are stored in the GPMC_ECCj_RESULT registers (where j = 1 to 9).

15.4.4.12.3.1.4 ECC Comparison and Correction

To detect an error, the computed ECC result must be XORed with the parity value stored in the spare area of the accessed page.

- If the result of this logical XOR is all 0s, no error is detected and the read data is correct.
- If every second bit in the parity result is a 1, 1 bit is corrupted and is located at bit address (P2048o, P1024o, P512o, P256o, P128o, P64o, P32o, P16o, P8o, P4o, P2o, P1o). Software must correct the corresponding bit.
- If only 1 bit in the parity result is 1, it is an ECC error and the read data is correct.

15.4.4.12.3.1.5 ECC Calculation Based on 8-Bit Word

The 8-bit-based ECC computation is used for 8-bit-wide NAND device interfacing.

The 8-bit-based ECC computation can be used for 16-bit-wide NAND device interfacing to get backward compatibility on the error-handling strategy used with 8-bit-wide NAND devices. In this case, the 16-bit-wide data read from or written to the NAND device is fragmented into 2 bytes. According to little-endian access, the LSB of the 16-bit-wide data is ordered first in the byte stream used for 8-bit-based ECC computation.

15.4.4.12.3.1.6 ECC Calculation Based on 16-Bit Word

ECC computation based on an 16-bit word is used for 16-bit-wide NAND device interfacing. This ECC computation is not supported when interfacing an 8-bit-wide NAND device, and the GPMC_ECC_CONFIG[7] ECC16B bit must be set to 0 when interfacing an 8-bit-wide NAND device.

The parity computation based on 16-bit words affects the row and column parity mapping. The main difference is that the odd and even parity bits P8o and P8e are computed on rows for an 8-bit-based ECC and on columns for a 16-bit based ECC. Figure 15-88 and Figure 15-89 show a 128 Word16 ECC computation scheme and a 256 16-bit word ECC computation scheme.

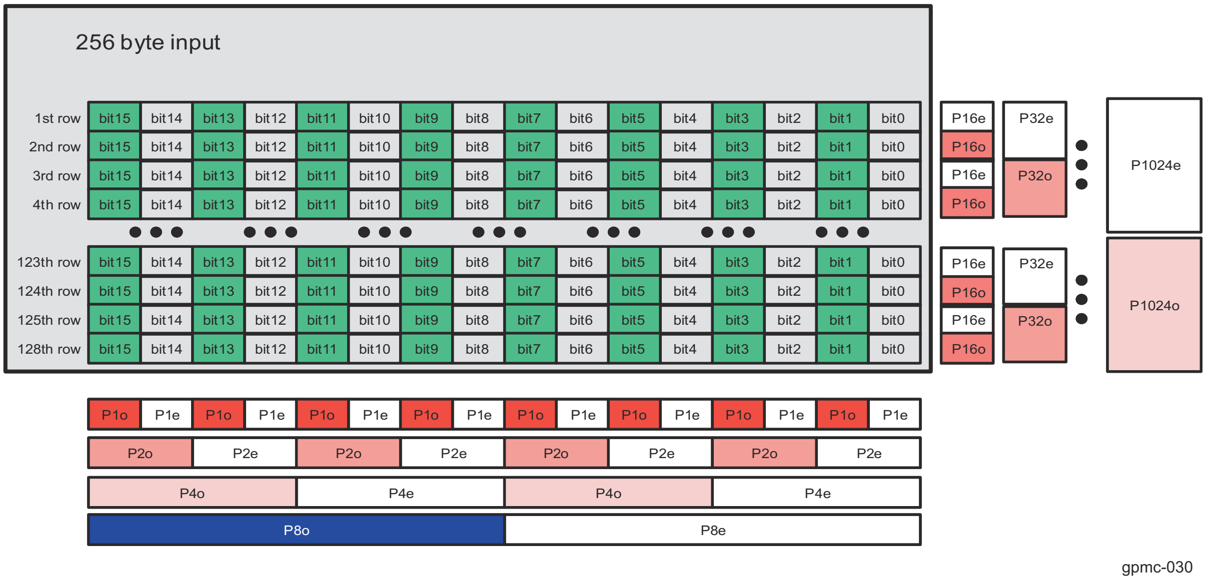

Figure 15-88. 128 Word16 ECC Computation

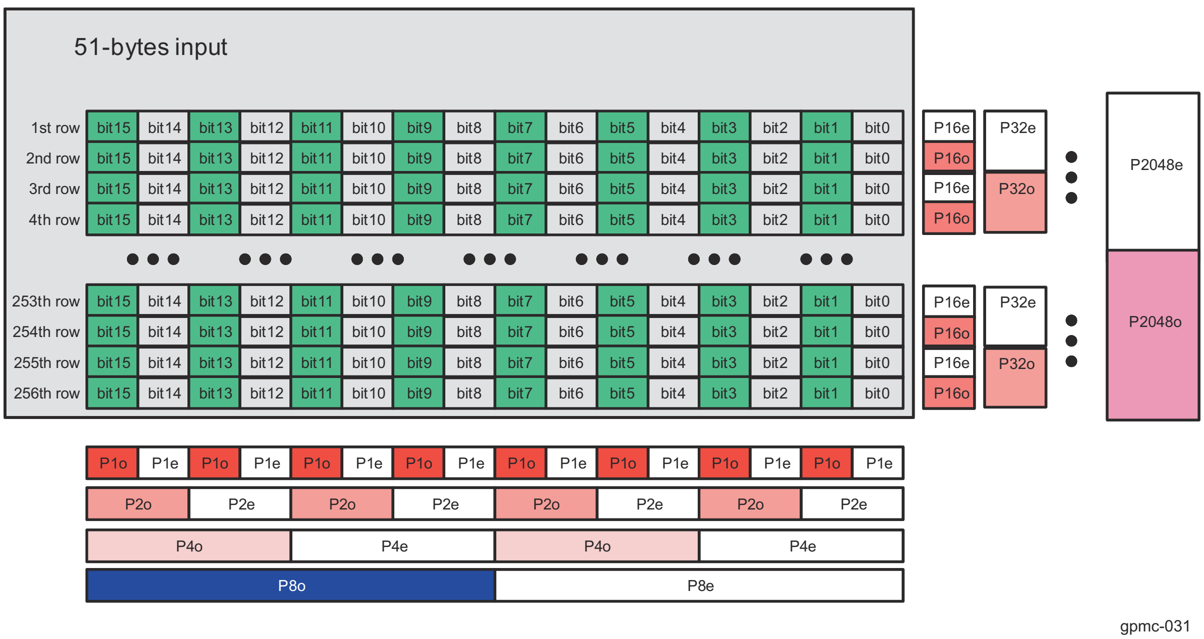

Figure 15-89. 256 Word16 ECC Computation

15.4.4.12.3.2 BCH Code

All references to ECC in this subsection refer to the 4- to 16-bit error correction BCH code.

15.4.4.12.3.2.1 Requirements

1. Read and write accesses to a NAND flash take place by whole pages, in a predetermined sequence: first the data byte page itself, and then some spare bytes, including the BCH ECC (and other information). The NAND device can cache a full page, including spares, for read and write accesses.
   - Typical page write sequence:
     – Sequential write to NAND cache of main data plus spare data, for a page. ECC is calculated on the fly. Calculated ECC can be inserted on the fly in the spares or replaced by dummy accesses.

  - When the calculated ECC is replaced by dummy accesses, it must be written to the cache in a second, separate phase. The ECC module is disabled during that time.
  - NAND writes its cache line (page) to the array.
- Typical page read sequence:
  - Sequential read of a page. ECC is calculated on the fly.
  - The status of the ECC module buffers determines the presence of errors.

2. Accesses to several memories can be interleaved by the GPMC, but only one of those memories at a time can be a NAND using the BCH engine; in other words, only one BCH calculation (for example, for a single page) can be ongoing at any time. The sequential nature of NAND accesses ensures that the data is always written or read out in the same order. BCH-relevant accesses are selected by the chip-selects of the GPMC.
3. Each page can hold up to 4KiB of data, spare bytes not included. This means up to 8 × 512-byte BCH messages. Because all the data is written or read out first, followed by the BCH ECC, the BCH engine must be able to hold eight 104-bit remainders or syndromes (or smaller, 52-bit ones) at the same time.

   The BCH module can store all remainders internally. After the page start, an internal counter is used to detect the 512-byte sector boundaries. On those boundaries, the current remainder is stored and the divider reset for the next calculation. At the end of the page, the BCH module contains all remainders.
4. NAND access cycles hold 8 or 16 bits of data each (1 or 2 bytes); Each NAND cycle takes at least four cycles of the GPMC internal clock. This means the NAND flash timing parameters must define a RDCYCLETIME and a WRCYCLETIME of at least four clock cycles after optimization when using the BCH calculator.
5. The spare area is assumed to be large enough to hold the BCH ECC; that is, to have a message of at least 13 bytes available per 512-byte sector of data. The zone of unused spare area by the ECC may or may not be protected by the same ECC scheme, by extending the BCH message beyond 512 bytes (the maximum codeword is 1023 bytes long, ECC included, which leaves much space to cover spare bytes).

15.4.4.12.3.2.2 Memory Mapping of BCH Codeword

BCH encoding considers a block of data to protect as a polynomial message M(x). In a standard case, 512 bytes of data (that is, 2^{12} bits = 4096 bits) are seen as a polynomial of degree $2^{12} – 1 = 4095$, with parameters ranging from M0 to M4095. For 512 bytes of data, 52 bits are required for 4-bit error correction, 104 bits are required for 8-bit error correction, and 207 bits are required for 16-bit error correction. The ECC is a remainder polynomial R(x) of degree 103 (or 51, depending on the selected mode). The complete codeword C(x) is the concatenation of M(x) and R(x), as described in Table 15-427.

Table 15-427. Flattened BCH Codeword Mapping (512 Bytes + 104 Bits)

	Message M(x)			ECC R(x)		
Bit Number	M4095	...	M0	R103	...	R0

If the message is extended by the addition of spare bytes to be protected by the same ECC, the principle is still valid. For example, a 3-byte extension of the message gives a polynomial message M(x) of degree ((512 + 3) × 8) – 1 = 4119, for a total of 3 + 13 = 16 spare bytes of spare, all protected as part of the same codeword.

The message and the ECC bits are manipulated and mapped in the GPMC byte-oriented system. The ECC bits are stored in the following registers (where i = 0 to 7):

- GPMC_BCH_RESULT0_i
- GPMC_BCH_RESULT1_i
- GPMC_BCH_RESULT2_i
- GPMC_BCH_RESULT3_i

15.4.4.12.3.2.2.1 Memory Mapping of Data Message

The data message mapping must follow the following rules:

- Bit endianness within a byte is little-endian; that is, the bytes LSB is also the lowest-degree polynomial parameter: a byte b7-b0 (with b0 the LSB) represents a segment of polynomial $b7 * x^{(7+i)} + b6 * x^{(6+i)} + ... + b0 * x^{i}$

- The message is mapped in the NAND starting with the highest-order parameters, that is, in the lowest addresses of a NAND page.
- Byte endianness within the 16-bit words in the NAND is big-endian (that is, the same message mapped in 8- and 16-bit memories has the same content at the same byte address).

Note

The BCH module has no visibility over actual addresses. The most important point is the sequence of data words the BCH sees. However, the NAND page is always scanned incrementally in read and write accesses, which produces the mapping patterns described in the following.

Table 15-428 and Table 15-429 describe the mapping of the same 512-byte vector (typically, a BCH message) in the NAND memory space. The byte address is only an offset modulo 512 (0x200), because the same page may contain several contiguous 512-byte sectors (BCH blocks). The LSB and MSB are, respectively, the bits M0 and M(2^{12}–1) of the codeword mapping discussed previously. In both cases the data vectors are aligned; that is, their boundaries coincide with the RAM data word boundaries.

Table 15-428. Aligned Message Byte Mapping in 8-Bit NAND

Byte Offset	8-Bit Word
0x000	(MSB) Byte 511 (0x1FF)
0x001	Byte 510 (0x1FE)
...	...
0x1FF	Byte 0 (0x0) (LSB)

Table 15-429. Aligned Message Byte Mapping in 16-Bit NAND

Byte Offset	16-Bit Word MSB	16-Bit Word LSB
0x000	Byte 510 (0x1FE)	(MSB) Byte 511 (0x1FF)
0x002	Byte 508 (0x1FC)	Byte 509 (0x1FD)
...	...	...
0x1FE	Byte 0 (0x0)	(LSB) Byte 1 (0x1)

Table 15-430 through Table 15-435 list the mapping in memory of arbitrarily-sized messages, starting on access (byte or 16-bit word) boundaries for more clarity. Note that message may actually start and stop on arbitrary nibbles. A nibble is a 4-bit entity. The unused nibbles are not discarded, and they can still be used by the BCH module, but as part of the next message section (for example, on the ECC of another sector).

Table 15-430. Aligned Nibble Mapping of Message in 8-Bit NAND

Byte Offset	8-Bit Word	
	4-Bit Most Significant Nibble	4-Bit Least Significant Nibble
1	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-3	Nibble S-4
...	...	...
S/2 – 2	Nibble 3	Nibble 2
S/2 – 1	Nibble 1	Nibble 0 (LSB)

Table 15-431. Misaligned Nibble Mapping of Message in 8-Bit NAND

	4-Bit Most Significant Nibble		4-Bit Least Significant Nibble	
0	Nibble S-3	Nibble S-4	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
...	...		...	
(S + 3) / 2 – 4	Nibble 2	Nibble 1	Nibble 4	Nibble 3
(S + 3) / 2 – 2			Nibble 0 (LSB)	

Many other cases exist than those given in the previous tables; for example, where the message does not start on a word boundary.

15.4.4.12.3.2.2.2 Memory-Mapping of the ECC

The ECC (or remainder) is presented by the BCH module as a single 104-bit (or 52-bit), little-endian vector. Software must fetch those 13 bytes (or 6 bytes) from the module interface and then store them to the spare area (page write) in the NAND or to an intermediate buffer for comparison with the stored ECC (page read). There are no constraints on the ECC mapping inside the spare area: it is software-controlled.

It is advised, however, to maintain a coherence in the respective formats of the message or the ECC remainder once they have been read out of the NAND. The error correction algorithm works from the complete codeword (concatenated message and remainder) once an error is detected. The creation of this codeword must be made as straightforward as possible.

There are cases in which the same NAND access contains both data and the ECC protecting that data. This is the case when the data/ECC boundary (which can be on any nibble) does not coincide with an access boundary. The ECC is calculated on the fly following the write. In that case, the write must also contain part of the ECC because it is impossible to insert the ECC on the fly. Instead:

- During the initial page write (BCH encoding), the ECC is replaced by dummy bits. The BCH encoder is by definition turned OFF during the ECC section, so the BCH result is unmodified.
- During a second phase, the ECC is written to the correct location, next to the actual data.
- The completed line buffer is then written to the NAND array.

15.4.4.12.3.2.2.3 Wrapping Modes

For a given wrapping mode, the module automatically goes through a specific number of sections as data is being fed into the module. For each section, the BCH core can be enabled (in which case the data is fed to the BCH divider) or not (in which case the BCH simply counts to the end of the section). When enabled, the data is added to the ongoing calculation for a given sector number (for example, number 0).

Wrapping modes are described as follows. To better understand and see the real-life read and write sequences implemented with each mode, see Section 15.4.4.12.3.2.3, *Supported NAND Page Mappings and ECC Schemes*.

For each mode:

- A sequence describes the mode in pseudo language, with, for each section, the size and the buffer used for ECC processing (if ON). The programmable lengths are size, size0, and size1.
- A checksum condition is given. If the checksum condition is not respected for a given mode, the module behavior is unpredictable. S is the number of sectors in the page; size0 and size1 are the section sizes programmed for the mode, in nibbles.

Wrapping modes 8 through 11 insert a 1-nibble padding where the BCH processing is OFF. This is intended for t = 4 ECC, where ECC is 6 bytes long and the ECC area is expected to include (at least) 1 unused nibble to remain byte-aligned.

15.4.4.12.3.2.2.3.1 Manual Mode (0x0)

This mode is intended for short sequences, added manually to a given buffer through the software data port input. A complete page may be built out of several such sequences.

To process an arbitrary sequence of 4-bit nibbles, accesses to the software data port, containing the appropriate data, must be made. If the sequence end does not coincide with an access boundary (for example, to process 5 nibbles = 20 bits in 16-bit access mode) and those nibbles must be skipped, a number of unused nibbles must be programmed in GPMC_ECC_SIZE_CONFIG[29:22] ECCSIZE1 In the same example, 5 nibbles to process + 3 to discard = 8 nibbles = 2 × 16-bit accesses. Software must set:

- GPMC_ECC_SIZE_CONFIG[19:12] ECCSIZE0 = 0x5
- GPMC_ECC_SIZE_CONFIG[29:22] ECCSIZE1 = 0x3

Note

In the following figures, size and size0 are the same parameter.

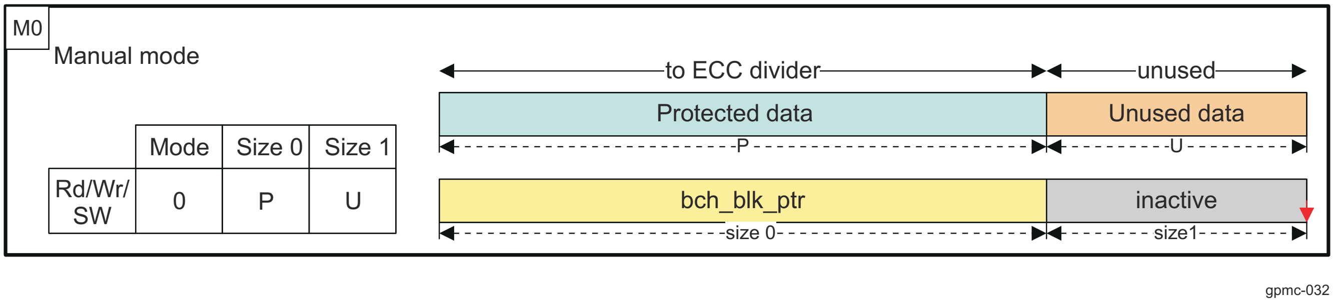

Figure 15-90. Manual Mode Sequence and Mapping

Section processing sequence:

- One time with buffer
  - size0 nibbles of data, processing ON
  - size1 nibbles of unused data, processing OFF

Checksum: size0 + size1 nibbles must fit in a whole number of accesses.

In the following sections, S is the number of sectors in the page.

15.4.4.12.3.2.2.3.2 Mode 0x1

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S – (size0 + size1)

15.4.4.12.3.2.2.3.3 Mode 0xA (10)

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
  - 1 nibble pad spare, processing OFF
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S – (size0 + 1 + size1)

15.4.4.12.3.2.2.3.4 Mode 0x2

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S – (size0 + size1)

15.4.4.12.3.2.2.3.5 Mode 0x3

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S – size1)

15.4.4.12.3.2.2.3.6 Mode 0x7

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = size0 + (S – size1)

15.4.4.12.3.2.2.3.7 Mode 0x8

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S – (1 + size1))

15.4.4.12.3.2.2.3.8 Mode 0x4

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time (no buffer used)
  - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S – size1)

15.4.4.12.3.2.2.3.9 Mode 0x9

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time (no buffer used)
  - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S – (1 + size1))

15.4.4.12.3.2.2.3.10 Mode 0x5

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S – (size0 + size1)

15.4.4.12.3.2.2.3.11 Mode 0xB (11)

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S – (size0 + 1 + size1)

15.4.4.12.3.2.2.3.12 Mode 0x6

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S – (size0 + size1)

15.4.4.12.3.2.3 Supported NAND Page Mappings and ECC Schemes

The following rules apply to the entire mapping description:

- Main data area (sectors) size is hardcoded to 512 bytes.
- Spare area size is programmable.
- All page sections (of main area data bytes, protected spare bytes, unprotected spare bytes, and ECC) are defined as explained in Section 15.4.4.12.3.2.2.1, *Memory Mapping of Data Message*.

Each of the following sections gives a NAND page mapping example (per-sector spare mappings, pooled spare mapping, per-sector spare mapping, with ECC separated at the end of the page).

In the mapping diagrams, sections that belong to the same BCH codeword have the same color (blue or green); unprotected sections are not covered (orange) by the BCH scheme.

Below each mapping diagram, a write (encoding) and read (decoding: syndrome generation) sequence is given, with the number of the active buffers at each point in time (yellow). In the inactive zones (grey), no computing is taking place but the data counter is still active.

In Figure 15-91 through Figure 15-93, the tables on the left summarize the mode, size0, and size1 parameters to program for, respectively, write and read processing of a page, with the given mapping, where:

- P is the size of spare byte section Protected by the ECC (in nibbles)
- U is the size of spare byte section Unprotected by the ECC (in nibbles)
- E is the size of the ECC (in nibbles)
- S is the number of Sectors per page (two in the current diagrams)

Each time the processing of a BCH block is complete (ECC calculation for write/encoding, syndrome generation for read/decoding, indicated by red arrows), the update pointer is pulsed. The processing for block 0 can be the first or the last to complete, depending on the NAND page mapping and operation (read or write). All examples show a page size of 1 KiB + spares; that is, S = 2 sectors of 512 bytes. The same principles can be extended to larger pages by adding more sectors.

The actual BCH codeword size is used during the error location work to restrict the search range: by definition, errors can happen only in the codeword that was actually written to the NAND, not in the mathematical codeword of $n = 2^{13} – 1 = 8191$ bits; that codeword (higher-order bits) is all-zero and implicit during computations.

The actual BCH codeword size depends on the mode, the programmed sizes, and the sector number (all sizes in nibbles):

- Spares mapped and protected per sector (below: see M1-M2-M3-M9-M10):
  - All sectors: (512) + P + E
- Spares pooled and protected by sector 0 (below: see M5-M6):
  - Sector 0 codeword: (512) + P + E
  - Other sectors: (512) + E
- Unprotected spares (below: see M4-M7-M8-M11-M12):
  - All codewords (512) + E

15.4.4.12.3.2.3.1 Per-Sector Spare Mappings

In these schemes, each 512-byte sector of the main area has its own dedicated section of the spare area. The spare area of each sector is composed of:

- ECC, which must be located after the data it protects
- Other data, which may or may not be protected by the ECC for its sector.

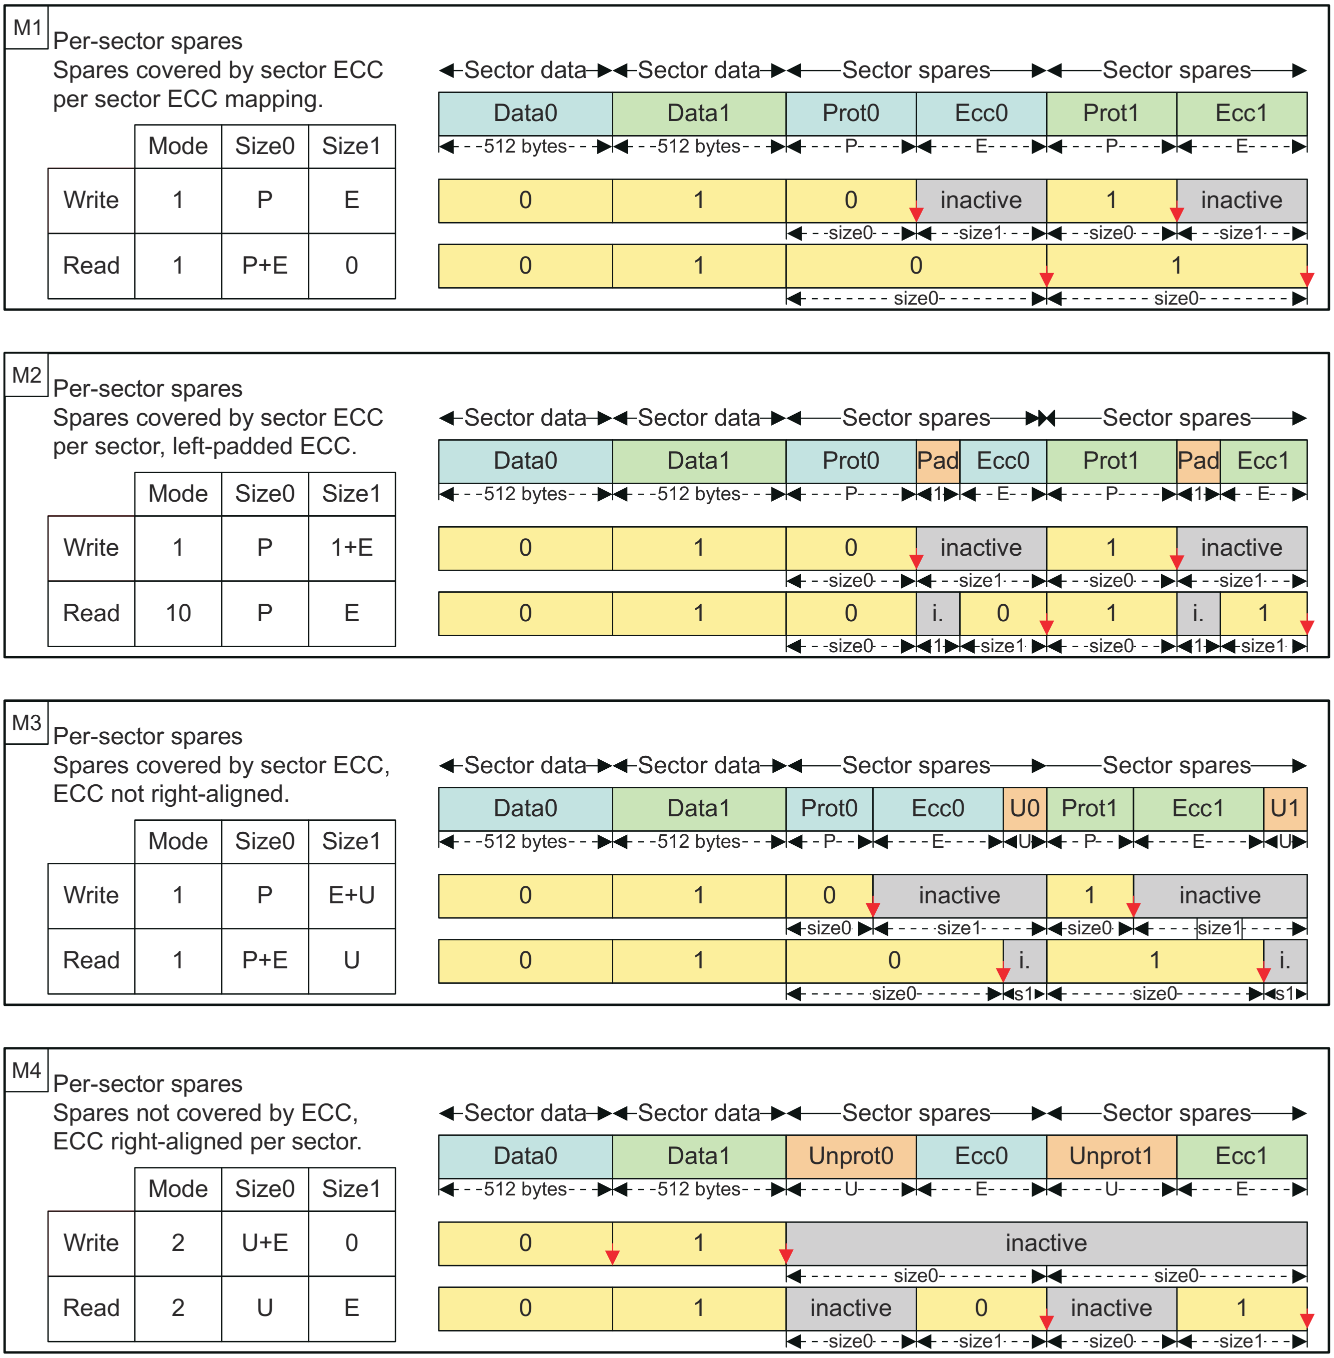

Figure 15-91. NAND Page Mapping and ECC: Per-Sector Schemes

15.4.4.12.3.2.3.2 Pooled Spare Mapping

In the following schemes, the spare area is pooled for the page.

- The ECC of each sector is aligned at the end of the spare area.
- The non-ECC spare data may or may not be covered by the ECC of sector 0.

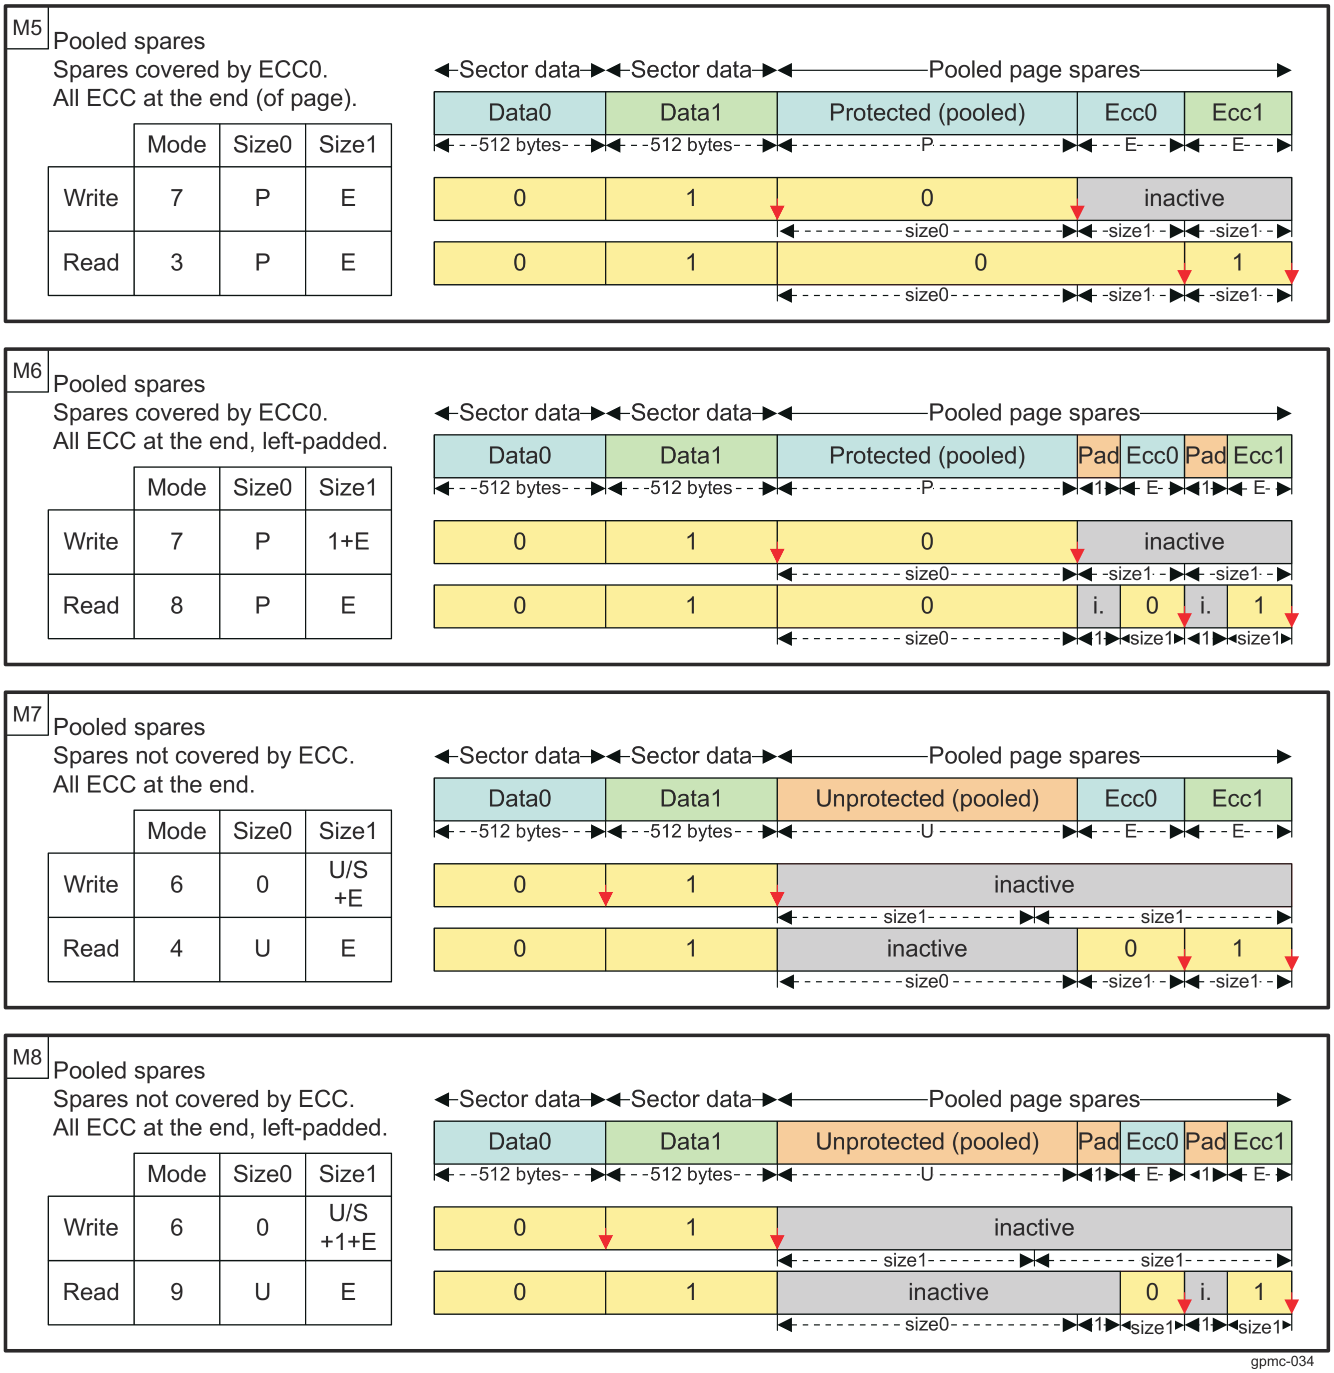

Figure 15-92. NAND Page Mapping and ECC: Pooled Spare Schemes

15.4.4.12.3.2.3.3 Per-Sector Spare Mapping, with ECC Separated at the End of the Page

In these schemes, each 512-byte sector of the main area is associated with two sections of the spare area.

- ECC section, all aligned at the end of the page
- Other data section, aligned before the ECCs, each of which may or may not be protected by the ECC for its sector.

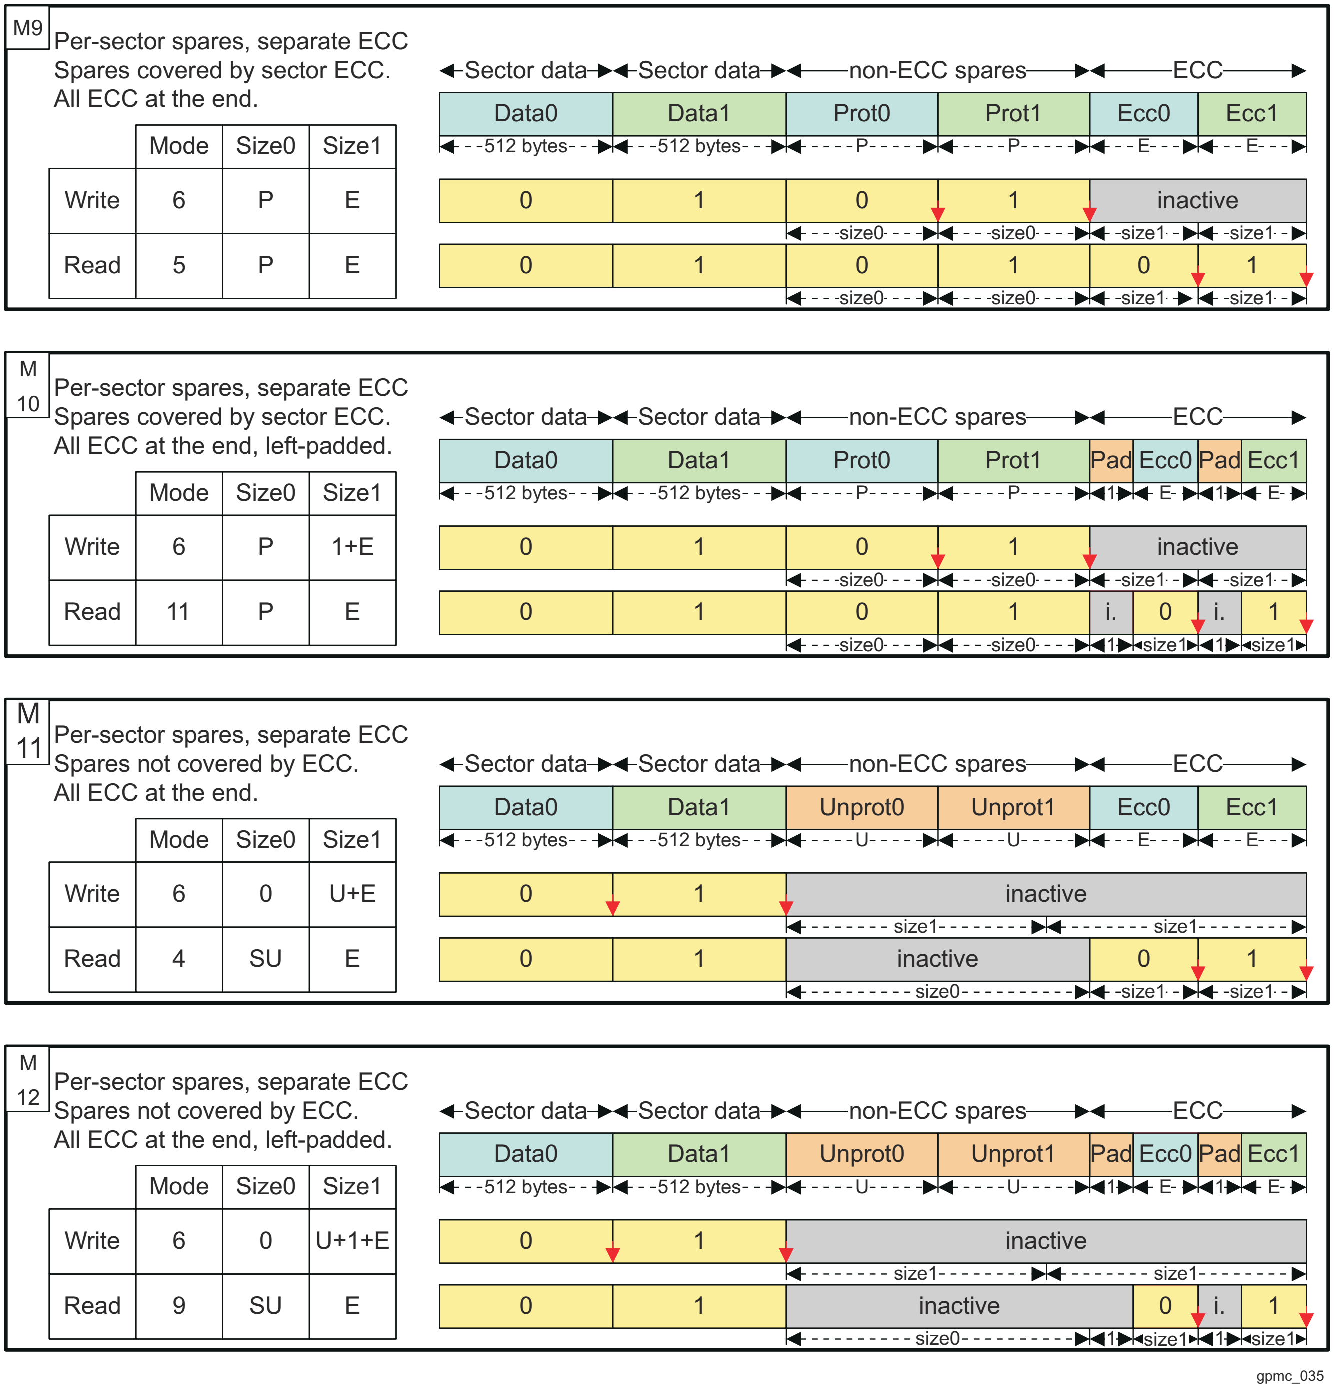

Figure 15-93. NAND Page Mapping and ECC: Per-Sector Schemes, With Separate ECC

15.4.4.12.4 Prefetch and Write-Posting Engine

NAND device data access cycles are usually much slower than the MPU system frequency; such NAND read or write accesses issued by the processor affect the overall system performance, especially considering long read or write sequences required for NAND page loading or programming. To minimize this effect on system performance, the GPMC includes a prefetch and write-posting engine, which can be used to read from or write to any chip-select location in a buffered manner.

The prefetch and write-posting engine is a simplified embedded-access requester that presents requests to the access engine on a user-defined chip-select target. The access engine interleaves these requests with any request coming from the L3 interface; as a default, the prefetch and write-posting engine has the lowest priority.

The prefetch and write-posting engine is dedicated to data-stream access (as opposed to random data access); thus, it is primarily dedicated to NAND support. The engine does not include an address generator; the request is limited to chip-select target identification. It includes a 64-byte FIFO associated with a DMA request synchronization line, for optimal DMA-based use.

The prefetch and write-posting engine uses an embedded 64-byte (32 16-bit word) FIFO to prefetch data from the NAND device in read mode (prefetch mode) or to store host data to be programmed into the NAND device in write mode (write-posting mode). The FIFO draining and filling (read and write) can be controlled by a device host processor through interrupt synchronization (an interrupt is triggered whenever a programmable threshold is reached) or by a device DMA module through DMA request synchronization, with a programmable request byte size in prefetch or posting mode.

The prefetch and write-posting engine includes a single memory pool. Therefore, only one mode, read or write, can be used at any given time. In other words, the prefetch and write-posting engine is a single-context engine that can be allocated to only one chip-select at a time for a read prefetch or a write-posting process.

The engine does not support atomic command and address phase programming and is limited to linear memory read or write access. As a consequence, it is limited to NAND data-stream access. The engine relies on the MPU NAND software driver to control block and page opening with the correct data address pointer initialization, before the engine can read from or write to the NAND memory device.

Once started, engine data read and write sequencing is based solely on FIFO location availability and until the total programmed number of bytes is read or written.

Any host-concurrent accesses to a different chip-select are correctly interleaved with ongoing engine accesses. The engine has the lowest priority access so that host accesses to a different chip-select do not suffer a large latency.

A round-robin arbitration scheme can be enabled to ensure minimum bandwidth to the prefetch and write-posting engine in the case of back-to-back direct memory requests to a different chip-select. If the GPMC_PREFETCH_CONFIG1[23] PFPWENROUNDROBIN bit is enabled, the arbitration grants the prefetch and write posting engine access to the GPMC bus for a number of requests programmed in the GPMC_PREFETCH_CONFIG1[19:16] PFPWWEIGHTEDPRIO bit field.

The prefetch/write-posting engine read or write request is routed to the access engine with the chip-select destination ID. After the required arbitration phase, the access engine processes the request as a single access with the data access size equal to the device size specified in the corresponding chip-select configuration.

Note

The destination chip-select configuration must be set to the NAND protocol-compatible configuration for which address lines are not used (the address bus is not changed from its current value). Selecting a different chip-select configuration can produce undefined behavior.

15.4.4.12.4.1 General Facts About the Engine Configuration

The engine can be configured only if the GPMC_PREFETCH_CONTROL[0] STARTENGINE bit is deasserted.

The engine must be correctly configured in prefetch or write-posting mode and must be linked to a NAND chip-select before it can be started. The chip-select is linked using the GPMC_PREFETCH_CONFIG1[26:24] ENGINECSSELECTOR bit field.

In prefetch and write-posting modes, the engine uses byte or 16-bit word access requests, respectively, for an 8- or 16-bit-wide NAND device attached to the linked chip-select. The FIFOTHRESHOLD and TRANSFERCOUNT bit fields must be programmed accordingly as a number of bytes.

When the GPMC_PREFETCH_CONFIG1[7] ENABLEENGINE bit is set, the FIFO entry on the L3 interconnect port side is accessible at any address in the associated chip-select memory region. When the ENABLEENGINE bit is set, any host access to this chip-select is rerouted to the FIFO input. Directly accessing the NAND device linked to this chip-select from the host is still possible through the following registers (where i = 0 to 7):

- GPMC_NAND_COMMAND_i
- GPMC_NAND_ADDRESS_i
- GPMC_NAND_DATA_i

The FIFO entry on the L3 interconnect port can be accessed with byte, 16-bit word, or 32-bit word access size, according to little-endian format, even though the FIFO input is 32 bits wide.

The FIFO control is made easier through the use of interrupts or DMA requests associated with the FIFOTHRESHOLD bit field. The GPMC_PREFETCH_STATUS[30:24] FIFOPOINTER bit field monitors the number of available bytes to be read in prefetch mode or the number of free empty slots that can be written in write-posting mode. The GPMC_PREFETCH_STATUS[13:0] COUNTVALUE bit field monitors the number of remaining bytes to be read or written by the engine according to the value of the TRANSFERCOUNT bit field. The FIFOPOINTER and COUNTVALUE bit fields are always expressed as a number of bytes even if a 16-bit-wide NAND device is attached to the linked chip-select.

In prefetch mode, when the FIFOPOINTER equals 0 (that is, the FIFO is empty), a host read access receives the byte last read from the FIFO as its response. In case of 32-bit word or 16-bit word read accesses, the last byte read from the FIFO is copied the required number of times to fit the requested word size. In write-posting mode, when the FIFOPOINTER equals 0 (that is, the FIFO is full), a host write overwrites the last FIFO byte location. There is no underflow or overflow error reporting in the GPMC.

15.4.4.12.4.2 Prefetch Mode

The prefetch mode is selected when the GPMC_PREFETCH_CONFIG1[0] ACCESSMODE bit is cleared.

The MPU NAND software driver must issue the block and page opening (READ) command with the correct data address pointer initialization before the engine can be started to read from the NAND memory device. The engine is started by asserting the GPMC_PREFETCH_CONTROL[0] STARTENGINE bit. The STARTENGINE bit automatically clears when the prefetch process completes.

If required, the ECC calculator engine must be initialized (that is, reset, configured, and enabled) before the prefetch engine is started so that the ECC is computed correctly on all data read by the prefetch engine.

When the GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE bit is cleared, the prefetch engine starts requesting data as soon as the STARTENGINE bit is set. If using this configuration, the host must monitor the NAND device-ready pin so that it sets the STARTENGINE bit only when the NAND device is in a ready state (that is, data is valid for prefetching).

When the SYNCHROMODE bit is set, the prefetch engine starts requesting data when an active-to-inactive WAIT signal transition is detected. The transition detector must be cleared before any transition detection (see Section 15.4.4.12.2.2, *Ready Pin Monitored by Hardware Interrupt*). The GPMC_PREFETCH_CONFIG1[5:4] WAITPINSELECTOR bit field selects which gpmc_wait pin edge detector triggers the prefetch engine in this synchronized mode.

If the STARTENGINE bit is set after the NAND address phase (page opening command), the engine is effectively started only after the actual NAND address phase completion. To prevent GPMC stall during this NAND address phase, set the STARTENGINE bit before NAND address phase completion when in synchronized mode. The prefetch engine starts when an active-to-inactive WAIT signal transition is detected. The STARTENGINE bit is automatically cleared on prefetch process completion.

The prefetch engine issues a read request to fill the FIFO with the amount of data specified by the GPMC_PREFETCH_CONFIG2[13:0] TRANSFERCOUNT bit field.

Table 15-436 describes the prefetch mode configuration.

Table 15-436. Prefetch Mode Configuration

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	0	Prefetch engine can be configured only if STARTENGINE is set to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1[26:24]	0 to 3	Selects the chip-select associated with a NAND device where the prefetch engine is active.
ACCESSMODE	GPMC_PREFETCH_CONFIG1[0]	0	Selects prefetch mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1[14:8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2[13:0]		Selects the number of bytes to be read or written by the engine to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1[3]	0/1	Selects when the engine starts the access to the chip-select
WAITPINSELECT	GPMC_PREFETCH_CONFIG1[17:16]	0 to 1	Selects wait pin edge detector (if GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE = 0x1)
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1[27]	0/1	See Section 15.4.4.12.4.6, *Optimizing NAND Access Using the Prefetch and Write-Posting Engine*.
CYCLEOPTIMIZATION	GPMC_PREFETCH_CONFIG1[30:28]		Number of clock cycle removed to timing parameters
ENABLEENGINE	GPMC_PREFETCH_CONFIG1[7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	1	Starts the prefetch engine

15.4.4.12.4.3 FIFO Control in Prefetch Mode

The FIFO can be drained directly by a device host processor or a DMA module channel.

In MPU draining mode, the FIFO status can be monitored through the GPMC_PREFETCH_STATUS[30:24] FIFOPOINTER bit field or through the GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bit. The FIFOPOINTER indicates the current number of available data to be read; FIFOTHRESHOLDSTATUS set to 1 indicates that at least FIFOTHRESHOLD bytes are available from the FIFO.

An interrupt can be triggered by the GPMC if the GPMC_IRQENABLE[0] FIFOEVENTENABLE bit is set. The FIFO interrupt event is logged, and the GPMC_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, the MPU must read all the available bytes , or at least enough bytes to get below the programmed FIFO threshold, and the FIFOEVENTSTATUS bit must be cleared to enable further interrupt events. The FIFOEVENTSTATUS bit must always be reset before asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt generation must be enabled after enabling the STARTENGINE bit.

Prefetch completion can be monitored through the GPMC_PREFETCH_STATUS[13:0] COUNTVALUE bit field. COUNTVALUE indicates the number of currently remaining data to be requested according to the TRANSFERCOUNT value. An interrupt can be triggered by the GPMC when the prefetch process is complete (that is, COUNTVALUE equals 0) if the GPMC_IRQENABLE[1] TERMINALCOUNTEVENTENABLE bit is set. At prefetch completion, the TERMINALCOUNT interrupt event is also logged, and the GPMC_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the MPU must clear the TERMINALCOUNTSTATUS bit . The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

Note

The COUNTVALUE value is valid only when the prefetch engine is active (started), and an interrupt is only triggered when COUNTVALUE reaches 0, that is, when the prefetch engine automatically goes from an active to an inactive state.

The number of bytes to be prefetched (programmed in TRANSFERCOUNT) must be a multiple of the programmed FIFOTHRESHOLD to trigger the correct number of interrupts allowing a deterministic and transparent FIFO control. If this guideline is respected, the number of ISR accesses is always required and the FIFO is always empty after the last interrupt is triggered. In other cases, the TERMINALCOUNT interrupt must be used to read the remaining bytes in the FIFO (the number of remaining bytes being lower than the FIFOTHRESHOLD value).

In DMA draining mode, the GPMC_PREFETCH_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes are ready to be read from the FIFO. The DMA channel that owns this DMA request must be programmed so that the number of bytes programmed in FIFOTHRESHOLD is read from the FIFO during the DMA request process. The DMA request is kept active until this number of bytes has effectively been read from the FIFO, and no other DMA request can be issued until the ongoing active request is complete.

In prefetch mode, the TERMINALCOUNT event is also a source of DMA requests if the number of bytes to be prefetched is not a multiple of FIFOTHRESHOLD, the remaining bytes in the FIFO can be read by the DMA channel using the last DMA request. This assumes that the number of remaining bytes to be read is known and controlled through the DMA channel programming model.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive-to-active prefetch (the STARTENGINE bit is set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that the out-of-date active DMA request does not trigger spurious DMA transfers.

15.4.4.12.4.4 Write-Posting Mode

The write-posting mode is selected when the GPMC_PREFETCH_CONFIG1[0] ACCESSMODE bit is set.

The MPU NAND software driver must issue the correct address pointer initialization command (page program) before the engine can start writing data into the NAND memory device. The engine starts when the GPMC_PREFETCH_CONTROL[0] STARTENGINE bit is set to 1. The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MPU NAND software driver must issue the second cycle program command and monitor the status for programming process completion (adding ECC handling, if required).

If used, the ECC calculator engine must be started (configured, reset, and enabled) before the posting engine is started so that the ECC parities are calculated properly on all data written by the prefetch engine to the associated chip-select.

In write-posting mode, the GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE bit must be cleared so that posting starts as soon as the STARTENGINE bit is set and the FIFO is not empty.

If the STARTENGINE bit is set after the NAND address phase (page program command), the STARTENGINE setting is effective only after the actual NAND command completion. To prevent GPMC stall during this NAND command phase, set the STARTENGINE bit field before the NAND address completion and ensure that the associated DMA channel is enabled after the NAND address phase.

The posting engine issues a write request when valid data are available from the FIFO and until the programmed GPMC_PREFETCH_CONFIG2[13:0] TRANSFERCOUNT accesses are complete.

The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MPU NAND software driver must issue the second cycle program command and monitor the status for programming process completion. The closing program command phase must be issued only when the full NAND page has been written into the NAND flash write buffer, including the spare area data and the ECC parities, if used.

Table 15-437 describes the write-posting configuration.

Table 15-437. Write-Posting Mode Configuration

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	0	Write-posting engine can be configured only if STARTENGINE is set to 0.

Table 15-437. Write-Posting Mode Configuration (continued)

Bit Field	Register	Value	Comments
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1[26:24]	0 to 3	Selects the chip-select associated with a NAND device where the prefetch engine is active
ACCESSMODE	GPMC_PREFETCH_CONFIG1[0]	1	Selects write-posting mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1[14:8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2[13:0]		Selects the number of bytes to be read or written by the engine from/to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1[3]	0	Engine starts the access to chip-select as soon as STARTENGINE is set.
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1[27]	0/1	See Section 15.4.4.12.4.6, *Optimizing NAND Access Using the Prefetch and Write-Posting Engine*.
CYCLEOPTIMIZATION	GPMC_PREFETCH_CONFIG1[30:28]		
ENABLEENGINE	GPMC_PREFETCH_CONFIG1[7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	1	Starts the prefetch engine

15.4.4.12.4.5 FIFO Control in Write-Posting Mode

The FIFO can be filled directly by a device host processor or a DMA module channel.

In MPU filling mode, the FIFO status can be monitored through the FIFOPOINTER or through the GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bit. FIFOPOINTER indicates the current number of available free byte places in the FIFO, and the FIFOTHRESHOLDSTATUS bit, when set, indicates that at least FIFOTHRESHOLD free byte places are available in the FIFO.

An interrupt can be issued by the GPMC if the GPMC_IRQENABLE[0] FIFOEVENTENABLE bit is set. When the interrupt is fired, the GPMC_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, the MPU must write enough bytes to fill the FIFO or to get below the programmed threshold, and the FIFOEVENTSTATUS bit must be cleared to get further interrupt events. The FIFOEVENTSTATUS bit must always be cleared before asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt must be enabled after enabling the STARTENGINE bit.

The posting completion can be monitored through the GPMC_PREFETCH_STATUS[13:0] COUNTVALUE bit field. COUNTVALUE indicates the current number of remaining data to be written based on the value of the TRANSFERCOUNT bit field. An interrupt is issued by the GPMC when the write-posting process completes (that is, COUNTVALUE equal to 0) if the GPMC_IRQENABLE[1] TERMINALCOUNTEVENTENABLE bit is set. When the interrupt is fired, the GPMC_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the MPU must clear the TERMINALCOUNTSTATUS bit . The TERMINALCOUNTSTATUS bit must always be cleared before asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

Note

The value of the COUNTVALUE bit field is valid only if the write-posting engine is active and started, and an interrupt is issued only when COUNTVALUE reaches 0; that is, when the posting engine automatically goes from active to inactive.

In DMA filling mode, the DMAMode bit field in the GPMC_PREFETCH_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes-free places are available in the FIFO. The DMA channel that owns this DMA request must be programmed so that a number of bytes equal to the value programmed in the FIFOTHRESHOLD bit field are written into the FIFO during the DMA access. The DMA request remains active until the associated number of bytes has effectively been written into the FIFO, and no other DMA request can be issued until the ongoing active request completes.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive-to-active prefetch (STARTENGINE set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that an out-of-date active DMA request does not trigger spurious DMA transfers.

In write-posting mode, the DMA or MPU fills the FIFO with no consideration for the associated byte enables. Any byte stored in the FIFO is written into the memory device.

15.4.4.12.4.6 Optimizing NAND Access Using the Prefetch and Write-Posting Engine

Access time to a NAND memory device can be optimized for back-to-back accesses if the associated nCS signal is not deasserted between accesses. The GPMC access engine can track prefetch engine accesses to optimize the access timing parameter programmed for the allocated chip-select, if no accesses to other chip-selects (that is, interleaved accesses) occur. Similarly, the access engine also eliminates CYCLE2CYCLEDELAY even if CYCLE2CYCLESAMECSEN is set. This capability is limited to the prefetch and write-posting engine accesses, and MPU accesses to a NAND memory device (through the defined chip-select memory region or through the GPMC_NAND_DATA_i location, where i = 0 to 7) are never optimized.

The GPMC_PREFETCH_CONFIG1[27] ENABLEOPTIMIZEDACCESS bit must be set to enable optimized accesses. To optimize access time, the GPMC_PREFETCH_CONFIG1[30:28] CYCLEOPTIMIZATION bit field defines the number of GPMC_FCLK cycles to be suppressed from the following timing parameters:

- RDCYCLETIME
- WRCYCLETIME
- RDACCESSTIME
- WRACCESSTIME
- CSOFFTIME
- ADVOFFTIME
- OEOFFTIME
- WEOFFTIME

Figure 15-94 shows that in the case of back-to-back accesses to the NAND flash through the prefetch engine, CYCLE2CYCLESAMECSEN is forced to 0 when using optimized accesses. The first access uses the regular timing settings for this chip-select. All accesses after this one use settings reduced by x clock cycles, x being defined by the GPMC_PREFETCH_CONFIG1[30:28] CYCLEOPTIMIZATION bit field.

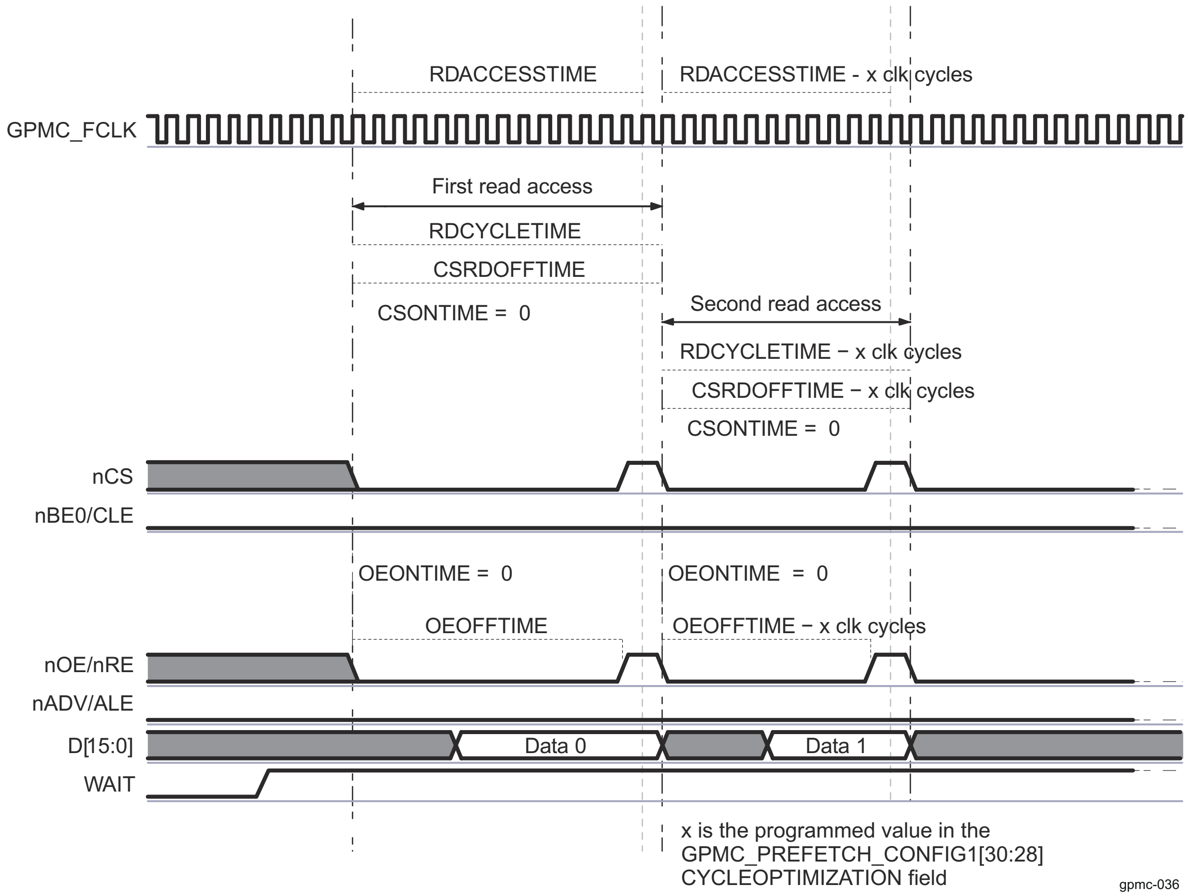

Figure 15-94. NAND Read Cycle Optimization Timing Description

15.4.4.12.4.7 Interleaved Accesses Between Prefetch and Write-Posting Engine and Other Chip-Selects

Any on-going read or write access from the prefetch and write-posting engine is completed before an access to any other chip-select can be initiated. As a default, the arbiter uses a fixed-priority algorithm, and the prefetch and write-posting engine has the lowest priority. The maximum latency added to access starting time in this case equals the RDCYCLETIME or WRCYCLETIME (optimized or not) plus the requested BUSTURNAROUND delay for bus turnaround completion programmed for the chip-select to which the NAND device is connected.

Alternatively, a round-robin arbitration can be used to prioritize accesses to the external bus. This arbitration scheme is enabled by setting the GPMC_PREFETCH_CONFIG1[23] PFPWENROUNDROBIN bit. When a request to another chip-select is received while the prefetch and write-posting engine is active, priority is given to the new request. The request processed thereafter is the prefetch and write-posting engine request, even if another interconnect request is passed in the mean time. The engine keeps control of the bus for an additional number of requests programmed in the GPMC_PREFETCH_CONFIG1[19:16] PFPWWEIGHTEDPRIO bit field. Control is then passed to the direct interconnect request.

As an example, the round-robin arbitration scheme is selected with PFPWWEIGHTEDPRIO set to 0x2. Considering that the prefetch and write-posting engine and the interconnect interface are always requesting access to the external interface, the GPMC grants priority to the direct interconnect access for one request. The GPMC then grants priority to the engine for three requests, and finally back to the direct interconnect access, until the arbiter is reset when one of the two initiators stops initiating requests.

15.4.5 GPMC Basic Programming Model

15.4.5.1 GPMC High-Level Programming Model Overview

The goal of the basic high-level programming model is to introduce a top-down approach to users that need to configure the GPMC module.

Figure 15-95 and Table 15-438 through Table 15-440 show a programming model top-level diagram for the GPMC, and a description of each step. Each block of the diagram is described in one of the following sections through a set of registers to configure.

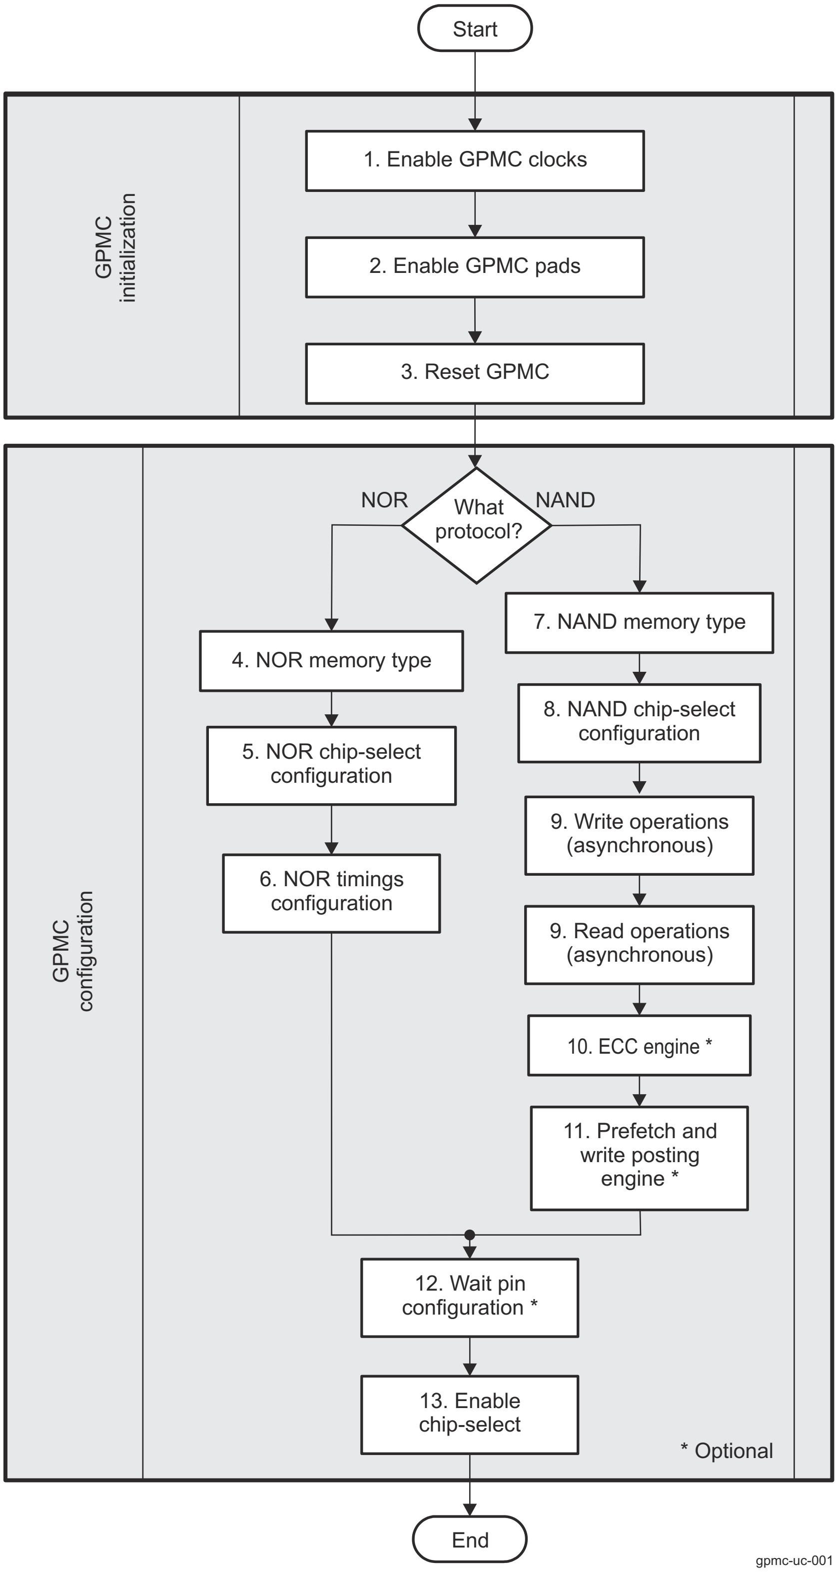

Figure 15-95. Programming Model Top-Level Diagram

Table 15-438. GPMC Initialization

Step	Description
Enable GPMC clocks.	Module interface and functional clocks must be enabled. See *Power, Reset, and Clock Management*.
Enable GPMC pads.	Module-specific pad multiplexing and configuration must be set in the control module. See *Pad Configuration Registers* in *Control Module*.
Reset GPMC.	See Table 15-441.

Table 15-439. GPMC Configuration in NOR Mode

Step	Description
NOR Memory Type	See Table 15-442.
NOR Chip-Select Configuration	See Table 15-443.
NOR Timings Configuration	See Table 15-444.
Wait Pin Configuration	See Table 15-452.
Enable Chip-Select	See Table 15-453.

Table 15-440. GPMC Configuration in NAND Mode

Step	Description
NAND Memory Type	See Table 15-447.
NAND Chip-Select Configuration	See Table 15-448.
Write Operations (Asynchronous)	See Table 15-449.
Read Operations (Asynchronous)	See Table 15-449.
ECC Engine	See Table 15-450.
Prefetch and Write-Posting Engine	See Table 15-451.
Wait Pin Configuration	See Table 15-452.
Enable Chip-Select	See Table 15-453.

15.4.5.2 GPMC Initialization

Table 15-469 describes the settings required to prepare the GPMC; that is enabling its clock and pads, and proceeding to a GPMC reset.

Table 15-441. Reset GPMC

Subprocess Name	Register/Bit Field	Value
Start a software reset.	GPMC_SYSCONFIG[1] SOFTRESET	0x1
Wait until	GPMC_SYSSTATUS[0] RESETDONE =	0x1

15.4.5.3 GPMC Configuration in NOR Mode

This section gives a generic configuration for parameters related to the NOR memory connected to the GPMC.

Table 15-442. NOR Memory Type

Subprocess Name	Register / Bit Field	Value
Set the NOR protocol.	GPMC_CONFIG1_i[11:10] DEVICETYPE	0x0
Set a device size.	GPMC_CONFIG1_i[13:12] DEVICESIZE	x
Select an address and data multiplexing protocol.	GPMC_CONFIG1_i[9] MUXADDDATA	x
Set the attached device page length.	GPMC_CONFIG1_i[24:23] ATTACHEDDEVICEPAGELENGTH	x
Set the wrapping burst capabilities.	GPMC_CONFIG1_i[31] WRAPBURST	x
Select a timing signals latencies factor.	GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY	x
Select an output clock frequency [(1)].	GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER	x
Choose an output clock activation time [(1)].	GPMC_CONFIG1_i[26:25] CLKACTIVATIONTIME	x
Set a single or multiple access for read operations [(1)].	GPMC_CONFIG1_i[30] READMULTIPLE	x

Table 15-442. NOR Memory Type (continued)

Subprocess Name	Register / Bit Field	Value
Set a synchronous or asynchronous mode for read operations.	GPMC_CONFIG1_i[29] READTYPE	x
Set a single or multiple access for write operations.	GPMC_CONFIG1_i[28] WRITEMULTIPLE	x
Set a synchronous or asynchronous mode for write operations.	GPMC_CONFIG1_i[27] WRITETYPE	x

(1) Applies only to synchronous configurations (or nonmultiplexed asynchronous for multiple access one)

Table 15-443. NOR Chip-Select Configuration

Subprocess Name	Register/Bit Field	Value
Select the chip-select base address.	GPMC_CONFIG7_i[5:0] BASEADDRESS	x
Select the chip-select mask address.	GPMC_CONFIG7_i[11:8] MASKADDRESS	x

Table 15-444. NOR Timings Configuration

Subprocess Name	Register/Bit Field	Value
Configure adequate timing parameters in various memory modes.	See Section 15.4.5.6, *GPMC Timing Parameters*	

Table 15-445. Wait Pin Configuration

Subprocess Name	Register/Bit Field	Value
Enable or disable wait pin monitoring for read operations.	GPMC_CONFIG1_i[22] WAITREADMONITORING	x
Enable or disable wait pin monitoring for write operations.	GPMC_CONFIG1_i[21] WAITWRITEMONITORING	x
Select a wait pin monitoring time.	GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME	x
Choose the input wait pin for the chip-select.	GPMC_CONFIG1_i[17:16] WAITPINSELECT	x

Table 15-446. Enable Chip-Select

Subprocess Name	Register/Bit Field	Value
When all parameters are configured, enable the chip-select.	GPMC_CONFIG7_i[6] CSVALID	x

15.4.5.4 GPMC Configuration in NAND Mode

This section gives a generic configuration for parameters related to the NAND memory connected to the GPMC.

Table 15-447. NAND Memory Type

Subprocess Name	Register/Bit Field	Value
Set the NAND protocol.	GPMC_CONFIG1_i[11:10] DEVICETYPE	0x2
Set a device size.	GPMC_CONFIG1_i[13:12] DEVICESIZE	x
Set the address and data multiplexing protocol to non-multiplexed attached device.	GPMC_CONFIG1_i[9] MUXADDDATA	0x0
Select a timing signals latencies factor.	GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY	x
Set a synchronous or asynchronous mode and a single or multiple access for read and write operations.	See Section 15.4.5.5, *Set Memory Access*.	x

Table 15-448. NAND Chip-Select Configuration

Subprocess Name	Register/Bit Field	Value
Select the chip-select base address.	GPMC_CONFIG7_i[5:0] BASEADDRESS	x
Select the chip-select minimum granularity (16MiB).	GPMC_CONFIG7_i[11:8] MASKADDRESS	x

Table 15-449. Asynchronous Read and Write Operations

Subprocess Name	Register/Bit Field	Value
Configure adequate timing parameters in asynchronous modes	See Section 15.4.5.6, *GPMC Timing Parameters*.	

Table 15-450. ECC Engine

Subprocess Name	Register/Bit Field	Value
Select the ECC result register where the first ECC computation is stored (applies only to Hamming).	GPMC_ECC_CONTROL[3:0] ECCPOINTER	x (2)
Clear all ECC result registers.	GPMC_ECC_CONTROL[8] ECCCLEAR	Write 1 to clear.
Define ECCSIZE0 and ECCSIZE1.	GPMC_ECC_SIZE_CONFIG[19:12] ECCSIZE0 and [29:22] ECCSIZE1	x (1)
Select the size of each of the 9 result registers (size specified by ECCSIZE0 or ECCSIZE1).	GPMC_ECC_SIZE_CONFIG[j-1] ECCjRESULTSIZE where j = 1 to 9	x
Select the chip-select where ECC is computed.	GPMC_ECC_CONFIG[3:1] ECCCS	x
Select the Hamming code or BCH code ECC algorithm in use.	GPMC_ECC_CONFIG[16] ECCALGORITHM	x
Select word size for ECC calculation.	GPMC_ECC_CONFIG[7] ECC16B	x
If the BCH code is used, Set an error correction capability and Select a number of sectors to process.	GPMC_ECC_CONFIG[13:12] ECCBCHTSEL and GPMC_ECC_CONFIG[6:4] ECCTOPSECTOR	x
Enable the ECC computation.	GPMC_ECC_CONFIG[0] ECCENABLE	0x1

(1) Depends on the size of each sector in the NAND page
(2) This parameter depends on the numbers of sectors in a page.

Table 15-451. Prefetch and Write-Posting Engine

Subprocess Name	Register/Bit Field	Value
Disable the engine before configuration.	GPMC_PREFETCH_CONTROL[0] STARTENGINE	0x0
Select the chip-select associated with a NAND device where the prefetch engine is active.	GPMC_PREFETCH_CONFIG1[26:24] ENGINECSSELECTOR	x
Select access direction through prefetch engine, read or write.	GPMC_PREFETCH_CONFIG1[0] ACCESSMODE	x
Select the threshold used to issue a DMA request.	GPMC_PREFETCH_CONFIG1[14:8] FIFOTHRESHOLD	x
Select DMA synchronized mode or software manual mode.	GPMC_PREFETCH_CONFIG1[2] DMAMODE	x
Select if the engine immediately starts accessing the memory upon STARTENGINE assertion or if hardware synchronization based on a WAIT signal is used.	GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE	x
Select which wait pin edge detector should start the engine in synchronized mode.	GPMC_PREFETCH_CONFIG1[5:4] WAITPINSELECTOR	x
Enter a number of clock cycles removed to timing parameters (for all back-to-back accesses to the NAND flash except the first one).	GPMC_PREFETCH_CONFIG1[30:28] CYCLEOPTIMIZATION	x
Enable the prefetch postwrite engine.	GPMC_PREFETCH_CONFIG1[7] ENABLEENGINE	0x1
Select the number of bytes to be read or written by the engine to the selected chip-select.	GPMC_PREFETCH_CONFIG2[13:0] TRANSFERCOUNT	x
Start the prefetch engine.	GPMC_PREFETCH_CONTROL[0] STARTENGINE	0x1

Table 15-452. Wait Pin Configuration

Subprocess Name	Register/Bit Field	Value
Selects when the engine starts the access to chip-select.	GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE	x
Select which wait pin edge detector should start the engine in synchronized mode.	GPMC_PREFETCH_CONFIG1[5:4] WAITPINSELECTOR	x

Table 15-453. Enable Chip-Select

Subprocess Name	Register/Bit Field	Value
When all parameters are configured, enable the chip-select.	GPMC_CONFIG7_i[6] CSVALID	x

15.4.5.5 Set Memory Access

This section describes the bit field to configure to set the GPMC in various memory modes. Table 15-454 and Table 15-455 provide check lists for mode parameters and access type parameters, respectively.

Table 15-454. Mode Parameters Check List

Register	Bit	Name	Asynchronous				Synchronous			
			Single Read Access	Single Write Access	Multiple Read (Page) Access	Multiple Write (Page) Access	Single Read Access	Single Write Access	Multiple Read (Burst) Access	Multiple Write (Burst) Access
GPMC_CONFIG1_i	30	READMULTIPLE	0x0	–	0x1 [(1)]	N/S	0x0	–	0x1	–
GPMC_CONFIG1_i	29	READTYPE	0x0	–	0x0 [(1)]	N/S	0x1	–	0x1	–
GPMC_CONFIG1_i	28	WRITEMULTIPLE	–	0x0	- [(1)]	N/S	–	0x0	–	0x1
GPMC_CONFIG1_i	27	WRITETYPE	–	0x0	- [(1)]	N/S	–	0x1	–	0x1

(1) Multiple read is not supported in address/data-multiplexed and AAD-multiplexed modes. Multiple read is supported in nonmultiplexed mode.

Table 15-455. Access Type Parameters Check List

Register	Bit	Name	Access Type		
			Nonmultiplexed	Address/ Data-Multiplexed	AAD-Multiplexed
GPMC_CONFIG1_i	9:8	MUXADDDATA	0x0	0x2	0x1

15.4.5.6 GPMC Timing Parameters

Figure 15-96 shows a programming model diagram for the NOR interfacing timing parameters.

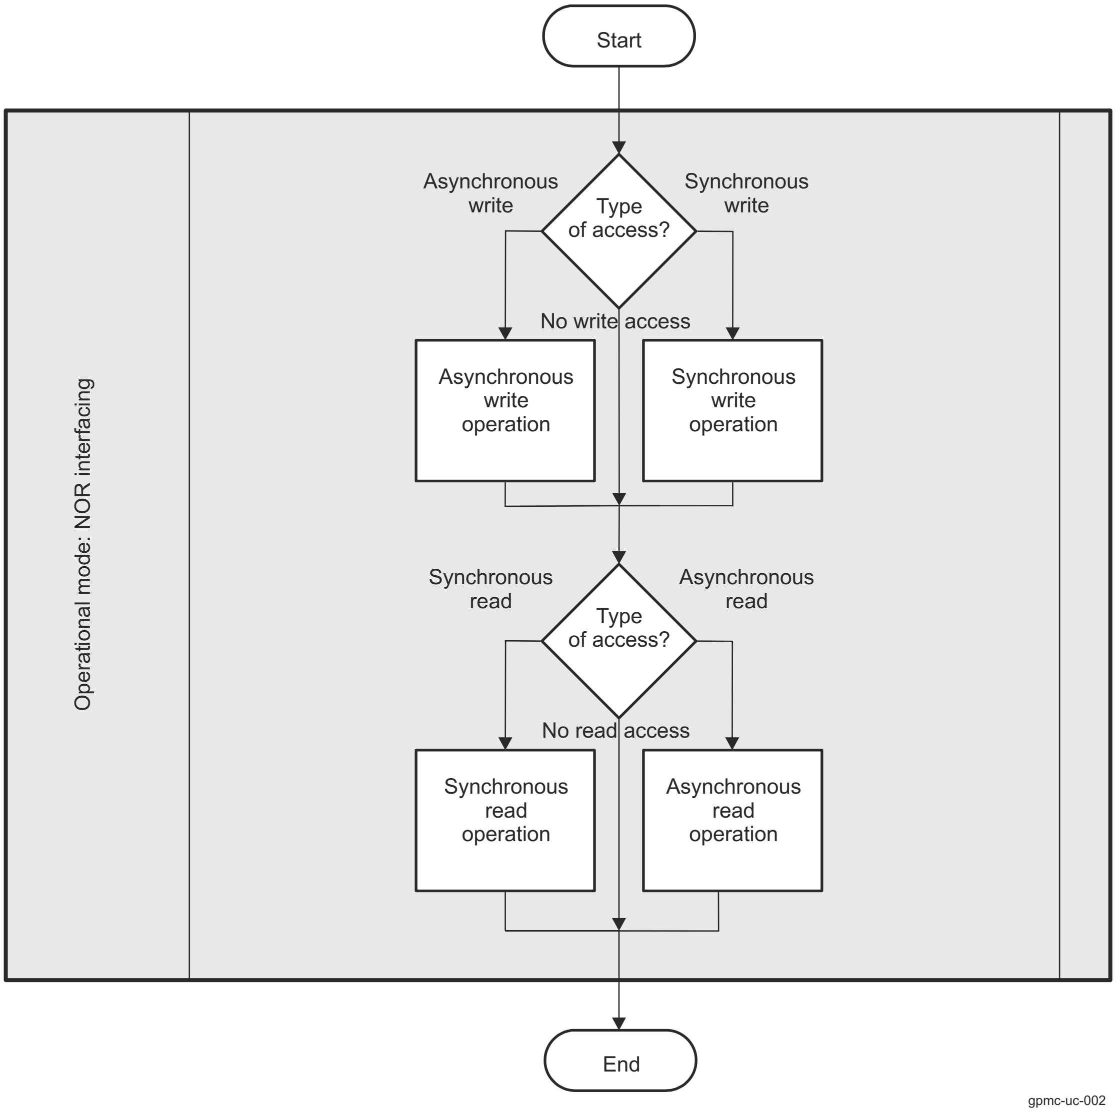

Figure 15-96. NOR Interfacing Timing Parameters Diagram

Table 15-456 lists the bit fields to configure adequate timing parameters in various memory modes.

Table 15-456. Timing Parameters

			Asynchronous			Synchronous				Access Type		
Register	Bit	Name	Single Read Access	Single Write Access	Multiple Read (Page) access	Single Read Access	Single Write Access	Multiple Read (Burst) Access	Multiple Write (Burst) Access	Non-multiplexed	Address/Data-Multiplexed	AAD Multiplexed
GPMC_CONFIG1_i	9	MUXADDDATA	y	y	y	y	y	y	y	y	y	y
GPMC_CONFIG1_i	29	READTYPE	y		y	y		y		y	y	y
GPMC_CONFIG1_i	30	READMULTIPLE	y		y	y		y		y	y	y

15.4.5.6.1 GPMC Timing Parameters Formulas

This section is intended to help the user calculate the GPMC timing bit field values. Formulas are not listed exhaustively.

The section describes:

- NAND flash interface timing parameters formulas
- Synchronous NOR flash timing parameters formulas
- Asynchronous NOR flash timing parameters formulas

For complete information, such as OPP and board effects on timings, see the device data manual.

15.4.5.6.1.1 NAND Flash Interface Timing Parameters Formulas

This section lists formulas to calculate NAND timing parameters. This is the case when GPMC_CONFIG1_i[11:10] DEVICETYPE = 0x2. Table 15-457 describes the NAND timing parameters.

Table 15-457. NAND Formulas Description

Configuration Parameter	Unit	Description
A	ns	Pulse duration – gpmc_wen valid time
B	ns	Delay time – gpmc_cs valid to gpmc_wen valid
C	ns	Delay time – gpmc_ben0/gpmc_advn_ale high to gpmc_wen valid
D	ns	Delay time – gpmc_ad[15:0] valid to gpmc_wen valid
E	ns	Delay time – gpmc_wen invalid to gpmc_ad[15:0] invalid
F	ns	Delay time – gpmc_wen invalid to gpmc_ben0/gpmc_advn_ale invalid
G	ns	Delay time – gpmc_wen invalid to gpmc_cs invalid
H	ns	Cycle time – Write cycle time
I	ns	Delay time – gpmc_cs valid to gpmc_oen_ren valid
J	ns	Setup time – gpmc_ad[15:0] valid to gpmc_oen_ren invalid
K	ns	Pulse duration – gpmc_oen_ren valid time
L	ns	Cycle time – Read cycle time
M	ns	Delay time – gpmc_oen_ren invalid to gpmc_cs invalid

The configuration parameters are calculated through the following formulas. For more information, see the device data manual.

A = (WEOffTime – WEOnTime) * (TimeParaGranularity + 1) * GPMC_FCLK period

B = ((WEOnTime – CSOnTime) * (TimeParaGranularity + 1) + 0.5 * (WEExtraDelay – CSExtraDelay)) * GPMC_FCLK period

C = ((WEOnTime – ADVOnTime) * (TimeParaGranularity + 1) + 0.5 * (WEExtraDelay - ADVExtraDelay)) * GPMC_FCLK period

D = (WEOnTime * (TimeParaGranularity + 1) + 0.5 * WEExtraDelay) * GPMC_FCLK period

E = (WrCycleTime – WEOffTime * (TimeParaGranularity + 1) – 0.5 * WEExtraDelay) * GPMC_FCLK period

F = (ADVWrOffTime – WEOffTime * (TimeParaGranularity + 1) + 0.5 * (ADVExtraDelay – WEExtraDelay) * GPMC_FCLK period

G = (CSWrOffTime – WEOffTime * (TimeParaGranularity + 1) + 0.5 * (CSExtraDelay – WEExtraDelay) * GPMC_FCLK period

H = WrCycleTime * (1 + TimeParaGranularity) * GPMC_FCLK period

I = ((OEOnTime – CSOnTime) * (TimeParaGranularity + 1) + 0.5 * (OEExtraDelay – CSExtraDelay)) * GPMC_FCLK period

J = ((RdAccessTime – OEOffTime) * (TimeParaGranularity + 1) – 0.5 * OEExtraDelay)) * GPMC_FCLK period

K = (OEOffTime – OEOnTime) * (1 + TimeParaGranularity) * GPMC_FCLK period

L = RdCycleTime * (1 + TimeParaGranularity) * GPMC_FCLK period

M = (CSRdOffTime – OEOffTime * (TimeParaGranularity + 1) + 0.5 * (CSExtraDelay - OEExtraDelay) * GPMC_FCLK period

Figure 15-97 shows a simplified example of command latch cycle timing where formulas are associated with signal waves.

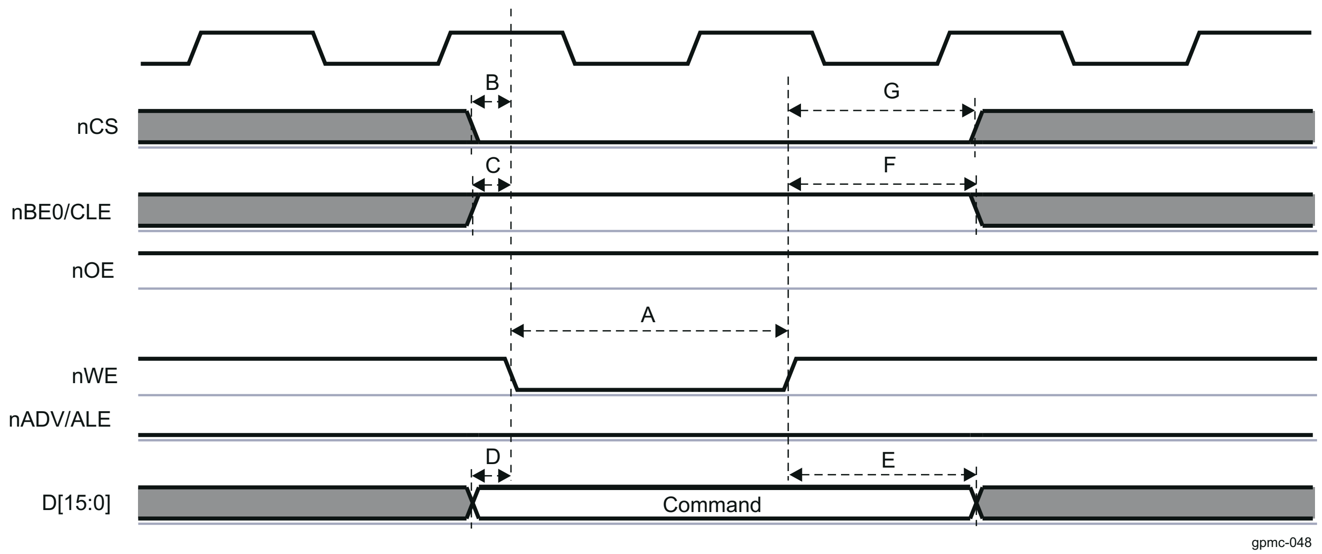

Figure 15-97. NAND Command Latch Cycle Timing Simplified Example

15.4.5.6.1.2 Synchronous NOR Flash Timing Parameters Formulas

This section lists all formulas to calculate synchronous NOR timing parameters. This is the case when GPMC_CONFIG1_i[11:10] DEVICETYPE = 0x0 and when READTYPE or WRITETYPE are set to synchronous mode. Table 15-458 describes the synchronous NOR formulas.

Table 15-458. Synchronous NOR Formulas Description

Configuration Parameter	Unit	Description
A	ns	Pulse duration – gpmc_cs low
B	ns	Delay time – address bus valid to gpmc_clk first edge
		Delay time – gpmc_ben0/gpmc_ben1 valid to gpmc_clk first edge
C	ns	Pulse duration – gpmc_ben0/gpmc_ben1 low
D	ns	Delay time – gpmc_clk rising edge to gpmc_ben0/gpmc_ben1 invalid
		Delay time – gpmc_clk rising edge to gpmc_advn_ale invalid
E	ns	Delay time – gpmc_clk rising edge to gpmc_cs invalid
		Delay time – gpmc_clk rising edge to gpmc_oen_ren invalid
F	ns	Delay time – gpmc_clk rising edge to gpmc_cs transition
G	ns	Delay time – gpmc_clk rising edge to gpmc_advn_ale transition
H	ns	Delay time – gpmc_clk rising edge to gpmc_oen_ren transition
I	ns	Delay time – gpmc_clk rising edge to gpmc_wen transition
J	ns	Delay time – gpmc_clk rising edge to gpmc_ad data bus transition
		Delay time – gpmc_clk rising edge to gpmc_ben0/gpmc_ben1 transition
K	ns	Pulse duration – gpmc_advn_ale low
L	ns	Delay time – gpmc_wait invalid to first data latching gpmc_clk edge

The configuration parameters are calculated through the following formulas. For more information, see the device data manual.

1. For single read accesses:
   A = (CSRDOFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   C = RDCYCLETIME * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   D = (RDCYCLETIME – RDACCESSTIME) * GPMC_FCLK period
   E = (CSRDOFFTIME – RDACCESSTIME) * GPMC_FCLK period

2. For burst read accesses (where n is the page burst access number):
   A = (CSRDOFFTIME – CSONTIME + (n – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   C = (RDCYCLETIME + (n – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   D = (RDCYCLETIME – (RDACCESSTIME + (n – 1) * PAGEBURSTACCESSTIME)) * GPMC_FCLK period
   E = (CSRDOFFTIME – (RDACCESSTIME + (n – 1) * PAGEBURSTACCESSTIME)) * GPMC_FCLK period
3. For burst write accesses (where n is the page burst access number):
   A = (CSWROFFTIME – CSONTIME + (n – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   C = (WRCYCLETIME + (n – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   D = (WRCYCLETIME – (RDACCESSTIME + (n – 1) * PAGEBURSTACCESSTIME)) * GPMC_FCLK period
   E = (CSWROFFTIME – (RDACCESSTIME + (n – 1) * PAGEBURSTACCESSTIME)) * GPMC_FCLK period
4. For all accesses:
   For nCS falling edge (chip-select activated):
   - Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period
   - Case where GPMCFCLKDIVIDER = 0x1:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and CSONTIME are odd) or (CLKACTIVATIONTIME and CSONTIME are even)
     F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period otherwise.
   - Case where GPMCFCLKDIVIDER = 0x2:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSONTIME – CLKACTIVATIONTIME) is a multiple of 3
     F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSONTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
     F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSONTIME – CLKACTIVATIONTIME – 2) is a multiple of 3
   - Case where GPMCFCLKDIVIDER = 0x3:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSONTIME – CLKACTIVATIONTIME) is a multiple of 4
     F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSONTIME – CLKACTIVATIONTIME – 1) is a multiple of 4
     F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSONTIME – CLKACTIVATIONTIME – 2) is a multiple of 4
     F = (3 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSONTIME – CLKACTIVATIONTIME – 3) is a multiple of 4

   For nCS rising edge (chip-select deactivated) in reading mode:
   - Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period
   - Case where GPMCFCLKDIVIDER = 0x1:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and CSRDOFFTIME are odd) or (CLKACTIVATIONTIME and CSRDOFFTIME are even)
     F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period otherwise.
   - Case where GPMCFCLKDIVIDER = 0x2:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSRDOFFTIME – CLKACTIVATIONTIME) is a multiple of 3
     F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSRDOFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
     F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSRDOFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3
   - Case where GPMCFCLKDIVIDER = 0x3:

F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSRDOFFTIME – CLKACTIVATIONTIME) is a multiple of 4
F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSRDOFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 4
F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSRDOFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 4
F = (3 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSRDOFFTIME – CLKACTIVATIONTIME – 3) is a multiple of 4

For nCS rising edge (chip-select deactivated) in writing mode:

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  F = 0.5 * CSEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and CSWROFFTIME are odd) or (CLKACTIVATIONTIME and CSWROFFTIME are even)
  F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSWROFFTIME – CLKACTIVATIONTIME) is a multiple of 3
  F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSWROFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSWROFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3
- Case where GPMCFCLKDIVIDER = 0x3:
  F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSWROFFTIME – CLKACTIVATIONTIME) is a multiple of 4
  F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSWROFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 4
  F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSWROFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 4
  F = (3 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSWROFFTIME – CLKACTIVATIONTIME – 3) is a multiple of 4

For nADV falling edge (nADV activated):

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and ADVONTIME are odd) or (CLKACTIVATIONTIME and ADVONTIME are even)
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (ADVONTIME – CLKACTIVATIONTIME) is a multiple of 3
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVONTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVONTIME – CLKACTIVATIONTIME – 2) is a multiple of 3
- Case where GPMCFCLKDIVIDER = 0x3:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (ADVONTIME – CLKACTIVATIONTIME) is a multiple of 4
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVONTIME – CLKACTIVATIONTIME – 1) is a multiple of 4
  G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVONTIME – CLKACTIVATIONTIME – 2) is a multiple of 4

G = (3 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVONTIME – CLKACTIVATIONTIME – 3) is a multiple of 4

For nADV rising edge (nADV deactivated) in reading mode:

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and ADVRDOFFTIME are odd) or (CLKACTIVATIONTIME and ADVRDOFFTIME are even)
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (ADVRDOFFTIME - CLKACTIVATIONTIME) is a multiple of 3
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVRDOFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3
  G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVRDOFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3
- Case where GPMCFCLKDIVIDER = 0x3:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (ADVRDOFFTIME – CLKACTIVATIONTIME) is a multiple of 4
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVRDOFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 4
  G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVRDOFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 4
  G = (3 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVRDOFFTIME – CLKACTIVATIONTIME – 3) is a multiple of 4

For nADV rising edge (nADV deactivated) in writing mode:

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and ADVWROFFTIME are odd) or (CLKACTIVATIONTIME and ADVWROFFTIME are even)
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (ADVWROFFTIME – CLKACTIVATIONTIME) is a multiple of 3
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVWROFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVWROFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3
- Case where GPMCFCLKDIVIDER = 0x3:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (ADVWROFFTIME – CLKACTIVATIONTIME) is a multiple of 4
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVWROFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 4
  G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVWROFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 4
  G = (3 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVWROFFTIME – CLKACTIVATIONTIME – 3) is a multiple of 4

For nOE falling edge (nOE activated):

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:

H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and OEONTIME are odd) or (CLKACTIVATIONTIME and OEONTIME are even)
H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period otherwise.

- Case where GPMCFCLKDIVIDER = 0x2:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (OEONTIME – CLKACTIVATIONTIME) is a multiple of 3
  H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEONTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  H = (2 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEONTIME – CLKACTIVATIONTIME – 2) is a multiple of 3
- Case where GPMCFCLKDIVIDER = 0x3:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (OEONTIME – CLKACTIVATIONTIME) is a multiple of 4
  H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEONTIME – CLKACTIVATIONTIME – 1) is a multiple of 4
  H = (2 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEONTIME – CLKACTIVATIONTIME – 2) is a multiple of 4
  H = (3 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEONTIME – CLKACTIVATIONTIME – 3) is a multiple of 4

For nOE rising edge (nOE deactivated):

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and OEOFFTIME are odd) or (CLKACTIVATIONTIME and OEOFFTIME are even)
  H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (OEOFFTIME – CLKACTIVATIONTIME) is a multiple of 3
  H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEOFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  H = (2 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEOFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3
- Case where GPMCFCLKDIVIDER = 0x3:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (OEOFFTIME – CLKACTIVATIONTIME) is a multiple of 4
  H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEOFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 4
  H = (2 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEOFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 4
  H = (3 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEOFFTIME – CLKACTIVATIONTIME – 3) is a multiple of 4

For nWE falling edge (nWE activated):

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and WEONTIME are odd) or (CLKACTIVATIONTIME and WEONTIME are even)
  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (WEONTIME – CLKACTIVATIONTIME) is a multiple of 3

I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEONTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
I = (2 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEONTIME – CLKACTIVATIONTIME – 2) is a multiple of 3
- Case where GPMCFCLKDIVIDER = 0x3:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (WEONTIME – CLKACTIVATIONTIME) is a multiple of 4
  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEONTIME – CLKACTIVATIONTIME – 1) is a multiple of 4
  I = (2 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEONTIME – CLKACTIVATIONTIME – 2) is a multiple of 4
  I = (3 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEONTIME – CLKACTIVATIONTIME – 3) is a multiple of 4

For nWE rising edge (nWE deactivated):
- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and WEOFFTIME are odd) or (CLKACTIVATIONTIME and WEOFFTIME are even)
  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (WEOFFTIME – CLKACTIVATIONTIME) is a multiple of 3
  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEOFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  I = (2 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEOFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3
- Case where GPMCFCLKDIVIDER = 0x3:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (WEOFFTIME – CLKACTIVATIONTIME) is a multiple of 4
  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEOFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 4
  I = (2 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEOFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 4
  I = (3 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEOFFTIME – CLKACTIVATIONTIME – 3) is a multiple of 4

For gpmc_nadv low pulse duration:
- Read operation:
  K = (ADVRDOFFTIME – ADVONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
- Write operation:
  K = (ADVWROFFTIME – ADVONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period

For gpmc_wait invalid to first data latching gpmc_clk edge:
- L = WAITMONITORINGTIME * (GPMCFCLKDIVIDER + 1) * GPMC_FCLK period + GPMC_CLK period

Figure 15-98 shows a simplified example of a synchronous NOR single read where formulas are associated with signal waves.

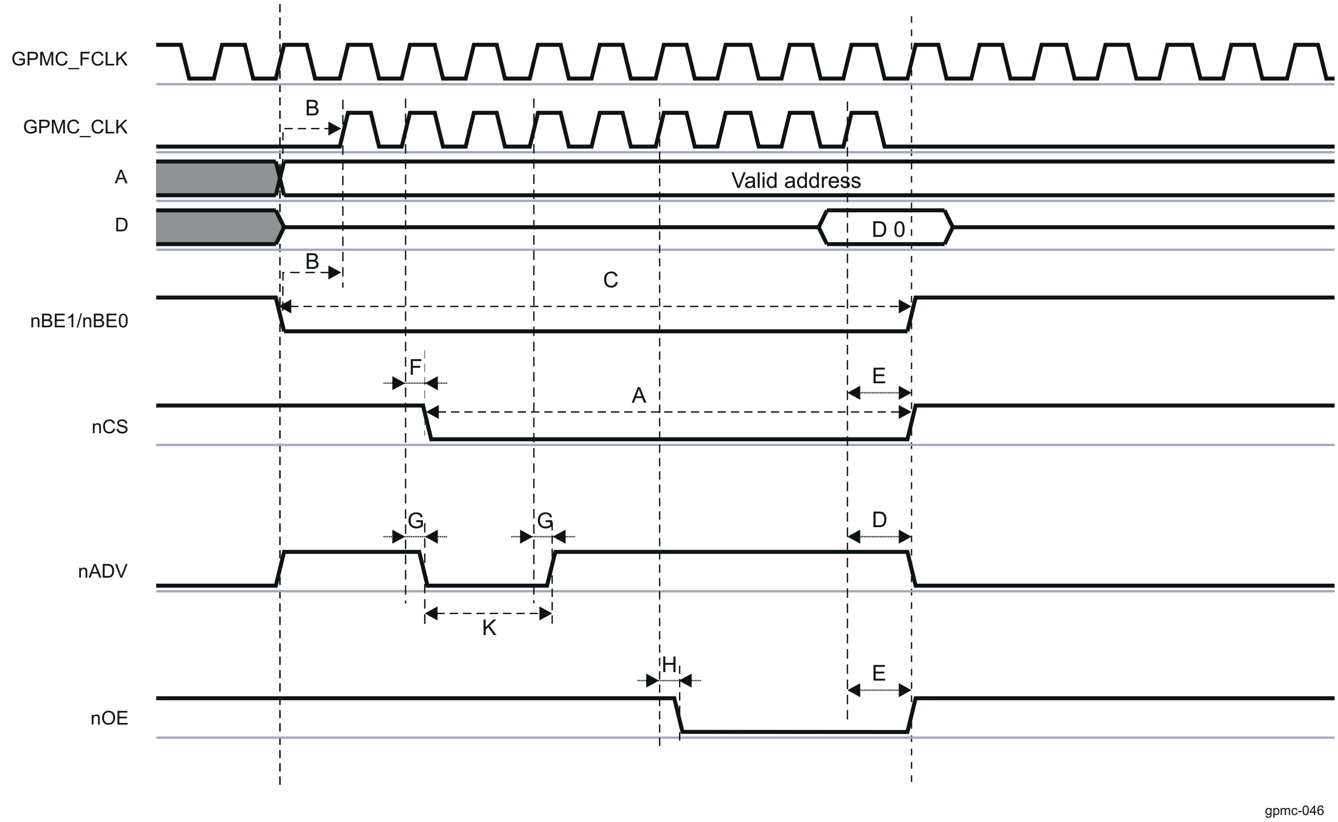

Figure 15-98. Synchronous NOR Single Read Simplified Example

15.4.5.6.1.3 Asynchronous NOR Flash Timing Parameters Formulas

This section lists all the formulas to calculate asynchronous NOR timing parameters. This is the case when GPMC_CONFIG1_i[11:10] DEVICETYPE = 0x0 and when READTYPE or WRITETYPE are set to asynchronous mode. Table 15-459 describes the asynchronous NOR formulas.

Table 15-459. Asynchronous NOR Formulas Description

Configuration Parameter	Unit	Description
A	ns	Pulse duration – gpmc_cs low
B	ns	Delay time – gpmc_cs valid to gpmc_advn_ale invalid
C	ns	Delay time – gpmc_cs valid to gpmc_oen_ren invalid (single read)
D	ns	Pulse duration – address bus valid - 2nd, 3rd and 4th accesses
E	ns	Delay time – gpmc_cs valid to gpmc_wen valid
F	ns	Delay time – gpmc_cs valid to gpmc_wen invalid
G	ns	Address invalid duration between two successive R/W accesses
H	ns	Setup time – read data valid before gpmc_oen_ren high
I	ns	Delay time – gpmc_cs valid to gpmc_oen_ren invalid (burst read)
J	ns	Delay time – address bus valid to gpmc_cs valid
		Delay time – data bus valid to gpmc_cs valid
		Delay time – gpmc_ben0/gpmc_ben1 valid to gpmc_cs valid
K	ns	Delay time – gpmc_cs valid to gpmc_advn_ale valid
L	ns	Delay time – gpmc_cs valid to gpmc_oen_ren valid
M	ns	Delay time – gpmc_cs valid to first data latching edge
N	ns	Pulse duration – gpmc_ben0/gpmc_ben1 valid time

Table 15-459. Asynchronous NOR Formulas Description (continued)

Configuration Parameter	Unit	Description
O	ns	Delay time – gpmc_cs valid to gpmc_advn_ale valid

The configuration parameters are calculated through the following formulas. These formulas are not exhaustive. For more information, see the device data manual.

- gpmc_cs low pulse:
  For single read: A = (CSRDOFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
  For burst read: A = (CSRDOFFTIME – CSONTIME + (N – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number
  For single write: A = (CSWROFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
  For burst write: A = (CSWROFFTIME – CSONTIME + (N – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number
- gpmc_cs valid to gpmc_advn_ale invalid delay:
  For reading: B = ((ADVRDOFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
  For writing: B = ((ADVWROFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- C = ((OEOFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (OEEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- D = PAGEBURSTACCESSTIME * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
- E = ((WEONTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (WEEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- F = ((WEOFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (WEEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- G = CYCLE2CYCLEDELAY * GPMC_FCLK period
- H = ((OEOFFTIME – RDACCESSTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * OEEXTRADELAY) * GPMC_FCLK period
- I = ((OEOFFTIME + (N – 1) * PAGEBURSTACCESSTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (OEEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period, where N = page burst access number
- J = (CSONTIME * (TIMEPARAGRANULARITY + 1) + 0.5 * CSEXTRADELAY) * GPMC_FCLK period
- K = ((ADVONTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- L = ((OEONTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (OEEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- M = ((RDACCESSTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) – 0.5 * CSEXTRADELAY) * GPMC_FCLK period
- gpmc_ben0/gpmc_ben1 pulse:
  For single read: N = RDCYCLETIME * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
  For burst read: N = (RDCYCLETIME + (N – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number
  For burst write: N = (WRCYCLETIME + (N – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number
- O = ((WRCYCLETIME + (N – 1) * PAGEBURSTACCESSTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period

Figure 15-99 shows a simplified example of an asynchronous NOR single write where formulas are associated with signal waves.

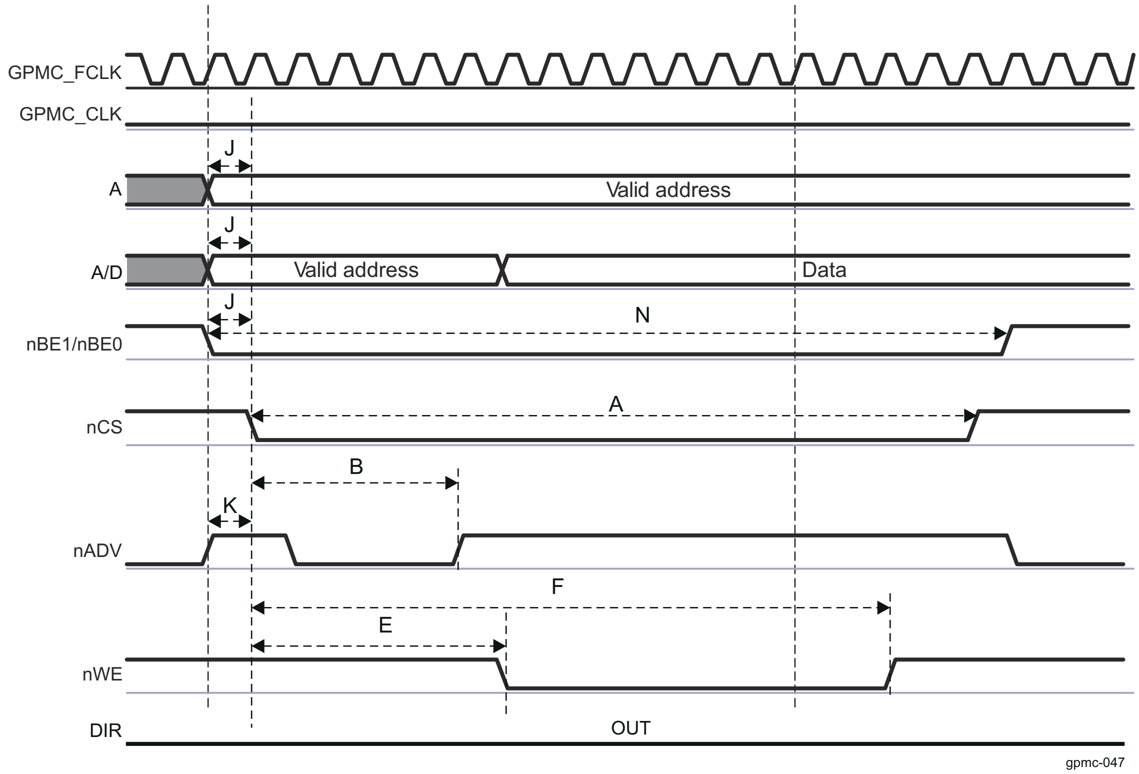

Figure 15-99. Asynchronous NOR Single Write Simplified Example

---

Note

Write multiple access is not supported in asynchronous mode. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

15.4.6 GPMC Use Cases and Tips

15.4.6.1 How to Set GPMC Timing Parameters for Typical Accesses

15.4.6.1.1 External Memory Attached to the GPMC Module

As discussed in the introduction to this chapter, the GPMC module supports the following external memory types:

- Asynchronous or synchronous, 8- or 16-bit-wide memory or device
- 16-bit address/data-multiplexed or not multiplexed NOR flash device
- 8- or 16-bit NAND flash device

The following examples describe how to calculate GPMC timing parameters by showing a typical parameter setup for the access to be performed.

The example is based on a 512-Mb multiplexed NOR flash memory with the following characteristics:

- Type: NOR flash (address/data-multiplexed mode)
- Size: 512M bits
- Data Bus: 16 bits wide
- Speed: 104-MHz clock frequency
- Read access time: 80 ns

15.4.6.1.2 Typical GPMC Setup

Table 15-460 lists some of the I/Os of the GPMC module.

Table 15-460. GPMC Signals

Signal Name	I/0	Description
GPMC_FCLK	Internal	Functional and interface clock. Acts as the time reference.
gpmc_clk	O	External clock provided to the external device for synchronous operations
gpmc_a[26:16]	O	Address
gpmc_ad[15:0]	I/O	Data-multiplexed with addresses A[16:1] on memory side
gpmc_csx	O	Chip-select (where x = 0, or 1)
gpmc_advn_ale	O	Address valid enable
gpmc_oen_ren	O	Output enable (read access only)
gpmc_wen	O	Write enable (write access only)
gpmc_wait[1:0]	I	Ready signal from memory device. Indicates when valid burst data is ready to be read

Figure 15-100 shows the typical connection between the GPMC module and an attached NOR Flash memory.

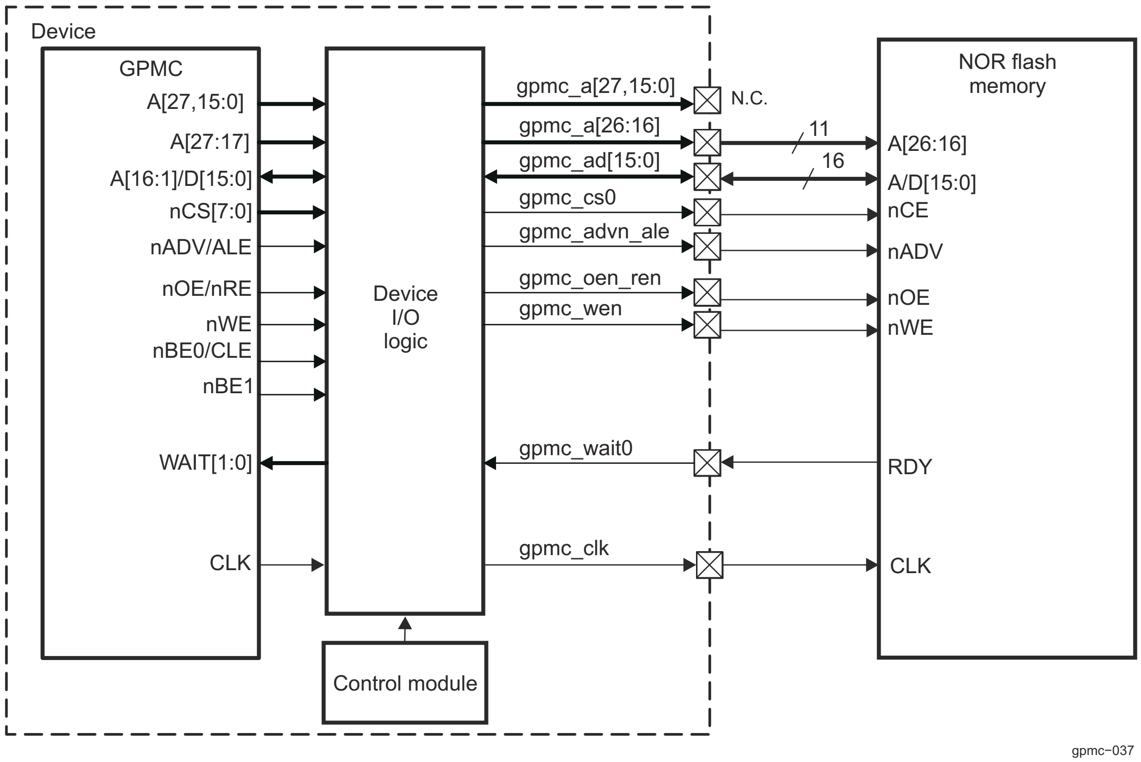

Figure 15-100. GPMC Connection to an External NOR Flash Memory

The following sections demonstrate how to calculate GPMC parameters for three access types:

- Synchronous burst read
- Asynchronous read
- Asynchronous single write

15.4.6.1.2.1 GPMC Configuration for Synchronous Burst Read Access

---

Note

The examples in Section 15.4.6.1.2.1 through Section 15.4.6.1.2.3 are based on a clock rate of 104 MHz. Refer to the device Data Manual for the maximum frequency appropriate for this device and to the memory datasheet for the maximum frequency for the particular memory device.

The clock runs at 104 MHz (f = 104 MHz; T = 9, 615 ns).

Table 15-461 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 15-462 shows how to calculate timings for the GPMC using the memory parameters.

Figure 15-101 shows the synchronous burst read access.

Table 15-461. Useful Timing Parameters on the Memory Side

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCES	nCS setup time to clock	0
tACS	Address setup time to clock	3
tIACC	Synchronous access time	80
tBACC	Burst access time valid clock to output delay	5,2
tCEZ	Chip-select to High-Z	7

Table 15-461. Useful Timing Parameters on the Memory Side (continued)

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tOEZ	Output enable to High-Z	7
tAVC	nADV setup time	6
tAVD	nAVD pulse	6
tACH	Address hold time from clock	3

The following terms, which describe the timing interface between the controller and its attached device, are used to calculate the timing parameters on the GPMC side:

- Read access time (GPMC side): Time required to activate the clock + read access time requested on the memory side + data setup time required for optimal capture of a burst of data
- Data setup time (GPMC side): Ensures a good capture of a burst of data (as opposed to taking a burst of data out). One word of data is processed in one clock cycle (T = 9,615 ns). The read access time between two bursts of data is tBACC = 5.2 ns. Therefore, data setup time is a clock period – tBACC = 4,415 ns of data setup.
- Access completion (GPMC side): (Different from page burst access time) Time required between the last burst access and access completion: nCS/nOE hold time (nCS and nOE must be released at the end of an access. These signals are held to allow the access to complete).
- Read cycle time (GPMC side): Read access time + access completion
- Write cycle time for burst access: Not supported for NOR flash memory

Table 15-462. Calculating GPMC Timing Parameters

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
GPMC FCLK Divider	–	–	–	GPMCFCLKDIVIDER = 0x0
ClkActivation Time	min (tCES, tACS)	3	1	CLKACTIVATIONTIME = 0x1
RdAccessTime	roundmax (ClkActivationTime + tIACC + DataSetupTime)	94.03: (9,615 + 80 + 4,415)	10: roundmax (94.03 / 9,615)	RDACCESSTIME = 0x0A
PageBurst RdAccessTime	roundmax (tBACC)	roundmax (5.2)	1	PAGEBURSTACCESSTIME = 0x1
RdCycleTime	RdAccess time + max (tCEZ, tOEZ)	101.03: (94.03 + 7)	11	RDCYCLETIME = 0x0B
CsOnTime	tCES	0	0	CSONTIME = 0x0
CsReadOffTime	RdCycleTime	-	11	CSRDOFFTIME = 0x0B
AdvOnTime	tAVC (1)	0	0	ADVONTIME = 0x0
AdvRdOffTime	tAVD + tAVC (2)	12	2	ADVRDOFFTIME = 0x02
OeOnTime (3)	(ClkActivationTime + tACH) < OeOnTime (ClkActivationTime + tIACC)	–	3, for instance	OEONTIME = 0x3
OeOffTime	RdCycleTime	–	11	OEOFFTIME = 0x0B

(1) The external clock provided to the NOR flash is not yet available.
(2) AdvRdOffTime – AdvOnTime = tAVD; thus, AdvRdOffTime = tAVD + AdvOnTime = tAVD + tAVC.
(3) OeOnTime must ensure that addresses are available. It must not exceed the availability of the first burst of data.

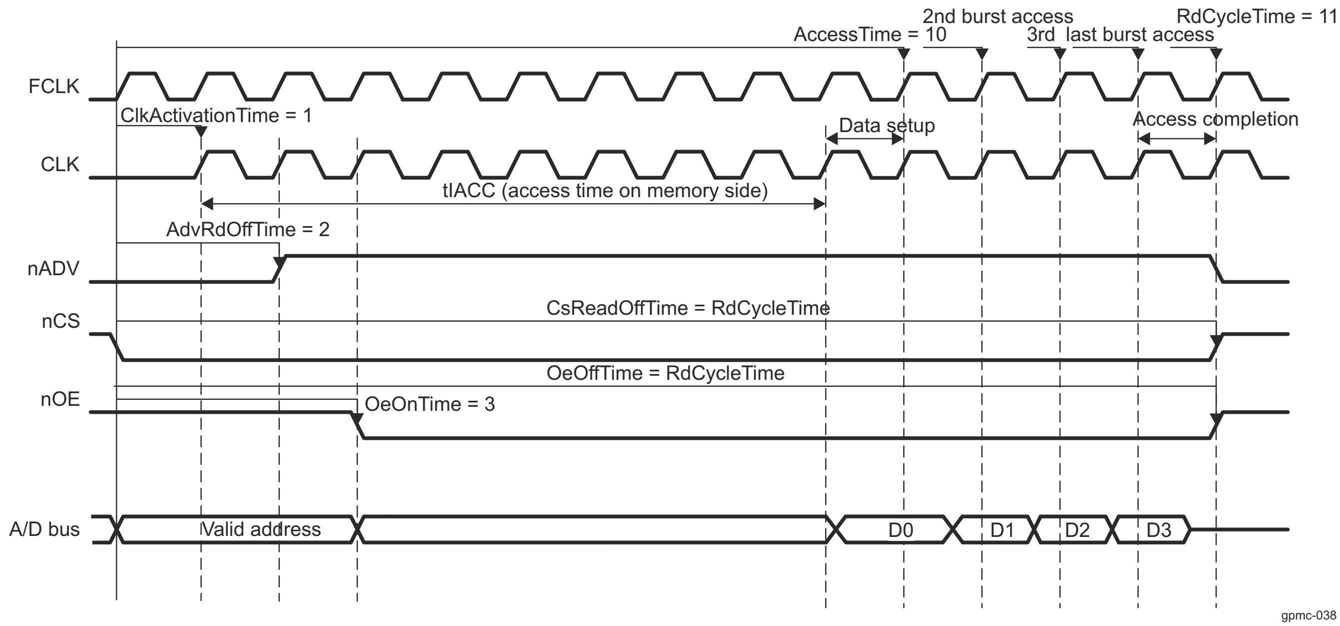

Figure 15-101. Synchronous Burst Read Access (Timing Parameters in Clock Cycles)

15.4.6.1.2.2 GPMC Configuration for Asynchronous Read Access

The clock runs at 104 MHz (f = 104 MHz; T = 9, 615 ns).

Table 15-463 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 15-464 shows how to calculate timings for the GPMC using the memory parameters.

Figure 15-102 shows the asynchronous read access.

Table 15-463. AC Characteristics for Asynchronous Read Access

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCE	Read Access time from nCS low	80
tAAVDS	Address setup time to rising edge of nADV	3
tAVDP	nADV low time	6
tCAS	nCS setup time to nADV	0
tOE	Output enable to output valid	6
tOEZ	Output enable to High-Z	7

Use the following formula to calculate the RdCycleTime parameter for this typical access:

RdCycleTime = RdAccessTime + AccessCompletion = RdAccessTime + 1 clock cycle + tOEZ:

1. On the memory side, the external memory makes the data available to the output bus. This is the memory-side read access time defined in Table 15-463: the number of clock cycles between the address capture (nADV rising edge) and the data valid on the output bus.

   The GPMC requires some hold time to allow the data to be captured correctly and the access to be finished.
2. To read the data correctly, the GPMC must be configured to meet the data setup time requirement of the memory; the GPMC module captures the data on the next rising edge. This is access time on the GPMC side.
3. There must also be a data hold time for correctly reading the data (checking that there is no nOE/nCS deassertion while reading the data). This data hold time is one clock cycle (that is, RdAccessTime + 1).

4. To complete the access, nOE/nCS signals are driven to High-Z. RdAccessTime + 1 + tOEZ is the read cycle time.
5. Addresses can now be relatched and a new read cycle begun.

Table 15-464. GPMC Timing Parameters for Asynchronous Read Access

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
ClkActivationTime	n/a (asynchronous mode)			
RdAccessTime	round max (tCE)	80	10	RDACCESSTIME = 0x0A
PageBurstAccessTime	N/A (single access)			
RdCycleTime	RdAccessTime + 1cycle + tOEZ	96, 615	12	RDCYCLETIME = 0x0C
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsReadOffTime	RdAccessTime + 1 cycle	89, 615	11	CSRDOFFTIME = 0x0B
AdvOnTime	tAAVDS	3	1	ADVONTIME = 0X1
AdvRdOffTime	tAAVDS + tAVDP	9	1	ADVRDOFFTIME = 0x01
OeOnTime	OeOnTime >= AdvRdOffTime (multiplexed mode)	-	3, for instance	OEONTIME = 0x3
OeOffTime	RdAccessTime + 1cycle	89, 615	11	OEOFFTIME = 0x0B

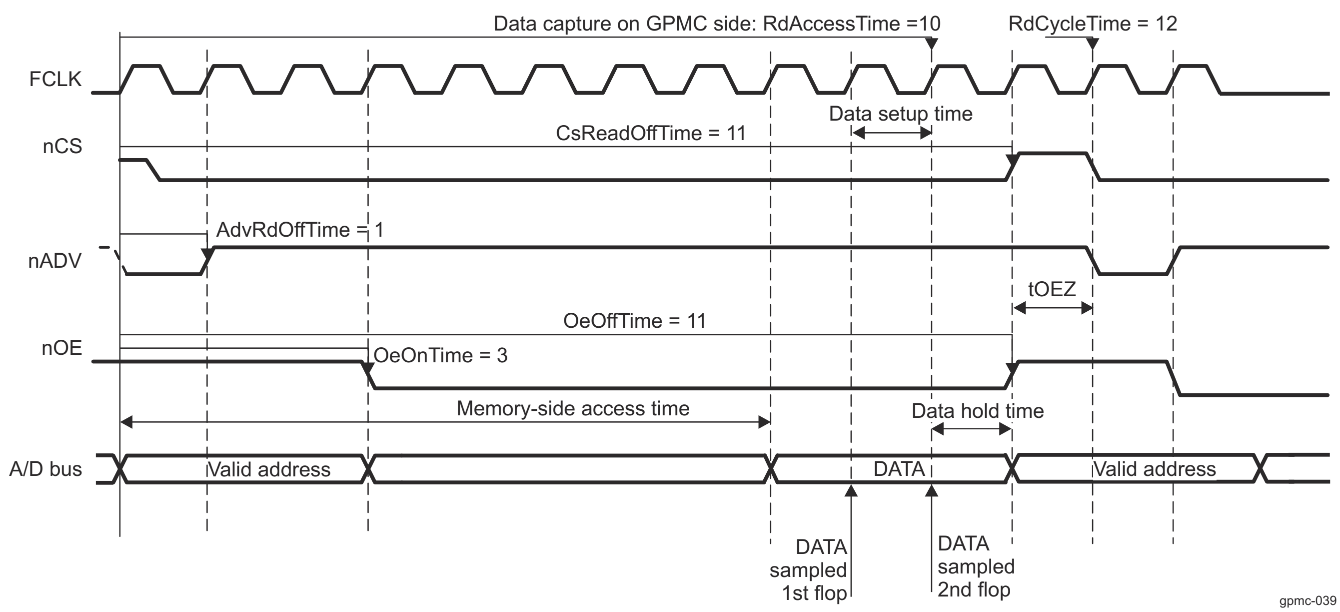

Figure 15-102. Asynchronous Single Read Access (Timing Parameters in Clock Cycles)

15.4.6.1.2.3 GPMC Configuration for Asynchronous Single Write Access

The clock runs at 104 MHz: (f = 104 MHz; T = 9, 615 ns).

Table 15-466 shows how to calculate timings for the GPMC using the memory parameters.

Table 15-465 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Figure 15-103 shows the synchronous burst write access.

Table 15-465. AC Characteristics for Asynchronous Single Write (Memory Side)

AC Characteristics on the Memory Side	Description	Duration (ns)
tWC	Write cycle time	60

Table 15-465. AC Characteristics for Asynchronous Single Write (Memory Side) (continued)

AC Characteristics on the Memory Side	Description	Duration (ns)
tAVDP	nADV low time	6
tWP	Write pulse width	25
tWPH	Write pulse width high	20
tCS	nCS setup time to nWE	3
tCAS	nCS setup time to nADV	0
tAVSC	nADV setup time	3

For asynchronous single write access, write cycle time is WrCycleTime = WeOffTime + AccessCompletion = WeOffTime + 1. For the AccesCompletion, the GPMC requires one cycle of data hold time (nCS deassertion). For more information, see the device data manual.

Table 15-466. GPMC Timing Parameters for Asynchronous Single Write

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Registers Configuration
ClkActivationTime	N/A (asynchronous mode)			
WdAccessTime	Applicable only to WAITMONITORING (the value is the same as for read access)			
PageBurstAccessTime	N/A (single access)			
WrCycleTime	WeOffTime + AccessCompletion	57, 615	6	WRCYCLETIME = 0x06
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsWrOffTime	WeOffTime + 1	57, 615	6	CSWROFFTIME = 0x06
AdvOnTime	tAVSC	3	1	ADVONTIME = 0x1
AdvWrOffTime	tAVSC + tAVDP	9	1	ADVWROFFTIME = 0x01
WeOnTime	tCS	3	1	WEONTIME = 0x1
WeOffTime	tCS + tWP + tWPH	48	5	WEOFFTIME = 0x05

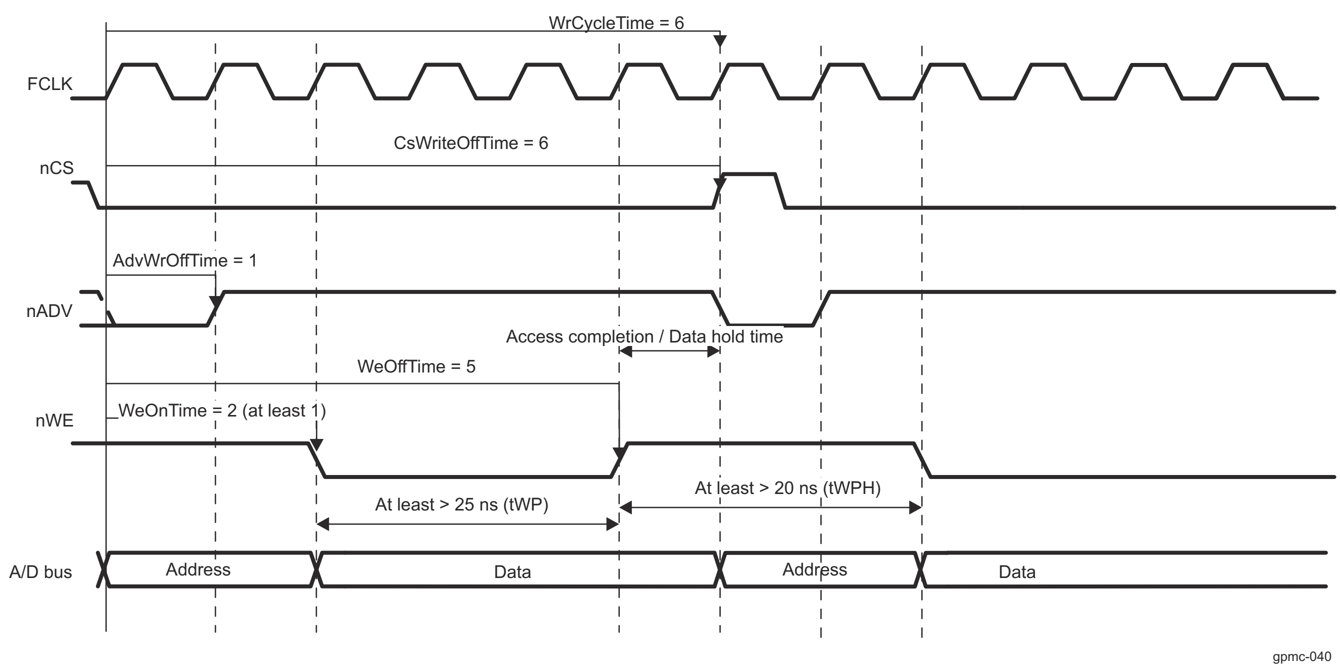

Figure 15-103. Asynchronous Single Write Access (Timing Parameters in Clock Cycles)

15.4.6.2 How to Choose a Suitable Memory to Use With the GPMC

This section is intended to help the user select a suitable memory device to interface with the GPMC controller.

15.4.6.2.1 Supported Memories or Devices

NAND flash and NOR flash architectures are the two flash technologies. The GPMC supports various types of external memory or devices, basically any one that supports NAND or NOR protocols:

- 8- and 16-bit-wide asynchronous or synchronous memory or device (only 8-bit: nonburst device)
- 16-bit address and data-multiplexed NOR flash devices (pSRAM, OneNAND™, etc.)
- 8- and 16-bit NAND flash devices

15.4.6.2.1.1 Memory Pin Multiplexing

This section describes the interfacing differences of the GPMC supported memories.

Table 15-467. Supported Memories Interfaces

(1) Addresses seen from the device side. When interfacing to the external device, A1 is connected to the memory A0, A2 to the memory A1, and so on.

15.4.6.2.1.2 NAND Interface Protocol

NAND flash architecture, introduced in 1989, is a flash technology. NAND is a page-oriented memory device; that is, read and write accesses are done by pages. NAND achieves great density by sharing common areas of the storage transistor, which creates strings of serially connected transistors (in NOR devices, each transistor stands alone). Because of its high density NAND is best suited to devices that require high capacity data storage, such as pictures, music, and data files. NAND nonvolatility makes of it a good storage solution for many applications where mobility, low power, and speed are key factors. Low pin count and simple interface are other advantages of NAND.

Table 15-468 summarizes the NAND interface signals level applied to external device or memories.

Table 15-468. NAND Interface Bus Operations Summary

Bus Operation	CLE	ALE	nCE	nWE [(1)]	nRE [(1)]
Read (cmd input)	H	L	L	RE	H
Read (add input)	L	H	L	RE	H

Table 15-468. NAND Interface Bus Operations Summary (continued)

Bus Operation	CLE	ALE	nCE	nWE [(1)]	nRE [(1)]
Write (cmd input)	H	L	L	RE	H
Write (add input)	L	H	L	RE	H
Data input	L	L	L	RE	H
Data output	L	L	L	H	FE
Busy (during read)	x	x	H [(2)]	H [(2)]	H [(2)]
Busy (during program)	x	x	x	x	x
Busy (during erase)	x	x	x	x	x
Standby	x	x	H	x	x

(1) RE stands for rising edge; FE stands for falling edge
(2) Can be nCE high, or WE and nRE high.

15.4.6.2.1.3 NOR Interface Protocol

NOR flash architecture, introduced in 1988, is a flash technology. Unlike NAND, which is a sequential access device, NOR is directly addressable; that is, it is designed to be a random access device. NOR is best suited to devices used to store and run code or firmware, usually in small capacities. While NOR has fast read capabilities, it also has slow write and erase functions when compared to the NAND architecture.

Table 15-469 summarizes the level of the NOR interface signals applied to external devices or memories.

Table 15-469. NOR Interface Bus Operations Summary

Bus Operation	CLK	nADV	nCS	nOE	nWE	WAIT	DQ[15:0]
Read (asynchronous)	x	L	L	L	H	Asserted	Output

Standby	x	x	H	x	x	High-Z	High-Z

15.4.6.2.1.4 Other Technologies

Other supported device types interact with the GPMC through the NOR interface protocol.

OneNAND is a high-density, low-power memory device. OneNAND is based on single- or multilevel-cell NAND core with SRAM and logic. It interfaces as a synchronous NOR flash and has synchronous write capability. It reads faster than conventional NAND and writes faster than conventional NOR flash. Hence, it is appropriate for mass storage and code storage.

pSRAM (pseudo-static random access memory) is a low-power memory device. pSRAM is based on the DRAM cell with internal refresh and address control features, and interfaces as a synchronous NOR flash. It also has synchronous write capability.

15.4.6.2.1.5 Supported Protocols

The GPMC supports the following interface protocols when communicating with external memory or external devices:

- Asynchronous read/write access
- Asynchronous read page access (4, 8, 16 Word16)
- Synchronous read/write access
- Synchronous read burst access without wrap capability (4, 8, 16 Word16)
- Synchronous read burst access with wrap capability (4, 8, 16 Word16)

15.4.6.2.2 GPMC Features and Settings

The features and settings of the GPMC are:

- Supported device type: Up to four NAND or NOR protocol external memories or devices
- Operating voltage: 1.8 V, 3.3 V
- Maximum operating frequency provided externally: See the device data manual for precise information.
- Maximum GPMC addressing capability: 512MiB divided into eight chip-selects
- Maximum supported memory size: 256MiB (must be a power-of-two)
- Minimum supported memory size: 16MiB (must be a power-of-two). Aliasing occurs when addressing smaller memories.
- Data path to external memory or device: 8, 16 bits wide
- Burst and page access: burst of 4, 8, 16 Word16
- Supports bus keeping
- Supports bus turnaround

15.4.7 GPMC Register Manual

This section provides information about the GPMC instance in this product. Table 15-471 provides a summary of the GPMC registers. The remaining parts of this section describe the registers within the module instance.

15.4.7.1 GPMC Register Summary

Table 15-470. GPMC Instance Summary

Module Name	Base Address	Size
GPMC	0x5000 0000	16 MiB

Table 15-471. GPMC Registers Mapping Summary

(1) i = 0 to 7 for GPMC
(2) j = 0 to 8 for GPMC

15.4.7.2 GPMC Register Descriptions

Note

All GPMC registers are aligned to 32-bit address boundaries. All register file accesses, except to GPMC_NAND_DATA_i register, are little-endian. If the GPMC_NAND_DATA_i register location is accessed, the endianness is access-dependent.

In this section i corresponds to the chip-select number, where i = 0 to 7.

Table 15-472. GPMC_REVISION

Address Offset	0x0000 0000		
Physical Address	0x5000 0000	**Instance**	GPMC
Description	This register contains the IP revision code.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REVISION																															

Bits	Field Name	Description	Type	Reset
31:0	REVISION	IP revision	R	TI internal data

Table 15-473. GPMC_SYSCONFIG

Address Offset	0x0000 0010		
Physical Address	0x5000 0010	**Instance**	GPMC
Description	This register controls the various parameters of the interconnect.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																											IDLEMODE		RESERVED	SOFTRESET	AUTOIDLE

Bits	Field Name	Description	Type	Reset
31:5	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0000000
4:3	IDLEMODE	0x0: Force-idle. An idle request is acknowledged unconditionally. 0x1: No-idle. An idle request is never acknowledged. 0x2: Smart-idle. Acknowledgment to an idle request is given based on the internal activity of the module. 0x3: Do not use.	RW	0x0
2	RESERVED	Write 0 for future compatibility Read returns 0.	RW	0x0
1	SOFTRESET	Software reset. Set this bit to 1 triggers a module reset. This bit is automatically reset by hardware. During reads, it always returns 0. 0x0: Normal mode 0x1: The module is reset.	RW	0x0
0	AUTOIDLE	Internal interface clock-gating strategy 0x0: Interface clock is free-running. 0x1: Automatic Interface clock gating strategy is applied, based on the interconnect activity.	RW	0x0

Table 15-474. GPMC_SYSSTATUS

Address Offset	0x0000 0014		
Physical Address	0x5000 0014	**Instance**	GPMC

Table 15-474. GPMC_SYSSTATUS (continued)

Description	This register provides status information about the module, excluding the interrupt status information.
Type	R

31-8	7-1	0
RESERVED	RESERVED	RESETDONE

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Read returns 0.	R	0x000000
7:1	RESERVED	Read returns 0 (reserved for interconnect-socket status information).	R	0x00
0	RESETDONE	Internal reset monitoring 0x0: Internal module reset is ongoing. 0x1: Reset is complete.	R	0x-

Table 15-475. GPMC_IRQSTATUS

Address Offset	0x0000 0018		
Physical Address	0x5000 0018	**Instance**	GPMC
Description	This interrupt status register regroups all the status of the module internal events that can generate an interrupt.		
Type	RW		

31-10	9	8	7-2	1	0
RESERVED	WAIT1EDGEDETECTIONSTATUS	WAIT0EDGEDETECTIONSTATUS	RESERVED	TERMINALCOUNTSTATUS	FIFOEVENTSTATUS

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x000000
9	WAIT1EDGEDETECTIONSTATUS	Status of the Wait1 Edge Detection interrupt Read 0x0: A transition on WAIT1 input pin has not been detected. Write 0x0: WAIT1EDGEDETECTIONSTATUS bit is unchanged. Read 0x1: A transition on WAIT1 input pin has been detected. Write 0x1: WAIT1EDGEDETECTIONSTATUS bit is reset.	RW	0x0
8	WAIT0EDGEDETECTIONSTATUS	Status of the Wait0 Edge Detection interrupt Read 0x0: A transition on WAIT0 input pin has not been detected. Write 0x0: WAIT0EDGEDETECTIONSTATUS bit is unchanged. Read 0x1: A transition on WAIT0 input pin has been detected. Write 0x1: WAIT0EDGEDETECTIONSTATUS bit is reset.	RW	0x0
7:2	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00

Bits	Field Name	Description	Type	Reset
1	TERMINALCOUNTSTATUS	Status of the TerminalCountEvent interrupt Read 0x0: Indicates that CountValue is greater than 0 Write 0x0: TERMINALCOUNTSTATUS bit is unchanged. Read 0x1: Indicates that CountValue is equal to 0 Write 0x1: TERMINALCOUNTSTATUS bit is reset.	RW	0x0
0	FIFOEVENTSTATUS	Status of the FIFOEvent interrupt Read 0x0: Indicates that less than GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bytes are available in prefetch mode and less than FIFOTHRESHOLD bytes free places are available in write-posting mode Write 0x0: FIFOEVENTSTATUS bit is unchanged. Read 0x1: Indicates that at least GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bytes are available in prefetch mode and at least FIFOTHRESHOLD bytes free places are available in write-posting mode Write 0x1: FIFOEVENTSTATUS bit is reset.	RW	0x0

Table 15-476. GPMC_IRQENABLE

Address Offset	0x0000 001C		
Physical Address	0x5000 001C	**Instance**	GPMC
Description	The interrupt enable register allows to mask/unmask the module internal sources of interrupt, on a event-by-event basis.		
Type	RW

15.5 Error Location Module

15.5.1 Error Location Module Overview

When reading from NAND flash memories, some level of error-correction is required. In the case of NAND modules with no internal correction capability, sometimes referred to as *bare NANDs*, the correction process is delegated to the memory controller.

The general-purpose memory controller (GPMC) probes data read from an external NAND flash and uses this to compute checksum-like information, called syndrome polynomials, on a per-block basis. Each syndrome polynomial gives a status of the read operations for a full block, including 512 bytes of data, parity bits, and an optional spare-area data field, with a maximum block size of 1023 bytes. Computation is based on a Bose-Chaudhuri-Hocquenghem (BCH) algorithm. The error-location module (ELM) extracts error addresses from these syndrome polynomials.

Based on the syndrome polynomial value, the ELM can detect errors, compute the number of errors, and give the location of each error bit. The actual data is not required to complete the error-correction algorithm. Errors can be reported anywhere in the NAND flash block, including in the parity bits.

The maximum acceptable number of errors that can be corrected depends on a programmable configuration parameter. 4-, 8-, and 16-bit error-correction levels are supported. The ELM relies on a static and fixed definition of the generator polynomial for each error-correction level that corresponds to the generator polynomials defined in the GPMC (there are three fixed polynomial for the three correction error levels). A larger number of errors than the programmed error-correction level may be detected, but the ELM cannot correct them all. The offending block is then tagged as *uncorrectable* in the associated computation exit status register. If the computation is successful, that is, if the number of errors detected does not exceed the maximum value authorized for the chosen correction capability, the exit status register contains the information on the number of detected errors.

When the error-location process completes, an interrupt is triggered to inform the software that its status can be checked. The number of detected errors and their locations in the NAND block can be retrieved from the module through register accesses.

The ELM has the following features:

- 4, 8 and 16 bits per 512-byte block error-location based on BCH algorithms
- Eight simultaneous processing contexts
- Page-based and continuous modes
- Interrupt generation on error-location process completion:
  - When the full page has been processed in page mode
  - For each syndrome polynomial in continuous mode

Figure 15-104 shows the ELM overview.

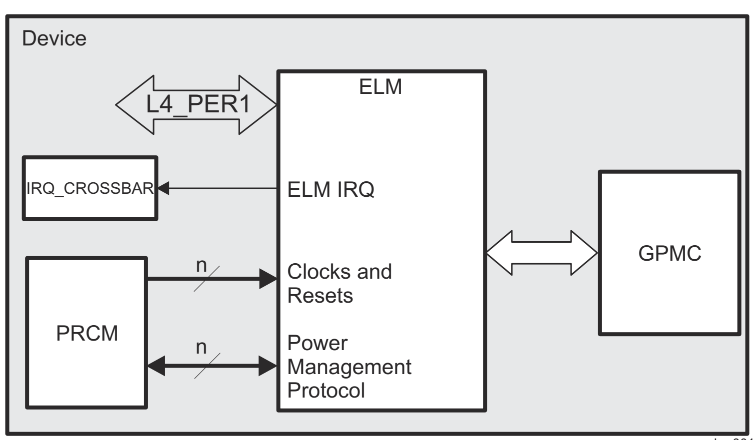

Figure 15-104. ELM Overview

15.5.2 ELM Integration

The ELM extracts error addresses from generated syndrome polynomials.

The ELM is used with the GPMC. Syndrome polynomials generated on-the-fly when reading a NAND flash page and stored in GPMC registers are passed to the ELM. The microprocessor unit (MPU) can then correct the data block by flipping the bits to which the ELM error-location outputs point.

Figure 15-105 shows the integration of the ELM subsystem in the device.

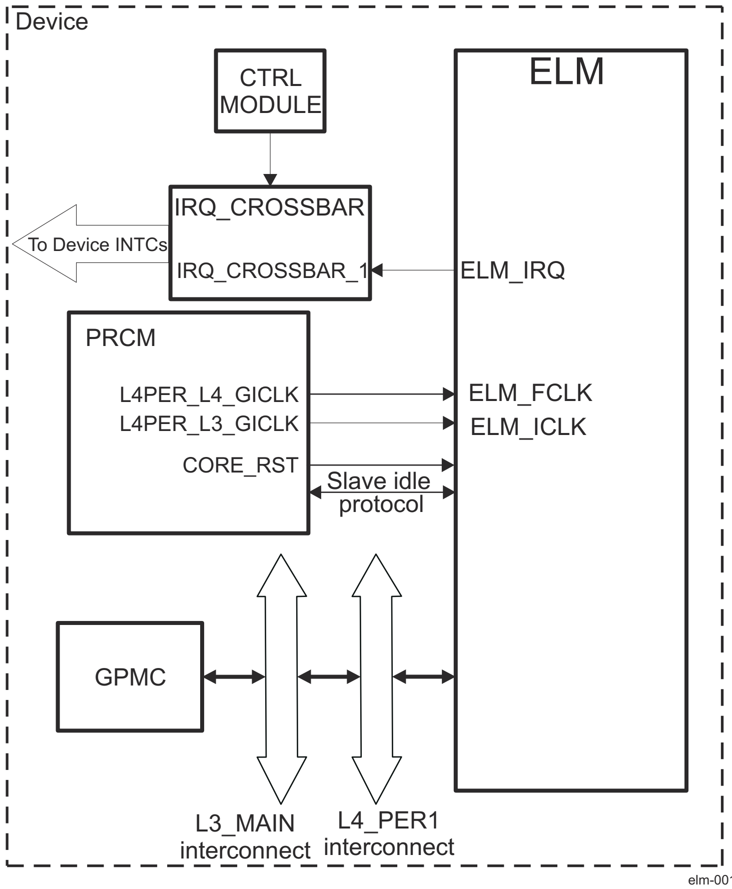

Figure 15-105. ELM Integration

Table 15-508 through Table 15-510 summarize the integration of the module in the device.

Table 15-508. ELM Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
ELM	PD_COREAON	No	L4_PER1

Table 15-510. ELM Hardware Requests

Interrupt Requests				
Module Instance	**Source Signal Name**	**IRQ_CROSSBAR**	**Default Mapping**	**Description**
			MPU_IRQ_4	BCH error-location module interrupt
ELM	ELM_IRQ	IRQ_CROSSBAR_1	DSP1_IRQ_32	BCH error-location module interrupt
			DSP2_IRQ_32	BCH error-location module interrupt
			EVE1_IRQ_1	BCH error-location module interrupt
			EVE2_IRQ_1	BCH error-location module interrupt

Note

The “**Default Mapping**” column in Table 15-510 *ELM Hardware Requests* shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR module.
For more information about the IRQ_CROSSBAR module, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.
For more information about the device interrupt controllers, see *Interrupt Controllers*.

15.5.3 ELM Functional Description

The ELM is designed around the error-location engine, which handles the computation based on the input syndrome polynomials.

The ELM maps the error-location engine to a standard interconnect interface by using a set of registers to control inputs and outputs.

15.5.3.1 ELM Software Reset

To perform a software reset, set the ELM_SYSCONFIG[1] SOFTRESET bit to 1. The ELM_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. When the software reset completes, the ELM_SYSCONFIG[1] SOFTRESET bit is automatically reset.

15.5.3.2 ELM Power Management

Table 15-511 describes the power-management features available to the ELM.

Note

- For information about source clock gating and a description of the sleep/wake-up transitions, see the *CD_L4_PER1 Clock Domain*, in *Power, Reset, and Clock Management*.
- For a general description of EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see *Clock Management Functional Description*, in *Power, Reset, and Clock Management*

Table 15-511. Local Power-Management Features

Feature	Registers	Description
Clock autogating	ELM_SYSCONFIG[0] AUTOGATING	This bit allows a local power optimization inside the module by gating the ELM_FCLK clock upon the interface activity.
Slave idle modes	ELM_SYSCONFIG[4:3] SIDLEMODE	Force-idle, no-idle, and smart-idle modes are available.
Clock activity	ELM_SYSCONFIG[8] CLOCKACTIVITY	The clock can be switched off or maintained during the wake-up period.
Master standby modes	N/A	
Global wake-up enable	N/A	
Wake-up sources enable	N/A	

CAUTION

The PRCM module has no hardware means of reading CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the ELM CLOCKACTIVITY and ELM clock PRCM control bits. For a description of the ClockActivity feature, see *Power, Reset, and Clock Management*.

15.5.3.3 ELM Interrupt Requests

Table 15-512 lists the event flags, and their masks, that can cause module interrupts.

Table 15-512. Events

Event Flag	Event Mask	Description
ELM_IRQSTATUS[8] PAGE_VALID	ELM_IRQENABLE[8] PAGE_MASK	Page interrupt
ELM_IRQSTATUS[7] LOC_VALID_7	ELM_IRQENABLE[7] LOCATION_MASK_7	Error-location interrupt for syndrome polynomial 7
ELM_IRQSTATUS[6] LOC_VALID_6	ELM_IRQENABLE[6] LOCATION_MASK_6	Error-location interrupt for syndrome polynomial 6
ELM_IRQSTATUS[5] LOC_VALID_5	ELM_IRQENABLE[5] LOCATION_MASK_5	Error-location interrupt for syndrome polynomial 5
ELM_IRQSTATUS[4] LOC_VALID_4	ELM_IRQENABLE[4] LOCATION_MASK_4	Error-location interrupt for syndrome polynomial 4
ELM_IRQSTATUS[3] LOC_VALID_3	ELM_IRQENABLE[3] LOCATION_MASK_3	Error-location interrupt for syndrome polynomial 3
ELM_IRQSTATUS[2] LOC_VALID_2	ELM_IRQENABLE[2] LOCATION_MASK_2	Error-location interrupt for syndrome polynomial 2
ELM_IRQSTATUS[1] LOC_VALID_1	ELM_IRQENABLE[1] LOCATION_MASK_1	Error-location interrupt for syndrome polynomial 1
ELM_IRQSTATUS[0] LOC_VALID_0	ELM_IRQENABLE[0] LOCATION_MASK_0	Error-location interrupt for syndrome polynomial 0

15.5.3.4 Processing Initialization

ELM_LOCATION_CONFIG global setting parameters must be set before using the error-location engine. The ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL bit field defines the error-correction level used (4-,8-, or 16-bit error correction). The ELM_LOCATION_CONFIG[26:16] ECC_SIZE bit field defines the maximum buffer length beyond which the engine processing no longer looks for errors.

Software can choose to use the ELM in continuous mode or page mode. If all ELM_PAGE_CTRL[i] SECTOR_i bits (i is the syndrome polynomial number, where i = 0 to 7) are reset, continuous mode is used. In any other case, page mode is implicitly selected.

- Continuous mode: Each syndrome polynomial is processed independently. Results for a syndrome can be retrieved and acknowledged at any time, regardless of the status of the other seven processing contexts.

- Page mode: Syndrome polynomials are grouped into atomic entities: only one page can be processed at any given time, even if all eight contexts are not used for this page. Unused contexts are lost and cannot be affected to any other processing. The full page must be acknowledged and cleared before moving to the next page.

For completion interrupts to be generated correctly, all ELM_IRQENABLE[i] LOCATION_MASK_i bits (where i = 0 to 7) must be forced to 0 when in page mode, and set to 1 in continuous mode. Additionally, the ELM_IRQENABLE[8] PAGE_MASK bit must be set to 1 when in page mode.

Software initiates error-location processing by writing a syndrome polynomial into one of the eight possible register sets. Each of these register sets includes seven registers: ELM_SYNDROME_FRAGMENT_0_i to ELM_SYNDROME_FRAGMENT_6_i. The first six registers can be written in any order, but ELM_SYNDROME_FRAGMENT_6_i must be written last because it includes the validity bit, which instructs the ELM that this syndrome polynomial must be processed (the ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID bit).

As soon as one validity bit is asserted (ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID = 0x1, where i = 0 to 7), error-location processing can start for the corresponding syndrome polynomial. The associated ELM_LOCATION_STATUS_i and ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i registers (where i = 0 to 7) are not reset. Software must not consider them until the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit is set.

15.5.3.5 Processing Sequence

While the error-location engine is busy processing one syndrome polynomial, further syndrome polynomials can be written. They are processed when the current processing completes.

The engine completes early when:

- No error is detected; that is, when the ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE bit is set to 1 and the ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS bit field is set to 0x0.
- Too many errors are detected; that is, when the ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE bit is set to 0 while the ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS bit field is set with the value output by the error-location engine. The reported number of errors is not ensured if ECC_CORRECTABLE is 0.

If the engine completes early, the associated error-location registers ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i (where i = 0 to 7) are not updated.

In all other cases, the engine goes through the entire error-location process. Each time an error location is found, it is logged in the associated ECC_ERROR_LOCATION bit field. The first error detected is logged in the ELM_ERROR_LOCATION_0_i[12:0] ECC_ERROR_LOCATION bit field; the second is logged in the ELM_ERROR_LOCATION_1_i[12:0] ECC_ERROR_LOCATION bit field, and so on.

Table 15-513 describes the ELM_LOCATION_STATUS_i value decoding.

Table 15-513. ELM_LOCATION_STATUS_i Value Decoding

ECC_CORRECTABLE Value	ECC_NB_ERRORS Value	Status	Number of Errors Detected	Action Required
1	0	OK	0	None
1	≠ 0	OK	ECC_NB_ERRORS	Correct the data buffer read based on the ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i results.
0	Any	Failed	Unknown	Software-dependent

15.5.3.6 Processing Completion

When the processing for a given syndrome polynomial completes, its ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID bit is reset. It must not be set again until the exit status registers, ELM_LOCATION_STATUS_i (where i = 0 to 7) for this processing are checked. Failure to comply with this rule leads to potential loss of the first polynomial process data output.

The error-location engine signals the process completion to the ELM. When this event is detected, the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit (where i = 0 to 7) is set. The processing exit status is available from the associated ELM_LOCATION_STATUS_i register, and error locations are stored in order in the ECC_ERROR_LOCATION bit fields. Software must read only valid error-location registers based on the number of errors detected and located.

Immediately after the error-location engine completes, a new syndrome polynomial can be processed, if any is available, as reported by the ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID bit, depending on the configured error-correction level. If several syndrome polynomials are available, a round-robin arbitration is used to select one for processing.

In continuous mode (that is, all bits in ELM_PAGE_CTRL are reset), an interrupt is triggered whenever a ELM_IRQSTATUS[i] LOC_VALID_i bit is asserted. Software must read the ELM_IRQSTATUS register to determine which polynomial is processed and retrieve the exit status and error locations (ELM_LOCATION_STATUS_i and ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i). When done, software must clear the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit by setting it to 1. Other status bits must be set to 0 so that other interrupts are not unintentionally cleared. When using this mode, the ELM_IRQSTATUS[8] PAGE_VALID interrupt is never triggered.

In page mode, the module does not trigger interrupts for the processing completion of each polynomial because the ELM_IRQENABLE[i] LOCATION_MASK_i bits are cleared. A page is defined using the ELM_PAGE_CTRL register. Each SECTOR_i bit set means the corresponding polynomial i is part of the page processing. A page is fully processed when all tagged polynomials have been processed, as logged in the ELM_IRQSTATUS[i] LOC_VALID_i bits. The module triggers an ELM_IRQSTATUS[8] PAGE_VALID interrupt whenever it detects that the full page has been processed. To make sure the next page can be correctly processed, all status bits in the ELM_IRQSTATUS register must be cleared by using a single atomic-write access.

Note

Do not modify page setting parameters in the ELM_PAGE_CTRL register unless the engine is idle, no polynomial input is valid, and all interrupts have been cleared.

Because no polynomial-level interrupt is triggered in page mode, polynomials cleared in the ELM_PAGE_CTRL[i] SECTOR_i bits (where i = 0 to 7) are processed as usual, but are essentially ignored. Software must manually poll the ELM_IRQSTATUS bits to check for their status.

15.5.4 ELM Basic Programming Model

15.5.4.1 ELM Low-Level Programming Model

15.5.4.1.1 Processing Initialization

Table 15-514. ELM Processing Initialization

Step	Register/Bit Field/Programming Model	Value
Resets the module	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1
Configure the slave interface power management.	ELM_SYSCONFIG[4:3] SIDLEMODE	Set value.
Defines the error-correction level used	ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL	Set value.
Defines the maximum buffer length	ELM_LOCATION_CONFIG[26:16] ECC_SIZE	Set value.
Sets the ELM in continuous mode or page mode	ELM_PAGE_CTRL	Set value.
If continuous mode is used	All ELM_PAGE_CTRL[i] SECTOR_i (where i = 0 to 7)	0x0
Enables interrupt for syndrome polynomial i	ELM_IRQENABLE[i] LOCATION_MASK_i	0x1
else (page mode is used)	One syndrome polynomial i is set ELM_PAGE_CTRL[i] SECTOR_i (where i = 0 to 7)	0x1
Disable all interrupts for syndrome polynomial and enable PAGE_MASK interrupt.	All ELM_IRQENABLE[i] LOCATION_MASK_i = 0x0 and ELM_IRQENABLE[8] PAGE_MASK = 0x1	Set value.
endif		Set value.

Table 15-514. ELM Processing Initialization (continued)

Step	Register/Bit Field/Programming Model	Value
Set the input syndrome polynomial i.	ELM_SYNDROME_FRAGMENT_0_i	Set value.
	ELM_SYNDROME_FRAGMENT_1_i	Set value.
	ELM_SYNDROME_FRAGMENT_5_i	Set value.
	ELM_SYNDROME_FRAGMENT_6_i	Set value.
Initiates the computation process	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID	0x1

15.5.4.1.2 Read Results

The engine goes through the entire error-location process and results can be read. Table 15-515 and Table 15-516 describe the processing completion for continuous and page modes, respectively.

Table 15-515. ELM Processing Completion for Continuous Mode

Step	Register/Bit Field/Programming Model	Value
Wait until process is complete for syndrome polynomial i: Wait until the ELM_IRQ interrupt is generated, or poll the status register.		
Read for which i the error-location process is complete.	ELM_IRQSTATUS[i] LOC_VALID_i	0x1
if the process fails (too many errors)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x0
It is software dependant.		
else (process successful, the engine completes)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x1
Read the number of errors.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS	
Read the error-location bit addresses for syndrome polynomial i of the ECC_NB_ERRORS first registers. Software must correct errors in the data buffer.	ELM_ERROR_LOCATION_0_i[12:0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_i[12:0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_i[12:0] ECC_ERROR_LOCATION	
endif		
Clear the corresponding i interrupt.	ELM_IRQSTATUS[i] LOC_VALID_i	0x1

A new syndrome polynomial can be processed after the end of processing (ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID = 0x0) and after the exit status register check (ELM_LOCATION_STATUS_i).

Table 15-516. ELM Processing Completion for Page Mode

Step	Register/Bit Field/Programming Model	Value
Wait until process is complete for syndrome polynomial i: Wait until the ELM_IRQ interrupt is generated, or poll the status register.		
Wait for page completed interrupt: All error locations are valid.	ELM_IRQSTATUS[8] PAGE_VALID	0x1
Repeat the following actions the necessary number of times. That is, once for each valid defined block in the page.		
Read the process exit status.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	
if the process fails (too many errors)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x0
It is software dependent.		
else (process successful, the engine completes)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x1
Read the number of errors.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS	

Table 15-516. ELM Processing Completion for Page Mode (continued)

Step	Register/Bit Field/Programming Model	Value
Read the error-location bit addresses for syndrome polynomial i of the ECC_NB_ERRORS first registers.	ELM_ERROR_LOCATION_0_i[12:0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_i[12:0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_i[12:0] ECC_ERROR_LOCATION	
endif		
End Repeat		
Clear the ELM_IRQSTATUS register.	ELM_IRQSTATUS	0x1FF

15.5.4.1.3

Next page can be correctly processed after a page is fully processed, when all tagged polynomials have been processed (ELM_IRQSTATUS[i] LOC_VALID_i = 0x1 for all syndrome polynomials i used in the page).

15.5.4.2 Use Case: ELM Used in Continuous Mode

In this example, the ELM is programmed for an 8-bit error-correction capability in continuous mode (see Table 15-517). After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, a nonzero polynomial syndrome is reported from the GPMC (polynomial syndrome 0 is used in the ELM):

- P = 0x0A16ABE115E44F767BFB0D0980

Table 15-517. Use Case: Continuous Mode

Step	Register/Bit Field/Programming Model	Value
Resets the module	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1
Configure the slave interface power management: Smart idle is used.	ELM_SYSCONFIG[4:3] SIDLEMODE	0x2
Defines the error-correction level used: 8 bits	ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL	0x1
Defines the maximum buffer length: 528 bytes (2 × 528 = 1056)	ELM_LOCATION_CONFIG[26:16] ECC_SIZE	0x420
Sets the ELM in continuous mode	ELM_PAGE_CTRL	0
Enables interrupt for syndrome polynomial 0	ELM_IRQENABLE[0] LOCATION_MASK_0	0x1
Set the input syndrome polynomial 0.	ELM_SYNDROME_FRAGMENT_0_i (where i = 0)	0xFB0D0980
	ELM_SYNDROME_FRAGMENT_1_i (where i = 0)	0xE44F767B
	ELM_SYNDROME_FRAGMENT_2_i (where i = 0)	0x16ABE115
	ELM_SYNDROME_FRAGMENT_3_i (where i = 0)	0x0000000A
Initiates the computation process	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (where i = 0)	0x1
Wait until process is complete for syndrome polynomial 0: IRQ_ELM is generated or poll the status register.		
Read that error-location process is complete for syndrome polynomial 0.	ELM_IRQSTATUS[0] LOC_VALID_0	0x1
Read the process exit status: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (where i = 0)	0x1
Read the number of errors: Four errors detected.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS (where i = 0)	0x4
Read the error-location bit addresses for syndrome polynomial 0 of the first four registers: Errors are located in the data buffer at decimal addresses 431, 1062, 1909, 3452.	ELM_ERROR_LOCATION_0_i (where i = 0)	0x1AF
	ELM_ERROR_LOCATION_1_i (where i = 0)	0x426
	ELM_ERROR_LOCATION_2_i (where i = 0)	0x775
	ELM_ERROR_LOCATION_3_i (where i = 0)	0xD7C

Table 15-517. Use Case: Continuous Mode (continued)

Step	Register/Bit Field/Programming Model	Value
Clear the corresponding interrupt for polynomial 0.	ELM_IRQSTATUS[0] LOC_VALID_0	0x1

The NAND flash data in the sector are seen as a polynomial of degree 4223 (number of bits in a 528 byte buffer minus 1), with each data bit being a coefficient in the polynomial. When reading from a NAND flash using the GPMC module, computation of the polynomial syndrome assumes that the first NAND word read at address 0x0 contains the highest-order coefficient in the message. Furthermore, in the 16-bit NAND word, bits are ordered from bit 7 to bit 0, and then from bit 15 to bit 8. Based on this convention, an address table of the data buffer can be built. NAND memory addresses in Table 15-518 are given in decimal format.

Table 15-518. 16-Bit NAND Sector Buffer Address Map

NAND Memory Address	Message Bit Addresses in Memory Word															
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	4215	4214	4213	4212	4211	4210	4209	4208	4223	4222	4221	4220	4219	4218	4217	4216
1	4175	4174	4173	4172	4171	4170	4169	4168	4183	4182	4181	4180	4179	4178	4177	4176
...																
47	3463	3462	3461	3460	3459	3458	3457	3456	3471	3470	3469	3468	3467	3466	3465	3464

49	3431	3430	3429	3428	3427	3426	3425	3424	3439	3438	3437	3436	3435	3434	3433	3432
50	3415	3414	3413	3412	3411	3410	3409	3408	3423	3422	3421	3420	3419	3418	3417	3416
...																
255	135	134	133	132	131	130	129	128	143	142	141	140	139	138	137	136
256	119	118	117	116	115	114	113	112	127	126	125	124	123	122	121	120
257	103	102	101	100	99	98	97	96	111	110	109	108	107	106	105	104
258	87	86	85	84	83	82	81	80	95	94	93	92	91	90	89	88
259	71	70	69	68	67	66	65	64	79	78	77	76	75	74	73	72
260	55	54	53	52	51	50	49	48	63	62	61	60	59	58	57	56
261	39	38	37	36	35	34	33	32	47	46	45	44	43	42	41	40
262	23	22	21	20	19	18	17	16	31	30	29	28	27	26	25	24
263	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8

The table can now be used to determine which bits in the buffer were incorrect and must be flipped. In this example, the first bit to be flipped is bit 4 from the 49th byte read from memory. It is up to the processor to correctly map this word to the copied buffer and flip this bit. The same process must be repeated for all detected errors.

15.5.4.3 Use Case: ELM Used in Page Mode

In this example, the ELM module is programmed for an 16-bit error-correction capability in page mode (see Table 15-519). After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, four non-zero polynomial syndromes are reported from the GPMC (polynomial syndrome 0, 1, 2, and 3 are used in the ELM):

- P0 = 0xE8B0 12ADDB5A318E05BE B0693DB28330B5CC A329AA05E0B718EF
- P1 = 0xBAD0 49A0D932C22E6669 0948DF08BE093336 79C6BA10E5F935EB
- P2 = 0x69D9 B86ABCD5EC3697FA A6498FEE54556EA0 1579EF7D60BA3189
- P3 = 0x0

15.5.5.2.2 ELM Register Description

Table 15-522 through Table 15-552 describe the individual ELM registers.

Table 15-522. ELM_REVISION

Address Offset	0x0000 0000		
Physical Address	0x4807 8000	**Instance**	ELM
Description	This register contains the IP revision code. (A write or reset of to this register has no effect.)		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REVISION																															

Bits	Field Name	Description	Type	Reset
31:0	REVISION	IP Revision (TI internal data)	R	0x-

Table 15-523. ELM_SYSCONFIG

Address Offset	0x0000 0010		
Physical Address	0x4807 8010	**Instance**	ELM
Description	This register allows controlling various parameters of the OCP interface.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																							CLOCKACTIVITYOCP	RESERVED			SIDLEMODE		RESERVED	SOFTRESET	AUTOGATING

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Reserved	R	0x000000
8	CLOCKACTIVITYOCP	OCP clock activity when module is in IDLE mode (during wake-up mode period) 0x0: OCP clock can be switched off. 0x1: OCP clock is maintained during wake-up period.	RW	0
7:5	RESERVED	Reserved	R	0x0
4:3	SIDLEMODE	Slave interface power management (IDLE req/ack control) 0x0: Force-idle. IDLE request is acknowledged unconditionally and immediately (Default *Dumb* mode for safety) 0x1: No-idle. IDLE request is never acknowledged. 0x2: Smart-idle. The acknowledgment to an IDLE request is given based on the internal activity. 0x3: Reserved - do not use	RW	0x2
2	RESERVED	Reserved	R	0

Bits	Field Name	Description	Type	Reset
1	SOFTRESET	Module software reset This bit is automatically reset by hardware (during reads, it always returns 0). It has same effect as the OCP hardware reset. 0x0: Normal mode 0x1: Start soft reset sequence.	RW	0
0	AUTOGATING	Internal OCP clock gating strategy (no module visible effect other than saving power) 0x0: OCP clock is free-running. 0x1: Automatic internal OCP clock gating strategy is applied based on the OCP interface activity.	RW	1

Table 15-524. ELM_SYSSTATUS

Address Offset	0x0000 0014		
Physical Address	0x4807 8014	**Instance**	ELM
Description	Internal reset monitoring (OCP domain) Undefined since: From hardware perspective, the reset state is 0. From software user perspective, when the accessible module is 1.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																															RESETDONE

Bits	Field Name	Description	Type	Reset
31:1	RESERVED	Reserved	R	0x0000 0000
0	RESETDONE	Internal reset monitoring (OCP domain) Undefined since: From hardware perspective, the reset state is 0. From software user perspective, when the accessible module is 1. Read 0x0: Reset is ongoing. Read 0x1: Reset is done (completed).	R	1

Table 15-525. ELM_IRQSTATUS

Address Offset	0x0000 0018		
Physical Address	0x4807 8018	**Instance**	ELM
Description	Interrupt status. This register doubles as a status register for the error-location processes.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																							PAGE_VALID	LOC_VALID_7	LOC_VALID_6	LOC_VALID_5	LOC_VALID_4	LOC_VALID_3	LOC_VALID_2	LOC_VALID_1	LOC_VALID_0

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Reserved	R	0x000000

Bits	Field Name	Description	Type	Reset
8	PAGE_VALID	Error-location status for a full page, based on the mask definition Read 0x0: Error locations invalid for all polynomials enabled in the ECC_INTERRUPT_MASK register Read 0x1: All error locations valid Write 0x0: No effect Write 0x1: Clear interrupt	RW	0
7	LOC_VALID_7	Error-location status for syndrome polynomial 7 Read 0x0: No syndrome processed or process in progress Read 0x1: Error-location process completed Write 0x0: No effect Write 0x1: Clear interrupt	RW W1toClr	0
6	LOC_VALID_6	Error-location status for syndrome polynomial 6	RW W1toClr	0
5	LOC_VALID_5	Error-location status for syndrome polynomial 5	RW W1toClr	0
4	LOC_VALID_4	Error-location status for syndrome polynomial 4	RW W1toClr	0
3	LOC_VALID_3	Error-location status for syndrome polynomial 3	RW W1toClr	0
2	LOC_VALID_2	Error-location status for syndrome polynomial 2	RW W1toClr	0
1	LOC_VALID_1	Error-location status for syndrome polynomial 1	RW W1toClr	0
0	LOC_VALID_0	Error-location status for syndrome polynomial 0	RW W1toClr	0

Table 15-526. ELM_IRQENABLE

Address Offset	0x0000 001C		
Physical Address	0x4807 801C	**Instance**	ELM
Description	Interrupt enable

15.6 On-Chip Memory (OCM) Subsystem

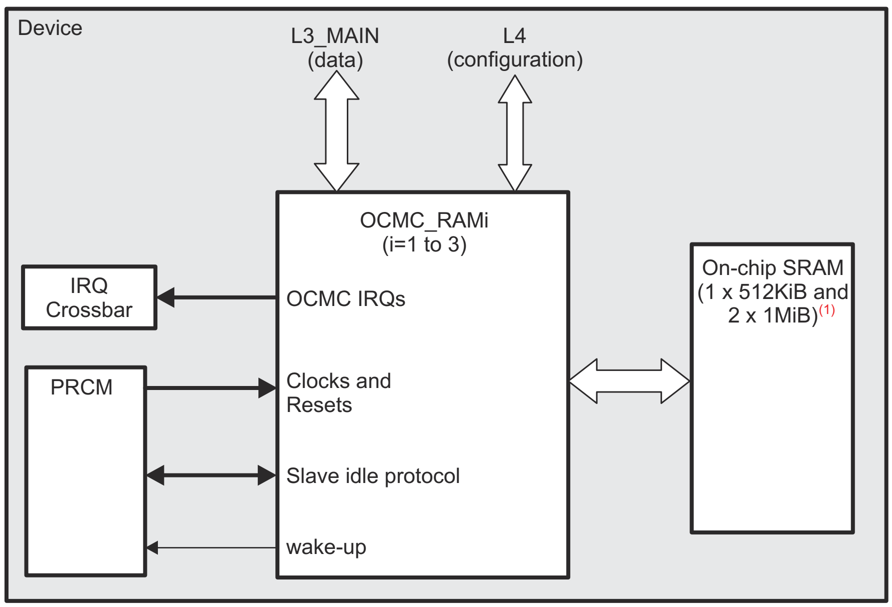
15.6.1 OCM Subsystem Overview

The OCM subsystem consists of three OCM Controllers (OCMC) that are associated with the on-chip RAM. The OCM controllers are also introduced in Section 15.1.6, *OCM Overview* of Section 15.1, *Memory Subsystem Overview*.

The RAM associated controllers are as follows:

- OCMC_RAM1 with 512 KiB of dedicated memory space.
- OCMC_RAM2 with 1024 KiB of dedicated memory space.
- OCMC_RAM3 with 1024 KiB of dedicated memory space.

Figure 15-106 shows the three OCMC_RAM controllers.



(1) Presence of RAM bank is device part number dependent. For more information, see the device Data Manual.

Figure 15-106. OCMC_RAMi (i = 1 to 3) Overview

15.6.2 OCM Subsystem Integration

Figure 15-107 shows the integration of the OCM Subsystem in the device.

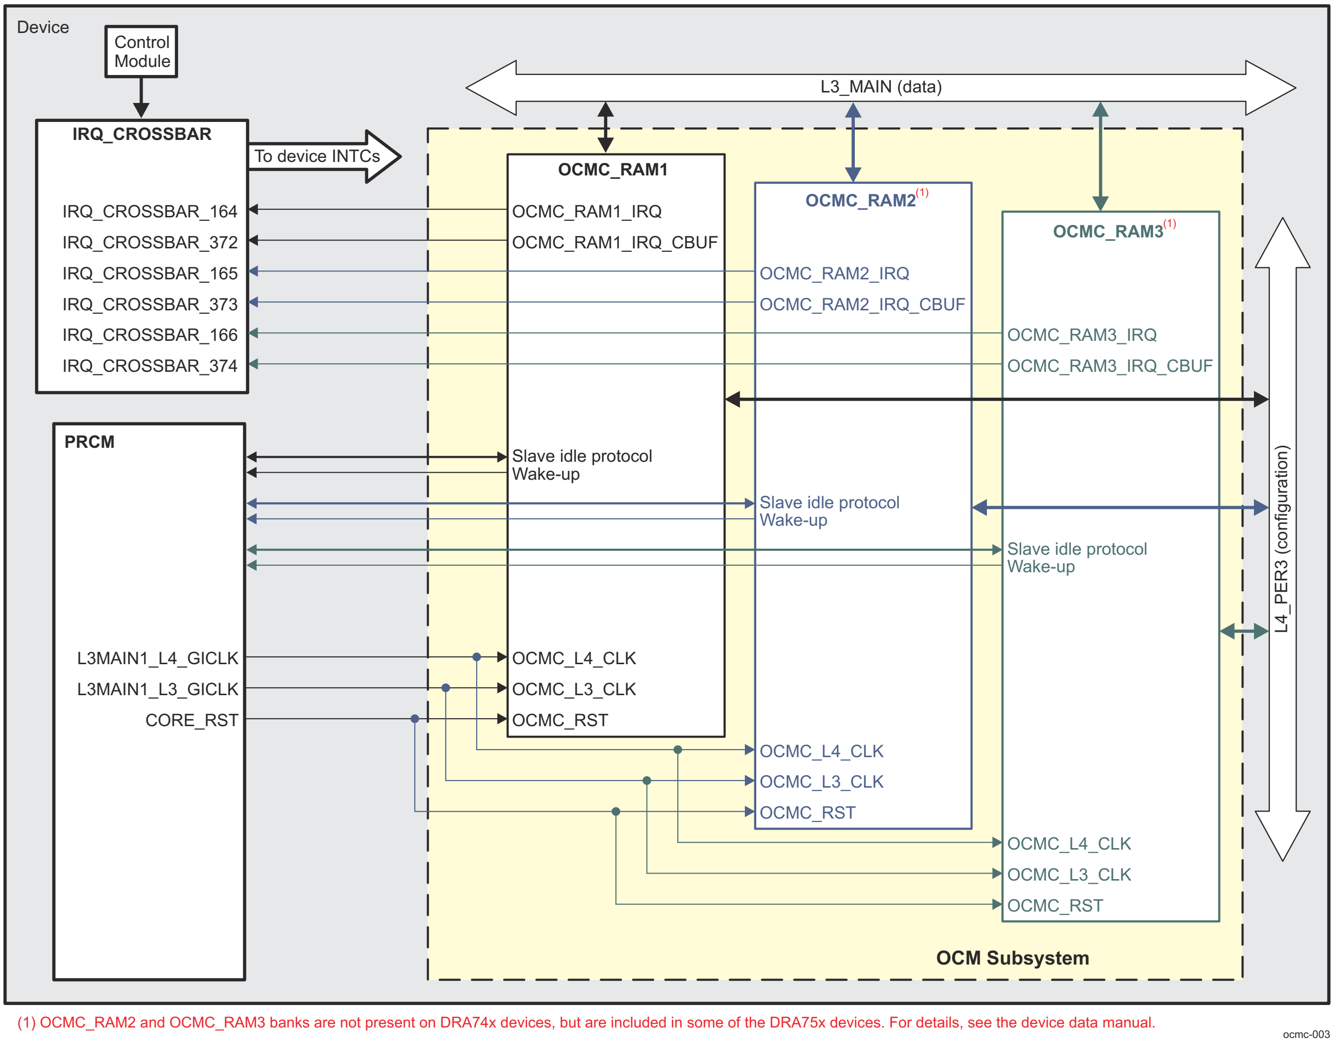


Figure 15-107. OCM Subsystem Integration

Table 15-553 through Table 15-555 summarize the integration of the OCM Subsystem in the device.

Table 15-553. OCM Subsystem Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
OCMC_RAM1	PD_COREAON	Yes	L3_MAIN
			L4_PER3
OCMC_RAM2	PD_COREAON	Yes	L3_MAIN
			L4_PER3
OCMC_RAM3	PD_COREAON	Yes	L3_MAIN
			L4_PER3

Table 15-554. OCM Subsystem Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description

Table 15-554. OCM Subsystem Clocks and Resets (continued)

Module Instance	Destination Signal Name	Source Signal Name	Source	Description
OCMC_RAM1	OCMC_L3_CLK	L3MAIN1_L3_GICLK	PRCM	Clock used to drive and receive data over the L3 data bus. This is also the processing clock of the OCM Controller and the SRAM. With this clock all internal data transfers are clocked.
	OCMC_L4_CLK	L3MAIN1_L4_GICLK	PRCM	Clock used to drive and receive data over the L4_PER3 configuration bus. This clock should run at half the OCMC_L3_CLK clock rate.
OCMC_RAM2	OCMC_L3_CLK	L3MAIN1_L3_GICLK	PRCM	Clock used to drive and receive data over the L3 data bus. This is also the processing clock of the OCM Controller and the SRAM. With this clock all internal data transfers are clocked.
	OCMC_L4_CLK	L3MAIN1_L4_GICLK	PRCM	Clock used to drive and receive data over the L4_PER3 configuration bus. This clock should run at half the OCMC_L3_CLK clock rate.
OCMC_RAM3	OCMC_L3_CLK	L3MAIN1_L3_GICLK	PRCM	Clock used to drive and receive data over the L3 data bus. This is also the processing clock of the OCM Controller and the SRAM. With this clock all internal data transfers are clocked.
	OCMC_L4_CLK	L3MAIN1_L4_GICLK	PRCM	Clock used to drive and receive data over the L4_PER3 configuration bus. This clock should run at half the OCMC_L3_CLK clock rate.

Resets

Module Instance	Destination Signal Name	Source Signal Name	Source	Description
OCMC_RAM1	OCMC_RST	CORE_RST	PRCM	Reset signal for the OCM Subsystem
OCMC_RAM2	OCMC_RST	CORE_RST	PRCM	
OCMC_RAM3	OCMC_RST	CORE_RST	PRCM	

Table 15-555. OCM Subsystem Hardware Requests

Interrupt Requests

Module Instance	Source Signal Name	Destination IRQ_CROSSBAR Input	Default Mapping	Description
OCMC_RAM1	OCMC_RAM1_IRQ	IRQ_CROSSBAR_164	-	First OCMC_RAM1 interrupt request. This IRQ source signal is not mapped by default to any device INTC.
	OCMC_RAM1_IRQ_CBUF	IRQ_CROSSBAR_372	-	Second OCMC_RAM1 interrupt request. This IRQ source signal is not mapped by default to any device INTC.
OCMC_RAM2	OCMC_RAM2_IRQ	IRQ_CROSSBAR_165	-	First OCMC_RAM2 interrupt request. This IRQ source signal is not mapped by default to any device INTC.
	OCMC_RAM2_IRQ_CBUF	IRQ_CROSSBAR_373	-	Second OCMC_RAM2 interrupt request. This IRQ source signal is not mapped by default to any device INTC.

Table 15-555. OCM Subsystem Hardware Requests (continued)

OCMC_RAM3	OCMC_RAM3_IRQ	IRQ_CROSSBAR_166	-	First OCMC_RAM3 interrupt request. This IRQ source signal is not mapped by default to any device INTC.
	OCMC_RAM3_IRQ_CBUF	IRQ_CROSSBAR_374	-	Second OCMC_RAM3 interrupt request. This IRQ source signal is not mapped by default to any device INTC.

Note

The “**Default Mapping**” column in Table 15-555 *OCM Subsystem Hardware Requests* shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR module.
For more information about the IRQ_CROSSBAR module, see *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.
For more information about the device interrupt controllers, see *Interrupt Controllers*.

Note

For description of the interrupt sources, see Section 15.6.3.4, *Interrupt Requests*.

15.6.3 OCM Subsystem Functional Desctiption

15.6.3.1 Block Diagram

Figure 15-108 shows the OCMC block diagram.

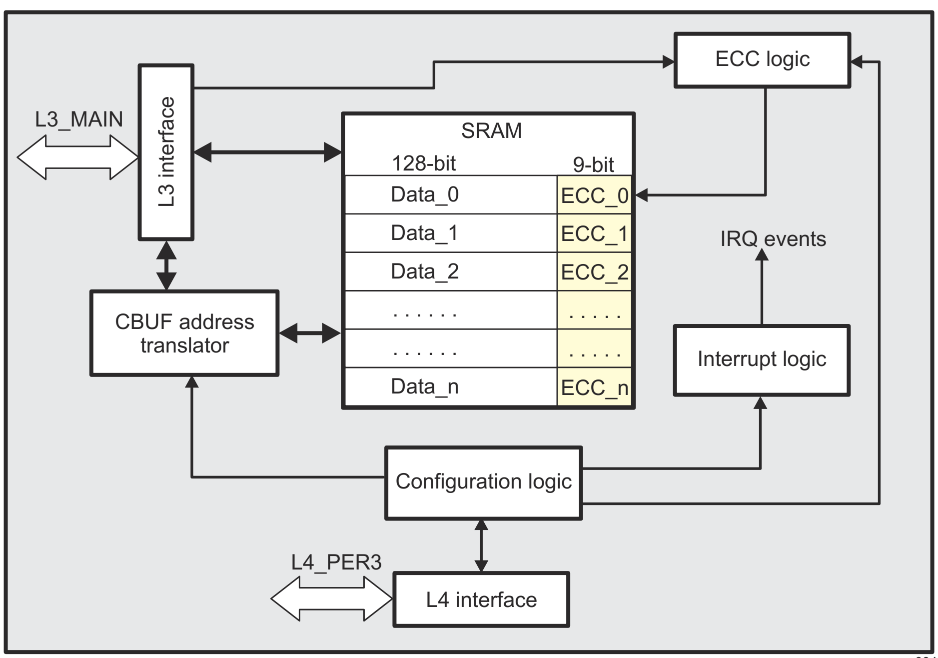

Figure 15-108. OCMC Block Diagram

The module is composed by the following main blocks:

- L3 interface used for data transactions
- L4 interface used for configuration

- CBUF address translator which converts the L3_MAIN VBUF addresses into SRAM addresses
- ECC logic to support single error correction and double error detection
- SRAM used for storring data and the corresponding for each 128-bit word ECC
- Interrupt logic used for generating interrupt requests
- Configuration logic in which reside the registers used for configuring the OCM controller operation modes

15.6.3.2 Resets

The OCMC_RST is the reset signal for the OCM controller which asynchronously resets the whole internal logic of the controller, including all configuration registers. It does not reset the SRAM. In addition, the OCMC_SYSCONFIG_RST[0] SW_RST bit provides a software way to reset the OCM controller. In this case all of its internal logic is reset except the configuration registers accessible through the L4_PER3.

15.6.3.3 Clock Management

The OCM controller complies with the PRCM slave idle protocol. The OCMC_L3_CLK and OCMC_L4_CLK clocks are gated based on the values loaded in the OCMC_SYSCONFIG_PM[3:2] IDLEMODE bit field.

15.6.3.4 Interrupt Requests

The OCM controller generates two interrupt requests, OCMC_RAMi_IRQ and OCMC_RAMi_IRQ_CBUF (i = 1, 2 and 3. i depends on the device part number).

The OCMC_RAMi_IRQ line is associated with the following registers:

- INTR0_STATUS_RAW_SET - interrupt raw status register
- INTR0_STATUS_ENABLED_CLEAR - interrupt status register
- INTR0_ENABLE_SET - interrupt enable register
- INTR0_ENABLE_CLEAR - interrupt disable register

The OCMC_RAMi_IRQ_CBUF line is associated with the following registers:

- INTR1_STATUS_RAW_SET - interrupt raw status register
- INTR1_STATUS_ENABLED_CLEAR - interrupt status register
- INTR1_ENABLE_SET - interrupt enable (event unmask) register
- INTR1_ENABLE_CLEAR - interrupt disable (event mask) register

Both the register groups previously described have identical bits. When for example, only one event occurs one or the two IRQ lines will be asserted depending on the masks applied to the INTR0_ENABLE_SET and INTR1_ENABLE_SET registers. When for example, a short frame detection event occurs and if both the INTR0_ENABLE_SET[14] CBUF_SHORT_FRAME_DETECT_FOUND and INTR1_ENABLE_SET[14] CBUF_SHORT_FRAME_DETECT_FOUND bits are set to 0x1, then both the OCMC_RAMi_IRQ and OCMC_RAMi_IRQ_CBUF lines are asserted. If only the INTR0_ENABLE_SET[14] CBUF_SHORT_FRAME_DETECT_FOUND bit is set to 0x1, then only the OCMC_RAMi_IRQ line is asserted and the OCMC_RAMi_IRQ_CBUF line remains inactive (deasserted). Thus depending on the mask applied one IRQ line of the OCM controller can be associated only with CBUF events for example, and the other one IRQ line can be associated with ECC events. In other words, two unique interrupts can be provided.

Table 15-556 lists the interrupt events which can assert the two interrupt lines of the OCM controller.

The OCM controller asserts each of its interrupt lines only if the interrupts are enabled by setting to 0x1 the corresponding bits in the INTR0_ENABLE_SET/INTR1_ENABLE_SET register. These interrupts can be disabled by setting to 0x1 the corresponding bits in the INTR0_ENABLE_CLEAR/ INTR1_ENABLE_CLEAR register. After the interrupt has been serviced the corresponding status flag must be cleared by software. This is done by setting to 0x1 the corresponding bit in the INTR0_STATUS_ENABLED_CLEAR/INTR1_STATUS_ENABLED_CLEAR register which also clears the corresponding bit in the INTR0_STATUS_RAW_SET/INTR1_STATUS_RAW_SET register. The status flags in the INTR0_STATUS_RAW_SET/INTR1_STATUS_RAW_SET register are set even if the corresponding interrupt is disabled as opposed to those in the INTR0_STATUS_ENABLED_CLEAR/ INTR1_STATUS_ENABLED_CLEAR register, which are set only if the corresponding interrupt is enabled. An interrupt is also generated by the OCM controller, if certain bit in the INTR0_STATUS_RAW_SET/

INTR1_STATUS_RAW_SET register is set to 0x1 and the corresponding interrupt is enabled through the INTR0_ENABLE_SET/INTR1_ENABLE_SET register. This is useful when user software debugging is performed. Additionally, even if interrupts are not enabled, certain status bit in the INTR0_STATUS_RAW_SET/ INTR1_STATUS_RAW_SET register can be cleared by setting to 0x1 the corresponding bit in the INTR0_STATUS_ENABLED_CLEAR/INTR1_STATUS_ENABLED_CLEAR register.

For additional details regarding the CBUF related events, see Section 15.6.3.11, *CBUF Mode Error Handling*.

Table 15-556. OCM Subsystem Events

Event Flag	Event Mask	Description
INTR0_STATUS_RAW_SET[14] CBUF_SHORT_FRAME_DETECT_FOUND/ INTR1_STATUS_RAW_SET[14] CBUF_SHORT_FRAME_DETECT_FOUND and INTR0_STATUS_ENABLED_CLEAR[14] CBUF_SHORT_FRAME_DETECT_FOUND/ INTR1_STATUS_ENABLED_CLEAR[14] CBUF_SHORT_FRAME_DETECT_FOUND	INTR0_ENABLE_SET[14] CBUF_SHORT_FRAME_DETECT_FOUND/ INTR1_ENABLE_SET[14] CBUF_SHORT_FRAME_DETECT_FOUND and INTR0_ENABLE_CLEAR[14] CBUF_SHORT_FRAME_DETECT_FOUND/ INTR1_ENABLE_CLEAR[14] CBUF_SHORT_FRAME_DETECT_FOUND	This bit indicates a short frame detection. It is set if at least one of the bits in the STATUS_CBUF_SHORT_FRAME_DETECT register is set to 0x1.
INTR0_STATUS_RAW_SET[13] CBUF_UNDERFLOW_ERR_FOUND/ INTR1_STATUS_RAW_SET[13] CBUF_UNDERFLOW_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[13] CBUF_UNDERFLOW_ERR_FOUND/ INTR1_STATUS_ENABLED_CLEAR[13] CBUF_UNDERFLOW_ERR_FOUND	INTR0_ENABLE_SET[13] CBUF_UNDERFLOW_ERR_FOUND/ INTR1_ENABLE_SET[13] CBUF_UNDERFLOW_ERR_FOUND and INTR0_ENABLE_CLEAR[13] CBUF_UNDERFLOW_ERR_FOUND/ INTR1_ENABLE_CLEAR[13] CBUF_UNDERFLOW_ERR_FOUND	Indicates CBUF underflow detction. This bit is set if at least one of the bits in the STATUS_CBUF_UNDERFLOW register is set to 0x1.
INTR0_STATUS_RAW_SET[12] CBUF_OVERFLOW_WRAP_ERR_FOUND/ INTR1_STATUS_RAW_SET[12] CBUF_OVERFLOW_WRAP_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[12] CBUF_OVERFLOW_WRAP_ERR_FOUND/ INTR1_STATUS_ENABLED_CLEAR[12] CBUF_OVERFLOW_WRAP_ERR_FOUND	INTR0_ENABLE_SET[12] CBUF_OVERFLOW_WRAP_ERR_FOUND/ INTR1_ENABLE_SET[12] CBUF_OVERFLOW_WRAP_ERR_FOUND and INTR0_ENABLE_CLEAR[12] CBUF_OVERFLOW_WRAP_ERR_FOUND/ INTR1_ENABLE_CLEAR[12] CBUF_OVERFLOW_WRAP_ERR_FOUND	Indicates Cbuf_Overflow_Wrap event
INTR0_STATUS_RAW_SET[11] CBUF_OVERFLOW_MID_ERR_FOUND/ INTR1_STATUS_RAW_SET[11] CBUF_OVERFLOW_MID_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[11] CBUF_OVERFLOW_MID_ERR_FOUND/ INTR1_STATUS_ENABLED_CLEAR[11] CBUF_OVERFLOW_MID_ERR_FOUND	INTR0_ENABLE_SET[11] CBUF_OVERFLOW_MID_ERR_FOUND/ INTR1_ENABLE_SET[11] CBUF_OVERFLOW_MID_ERR_FOUND and INTR0_ENABLE_CLEAR[11] CBUF_OVERFLOW_MID_ERR_FOUND/ INTR1_ENABLE_CLEAR[11] CBUF_OVERFLOW_MID_ERR_FOUND	Indicates Cbuf_Overflow_Mid event

Table 15-556. OCM Subsystem Events (continued)

Event Flag	Event Mask	Description
INTR0_STATUS_RAW_SET[10] CBUF_READ_SEQUENCE_ERR_FOUND/ INTR1_STATUS_RAW_SET[10] CBUF_READ_SEQUENCE_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[10] CBUF_READ_SEQUENCE_ERR_FOUND/ INTR1_STATUS_ENABLED_CLEAR[10] CBUF_READ_SEQUENCE_ERR_FOUND	INTR0_ENABLE_SET[10] CBUF_READ_SEQUENCE_ERR_FOUND/ INTR1_ENABLE_SET[10] CBUF_READ_SEQUENCE_ERR_FOUND and INTR0_ENABLE_CLEAR[10] CBUF_READ_SEQUENCE_ERR_FOUND/ INTR1_ENABLE_CLEAR[10] CBUF_READ_SEQUENCE_ERR_FOUND	This flag indicates that at least one CBUF read address is not incrementing in raster scan order(1).
INTR0_STATUS_RAW_SET[9] CBUF_VBUF_READ_START_ERR_FOUND/ INTR1_STATUS_RAW_SET[9] CBUF_VBUF_READ_START_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[9] CBUF_VBUF_READ_START_ERR_FOUND/ INTR1_STATUS_ENABLED_CLEAR[9] CBUF_VBUF_READ_START_ERR_FOUND	INTR0_ENABLE_SET[9] CBUF_VBUF_READ_START_ERR_FOUND/ INTR1_ENABLE_SET[9] CBUF_VBUF_READ_START_ERR_FOUND and INTR0_ENABLE_CLEAR[9] CBUF_VBUF_READ_START_ERR_FOUND/ INTR1_ENABLE_CLEAR[9] CBUF_VBUF_READ_START_ERR_FOUND	This flag indicates when at least one of the CBUF read accesses does not start at the VBUF start address(1).
INTR0_STATUS_RAW_SET[8] CBUF_READ_OUT_OF_RANGE_ERR_FOUND/ INTR1_STATUS_RAW_SET[8] CBUF_READ_OUT_OF_RANGE_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[8] CBUF_READ_OUT_OF_RANGE_ERR_FOUND/ INTR1_STATUS_ENABLED_CLEAR[8] CBUF_READ_OUT_OF_RANGE_ERR_FOUND	INTR0_ENABLE_SET[8] CBUF_READ_OUT_OF_RANGE_ERR_FOUND/ INTR1_ENABLE_SET[8] CBUF_READ_OUT_OF_RANGE_ERR_FOUND and INTR0_ENABLE_CLEAR[8] CBUF_READ_OUT_OF_RANGE_ERR_FOUND/ INTR1_ENABLE_CLEAR[8] CBUF_READ_OUT_OF_RANGE_ERR_FOUND	This flag indicates when at least one of the CBUF read addresses is out of the CBUF address range(1).
INTR0_STATUS_RAW_SET[7] CBUF_WRITE_SEQUENCE_ERR_FOUND/ INTR1_STATUS_RAW_SET[7] CBUF_WRITE_SEQUENCE_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[7] CBUF_WRITE_SEQUENCE_ERR_FOUND/ INTR1_STATUS_ENABLED_CLEAR[7] CBUF_WRITE_SEQUENCE_ERR_FOUND	INTR0_ENABLE_SET[7] CBUF_WRITE_SEQUENCE_ERR_FOUND/ INTR1_ENABLE_SET[7] CBUF_WRITE_SEQUENCE_ERR_FOUND and INTR0_ENABLE_CLEAR[7] CBUF_WRITE_SEQUENCE_ERR_FOUND/ INTR1_ENABLE_CLEAR[7] CBUF_WRITE_SEQUENCE_ERR_FOUND	This flag indicates that at least one CBUF write address is not incrementing in raster scan order(1).
INTR0_STATUS_RAW_SET[6] CBUF_VBUF_WRITE_START_ERR_FOUND/ INTR1_STATUS_RAW_SET[6] CBUF_VBUF_WRITE_START_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[6] CBUF_VBUF_WRITE_START_ERR_FOUND/ INTR1_STATUS_ENABLED_CLEAR[6] CBUF_VBUF_WRITE_START_ERR_FOUND	INTR0_ENABLE_SET[6] CBUF_VBUF_WRITE_START_ERR_FOUND/ INTR1_ENABLE_SET[6] CBUF_VBUF_WRITE_START_ERR_FOUND and INTR0_ENABLE_CLEAR[6] CBUF_VBUF_WRITE_START_ERR_FOUND/ INTR1_ENABLE_CLEAR[6] CBUF_VBUF_WRITE_START_ERR_FOUND	This flag indicates when at least one of the CBUF write accesses does not start at the VBUF start address(1).

Table 15-556. OCM Subsystem Events (continued)

Event Flag	Event Mask	Description
INTR0_STATUS_RAW_SET[5] CBUF_WR_OUT_OF_RANGE_ERR_FOUND/ INTR1_STATUS_RAW_SET[5] CBUF_WR_OUT_OF_RANGE_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[5] CBUF_WR_OUT_OF_RANGE_ERR_FOUND/ INTR1_STATUS_ENABLED_CLEAR[5] CBUF_WR_OUT_OF_RANGE_ERR_FOUND	INTR0_ENABLE_SET[5] CBUF_WR_OUT_OF_RANGE_ERR_FOUND/ INTR1_ENABLE_SET[5] CBUF_WR_OUT_OF_RANGE_ERR_FOUND and INTR0_ENABLE_CLEAR[5] CBUF_WR_OUT_OF_RANGE_ERR_FOUND/ INTR1_ENABLE_CLEAR[5] CBUF_WR_OUT_OF_RANGE_ERR_FOUND	This flag indicates when at least one of the CBUF write addresses is out of the CBUF address range(1).
INTR0_STATUS_RAW_SET[4] CBUF_VIRTUAL_ADDR_ERR_FOUND/ INTR1_STATUS_RAW_SET[4] CBUF_VIRTUAL_ADDR_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[4] CBUF_VIRTUAL_ADDR_ERR_FOUND/ INTR1_STATUS_ENABLED_CLEAR[4] CBUF_VIRTUAL_ADDR_ERR_FOUND	INTR0_ENABLE_SET[4] CBUF_VIRTUAL_ADDR_ERR_FOUND/ INTR1_ENABLE_SET[4] CBUF_VIRTUAL_ADDR_ERR_FOUND and INTR0_ENABLE_CLEAR[4] CBUF_VIRTUAL_ADDR_ERR_FOUND/ INTR1_ENABLE_CLEAR[4] CBUF_VIRTUAL_ADDR_ERR_FOUND	This flag indicates when a virtual address error is detected. This is a general interrupt event which is not associated with any specific CBUF(1).
INTR0_STATUS_RAW_SET[3] OUT_OF_RANGE_ERR_FOUND/ INTR1_STATUS_RAW_SET[3] OUT_OF_RANGE_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[3] OUT_OF_RANGE_ERR_FOUND/ INTR1_STATUS_ENABLED_CLEAR[3] OUT_OF_RANGE_ERR_FOUND	INTR0_ENABLE_SET[3] OUT_OF_RANGE_ERR_FOUND/ INTR1_ENABLE_SET[3] OUT_OF_RANGE_ERR_FOUND and INTR0_ENABLE_CLEAR[3] OUT_OF_RANGE_ERR_FOUND/ INTR1_ENABLE_CLEAR[3] OUT_OF_RANGE_ERR_FOUND	General interrupt for an access made with illegal VBUF address(1).
INTR0_STATUS_RAW_SET[2] ADDR_ERR_FOUND/ INTR1_STATUS_RAW_SET[2] ADDR_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[2] ADDR_ERR_FOUND/ INTR1_STATUS_ENABLED_CLEAR[2] ADDR_ERR_FOUND	INTR0_ENABLE_SET[2] ADDR_ERR_FOUND/ INTR1_ENABLE_SET[2] ADDR_ERR_FOUND and INTR0_ENABLE_CLEAR[2] ADDR_ERR_FOUND/ INTR1_ENABLE_CLEAR[2] ADDR_ERR_FOUND	This status flag is set when the value of the STATUS_ERROR_CNT[23:20] ADDR_ERROR_CNT bit field reaches the threshold counter value configured through the CFG_OCMC_ECC_ERROR[23:20] CFG_ADDR_ERR_CNT_MAX bit field. The status remains asserted until the counter is not cleared. This is done by setting to 0x1 the CFG_OCMC_ECC_CLEAR_HIST[2] CLEAR_ADDR_ERR_CNT bit. If the counter is not cleared another interrupt is re-issued.

Table 15-556. OCM Subsystem Events (continued)

Event Flag	Event Mask	Description
INTR0_STATUS_RAW_SET[1] DED_ERR_FOUND/ INTR1_STATUS_RAW_SET[1] DED_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[1] DED_ERR_FOUND/ INTR1_STATUS_ENABLED_CLEAR[1] DED_ERR_FOUND	INTR0_ENABLE_SET[1] DED_ERR_FOUND/ INTR1_ENABLE_SET[1] DED_ERR_FOUND and INTR0_ENABLE_CLEAR[1] DED_ERR_FOUND/ INTR1_ENABLE_CLEAR[1] DED_ERR_FOUND	This status flag is set when the value of the STATUS_ERROR_CNT[19:16] DED_ERROR_CNT bit field reaches the threshold counter value configured through the CFG_OCMC_ECC_ERROR[19:16] CFG_DED_CNT_MAX bit field. The status remains asserted until the counter is not cleared. This is done by setting to 0x1 the CFG_OCMC_ECC_CLEAR_HIST[1] CLEAR_DED_ERR_CNT bit. If the counter is not cleared another interrupt is re-issued.
INTR0_STATUS_RAW_SET[0] SEC_ERR_FOUND/ INTR1_STATUS_RAW_SET[0] SEC_ERR_FOUND and INTR0_STATUS_ENABLED_CLEAR[0] SEC_ERR_FOUND/ INTR1_STATUS_ENABLED_CLEAR[0] SEC_ERR_FOUND	INTR0_ENABLE_SET[0] SEC_ERR_FOUND/ INTR1_ENABLE_SET[0] SEC_ERR_FOUND and INTR0_ENABLE_CLEAR[0] SEC_ERR_FOUND/ INTR1_ENABLE_CLEAR[0] SEC_ERR_FOUND	This status flag is set when the value of the STATUS_ERROR_CNT[15:0] SEC_ERROR_CNT bit field reaches the threshold counter value configured through the CFG_OCMC_ECC_ERROR[15:0] CFG_SEC_CNT_MAX bit field. The status remains asserted until the counter is not cleared. This is done by setting to 0x1 the CFG_OCMC_ECC_CLEAR_HIST[0] CLEAR_SEC_ERR_CNT bit. If the counter is not cleared another interrupt is re-issued.

(1) The LAST_ILLEGAL_OCMC_ADDR register stores the last illegal L3_MAIN address caused the assertion of this event.

15.6.3.5 OCM Subsystem Memory Regions

The SRAM associated with the OCMC_RAM1 is accessible through the L3_MAIN interconnect. The start address is 0x4030 0000 and the end address is 0x4037 FFFF. That is address space of 512KiB. The configuration registers of the OCMC_RAM1 are accessible through the L4_PER3 starting at address 0x4880 4000.

The SRAM associated with the OCMC_RAM2 is accessible through the L3_MAIN interconnect. The start address is 0x4040 0000 and the end address is 0x404F FFFF. That is address space of 1MiB. The configuration registers of the OCMC_RAM2 are accessible through the L4_PER3 starting at address 0x4880 A000.

The SRAM associated with the OCMC_RAM3 is accessible through the L3_MAIN interconnect. The start address is 0x4050 0000 and the end address is 0x405F FFFF. That is address space of 1MiB. The configuration registers of the OCMC_RAM3 are accessible through the L4_PER3 starting at address 0x4881 0000.

Note

OCMC_RAM2 and OCMC_RAM3 banks are not present on DRA74x devices, but are included in some of the DRA75x devices. For details, see the device data manual.

15.6.3.6 OCM Controller Modes Of Operation

The OCM controller supports four modes of operation. Each of these modes is selected through the CFG_OCMC_ECC[2:0] CFG_OCMC_MODE bit field. The four supported modes are the following:

- Non-ECC mode (Data Access) - Accesses to the SRAM are non-ECC-enabled and an ECC is not calculated.

- Non-ECC mode (Code Access) - The L3_MAIN address is mapped to the SRAM memory space where the ECC code is stored. This mode allows read and write access to the 9-bit ECC word associated with each 128-bit data word. This mode is used for test purposes.
- Full-ECC mode - Accesses to the SRAM are ECC-enabled and a 9-bit ECC is calcualted for each 128 bits of data.
- Block-ECC mode - A 9-bit ECC is calcualted only for a 128KiB block of the SRAM. Accesses outside the 128KiB ECC-enabled block are non-ECC data acceses. In other words, a 9-bit ECC will be calculated not for each 128-bit data word of the whole SRAM space, but for each 128-bit data word within the boundaries of this 128KiB block of the SRAM. The selection of a 128KiB ECC-enabled block is done using bits[19:0] of the CFG_OCMC_ECC_MEM_BLK register. Each bit specifies which 128KiB block of the SRAM is ECC-enabled. 0x1 is the active value for each bit. In addition, more than one 128KiB ECC-enabled block can be selected.

The default mode of operation for the OCM controller is the non-ECC data access mode.

15.6.3.7 ECC Associated FIFOs

There are three FIFOs used when ECC mode is enabled. Each FIFO is four level deep. The FIFOs are the following:

- Address FIFO for single errors also referred to as SEC FIFO
- Address FIFO for double errors also referred to as DED FIFO
- Address FIFO for address errors also referred to as ADDRERR FIFO

The SEC FIFO stores the SRAM addresses at which a single error is detected. The FIFO is able to store up to four unique addresses of the single errors occured. If there are more than four single errors associated with unique addresses, then only the first four addresses are stored in the FIFO. In case of occurrence of multiple correctable errors, the addresses are stored in the order the errors occurred. The SEC FIFO can be optionally configured to store all addresses of the single errors occured including also the repeated addresses. This is done by setting to 0x0 the CFG_OCMC_ECC_ERROR[24] CFG_DISCARD_DUP_ADDR bit. The SEC FIFO can be cleared by setting to 0x1 the CFG_OCMC_ECC_CLEAR_HIST[0] CLEAR_SEC_ERR_CNT bit or by reding FIFO's content one by one through the STATUS_SEC_ERROR_TRACE[17:0] ADDRESS_128BIT bit field which points to the SEC FIFO. In addition, the STATUS_SEC_ERROR_TRACE[18] VALID bit shows whether the FIFO is empty or not. A value of 0x1 means that the SEC FIFO is not empty and valid address can be read.

The DED FIFO stores the SRAM addresses when a double error is detected. The FIFO is able to store up to four unique addresses, but it can also be configured to store the repeated addresses by setting to 0x0 the CFG_OCMC_ECC_ERROR[24] CFG_DISCARD_DUP_ADDR bit. The STATUS_DED_ERROR_TRACE[17:0] ADDRESS_128BIT bit field points to the DED FIFO. The STATUS_DED_ERROR_TRACE[18] VALID bit shows whether the FIFO is empty or not. The DED FIFO can be cleared by setting to 0x1 the CFG_OCMC_ECC_CLEAR_HIST[1] CLEAR_DED_ERR_CNT bit or by reading its content one by one through the STATUS_DED_ERROR_TRACE[17:0] ADDRESS_128BIT.

The ADDRERR FIFO stores the SRAM addresses where the single error occured is an addres error. The STATUS_ADDR_TRANSLATION_ERROR_TRACE[17:0] ADDRESS_128BIT bit field points to the ADDRERR FIFO. The STATUS_ADDR_TRANSLATION_ERROR_TRACE[18] VALID bit shows whether the FIFO is empty or not. The ADDRERR FIFO can be cleared by setting to 0x1 the CFG_OCMC_ECC_CLEAR_HIST[2] CLEAR_ADDR_ERR_CNT bit or by reading its content one by one through the STATUS_ADDR_TRANSLATION_ERROR_TRACE[17:0] ADDRESS_128BIT pointer. The ADDRERR FIFO is also able to store up to four unique addresses and can also be configured to store repeated addresses by setting to 0x0 the CFG_OCMC_ECC_ERROR[24] CFG_DISCARD_DUP_ADDR bit.

15.6.3.8 ECC Counters And Corrected Bit Distribution Register

There are three counters which are used to count different types of errors occured when the ECC mode is enabled. The counters are the following:

- SEC Counter - STATUS_ERROR_CNT[15:0] SEC_ERROR_CNT. This is the counter for the single errors occured. It keeps track of all single errors. That is, even for those with error addresses that have already been logged.

- DED Counter - STATUS_ERROR_CNT[19:16] DED_ERROR_CNT. This is the counter for the double error detections.
- ADDRERR Counter - STATUS_ERROR_CNT[23:20] ADDR_ERROR_CNT. This is the counter for the address errors found when a single error occurs. That is, when the single error is an addres error.

When a single error in the 128-bit data word occurs and this error is corrected, the OCM controller indicates for the corrected bit of this 128-bit word by setting to 0x1 a corresponding bit in the corrected bit distribution register. This is a 128-bit register composed by the following registers:

- STATUS_SEC_ERROR_DISTR_0[31:0] SEC_BIT_ERROR_FOUND - Bits [31:0] of the corrected 128-bit data word.
- STATUS_SEC_ERROR_DISTR_1[31:0] SEC_BIT_ERROR_FOUND - Bits [63:32] of the corrected 128-bit data word.
- STATUS_SEC_ERROR_DISTR_2[31:0] SEC_BIT_ERROR_FOUND - Bits [95:64] of the corrected 128-bit data word.
- STATUS_SEC_ERROR_DISTR_3[31:0] SEC_BIT_ERROR_FOUND - Bits [127:96] of the corrected 128-bit data word.

When a single error in the ECC itself occurs, the OCM controller indicates for this error by setting to 0x1 a corresponding bit in the STATUS_SEC_ERROR_DISTR_4[7:0] SEC_ECC_CODE_ERROR_FOUND bit field. The parity bit is not associated with this bit field.

15.6.3.9 ECC Support

The ECC mode is enabled through the CFG_OCMC_ECC[2:0] CFG_OCMC_MODE bit field. When enabled a 9-bit Hamming ECC is calculated and stored for each consecutive 128-bit block of the SRAM. The ECC is calculated based on a codeword constructed by concatenating the 128 bits of data with the address bits A21 through A4 of the L3_MAIN. The ECC generated is Hamming(155,146) code and has a Hamming distance of 4. The OCM controller uses this code to validate the content of the SRAM, to correct a single bit error that occurs within the 128-bit boundary or to determine if a non-correctable error has occurred within the 128-bit boundary.

During write transactions and when ECC is enabled, for every 128-bit data word, the ECC is calculated and stored in a 9-bit field of the SRAM associated only with the address where that 128-bit data word is written. If an initiator performs a write transaction which is less than 128 bits or it is non-128-bit aligned transaction, then the content of all 128 bits is read, the new sub-quanta of data is inserted and the ECC is calculated based on all 128 bits.

During read transactions and when ECC is enabled, the ECC is calcualated based on the memory address (bits A21 through A4) and the 128-bit data word read from the SRAM. This ECC is then compared to the ECC stored at the address when the data was written to the SRAM. If the two ECCs are matching then the data is transferred to the requesting initiator without further exceptions. If the two ECCs are not matching then a check is made to determine if the error is correctable or not. If the error is not correctable, that is a double error, then the address of the erroneous word is stored in the DED FIFO, the STATUS_ERROR_CNT[19:16] DED_ERROR_CNT counter is incremented by 1 and the double error flag is asserted. The double error flag is indicated by the INTR0_STATUS_RAW_SET[1] DED_ERR_FOUND/ INTR1_STATUS_RAW_SET[1] DED_ERR_FOUND bits, but its assertion depends on the threshold configured through the CFG_OCMC_ECC_ERROR[19:16] CFG_DED_CNT_MAX bit field. For more information see, Table 15-556, *OCM Subsystem Events*.

In case of a single error, the OCM controller first determines whether the erroneous bit is in the data, address or the ECC itself. In this case the following applies:

- If the single error is located in the data read, then the erroneous bit is corrected and the data is passed to the requesting initiator. The erroneous bit is corrected also in the SRAM location by the auto re-write feature of the OCM controller if this feature is enabled by setting to 0x1 the CFG_OCMC_ECC[3] CFG_ECC_SEC_AUTO_CORRECT bit field. In addition, the address of the corrected data word is pushed to the SEC FIFO and the STATUS_ERROR_CNT[15:0] SEC_ERROR_CNT counter is incremented by 1. The single error flag is asserted too, but only if the value of the STATUS_ERROR_CNT[15:0] SEC_ERROR_CNT counter reaches the threshold configured by the CFG_OCMC_ECC_ERROR[15:0] CFG_SEC_CNT_MAX bit field. The single error flag is indicated by the INTR0_STATUS_RAW_SET[0] SEC_ERR_FOUND/ INTR1_STATUS_RAW_SET[0] SEC_ERR_FOUND bits. For more information see, Table 15-556, *OCM Subsystem Events*.

- If the single error is located in the address portion of the quanta, then the data is passed to the requesting initiator unchanged and the STATUS_ERROR_CNT[23:20] ADDR_ERROR_CNT and STATUS_ERROR_CNT[15:0] SEC_ERROR_CNT counters are incremented by 1. The address associated with this error is stored in the ADDRERR FIFO and the address error flag is asserted. This flag is indicated by the INTR0_STATUS_RAW_SET[2] ADDR_ERR_FOUND/INTR1_STATUS_RAW_SET[2] ADDR_ERR_FOUND bits, but its assertion depends on the threshold configured through the CFG_OCMC_ECC_ERROR[23:20] CFG_ADDR_ERR_CNT_MAX bit field. For more information see, Table 15-556, *OCM Subsystem Events*.
- If the single error is located in the ECC itself, then the data is passed to the initiator unchanged but the STATUS_ERROR_CNT[15:0] SEC_ERROR_CNT counter is incremented by 1 and the address associated with this error is stored in the SEC FIFO.

Table 15-557 summarizes the actions taken by the OCM controller for the different error types.

Table 15-557. OCMC Error Handling In Case Of Different Error Types

Error Type	Data Returned	SRAM Data/ECC Update	SEC Counter	SEC FIFO	DED Counter	DED FIFO	ADDRERR Counter	ADDRERR FIFO	Error Bit Distribution
Single data error	Corrected	Data corrected/ECC re-generated	Incremented by 1	Address written	-	-	-	-	The content of the corrected bit distribution register is updated
Single address error	Unchanged	ECC re-generated	Incremented by 1	-	-	-	Incremented by 1	Address written	-
Single ECC error	Unchanged	ECC re-generated	Incremented by 1	Address written	-	-	-	-	The content of the STATUS_SEC_ERROR_DISTR_4[7:0] SEC_ECC_CODE_ERROR_FOUND bit field is updated
Double error	Unchanged	-	-	-	Incremented by 1	Address written	-	-	-

If ECC has to be used, before performing SRAM read/write operations the following steps should be performed:

- Configuring the ECC registers
- Enabling the ECC
- Initializing the SRAM with data
- Clearing the status flags

Table 15-558 describes in detail the steps to be performed.

Table 15-558. OCMC ECC Configuration

Step	Associated Register/ Bit Field	Value
(Optional) Enable the error response on L3_MAIN for a non-correctable error	CFG_OCMC_ECC[4] CFG_ECC_ERR_SRESP_EN	0x1
(Optional) Enable data auto correction in case of a single error	CFG_OCMC_ECC[3] CFG_ECC_SEC_AUTO_CORRECT	0x1
Enable the memory blocks to be ECC protected, if ECC block mode is used	CFG_OCMC_ECC_MEM_BLK[19:0] CFG_ECC_ENABLED_128K_BLK	0x-
(Optional) Configure the address errors count needed for triggering an interrupt	CFG_OCMC_ECC_ERROR[23:20] CFG_ADDR_ERR_CNT_MAX	0x-

Table 15-558. OCMC ECC Configuration (continued)

Step	Associated Register/ Bit Field	Value
(Optional) Configure the DED count needed for triggering an interrupt	CFG_OCMC_ECC_ERROR[19:16] CFG_DED_CNT_MAX	0x-
(Optional) Configure the SEC count needed for triggering an interrupt	CFG_OCMC_ECC_ERROR[15:0] CFG_SEC_CNT_MAX	0x-
Enable ECC	CFG_OCMC_ECC[2:0] CFG_OCMC_MODE	0x2 for full ECC or 0x3 for block ECC mode
Initialize the memory with data		
Clear the error counters in the STATUS_ERROR_CNT register	CFG_OCMC_ECC_CLEAR_HIST[2:0]	0x7
Clear the SEC bit distribution history from the following registers:	CFG_OCMC_ECC_CLEAR_HIST[3] CLEAR_SEC_BIT_DISTR	0x1
• STATUS_SEC_ERROR_DISTR_0		
• STATUS_SEC_ERROR_DISTR_1		
• STATUS_SEC_ERROR_DISTR_2		
• STATUS_SEC_ERROR_DISTR_3		
• STATUS_SEC_ERROR_DISTR_4		

15.6.3.10 Circular Buffer (CBUF) Support

The OCM controller provides up to 12 programmable circular buffers that are mapped to virtual video frames to support sliced based on-the-fly video frame processing. Each circular buffer must be programmed with the following:

- Unique virtual frame start address - configured through CBUF_i_VBUF_START_ADDR[31:4] ADDR.
- Unique virtual frame end address - configured through CBUF_i_VBUF_END_ADDR[31:4] ADDR.
- SRAM start address - configured through CBUF_i_OCMC_START_ADDR[31:4] ADDR.
- SRAM size allocated for that circular buffer - configured through CBUF_i_OCMC_BUF_SIZE[19:4] BUF_SIZE.

The circular buffer mode is enabled when the CFG_OCMC_CBUF_EN[0] CBUF_MODE_EN bit is set to 0x1. In addition, to enable certain circular buffer the corresponding bit in the CFG_OCMC_CBUF_EN[27:16] bit field must be set to 0x1. For example, to enable CBUF_0 both the CFG_OCMC_CBUF_EN[0] CBUF_MODE_EN and CFG_OCMC_CBUF_EN[16] CBUF_EN_0 bits must be set to 0x1.

The data transfers are made to the virtual frame addresses. The OCM controller translates these virtual addresses to SRAM addresses allocated for the CBUF. The address translation is done on-the-fly without leading to any additional latency and therefore has no performance impact on the overall operation of the OCM controller.

The L3_MAIN address ranges associated with the virtual frame addresses are the following:

- For OCMC_RAM1 the start address is 0x4180 0000 and the end address is 0x41FF FFFF.
- For OCMC_RAM2 the start address is 0x4900 0000 and the end address is 0x497F FFFF.
- For OCMC_RAM3 the start address is 0x4980 0000 and the end address is 0x49FF FFFF.

Note

OCMC_RAM2 and OCMC_RAM3 banks are not present on DRA74x devices, but are included in some of the DRA75x devices. For details, see the device data manual.

When an initiator performs an access to these L3_MAIN addresses, these virtual frame addresses will be translated automatically by the OCM controller into SRAM addresses. Figure 15-109 shows the address mapping of the virtual frame addresses to CBUF addresses.

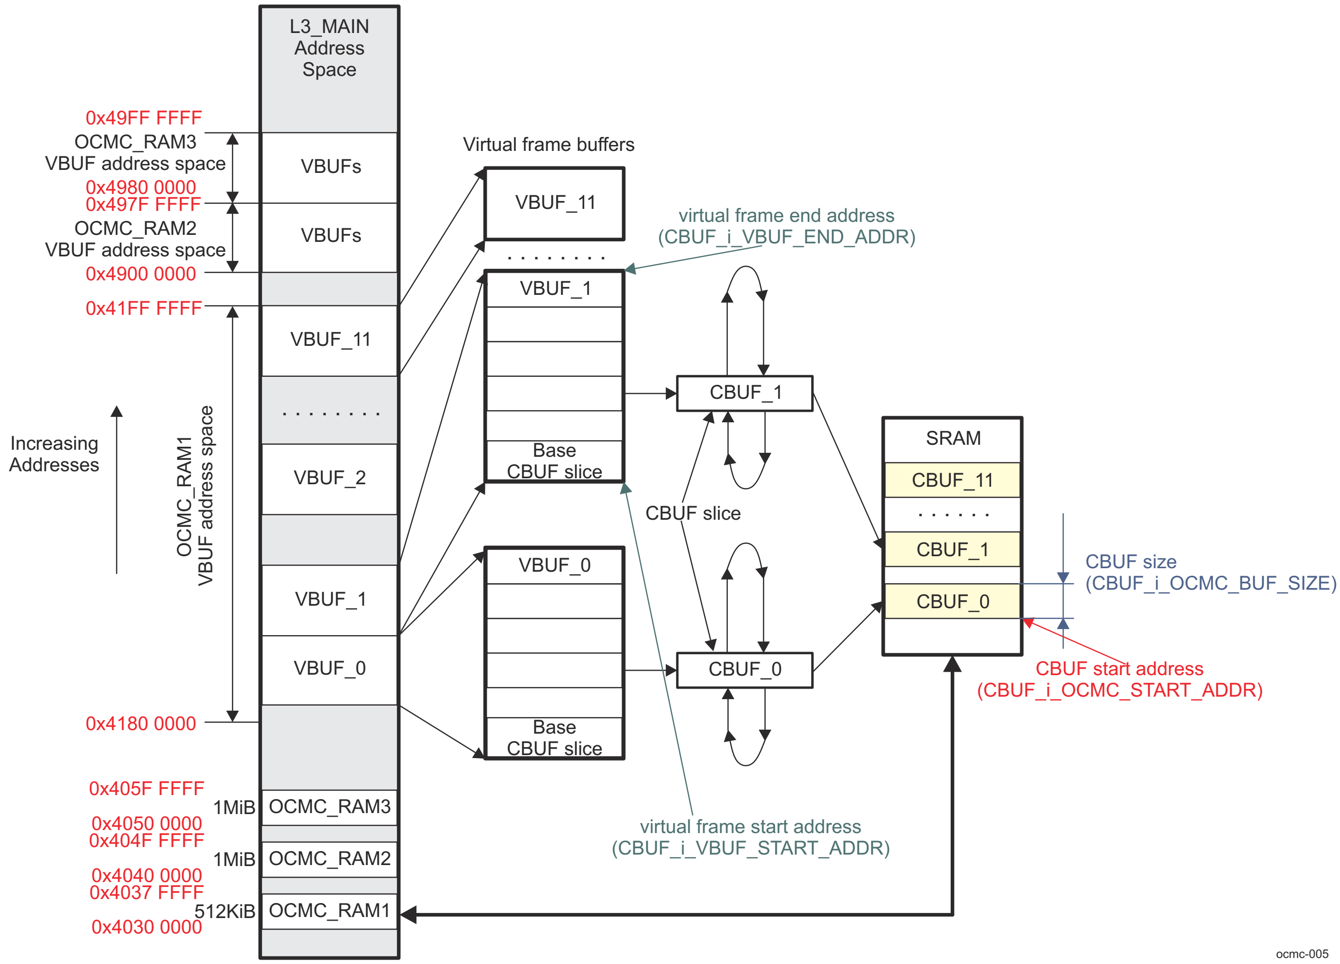

Figure 15-109. VBUF to CBUF Address Mapping

It must be taken into account that the start address of a virtual frame always begins at the start of the CBUF. Since the virtual frame buffer size is not necessarily to be a multiple of the CBUF size, the last VBUF write location may not be the last line of the CBUF. As the CBUF read and write pointers are independently managed the initiators that are writing to and reading from the CBUF should be coordinated in order to avoid overflow and underflow conditions.

15.6.3.11 CBUF Mode Error Handling

For each L3_MAIN write or read access associated with the virtual frame buffer, the OCM controller performs various address error checks to prevent illegal CBUF accesses from causing false overflow and underflow conditions. Once the L3_MAIN VBUF address is determined as valid, the OCM controller further checks for overflow and underflow conditions to properly handle the access to the CBUF during each one of these conditions and to notify for error condition an external host.

For more information regarding all CBUF events see, Table 15-556, *OCM Subsystem Events*.

15.6.3.11.1 VBUF Address Not Mapped to a CBUF Memory Space

The L3_MAIN VBUF address should be mapped to a valid CBUF region. If this address is mapped to none of the configured CBUF regions, then the OCM controller generates a virtual address error or out of range CBUF address error event. It is possible both virtual address error and out of range CBUF address error to be generated. The L3_MAIN VBUF address caused these two events can be read through the LAST_ILLEGAL_OCMC_ADDR[31:0] ADDR bit field.

Virtual address error is generated when the L3_MAIN VBUF address is lower than the virtual frame start address. This is indicated by asserting the INTR0_STATUS_RAW_SET[4] CBUF_VIRTUAL_ADDR_ERR_FOUND/INTR1_STATUS_RAW_SET[4] CBUF_VIRTUAL_ADDR_ERR_FOUND bit.

The out of range CBUF address error is generated when the L3_MAIN VBUF address is greater than the virtual frame end address. This error is an indication of an unexpected change in the frame size or a long frame and should be handled immediately to prevent further memory corruption. The out of range CBUF address error can be caused when performing write or read access. The out of range CBUF write address error is indicated by the STATUS_CBUF_WR_OUT_OF_RANGE_ERR[11:0] CBUF_ERR bit field. The out of range CBUF read address error is indicated by the STATUS_CBUF_RD_OUT_OF_RANGE_ERROR[11:0] CBUF_ERR bit field. Each bit in these registers is associated only with one CBUF. Bit 0 corresponds to CBUF_0, bit 1 corresponds to CBUF_1 and so on. A value of 0x1 for each bit means that there is an error (CBUF address is out of CBUF range) for the corresponding CBUF. Writing 0x1 for each bit clears the status.

The INTR0_STATUS_RAW_SET[5] CBUF_WR_OUT_OF_RANGE_ERR_FOUND/ INTR1_STATUS_RAW_SET[5] CBUF_WR_OUT_OF_RANGE_ERR_FOUND bit is asserted if at least one of the bits in the STATUS_CBUF_WR_OUT_OF_RANGE_ERR[11:0] CBUF_ERR bit field is set to 0x1.

The INTR0_STATUS_RAW_SET[8] CBUF_READ_OUT_OF_RANGE_ERR_FOUND/ INTR1_STATUS_RAW_SET[8] CBUF_READ_OUT_OF_RANGE_ERR_FOUND bit is asserted if at least one of the bits in the STATUS_CBUF_RD_OUT_OF_RANGE_ERROR[11:0] CBUF_ERR bit field is set to 0x1.

15.6.3.11.2 VBUF Access Not Starting At The Base Address

After (hardware of software) reset or on a new frame start condition, a frame write or read access for any VBUF must start from its virtual frame start address (CBUF_i_VBUF_START_ADDR[31:4] ADDR). If this is not met the OCM controller ignors all accesses which don't start at address CBUF_i_VBUF_START_ADDR[31:4] ADDR and also generates an interrupt. The STATUS_CBUF_WR_VBUF_START_ERR[11:0] CBUF_ERR register contains the status bits of this interrupt which are associated with frame write access. The STATUS_CBUF_VBUF_RD_START_ERROR[11:0] CBUF_ERR register contains the status bits associated with frame read access. Each bit in these two registers is associated only with one CBUF. A value of 0x1 for each bit means that the read/write access does not start at the VBUF start address.

While this error condition exists, no updates to the CBUF channel status registers are made. An exception to this constraint is when the last read/write access is still within the base CBUF slice. The enforcing of a frame starting at VBUF starting address is not done in this case to allow random access within the same CBUF. However, this will be flagged and handled as a short frame occurrence.

The INTR0_STATUS_RAW_SET[6] CBUF_VBUF_WRITE_START_ERR_FOUND/ INTR1_STATUS_RAW_SET[6] CBUF_VBUF_WRITE_START_ERR_FOUND bit is asserted if at least one of the bits in the STATUS_CBUF_WR_VBUF_START_ERR[11:0] CBUF_ERR bit field is set to 0x1.

The INTR0_STATUS_RAW_SET[9] CBUF_VBUF_READ_START_ERR_FOUND/INTR1_STATUS_RAW_SET[9] CBUF_VBUF_READ_START_ERR_FOUND bit is asserted if at least one of the bits in the STATUS_CBUF_VBUF_RD_START_ERROR[11:0] CBUF_ERR bit field is set to 0x1.

15.6.3.11.3 Illegal Address Change Between Two Same Type Accesses

The OCM controller requires both read and write accesses to a virtual frame buffer to be performed in the positive raster scan order, that is, successive write or read accesses should be to a higher address except on a new frame start for which the address jumps back down to the beginning of the virtual frame buffer. The OCM controller checks to make sure that a virtual address meets one of the following conditions:

- It is within the same CBUF slice as the last access of the same type (read or write)
- It is within the next CBUF slice of the last access of the same type (read or write)
- The virtual address is to the VBUF frame start address

Based on these constraints, the OCM controller generates an write/read address sequence error interrupt and invalidates the access, that is, writes are disabled and reads return unknown data, if the following two conditions are met:

- The current access address is not to a current or next CBUF slice space
- The current access address is not to the base of the virtual frame buffer (the first CBUF slice)

The random accesses within the current CBUF slice are permited to allow some variations in the line width of the captured video which often happens with weak video signal conditions.

To avoid illegal CBUF slice backward switching, the modules capturing the input video and sending it to the CBUF of the OCM controller should limit the maximum width of a line width to be less than the stride size (in pixels). This guarantees that a start of a new line does not point back to the previous CBUF slice.

If a write or read address sequence error event is detected on an access, the OCM controller will simply invalidate the accesses and will not update the CBUF status registers.

The bits in the STATUS_CBUF_WR_ADDR_SEQ_ERROR[11:0] CBUF_ERR bit field indicate write address sequence error event.

The bits in the STATUS_CBUF_RD_ADDR_SEQ_ERROR[11:0] CBUF_ERR bit field indicate read address sequence error event.

In both the registers each bit is associated only with one CBUF.

The INTR0_STATUS_RAW_SET[7] CBUF_WRITE_SEQUENCE_ERR_FOUND/INTR1_STATUS_RAW_SET[7] CBUF_WRITE_SEQUENCE_ERR_FOUND bit is asserted if at least one of the bits in the STATUS_CBUF_WR_ADDR_SEQ_ERROR[11:0] CBUF_ERR bit field is set to 0x1.

The INTR0_STATUS_RAW_SET[10] CBUF_READ_SEQUENCE_ERR_FOUND/ INTR1_STATUS_RAW_SET[10] CBUF_READ_SEQUENCE_ERR_FOUND bit is asserted if at least one of the bits in the STATUS_CBUF_RD_ADDR_SEQ_ERROR[11:0] CBUF_ERR bit field is set to 0x1.

15.6.3.11.4 Illegal Frame SIze (Short Frame Detection)

If a frame write access for any VBUF begins from its virtual frame start address without a CBUF software reset and the last write address is not the virtual frame end address or is in the last CBUF slice, then the previous frame is considered to be short. This includes the case where a new frame write happens twice without a new frame read in between, which is an indication of an extremely short frame. When a short frame event is detected, the OCM controller generates a short frame detection interrupt and temporarily disables overflow checking on the write access, including also the current access, until a frame read happens in order to avoid false overflow indication on a suspended read side following the short frame detection.

If the last write address is in the last CBUF slice the short frame detection can be ignored if the CFG_OCMC_CBUF_ERR_HANDLER[1] SHORT_FRAME_PREV_EOF_SEL bit is set to 0x1.

The STATUS_CBUF_SHORT_FRAME_DETECT[11:0] CBUF_ERR bit field has status flags to indicate a short frame detection for each CBUF. When a short frame condition occurs the corresponding bit is set to 0x1.

The INTR0_STATUS_RAW_SET[14] CBUF_SHORT_FRAME_DETECT_FOUND/ INTR1_STATUS_RAW_SET[14] CBUF_SHORT_FRAME_DETECT_FOUND bit is asserted if at least one of the bits in the STATUS_CBUF_SHORT_FRAME_DETECT[11:0] CBUF_ERR bit field is set to 0x1.

In addition, the short frame detection enabling/disabling is controlled by the CFG_OCMC_CBUF_ERR_HANDLER[0] SHORT_FRAME_DETECT_CHECK_EN bit.

15.6.3.11.5 CBUF Overflow

For each valid CBUF write access, the write address is compared to the last read address for an overflow condition. If an overflow is detected, the corresponding CBUF overflow status bit in the STATUS_CBUF_OVERFLOW_MID or STATUS_CBUF_OVERFLOW_WRAP registers is set to 0x1 and an interrupt is generated. This interrupt condition exists until the corresponding overflow status bit is cleared.

There are two types of overflow conditions referred to as Cbuf_overflow_wrap and Cbuf_overflow_mid.

Cbuf_overflow_wrap occurs in case at least one of the following two:
- VBUF write address – VBUF frame start address < CBUF size
- VBUF write address – VBUF frame start address > VBUF last read address – Current VBUF start address

Cbuf_overflow_mid occurs in case at least one of the following two:
- VBUF write address – VBUF frame start address > CBUF size
- VBUF write address – VBUF last read address > CBUF size

If an overflow condition is detected on a CBUF write access, the OCM controller generates a CBUF overflow (Cbuf_overflow_wrap or Cbuf_overflow_mid) interrupt and enter an overflow error handling state. In this state, the OCM controller do the following in the default error handling configuration:
- When a Cbuf_Overflow_Wrap condition occurs (write buffer wraparound with read from previous frame still remaining), writes are disabled but reads are serviced normally. This mechanism preserves the back end of the previous frame and discards the new frame which is already showing signs of overflowing. Writes will be re-enabled automatically on write to the virtual frame start address which indicates the next frame after the overflowed frame has begun. The overflow (and underflow) check for this CBUF will be disabled until detection of write to/read from the virtual frame start address. The module which reads should not start reading the next frame (which is being discarded) or stop reading the frame if the read of this new frame has already started. This mechanism allows both write and read sides to re-synchronize on the next frame after one-frame drop.
- When a Cbuf_Overflow_Mid condition occurs, writes and reads are serviced normally allowing the read side to catch up to the write side. The overflow (and underflow) check will be disabled until first a write to the virtual frame start address and then a read from the virtual frame start address is detected. This mechanism allows the frame with a “momentary” overflow condition to be saved. The reader side has an option to stop reading and discarding the data by just resetting its CBUF read pointer at the next frame start, if the read side is too far back.

These steps are taken to minimize the frame loss due to an overflow condition. To support the previously described behavior but to allow software to override the default error handling behavior the following controls are available:
- CFG_OCMC_CBUF_ERR_HANDLER[7:6] OVERFLOW_CHECK_REENABLE_SEL
- CFG_OCMC_CBUF_ERR_HANDLER[5:4] OVERFLOW_WRITE_HANDLER_SEL

In addition, the overflow check can be enabled or disabled through the CFG_OCMC_CBUF_ERR_HANDLER[2] OVERFLOW_ERR_CHECK_EN bit.

15.6.3.11.6 CBUF Underflow

According to the CBUF operation a read request can only be made when there are enough number of video lines written to the CBUF. Therefore, there should not be any underflow conditions due to normal processing speed variations. An underflow condition occurs when the VBUF read address is greater than the last VBUF write address. To detect an abnormal failure in the read/write mechanism which could cause an underflow condition, each valid CBUF read access is checked for an underflow condition and if detected, an underflow interrupt is generated for the selected CBUF. The STATUS_CBUF_UNDERFLOW[11:0] CBUF_ERR bit field has status flags indicating when underflow occurs. This interrupt condition exists until the corresponding underflow status bit in the STATUS_CBUF_UNDERFLOW register is cleared.

If an underflow is detected on a CBUF read access, the OCM controller generates an underflow interrupt and continues to perform reads and writes normally, but the return data will not be correct while the underflow condition exists.

To avoid a false underflow detection at the end of a frame (due to external decoders sending short last line or due to interlaced input video having different number of lines in even/odd fields), the CFG_OCMC_CBUF_ERR_HANDLER[8] UNDERFLOW_LAST_CBUF_SLICE_DISABLE bit can be set to 0x1 which disables the underflow checking in the last CBUF slice.

The INTR0_STATUS_RAW_SET[13] CBUF_UNDERFLOW_ERR_FOUND/INTR1_STATUS_RAW_SET[13] CBUF_UNDERFLOW_ERR_FOUND bit is asserted if at least one of the bits in the STATUS_CBUF_UNDERFLOW[11:0] CBUF_ERR bit field is set to 0x1.

In addition, the underflow check can be enabled or disabled through the CFG_OCMC_CBUF_ERR_HANDLER[3] UNDERFLOW_ERR_CHECK_EN bit.

15.6.3.12 Status Reporting

The OCM controller keeps a history of last valid write and read addresses for each CBUF. The CBUF_k_LAST_WR_ADDR register stores the address for the last valid write and the CBUF_k_LAST_RD_ADDR register stores the address for the last valid read access.

The OCMC_ECC generates also a general VBUF mode error event for an access made with illegal VBUF address. The INTR0_STATUS_RAW_SET[3] OUT_OF_RANGE_ERR_FOUND/INTR1_STATUS_RAW_SET[3] OUT_OF_RANGE_ERR_FOUND bit indicates for this event.

15.6.4 OCM Subsystem Register Manual

15.6.4.1 OCM Subsystem Instance Summary

Table 15-559. OCM Subsystem Instance Summary

Module Name	Module Base Address	Size
OCMC_RAM1	0x4880 4000	4KiB
OCMC_RAM2	0x4880 A000	4KiB
OCMC_RAM3	0x4881 0000	4KiB

Note

OCMC_RAM2 and OCMC_RAM3 banks are not present on DRA74x devices, but are included in some of the DRA75x devices. For details, see the device data manual.

Table 15-617. CFG_OCMC_CBUF_RESET

Address Offset	0x0000 0204		
Physical Address	0x4880 4204 0x4880 A204 0x4881 0204	**Instance**	OCMC_RAM1 OCMC_RAM2 OCMC_RAM3
Description	Writing 1 to bit n will set a reset bit to clear the corresponding CBUF_n address translation logic. Sliding CBUF frame tracking will be cleared so that the CBUF now points to the base of the virtual frame buffer. Normally, a reset is not required since the CBUF logic will clear itself when a VBUF access is to the base of the virtual frame.

Chapter 16

DMA Controllers

This chapter describes the features and operation of the device System DMA (DMA_SYSTEM) and Enhanced DMA (EDMA) controllers.

16.1 System DMA....3659
16.2 Enhanced DMA....3732

16.1 System DMA

This chapter describes the system direct memory access (DMA_SYSTEM) module.

16.1.1 DMA_SYSTEM Module Overview

The system direct memory access (DMA_SYSTEM) module, also called DMA4, performs high-performance data transfers between memories and peripheral devices without microprocessor unit (MPU) or digital signal processor (DSP) support during transfer. A DMA transfer is programmed through a logical DMA channel, which allows the transfer to be optimally tailored to the requirements of the application.

The DMA controller includes the following main features:

- Data transfer support in either direction between:
  - Memory and memory
  - Memory and peripheral device
- 32 logical DMA channels supporting:
  - Multiple concurrent transfers
  - Independent transfer profile for each channel
  - 8-bit, 16-bit, or 32-bit data element transfer size
  - Software-triggered or hardware-synchronized transfers
  - Flexible source and destination address generation
  - Burst read and write - max burst size is 16
  - Chained multiple-channel transfers
  - Endianism conversion
  - Draining
  - Linked-list support for descriptor types 1, 2, and 3
- First-come, first-serve DMA scheduling with fixed priority
- Up to 127 Hardware DMA requests
- DMA_CROSSBAR
- Constant fill
- Transparent copy
- Four programmable interrupt request output lines
- FIFO depth: 256 × 64-bit
- Data buffering
- FIFO budget allocation
- Power-management support
- Auto-idle power-saving support

Figure 16-1 shows an overview of the DMA_SYSTEM module.

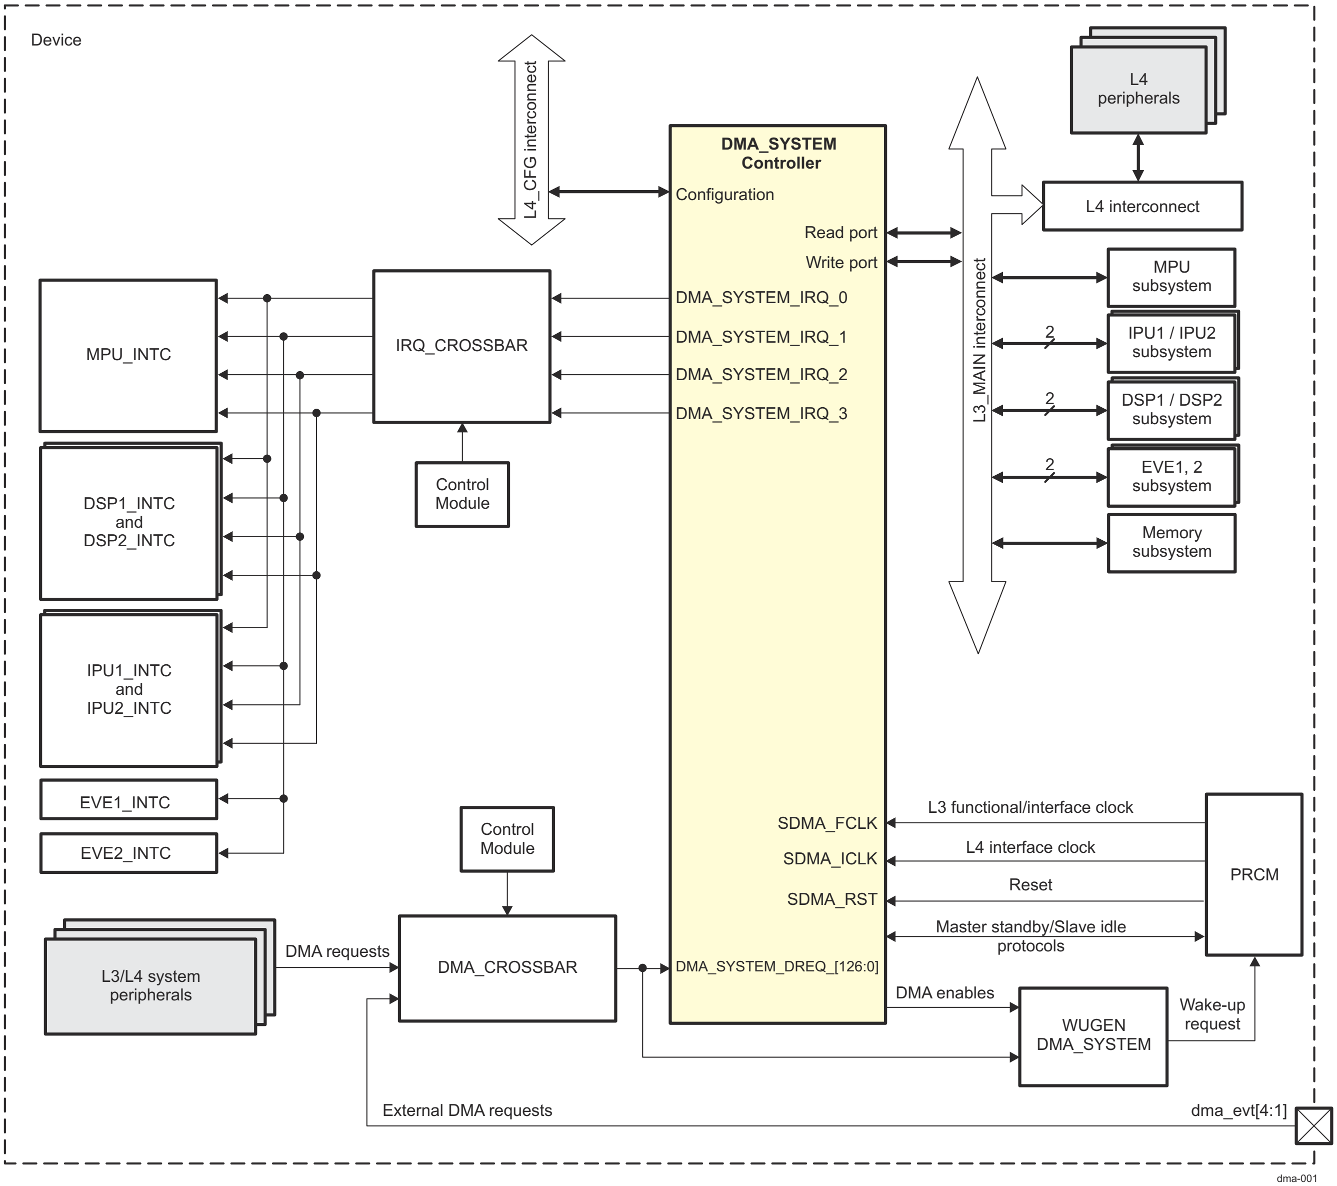

Figure 16-1. DMA_SYSTEM Overview

The DMA_SYSTEM module has three ports: one read, one write, and one configuration port, and provides multiple logical channel support. A dynamically allocated FIFO queue memory pool provides buffering between the read and write ports, which are multithreaded (two threads for the write port and four threads for the read port); this means that each transaction is flagged by a thread ID (0, 1, 2, or 3) in the request direction and in the response direction. This allows the read port to have four outstanding requests at a time. The write port has two threads budget available.

The MPU (or DSP) configures the DMA_SYSTEM through the L4_CFG interconnect.

16.1.2 DMA_SYSTEM Controller Environment

The DMA_SYSTEM controller supports external DMA requests through the dma_evt[4:1] pins (see Table 16-1). A logical channel can be configured to respond to an external synchronization request.

Table 16-1. External DMA_SYSTEM Request Signals

Pin Name	DMA_CROSSBAR Input	Signal Name	I/O[1]	Description	Module Reset Value
dma_evt1	DMA_CROSSBAR_2	EXT_SYS_DREQ_0	I	External DMA request 0 (system expansion)	Z
dma_evt2	DMA_CROSSBAR_3	EXT_SYS_DREQ_1	I	External DMA request 1 (system expansion)	Z
dma_evt3	DMA_CROSSBAR_167	EXT_SYS_DREQ_2	I	External DMA request 2 (system expansion)	Z
dma_evt4	DMA_CROSSBAR_168	EXT_SYS_DREQ_3	I	External DMA request 3 (system expansion)	Z

(1) I = Input, O = Output

Figure 16-2 shows an example of how to use the external hardware DMA request pins in the DMA_SYSTEM environment.

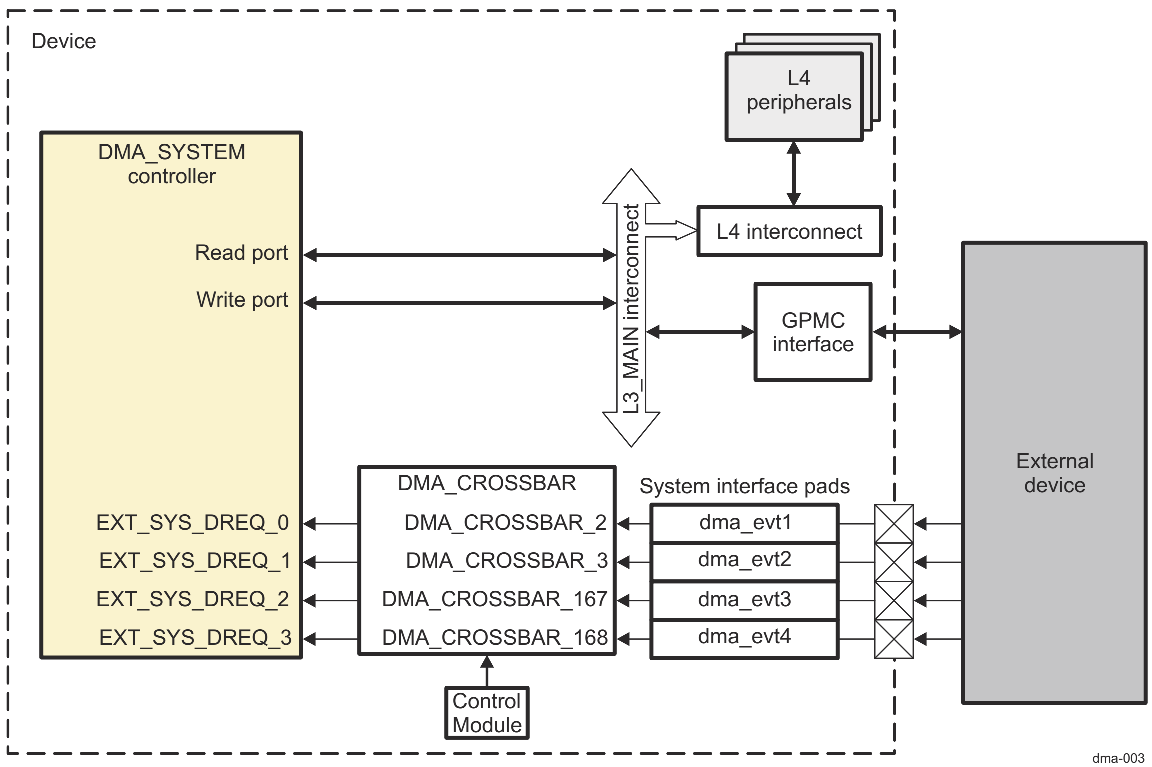

Figure 16-2. Example of External DMA Requests Use

An external device can use the external DMA request pins to start a logical channel transfer over the general-purpose memory controller (GPMC) interface. The transfer can be a memory-to-memory transfer in which the source memory is in the external device.

By default, the external DMA request signals are not available on external pins after a cold reset. For more information about multiplexing out the two signal lines to pins, see *Pad Configuration Registers* in the *Control Module*.

All 127 DMA request lines are transition sensitive.

For a transition-sensitive DMA request (see Figure 16-3), the line must be maintained low (asserted) until the first DMA access is complete, after which the line must be maintained high (deasserted) for greater than one clock cycle (DMA_L3_GICLK):

- When the deassertion time is less than one clock cycle, the DMA_SYSTEM may not detect the deassertion.
- When the channel is enabled one cycle after a DMA request is disabled, the channel detects the DMA request and starts the corresponding transfer.
- When the channel is enabled two cycles after the DMA request is disabled, the channel does not detect the DMA request.

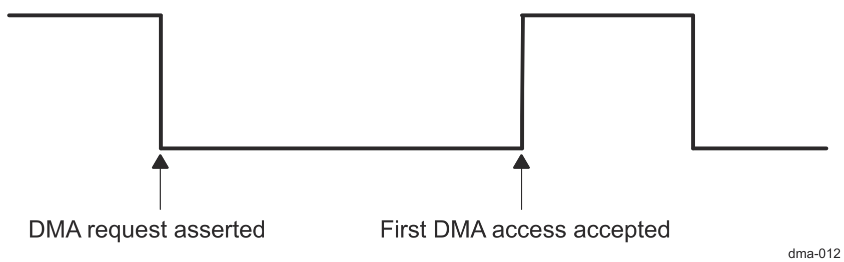

Figure 16-3. Transition-Sensitive DMA Request Scheme

16.1.3 DMA_SYSTEM Module Integration

This section describes the integration of the module in the device, including information about clocks, resets, and hardware requests.

Figure 16-4 shows the DMA_SYSTEM controller integration.

Table 16-2 through Table 16-4 summarize the integration of the module in the device.

Table 16-2. DMA_SYSTEM Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
DMA_SYSTEM	PD_COREAON	L3_MAIN and L4_CFG

Table 16-3. DMA_SYSTEM Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
DMA_SYSTEM	SDMA_FCLK	DMA_L3_GICLK	PRCM	Functional clock for all internal logic and for the two master read and write ports. For information about the power, reset, and clock management (PRCM) clock gating and management, see *Power, Reset, and Clock Management*.
	SDMA_ICLK	DMA_L4_GICLK		Interface clock. It supports the configuration port. For information about PRCM clock gating and management, see *Power, Reset, and Clock Management*.
Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
DMA_SYSTEM	SDMA_RST	DMA_RET_RST	PRCM	Hardware retention reset. It initializes all internal logic of the DMA_SYSTEM module, all global registers, and some of the per-channel registers, implemented in flip-flops. However, all remaining per-channel registers are memory-based, and, therefore, are not reset (have undefined values). Thus, when programming a channel for the first time, all bits that have undefined reset values must be configured before enabling the channel. For information about PRCM reset sources and distribution, see *Power, Reset, and Clock Management*.

Table 16-4. DMA_SYSTEM Hardware Requests (continued)

	DSP2_IRQ_41	DSP2 INTC

Note

The "**Default Mapping**" column in Table 16-4 *Hardware Requests* shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR or DMA_CROSSBAR modules.

For more information about the IRQ_CROSSBAR and DMA_CROSSBAR modules, see sections: *IRQ_CROSSBAR Module Functional Description* and *DMA_CROSSBAR Module Functional Description*, in *Control Module*.

For more information about the device interrupt controllers, refer to *Interrupt Controllers* in the device TRM.

Note

For a description of the interrupt source, see Section 16.1.4.2, *DMA_SYSTEM Controller Interrupt Requests*.

16.1.3.1 DMA Requests to the DMA_SYSTEM Controller

Table 16-5 lists the default DMA sources for the DMA_SYSTEM controller. In addition, the DMA_SYSTEM inputs (DMA_SYSTEM_DREQ_[126:0]) can alternatively be sourced through the associated DMA_CROSSBAR from one of the 256 multiplexed device DMA sources listed in Table 16-6. The CTRL_CORE_DMA_SYSTEM_DREQ_y_z registers (where *y* and *z* are indexes of DMA_SYSTEM input lines) in the Control Module are used to select between the default DMA sources and the multiplexed DMA sources.

Table 16-5. DMA_SYSTEM Default Request Mapping

DMA Request Line	DMA_CROSSBAR Instance Number	DMA_CROSSBAR Configuration Register	DMA_CROSSBAR Default Input Index	Default DMA Source Name	Default DMA Source Description
DMA_SYSTEM_DREQ_0	1	CTRL_CORE_DMA_SYSTEM_DREQ_0_1[7:0]	1	Reserved	Reserved by default but can be remapped to a valid DMA source

16.1.3.2 Mapping of DMA Requests to DMA_CROSSBAR Inputs

Note

For information about the DMA_CROSSBAR module, refer to *DMA_CROSSBAR Module Functional Description* in *Control Module*.

Table 16-6 shows the mapping of device DMA requests to DMA_CROSSBAR inputs.

Table 16-6. Connection of The Device DREQs to The DMA_CROSSBAR Inputs

DMA_CROSSBAR Input	Device Module DREQs	Description
DMA_CROSSBAR_0	Reserved	Reserved
DMA_CROSSBAR_1	Reserved	Reserved
DMA_CROSSBAR_2	EXT_SYS_DREQ_0	External DMA request 0 (system expansion) - coming from SOC IOs. Level sensitive only
DMA_CROSSBAR_3	EXT_SYS_DREQ_1	External DMA request 1 (system expansion) - coming from SOC IOs - level sentitive only
DMA_CROSSBAR_4	GPMC_DREQ	GPMC request from prefetch engine
DMA_CROSSBAR_5	Reserved	Reserved
DMA_CROSSBAR_6	DISPC_DREQ	The line trigger signal to synchronize a memory to memory logical channel in the DMA4 (system DMA) is generated by the Display Controller IP.
DMA_CROSSBAR_7	CT_TBR_DREQ	DMA request coming from CT_TBR in DEBUGSS (used to be External DMA request 2 - coming from SOC IOs)
DMA_CROSSBAR_8 to DMA_CROSSBAR_14	Reserved	Reserved
DMA_CROSSBAR_15	MCSPI3_DREQ_TX0	McSPI module 3 - transmit request channel 0
DMA_CROSSBAR_16	MCSPI3_DREQ_RX0	McSPI module 3 - receive request channel 0
DMA_CROSSBAR_17 to DMA_CROSSBAR_22	Reserved	Reserved
DMA_CROSSBAR_23	MCSPI3_DREQ_TX1	McSPI module 3 - transmit request channel 1
DMA_CROSSBAR_24	MCSPI3_DREQ_RX1	McSPI module 3 - receive request channel 1
DMA_CROSSBAR_25	I2C3_DREQ_TX	I2C module 3 - transmit request
DMA_CROSSBAR_26	I2C3_DREQ_RX	I2C module 3 - receive request
DMA_CROSSBAR_27	I2C1_DREQ_TX	I2C module 1 - transmit request
DMA_CROSSBAR_28	I2C1_DREQ_RX	I2C module 1 - receive request
DMA_CROSSBAR_29	I2C2_DREQ_TX	I2C module 2 - transmit request
DMA_CROSSBAR_30	I2C2_DREQ_RX	I2C module 2 - receive request
DMA_CROSSBAR_31 to DMA_CROSSBAR_34	Reserved	Reserved
DMA_CROSSBAR_35	MCSPI1_DREQ_TX0	McSPI module 1 - transmit request channel 0
DMA_CROSSBAR_36	MCSPI1_DREQ_RX0	McSPI module 1 - receive request channel 0
DMA_CROSSBAR_37	MCSPI1_DREQ_TX1	McSPI module 1 - transmit request channel 1
DMA_CROSSBAR_38	MCSPI1_DREQ_RX1	McSPI module 1 - receive request channel 1
DMA_CROSSBAR_39	MCSPI1_DREQ_TX2	McSPI module 1 - transmit request channel 2
DMA_CROSSBAR_40	MCSPI1_DREQ_RX2	McSPI module 1 - receive request channel 2
DMA_CROSSBAR_41	MCSPI1_DREQ_TX3	McSPI module 1 - transmit request channel 3
DMA_CROSSBAR_42	MCSPI1_DREQ_RX3	McSPI module 1 - receive request channel 3
DMA_CROSSBAR_43	MCSPI2_DREQ_TX0	McSPI module 2 - transmit request channel 0
DMA_CROSSBAR_44	MCSPI2_DREQ_RX0	McSPI module 2 - receive request channel 0
DMA_CROSSBAR_45	MCSPI2_DREQ_TX1	McSPI module 2 - transmit request channel 1

Table 16-6. Connection of The Device DREQs to The DMA_CROSSBAR Inputs (continued)

DMA_CROSSBAR Input	Device Module DREQs	Description
DMA_CROSSBAR_46	MCSPI2_DREQ_RX1	McSPI module 2 - receive request channel 1
DMA_CROSSBAR_47	MMC2_DREQ_TX	MMC/SD2 transmit request
DMA_CROSSBAR_48	MMC2_DREQ_RX	MMC/SD2 receive request
DMA_CROSSBAR_49	UART1_DREQ_TX	UART module 1 - transmit request
DMA_CROSSBAR_50	UART1_DREQ_RX	UART module 1 - receive request
DMA_CROSSBAR_51	UART2_DREQ_TX	UART module 2 - transmit request
DMA_CROSSBAR_52	UART2_DREQ_RX	UART module 2 - receive request
DMA_CROSSBAR_53	UART3_DREQ_TX	UART module 3 - transmit request (Also infrared - IRDA)
DMA_CROSSBAR_54	UART3_DREQ_RX	UART module 3 - receive request (Also infrared - IRDA)
DMA_CROSSBAR_55	UART4_DREQ_TX	UART module 4 – transmit request
DMA_CROSSBAR_56	UART4_DREQ_RX	UART module 4 – receive request
DMA_CROSSBAR_57	MMC4_DREQ_TX	MMC/SD4 transmit request
DMA_CROSSBAR_58	MMC4_DREQ_RX	MMC/SD4 receive request
DMA_CROSSBAR_59	Reserved	Reserved
DMA_CROSSBAR_60	Reserved	Reserved
DMA_CROSSBAR_61	MMC1_DREQ_TX	MMC/SD1 transmit request
DMA_CROSSBAR_62	MMC1_DREQ_RX	MMC/SD1 receive request
DMA_CROSSBAR_63	UART5_DREQ_TX	UART module 5 – transmit request (used to be External DMA request 3 - coming from SOC IOs)
DMA_CROSSBAR_64	UART5_DREQ_RX	UART module 5 – receive request (used to be USIM receive request)
DMA_CROSSBAR_65 to DMA_CROSSBAR_69	Reserved	Reserved
DMA_CROSSBAR_70	MCSPI4_DREQ_TX0	McSPI module 4 - transmit request channel 0
DMA_CROSSBAR_71	MCSPI4_DREQ_RX0	McSPI module 4 - receive request channel 0
DMA_CROSSBAR_72 to DMA_CROSSBAR_75	Reserved	Reserved
DMA_CROSSBAR_76	DSS_DREQ	Display subsystem HDMI Audio DMA request
DMA_CROSSBAR_77	MMC3_DREQ_TX	MMC/SD3 transmit request
DMA_CROSSBAR_78	MMC3_DREQ_RX	MMC/SD3 receive request
DMA_CROSSBAR_79	UART6_DREQ_TX	UART module 6 – transmit request (used to be USIM transmit request)
DMA_CROSSBAR_80	UART6_DREQ_RX	UART module 6 – receive request (used to be USIM receive request)
DMA_CROSSBAR_81 to DMA_CROSSBAR_123	Reserved	Reserved
DMA_CROSSBAR_124	I2C4_DREQ_TX	I2C module 4 - transmit request
DMA_CROSSBAR_125	I2C4_DREQ_RX	I2C module 4 - receive request
DMA_CROSSBAR_126	Reserved	Reserved
DMA_CROSSBAR_127	Reserved	Reserved
DMA_CROSSBAR_128	McASP1_DREQ_RX	McASP receive event
DMA_CROSSBAR_129	McASP1_DREQ_TX	McASP transmit event
DMA_CROSSBAR_130	McASP2_DREQ_RX	McASP receive event
DMA_CROSSBAR_131	McASP2_DREQ_TX	McASP transmit event
DMA_CROSSBAR_132	McASP3_DREQ_RX	McASP receive event
DMA_CROSSBAR_133	McASP3_DREQ_TX	McASP transmit event
DMA_CROSSBAR_134	McASP4_DREQ_RX	McASP receive event

Table 16-6. Connection of The Device DREQs to The DMA_CROSSBAR Inputs (continued)

DMA_CROSSBAR Input	Device Module DREQs	Description
DMA_CROSSBAR_135	McASP4_DREQ_TX	McASP transmit event
DMA_CROSSBAR_136	McASP5_DREQ_RX	McASP receive event
DMA_CROSSBAR_137	McASP5_DREQ_TX	McASP transmit event
DMA_CROSSBAR_138	McASP6_DREQ_RX	McASP receive event
DMA_CROSSBAR_139	McASP6_DREQ_TX	McASP transmit event
DMA_CROSSBAR_140	McASP7_DREQ_RX	McASP receive event
DMA_CROSSBAR_141	McASP7_DREQ_TX	McASP transmit event
DMA_CROSSBAR_142	McASP8_DREQ_RX	McASP receive event
DMA_CROSSBAR_143	McASP8_DREQ_TX	McASP receive event
DMA_CROSSBAR_144	UART7_DREQ_TX	UART module 7 - transmit request
DMA_CROSSBAR_145	UART7_DREQ_RX	UART module 7 - receive request
DMA_CROSSBAR_146	UART8_DREQ_TX	UART module 8 - transmit request
DMA_CROSSBAR_147	UART8_DREQ_RX	UART module 8 - receive request
DMA_CROSSBAR_148	UART9_DREQ_TX	UART module 9 - transmit request

16.1.4 DMA_SYSTEM Functional Description

The DMA_SYSTEM module provides high-performance data transfers between memories and peripheral devices with low processor use. A DMA transfer is programmed through a logical DMA channel, which allows the transfer to be optimally tailored to the requirements of the application.

Figure 16-5 shows the DMA_SYSTEM controller top-level block diagram.

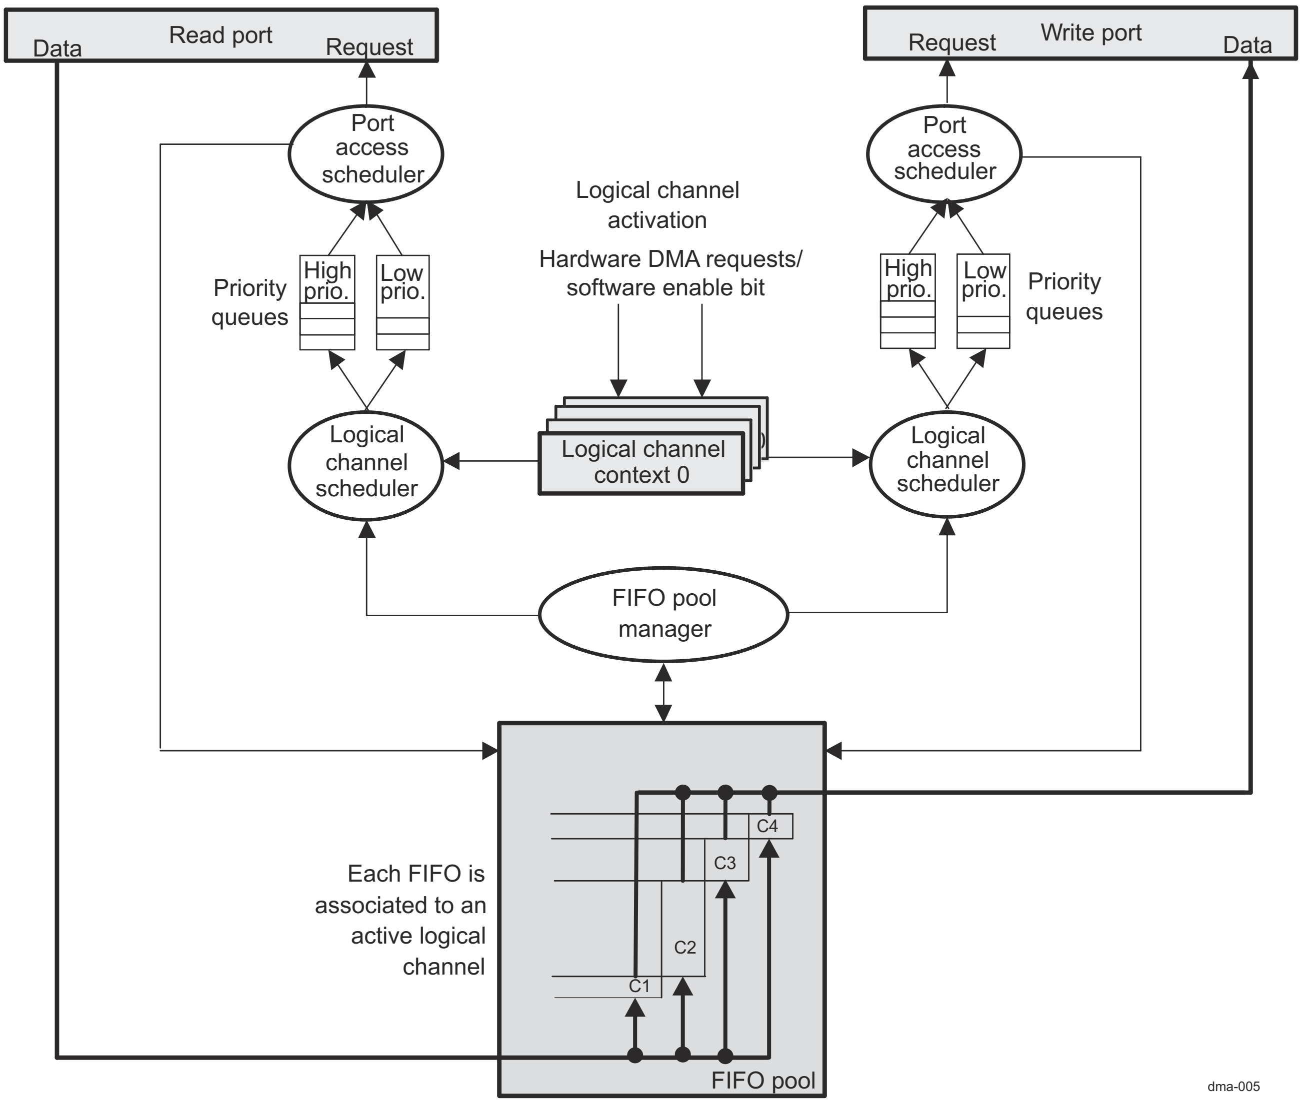

Figure 16-5. DMA_SYSTEM Controller Top-Level Block Diagram

16.1.4.1 DMA_SYSTEM Controller Power Management

Table 16-7 describes power-management features available for the DMA_SYSTEM controller.

Note

- For information about source clock gating and sleep/wake-up transitions, see secton *Clock Management*, in *Power, Reset, and Clock Management*.
- For a description of the EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see *Module Level Clock Management*, in *Power, Reset, and Clock Management*.

Table 16-7. Local Power-Management Features

Feature	Registers	Description
Clock auto gating	DMA4_OCP_SYSCONFIG[0] AUTOIDLE bit	This bit allows local power optimization inside the module by gating the SDMA_ICLK clock upon the interface activity.
Slave idle modes	DMA4_OCP_SYSCONFIG[4:3] SIDLEMODE bit field	Force-idle, no-idle, and smart-idle modes are available.
Clock activity	DMA4_OCP_SYSCONFIG[9:8] CLOCKACTIVITY bit field	For configuration details, see Table 16-8.
Master standby modes	DMA4_OCP_SYSCONFIG[13:12] MIDLEMODE bit field	Force-standby, no-standby, and smart-standby modes are available.
Global wake-up enable	N/A	Feature not available
Wake-up sources enable	N/A	Feature not available

Table 16-8. Clock Activity Settings

SDMA_CLOCKACTIVITY Values	Clock State When Module is in IDLE State	
	SDMA_ICLK	SDMA_FCLK
00	Off	Off
10	Off	On
01	On	Off
11	On	On

CAUTION

Because the PRCM module cannot read CLOCKACTIVITY settings through hardware, software must ensure consistent programming between the SDMA_CLOCKACTIVITY and DMA_SYSTEM clock PRCM control bits. For a description of the ClockActivity feature, see *Module Level Clock Management*, in *Power, Reset, and Clock Management*.

16.1.4.2 DMA_SYSTEM Controller Interrupt Requests

DMA4 has four interrupt lines (Lj, where j = 0, 1, 2, 3). Each logical channel can request an interrupt over any line. The attachment of a channel interrupt event to one of these four external lines is programmable. Software determines whether it attaches a channel interrupt to a single IRQ line or to multiple IRQ lines.

There are two different registers per interrupt line:

- The DMA4_IRQSTATUS_Lj CH_31_0_Lj field shows the status of the different sources of interrupt. If the DMA4_IRQENABLE_Lj bit is 1, channel *i* is the source of interrupt in line *j*. In contrast to the DMA4_CSRi registers, the DMA4_IRQSTATUS_Lj registers are updated regardless of the corresponding bits in the DMA4_IRQENABLE_Lj registers.
- The DMA4_IRQENABLE_Lj CH_31_0_Lj_EN field masks/unmasks the channel interrupt. If the DMA4_IRQENABLE_Lj bit is set to 0, channel interrupt *i* of the line *j* is masked.

Each logical channel can generate a number of different interrupt events when enabled (that is, set to 1) in the DMA4_CICRi register. Each status bit is updated in the DMA4_CSRi register only when the corresponding enable bit is enabled in the DMA4_CICRi register.

To determine an interrupt source when an interrupt rises on an interrupt line L*j*:

- Identify the channel (LCH*i*) generating the interrupt.

  Read DMA4_IRQSTATUS_Lj.LCH*i* (LCH0 to LCH31). If LCH*i* = 1, channel *i* is the originator of the interrupt.
- Identify the interrupt event.

  Read the LCH*i* DMA4_CSRi. For example, if the drop event (the DMA4_CSRi[1] DROP bit) is 1, a request collision will occur.

The interrupt event status bit in the DMA4_CSRi register is immediately reset after it is written to 1.

The interrupt status bit in the DMA4_IRQSTATUS_Lj register is cleared after it is written to 1.

16.1.4.2.1 Interrupt Generation

The DMA_SYSTEM module has four interrupt request output lines, DMA_SYSTEM_IRQ_0 to DMA_SYSTEM_IRQ_3. One or more logical channels can be programmed to generate an interrupt request on any of these lines when any one of the maskable DMA events listed in Table 16-9 occurs.

Table 16-9. Logical DMA Channel Events

Event	Description
End of packet	A packet transfer completed.
End of block	A block transfer completed.
End of frame	A frame transfer completed.
End of super block	A super block transfer completed.
Half of frame	Half of the current frame transferred.
Start of last frame	The first element of the last frame transferred.
Transaction error	A transaction error is returned by the interconnect in either the read or write port.
Address error	An attempt was made to perform a DMA access to an address not aligned on an ES boundary. Condition to occur: if DMA4_CENi[23:0] CHANNEL_ELMNT_NBR = 0x000000 or DMA4_CFNi[15:0] CHANNEL_FRAME_NBR = 0x0000 or DMA4_CSDPi[1:0] DATA_TYPE = 0x3.
Supervisor transaction error	An error occurred, for example, when an unauthorized initiator (that is not a supervisor) tries to use a supervisor transfer.
Drain end	Drain is completed (DMA4_CCRi[10] WR_ACTIVE becomes 0).
Drop error	A drop event interrupt is generated when a DMA request is being serviced while a second one is asserted and a third one arrives before the second DMA request is serviced.

The logical DMA channels that generate an interrupt on a particular IRQ output are specified through the DMA4_IRQENABLE_Lj register (where *j* is the IRQ number: 0, 1, 2, or 3). The events that generate an interrupt for a particular channel can be configured through the channel DMA4_CICRi register.

When an interrupt is detected, the logical DMA channel generating the event can first be identified by reading the DMA4_IRQSTATUS_Lj register. The event causing the interrupt then can be identified by reading the interrupt status via the relevant DMA channel DMA4_CSRi register.

16.1.4.3 Logical Channel Transfer Overview

As Figure 16-5 shows, the DMA_SYSTEM module has one read port and one write port operating independently of one another. Buffering is provided between the read and write ports through a FIFO queue memory pool that is shared dynamically between the active logical channels.

- Logical channel synchronization

  A logical channel is described as hardware-synchronized when the DMA transfers are triggered by DMA requests from a hardware device. Alternatively, a logical channel is described as nonsynchronized when the DMA transfer is triggered by software.
- Logical channel activation

  A logical channel becomes active as follows:
  – For hardware-synchronized transfers, when the logical channel is enabled and the hardware DMA request line is asserted
  – For software-triggered (nonsynchronized) transfers, as soon as software enables the logical channel
- Logical channel transfer composition

  A DMA transfer is divided automatically into a number of transactions. Depending on the logical channel context configured, the transfer size, start address alignment, addressing mode, and configured maximum burst size, each transaction can be a single access or a burst of accesses.
- Logical channel scheduling

When several logical channels are active at the same time, schedulers manage the read and write ports. The scheduling of logical channel transfers is similar for both read and write ports. When a logical channel becomes active, it is added to the tail of a scheduling queue. If more than one logical channel becomes active at the same time, the one with the lower number is queued first. This mechanism provides a first-come, first-serve scheduling scheme between the concurrently active logical channels.

In addition, each read and write port has a high-priority queue and a low-priority queue. The priority bits (WRITE_PRIORITY and READ_ PRIORITY) in the logical channel DMA4_CCRi register determine whether a logical channel is queued as high or low priority. A software-configurable 8-bit priority counter gives weighting to the priority write queue. For every N (1 to 255) schedules from the priority write queue, one is scheduled from the regular write queue. A channel that is scheduled goes to the end of the queue after it completes its turn on the port. The relative weighting of the scheduling of the high-priority queue to the low priority queue is programmable from 1:1 to 1:256 through the DMA global channel register using the DMA4_GCR[23:16] ARBITRATION_RATE bit field.

Note

The DMA4_GCR[23:16] ARBITRATION_RATE bit field does not depend on the DMA4_GCR[13:12] HI_THREAD_RESERVED bit field. The ARBITRATION_RATE bit field depends on the DMA4_CCRi[26] WRITE_PRIORITY bit and the DMA4_CCRi[6] READ_PRIORITY bit.

- Read/write port access scheduling policy

  When either the read or write port becomes available, the port access scheduler selects the next logical channel for which to perform a DMA transaction from either the high- or low-priority queue.

  When the current DMA transaction (single or burst access) is complete and the full DMA transfer is not finished, the logical channel returns to the tail of the queue. Because the port access scheduling is on a per-transaction basis, a logical channel can be queued repeatedly this way several times during its block transfer.

The DMA_SYSTEM module can have up to four outstanding read transactions and two outstanding write transactions in the system interconnect; four read and two write thread IDs exist. For an arbitration cycle to occur, these two conditions must be met:

- At least one channel is requesting
- At least one free thread ID is available

On an arbitration cycle, the scheduler grants the highest priority channel that has an active request, allocates the thread ID, and tags this thread as busy. At a given time, a channel cannot be allocated for more than one thread ID.

Note

If more than one channel is active, each channel is given a thread ID for the current service only, not for the whole channel transfer.

When only one channel is enabled, only one thread is allocated for the channel. In such a situation the channel can have maximum of four outstanding commands (without getting the responses) without rescheduling the channel at the end of each transaction. Each command can be either single access (8-bit, 16-bit or 32-bit) or burst access (2 × M, 4 × M, 8 × M or 16 × M, where M can be 8, 16, or 32 bits).

When nonburst alignment is at the beginning of the transfer, the channel is rescheduled for each smaller access until burst-aligned. When the end of the transfer is not burst-aligned, the channel is rescheduled for each of the remaining smaller accesses.

For a logical channel transfer completion, when the last access is written to the destination, the logical channel becomes inactive. If enabled, an interrupt request is generated (see Section 16.1.4.2.1, *Interrupt Generation*).

16.1.4.4 FIFO Queue Memory Pool

A FIFO queue memory pool provides buffering between the read and write ports. The hardware allocates the space dynamically to a number of FIFO queues, and each queue is associated with an active logical channel.

To avoid a memory pool overflow, if there are fewer entries in the FIFO queue memory pool than are required for the maximum configured source burst size of the next logical channel to be scheduled, the logical channel is returned to the tail of the queue, and the port access scheduler continues to search the queue until it finds a logical channel that can be scheduled.

The maximum FIFO depth that can be allocated to each individual logical channel can be limited globally through the DMA4_GCR[7:0] MAX_CHANNEL_FIFO_DEPTH bit field. This value should be configured to allow a fair allocation of the memory pool between the active channels.

A logical channel is scheduled if it has not yet reached its allocation limit, even if the access to be performed will exceed this limit. This means that the effective number of entries used by a particular logical channel is limited to the configured maximum entries per channel + channel maximum configured burst size (in words) 1.

16.1.4.5 Addressing Modes

A DMA transfer block consists of a number of frames (FN). Each frame consists of a number of elements (EN), and each element can have a size of 8, 16, or 32 bits (ES), as follows:

transfer block size = FN × EN × ES

The FN, EN, and ES are common for the source and destination. However, the way in which the data is represented (addressing profile/mode) is independently programmable for the source and destination devices, using one of these four addressing modes:

- Constant: The address remains the same for consecutive element accesses.
- Post-increment: The address increases by the ES, even across consecutive frames.
- Single-index: The address increases by the ES plus the element index (EI) value minus 1 (even across consecutive frames).
- Double-index: The address increases by the ES plus the EI value minus 1 within a frame. When a full frame is transferred, the address increases by the ES plus the frame index (FI) value minus 1.

The ES, EI, and FI values are expressed in bytes. The EI and FI values can be positive or negative.

When calculating the EI and FI values, it is critical to note that, after an element is accessed, the logical channel address pointer equals the address of the last byte (highest address) of the accessed element. The correct value for the EI or FI must be such that, when added to the logical channel address pointer, it results in the address of the first byte (lowest address) of the next element to be accessed.

The EI and FI values must be configured so that the address of each element in the transfer is aligned on an ES boundary.

Consequently, the single-index addressing mode with EI = 1 or double-index addressing mode with EI = 1 and FI = 1 is equivalent to post-increment addressing.

Note

The source and destination start addresses must also be aligned on an ES boundary.

When the address of an element to be accessed is not aligned on an ES boundary, the transfer is stopped and a misaligned address error interrupt occurs, if enabled (see Section 16.1.4.2.1, *Interrupt Generation*).

The DMA4_CFNi register configures the FN in a block.

The DMA4_CENi register configures the EN.

The DMA4_CSDPi register configures the ES.

The DMA4_CSSAi and DMA4_CDSAi registers configure the source and destination start addresses.

The DMA4_CCRi register configures the source and destination addressing modes.

The DMA4_CSEIi, DMA4_CSFIi, DMA4_CDEIi, and DMA4_CDFIi registers configure the source EI, source FI, destination EI, and destination FI, respectively.

The addressing profiles are expressed as equations as follows:

Equation 1. Constant addressing:

$$A(n + 1) = A(n)$$

Note

Constant addressing mode with DMA4 to/from DDR memory is not supported on the device. To fill the DDR memory with a single value, the constant fill feature of the DMA4 must be used, instead of a constant-addressing mode transfer.

Equation 2. Post-increment addressing:

$$A(n + 1) = A(n) + ES$$

Equation 3. Single-indexed addressing:

$$A(n + 1) = A(n) + ES + (EI\ 1)$$

Equation 4. Double-indexed addressing:

When not at the end of a frame or transfer (that is, when the element counter ≠ 0):

$$A(n + 1) = A(n) + ES + (EI\ 1)$$

When at the end of a frame but not at the end of the transfer (that is, when the element counter = 0 and the frame counter ≠ 0):

$$A(n + 1) = A(n) + ES + (FI\ 1)$$

Calculate the element and frame index as follows:

Equation 5. Element index

$$EI = [(Stride\ EI\ 1) * ES] + 1$$

Equation 6. Frame index

$$FI = [(Stride\ FI\ 1) * ES] + 1$$

where:

A(n): Byte address of the element *n* within the transfer.

ES is in bytes, ES{1, 2, 4}.

EI is in bytes, specified in a configuration register, 32768 EI 32767.

Stride EI: The difference in the number of elements between the start of the current element *n* to the start of next element, *n+1*.

Element counter: A counter that is (re)initiated with the number of elements per frame or per transfer. Decreased by 1 for each element transferred. The initial value is configured in the register DMA channel element number, DMA4_CENi.

FI is in bytes, specified in a configuration register, 2147483648 FI 2147483647.

Stride FI: The difference in the number of elements between the start of the last element of the current frame and the beginning of the first element of the next frame.

Frame counter: A counter that is (re)initiated with the FN per transfer. Decreased by 1 for each frame transferred. The initial value is configured in the register DMA channel frame number, DMA4_CFNi.

Figure 16-6 shows how a stride EI and FI are defined. When handling complex configurations, using strides can make it easier to calculate EI and FI because you can calculate in elements instead of bytes. (This approach is used in the 90-degree clockwise image rotation example shown in Figure 16-10.) The double-index addressing example shown in Figure 16-6 uses ES = 4, EN = 2, EI = 5, FI = 5, and FN = 2.

Figure 16-6 through Figure 16-9 show examples of addressing mode configurations. Table 16-10 lists parameter values for the examples.

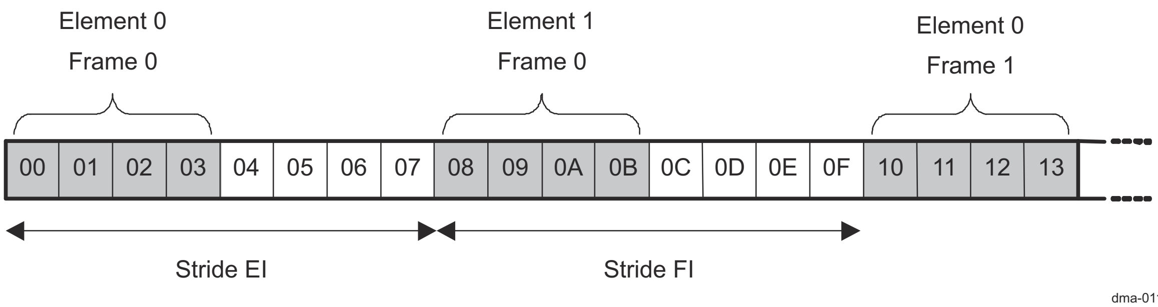

Figure 16-6. Example Showing Double-Index Addressing, Elements, Frames, and Strides

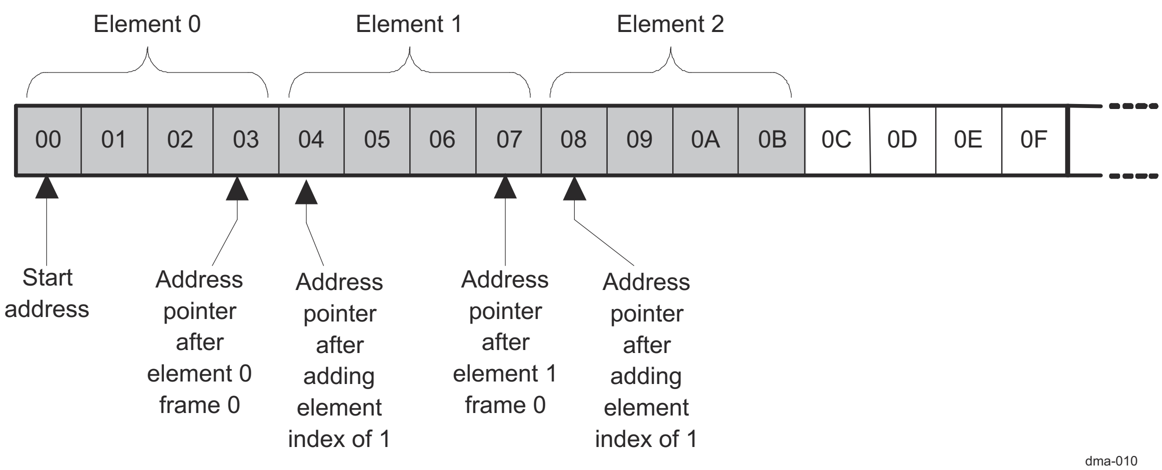

Figure 16-7. Addressing Mode Example (a)

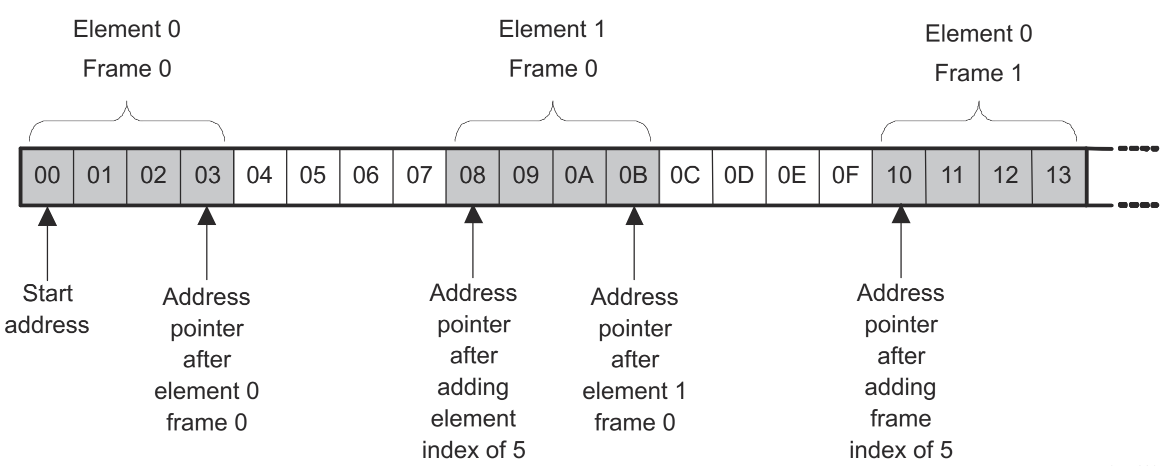

Figure 16-8. Addressing Mode Example (b)

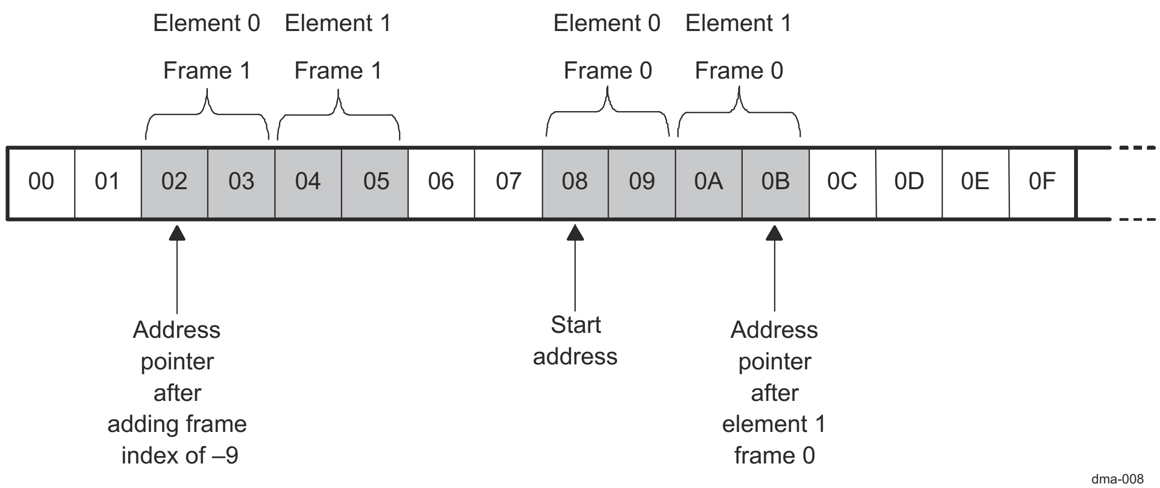

Figure 16-9. Addressing Mode Example (c)

Table 16-10. Parameter Values for Addressing Mode Examples (a), (b), and (c)

Parameter	Example (a)	Example (b)	Example (c)
Addressing mode	Single index (or post-increment)	Double index	Double index
Start address	0	0	8
ES	4 (32-bit)	4 (32-bit)	2 (16-bit)
EN	3	2	2
EI	1	5	1
FN	1	2	2
Frame index	N/A	5	-9

Double indexing can occur on source (read) or destination (write). Equations for rotation of xx degrees on destination are obtained by taking equations for rotation of (360 – xx) degrees on source, and swapping the width (x) and height (y) of the image in them. The opposite is also true. Table 16-11 lists the equations for 90-, 180-, and 270-degree rotations.

Table 16-11. Equations for Rotation

		90° Rotation	180° Rotation	270° Rotation
Double indexing on destination (write)	Base address	ES*(y–1)	ES*(x*y–1)	ES*y*(x–1)
	EI	ES*(y–1) + 1	1–2*ES	1–ES*(y + 1)
	FI	1 ES*[(x–1)*y + 2]	1–2*ES	1+ES*(x–1)*y
Double indexing on source (read)	Base address	ES*x*(y–1)	ES*(x*y–1)	ES*(x–1)
	EI	1–ES*(x + 1)	1–2*ES	ES*(x–1) + 1
	FI	1+ES*(y–1)*x	1–2*ES	1 ES*[(y–1)*x + 2]

Table 16-12 and Figure 16-10 show the configuration required to perform a 90-degree clockwise rotation of a 240 × 160 pixel, 32-bit image. The EI, frame size, and FI values are configured so that the image is rotated line-by-line starting at the left end of the top line.

Note

The FI value for the destination is negative so that the first pixel of each subsequent line of the source image is written to the correct location at the destination.

Equation 5 and Equation 6 calculate the destination, FI and EI. The example assumes that the image lines are stored at consecutive addresses in memory, meaning that both EI and FI on the source side are 1.

Rotations:

Section 16.1.5.7, *90-Degree Clockwise Image Rotation*, describes how to program an example of a 90-degree clockwise image rotation.

Observe that:

- One pixel = one element
- One line = one DMA frame
- Pixel size = element size = ES

Table 16-12. Example Parameter Values for a 90-Degree Clockwise Image Rotation

Parameter	Source Value	Destination Value
Bits per pixel	32	32
ES	4	4
Image width	SW	SH
Image height	SH	SW
Stride elements (stride EI)	1 element	SH
Stride frames (stride FI)	1 element	–[(SW-1)*SH + 1] = 38,241 elements
Start address	0x100000	0x200000 + (SH 1) x ES = 0x20027C
EN	SW	SW
EI	[(Stride EI 1) * ES] + 1 = 1	[(Stride EI 1) * ES] + 1 = 637
FN	SH	SH
FI	[(Stride FI 1) * ES] + 1= 1	[(Stride FI 1) * ES] + 1 = 152,967

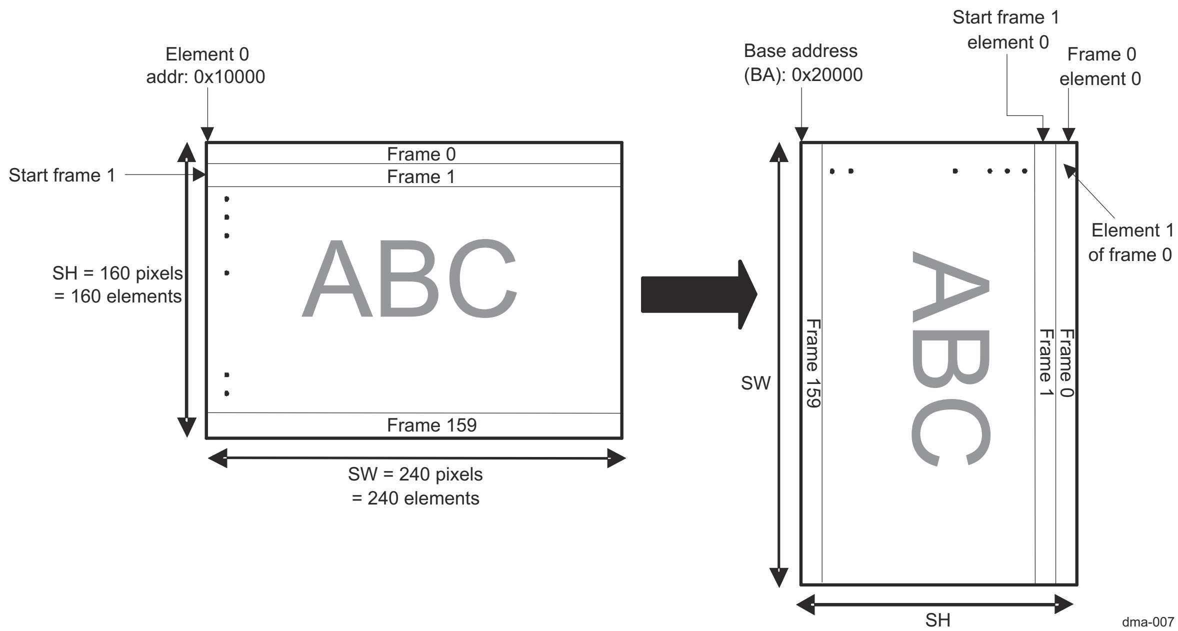

Figure 16-10. Example of a 90-Degree Clockwise Image Rotation

16.1.4.6 Packed Accesses

To pack data means to group data to match the bus size, thus optimizing a transfer. When the logical channel ES is less than the DMA module read/write port size, and the addressing profile supports it (post-increment mode or single- or double-index mode with EI = 1), the number of elements to transfer in each read/write port access can be maximized by specifying that the source or destination is packed through the channel DMA4_CSDPi register. Thus:

- For a read/write port size of 32 bits, the source or destination can be configured as packed for transfer ESs of 8 bits (four elements per access) and 16 bits (two elements per access).
- For a read/write port size of 64 bits, the source or destination can be configured as packed for transfer ESs of 8 bits (eight elements per access), 16 bits (four elements per access), and 32 bits (two elements per access).

Depending on the start address and transfer length, the first or last packed access can be only partially filled. This is indicated to the source or destination using the byte-enable signals.

16.1.4.7 Burst Transactions

Transfer performance can be improved so that the source or destination and addressing profile supports it. This can be achieved by configuring the logical channel to perform burst transactions consisting of multiple instead of single accesses. The channel can be programmed to use burst sizes equal to 16, 32, or 64 bytes through the DMA4_CSDPi register, with the read burst size programmable independently of the write burst size. Typically, the optimal burst size is 64 bytes (16 accesses for a 32-bit read/write port size or 8 accesses for a 64-bit read/write port size).

To obtain the maximum benefit from burst transactions, the source and destination start addresses must be aligned with the burst size. If this is not the case, the start of the transfer can consist of a number of smaller (single or burst) transactions until the first burst size boundary is reached.

Similarly, if the end of the transfer is not aligned on a burst size boundary, the final part of the transfer can consist of a number of smaller transactions.

Note

If post-incrementing is used, data must be packed to DMA data-port width, to use burst.

16.1.4.8 Endianism Conversion

The source and destination are each specified as little-endian or big-endian through the DMA4_CSDPi register for the particular logical channel. If the endianism of the source and destination differ, and if the logical channel ES is less than the DMA_SYSTEM module read/write port size, an endianism conversion is applied to the data before it is written to the destination.

When transferring data between a source and a destination with different endianism, it is important to specify an ES that equals the type of data being transferred to preserve the correct data image at the destination.

In the system, endianism conversion can be performed in more than one place. It is possible to instruct the source and/or destination to lock the endianism (that is, to not perform a conversion) through the logical DMA channel DMA4_CSDPi register.

Note

Because the device is little-endian by construction, the DMA_SYSTEM endianism registers must never be set to big-endian.

If DMA_SYSTEM is used to execute endian conversion by setting the source and destination to different endianism values, it is important to consider that the L3_MAIN interconnect also executes endian conversion if the DMA_SYSTEM and the source or destination have a different data bus width.

16.1.4.9 Transfer Synchronization

A logical channel can be programmed for software-triggered or hardware synchronized transfers.

16.1.4.9.1 Software Synchronization

A transfer is software-triggered when the logical channel is set up and started by software. To specify a software-triggered transfer, set the channel DMA DMA4_CCRi[4:0] and DMA4_CCRi[20:19] bit fields to 0. The transfer starts as soon as the DMA DMA4_CCRi[7] bit is set (when it enters the scheduling process).

16.1.4.9.2 Hardware Synchronization

A transfer is hardware-synchronized if the logical channel activation is driven by hardware requests from the source or destination target. A hardware-synchronized transfer is specified by configuring the DMA request line number in the channel DMA4_CCRi register to a value that corresponds to the DMA request line from the source or destination that generates the DMA requests. The DMA request numbers to be configured are specified in the DMA request mapping (see Table 16-9).

Specify the DMA request number in the DMA4_CCRi[4:0] SYNCHRO_CONTROL and DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER bit fields. After the DMA4_CCRi[7] ENABLE bit is set, the logical channel becomes enabled but not activated (it does not enter the scheduling process), which means that channel registers are not updated until the first DMA request is received.

Note

The channel synchronization control registers are 1-based. For example, to enable the S_DMA_1 request, the DMA4_CCRi[4:0] SYNCHRO_CONTROL bit field must be set to 0x2 (DMA request number + 1).

Note

A DMA request line must not be shared between concurrently enabled DMA channels. However, a DMA request line can be shared among several chained logical channels.

For hardware synchronization, the amount of data to be transferred for each assertion of the DMA request line is configured through the frame synchronization (FS) and block synchronization (BS) bits in the logical channel DMA4_CCRi register and the DMA4_CCRi[5] FS and DMA4_CCRi[18] BS bits, respectively.

The amount of data can be any of the following:

- A single element transfer: A complete element defined by data type. For example, 8/16/32 bits are transferred in response to a DMA request.
- A full frame: A complete frame of several elements is transferred in response to a DMA request.
- A full block (a full channel transfer): A complete block of several frames is transferred in response to a DMA request.
- A full packet (a full channel transfer): A complete packet of several elements is transferred in response to a DMA request.

Packets allow the size of each part of the full DMA transfer to be configured independently of the organization of the data to be transferred (typically a number of elements). This can be useful when the source or destination has a buffer (such as a FIFO queue) with a size unrelated to the frame size of the transfer. The packet size then can be set to the size of the buffer.

Packet transfer must be used only where the source or destination is addressed in constant addressing mode, because FI registers are reused to specify the packet size.

To support the burst mode, the logical channel must also be configured in target-port packed access mode.

The packet size is configured based on the DMA4_CCRi[24] SEL_SRC_DST_SYNC bit through either the channel DMA4_CDFIi register (source synchronized) or the DMA4_CSFIi register (destination synchronized).

When the logical channel transfer block is not an exact multiple of the packet size, the final packet consists of the remaining elements in the transfer, using burst or single accesses to complete the block transfer.

The maximum transfer size, regardless of the packet size, is always as follows:

Block_size = Number_of_Frame_in_Block * Number_of_Element_in_Frame * Element_Size

- Synchronized at the source

The DMA module optimizes the transfer with respect to the number and size of burst transactions for the given source and destination addressing profiles and configured maximum burst sizes. When writing to the destination is slower than reading from the source, data is buffered in the channel FIFO queue. If the transfer is packet-synchronized at the source, the end-of-packet interrupt is disabled (see Section 16.1.4.13, *Reprogramming an Active Channel*).

For a source synchronized transfer, buffering can be enabled or disabled by setting the DMA4_CCRi[25] BUFFERING_DISABLE bit. For a packet source synchronization with buffering disabled and the packed/burst across the packet boundary, the last packed/burst write transaction is split in optimized smaller accesses to complete the packet transfer size. However, for a packet source synchronized transfer with buffering enabled and with the packed/burst across the packet boundary, the DMA module waits for the next DMA request(s) to read enough data to issue an atomic packed/burst write transaction (assuming that the address is packed/burst aligned).

Note

Buffering is not performed between frames, even if it is enabled. If the packed/burst is across the frame boundary, the last packed/burst write transaction is split in optimized smaller accesses to complete the frame transfer size.

- Synchronized at the destination

The performance of a hardware-synchronized transfer can be improved by using the prefetch mode, enabled through the channel DMA4_CCRi[23] PREFETCH bit. Data is prefetched on the read port side before the DMA request received and buffered in the FIFO queue. Up to a full transfer block can be prefetched, although this can be limited by the specified maximum channel FIFO queue depth (see Section 16.1.4.4, *FIFO Queue Memory Pool*).

Buffering disable is not allowed for a destination-synchronized transfer.

Note

Behavior is undefined when prefetch is enabled and a transfer is synchronized to the source.

Regardless of whether buffering is enabled, the last transaction in the frame or in the block is write nonposted (WNP) even if the write mode is specified as write last nonposted (WLNP; the DMA4_CSDPi[17:16] WRITE_MODE bit field = 0x2). However, in a packet synchronization mode, the last transaction of each packet in the transfer is WNP only if the buffering disable is on (even if the write mode is specified as WLNP).

Regardless of whether buffering is enabled, the packet interrupt is not generated in the packet source synchronized mode.

CAUTION

The DMA4_CCRi[25] BUFFERING_DISABLE bit must be filled with an allowed value, as specified in Table 16-13.

Table 16-13. Buffering Disable

	BUFFERING_DISABLE	
	(0: Buffering enable, 1: Buffering disable)	
Destination synchronized	0	Allowed
	1	Not allowed
Source synchronized	0	Allowed
	1	Allowed

- Synchronized transfer monitoring using CDAC (DMA4_CDACi):

Context is restored only when the channel becomes active on a DMA request (not at software enable). The channel is software-enabled first, and then a DMA request is asserted followed by the first context restore.

The CDAC register is writable; thus, the CDAC can be initialized to monitor the transfer and determine whether the transfer is started (for more information, see Section 16.1.5.4, *Synchronized Transfer Monitoring Using CDAC*).

Note

For 16-bit transactions, start reading from or writing to the LSByte first to enable the register update. This is not an issue for 32-bit read-write transactions.

16.1.4.10 Thread Budget Allocation

When several concurrent channels are latency critical and hardware synchronized, a specific latency cannot be ensured until the target is served. This situation occurs when the number of concurrent channels is greater than the number of available threads.

Note

Four threads are available on the read port, and two threads are available on the write port.

For a hardware-synchronized transfer (memory to peripheral), a minimum bandwidth for a latency-critical transfer must be ensured to avoid collisions between two hardware requests.

Because it is latency critical, the software user is responsible for the following:

- Programming the synchronized channel as a high-priority channel
- Reserving one or several threads for high-priority channels

The proposed implementation is as follows (see Section 16.1.5.5, *Concurrent Software and Hardware Synchronization*):

Prevent the regular channel queue from exceeding more than a programmable (3, 2, or 1) number of threads on the read port and no more than one thread on the write port. This number can be set in the global register DMA4_GCR[13:12] .

The thread reservation is programmable for maximum use of thread resources for concurrent, low-priority channel transfer. Programmability can also allow a partial throughput control by limiting in software the number of concurrent outstanding requests that break the pipelining.

Depending on the DMA4_GCR [13:12] value, the following threadID on the read/write ports are allocated for a high-priority channel:

Read port priority thread reservation:

- DMA4_GCR[13:12] = 0x0 => No ThreadID is reserved for high-priority channels.
- DMA4_GCR[13:12] = 0x1 => Read ThreadID 0 is reserved for high-priority channels.
- DMA4_GCR[13:12] = 0x2 => Read ThreadID 0 and Read ThreadID 1 are reserved for high-priority channels.
- DMA4_GCR[13:12] = 0x3 => Read ThreadID 0, Read ThreadID 1, and Read ThreadID 2 are reserved for high-priority channels.

Write port priority thread reservation:

- DMA4_GCR[13:12] = 0x0 => No ThreadID is reserved for high-priority channels
- DMA4_GCR[13:12] = 0x1 => Write ThreadID 0 is reserved for high-priority channels.
- DMA4_GCR[13:12] = 0x2 => Write ThreadID 0 is reserved for high-priority channels.
- DMA4_GCR[13:12] = 0x3 => Write ThreadID 0 is reserved for high-priority channels.

Regardless of whether the enabled channels are high priority, only the setting of the DMA4_GCR[13:12] value forces the thread reservation to these values. Set the appropriate value to avoid losing threads using only regular channels.

To have an independent read and write priority context, a per-channel bit (DMA4_CCRi[26]) is added for write priority, and the previous priority bit becomes read priority bit (DMA4_CCRi[6]).

Note

The device has one priority bit per logical channel, not one priority bit per port.

16.1.4.11 FIFO Budget Allocation

To avoid fully occupying the FIFO with a high-priority transfer while low-priority channels wait in the arbitration queue, two separate FIFO budgets are specified: one for high-priority channels and one for low-priority channels. This is defined in the DMA4_GCR register, allowing the user to share the FIFO budget between the low- and high-priority channels. The amount of the FIFO allocated by the low- and high-priority channels is fixed by the value set in the DMA4_GCR[15:14] HI_LO_FIFO_BUDGET field. The maximum channel FIFO depth is limited by the HI_LO_FIFO_BUDGET field as follows:

If the channel is low priority:

- When HI_LO_FIFO_BUDGET = 0x1, then low priority cannot exceed 75 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x2, then low priority cannot exceed 25 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x3, then low priority cannot exceed 50 percent of the total FIFO.

If channel is high priority

- When HI_LO_FIFO_BUDGET = 0x1, then high priority cannot exceed 25 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x2, then high priority cannot exceed 75 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x3, then high priority cannot exceed 50 percent of the total FIFO.

The user must perform the following equation:

- For a high-priority channel: (Per_Channel_Maximum FIFO Depth + 1) x Number of High Channel =< High Budget FIFO
- For a low-priority channel: (Per_Channel_Maximum FIFO Depth + 1) x Number of Low Channel =< Low Budget FIFO

Note

Ensure that *Number of High Channel* means *Number of Active High-Priority Channel* and that *Number of Low Channel* means *Number of Active Low-Priority Channel*.

16.1.4.12 Chained Logical Channel Transfers

Chaining multiple logical channels permits transfers consisting of multiple parts to be executed without repeated software intervention. This results in better performance than the alternative of software setting up and starting each transfer separately. Each part of a chained transfer can have the data addressed in a different manner that permits the programming of a variety of complex transfers. For example:

- Interlaced video data with one logical channel configured to transfer the even lines and another logical channel configured to transfer the odd lines
- Protocol headers with a separate DMA4 channel configured to transfer each field in the header

Channels can be chained through each channel DMA4_CLNK_CTRLi register. When the transfer for the first channel completes, the next channel in the chain is enabled. The number of channels in the chain that are configured for hardware-synchronized transfers is flexible (although typically it may be all, none, or simply the first one). The DMA request line number must be set to 0 to specify that any or all of the channels in a chain are software-triggered or nonsynchronized.

The last channel in a chain can be chained to the first channel to create a continuously looping chain. The continuously looping transfer can be stopped on the fly at a specific channel by disabling the

DMA4_CLNK_CTRLi[15] ENABLE_LNK bit. The looping transfer stops after the specified channel transfer is complete.

Note

A DMA request line must not be shared between concurrently enabled DMA channels. However, a DMA request line can be shared between several chained logical channels.

For more information about the programming model, see Section 16.1.5, *DMA_SYSTEM Basic Programming Model*.

16.1.4.13 Reprogramming an Active Channel

A currently active logical DMA channel can be disabled through the DMA4_CCRi[7] ENABLE bit. When an ongoing transaction is complete and the read-active and write-active bits in the DMA4_CCRi register (DMA4_CCRi[9] RD_ACTIVE and DMA4_CCRi[10] WR_ACTIVE) are reset, the channel can be reprogrammed for a new transfer.

16.1.4.14 Packet Synchronization

A packet transfer notion is related to the behavior of some peripherals, which have certain buffering capability and requires to transfer the buffer content once an element number threshold is reached (a hardware DMA request is generated). To associate a frame synchronization to each DMA request is possible, but this limits the maximum transfer size. Indeed the maximum transfer size is proportional to the FIFO depth of the peripheral:

maximum_transfer_size =peripheral_FIFO_depth x number_of_frame_in_block

The packet synchronization allows to dissociate the transfer size from the FIFO depth of the peripheral. Only Constant addressing mode is allowed on a read port or a write port if source target or destination target is packet synchronized respectively.

Example:

Consider a camera interface with a FIFO_depth of 128 words and a FIFO_element_number_threshold of 128, and a picture to transfer with a size 320 lines by 240 columns. If frame synchronization is associated with each DMA request then the maximum transfer size that can be performed is $128x2^{16}$ words. In this case, a frame is 128-word long, which does not fit the size of a line, and it is not possible to generate an interrupt at the end of line. However, by introducing the packet transfer notion, which is related to the peripheral FIFO behavior/structure, the maximum transfer size (maximum_transfer_size = 2^{24} x 2^{16} words) is independent of both peripheral_FIFO_depth and FIFO_element_number_threshold. This allows a long-enough transfer within one channel context and rotation operation on a large image format.

The main features of DMA Packet transfer are as follows:

- DMA Packet_Data_Size for each DMA Request: The Peripheral_element_number_threshold (the number of elements in a packet) shares the DMA4_CSFIi and DMA4_CDFIi configuration registers. If the peripheral is the source target, the addressing mode is constant, and the DMA4_CSFIi[15:0] bit field is used to specify the packet data size in the DMA4_CSFIi register. The user must set the DMA.SDMA4_CCRi[24] SEL_SRC_DST_SYNC bit to 1. If the peripheral is the destination target, the addressing mode is constant, the DMA4_CDFIi[15:0], is used to specify the packet data size (PKT_ELNT_NBR), and the bit field [31:16] is unused. To specify the packet data size in the DMA4_CDFIi register, the user must set the DMA4_CCRi[24] SEL_SRC_DST_SYNC bit to 0.

Note

The packet size can be a submultiple or non-submultiple of a frame size. If DMA Packet_Data_Size is aligned on the DMA channel block data size boundary, then DMA transfers the last data in the channel block boundary and stops at the block boundary for the last packet DMA Request. If the Packet_Data_size is not aligned on the block boundary, the remaining data smaller than a packet size are transferred using burst or single accesses to complete the block.

- DMA Packet_Data_Transfer does not affect DMA channel capabilities in term of packing and bursting.

  The packet synchronization mode is active when DMA4_CCRi[5] FS = DMA4_CCRi[18] BS = 1. Then:
  - If DMA4_CCRi[24] SEL_SRC_DST_SYNC = 0, the DMA4_CDFIi[15:0] bit field gives the number of elements in the packet and the DMA4_CDFIi[31:16] bit field is unused for the packet size.
  - If DMA4_CCRi[24] SEL_SRC_DST_SYNC = 1, the DMA4_CSFIi[15:0] bit field gives the number of elements in the packet and the DMA4_CSFIi[31:16] bit field is unused for the packet size.

Note

The maximum transfer size, regardless of the packet size, is always:

Block_size = Number_of_Frame_in_Block x Number_of_Element_in_Frame x Element_Size.

If DMA channel packet/burst access is across the packet boundary, the DMA hardware automatically splits this packing/burst access into multiple smaller accesses that are aligned on the packet boundary. Otherwise, the DMA transfers data as a usual packing/burst access.

16.1.4.15 Graphics Acceleration Support

The DMA_SYSTEM supports two graphic acceleration features: transparent copy and constant fill.

Only one of these features can be enabled at a time through the DMA4_CCRi register for the particular logical DMA channel.

The transparent copy feature enables specification of a particular color through the DMA4_COLORi register so that when it is recognized in the data from the source, it is not copied to the corresponding location in the destination but instead leaves the data in the corresponding location in the destination as it is.

Figure 16-11 shows the 2-D graphic transparent color block diagram.

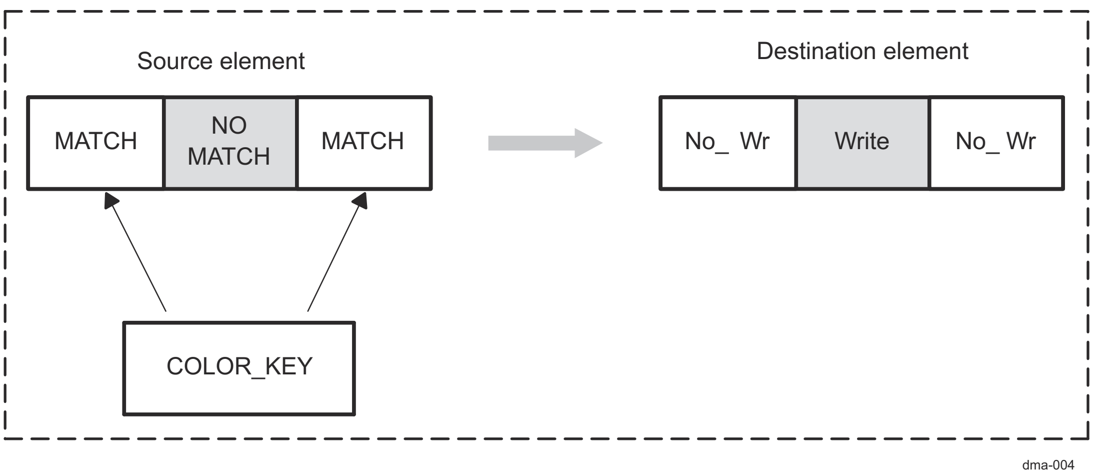

Figure 16-11. 2-D Graphic Transparent Color Block Diagram

The constant fill feature provides the ability to specify a particular color through the DMA4_COLORi register for every specified location in the destination. In this case, the transfer consists only of writing to the destination without reading from a source.

Both features support 8, 16, and 24 bpp, depending on what is specified as the DMA transfer ES through the DMA4_CSDPi register. An ES of 32 bits corresponds to 24 bpp. During a 32-bit (24 bpp) transfer, the 8 most-significant bits (MSBs) ([31:24]) are 0. Both features are compatible with packed and burst transactions.

16.1.4.16 Supervisor Modes

A logical DMA channel can be configured to operate in supervisor mode through the DMA4_CCRi[22] SUPERVISOR bit. This must be done using supervisor access. Once a channel is configured in supervisor mode, the channel configuration is protected from nonsupervisor accesses. All DMA transactions on a supervisor channel are supervisor transactions.

16.1.4.17 Posted and Nonposted Writes

A logical channel can be configured in its DMA4_CSDPi[17:16] bits to use one of three write access handshake modes for the destination:

- Nonposted write: Each write must complete before transfer can continue or complete.
- Posted write: Transfer continues without waiting for each write to complete (may improve performance with slow devices).
- Posted with final write nonposted: Transfer continues without waiting for each write to complete, but final write completes before transfer can complete.

16.1.4.18 Disabling a Channel During Transfer

When a channel is disabled during a transfer, the channel undergoes an abort, unless it is hardware-source-synchronized with buffering enabled (DMA4_CCRi[25] BUFFERING_DISABLE = 0). If this is the case, the FIFO is drained to prevent the loss of data. For more information about this feature, see Section 16.1.4.19, *FIFO Draining Mechanism*.

16.1.4.19 FIFO Draining Mechanism

When a source-synchronized channel is disabled during a transfer, the current hardware request (element/packet/frame/block) service completes and the channel DMA4_CCRi[9] RD_ACTIVE bit is set to 0, which means the channel is not active on the read port. The remaining data in the corresponding disabled channel FIFO is drained onto the write port and transferred to the programmed destination as in normal transfer.

At the end of the draining the DMA4_CCRi[10] WR_ACTIVE bit is set to 0 (channel is no longer active on the write port) and if the DMA4_CICRi[12] DRAIN_END_IE is set to 1, the DMA4_CSRi[12] DRAIN_END status bit is updated and an interrupt is generated.

Once a channel is disabled during a transfer, it must wait for the DMA4_CCRi[9] RD_ACTIVE and DMA4_CCRi[10] WR_ACTIVE bits to become 0 before being reenabled for a new transfer. The FIFO drain for a channel occurs only in the following cases:

- If the channel is a source synchronized channel and DMA4_CCRi[25] BUFFERING_DISABLE = 0
  and
- If the channel is not a solid fill channel
  and
- If the channel is not a transparent and copy channel
  and
- If the channel is a hardware, synchronized channel

Note

For a self-linked or chain-linked channel, the user must disable the DMA4_CLNK_CTRLi[15] ENABLE_LINK bit before disabling the channel.

In all other cases, the channel undergoes an abort.

16.1.4.20 Linked List

16.1.4.20.1 Overview

The DMA_SYSTEM supports the logical transfer-descriptor loader feature. A transfer descriptor represents a set of values that maps to a set of logical channel configuration registers.

A logical channel transfer descriptor can be loaded by DMA from memories, and then successive transfer descriptors can be autonomously loaded based on a linked-list scheme. This enables DMA4 scatter-gather transfers with minimum MPU support by removing successive channel configuration processing and associated interrupt handling overheads. It also optimizes DMA4 channel resources by enabling efficient transfer serialization on a single logical channel versus concurrent (multiple) logical channel use.

Different types of transfer descriptors are supported (full or partial logical channel configuration registers are set). This optimizes the memory size required for storing a long linked list, because parameter changes are limited to only a few logical channel configuration registers.

16.1.4.20.2 Link-List Transfer Profile

A linked-list transfer can be seen as a super-block transfer (where the block is composed of FN frames and each frame includes EN elements). The block size (FN x EN x ES) can be changed in the linked list by loading an updated transfer descriptor.

The end of the super block is signaled in the last descriptor associated with the last block. Generally, for a given link-list transfer, the logical channel is set at the beginning of the transfer and the logical channel configurations for the subsequent blocks are slightly changed. Thus, the descriptor can be limited to an update of only few parameters, such as FN or EN. This assumes that the content of unmodified registers is preserved when a new descriptor is loaded.

A transfer descriptor is composed of a set of channel configuration register values with the addition of the next-descriptor pointer register (DMA4_CNDPi) and a channel-descriptor parameter register (DMA4_CDPi). The next-descriptor pointer is the 32-bit address pointer from where the next transfer descriptor is to be loaded. The next-descriptor pointer is mapped depending on the descriptor type (1, 2, or 3).

16.1.4.20.3 Descriptors

A transfer descriptor is a set of values that maps to a set of logical channel configuration registers. The descriptor contains the parameters associated with a transfer profile (transfer size, source or destination addresses, etc). Four different types of transfer descriptors are supported to optimize the memory size required to store a long linked list and to minimize MPU use to create and maintain the descriptor list.

A transfer descriptor is a list of 32-bit values. A descriptor must be 32-bit aligned in memory. Only the 30 least-significant bits (LSBs) of the next-descriptor address pointer are updated from the descriptor, and the DMA4 forces the 2 LSBs to 0 on generation of the pointer address. The descriptor size is variable, depending on the descriptor type and the Nxt_Dv and Nxt_Sv bit fields.

Transfer descriptor bit mapping is the same as DMA4 logical-channel configuration register bit mapping, with the following exceptions:

- Src_Element_index and Dst_Element_index are concatenated in the same 32-bit location.
- DMA4_CICRi (interrupt event mask)
- CFN (frame number)
- Bit fields:
  – P: Corresponds to the PAUSE_LINK_LIST bit:
    - When set to 1 in the descriptor, the channel is suspended when the descriptor load completes.
    - The user must not set the PAUSE_LINK_LIST bit through the configuration port. Otherwise, behavior is undefined.
    - When set to 0 (through the configuration port) after pause, the linked-list channel resumes its transfer (descriptor load or data load).
  – B: Corresponds to the end-of-block enable bit (BLOCK_IE) of the DMA4_CICRi register; valid only for type 3. This value is don't care for descriptor types 1 and 2, where DMA4_CICRi is fully specified.
  – Nxt_Dv, Nxt_Sv: Mapped in the DMA4_CDPi register. They indicate one of the following possibilities:
    - Next descriptor contains an updated destination or source address.
    - Next descriptor does not update the source or destination address, but increments the last source or destination address (from the end of the last transfer).
    - The next source address and/or destination address are the last valid ones in the configuration memory. This means that the corresponding location in the configuration memory is not updated (assuming that they were initialized at least once in the past). This is also called wrapping addressing.

– Next_Descriptor_Type: Specifies the next descriptor type that corresponds to the NEXT_DESCRIPTOR_TYPE bit field in the DMA4_CDPi register

16.1.4.20.3.1 Type 1

A type 1 descriptor includes the overall channel configuration register value to be loaded (global registers are not part of the type 1 descriptor). This descriptor is used primarily when major changes are required:

- Channel read or write access profiles must be modified; for example, bursting and packing (included in the DMA4_CSDPi register)
- Attach a new DMA request to the same channel or change the priority or access privilege (included in the DMA4_CCRi register)
- Enable solid or transparent color fill (included in the DMA4_CCRi and DMA4_COLORi registers)
- Enable a channel link (included in the DMA4_CLNK_CTRLi register)

Table 16-14 shows a type 1 descriptor.

16.1.4.20.3.2 Type 2

A type 2 descriptor includes the overall logical channel transfer address register and transfer format register to be loaded. This descriptor enables 2D addressing linked-list transfer (for example, a multimedia application where 2D objects are moved in a link). Table 16-15 shows a type 2 descriptor with source and destination address updates. Table 16-16 shows a type 2 descriptor with one source or destination address update.

16.1.4.20.3.3 Type 3

A type 3 descriptor is limited to a few logical channel transfer address registers and transfer format registers to be loaded. This descriptor enables simple 1D addressing link transfer (for example, scatter-gather or ping-pong memory movement using a linked list). Table 16-17 shows a type 3 descriptor with source and destination address updates. Table 16-18 shows a type 3 descriptor with one source or address destination update.

16.1.4.20.4 Linked-List Control and Monitoring

16.1.4.20.4.1 Transfer Mode Setting

Four descriptor types are available in DMA4_CDPi[9:8] TRANSFER_MODE to distinguish the different transfer modes:

- DMA4_CDPi[9:8] TRANSFER_MODE = 00: The current channel is using normal mode.
- DMA4_CDPi[9:8] TRANSFER_MODE = 01: The current channel is using link-list channel mode for a type 1, 2, or 3 descriptor.

The reset value is normal mode (DMA4_CDPi[9:8] TRANSFER_MODE = 0).

16.1.4.20.4.2 Starting a Linked List

Like a nonlinked-list transfer, a link transfer starts under host control by enabling the associated logical channel (set the DMA4_CCRi[7] ENABLE bit to 1). The DMA4_CDPi[10] FAST bit sets the start mode of the link-list transfer:

In nonfast-start mode, the logical channel configuration is fully initialized so that the transfer can start without descriptor loading.

In fast-start mode, the descriptor pointer and other inputs are given. The channel starts by loading the descriptor and then starts the data transfer phase.

16.1.4.20.4.3 Monitoring a Linked-List Progression

In addition to the DMA4_CCENi (remaining elements) and DMA4_CCFNi (remaining frames) registers that are used to monitor the transfer progress, a per-channel register, DMA4_CCDNi (channel current active descriptor number), monitors which descriptor in the list is active. The user must initialize the DMA4_CCDNi register to 0 during the initial configuration. When the DMA4_CCDNi register is updated, the DMA4_CCFNi and the DMA4_CCENi registers are updated. The user must also initialize the DMA4_CCFNi and DMA4_CCENi registers to 0xFFFF and to 0xFFFFFF, respectively, to track the effective transfer start of synchronized transfer.

16.1.4.20.4.4 Interrupt During Linked-List Execution

Any logical channel source of interrupt can be triggered during a linked-list execution, if the interrupt source is enabled during the initial configuration in CICR. The DMA4_CICRi register can also be updated during the linked-list execution if descriptor types 1 and 2 are used.

The use of an interrupt event in a link execution can be difficult, because the link can progress in parallel with interrupt service routine (ISR) execution. This makes it difficult to synchronize them unless system assumptions are used. The most appropriate synchronization model is to get an interrupt-only on linked-list completion, when the last transfer block is complete. This prevents the interrupt from occurring during the link execution. An end-of-super-block interrupt event available in the DMA4_CICRi and DMA4_CSRi registers can be enabled at initial configuration or when using descriptor types 1 and 2. To prevent the use of descriptor type 1 or 2 to update BLOCK_IE (full DMA4_CICRi update), a dedicated BLOCK_IE bit field is also available in a type 3 descriptor.

16.1.4.20.4.5 Pause a Linked List

When the channel is suspended, it remains enabled.

The pause behaves differently, depending on the transfer mode:

- Normal transfer mode: If the user sets the DMA4_CDPi[7] PAUSE_LINK_LIST bit to 1, the channel completes the current read and write transactions and then suspends the channel. The channel can be resumed by setting the channel DMA4_CDPi[7] PAUSE_LINK_LIST bit to 0.
- Linked-list type 1, 2, or 3 mode: The user must not set the DMA4_CDPi[7] PAUSE_LINK_LIST bit through the configuration port; otherwise, transfer behavior is undefined.

A PAUSE_LINK_LIST bit (P) is set to 1 in the descriptor.
  – The channel is suspended after the descriptor load, translation, and configuration memory update are complete.
  – The linked list can be resumed by resetting the DMA4_CDPi[7] PAUSE_LINK_LIST bit (through the configuration port).

16.1.4.20.4.6 Stop a Linked List (Abort or Drain)

The channel can be stopped for a drain or an abort. These cases are exclusive.

16.1.4.20.4.6.1 Drain

- Drain conditions:

  A channel is a drain candidate if it is a hardware-source-synchronized transfer with DMA4_CCRi[25] BUFFERING_DISABLE = 0 and should not be doing any of the graphics operation (transparent copy or solid-color fill).
- Drain trigger:

  A drain candidate channel is drained if it is disabled (DMA4_CCRi[7] ENABLE = 0) or if it receives a transaction error on the read port.
- Drain behavior with a type 1, 2, or 3 descriptor. Drain trigger can occur in two situations:
  – During descriptor loading: Any ongoing current transaction is complete and the channel is aborted.
  – During data loading: The read is completed at the boundary of the request (element/frame/packet/block boundary), the FIFO is drained to the destination, and then a DRAIN_END interrupt can be asserted.

16.1.4.20.4.6.2 Abort

- Abort condition:

  A channel is an abort candidate if it is software-synchronized, hardware-destination-synchronized, solid color-fill, transparent-color fill, or hardware-source-synchronized with DMA4_CCRi[25] BUFFERING_DISABLE = 1.
- Abort trigger:

  A channel is an abort candidate if it is disabled (DMA4_CCRi[7] ENABLE = 0), if it receives a transaction error on the read or write port, or if there is a MISALIGNMENT_ERROR.
- Abort behavior with a type 1, 2, or 3 descriptor:

  If an abort trigger occurs, the channel aborts immediately after completion of current read/write transactions and then the FIFO is cleaned up.

  In type 1, 2, or 3, if an abort trigger or drain trigger occurs during the descriptor load phase, the channel aborts.

16.1.4.20.4.7 Status Bit Behavior

This section describes the behavior of the DMA4_CSRi[6] SYNC, DMA4_CCRi[9] RD_ACTIVE and DMA4_CCRi[10] WR_ACTIVE status bits:

- For a hardware-synchronized channel in linked-list mode, the DMA4_CSRi[6] SYNC bit becomes active (DMA4_CSRi[6] SYNC = 1) when the first data load transaction is scheduled and remains active until the last data load transaction in the block (not super block) is descheduled (DMA4_CSRi[6] SYNC = 0). The SYNC bit is not active during the descriptor load phase.
- The DMA4_CCRi[9] RD_ACTIVE bit is active during the data load phase and the descriptor load phase. It becomes active when the first read transaction is scheduled. It becomes inactive:
  – When (during the descriptor load phase) the last descriptor write request is descheduled
  – When (during the data load phase) the last read transaction in the block (not super block) is descheduled for software-synchronized transfer or destination-synchronized transfer with prefetch enabled
  – When (during the data load phase) the last read transaction in the request (element/frame/packet/block sync) is descheduled for hardware-source-synchronized transfer or hardware-destination-synchronized transfer without prefetch

- The DMA4_CCRi[10] WR_ACTIVE bit is active only during the data load phase. It becomes active when the first write transaction is scheduled and becomes inactive:
  - Until the last write transaction in the block (not super block) is descheduled and the FIFO is cleaned up for software-synchronized transfer
  - Until the last write transaction in the request (element/frame/packet/block sync) is descheduled and the FIFO is cleaned up for hardware-source-synchronized transfer (with DMA4_CCRi[25] BUFFERING_DISABLE = 0) or hardware-destination-synchronized transfer.

16.1.4.20.4.8 Linked-List Channel Linking

Channel linking for inter- and intra-super blocks is supported for type 1, 2, and 3 descriptors.

Assume that CHx and CHz are linked-list channels using generic descriptors. If CHx is composed of N descriptors and CHz is composed of M descriptors, then in nonfast mode:

CHx: CHx[Data1]-> CHx[DES1] -> . -> CHx[DESN]->CHx[DataN + 1]

CHz: CHz[Data1]-> CHz[DES1] -> . -> CHz[DESM]->CHz[DataM + 1]

It is possible to link CHx to CHz or CHx to itself after the completion of the CHx transfer (end of super block). To do this, the user must set the DMA4_CLNK_CTRLi[15] ENABLE_LNK bit to 1 and the DMA4_CLNK_CTRLi[4:0] NEXTLCH_ID bit to z (or to x for self linking) through the last descriptor using a type 1 descriptor. The sequence is:

CHx: CHx[Data1]-> CHx[DES1] -> . -> CHx[DESN]-CHx[DataN+1] -> CHz: CHz[Data1]-> CHz[DES1] -> . -> CHz[DESM]->CHz[DataM+1]

It is also possible to link CHx to CHz during the CHx transfer and before the end of super block. The user must set the DMA4_CLNK_CTRLi[15] ENABLE_LNK bit to 1 and the DMA4_CLNK_CTRLi[4:0] NEXTLCH_ID bit to z through descriptor p (CHx[DESp]) using a type 1 descriptor. The sequence is:

CHx: CHx[Data1]-> CHx[DES1] ->.-> CHx[DESp]->CHx[Data(p + 1)] -> CHz[Data1]-> CHz[DES1] -> .

The user must continue the linking until channels CHx and CHz complete their super-block transfers; otherwise, the channels remain enabled.

Note

In channel linking, the head of a chain can be in fast mode or nonfast mode. All channels that are not in the head of the chain can be in nonfast mode only. In self-linking, the channel cannot be in fast mode.

Note

If channel CHx links to CHz in the middle of the superblock transfer (remember link bit can be set through Type-1 descriptor load), CHx is disabled after the corresponding data load and enables the channel CHz.

16.1.5 DMA_SYSTEM Basic Programming Model

16.1.5.1 Setup Configuration

After a hardware reset, program all fields in the logical channel registers to default values for any channels used, because most fields are undefined following reset.

Before programming any DMA transfers, the priority arbitration rate and the maximum FIFO depth must be configured through the DMA4_GCR register, and any required interrupts must be enabled through the DMA4_IRQENABLE_Lj registers and the logical channel DMA4_CICRi registers.

Software clears the DMA4_CSRi register and the IRQSTATUS bit for the different interrupt lines before enabling the channel.

16.1.5.2 Software-Triggered (Nonsynchronized) Transfer

To program a software-triggered DMA transfer:

1. Configure the transfer parameters in the logical DMA channel registers:
   - DMA4_CSDPi:
     - Transfer ES (8, 16, or 32 bits) in the DMA DMA4_CSDPi[1:0] bit field.
     - Read and write port access types (single/burst), DMA DMA4_CSDPi[8:7] and DMA4_CSDPi[15:14] bit fields
     - Source and destination endianism, DMA DMA4_CSDPi[21] and DMA4_CSDPi[19] bits
     - Write mode (posted or nonposted) and DMA DMA4_CSDPi[17:16] bit field
     - Source or destination packed or nonpacked (if the ES is less than the read/write port size), DMA DMA4_CSDPi[6] and DMA4_CSDPi[13] bits
   - DMA4_CENi: EN
   - DMA4_CFNi: FN per transfer block
   - DMA4_CSSAi and DMA4_CDSAi: Source and destination start address (aligned with transfer ES)
   - DMA4_CCRi:
     - Read and write port addressing modes, DMA DMA4_CCRi[13:12] and DMA4_CCRi[15:14] bit field
     - Priority bit for both read and write ports, DMA DMA4_CCRi[6] and DMA4_CCRi[26] bits
     - DMA request number (set to 0 for a software-triggered transfer) and DMA register bit fields DMA4_CCRi[4:0] = 0 and DMA4_CCRi[20:19] = 0
   - DMA4_CSEIi, DMA4_CSFIi, DMA4_CDEIi, and DMA4_CDFIi: Source and destination element and frame indexes (depending on addressing mode)
2. Start the transfer through the enable bit in the channel DMA4_CCRi register and DMA DMA4_CCRi[7] bit

The following example performs a DMA transfer on channel 10 of a 240*160 picture from RAM to RAM (0x80C00000 to 0x80F00000):

```
UWORD32 RegVal = 0;
DMA4_t *DMA4;
DMA4 = (DMA4_t
      *)malloc(sizeof(DMA4_t));
/* Init. parameters
      */
DMA4->DataType = 0x2; //
      DMA4_CSDPi[1:0]
DMA4->ReadPortAccessType = 0; //
      DMA4_CSDPi[8:7]
DMA4->WritePortAccessType = 0; //
      DMA4_CSDPi[15:14]
DMA4->SourceEndiansim = 0; //
      DMA4_CSDPi[21]
DMA4->DestinationEndianism = 0; //
      DMA4_CSDPi[19]
DMA4->WriteMode = 0; //
      DMA4_CSDPi[17:16]
DMA4->SourcePacked = 0; //
      DMA4_CSDPi[6]
DMA4->DestinationPacked = 0; //
      DMA4_CSDPi[13]
```

```
DMA4->NumberOfElementPerFrame = 240; //
      DMA4_CENi
DMA4->NumberOfFramePerTransferBlock = 160; //
      DMA4_CFNi
DMA4->SourceStartAddress = 0x80C00000; //
      DMA4_CSSAi
DMA4->DestinationStartAddress = 0x80F00000; //
      DMA4_CDSAi
DMA4->SourceElementIndex = 1; //
      DMA4_CSEIi
DMA4->SourceFrameIndex = 1; //
      DMA4_CSFIi
DMA4->DestinationElementIndex = 1; //
      DMA4_CDEIi
DMA4->DestinationFrameIndex = 1; //
      DMA4_CDFIi
DMA4->ReadPortAccessMode = 1; //
      DMA4_CCRi[13:12]
DMA4->WritePortAccessMode = 1; //
      DMA4_CCRi[15:14]
DMA4->ReadPriority = 0; //
      DMA4_CCRi[6]
DMA4->WritePriority = 0; //
      DMA4_CCRi[23]
DMA4->ReadRequestNumber = 0; //
      DMA4_CCRi[4:0]
DMA4->WriteRequestNumber = 0; //
      DMA4_CCRi[20:19]
/* 1) Configure the transfer
      parameters in the logical DMA registers
      */
/*-------------------------------------------------------------------*/
/*
      a) Set the data type CSDP[1:0], the Read/Write Port access type

      Set the source frame index CSFI[15:0]*/
DMA4_CSFI_CH10 =
      DMA4->SourceFrameIndex ;
/* h)- Set the destination element
      index CDEI[15:0]*/
DMA4_CDEI_CH10 =
      DMA4->DestinationElementIndex;
/* i)- Set the destination
      frame index CDFI[31:0]*/
DMA4_CDFI_CH10 =
      DMA4->DestinationFrameIndex;
/* 2) Start the DMA transfer by
      Setting the enable bit CCR[7]=1 */

/*---------------------------------------------------------------*/

//write enable bit
DMA4_CCR_CH10 |= 1 << 7; /* start */
```

16.1.5.3 Hardware-Synchronized Transfer

To monitor a hardware synchronized DMA transfer, initialize the DMA4_CDACi register before the software enable.

To configure an LCh to synchronize by element, packet, frame, or block, the frame synchronization DMA4_CCRi[5] FS bit and the block synchronization DMA4_CCRi[18] BS bit must be programmed. For all the following synchronized transfers (element, packet, and frame or block-synchronized transfers), the user must first set the DMA4_CCRi[24] SEL_SRC_DST_SYNC bit to 1 when the source triggers on the DMA request and set it the DMA4_CCRi[24] SEL_SRC_DST_SYNC bit to 0 when the destination triggers on the DMA request.

Note

The user must take care when setting the DMA4_CCRi[23] PREFETCH bit it is in conjunction with DMA4_CCRi[24] SEL_SRC_DST_SYNC bit.

- To configure an LCh to transfer one element per DMA request:
  1. Set the number of DMA request associated with the current LCH in the DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER and DMA4_CCRi[4:0] SYNCHRO bit field.
  2. Set the data type, also referenced as element size (ES), in the DMA4_CSDPi[1:0] DATA_TYPE bit field.
  3. Set the Read Port access type (single or burst access) in the DMA4_CSDPi[8:7] SRC_BURST_EN bit field.
  4. Set the Write Port access type (single or burst access) in the DMA4_CSDPi[15:14] DST_BURST_EN bit field.
  5. Set the Read Port addressing mode in the DMA4_CCRi[13:12] SRC_AMODE bit field.

6. Set the Write Port addressing mode in the DMA4_CCRi[15:14] DST_AMODE bit field.
7. Set the Read start address in the DMA4_CSSAi[31:0] SRC_START_ADRS bit field.
8. Set the Write start address in the DMA4_CDSAi[31:0] DST_START_ADRS bit field.
9. Set both FS and BS to 0 in DMA4_CCRi[5] FS and DMA4_CCRi[18] BS.
10. Set to 1 the channel enable bit DMA4_CCRi[7] EN.

- To configure an LCh to transfer one frame per DMA request:
  1. Set the number of DMA request associated to the current LCH in the DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER and DMA4_CCRi[4:0] SYNCHRO bit field.
  2. Set the data type, also referenced as element size (ES), in the DMA4_CSDPi[1:0] DATA_TYPE bit field.
  3. Set the number of element per frame in the DMA4_CENi[23:0] CHANNEL_ELMNT_NBR bit field.
  4. Set the Read Port access type (single or burst access) in the DMA4_CSDPi[8:7] SRC_BURST_EN bit field.
  5. Set the Write Port access type (single or burst access) in the DMA4_CSDPi[15:14] DST_BURST_EN bit field.
  6. Set the Read Port addressing mode in the DMA4_CCRi[13:12] SRC_AMODE bit field.
  7. Set the Write Port addressing mode in the DMA4_CCRi[15:14] DST_AMODE bit field.
  8. Set the Read start address in the DMA4_CSSAi[31:0] SRC_START_ADRS bit field.
  9. Set the Write start address in the DMA4_CDSAi[31:0] DST_START_ADRS bit field.
  10. Set FS to 1 and BS to 0, respectively, in DMA4_CCRi[5] FS and DMA4_CCRi[18] BS.
  11. Set to 1 the channel enable bit DMA4_CCRi[7] EN.
- To configure an LCh to transfer one block per DMA request:
  1. Set the number of DMA request associated to the current LCH in the DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER and DMA4_CCRi[4:0] SYNCHRO bit field.
  2. Set the data type, also referenced as element size (ES), in the DMA4_CSDPi[1:0] DATA_TYPE bit field.
  3. Set the number of element per frame in the DMA4_CENi[23:0] CHANNEL_ELMNT_NBR bit field.
  4. Set in the DMA4_CFNi[15:0] CHANNEL_FRAME_NBR bit field the number of frame (transfers), to take place before the LCH gets disabled.
  5. Set the Read Port access type (single or burst access) in the DMA4_CSDPi[8:7] SRC_BURST_EN bit field.
  6. Set the Write Port access type (single or burst access) in the DMA4_CSDPi[15:14] DST_BURST_EN bit field.
  7. Set the Read Port addressing mode in the DMA4_CCRi[13:12] SRC_AMODE bit field.
  8. Set the Write Port addressing mode in the DMA4_CCRi[15:14] DST_AMODE bit field.
  9. Set the Read start address in the DMA4_CSSAi[31:0] SRC_START_ADRS bit field.
  10. Set the Write start address in the DMA4_CDSAi[31:0] DST_START_ADRS bit field.
  11. Set FS to 0 and BS to 1, respectively, in DMA4_CCRi[5] FS and DMA4_CCRi[18] BS.
  12. Set to 1 the channel enable bit DMA4_CCRi[7] EN.
- To configure an LCh to transfer one packet per DMA request:
  1. Set the number of DMA request associated to the current LCH in the DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER and DMA4_CCRi[4:0] SYNCHRO bit field.
  2. Set the data type, also referenced as element size (ES), in the DMA4_CSDPi[1:0] DATA_TYPE bit field.
  3. Set the number of elements per packet to transfer: If the packet requestor is in the source, set DMA4_CCRi [24] SEL_SRC_DST_SYNC to 1 and set the packet element number in the DMA4_CSFIi register and set the addressing mode of source to constant addressing in DMA4_CCRi[13:12] SRC_AMODE bit field; else, if the packet requestor is in the destination, set the DMA4_CCRi[24] SEL_SRC_DST_SYNC to 0 and set the packet element number in the DMA4_CDFIi register and set the addressing mode of destination to constant addressing in DMA4_CCRi[15:14] DST_AMODE bit field.
  4. Set the number of elements per frame in the DMA4_CENi[23:0] CHANNEL_ELMNT_NBR bit field.
  5. Set in the DMA4_CFNi[15:0] CHANNEL_FRAME_NBR bit field the number of frames (transfers), to take place before the LCH gets disabled.
  6. Set the element number in the packet in the DMA4_CSFIi[15:0] PKT_ELNT_NBR, if constant addressing or post-incremented addressing modes are used in the source side. However, the number of element in the packet is set in the DMA4_CDFIi[15:0] PKT_ELNT_NBR if constant addressing mode is used in the destination side.

7. Set the Read Port access type (single or burst access) in the DMA4_CSDPi[8:7] SRC_BURST_EN bit field.
8. Set the Write Port access type (single or burst access) in the DMA4_CSDPi[15:14] DST_BURST_EN bit field.
9. Set the Read Port addressing mode in the DMA4_CCRi[13:12] SRC_AMODE bit field.
10. Set the Write Port addressing mode in the DMA4_CCRi[15:14] DST_AMODE bit field.
11. Set the Read start address in the DMA4_CSSAi[31:0] SRC_START_ADRS bit field.
12. Set the Write start address in the DMA4_CDSAi[31:0] DST_START_ADRS bit field.
13. Set FS to 1 and BS to 1, respectively, in DMA4_CCRi[5] FS and DMA4_CCRi[18] BS.
14. Set to 1 the channel enable bit DMA4_CCRi[7] EN.

Note

It is possible to stop a transfer by disabling the channel by resetting the DMA4_CCRi[7] ENABLE bit.

16.1.5.4 Synchronized Transfer Monitoring Using CDAC

The DMA4_CDACi register is writable and non-initialized (value undefined). It can be initialized to monitor a transfer by applying the following programming model:

1. Write 0 in the DMA4_CDACi register.
2. Enable the channel.
3. If a time-out occurs, read DMA4_CDACi register.
4. If DMA4_CDACi != 0 (it is the value configured in DMA4_CDACi):

   This indicates that the corresponding transfer has started. The user can then rely on DMA4_CCENi and DMA4_CCFNi element and frame counters.

   Otherwise, if DMA4_CDACi = 0 (it is the value configured in the DMA4_CDACi):

   This indicates that the corresponding transfer did not start.

16.1.5.5 Concurrent Software and Hardware Synchronization

This section describes thread allocation only; it does not describe the entire transfer. Because synchronized transfers are latency critical, you must allocate a thread at least on the synchronized target side.

Even for multiple concurrent channels, thread reservation ensures that when a hardware DMA request arrives, the read/write scheduler finds available thread(s) to initiate a channel schedule and issue a read/write transaction.

Consider six concurrent channels:

- Channels 0, 1, 2, and 3 are dedicated to memory-memory transfer; they are software triggered and not synchronized.
- Channel 4 is dedicated to memory-peripheral transfer, hardware triggered, and synchronized on the write side.
- Channel 5 is dedicated to peripheral-memory transfer, hardware triggered, and synchronized on the read side.

To perform thread reservation:

1. Allow thread reservation for priority channel 4 and channel 5:

   Reserve one thread (Read ThreadID 0) on the read port and one thread (Write ThreadID 0) on the write port: set the DMA4_GCR[13:12] HI_THREAD_RESERVED bit field to 0x1.
2. Specify channel priority:

   Channel 4 is a write high priority channel: set DMA4_CCRi[26] WRITE_PRIORITY = 1.

   Channel 5 is a read high priority channel: set DMA4_CCRi[6] READ_PRIORITY = 1.

16.1.5.6 Chained Transfer

A chained DMA transfer can be programmed as follows:

1. Configure the transfer parameters for each logical DMA channel in the chain as in step 1 for either the synchronized or non-synchronized transfers described in Section 16.1.5.5, *Concurrent Software and Hardware Synchronization*.
2. For each channel in the chain, configure the DMA4_CLNK_CTRLi register as follows:
   - Next logical DMA channel number (for a looping chained transfer link last channel to first channel number), in the DMA4_CLNK_CTRLi[4:0] NEXTLCH_ID bit field.
   - Include the logical channel to the chain and enable link by setting the DMA4_CLNK_CTRLi[15] ENABLE_LNK bit.
   - For a non-looping chain, the last logical channel in the chain must have the DMA4_CLNK_CTRLi[15] ENABLE_LNK bit set to 0 to indicate the end of the chain.
3. Enable the transfer through the enable bit in the first logical channel DMA4_CCRi[7] ENABLE bit. All other channels in the chain must be disabled. Each channel is enabled automatically in turn when the previous logical channel transfer completes. A non-synchronized transfer starts immediately; a hardware-synchronized transfer starts when the DMA request line corresponding to the first DMA channel in the chain is asserted.

To stop a looping chained transfer, disable the DMA4_CLNK_CTRLi[15] ENABLE_LNK bit (by setting it to 0x0), of the final channel transfer.

In the RAM-to-RAM copy example, to copy in loop, it is possible to link channel 10 on itself. The following line can be added in the channel configuration:

```
/* g) Set link for loop */
DMA4_CLINK_CTRL_CH10 =
      0x0000800A;
```

16.1.5.7 90-Degree Clockwise Image Rotation

The 90-degree clockwise image rotation example described in Section 16.1.4.5, *Addressing Modes*, can be programmed as follows:

1. Configure the transfer parameters in the logical DMA channel registers:
   - DMA4_CSDPi:
     – Transfer ES = 32-bit (32 bpp), DMA4_CSDPi[1:0] DATA_TYPE bit field
     – Read and write port access types = maximum burst size supported by memory device, DMA4_CSDPi[8:7] SRC_BURST_EN and DMA4_CSDPi[15:14] DST_BURST_EN bit fields
     – Source and destination endianism, DMA4_CSDPi[21] SRC_ENDIAN and DMA4_CSDPi[19] DST_ENDIAN bits
     – Write mode = posted with last element nonposted, DMA4_CSDPi[17:16] WRITE_MODE bit field
     – Source and destination packed = Yes (although destination writes do not benefit because EI1), DMA4_CSDPi[6] SRC_PACKED and DMA4_CSDPi[13] DST_PACKED bits
   - DMA4_CENi: EN = 240
   - DMA4_CFNi: FN per transfer block = 160
   - DMA4_CSSAi: Source start address = 0x100000
   - DMA4_CDSAi: destination start address = 0x20013E
   - DMA4_CCRi:
     – Read and write port addressing modes = double-index addressing mode for both or post-increment addressing on source and double-index addressing on destination, DMA4_CCRi[13:12] SRC_AMODE and DMA4_CCRi[15:14] DST_AMODE bit fields
     – Low or high priority, DMA4_CCRi[6] READ_PRIORITY bit
     – DMA request number = 0 (for software-triggered transfer), DMA4_CCRi[4:0] SYNCHRO_CONTROL and DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER bit fields
   - DMA4_CSEIi: Source EI = 1
   - DMA4_CSFIi: Source frame index = 1

- DMA4_CDEIi: destination EI = 637
- DMA4_CDFIi: destination frame index = 152967

2. Start the transfer through the enable bit in the channel DMA4_CCRi register.

The following parameters are used to perform this rotation from 0x80C00000 RAM address to 0x80F00000, with the same code used in Section 16.1.5.2, *Software-Triggered (Nonsynchronized) Transfer*:

```
/* Init. parameters */
DMA4->DataType = 0x2; //
      DMA4_CSDPi[1:0]
DMA4->ReadPortAccessType = 0x3; // DMA4_CSDPi[8:7]

DMA4->WritePortAccessType = 0x3; // DMA4_CSDPi[15:14]

DMA4->SourceEndiansim = 0; // DMA4_CSDPi[21]

DMA4->DestinationEndianism = 0; // DMA4_CSDPi[19]

DMA4->WriteMode = 0x2; // DMA4_CSDPi[17:16]
DMA4->SourcePacked
      = 0x1; // DMA4_CSDPi[6]
DMA4->DestinationPacked = 0x1; //
      DMA4_CSDPi[13]
DMA4->NumberOfElementPerFrame = 240; // DMA4_CENi

DMA4->NumberOfFramePerTransferBlock = 160; // DMA4_CFNi

DMA4->SourceStartAddress = 0x80C00000; // DMA4_CSSAi

DMA4->DestinationStartAddress = 0x80F00000; // DMA4_CDSAi

DMA4->SourceElementIndex = 1; // DMA4_CSEIi

DMA4->SourceFrameIndex = 1; // DMA4_CSFIi

DMA4->DestinationElementIndex = 637; // DMA4_CDEIi

DMA4->DestinationFrameIndex = -152967; // DMA4_CDFIi

DMA4->ReadPortAccessMode = 0x3; // DMA4_CCRi[13:12]

DMA4->WritePortAccessMode = 0x3; // DMA4_CCRi[15:14]

DMA4->ReadPriority = 0; // DMA4_CCRi[6]
DMA4->WritePriority =
      0; // DMA4_CCRi[23]
DMA4->ReadRequestNumber = 0; // DMA4_CCRi[4:0]

DMA4->WriteRequestNumber = 0; // DMA4_CCRi[20:19]
```

16.1.5.8 Graphic Operations

- Transparent copy:
  1. Set the DMA4_CCRi[17] TRANSPARENT_COPY_ENABLE bit to 1
  2. Set the DMA4_CCRi[16] CONST_FILL_ENABLE bit to 0
  3. Set the value of the key color in the DMA4_COLORi[15:0] COLOR_KEY bit field

  To perform this graphic operation, the following lines can be added to the example of Section 16.1.5.2, *Software-Triggered (Nonsynchronized) Transfer*.

  ```
  DMA4_CCR_CH10 &= ~(0x1 << 16);
  DMA4_CCR_CH10 |= 0x1 << 17;

  DMA4_COLOR_CH10 = 0x00000003;
  ```

- Solid Color fill:
  1. Set the DMA4_CCRi[16] CONST_FILL_ENABLE bit to 1
  2. Set the DMA4_CCRi[17] TRANSPARENT_COPY_ENABLE bit to 0
  3. Set the value of key the color in the DMA4_COLORi[15:0] SOLID_COLOR bit field

To perform this graphic operation, the following lines can be added to the example of Section 16.1.5.2, *Software-Triggered (Nonsynchronized) Transfer*.

```
DMA4_CCR_CH10 &= ~(0x1 << 17);
DMA4_CCR_CH10 |= 0x1 << 16;

DMA4_COLOR_CH10 = 0x00000003;
```

16.1.5.9 Linked-List Programming Guidelines

- With the exception of the DMA4_CCRi[7] ENABLE bit and the DMA4_CDPi[7] PAUSE_LINK_LIST bit during a linked-list transfer (descriptor load phase or data load phase), avoid programming any register through the configuration port.
- Before enabling any linked-list transfer, ensure that all global registers and all registers in the descriptor are initialized. Some static channel registers (registers that are not updated by the descriptor to be loaded) must also be initialized correctly:
  – For type 2, the following registers must be initialized with consistent values:
    - All global registers
    - DMA4_CCRi
    - DMA4_CSDPi
    - DMA4_CLNK_CTRLi
  – For type 3, the following registers must be initialized with consistent values:
    - All global registers
    - DMA4_CCRi
    - DMA4_CSDPi
    - DMA4_CLNK_CTRLi
    - DMA4_CICRi
    - DMA4_CFNi
- In case of a linked list with descriptor types 2 and 3, the content of the DMA4_CCRi register must not change during super-block life.
- The PAUSE_LINK_LIST bit must not be set in the initialization phase.

16.1.6 DMA_SYSTEM Register Manual

16.1.6.1 DMA_SYSTEM Instance Summary

Table 16-19. DMA_SYSTEM Instance Summary

Module Name	Base Address	Size
DMA_SYSTEM	0x4A05 6000	4 KiB

16.1.6.2 DMA_SYSTEM Registers

16.1.6.2.1 DMA_SYSTEM Register Summary

Index *i* represents the logical channel number (where i = 0 to 31). The offset address for some registers is calculated from the channel *c* number. For example, the DMA4_CCR10 (channel 10) register has an offset address of 10 × 0x60 = 0x3C0, and thus a physical address of 0x4A05 6080 + 0x3C0 = 0x4A05 6440.

Index *j* represents the interrupt line number (where j = 0 to 3) The offset address for some registers is calculated from the channel *c* number. For example, the DMA4_IRQSTATUS_L3 (line 3) register has an offset address of 3 × 0x4 = 0xC, and thus a physical address of 0x4A05 6008 + 0xC = 0x4A05 6014.

Table 16-20. DMA_SYSTEM Registers Mapping Summary

16.1.6.2.2 DMA_SYSTEM Register Description

Note

Some registers have no reset value (marked with -) because of hardware implementation in memory. Software must ensure the correct programming of these registers, if needed.

Shadow registers are used to read run-time registers such as CCEN, CCFN, CDAC, and CSAC. Typically, when accessed in 8-bit or 16-bit access for two consecutive accesses, the value of the previous registers can change. A shadow register holds the entire value to let the next access recover the remaining 24 or 16 bits.

For non-32-bit transactions, start reading or writing from the LSByte first to enable the register update. There is no issue for 32-bit read-write transactions.

Table 16-21. DMA4_REVISION

Address Offset	0x0000 0000		
Physical Address	0x4A05 6000	**Instance**	DMA_SYSTEM

Bits	Field Name	Description	Type	Reset
31:15	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0x00000
14	EOSB_INTERRUPT_CPBLTY	End of Super Block detection capability.	R	1
13	RESERVED	Reserved for non-GP devices	R	1
12	DRAIN_END_INTERRUPT_CPBLTY	Drain End detection capability.	R	1
11	MISALIGNED_ADRS_ERR_INTERRUPT_CPBLTY	Misaligned error detection capability.	R	1
10	SUPERVISOR_ERR_INTERRUPT_CPBLTY	Supervisor error detection capability.	R	1
9	RESERVED	Reserved for non-GP devices	R	1
8	TRANS_ERR_INTERRUPT_CPBLTY	Transaction error detection capability.	R	1
7	PKT_INTERRUPT_CPBLTY	End of Packet detection capability. Read 0x0: Does not support end of packet interrupt generation capability Read 0x1: Supports end of packet interrupt generation capability	R	1
6	SYNC_STATUS_CPBLTY	Sync_status_capability Read 0x0: Does not support synchronized transfer status bit generation Read 0x1: Supports synchronized transfer status bit generation	R	1
5	BLOCK_INTERRUPT_CPBLTY	End of block detection capability. Read 0x0: Does not support end of block interrupt generation capability Read 0x1: Supports end of block interrupt generation capability	R	1
4	LAST_FRAME_INTERRUPT_CPBLTY	Start of last frame detection capability. Read 0x0: Does not support last frame interrupt generation capability Read 0x1: Supports last frame interrupt generation capability	R	1

Bits	Field Name	Description	Type	Reset
3	FRAME_INTERRUPT_CPBLTY	End of frame detection capability. Read 0x0: Does not support end of frame interrupt generation capability Read 0x1: Supports end of frame interrupt generation capability	R	1
2	HALF_FRAME_INTERRUPT_CPBLTY	Detection capability of the half of frame end. Read 0x0: Does not support half of frame interrupt generation capability Read 0x1: Supports half of frame interrupt generation capability	R	1
1	EVENT_DROP_INTERRUPT_CPBLTY	Request collision detection capability. Read 0x0: Does not support event drop interrupt generation capability Read 0x1: Supports event drop interrupt generation capability	R	1
0	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0

Table 16-30. DMA4_GCR

Address Offset	0x0000 0078		
Physical Address	0x4A05 6078	**Instance**	DMA_SYSTEM
Description	FIFO sharing between high and low priority channel. The Maximum per channel FIFO depth is bounded by the low and high channel FIFO budget. The high respectively low priority channels maximum burst size must be less than the min (high respectively low priority channel FIFO budget, per channel maximum FIFO depth)		
Type	RW		

31:25	24	23:16	15:14	13:12	11:8	7:0
RESERVED	CHANNEL_ID_GATE	ARBITRATION_RATE	HI_LO_FIFO_BUDGET	HI_THREAD_RESERVED	RESERVED	MAX_CHANNEL_FIFO_DEPTH

Bits	Field Name	Description	Type	Reset
31:25	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0x00
24	CHANNEL_ID_GATE	Gates the Channel ID bus monitoring on both Read and Write ports 0x0: Gates the Channel ID qualifiers on both Read and Write Ports 0x1: Does not gate the Channel ID qualifiers on both Read and Write Ports	RW	0x0
23:16	ARBITRATION_RATE	Arbitration switching rate between prioritized and regular channel queues	RW	0x01

Bits	Field Name	Description	Type	Reset
15:14	HI_LO_FIFO_BUDGET	Allow to have a separate Global FIFO budget for high and low priority channels. For Hi priority Channel: (Per_channel_Maximum FIFO depth + 1) x Number of active High priority Channel =< High Budget FIFO For Low priority channel: (Per_channel_Maximum FIFO depth + 1) x Number of active Low priority Channel =< Low Budget FIFO 0x0: no fixed budget for neither higher nor lower priority channel 0x1: 75% of FIFO for low priority and 25% for high priority channels 0x2: 25% of FIFO for low priority and 75% for high priority channels 0x3: 50% of FIFO for low priority and 50% for high priority channels	RW	0x0
13:12	HI_THREAD_RESERVED	Allow thread reservation for high priority channel on both read and write ports. 0x0: No ThreadID is reserved on the Read Port for high priority channels. No ThreadID is reserved on the Write Port for high priority channels. 0x1: Read Port ThreadID 0 is reserved for high priority channels. Write Port ThreadID 0 is reserved for high priority channels. 0x2: Read port ThreadID 0 and ThreadID 1 are reserved for high priority channels. Write Port ThreadID 0 is reserved for high priority channels. 0x3: Read PortThreadID 0, ThreadID 1 and ThreadID 2 are reserved for high priority channels. Write Port ThreadID 0 is reserved for high priority channels.	RW	0x0
11:8	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0x0
7:0	MAX_CHANNEL_FIFO_DEPTH	Maximum FIFO depth allocated to one logical channel. Maximum FIFO depth can not be 0x0. It should be at least 0x1 or greater. Note that If channel limit is less than destination burst size enough data will not be accumulated in the data FIFO and it will never be sent out on the WR port. The burst size should be less than the FIFO limit specified in this bit field.	RW	0x10

Table 16-31. DMA4_CCRi

Address Offset	0x0000 0080 + (0x60 * i)	**index:**	i = 0 to 31
Physical Address	0x4A05 6080 + (0x60 * i)	**Instance**	DMA_SYSTEM
Description	Channel Control Register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

RESERVED	RESERVED	WRITE_PRIORITY	BUFFERING_DISABLE	SEL_SRC_DST_SYNC	PREFETCH	SUPERVISOR	RESERVED	SYNCHRO_CONTROL_UPPER	BS	TRANSPARENT_COPY_ENABLE	CONST_FILL_ENABLE	DST_AMODE	SRC_AMODE	RESERVED	WR_ACTIVE	RD_ACTIVE	SUSPEND_SENSITIVE	ENABLE	READ_PRIORITY	FS	SYNCHRO_CONTROL

Bits	Field Name	Description	Type	Reset
31:30	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0x0
29:27	RESERVED	Reserved for non-GP devices	RW	0x0
26	WRITE_PRIORITY	Channel priority on the Write side 0x0: Channel has low priority on the write side during the arbitration process. 0x1: Channel has high priority on write sided during the arbitration process.	RW	0
25	BUFFERING_DISABLE	This bit allows to disable the default buffering functionality when transfer is source synchronized. 0x0: Buffering is enabled across element/packet when source is synchronized to element, packet, frame or blocks. 0x1: Buffering is disabled across element/packet when source is synchronized to element, packet, frame or blocks.	RW	-
24	SEL_SRC_DST_SYNC	Specifies that element, packet, frame or block transfer (depending on CCR.bs and CCR.fs) is triggered by the source or the destination on the DMA request 0x0: Transfer is triggered by the destination. If synch on packet the packet element number is specified in the CDFI register. 0x1: Transfer is triggered by the source. If synchronized on packet the packet element number is specified in the CSFI register.	RW	-
23	PREFETCH	Enables the prefetch mode 0x0: Prefetch mode is disabled. When Sel_Src_Dst_Sync=1 transfers are buffered and pipelined between DMA requests. 0x1: Prefetch mode is enabled. Prefetch mode is active only when destination is synchronized. It is software user responsibility not to have at the same time Prefetch=1 when Sel_Src_Dst_Sync=1. This mode is not supported.	RW	0
22	SUPERVISOR	Enables the supervisor mode 0x0: Supervisor mode is disabled. 0x1: Supervisor mode is enabled.	RW	0
21	RESERVED	Reserved for non-GP devices	RW	0
20:19	SYNCHRO_CONTROL_UPPER	Channel Synchronization control upper (used in conjunction with the 5 bits of synchro channel DMA4_CCRi[4:0]) Used in conjunction, as 2 MSB, with the 5 bits of the synchro channel bit field.	RW	0b00
18	BS	Block synchronization This bit used in conjunction with the fs to see how the DMA request is serviced in a synchronized transfer.	RW	-

Bits	Field Name	Description	Type	Reset
17	TRANSPARENT_COPY_ENABLE	Transparent copy enable 0x0: Transparent copy mode is disabled. 0x1: Transparent copy mode is enabled.	RW	-
16	CONST_FILL_ENABLE	Constant fill enable 0x0: Constant fill mode is disabled. 0x1: Constant fill mode is enabled.	RW	0
15:14	DST_AMODE	Selects the addressing mode on the Write Port of a channel. 0x0: Constant address mode 0x1: Post-incremented address mode 0x2: Single index address mode 0x3: Double index address mode	RW	0bxx
13:12	SRC_AMODE	Selects the addressing mode on the Read Port of a channel. 0x0: Constant address mode 0x1: Post-incremented address mode 0x2: Single index address mode 0x3: Double index address mode	RW	0bxx
11	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0
10	WR_ACTIVE	Indicates if the channel write context is active or not Read 0x0: Channel is not active on the write port. Read 0x1: Channel is currently active on the write port.	R	0
9	RD_ACTIVE	Indicates if the channel read context is active or not Read 0x0: Channel is not active on the read port. Read 0x1: Channel is currently active on the read port.	R	0
8	SUSPEND_SENSITIVE	Logical channel suspend enable bit 0x0: The channel ignores the MSuspend even if EMUFree is set to 0. 0x1: If EMUFree is set to 0 and MSuspend comes in then all current OCP services (single transaction or burst transaction as specified in the corresponding CSDP register) have to be completed before stopping processing any more transactions.	RW	0
7	ENABLE	Logical channel enable. It is SW responsibility to clear the CSR register and the IRQSTATUS bit for the different interrupt lines before enabling the channel. 0x0: The logical channel is disabled. 0x1: The logical channel is enabled.	RW	0
6	READ_PRIORITY	Channel priority on the read side 0x0: Channel has low priority on the read side during the arbitration process. 0x1: Channel has high priority on read sided during the arbitration process.	RW	0
5	FS	Frame synchronization This bit used in conjunction with the BS to see how the DMA request is serviced in a synchronized transfer FS = 0 and BS = 0: An element is transferred once a DMA request is made. FS = 0 and BS = 1: An entire block is transferred once a DMA request is made. FS = 1 and BS = 0: An entire frame is transferred once a DMA request is made. FS = 1 and BS = 1: A packet is transferred once a DMA request is made. All these different transfers can be interleaved on the port with other DMA requests.	RW	-

Bits	Field Name	Description	Type	Reset
4:0	SYNCHRO_CONTROL	Channel synchronization control This bit field used in conjunction with the second_level_ synchro_control_upper (as 2 MSB) 0000000 : Is reserved for non synchronized LCH transfer xxxxxxx (from 1 to 127)There are 127 possible DMA request to assign to any LCH. **Note:** The channel synchronization control registers are 1-based. For example, to enable the S_DMA_1 request, DMA4_CCR[4:0] SYNCHRO_CONTROL must be set to 0x2 (DMA request number + 1).	RW	0b00000

Table 16-32. DMA4_CLNK_CTRLi

Address Offset	0x0000 0084 + (0x60 * i)	**index:**	i = 0 to 31
Physical Address	0x4A05 6084 + (0x60 * i)	**Instance**	DMA_SYSTEM
Description	Channel Link Control Register		
Type	RW		

31–16	15	14–5	4–0
RESERVED	ENABLE_LNK	RESERVED	NEXTLCH_ID

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0x0000
15	ENABLE_LNK	Enables or disable the channel linking. 0x0: Channel linking mode is disabled When set on the fly to 0 the current channel will complete the transfer and stops the chain linking 0x1: Channel linking mode is enabled. The logical channel defined in the NextLCH_ID is enabled at the end of the current transfer	RW	0
14:5	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0x000
4:0	NEXTLCH_ID	Defines the NextLCh_ID, which is used to build logical channel chaining queue.	RW	0bxxxxx

Table 16-33. DMA4_CICRi

Address Offset	0x0000 0088 + (0x60 * i)	**index:**	i = 0 to 31

Bits	Field Name	Description	Type	Reset
31:15	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0x00000
14	SUPER_BLOCK_IE	Enables the end of super block interrupt	RW	-

Bits	Field Name	Description	Type	Reset
13	RESERVED	Reserved for non-GP devices	RW	1
12	DRAIN_IE	Enables the end of draining interrupt	RW	0
11	MISALIGNED_ERR_IE	Enables the address misaligned error event interrupt 0x0: Disables the misaligned address error event interrupt 0x1: Enables the misaligned address error event interrupt	RW	-
10	SUPERVISOR_ERR_IE	Enables the supervisor transaction error event interrupt 0x0: Disables the supervisor transaction error event interrupt 0x1: Enables the supervisor transaction error event interrupt	RW	1
9	RESERVED	Reserved for non-GP devices	RW	1
8	TRANS_ERR_IE	Enables the transaction error event interrupt 0x0: Disables the transaction error event interrupt 0x1: Enables the transaction error event interrupt	RW	-
7	PKT_IE	Enables the end of Packet interrupt 0x0: Disables the end of Packet transfer interrupt 0x1: Enables the end of Packet transfer interrupt	RW	-
6	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0
5	BLOCK_IE	Enables the end of block interrupt 0x0: Disables the end of block interrupt 0x1: Enables the end of block interrupt	RW	-
4	LAST_IE	Last frame interrupt enable (start of last frame) 0x0: Disables the last frame interrupt 0x1: Enables the last frame interrupt	RW	-
3	FRAME_IE	Frame interrupt enable (end of frame) 0x0: Disables the end of frame interrupt 0x1: Enables the end of frame interrupt	RW	-
2	HALF_IE	Enables or disables the half frame interrupt. 0x0: Disables the half frame interrupt 0x1: Enables the half frame interrupt	RW	-
1	DROP_IE	Synchronization event drop interrupt enable (request collision) 0x0: Disables the event drop interrupt 0x1: Enables the event drop interrupt	RW	0
0	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0

16.2 Enhanced DMA

This chapter describes the Enhanced Direct Memory Access (EDMA) controller.

16.2.1 EDMA Module Overview

The enhanced direct memory access module, also called EDMA, performs high-performance data transfers between two slave points, memories and peripheral devices without microprocessor unit (MPU) or digital signal processor (DSP) support during transfer. EDMA transfer is programmed through a logical EDMA channel, which allows the transfer to be optimally tailored to the requirements of the application.

The EDMA can also perform transfers between external memories and between Device subsystems internal memories, with some performance loss caused by resource sharing between the read and write ports.

EDMA controller is based on two major principal blocks:
- EDMA third-party channel controller (EDMA_TPCC)
- EDMA third-party transfer controller (EDMA_TPTC)

The **TPCC** is a high flexible Channel Controller. It serves as an user interface and an event interface for the EDMA controller. The EDMA_TPCC serves to prioritize incoming software requests or events from peripherals and submits transfer requests (TRs) to the transfer controller.

The **TPTC** performs read and write transfers by EDMA ports to the slave peripherals as programmed in the "Active" and "Pending" set of the registers. The transfer controllers are responsible for data movement and issue read/write commands to the source and destination addresses that are programmed for a given transfer in the EDMA_TPCC.

The SoC integrates the following EDMA instances:

- One system-level EDMA
- One DSP internal EDMA (per DSP)
- One EVE internal EDMA (per EVE)

Each of these EDMA modules consists of:

- One TPCC instance
- Two TPTC instances

Note

All EDMA modules in the SoC are functionally identical. Note that some of the configuration parameters may be different for the various EDMA instances (see Section 16.2.1.3, *EDMA Controllers Configuration*).

This chapter is mostly focused on describing the system-level EDMA module (in terms of configuration and integration in the SoC). For details on DSPx_EDMA / EVEx_EDMA integration, see their respective chapters.

Figure 16-12 shows an overview of the EDMA module.

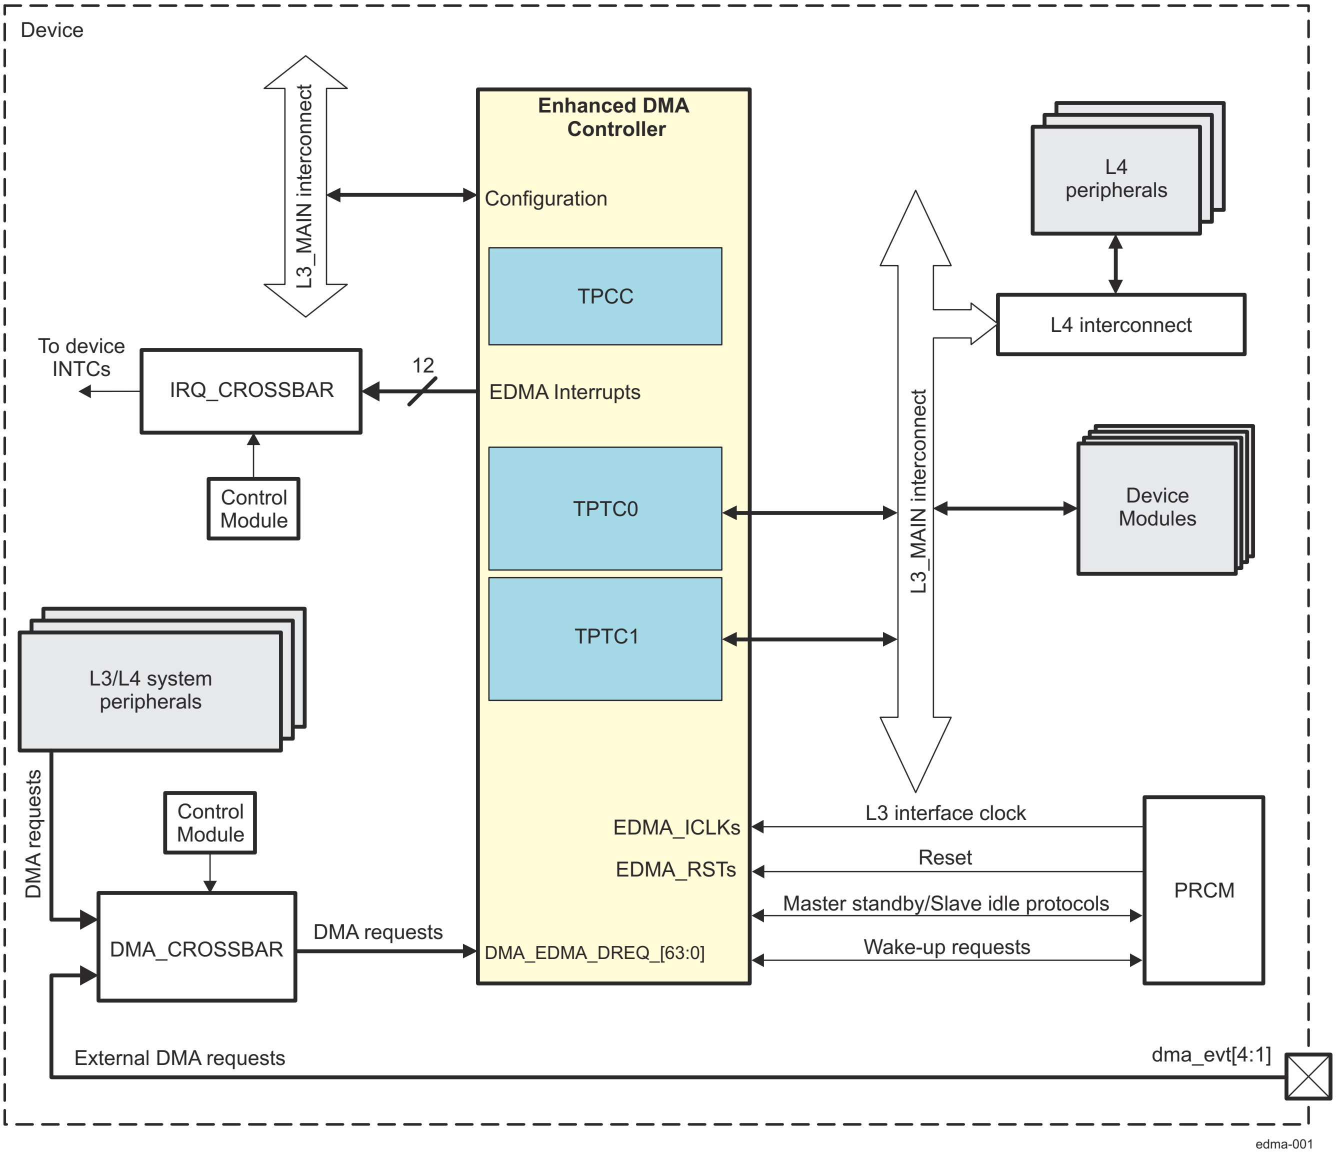

Figure 16-12. EDMA module Overview

The device CPUs can configure the EDMA controller blocks through the L3_MAIN interconnect.

16.2.1.1 EDMA Features

The **EDMA_TPCC** channel controller has following features:

- Fully orthogonal transfer description:
  - Three transfer dimensions.
  - A-synchronized transfers: one-dimension serviced per event.
  - AB-synchronized transfers: two-dimensions serviced per event.
  - Independent indexes on source and destination.
  - Chaining feature allows a 3-D transfer based on a single event.
- Flexible transfer definition:
  - Increment or FIFO transfer addressing modes.
  - Linking mechanism allows automatic PaRAM set update.
  - Chaining allows multiple transfers to execute with one event.
- Interrupt generation for the following:

  - Transfer completion.
  - Error conditions.
- Debug visibility:
  - Queue water marking/threshold.
  - Error and status recording to facilitate debug.
- 64 DMA request channels:
  - Event synchronization.
  - Manual synchronization (CPU(s) write to event set registers EDMA_TPCC_ESR and EDMA_TPCC_ESRH).
  - Chain synchronization (completion of one transfer triggers another transfer).
- Eight QDMA channels:
  - QDMA channels trigger automatically upon writing to a parameter RAM (PaRAM) set entry.
  - Support for programmable QDMA channel to PaRAM mapping.
- 512 PaRAM sets:
  - Each PaRAM set can be used for a DMA channel, QDMA channel, or link set.
- Two transfer controllers/event queues.
- 16 event entries per event queue.
- Memory protection support:
  - Proxy memory protection for TR submission.
  - Active memory protection for accesses to PaRAM and registers.

The **EDMA_TPTC** transfer controller has the following features:
- Two transfer controllers (TC).
- 128-bit wide read and write ports per TC.
- Up to four in-flight transfer requests (TRs).
- Programmable priority level.
- Supports two-dimensional transfers with independent indexes on source and destination (EDMA_TPCC manages the 3rd dimension).
- Support for increment or constant addressing mode transfers.
- Interrupt and error support.
- Memory-Mapped Register (MMR) bit fields are fixed position in 32-bit MMR regardless of endianness.

16.2.1.2

EDMA controller uses the shared MMU1 module for transfering to and from DSP module. This provides several benefits including:
- Protection of Host CPU memory regions from accidental corruption by EDMA TPTCs.
- Direct allocation of buffers in user space without the need for translation between CPU and DSP applications utilizing EDMA TPTCs.

Accesses by the EDMA TPTCs (both TPTC0 and TPTC1) may optionally be routed through the MMU1.

The TPTC0 and TPTC1 routing allows EDMA transfer controller to be used to perform transfers using only the virtual addresses of the associated buffers.

For more information about MMU1 module refer to Chapter 20 *Memory Management Units*.

16.2.1.3 EDMA Controllers Configuration

Table 16-52 summarizes the configuration for each of the EDMA channel controllers present on the SoC.

Table 16-52. EDMA Channel Controllers Configuration

Parameter	SYS_EDMA CC Configuration	DSPx_EDMA CC Configuration	EVEx_EDMA CC Configuration
Number of DMA channels (NUM_DMACH)	64	64	16
Number of QDMA channels (NUM_QDMACH)	8	8	8
Number of interrupt channels (NUM_INTCH)	64	64	16

Table 16-52. EDMA Channel Controllers Configuration (continued)

Parameter	SYS_EDMA CC Configuration	DSPx_EDMA CC Configuration	EVEx_EDMA CC Configuration
Number of PaRAM set entries (NUM_PARAMENTRY)	512	128	128
Number of event queues (NUM_EVQUE)	2	2	2
Number of transfer controllers (NUM_TC)	2	2	2
Memory protection existence (MPEXIST)	Yes	Yes	Yes
Number of memory protection and shadow regions (NUM_REGIONS)	8	8	8
Channel mapping existence (CHMAPEXIST)	Yes	Yes	Yes

Table 16-53 summarizes the configuration of each of the EDMA transfer controllers present on the SoC.

Table 16-53. EDMA Transfer Controllers Configuration

Parameter	SYS_EDMA TC0 / TC1 Configuration	DSPx_EDMA TC0 / TC1 Configuration	EVEx_EDMA TC0 / TC1 Configuration
Data FIFO size (FIFOSIZE)	1024 bytes	2048 bytes	2048 bytes
Bus width (BUSBYTE)	16 bytes	16 bytes	16 bytes
Number of destination FIFO register sets (DSTREGDEPTH)	4 entries	4 entries	4 entries
Default burst size (DBS)	Defined by CTRL_CORE_CONTROL_IO_1 register	Defined by DSP_SYS_BUS_CONFIG register	Defined by EVE_BUS_CONFIG register

16.2.2 EDMA Controller Environment

The EDMA controller supports external DMA requests through the dma_evt[4:1] pins (see Table 16-54). A logical channel can be configured to respond to an external synchronization request.

Table 16-54. External EDMA Request Signals

Pin Name	DMA_CROSSBAR Input	Signal Name	I/O(1)	Description	Module Reset Value
dma_evt1	DMA_CROSSBAR_2	EXT_SYS_DREQ_0	I	External DMA request 0 (system expansion)	Z
dma_evt2	DMA_CROSSBAR_3	EXT_SYS_DREQ_1	I	External DMA request 1 (system expansion)	Z
dma_evt3	DMA_CROSSBAR_167	EXT_SYS_DREQ_2	I	External DMA request 2 (system expansion)	Z
dma_evt4	DMA_CROSSBAR_168	EXT_SYS_DREQ_3	I	External DMA request 3 (system expansion)	Z

(1) I = Input, O = Output

Figure 16-13 shows an example of how to use the external hardware DMA request pins in the EDMA environment.

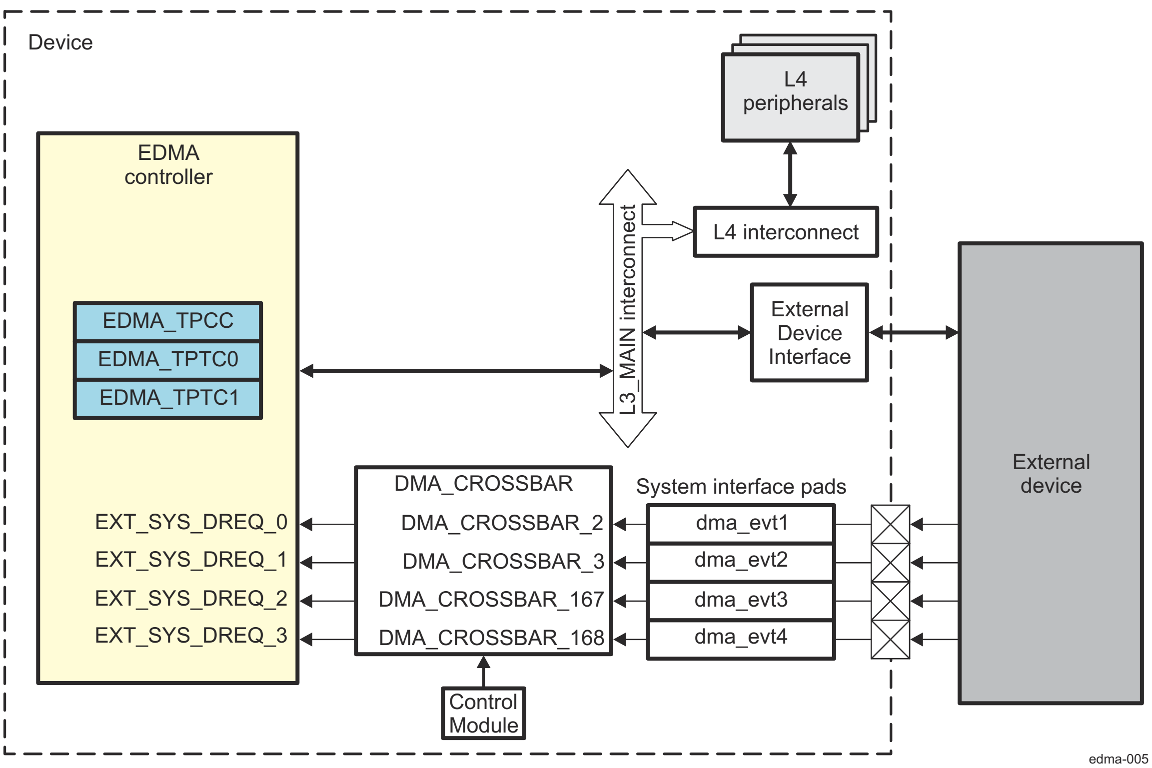

Figure 16-13. Example of External DMA Requests Use

An external device can use the external DMA request pins to start a logical channel transfer. The transfer can be a memory-to-memory transfer in which the source memory is in the external device.

By default, the external DMA request signals are not available on external pins after a cold reset. For more information about multiplexing out the two signal lines to pins, refer to *Control Module*.

All 64 DMA request lines are transition sensitive.

16.2.3 EDMA Controller Integration

This section describes the integration of the module in the device, including information about clocks, resets, and hardware requests.

Figure 16-14 shows the EDMA controller integration.

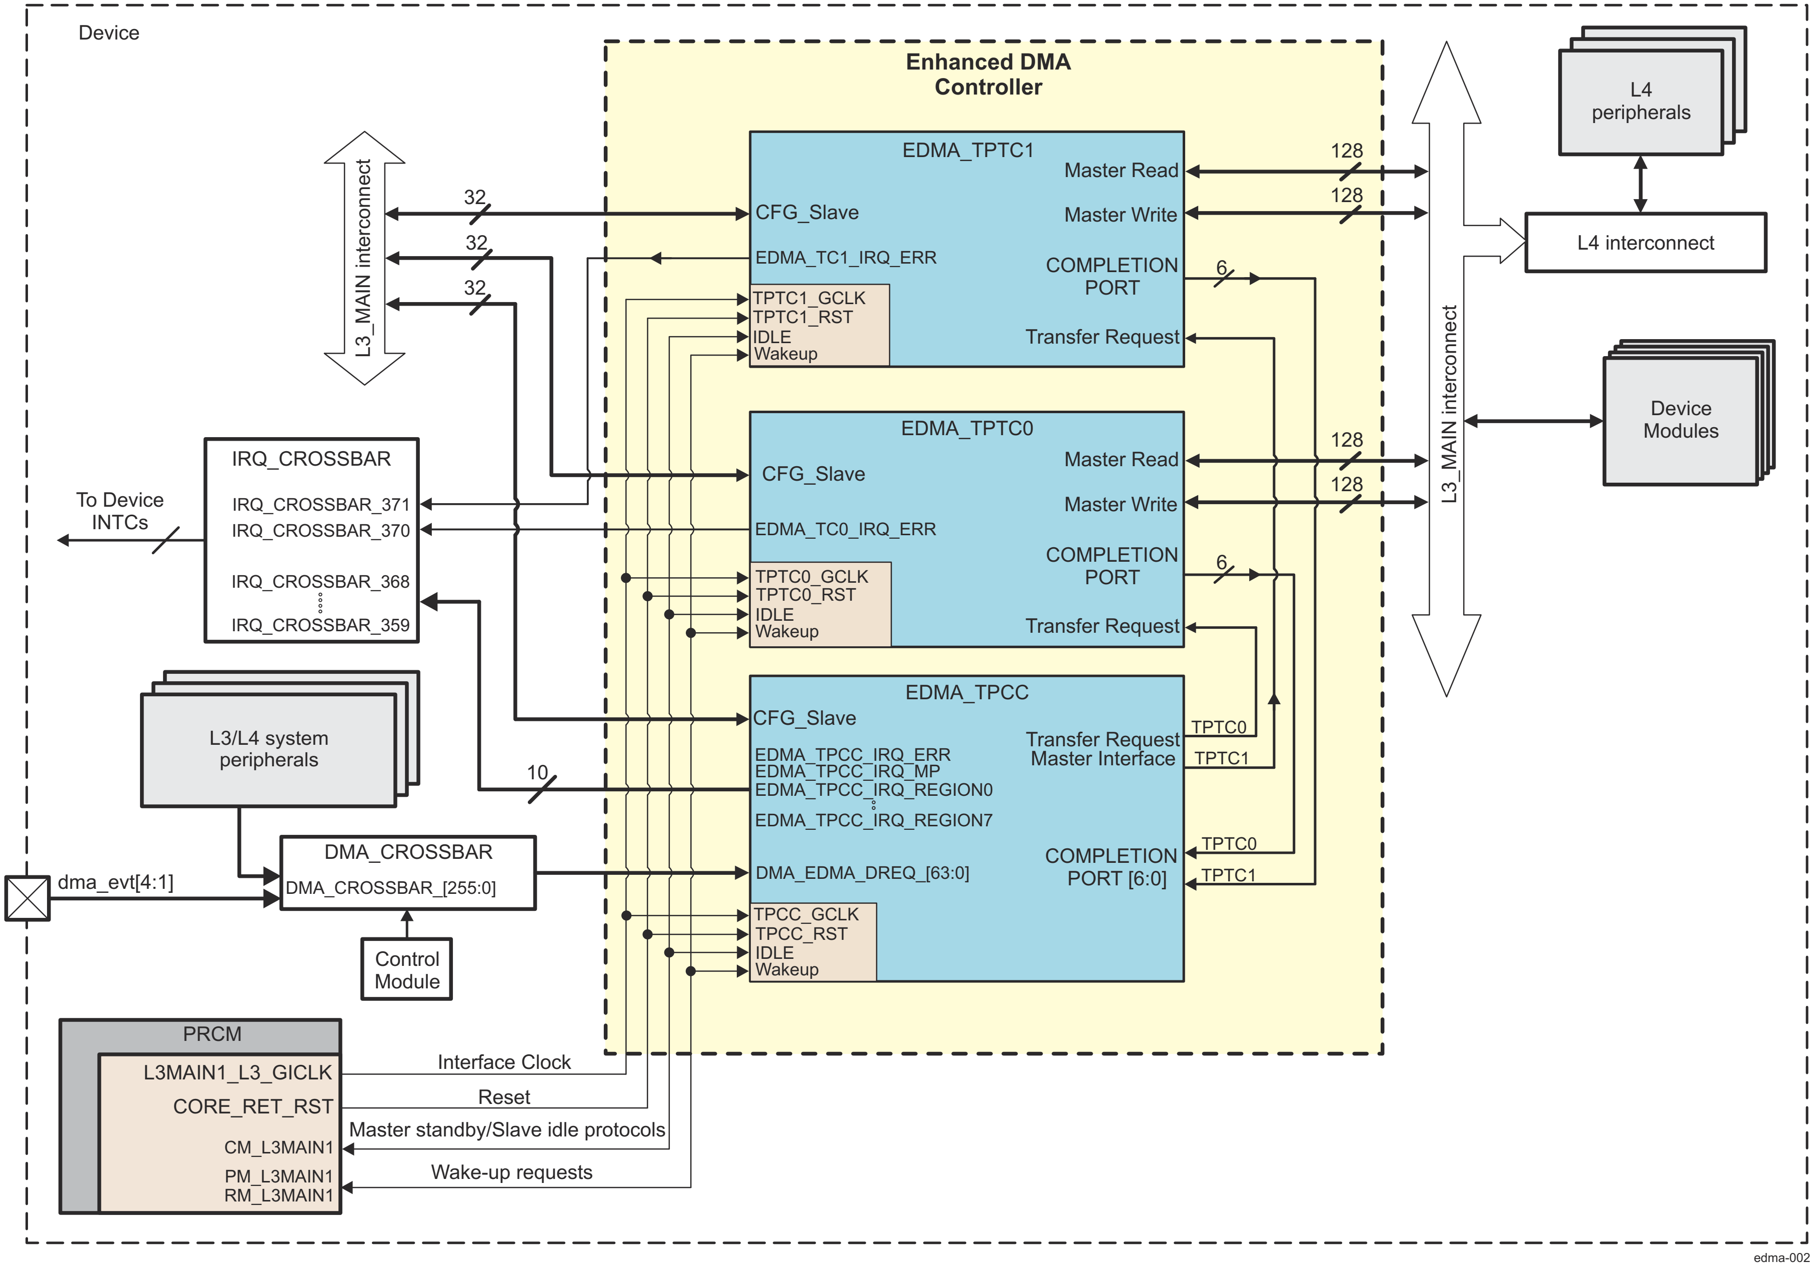

Figure 16-14. EDMA Controller Integration

Table 16-55 through Table 16-57 summarize the integration of the module in the device.

Table 16-55. EDMA Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
EDMA_TPCC	PD_COREAON	L3_MAIN
EDMA_TPTC0		
EDMA_TPTC1		

Table 16-56. EDMA Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
EDMA_TPCC	EDMA_TPCC_GCLK	L3MAIN1_L3_GICLK	PRCM	Interface clock. It supports the configuration port. For information about PRCM clock gating and management, see *Power, Reset, and Clock Management*.
EDMA_TPTC0	EDMA_TPTC0_GCLK			
EDMA_TPTC1	EDMA_TPTC1_GCLK			
Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
EDMA_TPCC	EDMA_TPCC_RST	CORE_RET_RST	PRCM	Hardware retention reset. It initializes all internal logic of the EDMA contrller modules, all global registers, and some of the per-channel registers, implemented in flip-flops. However, all remaining per-channel registers are memory-based, and, therefore, are not reset (have undefined values). Thus, when programming a channel for the first time, all bits that have undefined reset values must be configured before enabling the channel. For information about PRCM reset sources and distribution, see *Power, Reset, and Clock Management*.
EDMA_TPTC0	EDMA_TPTC0_RST			
EDMA_TPTC1	EDMA_TPTC1_RST			

Table 16-57. EDMA Hardware Requests

Interrupt Requests				
Module Instance	**Source Signal Name**	**Destination IRQ_CROSSBAR INPUT**	**Default mapping**	**Description**
EDMA_TPCC	EDMA_TPCC_IRQ_ERR	IRQ_CROSSBAR_359	-	TPCC error interrupt. This IRQ source signal is not mapped by default to any device INTC. For more information about INTC refer to *Interrupt Controllers*.
	EDMA_TPCC_IRQ_MP	IRQ_CROSSBAR_360	-	TPCC memory protection interrupt. This IRQ source signal is not mapped by default to any device INTC.
	EDMA_TPCC_IRQ_REGION0	IRQ_CROSSBAR_361	-	TPCC Region 0 interrupt. This IRQ source signal is not mapped by default to any device INTC.

Table 16-57. EDMA Hardware Requests (continued)

	EDMA_TPCC_IRQ_REGION1	IRQ_CROSSBAR_362	-	TPCC Region 1 interrupt. This IRQ source signal is not mapped by default to any device INTC.
	EDMA_TPCC_IRQ_REGION2	IRQ_CROSSBAR_363	-	TPCC Region 2 interrupt. This IRQ source signal is not mapped by default to any device INTC.
	EDMA_TPCC_IRQ_REGION3	IRQ_CROSSBAR_364	-	TPCC Region 3 interrupt. This IRQ source signal is not mapped by default to any device INTC.
	EDMA_TPCC_IRQ_REGION4	IRQ_CROSSBAR_365	-	TPCC Region 4 interrupt. This IRQ source signal is not mapped by default to any device INTC.
	EDMA_TPCC_IRQ_REGION5	IRQ_CROSSBAR_366	-	TPCC Region 5 interrupt. This IRQ source signal is not mapped by default to any device INTC.
	EDMA_TPCC_IRQ_REGION6	IRQ_CROSSBAR_367	-	TPCC Region 6 interrupt. This IRQ source signal is not mapped by default to any device INTC.
	EDMA_TPCC_IRQ_REGION7	IRQ_CROSSBAR_368	-	TPCC Region 7 interrupt. This IRQ source signal is not mapped by default to any device INTC.
EDMA_TPTC0	EDMA_TC0_IRQ_ERR	IRQ_CROSSBAR_370	-	TPTC0 error interrupt. This IRQ source signal is not mapped by default to any device INTC.
EDMA_TPTC1	EDMA_TC1_IRQ_ERR	IRQ_CROSSBAR_371	-	TPTC1 error interrupt. This IRQ source signal is not mapped by default to any device INTC.

Note

The “**Default Mapping**” column in Table 16-57 *EDMA Hardware Requests* shows the default mapping of module IRQ source signals. These IRQ source signals can also be mapped to other lines of each device Interrupt controller through the IRQ_CROSSBAR or DMA_CROSSBAR modules.
For more information about the IRQ_CROSSBAR and DMA_CROSSBAR modules, see sections: *IRQ_CROSSBAR Module Functional Description* and *DMA_CROSSBAR Module Functional Description*, in *Control Module*.
For more information about the device interrupt controllers, see *Interrupt Controllers*.

Note

For a description of the interrupt source, see *EDMA interrupts*.

16.2.3.1 EDMA Requests to the EDMA Controller

Table 16-58 lists the default DMA sources for the EDMA controller. In addition, the EDMA inputs (DMA_EDMA_DREQ_[63:0]) can alternatively be sourced through the associated DMA_CROSSBAR from one of the 256 multiplexed device DMA sources listed in Table 16-6. The CTRL_CORE_DMA_EDMA_DREQ_y_z registers (where *y* and *z* are indexes of EDMA input lines) in the Control Module are used to select between the default DMA sources and the multiplexed DMA sources.

Table 16-58. EDMA Default Request Mapping

DMA Request Line	DMA_ CROSSBAR Instance Number	DMA_CROSSBAR Configuration Register	DMA_ CROSSBAR Default Input Index	Default DMA Source Name	Default DMA Source Description
DMA_EDMA_DREQ_0	1	CTRL_CORE_DMA_EDMA_DREQ_0_1[7:0]	1	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_EDMA_DREQ_1	2	CTRL_CORE_DMA_EDMA_DREQ_0_1[23:16]	2	EXT_SYS_DREQ_0	External DMA request 0 (system expansion)
DMA_EDMA_DREQ_2	3	CTRL_CORE_DMA_EDMA_DREQ_2_3[7:0]	3	EXT_SYS_DREQ_1	External DMA request 1 (system expansion)
DMA_EDMA_DREQ_3	4	CTRL_CORE_DMA_EDMA_DREQ_2_3[23:16]	4	GPMC_DREQ	GPMC data transmit request from prefetch engine
DMA_EDMA_DREQ_4	5	CTRL_CORE_DMA_EDMA_DREQ_4_5[7:0]	5	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_EDMA_DREQ_5	6	CTRL_CORE_DMA_EDMA_DREQ_4_5[23:16]	6	DISPC_DREQ	Frame update request
DMA_EDMA_DREQ_6	7	CTRL_CORE_DMA_EDMA_DREQ_6_7[7:0]	7	CT_TBR_DREQ	DEBUG subsystem CT_TBR request
DMA_EDMA_DREQ_7	8	CTRL_CORE_DMA_EDMA_DREQ_6_7[23:16]	8	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_EDMA_DREQ_8	9	CTRL_CORE_DMA_EDMA_DREQ_8_9[7:0]	9	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_EDMA_DREQ_9	10	CTRL_CORE_DMA_EDMA_DREQ_8_9[23:16]	10	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_EDMA_DREQ_10	11	CTRL_CORE_DMA_EDMA_DREQ_10_11[7:0]	11	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_EDMA_DREQ_11	12	CTRL_CORE_DMA_EDMA_DREQ_10_11[23:16]	12	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_EDMA_DREQ_12	13	CTRL_CORE_DMA_EDMA_DREQ_12_13[7:0]	13	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_EDMA_DREQ_13	14	CTRL_CORE_DMA_EDMA_DREQ_12_13[23:16]	14	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_EDMA_DREQ_14	15	CTRL_CORE_DMA_EDMA_DREQ_14_15[7:0]	15	MCSPI3_DREQ_TX0	McSPI3 transmit request channel 0
DMA_EDMA_DREQ_15	16	CTRL_CORE_DMA_EDMA_DREQ_14_15[23:16]	16	MCSPI3_DREQ_RX0	McSPI3 receive request channel 0
DMA_EDMA_DREQ_16	17	CTRL_CORE_DMA_EDMA_DREQ_16_17[7:0]	17	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_EDMA_DREQ_17	18	CTRL_CORE_DMA_EDMA_DREQ_16_17[23:16]	18	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_EDMA_DREQ_18	19	CTRL_CORE_DMA_EDMA_DREQ_18_19[7:0]	19	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_EDMA_DREQ_19	20	CTRL_CORE_DMA_EDMA_DREQ_18_19[23:16]	20	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_EDMA_DREQ_20	21	CTRL_CORE_DMA_EDMA_DREQ_20_21[7:0]	21	Reserved	Reserved by default but can be remapped to a valid DMA source

Table 16-58. EDMA Default Request Mapping (continued)

DMA Request Line	DMA_CROSSBAR Instance Number	DMA_CROSSBAR Configuration Register	DMA_CROSSBAR Default Input Index	Default DMA Source Name	Default DMA Source Description
DMA_EDMA_DREQ_21	22	CTRL_CORE_DMA_EDMA_DREQ_20_21[23:16]	22	Reserved	Reserved by default but can be remapped to a valid DMA source
DMA_EDMA_DREQ_22	23	CTRL_CORE_DMA_EDMA_DREQ_22_23[7:0]	23	MCSPI3_DREQ_TX1	McSPI3 transmit request channel 1

16.2.4 EDMA Controller Functional Description

This chapter discusses the architecture of the EDMA controller.

16.2.4.1 Block Diagram

Figure 16-15 shows the functional block diagram of the EDMA controller.

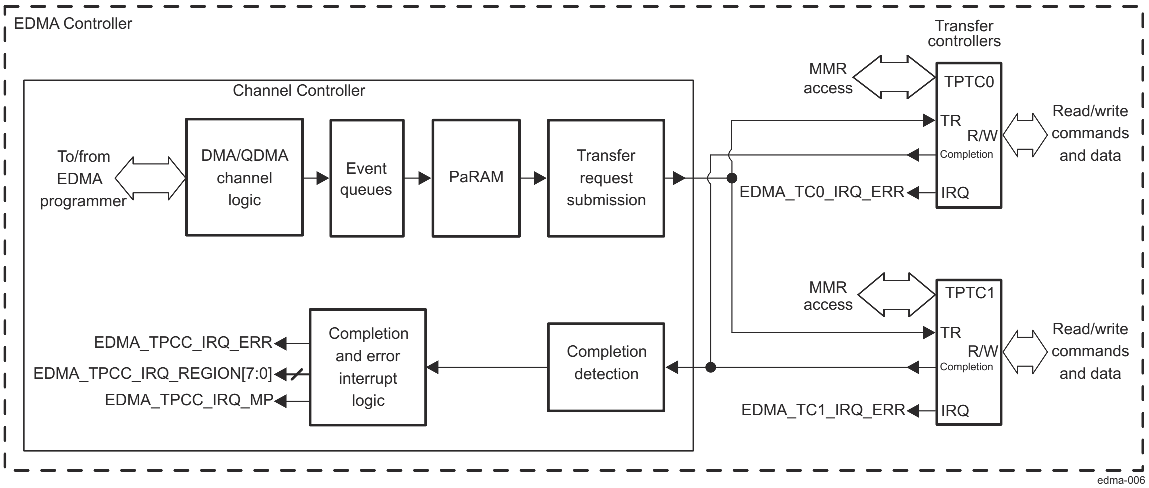

Figure 16-15. EDMA Controller Block Diagram

16.2.4.1.1 Third-Party Channel Controller

The TPCC is the EDMA transfer scheduler responsible for scheduling, arbitrating, and issuing user programmed transfers to the two TPTCs.

Figure 16-16 shows a functional block diagram of the EDMA channel controller (EDMA_TPCC).

The main blocks of the EDMA_TPCC are as follows:

- Parameter RAM (PaRAM): The PaRAM maintains parameter sets for channel and reload parameter sets. The PaRAM must be written with the transfer context for the desired channels and link parameter sets. EDMA_TPCC processes and sets based on a trigger event and submits a transfer request (TR) to the transfer controllers.
- EDMA event and interrupt processing registers: Allows mapping of events to parameter sets, enable/disable events, enable/disable interrupt conditions, and clearing interrupts.
- Completion detection: The completion detect block detects completion of transfers by the EDMA_TPTCs or slave peripherals. The completion of transfers can be used optionally to chain trigger new transfers or to assert interrupts.
- Event queues: Event queues form the interface between the event detection logic and the transfer request submission logic.
- Memory protection registers: Memory protection registers define the accesses (privilege level and requestor(s)) that are allowed to access the DMA channel shadow region view(s) and regions of PaRAM.

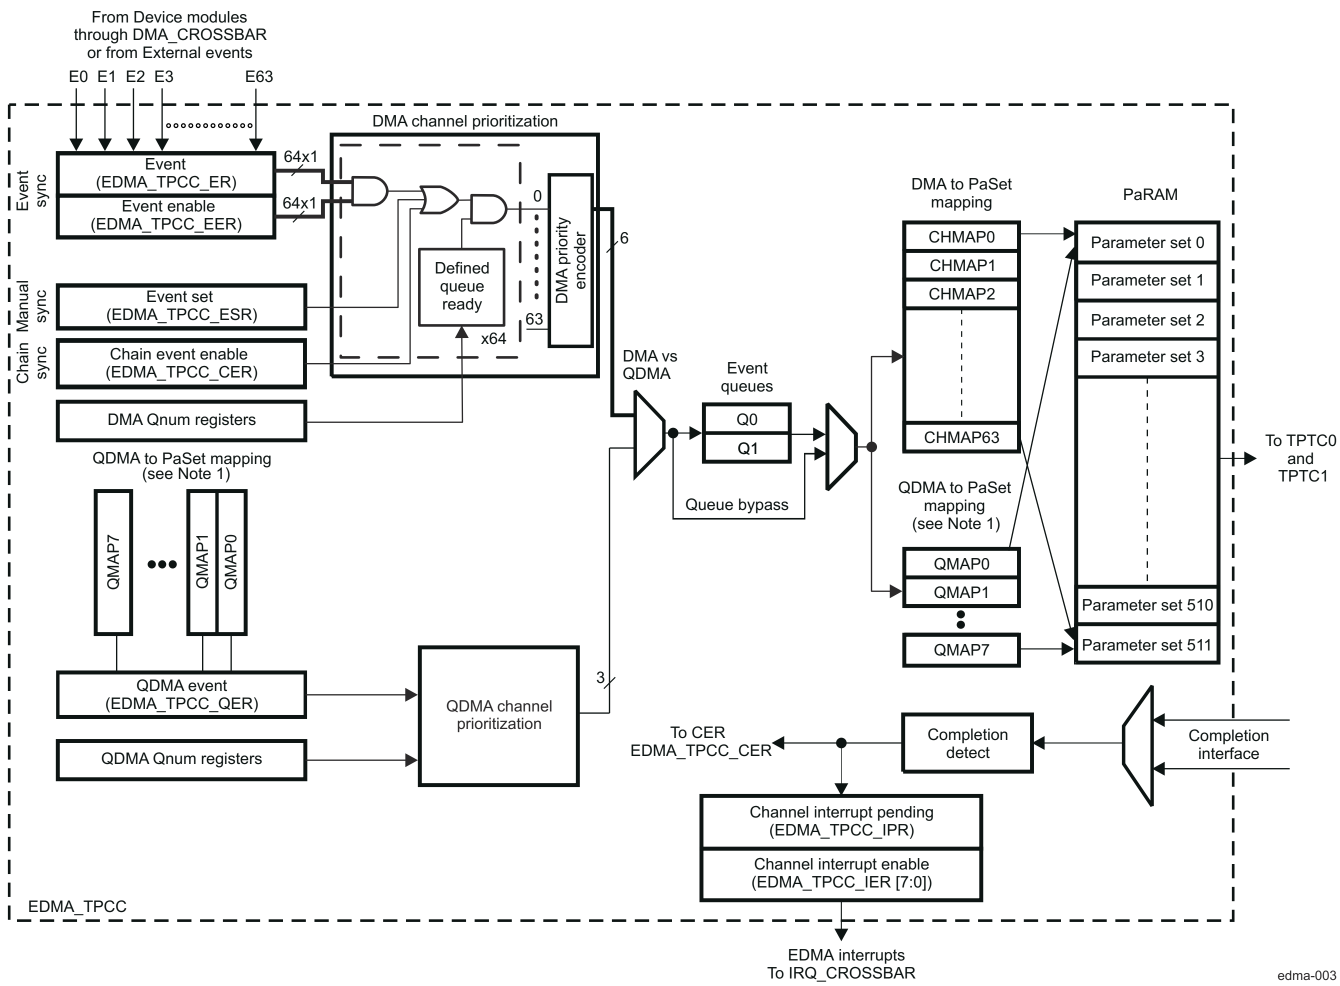
Other functions include the following:

- Region registers: Region registers allow DMA resources (DMA channels and interrupts) to be assigned to unique regions that different EDMA programmers own (for example, MPU or DSPs).
- Debug registers: Debug registers allow debug visibility by providing registers to read the queue status, controller status, and missed event status.

The EDMA_TPCC includes two channel types: DMA channels (64 channels) and QDMA channels (8 channels).

Each channel is associated with a given event queue/transfer controller and with a given PaRAM set. The main difference between a DMA channel and a QDMA channel is the method that the system uses to trigger transfers.

Figure 16-16 is a block diagram of the EDMA_TPCC.



A. Although it is depicted twice in Figure 16-16, there is only one physical register set for the QDMA to PaRAM set mapping block.

Figure 16-16. EDMA Channel Controller Block Diagram

The EDMA_TPCC supports up to 64 DMA channels and up to 8 QDMA channels. These channels are identical, except for how they are triggered:

- DMA channels are triggered by external events (such as McSPI modules TX event and McSPI modules RX event) by the event set registers EDMA_TPCC_ESR and EDMA_TPCC_ESRH, or through chaining register EDMA_TPCC_CER.
- QDMA channels are triggered automatically (auto-triggered) by the CPU. QDMAs allow a minimum number of linear writes to be issued to the TPCC to force a series of transfers to occur.

The TPCC arbitrates among pending DMA and QDMA events with a fixed [64:1] and [8:1] priority encoder for these events, respectively (a low channel number corresponds to a high priority).

DMA events are always higher priority than QDMA events. The higher-priority event is placed in the event queue to await submission to the transfer controllers, which occurs at the earliest opportunity. Each event queue is serviced in FIFO order, with a maximum of 16 queued events per event queue. If more than one TPTC is ready to be programmed with a transmission request (TR), the event queues are serviced with fixed priority: Q0 is higher than Q1. When an event is ready to be queued and the event queue and the TC channel are empty, the event bypasses the event queue and goes directly to the PaRAM processing logic for submission to the appropriate TC. If the transfer request TR bus or PaRAM processing are busy, the bypass path is not used. The bypass is not used to dequeue for a higher-priority event.

Events are extracted from the event queue when the EDMA_TPTC is available for a new TR to be programmed into the EDMA_TPTC (signaled with the empty signal, indicating an empty program register set). As an event is extracted from the event queue, the associated PaRAM entry is processed and submitted to the TPTC as a TR. The TPCC updates the appropriate counts and addresses in the PaRAM entry in anticipation of the next trigger event for that PaRAM entry.

The EDMA_TPCC also has an error detection logic that causes an error interrupt generation on various error conditions (for example: missed events EDMA_TPCC_EMR and EDMA_TPCC_EMRH registers, exceeding event queue thresholds in EDMA_TPCC_CCERR register, etc.).

16.2.4.1.2 Third-Party Transfer Controller

The TPTC module is the EDMA transfer engine that generates transfers as programmed in dedicated working registers, using two dedicated master ports: a read-only port and a write-only port.

Figure 16-17 shows a functional block diagram and of the EDMA transfer controller (EDMA_TPTC) and its connection to the EDMA_TPCC.

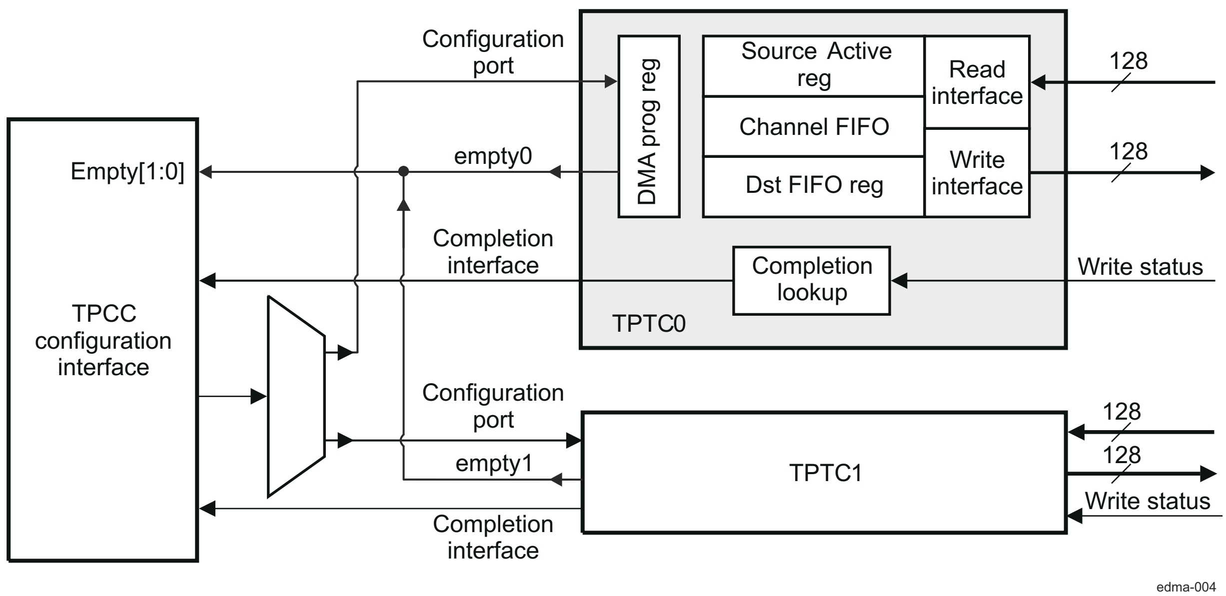


Figure 16-17. TPTC Block Diagram

Note

The port data bus width of the instances of the TPTC is fixed at 128 bits.

Two instances of the EDMA_TPTC generate concurrent traffic on the L3_MAIN interconnect. Each TC controller consists of the following components:

- DMA Program Register Set: Stores the context for the DMA transfer that is loaded into the active register set when the current active register set completes. The CPU or TPCC programs the Program Register Set, not the active register set. For typical standalone operation, the CPU programs the Program Register while the TC services the Active register set. The Program Register set includes ownership control such that CPU software and the EDMA stay synchronized relative to one another.
- Source Active Register Set : Stores the context (src/dst/cnt/etc) for the DMA Transfer Request (TR) in progress in the Read Controller. The Active register set is split into independent Source and Destination, because the source interconnect controller and the distant interconnect controller operate independently of one another.

- Destination FIFO Register Set: Stores the context (src/dst/cnt/etc) for the DMA Transfer Request (TR) in progress, or pending, in the Write Controller. The pending register must allow the source controller to begin processing a new TR while the distant register set processes the previous TR.
- Channel FIFO: Temporary holding buffer for in-flight data. The read return data of the source peripheral is stored in the Data FIFO, and then is written to the destination peripheral by the write command/data bus.
- Read Controller/Interconnect Read Interface: The Interconnect read interface issues optimally sized read commands to the source peripheral, based on a burst size of 128 bytes and available landing space in the channel FIFO.
- Write controller/Interconnect Write interface: The local interconnect write interface issues optimally sized write commands to the destination peripheral, based on a burst size of 128 bytes and available data in the channel FIFO.
- Completion interface: sends completion codes to the EDMA_TPCC when a transfer completes and generates interrupts and chained events in the TPCC module.
- Configuration port: Slave interface that provides read/write access to program registers and read access to all memory-mapped TPTC registers.

When one EDMA_TPTC module is idle and receive its first TR, DMA program register set receives the TR, where it transitions to the DMA source active set and the destination FIFO register set immediately. The second TR (if pending from EDMA_TPCC) is loaded into the DMA program set, ensuring it can start as soon as possible when the active transfer completes. As soon as the current active set is exhausted, the TR is loaded from the DMA program register set into the DMA source active register set as well as to the appropriate entry in the destination FIFO register set.

The read controller issues read commands controlled by the rules of command fragmentation and optimization. These are issued only when the data FIFO has space available for the data read. When sufficient data is in the data FIFO, the write controller starts issuing a write command again following the rules for command fragmentation and optimization.

Depending on the number of entries, the read controller can process up to two or four transfer requests ahead of the destination subject to the amount of free data FIFO.

16.2.4.2 Types of EDMA controller Transfers

An EDMA transfer is always defined in terms of three dimensions. Figure 16-18 shows the three dimensions used by EDMA controller transfers. These three dimensions are defined as:

- 1st Dimension or Array (A): The 1st dimension in a transfer consists of EDMA_TPCC_ABCNT_n[15:0] ACNT contiguous bytes.
- 2nd Dimension or Frame (B): The 2nd dimension in a transfer consists of EDMA_TPCC_ABCNT_n[31:16] BCNT arrays of ACNT bytes. Each array transfer in the 2nd dimension is separated from each other by an index programmed using bit-fields EDMA_TPCC_BIDX_n[15:0] SBIDX or EDMA_TPCC_BIDX_n[31:16] DBIDX.
- 3rd Dimension or Block (C): The 3rd dimension in a transfer consists of CCNT frames of BCNT arrays of ACNT bytes. The Count for 3rd Dimension is defined in register EDMA_TPCC_CCNT_n[15:0] CCNT. Each transfer in the 3rd dimension is separated from the previous by an index programmed using EDMA_TPCC_CIDX_n[15:0] SCIDX or EDMA_TPCC_CIDX_n[31:16] DCIDX.

Note

The reference point for the index depends on the synchronization type. The amount of data transferred upon receipt of a trigger/synchronization event is controlled by the synchronization types (EDMA_TPCC_OPT_n[2] SYNCDIM bit). For these three dimensions, only two synchronization types are supported: A-synchronized transfers and AB-synchronized transfers.

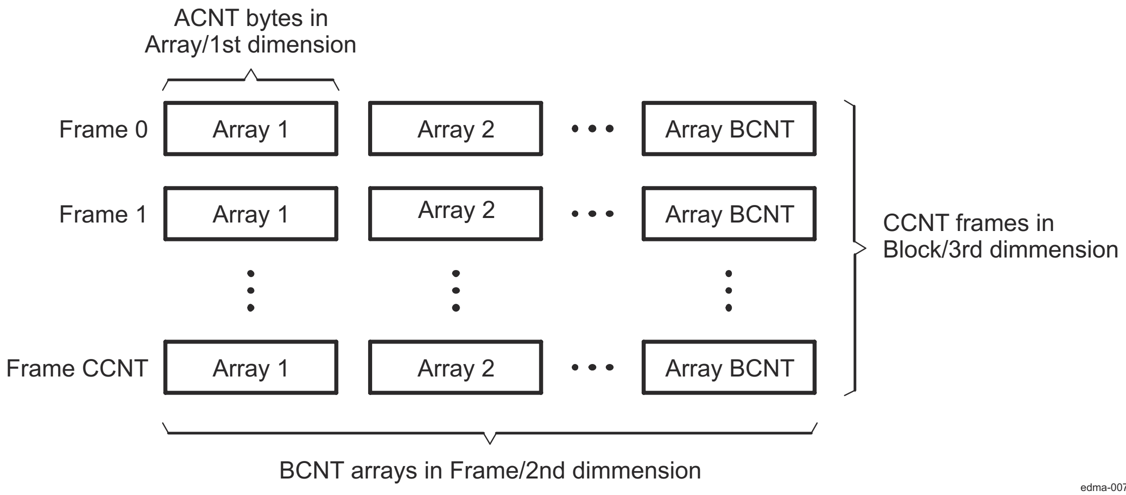

Figure 16-18. Definition of ACNT, BCNT, and CCNT

16.2.4.2.1 A-Synchronized Transfers

In an A-synchronized transfer, each EDMA sync event initiates the transfer of the 1st dimension of EDMA_TPCC_ABCNT_n[15:0] ACNT bytes, or one array of ACNT bytes. Each event/TR packet conveys the transfer information for one array only. Thus, BCNT × CCNT events are needed to completely service a PaRAM set.

Arrays are always separated by EDMA_TPCC_BIDX_n[15:0]SBIDX and EDMA_TPCC_BIDX_n[31:16] DBIDX, as shown in Figure 16-19, where the start address of Array N is equal to the start address of Array N – 1 plus source (SRC) or destination (DST) in EDMA_TPCC_BIDX_n register.

Frames are always separated by EDMA_TPCC_CIDX_n[15:0] SCIDX and EDMA_TPCC_CIDX_n[31:16] DCIDX. For A-synchronized transfers, after the frame is exhausted, the address is updated by adding SRCCIDX/ DSTCIDX to the beginning address of the last array in the frame. As in Figure 16-19, SRCCIDX / DSTCIDX is the difference between the start of Frame 0 Array 3 to the start of Frame 1 Array 0.

Figure 16-19 shows an A-synchronized transfer of 3 (CCNT) frames of 4 (BCNT) arrays of n (ACNT) bytes. In this example, a total of 12 sync events (BCNT × CCNT) exhaust a PaRAM set. See Figure 16-19 for details on parameter set updates.

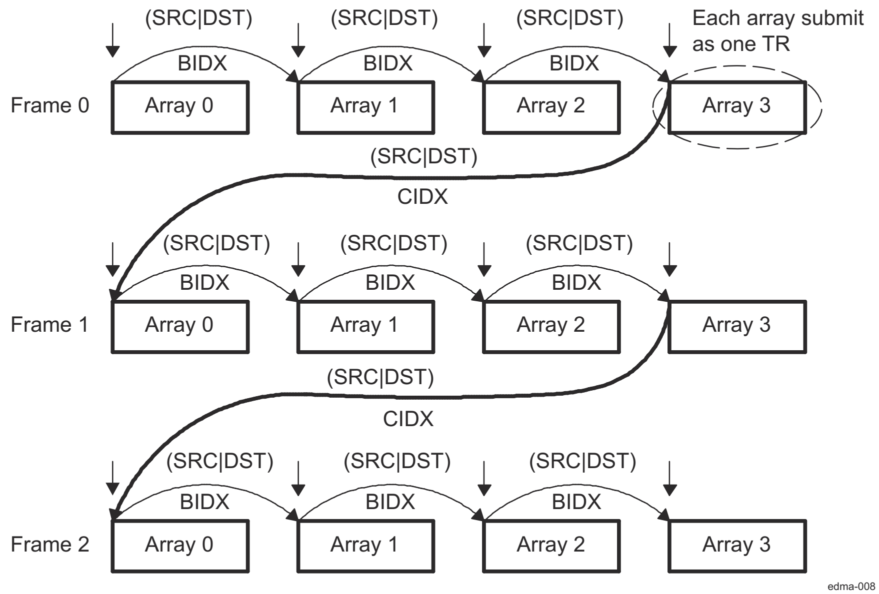

Figure 16-19. A-Synchronized Transfers (ACNT = n, BCNT = 4, CCNT = 3)

16.2.4.2.2 AB-Synchronized Transfers

In a AB-synchronized transfer, each EDMA sync event initiates the transfer of 2 dimensions or one frame. Each event/TR packet conveys information for one entire frame of BCNT_n arrays of ACNT_n bytes. Thus, EDMA_TPCC_CCNT_n events are needed to completely service a PaRAM set.

Arrays are always separated by EDMA_TPCC_BIDX_n[15:0] SBIDX and EDMA_TPCC_BIDX_n[31:16] DBIDX as shown in Figure 16-20. Frames are always separated by SRCCIDX and DSTCIDX.

Note that for AB-synchronized transfers, after a TR for the frame is submitted, the address update is to add EDMA_TPCC_CIDX_n[15:0] SCIDX / EDMA_TPCC_CIDX_n[31:16] DCIDX to the beginning address of the beginning array in the frame. This is different from A-synchronized transfers where the address is updated by adding SRCCIDX/DSTCIDX to the start address of the last array in the frame. See Section 16.2.4.3.6 *Parameter Set Updates* for details on parameter set updates.

Figure 16-20 shows an AB-synchronized transfer of 3 (CCNT) frames of 4 (BCNT) arrays of *n* (ACNT) bytes. In this example, a total of 3 sync events (CCNT) exhaust a PaRAM set; that is, a total of 3 transfers of 4 arrays each completes the transfer.

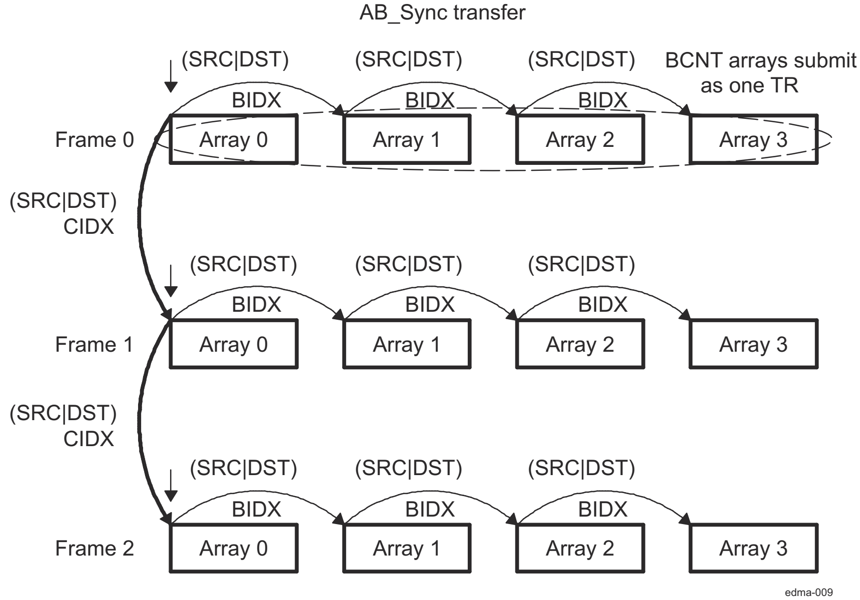

Figure 16-20. AB-Synchronized Transfers (ACNT = n, BCNT = 4, CCNT = 3)

Note

ABC-synchronized transfers are not directly supported. It can be logically achieved by chaining between multiple AB-synchronized transfers.

Note

VCP does not support Const/FIFO mode DMA transfers. The EDMA should be configured for AB-Synchronized transfer with ACNT = 8, BCNT = number of elements.

16.2.4.3 Parameter RAM (PaRAM)

The EDMA controller is a RAM-based architecture. The transfer context (source/destination addresses, count, indexes, etc.) for DMA or QDMA channels is programmed in a parameter RAM table in EDMA_TPCC. The PaRAM table is segmented into multiple PaRAM sets. Each PaRAM set includes eight four-byte PaRAM set entries (32-bytes total per PaRAM set), which includes typical DMA transfer parameters such as source address, destination address, transfer counts, indexes, options, etc.

The PaRAM structure supports flexible ping-pong, circular buffering, channel chaining, and auto-reloading (linking).

The contents of the PaRAM include the following:

- 512 PaRAM sets
- 64 channels that are direct mapped and can be used as link or QDMA sets if not used for DMA channels
- 64 channels remain for link or QDMA sets

By default, all channels map to PaRAM set to 0, they should be remapped before use by EDMA_TPCC_DCHMAPN_m and EDMA_TPCC_QCHMAPN_j registers.

Table 16-59. EDMA Parameter RAM Contents

PaRAM Set Number	Base Address	Parameters(1)
0	EDMA Base Address + 4000h to EDMA Base Address + 401Fh	PaRAM set 0
1	EDMA Base Address + 4020h to EDMA Base Address + 403Fh	PaRAM set 1
2	EDMA Base Address + 4040h to EDMA Base Address + 405Fh	PaRAM set 2
3	EDMA Base Address + 4060h to EDMA Base Address + 407Fh	PaRAM set 3
4	EDMA Base Address + 4080h to EDMA Base Address + 409Fh	PaRAM set 4
5	EDMA Base Address + 40A0h to EDMA Base Address + 40BFh	PaRAM set 5
6	EDMA Base Address + 40C0h to EDMA Base Address + 40DFh	PaRAM set 6
7	EDMA Base Address + 40E0h to EDMA Base Address + 40FFh	PaRAM set 7
8	EDMA Base Address + 4100h to EDMA Base Address + 411Fh	PaRAM set 8
9	EDMA Base Address + 4120h to EDMA Base Address + 413Fh	PaRAM set 9
...	...	...
63	EDMA Base Address + 47E0h to EDMA Base Address + 47FFh	PaRAM set 63
64	EDMA Base Address + 4800h to EDMA Base Address + 481Fh	PaRAM set 64
65	EDMA Base Address + 4820h to EDMA Base Address + 483Fh	PaRAM set 65
...	...	...
510	EDMA Base Address + 7FC0h to EDMA Base Address + 7FDFh	PaRAM set 510
511	EDMA Base Address + 7FE0h to EDMA Base Address + 7FFFh	PaRAM set 511

(1) The device has 8 QDMA channels that can be mapped to any parameter set number from 0 to 511.

16.2.4.3.1 PaRAM

Each parameter set of PaRAM is organized into eight 32-bit words or 32 bytes, as shown in Figure 16-21 and described in Table 16-60. Each PaRAM set consists of 16-bit and 32-bit parameters.

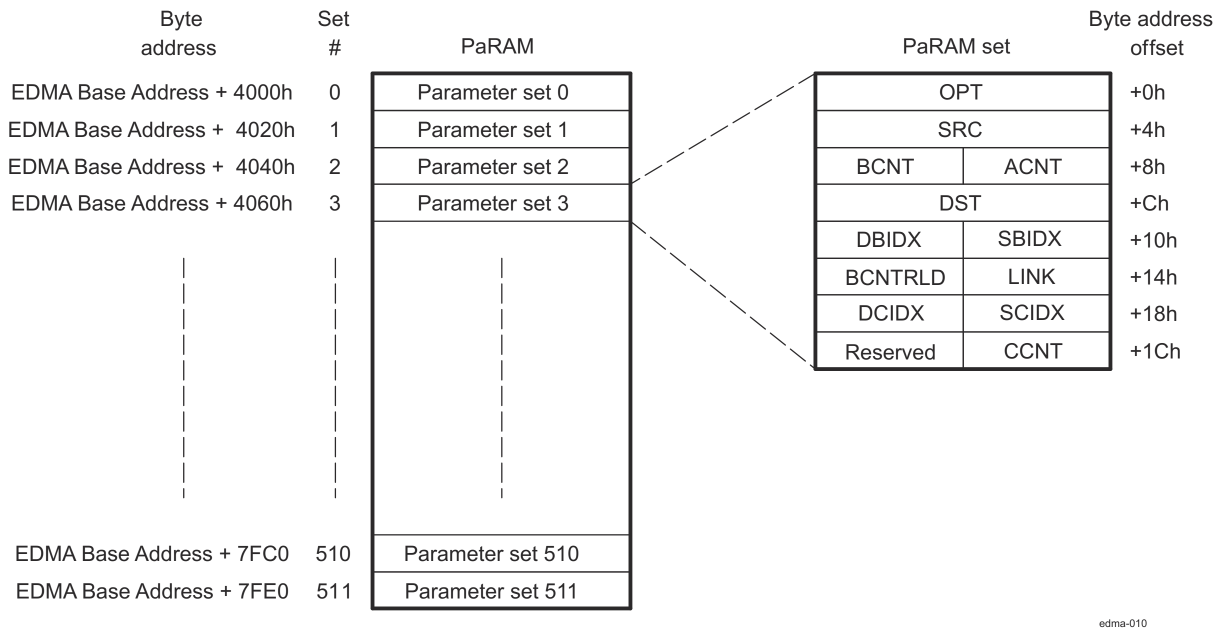

Figure 16-21. PaRAM Set

Table 16-60. EDMA Channel Parameter Description

Offset Address (bytes)	Acronym	Parameter	Description
0h	OPT	Channel Options EDMA_TPCC_OPT_n register	Transfer configuration options
4h	SRC	Channel Source Address EDMA_TPCC_SRC_n register	The byte address from which data is transferred
8h[(1)]	ACNT	Count for 1st Dimension EDMA_TPCC_ABCNT_n[15:0] ACNT bit-field.	Unsigned value specifying the number of contiguous bytes within an array (first dimension of the transfer). Valid values range from 1 to 65 535.
	BCNT	Count for 2nd Dimension EDMA_TPCC_ABCNT_n[31:16] BCNT bit-field.	Unsigned value specifying the number of arrays in a frame, where an array is ACNT bytes. Valid values range from 1 to 65 535.
Ch	DST	Channel Destination Address EDMA_TPCC_DST_n register	The byte address to which data is transferred
10h[(1)]	SBIDX	Source BCNT Index EDMA_TPCC_BIDX_n[15:0] SBIDX bit-field.	Signed value specifying the byte address offset between source arrays within a frame (2nd dimension). Valid values range from –32 768 and 32 767.
	DBIDX	Destination BCNT Index EDMA_TPCC_BIDX_n[31:16] DBIDX bit-field.	Signed value specifying the byte address offset between destination arrays within a frame (2nd dimension). Valid values range from –32 768 and 32 767.
14h[(1)]	LINK	Link Address EDMA_TPCC_LNK_n[15:0] LINK bit-field	The PaRAM address containing the PaRAM set to be linked (copied from) when the current PaRAM set is exhausted. A value of FFFFh specifies a null link.
	BCNTRLD	BCNT Reload EDMA_TPCC_LNK_n[31:16] BCNTRLD bit-field	The count value used to reload BCNT when BCNT decrements to 0 (TR is submitted for the last array in 2nd dimension). Only relevant in A-synchronized transfers.
18h[(1)]	SCIDX	Source CCNT index. EDMA_TPCC_CIDX_n[15:0] SCIDX bit-field.	Signed value specifying the byte address offset between frames within a block (3rd dimension). Valid values range from –32 768 and 32 767. A-synchronized transfers: The byte address offset from the beginning of the last source array in a frame to the beginning of the first source array in the next frame. AB-synchronized transfers: The byte address offset from the beginning of the first source array in a frame to the beginning of the first source array in the next frame.
	DCIDX	Destination CCNT index. EDMA_TPCC_CIDX_n[31:16] DCIDX bit-field.	Signed value specifying the byte address offset between frames within a block (3rd dimension). Valid values range from –32 768 and 32 767. A-synchronized transfers: The byte address offset from the beginning of the last destination array in a frame to the beginning of the first destination array in the next frame. AB-synchronized transfers: The byte address offset from the beginning of the first destination array in a frame to the beginning of the first destination array in the next frame.
1Ch	CCNT	Count for 3rd Dimension. EDMA_TPCC_CCNT_n[15:0] CCNT bit-field.	Unsigned value specifying the number of frames in a block, where a frame is BCNT arrays of ACNT bytes. Valid values range from 1 to 65 535.
	Reserved	Reserved	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.

(1) If OPT, SRC, or DST is the trigger word for a QDMA transfer, then a 32-bit access to that field is required. Furthermore, it is recommended to perform only 32-bit accesses on the parameter RAM for best code compatibility. For example, switching the endianness of the processor will swap addresses of the 16-bit fields, but 32-bit accesses avoid the issue entirely.

16.2.4.3.2 EDMA Channel PaRAM Set Entry Fields

16.2.4.3.2.1 Channel Options Parameter (OPT)

For detailed information about the channel options parameter, see the EDMA_TPCC_OPT_n register description in Section 16.2.7.2.2.1, *EDMA_TPCC Register Description*.

16.2.4.3.2.2 Channel Source Address (SRC)

The 32-bit source address parameter specifies the starting byte address of the source. For SAM in increment mode, there are no alignment restrictions imposed by EDMA. For SAM in constant addressing mode, it must program the source address to be aligned to a 256-bit aligned address (5 LSBs of address must be 0). If this rule is not observed, the EDMA_TPTC returns an error. Refer to Section 16.2.4.12.3 *Error Generation* for additional details.

16.2.4.3.2.3 Channel Destination Address (DST)

The 32-bit destination address parameter specifies the starting byte address of the destination. For DAM in increment mode, there are no alignment restrictions imposed by EDMA. For DAM in constant addressing mode, it must program the destination address to be aligned to a 256-bit aligned address (5 LSBs of address must be 0). If this rule is not observed, the EDMA_TPTC returns an error. Refer to Section 16.2.4.12.3 *Error Generation* for additional details.

16.2.4.3.2.4 Count for 1st Dimension (ACNT)

EDMA_TPCC_ABCNT_n[15:0] ACNT represents the number of bytes within the 1st dimension of a transfer. ACNT is a 16-bit unsigned value with valid values between 0 and 65 535. Therefore, the maximum number of bytes in an array is 65 535 bytes (64K – 1 bytes). ACNT must be greater than or equal to 1 for a TR to be submitted to EDMA_TPTC. A transfer with ACNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in EDMA_TPCC_OPT_n.

Refer to Section 16.2.4.3.5 *Dummy Versus Null Transfer Comparison* and Section 16.2.4.5.3 *Dummy or Null Completion* for details on dummy/null completion conditions.

16.2.4.3.2.5 Count for 2nd Dimension (BCNT)

EDMA_TPCC_ABCNT_n[15:0] BCNT is a 16-bit unsigned value that specifies the number of arrays of length ACNT. For normal operation, valid values for BCNT are between 1 and 65 535. Therefore, the maximum number of arrays in a frame is 65 535 (64K – 1 arrays). A transfer with BCNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in EDMA_TPCC_OPT_n.

Refer to Section 16.2.4.3.5 *Dummy Versus Null Transfer Comparison* and Section 16.2.4.5.3 *Dummy or Null Completion* for details on dummy/null completion conditions.

16.2.4.3.2.6 Count for 3rd Dimension (CCNT)

EDMA_TPCC_CCNT_n[15:0] CCNT is a 16-bit unsigned value that specifies the number of frames in a block. Valid values for CCNT are between 1 and 65 535. Therefore, the maximum number of frames in a block is 65 535 (64K – 1 frames). A transfer with CCNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in EDMA_TPCC_OPT_n.

A CCNT value of 0 is considered either a null or dummy transfer.

Refer to Section 16.2.4.3.5 *Dummy Versus Null Transfer Comparison* and Section 16.2.4.5.3 *Dummy or Null Completion* for details on dummy/null completion conditions.

16.2.4.3.2.7 BCNT Reload (BCNTRLD)

EDMA_TPCC_LNK_n[31:16] BCNTRLD is a 16-bit unsigned value used to reload the EDMA_TPCC_ABCNT_n[15:0] BCNT field once the last array in the 2nd dimension is transferred. This field is only used for A-synchronized transfers. In this case, the EDMA_TPCC decrements the BCNT value by 1 on each TR submission. When BCNT reaches 0, the EDMA_TPCC decrements CCNT and uses the BCNTRLD value to reinitialize the BCNT value.

For AB-synchronized transfers, the EDMA_TPCC submits the BCNT in the TR and the EDMA_TPTC decrements BCNT appropriately. For AB-synchronized transfers, BCNTRLD is not used.

16.2.4.3.2.8 Source B Index (SBIDX)

EDMA_TPCC_BIDX_n[15:0] SBIDX is a 16-bit signed value (2s complement) used for source address modification between each array in the 2nd dimension. Valid values for EDMA_TPCC_BIDX_n[15:0] SBIDX are between –32 768 and 32 767. It provides a byte address offset from the beginning of the source array to the beginning of the next source array. It applies to both A-synchronized and AB-synchronized transfers. Some examples:

- EDMA_TPCC_BIDX_n[15:0] SBIDX = 0000h (0): no address offset from the beginning of an array to the beginning of the next array. All arrays are fixed to the same beginning address.
- EDMA_TPCC_BIDX_n[15:0] SBIDX = 0003h (+3): the address offset from the beginning of an array to the beginning of the next array in a frame is 3 bytes. For example, if the current array begins at address 1000h, the next array begins at 1003h.
- EDMA_TPCC_BIDX_n[15:0] SBIDX = FFFFh (–1): the address offset from the beginning of an array to the beginning of the next array in a frame is –1 byte. For example, if the current array begins at address 5054h, the next array begins at 5053h.

16.2.4.3.2.9 Destination B Index (DBIDX)

EDMA_TPCC_BIDX_n[31:16] DBIDX is a 16-bit signed value (2s complement) used for destination address modification between each array in the 2nd dimension. Valid values for EDMA_TPCC_BIDX_n[31:16] DBIDX are between –32 768 and 32 767. It provides a byte address offset from the beginning of the destination array to the beginning of the next destination array within the current frame. It applies to both A-synchronized and AB-synchronized transfers. Refer to Section 16.2.4.3.2.8 *Source B Index (SBIDX)* for examples.

16.2.4.3.2.10 Source C Index (SCIDX)

EDMA_TPCC_CIDX_n[15:0] SCIDX is a 16-bit signed value (2s complement) used for source address modification in the 3rd dimension. Valid values for EDMA_TPCC_CIDX_n[15:0] SCIDX are between –32 768 and 32 767. It provides a byte address offset from the beginning of the current array (pointed to by SRC address) to the beginning of the first source array in the next frame. It applies to both A-synchronized and AB-synchronized transfers.

Note

When SCIDX is applied, the current array in an A-synchronized transfer is the last array in the frame (Figure 16-19), while the current array in an AB-synchronized transfer is the first array in the frame (Figure 16-20).

16.2.4.3.2.11 Destination C Index (DCIDX)

EDMA_TPCC_CIDX_n[31:16] DCIDX is a 16-bit signed value (2s complement) used for destination address modification in the 3rd dimension. Valid values are between –32 768 and 32 767. It provides a byte address offset from the beginning of the current array (pointed to by DST address) to the beginning of the first destination array TR in the next frame. It applies to both A-synchronized and AB-synchronized transfers.

Note

When DCIDX is applied, the current array in an A-synchronized transfer is the last array in the frame (Figure 16-19), while the current array in a AB-synchronized transfer is the first array in the frame (Figure 16-20).

16.2.4.3.2.12 Link Address (LINK)

The EDMA_TPCC provides a mechanism, called linking, to reload the current PaRAM set upon its natural termination (that is, after the count fields are decremented to 0) with a new PaRAM set. The 16-bit parameter EDMA_TPCC_LNK_n[15:0] LINK specifies the byte address offset in the PaRAM from which the EDMA_TPCC loads/reloads the next PaRAM set during linking.

It must program the link address to point to a valid aligned 32-byte PaRAM set. The 5 LSBs of the LINK field should be cleared to 0.

The EDMA_TPCC ignores the upper 2 bits of the LINK entry, allowing the flexibility of programming the link address as either an absolute/literal byte address or use the PaRAM-base-relative offset address. Therefore, if it use the literal address with a range from 4000h to 7FFFh, it will be treated as a PaRAM-base-relative value of 0000h to 3FFFh.

It should check that the programed value in the EDMA_TPCC_LNK_n[15:0] LINK field is correctly, so that link update is requested from a PaRAM address that falls in the range of the available PaRAM addresses on the device.

Value of FFFFh in EDMA_TPCC_LNK_n[15:0] LINK bit-field is referred to as a NULL link that should cause the EDMA_TPCC to perform an internal write of 0 to all entries of the current PaRAM set, except for the EDMA_TPCC_LNK_n[15:0] LINK field is set to FFFFh. Also, see Section 16.2.4.5 *Completion of a DMA Transfer* for details on terminating a transfer.

16.2.4.3.3 Null PaRAM Set

A null PaRAM set is defined as a PaRAM set where all count fields (EDMA_TPCC_ABCNT_n[15:0] ACNT, EDMA_TPCC_ABCNT_n[31:16] BCNT, and EDMA_TPCC_CCNT_n[15:0] CCNT) are cleared to 0. If a PaRAM set associated with a channel is a NULL set, then when serviced by the EDMA_TPCC, the bit corresponding to the channel is set in the associated event missed register (EDMA_TPCC_EMR, EDMA_TPCC_EMRH, or EDMA_TPCC_QEMR). This bit remains set in the associated secondary event register (EDMA_TPCC_SER, EDMA_TPCC_SERH, or EDMA_TPCC_QSER).
This implies that any future events on the same channel are ignored by the EDMA_TPCC and it is required to clear the bit in EDMA_TPCC_SER, EDMA_TPCC_SERH, or EDMA_TPCC_QSER for the channel. This is considered an error condition, since events are not expected on a channel that is configured as a null transfer.

16.2.4.3.4 Dummy PaRAM Set

A dummy PaRAM set is defined as a PaRAM set where at least one of the count fields (EDMA_TPCC_ABCNT_n[15:0] ACNT, EDMA_TPCC_ABCNT_n[31:16] BCNT, or EDMA_TPCC_CCNT_n[15:0] CCNT) is cleared to 0 and at least one of the count fields is nonzero.

If a PaRAM set associated with a channel is a dummy set, then when serviced by the EDMA_TPCC, it will not set the bit corresponding to the channel (DMA/QDMA) in the event missed register (EDMA_TPCC_EMR, EDMA_TPCC_EMRH, or EDMA_TPCC_QEMR) and the secondary event register (EDMA_TPCC_SER, EDMA_TPCC_SERH, or EDMA_TPCC_QSER) bit gets cleared similar to a normal transfer. Future events on that channel are serviced. A dummy transfer is a legal transfer of 0 bytes.

16.2.4.3.5 Dummy Versus Null Transfer Comparison

There are some differences in the way the EDMA_TPCC logic treats a dummy versus a null transfer request. A null transfer request is an error condition, but a dummy transfer is a legal transfer of 0 bytes. A null transfer causes an error bit (E*n*) in EDMA_TPCC_EMR to get set and the E*n* bit in EDMA_TPCC_SER remains set, essentially preventing any further transfers on that channel without clearing the associated error registers.

Table 16-61 summarizes the conditions and effects of null and dummy transfer requests.

Table 16-61. Dummy and Null Transfer Request

Feature	Null TR	Dummy TR
EDMA_TPCC_EMR / EDMA_TPCC_EMRH / EDMA_TPCC_QEMR is set	Yes	No
EDMA_TPCC_SER / EDMA_TPCC_SERH / EDMA_TPCC_QSER remains set	Yes	No

Table 16-61. Dummy and Null Transfer Request (continued)

Feature	Null TR	Dummy TR
Link update (STATIC = 0 in EDMA_TPCC_OPT_n)	Yes	Yes
EDMA_TPCC_QER is set	Yes	Yes
EDMA_TPCC_IPR / EDMA_TPCC_IPRH, EDMA_TPCC_CER / EDMA_TPCC_CERH is set using early completion	Yes	Yes

16.2.4.3.6 Parameter Set Updates

When a TR is submitted for a given DMA/QDMA channel and its corresponding PaRAM set, the EDMA_TPCC is responsible for updating the PaRAM set in anticipation of the next trigger event. For events that are not final, this includes address and count updates; for final events, this includes the link update.

The specific PaRAM set entries that are updated depend on the channel's synchronization type (A-synchronized or B-synchronized) and the current state of the PaRAM set. A B-update refers to the decrementing of EDMA_TPCC_ABCNT_n[31:16] BCNT in the case of A-synchronized transfers after the submission of successive TRs. A C-update refers to the decrementing of CCNT in the case of A-synchronized transfers after BCNT TRs for EDMA_TPCC_ABCNT_n[15:0] ACNT byte transfers have submitted. For AB-synchronized transfers, a C-update refers to the decrementing of EDMA_TPCC_CCNT_n[15:0] CCNT after submission of every transfer request.

Refer to Table 16-62 for details and conditions on the parameter updates. A link update occurs when the PaRAM set is exhausted, as described in Section 16.2.4.3.7 *Linking Transfers*.

After the TR is read from the PaRAM (and is in process of being submitted to EDMA_TPTC), the following fields are updated if needed:

- A-synchronized: BCNT, CCNT, SRC, DST.
- AB-synchronized: CCNT, SRC, DST.

The following fields are not updated (except for during linking, where all fields are overwritten by the link PaRAM set):

- A-synchronized: EDMA_TPCC_ABCNT_n[15:0] ACNT, EDMA_TPCC_LNK_n[31:16] BCNTRLD, EDMA_TPCC_BIDX_n[15:0] SBIDX, EDMA_TPCC_BIDX_n[31:16] DBIDX, EDMA_TPCC_CIDX_n[15:0] SCIDX, EDMA_TPCC_CIDX_n[31:16] DCIDX, EDMA_TPCC_OPT_n, EDMA_TPCC_LNK_n[15:0]LINK.
- AB-synchronized: EDMA_TPCC_ABCNT_n[15:0] ACNT, EDMA_TPCC_ABCNT_n[31:16] BCNT, EDMA_TPCC_LNK_n[31:16] BCNTRLD, EDMA_TPCC_BIDX_n[15:0] SBIDX, EDMA_TPCC_BIDX_n[31:16] DBIDX, EDMA_TPCC_CIDX_n[15:0] SCIDX, EDMA_TPCC_CIDX_n[31:16] DCIDX, EDMA_TPCC_OPT_n, EDMA_TPCC_LNK_n[15:0]LINK.

Note

PaRAM updates only pertain to the information that is needed to properly submit the next transfer request to the EDMA_TPTC. Updates that occur while data is moved within a transfer request are tracked within the transfer controller, and is detailed in Section 16.2.4.12 *EDMA Transfer Controller (EDMA_TPTC)*. For A-synchronized transfers, the EDMA_TPCC always submits a TRP for EDMA_TPCC_ABCNT_n[15:0] ACNT bytes (EDMA_TPCC_ABCNT_n[31:16] BCNT = 1 and EDMA_TPCC_CCNT_n[15:0] CCNT = 1). For AB-synchronized transfers, the EDMA_TPCC always submits a TRP for EDMA_TPCC_ABCNT_n[15:0] ACNT bytes of BCNT arrays (EDMA_TPCC_CCNT_n[15:0] CCNT = 1). The EDMA_TPTC is responsible for updating source and destination addresses within the array based on EDMA_TPCC_ABCNT_n[15:0] ACNT and EDMA_TPCC_OPT_n[10:8] FWID. For AB-synchronized transfers, the EDMA_TPTC is also responsible to update source and destination addresses between arrays based on EDMA_TPCC_BIDX_n[15:0] SBIDX and EDMA_TPCC_BIDX_n[31:16] DBIDX.

Table 16-62 shows the details of parameter updates that occur within EDMA_TPCC for A-synchronized and AB-synchronized transfers.

Table 16-62. Parameter Updates in EDMA_TPCC (for Non-Null, Non-Dummy PaRAM Set)

	A-Synchronized Transfer			AB-Synchronized Transfer		
	B-Update	C-Update	Link Update	B-Update	C-Update	Link Update
Condition:	BCNT > 1	BCNT == 1 && CCNT > 1	BCNT == 1 && CCNT == 1	N/A	EDMA_TPCC_CCNT_n[15:0] CCNT > 1	EDMA_TPCC_CCNT_n[15:0] CCNT == 1
SRC	+= SBIDX	+= SCIDX	= Link.EDMA_TPCC_SRC_n	in EDMA_TPTC	+= SCIDX	= Link.EDMA_TPCC_SRC_n
DST	+= DBIDX	+= DCIDX	= Link.EDMA_TPCC_DST_n	in EDMA_TPTC	+= DCIDX	= Link.EDMA_TPCC_DST_n

DCIDX	None	None	= Link.EDMA_TPCC_BIDX_n[31:16] DBIDX	None	None	= Link.EDMA_TPCC_BIDX_n[31:16] DBIDX
LINK	None	None	= Link.EDMA_TPCC_LNK_n[15:0]LINK	None	None	= Link.EDMA_TPCC_LNK_n[15:0]LINK
BCNTRLD	None	None	= Link.EDMA_TPCC_LNK_n[31:16] BCNTRLD	None	None	= Link.EDMA_TPCC_LNK_n[31:16] BCNTRLD
OPT[(1)]	None	None	= LINK.EDMA_TPCC_OPT_n	None	None	= LINK.EDMA_TPCC_OPT_n

(1) In all cases, no updates occur if EDMA_TPCC_OPT_n[3] STATIC == 1 for the current PaRAM set.

Note

The EDMA_TPCC includes no special hardware to detect when an indexed address update calculation overflows/underflows. The address update will wrap across boundaries as programmed by the user. It should ensure that no transfer is allowed to cross internal port boundaries between peripherals. A single TR must target a single source/destination slave endpoint.

16.2.4.3.7 Linking Transfers

The EDMA_TPCC provides a mechanism known as linking, which allows the entire PaRAM set to be reloaded from a location within the PaRAM memory map (for both DMA and QDMA channels). Linking is especially useful for maintaining ping-pong buffers, circular buffering, and repetitive/continuous transfers with no CPU intervention. Upon completion of a transfer, the current transfer parameters are reloaded with the parameter set pointed that the 16-bit link address field of the current parameter set points to. Linking only occurs when the EDMA_TPCC_OPT_n[3] STATIC bit is cleared.

Note

It should always link a transfer (EDMA or QDMA) to another useful transfer. If it must terminate a transfer, then link the transfer to a NULL parameter set. Refer to Section 16.2.4.3.3 *Null PaRAM Set*.

The link update occurs after the current PaRAM set event parameters have been exhausted. An event's parameters are exhausted when the EDMA channel controller has submitted all of the transfers that are associated with the PaRAM set.

A link update occurs for null and dummy transfers depending on the state of the EDMA_TPCC_OPT_n[3] STATIC bit and the EDMA_TPCC_LNK_n[15:0] LINK field. In both cases (null or dummy), if the value of EDMA_TPCC_LNK_n[15:0] LINK is FFFFh, then a null PaRAM set (with all 0s and EDMA_TPCC_LNK_n[15:0] LINK set to FFFFh) is written to the current PaRAM set.
Similarly, if EDMA_TPCC_LNK_n[15:0] LINK is set to a value other than FFFFh, then the appropriate PaRAM location that EDMA_TPCC_LNK_n[15:0] LINK points to is copied to the current PaRAM set.

Once the channel completion conditions are met for an event, the transfer parameters that are located at the link address are loaded into the current DMA or QDMA channel’s associated parameter set. This indicates that the EDMA_TPCC reads the entire set (eight words) from the PaRAM set specified by EDMA_TPCC_LNK_n[15:0] LINK and writes all eight words to the PaRAM set that is associated with the current channel. Figure 16-22 shows an example of a linked transfer.

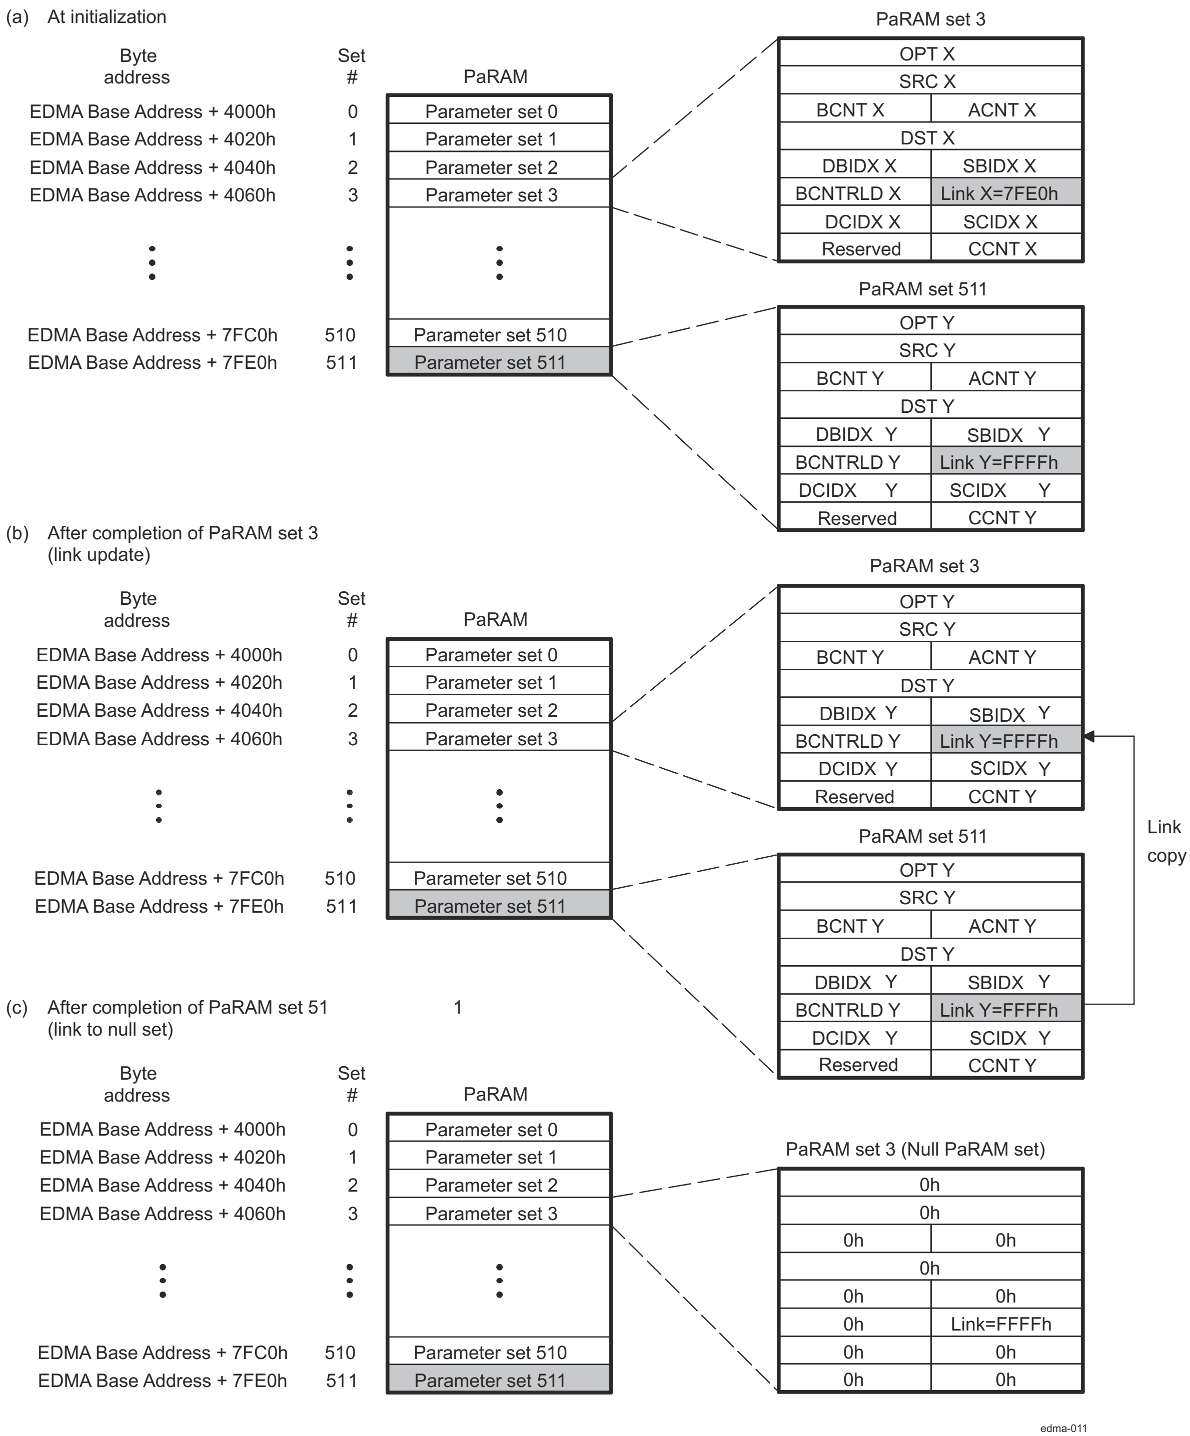

Figure 16-22. Linked Transfer

Any PaRAM set in the PaRAM can be used as a link/reload parameter set. The PaRAM sets associated with peripheral synchronization events (refer to Section 16.2.4.6 *Event, Channel, and PaRAM Mapping*) only use for linking if the corresponding events are disabled.

If a PaRAM set location is defined as a QDMA channel PaRAM set (by EDMA_TPCC_QCHMAPN_j register), then copying the link PaRAM set into the current QDMA channel PaRAM set is recognized as a trigger event. It is latched in EDMA_TPCC_QER because a write to the trigger word was performed. This feature is used to create a linked list of transfers using a single QDMA channel and multiple PaRAM sets. Refer to Section 16.2.4.4.2 *QDMA Channels*.

Linking to itself replicates the behavior of auto-initialization, thus facilitating the use of circular buffering and repetitive transfers. After an EDMA channel exhausts its current PaRAM set, it reloads all of the parameter set entries from another PaRAM set, which is initialized with values that are identical to the original PaRAM set. Figure 16-23 shows an example of a linked to self transfer. Here, the PaRAM set 511 has the link field pointing to the address of parameter set 511 (linked to self).

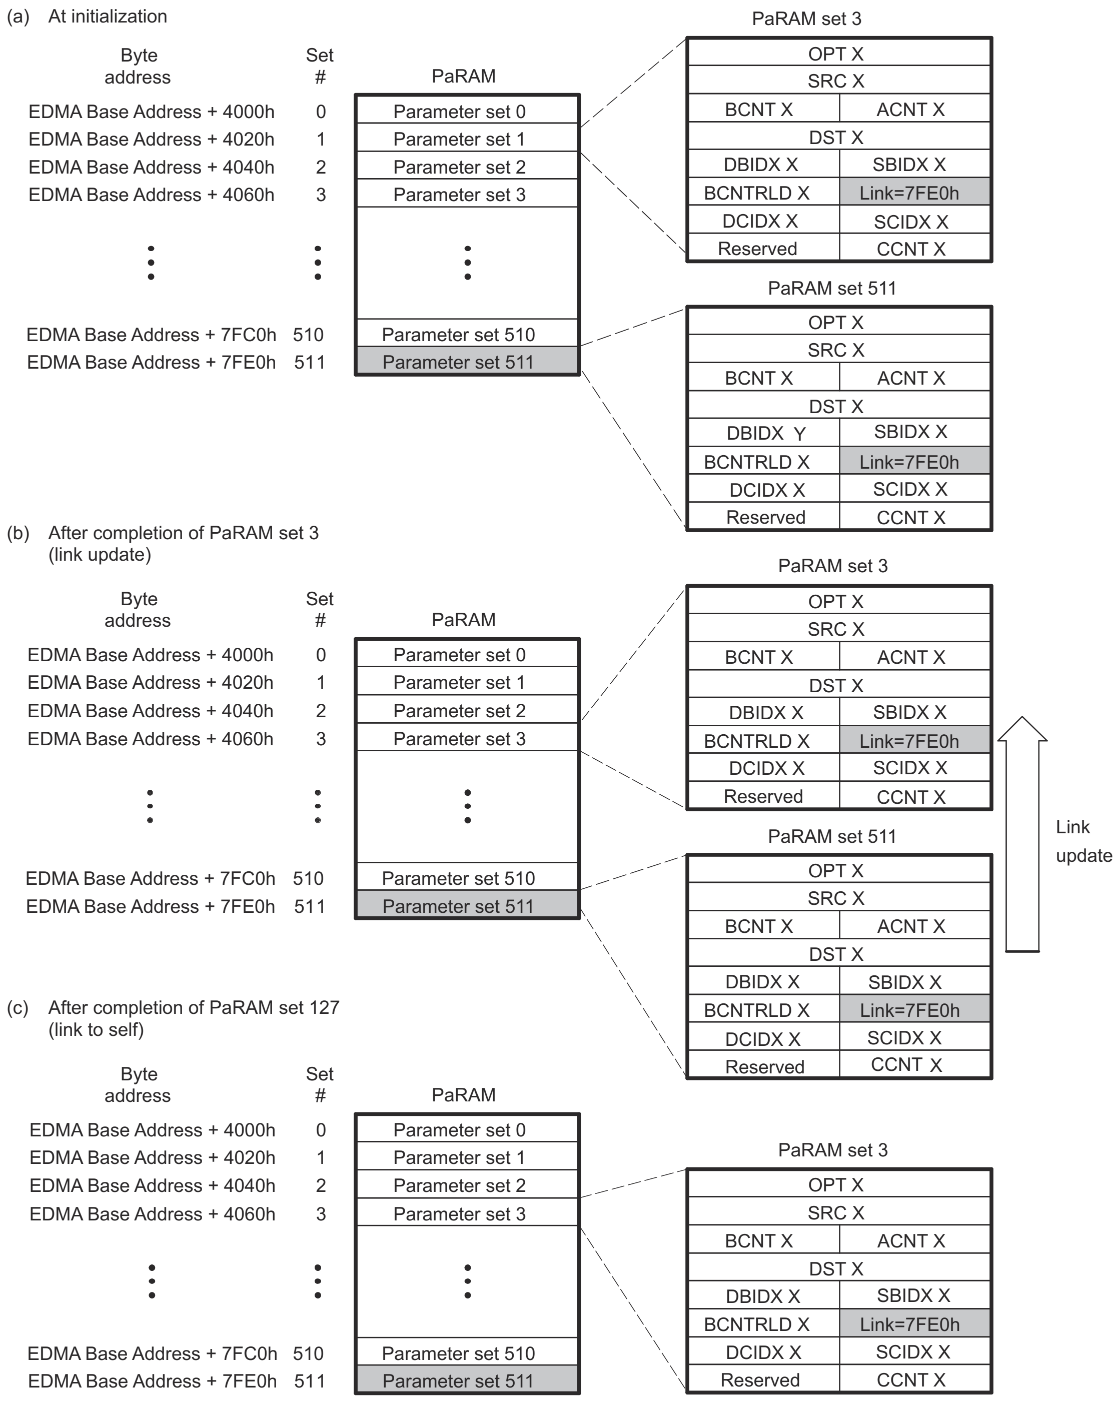

Figure 16-23. Link-to-Self Transfer

Note

If the in EDMA_TPCC_OPT_n[3] STATIC bit is set for a PaRAM set, then link updates are not performed.

16.2.4.3.8 Constant Addressing Mode Transfers/Alignment Issues

If either EDMA_TPCC_OPT_n[0] SAM or EDMA_TPCC_OPT_n[1] DAM is set (constant addressing mode), then the source or destination address must be aligned to a 256-bit aligned address, respectively, and the corresponding EDMA_TPCC_BIDX_n is an even multiple of 32 bytes (256 bits). The EDMA_TPCC does not recognize errors here, but the EDMA_TPTC asserts an error if this is not true. Refer to Section 16.2.4.12.3 *Error Generation*.

Note

The constant addressing (CONST) mode has limited applicability. The EDMA is configured for the constant addressing mode (EDMA_TPCC_OPT_n[0] SAM / EDMA_TPCC_OPT_n[1] DAM = 1) only if the transfer source or destination (on-chip memory, off-chip memory controllers, slave peripherals) support the constant addressing mode. If the constant addressing mode is not supported, the similar logical transfer can be achieved using the increment (INCR) mode (EDMA_TPCC_OPT_n[0] SAM / EDMA_TPCC_OPT_n[1] DAM =0) by appropriately programming the count and indices values.

16.2.4.3.9 Element Size

The EDMA controller does not use element-size and element-indexing. Instead, all transfers are defined in terms of all three dimensions: EDMA_TPCC_ABCNT_n[15:0] ACNT, EDMA_TPCC_ABCNT_n[31:16] BCNT, and EDMA_TPCC_CCNT_n[15:0] CCNT. An element-indexed transfer is logically achieved by programming EDMA_TPCC_ABCNT_n[15:0] ACNT to the size of the element and EDMA_TPCC_ABCNT_n[31:16] BCNT to the number of elements that need to be transferred. For example: If there are 16-bit audio data and 256 audio samples that must be transferred to a serial port, therefore the EDMA_TPCC_ABCNT_n[15:0] ACNT = 2 (2 bytes) and EDMA_TPCC_ABCNT_n[31:16] BCNT = 256.

16.2.4.4 Initiating a DMA Transfer

There are multiple ways to initiate a programmed data transfer using the EDMA_TPCC channel controller. Transfers on DMA channels are initiated by three sources.

They are listed as follows:

- **Event-triggered transfer request** (this is the typical usage of EDMA controller): A peripheral, system, or externally-generated event triggers a transfer request.
- **Manually-triggered transfer request:**The CPU manually triggers a transfer by writing a 1 to the corresponding bit in the event set registers (EDMA_TPCC_ESR / EDMA_TPCC_ESRH).
- **Chain-triggered transfer request:** A transfer is triggered on the completion of another transfer or sub-transfer.

Transfers on QDMA channels are initiated by two sources. They are as follows:

- **Auto-triggered transfer request:** Writing to the programmed trigger word triggers a transfer.
- **Link-triggered transfer requests:** Writing to the trigger word triggers the transfer when linking occurs.

16.2.4.4.1 DMA Channel

16.2.4.4.1.1 Event-Triggered Transfer Request

When an event is asserted from a peripheral or device pins, it gets latched in the corresponding bit of the event register (EDMA_TPCC_ER[31:0] E*n* = 1). For more information about peripheral events to EDMA events mapping, refer to *the device data manual*.
If the corresponding event in the event enable register (EDMA_TPCC_EER) is enabled (EDMA_TPCC_EER[31:0] E*n* = 1), then the EDMA_TPCC prioritizes and queues the event in the appropriate

event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

If the PaRAM set is valid (not a NULL set), then a transfer request packet (TRP) is submitted to the EDMA_TPTC and the EDMA_TPCC_ER[31:0] E*n* bit is cleared. At this point, a new event can be safely received by the EDMA_TPCC.

If the PaRAM set associated with the channel is a NULL set (see Section 16.2.4.3.3 *Null PaRAM Set*), then no transfer request (TR) is submitted and the corresponding EDMA_TPCC_ER[31:0] E*n* bit is cleared and simultaneously the corresponding channel bit is set in the event miss register (EDMA_TPCC_EMR[31:0] E*n* = 1) to indicate that the event was discarded due to a null TR being serviced. Good programming practices should include cleaning the event missed error before re-triggering the DMA channel.

When an event is received, the corresponding event bit in the event register is set (EDMA_TPCC_ER[31:0] E*n* = 1), regardless of the state of EDMA_TPCC_EER[31:0] E*n*. If the event is disabled when an external event is received (EDMA_TPCC_ER[31:0] E*n* = 1 and EDMA_TPCC_EER[31:0] E*n* = 0), the EDMA_TPCC_ER[31:0] E*n* bit remains set. If the event is subsequently enabled (EDMA_TPCC_EER[31:0] E*n* = 1), then the pending event is processed by the EDMA_TPCC and the TR is processed/submitted, after which the EDMA_TPCC_ER[31:0] E*n* bit is cleared.

If an event is being processed (prioritized or is in the event queue) and another sync event is received for the same channel prior to the original being cleared (EDMA_TPCC_ER[31:0] E*n* != 0), then the second event is registered as a missed event in the corresponding bit of the event missed register (EDMA_TPCC_EMR[31:0] E*n* = 1).

16.2.4.4.1.2 Manually-Triggered Transfer Request

The CPU or any peripheral device module initiates a DMA transfer by writing to the event set register EDMA_TPCC_ESR. Writing a 1 to an event bit in the EDMA_TPCC_ESR results in the event being prioritized/ queued in the appropriate event queue, regardless of the state of the EDMA_TPCC_EER[31:0] E*n* bit. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA_TPTC and the channel can be triggered again.

If the PaRAM set associated with the channel is a NULL set (see Section 16.2.4.3.3 *Null PaRAM Set*), then no transfer request (TR) is submitted and the corresponding EDMA_TPCC_ER[31:0] E*n* bit is cleared and simultaneously the corresponding channel bit is set in the event miss register EDMA_TPCC_EMR[31:0] E*n* = 1 to indicate that the event was discarded due to a null TR being serviced. Good programming practices should include clearing the event missed error before re-triggering the DMA channel.

If an event is being processed (prioritized or is in the event queue) and the same channel is manually set by a write to the corresponding channel bit of the event set register EDMA_TPCC_ESR[31:0] E*n* = 1 prior to the original being cleared EDMA_TPCC_ESR[31:0] E*n* = 0, then the second event is registered as a missed event in the corresponding bit of the event missed register EDMA_TPCC_EMR[31:0] E*n* = 1.

16.2.4.4.1.3 Chain-Triggered Transfer Request

Chaining is a mechanism by which the completion of one transfer automatically sets the event for another channel. When a chained completion code is detected, the value of which is dictated by the transfer completion code EDMA_TPCC_OPT_n[17:12] TCC of the PaRAM set associated with the channel, it results in the corresponding bit in the chained event register EDMA_TPCC_CER to be set EDMA_TPCC_CER[31:0] E[TCC] = 1).

Once a bit is set in EDMA_TPCC_CER, the EDMA_TPCC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA_TPTC and the channel can be triggered again.

If the PaRAM set associated with the channel is a NULL set (see Section 16.2.4.3.3 *Null PaRAM Set*), then no transfer request (TR) is submitted and the corresponding EDMA_TPCC_CER[31:0] E*n* bit is cleared and simultaneously the corresponding channel bit is set in the event miss register EDMA_TPCC_EMR[31:0] E*n* = 1 to indicate that the event was discarded due to a null TR being serviced. In this case, the error condition must be cleared before the DMA channel can be re-triggered. Good programming practices might include clearing the event missed error before re-triggering the DMA channel.

If a chaining event is being processed (prioritized or queued) and another chained event is received for the same channel prior to the original being cleared EDMA_TPCC_CER[31:0] E*n* != 0), then the second chained event is registered as a missed event in the corresponding channel bit of the event missed register EDMA_TPCC_EMR[31:0] E*n* = 1.

Note

Chained event registers EDMA_TPCC_CER, event registers EDMA_TPCC_ER, and event set registers EDMA_TPCC_ESR operate independently. An event E*n* can be triggered by any of the trigger sources (event-triggered, manually-triggered, or chain-triggered).

16.2.4.4.2 QDMA Channels

16.2.4.4.2.1 Auto-triggered and Link-Triggered Transfer Request

QDMA-based transfer requests are issued when a QDMA event gets latched in the QDMA event register EDMA_TPCC_QER[31:0] E*n* = 1. A bit corresponding to a QDMA channel is set in the QDMA event register EDMA_TPCC_QER when the following occurs:

- A CPU (or any device module) write occurs to a PaRAM address that is defined as a QDMA channel trigger word (programmed in the QDMA channel mapping register EDMA_TPCC_QCHMAPN_j for the particular QDMA channel and the QDMA channel is enabled via the QDMA event enable register EDMA_TPCC_QEER[31:0] E*n* = 1.
- EDMA_TPCC performs a link update on a PaRAM set address that is configured as a QDMA channel matches EDMA_TPCC_QCHMAPN_j settings and the corresponding channel is enabled via the QDMA event enable register EDMA_TPCC_QEER[31:0] E*n* = 1.

Once a bit is set in EDMA_TPCC_QER, the EDMA_TPCC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA_TPTC and the channel can be triggered again.

If a bit is already set in EDMA_TPCC_QER[31:0] E*n* = 1 and a second QDMA event for the same QDMA channel occurs prior to the original being cleared, the second QDMA event gets captured in the QDMA event miss register EDMA_TPCC_QEMR[7:0] E*n* = 1.

16.2.4.4.3 Comparison Between DMA and QDMA Channels

The primary difference between DMA and QDMA channels is the event/channel synchronization.

QDMA events are either auto-triggered or link triggered. Auto-triggering allows QDMA channels to be triggered by CPU(s) with a minimum number of linear writes to PaRAM. Link triggering allows a linked list of transfers to be executed, using a single QDMA PaRAM set and multiple link PaRAM sets.

A QDMA transfer is triggered when a CPU (or other device modules) writes to the trigger word of the QDMA channel parameter set (auto-triggered) or when the EDMA_TPCC performs a link update on a PaRAM set that has been mapped to a QDMA channel (link triggered).

Note

The CPUs triggered (manually triggered) DMA channels, in addition to writing to the PaRAM set, it is required to write to the event set register EDMA_TPCC_ESR to kick-off the transfer.

QDMA channels are typically for cases where a single event accomplishes a complete transfer since the CPU (or other device modules) must reprogram some portion of the QDMA PaRAM set in order to re-trigger the channel. QDMA transfers are programmed with EDMA_TPCC_ABCNT_n[31:0] BCNT =1 and EDMA_TPCC_CCNT_n[15:0] CCNT = 1 for A-synchronized transfers, and EDMA_TPCC_CCNT_n[15:0] CCNT = 1 for AB-synchronized transfers.

Additionally, since linking is also supported (if EDMA_TPCC_OPT_n[3] STATIC = 0) for QDMA transfers, it allows to initiate a linked list of QDMAs, so when EDMA_TPCC copies over a link PaRAM set (including the write to the trigger word), the current PaRAM set mapped to the QDMA channel automatically recognizes as a valid QDMA event and initiate another set of transfers as specified by the linked set.

16.2.4.5 Completion of a DMA Transfer

A parameter set for a given channel is complete when the required number of transfer requests is submitted (based on receiving the number of synchronization events). The expected number of TRs for a non-null/non-dummy transfer is shown in Table 16-63 for both synchronization types along with state of the PaRAM set prior to the final TR being submitted. When the counts (EDMA_TPCC_ABCNT_n[31:0] BCNT and/or EDMA_TPCC_CCNT_n[15:0] CCNT) are this value, the next TR results in:

- Final chaining or interrupt codes sent by the transfer controllers (instead of intermediate).
- Link updates (linking to either null or another valid link set).

Table 16-63. Expected Number of Transfers for Non-Null Transfer

Sync Mode	Counts at time 0	Total # Transfers	Counts prior to final TR
A-synchronized	ACNT BCNT CCNT	(BCNT × CCNT) TRs of ACNT bytes each	EDMA_TPCC_ABCNT_n[31:0] BCNT == 1 && EDMA_TPCC_CCNT_n[15:0] CCNT == 1
AB-synchronized	ACNT BCNT CCNT	CCNT TRs for ACNT × BCNT bytes each	EDMA_TPCC_CCNT_n[15:0] CCNT == 1

The PaRAM OPT field must program with a specific transfer completion code TCC or EDMA_TPCC_OPT_n[17:12] TCC along with the other EDMA_TPCC_OPT_n fields ([22] TCCHEN, [20] TCINTEN, [23] ITCCHEN, and [21] ITCINTEN bits) to indicate whether the completion code is to be used for generating a chained event or/and for generating an interrupt upon completion of a transfer.

The specific EDMA_TPCC_OPT_n[17:12] TCC value (6-bit binary value) programmed dictates which of the 64-bits in the chain event register EDMA_TPCC_CER [TCC] and/or interrupt pending register EDMA_TPCC_IPR [TCC] is set.

It can selectively program whether the transfer controller sends back completion codes on completion of the final transfer request (TR) of a parameter set EDMA_TPCC_OPT_n[22] TCCHEN or EDMA_TPCC_OPT_n[20] TCINTEN, for all but the final transfer request (TR) of a parameter set EDMA_TPCC_OPT_n[23] ITCCHEN or EDMA_TPCC_OPT_n[21] ITCINTEN), or for all TRs of a parameter set (both). Refer to Section 16.2.4.8 *Chaining EDMA Channels* for details on chaining (intermediate/final chaining) and Section 16.2.4.9 *EDMA Interrupts* for details on intermediate/final interrupt completion.

A completion detection interface exists between the EDMA channel controller and transfer controller(s). This interface sends back information from the transfer controller to the channel controller to indicate that a specific transfer is completed. Completion of a transfer is used for generating chained events and/or generating interrupts to the CPU(s).

All DMA/QDMA PaRAM sets must also specify a link address value. For repetitive transfers such as ping-pong buffers, the link address value must point to another predefined PaRAM set. Alternatively, a non-repetitive transfer must set the link address value to the null link value. The null link value is defined as FFFFh. Refer to Section 16.2.4.3.7 *Linking Transfers* for more details.

Note

Any incoming events that are mapped to a null PaRAM set results in an error condition. The error condition must clear before the corresponding channel is used again. Refer to Section 16.2.4.3.5 *Dummy Versus Null Transfer Comparison*.

There are three ways the EDMA_TPCC gets updated/informed about a transfer completion: normal completion, early completion, and dummy/null completion. This applies to both chained events and completion interrupt generation.

16.2.4.5.1 Normal Completion

In normal completion mode EDMA_TPCC_OPT_n[11] TCCMODE = 0, the transfer or sub-transfer is considered to be complete when the EDMA channel controller receives the completion codes from the EDMA transfer controller. In this mode, the completion code to the channel controller is posted by the transfer controller after it receives a signal from the destination peripheral. Normal completion is typically used to generate an interrupt to inform the CPU that a set of data is ready for processing.

16.2.4.5.2 Early Completion

In early completion mode EDMA_TPCC_OPT_n[11] TCCMODE = 1, the transfer is considered to be complete when the EDMA channel controller submits the transfer request (TR) to the EDMA transfer controller. In this mode, the channel controller generates the completion code internally. Early completion is typically useful for chaining, as it allows subsequent transfers to be chained-triggered while the previous transfer is still in progress within the transfer controller, maximizing the overall throughput of the set of the transfers.

16.2.4.5.3 Dummy or Null Completion

This is a variation of early completion. Dummy or null completion is associated with a dummy set Section 16.2.4.3.4 or null set Section 16.2.4.3.3. In both cases, the EDMA channel controller does not submit the associated transfer request to the EDMA transfer controller(s). However, if the set (dummy/null) has the OPT field programmed to return completion code (intermediate/final interrupt/chaining completion), then it sets the appropriate bits in the interrupt pending registers EDMA_TPCC_IPR and EDMA_TPCC_IPRH or chained event register EDMA_TPCC_CER and EDMA_TPCC_CERH. The internal early completion path is used by the channel controller to return the completion codes internally (that is, EDMA_TPCC generates the completion code).

16.2.4.6 Event, Channel, and PaRAM Mapping

Several of the 64 DMA channels are tied to a specific hardware event, thus allowing events from device peripherals or external hardware (via the dma_evt[4:1] pins) to trigger transfers. A DMA channel typically requests a data transfer when it receives its event (apart from manually-triggered, chain-triggered, and other transfers). The amount of data transferred per synchronization event depends on the channel's configuration (EDMA_TPCC_ABCNT_n[15:0] ACNT, EDMA_TPCC_ABCNT_n[31:16] BCNT, EDMA_TPCC_CCNT_n[15:0] CCNT, etc.) and the synchronization type (A-synchronized or AB-synchronized).

The association of an event to a channel is fixed within the EDMA Channel Controller, that is, each DMA channel has one specific event associated with it. The EDMA event crossbar can be used to select which level events (of which there are more than 64) are mapped to the 64 input events to the EDMA Channel Controller. The default mapping and event crossbar mapping are defined in Section 16.2.3.1, *EDMA Requests to the EDMA Controller*. The event crossbar mapping is controlled by the device Control Modules registers refer to *IRQ_CROSSBAR Module Functional Description*, in *Control Module*.

In an application, if a channel does not use the associated synchronization event or if it does not have an associated synchronization event (unused), that channel can be used for manually-triggered or chained-triggered transfers, for linking/reloading, or as a QDMA channel.

16.2.4.6.1 DMA Channel to PaRAM Mapping

The mapping between the DMA channel numbers and the PaRAM sets is programmable (see Table 16-59). The DMA channel mapping registers EDMA_TPCC_DCHMAPN_m in the EDMA_TPCC provide programmability that allows the DMA channels to be mapped to any of the PaRAM sets in the PaRAM memory map. Figure 16-24 illustrates the use of EDMA_TPCC_DCHMAPN_m. There is one EDMA_TPCC_DCHMAPN_m register per channel.

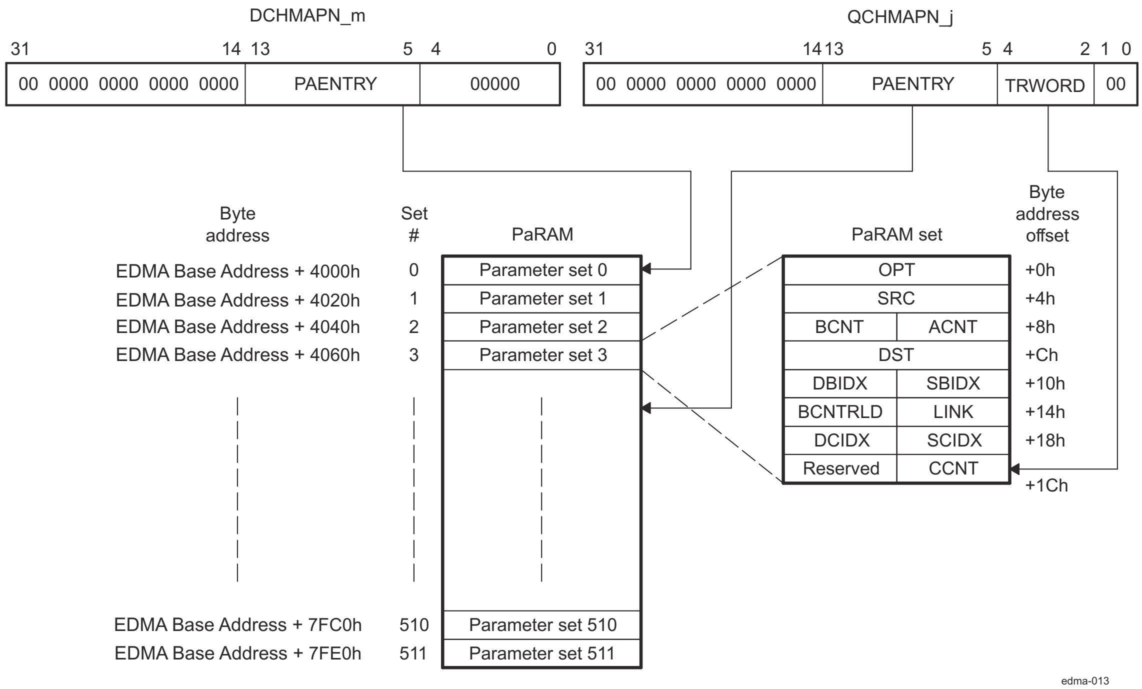

Figure 16-24. DMA Channel and QDMA Channel to PaRAM Mapping

16.2.4.6.2 QDMA Channel to PaRAM Mapping

The mapping between the QDMA channels and the PaRAM sets is programmable. The QDMA channel mapping register EDMA_TPCC_QCHMAPN_j in the EDMA_TPCC allows to map the QDMA channels to any of the PaRAM sets in the PaRAM memory map. Figure 16-25 illustrates the use of EDMA_TPCC_QCHMAPN_j.

EDMA_TPCC_QCHMAPN_j[4:2] TRWORD bit-field allows to program the trigger word in the PaRAM set for the QDMA channel. A trigger word is one of the eight words in the PaRAM set. For a QDMA transfer to occur, a valid TR synchronization event for EDMA_TPCC is a write to the trigger word in the PaRAM set pointed to by EDMA_TPCC_QCHMAPN_j for a particular QDMA channel. By default, QDMA channels are mapped to PaRAM set 0.

It must appropriately re-map PaRAM set 0 before use.

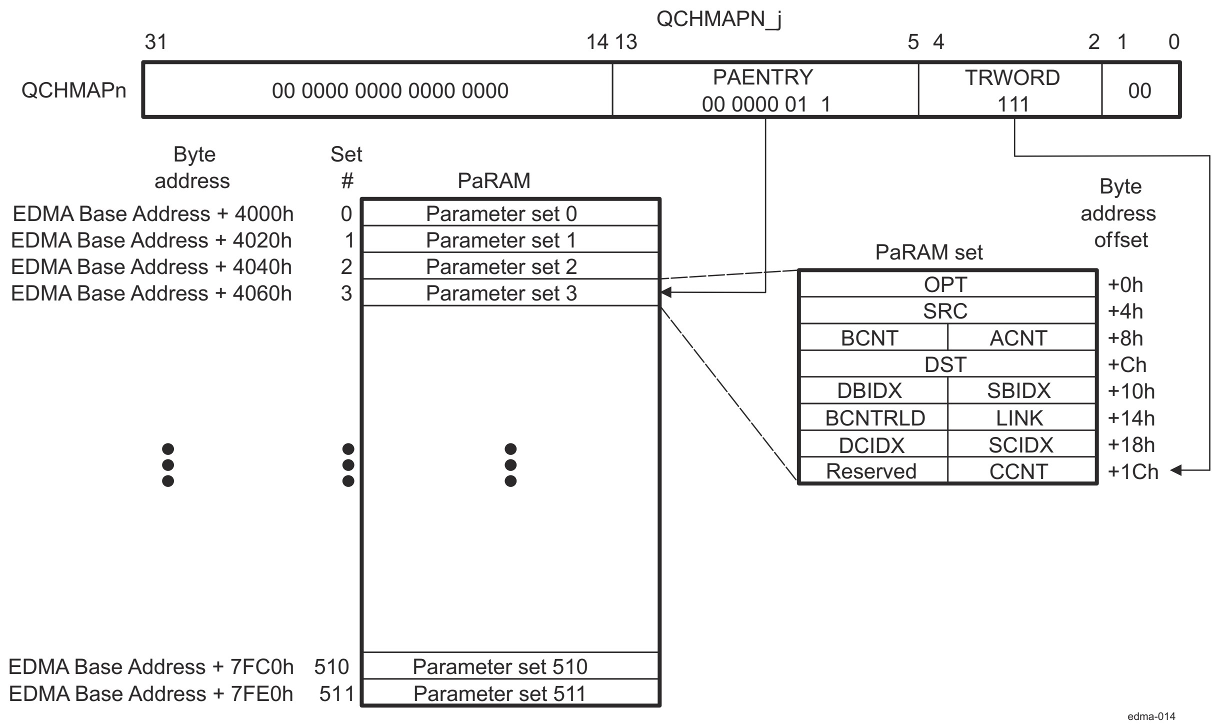

Figure 16-25. QDMA Channel to PaRAM Mapping

16.2.4.7 EDMA Channel Controller Regions

The EDMA channel controller divides its address space into eight regions. Individual channel resources are assigned to a specific region, where each region is typically assigned to a specific device module uses the EDMA controller.

Application software can use regions or to ignore them altogether. It can be used active memory protection in conjunction with regions so that only a specific device module which uses the EDMA (for example, privilege identification) or privilege level (for example, user vs. supervisor) is allowed access to a given region, and thus to a given DMA or QDMA channel. This allows robust system-level DMA code where each EDMA initiator only modifies the state of the assigned resources. Memory protection is described in Section 16.2.4.10 *Memory Protection*.

16.2.4.7.1 Region Overview

The EDMA channel controller memory-mapped registers are divided in three main categories:

1. Global registers
2. Global region channel registers
3. Shadow region channel registers

The global registers are located at a single/fixed location in the EDMA_TPCC memory map. These registers control EDMA resource mapping and provide debug visibility and error tracking information.

The channel registers (including DMA, QDMA, and interrupt registers) are accessible via the global channel region address range, or in the shadow *n* channel region address range(s). For example, the event enable register EDMA_TPCC_EER is visible at the global address of EDMA Base Address + 1020h or region addresses of EDMA Base Address + 2020h for region 0, EDMA Base Address + 2220h for region 1, … EDMA Base Address + 2E20h for region 7.

The DMA region access enable registers EDMA_TPCC_DRAEM_k and the QDMA region access enable registers EDMA_TPCC_QRAEN_k control the underlying control register bits that are accessible via the shadow region address space (except for EDMA_TPCC_IEVAL and EDMA_TPCC_IEVAL_RN_k registers). Table 16-64 lists the registers in the shadow region memory map. Refer to EDMA_TPCC register summary Table 16-80 for the complete global and shadow region memory maps.

Table 16-64. Shadow Region Registers

EDMA_TPCC_DRAEM_k	EDMA_TPCC_DRAEHM_k	EDMA_TPCC_QRAEN_k
EDMA_TPCC_ER	EDMA_TPCC_ERH	EDMA_TPCC_QER
EDMA_TPCC_ECR	EDMA_TPCC_ECRH	EDMA_TPCC_QEER
EDMA_TPCC_ESR	EDMA_TPCC_ESRH	EDMA_TPCC_QEECR

Figure 16-26 illustrates the conceptual view of the regions.

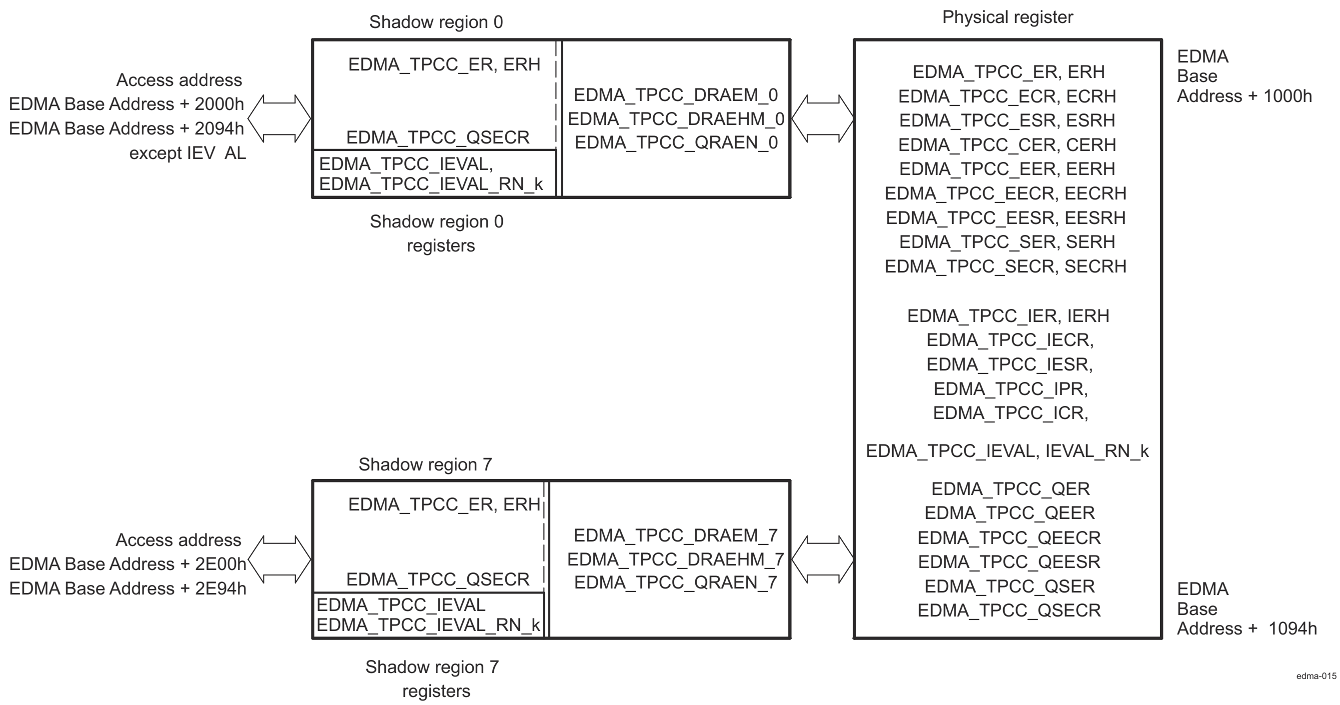

Figure 16-26. Shadow Region Registers

16.2.4.7.2 Channel Controller Regions

There are eight EDMA shadow regions (and associated memory maps). Associated with each shadow region are a set of registers defining which channels and interrupt completion codes belong to that region. These registers are user-programmed per region to assign ownership of the DMA/QDMA channels to a region.

- EDMA_TPCC_DRAEM_k and EDMA_TPCC_DRAEHM_k: One register pair exists for each of the shadow regions. The number of bits in each register pair matches the number of DMA channels (64 DMA channels). These registers need to be programmed to assign ownership of DMA channels and interrupt (or EDMA_TPCC_OPT_n[17:12] TCC codes) to the respective region. Accesses to DMA and interrupt registers via the shadow region address view are filtered through the DRAEM/DRAEHM pair. A value of 1 in the corresponding EDMA_TPCC_DRAEM_k[31:0] / EDMA_TPCC_DRAEHM_k[31:0] bit implies that the corresponding DMA interrupt channel is accessible; a value of 0 in the corresponding EDMA_TPCC_DRAEM_k[31:0] / EDMA_TPCC_DRAEHM_k[31:0] bit forces writes to be discarded and returns a value of 0 for reads.
- EDMA_TPCC_QRAEN_k: One register exists for every region. The number of bits in each register matches the number of QDMA channels (4 QDMA channels). These registers must be programmed to assign ownership of QDMA channels to the respective region. To enable a channel in a shadow region using shadow region 0 EDMA_TPCC_QEER, the corresponding bits in QRAE must be set or writing into EDMA_TPCC_QEESR there will be no the desired effect.
- EDMA_TPCC_MPPAN_k and EDMA_TPCC_MPPAG: One register exists for every region. This register defines the privilege level, requestor, and types of accesses allowed to a region's memory-mapped registers.

It is typical for an application to have a unique assignment of QDMA/DMA channels (and, therefore, a given bit position) to a given region.

The use of shadow regions allows restricted access to EDMA resources (DMA channels, QDMA channels, TCC, interrupts) by tasks in a system by setting or clearing bits in the EDMA_TPCC_DRAEM_k / EDMA_TPCC_QRAEN_k registers.

If exclusive access to any given channel / TCC code is required for a region, then only that region's EDMA_TPCC_DRAEM_k / EDMA_TPCC_QRAEN_k have the associated bit set.

Example 16-1. Resource Pool Division Across Two Regions

This example illustrates a resource pool division across two regions, assuming region 0 must be allocated 16 DMA channels (0-15) and 1 QDMA channel (0) and 32 TCC codes (0-15 and 48-63).

Region 1 needs to be allocated 16 DMA channels (16-32) and the remaining 7 QDMA channels (1-7) and TCC codes (16-47).

EDMA_TPCC_DRAEM_k should be equal to the OR of the bits that are required for the DMA channels and the TCC codes:

```
Region 0: DRAEHM, DRAEM = 0xFFFF0000, 0x0000FFFF QRAEN = 0x0000001
Region 1: DRAEHM, DRAEM = 0x0000FFFF, 0xFFFF0000 QRAEN = 0x00000FE
```

16.2.4.7.3 Region Interrupts

In addition to the EDMA_TPCC global completion interrupt, there is an additional completion interrupt line that is associated with every shadow region. Along with the interrupt enable register EDMA_TPCC_IER, DRAEM acts as a secondary interrupt enable for the respective shadow region interrupts. Refer to Table 16-57 *Hardware Request* for more information about EDMA Interrupts.

16.2.4.8 Chaining EDMA Channels

The channel chaining capability for the EDMA allows the completion of an EDMA channel transfer to trigger another EDMA channel transfer. The purpose is to allow the ability to chain several events through one event occurrence.

Chaining is different from linking (Section 16.2.4.3.7 *Linking Transfers*). The EDMA link feature reloads the current channel parameter set with the linked parameter set. The EDMA chaining feature does not modify or update any channel parameter set. It provides a synchronization event to the chained channel (see Section 16.2.4.4.1.3 *Chain-Triggered Transfer Request*).

Chaining is achieved at either final transfer completion or intermediate transfer completion, or both, of the current channel. Consider a channel *m* (DMA/QDMA) required to chain to channel *n*. Channel number *n* (0-63) needs to be programmed into the EDMA_TPCC_OPT_n[17:12] TCC bit-field of channel *m* channel options parameter (OPT) set.

- If final transfer completion chaining EDMA_TPCC_OPT_n[22] TCCHEN = 1 is enabled, the chain-triggered event occurs after the submission of the last transfer request of channel *m* is either submitted or completed (depending on early or normal completion).
- If intermediate transfer completion chaining EDMA_TPCC_OPT_n[23] ITCCHEN = 1 is enabled, the chain-triggered event occurs after every transfer request, except the last of channel *m* is either submitted or completed (depending on early or normal completion).
- If both final and intermediate transfer completion chaining (EDMA_TPCC_OPT_n[22] TCCHEN = 1 and EDMA_TPCC_OPT_n[23] ITCCHEN = 1) are enabled, then the chain-trigger event occurs after every transfer request is submitted or completed (depending on early or normal completion).

Table 16-65 illustrates the number of chain event triggers occurring in different synchronized scenarios. Consider channel 31 programmed with EDMA_TPCC_ABCNT_n[15:0] ACNT = 3, EDMA_TPCC_ABCNT_n[31:16] BCNT = 4, EDMA_TPCC_CCNT_n[15:0] CCNT = 5, and EDMA_TPCC_OPT_n[17:12] TCC = 30.

Table 16-65. Chain Event Triggers

	(Number of chained event triggers on channel 30)	
Options	**A-Synchronized**	**AB-Synchronized**
EDMA_TPCC_OPT_n[22] TCCHEN = 1, EDMA_TPCC_OPT_n[23] ITCCHEN = 0	1 (Owing to the last TR)	1 (Owing to the last TR)
EDMA_TPCC_OPT_n[22] TCCHEN = 0, EDMA_TPCC_OPT_n[23] ITCCHEN = 1	19 (Owing to all but the last TR)	4 (Owing to all but the last TR)

Table 16-65. Chain Event Triggers (continued)

	(Number of chained event triggers on channel 30)	
Options	**A-Synchronized**	**AB-Synchronized**
EDMA_TPCC_OPT_n[22] TCCHEN = 1, EDMA_TPCC_OPT_n[23] ITCCHEN = 1	20 (Owing to a total of 20 TRs)	5 (Owing to a total of 5 TRs)

16.2.4.9 EDMA Interrupts

The EDMA interrupts are divided into 2 categories: transfer completion interrupts and error interrupts.

There are nine region interrupts, eight shadow regions and one global region. The transfer completion interrupts are listed in Table 16-66. The transfer completion interrupts and the error interrupts from the transfer controllers are all routed to the device interrupt controllers INTCs through the inputs of the IRQ_CROSSBAR module.

Table 16-66. EDMA Transfer Completion Interrupts

Name	Description
EDMA_TPCC_INT0	EDMA_TPCC Transfer Completion Interrupt Shadow Region 0
EDMA_TPCC_INT1	EDMA_TPCC Transfer Completion Interrupt Shadow Region 1
EDMA_TPCC_INT2	EDMA_TPCC Transfer Completion Interrupt Shadow Region 2
EDMA_TPCC_INT3	EDMA_TPCC Transfer Completion Interrupt Shadow Region 3
EDMA_TPCC_INT4	EDMA_TPCC Transfer Completion Interrupt Shadow Region 4
EDMA_TPCC_INT5	EDMA_TPCC Transfer Completion Interrupt Shadow Region 5
EDMA_TPCC_INT6	EDMA_TPCC Transfer Completion Interrupt Shadow Region 6
EDMA_TPCC_INT7	EDMA_TPCC Transfer Completion Interrupt Shadow Region 7

Table 16-67. EDMA Error Interrupts

Name	Description
EDMA_TPCC_ERRINT	EDMA_TPCC Error Interrupt
EDMA_TPCC_MPINT	EDMA_TPCC Memory Protection Interrupt
EDMA_TC0_ERRINT	TC0 Error Interrupt
EDMA_TC1_ERRINT	TC1 Error Interrupt

16.2.4.9.1 Transfer Completion Interrupts

The EDMA_TPCC is responsible for generating transfer completion interrupts to the CPU(s) (and other EDMA masters). The EDMA generates a single completion interrupt per shadow region, as well as one for the global region on behalf of all 64 channels. The various control registers and bit fields facilitate EDMA interrupt generation.

The software architecture must either use the global interrupt or the shadow interrupts, but not both.

The transfer completion code EDMA_TPCC_OPT_n[17:12] TCC value is directly mapped to the bits of the interrupt pending register EDMA_TPCC_IPR / EDMA_TPCC_IPRH.

For example, if EDMA_TPCC_OPT_n[17:12] TCC = 10 0001b, EDMA_TPCC_IPRH[1] is set after transfer completion, and results in interrupt generation to the CPU(s) if the completion interrupt is enabled for the CPU. See Section 16.2.4.9.1.1 *Enabling Transfer Completion Interrupts* for details about enabling EDMA transfer completion interrupts.

When a completion code is returned (as a result of early or normal completions), the corresponding bit in EDMA_TPCC_IPR / EDMA_TPCC_IPRH registers is set if transfer completion interrupt (final/intermediate) is enabled in the channel options parameter (OPT) for a PaRAM set associated with the transfer.

Table 16-68. Transfer Complete Code (TCC) to EDMA_TPCC Interrupt Mapping

TCC values in EDMA_TPCC_OPT_n[17:12] TCC (EDMA_TPCC_OPT_n[20] TCINTEN / EDMA_TPCC_OPT_n[21] ITCINTEN = 1)	EDMA_TPCC_IPR Bit Set	TCC values in EDMA_TPCC_OPT_n[17:12] TCC (EDMA_TPCC_OPT_n[20] TCINTEN / EDMA_TPCC_OPT_n[21] ITCINTEN = 1)	EDMA_TPCC_IPRH Bit Set(1)
0	EDMA_TPCC_IPR[0]	20h	EDMA_TPCC_IPR[32] / EDMA_TPCC_IPRH[0]
1	EDMA_TPCC_IPR[1]	21h	EDMA_TPCC_IPR[33] / EDMA_TPCC_IPRH[1]
2h	EDMA_TPCC_IPR[2]	22h	EDMA_TPCC_IPR[34] / EDMA_TPCC_IPRH[2]
3h	EDMA_TPCC_IPR[3]	23h	EDMA_TPCC_IPR[35] / EDMA_TPCC_IPRH[3]
4h	EDMA_TPCC_IPR[4]	24h	EDMA_TPCC_IPR[36] / EDMA_TPCC_IPRH[4]
...	...	...	...
1Eh	EDMA_TPCC_IPR[30]	3Eh	EDMA_TPCC_IPR[62] / EDMA_TPCC_IPRH[30]
1Fh	EDMA_TPCC_IPR[31]	3Fh	EDMA_TPCC_IPR[63] / EDMA_TPCC_IPRH[31]

(1) Bit fields EDMA_TPCC_IPR [32-63] correspond to bits 0 to 31 in EDMA_TPCC_IPRH, respectively.

The transfer completion code (TCC) can program to any value for a DMA/QDMA channel. A direct relation between the channel number and the transfer completion code value does not need to exist. This allows multiple channels having the same transfer completion code value to cause a CPU to execute the same interrupt service routine (ISR) for different channels.

If the channel is used in the context of a shadow region and it intends for the shadow region interrupt to be asserted, then ensure that the bit corresponding to the TCC code is enabled in EDMA_TPCC_IER / EDMA_TPCC_IERH and in the corresponding shadow region's DMA region access registers (EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k).

Interrupt generation can be enabled at either final transfer completion or intermediate transfer completion, or both. Consider channel *m* as an example.

- If the final transfer interrupt (EDMA_TPCC_OPT_n[20] TCINTEN = 1) is enabled, the interrupt occurs after the last transfer request of channel *m* is either submitted or completed (depending on early or normal completion).
- If the intermediate transfer interrupt (EDMA_TPCC_OPT_n[21] ITCINTEN = 1) is enabled, the interrupt occurs after every transfer request, except the last TR of channel *m* is either submitted or completed (depending on early or normal completion).
- If both final and intermediate transfer completion interrupts (EDMA_TPCC_OPT_n[20] TCINTEN = 1, and EDMA_TPCC_OPT_n[21] ITCINTEN = 1) are enabled, then the interrupt occurs after every transfer request is submitted or completed (depending on early or normal completion).

Table 16-69 shows the number of interrupts that occur in different synchronized scenarios. Consider channel 31, programmed with ABCNT_n[15:0] ACNT = 3, EDMA_TPCC_ABCNT_n[31:16] BCNT = 4, EDMA_TPCC_CCNT_n[15:0]CCNT = 5, and EDMA_TPCC_OPT_n[17:12] TCC = 30.

Table 16-69. Number of Interrupts

Options	A-Synchronized	AB-Synchronized
EDMA_TPCC_OPT_n[20] TCINTEN = 1, EDMA_TPCC_OPT_n[21] ITCINTEN = 0	1 (Last TR)	1 (Last TR)
EDMA_TPCC_OPT_n[20] TCINTEN = 0, EDMA_TPCC_OPT_n[21] ITCINTEN = 1	19 (All but the last TR)	4 (All but the last TR)

Table 16-69. Number of Interrupts (continued)

Options	A-Synchronized	AB-Synchronized
EDMA_TPCC_OPT_n[20] TCINTEN = 1, EDMA_TPCC_OPT_n[21] ITCINTEN = 1	20 (All TRs)	5 (All TRs)

16.2.4.9.1.1 Enabling Transfer Completion Interrupts

For the EDMA channel controller to assert a transfer completion to the external environment, the interrupts must be enabled in the EDMA_TPCC. This is in addition to setting up the EDMA_TPCC_OPT_n[20] TCINTEN and EDMA_TPCC_OPT_n[21] ITCINTEN bits of the associated PaRAM set.

The EDMA channel controller has interrupt enable registers EDMA_TPCC_IER / EDMA_TPCC_IERH and each bit location in EDMA_TPCC_IER / EDMA_TPCC_IERH serves as a primary enable for the corresponding interrupt pending registers EDMA_TPCC_IPR / EDMA_TPCC_IPRH.

All of the interrupt registers (EDMA_TPCC_IER, EDMA_TPCC_IESR, EDMA_TPCC_IECR, and EDMA_TPCC_IPR) are either manipulated from the global DMA channel region, or by the DMA channel shadow regions. The shadow regions provide a view to the same set of physical registers that are in the global region.

The EDMA channel controller has a hierarchical completion interrupt scheme that uses a single set of interrupt pending registers EDMA_TPCC_IPR / EDMA_TPCC_IPRH and single set of interrupt enable registers EDMA_TPCC_IER / EDMA_TPCC_IERH. The programmable DMA region access enable registers EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k provides a second level of interrupt masking. The global region interrupt output is gated based on the enable mask that is provided by EDMA_TPCC_IER / EDMA_TPCC_IERH, see Figure 16-27

The region interrupt outputs are gated by EDMA_TPCC_IER and the specific EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k associated with the region.

Figure 16-27 shows the Interrupt diagram of the EDMA controller.

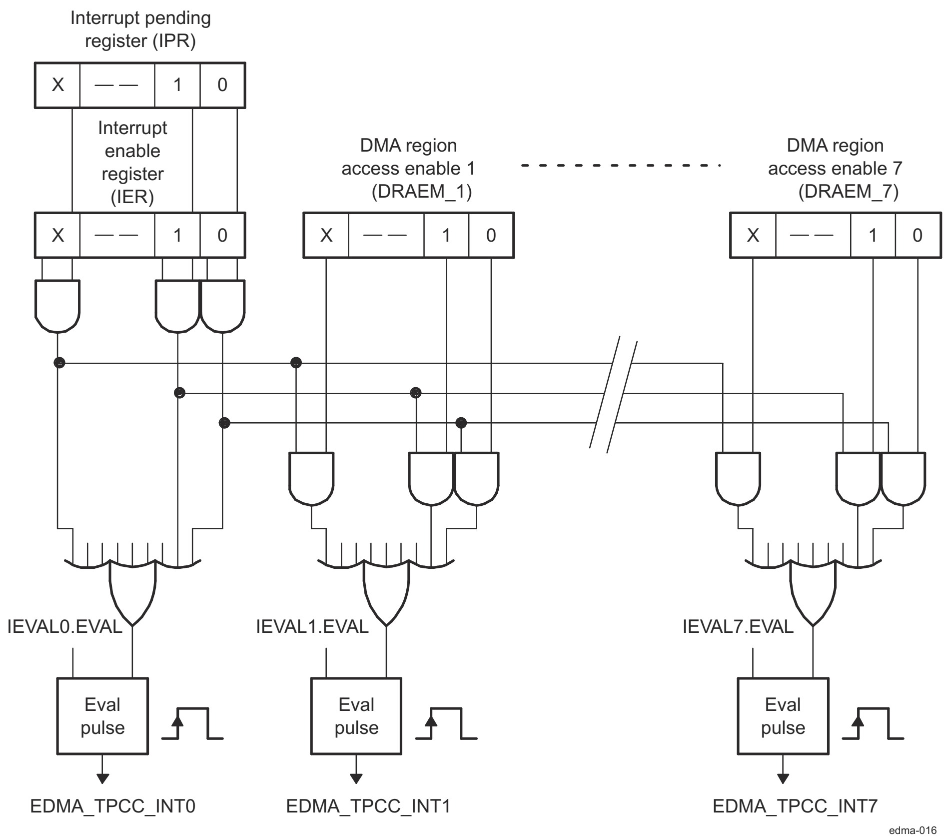

Figure 16-27. Interrupt Diagram

The EDMA_TPCC generates the transfer completion interrupts that are associated with each shadow region, the following conditions must be true:

- EDMA_TPCC_INT0: (EDMA_TPCC_IPR[0] E0 & EDMA_TPCC_IER[0] E0 & EDMA_TPCC_DRAEM_k.DRAEM_0[0] E0) | (EDMA_TPCC_IPR[1] E1 & EDMA_TPCC_IER[1] E1 & EDMA_TPCC_DRAEM_k.DRAEM_0[1] E1) | …|(EDMA_TPCC_IPRH[31] E63 & EDMA_TPCC_IERH[31] E63 & EDMA_TPCC_DRAEHM_k.DRAEHM_0[31] E63)
- EDMA_TPCC_INT1: (EDMA_TPCC_IPR[0] E0 & EDMA_TPCC_IER[0] E0 & EDMA_TPCC_DRAEM_k.DRAEM_1[0] E0) | (EDMA_TPCC_IPR[1] E1 & EDMA_TPCC_IER[1] E1 & EDMA_TPCC_DRAEM_k.DRAEM_1[1] E1) | …| (EDMA_TPCC_IPRH[31] E63 & EDMA_TPCC_IERH[31] E63 & EDMA_TPCC_DRAEHM_k.DRAEHM_1[31] E63)
- EDMA_TPCC_INT2: (EDMA_TPCC_IPR[0] E0 & EDMA_TPCC_IER[0] E0 & EDMA_TPCC_DRAEM_k.DRAEM_2[0] E0) | (EDMA_TPCC_IPR[1] E1 & EDMA_TPCC_IER[1] E1 & EDMA_TPCC_DRAEM_k.DRAEM_2[1] E1) | …|(EDMA_TPCC_IPRH[31] E63 & EDMA_TPCC_IERH[31] E63 & EDMA_TPCC_DRAEHM_k.DRAEHM_2[31] E63)....
- Up to EDMA_TPCC_INT7: (EDMA_TPCC_IPR[0] E0 & EDMA_TPCC_IER[0] E0 & EDMA_TPCC_DRAEM_k.DRAEM_7[0] E0) | (EDMA_TPCC_IPR[1] E1 & EDMA_TPCC_IER[1] E1 & EDMA_TPCC_DRAEM_k.DRAEM_7[1] E1) | …|(EDMA_TPCC_IPRH[31] E63 & EDMA_TPCC_IERH[31] E63 & EDMA_TPCC_DRAEHM_k.DRAEHM_7[31] E63)

Note

The EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k for all regions are expected to be set up at system initialization and to remain static for an extended period of time. The interrupt enable registers are used for dynamic enable/disable of individual interrupts.

Because there is no relation between the EDMA_TPCC_OPT_n[17:12] TCC value and the DMA/ QDMA channel, it is possible, the DMA channel 0 to have the EDMA_TPCC_OPT_n[17:12] TCC = 63 in its associated PaRAM set. This mean that if a transfer completion interrupt is enabled (EDMA_TPCC_OPT_n[20] TCINTEN or EDMA_TPCC_OPT_n[21] ITCINTEN is set), then based on the TCC value, EDMA_TPCC_IPRH[31] E63 is set up on completion. For proper channel operations and interrupt generation using the shadow region map - program the EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k that is associated with the shadow region to have read/write access to both bit 0 (corresponding to channel 0) and bit 63 (corresponding to EDMA_TPCC_IPRH bit that is set upon completion).

16.2.4.9.1.2 Clearing Transfer Completion Interrupts

Transfer completion interrupts that are latched to the interrupt pending registers (EDMA_TPCC_IPR / EDMA_TPCC_IPRH) are cleared by writing a 1 to the corresponding bit in the interrupt pending clear register (EDMA_TPCC_ICR / EDMA_TPCC_ICRH). For example, a write of 1 to EDMA_TPCC_ICR[0] E0 clears a pending interrupt in EDMA_TPCC_IPR[0] E0.

If an incoming transfer completion code TCC (EDMA_TPCC_OPT_n[17:12] TCC) gets latched to a bit in EDMA_TPCC_IPR / EDMA_TPCC_IPRH, then additional bits that get set due to a subsequent transfer completion does not result in asserting the EDMA_TPCC completion interrupt. In order for the completion interrupt to be pulsed, the required transition is from a state where no enabled interrupts are set to a state where at least one enabled interrupt is set.

16.2.4.9.2 EDMA Interrupt Servicing

Upon completion of a transfer (early or normal completion), the EDMA channel controller sets the appropriate bit in the interrupt pending registers (EDMA_TPCC_IPR / EDMA_TPCC_IPRH), as the transfer completion codes specify. If the completion interrupts are appropriately enabled, then the CPU enters the interrupt service routine (ISR) when the completion interrupt is asserted.

After servicing the interrupt, the ISR should clear the corresponding bit in EDMA_TPCC_IPR/ EDMA_TPCC_IPRH, thereby enabling recognition of future interrupts. The EDMA_TPCC only asserts additional completion interrupts when all EDMA_TPCC_IPR / EDMA_TPCC_IPRH bits clear.

When one interrupt is serviced many other transfer completions may result in additional bits being set in EDMA_TPCC_IPR / EDMA_TPCC_IPRH, thereby resulting in additional interrupts. Each of the bits in EDMA_TPCC_IPR / EDMA_TPCC_IPRH may need different types of service therefore, the ISR must check all pending interrupts and continue until all of the posted interrupts are serviced appropriately.

Examples of pseudo code for a CPU interrupt service routine for an EDMA_TPCC completion interrupt are shown in Example 16-2 and Example 16-3.

The ISR routine in Example 16-2 is more exhaustive and incurs a higher latency.

Example 16-2. Interrupt Servicing

The pseudo code:

1. Reads the interrupt pending register EDMA_TPCC_IPR / EDMA_TPCC_IPRH.
2. Performs the operations needed.
3. Writes to the interrupt pending clear register EDMA_TPCC_ICR / EDMA_TPCC_ICRH to clear the corresponding EDMA_TPCC_IPR / EDMA_TPCC_IPRH bit(s).
4. Reads EDMA_TPCC_IPR / EDMA_TPCC_IPRH again:

a. If EDMA_TPCC_IPR / EDMA_TPCC_IPRH is not equal to 0, repeat from step 2 (implies occurrence of new event between step 2 to step 4).
b. If EDMA_TPCC_IPR / EDMA_TPCC_IPRH is equal to 0, assure that all of the enabled interrupts are inactive.

Note

An event may occur during step 4 while the EDMA_TPCC_IPR / EDMA_TPCC_IPRH bits are read as 0 and the application is still in the interrupt service routine. If this happens, a new interrupt is recorded in the device interrupt controller and a new interrupt generates as soon as the application exits in the interrupt service routine.

16.2.4.9.3

Example 16-3 is less rigorous, with less burden on the software in polling for set interrupt bits, but can occasionally cause a race condition as mentioned above.

Example 16-3. Interrupt Servicing

If any enabled and pending (possibly lower priority) interrupts are left, force the interrupt logic to reassert the interrupt pulse by setting the EDMA_TPCC_IEVAL[0] EVAL bit in the interrupt evaluation register.

The pseudo code is as follows:

1. Enters ISR.
2. Reads EDMA_TPCC_IPR / EDMA_TPCC_IPRH.
3. For the condition that is set in EDMA_TPCC_IPR / EDMA_TPCC_IPRH:
   a. Service interrupt as the application requires.
   b. Clear the bit for serviced conditions (others may still be set, and other transfers may have resulted in returning the TCC to EDMA_TPCC after step 2).
4. Reads EDMA_TPCC_IPR / EDMA_TPCC_IPRH prior to exiting the ISR:
   a. If EDMA_TPCC_IPR / EDMA_TPCC_IPRH is equal to 0, then exit the ISR.
   b. If EDMA_TPCC_IPR / EDMA_TPCC_IPRH is not equal to 0, then set EDMA_TPCC_IEVAL so that upon exit of ISR, a new interrupt triggers if any enabled interrupts are still pending.

16.2.4.9.4 Interrupt Evaluation Operations

The EDMA_TPCC has interrupt evaluate registers EDMA_TPCC_IEVAL that exist in the global region and in each shadow region. The registers in the shadow region are the only registers in the DMA channel shadow region memory map that are not affected by the settings for the DMA region access enable registers EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k. Writing a 1 to the EDMA_TPCC_IEVAL[0] EVAL bit in the registers that are associated with a particular shadow region results in pulsing the associated region interrupt (global or shadow), if any enabled interrupt (via EDMA_TPCC_IER / EDMA_TPCC_IERH) is still pending EDMA_TPCC_IPR / EDMA_TPCC_IPRH. This register assures that the CPU does not miss the interrupts (or the EDMA master associated with the shadow region) if the software architecture chooses not to use all interrupts. Refer to Example 16-3 about the use of EDMA_TPCC_IEVAL in the EDMA interrupt service routine (ISR).

Similarly an error evaluation register EDMA_TPCC_EEVAL exists in the global region. Writing a 1 to the EDMA_TPCC_EEVAL[0] EVAL bit causes the pulsing of the error interrupt if any pending errors are in EDMA_TPCC_EMR / EDMA_TPCC_EMRH, EDMA_TPCC_QEMR, or EDMA_TPCC_CCERR. See Section 16.2.4.9.5 *Error Interrupts* for additional information regarding error interrupts.

Note

While using EDMA_TPCC_IEVAL for shadow region completion interrupts, check that the EDMA_TPCC_IEVAL operated upon is from that particular shadow region memory map.

16.2.4.9.5 Error Interrupts

The EDMA_TPCC error registers provide the capability to differentiate error conditions (event missed, threshold exceed, etc.). Additionally, setting the error bits in these registers results in asserting the EDMA_TPCC error interrupt. If the EDMA_TPCC error interrupt is enabled in the device interrupt controller(s), then it allows the CPU(s) to handle the error conditions.

The EDMA_TPCC has a single error interrupt (EDMA_TPCC_ERRINT) that is asserted for all EDMA_TPCC error conditions. There are four conditions that cause the error interrupt:

- DMA missed events: for all 64 DMA channels. DMA missed events are latched in the event missed registers EDMA_TPCC_EMR / EDMA_TPCC_EMRH.
- QDMA missed events: for all 8 QDMA channels. QDMA missed events are latched in the QDMA event missed register EDMA_TPCC_QEMR.
- Threshold exceed: for all event queues. These are latched in EDMA_TPCC error register EDMA_TPCC_CCERR.
- TCC error: for outstanding transfer requests that are expected to return completion code EDMA_TPCC_OPT_n[22] TCCHEN or EDMA_TPCC_OPT_n[23] TCINTEN bit is set to 1, exceeding the maximum limit of 63. This is also latched in the EDMA_TPCC error register EDMA_TPCC_CCERR.

Figure 16-28 illustrates the EDMA_TPCC error interrupt generation operation.

If any of the bits are set in the error registers due to any error condition, the EDMA_TPCC_ERRINT is always asserted, as there are no enables for masking these error events. Similar to transfer completion interrupts (EDMA_TPCC_INT), the error interrupt also only pulses when the error interrupt condition transitions from no errors being set to at least one error being set. If additional error events are latched prior to the original error bits clearing, the EDMA_TPCC does not generate additional interrupt.

To reduce the burden on the software, there is an error evaluate register EDMA_TPCC_EEVAL that allows re-evaluation of pending set error events/bits, similar to the interrupt evaluate register EDMA_TPCC_IEVAL. Unlike the EDMA_TPCC_IEVAL functionality, the EDMA_TPCC_EEVAL register must be written with ‘1’ after any error interrupts are serviced (even when all pending errors are cleared) in order for subsequent errors to trigger a new interrupt.

Note

It is good practice to enable the error interrupt in the device interrupt controller and to associate an interrupt service routine with it to address the various error conditions appropriately. Doing so puts less burden on the software (polling for error status), it provides a good debug mechanism for unexpected error conditions.

16.2.4.9.6

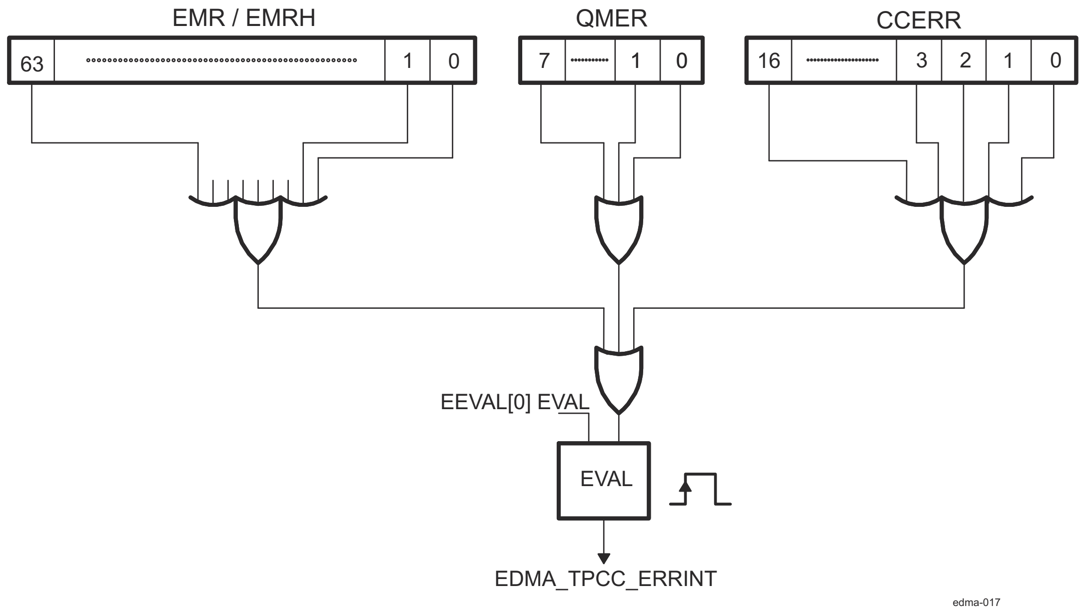

Figure 16-28. Error Interrupt Operation

16.2.4.10 Memory Protection

The EDMA channel controller supports two kinds of memory protection: active and proxy.

16.2.4.10.1 Active Memory Protection

Active memory protection is a feature that allows or prevents read and write accesses to the EDMA_TPCC registers. Active memory protection is achieved by a set of memory protection permissions attribute EDMA_TPCC_MPPAN_k registers.

The EDMA_TPCC register map is divided into three categories:

- a global region.
- a global channel region.
- eight shadow regions.

Each shadow region consists of the respective shadow region registers and the associated PaRAM. For more detailed information regarding the contents of a shadow region, refer to Table 16-80 *EDMA_TPCC Registers Mapping Summary*.

Each of the eight shadow regions has an associated EDMA_TPCC_MPPAN_k registers that defines the specific requestor(s) and types of requests that are allowed to the regions resources.

The global channel region is also protected with a memory-mapped register EDMA_TPCC_MPPAG. The EDMA_TPCC_MPPAG applies to the global region and to the global channel region, except the other EDMA_TPCC_MPPAN_k registers themselves.

Table 16-70 shows the accesses that are allowed or not allowed to the EDMA_TPCC_MPPAG and EDMA_TPCC_MPPAN_k. The active memory protection uses the EDMA_TPCC_OPT_n[31] PRIV and EDMA_TPCC_OPT_n[27:24] PRIVID attributes of the EDMA peripheral modules. TheEDMA_TPCC_OPT_n[31] PRIV is the privilege level (i.e., user vs. supervisor).

The EDMA_TPCC_OPT_n[27:24] PRIVID refers to a privilege ID with a number that is associated with an EDMA peripheral modules.

Table 16-70. Allowed Accesses

Access	Supervisor	User
Read	Yes	Yes
Write	Yes	No

Table 16-71 describes the EDMA_TPCC_MPPAN_k register mapping for the shadow regions (which includes shadow region registers and PaRAM addresses).

The region-based EDMA_TPCC_MPPAN_k registers are used to protect accesses to the DMA shadow regions and the associated region PaRAM. Because there are eight regions, there are eight EDMA_TPCC_MPPAN_k region registers (MPPA[0-7]).

Table 16-71. MPPA Registers to Region Assignment

Register	Registers Protect	Address Range	PaRAM Protect[(1)]	Address Range
EDMA_TPCC_MPPAG	Global Range	0000h-1FFCh	N/A	N/A
EDMA_TPCC_MPPAN_k. MPPAN_0	DMA Shadow 0	2000h-21FCh	1st octant	4000h-47FCh
MPPAN_1	DMA Shadow 1	2200h-23FCh	2nd octant	4800h-4FFCh
MPPAN_2	DMA Shadow 2	2400h-25FCh	3rd octant	5000h-57FCh
MPPAN_3	DMA Shadow 3	2600h-27FCh	4th octant	5800h-5FFCh
MPPAN_4	DMA Shadow 4	2800h-29FCh	5th octant	6000h-67FCh
MPPAN_5	DMA Shadow 5	2A00h-2BFCh	6th octant	6800h-6FFCh
MPPAN_6	DMA Shadow 6	2C00h-2DFCh	7th octant	7000h-77FCh

Table 16-71. MPPA Registers to Region Assignment (continued)

Register	Registers Protect	Address Range	PaRAM Protect(1)	Address Range
MPPAN_7	DMA Shadow 7	2E00h-2FFCh	8th octant	7800h-7FFCh

(1) The PARAM region is divided into 8 regions referred to as an octant.

Example *Access denied.*

Write access to shadow region 7's event enable set register EDMA_TPCC_EESR:

1. The original value of the event enable register EDMA_TPCC_EER at address offset 0x1020 is 0x0.
2. The EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[7] NS is set to prevent user level accesses (EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[1] UW = 0, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[2] UR = 0), but it allows supervisor level accesses (EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[4] SW = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[5] SR = 1) with a privilege ID of 0. (EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[10] AID0 = 1).
3. EDMA peripheral modules with a privilege ID of 0 attempts to perform a user-level write of a value of 0xFF00FF00 to shadow region 7's event enable set register EDMA_TPCC_EESR at address offset 0x2E30.

Note

The EDMA_TPCC_EER is a read-only register and the only way that write to it is by writing to the EDMA_TPCC_EESR. There is only one physical register for EDMA_TPCC_EER, EDMA_TPCC_EESR, etc. and that the shadow regions only provide to the same physical set.

4. Since the EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[1] UW = 0, though the privilege ID of the write access is set to 0, the access is not allowed and the EDMA_TPCC_EER is not written too.

Table 16-72. Example Access Denied

Register	Value	Description
EDMA_TPCC_EER (offset 0x1020)	0x0000 0000	Value in EDMA_TPCC_EER to begin with.
EDMA_TPCC_EESR (offset 0x2E30)	0xFF00 FF00 ↓	Value attempted to be written to shadow region 7's EDMA_TPCC_EESR. This is done by an EDMA connected device module with a privilege level of User and Privilege ID of 0.
EDMA_TPCC_MPPAN_k (offset 0x082C)	0x0000 04B0	Memory Protection Filter EDMA_TPCC_MPPAN_k[10] AID0 = 1, EDMA_TPCC_MPPAN_k[1] UW = 0, EDMA_TPCC_MPPAN_k[2] UR = 0, EDMA_TPCC_MPPAN_k[4] SW = 1, EDMA_TPCC_MPPAN_k[5] SR = 1.
	X	Access Denied
EDMA_TPCC_EER (offset 0x1020)	0x0000 0000	Final value of EDMA_TPCC_EER

Example *Access Allowed*

Write access to shadow region 7's event enable set register EDMA_TPCC_EESR:

1. The original value of the event enable register EDMA_TPCC_EER at address offset 0x1020 is 0x0.
2. The EDMA_TPCC_MPPAN_k.EDMA_TPCC_MPPAN_7 is set to allow user-level accesses (EDMA_TPCC_MPPAN_k.EDMA_TPCC_MPPAN_7[1] UW = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[2] UR = 1) and supervisor-level accesses (EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[4] SW = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[5] SR = 1) with a privilege ID of 0. (EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[10] AID0 = 1).
3. EDMA peripheral modules with a privilege ID of 0, attempts to perform a user-level write of a value of 0xABCD0123 to shadow region 7's event enable set register EDMA_TPCC_EESR at address offset 0x2E30.

Note

The EDMA_TPCC_EER is a read-only register and the only way that write to it is by writing to the EDMA_TPCC_EESR. There is only one physical register for EDMA_TPCC_EER, EDMA_TPCC_EESR, etc. and that the shadow regions only provide to the same physical set.

4. Since the EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[1] UW = 1 and EDMA_TPCC_MPPAN_k. MPPAN_7[10] AID0 = 1, the user-level write access is allowed.
5. The accesse to shadow region registers are masked by their respective EDMA_TPCC_DRAEM_k register. In this example, the EDMA_TPCC_DRAEM_k. EDMA_TPCC_DRAEM_7 is set of 0x9FF00FC2.
6. The value finally written to EDMA_TPCC_EER is 0x8BC00102.

Table 16-73. Example Access Allowed

Register	Value	Description
EDMA_TPCC_EER (offset 0x1020)	0x0000 0000	Value in EER to begin with.
EDMA_TPCC_EESR (offset 0x2E30)	0xFF00 FF00	Value attempted to be written to shadow region 7's EESR. This is done by an EDMA peripheral module with a privilege level of User and Privilege ID of 0.
EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7 (offset 0x082C)	0x0000 04B3	Memory Protection Filter EDMA_TPCC_MPPAN_k[10] AID = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[1] UW = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[2] UR = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[4] SW = 1, EDMA_TPCC_MPPAN_k. EDMA_TPCC_MPPAN_7[5] SR = 1.
	√ ↓	Access allowed.
EDMA_TPCC_DRAEM_k. EDMA_TPCC_DRAEM_7 (offset 0x0378)	0x9FF0 0FC2 ↓	DMA Region Access Enable Filter
EDMA_TPCC_EESR (offset 0x2E30)	0x8BC0 0102 ↓	Value written to shadow region 7's EESR. This is done by an EDMA peripheral module with a privilege level of User and a Privilege ID of 0.
EDMA_TPCC_EER (offset 0x1020)	↓ 0xBC0 0102	Final value of EER.

16.2.4.10.2 Proxy Memory Protection

Proxy memory protection allows an EDMA transfer programmed by a given peripheral module connected to EDMA, to have its permissions travel with the transfer through the EDMA_TPTC. The permissions travel along with the read transactions to the source and the write transactions to the destination endpoints. The EDMA_TPCC_OPT_n[31] PRIV bit and EDMA_TPCC_OPT_n[27:24] PRIVID bit is set with the peripheral module's PRIV value and PRIVID values, respectively, when any part of the PaRAM set is written.

The EDMA_TPCC_OPT_n[31] PRIV is the privilege level (i.e., user vs. supervisor). The EDMA_TPCC_OPT_n[27:24] PRIVID refers to a privilege ID with a number that is associated with an peripheral module connected to EDMA.

These options are part of the TR that are submitted to the transfer controller. The transfer controller uses the above values on their respective read and write command bus so that the target endpoints can perform memory protection checks based on these values.

Consider a parameter set that is programmed by a CPU in user privilege level for a simple transfer with the source buffer on an L2 page and the destination buffer on an L1D page. The EDMA_TPCC_OPT_n[31] PRIV is 0 for user-level and the CPU has a EDMA_TPCC_OPT_n[27:24] PRIVID to 0.

The PaRAM set is shown in Figure 16-29.

Figure 16-29. PaRAM Set Content for Proxy Memory Protection Example

(a) EDMA Parameters

Parameter Contents		Parameter	
0010 0007h		Channel Options Parameter (OPT)	
009F 0000h		Channel Source Address (SRC)	
0001h	0004h	Count for 2nd Dimension (BCNT)	Count for 1st Dimension (ACNT)
00F0 7800h		Channel Destination Address (DST)	
0001h	0001h	Destination BCNT Index (DBIDX)	Source BCNT Index (SBIDX)
0000h	FFFFh	BCNT Reload (BCNTRLD)	Link Address (LINK)
0001h	1000h	Destination CCNT Index (DCIDX)	Source CCNT Index (SCIDX)
0000h	0001h	Reserved	Count for 3rd Dimension (CCNT)

(b) Channel Options Parameter (OPT_n) Content

edma-018

Figure 16-30. Channel Options Parameter (OPT) Example

The EDMA_TPCC_OPT_n[31] PRIV and EDMA_TPCC_OPT_n[27:24] PRIVID information travels along with the read and write requests that are issued to the source and destination memories.

For example, if the access attributes that are associated with the L2 page with the source buffer only allow supervisor read, write accesses EDMA_TPCC_MPPAN_k[4] SW and EDMA_TPCC_MPPAN_k[5] SR, the user-level read request above is refused. Similarly, if the access attributes that are associated with the L1D page with the destination buffer only allow supervisor read and write accesses (EDMA_TPCC_MPPAN_k[4] SW, EDMA_TPCC_MPPAN_k[5] SR), the user-level write request above is refused. For the transfer to succeed, the source and destination pages must have user-read and user-write permissions, respectively, along with allowing accesses from a PRIVID = 0.

Because the privilege level and privilege identification travel with the read and write requests, EDMA acts as a proxy.

Figure 16-31 illustrates the propagation of EDMA_TPCC_OPT_n[31] PRIV and EDMA_TPCC_OPT_n[27:24] PRIVID at the boundaries of all the interacting entities (CPU, EDMA_TPCC, EDMA_TPTCs, and slave memories).

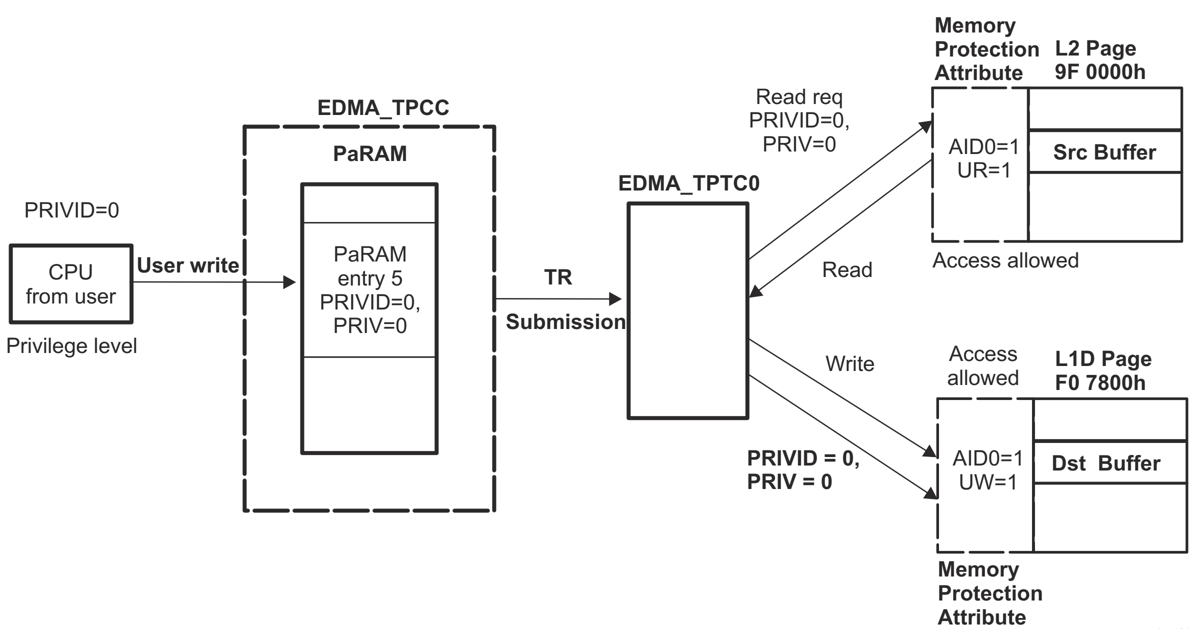

Figure 16-31. Proxy Memory Protection Example

16.2.4.11 Event Queue(s)

Event queues are a part of the EDMA channel controller. Event queues form the interface between the event detection logic in the EDMA_TPCC and the transfer request (TR) submission logic of the EDMA_TPCC. Each queue is 16 entries deep. Each event queue can queue a maximum of 16 events. If there are more than 16 events, then the events that cannot find a place in the event queue remain set in the associated event register and the CPU does not stall.

There are two event queues for the device: Queue0, Queue1. Events in Queue0 result in submission of its associated transfer requests (TRs) to TC0. The transfer requests that are associated with events in Queue1 are submitted to TC1.

An event that wins prioritization against other DMA and/or QDMA pending events is placed at the tail of the appropriate event queue. Each event queue is serviced in FIFO order. Once the event reaches the head of its queue and the corresponding transfer controller is ready to receive another TR, the event is de-queued and the PaRAM set corresponding to the de-queued event is processed and submitted as a transfer request packet (TRP) to the associated EDMA transfer controller.

Queue0 has highest priority and Queue1 has the lowest priority, if Queue0 and Queue1 both have at least one event entry and if both TC0 and TC1 can accept transfer requests, then the event in Queue0 is de-queued first and its associated PaRAM set is processed and submitted as a transfer request (TR) to TC0.

Refer to Section 16.2.4.11.4 for system-level performance considerations. All of the event entries in all of the event queues are software readable (not writeable) by accessing the event entry registers EDMA_TPCC_Q0E_p and EDMA_TPCC_Q1E_p. Each event entry register characterizes the queued event in terms of the type of event (manual, event, chained or auto-triggered) and the event number. Refer to Section 16.2.7.2.2.1 *EDMA_TPCC Register Description* for Q0E_p / Q1E_p descriptions of the bit fields.

16.2.4.11.1 DMA/QDMA Channel to Event Queue Mapping

Each of the 64 DMA channels and eight QDMA channels are programmed independently to map to a specific queue, using the DMA queue number register EDMA_TPCC_DMAQNUMN_k and the QDMA queue number register EDMA_TPCC_QDMAQNUM. The mapping of DMA/QDMA channels is critical to achieving the desired performance level for the EDMA and most importantly, in meeting real-time deadlines. Refer to Section 16.2.4.11.4 *System-level Performance Considerations*.

Note

If an event is ready to be queued and both the event queue and the EDMA transfer controller that is associated to the event queue are empty, then the event bypasses the event queue, and moves the PaRAM processing logic, and eventually to the transfer request submission logic for submission to the EDMA_TPTC. In this case, the event is not logged in the event queue status registers.

16.2.4.11.2 Queue RAM Debug Visibility

There are two event queues and each queue has 16 entries. These 16 entries are managed in a circular FIFO. There is a queue status register EDMA_TPCC_QSTATN_i associated with each queue. These along with all of the 16 entries per queue can be read via registers EDMA_TPCC_QSTATN_i and Q0E_p / Q1E_p, respectively.

These registers provide user visibility.

The event queue entry register (Q*x*E*y* Q0E_p / Q1E_p) uniquely identifies the specific event type (event-triggered, manually-triggered, chain-triggered, and QDMA events) along with the event number (for all DMA/ QDMA event channels) that are in the queue or have been de-queued (passed through the queue).

Each of the 16 entries in the event queue are read using the EDMA_TPCC memory-mapped register. To see the history of the last 16 TRs that have been processed by the EDMA on a given queue, read the event queue registers. This provides user/software visibility and is helpful for debugging real-time issues (typically post-mortem), involving multiple events and event sources.

The queue status register (QSTAT*n* EDMA_TPCC_QSTATN_i) includes fields for the start pointer EDMA_TPCC_QSTATN_i[3:0] STRTPTR which provides the offset to the head entry of an event. It also includes a field called EDMA_TPCC_QSTATN_i[12:8] NUMVAL that provides the total number of valid entries residing in the event queue at a given instance of time. The EDMA_TPCC_QSTATN_i[3:0] STRTPTR is used to index appropriately into the 16 event entries. EDMA_TPCC_QSTATN_i[12:8] NUMVAL number of entries starting from STRTPTR are indicative of events still queued in the respective queue. The remaining entry must be read to determine what's already de-queued and submitted to the associated transfer controller.

16.2.4.11.3 Queue Resource Tracking

The EDMA_TPCC event queue includes watermarking/threshold logic that allows to keep track of maximum usage of all event queues. This is useful for debugging real-time deadline violations that may result from head-of-line blocking on a given EDMA event queue.

The maximum number of events are programed that the queue up in an event queue by programming the threshold value (between 0 to 15) in the queue watermark threshold A register EDMA_TPCC_QWMTHRA. The maximum queue usage is recorded actively in the watermark EDMA_TPCC_QSTATN_i[20:16] WM field of the queue status register, that keeps getting updated based on a comparison of number of valid entries, which is also visible in the EDMA_TPCC_QSTATN_i[12:8] NUMVAL bit and the maximum number of entries.

If the queue usage is exceeded, this status is visible in the EDMA_TPCC registers: the QTHRXCD*n* bits in the channel controller error register EDMA_TPCC_CCERR[7:0] and the EDMA_TPCC_QSTATN_i[24] THRXCD bit, where *n* stands for the event queue number. Any bits that are set in EDMA_TPCC_CCERR also generate an EDMA_TPCC error interrupt.

16.2.4.11.4 Performance Considerations

The main system bus infrastructure (L3) arbitrates bus requests from all of the masters (TCs, CPU(S), and other bus masters) to the shared slave resources (peripherals and memories).

The priorities of transfer requests (read and write commands) from the EDMA transfer controllers with respect to other masters within the device IRQ_CROSSBAR are programmed using the Control Module registers. The EDMA_TPCC_QUEPRI register has no affect.

Therefore, the priority of unloading queues has a secondary affect compared to the priority of the transfers as they are executed by the EDMA_TPTC (dictated by the priority set using the Control Module registers, refer to *Control Module Register Manual* in *Control Module* chapter).

16.2.4.12 EDMA Transfer Controller (EDMA_TPTC)

The EDMA channel controller is the user-interface of the EDMA and the EDMA transfer controller (EDMA_TPTC) is the data movement engine of the EDMA controller. The EDMA_TPCC submits transfer requests (TR) to the EDMA_TPTC and the EDMA_TPTC performs the data transfers dictated by the TR, so the EDMA_TPTC is a slave to the EDMA_TPCC.

16.2.4.12.1 Architecture Details

16.2.4.12.1.1 Command Fragmentation

The TC read and write controllers in conjunction with the source and destination register sets are responsible for issuing optimally-sized reads and writes to the slave endpoints. An optimally-sized command is defined by the transfer controller default burst size (DBS), which is defined in Section 16.2.4.12.5 *EDMA_TPTC Configuration*.

The EDMA_TPTC attempts to issue the largest possible command size as limited by the DBS value or the EDMA_TPCC_ABCNT_n[15:0] ACNT and EDMA_TPCC_ABCNT_n[31:16] BCNT value of the TR. EDMA_TPTC obeys the following rules:

- The read/write controllers always issue commands less than or equal to the DBS value.
- The first command of a 1D transfer command always aligns the address of subsequent commands to the DBS value.

Table 16-74 lists the TR segmentation rules that are followed by the EDMA_TPTC. In summary, if the EDMA_TPCC_ABCNT_n[15:0] ACNT value is larger than the DBS value, then the EDMA_TPTC breaks the

EDMA_TPCC_ABCNT_n[15:0] ACNT array into DBS-sized commands to the source/destination addresses. Each EDMA_TPCC_ABCNT_n[31:16] BCNT number of arrays are then serviced in succession.

For BCNT arrays of ACNT bytes (that is, a 2D transfer), if the EDMA_TPCC_ABCNT_n[15:0] ACNT value is less than or equal to the DBS value, then the TR may be optimized into a 1D-transfer in order to maximize efficiency. The optimization takes place if the EDMA_TPTC recognizes that the 2D-transfer is organized as a single dimension (EDMA_TPCC_ABCNT_n[15:0] ACNT == EDMA_TPCC_BIDX_n) and the ACNT value is a power of 2.

Table 16-74 lists conditions in which the optimizations are performed.

Table 16-74. Read/Write Command Optimization Rules

ACNT ≤ DBS	ACNT is power of 2	BIDX = ACNT	BCNT ≤ 1023	SAM/DAM = Increment	Description
Yes	Yes	Yes	Yes	Yes	Optimized
No	x	x	x	x	Not Optimized
x	No	x	x	x	Not Optimized
x	x	No	x	x	Not Optimized
x	x	x	No	x	Not Optimized
x	x	x	x	No	Not Optimized

16.2.4.12.1.2 TR Pipelining

TR pipelining refers to the ability of the source active set to proceed ahead of the destination active set. Essentially, the reads for a given TR may already be in progress while the writes of a previous TR may not have completed.

The number of outstanding TRs is limited by the number of destination FIFO register entries.

TR pipelining is useful for maintaining throughput on back-to-back small TRs. It minimizes the startup overhead because reads start in the background of a previous TR writes.

Example 16-4. Command Fragmentation (DBS = 64)

The pseudo code:

1. EDMA_TPTCn_PCNT[15:0] ACNT = 8, EDMA_TPTCn_PCNT[31:16] BCNT = 8, EDMA_TPTCn_PBIDX[15:0] SBIDX = 8, EDMA_TPTCn_PBIDX[31:16] DBIDX = 10, EDMA_TPTCn_PSRC[31:0] SADDR = 64, EDMA_TPTCn_SADST[31:0] DADDR = 191

   Read Controller: This is optimized from a 2D-transfer to a 1D-transfer such that the read side is equivalent to EDMA_TPTCn_PCNT[15:0] ACNT = 64, EDMA_TPTCn_PCNT[31:16] BCNT = 1.

   Cmd0 = 64 byte

   Write Controller: Because DBIDX != ACNT, it is not optimized.

   Cmd0 = 8 byte, Cmd1 = 8 byte, Cmd2 = 8 byte, Cmd3 = 8 byte, Cmd4 = 8 byte, Cmd5 = 8 byte, Cmd6 = 8 byte, Cmd7 = 8 byte.
2. EDMA_TPTCn_PCNT[15:0] ACNT=128, EDMA_TPTCn_PCNT[31:16] BCNT = 1, EDMA_TPTCn_PSRC[31:0] SADDR = 63, EDMA_TPTCn_SADST[31:0] DADDR = 513

   Read Controller: Read address is not aligned.

   Cmd0 = 1 byte, (now the SADDR is aligned to 64 for the next command)

   Cmd1 = 64 bytes

   Cmd2 = 63 bytes

   Write Controller: The write address is also not aligned.

   Cmd0 = 63 bytes, (now the DADDR is aligned to 64 for the next command)

   Cmd1 = 64 bytes

   Cmd2 = 1 byte

16.2.4.12.1.3 Performance Tuning

By default, reads are as issued as fast as possible. In some cases, the reads issued by the EDMA_TPTC could fill the available command buffering for a slave, delaying other (potentially higher priority) masters from successfully submitting commands to that slave. The rate at which read commands are issued by the EDMA_TPTC is controlled by the EDMA_TPTCn_RDRATE register. The EDMA_TPTCn_RDRATE register defines the number of cycles that the EDMA_TPTC read controller waits before issuing subsequent commands for a given TR, thus minimizing the chance of the EDMA_TPTC consuming all available slave resources. The EDMA_TPTCn_RDRATE[2:0] RDRATE value must be set to a relatively small value if the transfer controller is targeted for high priority transfers and to a higher value if the transfer controller is targeted for low priority transfers.

In contrast, the Write Interface does not have any performance turning knobs because writes always have an interval between commands as write commands are submitted along with the associated write data.

16.2.4.12.2 Memory Protection

The transfer controller plays an important role in handling proxy memory protection. There are two access properties associated with a transfer: for instance, the privilege id (system-wide identification assigned to a master) of the master initiating the transfer, and the privilege level (user versus supervisor) used to program the transfer. This information is maintained in the PaRAM set when it is programmed in the channel controller. When a TR is submitted to the transfer controller, this information is made available to the EDMA_TPTC and used by the EDMA_TPTC while issuing read and write commands. The read or write commands have the same privilege identification, and privilege level as that programmed in the EDMA transfer in the channel controller.

16.2.4.12.3 Error Generation

Errors are generated if enabled under three conditions:

- EDMA_TPTC detection of an error signaled by the source or destination address.
- Attempt to read or write to an invalid address in the configuration memory map.
- Detection of a constant addressing mode TR violating the constant addressing mode transfer rules (the source/destination addresses and source/destination indexes must be aligned to 32 bytes).

Either or all error types may be disabled. If an error bit is set and enabled, the error interrupt for the concerned transfer controller is generated.

16.2.4.12.4 Debug Features

The DMA program register set, DMA source active register set, and the destination FIFO register set are used to derive a brief history of TRs serviced through the transfer controller.

Additionally, the EDMA_TPTC status register EDMA_TPTCn_TCSTAT has dedicated bit fields to indicate the ongoing activity within different parts of the transfer controller:

- The EDMA_TPTCn_TCSTAT[1] SRCACTV bit indicates whether the source active set is active.
- The EDMA_TPTCn_TCSTAT[6:4] DSTACTV bit indicates the number of TRs resident in the destination register active set at a given instance.
- The EDMA_TPTCn_TCSTAT[0] PROGBUSY bit indicates whether a valid TR is present in the DMA program set.

Note

If the TRs are in progression, it must realize that there is a chance that the values read from the EDMA_TPTC status registers will be inconsistent since the EDMA_TPTC changes the values of these registers due to ongoing activities.

It is recommended that to ensure no additional submission of TRs to the EDMA_TPTC in order to facilitate ease of debug.

16.2.4.12.4.1 Destination FIFO Register Pointer

The destination FIFO register pointer is implemented as a circular buffer with the start pointer being EDMA_TPTCn_TCSTAT[12:11] DFSTRTPTR and a buffer depth of usually 2 or 4. The EDMA_TPTC maintains two important status details in EDMA_TPTCn_TCSTAT that are used during advanced debugging, if necessary. The EDMA_TPTCn_TCSTAT[12:11] DFSTRTPTR is a start pointer, the index to the head of the destination FIFO register. The EDMA_TPTCn_TCSTAT[6:4] DSTACTV is a counter for the number of valid (occupied) entries. These registers are used to get a brief history of transfers.

Examples of some register field values and their interpretation:

- EDMA_TPTCn_TCSTAT[12:11] DFSTRTPTR = 0x0 and EDMA_TPTCn_TCSTAT[6:4] DSTACTV = 0x0 implies that no TRs are stored in the destination FIFO register.
- EDMA_TPTCn_TCSTAT[12:11] DFSTRTPTR = 0x1 and EDMA_TPTCn_TCSTAT[6:4] DSTACTV = 0x2 implies that two TRs are present. The first pending TR is read from the destination FIFO register entry 1 and the second pending TR is read from the destination FIFO register entry 2.
- EDMA_TPTCn_TCSTAT[12:11] DFSTRTPTR = 0x3 and EDMA_TPTCn_TCSTAT[6:4] DSTACTV = 0x2 implies that two TRs are present. The first pending TR is read from the destination FIFO register entry 3 and the second pending TR is read from the destination FIFO register entry 0.

16.2.4.12.5 EDMA_TPTC Configuration

Table 16-75 provides the configuration of the individual EDMA transfer controllers present on the device. The DBS for each transfer controller is defined by Control Module register (CTRL_CORE_CONTROL_IO_1) settings.

Table 16-75. EDMA Transfer Controller Configurations

Name	TC0	TC1
EDMA_TPTCn_TCCFG[2:0] FIFOSIZE	1024 bytes	1024 bytes

Table 16-75. EDMA Transfer Controller Configurations (continued)

Name	TC0	TC1
EDMA_TPTCn_TCCFG[5:4] BUSWIDTH	16 bytes	16 bytes
EDMA_TPTCn_TCCFG[9:8] DSTREGDEPTH	4 entries	4 entries
DBS	Defined by CTRL_CORE_CONTROL_IO_1[9:8] TC0_DEFAULT_BURST_SIZE	Defined by CTRL_CORE_CONTROL_IO_1[13:12] TC1_DEFAULT_BURST_SIZE

16.2.4.13 Event Dataflow

This section summarizes the data flow of a single event, from the time the event is latched to the channel controller to the time the transfer completion code is returned. The following steps list the sequence of EDMA_TPCC activity:

1. Event is asserted from an external source (peripheral or external interrupt). This also is similar for a manually-triggered, chained-triggered, or QDMA-triggered event. The event is latched into the EDMA_TPCC_ER[31:0]E*n* / EDMA_TPCC_ERH[31:0] E*n* (or EDMA_TPCC_CER[31:0] E*n* / EDMA_TPCC_CERH[31:0] E*n*, EDMA_TPCC_ESR[31:0] E*n* / EDMA_TPCC_ESRH[31:0] E*n*, EDMA_TPCC_QER[7:0] E*n*) bit.
2. Once an event is prioritized and queued into the appropriate event queue, the EDMA_TPCC_SER[31:0] E*n* \ EDMA_TPCC_SERH[31:0] E*n* (or EDMA_TPCC_QSER[7:0] E*n*) bit is set to inform the event prioritization / processing logic to disregard this event since it is already in the queue. Alternatively, if the transfer controller and the event queue are empty, then the event bypasses the queue.
3. The EDMA_TPCC processing and the submission logic evaluates the appropriate PaRAM set and determines whether it is a non-null and non-dummy transfer request (TR).
4. The EDMA_TPCC clears the EDMA_TPCC_ER[31:0] E*n*/ EDMA_TPCC_ERH[31:0] E*n* (or EDMA_TPCC_CER[31:0] E*n* / EDMA_TPCC_CERH[31:0] E*n*, EDMA_TPCC_ESR[31:0]E*n* / EDMA_TPCC_ESRH[31:0] E*n*, EDMA_TPCC_QER[31:0] E*n*) bit and the EDMA_TPCC_SER[31:0] E*n* / EDMA_TPCC_SERH[31:0] E*n* bit as soon as it determines the TR is non-null. In the case of a null set, the EDMA_TPCC_SER[31:0] E*n* / EDMA_TPCC_SERH[31:0] E*n* bit remains set. It submits the non-null/non-dummy TR to the associated transfer controller. If the TR was programmed for early completion, the EDMA_TPCC immediately sets the interrupt pending register (EDMA_TPCC_IPR[31:0] I[TCC] / EDMA_TPCC_IPRH[31:0] I[TCC] - 32).
5. If the TR was programmed for normal completion, the EDMA_TPCC sets the interrupt pending register (EDMA_TPCC_IPR[31:0] I[TCC] / EDMA_TPCC_IPRH[31:0] I[TCC]) when the EDMA_TPTC informs the EDMA_TPCC about completion of the transfer (returns transfer completion codes).
6. The EDMA_TPCC programs the associated EDMA_TPTC's Program Register Set with the TR.
7. The TR is then passed to the Source Active set and the DST FIFO Register Set, if both the register sets are available.
8. The Read Controller processes the TR by issuing read commands to the source slave endpoint. The Read Data lands in the Data FIFO of the EDMA_TPTC*n*.
9. As soon as sufficient data is available, the Write Controller begins processing the TR by issuing write commands to the destination slave endpoint.
10. This continues until the TR completes and the EDMA_TPTC*n* then signals completion status to the EDMA_TPCC.

16.2.4.14 EDMA controller Prioritization

The EDMA controller has many implementation rules to deal with concurrent events/channels, transfers, etc. The following subsections detail various arbitration details whenever there might be occurrence of concurrent activity. Figure 16-32 shows the different places EDMA priorities come into play.

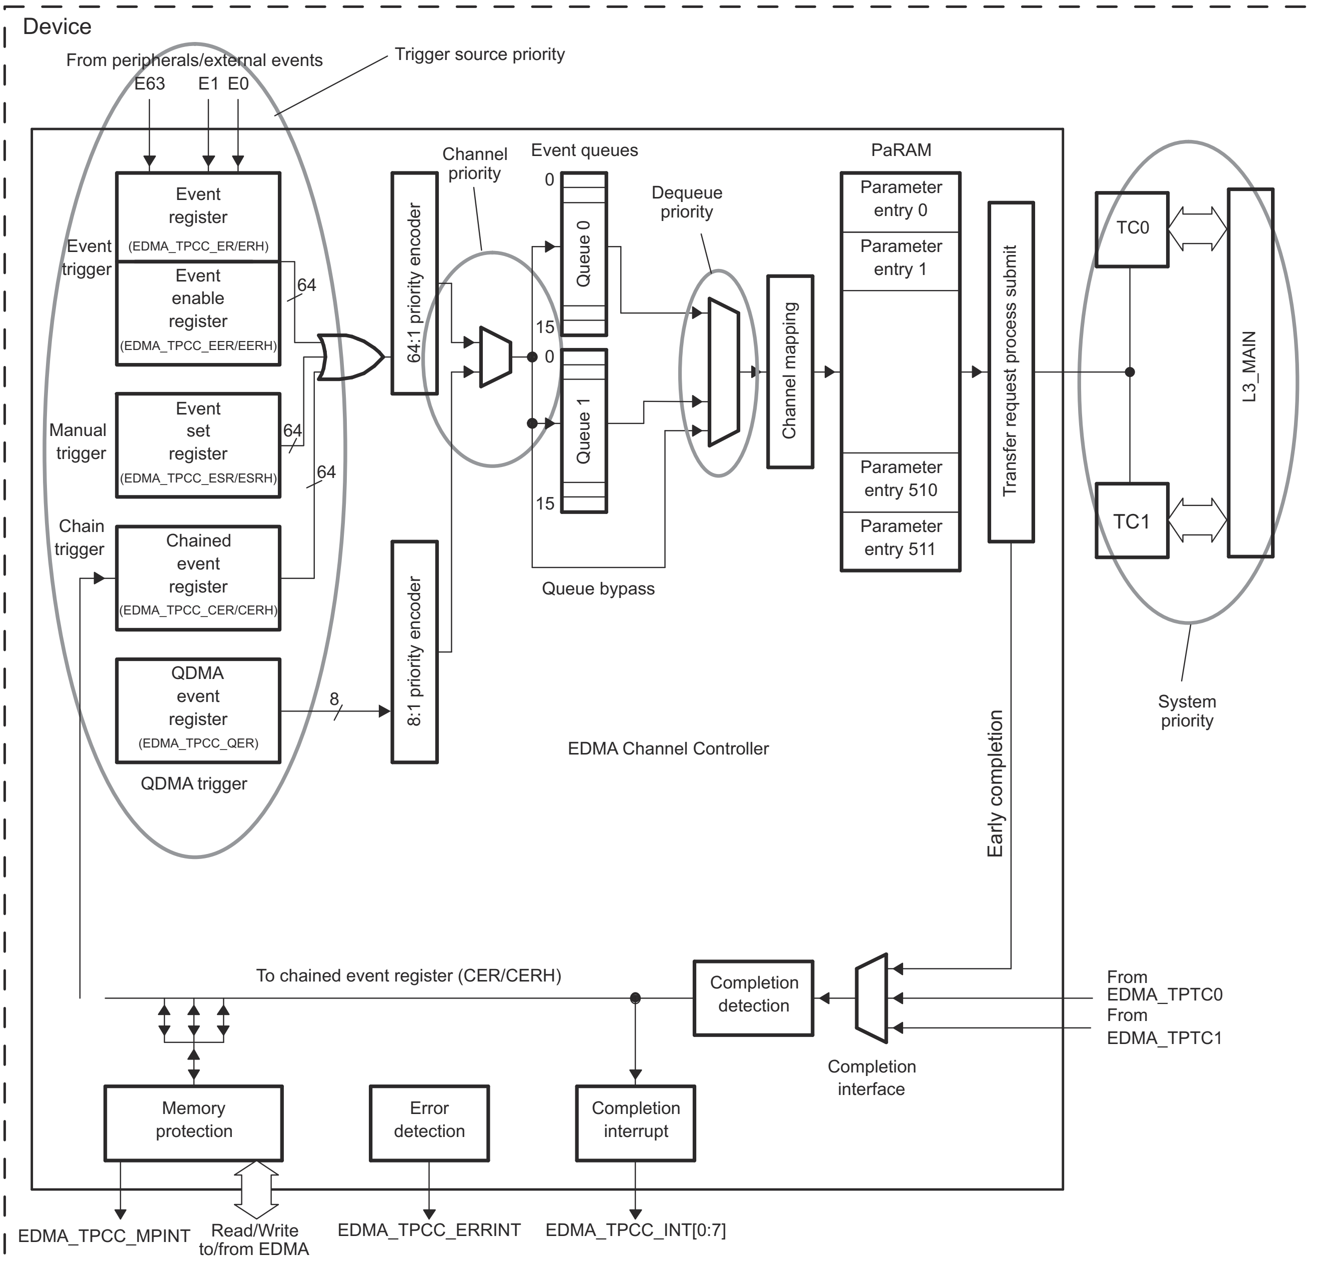

Figure 16-32. EDMA Prioritization

16.2.4.14.1 Channel Priority

The EDMA event registers EDMA_TPCC_ER and EDMA_TPCC_ERH capture up to 64 events, the QDMA event register EDMA_TPCC_QER captures QDMA events for all QDMA channels therefore, it is possible for events to occur simultaneously on the DMA/QDMA event inputs. For events arriving simultaneously, the event associated with the lowest channel number is prioritized for submission to the event queues (for DMA events, channel 0 has the highest priority and channel 63 has the lowest priority, for QDMA events, channel 0 has the highest priority and channel 7 has the lowest priority). This mechanism only sorts simultaneous events for submission to the event queues.

If a DMA and QDMA event occurs simultaneously, the DMA event always has prioritization against the QDMA event for submission to the event queues.

16.2.4.14.2 Trigger Source Priority

If a EDMA channel is associated with more than one trigger source (event trigger, manual trigger, and chain trigger), and if multiple events are set simultaneously for the same channel (EDMA_TPCC_ER[31:0] E*n* = 1, EDMA_TPCC_ESR[31:0] E*n* = 1 , EDMA_TPCC_CER[31:0] E*n* = 1) , then the EDMA_TPCC always services these events in the following priority order: event trigger (via EDMA_TPCC_ER) is higher priority than chain trigger (via EDMA_TPCC_CER) and chain trigger is higher priority than manual trigger (via EDMA_TPCC_ESR).

This implies that if for channel 0, both EDMA_TPCC_ER[0] E0 = 1 and EDMA_TPCC_CER[0] E0 = 1 at the same time, then the EDMA_TPCC_ER[0] E0 event is always queued before the EDMA_TPCC_CER[0] E0 event.

16.2.4.14.3 Dequeue Priority

The priority of the associated transfer request (TR) is further mitigated by which event queue is being used for event submission (dictated by EDMA_TPCC_DMAQNUMN_k and EDMA_TPCC_QDMAQNUM). For submission of a TR to the transfer request, events need to be de-queued from the event queues. Queue 0 has the highest dequeue priority and queue 1 the lowest.

16.2.4.15 EDMA Power, Reset and Clock Management

16.2.4.15.1 Clock and Power Management

The EDMA channel controller and transfer controller are clocked from L3MIAN1_L3_GICLK interface clock. The EDMA system runs at the L3 clock frequency.

The Auto clock gating for the EDMA_TPCC module is controlled by the EDMA_TPCC_CLKGDIS[0] CLKGDIS bit at the module level.

The L3MIAN1_L3_GICLK interface clock to EDMA controller's modules are controlled by the following registers in the PRCM module:

- PRCM.CM_L3MAIN1_TPCC_CLKCTRL - manages EDMA_TPCC module clock.
- PRCM.CM_L3MAIN1_TPTC1_CLKCTRL - manages EDMA_TPTC0 module clock.
- PRCM.CM_L3MAIN1_TPTC2_CLKCTRL - manages EDMA_TPTC1 module clock.

EDMA_TPCC and EDMA_TPTC0 and EDMA_TPTC1 modules have wakeup depandaces to several device modules. The wakeup dependency based on EDMA modules service requests are controlled by registers in PRCM module:

- PRCM.PM_L3MAIN1_TPCC_WKDEP - controls wakeup dependency based on TPCC service requests.
- PRCM.PM_L3MAIN1_TPTC1_WKDEP - controls wakeup dependency based on TPTC0 service requests.
- PRCM.PM_L3MAIN1_TPTC2_WKDEP - controls wakeup dependency based on TPTC1 service requests.

The EDMA_TPCC, EDMA_TPTC0 and EDMA_TPTC1 can be placed in reduced-power modes to conserve power during periods of low activity. The power management of the peripheral is controlled by the PRCM module. The PRCM acts as a master controller for power management for all peripherals on the device.

The EDMA controller can be idled on receiving a clock stop request from the PRCM. The requests to EDMA_TPCC and EDMA_TPTC0 and EDMA_TPTC1 are separate. In general, it should be verified that there are no pending activities in the EDMA controller

Note

When EDMA controler modules no longer require the interface clock, software can disable it at the PRCM level by configuring the MODULEMODE bit field (PRCM.CM_L3MAIN1_TPCC_CLKCTRL[1:0], PRCM.CM_L3MAIN1_TPTC1_CLKCTRL[1:0], PRCM.CM_L3MAIN1_TPTC2_CLKCTRL[1:0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it.

At the PRCM level, when all the conditions to shut off the L3MIAN1_L3_GICLK clock are met the PRCM module automatically launches a hardware handshake protocol to ensure EDMA modules are ready to have this clock switched off. Namely, the PRCM module asserts an IDLE request to the EDMA modules. For more information, refer to *Power, Reset, and Clock Management*.

16.2.4.15.2 Reset Considerations

A hardware resets the EDMA (EDMA_TPCC, EDMA_TPTC0 and EDMA_TPTC1) and the EDMA configuration registers. The PaRAM memory contents are undefined after device reset and it should not rely on parameters to be reset to a known state. The PaRAM entry must be initialized to a desired value before it is used. The EDMA modules are reset by CORE_RET_RST reset signal from PRCM.

16.2.4.16 Emulation Considerations

During debug when using the emulator, the CPU(s) may be halted on an execute packet boundary for single-stepping, benchmarking, profiling, or other debug purposes. During an emulation halt, the EDMA channel controller and transfer controller operations continue. Events continue to be latched and processed and transfer requests continue to be submitted and serviced.

Since EDMA is involved in servicing multiple master and slave peripherals, it is not feasible to have an independent behavior of the EDMA for emulation halts. EDMA functionality would be coupled with the peripherals it is servicing, which might have different behavior during emulation halts.

16.2.5 EDMA Transfer Examples

The EDMA channel controller performs a variety of transfers depending on the parameter configuration. The following sections provide a description and PaRAM configuration for some typical use case scenarios.

16.2.5.1 Block Move Example

The most basic transfer performed by the EDMA is a block move. During device operation it is often necessary to transfer a block of data from one location to another, usually between on-chip and off-chip memory.

In this example, a section of data is to be copied from external memory to internal L2 SRAM as shown in Figure 16-33.

The source address for the transfer is set to the start of the data block in external memory, and the destination address is set to the start of the data block in L2. If the data block is less than 64K bytes, the PaRAM configuration shown in Figure 16-34 holds true with the synchronization type set to A-synchronized and indexes cleared to 0. If the amount of data is greater than 64K bytes, EDMA_TPCC_ABCNT_n[31:16] BCNT and the B-indexes need to be set appropriately with the synchronization type set to AB-synchronized. The EDMA_TPCC_OPT_n[3] STATIC bit is set to prevent linking.

This transfer example may also be set up using QDMA. For successive transfer submissions, of a similar nature, the number of cycles used to submit the transfer are fewer depending on the number of changing transfer parameters. The QDMA trigger word must be programed to be the highest numbered offset in the PaRAM set that undergoes change.

Figure 16-34 shows the parameters Block Move transfer.

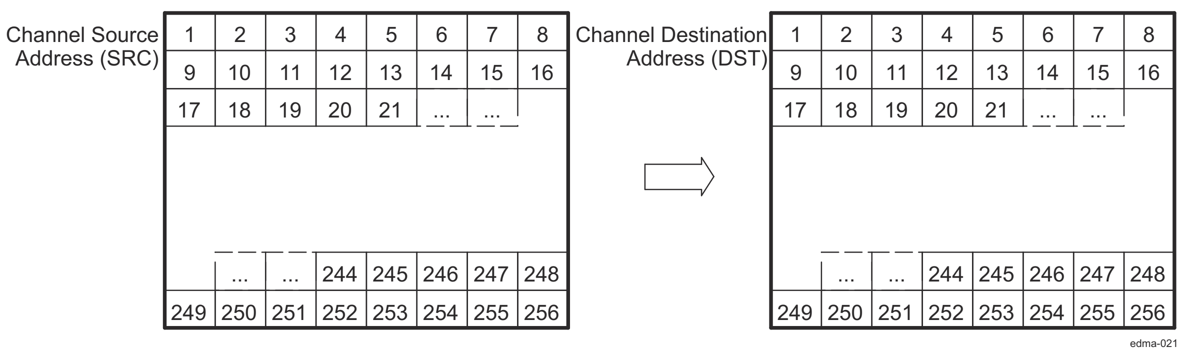

Figure 16-33. Block Move Example

Figure 16-34. Block Move Example PaRAM Configuration

(a) EDMA Parameters

Parameter Contents		Parameter	
0010 0008h		Channel Options Parameter (OPT)	
Channel Source Address (SRC)		Channel Source Address (SRC)	
0001h	0100h	Count for 2nd Dimension (BCNT)	Count for 1st Dimension (ACNT)
Channel Destination Address (DST)		Channel Destination Address (DST)	
0000h	0000h	Destination BCNT Index (DBIDX)	Source BCNT Index (SBIDX)
0000h	FFFFh	BCNT Reload (BCNTRLD)	Link Address (LINK)
0000h	0000h	Destination CCNT Index (DCIDX)	Source CCNT Index (SCIDX)
0000h	0001h	Reserved	Count for 3rd Dimension (CCNT)

(b)Channel Options Parameter (OPT) Content

- EDMA_TPCC_OPT_n[3] STATIC = 0x1
- EDMA_TPCC_OPT_n[20] TCINTEN = 0x1

16.2.5.2 Subframe Extraction Example

The EDMA can efficiently extract a small frame of data from a larger frame of data. By performing a 2D-to-1D transfer, the EDMA retrieves a portion of data for the CPU to process. In this example, a 640 × 480-pixel frame of video data is stored in external memory. Each pixel is represented by a 16-bit halfword. The CPU extracts a 16 × 12-pixel subframe of the image for processing. To facilitate more efficient processing time by the CPU, the EDMA places the subframe in internal L2 SRAM. Figure 16-35 shows the transfer of a subframe from external memory to L2.

The same PaRAM entry options are used for QDMA channels, as well as DMA channels. The EDMA_TPCC_OPT_n[3] STATIC bit is set to prevent linking. For successive transfers, only changed parameters need to be programmed before triggering the channel.

Figure 16-36 shows the parameters for Subframe Extraction transfer.

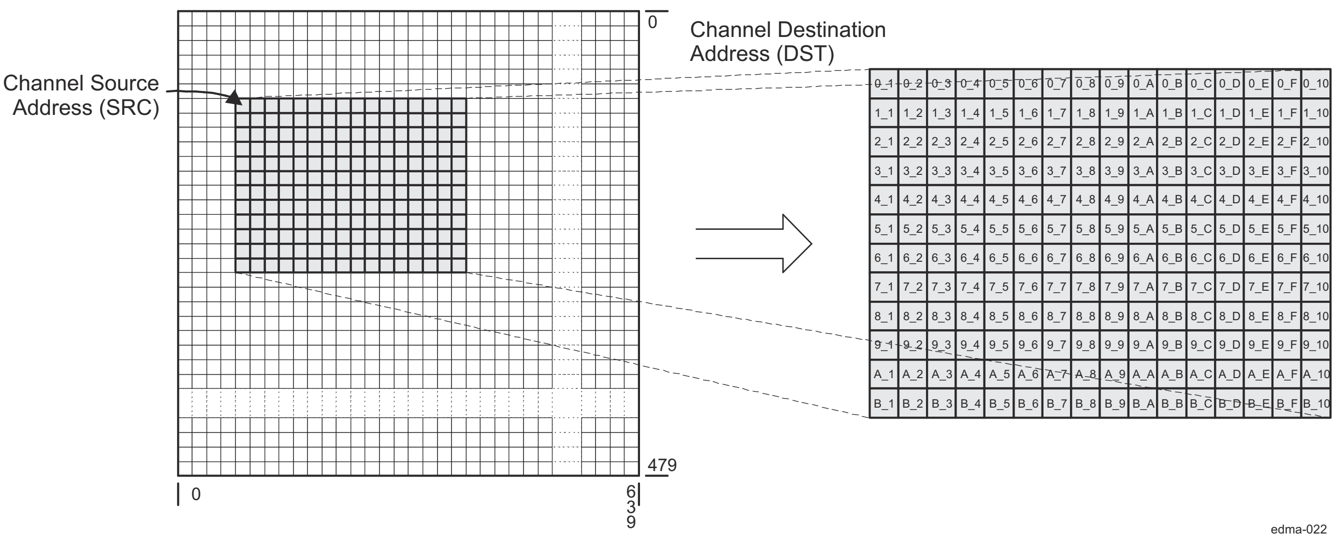

Figure 16-35. Subframe Extraction Transfer

Figure 16-36. Subframe Extraction Example PaRAM Configuration

(a) EDMA Parameters

Parameter Contents		Parameter	
0010 000Ch		Channel Options Parameter (OPT)	
Channel Source Address (SRC)		Channel Source Address (SRC)	
000Ch	0020h	Count for 2nd Dimension (BCNT)	Count for 1st Dimension (ACNT)
Channel Destination Address (DST)		Channel Destination Address (DST)	
0020h	0500h	Destination BCNT Index (DBIDX)	Source BCNT Index (SBIDX)
0000h	FFFFh	BCNT Reload (BCNTRLD)	Link Address (LINK)
0000h	0000h	Destination CCNT Index (DCIDX)	Source CCNT Index (SCIDX)
0000h	0001h	Reserved	Count for 3rd Dimension (CCNT)

(b)Channel Options Parameter (OPT) Content

- EDMA_TPCC_OPT_n[2] SYNCDIM = 0x1
- EDMA_TPCC_OPT_n[3] STATIC = 0x1
- EDMA_TPCC_OPT_n[20] TCINTEN = 0x1

16.2.5.3 Data Sorting Example

Many applications require the use of multiple data arrays, it is often desirable to have the arrays arranged such that the first elements of each array are adjacent, the second elements are adjacent, and so on. Often this is not how the data is presented to the device. Either data is transferred via a peripheral with the data arrays arriving one after the other or the arrays are located in memory with each array occupying a portion of contiguous memory spaces. For these instances, the EDMA can reorganize the data into the desired format.

To determine the parameter set values, the following need to be considered:

- ACNT - Program this to be the size in bytes of an element.
- BCNT - Program this to be the number of elements in a frame.
- CCNT - Program this to be the number of frames.
- SBIDX - Program this to be the size of the element or ACNT.
- DBIDX - CCNT × ACNT
- SCIDX - ACNT × BCNT
- DCIDX - ACNT

The synchronization type needs to be AB-synchronized and the EDMA_TPCC_OPT_n[3] STATIC bit is 0 to allow updates to the parameter set. It is advised to use normal EDMA channels for sorting.

It is not possible to sort this with a single trigger event. Instead, the channel can be programmed to be chained to itself. After BCNT elements get sorted, intermediate chaining could be used to trigger the channel again causing the transfer of the next BCNT elements and so on. Figure 16-38 shows the parameter set programming for this transfer, assuming channel 0 and an element size of 4 bytes.

Figure 16-37 shows the Data Sorting transfer

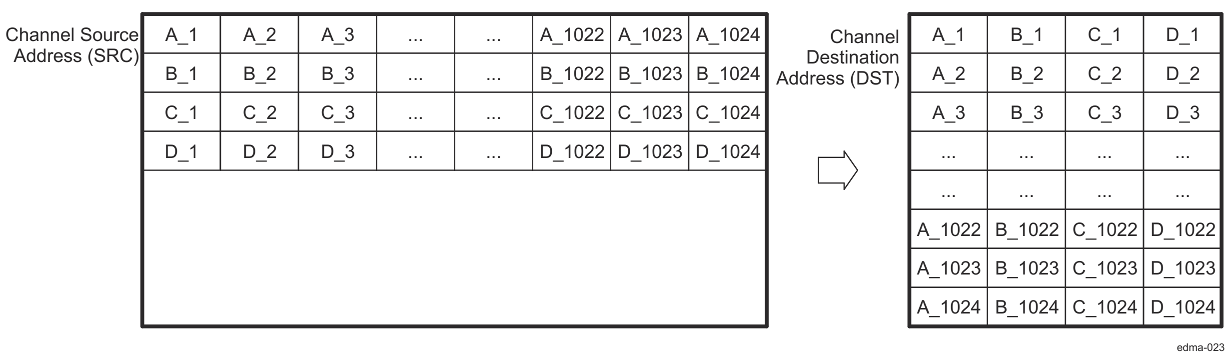

Figure 16-37. Data Sorting Example

Figure 16-38. Data Sorting Example PaRAM Configuration

(a) EDMA Parameters

Parameter Contents		Parameter	
0090 0004h		Channel Options Parameter (OPT)	
Channel Source Address (SRC)		Channel Source Address (SRC)	
0400h	0004h	Count for 2nd Dimension (BCNT)	Count for 1st Dimension (ACNT)
Channel Destination Address (DST)		Channel Destination Address (DST)	
0010h	0001h	Destination BCNT Index (DSTBIDX)	Source BCNT Index (SRCBIDX)
0000h	FFFFh	BCNT Reload (BCNTRLD)	Link Address (LINK)
0001h	1000h	Destination CCNT Index (DSTCIDX)	Source CCNT Index (SRCCIDX)
0000h	0004h	Reserved	Count for 3rd Dimension (CCNT)

(b) Channel Options Parameter (OPT) Content

- EDMA_TPCC_OPT_n[2] SYNCDIM = 0x1
- EDMA_TPCC_OPT_n[20] TCINTEN = 0x1
- EDMA_TPCC_OPT_n[23] ITCCHEN = 0x1

16.2.5.4 Peripheral Servicing Example

The EDMA channel controller also services peripherals in the background of CPU operation, without requiring any CPU intervention. Through proper initialization of the EDMA channels, they can be configured to continuously service on-chip and off-chip peripherals throughout the device operation. Each event available to the EDMA has its own dedicated channel, and all channels operate simultaneously. The only requirements are to use the proper channel for a particular transfer and to enable the channel event in the event enable register EDMA_TPCC_EER. When programming an EDMA channel to service a peripheral, it is necessary to know how data is to be presented to the processor. Data is always provided with some kind of synchronization event as either one element per event (non-bursting) or multiple elements per event (bursting).

16.2.5.4.1 Non-bursting Peripherals

Non-bursting peripherals include the on-chip multichannel audio serial port (McASP) and many external devices, such as codecs. Regardless of the peripheral, the EDMA channel configuration is the same.

The McASP transmit and receive data streams are treated independently by the EDMA. The transmit and receive data streams can have completely different counts, data sizes, and formats.

To transfer the incoming data stream to its proper location in DDR memory, the EDMA channel must be set up for a 1D-to-1D transfer with A-synchronization. Because an event (AREVT) is generated for every word as it arrives, it is necessary to have the EDMA issue the transfer request for each element individually. Figure 16-40 shows the parameters for this transfer. The source address of the EDMA channel is set to the data port address (DAT) for McASP, and the destination address is set to the start of the data block in DDR. Because the address of serializer buffer is fixed, the source B index is cleared to 0 (no modification) and the destination B index is set to 0x2 (increment).

Based on the premise that serial data is typically a high priority, the EDMA channel should be programmed to be on queue 0.

Figure 16-39 shows servicing incoming McASP data.

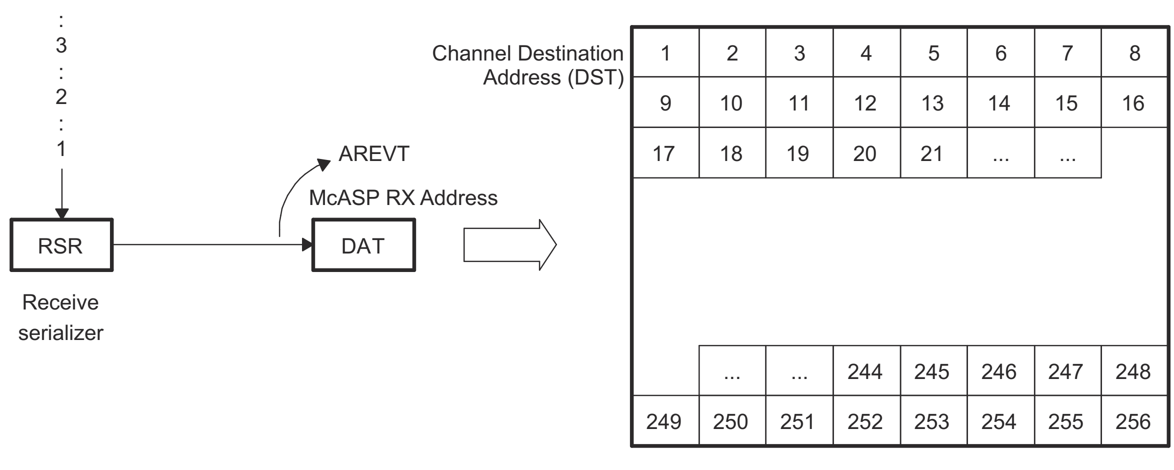

Figure 16-39. Servicing Incoming McASP Data Example

Figure 16-40. Servicing Incoming McASP Data Example PaRAM Configuration

(a) EDMA Parameters

16.2.5.4.2 Bursting Peripherals

Higher bandwidth applications require that multiple data elements be presented to the processor core for every synchronization event. This frame of data can either be from multiple sources that are working simultaneously or from a single high-throughput peripheral that streams data to/from the processor.

In this example, a port is receiving a video frame from a camera and presenting it to the DSP one array at a time. The video image is 640 × 480 pixels, with each pixel represented by a 16-bit element. The image is to be stored in external memory.

To transfer data from an external peripheral to an external buffer one array at a time based on EVT*n* , channel *n* must be configured. Due to the nature of the data (a video frame made up of arrays of pixels) the destination is essentially a 2D entity. Figure 16-42 shows the parameters to service the incoming data with a 1D-to-2D transfer using AB-synchronization. The source address is set to the location of the video framer peripheral, and the destination address is set to the start of the data buffer. Because the input address is static, the EDMA_TPCC_BDIX_n[15:0] SBIDX is 0 (no modification to the source address). The destination is made up of arrays of contiguous, linear elements; therefore, the EDMA_TPCC_BIDX_n[31:16] DBIDX is set to pixel size, 2 bytes. EDMA_TPCC_ABCNT_n[15:0] ANCT is equal to the pixel size, 2 bytes. EDMA_TPCC_ABCNT_n[31:16] BCNT is set to the number of pixels in an array, 640. EDMA_TPCC_CCNT_n[15:0] CCNT is equal to the total number of arrays in the block, 480. EDMA_TPCC_CIDX_n[15:0] SCIDX is 0 because the source address undergoes no increment. The EDMA_TPCC_CIDX_n[31:16] DCIDX is equal to the difference between the starting addresses of each array. Because one pixel is 16 bits (2 bytes), EDMA_TPCC_CIDX_n[31:16] DCIDX is equal to 640 × 2.

Figure 16-41 shows Bursting Peripherals Transfer.

- EDMA_TPCC_OPT_n[20] TCINTEN = 0x1

16.2.5.4.3 Continuous Operation

Configuring an EDMA channel to receive a single frame of data is useful, and is applicable to some systems. A majority of the time, however, data is going to be continuously transmitted and received throughout the entire operation of the processor. In this case, it is necessary to implement some form of linking such that the EDMA channels continuously reload the necessary parameter sets. In this example, McASP is configured to transmit and receive data on a T1 array. To simplify the example, only two channels are active for both transmit and receive data streams. Each channel receives packets of 128 elements. The packets are transferred from the serial port to internal memory and from internal memory to the serial port, as shown in Figure 16-43.

The McASP generates AREVT for every element received and generates AXEVT for every element transmitted. To service the data streams, them DMA channels associated with the McASP must be setup for 1D-to-1D transfers with A-synchronization.

Figure 16-44 shows the parameter entries for the channel for these transfers. To service the McASP continuously throughout DSP operation, the channels must be linked to a duplicate PaRAM set in the PaRAM. After all frames have been transferred, the EDMA channels reload and continue.

Figure 16-45 shows the reload parameters for the channel.

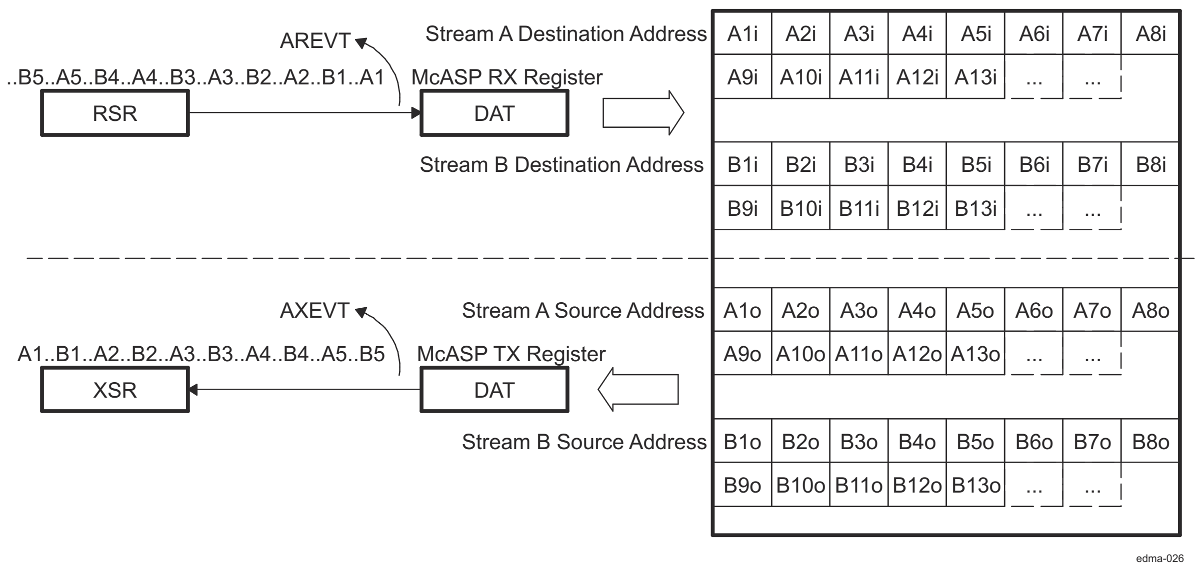

Figure 16-43. Servicing Continuous McASP Data Example

16.2.5.4.3.1 Receive Channel

EDMA channel 15 services the incoming data stream of McASP. The source address is set to that of the receive serializer buffer, and the destination address is set to the first element of the data block. Because there are two data channels being serviced, A and B, they are to be located separately within the L2 SRAM.

To facilitate continuous operation, a copy of the PaRAM set for the channel is placed in PaRAM set 64. The LINK option is set and the link address is provided in the PaRAM set. Upon exhausting the channel 15 parameter set, the parameters located at the link address are loaded into the channel 15 parameter set and operation continues. This function continues throughout device operation until halted by the CPU.

16.2.5.4.3.2 Transmit Channel

EDMA channel 12 services the outgoing data stream of McASP. In this case the destination address needs no update, hence, the parameter set changes accordingly. Linking is also used to allow continuous operation by the EDMA channel, with duplicate PaRAM set entries at PaRAM set 65.

16.2.5.4.4 Ping-Pong Buffering

Although the previous configuration allows the EDMA to service a peripheral continuously, it presents a number of restrictions to the CPU. Because the input and output buffers are continuously being filled/emptied, the CPU must match the pace of the EDMA very closely to process the data. The EDMA receive data must always be placed in memory before the CPU accesses it, and the CPU must provide the output data before the EDMA transfers it. Though not impossible, this is an unnecessary challenge. It is particularly difficult in a 2-level cache scheme.

Ping-pong buffering is a simple technique that allows the CPU activity to be distanced from the EDMA activity. This means that there are multiple (usually two) sets of data buffers for all incoming and outgoing data streams. While the EDMA transfers the data into and out of the ping buffers, the CPU manipulates the data in the pong buffers. When both CPU and EDMA activity completes, they switch. The EDMA then writes over the old input data and transfers the new output data. Figure 16-46 shows the ping-pong scheme for this example.

To change the continuous operation example, such that a ping-pong buffering scheme is used, the EDMA channels need only a moderate change. Instead of one parameter set, there are two; one for transferring data to/from the ping buffers and one for transferring data to/from the pong buffers. As soon as one transfer completes, the channel loads the PaRAM set for the other and the data transfers continue. Figure 16-47 shows the EDMA channel configuration required.

Each channel has two parameter sets, ping and pong. The EDMA channel is initially loaded with the ping parameters (Figure 16-47). The link address for the ping set is set to the PaRAM offset of the pong parameter set (Figure 16-48). The link address for the pong set is set to the PaRAM offset of the ping parameter set (Figure 16-49). The channel options, count values, and index values are all identical between the ping and pong parameters for each channel. The only differences are the link address provided and the address of the data buffer.

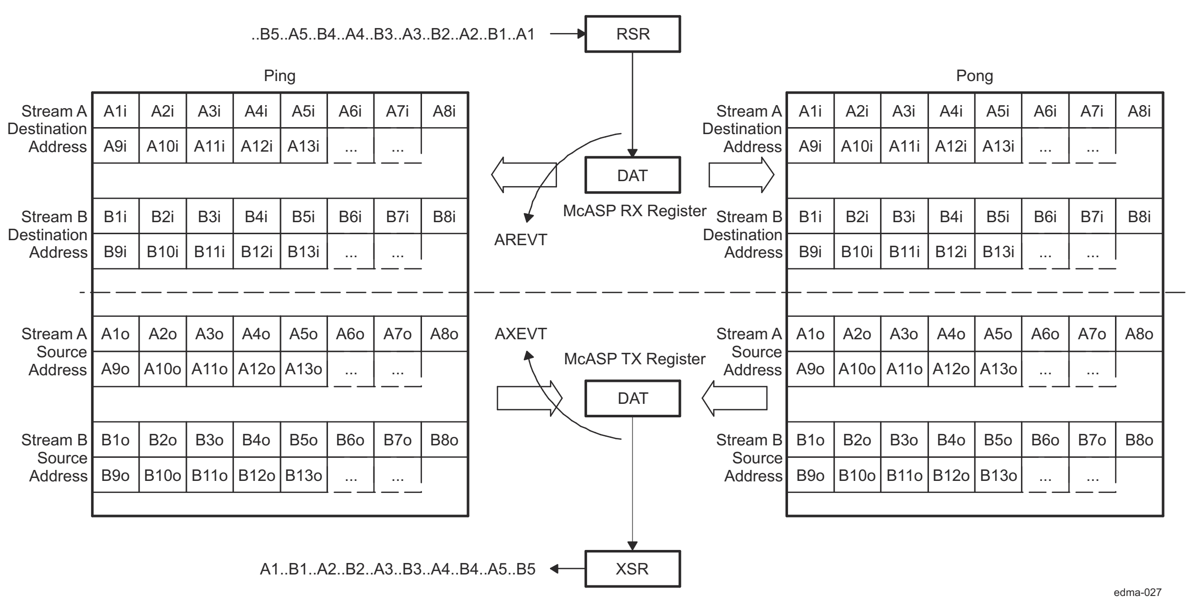

Figure 16-46. Ping-Pong Buffering for McASP Data Example

16.2.5.4.4.1 Synchronization with the CPU

To utilize the ping-pong buffering technique, the system must signal the CPU when to begin to access the new data set. After the CPU finishes processing an input buffer (ping), it waits for the EDMA to complete before switching to the alternate (pong) buffer. In this example, both channels provide their channel numbers as their report word and set the EDMA_TPCC_OPT_n[20] TCINTEN bit to generate an interrupt after completion. When channel 15 fills an input buffer, the E15 bit in the interrupt pending register EDMA_TPCC_IPR is set; when channel 12 empties an output buffer, the E12 bit in EDMA_TPCC_IPR is set. The CPU must manually clear these bits. With the channel parameters set, the CPU polls EDMA_TPCC_IPR to determine when to switch. The EDMA and CPU could alternatively be configured such that the channel completion interrupts the CPU. By doing this, the CPU could service a background task while waiting for the EDMA to complete.

16.2.5.4.5 Transfer Chaining Examples

The following examples explain the intermediate transfer complete chaining function.

16.2.5.4.5.1 Servicing Input/Output FIFOs with a Single Event

Many systems require the use of a pair of external FIFOs that must be serviced at the same rate. One FIFO buffers data input, and the other buffers data output. The EDMA channels that service these FIFOs can be set up for AB-synchronized transfers. While each FIFO is serviced with a different set of parameters, both can be signaled from a single event.

For example, an external interrupt pin can be tied to the status flags of one of the FIFOs. When this event arrives, the EDMA needs to perform servicing for both the input and output streams. Without the intermediate transfer complete chaining feature this would require two events, and thus two external interrupt pins. The intermediate transfer complete chaining feature allows the use of a single external event (for example, a GPIO event). Figure 16-50 shows the EDMA setup and illustration for this example.

A GPIO event (in this case, GPINT0) triggers an array transfer. Upon completion of each intermediate array transfer of channel 48, intermediate transfer complete chaining sets the E8 bit (specified by TCC of 8) in the chained event register EDMA_TPCC_CER and provides a synchronization event to channel 8. Upon completion of the last array transfer of channel 48, transfer complete chaining—not intermediate transfer complete chaining—sets the E8 bit in EDMA_TPCC_CER (specified by EDMA_TPCC_OPT_n[11] TCCMODE: TCC) and provides a synchronization event to channel 8. The completion of channel 8 sets the I8 bit (specified by EDMA_TPCC_OPT_n[11] TCCMODE: TCC) in the interrupt pending register EDMA_TPCC_IPR, which can generate an interrupt to the CPU, if the I8 bit in the interrupt enable register EDMA_TPCC_IER is set.

Figure 16-50 shows the Intermediate Transfer Completion Chaining Example.

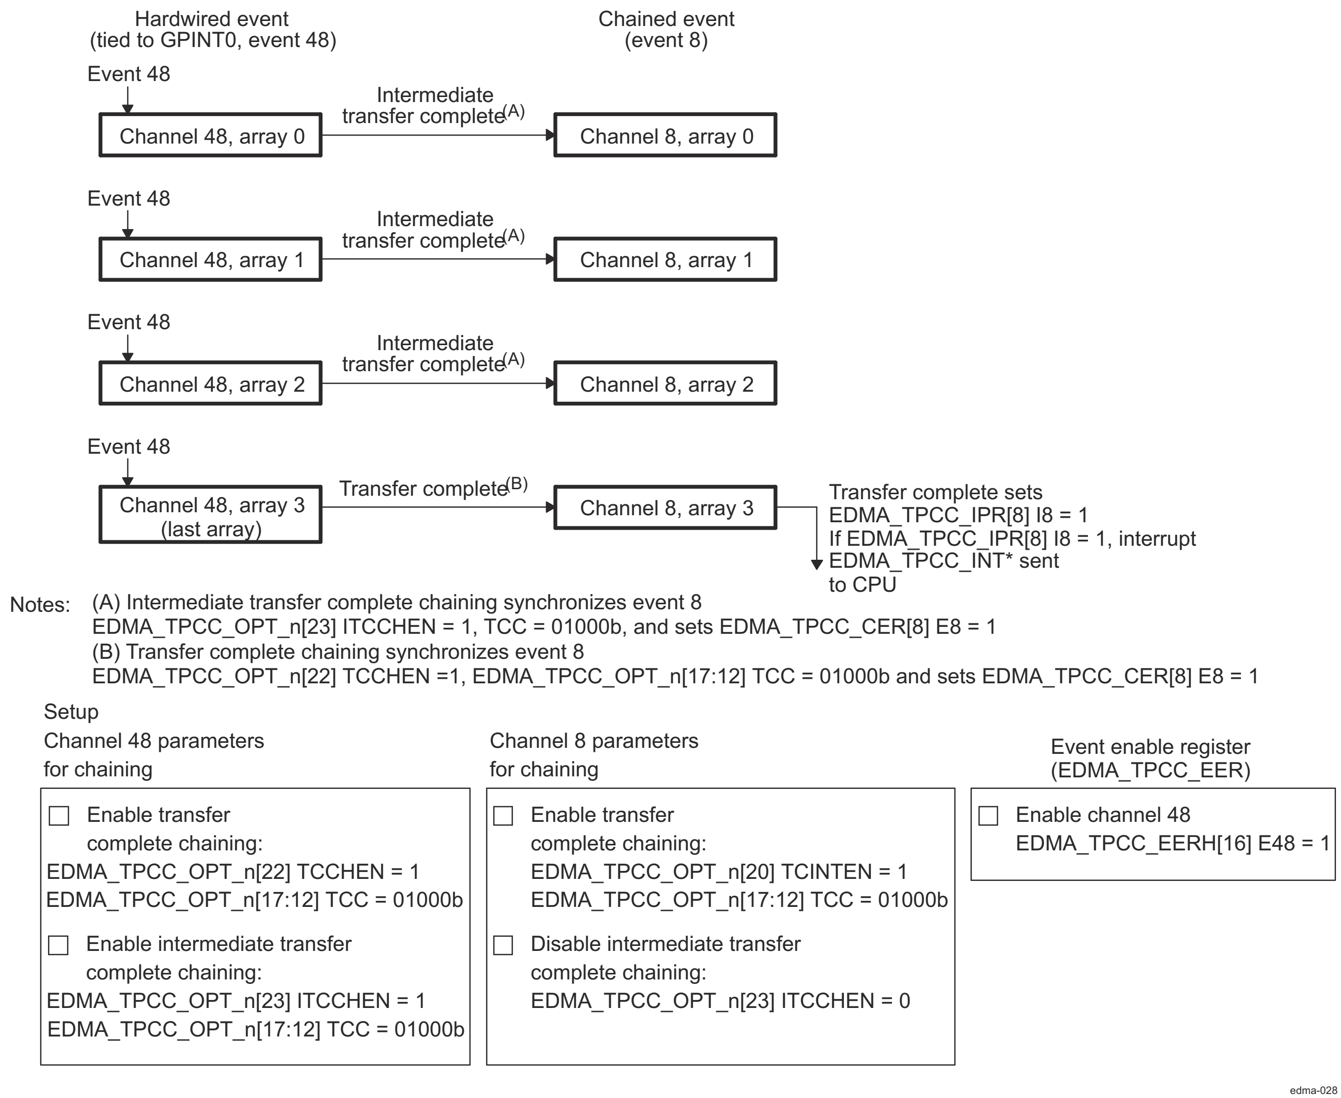

Figure 16-50. Intermediate Transfer Completion Chaining Example

16.2.5.4.5.2 Breaking Up Large Transfers with Intermediate Chaining

Another feature of intermediate transfer chaining EDMA_TPCC_OPT_n[23] ITCCHEN is for breaking up large transfers. A large transfer may lock out other transfers of the same priority level for the duration of the transfer. For example, a large transfer on queue 0 from the internal memory to the external memory using the EMIF may starve other EDMA transfers on the same queue. In addition, this large high-priority transfer may prevent the EMIF for a long duration to service other lower priority transfers. When a large transfer is considered to be high priority, it should be split into multiple smaller transfers. Figure 16-51 shows the EDMA setup and illustration of an example single large block transfer.

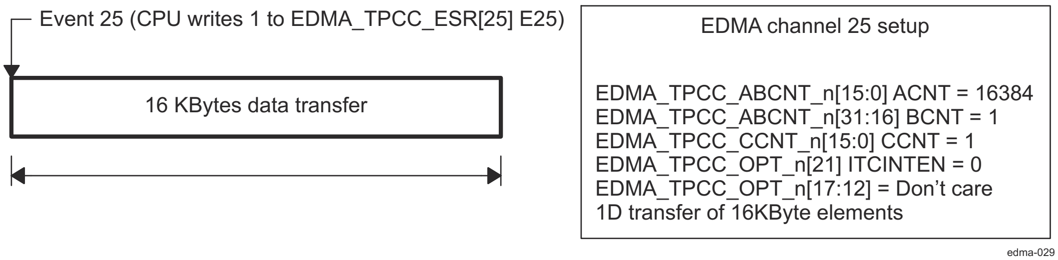

Figure 16-51. Single Large Block Transfer Example

The intermediate transfer chaining enable EDMA_TPCC_OPT_n[23] ITCCHEN provides a method to break up a large transfer into smaller transfers. For example, to move a single large block of memory (16K bytes), the EDMA performs an A-synchronized transfer. The element count is set to a reasonable value, where reasonable derives from the amount of time it would take to move this smaller amount of data. Assume 1 Kbyte is a reasonable small transfer in this example. The EDMA is set up to transfer 16 arrays of 1 Kbyte elements, for a total of 16K byte elements. The EDMA_TPCC_OPT_n[17:12] TCC field in the channel options parameter (OPT) is set to the same value as the channel number and EDMA_TPCC_OPT_n[23] ITCCHEN are set. In this example, EDMA channel 25 is used and EDMA_TPCC_OPT_n[17:12] TCC is also set to 25. The EDMA_TPCC_OPT_n[20] TCINTEN may also be set to trigger interrupt 25 when the last 1 Kbyte array is transferred. The CPU starts the EDMA transfer by writing to the appropriate bit of the event set register EDMA_TPCC_ESR[25] E25. The EDMA transfers the first 1 Kbyte array. Upon completion of the first array, intermediate transfer complete code chaining generates a synchronization event to channel 25, a value specified by the EDMA_TPCC_OPT_n[17:12] TCC field. This intermediate transfer completion chaining event causes EDMA channel 25 to transfer the next 1 Kbyte array. This process continues until the transfer parameters are exhausted, at which point the EDMA has completed the 16K byte transfer. This method breaks up a large transfer into smaller packets, thus providing natural time slices in the transfer such that other events may be processed. Figure 16-52 shows the EDMA setup and illustration of the broken up smaller packet transfers.

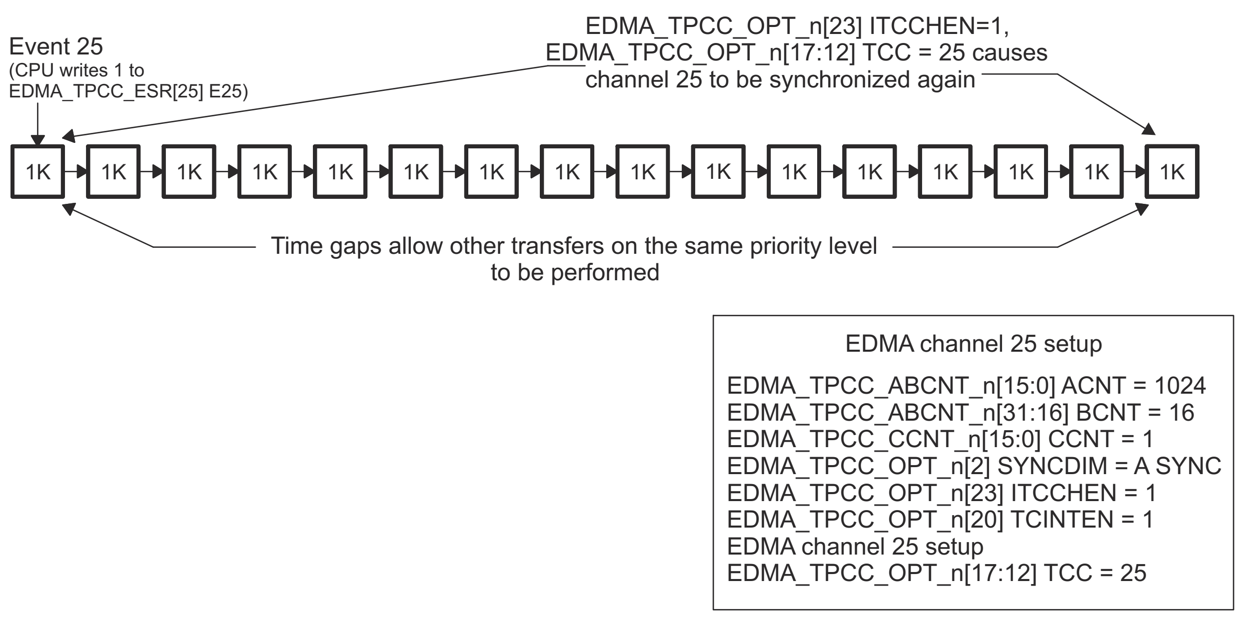

Figure 16-52. Smaller Packet Data Transfers Example

16.2.5.5 Setting Up an EDMA Transfer

16.2.5.5.1

The following list provides a quick guide for the typical steps involved in setting up a transfer.

1. Initiating a DMA/QDMA channel
   a. Determine the type of channel (QDMA or DMA) to be used.
   b. Channel mapping
      i. If using a QDMA channel, program the EDMA_TPCC_QCHMAPN_j with the parameter set number to which the channel maps and the trigger word.
      ii. If using a DMA channel, program the EDMA_TPCC_DCHMAPN_m with the parameter set number to which the channel maps.
   c. If the channel is being used in the context of a shadow region, ensure the EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k for the region is properly set up to allow read write accesses to bits in the event registers and interrupt registers in the Shadow region memory map. The subsequent steps in this process should be done using the respective shadow region registers. (Shadow region descriptions and usage are provided in Section 16.2.4.7.1.)
   d. Determine the type of triggering used.
      i. If external events are used for triggering (DMA channels), enable the respective event in EDMA_TPCC_EER / EDMA_TPCC_EERH by writing into EDMA_TPCC_EESR / EDMA_TPCC_EESRH.
      ii. If QDMA Channel is used, enable the channel in EDMA_TPCC_QEER by writing into EDMA_TPCC_QEESR.
   e. Queue setup
      i. If a QDMA channel is used, set up the EDMA_TPCC_QDMAQNUM to map the channel to the respective event queue.
      ii. If a DMA channel is used, set up the EDMA_TPCC_DMAQNUMN_k to map the event to the respective event queue.
2. Parameter set setup
   a. Program the PaRAM set number associated with the channel. Note that

Note

If it is a QDMA channel, the PaRAM entry that is configured as trigger word is written to last. Alternatively, enable the QDMA channel (step 1-b-ii above) just before the write to the trigger word.

3. Interrupt setup
   a. Enable the interrupt in the EDMA_TPCC_IER / EDMA_TPCC_IERH by writing into EDMA_TPCC_IESR / EDMA_TPCC_IESRH.
   b. Ensure that the EDMA_TPCC completion interrupt (either the global or the shadow region interrupt) is enabled properly in the device interrupt controller.
   c. Ensure the EDMA_TPCC completion interrupt (this refers to either the Global interrupt or the shadow region interrupt) is enabled properly in the Device Interrupt controller.
   d. Set up the interrupt controller properly to receive the expected EDMA interrupt.
4. Initiate transfer
   a. This step is highly dependent on the event trigger source:
      i. If the source is an external event coming from a peripheral, the peripheral will be enabled to start generating relevant EDMA events that can be latched to the EDMA_TPCC_ER transfer.
      ii. For QDMA events, writes to the trigger word (step 2-a above) will initiate the transfer.
      iii. Manually triggered transfers will be initiated by writes to the Event Set Registers EDMA_TPCC_ESR / EDMA_TPCC_ESRH.
      iv. Chained-trigger events initiate when a previous transfer returns a transfer completion code equal to the chained channel number.
5. Wait for completion
   a. If the interrupts are enabled as mentioned in step 3 above, then the EDMA_TPCC will generate a completion interrupt to the CPU whenever transfer completion results in setting the corresponding bits

in the interrupt pending register EDMA_TPCC_IPR / EDMA_TPCC_IPRH. The set bits must be cleared in the EDMA_TPCC_IPR / EDMA_TPCC_IPRH by writing to corresponding bit in EDMA_TPCC_ICR / EDMA_TPCC_ICRH.

b. If polling for completion (interrupts not enabled in the device controller), then the application code can wait on the expected bits to be set in the EDMA_TPCC_IPR / EDMA_TPCC_IPRH. Again, the set bits in the EDMA_TPCC_IPR / EDMA_TPCC_IPRH must be manually cleared via EDMA_TPCC_ICR / EDMA_TPCC_ICRH before the next set of transfers is performed for the same transfer completion code values.

16.2.6 EDMA Debug Checklist and Programming Tips

This section lists some tips to keep in mind while debugging applications using the EDMA controller.

16.2.6.1 EDMA Debug Checklist

Table 16-76 provides some common issues and their probable causes and resolutions.

Table 16-76. Debug Checklist

Issue	Description/Solution
The transfer associated with the channel does not happen. The channel does not get serviced.	The EDMA_TPCC may not service a transfer request, even though the associated PaRAM set is programmed appropriately. Check for the following: 1) Verify that events are enabled, i.e., if an external/peripheral event is latched in Event Registers EDMA_TPCC_ER / EDMA_TPCC_ERH, check that the event is enabled in the Event Enable Registers EDMA_TPCC_EER / EDMA_TPCC_EERH. Similarly, for QDMA channels, check that QDMA events are appropriately enabled in the QDMA Event Enable Register EDMA_TPCC_QEER. 2) Verify that the DMA or QDMA Secondary Event Register EDMA_TPCC_SER / EDMA_TPCC_SERH / EDMA_TPCC_QSER bits corresponding to the particular event or channel are not set.
The Secondary Event Registers bits are set, not allowing additional transfers to occur on a channel.	It is possible that a trigger event was received when the parameter set associated with the channel/event was a NULL set for a previous transfer on the channel. This is typical in two cases: 1) QDMA channels: Typically if the parameter set is non-static and expected to be terminated by a NULL set (i.e., EDMA_TPCC_OPT_n[3] STATIC = 0x0, EDMA_TPCC_LNK_n[15:0] LINK = 0xFFFF), the parameter set is updated with a NULL set after submission of the last TR. Because QDMA channels are auto-triggered, this update caused the generation of an event. An event generated for a NULL set causes an error condition and results in setting the bits corresponding to the QDMA channel in the EDMA_TPCC_QEMR and EDMA_TPCC_QSER. This will disable further prioritization of the channel. 2) DMA channels used in a continuous mode: The peripheral may be set up to continuously generate infinite events (for instance, in case of McASP, every time the data shifts out from the DXR register, it generates an XEVT). The parameter set may be programmed to expect only a finite number of events and to be terminated by a NULL link. After the expected number of events, the parameter set is reloaded with a NULL parameter set. Because the peripheral will generate additional events, an error condition is set in the EDMA_TPCC_SER[31:0] E*n* and EDMA_TPCC_EMR[31:0] E*n* set, preventing further event prioritization. Check the number of events received is limited to the expected number of events for which the parameter set is programmed, or check the bits corresponding to particular channel or event are not set in the Secondary event registers (EDMA_TPCC_SER / EDMA_TPCC_SERH / EDMA_TPCC_QSER) and Event Missed Registers (EDMA_TPCC_EMR / EDMA_TPCC_EMRH / EDMA_TPCC_QEMR) before trying to perform subsequent transfers for the event/channel.

Table 16-76. Debug Checklist (continued)

Issue	Description/Solution
Completion interrupts are not asserted, or no further interrupts are received after the first completion interrupt.	Check the following: 1) The interrupt generation is enabled in the EDMA_TPCC_OPT_n of the associated PaRAM set (EDMA_TPCC_OPT_n[20] TCINTEN = 0x1 and/or EDMA_TPCC_OPT_n[20] ITCINTEN = 0x1). 2) The interrupts are enabled in the EDMA Channel Controller, via the Interrupt Enable Registers (EDMA_TPCC_IER / EDMA_TPCC_IERH). 3) The corresponding interrupts are enabled in the device interrupt controller. 4) The set interrupts are cleared in the interrupt pending registers (EDMA_TPCC_IPR / EDMA_TPCC_IPRH) before exiting the transfer completion interrupt service routine (ISR). See Section 16.2.4.9.1.2 *Clearing Transfer Complerion Interrupts* for details on writing EDMA ISRs. 5) If working with shadow region interrupts, make sure that the DMA Region Access registers (EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k) are set up properly, because the EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k registers act as secondary enables for shadow region completion interrupts, along with the EDMA_TPCC_IER / EDMA_TPCC_IERH registers. If working with shadow region interrupts, make sure that the bits corresponding to the transfer completion code EDMA_TPCC_OPT_n[17:12] TCC value are also enabled in the EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k registers. For instance, if the PaRAM set associated with Channel 0 returns a completion code of 63 EDMA_TPCC_OPT_n[17:12] TCC = 63, ensure that EDMA_TPCC_DRAEHM_k[31] E63 is also set for a shadow region completion interrupt because the interrupt pending register bit set will be EDMA_TPCC_IPRH[31] I63 (not EDMA_TPCC_IPR[0] I0).

16.2.6.2 EDMA Programming Tips

1. For several registers, the setting and clearing of bits needs to be done via separate dedicated registers. For example, the Event Register (EDMA_TPCC_ER / EDMA_TPCC_ERH) can only be cleared by writing a 1 to the corresponding bits in the Event Clear Registers (EDMA_TPCC_ECR / EDMA_TPCC_ECRH). Similarly, the Event Enable Register (EDMA_TPCC_EER / EDMA_TPCC_EERH) bits can only be set with writing of 0x1 to the Event Enable Set Registers (EDMA_TPCC_EESR / EDMA_TPCC_EESRH) and cleared with writing of 0x1 to the corresponding bits in the Event Enable Clear Register (EDMA_TPCC_EECR / EDMA_TPCC_EECRH).
2. Writes to the shadow region memory maps are governed by region access registers (EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k / EDMA_TPCC_QRAEN_k). If the appropriate channels are not enabled in these registers, read/write access to the shadow region memory map is not enabled.
3. When working with shadow region completion interrupts, ensure that the DMA Region Access Registers (EDMA_TPCC_DRAEM_k / EDMA_TPCC_DRAEHM_k) for every region are set in a mutually exclusive way (unless it is a requirement for an application). If there is an overlap in the allocated channels and transfer completion codes (setting of Interrupt Pending Register bits) in the region resource allocation, it results in multiple shadow region completion interrupts.
   For example, if EDMA_TPCC_DRAEM_k.DRAEM_0[0] E0 and EDMA_TPCC_DRAEM_k.DRAEM_1[0] E0 are both set, then on completion of a transfer that returns a TCC = 0x0, they will generate both shadow region 0 and 1 completion interrupts.
4. While programming a non-dummy parameter set, ensure the EDMA_TPCC_CCNT_n[15:0] CCNT is not left to zero.
5. Enable the EDMA_TPCC error interrupt in the device controller and attach an interrupt service routine (ISR) to ensure that error conditions are not missed in an application and are appropriately addressed with the ISR.
6. Depending on the application, it can want to break large transfers into smaller transfers and use self-chaining to prevent starvation of other events in an event queue.
7. In applications where a large transfer is broken into sets of small transfers using chaining or other methods, it chooses to use the early chaining option to reduce the time between the sets of transfers and increase the throughput.
   However, keep in mind that with early completion, all data might have not been received at the end point when completion is reported because the EDMA_TPCC internally signals completion when the TR is submitted to the EDMA_TPTC, potentially before any data has been transferred.
8. The event queue entries can be observed to determine the last few events if there is a system failure (provided the entries were not bypassed).

(1) i = 0 to 1 for EVE1_EDMA_TPCC and EVE2_EDMA_TPCC
(2) j = 0 to 7 for EVE1_EDMA_TPCC and EVE2_EDMA_TPCC
(3) k = 0 to 7 for EVE1_EDMA_TPCC and EVE2_EDMA_TPCC
(4) p = 0 to 1 for EVE1_EDMA_TPCC and EVE2_EDMA_TPCC
(5) m = 0 to 15 for EVE1_EDMA_TPCC and EVE2_EDMA_TPCC
(6) n = 0 to 127 for EVE1_EDMA_TPCC and EVE2_EDMA_TPCC

Note

The value for "n" is from 0 to 1 in the Table 16-85. It corresponds of the Transfer Controller (EDMA_TPTC0 and EDMA_TPTC1) instances in the device.

31–2	1	0
RESERVED	SET	EVAL

Bits	Field Name	Description	Type	Reset
31:2	RESERVED	Reserved	R	0x000000
1	SET	Error Interrupt Set CPU writes 0x0 has no effect. CPU writes 0x1 to the SET bit causes the TPCC error interrupt to be pulsed regardless of state of EDMA_TPCC_EMR/EDMA_TPCC_EMRH, EDMA_TPCC_QEMR, or EDMA_TPCC_CCERR.	W	0x0

Bits	Field Name	Description	Type	Reset
0	EVAL	Error Interrupt Evaluate CPU writes 0x0 has no effect. CPU writes 0x1 to the EVAL bit causes the TPCC error interrupt to be pulsed if any errors have not been cleared in the EDMA_TPCC_EMR/EDMA_TPCC_EMRH, EDMA_TPCC_QEMR, or EDMA_TPCC_CCERR registers. The CPU must also write 0x1 after any error interrupts are serviced in order for subsequent interrupts to be asserted.	W	0x0

Description	DMA Region Access enable for bit N in Region M: En = 0 : Accesses via Region M address space to Bit N in any DMA Channel Register are not allowed. Reads will return 'b0 on Bit N and writes will not modify the state of bit N. Enabled interrupt bits for bit N do not contribute to the generation of the TPCC region M interrupt. En = 1 : Accesses via Region M address space to Bit N in any DMA Channel Register are allowed. Reads will return the value from Bit N and writes will modify the state of bit N. Enabled interrupt bits for bit N do contribute to the generation of the TPCC region M interrupt.
